A MORPHOMETRIC EXAMINATION OF EXTRASTRIATAL NUCLEI IN RATS WITH QUINOLINATE-INDUCED LESIONS OF THE STRIATUM. MF Mazurek\* and JCS Furtado, McMaster University Medical Centre, Hamilton, ON, Canada

While it is well known that the brunt of the degenerative process in Huntington's Disease (HD) is sustained by the striatum, it has recently been recognized that many extrastriatal areas, including cerebral cortex, substantia nigra and thalamus, are also affected in HD. It is unclear whether this extrastriatal damage is reflective of independent pathology or secondary to degeneration of the striatal outflow neurons. We have begun to investigate this issue in rats with chronic unilateral quinolinate-induced lesions of the medial striatum. Nissl and AChE stains were used to outline the striatum, cortex and thalamus, while immunocytochemistry for tyrosine hydroxylase and substance P was used to delineate the boundaries of the substantia nigra. In lesioned animals, the striatum, substantia nigra and two thalamic nuclei (VA, VL) were significantly reduced in area (using the Bioquant IV programme) on the lesioned side. No changes in area were observed in the thalamus as a whole or in the frontal cortex. These findings indicate that damage to the striatum can produce morphological changes in "downstream" nuclei of the striatal-pallidal-thalamic-cortical circuit.

EXCITATORY AMINO ACID RECEPTORS IN HUNTINGTON'S DISEASE NEOCORTEX. M.V. Wagster\*, J.C. Hedreen, W. Paschen, D.L. Price, S.E. Folstein and C.A. Ross. Neuropathology Lab. and Depts. of Pathology, Psychiatry, Neurology, and Neuroscience, The Johns Hopkins University School of Med., Balto., MD 21205. Several lines of evidence indicate the presence of lamina-specific neocortical pathology in individuals with Huntington's disease (HD), and excitotoxic mechanisms have been proposed. Using quantitative autoradiographic methods, we have measured

Several lines of evidence indicate the presence of lamina-specific neocortical pathology in individuals with Huntington's disease (HD), and excitotoxic mechanisms have been proposed. Using quantitative autoradiographic methods, we have measured NMDA, kainate, and AMPA receptor binding in HD and control middle frontal gyrus and motor cortex. In middle frontal gyrus, we detected no change in NMDA-sensitive [3H] glutamate binding but found a selective decrease in [3H] kainate (control=201.7; HD=156.1, corrected for shrinkage) and [3H] AMPA binding (control=1108.2; HD=713.3, corrected for shrinkage) in layer VI, where we previously had found neuronal loss. [3H] glutamate and [3H] AMPA binding values in whole motor cortex did not reveal any deficits in HD; laminar analyses are in progress. We are preparing DNA probes for glutamate receptor subtype mRNAs to attempt to corroborate these data with in situ hybridization.

BRAIN KYNURENINE AMINOTRANSFERASES AND KYNURENIC ACID LEVELS IN HUNTINGTON'S DISEASE. <u>D.A. Jauch\*. E. Urbańska.</u> <u>P. Guidetti, F. Peretti, <sup>1</sup>W.O. Whetsell, Jr. and R. Schwarcz, Maryland Psych. Res. Center, Baltimore, MD 21228 and <sup>1</sup>Vanderbilt Univ. School Med., Nashville, TN 37232.</u>

Two distinct kynurenine aminotransferases (KAT I and KAT II) exist in the human brain (Brain Res., 542: 307, 1991). Since their enzymatic product, the neuroprotective excitatory amino acid receptor antagonist kynurenic acid (KYNA), has been speculatively linked to the pathogenesis of Huntington's disease (HD; Life Sci., 35: 19, 1984), we have examined KYNA levels and the activity of KAT I and KAT II in several regions of brains from HD patients and control donors (N - 13 each). Using [³H]kynurenine as the substrate and pyruvate as a cofactor, the enzymes were determined under optimal conditions (pH 10.0 for KAT I and pH 7.4 for KAT II) in tissue homogenates. Under these conditions, KAT I activity was several-fold higher than KAT II activity in all samples. Both enzyme activities were highest in cortical areas (e.g. control frontal cortex: KAT I: 104 ± 15 fmoles/mg tiss/h; KAT II: 20 ± 2 fmoles/mg tiss/h). Activities of both enzymes, as well as KYNA levels, expressed on a mg tissue basis, showed significant decreases (32-568) in HD striata (P < 0.05). The effects were less pronounced when data were expressed per mg protein. These findings suggest diminished endogenous neuroprotection in the HD striatum. (This work was supported by USPHS grants NS 28236 and MH 31862).

EVIDENCE FOR ARNORMAL METAROLISM IN PATIENTS WITH EYIDENCE TWA BINORMAL METABOLISM IT FATIENTS WITH HUNTINGTON'S DISEASE USING LOCALIZED HIMM SPECTROSCOPY. W.J. Koroshetz B.B.G. Jenkins, M.F. Beal, B.R. Ros

Dept of Radiology and Neurology, Mass. Gen. Hospital, Boston Ma. 02114. Huntington's Disease (HD) is an autosomal dominantly inherited degeneration of striatum accompanied by generalized cerebral atrophy. Excessive excitatory stress and/or impaired mitochondrial function have been hypothesized to contribute to neurodegeneration in HD. Either mechanism might cause elevated lactate in the brain of patients with HD.

Using water suppressed STEAM-spectroscopy (Frahm et al,[1989] Magn

Reson Med,,9:79) we studied 18 patients with various clinical stages of HD. Proton-spectra from voxels including occipital cortex demonstrated elevated lactate peaks at 1.33 ppm in all symptomatic patients. Average estimated lactate in individuals with clinically evident HD was  $1.3 \pm 0.5$  mM (N=16) Normal lactate levels  $(0.4\pm0.15~\text{mM},\,\text{N}\!=\!12)$  were seen in 2 assymptomatic individuals who had a diagnosis made by DNA linkage analysis. Lactate levels in occipital cortex correlated best with duration of disease  $(p\!<\!.0005)$ . Because of the relatively high content of heavy metal in basal ganglia, spectra from voxels containing basal ganglia have a poorer signal to noise ratio as compared to those containing occipital cortex. In 17/19 patients no significant lactate peak at 1.33 pm was seen, in 2/19 patients a broad peak was seen in the basal ganglia. Intersubject averaging improved the signal to noise ratio without revealing a significant lactate peak in basal ganglia spectra from most patients or controls.

Elevated lactate occurs reliably in the occipital cortex of patients with HD. If lactate increases as a signature of metabolic stress then suppression of lactate may retard the neuronal degeneration in HD. Ongoing attempts to pharmacologically suppress brain lactate in HD patients will be discussed.

BASIC FIBROBLAST GROWTH FACTOR (FGF) AND RECEPTOR (FGFR) IN HUNTINGTON'S DISEASE A. Baird, E. G. Stopa ‡, V. Kuo-Leblanc M. Ong, L. Kanaley‡, R. Guillemin\*and E. D. Bird‡. Department of Molecular and Cellular Growth Biology, The Whittier Institute for Diabetes and Endocrinology, La Jolla, CA, ‡McLean Hospital, Harvard Medical School, Belmont, MA, and \*Department of Pathology, State University of New York, Health Science Center, Syracuse, NY

Huntingfon's disease (HD) is an autosomal dominant neurodegenerative disorder that localizes to the chromosome (#4) that contains the genes encoding a high affinity fibroblast growth factor receptor (FGFR) (Genomics 11:1133-1142, 1991) and basic fibroblast growth factor (FGF) (Biochem. Biophys. Res. Commun. 138:644-651, 1986). Because this growth factor is a potent neurotrophic growth factor that has 1986). Because this growth factor is a potent neurotrophic growth factor that has been implicated in neurodegenerative disease (Biochem. Biophys. Res. Commun. 171:690-696, 1990), we examined the presence of basic FGF and its high affinity receptors in control and HD brains. Immunocytochemical localization of basic FGF with a specific polyclonal antibody (773) shows that basic FGF-like immunoreactivity is widely distributed within the astrocytic population of the normal caudate nucleus. This staining is dramatically increased, particularly within the large reactive astrocytes that are typically seen in HD. Using a monoclonal antibody to FGFR-1, which recognizes FGFR-2 and FGFR-3, a positive reaction product is seen on the cell surface of neurons, astrocytes and endothelial cells in both HD cases and controls. The staining intensity, however, appears decreased in HD, although Western blotting establishes that the expected molecular forms of basic FGF and FGFR are present in extracts of cortex and caudate nucleus. The levels of basic FGF were then measured in tissues of HD patients and controls that were also matched for FGFR are present in extracts of cortex and caudate nucleus. The levels of basic FGF were then measured in tissues of HD patients and controls that were also matched for age, sex and the postmortem interval. A quantitative RIA demonstrates that the concentration of basic FGF within the caudate nucleus increases up to 6-fold in HD, but remains unchanged in cerebral cortex. These observations indicate that although the normal molecular forms of basic FGF appear to be present in HD, alterations in the regulation of basic FGF and/or FGFR may be involved in the pathogenesis of this disease. Supported by RVHPGSS3, AG10682, and DK-18811.

GLUCOSE TRANSPORTER ISOFORM EXPRESSION IN HUNTINGTON'S DISEASE BRAIN

W.C. Gamberino, W.A. Brennan, Jr. and E.D. Bird\* Dept. Cell.& Molec. Physiol, Penn State Univ. Coll.of Medicine, Hershey, PA 17033 and Ralph Lowell Laboratory, McLean Hospital, Harvard Medical School, Belmont, MA 02178.

School, Belmont, MA 02178.

Several reports over the past decade have suggested that decreased glucose utilization in the basal ganglia of Huntington's Disease (HD) patients may be a factor in the cellular atrophy of the caudate and putamen. We examined the expression of the two major glucose transporter isoforms of brain, GLUT 1 and GLUT 3. GLUT 1 is found in all cells of the brain, while GLUT 3 is localized primarily in neurons. Membranes were prepared from postmortem samples of HD caudate and cortex and non-HD caudate and cortex. Equivalent amounts of membrane protein were seperated on 7.5% SDS polyacrylamide gels, transferred to MSI membranes by western blotting and probed with antisera to GLUT 1 and 3. In all cases (n=6) there was a significant increase in GLUT 1 immunoreactivity in HD caudate compared with either HD cortex or non-HD caudate and cortex. When the same membrane preparations were probed with GLUT 3, no significant differences could be detected in HD versus control samples. These data suggest a specific upregulation in the expression of GLUT 1, a transporter known to increase in reponse to stress; i.e. hypoglycemia and hypoxia. Interestingly, the in reponse to stress; i.e. hypoglycemia and hypoxia. Interestingly, the consistent expression of GLUT 3 in HD caudate despite substantially reduced neuronal numbers suggests two novel reponses. I. The few remaining neurons in HD caudate express a greatly increased amount of GLUT 3, or 2. That glia are capable under these circumstances of expressing GLUT 3 in addition to enhanced GLUT 1 expression. Upregulation of GLUT 1 may be a response to the increased energy demands in HD basal ganglia.

SELECTIVE COGNITIVE IMPAIRMENT FOLLOWING TRAUMATIC BRAIN INJURY IN RATS. R.J. Hamm\*, D. O'Dell, B. Pike, B.G. Lyeth, L.W. Jenkins. Departments of Psychology and Neurosurgery, Virginia Commonwealth Univ./ Medical College of Virginia, Richmond, VA 23284.

Impairment of cognitive abilities is a frequent and significant sequelae of traumatic brain injury (TBI). The purpose of this experiment was to examine the generality of the cognitive deficits observed after TBI. The performance of three tasks was evaluated. Two of the tasks (passive avoidance and a constantstart version of the Morris water maze) were chosen because they do not depend on hippocampal processing. The third task examined was the standard version of the Morris water maze which is known to depend on hippocampal processing. Rats were either injured at a moderate level (2.1 atm) of fluid percussion brain injury or surgically prepared but not injured (sham-injured control group). Nine days after fluid percussion injury, injured (n=9) and shaminjured rats (n=8) were trained on the one-trial passive avoidance task with retention assessed 24 hr later. On days 11-15 following injury, injured (n=9) and sham-injured (n=8) rats were trained on a constant-start version of the Morris water maze that has the animals begin the maze from a fixed start position on each trial. Additional injured (n=8) and sham-injured (n=8) animals were trained on days 11-15 after injury on the standard (i.e., using variable start positions) version of the Morris water maze. The results of this experiment revealed that performance of the passive avoidance and the constant-start version of the Morris water maze were not impaired by fluid percussion TBI. However, performance on the variable-start version of the Morris water maze was significantly impaired by TBI. Thus, a moderate level of fluid percussion TBI does not produce a generalized deficit in learning and memory. These findings suggest that the hippocampus is selectively vulnerable to traumatic injury.

DIFFERENTIAL SENSITIVITY OF LOCOMOTOR RECOVERY AND DESCENDING MOTOR EVOKED RESPONSES FOLLOWING SPINAL CORD CONTUSION IN RATS. J.A. Gruner\*, C.K. Wade, G. Menna, B.T. Stokes. Dept. of Neurosurgery, NYU Medical Ctr., New York, NY 10016, and Dept. of Physiology, Ohio State Univ., Columbus, OH 43210.

Behavioral and electrophysiological recovery were evaluated in rats after experimental spinal cord contusion injuries in order to provide data for comparison with other contusion injuries in order to provide data for

experimental spinal cord contusion injuries in order to provide data for comparison with other contusion models, and to evaluate motor evoked responses as a measure of functional recovery. Ten 300 gm female rats under ketamine/xylazine anesthesia were injured using a controlled contusion device. A 2 mm diameter impactor head applied approximately 217 k dynes of force to compress the cord 0.8 mm. Histologically, the cord cross-sectional area was reduced by 70% at the impact site. Animals were rated using a 15-gradation open field locomotor score between 2d and 4 wks. They became capable of support by 8d and near-normal coordinated walking by 15d. Auditory startle responses (ASR) and cerebellar stimulated myoelectric evoked potentials (CMyEP) were recorded myographically from vastus lateralis and tibialis anterior hindlimb muscles. CMyEP were recorded under anesthesia. ASR and CMyEP were abolished up to 6 wks after injury. However, substantial myoelectric responses from cutaneous muscles of the However, substantial myoelectric responses from cutaneous muscles of the lower trunk, innervated from cervical spinal roots, were present. Dorsal cord lower trunk, innervated from cervical spinal roots, were present. Dorsal cord field potentials (DCFP) were recorded at the sciatic n. entry zone to cerebellar and tibial n. stimulation. Tibial responses were normal or perhaps enhanced, whereas cerebellar responses were abolished. ASR and CMyEP are thus more sensitive to SCI than locomotor function, suggesting they are mediated by distinct pathways, or that segmental excitability was altered. The injuries produced by this device were very consistent, and correspond roughly to an "intermediate" level injury produced the predecessor CSU impactor.

THE BEHAVIORAL AND ANATOMICAL EFFECTS OF CONTUSION INJURY TO THE MEDIAL FRONTAL CORTEX OF RATS. S.W. Hoffman\*, Z. Fullop. D.G. Stein. Institute of Animal Behavior, Rutgers University, Newark, NJ 07102.

In the MeDiaL FHONIAL CORTEX OF HATS. SW, Hotiman: Z. Fullob D.G. Stein. Institute of Animal Behavior, Rutgers University, Newark, NJ 07102.

Contusion injury to the medial frontal cortex (MFC) results in protound impairments of spatial navigation performance. Male rats (90 days of age) received bilateral contusion-injury to the MFC. Seven days after injury the rats were tested on a Morris water maze task for 10 days (2 trials/day; 20s on platform; 20s intertrial interval) and compared with sham-operated controls. Activity monitoring was performed on days 1, 5, 10, and 15 postinjury. At 18d postinjury, the brains were processed for reactive astrocytes and microglia. ANOVA revealed that the contused rats were impaired on both latency and distance (p < 0.05) to locate the platform as compared to shams. The swim strategy of the contused rats was also found to be impaired. These rats swam a significantly greater percentage of distance in the outer annulus; ie they swam closer to the wall of the maze. These water maze deficits were more severe following contusion than after bilateral aspirations of the same region of cortex. The mean overall time to reach the platform during the ten days of testing for aspiration-lesion rats was 30.3±4.6s and 54.8±3.4s for the contusion-lesion rats. ANOVA of open-field activity revealed that brain injured rats spent a longer period of time in the center of the apparatus compared to shams (p < 0.05). Descriptive histological analyses showed that after 18d survival, the lesion could be characterized by an inverted-wedge shape. This cavity was lined with GFAP-positive astrocytes and silver impregnated microglia. There was also a circular patch of gliosis in the dorsomedial caudate that extended through the entire rostral to caudal length of this structure. This region contained both astro- and microglia, which were evenly distributed over the cellular and fascicular areas. The presence of macrophage/microglia in the brain is an indication of an inflammatory immune reaction. This intens

MILD EXPERIMENTAL BRAIN INJURY: MEMORY DYSFUNCORRELATES WITH HIPPOCAMPAL NEURONAL LOSS IN RATS. MEMORY DYSFUNCTION R.R. Hicks\*, D.H. Smith, D.H. Lowenstein, K.G. Perlman, R.L. Saint Marie, and T.K. McIntosh, Surgical Research Center, Univ. of Conn. Health Center, Farmington, CT 06030 and Dept. of Neurosurgery, Univ. of Penn., Philadelphia, PA 19104.

Farmington, CT 06030 and Dept. of Neurosurgery, Univ. of Penn., Philadelphia, PA 19104.

Memory dysfunction following human traumatic brain injury is believed to result from damage to key structures in the brain, including the hippocampus. Profound memory impairment has recently been observed following moderate (2.3 atm.) and severe (2.6 atm.) lateral fluid-percussion (FP) brain injury in rats. In the present study, we examined the effects of FP injury of mild severity (1.0 atm.) on memory dysfunction and cell loss in the hippocampus. Male Sprague-Dawley rats (n=9) were trained in the Morris water maze to find a submerged platform using external cues. 2.5 hours after training animals were subjected to mild FP brain injury (1.0 atm.; n=6) or 'sham' (surgery with no injury; n=3). Memory function was evaluated 42 hours after injury/sham injury. Animals were sacrificed and their brains removed 6 hours after the memory tests (48 hours post-injury). Sections (40 um thick) were stained with a Nissi stain (thionin), and the number of surviving (stained) neurons in the hilus and injured area of CA3 were counted manually and using an image analysis was performed by comparing each animal's memory score to the amount of cell loss in the hilus or CA3. All animals that received FP brain injury demonstrated some hippocampal neuronal loss and a significant correlation between memory scores and hilar cell loss (r=0.810, p=0.008) and CA3 cell loss (r=0.878, p=0.002) was observed. These results suggest that there may be an important link between the magnitude of hippocampal cell loss and the severity of memory dysfunction following experimental brain injury. Furthermore, this combined assessment may prove to be a valuable measure in determining the efficacy of therapeutic interventions following traumatic brain injury. This work was supported in part by NIH NS26818 and a grant from the Brain Trauma Foundation.

HISTOLOGICAL AND BEHAVIORAL EXPERIMENTAL TETHERED SPINAL CORD. G. Mandybur,

S. Yamada, R. Adey, and B. Liwnicz\*. Division of Neurosurgery, Loma Linda University School of Medicine, Loma Linda, CA 92350.

Tethered cord syndrome is manifested by neurologic deficits in legs and incontinence associated with an elongated spinal cord and thick follow the property of the cord and thick follows the cord and thick follows the cord and thick follows the cord and t thick filum terminale. Oxidative metabolism is thick filum terminale. Oxidative metabolism is impaired in cat model and human tethered cord. In this report laminectomy and ligature of the filum terminale allowed traction of the lumbosacral cord. A ligature was passed over the pulley and connected to one of weights (3 g, 5 g, and 8 g) and dropped 1.0 cm. The animals were sacrificed 24 hours - 2 weeks after surgery. L2, L7, S3, and coccygeal cord segments were removed and examined under light and electron microscopy (LM and EM). Only high and electron microscopy (LM and EM). Only high grade (8g) drop traction resulted in urinary incontinence and tail anesthesia. Edema and Only high incontinence and tail anesthesia. Edema and lymphocytic infiltration in gray matter neurons were noted by IM; and numerous neuronal membrane breaks and loss of mitochondrial cristae found by EM. This is the first report to describe histological damage to the gray matter in cat cord tethering and to correlate these findings with permanent incontinence in tethered cord articular. tethered cord patients.

SPATIAL LEARNING DEFICITS IN RATS WITH CORTICAL CONTUSION INJURY. R.L. Sutton\*, R.J. Sutherland, G. Quintana, T. Gutierrez and D.M. Feeney. Division of Neurosurgery and Departments of Psychology and Physiology, University of New Mexico, Albuquerque, NM 87131.

Adult male rats received a traumatic brain injury (TBI) centered over the right motor cortex [Br. Res. (1981) 211:67]. Four days postsurgery sham injured and TBI rats were tested for 12 days (2 blocks of 4 trials per day) in a Morris water maze (MWM) task. The location of the escape platform was changed daily. TBI rats had longer escape latencies than shams during the 2nd trial block from Day 1-12 and showed little improvement 2nd trial block from Day 1-12 and showed little improvement over 8 trials in daily test sessions (deficient acquisition of spatial learning set). Groups did not differ in latencies to a visible platform on Days 13-14. Rats pretrained in the MWM exhibited only mild, transient deficits during postTBI reacquisition tests. At 18-22 days no electrophysiological abnormalities in the strength or plasticity of perforant path-dentate gyrus connections were detected in the contralateral hippocampus. This MWM deficit postTBI may not be due to secondary hippocampal injury alone [Neurosci. Abst. (1989) 15:69].

IN VIVO ROLES OF THROMBIN DURING WOUND HEALING IN THE CENTRAL NERVOUS TISSUE.

A. Nishino, M. Suzuki\*, M. Motohashi and T. Yoshimoto. Div. of Neurosurgery, Inst. of Brain Diseases, Tohoku Univ. Sch. of Med., Sendai, Japan 980.

This investigation was carried out to clarify the in vivo effect of thrombin during wound healing in the central nervous system (CNS). Thrombin, buffer, plasmin and albumin were infused into rat caudate nucleus by an osmotic mini-pump. Brains were examined by immunohistochemistry using antibodies for BrdU, GFAP, vimentin and laminin. The following data were quantitatively analyzed: the area of GFAP-positive cells, the area and number of vimentin-positive cells, the number of BrdU positive cells. We found that thrombin caused proliferation of immature mesenchymal cells, infiltration and recruitment of inflammatory cells, induction of angiogenesis, and an increase in vimentin-positive reactive astrocytes. These histological changes following thrombin infusion resembled the inflammation, scar formation and reactive gliosis which are part of wound healing in the central nervous system. These results suggest that thrombin may play an important role in neuronal regeneration and in the secondary injury caused by the inflammatory response following CNS injury.

# 75.3

SURVIVAL OF MAMMALIAN CNS NEURONS AFTER NEURITE TRANSECTION IN MODIFIED IONIC ENVIRONMENTS (MIE) G. Wang\* and LH. Lucas. Dept. of Physiology, Ohio State Univ., Columbus, OH 43210

<u>I.H. Lucas.</u> Dept. of Physiology, Ohio State Univ., Columbus, OH 43210 Reducing external Ca<sup>+2</sup> (≤ 30 μM) delays but does not prevent death of spinal cord (SC) neurons after dendrotomy (J. Neurotrauma 7, 1990). Reducing Ca<sup>+2</sup> and Na<sup>+</sup> or Cl<sup>-</sup> prevents destruction of the smooth endoplasmic reticulum (Exp. Brain Res. <u>86</u>, 1991). We are now studying lesioned neuron survival in low Ca<sup>+2</sup> MIE with low Na<sup>+</sup> or Cl<sup>-</sup>.

Studies involved sets of experiments; each experiment used three 21-28DIV mouse SC cultures seeded on the same date. Ten neurons/culture were chosen for laser microbeam transection of a primary dendrite 100 µm from the soma and ten were unoperated controls. Surgery was performed in a Hepes-buffered MIE. KCI replaced NaCl in low Na<sup>+</sup> MIE, and Na<sup>+</sup> isethionate replaced NaCl in low Cl<sup>-</sup> MIE. Survival was assessed by erythrosin B (EB) and phase microscopy (to identify morihund cells).

| Time No     | rmal Ions (NI) | Low Ca+2 (LC) | LC/low Cl- | LC/low Na+   | • |
|-------------|----------------|---------------|------------|--------------|---|
| 2h (5 sets) | 54% ± 13       | $68\% \pm 4$  |            | $92\% \pm 8$ |   |
| 2h (3 sets) | 50% ± 10       | 57% ± 15      | 77% ± 6    |              |   |
| 6h (5 sets) | 42% ± 8        | 56% ± 11      |            | $58\% \pm 8$ |   |
| 6h (3 sets) | 53% + 6        | 63% + 6       | 60% + 10   |              |   |

Thus, 2h EB-minus-moribund survival: (a) was higher in any MIE than in its matched NI control group, and (b) was 20-25% higher when Na<sup>+</sup> or Cl<sup>-</sup> was also reduced than in the matched LC control group. However, protection by Na<sup>+</sup> or Cl<sup>-</sup> reduction was lost by 6h. The results indicate that Na<sup>+</sup> and Cl<sup>-</sup> contribute to the very early neuronal death after injury. Delayed death was probably caused by residual Ca<sup>+2</sup>, but <1 µM Ca<sup>+2</sup> seems to accelerate Na<sup>+</sup> and Cl<sup>-</sup> damage (bid.). Studies: (1) in MIE with ionic or nonionic substitutes for all 3 ions, and (2) of NI restoration after 2h, are in progress. NIH NS29683 and Intl. Fndtn. for Ethical Res.

FUNCTIONAL SIZE OF THE HUMAN INTERVERTEBRAL FORAMEN. B. W. Bakkum\* and M. Mestan. Dept. of Anatomy, National College of Chiropractic, Lombard, IL 60148.

It is commonly believed that neural structures within the intervertebral foramen (IVF) occupy only a small fraction of that compartment. The presence of transforaminal ligaments (TFLs), ligamentous structures that traverse the IVF, has not been considered when calculating the functional size of the IVF. Four lumbar spines, including T12 and in one case T11, were obtained from embalmed human cadavers and carefully dissected to expose the contents of the IVFs. All ligamentous structures in the vicinity of the IVFs were preserved. A total of 57 TFLs were observed. Of 49 IVFs examined, at least one TFL was present in 34 (69.4%). The greatest superior-to-inferior dimension (SI)

The greatest superior-to-interior dimension (SI) (perpendicular to the plane of the intervertebral disc) and the greatest anterior-to-posterior dimension (AP) (parallel to the plane of the intervertebral disc) of each IVF were determined. When present, the TFLs helped define a compartment of the IVF that contained the spinal nerve root. The SI and AP of these compartments were also determined. 34 IVFs had at least one TFL that ran in an anteroposterior direction, and the SI of the compartment for the spinal nerve root was an average of 31.5% less than the SI of the IVF. 13 IVFs had at least one TFL that ran in a superoinferior direction, and the AP of the compartment for the spinal nerve root was an average of 5.7% less than the AP of the IVF. Therefore, in the presence of TFLs, there is less space in the IVF for the nerve root than originally thought. This may increase the incidence of sypmtoms after trauma or degenerative changes.

### 75.2

Conduction failure in traumatized earthworm giant axons is mediated partly by Na<sup>+</sup> influx via voltage-gated Na<sup>+</sup> channels, with recovery dependent on Na<sup>+</sup>-K<sup>+</sup>ATPase. M.Jayachandra and V.E.Amassian<sup>+</sup>. Dept. of Physiology, State Univ. of New York-Health Sciences Center at Brooklyn. Brooklyn N.Y. 11203.

The initial phase of loss of direct conduction in traumatized mammalian spinal axons occurs within the first sec of impact, with recovery within 30-60 min, implying a direct effect on nerve membrane (J.Physiol.1991,427:58P). To define the basic mechanisms, a 1gm weight was dropped on Lumbricus giant axons, monitoring conduction, extracellularly, in median giant (MGN) and lateral giant fibers (LGN). On impact, a high frequency discharge occurred (~200Hz for <1sec) , followed by a period of conduction loss varying with the height (4-25mm) of the weight drop. For a given weight drop, recovery was hastened by exposing the nerve cord to Tetrodotoxin (~500nM) prior to the trauma and then washing after trauma (n=4). Recovery period was delayed in nerve cords (n=4) treated with Strophanthidin (10 -4 M) suggesting that membrane bound Na\* - K\* ATPase is necessary for recovery of conduction. In a preliminary cat experiment, pretreatment with Strophanthidin completely blocked recovery of primary afferents in the dorsal column, following a small weight drop.

EITHER ACUTE MUSCARINIC BLOCKADE OR CHRONIC CHOLINE SUPPLEMENTATION ACCELERATES RECOVERY OF MOTOR FUNCTION FOLLOWING CORTICAL IMPACT IN RATS. C. E. Dixon\*, W.C. Taft, K. Yang, and R.L. Hayes. Dept. Neurosurgery, University of Texas Health Science Center, Houston, Texas 77030.

In the rat fluid-percussion model, substantial evidence suggests that traumatic

In the rat fluid-percussion model, substantial evidence suggests that traumatic brain injury produces a brief period of excessive excitation of specific receptor subtypes, including muscarinic receptors, that may produce excitotoxic neural injury. However, in the rat cortical impact model, it is not known whether cholinergic excitotoxic mechanisms contribute to the induction of functional deficits. The first study was to determine if blockade of excitation of muscarinic receptors would reduce beam walking deficits. Ten rats were injected with scopolamine (1 mg/kg) 15 min prior to a lateral cortical impact. Ten sham control animals were surgically prepared, but not injured. Beam walking deficits were assessed daily for 4 days. Animals treated with scopolamine returned to preinjury levels significantly (p<0.05) earlier than sham controls. Thus, cholinergic excitotoxic mechanisms may contribute to the induction of chronic functional deficits in the rat cortical impact model.

Intimiter the Action of Tentonic Tenton

TRAUMATIC BRAIN INJURY CAUSES A DECREASE IN MUSCARINIC (M1 and M2) RECEPTOR BINDING IN THE RAT BRAIN M.M. DeAngelis, B.G. Lyeth\*, L.W. Jenkins and R.L. Hayes¹. Division of Neurosurgery, Medical College of Virginia, Richmond, VA 23298; 'Division of Neurosurgery, University of Texas Medical School at Houston, TX 77030.

Traumatic brain injury (TBI) results in excessive release of acctylcholine (ACh). Previous studies have indicated that muscarinic receptor mediated processes are involved in TBI pathophysiology. We examined the effects of moderate fluid percussion TBI (2.2 atmosphere) on radioligand binding specific to M1 and M2 muscarinic receptor subtypes. After TBI or sham injury, animals were sacrificed by in situ freezing at 3h or 24h post-injury. Slide mounted tissue sections were incubated in either [³H]-pirenzipine (23nM) for M1 or [³H]-AFDX384 (9nM) for M2 receptor subtype labeling. Localization of M1 and M2 receptor subtypes, in the hippocampal formation and adjacent cortex was analyzed by quantitative autoradiography. There were statistically significant (p < .05) decreases in binding to M1 receptors in cingulate cortex, midparietal neocortex and amygdala at 3h post-TBI and to M2 receptors in the apical dendrites of sector CA 2,3 pyramidal cells and molecular layer of the dorsal blade of the dentate gyrus at 24h post-TBI. These results demonstrated temporal and spatial differences in receptor subtype binding alterations after TBI and suggest that M1 and M2 receptor subtypes may be differentially affected in the pathophysiology of TBI. IS SPINAL CORD INJURY INDUCED LOSS OF RATE-SENSITIVE DEPRESSION RELATED TO GABAB RECEPTOR DYSFUNCTION? F.J. Thompson', R. Parmer', J. Graham, R.G.Fessler'. Depts. of Neuroscience', Neurosurgery', College. of Medicine., Univ. of Florida, Gainesville. Florida 32610-0244

Gainesville, Florida 32610-0244
We recently reported several neurophysiological alterations in lumbar reflex excitability subsequent to midthoracic contusion or hemisection injury (Thompson et al., 1991; 1992a). These changes were characterized by progressive onset and permanent duration. The most significant change was the decrease in the magnitude of rate-sensitive depression of monosynaptic reflexes. By one month post injury, this process is significantly less effective and the reflex magnitudes produced by repetitive sensory inputs are 350 to 400% increased over those in normal animals. Since proprioceptive signals include slow adapting, repetitive inputs, this loss of rate-sensitive depression is proposed to contribute significantly to the development of hyperreflexic syndromes subsequent to spinal cord injury.

significantly to the development of hyperreliexic syndromes subsequent to spinal cord injury.

To identify a more specific substrate for this regulatory process, analysis of rate-sensitive depression was tested before and following focal application of CPG35348, a specific GABAb blocker, to the pial surface of the fifth lumbar spinal cord segment, in normal ketamine anesthetized adult rats. Following application of doses as small as 10 µg, decreased rate-sensitive depression of tibial monosynaptic reflexes (MSRs) was recorded. The decrease in rate-sensitive depression resulted in 10 Hz MSRs that were 300% larger than the pretreatment controls. Preliminary findings indicate that focal application of a specific GABAb blocker produced alterations in rate-sensitive depression which mimicked part of the change produced subsequent to thoracic cord lesions. CONTROLLED CORTICAL IMPACT INDUCES SUSTAINED ELEVATIONS IN THE EXTRACELLULAR CONCENTRATIONS OF EXCITATORY AMINO ACIDS P.E. Swedlow, M.L. Botscheller, D.W., Marion, R.J. Sclabassi and A.M. Palmer. Brain Trauma Research Center, Departments of Clinical Neurophysiology, Neurological Surgery, Psychiatry Pharmacology, University of Pittsburgh School of Medicine, Pittsburgh, PA 15213.

Traumatic brain injury (TBI) is associated with short-term elevations in extracellular concentrations of excitatory amino acids ([EAA]\_c) in both epidural compression and free weight drop models (I Neurosurg 73: 889-900; I Cereb Blood Flow Metab 10: 631-7). We used controlled cortical impact to define certain neurochemical and behavioral consequences of TBI in a rodent model. Maintaining a constant impact velocity (3.2 - 3.5 m/s), we varied depth of brain deformation (DBD). Rats were randomized to groups of severe (DBD=3.5 mm, n=6), mild (DBD=1.5 mm, n=7) and sham (n=9) injuries. Serial measurements of [EAA]\_e were collected by in vivo tissue microdialysis, and a beam balancing task was used to measure changes in behavior. Only severely injured animals displayed significant behavioral deficit 10 days after injury. However, both mild and severe groups demonstrated significant injury-dependent increases over mean pre-injury values (mean fold increase  $\pm$  SEM) in extracellular concentrations of aspartate (mild, 32  $\pm$  12; severe, 65  $\pm$  13) and glutamate (mild, 71  $\pm$  23; severe, 107  $\pm$  20). [EAA]\_e returned to baseline within 20 min after mild impact but remained significantly elevated for at least 60 min after severe Impact. A non-transmitter amino acid (serine) showed a similar pattern of injury-induced change, suggesting that trauma-induced increases in [EAA]\_e are attributable, at least in part, to cell lysis. A prolonged elevation of [EAA]\_e has not been reported in other models of TBI. (This work was supported by NINDS Grant 1P20NS30318-01).

EARLY CHANGES IN CATECHOLAMINE TURNOVER FOLLOWING TRAUMATIC BRAIN INJURY (TBI) IN RATS. S. Pan, A. Dunn-Meynell, B.E. Levin\*. Neurol. Serv. (127), VA Med. Ctr., E. Orange, NJ 07018; Dept. of Neurosciences, NJ Med. Sch., Newark, NJ 07103.

Manipulation of norepinephrine (NE) and dopamine (DA) activity alters the outcome of TBI. Since little is known about how TBI affects NE and DA metabolism, brain turnover (TO) rates were assessed by HPIC assay of the decline of NE and DA levels after synthesis inhibition with α-methyltyrosine at 6h and 24h after right sensorimotor cortex contusions produced by rapid, 2mm depression of cortex with a 5mm diaplunger. Lesion site NE TO decreased by 53% (p<0.001) and ipsilateral striatal DA TO was undetectable at 6h. Both recovered by 24h. NE TO increased at 6h and returned to sham control levels at 24h in contralateral anterior cortex (56%; p<0.005) and bilateral cerebellum (39%; p<0.005) and medulla (344%; p<0.001). Ipsilateral hypothalamic NE TO increased by 151% (p<0.001) at 6h and remained elevated at 24h. Bilateral hypothalamic DA TO increased at 6h (212%; p<0.001) but returned to control levels at 24h. Thus, TBI produced early, largely transient changes in brain NE and DA TO which might explain the effects of pharmacological manipulation of NE and DA on the outcome of TBI. Supported by the Research Service of the Department of Veterans Affairs.

IN VIVO MICRODIALYSIS MEASUREMENTS OF CEREBELLAR NOREPINEPHRINE FOLLOWING CORTICAL CONTUSION AND AMPHETAMINE. K.A. Krobert\*, R.L. Sutton and D.M. Feeney. Depts. of Physiology, Psychology, and Division of Neurosurgery, University of New Mexico, Albuquerque, NM 87131.

Rats had concentric dialysis probes (3 mm X 250 um fiber; in vitro recovery = 11.8 - 13.5%) placed bilaterally in the cerebellum (Cb) immediately after contusion [Br.Res. (1981) 211:67] of the right sensorimotor cortex or sham surgery. Analyses of 20 min dialysate samples (artificial CSF; flow = 1.5 ul/min) with HPLC (20 ul sample loop) revealed that mean  $\pm$  SEM basal levels in shams was 1.23  $\pm$  0.24 pg in left and 1.08  $\pm$  0.11 pg in right Cb. Contusion reduced basal NE levels to 0.57  $\pm$  0.27 in left and 0.48  $\pm$  0.08 pg in right Cb. D-amphetamine (2 mg/kg, i.p.) 24 hr after surgery bilaterally increased NE levels by 174 to 1051% in shams and 425 to 1188% in contused rats. Peak NE levels cocured 20-40 min postdrug, declined to basal levels by 3-4 hrs, and remained at predrug levels at 22-24 hours postdrug. These data indicate that amphetamine releasable NE stores are present in Cb despite injury-induced depression of spontaneous release. This finding may relate to amphetamine facilitated behavioral recovery after cortical injury. Supported by Army Grant DAMD17-91-7-1006.

LATERAL FLUID PERCUSSION BRAIN INJURY CAUSES CHOLINERGIC FOREBRAIN NEURON DEATH. M.S. Grady\*, J. Leonard, D.O. Maris Dep't. of Neurosurgery, Univ. of Wash., Seattle, WA 98104

Traumatic brain injury (TBI) results in widespread damage within the human CNS. Fluid percussion injury is used as a model of human TBI in experimental animals. This accepted model has been characterized extensively, but little attention has focussed on distal effects of the injury on specific neuron populations. Human TBI frequently causes memory disorders, with some data showing a causal relationship between TBI and Alzheimer's disease. The behavioral results of fluid percussion injury include spatial memory dysfunction. In the rat, cholinergic neurons located in the forebrain are known to play a role in memory function. We investigated the results of fluid percussion injury on this neuron population

Anesthetized rats underwent a 2.5 atmosphere lateral fluid percussion injury and were sacrificed at intervals of 7, 10, 14 and 28 days after injury. Sections were taken through the medial septal nucleus (MSN), site of injury and hippocampus and submitted for histology, including ChAT and NGFR immunocytochemistry, AChE histochemistry and Nissl stain. Cell area and number was analyzed in the MSN and AChE density in the hippocampus. Comparison was made to the opposite, uninjured side of the brain as well as to control animals.

There was a time dependent loss of ChAT in the ipsilateral MSN, beginning at 7 days and extending through 28 days. NGFR stained cells were also depleted though significant loss did not occur til 10 days post injury. There was a concomitant loss of AChE terminal density in the hippocampus. These results suggest that loss of specific neuron populations may account for some of the behavioral deficits in TBI, and may be amenable to reversal with pharmacologic intervention.

CELLULAR REACTIONS AT SPINAL CORD LESION SITES: NEUTROPHILS, MACROPHAGES, MICROGLIAL CELLS AND ASTROCYTES. I. Dusart\* and M.E. Schwab. Brain Research Institute, University of Zurich, August Forel str. 1, 8029 Zurich, Switzerland.

Local spinal cord lesions are often greatly enlarged by "secondary damage", a process which is poorly understood and results in scar and cavity formation and absence of tissue repair. From 24 bours to 3 months after transection of the dorsal 2/3 of the adult spinal cord, the different types of cells present in the lesion were identified by immunohistochemistry.

As soon as 24 hours after the lesion, massive cell death was observed in a region

As soon as 24 nours after the leston, massive cell death was observed in a region up to 200 µm from the primary mechanical lesion. At this time and throughout the next 24 hours, the only non-CNS cellular type present in the lesion are neutrophils (polymorphonuclear leukocytes). This cell type is present throughout the areal extent of the lesion and has been observed in this site for approximately 4 days. Within two days, a recruitment of blood-borne monocytes (ED-1+) began to be

Within two days, a recruitment of blood-borne monocytes (ED-1+) began to be apparent, simultaneously with a proliferation of cells. Some of these proliferating cells were OX42+ and were located in the periphery of the lesion which suggests that they are microglial cells. The number of microglial/macrophagic cells was very high between 4 and 8 days at the lesion site. During this first week, very few astrocytes remained in the lesion site itself. However, in the surrounding area, numerous activated astrocytes and some activated microglial/macrophagic cells

After one week, the astrocytic processes were dense around the lesion site, but only few of them entered the necrotic tissue area. The reactive microglial/macrophagic cells progressively disappeared from the lesion site leading, in most of the cases, to the formation of a cavity

in most or the cases, to the formation of a cavity.

Our results suggest an early role for neutrophils in tissue damage after spinal cord transections. The described CNS inflammatory process seems to correspond to that observed in the periphery. However, in contrast to the fibroblast bed forming in peripheral lesions, astrocytes wall off the necrotic CNS tissue resulting in the formation of a cavity.

INCREASED KININGGEN IMMUNOREACTIVITY IN INJURED SPINAL CORD

INCREASED KININOGEN IMMUNOREACTIVITY IN INJURED SPINAL CORD IN RAT. Z-H. Li, J. Xu, J. Chao, N. Bhat\* and E.L. Hogan. Neurology, Med Univ of SC, Charleston, SC 29425.

Bradykinin is a mediator of inflammation with receptors discovered in substantia gelatinosa and dorsal root ganglion of spinal cord (Stersanka et al., 1988). We have found an increase in kininogen, the bradykinin precursor, in traumatized cord (Xu et al., 1991).

Using the ABC immunocytochemical technique to study kininogen immunoreactivity (IR) in rat compression spinal cord trauma models, it was found that kininogen IR was increased in the injured spinal segment compared to sham (laminectomy). The kininogen IR was increased in the superficial layer of dorsal horn, mainly in the margin area, and in substantia gelantinosa when compared to sham. There was strong IR staining of astrocytes in both white and gray matter and IR positive endothelial cells in small blood vessels. In dorsal root ganglion, IR staining surrounded sensory neurons and a few axons. IR was increased in the superficial layer of the dorsal root and dorsal root ganglion. The increased kininogen IR was observed 30 minutes after trauma and its density was roughly proportional to the magnitude of compression. The results provide evidence that trauma may induce an increase in kininogen levels. The increase may be a protective response to inhibit protease, etc., or lead to increase of kinin peptides that mediates inflammation. These possibilities are being studied. Supported by NS-11066.

DAMAGE TO SPINAL CORD NEURONS BY HYDROXYL RADICALS GENERATED IN SITU. D. Liu\*, R. Yang, X. Yan and D. J. McAdoo. Marine Biomedical Institute and Dept. of Human Biological Chemistry and Genetics, Univ. of Texas Med. Branch, Galveston, TX 77550.

Our experimental model for studying secondary damage and drug actions on secondary injury uses microdialysis to sample substances released, to administer damaging substances and to administer drugs together with the damaging substance. We use electrophysiological recording to record decline in conduction, neurochemical analyses to obtain the identity and time course of released substances, and histological examination to assess neuron damage to characterize secondary damaging substances and study the effective mechanisms of the drugs. In this study we administer H<sub>2</sub>O<sub>2</sub> and FeCl<sub>2</sub>/EDTA through two parallel microdialysis fibers within the spinal cords of deeply anesthetized rats; the 'OH radical is generated when these substances mix between the fibers. The amount of 'OH generated is indicated by the amounts of tyrosine isomers formed from phenylalanine. 'OH generated by our procedure blocks electrical conduction, increases release of amino acids and destroys neurons. FeCl<sub>2</sub>/EDTA and H<sub>2</sub>O<sub>2</sub> administered actors and destroys neurons. FeC<sub>1</sub>/ED1A and  $H_2O_2$  administered alone have lesser or no effects on the parameters measured. Our method provides a model for studying damage by 'OH and testing the effects of drugs on damage by 'OH in vivo.

Paralysis Association and the NIH (NS11255).

CHARACTERIZATION OF LEUKOCYTE INFILTRATION IN TRAUMATIC BRAIN INJURY IN THE RAT. H.C. HOTNET. P.E. Setler. L.C. Fritz and 0. Hines. Athena Neurosciences, Inc., S. San Francisco, CA, 94080. Leukocytes have been implicated as factors contributing to the secondary damage which accompanies brain injury. We used immunhistochemical (IHC) and biochemical analysis to examine the time course of infiltration of neutrophils (N's) and monocytes (M's) after a 10gm weight was drooped from 10 cm onto the right sensorimotor cortex of the adult rat. At various times post injury (p.i.) the animals were anesthetized and perfused with periodate-lysine-paraformaldehyde fixative, The brains were removed, fixed and paraffin embedded. Serial brian sections (6um) were stained with anti-Leukosialin (anti-N antibody) and mab EDI (anti-M antibody). Four hrs p.i. N's were present only in the area of hemorrhage. At 16 & 24 hrs p.i. N's were seen at the center of the hemorrhagic/necrotic area as well as in nearby vessels, in the ipsilateral ventricle and in the surrounding parenchymal tissue (deen layers of parietal and occipital cortices). Distal to the focal necrosis, N's were localized in the optic tract, the external cansule and CA2 & 3 pyramiwdal cell fields of the hippocampus. Staining from animals sacrificed 2,3,4 and 7 days p.i. revealed that the N's were localized to injured tissue and were not seen migrating into uninjured neuropil. Furthermore, at 16 and 21 days p.i. there was no evidence of N's. By this time the injured area had resolved from a necrotic zone to a cavitation. There were no N's in or surrounding the cavitation. We also measured the change in myeloperoxidase (MPO) activity us a marker of the presence of N's in injured brain. The time course of the increase in brain MPO was the same as that of the LMC detection of N's: MPO activity (U/ym tissue) was 0.0525.0.703; 0.3574±0.049; 0.597±0.091; 0.710±0.105; 0.557±0.080 and 0.093±0.021 at 4,16,24,48,72 and 168 hrs. p.i.

M's showed a different pattern of localization and t

BRAIN HYDROXYL RADICAL GENERATION AFTER EXPERIMENTAL

BRAIN HYDROXYL RADICAL GENERATION AFTER EXPERIMENTAL HEAD INJURY. P.A. Yonkers, P.K. Andrus and E.D. Hall. CNS Res., The Upjohn Co., Kalamazoo, MI 49001.

The time course and intensity of brain hydroxyl radical (\*OH) generation were examined in male CF-1 mice during the first hour after concussive head injury. Hydroxyl radical production was measured using the salicylate trapping method in which the production of 2,3 and/or 2,5 dihydroxybenzoic acid (DHBA) in brain 15 min after salicylate administration was used as an index of \*OH formation. In mice injured with a of 2,3 and/or 2,5 dihydroxybenzoic acid (DHBA) in brain 15 min after salicylate administration was used as an index of \*OH formation. In mice injured with a concussion of moderate severity, a 60% increase in 2,5 DHBA formation was observed by 1 min post-injury compared to in uninjured mice. The peak in DHBA formation occurred at 15 min post-injury (+67.5%, p<0.02 compared to uninjured). At 30 min the increase in DHBA lost significance, indicating that the post-traumatic rise in brain \*OH formation is a transient phenomenon. In severely injured mice, the peak increase in DHBA (both 2,3 and 2,5) was observed at 30 min post-injury, but also fell off thereafter. Injury had no effect on plasma levels of DHBA. However, saline perfusion of the injured mice to remove the injury-induced increase in 2,5 DHBA. This implies that the source of the increased DHBA in the injured mice is the microvasular endothelium. The administration of the 21-aminosteroid U74006F, which possesses .OH scavenging properties, also attenuated the post-traumatic rise in DHBA. These results are a direct demonstration of the occurrence and time course of increased \*OH production in injured brain.

PHOSPHORYLATION OF A 61,000 DALTON PROTEIN KINASE C (PKC) SUBSTRATE INCREASES FOLLOWING TRAUMATIC BRAIN INJURY (TBI). K. Yang', W.C. Taft', C.E. Dixon', R.K. Yu², R.L. Hayes', Neurosurgery', UT Medical School at Houston, Houston TX 77030; Dept. Biochemistry<sup>2</sup>, Medical College of Virginia, Richmond VA 23298.

We have reported activation of PKC following moderate TBI in rat brain (J Neurotrauma 9:72, 1992). In order to investigate the consequences of PKC activation at the substrate level, we have examined in vitro phosphorylation patterns following injury. Male Sprague-Dawley rats were subjected to a moderate level (2.2 Atm) of fluid percussion injury. One hour after injury the animals were sacrificed by in situ freezing with liquid nitrogen, and dorsal hippocampi were dissected and homogenized at 4°C. Endogenous phosphorylation of homogenate protein was examined at 30°C; reactions were initiated with the addition of gamma-[<sup>32</sup>P]-ATP. Phosphorylations were stopped after 30s and the phosphorylated proteins were separated by 10% SDS-PAGE. A significant increase in the phosphorylation of a novel 61,000 dalton protein (TBI61) was observed. TBI61 phosphorylation was 120% higher in injured samples compared to sham control (Injury:3.86  $\pm$ 0.67; Sham control:1.75  $\pm$  0.50 [arbitrary dens. units]; P(0.05). TBI61 phosphorylation could be stimulated by the administration of exogenous phosphatidylserine and diacylglycerol. TBI61 also could be phosphorylated by exogenous PKC. In all cases, TBI61 phosphorylation was inhibited by the PKC inhibitor, staurosporine. Thus TBI enhances the phosphorylation of a novel PKC substrate, TBI61. (Supported by NIH grant NS21458).

REGIONAL ACTIVITY OF PROTEIN KINASE C AFTER EXPERIMENTAL BRAIN INJURY IN THE RAT. M. R. Prasad, C. Tzigaret, D. Smith, M. Thomas\* and K. McIntosh. Surgical Research Center, University of Connecticut Health Center, Farmington, CT 06030-1110.

Extracellular excitatory amino acids (EAA) and their receptors have been implicated in secondary neuronal damage after traumatic brain injury. Several in vitro studies suggest that excitatory EAA-stimulated neuronal damage of cultured neurons may involve protein kinase C translocation from cytosol to membrane. We examined the regional levels of lactate (a biochemical marker for cellular injury) and the distribution of protein kinase C (measured by phorbol-ester binding assay) or calcium-phospholipid-dependent protein kinase C (measured as co-factor stimulated <sup>32</sup>P-phosphorylation of histones) between cytosol and membrane fractions after lateral fluid-percussion (FP) brain injury. Adult rats were subjected to FP brain injury of moderate severity (2.2-2.4 atm). At 30 min post injury, the brains of injured (n = 4) and sham operated (n = 4)animals were frozen using *in situ* freezing techniques. The ipsilateral (injury site) left cortex (LC), contralateral right cortex (RC), and left and right hippocampi (LH and RH) were dissected out carefully at 0°C. The lactate levels of injured cortex were 3-fold higher than those of sham operated animals (p < 0.05). However, no significant differences were observed in lactate concentrations in other regions. Furthermore, no significant differences were observed in the distribution of protein kinase C between cytosols and membranes of LC, RC and LH of brain-injured animals, when compared to those of sham operated animals. These results suggest that at 30 min following FP brain injury, cellular damage is present only at the injury site, and translocation of cellular protein kinase C may not be involved in the pathogenesis of this neuronal damage. (Supported by funds from the Department of Surgery, a grant from UConn and, in part, by NIH NS26818 and a VA Merit Review Grant.)

CNS EXPRESSION OF IMMEDIATE EARLY GENE c-fos IN RESPONSE TO DIFFERENT SITES OF PERIPHERAL NERVE INJURY. S. Zhao, H. W. Thompsont, R. W. Beuermant D.H. Kim and

D.G. Kline Dept. of Neurosurgery, Louisiana State University Medical School, and <sup>‡</sup>Lab. of Molecular Biology, LSU Eye Center, New Orleans,

The brachial plexus of 30 rats was cut bilaterally, either just above or 1 cm below the dorsal root ganglia. Following nerve transection, individuals from each group were sacrificed at half, one and two hours post-operatively. Expression of *c-fos* protooncogene in the spinal cord and brain was determined by two methods: Northern blot hybridization to detect  $c ext{-}fos$  mRNA and immunohistocytochemistry to identify the  $c ext{-}fos$  protein product. When both groups of animals were compared to the untransected control animals, we found an increase in c-fos gene expression in both the spinal cord and brain half an hour after nerve transection. These levels continued to rise at one and two hours postnerve transection. While both groups demonstrated greater c-fos expression than controls, the group with nerve transection above the dorsal root ganglia showed a greater elevation than those with a transection below the ganglia. Additionally, immunocytochemistry showed that the increased c-fos protein appeared mainly in the dorsal hom of the spinal cord, somatosensory and pyriform cortex, hippocampus, and thalamus of the brain. Our results suggest that peripheral nerve transection near the spinal cord may have distinct effects on the central nervous system when compared to transection more lateral to the spinal cord

SUBCORTICAL NEURONAL DEGENERATION FOLLOWING EXPERIMENTAL RAT BRAIN INJURY. Holly D. Soares\* and Tracy K. McIntosh,Ph.D. \*Dept Surgery, Univ CT Health Critr, Farmington, CT 06030 and Dept of Neurosurgery, Univ of Penn, Philadelphia, PN 19104.

A common clinical neuropathological event following human traumatic

brain injury includes gross involvement of subcortical structures. Our lab uses experimental lateral fluid percussion (LFP) in the rat to examine neuropathological sequelae following brain injury. Although LFP brain injury is known to result in focal cortical and hippocampal damage, we investigated whether neuronal degeneration also occurs in subcortical structures. Adult male Sprague-Dawley rats were anesthetized i.p. with 60 mg/kg sodium pentobarbital and subjected to moderate (2.3-2.4 atms) LFP brain injury. Following trauma, animals were reanesthetized and perfused with 4% paraformaldehyde immediately (n=4), 2 hrs (n=4), 24 hrs (n=4), and 72 hrs (n=4) post-injury. 35u vibratome coronal brain sections were subjected to cell body silver degeneration techniques (Gallyas et. al., 1980; Nauta and Gyaux, 1954). Ipsilateral neuronal degeneration was observed in ventral and Gyaux, 1954). Ipsilateral neuronal oegeneration was observed in vertral and posterior thalamus, lateral geniculate, medial geniculate, superior colliculus, anterior pretectal, and parafascicular nuclei. Neuronal degeneration was also observed in ipsilateral caudate putamen and bilateral substantia nigra. In conclusion, subcortical structures exhibit significant neuronal degeneration following experimental LFP rat brain injury. Supported, in part, by a VA Merit Review grant and the Brain Trauma Foundation.

EFFECTS OF PROTEIN OR RNA SYNTHESIS INHIBITION ON SURVIVAL OF MAMMALIAN SPINAL CORD (SC) NEURONS AFTER NEURITE TRANSECTION J. H. Lucas\*, G. Wang and H. Azzazy Physiology Dept., Ohio State Univ., Columbus, OH 43210.

Hypothermia (2h at 17°C followed by rewarming to 37°C) and

Hypothermia (2h at 17°C followed by rewarming to 37°C) and thiopental (TP, 200 µM) significantly increased survival of SC neurons after dendrotomy (Brain Res. 517, 1990; Soc. Neurosci. Abst. 17, 1991). Cooling and TP both reduce cell metabolism. We are now evaluating interventions which inhibit specific aspects of metabolism. Experiments utilized pairs of mouse SC cultures (21-28 DIV) seeded

on the same date. Ten neurons/culture had laser microbeam transection of a primary dendrite 100 µm from the soma; 10 others were

of a primary dendrite 100  $\mu$ m from the soma; 10 others were unlesioned controls. The maximum nontoxic concentration (no death o stress of uninjured neurons exposed for 96h) of a protein synthesis (puromycin, PMN, or cycloheximide, CHX) or RNA synthesis (Actinomycin D, AD) inhibitor was added to one culture of the pair. Measurements of <sup>35S</sup>-Met uptake were employed to monitor inhibition. PMN (0.05  $\mu$ g/ml) or CHX (1.0  $\mu$ g/ml) was added 1h before surgery. Survival at 24h was 82%  $\pm$ 8 S.D. with PMN and 78%  $\pm$ 8 with CHX vs 54%  $\pm$ 13 and 48%  $\pm$ 13 in the respective control groups (p < 0.01, independent T test). Percentages are means of 5-8 experiments (50-80 lesioned cells). Removal of inhibition at 24h ( $^{35}$ S-Met confirmation) caused no additional death at 48h. If CHX was added immediately or 1h after surgery, survival fell to 63% and 53% cost-Met confirmation), caused no adminishal death at 46n. In CFA was added immediately or 1h after surgery, survival fell to 63% and 53% respectively vs 53% and 50% in the control groups (12 experiments). When AD (0.01 μg/ml) was added 12h before surgery (maximum effect on protein synthesis), survival at 24h was 63% vs 43% (6 experiments). Other RNA inhibitors will be studied. NIH NS29683.

CYTOSKELETAL PROTEIN LEVELS DECREASE FOLLOWING TRAUMATIC BRAIN INJURY (TBI). W.C. Taft, C.E. Dixon, M. Wiesmann, K. Yang, R.L. Hayes. Department of Neurosurgery, Univ. of Texas Health Science Center at Houston, Houston TX 77030.

Disruption of neuronal cytoarchitecture has long been implicated in the pathophysiology of TBI, but little is known about the specific molecular features of TBI-induced cytoskeletal derangements. In order to investigate the effect of TBI on cytoskeletal proteins, we have quantitated protein levels of predominant microtubule protein components. Male Sprague-Dawley rats were subjected to moderate fluid percussion injury (2.1 atm), a magnitude which produces a spectrum of long-lasting neurobehavioral deficits not associated with hippocampal neuronal death. Animals were sacrificed 3 hours later by in situ freezing with liquid nitrogen. Hippocampi from naive, sham and injured animals were dissected and homogenized at 4°C. Hippocampal proteins were balanced for protein content, separated by SDS-PAGE and transferred to nitrocellulose for quantitative immunoreactivity (IR) measurements. We observed a 44.3 + 9.2% decrease (compared to sham controls, p < 0.005) in hippocampal MAP2 levels. In addition, we found alterations in the labelling pattern of higher MW tau proteins. In contrast, we observed no changes in the labelling of  $\beta$  tubulin III, a neuron-specific tubulin isoform. The data are consistent with the conclusion that even sublethal levels of TBI can trigger the activation of neuron specific proteases which reduce cytoskeletal protein content in injured neurons. IMPAIRMENT IN REGIONAL ENERGY METABOLISM FOLLO-WING SPINAL CORD COMPRESSION INJURY IN THE RAT.

WING SPINAL CORD COMPRESSION INJURY IN THE RAT. A.Mautes and A.C. Nacimiento\*
Neurosurgical Research Laboratory, Saarland University Medical School, 6650 Homburg/Saar,FRG. We demonstrated, using bioluminescence imaging of ATP, glucose and lactate in serial spinal cord tissue sections, a clear impairment of regional energy metabolism after a 3h exposure by laminectomy (Soc.f.Neurosci.Abstr.1990,16,206.5) With this baseline we studied under identical experimental conditions the corresponding post-With this baseline we studied under identical experimental conditions the corresponding post-traumatic changes following compression at L4 with the method of Nacimiento et al (J.Neurosurg.1985, 62:, 898.) Results: a) ATP content decreased significantly in both lumbar and thoracic (left intact) segments; b) glucose content showed a clear, but not significant, tendency showed a clear, but not significant, tendency to increase in both regions; c) lactate increased significantly, both in lumbar and thoracic segments, by about 40% over laminectomy-only levels. Conclusions: i) non-adjacent intact segments may be involved in the posttraumatic changes; ii) the combination of inhibited glucose degradation, low ATP and high lactate indicates regional recirculation; iii) reperfusion tissue damage may contribute to posttraumatic metabolic changes. Supported by DFG-Grant Na 115/5-1.

CHANGES IN LOCAL CEREBRAL BLOOD FLOW FOLLOWING CONCUSSIVE BRAIN INJURY. C. Doberstein, F. Velade, H. Badie, D.A. Hovda, and D.P. Becker\*. Division of Neurosurgery, UCLA School of Medicine, Los Angeles,

Previous work has indicated a prolonged metabolic and ionic disturbance following concussive brain injury. The present study is a continuation of this previous work using a concussive injury in rats and describes our preliminary results regarding cerebral blood flow (CBF) using the iodo[14C]antipyrine autoradiographic technique. CBF was assessed within the cerebral cortex and comparisons were made between the two hemispheres as well as between different time points. A total of 11 male Sprague-Dawley rats (male, 230-275 g) were studied beginning immediately after, and up to 10 days following, a left parietal fluid percussion injury (FPI; 4.1-5.0 atm). Immediately following FPI, a bilateral reduction in cortical CBF was noted. Furthermore, a marked asymmetry was evident in the parietal and occipital regions which revealed nearly a 50% decrease in CBF compared to the corresponding uninjured right side. Cortical CBF recovered within 24 hours with no apparent asymmetry. From 2 to 5 days following FPI the injured cortex demonstrated reduced blood flow which, although not as severe (~ 35%) as that seen immediately following injury, fell to approximately 71 ml/100gm/min in the left parietal cortex. By 10 days after injury blood flow had normalized and cortical CBF values were comparable to those seen in the control animals. Our data suggest that CBF exhibits complex, prolonged changes following concussive brain injury. Secondly, CBF and metabolism are uncoupled immediately following FPI but become recoupled within 24 hours. Finally, that like cerebral metabolism, blood flow is reduced 2 to 5 days following concussive injury recovering to normal values by 10 days after the insult. (NS30308, NS27544 & The Brain Trauma Foundation)

INTERSTITIAL CO, AND PH TRANSIENTS LINKED TO SPREADING DEPRESSION IN RAT HIPPOCAMPAL SLICES. T. Taira, J. Voipio, P. Paalasmaa and K. Kaila, Dept. of Zoology, Div. of Physiology, Univ. of Helsinki, COlOO Helsinki,

Spreading depression (SD) in the brain is accompanied by large shifts in interstitial pH (pH $_0$ ). We have used a novel CO $_2$ HT-sensitive microelectrode for simultaneous monitoring of CO $_2$  and pH in the interstitial space of rat hippocampal slices (thickness 300-400  $\mu$ m), kept in an that space of rainprocaspar sinces (unicaness 300-400 pm), kept in an interface chamber at a temperature of 32 °C. The physiological solution contained (in mM): Racl 124, Kcl 3.0, CaCl, 1.5, NaBROO, 25, NaB.PO, 1.1. NgSO, 2.0, and D-glucose 10. It was equilibrated with 95t 0, + 5t CO, (P-CO, 38 mm Hg; pH 7.4). The recordings were made in stratum pyramidale of area CAI. Spreading depression was induced either by repeated trains of stimuli applied to the Schaffer collaterals or by microdrop application of 2 M KCI. The change in pH during SD was biphasic, with an initial alkaline transient followed by an acid shift and, finally, by a slow recovery of pH<sub>Q</sub> to its original baseline level. The initial alkaline transient was associated with a slight fall (about 5 mm Hg or less) in transient was associated with a slight fall (about 5 mm mg or less) in interstitial P-CO<sub>2</sub>, and the subsequent acid shift was paralleled by a rise in P-O<sub>2</sub> to about 60-70 mm Mg. Inhibition of extracellular carbonic anhydrase activity by bath applied beniolamide or by microdrop application of prontosil dextran 5000 (see Kaila et al., MeuroReport 3: 105, 1992) enhanced the initial alkaline shift, and there was now a large (20 mm Hg) fall in P-Co<sub>2</sub>. These results indicate that substantial transmembrane fluxes of Co<sub>2</sub> take place during SD, and that extracellular carbonic anhydrase plays a key role in SD-linked changes in interstitial

METABOLIC ALTERATIONS ACCOMPANY IONIC DISTURBANCES DURING A HYPOXIC INSULT TO THE RETINA: AN IN VITRO STUDY. I. Fineman\*, C. Doberstein, B. Badie, D.A. Hovda, N. Martin, and D.P. Becker. Div. Neurosurgery, UCLA School of Medicine, Los Angeles, CA 90024, USA.

In order to further our understanding of the ionic and metabolic derangements that occur following brain injury we utilized a retina in vitro model of hypoxia. Rats were administered a lethal dose of pentobarbital (150 mg/kg, IP), and the retinas dissected into oxygenated (95% O2, 5% CO2) Ames medium. Retinas were randomly assigned to either experimental (95%  $N_2$ , 5%  $CO_2$ ) or control conditions. All retinas were incubated at 37°C. Changes in extracellular potassium (K\*)using flame spectrometry intracellular calcium (Ca\*\*) using  $^{49}$ Ca (5uCi/ml in incubating solution) autoradiography/optical densitometry, and lactate using light spectrometry were measured as well as the alteration in glucose uptake using [14C]-2deoxy-D-glucose (2DG, 1 uCi/ul) following 10, 20, and 30 minutes of hypoxia (5 experiments per time point). All measurements were conducted pre- and post-hypoxic insult. The results indicate that compared to controls hypoxia produced an increase in: (1) the concentration of extracellular K\* (2) the concentration of intracellular Ca\*\*, (3) the difference in pre- compared to post-insult concentrations of <sup>14</sup>C and, (4) the amount of lactate. All of these effects were statistically significant (p <.05) and exhibited a dose response relationship with the exception of intracellular calcium which did not become significantly different until 30 minutes post-hypoxia. These results suggest that utilizing an in vitro model of hypoxia, ionic and metabolic derangement can be demonstrated which are similar to those seen following an in vivo traumatic brain injury. With the use of this model the mechanisms behind these ionic-metabolic relationships can be addressed at the molecular level. (NS27544, NS30308, Brain Trauma Foundation)

CEREBRAL HEMODYNAMIC CHANGES FOLLOWING PERCUSSIVE BRAIN INJURY IN ANESTHETIZED PIGLETS. M. Shibata\*, S. Einhausa, S. L. Zuckermanb, W. M. Armstead, and C. W. Leffler. Laboratory for Research in Neonatal Physiology, Departments of Physiology & Biophysics, and a Neurosurgery, University of Tennessee, Memphis and bDivision of Critical Care and Pulmonary Medicine, St. Jude Children's Research Hospital, Memphis, Tennessee. Effects of fluid percussion injury (PPI) to brain were studied using newborn pigs. Under a c-chloralose anesthesia, FPI was applied to the left occipital cortex in animals equipped with closed cranial windows over the

newborn pigs. Under  $\alpha$ -chloralose anesthesia, FPI was applied to the left occipital cortex in animals equipped with closed cranial windows over the right occipito-temporal cortex. The magnitude of FPI ranged from 2.07 and 2.56 atmospheres. Diameter changes of pial arterioles under the window were recorded using an intravital system for 3 h following FPI. Cerebral blood flow (CBF) was determined using radiolabelled microspheres, and periarachnoid cerebrospinal fluid (CSF) prostanoids were measured by radioimmunoassay. Immediately (within 1 min) following FPI, pial arteriolar diameter began to decrease reaching a minimum 23% below the baseline levels at 140 min post-FPI. The diameter remained unchanged thereafter. CBF in the cerebral cortex, thalamus, hypothalamus, midbrain, pons, medulla oblongata, and the cerebellum decreased 48% (mean) below the baseline values. Levels of CSF prostaglandin (PG) E2, 6-keto-PGF1 $_{10}$ , PGF2 $_{20}$ , and thromboxane B2 increased reaching their maximum within 60 min following FPI by, respectively, 218, 321, 452, and 361% above the baseline levels. Only thromboxane B2 fell to its pre-injury level by 3 h post-FPI. These results may suggest that the vasoconstriction and decreased CBF that follow FPI could induce asphyxic/sschemic brain damage, and that enhanced could induce asphyxic/ischemic brain damage, and that enhanced prostanoids could modulate FPI-induced CBF alteration. (Supported by NIH Grants)

THE CEREBRAL METABOLIC RATE OF OXYGEN AS AN INDEX OF EFFECTIVE HIGH-DOSE PENTOBARBITAL THERAPY IN PATIENTS WITH SEVERE HEAD INJURY. S.P.Godinath. C.S.Robertson, J.C.Goodman\*, R.G Grossman, Department of Neurosurgery and Pathology, Baylor College of Medicine, Houston, Tx. 77030.

High-dose pentobarbital is one of the treatment modalities to control the refractory intracranial hypertension in patients with severe head injury. To achieve the therapeutic end result, plasma barbiturate levels and EEG monitoring for burst suppression activity are usually considered. Experimental studies have shown that cerebral metabolic rate of oxygen(CMRO2) decreases progressively by increasing doses of barbiturates until the EEG was completely suppressed.

The intent of the present investigation was to know the effect of high-dose pentobarbital on CMRO2 in patients with severe head injury and to know whether CMRO2 could be used as an index in defining the therapeutic endpoint.

29 severely head-injured patients having refractory intracranial hypertension were studied. Pentobarbital was given in a dose of 10 mg/kg over 30 minutes, followed by 5 mg/kg/hr for 3 doses, followed by 1-2 mg/kg/hr. The parameters recorded include ICP, BP, CPP, CBF, cerebral A-V O2 difference, CMRO2, prior to and after the loading dose of pentobarbital, and while the plasma concentration of pentobarbital was higher.

The CMRO2 significantly decreased after the loading dose of pentobarbital by 34% and the change in CMRO2 was closely related to the pretreatment value (n=29, r=0.83,p<.001). CMRO2 levels ≥0.7μmol/gm/min were associated with decrease in CMRO2 of approximately 50% (n=18, r= 0.79, p=<0.001) while CMRO2 levels

< .7µmol/gm/min did not significantly change with pentobarbital (n=11,r=0.11)</p>

The present study demonstrates that only those patients with a CMRO2  $\geq 0.7\mu$ mol/gm/min had a reduction in CMRO2 with barbiturates, and that no additional reduction in CMRO2 was achieved at the higher plasma levels of pentobarbital. The CMRO2 could thus be employed as a therapeutic end-point in patients requiring highdose pentobarbital therapy

THE ABILITY OF BRAINSTEM ELECTRICAL STIMULATION TO DESYNCHRONIZE THE EEG IS TRANSITORILY INTERRUPTED FOLLOWING FLUID PERCUSSIVE INJURY. M.R. Purk\*J.B. Schweitzer, S.L. Einhaus: J.T. Robertson. Depts. Pathology, Anatomy & Neurobiology, and Neurosurgery, Univ Tenn., Memphis, College of Medicine, Memphis, TN 38163.

Ascending cholinergic fibers play a principle role in controlling thalamic function and, therefore, behavioral state. Loss of consciousness, often for prolonged periods, is a hallmark of blunt head trauma. It is known that immediately following head injury, a pulse of acetylcholine (ACh) can be detected in the the cerebral spinal fluid, suggesting that cholinergic systems might be profoundly affected. One well-known test of the integrity of ascending brainstem cholinergic systems is to monitor the effectiveness of brainstem electrical stimulation in causing EEG desynchronization. In the present experiments, we followed the changes of the desynchronizing effect, in cats, during the period following administration of a fluid percussive injury. The animals were maintained on propfol anesthesia. Preparatory surgery included the stereotaxic placement of concentric or paired-wire stimulating electrodes in the tegmentum at sites that are effective in causing EEG desynchronization. A single pressure pulse, in the range of 2.6-2.9 atmospheres, was then administered. Immediately following the injury, the EEG is characterized by a slow-wave (3-4 Hz), large-amplitude pattern. Within 6-10 minutes alpha rhythms (ca. 10 Hz) come to predominate. During this time and during the slow-wave phase, brainstem stimulation is no longer able to desynchronize the EEG. However, this is an acute effect. Recovery of the responsiveness to brainstem stimulation returns 20–60 minutes post-injury, preceding behavioral recovery by several hours. It is unlikely that this is a specific effect on ACh pathways. The animals are apnete following the injury, suggesting disruption of brainstem respiratory centers. Motor artifacts from the brainstem stimulation remain, but these can be attributed to direct stimulation of the oculomotor nerve.

EFFECTS OF NIMODIPINE ON TWO NEUROLOGIC MEASURES SENSITIVE TO SENSORIMOTOR CORTEX DAMAGE. C. Nelson, S. Finger\*. and Daniel Simons, University of Wyoming, Psych. Dept., University Station Box 3415, Laramie, WY 82070, Washington Univ., Psych. Dept., St. Louis, MO 63130, and Univ. Pitts. Med. School, Physiol. Dept., Pittsburgh, PA 15261.

Rats were given sensormotor cortex lesions centered in the features beat many context and the features beat dependent of the f

Rats were given sensorimotor cortex lesions centered in the forepaw regions, or sham operations, and were tested on their ability to run along a narrow bridge without slipping, and to hang on to a small diameter dowel suspended above the ground. 24 hours after surgery, half of the animals received daily oral treatments of the calcium channel blocker, nimodipine, for 2 weeks while the remaining rats received vehicle alone. Repeated measurements over the first three postoperative weeks showed that rats that received lesions performed worse on the bridge and dowel than animals given control operations. Among the animals with lesions, rats that received nimodipine performed significantly better than those that received vehicle alone. Examination of the barrel fields did not reveal differences in the lesions between the groups. These results extend previous findings from this laboratory, which have shown that the effects of acute brain injuries may be reduced by rapid nimodipine treatment.

NALMEFENE TREATMENT AFTER SENSORIMOTOR CORTEX CONTUSION IN THE RAT. E.C. Benzel\*, M.P. Weisend, R.L. Sutton and D.M. Feeney. Division of Neurosurgery and Department of Psychology, University of New Mexico, Albuquerque, NM 87131.

Ninety-six male Sprague Dawley rats were anesthetized with halothane and received contusion injury [Br. Res. (1981) 211:67] to the right sensorimotor cortex (N=60) or sham injury (N=36). Animals were given a single intraperitoneal injection of either saline or one of five doses of the long-lasting opiate receptor antagonist nalmefene (NAL; 0.05, 0.1, 0.5, 1.0, or 3.0 mg/kg) 45 min postsurgery. Neurobehavioral performance on beam-walking, inclined plane and a wire grip test was evaluated for 28 days postdrug. No dose of NAL treatment improved neurologic outcome. Higher doses of NAL increased contralateral forepaw wire grip time (pathological grasp). Injury-induced weight loss increased with increasing NAL dosage. Loss of hippocampal CA3 pyramidal cells ipsilateral to cortical contusion was attenuated by the 3.0 mg/kg dose of NAL.

EFFECT OF LAZAROID (21-AMINOSTEROID U-74389F) PRETREATMENT IN COMPRESSION TRAUMA TO THE RAT SPINAL CORD. SS Haghighi\*. XZ Geng, LE Spollen, JJ Oro. Div of Neurosurgery & Dept of Pathology, University of Missouri-Columbia.

Pathology, University of Missouri-Columbia.

Data on the early time course of steroid action on injured spinal cord is limited. In our study, the effect of U74389F (21-aminosteroid) treatment in rats with acute spinal cord trauma was studied. Cortical somatosensory evoked potentials (CSEPs), mean arterial blood pressure, and heart rate were recorded before and after a weight-induced compression injury of 200 grams up to 5 hrs after injury. Treatment with U74389F was a single intravenous injection (15mg/kg) 1 hr prior to injury, followed by a continuous infusion at the rate of 3mg/kg for 5 hrs after injury. The CSEPs were abolished after the injury in all animals. The majority of treated animals (86%) demonstrated a return of the CSEPs within the 2nd hr post-injury. Control group showed 14% CSEP recovery at this time period. Recovery rate remained the same for the 2 groups at the 3rd, 4th, and 5th hrs post-injury. Histologically, parenchymal disruption, hemorrhage, and edema were present in all specimens, nevertheless, these changes varied in severity from animal to animal. A histological difference was seen between the treated and non-treated groups in 2

We conclude that administrations of 21-aminosteroids ensuing 1 hr prior to spinal cord injury facilitated recovery of the spinal cord function as measured by the CSEPs in the compression model of acute spinal cord trauma.

EFFECTS OF METHYLPREDNISOLONE & YM-14673 AFTER SPINAL CORD INJURY IN RATS. <u>D.L. Behrmann,\* J.C. Bresnahan, M.S. Beattie.</u> Neuroscience Prog., Div. of Neurosurgery, Ohio State U., Columbus, OH 43210.

A model of acute spinal cord injury (ASCI) in rats that uses preset

A model of acute spinal cord injury (ASCI) in rats that uses preset differences in spinal cord displacement to produce a rapid (~20 msec) contusion injury (spinal T9) was used to evaluate behavioral and histologic effects of Methylprednisolone (MP) and the TRH analogue, YM-14673.

Methods: Compounds were administered IV at 5 min, 2, 4, and 6 hrs after the injury. Functional recovery was evaluated for 29 days using open field walking (OFW), inclined plane (IP), and grid walking (GW - Ex. 2 only); percent tissue spared was determined at the lesion epicenter.

percent tissue spared was determined at the lesion epicenter. Exp. 1: MP administered at 30 mg/kg (n=16) and 60 mg/kg (n=16) resulted in better OFW-scores compared with controls (n=16) over days 8-29 (p<.01) and at day 29 (p<.05); both performed better on IP over days 8-29 (p<.01); the MP-30 mg/kg animals scored higher at day 29 (p<.05). Histology showed greater sparing of white matter (p<.05) for MP-60 mg/kg animals (23.4%) compared to controls (17.3%).

Exp. 2: A better IP score was observed for the MP group (60 mg/kg, 30 mg/kg x 3; n = 15) over days 8-29 (p<.05). No improvement in OFW or GW scores of MP animals was observed at this relatively milder injury level as compared with Ex. 1. YM-14673 animals (1 mg/kg x 4 & 1 mg/kg/day; n = 15) scored better than both MP and control animals (n = 15) in OFW over days 8-29 (p<.01); these animals also performed better than controls on IP (days 8-29, p<.01; day 29, p<.05) and GW (day 29, p<.05). MP and YM-14673 produced no additive effect. Histologic analysis is pending. Both MP and YM-14673 produced positive behavioral results. This study

Both MP and YM-14673 produced positive behavioral results. This study demonstrates the utility of this model for preclinical assessment of pharmacologic agents and indicates that YM-14673 in addition to MP may be beneficial after clinical ASCI. Supported by NS-10165 and training grant NS-07291.

METHYLPREDNISOLONE PREVENTS THE EXCESSIVE SPINAL CORD DESTRUCTION AFTER MECHANIC-ENZYMATIC MANIPULATION OF SUBACUTE SPINAL CORD CONTUSED AREAS IN RATS. I. Grijalva, G. Guizar-Sahaqun, I. Madrazo, R.E. Franco-Bourland\*, H. Salqado-Ceballos, A. Ibarra, and A.L. Espitia. CAMINA Research Center, IMSS, UNAM, INNSZ. Mexico, D.F., Mexico.

Methylprednisolone (MP) is an effective neuroprotector given early after spinal cord (SC) injury. Here we assessed the effect of MP on previously injured SC areas, after mechanicenzymatic manipulation (M-EM) as a preliminary step for transplantation. Adult rats were sub-

step for transplantation. Adult rats were subjected to severe SC contusion. Nine days after SC injury all rats were subjected to mielotomy at injury all rats were subjected to mielotomy at the injured site. The necrotic and scarring tissues were removed by light aspiration, and by the use of a mixture of collagenase (0.25%) and hialuronidase (0.1%) for 20 min. After a 30 sec treatment with 0.1 M EDTA the area was irrigated with a saline solution. MP (30 mg/kg) was administered first IP and then IM to ten rats immediately before this procedure and 2, 4, 8 and 24 hours after. Ten lesioned rats subjected to M.FM hours after. Ten lesioned rats subjected to M-EM, hours after. Ten lesioned rats subjected to M-EM, that did not receive MP, were the controls. All rats were prepared for SC histology 9 days after M-EM. The SC parenchyma destruction observed in MP-treated rats was significantly smaller than that observed in the control group.

DOSE-RESPONSE STUDY OF METHYLPREDNISOLONE IN ACUTE SPINAL CORD INJURY IN THE RAT. I. Koyanagi, C.H. Tator\*. Div. of Neurosurgery and Playfair Neuroscience Unit, The Toronto Hospital and Univ. of Toronto, Toronto, M5T 2S8, CANADA.

High dose (30mg/kg) methylprednisolone (MP) has recently been found to have therapeutic effects in acute spinal cord injury (SCI) in a cat model and also in humans. However, the effect of this drug has not been determined in a rat model of SCI. The purpose of the present study was to assess the effect of MP on posttraumatic spinal cord blood flow (SCBF) and spinal cord electrophysiology in a rat model of SCI. Twenty-five Wistar male rats were subjected to a 51g clip compression injury at C8-T1, and were randomly divided into five treatment groups which received one of the following intravenous bolus injections 30 minutes after injury: vehicle, or 30, 60, 120, or 240mg/kg of MP. SCBF at the injury site and the adjacent level (C7) was measured by the hydrogen clearance technique. Evoked potentials were recorded over the somatosensory cortex (SSEP) and cerebellar surface (CSEP) following sciatic nerve stimulation. Descending volleys were recorded from the T9-10 spinal cord following posterior fossa stimulation (PFEP). SCBF measurement and evoked responses were performed before and 1, 2 and 3 hours after injury. The SCBF at both levels decreased after injury in the control group (pre-SCI mean SCBF:  $56.8\pm2.6$  at C8/T1 and  $54.5\pm4.7$  at C7; post-SCI 1 hour mean SCBF:  $27.3\pm2.7$  at C8/T1 and  $38.0\pm4.1$  at C7; scale: ml/100g/min), and there was no recovery at 3 hours. No significant increase in SCBF was observed in any of the MP groups. SSEP, CSEP and PFEP were abolished following SCI in all rats, and did not recover in the control or treatment groups. This study demonstrated that a single bolus dose of MP up to 240mg/kg had no beneficial effect on posttraumatic SCBF and electrophysiological activity in this model.

# 79.9

GM1 IMPROVES INJURY-INDUCED METABOLIC DEFICIT IN RAT OPTIC NERVE. E. Yoles, V. Lavie\* and M. Schwartz. Department of Neurobiology, The Weizmann Institute of Science, 76100 Rehovot, Israel.

The present study demonstrates the earliest reported effects of GM1 treatment of crush-injured mammalian axons. In order to assess the ability of GM1 to attenuate the immediate injury-induced response, we employed a noninvasive optical technique in which changes in NADH redox state during a 2-min episode of anoxia are used to monitor real-time metabolic responses resulting from optic nerve injury and subsequent GM1 treatment. Injury of the adult rat optic nerve was followed by a decrease in nerve metabolic activity adjacent to the injured site, as indicated by a reduction in the NADH response to anoxia. The metabolic activity was examined hourly from 1 to 4 h postinjury in two groups of GM1-treated injured nerves (where GM1 was administered intraperitoneally immediately after injury, n=6, or 30 min prior to injury, n=5) and in one group of control animals (where saline was administered intraperitoneally immediately after injury, n=11). ANOVA analysis revealed a significant beneficial effect of GM1 treatment (F=10.13, P=0.001) on the metabolic response after injury, but no statistical difference was found between the two GM1-treated groups. A positive interaction was found between the treatment effect and the time period after injury (F=6.74, P=0.0001). In the GM1-treated groups, the metabolic response increased with time from 65.6t5.3% and 56.5t9.8% of the preinjury response 1 h after injury to T2.7±3.6% and 88.7±11.6% 4 h after injury in the groups injected prior to and immediately after injury, respectively. In the saline-treated control group there was no significant change in the metabolic response with time (41.9±5.1% of the preinjury response 1 h after injury vs. 37.8±3.9% 4 h after injury). The results of this study show that intraperitoneal administration of GM1 30 min before or immediately after axonal injury reduces the metabolic deficit resulting from the injury.

# METHYLPREDNISOLONE ALTERS INTRACELLULAR ELEMENTAL SHIFTS 6HR AFTER SPINAL CORD TRAUMA.

ELEMENTAL SHIFTS 6HR AFTER SPINAL CORD TRAUMA.

L.G. Walsh\* and W.B. Greene. Neuropath Research, Dept. of Pathology, Medical Univ. of S. Carolina, Charleston, SC 29425-2245.

Electron probe x-ray microanalysis was used to measure the subcellular composition of dorsal axons 6 hr after 20 g·cm spinal cord impact trauma followed by high dose methylprednisolone (MP) in rats. In shams, relative to untreated, the agranular reticulum (AR) had \ total Na, Mg, Cl, K and most vesicles no longer contained elevated Ca. Similarly, mitochondria (mito) had \ Mg and were less dense and myelin had \ Na, Mg and Fe and \ K and Cl.

Two distinct groups of axons were found after trauma with or without MP. One group was entropic and had lost all normal elemental gradients in axoplasm (axo), AR, mito and myelin. As in untreated trauma, the intact group of axons could be further divided by their appearance. With MP, the less dense axons had \ axo P and density relative to both shams and less dense untreated axons. The AR had \ P relative to MP shams and \ Na, Mg, P, Cl, K and Ca relative to untreated. With MP both mito Na and density were < than shams. In untreated both were > than shams. The MP myelin was not different among shams, less or more dense axons but had \ density, P and Mg relative to untreated. With MP, the more dense axons were more similar to shams.

Our study indicates that in shams, MP inhibited Ca

untreated. With MP, the <u>more dense axons</u> were more similar to shams.

Our study indicates that in shams, MP inhibited Ca sequestration by the AR and stimulated Ma/K pumping within myelin. In traumatized axons, improved mitochondrial homeostasis and uniform alterations in myelin were

GM1 TREATMENT PROTECTS MOUSE SPINAL CORD NEURONS EXPOSED TO GLUTAMATE: LDH RELEASE REDUCED and GM1 MEMBRANE SURFACE DISTRIBUTION MAINTAINED.

C. Vorwerk, H. Laev, J. Bonheur and S.E. Karpiak\* Div. Neuroscience NYS-PI, & Dept. of Psychiatry, Columbia U. (Physicians and Surgeons), NY, NY.

As an in vitro model for spinal cord damage, spinal neurons cultured from Swiss Webster mice were challenged with glutamate (10mM), and the levels of released LDH [lactate dehydrogenase] were monitored at 24 and Albrs. Analysis of neuronal plasma membrane disorganization (damage) was determined by the distribution of endogenous GM1 ganglioside using cholera toxin anti-toxin immunohistochemistry. The effects of GM1 ganglioside on LDH release due to membrane damage were studied to further elucidate the mechanisms underlying this lipid's neuroprotective effects. Such GM1 effects are of particular interest due to the clinical reports which indicate the efficacy of GM1 treatment for spinal injury. Spinal cell cultures derived from ±13 day mouse fetuses were subjected to 10mM glutamate for 30min. Parallel cultures were treated with 40 or 80uM of GM1 ganglioside. Both glutamate damage and GM1's neuroprotective effects were assessed at 24 and 48hrs. Released LDH was expressed as the percent of the total LDH for each cultured plate. Without GM1 treatment 18-20% of the total LDH was released, indicating that <20% of the cultured spinal cells posses glutamate receptors. GM1 treatment significantly reduced the LDH release. The membrane structure changes observed by the GM1 immunohistochemistry paralleled the LDH release data. GM1 treated cultures showed significant structural integrity as evidenced by continuous staining of GM1 along the perykariya and processes. These data further support our hypothesis that GM1 treatment reduces plasma membrane damage.

STRUCTURAL CHANGES OF ASTROCYTIC PROCESSES IN RESPONSE TO GRAFTED FETAL BRAIN CELLS. N. Hawrylak\*, T. Schwarz and W.T. Greenough Beckman Inst., Neurosci. Prog., Dept. of Psych. and Cell & Struct. Biol., Univ. of Illinois, Urbana 61801.

Previous studies in our laboratory using the stab wound model of gliosis demonstrated a remodeling of astrocytic processes with reference to the damage site which first appeared at four days after injury (Isaacs K.R., et al., Soc. Neurosci. Abs. 1991 17:168). The present study examined the orientation of astrocytic processes in reference to a host-graft interface zone following grafting of fetal

brain cell suspensions into the adult cerebral cortex.

Immunohistochemical (GFAP) and computerized drawing techniques were employed to examine the orientation of astrocytic processes. Graft sites in 25 adult host rats were examined. Astrocytic somata with well stained processes were identified and digitized in three dimensions with a computerized tracking system. Twenty astrocytes from the grafted hemisphere and five astrocytes in the opposite (control) hemisphere were drawn. Processes and process terminals on cells located 150-300 µm distant from the interface zone were analyzed at 1,2,4,10, and 20 days post grafting and compared to control cells (n=5 for all post grafting intervals

Processes and terminals showed no statistically significant changes at 1, 2, 4 and 10 days post grafting. An increase in processes (14%, p<0.001) and terminals (12%, p<0.01) oriented toward the interface zone was significant at 20 days post

These results, taken together with the previous report, suggest that astrocytic process remodeling with a specific orientation is a significant component of glial scarring and that grafting of fetal brain tissue may in some way arrest or delay this aspect of astrocytic scar formation. TWO STEP ACTIVATION OF THE RESIDENT AND INVADING MICROGLIAL CELLS FOLLOWING BRAIN CONTUSION. Z. Fülöp\*, R. Duvdevani, S.W. Hoffman, and D.G. Stein. Institute of Animal Behavior, Rutgers University, Newark, NJ 07102.

Stein. Institute of Animal Behavior, Rutgers University, Newark, NJ 07102.

In contused brain large volumes of chemical by-products of tissue breakdown diffuse into undamaged areas causing secondary degeneration. Gliosis may be an important marker to evaluate the efficacy of possible treatment. Therefore, we studied the interaction between neuronal death, microglia, and astroglia in adult male rat brains perfused at 2, 6, 24h, 3, 7, 18d after frontal cortex contusion. During the first 3 days after injury, dead and dying cells, swelling neuropil, broken capillaries and scattered small hematomas characterized the impact area, but no stained microglial and/or astroglial cells were present. However, among some well defined neuronal groups in the neighboring cortical areas and axon bundles in the corpus callosum, cingulum, and striatum, showing mild degeneration, activated microglial cells were seen already at 2h (1st Activation). Beginning from the 3rd day a large number of macrophages appeared primarily in and around the lesion area. From this time on, both the number and size of microglial cells increased dramatically and they have dispersed to remote areas (2nd Activation), which was followed by reactivation of astrocytes. By day eighteen the impact area was transformed into a cavity around which an astroglial scar, intermingled with microglial cells and macrophages, had formed. We believe that the early activated microglial cells were intrinsic, while those which appeared after the third day may have been transformed from the invading macrophages and capillary pericytes. These data point on the importance of third posttraumatic day as a starting time of the inflammatory response in the contused brain.

ALTERED ACIDIC AND BASIC FIBROBLAST GROWTH FACTOR EXPRESSION FOLLOWING SPINAL CORD INJURY, M. Koshinaga\*, H.R. Sanon & S.R. Whittemore, The Miami Project and Department of Neurological Surgery, Univ. Miami School of Medicine, Miami, FL 33136

In normal spinal cord, aFGF immunoreactivity was localized in the cytoplasm of ventral motor neurons and sensory fibers in the dorsal columns. Basic FGF immunoreactivity was restricted to astrocyte nuclei and the cytoplasm of a few neurons in the intermediate gray matter. Spinal cord lesions resulted in complete destruction of the dorsal columns and corticospinal tract at T8. Two days postlesion (DPL), aFGF immunoreactivity was increased in ventral motor neurons and was now seen in intermediate gray matter neurons. Acidic FGF was not detected in the lesioned f. gracilis at T4-5, but markedly increased in the f. cuneatus. At L1-2, aFGF-positive fibers in the f. gracilis dramatically increased. This aFGF immunostaining was maintained 5 and 12DPL. The lesion-induced loss of aFGF immunoreactivity in the n. gracilis suggests that aFGF is anterogradely immunoreactivity in the in gracins suggests that arGr is anterogradely transported in sensory afferent fibers. Two DPL, GFAP immunoreactivity increased at the lesion site, as well as T4-5 and L1-2, with no change in bFGF staining. Five DPL, increased bFGF-immunoreactivity appeared at the edge of the cystic cavity and the dorsal columns at T4-5 in both the nucleus and cytoplasm of reactive astrocytes, and was increased at 12DPL. Western blots detected an 18 kDa bFGF-like protein in normal spinal cord, which increased at the lesion site. Full length and aminotruncated aFGFs (18.6, 17.1, 14.9 kDa) were detected, with unchanged levels following injury. We suggest that the differential temporal and spatial expression of aFGF and bFGF following spinal cord lesion are mediated by cytokine(s) released from activated microglia (Whittemore & Koshinaga, adjacent poster). Supported by The Miami Project, The Daniel Heumann Fund for Spinal Cord Research, and NS26887.

ASTROCYTIC RESPONSE FOLLOWING CORTICAL CONTUSION IN THE RAT. S. Baldwit, T. Carbary, and S.W. Scheff. Dept. Anatomy & Neurobiology, and Center on Aging, Univ. Kentucky, Lexington, KY 40536-0230.

Astrocytes play a key role in normal brain function by regulating amino acid uptake, the concentration of various ions and the blood brain barrier. These cells also respond to injury in the CNS. The injury response of the CNS is complex and wide spread. Presently, little is known about the degree of astrocytic reactivity in damaged cortex. An electronic controlled pneumatic impact (ECPI) animal model for cortical injury has been developed which manifests many of the neuropathologies seen in human closed head injury. To further characterize the pathology of nervous system injury we examined possible changes in cortical astrocytes.

Fisher 344 rats were subjected to a cortical contusion on the parietal region using the ECPI. Coronal brain sections were stained with GFAP antibody 1,2,4 and 10 days after the cortical damage. Cortical areas within the damaged cortex and ventral to the injury site both ipsilateral and contralateral to the contusion were examined for possible hyperplagia and hypertrophy of astrocytes. Image analysis revealed a time dependent increase in GFAP positive cells not only within the damaged cortex but in areas quite remote from the impact site. These results suggest that cortical regions remote from the initial injury site may be prone to secondary injury.

MICROGLIAL ACTIVATION OCCURS ONLY IN SPINAL CORD TRACTS UNDERGOING WALLERIAN DEGENERATION. S.R. Whittemore & M. Koshinaga, The Miami Project and Dept. Neurological Surgery, Univ. Miami School of Medicine, Miami, FL 33136

The role of microglia in the response to CNS injury is poorly understood. We

characterized the response of adult spinal cord microglia to a lesion which eliminated the dorsal columns and corticospinal tract at T8. In control spinal cord, significant numbers of OX42-positive, ramified microglia are found throughout the white and grey matter. Two days after lesion (DPL), the microglia in the severed T4-5 f. gracilis were ameboid and expressed intense OX42 and slightly increased class I major histocompatibility (MHC) antigen immunoreactivities. No activated microglia were seen in the intact f. cuneatus or the retrogradely degenerating corticospinal tract. In the f. gracilis 5DPL, OX42 immunoreactivity was slightly decreased and class I MHC expression was markedly enhanced. By 12DPL, OX42 and class I MHC immunoreactivities were near control levels. At L1-2, activated microglia and increased class I MHC expression was restricted to the corticospinal tract and was maximal 5DPL, returning to near control levels by 12DPL. In the medulla, microglia activation and enhanced class I MHC expres sion was seen in the n. gracilis, but not the n. cuneatus, at 2DPL. At 5DPL, OX42 immunoreactivity was markedly decreased, but class I MHC expression was still enhanced. Thus in both a descending motor and ascending sensory tract, microglial activation was seen only in those areas undergoing Wallerian, and not retrograde, degeneration. Microglial activation is a very early lesion-induced event in the CNS, and we suggest that cytokine(s) released from activated microglia may play a role in initiating part of the neuroprotective response to CNS injury (see Koshinaga et al, adjacent poster). Supported by The Miami Project, The Daniel Heumann Fund for Spinal Cord Research, and NS26887.

BLOOD-BRAIN BARRIER PERMEABILITY AND EDEMA FORMATION IN EARLY AND LATE PHASES OF FRONTAL CORTICAL CONTUSION. R. Duvdevani\*, R.L. Roof, Fulop, S.W. Hoffman, and D.G. Stein Brain Research Laboratory, Institute of Animal Behavior, Rutgers University, Newark, NJ 07102.

Blood-brain barrier (BBB) integrity may play an important role in both the injury and recovery processes following cerebral trauma. BBB integrity and edema formation in vivo were evaluated in sham rats and following bilateral frontal medial frontal contusion in adult male rats . Rats were sacrificed 2 hr, 24 hr, 3 days, 7 days and 18 days after injury. BBB integrity was assessed in these rats by measuring the area stained by Evans blue (EB) reaction 30 min after intravenous EB injection. Edema was assessed in fresh brains immediately following decapitation using the wet weight-dry weight tissue punch technique. EB was present in the injured area as early as 2 hrs, peaked at 3 days, and disappeared by 18 days. Edema was also observed in the injured area as early as 2 hrs, peaked at 24 hrs-3 days and disappeared by 7 days. Our findings suggest that medial frontal contusion is accompanied by changes in BBB permeability and brain water content and that these changes endure at least 7 days post-injury. We conclude that the duration of BBB permeability can either serve as a "window of opportunity" for allowing entry of therapeutic substances into the CNS, or impair recovery by introducing inflammatory agents into the CNS.

GENDER INFLUENCES OUTCOME OF BRAIN INJURY: GENDER INFLUENCES OUTCOME OF BROWN ....
PROGESTERONE PLAYS A PROTECTIVE ROLE. R.L.

Stein Brain Research Lab, Roof\* PROGESTERONE PLATS A PROTECTIVE ROLL. AND ALL R. Duvdevani, & D.G. Stein. Brain Research Lab, Inst. of Animal Behavior, Rutgers Univ., Newark, NJ 07102. Edema is a common and serious complication following brain injury.

producing intracranial pressure, axonal swelling, demyelination, and can be a producing intractantal pressure, axonal swelling, derivelination, and can be a major cause of secondary brain damage. In this experiment, male, normally cycling female (NC), and pseudopregnant (PP) female rats were examined for brain edema 24 hrs after a medial frontal cortical contusion injury. Tissue from the area immediately adjacent to the injury site as well as a distal site was examined using the wet weight/dry weight tissue punch technique. The edemic response differed depending on sex and hormonal condition. Tissue from the injured area in males showed a 6.4% increase in water content compared to tissue from the distal area. Tissue from the injured site in NC females, given tissue from the distal area. Tissue from the flujerd site in NC females, given contusion injuries on the day of proestrus, showed a 3.5% increases in water content. PP females showed almost no edema (0.3%). To determine whether the reduced edemic response observed in the PP females was due to the high levels of progesterone (P) present during PP, 12 additional female were ovariectomized to eliminate endogenous estrogen (E) and P. Of these, four were given E implants, four given the E implants as well as injections of 4 mg P were given E implants, four given the E implants as well as injections of 4 mg P for 6 days, beginning 2 days after ovx. 4 additional ovx rats received oil injections. These rats were then given cortical contusion injuries. Tissue punches taken 24 hrs after injury in the ovx, and ovx+E groups showed 4% and 5% increases in water content. Tissue punches from the rats in the ovx+E+P group showed a much lowered (p<0.01) edemic response (1.7%). The high levels of P present in the PP and ovx+E+P groups nearly eliminated the post injury edema. The lower levels of P present in NC females significantly reduced post injury edema compared to males. We conclude that P plays a protective role in the brain following traumatic injury.

EFFECT OF SPINAL CORD INJURY ON CSF/TRACER INFLUX.

BOLS

EFFECT OF SPINAL CORD INJURY ON CSF/TRACER INFLUX.

RH Tirgari, CP Barrett\*, ML Rennels, N Haynes, and RP Rees. Dept. of Anatomy, Univ. Md.Sch. of Medicine, Baltimore, MD 21201

Tracer substances injected intrathecally distribute throughout the entire spinal cord via perivascular spaces and pericapillary basal laminae. In regions of spinal cord injury, however, this trace influx does not occur, and is diminished in adjacent segments that appear normal. We compared injured and adjacent intact cord segments in rats injected intrathecally with HRP (10 m prior to sacrifice) at post injury times ranging from 1 h to 7 d. Fluid/solid influx into the spinal cord was assessed by immunostaining with anti-HRP (shown by the PAP method). Performed also were antibody staining to endothelial barrier antigen and routine histological evaluation. At 1-12 h, anti-EBA staining showed a disrupted vascular pattern in the lesion epicenter, but a normal pattern in the segments rostral and caudal to the lesion. However, unlike control spinal cords or segments very distant from the lesion epicenters, HRP influx into the segments near lesions was minimal at one hour and was further reduced in the adjacent 4-5 segments over the 4-12 h period after injury. At 7 d, some recovery of HRP influx was seen 4 segments from the epicenter, but not in the 1st to 3rd segments which showed histopathological degeneration. Thus, HRP uptake in revealing a change in CSF flow may have signaled subtle changes caused by spinal cord injury that led to secondary damage.

BRAIN TEMPERATURE BEFORE AND AFTER TRAUMATIC BRAIN INJURY IS RELATED TO OUTCOME. M.P. Weisend\* and D.M. Feeney. Depts. of Psych. and Physiol., Univ. of New Mexico, Alb., NM 87131.

We examined the effect of traumatic brain injury (TBI) on brain and

body temperature (TMP) and the relationship between TBI induced TMP

changes, neuronal pathology, and behavioral recovery.

Male, Sprague Dawley rats (300-360g) were anesthetized with halothane followed by: scalp incision only (n=8); scalp incision and craniectomy (n=8); or scalp incision, craniectomy and focal cortical impact to the right sensorimo-tor cortex (n=10). Body core TMP was measured from the rectum and brain TMP inferred from the temporalis muscle during, and for 6 hours after surgery. Beam-walking agility and "pathological grasp" were measured for 28

days after surgery. Rats were then sacrificed for thionin histology.

Surgery alone lowered brain, but not body TMP. TBI induced an additional transient (2-6 min.) drop in brain TMP, with no comparable effect on body TMP. However, during the first hour after TBI both brain and body TMP were elevated compared to controls. Additionally, TBI induced an abnormal pattern of identical brain and body TMP throughout the 6 hour measurement period whereas controls showed the normal pattern of higher brain than body TMP. Mean brain TMP before TBI was positively correlated with the severity of hippocampal and thalamic pathology. In contrast, absolute brain TMP after TBI was not correlated with hippocampal and thalamic pathology. The mean difference between pre- and post-TBI brain TMP was

negatively correlated with hippocampal and thalamic pathology.

These data indicate that low brain TMP prior to TBI reduces secondary pathology while prolonged depression of brain TMP after TBI indicates a more severe injury

Supported by U.S. Army Grant DAMD17-91-Z-1006.

HYPOTHERMIA ATTENUATES LOSS OF MICROTUBULE-ASSOCIATED PROTEIN 2 (MAP2) FOLLOWING TRAUMATIC BRAIN INJURY (TBI). R.L. Hayes\*, W.C. Taft, C.E. Dixon, K. Yang, G.L. Clifton. Dept. of Neurosurgery, Univ. Texas Health Science Center at Houston, Houston TX 77030.

Moderate hypothermia improves neurobehavioral outcome of rodents subjected to moderate fluid percussion injury (J.C.B.F. Metab. 11, 114, To investigate the effect of hypothermia on the molecular events which occur following TBI, we have quantitated protein levels of MAP2. Parallel groups of sham and injured rats were maintained at normothermic (37°) or hypothermic (30°C) temperatures, as measured within temporalis muscle. Hypothermia was initiated prior to injury and continued for 60 min. Animals were sacrificed 3 hours post-injury by in situ freezing with liquid nitrogen. Hippocampi were dissected and homogenized at 4°C. Hippocampal proteins were balanced for protein content, separated by SDS-PAGE and transferred to nitrocellulose for quantitative immunoreactivity (IR) measurements. Normothermic injury produced a 44.3 + 9.2% decrease in hippocampal MAP2 levels (p < 0.005, compared to sham controls). In animals maintained hypothermic, no change in MAP2 was detected after injury (injured value 103.3  $\pm$  9.9% of sham controls; p > 0.1). A similar pattern was observed in both membrane and cytosolic protein fractions. The data suggest that moderate hypothermia is effective at reversing indices of proteolysis, as well as some persistent neurological deficits, that occur following TBI. Thus hypothermia may represent a useful therapeutic approach to treatment of head injured patients. Supported by NIH NS 21458.

CHRONIC ALTERATION AND CATASTROPHIC FAILURE OF NETWORK ACTIVITY AFTER HYPOTHERMIA. G.W. Gross\* and J.H. Lucas. Dept. of Biological Sciences, Univ. of North Texas, Denton, TX 76203 and Dept. of Physiology, Ohio State Univ., Columbus, OH 43210.

Hypothermia has been used to treat a variety of CNS nathologies but

Hypothermia has been used to treat a variety of CNS pathologies but has recently been reported to cause neuronal cell death if cells are maintained at 10°C for over one hour (Lucas et al., Brain Res. 517, 1990). We have used multielectrode recordings to further elucidate this

phenomenon.

Monolayer networks derived from dissociated embryonic mouse spinal tissue and grown on multielectrode surfaces self-organize to generate complex spontaneous spike activity. Such networks display stable histiotypic responses to pharmacological manipulations (Gross and Kowalski, In Neural Networks, Concepts, Applications, and Implementations, Vol. IV, Prentice Hall, 1991) and remain electrophysiologically responsive after six months in culture. However, after 1h at temperatures below 17°C, irreversible changes in network activity, including channel loss, can be demonstrated after return to normothermic conditions (with temperature ramp times of 10-15 min). After 2h at 10°C, cell show extensive swelling and no 10-15 min). After 2h at 10°C, cell show extensive swelling and no spontaneous activity can be recovered at 37°C. This hypothermic injury is prevented by N-methyl-D-aspartate (NMDA) antagonists, indicating that irreversible network failure may be the result of NMDA complex-mediated Ca++ damage. Supported by grant NS29683-01 and the Hillcrest Foundation of Dallas, TX.

ULTRASTRUCTURAL EFFECTS OF HYPOTHERMIC INJURY ON CULTURED MOUSE SPINAL NEURONS. D.G.Emery,\* J.H.Lucas and G.W.Gross, Zoology and Genetics, Iowa State Univ., Ames, IA

and G.W.Gross, Zoology and Genetics, Iowa State Univ., Ames, IA 50011; Physiology, Ohio State Univ., Columbus OH, 43210; and CNNS, Univ. of N. Texas, Denton, TX 76203.

Cultured mouse spinal neurons swell progressively when cooled below 17° (J. Neurotrauma 7:1990). At 10° all of SC neurons swell, and 74% die when the cultures are rewarmed to 37°C. N-methyl-D-aspartate (NMDA) antagonists reduce the death rate to 10%. We have examined the ultrastructure of neurons cooled to 17° or below with transmission EM.

Neurons fixed after cooling to 17° for 2h (+/- rewarming) appeared nearly normal. Some after 2 h at 10° had slight dilation of the Golgi cisternae and electron lucent foci in the mitochondrial matrices. A few

cisternae and electron lucent foci in the mitochondrial matrices. A few neurons were dead, and only their nuclei remained intact. Neruons cooled to 10° and returned to 37° for 4h developed 3 patterns of ultrastructural change. Some were obviously dead and degenerated. Some developed electron dense cytoplasm, a condition associated with mortal injury and indicating a loss of cell volume, possibly caused by K+ efflux. However, although slightly dilated, was not vesiculated, and there was no mitochondrial swelling.

The NMDA antagonist D-2-amino-5-phosphonovalerate (D-APV, 100μM) prevented most ultrastructural effects of cooling and rewarming. Some cells had increased numbers of lysosomal bodies, indicating organelle damage, but no damaged organelles were seen. The ultrastructure of neurons subjected to cooling will be compared to that of neurons exposed to toxic concentrations of NMDA and to the calcium ionophore A23187. Supported by NIH grant NS29683-01.

R. DESCARTES AND THE ORIGINS OF MODERN CHRONOBIOLOGY. <u>E. Barrera-Calva\*</u>, <u>B. Barrera-Mera</u>. Esc. Nal. Preparatoria No. 2. ECQ. and Depto. de Fisiología. Fac. de Medicina. U.N.A.M. Postal 70250, México 04510. D.F.

A. Postal 70250, México 04510. D.F.
In his studies on natural sciences "Le Traite de L'Homme (1646) and "Les Pasions de L'ame" (1648), Descartes theoretical designs on autonomic reflex activity, engrams, and sensory perceptions, reveal an original and clever faculty of thought.Of particular interest is the Cartesian proposal regarding the pineal gland (PG) whose complex photosensitivity and endocrine properties have already been revealed. Recent advances in PG studies give the Cartesian model for PG function significant reality. Cerebral neural paths, drawn, for example in the Cartesian model, represent the cerebral cyclical activity as modified from PG time moment to moment during the day. Descartes suggested that the animal corporeal components constitute a machine automatically controlled by a structure of the PG which, like a clock, is working to tell the time. By illumination PG, by removing and reimplanting it(1), or simply by the oral ingestion effects of melatonine in birds(2), the coordinating role of that gland in the neuroendocrine processes devoted to regulate the locomotor cyclic control is indeed proved. Therefore, PG functions, recently revealed, emerge as a proof of the glorious traces of Cartesian thought which have inspired several generations of famous scholars not only in mathematics and philosophy but also in the field of experimental natural sciences.1.-Proc.Nat.Acad.Sci.59.414 1968. Ann.Rev.Physiol.40.501 1968;2.-Experientia 41.1615 1985.

### 82.

THE ANATOMY OF THE EYE: ALHAZEN AND VESALIUS. I. S. Russell\*. G. A. Russell, Department of Humanities in Medicine, 164 Reynolds Bldg., Texas A&M University, Texas, 77843-1114.

In his work on optics, the <u>Kitab al-Manazir</u>, Ibn al-Haytham (Latin: Alhazen) gave an accurate description of the biconvexity and the forward position of the lens in the eye. Historically, however, a diagram of a concentric onion eye with the lens dead in the center was attributed to him as the 'Alhazen eye'. Although neither the text nor the illustration in the Arabic original supports such an 'eye', the diagram appears in the printed Latin translation: the Risner ed. of Alhazen's <u>Opticae Thesaurus</u> (1572), which in turn can be traced to Vesalius' <u>De humani corporis fabrica</u> (1543).

Curiously, Vesalius places the diagram next to his dissection of the eye, where the lens is also in the middle of the globe. For Vesalius to make such an error, two possibilities emerge: either his illustration was not really based on dissection; or under the influence of the Graeco-Arabic medical tradition, he depicted what he expected to see. (The crystalline lens as the principal organ of vision was logically placed in the middle of the globe.)

Risner seems to have inserted the erroneous diagram in order to 'update' his edition of Alhazen on the authority of Vesalius' contemporary reputation. It is an historical irony that the misrepresentation of Ibn al-Haytham's eye is due to an error by the father of scientific anatomy.

# 82.5

THE 1906 NOBEL: PRIZE AND PARADOX. <u>J.L. Culberson\*, D.O. Overman and D.E. Haines</u>, Departments of Anatomy, West Virginia University, Morgantown, WV 26506 and University of Mississippi, Jackson, MI 39216.

That Camillo Golgi and Santiago Ramon y Cajal shared honors as corecipients of the 1906 Nobel prize is widely known. It is also generally
understood that the prize was based mainly on Cajal's extensive studies
using Golgi's renowned technique of 'black staining.' Much less well
known is the dramatic contrast between the Nobel lectures presented by
Golgi and Cajal on the occasion of the awards. Golgi, speaking first, on
The Neurone Doctrine-Theory and Facts, recited a litarry of his objections
to the neuron theory, which he had always opposed. He chose this
unlikely title, he said, because '(at this time) this doctrine is generally
recognized to be going out of favor.' Cajal spoke a day later on 'The
Structure and Connexions of Neurons.' His lucid summary of modern
(1906) understanding of neuroscience would have fit comfortably into the
program of our 1992 meeting; few revisions of the basic principles he
presented that day have been necessary. The differing personalities of
Golgi and Cajal and their divergent views of the nervous system set the
stage for this particularly fascinating occasion, a moment in the history of
neuroscience when two noted investigators shared the Nobel stage
without sharing any ideas about the fundamental organization of the
nervous system. This presentation will review the circumstances of the
1906 prize and highlight the differences in the views of these distinguished
neuroscientists, using illustrations and text from their Nobel lectures.

### 82.5

THE CONTRIBUTION OF VITTORIO MARCHI TO EXPERIMENTAL NEUROANATOMY. Marina Bentivoglio\* and Mario Lambiase°. Institute of Anatomy, University of Verona and °Division of Neurology, Hospital of Castellammare di Stabia, Naples, Italy.

Vittorio Marchi (1851-1908), a pupil of Golgi and of the physiologist Luciani, dedicated himself to clinical work since 1888 and left a limited number of publications on the structural organization of the CNS. These studies demonstrate that Marchi, although in favour of the reticular theory, has been a thorough, versatile and creative neuroscientist. In 1884 and 1885 he prepared in Golgi's laboratory a protocol based on the use of osmic acid and potassium bichromate for the selective staining of the myelin sheath of degenerating fibers. With this method, in 1886 Marchi provided together with Giovanni Algeri, a remarkable description of the "descending" degeneration following lesions of different areas of the cerebral cortex in dog and monkey. The anatomical data are accompanied in this study by a detailed behavioral description of the motor and sensory deficits observed after various cortical ablations. In 1887, using the Golgi impregnation in a large number of mammalian species including man, Marchi provided the first description of the "intimate structure" of the thalamus. In this study Marchi described Golgi type I and type II thalamic neurons and emphasized that the former were clearly prevalent in the thalamus. A careful observer, Marchi stands out as a pioneer of modern neuroanatomy.

### 82.4

THE HERITABILITY OF DEGENERACY AS REPRESENTED BY THE ABSINTHISM IN NINETEENTH CENTURY FRANCE; INFLUENCES UPON CONTEMPORARY SOCIETAL PERCEPTIONS OF DRUGS OF ABUSE. Randall B. Murphy and Linda H. Schneider, Dept. Chemistry and Center for Neural Science, New York University, and E.W. Bourne Laboratory, New York Hospital-Cornell Medical College, Dept. of Psychiatry, White Plains, New York 10605

The sources of a perceived increase in the worldwide incidence of mental disorder in the mid 19th century were widely discussed, both in the medical and popular media. The heritability of insanity was a mainstream current, particularly in the psychiatric literature of France. A unique component of these views was the fundamental heritability of acquired traits, which today would be viewed as neo-Lamarckist but was, in fact, fully compatible with conventional Darwinian concepts of that period. A paradigm of this concept is the case of absinthism in France, which, although not fully controlled by legislation until this century, was the topic of controversy as early as the 1860ties. This controversy, which is best known today by its representation in art, had as its central thesis the concept that a form of epileptic insanity was promoted by excessive consumption of absinthe; this degenerate trait was thought to be fully heritable through damage of the "germ plasm". The pharmacologically active component of absinthe, the terpene thujone, is indeed a potent convulsant, and excessive consumption of the drink may have produced acute or possibly chronic neurological changes. However, the alleged validation of the thesis of the heritability of degeneracy was so strongly reinforced by this episode that its consequences continue to persist, and may be traced to present-day views as to the definition of drugs of abuse and the intervention to prevent such abuse.

# 82.6

ENDBULB OF HELD. A.M. Berglund, Eaton-Peabody Lab., Mass. Eye and Ear Infirmary (Boston, MA 02114) and Res. Lab. of Electronics, MIT (Cambridge, MA 02139).

(Cambridge, MA 02139).

In 1891, using Golgi's new technique, Hans Held depicted large endings of the auditory nerve in the cochlear nucleus. A reticularist, Held used other techniques to argue that these "basketlike" axonal terminals joined with the apposing cell body. Cajal (1909), however, recognized these "endbulbs of Held" as unique terminals of individual neruons. He and later Lorente de No (1933; 1981) found that the bushy cells in the cochlear nucleus receive 1-3 endbulbs, thus indicating that a very few primary auditory neurons dominate the input of the target cell. Pfeiffer et al. (1966) found a physiological correlate: a positive potential, which represents the invasion of the endbulb by the parent fiber's action potential, occurs 0.5 ms prior to the target cell's response. Electron microscopy confirms the presence of numerous small synapses of excitatory morphology between the endbulb and the bushy cell (Lenn and Reese, 1966); immunocytochemical data suggest that the endbulb transmitter is glutamate (Altschuler et al., 1984). Thus, the endbulb of Held provides a secure excitatory input from primary to secondary neuron.

transmitter is glutamate (Altschuler et al., 1984). Thus, the endbulb of Held provides a secure excitatory input from primary to secondary neuron. Initial Golgi observations had revealed a spoon-shaped terminal projecting a number of thin filopodia (e.g., Morest et al., 1972). Ryugo and Fekete (1982), comparing Golgi preparations from young animals and endbulbs labeled with horseradish peroxidase from adult animals, showed that the mature endbulb is a "delicate reticulum which appears to enclose the postsynaptic cell body". The holes in the endbulb lattice are presumably filled with inhibitory terminals of CNS origin (Ibata and Pappas, 1976; Schwartz and Gulley, 1978; Cant and Morest, 1979; Adams and Mugnaini, 1987). Sento and Ryugo (1989) showed that endbulb complexity reflects whether the parent fiber has high or low spontaneous activity. Detailed knowledge of the endbulb of Held, derived from over a century of observation, provides an important model for demonstrating structural-functional relationships. (Support: NIH grant §T32DC00006.)

SUBSTRATES OF CONSCIOUSNESS: 1850 to 1950. L.H.Marshall\* Neuroscience History Program, UCLA, Los Angeles, CA 90024-1761.

Initial steps that considered seriously the neural substrates of consciousness began with Laycock's Mind and Brain (1860) and Carpenter's Principles of Human Physiology (1842). Carpenter suggested the thalami, which received the sensations and had a reciprocal relation with cortex. Head and Holmes (1911) added the emotions to the concept, and Ranson and Cannon shifted consciousness to the hypothalamus as the site of a "drive" that maintains a conscious state. AMA posters in 1948 concluded from clinical pathology that coma results from damage where mesencephalon, subthalamus, and hypothalamus meet. To those who placed consciousness in the cortex, Stanley Cobb (1952) said: "A healthy cortex cannot by itself maintain the conscious state." And about Penfield's centrencephalon he wrote: "There can be no center.... It is the streaming of impulses in a complex series of circuits...." This concept echoed the "stream of thought" of the psychologists. In spite of many attempts, it is apparent that the resolution of the hoary mind-brain problem is yet to come.

THE AMAZING FATE OF NIKOLAI BERNSTEIN AND HIS BOOKS. M.L. Latash, Jr. \* and L.P. Latash, Sr. Rush-Presbyterian-St. Luke's Medical Center, Chicago, IL 60612, University of Illinois, Chicago, IL 60612

N. A. Bernstein, the founder of theoretical neuroscience as an independent field of studies, wrote a number of books several of which were not published during his lifetime. One of the books was devoted to polemics with Pavlov, and Bernstein himself aborted its production after Pavlov had died. Another book, "On Dexterity and Its Development" was banned during the anti-Western and anti-semitic campaign of Stalin in the end of the forties. The latter book was saved by the family of Bernstein and found by one of his closest friends and students, I. M. Feigenberg. This book has recently been published in Moscow. The tragedy of scientific fate of Bernstein was determined by two major factors. First, his intellectual power and creativity allowed him to penetrate so deeply into the analysis of the principles of organization of brain functions, especially those related to control of voluntary movements, that he found himself ahead of his time by about 50 years. As a result, he could not be understood by most of his colleagues. Second, he was unfortunate to live and work in conditions of one of the most anti-humaine, totalitarian regimes which decided, in particular, what was right and what was wrong in science. The miraculously saved book, "On Dexterity..." represents a unique example of reader-friendly handling of the most complicated issues of motor control, motor development, motor skill acquisition, and more general aspects of brain activity. These issues have only recently moved into the center of attention of the scientific community. The scientific and historical value of the book is beyond any competition.

# 82.11

SPITZKA AND SPITZKA ON THE BRAINS OF THE ASSASSINS OF PRESIDENTS. <u>D. E.Haines</u>. Dept. of Anatomy, Univ. of Mississippi Med. Ctr., Jackson, MS 39216 Edward Charles Spitzka (1852-1914) and his son Edward

Anthony Spitzka (1876-1922) were prominent neurologists/neuroanatomists in the late 1800s and early 1900s respectively. At the early age of 29 E. C. Spitzka was called upon to testify for the defense at the 1881 trial of Charles Julius Guiteau the assassin of President James Garfield. He was a quick and competent witness who held his own against an aggressiv and experienced prosecutor. He was the only expert that argued forcefully that Guiteau was insane. This was an unpopular position as the general populace did not want Guiteau to escape execution via an "insanity dodge". Spitzka's view did not prevail; Guiteau was convicted and executed. Subsequent examination of the evidence supports Spitzka; Guiteau was almost certainly a paranoid schizophrenic. Almost exactly 20 years later (1901) the son, E. A. Spitzka, performed the autopsy on Leon F. Czolgosz the assassin of President William McKinley. Spitzka (E. A.) wrote a detailed account of the assassin's brain and concluded there was no anatomical indications of a diseased state. He concluded that Czolgosz was "socially diseased and perverted, but not mentally diseased". Spitzka (E. A.) studied the brains of criminals executed by electrocution; this earned him the enmity of underworld figures and repeated death threats. This poster highlights the lives and accomplishments of E. C. and E. A. Spitzka with particular emphasis on their involvement in the "neurology" of the assassins of Garfield and McKinley.

### 82.8

SIGMUND FREUD AND THE HISTORY OF NEUROTECHNIQUE: THE "LOST YEAR". B. Quinn, Division of Neuropathology & Laboratory for Neuroimaging, UCLA Medical School, Los Angeles, CA 90024.

From the 1870's through the early 1900's, fiber architectonics was a vigorously researched field which developed in step with studies of Nissl- and Golgi-stained material. While the cortical areas of Brodmann are still referenced frequently, myeloarchitectonic works from the same era are forgotten, perhaps because optimal myelin stains have always been more complex and capricious than the straightforward Nissl stain. Freud spent many months in 1883/84 laboriously altering the gold chloride myelin stain of Gerlach (1870) and Flechsig (1876) and his three papers on this stain, with his letters of the period, show he was convinced it would bring him great fame. Ironically, the stain, described by Freud as a "method which will never failt 1.2 was never reproduced and was soon described as "so unreliable as to be useless". I hypothesize that Freud's method, similar to that of Schmued\*, may also have been catalyzed by trace peroxide or a similar trace reactant<sup>5</sup>. Close examination of Freud's letters to his fiance show he may have experienced failures of the method, even as he reviewed his galleys declaring it "would never fail". The abysmal failure of his method may have disgraced Freud before those he most wanted to impress, such as Meynert, and the importance attached to novel stains in this era (Golgi, Nissl, etc.) may have been underappreciated by Freud's biographers. Ironically, within months he published his paper extelling the virtues of cocaine, which within two years was called "the third scourge of humanity" after alcohol and morphine. The failure of Freud's painstakingly described stain might reverberate in the absence of explicit technical instruction in his analytic work.

### 82.10

NEUROSCIENTISTS PORTRAYED ON COMMEMORATIVE MEDALS. R.R. Sonnenschein and C.H. Sawyer, Depts. of Physiology and Anatomy & Cell Biology, UCLA Sch. of Med., Los Angeles, CA 90024-1751.

Since the late 17th Century, it has been customary in most of Europe, and to a lesser extent in the U.S.A., to honor eminent individuals, including scientists and physicians, by the casting or striking of medals carrying their portraits. These may be privately commissioned by friends and colleagues; given as awards by scientific organizations; issued as mementos of scientific congresses; or produced for sale by private or governmental mints. Such medallic portraits of leading figures can give an historical overview of a scientific field. This exhibit will consist of photographs of medals in the private collection of R.R. Sonnenschein, of some important contributors to neuroanatomy, neurophysiology, neuroendocrinology, sensory and behavioral physiology, psychiatry and clinical neurology.

# 82.12

CLARENCE LUTHER HERRICK: THE FATHER OF NEUROSCIENCE IN AMERICA. <u>D. E. Haines</u>. Dept. of Anatomy, Univ. of Mississippi Med. Ctr., Jackson, MS 39216

In the late 1800s there were a number of U.S. scientists, such as H. H. Donaldson, B. G. Wilder, E. C. Spitzka, C. L. Herrick, and others, whose primary or sole interest was in the nervous system. Of these Clarence Luther Herrick, with his tireless approach to investigation, his integrated structural-functional view of the nervous system, and his founding of influential and enduring scientific journals, clearly had the greatest long-term influence on the subsequent development of the field of neuroanatomy/neuroscience in the U.S. Herrick approached the nervous system from the standpoint that seemed, at that time, most appropriate. That was the broad based use of comparative studies and attempts to correlate structural features of the nervous system with functional or behavioral abilities. Although Herrick did not use the emerging techniques of that time (his hands on neuro work was largely compressed into the period 1888-1893) it is likely that he would have done so had he not become seriously ill in 1893. He founded 3 scientific journals, the most notable being The Journal of Comparative Neurology; the impact and influence of JCN was immediate. Herrick's weekly meetings with his students to discuss research foreshadowed our journal clubs. Neuroscience today, that being attempts to understand structure and function of the nervous system using a multi-technique approach on a wide variety of forms is clearly Herrick's vision. Taken collectively Herrick's concepts, accomplishments, and initiatives formed the basis for the subsequent development of neuroanatomy/neuroscience in this country.

THE DISCOVERY OF ELECTRORECEPTION, OR MAN'S PROBLEMS WITH UNDERSTANDING A SENSE ABSENT IN HUMANS. B. Fritzsch\* and P. Moller#, \*Div. Anat., Creighton Univ., Omaha, NE 68178 and #Am. Mus. Nat History, New York, NY 10024.

Ideally, science should be a continuous accumulation of insight towards a more refined understanding of the world. In reality, however, science sometimes loses information because no agreement upon its value and meaning is achieved. Belated rediscoveries are best exemplified by the early work of Gregor Mendel published in 1865 and forgotten until 1900.

An equally remarkable example is the history of a sense present in many aquatic vertebrates that enables them to detect weak electric fields: the electroreceptive sense. Discovered by Lissmann in 1958 it is only since 1981 that we have been aware of its widespread existence in vertebrates. This presumably ancient vertebrate sense was lost in all terrestrial vertebrates, including man, presumably owing to the different physical properties of air as compared to water. While struggling to understand the stunning effects some fish have on man, suggestions in favour of a unique sense were raised repeatedly and rejected. Rejections were largely made by scientists who were otherwise extremely influential; particularly in furthering our understanding of phenomena surrounding the fish's stunning effects now known to be due to their electric organs. We will present quotations from 17th-18th centuries papers which explicitly argued in favour of such a unique sense. We will also present how the Zeitgeist led eminent experts to reject explicitlely the existence of an electric sense.

# 82.15

HISTORY OF NEUROSCIENCE IN MEXICO IS REPRESENTED BY ONE OF ITS LEADERS, PROF. J.J. IZQUIERDO. X. García\* and E. Gijón Department of Physiology, Sch. of Med., U.N.A.M., A.P. No. 70-250, 04510 México, D.F. MEXICO

Professor J.J. Izquierdo (1893-1974) studied medicine graduating in 1917 in the city of Puebla, where he was born. He was initiated in works of physiology at the School of Medicine, and he looked for further training abroad during 1927-1930, in the United States of America, England and Germany. He promoted educative reformation with his book "Curso de Fisiología de Laboratorio", 1929, and with works as "Balance Cuatricentenario de la Fisiología en México", 1934, "Harvey iniciador del método experimental", 1936, "Análisis experimental de los fénomenos fisiológicos fundamentales", 1939, "Bernard, creador de la medicina científica", 1942. Other writings as "Montaña y los orígenes del movimiento social y científico de México" 1955, "El Brownismo en México", 1956, "El Hipocratismo en México", 1957, y "La primera casa de las ciencias en México", 1958, allowed him to give knowledge to the historical scientífic and phylosophical basis of his line of thinking and to reveal unknown aspects, not analyzed or interpreted by the ancient mexican sciences. He was founder of several societies like Mexican Physiological Sciences Society in 1957. He was one of the most prominent physiologist in Mexico, without any doubt. He published more than 400 works He gained the most prominent prize as Emeritus Professor for the National Autonomous University of Mexico.

# 82.17

THE IMPACT OF 19TH CENTURY EXPERIMENTAL NEUROPHYSIOLOGY ON SLEEP RESEARCH OF THE 1960s. C. V. Alma. Dept. of Psychology, Univ. of Connecticut, Storrs, CT 06269-1020.

In the 18th and 19th centuries, the phenomenon of sleep was often explained by a combination of physiological concepts and metaphysical constructs. The successful introduction of the ablation procedure by the 19th centrury neurophysiologist Jean-Pierre Flourens lent support to the physiological explanations of sleep function. The ablation method involved the lesioning of certain brain loci and the formation of inferences concerning the function of the specific area by noting changes in behavior. This structure-function-behavior link was used in studies where a part of the cerebral lobe was ablated and the "deprivation of dreams" was observed. In the 1960s, localization studies were performed with kainic acid lesions in order to support the role of certain cell groupings of the pontine reticular formation in REM sleep generation. Jean-Pierre Flourens believed in both the principles of limited localization of function and cortical equipotentiality with respect to sleep function. The ablation studies of Jean-Pierre Flourens supported the localization of function ideas paved the way for modern sleep studies, which view an anatomically distributed system with some localization of function.

### 82.14

SAVING THE SEALS: LOGOS OF NEUROSCIENCE SOCIETIES AND ORGANIZATIONS. R.A. Johnson<sup>1,2</sup> and L.H. Marshall<sup>2</sup>. Graduate School of Library and Information Science<sup>1</sup> and Neuroscience History Program<sup>2</sup>, Brain Research Institute, UCLA, Los Angeles, CA 90024-1761.

Logos, emblems, and insignia are unique, readily-identifiable, primarily non-verbal markings which represent and distinguish products, organizations, publications, and services. Undoubtedly, one instantly recognizes the most effective of these: the medical caduceus, the snake-embraced rod or staff of Aesculapius. We will present both familiar and unusual examples of logos of neuroscience-related organizations and publications. This will be coupled with explanations of the significance and overall appearance and design of these graphic representations, in which the human brain motif predominates. A collection of entries from the first logo contest for the Society's Neuroscience Newsletter over twenty years ago will be complemented by descriptions and interpretations by the designers. The origins of several other attempts to capture the essence or define the scope of the neurosciences for specific organizations or publications will be traced. Attendees will be invited to discuss the characteristic elements that could be incorporated into a logo which reflects members' activities and interests and the Society's role in advocating neuroscience research.

### 82.16

ADRENAL GRAFTS: A 20TH CENTURY ADVENTURE IN NEUROSCIENCE.
A. Márquez-Orozco, Ma.C. Márquez-Orozco, G. Reyes and B. Barrera-Mera. Deptos. de Embriología y Fisiología, Fac. de Medicina, UNAM, A.P. 70-250, 04510 México, D.F. MEXICO
The adrenal glands originally described as "Glandula Renibus Incrumbentes" by Bartholomeus Eustachius (1520-

1574) were soon recognized as a valuable biological structure. These glands in which not only the molecular structure of a neurohormone was reported, but also its crude extract was first obtained, purified, cristallized, and "in vitro" synthesized (see Garmichel, 1989) have been studied. This gave the basis to use the medullar portion as a suitable neuronal model in nervous functional restitution. First, we must recognize that before the neonatal involution (Scheel 1908), and the functional initiation of adrenals were known (Lutz and Case, 1925), the survival conditions of the implanted adrenal glands (Wyman and tum Suden, 1932), and their maintainance depend on the integrity of the hypophysis host (Pomeratz et al, 1942). The fact that the adrenals are also endowed with a selfsustain ed activity (Andrews and Folk, 1964; Kendall, 1964), is a promissory fact. The neuronal autonomic activity could free-run in a coordinated manner with cerebral rhythmic activity during the day. So that the interest currently oriented to use the fetal adrenal cromaffin cells as a substitute neuron in the human brain (Backlund, 1985) is a suitable possibility. The use of fetal adrenal tissues was first considered at an early time of the presente century.

# 82.18

EUGENIO TANZI AND THE FIRST SYNAPTIC HYPOTHESIS OF LEARNING AND MEMORY. G. Berlucchi\* and M. Bentivoglio°. Institutes of Physiology and °Anatomy, University of Verona, Italy.

In 1893, in his review article 'The facts and inductions on the today's histology of the nervous system' the neurohistologist and psychiatrist Eugenio Tanzi (1856-1933), contrary to the opinion of the Italian neuroscientists community led by Golgi, provided a lucid overview, based mainly on Cajal's work, in support of the neuron theory. With a passionate belief in 'the microscopic interval that divides each neuron from the other' (the term synapse had not yet been coined), Tanzi clearly enunciated for the first time the synaptic (defined by him 'physio-psychological') hypothesis of learning and memory. He proposed that each external stimulus acts on the nervous system by producing, in addition to a temporary modification, a longer lasting impression that may become permanent ('a permanent trace, a sort of residual, sometimes even indelible'). According to Tanzi's theory, neurons activated by the stimulus tend to grow in length, and the reduction of interneuronal distance brings about an increase in the capacity of transmitting the 'nervous wave'. These phenomena are only temporary when a single activation occurs, but they produce a relatively permanent facilitative associative link between neurons when there is a repetitious activation, thus providing a basis for memories and learned motor skills. Tanzi's hypothesis, later referred to by Cajal (1911), arose little interest. Only after more than half a century Hebb (1949) revived interest in the possible importance of the modifiability of synaptic transmission in learning mechanisms.

NEUROPHYSIOLOGY LECTURE DEMONSTRATIONS. J. Hore, Dept. of Physiology, Univ. Western Ontario, London, ON N6A 5Cl, Canada

way to successfully interest students neurophysiology and thereby to improve student ratings of your lectures is to perform demonstrations in lectures. Advantages of demonstrations include the following: 1) they can illustrate important principles, 2) they grab the attention of the students, 3) they can make students actively think (especially if used together with "buzz" groups), 4) they improve your rapport with the class. Even such simple demonstrations as getting students in class to observe each others eye movements, vibrating a students arm to produce a false illusion of arm position and acting as if you have Parkinsonian akinesia can have a dramatic effect on student

A list of possible demonstrations together with the principle they illustrate will be presented and given as handouts. A few will be presented live on request. The audience will be invited to add to the list demonstrations they currently use or have witnessed.

### 83.3

INNERVATION OF A CRAYFISH POSTURAL MUSCLE: A STUDENT LABORATORY EXERCISE TO EXAMINE SYNAPTIC TRANSMISSION AND NERVE-TARGET MATCHING. B.R. Johnson\* and R.R. Hoy. Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

We are organizing a series of undergraduate laboratory modules for the neurosciences using the crayfish (Hoy et al. 1991. Neurosci Abst. 17: 516, 1991). These modules emphasize quantitative methodology, principles of nervous system function and physiological and morphological techniques of experimental neurobiology. The superficial flexor muscle in the crayfish abdomen is a postural muscle innervated by a purely motor nerve containing only 6 motor neurons. In this module, students simultaneously record spontaneous extracellular action potentials from the motor nerve and intracellular junctional potentials from muscle fibers. Action potentials of specific amplitude classes are matched with stereotyped muscle junctional potentials that are evoked as students sample recordings from different muscle areas. Students observe the cause (nerve action potential) and effect (synaptic potential) of synaptic transmission, temporal and spatial summation of excitatory and inhibitory synaptic activity leading to muscle contraction, and non-random distribution of multi-neuronal innervation. Tactile excitatory and inhibitory inputs modulate the level of spontaneous activity and these can be mapped out. These results lead to discussions of synaptic transmission and integration, sensory modulation of motor activity, invertebrate and werebrate motor organization, receptive field organization, and principles of neural development. Supported by NSF grant BNS8809445, the Howard Hughes Medical Institute, the Grass Foundation and Apple Computer, Inc.

# 83.5

DATA ACQUISITION, ELECTROPHYSIOLOGY, AND CELL CULTURING USING A GIANT AXON PREPARATION. S. A. George\*, K. E. Long, and J. L. Carroll, Jr. Neuroscience Program, Amherst College, Amherst MA 01002.

We use the ventral nerve cord of the common earthworm in a series of laboratories in the undergraduate Neurobiology course. The nerve cord has a median giant axon and fused lateral axons. Students begin with extracellular recording of the nerve cord in situ, using suction electrodes, to investigate the fundamentals of impulse initiation and propagation in the two giant axons. Because of the importance of data acquisition in modern neurobiology, students also learn simple programming using a PC-based data acquisition system including a MetraByte data acquisition board. During the following week, excised nerve cord preparations placed in a recording chamber are used to study the extracellular action potential waveform. Students then record intracellularly from the median giant axon, in order to learn the ionic mechanisms of impulses and impulse afterpotentials, which are prominent in this axon. Finally, students learn to prepare dissociated cell cultures of large neurons from the nerve cord. We have found this simple, inexpensive preparation to be very useful in teaching fundamentals of excitability in the Neurobiology course.

THE ACTION POTENTIAL THEATER -- ELECTROPHYSIOLOGICAL PERFORMANCE ART. M.L. Collagr. Behavioral Neuroscience Program, Psychology Department, UCLA, Los Angeles, CA 90024-1563.

An obstacle that many students encounter in trying to understand complex biological processes, such as electrophysiological events, is the inherent difficulty of visualizing seemingly arcane subcellular elements and the subtleties of their interactions.

In an effort to make their understanding of postsynaptic potentials and action potentials more concrete and comprehensible, students participating in weekly discussion sections of an upper division Psychobiology course at UCLA act out these processes.

Although the actual performance (with students acting out the flow of ions, opening of ion specific channels, neurotransmitter release and receptor binding) requires only about 15 minutes, background instruction and group discussion occur on the day of, and session preceding, the play. Students are given an overview of intra- and extracellular communication, membrane properties (emphasizing different types of ion channels) and the ionic basis of the resting. action and postsynaptic potentials.

The "Action Potential Theater" can be adapted for groups of students ranging in size from 12 to 30. A large outline of a cell is taped onto the floor or chalked onto a sidewalk. Students start in positions appropriate to their role, either inside or outside of the cell or in the membrane, and act out their role. They explain who they are, what they are doing and why. Although the exercise is approached in a lighthearted and nonthreatening way, the fear of looking foolish is a strong motivator for encouraging advance preparation.

Student evaluations have rated this exercise a 9 (out of 9) in its effectiveness as a learning tool and an 8 (out of 9) in its "enjoyableness."

SOME ADVANTAGES AND DISADVANTAGES OF USING THE IN VITRO NEUROPHYSIOLOGY. Sally Veregge\*, Department of Biological Sciences, San Jose State University, San Jose, CA 95192.

Graduate or upper division courses in neurophysiological

methods often use multiple animal models, each appropriate for the specific technique to be learned. The advantage to this approach is that the student is exposed to the different model systems used in neurophysiology different model systems used in neurophysiology. However, a student may spend as much time becoming proficient with each dissection or preparation technique as with the recording methodology. For our techniques course, we exclusively used the hippocampal slice preparation. With this in vitro model, it is possible to instruct the students in the principles and techniques of field potential, single-unit, intracellular, and patchfield potential, single-unit, intracellular, and patch-clamp recording. In addition, each student can become proficient with the dissection technique and learn the intricacies of maintaining tissue in vitro. The major disadvantage of using the slice preparation is that laboratory periods must be 4 to 6 hours long due to the 1 hour incubation period required for slices to recuper-ate from the trauma of dissection.

YET ANOTHER LABORATORY EXERCISE IN SOMATOSENSORY PSYCHOPHYSICS THAT IS EXPEDITIOUS, INEXPENSIVE, AND SUITABLE FOR LARGE CLASSES J.D. Greenspan, Depts. of Neurosurgery and Physiology, SUNY Health Science Center, Syracuse, NY 13210

A procedure is described which allows a large class (>100) to quickly and easily demonstrate the punctate nature of cutaneous sensitivity. This laboratory was conducted by a first year medical school class (N=128), but could be used for undergraduate or high school students. Each of the three students in a group took turns as the subject, experimenter, and record keeper. They were given a handout that included a drawing of a 4x5 grid on the dorsal surface of the middle phalanx of a digit. They were instructed to envision this grid on the third digit of the right hand. While the "subject" kept his/her eyes closed, the "experimenter" would use his pen (or pencil) to lightly touch the subject's skin at each of the 20 blocks formed by the grid. The subject, then, would respond after each contact whether he/she felt the touch as cool or not. The record keeper kept track of where on this grid the subject experienced a cool sensation. sensation

sensation.

All the students appreciated that some spots on the skin were more sensitive to cool than others. The average number of cool sensations reported out of 20 test spots was 8.3 (std. dev. = 3.0). This lab, along with a demonstration of two-point discrimination (Greenspan, Soc. Neurosci. Abst., 14:516, 1991), provides easily observable properties of the somatosensory system.

Easy-shaping material is a didactic resource used to support theaching in eye development at the ophtalmology specialty level, graduate studies of the School of Medicine (UNAM), imparted at the General Hospital (Ministry of Health).

This resouce eases the teaching-learning process, as it allows tridimensional modelling of the embryonary structures, and explanation of their evolution during development. A previous study with freshman students of the same School of Medicine had demonstrated its effectiveness as a didactic resource. Our aim was to evaluated its usefulness for the teaching of eye development, which contains a great deal of neuroembryology. Evaluation was performed through a structural interview of students taught with the use of this material. Results indicate that this teaching method fosters and eases comprehension of the contents of the eye embryology curriculum at a graduate level.

### 83.9

ELECTROPHYSIOLOGICAL MARKERS OF HYPERPARATHYROIDISM.
K.M. Perryman, L.J. Fitten\*, A. Brinkman, S. Ganzell and D. Ganzell.
Sepulveda VAMC Cognitive Neurophysiology Laboratory (116A-8A) and
UCLA School of Medicing Sepulvada CA 91343.

UCLA School of Medicine, Sepulveda, CA 91343.

Quantitative EEG (QEEG) and P300 evoked potentials were recorded from patients with primary hyperparathyroidism (PHP) and aged-matched controls (AC) during a resting, eyes closed (EC) state and while they were performing a auditory detection task (oddball paradigm). PHP and AC subjects were required to detect pseudo-random occurrences of 1kHz tones delivered 20% of the time among more frequent (80%), 600 Hz tones. Subjects motoric reaction times (RT) were also a performance measure of detection. P300 latencies were collected from midline scalp electrodes Fz, Cz and Pz and averaged across 30 presentations of the odd tone. QEEG activity was collected from frontal (F3, Fz, F4) and parietal (P3, Pz, P4) scalp regions and averaged across 4 second sampling epochs during the EC condition. PHP patients were divided into young (18-40yrs), middle (41-60yrs) and aged (61-80yrs) groups of 10 each for comparison against AC subjects.

Only the aged PHP group demonstrated significant electrophysiological differences compared to their aged-matched control group. There was significant (p<.05) slowing of their dominant EEG rhythms in the frontal regions and a increased latency of the P300 potentials recorded from Fz when compared to the AC group. Repeated electrophysiological measures are presently being collected following parathyroidectomy on some of these patients to evaluate possible effects of brain calcium levels.

UNDERGRADUATE NEURAL SCIENCE AT NEW YORK UNIVERSITY.

L. Kiorpes, C. Aoki, E.E. Coons, C.S. Leonard, and J. A. Movshon\*. Center for Neural Science and \*Howard Hughes Medical Institute, New York University, 4 Washington Place, NY, NY 10003.

We have developed a multidisciplinary undergraduate curriculum to provide broad training in the biological and behavioral sciences with a focus on neuroscience. Our aim is to attract students to research careers in science and medicine, and to prepare them for graduate and professional programs or other technical careers. The program is research-oriented — students learn current techniques and methods in neuroscience through laboratory courses. Also, students spend at least one semester involved in ongoing research in the active laboratories of the Center. Students take 3 core courses: Introduction to Neural Science, Cellular and Molecular Neuroscience, and Behavioral and Integrative Neuroscience, the latter two of which have an integrated laboratory component. Students can emphasize either behavioral or biological aspects of neuroscience by choosing elective courses and seminars in either Psychology or Biology. Additional requirements include foundation sequences in Biology, Chemistry, Physics, and Mathematics.

Program development supported by the Howard Hughes Medical Institute.

### 83.8

USE OF CASE STUDIES TO ENHANCE AN UNDERSTANDING AND COMPARISON OF HUMAN AMNESIA AND LIMITLESS MEMORY. M.R. Foy\*. Dept. of Psychology, Loyola Marymount University, Los Angeles, CA 90045.

The instruction of memory in neuroscientifically-based courses typically involves the discussion of memory deficits (amnesia) produced by some type of brain damage. The importance of the hippocampus and temporal lobes in human memory is clearly demonstrated in the handful of reports describing patients with bilateral hippocampal and/or temporal lobe damage. A discussion of these reports which detail the different types of amnesia from an individual such as H.M. aid the student in explaining some specific instances of amnesia, and how the study of the neurobiology of memory is concerned with the identification of brain structures involved in the formation and storage of memories. However, a more complete approach to the understanding of memory entails not only a discussion of individuals who have an extremely poor memory (such as H.M., who could not form new memories), but individuals who have demonstrated an extremely exceptional memory (such as S., who simply could not forget). In this presentation, a way to instruct students as to the extremes of human memory will be explored.

### 83.10

DEVELOPING AN ANALOGUE MODEL OF THE NERVOUS SYSTEM BY MAPPING THE ORGANIZATIONAL STRUCTURE OF A UNIVERSITY. S.A. Frutiger, Denison University, Granville, OH 43023.

Students in introductory neuroscience courses are often overwhelmed by the complexity of nervous system structure. This exercise encourages students to develop a conceptual model of nervous system organization which emphasizes the functional role of the nervous system as a communication network.

Students interviewed a representative of several university offices/departments (i.e. executive office, student support services, academic support services, physical plant, academic departments in the arts, humanities, sciences and physical education) with a standard set of interview questions designed to provide information about role definition, communication network, and functional output. Information from interviews was used to develop an organizational map for the institution and to develop a model of potential analogue structures in the nervous system which had similar functional roles. Potential discussion topics during model development include: hierarchical versus parallel organization, spatial and temporal summation of input, involvement of a single structure in several functional circuits, procedural versus declarative memory/learning systems, evolutionary pressures and adaptive modifications, etc.

# 83.12

A FLEXIBLE LABORATORY SEQUENCE FOR TEACHING NEUROSCIENCE AT THE UNDERGRADUATE LEVEL. <u>C.A. Paul\*, M. Sharma, J. Jenkins and J.E. Sweeney</u>. Dept. of Biology, Wellesley College, Wellesley MA 02181.

It is challenging to provide students with a broad foundation in neuroscience at a small undergraduate institution due to constraints of staffing and equipment. In order to maximize resources, we have designed a flexible laboratory sequence which could accompany different neuroscience courses; this year it accompanies an upper level course on the neural mechanisms of learning and memory. This lab integrates different techniques to examine the consequences of lesioning the medial septal area (MSA) in rodents. The four major components of the laboratory include: 1) stereotaxic surgery to lesion the MSA and implant recording electrodes in the hippocampus, 2) electrophysiological recordings of hippocampal theta waves in the behaving animal, 3) behavioral assessments using a passive avoidance and a spatial navigation test, and 4) lesion verification and efficacy using Nissl and acetylcholinesterase (AChE) histology and/or quantitative measurements of AChE and

esterase (AChE) histology and/or quantitative measurements of AChE and acetylcholine levels in the hippocampus.

This laboratory fulfills several teaching goals. First, students address real research questions and generate novel data. Second, students are exposed, first-hand, to the interdisciplinary nature of current neuroscience research. Third, this sequence is flexible and could accompany different types of neuroscience courses. Next year, the same basic sequence will be used in conjunction with a neuropharmacology course; a relevant pharmacological agent will be administered such as an AChE inhibitor. Students will then examine whether this drug restores brain electrophysiology, behavior and neurochemistry following the MSA lesion. We envision, in upcoming years, that this sequence could also be taught with a course on the neurobiology of gender (e.g. comparing females and males in the laboratory). This type of flexible laboratory sequence maximizes resources at a small institution and most importantly, expands opportunities in the undergraduate curriculum.

DEVELOPMENT OF AN INTERDISCIPLINARY MAJOR IN NEUROSCIENCE AT A LIBERAL ARTS COLLEGE, P. Naour, L. Normansell and D. Quinn. Muskingum College, New Concord, OH 43762

Neuroscience is an interdisciplinary field in which scientists from a diversity of disciplines investigate the full spectrum of structure and function in the brain. The small undergraduate liberal arts institution provides an excellent opportunity to properly integrate an interdisciplinary neuroscience major. The major we developed was designed to provide the undergraduate student a basic core of courses which serve as the foundation for common seminar experiences and advanced research opportunities with the faculty. The student becomes a part of a research team and engages in scientific inquiry rarely experienced by undergraduate students.

The neuroscience major at Muskingum College consists of three components. In the Basic Science Core, students are provided a foundation in physical, life, behavioral, and computational sciences by completings courses in chemistry, biology, psychology, and computer science. In the Neuroscience Core, students gain an in-depth understanding of brain organization and function. They do so in a combination of formal lecture and laboratory courses, informal seminar experiences, participation in an international forum on the brain (the annual meeting of the Society For Neuroscience), and the conduct of a comprehensive individual research project which serves as the capstone for their undergraduate experience. In the Neuroscience Distribution component, students may individualize their program by selecting from a group of advanced courses which provide either a behavioral, cognitive, computational, or molecular orientation to the basic major.

AN "ANIMAL RIGHTS" ATTITUDE SURVEY OF UNDERGRADUATE PSYCHOLOGY STUDENTS. M. Vigorito\*, D.T. Juliano, and D.M. Murph. Dept. of Psychology, Seton Hall University,

PSYCHOLOGY STUDENTS. M. Vigorito\*, D.I. Juliano, and D.M. Murph. Dept. of Psychology, Seton Hall University, South Orange, NJ 07079.

The "Animal Rights" issue is a topic of great concern to researchers and teachers of neuroscience. Yet little empirical work on students' attitudes toward "Animal Rights" issues have been conducted. Thus, an attitude survey on the use of animals in research and other related issues were given to students who had completed their first college introductory psychology course (n=112) and to psychology majors in their junior or senior year (n=63). Few significant differences in attitude were seen between the two groups. A notable exception was that more majors (80%) than introductory psychology students (40%) disagreed with the statement "Psychological experiments with animals are wasteful since they cannot be generalized to explain human behavior". Also, fewer majors (10%) than introductory psychology students (36%) agreed with a statement that biomedical research with animals is immoral and should be stopped. Seventy-seven percent of all students said they supported the animal rights movement and only 8% indicated that they did not support it. These and other findings of the survey suggest the need to discuss animal rights and animal welfare issues in the classroom.

# 83.17

STAINED BRAIN SECTIONS PLASTINATED FOR TEACHING HUMAN NEUROANATOMY AND NEUROEMBRYOLOGY. N. Ulfig (SPON: European Neuroscience Association) Dept. Anatomy, J.W.Goethe-University, D-6000 Frankfurt/M., F.R.G.

Teaching human neuroanatomy and neuroembryology is accompanied by two problems: Wet brain tissue is quite inconvenient to handle and not resistant enough when handled several times. Subcortical nuclei and their subdivisions are difficult to recognize in unstained sections. These difficulties can be overcome by combining staining of brain tissue sections with subsequent plastination.

Adult human brain: Staining of 1-4 mm thick frozen sections (or thicker sections made with a macrotome) with astra-blue or aldehydefuchsin provides a sharp contrast between white and grey matter. Aldehydefuchsin stains varying amounts of lipofuscin pigment (pigmento-architectonics).

Fetal human brain: Tissue is embedded in celloidin (because of the high vulnerability of the tissue). 0,5 - 2 mm thick sections are stained with Darrow-red for the demonstration of Nissl-substance.

The sections of adult and fetal brains are dehydrated and transferred to acetone. Then they are impregnated according to the standard S10/S3 plastination procedure (von Hagens, G: Heidelberger Plastinationshefter, 1985, Anatomisches Institut, Universität Heidelberg, Im Neuenheimer Feld 307, D-6900 Heidelberg).

TEACHING OF COGNITIVE NEUROSCIENCE A.C.N. Chen. NeuroCognition Institute, Los Angeles, CA 91408, USA

Background: Since 1982, the author has been teaching a graduate seminar on "Cognitive Neuroscience," originally at the University of Washington in Seattle. This 4-credit course covers are found to parallel those in the Journal of Cognitive
Neuroscience inaugurated in 1989.

Objectives: This course integrates theoretical developments and research findings in countive psychology as well as human neuroscience in recent decades. Major Objectives of this course are found to parallel those in the Journal of Seattle stream of the seater o

### 83.16

STUDY OF A CHANGE ON STRATEGIES FOR TEACHING HUMAN PHYSIO-LOGY TO MEDICAL STUDENTS. E. Gijón\*, X. García, and M.A. Lastiri. Department of Physiology, Sch. of Med. and Research and Educational Services Center. UNAM. Ap. P. 70-250

México, D.F. 04510 MEXICO.

The professor, students, objectives, contents and strategies are elements of the teaching-learning process of human physiology, that interact to obtain learning in two axis: one horizontal axis or learning axis, and one vertical axis or teaching axis. The learning axis is formed by the relation student-content-objective and the teaching axis is represented by the professor-content-strategy relationship. The strategies are selected by the professor but are prefigured by the educative institution. During 1992 some institutional changes have been incorporated on strategies for teaching human physiology. The active participation of students directed by one professor was changed to traditional lecture by four professors. The Human Physiolo gy course was divided in four sections, nervous, endocrine hematology and immunologic systems, cardiovascular-respiratory and renal-digestive systems. One professor for each section during 2 hours lecture twice a week; 10 weeks for the nervous system section and 8 weeks for each of the other sections. Emphasis was given for using audiovisual support to every lesson with slides selected by a group of professors giving each section, according to the contents and objectives of the program.

A SIMPLE PLASTIC MODELS SHOW A COMPLICATE NERVOUS PATHWAYS IN THE NEUROANATOMY TEACHING. <u>Z.Q.Liu</u>, <u>X.G.Luo\*</u>, <u>Z.H.Liu</u>. Dept. of Anatomy & Neurobiology, Hunan Medical University, Changsha, Hunan 410078,

The medical students often feel difficult, when facing the study of the complicate internal structures and pathways of the central nervous system (CNS). It will be necessary for the teachers to make their teaching picturesque. Here comes the question. How can we express the complex connections of CNS in a simple form? A set of plastic models of nervous pathways made by ourselves have been successfully applied in teaching, and the effect seems very good. Based on the teaching specimens of CNS and description of plane diagram. We made ten typical plane samples (coronal and horizontal) of CNS with plates of organic glass. The internal structures were drawn with different colour on the plates. The bodies of neurons are represented by plastic beads, and nerve fibers by plastic thread which pass through the corresponding region in the different planes. We have designed and produced each set of 8 models of motor and sensory pathways. They not only show the location of neurons in space, but also the connection between the centre and periphery. Indeed, it is very convenient for the students to understand and study the 3-dimensional structures and benefit them to achieve a better comprehension. In the meantime, the observation of models are combined with cases analysis. It evokes the students great enthusiasm and interest in study neuroantomy. It is also helpful to improve their ability for analysizing and solving the problems. Supported by Teaching Grant from HMU.

# NEUROANATOMY FLASH CARDS M. E. McNeill, East Carolina University School of Medicine; Greenville, NC 27858-4354

The visual format of flash cards capitalizes on the holistic or gestalt perception that is attributed to the right cerebral hemisphere. Nobel laureate Roger W. Sperry, in contrasting left/right hemispheres, said: "The main theme to emerge ... is that there appear to be two modes of thinking, verbal and nonverbal represented rather separately in left and right hemispheres, respectively, and that our educational system, as well as science in general, tends to neglect the nonverbal form of intellect" (in McGuigan & Schoonover, eds., The Psychophysiology of Thinking, NY Academic Press, 209-29, 1973).

The artistic, non-intimidating simplicity of a 62 page spiral bound collection of 8.5 x 11 inch flash cards has been an effective aid in teaching neuroanatomy. These cards: (1) Have visual clarity (2) Offer self-testing (3) Are convenient to use (4) Convey spatial organization (5) Facilitate repetition (6) Employ proprioceptive learning through the use of student work sheets. The use of flash cards has minimized the difficulties of students beginning to unravel the mysteries of the most complex system in the body. Student response has been enthusiastic. "A little picture is worth a thousand words", Chinese proverb.

# TEACHING OF NEUROSCIENCE: COMPUTER-ASSISTED INSTRUCTION

# THE GRAPHIC BRAIN: A COMPUTER GENERATED NEUROANATOMY

TEXT. T.J. Voneida. Neurobiology Dept., NEOUCOM, Rootstown, OH 44272. It has been our experience in teaching neuroscience to medical and graduate students that one of the most difficult areas for them to master is the integration between the three dimensional anatomy, the normally functioning central nervous system, and the diseased or injured brain and spinal cord.

Part One of this MS-DOS text is an interactive, self-testing ATLAS which allows one to select from a 3-D array of Weil stained sections of human spinal cord, hind-mid- and forebrain (in horizontal, sagittal and coronal planes). Cursor selection of any section causes it to "slide out" of the array (like a slice of bread), and enlarge. Each structure is numbered, and its name appears by cursor activation, along with "Input/output?" for nuclei and "Origin/termination?" for tracts. Activation of either of these provides the major connections for each labeled structure

Part Two, FUNCTIONAL SYSTEMS, contains 3-D displays of major ansory/motor systems and cranial nerves. Each sensory system begins with a digitized neurological examination, showing the stimuli required to activate its receptors. Activation results in a 3-D view of the peripheral path entering and coursing through the CNS. Synapses are highlighted by colored flashes. Cross referenced Weil stained sections can be activated from the Atlas at any point for a more detailed view of a specific pathway.

Part Three, CLINICAL CORRELATIONS, includes case study descriptions

of various neurological problems. In addition, digitized images of televised patient examinations are used to demonstrate the pathophysiology of several major neurologic disorders. These will include interactive questions, with specific crossreferences to material covered in Parts I and II.

Special thanks is given to Alive Centers of America and to Ms. Sharon Johnston for their invaluable assistance in this project.

# 84.3

COMPUTER ASSISTED INSTRUCTION IN BASIC NEUROLOGICAL ANATOMY: INTERACTIVE PROGRAMS ON THE MOTOR SYSTEM. P.A. Young\*, P.H. Young, S.L. McClain, J.C. Young, Department of Anatomy and Neurobiology, St. Louis University School of Medicine, St. Louis, MO 63104.

Over the past year a series of interactive programs have been developed to enhance the understanding of the anatomical basis of motor system disorders at the level required in neuroanatomy courses offered to medical and allied health professions students. Each program allows the user to access three different areas: anatomy, circuitry, and disorders. The anatomy sections feature gross specimens, myelin-stained sections, magnetic resonance images, and anatomical illustrations. In the sections on circuitry, input, output, and where applicable, the interconnections are presented using graphics and animation. The disorders sections include descriptions, illustrations, and video demonstrations of various motor system abnormalities. Animated renditions of the abnormal circuitries enable the user to visualize and understand the CNS mechanisms responsible for the disorders. Included in the programs are review quizzes consisting of multiple choice questions and the identification of structures in gross specimens, myelin-stained sections, and magnetic resonance images. (Supported in part by Practical Anatomy and Surgical Techniques Workshops of St. Louis.)

# 84.2

A COMPUTER AIDED INSTRUCTION PACKAGE DEMONSTRATING ANIMATIONS THROUGH A HIGH RESOLUTION THREE DIMENSIONAL DIGITAL MODEL OF THE WHOLE HUMAN HEAD. S.Naravan\*, D.Sensharma, A.Lee, B.A.Pavne, E.M.Santori and A.W.Toga, Laboratory of Neuro Imaging, Dept. of Neurology, UCLA School of Medicine, Los Angeles CA 90024.

We present here an interactive Computer Aided Instruction (CAI) package in neuroanatomy providing visualization of animated images through a three dimensional digital model of the unstained human head.

Full color digital images were taken of the blockface of a cryomicrotomed frozen human head every 200 microns. From this series a three dimensional digital volume with a resultant pixel resolution of 200µm<sup>3</sup> was created on a UNIX workstation. Resampled images were then computed along orthogonal axes and written sequentially to a write-once-read-many (WORM) times videodisc unit. Playback of this customized videodisc dataset provides an animated view of these slices. Other three dimensional surface models of brain structures, reconstructed from MRI data, were also included. A mouse driven CAI package was written for the IBM PC, and interfaces to this database. This tutorial program illustrates topics in basic and applied neuroanatomy by accessing videodisc frames to display animations and labeled still images. Animation and interaction as applied to these three dimensional data provides an appreciation of three dimensional relationships, and have great potential as teaching tools in the neurosciences

VETERINARY NEUROANATOMY: AN INTERACTIVE ATLAS OF THE BRAIN AND NEURAL PATHWAYS. S.L. Cummings\*. M.J. Guinan. D.J. Magliano. and R.L. Kitchell. Veterinary Anatomy and Cell Biology, University of California, Davis, CA 95616.

An interactive Macintosh computer program has been designed as an instructional adjunct for veterinary neuroanatomy and neurology students. The program may be used during laboratory periods as a reference guide and outside of formal class time as a study and review aid. Veterinary Neuroanatomy presents full color digital images of whole brain and brainstem of the sheep, gross transverse sections of sheep brain, and 36 stained histological transverse sections of the canine brain. Individual structures present in each image may be identified by using a mouse to indicate either the region of interest or a term from an accompanying list on the screen. Informational descriptions have been written for each labeled structure. Neural pathways are visualized in animated tutorial programs which are interactive with the Atlas. Relevant gross or histological sections may be viewed from any point in all pathways. The Ascending Pathways tutorial currently includes dorsal column-medial lemniscal, spinocervice-thalamic, and ventral trigeminothalamic pathways. The Descending Pathways tutorial currently includes corticospinal, corticobulbar, and corticorubral pathways. The Visual Pathways program includes tutorials on visual perception, visual Pathways reflexes, and autonomic regulation of pupillary diameter. Requires Macintosh II, IIx, IIsi, IIci, or IIfx; 5MB RAM; 8 bit 13" requires machinesis it, its, itsi, itsi, of its; 5MB RAM; 8 bit 13" color display; hard disk with 15MB of free space; high density floppy disk drive.

A PANTASTIC VOYAGE THROUGH THE HUMAN BRAINSTEM AND RASAL FORERAIN. C.F. Da Silva\*1. P. Dikkes² R.A. Pearlstein³ and R.L. Sidman⁴. University of Sao Paulo, Sao Paulo, Brazil; "Children's Hospital, Boston, USA; "Eidetics Inc., Watertown, USA; "Harvard Medical School, Boston, USA. Serial section cinematography was used as a method for visualizing the internal structure of the human brain. Three normal brains obtained from autopsies were fixed by immersion in formalin and, after dissection, were embedded in block in Paraplast Plus according to Bergman et al (Science Tools, 27:46, 1980). A LKB Multirange Microtome was used to cut 25 µm serial sections which, after being mounted on glass plates, were stained with gallocyanin/methyl-green (Augulis & Spinwall, Stain Technol., 46:137, 1971). The slides (more than 12,000) were aligned and registered onto a 35 mm cine film with a "blink comparator" similar in kind to those used by astronomers for star plate analysis. Briefly, the slides were mounted in pairs in the instrument. A beam chopper and splitter arrangement (Levinthal & Ware, Nature, 236:207, 1972) allowed rapid sequential viewing of the image pair. One slide of the pair was then translated and rotated relative to the other until the apparent "blinking" that results from out-of-register areas being seen in rapid succession was minimized. Section of the pair being registered was then photographed on a single frame of the cine film, after which was replaced by section 3 and the process iterated, overlapping pair by pair, throughout the series. The final product was a cine film in which each frame equals one serial section in tissue register. The film (now in a video disc format) can be viewed forwards and backwards repeatedly as a movie, allowing one to follow fiber tracts and nuclei into the brain at different speeds; it is also being used to create 3-D computer reconstructions.

# 84.7

THE GRAPHIC BRAIN - NEUROPHYSIOLOGY. T.J. Teyler Neurobiology Dept., NE Ohio Coll Med, Rootstown, OH 44272

The Graphic Brain - neurophysiology is a computer-assisted instructional aid for teaching neurophysiology to medical and graduate students. It was first used with students in 1991. The MS-DOS based courseware covers twelve topic areas, ranging from such elementary topics as diffusion and charge separation and resting and action potentials, to the dynamic actions of second messenger systems auditory and visual sensory systems, and cerebellar circuitry. Animated graphics are used to convey difficult concepts, particularly of a spatial or time-varying nature (ion flow, network activity, etc). The courseware has been used in two ways: as an adjunct to classroom lecture, and interactively by individual or small groups of students. For interactive use, the courseware contains a didactic segment followed by an interactive self-test with remediation loops. For classroom use, the the didactic courseware is used alone.

We have found the classroom use to be most effective when first used to introduce a topic, followed by a lecture which expands upon the information in the courseware. For complex topics, we often close the lecture by presenting the unit again. Even with this redundant presentation, we cover the same material in 75% of the time required in years past using traditional teaching methods. More importantly, the students rate the courseware highly and appear to have a better mastery of the material based on their exam scores increasing to 80.1% correct, from a previous average of 73.5% correct. Students are free to preview or review all of the courseware in library-based interactive computers established for this purpose

The courseware will be demonstrated in the poster session.

A SPREADSHEET MODEL OF SIMPLE MEMBRANE POTENTIAL RELATIONSHIPS. J. S. Thomas, ADSS, Meharry Medical College, Nashville, TN 37208

An EXCEL spreadsheet "workgroup" has been developed which can be used to illustrate the effects of changes in specific "causal" factors (Cm, [out]/[in], Gion, Istim, I\_int) on a variety of defined/derived electrical parameters (DPion, Gtotal, chordVm) and the resulting changes in Vm in a classroom or tutorial setting. The availability of multiple graphical 'windows" allows display of the time evolution of all response parameters in response to a change in one or more of the triggering parameters, and the triggering parameter changes themselves can be conveniently manipulated with a mouse by directly altering ("dragging") the values of a bar graph display of the "causal" values. The "outlining" and "cell annotation" facilities of the EXCEL program also facilitate the use of these spreadsheets in self-paced simulated laboratory exercises. Since all required manipulations can be made directly with a mouse (or from mouse selected macros) completion of prescribed exercises and exploration of novel combinations of parameters can be mastered with a minimum of computer specific instruction.

PROTOTYPE FOR INTERACTIVITY: A MULTIMEDIA PLATFORM AND A TIERED CASE STUDY DESIGN FOR MEDICAL NEUROBIOLOGY. W.F. Hughes, T. Tom, J. Kerns, H.A. Paul, and T.J. Hoeppner\* Rush-Presbyterian-St. Lukes Medical Center, Chicago, IL 60612

The objective of this project has been to provide a platform for small group discussion and to extend this style of interaction to a large group setting. Neuroanatomy graphics tutorials and case studies incorporating animations, sound, and video sequences were developed on a *Commodore-Amiga* computer featuring simple yet powerful multimedia authoring tools. Displayed with an RGB projector, these tutorials provide a focus for full-class (100 students) workshops and lectures, as well as independent small group study sessions facilitated by student group leaders. Three levels of case study target clinical applications of neuroanatomy and neurophysiology as a stimulus to developing solving strategies: 1) ten anatomically-oriented cases, presented in small groups coordinated with neurology residents, are available in computerized versions for group discussion; 2) two largegroup case-oriented workshops emphasize basic neurophysiology, evoked potentials, and EEG; and 3) two multidisciplinary case studies (neuro-immuno-microbiology) employ small group techniques developed in the problem-based "Alternative Curriculum" at Rush Medical College

Emphasis on open discussion linked to these computer-based tutorials (also available for independent student review) has transformed the character of one of our most popular basic science courses and re-energized student responsiveness in a large group.

# 84.8

NEUROSYS: A Simulation of Neuronal Electrical Activity. H. Levitan\* and Z. Eldadah. Zoology Department, University of Maryland, College Park, MD

The ability of nerve cells to generate impulses for communication is based on the complex relationship between membrane permeability and membrane potential. Gaining an understanding of the characteristics and consequences of this relationship is an essential part of a neuroscience course. As in most areas of science, this understanding is greatly enhanced when students perform laboratory exercises that are designed to illustrate the basic concepts and that provide an opportunity to test the validity and implications of the concepts. The program, NEUROSYS, allows students to initially control all the variable parameters that contribute to the interdependence of membrane potential and permeability. characteristics of the cell membrane, the membrane's environmental conditions, and the characteristics of two current or voltage stimuli applied to the neuron at specified times, can all be specified and modified. Using a modification of the Hodgkin-Huxley mathematical model, the complex patterns of impulse activity that arise spontaneously can also be studied. spontaneous simulation mode allows students to gain an appreciation of how apparently random or chaotic patterns can emerge from a completely deterministic system, and of the transitions that occur between regular, pacemaker, and bursting patterns of impulse activity and very irregular, unpredictable patterns. The results of the simulation are displayed as variations in the membrane potential, and membrane conductances or intracellular calcium concentration, as a function of time. This innovative program encourages students to design and carry out their own experiments, and demonstrates a creative application of computers for original research.

Axon Engineer<sup>TM</sup>: A versatile simulator of cellular ion fluxes and ionic signaling. K. Miller and P. Pennefather. Nerve Cell on Synapse Group, U of Toronto, ON, MSS 282, Aeon Software, 1553 Bailey Hill, Eugene, Or. 97402. Considerable effort has been expended in the last decade to quantify the dynamic properties of elements such as ion channels, ion transporters and ion buffers that interact to shape ionic signals in cells. In addition, advances in molecular biology have given form to those elements that traditionally have been dealt with as mathematical sektractions. There is a real loose that structural features can be nave given form to those elements that traditionally have been dealt with as mathematical abstractions. There is a real hope that structural features can be linked to kinetic components and that explicit structure-function hypotheses can be formulated. Despite these many advances, it remains difficult to package and present the available information in a manner that effectively communicates its significance. Interactive simulations are useful in helping to develop an intuitive appreciation of the factors that shape ionic signals. At last years meeting, we described an open ended general simulator of cellular ionic signals. Using this program and a 486 computer a complex simulation of a vertablest a nearest that program and a 486 computer, a complex simulation of a vertebrate neuron that considered many multi-state channels and transporters as well as intracellular buffering and diffusion of calcium could be executed in 10-100 × real time. As many important ionic signals occur on the ms. to s. time scale the rate of feedback is sufficient to keep the students attention. The parameters defining the simulation configuration are formulated in a standardized fashion from an intuitive user interface that facilitates the definition of the number of states of the channels or transporters and the influence of independent variable such as ions, chemicals, transporters and the influence of independent variable such as ions, chemicals, voltage and temperature on the transition rates between states. All parameters and assumptions are readily accessible to inspection and modification by the student. The program has now been extensively debugged and documented. We are in the process of developing learning modules that take advantage of the program to illustrate important advances in cellular neurobiology. For example, one module will compare the traditional Hodgkin-Huxley view of the action potential in the squid giant axon with a more modern view that is based on extensive voltage clamp, single channel and esting except measurements. single channel and gating current measurements.

UNDER - GRADUATE NEUROBIOLOGY LABORATORY USING MACINTOSH/MACLAB TO FACILITATE INDI EXPLORATIONS IN INTRACELLULAR RECORDING. INDEPENDENT Card Linden. Dept. Biology, Occidental College, L.A., CA 90041.

L.A., CA 90041.

An undergraduate neurobiology laboratory was designed to provide hands-on experience for students to record membrane and synaptic physiology. The emphasis was on close integration of lecture and laboratory materials, and to provide a series of experiments that inexperienced, but intelligent students could master. Lectures stressed molecular mechanisms of membrane physiology, biophysics and membrane biochemistry. The exercises were reliable and easy to execute. In each three hour laboratory the student needed to master dissection of tissues, manipulation and use of the electronics, computer, and collection of data (and problems associated with intracellular recording).

All projects used the frog sartorius; as the students dissections improved during the 10 week course so did their experimental results. Experiments involved recording of V<sub>rest</sub> varying extracellular K<sup>\*</sup>, R<sup>\*</sup>, and Li<sup>\*</sup>; measurement of spontaneous and evoked EPPs varying extracellular Ca<sup>\*\*</sup>, Mg<sup>\*\*</sup>, and eserine; visualization of neuromuscular junction morphology and biochemical properties using histochemical

Mg\*\*, and eserine; visualization of neuromuscular junction morphology and biochemical properties using histochemical stains, and fluorescent ligands. More sophisticated techniques, such as voltage clamp, were studied using highly interactive software simulating Hodgkin-Huxley modeling of squid axon membrane.

What makes this laboratory experience unique is that the students did all of the work themselves in one or sometimes two 3-hour sessions. The equipment for this laboratory was purchased from funding by a NSf/ILI grant to DCL and matching funds provided by Occidental College.

### 84.13

HYPERCARD PROGRAM TO TEACH NEUROSCIENCE R.J. Ilmoniemi and M. Perko, Low Temperature Laboratory, Helsinki University of Technology, 02150 Espoo, Finland.

We have developed a package for computer-aided learning to supplement lectures on neuroscience. The program runs as a HyperCard application in all Apple Macintosh computers. Special emphasis has been given to pedagogic issues. At each stage, there is an effort to motivate the student as well as to orient her to the topic before exposure to all the details. The student is an active participant in the teaching/learning process and is given a possibility to test her progress.

The package consists of sections (Hypercard stacks), each of which covers one topic such as gross anatomy or the synapse. The system can be expanded by adding stacks or adding material to existing sections. The student is guided through the sections, but it is possible to pick any stack or subsection at any time. The program keeps track of where

any stack or subsection at any time. The program keeps track of where the student is and how much time has been spent in different parts of the program. Since text is best read from books, we put emphasis on graphics and animation in explaining how the brain is organized and how it works. If the student is confused, help is available. Background material, e.g., on chemistry or physics, can be accessed as needed. At any time, the student can test his progress by invoking various kinds of tests. Success is rewarded by special displays, demonstrations, or games.

Besides learning material, stacks have been developed for student registration, for literature, background material, clossary, user's notes.

registration, for literature, background material, glossary, user's notes, etc. The teacher has the right to read registration information as well as to modify the material. There is an auxiliary stack containing high-level programming tools for the teacher who wishes to do his own program-

# 84.15

SLICE OF BRAIN, A VIDEODISC FOR NEUROSCIENCE EDUCATION, S. S. Stensaas, Cornell Univ. Med. Coll., Dept Path., P. Burrows, Univ. Utah, Instructional Media Serv., J. R. Bolles, Univ. of Wash. Health Sci. Cent. Educ. Res., J. W. Sundsten, Univ. Wash. Dept. Biol. Struc. and E. C. ALVORD, Jr., Univ. Wash., Dept of Path.

A cooperative videodisc, Slice of Brain, has been produced using material previously published on three other videodiscs: Slice of Life; The Digital Anatomist: Human Brain Animations; and Disorders of the Nervous System: Motor. In addition, unpublished images in neuropathology (6000), gross anatomy of the head and neck (500), and serial sections of a monkey brain have been added. A generic videodisc allows users to select equipment and develop interactive instructional materials to meet their unique needs. A generic disc is one that has no specific content or design, but can be used in different ways for independent study, or in multiple courses using a variety of hardware. When controlled by a computer (DOS, Macintosh, Amiga, Next) it becomes a powerful vehicle for independent and cross discipline teaching. The possibility now exists to introduce a series of courses of increasing complexity that appeal to beginners and also permits the more advanced students to review content at all levels as desired.

Slice of Brain uses a mixture of stills and motion sequences and is directed at the professional, graduate and undergraduate neuroscience community. The disc contains motion sequences in addition to the extensive collection of stills. Approximately 7 minutes of reconstructed digital brain animations demonstrate the interrelationships of major brain structures as they rotate. Patient sequences demonstrate dynamic pathologic terms such as a taxia, hyperreflexia and hemiplegia. Still images emphasize gross and microscoptic nantomy, radiology and pathology.

The videodisc will be demonstrated together with preliminary software that the authors are developing. It is hoped that these demonstrations will stimulate members to contribute material to future editions of the disc or to develop educational projects using the disc that can be distributed to enhance neuroscience education.

### 84.12

THE MYOTOTIC REFLEX. C.D. Barnes\*, R.D. Kirkpatric, K.B. Campbell and J.G. Meador. Departments of VCAPP and Electrical Engineering and Computer Science, Washington State University, Pullman, WA 99164-6520.

Traditionally students have difficulty grasping the functional consequences of feedback as it is exhibited with its various nuances in the myotatic reflex. They have particular difficulty understanding the modulatory effects of the gamma motor system on the reflex. As a teaching aid, an easy-to-use computer simulation of this reflex system was developed under Microsoft Windows. This graphical interface allowed real-time animated simulation. In the simulation, a variable static force can be applied to the muscle or the force can be applied as a "falling weight." "Supra spinal" inputs to the alpha motor neuron can be dynamically varied, as can the γ- static and γ-dynamic motor neurons to the muscle spindles. The reflex can be opened by interrupting the Ia from the muscle spindle. Output of each of the variables has its own real-time digital read-out and there are four "strip chart" channels of output for Ia discharge, alpha motor neuron discharge, muscle length and force. These can be run continuously or triggered by the weight drop with accumulated traces in different colors. Classroom use of this simulation has proven to be more effective than didactic lectures in teaching these difficult concepts.

### 84.14

"NEURAL COMMUNICATION": A NEW, HIGHLY VISUAL COMPUTER-ASSISTED PROGRAM BASED ON HYPERMEDIA PRINCIPLES. P.I. Magistretti" and B. Zaerpour<sup>2</sup>, Institut de Physiologie<sup>1</sup>, Université de Lausanne and OPAL <sup>2</sup>, 5 rue d'Evian, Lausanne, Switzerland.

A series of computer programs has been developed with the specific aim of promoting associative learning. "Neural communication" is the first such program. Using hypermedia principles, the information content of the program is distributed throughout an interactive network. The program is organized in over 40 windows, each containing images, text and animations connected to each other and to information in other windows through "active zones". This results in the connection of bits of information to dozen of others within the program. Various tools allow the user to wander throughout the program following his/her own associative thinking, rather than a sequential, predetermined and rigid pattern. Each user can create his/her own knowledge trail. A self-assessment option allows the student to test his/her knowledge through multiple-choice questions. In case of an incorrect answer, a "tutorial" option directly brings him/her back to the part of the program where the subject of the question is treated. New questions can also be prepared with the "question-maker" option. A "slideshow" option, through which a sequence of windows can be created, is also available for lectures, since, with a simple computer-projector interface, windows can be projected on a large screen. The program is available for PC (optimal configuration 386, 16 MHz, 2 MB RAM and VGA color screen) as well as for Macintosh. "Neural communication" is part of a series of OPAL modules (Open Programs for Associative Learning) that can be automatically interconnected when loaded on a computer. Presently other modules include "Calcium as a messenger" and "Immune cells". New modules are currently being developed.

# 84.16

SYNAPSE – THE MOVIE: GRAPHICAL ANIMATIONS OF SYNAPTIC FUNCTION FOR GRADUATE AND MEDICAL NEUROSCIENCE EDUCATION. R. P. Hammer, Jr., Lab. Cell. & Molec. Neuropharm., Dept. Anatomy & Reprod. Biol., Univ. Hawaii Sch. Med., Honolulu, HI 96822.

Computer-assisted self-learning has become a valuable tool by which to provide graphical, multimedia resources. Extensive use of such electronic resources in our problem-based learning medical curriculum has shown that optimal usage and student performance is attained from highly visual applications which utilize the unique capacities of the computer interface. In particular, graphical animations of physiological processes which are difficult to visualize in three dimensions are most useful. Current models of synaptic function at the cellular and molecular levels provide an ideal basis for such animated modules. Synapse – The Movie®, created using Aldus SuperCard®, is a Macintosh® application which illustrates the physiological and molecular events underlying the process of neurotransmitter function at the synapse using a series of colored graphical animations created with MacroMind Director®. The user navigates around the synapse either by viewing basic synaptic functions or by examining details of pre- and postsynaptic function, such as voltage-gated calcium channels, exocytosis, ligand-gated ion channel or G-protein-mediated receptor function (e.g., muscarinic and nicotinic acetylcholine, dopamine, or serotonin receptors), and presynaptic terminal, autoreceptor or transporter function. The sequence of events occurring upon receptor activation (e.g., P-mediated G<sub>sα</sub> activation, adenylate cyclase stimulation, and cAMP-dependent protein kinase-induced phosphorylation of DARPP-32) is graphically illustrated in simple 3D-rendered "cartoons." Textual and audio explantions are  $O_{s,\alpha}$  activation, adenyiate cyclase stimulation, and CAMr-dependent protein kinase-induced phosphorylation of DARPP-32) is graphically illustrated in simple 3D-rendered "cartoons." Textual and audio explanations are presented at each step, and users can control forward progress or replay a segment as needed. Synapse – The Movie© is a useful instructional tool in both graduate and medical neuroscience courses, and might be a valuable adjunct to continuing medical education and advanced undergraduate neuroscience curricula.

ENHANCEMENTS TO NEURODATABASE FOR TEACHING.
S.L. Wertheim\* and R.L. Sidman. Division of Neurogenetics, N.E. Regional Primate Research Center, Harvard Medical School, Southborough, MA 01727-9102.

NeuroDatabase is a software system for managing images, related graphics and text for research and teaching. Its teaching functionality has been substantially enhanced since it was shown at the 1991 Soc. for Neurosci. meeting. NeuroDatabase allows teachers to incorporate their own image sets and to store a caption, three types of overlay graphics, and labels for each image. Icons of all images in a series are viewable in a Series Browser. Choosing an icon displays the original image. Any series can have an associated orientation image for indicating the plane of section and moving through the series. Two self-testing modes have been added. "Structure names" presents a list of all structures defined for the current image and shows their outlines in random order, asking the student to choose the correct name from the list. "Structure borders" highlights a random structure name in the list and asks the student to indicate that structure in the image. The vocabulary system has been substantially enhanced. Classification information is kept for each term, allowing users to distinguish anatomy terms from neurochemistry or pathology terms while searching. It is possible to satisfy reasonably abstract requests such as "Show me all the fiber bundles in this image". Storing certain relationships between terms, allows users to see structures in a particular region or those related to a given functional system. Guided Tours provides a narrative for a particular topic, associating each text block with a set of images and graphics selected by the instructor. Creating Guided Tours has been made easier with a new user interface. A student tracking facility records the student name, date, session duration, time spent using the self-tests, and Guided Tour topics chosen. Supported by NIH Grant NS02820.

### 84.18

THE SECOND MESSENGER SYSTEM. Sheldon S. Ball\* & Vet H. Mah. Dept. of Pathology, University of Mississippi, Jackson MS 39216 & Dept. of Neuropathology, Thomas Jefferson University, Philadelpia, PA 19107.

Philadelpia, PA 19107.

The Second Messenger System is an interactive computer program for students, educators, and research investigators in the molecular neurosciences. The application allows an individual to ask a sequence of questions in a single interactive session, thereby facilitating the development and testing of several hypotheses in a short period of time. Graphical representations of molecules and molecular events enable individuals to grasp spatial and functional relationships (and in the future, temporal relationships) among molecules, cellular compartments, and cell regions. Fairly simple but well-defined reasoning capabilities allow an individual to ask sophisticated questions and to predict novel molecular events or pathways. The SECOND MESSENGER SYSTEM (SMS) contains information about: 1) the molecules of signal transduction processes and the motifs that impart function to these molecules; 2) the molecular events of signal transduction processes. Signal transduction is a particularly appealing area to develop a molecular neurosciences information system for two reasons: 1) the complexity of regulatory cascades that result from numerous but relatively simple interactions provides a system relatively straightforward to represent, and at the same time, exploits something computers do well, keep track of details; 2) the central role that abberrations in signal transduction play in disorders of development, aging, and mental health. SMS is being developed through object-oriented programming in a portable programming environment supported by COMMON LISP and the COMMON LISP INTERFACE MANAGER.

# TEACHING OF NEUROSCIENCE: ELEMENTARY AND SECONDARY GRADES

# 85.1

TEACHING NEUROSCIENCES TO THIRD GRADERS IN THE INNER CITY. V. Lemmon\*. S. Burden. A. Garner. D. Orentas. S. Piszczkiewicz. E. Wong, Dept. of Neurosciences, Case Western Reserve University, Cleveland, OH, 44106

We have developed a program to bring a hands-on scientific experience to elementary students with little or no previous science training. Our goals include teaching basic concepts about nervous system organization and function, showing that science is fun and providing positive role models for the children. The presentation begins with a 12-15' chalk talk where 4 concepts are introduced. These are 1) the brain has different parts that do different jobs, 2) it takes time for brain signals to move from one brain region to another, 3) the brain uses electrical and chemical signals, and 4) neurons come in many shapes and sizes. Students are involved in the presentation to capture their attention. In order to reinforce these concepts, the students are then divided into small groups that spend about 5-7' at each of 5 different hands-on activities. The activities include 1) a human brain and spinal cord, 2) a series of brain models from different vertebrates, 3) measurement of student reaction times, 4) a spirited Hypercard program that illustrates the effects of different drugs on chemical transmission and 5) a microscope for observation of different neuronal cell types. Each station is managed by a graduate or medical student. We are particularly fortunate to receive the assistance of members of the local chapter of the Student National Medical Association. At the end of the session the student with the fastest reaction time receives a prize. Detailed information, including the Hypercard program, can be obtained from V. Lemmon

BEEM-NET: BRAIN-EXCHANGE ELECTRONIC MAIL NETWORK FOR KIDS AND SCIENTISTS. D.L. Colbern¹. C. Collins³, J. Emerton², and D.A. Twombly³. Dept. of Physiology and Biophysics, Univ. of Illinois at Chicago¹, 60680; BioTechNet - Eaton Publishing³, Natick, MA 01760; Dept. of Pharmacology, Northwestern University³, Chicago, IL 60611.

Electronic mail is rapidly becoming a common mode of communication in the scientific and business communities. We are utilizing this technology to develop an electronic mail network between research neuroscientists and students in the school systems. This network is intended to provide opportunities for information exchange, and an environment where students can have direct access to university scientists. With the assistance of BioTechNet - Eaton Publishing, we have established the 'Brain-Exchange Electronic Mail Network' (BEEM-Net), which is being linked to schools in the Chicago Public School System. BEEM-Net allows students using computers in their schools or at home to access a consortium of neuroscientists and a number of on-line educational resources. Students may address questions or commentary to the network at large or to specific scientists. Participants may engage in interactive sessions and leave mail for one another. This dialogue could include questions concerning science fair projects, information learned in the classroom or at home, or even practical issues such as careers in science. The BEEM-Net system was first introduced at the Kids Judge! Neuroscience Exhibit (see UIC Graduate Students et al., Soc. Neurosci. Abstr., 1992). In preparation for this exhibit, 6 eighth grade students were trained to operate the BEEM-Net system. These students in turn demonstrated the system to 180 fourth graders who attended the Kids Judge! exhibit. At this event, students used BEEM-Net to send messages to neuroscientists at the University of Scranton, to BEEM-Net representatives in the Far East, and to parents with Internet access. We expect BEEM-Net to be a valuable supplement to science education, as well as a means of cultivating an interest in science and an appreciation for its value to society.

### 85.2

KIDS JUDGE! NEUROSCIENCE EXHIBIT. <u>UIC Graduate Students, <sup>1</sup> D.A. Twombly, <sup>2</sup> and D.L. Colbern <sup>1,2</sup>. Committee on Neuroscience and Dept. of Physiology and Biophysics <sup>2</sup>, Univ. of Illinois at Chicago (UIC), IL 60680; Dept. of Pharmacology <sup>3</sup>, Northwestern Univ., Chicago, IL 60611.

Science literacy is a critical problem facing today's society. At least part of this problem is due to a lack of communication between biomedical scientists and the bullet of the problem is due to a lack of communication between biomedical scientists.</u>

Science literacy is a critical problem facing today's society. At least part of this problem is due to a lack of communication between biomedical scientists and the public at large, particularly children being educated in the school systems. As a means of addressing this issue, we organized a "Kids Judge! Neuroscience Exhibit", geared toward children at the elementary school level. The program was designed to stimulate an interest in science, and to allow children to interact directly with university scientists.

Nineteen graduate students in the UIC Neuroscience program participated

Nineteen graduate students in the UIC Neuroscience program participated in the Kids Judge! exhibit. Each student created a display to illustrate concepts about the brain, in a fashion that would be both exciting and understandable for schoolchildren. In preparation for the exhibit, we obtained display-making guidance from professional staff of the Chicago Museum of Science and Industry. The exhibit itself was attended by 180 fourth grade children from three of the Chicago Public Schools. Many of these students were visually impaired; the displays were designed to be interesting and accessible to these children as well. In addition to the displays, the program included a "workshop" in which kids constructed brain parts with clay, a presentation on careers in science, and an introduction to the BEEM-Net (Brain-Exchange Electronic Mail) computer system (see Colbern et al. 1992). A novel aspect of the exhibit was to allow all of the kids to serve as judges. They evaluated displays on a number of indices, and voted for their favorite. The most popular exhibitors received awards in a ceremony at the end of the program. Based on the enthusiastic reactions from the schoolchildren, their teachers, and their principals, the exhibition was an overwhelming success. This forum proved to be an effective means of promoting interchange between scientists and representative members of the lay public.

# 85.4

BRAINLINK: NEUROSCIENCE TEACHING MATERIALS FOR ELEMENTARY GRADES. L.M. Miller, K.H. Taber\*, J.H. Dresden, W.A. Thomson. Departments of Community Medicine and Radiology, Baylor College of Medicine. Houston. TX 77030.

of Medicine, Houston, TX 77030.

BrainLink is a three year ADAMHA Science Education Partnership Award-funded science education project designed to present the latest factual information about the brain, while at the same time conveying the excitement of "doing science" to students in grades 1-6. The materials are being designed to teach normal brain function and the effects of injury and disease with an emphasis on how neuroscience research is helping to develop new insights and treatments. A total of six units will be developed. Instructional materials are designed to increase the participation and interest of students in the classroom setting through a creative combination of "hands on" activities and student-focused stories. An associated activities book for use in the home setting will provide opportunities for one-to-one parent/child explorations focusing on aspects of the nervous system and neuroscience related careers. An outline and summary of the entire project will be presented, as well as prototype materials.

HANDS-ON NEUROSCIENCE DEMONSTRATIONS FOR ELEMENTARY AND SECONDARY SCHOOL CLASSROOMS. J A Fiez\*, A Berkowitz, S T Carmichael, H.P. Goodkin, J.G. Keating, A.Lewis, J.S. Solomon, L.E. White. Div. of Biol. and Biomed. Sciences, Washington Univ., St. Louis, MO 63110.

We have used a participatory, hands-on approach to introduce neuroscience to more than 150 students (5th-8th graders). Our goal was to create activities (see below) which are both educational and fun Human Psychophysics: A series of short computer programs show how

performance measures, such as reaction time and accuracy, reveal information about higher brain functions, such as attention and language.

<u>Visual and Motor Illusions</u>: Visual illusions demonstrate how the brain can

be "fooled" and how it adapts to stimuli. Vibration of leg and arm tendons produce motor illusions which demonstrate the role of proprioception in determining body position and producing postural adjustments.

Sensory-motor adaptation: Prism goggles are used to distort visual input. and students attempt to hit a target throwing beanbags. Students deduce the importance of visual guidance and motor activity for the learning process Neuroanatomy: Brain anatomy is demonstrated using a human and various animal brains. An MRI demonstrates how living brains can be imaged and the location of damage determined. Slides of neurons show what neurons look like and how the connections between neurons can be traced

Neuropharmacology: A dissected turtle heart is used to show how heart rate and force can be affected by neurotransmitter agonists and antagonists Neurophysiology: An EKG shows that the electrical activity of muscles can be measured, while EMGs show the effects of force, movement, and reflexes on muscle electrical activity. The discharge of electric fish is recorded to show that electrical activity can also be used by an animal to sense its surrounding

### 85.7

# A FUN BOOK FOR TEACHING NEUROSCIENCE TO 8-12 YEAR OLD STUDENTS.

Philip R. Kennedy, Neuroscience Lab., Bioengineering Center, Georgia Institute of Technology, 400 10th. St. N.W., CRB Rm 325 -Atlanta, GA 30332.

Previous approaches taken by authors of non-fiction books on the central nervous system have attempted to describe an aspect of its anatomy or physiology as a simplified text. Titles might include "How we Hear", "How we See", and so on. This approach is rejected as being too didactic and impersonal for children of the 8 to 12 years age group. The present approach is based on the belief that the factual content is less important than the "imagination content". To stimulate the imagination, the reader is taken on an explanatory "walk" through his or her brain, spinal cord and muscles as he or she performs aspects of an everyday experience.

The present effort is a 9,000 word, non-fiction manuscript consisting of 9 chapters with 28 figures, titled "Get a Move On, Neuron!". The reader becomes involved in self-testing with such maneuvres as the finger-nose test, the patellar reflex test and so on.

After each chapter, parental involvement is encouraged.

The author is an MD, PhD, and a graduate of The Institute of Children's Literature of Redding Ridge, CT. The book was inspired

by the author's desire to write a simple explanation of brain function for his children. It is expected that this approach will benefit the Society's efforts to teach neuroscience to middle and high school students.

# 85.9

THE SCIENCE EDUCATION PARTNERSHIP: TEACHING NEUROSCIENCE IN THE SAN FRANCISCO PUBLIC SCHOOLS. D.C. Bowen\* and W. P. Milestone°. Program in Neurobiology, University of California, San Francisco and °Science Department, Abraham Lincoln High School, San Francisco.

The Science Education Partnership seeks to promote teaching partnerships between scientists at UCSF and teachers in the San Francisco Unified School District (SFUSD). In this abstract, we describe strategies which have proven effective in providing practical demonstrations of concepts in neuroscience and general biology. Given the linguistic heterogeneity of the SFUSD, it has proven critical to present information in a manner that is as independent of language as possible. We have found this goal to be best accomplished by designing projects conducted by small groups of students working together in close contact with both members of the teaching partnership. Two examples of

this approach are described briefly below.

(1) Drosophila genetics. Student lab groups worked together to determine the phenotypes of parental and offspring flies in a test cross using a sex-linked marker for eye color. This experiment emphasized collaboration among groups and testing hypotheses by comparing predicted results to actual data. (2) Neuroanatomy. Students were first familiarized with the cytoarchitecture of the brain then examined a post mortem human brain and discussed its functional organization. Since these experiments utilized materials that are available to most neurobiologists, we hope they provide helpful models for others interested in similar teaching partnerships. Supported by the UCSF Chancellor's Office, the Crocker Foundation and the American Honda Foundation (to SEP), the NSF and NIH (to DCB).

ANIMAL MODELS IN BASIC RESEARCH: A WORKSHOP FOR TEACHERS. E.M. Granger, P.C. Hayward, K.D. Vidergar, J.C. Smith\*. Depts. of Biological Sciences and Psychology, Florida State University, Tallahassee, FL 32306.

We have developed a series of workshops for middle and high school science teachers addressing, first, what basic research is and why it is done and, second, why responsible animal use is needed in basic as well as applied behavioral and biomedical research. Resource materials for dissemination to teachers include written materials, video materials, and hands-on exercises for classroom use. These materials are being distributed to classroom teachers through workshops held in local school districts. All middle- and high-school science teachers in Florida will have the opportunity to attend a workshop in their local school district. The long-term goals of the project are to increase scientific literacy by promoting public understanding of what basic research is, why it is necessary for progress toward improving health, and why the responsible use of animals is necessary in basic as well as in applied behavioral and biomedical research. These goals are essential for the Neuroscience community as well. Progress toward these goals will be assessed through the analysis of pre- and post-tests that have been developed for administration to all of the teachers before and after their participation in the workshop and to their students before and after classroom implementation. Workshop administration manuals and resource materials will be available to all interested Society for Neuroscience members by 1993.

## 85.8

A VISION OF TOMORROW IN TODAY'S STAR STUDENTS:
SCIENCE AS A MULTICULTURAL DISCIPLINE.
R.D.Brinton\*O.D.C. Moort and M. Mayo\* Dept. of Molecular Pharmacology and
Toxicology, School of Pharmacy, University of Southern California and \* Francisco

Toxicology, School of Pharmacy, University of Southern California and Francisco Bravo Medical Magnet High School, Los Angeles, CA 90033.

The declining numbers of persons entering fields of science is coupled with an equally drastic change in the ethnic and sexual composition of the pool of persons eligible to enter fields of science. Our approach in the Science Technology And Research (STAR) Program has been to address the decline of interest in science in Search with the chilleges of the sexual decemberity of searching desirability. tandem with the challenge of the new demographics of potential scientists. The STAR Program is a cooperative science education venture with Francisco Bravo Medical Magnet High School which is to the USC Health Sciences campus. The STAR Program provides junior and senior high school students interested in learning about scientific exploration the opportunity to participate in research projects. The ethnic composition of the STAR Program is 9% African-American, 45% Asian-American, 9% East Asian-American Pacific. American and 32% Hispanic-American. Gender composition of the STAR Program is 59% female and 41% male. The full ethnic and

composition of the STAR Program is 59% female and 41% male. The full ethnic and gender diversity of the STAR Program was reflected in the STAR students winning first place in the Bravo and STAR Science and LA County Science Fair competitions.

A fundamental goal of the STAR Program is to provide STAR students with a mentor that will be a consistently available presence in the life of the STAR student as she or he proceeds through college, graduate and postgraduate education onto their ultimate career choice. Therefore, an important criterion for selecting investigators to participate in the STAR Program is their capability and commitment to act as a mentor to the STAR student in their laboratory.

The multicultural composition of the STAR Program fosters an awareness and respect for other cultures as well as providing a forum for intellectual debate of varied perspectives. Evidence of multicultural harmony and mutual respect is evident in the pride that STAR students have in the accomplishments of their colleagues regardless of gender or race. Video and photographic presentation of STAR students and science competitions will be presented along with a description for implementing a similar program.

Supported by NIH grant SO3 RRO3011 to R.D.B.

SYMPOSIUM. PROTEIN PHOSPHATASES AND THE REGULATION OF NEURONAL EXCITABILITY. <u>D.L. Amstrong</u>, NIH (Chairperson); A. <u>Naim</u>, Rockefeller Univ.; <u>J.H. Byme</u>, Univ. Texas; <u>I.B. Levitan</u>, Brandeis Univ.; <u>M.P. Charlton</u>, Univ. Toronto.

Phosphoprotein phosphatases are proving to be important regulators of neuronal excitability and synaptic transmission. At the same time knowledge of protein phosphatase structure, function and regulation is beginning to explode with wide ramifications for cell signalling, membrane transport, cell cycle control, oncogenesis and environmental health (Shenolikar & Naim '91 Adv. Second Messenger & Phosphoprotein Res. 23: 3-121). Two important classes of biological toxins polluting both salt and fresh water are potent inhibitors of phosphoserine/phosphothreonine protein phosphatases.

The <u>structure and regulation</u> of these enzymes will be reviewed (Nairn). Novel mechanisms of <u>phosphatase activation by neuropeptides</u> will be presented (Armstrong). <u>Ion channel regulation</u> by protein phosphatases will be described at the cellular level (Byrne) and <u>analyzed at the molecular level</u> using purified enzymes on single channel proteins in a reconstituted system (Levitan). Finally, the <u>functional consequences</u> of these changes in excitability on synaptic transmission will be demonstrated at peripheral synapses in both mammalian and crustacean nervous systems (Charlton).

7

SYMPOSIUM. MOTILITIES OF THE AUDITORY PERIPHERY. R. Hallworth, Northwestern University (Chairperson); J. Schacht, University of Michigan; J. Assad, University of Rochester; M. Ulfendahl, Karolinska Institutet.

Hair cells of the inner ear are not simply passive mechanoreceptors. They exhibit several kinds of motilities that are expressed as shape changes or as force generation. Hair cells may use motilities to modify their responses to mechanical input. This symposium will explore the various forms of motility in hair cells and their possible roles in transduction. Dr. Hallworth will describe membrane-potential driven length changes in cochlear outer hair cells in vitro. The possible location and mechanism of the motility will be discussed. Cochlear outer hair cells also undergo tonic length changes. Dr. Schacht will highlight the role of intracellular calcium and efferent neurotransmission in the maintenance of outer hair cell length. In contrast to somatic length change, some hair cells show motility of their cilia. Dr. Assad will discuss a possible motor mechanism that controls adaptation in saccular hair cell cilia. Finally, a number of stimuli modify motility in isolated cells. Dr. Ulfendahl will present the results of experiments that use these agents to indicate what role motility plays in cochlear transduction.

## HYPOTHALAMIC-PITUITARY-GONADAL REGULATION

90.1

POLYSIALIC ACID NEURAL CELL ADHESION MOLECULE (PSA-NCAM or EMBRYONIC NCAM) IS EXPRESSED IN THE REGION OF THE GRRH PULSE GENERATOR OF THE PUBERTAL RHESUS MONKEY. <u>A.D. Perera</u>1, <u>C.F. Lagenaur</u>2 and <u>T.M. Plant</u>11. Depts. of 1 Physiology and 2 Neuroanatomy and Cell Science, University of Pittsburgh, Pittsburgh, PA 15261. Puberty in primates is triggered by the reinitiation of pulsatile GnRH release:

a neuroendocrine event that we hypothesize reflects a reorganization of the neural substrate underlying the GnRH pulse generator (PG). A precedent for such postnatal plasticity in neuroendocrine systems has been established for the magnocellular oxytocinergic neurons, where the capacity for structural change in adulthood has been linked to the expression of PSA-NCAM (PNAS 88:5494,1991). Further evidence that PSA-NCAM is indicative of postnatal plasticity is provided by the finding that in mature rodents this molecule is found in hippocampus and olfactory bulb, two areas where neuronal plasticity continues into adulthood. Here, we tested the hypothesis that the pubertal reinitiation of the PG in primates is also a plastic event, and therefore might be associated with the expression of PSA-NCAM. Using a monoclonal antibody raised against PSA-NCAM, intense immunoreactivity for this molecule was observed in the arcuate-median eminence region (ARC-ME) of the pubertal male monkey (n=3). Double-staining revealed an overlap of PSA-NCAM immunoreactivity with GnRH perikarya and nerve terminals in the ARC-ME: a region where the PG is thought to reside. Reduction in the intensity of PSA-NCAM staining after desialylation with neuraminidase, and Western blot analysis confirmed the presence of PSA-NCAM in the ARC-ME. The role, if any, of this molecule in the initiation of primate puberty is probably of a permissive nature, since PSA-NCAM was also observed in ARC-ME of the juvenile (n=1). These findings are consistent with the notion that neuronal plasticity in the ARC-ME may initiate primate puberty.

90.3

ESTRADIOL REDUCES THE AMPLITUDE AND INCREASES THE FREQUENCY OF PULSATILE GONADOTROPHIN RELEASING HORMONE (GnRH) SECRETION PRIOR TO THE PREOVULATORY GNRH SURGE IN THE EWE. N. P. Evans, \* G. E. Dahl and F. J. Karsch. Reproductive Sciences Program, University of Michigan, Ann Arbor, 48109.

Reproductive Sciences Program, University of Michigan, Ann Arbor, 48109. During the follicular phase of the ovine estrous cycle, GnRH is secreted into pituitary portal blood as pulses that increase in frequency and decrease in amplitude, followed by a sustained surge that triggers the preovulatory luteinizing hormone discharge. This study tested the hypothesis that the follicular phase rise in circulating estradiol (E) stimulates these changes in the pattern of GnRH secretion. Mid-luteal phase ewes were ovariectomized, treated with sc Silastic implants to mimic luteal phase concentrations of progesterone (P) and E, and implanted with an apparatus for collection of pituitary portal blood. One week later P was removed to simulate luteolysis, and the ewes received one of three E treatments: NO E (n=5) luteal phase E implant removed; BASAL E (n=5) luteal phase concentration of E maintained; INC E (n=5) E increased from basal to peak follicular phase concentrations by sequential addition of E implants. GnRH was monitored in pituitary portal blood sampled at 10 min intervals over a 20 hr period beginning 16 hr after P removal. E treatment significantly reduced (P < 0.05) the total amount of GnRH collected during the 20 hr period: NO E: 4.1 ± 0.9 ng; BASAL E: 2.1 ± 0.6 ng; INC E: 1.4 ± 0.2 ng. Moreover, E significantly (P < 0.01) reduced the size and increased the frequency of GnRH pulses. Analysis of GnRH secretion over time in the INC E group indicated the suppressive effect of E on both the amount of GnRH collected and GnRH pulses size were dose dependent. These results support the conclusion that E contributes to the increase in GnRH pulse frequency between luteolysis and the GnRH surge in the ewe, and that the follicular phase rise in circulating E causes diminution of the amount of GnRH sleecretion of the amount of GnRH pulse amplitude. (USDA-90-37240-5507, NIH-HD18337 and HD18258)

90.2

PATTERN OF GNRH SECRETION IN THE PITUITARY PORTAL CIRCULATION OF THE GROWTH-RETARDED FEMALE SHEEP DURING HYPOGONADOTROPISM. J.M. Manning\*, C.G. Herbosa, C.R. Friedman and D.L. Foster. Reproductive Sciences Program, and Departments of Obstetrics and Gynecology, and Biology, University of Michigan, Ann Arbor, MI 48109-0404.

Dietary-induced growth retardation produces hypogonadotropism and delayed puberty. In the sheep, even in the absence of ovarian steroid feedback, growth-retarded females exhibit slow luteinizing hormone (LH) pulses compared to normally-growing, ovariectomized females (Endo. 116:375, 1985). The infrequent LH pulses could reflect either: 1) correspondingly infrequent GnRH pulses could reflect either: 1) correspondingly infrequent GnRH pulses, or 2) normal frequency GnRH pulses of a depressed amplitude, such that only an occasional GnRH pulse attains an amplitude sufficient for LH release. To determine by which mechanism (frequency vs. amplitude) growth retardation suppresses GnRH secretion, we simultaneously collected pituitary portal blood for GnRH and jugular blood for LH over a 4-hr period in growth-retarded (28kg, n=8; "28kg") and normally-growing (60kg, n=7; "60kg") ovariectomized lambs at 52 wks of age, 20 wks beyond the normal age of puberty. As expected, the 28kg females were hypogonadotropic and exhibited a low LH pulse frequency (0.5±1.0 pulses/4h). The pattern of GnRH secretion corresponded with that of LH secretion, in that 28kg females exhibited slow GnRH pulses (0.5±1.0 pulses/4h), compared to 60kg females (7.0±0.4 pulses/4h). The failure to find high frequency, low amplitude GnRH pulses which are subthreshold for LH release supports the hypothesis that the frequency of GnRH secretion is suppressed by growth retardation. (Supported by NIH HD-07517, -18394, and -18258).

90.4

EFFECTS OF ESTRADIOL AND ENDOGENOUS OPIOIDS ON PULSATILE GNRH SECRETION DURING THE BREEDING SEASON OF THE EWE. R.L. Goodman\*, N.P. Evans, G.E. Dahl, and F.J. Karsch Department of Physiology, West Virginia Univ., and Reproductive Sciences Program, Univ. of Michigan, Ann Arbor, MI 48109

In breeding season ewes, estradiol (E) inhibits the amplitude of luteinizing hormone (LH) pulses. This action of E may involve endogenous opioid (EOP) neurons: EOP antagonists increase LH pulse amplitude in E-treated ovariectomized (OVX), but not in OVX, ewes. This study determined if these inhibitory actions of E and EOP neurons reflect changes in the secretion of gonadotropin-releasing hormone (GnRH) by administering naloxone to OVX and OVX+E ewes (6/group). Luteal phase ewes were OVX, an apparatus for hypophysial portal blood collection implanted, and steroids replaced with Silastic implants when needed. Two weeks later, portal blood samples were collected every 10 min for 6 hr before, 6 hr during, and 4 hr after iv naloxone infusion (1 mg/kg/hr) into OVX and OVX+E ewes. E treatment decreased the total amount of GnRH collected during the first 6 hr from 515 ± 126 to 248 ± 83 pg by inhibiting GnRH pulse size (OVX: 94.2 ± 27.7; OVX+E: 24.8 ± 9.3 pg/pulse). E increased GnRH pulse frequency from 5.8 ± 0.4 to 8.2 ± 0.6 pulses/6 hr. Naloxone did not alter pulse frequency, but increased GnRH pulse size, and did so in both OVX (250 ± 53 pg/pulse) and OVX+E (72.7 ± 20.5 pg/pulse) ewes. In summary, during the breeding season, E stimulates GnRH pulse frequency, while inhibiting the amount of GnRH released in each pulse. In contrast, EOP neurons appear to selectively inhibit GnRH pulse size and do so independently of E. Thus, EOP neurons may not mediate the feedback actions of E on pulsatile GnRH secretion. (NIH HD17864, HD18337, HD18258, USDA-90-37240-5507).

GnRH PULSE FREQUENCY AND THE DIFFERENTIAL REGULATION OF LH AND FSH IN THE MALE DJUNGARIAN HAMSTER. J.M. Meredith\* F.W. Turek, J.E. Levine. Dept. of Neurobiology and Physiology, Northwestern Univ., Evanston, IL 60208.

Northwestern Univ. Evanston, IL 60208.

In the Djungarian hamster photostimulation has been shown to evoke differential release of the gonadotropins, with FSH levels rising rapidly following the onset of photostimulation and LH levels rising significantly later. We hypothesize that GnRH pulse frequency gradually increases following photostimulation and that the differential rise times in the gonadotropins may correspond to time points when GnRH pulse frequencies are preferential for either LH or FSH release. To test this hypothesis, photoinhibited hamsters were given various GnRH treatments consisting of chronic 1 minute GnRH pulses administered s.c. at frequencies of 1 consisting of chronic 1 minute GnRH pulses administered s.c. at frequencies of 1 pulse every 45 (fast), 90 (medium), or 180 min (slow). Animals were then sacrificed at 0, 3, 5, 10, 20, and 30 days following treatment. LH levels following 10 d of fast frequency GnRH pulses (3.26±0.30 ng/ml) were significantly greater than LH levels in animals exposed to 10 d of medium, and slow GnRH pulse frequencies (1.57±0.19 and 1.17±0.21). On the other hand, 10 d of medium GnRH pulse frequency produced FSH levels which were significantly greater than 10 d of fast frequency GnRH pulses (15.21±2.02 vs. 9.81±1.68). Animals which had been exposed to 6nRH for 30 d at the fast and medium pulse frequencies had testes weights (871.02±102.03 and 965.10±19.63 mg) which were significantly greater than animals which had been exposed to 30 d of the slow GnRH pulse frequency (619.85±5.222). Testosterone levels at 30 d also differed according to the GnRH pulse frequency group, significantly lower levels in the medium frequency group (8.63±2.72), and nondetectable levels in the slow frequency group. These results are consistent with studies suggesting that slower GnRH pulse frequencies facilitate the release of FSH while faster GnRH pulse frequencies facilitate the release of LH. In addition, the present results suggest that GnRH pulse frequencies release of LH. In addition, the present results suggest that GnRH pulse frequency can secondarily regulate testicular functions through regulation of relative proportions of LH and FSH release. FACILITATION OF LHRH-INDUCED LH SURGES BY NEUROPEPTIDE Y

FACILITATION OF LHRH-INDUCED LH SURGES BY NEUROPEPTIDE Y (NPY) DEPENDS UPON PREOVULATORY PROCESTERONE SECRETION.

A.C. Bauer-Dantoin\* B. Tabesh, and J.E. Levine. Dept of Neurobio & Physiol, Northwestern Univ, Evanston, IL 60208. We have demonstrated that NPY potentiates LHRH-induced LH secretion only under the endocrine conditions in which preovulatory LH surges are generated. The present study was designed to test the hypothesis that the actions of progesterone (P) in particular are requisite for NPY's facilitory actions on LH secretion. Female rats were fitted with atrial catheters on diestrus. On proestrus, hourly blood samples were collected from 1100-2100h. At 1230h, rats received a s.c. injection of the P antagonist RU486 (6 mg/kg BW), or oil. At 1330h, rats received pentobarbital (PB; 40 mg/kg BW) to block hypothalamic LHRH release, or saline (SAL). Every 30 min from 1400-1800h, PB-treated rats received i.v. pulses of LHRH (15 ng/pulse) or SAL, along with concurrent pulses of NPY (5 µg/pulse), or SAL, Administration of RU486 to rats treated with SAL at 1330h completely blocked the endogenous LH surge. In oil-treated, PB-blocked rats, concurrent administration of NPY with LHRH significantly (p<.01) potentiated the ability of LHRH to restore LH surges. However, the potentiation by NPY of LHRH-induced LH surges in PB-treated rats was completely blocked by the administration of RU486 at 1230h. RU486 slightly attenuated the ability of LHRH alone to restore LH surges in PB-blocked rats. These results demonstrate that one function of preovulatory P secretion is to up-regulate pituitary sensitivity to the facilitory actions of NPY. We hypothesize that these actions of P, together with an increase in NPY neurosecretion, mediate the acute increase in pituitary sensitivity to LHRH that cours just prior to the LH surge (NIH HD20677, HD21921, HD00879, and MH10177).

# 90.9

A POSSIBLE ROLE OF GABA IN TONIC INHIBITION OF LHRH RELEASE BEFORE THE ONSET OF PUBERTY IN THE FEMALE RHESUS MONKEY. D. Mitsushima, S. Chongthammakun, and E. Terasawa, Reg. Primate Research Ctr., Univ. of Wisconsin, Madison, WI 53715.

It has been hypothesized that during the prepubertal period in the rhesus monkey a dominant inhibitory neuronal system controls LHRH neurons, suppressing pulsatile LHRH release. In the present study we have examined the role of  $\gamma$ -aminobutyric acid (GABA), known inhibitory neurotransmitter, in the control of LHRH release during puberty using a push-pull perfusion method. GABA (10<sup>-5</sup>M, 10<sup>-7</sup>M) or the GABA-A antagonist bicuculline methiodide (10<sup>-5</sup>M, 10<sup>-7</sup>M) was infused into the stalk-median eminence for 10 min in 4 prepubertal (14.5±0.6 mo) and 7 midpubertal (40.2±1.7 mo) monkeys. Results: While in prepubertal monkeys neither 10<sup>-5</sup>M nor 10<sup>-7</sup>M GABA infusion altered LHRH release, in midpubertal monkeys GABA at both doses significantly suppressed LHRH pulses (10°M; p<0.01; 10°7M: p<0.05). LHRH suppression occurred within 10 min after GABA infusion and lasted for at least 60 min with 10-5M and 30 min with 10-7M. In contrast, bicuculline infusion at both doses in prepubertal monkeys consistenty induced a prompt LHRH increase ( $10^{15}$ M: p<0.025;  $10^{7}$ M: p<0.02). The LHRH increase peaked during the infusion and returned to preinfusion levels within 20 min after the infusion. In midpubertal monkeys, bicuculline at  $10^{5}$ M also stimulated LHRH release (p<0.01), but bicuculline at  $10^{7}$ M was without effect. The results are interpreted to mean that in the prepubertal period there is a powerful GABA inhibition of the LHRH neurosecretory system: bicuculline removes endogenous GABA inhibition thereby stimulating LHRH release, while exogenous GABA is not effective because LHRH release is already inhibited by endogenous GABA. It is concluded that the LHRH neuronal system may be chronically inhibited by GABA neurons before the onset of puberty in primates. (Support: NIH grants HD11533 and RR00167.)

PULSATILE LHRH RELEASE IS INDEPENDENTLY CONTROLLED BY THE ALPHA-ADRENERGIC AND NEUROPEPTIDE Y (NPY) NEURONAL SYSTEMS IN THE RHESUS MONKEY. A. K. Yamane and E. Terasawa\*. Reg. Primate Research Ctr., Univ. of Wisconsin, Madison, WI 53715

Previously we have shown that both the  $\alpha$ -adrenergic and NPY neuronal systems play a role in the control of pulsatile LHRH release: The  $\alpha$ adrenergic antagonist prazosin suppressed, while the  $\alpha_1$ -adrenergic agonist methoxamine (MTX) stimulated LHRH release (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed, while NPY stimulated LHRH release (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed, while NPY stimulated LHRH release (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed, while NPY stimulated LHRH release (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed, while NPY stimulated LHRH release (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed, while NPY stimulated LHRH release (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed, while NPY stimulated LHRH release (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed, while NPY stimulated LHRH release (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed, while NPY stimulated LHRH release (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed, while NPY stimulated LHRH release (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed, while NPY stimulated LHRH release (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppressed (Endocrinology 123: 1808, 1988); a specific antiserum to NPY (aNPY) suppre lated LHRH pulses (Ibid. 130: 2333, 1992). However, it is unclear whether these neuronal inputs are independently involved in the regulation of LHRH release or whether one system is more proximal to the other. In the present study, using a push-pull perfusion method, we have conducted 2 experiments to examine the possible interactions between these two neuronal systems on the control of LHRH pulsatility in ovariectomized monkeys. Experiment I: To test whether the  $\alpha$ -adrenergic neuronal system mediates NPY input, NPY at 10 <sup>6</sup>M was directly infused into the stalk-median eminence (S-ME) before and 2 h after injection of prazosin. The results indicate that NPY infusion clearly stimulated LHRH release during the prazosin-induced LHRH suppression. The response of the NPY-induced LHRH release after prazosin did not differ from that after vehicle injection as a control for prazosin. Experiment II: To test whether the NPY neuronal system mediates α-adrenergic input, MTX at 10.5M was directly infused into the S-ME 10 min after infusion of aNPY. MTX stimulated LHRH release during the aNPY-induced LHRH suppression and the response was similar to that after NRS infusion as a control for aNPY. These results suggest that the  $\alpha$ -adrenergic and NPY inputs maintain a parallel relationship and are not dependent on each other in the control of pulsatile LHRH release. (Support: NIH grants RR00167 and HD15433.)

## 90.8

NEUROPEPTIDE Y STIMULATES LHRH RELEASE FROM SUPERFUSED

NEUROPEPTIDE Y STIMULATES LHRH RELEASE FROM SUPERFUSED HYPOTHALAMIC GT1-7 CELLS. L.M. Besecke\*, A.M. Wolfe, M.E. Pierce, J.S. Takahashi and J.E. Levine. Dept. of Neurobio. & Physiol. Northwestern Univ. Evanston, IL 60208. Neuropeptide Y (NPY) has been shown to stimulate LH release by actions at both the hypothalamic and pituitary levels. At the hypothalamic level, this effect is exerted via stimulation of LHRH release. To assess the possibility that these hypothalamic effects can be exerted by direct action on LHRH neurons, we used an in vitro superfusion system to examine the effects of pulses of NPY on LHRH release from immortalized GT1-7 cells (Mellon et al., 1990). We have found that addition of NPY (10<sup>-12</sup>-10<sup>-6</sup>M) produced a dose-dependent increase in LHRH release from these cells in three-day culture. A 10<sup>-6</sup>M dose produced a 300% increase in LHRH release, a 10<sup>-6</sup>M dose produced a 300% increase in LHRH release, a 10<sup>-6</sup>M dose produced a 115% increase, and a 10<sup>-12</sup>M dose elicited a modest 25% increase in LHRH release in these cells is 10<sup>-6</sup>M NPY. Robust LHRH responses were also seen when pulses of the LHRH secretagogues veratridine (50 MM), prostaglandin E<sub>2</sub> (25,100 MM), and norepinephrine (10<sup>-5</sup>,10<sup>-7</sup>,10<sup>-6</sup>M) were administered in the superfusate media. However, substance P (10<sup>-6</sup>M) and arg-vasopressin (10<sup>-6</sup>M) did not significantly alter LHRH release profiles. These data demonstrate that NPY directly stimulates LHRH release from superfused GT1-7 cells, and suggest that the mechanism by which NPY stimulates LHRH in vivo may be through direct action on the LHRH cell. In current studies we are attempting to characterize NPY receptor subtype(s) and signal transduction mechanism(s) involved in the NPY-induced LHRH release from GT1-7 cells. GLUTAMATE-IMMUNOREACTIVE TERMINALS SYNAPSE WITH GNRH NEURONS IN THE MONKEY HYPOTHALAMUS.

P.C. Goldsmith\*, K.K. Thind, and A.D. Perera 1. Reproductive Endocrinology Center, Univ. Calif., San Francisco, CA 94143 and <sup>1</sup>Dept. Physiol. Univ. Pitts. Sch. Med., Pittsburgh, PA 15261.

Glutamate (GLU) is the most prevalent excitatory transmitter in the brain.

GLU agonists rapidly stimulate reversible GnRH neurosecretion in sexually mature and even pre-pubertal animals. To determine whether GLU acts directly on GnRH neurons, we investigated GLU-GnRH interactions in hypothalami from adult female and juvenile male macaques. Monoclonal antibody specific for glutaraldehyde-fixed GLU (Glu-2) was used to label vibratome sections with an ABC peroxidase technique. GLU-immunoreactive (-ir) neurons were numerous throughout the diencephalon, most noticeably in the diagonal band, suprachiasmatic, supraoptic, paraventricular, and arcuate (ARC) nuclear regions. GLU-ir staining occurred chiefly in neuronal cytoplasm, and to a variable degree in many GLU-ir cell nuclei. Fiber density was greatest in the median eminence, where GLU receptor concentrations are reportedly high (Soc. Neurosci. Abstr. 16(1):284, 1990). Prior absorption of Glu-2 with a GLU-glutaraldehyde-BSA conjugate completely abolished immunostaining. To examine neurointeractions, GnRH-ir structures were locallized with the polyclonal antibody LR2, PAP reagents and DAB. GLU-ir elements were identified with Glu-2 and immunogold (15 nm). Electron microscopy revealed numerous GLU-GnRH contacts and synapses, almost exclusively axo-dendritic in the lamina terminalis, but occasionally also axosomatic in the ARC region. Postsynaptic membranes seemed rarely specialized, but GnRH-ir granules sometimes congregated nearby. Since few unlabeled inputs were noted, we conclude that GLU-ir afferents exent a major excitatory influence on GnRH neurons in the monkey hypothalamus. Their role during the normal menstrual cycle or reactivation of pulsatile GnRH secretion at puberty remains to be determined. Work supported by NIH grant HD10907 (P.C.G.) (-ir) neurons were numerous throughout the diencephalon, most noticeably in

NORADRENERGIC INNERVATION OF GNRH NEURON-CONTAINING AREAS: A COMBINED IMMUNOCYTOCHEMICAL AND RETROGRADE-TRACING STUDY, D.E. Wright and L. Jennes. Dept. Anatomy and Neurobiology, Univ. of Kentucky Medical Center, Lexington, KY 40536-0084

Norepinephrine (NE) influences the activity of gonadotropinreleasing hormone (GnRH) neurons during the female rat estrous cycle at both the axon terminal and the GnRH perikarya. Recent evidence suggests that NE-neurons in the A2 region may be important in conveying the feedback signals of estrogen to GnRH neurons. We therefor studied the relationship between the A2 region and areas containing GnRH neurons using two neuroanatomical tracers, fluorogold (FG) and fluororuby (FR) combined with immunohistochemistry (IHC) for tyrosine hydroxylase (TH), dopamine beta hydroxylase (DBH) and GnRH. Female rats received pressure injections of either FG or FR in the septum-diagonal band and rostral preoptic area. The proximity of injection sites to GnRH neurons was confirmed using GnRH-IHC. Both FG and FR injections resulted in retrogradely-labeled TH or DBHimmunoreactive neurons in the A2 region. The majority of these doublelabeled cells were located in caudal regions of A2 ipsilateral to the injection site. A few double-labeled neurons were also observed in the A<sub>1</sub> region. The results suggest that NE neurons in the A<sub>2</sub> region possess significant projections to areas containing GnRH neurons, supporting the hypothesis that noradrenergic A2 neurons play an important role in modulating GnRH neuronal activity in the female rat brain. Supported by NIH HD24697.

DO SCN EFFERENTS CONTACT GIRH CELLS IN THE HAMSTER? A

DO SCN EFFERENTS CONTACT GNRH CELLS IN THE HAMSTER? A COMBINED PHA-L TRACT TRACING AND IMMUNOCYTOCHEMICAL STUDY. E.L. Meyer. M.N. Lehman. and E.L. Bittman\*. Dept. of Zoology. Univ. of Massachusetts, Amherst 01003, and Dept. of Anatomy and Cell Biology, Univ. of Cincinnati Medical School, Cincinnati OH 45267.

A circadian pacemaker in the suprachiasmatic nucleus (SCN) regulates the timing of the preovulatory luterinizing hormone (LH) surge in the golden hamster. We used a combination of tract tracing and immunocytochemistry to determine whether SCN efferents control the timing of the surge by directly contacting gonadotropin-releasing hormone (GnRH) neurons. The lectin anterograde tracer, Phaseolus vulgaris leucoagglutinin (PHA-L) was iontophoretically applied to the SCN of 6 ovariectomized hamsters. Hamsters were perfused 10-14 days later with paraformaldehyde and sections (50um) were processed for simultaneous immunocytochemical detection of PHA-L and GnRH or vasopressin using a double-label immunoperoxidase technique. In several animals, PHA-L iontophoresis sites were limited to the SCN and in these cases PHA-L labeled fibers could be followed to a number of previously described efferent targets of the SCN, including the preoptic area (POA) and the subparaventricular zone of the hypothalamus. Intra-SCN connections, including efferents to the contralateral SCN, were also seen. Thus far, we have seen only rare close associations between SCN efferents and GnRH cells, althrough PHA-Llabeled SCN efferents may centred the proposition of the POA Me prevention that the proposition and contract after propositions. labelled SCN efferents form clusters of terminal boutons in adjacent areas of the POA. We speculate that SCN efferents may contact other preoptic or high POA. We speculate that SCN effects that contact of the problem of hypothalamic cells, such as those which express estradiol receptors, which then regulate the timing of the GnRH release. We are presently attempting to identify appositions of PHA-L labelled SCN fibers onto estrogen-receptor immunoreactive neurons in the POA. Supported by NS 24292 and 28175 to M.N.L. and by NIMH 44132 to E.L.B.

# PEPTIDES: BIOSYNTHESIS, METABOLISM, BIOCHEMISTRY I

IDENTIFICATION AND CHARACTERIZATION OF NEUTRAL ENDOPEPTIDASE-LIKE ACTIVITY IN APLYSIA CALIFORNICA. W. Bawab, Crine, and L. DesGroseillers\*. Department of biochemistry, University of Montreal, Montreal, Canada, H3C 3J7.

We are investigating the role of ectoenzymes in the inactivation of neuropeptides in Aplysia. Last year, we reported the characterization of a first neuropeptide-degrading enzyme in the kidney, ovotestis, heart and central nervous system of *Aplysia*. This enzyme has the same enzymatic characteristics as the mammalian aminopeptidase N (Biochem. J. 1992. In press). Using [3H]leu-enkephalin (YGGFL) as substrate, we now describe a second neuropeptide-degrading enzyme in the kidney and CNS of Aplysia. This enzyme cleaves leu-enkephalin at the Gly<sup>4</sup>-Phe<sup>4</sup> bond, as determined by HPLC analysis of metabolites. The degradation of the substrate was abolished by the neutral endopeptidase (NEP) inhibitors HACBO-Gly, thiorphan and phosphoramidon, and by the divalent cation chelating agent 1-10 phenanthroline, suggesting that this enzyme is similar to mammalian NEP. Phase separation experiments, using Triton X-114, showed that more than 60 % of the membrane-bound NEP activity in the *Aplysia* kidney comes from an integral membrane protein. The presence and size of the neutral endopeptidase can be revealed by a very potent inhibitor of NEP, [1251]RB104, after migration on SDS-PAGE and transfer unto nitrocellulose membranes Using this technique, we showed that the NEP-like enzyme in Aplysia kidney membranes has an apparent molecular mass of about 130 Kda. Finally, a partial cDNA has been isolated from a CNS cDNA library and the DNA sequence revealed about 50 % identity between the Aplysia and mammalian enzymes. The presence of a NEP-like enzyme may contribute to the extracellular degradation of *Aplysia* neuropeptides.

PROTEOLYTIC ENZYME INHIBITORS SUPPRESS IN VITRO GROWTH OF SMALL CELL LUNG CANCER WHICH CONTAINS PROHORMONE CONVERTASE 1 AND 2 mRNA. D. A. Clark R. Day, N. G. Seidah, and T.P.Davis. Dept. of Pharmacology, Univ. of Arizona Coll. of Med., Tucson, AZ 85724 USA and Clin. Research Instit. of Montreal, Montreal, Quebec H2W 1R7

Gastrin releasing peptide (GRP) functions as an autocrine growth factor in small cell lung cancer (SCLC) cells which contain GRP receptors. GRP is synthesized as a preprohormone and enzymatically processed to the active peptide in SCLC cells where we have measured the mRNA for prohormone convertase (PC) 1 and 2. In this study the effect of the specific enzyme inhibitors bestatin, Bowman-Birk inhibitor (BBI) and aprotinin on the in vitro clonal growth of two SCLC cell lines which contain GRP receptors was investigated. The cell lines NCI-H345 and NCI-N592 were mixed with a single dose of bestatin, BBI or aprotinin and incubated for 9-14 days in 35mmX10mm plastic petri dishes in a humidified atmosphere of 5% CO<sub>2</sub>/95% air. The SCLC cell colonies were counted with an automated FASII image analysis system. A dose-dependent and significant (p<0.05) inhibition of growth was observed in both cell lines with the aminopeptidase inhibitor bestatin inhibiting up to 75% of SCLC clonal growth at the 100µM dose. The trypsin-chymotrypsin inhibitor BBI inhibited up to 86% of SCLC clonal growth at 100µg/ml. Aprotinin, a trypsin inhibitor, decreased clonal growth of NCI-N592 at a dose of 100µg/ml and NCI-H345 at 500 µg/ml. A dose of 75-100µg/ml BBI also decreased GRP and proGRP radioimmunoassay levels and decreased the level of mRNA for PC1 and PC2 by 50%.

These data suggest that processing and metabolic enzymes serve an important role in regulating growth of SCLC and that enzyme inhibitors may be potent suppressors of SCLC. (Supported by NIH DK36289, HD26014 and DA06284)

INDUCTION OF PEPTIDYLGLYCINE ALPHA-AMIDATING MONOOXYGENASE (PAM) BY NERVE GROWTH FACTOR (NGF) IN PC12 CELLS. T.A. Ford and G.P. Mueller\*. Dept. Physiol., Uniformed Services

University of the Health Sciences, Bethesda, MD 20814.
Pheochromocytoma PC12 cells undergo dramatic neuronal differentiation in response to NGF. In this process gene expression is altered to establish specific neural properties. Here we sought to determine whether NGF induces the activity of PAM (EC1.14.17.3), the enzyme that  $\alpha$ -amidates neuropeptide Y, a peptide expressed during differentiation. PC12 cells were grown with or without NGF for 5-7 days to allow for maximum differentiation. Medium, whole cell extracts and soluble and membrane bound cell fractions were assayed under optimal conditions for PAM; activity was found to be primarily membrane bound (five-fold greater than soluble) and very little activity was released into the medium. As compared to control cells, PAM activity was increased significantly by NGF (0.71  $\pm$  0.03 vs. 0.49  $\pm$  0.03 pmol/ug/hr) (p<0.05). Through kinetic analysis, it was determined that the NGF-induction of PAM was due to an increase in  $V_{\text{max}}$  with no change in  $K_{\text{m}}$ . It has been previincrease in  $V_{max}$  with no change in  $K_m$ . It has been previously observed that glucocorticoids inhibit some, but not all, of the changes that occur during NGF-induced differentiation. We found that dexamethasone (DEX) decreased basal PAM activity and completely prevented its induction by NGF. Interestingly, DEX treatment did not alter the changes in cell morphology induced by NGF. These findings suggest cell morphology induced by NGF. These findings suggest that the process of differentiation in PC12 cells is a useful model for studying the expression of PAM.

'PROHORMONE THIOL PROTEASE' AND NEUROPEPTIDE PRECURSOR PROCESSING: PEPTIDE CLEAVAGE AT DIBASIC and MONOBASIC SITES, and EXPRESSION OF RECOMBINANT PROENKEPHALIN AND B-PROTACHYKININ. V.Y.H. Hook, L. Mende-Mueller+, Rama Kannan\*, and T.J. Krieger. Dept. of Biochem., Uniformed Services University of the Health Sciences, Bethesda, MD. 20814, and \*Dept. of Biochem., Medical College of Wisconsin, Milwaukee, WI.

Processing of the precursors of peptide neurotransmitters requires cleavage at dibasic (Lys-Arg, Arg-Arg, Arg-Lys, and Lys-Lys)and monobasic (Arg) sites. A novel 'prohormone thiol protease' (PTP) has been demonstrated to be involved in enkephalin precursor processing CT.J.Krieger and V.Y.H. Hook *J. Biol. Chem. 266*, 8376-8383, 1991). Examination of PTP's cleavage site specificity with the enkephalincontaining peptides peptide F, peptide E, and BAM-22P as substrates was conducted by HPLC separation of products followed by peptide microsequencing. PTP cleaved at dibasic Lys-Arg, Lys-Lys, and Arg-Arg sites, as well as at a single Arg; the preferred P1' position was Arg. These findings demonstrate that PTP possesses almost all of the necessary specificity for dibasic and monobasic sites required in neuropeptide precursor processing. To allow future characterization of PTP with authentic precursor substrates at estimated in vivo levels of precursor (requiring milligram amounts of precursor), high level expression of proenkephalin and 3-protachykinin in E. Coli has been achieved. It will be important to determine PTP's cleavage sites with authentic precursor substrates.

THE ONTOGENY OF ENZYMES INVOLVED IN THE POST-TRANSLATIONAL PROCESSING AND METABOLISM OF PEPTIDES IN THE BRAIN. M.G. Oakes\*, P.N.M. Konings and T.P. Davis. Duep. of Pharmacology, University of Arizona, College of Medicine, Tucson, AZ 85724.

We quantitated the level of activity of specific peptidases to determine if the enzymes involved in the post-translational processing and metabolism of peptides are involved in the age-related regulation of bioactive peptide levels in specific regions of the developing rat brain.

regions of the developing rat brain.

Carboxypeptidase H (E.C.3.4.17.10, CPH), a processing enzyme, showed a significant increase in activity from P0 (birth) to P7 in the hypothalamus (20.1 to 26.7 pmoles/mg protein/min) and cortex (11.5 to 18.9) but a decrease of activity in the cerebellum (19.1 to 16.2). The activity decreased in the cortex from P7 to P30 (18.9 to 15.0). CPH is expressed at high levels at birth and generally levels off after P7 to adult levels which may signify the involvement of this processing enzyme throughout the life of the rat in the synthesis of neuropeptides.

The metabolic enzymes, Metallo Endopeptidase (E.C.3.4.24.15, MEP) and Neutral Endopeptidase (E.C.3.4.24.11, NEP) do not present the same activity pattern as the processing enzyme CPH. MEP activity increased only in the cortex after birth (946.3 to 1268.8 pmoles/mg protein/min), leveled off, and then decreased in all three regions from P30 to P90. NEP activity increased in the hypothalamus after birth (1657.8 to 3080.4 pmoles/mg protein/min) but decreased in the other two regions. At P7 to P30 a significant decrease in NEP activity occurs in the cerebellum (779.0 to 319.9), no change in the hypothalamus was noted. These two metabolic enzymes are detectable at birth and may function in the degradation of peptides released. The presence of these processing and metabolic enzymes at birth and the pattern of their activity during development suggests a potential regulatory role in the production and degradation of bioactive peptides in the developing rat brain. (Supp. by NIH grant IID28310 and DA06284).

POSTTRANSLATIONAL PROCESSING OF PROENKEPHALIN IN AtT-20 CELLS: EVIDENCE FOR CLEAVAGE AT A LYS-LYS SITE. John Paul Mathis\* and Iris Lindberg. Dept. Biochem. and Mol. Biol., Louisiana St. Univ. Med. Ctr., New Orleans, LA 70112.

Proteolytic processing of proenkephalin was examined in several subclones of AIT-20 cells stably transfected with rat proenkephalin cDNA (AIT/PE cells). Proenkephalin is synthesized in both glycosylated and unglycosylated forms as demonstrated by treatment with tunicamycin. Radioimmunoassays and Western blot studies showed that AT/PE clones process proenkephalin at some but not all Lys-Arg sequences in a limited processing profile reminiscent of the chromaffin cells of the bovine adrenal gland. Pulse-chase studies using Met<sup>5</sup>-enk-Arg-Gly-Leu antiserum showed that 50% of the precursor is processed within 1 h and processing is complete after 2.5 h with the production of the 5.3 kDa peptide. Radiosequencing results verified the efficient cleavage of a Lys-Lys site within proenkephalin which resulted in the production of the 5.3 kDa peptide. Proenkephalin cleavage products stored within cells, which included the 5.3 kDa peptide, could be released upon stimulation of cells with BaCl<sub>2</sub> (2-fold above basal levels), 8-Br-cAMP or cortical releasing factor (8-fold above basal levels) and a mixture of BaCl<sub>2</sub> and 8-Br-cAMP (15-fold above basal levels). An important difference between the processing of proenkephalin and POMC in Atf-20 cells is efficient cleavage of a Lys-Lys site in proenkephalin and not in POMC. The ability of AT/PE to process proenkephalin in a natural manner makes it a suitable model system to determine whether structural elements are involved in the processing of proenkephalin at the Lys-Lys site. This work was supported by NIDDK35199.

EXPRESSION OF FOS AND CRF mRNA IN THE BRAIN OF FEMALE RATS SUBJECTED TO SINGLE OR REPEATED RUNNING SESSIONS. S. Rivest\*, S. Lee, C. Rivier and D. Richard. Peptide Biology Laboratory, The Salk Institute, La Julia, CA 22037 and Dént de Physiologie. Univ. Laval, Ouébec, Canada GIK 7P4.

Tolla, CA 92037 and Dept de Physiologie, Univ. Laval, Québec, Canada G1K 7P4. The regulation of early gene FOS and CRF biosynthesis in the rat brain by exercise and exercise-training was examined by immunocytochemistry and in situ hybridization. Exercise consisted in sessions of running on a rodent motor-driven treadmill during 2 h/day for a maximum of 21 days. Thirty min, 2, 12 and 24 h after the beginning of the first (acute exercise), the 8th (1 week of training) and the 21st exercise session (3 weeks of training), rats were sacrificed. Thirry min after the beginning of the acute running session, FOS expression was increased in several brain regions, including the arcuate nucleus, the bed nucleus of the stria terminalis, the central nucleus of the amygdala, the dorsomedial hypothalamic nucleus, the lateral hypothalamic area, the paraventricular nucleus of the hypothalamus (PVN), the suprachiasmatic nucleus and the ventral tegmental area. In the PVN, FOS was mainly located within the nuclei of CRF-immunoreactive (IR) perikarya. At the end of the acute 2 h-running session, FOS expression was still strongly activated in the above listed brains regions, and in the PVN Crosporteins were located in both the parvo- and magnocellular subdivisions. Ten h following the acute running period, FOS had largely vanished, while an increase in CRF mRNA levels was noted in the PVN. Thirty min into the 8th running session, FOS-IR cells were observed in the PVN; the number of cells expressing this gene was lower than that of rats sacrificed 30 min following the acute session. In animals subjected to exercise sessions over a 3 week period, no notable change in FOS expression was induced by the last 2 h-running period, while CRF mRNA levels in the PVN expression was induced by the last 2 h-running period, while CRF mRNA levels in the PVN acute running induced both FOS and CRF mRNA expression in the brain. The same exercise regimen did not notably influence FOS expression in the brain. The same exercise regimen did not notably inf

### 91.6

AGE-RELATED CHANGES IN THE CONTENTS OF NEUROPEPTIDES IN THE PITUITARY AND THE BRAIN OF THE RAT. F. Tang\* and Z.P. Wang, Department of Physiology, Faculty of Medicine, University of Hong Kong, Hong Kong.

Medicine, University of Hong Kong, Hong Kong.

To study the effect of age on neuorpeptide contents, male Sprague-Dawley rats aged 3 months, 12 months, and 22 months were kept on a 12 hr light: 12 hr dark lighting cycle (light on at 6:00 a.m.) and were sacrificed at 10:00 a.m. and 10:00 p.m. B-endorphin (B-E), leuenkephalin (LE), met-enkephalin (ME), substance P (SP), somatostatin (SRIF) and cholecystokinin (CCK) were measured in various brain regions and the anterior (AL) and neurointermediate (NIL) lobes of the pituitary (except SP and CCK) by RIA (Tang and Man, Neuropetides 19, 287-291, 1991). As expected, B-E, ME and LE in the NIL, and ME and LE in AL increased with age, but whereas the increases were both in the day and at night for B-E and ME, the increase for LE was at night only. Hypothalamic B-E and ME decreased with age in the day only. In addition, brainstem B-E and LE, and cortex LE decreased with age at night, and striatal LE decreased with age in the day, whereas hippocampal ME decreased with age both at night and in the day. While there was an age-related decrease in SRIF and SP in the corpus striatum and the hypothalamus only in the day, the decrease in CCK with age in the hippocampus and the hypothalamus was only confined to night levels. This study demonstrates that there are age differences in the neuropeptide levels (generally, a decrease, except for opioid peptides in the pituitary) and that these changes may follow a diurnal rhythm. As these neuropeptides may play a stimulatory or inhibitory role in neurotransmission, their changes with age and with diurnal rhythm may be related to alteration in the activity of the animal.

### 91.8

PROCESSING OF PRODYNORPHIN BY THE PROHORMONE CONVERTASES PC1, PC2 AND FURIN. R. Day\*, A.C. Dupuy, H. Akil, M. Chrétien, N.G. Seidah. Clinical Research Institute of Montreal, Montreal, Quebec, Canada, H2W 1R7 and Mental Health Research Institute, University of Michigan, Ann Arbor, MI, USA, 48109.

Institute, University of Michigan, Ann Arbor, MI, USA., 48109.

Limited proteolysis of inactive precursors at pairs of basic residues is a general intracellular mechanism utilized to produce active proteins and peptides. The convertases involved have recently been described as a family of serine proteinases of the Kex2/subtilisin type. Two of these convertases, PC1 and PC2, are primarily expressed in neural and endocrine tissues while another, Furin, is thought to be ubiquitously expressed. PC1 and PC2 have been shown to cleave POMC into β-endorphin, β-LPH, α-MSH and ACTH. Our study examines the processing of another opioid peptide precursor, prodynorphin (proDyn), by PC1, PC2 and Furin. Four pairs of basic residues are found in proDyn flanking the opioid end products, α-neo-endorphin (αNE), dynorphin A 1-17 (Dyn A 1-17) and dynorphin B 1-13 (Dyn B 1-13). A recombinant vaccinia virus (VV) vector was used to co-express PC1, PC2 and Furin together with proDyn in the constitutively secreting cell line BSC-40 and in the endocrine tissue-derived cell lines PC12 and AtT-20. ProDyn processing was monitored in cells and media, before and after separation by HPLC with RIAs to αNE, Dyn A 1-17, and Dyn B 1-13. Our results demonstrate partial proDyn processing by one or more enzymes present endogenously in each cell line tested and that Dyn AB 1-32 was the major product. However, the proDyn processing pattern was modified when the cells were also infected with each VV:convertase. A differential processing profile was obtained with each enzyme. Our data demonstrate the distinct cleavage specificities of PC1, PC2 and Furin in proDyn processing of proDyn.

# 91.10

PROCESSING OF CHOLECYSTOKININ IN THE SK-N-MCIXC CELL LINE P.N.M. Konings\*M.C.Beinfeld, M.J.C. Hendrix, R. Day, N.G. Seidah, B. J. Merrill and T.P. Davis, Dept. of Pharmacol and Anatomy, Univ. of Arizona, Tucson, 85724, Univ. Med. Center, St. Louis, Dept. of Biochem., CRI of Montreal, Quebec.

The human cholinergic neuroepithelioma cell line SK-N-MCIXC, expresses high levels of cholecystokinin (CCK) mRNA, with a robust band of approximately 0.8 Kb as shown with Northern Blot analysis. CCK mRNA is translated by the SK-N-MCIXC cells into proCCK fragments e.g. glycine extended CCK and bioactive amidated CCK, as detected by HPLC coupled to RIA using region specific antibodies of proCCK and CCK. Immunohistofluorescence demonstrated the presence of glycine extended CCK in distinct storage granules of SK-N-MCIXC cells which were grown on coverslips. The immunostaining was blocked by preincubation of the antibody with the glycine extended CCK peptide sequence showing the specificity of the staining.

staining.

To identify candidate processing enzymes in the SK-N-MCIXC cell line, the presence of mRNA for the intracellular processing enzymes, prohormone convertase 1 and 2 (PC1, PC2), and Furin were measured using Northern Blot analysis. As for PC1, we observed one band migrating at 4.0-4.2 Kb. This pattern was also found in human tissue. We observed two bands for PC2 of approximately 2.8 and 4.8 Kb in the SK-N-MCIXC cells, as was previously found in brain and pituitary. Furin appears as a band of 4.4 Kb. PC1, PC2 and Furin are subtilisin-like enzymes which preferentially cleave prohormones at the carboxyl side of pairs of basic amino acid residues. The abundance of PC1-, PC2-, and Furin mRNA suggests that these enzymes cleave at the dibasic amino acid pair Arg-Arg of the C terminal part of proCCK, as is predicted from the most frequent proprotein processing motifs. (Supported by grants DK 36289, MH 42600, HD 26013 to T.P.D., NS 18667 to M.C.B., MRC of Canada grant MT 11268 to R.D.)

HALOPERIDOL AND CHLORPROMAZINE TREATMENT ALTERS NEUTRAL ENDOPEPTIDASE 24.11 ACTIVITY IN NUCLEUS ACCUMBENS AND CAUDATE PUTAMEN. Thomas P. Davis\*Mary Oakes and P.N.M. Konings. Department of Pharmacology, University of Arizona College of Medicine, Tucson, AZ. 85724

Dopamine receptor blockade by chronic haloperidol or chlorpromazine treatment can affect both CCK- and neurotensin levels in specific regions of

Dopamine receptor blockade by chronic haloperidol or chlorpromazine treatment can affect both CCK- and neurotensin levels in specific regions of the rat brain. Haloperidol and chlorpromazine treatment has also been shown to alter central peptide metabolism/degradation (Konings et al. Eur. J. Pharmacol. 1990:191:115-128). In the present study, the effects of two doses of haloperidol (1 or 3 mg/Kg per day) and chlorpromazine (4 or 20 mg/Kg per day) were studied on the activity of the mammalian ectoenzyme neutral endopeptidase 24.11 (NEP) in nucleus accumbens, caudate putamen and hypothalamus. The contribution of NEP to neurotensin metabolism is markedly elevated in caudate putamen as compared to nucleus accumbens (Davis et al. J. Neurochem. 1992:58:608-617). Chronic haloperidol treatment (1mg/Kg per day x 12d) significantly increased NEP activity in caudate putamen. No effect was noted in hypothalamus. The increase in membrane associated NEP activity after haloperidol and chlorpromazine treatment may lead to increased peptide metabolism/degradation of synaptically released neuropeptides including the putative neuroleptic peptides CCK and neurotensin. (Supported by N.I.H. grants MH42600 and DA06289).

PROTEIN CHARACTERIZATION BY AMINO ACID HYDROLYSIS: NEW SO-LUTIONS. L.R.Murthy\*. Dept. of Psych., Mt. Sinai/VA Medical Center, Bronx, New York 10468.

My studies on the nature of phosphoamino acids in phos phoproteins from Alzheimer's disease brains poses some methodological problems, when phosphoproteins are hydrolysed in 6N HC1 at 100°C, such as incomplete hydrolysis of proteins, degradation of labile amino acids and conversion of some amino acids through dephosphorylation and deamination. Therefore, I developed an enzymatic hydrolysis procedure for phosphoproteins to overcome these problems. B Casein, a phosphoprotein, is subjected to enzymatic hydrolysis by incubation at ambienttemperature, with a series of proteases, endo and exopeptidases. These enzymes are coated on a solid support such as nitrocellulose(NC) or polyvinylidene difluoride membrane (PVDF). PVDF exhibits higher enzyme retention than NC. Proteases and peptidases bound on a solid support prevent the digestion of one protease or peptidase by another. The reaction between the protease and peptidase coated membranesand B casein in solutionare terminated by removing the enzyme coated membranes from the protein hydrolyzate. The latter along with the corresponding blank are derivatized with phenylisothiocyanate and subjected to HPLC analysis. This hydrolyzed B casein showed enhanced phosphoamino acid Jevel as compared to that hydrolysed with 6N HC1 at 100°C for 4 hours.

### 91.12

CHARACTERIZATION OF A NOVEL DBI PROCESSING PRODUCT PRESENT IN RAT BRAIN EXTRACT.

E. Slobodyansky', V.Sarisky, M.Whalin and E.Costa. Fidia-

Georgetown Institute for the Neurosciences, Georgetown University Medical School, 3900 Reservoir Rd., N.W., Washington, D.C. 20007. Some of the biological actions of DBI might be mediated by specific DBI processing products. Extracts from rapidly fixed rat brain contain a number of DBI processing products; some of them interact with an antibody raised against DBI 33-50 (ODN) which is termed anti-ODN. One of them, TTN (DBI 17-50)(J.Neurochem. 53:1276, 1989) displaces both <sup>3</sup>H-4-chlorodiazepam and <sup>3</sup>H-isoquinoline carboxamide (3H-PK 11195) from a mitochondrial DBI receptor (MDR) that regulates mitochondrial steroidogenesis in glial and endocrine cells. Using HPLC and anti-ODN immunoaffinity chromatography, we purified from rat brain extract another ODN-LI peptide and established its sequence as DBI 39-75. The estimated amount of DBI 39-75 in rat brain is 5-10 pmol/mg prot. Direct binding of <sup>125</sup>I- DBI 39-75 to crude synaptic membranes reveals the presence of high affinity binding site(s). This view is supported by bifunctional crosslinking of <sup>125</sup>I-DBI 39-75 in pmole amount that shows two major crosslinking species(around 22 and 50 kDa), which appear to be displaced by cold DBI 39-75. The <sup>125</sup>I-DBI 39-75 binding profile to mitochondrial preparations from brain, adrenals and kidney will be presented.

BRIGHT LIGHT SUPPRESSES MELATONIN AND IMPROVES COGNITIVE PERFORMANCE DURING NIGHTTIME HOURS IN HUMANS P Hannon\*, G Brainard, R Childs, W Gibson, J French, J Hanifin and M Rolle, Northern Arizona University, Coll. of Health Prof., Flagstaff, AZ,86011; Armstrong Laboratory/CFTO-Brooks AFB, Jefferson Medical College, and Uniformed Services University-Health Sciences.

This study assessed the effects of bright light on biological and behavioral measures to determine if bright light can reduce fatigue and enhance human work performance. Female subjects (N=37) were exposed to one of 3 lighting conditions in a between groups research design. Subjects in the bright light groups were exposed to 5000 lux white light from 1800 hrs to 2400 hrs (Early Bright) or from 2400-6600 hrs (Dim Red). Blood samples were taken every 90 minutes. Repeated measures ANOVA indicated a significant interaction effect (light x time) for tympanic temperature, (F=3.339, p=.001). The bright light conditions maintained higher tympanic temperatures from 2300 hrs through 0400 hrs. Plasma melatonin measures indicated a main effects difference of F=4.009, p=.029. Most importantly, the results showed that the "light" x "time of night" interaction was significant at F=59.436, p=.000. The suppression of plasma melatonin was greatest from 2230 hrs through 0500 hrs in the Early Bright and Late Bright groups. Cortisol was not affected by the ambient lighting conditions. Dim red light resulted in higher scores on the Stanford Steep Scale from 2400 hrs through 0500 hrs (light x time, F= 2.595, p=.023). Subjects under the bright light conditions performed better on the cognitive measures of Code Substitution accuracy (F= 3.918, p=.030) and Column Addition accuracy (F=4.660,p=0.17). These datas show some improvements in cognitive performance and alertness associated with bright light exposure and occur with changes in tympanic temperature and plasma melatonin at critical time periods. Supported by Dept. of Defense Grant(DOD 88450-1384), USAFOSR Grants (AFOSR 89-0164, 90-0305 and 91-0271) to PH; and USUHS Grant #R07049 to MR.

# 92.2

EFFECTS OF VARYING DOSES OF EXOGENOUS MELATONIN ON HUMAN DIURNAL MOOD AND PERFORMANCE. A.B. Dollins, H.J. Lynch, M.H. Deng, K.U. Kischka, R.E. Gleason, H.R. Lieberman\*, and R.J. Wurtman. Department of Brain and Cognitive Sciences, Massachusetts Institute of Technology, Cambridge, MA 02139.

We examined the effects of 10, 20, 40, and 80 mg of melatonin or

We examined the effects of 10, 20, 40, and 80 mg of melatonin or placebo, administered at 1145 h, on mood, performance, and oral temperature in 20 healthy male volunteers. Subjects were studied between 0930 and 1700 h on each of five separate occasions. They completed a battery of interactive computer tasks designed to assess performance and mood, the sequence and timing of which were held constant across test days. Temperature was assessed and blood samples were taken at regular intervals. Melatonin concentration was measured by radioimmunoassay. Melatonin levels (area under the time-melatonin concentration curve, AUC) differed significantly in response to the various doses. Mean AUC for the 0, 10, 20, 40, and 80 mg doses were 60, 12228, 27186, 52557, and 106223 pg/ml/7 h, respectively. All melatonin doses, relative to placebo, significantly decreased: oral temperature; number of correct responses on Wilkinson Auditory vigiliance; response latency on Four Choice reaction time; and self-reported Vigor (Profile of Mood States [POMS] questionnaire). Melatonin also increased self-reported Fatique, Confusion, and sleepiness (POMS) and Stanford Sleepiness Scale). Differences were not detected among the melatonin doses. Since no temperature, mood, or performance differences resulted from the melatonin doses tested, the dose of oral melatonin necessary to cause significant short term sedative-like effects may be lower than previously believed.

MORNINGNESS/EVENINGNESS IS HERITABLE M.D. Drennan, UCSD Dept. of Psychiatry, San Diego, CA 92126.
The study investigated heritability (H) of the Horne-Ostberg morningness-eveningness scale score

Horne-Ostberg morningness-eveningness scale score (H-O) in humans. Questionnaires were sent to 600 twin pairs, ages 18-40 years from the Kaiser-Permanente twin registry. Questionnaires from both has were received from 238 twin pairs. A twoquestion matrix classification system (Hrubec, 1976), identified 146 twin pairs as monozygotic, 74 dizygotic, and 18 unclassified. A nonsignificant dizygotic, and 18 unclassified. A nonsignificant ratio of the sum of mean squares (F=1.06, p=.69) showed monozygotic and dizygotic variances to be equal. The classical heritability method (H= 2 x (Rmz-Rdz)) yielded a H=.56 (p<.05), with H=.48, p=.07 in females and H=.54, p=.08 in males. The within-pair estimate of genetic variance method yielded H=.48, p<.05, with H=.41, p=.09 in females and H=.50, p=.11 in males. Deleting pairs with current use of psychotropic medications, illegal drugs more than 3x/wk, or persons using alcohol more than 14 drinks/wk made no difference in H. Results support the concept that a large proportion of morningness/eveningness in humans is determined by heritable factors. Expressed human circadian phase may be influenced by genes. Supported by a NARSAD Award, and VA Research Fellowship to MDD.

DYNAMIC ANALYSIS OF RESPIRATORY PATTERNING DURING SLEEP AND WAKING STATES IN INFANTS. S.L. Raetz.\* J.P. Wisor, V.L. Schechtman & R.M. Harper. Brain Research Institute and Dept of Anatomy & Cell Biology, UCLA, Los Angeles, CA 90024-1763.

Respiration undergoes marked patterning changes during the first few months of life. These changes include maturation of overall, as well as instantaneous, rate and variability during each sleep-waking state. Assessment of momentary respiratory changes provides important information about the nature of respiratory control. Thus, we characterized respiratory dynamics in normal infants using Poincaré procedures, a nonlinear method for assessing moment-to-moment interval changes. Recordings, consisting of electrocardiogram (ECG) and respiratory measures from 13 normal infants (2 - 63 days of age), were obtained over a 12 hr period. Each one-minute epoch was defined as waking (AW), quiet sleep (QS), or rapid-eye-movement (REM) sleep by a previously-developed state-classification system based upon ECG criteria. For each infant, 20 min of data from each sleepwaking state were randomly selected for analysis, and breath-to-breath intervals (BBI) were calculated from the respiratory signal. Each breath-to-breath interval (BBI<sub>n+1</sub>) within a particular sleep-waking state was plotted against the previous interval (BBIn) resulting in a Poincaré plot. Increased one breath - next breath dispersion and enhanced overall variation occurred during REM sleep when compared to QS and AW in all infants. The most marked characteristic of dynamic change occurred during AW; in younger infants (< 1mo), higher breathing rates were associated with diminished next-breath variation relative to lower rates. However, older infants showed similar next-breath dispersion at both high and low breathing rates. These data suggest that the influence of mechanisms underlying respiratory variation is diminished at higher breathing rates in younger infants. (Supported by HD22695)

DIMENSIONALITY OF THE ELECTROENCEPHALOGRAM IN ALPHA COMA DIFFERS FROM THAT OF AWAKE ALPHA

Y.W.Kim<sup>+</sup>, K.K.Kreible<sup>+</sup>, A.D.Rae-Grant<sup>#</sup>, and W.T.Blume<sup>\*</sup>, + Lehigh University, Bethlehem, PA 18015, # Lehigh Valley Hospital, Allentown, PA 18103, \* University Hospital, London, Ontario, Canada

The electroencephalogram (EEG), as a probe of scalp-recorded electrical activity arising from the cortex of the human brain, provides useful clinical information because of its temporal and spatial organization. As such, a measure of the organization embedded in the EEG pattern may characterize the state of consciousness. Recent developments in nonlinear dynamics suggest that an object can be constructed in an n-dimensional space out of a temporal sequence of data such as an EEG signal and that its organization is characterized by the dimensionality of the object. We have carried out such an analysis for a set of alpha coma EEG patterns in comparison to the EEG patterns of normal individuals. Alpha coma recorded from a single channel is visually indistinguishable from normal resting alpha rhythm. The results show that the alpha coma dimensionality reaches an asymptotic value of 5.5± 0.2 when the dimensionality of the space is increased to as large as 16. The normal EEG dimensionality, on the other hand, reaches 7.3±0.2 at the same maximum n value of 16, and is still growing without any sign of saturation. This is entirely consistent with the fact that the EEG patterns show increasingly rhythmic organization as the level of consciousness diminishes. The change in dimensionality commensurate with the clinical condition suggests it is possible not only to quantify but also to model the EEG by nonlinear methods.

EFFECTS OF CORTICOTROPIN-RELEASING HORMONE ADMINISTRATION IN PATIENTS SUFFERING FROM SLEEP APNEA SYNDROME. K. Mann, J. Röschke, M. Nink, J. Aldenhoff, J. Beyer, O. Benkert, H. Lehnert\*. Dept. of Psychiatry and Dept. of Endocrinology, University of Mainz, D-6500 Mainz, Germany.

Corticotropin-releasing hormone (CRH) is known to be a centrally acting respiratory stimulant after systemic application. centrally acting respiratory stimulant after systemic application. In a previous study this respiratory analeptic effect has been shown in normal subjects during sleep. We now extended these investigations to patients suffering from sleep apnea syndrome. Up to now 5 male patients aged 41 to 56 years participated. After an adaptation night polysomnography (EEG,EOG, EMG, ECG) was performed in two successive nights between 23.00 h and 7.00 h. While in one night placebo was applied, in the other night ovine CRH was administered intravenously as a bolus of 50 ug every hour from 0.00 h to 6.00 h. For assessment of respiration blood oxygen saturation and thoracic wall movements were measured as well as nasal and oral air flow by the thermistor method.

In all 5 patients the number of apnea periods per night was reduced under CRH. Blood oxygen saturation was clearly increased following CRH injection. The effect on sleep EEG parameters was not uniform. In most cases total sleep time was reduced with decrease of stage II and REM. In 3 patients a clear increase of slow wave sleep could be observed. Our data suggest a possible therapeutic value of CRH in sleep apnea syndrome.

## 92.6

DIMENSIONALITY OF **SLEEP EEG** DATA

DIMENSIONALITY OF SLEEP EEG DATA IN SCHIZOPHRENIA AND DEPRESSION J. Röschke and J. B. Aldenhoff\* Dept. of Psychiatry, University of Mainz, 6500 Mainz, Germany.

Neuropsychiatric sleep research has to deal with the problem that the brain's electrical activity seems to contradict the causality principle. One reason might be that the time history of the sleep EEG during a certain sleep stage is not predictable over a longer time period. Recently, it has become clear that under selected conditions unpredictability is a basic phenomenon of nonlinear dynamical systems, which are able to generate "deterministic chaos".

chaos". One of the commonly used attempts to investigate the behavior of dynamical systems is to measure the dimensionality of their attractors in phase space. Following a proposal of Grassberger and Procaccia we estimated the correlation dimension D<sub>2</sub> of different EEG epochs (n=16384 data points, f<sub>s</sub>=100 Hz), each an unambigeous representative collection of one of the sleep stages II, III, IV and REM.

In schizophrenia (n=11, Cz) we found a slightly higher dimensional attractor during slow wave sleep and a significant decrease of the dimensionality of sleep stages II and REM. On the contrary, we found in depression (n=9, Cz) a significant increase of the dimensionality of every sleep stage.

These results point out that the complexity and the degrees of freedom of the sleep EEGs of schizophrenic and depressive patients depict alterations, which cannot be obtained from conventional sleep EEG analysis.

EYE MOVEMENTS DURING PARADOXICAL SLEEP IN GUINEA PIG. M. Escudero and P.P. Vidal. Lab de Neurociencia, Univ. de Sevilla, Sevilla, Spain; and Lab. de Physiologie Neurosensorielle, C.N.R.S.

Paris, France.
As the eye motor system is not inhibited during paradoxical sleep (PS), it is interesting to characterize and compare eye movements in both PS and wakefulness. Animals were chronically implanted for EMG and EEG recordings. Eye movements were measured by the scleral search technique. During PS two different types of eye movements were detected: one was similar to spontaneous were detected; one was similar to spontaneous saccades during wakefulness, although with higher amplitudes and velocities; the other consisted of an oscillatory eye movement of high velocity and amplitude, different from any eye movement observed during wakefulness. During the oscillation, the eyes described an ellipsoidal movement with a mean frequency of 10.8 Hz. Periods of oscillatory and saccadic-like eye movements during call atory and saccalic-like eye movements during each episode of PS sleep showed a similar temporal distribution with a mean duration of 1.2 s. These results suggest that during PS the oculomotor system is characterized by an oscillatory behavior with a temporal pattern similar to that shown by the EEG recording during slow wave sleep. Supported by "Acc. Integ. Hispano-Francesa"/225B grant.

Alterations of Circadian Period by Acute Infusion of Amyloid Peptide into the Suprachiasmatic Nuclei (SCN) <u>B.A.Tate\*, M.K.Lee and C.A.Marotta</u>, Harvard College, Massachusetts General Hosp. and Harvard Med. Sch., Boston, MA 02114

The manifestations of Alzheimer Disease (AD) include dramatic disruption of circadian behaviors. The exact role of amyloid in the behavioral pathology of AD is not yet defined, but amyloid accumulation in brain is a hallmark of the disorder. Here we examined the effects on circadian rhythmicity of acute injections of amyloid into the rat SCN. Adult, female Sprague Dawley rats were implanted with stereotaxically placed injection cannulae and intraperitoneal Minimitters transmitters, by which activity was constantly monitored. Subjects housed in dim, constant light expressed normal free running rhythms. Amyloid peptide (amino acids 1-28, Peninsula Labs) or vehicle (8% DMSO) was injected bilaterally into the SCN at circadian time 13 on two consecutive days. Period, determined by periodogram analysis, was altered by amyloid. Amyloid may alter period by toxicity or disruption of normal cellular interactions. A similar phenomenon may occur in AD. Supported by POlAGO2126.

Forty Hz membrane potential oscillations and theta-like activity in basal forebrain neurones. M. Mühlethaler, A. Khateb, P. Fort, B.E. Jones\*, and A. Alonso\*, Dept. of Physiology, CMU, 1211 Geneva 4, Switzerland and Montreal Neurological Institute, McGill University, Canada H3A 2B4

We have recently demonstrated the distinct electrophysiological properties of identified cholinergic neurones in the substantia innominata of the basal forebrain using guinea-pig brain slices (Khateb et al., this meeting). We now report the presence in the same area of another class of cells, as yet chemically unidentified, which displays a different set of membrane properties and a very different firing pattern. These neurones, which represented approximately 1/3 of cells encountered, were characterized by the presence of a more or less prominent A-like current and a short, deep after-hyperpolarization. When they were depolarized from rest, they displayed subthreshold membrane oscillations interspersed with clusters of (3-10) action potentials. The frequency of either the subthreshold oscillations or the spikes within a cluster was within a range of 20-60 Hz and was often close to 40 Hz. The frequency of occurrence of the clusters themselves was voltage dependant and ranged from 2-10 Hz. In some cells, a further depolarization was associated with a tonic high frequency firing pattern. Although the chemical identity of these neurones remains to be established, preliminary immunohistochemical evidence suggests that biocytin injected cells having these characteristics are non-cholinergic. Given their spectrum of activity, this class of basal forebrain neurones could drive different rhythms in target structures, such as the cerebral cortex, that would include slow rhythms within the theta range (cluster pattern of firing) and fast rhythms within the gamma range (tonic mode of firing). NMDA RECEPTOR ANTAGONISTS PREVENT CARBACHOL-INDUCED PHASE SHIFTS IN THE CIRCADIAN RHYTHM OF LOCOMOTOR ACTIVITY IN THE HAMSTER. C.S. Colwell\*, C. Kaufman, and M. Menaker. NSF Center for Biological Timing, Biology, Univ. of Virginia, Charlottesville, VA 22901.

A variety of evidence now indicates that excitatory amino acid receptors mediate the effects of light on the circadian system of mammals. However, in mammals, the acetylcholine agonist carbachol is the only agent which has been reported to "mimic" the phase shifting effects of light in vivo. In the present study, we found that the administration of NMDA receptor antagonists could prevent carbachol-induced phase shifts of the circadian rhythm of wheel-running activity recorded from the golden hamster. In addition, we found that carbachol, unlike light, does not cause an induction of Fos-like immunoreactivity in the suprachiasmatic nucleus (SCN) of these animals. A simple explanation for the data presented in this paper is that the intraventricular administration of carbachol causes phase shifts through a pathway distinct from that of light. Alternatively, if carbachol is acting via the light-input pathway, then it does so by a mechanism independent of Fosinduction in the SCN. In either case, elucidating the mechanisms by which carbachol acts in the circadian system may provide novel insights into the cellular mechanisms by which phase shifts are generated.

DEGENERATIVE DISEASE: ALZHEIMER'S-OTHER

## 93.1

RARLY DETECTION OF ALZHEIMER'S DISEASE (AD) USING REGIONAL CEREBRAL GLUCOSE METABOLIC (rCMRglc) DATA OBTAINED BY POSITRON EMISSION TOMOGRAPHY (PET). N.P. Azari\*, K.D. Pettigrew², M.B. Schapiro¹, P. Pietrini¹, J.A. Salerno¹, C.L. Grady¹, J.V. Haxby¹, S.I. Rapoport¹ and B. Horwitz¹ ¹Lab. of Neurosciences, NIA/NIH, ²Division of Applied and Services Research, NIMH/NIH, Bethesda, MD 20892

Correlational analysis of resting (eyes/ears covered) rCMRglc PET data has shown reduced rCMRglc interactions in mildly/moderately demented patients with probable AD. Individual differences in patterns of rCMRglc may be important for the early detection of AD, particularly in subjects at-risk (family history of AD). Using multiple regression and discriminant analysis to assess individual differences in patterns of rCMRglc, we compared resting rCMRglc PET data from probable AD patients and age-matched controls. The aim was to find a discriminant function that would successfully separate the AD patients from controls, and detect an AD pattern of rCMRglc in the first scan of an at-risk subject diagnosed as possible AD (who later developed probable AD). A discriminant function correctly classified patients and controls, and classified the first scan of the at-risk subject as AD. The results suggest that this statistical procedure may be useful for the early detection of AD.

# 93.2

LONGITUDINAL CT STUDY OF CEREBRAL CSF VOLUME CHANGES IN ALZHEIMER'S DISEASE. P.K. Shear, E.V. Sullivan, D.H. Mathalon, K.O. Lim, L.F. Davis, J.A. Yesavage, J.R. Tinklenberg, and A. Pfefferbaum\*. Dept. of Psychiatry and Behavioral Sciences, Stanford University School of Medicine and DVA Medical Center (116A3), Palo Alto, CA 94304.

Neuroimaging studies have documented marked cerebral atrophy in patients with Alzheimer's Disease (AD). Few studies, however, have quantified *in vivo* longitudinal progression of cerebral atrophy. The present study examined change in volumetric brain CT indices for 41 AD subjects (26 men; 15 women; mean age 70.6±7.6 years) and 39 normal controls (NC) (24 men; 15 women; mean age 70.6±7.6 years). All participants completed two CT assessments (mean interscan interval: AD=2.1±1.0; NC=2.6±0.9 years). The AD patients met NINDS-ADRDA criteria for probable or definite Alzheimer's Disease and had a mean MMSE score of 17.5±5.6 (max=30 points) at baseline assessment. A semi-automated image analysis technique was used to quantify the CSF volume in each of four regions of interest (ROIs): frontal sulci, Sylvian fissures, parieto-occipital sulci, and the ventricular system. In comparison with the NC group, the AD group had significantly higher baseline CSF volumes in all ROIs (p<.001 for all comparisons). Mean CSF volume change per year over the interscan interval was computed as a slope for individual subjects on each ROI. A MANOVA performed on these slopes, with diagnosis and sex as grouping factors, revealed significantly more rapid progression of CSF volume abnormalities in the AD group, relative to the NC group (p<.001). No significant sex effects or interactions were identified. A final series of multiple regressions identified group differences in the relationship between age at first scan and rate of CSF volume change in the frontal correx (p<.03) and the ventricular system (p<.01). Specifically, younger AD patients exhibited more rapid progression than did the older patients; this negative correlation between age and slope was not present in the NC subjects. UBIQUITIN IMMUNOREACTIVITY IN CEREBROSPINAL FLUID (CSF) AND BRAIN TISSUE IN ALZHEIMER DISEASE. T. Kudo¹, K. Iqbal¹. R. Ravid², D.F. Swaab², and I. Grundke-Iqbal¹. ¹New York State Institute for Basic Research in Developmental Disabilities, New York, N.Y. 10314. ²Netherlands Brain Bank, Netherlands Institute for Brain Research, Amsterdam, The Netherlands.

Alzheimer disease (AD) is a neurodegenerative disorder with progressive dementia. At present neither the etiology nor the pathogenesis of this disease are understood. Previous studies have shown an association of ubiquitin with the cytosketetal protein pathology in AD. In the present study we report (i) the quantitation of ubiquitin immunoreactivity in CSF from histopathologically confirmed AD and control cases, using a rapid competitive immunoassay, the enzyme-linked immunofiltration assay and (ii) the determination of the ubiquitin levels in brain tissue taken from the same case, using a competitive ELISA. These studies were carried out using monoclonal antibody 5-25 as the primary antibody. This antibody, which was raised against isolated paired helical filaments, reacts with the carboxy terminal residues 64-76 of ubiquitin. Because ubiquitin is conjugated to other proteins through the carboxy terminal, the epitope that 5-25 recognizes is likely to be less prone to proteolysis. Preliminary results show that ubiquitin immunoreactivity is significantly higher both in AD CSF and brain than the corresponding values from normal control cases. There is some correlation between CSF and brain tissue ubiquitin levels. These studies suggest that ubiquitin is elevated in the central nervous system of AD patients and that the ubiquitin level in CSF most likely reflects that in brain tissue. INTRACELLULAR INJECTIONS REVEAL THE RELATIONSHIP OF GRANULE CELL DENDRITES TO NEURITIC PLAQUES IN ALZHEIMER'S DISEASE. G. Einstein\* and B. Crain. Depts. of Neurobiology and Pathology. Duke University. Durham, NC 27710. The hallmark of Alzheimer's Disease (AD) is the formation of neuritic

The hallmark of Alzheimer's Disease (AD) is the formation of neuritic plaques. Within the fascia dentata these are distributed in a characteristic laminar pattern in the molecular layer. Since granule cell (GC) dendrites innervate this region heavily, we wondered if GC dendrites underwent morphological changes in the vicinity of the plaques and if, in fact, they might participate in plaque formation. We therefore looked at the relationship of GC dendrites to plaques in 5 patients with AD and 4 agematched controls. Tissue was obtained within 1 hour post-mortem from the Rapid Autopsy Program of the Joseph and Kathleen Bryan Alzheimer's Disease Research Center, immersion fixed, and sectioned at 300 µm on a vibratome. In these slabs, GC were filled intracellularly with Lucifer Yellow. To visualize plaques, slabs with filled cells were resectioned on a freezing microtome and stained with Thioflavin S. Whether they were located under plaques or in plaque-free regions, GC dendrites in AD cases were shrunken and showed a severe loss of spines compared to controls. Dendrites were swollen and dystrophic and, in some cases, bore few or no spines. However, these changes did not seem to be caused directly by the plaques since filled dendrites often stopped short of or were pushed to the sides of plaques, and when they entered plaques there was no sprouting or hypertrophy. In sum, GC dendrites appear relatively unaffected by senile plaques and probably do not participate in their formation. Instead, GC changes seen in AD most probably result from deafferentation. Supported by NIH grants AG 09216 and AG 05128.

MIDKINE PROTEIN (MK) AND HEPARIN-BINDING NEUROTROPHIC FACTOR (HBNF): HOMOLOGOUS PROTEINS WITH DIFFERENT DISTRIBUTIONS IN ALZHEIMER'S DISEASE. E.G. Stopa\*, I. Kovesdi, V. Kuo-LeBlanc, A. Baird and P. Böhlen. SUNY HSC, Syracuse, NY 13210, The Whittier Institute, LaJolla, CA 92037 and American Cyanamid Corp., Pearl River, NY 10965.

Midkine protein (MK) and Heparin-Binding Neurotrophic Factor (HBNF) are two recently identified heparin-binding proteins which share approximately 60% sequence homology. Their biological roles have not yet been determined, but they are thought to be involved in embryogenesis and brain function. Since Basic Fibroblast Growth Factor (bFGF), another heparin binding protein, is abnormally increased in Alzheimer's disease (AD), we examined the distribution of MK and HBNF to determine if they may also be altered in this disease. The immunocytochemical procedures were performed on 50 µm sections of prefrontal cortex, basal ganglia, thalamus and hippocampus fixed in either 4% paraformaldehyde or 10% neutral buffered formalin. Free-floating sections, obtained from 5 control and 4 AD cases, were incubated in specific polyclonal antibodies raised against MK and HBNF, and used at a dilution of 1/1000. Staining was accomplished using a modified ABC technique. The most intense staining for both proteins was seen within the ependyma. HBNF immunoreactivity was also readily observed in endothelial cells. Faint staining for both proteins was seen in cortical neuropil and selected neurons and astrocytes. MK-like immunoreactivity was extremely robust within the senile plaques and neurofibrillary tangle bearing neurons of the AD cases examined, whereas HBNF did not stain these structures. Our observations biological roles, and that MK is abnormally distributed in Alzheimer's disease. AG10682 suggest that despite their structural homology, these proteins may have different

DISTINGUISHING FEATURES OF POTASSIUM CHANNELS IN FIBROBLASTS FROM ALZHEIMER, AGED AND YOUNG DONORS. R. Etcheberrigaray, G.E. Gibson, E. Ito, K. Oka, B. Tofel-Grehl & D.L. Alkon, Neural Systems Section, NINDS, National Institutes of Health, Bethesda, MD 20892 and The Burke Medical Research Institute, Cornell Medical College, White Plains, NY 10605. Since memory impairment is characteristic of Alzheimer's disease (AD), we

Since memory impairment is characteristic of Alzheimer's disease (AD), we examine here previously implicated biophysical substrates of memory storage, K⁺ channels (Alkon et al., Science 1982), in fibroblasts from AD and control patients. Different cell lines from AD, aged matched controls (AC) and young donors (YC) were plated in 35 mm. petri dishes. Patch-clamp recordings were obtained only in the pre-confluent stage, 2-4 days after plating. Electrodes were filled with a high K⁺ solution (140 mM K⁺). Cell-attached patches obtained from AD cell lines were silent in 7 out of 11 cells, while no silent patches were found in lines from YC (n=6) or AC (n=2). In the cell-attached comfiguration, the channel seen in YC has a slope conductance (determined by linear regression) of 111 pS and at 0 mV pipette potential remains mostly in the open state with relatively brief and rapid closures. Its % open time is 74.6±3.49 (mean±S.E., n=4, ≥ 3,200 events each). The K⁺ channel observed in the AD lines exhibited larger unitary currents and larger conductance (172 pS) than the channel from YC, and has a % open time of 7.28±1.64 (n=3), significantly lower than YC, p<0.0001. The channel observed in cells from AC has a conductance of 116 pS, which is very similar to the conductance found in cells from YC donors. Its pattern of activity and % open time (61.96±2.67, n=2) are also similar to those of the YC channel. A small channel (≈ 1.8 pA at 0 mV. pipette potential) has been also seen in all three cell lines, with no apparent differences. Initial observations in inside-out patches have also suggested differences in Ca²+ sensitivity between YC and AD. These preliminary observations may lead to new insights regarding memory impairment and pathogenic mechanisms in AD.

## 93.6

IDENTIFICATION OF THE TRANSITIONAL AND END-STAGE FORMS OF THE NEUROFIBRILLARY TANGLE IN NORMAL AGING AND ALZHEIMER'S DISEASE J.C. Vickers. A. Delacourte\* 1 and J.H. Morrison Fishberg Research Center for Neurobiology, Box 1065 Mount Sinai Medical Center, New York. N.Y. 10029, U.S.A. 1 INSERM U156, Place de Verdun, 59045 Lille, France.

Many of the clinical features of Alzheimer's disease are likely to reflect the progressive and selective degeneration of the neuronal subclasses that provide the association pathways of the neocortex and interconnect the hippocampal formation with the rest of the brain. The neurons in the entorhinal cortex and neocortex that are particularly vulnerable to neurofibrillary tangle (NFT) formation are characterized by their selective labelling for the neurofilament (NF) protein triplet class of intermediate filament proteins. Thioflavine S staining was combined with double labelling immunofluorescence for tau and the NF proteins to demonstrate the progressive alteration of the normal neuronal cytoskeleton into NFTs within these vulnerable subclasses of neurons. Transitional NFTs were identified by their thioflavine staining and the presence of tau and both phosphorylated and non-phosphorylated NF protein epitopes, whereas end-stage NFTs were stained with thioflavine but lacked NF and tau epitopes. Transitional pathology was present in the entorhinal cortex of neurologically normal controls with no NFTs in the neocortex (47 years of age +), whereas Alzheimer's disease was characterized by end-stage pathology in the entorhinal cortex and a mixture of end-stage and transitional pathology in the prefrontal neocortex. These data suggest that the cellular correlate of dementia may be the point at which cytoskeletal changes progress from transitional to end-stage in the entorhinal cortex, and begin to involve a large enough contingent of neocortical pyramidal cells to affect corticocortical integration. ABNORMALITIES OF THE CALPAIN-CALPASTATIN SYSTEM IN ALZHEIMER BRAIN. R. A. Nixon, K.-I. Saito, A. M. Cataldo, J. Hamos, D. Hamilton, T. Honda and A. Pope\*. McLean Hospital and Harvard Medical School, Belmont, MA 02178

Calcium-activated neutral proteinases (calpain or CANP) are key enzymes in intracellular signaling cascades and potential mediators of calcium-induced cell injury. The enzyme form requiring micromolar calcium levels ( $\mu$ CANP), which is enriched in neurons, has been most frequently implicated. As an index of changes in the *in vivo* activity of  $\mu$ CANP, the ratios of the activated isoforms of  $\mu$ CANP to the precursor isoform were measured immunochemically in regions of postmortem human brain. This ratio was elevated 3-fold in the prefrontal cortex from patients with Alzheimer disease but not from those with Huntington disease. Other brain regions (putamen and cerebellum) where neuronal degeneration is considered minimal in Alzheimer disease also displayed significantly increased  $\mu$ CANP activation (Saito et al., these proceedings). Total levels of  $\mu$ CANP were unaltered. Calpastatin, the endogenous inhibitor of  $\mu$ CANP, was purified from human brain and shown by immunocytochemistry to co-localize with  $\mu$ CANP in neurons and dendrites. Affinity purified antibodies to human brain calpastatin revealed marked depletion of calpastatin immunoreactivity in the neocortex of individuals with Alzheimer disease. Depletion was prominent in dendrites in cortical laminae 1-III, and was evident to a lesser extent in laminae IV-V. These results indicate that the CANP system may be abnormally activated in AD brain. Increased vulnerability of the neurons or their processes to degeneration under these conditions may involve a depletion or redistribution of calpastatin. Given the suspected biological roles of CANPs, persistent activation of  $\mu$ CANP could contribute to altered protein processing and abnormal phosphorylation in AD. Abnormal CANP-mediated proteolysis could provide a possible basis for synaptic loss and other degenerative events that underlie cognitive impairment in AD.

HEAT SHOCKED NEURONAL PC12 CELLS AS A MODEL OF THE ALZHEIMER'S DISEASE STRESS RESPONSE. G.Johnson\*, L.Refolo, C.Merril, W.Wallace. Lab. of Biochemical Genetics, NIMH, Washington, D.C. and Dept. Psychiatry and Neurobiology Center, Mount Sinai School of Medicine, New York

Heat shock refers to the cellular response to a variety of insults which minimizes damage and allows for the restoration of normal cellular activities after the period of stress. In order to investigate the response of neurons to stress, we used nerve growth factor-differentiated PC12 cells incubated at either 37°C (control cells) or 45°C (heat shocked The heat shocked PC12 cells exhibited several features characteristic of the stress response including a 45% reduction in total protein synthesis, the induction of heat shock protein 72, an overall decrease in protein phosphorylation, and an increased phosphorylation of the initiation factor eIF-2alpha. The Alzheimer's disease (AD) brain undergoes many changes characteristic of the heat shock response which we term the AD stress response. However, elongation factor 2, which is hyperphosphorylated in AD brain, exhibited no such increase in heat shocked PC12 cells. We have also examined the phosphorylation of amyloid precursor protein (APP). Two dimensional gel separation of immunoprecipitates of [32P]-labeled PC12 cells with two different antibodies revealed four phosphorylated isoforms of APP (120-140kD, 5.3pI). APP was dramatically dephosphorylated in the heat shocked PC12 cells.

### 93.11

## A THEORY OF THE PROGRESSION OF ALZHEIMER'S DISEASE.

R.E. Bergman\* & M.E. Hasselmo, Dept. Psych., Harvard Univ., Cambridge, MA, 02138. The neurofibrillary tangles of Alzheimer's disease appear with highest density in entorhinal cortex layer II and hippocampal region CA1 (Hyman et al., Science 225:1168-1170). Computational modeling suggests that this selective distribution could result from a breakdown of the mechanisms of cortical associative memory, due to imbalances induced by any of a range of actiological factors. In cortical models, previously strengthened connections can interfere with the learning of new associations, resulting in runaway synaptic modification (Hasselmo et al., J. Neurophysiol. 67:1230-1246). The metabolic demands or excitotoxic effects of runaway synaptic modification could be severe enough to cause degeneration. The initiation and progression of runaway synaptic modification can be described by the solution to an equation combining synaptic transmission and modification:

$$\frac{d\mathbf{W}_{ij}}{dt} = (\mathbf{A}_i + (1 - c) \sum_{k=1}^{n} \mathbf{W}_{ik} \mathbf{A}_{k} - \mathbf{H} - \mathbf{\Omega}) \mathbf{A}_j$$

where  $W_{ij}$  = excitatory associational synapses,  $A_i$  = post-synaptic afferent input,  $A_j$ - $A_k$ = pre-synaptic afferent input, c = suppression of synaptic transmission, H = inhibitory feedback, and  $\Omega$  = threshold of synaptic modification. This yields the solution:

$$\begin{aligned} W_{ij} &= Z_{ij} e^{\lambda j t} - Z_{ij} + W_{ij}(0) \\ \text{where } Z_{ij} &= [A_i + (1-c)\sum_{k=1}^n W_{ik}(0)A_k - H - \Omega]/(1-c)\sum_{k=1}^n A_k \quad \text{and} \quad \lambda_j = (1-c)\sum_{k=1}^n A_k A_j \end{aligned}$$

If Z>0 when  $A_i=0$ , runaway synaptic modification will progress with a time course determined by Z and the time constant  $\lambda$ . The results of this analysis match the qualitative features of non-linear simulations of cortical associative memory function. The increased overlap in post-synaptic activity resulting in one region could then underlie the spread of runaway synaptic modification into adjacent cortical regions, with similar dynamics. Supported by The French Foundation for Alzheimer Research.

POTENTIAL ROLE OF HSP 72/73 IN THE REVERSIBLE PHOSPHORYLATION OF TAU TO FORM A68 IN HEAT SHOCKED NEURONAL PC12 CELLS. W. Wallace\*, G. Johnson, C. Merril, J. Sugar, L. Refolo. Dept Psychiatry and Neurobiology Center, Mount Sinai School Of Medicine, New York and Laboratory of Biochemical Genetics, NIMH, Washington, D.C.

A68, the primary protein constituent of neurofibrillary tangles, has been proposed to be an abnormally phosphorylated form of tau, a microtubule-associated protein. We have found that A68 is produced in neuronal PC12 cells that have been subjected to heat shock (45° C, 30 minutes). A68, which was identified by immunoprecipitation with both tau-2 and ALZ50, exhibited the characteristic reduced electrophoretic mobility compared to normal tau as has been found in AD postmortem tissues. The A68 incorporated radiolabeled phosphate indicating that it is a phosphoprotein. Antibodies to hsp 72/73 co-precipitated the normal form of tau which indicated a stable complex formation between tau and hsp. Cell lysates that had been depleted of such hsp complexes contained A68. Thus, no A68:hsp complexes were formed. A68 was dephosphorylated and reverted to normal tau two to four hours after recovery from heat shock. In the presence of cycloheximide, A68 still formed with heat shock; however, its dephosphorylation was much more rapid during recovery.

# PAIN: PHARMACOLOGY

## 94.

NALOXONE POTENTIATES VISCERAL NOCICEPTION IN NEWBORN RATS. C.M. Conway, J. Martinez, D.M. Kaiser, S.J. Evans and L.D. Lytle\*. Laboratory of Psychopharmacology, Department of Psychology, University of California, Santa Barbara, CA 93106.

The importance of endogenous opiates for adult pain is well established, but nociceptive mechanisms in immature organisms are poorly understood. Development of an animal model to study nociception might therefore prove useful for understanding ontogenetic changes occurring in mechanisms mediating pain sensitivity and/or reactivity in immature organisms. The current investigation studied age-related changes in opiate mechanisms mediating visceral nociception by administrating palayone an opiate recenter blocking drug to developing and

administering naloxone, an opiate receptor blocking drug, to developing rats.

Neonatal albino rats (5, 15, or 25 days postnatal) were pretreated with naloxone HCl (1 mg/kg; free base; i.p.) or an equal volume of its 0.9% NaCl vehicle (1 ml/kg). Fifteen min later half of each group received 12% hypertonic NaCl (1 ml/kg; i.p.) as a noxious visceral stimulus, or an equal volume of a non-noxious control solution of 0.9% NaCl. The number, duration and timing of abdominal contractions (defined as waves of muscular contractions passing caudally from the thoracic abdominal wall towards the hindlimbs and tail, as well as an arching/stretching of the back and/or a dorsolateral splaying of the hindlimbs) were assessed using 2 single blind observers for up to 10 min after the second treatment. The hypertonic saline challenge failed to elicit pain responses in 5-day-old animals, and then produced progressive, age-dependent pain responses in the two older age groups. Interestingly, the naloxone pretreatment potentiated the hypertonic saline induced pain responses of the youngest group of animals to a greater extent than the older ones. Taken together, these data replicate earlier results [Bronstein et al., Dev. Psychobiol. 19:473 (1986)] and suggest that endogenous opiates and/or opiate dependent mechanisms may mature early in development so as to mitigate neonatal pain.

# 94.2

THE DIFFERENTIAL EFFECT OF MORPHINE AND  $\alpha 2$  AGONISTS ON THE PREVENTION AND TREATMENT OF EXPERIMENTAL NEUROPATHIC PAIN. M.J.C. Puke¹ and Z. Wiesenfeid-Hailin¹·². Karolinska institute, ¹Dept. of Anesthesiol., Karolinska Hosp. and ²Dept. of Clin. Neurophysiol., Huddinge Hosp., Sweden.

We have examined the effect of intrathecal (i.t.) morphine (MO) closiding (Cl.) deymodetomiding (DEY) and selling (SAI)

We have examined the effect of intrathecal (i.t.) morphine (MO), clonidine (CL), dexmedetomidine (DEX) and saline (SAL) on self-mutilation (autotomy) behavior, a sign of neuropathic pain after sciatic nerve section, in three groups of Sprague-Dawley rats. A single dose of MO (50 μg), CL (50 μg) or SAL was injected (1) 30-60 min prior to or (2) 15 min after nerve section. Alternatively, in group (3) MO (10 μg), CL (10 μg), DEX (1 μg) or SAL was injected twice daily for 21 d, starting 24 nafter axotomy.

MO reduced and delayed autotomy compared with CL and SAL in groups (1) and (2) and there was no difference between CL and SAL treatment. The beneficial effect of MO in group (1) was greater than in group (2). In contrast, CL and DEX reduced autotomy compared to MO and SAL in group (3) with DEX having a better effect than CL.

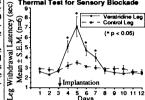

We conclude that opioid, but not  $\alpha 2$ , agonists are beneficial in preventing neuropathic pain, whereas  $\alpha 2$ , but not opioid, agonists are useful in treating such conditions. These differences can be related to the observations that MO is more effective in blocking "wind-up" and central sensitization of the spinal cord than CL. Furthermore, the sensitivity of the spinal cord to MO is reduced (Xu and Wiesenfeld-Hailin, Pain, 1991) and to CL increased (Xu et al., Pain. in press) after axotomy.

PROLONGED SCIATIC NERVE BLOCKADE USING SUSTAINED RELEASE OF

PROLONGED SCIATIC NERVE BLOCKADE USING SUSTAINED RELEASE OF VERATRIDINE FROM A BIODEGRADABLE POLYMER MATRIX. D.B. Masters', D. Hu. S. Dutta. C.T. Griggs, G. Strichartz & C.B. Berde, Anesthesia Depts., Children's Hospital and Brigham & Women's Hospital, Harvard Med. Sch., Boston, MA 02115. Biodegradable polymer/ local anesthetic matrices sustain drug release in vitro (Berde et al., Anes. 73: A776, 1990). Veratridine (VTD), a sodium channel activator, produces usedependent neural block with greater potency in C-fibers than A-fibers in vitro (Schneider et al., Anes. 74: 270, 1991). Preliminary work also suggests analgesia in rats (Strichartz et al., Anes. 74: 270, 1991). The aim of the present study was to measure sensory and motor block of the rat sciatic nerve in vivo, using VTD-impregnated polymer implants. Pellets were produced by casting molten (115 °C). 1, 3 bis (p-carboxyphenoxy) propane: sebasic acid (CPP:SA; 20:80 or 50:50) polymer/VTD mixtures in Teflon molds. Anesthetized male rats (Sprague-Dawley) received implants adjacent to the sciatic nerve on one side with either 5%, 10%, or 20% VTD pellets (300 mg total); an equal mass of control pellets were implanted adjacent to the contralateral sciatic nerve. Motor blockade was assessed using a scale just prior to sensory testing. Paw withdrawal lateracy to a 56 °C surface was used to assess analgesia. The experimenter was blind as to the treatment.

Control pellets produced no analgesia or motor blockade. The 5% VTD/50:50 CPP:SA pellets did not produce significant analgesia or motor blockade. The 5% VTD/50:50 CPP:SA pellets did not produce significant analgesia or motor blockade. The 5% VTD/50:50 CPP:SA pellets did not produce significant analgesia or motor blockade. The 5% VTD-impregnated of prolonged nerve block. Further studies are required to assess toxicity, alternative methods of VTD incorporate drug homogeneously into the polymer, and all three animals receiving 20% implants died.

VTD can produce analgesia with little compromise of motor capacity in

### 94.5

THE INDUCTION OF C-FOS EXPRESSION IN VARIOUS SUBCORTICAL BRAIN AREAS BY THE ADMINISTRATION OF COPPER SULFATE IN RATS. <u>D.Y. Chen\*, M.F. Gonzalez, J.A. Deutsch and Y. Gu.</u> Department of Psychology, UCSD, La Jolla, CA 92093

It has been suggested that two mechanisms mediate the transduction of toxic signals to the brain. One group of emetic agents, represented by CuSO<sub>4</sub> exert their action on receptors on the gastric wall and then this signal is relayed to the nucleus of the solitary tract via the vagus nerve. Another group of nausea-inducing agents, like LiCl, may be transported via the circulatory system and act directly on the CNS. In the present study the mechanism of action of CuSO<sub>4</sub> was studied using *c-fos* immunoactivity.

Male Sprague-Dawley rats were tested after a 15 hour-fast. CuSO<sub>4</sub>

isotonic to physiological saline was administered orally(300mg/kg), while corresponding volume of normal saline was given to control animals. Two hours after the injections the rats were perfused and their brains extracted and sectioned. The sections were reacted for fos immunocytochemistry using commercially available fos antibody (Microbiological Associates) and ABC reagents (Vector Lab). The most striking fos expression was found in the nucleus of the solitary tract, both in the frontal and far caudal parts. In addition, fos-positive neurons were found in the parvocellular region of the paraventricular nucleus, and amygdala. In the supraoptic area, very weak tos immunoactivities were also observed. It was noted that there was no apparent induction of fos in neurons of the area postrema.

These findings suggest an action of CuSO<sub>4</sub> on the gastric wall and the mediation of the signal to nucleus of the solitary tract via the vagus nerve, which has reciprocal connection with paraventricular nucleus. More investigation is necessary to further clarify the relay pathway of the signal, which, by now, apparently includes amygdala as one of the stations

PERIPHERAL BOMBESIN INDUCES C-FOS-LIKE IMMUNOREACTIVITY (C-FOS-LI) IN THE RAT BRAIN. <u>B. Bonaz, Y. Tache</u>. CURE, VA Wadsworth Medical Center, Dept. of Medicine and Brain Res. Inst., UCLA, Wadsworth, Los

CCK-8 induces c-fos-LI in the hypothalamus (1) and the nucleus of the solitary tract (NTS) (2) via vagal capsaicin sensory fibers (2). <u>Purpose:</u> to investigate whether peripheral bombesin, known to influence food intake, induces c-fos-LI in the brain. Methods: male SD rats were injected ip either with vehicle (2 ml 0.1% BSA) or with CCK-8 or bombesin (100  $\mu$ g/kg) alone or combined with systemic capsaicin pretreatment. Rats were perfused 60 min later with 4% paraformaldehyde. Brains were removed, post-fixed 3 h at +4° C and cryoprotected in sucrose. Frozen sections (30  $\mu$ m) were then incubated with the primary antibody (c-fos AB-2 rabbit antibody, Oncogene Science) at a dilution of 1:2000 for 24h at +4° C. The biotinylated secondary antibody (goat anti-rabbit, 1:100) was applied for 2 h. Sections were then processed for avidin-biotin-peroxidase using diaminobenzidine as the chromogen. <u>Results</u>: after CCK injection (n=7), e-fos-LI was densily distributed in the area postrema, NTS (medial and dorsal subnuclei), paraventricular nucleus of the hypothalamus (PVN) and amygdala. In bombesin treated rats (n=8), c-fos-LI was mainly localized in NTS (medial subnucleus) and the PVN (parvocellular part). Overall, fewer cells and lighter immunostaining was observed compared to CCK. c-fos-LI-induced by bombesin was not attenuated by capsaicin pretreatment (n=5), whereas that of CCK was attenuated (n=3). Conclusions: peripheral bombesin activates selected brain nuclei involved in the regulation of autonomic function.

PGE -- INDUCED ENHANCEMENT OF BRADYKININ RESPONSES OF POLYMODAL RECEPTORS IS MEDIATED BY EP3 RECEPTORS. T.Kumazawa\*, K.Mizumura, M.Minagawa, S.Narumiya & T.Namba. Dept. of Neural Regulation, Res. Inst. of Environ. Med., Nagoya Univ., Nagoya 464-01 JAPAN

PGE<sub>2</sub> enhances bradykinin (BK) responses of polymodal PGE<sub>2</sub> eminances bradykimin (BK) responses of polymodal receptors which signal pain. We studied what subtype of PG receptor is implicated in the PG effect, using an EP<sub>1</sub> antagonist, AH 6809; an EP<sub>2</sub> agonist, butaprost; an EP<sub>3</sub> agonist, M&B 28767. Discharges of polymodal receptors were recorded in in vitro canine testis-spermatic nerve preparations. The testis was immersed in Krebs-solution with aspirin (550  $\mu M$ ) to prevent release of endogenous BK (1  $\mu$ M) mixed with aspirin and captopril (10  $\mu$ M), an inhibitor of BK-degradation, was applied by replacing the Krebs-solution for 10–15 min. PG agonists at concentrations from  $10^{-9}$  to  $10^{-8}$  M were applied cumulatively when the BK-induced discharge rate reached a quasi steady state or slowly declining phase. PGE $_2$  enhanced BK-responses at concentrations above  $10^{-8}$  M; a more potent effect was induced by the EP $_3$  agonist. The EP $_2$ agonist up to 10<sup>-5</sup> M did not modify BK-responses. The EP<sub>1</sub> antagonist (10<sup>-6</sup> and 10<sup>-5</sup> M), which was applied during BK application, did not affect the enhancing effects of PGE<sub>2</sub> and the EP<sub>3</sub> agonist as well. It is most likely that  $EP_3$  receptors mediate the enhancing effect of  $PGE_2$  on the BK-response of polymodal receptors.

RECURRENT NEOCORTICAL SPREADING RECURRENT NEOCUKTICAL SFREADING CAUDALIS VIA
PROVOKES C-FOS-LI WITHIN V NUCLEUS CAUDALIS VIA
TRIGEMINOVASCULAR MECHANISMS. M.A. Moskowitz\*,

PROVOKES C-FOS-LI WITHIN V NUCLEUS CAUDALIS VIA TRIGEMINOVASCULAR MECHANISMS. M.A. Moskowitz\*, K. Nozaki, R.P. Kraig. Neurology Dept., MGH, Boston, MA 02114 and Neurology, Univ. of Chicago, Chicago, III 60637.

KCl was microinjected into left parietal cortex every 9 min over 1 hr, and SD detected by a shift in DC potential. Cells were stained using polyclonal antisera and counted in serial sections. C-fos-LI was visualized in ventrolateral TNC, chiefly in lamina I, II, and mostly below the C-M junction, ipsil. The ratio of cells (1/r) was 1.32 after 1M KCl versus 1.06 in control animals (1M NaCl) (p<0.01). The ratio was also lower (p<0.01) after i.v. sumatriptan, a 5-HT1-like agonist which blocks meningeal C-fibers and attenuates c-fos-LI after noxious meningeal stimulation. Sumatriptan did not reduce SD after KCl injection. However, combined reduce SD after KCl injection. However, combined hyperoxia and hypercapnia reduced the number of SD's, and also c-fos-LI in TNC (p<0.01).

Hence, multiple SD's activate cells within TNC probably by stimulation of meningeal afferents. If true, this is the first report demonstrating that events within cerebral cortex can activate brain stem regions involved in the processing of nociceptive information.

ENHANCED LEVELS OF ENKEPHALIN & DYNORPHIN mRNA IN RAT SPINAL CORD DURING PREGNANCY. K.E. Miller\*, M. Brown and B. Srinivasan. Dept. Anatomical Sciences, University of Oklahoma Health Sciences Center, Oklahoma City, OK 73190

During pregnancy, activation of the spinal opioid system is thought to cause attenuated responses to aversive stimuli (A. Gintzler, Science 210:193,'80). In the present study, preproenkephalin (ENK) and preprodynorphin (DYN) mRNA levels were compared between the spinal cords of pregnant and normal female rats. Spinal cords from 10 & 20 day pregnant and normal rats were removed and total RNA was extracted from lumbar and cervical enlargements. 32P-labelled cDNA's for ENK (s.Sabol) and DYN (J.Douglass) were used to probe RNA blots. For normalization, blots were stripped and reprobed with B-actin cDNA. Following densitometry and normalization, ENK & DYN mRNA levels did not change in the cervical spinal cord. In lumbar cord, ENK levels were increased by 200-300% at 10 and 20 days. DYN levels were increased similarly at 20 days. These data indicate that changes in afferent activity from the uterus during pregnancy results in enhanced production of ENK and DYN mRNA in spinal opioid neurons of the lumbar cord. The large increase in ENK mRNA is different from that observed after neuropathy or peripheral inflammation (Draisci et al., Br. Res. 560:186, '91), and may be related to visceral afferent activity.

DORSAL COLUMN INHIBITION OF FELINE NOCICEPTIVE THALAMIC CELLS VIA GABAERGIC MECHANISMS.

B. Olausson<sup>1</sup>, B-C Shyu<sup>2</sup> and R.G. Hallin<sup>3,\*</sup>. 1) Dept Physiol, Univ of Göteborg, S-400 33 Göteborg, Sweden. 2) Neurosci Lab, Inst of Biomed Sci, Academia Sinica, Taipei 11529, Taiwan, ROC. 3) Dept Clin Neurophysiol, Huddinge Hospital, S-14186 Stockholm, Sweden.

Cells in posterior parts of the feline thalamus were investigated to influences from afferents in the spinothalamic tract (STT), the dorsal column lemniscal pathway and the canine tooth pulp (TP). The cells had a spontaneous resting activity which could be increased by extracellular iontophoretic application of DL-homocysteic acid (DLH) and decreased by gamma-amino butyric acid (GABA). No effect on the spontaneous firing rate was observed following iontophoresis of the selective GABA-antagonists, picrotoxin (GABA-A antagonist) or saclofen (GABA-B antagonist). The evoked activity following stimulation of the dorsal column nuclei (DCN) was increased by simultaneous administration of picrotoxin. Such an increase in activity was not observed following STT or TP stimulation when picrotoxin was given simultaneously. The extracellular activity evoked by electrical stimulation of STT and TP was significantly depressed by preceding electrical stimulation in the DCN. This decrease in activity could be disinhibited by simultaneous administration of picrotoxin, indicating that the DCN induced inhibition is mediated via GABA-A receptors. A disinhibition of the DCN induced depression on the late responses following STT stimulation occurred after application of saclofen suggesting that the late inhibition is partly mediated via GABA-B receptors. Results in the present study indicate a thalamic interaction between lowthreshold (DCN) and high-threshold afferents (STT and TP) similar to that described in the spinal cord. A thalamic "gate-mechanism" is proposed.

Serum (S) ionized magnesium (IMg<sup>2+</sup>) and calcium (ICa<sup>2+</sup>) in headache (H) classification.
Comparison of patients (P) with continuous headaches (CH) and migraines (MH).
A. Mauskop, B.T. Altura, R.Q. Cracco,
B.M. Altura\*. Depts. of Neurology &
Physiology. SUNY-MSCB. Brooklyn. NY 11203

A. Mauskop, B.T. Altura, R.Q. Cracco, B.M. Altura\*. Depts. of Neurology & Physiology, SUNY-HSCB, Brooklyn, NY 11203
Due to lack of objective parameters, the classification of headaches relies on descriptions. It has been suggested that Mg may play a role in MH. Studies of intracellular and Stotal Mg (TMg) levels have produced inconsistent results. Using a new ion-selective electrode for Mg<sup>-+</sup> we have assessed IMg<sup>2+</sup> in S of P with several types of H. Measurements of ICa<sup>2+</sup>, TMg and calculation of ICa<sup>2+</sup>/IMg<sup>2+</sup> ratios were also done. We have selected for comparison 14 P with CH, 32 P with an acute attack of MH and age matched controls. P in both H groups had a severe H at the time of blood sampling. 46% of P with MH had a low IMg<sup>2+</sup> and a high ICa<sup>2+</sup>/IMg<sup>2+</sup> ratio as compared to 21% of P with CH (p 0.01). The S levels of TMg were normal, but were lower in P with MH as compared to P with CH or controls (p 0.05). This study suggests that IMg<sup>2+</sup> may be useful in the diagnosis and treatment of headaches.

SUPRASPINAL MECHANISMS OF CANNABINOID-INDUCED ANTINOCICEPTION IN RATS. A.H. Lichtman\* and B.R. Martin, Department of Pharmacology and Toxicology, Medical College of Virginia-Virginia Commonwealth University, Richmond, VA 23298. The naturally occurring as well as the synthetic cannabinoids have

201

The naturally occurring as well as the synthetic cannabinoids have been shown to be potent antinociceptive agents. However, little is known of their underlying mechanism. Therefore, the purpose of this ongoing investigation was to elucidate their mechanism of action. The finding that CP-55,940 (15  $\mu g$ ), a synthetic bicyclic analog, produced potent antinociception (84  $\pm$  16 %MPE) when administered directly into the ventral lateral region of the posterior periaqueductal gray (PAG) was the first demonstration implicating a brain region in the antinociceptive actions of the cannabinoids. In contrast, CP-56,667 (15  $\mu g$ ), the inactive stereoisomer of CP-55,940, failed to produce any appreciable antinociception, thus indicating stereoselectivity. Furthermore, this antinociceptive effect of CP-55,940 exhibits regional specificity as microinjection into either the dorsolateral region of the posterior PAG, the anterior ventrolateral region, or outside of the PAG failed to produce any antinociception. Finally, a 4 day pretreatment with pertussis toxin (0.2  $\mu g$ ) into the PAG completely blocked the antinociceptive action of CP-55,940, indicating that these effects are mediated through an inhibitory action on cyclic AMP at a G-protein coupled receptor. Taken together, these findings suggest that the cannabinoids produce antinociception through a G-protein coupled receptor mechanism in the PAG. This research was supported by NIDA grants DA-03672 and DA-05421.

FACTORS DIFFERENTIATING BETWEEN ANALGESIA AND SEDATION IN SPONTANEOUS AND EVOKED EEG.

B. Bromm\* and E. Scharein\* (SPON: European Neuroscience Association), Inst. Physiol., Univ. Hamburg, 2000 Hamburg 20.

The paper analyses the factorial structure of spontaneous and evoked EEG activity under the opioid meperidine (100 mg p.o.) and the tranquilizer diazepam (10 mg) in a placebo-controled double blind repeated measures study with 21 volunteers. Peri-stimulus EEG segments (Cz vs linked ear lobes) with 500 ms before and 500 ms after pain-inducing intracutaneous current pulses were spectrally analysed by means of the parametric maximum entropy method. The extracted principal component scores were correlated to pain relief and changes in vigilance. Pain relief was measured by the subjects ratings, vigilance was tested by a motor reaction task.

Results: 90 % of variance in all EEG activity could be explained by 4 varimax rotated principal components (PCs): The analgesic effect was predominantly reflected by the score of PC3 (delta power of poststimulus EEG). Decrease in vigilance could best be described by the score of PC2 (alpha power of both spontaneous and evoked EEG activity). The two other components, PC1 (beta power of spontaneous and evoked EEG) and PC4 (delta and theta power of spontaneous EEG), were not correlated with sedation or with pain relief.

ELECTROPHYSIOLOGICAL EVIDENCE FOR THE DESENSITIZATION OF α<sub>2</sub>-ADRENERGIC HETERORECEPTORS ON SEROTONIN (5-HT) TERMINALS IN THE RAT HIPPOCAMPUS FOLLOWING CHRONIC ANTIDEPRESSANT TREATMENTS. <u>R. Mongeau\*</u>, <u>P. Blier and C. de Montigny</u>, Neurobiological Psychiatry Unit, McGill Univ., Montreal, Canada. Previous results from our laboratory have indicated that small doses of the

α2-adrenergic agonist clonidine increase 5-HT transmission by attenuating the release of endogenous norepinephrine (NE), as a result of the activation of  $\alpha_2$  adrenergic autoreceptors on NE neurons, and that high doses decrease 5-HT transmission by activating directly  $\alpha_2$ -adrenergic heteroreceptors on 5-HT terminals. The aim of the present study was to assess whether antidepressant treatments that increase the synaptic availability of NE or 5-HT change the ability of either of these two  $\alpha_2$ -adrenoceptors to modulate 5-HT transmission. The effect of the activation of these receptors was studied by comparing the effectiveness of the electrical stimulation (200 pulses: 0.5 msec, 300 μA, 1 Hz) of the ascending 5-HT pathway in suppressing the firing activity of dorsal hippocampus  $\mathrm{CA}_3$  pyramidal neurons prior to, and following, the i.v. administration of 10 and 400 µg/kg of clonidine. Rats were treated for 3 weeks with s.c. osmotic minipumps (removed 48 h before the experiment) delivering 10 mg/kg/day of paroxetine (a selective 5-HT reuptake inhibitor), 0.75 mg/kg/day of befloxatone (a reversible inhibitor of monoamine oxidase A), 10 mg/kg/day of nisoxetine (a selective NE reuptake inhibitor) or saline. None of these treatments altered the effect of the small dose of clonidine. However, the reduction of 5-HT transmission by the large dose of clonidine was abolished in rats treated with nisoxetine and befloxatone, but not in those treated with paroxetine. These results suggest that antidepressant drugs that increase NE synaptic concentration induce a desensitization of  $\alpha_{\!\scriptscriptstyle 2}$ -heteroreceptors on 5-HT terminals.

ATTENUATED EFFECT OF PAROXETINE FOLLOWING ITS LONG-TERM ADMINISTRATION: AN ELECTROPHYSIOLOGICAL STUDY IN THE RAT HIPPOCAMPUS. G. Piñeyro\*, C. de Montigny and P. Blier. Neurobiological Psychiatry Unit, McGill Univ., Montréal, Québec, Canada. Long-term administration of antidepressant selective 5-HT reuptake

Long-term administration of antidepressant selective 5-HT reuptake inhibitors, has been shown to enhance 5-HT neurotransmission. The present experiments were undertaken to assess the effect of long-term paroxetine treatment on the 5-HT reuptake process. The recovery time of the firing activity of dorsal hippoccampus pyramidal neurons following microiontophoretic application of 5-HT was used as an index of reuptake activity.

In å first series of experiments, the effect of acute i.v. administration of paroxetine was assessed in control rats and in rats treated with paroxetine (10 mg/kg/day, s.c.) for 21 days, 48 h after the removal of the osmotic minipump. Before the injection of paroxetine, the effect of 5-HT was similar in treated and control rats. At the dose of 1 mg/kg, paroxetine prolonged the effect of 5-HT to the same extent in the two groups; however, at the dose of 4 mg/kg, its effect was much smaller in paroxetine-treated rats. In rats pretreated with 5,7-dihydroxytryptamine, there was a prolongation of the effect of 5-HT, and the

acute administration of paroxetine did not induce any further prolongation. In a second series of experiments, the effect of 5-HT was measured in control rats and rats treated for 2 or 21 days with paroxetine (10 mg/kg/day, s.c.), the experiment being carried out with the minipump in place. In both treated groups, the suppressant effect of 5-HT was longer than in controls, whereas the effect of the 5-HT1A agonist gepirone was unchanged. However, the prolongation of the effect of 5-HT was significantly smaller in rats treated for 21 days than those treated for 2 days.

for 21 days than those treated for 2 days.

In conclusion, these data suggest that the long-term administration of paroxetine results in a down-regulation of paroxetine binding sites.

AN EVALUATION OF SC 48,274, A NOVEL ANXIOLYTIC, IN GENERALIZED ANXIETY DISORDER (GAD). N.R. Cutler, J.J. Sramek, A. Macpherson, R.D. Seifert, C.O. Benes, S.F. Howard. California Clini Trials, Beverly Hills, CA 90211; Searle Res. & Dev., Skokie, IL 60077.

The data presented here as a single site study is part of a multicenter double-blind, placebo-controlled trial to evaluate the efficacy of two fixed dosages (1.0 mg and 25 mg bid) of the unique anxiolytic SC 48,274 in GAD. Sixty-five patients at this site (52 M;  $\vec{x}$  age, 33 years; range 19-64) were randomly assigned to a 4-week trial of one of the SC 48,274 dosages (1 mg, n=28; 25 mg, n=9) or placebo (n=28), followed by a 7-day single-blind placebo follow-up. Baseline HAM-A scores for the 1 mg, 25 mg, and placebo groups were 25.1, 25.9, and 24.5, respectively; after 4 weeks, HAM-A changes for the three groups were -5.1, -4.2, and -1.9. The 1 mg group showed a significant improvement compared to placebo (F=8.93; p=0.004), whereas the 25 mg group did not (F=2.26; p>0.05). Clinical Global Impression (CGI) severity of illness scores were significant for the 1 mg group vs. placebo ( $X^2 = 3.84$ ; p=0.05), but not significant for the 25 mg group ( $X^2 = 0.90$ ; p>0.05). Adverse events were typically mild, occurring in 67.6% of study drug subjects and in 78.6% of placebo subjects. The most frequent adverse events for drug subjects included headaches, myalgia, rhinitis, abdominal pain and nausea; however, there was no apparent pattern of adverse events distinguishing drug and placebo groups. The 1 mg dosage appeared to be slightly better tolerated than the 25 mg dosage (adverse event incidence, 64.3% vs. 77.8%). This single site study demonstrated efficacy of SC 48,274 at the 1 mg bid dosage in GAD, while the multicenter study as a whole did not demonstrate significance (p>0.05).

## 95.5

ELECTROCONVULSIVE SHOCK INCREASES  $\alpha_{18}$ -ADRENERGIC RECEPTORS BUT NOT  $\alpha_{1A}$  OR NE-STIMULATED INOSITOL PHOSPHATE FORMATION IN RAT BRAIN. <u>G.N.</u> Pandey\*, S.C. Pandey, L. Isaac, J.M. Davis. Illinois State Psychiatric Institute and University of Illinois, Chicago, IL, 60612

Repeated administration of electroconvulsive shock (ECS) increases  $\alpha_1$ -adrenergic receptors, as measured by [3H]-prazosin binding.  $\alpha_1$ adrenergic receptors have been subdivided into  $\alpha_{1A}$  and  $\alpha_{1B}$  subtypes. The purpose of this study is to investigate whether ECS increases one or both  $\alpha_1$ -adrenergic receptor subtypes in rat cerebral cortex. We also studied the effect of ECS on NE-stimulated [<sup>3</sup>H]inositol-1-phosphate (IP<sub>1</sub>) formation in rat cortex. ECS (75 mA for 0.2 seconds) was administered to rats once daily for 14 days by means of earclip electrodes. The rats were decapitated 24 hrs after the last shock, and brain was removed for separation of cortices.  $\alpha_1$ -adrenergic receptors were measured by  $\pm B(^{125}\text{I-iodo-4-hydroxy-phenyl})$ -ethyl-aminomethyltetralone binding using 5-methylurapidil as displacer. We observed that repeated ECS administration caused a significant increase in the number of  $\alpha_1$ -adrenergic receptors and the  $\alpha_{1B}$ -adrenergic receptor subtype in cortex. However, it had no effect on the  $\alpha_{1A}$ -adrenergic receptor subtype or NE-stimulated [ ${}^3H$ ]-IP<sub>1</sub> formation. These results thus suggest that upregulation of  $\alpha_1$ -adrenergic receptors is not associated with changes in NE-stimulated PI turnover. The lack of effects on NE-stimulated [<sup>3</sup>H]-IP<sub>1</sub> formation in ECS-treated rats may be due to its lack of effect on the  $\alpha_{1A}$ -adrenergic receptor subtype.

# 95.7

EFFECTS OF CHRONIC ANTIDEPRESSANT TREATMENT ON CORTICOTROPIN-RELEASING FACTOR NEURONS IN THE RAT. C.B. Nemeroff, M.J. Owens and D.L. Knight. Lab. of Neuropsychopharmacology, Dept. of Psychiatry, Emory Univ. Sch. Med., Atlanta GA 30322.

The unique distribution of CRF and CRF receptors within the CNS, its preeminent role in coordinating the endocrine, behavioral, autonomic and mmunological effects of stress and its behavioral and physiological effects after direct CNS administration all support the hypothesis that alterations in CRF neuronal systems contribute to the pathophysiology of depression and perhaps certain anxiety disorders

We hypothesized that the efficacy of antidepressant drugs may be due, at least in part, to their actions on CRF-containing neurons in the CNS. Although acute imipramine administration was without effect on regional brain CRF concentrations in the rat, the present study sought to investigate the effects of chronic imipramine infusion. Imipramine was infused via osmotic minipumps for 28 days with plasma imipramine and desipramine concentrations maintained at levels comparable to those observed in humans (i.e., combined imipramine and desipramine concentrations of >150 ng/ml plasma). A similarly treated group was exposed to acute restraint stress on day 28 to determine whether chronic imipramine administration attenuates the effects of stress on regional brain CRF concentrations. Chronic imipramine administration, as expected, decreased (35%) the density of cortical  $\beta$ adrenergic receptors, as assessed by [125I]-iodopindolol binding. Cortical 5-HT2 receptor binding, as assessed by [H]-ketanserin binding was decreased by 40% and anterior pituitary CRF receptor binding was increased 20% after chronic administration. Acute stress did not alter either  $\beta$ , 5-HT<sub>2</sub> or CRF receptor binding. In situ hybridization and radioimmunoassay studies in these animals are currently underway. Supported by NIMH MH-42088.

LONG-TERM MAZINDOL AUGMENTATION OF NEUROLEPTIC IN NEGATIVE SCHIZOPHRENIA. J. Seibyl\*, Johnson, L. Brenner, G. Heninger, D. Charney, J. Krystal, Psychiatry Service, Yale University School of Medicine and West Haven VA Medical Center, West Haven, CT, 06516

Decreased dopaminergic function has been implicated in negative schizophrenic symptoms including anhedonia, amotivation, and affective impairment. Standard antipsychotics are ineffective or even deleterious in management of negative symptoms. Preliminary work in schizophrenic patients has shown mazindol, a long-acting dopamine transporter agent, reduces negative symptoms compared to placebo. The present study evaluates the long-term efficacy of mazindol augmentation of standard antipsychotics in stable negative symptom outpatient schizophrenics. METHODS: Seventeen schizophrenics received open-label mazindol 2-4 mg/day for 4-6 months. Biweekly ratings included the Brief Psychiatric Rating Scale (BPRS), Positive and Negative Symptom Scale (PANSS), Webster Scale of extrapyramidal symptoms and the Abnormal Involuntary Movement Scale (AIMS). Fasting prolactin and HVA were obtained biweekly. RESULTS: Mazindol caused a 30-40% reduction in total and negative symptom scores while having no effect on positive symptoms. There was a trend toward the reduction of antipsychotic-induced extrapyramidal side effects, but no exacerbation of tardive dyskinesia scores. Mazindol caused an initial increase in prolactin followed by reduction to sub-baseline levels. IMPLICATIONS: This study suggests that mazindol is a useful agent for the long-term treatment of negative schizophrenic symptoms.

BIOCHEMICAL MEASURES RELATED TO THERAPEUTIC RESPONSE TO A SPECIFIC SEROTONIN REUPTAKE INHIBITOR IN EARLY ONSET PRIMARY DYSTHYMIA. A.V. Ravindran, R.J. Bialik." G.M. Brown." Y.D. Lapierre. Institute of Mental Health Research and Dept. of Psychiatry, University of Ottawa, Ottawa, Ontario K1Z 7K4 and Clarke Institute of Psychiatry, 250 College Street, Toronto, Ontario M5T 1R8.

This prospective study examined biochemical correlates of the therapeutic response to a specific serotonin reuptake blocker (SSRI). The study included twenty-six patients that satisfied DSM-III(R) criteria for dysthymic disorder with no concurrent illness. They also satisfied Akiskal's criteria for primary early onset dysthymia of the subaffective type. Psychiatric rating instruments and biochemical measures were taken following a one-week washout period and again following six weeks of pharmacotherapy with an SSRI. As a group, patients had significantly lower platelet monoamine oxidase compared to normal controls and 85% showed a therapeutic response to pharmacotherapy. Responders had marked reduction in both depression and anxiety symptoms as measured by the Hamilton Rating Scale for Depression and the Hamilton Anxiety Scale. Prior to treatment, responders had significantly higher: plasma oxidase activity; serum cortisol levels following dexamethasone; urinary melatonin (as indicated by its major metabolite, 6-sulphatoxymelatonin; and urinary metanephrine levels. Responders also had lower baseline urinary levels of the major metabolite of serotonin, 5-HIAA, and showed an increase in levels following treatment. In response to treatment, urinary excretion of the major metabolite of norepinephrine, MHPG, was reduced. Non-responders showed an increased adrenal medullary output. Surprisingly, five patients showed clinical non-non-suppression of cortisol by dexamethasone following treatment. Four of these patients were responders and continued to be symptom free during one year of follow up. In summary, indices of serotonininactivity were lower

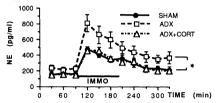

# 95.8

PRECLINICAL PHARMACOLOGY AND CLINICAL EFFECTS IN HUMANS OF DOPAMINE D-1 RECEPTOR ANTAGONISM. E.B. Nielsen', P.H. Andersen, L. Farde, P. Karlsson, F.C. Grønvald, B.K. Skrumsager Pharmaceuticals Research, Novo Nordisk A/S, Novo Nordisk Park, DK-2760 Måløv, Denmark and Karolinska Hospital, S-10401 Stockholm, Sweden.

Biochemical receptor profiling of the benzazepine D-1 antagonists NNC-112, NNC-687 and NNC-756 indicated potent and selective D-1 antagonistic effect in the low nM range. The compounds were nonselective for D-5 vs D1A receptors. The selectivity and potency was confirmed in in vivo binding receptor assays in mice and rats. Animal pharmacological evaluation indicated that approximately 50% D-1 receptor occupancy exerted similar pharmacological antagonism as approximately 80% D-2 receptor occupancy in vivo. Thus, antipsychotic effects of D-1 antagonism may be expected at 50% receptor occupancy in vivo. Increasing doses (1-25 mg total) of NNC-687 were administered orally to human male volunteers. The highest doses produced approximately 50% receptor occupancy as determined by PET. Only "questionable" or mild akathisia was recorded in the subjects. Thus, 50% D-1 receptor blockade may convey antipsychotic effect in the absence of the D-2-receptor-related extrapyramidal syndromes of Parkinsonism and dystonia.

ADRENALECTOMY AUGMENTS IN VIVO RELEASE OF NOREPINEPHRINE IN THE PARAVENTRICULAR NUCLEUS DURING IMMOBILIZATION STRESS. K. Pacak\*. R. Kvetnansky, M. Palkovits, I. J. Kopin, D. S. Goldstein, NINDS and NIMH, NIH, Bethesda, MD 20892.

Removal of endogenous glucocorticoids by adrenalectomy (ADX) activates corticotropin-releasing hormone (CRH) neurons in the paraventricular nucleus (PVN) and increases hypothalamic norepinephrine (NE) tumover. Immobilization (IMMO) stress markedly increases release of NE into extracellular fluid in the PVN. This study assessed whether ADX affects release of NE in the PVN under basal conditions and during IMMO and whether cortisol (CORT) replacement attenuates the effects of ADX. In vivo microdialysis was used to measure microdialysate concentrations of NE, neuronal NE metabolite dihydroxyphenylgclycol (DHPG), and the dopamine metabolite dihydroxyphenylacetic acid (DOPAC). Seven-10 days following ADX or ADX plus CORT (20 mg/kg/day), animals underwent 2 h of IMMO. Microdialysate collection began 24 h after probe implantation. ADX rats tended to have increased baseline NE, DHPQ, and DOPAC levels and had significantly larger stress-induced responses of NE and DOPAC (p-0.05) than sham-operated animals. CORT replacement completely normalized both the elevated baseline NE and the exagerated NE and DOPAC responses of NE and that these effects are due to removal of endogenous glucocorticoids. Stress-induced release of NE in the PVN therefore appears to be regulated by feedback inhibition by glucocorticoids; conversely, enhanced PVN NE release after ADX is likely involved in the stimulatory effect of ADX on CRH release.

## 96.3

ACUTE STRESS OR ETHANOL (ETOH) CAN HAVE A VERY LONG LASTING INFLUENCE ON IN VITRO DOPAMINE (DA) RELEASE FROM STRIATAL SLICES S.M. Antelman, A.R. Caggiula, D.J. Edwards\*, S. Kiss, D. Kocan, H. Barry, III Depts. of Psychiatry, Psychology and Pharmacology/Physiology, University of Pittsburgh, Pittsburgh, PA. 15213

We have shown that one exposure to stress or ETOH has long term effects on drug responsiveness of male rats as reflected by blunted behavioral (catalepsy) and neurochemical (increased medial frontal cortical DOPAC/DA ratio) responses to haloperidol. The present 2 studies found that when an i.p. injection of ETOH (0.5 or 2 g/kg) or a stressor (2 ml/kg saline) was given either 30-120 min or 2 wks before sacrifice, it produced a 60-80% decrease in DA release in response to amphetamine (AM; 2.5-10 µM) from striatal slices. However, when ETOH was given BOTH 2 wks AND 30 min before sacrifice, the earlier treatment significantly prevented the ability of the latter to decrease AM-induced DA release. These findings suggest that the effect on DOPAC/DA ratio earlier observed probably does reflect a change in DA release. Furthermore, by showing that prestress can act to both decrease and prevent the decrease in AM-induced DA release, they extend our previous findings on the long term, biphasic actions of stress on drug responsiveness. STRESS PREFERENTIALLY ENHANCES EXTRANEURONAL LEVELS OF EXCITATORY AMINO ACIDS IN THE PREFRONTAL CORTEX: COMPARISON TO HIPPOCAMPUS AND BASAL GANGLIA, Bita Moghaddam, Psychiatry, Yale Univ. Sch. Med., VA Med. Center, 116A/2 West Haven, CT, 06516.

The technique of intracerebral microdialysis was to assess the effect of stress on the extracellular (EC) concentration of excitatory amino acids (EAAs), glutamate (GLU) and aspartate (ASP), in the rat prefrontal cortex (PFC), hippocampus, striatum, and nucleus accumbens. A 20minute restraint procedure led to enhancement of EC GLU levels in all regions tested. The increase in GLU levels was significantly higher in the PFC than that observed in other regions. With the exception of the striatum, EC other regions. With the exception of the striatum, BC levels of ASP also were increased in all regions. Furthermore, ASP levels were higher in PFC compared to hippocampus and nucleus accumbens. In order to ensure that the above results were not an artifact of restraint that is not associated with stress (e.g. decreased mobility), we also examined the effect of swimming stress on the EC levels of EAAs in selected regions, i.e., striatum and medial PFC. Both regions displayed a significant increase in EC ASP and GLU following 20 minutes of swimming in room temperature water. This study provides direct evidence that stress enhances the EC levels of EAAs and that EAAs may be involved in adaptive stress response. These findings also may have implications for stress-induced catecholamine release and/or hippocampal degeneration.

GLUCOCORTICOID ADMINISTRATION REVERSES AUGMENTED SYMPATHONEURAL RESPONSIVENESS TO IMMOBILIZATION STRESS IN ADRENALECTOMIZED RATS. R. Kvetnansky\*, K. Fukuhara, U.K. Weise, G. Cizza, K. Pacak, D.S. Goldstein and I.J. Kopin. Clin. Neurosci. Branch, NINDS, NIH, Bethesda, MD. 20892.

The sympathoadrenal and hypothalamic-pituitaryadrenocortical systems interact at several levels. Adrenalectomy elevates basal and stress levels of plasma norepinephrine (NE), and this effect was reversed by glucocorticoid administration. The present study investigated plasma levels of catecholamine precursor Investigated plasma levels of catecholamine precursor DOPA, NE metabolites dihydroxyphenylglycol (DHPG), methoxyhydroxyphenylglycol (MHPG), and dopamine (DR) metabolites dihydroxyphenylacetic acid (DOPAC) and homovanillic acid (HVR) in adrenalectomized or shamoperated animals with or without glucocorticoid treatment (cortisol 25 mg/kg/24h for 7 days by osmotic minipumps) in rats at 5, 20, 60, and 120 min. of immobilization stress. Adrenalectomy eliminated the plasma levels of epinephrine and corticosterone but increased basal and and corticosterone but increased basal and immobilization-related levels of NE, DHPG, MHPG, DDPA, DOPAC, and HUA. Cortisol administration to adrenalectomized rats (plasma levels about 600 pmol/ml) reversed the increases in these parameters. The results indicate that adrenal glucocorticoids restrain stress-induced increases in catecholamine release, reuptake, metabolism, and synthesis.

### 96.4

FOS-IMMUNOREACTIVITY (F-IR) IN BRAINS OF RATS EXPOSED TO INESCAPABLE SHOCK OR ADMINISTERED CORTICOTROPIN-RELEASING FACTOR (CRF). B.J. Valentino\*. S. de Boer. P. Bicanich. Bowen Kang and G. Aston-Jones. Div. of Behavioral Neurobiology, Dept. of Mental Health Sci., Hahnemann Univ., Philadelphia, PA 19102, U.S.A.

Immunoreactivity of Fos, the protein product of the gene, c-fos, was compared in brains of rats exposed to 30 min of mild footshock (1.5 mA, 0.5 compared in brains of rats exposed to 30 min of mild footshock (1.5 mA, 0.5 ms, 0.033 Hz) and rats administered CRF (3.0 µg, i.c.v.). Control rats for the 2 groups were placed in identical chambers as shocked rats but were not shocked, or were administered saline (3 µl, i.c.v.), respectively. Rats were perfused 2 h after the procedures and 30 µm coronal sections were cut and processed for F-IR. The distribution of F-IR in shocked rats included the nucleus tractus solitarius, A1 area, cuneate nucleus, nucleus paragigantocellularis,dorsal cochlear nucleus, locus coeruleus, central gray, Barrington's nucleus, periaqueductal gray, rostral Kolliker-Fuse, habenula, lateral hypothalamus, supramammillary nucleus, paraventricular nucleus of the hypothalamus, and the cortex. Double labeling studies demonstrated tyrosine hydroxylase-IR neurons in the A1 area, nucleus paraginantocellusris and hydroxylase-IR neurons in the A1 area, nucleus paragigantocelluaris, and locus coeruleus that were also F-IR. Likewise, all F-IR neurons in Barrington's nucleus of sampled sections were CRF-IR. The distribution of F-IR in brains of rats administered CRF was similar to that observed in brains from shocked rats. rats administered CRF was similar to that observed in brains from shocked rats. However, greater numbers of F-IR neurons were observed in the spinal trigeminal nucleus, vestibular nuclei, olivary nuclei, nucleus prepositus hypoglossi, lateral parabrachial nucleus, medial central gray, pontine nuclei, central nucleus of the amygdala, and cortex of rats administered CRF. Moreover, F-IR was much less or absent in the locus coeruleus and cochlear nucleus of rats administered CRF. F-IR was virtually absent in brains from control rats. The similarities in F-IR distribution in the two conditions suggest that endogenous CRF is involved in, but is not the sole mediator of neuronal activation by inescapable shock. Supported by MH 40008, MH 00840 and NS 24698.

LATERAL SEPTAL STIMULATION ABOLISHES COLD-IMMOBILIZATION STRESS-INDUCED ULCERS. E. Yadin\* and E. Thomas. Department of Psychiatry, The Medical College of Pennsylvania, Philadelphia, PA 19129, and Department of Psychology, Bryn Mawr College, Bryn Mawr, PA 19010.

The involvement of structures within the limbic system in exacerbation or mitigation of stomach ulcers induced by immobilization stress procedures in rats has been widely documented. Much of the work has focused on the central nucleus of the amygdaloid complex (Henke, Neurosci Biobehav Rev 12:143-150, 1988), stimulation of which resulted in increased number and size lesions. Food-deprived rats were restrained in a Plexiglass restrainer for 3 hours at a temperature of 4°C. Throughout the session, experimental animals received brain stimulation, 50 microamp square wave trains, 0.1 ms pulse duration, at a rate of 100 pulses/sec, delivered every 90 sec, via bipolar electrodes implanted earlier in their anterior dorsolateral septum. Implanted control animals were restrained but received no brain stimulation. At the end of three hours animals were anesthetized, blood drawn cardially for corticosteroid analysis, stomachs removed and cut along the greater curvature for ulcer formation analysis, and brains removed and fixed for electrode tip location determination. Lateral septal stimulation during the stress procedure dramatically reduced the formation of stress-induced gastric lesions. The experimental animals' stomachs had virtually no hemorrhages and ulcers, while the non-stimulated controls' stomachs showed severe ulceration. The results suggest a stress-inhibitory role for the lateral septal nucleus.

Supported in part by Ciba-Geigy Corporation.

EFFECTS OF 2DG-INDUCED GLUCOPRIVIC STRESS IN HUMANS AND THE RAT. A. Breier\*, A.M. Crane, O.R. Davis, R.W. Buchanan, C. Kennedy, and L. Sokoloff. MD Psychiatric Research Cntr, Univ of MD Sch Med, Baltimore, MD. 21228.

Interruption of glucose metabolism is a potent CNS stressor. Administration of pharmacologic doses of 2deoxyglucose (2DG) results in inhibition of glycolysis and has been used as a paradigm to examine the effects of glucoprivation in clinical and preclinical studies. We report now the results of two studies examining the effects of 2DG-induced glucoprivation on classical stress systems in man and local cerebral blood flow (1CBF) in the rat. 2DG (50mg/kg), placebo, and the high potency benzodiazepine alprazolam (1.5 mg) were administered to 10 healthy humans. 2DG resulted in 50-fold increases in plasma epinephrine, 15-fold increases in plasma ACTH, and modest increases in plasma norepinephrine. Alprazolam pretreatment significantly attenuated 2DG-induced plasma epinephrine and ACTH elevations but did not effect plasma norepinephrine. In the second study, 2DG (500mg/kg) (N-6) or saline (N-6) were administered IV to normal adult male Sprague-Dawley rats and ICBF was subsequently determined with 14-C-iodoantyprine while the animals were conscious and unrestrained. 2DG produced increases in ICBF in most regions with the largest effects in cortical areas, caudate-putamen, nucleus accumbens, and thalamus. Smaller changes occurred in amygdala, lateral lemniscus, dorsal raphe, and hypothalamus. The implication of these data will be discussed.

# 96.9

OPTICAL REFLECTANCE IN THE CAT DORSAL HIPPOCAMPUS AFTER EXPOSURE TO AROUSING STIMULI. M.P.Kristensen\*, D.M.Rector, G.R.Poe and R.M.Harper. Interdepartmental Program in Neuroscience and Department of Anatomy and Cell Biology, UCLA Sch. of Med., Los Angeles, CA, 90024.

Electrical activity of the hippocampus is greatly modified during arousal. We measured the functional topography of cellular activity in the dorsal hippocampus following exposure to arousing stimuli by assessing patterns of 700 nm reflected light. A 1.6 mm coherent optical probe and charge coupled device camera were placed on the dorsal hippocampus. Electrodes were also placed for monitoring EOG, ECG, diaphragmatic EMG, and cortical and hippocampal EEG to determine state and EEG characteristics.

After surgical recovery, images were collected every 2-3 s from freely behaving cats at times synchronous with the ECG R-wave before, during, and after exposure to arousing stimuli of different modalities (acoustic noise, intravenous injection of saline, and complex auditory/visual stimuli). Images were digitized, averaged, subtracted between conditions, and subjected to ANOVA. All stimuli accentuated respiratory and cardiac rates as well as EMG activity. Concomitant with these physiological changes, significant overall increases in optical reflectance from the dorsal hippocampus occurred in response to complex stimuli and saline injection, indicating decreased cellular activity. The reflectance changes appeared immediately after exposure to the stimulus during waking. No such change in reflectance could be detected after exposure to simple acoustic stimuli.

These findings suggest that arousing stimuli of a complex nature and/or particular modalities reduce overall activity of the dorsal hippocampus, whereas simple stimuli of other modalities have little overall effect on this area (Supported by HL22418)

INVOLVEMENT OF CORTICOSTEROIDS IN THE PROCESSING OF

INVOLVEMENT OF CORTICOSTEROIDS IN THE PROCESSING OF STRESSFUL LIFE-EVENTS: A POSSIBLE IMPLICATION FOR THE DEVELOPMENT OF DEPRESSION. B.W.M.M. Peeters. C.L.E. Broekkamp and J.A.D.M. Tonnaer\* Dept. of Neuropharmacology, Organon Int. B.V. P.O. Box 20, 5340 BH Oss, The Netherlands.

In a subpopulation of endogenously depressed patients disturbances of the hypothalamus-pituitary-adrenal (HPA) axis occur. Cortisol is increased and dexamethasone suppression is blunted. However, the relationship between these disturbances and the development of depression is unknown.

Corticosteroids act mainly via two receptor types, the mineralocorticoid (MR) and the glucocorticoid (GR) receptor. These two receptors differ in a number of aspects among which, their affinity for cortisol (MR: high affinity; GR: low affinity).

By means of the behavioural despair paradigm, we investigated the role of both receptors in the processing of stressful life-events. In this paradigm, mice have to adapt to a stressful event (water stress) and retain the adaptation response until retest. It was shown that the MR receptor is critically involved in the acquisition of the adaptation response. The MR receptor agonist aldosterone increased the acquisition speed in adrenalectomized animals while the MR antagonist spironolactone had an opposite effect in controls. The GR receptor appeared to play a role in the consolidation of the response. Adrenalectomy disturbed the consolidation process and this could be restored by means of the glucocorticoid agonist dexamethasone.

Corticosteroid levels gradually increased during the test (duration 15min), resulting in peak levels at the end of the session. This also is in agreement with an involvement of the MR receptor in the acquisition process and of the GR receptor in the consolidation.

Our results indicate that both the MR and the GR receptor are involved in the

the consolidation

the consolidation.

Our results indicate that both the MR and the GR receptor are involved in the processing of stressful life-events. The MR receptors seem to be involved in the adaptation process itself while the GR receptors appear to play a role in remembering the event and the displayed response. In depressed patients, cortisol levels are chronically elevated which means that GR receptors will be activated after mild stressors which induce only a small extra steroid release. Such aberrant response on mild stressors might play a role in the pathology of the depressed patient.

Prolonged stress does not reduce increased bloodcord barrier (BSB) permeability experimental autoimmune encephalomyelitis (EAE). W.D. Lo\*, A.C. Wolny, A. Griffin, C.C. Whitacre. Ohio State University, Columbus, OH, 43210. Prolonged stress in female Lewis rats suppresses EAE, but the mechanism is unknown. Since stress increases plasma corticosterone, we hypothesized that stress exerts its effect by reducing the BSB permeability that occurs in this model. EAE was induced by injecting guinea pig myelin basic protein (MBP) and Freund's adjuvant. Stressed animals were restrained for 9 hrs beginning 5 animals were restrained for y has beginning of days before MBP injection; controls were food and water deprived for the same period. Controls demonstrate peak signs of disease 14 days after induction while stressed animals show demonstrate peak signs of disease 14 days after induction while stressed animals show significantly decreased signs of EAE. We measured the PS product to 125I-albumin and 3H-AIB in separate groups with a tissue sampling method. There was no difference between the two groups for the 125I-albumin and AIB PS products. Indeed, the AIB PS product was slightly increased in stressed compared with control animals. These results suggest that stress does not inhibit the development of increased BSB permeability in EAE, and imply that the effect of stress is mediated through some other mechanism.

NEOPHOBIA AND NEOPHILIA IN SOCIALLY ISOLATED RATS. FS Hall\*, TW Robbins, T Humby and LS Wilkinson. Dept. of Experimental Psychology, Cambridge University, Cambridge, England.

Male Lister Hooded rats were divided into socially housed and isolation housed groups at day 21 postnatal. Testing began after 8 weeks of housing. In the first experiment half of each group of subjects were habituated to an open field, half were not. Subjects were pre-exposed to either chocolate chip cookies or cheddar cheese in the home cage. Neophobia testing was done in a 1m<sup>2</sup> open field for 15 minutes with food bowls containing each of the foods placed in the center of the open field (one novel and one familiar for each rat). For each food the following measures were observed: latency to contact and eat the food, the duration of contact and eating, the number of bouts of contact and eating and the amount consumed. In addition locomotion, rearing and grooming were also scored. The basic method was replicated: all rats ate more of the familiar food, for a longer time and at a shorter latency. Habituation to the environment reduced the latency to eat the familiar food, locomotor acitivity and the time between contacting each food and eating each food. Isolates showed an increased latency to contact and to eat the familiar food. There was no difference for the novel food. In a second experiment social and isolated rats were confined to one side of a two-sided apparatus for 1 hour. They were then placed in a choice chamber and allowed free movement between both sides. Isolates spent more of their time on the novel side than socially housed rats. The neophilia observed in the experiment 2 may have acted in experiment 1 to counteract neophobia for the novel food.

IN VIVO IMAGING OF BRAIN ACETYLCHOLINESTERASE WITH [11C]PHYSOSTIGMINE. B. Tavitian\*, S. Pappata, A. Jobert, F. Hinnen, C. Crouzel and L. DiGiamberardino. INSERM U334, CEA, SFHJ, Orsay, France.

Acetylcholinesterase (AChE) activity is dramatically reduced in specific areas of the brain in patients suffering from some neurodegenerative disorders. For example, AChE is diminished in the caudate-putamen of Huntington's disease patients and in the cortex of Alzheimer's disease patients, while there appears to be no change in its activity in Parkinson's disease. In vivo measurement of this enzyme's activity would

activity in Parkinson's disease. In vivo measurement of this enzyme's activity would thus provide a means to define and quantify regional cholinergic deficits in the brains of these patients for diagnostic and therapeutic purposes.

Our group is engaged in the search for ligands suitable for the imaging of AChE activity in the living brain using Positron Emission Tomography (PET). Previous studies using an [11C]-labeled derivative of THA (tacrine) have led to the conclusion that the distribution of TIA histories does not see float AChE for this in the beginning of the beginning of the beginning of the beginning of the property of that the distribution of THA binding sites does not reflect AChE activity in the brain (Tavitian et al., submitted). In the present study, we labeled physostigmine (PHY), a competitive inhibitor of AChE, and performed PET imaging in baboons with an

ECAT 953B camera.

Results from both ex vivo experiments in rodents and in vivo imaging in nonhuman primates demonstrate a strong match between the localization of [11C]PHY
and AChE activity. After injection of [11C]PHY, the radioactivity is rapidly cleared
from the blood and taken up into tissues (brain peak at 1.5 min). Early PET images
reflect essentially the blood-flow dependant distribution, while images obtained later
than 12 minutes after the injection show a specific uptake in structures known to
have the highest AChE ac—vity such as the caudate-putamen. The ratio of cerebellar
to striatal uptake is 3 at 30 vin. Wash out of the radioactivity is more rapid in the
cerebellum than in the cauda\_putamen (half-lives 8 and 30 min, respectively).

In contrast to THA or its derivatives, [11C]PHY thus appears to represent a good
marker of Pain AChE activity, which makes it of considerable clinical interest.

marker of brain AChE activity, which makes it of considerable clinical interest. Work is now in progress to investigate the use of [11C]PHY for in vivo imaging of human neurodegenerative disorders.

## 97.3

PRETREATMENT WITH THE 5-HT3 RECEPTOR PRETREATMENT WITH THE 5-HT3 RECEPTOR
ANTAGONIST, ZACOPRIDE, BLOCKS THE EMESIS
INDUCED BY THE MUSCARINIC AGONIST, CI-979, IN
THE FERRET. H.J. Altman\*, H.J. Normile, M.
Callahan\* and R. Davis\*. Dept. of Psychiatry,
Wayne State Univ. Sch. Med., Detroit, MI 48207;
Dept. of Pharmacol., Parke-Davis
Pharmaceutical Research, Ann Arbor, MI 48105.

The purpose of the study was to determine whether pretreatment with the 5-HT3 receptor antagonist, zacopride, could effectively block the emesis induced by the muscarinic cholinergic receptor agonist, CI-979, in the ferret. CI-979 was injected sub-Q at a dose of 0.1 mg/kg. At this dose all animals exhibited substantial retching. Thirty minute (sub-Q) attenuated retching at all doses examined.

This study represents, therefore, the first successful demonstration of an antagonism of

cholinomimetic-induced emesis by a drug that does not act directly on cholinergic neurotransmission. These results are particularly important in light of the potential usefulness of cholinomimetics in the treatment of memory loss associated with Alzheimer's disease.

CEREBRAL GLUCOSE TRANSPORTER DEFICITS IN ALZHEIMER DISEASE: REDUCTION IN GLUTI AND GLUT3 ISOFORMS. I. A. Simpson', K. Chundu, T. Davies-Hill and P. Davies<sup>1</sup>. NIDDK /NIH, Bethesda MD. and <sup>1</sup>Albert Einstein College of Medicine, Bronx, NY.

PET scanning studies in patients with Alzheimers disease (AD) have revealed a reduction in glucose metabolism in parietal and temporal cortex. In this study we have determined the level of expression of the GLUT1 and GLUT3 glucose transporter isoforms in six regions (frontal, parietal, occipital and temporal cortex, hippocampus and caudate nucleus) of post mortem brains from 12 AD (68-85 y) and 12 control subjects (21-96 y). GLUT1 and GLUT3 expression was measured by Western Blot analysis using specific antibodies raised against the human erythrocyte glucose transporter (GLUT1) and the C-terminal amino acid sequence of human GLUT3. Averaging the GLUT1 data for all regions revealed a significant 45-50% (p<0.05) deficit in both the microvessel (M, 55 Kda) and the neuronal/glial (M, 45 Kda) forms of GLUT1. An overall reduction in GLUT3, the neuronspecific glucose transporter was also observed with significant reductions being observed in the parietal (67%), temporal cortex (65%) and the hippocampus (56%) of the AD subjects. These decreases correlate well with the deficits in cerebral glucose metabolism and neuronal function.

PRO-IL-1\$ IS PROCESSED TO ITS MATURE FORM BY THE CYSTEINE PROTEINASE CATHEPSIN B: A POTENTIAL THERAPPUTIC TARGET IN ALZHEIMER DISEASE. R. Ryan, L. Greco, Z. Stengelin and P.L. Wood\*. Mayo Clinic, Jacksonville, FL 32224 & Hoechst

P.L. Wood\*. Mayo Clinic, Jacksonville, FL 32224 & Hoechst Pharma, NJ.
Interleukin 1β (IL-1β) is a cytokine generally associated with macrophages that mediates a broad spectrum of biological actions on immune and inflammatory responses, as well as being a modulator of CNS activity. Several recent studies have indicated that IL-1β may play a detrimental role in Alzheimer's disease. Cathepsin B (CB) is a cysteine proteinase observed to be strongly induced in activated macrophages as well as being associated with neuritic plaques in Alzheimer brains. Catalytically active CB has been observed in the synovial fluid of arthritis patients. Since CB and IL-1β appear to be temporally associated in different pathological conditions we examined the ability of CB to process 36 kDa pro-IL-1β into its 17 kDa mature species.

A time dependent conversion of 36 kDa pro-IL-1β into the mature 17 kDa species by CB was observed and this conversion was inhibited by the thiol proteinase inhibitors E-64, cystatin and leupeptin. Bestatin an aminopeptidase inhibitor and the serine proteinase inhibitors secretory leukocyte protease inhibitor and elastin did not effect the processing. The addition of CB and Pro-IL-1β to boiled Alzheimer CSF also resulted in the processing of the precursor, indicating that CB may be active in the Alzheimer physicochemical environment. These data suggest that if pro-IL-1β gains access to environments rich in CB it may be processed to the 17 kDa biologically active species. [Support: Mayo Foundation]

INCREASED LEVELS OF TRUNCATED NGF RECEPTOR IN URINE OF MILDLY DEMENTED PATIENTS WITH ALZHEIMER'S DISEASE. M.D. Lindner, D.D. Gordon, J.M. Miller, P.N. Tariot, McDaniel, R.W. Hamill, P.S. DiStefano, and R. Loy. U. Rochester Sch. of Med., Monroe Community Hospital, 435 E. Henrietta Rd., Rochester, NY 14620.

Research on peripheral Schwann cells has shown that the extracellular portion of the NGF receptor is truncated and excreted in urine. Following peripheral axotomy, the number of Schwann cell NGF receptors and urine levels of the truncated NGF receptor (NGF-Rt) increase. NGF receptors are also located on cholinergic basal forebrain neurons that degenerate in Alzheimer's disease, and the present study was conducted to determine if urine levels of NGF-Rt

might be altered in patients with Alzheimer's disease.

A new protocol for an enzyme-linked immunosorbent assay was developed to measure urine levels of NGF-Rt in nondemented aged controls (n=19) and patients with dementia of the Alzheimer type (n=62). Dementia severity was quantified with the expanded Clinical Dementia Rating.

Urine levels of NGF-Rt were substantially elevated in mildly demented patients and decreased to low levels in severely demented patients. The initial increase in urine levels may represent an upregulation in the production of NGF receptors, and/or an increase in the number of receptors being shed as a consequence of the degeneration of NGF receptor-containing neurons, but their precise source remains to be determined.(AG09231, AG08231, K07MH00733, AG03644

LOSS OF DOPAMINE D2 RECEPTORS IN THE TEMPORAL LOBE AND HIPPOCAMPUS OF DEMENTING DISEASES
J.N. Joyce\*, C. Kager, H. Ryoo, S. Goldsmith, Dept. Psychiatry, Lab

Chemical Neuroanatomy, Univ. Penn. Sch. Medicine, Philadelphia, PA
We have previously described the autoradiographic mapping of the D2 receptor with [125]epidepride in human brain (Joyce et al., JPET, 253:1253 -1263,1991). The temporal cortex, except for primary auditory cortex, shows 3-fold higher numbers of binding sites than prefrontal cortex. In the middle and inferior temporal cortex the predominant pattering is of D2 receptors in the deep laminae. At the border of the collateral sulcus this pattern changed such that D2 receptors are located in the superficial and deep laminae. The perirhinal cortex (PR) showed dense binding in the external laminae only, perirhinal cortex (PR) showed dense binding in the external laminae only, whereas the entorhinal cortex (EC) showed very low binding. The projection zone of the PR within the dentate gyrus (DG) exhibited D2 binding sites as did the the CA3 and subicular fields of the hippocampus and the basolateral nuclei of the amygdala. These data suggest that the D2 receptor is an important mediator of the actions of dopamine (DA) in limbic cortex. We explored this turther by examining the binding in 6 cases of dementia (means of 64.8 yrs age, 9.5 hrs PMI) and 7 control cases (means of 71.5 yrs age, 9.1 hrs PMI). 4 of the 6 cases of dementia were confirmed as Alzheimer's disease (AD)and 2 cases diagnosed at autopsy as cortical atrophy. In 5 of 6 cases there was a marked reduction in the density of D2 receptors in the DG, CA3, subiculum and PR. In the AD but not the cortical atrophy cases there was, in addition, a marked reduction of D2 receptors in the basolateral nucleus of the amygdala. An additional 6 schizophrenic cases and 5 AD cases are currently being processed for D2 receptor autoradiography. Given the important roles that the PR, EC and hippocampus play in memory, it is likely that the actions of DA at D2 receptors can differentially modify memory functions in humans. This is the first direct evidence that the expression of DA receptors is modified in the limbic lobe of the dementias and could contribute to the symptoms. Funded by MH43852, MH 43880, AG 09215.

BASALOCORTICAL GABAERGIC AND CHOLINERGIC NEUR-ONS CHARACTERIZED ELECTROPHYSIOLOGICALLY AND IMMUNOCYTOCHEMICALLY IN CULTURE. A.A. Khan\* and R.W. Baughman. Dept Neurobiol, Harvard Med Sch, Boston MA 02115.

he existence of cholinergic magnocellular new ons projecting from the basal forebrain to the neocortex and hippocampus is well established. We have obtained evidence that in addition there are gabaergic basalocortical neurons. Basalocortical cells were labelled retrogradely in vivo with injections of Dil on postnatal day 5 or 6, and on day 8 the magnocellular basal forebrain area was dissociated enzymatically and placed in monolayer culture on small collagen islands (Baughman, et al. '91). After 14-90 days in culture, whole-cell patch recordings of membrane potentials and currents were made from 129 magnocellular basal forebrain cells. Action potential widths of the cells fell into two populations with means of  $0.9\pm0.08$  ms (n=25, 19 % of total) and  $1.9\pm0.5$  ms (n=104, 78% of total) at half height. Previously we found that APs of identified gagaergic and glutamatergic cortical neurons fell into two similar populations. Synaptic responses were studied in cocultures of basal forebrain and cortex. Of 11 narrow-AP cells studied in this way, 3 produced ipsps that were blocked with bicuculline and that reversed at about -60 mV. When cultures were stained immunocytochemically for gaba, 25% of the DiI-labelled cells were positive for gaba; this complements our previous finding that 74% of the basalocortical cells are ChAT positive. In summary, we find that a significant proportion, about 20%, of the cells in the basalocortical pathway appear to be inhibitory gabaergic neurons. Identification of the role of this system is important in view of the involvement of the basalocortical pathway in Alzheimer's disease and memory.

RAPID DEPHOSPHORYLATION AND UPREGULATION OF IMMUNOREACTIVITY IN HEAT-SHOCKED CEREBRAL EXPLANTS.
MODIFYING EFFECTS OF HYDROCORTISONE, ESTROGEN AND
BIOCHEMICAL MATURATION. S.Ch. Papasozomenos\* and Y. Su. Dept. of
Path., Univ. of Texas Med. Sch., Houston, TX 77225.

We showed that phosphorylation of the Tau-1 epitope is similarly altered in heat-shocked rats and patients with Alzheimer's disease (PNAS 88:4543, 1991). To produce a comparable in vitro model, we heat shocked 21-day-old fetal rat cerebral explants at 45°C for 15 min, 42°C for 15 min and 42°C for 90 min. Explants were analyzed at 0, 3, and 6 h after heat shocking by immunocytochemistry and qualitative and quantitative (251-labeled protein A) immunoblotting using the Tau-1 and Tau-5 monoclonal anti- $\tau$  antibodies. At all 3 time intervals (0, 3 and 6 h) in heat-shocked explants, the amount of  $\tau$ recognized by Tau-5 doubled (P<0.001), the nonphosphorylated Tau-1 epitope was markedly increased (P<0.001) due to dephosphorylation indicated by a significant (P<0.001) reduction of the ratio of total  $\tau$  to nonphosphorylated  $\tau$  and loss or attenuation of the 60-kDa and accentuation of the 50-kDa  $\tau$ polypeptides. Also, heat-shocked explants were more intensely stained than controls. These in vitro changes of the Tau-1 epitope were antithetic to those observed in situ. To investigate the in situ vs in vitro differences, 21-day-old explants were treated with 1  $\mu$ M hydrocortisone or  $\beta$ -estradiol or both for 20 h and then heat-shocked or 35-day-old explants were heat-shocked. While all 3 pretreatments prevented the Tau-5 upregulation, only hydrocortisone reduced to non-significant levels the degree of Tau-1 dephosphorylation. While in 35-day-old explants biochemical maturation of  $\tau$  to its adult isoform complement (50-, 52-, 60- and 66-kDa) did not prevent the above rapid (0 h) changes, heatshocked explants were similar to controls by 6 h. Thus, both the external milieu and the state of differentiation modify the response of  $\tau$  to stressful stimuli.

THE LOCUS COERULEUS AND DEPRESSION IN ALZHEIMER'S R.M. Zweig\*, M.E. McWilliams, J.C. Hedreen, C. Steele, C.A. Kitt, M.F. Folstein, D.L. Price, C.A. Ross. LSUMC, Shreveport, LA 71130 and Johns Hopkins Sch of Med, Baltimore, MD 21205.

MONDAY PM

We previously reported a relationship between depression and severity of neuronal loss in the locus coeruleus (LC) in Alzheimer's disease (AD) Neurol 1988;24:233-242]. Using similar [Ann Neurol 1988;24:233-242]. Using similar methods, we counted neuronal profiles at up to three levels of LC in 23 new AD cases. Eight depressed cases (mean age 65.9) had fewer profiles than 15 nondepressed cases (mean age 78.7) at all LC levels: 9.9(±8.8) vs 17.1(±9.6) rostral; 23.8(±18.1) vs 63.1(±21.3), p=.006 mid; and 49.0(±7.9) vs 74.0(±27.3), p=.035 caudal (1 tailed t-tests). Severity of AD-related pathology in sections of inferior temporal gyrus were comparable in the two groups. When 7 depressed and 12 nondepressed cases with definite severe and 12 nondepressed cases with definite severe dementia (last MMSE<6) were compared (post hoc), the significant mid level difference persisted. When age-matched subsets of depressed (n=4) and nondepressed (n=9) cases were compared (post hoc), significant differences at mid and caudal levels persisted. These results, similar to those of our original study, suggest that LC pathology may have a role in depression occurring in AD.

EXCITOTOXIN INDUCED LESIONS OF THE RAT VENTRAL GLOBUS PALLIDUS AND MEDIAL SEPTUM. AN IMMUNOCYTOCHEMICAL ANALYSIS OF LONG TERM COMPENSATORY EVENTS. N. Mghy\*1, G. Bendahan, <sup>1</sup>Ll. Boatell <sup>1</sup>, C. Wetmore, <sup>2</sup> B. Bielke, <sup>2</sup> B. Tinner <sup>2</sup> L. Olson <sup>2</sup> and K. Fuxe, <sup>2</sup> U.

Bendahan, <sup>1</sup>LL Boatell <sup>1</sup>, C. Wetmore, <sup>2</sup>B. Bjelke, <sup>2</sup>B. Tinner <sup>2</sup>L. Olson <sup>2</sup> and K. Fuxe, <sup>2</sup>U. Biochemistry, School of Medicine, University of Barcelona, Barcelona, Spain <sup>1</sup> and Dept of Histology and Neurobiology, Korolinsko Institute, Slockholm, Sweden.

Micronipction of quisqualic acid (QA)(GOMM/ul) and ibotenic acid ((A) (25mM/ul)) were made into the medial septal nucleus (.6ul) and the ventral globus pallidus (GP)(1ul) of adult male Sprague-Dowley rats. Decreased neuronal levels of brain-derived neurotrophic factor (BDNF) and glial basic fibroblast growth factor (bFGF) immunoractivities (IR) were detected in the hippocampal formation at 1 year but not 13 days postlesion of the septum and ventral GP. In controst to the 1 year septal lesions, which also produced a reduction in the number of BDNF IR cells in the septal area the QA and M induced GP lesions produced an increase in the number of BDNF IR cells in this area. The 1 year QA and IA induced septal lesions were also associated with increases in C-loss IR within the lateral septal nucleus. All the induced lesions were also associated with a partial disappearance of cholinergic nerve cell badies and their never terminal networks within the hippocampal formation and the cerebral cortex as studied by choline acetylase and acetylcholine esterose immunocytochemistry. Within the ventral GP but not within the medial septum nucleus, the nerve cell death was associated with the appearance of calcium deposits were found extracellularly as rounded profiles throughout the entire ventral GP and the adjacent dorsal part. The present findings give evidence that subcortical excitatosic lesions for nerve cells in other general contents of the present findings give evidence that subcortical excitatosic lesions for nerve cells in other general contents of the first filter of the first filter of the filter of the filter of the filter of the filter of the filter of the filter of the filter of the filter of the filter of the filter of the filter of the filter of the

The present findings give evidence that subcortical excitatoxic lesions of nerve cells involving inter aliacholinergic neurons leads to altered and reduced presence of BDNF IR and of glial bFGF meet Ameronimetric neutrons leads to altered and reduced presented a but in a find a spill of spill of the finding and areas. Finally, calcium toxicity may be a major factor in the mediation of excitatoxin induced nerve cell death within the GP. Thus, calcium deposits in aging brain and in patients with dementia may be a consequence of pathological enhancements of glutamate transmission. (Supported by Swed. Med. Res. PRE- AND POSTSYNAPTIC PARAMETERS DURING DEVELOPMENT OF GABAERGIC SYNAPTIC TRANSMISSION IN TECTAL CULTURES R. Grantyn\*, K. Kraszewski, M. Samoilova and R. Warton. Dept. Neurophysiology, Max Planck Inst. for Psychiatry, D-8033 Martinsried,

The aim of this study was to establish a culture assay for GABAeroic synapses with increasing efficacy of transmission, and to find out which of the most relevant parameters (quantal size go, number or release sites n, probability of release p) undergoes changes in the course of synapse development. Over a period of 3 weeks in vitro (DIV5-26) the fraction of neurons generating evoked IPSCs raised from 17% to 76%. Average amplitudes of evoked unitary IPSCs (range 3-640 pA) increased during this period by a factor of 4 (about 150 neuron pairs tested), thus indicating a significant rise in the efficacy of GABAergic transmission. In contrast, no developmental change has been observed in the average amplitudes of miniature somatic IPSCs and the quantal size of evoked IPSCs (gQ about 110 pS). No increase was found also in whole cell current densities, as determined by evaluating current responses to saturating concentrations of exogenous GABA and whole cell capacitances. Changes in single channel activity in outside-out patches were also subtle and concerned only the concentration-dependence of desensitization. In contrast, bouton density significantly increased (from about 1 bouton per neuron at DIV3 to more than 40 boutons per neuron at DIV24) and the average probability of release nearly doubled.

Our results suggest that in this culture system synapse maturation was primarily the result of presynaptic sprouting and increased p in part of the terminals. Receptor accumulation, if present, has remained very low reaching less than 3-4 times the average density of  $\mathsf{GABA}_\mathsf{A}$  receptors.

ANDROGENIC NOT ESTROGENIC STEROIDS ALTER NEUROMUSCULAR SYNAPSE ELIMINATION. C.L. Jordan\* & S. Watamura, Dept. Psych., Univ. California, Berkeley, 94720

In the levator ani (LA) muscle of rats, synapse elimination (SE) is regulated by androgen: treatment of castrated male rats with testosterone propionate (TP) during SE prevents much of the normal loss of multiple innervation in this muscle. The present study sought to identify the active form of TP, since TP might be converted to either an estrogenic or androgenic metabolite before affecting SE in the LA. At P7, anesthetized male rats were castrated and then treated for the next 3 weeks with 1 of 5 treatments: 1) TP, 2) dihydrotestosterone propionate (DHTP), 3) estradiol benzoate (EB), 4) EB and DHTP, or 5) the oil vehicle. At P28, rats were killed and their LA muscle dissected and stained with tetranitroblue tetrazolium salts. The pattern of innervation in the LA was assessed by counting the number of different motor axons that contact individual muscle fibers. We found that the level of multiple innervation in the LA at P28 is unaffected by EB whereas DHTP appears to mimic the effect of TP. This finding suggests that the effect of T on SE is mediated through an androgen, such as T itself or DHT, acting upon androgen receptors. Since biochemical evidence suggests that T rather than DHT is active in the LA muscle, our present findings also suggest that androgen acts at a site(s) other than the LA muscle to influence SE. Supported by NS08686 and NS28421.

ELEVATION IN PRESYNAPTIC CALCIUM LEVEL ACCOMPANYING INITIAL NERVE-MUSCLE CONTACT. <u>Zhengshan Dai</u> and <u>H.B. Peng</u>. Dept. of Cell Biol. and Anatomy and Curr. in Neurobiology, Univ. of North Carolina, Chapel Hill, NC 27599.

sis at the neuromuscular junction (NMJ) is induced by nerve-muscle (N-M) contact as shown by the immediate onset of transmitter release upon contact in vitro. Since presynaptic calcium level plays a pivotal role in transmitter release, we used N-M cultures to examine the relationship between neuronal calcium level and the earliest N-M interaction. Xenopa spinal cord neurons were loaded with the membrane permeant calcium indicator fluo-3/AM and monitored with confocal microscopy as an unlabeled myoball was manipulated into contact with it. In 50% of N-M contacts, an increase in neuritic fluo-3 fluorescence was observed in the vicinity of muscle contact. To obtain more quantitative information, we used fura-2 ratio imaging to correlate the presynaptic calcium level with transmitter release monitored by whole-cell patch clamping of the contacting myoball. This analysis showed a 1.5 to 6-fold increase in calcium level in the neurite upon contact with a myoball in 80% of the N-M pairs. 50% of the pairs showing calcium elevation were also positive in neurotransmission. Both the calcium rise and transmitter release were suppressed by lifting away the myoball or by calcium-free solution. Suramin, a polyanionic compound that interferes with cell surface receptors, also suppressed the calcium rise and transmitter release, suggesting a role of cell surface molecules in mediating this phenomenon. In addition to manipulated contacts, naturally formed NMJs in culture also showed an elevation in presynaptic calcium level. Thus, this elevation appears to be a physiological step in the early stage of synaptogenesis and is likely mediated by interaction of molecules at the N-M cell surfaces. ANTIBODIES TO SYNAPTOPHYSIN INTERFERE WITH TRANSMITTER SECRETION AT DEVELOPING SYNAPSES. J. Alder + \*, Z-P. Xie +, F. Valtorta +, P. Greengard #, and M-m. Poo +. + Dept. Biol. Sci., Columbia U., NY, NY 10027. + Dept. Pharm., U. Milan, Milan, Italy 20129. # Lab. Molec. Cell. Neurosci., Rockefeller U., NY, NY

The functional importance of synaptophysin, a synaptic vesicle-specific protein, in transmitter release at neuromuscular synapses in Xenopus cell culture was studied by loading of synaptophysin antibodies into presynaptic neurons. Polyclonal antibodies or their Fab fragments were loaded into spinal neurons by injection into one of the early blastomeres of *Xenopus* embryos one day prior to culturing. Immunocytochemical staining confirmed the presence of the antibody in the cultured nervons. At synapses made by synaptophysin antibody-loaded neurons, the spontaneous synaptic currents (SSCs) showed marked reduction in frequency compared to control neurons loaded with pre-immune serum or non-specific antibody or in the absence of loading. The average amplitude of the SSCs of antibody-loaded neurons was similar to that of control neurons, suggesting that the antibody reduces the frequency of spontaneous ACh secretion without affecting quantal size. Antibody-loaded neurons showed reduced amplitude and increased failure rate, or even complete failure, in the impulse-evoked synaptic response. In an alternative method, the effect of acute application of antibody was examined by direct loading of antibody through a whole-cell pipette at the soma of a presynaptic neuron. This treatment also diminished the frequency of spontaneous synaptic currents as well as the amplitude of evoked responses, indicating an immediate presynaptic effect of antibodies. Taken together, these results suggest that functional synaptophysin is required for transmitter secretion.

PS. 4

A POSSIBLE ROLE FOR ATP RECEPTORS IN THE EARLY DEVELOPMENT OF CHICK NEUROMUSCULAR SYNAPSES, J. J. Walker\* and R. I. Hume. Dept. Biol., Univ. of Michigan, Ann Arbor, MI 48109.

ATP receptors (ATPR) are expressed on the surface of embryonic chick skeletal muscle cells during the time that neuromuscular synapses are forming. Functional ATPR disappear by birth, but reappear if the muscles are denervated. The observation that the expression of ATPR is correlated with synaptogenesis raises the possibility that ATPR may be involved in the initial stages of neuromuscular synapse formation. We have tested this hypothesis by co-culturing neurons and muscle in the presence of an ATPR antagonist.

Our experimental approach was to pre-incubate established cultures of myotubes for 30 minutes in media containing 50 \( \theta \) M DIDS. At this concentration, muscle ATPR are completely blocked (Thomas et al. Brit. J. Pharmacol 103:1963). Dissociated ciliary ganglion neurons were then added, and synaptic function was tested a various times after the addition of neurons. To assess synaptic function we evoked action potentials in neurons sitting directly atop muscle fibers with extracellular stimulation, and visually assayed muscle contraction as an indicator of synaptic function. Thus our assay detected only

muscle fibers with extracellular stimulation, and visually assayed muscle contraction as an indicator of synaptic function. Thus our assay detected only suprathreshold synaptic contacts.

In the absence of DIDS, some neurons made suprathreshold connections within an hour, and more than half of the neurons made suprathreshold connections by 12 hours. In contrast, in the presence of DIDS, no suprathreshold connections were detected within the first 12 hours of co-culture. The effect of DIDS seems likely to be associated with its ability to block ATPR, since DIDS had no effect on the ability of acetylcholine to elicit contraction in muscle cells. Suprathreshold synaptic connections eventually formed in the continuous presence of DIDS; the earliest such responses were noted at 14 hours, and responses were common by 24 hours. Thus DIDS delays, but does not prevent the formation of suprathreshold synaptic connections.

These results demonstrate that a blocker of ATPR can delay the maturation of synaptic function, and are consistent with the idea that ATPR may play a role in the early development of neuromuscular transmission.

# 98.6

DISTRIBUTION OF AGRIN MRNAs IN THE DEVELOPING CHICK EMBRYO. E. Ma and E. W. Godfrey\*. Department of Cellular Biology and Anaton Medical College of Wisconsin, Milwaukee, WI 53226.

Medical College of Wisconsin, Milwaukee, WI 53226.

Agrin is a protein associated with synaptic basal lamina that is thought to organize the postsynaptic apparatus at the neuromuscular junction, causing aggregation of ACh receptors and other postsynaptic components. Motor neurons appear to be the major source of synaptic agrin with this activity, but most other basement membranes also contain agrin-like molecules. In the chicken, agrin-like proteins from muscle, heart and kidney induce fewer and smaller ACh receptor clusters than neural agrin (Godfrey, Exp. Cell Res. 195:99, 1991). This difference in activity may reflect differential expression of proteins encoded by 3 alternatively spliced forms of agrin mRNA, the most active of which has only been found in the nervous system (Ruegg et al., Neuron 8:691, 1992). Here we report the distribution of mRNAs coding for agrin and closely related proteins in the developing chick embryo.

In situ hybridization was performed using digoxigenin-labeled cRNA probes

In situ hybridization was performed using digoxigenin-labeled cRNA probes specific for chicken agrin mRNAs, which should hybridize to all 3 isoforms (gift of Drs. K. Tsim and U.J. McMahan). Antisense but not sense cRNA hybridized specifically to many embryonic tissues. The most heavily labeled tissues were ventral spinal cord (presumably motor neurons), kidney and heart. Somitic myotome and early skeletal muscle were less intensely labeled. At embryonic day 3 (E3, st 18) spinal cord was uniformly stained, but by E4 (st 23) ventrolateral cells were much more heavily labeled. Intensity of signal in these presumptive motor neurons appeared to decrease steadily with development, as did signal in kidney, heart and muscle. In the brain, agrin mRNAs appeared as early as E7.5 and were localized to cranial motor nuclei, laminae in cerebellum and optic tectum, and ventricular zones. We are using polymerase chain reaction to define the distribution of agrin mRNA isoforms in regions of embryonic brain and other tissues. The agrin proteins may participate in synaptogenesis and other neuron-neuron interactions in the developing brain. Supported by NIH (NS27218, HD20743).

EXTERNALIZATION OF AGRIN-LIKE MOLECULES BY EMBRYONIC NEURONS. M.W. Cohen\*, F. Moody-Corbett and E.W. Godfrey. Dept. of Physiol., McGill Univ., Montreal, Que., Div. of Basic Med. Sci., Memorial Univ., St. John's, Nfld. and Dept. of Cell. Biol. & Anat., Med. Coll. of Wisconsin, Milwaukee, WI.

In order to examine neuronal externalization of agrin-like molecules, spinal cord neurons from Xenopus embryos were cultured on a substrate which binds these molecules tightly. Immunofluorescent staining revealed agrin-like molecules along the path of many neurites, even in regions of new neuritic growth less than 1-hrold. The molecules remained associated with the surface of the culture dish following removal of the neurites by aggressive rinsing. When embryonic Xenopus muscle cells were added to cultures after complete removal of the neurons and neurites, their acetylcholine receptors (AChRs) accumulated along the paths of substrate-bound agrin-like molecules. The lengths of AChR aggregation along these paths were similar to those which occur along neurite-muscle contacts in nerve-muscle co-cultures. Besides demonstrating that embryonic spinal cord neurons externalize agrin-like molecules along most of their neuritic growth, the findings are consistent with the notion that sufficient quantities are externalized to account fully for nerve-induced aggregation of AChRs at embryonic nerve-muscle

## 98.9

CHARACTERIZATION OF A BASAL LAMINA BINDING DOMAIN IN AGRIN. M.J. Werle\* S. Kröger, K.W.K. Tsim, M. A. Ruegg, and U.J. McMahan, Department of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305.

The C-terminal half of agrin contains the domain that induces myotubes to form aggregates of AChRs and other postsynaptic proteins including basal lamina components. The C-terminal half has also been found to contain a domain that binds to isolated sheets of chick retinal basal lamina (Kröger et al., Soc. Neurosci. Abs., 1991, 17:179). To learn whether this basal lamina binding domain binds to postsynaptic components on the surface of myotubes, we transfected myotubes with cDNA constructs coding for the C-terminal half of active agrin either having or lacking a series of 100 amino acids that are required for binding to retinal basal lamina. We found that in both cases the myotubes secreted agrin which, in turn, induced the myotubes to form aggregates of AChRs and, accordingly, the other to form by agrin having the basal lamina binding domain had associated with them aggregates of secreted agrin, whereas the protein aggregates induced to form by agrin having the basal lamina binding domain had associated with them aggregates of secreted agrin, whereas the protein aggregates induced to form by agrin lacking the basal lamina binding domain did not. These findings would be expected if the basal lamina binding domain in the C-terminal half of agrin recognizes basal lamina components of the neuromuscular junction. They are also consistent with the hypothesis (Nitkin et al., 1987, J. Cell Biol. 105:2471-2478) that at developing neuromuscular junctions agrin induces the aggregation of the basal lamina components to which it binds.

DIFFERENTIAL DISTRIBUTION OF MEMBERS OF THE AGRIN PROTEIN FAMILY IN THE NERVOUS SYSTEM. S.E. Horton, M.A. Ruegg, G. Escher, S. Kröger and U.J. McMahan\*, Department of Neurobiology, Stanford University School of Medicine, Stanford,

Several lines of evidence indicate that the agrin is synthesized and released by motor neurons to induce the aggregation of AChRs and other components of the postsynaptic apparatus at the neuromuscular junction. The agrin gene also codes for agrin-related proteins (ARPs) which are inactive in protein aggregation on muscle fibers. In chick, agrin is distinguished from ARPs by an 11 amino acid insertion which is required for agrin's activity. As a step toward learning whether agrin is involved in the induction of postsynaptic apparatus at neuron-neuron synapses and defining the role of ARPs in the nervous system, we used PCR to screen for transcripts encoding proteins having or lacking the 11 amino acid insert in regions of the nervous system having or lacking neuronal mRNA. We found that optic nerve and sciatic nerve, which contain mRNA of endothelial and glial or Schwann cells but not neurons, had transcripts encoding ARPs but not agrin. On the other hand, the retina and dorsal root ganglion, which contain mRNA not only of endothelial cells and glial or Schwann cells but also neurons, had transcripts that encoded not only ARPs but also proteins with the 11 amino acid stretch typical of agrin. The results indicate that non-neuronal cells in the nervous system synthesize ARPs. They also lead to the conclusion that neurons other than motor neurons synthesize members of the agrin family and that these members have the 11 amino acid stretch required for agrin's protein aggregating activity.

## 98.10

FLUORESCENCE PHOTOBLEACHING RECOVERY IN LIVING MICE DEMONSTRATES ACETYLCHOLINE RECEPTOR MOVEMENT IN POSTSYNAPTIC MUSCLE MEMBRANE A.P. Brown, P. van Mier\*, J. W. Lichtman, Depts. Anatomy and Neurobiology, and Neurosurgery, Washington Univ. Sch. of Med., St. Louis, MO 63110 Acetylcholine receptor (AChR) mobility in muscle membrane may be

Acetylcholine receptor (AChR) mobility in muscle membrane may be important in the formation of synapses in the embryo, and perhaps also during synaptic reorganization in later life. Studies following AChRs for up to one day in vitro have suggested that, once inserted in the postsynaptic membrane, AChRs are essentially immobile. By monitoring AChRs at the living adult mouse neuromuscular junction using fluorescence photobleaching recovery, we assayed for receptor mobility over much longer times and thus could detect slower diffusion rates than required to each of the strength of the s recovery, we assayed for receptor mosming recovery, we assayed for receptor mosming recovery, we assayed for receptor mosminated over much longer times and thus could detect slower diffusion rates than previously possible. In young adult mice (n=50) the sternomastoid muscle was exposed, and AChRs stained with a saturating dose of rhodaminated  $\alpha$ -bungarotoxin (Rh- $\alpha$ BTx). An 8  $\mu$ m diameter spot of labelled AChRs was irreversibly bleached in a superficial junction using a He-Ne laser (0.5mW, 543.5nm). In subsequent views for up to 11 days (without adding new Rh- $\alpha$ BTx), progressive recovery of fluorescence occurred until the bleached area was nearly indistinguishable from the rest of the junction Despite the decrease in fluorescence of the entire junction due to receptor turnover, the absolute brightness of the bleached spots increased for several days. When the entire junction was bleached, however, no significant recovery occurred over 5 days. Control experiments ruled out that fluorescence recovery was due to the unbinding and rebinding of aBTx. Our results show that AChR mobility in the adult postsynaptic membrane in vivo is slow when compared to that reported during synapse formation in vitro. Nonetheless this movement is rapid enough to explain the disappearance of postsynaptic sites during postnatal synapse elimination. We are currently studying AChR movement at developing junctions and after denervation.

# VISUAL CORTEX: FUNCTIONAL ORGANIZATION OF STRIATE CORTEX

99.1
DEPOLARIZATION-ACTIVATED POTASSIUM CURRENTS IN IDENTIFIED VISUAL CORTICAL NEURONS. J.L. Albert and J.M. Nerbonne\*, Department of Molecular Biology and Pharmacology, Washington University School of Medicine, St. Louis, MO 63110. In vivo and in vitro recordings have revealed cortical neurons with distinct electrophysiological phenotypes: "regular spiking", "fast spiking", or "bursting". In order to assess directly the role of intrinsic membrane properties in determining these distinct firing patterns, we are characterizing voltage-gated outward K\* currents in isolated identified superior colliculus-projecting (SCP) visual cortical neurons, selected to correspond to the bursting phenotype.

isolated identified superior colliculus-projecting (SCP) visual cortical neurons, selected to correspond to the bursting phenotype.

SCP cells were identified in vitro following in vivo retrograde labelling with rhodamine beads. Outward K' currents were evoked by voltage jumps positive to -30 mV from holding potentials between -90 - -30 mV. In 18 of 42 cells, currents elicited from a holding potential of -90 mV activated quickly, peaked within 10 ms, and decayed slowly during the 100 ms pulse. In the remaining 14 of the neurons, currents peaked more slowly (10-30 ms). When currents were evoked from -40 or -30 mV, both the peak and the current remaining at the end of the pulse were reduced by -50%. Prolonged depolarizations revealed that inactivation of the K+ currents to steady state levels proceeded with a biexponential time course with time constants separated by an order of magnitude. Pharmacological experiments suggest at least 2 distinct current components: 1) a fast activating and inactivating current sensitive to 5 mM 4-AP, and 2) a more slowly activating, slowly inactivating current sensitive to 30 mM TEA. Experiments are underway to assess K' channel toxin sensitivity and to characterize depolarization-activated K' currents from cells with regular and fast spiking phenotypes. fast spiking phenotypes.

ACETYLCHOLINE INHIBITS POSTSYNAPTIC POTENTIALS THROUGH MUSCARINIC RECEPTORS IN CULTURED VISUAL CORTICAL NEURONS F. Kimura\* & R. W. Baughman Dept of Neurobiology, Harvard Medical School, Boston, MA 02115

Mammalian visual cortex recieves a dense cholinergic innervation from nucleus basalis magnocellularis in the basal forebrain. Recent in vivo studies demonstrated that iontophoretic application of ACh produces facilitation on visually driven responses in a majority (61-74%) of visual cortical cells. To better understand the mechanism of this modulatory effect of ACh, we looked at the effect on EPSPs and IPSPs elicited by single neuron and found that ACh inhibits both PSPs quite efficiently

Visual cortical cultures were prepared from Long Evans rat pups 1-5 days of age. Cells were dissociated enzymatically and plated on monolayer glial islands grown on collagen dots. Electrophysiological experiments were performed with whole-cell patch pipettes in current clamp mode from 2 neighboring cells after at least 1 week in culture.

Application of ACh at 5-10  $\mu$  M reversibly depressed all EPSPs (n=14) and 6 of 7 IPSPs tested. The concentration that gave 50% reduction (EC<sub>50</sub>) was in the range of 1 - 3  $\mu$  M. Since 1  $\mu$ M atropine blocked this depressive effect of ACh, we carried out further experiments with pirenzepine and 4-DAMP to determine what type of muscarinic receptor is involved in this effect. With EPSPs the EC<sub>50</sub> for pirenzepine was about 100 times higher than that for 4-DAMP (20  $\mu$ M and 200 nM, respectively) with 5  $\mu$ M ACh, suggesting that the depressive effect of ACh on EPSPs is mediated by M3 receptors

THE FIRST STAGE OF SYNAPTIC INTEGRATION IN STRIATE CORTEX. J.A. The Rockefeller University, Laboratory of Neurobiology, NY, NY 10021.

Neurons in the striate cortex respond differently to light than do the thalamic cells that convey ascending visual information. Novel cortical response properties can be explained only in part by geniculocortical patterns of convergence; circuits intrinsic to the cortex must contribute additional influence. To study the integration of thalamic and intracortical inputs in layer 4 of area 17, I have made patch recordings with dye-filled pipettes in brain slices prepared from young adult cats and ferrets. Synaptic responses were evoked by applying shocks to two sites, one in the white matter and the other in layer 6.

Recordings were made from both spiny stellate neurons and nearby pyramids; all cells fired only large, regular spikes. Weak stimulation of either site often evoked a solitary EPSP that was amplified when the membrane was depolarized above rest, an enhancement that sometimes produced a train of impulses. Stronger stimuli evoked synaptic responses comprising various combinations of polysynaptic EPSPs mixed with fast and slow IPSPs. Reminiscent of the absence or presence of end inhibition seen in simple cells in vivo, some neurons grew more strongly excited as stimulus strength was raised while others became more deeply inhibited. Typically, the general patterns evoked from both the white matter and layer 6 were similar for a given cell. This resemblance was not due to spatial spread of the stimulus or to excitation of a common stream of passing fibers since responses from both sites summed, and fatiguing one pathway by rapid activation failed to eliminate the response provided by the other. There were no clear-cut differences in synaptic physiology that correlated with spiny stellate as opposed to pyramidal morphology. Possible distinctions between the synaptic responses of smooth and spiny cells are being evaluated currently. Support was from NSF grant BNS8918951 to C.D. Gilbert and NIH grant 5 R37 EY05253 to T.N. Wiesel.

Orientation selectivity of synaptic currents during intracellular blockade of inhibition in visual cortex in vivo. L. J. Toth\*, S. Nelson, B. Sheth, M. Sur. Dept. of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139

A discrepancy exists as to the role of inhibition in shaping the orientation selectivity of cortical neurons. On the one hand, application of bicuculline, a GABA, antagonist, reduces orientation selectivity. On the other hand, EPSPs and IPSPs in cortical simple cells appear to be already tuned for orientation. Thus it is interesting to observe what happens to orientation selectivity if inhibitory currents within a single cell are blocked.

We have used the whole-cell technique to record intracellularly from visual cortical neurons in anesthetized, paralyzed cats while stimulating with oriented bars of light. We found that a pipette solution containing cesium fluoride and picrotoxin, and lacking ATP and Mg\*\*, dramatically reduces inhibitory (GABA, and GABA, currents, while leaving excitatory currents intact. Thus, we were able to block inhibitory inputs to a single cell while leaving inhibitory connections to neighboring cells intact. Neurons were first characterized extracellularly, while the electrode wa patched to the membrane, and then intracellularly by rupturing the membrane. The absence of outward currents was confirmed by voltage clamping cells at depolarized potentials. In agreement with previous studies, we found few observable synaptic currents at orientations orthogonal to the preferred. Importantly, we found that blocking inhibitory currents in single cells does not in general lead to any dramatic change in orientation specificity.

Our results suggest a major role for oriented excitatory inputs in generating orientation selectivity, although inhibitory inputs may sharpen selectivity. It is possible that global blockade of inhibition leads to positive feedback and a loss of selectivity that is much greater than is seen when inhibitory inputs to a single cell are blocked. CORTICAL MECHANISMS OF RECEPTIVE FIELD EXPANSION IN THE CAT STRIATE CORTEX. E. Volchan\* and C. D. Gilbert. Lab. of Neurobiology, The Rockefeller University, York, NY 10021

It has been shown that the response properties of cells in the superficial layers of cat and monkey striate cortex can be modulated by stimuli lying outside the receptive field. In the adult cat, receptive field (RF) size can be altered by stimulating a large area of the visual field with an array of moving bars while occluding the cell's RF with a mask several times its diameter. Conditioning with this artificial scotoma for a few minutes, the RF area is enlarged severalfold; an effect that can be reversed by stimulating the RF's central region (Pettet and Gilbert, Soc. Neurosci. Abstr., Vol. 17, p. 1090, 1991). This transient increase could reflect dynamic changes at either subcortical or cortical levels. The present study favours the latter. We recorded from binocular cells in the superficial layers of the cat striate cortex. After mapping the RFs for each eye, one eye was conditioned with the artificial scotoma, while the other eye was occluded. In addition to the RF expansion in the conditioned eye we also observed an increase in field size in the occluded eye, showing that the RF expansion can be transferred from one eye to the other. The interocular transfer suggests that the substrate for the expansion is intrinsic to the cortex rather than to antecedent levels of the visual pathway.

Spatial and Temporal Integration of Synaptic Inputs by Visual Cortical Neurons. S.B. Nelson\*, L. J.Toth and M. Sur, Dept. of Brain and Cognitive Sciences, MIT, Cambridge, MA 02139

We have used whole-cell recording techniques to study interactions between electrically evoked synaptic responses in an in vitro slice preparation of rat primary visual cortex. Responses recorded under voltage clamp using pipettes that contained K'-gluconate, ATP and Mg'' (n=17) consisted primarily of a short-latency EPSC that reversed near 0 mV followed by an IPSC that reversed near the chloride reversal potential. With pipettes filled with cesium fluoride and lacking ATP and Mg2+ (n=21), it was frequently possible to record EPSCs in isolation. In many cases, the brief latency, smooth waveform and ablity to follow high frequency stimulation suggested they were monosynaptic. Pairs of stimuli delivered to the same electrode yielded facilitation of the second response at short intervals (<100 ms) in most cells (34/38). In about half the cells tested, suppression was seen at longer intervals (>200 ms). When sequences of stimuli were delivered to two or more electrodes displaced laterally by 200-1000 microns, most cells showed no facilitation or suppression (19/24). Hence for these cells facilitation and suppression are input-specific and may be presynaptic. In the remaining cells (5/24), however, dramatic sequence-specific interactions were observed. In these cells the net response depended strongly on the order in which spatially separated stimuli were delivered. Both sequence-specific suppression and facilitation were observed

These results indicate that sequential synaptic inputs to cortical neurons are not always summed linearly. Paired-pulse suppression observed in vitro may underlie a similar suppression observed in vivo using pairs of visual stimuli. Sequenceselective responses could underlie direction selectivity. We are currently investigating these possibilities by using whole-cell techniques to record in vivo responses of cat cortical neurons to pairs of flashed visual stimuli.

CELLS SELECTIVE FOR ORIENTATION, DIRECTION, AND COLOR IN LAYER 4Cβ OF MONKEY STRIATE CORTEX. Dan Liu, Kirk G. Thompson, Tiande Shou, Steven J. Ault, and Audie G. Leventhalt Anat. Dept., Univ. of Utah Sch. of Med., Salt Lake City, UT 84132

We recorded from single cells in the parvocellular layers of the LGNd and striate cortex of nine old-world monkeys. Both Macaca fascicularis and Macaca mulatta were studied. Broad band and colored sinusoidal gratings, bars, and spots were used as stimuli. All responses were studied quantitatively and analyzed statistically by computer.

In the parvocellular layers of the LGNd of both species many cells encountered were selective for color, orientation, and direction. Color sensitive cells were observed that responded many times better to the preferred than to the non-preferred orientation and direction.

Cells in layer 4Cβ of striate cortex were also

direction. Cells in layer  $4C\beta$  of striate cortex were also selective for color, orientation, and direction. Their responses were qualitatively and quantitatively similar to those of the cells in the parvocellular layers providing their inputs. Penetrations that were roughly parallel to layer  $4C\beta$  provided evidence that cells with similar preferred orientations are grouped together in that layer. Contrary to previous reports, we conclude that cells in layer  $4C\beta$  are sensitive to stimulis orientation. The organized arrangement of the orientation preferences of these cells strongly suggests that subcortical orientation and direction sensitivity contributes to the generation of these properties of cortical cells.

cortical cells.

# Ocular dominance columns in monkey striate cortex revealed by activity-dependent expression of Zif268

A. Chaudhuri, \* R. Dyck, J.A. Matsubara, and M.S. Cynader

Dept. of Ophthalmology, Univ. of British Columbia, Vancouver, B.C. CANADA

The use of transcription factors for visualizing neuronal activity has been demonstrated in several non-primate species. The principal advantages of this approach are that:1) relatively short stimulation periods are required, 2) the technique can be combined with procedures for other cytochemical markers, and 3) single-cell resolution can be obtained with immunodetection.

We have used standard immunohistochemical techniques to detect the presence of one specific transcription factor, Zif268, in the visual cortex of vervet monkeys (Cercopithecus aethiops). Immunoreactive neurons were present in large numbers throughout the visual cortex of the normal animal being concentrated mainly within the supragranular layers and layer VI. Simultaneous immunodetection for Zif268 and the calcium-binding proteins calbindin and parvalbumin showed a negative correlation, suggesting that the Zif268 protein may be expressed selectively within excitatory neurons.

In order to determine if Zif268 expression is affected by afferent

stimulation in the monkey, we restricted visual input to one eye with the aim of revealing ocular dominance columns in striate cortex. We found that shortterm monocular deprivation by either enucleation, intravitreal TTX injection, or eyelid-suturing showed dramatic changes in Zif268 levels, revealing vertically oriented columns of reduced Zif268 staining interdigitated with columns of normal expression. Furthermore, these columns were discernible after just 5 hours of monocular deprivation by all three methods of selective exposure. A comparison of the ocular dominance pattern obtained with Zif268 and cytochrome oxidase histochemistry showed a coincident reduction of both markers along columns that were precisely aligned in adjacent sections

A NEW "BLOB" SYSTEM IN THE VISUAL CORTEX OF THE SQUIRREL MONKEY REVEALED BY NITRIC OXIDE SYNTHASE. C.W. Picanço-Diniz.† K.A.C. Martin.§ J.G. Franca.† J.A.S. Quaresma.† J.L.M. do Nascimento.† and M.J. Friedlander.\*\*¥ †Department of Physiology, University of Para, Belem, Brazil, \$MRC Anatomical Neuropharmacology Unit, Oxford University, Oxford, U.K., \*Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, AL 35294 USA.

Cytochrome oxidase (cytox) is a useful marker for different functional pathways in the primate visual system. In V1 the cytox-rich zones appear as rows of "blobs" when viewed from the cortical surface; in V2 they appear as a system of parallel stripes. Other proteins colocalize with cytox (Martin, TINS 11, 380, 1988). We examined the relationship between cytox and the synthetic enzyme for nitric oxide (NOS) by combining the two methods in single sections. The NADPH-diaphorase method (Vincent & Kimura, Neuroscience 46, 755, 1992) reveals NOS positive blobs in V1 and stripes in V2. However, in VI of squirrel monkey the NOS positive blobs do not always overlap with the cytox blobs. The NOS blobs are slightly larger on average than cytox blobs  $(29,578 \text{ vs. } 26,712 \text{ }\mu\text{m}^2)$  and form rows that are more widely spaced than the rows of cytox blobs (583 vs. 513 µm). Most of the NOS positive neurons are in the white matter (the subplate) and have rich axonal projections to the grey matter. The NOS positive subplate neurons are larger than those in the grey matter, but both sets are sparsely spiny and probably colocalize GABA and NPY. NOS blobs contain more NOS positive neurons than the interblob zones (10.5 neurons per mm<sup>2</sup> vs 7.4). We are exploring the connections of the NOS (10.5 lethous per limit vs 7.9). We are exploring the collections of the view to its potential importance in development and plasticity (Montague, et al., Cerebral Cortex 1, 199, 1992).

ACTIVITY-DEPENDENT ALTERATION OF NITRIC OXIDE SYNTHASE IMMUNOREACTIVITY IN CORTICAL AREA VI OF MONOCULAR MONKEYS. C. Aoki<sup>11</sup>, S. Fenstemaker<sup>1,2</sup>, C-G Go<sup>1</sup>,T.M. Dawson<sup>3</sup> & S.H. Snyder<sup>3</sup>. <sup>1</sup>Center for Neural Science & <sup>2</sup>Howard Hughes Med. Inst., New York Univ., NY, NY, 10003 & Dept. of Neurol., Pharmacol. & Mol. Sci., The Johns Hopkins Univ. Schl. of Med., Baltimore, Md, 21205.

NO is a neuronal messenger with vasodilatory and synapse-strengthening properties (Bredt & Snyder, '92, Neuron 8:3). We examined the distribution of NO synthase (NOS) in visual cortical area V1 of monkey cerebral cortex using a previously characterized anti-NOS antiserum. Adjacent sections were reacted for cytochrome oxidase histochemistry to delineate cortical laminae and, in the case of monocular monkeys, ocular dominance columns (ODC). Two years following removal of one eye, NO synthase (NOS)immunoreactivity was detectably less in layer 4C of the enucleated eye's ODC compared to that of the intact eye. Light microscopy revealed that NOS is concentrated in non-pyramidal neurons of supra- and infragranular layers whose processes are juxtaposed to large parenchymal blood vessels. These darkly stained neurons showed no detectable intercolumnar difference and were absent in lamina 4C of either ODC. The difference in NOS levels of 4C was, instead, due to the greater prevalence of short and punctate profiles containing NOS. Electron microscopy revealed that almost all of these profiles correspond to axons of passage and terminals that form synaptic junctions onto dendrites without contacting blood vessels. The observations suggest that the level of NOS in lamina 4C is regulated by local synaptic activity. These processes may be modulating synapse strength rather than cerebral blood flow. MULTIPLE CLASSES OF NITRIC OXIDE SYNTHASE IMMUNOREACTIVE NEURONS IN MONKEY VISUAL CORTEX.

IMMUNOREACTIVE NEURONS IN MONKEY VISUAL CORTEX. S.B. Fenstemaker\*1.2, C.J. Aoki¹, T.M. Dawson³-& S.H. Snyder³.¹Center for Neural Science & ²Howard Hughes Med. Inst, New York Univ., NY, NY 10003 & ³Depts. of Neurosci. and Neurol., The Johns Hopkins Sch. of Med., Baltimore, MD. 21205 Nitric Oxide has been proposed as a modulator of both cerebral blood flow and of synaptic strength (Bredt & Snyder, '92, Neuron 8:3). We describe here nitric oxide synthase immunoreactivity (NOS-ir) in macaque visual cortical areas V1 and V2, and compare it with cytochrome oxidase (CO) and NADPH-diaphorase histochemistry, and ir for Neuropeptide Y (NPY). Multiple forms of NOS-ir were found in V1 and V2. Most prominent were large, densely labeled irregularly shaped neurons scattered through lavers 2. 3. and 5. and concentrated in deen laver 6 and the white matter. through layers 2, 3, and 5, and concentrated in deep layer 6 and the white matter. These neurons and their long, thick processes often abutted large blood vessels. They appear indistinguishable from NPY-ir cells, except that occasional NPY neurons are found in layer 4. Smaller cells with round perikarya and shorter, finer caliber dendrites that tended to be radially symmetric were also NOS-ir. These neurons spanned the that tended to be radially symmetric were also NOS-ir. These neurons spanned the cortical layers and had no apparent relation to the vasculature. More intensely reactive clusters of these were found in upper layer 2 in V1; these clusters bore no consistent relation to the CO "blobs" in layers 2 and 3. Within layer 4, relatively dense NOS-ir was also seen in fine caliber processes and puncta. Variation in the density of NOS-ir in layer 4C has been found to be activity-dependent (Aoki et al., this volume). In Area V2, the same overall laminar distribution of NOS-ir was seen, but the most Area V2, the same overall laminar distribution of NOS-ir was seen, but the most dense labeling of both neurons and neuropil occurred in register with both the thick and thin CO-dense stripes. NADPH-d histochemistry produced labeling that was almost indistinguishable from the NOS-ir. A possible exception was that the large NADPH-d neurons in the white matter adjacent to V2 were clustered among the more plentiful NOS neurons. These results suggest that NO may influence neuronal activity in V1 and V2 by distinct mechanisms: 1) control of blood flow via large neurons that may also contain NPY, and 2) direct synaptic modulation by a separate class of smaller, more locally restricted neurons. ## 99.12

ROLE OF NITRIC OXIDE IN NMDA-RECEPTOR MEDIATED RELEASE OF NEUROTRANSMITTER IN VISUAL CORTEX.
M.J. Friedlander, P.R. Montague, F. Hester\* and R.B. Marchase. Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, AL 35294 USA.

Nitric oxide (NO) is a non-polar gas made in the mammalian brain by a calcium/calmodulin dependent enzyme upon N-methyl-D-aspartate (NMDA) receptor activation. NO may serve as a diffusible signal that communicates the status of postsynaptic sites at excitatory amino acid (EAA) synapses to neighboring pre- and postsynaptic sites. We investigated the role of NO in synaptosomes prepared from anesthetized adult guinea pig and cat visual cortex. The release of exogenously applied neurotransmitter (3H-D-aspartate or 3H-L-norepinephrine) or endogenous neurotransmitter (L-glutamate) was measured by scintillation counting and luminometry, respectively. NMDA caused release of all three neurotransmitters (EC50 =  $10\text{-}30\,\mu\text{M}$ , n=25). This effect was blocked in zero calcium or by APV (n=7). Preincubation of synaptosomes with competitive blockers of NO production (100 µM NG-monomethyl-L-arginine [LMMA] or NG-nitro-L-arginine [LNNA] (n=19)) reversibly blocked the NMDA mediated release of neurotransmitter as did 20 μM Hemoglobin (Hb, n=10). The D-isomers of the NO blockers were ineffective. The block of NO production did not affect K+-induced release of neurotransmitter. Activation of the NMDA receptors on a second nearby group of synaptosomes induced neurotransmitter release from the first group. This effect was also blocked by Hb. Thus, NMDA receptor activation can cause neurotransmitter release from neighboring synaptic elements via NO production, and can link the EAA and catecholamine pathways in visual cortex. # MOLECULAR BIOLOGY OF SEROTONIN RECEPTORS

# 100.1

MOLECULAR CLONING OF A NOVEL HUMAN SEROTONIN RECEPTOR (5-HT1F) G.McAllister , A.Charlesworth, M.S.Beer, A.J.Noble, D.N.Middlemiss and P.Whiting\*. Merck Sharp and Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Eastwick Road, Harlow, Essex, CM20

A novel human serotonin receptor (5-HT<sub>1E</sub>) cDNA(AC1) was isolated from a hippocampal cDNA library using polymerase chain reaction (PCR) techniques. When expressed transiently in HEK293 cells the AC1 encoded receptor displayed high affinity for [3H]5-HT(K<sub>d</sub>=15nM) but low affinity for 5-CT. The pharmacology of the receptor expressed both transiently and stably in HEK293 cells correlated well with the observed binding of the putative 5-HT<sub>1E</sub> receptor in human cortex. The AC1 encoded 5-HT<sub>1E</sub> receptor is functionally coupled in stably transfected HEK293 cells and has been shown to mediate the inhibition of adenylate cyclase activity.

THE HUMAN GENE S31 ENCODES THE PHARMACOLOGICALLY-DEFINED SEROTONIN 5-HT<sub>IE</sub> RECEPTOR. J.M. Zgombick, L.E. Schechter, M. Macchi, P.R. Hartiq, R.L. Weinshank, and T. A. Branchek. Synaptic Pharmaceutical Corporation, Paramus, NJ 07652

The gene encoding a human 5-HT<sub>i</sub> receptor subtype was isolated from a human placental genomic library using oligonucleotide probes derived from transmembrane (TM) regions of the cloned human 5-HT<sub>ie</sub> receptor. The deduced amino acid sequence of the genomic clone hp75d is identical to the recently isolated, but uncharacterized, novel serotonin receptor gene S31. TM domain sequence comparison of clone hp75d to other quantum nucleotide-binding protein-coupled receptors (GPCR) revealed the highest degree of homology (54%) with the 5-HT<sub>ID</sub> and 5-HT<sub>IE</sub> subtypes and lower degrees of homology (35-52%) to other serotonergic and catecholaminergic receptors. A stable cell line expressing this gene was established using murine fibroblasts as the host cell for pharmacological evaluation. High affinity (K,=9.7 nM), saturable (B<sub>m-2</sub>-2.4 pmol/mg protein) (\*H)5-HT binding was detected using membranes derived from stable transfectuants. Most compounds displayed low affinity (K,>0.7 OH, M). On the expressed gene with the exception of 5-MT<sub>IE</sub> of the high-stable delice best matched the pharmacologically-defined 5-HT<sub>IE</sub> binding site: 5-HT.> metovsergide > ergotamina > DPAT Thinding site: 5-HT.> metovsergi

THR355→ASN SITE-DIRECTED MUTAGENESIS CONVERTS THE HUMAN 5-HT1B (5-HT1DB) SEROTONIN RECEPTOR TO THE RAT 5-HT1B PHENOTYPE. M.W. Hamblin\*, M.A. Metcalf and R.W. McGuffin. GRECC, Seattle VAMC, and the Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA 98108.

Despite 93% amino acid identity, the human and rat 5-HT<sub>1B</sub> (5-HT<sub>1DB</sub>) receptors display markedly different drug specificities. Based on the discrete species distribution of the two receptor phenotypes and mutagenesis work on adrenergic receptors by Kobilka and colleagues, we and others proposed that much of this pharmacological species-dimorphism is produced by a single (human Thr355/rat Asn351) residue difference in the seventh transmembrane region. We compared the drug specificity of a human 5-HT<sub>1B</sub> Thr355Asn mutant with those of wild type human and rat 5-HT<sub>1B</sub> receptors expressed in COS-7 cells. Drug ICS0's in 2nM [3H15-HT competition binding assays were:

| 1030 3 in Zinit   1113 111 Competition officing assays were. |           |           |           |  |

| CGS12066B  | 4.2       | 37        | 64        |  |
| YOHIMBINE  | 140       | 7400      | 3300      |  |
| DPAT   | 750       | >10000    | >10000    |  |

These results demonstrate that much of the inter-species difference in 5-HT1B drug selectivity is due to this single amino acid change and may provide further insight into the nature of 5-HT1B receptor/ligand interactions. (Supported by the Department of Veterans Affairs.)

### 100.5

A SINGLE AMINO ACID ACCOUNTS FOR THE MAJOR PHARMACOLOGICAL DIFFERENCE BETWEEN THE HUMAN AND RAT 5-HT<sub>1B</sub> RECEPTOR.

Dougle of the Human of the Human of the Human of the Human of the Human of the Human of the Human of the Human of the Human of the Human of the Human of the Human of

Serotonin (5-HT) exerts its diverse actions via pharmacologically distinct receptors. Homologous human genes have been cloned recently that encode the 5-HTlA, 5-HTlB, 5-HTlB, 5-HTS31 and 5-HT2 receptors. The human 5-HTlB receptor has 93% amino acid sequence identity with the rat 5-HTlB receptor; however, while both receptors bind 5-HT with similarly high affinity, the rat, but not the human, receptor also exhibits high affinity for beta-adrenergic receptor (beta-AR) antagonists. Using site-directed mutagenesis, we replaced a threonine residue in the seventh transmembrane domain of the human receptor (position 355) with asparagine, found at the same position in the rat 5-HTlB receptor, as well as in the 5-HTlA and beta-AR. This single amino acid substitution, while not affecting the affinity for 5-HT, increases the affinity for alprenolol, DL- propanolol, and (-) pindolol by 670, 420 and 370-fold, respectively. These results indicate that the residue at position 355 in the seventh transmembrane domain plays a critical role in determining the ligand binding specificity of 5-HTlB receptors, particularly with respect to drugs that also bind to beta-AR.

THE MOUSE 5HT1Bβ SEROTONIN RECEPTOR IS LOCALIZED PRESYNAPTICALLY ON AXON TERMINALS. R.Hen. U.Boschert, F.Saudou .N.Amlaiky, J.L.Plassat. D.°Ait Amara, J.°Lanoir\* and L.°Segu . CNRS, INSERM. Faculté de Médecine . 11 rue Humann. .67085 Strasbourg - °CNRS, Laboratoire de Neurobiologie .BP 71,13402 Marseille .09 -France.

5-HT is a neuromodulator which mediates a wide range of effects by interacting with multiple receptors. Using a strategy based on nucleotide sequence homology between genes encoding 5-HT receptors that interact with G proteins, we have isolated a mouse gene encoding a new serotonin receptor. When expressed in cultured cells, it displayed the pharmacological profile and negative coupling with adenylate cyclase characteristic of the 5HT1B receptor subtype. In 3T3 cells expressing this receptor, serotonin induced a decrease in forskolin stimulated cAMP levels. This effect was blocked by pertussis toxin indicating that the 5HT1Bβ receptor interacts with a pertussis toxin-sensitive G protein. We have analyzed the pattern of expression of the 5HT1Bβ receptor in the mouse brain by in situ hybridization and receptor autoradiography, using a 5HT1B/1D specific ligand, SCMG(125I)TNH2 (Immunotech SA). Our results indicate that the 5HT1Bβ receptors are probably localized presynaptically on the axon terminals of striatal neurons projecting to the globus pallidus and substantia nigra, on the terminals of Purkinje neurons in the deep cerebellar nuclei and on the terminals of retinal ganglion cells in the colliculus. These receptors might therefore modulate the release of neurotransmitters such as GABA. The expression of the 5HT1Bβ receptor in the striatum, cerebellum and retina points to an involvement of this receptor in motor control and visual function.

### 100.4

THE CLONED HUMAN SEROTONIN-1B RECEPTOR INDUCES PERTUSSIS TOXIN-SENSITIVE CALCIUM MOBILIZATION AND ADENYLYL CYCLASE INHIBITION IN FIBROBLAST CELLS. P.R. Albert', D. Raquidan, H. Jin, B.F. O'Dowd. Department of Pharmacology and Therapeutics, McGill University, Montreal, Canada H3G-1Y6 and Add. Res. Found., Ontario.

The cloned human serotonin-1B receptor (Jin, H. et al., J. Biol. Chem. 267: 5735, 1992) was stably-transfected into two serotonin receptor-negative murine fibroblast cell lines, Ltk- (clones L-1B) and Balb/c-3T3 (clones Balb/c-1B) cells, to investigate the transmembrane signaling of the receptor. Several clones were isolated, screened for receptor expression using RT-PCR and tested for responsiveness in an acute (20 min incubation) assay for cAMP levels. In both cell lines serotonin had no effect on basal levels of cAMP but inhibited forskolin-induced elevation by 50% maximally. In both cell lines, serotonin induced an immediate 3-fold increase in [Ca++]; which decayed within a minute to a plateau level of 1.5-fold. Both the serotonin-induced increase in [Ca++]; and the inhibition of cAMP accumulation were completely blocked by 24h pretreatment with 20 ng/ml pertussis toxin. We conclude that the serotonin-1B receptor, like the dopamine-D2 and serotonin-1A receptors, induces both calcium mobilization and inhibits cAMP accumulation by coupling to pertussis toxin-sensitive G proteins. These cells should prove useful for further characterization of the pharmacology and function of the human 5-HT1B receptor.

### 100.6

CLONING, EXPRESSION, AND FUNCTIONAL CHARACTERIZA-TION OF THE RAT STOMACH FUNDUS SEROTONIN RECEPTOR. M. Foguet, D. Hoyer\*, L.A. Pardo, A. Pareck, H.O. Kalkman, W. Stühmer, and H. Lübbert. Preclinical Research, Sandoz Pharma Ltd., 4002 Basel, Switzerland, and Max-Planck-Institute for Biophysical Chemistry, 3400 Göttingen, Germany.

A segment of DNA with high homology to the third exons of the serotonin 1C and 2 receptor genes was isolated by low stringency screening of a mouse genomic library. The positions of the introns flanking these exons are conserved in the three genes. To examine whether the new fragment was part of an active gene, we used a quantitative PCR protocol to analyze rat RNAs from different tissues and ages. The gene was expressed in stomach fundus at an abundance of one in about 2x10<sup>5</sup> mRNA molecules. This tissue contracts in response to 5-HT via a receptor that has previously refuted characterization. We next constructed a cDNA library from rat stomach fundus and, using oligonucleotides from the known sequence as probes, isolated positive clones containing 2000 bp inserts with open reading frames of 465 amino-acids comprising seven putative membrane-spanning regions. The protein was transiently expressed in COS cells and binding of serotonergic ligands to the membranes was analyzed. The pharmacological profile resembled that described for the serotonin-stimulated contraction of the stomach fundus. After expression of this receptor in Xenopus oocytes the application of serotonin triggered the typical chloride current which results from the activation of phospholipase C.

# 100.8

CLONING OF THE MURINE SEROTONIN, RECEPTOR cDNA AND FUNCTIONAL CHARACTERIZATION IN A SEPTAL CELL LINE. Alain Charest, Bruce H. Wainer, and Paul R. Albert. Dept. of Pharm. and Therap., McGill University, Montreal, Canada, H3G 116, Dept. of Pharm. and Physiol. Sci., University of Chicago, Chicago, IL, 60637.

We have cloned a 2.5 Kb cDNA encoding the serotonin, (5-HT, <sub>1</sub>) receptor from a mouse brain library. Analysis of the nucleotide sequence revealed striking homology with the rat and human counterparts (94% and 84% respectively). Ligand binding studies on stably transfected mouse Ltk fibroblast membranes showed high affinity binding of <sup>3</sup>H-DPAT with a pharmacological profile corresponding to that of the 5-HT<sub>1A</sub> subtype: DPAT-5-HT> spiroxatrine> spiperone. In order to study the functional coupling of the receptor we have identified, using RT-PCR, a mouse septum X neuroblastoma fusion cell line (named SN-48) which endogenously express low amount of the receptor. Upon 48 hr treatment with 10 μM retinoic acid (RA), the cells morphologically differentiated into neurons and the level of expression of the receptor was greatly augmented as shown by northern blot analysis. In the undifferentiated SN-48, both VIP (200 nM) and PGE<sub>2</sub> (10 μM) induced a 5- to 10-fold enhancement of cAMP accumulation upon which DPAT (1-10 μM) had no inhibitory effect. However, in RA-differentiated cells, DPAT inhibited the VIP- and PGE<sub>2</sub>-stimulated levels of cAMP by 50% and had no effect on basal cAMP levels. The DPAT-mediated inhibition of stimulated cAMP accumulation exhibited an EC<sub>50</sub> of 10 nM and was abolished by 16h pretreatment with pertussis toxin (20 ng/ml), consistent with ke known pharmacology of the 5-HT<sub>1A</sub> receptor. We conclude that the SN-48 septal cells will provide an excellent model system for investigating the aspects of neuronal differentiation leading to the development of sensitivity to serotoninergic input. PRA was supported by the FRSQ and MRC, Canada, and BHW by US PHS NS-25787.

# **IDENTIFICATION OF DOMAINS WHICH MODIFY LIGAND** BINDING TO 5-HT<sub>2</sub> AND 5-HT<sub>1c</sub> SEROTONIN RECEPTORS.

S. Choudhary\*, S. Craigo and B.L. Roth. Department of Psychiatry, Case Western Reserve University School of Medicine, Cleveland, OH

To define structural determinants essential for serotonin (5hydroxytryptamine; 5-HT) pharmacology, we constructed and characterized chimeric 5-HT<sub>2</sub>/5-HT<sub>1c</sub> serotonin receptors. transient expression in COS-7 cells, high affinity and saturable [3H]mesulergine binding was measured (Kd=1-2 nM;  $\beta$ max=1.2-2.0 pmol/mg protein). For chimeric receptors in which the putative transmembrane (TM) domains V to VII were exchanged, a change in affinity of 5 to 10-fold for [3H]-ketanserin toward that of the donated sequence was measured. Additionally, these same chimeras displayed altered affinities for a number of other serotonergic antagonists including spiperone, cinanserin, fluphenazine, risperidone and cinanserin. No changes in [3H]-mesulergine, mianserin, ritanserin or LSD affinities were noted. One of the chimeras (Chimer2) displayed a 131-fold decrease in 5-HT's ability to activate phosphoinositide hydrolysis in stably transfected cells. Our results suggest that structural features essential for specifying the unique pharmacology of  $5\text{-HT}_2$  and  $5\text{-HT}_{1c}$  receptors reside in discrete transmembrane domains. BRAIN DISTRIBUTION OF 5-HT3 RECEPTOR mRNA: AN IN SITU HYBRIDIZATION STUDY. L.H. Tecott\*, A.V. Maricq and D. Julius. Depts. of Pharmacology and Psychiatry, University of California, San Francisco, CA

5-HT3 receptors have been implicated in a variety of central nervous system functions, and antagonists of this receptor have anxiolytic, antipsychotic and antiemetic properties in animal models. To determine with cellular resolution the anatomical distribution of 5-HT<sub>3</sub> receptors, a <sup>35</sup>S-labelled RNA probe was used for <u>in situ</u> hybridization in mouse brain sections. A highly restricted pattern of hybridizing cells was observed. Scattered positive cells were observed in all cortical areas, with highest densities in piriform, entorhinal and cingulate regions. Strongly hybridizing cells were seen in the hippocampal formation, where expression appeared restricted to interneurons. Positive cells were most abundant in the posteroventral hippocampal region, particularly in the lacunosum-moleculare layer of CA1. Scattered hybridizing cells were also seen in the major subdivisions of the amygdaloid complex, the subiculum, the olfactory bulb, the pontine dorsal raphe region, the dorsal tegmental nucleus, the nucleus of the spinal tract of the trigeminal nerve and in the spinal cord dorsal horn. Strongly hybridizing cells were also observed throughout the superior olivary complex. In the periphery, intense hybridization was observed within a subpopulation of dorsal root ganglion neurons. The above findings are in general agreement with prior radioligand binding and receptor autoradiographic studies (see review by Tyers, et. al. <u>Pharmac. Ther.</u> 47: 181, 1990). However, the results also suggest the presence of 5-HT<sub>3</sub> receptors in regions where they have not been previously seen, such as the superior olivary complex and the dorsal tegmental nucleus. In general, the observed distribution of signal is consistent with the involvement of 5-HT<sub>3</sub> receptors in the modulation of cognition and affect and in the modulation of sensory systems

LOCALIZATION AND DESCRIPTION OF 5-HT2 IMMUNOREACTIVE NEURONS IN THE RAT BRAIN. D. A. Morilak\*, S.J. Garlow and R.D. Ciaranello,

Nancy Pritzker Lab, Dept. Psychiatry, Stanford Univ., Stanford, CA 94305 5-HT2 receptors have been implicated in a variety of behavioral and physiological processes, as well as a number of neuropsychiatric disorders. To specify the brain regions and specific cell types possessing 5-HT2 receptors, we performed immunocytochemistry using a polyclonal 5-HT2 receptor antibody which we have previously characterized (Soc. Neurosci. Abstr. 17: 720, 1991). Rats were anesthetized and perfused with 4% paraformaldehyde. 50 µm sections were incubated in affinity-purified 5-HT2 antiserum, and immunoreactivity was visualized using an immunoperoxidase reaction. Numerous small round neurons were heavily labelled in the granular and periglomerular regions of the offactory bulb. Heavy labelling of medium-sized multipolar and bipolar neurons was also seen in the ventral forebrain, including the nucleus accumbens, offactory tubercle and ventral pallidum. A dense band of small round cells was stained in layer 2 of pyriform cortex. A moderate number of round cells was stained in layer 2 of pyriform cortex. A moderate number of medium bipolar and multipolar cells were scattered throughout the neostriatum, and a moderate number of pyramidal and pyramidal-like cells were seen in the CA fields of the hippocampus. Other areas showing labelling were the medial habenula and anterior pretectal nucleus. In the hindbrain, two dense populations of multipolar cells were heavily labelled in the pedunculopontine and lateral dorsal tegmental nuclei, while lesser labelling was seen in the periacqueductal grey, spinal trigeminal and solitary tract nuclei. A sparse and even distribution of immunopositive cells were seen throughout layers 2-6 of cortex. This distribution suggests that central 5-HT2 processes are mediated by distinct populations of cells in the ventral forebrain and in the hindbrain. The localization and morphology of cells in many of these regions suggests that localization and morphology of cells in many of these regions suggests that subpopulations of 5-HT2 receptor-bearing cells may be GABAergic interneurons or cholinergic neurons. We are currently in the process of testing these hypotheses using double-labelling with immunofluorescence.

THE MOUSE 5HT5 AND 5HT6 RECEPTORS: TWO NEW "5HT1D- LIKE" SEROTONIN RECEPTORS: CLONING AND EXPRESSION. N. Amlaiky, J.L. Plassat, S. Ramboz, U. Boschert and R. Hen.\* LGME/CNRS-U184/INSERM 11 Rue Humann 67085 Strasbourg France.

Serotonin is a neuromodulator which mediates a wide range of effects

Serotonin is a neuromodulator which mediates a wide range of effects by interacting with multiple receptors. The G protein-coupled 5-HT receptors which have been cloned so far, can be divided into two families: the 5HT1 family, including the 5HT1A, 5HT1B/1D and three Drosophila 5-HT receptors which have been cloned so far, can be divided into two families: the 5HT1 family, including the 5HT1A, 5HT1B/1D and three Drosophila 5-HT receptors that modulate adenylate cyclase and the 5HT2 family containing the 5HT1C and 5HT2 receptors that activate phospholipase C. We took advantage of the amino-acid sequence homologies found in transmembrane domains III and VI of all these receptors to isolate mouse cDNAs that encode two new members of the G protein-coupled receptor family, 5HT5 and 5HT6. Amino-acid sequence comparisons revealed that the 5HT6 receptor belonged to the 5HT1 family while the 5HT5 receptor did not belong to either 5HT1 or 5HT2 families. When expressed transiently in Cos-7 cells both receptors had a high affinity for the serotonergic radiologand [1251]-LSD. The 5HT5 receptor displayed the following pharmacological profile: ergotamine >5-CT >methysergide > 5-HT = RU24969 > yohimbine = bufotenine = 80HDPAT, (ketanserine, sumatriptan and pindolol were inactive). The 5HT5 receptor might therefore correspond to previously reported "sumatriptan insensitive" 5HT1D- like binding sites. The 5HT6 receptor displayed also a "5HT1D- like" profile: methysergide > 5-CT, ketanserine and cyanopindolol were inactive). The 5HT5 receptor might be related to "5-CT insensitive" 5HT1D-like sites. We have generated stable cell lines expressing these receptors and shown that the 5HT6 receptor might be related to "5-CT insensitive" 5HT1D-like sites. We have generated stable cell lines expressing these receptors and shown that the 5HT6 receptor is negatively coupled to adenylate cyclase. In situ hybridization experiments have revealed that the 5HT5 mRNA is expressed predominantly in the cerebral cortex, hippocampus and granular lay

AND ELECTROPHYSIOLOGICAL PHARMACOLOGICAL PROPERTIES OF LGNd INTERNEURONS. D. A. McCormick 1, H.-<u>C. Pape<sup>2</sup>, Z. Kisvárday<sup>2</sup> and U.T. Eysel<sup>\*2</sup>.</u> Yale Univ. Med. Sch. New Haven, CT1 and Ruhr Universitaet, Bochum, Germany2.

The flow of visual information from retina to visual cortex is regulated by inhibitory interneurons located in the dorsal lateral nucleus (LGNd). Here we investigated the electrophysiological and pharmacological properties of cat LGNd interneurons using standard in vitro slice techniques. Intracellular recordings from morphologically identified interneurons revealed unique electrophysiological properties including short duration action potentials, a lack of sharp, rebound burst firing (although some cells could generate slower, rebound bursts), and the ability to generate high frequency (>500 Hz) trains of action potentials. Pharmacologically, putative LGNd interneurons responded to 1) ACh and GABA with marked inhibition of action potential generation, 2) Glutamate, kainate and quisqualate (and cortical and retinal afferents) with marked excitation, and 3) histamine and serotonin with weak excitation and with no response to noradrenaline. In addition, the occurrence of spontaneous IPSPs of all durations were inhibited in relay neurons by These results suggest that the excitability of intrageniculate interneurons is controlled largely by retinal, cortical, GABAergic (nRt?), and cholinergic (brainstem) afferents with less of a contribution by histaminergic, serotoninergic, and noradrenergic inputs.

A Nitric Oxide Synthetase Co-localizes with ACh in Brainstem Inputs to the Cat's LGN. A.E. Günlük\*, M.E. Bickford, W. Guido, and S.M. Sherman. Dept. of Neurobiology, SUNY, Stony Brook, NY 11794-5230. The NADPH-diaphorase reaction stains neurons containing an enzyme used to produce citrulline and nitric oxide (NO) from arginine and NADPH. It has been suggested that NO acts retrogradely to affect the process of long term potentiation (LTP) in hippocampus. An LTP-like potentiation of retinal and cortical EPSPs has recently been demonstrated in the cat's lateral geniculate nucleus (LGN), raising the question of an NO contribution to LGN functioning. We found that, in the LGN, the NADPH-diaphorase reaction stains a subset of axons and terminals that closely resembles axons stained positively for choline acetyl transferase (CHAT). To determine the source of these axons positive for NADPH-diaphorase, we injected WGA-HRP into the LGN to retrogradely label afferent neurons and then employed the NADPH-diaphorase reaction on these neurons. The only area that contained a significant population of cells positive for both HRP and NADPH-diaphorase was the parabrachial region of the brainstem. In this region, 55% of the HRP-labeled neurons also contained NADPH-diaphorase In experiments combining immunocytochemical and NADPH-diaphorase staining, no cells were double-labeled for NADPH-diaphorase and serotonin or tyrosine hydroxylase. However, 82% of the CHAT-positive cells also contained NADPH-diaphorase. Many of the axons innervating the LGN from the parabrachial region thus seem to contain both CHAT and NADPH-diaphorase. These terminals may influence LGN cells by release of both ACh and NO. Stimulation of the parabrachial region enhances visual responses in geniculate cells, presumably through the release of ACh. NO may complement ACh in increasing the visual responses of LGN cells, perhaps by enhancing the potentiation of retinal and cortical EPSPs. If so, our data also suggest that NO acts in an orthograde rather than retrog

Activation of PBR switches responses of cat LGN cells from burst to relay mode during visual stimulation. S.-M. Lu\*, W. Guido, and S.M. Sherman. Dept. of Neurobiology, SUNY, Stony Brook, NY 11794-5230.

LGN relay cells respond in one of two distinct modes, relay and burst.

LGN relay cells respond in one of two distinct modes, relay and burst. The burst mode is due to a voltage-dependent Ca<sup>2+</sup> conductance that can be activated from hyperpolarized V<sub>m</sub>; this is the low threshold (LT) spike. When activated, the LT spike leads to a burst of action potentials. The LT spike is inactivated at depolarized V<sub>m</sub>, leading to the relay mode during which the cell responds with a more tonic stream of action potentials. We recently demonstrated that both of these response modes participate in the transmission of visually-evoked responses to cortex. In the present study, we used an in vivo preparation with intracellular and extracellular recording to examine the effects of activating the parabrachial brainstem region (PBR) on switching between relay and burst response modes during visual stimulation by drifting sinusoidal gratings. The PBR provides a mostly cholinergic input to the cat's LGN. We found that PBR activation completely blocked LT spikes and switched all cells to the relay mode. Nearly all of our cell sample showed an increase in total response does not not part of the loss of LT bursts. Because the tonic response components shows much more linear summation than do the LT bursts, overall response linearity was also enhanced by PBR activation. Interestingly, our intracellular records suggest that the slight, gradual depolarization of V<sub>m</sub> caused by PBR activation (5-8 mV) was often insufficient by itself to explain the large increases in overall response. This may result from PBR inhibition of local inhibitory cells, which serves to disinhinbit the relay cells we recorded. (Supported by USPHS grants EY03038 and EY06082).

ROC Analysis of Cat LGN Cells during Burst and Tonic Response Modes. W. Guido\*, S.-M. Lu, and S.M. Sherman. Dept. of Neurobiology, SUNY, Stony Brook, NY 11794-5230.

Previous studies have demonstrated that relay cells of the cat's LGN can respond in one of two modes: relay and burst. These modes depend on membrane voltage, because the burst mode is due to activation of low threshold Ca<sup>2+</sup> (LT) spikes, and these are activated only when the cell is relatively hyperpolarized. We wished to determine the ability of LGN cells to detect visual stimuli during both response modes. A powerful means of measuring such signal detectability is to construct receiver operating characteristic (ROC) curves, the area under the curve providing a reliable measure of detectability. We did this for a population of LGN cells, which we recorded, both extracellularly and intracellularly, in anesthetized, paralyzed cats. We analyzed neuronal responses to drifting sinusoidal gratings. We were able to distinguish the relay and burst response modes for these cells. Initially, we concentrated on responses to gratings of optimal spatial and temporal frequency, which thus provided the largest areas for the ROC curves. We found a small but consistent tendency for cells responding in the burst mode to display larger areas under the ROC curves than did cells responding in the relay mode. Furthermore, in a small cell sample, we were able to maintain recording while the cell switched response modes, and in each of these cases, the area under the ROC curve was larger when the cell responded in the burst mode than when in the relay mode. Our data from ROC analysis suggest that LT spiking and the burst response mode, while less linear and perhaps less useful in subserving a detailed analysis of visual stimuli, operate to enable a hyperpolarized cell to detect a visual stimulus. (Supported by USPHS grants EY03038 and EY06082).

SYNCHRONIZATION OF OSCILLATORY RESPONSES IN THE AVIAN OPTIC TECTUM. S. Neuenschwander and F.J. Varela\*. Institut des Neurosciences, CNRS, 9, quai St. Bernard, 75005 - Paris.

We have recorded multi-unit activity and local field potentials simultaneously from two spatially separate sites (1 mm) in the optic tectum of awake pigeons. The animal's head was fixed while a moving light bar was swept over the receptive fields of the two cell groups. The temporal structure of the responses was analysed by computing averaged auto- and cross-correlograms of the spike trains and local field potentials. As reported before<sup>1</sup> the autocorrelograms typically exhibited a pronounced periodic modulation, indicating that the responses were oscillatory. Oscillation frequency was in the gamma range, showed considerable variability and was centered around 35 Hz. Cross-correlation analysis revealed that the responses of the spatially separate cell groups were in most cases synchronized with close to zero phase lag. Cross-correlograms calculated from responses shuffled by one stimulus period (shift predictor) were flat. This indicates that the synchronization was not due to phase locking of the responses for the stimulus. Our results indicate that oscillatory responses int he gamma range and their synchronization across spatially segregated groups of neurons occur also in laminated structures other than the mammalian visual cortex, suggesting that response synchronization may serve as a binding mechanism in the optic tectum.

BRAINSTEM INFLUENCE ON THE RECEPTIVE FIELD STRUCTURE OF CELLS IN THE LATERAL GENICULATE NUCLEUS OF THE CAT.

P. Heggelund\*, E. Hartveit and S.I. Ramberg. Dept. of Neurophysiol., Univ. of Oslo, Oslo. Norway

The visual response of cells in the lateral geniculate nucleus (LGN) can be markedly influenced by modulatory input originating from the peribrachial region (PBR) of the brainstem. Cholinergic afferents seem to play a major role. In the temporal domain increased PBR input increases mainly the sustained response component of non-lagged cells to a stationary flashing light spot. Thereby the visually driven response becomes more similar to that of the retinal input. The influence of the PBR input in the spatial domain is less well understood. We studied the influence of electrical PBR stimulation on the spatial response profile of single nonlagged LGN cells. The profiles were determined from the response to a stationary light slit presented in a series of positions across the receptive field. We also studied the effect of iontophoretic application of acetylcholine (ACh) on the LGN cells.

The most marked effect of PBR stimulation was an enhancement of the response in the centre of the receptive field. The strongest enhancement occurred around the response maximum. Thus, the slope at the flanks of the profiles became steeper. There was no marked change in the width of the receptive field centre, although a slight increase was found for some of the cells. The spontaneous activity increased, but less than the visually driven response. We found no marked change in the strength of the receptive field surround. The effects of ACh were generally similar to those of PBR stimulation.

We conclude that in the spatial domain a major effect of PBR stimulation and ACh on the retinogeniculate transmission is to enhance the response, in particular the response of the centre component of the receptive field. We found no evidence for any reduction of the spatial extent of the receptive field centre.

## 101.6

# RECEPTIVE FIELDS AND VISUAL RESPONSES OF GANGLION CELLS ACROSS THE PRIMATE RETINA.

Lisa J. Croner\* and Ehud Kaplan. Rockefeller University, N.Y., N.Y. 10021.

The primate retina is inhomogeneous, varying in anatomy with distance from the fovea. In order to understand the effects and purpose of this architecture, we studied how receptive fields and visual responses of parvocellular-projecting (P) and magnocellular-projecting (M) ganglion cells vary with position on the primate retina.

Ganglion cell activity was recorded as synaptic (S) potentials in the LGN of anesthetized and paralyzed macaques. The receptive field organization, responses to contrast, and response variability of 149 cells in the central 80 (radius of 40) degrees of the retina were studied with drifting sinewave gratings. The effects of the eyes' optics on the stimuli appearing on the retina were determined. Thus, receptive field organization and contrast sensitivity in visual space ("visual" properties) and on the retina ("retinal" properties) were evaluated.

Spatial resolution decreases with increasing distance from the fovea, but other properties remain relatively constant. Contrast gains of P and M cells, to stimuli in the visual world, are constant and distinct from each other across the retina; in fact, P cells counteract the blur introduced by optical aberrations in the periphery by increasing the retinal contrast gain of peripheral cells in order to maintain constant visual gain across the retina. In addition, response noise of P and M cells is virtually constant across the retina, and color-selectivity of P cells persists into the periphery. Thus it appears that the primate eye maintains several important visual capacities of ganglion cells constant across the visual field. Supported by EY 4888, EY 1428, and T32GM07524.

BILATERAL PARIETAL INVOLVEMENT IN THE EXECUTION OF A SEQUENCE OF MEMORIZED SACCADES IN MAN. A. Berthoz\*. B. Mazover. L. Petit. C. Orssaud. L. Raynaud. N. Tzourio, S.H.F. Joliot, C.E.A., Orsay, 91406, and L.P.N., C.N.R.S., Paris, France. We measured regional cerebral blood flow (rCBF) using PET and

[150]-water in 5 young healthy volunteers (4 right-handed), during 3 or 4 runs of 2 different conditions: 1- fixation of an imagined central or 4 runs of 2 different conditions: 1- fixation of an imagined central diode, 2 - repetition, at maximal frequency, of a sequence of 6 horizontal saccades (3 to both sides) that was memorized in the minutes preceding the rCBF measurement. All examinations were performed in total darkness and task performance was controlled by electro-oculogram recording. rCBF images were aligned with individual magnetic resonance images, and normalized CBF variations between pairs of measurements (N=18) were computed in individual anatomically defined regions of interest.

individual anatomically defined regions of interest. Cortical activations were found in the left precentral gyrus (2.1  $\pm$  2.9, mean  $\pm$  SD in %, p = 0.007, paired t-test), right supplementary motor area (SMA, 5.8  $\pm$  5.7, p = 0.0005), both superior parietal lobes (LSP, 3.8  $\pm$  4.8, p = 0.004, RSP 3.7  $\pm$  7.6, p = 0.05), the left inferior parietal gyrus (LIP, 2.8  $\pm$  3.1, p = 0.001), and in a region lying around the right intraparietal sulcus (4.6  $\pm$  4.1, p = 0.006). Activated subcortical structures were the thalami (left: 2.7  $\pm$  4.4, p = 0.02; right: 4.4  $\pm$  4.1, p = 0.0003) and the left lenticular nucleus (3.1  $\pm$  6.2, p = 0.047) 0.047).

These results should be compared with our previous results obtained in subjects performing self-paced horizontal saccades in total darkness (Eur. J. Neurosc., suppl 4, pp. 169, 1991). In this paradigm, bilateral precentral gyri, SMA, lenticular nuclei, left median cingulate, right thalamus, and cerebellar vermis were

NONCONJUGATE ADAPTATION OF HUMAN SACCADES: FAST CHANGES IN BINOCULAR MOTOR PROGRAMMING. J. Van der Steen. Dept. of Physiology, Fac. of Medicine, Erasmus University, Rotterdam, 3000DR, The Netherlands. SPON: European Neuroscience Association.

Under normal conditions the oculomotor system programs saccades of approximately equal magnitude for both eyes. Nonconjugate saccades are made instantaneously in the presence of a vergence stimulus or can be made after an adaptation period in the situation where subjects are wearing anisometropic spectacles. The time course and limitations of the adaptation to such spectacles have been investigated in short-term (1-2 hrs) and in long-term (>2 hrs) experiments. In this study the early stages of the adaptation process resulting in differential saccadic motor programming for the two eyes were investigated using scleral search coils. Four subjects viewed two dichoptically presented, identical but aniseikonic, random checkerboard patterns (30°x30° visual angle). The size difference of all elements along both meridians or the horizontal or vertical meridian alone was 8%. Saccadic eye movements were made horizontally, vertically and diagonally symmetrical about the center in alternating trials and recorded before, during and after the adaptation period.

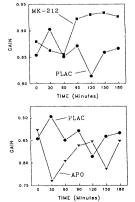

An adaptation period of 20 minutes was sufficient to obtain nonconjugate saccades. For nonconjugate horizontal saccades in the divergent direction the intrasaccadic adaptation was complete within this period. For convergent horizontal saccades the intrasaccadic adaptation amounted 80%. For vertical saccades the intrasaccadic differences were up to 60% for upward saccades and 40% for downward saccades, leaving a considerable postsaccadic vergence drift. The differences in saccadic metrics persisted in open-loop trials immediately after the adaptation period. The dynamics of vergence eye movements in response to steps before and after the adaptation remained unchanged. These results suggest that the nonconjugate adaptation is produced at the motor level by a differential strength of the motor commands to the muscles of both eyes.

SEROTONERGIC STIMULATION INCREASES WHEREAS DOPAMINERGIC STIMULATION DECREASES SMOOTH PURSUIT GAIN IN NORMAL VOLUNTEERS.

L. Friedman\*, J.A. Jesberger, and H.Y. Meltzer. Lab. of Biological Psychiatry, Case Western Reserve University, Cleveland, OH 44106.

The effect of the directacting DA agonist apomorphine (0.01 mg/kg gc) or the directacting 5-HT agonist MK-212 (6-chloro-2-[1-piperaziny1]-pyrazine)(0.30 mg/kg po) on smooth pursuit gain was evaluated in 7 male normal volunteers. The target was a constant velocity (5 deg/sec) trapezoid. Eye movements were recorded with IR oculography. Apomorphine produced a statistically significant reduction (p=.001) in gain at 30 minutes post injection, whereas MK-212 produced a significant elevation in gain (p<.03) from 90 until 150 min. The results could not be attributed to side effects of the agonists, and are consistent with a role for 5-HT in motor facilitation. Pursuit gain may be a useful index of DA or 5-HT receptor sensitivity in clinical populations.

## 102.2

DIFFERENT MODES OF VISUALLY GUIDED SACCADES IN MAN DETERMINED BY REACTION TIME AND AMPLITUDE. H. Weber and B. Fischer \*. Dept. Neurophysiology, Hansastr. 9a, D-7800 Freiburg

The saccadic eye movements of 39 naive subjects (age 10 to 50 yrs) were measured. Two single target (Tg) saccade tasks were used: In the gap task the fixation point (Fp) went off before the Tg occurred, in the overlap task it remained on throughout a trial. Tgs were randomly presented 4 deg to the left or right of the Fp. Subjects were instructed to look at the Tg when it appeared, not to "react as fast as possible" without any feed-back about their performance. Contrary to recent objections 31 naive subjects exhibited clearly separated peaks in the distribution of the saccadic reaction times (SRTs) in the gap task: at 100-135 ms (express saccades), at 140-180 ms (fast regular), and eventually at about 200 ms (slow regular). Five subjects, however, did not show clear signs of two modes between 100 and 180 ms. 3 did not produce any SRTs below 130 ms. In addition, many subjects produced three peaks with about the same modes also in overlap trials. The SRT data of individuals and of different age groups were fitted by the superposition of three gaussian functions. Analysis of over- and undershooting saccades show that express saccades almost never overshoot. Their mean size was smaller by 8% in gap and by 25% in overlap trials as compared with regular saccades. Therefore express saccades are not a phenomenon of exceptional subjects nor the result of lengthy training. Neither is the offset of the fixation point in the gap task a necessary condition for their occurrence. The neural mechansims for express saccades may be present in all subjects, but some may be unable to use this pathway due to their fixational/attentional habits. It is still unclear why in a given session some saccades are of the express and others of the regular type.

## 102.4

IMPAIRED INITIATION OF PURSUIT EYE MOVEMENTS IN SCHIZOPHRENIA. J.A. Sweeney\*, J.R. Carl, M.S. Keshavan, G.L. Haas. Laboratories of Neuropharmacology, University of Pittsburgh, Pittsburgh, PA 15213.

Impairments of pursuit eve movements are well-established in schizophrenia. Investigation of pursuit initiation may help clarify the cause of pursuit impairment in such illnesses. IR recordings were obtained from 15 unmedicated schizophrenic patients and 14 age-matched controls during tracking of unpredictable Rashbass-style step-ramps moving in the horizontal plane. As expected, average pursuit velocity was reduced in schizophrenic patients when they tracked constant-velocity targets moving at 8, 16, 24 or 32 deg/sec.

Several analyses indicate impaired pursuit initiation in schizophrenia. Latency to achieve a velocity of 2 deg/sec was increased across all target velocities. Eye velocity 175 msec after target motion onset, during the open loop period of pursuit, was significantly lower in patients. Peak eye velocity in the first 500 msec of target movement was lower in patients. This latter effect was greater at higher target velocities, suggesting that velocity saturation may occur at lower velocities in schizophrenia.

The findings indicate that the early phase of pursuit initiation is abnormal in unmedicated schizophrenic patients. Average pursuit gain was also impaired. Abnormalities in the open loop response and average pursuit gain were highly correlated. Supported by MH43613, MH42969 and MHCRC46745.

# 102.6

SACCADE-FACILITATED VERTICAL MOTOR FUSION, J. Ygge and D.S. Zee\*, Department of Neurology, Johns Hopkins Hospital, Baltimore, MD, 21205.

We recorded movements of both eyes (search coil technique) in two emmetropic human subjects (\$1,\$2) during refixations between three vertically-aligned LEDs (0 ± 10 deg), located close to (about 11cm) and in front of the right eye. This near target array required about 29 deg of (hortzontal) convergence and called for a <u>change</u> in relative <u>vertical alignment</u> (**ΔVA**) of about 1.15 deg for 0 - Up and 0 - Down saccades (right eye 10 deg, left eye 8.85 deg). Each eye was calibrated independently. First the eye was rotated into the same horizontal position as when viewing the near targets. Then, the subject refixated between vertically-aligned targets located at distance (125cm). Data were sampled at 500Hz.

For vertical refixations on the near array there was a vertical motor fusional response with two components. During the saccade, which lasted about 60ms for both Ss, there was a rapid AVA (peak vel 20 deg/s up and down for S1, and 18 deg/s up and 27 deg/s down for S2). Immediately following the saccade, a much lower velocity **AVA** ensued (in the first 160ms following the saccade the mean speed was 1.5 deg/s (range 1.0-1.7)). On average, 56% of the requisite AVA (range 29-87%) was completed within the saccade and 76% (range 52-100%) by 160ms following the saccade. As a control, subjects also refixated binocularly between vertically-displaced targets located at distance (125cm). There was little AVA (<0.11 deg for 10 deg saccades).

These results suggest that motor mechanisms can rapidly realign the eyes to assure vertical fusion when refixating between targets that create a vertical disparity under natural circumstances (ie, a target close to one eye). The speed of the change in vertical alignment during the saccade was markedly higher than that usually attributed to the vertical motor fusional system. This facilitation of vertical motor fusion by vertical saccades may be analogous to the facilitation of horizontal vergence by horizontal and vertical saccades.

FAST DISCONJUGATE ADAPTATIONS TO ANISEIKONIA. T. Eggert and Z. Kapoula Lab. de Physiologie Neurosensorielle, CNRS-UPR2, Paris, France.

Normal human subjects wearing anisometropic spectacles for 1-6 hr adapt to the resulting aniseikonia by making disconjugate eye movements (Lemij and Collewijn, 1991). We tested whether even faster adaptations to aniseikonia can occur.

In a dichoptic viewing condition, a grid of lines was viewed by each eye at a different magnification (1, 1.07). Three emmetropic subjects were asked to scan this grid with saccades for 10-25 min. Eye movements were recorded binocularly with search coils. In the presence of the adapting stimulus, all subjects exhibited saccade disconjugacies in the appropriate direction. For 2 subjects these effects persisted even for saccades in the dark, indicating adaptive changes. Subj YS was trained for only 10 min and showed a large saccade size disconjugacy: his pre-post change as estimated for saccades in the dark, was 10% for horizontal and 5% for vertical saccades. Subj SG trained for 25 min, showed smaller changes 4% (horizontal) and 2% (vertical). Subj SB exhibited post-saccadic eye drift disconjugacy but this effect did not persist in the dark.

These results indicate that disconjugate adaptations of saccades are possible within only a few minutes. Such adaptations seem to be larger for horizontal than for vertical saccades and may be produced by intra-saccadic, disparity driven vergence. Like disparity vergence, disconjugate changes in saccades could depend on the complexity of the image; in additional experiments we compare adaptations obtained with line grids vs random-dot patterns.

### 102.9

EFFECT OF LUMINANCE AND STIMULUS PREDICTABILITY ON HUMAN VERTICAL PURSUIT, OPTOKINETIC NYSTAGMUS (OKN), AND VISUAL-VESTIBULAR INTERACTION (VVI). J. L. Demer\*, Jules Stein Eye Institute & Dept. of Neurology, University of California at Los Angeles, 90024.

To investigate the effects of predictability and large changes in target luminance, gain (eye velocity/stimulus velocity) and phase of vertical eye movements were measured in 5 normal adults using magnetic search coils. Projected targets were bright (185 Cd/m²) as well as dimmed (2 log neutral density filter). Pursuit was tested using a small white spot, while OKN was tested using a 13° x 16° horizontal square wave grating (0.7 cycle/°, contrast 97%). The vestibulo-ocular reflex (VOR) was tested in darkness. VVI was tested during passive, whole-body, sinusoidal rotation while subjects viewed the stationary grating through 4× binocular telescopic spectacles (field diam. 10°). Predictable stimuli were single frequency sinusoids; unpredictable stimuli were sums of harmonics of 0.4 Hz (0.4-3.2 Hz).

For predictable motion, pursuit and OKN phase was always near 0° regardless of brightness. OKN gain consistently exceeded pursuit gain, although gains for both decreased with dimming, and with increasing stimulus frequency and velocity. For unpredictable motion, there were phase lags increasing with frequency, greater for pursuit than OKN. Target dimming reduced gain and increased phase lag.

For predictable head motion, enhancement of VOR gain by magnified vision was greatest at lower frequencies, and was reduced by target dimming. For predictable motion, phase was always compensatory regardless of brightness. For unpredictable motion, there was a phase lag increasing with frequency; target dimming reduced gain enhancement and introduced additional phase lag at high frequencies.

These data suggest that target brightness and extent may influence the speed of processing of visual afference to the human vertical ocular motor system, and may influence response gain even when motion is predictable.

THE ROLE OF OCULAR PROPRIOCEPTION IN DISCONJUGATE OCULAR MOTOR ADAPTATION. R.F. Lewis, D.S. Zee, and B.L Guthrie\*, The Johns Hopkins Hospital, Baltimore, MD 21205.

We examined the role of ocular proprioception in disconjugate adaptation to a unilateral ocular muscle paresis. Two rhesus monkeys wore search coils and were trained to fix upon targets. A vertical muscle weakness was created in one eye (in the orbit, or by intracranial nerve section). Static alignment (phoria) and the ratio of the movements of the two eyes during saccades (Pulse-Pulse (P-P) ratio) were used as indices of yoking. Measurements were made after habitual (>7 days) monocular (nonparetic eye) viewing, and after habitual binocular viewing with a corrective prism.

Proprioceptive afference was eliminated from the paretic eye by intracranial section of the ophthalmic branch of the trigeminal nerve, and the animals were restudied. After deafferentation, the static misalignment and the P-P ratio significantly increased following both the habitual monocular and the binocular viewing conditions. For example, after habitual monocular (nonparettic) viewing the phoria value at primary position increased from 6.0 to 7.2 deg and the slope of the line relating the phoria to the position of the normal eye increased from 0.14 to 0.19. The mean P-P ratio increased from 1.13 before, to 1.21 after, deafferentation. Similar changes were observed after habitual binocular viewing.

We conclude that ocular proprioception contributes to disconjugate adaptation to asymmetrical ocular muscle weakness, under conditions of both monocular and binocular (disparity present) viewing. We hypothesize that proprioceptive information is used in the <a href="Long-term">Long-term</a> calibration of the internal, efferent copy map of the position of the eyes in the orbit.

### 102.

EGOCENTRIC LOCALIZATION OF A BRIEF PERISACCADIC FLASH BY MANUAL POINTING. <u>Joel M Miller\*</u> Smith-Kettlewell Eye Research Institute, 2232 Webster Street, San Francisco CA 94115
Reaching toward a visual object, without visual referents, requires

Reaching toward a visual object, without visual referents, requires information about position of eye in head supplied by an extraretinal signal (ERS). When a saccade occurs, ERS must be synchronized to the eye's rapidly changing position, or perisaccadic visual targets will be mislocalized.

rapidly changing position, or perisaccadic visual targets will be mislocalized. We measured perisaccadic visual localization by presenting brief (250 µsec) monocular flashes in an otherwise dark field to normal human subjects instructed to point with unseen hand in the apparent direction of the flashes. Saccades were made toward auditory targets to eliminate intravisual comparison. Control trials, employing non-perisaccadic flashes and providing feedback of pointing errors, were randomly interspersed, to monitor and control drift of hand-eye coordination. The flash was presented randomly, on fovea. 10° nasal of fovea, or 10° temporal of fovea.

to the first of the first was presented fariotistic, or 10° temporal of fovea, 10° nasal of fovea, or 10° temporal of fovea. Saccades had mean magnitude 12.6°. For leftward saccades, loci in right hemiretina were updated faster ( $\tau$  = 65 msec) than in left hemiretina ( $\tau$  = 129). For rightward saccades, loci in left hemiretina were updated faster ( $\tau$  = 62 msec) than in right hemiretina ( $\tau$  = 90). Updating began within 1 msec of saccade initiation and was not a function of saccade direction or retinal locus.

Thus, there were no systematic mislocalizations preceding eye movement, and large errors during and after. Errors were maximal about 2/3 of the way through a saccade, and were about half the magnitude of the completed saccade. Stable post-saccadic localization was not achieved until about 150 - 350 msec after completion of a saccade; ERS was updated slowly, compared to eye position itself. The retina was not remapped uniformly: the hemiretina containing the target of a normal visually-evoked saccade (usually the target of a subsequent, corrective saccade) was updated with a shorter time constant. Updating began at about the time that saccade-related brainstem activity began, suggesting that collaterals of oculomotor signals drive egocentric localization.

### 102.1

EVIDENCE FOR DISTRIBUTED PARALLEL INTEGRATION IN THE INTERSTITIAL NUCLEUS OF CAJAL J.D. Crawford\* and T. Vilis Depts. of Physiology and Ophthalmology, University of Western Ontario, London, Canada, N6A 5C1.

We have previously shown that the interstitial nucleus of Cajal (INC) is an essential part of the integrator for vertical and torsional eye movements. Here we examine the time course of the effects produced by injection of 0.3 μl of a 0.05% muscimol solution into a total of 40 INC sites in 5 alert monkeys (Macaca fascicularis) while recording eye movements in 3-D. After injection, saccades in the light were followed by torsional and vertical positional drift. In some cases, eye position drifted towards a unique vertical and torsional null position, at a time constant that progressively decreased. The torsional time constant was always lower than the vertical constant at intermediate stages This can be simulated by single leaky vertical and torsional integrators. More often, eye position drifted rapidly immediately after muscimol injection (time constant ~ 200 ms), but not to a unique null position. Instead, this drift resembled a pulse-step mismatch, except that it only occurred after eccentric vertical and torsional saccades. This deficit progressed as if the step were getting smaller and smaller compared to the pulse. At intermediate stages of the deficit, the animal was still able to maintain a progressively narrowing band of vertical, and to a lesser extent, torsional positions. In some cases the drift clearly had more than one time constant. Similar observations were made when animals made spontaneous saccades in the dark. These results cannot be simulated by single integrator models. However, they were easily simulated by a model which incorporated a bank of parallel integrators in its velocity-to-position transformation.

PRIMATE FRONTAL CORTEX: NEURONAL ACTIVITY FOLLOWING ATTENTIONAL VS. INTENTIONAL CUES D. Boussaoud\*and S.P. Wise.

Laboratory of Neurophysiology, NIMH, Poolesville, MD 20837
We examined neuronal activity in the dorsal (PMd) and ventral (PMv) premotor cortex and in the prefrontal (PF) cortex of two rhesus monkeys. Each monkey fixated a 0.2° white square in the center of a video display while depressing a switch located between two touch pads. Red or green squares (2°x2°) served as cues. On each trial, a spatial/attentional cue (SAC) was presented for 0.8 s. The SAC consisted of one square, red or green, and its location indicated where a relevant motor instructional cue (MIC) would appear 1.8 to 3.3 s later. The MIC consisted of either one square (red or green) or both a red and green square presented simultaneously. A green square at the previously cued location instructed a forelimb movement to the right touch pad; red instructed movement to the left. At the offset of the MIC (duration 1 to 3 s), the monkey had to execute a forelimb movement within 1 s (and could break fixation).

Because the SAC and MIC could be physically and spatially identical, the

behavioral design allowed us to test the hypothesis that task-related activity reflects attentional (SAC) vs. intentional (MIC) processes.

Our results from a sample of 101 frontal cortex neurons show that the vast majority of cells in PMd (71%) have greater activity following intentional cues than after attentional cues. In most instances, there is no activity following SAC, although the identical stimulus causes profound modulation when presented as the MIC. In PMv and PF, by contrast, more cells showed comparable or greater activity following the attentional cue (50% and 61%, respectively). Responses to the SAC often showed spatial selectivity, but rarely if ever were affected by color.

PARALLEL CORTICAL PATHWAYS FOR THE CONTROL OF MOVEMENT J.-O. Hahm\*, M.F. Huerta, P.L. Strick\*, I. Danielsson & T.P. Pons. Laboratory of Neuropsychology, NIMH, Bethesda, MD 20892, and \*Research Services, VA Medical Center, SUNY, Syracuse, NY 13210.

Most current theories on the cortical control of movement hold that "premotor" (area 6) and "supplementary" motor cortex (SMA) act to program primary motor cortex (M-I) and that M-I corticospinal projections directly control movement. The discovery that cortical motor areas outside M-I also have direct corticospinal projections raises the possibility that the control of movement is mediated by multiple cortical pathways organized in parallel

To test this hypothesis, we used microstimulation techniques to map primary and supplementary motor cortex in the relatively agyric owl monkey. After identifying various movement representations and determining current thresholds for stimulation sites, we ablated M-I representations of the forelimb (n=2) or vibrissae (n=1), or all movement representations in the SMA (n=1), and then remapped the regions of motor cortex left intact.

After ablation of either the forelimb or vibrissae region of M-I, After ablation of eitner the foreimb or viorissae region of M-I, forelimb and vibrissae movements could still be elicited by microstimulation in the respective regions of SMA. Current thresholds for stimulation sites were in the normal range. Similarly, ablating SMA had no detectable effect on the ability drive movements in M-I. These results indicate that SMA is sufficient to drive movement, even in the absence of M-I, and likewise M-I is sufficient in the absence of SMA, providing strong support for the proposal that movement is under the control of at least two parallel corticospinal systems.

RECOVERY OF FORCE CAPACITY AFTER LESIONS OF THE FORELIMB PRIMARY MOTOR CORTEX IS DUE TO THE REORGANIZATION OF ADJACENT AREAS OF THE CORTEX. M.A. Castro-Alamancos, J. De Felipe\* & J. Borrell.Cajal Institute (CSIC), Avenida Dr. Arce 37, 28002-

We were interested in studying if reorganizational processes taking place in the cortex mediate recovery after cortical damage. Wistar rats were trained to press two independent isometric levers, each with one forelimb, in order to obtain a food reward. Three groups were formed. In group 1 the motor cortex was mapped bilaterally by using a microstimulation technique and lesions were placed in the primary motor cortex (MI) forelimb representations. Group 2 followed the same procedure as group 1 and an electrode was implanted in the ventral tegmental nucleus (VTN) unilaterally. Group 3 received sham surgery. The forelimb force and response velocity was evaluated as before surgery with the only difference that the animals with an electrode implanted in the VTN received an electrical stimulation in this nucleus each time they pressed the lever. The intensity of the current delivered increased with the force exerted on the levers. The results showed that after ablation of the MI forelimb representations (group 1) the animals showed a deficit in force capacity and in response velocity. In contrast, the animals that received VTN stimulation (group 2) recovered rapidly their force capacity and response velocity. The motor cortex of these animals was mapped again and forelimb movements were evoked posterior to the lesion in recovered animals. Finally, when the cortical area that evoked forelimb movements was ablated in recovered animals the behavioral deficit was reinstated. In conclusion, recovery after ablation of the MI forelimb representation of the rat seems to depend on the reorganization of adjacent areas of the motor cortex.

MOTOR AND ATTENTIONAL COMPONENTS OF SENSORY EXTINCTION. R.K. Deuel, Ped. Neurology, Washington Univ. Sch. of Med., St. Louis, MO 63110. Unilateral frontal and parietal lesions often result in extinction of stimuli in contralesional sensory in extinction of stimuli in contralesional sensory fields. We tested responses on 10 trials each of bilateral simultaneous visual and somatosensory stimuli in macaques, removed frontal periarcuate (N=14) or posterior parietal (N=14) cortex, and retested within fourteen days. Ipsilesional fields were addressed first and with the ipsilesional hand in 91-100% of trials. The contralesional field was usually addressed second, but was sometimes omitted (30% of somatosensory trials and 7% of visual trials). In the 70% of trials where the second somatosensory stimulus was attended, the ipsilesional second trials). In the /0% of trials where the second somatosensory stimulus was attended, the ipsilesional hand was used to grasp it. For the second visual stimulus, parietal subjects used the contralateral hand in 16% of trials and the frontals used it in 50%, as before operation, i.e. the motor performance of the contralesional hand was significantly different between the groups although they attended contralesional stimuli with equal frequency. Motor and attentional aspects of extinction are separable. and attentional aspects of extinction are separable, and frontal subjects use the contralesional hand with normal frequency to grasp contralesional stimuli.

CORTICOSPINAL PROJECTIONS IN THE MATURE AND INFANT MACAQUE. Galea, M.P. & I. Darian-Smith\*. Brain Research Lab., Dept. of Anatomy, Univ. of Melbourne, Parkville, Victoria, 3052. Australia Retrograde labelling of corticospinal (CST) neurons was achieved by the injection of up to four different fluorescent dyes, Fast Blue, Diamidino Yellow, Rhodamino and Green Latex Microspheres, into several defined zones in the cervical spinal cord of mature and infant monkeys. Maps of the CST projections resulting from these dye injections could then be compared in the one animal. A series of planar maps was generated to represent the 3-D spatial distributions of the different CST populations and to correlate them with their spinal target zones In the mature monkeys, CST somata labelled by a dye injection in the dorsolateral column were extensively distributed throughout the sensorimotor cortex, with peak densities in four cortical regions: frontal, parietal, mesial and perisylvian The ipsilateral projection had a similar distribution but was less dense. When the projections to the cervical grey matter were analyzed, a shift in the relative weighting of pre- and post-central projections could be demonstrated according to the location of the injection site in the ventral or dorsal horn respectively. The CST projection in the cervical dorsolateral column in the infant macaque had a similar distribution to that in the mature animal, but was more dense. Additional, transient projections were observed from the mesial, prefrontal, insular and posterior parietal areas, around the periphery of the mature distribution, and from regions that did not project to the spinal cord in the mature macaque. The changing postnatal corticospinal projection is a reflection of regressive changes which have also been observed in other central nervous system projections in infant macaques. Analysis of CST projections to the cervical grey matter in the infant showed that these were less than in the mature animal, suggesting that many CST terminals still had not formed synapses on spinal neurons and that this synaptogenesis was largely postnatal.

REORGANIZATION OF DISTAL FORELIMB REPRESENTATIONS IN PRIMARY MOTOR CORTEX OF ADULT SQUIRREL MONKEYS FOLLOWING FOCAL ISCHEMIC INFARCT. R.J. Nudo\* & R. Grenda. Dept. of Neurobiol. & Anat., Univ. of Texas Med. Sch., Houston, TX 77030.

Early studies using surface stimulation techniques suggested that the hand representation in primary motor cortex of adult primates undergoes substantial reorganization following small lesions, and that cortical reorganization is correlated with functional recovery (Glees & Cole, 1950). In order to examine lesion-induced plasticity in primary motor cortex (area at order to examine lesion-induced plasticity in primary motor cortex tarea 4) of adult squirrel monkeys, we have employed intracortical microstimulation techniques to derive detailed maps of the hand representation before and a few months after a focal ischemic infarct. Representational maps were derived from hundreds of closely spaced microelectrode penetrations. Infarcts were made by bipolar electrocoagulation of a small vascular bed supplying a portion of the hand representation. To determine the extent of spontaneous recovery, no postinfarct training was conducted.

In sharp contrast to the results obtained by Glees & Cole, movements represented in the infarcted zone did not reappear in the cortical sector surrounding the infarct. Instead, relatively small lesions in representations of distal movements resulted in widespread reduction in the spared distal representations adjacent to the lesion, and apparent increases in adjacent proximal representations. Thus, it would appear that extensive reorganization occurs in primary motor cortex following focal ischemic infarct, but at least in the absence of post-infarct training, the movements formerly represented in the infarcted zone do not reappear in adjacent cortical regions. Supported by the Whitehall Foundation.

SLOW (0.3 Hz) SYNCHRONIZED OSCILLATION IN NEOCORTICAL CELLS. M. Steriade\*, A. Nuñez and F. Amzica. Lab. of Neurophysiology, Laval Univ. Sch. of Med., Quebec, Canada G1K 7P4.

During the synchronization of electrical activity in the neocortex, various wave patterns are grouped in sequences that recur periodically at slow (<1 Hz) rhythms. To shed light on cellular bases of these rhythms, we have analyzed a slow oscillation of cortical neurons by means of intracellular recordings from association cortical areas 5 & 7 of cats under urethane anesthesia. Neurons were physiologically identified by ortho- and antidromic activation from LP and CL thalamic nuclei as well as from homotopic foci in the contralateral suprasylvian cortex. A group of representative elements were intracellularly stained

In a majority (65%) of the 190 analyzed cells, the oscillation consisted of full action potentials or dendritic spikes riding on depolarizing envelopes that recurred rhythmically at 0.1-0.7 Hz, mostly around 0.3 Hz. The amplitude and/or duration of depolarizing envelopes were reduced at Vm more negative than -90 mV or by intracellular injection of QX-314. In the remaining neurons, the oscillation consisted of hyperpolarizations that periodically ( $\approx$ 0.3 Hz) sculptured the irregular firing or of rhythmic ( $\approx$ 0.3 Hz) sequences of IPSPs which could only be revealed by DC depolarization. All these slow oscillatory patterns were dramatically synchronous with EEG complexes at  $\approx$ 0.3 Hz, recorded from a variety of cortical foci. Ten oscillatory neurons were intracellularly stained and all proved to be pyramidal-shaped cells located in layers II to VI. The slow oscillation survived in thalamectomized animals. Experiments in progress revealed the presence of the same type of slow rhythm in intracellularly recorded visual and motor cortical same type of slow rhythm in intracellularly recorded visual and motor cortical neurons. The discharges of slowly oscillating cells, simultaneously recorded from association and visual areas, displayed a time-lag around 90-120 ms, suggesting either slowly conducting corticocortical axons or, more probably, corticothalamocortical linkages. Supported by MRC of Canada (grant MT-3689).

CALCIUM CURRENTS IN THE APICAL DENDRITES OF NEOCORTICAL PYRAMIDAL NEURONS. H.G. Kim and B.W. Connors. Depart Providence, RI 02912. Department of Neuroscience, Brown University,

Pyramidal cells of neocortical layer V often have a long, elaborate apical dendrite that reaches layer I. This dendritic design allows the single neuron to combine synaptic inputs from deep and very superficial cortical layers. However, electrotonic considerations predict that the dendrites must have nonlinear membrane properties in order for the most distal inputs to be effective.

We have obtained whole-cell voltage- and current-clamp recordings directly from the apical dendrites of layer 5 pyramidal neurons, using a slice preparation of mature rat SI neocortex at 35°C. Recording sites were confirmed by measuring the electrode position and intracellular staining with biocytin. Stained dendrites often showed a distinct swelling at the presumed recording site. Recordings from apical dendrites were readily distinguishable from somatic from apical dendrites were readily distinguishable from somatic recordings when K<sup>+</sup>gluconate-filled pipettes were used under control conditions. Dendrites showed three general responses to current injections: 1) small, broad, TTX-sensitive, Na<sup>+</sup>-dependent action potentials, 2) complex, often clustered patterns of spikes, and 3) high threshold, long-lasting spikes and plateaus (no K<sup>+</sup> currents blocked). Co<sup>2+</sup> (2 mM) and Ni<sup>2+</sup> (2 mM) reduced complex spiking and blocked long-lasting spikes and plateaus, suggesting an involvement of regenerative, high-threshold Ca<sup>2+</sup> currents. Calcium currents may amplify the effectiveness of distal synaptic inputs, and serve as a mediator or substrate for the modification of dendritic properties.

EFFECTS OF BICUCULLINE ON LEARNING A HIDDEN OBJECT, PICK-UP TASK IN INFANT MONKEYS. K. Kubota\*. Dept. of Neurophysiology, Primate Res. Inst., Kyoto Univ., Aichi 484, Japan.

Supported by NS25983 from NIH, and ONR.

Five newborn macaque monkeys were trained in a hidden object pick-up Task, comparable to a Delayed Response or AB Task. During the course of learning the Task, Bicuculline (BMI, 1-3µg in 0.5-1.0µl saline), was injected locally into the decadated trade and the saline of t dorsolateral prefrontal cortex. While the monkey watched from a cage, a piece of apple was hidden under one of two opaque bottle caps (left or right)(11-12 w old). The transparent screen in front of the monkey was then raised and the monkey reached out to one of the bottle. front of the monkey was then raised and the monkey reached out to one of the bottle caps, picked up the piece of apple and ate it. When the monkeys performed correctly  $\langle$  75% of the time, BMI did not influence the Task performance level (12 sites). However, when they had learned the Task, with the piece of apple hidden for 2-3 s (19-21 w old). BMI decreased the performance level (18 sites). The number of perseverative errors on the side contralateral to the hand used, increased, regardless of which side of the brain was injected. Apparently, GABA inhibition in infant monkeys is involved in reducing the number of contralateral erroneous responses and number of contralateral erroneous responses and promoting correct Task performance. Supported by the Human Frontier Science Program.

FUNCTIONAL PROPERTIES OF BURST AND SINGLE SPIKE FIRING IN LAYER V CORTICAL BURST GENERATING NEURONS Z. Wang\* and D.A. McCormick Sect. Neurobiology Yale Univ. Sch. Med. New Haven, CT

A subset of layer V pyramidal cells in the cerebral cortex can intrisically generate bursts or trains of action potentials in response to depolarization. Here we investigate the functional properties and the modulation by neurotransmitters of these two modes of action potential generation using standard in vitro slice techniques.

Recordings from cortical burst generating neurons revealed that a subset of these cells generated rhythmic spontaneous bursts at frequencies of around 0.2-2 Hz (n=20). Intracellular injection of repetitive inputs (e.g. sine waves) of varying frequencies into these cells revealed that they can faithfully generate repetitive bursts in the frequency range of only 1-4 Hz. Higher frequencies inhibited burst firing and could switch the cells to the single spike mode of action potential generation, where the cells fired predominately at 5-40 Hz with no evidence of spike frequency adaptation. Similar changes in firing mode and frequency could be induced by stimulation of a1adrenergic, muscarinic or glutamate metabotropic receptors.

These results indicate that the burst firing mode enhances the appearance of slow oscillations or EPSPs which occur at low frequencies, while the single spike mode predominates during high frequency sustained activity.

## 103.10

NMDA AS WELL AS NON-NMDA RECEPTORS ARE INVOLVED IN MOTOR TASK-RELATED NEURONAL ACTIVITY IN THE MOTOR CORTEX OF AWAKE MONKEYS. K. Shima and J. Tanji\*

Dept. of Physiology, Sch. of Med. Sendai, 980, JAPAN

The effects of iontophoretic application of agonists and antagonists for both NMDA and non-NMDA glutamate receptors on neuronal activity in the primary motor cortex of two monkeys (Macaca fuscata) was examined during performance of a trained motor task. Multibarreled glass micropipettes were used for application of chemicals. A central pipette was equipped with a fine carbon fiber for extracellular unit recording. Motor task-related neuronal activity (both movementand motor set-related), as well as background neuronal activity was quantitatively assessed before, during and after drug application. The following findings emerged from this study. 1) Both APV and CNQX reduced task-related activity with or without affecting background activity. NMDA and quisqualic acid (or kainic acid) had the opposite effects. 2) CNQX suppressed movement-related activity more often than APV. 3) APV suppressed background discharge more effectively than CNQX. 4) Unitary spikes of motor cortex neurons evoked by stimulation of the somatosensory cortex were suppressed more effectively by CNQX than by NMDA. These results indicate that both NMDA and non-NMDA glutamate receptors are involved in activating motor cortex neurons in relation to performance of the motor task. Differences in relative contribution of these two receptors among motor cortex neurons with different properties seem to exist.

THE CONE ELECTRODE: CHRONIC RECORDING TECHNIQUES. P.R.Kennedy\*, A.Hopper, C.Linker, S.M.Sharpe and R.A.E.Bakay. Yerkes Res. Center of Emory Univ., &

R.A.E.Bakay. Yerkes Res. Center of Emory Univ., & Neurosci. Lab., GA Tech, Atlanta, GA 30332.
Previous studies (Kennedy, J. Neurosci. Methods, 29(1989)181-193) demonstrate chronic recording of multi-units via the Cone Electrode. Recent long-term studies demonstrate viable myelinated axons and supporting stroma inside the glass enclosure at the electrode tip (Neurosci. Letters, accepted 1992). Present studies focus on burying the electrode and electronics under the burying the electrode and electronics under the scalp to minimize infection and traumatic damage. Following implantation, a headstage amplifier and FM transmitter are attached to the electrode

and FM transmitter are attached to the electrode pins. These electronic components are also linked to the secondary coil of a power induction system. They are protected by Elvax (moisture barrier), silastic (mechanical barrier), Acrylic cement (insulator of electrode pins and mechanical barrier) and intact scalp (pathogenic barrier). The system is powered by placing a tuned primary coil near the secondary coil in the awake monkey for transcutaneous power transmission by RF induction. AC components are rectified to DC, and voltage is regulated to 3 volts.

The system is implanted long-term in a monkey

The system is implanted long-term in a monkey and provides visual and auditory feedback of the firing rates of units recorded in motor areas.

INCREASED RATE OF SYMPATHETIC INGROWTH TO SMOOTH MUSCLE OF NEONATAL RAT. Hiebert and Peter G. Smith\*. Department of Physiology, University of Kansas Medical Center, Kansas City, KS 66160.

Target tissue reinnervation is known to decrease as a function of age. One contributing factor may involve age related changes in the target tissue that prevent or deter ingrowth. The purpose of this study was to determine if sympathetic sprouting into smooth muscle targets is diminished in older animals. Superior tarsal smooth muscle from 6, 14, 30, and 48 PND donors was sympathetically denervated by performing a superior cervical ganglionectomy. Three days later, the muscle was removed from the donor and small pieces were implanted into the anterior chamber of host rats 84-90 days of age. Dopamine β-hydroxylase immunoreactivity was used to assess ingrowth of iris sympathetic nerves at 3, 6, and 10 days post implant.

Sympathetic ingrowth occurred in all four age groups. The rate of ingrowth was most rapid in tissue from the youngest donors; however, all age groups achieved similar innervation by day 10. These findings support the conclusion that while smooth muscle reinnervation can occur at all ages studied, it is facilitated in the neonatal animal. Supported by NS23502.

FUNCTIONAL AXON SPROUTING OF TETRODOTOXIN-INACTIVATED

FUNCTIONAL AXON SPROUTING OF TETRODOTOXIN-INACTIVATED RAT PLANTARIS MOTOR UNITS AFTER PARTIAL DENERVATION OF THE MUSCLE. R.N. Michel\*, and C. Boudreau. School of Human Movement, Laurentian University, Sudbury, Ontario, P3E 2C6.

Partial denervation (PD) of mammalian skeletal muscle causes surviving motor axons to sprout and reinnervate neighboring denervated muscle fibers. The purpose of this study was to determine whether there is an advantage for surviving motor units to be inactive (i.e. not propagating action potentials) during the short-term phase of this neuronal growth response. Sprague-Dawley rats had the sciatic nerve of both hindlimbs inactivated with tetrodotoxin (TTX) using an osmotic pump and cuff delivery system. After inactivation, approximately 80% of plantaris muscle fibers in one hindlimb were denervated by cutting radicular nerve L4. The extent of functional motor unit sprouting was assessed 10 days later by the ratio of force and electromyographic (EMG) responses evoked via stimulation of the sprouting L5 nerve to that produced by stimulation of its contralateral force and electromyographic (EMG) responses evoked via stimulation of the sprouting L5 nerve to that produced by stimulation of its contralateral intact counterpart. Results were compared to plantaris from control animals that underwent PD only. TTX-inactivation alone caused plantaris mass (35%) fiber area (50%), and maximum force (70%) to be smaller than control. In spite of these changes, both TTX-inactivated and normally active sprouted motor units increased their functional size (force and EMG) more than 2-fold. The performance of the newly formed sprouts (i.e. maintenance of tension envelope and EMG profile at high stimulation frequencies) was not altered by TTX-inactivation. Our results demonstrate that motor units surviving a PD lesion but rendered inactive are comparably efficient at capturing and activating previously denervated muscle fibers. Neuromuscular denervation products seem to be a major prerequisite for robust and functional motor axon sprouting.

TEMPORAL PROGRESSION OF DESCENDING AXONS IN THE CHICKEN EMBRYO SPINAL CORD. <u>I. C. Glover' and A.-L. Eide.</u> Dept. of Physiology, Institute of Basic Medical Sciences, University of Oslo, 0317

The temporal pattern of growth of descending projections in the spinal cord of the chicken embryo has been inferred from retrograde labelling of supraspinal neurons after injections of WGA-HRP at different spinal levels (Okado & Oppenheim, J. Comp Neurol. 232:143-161, 1985). To provide a more complete description of the pattern of axon growth, we have labelled the descending axons anterogradely with the lipophilic tracer DiI in fixed spinal cords from embryonic day (E) 5 to E10. DiI was injected into a hemisection at the first cervical segment, with the aim of labelling all longitudinal axons traversing the hindbrain/spinal cord transition

Labelled axons extended varying distances caudally in any given preparation. Typically we observed a wave of some tens of axons that were outpaced by a minority (<10) that extended 3-5 segments further. These few most caudally-projecting axons were restricted to cervical levels until E7-8, and had begun to sprout short primary collaterals in the cervical cord by E7. Some of the most caudally-projecting axons at these stages were descending branches of bifurcating axons that originated from spinal interneurons. By E10 the most caudally-projecting axons extended to mid-lumbar levels and had established more elaborate collaterals there, some crossing the midline in the ventral commissure.

Control experiments in which Dil was injected in mid-thoracic segments support the indication that axons originating from supraspinal levels do not reach the lumbar spinal cord until after E7-8. The progression of descending axon growth revealed by anterograde labelling is therefore about 2 days delayed relative to that suggested by retrograde labelling

OUTCROWTH IS ACCELERATED BY ONE WEEK AFTER AXOTOMY. J.M. Jacob\* and I.G. McQuarrie. Neural VA Med. Ctr., Cleveland, Oh. 44106. Neural Regen. Ctr., Cleve.

In a conditioning lesion paradigm using rat sciatic motor neurons, we have previously shown that the rate of axonal outgrowth increases after a testing lesion. This is apparently due to an increase in the rate of structural protein transport (SCb) throughout the axon by 7 d after the initial (conditioning) axotomy. acceleration of SCb can be assayed indirectly by radiolabeling fast axonal transport and measuring the rate of advance of growth cones. Using this assay without a conditioning axotomy, we now show that axonal outgrowth begins to accelerate at approximately 7 d after axotomy, i.e., when SCb begins to accelerate. between 3 and 6 d after axotomy the outgrowth rate was 3.6  $\pm$  0.5 mm/d, whereas, between 9 and 12 d it was 5.1  $\pm$ 0.5 mm/d (p < 0.001). A non-axotomizing growth stimulus of IA sciatic motor neurons (partial denervation of hindlimb muscles by excision of the L5 spinal nerve) did not accelerate SCb by the outgrowth rate assay. Our data confirm that a single axotomy is sufficient to induce an acceleration of SCb, and suggest that the formation of collateral sprouts by uninjured neurons is not sufficient to induce an acceleration of SCb.

SYNAPTIC REMODELING REVEALED BY COMBINED VIDEO-ENHANCED FLUORESCENT MICROSCOPY AND ELECTRON MICROSCOPY OF IDENTIFIED FROG NEUROMUSCULAR JUNCTIONS. C. P. KO', L. CHEN & A. THOMPSON. Dept. of Biol. Sci., Univ. of Southern California, Los Angeles, CA 90089.

Our previous studies using in vivo observations of identified frog neuromuscular junctions (NMJs) suggest that synaptic extracellular matrix (ECM) precedes nerve terminal during junctional extension and sprouting (J. Neurosci. 11:2920; Soc. Neurosci. Abstr. 17:735). The present work aims to examine at the ultrastructural level the sprouted region where synaptic ECM is longer than the nerve terminal. Sartorius muscles were double-labeled with 4-Di-2-Asp and rhodamine conjugated peanut agglutinin (PNA) to stain nerve terminals and synaptic ECM respectively. The identified NMJs were observed in vivo with video-enhanced fluorescent microscopy. Segments of contralateral sciatic nerve were then placed on the muscle surface to induce nerve sprouting. During the peak of sprouting (2-3 months later), the same NMJs were re-stained and reexamined as above. The identified NMJs which showed sprouting with synaptic ECM longer than the nerve terminal were then stained with HRP conjugated PNA and processed for electron microscopy. The result at the ultrastructural level showed the absence of nerve terminal in the extended PNA-stained region. In addition, Schwann cells surrounded by PNAstained ECM were seen at this region. These findings confirm the validity of 4-Di-2-Asp staining for nerve endings seen with light microscopy and further support the suggestion that synaptic ECM precedes nerve terminal outgrowth during synaptic remodeling.

INITIAL DIFFERENCE IN THE GROWTH PATTERNS OF CUTANEOUS AND MUSCLE SENSORY AFFERENT COLLATERALS. A.-L. Eide\* and I. C. Glover. Dept. of Physiology, Institute of Basic Medical Sciences, University of Oslo, 0317 Oslo, Norway.

Sensory neurons that innervate cutaneous versus muscle receptors in the periphery innervate different sets of central targets. In particular, muscle afferents project collaterals to the ventral horn where they innervate MNs, while cutaneous afferents project collaterals to the dorsal horn where they innervate interneurons. To investigate the development of these different patterns of collateral termination, the lipophilic tracer Dil was applied selectively to identified cutaneous and muscle nerves in the lumbar region of chicken embryos from embryonic day (E) 6 to E18. Tracer was applied to fixed preparations that were incubated for 4 to 400

days.

Sensory afferents in the lumbar region enter the cord on E4 and bifurcate

The longitudinal trajectory of muscle to course rostrally and caudally. The longitudinal trajectory of muscle afferent axons is restricted more medially than that of cutaneous afferent axons. Ventrally-directed collaterals from both types of afferent begin to sprout on E6-E7. However, the cutaneous and muscle afferent collaterals differ in length already during the first day of growth. On E8, when cutaneous afferent collaterals have grown to a depth of about 50  $\mu m$ , muscle afferent collaterals have grown about 250 µm, over halfway to the ventral limit of the gray matter. Cutaneous afferent collaterals are restricted to the dorsal region of the gray matter during subsequent stag Thus, differences in the termination patterns of cutaneous and muscle afferents do not arise by equivalent growth followed by differential retraction, but through an initial difference in the extent to which the collaterals invade the gray matter

CENTRAL PROJECTIONS OF SENSORY NEURONS IN ORGANOTYPIC CULTURES OF EMBRYONIC CHICK SPINAL CORD, Z. Korade\* and E. Frank. Dept of Neurobiology, Anatomy and Cell Science, Univ. of Pittsburgh Medical School, Pittsburgh PA 15261.

During development, spinal sensory neurons establish an orderly set of central projections into the spinal cord. Cutaneous sensory neurons terminate within the dorsal horn, while muscle spindle afferent axons project nearly unbranched through the dorsal horn, while muscle spindle afferent axons project nearly unbranched through the dorsal horn, while muscle spindle afferent axons project nearly unbranched through the dorsal horn, while muscle spindle afferent axons project to real training the spinal cord occur shortly after sensory neurons are born, the characteristic central projection patterns are established only after sensory axons project to their targets in the periphery. In order to begin to understand the mechanisms responsible for the establishment of these orderly projections, we have developed an organotypic co-culture of embryonic chick spinal cord and dorsal root ganglia.

Slices of spinal cord are prepared from E6 chick embryos, a time at which some sensory axons have grown into the dorsal root entry zone but have not begun to arborize within the developing gray matter. Dorsal root ganglia, also from E6 embryos, are positioned next to the spinal cord slice or are left attached to it during the dissection. The explants are immobilized in a thrombin clot and cultured in normal medium with added muscle extract and NGF for 3-4 days. After fixation, DRG's are labeled with Dil to visualize the arborization of sensory fibers within the spinal cord.

Sensory axons growing from detached DRGs are normally excluded from the cord is much more successful when DRGs are left attached and the axons enter the cord through the dorsal and, to a lesser extent, ventral roots. Arborizations of these fibers within the developing gray matter is virtually entirely limited to the dorsal horn; few pro

VISUALIZATION OF OPTIC ARBORS IN NORMAL AND REGENERATING LIVING ADULT GOLDFISH. A.M. Danks\* P. Kim, Z. Wang, and R.L. Meyer. Developmental Biology Center, Univ. of Calif., Irvine, CA 92717.

The fluorescent lipophilic membrane probe Dil (2.67 mM, 1.5 nl) was injected into the ganglion cell layer of the retinas of challe goldfish, by allow in viting light in of the ganglion.

adult goldfish to allow in vivo visualization of axons and arborization of individual nerve cells as they project into the optic tectum. After allowing several days for dye transport, the tectum was exposed and the live fish were placed under a fluorescence microscope equipped with a cooled CCD camera. Individual axons and terminal arbors including many fine branches could be resolved.

Arbors were visualized repeatedly for as long as 5 hours. In addition, fish could be resuscitated and the arbor reexamined a day later. We found that the pattern of branching remains stable over time. No remodeling of fine processes could be detected. These data will be compared to regenerating goldfish that had been been subjected to optic nerve crush 2 to 5 weeks previously, and whose regenerating axons show a less developed arbor network Supported by NIH-EY 6746.

FORMATION OF NEURAL CONNECTIONS BETWEEN AGGREGATES OF RAT VISUAL CORTICAL CELLS CULTURED IN A MULTIELECTRODE DISH. H. Sugihara 1, T. Mitumata<sup>1</sup>, N. Yamamoto<sup>2</sup>, K. Toyama<sup>2</sup> \*. <sup>1</sup>Central Research Lab., Matsushita Elec. Co., Moriguchi, Osaka, 570, Japan. <sup>2</sup>Kyoto Prefectural Univ. of Medicine, Kamigyo-ku, Kyoto, 602, Japan.

Aggregates of cortical cells dissected from embryonic (E18-17) rat visual cortex were cultured in a dish implanted with a 6 x 6 (or 8 x 8) multielectrode array made of indium-tin-oxide (interpolar distance, 300 um). Observed with ordinary light microscopy, neurites began to extend from each aggregate in 2-3 days in vitro, and neurite connectivity was formed among the aggregates within an additional few days. Anterograde labelling by fluorescent dye (DiI) at this stage indicated that a number of axons extended from the source aggregates to the target aggregates and formed axonal arborizations. However, establishment of synaptic transmission still required additional several days, studied by extracellular recording of the field potentials (FPs) evoked in the target aggregates by stimulation of the source aggregate. Development of synaptic transmission determined as the amplitude of FPs began at 7-9 days in vitro and completed at 11 days in vitro. The neural connections and synaptic transmission were maintained up to 1 month. A good parallelism was found during the later stage of development between the intensities of anterograde labelling in the target aggregates transferred from the source aggregates where the dye was injected and the amplitudes of FPs evoked in the target .

VIDEO MICROSCOPY OF GROWTH CONES IN DECISION REGIONS OF THE CORPUS CALLOSUM IN LIVING CORTICAL BRAIN SLICES. M.C. Halloran\* and K. Kalil, Neuroscience Training Program and Dept. of Anatomy, University of Wisconsin, Madison, WI 53706.

We have studied the behavior of growth cones extending in the corpus calloss of hamster cortical brain slices, using time lapse video microscopy under low light level conditions (Halloran and Kalil, Soc. Neurosci. Abstr., 1991). We found that DiI-labeled growth cones in the callosal pathway generally advanced steadily and rapidly and exhibited continual lamellipodial shape changes, whereas growth cones extending into the cortical target had smaller growth cones that maintained more constant morphologies. However, an important unanswered question is how growth cones make the decision to leave the callosal tract and enter the cortical target. We have therefore examined the behaviors of callosal growth cones in this transition region beneath their ultimate target area. We found that growth cones typically slowed down in these regions and repeatedly extended and retracted branches tipped with lammellipodia. In some cases the entire growth cone withdrew, leaving behind a filopodial extension, which then formed the pathway for the subsequent resurgence of the growth cone. In other cases the primary growth cone maintained its position while its numerous side branches extended and withdrew. This saltatory behavior can last for several hours, suggesting that the growth cone is undergoing a decision making process. We are currently investigating whether any of these transient branches ultimately become permanent axon collaterals extending into cortical targets. Supported by NIH Grant NS14428 to K.K.

THE STRUCTURE AND FUNCTION OF DROSOPIILA NEURONAL CLUSTERS DEVELOPED IN VITRO. K, Ikeda\* and J,H, Koenig. Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010.

The structure and function of neuronal systems was studied with a primary culture of Drosophila neuroblasts. The neurons were developed from undifferentiated neuroblasts dissociated from Drosophila embryos at the early gastrula stage. The clusters of neurons in this culture developed into a structure reminiscent of an insect ganglion. This structure exhibited activities similar to an in vivo ganglion, such as spontaneous firing and patterned output in response to a simple train of input impulses. The structure of the cluster was strikingly similar in general architecture to a typical insect ganglion; i.e., the outer layer consisted of one or several layers of somata, while the inner space (core) consisted of a structure very similar to a typical neuropile. The neuropile was composed of many neurites which formed synapso on each other. The axons, which extended from the somata into the neuropile, made many dendritic branches before running toward the bottom of the cluster. There, they turned horizontally, forming several bundles which emerged from the cluster The axon bundles coming out from a cluster eventually reached other clusters. Thus, various interconnected ganglion-like clusters were formed. The connections between these clusters were not only structural, but functional. Thus, stimulation with a train of electrical pulses of axons entering a cluster elicited variously patterned impulses in other bundles emerging from this cluster. Coordinated activity among separate ganglia was also observed. Furthermore, the activity pattern of a cluster was modulated by the input from the other cluster. Thus, a structure which functions similarly to a ganglion can develop in vitro without specific positional clues which are available during normal development in vivo. Supported by NIH grant, NS-18856.

NEURITE OUTGROWTH FROM EMBRYONIC CORTICAL NEURONS ON ADULT OLIGODENDROCYTES IN CULTURE. March D. Ard\* Dept. of Anatomy, Univ. of Mississippi Med. Ctr., Jackson, MS 39216

To test inhibition of neurite outgrowth by oligodendrocyte surfaces, cocultures of oligodendrocytes and neurons were established and the areas occupied by each cell type measured. Oligodendrocytes were cultured from adult rat spinal cord under conditions prohibiting proliferation of precursor cells (addition of fluorodeoxyuridine, FDUR, to the medium). The primary cells were subcultured onto polylysine-coated coverslips, where they emitted branched processes labeled with anti-galactocerebroside monoclonal antibody but not with A2B5 antibody. After 5 days, dissociated cortical neurons from embryonic day 15 rat cerebral cortex were added, still with FDUR present. The MCID image analysis system of Imaging Research, Inc., was used to measure areas covered by immunostained processes of oligodendrocytes and of neurons in double-labeled cultures

Neurite outgrowth after 2 days was vigorous. Neurites labeled with A2B5 extended onto both oligodendrocytes and polylysine. Oligodendrocyte processes covered about 19% of the surface in these cultures, and neuronal processes covered about 8%. In spite of the availability of unoccupied polylysine areas, neurites frequently overlapped and sometimes closely followed oligodendrocyte processes. The average area occupied by neurons and neurites was not reduced when oligodendrocytes were present. On the other hand, instances of exclusive territories where neighboring cells of different types refused to commingle indicated that neurite-inhibitory interactions did occur in some cell contacts. It appears likely that many of the oligodendrocytes in these culture conditions may lack neurite-inhibitory properties.

VIDEO MICROSCOPY OF CELL-CELL INTERACTIONS IN DISSOCIATED CULTURES OF DEVELOPING MAMMALIAN CEREBRAL CORTEX. M. Lu\* and K. Kalil. Neuroscience Training Program and Dept. of Anatomy, University of Wisconsin, Madison, WI 53706.

During cortical development growth cones make cell specific choices to establish precise connectivity. To investigate the behaviors of growth cones during these cellular interactions, we have used video enhanced contrast-differential interference contrast (VEC-DIC) microscopy to observe attractive and inhibitory responses of neurites growing in dissociated cultures of embryonic (E-14) hamster cerebral cortex. The dissociated cultures, consisting primarily of cortical neurons and glia, were grown on coverslips coated with laminin alone to create a more natural substrate for axon outgrowth. Results from over 25 video recording sessions lasting about 5 hours for a single coverslip, in which images were taken every 5s, showed robust neurite outgrowth. Rates of extension ranged from 40-100 µm/hr, which is consistent with cortical axon outgrowth in vivo. The mode of axon elongation was similar to that previously described for Aplysia neurons by Goldberg and Burmeister (J. Cell Biol., 1986). Growth cones (-15µm) had large lamellae and extensive filopodia and were highly motile. Observations of individual cell-cell interactions during periods of 1-2 hours revealed that cell specific responses were mediated either by direct contact or by influences at a distance. Growth cones encountering other axons could either grow over them, turn and fasciculate upon them or collapse and retract away from them. Similarly, growth cones encountering other growth cones grew over one another or collapsed and retracted after brief filopodial contact. Glial cells could provided a flavorable substrate for growth cone extension and in some cases glial cells responded to the approach of a growth cone by extending filopodia from the glial cell margin. However, growth cone contacts with glial cells were sometimes inhibitory, inducing the retraction of the growth cone extension and in some cases glial cells free results suggest that growth cones respond characteristically to specific neuronal and glial cell processes and thereby establish appro

MATHEMATICAL APPROACH TO MODELING DENDRITIC GROWTH *IN VITRO*. E. Uemura,\*W. Kliemann, A. Carriquiry, J. Goodwin. and C. Martens. Neuroscience Program, Departments of Anatomy, Mathematics, and Statistics, Iowa State University, Ames, IA 50011.

A mathematical model that predicts the quantitative branching pattern of dendritic tree in vitro was evaluated. The apical dendrites of rat hippocampal neurons were measured at postplating days 1, 2, 3, 4, 6, and 7. Cultured cells were stained with dil and pyramidal-shaped neurons that are physically separated from one another are photographed for digitizing apical dendrites. A Wald statistic for  $\chi^2$ -test was developed for the branching pattern of dendritic trees and for the distribution of the maximal order of the tree. Using this statistic, we obtained an excellent fit of the mathematical model for the dendritic data. The apical dendrites of hippocampal neurons are characterized by a completely random splitting, i.e., splitting of each branch independent of all other branches. Being able to predict the form of a dendritic tree from a mathematical model implies that a mathematical model could be used for simulating the development of dendrites under various experimental conditions. Supported by NS28416.

TERMINAL AND SYNAPSE NUMBERS AND TYPES IN MEDULLARY DORSAL HORN LAYERS I-III IN NEWBORN RAT. J.P. Golden\*, D.S. Zahm & M.F. Jacquin. Dept. of Anatomy & Neurobiology, St. Louis University School of Medicine, St. Louis, MO 63104.

It is known that in adult rats subjected to infraorbital nerve section at birth. layers I and II of the medullary dorsal horn have a normal cytoarchitecture and at least normal #s of terminals and synapses, despite only a 26% survival of infraorbital axons. The selective sparing of inputs to layers I and II may reflect axon sprouting, a high survival rate for ganglion cells that normally project here, or maintenance of a synaptic organization that exists at the time of the lesion. As a first step in testing the latter hypothesis, total #s of synaptic and terminal profiles were determined in randomly selected transverse sections through the maxillary portions of layers I-III in 1 rat sacrificed at birth. Terminal and synaptic densities in the layer I-II region were 14.5 and  $3.1~\text{per}~100~\mu\text{m}^2\text{,}$  respectively. A paucity of terminals and synapses at birth was also noted in a 2nd animal. Comparable values from an adult subjected to nerve section at birth were 37.6 and 10.3, respectively. On the intact side, comparable values were 28.0 and 9.5, respectively. These data suggest that there are far fewer terminals and synapses in layers I and II at birth than there are in the neonatally deafferented or normal adult. Thus, the presence of normal #s of terminals and synapses following deafferentation at birth does not reflect the preservation of an immature synaptic condition. In newborns, we also saw a significant # of terminals with large pleomorphic vesicles, some of which resembled growth cones, as well as dendrodendritic synapses. Higher terminal activity in more superficial, as opposed to deeper, laminae were also seen at birth: #s of terminals in layers I-III were 14, 15 and 8 per 100  $\mu m^2$ ; #s of synapses were 4, 2 and 2. TRIGEMINAL GANGLION OUTGROWTH IN ORGANOTYPIC CO-CULTURES. R. Erzurumlu\*, H. Takahashi, S. Jhaveri and R. McKay. Dept. Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139.

Organotypic co-cultures of specific neuronal assemblies and their targets provide a powerful tool to address questions of axon-target interactions in developing nervous system. In serum-free medium isolated trigeminal ganglia from E15 rats were co-cultured for 6-8 days on Millicell wells (Brewer and Cotman, 1989; Molnár and Blakemore, 1990) with explants of vibrissa pads and hindbrain. The cultures were then fixed with 4% paraformaldehyde and the outgrowth of ganglion cell processes was labeled by implants of Dil crystals in the ganglia.

"Peripheral" and "central" projections from the trigeminal ganglion are strikingly different in their morphology. Peripherally directed axonal processes enter the vibrissa pad along a broad front and fan out towards vibrissa rows in thick fascicles. The elaborate branching of these processes in the vicinity of their targets, the vibrissa follicles, recapitulates their growth pattern in vivo. On the other hand, ganglion cell processes which enter the hindbrain explants consist of thin, beaded axons which are predominantly unfasciculated. Many of these axons form a distinct tract with an ascending and descending component. Other processes radiate into the brainstem. The presence of several retrogradely labeled cells in the hindbrain explants may represent the mesencephalic component of the trigeminal system.

These results demonstrate that many features of the trigeminal pathway can be replicated in vitro. The technique holds promise for future studies of brain development in a relatively simple culture system.

DEVELOPMENT OF DORSAL ROOT AFFERENT ARBORIZATIONS IN HUMAN SPINAL CORD. A. Konstantinidon\*, N. Flaris. I. Silos-Santiago and W.D. Saider. Dept. Neurology, Washington University Medical School, St. Louis, MO, 63110.

The primary sensory modalities are subserved by physiologically distinct classes of dorsal root ganglion (DRG) cells. Each of these DRG cell classes has a characteristic central arborization in the spinal cord. Although these arborizations have been well characterized in experimental mammals, no previous study has described spinal arborizations of DRG cells in humans. We have taken advantage of the ability of the lipid-soluble tracer, Dil, to reveal axonal arborizations in fixed tissue to study the devopment of primary sensory afferents in human spinal cord. We have found that the DRGs are well developed by 6 weeks of age. By 9

We have found that the DRGs are well developed by 6 weeks of age. By 9 weeks, some classes of dorsal root axons have entered the gray matter of the spinal cord and a few Ia axons have already reached the vicinity of motor neurons somata. By 14 weeks, fascicles of Ia axons traverse the dorsal horn along the entire mediolateral axis and project toward the ventral horn. Many ofthe fascicles converge near an area of the midline that presumably represents Clarke's column and then diverge in complex patterns to innervate motor neurons. Ia axons defasciculate in the ventral horn and elaborate boutons that appear to be in striking proximity to motor neuron cell bodies.

Several other classes of afterents have also entered the cord at this age. One major class enters the cord in a variety of mediolateral locations and projects in fascicles to lamina IV. These afferents have their major arborizations in the rostro-caudal axis. Between 14 and 16 weeks smaller afferents enter the cord and populate the superficial dorsal horn, primarily oriented rostro-caudally as well.

This is the first study to reveal the morphology of primary sensory afferents in humans. Supported by the American Paralysis Association.

THE EXTENT OF AXONAL ARBORIZATION OF THE MESENCEPHALIC DOPAMINERGIC NEURON IS INDEPENDENT OF THE SIZE OF THE STRIATAL TARGET FIELD. H.K. Choi\*, L.A. Won, B. Heller and A. Heller, Dept. of Pharmacological and Physiological Sciences, The University of Chicago, Chicago, IL 60637 and Dept. of Mathematics, Illinois Institute of Technology, Chicago, IL 60616

Using a three-dimensional reaggregate culture system we have previously demonstrated that the survival of mesencephalic dopaminergic (DA) neurons is dependent on the presence of striatal target tissue (Brain Res. 274:275, 1983). In the present study, we examined whether or not there is competition among DA neurons for a target field or whether the axonal arbor of such neurons grows to a given size, no matter what the extent of the available target field. Rostral mesencephalic tegmentum (RMT) containing DA neurons and corpus striatum (CS) were dissected from E14 mice and dissociated. Varying numbers of RMT cells ranging from 10,000 to 1 million were coaggregated with 5 million CS cells. After 3 weeks in culture, half of the aggregates in each flask were analysed for DA and protein content. The other half of the aggregates were sectioned and processed by tyrosine hydroxylase (TH) immunocytochemistry to allow identification and quantitation of DA neurons per flask as well as DA cell density within the aggregates. The results obtained demonstrated that there was a linear relationship between the number of RMT cells added and the DA content per flask. A linear relationship was also found between numbers of THpositive cells within a flask and the number of RMT cells added. The percent of DA neurons remained constant (approximately 1%) over the entire range of RMT cells added. Similarly, there was a linear relationship between nanograms of DA content per flask and number of TH-positive cells per flask. From this linear relationship, it is evident that each DA neuron in these cultures contained approximately 2.8 pg of DA. Assuming that the DA content of a neuron is related to the extent of the axonal arborization, these results provide evidence that the DA neuron is intrinsically programmed to elaborate an axonal field of a given size even when presented with excess target field. Supported by MH-28942.

THE DISTRIBUTION OF A MYOSIN I mRNA IN THE DEVELOPING MOUSE BRAIN. M.P. Joyce\*,

university, Coll. of Pathology, Columbia
University, Coll. of Pathology, Ny 10032.

Myosin I is a one-headed version of the two-headed muscle myosin. Myosin I-immunoreactivity has been found at the leading edge of locomoting Dictyostelium, and may participate in generating propulsive movement in neuronal growth cones. We previously reported the identification of PCR previously reported the identification of PCR products that corresponded to 3 novel myosin I genes. One of these, mouse myosin IC, showed strong expression in the developing brain. To map the expression of this gene, CDNA probes spanning different regions of the gene have been constructed. In situ hybridization using the digoxigenin-alkaline phosphatase method was digoxigenin-alkaline phosphatase method was performed on paraffinized tissue sections from the brains of 2-day-old, 12-day-old, and adult mice. Labeling was observed in many CNS sites including the cerebral cortex, hippocampus, cerebellum and brain stem. The 2-day-old and 12day-old mice showed extensive labeling. In the adult animals, the intensity and extent of the distribution of the reaction product was significantly diminished. These results suggest that myosin I may participate in neuronal development.

DEVELOPMENT OF THE RAT SEPTOHIPPOCAMPAL PROJECTION: LIGHT AND ELECTRON MICROSCOPY OF IDENTIFIED GROWTH CONES. R. Linke\* and M. Frotscher. Inst. Anat., Univ. Freiburg, D-7800 Freiburg, FRG.

We studied the ontogeny of the septohippocampal projection in rats from embryonic day (ED) 15 to postnatal day (PD) 10 by means of retrograde and anterograde transport of the fluorescent tracer Dil. In fixed material, injections of DiI (2% in abs. ethanol) were placed into the septal region, and horizontal sections were processed for fluorescent microscopy or for electron microscopy after photoconversion. We consistently found retrogradely labeled cells in the hippocampus at ED 17, but no anterogradely labeled fibers. At ED 18, the first septal axons arrived at the hippocampus proper but continued to grow to the subiculum and entorhinal cortex. The innervation of the hippocampus proper seemed to occurr mainly via collaterals of these passing axons. Septal axons in the dentate gyrus were not seen before PD 1. A nearly adult pattern was found at PD 15. Ultrastructural analysis of identified growth cones and their micromilieu in the fimbria and the hippocampus proper indicates that septal axons in the fimbria use other axons as guiding cues, probably those originating in the hippocampus. In the hippocampus contacts of the growth cones with all elements present were found.

# 105.1

ABNORMAL NEURONAL DIFFERENTIATION IN THE SPINAL CORD OF A MUTANT ZEBRAFISH LACKING FLOOR PLATE CELLS. R.R. Bernhardt\*, C.K. Patel, S.W. Wilson, and J.Y. Kuwada, Dept. Biology, University of Michigan, Ann Arbor, MI 48109-1048 and Neurobiology, ETH-Hoenggerberg, Zuerich.

We compared the differentiation of putative GABAergic neurons in wildtype zebrafish spinal cord and in cyc-1 mutant embryos that are missing the midline floor plate cells (Hatta et al., '91). In wildtype embryos, an antibody against the neurotransmitter GABA labeled the cell bodies and axons of four classes of cells; DoLA, CoSA, VeLD, and Kolmer-Agduhr (KA) neurons. In the mutant, abnormal axons were observed in some, but not all, of the GABA reactive CoSA, VeLD, and KA neurons while the axonal trajectories of DoLA neurons were not affected. Furthermore, the number of KA cells was significantly reduced in the mutant while the numbers of the other GABAreactive cells were unperturbed. These observations corroborate the hypothesis that floor plate cells are one of several guidance cues that direct axonal outgrowth near the ventral midline of the spinal cord (Bernhardt et al., '92) and suggest a role of the floor plate in the determination of ventral cells in the zebrafish spinal cord. Supported by grants from NIH.

PRENATAL DEVELOPMENT OF CALLOSAL AXONS IN ACALLOSAL STRAIN MICE: A QUANTITATIVE STUDY WITH CARBOCYANINE DYES. H. S. Ozaki<sup>1,2</sup> and D. Wahlsten<sup>1\*</sup>. Dept. of Psychology, Univ. of Alberta, Edmonton, Alberta, Canada T6G 2E9, and <sup>2</sup>Dept. of Anatomy, Kagawa Medical School, Kagawa, Japan 761-07

We have recently established a standard for normal callosal development in mice (Ozaki and Wahlsten, J. Comp. Neurol., in press). In the present study, callosal axons in acallosal 129/J and BALB/cWah1 mice were studied from frontal, parietal, temporal and occipital cortex using postmortem fluorescent tracers DiA and DiI.

The emergence and rate of growth of callosal axons are evidently normal in 129/J and BALB/cWah1 fetuses until the axons reach midplane, where there is a gap between the two hemispheres. Finding no bridge to the other side, the callosal axons loop back and form a large whorl, the Probst bundle. In some fetuses a few callosal axons cross over the dorsal surface of the hippocampal commissure. Growth cones of callosal axons in acallosal fetuses are very similar in size and morphology to normal fetuses.

These results indicate that the problem with callosal agenesis does not reside in the cells of origin or the axons themselves, but it does occur in the substrate of axon guidance at the midsagittal plane. Supported by grants from NSERC and AHFMR.

FORMATION OF THE DORSAL COMMISSURE IN RELATION TO INHIBITORY ECM MOLECULES IN THE SPINAL CORD ROOF PLATE. R. R. Pindzola\*, M. de L. Gonzalez, and J. Silver. Dept. of Neurosciences, Case Western Reserve University, Cleveland, OH, 44106-4975.

It has been suggested that inhibitory ECM molecules in the roof plate forms beginning the 1811 of the processor of Computer States.

form a barrier to all nearby axons during early development (Snow et al., Dev. Biol., '90). However, in late stage embryos the dorsal commissure does cross through the roof plate. How could the roof plate first restrict and later allow the passage of axons? We investigated the development of and later allow the passage of axons? We investigated the development of the rat dorsal commissure in relation to roof plate glia and the molecular environment in this region. The axons in the vicinity of the roof plate were identified with Dil or TUJ1 staining in a series of embryonic rats. The glia of the roof plate were analyzed with Dil labeling and staining for vimentin, in order to determine their geometry when the commissure first appears. The roof plate was also stained for the putative inhibitory matrix molecules, cytotactin/tenascin (CT), chondroitin sulfate (CS-PG) and keratan sulfate (KS-PG) proteoglycans to learn if the expression of these molecules decreases when the commissure forms.

From Dil and TILI staining it appeared that the first dorsal commissural

these molecules decreases when the commissure forms.

From Dil and TUJ1 staining it appeared that the first dorsal commissural axons crossed the midline on E16. The vimentin labeled glia in the midline of the roof plate formed closely opposed processes, attached at the ventricular and pial surfaces, but which separated where commissural axons first traveled. It was clear that dorsal commissural axons crossed through the roof plate rather than through the more ventral area of ventricular fusion since measurements verify precisely where crossing first occurred. CT and CS-PG staining were no longer present at E16. KS-PG was still present, but only in a small area in the dorsal most part of the roof plate. The abundance of inhibitory molecules in the roof plate in early gestation and their disappearance when axons first crossed the dorsal midline is further evidence that these molecules may indeed act as barriers to elongating axons. barriers to elongating axons.

FORMATION OF THE HIPPOCAMPAL COMMISSURE IN NORMAL MOUSE EMBRYOS. Daniel Livy. Dept. of Zoology, Univ. of Alberta, Edmonton, Alberta, Canada T6G 2E9.

The routing and timing of axon growth from the ventral hippocampal formation through the hippocampal commissure (HC) were studied in normal B6D2F2/J hybrid mouse embryos using fixation by perfusion and then insertion of crystals of the carbocyanine dyes DiI and DiA. Specimens ranged from 0.2 to 0.7 g body weight or 14 to 16 days of chronological age. In several embryos the corpus callosum (CC) or anterior commissure was also labelled with dye placements in the cerebral cortex.

The first crossing of HC axons between the hemispheres was seen in embryos weighing about 0.4 g, which occurs about a day earlier than the first crossing of the CC axons at body weights of 0.6 to 0.62 g. Prior to turning toward the midsagittal plane, the putative HC axons are part of the large bundle of fibres of the fornix, which appears in the septal region more than a day before the HC forms. The HC axons cross midplane at the base of a deep cleft in the septal region. Before they enter the opposite hemisphere, the growth cones of the HC axons in the vicinity of midplane are complex, having many filopodia. Once they have crossed and entered the fimbria on the opposite side, the growth cones adopt a much simpler morphology.

ANTERIOR COMMISSURE PROJECTIONS IN DEVELOPING HAMSTERS. M.A. Pires-Neto\*, R. Lent and A.L.C. Hartmann. Instituto de Biofísica Carlos Chagas Filho, U.F.R.J., 21941 Rio de Janeiro, Brasil.

We have studied the prenatal and postnatal development of anterior commissure (AC) projections in hamsters, employing fluorescent carbocyanines as neuronal tracers. Fixed brains of embryos from E12 through E16, and from P1 to P10 (E16 = P1 = day of birth), had crystals of DiI and/or DiA implanted into the paleocortex at different locations. The brains were vibratome-sectioned at 100  $\mu m$  in the coronal, parasagittal and horizontal planes, and the sections were analyzed, charted and photographed using a fluorescent microscope coupled to a microcomputer. Anterogradelylabeled AC fibers tipped with growth cone-like swellings were seen approaching the midplane on E13, and crossing it on E14. On E14, a few (pioneer) axons took the lead and penetrated long into the opposite hemisphere, followed behind by the bulk of growing fibers. In some experiments, pioneer cell bodies could be identified by retrograde labeling in the paleocortex. A topographic organization was present from the start of AC formation: fibers from rostral paleocortex crossed through the rostral sector of the AC tract, while those originating more caudally took a caudal location. On E15 axons reached their targets, and initiated branching by interstitial budding. On E16 and later, a profuse terminal field was present at the olfactory peduncle and cortex, and in nuclei of the amygdaloid complex. The topography of crossing fibers was maintained throughout postnatal development.

CORTICOSPINAL TARGET SPECIFICITY DEMONSTRATED IN EXPLANT CULTURES. R.Z.Kuang\* M.Merline, and K.Kalil. Dept. of Anatomy and Neuroscience Training Program, University of Wisconsin, Madison, WI 53706.

Corticospinal axons develop arbors specific for their targets from the onset of innervation. (Kuang and Kalil, 1990 Neurosci. Abstr.). To test the degree of specificity in developing corticospinal connections we used an explant coculture system in which newborn hamster sensorimotor cortex was presented with choices of target tissue. Explants of P0-P1 cortex were cocutured in collagen gels with explants of P1-P3 cervical spinal cord (target) and cerebellar or olfactory bulb (control) placed on opposite sides of the cortical explant. After incubation in roller tubes for 4-7 days, the cultures were fixed and injected with Dil to label either cortical axons or cortical neurons. In over 200 successful experiments, cortical axons grew out into the collagen matrix ventrally and laterally showing no preferential attraction toward either the target or control explants. However, in all cases axons extending toward the spinal cord explan grew into it and established terminal branches resembling normal corticospinal arbors. By contrast, axons directly contacting the control explant were invariably deflected away from the edges of the tissue, even when cortical axons were presented only with control tissue. Axons extending randomly into the collagen matrix or toward the control tissue originated from neurons distributed throughout the cortical explant. By contrast, cortical axons growing into the spinal cord explant originated from pyramidal neurons that, in comparison with age-matched cortical explants retrogradely labeled in vivo from the spinal cord, resemble the distribution of layer V corticospinal neurons. We are now investigating whether axons from cortical explants can distinguish tissue from different levels of the spinal cord. The present results suggest that contact mediated inhibitory or permissive effects on growing axons may be important in determining target specificity during development. Supported by NIH Grant NS14428 (K.K.) and Training Grant T32 GM 07048 (M.M.).

INHIBITORY INTERACTIONS MAY PROMOTE TARGET SELECTION BY RETINAL AXONS IN THE MAMMALIAN THALAMUS. R. Tuttle\* and D.D.M. O'Leary. Molecular Neurobiology Lab, The Salk Institute, La Jolla, CA 92037.

We are using in vivo and in vitro approaches to characterize axon-target interactions and molecules that influence the development of retinal ganglion cell (RGC) connections to their principal thalamic target, the lateral geniculate nucleus (LGN), In rodents, RGC axons enroute to the superior colliculus (SC) have been reported to extend past the LGN and later extend side branches into LGN (Bhide and Frost, J. Neurosci. 91). We injected Dil intraocularly in E17 and E18 rats and perfused at E18. and E19. Thalamic nuclei were identified by retrograde fast blue labeling from cortex and acetylcholinesterase staining. Whole mounts reveal that RGC axons are tightly bundled in the optic tract in ventral diencephalon (vD). Upon entering the dorsal diencephalon (dD), however, RGC axons defasiculate and splay out dramatically over roughly a 3 mm rostral-caudal area of the dD. At these ages, many RGC axonal growth cones are apparent in this region of the dD, although others have entered the SC. Examination of sectioned material shows that while most RGC axons are on the surface of the diencephalon, some in the dD are in the parenchyma in both target and nontarget nuclei. In addition, a small number of side branches extend into target and nontarget nuclei of E18 and E19 dD, but by E19 branches appear to be more and nontaget nuclei of E16 and E19 dD, but by E19 branches appear to be more numerous and more complex in LGN. Collagen gel cocultures of retina and thalamus suggest that only subregions of diencephalon are stimulatory (or permissive) for RGC axon growth. While explants from most regions of diencephalon were inhibitory (or nonpermissive) for RGC axon growth, explants from a specific region, presumed to be LGN, were robustly invaded by RGC axons. Immunohistochemical detection of chondroitin sulfate proteoglycan (CSPG), a molecule shown to inhibit to the control of the co RGC axon growth in vitro (Snow et al., Develop. 91), reveals intense staining in the vD (optic tract and regions medial to it), and much lower staining in the dD. These findings raise the possibility that inhibitory interactions may contribute to the specificity of RGC innervation of thalamus, and that CSPG may contribute to this process. (Support: Spinal Cord Res. Fnd. and NIH EY07025)

CELLS OF THE OPTIC CHIASM MIDLINE INHIBIT UNCROSSED RETINAL FIBER OUTGROWTH IN VITRO. L.-C. Wang\* P. Godement and C.A. Mason, Dept. Pathology, Coll. Physicians and Surgeons, Columbia Univ., NY, N.Y., 10032 and CNRS, Gif-Sur-Yvette, France.

Our previous studies have shown that retinal axons diverge to each side of the brain near the midline of the optic chiasm (Godement

each side of the brain read the inflame of the optic chasm (codement et al., Neuron 5:173,1990). In vitro, whereas fibers from dorsal retina (crossed fibers) grow well on monolayers of cells dissociated from the chiasm midline, fibers from inferior temporal retina (uncrossed fibers) grow short neurites on such monolayers (Guillaume et al, Soc. Neurosci. Abstr. 17: 40, 1991). Within the monolayers are "Islands" of neuronal cells settled around "spokes" of long glial processes, reminiscent of the radial glial palisade that spans the midline zone in vivo (Mason et al., Soc. Neurosci Abstr. 17: 39, 1991). To test whether the islands inhibit or permit retinal axon growth, chiasm cells were allowed to reaggregate before plating to preferentially form islands, and retinal axon growth monitored by dye labeling and video microscopy. Crossed fibers grew over islands. When uncrossed fibers met an island, their growth cones developed complex spread fibers met an island, their growth cones developed complex spread morphology along the border of the island, and continued to extend but at the outskirts of the island, resembling the behavior of uncrossed fibers in vivo. We are currently investigating whether the inhibitory properties of the midline require both neurons and glia, or reside in the radial glia themselves, by coculturing retinal explants with purified midline glia.

These studies provide further evidence that cells from the chiasm midline present cues for retinal axon divergence, and raise the issue of the role of cellular interactions between resident chiasm cells in the differential signalling for retinal axon divergence.

THE DEVELOPMENT OF THE AXONAL PROJECTIONS FROM THE BASAL FOREBRAIN IN THE RAT. K. Murakami, M. Kuroda and K. Kishl. Dept. Anat., Toho Univ. Sch. of Med. Tokyo

Development of the axonal trajectories from cells in the basal forebrain structures (BF) was studied by application of Dil to medial prefrontal cortices (ML), the olfactory bulb (OB) and the vertical or horizontal of the diagonal band (VDB or HDB) during ages from embryonic day 14 (E14) through postnatal day

Of (PB). At E18, the axonal projections from BF did not reach OB and ML, but they were found to enter into the olfactory peduncle and medial septum. On E19, retrogradely labeled cells, after implantation of DiI into OB, were seen in MDB, VDB, the ventral pallidum, the lateral preoptic area (LPO), and the locus cocruleus (LC). On the other hand, DII implantation in the cingulate cortex resulted in the finding that retrogradely labeled cells were detectable in VDB and HDB. Retrogradely labeled cells after DiI implantantion in the occipital cortex were not found in BF neurons. On PO, following placement of DiI in OB, retrogradely labeled neurons were found predominantly in HDB, LPO and LC. Additionally, some of cells in other BF structures (VDB, the substantia innominata, the bed nucleus of the stria terminalis, the lateral hypothalamic area ) and in the orbital cortex were also labeled. Placement of DiI into OB resulted in the retrograde labeling of cells in BF, whose axon collaterals preferentially invaded the prelimbic and anterior cingulate cortex. These labeled collaterals traveled tangentially and rostrocaudally in the intermediate layer of the cingulate cortex, and gave off their branching into the subplate zone below the cingulate and prelimbic cortex. However, these fibers did not reached the occipital cortex. Retrogradely labeled cells after Dil implantation into ML (the prelimbic, anterior cingulate, occipital cortex) were scattered throughout BF. In conclusion, the first axons from VDB, HDB, LFO and LC begin to enter OB and ML on E19, and by PO they further reach the occipital cortex. By PO, some of BF neurons have axon collaterals projecting to divergent forebrain area (OB and ML).

QUANTITATIVE ANALYSIS OF TOPOGRAPHIC TARGETING OF RETINAL AXONS IN DEVELOPING RAT SUPERIOR COLLICULUS AL. Roskies\* and D.D.M. O'Leary.

Molecular Neurobiology Laboratory, The Salk Institute, La Jolla, CA 92037.

Axons of retinal ganglion cells (RGCs) form a precise topographic projection to the adult mammalian superior colliculus (SC). Anterograde axon tracing using Dil shows that in E18-E19 rats RGC axons exhibit no tendency to target to the correct half of the SC (Simon & O'Leary, Soc Neurosci Abstr '91) and reveals a half of the SC (Simon & O'Leary, Soc Neurosci Abstr '91) and reveals a topographically diffuse retinocollicular projection in neonates (Simon & O'Leary, J Neurosci '92). However, retrograde tracing studies using Fast Blue (O'Leary et al J Neurosci '86) or rhodamine beads (Yhip & Kirby, Vis Neruosci '90) in neonates suggest that only a small proportion of temporal RGCs transiently project to the topographically inappropriate caudal SC. These tracers are less effective than Dil at labeling axons of passage. We have used Dil as a retrogarde tracer to reassess quantitatively the topographic targeting of RGC axons in neonatal rats. Dil was injected into various points along the rostrocaudal extent of the SC. The distribution of retrogradely labeled RGCs shows some bias toward the correct topographic region by P2: however. in all cases a large percentage of cells project to topographically of retrogradely labeled RGCs shows some bias toward the correct topographic region by P2; however, in all cases a large percentage of cells project to topographically incorrect locations. About 1/3 of all RGCs labeled with injections in far caudal SC are found in temporal retina, indicating that at least 1/3 of RGC axons topographically matched with rostral SC greatly overshoot their correct region at this age. This figure, though, is an underestimate, since injections in far rostral SC indicate that even Dil is not as effective at labeling axons of passage as it is axon topographically matched with the injected region. Labeling patterns from injections made either immediately rostral to or caudal to the rostrocaudal midline of the SC are made either immediately rosura to or caudat to the rostrocaudat motine of the SC are similar to each other; in both cases a large proportion of temporal RGCs are labeled and no drop-off in labeling density is apparent at the temporal-nasal retinal midline. These observations indicate that position dependent molecular cues hypothesized to guide or restrict the growth of RGC axons do not operate effectively in vivo in the developing rat SC. (Support: NIH grant ROI EY07025 and training grant GM08107.)

REGIONAL POLARIZATION OF EARLY AXON EXTENSION BY CORTICAL NEURONS S.E. Koester\*, C.A. Lucidi-Phillipi, D.D.M. O'Leary. Molecular Neurobiology Lab, The Salk Institute, La Jolla, CA 92037.

The two major cortical outputs are to subcortical targets via the internal capsule (IC) and to contralateral cortex via the corpus callosum (CC). In rats, axons from the neocortical preplate form the IC at E14 (DeCarlos & O'Leary J.Neurosci. 1992) while axons from the earliest generated neurons in medial (cingulate) cortex form the CC at E17 (Koester & O'Leary Soc.Neurosci.Abs. 1991). Neurons projecting subcortically send axons laterally through the intermediate zone (IZ) to the IC, and other cells later send axons medially through the IZ toward the CC, suggesting that initial cortical axon outgrowth must be polarized. We injected Dil in fixed rat cortex at various sites to determine when and where this polarization of axon extension breaks down. TuJ1 munohistochemistry (Lee et al Cell Motil.Cytoskel 1990) was used to visualize the overall pattern of the cortical axon pathways. At E14, essentially all long axons extend toward the IC. As late as E16, all retrogradely labeled neurons are found medial to Dil injections in the lateral wall, but their distribution stops abruptly in dorsal cortex and no labeled cells are found more medially in cingulate cortex. Anterogradely labeled axons emerge from the Dil site and extend toward the IC. These findings indicate that all neocortical axon growth is still directed toward the IC at E16. TuJ1 staining shows that the axon pathway in the IZ thickens from dorsal cortex laterally, but not medially, confirming the addition of axons to the pathway in the lateral IZ. At E17, the medial border of subcortically projecting neurons persists. In lateral (more mature) regions of cortex, a large number of neurons lateral to the injection are now retrogradely labeled indicating that they have begun to extend axons along the callosal trajectory. Observations using Tul 1 are again consistent with this finding. These data demonstrate a strong polarity in the early extension of cortical axons; the most medially located cells extend axons medially, cells lateral to these extend axons laterally. The boundary representing the reversal in this polarity may correspond to the horder between cingulate cortex and neocortex

## 105.13

EARLY DEVELOPMENT OF OLIVOCEREBELLAR PROJECTIONS IN THE FETAL RAT USING CGRP-IMMUNOCYTOCHEMISTRY.

C. Sotelo\* and A. Chédotal, INSERM U. 106, 75013 Paris (France).

We have shown that calcitonin gene-related peptide (CGRP) immunocytochemistry reveals a selective subpopulation of inferior olivary axons from embryonic day 17 (E17), as they start penetrating medially the rostral cerebellar surface. The expression of the labelling is transient and decreases progressively, although not completely, after postnatal day 6. During development: i) Olivocerebellar axons are not randomly distributed in the restiform bundle before they enter the cerebellum. ii) Just after their penetration, the olivary axon growth cones acquire more complex morphologies, and they abut in a region solely composed of migrating Pukinje cells (visualised on double-labelled sections by their Calbindin-D $_{28K}$  immunoreactivity). iii) From E18 to E19, the labelled fibers are bypassed by migrating Purkinje cells, and a new vermal lateral stripe is formed. The distribution of CGRP-IR fibers in the vermal cortex coresponds to the known sites of axonal pojection of the observed CGRP olivay neurons.

The results suggest that there is neither a waiting period nor an initial phase of randomness in the formation of the olivocerebellar pojection map. This absence of chaotic cerebellar invasion, and the high selectivity of the entry points, let us suppose that the orientation of CGRP positive olivocerebellar fibers toward their targets is regulated on the basis of positionnal information shared between subsets of olivary neurons and clusters of Purkinje cells. This preliminary coarse topography would need further refinement.

DEMONSTRATION OF SPECIFIC PROJECTIONS TO HIPPOCAMPUS IN ORGANOTYPIC SLICE CO-CULTURE. P.M. Field, D. Li and G. Raisman. (SPON: Brain Research Association\*), Norman and Sadie Lee Research Centre, Laboratory of Neurobiology, NIMR, The Ridgeway, Mill Hill, London NW7 1AA, UK.

Species-specific markers (Thy-1 and M6) and anterograde axonal transport of biocytin have been used to demonstrate projections from embryonic mouse explants co-cultured with postnatal rat hippocampus.

Mouse entorhinal pyramidal cells send axons to rat hippocampal slices both in roller tube and static culture. The densest part of the projection was to the stratum moleculare of the dentate gyrus but the entorhinal axons also projected to the stratum lacunosum-moleculare and outer stratum oriens of the hippocampus, and in some cases perforated the pyramidal cell layer of the subiculum.

Projections from other brain areas that normally terminate in the hippocampus will be demonstrated using this co-culture technique.

### 105.12

HIPPOCAMPAL GROWTH CONE ORIENTATION IN FOCAL ELECTRIC FIELDS C.D. McCaigl, L. Davis2\*, R.W. Davenport2

1 Department of Biomedical Sciences, University of Aberdeen, Aberdeen AB9 1AS, Scotland, 2 Program in Neuronal Growth and Development, Colorado State University, Fort Collins, Colorado 80523

A wide variety of cell types respond to electric fields in culture. Despite evidence for electric fields existing in the mammalian embryo, there are few studies testing the effects electric fields exert on neurons from the mammalian CNS. The present study demonstrates orientation responses to focally applied electric fields of embryonic rat hippocampal neurons isolated in culture. The most striking result is that different growth cones of the same neuron can show differential responsiveness to focally applied electric fields: growth cones on short, straight processes, the presumptive dendrites, oriented toward the cathode, while growth cones on the longest process, the presumptive axon, did not orient. Additionally, the present experiments bring a significant increase in resolution to the study of neuronal growth cone orientation by applied electric fields: a novel examination of the early events involved in orientation. A new method for quantitation of these events was devised. Growth cones on dendrites displayed a spectrum of orientation responses: directed lamellipodial extension, directed filopodial extension and/or re-orientation, cytoplasmic swelling of existing filopodia, consolidation of filopodia and rapid elongation of the entire process. Individual growth cones displayed only one or two of these responses. Additionally, not all growth cones on dendrites sustained their initial orientation response. Thirty-five percent of these growth cones adapted within 6 minutes. Thus, focal electric fields can orient mammalian CNS growth cones and ultimately may affect the final neuronal architecture.

### 105.14

LONG AXON GROWTH FROM EMBRYONIC NEURONS TRANSPLANTED INTO AN UNDAMAGED ADULT MYELINATED FIBRE TRACT. S.J.A. Davies. P.M. Field and G. Raisman\*, Norman and Sadie Lee Research Centre, Laboratory of Neurobiology, National Institute for Medical Research, The Ridgeway, London NW7 1AA, UK.

A few thousand cells from embryonic (E14-E19) mouse hippocampi were microtransplanted into the fimbria of immunosuppressed adult rat hosts.

 $\dot{M}6$  and Thy-1.2 immunohistochemistry showed that the donor mouse neurons grew fine (<0.5  $\mu$ m diameter) axons which extended through the host tract at a rate of around 1-2mm per day, reaching their ipsilateral terminal field destinations (about 7mm) by about one week, and their contralateral destinations (at least 10mm) by about 2 weeks.

The axons ran singly or in fascicles and were closely aligned to the host tract axons and the interfascicular glial rows of the host tract

These observations suggest that the microenvironment of unlesioned myelinated adult fibre tracts is permissive for an abundant and rapid growth of axons from transplanted mouse embryonic hippocampal cell suspensions. These axons can form collaterals and leave the host tracts to invade the appropriate terminal fields.

# 105.16

REGENERATING AXONS OF THE ADULT RAT RETINA GROW PREFERENTIALLY TOWARDS TOPOGRAPHIC APPROPRIATE TARGET REGIONS IN VITRO. Mathias Bähr\* and Andrea Wizenmann. Neurologische Universitätsklinik and Max-Planck-Institut für Entwicklungsbiologie, Tübingen,F.R.G.

We have recently described that adult rat retinal ganglion cell (RGC) axons are able to reconnect with target neurons in vitro (Bahr and Eschweiler, 1991). In the present study, we have asked the question whether regenerating RGC axons can recognize topographic cues within their main target region. During development, RGC fibers establish a topographic projection where temporal axons preferentially terminate in the anterior and nasal ones in the posterior part of the colliculus superior (SC).

superior (SC).

We have explanted pieces of nasal and temporal retina 4-6 days after crushing the optic nerve. They were cocultured with midbrain slices from embryonic rats (E17-19), including the SC as a primary visual target region. Retinal explants were placed in between the anterior and posterior part of the SC. In all cases examined, a majority of fibers oriented towards one or the other end of the SC, only one third of the axons did not show a clear orientation. With temporal explants (n=46), the number of fibers growing towards the anterior pole of the SC exceeded that of axons orienting in the other, inappropriate direction by a factor of 2.49. For nasal explants (n=43), this factor was 2,64 for axons growing towards the posterior SC. In controls where retinal explants were placed at the border between SC and Colliculus inferior, only nasal fibers grew preferentially towards the posterior SC (55%) whereas temporal axons did not show an oriented growth. Thus, we conclude that also regenerating, adult RGC axons are able to recognize position specific cues from embryonic target regions

from embryonic target regions.

Bähr and Eschweiler (1991), NeuroReport 2, 581-584.

AXONAL GROWTH AND BRANCH FORMATION OF GENICULATE FIBERS IN VISUAL CORTEX STUDIED IN COCULTURE PREPARATIONS. N. Yamamoto\*, S. Higashi, H. Sugihara and K. Toyama Department of

Physiology, Kyoto Prefectural University of Medicine, Kyoto 602, Japan.
Our previous studies have demonstrated that geniculocortical connections are established with normal laminar specificity in cocultures of the lateral geniculate nucleus (LGN) and the visual cortex (VC) (Yamamoto et al. 1989, Science, 245, 192). To reveal cellular interactions which underlie the formation of the laminaspecific connections, axonal extension and branch formation of living LGN axons were studied in cocultures of the LGN and VC. A rat VC slice (P1-3) and a block of the LGN (E15-17) were cocultured so that the LGN faced the ventral side of the VC, and at 4-6 days in vitro a fluorescent dye (Dil) was placed on the LGN. A few days later, labeled LGN axons were observed for 1-2 days under a laser scanning confocal microscope at 0.01-2 hr intervals. All sampled LGN axons (n=7) were led by a growth cone (5-10 μm in length) and extended radially toward the pial surface of the VC. In 5 out of the 7 cases, the axons traveled through the infragranular layers at constant growth rates (20-60  $\mu$ m/hr) and suddenly stopped when they reached around the granular layer. After a while (1-3 hr), some axons (3/5) began to branch behind the growth cone, while the other axons (2/5) began to regrow without forming any branches (one axon toward the pial surface, the other along the layer). The remaining 2 axons traveled through all cortical layers at constant speeds, and reached the surface without branching. These findings suggest that LGN axons stop and branch in response to local environments in the

GENE CLONING AND EXPRESSION OF BRAIN-DERIVED NEURO-

GENE CLONING AND EXPRESSION OF BRAIN-DERIVED NEURO-TROPHIC FACTOR. Z.W. Hua, Y.K. Yu, S.Y. Cai, Y.S. Li and F.Z. Wang. Lab. of Neuroscience, Institute of Basic Medical Sciencas, Beijing, 100859, P.R. China.

Human and pig brain-derived neurotrophic factor (BDNF) games were amplified by polymerase chain reaction (PCR). The primers used in both human and pig BDNF gene amplification were synthesized according to the sequence of pig BDNF gene (Leibrock, 1989). It was found that, (1) within the pig sequence, there was one nucleotide variation at position 288 (A-G) when comparing the present result with that from Leibrock (1989), (2) in the human sequence, only three nucleotide variations within the two synthesized primer areas were realized at position 6 (G-T), 12 (G-T) and 384 (G-A) when comparing with that reported by Jones (1990), and which could be attributed to the primers of pig sequence used in this work; (3) all the nucleotide variations reported above occurred at the third base of amino acid codons and no amino acid alteration was resulted because of the degeneracy of codon.

The human BDNF gene was ligated to the fusion protein-

The human BDNF gene was ligated to the fusion protein-expression vector pBC2, which contains the strong PL pro-moter of bacteriophage lamda and directs the synthesis of fusion proteins consisting of part of protein G. After transformation, positive clones were obtained by in situ hybridization. The induced products of several clones were further identified positive by Western blotting. Works on chemical treatment of the fusion protein is going on.

# 106.3

DETECTION OF BDNF mRNA IN THE DEVELOPING CHICKEN EMBRYO. Daryn Kenny, Mike Cullen\* and Marianne Bronner-Fraser, Developmental Biology Center,

University of California, Irvine, Ca. 92717

Trophic factors regulate the survival of neurons and may be involved in neuronal differentiation. For example, Brain-Derived Neurotrophic Factor (BDNF) supports survival of dorsal root ganglion cells and some central neurons. To better understand the function of this neurotrophic factor, it is important to know its distribution in the embryo. Using a nuclease protection assay, we first detected BDNF mRNA in 2.5 day old embryos. This is just prior to the differentiation of dorsal root ganglia, which occurs at around 3 days of development. BDNF message was expressed continuously through 13 days, the last stage examined. Using *in situ* hybridization, we detected BDNF mRNA in individual cells in the developing embryo. In stage 24 embryos, high levels of BDNF mRNA were observed in a few cells near the lumenal portion of the trunk neural tube. This expression pattern was mointained at all subsequent tages. portion of the trunk neural tube. Inis expression pattern was maintained at all subsequent stages. Interestingly, in the midbrain region of 9 day embryos, blood cells within endothelial vessels strongly expressed BDNF. Although we cannot rule out the possibility that other cells within the embryo express low levels of BDNF, below the limits of detection by in situ hybridization, our results suggest that BDNF mRNA is detectable in a few neural tube/spinal cord cells as well as selected blood cells close to regions which may contain BDNF responsive neurons. (Supported by USPHS HD-25138)

## 106.2

REGUALTION OF HUMAN BRAIN DERIVED NEUROTROPHIC FACTOR GENE EXPRESSION. M. Jiang and G. Heinrich\*. Dept. of Medicine, Boston University, Boston MA. 02118
Brain-derived neurotrophic factor (BDNF) is critical
for the differentiation and survival of specific central
neurons yet little is known about the regulation of
BDNF gene expression in the human. We recently found that BDNF mRNA levels are increased by serum and the phorbol ester TPA were additive whereas they are known to be synergistic in stimulating NGF mRNA. To identify a suitable cell model for studies of human BDNF gene expression we examined W138 cells. These extensively studied fibroblast-like cells were derived from human fetal lung by Hayflick and coworkers in 1968. A single BDNF mRNA of 1.6kb was observed on a Northern blot. PCR analysis did not detect NGF or NT-3 mRNAs. Vitamin D, TPA, and serum stimulated the secretion of biologically active BDNF. Co-treatment with corticosterone inhibited the stimulation. These results indicate that BDNF gene expression is regulated by multiple stimuli in mouse and human cells in culture. WI-38 cells represent a model system for culture. W1-38 cells represent a model system for analyses of the mechanisms that mediate the cell-specific and developmental regulation of human BDNF gene expression and its modulation by extracellular signals.

DOPAMINERGIC NEURONS EXPRESS NT-3 AND BDNF mRNAS IN RAT MESENCEPHALON. K.B. Seroogy!\* K.H. Lundgren!, K.M. Guthrie', T.D. Tran², P.J. Isackson² and C.M. Gall². Departments of Anatomy & Neurobiology, <sup>1</sup>University of Kentucky, Lexington, KY 40536 and <sup>2</sup>University of California, Irvine, CA 92717.

We recently demonstrated that in normal adult rat brain neurotrophin-3 (NT-3) and brain-derived neurotrophic factor (BDNF) mRNAs are localized to specific ventral mesencephalic regions that contain dopaminergic cell bodies, including the ventral tegmental area (VTA) and medial substantia nigra (Gall et al., Mol. Cell. Neurosci. 3: 56-63, 1992). These data suggest that neurotrophic support for the dopaminergic neurons may arise from local synthesis. To determine whether the midbrain dopaminergic neurons, themselves, synthesize the neurotrophic factors we combined in situ hybridization of <sup>35</sup>S-labeled cRNA probes for the neurotrophic factor mRNAs with 6-hydroxydopamine (6-O-HDA) lesions and with immunocytochemistry for the dopamine biosynthetic enzyme tyrosine hydroxylase (TH). Unilateral injection of the neurotoxin 6-O-HDA into the ascending medial forebrain bundle or the ventral mesencephalon (which selectivals determs the present leaves belief degrees calls) of Clausel but in the second content of the control selectively destroys the mesotelencephalic dopamine cells), followed by a 1-5 week survival period, resulted in substantial depletion of NT-3 and BDNF mRNA-containing cells in the ipsilateral VTA and substantia nigra pars compacta. Combined in situ hybridization/TH immunocytochemistry revealed that the majority, but not all, of the NT-3 and BDNF mRNA-expressing cells in the VTA and medial substantia nigra pars compacta also contained TH. present results indicate that the neurotrophins are indeed synthesized by midbrain dopamine neurons. These data also raise the possibility that aberrant expression of NT-3 and BDNF by the dopaminergic neurons, themselves, could contribute to the neuropathology of disorders such as Parkinson's disease and schizophrenia. EXPRESSION OF BDNF mRNA IN THE DEVELOPING OPTIC TECTUM OF XENOPUS LAEVIS. S. Cohen-Cory\* P. J. Isackson and S. E. Fraser. Division of Biology, Beckman Institute 139-74, California Institute of Technology, Pasadena, CA 91125, and Mayo Clinic, Jacksonville, Fl 32224

The visual system of the frog provides a valuable system to study the formation and maintenance of topographically ordered connections between developing neurons and their targets. However, little is known about the trophic mechanisms that subserve it. Previous studies suggest that brain-derived neurotrophic factor (BDNF) plays an important role in the development of the visual system. BDNF promotes survival of retinal ganglion cells in culture, and is expressed in the optic tectum of higher vertebrates. To begin investigating the role of neurotrophic factors in the development of the visual system of the frog, the expression of BDNF message in the optic tectum of developing Xenopus laevis was analyzed. A Xenopus laevis specific, BDNF cRNA probe (Isackson et al., FEBS lett. 285; 260-264, 1991) was used to study BDNF gene expression by both Northern blot and RNAse protection assays. Two major BDNF transcripts highly expressed in the developing optic tectum were identified, and the time course of their expression was investigated. These results were compared with the expression of BDNF mRNA in various Xenopus laevis tissues of both neural and non-neural origin. (Supported by the Muscular Dystrophy Association).

EXPRESSION OF THE BDNF GENE IN THE VISUAL SYSTEM OF THE CHICK EMBRYO. K.-H. HERZOG AND Y.-A. BARDE\*. Dept. of Neurobio-chemistry, Max Planck Inst. for Psychiatry, Am Klopferspitz 18a, 8033 Planegg-Martinsried, Germany

The in vitro survival of Ell chick retinal ganglion cells (RGC) has been shown to depend on the addition of brain-derived neurotrophic factor (BDNF). Partly because of the low levels of BDNF mRNA and the difficulties to recognize on Northern blots discrete mRNA transcripts, BDNF mRNA was measured with a PCR-based quantification method. This method includes the addition to the tissue homogenates of an artificial BDNF RNA standard containing a mutated nucleotide, allowing the introduction of a cleavage site not normally present in chick BDNF mRNA. This allows for the separate detection of the endogenous message from the standard. BDNF mRNA could be detected in tecta as early as E4, i.e. 2 days before the arrival of the earliest axons of the RGCs, and persisted until E17 (the last time-point investigated). While the BDNF mRNA levels were not changed after the in vivo application of NMDA antagonists, a reduction was observed after blockade of muscarinic receptors.

SYNTHESIS AND PURIFICATION OF BIOLOGICALLY ACTIVE RAT BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) FROM E.COLI.

A. Negro. V. Corsa., C. Moretto<sup>2</sup> S. D. Skaper<sup>1</sup> and L. Callegaro\*, Advanced Technology Div. and Fidia Research Laboratories<sup>1</sup>, Fidia S.p.a., Abano Terme and Dept. of Organic Chemistry. University of Padua<sup>2</sup>-Italy

Chemistry, University of Padua<sup>2</sup>-Italy.

The cDNA for rat BDNF was cloned as the prepro and mature sequences into two independent expression vectors under the control of the T7 promoter. When the vectors were transfected into Escherichia coli, the prepro and mature forms of BDNF accounted for about 20% and 25% of total Eccoli proteins, respectively displaying molecular sizes of 26kDa and 15kDa. Mature BDNF was extracted from Eccoli inclusion bodies, refolded in the presence of CuCl<sub>2</sub> and purified by HPLC. The resulting protein supported the survival of cultured embryonic dorsal root ganglion neurons with an ED<sub>50</sub> of 3ng/ml. Although polyclonal antibodies against mature BDNF recognized 26kDa and 15kDa bands on Western blots, but they failed to block its biological activity. This represents the first successful expression of biologically active BDNF in bacteria. The availability of pure recombinant BDNF will facilitate studies on the role of this neurotrophic protein in CNS physiology and pathology.

EXPRESSION OF LOW-AFFINITY NGF-RECEPTOR-IMMUNOREACTIVITY (IR) AND BDNF AND NT-3 mRNAs IN DEVELOPING RAT RETINA AND SUPERIOR COLLICULUS. D. Rickman\*, J. Lauterborn, N. Brecha and C. Gall. Depts. of Anat. & Cell Biol. & Med., UCLA & VAMC, LA, CA 90073; Dept. of Anat. & Neurobiol., UCI, Irvine, CA 92717.

In the rat, most retinal ganglion cells project to the superior colliculus (SC), where their axons terminate in a precise retinotopic pattern. Little is known about the molecular mechanisms which guide ganglion cell axons or determine the specificity and maintenance of their central connections. Using immunohistochemistry with an antibody to the rat low-affinity NGF-receptor (LNGF-R), which binds all neurotrophins, and in situ hybridization with 35-labeled RNA probes to brain-derived neurotrophic factor (BDNF) and neurotrophin-3 (NT-3), we examined the distribution of these molecules in the developing rat visual system. At postnatal day 0 (PD-0), LNGF-R-IR was present in retinal ganglion cells, especially in peripheral retinal regions. At PD-7, LNGF-R-IR was confined to far peripheral regions, and at PD-12 only rare staining was observed. In the SC, NT-3 mRNA was present at PD-1 in the superficial gray (retinorecipient) layer. The signal was less intense at PD-12, similar to adult levels. BDNF mRNA, however, was not observed in the SC until PD-6. The signal was higher at PD-12 and continued to increase until PD-25, when it reached adult levels. These data suggest that neurotrophins influence retinal ganglion cells and play a role in the establishment and maintenance of retinotectal connections.

## 106.8

CO-EXPRESSION OF NGF, BDNF AND NT-3 IN THE DEVELOPING AND ADULT RAT CARDIOVASCULAR SYSTEM. <u>I.A. Scarisbrick</u> 1, <u>P.J. Isackson</u> and <u>E.G. Jones.</u> Dept. of Anatomy and Neurobiology, University of California, Irvine, <sup>1</sup> and Dept. of Biochemistry and Molecular Biology, Mayo Clinic, Jacksonville. 2

The neurotrophic factors nerve growth factor (NGF), brain derived neurotrophic factor (BDNF) and neurotrophin-3 (NT-3) provide trophic support to select sets of peripheral neurons. We use in situ hybridization histochemistry to describe the expression of these factors within the embryonic, postnatal and adult cardiovascular system a major target of sensory, sympathetic and parasympathetic nerve fibers. Peripheral neurons of neural crest and epidermal placode origin innervating the great wessels have been examined using immunocytochemical localization of the cell surface markers, neural cell adhesion molecule (NCAM) and HNK-1.

Hybridization for the three riboprobes is robust within the tunica media of the major clastic arteries arising from the heart, from embryonic day 13 onwards, approximately one day following the earliest detectable innervation of these vessels. cRNA hybridization for each generally overlaps but is not co-extensive, and until PO, NT-3 is by far the most widespread. In each case hybridization is dense over the smooth muscle cells of the aorta, ductus arteriosus and pulmonary arteries and continues at a lesser intensity into their major branches, but in the ventricular wall is restricted to the bases of the aortic and pulmonary valves. Hybridization was not detected in the remainder of the ventricle or in the atria. In the postnatal period, mRNA encoding each neurotrophin also becomes detectable in the coronary arteries, but not in the heart proper. BDNF and NT-3 continue to be expressed at high levels by arterial smooth muscle cells of adult major elastic arteries, but the level of NGF is reduced.

THE EFFECTS OF GRAFTING BDNF-PRODUCING FIBROBLASTS ON CHOLINERGIC NEURONS *IN VIVO*. <u>CA Lucidi-Phillipi</u>. <u>UI Kang\*</u>. <u>CW Shults</u>. <u>KR Jones</u>. <u>LF Reichardt</u>, and FH <u>Gage</u>. Depts Neurosci, UCSD, La Jolla, CA 92093 and UCSF, San Francisco, CA 94143.

Brain-derived neurotrophic factor (BDNF) is a member of a family of related neurotrophins. Nerve growth factor (NGF)-producing fibroblasts induce sprouting of cholinergic neurons when grafted into the intact adult rat striatum (Kawaja and Gage, 1991). We attempted to determine the effect of BDNF on central adult neurons by grafting putative BDNF-producing fibroblasts into the striatum of the adult rat.

We first inserted an expression cassette DNA encoding human BDNF into

we first inserted an expression cassette DNA encoung infinian BDNF into a retroviral vector to establish a producer line. Primary fibroblasts were then infected with the recombinant virus and selected for neomycin resistance. The evidence suggesting that BDNF is transcribed and translated by fibroblasts is fourfold: 1) Northern blot analysis 2) In situ hybridization at one and two weeks in vivo 3) Conditioned media from infected fibroblasts promote the survival of embryonic chick dorsal root ganglia and 4) fetal mesencephalic neurons in culture.

unike NGF-producing fibroblasts, grafts of BDNF-producing fibroblasts into the striatum did not induce the ingrowth of p75LNGFR- or neurofilament-immunoreactive axons at time points of one, two, three, or eight weeks. There are, however, a variety of issues regarding the grafted cells that need to be addressed, including long term expression, immunological tolerance, and cell survival. In addition, we are currently investigating the role of BDNF in promoting survival of fetal cholinergic neurons by co-grafting fetal cholinergic neurons with BDNF-producing fibroblasts into the denervated hippocampus.

REGULATION OF PEPTIDE EXPRESSION IN CULTURED CORTICAL NEURONS BY BDNF. H. Nawa (1,2), Y. Bessho (2), J. Carnahan (3), S. Nakanishi (2) and K. Mizuno (1). Brain-derived neurotrophic factor (BDNF) was recently shown to promote the current of memory of the control of the complexity of memory of the control of the current of the cur

Brain-derived neurotrophic factor (BDNF) was recently shown to promote the survival of mesencephalic dopaminergic neurons and basal forebrain cholinergic neurons. The differentiation activity of BDNF, however, has been less clear. In this study, we examined the effects of the neurotrophic actors, BDNF, neurotrophin-3 (NT-3) and neurve growth factor (NGF) on neuropeptide expression in cultured cerebral cortical neurons. BDNF and NT-3 produced by COS cells and mouse NGF were added separately to gliariee cortical cultures. Only BDNF remarkably increased peptide contents of neuropeptide Y (10-fold) and somatostatin (5-fold) while CCK and GABA contents were modestly influenced (<2-fold) and neuronal viability was not affected. To determine whether the peptide elevation by BDNF resulted from increased synthesis of the peptides, we assayed their mRNA levels. The expression of those mRNAs was enhanced by BDNF to the same extent of the peptide increase. The elevation of the mRNA expression was fully dependent on the presence of BDNF in culture: Removal of BDNF during the culture decreased the mRNAs to a control level while delaying the addition of BDNF still elevated the mRNAs to he same maximum levels. This observation supports that the peptide-inducing activity of BDNF is independent of its activity in promoting neuronal survival reported previously. More than 90% of neuropeptide Y and somatostatin immunoreactivities are associated with GABAergic interneurons in the cortex. Therefore, our results suggest that in the cerebral cortex, the BDNF activity may regulate neuropeptide phenotype locally and could modify the mode of neurotransmission of GABAergic neurons.

TROPHIC EFFECTS OF NEUROTROPHIN-3 ON HIPPOCAMPAL NEURONS. D. L. Needels. M.E. McGuire, S.B. Roberts. K.M. Ingalls, and J.P. Hammang. Cell and Molecular Neurobiology, Bristol-Myers Squibb, Wallingford, CT 06492.

Neurotrophin-3 (NT-3) is a member of the neurotrophic

Neurotrophin-3 (NT-3) is a member of the neurotrophic factor family that also includes nerve growth factor (NGF) and brain derived neurotrophic factor (BDNF). We report here the effects of NT-3 on neuronal survival and neurite outgrowth in dissociated hippocampal cultures.

Dissociated E18 rat hippocampal cells were seeded in a defined serum free medium under one of three conditions: without growth factor, with 20 ng/ml of recombinant NT-3 (purified from a baculovirus expression system) or with 50 ng/ml NGF. After 2-7 days in culture, neuronal survival was assessed by counting process-bearing cells expressing either neurofilament-L or neurofilament-M by immunocytochemistry.

In these short term cultures, only a small percentage of cells with a neuronal morphology displayed unambiguous neurofilament protein immunoreactivity. NT-3 (but not NGF) resulted in a 2- to 5- fold increase in the number of neurofilament-M labeled cells. There was also a concomitant increase in both the extent and complexity of neuritic outgrowth. Neurofilament-positive cells did not show the intense nuclear labeling characteristic of dividing cells for up to 6 days following a pulse of <sup>3</sup>H-thymidine. Thus, NT-3 was found to display neurotrophic activity for hippocampal neurons, as assessed by increased survival and differentiation of neurofilament-positive cells.

NEUROTROPHIN-4 (NT-4) INCREASES THE NUMBER OF POSTNATAL CHOLINERGIC BASAL FOREBRAIN NEURONS IN CULTURE. M. Yokoyama\*, L.D. Cain, W.J. Friedman, I.B. Black, & C.F. Dreyfus, Dept. Neuroscience & Cell Biology, Robert Wood Johnson Medical School, UMDNJ, Piscataway, NJ 08854.

Previous work in our laboratory has demonstrated that nerve growth factor (NGF) and related trophic factors affect embryonic day 17 (E17) basal forebrain (bf) cholinergic neurons. To define the role of these agents on postnatal bf cholinergic neurons, we established bf cultures from older rats (postnatal day 1: P1). E17 bf served as control. Cholinergic neurons were studied by acetylcholinesterase staining (AChE) and CAT activity. With time in culture, the number of cholinergic neurons in E17 and P1 cultures decreased. This loss was most dramatic in P1 cultures. To determine whether NGF can elicit an increase in postnatal cholinergic cell number, we grew E17 and P1 cultures in the presence of NGF, which increased CAT activity, but did not affect the number of cholinergic neurons surving in either. In contrast to the lack of effect of NGF on cholinergic neuronal number, NT-4, a related neurotrophin produced in transfected COS cells, elicited a significant 5-7-fold increase in the number of cholinergic neurons in cultures grown in COS cell medium. These data indicate the selectivity of distinct trophic molecules in the regulation of survival. Supported by NIH grant HD23315 and NS10259.

BDNF INCREASES TH-IMMUNOREACTIVITY IN HUMAN FETAL VENTRAL MESENCEPHALIC NEURONS IN AN ORGANOTYPIC CULTURE. C.Spenger', I.Stromberg\*, L.Studer and R.Seiler. Dept. of Neurosurgery, Inselspital, CH-3010 Bern Switzerland; Dept. of Histology and Neurobiology, Karolinska Institute. S-10401 Stockholm, Sweden\*.

There is evidence that BDNF has trophic actions on rat dopaminergic neurons in vitro (Hyman et al., 1991). Here we have studied the effects of BDNF on human fetal ventral mesencephalic tissue in an organotypic culture. The tissue was grown by the roller tube method for 12 to 31 days. The number of TH positive cells in cultures grown with 10 ng/ml BDNF was compared with that of cultures grown without BDNF. In cultures grown for 21 days with BDNF 11.1  $\pm$  9.5 TH positive cells per 16000  $\mu$ m<sup>2</sup> (n = 70) and in cultures grown for 21 days without BDNF 2.3  $\pm$  2.6 TH positive cells per 16000  $\mu$ m<sup>2</sup> (n = 45) (p<0.001) were counted. The immunoreactivity of the pericaryon of the neurons of these cultures was measured by an image analysis system. Cells grown with BDNF showed a significantly (p < 0.001) higher TH-immunoreactivity compared with that of cells grown without BDNF. These results demonstrate a trophic action of BDNF on human fetal ventral Supported by: SNF-grant mesencepablic neurons in vitro. No.31-32561.91 and the Swiss Parkinson Foundation. BDNF was kindly supplied by Regeneron Inc, NY.

TROPHIC EFFECTS OF NT-3 ON ASTROCYTES IN MIXED CELL CULTURES FROM FETAL RAT HIPPOCAMPUS. M.E. McGuire\*, D.L. Needels, S.B. Roberts, K.M. Ingalls and J.P. Hammang. Cell and Molecular Neurobiology, Bristol-Myers Squibb, Wallingford, CT 06492.

Neurotrophic factors have been shown to promote cell survival, differentiation and proliferation in a variety of cell types. We report here the effects of two structurally related neurotrophic factors, NT-3 and NGF, on glial cell proliferation in dissociated rat E18 hippocampal cultures.

Dissociated fetal rat hippocampal cells were seeded in a defined serum free media under one of three conditions:

Dissociated fetal rat hippocampal cells were seeded in a defined serum free media under one of three conditions: without growth factor, with 20 ng/ml of recombinant NT-3 (purified from a baculovirus expression system) or with 50 ng/ml NGF. An overnight pulse of 1 µCi/ml <sup>3</sup>H-thymidine was added to the cultures either 2 or 24 hours after plating. Cultures were fixed after 2, 4 and 7 days, then labeled with antibodies against glial fibrillary acidic protein (GFAP) and prepared for autoradiography.

Virtually all <sup>3</sup>H-thymidine incorporating cells also expressed GFAP, independent of growth factor treatment. In the NT-3 treated cultures the total number of double labeled cells increased 2 to 5-fold over control depending upon days

Virtually all <sup>3</sup>H-thymidine incorporating cells also expressed GFAP, independent of growth factor treatment. In the NT-3 treated cultures the total number of double labeled cells increased 2- to 5-fold over control, depending upon days in culture and length of exposure to NT-3. NGF treated cultures did not differ significantly from control. These results suggest that NT-3 may play a unique role in the proliferation and/or differentiation of hippocampal astrocytes.

THE NEUROTROPHINS BDNF AND NT-3 RAPIDLY STIMULATE THE PHOSPHORYLATION OF PHOSPHOLIPASE-Cy1 IN CORTICAL CULTURES BY THE the PROTONCOGENE PRODUCT ASSOCIATED KINASE. Hans R. Widmer\*. \*David R. Kaplan, Beat Knusel, Klaus D. Beck, and Franz Hefti, Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089 and \*NCI-Cancer Research and Developmental Center, Frederik, MD 21701

Phospholipase-Cy1 (PLC) is involved at an early step in signal transduction of many hormones and growth factors. PLC catalyzed hydrolysis of phosphatidyl 4,5 bisphosphate (Pl) produces two potent intracellular second messengers molecules. We recently reported that the neurotrophins BDNF and NT-3 stimulate Plhydrolysis in primary cell cultures of fetal brain neurons. We now present evidence that BDNF and NT-3 stimulate the phosphorylation of PLC by activating rk-type protein kinase receptors in these cultures. The stimulation was very rapid i.e. within 20 seconds after addition of the neurotrophins. The effect lasted up to 30 min with a peak after 4 min. ED<sub>50</sub> values were similar for BDNF and NT-3 with 25-50 ng/ml. As earlier shown for Pl hydrolysis, phosphorylation of PLC by neurotrophins was found in cultures from all major brain areas. K-252b which has been shown to block the neurotrophin actions by inhibiting th-type receptor proteins prevented the BDNF and NT-3 stimulated phosphorylation of PLC. The presence of th/B mRNA in our culture systems was substantiated by northern blot analysis. The action of BDNF and NT-3 seems to be neuron specific since no phosphorylation was observed in preparations from non-neuronal cultures. The results suggests that the BDNF and NT-3 dependent increase in Pl hydrolysis in primary cell cultures from rat brain is due to selective phosphorylation of PLC by the the receptor protein and that cortical neurons are functionally responsive to BDNF and NT-3 during early development.

BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) PREVENTS FUNCTIONAL SENSORY LOSS FOLLOWING CAPSAICIN TREATMENT IN MICE. L. M. Liu\*. L. B. Fu. V. Wong. R. F. Alderson, P. S. DiStefano, S. J. Wiegand, R. M. Lindsay. Regeneron Pharmaceuticals, 777 Old Saw Mill River Road, Tarrytown, NY 10591.

The excitotoxin capsaicin selectively damages most of the small and some medium sized primary sensory fibers that are involved in the response to noxious stimuli. The neurotrophin, BDNF, has been shown both *in vitro* and *in vivo* to protect survival of dorsal root ganglion sensory neurons. In seeking to develop an animal model for small fiber sensory neuropathy, we have examined the effects of BDNF in protecting or restoring sensory functions following capsaicin treatment *in vivo*. The degree of capsaicin neurotoxicity can be conveniently measured by testing the thermal nociceptive response in experimental animals, using tall flick latency ets. Adult CD 1 female mice were injected with 3 doses of capsaicin over a 2 day period. Prior to and on day 12 post capsaicin treatment, tail flick latency was recorded in anesthetized mice to the nearest 0.1 second. Tail flick latency in normal animals was about 4 seconds. After capsaicin treatment (85 mg/kg), it was increased by 3-fold or greater. A cut off time of 15 seconds was used to prevent injury. Treating animals with BDNF was found to improve the tail flick response in a dose dependent manner. When injected daily at 10 mg/kg s.c. for 12 days, BDNF was found to totally restore tail flick latency to normal levels. Doses of 5 mg/kg or 1 mg/kg had significant but smaller effects. BDNF is effective when administered before or during, but not after the capsaicin treatment. We conclude that BDNF can prevent/reduce the functional sensory loss from capsaicin insults in mice.

## 106.19

REGULATION OF BRAIN-DERIVED NEUROTROPHIC FACTOR mRNA AND PROTEIN AT THE CELLULAR LEVEL IN PENTYLENETETRAZOL-INDUCED EPILEPTIC SEIZURES. <u>C. Humpel\*, C. Wetmore and L. QIson.</u> Dep.Histology and Neurobiology, Karolinska Institute, POB60400, S-10401 Stockholm, Sweden
Brain-derived neurotrophic factor (BDNF) mRNA has been

Brain-derived neurotrophic factor (BDNF) mRNA has been reported to increase in the hippocampal formation and in some other brain areas after seizures induced by lesions, electrical kindling or kainic acid injection. Pentylenetetrazol (PTZ) acts at the picrotoxin site of the GABAA receptor and induces seizures by decreasing the inhibitory activity. The effects of a single acute convulsive dose (50 mg/kg) of PTZ on BDNF mRNA and protein were analyzed at different time points by in situ hybridization or immunohistochemistry, respectively. Kindling was induced by daily subconvulsive injections (30 mg/kg) of PTZ. At different time points during the kindling process, BDNF mRNA and BDNF protein were measured. We show that BDNF mRNA is dramatically increased in the dentate gyrus, piriform cortex and amygdala 3h but not 6h after an acute high dose of PTZ, while BDNF protein levels are decreased in dentate gyrus and hilar region. In fully kindled rats, BDNF mRNA is slightly increased in the hippocampal formation 3h after the last PTZ injection, and still increased after 10 days. These changes suggest that BDNF may be involved in protection mechanisms after damage during seizures and in sprouting responses.

AGE-RELATED CHANGES IN EXPRESSION OF NEUROTROPHINS AND TRKS IN THE SENESCENCE-ACCELERATED MOUSE (SAM P/8). H. S. Phillips, M. P. Armanini, G. R. Laramee, J. W. Winslow, J. F. Flood, J. E. Morley, & R. Strong, Dept. of Neuroscience, Genentech, S.S.F., CA 94080 and Dept. of Internal Medicine., St. Louis U. School. of Med. & VA Med. Ctr., GRECC, St. Louis MO 63125.

SAM P/8 mice display early onset changes in learning and memory (Yagi et al, 1988; Flood et al, 1992). Recent obsevtions of an age-related decline in hippocampal ChAT activity (Strong, et al these proceedings) led us to examine the distribution of mRNA for neurotrophins and their receptors in the septo-hippocampal system of these animals. In situ hybridization was employed to examine age-related changes in expression of mRNAs for the neurotrophins NGF, BDNF, and NT3 and for the receptors trkA, trkB, and trkC in basal forebrain and hippocampus of SAM P/8 mice. Optical density readings from sheet film autoradiographs and visual inspection of emulsion autoradiography revealed no age-related changes in expression of NGF, BDNF, or NT3 in the hippocampal formation of SAM P/8 animals. TrkA expressing cells were observed in the medial septum, diagonal band, nucleus basalis, and striatum. Visual inspection of emulsion autoradiographs from young (4 month) and old (12 month) SAM P8 and R1 animals revealed no substantial differences in number of trkA expressing cells in medial septum and diagonal band between any of the groups. Trk B expression was examined in the hippocampus and found to exhibit age-related changes in the P/8 animals that were not apparent in the R/1 controls. These findings raise the possibility that BDNF receptor function may be altered in the SAM P/8 mouse.

COMPARISON OF TRK C mRNA EXPRESSION WITH NT-3 RECEPTOR BINDING AUTORADIOGRAPHY IN BRAIN J.W. Winslow\*, M.P. Armanini, G.R. Laramee, H.S. Phillips, A. Shih, Dept. of Neuroscience, Genentech, Inc. South San Francisco, CA. 94080.

Significant levels of specific [125-I]NT3 binding sites have been observed by receptor binding autoradiography in neocortex, hippocampus, and cerebellar granule cell layer of 1 month old rat brain. To gain further insight into the cellular localization of NT3 receptors in the brain, in situ mRNA hybridization of trkC, a putative NT3 receptor, was compared with [125-I]NT3 binding in 1 month old rat brain. In situ hybridization was performed with a 600 bp antisense riboprobe encoding a portion of the mouse trk C extracellular domain sharing minimal homology with other trk genes. Prominent trkC hybridization was observed within hippocampal pyramidal and granule neurons, neuronal layers of neocortex, and the granule cell layer of cerebellum. Although the pattern and resolution of [125-I]NT3 binding does not allow absolute cellular assignments, the autoradiographic distribution of NT3 binding sites is consistent with the trkC expression pattern within these regions. In particular, the significant [125-I]NT3 binding within the molecular, oriens, and radiatum layers of the hippocampal pyramidal neurons, and the molecular layer of dentate gyrus granule neurons, may partly result from binding to trkC receptors on dendrites of these neurons. Additional sites of trkC mRNA expression will be compared to the distribution of NT3 binding within other brain regions.

# 107.2

DISTRIBUTION OF TRKB TYROSINE KINASE IMMUNO-REACTIVITY IN THE RAT CENTRAL NERVOUS SYSTEM. R.A. Rush\*, X-F. Zhou, L. Parada. Centre for Neuroscience, 1

R.A. Rush\*, X-F. Zhou, L. Parada. Centre for Neuroscience, Flinders University, Adelaide, South Australia, 5042 and Molecular Embryology, NCL-FCRF, Frederick, MD 21701

Recent evidence suggests that TrkB tyrosine kinase is a high affinity receptor for brain-derived neurotrophic factor (BDNF). BDNF can act as a survival factor for several neuronal subgroups and its mRNA is distributed widely throughout the central nervous system. However, the functional targets of BDNF are poorly defined. We have used immunochemical and immunohistochemical techniques to determine the regional distribution and cellular localization of TrkB tyrosine kinase-like immunoreactivity. The staining pattern indicates that the TrkB-like antigen is widely distributed and present within both glia and neurons. Astrocytes were the most intensively labelled but many neuronal populations were also detected. In some regions including the brain stem, spinal cord, hippocampus, and diagonal band of the Broca, neurons were stained with varying intensities. In other areas such as the cortex of the forebrain and amygdaloid nucleus the stain was intense but diffuse preventing positive identification of the cell types involved. Immunoblot results indicated two bands, in all the brain and spinal cord regions examined, of molecular weights 145 and 85 kDa respectively. These findings aid the definition of neuronal and glial subpopulations of the central nervous system that utilise BDNF.

DEVELOPMENTAL REGULATION OF NEUROTROPHIC FACTOR RECEPTORS IN THE MAMMALIAN VISUAL SYSTEM K.L. Allendoerfer\*, R.J. Cabelli, E. Escandon#, K. Nikolics#, and C.J. Shatz. Dept. of Molecular and Cell Biology. U.C. Berkeley. CA 94720 and #Genentech Inc., S.S.F., CA 94080.

Cabelli, E. Escandon#, K. Nikolics#, and C.J. Shatz. Dept. of Molecular and Cell Biology, U.C. Berkeley, CA 94720 and #Genentech Inc., S.S.F., CA 94080.

The development of specific patterns of connections in the CNS is characterized by the selective loss of neurons and by remodelling of axonal projections. To address the possibility that neurotrophic factor may play a critical role in these events, we have begun to identify the neurotrophic factor receptors that are present in the ferret visual system using EDAC-mediated cross-linking of iodinated BDNF and NT-3 to their receptors (Escandon et al., Soc. Neuro. Abs. 1991, 362.4). Bands corresponding to BDNF cross-linked to p75, to a truncated form of trkB that lacks the tyrosine kinase domain, and to a molecule that most likely is full-length trkB have been positively identified by immunoprecipitation and competition analysis. At the earliest developmental age examined (E30), the ratio of full-length to truncated trkB is >>1 in the retinal target tissues, lateral geniculate nucleus (LGN) and superior colliculus (SC). During the ensuing period of retinal ganglion cell death and segregation into eye-specific layers, the amount of truncated trkB increases markedly relative to full-length trkB. By P27 truncated trkB is the predominant receptor for BDNF in the retinal target tissues and this pattern is maintained into adulthood. In visual cortex, a similar profile of bands is observed, but the developmental increase in abundance of truncated trkB relative to full-length cours later, with the major increase between P27 and P50. This delay correlates with the later maturation of connections and onset of cell death in the cortex. Using iodinated NT-3, a band most likely corresponding to full-length trkC was observed in cortex, LGN, and SC at all developmental ages studied. We have also observed or cost-linking of neurotrophic factors to p75 within the retina and to a lesser extent within the other tissues. These data demonstrate that receptors for BDNF and NT-3 are pres

NT3 AND trkB mRNA EXPRESSION IN THE DEVELOPING RAT BRAIN FOLLOWING KAINIC ACID-INDUCED SEIZURES F. Ohsawa\*, R. W. Rodgers, K. D. Beck, F. Hefti, and M. M. Dugich-Djordjevic, Andrus Gerontology Center, University of Southern California, Los Angeles, CA

We have previously reported that increases in BDNF mRNA expression in the rat brain following kainic acid-induced seizures is developmentally dependent, with the onset of stimulus-transcription coupling in response to seizure occuring after P13 (Dugich-Djordjevic et al., Neuron, 1992, in press). In the present study we used Northern blot and in situ hybridization analyses to investigate the expression of NT3 and rkB mRNAs during development and following kainic acid-induced seizure activity. TrkB expression was evaluated with probes specific for (1) the full receptor with the tyrosine kinase domain (trkB) and (2) the truncated receptor lacking the intracellular protein kinase domain (trkB) (-)) keep conditions of trkB and trkB (-) were similar. From P4 to P13, high levels of trkB and trkB (-) mRNA expression were evident in cortex and dorsal thalamic nuclei, subiculum, CA1 and CA3, with low levels in DG. From P13 to adult, cortical and thalamic levels were decreased, while hippocampal levels were slightly increased. Following KA-induced seizure activity NT3 mRNA expression in the hippocampus was decreased after P17. TrkB and trkB (-) mRNA expression was increased in hippocampal subregions from P17 to adult; however, the time course and localization of the increases in response to seizure activity differed among the full length and truncated trkB receptors.

These data indicate that, similar to BDNF, the regulation of NT3 and trkB mRNA expression in response to seizure activity is developmentally dependent.

These data indicate that, similar to BDNF, the regulation of NT3 and trkB mRNA expression in response to seizure activity is developmentally dependent. However, the onset of stimulus-transcription coupling for NT3 and trkB mRNAs is observed at a later stage of development compared to the onset of changes in BDNF mRNA following seizure. The delayed developmental onset of transcriptional regulation of trkB mRNA compared to BDNF mRNA following seizure activation and the differential time course and distribution of trkB mRNA expression following seizure activity suggests that the regulation of neurotrophin receptor transcription differs from that of their neurotrophin ligand.

DIFFERENT TRK B TRANSCRIPTS IN THE RAT RETINA AND OPTIC NERVE. T.N. Jelsma, M. Berkelaar, G.M. Bray, and A.J. Aquayo\*. McGill University Centre for Research in Neuroscience, Montreal General Hospital Research Institute, 1650 Cedar Avenue, Montreal, Quebec, H3G 1A4.

We have investigated the expression of the neurotrophin receptor *trkB* in the retina and optic nerve of adult and developing rats.

In adult and newborn (P1) rats, Northern analysis of total brain RNA showed two major bands of approximately 8-10 kb hybridising to the full length trkB probe (provided by Regeneron). The upper band alone was observed in the retinal RNA while the RNA obtained from adult optic nerves showed only the lower band. The origin of this band was also investigated in cultured astrocytes where again only the lower band was detected. Furthermore, a probe specific for the internal tyrosine kinase domain of trkB hybridised only to the upper band in brain RNA and to neither band in optic nerve RNA.

In situ hybridisation of adult retina with probes corresponding to extracellular and intracellular portions of trkB gave the strongest signal in the photoreceptor layer.

In summary, while *trkB* transcripts are expressed in both the retina and optic nerve, different forms are produced in these two regions of the CNS. The *trkB* transcript found in the retina, expressed primarily in the photoreceptor layer, contains the internal tyrosine kinase domain, while that expressed in the optic nerve and cultured astrocytes lacks this domain.

## 107.6

Urine levels of NGF Receptor-truncated are Elevated in Diabetic Neuropathy. R.E. Hruska\*, M.M. Chertack, and D. Kravis. Dept. 90J, Abbott Labs, Abbott Park, IL and 64 Old Orchard Rd., Skokie, IL.

NGF receptor-truncated (NGFR-t) is the cleaved extracellular portion of NGFR and contains the NGF binding domain. NGFR-t is present in the urine and (corrected for creatinine) is elevated in infants, in patients with ALS, and in an animal model with a sciatic nerve lesion. In order to reproducibly measure NGFR-t, a two-site EIA was developed with sensitivity of < 5 ng/ml and capacity of at least 800 ng/ml. In multiple studies, the variation between analyses was less than 10%. Reagents, including the recombinant standard, were stable in the appropriate matrix for at least 30 days at 5°C. For accuracy, urine specimens were pH normalized with a 0.15 M phosphate buffer. Urine creatinine levels were quantitated on the TDx analyzer. Using these methods, the level of NGFR-t (ng/ $\mu$ g creatinine) in normals is 0.085  $\pm$  0.022 (mean  $\pm$ SD, N=45), in diabetics is  $0.105 \pm 0.034$  (N=63), and in diabetics with neuropathy is 0.144  $\pm$  0.046 (N=98). These results show a significant elevation of NGFR-t (P < 0.001) in patients with neuropathy, 66% having levels more than 2-SD above the mean of normals. Proteinuria, as measured by microalbumin, does not alter these results. These changes were found in males and females and in Type I and Type II diabetics. Interestingly, a few females over the age of 60 and with Type II diabetes also have elevated levels. NGFR-t is easily measured in urine specimens, is stable under normal storage conditions, and is elevated in patients with diabetic neuropathy. The elevation in NGFR-t urine levels could be associated with increased neuronal damage and neurotrophic factor turnover. In conclusion, measurement of NGFR-t provides an independent assessment of a biochemical change associated with neuropathy.

MORPHOMETRY REVEALS MARKED RECOVERY OF RAT BRAIN HIPPOCAMPUS AND DENTATE GYRUS FROM EARLY HYPOTHYROID GROWTH RETARDATION. <u>Arash Farahvar and Esmail Meisami</u>\*, Physiology Dept., Univ. of Illinois, Urbana, IL 61801.

Early thyroid deficiency causes major retardation in brain growth, behavior and learning ability. Less is known about the capacity of the brain to recover from this cretinoid retardation. Growth of hippocampus (HC) and dentate gyrus (DG) of the rat brain was used as a model system. Sprague-Dawley rats were made hypothyroid by administration of the reversible goitrogen PTU (propylthiouracil, 0.1% w/v) from birth. Some of the hypothyroid rats were allowed to recover by withdrawal of PTU at 25d (weaning). Control, hypothyroid and recovery rats were compared for surface area and volume of HC and DG at 25d & 90d postnatal. At 25d, DG measures in hypothyroid rats were significantly less than normal (surface area 16%, volume 23%, p<0.01). The retarding effects on HC were less severe. In normal rats, between 25d & 90d, surface area and volume of DG increased by 37% & 51%, reaching mean values of 24.5 mm<sup>2</sup> & 14.2 mm<sup>3</sup>; in HC, surface area and volume increased by 44% & 35%, reaching mean values of 42.9 mm<sup>2</sup> & 23.5 mm<sup>3</sup>. In the 90d hypothyroid rats, growth was retarded, resulting in mean values that were significantly (20-30%) below normal. In contrast, the growth of DG & HC in recovery rats was more robust than normal, compensating for the earlier hypothyroid deficits, so that by 90d the mean values of normal and recovery rats were not significantly different. Supported by University of Illinois Research Funds.

OUABAIN INHIBITION OF ADULT HYPOTHYROID MOUSE BRAIN Na,K-ATPase. J.M. Bertoni\* and P.M. Sprenkle. Neurology Department, Creighton University, Omaha, NE 68131.

Na,K-ATPase activity is regionally reduced in the brain of the adult genetically hypothyroid mouse hyt/hyt. These local reductions in enzyme activity may be accompanied by altered ratios of Na,K-ATPase isoforms. Since Na,K-ATPase isoforms show characteristic affinities for binding by ouabain, we examined the effects of ouabain on K-pNPPase activity (a partial reaction of Na,K-ATPase) in subcortical and hindbrain homogenates from hyt/hyt (hypothyroid) and hyt/+ (euthyroid) mice. K-pNPPase activity (V<sub>max</sub>) was only slightly depressed in hyt/hyt hindbrain relative to hyt/+ controls  $(175\pm3.68$  and 188+1.63 nmol/mg/min, respectively), while subcortical KpNPPase activity was 28% lower (p<0.001) in hyt/hyt mice (108+11.1 vs 150+6.74 nmol/mg/min). Both hindbrain and subcortical data were best fit to one-site, rather than two-site, ouabain binding models with no significant differences in hyt/hyt vs hyt/+ Ki's. This suggestion of single-site ouabain binding models for both thyroid hormone-sensitive and insensitive brain regions does not support the hypothesis that reductions in Na,K-ATPase activity are related to altered isoform ratios in the hypothyroid state.

THE DISTRIBUTION OF THYROID HORMONE RECEPTOR MRNAS IN THE CNS OF *XENOPUS LAEVIS* DURING METAMORPHOSIS. <u>M.S. Beattie\*¶\$</u>
<u>J.C. Bresnahan\*</u> and <u>J.N. Masters</u> Department of Cell Biology, Neurobiology and Anatomy, § Division of Neurosurgery, ♦ Ohio State Biotechnology Center, The Ohio State University, Columbus, OH 43210

The metamorphosis from larval to juvenile form in anuran amphibians encompasses a radical transformation from swimming to quadrupedal locomotion and includes the addition and innervation of limb musculature, additions and deletions of central neuronal elements and connections, and tail resorption. This process is dependent on thyroid hormones (TH) which rise dramatically during metamorphic climax and fall to very low levels immediately after metamorphosis. The alpha and beta forms of the Xenopus thyroid hormone receptor (TR) mRNAs have been recently shown to be independently regulated during development (Yaiota et al., Genes Dev. 4:1917 (1990), Kawahara et al., Development 112:933 (1991)). The TRa transcript is present relatively early in development while TRβ expression correlates with metamorphosis. Thus we hypothesize that TRa may mediate generative processes while TRβ mediates the degenerative components during Xenopus development. As a test of this hypothesis, we used in situ hybridization with probes specific for the TRa and TRβ mRNA (provided by D. Brown) to localize expression of the receptor subtypes during Xenopus development. The TRa mRNA is easily observed by in situ hybridization and is expressed in highest amounts in the developing central nervous system. Its expression in the brain or spinal cord follows the relative abundance previously reported by others using isolated RNA measurements; namely a peak at stage 58 which declines rapidly by stage 62. We were not able to localize expression of the TRβ mRNA in any of the developing frogs, in agreement with others. This result most probably reflects the detection limits of in situ hybridization with relatively rare transcripts. (NS10165)

Effects of Adrenalectomy on the Dentate Gyrus of Rats and Hamsters in Both Sexes. D. Leone, C.D. Condon, V. Doppalapudi, and E.J. Roy\*. Neuroscience Program & Dept. Psychology, Univ. of Illinois, Champaign, IL 61820.

Adrenalectomy (ADX) has been shown to cause specific degeneration in the hippocampus of male rats. Given that progesterone can bind to corticosteroid receptors in the hippocampus, we determined whether females show degeneration similar to males. We also determined whether a species that differs from rats in its primary glucocorticoid and in characteristics of corticoid receptors would show the same degeneration. We therefore quantified the volume of the dentate gyrus of rats and hamsters in both sexes using stereological estimates.

Long-Evans rats and Syrian hamsters were approximately 10 weeks old at the time of the ADX/SHAM operation. Rats and hamsters were sacrificed 6 and 12 weeks after ADX respectively. Both female and male ADX rats showed significant reduction (p<0.001) in volume of the ventral and dorsal blades of the dentate gyrus. These results are the first to show that female rats are susceptible to ADX-induced degeneration in the dentate gyrus. The hamster dentate gyrus results were complex, with sex differences and regional differences in the effects of ADX. Supported by MH18412 and Univ. of Illinois Neuroscience Prog.

HYDROCORTISONE (HC) INCREASES DYSTROPHIN IMMUNO-REACTIVITY AND CAUSES DYSTROPHIN AGGREGATION IN ANEUR-ALLY CULTURED HUMAN MUSCLE. J McFerrin, V Askanas\* and WK Engel. USC Neuromuscular Center, Los Angeles, CA 90017-1969.

The glucocorticoid (GC) prednisone is widely used as an immunosuppressant for treating myasthenia gravis and polymyositis. Recently, its beneficial effect in Duchenne muscular dystrophy (DMD) has been reported. Nevertheless, a direct influence of GC on NMJs and on muscle fibers themselves is not established. In aneurally cultured human muscle, GCs increase the number of non-junctional acetylcholine receptors (AChRs) and the number and size of AChR clusters (Askanas et al., 1986); and in innervated cultured human muscle, GCs increase accumulation of junctional-AChRs (Braun et al., 1991). We have now studied the influence of HC on dystrophin immunoreactivity (Dys-IR), using a mono clonal antibody against the C-terminus region of dystrophin. (Novocastra). In seven experiments, each from a different patient's biopsy, treatment with 20 uM HC, a GC, was initiated on 8-day-old aneurally cultured normal human muscle and was continued for 2,3 and 4 weeks. In both HCtreated cultures and controls, Dys-IR was increased in more mature cultures and it had a more distinct sarcolemmal localization. In the HCtreated muscle, Dys-IR was quantitatively increased on immunoblot. In contrast to the uniform distribution of Dys-IR in cultured control muscle, in all experiments (evaluated blind), 80% of the HC-treated muscle fibers contained large patchy aggregates of strikingly increased Dys-IR. Our study demonstrates that in addition to AChRs, treatment with GC influences Dys and perhaps other proteins of human muscle plasmalemma.

5HT<sub>3</sub> RECEPTOR MEDIATION OF TRH INDUCED INCREASES IN INTESTINAL TRANSIT IN DEVELOPING RATS. <u>M. Heitkemper, E. Bond, K. Gruver, and A. Horita\*</u>. Departments of Nursing and Pharmacology, Univ. of Washington, Seattle, WA 98195.

Intracisternal (Ic) injection of thyrotropin releasing hormone (TRH) increases gastric contractile activity and small intestinal transit. Both responses are mediated primarily by a vagal cholinergic mechanism. However, the 5HT3 antagonist MDL-72222 blocked TRH induced increases in gastric motility in young (<14 day [D]) but not older rats, suggesting a serotonergic component is involved early in development. Serotonergic contribution to TRH stimulation of intestinal transit is not described. This study examined the effects of 5HT2 antagonists (ketanserin, xylamidine) and 5HT3 antagonists (MDL-72222, ICS 205-930) on TRH stimulated transit of a charcoal bolus in rats 7, 10, 14 and  $\geq$ 50D. Rats were anesthetized with urethane (1.25mg/kg). One of the following agents was administered intraperitoneal: ICS 205-930 (1mg/kg), MDL-72222 (1mg/kg), ketanserin (5mg/kg), xylamidine (10mg/kg). A midline incision was made, the gastroduodenal junction identified and 50µl (7 and 10D), 100µl (14D) or 200µl (adult) of a 20% charcoal in saline solution injected into the duodenum. At 25 min post charcoal instillation, TRH (15µg) in saline or saline alone was administered via ic injection (0.6µl). Two hrs post TRH/saline injection transit (distance travelled by charcoal expressed as a percentage of total small intestinal length) was measured. ICS 205-930 effectively blocked TRH induced intestinal transit in all age groups while MDL-72222 blocked in 7 and 10D rats. 5HT2 antagonists did not block TRH induced transit in 7D but did in older rats. These results suggest that while serotonin may mediate TRH induced transit increases, receptor expression is dynamic during development. (Supported by K07 NR00007)

BRIEF ASPHYXIA DURING BIRTH PRODUCES PERMANENT CHANGES IN STRESS-INDUCED GLUCOCORTICOID SECRETION. W. Brooks \*, K. Betito, S. Bhatnagar, M.J. Meaney and P. Boksa, McGill University, Dept. of Psychiatry, Douglas Hospital Research Centre, Montreal, Quebec, Canada, H4H 1R3.

Little is known about the specific long-term functional consequences, to the CNS, of periods of asphyxia during the birth process. Morphological studies indicate that the hippocampus is particularly vulnerable to damage resulting from perinatal asphyxia. The hippocampus plays an important role in feedback regulation of glucocorticoid (GC) secretion in response to stress. Thus the current study examined consequences of brief asphyxia during birth on subsequent regulation of GC secretion in the adult rat. Birth asphyxia was produced as described by Bjelke et al (Brain Res., 1991, 543, 1); in this model the entire uterus was removed on the day of birth and immersed in a water bath for 10-20 min before delivery. Control animals were either born vaginally or delivered by Caesarian section without delay. At 3 months of age, asphytic and control rats underwent 20 min of restraint stress and corticosterone was measured in tail vein samples taken before and after the stressor. Adult rats exposed to a period of asphyxia during birth exhibited a prolonged hypersecretion of corticosterone following termination of the acute stressor. Alterations (hypersecretion) in the diurnal pattern of basal corticosterone levels were also observed in adults exposed to perinatal asphyxia. Long-term exposure to elevated GC levels has been previously associated with neuronal damage in a number of paradigms. It is possible that the permanent alterations in GC secretion we observed in asphytic animals may contribute to the production of long-term CNS damage following a brief period of asphyxia during birth.

PRENATAL STRESS REDUCES T-LYMPHOCYTE
PROLIFERATION IN RATS. M. Flory, S. Klein &
C.H. Kinsley Dept. of Psych., Univ. of
Richmond, VA 23173 and Randolph-Macon College,
Ashland, VA, 23005.
Both sexual differentiation and immune system

Both sexual differentiation and immune system development occur largely prenatally. Prenatal stress (PS) disrupts the former, and we have begun to investigate its effects on the latter, process. Adult offspring from mothers stressed on days 15-22 of pregnancy (thrice-daily exposures to heat, light and restaint) were stressed for 60-min in a restraint tube. One ml trunk blood samples were obtained and all subclasses of IgG T-lymphocytes were extracted through affinity chromatography with immunologically-coated, magnetic beads (Dynabeads, Inc.) and visually quantified. PS animals displayed a marked and significant decrease in the number of T-lymphocytes, relative to controls (1.7 x 106 v. 4.0 x 106, respectively). These data, in combination with our work on thymus and on skin graft transplantation immunity, suggest that PS reduces the integrity and effectiveness of the immune system. Prenatal events, therefore, may be considered a significant force in shaping the immune system. (Supported by UR research funds.)

THE COMPARISON OF ANGIOTENSIN LEVELS IN THE BRAINS OF SHR AND WKY RATS DURING PERINATAL DEVELOPMENT. V.I. Cook.\* V. Puig. D. Lu and M.I. Phillips. Dept. of Physiology, Univ. of Florida, Gainesville, FL 32610.

Our previous work has shown that during perinatal development SHR and WKY rats exhibit some significant differences in the number of antiotensin recenture recontage.

differences in the number of angiotensin receptors and the timing of receptor appearance in specific brain areas. Because the SHR's appear to be on a different developmental schedule than the WKY, as exhibited by angiotensin receptors in the brain, we decided to examine the levels of angiotensin to see if the same developmental differences would be seen.

Utilizing radioimmunoassay (RIA), we determined the levels of angiotensin in the brains of each strain at different perinatal time points. By the 21<sup>st</sup> day of gestation, SHR's already show significantly more brain angiotensin than WKY rats (227.7±14.68, 125.8±37.5 pg/g of tissue), respectively. By the 5<sup>th</sup> postnatal day, the difference is even greater (SHR = 323.3±69.1 pg/g tissue and WKY rats = 162.5±22.6 pg/g tissue).

These data support the idea that abnormalities of the reninality of the state of development.

angiotensin system, as early as the fetal stage of development, may be associated with subsequent hypertension.

THE DEVELOPMENT OF POTASSIUM CURRENTS IN CULTURED INSECT OLFACTORY NEURONS. J.H. Hayashi\* L.A. Oland. and J.G. Hildebrand. ARL Div. of Neurobiology, Univ. of AZ., Tucson, AZ, 85721. During metamorphic adult development in Manduca sexta neurons in the developing antennal lobe undergo extensive process outgrowth and are During metamorphic adult development in Manduca sexta neurons in the developing antennal lobe undergo extensive process outgrowth and are contacted by ingrowing sensory axons from the antenna. In addition, the neurons develop in a background of a rapidly rising titer of the steroid hormone 20-hydroxyecdysone (20-HE). To assess the role of sensory input and 20-HE on the biophysical development of antennal lobe neurons, we dissociated neurons from the developing antennal lobe and grew them in primary culture where several types can be identified on the basis of their characteristic morphologies. Neurons were dissociated from antennal lobes at stage 2, when antennal sensory axons have not yet arrived at the lobe, and at stage 5, when the sensory axons have just begun to exert their influence over the morphological development of the lobe. We controlled the titer of 20-HE to mimic either the low (0.2 µg/ml) stage-2 level or the elevated (1µg/ml) stage-5 levels. We used whole-cell patch-clamp technique to study the expression of specific voltage-gated currents in four neuronal types. We found that both morphological cell type and developmental stage affected neuronal responses to 20-HE by altering their level of A-type and delayed rectifier potassium current expression. The responses of the individual neuronal types to a given protocol differed suggesting to us that the response to ecdysone is a specific developmental cue. Finally, we compared the expression of currents in neurons derived from normal stage-5 antennal lobes with those that had developed in vivo in the chronic absence of antennal sensory axons. Within a neuronal type, a history of exposure to ingrowing sensory axons in vivo led to decreased expression in vitro of A-type currents and increased expression of inward or inward or invariant of invariant of invariant or invariant of invariant or invariant of invariant or invariant of invariant or invariant or invariant or invariant or invariant or invariant or invariant or invariant or invariant or invarian

EFFECT OF THE STEROID HORMONE 20-HYDROX YECDYSONE ON THE BRANCHING PATTERNS OF CULTURED NEURONS FROM THE DEVELOPING OLFACTORY LOBE OF THE MOTH. Lynne A. Oland\*, Jon H. Hayashi, and Leslie P. Tolbert. ARL Div. of Neurobiology Arizona, Tucson, 85721.

Artzona, 1ucson, 83/21.

During metamorphic adult development in *Manduca sexta*,
20-hydroxyecdysone (20-HE) titers rise rapidly during the same period in 20-hydroxyecdysone (20-HE) titers rise rapidly during the same period in which the developing antennal lobe (AL) neurons undergo extensive process outgrowth and branching. While patterning of the shape of the arbors has been shown (Tolbert and Oland, 1990) to be dependent upon an interplay among ingrowing antennal sensory axons, AL glia, and the AL neurons, the role of 20-HE on growth has not been examined. Using a well-established culture system, we examined the effect of 20-HE on the number of branches and total neurite length of several morphological types of neurons. Neurons were grown for two weeks in 0.2, 1, or 10 µg 20-HE/ml medium, values that span the physiological range in the blood. Solitary neurons were photographed and their arbors traced on a digitizing pad for subsequent morphometric analysis. In all cases, the pattern of changes in values for number of branches mirrored changes for total length. Among the 6 cell types examined, the response within a stage pattern of changes in values for number of branches mirrored changes for total length. Among the 6 cell types examined, the response within a stage to increasing hormone (increase, decrease, or no response) depended upon the type as well as on the stage of ALs from which the neurons were dissociated. Several types showed significantly greater outgrowth when the neurons had been dissociated from stage-5 ALs, which have begun to receive sensory innervation, compared with those from stage-2 ALs, which have not yet received sensory innervation, compared with those rom stage-2 ALs, which have not yet received sensory innervation. In addition, outgrowth was significantly greater in neurons from stage-5 ALs than in stage-5 ALs that had developed in the chronic absence of sensory axons. Taken together, these results suggest that sensory input promotes neurite outgrowth and branching, but that, where 20-HE has an effect on outgrowth, the polarity of the effect is cell-type specific. [Supported by NS 28495.]

# HORMONES AND DEVELOPMENT. GONADAL HORMONES I

MECHANISMS OF ESTROGEN-INDUCED NEURON ADDITION TO AN AVIAN SONG CONTROL NUCLEUS. M.J. Burek\*, K.W. Nordeen, and E.J. Nordeen. Dept. Psych. and Neurosci. Program, U. of Rochester, Rochester, N.Y. 14627.

In zebra finches, only males sing and most brain regions controlling song contain more neurons in adult males than females. In one region, the higher vocal cente (HVC), neurogenesis extends throughout sexual differentiation and the addition of new neurons is greater in young males than in females. Estradiol (E2) can masculinize (increase) the incorporation of HVC neurons in females and render them capable of male-typical song. Using 3[H]-thymidine autoradiography to label HVC neurons born on days 15 and 16 post-hatch, we established previously that these neurons are sexually dimorphic in number within days after their production, implying that sexual differentiation affects their production or early survival, rather than long-term

To further distinguish between these possibilities, we determined if E2 could increase the incorporation of HVC neurons born before hormone exposure. Females were given 3H-thymidine on days15-16, and on day 17 received either E2-conta or blank subcutaneous silastic implants. On day 35, birds were sacrificed and autoradiograms through HVC were analyzed to determine neuron number and the incidence of thymidine-labeling. Heavily-labeled neurons (HL) had grain densities exceeding one-half the maximum observed and were presumed to have undergone their last division on day 15 or 16 (i.e. <u>before</u> E2 exposure). Lightly-labeled neurons (LL) had grain densities below one-half maximum, but still exceeding 5X background, and were believed to consist mostly of cells born after the thymidine regime, (i.e during E2 exposure). As expected, E2 treatment significantly increased neuron number in HVC. E2 also significantly increased the incidence of LL neurons, but did not affect the proportion of HL cells. Insofar as neurons born during E2 exposure were disproportionately affected by the hormone, our results support the hypothesis that estrogenic regulation of neurogenesis contributes to the sexual differentiation of HVC neuron number.

# 109.2

LACK OF SYNERGISTIC EFFECT OF DIHYDROTESTOSTERONE AND ESTRADIOL ON MASCULINIZATION OF THE SONG SYSTEM OF THE ZERRA FINCH. E.C. Jacobs' and A.P. Arnold. UCLA Brain Research Inst. and Dept. Psychol., Los Angeles, CA 90024-1563.

Previous studies have suggested that both major active metabolites of testosterone, estradiol (E2) and dihydrotestosterone (DHT), are needed for complete masculinization of the brain regions controlling song in passerine birds. However, DHT treatment of hatchling female zebra finches (ZFs) has only small masculinizing effects on the song system.

We examined the effects of DHT given to female ZFs in combination with E2. Female ZFs were given one of the following hormone treatments: 1) E2 at day (D)1; 2) E2 + DHT at D1; 3) E2 at D1 + DHT at D14; 4) E2 at D1 + DHT at D70; 5) no treatment (n=4-6 per group). Control males were untreated. Hormone treatments at D1 consisted of Silastic pellets mixed with 50µg of each steroid. Treatments at D14 or D70 consisted of 5mm Silastic tubes filled with DHT, left in place for 35 days. Each bird was perfused at D105-110 and the brain was sectioned at 30µm and stained with thionin. Volumes of HVC in E2+DHT birds were 114-117% of volumes of E2-alone birds (not statistically significant). Volumes of RA in E2+DHT birds were 69-104% of volumes of E2-alone birds (not statistically significant). Volumes of HVC in E2+DHT birds were 56-64% of male values (not statistically significant), and volumes of RA in E2+DHT birds were 44-67% of male values (some significantly smaller than males). These results suggest that androgens play a relatively minor role in the sexual differentiation of these attributes of

GLIA EXPRESS HIGH LEVELS OF AROMATASE IN CULTURES OF DEVELOPING ZEBRA FINCH TELENCEPHALON. <u>A.P. Arnold\*, S.Amur-Umarjee, A. Campagnoni and B.A. Schlinger.</u> Depts. of Psychology and Psychiatry, BRI, UCLA, Los Angeles, CA 90024.

Conversion of androgen to estrogen (aromatization) in brain regulates effects of circulating androgen on neural development and behavior in males of many vertebrate species. Previous studies indicate that aromatase, the enzyme that catalyzes this conversion, is expressed most abundantly in neurons present in limbic brain regions. Songbirds are unique in that aromatase is expressed at high levels in the telencephalon (TEL) of both males and females. Because estrogens masculinize TEL brain regions that control song, we are interested in whether the brain itself synthesizes the estrogen responsible for masculinizing the song system. Accordingly, we have established primary cultures using TELs from 1-6 day old zebra finches. Immunohistochemical analysis of these cultures 1-3 weeks in vitro indicate the presence of neurons and glia. Aromatase activity (3H-androstenedione conversion to 3H-estrone plus <sup>3</sup>H-estradiol) was abundant in these cultures (up to 6.7 pmoles/min/mg protein). To identify the cell type responsible for aromatization, cultures were treated with the neurotoxin kainic acid (KA, 10<sup>-2</sup> M) for 4-7 days. Although KA reduced neuronal numbers by as much as 90%, it had no effect on aromatase activity. We conclude that aromatase in the TEL of the developing zebra finch is present in non-neuronal elements, probably astrocytes. This unique cellular localization may account for some of the unusual properties of brain aromatase in this species, including the capacity to secrete estrogen into the general circulation of adults. INTRAUTERINE POSITION MODULATES SACCHARIN PREFERENCE IN ADULT MALE MICE. M.E. Bushong and M.A. Mann\*. The University of Texas at Arlington, Arlington, TX 76019. Saccharin preference is a sexually dimorphic trait in

Saccharin preference is a sexually dimorphic trait in rats in that adult females exhibit a greater preference relative to males. To establish a preference profile for adult mice, separate groups of males and females received tap water and one of five concentrations of saccharin solution (either 0.1, 0.25, 0.5, 0.75 or 1.0%). A significantly higher preference score was obtained for females vs. males that received the .25% solution; other concentrations did not yield a reliable sex difference.

To examine if the preference patterns of adult males are organized during prenatal life, mice were delivered by C section to determine their position relative to same— or opposite—sex fetuses. Males were classified as having resided between two male (2M), two female (0M) or one male and one female (1M) fetuses. As adults, saccharin preference was examined in separate groups that received one of two preferred solutions, 0.25 (which in Experiment 1 yielded a significant sex difference) or 0.75% (which yielded no sex difference). A significantly higher preference score was obtained for OM vs. 2M males that received the 0.25 but not the 0.75% solution. Since OM males are exposed prenatally to higher titers of estradiol than 2M males, estradiol may be responsible for organizing a pattern of saccharin preference that resembles that reported for females.

CORPUS CALLOSUM: INTERACTIVE EFFECTS OF HANDLING AND OVARIECTOMY IN THE RAT. C. M. Mack\*. P. E. Cowell, and V. H. Denenberg. Biobehavioral Sciences Graduate Degree Program, University of Connecticut, Storrs, CT 06269.

Both testosterone treatment and ovariectomy in early postnatal development have independently been shown to increase the midsagittal area of the corpus callosum (CC) of female rats handled in infancy. This effect of testosterone on the CC is not observed in nonhandled females. This raised the possibility of interactive effects of handling and ovariectomy on the female callosum. Whole litters (N=6 females, 2 males) of rats were handled or nonhandled between Days 1-21. On Day 12, three females within each litter were ovariectomized and the other three received sham surgery. The CC was examined at 110 days of age. Midsagittal callosal area and seven regional width factors, derived from a prior factor analysis of the rat callosum, were used to analyze group differences. Both handled and nonhandled ovariectomized females had increased callosal area compared to their respective controls. Analysis of the width factors revealed that handled ovariectomized females were significantly larger in the genu and body of the callosum, whereas the nonhandled group was significantly larger in the body and splenial regions. Thus although infantile handling had no effect on overall callosal area, there is regional specificity of the handling effect in ovariectomized females.

3\$\textit{3}\textit{6}\textit{1}\textit{1}\textit{7}\textit{1}\textit{N}\textit{PRIMARY CULTURES FROM DEVELOPING ZEBRA FINCH TELENCEPHALON. B.A. Schlinger\*, A.M. Vanson, S. Amur-Umariee, A. Campagnoni and A.P. Arnold. Depts. of Psychology and Psychiatry, Brain Res. Inst., UCLA, Los Angeles, CA 90024-1563.

Sex steroid metabolism and synthesis are important properties of brain tissue. Steroid synthesis is present in glia, whereas neurons and glia metabolize circulating sex steroids to active or inactive products. We have recently found that aromatase, the enzyme that catalyzes the synthesis of estrogen from androgen, is expressed at extremely high levels in primary cultures derived from the telencephalon (TEL) (1-3 weeks in vitro) of zebra finches (1-4 days post hatching). Thus, we are interested in whether other steroidogenic enzymes might also be expressed at high levels in these cultures. 3β-Hydroxysteroid dehydrogenase/isomerase (3β-HSD) is an essential enzyme in steroidogenic tissues and synthesizes active sex steroids from pregenenolone (Preg) and dehydroepiandrosterone (DHEA). 3\beta-HSD activity was identified in these cultures since <sup>3</sup>H-progesterone or <sup>3</sup>H-androstenedione (AE) was present in the media (products verified by recrystallization to constant specific activity) after incubating cultures (2.5 to 24 hrs) with 130-430 nM [7-3H]-Preg or 62.5-130 nM [1,2,6,7-3H]-DHEA, respectively. 3H-Estrogens were also identified (and recrystallized) in media after incubation with 3H-DHEA, presumably derived from 3H-AE or 3Htestosterone. These data further identify glia as important modulators of the steroidal environment in the zebra finch TEL and indicate that DHEA can serve as a precursor for brain synthesis of active androgen and estrogen. Supported by NSF and NIH grants BNS9020953, DC00217 and NS23022.

## 109.6

ASYMMETRY AND SEXUAL DIMORPHISM INDUCED BY CORTICAL DAMAGE IN RATS: EFFECT OF NEONATAL EXPOSURE TO TESTOSTERONE PROPIONATE IN FEMALES. C.H. Woodworth\* and R.G. Robinson. Dept. Psychiatry, Univ. of Iowa Coll. Med., Iowa City, IA 52242.

Previous work in this laboratory has shown that female rats differ from male rats in their lack of a lateralized behavioral response to focal cortical damage. Although right frontocortical suction lesions induce hyperactivity in male rats, neither right nor left lesions produce hyperactivity in female rats, regardless of whether the females are intact, ovariectomized prior to puberty, or exposed to the activating effects of testosterone proprionate (TP) in adulthood. The present experiment investigates whether female rats exposed as neonates to the organizing effects of TP will display male-pattern hyperactivity to cortical suction lesions as adults.

Subjects were F1 Sprague-Dawley females born to commercially-obtained breeders mated in our colony. Pups were either ovariectomized or shamperated within 24 hours after birth (Postnatal Day 0), and injected with either TP or vehicle on Postnatal Days 1 and 5. At 90 days of age, females were subjected to either right or left cortical suction lesions and implanted with either empty or TP-filled silastic capsules. Subjects were housed in running-wheels, and activity was monitored by computer for 21 days preceding, and for 30 days following surgery.

Results indicate that baseline running-wheel activity was significantly lower in ovariectomized females and in all females exposed neonatally to TP. TP implants produced hyperactivity in ovariectomized but not sham-operated females. Lesions were found to have a complex effect, depending both on neonatal treatment and on availability of circulating TP. These data support the conclusion that behavioral lateralization depends on the hormonal environment of the developing brain.

WHAT IS THE INFLUENCE OF TESTOSTERONE ON RAT VISUAL CORTEX DENDRITTC PLASTICITY? P. Seymoure\*, J. Jang, J. Pluskwa and J. M. Juraska. Dept. of Psychology. University of Illinois, Champaign, IL 61820.

Sex differences in dendritic morphology of

Sex differences in dendritic morphology of pyramidal neurons occur in rat visual cortex layer III in response to differential housing. Males show robust increases in dendritic field size, but females do not (Juraska, Brain Res., 295:27, 1984). The present study investigates whether testosterone influences this plasticity. Six littermate sets of Long-Evans male rats were used. Within 6 hours of birth two rats from each litter were castrated and the other two rats received a sham operation. At 25 days of age, castrated and sham rats from each litter were housed in either a complex environment (BC) or in individual lab cages (IC). After 30 days of housing the rats were sacrificed and 16 Golgi-Cox stained pyramidal cells were quantified from the monocular and binocular regions of the visual cortex. Sholl ring analysis of the basilar dendrites revealed that EC rats had larger dendritic fields than IC rats (p < 0.02). However, there was no difference between sham and castrated males. This result indicates that if testosterone has an influence on this plasticity, postnatal testosterone is not required. We are currently examining the size of the apical field and analyzing branch number and length. Supported by NSF BNS 89-09164.

ESTROGEN RECEPTOR OCCUPATION IN THE CEREBRAL CORTEX OF THE DEVELOPING RAT. N. J. MacLusky\*. T.J. Brown and R.B. Hochberg Division of Reproductive Science, The Toronto Hospital, Toronto, Canada MSG 1L7, and Dept. of Obstetrics and Gynecology Yale University New Haven, CT06510

Previous studies have demonstrated the presence of aromatase activity and estrogen receptors (ER) in regions of the developing mammalian cerebral cortex, raising the possibility that local conversion of testosterone to estradiol may play a role in the sexual differentiation of higher cognitive functions. Attempts to demonstrate occupation of ER in the developing brain have, however, been unsuccessful. Using in vitro exchange autoradiography (Walters et al., Soc. for Neurosci., 17:1410, 1991), we re-examined the distribution of occupied ER in the brain of developing male and female rats, throughout the first two weeks of postnatal life. Cryostat sections (10µm) through the brain were incubated with either 11β-methoxy 16α-{1<sup>25</sup>l} iodoestradiol or [<sup>3</sup>H] Moxestrol, then washed, dried and exposed against Hyperfilm (Amersham). Regional distribution of estrogen binding was assessed from the autoradiograms by computerized densitometry. ER ocupation was lower in the brain of the female than in the corresponding regions of the male. In males, particularly high ER occupation was observed in the periventricular preoptic area and ventromedial nucleus. Weaker labelling was observed in the hippocampus, as well as in the anterior cingulate and suprarhinal cortices. In all regions of the neocortex, ER occupation declined with age. In the hippocampus, however, estrogen binding remained high until postnatal d10, paralleling the elevated levels of aromatase activity observed in this region of the brain throughout the first two weeks of life. These results support the view that local estrogen biosynthesis may contribute to cerebral cortical differentiation during early life, and suggest that the hippocampus may be a particularly important target site for the developmental effects of aromatizable androgens [Supported by grants MT-11235 (to TJB) and PG 11115 (to NJM) from MRC Canada, and CA 37799 from NIH (to RBH)].

## 109.11

THE SEXUALLY DIMORPHIC VOLUME OF THE MEDIAL AMYGDALA IS RESISTANT TO THE DEMASCULINIZING EFFECT OF PRENATAL STRESS. M. Kerchner<sup>1\*</sup> and I.L. Ward<sup>2</sup>. Department of Psychology, 1 Washington College, Chestertown, MD 21620, and <sup>2</sup>Villanova University, Villanova, PA 19085.

Villanova, PA 19085.

Prenatal stress diminishes levels of plasma testosterone and diencephalic aromatase activity in male rats on the 18th and 19th day of gestation. As a result, many sexually dimorphic behaviors (e.g., play and copulatory patterns) and CNS structures (SDN-MPOA, DLN, SNB) are incompletely masculinized. In the present study we examined the effect of prenatal stress on a dimorphic feature of the amygdala (Mizukami, et al., Exp. Neurol., 1983, 79, 569). Using a computer-assisted image analysis technique, the volume of the medial amygdala was measured unilaterally in adult male rats (N=43) whose mothers had been exposed to a combination of heat and restraint stress during days 14-21 of pregnancy and compared it to that in the male (N=52) and female (N=8) offspring of nonstressed mothers. The medial amygdala in nonstressed males was nearly twice as large as in females (mean = 8.45 vs 4.59 mm³ x 10-1, p< 0.01). There was no significant difference in the volume of this nucleus between prenatally stressed (mean = 8.58) and nonstressed males. While the abnormal androgenic milieu produced in male fetuses by maternal stress alters the sexual differentiation of some brain and spinal nuclei, the present findings indicate that it does not influence the development of all dimorphic CNS structures. PRENATAL GONADAL STEROIDS AFFECT DEVELOPMENT OF THE GERBIL SNB. T. B. Decker, C. Ulibarri, and T. R. Akesson. Dept of Vet & Comp Anat, Pharm, & Phys, Wash State Univ, Pullman, WA 99164-6520.

In gerbils the spinal nucleus of the bulbocavernosus (SNB) is located above the central canal in lamina X. The SNB of male gerbils contains about 200 motoneurons that innervate the bulbocavernosus muscle (BC), levator ani (LA), and anal sphincter (AS). Female gerbils lack a BC and LA and have an SNB that contains about 30 motoneurons that innervate only the AS. Previous work demonstrated that postnatal estrogens and androgens were important in differentiation of SNB motoneuron number, size, and placement. However, these studies did not completely masculinize the SNB. This suggested that prenatal steroids may also be important in the development of the gerbil SNB.

To test this hypothesis, timed-pregnant female gerbils (n = 8/group) were injected daily from embryonic day 16 until birth (postnatal day 1, PND1) with either testosterone propionate (TP, 4mg), dihydrotestosterone P (DHTP, 4mg), androst-1,4,6-triene-3,17-dione (ATD, 6mg), or safflower oil. At birth pups were fostered to untreated mothers. As adults gerbils were castrated and implanted with Silastic capsules containing T (10mm). Five weeks later, gerbils were anesthetized and injected bilaterally with 0.5  $\mu$ 0 of cholera toxin conjugated to HRP (CT-HRP) in the BC or AS. One week later gerbils were anesthetized and aldehyde perfused. Lumbosacral spinal cords were removed, sectioned. Alternate sections were processed for CT-HRP and thionin staining.

Control males had about 200 SNB motoneurons. TP- and DHTP-treated females had about 180 and 150 SNB motoneurons respectively. ATD-treated males had about 250 SNB motoneurons. Control females had about 30 SNB motoneurons. Few of the BC-projecting motoneurons were displaced from the SNB. Prenatal steroids seem to be important in development of the number of SNB motoneurons but not migration. BSN9112097 (CU) & HD22869 (TRA).

## 109.10

ESTROGEN RECEPTOR MESSENGER RNA LEVELS ARE TRANSIENTLY ELEVATED IN THE RAT HIPPOCAMPUS \* DURING THE EARLY POSTNATAL PERIOD. J. A. O'Keefe and R.J. Handa, Dept. of Cell Biology, Neurobiology and Anatomy, Loyola University School of Medicine, Maywood, IL. 60153

We previously reported a transient elevation in estrogen receptor (ER) protein levels in the postnatal rat hippocampus. This suggests that this limbic cortical structure may be sensitive to the trophic and organizational influence of gonadal steroids during a critical period of sexual differentiation. In order to examine whether alterations in ER gene expression underlie the ontogenetic pattern of the hippocampal ER, we examined steady-state ER mRNA levels over the early postnatal period and in adult male rats. ER mRNA was measured with a highly sensitive RNAse protection assay. Hippocampal ER mRNA levels increased significantly (p < 0.005) between birth and postnatal day (PND) 4 when peak concentrations were found (0.1848  $\pm$  0.014 fmoles/mg total RNA) and declined by PND-10 (0.1206  $\pm$  0.017). Adult male hippocampal ER mRNA values were similar to those found in newborn and PND-10 animals but were significantly less (p < 0.05) than those observed on PND-4. Thus, the temporal pattern in steady-state ER mRNA levels in the developing hippocampus correlates with our previous developmental profile of the ER protein. These results suggest that the ontogeny of ER protein in the hippocampus may be regulated by alterations in ER gene expression.

## 109.12

TIMING OF PRENATAL TESTOSTERONE EXPOSURE AND NEURON NUMBER IN THE SNB OF FEMALE RATS. O.B. Ward\*, J.R. Carlucci and I.L. Ward. Dept. of Psychology, Villanova University, Villanova, PA 19085.

Ward & Weisz (Science, 207, 328, 1980) suggested that the surge in plasma testosterone (T) found in fetal male rats on days 18 and 19 of gestation sensitizes the developing nervous system to the lower levels of T which circulate at later stages. The present study supports this hypothesis in that the number of neurons in one sexually dimorphic nucleus of the lumbar spinal cord (the spinal nucleus of the bulbocavernosus [SNB]) was maximized in female rats that were exposed to testosterone propionate (TP) during two stages of ontogeny; on days 17.5 & 18.5 of gestation (2 mg daily to the dam) and again on day 25 (5  $\mu$ g/pup) postconception (2 to 3 days postpartum).

TP on fetal days 15.5 & 16.5 (early) or 17.5 & 18.5 (mid) without postnatal TP caused a 50% increase in the number of SNB neurons. Animals exposed to TP only on days 19.5 & 20.5 (late) or only postnatally did not differ from control females. However, the combination of either early, mid, or late prenatal TP together with the low dose of postnatal TP significantly increased the number of SNB neurons above the corresponding prenatal alone condition. Mid prenatal plus postnatal TP produced a 120% increase, yielding a significantly higher number of SNB neurons than any other condition. (Supported by grants HD-04688 from NICHHD and RSA 2K-05-MH-00049 from NIMH to 1.L.W.).

# 109.14

ROLE OF PRENATAL GONADAL STEROIDS IN SEXUAL DIFFERENTIATION OF THE GERBIL SDApc. C. Ulibarri. Dept of Vet & Comp Anat, Pharm, & Phys, Wash State Univ, Pullman, WA 99164.

The sexually dimorphic area of the gerbil hypothalamus (SDA) is a complex of cell groups found between the preoptic area and anterior hypothalamus. One of these cell groups, the SDA pars compacta (SDApc), typically exists only in males. Adult female gerbils do not develop an SDApc even after testosterone (T) therapy. Ulibarri and Yahr (Behav. Neural Biol. 49:27) showed that gonadal steroids present postnatally affect the development of the SDApc. Female gerbil pups given T shortly after birth develop SDApcs. The SDApcs of these androgenized females do not become as large of those of normal males, even after adult T treatment. Further, neonatal castration does not prevent the development of the SDApc. These data suggest that sexual differentiation of the SDApc begins prenatally and continues into the postnatal period. This research investigated the role of prenatal gonadal steroids in development of the SDApc.

Beginning on embryonic day 16 (E16) timed-pregnant females (n = 8/group) received daily injections of one of the following compounds, T propionate (TP; 4 mg), dihydrotestosterone P (DHTP; 4mg), androst-1,4,6-triene-3,17-dione (ATD; 6mg), or safflower oil vehicle. Injections continued until the day of birth (E25/PND1). At birth pups were fostered to untreated mothers. On PND30 pups were weaned into same-sex, same-treatment pairs. As adults gerbils were castrated and implanted with Silastic capsules containing TP (10mm). Six weeks later, the gerbils were anesthetized and aldehyde perfused. Brains were removed and sectioned coronally at 60 μm. Sections were examined for SDApes.

All oil-treated males had bilateral SDApcs. Only 50% of ATD-treated males had SDApcs. All DHTP- and TP-treated females had SDApcs. Oil-treated females rarely (20%) had SDApcs. The data suggest that prenatal estrogens and androgens are important for development of the SDApc. Support BSN9112097.

DEVELOPMENT OF ALTERED MOTONEURON-TO-MUSCLE SPECIFICITY IN ANDROGEN-SENSITIVE RAT SPINAL NUCLEI. A.E. Kalkbrenner and D.R. Sengelaub\*. Program in Neural Science, Department of Psychology, Indiana University, Bloomington, IN 47405.

In male rats, the spinal nucleus of the bulbocavernosus (SNB) projects to the bulbocavernosus muscle (BC) and the dorsolateral nucleus (DLN) projects to the ischiocavernosus muscle (IC). Development of this system is androgen-dependent, and the motoneurons and muscles are normally present in females but degenerate perinatally. However, females treated prenatally with dihydrotestosterone propionate (DHTP) lose SNB motoneurons but retain the BC muscle which is now anomalously innervated by motoneurons in the DLN (Breedlove, '85; Kurz et al., '90). To examine the factors which influence motoneuron specificity, we compared the development of normal and hormonally altered connectivity in this system.

Motoneuron projections to the BC muscle were examined in normal males and in females who were treated with DHTP (4 mg/day, embryonic days 17-22). Counts of HRP labeled motoneurons in the SNB and DLN were made following unilateral injections of cholera toxin-HRP (BHRP) into the BC on postnatal days 4, 10, 28 and 90. At P4, labeled motoneurons (mean=73) were found almost exclusively (95%) in the SNB of normal males; DHTP females did not differ from normal males in either the number (mean=78) or location of labeled motoneurons (92% in SNB). Following the postnatal SNB motoneuron death in DHTP females, increasing percentages of labeled motoneurons were located in the DLN after BC injection, and at adulthood about 40% of labeled motoneurons were located in the DLN. Injections of Fluorogold and BHRP into the IC and BC muscles indicated that anomalously projecting DLN motoneurons projected exclusively to the BC. Thus, the anomalous DLN-BC projection results from the death of SNB motoneurons and a subsequent BC invasion by DLN axons. (Supported by NIH NS24877)

## 109.17

EFFECT OF UNILATERAL DORSAL RHIZOTOMY ON MOTONEURON NUMBER IN A SEXUALLY DIMORPHIC RAT SPINAL NUCLEUS. A. Mills\* and D.R. Sengelaub. Program in Neural Science, Indiana University, Bloomington, IN 47405.

Normally occurring motoneuron death in the sexually dimorphic spinal nucleus of the bulbocavernosus (SNB) is regulated by androgens. It is unclear if this steroid-induced rescue of SNB motoneurons is a direct effect, is due to retention of target muscle, or if androgens act at another site. Neuron number in the dorsal root ganglia (DRG) serving the SNB decline during the same perinatal period as SNB motoneuron number, and this decline in DRG number is also androgen-sensitive (Mills and Sengelaub, '91). As primary afferent input is important to the survival of spinal motoneurons (Davis et al., '83; Okado and Oppenheim, '84), it is possible that afferents are important in the androgen regulation of SNB motoneuron survival.

Primary afferent input to the SNB was reduced by left dorsal rhizotomy (L3-S2) of male rats on the day of birth (P1). Since SNB primary afferents are thought to project bilaterally, this manipulation should deprive both sides of the SNB. At P10, SNB motoneurons were counted after rhizotomy (n=6) and in intact males (n=4). In intact rats, there was no difference in average motoneuron number between the left and right sides of the SNB (127 vs. 123). SNB counts from the unoperated side of rhizotomized animals (131) were not different from counts in intact rats, but there were significantly fewer motoneurons in the operated side of the SNB (57). Failure of rhizotomy to affect SNB motoneuron number on the unoperated side could indicate that either the degree of deafferentation was insufficient, or that primary afferents are not critical for SNB survival. Loss of SNB motoneurons on the operated side could indicate an effect of deafferentation r inadvertent axotomy of ventral roots. (Supported by NIH NS08917 to AM.)

SEX DIFFERENCES IN SYNAPTIC EFFICACY: PHYSIOLOGICAL AND MORPHOLOGICAL CHARACTERIZATION IN XENOPUS LAEVIS LARYNX. M.T. Tobias\*, M.H. Ellisman† and D.B. Kelley. Dept. Biol. Sci., Columbia Univ., NY, NY. 10027, †San Diego Microscopy and Imaging Resource, Dept. Neurosci., Univ. Calif. at San Diego, LaJolla, CA. 92093

In Xenopus laevis the response of laryngeal muscle fibers to nerve stimulation is sexually dimorphic: males produce subthreshold events while females produce action potentials (Tobias and Kelley, J. Neurosci., 1988). These data suggested an underlying sex difference in synaptic efficacy at laryngeal neuromuscular junctions. To further investigate the mechanism for weak synapses in males and strong synapses in females, we performed a quantal analysis in adult male and female frogs using the method of synaptic failures. At a Ca++/Mg++ ion concentration sufficient to block visible muscle contractions in female larynx, quantal content was significantly lower in males than in females (p<.0005). Sex differences in quantal content are Ca++ dependent; at a higher Ca++/lower Mg++ concentration, quantal content in male larynx can be increased to values in the female range. Sex differences in quantal content are due to the probability of transmitter release rather than to the amount released. Analysis of spont miniature endplate potentials revealed no significant sex difference in amplitude or frequency.

Calcium entry and subsequent transmitter release occur at active zones in the motor nerve terminal. We measured the number, length and density of active zones in freeze fracture micrographs and produced 3-D reconstructions of male and female laryngeal motor terminals. The number of active zones/ terminal does not differ in males and females. However, length of active zones (p<.0005) and length of active zone/unit length of terminal (p<.01) are significantly greater in females than in males. Thus, female laryngeal motor terminals probably contain more sites for Ca++ entry than do male terminals, a factor which may contribute to the greater probability of transmitter release in this sex.

TIME COURSE OF REGRESSIVE CHANGES IN AN AGING ANDROGEN-SENSITIVE RAT SPINAL NUCLEUS. M.C. Clark\*, C.L. Iwema, E.M. Kurz, and D.R. <u>Sengelaub</u>. Program in Neural Science, Department of Psychology, Indiana University, Bloomington, IN 47405.

Motoneurons in the spinal nucleus of the bulbocavernosus (SNB) in rats are sensitive to androgens during development, at adulthood, and in old age. In sensitive to androgens during development, at adultnood, and in old age. In adults, castration significantly reduces SNB soma area and dendritic length, which can be restored with androgen treatment. Androgen titlers decline with normal aging in male rats, and we have previously reported reductions in both SNB motoneuron soma area and dendritic length at 22 months of age. In this experiment we examine the time course of these changes.

SNB motoneuron number and morphology were assessed over a period which spans normal changes in testosterone titers in male rats (2, 9, 16, and 22 months of age). Counts of SNB motoneurons (cresylecht violet stained, 10 µm paraffin sections) did not vary with age (n=42). morphology was assessed after retrograde labeling following unilateral muscle injection with cholera-toxin HRP (n=19). Labeling was comparable across groups, and no reductions in arbor area or radial dendritic extent were observed through 22 months of age. However, SNB dendritic length regressed 29% by 16 months of age, and continued to decline thereafter (54% overall). SNB soma area was reduced 14% by 22 months of age. weight of the androgen-sensitive SNB target muscles also decreased by 9 months of age (bulbocavernosus/levator ani, 18%; ischiocavernosus, 32%) and continued to decline thereafter (overall decrease approximately 45%). Because the timing of these changes closely parallels declines in testosterone titers, age-related regressive changes in SNB motoneurons and their target muscles may result from declining androgen levels. (Supported by NIH AG09309)

NEURON SPECIFIC ENOLASE (NSE)-IMMUNOREACTIVITY IS PRESENT IN CELLS ON THE MIGRATION ROUTE OF LUTEINIZING HORMONE-RELEASING HORMONE (LHRH) NEURONS ORIGINATING FROM THE OLFACTORY PLACODE IN MICE. M.

Schwanzel-Fukuda and D.W. Pfaff, The Rockefeller University, N.Y., N.Y. LHRH-immunoreactive (ir) neurons originate in the epithelium of the olfactory pit on day 11 of embryogenesis (E) and migrate into the brain along branches of the terminal and vomeronasal nerves. Neural cell adhesion molecule (NCAM)-ir "pioneer" cells migrate out of the epithelium of the olfactory pit, form an aggregate between the olfactory pit and the developing forebrain, and receive the ingrowing NCAM-ir central processes of the olfactory, vomeronasal and terminal nerves. By E11, the NCAM cellular aggregate contacts the rostral forebrain, and NCAM-ir central processes form a scaffold along which the LHRH neurons migrate into the brain [Schwanzel-Fukuda et al.(1992) J. Com Neurol. 320:1-18]. Among cells which come from the olfactory placode, which are neurons? Our results show NSE-ir in cells in the epithelium of the olfactory pit, in clumps and cords along nerve fibers on the nasal septum, and in cells limited to the medial edge of the cellular aggregate below the forebrain from day 12. Double-label immunocytochemistry indicates that LHRH-ir neurons show NSE-ir. We speculate that a population of NCAM-expressing neurons show NSE-ir. We speculate that a population of NCAM-expressing glial cells necessary for normal migration [Schwanzel-Fukuda et al. Soc. Neurosci. Abstr.(1991) 17:427] emerge early from the placode and lay down the NCAM scaffolding, later followed by processes of the vomeronasal and terminal nerves, and the LHRH neurons themselves. Supported by NIH grant DC 00880 (M.S.-F).

CALCITONIN GENE-RELATED PEPTIDE- AND METHIONINE-ENKEPHALIN-IMMUNOREACTIVE NEURONS WERE INFLUENCED BY ESTRADIOL-17B TREATMENT IN THE ESTROGEN SENSITIVE REGION. K. Yuri\* and M. Kawata. Dept. of Anatomy, Kyoto Pref. Univ. of Med., Kyoto 602, Japan.

Estrogen receptor-immunoreactive cells were distributed in the periventricular preoptic nucleus (Pe), the medial preoptic nucleus (MPN) and around the third ventricle in the female rat, and these were regarded as estrogen sensitive nuclei. In the present study, female rats were ovariectomized and administered with estradiol-17β (E2)-contained silastic capsule or a blank. After 28days of E2 exposure, the rats were sacrificed and the brain sections were immunohistochemically examined using anti-calcitonin generelated peptide (CGRP)- and anti-methionine-enkephalin (Met-Enk)-antisera. Colchicine was also injected into the lateral ventricle 48hr before fixation. Semi-quantitative analysis showed that the number of CGRP- and Met-Enk-immunoreactive fibers was increased by the E2 treament in the Pe and the MPN. In the colchicine treated rats, a large number of CGRP- immunoreactive cell bodies was recognized in the Pe and the MPN; numerous Met-Enk-immunoreactive cells were observed in the MPN. These findings suggest that estrogen sensitive neurons make an increase of CGRP- and Met-Enk-immunoreactive materials in their perikarya as well as processes.

## 110.3

SEXUAL DIFFERENTIATION OF VASOPRESSIN CELLS OF THE BED NUCLEUS OF THE STRIA TERMINALIS AND MEDIAL AMYGDALOID NUCLEUS IN RATS. Z.X. Wang, G.J. De Vries, N.A. Bullock, N.R. Carlson and E. Rabin. Prog. in Neurosci. and Behav., U. of Mass., Amherst, MA 01003

The vasopressin-immunoreactive (AVP-IR) projections of the bed nucleus of the stria terminalis (BST) and medial amygdaloid nucleus (MA) are much denser in male than in female rats even if they are treated with similar amounts of testosterone. Previous studies have indicated that testosterone influences AVP-IR projections during development, but they did not indicate whether these effects of testosterone were permanent. This study tests the effects of various hormonal manipulations during development on the ability of testosterone to influence the AVP immunostaining in cells of the BST and MA and of fibers in the lateral septum during adulthood.

In the first experiment, male and female rats were gonadectomized or shamoperated at the day of birth. Three months later, the subjects that had been sham-operated were gonadectomized and all subjects were implanted with testosterone capsules for four weeks before their brains were processed for AVP immunocytochemistry. Males castrated at three month of age had more AVP-IR cells in the BST and a higher density of AVP-IR fibers in the lateral septum. This suggests that androgens influence sexual differentiation of AVP pathways after birth. The second experiment showed that male rats castrated at the day of birth or day 7 had less AVP-IR cells in the BST and MA and a lower AVP-IR fiber density in the lateral septum after four weeks of testosterone treatment in adulthood than similarly treated males castrated on days 21 and 90. This suggests that testicular secretions influence the differentiation of AVP-IR cells around day 7. This was confirmed in a third experiment, in which male and female rats that vere neonatally gonadectomized and treated with testosterone at day 7 showed a higher AVP-IR fiber density in the lateral septum than those treated with vehicle

# 110.5

CALCITONIN GENE-RELATED PEPTIDE (CGRP) IS SEXUALLY DIMORPHIC IN THE DEVELOPING SNB. L.L. Hodges, N.G. Forger, S.M. Breedlove, and R.B. Fishman\*, Dept. of Psychology, Univ. of California, Berkeley, CA 94720.

Motoneurons of the spinal nucleus of the bulbocavernosus (SNB) innervate sexually dimorphic perineal muscles which rely on androgen for development. Last year we reported that CGRP expression in the SNB of males is delayed relative to that in other lumbar motoneurons. We now report the proportion of motoneurons positive for CGRP in the three major motoneuron groups of the lumbar spinal cord of male and female rats from postnatal days 1-55. CGRP was expressed by most motoneurons outside of the SNB at all ages examined. CGRP-LI was again low in the SNB of neonatal males, but was virtually undetectable in the female SNB prior to day 27, then rapidly approached male levels:

Proportion of CGRP-positive SNB cells on postnatal day: <u>9-10</u> <u>16</u>

<u>16</u> <u>27</u> .033 .288 .676 .532 .009 .009 .016 .593 .464 Females .197 .693 .645 Males .064 .424

Because androgen inhibits CGRP expression in adult male rats (Popper & Micevych, '89), the finding of lower expression in females was somewhat unexpected. We are now expression in effect of exogenous androgen on CGRP expression of neonates to test the possibility that androgen were compared to the control of the control o test the possibility that androgen regulates CGRP expression differently in developing and adult motoneurons.

SEX DIFFERENCES IN ANDROGEN AND ESTROGEN ACTIONS ON VASOPRESSIN mRNA LEVELS IN THE BED NUCLEUS OF THE STRIA TERMINALIS OF RATS. G.J. De Vries, Z.X. Wang, N.A. Bullock and S.Numan. Prog in Neurosci. and Behav., Univ. of Mass., Amherst, MA 01003

MONDAY PM

The vasopressin-immunoreactive (AVP-IR) neurons of the bed nucleus of the stria terminalis (BST) lose their immunoreactivity and their AVP mRNA content after castration. They are also sexually dimorphic: male rats have more AVP-IR cells than females even if they are given similar testosterone treatment. To analyze the cellular basis of this sex difference, we compared the effects of testosterone metabolites on AVP mRNA expression in BST cells in both sexes

Males and females were gonadectomized at 3 months of age and divided into 4 groups receiving either empty tubing, dihydrotestosterone (DHT), estradiol (E), or E plus DHT. Four weeks later, all subjects were decapitated and their brains were processed for in situ hybridization with a 35S-labeled oligonucleotide. There were hardly any labeled cells in rats with empty implants or implants with DHT. The results of the remaining steroid treatments indicated that there are at least three sex differences in AVP cells of the BST. First our results confirm that there is ar absolute sex difference in the number of cells that produce AVP mRNA under equal steroid treatment. Second, E significantly increases AVP mRNA levels in both sexes, but more so in males than in females: the peak number of labeled cells per section was 37.8 in males and 29.1 in females. The number of grains per cell in these animals was 87.6 in males and 71.7 in females. Third, DHT when given in combination with E significantly increases AVP mRNA levels in males only: E plus DHT-treated males and females had 52.4 and 28.8 cells per section with a density of 124.5 and 76.5 grains per cell, respectively. The frequency distribution of cells with different numbers of grains suggests that DHT not only boosts AVP mRNA levels per cell, but also recruits new cells that were not synthesizing AVP mRNA before

## 110.4

EXPRESSION OF pCCK mRNA IS DEPENDENT ON ADULT GONADAL STEROIDS NOT NEONATAL STEROID ENVIRONMENT, P. E Micevych\*. C. Ulibarri, L. Abelson, and H. Fok. Dept. of Anatomy & Cell Biology, Laboratory of Neuroendocrinology, UCLA School of Medicine, Los Angeles, CA 90024 and the Dept. VCAPP, Washington State University, Pullman, WA 99164.

The expression of cholecystokinin (CCK) in the medial amygdala, the bed nucleus of the stria terminalis and the medial preoptic nucleus is highly dependent on the gonadal steroid environment of the animal. Estrogen, in females and males, increases the levels of CCK peptide, the number of CCK immunoreactive cells and levels of preproCCK (pCKK) mRNA in these limbic-hypothalamic nuclei. Microinjections of CCK alter female reproductive behavior. Neonatal gonadal steroids determine the adult behavioral response to exogenous CCK. experiment tested whether alteration of the neonatal environment influences the expression of pCCK mRNA. Neonatal rats were gonadectomized and/or treated with Silastic™ capsules filled with testosterone (4 mm), estrogen (1 mm) or 1,4,6androstrien-3,17-dione (ATD, 4 mm). At 90 days of age, the animals were gonadectomized as needed, implanted with an estrogen, testosterone or blank Silastic zapsule (see above), and allowed to survive 4 weeks. All animals were killed by transcardial perfusion under pentobarbital anesthesia and processed for pCCK in situ hybridization using a 35S-labeled riboprobe. Both male and female rats treated with estrogen or testosterone in adulthood, regardless of the neonatal treatment, had large numbers of pCCK cells and the highest levels of hybridization (measured by the density of silver grains/cell) in the limbic-hypothalamic nuclei. These results suggest that reproductively relevant circuits of both male and female brains expressing high levels of pCCK are dependent on levels of sex steroids in adulthood and not during neonatal development. Supported by NS 21220.

GONADAL STEROIDS MODULATE THE GROWTH-ASSOCIATED PROTEIN GAP-43 mRNA IN POSTNATAL RAT BRAIN. P.J. Shughrue and D.M. Dorsa. University of Washington, Department of Pharmacology, and GRECC, VA Medical. Center., Seattle, WA 98108.

The growth-associated protein GAP-43 is concentrated in axonal growth

cones and has been implicated in axonal elongation and synaptogenesis. The results of recent studies indicate that estrogen modulates GAP-43 mRNA in adult rodent hypothalamus. Since gonadal steroid hormone action during early postnatal life determines the growth and connectivity of certain neuronal populations in hypothalamus, the present study investigated the effect of various gonadal hormonal conditions on GAP-43 mRNA levels in postnatal rat various gonadal hormonal conditions on GAP-43 mRNA levels in postnatal rat brain. Postnatal male rats were castrated at birth and sc injected daily with 50µl sesame oil. Intact male and female postnates were also injected daily with oil, while additional females were administered 50µg testosterone propionate (TP). On postnatal day 6, brains were frozen and 16µm cryostat sections processed and hybridized with a <sup>35</sup>S-labeled antisense riboprobe for GAP-43 mRNA. Section-mounted slides were apposed to x-ray film and then dipped in liquid emulsion. After exposure, slides were developed and the regional silver ratin count determined with a computer assisted analysis extens. Film liquid emulsion. After exposure, slides were developed and the regional silver grain count determined with a computer assisted analysis system. Film autoradiograms revealed an extensive presence of GAP-43 mRNA in the medial preoptic area, bed nucleus of the stria terminalis, basal hypothalamus, and cerebral cortex. In the central aspect of the medial preoptic nucleus, GAP-43 gene expression was elevated in intact male, attenuated after male castration, low in intact females, and augmented in TP treated females. These changes were positively correlated with changes in serum testosterone levels as determined by RIA. The results of these studies indicate that GAP-43 mRNA levels in the medial preoptic area are modulated by changes in gonadal steroid hormone levels. The differential regulation of GAP-43 mRNA by sex steroids in the male and female postnatal hypothalamus may influence the phenotype of neuronal circuitry and thereby determine the pattern of adult hypothalamic function. Supported by NS20311 and NS07332.

ESTROGEN RECEPTOR mRNA IN THE PREOPTIC AREA OF NEONATAL RATS. L.L. DonCarlos\*, R.J. Handa, C.A. Lisciotto & C.K. Wagner. Dept. Cell Biol., Neurobiol., & Anat., Loyola Univ. Stritch Sch. Medicine, Maywood, IL 60153, & Inst. Animal Behav., Rutgers Univ., Newark NJ 07102. Exposure to the estrogenic metabolites of testosterone during the early

postnatal period has permanent effects on rodent brain developme We used in situ hybridization to chart the development of ER mRNA expression in the rat preoptic area, a brain region for which sexual dimorphisms and the effects of estrogen on development are particularly well-documented. Neonatal male and female rats were sacrificed by perfusion fixation on selected postnatal days (PND; day of birth is PND 0). ER mRNA was detected using an 850 base 35S-labeled riboprobe (ER cDNA gift of M. Muramatsu); autoradiograms were exposed 4 weeks. Many ER mRNA-labeled cells were detected in the periventricular preoptic area and medial preoptic nucleus at the three time points examined so far: PND 4, which corresponds to the period of maximal sensitivity to the masculinizing effects of estrogenic metabolites of testosterone, PND 7 and PND 10. The distribution of ER mRNA containing cells was identical in both sexes although the intensity of label was consistently higher in females compared with males. In adult rats, estrogen down regulates ER mRNA (Simerly and Young, 1991). Aromatization of androgens in the preoptic area may provide sufficient local estrogen to down-regulate ER mRNA in the neonatal male preoptic area. Further analyses of the distribution and relative abundance of ER mRNA in males and females of earlier ages are in progress. Supported by the Potts Foundation.

EARLY POSTNATAL ADMINISTRATION OF THE PHYTOESTROGEN COUMESTROL DOES NOT INDUCE C-FOS IN BRAIN OR UTERUS IN ADULTHOOD. F. A. Caputo\*, K. L. Medlock and A. C. Scallet. National Center for Toxicological Research, Jefferson, AR

Phytoestrogens are estrogens which occur naturally in Phytoestrogens are estrogens which occur naturally in plants and are commonly found in the human diet in foods such as grains, soya and other fiberous plants. It has been shown that prenatal and postnatal exposure to sex steroid hormones have profound effects on the anatomy of the brain in the developing rodent fetus. Female rats were injected with the phytoestrogen coumestrol (100 ug/10 ul/pup) on postnatal days 1-10. Control animals received no injection. At 60 days of any applies were secrificed and pup) on postnatal days 1-10. Control animals received no injection. At 60 days of age, animals were sacrificed and brain and uterus examined for c-fos immunoreactivity. Results suggest that early phytoestrogen exposure does not induce c-fos immunoreactivity in estrogen concentrating areas of the brain or in the uterus in adult female rats.

EFFECTS OF TESTOSTERONE ON MUSCLE FIBER SIZE: REPEATED  $\it{in}$ VIVO OBSERVATION OF A FORELIMB FLEXOR MUSCLE IN XENOPUS LAEVIS. M. Dorlöchter, A.A. Herrera\*, and T. Guyette. Dept. of Biological Sciences, University of Southern California, Los Angeles, CA 90089-2520.

The flexor carpi radialis (FCR) is a sexually dimorphic muscle used by male frogs to clasp females during mating. A previous study from our laboratory revealed differences in fiber size between FCR muscles of castrated (C) frogs compared with castrated but testosterone provided ones (CT). As measured from frozen sections 8 weeks after the surgery, the average fiber cross sectional area was 45% smaller in C than in CT frogs (Regnier & Herrera, Soc. Neurosci. Abstr. 16, 329, 1990).

To define the time course of fiber size changes we studied FCR muscles of C and

CT frogs in vivo at the time of castration and 2, 4, and 8 weeks thereafter. Surgically exposed muscles in anaesthetized frogs were stained with the vital mitochondrial dye DIOC (1  $\mu$ M) and fibers recorded on videotape using a fluorescence microscope (x50/1.0 W objective) and a SIT camera. Already at 2 weeks the apparent muscle fiber diameter was increased by 9 % in CT and decreased by 15 % in C frogs (n = 5 each). After 8 weeks muscle fibers in CT animals were on average 21 % larger and in C animals 30 % smaller than at the day of castration (n = 3 each). For comparison, fiber diameter was measured in sartorius muscles in some of the frogs. It was found to steadily decline within 4 weeks to about 80 % of the value on the day of castration; no difference was detected between C and CT frogs. Since body weight in these animals decreased similarly, we conclude that this was the cause of sartorius muscle fiber atrophy. Our data suggest that manipulation of the hormonal status in male Xenopus leads to a fast regulation of fiber size in the FCR muscle. Supported by NIH grant NS27209.

DEVELOPMENTAL EXPRESSION OF 3-ALPHA HYDROXYSTEROID OXIDOREDUCTASE IN RAT CNS M.S. Ward. N.S. Nadi, A.E. Schaffner\*, and J.L. Barker. Laboratory of Neurophysiology NINDS, NIH, Bethesda, MD 20892.

This study examines the developmental expression of 3α-hydroxysteroid oxidoreductase (30:OHSOR), an enzyme responsible for reduction of A-ring reduced 3-keto steroids such as dihydrocortisone, dihydrotestosterone, and dihydroprogesterone. This enzyme converts 5α-pregnane-20-one to 3α-hydroxy-5αpregnane-20-one (3\alpha-THP), a ligand that has been found to be active at the embryonic GABA-A receptor. Preliminary results from enzymatic analysis using newly developed chromatographic techniques for the separation of tritium labeled pregnane steroids indicate that the enzyme is active early in development and that embryonic brain is one of the first tissues to produce  $3\alpha$ -THP. Enzymatic activity first appears in a craniocaudal gradient. In later stages there is little difference among brain regions but significant differences are seen between the sexes. These differences are believed to be due to estradiol regulation of enzyme expression.

These results indicate that local brain metabolism may be an important part of producing steroid ligands for the GABA-A receptor in development. Current investigation focuses on regulation of enzyme expression and the relationship of 3α-THP to other GABA-A ligands throughout development.

## 110.10

FACILITATION COMPENSATES FOR LOWERED SYNAPTIC EFFICACY IN A SEXUALLY DIMORPHIC MUSCLE. N. Nagaya and A.A. Herrera, Neurobiology Section, Dept. of Biological Sciences, University of Southern California, Los Angeles, CA 90089-2520.

The flexor carpi radialis (FCR) is a sexually dimorphic forelimb muscle used by male frogs during mating. The FCR is innervated by motor neurons in spinal segments 2 and 3. Studies comparing castrates given testosterone implants (CT) with castrates given blank implants (C) have shown that FCRs from CT males have more junctions that are subthreshold in response to single nerve stimuli. This effect of testosterone is most pronounced in spinal nerve 2 (SN2) motor units. In CT muscles, 28 % (n=213) of fibers in SN2 motor units were subthreshold compared to 4 % (n=133) in C muscles (p<0.01). The lowered synaptic efficacy in CT muscles may result from significant decreases in input resistance (0.28 M $\Omega$ , n=214 vs. 0.44 M $\Omega$ , n=109) and quantal content in low Ca<sup>2+</sup> (1.63, n=24 vs. 3.42, n=31).

Muscles were bathed in Ringer with 10-12 µM curare and intracellular recording was used to study facilitation of transmitter release in the FCR in response to 30 nerve stimuli at 70 Hz. Facilitation was measured as the ratio of the 5th endplate potential (EPP) to the 1st. There were no significant differences between junctions of SN2 and spinal nerve 3 (SN3) motor units or between CT and C muscles. All junctions facilitated greatly (median=2.74, interquartile range: 1.99-3.57) and EPPs at the end of the stimulus train did not fall below the level of the 1st EPP. The magnitude of facilitation in FCR junctions suggests that repetitive nerve stimulation can recruit otherwise subthreshold junctions. Our data indicate that FCR junctions can be active and can maintain high levels of transmitter release even though testosterone reduces synaptic efficacy. Supported by NIH grant NS 27209.

LAMPREY NEUROFILAMENTS LACK THE 'KSP' REPEATS FOUND IN OTHER VERTEBRATE NEUROFILAMENTS. Al Jacobs. MA Peck. ME Selzer\*. Department of Neurology and David Mahoney Institute of Neuroscience, University of Pennsylvania, Philadelphia, PA 19104

of Pennsylvania, Philadelphia, PA. 19104

Spinal axons of the sea lamprey regenerate following transection and unlike cultured mammalian neurons, their growth cones are packed with neurofilaments (NF). In contrast to the triplet proteins making up mammalian neurofilaments (NF). In contrast to the triplet proteins making up mammalian neurofilaments (NF). L. NF-M, NF-H), lamprey neurofilaments are homopolymers of a single 180 kDa subunit (NF180). We have cloned and sequenced two overlapping cDNAs (identified by hybridization to mammalian NF cDNA probes and expression screening with NF specific mAbs) that encompass the entire coding region for NF180. Deduced amino acid sequence shows NF180 is most homologous to NF-M of mouse (40% overall identity and 61% in the core). However, there is a conservative substitution of aspartate for glutamate\* in the highly conserved KLLE\*GEE sequence found at the carboxy terminus of the core in all intermediate filaments. The carboxy sidearm of NF180 is rich in glutamate and contains multiple tandem EAEAEE repeats. However, KSP and KSP-like repeats are conspicuously absent. It has been postulated that the phosphoserine repeats in the sidearm of mammalian NFs extend the sidearm away from the filament core by electrostatic repulsion, and thereby regulate axon diameter. The glutamate rich sidearm of NF180 may serve the same function in the lamprey, but with a fixed charge would not be under the regulatory control of NF kinases and phosphatases. Chou and Fasman analysis of NF180 predicts an alpha helical structure within the core similar to that described by Geisler and Webber (1982), except one additional non-helical spacer may be present in each of the three core coils (total of 6 coils). An extended alpha helical structure is also predicted for the long carboxy sidearm of NF180. The extreme carboxy termini of human, rat and mouse NFM are 98% identical and contain two amino acid repeats. Lamprey NF is weakly homologous to NFM in this region, but does contain two repeated sequences whi

## 111.3

Viral Latency and GAP-43: Changing Enrichment of a Growth Associated Protein in Wound Healing and Viral Infection. Rex E. Martin<sup>1\*</sup>, Jim M. Hill, and Nicolas G. Bazan<sup>1</sup>. L.S.U. Eye Center and Neuroscience Center<sup>1</sup>. New Orleans, LA, 70112.

Trigeminal nerves are linked to the wound healing response of cornea, and the GAP-43 in these nerve fibers may be involved. Using a rabbit model, the effect of latent viral infection on GAP-43 content in cornea was investigated. Corneas were infected with Herpes simplex virus, type 1 (HSV-1). At 52 days post-infection (viral latency), the relative GAP-43 content of uninfected and infected corneas was quantified. In nerve endings of uninfected corneal epithelium, GAP-43 appeared equally enriched in membrane and cytosolic fractions. Viral latency resulted in 29% enrichment in membrane associated GAP-43 and 3-4 fold overall enrichment of the protein in comparison to uninfected rabbits. Within 12h of mild alkali burn to corneal epithelium, the relative enrichment of GAP-43 between membrane and cytoplasm was reversed. Membrane-associated GAP-43 was most enriched 48h post-burn and decreased in parallel with cytoplasmic GAP-43 over the next 48h. Higher levels of GAP-43 expression may be induced in the trigeminal ganglia by HSV-1 and modify plasticity or intracellular trafficking in corneal nerves. Relationships between HSV-1 latency and modifications in wound healing are being explored. Supported by EYO6635, EYO6311.

LOCALIZATION OF CALMODULIN (CaM) AND THE MULTIPLE CaM mRNAs IN DIFFERENTIATED PC12 CELLS. S.P. Zhang\*, N. Natsukari, R.A. Nichols and B. Weiss. Div. of Neuropsychopharmacology, Dept. of Pharmacology, Medical College of Pennsylvania, Philadelphia, PA 19129.

Calmodulin (CaM) is encoded by three genes from which five CaM mRNAs are transcribed. Earlier studies showed that all five CaM mRNAs are present in the PC12 pheochromocytoma cell line, and that both nerve growth factor (NGF) and dibutyryl cyclic AMP (db-cAMP), which induce neurite outgrowth in these cells, increase the levels of CaM and the CaM gene mRNAs. In the present study we examined the subcellular distribution of CaM and its mRNAs in PC12 cells differentiated with NGF (50 ng/ml) and db-cAMP (1 mM). We determined the levels of CaM by Western blot analysis and its subcellular distribution using immunocytochemistry. We measured the cellular distribution of the CaM mRNAs by in situ hybridization cytochemistry, using radiolabeled oligodeoxynucleotide probes. Intense, patch-like staining for CaM was associated with the nucleus; a diffuse, weaker signal was found in the cytoplasm; and significant staining for CaM was detected along some of the neurites. Results of experiments using an oligodeoxynucleotide probe which detects all the CaM transcripts showed that the CaM mRNAs were distributed throughout the PC12 cell bodies; significant amounts of the CaM mRNAs were also found in some, but not all, neurites. Using separate probes specific for the CaM mRNAs for each CaM gene, we found a distinct pattern of localization for the mRNAs of each CaM gene. The mRNAs transcribed from CaM genes I and II were found in neurites as well as in cell bodies. By contrast, CaM gene III mRNAs were in relatively low abundance in the PC12 cells, and no significant signal was found in neurites. That different CaM mRNAs are localized in different compartments in PC12 cells suggests that the various CaM mRNAs might synthesize CaM in different cellular locations and, therefore, may have different functional roles. (Supported by MH42148).

### 111.2

A NEURAL KERATAN SULFATE PROTEOGLYCAN, CLAUSTRIN, IS RECOGNIZED BY ANTIBODIES TO MAP1B. <u>Michael Burg</u> and <u>Gregory J. Cole\*</u>, Dept. Anat. & Cell Biol., Med. Univ. of South Carolina, Charleston, SC <u>29425</u>.

Our laboratory has recently described the identification of a chick nervous system keratan sulfate proteoglycan (KSPG), named claustrin, that inhibits neural cell adhesion and neurite outgrowth. Polyclonal antisera raised against the intact proteoglycan (PG) and the major core protein, a 70 kDa polypeptide, were used to screen an E9 chick Uni-Zap cDNA library, with eight overlapping partial cDNAs isolated that reacted with both antisera. Initial sequence analysis indicated that the cDNAs encoded a protein homologous to MAP1B, although the claustrin cDNAs represent a 5' fragment of MAP1B, with the 3' MAP1B coding region missing from these cDNAs. Since previous studies of MAP1B have identified in rat a 3' fragment termed neuraxin, encoding a 94 kDa protein, and a similar clone was isolated from our chick library upon screening with an antiserum to chick brain PGs, this raised the possibility that MAP1B is a PG(s), specifically a KSPG. Our present studies show that the MAP5 MAb recognizes only claustrin in chick, and that antisera to chick claustrin react only with MAP1B in rat. In addition, a MAb (5D4) to human cartilage keratan sulfate reacts with MAP1B in rat and claustrin in the chick. Keratanase treatment eliminates the immunoreactive protein (MAP1B) in rat that is recognized by both the MAP5 and MAP1B-4 MAbs. In addition, in immunohistochemical studies we show that MAP5 MAb recognizes midline glial structures in E20 rat spinal cord, hindbrain and midbrain, which are putative barrier structures known to express claustrin in the chick. Interestingly, the rat midbrain midline expression does not extend into the decussation of the superior cerebellar peduncle, raising the possibility that claustrin may regulate the midline crossing of these axons. These data also suggest that MAP1B is a KSPG, and that the two core proteins of claustrin, with molecular weights of 100 and 70 kDa, may be encoded by distinct cDNAs previously suggested to identify MAP1B.

## 111.4

FACTORS REGULATING PROTEOLYSIS AND CALMODULIN BINDING OF B-50/GAP-43. P.J.Coggins, and H. Zwiers Departments of Medical Physiol/ Medical Biochem. University of Calgary, Calgary, Canada, T2N 4N1.

The neuronal growth-associated protein B-50/GAP-43 is a substrate for Protein kinase C, binds to Calmodulin in a calcium independent manner, and is subject to hydrolysis adjacent to the single kinase C phosphorylation site. All of these processes can be inhibited by corticotrophin (ACTH). We have investigated the structural requirements for ACTH-mediated inhibition of B-50 proteolysis by an endogenous protease that co-purifies with B-50 in a detergent extract of synaptosomal plasma membranes. The results indicated that inhibition of proteolysis is related to the presence of a basic amphiphilic helix in those ACTH fragments and analogues that were inhibitory, and moreover, the presence of this motif in other peptides appears to confer inhibitory activity. Chymotryptic digestion of B-50 in the presence and absence of a non-ionic detergent, and ACTH, demonstrated that hydrolysis is also influenced by a lipid-like environment that primarily effects the protein rather than the protease or the peptide. Furthermore this lipid dependency appears to extend to the binding of dephosphorylated-B-50 to Calmodulin which appears to occur only in the presence of non-ionic detergent and the absence of calcium. The results are discussed with reference to the putative secondary structure of B-50 and changes that may take place in the presence of membrane lipids or non-ionic detergents. The conclusions of this study suggest that B-50 is subject to regulation by post-translational enzymes and binding proteins as a consequence of its structural conformation at the cytoplasmic side of the plasma membrane.

# 111.6

ALTERATION IN THE LEVELS OF CALMODULIN-BINDING PROTEINS DURING DIFFERENTIATION OF PC12 CELLS. Natsukari, S-P. Zhang, R.A. Nichols\* and B. Weiss. Div. of Neuropsychopharmacology, Dept. of Pharmacology, Medical College of Pennsylvania, Philadelphia, PA 19129.

Calmodulin (CaM) plays a pivotal role in numerous cellular processes by interacting with its target proteins, CaM-binding proteins (CaMBPs). To elucidate the role of these CaMBPs in neuronal differentiation and their possible role in determining the compartmentation of CaM within cells, we examined the expression and subcellular distribution of CaMBPs during differentiation of the PC12 pheochromocytoma cell line. Undifferentiated cells and those differentiated with either nerve growth factor (NGF), dibutypt cyclic AMP (db-cAMP) or both agents were subfractionated at various times, and their CaMBPs were separated by SDS gel electrophoresis and assayed using <sup>125</sup> I-CaM gel overlay autoradiography. In membrane fractions from untreated cells, proteins having apparent MWs of >200, 110, 52, and 47 kDa exhibited Ca<sup>2+</sup>-dependent binding to CaM, while many smaller proteins (20, 17 and <15 kDa) displayed predominantly ca<sup>2+</sup>-independent binding. Many protein bands in the molecular weight range of 25-37 kDa bound CaM equally in the presence and absence of Ca<sup>2+</sup>. Most of the CaMBPs of the Ca<sup>2+</sup>-independent type were relatively small and were present in the particulate fractions, consistent with previous findings obtained with fractions from brain. Upon treatment with NGF and/or db-cAMP, the pattern of CaM-binding changed dramatically. The 20 kDa CaMBP of the Ca<sup>2+</sup>-independent type increased after 4 days of treatment with db-cAMP. NGF itself had only a small effect on this protein, while simultaneous treatment of cells with both NGF and db-cAMP led to a marked increase in this 20 kDa CaMBP. In contrast, other Ca<sup>2+</sup>-independent CaMBPs (17 and <15 kDa) decreased during differentiation. These results show that CaMBPs are differentially altered by NGF and db-cAMP, suggesting that they may play a role in neuronal differentiation. (Supported by MH42148).

CHANGES IN THE DISTRIBUTION OF RYANODINE RECEPTOR ISOFORMS IN THE CNS DURING DEVELOPMENT. Y. Ouyang +, I. J. Deerinck+, J. A. Airey0, J. L. Sutko0, and M. H. Ellisman+. San Diego Microscopy and Imaging Resource, +Dept. of Neurosciences, Univ. of Calif. San Diego, La Jolla, CA.92093; Open. of Pharmacology, Univ. of NV., Beno, NV. 89557.

We recently identified two ryanodine binding proteins (α and β ryanodine receptors, RR's) in the chicken CNS using antibodies against the purified skeletal muscle RR (Ellisman et al., Neuron, 5:135-146, 1990). The RR's are caffeine sensitive calcium activated calcium release channels of intracellular membrane systems. Well characterized isoform specific monoclonal antibodies (mab) 110F and 110E (Airey et al., J. Biol. Chem. 265:14187-14194, 1990) discriminate between skeletal and cardiac muscle species as well as two species found in the CNS of the chick. Mab 110F recognizes only the skeltal muscle α form while mab 110E is specific for skeltal muscle β and the cardiac muscle form. The pattern of appearance of α and β/cardiac isoforms has been investigated during development of the chick CNS using histochemical methods. The α form of the RR is in highest concentration in cerebellar nuclei and some large neurons of the pons. The α form appears relatively early in these neurons before hatching and persists thereafter through adulthood. In contrast, strong β/cardiac form-like immunoreactivity is found throughout the brain, including the deep cerebellar nuclei and large neurons of the pons. The distribution of β/cardiac immunoreactivity changes markedly in the cerebellum during the first few weeks of development. Weak β/cardiac labeling was observed in all PC's of hatchlings but restricted to clusters of PC's at 1 week post hatch (PH). At this time weak β/cardiac-like immunoreactivity appears in the granule cell layer which is more strongly labeled at 4 wks. PH. This increase in β/cardiac form at 4 wks. PH. The developmental changes in the distribution of the β/cardiac form at 4 wks. PH. The development changes in the distribution of the β/cardiac form of the RR suggests involvement in the maturation of neuronal properties.

MODIFICATION OF PHOSPHOLIPID COMPOSITION IN BRAIN SYNAPTOSOMES ISOLATED FROM RATS TREATED WITH GUANIDINOETHANESULFONATE. P.-L. Lleu, R.J. Bowers and R.J. Huxtable\*, Department of Pharmacology, College of Medicine, University of Arizona, Tucson, Arizona 85724

Recently, developmental decreases in taurine concentration in rat brain synaptosomes (P2B fraction) have been shown to be correlated with: (1) an increase in the phosphatidylethanolamine/phosphatidylcholine (PE/PC) ratio and (2) a decrease of [3H-methyl]methionine incorporation into synaptosomal phospholipids (Huxtable et al., Neurochem Int. 15:233; 1989, and Lleu and Huxtable, Neurochem Int., in press, 1992). The relationship between taurine and phospholipid methylation has been explored further in rats depleted of taurine during development by treatment of the mothers during pregnancy and lactation with 1% guanidinoethane sulfonate (GES) in drinking water. P<sub>2</sub>B fraction was isolated from brain hemispheres of rats at 7, 14, 21, 28, and 56 days of age, and the phospholipid composition determined. The PE/PC ratio was systematically decreased at all time points, the largest decrease (15%) being seen in 56 day-old animals. These findings suggest that taurine and its analog, GES, are directly influencing the alteration in neutral phospholipid ratio and the marked decrease in phospholipid methylation seen in rat brain synaptosomes during development.

DIFFERENTIATION-INDUCED CHANGES INSECOND MESSENGER-DEPENDENT PROTEIN KINASE ACTIVITIES IN A RAT NEURONAL CELL LINE. H.B. Rind 1. J.T. Neary3, and S.R. Whittemore 1.2. The Miami Project1, Depts. Physiology and Biophysics1 and Neurological Surgery2, Univ. Miami and V.A. Medical Center3, Miami, FL 33136 Protein phosphorylation is an important mechanism by which neuronal

Protein phosphorylation is an important mechanism by which neuronal differentiation may be transduced intracellularly. Elucidation of both the dynamics and substrates of the kinase pathways activated during neuronal differentiation may provide insight into the specific effector molecules involved. Our studies focused on changes in Ca<sup>2+</sup>/calmodulin, cAMP, and Ca<sup>2+</sup>/phospholipid dependent protein kinases (CaMK, PKA, and PKC, respectively) in RN33B cells. RN33B is a temperature sensitive, neuronally differentiating cell line derived from E12.5 rat medullary raphe. Significant levels of all 3 enzymes were detected in undifferentiated RN33B cells. While the total CaMK activity in membrane and soluble fractions did not change upon differentiation, increased phosphorylation of a number of CaMK substrates was observed. One of these substrates was an approximately 67 kDa phosphoprotein suspected to be the autophosphorylated subunit of Ca<sup>2+</sup>/CaM Kinase II. Differentiated cells also exhibited a significant decrease in PKA activities in both cytosolic (83%) and membrane (48%) fractions. Differentiation, however, did not appear to induce an activation of PKC or its translocation from cytosol to membrane. Instead, soluble PKC activities decreased by 54% with a more conservative decrease in the particulate fraction upon differentiation. Current studies are aimed at examining the role of these second messenger-dependent protein kinases in neurotrophic factor-induced differentiation of RN33B cells. Supported by the Miami Project and NS26887.

OPPOSITE TRANSITION OF CHICK BRAIN CREATINE KINASE ISO-ENZYMES DURING EMBRYONIC AND POST-NATAL DEVELOPMENT. O.C. Ramírez\*, E. Jiménez and A.M. Cibrián. Departamento de Bioquímica, Centro de Investigación y de Estudios Avanzados del Instituto Politécnico Nacional México, D. F. 07000.

Owing to its dimeric structure, cytosolic creatine kinase (cCK) exists as three main isoenzymes; skeletal muscle (MM), heart (MB) and brain (BB). During ontogeny of heart and skeletal muscles it is believed that cCK isoenzyme transition is similar among vertebrates. As in skeletal muscle cultures, during differentiation the appearing of BB-CK type is followed by the MB-CK type and concludes with the adult MM-CK isoenzyme. It is currently accepted that BB-CK is the only type present in brain tissue during the entire life of vertebrates and a faint trace of MM-CK may appear only in older rats. However, evidence was presented that, as in muscle tissues, post-natal rat brain synthesizes abundant catalytic forms of MM and MB-CK in addition to the brain type (Ramfrez O. & Licea, G. Exptl. Neurol. 77:225 1982).

In this work it is shown that transition of chick brain cCK isoenzymes follows a pattern opposite to the universally accepted one. In the absence of creatine, developing chick brain initiates with catalytic MM-CK isoforms (from 46 h through the 7th day of incubation); with creatine in brain, the MB-CK types are present from the 7th to the 14th day; from hatching to adulthood (1.5 years), the BB-CK isoforms are synthesized, coinciding with higher brain energy demands.

PKC ACTIVITY AND SUBCELLULAR LOCALIZATION DURING NEURONAL DIFFERENTIATION OF SH-SY5Y HUMAN NEUROBLASTOMA CELLS. V. Parrow\*, G. Meyerson, E. Nänberg and S. Pählman Department of Pathology, University Hospital, S-751 85 Uppsala, Sweden.

SH-SY5Y neuroblastoma cells can be induced to differentiate into neuron-like cells by treatment with nanomolar concentrations of the phorbolester 12-0-tetradecancyl-phorbol-13-acetate (TPA), in the presence of serum or growth factors. The optimal concentration of TPA for neuronal differentiation is 16 nM. To evaluate the possible role of a sustained protein kinase C (PKC) activation during the neuronal differentiation, PKC protein and RNA levels as well as the PKC activity were determined during 4 days of TPA treatment. PKC activity, measured by the phosphorylation of the 80 kDa PKC substrate, was not down-regulated when the cells were treated with this low concentration of TPA. In contrast, high concentrations of TPA (1.6 µM) resulted in downregulation of PKC and a poor neuronal differentiation. Translocation of PKC to the membrane compartment could be measured within one hour after stimulation with 16 nM TPA. However, Western blots showed that the PKC- $\alpha$  protein was present after four days of TPA treatment and subcellular fractionation revealed that the PKC- $\alpha$  protein, as well as the 80 kDa PKC substrate, could be found in the growth cones and in the nuclear fractions, as well as in the cytosolic compartment.

PHORBOL ESTER- AND GLUTAMATE-SENSITIVE PHOSPHORYLATION OF HIPPOCAMPAL MEMBRANE PROTEINS FROM ADULT AND NEONATAL RATS. <u>L. M. Shaffer and L. A. Dokas\*</u>. Departments of Biochemistry & Molecular Biology, and Neurology\*, Medical College of Ohio, Toledo, OH 43699.

The phosphoinositide (PI) system in the neonatal rat brain is differentially stimulated as compared to that of the adult by glutamate. Hydrohysis of PI generates diacylglycerol (DAG), which activates protein kinase C (PKC). Phorbol esters directly activate PKC and inhibit agonist-stimulated PI hydrolysis, presumably via PKC substrate proteins. This study compared membrane protein phosphorylation under conditions that affect PI hydrolysis in neonatal and adult rat hippocampus. Basal phosphorylation of two membrane proteins (M.; 46,000, and 80,000, pl: 4.4 and 4.2, respectively) is enhanced when compared to the adult. The former protein is found only in neonates. Phosphorylation of a 48,000 M, protein (pI of 4.5) is prominent in both neonatal and adult membranes. Incubation of hippocampal slices with 12-O-Tetradecanoyl phorbol-13-acetate (TPA, 10µM) decreased post-hoc phosphorylation of neonatal proteins, while increasing that of the adult 80,000 M, protein, implying that phosphorylation in neonates may not be as efficiently coupled to receptor stimulation as in the adult. Immunoblot analysis identified the 48,000 M, protein as a B-50/GAP-43, the 80,000 M, protein as a membrane-associated form of MARCKS, and showed that MARCKS is expressed at higher levels in the neonatal rat hippocampus. The proteins differentially phosphorylated in neonates as compared to adults may mediate developmental differences in PI metabolism.

NEUROGRANIN (RC3): DEVELOPMENTAL EXPRESSION OF PKC SUBSTRATE IN THE HUMAN VISUAL CORTEX; Y.H.Yücel\*+. J.Baudier # and L.E. Becker +. + Dep. Path. /Neuropath., Hospital for Sick Children,

U. of Toronto, CANADA, # Lab. de BMCC, INSERM U 309 Grenoble, FRANCE.
The developmental expression of Neurogranin (NG), a brain specific protein kinase C (PKC) substrate, was investigated in human calcarine cortex (autopsy material without neuropathological findings at macroscopic and microscopic examination) with immunocytochemical techniques using a specific anti-NG polyclonal antibody. NG and GAP-43 bind calmodulin in the absence of calcium and share a 17 aminoacid sequence that corresponds to the PKC phosphorylation site and to the calmodulin binding domain. Immunoreactivity was localized in cell calmodulin binding domain. Immunoreactivity was localized in cell bodies and occasionally in dendrites. In adult human correx, NG immunoreactivity (NGI) was distributed mainly in layer II and in layer VI. The superficial layer II showed the highest number of cells labelled and greatest intensity of NGI. Layer VI also demonstrated marked NGI relative to the other layers. Few NGI cells were detected in layer III and layer V. In layer II, pyramidal cells were the main cells identified by NG. In younger visual cortex, there was a similar pattern of NGI observed in all cases older than 3 years (n=5). In cases younger than 12 months (m) and older than 3 m, NGI was found only in deep layer VI or was negligible (n=5). In all cases younger than 3 m, no immunoreactivity was observed in the cortical layers (n=6). These preliminary results suggest that the developmental pattern of NGI in human visual results suggest that the developmental pattern of NG in human visual cortex shows an "inside first outside last" spatio-temporal distribution, similar to what we described in cat visual cortex (21st SFN Meeting, 1, p366, 1991). Its postnatal developmental expression suggests a role for this substrate of PKC in human visual cortex development.

THE RECEPTOR PROTEIN-TYROSINE KINASE TYRO-3, EXHIBITS AMINO ACID SEQUENCE WITH NEURAL SIMILARITY ADHESION MOLECULES. <u>C. Lai<sup>1</sup></u> and <u>G. Lemke\*</u>. Molecular Neurobiology Laboratory, The Salk Institute and Department of Neuropharmacology, The Scripps

Research Institute<sup>1</sup>, La Jolla, CA 92037. We have isolated and characterized full-length cDNA clones encoding the novel neural protein-tyrosine kinase (PTK), tyro-3 [Neuron 6, 691-704 (1991)]. The deduced amino acid sequence reveals a putative transmembrane (PTK) receptor. The composed of extracellular region is immunoglobulin-like domains and two fibronectin type III repeat motifs. The tyro-3 extracellular region shows sequence similarity to neural adhesion molecules including N-CAM, L1, TAG-1 and fasciclin II. It also exhibits similarity to protein-tyrosine phosphatases including the leukocyte common antigen-related protein (LAR). These observations suggest that tyro-3, which has been observed in large neurons in cortex and CA1 hippocampus, is involved in cell-cell interactions. (Supported by grants from the N.I.H. and the National Multiple Sclerosis Society)

CLONING AND CHARACTERIZATION OF A NOVEL PUTATIVE PROTEIN TYROSINE PHOSPHATASE FROM THE NEONATAL RAT CORTEX. Mustafa Sahin\* and Susan Hockfield. Section of Neurobiology, Yale University School

of Medicine, New Haven, CT 06510.

Regulation of protein function through tyrosine phosphorylation is critical for control of cellular processes, including proliferation and differentiation. The state of tyrosine phosphorylation of a protein is determined by the The state of tyrosine phosphorylation of a protein is determined by the opposing actions of kinases and phosphatases. Recently, a growing number of protein tyrosine phosphatases (PTPases) have been identified from various species and tissues, including the mammalian nervous system. These enzymes share a conserved catalytic domain and can be divided into two groups based on subcellular location: intracellular vs. transmembrane. PTPases are thought to play roles in such divergent functions as cell cycle regulation, tumor suppression, cell adhesion and axon guidance. Given these observations and our interest in cellular diversity in the mammalian CNS, we sought to identify PTPases in the developing rat cortex. A cDNA library from neonatal rat neccortex was used as a template for PCR and amplified with degenerate primers to a conserved terriou of PTPases.

and amplified with degenerate primers to a conserved region of PTPases. PCR products were subcloned and sequenced. One of the products PCR products were subcloned and sequenced. One of the products encodes a novel PTPase. The predicted amino acid sequence shows highest homology to previously described human transmembrane PTPases. Analysis by Northern blotting demonstrates a predominant mRNA species at 5.5 kb. The message is enriched in the brain compared to the liver or kidney. Furthermore, the expression of the novel PTPase is dramatically downregulated in adult cortex compared to postnatal day 1 cortex. In-situ hybridization reveals that the mRNA is present in the gray, but not white matter of the cortex, suggesting expression by neurons not by glia.

Further characterization of this developmentally-regulated PTPase will provide insight into its functions during CNS development. (Supported by NS22807)

ASTROCYTE HETEROGENEITY IDENTIFIED BY EXPRESSION OF GFAP-LACZ TRANSGENES. M. Brenner, Y. Su, W.C. Kisseberth, F. Besnard, & A. Messing. University of Wisconsin-Madison, Madison, WI; NIH, Bethesda, MD Glial fibrillary acidic protein (GFAP) is an intermediate filament expressed in nearly all astrocytes of the central nervous system. Cell transfection studies (J Biol Chem 266:18877, 1991) found that astrocytes specific expression can be directed by a 2 kb 5'-flanking segment of the human GFAP (hgfa) gene. In addition, two subregions were identified, one adjacent to the basal promoter and one about 1500 bp upstream, that when juxtaposed to form a synthetic (400 bp) promoter produced increased levels of astrocyte-specific expression in cell lines. Transgenic mice carrying the bacterial β-galactosidase (lacz) reporter under the control of the full length (2 kb) or synthetic (400 bp) promoters have now been examined for specificity of expression. The 2 kb promoter drives lacz expression in astrocytes throughout the central nervous system, whereas the 400 bp promoter is active primarily in cerebral astrocytes. These studies demonstrate heterogeneity among astrocytes in their use of regulatory elements to control expression of GFAP.

IDENTIFICATION OF PUTATIVE TRANSCRIPTIONAL REGULATORY ELEMENTS IN THE OLFACTORY MARKER PROTEIN (OMP) PROMOTER. K. Kudrycki, C. Behn, C. Stein-Izsak\* and F.L. Margolis. Dept. of Neurosciences, Roche Inst. of Molec. Biol., Nutley, NJ 07110.

OMP is found almost exclusively in cytoplasm of mature olfactory receptor

neurons and its expression must be tightly controlled by tissue specific and age dependent factors. In order to understand the mechanism of OMP transcriptional regulation we have initiated a study aimed at identification of possible cis-regulatory elements within the rat OMP promoter and their corresponding transcriptional elements within the rat OMP promoter and their corresponding transcriptional factors. Studies with transgenic mice previously conducted in our laboratory indicated that at least 800 nucleotides upstream of the transcriptional start site are required for correct expression of OMP. DNase I footprinting analysis and gel mobility shift assays with nuclear protein enriched extracts from the olfactory mucosa and other neuronal and nonneuronal tissues have allowed us to identify several regions within this promoter area that may be involved in transcriptional regulation of the OMP gene (C. Stein-Izsak et al. Soc. for Neurosci., Abstr. 513.5, 1991, New Orleans). Two of these regions contain the sequence motif TCCC(A/T)PuGGAG and interact Two of these regions contain the sequence motif TCCCC(A/T)PuGGAG and interact only with nuclear protein enriched extracts from the olfactory mucosa. The activity binding to these sites was designated Olf-1. Gel mobility shift assays with a number of synthetic oligonucleotides demonstrated that Olf-1 binding activity requires both the five purines and the TCCCC sequence. Another putative regulatory element located between the two Olf-1 binding sites interacts with nuclear protein enriched extracts from a number of tissues resulting in various gel mobility shifts and DNase I footprinting patterns. In addition, we have identified sequence motifs adjacent to the OMP transcriptional start site that bind factors present in nuclear protein extracts from the olfactory mucosa and some other tissues that we have tested. These results demonstrate existence of several putative transcriptional regulatory elements results demonstrate existence of several putative transcriptional regulatory elements in the OMP promoter, two of which seem to be controlled by the newly defined offactory specific binding activity, Olf-1. These elements may also play a role in transcriptional regulation of other olfactory specific genes.

TRANSGENIC ANALYSIS OF OMP PROMOTER USING TWO REPORTER GENES. M. Grillo\*, R. Morris<sup>1</sup>, R. Akeson<sup>2</sup>, M. Sakai, R.J. Smeyne, C. Stein-Izsak, C. Bocchiaro, J. Corbin, A. Phillips and Proceedings of Neurosciences, Roche Inst. of Molec, Biol., Nutley, NJ 07110. <sup>1</sup>National Inst. for Neurosciences, Roche Inst. of Molec, Biol., Nutley, NJ 07110. <sup>1</sup>National Inst. for Neurosciences, Roche Inst. of Molec, Biol., Nutley, NJ 07110. <sup>1</sup>National Inst. for Neurosciences, Roche Inst. of Neurosciences, Roche Med. Research, The Ridgeway, Mill Hill, London, England. <sup>2</sup>Inst. Developmental Res., Children's Hosp. Res. Foundation, Cincinnati, OH 45229

Developmental Res., Children's Hosp. Res. Foundation, Cincinnati, OH 45229. Olfactory chemoreceptor neurons express a unique, phylogenetically conserved, developmentally regulated protein, the olfactory marker protein (OMP). The highly specific cell and tissue distribution of the protein implies that the expression of the OMP gene is spatially and temporally controlled at the level of transcription. To study the elements regulating OMP expression in vivo we have utilized transgenic mice. Chimeric gene constructs have been generated that combine varying amounts of the rat OMP 5' upstream genomic sequence with the coding region of Thy 1.1 or LacZ as reporters. Immunocytochemistry, reverse transcriptase/PCR and RIA have shown that consistent, robust tissue-specific expression of the Thy 1.1 reporter is seen if 0.8 Kb or more of the 5' OMP sequence is present in the transgene. However, 0.3 Kb of 5' upstream sequence gives, at best, variable, borderline Thy 1.1 expression in several independently derived lines. In contrast, results obtained from histochemical (Xeal) and immuno-enzyme assay of tissues from mice bearing similar expression in several independently derived lines. In contrast, results obtained from histochemical (Xgal) and immuno-enzyme assay of tissues from mice bearing similar constructs directing the E. coli LacZ gene indicate that unambiguous, tissue-specific expression of reporter gene activity can be seen with as little as 0.3 Kb of 5' OMP sequence. These observations indicate that genomic motifs for olfactory specific gene expression reside within 0.8 and possibly 0.3 Kb of 5' upstream OMP sequence. Further, these data are consistent with our report of two copies of a novel DNA sequence motif (Olf-1) that are located 5' of the OMP transcription start site (Kudrycki et al., Soc. Neurosci. 1992). Evaluation of the minimal amount of promoter sequence required to determine timing and tissue-specific regulation of gene expression may depend on the choice of reporter gene and on the sensitivity of its assay.

## 112.5

TRANSGENIC CONSTRUCTS FOR ASSESSING THE ROLE OF SNAP-25 EXPRESSION IN THE PHENOTYPE OF THE HYPERACTIVE MOUSE MUTANT COLOBOMA. E.J. Hess.\*, J.B. Bergsman, T.M. Slater and M.C. Wilson, Dept. of Neurosci. & Anat., Penn State Univ., M.S. Hershey Medical Center, Hershey, PA 17033 and Dept. of Neuropharm., The Scripps Research Institute, La Jolla, CA 92037.

SNAP-25 is a neuron-specific synaptosomal associated protein that contributes to synapse formation. In characterizing SNAP-25 expression and function, we have identified the mouse mutant coloboma (Cm/+) as carrying a chromosome 2 deletion mutation that includes the Snap gene. and function, we have identified the mouse mutant coloboma (Cm/+) as carrying a chromosome 2 deletion mutation that includes the Snap gene. Coloboma mice are heterozygous neurological mouse mutants whose phenotype includes opthalmic deformation, stereotypic head shaking and extreme hyperactivity. Although it is clear that the coloboma mutation is a deletion of less than 5 cM, it is not known if other genes surrounding Snap are also deleted. To determine the specific contribution of SNAP-25 expression to the coloboma phenotype, we have assembled Snap constructs for generating transgenic mice. Both constructs consist of a Snap promoter that includes -11 kb of undefined, untranslated genomic DNA 5 to the first Snap exon. One construct, designed to test the specificity of the Snap promoter in vivo and in vitro, consists of the promoter, an SV40 splice site, the &-galactosidase cDNA and an SV40 polyadenylation signal. This reporter construct was transfected into PC12 cells, which express low levels of SNAP-25, and promoter efficacy was tested. In situ X-gal staining and a quantitative &-galactosidase enzyme assay revealed that the 11 kb Snap promoter was effective in neuronal cells and is a good candidate for driving SNAP-25 expression in neurons of transgenic mice. Therefore, this promoter was used to assemble a Snap mini-gene to rescue the coloboma phenotype; this construct contains a rat insulin intron, the SNAP-25 cDNA and an SV40 polyadenylation signal in addition to the promoter. Both the Snap mini-gene and the Snap/&-galactosidase constructs are currently being used to generate transgenic mice. Supported by PHS MH48989.

PRODUCTION OF TRANSGENIC MICE MODEL FOR THE SPATIOTEMPORAL EXPRESSION STUDY OF CHOLINE ACETYLTRANSFERASE GENE. J.H.Son. T.Wessel, H.Baker, C.Peng. T.H.Joh Lab. of Molec. Neurobiol., Cornell Univ. Med. Coll., Burke Med. Res. Inst., White Plains, NY 10605

Progressive cell loss or degeneration of particular central cholinergic neurons is observed in normal aging and several fatal neurological disorders, such as Alzheimer's and Huntington's diseases. Choline acetyltransferase (ChAT) has served as a specific phenotypic marker for cholinergic neurons due to its selective expression in these neurons. Expression of ChAT mRNA and ChAT enzyme activity in the central nervous system has been known to be developmentally regulated in different regions of rat brain, such as basal forebrain, cerebral cortex, hippocampus and corpus striatum. Furthermore various growth factors, such as nerve growth factor (NSF), brain-derived neurotrophic factor (BDNF), basic fibroblast growth factor (bFGF), interleukin 3 (IL-3) or leukemia inhibitory factor (LIF), affect the cholinergic phenotype by inducing or enhancing ChAT activity. We cloned and determined the genomic organization of rat ChAT gene in order to study the differential and developmental expression of the ChAT gene in the CNS using transgenic mice. The 15 exons of the ChAT gene are distributed over a distance at least 64 kb in the rat genome. Immediate upstream from the putative transcription start site, we found several potential known cis-acting DNA sequences. This allowed us to make several lacZ fusion DNA constructs with various amount of the upstream DNA sequence and/or some intron sequence to generate transgenic animals. Preliminary analysis of the animals containing the upstream 1.9 kb/lacZ fusion construct showed that this construct was not fully sufficient to give correct expression in mouse brain. Results from further analyses of other transgenic animals will be presented.

3' ENHANCER ELEMENTS FROM THE HUMAN TH GENE DIRECT HIGH LEVELS OF GENE EXPRESSION IN ADRENALS OF TRANSGENIC MICE. S. C. Wong\*, M. A. Moffat, J. Merlie<sup>†</sup>, and K. L. O'Malley, Departments of Anatomy and Neurobiology, and <sup>†</sup>Molecular Biology and Pharmacology, Washington University School of Medicine, St. Louis, MO 63110.

Our previous studies indicated tissue specific elements involved in human tyrosine hydroxylase (TH) gene expression were 3' of the last exon. A maximal response element was defined within 261 bp of exon 13 which averaged 120-fold increased activity over basal level controls. To extend these results in vivo, we generated 9 lines of transgenic mice with a vector containing the 261 bp fragment cloned in front of a thymidine kinase promoter driving a chloramphenicol acetyl transferase (CAT) reporter. We have analyzed 4 lines of mice using reverse-transcription-polymerase chain reaction (RT-PCR) with CAT specific primers. In all cases CAT mRNA was expressed primarily in the adrenal gland followed by pancreas (26% of adrenal gland expression), cerebellum (8%), midbrain (6%), heart (3%), Pons (3%), lung (2%), and spleen (1%). CAT mRNA could not be detected in cerebral cortex, liver, spleen and thymus. Despite abundant CAT mRNA, CAT enzyme activity could not be detected in any of these tissues. Preliminary RT-PCR data indicated cryptic splicing within the CAT transcript generated a truncated CAT gene product. These data suggest that the human TH 3' enhancer can function in vivo but that additional sequences are required for total tissue specific responses.

## 112.6

REGULATION OF TYROSINE HYDROXYLASE GENE EXPRESSION DURING BRAIN DEVELOPMENT IN TRANSGENIC MICE. T.H.Joh, K.S.Kim, H.Baker, J.H.Son Lab. of Molec. Neurobiol., Cornell Univ. Med. Coll., Burke Med. Res. Inst., White Plains, NY 10605

Tyrosine hydroxylase (TH) enzyme is specifically expressed in the of catecholamine gio neurons in the brain and plays a key role in the regulation of catecholamine biosynthesis. The expression of catechoaminergic phenotype is developmentally regulated in the different brain regions including the dopaminergic neurons of the substantia nigra, ventral tegmental area and olfactory bulb and the noradrenergic neurons of the locus ceruleus. For example, TH immunoreactivity was first detected at rat embryonic day (E) 12.5 in the substantia nigra, but in locus ceruleus it became visible on E14. In substantia nigra an overshoot of TH activity was seen by postnatal day (PD) 15 and gradually decreased to adult level by PD 28.

To investigate the tissue-specific expression of TH gene during prenatal and postnatal development, we generated a series of lacZ fusion DNA constructs using various amounts of the 5' flanking promoter region of the rat TH gene. With these fusion DNA constructs we established a total of 19 different transgenic mouse lines. Among them, the transgenic lines harboring the 2.4 kb of 5' flanking TH sequence showed the correct expression in most brain regions, which correlates with our results from in vitro functional analysis of the upstream promoter region of TH gene. To further investigate whether the expression of the lacZ reporter gene is colocalized with the endogenous expression of TH gene during the development of murine central nervous system, these and the other transgenic animals are being examined.

# 112.8

SOMATIC DNA RECOMBINATION IN THE TRANSGENIC MOUSE BRAIN: CONTRASTING AND COMPLEMENTARY PATTERNS REVEALED BY COMPARISON OF TWO FOUNDERS.

L Kingsbury, M. Matsuoka, D.T. Larue<sup>1</sup>, J.A. Winer<sup>1</sup> and H. Sakano. Divisions of Immunology and 
Neurobiology, Dept. of Molecular and Cell Biology, University of California, Berkeley, CA 94720. 
DNA recombination enables lymphocytes to generate the genetic diversity required to produce 
immunoglobulins against billions of potential antigens. We recently reported (Matsuoka et al., 
Science [1991] 254:61-86) evidence that somatic DNA rearrangement also occurs in the brain of a 
transgenic mouse. The transgene construct contained a reporter gene, *IacZ*, in reverse orientation

Science [1991] 254.81-86) evidence that somatic DNA rearrangement also occurs in the brain of a transgenic mouse. The transgene construct contained a reporter gene, *Iad2*, in reverse orientation with respect to a promotor, such that rearrangement results in B-galactosidase expression. Treatment of fixed brain sections with X-gal, a chromogenic substrate for B-galactosidase, yields ablue reaction product which labels areas where the reporter gene rearranges. A polymerase chain reaction procedure (PCR) which amplifies only rearranged genes showed that the *Lac2* expression is due to actual DNA rearrangement rather than integration of the transgene near an endogenous tissue-specific promotor. We described the distribution of B-gal activity in the brain of one founder mouse that produced progeny. Here we compare the staining of the second (intertile) founder and offer speculation about the functional significance of DNA recombination in the brain. The patterns of B-gal activity in founders No. 1 and No. 2 were similar but not identical. In general, the staining in No. 2 was less intense but more widespread than in No.1. For example, in No. 1, onesting a staining was strong, but restricted to lobes IX and X, while in No. 2, the B-gal activity was lower but was distributed over the entire cerebellum. Likewise, staining in sersory and motor cortex, which was concentrated in layers III-IV in No. 1, was spread over layers III-VI in No. 2. Overall, most regions of the brain showed some B-gal activity in one or both tounders. The different distribution of B-gal activity in the two founders may reflect different sites of transgene integration which affect its accessibility to putative recombination capability but that only a subset might have access to the reporter gene in each transgenic founder. Why central neuronal populations have DNA recombination capability but that only a subset might have access to the reporter gene in each transgenic founder. Why central neurons have the capacity to rearrange DNA is unclear. Howe

TRANSFECTION OF CEREBELLAR GRANULE NEURONS AND ASTROCYTES BY ELECTROPORATION.
R.G. King\*

Lab. of Molecular Biology, NINDS, NIH, Bethesda. MD 20892
Several techniques for gene transfer into dividing cells have been devised (Biotechniques 1988, Vol.6, No. 7). Gene transfer into post-mitotic cells has proven very difficult. Few methods have been successful in transferring genes into a variety of post-mitotic cells. We investigated the use of electroporation to transfer the RSV-B galactosidase (B-gal) and RSV chloramphenicol acetyltransferase (CAT) genes into primary cultured cerebellar granule neurons and astrocytes. We found that the efficiency of gene transfer is about 3-to 5-fold greater in astrocytes than neurons.

Assays of these cultures gives an easily detectable signal for CAT activity. Preliminary results comparing electroporation and liposomal techniques have shown them to be comparable. We have successfully used electroporation to transfer genes into primary neurons and astrocytes. Our results suggest that electroporation is an easy and rapid method to transfer genes into post-mitotic cells such as neurons.

KBEnhancerBindingComplexesinMammalian<br/>and L. VermaBrain.<br/>Dept.K. Cauley\* L. Chen.<br/>Obert.F. H. Gage.<br/>Obert.and The SalkInstitute, La Jolla, CA. 92037.

KB enhancer binding proteins have been shown to play key roles in the regulation of tissue specific gene expression, primarily in lymphoid cells. Very little is known about the role of these factors in the regulation of gene expression in the mammalian nervous system. Utilizing the electrophoretic mobility-shift assay, we have identified several complexes from extracts of rat brain which specifically bind to the KB site of the HIV-LTR. We have identified a factor indistinguishable from NF-KB, and another factor which includes a protein identical with, or highly related to, the nuclear oncoprotein cRel. Both of these KB binding complexes are found throughout the brain. Considerable levels of the NF-KB-like factor is present in the inactive form in the adult brain; presumably the appropriate input signal would activate this transcription complex.

# 112.13

Cell-Specific Regulation of Preproenkephalin Intron-A Derived Heteronuclear RNA in the Rat Basal Forebrain, Thalamic Reticular Nucleus, and Testis. P.J. Brooks\* T. Funabashi, S.P. Kleopoulos, C.V. Mobbs, and D.W. Pfaff. The Rockefeller University, Box 275, New York, NY 10021

Using *in situ* hybridization with single-stranded DNA probes to different regions of the rat preproenkephalin (PPE) gene, we have identified a population of neurons in the rat reticular thalamic nucleus (RT) and basal forebrain (BF) which utilize a novel mechanism for the control of preproenkephalin gene expression. These cells contain very high levels of heteronuclear preproenkephalin RNA derived from downstream of a previously described (Mol. Cell Biol. 10:3717) germ-cell specific transcription initiation site within somatic intron A, without detectable PPE RNA derived from exon 2. Sites of hybridization in these neurons appear as 1-3 intranuclear foci of silver grains using tritium labeled probes. Similar foci of hybridization are also observed with the same probes in a population of testicular germ cells. The data indicate that in cells in which PPE gene transcription initiates from the intron A initiation site, PPE gene expression can also be regulated by an additional mechanism involving transcriptional termination prior to the 5' end of exon 2, which results in the accumulation of high levels of nuclear PPE intron A-derived heteronuclear RNA. Weisinger et al (Soc. Neurosci. Abst. 16:71.12, 1990) have previously proposed a transcriptional down-regulation process regulating PPE transcripts initiating from exon 1 in the striatum.

Neurons in the horizontal and vertical limbs of the diagonal band of Broca, the ventral pallidum, and medial septum contain high levels of PPE Intron A derived heteronuclear RNA, as do GABAergic neurons of the RT. A population f BF neurons project to the RT (JCN 262:105) indicating that neurons utilizing this mechanism may be connected, and that many of them are importantly involved in the control of cerebral cortical function.

MOLECULAR MECHANISMS OF SYNAPTIC REGULATION OF TYROSINE HYDROXYLASE GENE EXPRESSION. A. Goc., E. Puchacz, M.K. Stachowiak. Barrow Neurological Institute, Phoenix AZ 85013.

Synaptic stimulation of TH gene expression in catecholaminergic cells is mediated via depolarization of cellular membrane and influx of Na<sup>+</sup> ions. The present study was undertaken to elucidate molecular mechanisms underlying this regulation. Incubation of bovine adrenal medullary cells (BAMC) with depolarizing agent veratridine increased mRNA levels of TH and another catecholamine biosynthetic enzyme, PNMT. The increases in PNMT mRNA were prevented by Ca\*\* channel antagonist, nifedipine, and by down-regulation of protein kinase C (PKC) with PMA, indicating mediation through Ca\*\*/PKC. In contrast, induction of TH mRNA was not affected by nifedipine, down-regulation of PKC, or calmodulin antagonist calmidazolium. It was also not affected by TMB-8 an inhibitor of intracellular Ca\*\* mobilization. This suggested induction via Ca\*\*, PKC-, and calmodulin-independent mechanisms. To elucidate nuclear mechanisms of TH gene activation we transiently expressed chimeric TH promoter(-428/+21 bp)-luciferase genes in cultured BAMC. Veratridine produced 3-fold increase in LUC activity (normalized to amount of intracellular plasmid DNA), but had no effect on expression of LUC from promoterless polluc plasmid. Deletions of sequences from -194 to -54 or from -269 to -54 had no significant effect on stimulation of TH promoter activity. This indicated that POU/OCT and AP-1 elements contained within deleted regions may not participate in depolarization induced activation of TH gene, and that remaining elements including proximal CRE and further upstream sequences may be sufficient. In contrast, in parallel studies we showed that Ca\*\*/PKC-dependent activation of TH gene expression by angiotensin II receptors was mediated by multiple regions of the TH promoter including those upstream from -54 nt (Stachowiak, abstract). Thus, different signaling pathways and promoter mechanisms participate in synaptic and hormonal induction of the TH gene.

## 112.12

TISSUE-SPECIFIC DNA METHYLATION AND DNASE HYPER-SENSITIVE SITES IN THE PROMOTER AND TRANSCRIBED REGIONS OF THE RAT PREPROENKEPHALIN GENE T. Funabashi\*, P. J. Brooks, C. Mobbs and D. W. Pfaff

Box 275, The Rockefeller Univ., New York, NY 10021
To examine the mechanisms involved in tissue-specific regulation of preproenkephalin (PPE) gene expression, we have studied the methylation state of C-residues in the promoter and intron A regions of the PPE gene. Rat genomic DNA was digested with the methylation sensitive restriction enzyme Hpall, followed by southern blot analysis using single stranded DNA probes produced by linear PCR (Soc. Neurosci. Abst. 17:219.5,1991). We found that two sites in the promoter region are partially methylated in all tissues examined (liver, testis, brain and adrenal gland), and that the methylation pattern of the sites varies significantly between tissues. In contrast to the promoter region, two sites within intron A were found to be completely unmethylated in all tissues. We have also investigated the chromatin structure of the PPE gene using the DNase hypersensitivity (DH) assay. Crude nuclei isolated from fresh tissues were digested with DNase and DH's were mapped by indirect end-labeling with single stranded DNA probes. Several DH sites, which are located near the TATA box and within transcribed region, have been identified in brain, including the caudate, cortex, ventromedial hypothalamus (VMH), and adrenal gland. In liver, only one site is present, suggesting that the identified sites in brain and adrenal gland correlate with PPE gene expression. Since estrogen increases PPE mRNA in the VMH, we are presently determining whether estrogen can induce any additional DH sites in VMH nuclei.

# 112.14

CHARACTERIZATION OF BRAIN MEF-2 ACTIVITY. D. Kraine\*, D. Leifer, Y.-T. Yu, R. E. Breitbart, R. L. Neve, B. Nadal-Ginard, and S. A. Lipton. Depts. of Neurology, Cardiology, and Psychiatry, Harvard Medical School, Boston, MA. We have cloned a novel transcription factor that belongs to the MADS (MCM1-AGAMOUS-DEF A-serum response factor) family and is expressed in brain and muscle. Our transcription factor has several information of the proceedings of the processing and brinds repetitedly to the mycotte specific and process birding.

We have cloned a novel transcription factor that belongs to the MADS (MCM1-AGAMOUS-DEF A-serum response factor) family and is expressed in brain and muscle. Our transcription factor has several isoforms and binds specifically to the myocyte-specific enhancer binding factor-2 (MEF-2) regulatory element and to a variant MEF-2 site present in the promoter region of the brain creatine kinase gene (Leifer et al., this meeting). A nuclear factor that has previously been identified only in muscle binds to the MEF-2 site ([C/T]T[A/T]AAATA[A/G]), and MEF-2 activity in muscle correlates with muscle differentiation.

Here, we show that a factor present in nuclear extracts from rat brain (P2) and from human fetal cerebral cortex also binds to the MEF-2 site. The binding is specific since it is competed by excess unlabeled probe in gel-shift assays but not by certain double-stranded oligonucleotides with mutated MEF-2 sites. An antiserum against our cloned proteins specifically recognizes the MEF-2 binding activity in both extracts. The endogenous brain activity and in vitro-translated proteins derived from our cDNA clones have indistinguishable properties both in terms of their electrophoretic mobility and their target specificity as determined by gelshift assays. In addition, there is no MEF-2 binding activity in extracts of human fetal brainstem, where we have not detected RNA transcripts of our clones by Northern blotting. Our findings raise the possibility that the MEF-2 activity that we have identified in brain has a specific role in neural development.

### 112 15

CHARACTERIZATION OF THE RAT B-50/GAP-43 PROMOTER. B.J.L. Eggen\*, L.H. Schrama, E.R.A. Jap Tjoen San and W.H. Gispen. Rudolf Magnus Inst., Lab. Physiol. Chem., Inst. Molec. Biol. & Med. Biotechnol., Univ. of Utrecht. Padualaan 8, 3584 CH Utrecht, The Netherlands.

In an attempt to determine regulatory elements controlling transcription of the neural-specific phosphoprotein B-50 (GAP-43) we have characterized a B-50 promoter and modulatory regions located within the first 1016 basepairs (bp) upstream (5') of the ORF. B-50 promoter constructs are driving the firefly-luciferase gene as a reporter, and their activities are assayed via lipofection in P19 EC cells. Transfection efficiency and cell number are corrected for by co-transfecting the B-50 constructs with the Rous Sarcoma Virus (RSV) promoter fused to the LacZ gene. The RSV promoter fused to luciferase is used as an internal reference for B-50 promoter activity. The murine embryonal carcinoma cell (EC) line P19 and its differentiated derivatives are used as a model system for a neural and non-neural specific cell line. Previous experiments (1) have shown an increase in B-50 mRNA and protein levels after differentiation by aggregation in the presence 10 °M retinoic acid (RA). In these cells cence is restricted to neurons. Transfections in P19 EC cells which were either aggregated in the presence of 10.6M RA, resulting in a heterogenous culture consisting of neurons, glia and fibroblasts, or in the absence of RA, yielding a non-neuronal phenotype thereby generating a system in which possible neural-specific element(s) in the B-50 promoter can be determined within one cell

Deletion of the stretch of 80 alternating AG residues shows a decrease (±50%) in promoter activity as compared to the 1016 bp construct, only when the first 115 bp 5' of the ORF are present. The 1016 bp construct itself reaches up to 15% of the activity of the RSV promoter. Studies of truncated promoter contructs, to determine modulatory elements are currently under investigation. 1) Jap Tjoen San *et al.*, <u>Abst. Soc. Neurosci.</u> 17, 222.9: 1991.

DIFFERENTIAL EXPRESSION OF NEUROTRANSMITTER TRANSPORTER GENES IN WILD TYPE PC12 CELLS AND IN WNT1-EXPRESSING FLAT CELL VARIANTS. Ramachandran, K. Houben and B. D. Howard\*. Dept. of Biol. Chem. UCLA Sch. of Med. Los Angeles, CA 90024

Wild type PC12 cells exhibit several sodium-dependent transporters for various catecholamine and amino acid substrates exclusive of aspartate. Flat cell variants, including those induced by expressing the Wnt-1 oncogene, lack catecholamine uptake but do take up aspartate. This difference in aspartate transport makes the flat cells more sensitive to alanosine, a toxic aspartate analog. Using PCR and degenerate oligonucleotides corresponding to the conserved regions of previously cloned transporters, we obtained partial clones for several distinct transporter cDNAs from PC12 wild type and flat cell variant cells. These partial clones were subsequently used to screen cDNA libraries to obtain full length clones. One of these clones is almost identical in sequence to the The other clones are human norepinephrine transporter. homologous to, but distinct from all previously cloned neurotransmitter transporters. Northern blot analysis revealed that these clones are expressed differentially by wild type and flat cell variant PC12 cells and by rat brain and liver. These results suggest that transporter expression can be used to study the signalling pathway induced by Wnt-1.

## 113.1

CHARACTERIZATION OF ENHANCER, SILENCER, AND GROWTH FACTOR RESPONSIVE REGULATORY SEQUENCES IN THE PROMOTER FOR THE MOUSE CHOLINE ACETYLTRANSFERASE GENE Haifeng Pu\*, Ping Zhai, and Mark Gurney Department of Cell, Molecular & Structural Biology, Northwestern University, 303 East Chicago Ave. Chicago, IL 60611.

A genomic clone containing the upstream flanking region of the mouse choline acetyltransferase gene has been isolated and functionally characterized. The transcription start-site was determined by RNA primer extension. ChAT promoter-lacZ fusion genes have been constructed and transfected into various cell lines. Transient expression of  $\beta$ -galactosidase in transfected cells showed that the ChAT DNA spanning -930 to +335 confers promoter activity in cholinergic neuronal PC12 cells, but not in the noncholinergic neuronal cell lines B 103 and F11, or in the myoblast cell line L6. Cholinergic-cell type specific promoter activity was lost by deleting the region from -935 to -558. Both NGF and bFGF potentiated promoter activity of the -935 to +335 construct in PC12 cells. Growth factor responsiveness was lost when the region from -935 to -499 was deleted from the constructs. Enhancer activity was localized to the region -430 to -115 by its ability to activate by more than 10-fold transcription from a heterologous, minimal SV40 promoter and addition of the region -825 to -430 to the construct conferred responsiveness to NGF. Thus, the region from -925 to -558 upstream of the ChAT gene transcription start-site contains a probable silencer which restricts expression to cholinergic PC12 cells, NGF and bFGF responsive regulatory elements reside in the region -825 to -430 and enhancer elements have been mapped to the region -430 to -115.

POSITIVE TRANSCRIPTIONAL ACTIVITY OF LIKE ELEMENT IN THE PROMOTER REGION OF THE DYNORPHIN GENE. D.J. Messersmith\*, J. Gu, R. Dubner, J. Douglass, M.J. Iadarola. Neurobiology and Anesthesiology

Branch, NIDR, NIH, Bethesda, MD 20892.

During experimental nerve injury and inflammation, spinal cord dynorphin gene expression is markedly increased. While multiple protein-DNA interactions likely regulate such transcription, we have focused on a promoter element located at -1546 which has sequence similarity to the AP-1 element and homology with the ENKCRE2 enhancer. The dynorphin AP-1-like site (DAP), TGCGTCA, differs from the AP-1 consensus sequence (TGAGTCA) by a one base-pair substitution. previous studies demonstrated that a Fos and non-Fos-containing protein-DNA complex formed with DAP-containing oligonucleotides using nuclear extracts of CNS regions or HeLa cells. To examine the functional significance of the DAP site, constructs of 100 and 350 base pairs containing the DAP site and a non-DAP containing 250 base pair region were subcloned into the pCAT-promoter plasmid vector with a 200 base pair region containing the minimal dynorphin promoter. heLa or PC-12 cells were transiently transfected with these plasmids and levels of the CAT reporter gene were measured in cell extracts. In cells transfected with constructs containing the DAP site, CAT conversion levels were approximately four-fold greater than in cells transfected with the non-DAP containing In cells transfected with constructs containing the construct. These data support the role of this site as a positive transcriptional regulatory element of the dynorphin gene.

CHARACTERIZATION OF HORMONE RESPONSE ELEMENTS IN THE RAT OXYTOCIN PROMOTER Roger A.H. Adan, Sophia F. Lopes da Silva, Joke J. Cox. H. Rigter\* and J. Peter H. Burbach Rudolf Magnus Institute, Department of Pharmacology, Medical Faculty, University of Utrecht; \*Gezondheidsraad, Den Haag, The Netherlands.

The oxytocin (OT) promoter has several TGACC motifs suggesting that it is regulated by members of the ER/TR subfamily of nuclear receptors. The transactivation of the OT gene by estrogen, retinoic acid (RA) and thyroid hormone is demonstrated in transient heterologous expression systems using luciferase as reporter enzyme. One region confering RA-responsiveness was located between nucleotides -172 and -148 and another was located between nucleotides -112 and -77 from the start site of transcription. The same regions were involved in estrogen transactivation of the OT gene. Both these regions were bound by the estrogen receptor (ER) and the DNA-binding domain of RARB as shown by gel retardation and footprint analysis. This profile of RA- and ER-responsive elements in the rat OT promoter was different from that of thyroid hormone-responsiveness, but overlap was found in the -172/-148 element. Another member of this nuclear receptor family for which thusfar no ligand has been found and which is known as the COUP factor suppressed the transactivation by estrogen via the same element. This element can be considered as a composite hormone response element, forming an important enhancer for the regulation of OT gene expression. The core sequence of this element GGTGACCTTGACC was analyzed in more detail by site directed mutagenesis. The sequence motifs within this element necessary for optimal transactivation by the different receptors differed. The organization of the regulatory regions in the OT promoter suggests that the rat OT gene can integrate multiple stimuli to be able to exert an adequate transcriptional response. The composite hormone response element renders the OT gene to a potential target for multiple members of the ER/TR/RAR subclass of receptors in the brain.

# 113.4

A CLONE ENCODING A PROTEIN THAT BINDS TO AN UPSTREAM REGULATORY ELEMENT IN THE PROMOTER REGION OF THE RAT PRODYNORPHIN GENE. J.Gu, D.J.Messersmith, R.Dubner\* and M.J.Iadarola. Neurobiology and Anesthesiology Branch, NIDR, NIH, Bethesda MD 20892.

An upstream regulatory element (URE) in the promoter

region of the rat prodynorphin gene was identified by gel mobility shift and footprinting assays. The URE contains a pyrimidine-rich, initiator (Inr) consensus sequence YAYTCYYY at -209 from the transcription start site. Trans transfection assays of PC12 cells suggest that the URE is important for optimal expression of a chlorambenical accurate. transfered assays of PC12 cens suggest that the URE is important for optimal expression of a chloramphenicol acetyl transferase reporter gene. Labeled URE was used for southwestern screening of a rat brain cDNA library. Two clones UreB1 and UreB2 were isolated. One of them, UreB1, has been characterized further. It contains a 1.9 kb cDNA insert with an open reading frame that encodes a 309 amino acid polypeptide. Fusion protein, induced by IPTG from the UreB1 clone, was capable of forming a complex with a labeled Ure-containing oligonucleotide in a gel mobility shift assay. In comparison to sequence data bases, UreB1 is a novel molecule comparison to sequence data bases, UreB1 is a novel molecule at both the DNA and protein levels. UreB1 does not bear structural motifs for known DNA binding proteins. Northern blots showed that transcripts of the UreB1 gene were expressed in a tissue specific fashion and widely expressed in regions of the CNS. The results suggest that UreB1 is a novel transcription factor involved in the control of expression of the prodynorphin gene, and possibly other genes, in the CNS.

REGULATION OF PINIT GENE PROMOTER CONSTRUCTS TRANSFECTED INTO MEDULLOBLASTOMA AND PRIMARY ASTROCYTE CELL LINES. L.M. Hemmick\*, M.E. Ross\*, E.F. LaGamma, and M.J. Evinger "Depts. of Neurobiol.& Behav., Pediatrics, SUNY Stony Brook, \*Dept. Neurol., Univ. Minn.

Promoter constructs for phenylethanolamine N-methyltransferase (PNMT), exhibit considerable cell specificity of expression in transient transfection assays. Studies of gene expression in terminally differentiated cells of neuronal origin have generally been limited by low efficiencies of transfection and reproducibility. We sought to identify replicating cell lines capable of expressing PNMT gene constructs that also share regulatory features common to adrenal ry PNMT expression. We report that the human medulloblastoma line TE 671 (provided by R.J. Lukas), and primary rat striatal astrocytes each possess features suitable for investigating neural regulation of the PNMT gene.

TE 671 cells express nicotinic plus M3 and M4 muscarinic AChRs. When TE 671 cells were electroporated with constructs containing the proximal 900 bp of the rat PNMT promoter, both nicotine (50 uM) and carbachol (200 uM) increased CAT and luciferase reporter gene expression. Hexamethonium (50) uM) blocks the nicotine response, while the muscarinic antagonist atropine (20 uM) partially inhibits the carbachol increase, thus indicating that nicotinic and muscarinic AChRs are coupled to PNMT expression in these cells.

Primary rat astrocytes likewise support basal expression of the 100 and 900

bp PNMT-CAT constructs. Muscarine increases CAT expression ~3 fold for both constructs. However, nicotine fails to increase CAT production, consistent with the reported lack of nAChRs on astrocytes. Consequently, astrocytes provide a suitable system in which to examine cholinerals regulation of the PNMT gene exclusively by muscarine. Therefore, TE 671 cells in conjunction with primary striatal astrocytes are two convenient alternatives to primary cultures for the study of cholinergic regulation of the PNMT gene.

IDENTIFICATION OF A BIFUNCTIONAL GENETIC REGULATORY ELEMENT IN THE RAT DOPAMINE B-HYDROXYLASE GENE. E.J. Lewis'. D. Greco. L. Asnani and J. Shaskus. Dept. Biochemistry and Molecular Biology, Oregon Health Sci. Univ., Portland, OR 97201

Dopamine B-hydroxylase (DBH), the enzyme which converts dopamine to norepinephrine, is expressed in a cell-type restricted pattern in neuroendocrine tissue. The molecular mechanisms which contribute to specificity of expression of this enzyme were investigated by an analysis of the specificity of expression of this enzyme were investigated by an analysis of the genetic regulatory elements present on the rat gene. A segment of the gene containing 395 bases of 5-flanking sequence was cloned adjacent to a reporter gene. When transfected into mammalian cells, this construct is expressed in a cell-type specific pattern, with the highest level of expression observed in the human neuroblastoma cell line SHSY-5Y. Progressive deletion of the 5-flanking sequence led to the identification of a 30 base genetic regulatory element, designated DB1. Recombinants containing multiple copies of DB1 cloned adjacent to a heterologous promoter exhibit a 5-20 fold elevation in reporter activity when transfected into neuroendocrine cell types, but do not enhance transcription in C6 glioma or CV1 kidney cells. DB1-specific DNA-protein complexes are found in nuclear extracts from all cell lines examined, and the migration pattern differs between cell lines. The 5-flanking region of the DBH gene also contains genetic regulatory elements responsive to cyclic AMP and phorbol ester stimulated second messenger pathways. DBH mRNA and reporter gene activity are increased in neuroblastoma cells treated with these effectors, and simultaneous treatment

neuroblastoma cells treated with these effectors, and simultaneous treatment with both agents results in a synergistic response. Deletion analysis has localized the second messenger response site to the region containing the DB1 element. Reporter plasmids containing the DB1 element respond to treatment with inducers with an increase in reporter gene activity. The results of this study identify a cis-acting element in the dopamine  $\beta$ -hydroxylase gene which acts as a dual function transcriptional enhancer, influencing both cell type specificity and the response to second messengers.

# 113.9

RAT GAD65 CONTAINS TWO TRANSCRIPTION START SITES. C.S. Pinal\* and A.J. Tobin, Department of Biology, University of California, Los Angeles, California, 90024.

Our laboratory has cloned the human and rat genes encoding the 67,000 and 65,000 Mr forms of glutamic acid decarboxylase (GAD<sub>67</sub> The human GAD<sub>67</sub> gene contains at least two transcriptional start sites in human adult and fetal brain (Erlander and Tobin, J. Neurochem., in press). The rat GAD<sub>65</sub> gene also contains at least two transcription start sites. We are using ribonuclease protection assays to determine whether the two start sites in adult rat brain are used in a region-specific or developmentally regulated manner. Computer analysis of the genomic sequence upstream of the proposed transcription start sites for rat GAD<sub>65</sub> contains sequence similarities to the consensus sequences for several transcription factors, including pancreas-specific transcription factors, whose significance we are evaluating in transient expression assays. (supported by NS22256)

PROMOTER ORGANIZATION OF HUMAN MONOAMINE OXIDASE (MAO) A AND B GENES. Q.S. Zhu, J. Grimsby and J.C. Shih\*. Dept. of Mol. Pharm. and Tox., Sch. of Pharmacy, Univ. of Southern California, Los Angeles, CA 90033.

The promoter regions for human MAO A and B genes have been characterized using a series of 5' flanking sequences linked to a human growth hormone reporter gene and transfected into NIH3T3. SHSY-5Y and COS7 cells. The highest promoter activity is found in a 0.14 kb Pvull/Drall fragment (A0.14) for MAO A and a 0.15 kb Pstl/Nael fragment (B0.15) for MAO B. Both fragments are GC rich, contain potential Sp1 binding sites and are in the region where the MAO A and B 5' flanking sequences share the highest identity. However, the organization of the transcription elements are different between these two promoters. Fragment A0.14 consists of three Sp1 sites, all in reversed orientations and lacks a TATA box. Fragment B0.15 contains a Sp1-CACCC-Sp1-TATA structure. Additional transcription elements are found in further upstream sequences of both genes, inclusion of these sequences decreases promoter activity. The different promoter organization of MAO A and B genes may provide the basis for their different tissue and cell specific expression. ## 113.8

DISCORDANT ESTIMATES OF TPA-INDUCED CMV PROMOTER ACTIVITY AS DETERMINED BY REPORTER GENE MRNA LEVELS AND ENZYMATIC

AS DETERMINED BY REPORTER GENE mRNA LEVELS AND ENZYMATIC ACTIVITY. D.M. Kovacs\*and B.B. Kaplan, Dept. of Psychiatry, Univ. of Pittsburgh Sch. of Med., Pittsburgh, PA 15213

Transient cell transfection methodology is widely employed in the analysis of neural-specific gene expression. To augment the sensitivity of the transfection assay in neural clonal cell lines, we have employed quantitative PCR to assess reporter gene activity. Advantage was taken of the API elements present in the human cytomegalovirus (CMV) promoter to compare both basal and stimulated transcription activity. and stimulated transcription activity by PCR and standard enzymatic assay. The CMV promoter fused to the  $\beta$ -gal reporter gene, was introduced into human neuroblastoma SK-N-BE(2)-C cells, and cultured in the presence TPA (0.1  $\mu$ M), various time periods. Surprisingly, significant differences were observed in the TPA induction profile of GMY promoter activity, as judged by  $\beta$ -gal mRNA levels and activity. For example, 24 h post-transfection  $\beta$ -gal mRNA levels increased 2.4 fold in TPA-treated cells, whereas 7.3 fold increases were observed in  $\beta$ -gal activity. This apparent discrepancy could derive from TPA-induced alterations in (1)  $\beta$ -gal mRNA translation efficiency, post-translational modification of the enzyme, or (3) half-life of the protein. Regardless of the mechanism, these findings raise a cautionary note on the reliance of reporter gene activity to estimate the transcriptional activity of heterologous promoters.

# 113.10

CAMP-MEDIATED TRANSCRIPTIONAL REGULATION OF GENE EXPRESSION IN C6 CELLS. G.M. Lawless, J. Segovia, M. Brenner, and A.J. Tobini, Department of Biology, Brain Research Institute, and Molecular Biology Institute, University of California, Los Angeles, CA 90024, and <sup>2</sup>Lab. of Molec. Biol., NINDS-NIH, Bethesda, MD 20892. The C6 rat neuroglioma cell line is known to exhibit strong biochemical

responses to increased intracellular cAMP, which are accompanied by major morphological changes. We have previously reported that such increases in cAMP result in a decrease in both GAD<sub>67</sub> mRNA and GAD activity (Segovia, J. et al. *Neurosci. Abs.*, 17:159.11, 1991). These decreases appear to represent a shift from a neuronal to glial phenotype. Using forskolin, which directly stimulates adenylate cyclase, we have observed increases in GFAP mRNA levels. In order to determine if these changes in gene expression occur at the transcriptional level, we have obtained the DNA sequences of the human GFAP gene, 5' to the transcriptional start site, linked to the CAT reporter gene. This construct was transiently transfected into C6 cells, and the transfected cells were treated with forskolin and assayed for CAT activity. Preliminary results show a 300% increase of CAT activity. This result suggests that at least part of the observed increase in GFAP mRNA results from an increase in transcription. We have linked 5' upstream DNA sequences of the human GAD67 gene, previously cloned in our laboratory, to a CAT reporter vector. We are currently studying the transcriptional regulation of the GAD<sub>67</sub> gene in forskolin- treated C6 cells. (Supported by NS22256 and The Scottish Rite Schizophrenia Research Program)

VARIABLE MODES OF HUMAN GONADOTROPIN-RELEASING HORMONE(GNRH) GENE TRANSCRIPTION IN JEG AND MDA CELL LINE. K.W. Dong and J.L.Roberts\* Fishberg Research Center for Neurobology, Mount Sinai Medical Center, New York, N.Y.10029

Previous studies have shown GnRH gene expression in the human hypothalamus with a transcriptional start site similar to that observed in rodent hypothalamus, however GnRH expression in non-brain tissue appeared to have additional 5' promoter starts. Since several non-brain cell lines are being used to study GnRH promoter structure, we characterized the transcriptional start sites in these cells. By using ribonuclease protection assay and primer extension, we identified an upstream transcriptional start site in a human placental tumor cell line (JEG) and a human breast tumor cell line (MDA). The downstream start site has a typical TATA box (-25 to-31) and CAAT box (-49 to -52) while the upstream start site lacks the TATA and CAAT box. However, the upstream start site contains the sequence 5'-GTCTTGCT-3' (84 bases upstream )that is similar to the sequence 5'-CTCCCTGCT-3' located in the 5'-flanking region of the murine brain expressed Thy-1 gene, which also lacks TATA and CAAT boxes and has multiple transciption start sites. In JEG cells about 68% and in MDA cells about 81% of the GnRH mRNA is transcribed from the upstream start site in both cytoplasm and nucleus. The mRNA encoded from this upstream transcriptional start site still encodes the GnRH precursor protein. These results indicate that human GnRH gene actively uses an upstream start site for mRNA transcription in the tissues outside the brain.

## 113.13

FUNCTIONAL ANALYSIS OF THE cis-ACTING ELEMENTS INVOLVED IN EXPRESSION AND REGULATION OF TRYPTOPHAN HYDROXYLASE GENE S. O. Huh\*, D.H. Park, T. H. Joh, and J. H. Son Lab. of Molecular Neurobiol. Cornell Univ. Med. Coll., The Burke Med. Res. Inst., White Plains, NY 10605

Res. Inst., White Plains, NY 10605

Tryptophan hydroxylase (TPH), the rate-limiting enzyme in the biosynthesis of serotonin, is expressed in a distinct cell-type specific manner. To identify the cis-acting regulatory elements of the mouse TPH gene that direct this tissue specific expression in both neuronal and non-neuronal tissue types, we carried out both in vitro and in vivo functional analyses. A mouse mastocytoma cell line that expresses TPH was used to test TPH promoter activity in a transient transfection assay. A series of constructs containing TPH upstream sequences of varying lengths fused to a firefly luciferase (Luc) reporter gene were constructed and examined for their ability to confer expression. The 1.1kb-Luc construct showed at least 20 fold more activity than that of promoter-less Luc plasmid. In addition, this construct represented 20% of the activity of a positive control vector, pRSVLuc, suggesting that the functional promoter/enhancer elements for appropriate expression of the mouse TPH gene in this cell type were located in the 1.1 kb 5:-flanking region. In order to corroborate our results from the transfection experiments, we also generated transgenic lines containing two different TPH-lacZ fusion constructs, pWH6.4-LacZ and pWH1.1-LacZ, containing TPH promoter fragments with 5' endpoints at -6.4 kb and -1.1 kb, respectively. Four transgenic lines containing pWH1.1-LacZ and 5 lines with pWH6.4-lacZ transgene were established. The expression pattern of these gene constructs in transgenic mice will permit us to determine if 1.1 kb is sufficient for tissue specific expression in typo.

DISCOORDINATE REGULATION OF α-2 AND β-3 nAChR GENE EXPRESSION IN THE DEVELOPING RETINA: CLONING AND CHARACTERIZATION OF THE α-2 AND β-3 nAChR GENE PROMOTERS F. Hoover\*, F. Locklear and D. Goldman, Department of Biological Chemistry and Mental Health Research Institute University of Michigan, Ann Arbor, MI. 48100

Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109. We have previously shown that the nicotinic acetylcholine receptor (nAChR) α-3, α-4, β-2, β-3 and β-4 subunit genes are induced in developing rat retinal cells around E13-14 (Exp. Eye Res., in press). Retrograde labelling and the anatomical position of these cells indicated that they were recently differentiated ganglion cells. We have now identified a member of the nAChR gene family (α-2) whose expression in the developing retina is not temporally correlated with the above nAChR subunit genes. RNase protection assays show the α-2 gene is induced in the postnatal retina. In situ hybridizations are being performed to determine the retinal cell type(s) expressing the

α-2 gene. In order to determine the molecular mechanisms by which nAChR genes are induced in the retina, we have cloned the  $\alpha$ -2 (induced postnatally) and  $\beta$ -3 (induced at E13-14) gene promoter regions. We have mapped the 5' ends of the mRNAs encoding the  $\alpha$ -2 and  $\beta$ -3 genes and report that both genes use multiple transcriptional start sites. The DNA sequence has been determined for 1354 nucleotides and 570 nucleotides 5' to the initiator methionine of the  $\alpha$ -2 and  $\beta$ -3 genes, respectively. Canonical promoter CCAAT and TATAA sequences were not present in the  $\alpha$ -2 gene. However, the  $\beta$ -3 gene contained a CAAAAAT sequence and a TAATAA sequence 168 nucleotides and 109 nucleotides upstream from the most 5' start site, respectively. In order to identify cis-acting DNA sequences conferring tissue and developmental stage-specific expression, we have constructed expression vectors with the  $\alpha$ -2 or  $\beta$ -3 promoter driving the expression of a luciferase structural gene. Introduction of these expression vectors into retinal, neuronal, muscle, and fibroblast-like cell indicates the  $\alpha$ -2 gene is promiscuously expressed, while the  $\beta$ -3 gene is preferentially expressed in retinal and muscle cells

FUNCTIONAL ANALYSIS OF THYMOSIN BETA-10 GENE PROMOTER REVEALS ELEMENTS SENSITIVE TO RETINOIC ACID AND AT LEAST ONE NUCLEAR RETINOIC ACID RECEPTOR. M.K.Sihdu.,M.R.Condon.,S.D.Cook\* and A.K.Hall.,Depts of Surgery & Neuroscience, UMDNJ-NJ Medical School,Newark,NJ 07103,U.S.A.

The 5Kda putative G-actin binding protein, namely, thymosin beta-10 has been identified as a retinoid-responsive gene expressed during the early phases of neuroembryogenesis [see Hall(1991)Molecular Brain Res 9:175-177]. To identify possible regulatory elements (RARE) in the beta-10 gene we constructed a chimeric expression vector harboring a Taq 1 restriction fragment containing approximately 900bp (which encompass the human beta-10 gene promoter and 5'flanking region) cloned upstream from the bacterial CAT reporter gene. Retinoic acid (RA) failed to induce CAT activity in rat NB cells but did induce a 3-5 fold stimulation of CAT in human osteosarcoma cells cotransfected with the hRAR-alpha gene. These findings in concert with DNA sequence analysis favor the likely presence of elements responsive to at least one class of nuclear retinoic acid receptor in the human thymosin beta-10 gene promoter.

THE 5' UPSTREAM REGION OF THE HUMAN DOPAMINE-\$-HYDROXYLASE GENE DRIVES TRANSCRIPTION IN A CELL-TYPE SPECIFIC MANNER. H. Ishiguro', T.H. Joh and K.S. Kim. Cornell Univ. Med. Coll. at the Burke Med. Res. Inst., White Plains, NY 10605.

Dopamine-β-hydroxylase (DBH) catalyzes the conversion of dopamine to norepinephrine. In vivo, DBH expression is limited to adrenergic and noradrenergic neurons as well as chromaffin cells of the adrenal gland, indicating the existence of tight tissue-specific regulation of this gene. In order to gain a better understanding of the underlying molecular mechanisms involved in transcriptional control of the human DBH gene, a genomic clone containing 4.3 kb upstream region of the DBH gene was isolated from a human placenta genomic library. A series of deletion constructs fused to the chloramphenicol acetyltransferase (CAT) gene were prepared. Transient transfections in DBH-expressing human neuroblastoma SK-N-BE(2)C and DBHnonexpressing HeLa cell lines indicated that the upstream region of the human DBH gene directs transcription in a cell-type specific manner. Furthermore, when the upstream sequence was deleted to -1.0 kb or -262 bp, CAT activity increased 2-fold and 4-fold, respectively, indicating the presence of some negative elements in this upstream region. When the upstream region was further trimmed up to -114 bp, >90% of the CAT activity disappeared. These data suggest that there is an important positive element(s) in a region ranging from -262 to -114 bp. Supported by MH24285.

REGULATION OF TYROSINE HYDROXYLASE GENE EXPRESSION BY CYCLIC AMP AND PHORBOL ESTER. Y. Chen\*, J.A. Best and A.W. Tank, Department of Pharmacology, University of Rochester, Rochester, NY 14642.

The specific intracellular signal transduction pathways that mediate the regulation of tyrosine hydroxylase (TH) gene transcription rate are not known. Receptors that are linked to the elevation of cyclic AMP and the activation of phosphatidylinositol turnover have been shown to regulate TH gene expression in vivo. We have used transiently transfected rat pheochromocytoma cell lines to test the effects of cyclic AMP analogs and phorbol esters on the TH gene promoter-driven expression of the reporter gene, chloramphenicol acetyltransferase (CAT). The wild-type pTH-CAT construct (pTH.3-CAT) contains the region from -272 to +27 of the TH gene promoter linked upstream to the coding region of CAT. A second construct (pTH.3mCRE-CAT) contains this same promoter region in which the cyclic AMP response element (CRE) is mutated. Both these constructs are kind gifts from Dr. Dona Chikaraishi, Tufts University. Both the cyclic AMP analog, 8-CPT-cyclic AMP and the phorbol ester, TPA, increase the expression of CAT in all tested rat pheochromocytoma cell lines transfected with pTH.3-CAT. As expected, 8-CPT-cyclic AMP does not increase CAT expression in cells transfected with pTH.3mCRE-CAT. Surprisingly, in rat pheochromocytoma PC18 cells the effect of TPA on CAT expression is totally blocked by mutating the CRE. However, this dependence of the TPA effect on an intact CRE is cell-line dependent, because the response to TPA is only partially inhibited using the mutated CRE construct in two other cell lines. In all tested cell lines, the basal expression of CAT is diminished, when the CRE is mutated compared to that observed using the wild-type promoter. These results suggest that the TH gene CRE participates in the response of the gene to receptors that elevate cyclic AMP and in some cell types to receptors that activate protein kinase C. The TH gene CRE may also play a role in maintaining the basal transcription rate of the TH gene. (Supported by DA 05014 and DE 00159).

PROTEIN INTERACTIONS WITH A PUTATIVE API ELEMENT IN THE RAT TYROSINE HYDROXYLASE GENE PROMOTER. K.M. Piech\*, J.A. Best and A.W. Tank, Department of Pharmacology and Department of Dental Research, University of Rochester, Rochester, NY 14642.

Using gel shift assays rat pheochromocytoma PC12 cell extracts were used to examine protein binding to a portion of the rat TH gene promoter (-192 to -212) that contains a consensus AP1 binding sequence (GTGATTCAGA). The affinity and/or level of proteins binding to the TH gene AP1 element was increased in nuclear extracts isolated from PC12 cells treated for 3 hr either with a cAMP analog or with phorbol 12-myristate 13-acetate (PMA). The binding of proteins to the AP1 element was shown to be specific in gel shift assays utilizing competitor DNAs. Formation of the TH gene AP1-protein complex was inhibited, when an antibody to c-fos was preincubated with the PC12 cell nuclear extracts. These results suggest that Fos and/or Fos related antigens may participate in the formation of this complex. TH gene AP1-protein binding was also examined in nuclear protein extracts isolated from Sprague-Dawley rat adrenal medullary cells. The protein extracts were isolated 3 hrs. after repeated injections with either saline, bethanechol (5mg/kg) or nicotine (2.3mg/kg). Formation of a protein-DNA complex was apparent using adrenal medullary nuclear extracts isolated from rats treated with bethanechol or nicotine, but not saline. No TH gene AP1-protein complex was formed using rat adrenal medullary nuclear extracts isolated 20 minutes after one injection of saline, bethanechol (10mg/kg) or nicotine (2.3mg/kg). These results suggest that the activation of either cyclic AMP-dependent protein kinase or protein kinase C in PC12 cells may lead to the regulation of the TH gene via the AP1 response element. Furthermore, these data indicate that the TH gene may be regulated by AP1 binding factors in vivo in the adrenal medulla when rats are administered cholinergic agonists repeatedly. ## 113.19

NUCLEAR FACTORS INTERACTING WITH THE CHICK MUSCLE ACETYLCHOLINE RECEPTOR 5-SUBUNIT GENE DURING CHICK EMBRYO DEVELOPMENT. Y. E. Lee\* and J. Schmidt. Dept. of Neurobiol. & Behavior and Dept. of Biochem. & Cell Biol., State Univ. of New York at Stony Brook, Stony Brook, NY 11794.

Transacting factors that interact with the acetylcholine receptor (AChR) δ-subunit enhancer region were studied by EMSA. Nuclear extracts from embryonic hind limb muscle were examined. Two major protein-DNA complexes were observed with a δ-subunit enhancer-derived probe. Using point-mutated DNA fragments as competitors in EMSA and DNAse I footprinting, the specific binding sites were identified as an E-box or MEF1 site and a CG rich element.

Among these complexes, the E-box binding activity is developmentally regulated, with the highest intensity in embryonic day 11 hind limb muscle. The migration of this E-box binding complex can be retarded when a polyclonal antibody specific for human E12/E47 proteins is applied, suggesting that the complex contains a chick E12/E47-like protein.

The mRNA levels of the five bHLH proteins MyoD, myogenin, Myf5, herculin, and CTF4, which have the ability to bind and transactivate E box-containing promoters, were also measured and compared with the mRNA levels of the AChR subunit genes during embryonic hind limb muscle development. Preliminary results indicate that the mRNA expression pattern of MyoD, myogenin, Myf5 and CTF4, but not of herculin, positively correlates with the expression of AChR subunit mRNAs.

EVIDENCE THAT RETINOIC ACID, GLUCOCORTICOIDS AND CYCLIC AMP MAY REGULATE GENE EXPRESSION AT A COMMON REGULATORY SEQUENCE IN C6 GLIOMA CELLS. Wayne A. Schreier\*. Andrus Gerontology Center, Univ. Southern California, Los Angeles, CA 90089-0191.

The upstream regulatory region of the rat glutamine synthetase (GS) gene contains a potential GRE/CRE consensus sequence. 5'-GGTAAAATTCTCT (Mill et al., Mol. Brain Res. 9:197, 1991), with similarity to previously identified glucocorticoid/cAMP regulatory elements. We examined the effects of the combined treatment of hydrocortisone (HC) and forskolin (F) with retinoic acid (RA) on GS activity in C6-2BD cells. HC and F both induce an increase in GS activity. RA reduces both the HC- and Finduced increase in GS activity by ≈ 50%. RA also reduces the basal levels of GS activity to a similar extent. It is possible that HC (via the glucocorticoid receptor) and forskolin (via activation of an ATF/CREB transcription factor) may stimulate GS mRNA transcription by binding at this common site. RA, on the other hand, may inhibit GS mRNA transcription via the retinoic acid receptor binding to this same site in a competitive manner. (This work was supported by NIH grant HD-06576 to Jean deVellis, UCLA Mental Retardation Research Center).

# PRESYNAPTIC MECHANISMS I

# 114.1

Ca++-INDUCED DOCKING OF SYNAPTIC VESICLES AT THE ACTIVE SITE. <u>I.H. Koenig\*, K. Yamaoka and K. Ikeda</u>. Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010.

The involvement of Ca++ in the transmitter release mechanism, while recognized many years ago, is still poorly understood. One process in the release mechanism in which Ca++ may be involved is the translocation and docking of vesicles at the release site, possibly mediated by such vesicle-associated proteins as fodrin, synapsin or actin. In this study, the effect of raising [Ca<sup>++</sup>]<sub>0</sub> on the docking of vesicles at the active site was investigated using the coxal neuromuscular junction of Drosophila. In the resting coxal synapse in normal saline (1.8 mM Ca++) only a small percentage active sites possess vesicles in a docked position under the dense body adjacent to the plasma membrane. After 10 m exposure to 18 mM Ca<sup>++</sup> saline, however, a dramatic increase occurs in the number of sites possessing docked vesicles, as well as in the number of docked vesicles per site. Intracellular recordings reveal that 18 mM Ca++ saline induces both an increase in the frequency of spontaneous release and an increase in the frequency of multiquantal MEJPs. Thus, an increase in the number of sites possessing docked vesicles is accompanied by an increase in spontaneously released MEJPs. Also, an increase in the number of quanta/MEJP is accompanied by an increase in the number of docked vesicles/site.

USE OF ANTISENSE OLIGONUCLEOTIDES WITH THE PATCH-CLAMP TECHNIQUE REVEALS A SMALL GTP-BINDING PROTEIN IN THE CONTROL OF EXOCYTOSIS. P.-M. Lledo\*, R. Zorec¹, P. Vernier² and W.T. Mason, Dept. of Neurobiology, AFRC, Babraham, Cambridge CB2 4AT, U.K.; ¹Inst of Pathophysiol, School of Medicine, 61105 Ljubljana, Slovenia and ²CNRS, Lab de Neurobiol., 91198 Gif-sur-Yvette, France.

Low-molecular-weight GTP-binding proteins (G-proteins) are strong candidates for regulators of membrane traffic. Recently, we have demonstrated that GTP-y-S regulates secretory processes in anterior pituitary cells. To identify the G-protein, we screened G-proteins with Northern blotting and found a high content of a small G-protein of the p21ras superfamily (rab3B protein) in anterior pituitary cells. To determine whether this rab3B protein could have a physiological function, we developed a new approach using patch-clamp recordings and intracellular perfusion of antisense (AS) and sense (S) oligodeoxynucleotides designed to block specifically the translation of rab3B. The whole-cell recording configuration with a dual-phase lock-in amplifier was employed to measure cell membrane capacitance (Cm) to monitor secretory activity, and to load rat pituitary cells with AS or S. Cells were bathed with 5 mM CaCl2 and loaded for 2 min with intracellular solution containing 1 µM Ca<sup>2+</sup> and about 50,000 molecules AS or S. Effects on Ca<sup>2+</sup> induced exocytosis were determined in the same cells 48-52h after loading with oligonucleotides. We found that the calcium-induced increase in membrane capacitance was dramatically reduced by the injection into cells of AS but not S. Endocytotic processes were not altered. These results provide evidence for the involvement and identification of a small G-protein which directly modulates the Ca<sup>2+</sup>-induced exocytosis in anterior pituitary cells.

GTP-BINDING PROTEINS REGULATE SYNAPTIC VESICLE CYCLING. P.A. Doroshenko and G.J. Augustine\*. Dept. Neurobiology, Duke Univ. Medical Center and MBL, Woods Hole.

The non-hydrolyzable GTP analog, GTPγS, inhibits neurotransmitter release when injected into squid giant presynaptic terminals (Biol. Bull. 181, 320,1991). Because this inhibition is not associated with any change in presynaptic Ca signalling, it is possible that the synaptic vesicle cycling pathway may be a target of the nucleotide. We have tested this possibility by using electron microscopy to examine the distribution of synaptic vesicles in terminals. Active zones of control terminals were surrounded by a dense cloud of synaptic vesicles, including a sub-set apparently docked at the presynaptic membrane. Terminals injected with GTP<sub>\gammaS</sub> had a dramatically reduced total number of vesicles associated with the active zone. Comparison of the distribution of vesicles in control and GTP<sub>\gammaS</sub> injected terminals revealed a gradient of vesicle depletion within the active zone, with virtually no depletion of docked vesicles but a 60% loss of vesicles found 0.5  $\mu$ m away from the membrane. The observation that GTP $\gamma$ S inhibits transmitter release without reducing the number of docked vesicles indicates that a GTP-binding protein is involved in a step of the vesicle life cycle that is at or near the docking step. The depletion of upstream vesicles suggests that one or more additional GTP-binding proteins are involved at other steps in the cycle. Supported by NIH grant NS-21624.

## 114.5

THE PRESYNAPTIC EFFECT OF ω-CONOTOXIN ON IPSPS IN RAT HIPPOCAMPUS INVOLVES A PERTUSSIS TOXIN (PTX)-SENSITIVE G-PROTEIN. P. Dutar\*, B. Potier and Y. Lamour. INSERM U161, 75014 Paris France.

The nature of the coupling mechanism of presynaptic calcium channels involved in the release of neurotransmitters in the mammalian central nervous system is unknown. Omega-conotoxin (ω-CgTx) blocks partially the excitatory (EPSP) and totally the inhibitory (IPSP) synaptic transmission in CA1 hippocampal pyramidal neurons through an action on N-type calcium channels. We show in this study that the inhibitory effect of ω-CgTx on IPSP is blocked by the intrahippocampal injection of PTX. PTX (Sigma) (or vehicle for control rats) was injected into str. radiatum (s.r.) of hippocampus (1.5-2µg) of male Sprague-Dawley rats, 3 days before electrophysiological experiment. Intracellular recordings from CA1 neurons in the rat hippocampal slice preparation were performed using standard procedures. EPSPs and IPSPs were induced by electrical stimulation of CA1 afferents in s.r.  $\omega$ -CgTx was applied at 3 different concentrations: 0.1, 0.5 and 1 $\mu$ M. In control rats, ω-CgTx depressed EPSP and IPSP respectively by 23.1 (n=7) and 48% (n=6) at  $0.1\mu M$ , 49.5 and 78% at  $0.5\mu M$  (n=11), 65.7 (n=4) and 91.6% (n=3) at 1µM. In rats pretreated with PTX, percentages of inhibition were respectively 24.2 (n=5) and 20.3% (n=4) at 0.1µM, 40.1 (n=10) and 31.3% (n=9) at 0.5µM, 57.1 (n=5) and 57.9% (n=4) at 1µM.

These results show that 1) IPSPs are more sensitive to the effect of ω-CgTx than EPSPs in control rats; 2) The inhibitory effect of ω-CgTx on IPSPs is blocked (at least in part) by PTX while the effect on EPSP is not. The results suggest that the nature or the regulation of calcium channels might be different depending on their location on excitatory or inhibitory terminals. Supported by grants from Bayer Pharma France and MGEN.

# 114.7

PRESYNAPTIC CALCIUM AND SHORT TERM SYNAPTIC ENHANCEMENT AT HIPPOCAMPAL MOSSY FIBER SYNAPSES: ENHANCEMENT AT HIP OCAMPAL MOSS I FIBER STNAPSES: EXPERIMENTS AND KINETIC MODELING. W.G. Regehr\*, K.R. Delaney and D.W. Tank, Biological Computation Research Dept., AT&T Bell Labs, Murray Hill, NJ 07974.

Calcium in presynaptic terminals ([Ca]) and post synaptic field potentials

exactum in pesynaptic terminals ((Ea)) and post synaptic held potentials were simultaneously measured at hippocampal mossy fiber synapses to examine the role of presynaptic [Ca] in short-term synaptic enhancement. Following the onset of moderate frequency stimulation (.1-5 Hz) both synaptic enhancement and presynaptic [Ca] buildup and reach a steady state plateau. During the plateau phase, a linear relationship between presynaptic [Ca] and synaptic enhancement is observed. However, during the buildup the presynaptic solicium leads rice are president. the initial buildup, the presynaptic calcium levels rise more rapidly than synaptic enhancement. Similarly, during the decay phase immediately following termination of the stimulus train, the Ca decay rate exceeded the

decay rate of synaptic enhancement.

High concentrations of intracellular EGTA greatly slow the buildup and decay of presynaptic [Ca] produced by moderate frequency trains. In the presence of this elevated calcium buffering, the time course of the buildup and decay of synaptic enhancement and presynaptic [Ca] are the same. This suggests that despite the mismatch in time courses observed under normal Ca buffering conditions, increases in presynaptic [Ca] play a causal role in synaptic enhancement.

A simple kinetic model that assumes that synaptic enhancement is controlled by the concentration of a Ca-dependent first order reaction product can account for the temporal mismatch between [Ca] and enhancement. Accordingly, the enhancement is produced by presynaptic calcium, but the biochemical reactions implement a temporal filtering.

INHIBITION OF EXOCYTOSIS BY MYOSIN LIGHT CHAIN KINASE INHIBITOR IN ADRENAL CHROMAFFIN CELLS. M. O.-Imaizumi<sup>1</sup>, T. Sakurai<sup>2</sup>, S. Nakamura<sup>2</sup>, Y. Nonomura<sup>2</sup>, and K. Kumakura<sup>1\*</sup>. <sup>1</sup>Life Science Inst. Sophia Univ., Tokyo 102, and <sup>2</sup>Dept. Pharmacol., Univ. of Tokyo Sch. Med., Tokyo 113, Japan

To elucidate the possible involvement of mvosin light chain kinase (MLCK) in the mechanism of exocytosis, we studied the effects of wortmannin, a specific MLCK inhibitor, on the secretory function of bovine adrenal chromaffin cells. Wortmannin inhibited both acetylcholine-evoked and high K+evoked release of catecholamines (CA). It also blocked the Ca2+-induced release of CA from the digitonin-permeabilized cells. The inhibiton of both high  $K^+\text{-evoked}$  and  $Ca^{2+}\text{-induced}$  CA release was dose-dependent (IC50 = 1  $\mu M$ ), and there was complete inhibition at 10 µM. Thus, MLCK seems to be involved in the mechanism of exocytosis at downstream of Ca2+ increase in adrenal chromaffin cells, although it has been debatable.

## 114.6

REAL-TIME CONFOCAL MICROSCOPY OF DYNAMIC CALCIUM CHANGES IN SINGLE PRESYNAPTIC BOUTONS. DeBello, G.J. Augustine and J.W. Moore\*. Dept. Neurobiology, Duke University Medical Center, Durham, NC 27710.

We have used a Noran confocal laser scanning microscope to measure dynamic changes in calcium concentration ([Ca]) within presynaptic terminals of the lizard (Anolis carolinensis) neuromuscular synapse. The high resolution of this system allows measurement of changes in presynaptic [Ca] in single boutons loaded with the fluorescent Ca indicator, fluo-3-AM. In response to brief trains of action potentials (1-50 Hz, 1-10 s), presynaptic [Ca] rose transiently and subsequently decayed over many seconds. The magnitude and time-course of this Ca signal varied with the number of action potentials and with fluo-3 concentration. In optimum conditions, responses to single action potentials could be detected and the measured changes in [Ca] were approximately 100 nM per action potential. We saw no evidence for independent activation of single boutons; rather, action potentials elevated [Ca] simultaneously in all boutons within a given presynaptic terminal. Additionally, stimulation frequently evoked a damped [Ca] oscillation that superimposed on the decay phase of the response. In summary, we have demonstrated that it is possible to make high-resolution measurements of presynaptic [Ca] dynamics in single boutons. Supported by a NIH grants NS-21624 and NS-03437.

CALCIUM CHANNELS ON HIPPOCAMPAL MOSSY-FIBER NERVE TERMINALS. H.J. Markram, K.E. Krebs\* and E.F. Stanley. NINDS Biophysics Lab, NIH Bethesda Md 20892.

The direct examination of calcium influx through calcium channels in presynaptic nerve through calcium channels in presynaptic nerve terminals in the vertebrate CNS has been greatly limited by the general small size and inaccessibility of these structures. We have used the patch clamp technique to record calcium currents in the unusually large mossyfiber terminals of the rat hippocampus.

The CA3 region of the hippocampus was dissected and acutely dissociated. Nerve terminals were identified with a specific fluorescent stain and were whole-cell patched using the nystatin perforation technique. Voltage steps were applied from a negative

Voltage steps were applied from a negative holding potential of -90 mV. A calcium current was recruited at -50 mV that peaked at -40 mV and exhibited significant inactivation during a 200 ms pulse that was tentatively identified as T-like. In some terminals a second non-inactivating component was recruited at more depolarized voltages (>0 mV).

CALCIUM ENTRY, BUFFERING AND EXOCYTOSIS IN ISOLATED PEPTIDERGIC NERVE TERMINALS. E.P. Seward, \* N. Chernevskaya, and M.C. Nowycky. Dept. Anat. & Neurobiol. Med. Coll. PA, Philadelphia, PA 19129.

Ca2+-secretion coupling in neurohypophysial terminals was studied with the capacitance  $(C_m)$  recording technique (preceeding abst.). Trains of depolarizing pulses (20-200 msec duration; 300-700 msec intervals; delivered every ~1-2 min) elicited  $Ca^{2+}$  entry and  $C_m$  increases.  $Ca^{2+}$  buffering was manipulated by adding exogenous buffers to the pipette. With 0.5 mM EGTA, the first pulse of a train increased C<sub>m</sub> by ~10 fF. This step size occured over a broad range of pulse durations and Ca2+ entry rates. Pulses later in the train can elicit larger C<sub>m</sub> steps (15 to 40 fF), which are often followed by slow, post-stimulus increases (\*, Fig.). With low EGTA (0.1 mM), the first pulse produced a large step. High EGTA (10 mM) abolished all  $C_m$  increases in the train except for the first step (Fig). With BAPTA (0.5 mM), both the first and many of the later pulses elicited small steps; larger steps and "slow" increases were not observed. The effects of buffers in peptidergic terminals are strikingly different from those at a fast synapse (Adler et al., J. Neurosci. 11: 1496, 1991) and will be interpreted using Ca2+ transients predicted from computer modeling (next abst.).

 $C_m$  traces from two terminals, stimulated with 5 pulses, 40 ms duration. [EGTA]<sub>i</sub> = 0.5 mM (top), 10 mM (bottom). \* slow secretion. Total Ca<sup>2+</sup> entry ~ equal for 2 terminals.

## 114.11

THE INFLUENCE OF BUFFER KINETICS ON CALCIUM TRANSIENTS IN A MODEL CELL. M. C. Nowycky, A.G. Romano, \* and M.J. Pinter, Depts. Anatomy &

Neurobiology and Pharmacology\*, Med. Coll. Penn., Philadelphia, PA 19129.

The spatial and temporal profiles of free [Ca<sup>2+</sup>] following Ca<sup>2+</sup> entry through voltage-gated ion channels are shaped by Ca<sup>2+</sup> diffusion and by intracellular Ca<sup>2+</sup> buffers. We have used a model that incorporates Ca2+ diffusion and both fixed and diffusible buffers in a spherical cell to calculate levels of free Ca2+ and of Ca2+-bound buffer in a series of concentric shells. The interaction of buffer affinity, binding rate. and concentration and Ca<sup>2+</sup> current amplitude were explored for a 15 micron diameter cell.

Fixed buffers tend to restrict Ca2+ elevation to the outer shells and slow Ca2+ equilibration. Bound fixed buffer in the outer shells acts a Ca2+ source after termination of Ca2+ influx. Diffusible buffers speed Ca2+ equilibration throughout the cell. The relative contribution of fixed vs. diffusible buffers to shaping the Ca2 transient is determined to a large extent by the forward binding rate of each buffer, with the diffusible buffer dominating at equal binding rates. Buffer affinity has little effect on Ca2+ transient amplitude in superficial shells, despite large effects in deeper shells and at equilibrium. The results of calculations are considered from two viewpoints: 1) the use of various exogenous buffers as tools to experimentally manipulate [Ca2+] and 2) limitations on the use of mobile Ca2+ dyes as indicators of free Ca2+.

CALCIUM IONOPHORE A23187 ACTIVATES REPRESSED SYNAPSES IN THE CRAYFISH. E.R.Smith and S.J.Velez\* Dept. of Biological Sciences, Dartmouth College, Hanover, N. H. 03755.

Neuromuscular synapses in the superficial flexor muscle system of the crayfish <u>Procambarus clarkii</u> become physiologically repressed (no <u>junction potentials</u> are detected under normal physiological conditions) after cutting the nerve in the middle of the muscle field and removing the lateral fibers (Prosser & Velez, Soc. Neurosci. Abstr. 12: 1575, 1986). These repressed synapses do not respond to changes in calcium concentrations of the Ringers bathing the preparation, junction potential (jp) sizes of control synapses increase significantly in size while those few detected from repressed synapses remain essentially constant (Gupta & Velez, Soc. Neurosci. Abstr. 16: 1162, 1990). We suggested then that calcium was involved in the mechanisms underlying repression in this system. In the present experiments we recorded jp's from identificable control and repressed synapses that were bathed in Ringers containing normal and 200% calcium concentrations and Ringers containing the calcium ionophore A23187 dissolved in IMSO. Control synapses showed a 1.3x-1.5x increase in jp sizes in 200% calcium and a 2x-3x increase in jp sizes in the presence of the ionophore. Repressed synapses had no change in jp sizes in 200% calcium but showed a 4x-5x increase in jp sizes in the presence of the ionophore. These results suggest that in repressed synapses the presynaptic calcium channels are not working properly, i.e. they are blocked or have become less voltage sensitive.

## 114.10

GTP-7-S INHIBITS CALCIUM CURRENTS BUT NOT EXOCYTOSIS IN ISOLATED PEPTIDERGIC NERVE TERMINALS. N. Chernevskaya and M.C. Nowycky\*. Dept. Anatomy & Neurobiol., Med. Coll. Penn., Philadelphia, PA, 19129.

Axons of hypothalamic magnocellular neurons project to the neurohypophysis (NHP) where they form numerous large endings that secrete vasopressin or oxytocin in response to bursts of action potentials. Secretion of the neuropeptides is evoked by Ca2+ entry through voltage-dependent Ca2+ channels. Nerve endings were isolated, and whole-"terminal" patch clamp recordings were used to monitor Ca2+ currents. NHP terminals contain both N- and L-type Ca2+ channels (Lemos & Nowycky, Neuron 2: 1419, 1989). Inclusion of 50 or 100 μM GTP-γ-S in the pipette decreased the peak Ca2+ current. The remaining Ca2+ current had slow kinetics of activation (figure). This suggests that Ca2+ channels in peptidergic terminals undergo inhibitory G-protein modulation as previously characterized in neuronal cell bodies.

Time-resolved capacitance measurements were used to monitor changes in surface membrane area  $(\Delta C_m)$  arising from exocytosis.  $C_m$  increased in response to trains of depolarizations (see next abst.).  $Ca^{2+}$  currents remaining in the presence of GTP- $\gamma$ -S were able to trigger  $C_m$  increases. Thus, GTP- $\gamma$ -S does not disrupt  $Ca^{2+}$ -secretion coupling in terminals.

Ca2+ current traces from 2 terminals. Trace (a): typical control. Trace(b): current remaining in presence of 100 μM GTP-γ-S.

A POSSIBLE ROLE OF CALCIUM BUFFERING IN LONG-TERM ADAPTATION OF NEURONS. J. C. McMahon and A. J. Mercier Dept. of Biol. Sci., Brock University, St. Catharines, Ont., L2S 3A1.

Increasing the impulse activity of neurons in vivo over 3 or more days causes a reduction in transmitter release that persists for days to weeks (eg. Mercier & Atwood, J. exp. Biol. 145: 9-22, 1990). This effect is usually accompanied by decreased synaptic fatigue. These two changes involve presynaptic mechanisms and indicate "long-term adaptation" (LTA) of nerve terminals. Previous experiments indicate that LTA requires extracellular calcium and protein synthesis (eg. Hong & Lnenicka, Soc. Neurosci. Abstr. 17: 1322) and appears to involve communication between the cell body and the nerve terminals. The present study examines the possibility that the reduction in transmitter release is caused by an increase in the calcium buffering ability within the nerve terminals. It examines the responses of adapted and control nerve terminals to the exogenously applied calcium buffer, BAPTA-AM. If LTA increases intrinsic Ca2+

calcium buffer, BAPTA-AM. If LTA increases intrinsic Ca<sup>2+</sup>buffering, the membrane permeant form of BAPTA should have less of an effect on adapted nerve terminals than on controls.

Experiments are performed on the phasic abdominal extensor motor neurons of the crayfish, Procambarus clarkii. BAPTA-AM decreases excitatory postsynaptic potentials (EPSP's) of the phasic extensors in a dose-dependent manner between 5 and 50 µM. LTA is elicited by in vivo stimulation at 2.5 Hz for 2 h per day over 3 days, which reduces EPSP's by over 50%. Experiments to date (n=4) indicate that BAPTA-AM produces a smaller change in EPSP's in adapted neurons than in controls. These preliminary results support the hypothesis that impulse activity alters intrinsic calcium buffering. impulse activity alters intrinsic calcium buffering. Supported by NSERC Canada.

DIFFERENTIAL EFFECTS OF CALCIUM ENTRY ON PHASIC AND TONIC MOTOR AXONS OF CRAYFISH. H.L. Atwood and G.A. Lnenicka. Department of Physiology, University of Toronto, Toronto, Canada; and Department of Biological Sciences, State University of New York, Albany, New York 12222.

The closer muscle of the crayfish claw is innervated by two motor axons a obserie axon which Gives only when maximal muscle activity.

axons: a phasic axon which fires only when maximal muscle activity is required, and a tonic axon which is active much of the time and which regulates normal ongoing muscle activity. The phasic axons shows more rapid synaptic depression and is more susceptible to the actions of metabolic inhibitors. We examined these axons with video-enhanced contrast DIC microscopy during exposure to calcium ionophores to observe the effects of calcium entry on axonal transport and mitochondrial morphology. A bundle containing the two axons was mounted in a small perfusion chamber and different concentrations of the ionophore A-23187, in combination with various concentrations of exernal calcium, were delivered. In zero-calcium solutions, axonal transport persisted for over 2 hours. In calcium-containing solutions, axonal transport was blocked in ionophore concentrations of 2  $\mu$ m or higher; mitochondrial morphology was also affected. These changes always occurred first in the phasic axon. The tonic axon apparently is better adapted to handle a calcium load; this may be linked to its normal activity pattern.

RESIDUAL FREE CALCIUM IS NOT RESPONSIBLE FOR FACILITATION OF NEUROTRANSMITTER RELEASE. <u>I. Blundon\*, S. Wright, M. Brodwick, & G. Bittner.</u> Dept. Zoology, Univ. TX, Austin, TX 78712; Dept. Physiology & Biophysics, Univ. TX Medical Branch, Galveston, TX 77550.

Using a two electrode current clamp of the presynaptic terminal and a single microelectrode impalement of the subsynaptic muscle fiber of the crayfish opener neuromuscular junction, we have previously reported that measures of  $\text{Ca}^{2+}$ -activated  $K^*$  conductance  $(gK_{\text{Ca}})$  can be used as a bioassay for submembrane levels of free  $\text{Ca}^{2+}$  within the presynaptic terminal (Sivaramakrishnan et al., 1991, J. Gen. Physiol. 98:1181). We now demonstrate that the time constant (10 of  $gK_{\text{Ca}}$  decay ranges from 2 to 6 msec. In contrast, facilitation of transmitter release evoked with depolarizing pulses in the same terminals has a  $\tau$  of decay of 10 to 35 msec. If the activation of  $gK_{\text{Ca}}$ , and facilitation of transmitter release both require free  $\text{Ca}^{2+}$ , then differences in the time constants of these two phenomena might be due to a lower affinity or stoichiometry of  $gK_{\text{Ca}}$ . Using a conditioning pulse – test pulse paradigm in which conditioning pulse amplitude and interpulse interval can vary, we now report that two different test pulses which generate identical  $gK_{\text{Ca}}$ 's and membrane voltages at different time intervals release markedly different amounts of transmitter. We conclude that the residual free  $\text{Ca}^{2+}$  hypothesis does not explain facilitation at this synapse. Rather, facilitation of transmitter release is better explained by residual  $\text{Ca}^{2+}$  in the presynaptic terminal bound to the transmitter release machinery.

## 114.17

ω-CONOTOXIN-SENSITIVE CALCIUM CURRENT MEDIATES PRESYNAPTIC INHIBITION AT THE SENSORY NEURON-SPINAL CORD SYNAPSE. W. Gruner, L.R. Silva \* and K. Dunlap. Dept. of Physiology, Tufts Medical School, 136 Harrison Ave., Boston, MA 02111.

We have studied synapses between individual dorsal root ganglion (DRG) neurons and spinal neurons grown together in primary culture. DRGs and spinal cords were dissected from chick embryos, dissociated, and plated onto dishes containing small collagen "islands" (Segal and Furshpan '90, <u>J. Neurophys.</u> 64: 1390). Dual recordings from DRG-spinal cell pairs were made using whole cell patch clamp techniques.

DRG action potentials evoked short-latency EPSPs in spinal neurons. EPSPs were rapidly and reversibly blocked by CNQX (1 µM). \(\text{\pm}\)

These data support the hypotheses: 1) that N-type Ca<sup>2+</sup> currents mediate transmitter release during fast excitatory transmission at the primary afferent synapse; 2)that presynaptic inhibition of primary afferents is mediated via modulation of these same N-type calcium currents. (Supported by the NIH.)

NON-SINGLE STEP CALCIUM CHANNEL OPENING AND THE TIME COURSE OF TRANSMITTER RELEASE. D. M. J. Quastcl\*, J. Zhai, and G. Polyakov. Dept. of Pharmacology & Therapeutics, Univ. of British Columbia, Vancouver, Canada V6T 1Z3

In mouse diaphragm brief (0.2ms) depolarizations of end-plates in the presence of tetrodotoxin (and TEA and 4-AP to suppress K currents) elicit EPPs in the presence of Ca<sup>2+</sup> or Sr<sup>2+</sup>. Repetitive stimulation (10-60 Hz) in the presence of Sr<sup>2+</sup> causes increase in MEPP frequency which (from previous work) is attributable to temporary accumulation of Sr<sup>2+</sup> within the nerve terminal and provides a measure of Ca-channel opening per pulse. When a depolarizing pulse is followed at short intervals (0-0.5 ms) by a relatively small brief depolarizing pulse (25% the amplitude of the first pulse and 0.1 or 0.2ms duration), which alone causes little detectable quantal release, it substantially increases the EPP quantal content, per pulse Sr<sup>2+</sup> entry, and mean latency of quantal components of the EPP. The opposite occurs with hyperpolarizing postpulses. At low temperature (16° C) latency histograms show changes (with Sr<sup>2+</sup> or Ca<sup>2+</sup>) mainly in components delayed from the start of release by the interpulse interval - early components alter as expected from modification by the postpulse of ion entry through channels already opened. We conclude that changes in the time course and magnitude of transmitter release by postpulses reflect changes in Ca<sup>2+</sup> or Sr<sup>2+</sup> entry, rather than any "direct" action of voltage on release. Taking into account the effective time constant of the terminal (obtained from the effect of hyperpolarizing prepulses) and the relation between release and stimulation intensity, calculations show the data to be incompatible with a Hodgkin-Huxley type scheme in which Ca-channel opening occurs with one voltage-sesensitive step, but easily explained by a scheme with three sequential voltage-sensitive steps.

MUTAGENESIS OF HOMOMERIC NMDA-R1 RECEPTOR IN PUTATIVE CHANNEL REGION. <u>S. Kawajiri\*</u>, G.-C. Yoh and R. Dingledine, Dept. Pharmacol., Univ. North Carolina, Chapel Hill, NC 27599.

A single amino acid position in the GluR1-GluR4 family of

glutamate receptor subunits controls the degree of divalent ion permeability of the activated receptor channel. A glutamine (Q) or asparagine (N) in this position allows high divalent ion permeability, whereas an arginine (R) in heteromeric assemblies with Q-containing subunits greatly reduces divalent ion permeability. An arginine containing homomeric receptor channel carries very little current. The homologous position in the NMDA-R1 subunit contains an asparagine. To explore whether the same "rules" may apply for control of permeation through NMDA receptor channels, we used sitedirected mutagenesis to convert this asparagine of NMDA-R1 to an arginine. RNA transcribed from plasmids harboring NMDA-R1 or the N615R mutant was injected into Xenopus oocytes and voltage-clamp recordings obtained 2-4 days later in solutions containing 1 uM TPA. Substitution of Ba for Na in the external solution caused a large rightshift in the reversal potential for NMDA-activated currents in NMDA-R1, confirming the high divalent ion permeability of these homomeric receptors. Homomeric N615R receptors carried little NMDA current in Na-solution; in Ba-solution the reversal potential appeared to be very negative indicative of low Ba permeability. Heteromeric NMDA-R1 + N615R receptors (1:1 molar ratio) exhibited no consistent shift in reversal potential upon changing from Na to Ba solution. These results suggest NMDA and AMPA receptors may use similar structural determinants for control of divalent ion permeability. NMDA-R1 cDNA was a gift from Dr. S. Nakanishi.

# KINETICS STUDY OF NMDA RECEPTOR DESENSITIZATION

Fan Lin\* and Charles F. Stevens

The Salk Institute, MNL, La Jolla, CA 92038

We have studied NMDA receptor desensitization with patch clamp techniques in hippocampus CA region neuron. Under our experimental condition, the NMDA receptor desensitization is membrane potential and extracellular Ca<sup>2+</sup> concentration insensitive, but is an increasing function of NMDA concentration. The desensitizing time course, measured as the decay phase of NMDA current, has to be described as a multiple exponential process. The recovery rate from the desensitized state is in range of seconds. From our results, it appears that NMDA receptor need not open in order to reach the desensitized

MULTIPLE EFFECTS OF SPERMINE ON NMDA RECEPTOR RESPONSES OF RAT CULTURED HIPPOCAMPAL NEURONS.

M. Benveniste\* and M. L. Mayer, Lab. Cellular and Molecular Neurophysiology, NICHD, NIH, Bethesda, MD 20892.

NICHD, NIH, Bethesda, MD 20892. Concentration in wineteniar Neurophystology, NICHD, NIH, Bethesda, MD 20892. Concentration jump responses to  $100 \, \mu M$  NMDA in saturating glycine  $(10 \, \mu M)$  revealed potentiation by 3 mM spermine under whole cell voltage clamp at  $+60 \, \text{mV}$ , but depression at  $-120 \, \text{mV}$ . Dose-response analysis of spermine-evoked potentiation of responses to NMDA with  $10 \, \mu M$  glycine at  $+60 \, \text{mV}$  revealed a half maximal effect at  $126 \, \mu M$ . In addition, dose-response analysis for glycine yielded a 3.5- and 5.4-fold decrease in peak and steady state  $EC_{50}$  values in the presence of  $1 \, \text{mM}$  spermine. This increase in potency for glycine was accompanied by a 3.5-fold decrease in the rate of dissociation of glycine-sensitive desensitization, and a 2.4-fold decrease in the rate of dissociation of glycine from NMDA receptors.

The block of responses to NMDA by spermine was highly voltage-dependent ( $2.6 \, \text{m}$  = 1.13) with a  $K_d$  at  $-60 \, \text{mV}$  of  $1.7 \, \text{mM}$ . Arcaine, DET and DA10 also produced voltage-dependent block with  $K_d$  values at  $0 \, \text{mV}$  of 0.75,  $2.93 \, \text{and}$  4.79 mM, espectively. These compounds did not block spermine-induced potentiation or the spermine-induced decrease in the rate of glycine-sensitive desensitization.

The time course of potentiation at  $+60 \, \text{mV}$  induced by concentration jump application of  $1 \, \text{mM}$  spermine in the presence of  $100 \, \mu M$  NMDA developed with a slow exponential component, the amplitude and time constant of which decreased

slow exponential component, the amplitude and time constant of which decreased with increasing glycine concentration (30 nM glycine:  $\tau = 780 \pm 79$  ms; 3  $\mu$ M glycine:  $\tau = 45 \pm 13$  ms), and a faster exponential component ( $\tau < 20$  ms at all concentrations of glycine) the amplitude of which appeared to be proportional to the number of active NMDA receptor channels. The decrease in NMDA receptor current measured upon removal of spermine also showed double exponential kinetics with a similar dependence on glycine concentration.

Our results suggest that spermine acts at a minimum of 2 and more likely 3 distinct sites on NMDA receptors to produce voltage-dependent block; potentiation via an increase in affinity for glycine; and potentiation via a glycine-independent

INHIBITION OF EXCITATORY AMINO ACID-ACTIVATED ION

INHIBITION OF EXCITATORY AMINO ACID-ACTIVATED ION CURRENTS BY INHALATIONAL ANESTHETICS.

Robert W. Peoples\* and Forrest F. Weight. Section of Physiology, Laboratory of Molecular and Cellular Neurobiology, National Institute on Alcohol Abuse and Alcoholism, Rockville, MD 20852.

Previous studies in this and other laboratories have shown that

several substances with general anesthetic activity, including aliphatic alcohols, diethyl ether, and barbiturates, inhibit excitatory amino acidactivated ion currents in mammalian neurons at physiologically relevant concentrations. We have investigated the actions of inhalational anesthetics on currents activated by kainate (KA), N-methyl-D-aspartate (NMDA), and quisqualate (QUIS) in voltageclamped mouse hippocampal neurons in culture using the whole-cell patch-clamp technique. Halothane inhibited currents activated by each of the agonists tested in a concentration-dependent manner with the order of potency KA > QUIS ≥ NMDA. Isoflurane inhibited currents activated by each of the agonists tested with the order of potency KA > NMDA ≥ QUIS, but was less potent than halothane. We are currently evaluating the effects of other anesthetic agents on excitatory amino acid-activated currents. Inhibition of excitatory amino acid-mediated neurotransmission in the CNS by general anesthetics may contribute to their behavioral effects. (This work was supported in part by a National Research Council-NIH Research Associateship to R.W.P.).

INSURMOUNTABLE INHIBITION OF AMPA INDUCED INCREASE OF INTRACELLULAR Ca++ IN RAT CORTICAL NEURONS BY EMOPAMIL. T. J. Mangano\*, M. Britt, L.M. Pullan, C. Thompson and R. A. Keith. Dept. of Pharmacology, ICI Americas, Inc. Wilmington, De. 19897.

The effects of emopamil on α-amino-3-hydroxy-5-methylisoxazole-4propionic acid hydrobromide (AMPA), kainic acid (KA) and N-methyl-Daspartate (NMDA) induced increase in intracellular calcium ([Ca++]i) in 14-21 day old rat cortical neurons in primary cultures were examined using fura-2. Emopamil caused a concentration-dependent and virtually complete inhibition of 10  $\mu M$  AMPA induced increase in [Ca<sup>++</sup>]<sub>i</sub> (IC<sub>50</sub>  $\cong$  5  $\mu M$ ). Nitrendipine (1  $\mu M$ ) and ω-conotoxin GVIA (0.1 μM), inhibitors of L- and N-type voltage-sensitive calcium channels (VSCC), respectively, had no effect on 10 µM AMPA induced increase in [Ca++]i. At 30 µM, emopamil had little effect on 100 µM NMDA or 100  $\mu$ M KA induced increases in [Ca++]<sub>i</sub>. NBQX (1  $\mu$ M) caused > 90% inhibition of 10 µM AMPA and 100 µM KA induced increase in [Ca++]i, while MK-801 (3  $\mu$ M) caused > 90% inhibition of 100  $\mu$ M NMDA-induced increase in [Ca++]i. NBQX (1  $\mu$ M) caused a parallel displacement of the AMPA concentration-response curve, whereas emopamil (30 µM) inhibition was insurmountable at all concentrations of AMPA. Emopamil (up to 300  $\mu\text{M}$ ) had no effect on NBQX sensitive (IC50=0.14  $\mu M$ ) <sup>3</sup>H-AMPA binding to brain mbrane fragments. The results suggest that emopamil inhibits AMPAinduced increase of [Ca<sup>++</sup>]<sub>i</sub> by a mechanism that is distinct from direct AMPA receptor interaction. Emopamil also inhibited cortical neuron VSCC responses, as indicated by its ability to inhibit K+-induced increase in [Ca++]; (IC50 ≅ 2 uM). Thus, AMPA receptor stimulation may activate, either directly or indirectly, VSCC which are sensitive to emopamil.

## 115.4

GLUTAMATE AND GLYCINE DECREASE [<sup>3</sup>H]MK-801 BINDING IN THE PRESENCE OF MAGNESIUM <u>G. von Euler\* and Y. Liu</u> Dept. of Histology and Neurobiology, Karolinska Institutet., Box 60400, S-10401

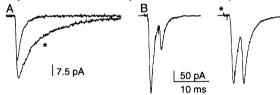

In order to elucidate the complex actions of Mg2+ on the NMDA receptor-coupled ion channel, we have investigated the effects of glutamate and glycine on [3H]MK-801 binding in cerebrocortical membrane preparations from male rats in the presence of various concentrations of <sup>+</sup>. The affinity of [<sup>3</sup>H]MK-801 binding correlates to the activation of the NMDA receptor-coupled ion channel

Glutamate and glycine synergistically decreased specific [3H]MK-801 binding in the presence of 4 mM Mg<sup>2+</sup> or in Krebs solution. The potencies of glutamate and glycine alone or together to decrease [3H]MK-801 binding in the presence of Mg<sup>2+</sup> were similar to their respective potencies to increase [<sup>3</sup>H]MK-801 binding in the absence of Mg<sup>2+</sup>. The glutamate- and glycineinduced decreases of [3H]MK-801 binding were due to a reduced affinity of [3H]MK-801 binding without affecting the number of [3H]MK-801 binding sites, and could be reversed by the competitive NMDA-receptor antagonist D-AP7 and the glycine antagonist 5-chloroindole-2-carboxylic acid.

These results indicate that glutamate and glycine may inactivate the NMDA receptor-coupled ion channel in the presence of physiological concentrations of  $\mathrm{Mg}^{2+}$ . Since electrophysiological experiments have shown that Mg<sup>2+</sup> only affects NMDA receptor-coupled ion channels at negative membrane potentials, it is suggested that glutamate and glycine inactivate the NMDA receptor-coupled ion channel during resting membrane potentials and activate the channel during action potentials.

## 115.6

CYCLOTHIAZIDE MODULATES EXCITATORY SYNAPIIC TRANSMISSION AND AMPA/KAINATE RECEPTOR DESENSITIZATION IN HIPPOCAMPAL CULTURES. D. K. Patneau\*. L. Vyklicky, Jr., and M. L. Mayer. Laboratory of Cellular and Molecular Neurophysiology, NICHD, NIH, Bethesda, MD 20892. To determine whether desensitization of AMPA/kainate receptors contributes to the rate of decay of excitatory synaptic responses, we analyzed the effects of cyclothiazide, a novel modulator of desensitization. A saturating dose of cyclothiazide (100  $\mu$ M) fully blocked desensitization of the response to L-glutamate in whole-cell and outside-out patch recordings and dramatically slowed the decay time constant of monosynaptic EPSCs evoked between pairs of neurons in low-density hippocampal cultures. The decay of control EPSCs was well fit with a single exponential, T=3.5±1.0 ms, but in the presence of cyclothiazide (\*) the decay exhibited double exponential kinetics,  $\tau_{\rm fast}$ =10.1±3.1 ms (61%),  $\tau_{\rm slow}$ =43.6±13.2 ms (39%). Cyclothiazide also increased both the amplitude and decay time constant of sucrose-evoked miniature EPSCs (Fig. A), and similarly slowed the decay time constant of responses to 1 ms applications of 1 mM L-glutamate in outside-out patches. The amount of desensitization was examined with a twin-pulse paradigm. Responses separated by an interval of 3-8 ms showed 40-60% desensitization; this was completely abolished by cyclothiazide (\*) (Fig. B). Similar to the results of Trussell and Fischbach (1989) and Colquhoun, Jonas and Sakmann (1992), our experiments suggest that AMPA/kainate receptor desensitization occurs during single synaptic responses and in addition that this may contribute to the rate of decay of EPSCs. A

IDENTIFICATION OF CYCLIC NUCLEOTIDE-GATED

IDENTIFICATION OF CYCLIC NUCLEOTIDE-GATED CHANNEL VARIANTS BY PCR. Peter J. McKinnon and Robert F. Margolskee\*, Department of Neurosciences, Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ 07110.

The cyclic nucleotide-gated ion channels are a class of cation channels activated directly by intracellular cAMP or cGMP. The channels from the retina and olfactory epithelium are well characterized, and have recently been cloned. The molecular structure of the gettle problem of the continuous control of the continuous control of the continuous control of the continuous control of the continuous control of the continuous control of the continuous control of the continuous control of the continuous control of the continuous control of the continuous control of the control of the continuous control of the of the cyclic nucleotide-gated channels is distinct from other known of the cyclic nucleotide-gated channels is distinct from other known ligand gated channels. However, there is some homology between this class of channel and the transmembrane topography and voltage sensor motif of the voltage-gated channels. Recently, cyclic nucleotide-gated channels have been identified in heart (the pacemaker current), kidney, inner ear, pineal gland, bipolar cells of the retina and Drosophila larval muscle. The wide distribution of these channels surgette the possibility of a publicage fearily. these channels suggests the possibility of a multigene family. However, presently only the genes for the olfactory (rat and catfish) and retinal (bovine) cyclic nucleotide-gated channels have been isolated. These genes show a high degree of conservation at the amino acid level, particularly in the transmembrane and cyclic nucleotide binding regions. To identify and characterize other cyclic nucleotidegated ion channel genes, we have used PCR with degenerate primers designed against various conserved regions of the olfactory and retinal genes. Using this aproach, we have found a number of new genes closely related to the previously known cyclic nucleotide-gated ion channels. These new sequences were identified in various rat cDNA libraries, and rat genomic DNA and show a high degree of relatedness at the amino acid level to the olfactory and retinal channels.

ACTIVATION AND DEACTIVATION KINETICS OF CYCLIC NUCLEOTIDE GATED CHANNELS FROM OLFACTORY NEURONS STUDIED WITH CONCENTRATION JUMP TECHNIQUES. F. Zufall, H. Hatt+ and S. Firestein\*. Section of Neurobiology, Yale Univ. Medical School, New Haven CT 06510 and +Physiological Institute, Technical University, D-8000 Munich 40, Germany.

A critical step in vertebrate olfactory transduction is the gating of a cyclic nucleotide-activated cation channel. Gating kinetics of this channel have been studied under steady state conditions, i.e. in the continuous presence of cAMP or cGMP. It is known, however, that in response to odors cAMP production is transient, with a peak (in vivo) around 50

Here we have studied the gating kinetics of recombinant cyclic nucleotide channels from rat olfactory neurons (expressed in a kidney cell line) and native channels from salamander olfactory neurons with fast application and removal of cyclic nucleotides. Agonist pulses were delivered by a piezo-driven 'liquid filament' that allowed solution exchange at excised membrane patches in less than 200 us. Upon application of a step of cyclic nucleotide containing solution the current rose to plateau along a time course that was dependent on agonist concentration. With 1 mM cGMP the rise time could be as short as 2 ms, under optimal conditions. Upon rapid removal of the stimulus (i.e. stepping back to control solution) the current decay was much slower. Typically after removal of agonist (1 mM cGMP) several hundred milliseconds were required to reach 50% of the plateau value. Several tests were undertaken to assure that kinetic components were due to channel gating and not to restricted diffusion in the patch. These included tests of the voltage sensitivity of kinetic states and the use of solutions with different ionic compositions. Supported by NIH DC 00086 and Deutsche Forschungsgemeinschaft

POTENTIATION OF GABA - INDUCED CHLORIDE CURRENT LANTHANIDES. M.Yan\* and T.Narahashi. Dept. of Pharmacol., Northwestern Univ. Med. Sch., Chicago, IL 60611. Lanthanides, or rare-earth metals, constitute a series of

fifteen metals starting with lanthanum (atomic number, 57) and ending with lutetium (atomic number, 71). We have previously reported that lanthanum reversibly potentiates the GABA-induced chloride current by acting at a distinct site on the GABA receptor-channel complex (Yan and Narahashi, Soc. Neurosci. Abstr. 17:1333, 1991). We now report that in addition to lanthanum, all other lanthanides tested potentiate the GABA-induced chloride current with greater efficiencies. The currents were recorded from the rat dorsal root ganglion neurons in primary culture by the whole cell patch clamp technique. At a concentration of 1 mM, lanthanides reversibly potentiated GABA response (times of control): lutetium ( $\text{Lu}^{3+}$ ) 12.64 > exbium ( $\text{Er}^{3+}$ ) 11.87 > terbium ( $\text{Tb}^{3+}$ ) 10.28 > europium ( $\text{Eu}^{3+}$ ) 6.15 > neodymium ( $\text{Nd}^{3+}$ ) 4.32 > cerium ( $\text{Ce}^{3+}$ ) 3.70 > lanthanum ( $\text{La}^{3+}$ ) 2.41. This order of potentiation exactly follows the atomic number: the larger the atomic number, the greater the potentiation. The enhancing effect of  ${\rm Tb}^{3+}$  was dose dependent with an EC50 ennancing effect of Tb" was dose dependent with an EC $_{50}$  around 350  $\mu$ M and weakly voltage dependent increasing with hyperpolarization. Tb $^{3+}$  shifted the GABA dose-response curve in the direction of lower concentrations without significantly changing the maximum response. These data strongly support the existence of a lanthanide regulatory site at the  $GABA_{\mbox{\scriptsize A}}$  receptor-channel complex.

Cloning and Expression of the Rat 5HT<sub>3</sub> Receptor Reveals Species-Specific Sensitivity to Curare Antagonism. David S. Johnson and Stephen F. Heinemann, The Salk Institute, La Jolla, CA 92037; UCSD, Group in Neurosciences, San Diego, CA 92037. We have cloned the rat homolog of the 5HT3 receptor cloned in mouse by

Maricq et al. last year. The rat clone was isolated from a superior cervical ganglion cDNA library. The cDNA is 2230 bp and encodes a protein of 461 amino acids. The mature protein, after removal of the predicted signal peptide, exhibits 94% identity with the mouse receptor.

Voltage clamp studies of Xenopus oocytes injected with RNA transcripts of this clone demonstrate a serotonin-gated current which is sensitive to external Ca<sup>2+</sup> concentrations and exhibits a region of negative-slope conductance in the IV curve. Preliminary pharmacological studies reveal similarities to the mouse 5HT3 receptor. One exception to the similarities is the sensitivity of the rat receptor to curare antagonism. Wheras the current induced by 10 µM 5HT in oocytes expressing the mouse 5HT3 receptor is completely blocked by 5 nM curare, currents in oocytes expressing the rat consplictely blocked by 5 mix cutate, currents in occycles expressing tire 5 5HT3 receptor are attenuated only about 20% by 100 nM curare. This is consistent with previous studies from other laboratories indicating murine neurons and cell lines which possess 5HT3 receptors are extremely sensitive to curare block, wheras 5HT3 receptors in other species (raf, rabbit, guinea pig) are roughly three orders of magnitide less sensitive to curare antagonism. We are conducting site-directed mutagenesis to determine which of the few amino acids which differ between the rat and mouse sequences confer the extreme sensitivity to curare.

FUNCTIONAL EXPRESSION OF GABA,-CI CHANNELS AND BENZODIAZEPINE BINDING SITES IN BACULOVIRUS INFECTED INSECT CELLS. D.B. Carter, D.R. Thomsen, W.B. Im\*, D.J. Lennon, D.M. Ngo, W. Gale, H.K. Im, P.H. Seeburg and M.W. Smith. CNS Research, The Upjohn Company, Kalamazoo, MI 49001.

Recent cloning of the cDNAs coding for the subunits comprising the GABA,-benzodiazepine receptors has afforded the opportunity to study this complex receptor-channel system in transient expression systems. However to date high level production of this receptor-channel complex with an intact benzodiazepine (BZD) binding site has not been possible in animal cells. Since it was recently shown that functional multi subunit proteins and ion channels could be expressed in the baculovirus expression system (BVS) we investigated the BVS for the high level production of the GABA<sub>A</sub>-BZD Cl<sup>-</sup> channel complex. Membranes from cells infected with baculoviruses harboring subunits encoding cDNAs of the rat GABA,-BZD receptors were tested with a panel of well characterized small molecule ligands and found to have the appropriate binding pharmacology. The GABA, receptor subunit combinations investigated are  $\alpha_1\beta_2\gamma_2$ ,  $\alpha_6\beta_2\gamma_2$  and  $\alpha_6\beta_2\gamma_2$ . Several novel non-benzodiazepine ligands having low to high affinity for the  $\alpha_6\beta_2\gamma_2$ are described. In addition, whole-cell patch clamp of infected cells indicates the formation of GABA-gated Cl channels having the appropriate responses to GABA and diazepam.

## 115.12

GLYCINERGIC INHIBITION IN THE MAMMALIAN OLFACTORY BULB. Paul Q. Trombley\* & Gordon M. Shepherd. Section of Neurobiology, Yale University School of Medicine, 333 Cedar Street, New Haven, CT 06510.

Glycine is considered the principal inhibitory transmitter in the brainstem and spinal cord, whereas GABA is generally believed to dominate inhibition in the brain. In the olfactory bulb (0B) GABA localization to periglomenular and granule cells supports the notion that GABA contributes to the inhibition mediated by these cells. However, several laboratories have observed some components of inhibition in the OB that were resistant to GABA antagonists. In addition, recent immunohistochemical experiments have demonstrated localization of glycine receptors in the OB. These sults have led us to hypothesize that glycine may contribute to synaptic inhibition

results have led us to hypothesize that glycine may continue to synaphe immediation in the OB.

We examined the responses of OB neurons to glycine using primary cell culture and whole cell recording techniques combined with a rapid flow drug application system. Olfactory bulb neuron cultures from E18-P2 rat pups contained both mitral/fulted cells and periglomental/granule cells. All neurons tested (n=20) responded to glycine with an apparent ECSO of 125 µM. When intracellular [CI] was altered, the membrane current reversed at the Nernst value for CI\*, consistent with activation of the alucine stated CI\* channel. The glycine evoked current was blocked by activation of the glycine gated Cl<sup>-</sup> channel. The glycine evoked current was blocked by the glycine antagonist strychnine but not by the GABA antagonist bicuculline. GABA

the glycine antagonist stryctimine out not by the GABA antagonist dicturing. GABA evoked a distinct CI current which was antagonized by bicuculline. All neurons responded to both glycine and GABA although the ratio of current amplitudes evoked by glycine vs GABA was not the same for all cells.

We propose that glycine as well as GABA may contribute to inhibitory mechanisms in the olfactory bulb. The use of more than one inhibitory transmitter could allow for differential inhibition through selective modulation. Glycine receptors could anow for differential minoritor furgoing selective modulation. Gynelli exceptors for example, are not thought to be sensitive to substances that modulate GABA receptors. Our proposal is supported by immunohistochemical evidence demonstrating that glycine receptor immunoreactivity is localized in the external plexiform layer, whereas GABA immunoreactivity is highest in the glomerular layer. Supported in part by an NRSA to PQT and an NIDCD research grant to GMS.

SINGLE CHANNEL CONDUCTANCE UNDERLYING SINGLE CHANNEL CONDUCTANCE UNDERLYING SEROTONIN DEPENDENT DEPOLARIZATION OF AN IDENTIFIED NEURON FROM HELISOMA. <u>C. J. Price\* and J. I. Goldberg.</u> Department of Zoology, University of Alberta, Edmonton, Alberta, Canada T6G 2E9.

The neurotransmitter serotonin (5-HT) regulates neurite outgrowth in an identified neuron from the snail *Helisoma trivolvis*. Membrane depolarization, involving gating of a sodium conducting channel, is necessary for this response to occur. To gain an understanding of the nature of the ion channel responsible, single channel studies have been initiated. Cell-attached patch recordings were made from the soma of neuron B19 isolated in cell culture (pipette solution: 70mM NaCl and 5mM Hepes; pH 7.4). These recordings revealed an inwardly directed current, with a conductance of approximately 5pS, that appeared following bath application of 5-HT (final concentration: 25µM). Such single channel events were, however, rather rare in occurrence, since single channel events were, however, rather rare in occurrence, since less than 20% of patches contained channel activity. Channel openings were generally burst-like in nature, involving flickering between open and closed states. Moreover, channel activity was typically interrupted by variable periods of inactivity, that ranged from several seconds to minutes in duration. Owing to the nature of the recordings performed and the method of 5-HT application, a diffusible second messenger is likely involved in the gating of this channel. This is consistent with findings from whole cell recordings which implicated a role for cAMP in the generation of serotonin dependent depolarization.

ATOMIC FORCE MICROSCOPY IMAGING OF CLONED NEUROTRANSMITTER RECEPTORS. R. Lal\*, J. Liu², J. Hurley², L. J. Bloem² and L. Yu². ¹Dept. of Med., Univ. of Chicago, Chicago, IL 60637; 2Dept. of Med/Mol Genetics, Indiana Univ. Sch. Med., Indnpls, IN 46202.

Atomic force microscopy (AFM) is a powerful tool that allows high resolution imaging of the surface topography with nondestructive scanning probes under physiological conditions. A large numbers of membrane proteins, such as receptors, ion channels, and transporters, have been molecularly cloned. The structural information of most of these proteins, however, is lacking. In an attempt to develop a convenient method for obtaining such information, we used two expression systems, Xenopus oocytes and COS cells, for AFM imaging of cloned receptors. Two neurotransmitter receptors were studied: the nicotinic acetylcholine receptor (AChR), an ion channel, and the serotonin 1c (5-HT<sub>1C</sub>) receptor, a G protein-coupled receptor. The AChR was expressed in Xenopus oocytes by microinjection of the mRNAs synthesized in vitro from the cDNA clones for the mouse muscle AChR  $\alpha$ ,  $\beta$ ,  $\gamma$ , and  $\delta$  subunits. Recording of these oocytes by two-electrode voltage clamp showed an ACh-induced slow depolarizing current, indicating the functional expression of the AChR. AFM imaging of these oocytes revealed a pentameric structure of  $\sim7$ -9 nm in diameter with a central pore, consistent with the proposed AChR topography. The 5-HT<sub>1c</sub> receptor was expressed in COS cells from a mouse 5-HT<sub>IC</sub> receptor cDNA clone, as confirmed by membrane binding to radiolabeled mesulurgine. AFM imaging showed a protein protrusion of  $\sim 5 - 7$  nm in diameter without a central pore, consistent with the calculated molecular size of the receptor. PROTON-GATED SODIUM CURRENT IN MESECENPHALIC DOPAMINERGIC NEURONS.
Andrew Bullen\* & Martin Morad. Dept. of Physiology. University of Pennsylvania. Philadelphia, Pa 19104-6085

Small acid shifts (to pH = 6.7) in external solution were used to activate a fast inward Na\* current from mesecenphalic neurons in primary culture. Currents were measured from all neurons present (after 5 days) but predominantly from dopaminergic cells. Dopaminergic neurons were identified by their uptake of the autofliuorescent marker, 5,7-DHT (Silva et al., 1988). Currents were measured in both the whole cell and perforated patch configuration of the patch deally leaven changed using a rapid perfusion system. In a control solution, a shift to pH = 6.7 elicited a fast activating (r = 0.2 s) inward current of 0.5 - 3 nA. This current inactivated in the continued presence of an activating pH and rapidly deactivated if the bathing solution was returned to pH = 7.4. The size of this current was graded with proton concentration reaching a maximum at pH = 6.5. The current reversed close to sodium equilibrium potential suggesting Na was the primary charge carrier. However, the relative selectivity of this channel to Ca++ and K+ remains to be quantified. Although this current was somewhat similar to other proton-gated currents seen in peripheral neurons (Krishtal & Pidoplichko, 1981; Konnerth et al., 1987) thad significantly different inactivation kinetics (r = 2.4 s vs 0.3 s). The physiological role of this protongated current remains to be determined but it appears some form of this current is expressed in many neuron types.

SK&F 96365 INHIBITS PHOSPHOINOSITIDE HYDROLYSIS BY BLOCKING RECEPTOR-MEDIATED CALCIUM INFLUX. W.C. Moore\*, H.H. Hargrove, and J. Patel, Dept. of Pharmacology, ICI Americas Inc., Wilmington, DE 19897.

Calcium response to agonist-stimulated phosphoinositide (PI) hydrolysis is typically biphasic. It is composed of an initial transient increase, corresponding to the release of calcium from intracellular stores, followed by a sustained elevation of calcium due to influx. In fura-2 loaded SH-SY5Y neuroblastoma cells, SK&F 96365 (30µM) was shown to selectively block carbachol- (CB) mediated Ca $^{2+}$  influx without effecting the initial intracellular Ca $^{2+}$  release. Similar results were observed with La $^{3+}$  (10µM), however, nitrendipine (10µM) and  $\omega$ -conotoxin (10nM) were without effect. These data demonstrate that the CB-stimulated Ca $^{2+}$  entry in neuronal cells is via a SK&F 96365-sensitive, non-voltage-operated calcium channel.

Previously it has been demonstrated that sustained PI hydrolysis in neuronal cells requires continued influx of extracellular Ca<sup>2+</sup>. In the present study, SK&F 96365 inhibited CB-stimulated PI turnover in SH-SY5Y cells with an apparent IC50 of 29.1 μM. No inhibition of PI hydrolysis was observed in the presence of maximal concentrations of nitrendipine or ω-conotoxin. Inhibition of PI hydrolysis was not the result of muscarinic receptor antagonism as SK&F 96365 showed very weak inhibition of <sup>3</sup>H-QNB binding. Additionally, it was determined that SK&F 96365 was able to inhibit quisqualate- and CB-stimulated PI hydrolysis in primary cultures of cortical neurons with a potency similar to that found in SH-SY5Y cells. Taken together, these data suggest that SK&F 96365 inhibits PI hydrolysis in neuronal cells by inhibiting receptor-mediated calcium influx.

PATCH-CLAMP RECORDING IN HIPPOCAMPAL SLICES USING DRY OBJECTIVE. P. Bregestovski. A. Kurchikov and Y. Ben-Ari. INSERM, Unité 29, Hopital Port-Royal, 75014, Paris, FRANCE

High-resolution patch -clamp recording from slices provides a wide range of possibilities for the analysis of molecular mechanisms of mammalian CNS functioning. In the method originally developed by Edwards et al. (Pflugers Arch, 414: 600, 1989) a water immersion objective was used to identify single neurons in thin slices . However, this approach has two inconveniences: (i) limited working distance (less than 1,6 mm with a x40 objective) and restricted space electrode manipulation; (ii) high probability of damage of the expensive water immersion objective by leak curren via small scratches of the insulation. We have now developed a new chamber with a cover glass support system. This allows the use of an upright microscope with a dry long distance (5 mm) objective (Plan x40 NIKON). The slice is located in the water stream with about 4 mm of free space between the cover glass and the surface of the slice. In contrast to the

system of Edwards et al., we can bring the recording and the stimulation electrodes to the preparation at a high angle ( $\approx$  45°). With an ordinary TV-camera one can readily visualize pyramidal cells and interneurones lying on the surface of the slice. Using this chamber, whole-cell and single channel ionic currents from neurones in neonatal hippocampal slices have been recorded.

PHYSIOLOGICAL RELEASE OF ACETYLCHOLINE IN RAT STRIATUM MONITORED

IN VIVO: MODULATION BY DOPAMINERGIC DRUGS.

P. DeBoer and E.D Abercrombie. Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102

Striatal acetylcholine (ACh) release, as measured with in vivo microdialysis, is stimulated by systemic administration of dopamine (DA) D-1 receptor agonists and is inhibited by systemic or local administration of DA D-2 receptor agonists. When indirect DA agonists like amphetamine (AMPH) are given systemically, the stimulatory effect of DA on in vivo striatal ACh output predominates. Tissue levels of striatal ACh, however, are found to increase after such treatments, suggesting a decrease in ACh utilization. To determine whether the presence of an inhibitor of acetylcholinesterase (AChE) might have altered the pharmacological responsivener of striatal ACh in previous in vivo studies, the effect of DA-ergic drugs on the output of striatal ACh was studied using in vivo microdialysis in the absence of AChE inhibition. ACh output was 2.7 fmol/sample under physiological conditions vs. 1.44 pmol/sample in the presence of the AChE inhibitor neostigmine (NEO; 300 nmol/l). Systemic AMPH (2 mg/kg) increased the output of ACh by 116% under physiological conditions. This increase was greater (180%) and more prolonged in the presence of NEO. Increases in striatal ACh output after AMPH (without NEO) most closely paralleled increases in the output of DA in frontal cortex and substantia nigra rather than DA changes in striatum. Further pharmacological characterization of striatal ACh output in the absence of AChE inhibition revealed an increased output after systemic administration of the D-1 agonist CY 208-243 (2 mg/kg; 180% of control) and a decreased output after systemic administration of the D-2 agonist quinpirole (3 mg/kg, 48% of control). These data show that 1) DA D-1 receptors stimulate and DA D-2 receptors inhibit striatal ACh output measured under physiologically relevant conditions, 2) AChE inhibition alters pharmacological responsivity of striatal cholinergic neurons, and 3) changes in tissue levels of neurotransmitters do not neccesarily correlate with release. ## 116.3

ULTRASENSITIVE MEASUREMENT OF ACETYLCHOLINE RELEASE IN THE CONSCIOUS HUMAN HIPPOCAMPUS AND ANESTHETIZED RAT STRIATUM USING MICRODIALYSIS. M.D. Greaney, D.L. Marshall 1, M.J. During<sup>2</sup>, B.A. Balley\* and I.N. Acworth. ESA, Inc., Bedford, MA 01730; <sup>1</sup>Dept. of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139; <sup>2</sup>Yale University School of Medicine, New Haven, CT 06510.

Due to the low basal levels of acetylcholine (ACh) present in brain microdialysis samples, the use of a highly sensitive and selective mode of detection is necessary. We have improved on current methodologies for the simultaneous analysis of ACh and choline (Ch) using electrochemical detection. The limit of detection for both ACh and Ch is below 50 femtomoles. With this method, the analysis of ACh in rat and human microdialysis samples is possible using ultralow levels of an acetylcholinesterase (AChE) inhibitor. Use of high levels of AChE inhibitors significantly interferes with the responsiveness of muscarinic autoreceptors. Thus, lower amounts of inhibitor should minimize the degree to which physiological conditions are altered.

ACh and Ch release was monitored in the striatum of anesthetized rat over

a range of AChE inhibitor concentrations, 10nM to  $10\mu M$  Neostigmine, in the artificial CSF perfusate. At the lowest inhibitor level (10nM Neostigmine), basal ACh and Ch levels were determined to be 36.7±7.2fmol and 21.8±2.7pmol per 10uL (mean ± S.E.M..n = 6) respectively.

Intrahippocampal human microdialysis samples from an awake epileptic patient were also monitored for ACh and Ch. With 150nM Neostigmine in the artificial CSF perfusate, basal levels were determined to be 2.6±0.2pmol ACh and 65.3 ± 6.4pmol Ch per 10 µL (mean ± S.E.M.,n=10). Since these human ACh values do not approach the sensitivity limits of this system, Neostigmine concentrations lower than 150nM can easily be used or temporal resolution can be enhanced.

COCAINE RELEASES ACETYLCHOLINE VIA AN ACTION OF DOPAMINE ON D1 RECEPTORS. A.Imperato\*, M.V. Demontis, M.C.Obinu and G. L.Gessa. Dept.Neuroscience "B.B.Brodie"Univ.of Cagliari,

COCAINE RELEASES ACETYLCHOLINE VIA AN ACTION OF DOPAMINE ON DIRECTPORS. A.Imperato\*, M.V. Demontis, M.C.Obinu and G. L.Gessa. Dept.Neuroscience "B.B.Brodie"Univ.of Cagliari, Italy
The effect of cocaine on dopamine (DA) and acetylcholine (ACh) release in the striatum was compared using brain microdialysis in freely moving rats. Cocaine (10 and 20 mg/kg i.p.) produced a parallel increase in the dialysate content of DA (by 350 and 500%) and ACh (by 55 and 80%). Release of DA and ACh by cocaine was markedly enhanced by the blockade of D2 receptors with (-) sulpiride (10 mg/kg s.c.) on the other hand, blockade of D1 receptors with SCh 23390 (0.050 mg/kg s.c.) prevented cocaine-induced ACh release but not that of DA. These results suggest that ACh release stimulation after cocaine results from two opposite effects mediated by DA on D1 and D2 receptors, and that the effect of DA on D1 is predominant in respect to that exerted on D2 receptors. To further clarify the role of endogenous DA on ACh output, rats were treated with reserpine (3 mg/kg i.p.) and both DA and ACh release monitored at various time afterwards. Following reserpine administration both DA and ACh output underwent an initial increase (by 65 and 35% respectively) during the first two hours when animals were hyperactive, followed by a prolonged decrease (by 85 and 80% respectively, over at least 9 hours) when animals were sedated. Reserpine-induced increase in ACh output was prevented by SCh 23390 but was potentiated by (-) sulpiride. The results suggest that an increased output of endogenous DA causes an increased ACh release mediated by a preferential stimulation of D1 receptors.

ACETYLCHOLINE MICRODIALYSIS IN THE FREELY MOVING RAT USING HPLC-ED: METHODOLOGICAL ASPECTS. R.S.Kulkarni\*, S.Aspley\*, G.W.Bennett\*, C.A.Marsden\* and C.R.Gardner<sup>1</sup>\*. (SPON:Brain Research Association) Dept. Physiol. & Pharmacol., Queen's Medical Centre, Nottingham, NG7 2UH, U.K. <sup>1</sup>Roussel Laboratories Ltd, Covingham, Swindon, SN3 5BZ,

Microdialysis is a well established technique which permits direct in vivo impling of neurotransmitters from specific brain regions in the conscious animal. High performance liquid chromatography with electrochemical detection (HPLC-ED) is a sensitive method for the measurement of acetylcholine (ACh). Enzyme catalysis is necessary to detect ACh and its metabolite choline (Ch) which are not electroactive and do not absorb U.V. light under normal conditions. The method consists of the separation of ACh and Ch by reverse phase HPLC followed by the detection of hydrogen peroxide (H202) produced enzymatically by the reaction of the column effluent with acetylcholinesterase (AChE) and choline oxidase (ChO) which are immobilised on a small column. AChE converts ACh to Ch and acetate, the former is then broken down to betaine with the production of  $H_2O_2$  In previous studies where the enzymes are immobilised on a post column reactor (IMER-Immobilised Enzyme Reactor) the detection of ACh in dialysate samples from freely Immobilised Enzyme Reactor) the detection of ACh in dialysate samples from freely moving Hooded Lister rats was limited both by inadequate chromatographic separation of ACh from the solvent front and Ch peak, and baseline noise. In current studies the use of a novel double IMER system where a second IMER, containing ChO only, is placed before the analytical column and a new prototype platinum electrode developed by Antec Analytical Systems has led to improved chromatographic separation with reduced baseline noise. The system is currently being used to investigate the effects of the benzodiazepine inverse agonists, S 135 and RU 33965 on ACh release in the hippocampus of Hooded Lister rats using microdialysis. Full metholodological details of the system and drug effects will be

R.S.K is sponsored by Roussel Laborarories.

LESIONS OF THE MESOTELENCEPHALIC DOPAMINE SYSTEM ENHANCE THE EFFECTS OF SELECTIVE D1 AND D2 DOPAMINE RECEPTOR AGONISTS ON STRIATAL ACETYLCHOLINE RELEASE. G.W. HUBERT, G.S. ROBERTSON\*, C.-S. THAM, AND H.C. FIBIGER. Division of Neurological Sciences, Department of Psychiatry, University of British Columbia, Vancouver, British Columbia, Canada V6T 1Z3

In vivo microdialysis was used to determine the effects of 6-hydroxydopamine (6-OHDA) lesions of the mesotelencephalic dopamine system on dopamine receptor agonist induced changes in extracellular acetylcholine (ACh) concentrations in the striatum. Such lesions increased the inhibitory effect of a low dose of the D2 receptor agonist quinpirole on striatal ACh release. In addition, 6-OHDA lesions enhanced the facilitatory effect of the selective D1 receptor agonist CY 208-243 on striatal ACh release, enabling a subthreshold dose to increase striatal dialysate concentrations of ACh by over 60%. These results indicate that denervation supersensitivity potentiates both the facilitatory effects of D1 receptor agonists and the inhibitory effects of D2 receptor agonists on striatal cholinergic activity. It was also found that the 6-OHDA lesions reduced basal interstitial ACh concentrations by 75% in the ipsilateral striatum. The latter results are consistent with the hypothesis that the prepotent action of dopamine in the forebrain is to enhance striatal ACh release via a D1 mechanism. Experiments are underway to identify the locus of the D1 mediated enhancement of striatal ACh release.

# 116.6

DOPAMINERGIC REGULATION OF CORTICAL ACETYLCHOLINE RELEASE. J. DAY\* and H.C. FIBIGER. Div. of Neurological Sciences, Dept. of Psychiatry, Univ. of British Columbia, Vancouver, B.C. V6T 1Z3

Cortically projecting basal forebrain cholinergic neurons are thought to play a major role in cortical activation. The transsynaptic regulation of this cholinergic system is thus of great interest. We have previously reported that amphetamine-induced increases in cortical acetylcholine (ACh) release can be partially attenuated by dopamine (DA) receptor antagonists and that the nonselective DA receptor agonist apormorphine can increase ACh release. To further define the regulation of the basal forebrain cholinergic system by DA receptor mechanisms, in vivo microdialysis and HPLC-ECD was used in the present experiments to assess the effects of selective DA receptor agonists on cortical ACh release. The ability of selective DA receptor antagonists to block apomorphine-induced increases in ACh release was also studied.

The  $D_1$  receptor agonist CY 208-243 (1.0 mg/kg) significantly increased cortical dialysate concentrations of ACh to 180% of baseline. The  $D_2$  agonists quinpirole (0.2 and 0.5 mg/kg) and PHNO (0.05 mg/kg) did not sign affect ACh release. In addition to having no effect on basal ACh release, quinpirole (0.2 mg/kg) did not potentiate the D<sub>1</sub>-mediated increase. The increase in ACh release (220% of baseline) caused by apomorphine (1.0 mg/kg) was completely blocked by the  $D_1$  receptor antagonist SCH 23390 (0.3 mg/kg). The  $D_2$  receptor antagonist raclopride (1.0 mg/kg) did not significantly attenuate the apomorphine-induced increase. The above results confirm that the basal forebrain cholinergic system is regulated in an excitatory manner by DA and indicate that D1 receptor mechanisms are preferentially involved.

DOPAMINE RELEASE AND TURNING BEHAVIOR EVOKED BY INTRANIGRAL CARBACHOL: A MICRODYALISIS STUDY. S. Hernández, J.L. Góngora, D. Martínez-Fong\*, M. Rosales and J. Aceves.
Dept. of Physiology, CINVESTAV-IPN, Ap. Postal 14740, 07000 México, D.F., México.
A recent immunological study demonstrated that cholinergic terminals make synaptic contacts with

A recent immunological study demonstrated that cholinergic terminals make synaptic contacts with dopaminergic (DA) neurons in the substantia nigra pars compacta (SNc) of the rat (Bolam et. al., Neurosci. 41:483, 1991). The aim here was to evaluate the striatal DA release and the turning behavior evoked by activation of acetylcholine receptors in the SNc. Male Wistar rats (280-320g) were anaesthetized and implanted with a guide cannula into right striatum. Five or seven days after surgery, DA was collected by a microdyalisis probe and measured by HPLC. Carbachol or vehicle were injected into right SNc. Carbachol (2  $\mu$ g) administrated into caudal SNc increased the DA release (50%) and a concomitant contralateral turning was observed. In contrast, when carbachol was applied into rostral SNc, striatal DA decreased (46%) and ipsilateral turning was elicited. This results indicate the existence of at least two subpopulations of DA neurons in the SNc which differently respond to carbachol application. (Supported by CONACYT No. P228CCOX891561)

## 116.9

NICOTINIC AGENTS ENHANCE ACETYLCHOLINE RELEASE FROM RAT FRONTAL CORTEX. Kathleen L. Summers\*, Ezio Giacobini and Elizabeth Williams, Dept. Pharmacology, Southern Illinois Univ. Sch. of Med., Springfield, IL 62794-9230

Nicotine has been shown to improve learning as well as shortand long-term memory. Patients with Alzheimer disease (AD) may benefit from treatment with nicotinic agents. We have studied the effects of nicotine and nicotine analogues on cortical acetylcholine (ACh) release in rat cortex in vivo with microdialysis and in vitro in slices. Nicotine (.59 mg/kg s.c.) produces a significant (40%) and long-lasting (3 hrs) increase in cortical ACh as determined by microdialysis without a cholinesterase inhibitor in the probe. We found that its presence decreases the duration of the nicotinic effect, probably by activating muscarinic autoinhibitory receptors. Nicotine (3.6 µM) also increases the potassium-evoked release of <sup>3</sup>H-ACh from cortical slices. Total ACh levels in cortex and striatum were found to remain constant or decrease slightly, supporting the hypothesis that nicotine increases release rather than synthesis of ACh. (Supported in part by R.J. Reynolds Tobacco Co.; NIA #P30 AG08014; S.I.U. Central Research Committee)

# 116.11

NMDA RECEPTORS MODULATE THE SEPTO-HIPPOCAMPAL CHOLINERGIC PATHWAY THROUGH GABAERGIC INTERNEURONS.

M.G.Giovannini, L.Bianchi and G.Pepeu\*. Dept.of Pharma-cology, University of Florence, 50134 Florence, Italy.

The regulation of the septo-hippocampal cholinergic pathway was investigated by transversal microdialysis technique in freely moving male adult rats. ACh and GABA in the perfusate were quantified by HPLC methods. I.c.v. injections of the NMDA antagonists CPP, MK801 and AP-7 brought about an increase in ACh release while the non-NMDA receptor antagonist DNQX had no effect. The increase following CPP injection was dose-dependent, in the range of 1-50 nmol, and reached a maximum of about +500%. It was abolished by TTX perfused through the dialysis probe, and prevented by i.c.v. injection of muscimol. CPP perfusion through the septum resulted in a decrease in GABA release from the septum and a concomitant increase in ACh release from the hippocampus. Muscimol administration to the septum abolished the effect of CCP. These results demonstrate that in the septum NMDA receptors tonically activate GABAergic neurons which in turn inhibit the cholinergic septo-hippocampal neurons. Supported by a grant from MURST, Italy.

### 116 8

MEASUREMENTS OF ACETYLCHOLINE (ACh) RELEASE FROM THE BARREL FIELD OF RAT SOMATOSENSORY CORTEX. M.E. Jiménez-Capdeville and R.W. Dykes\*. Centre de recherche en sciences neurologique Départements de physiologie Université de Montréal (Québec) CANADA. ACh release is correlated with wakefulness and other factors related to levels

of cortical activity. The technique of microdialysis in awake, unrestrained animals provides an opportunity to measure regional variations in ACh release that may be correlated with local neuronal activity. Three mm microdialysis probes (BAS) were obliquely inserted into the vibrissae representation of the primary somatosensory cortex. The collection of samples started 48 hours after the probe implantation and continued during a 24 hours period. The perfusion medium, a Ringer solution containing 5 µM neostigmine bromide, was pumped through the probe at a rate of 1.5 µl/min. One hundred and fifty µl aliquots were obtained each 100 min and immediatly injected into a reverse-phase HPLC column coupled to an electrochemical detector. The retention time for ACh in our system was 9 min and the limit of detection was 500 fmoles. After the Ach content of the sample was corrected for the probe efficiency,the results from 8 rats showed a release rate of 264 ± 22 fmol/min (x ± SEM, n=51). This value varied among animals ranging from x=189 fmol/min to x=525 fmol/min during the day and increasing up to twice these values in the evening. At the end of each experiment, the animal was sacrificed and the location of the probe in the brain was verified histologically.

## 116.10

EFFECTS OF NICOTINIC ACETYLCHOLINE RECEPTORS ON MOTOR NERVE. R.J. Storella\*, J. Hill and S.T. Begen. Dept. of Anesthesiology, Hahnemann U., Philadelphia, PA 19102

Previous studies on acetylcholine (ACh) overflow using anticholinesterases have not controlled for potential drug effects on muscarinic receptors and resting release. We measured ACh overflow from 6 mouse phrenic nerve diaphragms perfused with neostigmine (10 µM), atropine (20 µM) and d-tubocurarine (dTC). ACh was assayed by HPLC. Nerve was stimulated for 20 minutes with trains of 5 stimuli at 10 Hz, equilibrated first with 40 µM then 0.4 µM dTC. Perfusate was collected every 5 min. Resting release was greater with 0.4 µM than 40 µM dTC (0.66±.08[SE] vs 0.36±.09 pmole/min, paired T-test). ACh collected at steady-state release during stimulation (last 10 minutes) was greater for 0.4 than 40 µM dTC (2.04±.16 and 2.10±.22 vs. 1.77±.20 and 1.78±.17 pmole/min, repeated measures ANOVA). However there was no difference between 0.4 and 40 µM dTC (1.38±.11 and 1.44±.16 vs. 1.41±.14 and 1.42±0.11, repeated measures ANOVA) in evoked release (i.e. stimulated minus resting). Twitch tension was blocked completely at 40 µM, but only partially at 0.4 µM dTC (peak block = 59±4.7%, compared to drug free Krebs control). Thus, compared to 40 µM dTC (the 0.4 µM dTC allowed greater activation of nicotinic ACh receptors. We conclude that when muscarinic receptors are blocked, activation of nicotinic AChR may increase total ACh release but not evoked release.

EVIDENCE FOR FACILITATORY  $\alpha_1$  . ADRENOCEPTORS ON NERVE TERMINALS OF THE RAT URINARY BLADDER  $\underline{G.T.}$ ADRENOCEPTORS ON Somgyi\*, M. Tanowitz and W.C. de Groat, Department of Pharmacology, University of Pittsburgh, Pittsburgh PA, 15261. Adrenergic facilitatory modulation of cholinergic transmission was studied in the urinary bladder (UB) of the rat. <sup>3</sup>H-ACh release and contractions evoked by electrical field stimulation were measured in UB strips prelabelled with  $^3H$ -choline. Phenylephrine (PE 0.2-10  $\mu M)$ , an  $\alpha_1$  adrenoceptor agonist, increased 3H-ACh release and evoked contractions in a dose dependent manner. The  $\alpha_1$  adrenoceptor blocker terazosin  $(0.1-1 \mu M)(TRZ)$  or prazosin  $(1.0-5.0 \mu M)$  (PRZ) blocked both effects. TRZ was more potent than PRZ. The facilitation of the evoked contractions was also blocked by 0.1  $\mu$ M WB 4101, a selective  $\alpha_1$ antagonist. Atropine (1  $\mu$ M) reduced UB contractions, but did not block the facilitatory effect of PE. A reduction in the concentration of the Ca<sup>2+</sup> in the perfusion fluid to 0.75-1 mM reduced <sup>3</sup>H-ACh release, but enhanced the facilitatory effect of PE. PE did not change the release of norepinephrine from UB strips. It is concluded that ai adrenoceptormediated facilitation occurs on cholinergic and non-cholinergic non-noradrenergic nerve terminals, but not on adrenergic terminals in the rat UB and that the magnitude of facilitation is inversely related to Ca,2+. Supported by a grant from Abbott Labs.

ACETYLCHOLINE RELEASE IN THE MEDIAL PONTINE RETICULAR FORMATION (mPRF) IS INHIBITED BY SYSTEMIC MORPHINE. J.C.Keifer, H.A.Baghdoyan, R.Lydic (Spon:J.F.Biebuyck\*) Dept. of Anesthesia, Penn State Univ., Col. Med., Hershey, PA 17033.

The mPRF has been well characterized as a site mediating the cholinergically induced REM sleep-like state and state-dependent respiratory depression. Recent studies in our laboratory showed that morphine sulfate microinjected into the mPRF decreased the REM sleep-like state and increased apneas (Keifer et al, Neurosci. Absts. 17:620, 1991). Since morphine suppresses acetylcholine (ACh) release in a variety of central nervous system structures, we are testing the hypothesis that morphine inhibits REM sleep by suppressing ACh release in the mPRF. The effect of systemic morphine on mPRF ACh release evoked by electrical stimulation of the pedunculopontine tegmental nucleus (PPT) in barbiturate anesthetized cats was measured. PPT stimulation caused a significant increase (241%) in mean ACh release (2.46 pmole) compared to mPRF dialysis with no PPT stimulation (0.72 pmole). Following the administration of intravenous morphine sulphate (283ug/kg) there was a significant reduction (41%) in PPT-evoked ACh release (1.45 pmole). These data support the hypothesis that morphine inhibits REM sleep by decreasing ACh release in the mPRF. Support: Parker B. Francis Young Investigator Award (JCK), MH45361 (HAB), HL40881(RL).

NIMODIPINE PREVENTS THE DECREASE IN HIPPOCAMPAL EXTRACELLULAR ACETYLCHOLINE RELEASE PRODUCED BY HYPOBARIC HYPOXIA. B. Shukitt-Hale\*, M.J. Stillman, A. Levy, 2 D.I. Welch, J.A. Devine, and H.R. Lieberman, Military Performance and Neuroscience, U.S. Army Research Institute of Environmental Medicine, Natick, MA 01760, 'GEO-CENTERS, INC., Newton Centre, MA 02159, and 'IIBR, Ness Ziona, Israel.

Hypoxia has been shown to decrease acetylcholine (ACh) synthesis and release in vitro, and to decrease ACh synthesis in vivo; however, it is not known whether it affects extracellular release of ACh in vivo. Since the calcium channel blocker mimodipine has been shown to increase extracellular ACh, it may provide protection from the effects of hypobaric hypoxia on the cholinergic system. The purpose of this study was to examine the effect of hypobaric hypoxia on extracellular ACh levels, as measured by microdialysis, and to test the effects of nimodipine under these conditions. Microdialysis guide cannulae were implanted into the hippocampal region of male Fischer rats so that probes would sample from the CA1 and DG regions. Animals were then exposed for eight hours to a simulated altitude of 5500 m (18,000 ft) or tested at sea level for an equivalent duration. High performance liquid chromatography with electrochemical detection was used for on-line analysis of the dialysates. At 5500 m extracellular ACh levels in the placebo-treated group were significantly lower than the sea level group values. This decrement was reversed by nimodipine administered i.p. immediately preceding altitude ascent (10 mg/kg) and 250 min post-altitude ascent (10 mg/kg). These data suggest that nimodipine may provide protection from the detrimental effects of hypoxia on hippocampal cholinergic functions.

MUSCARINIC RECEPTOR SUBTYPES IN INTRAPARENCHYMAL MICROVESSELS FROM BOVINE AND HUMAN CEREBRAL CORTEX. D.G. Linville and E. Hamel, Montreal Neurological Institute, McGill University, Montréal, Québec, Canada H3A 2B4

Acetylcholine is a recognized regulator of cortical cerebral blood flow,

possibly via interaction with vascular muscarinic receptors. Since these receptors are highly heterogeneous, the subtypes present in bovine and human cerebral cortical microvessels (MV) were characterized pharmacologically by competition studies against [³H]-N-methylscopolamine ([°H]-NMS) binding. Both bovine and human MV were highly enriched in marker enzymes alkaline phosphatase and  $\gamma$ -glutamyl transpeptidase. The [ $^{3}$ H]-NMS binding parameters were comparable in bovine and human MV ( $B_{max}=29.8\pm3.9$  and 25.6 fmol/mg protein and  $K_{D}=183\pm57$  and 178 pM, respectively). In competition studies, the antagonist vascular potencies (pK<sub>D</sub>) were (bovine; human): HHSiD (7.15; 7.47); AF-DX 384 (7.33; 7.44); AQ-RA 741 (7.41; 6.91); methoctramine (7.41; 6.89) and DAU 6202 (8.16; 8.62). In bovine MV, pirenzepine delineated two sites, one of high ( $pK_{DH}=8.25$ ) and one of low affinity (pK<sub>DL</sub> = 6.88). In contrast, in human MV, pirenzepine was best fitted to a single site ( $pK_D = 7.87$ ). Using correlation analysis with the antagonists published affinities at various muscarinic receptors, m<sub>1</sub> sites were identified in both bovine and human MV. The m<sub>2</sub> and m<sub>3</sub> subtypes were excluded in both species but the m3 and m4 remained as possible candidates for the low affinity site identified with pirenzepine in bovine MV. In conclusion, bovine MV appear to contain a heterogeneous population of muscarinic receptors while in human, a single population of m<sub>1</sub> sites was identified. These results suggest species differences in cholinergic regulation of local brain perfusion. Supported by MRC of Canada, FRSQ and Dr. Karl Thomae GmbH.

MOLECULAR CLONING OF BOVINE MUSCARINIC ACETYLCHOLINE m3 RECEPTOR. P.H.K. Lee\*P.K. Hodges, J. F. Glickman and K.-J. Chang. Division of Cell Biology, Burroughs Wellcome Co, Research Triangle Park, NC 27709.

With the use of the polymerase chain reaction (PCR), we have taken advantage of the sequence similarity at the seven transmembrane domains displayed by known G protein-coupled receptors to amplify and clone new gene members of this receptor family. Degenerate oligonucleotide primers were designed according to the conserved regions corresponding to transmembrane regions III and VI of cloned G protein-coupled receptors. cDNA obtained by reverse transcription of poly (A)+ RNA from bovine striatum was submitted to 30 cycles of PCR with the primers. When examined by 1% agarose gel, the PCR product revealed a major band at about 600 bp and another at 800 bp. The bands were excised and purified for subcloning in M13 and sequenced. Three clones had sequence characteristics similar to the G protein-coupled receptor gene family. One of these clones was used as a probe in screening of a bovine brain cDNA library by plaque hybridization method. Six clones were identified and one, S40A1, has 2538 bp and contains an open reading frame of 590 amino acids. The hydropathy profile analysis suggested that this protein comprised of seven putative transmembrane segments. Comparisons of \$40A1 with those cloned G protein-coupled receptors show that the protein is highly homologous to porcine (98%), human (95%) and rat (92%) m3 receptors, therefore suggesting that \$40A1 is encoding a bovine muscarinic acetylcholine m3 receptor

DEVELOPMENT OF SITE-DIRECTED POLYCLONAL ANTIBODIES AGAINST m1, m2, and m4 MUSCARINIC CHOLINERGIC RECEPTORS. A. Hersi, R. Quirion and P. Gaudreau. Douglas Hospital Research Ctr., Dept. Psychiatry, McGill University and Notre-Dame Hospital Research Ctr., Dept. Medicine, University of Montreal, Montreal, Canada.

Five subtypes (m1-m5) of muscarinic receptors have been cloned. However, their pharmacological and biochemical study is complicated in the brain because many regions express a mixed population of receptors. Consequently, we have developed site-directed polyclonal antibodies against muscarinic receptors. Peptides corresponding to subtype specific sequences of the carboxy-terminus of m1 and the third cytoplasmic loop of m2 and m4 rat muscarinic receptors were synthesized by solid-phase peptide chemistry. Rabbits were immunized with the purified peptides adsorbed onto methylated bovine serum albumin as carrier protein, in Freund's adjuvant. Both crude antisera and affinity purified IgGs are functioning in Western blot. In rat brain, a major band was labeled with each antisera while no signal was detected with pre-immune sera. This major band was erasable by pre-incubating the antisera with the corresponding but not hetero-logous peptides. Similar results were observed in human postmortem brain tissues. The apparent molecular weight of these bands were 90, 88 and 60 Kd for m1, m2 and m4, respectively. These antibodies should prove useful in assessing the fate of muscarinic receptor subtypes in neurode generative processes such Alzheimer's disease.

ONTOGENY OF ml-m5 MUSCARINIC ACETYLCHOLINE RECEPTOR GENE EXPRESSION IN THE RAT CNS. <u>S. Vincent\*, L. Tsiokas and M. Watson</u>. Department of Pharmacology, UMDNJ-NJ Med. Sch., Newark, NJ 07103-2714.

The postnatal ontogeny of muscarinic receptor (mAChR) subtypes in rat brain (10um) sections at days 1,7,14,21,28,35 and adult (3mo) was studied via quantitative ligand autoradiography and in situ hybridization histochemistry (ISHH). LiCl was used in cerebral cortical slices (350x350um) to study inositol phospholipid (IP) hydrolysis by prelabeling with myo[-2-3H]inositol (.5uM) in Krebs buffer (95%0<sub>2</sub>,5%C0<sub>2</sub>). [3H](-)quinuclidinylbenzilate, a specific nonsubtype selective antagonist, [3H]cismethyldioxolane, a label for the super high affinity agonist state, [3H]pirenzepine, an M1 antagonist, [3H]AF-DX 384, an M2 antagonist and [3H]hemicholinium-3, a Na+-dependent high affinity choline uptake inhibitor, were each used as previously described to obtain quantitative autoradiograms. Quantitative ISHH data was done via 3'-end labeled oligonucleotide probes (35S-dATP;>1,000 Ci/mmol) complementary to 4-48 or 4-51 base sequences of m1-m5 mRNA after verifying specificity via Northern blot analysis. Sections were incubated (25°C, 24h), washed (Tm=55°C;0.5xSSC), dried, apposed (-4wk; 0-4°C) to Hyperfilm-Bmax and quantified via DUMAS densitometer. Differential progressive alterations in m1-m5 mRNA and mAChR levels occur during ontogeny. (MH-43024).

DENERVATION-INDUCED CHANGES IN HIPPOCAMPAL MUSCARINIC RECEPTOR SUBTYPES AND THEIR MRNA. Z. Zang\*, G. Buzsaki, and Ian Creese. Center for Molecular & Behavioral Neuroscience, Rutgers, The State University of New Jersey, Newark, NJ 07102.

Alzheimer's disease is associated with cholinergic neuronal cell loss in the basal forebrain. Previous studies have shown that the major cholinergic projection to the hippocampus is derived from major cholinergic projection to the hippocampus is derived from the medial septum and can be destroyed by lesions of the fimbria and fornix. The present study examined the expression of muscarinic receptor subtype mRNAs (m1 and m3) by solution hybridization/RNase protection assay and the level of pharmacologically defined M1 and non-M1 muscarinic receptors by autoradiography in rat hippocampus following fimbria/fornix aspiration lesion. The receptor autoradiography data demonstrated that 3 weeks following unitateral lesion there was an aspiration lesion. The receptor autoradiography data demonstrated that 3 weeks following unilateral lesion there was an overall 20% increase in non-pirenzepine displaceable [<sup>3</sup>H]QNB binding in the denervated hippocampus (CA3 +51%, CA4 +75% and dentate gyrus +16%). In bilaterally lesioned rats, the solution hybridization/RNase protection analyses indicated that hippocampal m3 receptor mRNA was significantly increased (1 week post lesion: +22.7%, 3 weeks: +54.2%). However, the level of m1 post lesion: 422.7%, 3 weeks: +34.2%). However, the level of m1 receptor mRNA was not significantly affected by the lesion. These results suggest that: (a) the non-M1 receptors are coded by the m3 gene, (b) the localization of these receptors is probably post-synaptic to the septohippocampal cholinergic terminals, and (c) they are upregulated following denervation.

EFFECTS OF CHRONIC DFP ON MUSCARINIC AND NICOTINIC NEUROTRANSMISSION DURING RAT BRAIN DEVELOPMENT: M. Cmino, W. Bakhuini, F. Reno', P. Marini, A. Princivalle, C. Tromba\*, F. Clementi, F. Cattabeni, Inst of Pharmacol and Pharmacogn, Univ. of Urbino, Urbino; Inst of Pharmacol. Sci. and CNR Center of Cynopharmacol and Dept. of Medical Pharmacol. Univ. of Milano, Italy.

Organophosphates are widely used as pesticides and as experimental nools to study the regulation of cholinergic receptors due to their activity as acetylcholinesterase inhibitors. However, little is known about the effects elicited by the chronic exposure to these compounds during brain maturation. In this study, we have chosen two particular stages of brain development, postnatal day 10 (P10) and postnatal day 21 (P21), characterized by an active process of synaptic modeling. Rats at different ages were chronically treated with DFP 1 mg/kg the first day and 0.5 mg/kg the following days. Cholinesterase activity, binding of [3H]mg/kg me insteady and u.5 mg/kg me routowing cays. Choinesterase activity, oricing of [91]-QNB and the accumulation of radiolabeled phosphoinostitides ([91]-Ins Ps) after carbachol stimulation were measured in the cortex of P10, P21 and adult animals. The cholinesterase activity was reduced by 81%, 88% and 94% at P10, P21 and adult respectively. In P21 and adultaminals, the treatment with DFP included a statistically significant decrease in the Briax of CRI ONDI. [3H]-ONB binding and in the turnover of Ins Ps. In contrast, at P10 the treatment with DFP is still able to reduce the total number of cortical QNB binding sites but doesn't have any effect on the numover of the Ins Ps. The Kd of the receptor for [3H]-QNB was never affected by the treatment. This observation may suggest that at P10 there is an uncoupling of the muscarinic receptor with its transduction machinery, in contrast to what observed at P21 and in the adult where the receptor and the turnover of Ins Ps are both regulated by the treatment. We are currently evaluating the effects of DFP treatment on nicotinic parameters such as [3H]-Nicotine, [1251]-a bungarotoxin binding and the expression of some neuronal nicotinic receptor suburnits using receptor autoradiography and in situ hybridization techniques. Supported by grant 91.00124.PF41 of the National Research Council (CNR); targeted project "Prevention and Control of Disease Factors"- Subproject 2.

MUTAGENIC STUDIES OF A CONSERVED ARGININE IN THE RAT ml

MUTAGENIC STUDIES OF A CONSERVED ARGININE IN THE RAT ml RECEPTOR. P.G. JONES, C.A.M. CURTIS and E.C. HULME (SPON: Brain Research Association), Division of Physical Biochemistry, NIMR, LONDON. NWT 1AA, UK.

The muscarinic acetylcholine receptors are members of the "superfamily" of G-protein coupled receptors. These receptors form seven transmembrane domains and within the family, there are many conserved residues. These are likely to serve important roles in ligand binding, receptor conformation or G-protein interaction. One such residue is the arginine of the aspartate-arginine-tyrosine motif occurring at the cytoplasmic interface of the third transmembrane helix. The reversal of the arginine and tyrosine in rhodopsin, whilst not affecting the ground (non-G protein coupled) state, severely impairs its coupling to transducin.

Using oligonuclectide-directed mutagenesis, we have replaced this residue in the rat ml receptor, by lysine and the mutant receptor was expressed in COS-7 cells at similar levels to the wild type. The mutation had little effect on the binding of the antagonist [H]-N-methylscopolamine, K, for both wild type and mutant being approximately U.InM. This will allow detailed analysis to be performed and although ground state binding is unlikely to be affected, it is possible that this residue has an important role to play in receptor function.

OF MUSCARINIC RECEPTORS CHOLINERGIC DENERVATION OF PLASTICITY A.D. Peagler and D.S. Parsons. Behavioral Neuroscience Program, Dept.s of Neurology and Psychology, VA Medical Center and U. of Alabama, Birmingham, AL 35294-0017.

Cholinergic denergetion (20) **FOLLOWING** 

electrolytic lesions of the medial septum (MS) results in abnormal adrenergic innervation of the hippocampus [Hippocampal sympathetic ingrowth (HSI)] by sympathetic fibers that originate from the superior cervical ganglion (SCG) and are normally restricted to the cerebral blood vessels. We now report that CD and HSI alter binding parameters of the muscarinic antagonist, Quinuclidinyi benzilate, L-[benzilic-4,4-3H]- (QNB). Adult male Sprague-Dawley rats were divided into 3 surgical groups: Control; CD (MS lesion + Ganglionectomy: Gx); or HSI (MS lesions + sham ganglionectomy). Receptor binding studies were performed on hippocampal membranes 4 weeks post-surgery, using 1  $\mu$ M Atropine to measure non-specific binding. Preliminary results indicate that compared to controls,  $K_0$  was increased in the CD group, while HSI appeared to "normalize" the  $K_0$ ; and the  $B_{max}$  was ised in both the experimental groups. These results indicate that HSI, which normalizes both carbachol-stimulated PI hydrolysis, and protein kinase C (PKC) levels at this time point after surgery, may actually affect the entire cholinergic signal transduction pathway. This in turn may contribute to the observable behavioral deficits induced by

MUTATION OF ASP TO GLU IN TRANSMEMBRANE HELIX 3 OF THE MUSCARINIC RECEPTORS. K.M. Page, C.A.M. Curtis and E.C. Hulme. (SPON: Brain Research Association). Division of Physical Biochemistry, National Institute for Medical Research, Mill Hill, London, NW7 1AA, U.K.

The third transmembrane helix of the muscarinic acetylcholine receptors (mAchRs) contains a conserved aspartic acid residue (Asp105, ml mAchR) found in all members of the cationic amine-binding subclass of G-protein-coupled receptors. It has been suggested that the carboxylate side-chain may form an ionic bond with the positively-charged headgroups of both agonists and antagonists. We have probed the function of this residue in detail by mutating it to glutamic acid in both ml and m2 mAchRe, which differ in their primary G-protein selectivities. The binding properties of wild-type and mutant receptors were compared after expression in COS7 cells. In contrast to the large effect of homologous mutation on the β-adrenergic receptor, the affinity of the muscarinic antagonist N-methylscopolamine was reduced only 3-fold. Ach underwent a much larger reduction in potency, the corrected ICSO value increasing by 30-fold (ml) to 100-fold (m2). Analysis using a ternary complex model of binding suggested that induction of the agonist-receptor-G-protein complex was more strongly inhibited than formation of the binary agonist-receptor complex. Inhibition of ternary complex formation was also seen with several agonists structurally related to Ach. Interestingly, however, their overall potencies were less affected.

# 117.10

REGIONAL DELETION OF THE THIRD INTRACELLULAR LOOP OF THE m1 MUSCARINIC ACETYLCHOLINE RECEPTOR IMPAIRS AGONIST-INDUCED DOWN-REGULUATION BUT NOT UNCOUPLING. Norman H. Lee\* and Claire M. Fraser, Section on Molecular Neurobiology, Laboratory of Neurogenetics, NIAAA, ADAMHA, Rockville, MD 20852. The role of the third intracellular (i3) loop in homologous and heterologous

down-regulation of the m1 muscarinic acetylcholine receptor (m1 mAChR) was investigated upon expression in Chinese hamster ovary cells. Deletions were constructed where the majority or small sections of the i3 loop is missing, but leaving the membrane proximal portions intact. All mutants were able to fully stimulate phosphatidyl inositol (PI) turnover and were pharmacologically indentical to the wild-type receptor. expressing wild-type m1 mAChR and β2 adrenergic receptors, homologous and heterologous down-regulation of the m1 mAChR occurs when cells are pretreated with the muscarinic agonist carbamylcholine (CBC) or adrenergic agonist isoproterenol (Iso), respectively. Deletions of amino acids 227-269 (del 227-269) at the amino terminal of i3 produced a mutant receptor with impaired ability to down-regulate when exposed to CBC for up to 12 hours or Iso for up to 24 hours. However, this same deletion did not impair the ability of CBC-pretreatment to desensitize receptor-mediated PI turnover. Del 275-348, where 74 amino acids from the carboxyl terminal side of i3 Del 275-348, where 74 amino acids from the carboxyl terminal side of i3 is deleted, was indistinguishable from wild-type m1 mAChR in terms of homologous and heterologous down-regulation. The deletion encompassing amino acids 227-341, in which the majority of i3 is missing, exhibited an impaired ability to down-regulate similar to del 227-269. In conclusion, a stretch of amino acids from 227-269 on the amino terminal side of i3 may play an important role in homologous and heterologous down-regulation of the m1 mAChR but is not necessary for CBC-mediated receptor uncoupling.

MUTATIONS OF ASPARTATE 103 IN HUMAN MUSCARINIC RECEPTOR SUBTYPE m2 EXPRESSED IN COS-7 CELLS: EFFECTS ON RECEPTOR BINDING AND SIGNAL TRANSDUCTION. C.J. Spencer, R.D. Schwarz and LL. Lauffer. Parke-Davis Pharm. Res. Div., Warner-Lambert Co., Ann Arbor, MI 48105

Based upon molecular biological characterization, five subtypes of the human muscarinic receptor have been cloned and expressed in mammalian cells in culture. Recent results using rat m1 receptors have shown that the Asp residue at position 105 was crucial for both agonist and antagonist muscarinic ligand binding. To gain a greater understanding of the involvement of this Asp in agonist/antagonist binding, Asp 103 in the Hm2 receptor (corresponding to Asp 105 in m1) was mutated to Asn, Ala, and Glu. Hm2 was chosen since both agonist (3H-CMD) and antagonist (3H-NMS) binding could be performed as well as measurement of alterations in signal transduction, e.g. adenylate cyclase activity. Mutagenesis was achieved by a modification of the Kunkle method and mutant and wild type receptors were expressed in COS-7 cells by transient transfection. Similar to the rat m1 receptor, changing Asp to Asn in Hm2 markedly inhibited 3H-NMS binding. Comparisons to this effect will be made for the Ala and Glu mutations. Thus, our results confirm the key role Asp 103 plays in binding of agonists and antagonists to the Hm2 receptor.

## 117.13

RECONSTITUTION OF FUNCTIONAL MUSCARINIC RECEPTORS BY COEXPRESSION OF N- AND C-TERMINAL RECEPTOR DOMAINS R. Maggio, Z. Vogel, A. Zuddas\*, S. Nanavati and J. Wess. Natl. Inst. of Neurol. Disorders and Stroke, Lab. of Mol. Biology, Bethesda, MD 20892

Truncated m2 and m3 muscarinic receptor genes were created and coexpressed in COS-7 cells with gene tragments encoding the C-terminal receptor portions. The truncated receptors (referred to as m2- and m3-trunc) contained transmembrane domains (TMD) I-V and the N-terminal portion of the third cytoplasmic loop (i3), whereas the C-terminal receptor fragments (referred to as m2- and m3-tail) contained TMD VI and VII and the adjacent intra- and extracellular sequences. Expression in COS-7 cells of any of these four polypeptides alone did not result in any detectable [3H]NMS binding activity. Likewise, coexpression of m3-trunc with m2-tail did not give any [<sup>3</sup>H]NMS binding. However, specific [<sup>3</sup>H]NMS binding could be observed after coexpression of m2-trunc with m2- or m3-tail, and of m3-trunc with m3-tail. The "reconstituted" muscarinic receptors displayed agonist and antagonist binding properties similar to those of the wild-type m2 and m3 receptors. The "reconstituted m3-trunc/m3-tail receptor" was able to stimulate agonist-dependent phosphoinositide hydrolysis to the same maximal extent as did the wild-type m3 receptor. The data raise the intriguing possibility that muscarinic receptors could behave in a fashion analogous to multiple subunit receptors, with the i3 loop serving as a linker sequence between the two functional domains. Since the muscarinic receptors share high structural homology with all other G protein-coupled receptors, our findings may be of general importance for the entire superfamily of receptors.

# 117.15

USE OF CHIMERIC MUSCARINIC RECEPTORS TO INVESTI-GATE EPITOPES INVOLVED IN ALLOSTERIC INTERACTIONS John Ellis, Margaret Seidenberg, Jürgen Wess and Mark R. Brann Mol. Neuropharmacol. Section, Dept. of Psychiatry, Univ. of Vermont, Burlington, VT and <sup>1</sup>Lab. of Molec. Biol., NINDS, Bethesda, MD.

All five (m1-m5) muscarinic receptors are sensitive to allosteric regulation, but gallamine is considerably more potent at slowing the dissociation of [3H]N-methylscopolamine (NMS) from the m2 subtype than from the m3 or m5 subtypes (Ellis et al., Biochem. Pharmacol. 42:1927, 1991). In order to study the structural basis of gallamine's preference for the m2 subtype, we evaluated [3H]NMS-gallamine interactions at chimeric receptors in which segments of the m5 receptor were systematically replaced with the corresponding m2 sequence. Substitutions that included the sixth transmembrane domain and third extracellular loop resulted in marked increases in gallamine's potency, but substitutions that did not include these regions were without effect. A similar substitution was investigated using m2/m3 chimeric receptors, in which a segment extending from the middle of the sixth transmembrane domain to the carboxyl terminal was exchanged. As with the m2/m5 constructs, substituting the m2 C-terminal segment into the m3 subtype significantly increased gallamine's potency. Furthermore, the converse substitution reduced the potency of gallamine dramatically, to approximately that seen for the m3 subtype itself. It appears that this portion of the receptor is very important for the binding of gallamine and/or the allosteric interactions between gallamine and [3H]NMS. (Supported in part by R01 AG05214.)

FUNCTIONAL ROLE OF PROLINE AND TRYPTOPHAN RESIDUES HIGHLY CONSERVED AMONG G PROTEIN-COUPLED RECEPTORS: A STUDY WITH m3 MUSCARINIC ACETYLCHOLINE RECEPTOR POINT MUTANTS. . Wess\*, S. Nanavati. Z. Vogel and R. Maggio. Natl. Inst. of Neurological Disorders and Stroke, Lab. of Molecular Biology, Bethesda, MD 20892.

A series of four proline and three tryptophan residues are well conserved among the entire superfamily of G protein-coupled receptors. All of these amino acids are located within the hydrophobic core of these receptors on transmembrane domains (TMD) IV, V, VI, and VII. To study their role in ligand binding and receptor function, the rat m3 muscarinic acetylcholine receptor ed as a model system. A series of mutant m3 muscarinic receptors in which the conserved proline and tryptophan residues were individually replaced by alanine and phenylalanine, respectively, were created and transiently expressed in COS-7 cells. As found in [3-H]NMS binding studies, Pro242->Ala (TMD V), Pro505->Ala (TMD VI), and Pro540->Ala (TMD VII) were expressed at >30 times lower levels than the wild-type receptor. Pro201->Ala (TMD IV) showed drastically reduced binding affinities (two to three orders of magnitude as compared with the wild-type receptor) for both muscarinic agonists and antagonists. In contrast to all other mutant receptors studied, Trp503->Phe (TMD VI), Trp530->Phe (TMD VII), and Pro540->Ala (TMD VII) proved to be severely impaired in their ability to mediate carbachol-(TMD VII) proved to be severely impaired in their ability to mediate carbachoi-induced stimulation of phosphoinositide hydrolysis (E-max ca. 20-40% of that of the wild-type receptor). These data suggest that the examined proline and tryptophan residues play important roles in ligand binding and receptor function. Since these residues are found in almost all G protein-coupled receptors, our findings may be of general importance for this whole class of receptors.

DIFFERENTIAL DOWN-REGULATION OF STRIATAL m4
MUSCARINIC RECEPTORS DETECTED BY SUBTYPE-SPECIFIC
RECEPTOR IMMUNOPRECIPITATION. K.A. Frey, T. Desmond and
A.I. Levey. Neuroscience Laboratories, The University of Michigan, Ann A.I. Levey. Neuroscience Laboratories, Ine University of Patennam, Arbor, MI 48109 and Department of Neurology, Emory University, Atlanta,

Previous studies from our laboratories have identified muscarinic receptor down-regulation in the rat following one week of acetylcholinesterase (AChE) inhibition by repeated administration of diisopropylfluorophosphate (DFP). Subtype-selective muscarinic receptor autoradiographic assays (AChE) inhibition by repeated administration of disopropylfluorophosphate (DFP). Subtype-selective muscarinic receptor autoradiographic assays indicate widespread changes in cerebral receptors of the M1 and M2, but not the M3 subtypes. Receptor decreases were greatest for non-M1 receptors within the striatum and olfactory tubercle. Due to enrichment in m4 mRNA in these regions, we hypothesized involvement of this subtype. In the present work we have specifically identified the receptors involved. Receptors were solubilized from cerebral cortices and striata of control and DFP-treated rats, radiolabeled with [³H]methylscopolaine, and individual subtypes precipitated by addition of subtype-specific rabbit antisera followed by goat anti-rabbit secondary antibodies (Levey et al., J. Neurosci. 11:3218-3226, 1991). Precipitated receptors were then quantified by liquid scintillation spectroscopy. In control animals, receptors solubilized from frontal cortex consisted of relatively equal admixtures of the m1, m2 and m4 subtypes (25, 36, and 29% of total, respectively) while the m4 receptor predominated in the striatum (27, 12, and 48% attributable to m1, m2, and m4, respectively). Following DFP administration, total cortical binding was reduced by 25%, without differential effects on receptor subtypes. Striatal m4 receptors, however, were decreased by 50% compared to a reduction of only 20% in m1 receptors. These results provide evidence for specific effects on striatal m4 receptors during AChE inhibition. This may indicate distinct mechanisms of receptor regulation, or differential treatment effects on distinct cell populations expressing subsets of the muscarinic receptors.

THAPSIGARGIN (TGN), BUT NOT RYANODINE, INHIBITS NMDA-EVOKED INTRACELLULAR Ca2+ MOBILIZATION IN RAT CORTICAL NEURONS. Sizheng Z. Lei\*. Dongxian Zhang. and Stuart A. Lipton. Dept. of Neurology, Children's Hospital and Program in Neuroscience, Harvard Medical School, Boston, MA 02115.

Previously, we demonstrated that Ca2+ influx triggered by NMDA receptor activation can mobilize intracellular Ca2+ stores, and NMDA receptor activation can mobilize intracellular Ca<sup>2+</sup> stores, and this effect can be inhibited by dantrolene or ionomycin (Lei et al., Soc. Neurosci. Abstr., 1991;17:1291). Here, we further characterize the effect of NMDA on intracellular Ca<sup>2+</sup> stores using digital calcium imaging with fura-2 and whole-cell recording techniques in cultures of rat primary cortical neurons. Thapsigargin (TGN; 10 µM), a tumor promoter known to block the Ca<sup>2+</sup> pump of the endoplasmic reticulum, increases intracellular. Ca<sup>2+</sup> concentration [Ca<sup>2+</sup>]. At a lower increases intracellular  $Ca^{2+}$  concentration,  $[Ca^{2+}]_i$ . At a lower concentration, that does not by itself affect  $[Ca^{2+}]_i$ ,  $TGN (1 \mu M)$  inhibited NMDA (10  $\mu$ M)-evoked increases in  $[Ca^{2+}]_i$  by 50%. In contrast, 1-2 µM TGN did not block kainic acid (50 µM)-evoked [Ca2+]i responses. In whole-cell recordings, TGN (1 µM) did not decrease NMDA-activated currents. Also, application of 1-20 µM ryanodine, an alkaloid known to promote Ca<sup>2+</sup> leak out of caffeine-sensitive intracellular stores in a use-dependent manner, failed to inhibit the [Ca<sup>2+</sup>]<sub>i</sub> responses elicited by repetitive applications of NMDA. Taken together with our previous findings, these results suggest that NMDAstimulated Ca2+ influx through ion channels leads to the mobilization of specific intracellular Ca2+ stores, and this increase in [Ca2+]; can be inhibited ~50% with pharmacological manipulation of these stores.

SIMILAR EFFECTS OF  $N^{\omega}$ -MONOMETHYL-L-ARGININE (L-NMMA) SIMILAR EFFECTS OF N<sup>M</sup>-MONOMETHYL-L-ARGININE (L-NMMA) AND SODIUM NITROPRUSSIDE (SNP) ON NMDA-INDUCED GLUTAMATE RELEASE AND ELEVATION OF INTRACELLULAR CALCIUM LEVELS ([Ca<sup>+</sup>]), BUT OPPOSITE EFFECTS ON THE NMDA-INDUCED ELEVATION OF CYCLIC GMP IN NEURONAL CULTURE. S. Oh., Z. Cai, R.W. Rockhold\* and P. P. McCaslin, Dept. Pharmacol./Toxicol., Univ. Miss. Med. Ctr., Jackson, Ms., 39216

These studies were designed to examine the effects of a nitric oxide (NO) generator (SNP) and an inhibitor of NO synthase (L-NMMA) on glutamate neurotransmission. In primary cultures of cerebellar granule cells, the glutamate receptor agonist, N-methyl-D-aspartate (NMDA), resulted in the elevation of [Ca<sup>++</sup>] (measured by fura-2 fluorometry), the number of the company of the comp [Ca<sup>++</sup>]i (measured by fura-2 fluorometry), the release of glutamate (measured by HPLC) and an increase in cyclic GMP levels (measured by RIA). Both L-NMMA and SNP partially prevented the NMDA-induced release of glutamate, but neither compound had effects on the basal release of glutamate. Elevation of [Ca<sup>++</sup>]; induced by NMDA were very slightly elevated by L-NMMA and markedly antagonized by SNP when the compounds were added after the addition of NMDA. However, if cells were preincubated with L-NMMA or SNP 10 min before the addition of NMDA, the NMDA-induced elevation of [Ca++]i was markedly reduced by L-NMMA and completely blocked by SNP. These compounds also had opposite effects on the NMDA-induced elevation of cyclic GMP; SNP greatly augmented cyclic GMP levels while L-NMMA completely blocked NMDA-induced increases in cyclic GMP. Both compounds had effects on basal levels of cyclic GMP in these cultures. These results show similar effects of compounds which are thought to increase (SNP) and decrease (L-NMMA) NO levels. It is unclear whether these effects result from a biphasic effect of NO or from partial antagonism of the NMDA receptor by L-NMMA.

CARBACHOL POTENTIATES NMDA CURRENT VIA PROTEIN KINASE C IN RAT HIPPOCAMPAL SLICES. L. Aniksztejn, A. Kleschevnikov, Y. Ben-Ari and A.Represa\*. INSERM U29, Hôpital de Port-Royal, 123 Bld de Port-Royal, 75014 Paris (France).

Activation of the protein kinase C (PKC) by a  $\mu$  opioid agonist (Chen and Huang, Neuron 7, 319, 1991 and Nature, 356, 521, 1992) or  $Q_p$  agonists (Aniksztejn et al., Eur. J. Neurosci. June 1992) enhances selectively the currents mediated by N-methyl-D-aspartate (NMDA). Markram and Segal (J. Physiol. 447, 513,1992) have described in CA1 hippocampal neurons a similar enhancement of NMDA current by stimulation of muscarinic receptors, however they suggested that this effect was not mediated by PKC since it was not blocked by intracellular injection of H-7, a broad spectrum unselective PKC blocker. We now report that in CA1 neurons, intracellular injection of the specific PKC (19-36) inhibitory peptide totally prevents the enhancement of NMDA currents induced by carbachol. Currents were recorded with the single electrode voltage clamp technique. Electrodes were filled with KCI (3M). TEA (10mM), 4-AP (1mM), CsCl (3mM) and TTX (1µM) were added to the bath solution to block voltage dependent K+ and Na+ channels and improve space clamp. Bath application of NMDA (5-10 $\mu$ M; 90 sec) generated an inward current I<sub>NMDA</sub> of 277 ± 75 pA (mean ± S.D. n=9) at mean holding potential of 59  $\pm$  8mV. In presence of carbachol (10 $\mu$ M, 180-240 sec), NMDA peak current was potentiated (424 ± 115 pA). This effect fully reversed since 5 min after washing carbachol,  $I_{NMDA}$  was of 277  $\pm$  80 pÅ. In contrast , in similar experiments performed with microelectrodes containing the PKC (19-36) inhibitory peptide (50 $\mu$ M), carbachol did not potentiate the NMDA current (228  $\pm$  50 pA in control and 183  $\pm$  50pA with carbachol (mean  $\pm$  SD, n=9)). Therefore, in contrast to the data obtained by Markram and Segal, our results suggest that the enhancement of I<sub>NMDA</sub> induced by carbachol is mediated by PKC.

NITRIC OXIDE (NO) GENERATION DOWN-REGULATES MMDA RECEPTOR ACTIVITY VIA A REDOX
MODULATORY SITE. H.-S. Vincent Chen\*. S.K. Aggarwal.
S.Z. Lei, Z.-H. Pan, J. Hartman, N.J. Sucher, and Stuart A. Lipton.
Department of Neurology, Children's Hospital and Program in
Neuroscience, Harvard Medical School, Boston, MA 02115.

NMDA-evoked increases in [Ca2+]i and whole-cell current of rat cortical neurons were monitored using fura-2 digital imaging and patch-clamp recording techniques. Extracellular application of nitroglycerin (NTG; 100  $\mu$ M) or the NO-generating drug S-nitrosocysteine (SNOC; 100 µM) inhibited NMDA responses; most of this inhibitory effect persisted after extensive washing for several min. Partial prevention of NO formation from NTG (by prolonged pre-incubation with glutathione) attenuated the action of NTG, suggesting that the decrease in NMDAevoked responses by this nitroso compound was related to its generation of NO. One possibility for these effects is that the thiol group(s) comprising the redox modulatory site of the NMDA receptor react in the comprising the redox modulatory site of the NMDA receptor react in the presence of NO, analogous to the manner in which other oxidizing agents down-regulate NMDA receptor activity (Aizenman, Lipton, Loring, Neuron 1989;2:1257). Consistent with this notion, the reducing agent dithiothreitol (DTT; 2 mM for 2 min) reversed the effects of NTG or SNOC by ~90%. Moreover, alkylation of thiols with N-ethyl-maleimide (NEM; 1-5 mM for 2 min) completely prevented the inhibitory effects of NTG or SNOC on NMDA-evoked responses. NOgenerating compounds also protected cortical cultures from NMDA receptor-mediated neurotoxicity, an effect blocked by complexing NO with hemoglobin. These results suggest a new NO regulatory pathway involving reactions with thiol groups on the NMDA receptor complex.

## 118.4

INHIBITION OF N-METHYL-D-ASPARTATE-STIMULATED NEUROTRANSMITTER RELEASE BY SODIUM NITROPRUSSIDE NOT DUE TO NITRIC OXIDE. A.K. Stout\* and J.J. Woodward. Dept. of Pharmacology and Toxicology, Medical College of Virginia, Richmond, VA 23298. Previous studies in our lab have suggested that nitric oxide (NO) may act as a feedback inhibitor of the N-methyl-D-aspartate receptor. In these experiments the NO generator sodium nitroprusside (SNP, 100 µM) inhibited NMDA-stimulated release of tritiated norepinephrine from hippocampal slices of adult male of tritiated norepinephrine from hippocampal slices of adult male Sprague-Dawley rats by approximately 50% and also stimulated Sprague-Dawiey fats by approximately 50% and also stimulated the production of cyclic guanosine monophosphate (cGMP) in primary neuronal cultures to over 400% of basal levels. However, our recent experiments suggest that the inhibition of transmitter release seen with SNP was not due to NO. Treatment of hippocampal slices with the photolysis degradation products of SNP, which presumably cannot generate NO, also inhibited NMDA-stimulated transmitter release (IC50 < 10  $\mu$ M). In addition, potassium ferricyanide and potassium ferrocyanide complexes (100-300 µM) were also shown to inhibit release. Finally, the NO generator S-nitroso-N-acetyl-penicillamine (SNAP) stimulated cGMP formation to nearly 3000% of basal levels in primary neuronal cultures but failed to inhibit release in the hippocampal slices. Thus the role of nitric oxide in modulating NMDA-stimulated neurotransmitter release remains to be determined. Supported by NIAAA AA08089, DA 07027, and grant from the Alcoholic Beverage Medical Research Foundation.

# 118.6

EFFECTS OF PCP ON SINGLE NMDA CHANNELS IN **EXCISED PATCHES FROM RAT HIPPOCAMPAL NEURONS** R.C.Araneda\*, R.S. Zukin, and M.V.L. Bennett. Dept. of Neuroscience, A. Einstein Coll. Med.,Bronx, NY 10461.

Phencyclidine (PCP) has been shown to produce a use- and voltage-dependent block of NMDA-activated currents. In whole cell recordings PCP block is relieved by depolarization during NMDA application. There is evidence that PCP enters closed channels, possibly from the intracellular side since it readily crosses cell membranes. To address this question we are studying the effects of PCP at the single-channel level using outside-out and inside-out patches from hippocampal neurons.

In inside-out experiments when the pipette contained NMDA (30  $\mu$ M) and glycine (1  $\mu$ M), PCP (1  $\mu$ M) applied to the intracellular (bath) side blocked NMDA channels at negative potentials, but the block was relieved at positive potentials. In outside-out experiments when PCP (10  $\mu$ M) was included in the pipette and the outside was perfused with NMDA (30 µM) and glycine (1 µM), the channel became blocked at -60 mV. Stepping to +40mV relieved the block and on repolarizing to -60 mV block developed again. PCP applied externally also blocked at -60 mV but not at +40 mV. In the outside-out configuration block by PCP from the inside seems unlikely to result from PCP crossing the membrane into the flowing solution and then acting on the NMDA channels from the extracellular side.

THE EFFECTS OF GLUTATHIONE ON N-METHYL-D-ASPARTATE MEDIATED CALCIUM UPTAKE IN DISSOCIATED NEURONS. R. D. Trent, P. K. Randall and S. W. Leslie\*. Div. of Pharmacol. and Toxicol., and Inst. for Neurosci., Univ. of Texas, Austin, TX 78712.

Previous receptor binding studies in this laboratory have suggested a modulatory role for low micromolar concentrations of glutathione (GSH) at the agonist recognition site of the *N*-methyl-D-aspartate (NMDA) receptor complex. Functional studies using the intracellular calcium probe fura-2 in dissociated neurons isolated from newborn rat brain have demonstrated calcium uptake following GSH addition (ECs0 = 914  $\mu$ M) which is reversed by specific NMDA antagonists. The present experiments examined the effect of GSH (0.2 - 8000  $\mu$ M) on NMDA-stimulated calcium uptake using fura-2 loaded dissociated brain cells from newborn rats. Dissociated cells were treated with or without GSH for 100 seconds prior to NMDA stimulation (4 - 500  $\mu$ M NMDA). ECs0's and minimum and maximum calcium uptake following NMDA addition were not significantly different from controls when cells were pretreated with GSH at concentrations from 0.2 to 200  $\mu$ M. However, GSH concentrations within the range of 1000 to 8000  $\mu$ M exhibited partial agonist characteristics at the NMDA recognition site to modify agonist responsiveness mediated by NMDA. High micromolar concentrations of GSH may be necessary for this interaction. (Supported by NIAAA grants AA05809 and AA08104)

PREGNENOLONE SULFATE POTENTIATES NMDA-INDUCED RISES IN INTRACELLULAR Ca<sup>2+</sup>: STUDIES IN CULTURED RAT HIPPOCAMPAL NEURONS WITH FURA-2 MICROSPECTROFLUORIMETRY S.M. Paul<sup>1</sup>, R.P. Irwin<sup>1</sup>, N.J. Maragakis<sup>2</sup>, R.H. Purdy, D.H. Farb<sup>3</sup>, M.A. Rogawski<sup>4\*</sup>. <sup>1</sup>Clinical Neuroscience Branch, NIMH, Bethesda, MD 20892, <sup>2</sup>University of Utah, Salt Lake City, UT 84132, <sup>3</sup>Boston University School of Medicine, Boston, MA 02118, <sup>4</sup>Enilensy Research Branch, NINDS, Bethesda, MD 20892

02118.  $^4$ Epilepsy Research Branch, NINDS, Bethesda, MD 20892. Recently it has been reported that pregnenolone sulfate, in addition to antagonizing GABA activated Cl $^2$  currents, is also a potentiator of NMDA receptor responses in cultured fetal chick spinal cord neurons. We confirm and extend this observation by demonstrating that pregnenolone sulfate modulates NMDA receptor-mediated increases in intracellular Ca $^{2+}$  ([Ca $^{2+}$ ], [Ca $^{2+}$ ], was monitored in 7-14 day fetal rat hippocampal neurons using microspectrofluorimetry and the Ca $^{2+}$  sensitive indicator fura-2. In these neurons NMDA (5  $\mu$ M) produced a rapid and reversible rise in [Ca $^{2+}$ ], of 145  $\pm$ 28 nM. Coapplication of pregnenolone sulfate (5-250  $\mu$ M) resulted in a concentration-dependent potentiation of the NMDA induced rise in [Ca $^{2+}$ ], ( $E_{max}$  789 %, EC $_{50}$  33  $\mu$ M). The steroid failed to alter basal (unstimulated) [Ca $^{2+}$ ]- $_{10}$  or modify the rise in [Ca $^{2+}$ ]- $_{11}$  when hippocampal neurons were depolarized by K+ (20 mM) in the presence of the NMDA receptor antagonist 3-[(±)-2-carboxypiperazin-4-yl]-propyl-1-phosphonic acid (CPP). Structure activity studies on the pharmacophore for the steroid modulatory site on the NMDA receptor are in progress. Preliminary findings indicate a high degree of structural specificity for the modulatory actions of pregnene steroids. Our results suggest that pregnenolone sulfate or a structurally related steroid may be an endogenous modulator of NMDA receptor responses.

EFFECTS OF ETHANOL ON NMDA RECEPTOR-CHANNELS IN SINGLE CHANNEL RECORDINGS. J.M. Wright\* and F.F. Weight. Laboratory of Molecular and Cellular Neurobiology, National Institute on Alcohol Abuse and Alcoholism, Rockville, MD 20852.

Previous studies from this laboratory indicated that ethanol (EtOH) inhibits NMDA-activated currents in mouse hippocampal neurons in a concentration-dependent manner (1). We are currently extending the investigation on mechanism of action with single channel recordings from mouse cortical and hippocampal neurons.

mouse cortical and hippocampal neurons.

Neurons from day 15-17 fetal mice were plated on collagen/polylysine-coated plates and cultured for 1-4 weeks in an enriched MEM medium prior to use. Single channel recordings were made from excised outside-out patches. Pipettes contained (in mM) 75 CsCl or NaCl, 75 CsAcetate, 10 HEPES (pH 7.2), 10 EGTA, 1 CaCl<sub>2</sub>. The bath solution contained (in mM) 160 NaCl, 2.8 KCl, 1 CaCl<sub>2</sub>, 10 HEPES (pH 7.2). Channel conductance was not changed by EtOH. EtOH effects were determined by comparing the steady state probability of opening (nPo) in 2-40 µM NMDA (1 to 12 min) followed by 0.25-100 mM ethanol (1 to 10 min) N=16. There was a 20% increase in nPo with application of 0.5 mM EtOH (N=3). 2-10mM EtOH had no effect on nPo (N=4). Inhibition of nPo was 47% in 100 mM EtOH, 38% in 50 mM and 19% in 20 mM. Changes in nPo at EtOH concentrations < 100 mM were primarily due to changes in frequency of opening with elementary open time changing < 10%. In 100mM EtOH mean open time decreased 30% and frequency of opening decreased 25%.

PREGNENOLONE SULFATE ALLOSTERICALLY POTENTIATES THE NMDA CURRENT IN HIPPOCAMPAL NEURONS. M.R. Bowlby\* and E.A. Kravitz. Department of Neurobiology, Harvard Medical School, Boston, MA 02115.

Steroid hormones have profound influences on behavior. While many of the mechanisms of action of this class of substances appear to be at the level of transcriptional regulation, recent studies suggest that brain metabolites of steroids might exert important non-genomic modulatory effects on neuronal mechanisms (reviewed by Paul and Purdy, 1992, FASEB 6: 2311). In this regard, we examined the potentiation of the NMDA subtype of glutamate current by the endogenous neurosteroid pregnenolone sulfate in cultured hippocampal neurons using patch clamp techniques. The magnitude of the NMDA activated current was approximately doubled in the presence of 100  $\mu M$  pregnenolone sulfate. The dose response curve predicts an ECso of about 25  $\mu M$  and a Hill coefficient of 1. Pregnenolone sulfate acts via an allosteric mechanism at a site distinct from the NMDA and glycine binding sites, as the dose response relationships for NMDA and glycine, even at saturating concentrations, are shifted upwards. The potentiation appears to be specific for the NMDA activated current; no modulation of non-NMDA currents are seen. The enhancement of the current probably is not due to activation of a second ionic conductance, as the reversal potential of the I-V curve does not shift in the presence of the steroid. The effect is specific for pregnenolone sulfate; corticosterone, tetrahydroprogesterone, and pregnenolone sulfate saturates in about 30 s, and reverses with a similar time course. (Supported by NINDS).

GLUTAMATE EXPOSURE RAPIDLY DECREASES INTRACELLULAR pH IN RAT HIPPOCAMPAL NEURONS IN CULTURE.

R. P. Irwin\* and S. M. Paul. Clinical Neuroscience Branch, National Institute of Mental Health, Bethesda, MD 20892

The ability of glutamate to alter intracellular pH (pH<sub>i</sub>) was studied in fetal rat hippocampal neurons (day 10-12 in culture) using the pH sensitive fluorescent indicator BCECF. Exposure (120 sec) of hippocampal neurons to glutamate (100 μM) reversibly reduced pH<sub>i</sub> from 7.197±0.041 to 7.001±0.040 (n=49,  $p \le 0.001$ ) with recovery taking several minutes. In some neurons a reduction in pH<sub>i</sub> of greater than 0.4 was induced by glutamate exposure (120 sec). The effect of glutamate in reducing the pHi of hippocampal neurons was dependent on agonist concentration (0.01-1.0 mM) and time of exposure. NMDA (100 μM) also decreased pH; and the latter effect was attenuated by the NMDA receptor antagonist 3-[(±)-2carboxypiperazin-4-yl]-propyl-l-phosphonic acid (CPP). Experiments in which extracellular Ca<sup>2+</sup> was removed prior to glutamate exposure suggest that Ca2+ influx may be required for the decrease in pH; induced by glutamate. This relatively rapid intracellular acidosis induced by glutamate exposure may be involved in the cascade of events leading to excitotoxic cell death.

# 118.12

DIFFERENTIAL EFFECTS OF TRICYCLIC ANTIDEPRESSANTS AND BARBITURATES ON THE QUISQUALATE, KAINATE-AND NMDA-INDUCED ELEVATION OF INTRACELLULAR CALCIUM LEVELS IN NEURONAL CULTURE. Z. Cai and P. P. McCaslin, Dept. Pharmacol, Toxicol, Univ. Miss. Med. Ctr., Jackson, Ms., 39216

In these studies, we examined the ability of tricyclic antidepressants (TCAs) and barbiturates, in therapeutic concentrations, to block the elevation of intracellular calcium levels ( $\{Ca^++|j\}$ ) induced by excitatory amino acids (EAAs) in neuronal tissue culture. The glutamate receptor agonists, kainate and N-methyl-D-aspartate (NMDA), resulted in the elevation of  $\{Ca^++|j\}$  as measured with fura-2 fluorometry in primary cultures of cerebellar granule neurons. Several TCAs, amitriptyline and cyproheptadine, partially prevented this elevation induced by both of these EAAs, but not elevations of  $\{Ca^++|j\}$  induced by another EAA, quisqualate. The fast acting barbiturates, secobarbital and thiamylal were effective in reducing elevations induced by all three EAA agonists, while a slower acting barbiturate, pentobarbital, was only effective in reducing elevations of calcium induced by kainate but had weak or no effects on elevations of  $\{Ca^++|j\}$  induced by quisqualate or NMDA. Evidence suggests that this TCA and barbiturate interaction with EAAs may involve voltage-dependent calcium channels since the fast acting barbiturates and TCAs also partially blocked the elevation of  $\{Ca^++|j\}$  induced by membrane depolarization with 40 mM KCl. However, in the case of TCAs, the blockade is not reversed in high concentrations of extracellular calcium  $\{Ca^++j\}_0$  as would be predicted by a direct interaction with calcium channels. These results show that both TCAs and barbiturates interact with EAA neurotransmission and suggest that this interaction may involve selective types of calcium channels differentially activated by EAAs.

CHRONIC BARBITURATE TREATMENT INCREASES NMDA RECEPTORS BUT DECREASES KAINIC ACID RECEPTORS IN MOUSE CORTEXX. R. Short\* and B. Tabakoff, Department of Pharmacological University of Colorada Health Sciences Center Deniver. Co. 80262

Pharmacology, University of Colorado Health Sciences Center, Denver, CO 80262. Several studies of sedative/hypnotic drugs have revealed that these drugs inhibit NMDA and kainate receptor function. Ethanol, pentobarbital, and plenoharbital all reduce the NMDA and kainate induced Ca<sup>2+</sup> uptake in cells grown in culture. Furthermore, chronic treatment of animals with ethanol increases NMDA receptor number in hippocampus (but not cortex), and chronic barbital enhances cGMP response to kainate (but not NMDA) in cerebellum. These results suggest an adaptive change in glutamate receptors due to extended exposure to sedative/hypnotic drugs. We report the effects of chronic plenoharbital on NMDA and kainate receptors.

change in glutamate receptors due to extended exposure to sequiverinymous drugs. We report the effects of chronic phenobarbital on NMDA and kainate receptors.

C57BL/6 mice had continuous access for 7 days to normal chow or chow containing 3.0 g phenobarbital (free acid) per kg food (increased to 3.5 g/kg after 5 days). Serum phenobarbital levels at the time of sacrifice were approximately 150 µg/ml. Equilibrium saturation [3H]MK-801 binding (0.25 to 25 mM) to crude synaptosomal membranes was determined in the presence of 10 µM glutamate, 1 µM glycine, and 100 µM MgSQ4. Equilibrium saturation [3H]kainate binding (1 nM) was determined in the presence of 0.5 to 64 nM kainate

glycine, and 100  $\mu$ M MgSO<sub>4</sub>. Equilibrium saturation [<sup>2</sup>H]Kainate binding (1 nM) was determined in the presence of 0.5 to 64 nM kainate. In cortex, the K<sub>d</sub> values for kainate and MK-801 binding were unaffected by drug treatment (rs < 1,  $\rho$  >0.5). The B<sub>max</sub> for MK-801 increased 35% ( $\rho$  < .05) while the B<sub>max</sub> for kainate decreased 37% ( $\rho$  < .05) in chronically barbiturate treated mice. In hippocampus, neither the K<sub>d</sub> nor B<sub>max</sub> for MK-801 binding was affected by drug treatment. B<sub>max</sub> changes in cortex were uncorrelated with weight loss.

The decrease in kainate receptor number suggests a possible mechanism (in addition to their GABA<sub>A</sub>/Cl<sup>-</sup> effects) by which barbiturates may exert anti-convulsant action following extended exposure. This may help explain the effectiveness of phenobarbital in the long-term treatment of epilepsy. (Supported by AA-09014 & AA-09005)

# Evolutionary Homologies of Glutamate Receptors.

Marcelo O. Ortells<sup>1</sup>, V. B. Cockcroft<sup>2</sup>, George G. Lunt\*. Biochemistry Department, Bath University, Bath, BA2 7AY, UK. <sup>2</sup>Centre for Protein Engineering, MRC Centre, Hills Road. Cambridge. CB2 2OH UK.

Hills Road, Cambridge, CB2 2QH UK.
Tentative homologies were proposed in the literature for glutamate receptors, both iontropic (ie. Kainate, AMPA and NMDA) and metabotropic, based on pairwise sequence comparison:

- Homology of a part of the Nterminal extracellular domain of the ionotropic Glutamate receptors with a procaryote amino acid binding protein (GlnH) (Nakanishi et al: Neuron 5: 569, 1990).
- A domain homology of the N-terminal extracellular region of ionotropic and metabotropic Glutamate receptors. (Masu et al: Nature 349: 760, 1991).
- Homology between the N-terminal extracellular domain of the metabotropic Glutamate receptors and a region similarly located in a family of receptor proteins having a guanylate cyclase domain located cytoplasmically (Houamed et al: Science 252: 1318, 1991).

Using <u>multiple</u> sequence alignments analysis, in case (2) above homology was ruled out, and the analysis supports the proposal that the ionotropic receptors constitute a single family. For the ionotropic receptors/procaryote amino acid binding proteins, molecular modelling indicated an invariant Arg 499 (GluR1 numbering) is essential in binding the amino acid carboxylate group, and steric restriction may be important in AMPA and NMDA selective recognition.

recognition.

ANTISENSE OLIGONUCLEOTIDES TO A 71 kDa GLUTAMATE-BINDING PROTEIN DECREASE EXPRESSION OF FUNCTIONAL NMDA RECEPTORS. K.N. Kumar\*, M.P. Mattson, H. Wang, B. Cheng and E.K. Michaelis. Depts. of Anatomy and Neurobiology, Univ. Kentucky, Lexington, KY 40536, and Dept. of Pharmacol. & Toxicol., Univ. Kansas, Lawrence KS 66045.

NMDA receptors play important roles in neuronal development, plasticity and pathology in the mammalian CNS. Roles for specific NMDA receptor proteins in neuronal function have not yet been fully established. We recently isolated and cloned a 71 kDa NMDA receptor protein (NMDARP) from rat brain that comprises the glutamate binding subunit of a 4-protein NMDA receptor complex. Using antisense oligonucleotides directed against this NMDARP, we now demonstrate the requirement for this protein in calcium responses to NMDA and excitotoxicity in cultured hippocampal neurons. Western blot analysis and immunocytochemistry demonstrated that NMDA antisense oligonucleotides (50 uM) caused a selective suppression in NMDARP levels during 12-48 hr exposure periods. Elevations in intracellular Ca²+ levels normally caused by glutamate and NMDA were reduced in neurons exposed to NMDARP antisense oligonucleotides (Ca²+ responses to kainate were relatively unaffected. NMDARP antisense oligonucleotides protected the neurons completely against NMDA and partially towards kainate neurotoxicity. Thus, the 71 kDa NMDARP is a necessary component of the NMDA receptor-mediated Ca²+ responses and neurotoxicity in hippocampal neurons. ## 119.2

CLONING OF A cDNA FOR A CGP 39653-BINDING PROTEIN FROM HIPPOCAMPAL cDNA LIBRARIES. P. Johnson\*, K. Kumar, M. Ahmad, D. Wong, K. Eggeman, J.-P. Wu, C. Bigge and E. Michaelis. Dept. of Pharmacol. and Toxicol., Univ. Kansas, Lawrence, KS 66045, and Neurosci. Chem., Parke-Davis, Ann Arbor, MI 48106.

We previously reported on the isolation of a hetero-oligomeric complex of 4 proteins that has the ligand recognition sites and functional properties of an NMDA receptor. We have also reported the cloning of the largest subunit of this complex, an ~60 kDa glutamate-binding subunit (Nature 354, 70), and the isolation of a second subunit, the ~50 kDa competitive-antagonist-binding subunit (J. Biol. Chem. <u>265</u>, 7768). We have recently raised polyclonal antibodies against the ~50 kDa CPP-binding protein and used these antibodies to screen a rat hippocampal cDNA library from which a 3.0 kb cDNA was isolated, cloned and sequenced. E. coli transfected with the vector pBluescript harboring the 3.0 kb insert express a fusion protein that is recognized by the anti-CPP-binding protein antibodies. The fusion protein was purified from IPTG-induced E. coli extracts using diaminophosphonopentanoic acid linked to a ReactiGel matrix. The fusion protein was eluted from the column by the introduction of 10 mM MgSO, and had high specific binding activity for [3H]CGP 39653. This binding was completely inhibited by 2-AP5. We believe that this clone represents the cDNA for the antagonist-binding subunit of an NMDA receptor complex. Supported by grants from DAAL-03-88-K-0017 (ARO), AA04732 (NIAAA), DA05472 (NIDA) and an unrestricted grant from Parke-Davis.

MOLECULAR STRUCTURE AND PHARMACOLOGICAL CHARACTERIZATION OF humEAA2, A NOVEL HUMAN KAINATE RECEPTOR SUBUNIT. R.K. Kamboj#, D.D. Schoepp¶, S. Nutt#, L. Shekter#, B. Korczak# R.A. True¶, D.M. Zimmerman¶\* and M.A. Wosnick#. #Allelix Biopharmaceuticals Inc., Mississauga, Ontario, Canada L4V IP1, ¶Central Nervous System Research, Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, Indiana 46285. USA.

Indiana 46285, USA.

A CDNA encoding a novel human glutamate receptor subunit protein was isolated from a human hippocampal library, This cDNA termed human EAA2 (humEAA2) is most closely related to rat cDNAs for kainate receptor proteins, and when expressed in COS cells is associated with highaffinity kainate receptor binding. The relative potency of compounds in displacing <sup>3</sup>H-kainate binding was kainate >quisqualate > domoate > L-glutamate >> DNQX > dihydrokainate > CNQX > AMPA. Homomeric expression of humEAA2 does not appear to elicit ligand-gated channel activity. Nevertheless, the molecular structure and pharmacology of high-affinity kainate binding suggest the humEAA2 is a novel subunit protein of a human kainate receptor commolex.

CLONING AND DISTRIBUTION OF MESSENGER RNA'S ENCODING FOR AVIAN GLUTAMATE RECEPTORS Ottiger, H.P.\*, Moser, A., Del Principe, F., and Streit, P. Brain Research Institute, University of Zürich, CH-8029 Zürich,

Brain Research Institute, University of Zürich, CH-8029 Zürich, Switzerland.

Glutamate receptors form part of a major excitatory neurotransmitter system. Three avian glutamate receptor subtypes, which have been designated pigeon GluR-62, GluR-26, and GluR-21, respectively have been cloned from a cerebellar library. Based on amino acid sequence homology the obtained sequences revealed that they encode for AMPA-sensitive glutamate receptors.

Northern blot analysis performed on total RNA from cerebellum and from optic tectum of the pigeon with radioactively labeled cDNA probes revealed hybridization to transcripts >5 kb. To investigate their patterns of expression in the pigeon brain, in-situ hybridization histochemistry on cryosections was performed using 35-S and Digoxigenin-labeled cRNA probes. Within the brain regions analyzed, the receptor subtypes showed distinct and regionally specific hybridization patterns. Particularily striking differences were seen for cell types within the cerebellar cortex: Purkinje cell perikarya showed very high messenger RNA expression for pigeon GluR-62 and -21, however no transcripts for pigeon GluR-26 were detected in this cell type. The non-neuronal Golgi epithelial/Bergmann glial cells were strongly positive for pigeon GluR-62 and -26 transcripts, and weakly positive for GluR-21. Granular cells showed a strong signal for GluR-62 only. The hybridization pattern is highly comparable to that found with glutamate receptor subtypes in rats, with high resemblance of GluR-62, -26 and -21 to the rat subtypes GluR-B, -D and -C respectively.

CONANTOKIN PEPTIDES FROM MARINE SNAIL VENOM AFFINITY-LABELS SUBUNITS OF THE CONANTOKIN RECEPTOR. R. A. Myers\*, J.P. Fernandez#. J. Rivier# and B. M. Olivera. Department of Biology, University of Utah, Salt Lake City, UT 84112, and #The Clayton Foundation Laboratories for Peptide Biology, Salk Institute, La Jolla, CA 92037.
The conantokins are small peptides (17-27 amino acids) which

derive from the venom of *Conus* marine snails. The only known peptides which target the NMDA receptor, conantokins inhibit NMDA-induced currents, while eliciting no effect on either kainate or AMPA conductances. Conantokin analogs amenable to radioiodination were synthesized and radiolabeled. These probes were used to affinity-label crude rat brain membranes by reaction with divalent crosslinking agents. When detergent-extracted rat brain membranes were subjected to affinity chromatography, affinity crosslinking of the column retentate revealed enrichment of aminity crosslinking of the column retentate revealed efficilitient of selectively (competed by excess cold ligand) and intensely labeled bands of high molecular weights, 90-160 kd. Components of this size are consistent with a glycosylated NMDA receptor polypeptide (10 putative glycosylation sites) sequenced by expression cloning by the Nakanishi group [Nature (1991) 354, 31-37]. Selectively labeled bands also observed at lower molecular weights receiptly as a labeled bands also observed at lower molecular weights receiptly as a labeled bands also observed at lower molecular weights receiptly as a labeled bands. labeled bands also observed at lower molecular weights presumably represent other subunits of the same receptor complex or different conantokin receptor subtypes. Size-exclusion HPLC indicates that these are subunits of a larger complex of several hundred kd. These receptors are presently being purified and characterized. (Supported by GM22737.)

CHARACTERIZATION OF A SPLICE VARIANT OF THE NMDAR1 RECEPTOR. J.W. Kusiak\*, D.D. Norton and G.A. Higgins. Molecular Neurobiology Unit, NIA, NIH, Baltimore, MD 21224.

We have discovered a splice variant of the recently cloned receptor, NMDAR1. RT-PCR of rat brain RNA with primers near the carboxyl end gave two products, one of the expected size (~410bp) and one smaller (~300bp). Sequence of the smaller product was identical to the expected product but lacked 111 internal nucleotides. This sequence also contained an open reading frame identical to the expected product but lacked 37 internal amino acids. PCR of rat genomic DNA with these same primers gave an ~ 3.8 Kb product, which contained the deleted sequence bordered by consensus intron/exon junctions and adjacent upstream and downstream sequences suggesting that these two PCR products arise by alternative splicing of a single gene. A partial restriction map of the genomic fragment localized the coding region of the deleted sequence to an exon ~600 bp downstream of the common upstream exon. RT/PCR of RNA isolated from different brain regions showed differential expression of the two forms of the receptor with the deletion variant more abundantly expressed in the brain stem and cerebellum and the full length form more abundant in olfactory bulb, cortex, hippocampus, and striatum. Probing Southern blots of the RT/PCR reactions with splice junction, insert, and common probes confirmed the identity of the products. Preliminary in situ hybridization experiments show that both forms are widely distributed in the CNS. The results show that the NMDAR1 gene undergoes brain region specific alternative splicing to produce variants that differ in the carboxyl terminal portion of the receptor.

AMPA RECEPTORS FROM THE CHICK BRAIN. M.E. Schneider, A.S. Niedzielski', R.J. Wenthold. Lab of Molecular Biology, NIDCD, Natl. Inst. Health, Bethesda, MD 20892,

The chick auditory system is a useful comparative model for hearing science. Recent evidence suggests that the functionally mature cochlea can withstand enormous levels of noise exposure and suffer over 80 dB SPL threshold shifts followed by complete recovery. One mechanism for such recovery may be by replacing damaged hair cells of the reticular lamina. In order to study the role of the glutamate selective afferent receptors in the reinnervation of these nascent hair cells, suitable molecular probes must be developed.

An adult lambda gt10 chicken brain library was screened with various probes Ari audit famous girlo entices of the AMPA family. Using random primed probes containing the conserved transmembrane regions of each of the 4 members of the AMPA family, many partial clones representing all members of the AMPA family were identified. The majority of isolates cloned contained intronic material from incompletely spliced nuclear RNA's. The library was further screened using an oligonucleotide to the most 5' region of a chick GluR2 or with a degenerate pool of oligos based on the amino acid sequence from rat. Two clones were isolated using a specific oligonucleotide to GluR2. However, neither clone was correctly spliced. The presumptive correctly spliced gene was constructed from the two phage isolates and coexpressed in frog oocytes with rat cDNA's. Only one family member was cloned in its entirety (GluR2).

Based on both chick and rat sequences, PCR primers unique to each family member were synthesized and chick poly A RNA from total brain was reverse transcribed and the cDNA was PCR amplified, cloned and sequenced. AMPA family members 2 through 6 were detected in this manner.

## TISSUE-SPECIFIC PROCESSING OF AMPA-TYPE GLUTAMATE RECEPTOR PRE-MRNA IN GOLDFISH VISUAL SYSTEM

H. Ueda\*# and D. Goldman, MHRI, Univ. of Michigan, Ann Arbor, MI 48109

Goldfish ganglion cells have the unique ability to regenerate their axons following optic nerve crush. Regeneration leads to synapse formation between retinal ganglion cell axons and their targets in the optic tectum, ultimately reunia ganginoi cen axons and tient algests in the optic tectum, infinitely resulting in visual recovery. Glutamate is the major neurotransmitter used by ganglion cells to communicate with postsynaptic targets. In addition, glutamate receptors have been implicated to play a role in stabilization of appropriate retino-tectal synapses. In order to determine the number of different glutamate receptors expressed in the visual system and ultimately the role they may play in mediating retino-tectal synaptogenesis, we have begun to characterize glutamate mediating retino-tectal synaptogenesis, we have begun to characterize glutamate receptor gene expression during optic nerve regeneration. Here we report the cloning of two different glutamate receptors expressed in retina and tectum. GFGR52 is most similar to rat GluR D-Flop with 91% amino acid identity. GFGR49 represents a partially processed RNA. It is most similar to GluR C-Flip with 92% amino acid identity. GFGR49 is not a full length clone and contains introns. The coding regions of this clone encode a Flip exon and transmembrane domain 4 with sequence extending 3'. Both these exons are flanked by intronic sequences. RNase protection experiments show genes corresponding to GFGR52 and 49 are expressed in retina and tectum. Using probes that correspond to intron and exon sequences of GFGR49 we find approximately 50% of the protected RNAs contain introns. Surprisingly the protected fragments differ between retina and tectum. These latter results suggest cell-specific splicing may contribute to the heterogeneity of glutamate receptors expressed in the visual system.

ALTERNATIVE mRNA SPLICING OF THE MOUSE GLUR2

ALTERNATIVE mRNA SPLICING OF THE MOUSE GLUR2 GENE. J. A. Izzo. H. Endo\*, J. W. Kusiak, Molecular Neurobiology, NIA, NIH, Baltimore, MD 21224

Molecular cloning of the cDNAs for the AMPA-selective glutamate receptors GLUR-1, -2, -3, -4 has shown that each gene produces several mRNA isoforms. The mutually exclusive splicing of two exons, termed "flip" and "flop", generates two protein isoforms which confer different electrophysiological properties to cells expressing these receptor subunits. The expression of flip and flop containing mRNAs is regulated during development with flom mRNAs appearing after the flin regulated during development with flop mRNAs appearing after the flip forms. Flip and flop mRNAs are also differentially expressed within specific regions of the adult brain. The molecular mechanisms responsible for the alternative splicing of the GLUR mRNAs are unknown.

We have cloned and characterized the genomic region surrounding the flip and flop exons. Sequence analysis revealed the presence of an unusually long polypyrimidine tract located between the two exons. Similar long polypyrimidine stretches have been shown to be important in the alternative splicing of muscle-specific genes. To investigate whether this unusual sequence is reponsible for the mutually exclusive splicing of the flip and flop exons, we constructed a minigene that contains the flip and flop genomic region, the upstream splice donor and downstream splice acceptor sites and flanking coding sequences. We have examined several cell lines for GLUR2 expression by RT-PCR. HeLa cells do not express either the flip or flop forms of GLUR2 mRNA. In contrast, PC12 cells induced to differentiate with nerve growth factor express both flip and flop-containing isoforms. Similarly, undifferentiated PC12 cells also express both flip and flop mRNAs.

CELL LINES STABLY EXPRESSING GLUA-D FLIP AND FLOP RECEPTOR SUBUNITS OR COMBINATIONS THEREOF. J. S. Rasmussen, L. S. Nielsen, A. Hansen, K. Hansen, E. Boel, K. M. Houamed, P. H. Andersen\*. Depts. of Molecular Biology I and Molecular Pharmacology, Pharmaceutical Biotechnology, Novo Nordisk A/S, Novo Allé, DK-2880, Bagsvaerd, Denmark

Rat Glu A-D flip and flop subunits were cloned by PCR using rat cerebellar or hippocampal derived 1.strand cDNA's as template and sequence specific oligonucleotides as primers. Each cDNA was assembled from two or three PCR fragments ranging from 0.8 - 1.5 kb. The cDNA'S were transfected into BHK 570 cells under control of a constitutively active metallothionine promoter. Following addition of selection agent(s), subclones were isolated expressing high fmol - low pmol receptor/mg membrane protein. Using specific antibodies, the molecular weight of the various subunits was found to be in close agreement with previous reports investigating these proteins in rat brain tissue. Using binding of <sup>3</sup>H-AMPA, the pharmacological profile of the subunits or combinations thereof was investigated. These results indicated no difference between the flip and flop version of each subunit. Further, the profile of the A-D subunits was somewhat similar, showing high affinity for AMPA (10-30 nM) and quisqualic acid (2-20 nM), medium affinity for CNOX, DNOX and NBOX (60-600 nM), medium to low affinity for kainate (300-4000 nM) and very low affinity for ibotenic acid (>30 uM). Thus, the pharmacological profile of the glutamate receptors expressed in these cell lines corresponds to the profile of the high affinity AMPA binding site found in rat brain.

## 119.13

RAPID QUANTITATION OF NMDAR1 RECEPTOR mRNA BY SOLUTION HYBRIDIZATION (SH). S.O. Franklin, K. Elliott, Y-S. Zhu, C. Wahlestedt and C.E. Inturrisi\*. Depts. of Pharmacology and Neuroscience, Cornell U. Med. College, New York, NY

To facilitate the study of the regulation of NMDA receptor gene expression, a rapid, sensitive and quantitative method for measuring the levels of the mRNA which codes for a protein sequence (NMDAR1) of a functional The assav is based on NMDA receptor was developed. ribonuclease protection of a 32P-labeled riboprobe (prepared from a 1413 bp fragment of the rat NMDAR1 cDNA (Moriyoshi et al., Nature 354, 1991). After hybridization for 4 hrs at 75°C, resistant riboprobe is precipitated with TCA and filtered using a cell harvester. Analysis was by scintillation counting and quantitation of mRNA was by use of a standard curve generated from a full length (4.2 kb) sense transcript of NMDAR1. The hybridization conditions produced a linear curve from 7.8 to 500 pg of sense transcript (i.e., NMDAR1 mRNA). NMDAR1 mRNA levels in RNA extracts from normal rat tissues were highest in cerebellum (26 pg/ug RNA), while olfactory bulb, frontal cortex, hippocampus, and striatum had similar values that ranged from 15 to 19 pg/ug RNA). Hypothalamic levels were (in pg/ug RNA) 12, spinal cord 7, liver <2 and E. coli tRNA undetectable. The distribution of NMDAR1 mRNA was similar in mouse CNS regions. These results demonstrate the sensitivity and utility of this method for the quantitation of NMDA receptor mRNA. (Supported by DA01457.)

CULTURED CEREBELLAR GRANULE CELLS EXPRESS THE mGlurl SUBTYPE OF METABOTROPIC GLUTAMATE RECEPTORS. G. Casabona'. E. Aronica'. P. Dell'Albani'. A.A. Genazzani'. V. Bruno'. D.F. Condorelli'. R. Bàlazs' and F.Nicoletti'. Institutes of Pharmacology' and Biochemistry'. University of Catania. Italy: and "Netherland Institute for Brain Research. Amsterdam. The Netherlands.

In cultured cerebellar granule cells, glutamate and quisqualate were more efficacious than 1s.3s. ACPD to stimulate polyphosphoinositide (PPI) hydrolysis, as observed in cells expressing the mGluR1 but not the mGluR5 receptor subtype (Masu M., personal communication). L-AP3 acted as a weak antagonist, and was devoid of intrinsic activity. Changes in agonist-stimulated PPI hydrolysis during cell maturation in vitro were paralleled by changes in the expression of the mRNA encoding the mGluR1 receptor protein. Metabotropic receptor agonists did not attenuate the stimulation of cAMP formation produced by forskolin, cholera toxin or norepinephrine, excluding the presence of receptor subtypes negatively coupled to adenylate cyclase. Rather, quisqualate stimulated cAMP formation in a concentration-dependent fashion, an effect that may be secondary to the mobilization of intracellular Ca² and activation of mGluR1 receptors.

STABLE FUNCTIONAL EXPRESSION OF GLUTAMATE RECEPTOR SUBUNITS IN MAMMALIAN CELL LINES. K. M. Houamed\*, J. S. Rasmussen, L. S. Nielsen, A. Hansen, K. Hansen, E. Boel, P. H. Andersen. Depts. of Molecular Pharmacology and Molecular Biology I, Pharmaceutical Biotechnology, Novo Nordisk A/S, Novo Allé, DK-2880 Bagsvaerd, Denmark.

Glutamate receptor subunits A - D, in flip and flop versions, cloned from rat brain (abstract by Rasmussen et al in this issue), have been stably expressed in the mammalian cell line BHK 570. Whole cell patch clamp recordings, at holding potential of -70 mV, from cells carrying single subunit or a binary combination, revealed sustained inward currents activated by the potent glutamate receptor agonist kainate. The currents became outward when the holding potential was made positive, indicating the activation of a mixed cation conductance.

The pharmacological profile of these cell lines, with respect to agonists, antagonists, and allosteric modulators, as well as the ionic mechanisms underlying the agonist induced conductances will be presented.

## 119.14

ISOLATION OF NMDA RECEPTOR FROM ADULT RAT BRAIN. Y. Huang, M. Stanley\* and K. Wu Div. of Neuroscience, New York State Psych. Inst., NY, NY 10032.

Abundant evidence suggests that NMDA (N-methyl-Daspartate) receptor, a subclass of glutamate receptors, plays important roles in several neural processes in the central nervous system. The NMDA receptor appears to be associated with long-term potentiation, memory acquisition, learning as well as some neuronal disorder such as stroke and epilepsy. Remarkably, however, despite physiological importance, the molecular characteristics of NMDA receptor remain to be elucidated. Nearly all of the structural information about NMDA receptor has been deduced from cDNA sequence. To further characterize the NMDA receptor biochemically and functionally, we isolated the receptor from cerebral cortex of adult rat brain. Full characterization of the receptor will reveal whether the purified receptor exhibits properties characteristic of native receptor deduced from cDNA sequence and address the possibility of the posttranslational modifications crucial to the physiological function of the receptors.

GROWTH CONDITIONS REGULATE THE EXPRESSION OF ME-TABOTROPIC GLUTAMATE RECEPTORS IN CULTURED CERE-BELLAR GRANULE CELLS, E. Aronica', F. Nicolettia D.F. Condorelli". P. Dell'Albani". C. Amico". and R. Balazs'". Netherlands Institute for Brain Research, Amsterdam. The Netherlands': and Insti-tutes of Pharmacology" and Biochemistry". University of Catania. Italy, (Spon: ENA) Cultured cerebellar granule cells grown in medium containing 25 mM K (K25) express a metabotropic glutamate receptor coupled to polyphosphoinositide (PPI) hydrolysis. The functional expression of the receptor increased steeply during the first 4 DIV, and then progressively declined. This decline was prevented by conditions that deplete the glutamate present in the medium, suggesting that the latter down regulates metabotropic receptors. The decline in receptor function was also abolished when cultures were grown in medium containing 10 mM K\* (K10) and NMDA. The action of NMDA was concentration-dependent, was antagonized by D-AP5,, and was not mimicked by AMPA. Cultures at DIV grown in K10 + NMDA also expressed higher levels of mGluR1 mRNA, as compared with cultures grown in K25. These results indicate that the expression of metabotropic receptors is regulated by growth conditions, which are known to exert a influence on granule cells differentiating in culture.

EXCITATORY AMINO ACID (EAA) -MEDIATED SIGNAL TRANSDUCTION IN CULTURED NEURONS. <u>Y.-H. Lee.\*M. Yarom. D. L. Deupree and J.-Y. Wu.</u> Dept. of Physiology and Cell Biology, Univ. of Kansas, Lawrence, KS 66046 Two major G-protein-linked metabolic pathways, namely adenylate cyclase-triggered protein phosphorylation cascade and phospholipase C (PLC)-

Two major G-protein-linked meiabolic pathways, namely adenylate cyclase-triggered protein phosphorylation cascade and phospholipase C (PLC)-catalyzed phosphatidylinositol (PI) hydrolysis, are involved in transmitter-mediated signal transduction in mammalian CNS. In this communication, we described the effect of EAA on poly-PI turnover in the cultured neurons. Briefly, whole brains of 16-day-old rat embryos were used for the neuronal culture and cells at various time intervals, including early (4-6 days, referred to as DIV), middle (9-11 DIV), mature (16-18 DIV), and late (23-26 DIV) stages in culture were used. We used the ratio of inositol phosphates (IPn) to PI as an index of poly-PI hydrolysis. For receptor activity, [3H]-glutamate was used as a general ligand for all EAA receptor binding. It was found L-glutamate mediated stimulation of poly-PI turnover in the cultured neurons increased rapidly in the early stage, reached maximum in the mature stage, and decrease rather gradually in the late stage. A similar pattern was obtained for EAA receptor activity. Furthermore, AMPA and kainic acid-mediated poly-PI turnover appeared to be Ca<sup>2+</sup>-dependent and expressed transiently, whereas those mediated by L-glutamate and trans-ACPD, a specific ligand for the metabotropic EAA receptor, were Ca<sup>2+</sup>-independent and expressed over a longer time span. These results suggest that different EAA receptor subtypes are probably expressed and responsible for signal transduction at different stages of neuronal differentiation and maturation. [Supported in part by grants NS20978 (NIH) and BNS-8820581 (NSF).]

DEPOLARIZATION BY KC1 MODULATES THE EXPRESSION OF METABOTROPIC GLUTAMATE RECEPTORS IN CULTURED CEREBELLAR NEURONS. M. Favaron\*, J.M. Rimland, R.M. Manev, P. Candeo, D. Milani and H. Manev. FIDIA Research Laboratories, 35031 Abano Terme, Italy.

In primary cultures of rat cerebellar granule neurons the variations in the medium KCl content and KCl- mediated depolarizing growing conditions lead to a differential expression of the metabotropic glutamate receptor 1 (mGluR1) mRNA. The presence of 10-15 mM KCl in the growing medium allows a higher expression of mGluR1 mRNA as compared to the standard growing conditions of 25-30 mM KCl. The higher levels of mRNA correlated with the expression of a functional neuronal mGluR1 receptor as monitored by measuring the agonist-stimulated phosphoinositide formation and the agonist-stimulated phosphoinositide formation and the agonist-induced rise in free intracellular Ca<sup>2+</sup> levels. The exposure of established 8-12 days old cultures to a new environmental depolarizing condition lead to a novel pattern of mGluR1 expression. Hence, 15 mM KCl-grown neurons expressing high levels of mGluR1 can be shifted to low levels mGluR1 neurons after overnight exposure to an extra 5 mM KCl. Here we demonstrated that the mGluR1 expressing neurons quickly adapt to the new environmen- tal conditions by changing the level of receptors expressed even when maturation has been reached. The present model should help in understanding the mechanism of this plasticity.

# GABA RECEPTORS: STRUCTURE

#### 120.1

SPECIFIC EXPRESSION OF THE GABA<sub>A</sub>-RECEPTOR  $\alpha_3$ -, BUT NOT  $\alpha_1$ -SUBUNIT, ON MONOAMINERGIC AND CHOLINERGIC NEURONS. B. Gao¹, J.P. Hornung¹² and J.M. Fritschy¹ 1) Institute of Pharmacology, University of Zurich, 8006 Zurich, Switzerland; 2) Institute of Anatomy, University of Lausanne. 1005 Lausanne. Switzerland;

University of Lausanne, 1005 Lausanne, Switzerland; 2) Institute of Anatomy, University of Lausanne, 1005 Lausanne, Switzerland. The extraordinary structural heterogeneity of GABA<sub>A</sub>-receptors is thought to reflect the existence of multiple subtypes with different sensitivities to GABA and pharmacological profiles. The allocation of receptor subtypes to identified neurons is a prerequisite for analyzing the functional relevance of GABA<sub>A</sub>-receptor heterogeneity. Since monoaminergic (MA) and cholinergic neurons receive a prominent GABAergic input and can be influenced by benzo-diazepines, the present study was undertaken to identify the type of GABA<sub>A</sub>-receptor subunitis expressed by these neurons. Rat and marmoset monkey (*Callithrix jacchus*) brain sections were processed for double-immunofluorescence staining using antibodies specific to the GABA<sub>A</sub>-receptor  $\alpha_1$ - or  $\alpha_3$ -subunits and antibodies to markers for serotonergic, catechol-aminergic (tyrosine hydroxylase) and cholinergic (choline acetyltransferase) neurons. In rat raphe nuclei, numerous neurons were immunoreactive for either the  $\alpha_1$ - or the  $\alpha_3$ -subunits. However, serotonergic neurons selectively expressed the  $\alpha_3$ -subunit immunoreactivity (IR) only. Catecholaminergic neurons of the A1-A9 cell groups were strongly labeled with the  $\alpha_3$ -subunit antibody, as well. Throughout the rat brainstem, the  $\alpha_1$ -subunit-IR decorated a population of neurons distinct from MA neurons. Similarly, cholinergic neurons in both rat and monkey basal forebrain were selectively labeled with the  $\alpha_3$ -subunit-IR, whereas the  $\alpha_1$ -subunit-IR decorated other cells in these nuclei. Thus, the results demonstrate that the GABA<sub>A</sub>-receptor  $\alpha_1$ - and  $\alpha_3$ -subunits are expressed by different neuron populations in MA and cholinergic nuclei. The selective  $\alpha_3$ -subunit expression by MA and cholinergic neurons suggest that these cells contain benzodiazepine type II receptors.

## 120.3

DEVELOPMENTAL CHANGES IN mRNA ENCODING HUMAN GABAA RECEPTOR SUBUNITS. A.R. Brooks-Kayal\* and D.B. Pritchett. Children's Hosp. of Phila.; Children's Seashore House; Depts. of Peds., Pharm. and Neuro., Univ. of Penn, Phila., PA 19104. The receptor for GABA, the major inhibitory neurotransmitter in the

The receptor for GABA, the major inhibitory neurotransmitter in the brain, is composed of multiple distinct subunits which confer pharmacological specificity for anticonvulsant drugs such as benzodiazepines. Recently GABAA receptor subunit mRNA levels have been shown to change in rat brain during development, with increases in  $\alpha 1$  and decreases in  $\alpha 5$  and  $\beta 1$  subunits. In this study we demonstrate similar changes in GABAA receptor subtype composition during human neurodevelopment. Samples of frontal cortex and cerebellum were collected at autopsy from patients without known neurological disease, aged 36 weeks post-conception to adult. GABAA receptor subunit mRNA levels were measured using the ribonuclease protection assay to hybridize radiolabeled antisense mRNA probes specific for  $\alpha 1$  and  $\alpha 3$  subunits to human brain mRNA. Levels of  $\alpha 1$  were lowest at 36 weeks and highest in adult in both cortex (17-fold increase) and cerebellum (4-fold increase). By contrast,  $\alpha 3$  mRNA levels in cortex were highest at 36 weeks and lowest in adult (3-fold decrease). At 36 weeks,  $\alpha 3$  mRNA levels were 2-fold greater than  $\alpha 1$  levels in cortex, but fell to only 4% of  $\alpha 1$  levels by adulthood. Our findings suggest a marked change in GABAA receptor subunit composition during human development similar to that previously described in rats. Such a change could influence receptor activity, which might play a role in specific developmental patterns seen in some childhood seizure types as well as alter the efficacy of certain anticonvulsant drugs during development.

## 120.2

DEVELOPMENTAL EXPRESSION OF THE GABA<sub>A</sub> RECEPTOR α1 SUBUNIT POLYPEPTIDE IN RAT CEREBELLAR CELLS *IN WIVO* AND IN CULTURE. <u>L. Nadler. K. Behringer. and R.E. Siegel</u>\*. Dept. of Pharmacology. Case Western Reserve Univ., Cleveland, OH 44106.

Pharmacology, Case Western Reserve Univ., Cleveland, OH 44106. The GABA<sub>A</sub> receptor complex is a multisubunit ligand-gated ion channel that mediates the actions of GABA, the major inhibitory neurotransmitter in the CNS. The receptor is composed of multiple subunits, each of which exhibits distinct regional and temporal patterns of expression. Our previous studies demonstrated that α1 subunit mRNA levels in the rat cerebellar cortex are low in early postnatal development but subsequently increase 3- to 5-fold in the second week. To examine the relationship between the expression of the α1 subunit mRNA and the encoded polypeptide, we have generated an α1 subunit-specific antiserum. Use of this antiserum for Western blot analysis and immunohistochemistry demonstrated that α1 subunit polypeptide and mRNA expression change in parallel. While relatively weak signals are detected in early postnatal development, α1 subunit polypeptide levels rise several-fold in the second week. Subunit polypeptide expression peaks by postnatal day 21 (P21) after which it decreases to adult levels. In previous studies we demonstrated that the developmental changes in subunit mRNA expression appear to be mimicked in cerebellar neurons cultured from P10 rats. While low levels of the α1 subunit mRNA were initially found, 2.5-fold increases occurred between days 2 and 4 in culture. Immunohistochemistry indicates that subunit mRNA and polypeptide expression in the cultured cells also change in parallel. Together, these *in vivo* and *in vitro* studies suggest that the regulation of GABA<sub>A</sub> receptor α1 subunit expression occurs at the transcriptional level.

# 120.4

ISOLATION AND CHARACTERIZATION OF THE HUMAN GABA<sub>A</sub>/BENZODIAZEPINE RECEPTOR α1-SUBUNIT GENE. M.D. Leach\* and D.H. Farb. Dept. of Pharmacology & Experimental Therapeutics, Boston University School of Medicine, Boston, MA 02118.

The GABAA receptor is of great interest as it may have a large number of isoforms that mediate inhibitory synaptic transmission in the nervous system. There are  $\alpha 1$ -6,  $\beta 1$ -4,  $\gamma 1$ -3,  $\delta 1$  and  $\rho 1$ -2 subunit transcripts as well as alternatively spliced forms of  $\beta$  and  $\gamma$  subunits. In situ hybridization shows that each subunit is differentially distributed in the central nervous system, with the  $\alpha 1$  subunit being the most abundant isoform. Our work has focused on identifying the gene structure and the regulatory elements that contribute to this subunit's pattern of expression.

Screening of a human chromosome 5 cosmid library using probes derived from human  $\alpha 1$  cDNA sequences has identified a number of positive clones. Subsequent subcloning and sequencing of a 25 kb clone has yielded a 9 kb subclone which has sequence identity with the human  $\alpha 1$  cDNA. This clone contains sequence for the last two introns and exons of the human  $\alpha 1$  gene. We have previously reported the cloning and sequencing of the 5'-flanking region for the  $\beta 1$  gene of the GABAA receptor (S.J. Russek and D.H. Farb (1991) Soc. Neurosci. Abst. 17:526). We now report the isolation and sequencing of the 5' end of the human  $\alpha 1$  gene. The 5' end of the human  $\alpha 1$  gene was isolated using nesting and inverse polymerase chain reaction techniques. Primer extension analysis indicates the presence of a transcriptional initiation site. Various consensus sequences for regulatory elements have been identified and their potential roles in the control of gene expression are being evaluated.

CLONING AND CHARACTERIZATION OF 5' UPSTREAM REGULATORY REGION OF GABAA RECEPTOR ALPHA-1 SUBUNIT. I. Kang\*, L.G. Miller. Dept. of Pharmacology and Experimental Therapeutics and Neuroscience Program, Tufts Univ. School of Medicine, Boston, MA, 02111

From the published human GABAA receptor alpha-1 subunit cDNA sequence, a 200 bp stretch of DNA that encompasses the sequence upstream of the initiation codon was synthesized and has been used to screen human genomic library. Positive clones have been sequenced. Fragments of varying size have been fused to the upstream of lac Z gene and transfected into primary chick neurons in order to assess the presence of promoter activity and delineate the factors that regulate its function. Transcription start site is determined by S1 ribonuclease mapping.

PCR-BASED HOMOLOGY PROBING REVEALS A FAMILY OF GABA RECEPTOR-LIKE GENES IN *DROSOPHILA*. Joseph E. Henderson, Patricia Marsella-Herrick, Douglas C. Knipple and David M. Soderlund.\* Field of Environmental Toxicology and Dept. of Entomology, New York State Agric. Expt. Station, Cornell Univ., Geneva, NY 14456.

The GABA (γ-aminobutyric acid) receptor - chloride ionophore complex mediates synaptic inhibition in the central nervous system of both mammals and insects and is also a site of action for drugs and insecticides. The cloning and characterization of mammalian GABA receptors have identified genes encoding five groups of homologous subunits which, together with the gene encoding the strychnine-binding subunit of the glycine-gated chloride channel, comprise a family of ligand-gated chloride channel genes. We have taken advantage of a conserved octapeptide "signature motif" found in all members of this gene family to isolate genomic sequences encoding putative subunits of GABA receptors and other ligand-gated chloride channels in *Drosophila melanogaster* by employing a modification of the polymerase chain reaction (PCR) technique that depends on knowledge of only a single gene-specific amino acid sequence. The unique genomic sequence elements isolated and analyzed to date provide evidence for members of this gene family in *Drosophila* with varying degrees of homology to vertebrate GABA and glycine receptor subunit genes.

MUTAGENESIS OF N-LINKED GLYCOSYLATION SITES OF THE GABAA/ BENZODIAZEPINE (BZ) RECEPTOR a1 SUBUNIT DECREASES THE LEVEL OF RO15-1788 BINDING IN TRANSFECTED 293 CELLS. G.A. Hastings. A.L. Buller, E.F. Kirkness and C.M. Fraser\*. Section on Molecular Neurobiology, LNG, NIAAA, Rockville, MD 20852.

The addition of oligosaccharide chains to polypeptides by N-linked glycosylation is an important step in the maturation of membrane-bound proteins. The GABAA/BZ receptor subunits have consensus sites for N-linked glycosylation which may affect GABA/BZ binding affinities and/or receptor complex formation. We have begun to assess the role of N-linked glycosylation on GABAA/BZ receptor function by eliminating these sites on the  $\alpha 1$  subunit by mutagenesis. There are two consensus N-linked glycosylation sites located on the extracellular portion of each  $\alpha$  subunit. The rat  $\alpha 1$  cDNA was mutagenized, changing Asn to Gln, at positions 10 (Gln10) and 110 (Gln110) or both (Gln10/110). The wildtype and mutant a1, \$1 and \gamma2 long-form cDNAs were transiently transfected into human kidney 293 cells. Saturation binding of the BZ antagonist [3H]RO15-1788, with 25µM clonazepam as competitor, was performed with crude membranes prepared from transfected cells. There was no significant change in KD between wild-type al (0.66 nM), Gln10 (0.54 nM) and Gln110 (0.50 nM). [3H]RO15-1788 specific binding was undetectable in the Gln 10/110 mutant, however. There was a consistent decrease in  $B_{max}$  of 18-43% with the Gln 10 and Gln 110mutants compared to wild-type. These results suggest that the N-linked oligosaccharide chains of al do not affect the affinity of the GABAA/BZ receptor for BZs. However, al N-linked glycosylation is necessary for normal GABAA/BZ receptor processing or stability.

CLONING AND SEQUENCING OF THE RAT α6 SUBUNIT GENE FOR THE GABA<sub>A</sub>/BENZODIAZEPINE RECEPTOR. P.J. McLean\*, S.J. Russek and D.H. Farb, Department of Pharmacology and Experimental Therapeutics, Boston University School of Medicine, Boston, MA 02118.

The GABAA receptor is a member of the ligand-gated ion channel superfamily which includes the nicotinic acetylcholine receptor and the glycine receptor. In situ hybridization studies demonstrate that each subunit of the GABAA receptor has a differential distribution in the brain and spinal cord. We are identifying the regulatory elements of this gene family to study the differential regulation of GABA $_{A}$  receptor expression in the nervous system. Previously we reported the identification of the 5' flanking region of the human  $\beta 1$  gene and the position of several intron/exon boundaries with respect to the human and rat β1, β2 and β3 genes (S.J. Russek & D.H. Farb (1991) Soc. Neurosci. Abst. 17:526). We now report the cloning and sequencing of the rat α6 subunit gene for the GABAA receptor. The α6 gene is unique in that it is expressed in the cerebellum but not in other regions of the brain or spinal cord. The polymerase chain reaction (PCR) was used to amplify segments of rat genomic DNA using primers made to the rat  $\alpha$ 6 cDNA. Cloning and sequencing of the PCR products revealed sequence identity with the 5' end of the rat  $\alpha$ 6 cDNA, and several intron/exon boundaries have been mapped. Sequence comparison studies of alpha subunit genes suggest that the position of the introns at the 5' end of the  $\alpha$ 6 subunit gene are not conserved in the same way as was demonstrated for the beta subunits. Using inverse PCR, we have identified the 5' flanking region of the gene. This region may contain regulatory elements necessary for the control of the gene's expression in the central nervous system.

#### 120.8

NATURAL MUTATION OF A CONSERVED TYR TO HIS IN THE MI NATURAL MUTATION OF A CONSENSED THE TO HIS IN THE MI REGION OF THE MOUSE GABA, RECEPTOR DELTA SUBUNIT. G.L. Kamatchi, J.B. Wang, J. Yang and D.R. Burt\*. Depts. of Pharmacology and 'Anesthesiology, Univ. of Maryland School of Medicine, Baltimore, MD 21201.

GABA<sub>A</sub> receptors are multisubunit inhibitory chloride channels which are opened by  $\gamma$ -aminobutyric acid (GABA), the major inhibitory neurotransmitter in the brain. The  $\delta$  subunit, originally detected by homology screening, has no known role in receptor function. In sequencing cDNAs for this subunit in audiogenic seizure prone (DBA/2J) and seizure resistant (C57BL/6J) inbred strains of mice, we detected in some clones from both strains a substitution of His for a conserved Tyr (#239) in the first putative transmembrane region (M1). This Tyr is conserved in other published GABA, and glycine receptor subunit sequences. As assessed by polymerase chain reaction amplification of tail genomic DNA, His was rare in both inbred strains. Its occurrence as an apparent allelic variant in one strain, let alone two, is extremely unusual, and it may not occur in homozygous form due to lethality. Further study of this mutation and its functional consequences, through breeding and expression studies, should help reveal the roles of & subunits in GABA<sub>A</sub> receptor composition and function. (Supported by USPHS grants NS25525 and AA07559 to DRB)

## 120.10

CHARACTERIZATION OF STABLE CELL LINES EXPRESSING A CLONED GABA, BENZODIAZEPINE RECEPTOR CI CHANNEL COMPLEX. B.J. Hamilton, D.J. Lennon, D.D. McKinley, W.B. Im, H.K. Im, P.H. Seeburg, and D.B. Carter. CNS Research, The Upjohn Company, Kalamazoo, MI 49001 and Zentrum Fur Moleckulare Biologie, University of Heidelberg, Germany

The GABA,/Benzodiazepine receptor-Cl channel complex is composed of various combinations of 48-55kd subunits from at least three different classes various combinations of 48-56kd subunits from at least three different classes of genes resulting in a highly diverse group of GABA, receptors. To elucidate the pharmacologies of various GABA, receptor subunit combinations, rat GABA, receptor cDNA's coding for  $\alpha_1$ ,  $\alpha_3$ ,  $\alpha_5$ ,  $\alpha_6$ ,  $\beta_1$ ,  $\beta_2$ , and  $\gamma_2$  were transfected into a human embryonic kidney cell line previously transfected with Adenovirus 5 (HEK-293). Stable cell lines expressing  $\alpha_1\beta_2\gamma_2$ ,  $\alpha_5\beta_2\gamma_2$ ,  $\alpha_6\beta_2\gamma_2$ , and  $\alpha_5\beta_1\gamma_2$  were obtained by selection in G418 and/or hygromycin containing media at a frequency of 0.008-0.04, as determined by Northern blot analysis. Subsequent Northern blot analysis of the four cell lines has shown stable expression of the three subunit messages over twenty-five passages. Membrane binding studies using the ligand flunitrazepam demonstrate saturable binding for the GABA, receptor subtype combinations  $\alpha_1\beta_2\gamma_2$ ,  $\alpha_3\beta_4\gamma_2$ , and  $\alpha_6\beta_1\gamma_2$ . While the  $\alpha_6\beta_2\gamma_2$  combination shows no significant binding to flunitrazepam, saturable binding was demonstrated using the imidazodiazepine Ro15-4513. Electrophysiological studies of these cell lines reveal a typical dose response to GABA. The GABA response is potentiated by diazepam in the  $\alpha_0\beta_2\gamma_2$ ,  $\alpha_0\beta_2\gamma_2$ , and  $\alpha_0\beta_1\gamma_2$  expressing cell lines, and by Ro 15-4513 in the  $\alpha_0\beta_2\gamma_2$  expressing cell line. The expression of recombinant subunits in these stable cell lines produces functional GABA, receptor molecules which provides a tool for elucidating the features of the GABA mediated Cl channel and determining the intrinsic efficacy of drugs modulating the system.

IMMUNOHISTOCHEMICAL MAPPING OF GABA, RECEPTOR  $\alpha$  SUBUNITS IN RAT RRAIN

J.D. Turner; G. Bodewitz, C.L. Thompson<sup>+</sup> and F.A. Stephenson<sup>+\*</sup>
Research Laboratories of Schering AG, Berlin, F.R.G. <sup>+</sup>School of Pharmacy,
University of London, 29/39 Brunswick Square, London, UK

GABA, receptors are hetero-oligomeric membrane glycoproteins, in which five subunits are thought to assemble to form individual ion channel complexes. Five distinct classes, some containing several isoforms ( $\alpha$ 1-6,  $\beta$ 1-3,  $\gamma$ 1-3,  $\delta$  and  $\rho$ 1-2) encoded by separate genes have been identified by molecular cloning. To facilitate identification of putative native receptor subtypes, we have generated antibodies against the  $\alpha$ 1,  $\alpha$ 2,  $\alpha$ 3,  $\alpha$ 5 and  $\alpha$ 6 subunits, employing as antigens peptide sequences unique to the respective isoforms.

The affinity purified antibodies generated in rat brain sections characteristic patterns which could be blocked by preadsorption with their respective peptide antigens.  $\alpha 1,~\alpha 2$  and  $\alpha 3$  subunit-like immunoreactivities were widespread, overlapped in some structures (e.g. neocortex and offactory bulb) and were mutually exclusive in others (e.g. basal forebrain, substantia nigra). In contrast,  $\alpha 5$ - and  $\alpha 6$  subunit-directed antibodies showed much more circumscribed staining patterns:  $\alpha 5$  in CA3 cell fields in hippocampus, some cortical interneurones and thalamic reticular nucleus, and  $\alpha 6$  principally in cerebellar granule cells. Double staining with antibodies to  $\alpha 1$  and parvalbumin indicates that this subunit is very prominently expressed by GABAergic neutrones

The distributions are consistent with previous biochemical studies indicating that the majority of GABA, receptors contain only a single  $\alpha$  subunit species, but do not exclude the possibility that in some brain areas different  $\alpha$  subunits coexist within receptors.

### 120.13

IDENTIFICATION OF β2 AND β3 SUBUNITS OF THE GABAA RECEPTOR FROM RAT BRAIN WITH SUBUNIT SUBTYPE-SPECIFIC ANTIBODIES. Timothy M. DeLorey\*. Shuichi Endo, Tina K. Machu, Michael D. Browning and Richard W. Olsen, Department of Pharmacology, UCLA, Los Angeles, CA 90024 and Colorado Health Sciences Center, Denver, CO 80262.

GABAA receptors are hetero-oligomeric complexes composed of a combination of polypeptides which are encoded by 15 different genes. These polypeptides have been subclassed into  $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\delta$ , and  $\rho$  subunits. To date four different  $\beta$  subunit subtypes have been identified. Specific molecular weight assignments of the four  $\beta$  subtypes has been inferred by a variety of methods. Using subtype specific antibodies we were able to assign molecular weights to the  $\beta_2$  and  $\beta_3$  subunit subtypes. Purified GABAA receptors from bovine brain were separated by 7.5% acrylamide gel and transferred to nitrocellulose. Subunits were identified on Western blots using affinity purified  $\beta_2$  and  $\beta_3$  subtype-specific antibodies. Both antibodies were raised in rabbits against subtype specific peptides based on hydrophilis equences in the cytoplasmic loop deduced from rat cDNA sequences. The  $\beta_2$  subunit was identified as a protein band at 57 kDa and the  $\beta_3$  was identified as a 54 kDa band. Supported by NIH Grant N528772.

## 120.15

ANTIBODIES TO THE HUMAN  $\gamma_2$  SUBUNIT OF THE GABAA RECEPTOR. L.P. Fernando, Z.U. Khan, P. Escribá, X. Busquets, C.P. Miralles and A.L. De Blas. Div. Molec. Biol. and Biochem., SBLS, UMKC, Kansas City, MO 64110

A  $\gamma_2$  subunit (short form) of the GABAA receptor/benzodiazepine

A  $\gamma_2$  subunit (short form) of the GABA<sub>A</sub> receptor/benzodiazepine receptor (GABA<sub>A</sub>R/BZDR) was cloned from an adult human cerebral cortex cDNA library in  $\lambda$ gtl1. The 261 base pair intracellular loop located between M3 and M4 was amplified using polymerase chain reaction (PCR) and inserted into the expression vectors  $\lambda$ gtl1 and pGEX-3X. Both 8-galactosidase (LacZ) and glutathione-S-transferase (GST) fusion proteins containing the  $\gamma_2$  intracellular loop (IL) were purified and both rabbit antisera and monoclonal antibodies were made.

antisera and monocional antibodies were made.

The rabbit antibody reacted with the  $\gamma_2 IL$  of both LacZ and GST fusion proteins and immunoprecipitated the GABA\_R/BZDR from bovine and rat brain. The antibody reacted in immunoblots of the affinity-purified GABA\_R/BZDR from bovine cerebral cortex with a wide peptide band of 44,000-49,000 Mr. Immunoprecipitation studies with the anti- $\gamma_2 IL$  antibody suggest that in the cerebral cortex 87% of the GABA\_R with high affinity for benzodiazepines and 70% of GABA\_R with high affinity for muscimol contain at least a  $\gamma_2$  submit. Immunoprecipitations with various antibodies indicate that the most abundant combination (over 60%) of GABA\_R subunits in the cerebral cortex involves  $\alpha_1$ ,  $\gamma_2$  and  $\beta_2$  and/or  $\beta_3$ . The monoclonal antibodies to  $\gamma_2 IL$  are being characterized. This work was supported by grant NS17708 from NINDS.

#### 120.12

CHARACTERIZATION OF STRUCTURAL AND FUNCTIONAL SUBTYPES OF GABA-A RECEPTORS WITH ANTIBODIES TO THE  $\beta_3^2$  SUBUNIT. K.H. Huh, T.M. DeLorey, S. Endo, and R.W. Olsen, Dept. Pharmacology, UCLA, Los Angeles, CA 90024.  $\beta$ -Subunit subtype-specific antibodies were used to separate

β-Subunit subtype-specific antibodies were used to separate pharmacological subtypes of GABA-A receptors. GABA-A receptors are hetero-oligomers whose subunit composition is unknown. Antibodies were prepared against a synthetic peptide selective for the cow β3 subunit in the cytoplaşmic loop. These antibodies immuno-precipitated 50% of [ H]flunitrazepam binding sites from crude soluble extracts of bovine cortex, whereas antibodies which recognize all β subunits (Endo & Olsen, J. Neurochem. 1992) precipitated 100%. The GABA analog THIP differentially inhibits [ H]muscimol photoincorporation into different β polypeptides (Bureau & Olsen, Mol. Pharm. 37,497,1990), and binding in different brain regions (Olsen et al. Mol.Neuropharm.1992). Heterogeneity of THIP binding affinity is evident in membranes, soluble extracts, and affinity-purified receptors. [ H]Muscimol binding sites in purified receptors immunoprecipitated with anti-β3 antibodies had higher affinity for THIP than the supernatant receptor subpopulations disenriched in β3 and enriched in other β subunit but the nature of the β subunit varies and results in receptor subtypes showing differential pharmacological specificity at the GABA site. Supported by NIH grant NS28772.

## 120.14

LOCALIZATION OF THE \$3 SUBUNIT OF THE GABA-A RECEPTOR IN RAT FOREBRAIN. M. Esclapez, T.M. DeLorey. R.F. Tyndale, N.J.K. Tillakaratne, A.J. Tobin, R.W. Olsen and C.R. Houser\*. Brain Research Institute, UCLA, and VA Medical Center, Los Angeles, CA 90024.

The  $\bar{\Omega}3$  subunit subtype of the GABA-A receptor was localized with in situ hybridization (ISH) and immunocytochemical (ICC) methods. ISH histochemistry using digoxigenin-labeled &3 cRNA probes demonstrated strong neuronal labeling in pyramidal and granule cell layers of the hippocampal formation and pyriform cortex. Moderate levels of labeling were present in striatal neurons, and moderate to light labeling was observed in many cortical neurons. The antiserum used for ICC studies was produced in rabbits to a synthetic peptide sequence that was specific for the ß3 subunit and found within the cytoplasmic loop of the rat receptor sequence. Two types of labeling were observed: 1) a diffuse, fine punctate labeling that was present at high levels in dendritic layers of the hippocampal formation and at moderate levels in the striatum and cerebral cortex; and 2) a discrete outlining of some neuronal cell bodies and proximal dendrites that was most prominent around nonpyramidal neurons of the cerebral cortex. Double labeling studies demonstrated that a high percentage of the heavily outlined neurons contained GAD. While the results from the two methods are consistent with each other, they emphasize important differences between the cellular localization of the mRNA and the protein for this GABA-A receptor subunit. Supported by VA Medical Research Funds, NS29231, NS28772 and NS22256.

## 120.16

IDENTIFICATION OF 5 DISTINCT GABA, RECEPTOR SUB-TYPES BY DOUBLE AND TRIPLE-IMMUNOFLUORESCENCE STAINING WITH SUB-UNIT SPECIFIC ANTIBODIES. J.- M. Fritschy, D. Benke, S. Mertens & Mohler, Inst. of Pharmacology, Univ. of Zurich, CH-8006 Zurich, Switzerland.

A family of at least fifteen sub-units provides the basis for an extraordinary

A family of at least fifteen sub-units provides the basis for an extraordinary structural heterogeneity of GABA<sub>A</sub> receptors in the CNS. To assess the functional relevance of GABA<sub>A</sub> receptors subtypes on defined neurones, physiological sub-unit combinations must be clarified at the cellular and subcellular levels. Co-localisation of prevalent GABA<sub>A</sub> receptor sub-units in a train neurones was assessed by confocal laser microscopy using double and triple immunofluorescence staining in restricted areas with polyclonal antisera recognising the  $\alpha_1$ ,  $\alpha_2$  and  $\gamma_2$  sub-units and the monoclonal antibody bd17 ( $\beta_{2/3}$  sub-units). Five distinct sub-unit combinations were identified. Four sub-units ( $\alpha_1$ ,  $\alpha_3$ ,  $\beta_{2/3}$ ,  $\gamma_2$ ) were co-localised in neurones of the basal forebrain, olfactory bulb and brainstem reticular formation. The triple combination,  $\alpha_1$ ,  $\beta_{2/3}$ ,  $\gamma_2$ , again recognised neurones of the brainstem reticular formation plus the pallidum and substantia nigra reticulata. Offactory bulb granule cells were immunofluorescent for  $\alpha_3$ ,  $\beta_{2/3}$ , and  $\gamma_2$  sub-units whist the combination of  $\alpha_1$ ,  $\alpha_3$ ,  $\gamma_2$  sub-units was detected in brainstem motor nuclei neurones. Finally, adouble combination,  $(\alpha_3, \gamma_2)$  was observed in the inferior olive. Using single  $\alpha_1$  and  $\alpha_3$  sub-unit immunostaining, segregation of two different receptor subtypes within a single neurone was seen in Purkinje cells; whereas the  $\alpha_3$  sub-unit was found on dendrites and soma of these cells, the  $\alpha_1$  sub-unit was detected on the soma only. By demonstrating the existence of distinct GABA<sub>A</sub> receptor sub-types on identified neurone populations, the results provide the basis for a functional analysis of GABA<sub>A</sub> receptors *in situ* and may lead to novel therapeutic approaches based on sub-type-specific drugs.

AUTORADIOGRAPHIC LOCALIZATION OF GABAA AND GABAB BINDING SITES IN THE NUCLEUS TRACTUS SOLITARII OF THE CAT <u>B.E. Maley\*</u>, Dept. Of Anatomy And Neurobiology, University Of Kentucky Medical Center, Lexington, KY 40536

Gamma-aminobutyric acid (GABA) is one of the major inhibitory neurotransmitters in the central nervous system. Previous studies from our laboratory have demonstrated a uniform distribution of GABA immunoreactive synaptic terminals throughout the neuropil of the various subdivisions of the cat nucleus tractus solitarii. In the present investigation we have studied GABAA and GABAB binding sites using in vitro autoradiography with [3H] muscimol to label high affinity GABA<sub>A</sub> binding sites and [<sup>3</sup>H]baclofen for GABA<sub>B</sub> binding sites. Each ligand was used at or below its calculated KD. Autoradiograms of [3H]muscimol and [3H]baclofen labeled tissues demonstrated homogeneously moderate grain density over the entire nucleus tractus solitarii. There appeared to be no preferential localization of autoradiographic grains within specific subdivisions of the nucleus for either ligand used. The distribution of GABAA and GABAB binding sites reminiscent of the pattern for GABA immunoreactive terminals in the nucleus tractus solitarii, suggests a possible morphological correlate for GABAergic receptors in the cat nucleus tractus solitarii.

SULFHYDRYL MODIFICATION OF GABA, RECEPTORS HAS DIFFERENTIAL EFFECTS ON BENZODIAZEPINE BINDING. L.L. Duncalfe' and S.M.J. Dunn. Department of Pharmacology, University of Alberta, Edmonton, Canada T6G 2H7

The effect of sulfhydryl modification on benzodiazepine binding to the GABA, receptor has been studied in crude brain membranes prepared from bovine cerebral cortex. The bovine brain membranes were reduced with increasing concentrations of dithiothreitol (DTT). The binding of the partial inverse agonist [3H]-Ro15-4513 (2.5 nM) was reduced to about 30% of control by 5 mM DTT, while the binding of the classical agonist [3H]flunitrazepam (2.5 nM) was unaffected by 30 mM DTT. Binding assays of [3H]-Ro15-4513 in the presence of 10 mM DTT indicated that the K<sub>D</sub> increased by more than 2-fold and the binding site density was reduced from 2.8 to 1.1 pmol/mg. DTT (10 mM) had no significant effect on either the  $K_D$  for [ $^3$ H]-flunitrazepam binding or the density of binding sites. DTT reduction of the membranes followed by alkylation of free sulfhydryl groups with iodoacetamide reduced the number of sites for both [3H]-Ro15-4513 and [3H]-flunitrazepam to about 60% of control, but had no effect on the equilibrium dissociation constants. This work was supported by the Medical Research Council of Canada, Alberta Heritage Foundation for Medical Research and Nordic Laboratories Inc.

CHRONIC EXPOSURE OF CORTICAL NEURONS TO GABA, AGONISTS DOWN-REGULATES GABA, /BENZODIAZEPINE RECEPTOR PEPTIDES ON THE CELL SURFACE. P.A. Calkin and E.M. Barnes, Jr. \*, Dept. of Biochemistry, Baylor Col. of Med., Houston, TX 77030.

Chronic exposure of cortical neurons to GABA has been shown to reduce the density of [<sup>3</sup>Hiffunitrazepam binding sites and GABA-gated CI<sup>-</sup> currents by more than 60% [Hablitz et al. (1989) *Brain Res. 501*, 332-338]. In this study, we measured the levels of GABA<sub>A</sub> receptor (GaR) peptides on the surface of neurons which had been treated for 5 days with 100 µM GABA, isoquvacine or 4,5,6,7-tetrahydrosioxazolo(5,4-c)pyridin-3-ol (THIP). GaR peptides on the surface of intact neurons were labeled with the cleavable, membrane-impermeant reagent 3,3'-dithiopropionyl 1-sulfosuccinimidyl glycyltyrosinel<sup>126</sup>Ilextracts from the [1<sup>25</sup>fllabeled cells were immunoprecipitated with polyclonal antibodies against affinity-purified chicken GaR. Analysis of the immunoprecipitates on nonreducing SDS-polyacrylamide gels showed incorporation of <sup>126</sup>I into 50- and 53-kD peptides. The label on these peptides was removed by treatment of intact neurons with 100 mM glutathione which cleaves the disulfide linkage. In cells chronically exposed to GABA or isoguvacine, the level of iodinated 50- and 53-kD peptides was greatly reduced, while a lesser effect was produced by the partial GABA<sub>A</sub> agonist, THIP. The effect of GABA on cell-surface GaR peptides was prevented by co-exposure of the neurons to 1 µM R 5135, a GABA<sub>A</sub> antagonist. Alone, R 5135 had no noticeable effect. The data suggest that agonist-dependent downregulation reduces the levels of GaR subunit peptides on the neuronal surface.

Supported by DK17436, MH47715, and NS11535 from USPHS.

IDENTIFICATION OF A [3H]FLUNITRAZEPAM PHOTO-AFFINITY SUBSTRATE IN BOVINE GABA-A RECEPTOR. G.B. Smith and R.W. Olsen, Dept. of Pharmacology, UCLA School of Medicine, Los Angeles, CA 90024.

We previously showed that the site of covalent modification by [3H]flunitrazepam ([3H]FLU) photoaffinity labeling of partially purified GABA-A receptor lies within the N-terminal 30kD of the  $\alpha$  subunit. This would include the N-terminal extracellular domain and could extend up to the cytoplasmic end of the proposed first transmembrane spanning domain. Here, we have tentatively identified a hydrophobic tryptic peptide containing incorporated radioactivity in aromatic residues. The receptor was purified by benzodiazepine affinity chromatography from bovine cortex. After photoaffinity labeling with 10nM [3H]FLU, receptor polypeptides were separated by SDS-PAGE, sliced and counted for radioactivity, electroeluted and subsequently digested with TPCK trypsin. Digest products were separated by reverse phase HPLC and fractions containing label were manually collected. N-terminal sequencing showed a mixture of sequences one of which could be matched with 4/5 residues beginning at residue 1223 of the published bovine a 1 subunit. This sequence, following the tryptic cleavage site K222, begins at the extracellular surface of the first transmembrane domain and is conserved in all currently identified  $\alpha$  subunit clones. Supported by NS

# PEPTIDES: ANATOMICAL LOCALIZATION—NON-PRIMATES

## 121.

LOCALIZATION OF PROLACTIN-IMMUNOREACTIVE NEURONS IN THE RABBIT CNS USING A MONOCLONAL ANTIBODY. R.J. Walsh\*, M.F. Sherif, and J.G. Scammell Dept. of Anatomy, George Washington Univ., Washington, DC 20037, Dept. of Anatomy, Kuwait University, Kuwait, Dept. of Pharmacology, Univ. of South Alabama College of Medicine, Mobile, AL 36688

Evidence suggests that the CNS produces prolactin (PRL). Immunocytochemistry using 6F11, a monoclonal antibody which cross-reacts with PRL from several species

Evidence suggests that the CNS produces prolactin (PRL). Immunocytochemistry using 6F11, a monoclonal antibody which cross-reacts with PRL from several species including rabbit, was used to identify PRL-positive cells in the CNS and pituitary of female New Zealand white rabbits. Colchicine was injected into the lateral cerebral ventricle 20 h prior to perfusion with PBS and 4% paraformaldehyde. Cryostat sections were sequentially incubated in 3% H<sub>2</sub>O<sub>2</sub>, 0.2% Triton X-100, 10% goat serum and then for 2 days at 4° C with 6F11 diluted 1:1000 in PBS-18 SBA. Sections were exposed to avidin biotinylated goat anti-mouse IgG, washed, and incubated with DAB or AEC. Lactotrophs of the pituitary exhibited a prominent staining reaction. PRL-positive neurons occurred in the supraoptic, paraventricular, anterior hypothalamic, periventricular, lateral hypothalamic, mammillary, and perifornical hypothalamic nuclei. PRL-positive neurons also resided in the globus pallidus, zona incerta, entorhinal cortex, septal nuclei, and various thalamic nuclei. Preabsorption of 6F11 with PRL abolished the staining as did elimination of 6F11 from the incubation. The results indicate 1) 6F11 Mab recognizes PRL-positive neurons within the rabbit CNS, and 2) PRL-positive neurons have a broad distribution in the rabbit CNS.

## 121.2

IMMUNOCYTOCHEMICAL LOCALIZATION OF ACTH 4-10 IN RAT BRAIN. <u>S.J. Lee\*C.J. Aoki, and F.L.Strand.</u> Dept of Biology and the Center for Neural Science, New York University, New York, N.Y. 10003.

A naturally secreted neuropeptide, adrenocorticotropin (ACTH 1-39), contains all of its bioactivity within the peptide ACTH 1-24. While the corticotropic properties reside in the peptide 11-24, the neurotrophic properties appear to be in the peptides 1-10, 4-10, and 1-13 ( $\alpha$ -MSH) (rev. Strand et al., 1991, Physio Rev 71: 1017). Although previous studies have shown immunoreactivity to anti-ACTH 1-39 and anti-ACTH 11-24 in the hypothalamus, thalamus, amygdala and periaqueductal gray area (Watson et al., 1978, Science 200:1180; Watson et al., 1978, Nature 275: 226), the immunoreactivity to anti-ACTH 4-10 has never been examined. Antisera against ACTH 4-10 were raised by immunizing male Sprague-Dawley rats. ACTH 4-10 was modified by cross linking to hemocyanin (30mg/ml) using glutaraldehyde (5%). The glutaraldehyde conjugated form of the peptide (4mg/ml) was mixed with complete Freund's adjuvant and injected subcutaneously into two rats. Sera were collected after the third immunization. Immunodot blot analysis indicated that amino acids 7-10 may be the major antigenic site. Antisera were not immunoreactive to ACTH 1-39 or ACTH 1-16. In brain sections, immunolabeling was seen within processes in the septal area and the perimeter of the third ventricle, including the median eminence. Furthermore, these processes, presumably axons, were more pronounced in young adult rats weighing 150-170gm than in adult rats weighing 250-270gm. However, perikaryal labeling was not observed in any of the brains. These results indicate that the neurotrophic fragment has a more restricted distribution than of its precursor ACTH 1-39. Supported by 2-S07-RR07062-26 to CA and Organon.

GASTRIN (CCK-8) IMMUNOHISTOCHEMICAL STAINING PAT-TERNS IN THE NORMAL AND NEONATALLY DEAFFERENTED TRIGEMINAL (V) BRAINSTEM COMPLEX. P.H. Young\*, D.S. Zahm, M.C. Beinfeld & M.F. Jacquin. Depts. Anat. & Neurobiol. and Pharm. & Physiol. Sci., St. Louis Univ. School of Medicine, St. Louis, MO 63104.

Prior studies indicate that high levels of CCK in medullary dorsal horn (MDH) laminae I and II reflect a higher-order CCK-containing projection. However, it is unclear which neurons give rise to this projection because polyclonal CCK antibodies stain very few CNS neurons that project to the V complex. Elution of CCK immunoreactive peptides extracted from micropunches of the superficial MDH indicated that a monoclonal antibody to Gastrin (courtesy of Dr. J. Walsh) detects mainly CCK8-like material in the MDH. In 16 adult rats, gastrin immunohistochemistry revealed a mean (+SD) of 8.6 + 3.1 labeled cells per 50 μm transverse section through MDH laminae I and II. The largest #s were in lamina II and their processes formed a dense, continuous, circumferential and thin band that was prominent in lamina II. It is likely that these labeled neurons represent a significant source of CCK in the V complex. Dense terminal label was also noted in rostrally displaced pockets of substantia gelatinosa embedded in each of the V spinal tract and subnuclei interpolaris and oralis. Weak terminal staining was also seen in non-gelatinous regions of all 4 V subnuclei.

Prior studies also revealed elevated CCK levels in the MDH after infraorbital nerve section at birth. In 7 similarly lesioned rats, immunohistochemistry indicated a near total elimination of Gastrin + cells and more diffuse terminal staining in deafferented regions of the MDH. Thus, V primary afferent inputs may affect CCK expression, transport and/or release mechanisms. Support: NIH DE07662, DE07734, NS18667, NS23805.

## 121.5

NEURONAL AND NON-NEURONAL ORIGINS OF CGRP IN THE GASTRIC WALL. G. Jakab, 1 K. Pacak2, I. Salamon3, L. Rosivall3, H.deF.Webster1\*. Lab. of Neuropathology1, CNB2, NIH, Bethesda, MD 20892 and Semmelweis Univ. Med. Sch. Budapest, Hungary<sup>3</sup>

The distribution of calcitonin gene-related peptide-immunoreactive (CGRP-IR) primary afferent fibers was studied in the rat gastric wall. The CGRP-IR fibers showed a characteristic arrangement in each layer of the gastric wall. The fine, varicose CGRP-IR fibers arborized in the basal region of the mucosa and followed either blood vessels or smooth muscle cells while running in the tunica propria toward the lumen of the stomach. The nerve fibers' branching pattern suggests that there may be columnar neurovascular regulatory units in the mucosa which are oriented perpendicular to the luminal epithelial surface and which do not overlap. When examined electron microscopically, boutons and axon terminals of these varicose nerve fibers contained large dense core vesicles. Also both immunohistochemistry and in situ hybridization histochemistry revealed the presence of a number of CGRP-producing cells located mainly in the lower mucosa. Some of them were inserted between the cells of gastric glands. Induction of gastric stress ulcers changed the distribution of CGRP mRNA and peptide. The results suggest that CGRP provided by these two systems may act as a neurotrophic factor. It may also regulate gastric microcirculation have a role in the pathogenesis of gastric ulcers.

EXPRESSION OF A CHIMERIC GALANIN GENE IN TRANSGENIC MICE. A. Rökaeus\* and J. A. Waschek. Dept. of Biochemistry I, Molecular Endocrinology Unit, Karolinska Institute, S-104 01 Stockholm, Sweden and The Mental Retardation Research Center and Dept. of Psychiatry, Neurobiochemistry Research Group, University of California, Los Angeles, CA 90024-1759.

Galanin (GAL), a biologically active neuropeptide has been suggested to play a role in dementia of the Alzheimer's type and possibly also in diabetes. A linearized DNA fragment containing 5 kb of bovine GAL gene 5 flanking-sequence fused to the intronless cDNA encoding firefly luciferase have been introduced into fertilized eggs to raise transgenic mice, in order to establish lines of mice which could be used to identify upstream sequences mediating constitutive and inducible transcriptional activity in a tissue specific manner. Screening for transgenic founders (F0) and offspring (F1) was performed by slot-blot analysis and/or PCR. Nine out of 25 developed mice became hybrydization positive; six of

the latter mice mice appeared to express less then one copy of the gene, suggesting that these animals may be mosaic. When two low as well as one high expressing male were mated with non-transgenic females, only the latter male transmitted the gene-construct to the offspring (F1; 9 out of 21). When tissue extracts (2.5-10% of total) from two 12 week old PCR-positive female mice were analyzed for luciferase activity, detectable activity was found in the brain and spinal cord, uterus and heart, i.e. in organ with known GAL expression, as well as in the thymus; no activity could be detected in the printery, adrenal glands, wringry. no activity could be detected in the pituitary, adrenal glands, urinary bladder, jejunum or lung.

This set of limited data, indicate that 5 kb of bovine GAL gene 5 flanking-sequence appears to direct expression of luciferase activity to at least some of the organs with known vertebrate GAL expression.

SYNAPTIC CONNECTIONS IN THE PARACERVICAL GANGLION OF THE FEMALE RAT: CALCITONIN GENE-RELATED PEPTIDE-, GALANIN-, AND TACHYKININ (SUBSTANCE P AND NEUROKININ A)-IMMUNOREACTIVE NERVE TERMINALS. R.E. Papka\* and D.L. McNeill. Dept. Anatomical Sciences, Univ. Oklahoma HSC, Oklahoma City, OK 73190

Many nerve fiber varicosities in the pelvic paracervical ganglia (PG) immunoreactive for calcitonin gene-related peptide (CGRP), galanin (GAL) and the tachykinins substance P (SP) and neurokinin A (NKA) are capsaicin-sensitive, originate in dorsal root ganglia and are considered primary afferents. Even though these varicosities are pericellular and closely adjacent to principal neurons, are they synaptically related? The present study addresses this question. In order to reveal the relationship between varicosities and neurons, PG of female rats were immunostained with antisera against synapsin I (SYN), a nerve terminal marker, and microtubule-associated protein-2 to define somata and dendrites. SYN endings were predominantly axosomatic with fewer being axodendritic. PG were processed for electronmicroscopic immunohistochemistry using standard immunogold and peroxidase-antiperoxidase procedures. Unmyelinated fibers and varicosities immunoreactive for CGRP, GAL, SP and NKA were observed in the interstitium between neurons. Immunoreactive varicosities were within the satellite-cell sheath of the neuron somata and intimately associated with the membrane of the somata, somatic spines or with the proximal part of dendrites. Membrane specializations, indicative of synaptic contacts, between the fibers and the principal neurons were observed. It is suggested that these peptide immunoreactive sensory fibers and varicosities are involved in regulation of activity in the PG. (Supported by NIH NS 22526).

#### 121.6

GROWTH HORMONE RELEASING HORMONE (GHRH) IN THE GROWTH HORMONE (GH)-DEFICIENT DWARF MOUSE BRAIN. H. Dalcik 1\*, H. Endo2, F. Talamantes<sup>2</sup> and C.J. Phelps<sup>1</sup>, <sup>1</sup>Dept. Anatomy, Tulane Univ. Sch. Med., New Orleans, LA 70112, and 2Dept. Biol, Univ. Calif., Santa Cruz, CA 95064.

Orleans, LA 70112, and 2 Dept. Biol, Univ. Calif., Santa Cruz, CA 95064.

Ames dwarf mice bear a genetic mutation which, in the homozygous condition (df/df), results in absence of GH and prolactin expression. These mice were used as a model to evaluate negative feedback regulation of hypothalamic GHRH in chronic GH deficiency. Hypophysectomy in adult rats has been reported to result in decreased GHRH (Merchenthaler and Arimura, Peptides, 1985, Leidy et al., Neuroendocrinology, 1990). Conversely, GHRH mRNA increases after hypophysectomy (Chomczynski et al., Mol. Endocrinol., 1989) and mice (Frohman et al., Mol. Endocrinol., 1989). Ames dwarf mice (df/df), which completely lack GH, also show increased hypothalamic GHRH mRNA (Hurley et al., Endocrine Soc. abs., 1991). Investigation of GHRH peptide expression in mice has been hampered by the absence of a homologous antiserum. This study employed an antiserum to a 25 aa c-terminal synthetic peptide specific to mouse-GHRH. In RIA, the antiserum did not detect several CNS peptides, including hGHRH, GHRH, CRF and oxytocin. For ICC, some mice were treated with intracerebroventricular colchicine prior to sacrifice. Thirty µm coronal brain sections were incubated in anti-mGHRH antiserum (1:10,000), and processed using ABC method for ICC. In untreated mice, intensely stained GHRH terminals were apparent in both DF/? and df/df median eminence, but neuronal cell bodies were few, and limited to method for ICC. In untreated mice, intensely stained GHRH terminals were apparent in both DF/3 and df/df median eminence, but neuronal cell bodies were few, and limited to ventral hypothalamus and arcuate nuclei. In-colchicine treated normal (DF/?) and dwarf mice, immunoreactive cell bodies were noted in hypothalamic MPOA, and in ARC, VMH, DMH, PeN, SON and in PVN. GHRH-immunoreactive fibers were observed mainly in the vicinity of the cell bodies in both DF/? and df/df mice. The number of immunoreactive cell bodies, in colchicine-treated dwarf mice appeared to be increased in the PVN and in ARC. These results indicate that GHRH displays a unique distribution in the mouse, and that GHRH peptide and mRNA are similarly affected in the GH-deficient Ames dwarf brain. Supported by PHS grant NS25987 (CJP).

## 121.8

THE IMMUNOHISTOCHEMICAL LOCALIZATION OF SUBSTANCE P IN THE SPINAL DORSAL HORN IN THE WOBBLER MOUSE. Y-H Du and J Xu\*. Anatomy, Med Coll Jinan Univ, Guangzhou 510632, PR China; Neurology,\* Med Univ SC, Charleston, SC 29425 USA.

The wobbler mouse mutant possesses a recessively inherited degeneration of motor neurons in spinal cord and has been considered a model for human hereditary motor neuron disease. It has been reported that Substance P (SP)-containing nerve fibers connect closely the motor-neurons in rat ventral horn plays a role in control and regulation of motor function.

rat ventral horn plays a role in control and regulation of motor function.

Using PAP technique, the distribution of SP in the wobbler mouse spinal cord dorsal horn was studied. In the homozygous, distribution of SP immunoreactive (IR) fibers were widespread in the dorsal horn but more dense in laminae I and II than in other laminae. SP IR fibers concentrated in a cap-like area covering the margin of the dorsal horn. IR in the lateral area of the dorsal horn was usually higher than in the medial area. In laminae V and VI, SP IR nerve fibers formed large plexuses. The IR fibers passed from dorsal horn into the intermediolateral gray matter and the dorsal gray commissures and entered the ventral horn. In the heterozygous, the distribution of SP IR in the dorsal horn were similar to that of the homozygous mouse. SP IR nerve fibers were concentrated mainly in the laminae I and II, and fewer in other laminae. No obvious difference was observed on SP IR in the dorsal horn between the homozygous mouse and heterozygous mouse. The present results indicate that heredity only affect the motor neurons in ventral horn and do not involve dorsal horn even in heterozygous mouse.

NEUROKININ B PEPTIDE-2 NEURONS PROJECT FROM THE HYPOTHALAMUS TO THE SPINAL CORD OF THE RAT. Huang Zhuo and C.J. Helke.\* Dept. of Pharmacology, Uniformed Services Univ. of the Health Sciences, Bethesda, MD 20814.

Our studies of the spinal distribution of neurokinin B peptide-2 (NKB P2) (one fragment of the NKB precursor protein) showed that NKB P2-like immunoreactive (LI) fibers and terminals were mainly distributed in the superficial dorsal horn and central autonomic area. NKB P2-L1 fibers and terminals were also found in the intermediate grey of the spinal cord. Neurons having NKB P2-LI were recently located in the hypothalamus, epithalamus, amygdaloid complex, and cerebral cortex (J. Comp. Neurol. 317:341, 1992). To explore the origins of spinal NKB P2, we combined the retrograde transport of Fluoro-Gold (FG) with NKB P2 immunohistochemistry (antibody from J. Krause, Washington Univ.) in the rat. Whereas neurons labeled with either NKB P2-LI or FG were found in many CNS regions, spinally projecting NKB P2-LI neurons were only found in the dorsal hypothalamic area. About 30% of the spinal projecting neurons in the dorsal hypothalamic area had NKB P2-LI. About 35% of the NKB P2-LI neurons in the dorsal hypothalamic area projected to the spinal cord. Most of these irregularly-shaped spinally projecting NKB P2-LI neurons have a cell size of 15 by 25μm. The results of the present study indicate that hypothalamic NKB-P2 neurons are the main CNS source of the spinal NKB P2-LI. (Supported by NIH grant N\$20991)

### 121.11

SEPARATE POPULATIONS OF CELLS IN THE NUCLEUS OF THE SOLITARY TRACT (NTS) PROJECT TO THE PARABRACHIAL NUCLEUS (PBN) AND THE SPINAL TRIGEMINAL NUCLEUS (Sp.5). R. D. Hofbauer, J. A. Yuan. C. Cozzari¹. B. K. Hartman and P. L. Faris¹. Division of Neuroscience Research in Psychiatry, Univ. of MN 55455 and ¹ Instituto Biologia Cellulare CNR, Roma, Italy.

Several neuropeptides, e.g., CCK and enkephalin, have been localized in NTS projections to both the PBN and the Sp5. This study was aimed at determining if these projections arise from separate populations of cells or if the same cells collateralize to innervate both areas. This was accomplished using two fluorescent retrograde tracers: Fluorogold (20 nl) and rhodamine-conjugated latex beads (200 nl) injected into the PBN and into the interpolar Sp5. Two distinct staining patterns resulted from the two injection sites. Cells projecting to the PBN were localized mainly to the medial subdivision of the NTS and the area postrema. Cells projecting to the Sp5 were localized to more lateral aspects of the NTS. Only an occasional cell (3-5 per brain) was found to be double-labeled. We are currently conducting additional experiments in which the Sp5 injections are centered in the caudal portion of this nucleus. In addition to the NTS labeling results described above, two other interesting findings arose from this study. First, interiore described above, two other interesting findings arose from this study. First, interiores for the page to the p described above, two other interesting findings arose from this study. First, injections of tracers into the PBN also resulted in extensive labeling in the injections of tracers into the PBN also resulted in extensive labeling in the Sp5. Since administration of the latex beads produces a small injection site, which was highly restricted to the dorsolateral PBN, it appears that the Sp5 and NTS both project to the same subdivision of the PBN. Thus, this confirms the role of the PBN in the integration of visceral and somatosensory information. Second, injections of a tracer into the Sp5 also resulted in cell labeling in the PBN. A large number of these retrogradely labeled cells lay within the PBN tracer injection site. Thus, it appears that the PBN-Sp5 projections are truly reciprocal, i.e. projecting to or from the same subdivision. subdivision

IDENTIFICATION OF KINDLING ACTIVATED NEURONS IN THE PARAVENTRICULAR NUCLEUS. <u>D.T. Piekui\*</u>, S. Pretel and C. Applegate. Neuroendocrine Unit and Dept. of Neurology, University of Rochester, Rochester, NY 14642.

Neurons of the paraventricular nucleus of the hypothalamus are known to Neurons of the paraventricular nucleus of the hypothalamus are known to respond to stressful stimuli. We have used the immunocytochemical identification of the Fos protein to identify anatomically PVN neurons which are activated following kindling elicited epileptic seizures and subsequently combined this procedure with in situ hypothidization to determine which peptides are synthesized in the activated, c-los expressing neurons. Rats were kindled from sites in the a) amygdala, b) entorhinal cortex or c) exposed to a one time strong, electrical seizure evoking stimulation. The animals were perfused following survival times of 1-12 hrs. and vibratome sections were labeled for the immunocytochemical detection of the Fos protein using antisera provided by Drs. Slammon, Curran and from Oncogene. We observed a substantial increase in the immunocytochemical expression of Fos in specific and distinct CNS sites of the experimental animals. Numerous activated (i.e. Fos expressing) neurons were identified in specific parvocellular components of the paraventricular nucleus of rat hypothalamus, fewer in magnocellular components. Maximal immunolabeling was seen at 2-3 hrs. following the seizure stimulation, and a significant decrease of Fos immunolabeling was evident following a survival time of 4-6 hrs. few immunolabeled neurons remained at 12 hrs. following time of 4-6 hrs.; few immunolabeled neurons remained at 12 hrs. following stimulation. Little Fos immunoreactivity was evident in control animals which received the same intensity of current as the kindled rats, but at a frequency not inductive of seizure behavior. Combined immunocytochemical and in situ hybridization procedures show that numerous PVN neurons activated in kindling express the CRF mRNA, while others express the ENK mRNA. Thus a classical population of stress associated PVN neurons appears to be activated during seizure. This indicates that seizure elicitation has an effect on the central control of the pituitary adrenal axis. NIH grant NS18626

ULTRASTRUCTURAL LOCALIZATION OF NEUROTENSIN (NT) IMMUNOREACTIVITY (IR) IN THE STELLATE GANGLION (SG) OF THE CAT. M.A. Morales, M. Bachoo, B. Collier, A. Beaudet, and C. Polosa\*. Depts. of Pharmacology, Physiology and Neurology, McGill University, Montreal, Quebec, Canada H3G 1Y6.

The NT content of the SG is depleted by prolonged stimulation, and lost after chronic section, of the preganglionic input (Maher et al., 1991). Exogenous NT excites SG cells (Bachoo & Polosa, 1988). In anesthetized cats, the localization of NTIR in the SG was examined. Light microscopy showed NT varicosities in between ganglion cells throughout the ganglion, although the density around individual cells was variable. With electron microscopy, NTIR was localized exclusively to cholinergic-type synaptic boutons which mainly formed axo-dendritic synapses. The NT boutons had the same morphology as non-immunoreactive ones. Occasionally both types formed synapses on the same dendrite. Within the bouton, NTIR was most intense in large dense core vesicles (LDCV), but often cytoplasmic staining was also evident. Small, clear, synaptic vesicles were not labelled. Prolonged stimulation (20 min 40 Hz) of the preganglionic input to the ganglion reduced the number of LDCV per bouton (from 6.6 to 3.0) as well as the extent and intensity of NTIR within labelled boutons. The data suggest that NT is released in a stimulus-dependent manner from a subset of preganglionic axons in the cat SG. (With MRC support).

## 121.12

SOMATOSTATIN INTERNEURONS AND THE PATCH/MATRIX COMPARTMENT W.J.Rushlow\*, C.C.G.Naus and B.A.Flumerfelt. Dept. of Anatomy, University of Western Ontario, London, Canada, N6A 5C1.

The patch/matrix compartments represent functionally distinct components of the caudate-putamen. It has been suggested that virtually no intermingling of the afferents and efferents to and from these compartments occurs but the GABAergic, cholinergic and somatostatinergic (SOM) interneurons may bridge the compartmental boundary. In particular, SOM interneurons have been chosen as likely candidates. Examination of SOM neurons and their corresponding fibre plexus using fluorescence microscopy reveals that SOM neurons may be found within the patch, within the matrix, and on or around the patch/matrix border. Dendrites of SOM matrix neurons may sometimes be traced over long distances (>50um) and occasionally approach and enter the patch compartment, suggesting an interaction. SOM interneurons found deep within the patch are also fairly common. In order to help clarify the possible role of SOM with regards to the patch/matrix a scanning laser confocal microscope was utilized. Using this technique it is possible to obtain three dimensional reconstructions of the area in and around the patch compartment. SOM interneurons found in and around the patch/matrix border sent dendrites into both compartments. Those dendrites which passed into the patch tended not to remain in the patch but exited to the matrix. Occasionally, a SOM interneuron sent an axon into the patch but it also exited to the matrix. SOM interneurons located deep within the patch were not common. The patch was almost devoid of SOM fibres which were prevalent in the matrix compartment. This suggests that SOM interneurons are involved in patch/matrix communication but the interaction is one-way. Though the SOM neurons may receive a synaptic input from both the patch and matrix, the target of the SOM neurons resides within the matrix. Supported by grants from MRC (B.A.F.) and NSERC (C.C.G.N.).

## 121.14

COEXISTENCE OF FOS IMMUNOREACTIVITY AND SOMATOSTATIN mRNA IN THE HIPPOCAMPAL FORMATION. S. Pretel\*. C. Applegate and D.T. Piekut. Neuroendocrine Unit and Dept. of Neurology, University of

<u>D.T. Piekut</u>. Neuroendocrine Unit and Dept. of Neurology, University ot Rochester, Rochester, NY 14642.
The animal model of kindling is a well established electrophysiological paradigm for the investigation of neuronal mechanisms underlying neuroplasticity. The neuroanatomical basis for the occurrence of kindling is largely unknown. We have used the expression of c-fos to identify neurons which are activated during different stages of the kindling process and have begun to examine which peptides are synthesized in these neurons. Rats were stimulated from the entorhinal cortex and perfused following a) the light distriction of stage 3 behavior and elicitation of the first afterdischarge, b) the elicitation of stage 3 behavior and c) the elicitation of stage 5 behavior; control animals received the same intensity of current as the kindled rats, but at a frequency not inductive of seizure. Tissue sections were then processed for immunocytochemistry seizure. Tissue sections were then processed for immunocytochemistry and in situ hybridization, using antibodies against the Fos protein and an oligonucleotide probe to label somatostatin mRNA (provided by Drs. Stammon, Curran and Young, resp.). The results of the single-labeled studies showed a progressive increase in the immunocytochemical expression of c-fos in animals perfused following the different stages of kindling in comparison to control animals. The results of the double-labeled studies showed that a majority (>60%) of the somatostatin-synthesizing neurons in the hippocampus and dentate gyrus were activated following seizure stimulation. It is apparent, however, that the somatostatin synthesizing neurons represent only one component of the kindling activated, i.e. c-fos expressing neuronal network. The data provide anatomical evidence for the hypothesis that the development of kindling involves the progressive recruitment of a neuronal network over time. The data also show that a substantial percentage of somatostatin synthesizing neurons in hippocampus and dentate gyrus are activated during kindled neurons in hippocampus and dentate gyrus are activated during kindled seizures. NIH grant NS18626

#### 121 15

EXPRESSION OF mRNAs CODING FOR THE PROHORMONE CONVERTASES PC1 AND PC2 IN THE CENTRAL (CNS) AND PERIPHERAL (PNS) NERVOUS SYSTEMS IN ADULT AND FETAL MOUSE. M. Marcinkiewicz\*, N.G. Seidah and M. Chrétien. Clinical Research Institute of Montreal, Montreal, Quebec, Canada, H2W 1R7.

Neural and endocrine tissues express the prohormone convertases PC1 and PC2 (PCs) which cleave precursor proteins into active products. Here, and PC2 (PCs) which cleave precursor proteins into active products. Here, we studied the comparative tissue-specific expression of these convertases in the CNS and PNS of embryonic and adult mice, and during development. In the adult CNS both PCs are widely distributed from the olfactory bulb to the spinal cord including the cortex, hippocampal formation, amygdala and hypothalamus where a distinct distribution pattern and different (low to high) levels of hybridization are revealed. PC2 is very enriched in the caudate nucleus and thalamus. The localization of PC1 and PC2 overlaped with the sites of neuropeptides production including: AVP, OX, POMC peptides, enkephalins and LH-RH (hypothalamus) or SP (epithalamus). Turthermore, we noted that the nuclei which produce the biogenic amines (substantia nigra, raphe nuclei and locus coeruleus) also express PC1 and PC2. During ontogeny, PC1 and PC2 are first detected at embryonic day 11 (E11) in a small group of and locus coeruleus) also express PC1 and PC2. During ontogeny, PC1 and PC2 are first detected at embryonic day 11 (E11) in a small group of pontine neurons within the CNS. Later, the hybridization gradually increased and extended to many areas. Around the time of birth (E21), a high level of PC2 hybridization was detected in the caudate nucleus. In general, the CNS levels of PC1 and PC2 gradually increased until adulthood. In contrast, in the PNS, including the trigeminal and spinal ganglia, the levels of PC1 and PC2 mRNAs were much more elevated during embryonic development (E11-E21 with a peak between E14-E18) as compared to that in adult mice. These data demonstrate unique spatial and temporal expression patterns of PC1 and PC2 within the CNS and PNS.

### 121.17

LHRH-IMMUNOREACTIVE TERMINAL NERVE PROJECTIONS IN THE NASAL CAVITY OF THE TIGER SALAMANDER. C.R. Wirsig-Wiechmann Department of Neurobiology & Anatomy and Program in Neuroscience, Bowman Gray School of Medicine, Winston-Salem, NC 27157-1010.

There is a paucity of information on the peripheral projections of the terminal nerve (TN) in most vertebrate species due to the weak immunoreactive labelling of this nerve in the nasal cavity. We have performed two experimental manipulations in the tiger salamander in an attempt to increase the luteinizing hormone-releasing hormone-immunoreactive (LHRH-ir) labelling of TN peripheral processes: 1) the TN was sectioned just caudal to the offactory bulbs or 2) a 100 mg melatonin pellet was embedded subcutaneously for 3 days. The latter procedure decreases LHRH release thereby causing a buildup of LHRH in fibers. Following these procedures animals were sacrificed and tissue was processed for light microscopic analysis of the distribution of LHRH-

LHRH-ir fibers were observed projecting 1) into the rostral offactory epithelium, 2) to glands in the lamina propria of the rostral offactory epithelium and to a collection of glands situated between the main nasal cavity and Jacobson's organ, 3) into the smooth muscle which controls nares movements, and 4) along trigeminal branches to reach the pterygopalatine ganglion (PPG). Some LHRH-ir fibers extended through the PPG and projected caudally along trigeminal branches to the trigeminal ganglion.

The lesion and hormone manipulations have allowed the detection of TN projections not seen previously with immunocytochemical procedures alone. The wide distribution of LHRH-ir TN processes in the nasal cavity and cranium suggests that this nerve may influence many different cranial structures during appropriate pheromonal or neuroendocrine events.

(Supported by NIH grant NS27586)

## 121.19

ANTHO-RF AMIDE-LIKE IMMUNOREACTIVITY IS PRESENT AT A TWO-WAY SYNAPSE IN THE SEA ANEMONE. <u>J.A. Westfall, C-Z Yu, ' K. Sayyar, ' and</u> C.J.P. Grimmelikhuijzen<sup>2</sup> Department of Anatomy and Physiology, Kansas State University, Manhattan, KS 66506, <sup>2</sup> Center for Molecular Neurobiology, University of Hamburg, 2000 Hamburg 20, Germany.

Ultrastructural evidence of synapses with clear, opaque, or dense-cored vesicles aligned at one or both sides of a pair of paramembranous densities has been demonstrated in several species of sea anemones. The localization of a specific neuropeptide in vesicles at one of these synapses has not been reported previously. To date, 13 novel neuropeptides, including Antho-RFamide (<Giu-Giy-Arg-Phe-NH<sub>2</sub>), have been isolated from sea anemones. Our goal was to localize Antho-RFamide-like immunoreactivity at synaptic loci in tentacles of the sea anemone Anthopleura elegantissima. Tentacles were extirpated, fixed in 4% paraformaldehyde and 0.1% glutaraldehyde in 0.1M phosphate buffer, pH 7.6, with 0.3N NaCl, for 2 hours at 4°C and osmicated for embedding in Epon/Araldite or nonosmicated and embedded in Lowicryl K4M. Immunogold staining of thin sections was done using rabbit anti-Antho-RFamide (#177IV or #177IVA at a dilution of 1:500) for 1-2 hours followed by 15-nm-gold-conjugated, goat antirabbit IgG diluted to 1:10 (Lowicryl) and 1:40 (Epon-Araldite). Opaque vesicles, ranging from 50-150 nm in diameter, were gold-labeled in nerve cells and on both sides of a two-way synapse. Vesicles associated with the paramembranous densities were smaller (~50 nm) than those not associated with synaptic loci. Clear vesicles and dense-cored vesicles with prominent halos were not labeled. Our findings suggest that a population of neurons containing 50-150 nm opaque vesicles is immunoreactive to Antho-RFamide antiserum and that these neurons are synaptically connected in the sea anemone Anthopleura elegantissima. (Supported by NSF grant no. IBN-9120161)

DISTRIBUTION OF THE SUBTILISIN-LIKE PROCESSING ENZYME PC1 AND MET-ENKEPHALIN IN ArT-20 CELLS AND HYPOTHALAMUS. P.J. Hornby\*, S.D. Rosenthal, O. Vindrola, J. P. Mathis, and I. Lindberg. Depts. of Pharmacology and Biochemistry, Louisiana State University Medical Center, New Orleans, LA 70112

The subtilisin-like prohormone convertase PC1, found in certain neuroendocrine organs and in brain, can accurately cleave the opioid peptide precursor proopiomelanocortin into bioactive peptide products. We have applied single and dual-staining immunocytochemical techniques to determine both the cellular localization of PC1 as well as its anatomical relationship to met-enkephalin in AtT-20 cells stably transfected with proenkephalin cDNA. Rat hypothalamic tissue was also studied. Antiserum to PC1 was generated in rabbit to a fragment of the mature protein corresponding to the presumed amino terminus. Using this antiserum, avidin-biotin immunocytochemistry revealed a dense immunoreaction product within AtT-20 cells immediately adjacent to the nucleus; staining was also apparent in the cell tips. This staining could be abolished by preadsorption with the immunizing peptide but not by a C-terminal fragment of the same protein. PC1-immunostained AtT-20 cells were then incubated in metenkephalin antiserum and the glucose-antiglucose oxidase reaction product was used to stain met-enkephalin-containing areas blue. Met-enkephalin staining was present throughout the cell body and was especially prominent in the tips of the cells. The dense accumulation of PC1 immunoreaction products adjacent to the nucleus suggests that the Golgi apparatus may be a major site of PC1 in these cells. In vibratome-sectioned normal rat hypothalamus, diffuse light punctate staining of PC1 was noted in the supraoptic nucleus and the medial hypothalamus. Supported by an LSU Neuroscience Center incentive grant and PHS grants DK42714 (PH) and DA05084 (IL).

### 121.18

AFFERENT AND EFFERENT INNERVATION OF LEECH NEPHRIDIA OCCURS BY A SINGLE IDENTIFIED NEURON EXPRESSING FMRF-NH2

LIKE IMMUNOREACTIVITY. A. Wenning\*1. U. Kattenhäuser1, U. Greisinger1 and U. Hoeger<sup>2</sup>. <sup>1</sup>Fak. f. Biologie, Universität Konstanz, W-7750 Konstanz, FRG; <sup>2</sup>Inst. f. Zoologie, Universität Mainz, W-6500 Mainz, FRG.

Each of the 34 nephridia in the leech, Hirudo medicinalis, is individually innervated by a single peripheral neuron, the nephridial nerve cell (NNC). Resting potential and activity of the NNC depend on the extracellular Cl concentration (Wenning & Calabrese, J Comp Physiol , 168:53,1991). The NNC expresses FMRF-NH2-like immunoreactivity (FLI), as shown here by injecting the NNC intracellularly with Lucifer yellow and subsequent processing for FLI using a polyclonal antibody. The numerous arborizations of the NNC in the nephridium are dotted with varicosities and, as seen in ultrathin sections processed for FLI, they directly innervate the urine-forming cells. Further, the NNC sends an axon branch to the sphincter of the urinary bladder.

The amount of FMRF-NH2-like peptide present in one nephridium was determined using a competitive ELISA with an FMRF-NH2- thyroglobulin conjugate in the solid phase, nephridial extracts, and the same polyclonal antibody as for immunocytochemistry. We found 1.3±0.75 pM peptide (±s.d., N=24) per nephridium. Application of FMRF-NH<sub>2</sub> at 1.7x10<sup>-10</sup> M tripled urine flow in unstimulated, isolated nephridia (N = 9), suggesting that the NNC functions as a receptor and as a modulator. This is the first reported evidence that FMRF-NH<sub>2</sub>-like peptides may modulate the activity of transporting epithelia.

The antibody was generously donated by R. Elde (U Minnesota). Supported by the Deutsche Forschungsgemeinschaft (We 745/4-1).

CHARACTERIZATION. LOCALIZATION AND EFFECT OF PACAP (PITUITARY ADENYLATE-CYCLASE ACTIVATING POLYPEPTIDE) IN FROG BRAIN AND FITUITARY. L. YON, N. Chartrel, J.M. Conlor, M. Lamacz, F. Gracia-Navarro, L. Jeanel, A. Kournier, M. Feuilloley, A. Arimura, M.C. Tonon and H. Vaudry, (1) Eur. Inst. Pept. Res., Lab. Mol. Endocr., CNRS URA 660, Univ. Rouen, France; (2) Regul. Peptide Center, Creighton Univ. Rouen, France; (2) Regul. Peptide Center, Creighton Univ. Roman, USA; (3) Dept. Cel. Biol. Univ. Cordoba, Spain; (4) INRS Santé, Québec Univ., Québec, Canada; (5) Blomed. Res. Lab., Tulane Univ., Belle Chasse, USA.

PACAP is a 38-amino-acid neuropeptide that was isolated from the ovine hypothalamus on the basis of its abblity to stimulate adenylate-cyclase activity in anterior pituitary cells. The NH2-terminal region of PACAP is structurally similar to VIP and thus identifies the peptide as a member of the secretin-glucagon family. In this study, we have purified PACAP from an extract of 1200 frog brains (Rana Tiddbunda) by gel chromatography and reverse phase HPLC and determined the primary structure of the peptide by automated Edman degradation. The sequence of frog PACAP shows only one amino acid substitution (11e instead of Val at position 35; compared with the mammalian sequence. The distribution of PACAP-containing neurons was studied by immunofluorescence using an antiserum raised against PACAP(1-27). The main populations of immunoreactive perikarya were found in the medial and ventral diencephalon i.e. the ventral and ventral tiencephalon i.e. the ventral and ventral tiencephalon i.e. the ventral and ventral tiencephalon is. The distribution of PACAP-containing neurons was studied by immunofluorescence using an antiserum raised against PACAP(1-27). The main populations of immunoreactive perikarya were found in the medial and ventral diencephalon i.e. the ventral infundibulum to the external vascular layer of the median eminence. Frog PACAP(1-38) and PACAP(1-27) produced dose-dependent increases in cAMP concentrat

A CANDIDATE SUBTILISIN-LIKE PROHORMONE PROCESSING ENZYME EXPRESSED BOTH IN THE NEUROENDOCRINE BAG CELLS AND IN THE EXOCRINE ATRIAL GLAND QF APLYSIA CALIFORNICA. W.R.A. van Heumen, S.L. Knock G.T. Nagle, and A. Kurosky. Department of Human Biological Chemistry and Genetics and Marine Biomedical Institute, Univ. of Texas Med. Branch, Galveston, TX 77555.

The neuroendocrine bag cells and the exocrine atrial gland of Aplysia californica synthesize multipeptidergic ELH-related precursors that upon enzymatic processing give rise to a number of well characterized (neuro)peptides. Using the polymerase chain reaction we have shown that the bag cells express a candidate prohormone processing enzyme that belongs to the subtilisin-related class of enzymes (see accompanying abstract, Nagle et al.). We have conducted in situ hybridization studies utilizing complementary oligonucleotide probes to establish the occurrence of the enzyme in the bag cells and atrial gland. Preliminary results indicate that in addition to synthesizing related peptide precursors, both the atrial gland and the bag cells use a similar enzyme for their processing. The occurrence of the subtilisin-like mRNA in the atrial gland is particularly interesting since it produces large amounts of ELH-related peptides and may be a relatively rich natural source for the subtilisin-related enzyme. Supported by NIH NS 29261 and the Robert A. Welch Foundation (H-1190).

### 122.3

PROCESSING OF PRO-OPIOMELANOCORTIN (POMC) BY A YEAST ASPARTIC PROTEASE, YAP3: SIMILARITY TO THE MAMMALIAN POMC-CONVERTING ENZYME. A. Azaryan, M. Wong, F. Estivariz, Y.P. Loh\*. Section on Cell. Neurobiology, LDN, NICHD, NIH, Bethesda, MD 20892.

The yeast aspartic prolease gene, YAP3, is expressed in a mutant that lacks the KEX2 gene which encodes the processing enzyme for proα-mating factor (Egel-Mitani et al., 1990). In order to compare the
YAP3 gene product with the aspartic prolease, POMC converting enzyme
(Loh et al., 1985) found in pituitary, that can cleave POMC at paired
basic residues, we have overexpressed the YAP3 gene in yeast and
characterized its activity. The YAP3 gene (a gift from Nova Nordisk,
Denmark) was cloned into pEMBLyex plasmid and the YAP3 gene
product was then overproduced in S. cerevisae strain BJ 3501. To
purify YAP3 protease, a 10,000g supernatant of yeast cell lysate was
applied on con A-agarose column followed by a pepstatin A-agarose
chromatography. Protease activity was assayed with 1251-Blipotropin (B-LPH) as substrate. The enzyme was characterized as
Mr-70,000 glycoprotein with a pH optimum of 4.0-4.5. It was
activated by DTT and Ca++ and potently inhibited by pepstatin A. The
YAP3 enzyme cleaved POMC at Lys-Arg pairs to yield Mr-21-23,000
ACTH and B-LPH. It also generates B-endorphin from B-LPH and Lysγ-MSH and γ-MSH from bovine N-POMC1-77 as identified by SDSPAGE, RIA or HPLC. The YAP3 protease appears to share a number of
properties (substrate specificity, inhibitor sensitivity, pH optimum)
with the POMC-converting enzyme found in bovine pituitary secretory
granules. YAP3 may be a homologue of this mammalian prohormone
processing enzyme.

## 122.5

THE DEVELOPMENTAL EXPRESSION OF FURIN, PC1, AND PC2 IN THE RAT. M. Zheng, R.E.M. Scott, T. Wood\*, N.G. Seidah, and J.E. Pintar. Dept. Anat. and Cell Biol., Columbia P&S, NY, NY 10032 and Lab. Biochem. Neuro-endocrinol., Clin. Res. Inst. Montreal, Montreal, Quebec H2W 1R7, Canada.

The genes for mammalian subtilisin-like endoproteases furin, PC1, and PC2

The genes for mammalian subtilisin-like endoproteases furin, PC1, and PC2 have recently been isolated and are implicated in endoproteolytic cleavage of precursor molecules, which is a key step in postranslational maturation of polyproteins. We have begun to examine the expression of these genes during rat development by in situ hybridization and to compare their expression patterns to those of potential substrates. Furin mRNA thus far has been detected earlier than PC1 and PC2 mRNA and is present in the heart primordium as early as e9.5. At this age, proenkephalin mRNA is also present in the heart, but in a much lower proportion of cells. By midgestational ages (e12-e14), the expression domain of furin has expanded to encompass most tissues outside of the nervous system, with the highest level of expression detected in the liver. Furin, therefore, may contribute to endoproteolytic processing of precursor proteins in peripheral tissues during development. Unequivocal expression of both PC1 and PC2 thus far has been detected as early as e12.5. At this age, expression of PC2 is predominant in the peripheral cranial ganglia, DRG, and mesencephalon, while PC1 expression is detected in the ventral hypothalamus. By e13.5, PC1 is also detected in a cell population adjacent to the DRG. In the CNS, more widespread expression of both PC1 and PC2 occurs by e14. In general, the expression patterns thus far identified for PC1 and PC2 characterize regions throughout the nervous system containing differentiated neurons rather than neuronal precursors. PC1 expression is particularly evident in the ventral myelencephalon, hypothalamus, and ventral spinal cord. PC2 appears to be expressed at a relatively higher level than PC1; this difference is especially apparent in the mesencephalon, one and hypothalamus. The different levels and partially overlapping expression patterns of PC1 and PC2 suggest that these endoproteases may dictate differential neuropeptide precursor processing in the developing nervous system. #### 122.2

A PUTATIVE SUBTILISIN-LIKE DIBASIC PROHORMONE PROCESSING ENZYME IN APLYSIA NEUROENDOCRINE BAG CELLS. G.T. Nagle, W.R. van Heumen, S.L. Knock, A.T. Garcia and A. Kurosky. Warine Biomedical Institute and Department of Human Biological Chemistry and Genetics, Univ. of Texas Med. Branch, Galveston, TX 77555.

Strong evidence is accumulating that the endoproteases which process prohormones at dibasic residue cleavage sites are members of a subtilisin-related class of proteases. Using the polymerase chain reaction (PCR), we have isolated and characterized a cDNA product from Aphysia californica neuroendocrine bag cells that encodes a sequence which is highly homologous to the subtilisin-related class of processing proteases. The characterized cDNA PCR product showed the highest degree of residue identity with the furin-related group of proteins (human/mouse furin 71%; Drosophila furin 63%). These results establish that Aphysia contain a subtilisin-like gene and suggest that the expression of this gene may play a role in processing Aphysia precursor proteins in the bag cells and likely also in the endocrine atrial gland. Furthermore, these results, together with sequence results of other furin-like enzymes provide evidence that the furin-like enzymes may represent a separate subclass of the subtilisin-like processing enzymes. Supported by NIH NS 29261 and the Robert A. Welch Foundation (H-1190).

#### 122.4

ROLE OF THE MAMMALIAN ENDOPROTEASES PC1 AND PC2 IN PROSOMATOSTATIN (PSS) PROCESSING. A.S. Galanopoulou, G. Kent, H.H. Zingg\*, and Y.C. Patel. Fraser Laboratories, McGill University, Royal Victoria Hospital, Montreal, Quebec, Canada, H3A 1A1.

Royal Victoria Hospital, Montreal, Quebec, Canada, H3A 1A1. Mammalian PSS is processed at a dibasic Arg.-Lys and a monobasic Arg site to produce SS-14 and SS-28 respectively. We have previously shown that PSS is capable of monobasic conversion to SS-28 in the constitutive secretory pathway of COS-7 cells by a furin-like enzyme (the only known endoprotease found in these cells) but that this conversion is relatively inefficient based on the amount of unprocessed PSS. We have also shown that efficient processing of PSS occurs in neuroendocrine cells and correlates with PC1 and PC2 expression. In this study we have determined directly the ability of PC1 and PC2 to influence PSS processing in COS-7 cells cotransfected with PKS5 (PSS expression vector) and either pmPC1 or pmPC2 (PC1 and PC2 expression vectors). Cell lysates and media were analysed for SS-14, SS-28 and unprocessed PSS by HPLC and RIA. PC1 and PC2 expression was confirmed by Northern analyses with cRNA probes.

SS-28 (%) SS-14 (%) Unprocessed PSS (%) cells media cells media <u>media</u> PK S5 35 62 PKS5+pmPC1 14 31 22 11 64 PKS5+pmPC2

CONCLUSIONS: (i) PC1 is capable of dibasic cleavage of PSS to SS-14; such processing, however, is relatively inefficient. (ii) PC1 is without effect on monobasic SS-28 conversion. (iii) PC2 does not influence PSS processing. (iv) The relative inefficiency of PC1, and lack of activity of PC2 on PSS processing in the constitutive pathway of COS-7 cells suggest that compartmentalization of proteolytic events in secretory vesicles or other, more specific endoproteases may be required.

## 122.6

RECOMBINANT PROHORMONE CONVERTASE 1: CHARACTERIZATION AND PURIFICATION. Y1 Zhou\* and Iris Lindberg. Dept. of Biochemistry and Molecular Biology, LSU Medical Center, New Orleans, LA 70112. Proteolytic cleavage of propeptides at dibasic residues is a very important

processing event in neuropeptide biosynthesis. The mammalian subtilisin-like proteases may contribute to this processing. Prohormone convertase 1 (PC1; also known as PC3), one member of this family, has been identified by reverse transcription-PCR. While co-transfection experiments have provided evidence that PC1 is involved in propeptide processing, no work has been done thus far at the protein level. In order to characterize the biochemical properties and enzymatic activity of PC1, we established a stable recombinant Chinese hamster ovary cell line (CHO) which constitutively synthesizes and secretes PC1 protein, amplified by means of the dihydrofolate reductase-coupled method. Immunoblotting and pulse-chase labeling were performed to study PCI protein biosynthesis in this recombinant cell line. The results demonstrated that PC1 protein was mainly synthesized and secreted in an 87 kDa form; 74 and 66 kDa forms were also found in both the cell extracts and cell medium. Neither the 74 nor the 66 kDa PC1 proteins were recognized by PC1 carboxyl-terminal antibody, suggesting that proteolytic cleavage at the carboxyl terminus occurred before secretion. The 87 kDa PC1 protein has been purified from conditioned medium to near homogeneity using ion exhange and hydrophobic interaction chromatography. Amino-terminal using for exhalper and hydrophotoc interaction cultural organity. Animo-terminal sequence analysis showed that the 87 kDa PCI protein was generated by cleavage after the RSKR sequence at the amino terminus of the PCI precursor. Weak calcium-dependent proteolytic activity was detected in conditioned medium with the fluorogenic substrate RSKR-AMC. This proteolytic activity, which was very labile, co-purified with PC1 immunoactivity upon hydrophobic interaction chromatography and could not be detected in the medium of control cells.

CHARACTERIZATION OF THE PROHORMONE CONVERTASE PC2 OVEREXPRESSED IN CHINESE HAMSTER OVARY CELLS. Fu-Sheng Shen and Iris Lindberg\*. Dept. Biochem. and Mol. Biol. Louisiana State Univ. Med. Cen., New Orleans, LA 70112.

PC2 is a member of a family of recently discovered subtilisin-like prohormone converting enzymes, two of which (PC1 and PC2) are primarily distributed in neuroendocrine tissues where they are thought to play a role in the proteolytic conversion of neuropeptide precursors to active neuropeptides. Little information is available on the biochemical properties of these important cellular enzymes. In the present study, mouse PC2 was overexpressed in Chinese Hamster Ovary (CHO) cells using the dihydrofolate reductase-coupled genetic amplification method, purified from the conditioned medium, and characterized biochemically. Purification of recombinant protein from the medium was carried out using hydrophobic interaction and ion-exchange chromatography. The purified material shows one major Coomassie blue-stained band on SDS-PAGE gel with a molecular weight of 75 kDa. The results of cell labeling experiments showed that two proteins labeled with methionine could be immunoprecipitated from cell and medium samples using a carboxy-terminal specific antibody with molecular weights of about 75 and 72 kDa. Based on the work of others using oocytes, the 75 kDa protein may represent proenzyme and the 72 band might represent a processing intermediate. After a 5 h treatment of the cells with 5 ug/ml tunicamycin, the profile of labeled immunoprecipitated proteins was altered; the 75 and 72 kDa bands shifted down to 69 and 68 kDa, respectively. This result implies that CHO PC2 protein is glycosylated, and concanavalin A binding experiments support this idea. Further experiments are underway to identify each molecular weight form of the enzyme and to obtain an enzymatically active species.

#### 122.9

DIBASIC RESIDUE SPECIFIC ENDOPEPTIDASE IN ADRENAL MEDULLARY CHROMAFFIN GRANULES IS IMMUNOLOGICALLY RELATED TO PC1/PC2 ENZYMES. A.V. Azaryan\* and V.Y.H. Hook. Dept. of Biochemistry,

Uniformed Services University, Bethesda, MD. 20814.

Recently a new family of Kex2-like proteinases has emerged that is proposed to participate in the processing of hormone and neuropeptide precursors at paired basic sites; these include furin and prohormone convertases 1 and 2 (PCs) (Smeekens and Steiner, 1990; Seidah et al., 1990, 1991). We found that bovine adrenal medullary chromaffin granule membranes possess boc-Gln-Arg-Arg-MCA hydrolyzing proteolytic activity that is related to Kex2/furin/PC subtilisin-like superfamily of processing proteinases (Azaryan and Hook, BBRC, in press). This activity shows calcium sensitivity, pH optimum of 7.5-8.2 and belongs to the class of serine proteases based on inhibitor profile. Preference was demonstrated for cleavage at the on inhibitor profile. Preference was demonstrated for cleavage at the carboxyl side of Arg-Arg and Lys-Arg, over Lys-Lys pairs. Specificity for Lys-Arg site was also indicated by potent inhibition by the active site-directed inhibitor [D-Tyr]-Glu-Phe-Lys-Arg-chloromethyl ketone. In addition, membrane solubilized boc-Gln-Arg-Arg-MCA cleaving activity was significantly immunoprecipitated by PC1 and PC2 antisera+. Our biochemical and immunological data indicate that this chromaffin grapula disease residue specific endoprotectivity. this chromaffin granule dibasic residue specific endoproteolytic activity is related to PC1/PC2 enzymes. +(We thank Dr. Y. Peng Loh (NICHD, NIH for the generous gift of PC1 and PC2 antisera)

## 122.11

DYNORPHIN PROCESSING ENZYMES IN BRL3A CELLS, A LIVER-DERIVED CELL LINE; IMPLICATIONS FOR NEUROPEPTIDE BIOSYNTHESIS. Lakshmi Devi, Julie Zikherman, Suzanne Petanceska, and Lloyd D. Fricker\*. Dept. of Pharm., New York Univ. Medical Center, NY, NY 10016, and "Dept. of Molec. Pharm., Albert Einstein College of Medicine, Bronx, NY 10461 A key question regarding neuropeptide biosynthesis concerns the specificity of the peptide processing enzymes. Dynorphin is produced from prodynorphin by a series of endoproteolytic cleavages at dibasic and monobasic sites, followed by a carboxypeptidase which removes the C-terminal basic residues. BRL3A cells secrete insulin-like growth factor II (IGF-II), which also requires dibasic and monobasic endopeptidase, and carboxypeptidase activities.

To examine whether the IGF-II and dynorphin processing enzymes are similar, we transfected BRL3A cells with rat prodynorphin; transfected cells express low levels of immunoreactive dynorphin B, indicating that the appropriate monobasic endoprotease and carboxypeptidase activities are present in these cells. Medium from BRL3A cells was directly examined for enzyme activities. A monobasic 'dynorphin converting enzyme' (DCE) and carboxypeptidase E (CPE) were detected; these activities showed similar inhibitor sensitivities and pH optima as DCE and CPE previously characterized from brain and pituitary.

these activities showed similar inhibitor sensitivities and pH optima as DCE and CPE previously characterized from brain and pituitary.

The properties of these enzymes were further studied by partial purification. The DCE activity eluted from ion exchange FPLC under identical conditions as the rat brain DCE. The CPE activity bound to a substrate affinity column under selective condition, and the molecular weight of the purified CPE was similar to that of CPE purified from brain and pituitary (approximately 50 kDa). Also, CPE mRNA was detected on Northern blots of BRL3A RNA. Both DCE and CPE are secreted from detected on Northern blots of BRL3A RNA. Both DCE and CPE are secreted from the BRL3A cells via a regulated secretory pathway. Secretion of both enzyme activities is stimulated several-fold by secretagogues such as 8-bromo cAMP, KCl, and phorbol esters. These results suggest that DCE and CPE are general peptide processing enzymes that function in the biosynthesis of peptide growth factors, as well as peptide hormones and neurotransmitters. This is consistent with the similarities between the cleavage sites of most secreted bioactive peptides.

BIOSYNTHESIS OF THE PROHORMONE CONVERTASE mPC1 IN AtT-20 CELLS. Osvaldo Vindrola\* and Iris Lindberg. Depart. Biochem. and Mol. Biol., Louisiana St. Univ. Med. Cen., New Orleans, LA 70112.

A new family of mammalian subtilisin-like enzymes, probably involved in the processing of pro-proteins in regulated and constitutive cells at paired basic residues, has recently been discovered. Little information exists as yet concerning the biosynthesis of these endogenous subtilisin-like enzymes. In the present work we have studied the biosynthesis and release of the endogenous prohormone convertase PC1 in AtT-20 cells. As predicted from mRNA studies, AtT-20 cells contain high levels of PC1 protein. Through immunoblotting, 87 kDa and 66 kDa bands were detected with an amino terminally-directed antiserum; however, only the 87 kDa product was detected with carboxyl terminally-directed antiserum, carboxyl-terminal truncation. Pulse-chase experiments, using [35S]methionine/ cysteine, showed that after 20 min of pulse the main product in the cells was the 87 kDa protein. Cells chased for varying amounts of time exhibited a progressive increase in the intensity of a 66 kDa band, along with a corresponding decrease of the 87 kDa band. The 87 to 66 kDa conversion was nearly complete after 4 h of chase. This post-translational processing was inhibited by the ionophore monensin, a Golgi disruptor, with a corresponding accumulation of the 87 kDa protein within the cell. Both the 87 kDa and 66 kDa labeled proteins were detected as membrane-bound rather than soluble proteins. The 87 kDa protein was the main product secreted by non-stimulated AtT-20 cells, while the 66 kDa product was only released when the cells were stimulated with corticotropin releasing factor or BaCl<sub>2</sub> and Br-cAMP. In conclusion, our results show that PC1 in AtT-20 cells is initially synthesized as an 87 kDa membrane-bound protein which is then converted intracellularly to a 66 kDa species which can be released by the regulated pathway.

IDENTIFICATION OF MAJOR PAM PROTEINS IN HYPOTHALAMIC AND httpPOCAMPAL SYNAPTOSOMES. A.M. OYARCE AND B.A. EIPPER\*. Dept. of Neuroscience, The Johns Hopkins University School of Medicine, Baltimore, Maryland 21205.

Bailmore, Maryland 21205. Peptidylglycine  $\alpha$ -amidating monooxygenase (PAM) (EC1.14.17.3), a bifunctional enzyme, catalyzes the COOH-terminal amidation of many neuropeptides. The reaction requires the sequential action of peptidylglycine  $\alpha$ -amidating monooxygenase (PHM) and peptidyl- $\alpha$ -hydroxyglycine  $\alpha$ -amidating lyase (PAL). Alternative splicing of the single copy gene for rat PAM generates the two major forms of PAM mRNA (rPAM-1 and -2) found in the central nervous system. Both proteins are integral membrane proteins (TMD=putative transmembrane domain) with an NH<sub>2</sub>-terminal signal sequence

smembrane domain) with an NH<sub>2</sub>-terminal signal sequence

presence of a non-catalytic domain,
exon A, between the PHM and PAL
domains only in rPAM-1. Subcellular
fractionation of adult rat hypothalamus
and hippocampus demonstrated the
localization of PHM and PAL activity

soluble and particulate fractions, 70% of the PHM and PAL activity to synaptosomel fractions. Following separation of synaptosomes into secovered in the particulate fraction. The major PAM proteins identified by Western blot analysis using antisera specific to PHM, PAL, Exon A and the COOH-terminal domain (CD) are illustrated. Major products include soluble monofunctional PHM and PAL proteins along with intact PAM-1 and PAM-2 and a monofunctional integral membrane PAL protein. A significant proportion of the PHM and PAL proteins lacking the transmembrane domain remain membrane associated following removal of peripheral proteins by treatment with carbonate. Following exocytosis, the membrane associated PAM proteins may go to the cell surface where they may remain or from which they may be internalized. Supported by DA-00266 and DA-00098.

DIFFERENTIAL ENDOPROTEOLYTIC CLEAVAGE OF MONKEY DIFFERENTIAL ENDOPROTEOLYTIC CLEAVAGE OF MONKEY PROOPIOMELANOCORTIN (mPOMC) AT TWO LYS-LYS PROCESSING SITES: POSSIBLE ROLE OF SURROUNDING SEQUENCES. H. Lin, N. Day, N. Seidah, and H. Akil.\* Mental Health Research Institute, University of Michigan, Ann Arbor MI 48109.

POMC processing at dibasic cleavage sites within a given tissue is a function of several factors, including the complement of expressed endoproteases, the specific sequence of the dibasis signal (e.g. Lys-Arg vs. Lys Lys as well as other factors with the deductions of the green search. Lys Arg vs.

Lys-Lys), as well as other factors yet to be determined. For example, Lys-Arg cleavage within POMC is mediated via the action of at least two different enzymes, termed PC1 and PC2, which exhibit selectivity toward the various Lys-Arg signals. This suggests that sequences surrounding the dibasic cleavage site may direct enzymatic specificity. We have recently demonstrated a similar phenomenon for Lys-Lys cleavage within POMC. We compared Lys-Lys processing at one site at the amino-terminus of β-MSH and at another site in the carboxy-terminus of β-Endorphin (βΕ). mPOMC cDNA was transfected into two endocrine cell lines: AtT-20 and Rin m5F. Our results have demonstrated both tissue-specific and site specific factors controlling Lys-Lys cleavage. AtT-20 cells do not to process at either site. On the other hand, Rin m5F cells fail to process at the site in the carboxy-terminus of  $\beta E$ , but do process, to a significant extent the site N-terminal to  $\beta$ -MSH. To determine whether this differential processing was due to a conformational hindrance of the  $\beta E$  sites, we mutated both sites to Lys-Arg. Rin m5F cells fully processed at both locations, suggesting that the sites were both accessible to endoproteases. These results suggest that the differential processing of the two Lys-Lys sites may be due to sequences beyond the dibasic residues, which may determine likelihood of cleavage. Mutants altering the residues surrounding the Lys-Lys sites have been constructed and the effect of these mutations on processing will be described.

IDENTIFICATION OF TWO MEMBRANE-ASSOCIATED NEUROPEPTIDE-DEGRADING ENZYMES FROM OVINE MEDIAN EMINENCE ENDOTHELIAL CELLS. R.A. Lew, K.E. Sheppard\* and A.l. Smith. Baker Medical Research Institute, Prahran, Victoria, Australia 3181.

The capillary endothelial cells (EC) of the median eminence (ME) represent a potential site of regulation for both circulating and hypothalamic neuropeptides passing through the hypophysial portal blood system toward the pituitary. The present study examines in vitro the metabolism of gonadotropin releasing hormone (GnRH) and other peptides by cultured EC from sheep ME. Non-vascular tissue was dissected away prior to enzymatic dispersion of the capillary bed of ovine ME, and the cells obtained were cultured using standard techniques. After 2-13 passages, confluent EC (positively identified by staining for von Willebrand factor) were removed from culture plates frozen and thawed three times to lyse the cells, and centrifuged at 100,000g. The pellet was washed, re-centrifuged, resuspended in buffer, aliquoted and frozen at -70°C Aliquots (0.2 mg protein) were incubated with synthetic GnRH (10-50 µg) in the presence or absence of a variety of protease inhibitors. The GnRH fragments generated were separated by HPLC and identified by amino acid analysis as GnRH1-5 and GnRH1-3. The degradation profile produced by EC differed from that produced by bovine aortic EC and AtT-20 cell membranes. Generation of GnRH1-3 was diminished in the presence of thiol protease inhibitors such as leupeptin and iodoacetamide, while formation of GnRH1-5 was inhibited by PMSF, a serine protease inhibitor. EDTA, phosphoramidon and angiotensin converting enzyme (ACE) inhibitors were ineffective, indicating that neither endopeptidase 24.11 nor ACE is involved. These novel membrane-bound peptidases may also be involved in the regulated degradation of other peptides such as angiotensin, bradykinin and neuropeptide Y by these cell membrane Thus the capillary endothelium of the ME expresses peptidases capable of cleaving hypothalamic and cardiovascular peptides en route to the pituitary; their role in the fine regulation of both pituitary function and local blood flow is currently under

## 122.15

CARBOXYPEPTIDASE M IN BRAIN AND PERIPHERAL NERVES A. Nagae, P.A. Deddish, R.P. Becker, C.H. Anderson, M. Abe, F. Tan, H.L. Jackman\*, R.A. Skidgel, E.G. Erdös Lab. of Peptide Res., Depts. of Pharmacol., Anesthesiol., and Cell Biol., U. of Ill., Coll. of Med., Chicago, IL 60612.

Carboxypeptidase M (CPM), a plasma membrane-bound enzyme with a neutral pH optimum, cleaves C-terminal Arg or Lys of peptides such as kinins and Arg6- or Lys6- enkephalins. It is present in several organs and cultured cells, and was purified, cloned and sequenced from human placenta. We investigated CPM activity in human, baboon, and dog brain and dog peripheral nerves. Brain areas were dissected, homogenized, fractionated by centrifugation and assayed with Dansyl-Ala-Arg. The corpus callosum, pons and the pyramidal and optic tracts had high activity, while the basal ganglia, cerebellum, amygdala and cortex were low in CPM. This carboxypeptidase activity was due to CPM, as shown by membrane attachment, substrate hydrolysis, inhibition pattern and immunoprecipitation of activity with anti-human CPM antiserum (85% of human and baboon, 66% of dog brain CPM). CPM co-purified with myelin-rich fractions from the brain where it was membrane-bound via a phosphatidylinositol glycan anchor. The mRNA of CPM was detected in Northern analysis of the baboon brain. Dog sciatic and vagus nerves also had high activity and in immunohistochemical studies, the outer aspect of myelin sheaths and Schwann cells stained. In conclusion, CPM is present in the CNS and peripheral nerves, and in some areas it is closely associated with myelin and/or myelin forming cells. Supported by NIH, HL36473, 36082 and DK41431.

## 122.17

FOST-MORTEM STABILITY STUDY OF METHIONINE ENKEPHALIN, SUBSTANCE P,AND BETA-ENDORPHIN IN RAT PITUITARY. X.Zhu\* and D.M.Desiderio. Stout Neurosci. Mass Spec. Lab., Univ. of Tenn., Memphis, TN 38163.

The post-mortem stability of three neuropeptides, methionine enkephalin(ME), substance P(SP), and beta-endorphin(BE) was studied in the rat pituitary to test the hypothesis that significant changes occur postmortem in the concentration of those neuropeptides. Those neuropeptides represent the three gene products proenkephalin A(ME), tachykinins(SP), and proopiomelanocortin(BE). Post-mortem stability data of neuropeptides from the rat pituitary provide important reference data for our qualitative and quantitative studies of neuropeptides in human post-mortem pituitary tissues and of the genesis of human pituitary tumors. The Spokes-Koch model, which simulates human autopsy conditions, was used to monitor and to control the time-vs.-temperature cooling curve of the rat pituitary. Decapitated heads were incubated for various time before pituitaries were dissected and neuropeptides extracted. Radioimmunoassay (RIA) was used to measure HPLC fractions for the three peptides, and the confirmation of the molecular weights of those peptides is proveded by using mass spectrometry(NS) to detect the corresponding protonated molecule ions, MH+. The data demonstrate the importance of: 1) measuring HPLC-purified neuropeptide-like immunoreactivity rather than only the total peptide-immunoreactivity; and 2) accurately defining a time-course series of measurements especially in the critical portion of the cooling curve when rapid temperature changes occur, rather than measuring peptid immunoreactivity at only one, generally later, time. Statistically increases and decreases are demonstrated within five hours for peptidelike immunoreactivities from the proenkephalin A and the proopiomelanocortin neuropeptidergic systems.

PURIFICATION, CHARACTERIZATION, AND IMMUNOELECTRON MICROSCOPIC LOCALIZATION OF A CATHEPSIN D-LIKE PROTEASE FROM BOVINE CHROMAFFIN GRANULES. T.J. KRIEGER. Y.H. Kang, and Y.Y.H. Hook\*. Dept. of Biochem., Uniformed Services University, Bethesda, MD. 20814, and Naval Medical Research Institute, Bethesda, MD.

A chromaffin granule aspartyl protease (CGAP), preferring as substrate the model tachykinin precursor (35 S-(Met)-β-preprotachykinin) over the enkephalin precursor (35 S-(Met)-β-preproenkephalin), was purified by ConA-Sepharose, Sephacryl S200, and chromatofocusing. CGAP was composed of 47, 30, and 16.5 kDa polypeptides that migrated as a single band in a non-denaturing gel system, and coeluted with an apparent Mr of 45-55 kDa by gel filtration. These results suggest that two forms exist: a single 47 kDa polypeptide and a complex of 30+16.5 kDa associated subunits. Microsequencing and amino acid composition studies showed that the three CGAP polypeptides were similar, but not identical, to bovine cathepsin D. CGAP cleaved at a dibasic Lys-Arg site and at hydrophobic residues (Leu-Tyr, Phe-Val). Processing of proendothelin in chromaffin granules requiring cleavage at both hydrophobic and dibasic residues would be compatible with CGAP's cleavage specificity. Cleavage at hydrophobic residues, like cathepsin D, also suggests that CGAP may be involved in degrading precursor segments that do not become part of active peptide sequences. Immunoelectron microscopy with immunogold confirmed colocalization of CGAP with (Met)enkephalin within chromaffin granules. These results show that secretory vesicles of adrenal medulla possess a cathepsin D-like protease that may be involved in peptide precursor processing.

CHARACTERISTICS OF N-ACETYL-ASPARTATE AS AN ACETYL DONOR IN THE RAT BRAIN. <u>V. Mehta and M.A.A. Namboodiri\*</u>, Lab. Mol. Neurobiol, Dept. Biol., Georgetown Univ., Washington, DC 20057.

Recent findings have suggested that the incorporation of acetyl groups from N-acetyl-asparlate (NAA) into lipids may involve a mechanism independent of free acetate. In the present study, we have investigated this question by analyzing the products formed when a brain slice preparation (300-400 microns) incubated with (C-14)-NAA (250 uM) in an artificial cerebrospinal medium in presence of 95% CO2. Parallel incubations were performed using (C-14)-acetate (250 uM). The tissue was extracted with chloroform/methanol (2:1) and the chloroform phase was analyzed using TLC. The aqueous phase was analyzed using an anion exchange HPLC. Significant amounts of radiolabeled lipids were detected on TLC analysis in both cases, with (C-14)-acetate sample showing 2-3 fold higher incorporation. Analysis of the aqueous phase from the NAA samples showed that a significant amount of free acetate was formed during the incubation. In addition, an early eluting peak which is distinct from free acetate and NAA was observed. Radiolabel incorporation into this peak was two to three fold higher in the case of the NAA samples. These preliminary studies showing a differential radiolabel incorporation pattern between NAA and acetate suggest that NAA may be metabolized with and without the formation of free acetate.

SUBSTANCE P ELEVATES  $[Ca^{2+}]_i$  IN NEONATAL DORSAL HORN CELLS WITH NEURONAL AND GLIAL PROPERTIES. M.J.S. Heath and A.B. MacDermott\*. Departments of Physiology and Anesthesiology, and Center for Neurobiology and Behavior, Columbia University, New York, NY 10032. We previously defined two different populations of spinal cord dorsal horn cells that respond to substance P (SP) by elevation of intracellular  $Ca^{2+}$  ( $[Ca^{2+}]_i$ ). In one population (type E cells), SP promotes  $Ca^{2+}$  entry while in the other population (type R cells), SP evokes elevation of  $[Ca^{2+}]_i$  in the abeance of extracellular Ca indicating that Ca is released from internal absence of extracellular Ca, indicating that Ca is released from internal stores. Both populations were believed to be neurons (Womack et al. Neurosci Abs. 15:184, 1989).

In the present study, we have used additional criteria to further define these In the present study, we have used additional criteria to further define these two populations of cells. Cells were acutely dissociated from P0-P4 rat spinal cords and  $\{Ca^{2+}\}_1$  was monitored using the  $Ca^{2+}$  indicator, indo-1. Spsensitive cells were first classified as type E or R by removal of bath  $Ca^{2+}$  and addition of La<sup>3+</sup>. Type E cells were large and smooth, with few processes. Type R cells were smaller than type E cells and surrounded by multiple fine filamentous processes. Type R were morphologically indistinguishable from 04-immunoreactive oligodendrocytes, and often expressed GD3, a marker of immature neuroectodermal cells and oligodendrocyte precursors. The type R response exhibited longer latency and faster rise time than the type E response. Both type E and type R cells responded to glutamate, but only type E cells responded to NMDA. Thus, while type E cells exhibit the morphological and pharmacological characteristics of mature neurons, type R cells may represent a population of immature neuronal or glial precursors. Inhibitory Effects of an NK-1 (Substance P, SP) Receptor Antagonist, Inhibitory Effects of an NK-1 (Substance P, SP) Receptor Antagonist, (±) CP96345 (CP), on Visceral Nociceptive Activity and Non-nociceptive Bladder (BL) Activity in Rats. <u>Ivengar. S.\*</u>, <u>Muhlhauser. M.A.</u>, <u>Howbert. J.J. and Thor. K.B.</u> Lilly Research Laboratories, A Division of Eli Lilly and Co., Indianapolis, IN. SP is contained in BL primary afferent neurons, sacral spinal interneurons, and bulbospinal neurons. SP binding sites are preferentially distributed in spinal autonomic and somatic nuclei that

preferentially distributed in spinal autonomic and somatic nuclei that regulate BL function. The present study examined the effects of a potent and selective NK-1 antagonist, (±)CP96345 (CP), in a model of visceral nociception (see Thor, K.B., this meeting). BL activity (cystometry) and anal and urethral sphincter activity (EMG) were recorded in urethane-anesthetized rats. In 6 rats, the BL was infused with 0.5% acetic acid (a.a.), which consistently produced increases in BL and anal activity. Within 1-4 minutes, CP produced dose-dependent (0.1 - 30 mg/kg, i.v.) decreases in a.a.-induced anal activity (to 10% of control) and BL activity. (The inhibitory effects of CP (0.3 mg/kg) partially recovered after 45 min). In rats with saline-infused BL (n=3), CP also produced decreases in bladder activity and increases in bladder capacity (up to 4 fold) beginning at 1 mg/kg and abolished BL contractions at doses of 10 or 30 mg/kg. In contrast, functional activity of the urethral sphincter was maintained even at high doses of CP, as indicated by significant elevations in intravesical pressure before indicated by significant elevations in intravesical pressure before overflow incontinence ensued. Thus, these studies are suggestive of NK-1 receptor involvement in a.a.-induced vesicoanal nociceptive activity and BL activity, as well as distension-induced bladder activity whereas urethral sphincter activity appears to be less dependent upon NK-1-mediated SP transmission

## 123.5

EVIDENCE THAT THE N- BUT NOT THE C-TERMINUS OF SUBSTANCE P (SP) POTENTIATES NON-NMDA ACTIVITY BY AN INTERACTION WITH PCP RECEPTORS. X. Sun\*, K. Kovács and A. A. Larson. Department of Veterinary Pathobiology, University of Minnesota, Saint Paul, MN 55108, U.S.A.

Behavioral sensitization to kainic acid (KA) administered intrathecally in mice appears to be mediated by the N-terminus of substance P (SP) released from primary afferent C-fibers. To determine whether KA sensitization, like pain, is sensitive to PCP ligands, we compared effects of MK801, PCP, d-APV and CPP on sensitization. At doses that inhibited NMDA-induced behavior, d-APV and CPP had no effect whereas MK801 and PCP inhibited sensitization to KA. Pretreatment with 10 nmoles of SP1-7, but not SP5-11, 24 hr prior to testing appeared to downregulate SP1-7-sensitive sites and attenuate KA sensitization. MK801, but not d-APV or haloperidol, blocked downregulation of SP1-7 sites, preventing the effect of SP1-7-pretreatment on KA sensitization. These data suggest a direct interaction of SP1-7 with PCP sites. Binding of SP and its N- and C-terminal fragments, SP1-7 and SP5-11, respectively, to PCP sites was studied using tissue homogenates of whole mouse brain. Whereas high concentrations of SP and SP1-7 displaced [3H]TCP, the C-Behavioral sensitization to kainic acid (KA) administered intrathecally high concentrations of SP and SP1-7 displaced [3H]TCP, the Cterminal fragment, SP5-11, did not compete for this binding site. When MK-801 was added to the reaction mixture, displacement of [3H]TCP by SP1-7 was increased in an additive manner. These results provide evidence that the N-terminus of SP modulates non-NMDA mediated activity by an interaction with PCP receptors. (Supported by NIDA 04190, 04090, 00124)

BLOCKADE OF NK1 RECEPTORS BY CP-96345 ENHANCES THE DOPAMINE EFFECTS OF METHAMPHETAMINE IN RATS. S.P. Gygi, J.W. Gibb, and G.R. Hanson\*, Department of Pharmacology and Toxicology, University of Utah. S alt Lake City, UT, 84112.

The major extrapyramidal dopaminergic pathway to the striatum is a nigrostriatal projection. Striatonigral substance P (SP) neurons are

However, the lack of a specific SP antagonist has made it impossible to determine the precise physiological role of this SP pathway. Recently, a nonpeptide, NK1 receptor antagonist, CP-96345 (CP), was developed by Pfizer Inc. which is centrally active when administered systemically. We combined CP (15 mg/kg:PNAS [1991] 88:10042) with the DAreleasing stimulant, methamphetamine (METH) (10 mg/kg) for 5 doses, 6 hours apart. The animals were sacrificed 18 hours after the last dose, and neuropeptide content (i.e., SP, neurotensin [NT], and dynorphin) was determined by RIA in order to assess the response of DA activity to METH treatment. CP did not alter any peptide content when given alone; however, when given in combination, CP usually substantially enhanced METH-induced increases in both striatal and nigral neuropeptide-like immunoreactivity. For example, NT-like immunoreactivity in the striatum increased 209% of control after METH treatment alone, while in combination with CP the increase was 367% of control. CP had similar effects on METH-induced striatal and nigral changes in SP and dynorphin content. Surprisingly, our findings suggest that the physiological role of the SP pathway is to antagonize the dopaminergic extrapyramidal systems. (We thank Pfizer Inc. for their generous gift of CP-96345. ## 123.4

INTERACTIONS OF THE SUBSTANCE P NH2-TERMINAL INTERACTIONS OF THE SUBSTANCE P NH<sub>2</sub>-TERMINAL METABOLITE SP(1-7) WITH THE SIGMA RECEPTOR IN VIVO (BEHAVIOR) AND IN VITRO (BINDING). <u>D.D. Mousseau, X. Sun and A.A. Larson\*</u>, 295 AnSci/VetMed Bldg, Univ. on Minnesota Dept. of Veterinary PathoBiology, St. Paul, MN, 55108.

Sensitization of caudally-directed biting and scratching (CBS) in mice induced by repeated intrathecal kainic acid injections is used to investigate effects of compounds on spinal excitatory amino acid systems. Interactions between the substance P (SP) NH<sub>2</sub>-terminal metabolite SP(1-7) and the sigma receptor water investigated queen their similar.

7) and the sigma receptor were investigated given their similar distributions in the mammalian CNS. Both the sigma agonist 1,3-di-o-tolylguanidine (DTG; 5 nmol 30 min) and SP(1-7) (22.5 pmol 30 min) potentiated kainic acid-induced CBS activity. In contrast, the sigma antagonist haloperidol (HAL; 1 nmol 5 min) attenuated the initial response without affecting sensitization, whereas the SP(1-7) antagonist D-SP(1-7) (1 nmol 30 min) blocked behavioral sensitization but did not affect the initial response to kainic acid. Radioligand binding revealed that DTG and HAL were almost as potent at competing for the [3H]DTG-labeled binding site but that SP(1-7) and D-SP(1-7) were much less potent at binding site but that SP(1-7) and D-SP(1-7) were much less potent at competing for this site, although they were equipotent in their respective effects on [3H]DTG binding. The relevance of the effect of SP(1-7) was demonstrated when SP itself, but not its COOH-terminal metabolite SP(5-11), inhibited [3H]DTG binding in a similar fashion. While the mechanism of action of SP(1-7) with sigma sites is unclear, the ability of SP(1-7) to mimick the effect of DTG on behavior, while their respective antagonists D-SP(1-7) and HAL antagonize these actions clearly indicates a similar mode of extreme of these two clears of forements. a similar mode of action of these two classes of compounds. (Supported by NIDA 04090, 04190, 00124).

## 123.6

THE NK-1 RECEPTOR ANTAGONIST (±)-CP-96,345 PRODUCES BIPHASIC CHANGES IN RAT STRIATAL DOPAMINE RELEASE WHEN ADMINISTERED VIA A MICRODIALYSIS PROBE. L. A. Phebus\*, J. J. Howbert and J. A. Nixon. The Lilly Research Laboratories, Eli Lilly & Co., Indianapolis, IN 46285.

Substance P, contained in striatal neurons which project to the substantia nigra, may modulate striatal dopamine release by a direct action on striatal dopamine-containing terminals, or by an action on dopaminergic cell bodies and dendrites in the substantia nigra. We used microdialysis to examine the effects of striatal NK-1 blockade on striatal dopamine release.

Male Wistar rats were anesthetized with isoflurane and placed in a stereotaxic apparatus where a plastic loop-style dialysis probe was implanted into the striatum and cemented in place. The next day, after recovery from anesthesia, the dialysis probe was perfused with artificial CSF (pH=7.4), at a rate of 1.3 microliters / minute. Striatal dialysate dopamine, DOPAC, HVA and 5-HIAA were assayed every 15 minutes using "on line" HPLC. After baseline samples were measured, 15 microliters containing 3 micrograms of (±)-CP-96,345 in artificial CSF (pH=7.4) were perfused through the probe.

Shortly after striatal exposure to (±)-CP-96,345, striatal dialysate dopamine levels increased briefly and then decreased, reaching a level of about 50% baseline. Dopamine levels remained significantly decreased for several hours. Striatal dialysate DOPAC and HVA levels were significantly decreased. The biphasic and prolonged effects of brief NK-1 antagonism on dopamine release indicate that this interaction may have a complex mechanism.

EFFECTS OF SUBSTANCE P (SP) FRAGMENTS ON EVOKED RESPONSES OF RAT SPINAL NOCICEPTIVE NEURONS. D. Budai.\* G. L. Wilcox and A. A. Larson. Departments of Pharmacology and Veterinary Pathobiology, University of Minnesota, Minneapolis, MN 55455, U.S.A.

The effects of N- and C-terminal fragments of substance P, SP1-7 and SP5-11, respectively, were tested on nociceptive neurons in the dorsal horn of the anesthetized rat. Neuronal activity was evoked by iontophoretic application of excitatory agents (NMDA, AMPA, kainic acid) or by electrical stimulation of the receptive field and recorded extracellularly. While SP(1-7) had no effects when applied iontophoretically by itself, it was a potent and long-lasting modulator of spinal nociception. NMDA responses were transiently decreased (by an average of 36% of control at minimum) by SP(1-7) followed by a more sustained increase (by 76% at time of maximum effect). In contrast, AMPA and kainate responses were only increased by SP(1-7) (by 81 and 105 % at time of maximum effect, respectively). SP(1-7) reduced both the initial responses and the frequency dependent potentiation (wind-up) of the neurons to repeated C-fiber stimulation. Inhibitions by SP(1-7) of chemical- as well as peripheral stimulation-evoked responses proved to be naloxone sensitive. On the other hand, the C-terminal fragment, SP(5-11), exerted naloxone insensitive increase in the responses of nociceptive neurons. These results show that the C- and N-terminal fragments of SP may exert their effects through different mechanisms. The inhibitory component of the SP(1-7) effects is related to opioid receptors. (Supported by NIDA Grants RO1-04090 and KO2-00124 to A.A.L. and RO1-04274, RO1-01933 and KO2-000145 to G.L.W.)

CAPSAICIN PRETREATMENT REDUCES PHOSGENE LUNG INJURY R.M. Bauer\*, G.D. Young and J.R. Keeler Pathophysiology Division, U.S. Army Medical Research Institute of Chemical Defense, Aberdeen Proving Ground, MD 21010-5425

Phosgene (CG) is an irritant gas which elicits lung inflammation and noncardiogenic edema when inhaled. We examined the role of airway neuropeptides in CG-induced lung injury. Anesthetized adult guinea pigs were injected with vehicle, or capsaicin (CAP, 5 mg/kg or 50 mg/kg, sc) to deplete neuropeptides from airway sensory nerves. One week later, guinea pigs were exposed to air or CG (200 mg/m<sup>3</sup>) for ten minutes. Four hours after exposure, lung wet weight to dry weight ratios were obtained as indices of pulmonary edema. Substance P- (SP) and neurokinin A- (NKA) like immunoreactivity (LI) in trachea, bronchi and lungs were measured by radioimmunoassay. CG-exposed guinea pigs had higher lung weight ratios than air-exposed guinea pigs. Edema indices of CG-exposed guinea pigs treated with 5 mg/kg CAP were lower than those of 50 mg/kg CAP- or vehicle-treated guinea pigs. SP-LI at all levels of the respiratory tract was 275% lower in CAP-treated guinea pigs. NKA-LI was reduced only in 50 mg/kg CAP-treated guinea pigs. Vehicle-treated CG-exposed guinea pigs had 60% lower lung SP-LI and bronchial NKA-LI than those exposed to air. We conclude that 1) CG inhalation evokes lung SP and bronchial NKA release; 2) SP release in the lung may contribute t CG-induced pulmonary edema. Precise mechanisms of 5 mg/kg CAP effect are to be determined.

## 123.11

NEUROTENSIN EXCITES DOPAMINERGIC NEURONS IN RAT VENTRAL TECMENTAL AREA (VTA) BY REDUCING POTASSIUM AND INCREASING SODIUM CONDUCTANCES. Z.G. Jiang\*, M. Pessia and R.A. North, Vollum Institute, Oregon Health Sciences Univ., Portland, OR 97201.

Portland, OR 97201. Whole cell recording techniques were used to study the actions of neurotensin (NT) on VTA neurons in rat midbrain slices. NT dose-dependently (EC $_{50}$  = 37 nM) caused an oscillatory inward current (up to 260 pA at holding potential -60 mV) in 81% of principal (presumed dopaminergic) neurons (n=106), but 30% of secondary cells (n=47). TTX (1  $\mu$ M) or glutamate-antagonists reduced the NT-induced current in 20% of cells; thus, either one or both were added. NT-induced current was associated with a small reduction in instantaneous conductance at -60 mV. NT-current was not blocked by TEA (10 mM), Ba (1 mM) or Cs (3 mM). In most cells, the NT-current became smaller with depolarization and larger with hyperpolarization; but in some cells the current became smaller with hyperpolarization and even reversed polarity at about -100 mV. With internal and external solutions to suppress potassium and calcium currents, the NT-induced current had a reversal potential between -10 and 30 mV, and was inhibited 70 - 90% by low Na'(20 mM). The results suggest that both potassium codncutance decrease and cation condutance increase contribute to the depolarization caused by NT.

EVIDENCE FOR POSSIBLE INTERACTIONS BETWEEN MORPHINE AND CGRP IN THE DEVELOPMENT OF TOLERANCE TO OPIATES IN THE SPINAL CORD. R. Quirion 1, D. Menard 2, S. Kar 1, D. van Rossum 1, C. Gouardères 1, K. Jhamandas 3 and F. Jolicoeur 2. 1DHRC and Dept. of Psychiatry and Pharmacol. and Ther., McGill Univ., Montréal, QC., Canada. 2Dept. of Psychiatry and Pharmacol., Univ. of Sherbrooke, QC, Canada. 3Dept. of Pharmacol., Oucen's Univ. Kineston. Ont. Canada.

³Pept. of Pharmacol., Queen's Univ., Kingston, Ont. Canada. Spinal administration of morphine induces an antinociceptive effect through the activation of receptors localized in the substantia gelatinosa. Rapid tolerance develops to this effect. The mechanism involved in this phenomenon mostly remains to be established but clearly does not involve a down regulation of opioid receptors. A possible alternative relates to an action via nociceptive sensory inputs containing neuropeptides such as Calcitonin Gene-Related Peptide (CGRP). The present investigation was undertaken to determine if any relationship existed between tolerance induced by morphine and CGRP in the dorsal horn of the cord. Morphine sulfate  $(7.5\mu g/h/\mu l)$  was continuously administered at lumbar level L4, for a 3 day or 5 day time period, using Alzet mini-osmotic pumps. The analgesic effect monitored by tail-flick test from the 3-day treatment was similar to the analgesia produced by a single intrathecal injection of morphine sulfate  $(7.5\mu g)$ . In contrast, tolerance to nociceptive action of morphine was evident at day 5 of treatment. Following behavioral evaluation, animals were sacrificed and L4 segments processed for either CGRP immunohistochemistry or quantitative in vitro [1251]hCGRP receptor autoradiography. While no changes were detectable for either parameters by day 3, CGRP-like immunoreactivity was apparently increased while [1251]CGRP binding decreased (25-30%) in the dorsal horn at day 5 of morphine treatment. This may suggest the possible involvement of CGRP and its receptors in the phenomenon of tolerance to the antinociceptive effect of morphine. Supported by MRCC.

INTRIGUING EFFECTS OF NEUROTENSIN ON RETINAL DOPAMINE METABOLISM Henni H., Drumheller A. and Jolicoeur F.B.\* Depts. of Psychiatry and Pharmacology, Faculty of medicine. University of Sherbrooke, Sherbrooke Qc. Canada J1H 5fM.

Neurotensin has been found in a subpopulation of amacrine cells in

Neurotensin has been found in a subpopulation of amacrine cells in the retina of several vertebrates. Also, we have reported previously that this neuropeptide may be co-localized within dopaminergic retinal cells in mammalian retina ( Invest. Ophthalmol. Visual Sci. 28: 351, 1987). The purpose of this study was to investigate possible neurochemical effects of neurotensin on dopamine systems in the retina. Various doses of neurotensin were injected in the vitreous of anesthesized rats. Retinal concentrations of dopamine and its main metabolites, DOPAC and HVA were determined using HPLC with electrochemical detection 15 min following injections. Serotonin and its metabolites, DOPAC and HVA were determined using HPLC with electrochemical detection 15 min following injections. Serotonin and its metabolites, Experiments were conducted in both light and dark adapted animals. The results indicate that, while concentrations of dopamine remained unaffected, the turnover of dopamine, as evaluated by metabolite concentrations as well as by the metabolites to dopamine ratios, was significantly reduced in a dose related fashion by the peptide. Threshold doses for producing these effects under light and dark conditions were 0.78 µg and 12.5 µg respectively demonstrating a markedly greater influence of the peptide when retinal dopamine release is increased by photopic stimulation. Retinal dopamine release is increased by photopic stimulation. Retinal dopamine restonin or its metabolite were unaffected by the treatment, indicating a selective action of the peptide on dopaminergic transmission. The observed decrease in retinal dopamine metabolism is contrary to the well known enhancing effect of the peptide found in other areas of the CNS. At the present time the reasons for these opposite effects cannot be adequately explained, but they surely reveal the complexity of the dopamine-neurotensin interaction in the CNS. Supported by MRC Canada, Grant No P6-287

## 123.12

ALTERATIONS IN THE ACTIVITY OF CENTRAL CATECHOLAMINERGIC NEURONS FOLLOWING SYSTEMIC ADMINISTRATION OF A SUBSTITUTED NEUROTENSIN ANALOG K.J.Lookingland<sup>1</sup>, Y.Tian<sup>1</sup>, M.D.Davis<sup>2</sup>, D.J.Wustrow<sup>2</sup>, W.L.Cody<sup>2</sup> and K.E.Moore<sup>1</sup>. Dept. Pharmacology and Toxicology, Michigan State University, East Lansing, MI 48824 and <sup>2</sup>Parke-Davis Pharmaceutical Research Division, Warner-Lambert, Ann Arbor, MI 48105.

The effects of systemic administration of a substituted neurotensin analog (Sub-NT<sub>B-13</sub>) were examined on the activity of central catecholaminergic neurons in the male rat. The activity of mesolimbic (ML), tuberoinfundibular (TI) and incertohypothalamic (IH) dopaminergic (DA) neurons was estimated by measuring the concentrations of the dopamine metabolite 3,4 dihydroxyphenylacetic acid (DOPAC) in regions of the brain containing terminals of these neurons (I.e. nucleus accumbens [NA], median eminence [ME] and dorsomedial nucleus [DMN], respectively). Sub-NT<sub>B-13</sub> (sc) produced dose- and time-dependent increases in DOPAC concentrations in the NA, ME and DMN. Sub-NT<sub>B-13</sub> also increased dopamine concentrations in the DMN, but had no effect in the NA or ME. To determine if concurrent increases in DOPAC and dopamine reflect an increase in the activity of noradrenergic neurons the effects of Sub-NT<sub>B-13</sub> were examined on concentrations of the norepinephrine metabolite 3-methoxy-4-hydroxyphenylethylene glycu (MHPG). Sub-NT<sub>B-13</sub> (1.0 mg/kg; sc) increased MHPG concentrations in the DMN, and this was accompanied by a decrease in concentrations of norepinephrine. Furthermore, neurochemical-induced lesions of the ventral noradrenergic bundle blocked the ability of Sub-NT<sub>B-13</sub> increases the activity of DA neurons comprising the ML, TI and IH systems, and noradrenergic neurons terminating in the DMN. (Supported by NIH Grant NS15911).

EVIDENCE FOR PROTEIN KINASE C MEDIATION OF THE NEUROTENSIN INDUCED ACTIVATION OF TUBERO-INFUNDIBULAR DOPAMINE (TIDA) NEURONS. G.A. Gudelsky\* and S.A. Berry, Depts. of Psychiatry and Neuroscience, Case Western Reserve University, Cleveland, OH 44106

The purpose of the present study was to determine whether neurotensin acts within the arcuate nucleus/median eminence to activate tyrosine hydroxylase (TH) within TIDA neurons and to assess the role of protein kinase C in this activation. The activity of TH within TIDA neurons was assessed by quantification of the formation DOPA in the arcuate nucleus/median eminence under in vitro conditions after inhibition of DOPA decarboxylase. Neurotensin (0.1-10 nM) increased the activity of TH within TIDA neurons under in vitro conditions by The activity of TH also was increased approximately 80%. approximately 55% by the phorbol ester, TPA (1-1000 nM), which activates protein kinase C. Sphingosine (10  $\mu$ M), an inhibitor of protein kinase C, attenuated the activation of TH within TIDA neurons that was induced by TPA and neurotensin. Sphingosine alone did not alter the activity of TH nor did it alter the dibutyryl-cAMP-induced activation of TH. It is concluded that neurotensin acts directly within the arcuate nucleus/median eminence to activate TIDA neurons. Furthermore, it is suggested that the activity of TH within these neurons is enhanced following the activation of protein kinase C and that protein kinase C may mediate the neurotensin-induced activation of TIDA neurons.

## 123.15

NITRIC OXIDE PARTICIPATES IN THE INHIBITION OF UTERINE CONTRACTION BY CALCITONIN GENE-RELATED PEPTIDE. R.L. Shew, J.A. Yee, R.E. Papka and D.L McNeill. Department of Anatomical Sciences, University of Oklahoma Health Sciences Center, Oklahoma City, OK 73190 and Department of Biomedical Sciences, Creighton University School of Medicine, Omaha, NE 68178

We have demonstrated that calcitonin gene-related peptide (CGRP) inhibits substance P- (SP) stimulated uterine contraction in vitro. In an attempt to clucidate the mechanism of action of CGRP, the present study was undertaken to examine the role nitric oxide might have in the inhibitory action of CGRP on uterine contraction. The effect of CGRP on SP- and neurokinin A- (NKA) stimulated uterine contraction was examined in vitro on uterine horns from diethylstilbestrol-treated rats (50 µg/rat,i.p. 14-16 hrs prior to the study). These experiments were done in the absence or presence of two arginine analogs which inhibit nitric oxide formation (N<sup>G</sup>-monomethyl-Larginine [CH<sub>3</sub>-ARG] and N<sup>G</sup>-nitrol-arginine [N0<sub>3</sub>-ARG]). CGRP (10<sup>7</sup> M) significantly reduced SP- (10<sup>7</sup> or 10<sup>6</sup> M) and NKA- (10<sup>6</sup> M) stimulated uterine contraction. The inhibitory action of CGRP on SP- and NKA-stimulated uterine contraction was blocked by 10<sup>3</sup> M CH<sub>3</sub>-ARG. In contrast, 10<sup>-3</sup> M NO<sub>2</sub>-ARG had no effect on the inhibitory action of CGRP on NKA-stimulated uterine contraction. Neither CH<sub>3</sub>-ARG or NO<sub>2</sub>-ARG alone had any effect on SP- or NKA-stimulated uterine contraction. These data demonstrate that CH<sub>3</sub>-ARG, a blocker of induced nitric oxide formation, suppresses the relaxant effect of CGRP on myometrial activity and that NO<sub>2</sub>-ARG, a blocker of constitutive nitric oxide formation, has no effect on CGRP inhibition of SP- and NKA-stimulated uterine contraction. These data suggest that the inhibitory action of CGRP may be dependent on induced nitric oxide formation.

## 123.14

EFFECT OF SYSTEMIC AND CENTRAL ADMINISTRATION OF NATURAL AND NOVEL NEUROTENSIN ANALOGUES ON BEHAVIOR AND NEUROTRANSMITER TURNOVER IN THE RODENT BRAIN. L.W. Cooke\*, D.J. Wustrow, T.A. Pugsley, H. Akunne, T.G. Heffner, W. Cody and M.D. Davis. Neuroscience Section, Parke-Davis Pharmaceutical Research Division, Warner-Lambert Company, 2800 Plymouth Road, Ann Arbor, MI 48105. Neurotensin (NT) is a tridecapeptide with a broad range of activity and is distributed along with its receptor in discrete peripheral and brain regions. This study evaluated the central effects of both native and novel NT fragments.

Neither NT1-13 nor NT8-13 had any measurable effects on locomotor or biochemical activity in rodents when given systemically (0.1-10mg/kg S.C.). In contrast, a nanomolar-affinity analogue of NT8-13 with selective amino-acid substitutions produced a profound and prolonged suppression of locomotor activity (ED50 <0.2 mg/kg S.C.) in rats and mice. This fragment also evoked elevations in dopamine and acetylcholine turnover in rats, being more pronounced in the nucleus accumbens than in the striatum. In addition, NT1-13, NT8-13 and other modified fragments all produced similar effects when administered ICV. These results suggest that certain modified NT fragments can be made resistant to peptidase degradation and are able to cross the blood-brain barrier.

CALCITONIN GENE-RELATED PEPTIDE AND MUSCLE ACETYLCHOLINESTERASE REGULATION. <u>C.A. Hodges-Savola\* and H.L. Fernandez.</u> Neuroscience Res. Lab., US Dept. Veterans Affairs Med. Ctr., Kansas City, MO 64128

Calcitonin gene-related peptide (CGRP) in mammalian skeletal muscles is predominantly localized within motor nerve terminals and it has been shown that this peptide modulates the metabolism/function of nicotinic acetylcholine receptors (nAChRs). Here we describe data suggesting that CGRP also influences muscle acctylcholinesterase (AChE), particularly the globular tetrameric  $(G_4)$  molecular form. Young adult (3 month-old) male Sprague-Dawley rats received two subcutaneous injections of rat CGRP [40-120 ug in 0.3 ml phosphate buffered saline (PBS)], one at time 0 and the second 24 hr later. Immediately after the first injection, the anterior gracilis muscle in one leg was denervated. Controls included other similarly denervated animals that were either injected with PBS or that received no injections. In all cases, muscle samples enriched in motor endplates (+EPs) were removed 48 hr after the initial injection/denervation and processed for AChE isoform analysis. We observed the expected AChE isoform changes in non-treated, as well as PBS-treated denervated muscle +EPs; i.e., a significant increase in G<sub>4</sub> AChE, and marked declines in the  $G_1$ ,  $G_2$ , and  $A_{12}$  molecular forms. In turn, CGRP did not dramatically alter the denervation-induced changes in  $G_1$ ,  $G_2$ , and  $A_{12}$  AChE, whereas the peptide (at doses of 80 and 120 ug) completely eliminated the tetramer's response to denervation; i.e., CGRP had an "innervation-like" effect that was specific for G<sub>4</sub> AChE. These observations may be explained by assuming that the exogenous CGRP served to replenish that peptide which is known to decrease following denervation The foregoing results, together with other data from our laboratory, suggest that CGRP may not only serve as a trophic agent for nAChRs, but may also participate in the regulation of G4 AChE.

# CATECHOLAMINES: RECEPTORS I

## 124.

IMMUNOHISTOCHEMICAL LOCALIZATION OF THE D1 DOPAMINE RECEPTOR IN THE RAT BRAIN. Q. Huang<sup>1\*</sup>, D. Zhou<sup>1</sup>, K. Chase<sup>2</sup>, J.F. Gusella<sup>3</sup>, N. Aronin<sup>2</sup> and M. DiFiglia<sup>1</sup>. Lab. of Cellular Neurobiology<sup>\*</sup>, Lab. of Molecular Neurogenetics<sup>3</sup>, Massachusetts General Hospital, Boston, MA 02114 and Dept. of Medicine and Cell Biology<sup>2</sup>, Univ. of Massachusetts Med. Ctr., Worcester, MA 01655.

Localization of the D1 receptor was examined using a purified polyclonal antipeptide antibody, which immunoprecipitated a protein of approx. 45 kDa on a silver-stained 8% SDS-PAGE. The regional distribution of D1 immunoreactivity overlapped with all dopamine-containing pathways and with patterns of D1 receptor binding and mRNA localization previously reported. D1 was heavily concentrated in cortical and subcortical neurons and neuropil of the limbic forebrain. Regions included the prefrontal, cingulate, parietal, prinform and entorhinal regions, the hippocampal formation, the amygdala, septal area, substantia inominata, thalamus (eg., medial dorsal complex), hypothalamus (eg., mammillary complex) and the neurohypophysis. Axonal transport of receptor protein was indicated by the prominent staining found in fiber bundles which connect limbic areas and in axons traversing the hypothalamus and other subcortical regions. Intense immunoreactivity was also seen in neurons and fibers of the thalamic reticular nucleus, a region known to integrate ascending basal forebrain inputs with thalamocortical and corticothalamic pathways, and throughout the basal ganglia (see also D. Zhou et al., this meeting). Results provide the first direct immunohistochemical evidence for the regional distribution of D1 receptors in the brain. The high density of D1 receptors in the limbic system and thalamic reticular nucleus supports an important role for this receptor in mediating functions involved with learning, memory, and cognitive processing. (Supported by NIH NS 16367 to MD and JFG and NSF BNS8819989 to NA).

## 124.2

ULTRASTRUCTURAL LOCALIZATION OF DOPAMINE D1 AND D2 RECEPTOR PROTEINS IN RAT STRIATUM. S. M. Hersch\*, S. M. Edmunds, B. J. Ciliax, and A. Levey. Dept. of Neurology, Emory University School of Medicine, Atlanta, GA 30322

A family of at least five dopamine receptors (D1-5) mediate motor, cognitive, and endocrine effects of dopamine neurotransmission. D1 and D2 receptor mRNAs are most abundant in striatum and are differentially expressed in medium spiny neurons projecting to substantia nigra and globus pallidus, respectively. To better understand the synaptic organization of neurons expressing D1 and D2, we developed subtype-specific antibodies and used them for electron microscopic immunocytochemistry. Antibodies were raised to fusion proteins derived from divergent regions of the i3 loop and C-termini, affinity-purified, and used to localize the native D1 and D2 receptors (Kitt et al., 1991). The antibodies are specific for the respective fusion proteins, cloned receptors, and native striatal receptors on immunoblots. These antibodies were applied to 40µm thick vibratome sections from rat striatum and visualized using the avidin-biotin method. At the ultrastructural level, D1 immunoreactivity was localized to selected somata with the typical characteristics of medium spiny cells; to medium sized spiny dendrites, and to the postsynaptic elements of axospinous synapses in the neuropil. No axonal labeling was noted. D2 immunoreactivity was similar with the additional finding that some axon terminals were also labeled. In each, label was visible within the cytoplasm of these neural elements and also at postsynaptic densities. D1 and D2 immunoreactivity was present in subpopulation of spiny somata and dendrites.

IMMUNOCYTOCHEMICAL LOCALIZATION OF DOPAMINE D5 RECEPTOR IN RAT BRAIN. B.J.Ciliax\*, N. Nash, C.Heilman and A.

Levey. Dept. of Neurology, Emory University School of Medicine,
Atlanta, GA 30322 and Nova Pharm. Corp., Baltimore, MD 21224
A human D5 doparmine receptor gene, closely related to D1, was
recently cloned. However, the encoded D5 protein has yet to be identified in tissues because selective ligands are unavailable. A recombinant protein derived from D5 (<8% identity to D1) was prepared by PCR amplification from human genomic DNA, subcloned into pGEX2T, and expressed in *E. coli*. Rabbit antibodies to the purified protein were produced, affinity-purified, and shown to have no cross-reactivity with D1 or D2 fusion proteins on immunoblots. D5-like immunoreactivity (D5LI) was localized in rat brain by immunocytochemistry. In general, D5LI was highly consistent with the distribution of D5 mRNA, and distinct from D1 and D2. D5LI was most dense in the olfactory tubercle, including the Islands of Calleja, and in the outer molecular layer of piriform cortex. Less dense D5LI was present in the neuropil in superficial layers of other cortical regions, and in pyramidal neurons in layers 2/3 and 5. In hippocampus, D5LI was present in pyramidal neurons and stratum radiatum, especially in CA3. Diffuse, weak D5LI was present throughout dorsal and ventral striatum. Scattered, large striatal neurons expressed more intense D5LI. Small neurons in the substantia nigra, ventral tegmental area, hypothalamus, raphe and several other brainstem regions were also labeled. Preadsorption of antibodies with D5 protein eliminated specific labeling. These results suggest D5 may be relevant in a variety of dopaminergic pathways. The antibodies should be useful for further studies of the D5 receptor, including its regulation and subcellular distribution.

## 124.5

D<sub>1</sub>, D<sub>2</sub> and D<sub>3</sub> DOPAMINE RECEPTOR DEVELOPMENT IN THE INFANT AND JUVENILE HUMAN BASAL GANGLIA. C.E. Adams\* and S.J. Boyson. Depts. of Neurology and Pharmacology, Univ. Colo. Hlth. Sci. Cntr., Denver, CO 80262.

D<sub>1</sub>, D<sub>2</sub> and D<sub>3</sub> dopamine receptor densities within the caudate (Cd), putamen (Put), external (GPe) and internal globus pallidus (GPi) of 3 infant, 2 juvenile and 4 adult human brains were examined using quantitative autoradiography.  $D_1$  receptors were labeled with a single concentration of  $^3H$ -SCH-23390.  $D_2$  receptors were labeled with  $^3H$ spiperone in adjacent tissue sets under two conditions; the first with the D<sub>3</sub>-selective antagonist 7-OH-DPAT (DPAT/D<sub>2</sub>) and the second without 7-OH-DPAT (non-DPAT/D2). All buffers also contained 300 nM ketanserin. Nonspecific buffers also contained 2 μM (+)-butaclamol. The specific density of D3 receptors was calculated by subtracting the density of total D<sub>2</sub> receptors in a DPAT/D<sub>2</sub> section from the density of total D<sub>2</sub> receptors in the adjacent non-DPAT/D<sub>2</sub> section. In general, the density of D<sub>1</sub> receptors was found to decrease with increasing age in all density of D<sub>1</sub> receptors was round to decrease with increasing age in an structures, most markedly within the GPi. D<sub>2</sub> receptor density also decreased with increasing age within the Put and GPe, but did not change within the Cd or GPi. D<sub>3</sub> receptors were present at low, highly variable levels in all structures examined but the density of D<sub>3</sub> receptors did not change systematically with maturation. These results suggest that the D<sub>1</sub> receptor, which is elevated throughout the basal ganglia in early life may play a role in development, as may the D2 receptor in the Put and GPe. D<sub>3</sub> receptor levels are very low, as might be predicted from mRNA studies in rat. Supported by NIH NS019199.

## 124.7

PROMOTER ANALYSIS OF THE D1A DOPAMINE RECEPTOR GENE. M. T. Minowa, T. Minowa, Y-S. Lau\* and M. M. Mouradian. Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892.

The D1A dopamine receptor plays an integral role in propagating neural information in the basal ganglia and other brain structures. We recently reported the primary structure of the promoter of the human D1A gene and found it to be TATA-less with multiple transcription start stites between -1061 and -1040 relative to the adenosine in the first ATG codon (Minowa et al., PNAS, 89:3045-3049, 1992).

In the present report, we carried out detailed promoter analysis by making deletion mutants of the -1343 to -1103 region of the gene which showed strong transcriptional activity in the D1A expressing NS20Y cells. Results indicated that the -1197 to -1120 region retains high promoter activity with specificity to these cells. Gel shift and footprinting suggested that recombinant human AP2 binds to two of its consensus sites in the D1A promoter between 1197 and -1070 but no Sp1 binding could be detected. Gel retardation with NS20Y nuclear extract suggested that additional factor(s) are involved in the transcriptional regulation of this gene.

We conclude that the D1A dopamine receptor gene is subject to complex regulatory control even though its promoter has features of "housekeeping" genes.

LOCALIZATION OF THE D5 DOPAMINE RECEPTOR IN THE CENTRAL NERVOUS SYSTEM AND PERIPHERAL TISSUE OF THE RAT. D.K. Grandy\*1.2, J. Meador-Woodruff<sup>3</sup>, C. Saez<sup>1</sup>, Y. Zhang<sup>2</sup>, R.A. Johnson<sup>1</sup>, A. Mansour<sup>3</sup>, S.J. Watson, Jr<sup>3</sup>, and O. Civelli<sup>1</sup>.2. Vollum Institute for Advanced Biomedical Research and <sup>2</sup>Dept.Cell Biology and Anatomy, Oregon Health Sciences University, Portland, OR 97201; 3 Department of Psychiatry and the Mental Health Research Insitute, University of Michigan, Ann Arbor, MI

Dopamine affects a number of physiological processes in both the central nervous system and select peripheral tissues. In the brain, acting as a neurotransmitter, dopamine stimulates at least five different receptor subtypes: D1, D2, D3, D4 and D5, which are coupled via G proteins to the formation of cAMP, potassium channel conductance, and the mobilization of intracellular Ca+2. In the periphery dopamine influences several processes including the absorption of Na+by renal tubules (natriuresis) and the hemodynamics of the renal and mesenteric vasculature. These effects are thought to be mediated by two different subtypes of G protein-coupled receptors designated DA1 and DA2 to distinguish them from their central nervous system counterparts. However, whether or not these two peripheral dopamine receptor subtypes are molecularly distinct from those expressed in the central nervous system remains to be determined. We have begun to address this question by asking whether the recently described rat D5 dopamine receptor is expressed in tissues of both the central nervous system and periphery. Using in situ hybridization and the polymerase chain reaction (PCR) we have obtained evidence for the expression of the rat D5 dopamine receptor in both rat brain and kidney. In the brain the D5 mRNA is expressed at very low levels in the hippocampus and the parafascicular nucleus of the thalamus. In the kidney we find that the D5 receptor mRNA is also expressed at low levels in the proximal convoluted tubules.

## 124.6

POSTNATAL DEVELOPMENT OF DOPAMINE D<sub>1</sub>, D<sub>2</sub>, and D<sub>3</sub> RECEPTOR mRNAs IN RAT BRAIN. L.K. Srivastava\* and R.K. Mishra. Depts. of Psychiatry and Biomedical Sciences, McMaster University, Hamilton, Ont., Canada, L8N 3Z5.

The postnatal development of the mRNAs for brain dopamine D<sub>1</sub>, D<sub>2</sub>, and  $D_3$  receptors was investigated in Sprague-Dawley rats by Northern blotting and polymerase chain reaction. The levels of expression of striatal dopamine D1 receptor mRNA was appreciable at birth, increased to a maximum at day 14, and remained at that level until day 28. There was a significant decline of D1 mRNA level in six-month and one-year old rats. The expression of D2 mRNA followed a similar pattern of development except that maximal level mRNA was observed at day 28. In contrast, very low level of D<sub>3</sub> receptor mRNA was observed at birth. The D<sub>3</sub> mRNA expression increased to a maximum at day 14 and then showed a gradual decline until age one-year. The development of the D<sub>1</sub> and D<sub>2</sub> receptors as measured by [3H]SCH 23390 and [3H]spiroperidol followed the pattern of their respective mRNAs except that there was a lack of correlation between ligand binding and message level especially during early developmental periods. For example, although the message levels of both receptors at birth were 70-75% of the maximal level seen at day 14-28, the respective ligand bindings were only 15-20%. PCR analysis of alternatively spliced forms of D2 receptor mRNA showed that the developmental expression of the two isoforms proceeds in parallel. In situ hybridization revealed a differential developmental profile of D2 mRNA in major dopaminergic regions of brain such as caudate-putamen, nucleus accumbens, olfactory tubercle, and substantia nigra.

ORGANIZATION OF THE 5'-REGION OF THE RAT D1 AND HUMAN AND RAT D2 DOPAMINE RECEPTOR GENES. K.J. Buck<sup>1,2\*</sup>, Q.-Y. Zhou<sup>1</sup>, C. Li<sup>1</sup>, D.K. Grandy<sup>1</sup>, and O. Civelli<sup>1,3</sup>. Vollum Institute<sup>1</sup>, Department of Medical Psychology<sup>2</sup>, and Department of Cell Biology & Anatomy<sup>3</sup>, Oregon Health Sciences University, Portland, OR 97201.

Anomolous function and/or expression of dopamine receptors has been

implicated in several neurological disorders including schizophrenia and Parkinson's disease. Genomic and cDNA clones encoding the rat D<sub>1</sub>, rat D<sub>2</sub> and human D<sub>2</sub> dopamine receptors were isolated and sequenced. The rat D<sub>1</sub> receptor gene (rDRD1) is organized into two exons separated by a small intron in the 5'-UT region. The transcription start site is located 864 bp upstream from the translational initiation site. The 5'-flanking sequences of rDRD1 do not contain TATA and CAAT canonical sequences, but have a high GC content, potential CRE and GRE sequences and binding sites for transcription factors, e.g. Sp1, Ap1 and Ap2. Transfection studies using CAT gene fusion constructs demonstrated that 735 bp of the 5-flanking

CAT gene fusion constructs demonstrated that 735 bp of the 5'-flanking region of DRD1 is sufficient to confer cell-specific expression. The rDRD1 promoter responds to cAMP induction, suggesting the possibility of an autoregulation mechanism by which stimulation of the D<sub>1</sub> receptor exerts a positive feedback on its own gene expression. This effect was enhanced by PMA and dexamethasone, although they alone had no effect. Recent studies indicate that the human DRD2 gene extends over 270 kb and includes an intron of approximately 250 kb separating the 5'-region of DRD2 from the 7 exons encoding the receptor protein. We have identified an exon, putatively exon 2, in the 5'-UT region of the DRD2 gene. Exon 2 is 80% identical between human and rat, and is 331 bp and 333 bp in length, respectively. Primer extension analyses indicate that 200 bp of human and rat D<sub>2</sub> dopamine receptor mRNAs are encoded by an upstream exon(s). (Supported by MH45614, AA07468 and S.C.S.R.) (Supported by MH45614, AA07468 and S.C.S.R.)

MOLECULAR CLONING AND CHARACTERIZATION OF THE 5'-FLANKING REGION AND PROMOTER OF THE HUMAN DOPAMINE DS-RECEPTOR GENE. T.Y. Beischlag\*. A.E. Tirpak, R.K. Sunahara, H.H.M. Yan Tol. P. Seeman, and H.B. Niznik. Depts. of Pharamacology and Psychiatry, University of Toronto, Toronto, Canada, M5S 1A8, and The Laboratory of Molecular Neurobiology, The Clarke Institute of Psychiatry, Toronto, Canada, M5T 1R8.

The human dopamine D5-gene encodes for a protein that is a member of the guanine nucleotide-binding protein-linked superfamily of receptors. It has a higher affinity for dopamine than either the D1 or D2 receptors. Furthermore, the D5 gene has 2 closely related pseudogenes that are expressed but do not produce functional proteins. In order to study the transcriptional regulation of this gene a 3.6 Kb genomic clone 5' of the first ATG codon was isolated using a Sac 2.4 Kb fragment that overlapped the coding and 5' non-coding region of the D5- receptor gene. Amplification of human putamen and temporal cortex cDNA libraries by PCR using specific oligonucleotides to different regions of this clone yielded partial cDNA colones that suggest transcription of this gene initiates 1.4-1.9 Kb away from the first ATG codon. Sequence analysis reveals that this area and the region immediately 5' to it lacks conventional TATA and CAAT boxes, similiar to the D1 receptor gene promoter. It does however, contain several transcription factor binding domains and two antisense Alu motifs which contain transcription initiation sites for DNA polymerase III. To test for transcriptional activity, various regions of genomic DNA from the 5'-flanking region of the D5 gene have been fused in front of the firefly luciferase reporter gene. Data concerning the transient expression of these mutants in human and non-human immortal cell lines will be presented and reverse transcription of RNA from human putamen by PCR will be performed in order to delineate the exact site of transcription initiation

EXPRESSION AND REGULATION OF THE D<sub>1A</sub> DOPAMINE RECEPTOR IN STABLY TRANSFECTED CHO CELLS. <u>E.M. Smyk-Randall\*, L.-J. Zhang, F.J. Monsma, Jr. & D.R. Sibley.</u> Experimental Therapeutics Branch, NINDS, NIH, Bethesda MD, 20802

To investigate the functional and regulatory properties of the  $D_{1A}$  dopamine receptor, we have stably expressed a cDNA encoding the rat  $D_{1A}$  receptor in Chinese Hamster Ovary (CHO) cells. Following transfection and selection in G418, several clonal lines were isolated which exhibited a wide range of  $D_1$  receptor binding activities as determined using the  $D_1$ -selective antagonist  ${}^3\!H_1\!$ -SCH-23390. One cell line, expressing about 1.8 pmol/mg protein, was selected for further characterization. Saturation analysis revealed a  $K_d$  value of about 0.3 nM for  ${}^3\!H_1\!$ -SCH-23390 in good agreement with radioligand binding assays using rat striatal membranes. Dopamine produced a dose-dependent and pharmacologically-specific stimulation of adenylyl cyclase activity in both intact cell and membrane preparations. Dopamine's EC $_{50}$  for stimulating cAMP accumulation was about 1  $\mu$ M with a maximal response at 100  $\mu$ M which represented a 20-fold stimulation over basal levels. Pretreatment of the cells with dopamine was found to produce a profound desensitization of the dopamine-stimulated cAMP response and a loss of  ${}^3\!H_1\!$ -SCH-23390 binding. The dopamine-induced desensitization/down regulation was time-dependent reaching maximal levels after 20 hr with a  $1/12 \ge 5$  hr. The dopamine dosersponse for promoting these regulatory effects shows an EC $_{50}$  of about 10 nM with an EC $_{max}$  of 10  $\mu$ M. After maximal desensitization, the EC $_{50}$  of dopamine for stimulating cAMP accumulation is unchanged whereas the maximum response is decreased by about 75-90%. Similarly, there is no change in the affinity ( $K_d$ ) of  ${}^3\!\!H_1\!\!>$ SCH-23390 but a >50% decrease in maximum binding capacity is observed. The agonist-induced desensitization is pharmacologically-specific being mimicked by 6,7-ADTN, fenoldopam, and SKF38393. The biochemical mechanisms responsible for these regulatory effects are currently under investigation.

BINDING OF A FLUORESCENT D<sub>1</sub> DOPAMINE RECEPTOR ANTAGONIST TO SINGLE LIVE CULTURED NEURONS. <u>K.R.</u>
<u>Hoyt' and I.J. Reynolds.</u> Department of Pharmacology, Univ. of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

Fluorescent D<sub>1</sub> and D<sub>2</sub> dopamine receptor antagonists have recently become available (Monsma et al., J. Neurochem. (1989) 52, 1641-1644). Using these ligands, we are attempting to identify dopamine receptors on live cultured striatal neurons. We are using quantitative fluorescence microscopy (ACAS 470, Meridian Instruments, Okemos, MI) to characterize the binding of a fluorescent D<sub>1</sub> dopamine receptor antagonist (bodipy-SCH 23390; Molecular Probes, Eugene, OR) to live cultured striatal neurons from fetal rats (E17). We have been able to demonstrate specific binding as assessed by competition of the fluorescent ligand with an unlabelled competitor, (+)butaclamol. Total fluorescent binding of bodipy-SCH 23390 to individual striatal neurons has been quantified and the median total binding per neuron was 20189 arbitrary fluorescence units (AFU) (n = 256 cells) and median total binding in the presence of excess unlabelled (+)butaclamol was 2329 AFU (n = 252 cells). In addition, in kinetic experiments, bodipy-SCH 23390 binding to individual neurons can be reversed with unlabelled (+)butaclamol. This specific labelling of live neurons that possess D1 dopamine receptors should allow the study of functional responses (e.g. changes in [Ca2+];) in single cells that specifically express certain dopamine receptor subtypes, rather than in a heterogeneous population of neurons or in a random fashion. Supported by NIMH (MH18273).

#### 124.10

ALU REPEAT INVOLVED IN THE DUPLICATION OF THE HUMAN D5-DOPAMINE RECEPTOR GENE <u>A. Marchese</u>, <u>T. Beischlag</u>, <u>T. Nguyen</u>, <u>H. Niznik</u>, <u>L. Grupp\*</u>, <u>P. Seeman</u>, and <u>B.F. O'Dowd</u>. Dept. of Pharm., Univ. of Toronto, and Addiction Research Foundation, Toronto, Canada M5S 1A8.

We have previously reported the cloning of the functional D5-dopamine receptor DR and the two related pseudogenes (PGs) (Gene, 109: 211-218, 1991). These three genes are the most recent duplications in the large family of G-protein linked receptor genes, and they represent an opportunity to study the mechanism by which genes in this family have evolved. We have sequenced both the 5' and 3' regions flanking the coding region of the D5 DR and the equivalent regions in the two PGs. So far these three genes share close homology spanning a total region of at least 5 kb. In the 5'-untranslated region of these genes following 1.9 kb of homologous sequence, a transition to nonhomologous sequence occurs in the D5 DR gene. The transition site to nonhomologous sequence occurs at an Alu sequence that is present in both of the PGs, but is not found in the D5 DR gene. It is possible, given the position of the Alu repeat in the PGs, that this element was involved in the duplication of D5 DR which produced the first PG. The Alu sequences in both PGs are of the monomeric type (162 bp) and are composed of the right side of the Alu repeat with the characteristic poly-A tract terminating the repeat element and direct repeats flanking the entire structure. The orientation of the Alu is opposite to that of the PGs. Each of the PGs continue to be homologous beyond the Alu repeats suggesting that they were not involved in the duplication event forming the second PG. We have detected transcription of at least one PG in several brain areas and this mRNA transcript could produce a truncated receptor of 154 amino acids. We have determined that genomes of related primates, such as gorilla, also contain two PGs, however transcription of these genes would produce a truncated protein of only 95 amino acids.

## 124.12

CHARACTERISTICS OF DOPAMINE-STIMULATED PHOSPHOINOSITIDE METABOLISM IN RAT BRAIN. A. S. Undie and E. Friedman'. Departments of Psychiatry and Pharmacology, Medical College of Pennsylvania, 3200 Henry Avenue, Philadelphia, PA 19129.

Previous investigations have demonstrated that dopamine enhances inositol phosphate formation in rat brain slices, and that this action is mediated through a D<sub>1</sub>-like dopamine receptor. The present studies were directed at elucidating the mechanism of this dopaminergic response in rat striatal slices incubated in the presence of LiCl. Neomycin, a polyphosphoinositide phospholipase C inhibitor, dose-dependently and completely inhibited SKF38393-stimulated formation of inositol phosphates. Moreover, time course studies in slices simultaneously treated with [³H]inositol and SKF38393 showed that [³H]inositol trisphosphate was the first inositol phosphate to accumulate following agonist stimulation. These observations suggest that phosphatidylinositol-4,5-bisphosphate is the preferential or primary substrate for dopamine-stimulated phospholipase C.

Using a number of benzazepine and other dopamine  $D_1$  receptor agonists at concentrations from  $10^{-8}$  to  $10^{-3}$  M, we studied the relative efficacies of these drugs in stimulating phosphoinositide metabolisms. Whereas dopamine and several benzazepines including SKF38393 and SKF82526 were highly potent or efficacious in stimulating inositol phosphate accumulation, several otherwise potent  $D_1$  receptor agonists were without effect. This differential pattern of agonist effects suggests that the phosphoinositide-linked dopamine receptor is different from the classical  $D_1$  receptor. SUPPORTED BY USPHS GRANT #NS-29514 AND BY THE TOURETTE SYNDROME ASSOCIATION.

## 124.14

POTENCY OF D<sub>1</sub>-RECEPTOR AFFINITY LIGANDS WITH ALKYLATING MOIETIES. M Hartmann\*, RJ Baldessarini, N Kula, D Huston-Lyons, N Baindur, & JL Neumeyer, Department of Psychiatry & Neuroscience Program, Harvard Medical School, Mailman Research Center, McLean Lander (1998)

Huston-Lyons. N. Baindur. & Jl. Neumeyer, Department of Psychiatry & Neuroscience Program, Harvard Medical School, Mailman Research Center, McLean Hospital, Belmont, MA 02178 & Research Biochemicals, Inc., Natick, MA 01760. Derivatives of D₁-selective dopamine receptor antagonists were prepared and tested for affinity and apparent alkylating potency in rat striatum with radioreceptor assays using tritiated SCH-23390 (D₁) or YM-09151-2 (D₂) as radioligands. The p-bis-chloroethylamino (b-CEA) derivative of SKF-83566 (7-Br-8-0H-3-methyl-1-(4'-bis-chloroethylaminophenyl)-2,3,4,5-tetrahydro-1H-3-benzazepine), had 132x higher D₁ affinity (K₁ = 0.8 ± 0.1 pM) and 1176x greater D₁/D₂ selectivity (1.7 x 106) than the parent compound SKF-83566 with striatal homogenates. It also was more potent and D₁-selective than previously reported congeners containing other alkylating groups, in order of D₁ affinity (K₁ = 0.5-17 µM): chloroethylamino > chloracetamido ≥ bromoacetamido ≥ isothiocyanato > ethylfumaramido > maleimidoacetamido. For in vitro tests of D₁ alkylation, striatal minces were preincubated with test agents (37° c, 40 min), extensively washed, then homogenized and assayed with ca. Kd concentrations of the radioligands. Again, the b-CEA henylbenzazepine showed very high potency and D₁/D₂ selectivity (D₁ K₁ = 180 ± 30 nM; D₁/D₂ selectivity = 580x). Congeners had K₁ values of 1-3.4 μM, and selectivity ratios of 8-500x. Scatchard analysis of inhibition of 3H-SCH-23390 binding after preincubation of striatal tissue with the b-CEA derivative showed concentration-dependent decreases in B<sub>max</sub> without changes in ligand affinity; these were prevented by coincubation with nonalkylating D₁, but not D₂, agents. These results are consistent with potent and selective alkylation of striatal D₁ receptors in vitro. [Supported by NIMH awards 14275, 31154, 36004, 45692 & 47370 & Deutsche Forschungsgemeinschaft.]

DIHYDREXIDINE BINDS DIFFERENTLY TO HUMAN CLONAL AND RAT STRIATAL D, DOPAMINE RECEPTORS. Val J. Watts¹ Pavid M. Mottola¹, Olivier Civelli², Robert A. Johnson², David E. Nichols³ and Richard B. Mailman¹. University of North Carolina¹., Chapel Hill, NC 27599, Oregon Health Sciences University²-, Portland OR, and Purdue University³, W. Lafayette IN.

Dihydrexidine (trans-10,11-dihydroxy-5,6,6a,7,8,12b-hexahydrobenzo[a]phenanthridine) (DHX) is a full efficacy D₁ agonist in rat striatum and has been shown to bind D₁ receptors with an IC50 of 10 nM. SKF82958 (6-chloro-7,8-dihydroxy-3-ally1-1-phenyi-2,3,4,5-tetrahydro-1H-3-benzapine) has also been characterized as a full efficacy agonist at D₁ dopamine receptors with an IC50 value of 8 nM. Although both agonists display high potency in striatal homogenates, their receptor recognition characteristics differ. Several studies have reported that SKF82958 binds only to the high affinity state of the D₁ receptor, whereas DHX displays a typical agonist binding profile, binding to both high and low affinity states of the receptor. This study was undertaken to examine and characterize the interactions of D₁ agonists in a homogeneous population of D₁₁ receptors. The cloning and stable expression of D₁a receptors in Lik. cells provides an ideal system in which to examine the guanine nucleotide-dependent binding properties of DHX and other full efficacy agonists. The results from these studies showed that SKF82958 binds to D₁a receptors with a potency similar to that observed in striatal homogenates (IC50 ≈ 4.0 nM). In contrast, DHX binds to D₁a receptors in this cell line with more than five-fold lower potency (IC50 ≈ 60 nM) compared to binding in striatal homogenates (IC50 ≈ 10 nM), both ligands had Hill slopes significantly < 1.0. In this cell line, the addition of GTP shifted competition curves for both drugs such that they fit a one site model (n<sub>H</sub> ≈ 1.0) of a low affinity state. There are at least three possible mechanisms that may explain these data. First, there may be a

AGONIST-INDUCED CHANGES IN DENSITY OF D1, D2 AND CHIMERIC DI/I/D2 RECEPTORS. L.B. Kozell\*, S. Starr, C.A. Machida, R.L. Neve and K.A. Neve. VA Medical Center and Oregon Health Sciences Univ., Portland, OR; Primate Research Center, Beaverton, OR; and McLean Hospital, Belmont, MA.

Treatment of C<sub>6</sub> glioma cells expressing recombinant D1 dopamine receptors with the agonists dopamine or NPA decreased the density of receptors by 51% and 39%, respectively. In contrast, the density of D2 receptors on  $C_6$  glioma cells transfected with D2<sub>444</sub> cDNA was increased by 41%, 130% and 59%, respectively, after treatment with dopamine, NPA or quinpirole. NPA-induced upregulation of receptor density (26%) was also seen in LZR1 cells, a fibroblast cell line expressing recombinant D2415. Agonist-induced increases in receptor density do not involve G-proteins or adenylyl cyclase inhibition. Thus, neither treatment with pertussis toxin nor mutation of Asp-80, which prevents interaction with G proteins, blocked NPA-induced D2 receptor proliferation. The density of D1/D2 chimeras containing D1 sequence from the amino terminus to the amino-terminal end of transmembrane domain (TM) 6 or 7 was decreased by treatment with NPA or dopamine, whereas agonist treatment of a D1/D2 chimera with D1 sequence only up to the amino-terminal end of TM 5 increased the density of the receptors. These results suggest that the 3rd cytoplasmic loop or TM 5 may confer agonist-induced changes in receptor density. (MH 45372, VA Merit Review Program)

## 124.19

D1/D2 RECEPTOR INTERACTIONS: STIMULATING BOTH RECEPTORS INDUCES AN EFFECT OPPOSITE TO THAT OF STIMULATING D1 ALONE IN THE SUBSTANTIA NIGRA PARS RETICULATA AFTER RESERPINE TREATMENT. K.-X. Huang\* and J.R. Walters. NINDS, Bethesda, MD 20892. Synergistic interactions between D1 and D2 receptor processes have been described in normal and dopamine (DA)-depleted rats; mechanisms remain undefined. Present studies show D1/D2 synergy in responses of globus pallidus (GP) neurons to DA agonists after subchronic reserpine treatment (1 mg/kg/day for 6 days, s.c., then a 5-day wash-out). treatment altered the response of GP cells to the D1 agonist SKF 38393 (10 mg/kg, i.v.): 14/17 neurons had firing rates increased by 50%. Combining SKF 38393 with quinpirole (0.16 mg/kg, i.v.) caused greater increases in firing rates while quinpirole alone had only a limited effect. These results are similar to those in rats with 6-hydroxydopamine (6-OHDA)-induced nigrostriatal lesions. Interestingly, another type of D1/D2 interaction was found in the substantia nigra pars reticulata (SNpr) of reserpine-treated rats. SKF 38393 increased the firing of SNpr neurons by 91% (n = 18). Quinpirole itself had no effect but, given with the D1 agonist, it reversed the excitatory effect of SKF 38393 and induced a profound inhibition (80%, n = 11). In contrast, in lesioned rats, SKF 38393 alone has been shown to inhibit SNpr activity, an effect potentiated by quinpirole. Thus, consequences of D1/D2 interaction differ in the GP and SNpr and after reserpine and 6-OHDA treatments; an effect of one of these treatments, other than DA depletion, appears to alter DA processes. The possibility is raised that D1-mediated effects in reserpinized rats reflect a basic ability of D1 receptors, when acting independently of D2 stimulation, to mediate inhibition of striatal output, while concomitant D2 stimulation leads to striatonigral excitation and enhanced striatopallidal inhibition.

Substitutions on the Pendent Phenyl Ring of Dihydrexidine Alter D<sub>1</sub>:D<sub>2</sub> Selectivity. D.H. Mooney<sup>1,4\*</sup>, D.M. Mottola<sup>2</sup>, S.B. Southerland<sup>4</sup>, T.A. Knoerzer<sup>5</sup>, D.E. Nichols<sup>5</sup>, and R.B. Mailman<sup>1,2,3,4</sup>. Curriculum in Toxicology<sup>1</sup>, Departments of Pharmacology<sup>2</sup> and Psychiatry<sup>3</sup>, and Brain and Development Research Center<sup>4</sup>, University of North Carolina, Chapel Hill, NC, 27599 and School of Pharmacov Purdue University<sup>5</sup>, West Lafayette, IN, 47907.

University of North Carolina, Chapel Hill, NC, 27599 and School of Pharmacy Purdue University<sup>5</sup>, West Lafayette, IN, 47907.

We have demonstrated previously that dihydrexidine (DHX) is a high potency, full efficacy D<sub>1</sub> agonist with significant D<sub>2</sub> potency (e.g., Brewster et al., J. Med. Chem. 33:1756, 1991). Our molecular modeling studies (Mottola et al., SN Abstr. 16:79, 1990) have predicted that substitutions at the 2- and 3- positions of DHX (the pendent phenyl ring) might affect dopamine receptor affinity and/or selectivity. Thus, the 2-methyl, 3-methyl, and 2-phenyl analogs of DHX where synthesized and tested for their ability to compete for D<sub>1</sub> and D<sub>2</sub> binding sites (labeled with <sup>3</sup>H-SCH23390 and <sup>3</sup>H-spiperone, respectively) in rat brain striatal homogenates. Similar to earlier studies, the affinity (IC50) of DHX for D<sub>1</sub> binding sites was ca. 8 nM whereas the D<sub>2</sub> affinity was ca. 100 nM (D<sub>1</sub>:D<sub>2</sub> selectivity of ca. 13). Addition of a methyl group to the 2-position of dihydrexidine (2-MeDHX) had slight effects on D<sub>1</sub> potency (IC50=14 nM), whereas D<sub>2</sub> affinity is decreased more (to ca. 650 nM), thus increasing the D<sub>1</sub>:D<sub>2</sub> selectivity to ca. 46. Conversely, addition of a methyl group to the 3-position did not significantly affect the D<sub>1</sub> potency (IC50=7 nM), whereas the D<sub>2</sub> affinity of 3-MeDHX was doubled (45 nM) compared to DHX. Substitution of a bulkier phenyl ring at the 2-position of DHX drastically reduces D<sub>1</sub> affinity (IC50=290 nM), but has less effect on D<sub>2</sub> affinity (IC50=185nM). The functional activity of these analogs was also tested using adenylate cyclase assays in rat striatal homogenates. Preliminary studies indicate that 2-MeDHX and 3-MeDHX were, like DHX, full efficacy agonists. The functional potency of 2-MeDHX relative to DHX, however, appears to be affected more than its competition for <sup>3</sup>H-5CH23390. While studies of phenylletrahydrobenzazepines suggest great tolerance for steric bulk on the pendent phenyl ring, these data indicate that this region may be an important si

BIOLOGICAL ACTIVITIES OF DOPAMINE RECEPTORS IN VARIOUS CELL ENVIRONMENTS. C. Bouvier\*, J.A. Salon‡, R. Johnson, J.R. Bunzow, H.H.M. VanTol<sup>†</sup> and O. Civelli. Vollum Institute, Oregon Health Science University, Portland, OR 97201, \*Synaptic Pharmaceuticals, Paramus, NJ 07652, \*Department of Pharmacology, University of Toronto, Toronto, Canada M5S1A8

The dopaminergic system implicated in several human disorders including schizophrenia, Parkinson's disease and prolactinomas, exerts its effects through several dopamine receptors coupled to G proteins. Upon stimulation, the D<sub>1</sub> and D<sub>2</sub> dopamine receptor respectively activates and inhibits the adenylate cyclase. Recently, these receptors have been found to couple to several other second messenger pathways, and moreover these couplings were found to be dependent on the cellular environment. In order to understand the metabolic response of dopamine receptors upon stimulation with dopaminergic agents, we used a silicon-based microphysiometer which allows real-time measurement of metabolic activity of living cells. The use of several cell lines transfected with the cDNA of the  $D_1$  and  $D_2$  receptors confirm the importance of the cellular environment not only for the coupling of these receptors but also for their metabolic response to a stimuli. The possibility to determine the coupling of these receptors by studying their metabolic response will be examined. Other subtypes of dopamine receptors have recently been cloned, the functions of which are still under investigation. The coupling and metabolic responses of these receptors will be discussed.

INTRASTRIATAL RESERPINE ADMINISTRATION DECREASES DOPAMINE RECEPTOR mRNA LEVELS IN RAT STRIATUM. T. Mukherjee, P. Seeman\* and S.R. George, Depts of Medicine and Pharmacology, University of Toronto, Toronto, Ont, CANADA M5S 1A8

Peripheral reserpine treatment has been shown to increase and then decrease D1 (DRD1) and D2 (DRD2) receptor density in rat striatum in a time dependent manner. To determine the effect of localized dopamine depletion on the synthesis of DRD1 and DRD2, reserpine was administered stereotactically via unilateral implantation of cannulas into the rat striatum using coordinates (from bregma): 0.2mm anterior, 3mm lateral, 5.5mm ventral (atlas by Paxinos and Watson). Positioning of the cannula was verified by microscopic section analysis. Alzet minipumps were attached to the cannula and implanted subcutaneously. Reserpine was infused at 10ug/day for a period of 2 weeks. Northern blot analysis was used to measure D1 and D2 receptor mRNA using a 500bp cDNA probe for D1 and D2 was hybridized using a 48bp synthetic oligonucleotide corresponding to bases 782-826 of the D2 receptor gene. A decrease in both D1 and D2 receptor mRNA was observed in the striatum of the treated rats compared to control. Furthermore, within the treated group, a decrease in D1 and D2 receptor mRNA was observed in the striatum ipsilateral to the injection site compared to contralateral. To correlate with RNA changes, D1 binding analysis was performed on striatal tissue homogenate using the D1 antagonist 3H-SCH23390. Results showed a 53% decrease in D1 receptor density on the ipsilateral side of the injection compared to contralateral. No changes were observed in Kd. Thus, the decrease in D1 binding is consistent with the decrease in D1 mRNA on the ipsilateral side of the treated animals. Our results suggest that localized administration of reserpine may cause decreased synthesis of dopamine receptors

ONTOGENY OF NIGROSTRIATAL DOPAMINE NEURON AUTORECEPTORS: IONTOPHORETIC STUDIES. L. Wang \*and D.K. Pitts, Dept. of Pharm. Sci., Coll. of Pharmacy & A.H.P., Wayne State Univ., Detroit, MI 48202. Antidromically (AD) identified nigrostriatal dopamine

Antidromically (AD) identified nigrostriatal dopamine (DA)-containing (NSDA) neurons were studied during postnatal development using standard extracellular iontophoretic techniques under chloral hydrate anesthesia. Stimulation of somatodendritic (SD) D2 receptors on adult NSDA neurons results in membrane hyperpolarization and inhibition of spontaneous activity. Pitts et al. (Synapse 6:309, 1990) examined NSDA neurons SD DA autoreceptor sensitivity to cumulative i.v. doses of either apomorphine or quinpirole. NSDA neurons from 2- and 4-week-old rats were found to have lower sensitivity to apomorphine (D2/Dl agonist) than NSDA neurons from adults. However, the sensitivity of NSDA neurons from adults. However, the sensitivity of NSDA neurons to quinpirole (D2 agonist) was not found to be age dependent. To resolve this discrepancy between test agonists given by the i.v. route both quinpirole and apomorphine were applied iontophoretically. 2-week-old, 4-week-old and adult rats were found to be equally sensitive to both apomorphine and quinpirole. These results suggest that adult-like SD DA autoreceptor sensitivity is exhibited as early as the second postnatal week of development. (Supported by MH-47857 [DKP])

## 125.3

GABAERGIC MODULATION OF NIGROSTRIATAL DOPAMINE NEURON ACTIVITY IN NEONATAL RATS. D.K. Pitts and L. Wang. Dept. of Pharm. Sci., Coll. of Pharmacy & A.H.P., Wayne State Univ., Detroit. MI 48202.

Detroit, MI 48202.

Nigrostriatal dopamine (DA)-containing (NSDA) neurons were antidromically identified in chloral hydrate anesthetized rats using standard extracellular recording techniques. Iontophoretically applied GABA inhibited NSDA neurons from 2-week-old and adult rats in a similar fashion indicating the presence of functional GABA receptors early in postnatal development. Likewise functional GABA receptors could be demonstrated on zona reticulata (ZR) neurons using iontophoretic techniques. DA neurons in the zona compacta (ZC) are thought to receive inhibitory afferents from ZR neurons. Grace and Bunney (Eur. J. Pharmacol. 59: 211, 1979) have shown that in adult rats: (i) GABA has more potent inhibitory effects on ZR neurons than ZC DA neurons, and (ii) the GABA-A agonist, muscimol, when given i.v., excites ZC DA neurons by a mechanism most likely involving selective inhibition of ZR neurons and disinhibtion of ZC DA neurons. In the present study i.v. muscimol (0.1 to 1.6 mg/kg) was found to excite NSDA neurons from both adults and 2-week-old rats. This suggests that a tonic endogenous inhibitory input to NSDA neurons is present at the postnatal age of 2-weeks. Preliminary results also suggest that muscimol is more likely to induce or increase burst discharge activity in adults than in 2-week-old pups. (Supported by MH-47857 [DKP]).

## 125.5

NUMERICAL SOLUTION TO THE DIFFUSION EQUATION WITH NON-LINEAR MICHAELIS-MENTEN UPTAKE FOR DOPAMINE IONTOPHORESIS IN THE STRIATUM. C. Nicholson\* and M. E. Rice. Dept. Physiology and Biophysics, New York University Medical Center, 550 First Avenue, New York, NY 10016.

The migration of dopamine released into the extracellular space (ECS) of the striatum is governed by diffusion and by an avid uptake system that obeys non-linear Michaelis-Menten (MM) kinetics (Wightman et al. Neurosci. 25: 513, 1988). We previously showed the validity of analytical solutions to the diffusion equation with linear uptake for the movement of tetramethylammonium through the ECS of the striatum (Rice and Nicholson, J. Neurophysiol. 65: 264, 1991). The addition of MM kinetics, however, necessitates a numerical solution. Here we describe a solution representing a typical experimental paradigm.

The spherically symmetric partial differential diffusion equation with MM uptake was converted to an integral equation. Using Simpson's rule a set of simultaneous equations was constructed which also incorporated the boundary conditions representing iontophoresis from a micro-electrode. These equations were solved by the Newton-Raphson method using LU decomposition. This solution was programmed in Turbo Pascal and required 2-6 hours of run time on a 33 Mhz 486 PC.

Preliminary experiments using fast cyclic voltammetry in slices of the rat striatum confirmed that typical literature values (Wightman et al., ibid) of the MM parameters,  $V_{max}$  and  $K_m$ , are appropriate. Further comparisons of numerical solutions with experiment are expected to refine the values of these parameter.

This study was supported by NIH Grant NS 28642.

#### 125.2

NEONATAL NIGROSTRIATAL DOPAMINE NEURONS ARE LESS RESPONSIVE THAN ADULT NEURONS TO THE INHIBITORY EFFECTS OF AMPHETAMINE G. Zhang \*and D.K. Pitts. Dept. of Pharm. Sci., Coll. of Pharmacy & A.H.P., Wayne State Univ., Detroit, MI 48202. The inhibition of DA neuronal impulse flow has been

attributed to an enhancement of both the stimulation of somatodendritic (SD) dopamine (DA) autoreceptors by dendritically released DA and the activity of inhibitory feedback pathways which are activated by DA released from neuronal terminals in forebrain regions. In the present study standard extracellular electrophysiological techniques were used to examine the responses of antidromically identified nigrostriatal DA-containing (NSDA) neurons to amphetamine. NSDA neurons from both urethane and chloral hydrate anesthetized 2-week-old (postnatal day 14 or 15) rats were less sensitive to the inhibitory effects of cumulative i.v. amphetamine doses than similarly anethetized adults. These results confirm those of Trent et al. (Eur. J. Pharmacol. 204:265, 1991) using the i.p. route of administration. In the present study excitatory responses to i.v. amphetamine were also observed in 2-week-old rats but not in adults. Since SD DA autoreceptor sensitivity in 2-week-olds appears to be similar to that of adults (see Wang and Pitts, Soc. Neurosci. Abstr., 1992) these results suggest that the functional expression of feedback pathways and/or the dopamine transporter are not adult-like at this postnatal age. (Supported by MH-47857 [DKP]).

### 125.4

EFFECTS OF DOPAMINE ANTAGONIST ADMINISTRATION ON THE ACTIVITY OF MIDBRAIN DOPAMINE NEURONS RECORDED IN VITRO. M. L. Pucak\* and A. A. Grace. Depts. of Behavioral Neuroscience and Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA 15760

Stimulation of somatodendritic autoreceptors by dendritically released dopamine (DA) has been proposed to be an important mechanism regulating the activity of DA neurons in the substantia nigra. We have assessed 1) whether dendritically released DA modulates the activity of DA neurons in the *in vitro* slice preparation and 2) the mechanism of this regulation by examining the effect of blocking somatodendritic autoreceptors with DA antagonists. Intracellular recordings from DA neurons were performed in rat midbrain slices containing the substantia nigra. Administration of 10 µM haloperidol caused the input resistance to decrease by approximately 30% in most DA neurons tested. Haloperidol also depolarized the membrane potential by approximately 5 mV; this was associated with an increase in spontaneous firing rate and a 10-100% increase in the slope of the slow depolarization which precedes spontaneously generated action potentials. The amplitude of the afterhyperpolarization was decreased by 20-60% in most of the neurons. In addition, there was a small (10%) decrease in the amplitude of the action potentials. Thus, dendritically released DA does appear to regulate the activity of at least some DA neurons *in vitro*. The haloperidol-induced depolarization and associated membrane changes are consistent with the previously observed DA-induced hyperpolarization of DA neuron membrane potential; furthermore, the effects of haloperidol suggest that the actions of endogenous DA on DA neuron activity may be mediated by more than a single mechanism. ## 125 6

ELECTROPHYSIOLOGICAL RESPONSES OF MESENCEPHALIC DOPAMINE NEURONS TO DORSAL RAPHE STIMULATION. C. Rouillard\* and J. Gervais. Lab. of Neurobiology and Dept. of Pharmacology, Laval University, Quebec, Canada GIJ 1Z4.

University, Québec, Canada G1 11Z4.

Neuroanstomical data indicate that mesencephalic dopamine (DA) neurons receive a serotonergic (5-HT) input from the dorsal raphe (DR) nucleus and electron microscopic evidence have shown that a fair proportion of this 5-HT input is aimed at dendrites of DA neurons. Recent electrophysiological studies have suggest that the 5-HT input from the DR may act in a phasic rather than tonic manner to regulate presynaptic functions of DA neurons without affecting neuronal excitability as a whole. The present study was designed to examine the effects of dorsal raphe stimulation on the spontaneous activity of substantia nigra pars compacta (SNpc) and ventral tegmental area (VTA) DA neurons. Extracellular single unit recordings were performed in vivo on male Sprague Dawley rats, anesthetized with chloral hydrate. DA neurons in the SNpc and VTA were recorded using single barrel micropipettes and were identified by their location, waveform, firing rate and pattern. DR stimuli consisted of monophasic square wave pulses of 800 µA intensity and 350 µsec duration delivered at a rate of 0.5 Hz. Peristimulus time histograms were generated on line by cumulating 250 consecutive stimuli. Two different types of response were found both in SNpc and VTA. Some DA cells exhibited an inhibition-excitation sequence while in others DA neurons, the initial response was an excitation followed by a long lasting inhibition. In SNpc, 53,3% of the DA cells recorded were initially inhibited (latency: 23±8 msec; duration: 109±22 msec) and 33,3% of the DA neurons were initially excited (latency: 20±5 msec; duration: 80±31 msec). However, in VTA 56% of the DA cells recorded were initially excited (latency: 20±5 msec; duration: 80±31 msec). However, in VTA 56% of the DA cells recorded were initially excited (latency: 20±6 msec; duration: 75±11 msec) and 37% were initially excited (latency: 8±2 msec; duration: 75±11 msec) and 37% were initially inhibited (latency: 8±2 msec; duration: 75±11 msec). In some DA cells, DR

EFFECTS OF CRUS CEREBRI LESIONS AND LONG-TERM AMPHETAMINE TREATMENT ON PATTERNS OF SPONTANEOUS UNIT ACTIVITY OF NIGRAL DOPAMINERGIC NEURONS. B.A. Heidenreich\* and G.V. Rebec. Prog. Neural Science, Dept. Psychol., Indiana Univ., Bloomington, IN 47405.

The spontaneous activity of dopamine- (DA) containing neurons in the substantia nigra compacta (SNC) in vivo consists of irregular spikes and bursts of 2-10 spikes fired rapidly (Grace and Bunney, J. Neurosci., 4: 2877, 1984). Because disruption of feedback from forebrain target areas (Bunney and Aghajanian, Science, 192: 391, 1976) and chronic treatment with DA agonists (Kamata and Rebec, Neuropharmacology, 22: 1377, 1983) have marked effects on DA neurons, we examined the firing patterns of DA units in adult male rats after electrolytic lesions of the crus cerebri (CC) and repeated d-amphetamine (AMPH) administration. One week after surgery, rats received either 5.0 mg/kg AMPH or saline twice daily for 6 days. On the following day, single-unit activity of DA neurons was recorded in the SNC under urethane anesthesia. Firing patterns were analyzed off-line with a PC-based program (courtesy of Dr. L.A. Chiodo). Mean spontaneous firing rate was reduced by AMPH treatment (p<.05), but not CC lesions. With burst categorization added as a third factor, bursting cells had markedly faster firing rates (p<.01), but the effect of AMPH treatment was reduced to a non-significant trend (p=.13). Units from CC-lesioned animals showed a higher number of bursts during the period analyzed (p<.05). The number of bursts and the mean number of spikes/burst were significantly correlated with firing rate in all treatment groups except AMPH-treated shams. Taken together, these results demonstrate the complex influences on the rate and pattern of DA cell activity.

### 125.9

ELECTROPHYSIOLOGICAL EFFECTS OF DIPHENYLPYRAZOLIDINONE CCK-B AND CCK-A ANTAGONISTS ON A9 AND A10 DOPAMINE CELLS.

J. F. Czachura. J. J. Howbert\*. and K. Rasmussen. Lilly Research

Labs, Eli Lilly & Company, Indianapolis, IN 46285.

Chronic administration of antipsychotic drugs has been shown to decrease the number of spontaneously active dopamine (DA) cells in the ventrotegmental area (A10) and the substantia nigra (A9). The selective CCK-B antagonist LY262691 (a diphenylpyrazolidinone) has recently n demonstrated to decrease the number of spontaneously active A9 and A10 DA cells following acute administration. The present study evaluated the effects of structural analogs of LY262691 on the number of spontaneously active A9 and A10 DA cells using extracellular, singleunit recordings in the anesthetized rat. Three diphenylpyrazolidinone CCK-B antagonists (LY262684, LY242040, and LY191009) decreased the number of spontaneously active A9 and A10 DA cells. However, both an inactive analog (LY206890) and a CCK-A selective analog (LY219057) did not affect the number of spontaneously active A9 and A10 DA cells. In addition, L-365,260, a benzodiazepine CCK-B antagonist, also decreased the number of spontaneously active A10 cells. Unlike typical antipsychotics (e.g., haloperidol), which produce pronounced catalepsy, these compounds showed no cataleptogenic effects. These results indicate that the firing of A9 and A10 DA neurons is suppressed specifically by antagonism of CCK-B, but not CCK-A, receptors. CCK-B antagonists may therefore represent a novel class of antipsychotic drugs. Further, since CCK-B antagonists have no cataleptogenic effects, they may also have a reduced propensity for producing extra-pyramidal side effects. In addition, these actions on midbrain DA neurons may contribute to the known anxiolytic activity of CCK-B antagonists.

## 125.11

COMPARISON OF THE EFFECTS OF THE CCK-B RECEPTOR ANTAGONIST, PD 134308, AND THE CCK-A RECEPTOR ANTAGONIST, L-364,718, ON A9 AND A10 DOPAMINE NEURONAL ACTIVITY. C.L. Christoffersen, K.A. Serpa and L.T. Meltzer. Dept. of Pharmacology, Parke-Davis Pharm. Res. Div., Warner-Lambert Co., 2800 Plymouth Rd., Ann Arbor, MI 48105

Extracellular single-unit recording techniques were used to study the effects of selective CCK-A and CCK-B antagonists on the basal firing activity and apomorphine (APO)-induced inhibition of DA neurons in chloral hydrate anesthetized rats. Neither L-364,718 (CCK-A; 0.1-1.6 mg/kg i.v.) nor PD 134308 (CCK-B; 0.1-6.4 mg/kg) altered the basal firing rate of A9 or A10 DA neurons. Pretreatment with L-364,718 (0.6 or 6.4 mg/kg i.v.), produced dose-related, significant shifts to the right of the APO dose-response curve. However, these effects were small in comparison to the haloperidol (0.1 mg/kg i.p.)-induced shift of the APO curve. These data suggest that in the substantia nigra, there may be a tonic release of CCK, that, through actions on CCK-B receptors, may modulate DA agonist-induced inhibition of DA neuronal activity.

QUINAZOLINONE CCK-B ANTAGONISTS DECREASE THE NUMBER OF SPONTANEOUSLY ACTIVE DOPAMINE NEURONS. M. J. Yu\*, J. F. Czachura, M. E. Stockton, J. R. McCowan and K. Rasmussen. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

Cholecystokinin (CCK) has been shown to exist in a subpopulation of dopaminergic neurons in the ventral tegmental area (A10). These CCK-containing dopaminergic efferents project to limbic regions, in particular, the caudodorsomedial part of the nucleus accumbens. Although the functional relationship between CCK and dopamine is complex, these pathways may be associated with a number of neuropsychiatric disorders. Since CCK has potent excitatory effects on dopamine neurons and can potentiate dopamine mediated behaviors, CCK receptor antagonists may reduce midbrain dopaminergic hyperactivity associated with schizophrenia and thereby act as an antipsychotic agent. This study evaluated the effects of two structurally related and novel CCK-B antagonists, 2-[2-(1H-indol-3-yI)ethyI]-3-phenyI-4(3H)-quinazolinone (1) and a 5chloroindole derivative (2), on the number of spontaneously active midbrain dopamine neurons using extracellular, single-unit recordings in anesthetized rats. Acute intraperitoneal administration of either 1 or 2 decreased the number of spontaneously active A10 dopamine cells. Thus, in contrast to currently prescribed antipsychotic drugs, these compounds as CCK-B receptor antagonists may exhibit antipsychotic effects without a delayed onset of action.

### 125.10

LOCALIZATION OF RECEPTORS MEDIATING EFFECTS OF THE SELECTIVE CCK-B ANTAGONIST LY262691 ON A9 AND A10 DOPAMINE CELLS: LESION AND MICROINJECTION STUDIES M. E. Stockton, J. J. Howbert, and K. Rasmussen\*. Lilly Research Labs, Eli Lilly & Co., Indianapolis, IN 46285. Previous studies have shown that peripherally administered LY262691 (LY), a selective CCK-B antagonist, decreases the number of spontaneously active dopamine (DA) neurons in the substantia nigra (A9) and ventral tegmental area (A10) of rats. This study examined the localization of the receptors mediating the effects of LY on A9 and A10 cells. The number of spontaneously active A9 or A10 DA cells was determined using extracellular, single-unit recordings in anesthetized rats following either radio-frequency lesions or intracerebral microinjection of LY in: n. accumbens (NA), striatum (ST), or medial prefrontal cortex (PC). Lesions of the NA decreased by 75% (p<0.01) the inhibitory effects of LY (10mg/kg, i.p.) on A10, but not A9, DA cells. ST lesions decreased by 34% (p<0.05) the inhibitory effects of LY on A9, but not A10, DA cells. PC lesions completely blocked the effects of LY on A10 DA cells and decreased by 25% (p<0.05)

the inhibitory effects of LY on A9 DA cells. Microinjections of LY (1µg in 1µl) into the NA and PC decreased the number of spontaneously active A10 [by 54% (p<0.01) and 52% (p<0.01), respectively], but not A9, DA cells. Microinjections of LY into ST decreased the number of A9 (by 62%, p<0.01), but not A10, DA cells. Vehicle control injections had no effect on the number of spontaneously active DA cells. These data indicate that, consistent with known feedback pathways between forebrain structures and midbrain DA neurons, the effects of LY262691 on A9 and A10 DA cells are mediated, at least in part, by actions on CCK-B receptors located in the ST and PC/NA, respectively.

CHOLECYSTOKININ (CCK) B-TYPE RECEPTOR ANTAGONIST

CHOLECYSTOKININ (CCK) B-TYPE RECEPTOR ANTAGONIST ATTENUATES STRESS-INDUCED INCREASES IN DOPAMINE (DA) METABOLISM IN RAT FRONTAL CORTEX IN VIVO.

M. Marien\*, S. Tacconi, L. Romanelli, G. Gaviraghi and E. Ratti. Glaxo Res. Labs., Verona, Italy.
Activation of the mesocortical DA pathway has been suggested to be a neurochemical correlate of stress and anxiety, since stressors (eg. immobilization) or anxiogenic agents (eg. the benzodiazepine receptor inverse agonist FG7142) preferentially augment DA release and metabolism (DOPAC levels) in the rat prefrontal cortex (PFC) and tially augment DA release and metabolism (DOPAC levels) in the rat prefrontal cortex (PFC) and amygdala (AMYG) in vivo. We have used this biochemical index to evaluate the effect of PDI34308, a selective CCK-B receptor antagonist which has non-sedating anxiolytic effects in animal models of anxiety. FG7142 (30 mg/kg i.p.) increased levels of DOPAC in microdialysates from the DEC of conscious rate by up to 75%: preincreased levels of DOPAC in microdialysates from the PFC of conscious rats by up to 75%; pretreatment with PD134308 (1 mg/kg i.p.) 2h prior to FG7142 attenuated this effect to 39%. Physical restraint of rats for 20 min increased ex vivo tissue DOPAC:DA ratios in the PFC and AMYG by 75% and 67%, respectively; PD134308 reduced these changes to 23% and 15%. Results confirm a stressinduced activation of DA metabolism in the rat PFC and AMYG, demonstrate a suppression of this effect by a CCK-B antagonist, and suggest that some anxiolytic properties of these agents might involve modulation of the mesocortical DA system.

ELECTROPHYSIOLOGICAL AND PHARMACOLOGICAL PROPERTIES OF MIDBRAIN DOPAMINE NEURONS IN CULTURE CORRESPOND TO THEIR PROPERTIES REPORTED IN VIVO. D.L. Cardozo\*

Department of Neurobiology, and Program in Neuroscience, Harvard Medical School, Boston, MA 02115.

Midbrain neurons have been dissected from neonatal rat pups and maintained in dissociated cell culture for several months. The dopaminergic (DA) phenotype was confirmed by catecholamine fluorescence and by tyrosine hydroxylase immunocytochemistry Recordings have been made from over 70 DA neurons identified for electrohysiology by 5,7-DHT fluorescence. The neurons had the following properties: (1) Resting potential:  $-52 \pm 5$  mV; (2) Action potential amplitude:  $66 \pm 12$  mV; (3) Action potential duration:  $2.9 \pm 10$ 1.3 ms; (4) 50% of neurons displayed pacemaker-like activity with a spontaneous firing frequency of 2.3  $\pm$  1.3 Hz; (6) 65% of neurons displayed anomalous rectification; (7) 38% of neurons displayed bursting activity, typically having 2-6 action potentials per burst; (8) 90% of neurons expressed the D2 receptor, (9) 100% of neurons had glutamate and GABA receptors. Application of the neuroleptic haloperidol significantly increased the duration of the action potential in DA neurons. The pharmacology and physiological mechanism of the action of haloperidol is currently under investigation. COOPERATIVE D1:D2 RECEPTOR INVOLVEMENT IN DOPAMINERGIC MODULATION OF GLUTAMATE'S EXCITATORY EFFECT ON STRIATAL NEURONS IN VIVO. X.-T. Hu\* and F.J. White. Dept. Psychiatry, Wayne St. Univ. Sch. of Med., Detroit, MI 48207

In addition to the often noted inhibitory effect of iontophoretic dopamine (DA) on striatal neurons, this transmitter can also potentiate the excitatory effect of glutamate. The specific DA receptor subtypes involved in this modulatory effect have not been established. In the present study, extracellular single cell recording and microiontophoresis were used to investigate this issue. At low ejection currents (1-8 nA), DA facilitated glutamate-evoked activity of quiescent striatal neurons and also enhanced the firing of spontaneously discharging cells. This effect of DA was mimicked by both the selective D1 agonist SKF 38393 and the selective D2 agonist quinpirole as well as by the (Na<sup>+</sup>-K<sup>+</sup>)ATPase inhibitor ouabain. In contrast, high currents (≥ 16 nA) of these compounds suppressed the firing of striatal neurons. The DA receptor antagonist haloperidol blocked either the excitatory or inhibitory effects of DA, but not of ouabain. Although acute depletion of DA produced by combined treatment with reserpine and the DA synthesis inhibitor α-methyl-ptyrosine failed to alter the excitatory effects of DA or ouabain, it completely abolished similar effects of both SKF 38393 and quinpirole. Coadministration of SKF 38393 and quinpirole restored the excitatory response in acutely depleted rats. These findings indicate that the ability of DA to modulate the excitatory response of striatal neurons to glutamate requires both D1 and D2 receptor stimulation. Moreover, the similarity of this effect to that produced by ouabain suggests the possibility that inhibition of (Na<sup>+</sup>-K<sup>+</sup>)ATPase activity may be involved in the effect (Bertorello et al., Nature 347:386, 1990). Supported by USPHS Grants MH 40832 and DA 04093 to FJW.

## 125.17

EFFECTS OF LIGANDS FOR PCP AND SIGMA RECEPTORS ON NMDA-EXCITATION OF A9 DA NEURONDS. <u>J. Zhang\* and A. S. Freeman.</u> Cellular and Clinical Neurobiology Program, Department of Psychiatry, Wayne State University School of Medicine, Detroit, MI.

Electrophysiological studies in chloral hydrate-anesthetized rats assessed the effects of six sigma and/or PCP receptor ligands on microiontophoretic N-methyl-D-aspartate (NMDA)-induced activation of substantia nigra pars compacta (A9) dopaminergic (DA) neurons. I.V. administration of the selective sigma ligands DTG (cumulative doses of 0.02-2.22 mg/kg) and (+)-pentazocine (0.04-12.44 mg/kg) did not after the stimulatory effects of NMDA. The nonselective sigma ligand BMY 14802 (0.04-4.44 mg/kg) increased A9 DA neuronal firing rate as previously reported, but did not affect NMDA-induced stimulation. Co-iontophoresis of BMY 14802 with NMDA also did not after the response to NMDA. In contrast, the selective PCP receptor ligand, (+)-MK-801 (0.02-2.2 mg/kg), and the mixed PCP receptor/sigma receptor ligands, PCP (0.05-4.55 mg/kg) and (+)-SKF 10047 (0.05-12.55 mg/kg), dose-dependently blocked the NMDA-activation with an order of potency ((+)-MK-801 > PCP > (+)-SKF 10047) consistent with the affinities of these drugs for the PCP receptor. Co-iontophoresis of (+)-MK-801 or PCP with NMDA also blocked the response to NMDA.

In conclusion, sigma receptor occupation does not appear to modulate the NMDA-induced activation of A9 DA neurons. The antagonism of NMDA produced by PCP and (+)-SKF 10047 is likely due to the noncompetitive NMDA antagonist properties of these drugs that are due to PCP receptor occupation. (Supported by DA07844.)

IN VITRO ELECTROPHYSIOLOGICAL PROPERTIES OF SOMA-TO-TERMINAL DOPAMINE NEURONS IN EXPLANT CORES OF RAT NIGROSTRIATAL AND MESOLIMBIC PROJECTIONS. M.D. Davis\* and Melinda Hyde. Neuroscience Section, Parke-Davis Pharmaceutical Research Division, Warner-Lambert Company, 2800 Plymouth Road, Ann Arbor, MI 48105.

Research Division, warner-Lambert Company, 2800 Plymouth Road, Ann Arbor, MI 48105.

Electrophysiological measurements of dopamine neurons have been studied in vitro for some time now. However, past studies have been limited for the most part to recordings made from cell bodies in tissue slices of the substantia nigra pars compacta (A9) and ventral tegmental nucleus (A10) regions where all their axons have been severed. In this investigation, we report on measurements obtained from whole dopamine cells using a novel explant technique.

Male, 14-21 day old rats were decapitated, their brains removed and the intact nigrostriatal or mesolimbic projection "cored" out using a sharpened cannula. The resulting cylinder of tissue was perifused with media in vitro and standard extracellular electrophysiological tests applied. In successful explants, putative A9/A10 dopamine neurons were antidromically activated by stimulating electrodes placed in the terminal regions (striatum or accumbens). The dopamine D2 agonist LY171555 depressed, while neurotensin elevated the firing rate of these neurons.

## 125.16

EFFECTS OF PCP, MK-801 AND DTG ON RAT MIDBRAIN NON-DOPAMINERGIC NEURONS.

A.S. Freeman\* and J. Zhang. Cellular and Clinical Neurobiology Program, Department of Psychiatry, Wayne State University School of Medicine, Detroit, MI.

Low i.v. doses of phencyclidine (PCP) stimulate the firing rate of midbrain DA neurons. This response has been attributed to occupation of the "PCP receptor" which results in the noncompetitive blockade of the NMDA subtype of glutamate receptor. The selective noncompetitive NMDA antagonist, MK-801, also excites DA neurons. Blockade of excitatory glutamatergic inputs to DA neurons would, however, be expected to decrease not increase DA cell firing. The current experiments begin to test the hypothesis that the excitatory effects of noncompetitive NMDA antagonists on DA neuronal firing rate are due to disinhibition resulting from blockade of NMDA receptors on DA cell afterents.

As reported previously, substantia nigra pars reticulata (SNPR) neurons in chloral hydrate-anesthetized rats were either excited {P(+)} on the excited {P(+)} by tail-pinch. P(+) cells are putative GABAergic interneurons that inhibit DA neurons. PCP (1-8 mg/kg, i.v.) and MK-801 (0.1-3.2 mg/kg, i.v.) inhibited the spontaneous activity of P(+) SNPR neurons but excited or had no effect on P(-) SNPR neurons. Lower doses of these drugs were inactive. The sigma/sigma\_ligand, DTG (0.125-2 mg/kg, i.v.) did not significantly alter the firing rate of either type of SNPR neuron. The doses of MK-801, in particular, that inhibited P(+) SNPR neurons correlate well with doses known to stimulate the firing rate of nigrostriatal DA neurons. These results suggest that the excitatory effects of noncompetitive NMDA antagonists on DA cell firing rate are at least partly due to disinhibition as the result of inhibition of non-DA interneurons. (Supported by DA07844.)

## 125 18

EFFECTS OF ETHANOL ON EXCITATORY AMINO ACID-EVOKED ELECTROPHYSIOLOGICAL ACTIVITY OF NUCLEUS ACCUMBENS NEURONS. R. Shen\*, A.S. Freeman and L.A. Chiodo. Cellular and Clinical Neurobiology Program, Department of Psychiatry, Wayne State University, School of Medicine, Detroit, MI.

Recent evidence indicates that acute and chronic ethanol administration may alter neuronal activities by modifying the functions of the *N*-methyl-*D*-aspartate (NMDA) receptor. In the present study, we utilized *in vivo* extracellular single-unit recording techniques to investigate the effects of acute ethanol administration on the electrophysiological activity evoked by agonists of the NMDA receptor and the other two major excitatory amino acid (EEA) receptors, the α-amino-3-hydroxy-5-methyl-4-isoxazole propionate (AMPA) receptor and the kainate receptor. The agonists were administered microiontophoretically to nucleus accumbens neurons in chloral hydrate- or urethane-anesthetized rats. Ethanol (40% w/v) was administered intravenously in cumulative doses of 0.125 g - 2.0 g/kg. Ethanol exhibited a dose-dependent inhibitory effect on the neuronal discharge evoked by all three EEA receptor agonists. At lower doses (0.125-0.5 g/kg) a transient excitation was regularly observed following the initial inhibition. Ethanol also showed a greater potency in inhibiting the electrophysiological activity evoked by AMPA than the activity evoked by kainate and NMDA. Experiments to study the interactions between selective EEA antagonists and ethanol are currently in progress.

These findings indicate that acute ethanol administration produces a general

These findings indicate that acute ethanol administration produces a general inhibitory effect on the EEA receptor-stimulated electrophysiological activity of nucleus accumbens neurons. [MH41557, DA07844]

IN VIVO EFFECTS OF INTRAPALLIDAL MORPHINE MICROINJECTIONS AS STUDIED BY BRAIN MICRODIALYSIS AND LOCOMOTOR ACTIVITY ANALYSIS.

Y.E. Anagnostakis and C. Spyraki\*. Lab. of Pharmacology, Medical School, University of Crete, P.O. Box 1393, Heraklion, GR.

University of Crete, P.O. Box 1393, Heraklion, GR.

Injections of morphine into different parts of the globus pallidus (GP), are associated with increases in locomotion, as we showed in earlier studies. The present study was designed to determine if the observed changes in locomotion are (a) mediated by opiate receptors, and (b) correlated with DA and its metabolites concentrations in the nucleus accumbens and striatum. In the first series of experiments, male Sprague-Dawley rats were treated with subcutaneous injections of 1 mg/kg naloxone or vehicle 10 min before the intrapallidal (dorsal, medial, ventral) administration of morphine (7.5 µg/05µl/site) and tested for locomotion. Blockade of opiate receptors with naloxone resulted in an inhibition of the effect of morphine on locomotion. In the second series of experiments microdialysis probes (2.3 or 4.0 mm) were implanted unilaterally in the nucleus accumbens (NAC), or antero-medial striatum, or antero-lateral striatum of male Sprague-Dawley rats. Microinjections of morphine were made through microdialysis probes which were implanted in ventral pallidum (VP) (10 µl of 0.2, 4.0, 13, 26 mM) or dorsal GP (10 µl of 26 mM). Samples were collected every 45 min (flow rate: 0.75 µl/min) over 3 and 6 hrs before and after challenging rats with morphine respectively. Dopamine (DA) and metabolites (DOPAC, HVA) were determined in NAC and striatal dialysates using HPLC-EC coupled. We have found that (a) Morphine microinjections in VP are associated with dose dependent increases in the concentration of DOPAC and HVA in NAC, (b) Morphine microinjections in VP are associated with dose dependent increases in the concentrations in antero-medial striatum. These findings provide evidence that the increases in locomotor activity observed following intrapallidal morphine microinjections are mediated through opiate receptors and associated mainly with an enhancement of DA overflow in NAC rather than in the striatum.

### 126.3

DIFFERENTIAL BEHAVIORAL INTERACTIONS BETWEEN DOPAMINE DI/DZ AGONISTS AND N.METHYL.D.ASPARTATE ANTAGONISTS IN MONOAMINE-DEPLETED MICE. M.L. Carlsson\*, A. Svensson and A. Carlsson. Department of Pharmacology, University of Göteborg, Medicinaregatan 7, S-413 90 Göteborg, Sweden.

Previous work in our laboratory has shown that the noncompetitive N-methyl-D-aspartate (NMDA) antagonist MK-801 (dizocilpine) interacts synergistically with the mixed dopamine (DA) receptor agonist apomorphine to promote locomotion in an animal model of Parkinson's disease (monoamine-depleted mice). The purpose of the present study was to investigate the relative importance of DA D1 receptors compared to DA D2 receptor in this interaction. To that end, MK-801 was given in combination with either the DA D1 receptor agonist SKF 38393, or the DA D2 receptor agonist quinpirole or the preferential DA D2 agonist promocriptine. Locomotor stimulation was generally more pronounced if MK-801 was combined with a DA D1 receptor agonist than with a DA D2 receptor agonist, although baseline dopaminergic activity seems to be an important role of the nucleus accumbens in generating the locomotor response.

important role of the nucleus accumbens in generating the locomotor response.

Moreover, the effects on rotation following a unilateral injection of the competitive NMDA antagonist AP-5 into the nucleus accumbens in situations with varying dopaminergic tone were studied. AP-5 was found to induce contralateral rotation in monoamine-depleted mice when given alone or in combination with a systemic injection of SKF-38393. In contrast in intact mice, as well as in monoamine-depleted mice receiving quinpirole systemically, AP-5 induced predominantly ipsilateral rotation.

The results will be discussed in relation to 1) what is known about the cellular distribution of DA D1 and DA D2 receptors in the (ventral) striatum 2) the anatomy and function of the so-called direct and indirect pathways projecting from the striatum to the thalamus.

DIRECT CATECHOLAMINE INHIBITION OF ENKEPHALINASE. F.C. Westall\* and M.S. Graige. Institute for Disease Research, P.O. Box 890193, Temecula, CA 92589-0193

and Dept. Chem., Calif. State Poly. University, Pomona, CA. Root-Bernstein and Westall (Brain Res. Bull. 12, 425, 1984; ibid. 17, 519, 1986; ibid. 18, 509, 1987; ibid. 25, 827, 1990, ibid. 25, 827, 817, 1990; Endogenous Sleep Factors, Inoue and Krueger, eds. p289, 1990) have shown the possibility that many drugs, hormones, neurotransmitters, and their metabolities can interact directly. In this study we examine the effect of dopamine and norepinephrine binding to met-enkephalin on the hydrolysis of the peptide by enkephalinase. Using paper chromatographic techniques, we find that as the concentration of dopamine or norepinephrine increases the ability of enkephalinase to digest met-enkephalin drops. Furthermore, chromatography easily shows that the catecholamines bind met-enkephalin. As was also shown previously using spectral techniques, this binding is quite specific. Therefore, we have found that not only catecholamines will bind met-enkephalin, but that this will occur in the presence of an enzyme which in vivo utilizes enkephalin. The actions of enkephalinase  $\overline{\text{and several}}$ peptidases are considered the prime processes for inactivating the enkephalins. Our results suggest that binding of enkephalin to the catecholamines acts as a second mechanism in enkephalin inactivation.

CHOLECYSTOKININ POTENTIATES MORPHINE ANTICONVULSANT

CHOLECYSTOKININ POTENTIATES MORPHINE ANTICONVULSANT ACTION THROUGH BOTH BRAIN CCK-A AND CCK-B RECEPTORS. A. Legido, M. W. Adler, C. Karkanias, E. B. Geller\*, J. I. Greenstein and W. D. Grover. Temple Univ. Sch. of Med., Dept. of Pediatrics, Pharmacology and Neurology & Merck Res. Lab., Philadelphia, PA 19140

The role of cholecystokinin (CCK) in epileptogenesis is unclear. Exogenously applied to the hippocampus CCK evokes a marked increase in neuronal excitability, but an anticonvulsant effect has also been suggested atter subcutaneous (sc) or intracerebroventricular (icv) CCK administration. The anticonvulsant action of opioids (e.g., morphine) has been well documented in the past. CCK interacts with morphine (M) in the regulation of some physiologic functions; e.g., CCK blocks opiate analgesia. However, the possible interaction of CCK and M in epileptogenesis is unknown. We studied the effect of sc M and icv administered CCK catapeptide sulphate ester (CCK-3-SE), and CCK-4 (MK 329) and CCK-B (L 365260) receptor antagonists (Ant) (M. rck Lab.) on seizures induced by maximal electroshock (MES). Male Sprague-Dawley rats weighing 250-300 gm were used in all experiments (N=7-34). CCK-8-SE (100 ng), CCK-A Ant (9 µg) and CCK-B and CCK-B (CK-B and CCK-B infusion, through electrode-gel coated ear clip electrodes by a high induced, 30 min after M administration and 10 min after CCK-8-SE, CCK-A and CCK-B infusion, through electrode-gel coated ear clip electrodes by a high voltage, high internal resistance constant current generator (50 mA for 200 msec). The % change (%C) of the tonic component (TC) from the mean of the TC from controls (C) was (mean±SE): -3.6±5.7 for CCK (NS =not significant from C), 21.7±2.1 for M (p<0.001 vs. C), 45.2±7.7 for M+CCK (p<0.01 vs. M), 20.8±3.4 for M+CCK+CCK-A Ant (NS vs. M), and 14.0±1.8 for M+CCK+CCK-B Ant (NS vs. M). The %C of the TC after icv administration of CCK-A and CCK-B Ant alone was not significant: -5.4±5.5 and -7.5±3.5, respectively. We conclude that CCK potentiates the antinconvulsant action of M through both brain CCK A and B receptors. #### 126.4

DETERMINATION OF MONOAMINES IN HUMAN CEREBRAL SPINAL FLUID (C.S.F.) AFTER FLUNITRAZEPAM (FLU) AND HYDROXYZINE (HYD) ADMINISTRATION

B. Delbarre\*, V. Lacore, G. Delbarre, F. Calinon and G. Leroy. Faculté de Médecine and Dept Anesth, C.H.U., 37000, Tours,

Recently, the study of various actions of benzodiazepines (BZDs) highlighted the role of noradrenergic and serotoninergic system. To elucidate this role in human we have determined levels of monoamines in C.S.F. after administration of drugs mostly used in pretreatment of rachianesthesia : benzodiazepine (FLU 0.01mg.kg-1 i.v.) or HYD (1.5mg.kg-1 Per Os), a sedative antihistaminic agent. FLU was administered 10 min. and HYD 60 min. before lumbar puncture (L3-L4) for rachianesthesia.

(ng.ml-1) Control (n=15) BZD (n=11) Hydroxyzine (n=6) MHPG 60.78±4.93 21.47±4.10\*\*\* 51.25±8.81 NS 5-HIAA 18.12±1.56 7.62±1.41 \*\*\* 20.48±2.34 NS 3.15±1.92 \*\* HVA 29.66±3.52 45.27± 7.28 \* (Unpaired Stutent t test -p<0.05 \* - p<0.01\*\* - p<0.001\*\*\*). These results, in accordance with animal pharmacological data, demonstrate that Flunitrazepam interferes with metabolism of serotonin, dopamine and norepinephrine, while hydroxyzine only significantly increases homovanillic acid.

## 126.6

ATIPAMEZOLE, A SELECTIVE ALPHA2-ANTAGONIST, INC-REASES NORADRENALINE AND HISTAMINE RELEASE IN THE RAT HYPOTHALAMUS. K. Laitinen, L. Tuomisto, E. MacDonald. Dept Pharmacol and Toxicol, Univ Kuopio, 70211-Kuopio, Finland. Recent studies suggest that histamine (HA)

release in the hypothalamus is modulated by  $\alpha_2$ -adrenoceptors located on histaminergic neurons. Noradrenaline (NA) release is primarily regulated by presynaptic  $\alpha_2$ -autoreceptors. We used in vivo microdialysis to examine the effects of the selective  $\alpha_2$ -adrenergic antagonist, atipamezole (ATI) on HA and NA release in the hypothalamus. Rats were anesthetized and microdialysis probe was implanted into the medial hypothalamus. ATI was given either via the probe  $(50~\mu\mathrm{M})$  or s.c.  $(1~\mathrm{mg/kg})$ . NA and HA in the dialysate were analyzed HPLC methods. Basal levels of NA and HA were by HPLC methods. Basal levels of NA and HA were 83±7 and 53±7 fmol/30 min, respectively. ATI, through the microdialysis probe and s.c. injection, increased NA release up to about 250 % of the control values, reaching max effect at 90 min after drug administration. ATI injection (s.c.) had no effect on basal HA release, but ATI infusion (1 h) via probe into the hypothalamus increased HA release and returned to the basal level at 120 min. The results suggest that there is a potential interaction between histaminergic and noradrenergic neurones in the hypothalamus. and noradrenergic neurones in the hypothalamus.

#### 126 7

EFFECTS OF PHENCYCLIDINE AND (+)MK801 ON CEREBRAL SUBSTANCE P CONTENT IN THE RAT. Y.Shirayama, H.Mitsushio, T.Nishikawa and K.Takahashi\*. Div. Mental Disorder Res., Natl. Inst. Neurosci., NCNP, Tokyo, Japan.

The effects of a schizophrenominetic drug, phencyclidine (PCP), on substance P contents have been investigated

The effects of a schizophrenominetic drug, phencyclidine (PCP), on substance P contents have been investigated in the discrete brain areas of the rat. To this end, a simple and sensitive enzyme-immunoassay for substance P has been developed. An acute administration of PCP (10 mg/kg, intraperitioneally (i.p.)), which is a non-competitive antagonist of N-methyl-D-aspartate (NMDA) typed excitatory amino acid (EAA) receptor, reduced the concentration of the peptide in the prefrontal cortex, limbic forebrain (nucleus accumbens, septum, olfactory tubercule, etc.), striatum and substantia nigra, but not in the ventral tegmental area, 60 min thereafter. PCP no longer diminished substance P content in these areas at 120 min postinjection. A selective non-competitive NMDA antagonist, (+)MK801 (1 mg/kg, i.p.) also caused a decrease in substance P content in the prefrontal cortex and limbic forebrain, but failed to alter the contents in the striatum, substantia nigra and ventral tegmental area, 30 min later. There was no change in the peptide concentration 60 min following i.p. injection of (+)MK801. The present results suggest that EAAergic transmission might be involved in the regulation of substance Pergic systems in the prefrontal cortex and limbic forebrain.

### 126.9

SEROTONIN MANIPULATIONS ALTER LEVELS OF mRNA CODING FOR THYROTROPIN-RELEASING HORMONE IN MEDULLARY RAPHE NEURONS LA. Riley\* Dept. Biol. Sci., Rutgers Univ., Newark, NJ 07102. Thyrotropin-releasing hormone (TRH) and substance P (SP) are

Thyrotropin-releasing hormone (TRH) and substance P (SP) are colocalized with serotonin (5-HT) in neurons of the medullary raphe. To begin to understand the role and regulation of multiple neurotransmitters housed within individual neurons, we have sought to determine whether changes in serotonin levels alter the biosynthesis of the colocalized neuropeptides. Previously we showed that pharmacological manipulations of serotonin alter levels of mRNA coding for the prohormone precursor of SP (PPT; Walker et al., Mol. Brain Res., 1990; Riley et al., Mol. Cell. Neurosci., 1991).

In general, pharmacological manipulations of serotonin altered levels of TRH mRNA like that of PPT mRNA. Decreases in serotonin following a one week constant infusion of the serotonin synthesis inhibitor pCPA led to a 117% (p<0.001) increase in TRH mRNA. Increases in local serotonin induced by a 5 day treatment with the serotonin selective reuptake blocker zimelidine decreased TRH mRNA 69% (p<0.001).

However, in several respects PPT and TRH responded differently to changes in serotonin neurotransmission. After 14 days of zimelidine treatment, levels of TRH mRNA were still 66% (p<0.001) below control, while in the same animals, PPT mRNA levels recovered. PPT mRNA levels were decreased 38% (p<0.02) 1 day after treatment with 0.2 mg/kg of 8-OH-DPAT, but TRH mRNA levels were unchanged. Finally, levels of TRH but not PPT mRNA were increased 50% after a 5 day treatment with 2 mg/kg/day 8-OH-DPAT. While TRH and PPT react similarily to changes in serotonergic neurotransmission these differences suggest differential mechanisms may be involved. Supported by the Tourette Syndrome Assoc.

## 126.11

PURINERGIC MODULATION OF GLUTAMATE LEVELS IN THE NUCLEUS TRACTUS SOLITARII. C.L. Beck\*, M. Appalsamy, D. Robertson and R. Mosqueda-Garcia. Dept. of Pharmacology, Vanderbilt University, Nashville, TN 37232.

Adenosine (Ado) generally has been considered an inhibitory neuromodulator. Recent work from our lab, however, has challenged this concept. We showed that Ado has excitatory cardiovascular effects in the nucleus tractus solitarii (NTS) which are associated with selective increases in glutamate (Glu) levels. In this study we further characterize the effect of Ado on Glu levels. Male New Zealand white rabbits (3-4kg) were anesthetized with sodium thiopental and urethane. A carotid artery and jugular vein were cannulated for recording of blood pressure and heart rate. A tracheostomy tube was placed for airway patency. The rabbits were placed in a stereotaxic frame and following a partial occipital craniotomy, a microdialysis probe (CMA-11, BAS) was implanted into the right NTS. Basal levels of Glu were obtained over a 2 hour resting period (saline perfusion; 5  $\mu$ l/min.) followed by perfusion of increasing concentrations of Ado ( $10^4$  to  $10^2$ M) or the  $A_3$  selective agonist CGS 21680 (4.5x10 $^3$ M). At the end of the study, the brains were removed and fixed for histological confirmation of probe location. Samples were analyzed for free amino acids by HPLC.

| μМ  | Basal   | Ado<br>10⁴M | Ado<br>10 <sup>-3</sup> M | Ado<br>10 <sup>-2</sup> M | CGS<br>4.5x10 <sup>-3</sup> M |
|-----|---------|-------------|---------------------------|---------------------------|-------------------------------|
| Glu | 1.5±0.1 | 4.5±2.6     | 13.9±3.4                  | 63.6±37.2                 | 2.3±0.4                       |
| n   | 3       | 3           | 3                         | 3                         | 8                             |

Purinergic substances in the NTS increase Glu levels in a dose-dependent manner. This effect, however, could involve more than A<sub>2</sub> receptor activation.

COMPARISON OF EXCITATORY-AMINO-ACID RECEPTOR AGONIST RESPONSES IN CULTURED CEREBELLAR PURKINJE NEURONS. E.A. Fox\* and D.L. Gruol. The Scripps Res. Inst., La Jolla, CA, 92037.

We previously reported that corticotropin-releasing-factor (CRF) modulates Quisqualate (Quis) responses in rat cerebellar Purkinje neurons (PNs; Neurosci. Abst. 16:521, 1990). As a first step toward determining whether CRF interacts with the ionotropic or the metabotropic excitatory amino acid receptor subtypes activated by Quis, we are characterizing the responses of PNs to selective agonists using extracellular recordings. AMPA (10μM) and (1S,3R)-1-aminocyclopentane-1,3,-dicarboxylic acid (ACPD; 100μM) were used to activate the ionotropic and metabotropic receptor subtypes, respectively, and Quis (1μM) was used to activate both.

Micropressure application (50-200 ms) of Quis, AMPA, or an AMPA+ACPD mixture produced characteristic and repeatable biphasic responses (excitatory phase followed by inhibitory phase). In contrast, 300-900 ms applications were required to elicit biphasic ACPD responses and repeated applications often produced variable responses. Some characteristics of the biphasic response were agonist-dependent. These included: (1) The duration of the excitatory phase was 2.5-fold greater for Quis than for AMPA or AMPA+ACPD. (2) The duration of the inhibitory phase for AMPA+ACPD was 20% shorter than for Quis or AMPA, (3) Quis produced a higher firing rate during the inhibitory phase than did AMPA, ACPD or AMPA+ACPD. (4) Both Quis and AMPA produced more bursting during the excitatory phase than AMPA. Co-application of ACPD with AMPA slightly increased this bursting relative to AMPA alone but it was still much less than that produced by Quis or ACPD. The interaction of CRF with these responses is under investigation. Supported by NS21777 and AA0756.

GLYCINE MODULATES ENHANCEMENT OF NMDA RESPONSE BY SOMATOSTATIN IN VAGAL MOTONEURONS D. Bieger\* M. Zhang. Y.T. Wang and R.S. Neuman. Faculty of Medicine, Memorial University of Newfoundland, St. John's, Newfoundland, Canada A1B 3V6.

NMDA receptors contribute to the fast rising phase of EPSPs in neurons of the nucleus ambiguus compact formation (AMB<sub>c</sub>), synaptically driven spike production in these neurons being dependent on NMDA receptor activity (1). Recently we have shown that exogenous SST augments NMDA-induced depolarization and endogenous somatostatin (SST) is required for the expression of NMDA receptor activity during the EPSP (submitted). Here we report that glycine inhibits the permissive action of SST

Intracellular recordings of EPSPs and responses to pressure-ejected or bath-applied test substances were obtained from sagittal slices of rat medulla containing the AMB<sub>c</sub> and the solitario-ambigual pathway (SAP). Bath-applied glycine (100 $\mu$ M) had little effect on AMB<sub>c</sub> depolarizing responses to NMDA (0.5-1.0pmol) pulses delivered by pressure-ejection; however, in the presence of glycine, SST (0.1pmol) failed to augment the NMDA response. SAP-driven EPSPs in AMB<sub>c</sub> neurons were inhibited by glycine both in the presence and absence of strychnine (1-50 $\mu$ M). This effect was abolished by depletion of SST with cysteamine (100-200 $\mu$ M).

In conclusion, our data provide evidence for modulation of the NMDA channel by a novel mechanism involving an interaction between glycine and SST. Supported by MRC (Canada).

## 126.12

THE EFFECTS OF DYNORPHIN A(1-13) ON GLUTAMATE AND SYNAPTIC RESPONSES OF RAT SPINAL DORSAL HORN NEURONS. M. Kolaj, R. Cerne, M.C. Jiang, T.H. Lanthorn and M. Randic. Dept. Vet. Physiol. Pharmacol. Iowa State University, Ames, IA 50011 and Neurological Diseases Research, G.D. Seate & Co., Skokie, IL 60077.

The effects of dynorphin A(1-13) on inward currents induced by excitatory amino acids (EAA) and the evoked excitatory synaptic potentials (EPSPs) we studied in dorsal horn (DH) neurons of young rats using whole-cell voltage-clamp and intracellular recording techniques. When the freshly isolated DH cells were clamped to -60mV, application of 1-10 nM dynorphin A(1-13) reversibly enhanced the peak amplitude of the initial transient component of the glutamate-induced current in about 60% of the examined cells. With 0.1-10µM dynorphin A(1-13), the reduction of the glutamate response was seen. In addition, 1-50 nM dynorphin A(1-13) potentiated the initial peak N-methyl-D-aspartate (NMDA) current by  $176.4 \pm 17.2\%$  in 8 of 10 tested cells and reduced it when  $0.5-10\mu M$  of the peptide was used. The enhancing effect was absent in 2 cells pre-treated with norbinaltorphimine, a kappa receptor antagonist. Both, a small increase  $(128.2 \pm 13.7\%, n=6)$  and a decrease  $(90.7 \pm 1.6\%, n=4)$  in the transient component of a-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA)induced current was seen with dynorphin A(1-13). The enhancing effect was frequently preceded by a transient depression of the responses to glutamate, NMDA and AMPA. In a transverse slice preparation, electrical stimulation of a dorsal root evoked EPSPs in the substantia gelatinosa neurons that were sensitive to NBQX. We found that 1-10  $\mu{\rm M}$  dynorphin A(1-13) reduced or completely abolished the fast EPSPs in 4/4 tested cells. These results are consistent with the possibility that the activation of kappa opioid receptors may contribute to the regulation of the strength of EAA-mediated primary afferents neurotransmission, including nociception (Supported by BNS 8418042 and Searle CNS Research).

TRANSIENT TRANSLOCATION OF PKC BY HIPPOCAMPAL SLICE PREPARATION Helen Valsamis, Maria Naik, and Todd C. Sacktor\* (SUNY-HSC at Brooklyn, NY, 11203)

In order to characterize the effect of hippocampal slice preparation on protein kinase C, a time course was determined for the subcellular distribution of PKC following dissection and placement in a recording chamber. Each of the 8 known PKC isozymes was identified by Western blot using affinity-purified carboxy-terminal antibodies, which recognized the proteins at their reported molecular weights. With the PKCζ antibody, an additional band was noted at 51 kDa, which may be the isozyme's catalytic fragment. All isozymes translocated to membrane, corresponding to activation, 15-30 min after hippocampal slice preparation. The membraneassociated level of each isozyme then declined to a stable baseline, with the exception of PKC $\zeta$ 51, which in some experiments continued to rise. The concerted activation of PKC isozymes may be due to the trauma of slice preparation with concomitant release of neurotransmitters. Slice preparation may activate a sequence of molecular steps similar to that which occurs following synaptic activation by tetanus. In addition, PKC\(\zeta\)51 may play a special role in longterm synaptic modulation (Osten and Sacktor, this volume).

## 127.3

CHARACTERIZATION OF HIPPOCAMPAL PROTEIN KINASE C ISOZYMES

CHARACTERIZATION OF HIPPOCAMPAL PROTEIN KINASE C ISOZYMES IN DBA/2 AND C57BL/6 MICE. B.J. Bowers. C.L. Parham, J.M. Sikela and J.M. Wehner. Instit. for Behavioral Genetics, Univer. of Colorado, Boulder, CO 80309. We have previously shown that DBA/2 and C57BL/6 strains of mice differ in performance on the Morris water task. A genetic analysis of 11 B x D recombinant inbred strains indicates that performance of the spatial task is correlated with hippocampal protein kinase C (PKC) activity. The PKC enzyme is composed of a family of isozymes. Differences in PKC activity between C57BL and DBA mice may originate from variations in the isozymes at the molecular level. In order to examine possible molecular differences we have begun a characterization of three PKC isozymes,  $\alpha$ ,  $\beta$ -, and  $\gamma$ -PKC in DBA and C57BL hippocampus. Gene expression was evaluated by Northern analysis. Both strains of mice expressed the three isozymes, indicating that the difference in PKC activity is not due to a missing isozyme(s). Western blots measuring  $\alpha$ -,  $\beta$ -, and  $\gamma$ -PKC protein expression in hippocampus confirmed that the proteins are also expressed in both strains of mice. In order to compare primary gene and amino acid sequences, we have isolated clones for the  $\alpha$ -,  $\beta_{17}$ -, and  $\gamma$ -isozymes from C57BL and DBA brain cDNA libraries, provided by David Burt (Dept. Pharm., Univ. of Maryland, Sch. Med.). A comparison of a full length C57BL cDNA clone and partial length (90%) DBA cDNA clone of the  $\gamma$ -PKC isozyme indicates no differences in amino acid sequences between the strains. Future sequence comparisons of the remaining isozymes as well as quantitative characterizations of PKC isozymic gene and protein expression may reveal differences in PKC activity. Supported by RSDA AA-000141 and NSF BNS 8820076.

PROTEIN KINASE C β IS ABSENT IN HUMAN GLIOMA CELL LINES. N.P. Dooley\*, J.G. Villemure and V.W. Yong. Neuroimmunology Unit, Montreal Neurological Institute, Montreal, Quebec, CANADA, H3A

Investigations in our laboratory have shown that the total protein kinase C (PKC) enzyme activity in both malignant and non-malignant human glia positively correlates with their rate of proliferation. As well, the PKC enzyme activity in glioma cell lines was found to be significantly greater than that in both non-transformed fetal and adult astrocytes.

To date, nine isoforms of PKC have been identified of which seven are highly enriched in the central nervous system. In order to determine whether both malignant and non-malignant human glia express the same isoforms of PKC, oligonucleotide primers specific for the group one isoforms of PKC  $(\alpha, \beta_1, \beta_2 \text{ and } \gamma)$  were employed in a reverse transcriptase - polymerase chain reaction (RT-PCR). Total RNA was isolated from cultured cells using a modified guanidinium thiocyanate-phenol-chloroform protocol. Adult human astrocytes, oligodendrocytes, and microglia as well as fetal human astrocytes were found to express PKC  $\alpha$  but not PKC  $\gamma$ . Glioma lines (A172, U251, U373, U178) with growth rates ranging from fast to slow, exhibited this same pattern of PKC expression. However, unlike non-transformed glia, the glioma cell lines did not express RNA for either PKC  $\beta_1$  or PKC  $\beta_2$ . This finding is of particular interest since astrocytes, which do express PKC  $\beta$ , are believed to be the antecedents of glioma cells. Given that recent studies in colon cancer cell lines have indicated a role for PKC  $\beta_1$  in tumor suppression (Choi et al., Mol Cell Biol 10, 1990), we believe that the absence of PKC  $\beta$  in glioma cell lines may underlie their abnormally high rate of proliferation.

EVIDENCE FOR A NEW ISOFORM OF PKC SPECIFIC TO RAT BRAIN. Elizabeth Sublette\*, Maria Naik, Xiaolan Jiang, and Todd C. Sacktor (SUNY-HSC at Brooklyn, NY)
Protein kinase C is a gene family of isozymes important

in signal transduction and which, in brain, participates in the regulation of synaptic strength. The PKC gene family is divided into two groups: "conventional" cPKC's, regulated by both Ca<sup>2+</sup> and lipid second messengers, and 'novel", activated only by the latter. All known isozymes are present in the rat hippocampus. In addition, antibodies toward the carboxy-terminus of the relatively lung-specific isoform  $nPKC\eta$  (generous gift from Dr. Shin-ichi Osada, Yokohama, Japan) detect on Western blot a protein of molecular weight higher than that of the known PKC's, including nPKCn from lung. This hippocampal protein does not cross-react with antisera made toward the aminoterminus of nPKCn. Nonetheless, the protein translocates to membrane following applications of phorbol esters to hippocampal slices. The protein is detectable by Western blot in most areas of the brain but not in other tissues of the rat. Since this protein contains a phorbol-ester binding site and cross-reacts with an antibody made largely to the conserved catalytic domain of nPKCn, we believe that it may be either alternatively spliced nPKCn or a new isozyme.

## 127.4

Purification and Characterization of Two Forms of Protein Kinase C runn-cation and Characterizagon of two Forms of Protein Kinase C  $\epsilon$  From Rat Brain. F. L. Huang, K. Osada, and H. Nakabayashi, NICHD, NIH, Bethesda, MD 20892

From Rat Brain. F. L. Huang, K. Osada, and H. Nakabayashi, MICHD, NIH, Bethesda, MD 20892

Protein kinase C (PKC)  $\epsilon$  was purified to near homogeneity from rat brain by column chromatography on DEAE-cellulose, phenyl-Sepharose, Sephacryl S-200, polylysine-agarose, Mono Q and hydroxyapatite. In the initial three steps PKC  $\epsilon$  was copurified with other PKCs ( $\alpha$ ,  $\beta$  and  $\gamma$ ) and was separated from them on polylysine-agarose. Subsequently on Mono Q, PKC  $\epsilon$  was separated into two activity peaks, eluted at 0.2 and 0.4M KCl (designated  $\epsilon$ , and  $\epsilon$ <sub>2</sub> respectively) and both exhibited immunoreactivities toward  $\epsilon$ -specific antibodies at 94-96 kDa.  $\epsilon$ <sub>2</sub> is pure at this step, and  $\epsilon$ <sub>1</sub> was further purified on hydroxyapatite. Using myelin basic protein or peptide (MBP4-14) as substrate,  $\epsilon$ <sub>1</sub> displayed absolute requirement of PS and DG but not  $C_2^{A\pm}$  in the absence of NP40, however,  $C_2^{A\pm}$  was also required in the presence of detergent. In contrast,  $\epsilon$ <sub>2</sub> while showing no proteolysis, was active in the absence of any activator with or without NP40, and PS and DG were only slightly stimulatory.  $\epsilon$ <sub>1</sub> could be phosphorylated when incubated with PS/DG, ATP/Mg, and  $C_2^{A\pm}$ , as evidenced by autoradiography after SDS/PAGE and mobility change in immunoblot analysis. This incubation also gradually converted  $\epsilon$ <sub>1</sub> from activator-dependent into -independent enzyme similar mobility change in immunoblot analysis. This incubation also gradually converted  $\epsilon_1$  from activator-dependent into -independent enzyme similar to that of  $\epsilon_2$  without detectable proteolysis. Furthermore, this conversion of  $\epsilon_1$  to  $\epsilon_T$ -like activity also occurred in the absence of ATP, suggesting that phosphorylation of the enzyme is not important for such conversion. However, this process absolutely required  $Ca^2$  in addition to PS/DG, even though autophosphorylation occurred in the absence of  $Ca^{2+}$ . It appears that PKC  $\epsilon$  may exist as an inactive form of enzyme like  $\epsilon_2$  which is spontaneously active even in the absence of activator. It is possible such a conversion and activation of PKC  $\epsilon$  occurs physiologically during agonist-mediated signal transduction. agonist-mediated signal transduction.

EFFECT OF CARBACHOL ON PROTEIN PHOSPHORYLATION PRODUCED BY PKC IN HIPPOCAMPAL NEURONS. V. Alemán, B. Osorio .Dept. of Physiology, CINVESTAV, IPN, Mexico City, POB14-740 CP07000 Neuronal fractions from cultures were immediately prepared Neuronal fractions from cultures were immediately prepared in presence of 10 mM ZnCl<sub>2</sub> and 1.0 mM PMSF. Protein samples of 70ug from each fraction were placed in 3MM Whatman Discs dried and treated by Mans and Novelli's method. Quadruplica te samples of 300,150 and 100 Ug of protein from cell homogenates, synaptosomal or nuclear fractions in the presence of Krebs-Hepes buffer pH 7.4 and of 60nM of (3H)-PDBu in a final volume of 600 Ul were incubated at 37°C for 40 min. Samples filtered in GF/B discs pretreated with 0.4% polyethylenimine. Thus, carbachol in hippocammal plasma membrane thylenimine. Thus, carbachol in hippocampal plasma membrane fractions from neuronal cultures, in a dosis response manner produced first a 40% increase of PKC density and then returned to basal values. A dosis-response curve in the  $P_2$  fraction, carbachol produced a maximal increase of about 300%. In the nuclear fraction, carbachol produced a significant decrease of 35%. A decrease of 35% is induced in hippocampal cells nuclei, from rats injected with 0.085mg/kg of car bachol. Carbachol produced significant increase of protein phosphorylation in both the synaptosomal (20%) and cytoplas mic fraction (12%), but an important decrease in thenuclear fraction (-60%). In nuclear subfractions carbachol produced a decrease in the chromatine subfraction of 25%, a smaller decrease in the nuclear membrane (11%) and an increase in the nucleoplasm (12%). These PKC changes were significantly reverted for synaptosomal, cytoplasmic and the nuclear fraction by 20 mM polymyxin B.

ETHANOL ACTIVATES PROTEIN KINASE C (PKC) IN CULTURED BOVINE ADRENAL MEDULLARY (BAM) CHROMAFFIN CELLS. R.K.Tuominen, S.Lustig, P.T.Männistö and M.Viluksela. Dept. of Pharmacology and Toxicology, Univ. of Helsinki, SF-00170 Helsinki, Finland.

Effect of ethanol on PKC-activity in primary cultured BAM cells was studied. The cells were dissociated by using a retrograde collagenase digestion and purified by a renografin gradient. The cells were used after growing for 2 days in fetal calf serum (10%) supplemented and for one day in serum free DME/F12 medium. Phosphorylation of calf thymus histone in vitro was used to measure PKC activities of soluble and particulate protein exstracts. Continuous incubation of BAM cells with ethanol increased particulate PKC activity at 30 min and at 24 hrs. The effect of ethanol was concentration dependent (0 - 200 mM). Time-course study showed a biphasic effect of ethanol (300 mM) on BAM cell PKC activity; a significant activation at 1 and 3 min, no effect at 10 min and a significant activation at 30 min. These results suggest a role for PKC in the signal transduction of the effects of ethanol in BAM cells. The biphasic effect may indicate different mechanisms of activation of PKC during the shortand long-term exposures to ethanol.

NEUROTRANSMITTERS AND CALCIUM STIMULATE EXOGENOUS PHOSPHOINOSITIDE HYDROLYSIS BY PHOSPHOLIPASE C IN HUMAN BRAIN MEMBRANES. F.T. Grews. P. Kurian and G. Freund'. Departments of Pharmacology and Medicine', University of Florida College of Medicine, Gainesville, FL 32610-0267.

Agonist stimulated phosphoinositide (PPI) hydrolysis is a major signal transduction pathway in brain. Previous studies have shown that muscarinic and serotonergic receptors activate PLC in membranes incubated with a mixture of [3H]PdIns (87 %), [3H]PdIns (87 %), [3H]PdIns (49) [10.4 %) and [3H]PdIns(4,5)P (2.6%) which is comparable to that found in intact tissue. To determine if postmortem delay and other factors associated with obtaining human brains would disrupt receptor - PLC coupling, rat brain membranes were prepared from fresh, brains incubated for 4 hours at 24°C and then frozen and brains incubated at 24°C for 4 hours and then at 4°C for 24 hours. All three preparations showed similar receptor simulation of PLC suggesting that human postmortem tissue may be reliably studied for differences in receptor - PLC coupling. The time course for GTP-6 and GTP-76 carbachol stimulated PPI hydrolysis by human brain membranes (frontal cortex) was linear for at least 20 min. GTP-75 stimulated [3H]InsP formation was enhanced by carbachol (232 %) and 5-HT (147%). There was no effect of carbachol in the absence of GTP-78 and atropine prevented carbachol enhancement of PPI hydrolysis. The EC50 for carbachol was approximately 8 µM. SAX-HPLC separation of [3H]inositol polyphosphates indicated that the major isomer of InsP3 was Ins(1,4,5)P3, the expected product of PtdIns(4,5)P2, hydrolysis. No Ins(1,3,4,5)P4 was formed in this assay. Two isomers of InsP1 were formed, Ins(1)P1 and Ins(4)P1. These isomers could be formed by direct hydrolysis of [3H]PtdIns substrate and/or phosphatase activity within our membrane preparation [Ins(1)P1 rom PtdIns and Ins(4)P1 from PtdIns(4)P2 and PtdIns(4,5)P2]. Ca++ increased PP1 hydrolysis progressively from 100 nM thro

## 127.11

SUBCELLULAR DISTRIBUTION AND GLUTAMATE-STIMULATED PHOSPHORYLATION OF MARCKS AND A NOVEL 48 KDA PROTEIN IN DEVELOPING CULTURED HIPPOCAMPAL PYRAMIDAL NEURONS. W, K, Scholz\* and H. C. Palfrey. University of Chicago, Dept Pharmacol./Physiol. Sci.,

Glutamate stimulation of cutured rat hippocampal pyramidal neurons results in the rapid transient phosphorylation of 3 PKC substrates (Scholz and Palfrey, 1991; J. Neurosci. 11, 2422). The 3 phosphoproteins are very acidic (p1 4-5), of 48, 87 and 120 kDa. The 87 kDa protein has been indentified as myristoylated alanine-rich C kinase substrate (MARCKS). The 48 kDa protein is related to MARCKS by virtue of its very similar isoelectric point, elution from a mono-Q column, phosphopeptide of its very similar isoelectric point, elution from a mono-Q column, phosphopeptide fingerprint, and time course of phosphorylation/dephosphorylation following glutamate stimulation, but could be distinguished from MARCKS by its failure to react with a polyclonal anti-MARCKS antibody and lack of expression in the adult brain. The 48 kDa phosphoprotein is not GAP-43. To assess the subcellular distribution of these proteins, cells were prelabeled with 32P, stimulated with glutamate and neuronal proteins were separated into cytosolic, membrane bound and cytoskeletal bound fractions by sequential extraction of cultures with digitonin, triton-X-100 and SDS-sample buffer. Following glutamate stimulation there is an immediate increase in 32P-labeled 87 and 48 kDa in cytosolic fractions. The subcellular distribution of MARCKS and the 48 kDa protein was also examined during development of cultured neuron. In neurons cultured for 2 days, at a stage. during development of cultured neurons. In neurons cultured for 2 days, at a stage when growth cones are most prevalent, these phosphoproteins are found in membranes. bound and cytosolic fractions. At 2 wks in culture, after most process outgrowth has been completed, MARCKS and the 48 kDa phosphoprotein are found predominantly in membrane and cytoskeletal bound fractions with very little in cytosolic fractions. Immunostaining of pyramidal neurons with antibodies recognizing MARCKS shows intense staining of growth cones in neurons cultured for 2-3 days, and cell soma, processes and some growth cones of older neurons. These results suggest that the subcellular distribution of both MARCKS and the 48 kDa protein shifts from primarily cytosolic to membrane/cytoskeletal association during development.

PHORBOL 12-MYRISTATE-13-ACETATE ATTENUATES GABA-MEDIATED INHIBITION IN THE HIPPOCAMPUS. R. Mora and S. Springfield\*. Dept. of Biology, City College of New York, NY 10031.

This investigation examined the effect of a protein kinase C (PKC) activator, phorbol 12-myristate-13-acetate (PMA), on GABA-mediated inhibition in the hippocampal slice. PMA is able to activate PKC by the state of the protein the mimicking the action of the second messenger, diacylglycerol (DAG). Previous studies in this laboratory have shown that serotonin attenuates GABA-mediated inhibition. Ultimately, we wish to determine if PKC plays a role in the neuromodulatory action of

serotonin.

Hippocampal slices (350-400 µm) were obtained from adult male Sprague-Dawley rats weighing 150-300 g. Slices were constantly superfused with a bicarbonate-buffered balanced salt solution and aerated with 95%O2/5%CO2. After a 1 hr equilibration period, twin stimuli (0.2-3.0 msec; 1-10 V; 1/60 Hz) of interstimulus intervals of 5 to 15 msec were applied to the stratum radiatum at the border of the CA1-CA2 region. Extracellular recordings were taken from the CA1 pyramidal cell layer. Local inhibition occurred when the amplitude of the test (second) population spike was smaller than the conditioning (first) spike. This reduction in the amplitude of the test spike is attributed to the action of a GABA-mediated inhibition superimposed upon orthodromic excitation. superimposed upon orthodromic excitation

Application of a hydrophobic phorbol ester, PMA (10<sup>-4</sup>-10<sup>-7</sup> M) resulted in a significant decrease in GABA-mediated inhibition resulted in a significant decrease in GADA-mediated inhibition (n=33). This result may indicate an increase in the excitability of hippocampal pyramidal cells. Experiments are now in progress using structurally analogous synthetic compounds of DAG and a hydrophilic phorbol ester to further explore a possible neuromodulatory mechanism of serotonin involving PKC. (Supported by NSF 860641 and NIH/NIGMS GM 08168.)

MUSCARINIC RECEPTOR-MEDIATED INCREASE IN ZETA-PKC EXPRESSION. J. Baumgold and K.D. Dyer. Dept. of Radiology, George Washington Univ., Washington, DC 20037

The PKC family of enzymes include at least 8 isotypes, each with a discrete structure, tissue distributions, calcium and lipid sensitivity. ζ-PKC is insensitive to calcium and lacks one of the two zinc fingers necessary for phorbol ester and DAG activation, thus raising questions regarding its physiological function. To address this, we used antipeptide antibodies to each PKC isotype to study receptor-mediated activation of PKC isozymes in SK-N-SH human neuroblastoma cells. Western blot analysis of these cells revealed that they express only the  $\alpha$ -PKC and  $\zeta$ -PKC isozymes. As expected, stimulation of these cells with PMA (1  $\mu$ M, 10 min) caused the α-PKC but not ζ-PKC to translocate from a cytosolic to a particulate fraction. Stimulation of these cells with 0.5 mM carbachol or with 10 µM bradykinin elicited PIP<sub>2</sub> hydrolysis and a small, transient translocation of α-Suprisingly, stimulation of these cells with either carbachol or bradykinin also induced a several-fold increase in immunoreactive ζ-PKC, most of which remained in the cytosolic fraction. The amount of ζ-PKC increased over time and was maximal after a 60 min carbachol stimulation, and gradually decreased thereafter. This response was blocked by atropine. In order to determine whether this increase was the result of increased protein synthesis, we pre-treated SK-N-SH cells with 1 µM cycloheximide and found that this pre-treatment prevented the carbachol-mediated increase in ζ-PKC. These findings demonstrate that stimulation of muscarinic and of bradykinin receptors induce increased synthesis of ζ-PKC by a mechanism that is calcium and DAG-independent.

# 127.12

Protein Phosphorylation by Protein kinase C in Rat Hippocampus: Effect of Cis-fatty Acid and Diacylglycerol. S.G. Chen and K. Murakami\*, Department of Biochemical Pharmacology, SUNY-Buffalo, Buffalo, NY 14260 Protein phosphorylation has been indicated to play an important role in the regulation of synaptic plasticity. It has been shown that cisfatty acid (CFA) activates protein kinase C (PKC) either independently of or in concert with diacylglycerol (DAG). We have recently shown that rat brain PKC, particularly type III (a) PKC, can be synergistically activated by CFA and DAG in the presence of phosphatidylserine (Biochem. J. 282:33-39,1992). The synergism can also be supported by phosphatidylcholine, a neutral lipid, but inducing a different activation state of PKC (Biochem. J. 284:221-226,1992). These indicate that both CFA and DAG can act as second messengers for PKC activation and that the different activation state may lead to selective protein phosphorylation. In order to examine whether synergistic PKC activation mode is of physiological relevance, we studied the effect of CFA and DAG on protein phosphorylation in rat hippocampus. We have found that at least three hippocampal proteins are responsive to the synergistic activation of type III PKC by CFA and DAG in vitro. Further studies using intact hippocampal slices showed that phosphorylation state of the two of those proteins can be altered by the treatment with CFA. These results suggest that synergistic mode of PKC activation is operative in hippocampus.

SPHINGOSINE AND PSYCHOSINE ALTER PHOSPHOINOSITIDE HYDROLYSIS IN CULTURED ASTROCYTES. <u>T. Ritchie\*</u>, A. Rosenberg and <u>E.P. Noble</u>. Neuropsychiatric Institute, Univ. California, Los Angeles,

The effects of sphingosine and psychosine on phosphoinositide (PI) hydrolysis in primary cultured astrocytes were investigated. Astrocytes prelabeled for 24 hrs with  $^3H$ —inositol were incubated with sphingosine for 1 hr. PI hydrolysis was measured subsequently by incubating the intact cells with 10 mM Li $^+$  for 30 min at 37 $^9$ C and isolating the generated inositol phosphates. Exposure to sphingosine produced a dose-dependent stimulation of PI hydrolysis requiring the presence of external Ca $^{2+}$  for optimal activity. The addition of 10  $\mu$ M norepinephrine (NE) resulted in a stimulation additional to that with sphingosine. The  $\alpha_1$ -antagonist prazosin completely inhibited NE-induced PI hydrolysis but had no effect on that produced by sphingosine. Psychosine (50  $\mu$ g/ml), when co-incubated with sphingosine, produced complete inhibition of sphingosine-induced PI hydrolysis at all doses of sphingosine tested (10–200  $\mu$ g/ml). Likewise, psychosine totally inhibited NE-induced PI hydrolysis. The protein kinase C inhibitor staurosporine (1  $\mu$ M) had no effect on sphingosine-induced PI hydrolysis. Taken together, these findings suggest that lysosphingolipids such as sphingosine and psychosine may play an important role in the regulation of PI turnover in astrocytes by a mechanism dependent on extracellular Ca $^{2+}$  and independent of the  $\alpha_1$ -adrenergic receptor and protein kinase C. (Supported by grant AA 07653.)

## 127.15

PURIFIED 14-3-3 PROTEIN FROM BOVINE BRAIN ACTIVATES BOTH TYROSINE HYDROXYLASE AND PROTEIN KINASE C. R. Horwitz, M. Tanji, and J. C. Waymire\*. The University of Texas Medical School, Houston, TX, 77030

14-3-3 protein, a soluble acidic protein present in high concentrations in the brain, is believed to function in monoamine biosynthesis through its capacity to activate tyrosine hydroxylase and tryptophan hydroxylase in the presence of phosphorylation by  ${\rm Ca}^{2+}/{\rm calmodulin-dependent}$  protein kinase II (Ichimura, T., et al.FEBS Letters 219, 79-82 (1987)). Moreover, Toker, A., et al. Eur. J. Biochem. 191, 421-429 (1990) suggest that 14-3-3 protein also inhibits protein kinase C.

In the present study, protein bovine 14-3-3 was purified from forebrain by assessing the presence of 14-3-3 with an antibody that cross-reacts with 14-3-3 protein (gift of Dr. G.C. Rosenfeld, Department of Pharmacology, U. Texas Med School, Houston, TX). The purified protein was estimated to be homogeneous as judged by native gradient-gel electrophoresis with a  $\rm M_{T}$  of 50,000. The subunit composition on SDS-PAGE revealed a pattern,  $\rm M_{T}$  32,000, 30,000, and 29,000, similar to that previously reported for 14-3-3. Although the purified bovine 14-3-3 activates purified bovine adrenal tyrosine hydroxylase in the presence of  $\rm Ca^{2+}/calmodulin-dependent$  phosphorylation, it activates, rather than inhibits, protein kinase C. Moreover, the concentration dependence of the activity of 14-3-3 was the same for the activation of tyrosine hydroxylase and protein kinase C, and is the same as that previously reported to inhibit protein kinase C. Supported by USPHS NS 11061.

CHARACTERIZATION OF HIPPOCAMPAL PHORBOL ESTER BINDING DIFFERENCES BETWEEN C57BL/6 AND DBA/2 MICE. <u>B. Paylor, J.R. Pauly, and J.M. Wehner.</u> Institute for Behavioral Genetics, University of Colorado, Boulder, 80309.

The present study was designed to characterize differences in C57BL/6 and DBA/2 brain protein kinase C (PKC) activity which have previously been shown to be important for spatial learning performance. Using quantitative autoradiography, we observed that C57BL/6 mice had higher levels of [3H]PDBu binding compared to DBA/2 mice in CA regions of the hippocampus and the substantia nigra. Filtration receptor binding experiments on hippocampal homogenates indicated that C57BL/6 mice have higher levels of [3H]PDBu binding in particulate, but not cytosolic fractions. To determine if the strain difference in hippocampal [3H]PDBu binding is simply quantitative, or if there are also qualitative differences in the binding protein, heat denatuarion experiments at 43° C using Bmax concentrations of PDBu showed that over time both C57BL/6 and DBA/2 mice [3H]PDBu binding decreased. Although there appeared to be no overall difference in the rate of denaturation between the two strains, C57BL/6 tissue appeared to lose more binding sites in the first minute of exposure to heat than DBA/2 tissue. C57BL/6 mice showed a significant decrease in both the Bmax and Kd values when saturation analyses were performed at 33.5° C compared to at 22° C. Bmax and Kd values were not different in DBA/2 tissue at the two temperatures. Finally, we examined the development the hippocampal PKC activity differences between C57BL/6 and DBA/2 mice may be due to decreased amount of the PKC protein as measured by [3H]PDBu binding sites emerged around 24 days of age. These results suggest that hippocampal PKC activity differences between C57BL/6 and DBA/2 mice may be due to decreased amount of the PKC protein as measured by [3H]PDBu binding that appear before adulthood. This strain may result from a difference in both the quantitative as well as the qualitative nature of the PKC protein. Supported by NSF BNS 8820076.

PHORBOL ESTER-INDUCED REGULATION OF THE MYRISTOYLATED ALANINE RICH C KINASE SUBSTRATE (MARCKS) IN IMMORTALIZED HIPPOCAMPAL CELLS IN CULTURE. D.G. Watson B.H. Wainer and R.H. Lenox B. Molecular Neuropharmacol, Dept Psychiatry, Univ Vermont Coll Med Burlington, VT 05405 & Dept Pathol & Pharm/Physiol, Univ Chicago Chicago, IL 60637.

We have previously reported that chronic lithium admin-

We have previously reported that chronic lithium administration results in a marked reduction in a major protein kinase C (PKC) substrate (MARCKS) in rat hippocampus (Lenox et al, Brain Res 570:1991). In an effort to better understand the mechanism of action of lithium we have initiated studies to examine the regulation of PKC and MARCKS in an immortalized line of mouse hippocampal cells (HN33) characterized for neuronal properties (Lee et al, J. Neurosci 10:1990). These cells were shown to possess muscarinic receptors using [3H]NMS binding and could be further differentiated in the presence of 10µM retinoic acid. Western Blot analysis with MARCKS antibody (J. Patel, ICI) was used to identify the major (80kDa) phosphoprotein substrate of PKC in this cell line. Exposure of the HN33 cells to the phorbol ester, PDBu (1µM), for 12 to 24 hrs. revealed a progressive reduction of MARCKS in the soluble fraction. These findings are similar to recent data demonstrating a phorbol ester induced down regulation of MARCKS in non-neuronal cell populations (Brooks et al, EMBO J 10:1991; Otsuka and Yang BBRC 178:1991). Ongoing studies are examining the action of lithium on MARCKS in these hippocampal cells and the possible role that PKC plays in its mechanism of action in the brain. IMMUNOLOCALIZATION OF PROTEIN KINASE C-delta IN PARASAGITTAL BANDS OF THE CEREBELLAR CORTEX. <u>5. Chen\* R. Bing. T.T. Aung. and D.E. Hillman</u>, Department of Physiology and Biophysics, New York University Medical Center, New York, NY 10016.

Biophysics, New York University Medical Center, New York, NY 10016.

Protein kinase C (PKC) is a key phosphorylation enzyme in signal transduction. So far, eight isozymes have been isolated (α, βl, βll, γ, δ, ε, ζ & η) and are encoded by different genes. Using commercially available antibodies (GIBCO-BRL, Gaithersburg, MD), we found that α,γ, & ζ labeled Purkinje cells uniformly while the δ isozyme labeled groups of Purkinje cells as parasagittal bands. Beta and ε did not label Purkinje cells at all. Variable-width bands of Purkinje cell somas and their dendrites were interspersed with negative zones in the caudal vermis of coronal sections. The hemispheres had lighter bands while the floccular and parafloccular lobules were quite uniformly intense. In addition, interneurons in the molecular layer exhibited regional variations which were reciprocal to that of Purkinje cells. Strong labelling of Purkinje cells somas lacked basket axonal plexuses, in contrast to the negative Purkinje somas, which were cupped by intense basket staining. Parasagittal compartments in the cerebellar cortex have been found, previously, by AchE, B1, motilin, cytochrome oxidase, zebrin, 5' nucleotidase, GAD and taurine, and have been attributed to grouping of terminal fields for climbing or mossy fibers. Additionally, compartmentalization of PKC δ isozyme could be due to: 1) function-related signal-transduction, or 2) genetic coded proteins of neurons and glia. EFFECT OF PROTEIN KINASE C(PKC) ON CYCLIC AMP ACCUMULATION IN RAT BRAIN SLICES AND PC12 CELLS. N. W. DeLapp\*, C. A. Luttman and R. D. Saunders. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, Ind 46285.

Phorbol ester activation of PKC augments or in-

Phorbol ester activation of PKC augments or inhibits receptor-mediated increases in cAMP. A recent report showed that PKC activation reduced (controls-PKCa) or augmented(PKCYtransfected) cAMP levels in NIH 3T3 cells(Gusofsky et. al., Mol Pharm 39: 124, 1991). This study explored the suggestion that PKCY may augment cAMP increases in brain slices and PC12 cells.

cAMP was determined in 3H-adenine prelabeled brain slices and in PC12 cells using an ELISA. Phorbol dibutyrate(PDBu) augmented 2-chloroadenosine(2CA)-stimulated cAMP accumulation equally in adult and neonatal rat cortex slices although neonatal levels of PKCYare low(Yoshida et. al., JBC 263: 7868, 1988). PDBu reduced 2CA and forskolin-stimulated cAMP increases in PC12 cells in contrast to the findings of Gusofsky et. al. Immunoblots of PC12 extracts showed the  $\alpha$  and  $\gamma$  isoforms. These results indicate that PKC  $\gamma$  augmentation of cAMP responses may depend upon the cell type in which the  $\gamma$  isoform is expressed.

TUBULIN MODIFIES NEURONAL SIGNAL TRANSDUCTION THROUGH THE ASSOCIATION WITH G PROTEINS IN RAT CEREBRAL CORTEX AND STRIATUM. S. HATTA\*, N. AMEMIYA, H. OHSHIKA, T. SAITO, AND H. OZAWA. Depts. of Pharmacology and Neuropsychiatry, Sapporo Med. Coll., Sapporo 060, Japan.

Tubulin dimers, when polymerized with GppNHp (tubulin-GppNHp) or azidoanilido GTP (AAGTP) (tubulin-AAGTP), have been shown to form a complex with and transfer guanine nucleotide to  $\text{Gi}_{\alpha}$  or  $\text{Gs}_{\alpha}$  thereby regulate adenylate cyclase (AC). The present study examines effects of tubulin on the regulation of receptor affinity for its agonist via nucleotide transfer from tubulin to  $\mathrm{Gi}\,\alpha$  or  $\mathrm{Gs}\,\alpha$ . Addition of the tubulin-[ $^{32}$ P]AAGTP to rat cerebral cortex membranes resulted in incorporation of [ $^{32}$ P]AAGTP into Gia, indicating transfer of AAGTP from tubulin to Gia. Similar experiments with striatal membranes showed the transfer of  $[^{32}P]AAGTP$  from tubulin to Gia and Gsa. To ascertain whether tubulin-GppNHp would affect agonist binding affinity, we examined the isoproterenol competition of  $[^3H]$ CGP12177 binding in cerebral cortex membranes and the dopamine competition of  $[^3H]$ spiperone memoranes and the dopamine competition of [4]spiperone binding in striatal membranes. Tubulin-GppNHp decreased agonist binding affinities for the  $\beta$ -adrenergic receptor and the dopamine  $D_2$ -receptor (i.e., right shifted the agonist competition curves) with potency similar to that of GppNHp. These results suggest that tubulin participates in the regulation of receptor affinity by transferring guanine nucleotide to Gi and Gs.

A NOVEL IN VITRO ASSAY FOR PHOSPHOLIPASE D ACTIVITY. J. Horwitz\* and L. L.Davis. Dept. of Pharmacology, Medical College of Pennsylvania, Philadelphia, PA 19129.

Neurotransmitters activate a phospholipase D that is thought to specifically hydrolyze phosphatidylcholine. This enzyme has a unique property called transphosphatidylation; in the presence of an appropriate nucleophilic receptor such as alcohol, phospholipase D will catalyze the production of phosphatidylalcohol. We have studied phospholipase D using an in vitro assay that uses high specific activity [<sup>3</sup>H]butanol (15 Ci/mmol) as an acceptor. In the presence of [<sup>3</sup>H]butanol and phosphatidylcholine, a microsomal membrane fraction from rat brain catalyzed the production of phosphatidyl[3H]butanol. Phospholipase D catalyzed the production of phosphatidyll H butanol. Phosphotipase D activity was dependent upon a detergent. At a phosphatidylcholine concentration of 2.5 mM the optimal sodium oleate concentration was between 4 and 6 mM. The Rf of the phosphatidyll H butanol on thin-layer chromatography was identical to the Rf of the phosphatidylbutanol formed when [3H]phosphatidylcholine was incubated with 100 mM butanol. These data confirm the identity of phosphatidyl[3H]butanol. This assay has two important advantages. It is not necessary to add high concentrations of alcohol that may affect the regulation of the enzyme The other advantage is that the substrate does not need to be labeled. Microsomal membranes were found to catalyze the production of phosphatidyl[3H]butanol from all four phospholipid classes. These data suggest that under appropriate conditions brain phospholipase D is not specific for phosphatidylcholine. This assay should be useful in the Alcoholic Beverage Medical Research Foundation and NIA-AG00532)

## PAIN PATHWAYS: HYPERALGESIA

### 128.1

CUTANEOUS INJECTION OF THE CAPSAICIN ANALOG, NE-21610, PRODUCES ANALGESIA TO HEAT BUT NOT MECHANICAL STIMULI IN MAN. K.D. Davis', R.A. Meyer, J.L. Turnquist, M. Pappagallo, T.G. Filloon', and J.N. Campbell, Johns Hopkins Univ., Baltimore, MD 21205 and 'Procter & Gamble Co., Cincinnati, OH 45329.

The present study examined the effects of the capsaicin analogue, NE-21610, on heat and mechanical sensation in human volunteers. In the first series of experiments, subjects received intradermal (ID) injections (30 µl) of the drug (0, 0.3, 3.0, 10 µg) in ascending order into different sites on the volar forearm. Subjects were randomly assigned to one of three protocols to examine drug-evoked pain (n=8), or drug-induced alterations in sensitivity to mechanical (n=8) or heat (n=8) stimuli. In a subsequent study, subjects (n=8) rated sensations evoked by mechanical and heat stimuli before and after subcutaneous (SC) injections (300 µl) of the drug (0, 100 µg). The peak pain (rated by means of a visual-analog scale) occurred at the time of injection, was of short duration, and was similar for vehicle and the highest drug dose. A dose-related algesic effect of NE-21610 was detected by summing the pain ratings for the 10 minutes after injection. Von Frey thresholds for detection, sharpness, and pain at the injection site (measured 24 hr after injection) were not significantly altered by either ID or SC drug administration. However, pain to stepped heat stimuli (ranging from 40 to 48°C, 1 s) was reduced in a dose-dependent fashion for both types of injection. At the highest doses (10 µg ID and 100 µg SC), analgesia to heat stimuli was still present one week after injection. This dissociated loss of heat but not mechanical pain-sensibility may be due to: 1) a selective action of the drug on heat transducers in nociceptors responsive to both heat and mechanical stimuli, or 2) a selective action on a subset of nociceptors. (Supported by Procter and Gamble.)

INTRADERMAL INJECTION OF THE CAPSAICIN ANALOG, NE-21610, PREVENTS THE DEVELOPMENT OF HYPERALGESIA FOLLOWING A BURN. R.A. Meyer, K.D. Davis, J.I. Turnquist, T.G. Filloon', M. Pappagallo and J.N. Campbell, Johns Hopkins Univ., Baltimore, MD 21205 and 'Procter & Gamble Co., Cincinnati, OH 45329.

Baltimore, MD 21205 and 'Procter & Gamble Co., Cincinnati, OH 45329.

Intradermal and subcutaneous injection of the capsaicin analogue, NE-21610 (Procter & Gamble), produces analgesia to heat but not mechanical stimuli in man. The present study examined whether pretreatment of the skin with NE-21610 prevents the development of hyperalgesia following a thermal injury. On day one, eight volunteers received an intradermal injection (30 µl) of vehicle to one volar forearm and drug (10 µg) to the other volar forearm. On day two, the subjects used a visual-analog scale to rate the pain to mechanical and heat stimuli before and after a burn (48°C, 120 s) to each injection site. At the vehicle site, the pain evoked by the burn was rated as moderate to strong. In addition, primary hyperalgesia to heat stimuli, secondary hyperalgesia to mechanical stimuli, and flare were observed after the burn. In contrast, the pain evoked by the burn at the drug treated site was rated as weak, and primary hyperalgesia to heat stimuli dnot develop. In addition, the zones of secondary hyperalgesia and flare appeared smaller than those observed at the vehicle site. These data suggest that pretreatment with the capsaicin analog, NE-21610, may be helpful in ameliorating the pain associated with injury. (Supported by Procter & Gamble.)

# 128.3

MECHANISMS OF NEUROPATHIC PAIN FOLLOWING CHROMIC GUT LIGATION OF THE SCIATIC NERVE IN THE RAT. T.J. Maves. <sup>2+</sup> P.S. Pechman. <sup>2</sup> G.F. Gebhart. <sup>1</sup> and S.T. Meller. <sup>1</sup> Departments of Pharmacology <sup>1</sup> and Anesthesia, <sup>2</sup> University of Iowa, Iowa City IA, 52242, USA.

The aim of this study was to evaluate the mechanisms involved in the development and maintenance of the behavioral changes produced by loose chromic gut ligation of the sciatic nerve in a model of neuropathic pain.

Four loose ligatures of either silk (4-0), plain gut (4-0), or chromic gut (4-0, 3-0, or 2-0) were placed around the left sciatic nerve of male Sprague-Dawley rats. An additional group of rats had 8 pieces (0.5 cm pieces each) of 4-0 chromic gut laid in adjacent to the left sciatic nerve. The right sciatic nerve exposed in all rats as a sham surgery. Rats were tested prior to surgery (day 0) and on post-operative days 3, 5, 10, 20, and in some groups on day 30.

Chromic gut sutures (4-0, 3-0, and 2-0) tied loosely around the left sciatic nerve produced a 'dose-dependent' decrease in thermal withdrawal latency that was maximal on postoperative day 3 (28 ± 4%, 38 ± 5%, and 46 ± 6%, respectively) which returned to baseline by day 20 (4-0) or day 30 (3-0 and 2-0). 4-0 chromic gut laid in adjacent to the sciatic nerve produced a decrease in thermal withdrawal latency of 21 ± 5% that was maximal on day 5 and returned to baseline by day pp20. In contrast, neither 4-0 silk nor 4-0 plain gut produced any evidence of latency of  $21\pm5\%$  that was maximal on day 5 and returned to baseline by day pp20. In contrast, neither 4-0 silk nor 4-0 plain gut produced any evidence of thermal hyperalgesia on any day tested. There was no evidence of mechanical hyperalgesia on any day tested in rats from any of the 6 groups. After chromic gut, but not plain gut or silk ligatures had been placed around or laid next to the sciatic nerve, rats altered their posture and gait, suggestive of both spontaneous pain and allodynia. Sections of the sciatic nerve through the ligation site revealed no change in content of large or small diameter myelinated fibers compared to the right (sham) sciatic nerve in silk, plain gut or 4-0 chromic gut groups. There was a variable change in the content of large and small diameter myelinated fibers in 2-0 or 3-0 chromic gut treated rats. These data support the hypothesis that a chemical component of chromic gut sutures interacts with sciatic/sympathetic nerves, and that a mechanical insult is not a requirement for the development of the behavioral symptoms in this model of neuropathic pain.

## 128.4

NITRIC OXIDE (NO) MEDIATES THE THERMAL HYPERALGESIA PRODUCED IN A MODEL OF NEUROPATHIC PAIN. P.S. Pechman. \*\* G.F. Gebhart. 1 T.J. Maves. 2 and S.T. Meller. 1 Departments of Pharmacology 1 and Anesthesia. 2 University of lowa, lowa City 1A, 52242, USA.

Loose ligation of the sciatic nerve with chromic gut sutures (4-0) produces behavioral evidence of neuropathic pain in rats, including a marked thermal hyperalgesia. It has been suggested that activation of NMDA receptors in the dorsal horn are critical to the development of thermal hyperalgesia. In other regions of the CNS, such as the cerebellum, NMDA receptor activation has been shown to result in a Ca\* - dependent increase in cGMP through the production of NO, or an NO-containing moiety from free L-arginine. Therefore, the aim of the present study was to determine whether the thermal hyperalgesia produced in a model of neuropathic pain is mediated through the production of endogenous NO and subsequent activation of soluble guanylate cyclase (GC).

Four loose chromic gut ligatures (4-0) were tied around the left sciatic nerve. The right sciatic nerve was exposed as a sham surgery. Thermal withdrawal latencies of the left and right hindpaw were measured prior to surgery (day 0), and on the day of maximal thermal hyperalgesia (day 3 post-surgery). On day 0 there was no left hindpaw/right hindpaw difference in withdrawal latencies, but on day 3 all rats showed a significant thermal hyperalgesia of the left hindpaw compared to the right. One hour after determining the magnitude of the thermal hyperalgesia, the same rats were given an intrathecal (i.t.) dose of either saline, an alternate substrate for NO synthase, N<sub>W</sub>-nitro-L-arginine methyl ester (L-NAME, 20 nmol) or the GC inhibitor, methylene blue (MB, 20 nmol). Testing began 10 min later and continued every hour until thermal hyperalgesia was reestablished. I.t. administration of L-NAME and MB, but not saline, blocked the thermal hyperalgesia for 2 and 4 hours, respectively. L-NAME (20 nmol, i.t.) produced n

PERSISTENT HINDLIMB FLEXION IS ASSOCIATED WITH AN EXPERIMENTAL PERIPHERAL MONONEUROPATHY. S. Hanning, D.J.Mokler, & B.J. Winterson\* Depts. Physiol. & Pharmacol., Univ. New Eng. Coll. Ost. Med., Biddeford, ME 04005.

Loose ligation of the common sciatic nerve produces an experimental mononeuropathy (EMN), a syndrome of hyperalgesia, trophic changes and "guarding" of the hindlimb. We have been studying the persistent hindlimb flexion induced by prolonged percutaneous electrical stimulation. We examined rats with EMN to determine whether they also developed persistent hindlimb flexion.

EMN was produced in Long-Evans rats by the method of Bennett and Xie (Pain, 1988) (LIGATE). On days 3,7,10, and 14 rats were anesthetized with pentobarbital and persistent flexion was measured by applying known weights until leg lengths were equal. LIGATEd rats routinely showed flexion on the ligated side (3d: X=6.2g; 7d: X=4.8g; 10d: X=6.4g; 14d: X=7.1g). Sham surgical controls showed little flexion (Overall X = 1.1g). To test whether the flexion was due to the hypersensitivity of the foot, the foot was anesthetized with lidocaine. There was no reduction in flexion (X = 7.1 g). Rats were spinalized at T7 and the flexion remained (X = 6.0 g). The results suggest that the persistent flexion of EMN is a segmentally maintained process that does not depend upon sensory input from the foot. These features are similar to persistent hindlimb flexion induced by electrical stimulation. (supported by AOA)

## 128.7

SUTURE MATERIAL AFFECTS HINDPAW POSITION AFTER CHRONIC CONSTRICTION INJURY (CCI). C.H. Pollock, J.D. Coltz, G.L. Wilcox, and K.C. Kaiander\*. Depts of Psychology, Pharmacology, Oral Science & Prgm in Neuroscience, Schools of Med and Dent, U of Minnesota, Mpls, MN 55455.

A model of neuropathic pain in the rat (CCI) is produced by ligating the sciatic nerve with chromic gut (Bennett and Xie, 1988). Attal et al. (1990) report that after the CCI ipsilateral hindpaw position is abnormal. In this study, we investigated whether ligating with other suture materials produces this effect on the hindpaw position.

Rats stood with hindpaws flat on the glass testing surface before surgery We ligated the left sciatic nerve of each rat with chromic gut (n=6), gut (5), or vicryl (6). Control rats (6) received a sham surgery. After surgery all rats were evaluated for two months (13 sessions, 180 s each). A "blind" observer recorded the total time each rat held the left hindpaw in one of eight specified positions during each session.

Significant differences in hindpaw position existed between treatments (Kruskal-Wallis, p < .05). In sessions 1-13, rats in the sham surgery group spent 100% of the time with the left hindpaw flat on the glass surface. In sessions 1-5, rats in the vicryl group spent 67% of the time in one of two positions: paw ventroflexed or paw resting on its the medial surface. In sessions 6-13, these rats spent 100% of the time in the hindpaw flat position In sessions 1-8, rats in the chromic gut and gut groups spent nearly 100% of the time with the hindpaw in the paw ventroflexed, elevated, and medial surface positions. In sessions 9-13, these rats still spent 50% of the time with the hindpaw off the glass surface.

The effect of chromic gut or gut ligatures on hindpaw position differed from the effect of vicryl ligatures or sham surgery. It is possible that suture material also alters other behavioral sequelae.

## 128.9

RESPONSES OF VLO NEURONS TO NOXIOUS COLD PRESSOR IN RATS WITH AND WITHOUT SCIATIC NERVE LIGATION. B. Wang, M. Backonja and V. Miletic\*. Dept. Comp.

Biosci. and Neurol., Univ. of Wisconsin, Madison, WI 53706.

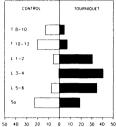

We compared the responses of ventrolateral orbital cortex (VLO) neurons to noxious cold pressor in two groups of animals. In 13 rats loose ligatures were tied around the sciatic nerve subsequent to its exposure. In 12 rats the sciatic nerve was similarly exposed but no ligatures were tied. Extracellular recordings were performed 14-28 days after surgery by an experimenter who was unaware as to which animal underwent sciatic ligation. At the time of recording none of the ligated or sham-operated animals exhibited hind limb elevation (i.e., neuropathic pain). To date responses of 33 VLO neurons to noxious cold pressor (immersion of a hind-limb in ice-cold water for 3 min) have been adequately characterized. Statistical analysis (t-test with Bonferroni corrections) was used to differentiate responding from nonresponding neurons. In ligated rats a greater proportion of units responded to the cold pressor stimulus than in sham-operated animals (12/15 vs. 11/18). In addition, the average afterdischarge to the cold pressor was longer in ligated than in sham-operated animals  $(4.69\pm6.30 \text{ vs. } 1.93\pm2.60 \text{ min, p}<0.05)$ . There was no difference in the average background firing rate (2.24±1.80 vs. 1.94±1.45 spikes/sec), or the magnitude of response to the cold pressor (189±206 vs. 189±193% increase) between VLO neurons in ligated and sham-operated animals. Sciatic ligation apparently increases the number of VLO neurons responding to noxious cold pressor. [NIH NS21278].

C-FOS MAPPING OF CENTRAL NOCICEPTIVE PROJECTIONS IN ACUTE COMPRESSION-RELATED NEUROGENIC PAIN. JC Crews\*, CS Sehlnorst, TM Reed, MM Behbehani. Dept. of Anesthesia, Univ. of Cincinnati, Cincinnati, OH 45267-0531.

To determine the nociceptive pathways for acute compression-related pain, c-fos immunohistochemical labeling techniques were used to identify activation of spinal cord and central nociceptive neurons in anesthetized rats. A pneumatic tourniquet was applied to the animals' right lower extremity and inflated to 300 mmHg for 120 mins. The animals were perfused, and the spinal cord and brain were sectioned and prepared for c-fos immunohistochemical labeling using the ABC technique. Brain and spinal cord sections were labeled for R and L sides and cells staining for c-fos expression were counted in 5-10 spinal cord sections at each level by a blinded observer. blinded observer.

Fos expression was greatest in the ipsilateral lumbar spinal cord levels, consistent with cfos expression following formalin injection of the hind paw. However, bilateral nociceptive injection of the hind paw. However, bilateral nociceptive activation of dorsal horn neurons in the thoracic levels suggests that novel peripheral nociceptive pathways may be associated with acute compression-related pain. Fos expression was detected bilaterally in LRN, NRM, LC, and PAG, but no expression was detected in the hypothalamus.

REFLEX SYMPATHETIC DYSTROPHY (RSD): PERIPHERAL NERVE STIMULA-TION AND ANIMAL MODEL INVESTIGATION. S. J. Hassenbusch\*, N. A. Mekhail, D. N. Doss, M. S. Stanton-Hicks, J. G. Walsh. Dept. Neurosurgery and Pain Management Center. Cleveland Clinic, Cleveland, OH 44195.

Peripheral nerve stimulation was utilized in 23 patients with Stage III RSD and failure to improve significantly with conservative measures and blocks. RSD symptoms/findings were located entirely or mostly in the distribution of one major peripheral nerve (median, ulnar, common peroneal, posterior tibial). All patients underwent placement of a peripheral nerve stimulator electrode with an implanted generator. The patients were followed for one year with frequent generator reprogramming, thermography, McGill pain questionnaire and verbal pain scale ratings. Long-term, all patients experienced mild-marked relief of changes. Best results were seen in marked reduction or elimination of allodynia and cutaneous flow changes. Deep, stimulation-independent pain was improved moderately and motor weakness was least improved. Chronic peripheral nerve stimulation is a valuable treatment for high-stage RSD patients but more information concerning stimulation voltages, on/off periods, and detailed selection criteria is required.

In order to examine physiologic and biochemical effects of peripheral nerve stimulation for RSD, an animal model for upper limb involvement is being investigated. This model is produced by application of 4 ligatures around the median nerve similar to the sciatic nerve compression model of Bennett & Xie (1988). Apparent vasomotor changes and exaggerated thermal stimulation responses developed in affected forelimbs. Thermography, 7 days after operation, of 8 Sprague-Dawley rats revealed significant (p<0.01) decreases (1.065  $\pm$  0.27°, mean  $\pm$  s.e.m.) in average skin temperature in operated forelimbs as compared to contralateral sham forelimbs. Effects of this model upon stellate sympathetic neurons and granule-containing cells (electron microscopy) and distal arterial wall catecholamine stores (fluorescent microscopy) are being quantitated for comparison to effects of peripheral nerve stimulation in the same model.

# 128.10

MORPHINE EFFECTS HYPERALGESIA AND ALLODYNIA DIFFERENTIALLY MORPHINE EFFECTS HYPERALGESIA AND ALLODYNIA DIFFERENTIALLY IN EXPERIMENTAL PERIPHERAL NEUROPATHY. J.S. Kroin\*, E.N. Tanck, R.J. McCarthy, R.D. Penn. Departments of Neurosurgery and Anesthesiology, Rush Medical College, Chicago, IL 60612

Sciatic nerve ligation produces a syndrome in rats exhibiting both hyperalgesia and allodynia. The effect of

exhibiting both hyperalgesia and allodynia. The effect of analgesic drugs on the various aspects of the model has not been fully examined as yet. Fourteen young adult (250-300 g) rats underwent ligation of the left sciatic nerve (Bennett & Xie, Pain, 33:87, 1988). A sham operation was performed on the right side. After 2 weeks, rats developed allodynic responses to cool water (withdrawal) and mechanical stimulation (vocalization) and a hyperalgesic response to hot water (faster withdrawal) on the lesioned side. Rats were tested 3 weeks after surgery with systemic injections of morphine sulfate (0,0.5,1,2, and 5 mg/kg i.p.). In tests for allodynia, morphine produced a dose-.p.). In tests for allodynia, morphine produced a dose dependent increase in both the withdrawal latency to cool water and the number of non-vocalizations to mechanical stimulation on the lesioned side. In comparison, withdrawal to hot water was not significantly increased at morphine doses up to 2 mg/kg. At 5 mg/kg, there was a large increase in withdrawal latency on the lesioned side but it was not significantly greater than the increase on the sham side. Therefore, in this model, morphine can alleviate allodynia at moderate doses, but high doses are required to have a significant effect on hyperalgesia.

SYMPATHECTOMY INDUCES NOVEL ADRENERGIC EXCITATION OF CUTANEOUS NOCICEPTORS D.F. Bossut\* and E.R.Perl, Physiology, Univ. N. Carolina, Chapel Hill 27599-7545

Partial injury of a peripheral nerve induces some remaining C-fiber cutaneous polymodal nociceptors (CPMs) to develop an excitatory response to nor-epinephrine (NE) and sympathetic stimulation (Sato and Perl, Science 251, 1991). CPMs from normal animals are excited neither by NE nor by sympathetic stimulation. The role of sympathetic denervation in the induction of adrenergic responsiveness was tested by unilateral excision of the superior cervical ganglion in deeply-anesthesized domestic rabbits. After survival for 4 to 55 days recordings were made under areflexic anesthesia from discharges of single C-fibers with established receptive characteristics of CPM units in filaments of the ipsilateral great auricular nerve. In sympathectomized animals, close arterial injection of 200ng NE evoked responses unrelated to vasoconstriction from about 50% of CPM units. The evoked activity varied from a few to many impulses at latencies of 1 to 94 sec. A number of CPM units developed ongoing discharge after NE trials, sometimes of a crescendo quantity. This effect of sympathectomy implicates loss of sympathetic innervation in development of adrenergic responsiveness of cutaneous nociceptors and in the etiology of sympathetically-aggravated pain states such as causalgia. (Supported by grant NS-10321 from the NINDS and NRSA DE05585 to DFB.)

## 129.3

HYPOESTHESIA ERASED BY SOMATIC NERVE BLOCK, OR PLACEBO: A PSEUDONEUROPATHIC, PSYCHOGENIC SIGN, IN CAUSALGIARSD. R.J. Verdugo and J.L. Ochoa\*. Dpts. Neurology and Neurosurgery, Good Samaritan Hospital and Oregon Health Sci. Univ., Portland, OR, 97210. Diagnostic anesthetic nerve blocks provide clues on neuropathic pain mechanisms. While abolition of hyperalgesia by somatic block is a stereotype, the variable behavior of spontaneous pain predicts peripheral versus central mechanisms. Many patients with neuropathic pains also express cutaneous hypoesthesia (CH); however, its outcome in response to somatic block has not been duly investigated.

Abolition of sensory deficit during placebo-controlled somatic block was tested

hypoesthesia (CH); however, its outcome in response to somatic blocks has not been duly investigated.

Abolition of sensory deficit during placebo-controlled somatic block was tested in 19 adult patients with chronic regional causalgiform syndromes who estimated CH as 40 to 95% (average 72%) loss. The area of CH (pinprick and/or light touch) was finely mapped and magnitudes of spontaneous pain (SP), dynamic and static mechanical hyperalgesias (MH) and Tinel sign (TS) were rated. Saline was injected close to the site of pain. After thirty min., CH, SP, MH, and TS were again rated. A nerve serving the area of pain was then blocked. Thirty min. later, the area of lidocaine-induced CH was mapped, and SP, MH, and TS were again rated. Pre-existing CH was finely remapped and rated. After saline there was abolition of CH in 58% of patients and significant improvement in another 21%. SP diminished by 50% or more in 93% of patients whose CH improved with placebo. After lidocaine the residual CH, beyond the area of lidocaine-induced hypoesthesia, improved in all 19 patients, 95% of whom volunteered abolition of CH (active placebo effect).

That this phenomenon is psychogenic is supported by:

a) In 95% of the patients there was evidence of absence of nerve lesion behind the pseudoneuropathic symptoms, by electrophysiological, quantitative sensory, thermographic and sympathetic function criteria. b) In 89.5% the area of hypoesthesia was non-anatomical c) In 95% of patients there was explicit evidence of psychogenic origin for sensory-motor complaints, such as presence of hysterical anesthesia, or weakness due to cortical effort interruptus, even in asymptomatic limbs. (Supported by NIH NS 24766 and 28747)

## 129.5

RESPONSES OF SPINOTHALAMIC TRACT NEURONS TO MECHANICAL AND THERMAL STIMULI ARE INCREASED IN AN EXPERIMENTAL MODEL OF PERIPHERAL NEUROPATHY IN PRIMATES. J. Palecek\*, P.M. Dougherty, S.H. Kim, V. Paleckova, H. Lekan, J.M. Chung, S.M. Carlton, and W.D. Willis. Marine Biomedical Institute, UTMB, Galveston, TX-77555 - 0843.

An experimental peripheral neuropathy was induced in three monkeys (Macaca fascicularis) by tight ligation of spinal nerve L, Behavioral responses to innocuous mechanical stimuli were tested before and after the surgery. Responses of spino-thalamic tract (STT) neurons to stimuli applied to the skin were recorded under general anesthesia 14 days after the ligation: graded mechanical stimuli (BRUSH, PRESS, PINCH and SQUEEZE), von Frey filaments (0.077 - 19.05g), 5 s hear stimuli (39° - 53°C) and 15 s cooling stimuli (32° - 8°C).

Innocuous stimulation of the foot did not evoke hindlimb withdrawal in the

animals before surgery. Within 24 - 48 hours after nerve ligation, the animals showed hindlimb withdrawal to the same innocuous stimuli. Responses of 51 STT neurons on the side of the ligation showed several statistically significant differences when compared to responses of 33 STT cells on the sham operated side and STT neurons in unoperated animals. These differences included: 1) increased spontaneous activity, 2) higher responses to BRUSH stimulus (mean evoked frequency 35 Hz compared to 15 Hz), 3) lower thresholds and higher discharge frequencies with von Frey filament stimulation, 4) decreased threshold temperatures and increased responses to suprathreshold heat stimuli, 5) responses to cooling stimuli with a threshold around 28°C.

Our results strongly suggest that tight ligation of spinal nerve L, in monkey results in generation of behavioral and electrophysiological changes that parallel symptoms found in humans with chronic neuropathic pain - mechanical allodynia, thermal hyperalgesia, cold allodynia and possibly spontaneous pain. RECEPTIVE FIELDS OF HYPERALGESIA CONFINE TO DISTRICTS OF INJURED NERVES; FIELDS "EXPAND" IN "RSD" WITHOUT NERVE INJURY.

M. Campero, J.L. Ochoa and L. Pubols\* Dpts. Neurology and Neurosurgery,
Good Samaritan Hospital and Oregon Health Sci. Univ., Portland, OR, 97210.

Mechanical hyperalgesia (MH) (Allodynia) is a symptom of causalgia/RSD.

Animal studies have reported striking expansion of receptive fields of Wide
Dynamic Range neurons (WDRN's) secondary to nerve injury, enabling
mechanoreceptor input from broad cutaneous fields to activate WDRN's\*. Under
the premises that a) WDRN's may signal pain and, b) that patients with chronic
"neuropathic" pains following (even mild) tissue injury often express broad areas
of MH, it has been hypothesized that post-injury MH that trespasses nerve districts
is due to 2" changes in WDRN's. Since animal studies forbid optimal mapping of
fields of MH it becomes imperative to test, in humans expressing MH, the clinical
hypothesis that generated by extrapolation from animal nerve injury.

Thirty six patients expressing post traumatic MH underwent rigorous
neurological evaluation plus Quantitative Sensory, Sympathetic reflex,
Telethermography, and electrophysiological testings. Eighteen (10 F, 8 M) had
histologically proven nerve injury and another 18 (11 F, 7 M) had evidence of
absence of organic nerve dysfunction. Magnitude of dynamic MH, defined as an
unpleasant subjective response to brushing the skin'e, was rated, and the fields were
mapped and photographed. The nerve to symptomatic skin was then anesthetized.

In the 18 patients with partial neuromas, the district of lidocaine-induced
hypoesthesia (LiH) matched the field of dynamic MH. In contrast, in "RSD"
patients with evidence of absence of nerve injury, cutaneous hyperalgesia
overlapped multiple nerve districts in 10, and covered an extremity in 8. In these
patients the districts of LIH were confined to the anatomical nerve territory.

Conclusions: a) The expansion of physiological receptive fields following animal
ner

BEHAVIORAL RESPONSES FOLLOWING AN EXPERIMENTAL NEUROPATHY IN PRIMATES. H.A. Lekan\*, S.H. Kim, J.M. Chung and S.M. Carlton. Marine Biomedical Institute, UTMB, Galveston, TX 77555-0843

An experimental peripheral neuropathy was induced by tight unilateral ligation of spinal nerve L, in one monkey (Macaca fascicularis). Behavioral responses to mechanical and thermal stimuli were determined before and for 14 days after surgery. The stimuli employed consisted of a graded series of von Frey Islaments (0.068 - 15.0g), brushing with a camel hair brush, application of 68 and 128 HZ tuning forks, 5 s heat pulses (39° - 55°C), 15 s cooling pulses (28° - 8°C) and application of acetone to the plantar and dorsal surface of the feet. Thermographic temperature readings of the ventral feet were also obtained. Prior to surgery, withdrawal responses were not obtained with the mechanical

and cold stimuli. The threshold for response to the heat stimuli was 55°C. There was no temperature difference between sides according to thermographic temperature readings. Following the induction of neuropathy, robust bilateral responses to all von Frey filaments and to brushing developed within 24 hours and were still present 14 days following surgery. During this time period, the threshold for a withdrawal response to heat stimuli decreased to 49°C on the neuropathic side only. Responses to the acetone stimuli were seen bilaterally on day 5 and 6. No responses developed to the cold pulses or vibratory stimuli. Thermographic temperature readings indicated the neuropathic foot was consistently warmer than the contralateral foot by at least 1°C.

The behavioral responses are compatible with electrophysiological findings in this model (see Palecek, adjacent poster). The behavioral manifestations of this model, which parallel the human condition, are indicative of mechanical allodynia, cold allodynia and thermal hyperalgesia and will be very useful for investigations of the mechanisms underlying neuropathic pain. Supported by NS11255, NS27910, NS21266, and Bristol-Myers Squibb Corp.

## 129.6

ANATOMICAL CHANGES IN A PRIMATE MODEL OF EXPERIMENTAL PERIPHERAL NEUROPATHY (EPN) S.Carlton\*, S.Kim, H.Lekan, J.Palecek. V.Paleckova, P.Dougherty, J.Chung and W.Willis. Marine Biomedical Institute, UTMB, Galveston, TX 77555-0843.

In the present study, we adapted a rat model of EPN (Kim and Chung,'91) to the primate. In 3 monkeys (M. fascicularis), the L<sub>2</sub> spinal nerve was tightly ligated. Compared to presurgery levels, all showed increased behavioral responses bilaterally to application of innocuous mechanical stimuli on the ventral surface of the feet; responses were more dramatic on the operated side. Following 14 days, the animals were perfused and the L6, L7 and S1 spinal cord segments removed and immunostained. Compared to the contralateral side, the dorsal horn ipsilateral to the surgery demonstrated a decrease in the staining density for SP and CGRP. In contrast, there was an increase in galanin and in glial (GFAP) staining. These changes occurred in L7 and L6 but were more dramatic in L7, the segment which sustained the greatest peripheral deafferentation. Minimal changes were observed in staining densities in S1. The increased glial staining was most likely due to glial hypertrophy, which can occur in response to excess glutamate. Electrophysiological studies in the same animals demonstrated that STT cells in the L7 segment were generally non-responsive to peripheral stimulation, however, STT cells in L6 showed maximal changes in response to mechanical and thermal stimulation. These findings indicate that changes in dorsal horn peptide levels may be related to the allodynia and hyperalgesia demonstrated in the behavioral and electrophysiological studies (see Palecek et al and Lekan et al adjacent posters). Elucidating the neuroplasticity occurring in this model of peripheral neuropathy may clarify underlying mechanisms which might be clinically exploited. Supported by NS11255, NS27910, Bristol-Myers Squib.

CORRELATION OF AXONAL NUMBERS AND BEHAVIORAL SYMPTOMS IN A RAT EXPERIMENTAL NEUROPATHY MODEL. C. M. Pover\*, P. M. Dougherty, S. M. Carlton and R. E. Coggeshall. Departments of Anatomy and Neuroscience, University of Texas Medical Branch, Galveston, Texas, 77555-0843.

Chronic partial constriction of rat sciatic nerve produces hyperalgesia and allodynia, symptoms also found in human neuropathies (Bennett & Xie 1988, 1989). A proposed mechanism is loss of central inhibitory controls due to the preferential interruption of large diameter afferents (Gautron et al., 1989; Basbaum et al., 1991), but severe losses of unmyelinated and myelinated fibres of all sizes are also found in this injury (Basbaum et al.,1991; Carlton et al., 1991). The problem with all these studies, however, is that they were all done at one time point and the neuropathic symptoms are not static. We have tested 19 rats for paw withdrawal latency (PWL) and sustained paw elevation time (PET) before nerve constriction, at weekly intervals and then immediately before sacrifice at 3, 5, 14, 28 and 56 days post-op. Myelinated and unmyelinated axons were counted in E.M. montages of the sciatic nerve segments proximal and distal to the site of injury. Results show that behavioral symptoms are maximal at 3 days and virtually gone by 28 days (PWL) or 14-21 days (PET), whereas axon numbers are most diminished distally at 14 days, are recovering by 28 days and approximately equal to proximal numbers at 56 days. We suggest that behavioral changes initially correspond with axon loss, particularly large myelinated axon loss, but at later stages the behavioral symptoms and axonal changes do not coincide. ## 129.9

QUANTITATIVE ANALYSIS OF SUBSTANCE P AND CALCITONIN GENE-RELATED PEPTIDE IMMUNOHISTOCHEMICAL STAINING IN THE DORSAL HORN OF NEUROPATHIC RATS TREATED WITH MK-801. CJ. Garrison\*, P.M. Dougherty, S.M. Carlton. Marine Biomedical Institute, UTMB. Galveston. TX 77555-0843.

Neuropathic pain remains a major complication following various forms of peripheral nerve injury in humans. An animal model of peripheral neuropathy resulting in a unilateral thermal hyperalgesia has recently been developed. It is the purpose of this study to quantitate the immunohistochemical changes in Substance P (SP) and Calcitonin Gene-Related Peptide (CGRP) within the spinal cord of neuropathic animals and examine these changes under experimental conditions which limit excitatory primary afferent input into the dorsal horn. The model is induced by placement of 4 loose ligatures around the sciatic nerve (Bennett & Xie, 1988) of 24 rats. On post-surgical days 7 and 14, immunohistochemical staining of SP and CGRP within the lumbar spinal cord was conducted on non-treated animals (n=8) and animals treated for 7 days with MK-801 (0.5mg/kg or 1mg/kg, n=16). Non-treated animals demonstrated thermal hyperalgesia and an ipsilateral decrease in SP staining density. MK-801 treatment resulted in a dose dependent attenuation of the hyperalgesia. In addition, the lower dose of MK-801 eliminated the decrease in SP and the higher dose resulted in an ipsilateral increase of SP. Although MK-801 treatment increased both peptides in non-neuropathic rats, no side to side change was demonstrated in CGRP staining in neuropathic rats. It can be concluded that blocking excitatory amino acid transmission can eliminate or reverse the changes in spinal cord SP induced by a nerve constriction, and that the changes in SP are not accompanied by changes in CGRP staining in this model. Supported by NS1255, NS27910, and Bristol Myers-Squibb.

## 129.11

NEURAL ACTIVITY OF MEDIAL AND LATERAL THALAMUS IN A DEAFFERENTATION MODEL. M. Lis-Planells, V.M. Tronnier, P.C. Rinaldi and R.F. Young \*. Dept of Neurosurgery, University of California, Irvine, CA, 92717. Neuronal hyperactivity ("bursting") has been identified in the somatosensory

system following neurological insults in animal and human studies, and recently in nociceptive pain patients. This study characterizes neuronal activity in medial as well as lateral thalamic nuclei in a deafferentation model. Male rats (n=26) underwent unilateral dorsal rhizotomy. Following signs of active autotomy, thalamic (VPL/VPM, MD, CM, CL) extracellular recordings were obtained in sedated rats. Control data were obtained from thalamic recordings in naive rats. Our results show that 80% of the deafferented animals exhibited autotomy 2 to 59 days after rhizotomy (mean 20.8). A total of 208 thalamic neurons were studied in 10 deafferented and 9 control rats. In the deafferented group, 65% (96/148) of the neurons showed spontaneous bursting, whereas only 21% (12/56) of the cells from controls burst. In the medial thalamus, 19% of the neurons in deafferented and 5% in control rats were responsive to noxious stimuli. In the lateral thalamus, 24% of the cells in deafferented and 17% in control rats responded to pain. Computerized interval histograms and burst analyses were completed for 23 cells in deafferented and 10 cells in control rats. Bursting cells in deafferented rats showed longer bursts (4-10 spikes) than controls (2-7 spikes). In control rats, the average duration for successive intervals between spikes in a burst was progressively longer. Bursting cells in deafferented rats showed intervals that decreased in duration from the first to the third one and increased thereafter. We conclude that increases in noxious-responsive cells and bursting activity of neurons occur early following deafferentation in both medial and lateral thalamus. Deafferentation produces longer bursts by increasing both the number of spikes per burst and the duration of the intervals between spikes. Our data indicate an important role for medial as well as lateral thalamic hyperactivity in deafferentation.

#### 129.8

THE TIME COURSE OF HISTOCHEMICAL CHANGES AND THE TRANSYNAPTIC INDUCTION OF A 29KD LECTIN IN THE DORSAL HORN IN A RAT MODEL OF NEUROPATHY. <u>A.A.Cameron\*. P.M. Dougherty, C.J. Garrison, W.D. Willis and S.M. Carlton.</u> Marine Biomedical Institute, UTMB, Galveston, TX, 77555-0843.

In a rat model of peripheral neuropathy (Bennett and Xie, 1988), behavioural hyperalgesia is observed. We have investigated the time course of effect this peripheral nerve lesion has on the histochemistry of the dorsal horn. Four loose ligatures were tied around the sciatic nerve in anaesthetised rats. All animals demonstrated behavioural hyperalgesia. At various time points (3, 5, 14, 28 days and 10 weeks) the animals were perfused and sections of the L4 and L5 spinal cord were stained with soybean agglutinin (SBA) and immunostained for the lectins RL-14.5 and RL-29, the growth associated protein GAP-43 and the neuropeptides substance P and calcitonin gene-related peptide (CGRP). In the superficial dorsal horn, the densities of reactivity to SBA and RL-29 were unchanged at 3 days and increased at 5, 14, 28 days and 10 weeks. The density of GAP-43 was unchanged at 3 days, and increased at 5, 14 and 28 days, and decreased at 10 weeks. Reactivity to SP was unchanged at 3 and 5 days and decreased at 10 weeks. Reactivity to SP was unchanged at 3 and 5 days and decreased at other time points. Reactivity to SP was unchanged at 3 and 5 days and decreased at other time points. Reactivity was induced in a subpopulation of neurons in lamina V in the dorsal horn ipsilateral to the injury.

The results suggest that following sciatic nerve damage, complex degenerative and regenerative changes occur in sensory neurons and that these are reflected in the L4 and L5 dorsal horn within five days of injury. It appears that the temporal sequence of changes in the numbers of axons in the sciatic nerve in animals with the neuropathic lesion is coincident with the changes in dorsal horn histochemistry. (Supported by NS11255, NS09743, NS27910, NS08660 and Bristol Myers-Squibb).

SENSORY RECEPTORS RESPONSIBLE FOR MECHANICAL ALLODYNIA IN A RAT NEUROPATHIC PAIN MODEL. H.S. Na, J.W. Leem, S.H. Kim and J.M. Chung. Marine Biomed. Inst., Depts. of Anat. & Neurosci. and of Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX, 77555.

Mechanical allodynia in causalgia is thought to be signalled by activity of low threshold mechanoreceptors. The aim of this study is to determine the exact type of mechanoreceptors mediating allodynia using an animal model for neuropathic pain.

Neuropathic animals were produced by ligating the L5 and L6 spinal nerves of one side in rats. These animals showed behavioral signs of mechanical allodynia. One week after neuropathic surgery, single fiber recordings were made from fine filaments dissected from the L4 dorsal root under urethane anesthesia.

We found an unusually large number of intermediate mechanoreceptors, which are characterized by weak sustained discharges during maintained mechanical stimulation. Furthermore, they changed to purely rapidly adapting receptors after an intravenous injection of phentolamine (0.5mg/kg). The drug had no effect on other types of mechanoreceptors.

The data suggest that the rapidly adapting mechanoreceptors change their responsiveness in causalgia and are responsible for allodynia. (Supported by NIH grants NS21266 and NS11255 and a grant from Bristol-Myers Squibb Co.)

## 129.12

ACTIVITY-DEPENDENT INTERACTIONS AMONG DORSAL ROOT GANGLION NEURONS BEFORE AND AFTER PERIPHERAL NERVE INJURY D.A. Utzschneider<sup>18</sup> M. Devor<sup>2</sup>, and J.D. Kocsis<sup>1</sup>. Dept of Neurology, Yale Med Sch<sup>1</sup>, VA Med Ctr, West Haven CT. 06516<sup>1</sup>; and Dept of Cell and Animal Biol., Hebrew Univ., Jerusalem, Israel<sup>2</sup>

A variety of afferent excitability changes are known to occur after peripheral nerve injury; most of the experimental work to date has focused on either the initial site of injury or within the CNS to determine the mechanisms of these alterations in sensation. Single fiber recordings from peripheral nerve have shown, however, that it is likely that cross-excitation does occur among the cell bodies of dorsal root ganglion (DRG) neurons (Devor and Wall, J. Neurophys., 64:1733-1746, 1990). To verify this possibility a combination of intracellular recordings and extracellular potassium measurements were obtained from whole excised DRGs from uninjured rats and potassium measurements were obtained from the DRGs 20 days after ligation and transection of the sciatic nerve. In the control DRGs the dorsal root was split into two branches allowing for separate stimulation of either branch; the S1 branch could then be identified as containing the axon of the impaled neuro and the S2 branch would contain only the axons of neighboring neurons. Tetanic stimulation of the S2 branch (10 sec., 50 Hz) resulted in a frequency- and amplitude-dependent depolarization of the neuron whose axon projected to the S1 branch, clearly indicating that the depolarization in this recorded neuron was due to activity in neighboring neurons, and not from stimulation of its own axon. A rise in extracellular potassium with a timecourse similar to the depolarization was also observed in the control (1.42  $\pm$ 0.86 mM) and ligated (1.85  $\pm$ 0.57 mM) DRGs. The potassium increase observed in the control DRGs was significantly greater than that seen in the dorsal roots  $(0.66 \pm 0.25 \text{ mM})$ . An activity-dependent accumulation of extracellular potassium within the DRG could account for some of the pathologic sensory disturbances seen after peripheral nerve injury.

COMPARISONS BETWEEN REGIONAL CHANGES IN SPINAL CORD NEURAL ACTIVITY AND MEMBRANE-BOUND PROTEIN KINASE C IN A RAT MODEL OF PAINFUL PERIPHERAL MONONEUROPATHY D.D. Price', J. Mao, and D.J. Mayer. Dept. of Anesthesiology, Medical College of Virginia, Richmond, Virginia 23298

Spatial distributions of spinal cord neural activity and membrane-bound protein kinase C (PKC) were compared in a rat model of painful peripheral mononeuropathy (Bennett & Xie, Pain, 1988, 33:87) following chronic constrictive sciatic nerve injury (CCI) by employing the [¹C]-2-deoxyglucose ([¹C]-2-DG) metabolic mapping and the [³H]-phorbol-12,13-dibutyrate ([³H]-PDBu) binding assay, respectively. CCI rats exhibited demonstrable thermal hyperalgesia and spontaneous pain behaviors 10 days after nerve ligation when [\(^{14}C)-2-DG and [\(^{2}H)-PDBu experiments were carried out. Reliable increases in both metabolic activity and PKC membrane binding occurred bilaterally in the lumbar dorsal horn (laminae I-VI of L<sub>2</sub>-L<sub>3</sub>) of CCI rats as compared to sham-operated rats. In both cases, activity was higher in the ipsilateral than in the contralateral spinal cord grey matter of CCI rats. In addition, regional increases in both activities occurred over an extensive rostro-caudal area from L2-L3. However, major differences between the two patterns of increased activity are that increases in PKC binding peaked in laminae I-II and did not occur in the ventral horn, whereas neural activity (2-DG) peaked in laminae V-VI and increased considerably within the ventral horn (lamina VII). While the spatial overlap between PKC binding and neural activity in CCI rats indicates a possible causal relationship between the two, much of the increased neural activity within the deep dorsal horn and ventral horn may occur as a consequence of excitation from more superficial dorsal horn neurons that undergo PKC-mediated neuronal plastic changes.

ELECTRON MICROSCOPIC ANALYSIS OF AXON FIBER SPECTRUM FOLLOWING MONONEUROPATHY HYPERPATHIA PRODUCED BY FIXED DIAMETER NERVE CONSTRICTION. T. Mosconi\* and L. Kruger. Dept. of Anatomy and Cell Biology and the Brain Research Institute, UCLA Medical Center, Los Angeles, CA

A constriction mononeuropathy model was developed in which the degree of compression exerted on the nerve could be standardized. Thick wall polypropylene tubing ranging in diameter from 0.010"-0.030" was cut either in short (<0.5 mm) rings or in longer (3 mm) tubes. The walls of 4-6 rings were slit, and the rings were applied to either sural or sciatic nerves at intervals of <1 mm over a distance of 3-6 mm. Tubes the residual to exist the party of the sural of the control of the rings were slit to the sixth of the control of the rings were slit to the sixth of the sixth of the rings were slit to solid the solid to exist the sixth of sciatic nerves at intervals of < 1 mm over a distance of 3-6 mm. Tubes were slit longitudinally and applied to sciatic nerves. The walls of the rings and tubes were resilient enough to appose the edges of the slit and lightly constrict the nerve. Clear tubing allowed for verification of continued blood flow through epineurial vasculature. Constriction produced behavioral signs of hyperpathia and allodynia in a majority of animals similar to that described by Bennett and Xie ('88) using suitible sufficiency for the produced of the produc multiple suture constriction. Electron microscopic determination of fiber spectrum in sections of nerves distal to the constriction showed degeneration in a large proportion of heavily myelinated axons and in a smaller proportion of lightly myelinated axons. Unmyelinated axons were distinctly more resistant to constriction. The ability to regulate the extent of compression exerted in this model can be useful for future studies of the alterations produced in sensory ganglia. The cutaneous sural nerve provides a model for analysis of sensory fiber spectrum relating to pain pathology. Supported by NIH grants NS-5685 and F32 NS-9176.

SPONTANEOUS PAIN AND COLD HYPERALGESIA IN A RAT NEUROPATHIC MODEL. Y. Choi', H.S. Na, S.H. Kim and J.M. Chung. Marine Biomed. Inst., Depts. of Anat. & Neurosci. and of Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX, 77555.

We previously developed an animal model for causalgia by tightly ligating the L5 and L6 spinal nerves unilaterally in rats. These rats showed a long-lasting heat hyperalgesia and mechanical allodynia. The aim of this study is to extend the model by demonstrating the existence of two additional important characteristics of causalgia: spontaneous pain and cold hyperalgesia.

Each rat was placed on a brass plate at a neutral (30°C) or a cold (4°C) temperature. The total duration of hind paw elevation during a 5 min observation period was used as a pain rating for spontaneous pain or cold hyperalgesia, respectively.

After neuropathic injury, pain ratings of both spontaneous pain and cold hyperalgesia were significantly increased on the affected hind paw as compared to either the control side or the preoperative state. This occurred as early as 2 days after the operation and continued for the 2 week test period. These rats also showed heat hyperalgesia and mechanical allodynia, confirming the previous data.

These results suggest that two additional features of causalgia, spontaneous pain and cold hyperalgesia, are also present in our rat model for causalgia. (Supported by NIH grants NS21266 and NS11255 and a grant from Bristol-Myers Squibb Co.)

#### 129.14

PAIN-RELATED INCREASES IN SPINAL CORD MEMBRANE-BOUND PROTEIN KINASE C AFTER PERIPHERAL NERVE INJURY J. Mao''. D.D. Price1, R.L. Hayes2, J. Lu1 and D.J. Mayer1. Dept. of Anesthesiology, Medical College of Virginia, Richmond, Virginia 23298, <sup>2</sup>Division of Neurosurgery, University of Texas, Houston, Texas 77030

Mechanisms underlying post-injury neuropathic pain are thought to involve excitatory amino acid-mediated central nervous system neuronal plastic changes. Using a rat model of painful peripheral mononeuropathy (Bennett & Xie, Pain, 1988, 33.87), we examined changes in spinal cord membrane-bound protein kinase C (PKC) resulting from PKC translocation, a Ca\*\*-dependent process known to mediate central nervous system neuronal plasticity, by employing the [3H]-phorbol-12,13-dibutyrate ([³H]PDBu) autoradiographic assay. Consistent with demonstrable thermal hyperalgesia and spontaneous pain behaviors in sciatic nerve-ligated (chronic constrictive injury, CCI) rats 3 and 10 days after nerve ligation, increases in [3H]PDBu binding also occurred in these CCI rats in the fourth lumbar spinal cord segment (laminae I-II, III-IV, and V-VI) both ipsilateral and contralateral to the ligated side as compared to corresponding regions of sham-operated rats. The [3H]PDBu binding was reliably higher on the side ipsilateral as compared to contralateral to nerve ligation in CCI rats. In addition, three daily intrathecal treatments with 80 nmol GM1 ganglioside (a glycolipid shown to prevent PKC translocation/activation) beginning 1 hr after nerve ligation reliably reduced both increased levels of [3H]PDBu binding and nociceptive behaviors in CCI rats when examined 24 hrs (day 3 after nerve ligation) but not 7 days (day 10 after nerve ligation) after the last GM1 treatment, suggesting a possible causal relationship between increases in membrane-bound PKC and pain-related behaviors. Thus, central mechanisms underlying persistent neuropathic pain may be mediated by the initiation of central nervous system neuronal plastic changes resulting from the increase in membrane-bound PKC. Supported by Fidia Pharmaceuticals.

EXPLOSIVE AUTOTOMY (AT) INDUCED BY SIMULTANEOUS DORSAL COLUMN (DC) LESION AND LIMB DENERVATION: A POSSIBLE MODEL FOR ACUTE DEAFFERENTATION PAIN. N.E. Saade'\*, M.Z.M. Ibrahim, S.F. Atweh and S.J. Jabbur. Faculty of Medicine, American University of Beirut, Beirut, Lebanon.

In rodents, AT appears 2-3 weeks after limb denervation and lasts for 2-3 weeks progressing from distal to proximal parts of the leg; it has served as an experimental model for chronic deafferentation pain. We examine here the neural basis of a new form of AT (explosive AT) characterized by rapid onset (1-2 days), short duration (1-2 days) and unpredictable progression. occurs when rats are subjected to simultaneous DC lesion and leg denervation but fails to occur when these procedures are immediately preceded by lumbar spinal anesthesia. Regular, rather than explosive, AT occurs with DC lesion carried out one week before or after leg denervation, with simultaneous lesion of other spinal tracts and leg denervation, and with simultaneous DC lesion and leg denervation immediately preceded by lumbar spinal anestheseia. These results support the concept that explosive AT could be due to simultaneous injury to peripheral and central ends of primary afferent neurons involved in nociceptive transmission and modulation, combined with injury to other afferent fibers involved in nociceptive transmission. THE SITE OF SYMPATHECTOMY ALLEVIATING ME-CHANICAL ALLODYNIA IN A RAT NEUROPATHIC PAIN MODEL. S.H. Kim, H.S. Na, and J.M. Chung. Marine Biomed. Inst., Depts. of Anat. & Neurosci. and of Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX, 77555.

Sympathectomy is known to be the most effective treatment of causalgia. The aim of this study is to localize the critical site of sympathetic-afferent interactions for mechanical allodynia in causalgic symptoms.

Neuropathic injury was produced by tightly ligating the L6 spinal nerve of one side in 20 rats. These animals showed behavioral signs of mechanical allodynia. Two weeks later, a differential sympathectomy was performed and the result was verified by examining noradrenergic axons with the glyoxylic acid reaction at various sites. One group received a sympathectomy at the injured site, and the other group in the intact segment.

Signs of mechanical allodynia remained in animals which received a sympathectomy at the injured segment. On the other hand, a sympathectomy at the intact (uninjured) segment alleviated the mechanical allodynia almost completely.

The data suggest that sympathetic nerve fibers innervating the intact sensory receptors play a critical role in mediating the mechanical allodynia of causalgia. (Supported by NIH grants NS21266 and NS11255 and a grant from Bristol-Myers Squibb Co.)

THE ROLE OF INJURED FIBERS FOR NEUROPATHIC PAIN IN AN EXPERIMENTAL ANIMAL MODEL. J.M. Chung' and K. Sheen. Marine Biomed. Inst., Depts. of Anat. & Neurosci. and of Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX, 77555.

The aim of this study was to determine the role of injured fibers for the initiation and maintenance of neuropathic pain in an experimental animal model.

Neuropathic pain was produced by injuring spinal nerves in rats and signals entering the spinal cord from the injured fibers were blocked by dorsal rhizotomy at different times. Behavioral tests were performed to determine the presence of mechanical allodynia and heat hyperalgesia for several weeks after neuropathic injury.

Resection of the L5 and L6 spinal nerves produced neuropathic pain, as did tight ligation of the nerves. However, dorsal rhizotomies (at the L5 and L6 segments) which were preceded by the same spinal nerve injury prevented the development of neuropathic pain. Furthermore, dorsal rhizotomies (at the injury segments) which were performed 3 weeks after neuropathic injury abolished the signs of neuropathic pain.

The results suggest that signals entering the spinal cord from injured fibers are important for both initiation and maintenance of neuropathic pain in an experimental animal model. (Supported by NIH grants NS21266 and NS11255 and a grant from Bristol-Myers Squibb Co.)

INTRANEURAL MICROSTIMULATION OF LOW THRESHOLD MECHANORECEPTORS IN PATIENTS WITH CAUSALGIA/RSD/SMP R. Dotson', J. Ochoa, M. Cline, P. Marchettini, D. Yarnitsky. Depts. of Neurology, Good Samaritan Med. Ctr. and Oregon Health Sci. Univ., Portland, OR, and Medical College of Wisconsin, Milwaukee, Wl. We directly tested hypothetical models of neural mechanisms for spontaneous pain and hyperalgesia in causalgia/RSD/SMP which propose that low threshold mechanoreceptors (LTMs), or alternatively nociceptors, activate sensitized W.D.R. dorsal horn neurons that transmits signals subjectively decoded as pain. The microneurographic technique was used to record identified mechanoreceptor units from peripheral nerves supplying the painful/hyperalgesic area of skin in 9 patients with clinical diagnoses of causalgia/RSD/SMP conventionally endorsed by temporary relief of pain by peripheral sympathetic blockade (SMP). Thirty LTMs (12 RA, 5 PC, 9 SAI, and 4 SAII) all but one of each type innervating glabrous skin, were isolated and identified by receptive field (RF) and stimulus-response characteristics. Intraneural microstimulation up to threshold intensity for first sensation, with trains of square wave pulses at 2-30 Hz was performed for each unit. Patients reported subjective quality of the initial projected sensation as stimulus intensity reached threshold, usually by 0.2-0.3 V. Receptor responses were re-evaluated after stimulation to confirm that the unit retained proximity to the electrode throughout the stimulus period. Each of the identified with held reach IPS end the present the properties and the JES and the production and the productive and the JES and the productive and the JES and the productive and the JES and the productive and the JES and the productive and the JES and the productive and the JES and the productive and the JES and the productive and the JES and the productive and the JES and the productive and the JES and the productive and the JES and the productive and the JES and the productive and the JES an proximity to the electrode throughout the stimulus period. Each of the identified units had normal RF and stimulus-response characteristics, and the RF and the projected field of sensation matched in space. This test consistently evokes intermittent tapping or vibration in control subjects (Ochoa and Torebjork, 1983). In patients, threshold stimulation of RA, PC, and SAI units also resulted in

painless sensations. As in controls, stimulation of SAII units resulted in no perceived sensation in patients.

We conclude that stimulation of single LTMs at liminal intensity in patients with causalgia/RSD/SMP does not evoke pain. Therefore, in these patients LTMs are either not responsible for peripheral encoding of signals for pain or spatial/temporal summation is required for this to occur.

#### PAIN MODULATION: DORSAL HORN

#### 130.1

EFFECTS OF NMDA AND SUBSTANCE P ON EVOKED DISCHARGE OF SINGLE DORSAL HORN NEURONES.

A. Tjølsen\*, K. Hole, V. Chapman¹ and A.H. Dickenson¹, Department of Physiology, University of Bergen, Norway, and Department of Pharmacology,

University College London, England.

The excitatory amino acid (EAA) glutamate and the peptide substance P (SP) are important in nociceptive transmission in the dorsal horn of the spinal cord. The NMDA receptor subtype is involved in the phenomenon of wind-up, and both the NMDA and the SP receptors have been suggested to play a role in long-term changes in nociceptive modulation.

The experiments were carried out in Halothane/N2O-anaesthetized rats. Deep dorsal hom neurones were recorded extracellularly using tungsten electrodes. All cells responded to both noxious and non-noxious stimulation electrodes. All cells responded to both noxious and non-noxious stimulation of the ipsilateral hind paw. The receptive field was stimulated electrically (16 pulses, 2 ms wide, 0.5 Hz, 0.3–4.5 mA). Drugs were applied directly onto the cord, akin to intrathecal application, dissolved in 50 μl saline.

With stimulation at 1.5 × C-fibre threshold, the effect of NMDA was to in-

crease the C-fibre response at low doses and reduce it at high doses, while the response to electrical stimulation at 3 x C-fibre threshold (mA) was not altered by intrathecal NMDA. Conversely, SP alone had little effect, but coadministration of SP inhibited the increase in response induced by NMDA

These experiments confirm the facilitatory role of NMDA-receptor stimula-tion during nociceptive transmission in the dorsal horn. The lack of effect when strong stimulation was used may be due to high synaptic EAA release with already maximal NMDA receptor stimulation, and therefore no additional effect after application of NMDA. The reduction of facilitation when SP and NMDA were coadministered may be due to the induction of inhibitory sys-

### 130.2

RESPONSE BEHAVIOR OF RAT NOCICEPTIVE MEDULLARY DORSAL HORN NEURONS TO DEFINED CO<sub>2</sub> PULSES APPLIED TO THE NASAL MUCOSA.

P. Peppel and F. Anton (Spon: European Neuroscience Association). Dept. of Physiology I, University of Erlangen-Nürnberg, F.R.G.

The response behavior of chemo-nociceptive medullary dorsal

horn neurons was determined by extracellular single unit recordings in halothane anesthetized rats.

recordings in halothane anesthetized rats. For noxious stimulation we applied 2s lasting  $\rm CO_2$  pulses of different concentrations (25-100%) to the nasal mucosa. The observed neuronal discharges revealed that WDR and NS neurons encoded the stimulus intensities in a linear fashion. Although NS cells generally displayed weaker responses, the discriminatory capacity of both categories of neurons was comparable. We compared stimulus response functions (SRFs) obtained with different interstimulus intervals (ISIs: 30s and 120s) and consistently found the neuronal responses to be depressed under the short ISI condition. Stable responses to identical stimuli were obtained with 120s ISIs, proving that the chemical stimuli themselves do not per se alter the response characteristics.

themselves do not per se alter the response characteristics. In a second set of experiments we examined whether the SRFs were altered by subsequent heterotopic conditioning. Once stable baseline SRFs had been recorded, a mixture of inflammatory agents was applied to the ipsilateral cornea or a radiant heat pulse (55°C; 100s) was applied to the ipsilateral upper lip. The subsequent SRFs of some neurons became steeper following heterotopic conditioning, reflecting central sensitization. In other neurons we observed a flattening of the SRFs, possibly due to dominating effects of descending inhibition. (supported by DFG)

NOCICEPTIVE AND PHYSIOLOGICAL BEHAVIOR IN THE FLUOROCARBON EXCHANGED-TRANSFUSED RAT. S.A. Green\*, C.L. Cleland and G.F. Gebhart. Department of Pharmacology, University of Iowa, Iowa City, IA 52242

The relation between sensory stimulation and the perception of pain is subject to modulation by psychological, neural, local and humoral factors. The investigation of humoral factors, however, has been complicated by the complexity of blood constituents. Consequently, we have developed a new model system for investigating the role of circulating factors in the modulation of nociception - the fluorocarbon, exchanged-transfused whole rat preparation.

Awake male Sprague-Dawley rats, chronically instrumented with femoral venous and arterial catheters and EMG electrodes, were continuously infused with artificial blood through the femoral vein at 1ml/minute for 70 ml. Simultaneously, blood was withdrawn manually from the arterial line via a 1ml syringe at 1ml/minute. Responses to nociceptive thermal (tail immersion in hot water), mechanical (von Frey stimulation of the tail) and visceral (colorectal distension, CRD) stimuli were measured before, during and following transfusion

We found that the exchange-transfused rat can exhibit normal responses to thermal, mechanical and visceral nociceptive stimuli following transfusion. The sensitivity to nociceptive stimuli, however, varied during the course of the transfusion. Overall, transfusion decreased the sensitivity to all three nociceptive stimuli. Individually, different nociceptive responses exhibited different trends: sensitivity to mechanical stimuli decreased rapidly, sensitivity to heat decreased slowly, and the visceromotor response to CRD initially decreased but later returned toward control levels. These results provide a baseline against which the effects of blood-borne factors can be experimentally tested by manipulating the contents of the blood in conditions such as inflammation or nerve injury where circulating factors are likely to influence nociceptive transmission. Funded by NS19912.

## 130.4

AND SYNAPTIC MODULATION OF NOCICEPTIVE TRANSMISSION IN THE SPINAL CORD OF THE FLUOROCARBON PERFUSED RAT. C. L. Cleland\*. M. C. Jiang and G. F. Gebhart. Department of Pharmacology, University of Iowa, Iowa City, IA 52242

Nociceptive transmission in the spinal cord can be modulated by synaptic and cellular processes. Repetitive synaptic activity can produce wind-up, slow post-synaptic potentials (sEPSPs), central sensitization and hyperalgesia. Cellular properties such as plateau potentials can influence neuronal responses to synaptic input for prolonged periods of time. Our goal is to evaluate the relative contributions of synaptic and cellular properties to the modulation of nociceptive processing in the spinal cord of the rat.

Intracellular recordings from 42 spinal cord neurons in the L4-L5 spinal segments of the adult rat were obtained using the fluorocarbon perfused, whole rat preparation. The perfused preparation allows stable intracellular recordings in excess of 2 hours in intact rats at normal physiological temperature. Synaptic input was tested by natural stimulation of receptive fields and electrical stimulation of the sciatic nerve. Cellular properties were tested by intracellular current passage.

We have identified several processes that could underlie long-term modulation of nociceptive processing. Wind-up (n = 13) or wind-down (n=2) was observed in most neurons tested (n=15) and three neurons exhibited long-lasting sEPSPs following repetitive sciatic nerve stimulation. Four neurons displayed long-lasting plateau potentials following depolarization evoked by intracellular current passage and one neuron exhibited reproducible oscillations in membrane potential. We are currently investigating the characteristics, mechanisms and significance of these synaptic and cellular processes. Funded by NS 19912.

HABITUATION OF THE RESPONSES OF TRIGEMINAL BRAIN-STEM NEURONES TO TOOTH-PULP STIMULATION IN CHRONICALLY PREPARED, ANAESTHETIZED CATS.

D. Banks, M. Kuriakose and B. Matthews\*. Department of Physiology, University of Bristol, BS8 1TD, England.

The jaw opening reflex (JOR) evoked by electrical stimulation of tooth-pulp (TP) in chronically prepared cats habituates at frequencies >0.5Hz to 20-25% of its initial value after 5-10 minutes. In the present experiments we have examined the responses of trigonical

present experiments we have examined the responses of trigeminal brain-stem neurones (main sensory and spinal pars oralis) under similar conditions to determine whether their responses also habituate. Three tonditions to determine whether their responses also habituate. I free male cats were prepared for chronic recording of the JOR and from brain-stem neurones as described previously (*J. Neurosci. Meth.* 38, 35-40, 1991; *J. Physiol.* 446, 78P, 1992). Following complete recovery the cats were anaesthetized and recordings made from 12 neurones responding to TP stimulation (thresholds 20-100µA, 0.1ms, 34Hz). neurones responding to TP stimulation (thresholds  $20-100\mu$ A, 0.1ms, 0.3Hz). Changes in the number of spikes and their latency, and in the integral of the digastric EMG were recorded during a period of TP stimulation (0.1ms,  $40-1000\mu$ A, 10Hz, 30s). In all cases the JOR habituated but the responses of the neurones fell into two distinct patterns. Of the total, 10 were short latency (3-6ms, SL) neurones and showed habituation whereas the remaining 2 were long latency neurones (15-17ms) and did not habituate. Changes in the responses of most SL neurones parallelled those of the EMG. The habituation of both the JOR and SL neurones was tooth specific, i.e. after habituation to upper tooth stimulation, the response from the corresponding lower tooth was unchanged from its initial value. We suggest that the SL tooth was unchanged from its initial value. We suggest that the SL neurones may be interneurones in the JOR pathway.

RESPONSES OF SPONTANEOUS AND NOXIOUS EVOKED DORSAL HORN CELL ACTIVITY IN CAT TO PROLONGED TRANSCUTANEOUS FREQUENCY. D.W. Garrison\* and R.D. Foreman. Depts. of Physical Therapy and Physiol. and Biophys, Univ. of Okla. Hlth. Sci. Ctr, Okla. City, OK. 73190. ELECTRICAL NERVE STIMULATION (TENS) AND CHANGE IN TENS

We have shown that TENS applied to somatic receptive fields for short periods of time (20-30 s), decreases spontaneous and noxious evoked activity of dorsal horn neurons. This study examined the effects of cell activity during prolonged TENS application and changes in stimulation frequency (Hz). In 9 alpha-chloralose anesthetized cats, spontaneously firing dorsal horn neurons were recorded from the lumbar spinal cord. Continuous TENS was applied for 5 minutes to dermatomes corresponding to cord level. Of 17 spontaneously firing cells, 88% had a mean decrease from control activity of 17 ± 2.4 imp/s to  $7 \pm 1$  imp/s. Two cells did not respond. For 86% of 7 noxiously evoked cells, mean control activity decreased from  $34 \pm 8$  imp/s to  $10 \pm 1$ imp/s (Medtronic TENS unit:mode = norm; pulse duration = 100 us; 5-125 Hz; 5-60 mA). Spontaneous and evoked activities were reduced consistently for 5 min. When the TENS unit was turned off activity immediately increased for all cells but at a level which was less than control for the majority of cells. Responses to changing frequency (5-125 Hz) during TENS were recorded for 10 spontaneously active cells and were found to be frequency dependent for each. The results indicate that 1) TENS can maintain decreased cell activity for a prolonged period of time and 2) variation in the frequency (Hz) has a graded response on dorsal hom cell activity. ## 130.9

COMPARISON OF THE NOXIOUS-EVOKED ACTIVITY OF DORSAL HORN MULTIRECEPTIVE NEURONS AND PAW WITHDRAWAL LATENCY IN THE LIGHTLY ANESTHETIZED

WITHDRAWAL LATENCY IN THE EIGHTLY ANESTHETIZED RAT. M. M. Morgan\* and H. L. Fields. Depts. of Neurology and Physiology, Univ. of California, San Francisco, CA 94143.

Noxious cutaneous stimuli evoke intensity-dependent increases in the activity of nociceptive specific (NS) and multireceptive (MR) neurons in the dorsal horn of the spinal cord. Such stimuli also evoke spinally mediated withdrawal reflexes. The present study compared the activity of NS and MR neurons in the lumbar dorsal horn with the latency for paw withdrawal during application of noxious heat. In addition, changes in noxious-evoked neuronal activity and withdrawal latency produced by a distant noxious stimulus was assessed. Male Sprague-Dawley rats were anesthetized with halothane and a laminectomy was performed so as to record single unit activity from the lumbar enlargement. The latency to elicit a paw withdrawal reflex and the number of spikes occurring prior to the reflex were determined before, during, and after submersion of the distal third of the tail in 50 °C water. Placing the tail in hot water (or noxious ear pinch) caused a reduction in the evoked activity of almost all MR, and many NS neurons, but did not inhibit the paw withdrawal reflex. In fact, the latency of the reflex often was shortened by tail heat. These results demonstrate that the relationship between noxious-evoked activity of dorsal horn neurons and withdrawal reflexes is not simple. In certain circumstances, simultaneously activated descending input to the dorsal and ventral horns may result in inhibition of the evoked activity of MR neurons yet facilitation of withdrawal reflexes.

NOCICEPTIVE SPINAL DORSAL HORN NEURONS RECEIVE ABUNDANT SYNAPTIC CONTACTS FROM SENSORY FIBRES CO-LOCALIZING SUBSTANCE P AND CGRP IMMUNOREACTIVITIES. AN ULTRASTRUCTURAL, TRIPLE-LABELLING STUDY IN THE CAT. A. Ribeiro-da-Silva\*, W. Ma, Y. De Koninck, A.C. Cuello and J.L. Henry. Depts. of Pharmacology & Therapeutics, Psychiatry, Physiology & Anaesthesia Research, McGill University, Montréal, Québec, Canada H3G 1V6. H3G 1Y6

In a previous study (De Koninck et al., PNAS, in press), we demonstrated at ultrastructural level that nociceptive neurons receive an abundant substance P (SP)-immunoreactive (IR) input, whereas non-nociceptive neurons have minimal SP-IR input. However, SP-IR fibres originate from sensory afferents, intrinsic spinal neurons and brain stem neurons. As calcitonin gene-related peptide (CGRP) is a useful marker for peptidergic primary sensory fibres, we studied the ultrastructural distribution of SP and CGRP immunoreactivities in association with physiologically classified dorsal horn neurons which had been labelled by intracellular iontophoresis of HRP. SP immunostaining was demonstrated by means of a bi-specific anti-SP/anti-HRP monoclonal antibody, using a DAB based pre-mbedding protocol. CGRP immunoreactivity was resulted by means of embedding protocol. CGRP immunoreactivity was revelaed by means of a post-embedding immunogold protocol. CGRP and SP immunoreactivities post-embedding immuniogou protocot. CGRP and SP immunoreactivities were co-localized in many varicosities contacting wide-dynamic range and nociceptive-specific cells, although other boutons were immunoreactive exclusively for SP or CGRP. Immunoreactivities for these peptides were infrequent in boutons apposed to non-nociceptive neurons. These results confirm the primary sensory origin of many of the SP-immunoreactive boutons which are presynaptic to nociceptive neurons in the cat spinal dorsal horn. (supported by NID) horn. ## 130.8

DO WDR NEURONS PARTICIPATE IN THE HIND LIMB NOXIOUS HEAT EVOKED FLEXION WITHDRAWAL REFLEX? K. Nishioka, Y. Harada, L.M. Kitahata\* and J.G. Collins. Dept. of Anesthesiology, Yale Univ. Sch. of Med., New Haven CT 06510 (USA)

The role of WDR neurons in a withdrawal reflex(WR) evoked by noxious heat applied to the hind limb is not well understood. This IACUC approved study examined the relationship between WDR neuronal activity and WR evoked by the same heat stimulus in the same animals. Male rats were initially anesthetized with an injection of pentobarbital I.P. for tracheostomy, a jugular vein and a carotid artery cannulation. Anesthesia was maintained with I.V. pentobarbital. Animals were artificially ventilated, and PaCO<sub>2</sub>, arterial pressure and rectal temperature were maintained within normal limits. A laminectomy (Th12-L1) was performed and animals were fixed in a stereotaxic frame. For the WR experiment, a projector lamp was focused on the blackened hind paw. The response latency and the threshold temperature were measured. After obtaining WR data, neuronal activity from a single WDR neuron with a receptive fields in the foot was recorded in the same animal. The response latency and the threshold temperature to activate the WDR neuron were measured and compared with WR latency and temperature. In addition, the maximum firing frequency(FF) produced by innoxious receptive field brushing and the heat evoked FF at the time point when WR occurred were compared. Student's t test was used for statistical analysis. Differences were determined to be significant with P<0.05. The latency of neuronal activity was significantly shorter than that of WR. The threshold temperature ron sotatistically significant difference between the maximum FF of WDR neurons evoked by the heat stimulus at the time point each animal showed a WR (22.26±4.15 spikes/sec). These results suggest that the FF of individual WDR neurons may not distinguish between noxious and non noxious stimuli at the time of WR. (Supported by N.I.H. NS-09871 fo

## 130.10

IS THE RELATIONSHIP BETWEEN SUBJECTIVE PAIN SENSATION AND FLEXION REFLEX IN MAN INFLUENCED BY ELECTROACUPUNCTURE? C.W.Y. Hui-Chan\* and S. Mah. School of Physical and Occupational Therapy, McGill University, Montreal, Quebec, Canada U.C. 176 Physical and Occ Canada H3G 1Y5.

The purpose of this study was to investigate whether the flexion reflex (a physiological measure) will vary with a psychophysical measure (the visual analog scale) in a systematic manner during three stimulating conditions: placebo-TENS, electroacupuncture to the contralateral leg (EA1), and electroacupuncture to the

scale) in a systematic manner during three stimulating conditions: placebo-1ENs, electroacupuncture to the contralateral arm and leg (EA2).

Sixteen normal healthy subjects participated in the study. Electrical stimuli were delivered at maximally tolerable intensity to the sole of their right foot. Flexion reflex (FR) was recorded electromyographically in the ipsilateral biceps femoris, with subjects' estimates of perceived sensation registered on a visual analog scale (VAS) connected to a linear potentiometer.

A high positive linear correlation between VAS and FR area was observed for all three stimulating conditions in 56-63% of subjects showing a decrease in the FR area, the r value being 0.89 and 0.93 respectively for EA1 and EA2, in contrast to r=0.63 for placebo stimulation. Interestingly, a high negative linear correlation was noted in 37-44% of subjects showing an increase in the FR area, with r=-0.93 and -0.97 respectively for EA1 and EA2, as compared with r=-0.47 for placebo stimulation. In other words, electroacupuncture could modulate the (perceptual) output at the cortical level in the same or opposite manner from that at the spinal motoneuronal level (the FR), according to whether the latter output is inhibited or facilitated. A possible goal appears to be to generate an overall "subjective" perception of a decrease in pain sensation consequent to electroacupuncture, at least under the experimental paradigm investigated.

This research was supported by a grant from the Fonds de la recherche en Santé du Ouébec.

SENSITIZATION OF THE TAIL-FLICK REFLEX FOLLOWING EXPOSURE TO A SINGLE PROLONGED TEST STIMULUS A.E. Baldwin, E.J. Weinbrecht, J.G. O'Neill III, & J.T. Cannon\*. Dept. of Psychology & Neuroscience Program, University of Scranton, Scranton, PA 18510-4596.

The tail-flick response to radiant heat has long served as a benchmark for research involving nociception in rodents. This reflex figured prominently in studies of stimulation-produced analgesia in which a common criterion for analgesia has been reflex inhibition to a "cutoff" latency (often twice the baseline, or more) at which time both the heat stimulus and the brain stimulation are terminated. It is not uncommon, at this point, for animals to emit a vigorous lick response, suggesting that the analgesic effects of stimulation are short lived and that the animal is now exposed to the sequelae of supra-threshold tail heating. We examined the effects of a single supra-threshold tail-flick trial on subsequent responding. Male albino rats were individually housed with food and water freely available on a 12/12 hour light/dark cycle and tested during the dark phase. Anesthetized animals were tested beginning 40 min after pentobarbital injection (55 mg/kg, i.p.). Baseline tail-flick latencies (M = 3.7 sec) were from the tail tip. At the next test interval, animals (6/group) were either tested as before (control) or manually prevented from responding to heating of the tail for 5 or 7 sec or a hindpaw for 5 sec. Testing then continued as before for 30 min. Compared to controls, tail-flick latencies were significantly reduced for both the 5 and 7 sec conditions, with no significant difference between them. This reduction occurred for all spots but was greatest for the spot which received supra-threshold stimulation. Reduced latencies were evident throughout the session. Stimulation of the hindpaw did not change tail-flick latencies. Animals in the 5 and 7 sec conditions were tested awake 1-3 days after the preceding and no differences between test spots were observed at

PHYSIOLOGICAL STUDIES ON MECHANISMS OF ACUPUNCTURE ANTINOCICEPTION IN THE RAT SPINAL CORD V.V. Romita\* K. Yashpal, C. Hui-Chan and J.L. Henry, Departments of Physiology & Psychiatry, and School of Physical & Occupational Therapy, McGill University, Montreal, Quebec H3G 1Y6 In a study of the neurophysiological and neurochemical mechanisms underlying analgesia produced by aversive sensory stimuli, male Sprague Dawley rats were anaesthetized i.p. with Na-pentobarbital (20 mg/kg) and chloral hydrate (120 mg/kg) and the effects of electroacupuncture were studied on the tail flick reflex. Electroacupuncture (20 x threshold for muscle twitch) was applied for 20 min to points femur-futu (ST-32) and fengshi (GB-31), approximated from charts localizing these points in humans. In control animals (n=7), analgesia began within 5 min of in humans. In control animals (n=7), analgesia began within 5 min of the start of the stimulation, with maximum effect occurring after 15 min. This effect lasted 30-40 min after the end of the stimulation. Each of This effect lasted 30-40 min after the end of the stimulation. Each of the substance P receptor antagonist, CP-96,345 (5 mg/kg, s.c., n=6), and the opiate antagonist, naloxone (25 mg/kg, i.p.; n=8), attenuated the analgesia during the stimulation by 50-60%. Furthermore, each drug abolished the analgesia which persisted after the stimulation. In spinal transected rats (n=11) electroacupuncture had no effect within the first 2 days. However, in days 3-7 antinociceptive effects began to reappear. These results indicate the partial involvement of opioid and substance P mechanisms in the mediation of acupuncture analgesia. Among other possibilities, these data suggest that electroacupuncture may activate possibilities, these data suggest that electroacupuncture may activate substance P-containing primary afferents which excite opioid-containing intrinsic spinal neurones. They also suggest recovery or plasticity of antinociceptive mechanisms following spinal transection. (Supported by the Fonds de la recherche en santé du Québec and the Canadian MRC)

## VISUAL CORTEX: FUNCTIONAL CIRCUITS AND OSCILLATIONS II

## 131.1

OSCILLATORY DISCHARGES OF THE VISUAL CORTEX IN THE BEHAVING CATS. C. Lee\*, J. Kim, J. Park, and S. Chung. Dept. of Psychology, Seoul Nat'l University, Seoul, Korea 151-742.

Synchronized oscillations in the stimulus-induced activities of neurons in the cat visual cortex have been implicated to encode global stimulus properties (Gray et als, Nature, 388:334, 1989). As a preliminary step toward understanding the behavioral significance of the synchronized oscillations, we examined the occurrence of the oscillatory discharge in the activities of the areas 17 and 18 of the alert cats implanted with scleral search coil for monitoring eye movements.

Periodic activities (20-120Hz) with varying magnitudes were observed in autocorrelograms derived from the stimulus-induced responses as reported previously (Gray et als, 1989), while the eyes are fixed. Similar oscillations were also found in discharges obtained across wide range of behavioral states unrelated with encoding stimulus features: during saccadic eye movements, slowwave sleep and REM sleep. These results indicate that the oscillatory discharge itself is not a sufficient conditon for encoding stimulus features. (Supported by Korea Science and Engineering Foundatin Grant 91-01-00-04).

## 131.2

Bursting Cells in Visual Cortex Exhibit Properties Characteristic of Intrinsically Bursting Cells in Sensorimotor Cortex .M. Gray

The Salk Institute for Biological Studies, La Jolla, CA Synchronous, 30-60 Hz oscillatory activity recorded in-vivoin visual cortex is often associated with burst firing in single cells (Gray et al 1990). Synchronous activity recorded in-vitro in sensorimotor cortex depends on the activity of intrinsically busting cells in layers IV and V (Silva et al 1991). These findings suggest a dependence on bursting cells for the synchronization of activity in visual cortex. In order to investigate the relationship between the two types of burst firing I have measured the amplitude and time dependent properties of These cells exhibit the following properties: 1) bursts of spikes having 2-9 spikes/burst; 2) a large percentage of inter-spike intervals less than 3-4 msec in duration; 3) peak firing rates within a burst as high as 600 Hz; 4) three forms of spike modulation occurring within a burst over time: amplitude decrease; firing rate descrease; and spike width increase. Each of these properties, with the exception of peak firing rate, characterize the behavior of intrinsically bursting cells recorded in-vitro, and thus provide indirect evidence that burst firing in visual cortex is an intrinsic cellular property. A direct test of this hypothesis will require intracellular recording.

Stimulus-Induced Oscillatory Synchronization is Inhibited by Stimulus-Locked Non-Oscillatory Synchronization in Cat Visual Cortex: Two Modes That Might Support Feature Linking. W.Krusc, R.Eckhorn. Th.Schanze, and H.J.Reitboecké. Philipps-University, Dept. Biophysics, Renthof 7, 3550 Marburg, Germany

Stimulus-induced oscillatory synchronizations (35-80Hz) were found in cat visual cortex. They were proposed to support feature linking in visual perception (Eckhorn et. al.1988, Biol. Cybern. 60:121). It was further suggested that stimulus-locked cortical synchronization supports feature linking in stimulus-dominated states. (Eckhorn et al. 1990; Neural Computation 2:293), and we found that stimulus-locked synchronizations can supress oscillatory activities completely. The present work concentrated on mechanisms and quantitative aspects of such depression. For this multiple microelectrode recordings were made from visual cortical areas 17 and 18. Oscillatory synchronizations were evoked by random stimulus movements. A systematic change from oscillatory to stimulus-locked responses was achieved by superimposing random movements of different amplitudes upon the constant velocity. This caused a successive increase of synchronized stimulus-locked response power while oscillatory power was progressively suppressed, and the mean oscillation frequencies were slightly increased (grand average, N=104). Additionally, with our stimuli Al8 showed on average higher levels of stimulus-locked power than Al7. We propose that stimulus-locked activities suppress oscillatory synchronizations, (1.) because they activate inhibitory cortical neurons, that act on the oscillatory units and (2.) because they disturb the oscillatory cortical processes by their different time courses. We assume that feature-linking is supported by stimulus-locked synchronizations directly after ocular saccades or sudden object movements, while it is supported by oscillatory synchronizations during fixation and smooth ocular pursuit.

Neuroinformatik, Ruhr-Universität, P.O. Box 102184, 4630 Bochum, Germany.

Cross-correlation analysis in visual cortex has revealed that the most frequent pattern of neuronal interaction is synchronous firing - the so called 'common input'. To investigate whether the strength in coherent firing ('effective connectivity') might be used for encoding stimulus properties we recorded simultaneously from pairs of nearby single neurons or multi units in cat area 17 and 18 using various stimulus conditions. Combined variation in firing rates were estimated by the product of the peri-stimulus time histograms of the two sites (PSTprod). 'Effective connectivity' along the stimulus period (normalized peri-stimulus time coincidence histogram; NPSTCH) was assessed by computing normalized cross-correlograms (NCC) based on the joint peri-stimulus time histogram (JPSTH; A. Aertsen et al., J. Neurophysiol. 61: 900, 1989). Most cells in the same cortical column displayed narrower peaks in the NCC (range 1-6ms) as compared to cells in distant columns (range 5 - 12ms; C.Schwarz and J.Bolz, J. Neurosci. 11:2995, 1990). Whenever the NCC showed signs of synchronous firing, this synchrony was preserved under all stimulus conditions tested. However, NPSTCH's revealed that the 'effective connectivity' was enhanced as the stimulus moved across the receptive fields. Orientation tunings computed with NPSTCH's and PSTprod's showed in most cases similar orientation preferences. In several pairs NPSTCH tuning curves matched the selectivity of those measured with single PSTH's, but usually they were broader than those of PSTprod's. Similar results were obtained with cells in distant columns. In view of the weak interconnections usually observed among cortical cells, the modulations in 'effective connectivity' described here might be used to encode stimulus information in a form suitable for higher stages along the visual pathway.

THE EFFECTS OF BACKGROUND PHOTIC STIMULATION ON VISUAL CORTICAL HYPERSYNCHRONOUS BURSTING. E.W. Kinghorn, D.E. Fleming\*, R.W. Rhees, Psychology and Zoclogy, Brigham Young University, Provo, UT 84602.

Photically evoked after-discharge (PhAD) bursting is initiated by retinal processes, entrained by the dorsal lateral geniculate nucleus (dLGN) of the thalamus, and modulated by input from the brainstem reticular formation. The current study was designed to investigate retinal processes, specifically the recovery time necessary for the initiation of PhAD following a conditioning The Sprague-Dawley rat was used for the experimental light pulse. procedures. A Grass PS22 photostimulator delivered photic brief pulses at intensity values of either 4, 8, or 16 on a scale of 1-16 as required by the experimental treatment. A second PS22 photostimulator was programmed to deliver a test photic pulse 50, 100, 150, or 200 msec following the first (conditioning or background) pulse. The intensity level of the second photic stimulator was set at 8 on the 1-16 scale. Recording of the evoked cortical after-discharge was time-locked with the test (second) photic pulse. Examination of the data indicated that the intensity of the conditioning pulse had no significant effect on the occurrence of PhAD. On the other hand, the interval between the conditioning and the test pulses significantly impacted the production of PhAD. PhAD was significantly reduced in animals that received the test pulse 50, 100, or 150 msec following the conditioning pulse. At an interval of 200 msec between conditioning and test pulses PhAD bursting was not significantly different from control values. These data suggest that at the brightness values used in this study, a relatively long retinal time-constant exists for the recovery of cortical hypersynchronous bursting.

A COMPARISON OF SINGLE NEURON AND NEURAL POPULATION DYNAMICS. Heather L. Read' and Ralph M. Siegel. CMBN, Rutgers University, Newark, NJ 07102.

When the retina is bombarded with periodic flash stimuli, primary visual cortical neurons become entrained to the stimulus rhythm to various degrees depending on the stimulus parameters (Siegel, 1990). Some of the essential features of periodically driven visual cortical neurons are observed in a periodically driven model of a population of neurons with intralaminar excitatory connections. Firing of neurons in this model is  $dictated \, by \, the \, Hodgkin-Huxely \, differential \, equations. \, In \, the \, present \, study, the \, dynamics \,$ of a single sinusoidally driven H-H model neuron were explored and the frequency amplitude parameter space was mapped. Over much of the parameter space the model neuron displayed simple phase locking patterns. That is, action potentials occurred at a regular phase of the stimulus cycle so that the ratio of spikes to stimulus cycle was some rational value. Transitions from a given phase locked pattern to another with changes in stimulus frequency were abrupt, particularly when low amplitude stimuli were used. Phase locking and transition zones of the model neuron were similar to those observed in the normal squid axon but were considerably more compressed than those of the spontaneously oscillating squid axon (Gutman et al., 1980; Matsumoto et al., 1987). instable, quasi-periodic firing patterns were observed between regions of stable phase locking. In these regions, spikes no longer occurred at a fixed phase but instead occurred unpredictably. Interspike interval times for phase locked and quasi-periodic activity were exact or near integer multiples of the stimulus period. During quasi-periodic activity, the range of ISIs was extended in a manner similar to that of the population model and real visual neurons. The isolated H-H model neuron differed from the H-H neuron population in that: 1) the parameter space for evoking quasi-periodic activity was larger in the population and 2) the deviations of ISIs from multiples of the stimulus period were more prominent in the population. These results suggest that flash evoked visual cortical neuron activity patterns arise from the dynamics of the population rather than from the quasi-periodic behavior of the single neuron.

THRESHOLD PROPERTIES OF INDIVIDUAL MODEL NEURAL OSCILLATORS CONTRIBUTE TO RAPID NETWORK SYNCHRONIZATION AND MAY POTENTIALLY PLAY A ROLE IN PERCEPTUAL FEATURE BINDING. D. Somers\* and N. Kopell, Department of Cognitive and Neural Systems and Department of Mathematics, Boston University, Boston, MA 02215

The synchronization properties of locally coupled neural oscillators were investigated analytically and by computer simulation. When coupled in a manner that mimics excitatory chemical synapses, oscillators having fast-slow interactions (relaxation oscillators) were found to approach synchrony using very different mechanisms than oscillators with a more sinusoidal waveform. The relaxation oscillators make critical use of fast modulations of their thresholds, a mechanism that leads to a rate of synchronization relatively independent of coupling strength within some basin of attraction; this rate is faster for oscillators that model conductance attributes than for neural caricatures such as the FitzHugh-Nagumo equations that lack such attributes. Computer simulations of one-dimensional network arrays show that oscillators in the relaxation regime synchronize much more rapidly than oscillators with the same equations whose parameters have been modulated to yield a more sinusoidal waveform. These results suggest that the emergent synchronization behavior of oscillating neural networks can be dramatically influenced by the intrinsic properties of the network components.

In the context of the reported synchronized oscillations in visual cortex (Gray et al., Nature, 338,1989), these results show that prior conclusions (Kammen et al., 1989) drawn about the neural connectivity required for rapid synchronization do not generalize as claimed; purely local connections may yield rapid synchronization. Furthermore, under the synchronized binding hypothesis of perception, selective modulation of intrinsic oscillator properties may permit a focal subpopulation of cells to synchronize (and thus become perceptually coherent) much more rapidly than the rest of the population and thus may potentially serve as an "attentional searchlight" mechanism.

MEASURING NEURONAL INFORMATION TRANSMISSION WITH NEURAL NETWORKS. T. W. Kjaer, B. J. Richmond\*, and J. A. Hertz. Nordita, Copenhagen, and Laboratory of Neuropsychology, NIMH, Bethesda, MD.

The content and utility of the signals carried by single neurons in the visual system is not always obvious. Thus, methods that help identify and quantify the contents of these signals are needed for making and testing hypotheses about neuronal function. We have used neural networks to decode signals from neurons in macaque primary visual cortex. The inputs to the net were the principal components of the responses elicited by a set of 16 1-dimensional Walsh-pattern stimuli. The network had 16 normalized-exponential output units, one for each stimulus pattern, and when the input was a signal produced by pattern number p, the target output pattern consisted of a 1 for unit number p and 0 for all other units. Back-propagation learning was used to minimize a cross-entropy cost function. The numbers of hidden units and training cycles were optimized by cross-validation on data not used in making the fit. Once this fit has been made, the average transmitted information was computed by sampling either the training or validation sets. We also tried networks that implement a Parzen-window fit similar to the one used previously by Optican and Richmond (1987) and by Optican et al (1991). The back-propagation neural network gave superior fits: The validationset cross-entropy for it was always lower than that for the Parzen-window net, with an average difference of 0.17 bits. We computed the information transmitted about the stimulus pattern from the optimized model for each of the 9 cells, finding an average transmitted information of 0.74 bits, with a fraction ranging from 14% to 60% contained in the temporal variation of the signal. The systematic fit optimization using the validation-set error criterion permits greater confidence in the resulting information transmission estimates than was possible with previous calculations.

# VISUAL CORTEX: ANATOMY OF EXTRASTRIATE CORTEX

## 132.

LOCAL PATCH NEURONS AND CALLOSAL NEURONS COMPRISE SEPARATE, MORPHOLOGICALLY DISTINCT POPULATIONS IN THE UPPER LAYERS OF CAT AREA 18. <u>D.M. Thejomayen\*, J. Zhang.</u> and <u>J.A. Matsubara</u>. Depts. of Anatomy and Ophthalmology, University of British Columbia, Vancouver, British Columbia, Canada, V5Z 3N9.

The pyramidal neurons in the upper layers of cat visual cortex participate in several anatomical systems, such as the patchy, intrinsic connections, the corticocortical and callosal projections. Earlier intracellular studies suggest that many upper layer pyramids possess a local axon collateral, which is often patchy in its arborization pattern, plus a descending axon trunk entering white matter. Thus, it would appear that at least some, if not all, of the local patch neurons in the superficial layers may network locally and participate in a projection pathway.

The morphology of callosal neurons in the upper layers was compared to the local

The morphology of callosal neurons in the upper layers was compared to the local patch neurons. Cells belonging to different projection pathways were identified by retrograde transport of fluorescent dextrans, followed by intracellular filling with lucifer yellow of prelabeled cells in 250 µm fixed sections taken in coronal and tangential planes. Cells were imaged with a confocal microscope (Biorad MRC 600).

Overall, the callosal and local patch cells form separate and distinct populations based on 1. somatic size, 2. dendritic branch pattern and 3. dendritic field dimensions. 1. The somatic areal measurements showed mean values which were quite distinct: local cells at 236 µm² (sd=99 µm²) vs callosal cells at 379 µm² (sd=93µm²). In the callosal population, there were more star pyramids, of all sizes, whereas only a few, small star pyramids were seen in the local patch sample. 2.Callosal cells possess a much more complex dendritic branch pattern, with numerous branch points. 3. Finally, callosal cells have a symmetric, circular dendritic field when viewed in the tangential plane, with the medial-lateral (ML) axis dimension equivalent to the anterior-posterior (AP), while local patch cells have a ML-AP ratio of 1.3. Thus, we await future studies to identify the output target(s), if any, of the local patch neurons. This work funded by MRC (Canada) 5-99150 (JM).

## 132.2

THE DISTRIBUTION OF CALLOSAL CELLS CORRELATES WITH DENSE CYTOCHROME OXIDASE STRIPES IN V2 OF THE MACAQUE MONKEY. JF. Olavarria\* and J. W. Lewis, Department of Psychology, University of Washington, Seattle, WA 98195. In visual cortex, the patterns formed by inhomogeneities in the distribution of callosal connections are thought to be closely associated with spatial

In visual cortex, the patterns formed by inhomogeneities in the distribution of callosal connections are thought to be closely associated with spatial attributes of the underlying visual maps. For instance, callosal connections accumulate preferentially in regions representing the vertical meridian of the visual field. However, the possibility that callosal connections also participate in the preferential transfer of specific kinds of visual information has received less attention. We have investigated this possibility by correlating the distribution of callosal cells with the pattern of cytochrome oxidase (CO) stripes in V2 (CO-dense thick and thin stripes, and pale interstripes). Several lines of evidence suggest that these stripes relate to specialized functional streams in visual cortex.

visual cortex.

Callosal cells were retrogradely labeled with the TMB-HRP technique after implants of acrylamide gel-HRP were placed in the transected corpus callosum. The patterns of callosal connections and of CO staining were revealed in series of sections cut tangentially to the surface of the physically unfolded and flattened cortex, and close correlation of both labeling patterns was facilitated by careful superimposition of these sections.

Data from three monkeys indicate that callosal cells accumulate in finger-like

Data from three monkeys indicate that callosal cells accumulate in finger-like clusters which extend perpendicularly from the V1/V2 border up to 7 mm into V2. In addition, these clusters are in register with CO-dense stripes (thick and thin), with few cells in the interstripe regions. Statistical tests confirmed the significance of this correlation. Thus, it appears that the distribution of callosal connections in V2 is dictated not only by the topography of V2, but also by the arrangement of functional streams. By extending to interhemispheric pathways the notion of functional streams. By extending to interhemispheric pathways, these results also open additional avenues for teasing apart the functional contributions of the CO subregions in V2.

COMPARTMENTAL DISTRIBUTION OF GABA NEURONS AND THEIR SUBPOPULATIONS IN MONKEY V2. R.K. Carder, V. Wan and S.H.C. Hendry. Dept. of Anatomy and Neurobiology, College of Medicine, University of California, Irvine, CA 92717.

V2 is a mosiac of three compartments, thick, thin and pale cytochrome oxidase (CO) stripes, each displaying unique physiological and connectional properties. To determine the neurochemical features of these compartments we have focussed upon GABA neurons which comprise the major population of inhibitory interneurons within the cerebral cortex. In V2 of normal Old and New World monkeys, somata and terminals immunoreactive for GABA are unevenly distributed, forming stripes perpendicular to the V1/V2 border. Comparison with an adjacent section stained for CO demonstrates increased GABA immunostaining within both the thick and thin CO stripes. Neurochemically distinct subpopulations of GABA neurons labelled by two members of the calcium binding protein family, calbindin and parvalbumin, are also preferentially distributed within the CO stripes. These patterns within the CO stripes include calbindin immunoreactive neurons as well as parvalbumin immunoreactive neuropil. The distribution of GABAergic elements parallels the organization of monkey V2 into functionally distinct subdivisions, suggesting that intrinsic elements as well aspecific afferents may contribute to unique physiological properties within each of the compartments of V2. PHA-L STUDY OF CONNECTIONS FROM TEO AND V4 TO TE IN THE MONKEY VISUAL CORTEX. K.S. Saleem<sup>1‡</sup> K. Tanaka<sup>1,2</sup>, and K.S. Rockland<sup>3</sup>, <sup>1</sup>Lab. for Neural Information Processing and <sup>2</sup>Information Science Lab. BIKEN, Janan. <sup>3</sup>Dept of Neurology, University of Iowa, USA.

K.S. Rockland<sup>3</sup>, 'Lab. for Neural Information Processing and \*Information Science Lab., RIKEN, Japan; 'Dept. of Neurology, University of Iowa, USA. TE is an anterior extrastriate area located at a latter portion of the ventral visual pathway. Cells in TE require complex object-features for activation, and cells with similar stimulus selectivity cluster in columns within TE (Fujita et al., Soc Neurosci Abstr, 1991; Vol 17, p 1283). In the present study, we analyzed the organization of afferents to TE by injecting PHA-L in two Japanese monkeys (Macaca fuscata). Iontophoretic injections were made in two sites in TEO in the first case and in two sites in V4 in the second case. The diameter of the injection sites was 0.7 to 1.0 mm

injection sites was 0.7 to 1.0 mm. After injections in TEO, labeled axons were distributed with 3 dense core regions in TE. In the core regions, labeled axons formed distinct clusters, which extended through all cortical layers. The core regions measured 250 to 400  $\mu m$  along the mediolateral axis. Along the postero-anterior axis, one core measured 800  $\mu m$  and the other two were split into two subregions, which measured 200 to 300  $\mu m$  each and were separated by 120-160  $\mu m$ . Beyond the core regions, labeled axons became less prominent in the supragranular layers, and, at the fringe of the projection zone, were more limited to layers 4, 5 and lower 3 (middle layers). After Injections in V4, labeled axons were more

the core regions, labeled axons became less prominent in the supragranular layers, and, at the fringe of the projection zone, were more limited to layers 4, 5 and lower 3 (middle layers). After Injections in V4, labeled axons were more sparsely distributed in TE and more limited to layer 4 than TEO case.

Single axons reconstructed in the TEO case from regions just surrounding the cores have prominent branches reaching layers 1 and 2 (n=2), whereas those reconstructed from fringe regions have arbors limited to the middle layers (n=2). There were 3-5 arbors, each 100-250 µm in diameter. The total postero-anterior extent of the arbors of single axons ranged 0.64 to 3.6 mm. Axons reconstructed in the V4 case (n=3) also had arbors mostly limited to the layer 4. There were 2-3 arbors, each 100-250 µm in size.

We suogest that the specific and columnar projection from TEO to TE may

We suggest that the specific and columnar projection from TEO to TE may constitute one of the bases of the functional columnar organization in TE.

ARBORIZATION PATTERNS OF INDIVIDUAL AXONS PROJECTING FROM CAUDAL TO ROSTRAL INFERIOR TEMPORAL CORTEX IN SQUIRREL MONKEYS. G. E. Steele\* and R. E. Weller. Dept. of Psychology, Univ. of Alabama at Birmingham, Birmingham, AL

Psychology, Univ. of Alabama at Birmingham, Birmingham, AL 35294.

Based on patterns of cortical connections and architectonics, inferior temporal (IT) cortex of squirrel monkeys consists of rostral (ITR) and caudal (ITC) regions. ITR is defined as the projection zone of ITC (Weller & Steele, J. Comp. Neurol., in press). In macaque monkeys, the region of cortex comparable to ITR contains nontopographically organized neurons with large receptive fields that respond best to complex visual stimuli. These characteristics may be due to convergent and/or divergent input from ITC. In order to investigate these possibilities, the present study examined the terminations of individual axons in ITR labeled from iontophoretic injections of the neuronal tracer biocytin in ITC (4 cases) or from pressure injections of horseradish peroxidase into the white matter underlying ITC (4 cases). Axons in ITR terminate in layer IV and lower layer III. Individual boutons were evenly spaced along terminal branches, with approximately 3 boutons per 20 microns. Axons reconstructed to date have relatively limited terminal arbors, suggesting that the receptive field properties of neurons in ITR are not due to divergent projections from single neurons in ITC. Supported by EY07147 to REW and MH10070 to GES.

INTRINSIC CONNECTIVITY IN MACAQUE V2: EVIDENCE FOR INTERACTION BETWEEN FUNCTIONAL STREAMS. J.B. Levitt\*. T. Yoshioka and J.S. Lund. Center for Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA 15761

Primate visual cortical area V2 contains three alternating stripelike compartments distinguished by their differential staining for cytochrome oxidase (CO) and Cat-301. These three compartments have different afferent and efferent connectivity, and contain neurons with predominantly different physiological properties. Since different types of visual information are relayed through closely-apposed parallel stripes of tissue in V2, this area might provide a locus for interaction of different visual channels.

We made focal (200-300  $\mu$ m) microinjections of biocytin into V2 to determine whether there are specific interconnections between compartments. Alternate tissue sections were reacted for CO or Cat-301, to identify injected and labeled sites relative to compartments. Discrete patches of terminal label (250-300  $\mu$ m diam) were found within both injected and neighboring stripes. Clusters were found up to 4 mm from an injection site, and were distributed in an elongated field orthogonal to the stripes. While a substantial proportion of each stripe's local afferent and efferent connectivity was within the same compartment, connections were also made with both the other compartments. As previously reported (Livingstone and Hubel, 1984), we found preferential connections between CO-rich compartments, and we have confirmed that pulvinar terminals in V2 are precisely coincident with the CO-rich stripes. However, pale stripes were equally connected to CO-rich or pale zones. Patchy connectivity within stripes, and interconnections between all compartments, suggests both compartment substructure and a substrate for channel interactions. Specific inter-compartment connectivity rules may not be necessary to explain these data; we are currently exploring whether they might reflect simple constraints on the range over which local connections may occur. (Supported by NIH grants EY05282, EY06275, EY08098, and ARVO/Alcon).

## 132.6

PROJECTIONS TO VISUAL AREAS V4 AND TEO FROM TEMPORAL, PARIETAL, AND FRONTAL LOBES IN MACAQUES. H. Nakamura. R. Gattass, R. Desimone, and L. G. Ungerleider. Lab. Neuropsychology, NIMH, Bethesda, MD 20892.

To investigate differential inputs to areas V4 and

To investigate differential inputs to areas V4 and TEO, we injected them with different retrograde tracers and analyzed the distributions of labeled neurons in the temporal, parietal, and frontal lobes in flattened preparations of the cortex. In inferior temporal area TE, V4- and TEO-projecting cells showed a patchy distribution with overlapping and nonoverlapping regions extending forward to the rostral tip of the area. Whereas the labeled cells were predominantly in the infragranular layers in rostral TE, in caudal TE they had a bilaminar distribution. In parahippocampal area TF and perirhinal area 36, V4- and TEO-projecting cells were intermingled. In the intraparietal sulcus, labeled cells were located mainly in the infragranular layers of LIPV, while TEO-projecting cells were located mainly in LIPd where they had a bilaminar distribution. In the prefrontal cortex, V4- and TEO-projecting cells were intermingled in the anterior bank of the arcuate sulcus (area 8) and extended rostrally into area 46, although there was a tendency for V4-projecting cells to be located more posteriorly than TEO-projecting cells. Thus, V4 and TEO receive similar, though not identical, inputs from temporal, parietal, and frontal areas.

## 132.8

ORGANIZATION OF CORTICAL VISUAL PROJECTIONS TO THE DORSAL AND VENTRAL PARTS OF AREA TE OF THE INFEROTEMPORAL CORTEX IN MACAQUES. MYukie\* K. Hikosaka and E. Iwai. Dept. of Behav. Physiol., Tokyo Metro. Inst. Neurosci., 2-i6, Musashidal, Fuchu-City, Tokyo 183, Japan.

In previous studies we have shown that the dorsal and ventral parts (TEd and TEv parts) of area TE of the macaque inferotemporal cortex are distinguished from each other by their connectivity with the amygdala and hippocampus CA1 area and have suggested that area TE may not be always an unitary area. However, it is unclear in what manners visual afferents into area TE are organized from the posterior visual areas TEO and V4. In the present study, to clarify organization of cortical visual afferents to the TEd and TEv areas. injections of retrograde tracers, WGA-HRP and fluorescent dyes, Fast Blue (FB) and Diamidino Yellow (DY), were made into different levels of area TE of Japanese monkeys (*Macaca fuscata*). Following WGA-HRP injections into the anterior and posterior TEd (TEad and TEpd) portions, predominant distribution of labeled cells was seen, respectively, in the TEpd and dorsal TEO (TEOd) areas and in the TEOd portion and part of area V4 located between the lunate and inferior occipital sulci. By contrast the anterior and posterior TEv (TEav and TEpv) received an abandunt projection from the TEpv and ventral TEO (TEOv) portions and from the TEOv and part of area V4 of the inferior occipital gyrus, respectively. Separate injection of DY and FB into the TEpd and TEpv in an animal produced discrete regions of DY and FB labeled cells in each of areas TEO and V4, with some small overlap of distribition. These results demonstrate that area TE is subdivided into the anterior and posterior TE areas by presence or absence of direct afferents from area V4 and that visual afferents to the TEd and TEv areas from areas TEO and V4 are differentiated roughly and suggest that the TEd and TEv areas receive major afferents, respectively, from the representation of the central visual field and from that of the peripheral visual field of areas TEO and V4.

ORGANIZATION OF CORTICAL PROJECTIONS TO SUPERIOR TEMPORAL POLYMODAL CORTEX OF THE RHESUS MONKEY: DOUBLE ANTEROGRADE LABELLING STUDIES. B. Seltzer\*, M. Cola, M. Massee, C. Weldon, and C.G. Cusick. Depts. of Psychiatry & Neurology and Anatomy, Tulane Univ. Schl. of Med.; VA Med. Ctr., New Orleans LA 70112.

Previous studies showing multiple cortical projections to superior temporal polymodal (STP) cortex in the upper bank of the superior temporal sulcus (STS) involved tracing connections in multiple hemispheres. To examine how different afferent cortical inputs interrelate within STP cortex, we used a double anterograde labelling strategy. In 5 different cases, 1 cortical zone that projects to STP cortex, e.g. caudal inferior parietal lobule, was injected with tritiated amino acids and another, e.g. mid-superior temporal gyrus, with WGA-HRP. Alternate coronal sections of the hemisphere, processed for radio- and HRP-labelled terminal fibers, were then compared. Many afferents of terminal fibers, were then compared. Many afferents of different cortical origins are segregated, but there are also columns within STP cortex that receive directly converging input from 2 different regions. Both overlapping and nonoverlapping laminar patterns of termination are found. The different target zones correlate with cyto-, myelo- and chemoarchitectonic divisions of the STS. Most of the convergence takes place within areas "TPO" and "PGa" (Seltzer and Pandya, '78). Supported by the VA, NIH, and Tulane University.

#### 132.10

PROJECTIONS OF THE CORTICAL LENS ACCOMMODATION AREA IN THE CAT. H. Maekawa, K. Ohtsuka\* and M. Sawa. Dept. of Ophthalmology., Sapporo Medical College, Sapporo 060, Japan.

It is well known that the lateral suprasylvian (LS) area of the cat has important roles in the control of lens accommodation. Neurons in the LS area exhibit burst of discharge preceding the onset of accommodative responses, and microstimulation of the LS area elicite accommodative responses. However, anatomical connections of accommodation-related area in the LS area are not established. In the present study, we injected WGA-HRP into the accommodation-related area which was identified by microstimulation, and examined afferent and efferent connections of the cortical accommodation area in the cat.

Retrogradely labeled cells were found mainly in ipsilateral Brodmann's area 18 and 19, pulvinar, lateral posterior nucleus of the thalamus and the contralateral LS area. Axons arising in the accommodation area ran through the retrolenticular portion of the internal capsule and the pulvinar, and then terminated in the ipsilateral pretectum, superior colliculus, and pontine nuclei. Labeled terminals were also found in the ipsilateral lateral posterior nucleus of the thalamus, pulvinar and the contralateral LS

These findings suggest that the cortical accommodation area receives visual inputs from Brodmann's area 18 and 19, and projects accommodation-related signals to the superior colliculus, pretectum and thalamus.

RESPONSES OF CELLS IN THE CAT'S LGN AND AREA 17 TO RIVALROUS STIMULI. Frank Sengpiel<sup>1</sup>, Richard Harrad<sup>2</sup> and Colin Blakemore<sup>1</sup>. University Laboratory of Physiology, Oxford OX1 3PT, and <sup>2</sup>Department of Ophthalmology, Bristol

and Colin Blakemore". University Laboratory of Physiology, Oxford OXI 3PT, and Department of Ophthalmology, Bristol BS1 2LX, U.K.

Current models of binocular rivalry, supported by recent psychophysical evidence, postulate the existence of reciprocal feedback inhibition between monocular neurons prior to binocular integration. Hence, the suppressive circuitry should be located in either the LGN or layer 4 of area 17.

We recorded from neurons in both LGN and area 17 of anaesthetized cats. Moving grating stimuli were presented to the two eyes separately on two CRT monitors. Binocular interaction was tested by presenting a constant stimulus of optimal orientation to the dominant eye, and varying stimuli, randomly interleaved, to the non-dominant eye.

Responses of cells studied in the A and Al laminae of the LGN were either not affected by stimulation of the non-dominant eye, or were tonically inhibited, independent of the orientation or phase difference between the stimuli. In area 17, many binocular units were transiently or tonically inhibited by gratings presented to the non-dominant eye, when the orientation of the grating differed by more than 30° from the preferred one. In some cells inhibition occurred in some trials, but was absent in others. The effect did not depend on the relative phases (disparity) of the gratings, in contrast to interactions found for orientation differences of 25° or less. No monocular cells found so far displayed inhibition of this type relayed through the silent eye.

Our data give the first evidence for a type of suppression in the primary visual cortex that might underlie binocular rivalry. It is observed at the level of binocular rather than monocular cells. - Supported by the MRC.

connections between large cortical areas. We found these anatomical connections between large cortical areas. We found these anatomical data did not reflect classical receptive fields of single units, but did "receptive fields" of postsynaptic potentials evoked within a small cortical mass (Soc. Neurosci. abst. 1991). In the present study, we simultaneously recorded local field potentials from two cortical sites within area 17 of the anesthetized and paralyzed cat using two pairs of bipolar electrodes. One pair of bipolar electrodes (tip separation, ~Imm) were placed at corresponding sites near the area centralis (P,5mm; L,1mm; D,1mm), the other was near the 15-deg periphery (P,1 mm; L,2mm; D,6.5mm). Field potentials were evoked by the pseudorandom temporal modulation of contrast reversal of gratings at 61.5-deg patches covering a 45-deg visual field centered on the area

SPATIOTEMPORAL INTERACTIONS OF POSTSYNAPTIC FIELD POTENTIALS IN CAT VISUAL CORTEX: POSSIBLE INTRA-CORTICAL INTEGRATION OF VISUAL AFFERENTS.

 Dept. of Neurosurgery, Kinki Univ. Sch. of Med., Osaka 589, Japan.
 Cortical neurons in area 17 have extensive afferent and efferent

of 15-deg patches covering a 45-deg visual field centered on the area centralis. Each of the 61 patches was modulated simultaneously but independently. Responses corresponding to each of the 61 patches were extracted by a multi-input, non-linear systems analysis method.

With single-patch stimulation at least two types of postsynaptic components were identified: a fast retinotopic component and a slow non-retinotopic component with a very large receptive field. With all-patch stimulation only the retinotopically restricted fast component of field potentials was obtained. The disappearance of the non-retinotopic components with all-patch stimulation indicates the presence of non-linear spatial interactions. These findings confirm our early suggestion of the presence of long-range lateral interactions within visual cortex.

RESPONSES TO BROAD-BAND AND BAND-LIMITED NOISE IN V1: DEPENDENCE ON SPATIAL FREQUENCY, COLOR, AND ORIENTATION. E. Katz\*, K. Purpura, B. Mao, C. Schroeder' and J. Victor Dept. of Neurology and Neuroscience, Cornell University Medical College, New York, NY 10021 and 'Dept. of Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461 Responses to visual patterns were recorded from anesthetized

and paralyzed monkeys using multi contact electrodes that spanned the depth of parafoveal V1. We used visual stimuli that were broad-band in space and time (based on M-sequences) to map the linear and non-linear inputs to the local field potential (LFP). In all cases these inputs were localized to a one deg. region, and often in a 20 min region.

We used band-limited Gaussian noise to define the spatial

frequency and orientation tuning of the LFP at each of the 16 electrode contacts. On a scale of 150µ, neural assemblies showed well-defined spatial frequency preferences which correlated with their responses to checkerboards and gratings. In some cases spatial frequency tuning varied along the vertical penetration. Upper sites tended to show a preference for higher spatial frequencies. Substitution of chromatic isoluminant patterns for achromatic patterns shifted the spatial frequency tuning to lower frequencies. Many electrode sites showed evidence of orientation tuning. Orientation tuning was manifest by changes in LFP dynamics, but not necessarily amplitude.

RESPONSES TO BROAD-BAND AND TEXTURE STIMULI IN VI: EVIDENCE FOR SPATIAL AND TEMPORAL INTERACTIONS. K. Purpura\*, E. Katz, B. Mao, A. Canel, and J. Victor. Department of Neurology and Neuroscience, Cornell University Medical College, New York, NY 10021.

Grouping of spatial and temporal features in the visual world is an important aspect of early visual processing. We examined response properties of neural assemblies in monkey VI to evaluate the extent of spatial and temporal interactions (nonlinearities) and their contributions to visual grouping.

Recordings were made in 5 anesthetized and paralyzed monkeys (Macaca fascicularis). Local field potentials (LFPs) were sampled simultaneously from many layers of parafoveal VI with a 16-element electrode. The texture stimuli all shared the same spatial power spectrum but differed in higher-order correlation statistics (elements of form). Broad-band stimuli were generated by assigning regions of the visual stimulus to different taps into a binary M-sequence. Binary M-sequence values were mapped to either two luminances or orientations of a bar.

At all electrode penetration sites in V1, and in many cortical layers, differential responses were observed to the interchange between textures differing in form elements. Linear summation, rectification or energy computation cannot account for these results; a successful model requires cooperative interaction between spatial subunits. Responses to M-sequence stimuli also revealed interactions in space and time. There was a significant contribution to the LFP which depended on whether or not stimulus tokens (luminance or orientation) presented simultaneously to two neighboring regions matched. Similarly, there was a significant contribution to the LFP which depended on whether the tokens presented to a single region on successive frames matched. The nature of the LFP suggests that these interactions occur at the level of local neural assemblies in V1. Our data suggest that such interactions are widespread in monkey V1 and as such, V1 may perform simple spatial grouping operations.

VERGENCE ANGLE MODULATES NEURAL ACTIVITY IN PRIMATE AREA VI.

Y. Trotter, B. Stricanne, S. Celebrini, S. Thorpe and M. Imbert\*, IDN, Lab. Neurosc. Vision, Univ. Paris 6, France.

We recently demonstrated (Trotter et al, Neurosci. Abstract, 1991) in behaving monkeys that the visual responsiveness and the background activity of neurons in area V1 were clearly modulated by the viewing distance. Disparity sensitivity was often present only or sharpened at a given distance of fixation (20, 40, 80 cm) with no obvious change in peaks. An increase in the amount of spontaneous activity for a particular viewing distance was often associated but independent of the modulation of the visual responsiveness. The question now is to determine the origin of these modulations.

To emphasize these phenomena, additional experiments were repeated in a

behaving monkey performing a fixation task by using random dot stereograms of different dot densities. In all nine neurons tested with RDSs of dot densities offerent dot defisities. In an inter fections tested with RDSs of not defisities between 10 and 30% at different viewing distances, the modulation of disparity sensitivity and of background activity was shown to be independent of the dot pattern. Although some neurons preferred a particular dot density, the qualitative effect of the viewing distance was always maintained.

The question is raised as to whether vergence angle or accommodation or both are implicated in these phenomena. The preliminary data show that changing the vergence angle by using wedge prisms (from 4 to 10 dioptries), replicates the effects of real changes of the fixation distance. When the effects of distance on disparity sensitivity are present, they can be replicated by using prisms producing similar vergence angles. We conclude that vergence angle is implicated in the modulation of visual responsiveness of neurons in area V1, emphazing the hypothesis of an extraretinal control of neural activity in the primary visual

BINOCULAR COMBINATION OF CONTRAST SIGNALS IN THE STRIATE CORTEX OF MACAQUE MONKEYS. E.L. Smith III\*, Y.M. Chino, J. Ni, and H. Cheng, College of Optometry, University of Houston, Houston, TX, 77204-6052.

We used extracellular microelectrode recording techniques to examine the binocular combination of contrast signals in the monkey's striate cortex. Neuronal responses were measured for dichoptic sinusoidal gratings. The spatial frequency, orientation, and relative interocular spatial phase parameters were optimized for each cell. The dependent variable was the interocular contrast ratio. For each interocular contrast asymmetry, the threshold contrasts required to produce a criterion response were derived from contrast response functions and used to construct binocular interaction contours.

Simple cells, with few exceptions, combined contrast signals from the two eyes in a linear manner. Complex cells exhibited a range of binocular interactions. Complex cells that were sensitive to relative interocular spatial phase and some non-phase selective cells also demonstrated linear binocular interactions. As with simple cells, the slope of the binocular interaction contours for these complex cells varied with ocular dominance, and the nature of the binocular interactions, i.e., facilitation vs suppression. The remaining complex cells demonstrated non-linear interactions, which in some cases, resembled quadratic binocular summation.

AXES OF REFERENCE FOR THE STUDY OF THE VISUAL SYSTEM AND VISUAL TOPOGRAPHY OF STRIATE CORTEX (V1) IN THE MEGACHIROPTERAN BAT. \*\*Pteropus.\*\* M.G.P. \*\*Rosa.\*\* L.M. \*\*Schmid.\*\* L.A. \*\*Krubitzer.\*\* J.D. \*\*Pettigrew\*\* Vision, Touch & Hearing Research Centre, Univ. of Queensland, 4072, Australia.

As a first step in the electrophysiological study of the coritcal and subcortical visual areas in megachiropterans, we defined the relationship between the horizontal (HM) and vertical (VM) meridians and the optic disc (OD), and explored the visuotopy of area V1. The representation of the visual field in area V1 was studied by multi-unit recordings in 5 flying foxes anaesthetised with thiopentone and paralysed with pancuronium bromide. \*\*Receptive fields (RFs) were recorded across the striate/prestriate border in both hemispheres, and the position of the VM was defined as the mean reversal point of the RF sequences across the border. The mean position of the VM was found to be 35° nasal to the projection of the OD. The ipsilateral invasion of RF borders did not exceed 5° in the central field, and 20° in the periphery. The HM was estimated by determining the visual streak, using ganglion cell counts in retinal flat-mounts, and was found to lie 4.5° below the centre of the projection of the OD. Perimetric studies revealed at least 110° of binocular overlap along the HM; the whole visual field encompasses approximately 260°. A precise map of the contralateral hemifield was observed in V1, with lateral sites yielding upper quadrant RFs, medial sites yielding lower quadrant RFs, and the HM bisecting V1 in nearly equal halves. Only the central 20·30° are represented on the dorsal surface. The remaining parts of the visual field are located along the medial wall and splenial sulcus. Typical receptive field sizes in V1 are about 1° in the central representation and 8·10° in the far periphery. Along the HM, the areal cortical magnification factor (ACMF) in the centre is at least 15 times as large as in the periphery. The ACMF falls

MULTI-DIMENSIONAL RECEPTIVE FIELD PROPERTIES OF NEURONS IN VI OF THE AWAKE MONKEY, E. A. Stern\*', V. Yakovley', A. M. H. J. Aertsen' & S. Hochstein', Dept. of Neurobiology, Hebrew University, Jerusalem, Israel; "Institut für Neuroinformatik, Ruhr-Universität,"

Multiple single neuron responses were recorded from a single electrode in V1 of a monkey performing a fixation task. Drifting sinusoidal gratings were presented for 500 ms in the cells' overlapping receptive fields. The stimulus was varied along several visual dimensions: orientation, spatial and temporal frequency, and direction of motion. Several cells exhibited inseparability of tuning to these visual dimensions. The strength of the interactions varied among neurons, suggesting a continuum from fully separable to truly multi-dimensional receptive fields. In addition, several cells showed different temporal response dependences to variation of different stimulus dimensions. For example, a cell might respond with a change in average firing rate as a function of one dimension (e.g. orientation), and a change in depth of modulation to variations of another (e.g. spatial frequency). Thus neurons may simultaneously code for different stimulus dimensions, increasing their information-processing capabilities.

Although tuning of most simultaneously recorded cell pairs was similar, each of the dimensional preferences and bandwidths could differ considerably. Time-dependent cross-correlation analysis revealed that joint tuning for pairs of neurons was often narrower than for either of the two individual receptive fields.

A model is proposed, based on statistical wiring within the cortical column, and differential temporal response properties controlled by cell membrane potential. The model accounts for multi-dimensional response properties and the computation of a precisely tuned population response despite individual neuron variance.

## 133.8

DISTRIBUTION OF PROPERTIES OF ENVELOPE RESPONSIVE NEURONS IN AREA 17 AND 18 1Y.-X. Zhou\* and 2C. L. Baker Psych. Dept. and <sup>2</sup>McGill Vis. Res. Center, McGill Univ., Montreal,

Some neurons respond to envelope stimuli which consist of a stationary high spatial frequency luminance grating (carrier) with its contrast modulated by a moving low spatial frequency sinusoidal grating (envelope). For a given neuron, the dependency on carrier spatial frequency (SF) shows a narrow bandpass higher than the luminance passband of the cell; effective envelope SFs are lower than the luminance passband. A model involving two parallel streams has been proposed to explain the envelope and carrier SF dependencies (ARVO, 1992). One is the luminance response stream, a bandpass tuning mechanism. The other is the envelope response stream, a three-stage cascade: high SF bandpass subunits, a pointwise nonlinearity, and a low SF bandpass.

The distribution of optimal carrier SFs for different neurons suggests that the upper limit of the optimal carrier is the cutoff SF of retinal ganglion X-cells. The optimal carrier-to-luminance SF ratio covers a range from 4 to 30, among 28 envelope responsive cells. This ratio appears to be an even distribution over 4 to 20, with only one cell's ratio at 30. Furthermore, there is no correlation between the optimal carrier and luminance SFs. This distribution of optimal carrier and luminance SFs imposes constraints on the passband of the subunits in the envelope response stream for a given neuron.

EVIDENCE OF A RELATIONSHIP BETWEEN ELECTROTONIC PROPERTIES AND MORPHOLOGY OF PYRAMIDAL CELLS IN TURTLE VISUAL CORTEX. M. Fowler\*, P. S. Ulinski, L. Smith & L. J. Larson-Prior. Dept. Org. Biol. and Anat., U. Chicago, Chicago, Il. 60637

The cerebral cortex of turtles contains neurons that respond to visual stimuli moving anywhere in the binocular visual field. Geniculocortical fibers course from lateral to medial across the cortex, establishing a series of overlapping isoazimuth lamellae which consist of cortical neurons responding to the same azimuth line of visual space. However, pyramidal cells within a lamellae vary in their morphology and their spatial relationship to geniculocortical fibers. Pyramidal cells in the lateral part of visual cortex have extensive apical and basal dendritic fields. Geniculate axons synapse upon the distal tips of their apical dendrites. Pyramidal cells in medial cells in the lateral part of visual cortex have extensive apical dendrites. Pyramidal cells in medial axons synapse upon the distal tips of their apical dendrites. Pyramidal cells in medial axons synapse upon the distant into or une apirca declinines. Fyraindar cets in inclusion visual cortex possess only apical dendritic trees. Geniculate axons synapse upon their proximal dendrites and somata. These differences suggest that there may be major differences in the functional organization of the geniculocortical synapses within lamellae. This study correlates the electrotonic structure of pyramidal neurons with their position along the isoazimuth lamellae.

We recorded intracellularly in current clamp from pyramidal cells in a reduced in vitro preparation. Analysis of voltage responses to subthreshold hyperpolarizing s allowed the calculation of the cells' membrane time constants (Tm) and two equalizing time constants ( $T_1$  and  $T_2$ ) which yielded a value for the electrotonic length (L) of each cell. The values of  $T_m$ ,  $T_1$ ,  $T_2$  and L were plotted as a function of distance along the isoazimuth lamellae.  $T_m$  remained constant (Mean =  $10\pm36$ ) while  $T_1$  (Mean = 30±14) and  $T_2$  (Mean = 20±10) decreased with increasing distance along the lamella. Consequently, L (Mean = 2.3±1.0) decreased from about 2.8 to 2.2 along the lamella. This suggests that changes in the electrotonic structure of pyramidal cells along the isoazimuth lamellae compensate for differences in the synaptic position of geniculocortical afferents. Thus, geniculocortical afferents can have significant effects at the soma despite the major differences in the geometry of the geniculocortical system. Supported by PHS Grant EY 08251.

ELECTROTONIC MODEL OF GABAERGIC HORIZONTAL CELLS IN TURTLE VISUAL CORTEX. J. M. Nicolaus\*, P. S. Ulinski and L. J. Smith. Department of Organismal Biology and Anatomy, University of Chicago, Chicago, IL 60637 Turtle visual cortex is a trilaminar nerve network involved in visual

motion analysis. Its third layer contains GABAergic horizontal cells whose dendrites extend within the layer parallel to the ependyma. Their axons have collaterals within visual cortex and also project from the cortex to the lateral geniculate complex. Knowledge of the biophysical properties of these cells is important in understanding the microcircuitry of visual cortex. We combined morphological data from GABA-immunoreactive neurons in cortical wholemounts with physiological data from current-clamp recordings to construct a compartmental model of a small horizontal cell.

The morphological data were used to calculate compartmental lengths and areas (total area =  $2,764 \mu m^2$ ). Analysis of voltage responses to current pulses (-0.1 nA, 1 sec) by the method of peeled exponentials yielded a membrane time constant of 55 ms and a first equalizing time constant of 29 ms. The cell had an electrotonic length of 4.3 and a space constant of 31 µm. The model was used to estimate membrane parameters by fitting its responses to current injection to the actual value of total input resistance (106 M $\Omega$ ) and the real neuron's charging function. Axial resistance was 400  $\Omega$ , specific capacitance was 0.8μF/cm<sup>2</sup> and specific resistance was 9,322 Ωcm<sup>2</sup>. Attenuation of voltage response with dendritic distance indicates these neurons are not electrotonically compact, so inputs from many pyramidal cells would be required to fire them.

CONTRAST SENSITIVITY IN CATS AFTER REMOVAL OF THE Y-INPUT. C. Trimarchi<sup>1</sup>, C.A. Marzi<sup>2</sup>, G. Tassinari<sup>2</sup> and S. Bisti\*<sup>1</sup>. <sup>1</sup> Istituto di Neurofisiologia C.N.R., Pisa, I-56127 & <sup>2</sup> Istituto di Fisiologia Umana, Università di Verona, I-37100.

The spatial performance of the visual system is best described by its contrast sensitivity function. Visual information reaches the visual cortex mainly through two parallel and functionally distint pathways originating in the retina from two classes of ganglion cells, X and Y. Several hypotesis have been advanced of the possible role of the two system in the analysis of visual pattern. A direct evaluation of the role of the two pathways can be made by analyzing the contrast sensitivity after selective elimination of either X or Y input. A lesion on the ventral sub-pial portion of the optic tract causes a selective degeneration of the Y-axons with a partial involvement of W-axons while the X-axons remain largely unaffected. This surgical procedure was utilized in the present study with the purpose of analyzing the was utilized in the present study with the purpose of analyzing the properties of visual cortical neurones in cat with Y-input removed on one side. We have recorded Visual Evoked Potentials (VEPs) in response to gratings of sinusoidal luminance profile that were modulated sinusoidally in time. Responses to stimuli of different contrast and spatial and temporal frequencies were compared between normal and Y-deafferented visual cortical areas 17 and 18 of the same cat. The amplitude of VEPs recorded in the deafferented visual areas was reduced at low spatial and temporal frequencies and this reduction becomes more evident at increasing values of contrast. Spatial and temporal acuities were similar in both normal and deafferented hemispheres. Supported by EEC grant SC1000224

INTRINSIC FIRING PATTERNS IN NEURONS OF THE TURTLE VISUAL CORTEX. L.J. Larson-Prior\* and P.S. Ulinski, Dept. Org. Biol. and Anat., U. Chicago, Chicago, IL 60637

Anat., U. Chicago, Chicago, IL. 60637

Intrinsic physiologic properties of neuronal membranes play a critical role in the transformation of received input to a specific output, defined by the temporal patterns of action potential generation. Neuronal firing patterns correlated with anatomical properties have recently been utilized to classify neurons in the cortex of several species (eg. McCormick et al., 1985; Conners and Kriegstein, 1986)

In order to develop a quantitative method by which variations in firing pattern could be compared, intracellular recordings were obtained in a turtle visual cortical preparation in vitro. Direct responses of neurons to intracellularly injected square current pulses (+0.1-1.5 nA, 400-1000 msec.) were used to assess intrinsic firing pattern. Neuronal firing patterns changed significantly as levels of injected current were increased. Therefore, a method was devised in which firing responses to all were increased. Therefore, a method was devised in which firing responses to all levels of current intensity could be used to quantify a given cell's firing pattern. Initial firing rate was measured as the slope of a line derived from the first two points in the cumulative firing curve, normalized to the time of firing of the last action in the cumulative firing curve, normalized to the time of firing of the last action potential generated at the highest current intensity. The degree of spike frequency adaptation was measured by comparing the initial firing rate of the cell to its firing rate later in the spike train. The line generated to determine the initial firing rate represents the cell's response if no frequency adaptation occurs. A third order polynomial fit to the response of a cell to steps of increasing current intensity yielded a response curve which-when subtracted from the linear response profile expected with no adaptation-represents the degree of adaptation present in that cell. The area between the line of initial firing rate and the polynomial was taken as an index of adaptation The firing rate was then plotted against this index of adaptation in order to generate a curve which depicts the firing rate pattern of that cell across a large range of current injection steps.

This analytical method introduces descriptive parameters that can be used to describe the behavior of any neuron to depolarizing current injection. Supported by NS 30759 (LLP) and EY 08352 (PSU).

SUBCORTICAL PROJECTION PATTERNS OF INDIVIDUAL NEURONS IN LAYER V OF STRIATE CORTEX <u>P. Stawinski, M. Conley and D. Fitzpatrick\*</u>. Dept. Neurobiology, Duke University, Durham, NC 27710. Pyramidal neurons in layer V of striate cortex are the source of

projections to a number of brainstern targets, including the superior Retrograde double label experiments have shown that some layer V neurons have axons that branch to innervate more than one subcortical target, but the complete branching pattern of individual axons remains unknown. To address this issue we made small injections of biocytin into area 17 of tree shrew striate cortex and traced individual axons from layer V cells to their brainstem targets.

Layer V neurons display axonal branching patterns that vary from innervation of a single target to innervation of all four targets. Despite this variation, there seem to be certain rules that govern the patterns of axonal branching. For example, only the superior colliculus and the pons receive projections from neurons whose axons are restricted to a single target; all the projections to the ventral lateral geniculate nucleus and pretectum arise from neurons that send collaterals to other targets.

These results show that pyramidal neurons in layer V comprise several distinct populations that differ in their axonal branching patterns. It remains to be determined whether these populations can also be distinguished on the basis of other characteristics such as axon diameter, soma size, dendritic morphology or laminar position within layer V. Supported by EYO6821 and EYO6661.

# 134.2

INTRINSIC AND EXTRINSIC PROJECTIONS OF NEURONS IN LAYER VI OF STRIATE CORTEX: ANATOMICAL EVIDENCE FOR SELECTIVE INFLUENCE ON PARALLEL GENICULOCORTICAL PATHWAYS. W.M. Usrey\* and D. Fitzpatrick. Dept. of Neurobiology, Duke Univ. Med. Ctr., Durham, NC 27710.

Durham, NC 27710.

Pyramidal neurons in layer VI of striate cortex are the origin of descending projections to the lateral geniculate nucleus (LGN) as well as a major source of axon terminals in the layers of striate cortex that receive LGN projections. Since the pathway from the LGN to striate cortex is organized into parallel streams that target different cortical layers, we asked whether layer VI neurons might also comprise separate classes that differ in their patterns of intrinsic projections and in their projections to the LGN. To address this question, we made small extracellular injections of biocytin into layer VI of tree shrew striate cortex and traced the intrinsic and extrinsic axonal projections of individual labeled neurons

Analysis of single cell reconstructions reveals two classes of intrinsic axon

Analysis of single cell reconstructions reveals two classes of intrinsic axon arbors that arise as collaterals from layer VI projection neurons. One class terminates in layer IV, while the other rises through layer IV to terminate throughout layers III-I. Reconstructions of individual corticogeniculate axons also reveal two distinct classes. One class terminates preferentially in LGN layers 1,2, 4 and 5, with little involvement of layers 3 and 6; the other terminates preferentially in LGN layers 3 and 6 and gives rise to a collateral projection to the

pulvinar nucleus.

The differences between the classes of intrinsic axons and geniculate-projecting axons are significant in light of the organization of parallel geniculocortical pathways in this species: LGN layers 1,2 4 and 5 terminate in layer IV, while paniways in this species: LON layers 1,24 and 5 terminate in layer IV, while LGN layers 3 and 6 terminate primarily in the supragranular layers. This raises the possibility that individual layer VI neurons could exert a selective influence over the activity in functionally distinct geniculocortical pathways at the level of the LGN as well as the striate cortex.

CYTOCHROME OXIDASE AND CALBINDIN STAINING IN VISUAL CORTEX OF THE GROUND SQUIRREL. H.R. Rodman, H.J. Karten and M.I. Sereno Dents of Neurosci & Con Sciences LICSD La Jolla CA

and M.I. Sereno. Depts. of Neurosci. & Cog. Sciences, UCSD, La Jolla CA. Ground squirrels are diurnal mammats with an expansive visual cortex containing many distinctive visual areas (Sereno et al., NS Abs. 1991). We used cytochrome oxidase (CO) and calbindin D-28K (CaBP) to aid in the parcellation of cortical areas in the California ground squirrel (Spermophilus beechey) and the thirteen-line ground squirrel (Sp. tridecimlineatus).

CO. In flat mounts through the middle layers of cortex, CO staining formed a web-like pattern in the *monocular* segment of V1, especially in the thirteenline squirrel. Staining in both the binocular segment of V1 and in V2 appeared uniform and relatively dense, showing no obvious blobs or stripes. Moving laterally, the intermediate zone was moderately stained, areas ML and L were lightly stained, and densely myelinated area Tp stained heavily and somewhat patchily. In coronal sections, the binocular compartment of V1 is sharply demarcated by a thick CO-dense layer IV. The uniform staining in V2 gives way laterally to a dark band in layer V of cytoarchitectonic area 19.

gives way rateriary to a dark band in layer V. Cylorical CaBP. In flat mounts, CaBP produced a pattern complementary to that seen in CO in many regions of neocortex, as reported for some layers of monkey V1 by Celio et al. (Nature 323: 715, 1986). In standard planes the most salient features of the CaBP pattern are the heavy staining of layers I and II and the paucity of staining in thalamorecipient layers of V1 and other primary sensory areas. Both pyramidal and nonpyramidal neurons were labelled by CaBP and were especially dense in superficial layers of the binocular portion of V1. The results suggest that CO and CaBP are valuable for delineating compartments within and borders between cortical areas in these species and support the association of CaBP staining with extrathalamocortical processing.

BLOB-LIKE PATTERN OF CYTOCHROME OXIDASE STAINING IN FERRET VISUAL CORTEX. H.S.Cresho<sup>1</sup>, L.M.Rasco<sup>1</sup>, G.H.Rose<sup>1</sup>, and G.J.Condo<sup>2\*</sup>. Neuroscience Prog.<sup>1</sup> and Dept. of Psychology<sup>2</sup>, Bowdoin College, Brunswick, ME 04011

The organization and differential staining of cytochrome oxidase (CO) patterns in visual cortex is a useful marker for visual cortical modules. This study evaluated the pattern of CO staining in adult ferret areas 17 and 18. Cortices were reacted for CO activity after postfixing for 24-48hrs in 2%paraformaldehyde - 1.25% glutaraldehyde. Sagittal and frontal sections yielded pattern of CO staining similar to that reported for other species: dense staining of layer IV, darkly reactive pyramidal cells in layer V, weak irregular periodic staining in layer VI, and regular periodic staining in layer III. The blob-like pattern seen in supragranular layers was more evident in flattened cortical preparations in both central and peripheral areas. CO blob-like areas in layer III of area 17 were lighter and more irregular in shape than blobs reported in primates or cats. At the area 17/18 border irregular stripe-like CO staining in supragranular layers of area 18 is evident perpendicular to the border. Last, within area 18 darkly reactive layer V pyramidal cells increase in relative frequency but not in soma size at the area 18/19 border relative to samples of layer V CO reactive pyramidal cells at the area 17/18 border.

The calcium binding proteins (CaBPs), parvalbumin, calbindin D-28k, and calretinin define cytoarchitectural features of the monkey occipital cortex Blümcke 1\*, Hof PR, Lüth HI, and Celio MR

Institute of Histology, University Fribourg, CH - 1700 Fribourg; Dept of Neurobiology, Mount Sinai School of Medicine, 10029 New York, USA

Previous studies have demonstrated that CaBPs are highly reliable anatomical markers in that they define clear patterns of regional and laminar specialization. We have systematically studied their distribution in two visual areas (V1 and V2) in the macaque monkey, using immunohistochemical methods, in order to further precise their cytoarchitectural features. Of the three CaBPs studied, PARVALBUMIN immunoreactivity (PV-ir) was the densest, and occurred preferentially in the thalamorecipient layers of V1. The neurons showed the typical features of multipolar interneurons. These morphological and laminar distribution patterns were maintained in V2. Only the projection lamella in the white matter (WM), related to V1, contained thick PV-ir fibers. CALRETININ immunoreactivity (CR-ir) was less abundant than PV, and ir-neurons occurred predominantly in the superficial layers of V1 and V2, including layer 1. Most CR-ir neurons were vertically oriented and resembled double-bouquet cells (more distinct in V2 than in V1). In V1 a narrow band of labeled neurons was present at the border of 4CB/5A. CR-ir labeled cells were always visible in short association fibers in the WM. CALBINDIN D-28k immunoreactivity (CB-ir) was the less densest of the three CaBPs. In the superficial layers of V1 and V2, interneurons as well as pyramidal cells were stained; CB-ir neurons showed also a vertical organization (more distinct in V2). CB-ir and CR-ir were not colocalized. The cytoarchitectural patterns revealed by the three CaBPs demonstrate their complementarity in defining neuronal typology, and outlining functional systems. SEGREGATED PROCESSING STREAMS IN CAT VISUAL CORTEX? RELATIONSHIP OF PATCHY CONNECTIVITY TO AN EXTRASTRIATE AREA, CYTOCHROME OXIDASE STAINING, AND LOCAL CONNECTIONS. LD. Boyd\*1 and J.A. Matsubara. 1.2. Depts of 1 Ophthalmology and 2 Anatomy, University of British Columbia, Vancouver, British Columbia, Canada, VSZ 3N9.

Primate area 17 is compartmentalized into distinct processing streams which deal with different types of information, i.e., colour, form, motion. These compartments can be seen by cytochrome oxidase (CO) staining, by their different projections to extrastriate visual areas, and by local connectivity (same stream compartments interconnect). Recent examinations of Lateral Suprasylvian projections (LS; Shipp and Grant, 1991), serotonin receptors and zine staining (Dyck et al., 1991) and CO staining (Murphy et al., 1991), all showed heterogeneity within cat area 17, suggesting it contains processing streams analogous to those in primates.

After making multiple large injections of 1% wheat germ agglutinin-horseradish peroxidase (HRP) into the LS (10-12 µL at 18 sites), we examined the labeling in flattened tangential sections through area 17. Neurons projecting to the LS were arranged in clusters that tended to form an irregular lattice with a spacing of roughly 0.6mm to 0.9mm. In two cases where serial sections were run for HRP or CO, the clusters of cells colocalized with the blobs of high CO activity visible at the layer 3-4 border. In two cases, injections of HRP in the LS were combined with focal injections of 0.02µl 1% cholera toxin subunit B (CTB) into area 17. In both cases, the clusters of locally projecting cells labeled with CTB were preferentially colocalized with the clusters of LS projecting cells labeled with HRP.

the clusters of the projecting cells labeled with HRP.

The alignment of CO staining, local, and LS connections suggests that the LS projection demarcates a segregated stream in cat area 17. Although segregation of streams within primary visual cortex may be common to cats and monkeys, the particular streams in feline visual processing are unlikely to match those in the primate. THE DISTRIBUTION OF PARVALBUMIN AND CALBINDIN POSITIVE NEURONS IN VISUAL CORTEX OF THE TREE SHREW (*Tupaia belangeri*). M. A. Sesma\*, School of Optometry, University of Missouri-St. Louis, St. Louis, MC 63121.

The calcium binding proteins parvalbumin and calbindin-D28K mark separate populations of GABAergic neurons in mammalian CNS. The role of these proteins is unclear but their differential distribution may be related to distinct processing channels. To better understand the microarchitecture of visual cortex in the tree shrew the distribution of neurons immuno-positive for parvalbumin and calbindin were compared with the distribution of GABA immunoreactive neurons using commercially available antibodies and conventional immunohistochemical methods (avidin-biotin-peroxidase) on aldehyde-fixed, vibratome sections.

Parvalbumin immunoreactive neurons were distributed uniformly throughout layers II-VI in area 17, 18 and Temporal Dorsal area (TD). Most were medium to large in diameter (>10 µm), even within layer IV of area 17. Calbindin immunoreactive neurons were distributed predominantly in the superficial layers (II, III) in small to medium size (<15 µm) neurons. In area 17, layer IV was densely stained while layer III was calbindin-free allowing easy discrimination of the 17/18 architectonic border. Calbindin staining in the infragranular layers was uniform but quite sparse and in area 17, a

easy dischimination of the "I/16 a chinetcoline botton". Calonium staining in the infragranular layers was uniform but quite sparse and in area 17, a population of medium size pyramids was seen in upper layer V.

The pattern of visual cortical staining with antibodies directed against parvalbumin and calbindin-D28K differs in some respects from the distribution described for primates and carnivores, especially in the dense staining in the granular layers of area 17. This may reflect basic differences in a visual cortex evolved to segregate ON- and OFF-center channels rather than MCA DEV centures.

than M(Y), P(X) pathways.

CHANGES IN CYTOCHROME OXIDASE AND NEURONAL ACTIVITY IN V1 INDUCED BY MONOCULAR TTX BLOCKADE IN MACAQUE MONKEYS. T. C. Trusk\*, M. Wong-Riley, & E. A. Deyoe. Dept. of Cellular Biology & Anatomy, Medical College of Wisconsin, Milwaukee, WI 53226.

To determine if changes in metabolic capacity revealed by cytochrome oxidase (CO) histochemistry are related to sustained changes in energy-utilizing neuronal activity, we recorded multiunit firing rates along nearly tangential penetrations of V1 before and after single injections of TTX into the left eye of 5 adult macaques. To ensure that changes in cortical activity reflect the effect of TTX alone, we matched adaptation conditions by occluding the left eye and exposing the right eye to 1 of 4 adapting fields: black, gray, white and textured. Five sec samples of multiunit spike rate were obtained after 2 min adaptation to each condition. Results were similar for these 4 conditions. TTX blockade began to reduce CO activity in left-eye columns of layer 4C within as little as 12 hrs but reached <sup>2</sup>/<sub>3</sub> of maximal depletion only after 72 hrs. Activity recorded in left-eye columns of layer 4C following TTX averaged 48% of that in right-eye columns. Immediately after TTX injection, ongoing activity in layers 2/3 measured repeatedly at single sites in both left- and right-eye dominated interpuffs decreased up to 3-fold in less than 1 hr but stabilized within 3-4 hrs to an average of 50% (p<.01) of pre-TTX rates. Before TTX, spike rates in CO-rich puffs were 33% greater than in CO-pale interpuffs. These data support the notion that energy-utilization linked to sustained spike rates partially regulates CO levels, at least in layer 4, and suggest that changes in neuronal activity induced by retinal TTX precede the detectable reduction in CO activity in V1. (Supported by NIH grant EY05439.)

INTERPUFFS IN THE MACAQUE STRIATE CORTEX: QUANTITATIVE EM ANALYSIS OF NEURONS BEFORE AND AFTER UNILATERAL RETINAL IMPULSE BLOCKADE. M. Wong-Riley\*T. Trusk. W. Kaboord and Z. Huang. Dept of Cellular Biology & Anatomy, Med. Coll. Wisconsin, Milwaukee, WI 53226. Our previous studies indicate that unilateral retinal impulse blockade

Our previous studies indicate that unilateral retinal impulse blockade causes a down-regulation of cytochrome oxidase (CO) in the supragranular puffs along the deprived eye column, and that the effect is more detrimental to certain classes of neurons than to others. The present study aimed at analyzing the effect of TTX on interpuffs (IRI) from normal monkeys, and intra-control row interpuffs (IRI) from normal monkeys, and intra-control row interpuffs (ICI) and intra-experimental row interpuffs (IEI) from unilateral TTX-injected animals. We found the same three major neuronal types in interpuffs as in puffs: Type A neurons were small nonpyramidal and pyramidal cells with relatively low levels of CO activity; type B neurons were medium-to-large pyramidal cells that were moderately reactive for CO; and type C neurons were medium-sized nonpyramidal cells darkly reactive mitochondria than those in puffs. Both types A and B received exclusively symmetrical axosomatic synapses, while type C received both symmetrical and asymmetrical axosomatic synapses. Two weeks of TTX blockade induced a significant downward shift in the size and reactivity of mitochondria in type C neurons, while types B and A neurons were much less affected. Thus, our present data support our previous findings that retinal impulse blockade is most detrimental to the metabolically most active neurons in the adult visual cortex. (Supported by NIH grant EY05439).

Inhibitory and Excitatory Amino Acid Receptor Distributions in

Adult Human Visual Cortex. <sup>1\*</sup>D.F. March. <sup>\*\*</sup> <sup>2</sup>A. E. Hendrickson and <sup>1</sup>C. Shaw.

<sup>1</sup>Dept. of Ophthalmology, Univ. of British Columbia, Vancouver, Canada and <sup>2</sup>Dept. of Biological Structure, Univ. of Washington, Seattle.

In previous studies we have examined the characteristics and distributions of the inhibitory GABA, receptor complex (Jour. of Neurosci 1991,11:3943) and the excitatory NMDA and AMPA receptors (Soc. Neurosci Abstr. 1991,17:365) in the visual cortex of the macaque monkey. We have now extended these studies to human visual cortex. In order to use human postmortem material we have also completed parametric experiments on receptor degradation in postmortem rat cerebral cortex. At 4°C the receptor populations in this study were stable for at least 24 hours. In adult human visual cortex GABA "/benzodiazapine receptors showed moderate to low binding in layers 1,5 and 6, high binding in layers 2/3 and the densest binding in 4C. AMPA receptors showed the densest binding in layers 1-3, with moderate binding in layers 5/6 and low binding in layer 4. NMDA receptors showed moderate binding in layers 1-3, low binding in layers 5/6, and high binding in 4C. These studies reveal similarities for GABA, and AMPA receptor distributions between human/monkey visual cortex and that of lower mammals. There are, however, profound differences between primates and lower mammals in the distribution and time of expression of NMDA receptors. Since the NMDA receptor population is often considered crucial for the modification of neuronal activity, these data may suggest caution in the use of some animal models (eg., cat) of visual cortex function, development, and plasticity.

PATTERNS OF LATERAL CONNECTIONS IN MACAQUE VISUAL AREA V1 REVEALED BY BIOCYTIN HISTOCHEMISTRY AND FUNCTIONAL IMAGING. T. Yoshioka\*, G.G. Blasdel, J.B. Levitt, J.S. Lund, Center for Neuroscience, Univ. of Pittsburgh, Pittsburgh, PA 15261; Dept. Neurobiology, Harvard Medical School, Boston, MA 02115 We made small iontophoretic injections (diameter:100-200µm) of biocytin

in layers 1-3 of macaque area V1, and sectioned the tissue tangentially to examine the intrinsic lateral connectivity. Alternate tissue sections were reacted for biocytin or cytochrome oxidase (CO) to correlate the locations of njections and transported label in relation to the CO subcompartments (blobs, interblobs, and blob edges). Anterograde and retrograde label formed oval or circular shaped patches with maximum mean diameter of  $250\mu m$ regardless of the size or location of the injection in relation to the CO compartments, with an average of 10 labeled patches per injection. Injections in each compartment showed projections mainly but not exclusively to the same compartment. The emphasis on connectivity within similar compartments (Livingstone and Hubel, '84) was about 70%. The total area of clearly distinguishable patches derived from single injections averaged 2.3mm by 1.5mm (average anisotropy 1.6). In most cases, anisotropy was at right angles to CO blob rows and ocular dominance bands visualized by voltage-sensitive dye imaging. The patches from single injections were predominantly (about 75%) in domains of the same ocular dominance. Although these results are consistent with previous suggestions that these connections primarily link cells of like property, nonetheless there is a substrate for interaction between neurons of unlike property. (Supported by NEI grants EY05282, EY08098, EY06275, ARVO/Alcon; EY05403, Office of Naval Research.)

#### 134.10

DIFFERENTIAL REGULATION OF GABAA RECEPTOR SUBUNIT mRNAS IN ADULT MONKEY VISUAL CORTEX BY MONOCULAR DEPRIVATION.

M. M. Huntsman\*, P. J. Isackson<sup>1</sup>, and E. G. Jones. Dept. of Anatomy and Neurobiology, University of California, Irvine, CA 92717, and <sup>1</sup>Dept. of Molecular Biology and Biochemistry, The Mayo Clinic, Jacksonville, FI 32224

The GABAA receptor is composed of a number of subunits that, in addition to GABA, contain binding sites for benzodiazepines and barbituates. These polypeptide subunits are structurally similar, and can be divided into distinct classes  $(\alpha, \beta, \gamma, \delta, \epsilon)$ , and subclasses  $(\alpha 1, \alpha 2, \alpha 3, \alpha 4, \alpha 5)$ , based on sequence identity. Immunoreactivity for various GABAA receptor subunits shows a distinct yet overlapping distribution in the primate visual cortex (Huntsman et al., 1991, Neurosci. Abstr. 16, 115). Portions of monkey specific cDNAs of previously published sequences were cloned into the pBS transcription vector for the localization of mRNA in area 17 of the monkey visual cortex. The localization of mRNAs for one representative of each receptor class  $(\alpha, \beta, \gamma)$  was identified. The distributions of  $\alpha 1$  and  $\gamma 2$  subunit mRNAs are similar and their distribution is a reflection of geniculocortical terminations, with highest grain density in layers IV and II/III. The  $\beta 1$  subunit, however, displays no laminar

Neural activity has a profound effect on the regulation of genes for these subunits. Following monocular deprivation by tetrodotoxin injection, mRNAs for the Ω1 and γ2 subunits decrease in deprived ocular dominance columns, whereas, the mRNA for the β1 subunit is not affected. These data indicate that levels of mRNAs for the polypeptide subunits of the GABAA receptor are not only localized in a specific laminar distribution, but are also regulated in an activity-dependent manner. Differential localization of these subunits may give rise to variations in the pharmacological properties of GABAA receptors in different layers of the primate visual cortex. Supported by grants EY07193 and NS26748.

IMMUNOCYTOCHEMICAL DETECTION OF GABA, RECEPTORS IN THE CAT VISUAL CORTEX. A.M. Rosier, G.A. Orban and F. Vandesande\* Lab. of Neuroendocrinology and Immunological Biotechnology, Lab. of Neuro- and Psychophysiology, Catholic Univ. Leuven, Belgium.

Psychophysiology, Catholic Univ. Leuven, Belgium.

The purpose of this study was to raise specific monoclonal antibodies against a synthetic peptide selected from the B-subunit of the bovine GABAA receptor in order to identify distinct cells in the cat visual cortex, exhibiting GABAA-receptorir. Solubilized and affinity-purified GABAA receptors were used to examine the selectivity of the antibody with SDS-PAGE and immunoblotting, and with immunoadsorption.

In the cat visual cortex, two major populations of GABAx-receptor-ir cells were observed: neurons and astroglial-like cells.

Positive neurons occurred in all layers (± 250-400 neurons/mm²), with a minimum in layer I (± 50 neurons/mm²). Expressing the number of positive neurons as a function of the total laminar neuronal population, yielded the highest density in layer V (±60%), compared to ±40% in layers III-IV-VI; ±25% in layer II; and ±10% in layer I. Double stainings using receptor- and GFAP-antibodies, confirmed that the observed glial-like positive cells observed both in cortical grey matter and in the white matter are astrocytes.

INTRINSIC CONNECTIONS IN HUMAN VISUAL CORTEX REVEALED BY EXTRACELLULAR BIOCYTIN APPLICATION IN-VITRO. G. Kenan-Vaknin\*, G.E. Ouaknine, N. Razon and R. Malach, Neurobiology Dept. Weizmann Institute, Rehovot and Neurosurgery Dept. Ichilove Medical Center, Tel Aviv, Israel.

Studies of human cortical circuitry, although of extreme interest, are limited by the poor resolution of analysis available on post-mortem material. Here we report on a novel tract tracing approach, using the anterograde tracer biocytin, which provides unprecedented detail in the study of cortical axonal projections. Human cortical specimens were obtained from non-diseased cortical tissue removed from the occipital lobes during neurosurgical procedures to treat tumors or brain malfunctions. Coronal and tangential slices were iontophoreticlly injected with biocytin, incubated for additional 2 hours and then processed according to Horikawa and Armstrong (1988). The results show Golgi-like staining of axons carrying numerous boutons extending up to 4 mm from the injection sites. Dendritic arbors and spines could be clearly observed as well. In coronal slices, injections in supragranular layers revealed axon trunks descending vertically to the white matter with dense collaterals in supra- and infragranular layers. Few oblique and horizontal collaterals were seen in layer VI. Injections in infragranular layers revealed long horizontal collaterals and vertical and oblique ascending axons towards layer I. Long oblique and horizontal collaterals were found in the white matter. In tangential slices, axons radiated from the injection sites forming a dense halo. results indicate that biocytin injections provide a powerful tool for systematic analysis of local circuits in the human cortex.

CORTICOCORTICAL FEEDBACK CONNECTIONS IN VISUAL CORTEX SYNAPSE SELECTIVELY WITH DENDRITIC SPINES. R. R. Johnson and A. Burkhalter. Dept. Neurosurgery, Washington Univ. Sch. Med., St. Louis, MO 63110.

Louis, MO 65110.

Although the feedback pathway from extrastriate to striate visual cortex in the rat, as in other mammals, is known to provide a very prominent input to both upper and lower layers, its function is largely unknown. In order to understand the role of the feedback pathway, we have identified the targets of feedback axons in primary visual cortex at the synaptic level. Feedback axons are labeled by the anterograde tracer Pha-L. Sections containing the feedback pattern of projections are embedded, and feedback terminals are identified in serial thin sections by an electron dense DAB product. Postsynaptic profiles of dendritic spines, shafts and cell bodies are identified by standard ultrastructural criteria.

Although we predicted that many feedback terminals would synapse with inhibitory interneurons (Johnson and Burkhalter, 1991, Soc. Neurosci. Abstr. 17:844), examination of profiles postsynaptic to feedback terminals indicates that input to interneurons may be very minor. Of the first 59 feedback synapses identified in upper layers, all feedback terminals in layer 1 (19/19) and almost all in layer 2/3 (39/40) made synapses with dendritic spines. Only one terminal in layer 2/3 was found to synapse with a dendritic shaft. In this preliminary data, therefore, the postsynaptic targets of the feedback pathway are ~98% spines and ~2% shafts.

Interestingly, these results suggest that (1) the organization of feedback connections is more like association pathways across the corpus callosum (Circultoria) and the properties of the corpus callosum (Circultoria) and the properties of the corpus callosum (Circultoria) and the properties of the corpus callosum (Circultoria) and the properties of the corpus callosum (Circultoria) and the properties of the corpus callosum (Circultoria) and the properties and properties and properties and properties and properties and properties and properties and properties and properties and properties and properties and properties and properties and properties and properties Although the feedback pathway from extrastriate to striate visual cortex

Interestingly, these results suggest that (1) the organization of reedback connections is more like association pathways across the corpus callosum (Cipolloni and Peter, 1983, J. Neurocytol. 112:713) than forward connections (Lowenstein and Somogyi, 1991, J. Comp. Neurol. 310:253) or lateral connections (McGuire et al., 1991, J. Comp. Neurol. 305:370), and (2) feedback to inhibitory interneurons is unlikely to be the mechanism for interareal synchronization of oscillations (Engel et al., 1991, PNAS 88:6048) as suggested by Crick and Koch (Cold Spring Harbor Symp., 1990, 55:953).

TOPOGRAPHICAL ORGANIZATION OF AXONS IN THE SPLENIUM OF THE RAT CORPUS CALLOSUM. J.H.Y.Kim\*, A.B.Ellman & J.M.Juraska.
Neuroscience Program & Dept. of Psychology,
Univ. of Illinois, Champaign, I1 61820
 While callosal fibers show at least a rough

topographical organization depending on the cortical region of origin, the precise organization of axons in the rat splenium has not been investigated. In the present study, discrete injections of WGA-HRP were made into the 17/18a border of the visual cortex of adult Long Evans male and female rats. Our results indicate that posterior injections labelled the posterior end of the splenium, while anterior injections labelled fibers located slightly anterior within the splenium. Injection sites which included the anterior-most extent of the primary visual cortex suggest that visual callosal fibers project through approximately the posterior eighth of the corpus callosum. Injections restricted to the secondary visual areas and the temporal cortex will be made to map their callosally projecting axons within the splenium. The topography of axons within the splenium will also be examined at younger Supported by NSF BNS 89-09164

# INVERTEBRATE SENSORY SYSTEMS

DEVELOPMENTAL APPEARANCE OF PROCESSING UNITS IN THE OLFACTORY AND ACCESSORY LOBES OF THE AMERICAN LOBSTER. S. M. Helluy'. M. L. Ruchhoeft and B. S. Beltz. Bio. Dept., Wellesley College,

Wellesley, MA. 02181.

The brain of Homarus americanus enlarges 500 times (from 0.05 to 25 mm<sup>3</sup>) between hatching and maturity. The aims of this study are 1) to characterize the accompanying enlargement of the offactory (OLs) and accessory (ALs) lobes in the deutocerebrum; 2) to document the changes in the number of processing units (glomeruli) in these lobes; and 3) to acquire base-line data for a study of the potential morphogenic effects of serotonin on the organization and maturation of the deutocerebral lobes.

Serial sections of brains at different stages of development were traced on a diritizing and linked to a 3-D computarized reconstruction system which also

Serial sections of brains at different stages of development were traced on a digitizing pad linked to a 3-D computerized reconstruction system which also yielded morphometric data. Between a hatchling and a one pound lobster the volume of the OLs and of the ALs increases by a factor of 300 (from 0.0025 to 0.7 mm³) and 550 (from 0.001 to 0.55 mm³) respectively. Preliminary estimates show that the number of offactory glomeruli (which are columnar and radially arranged at the periphery of the lobes) reaches more than 100 per lobe at hatching, increases rapidly during larval life, and stabilizes at about 200 to 300 in juvenile and adult lobsters. Glomeruli in the ALs are spherical structures scattered throughout the lobes and are seen for the first time in larval stage 2. There are about 2000 glomeruli per AL. in stage 4 and this number seems to remain constant during the life of the lobster. In both lobes, it is the size of the interglomerular spaces and of the glomeruli themselves that increases (mean diameter; 21 to 100 um at the distal surface of the columnar offactory glomeruli. intergiornerular spaces and or the giomeruli intermserves that increases (mean diameter. 21 to 100 μm at the distal surface of the columnar offactory glomeruli, 6 to 30 μm for the spherical accessory glomeruli). Therefore the data suggest that in both OLs and ALs most of the glomeruli have been generated when the lobster metamorphoses (stage 3 to 4) and switches from a pelagic to a benthic existence. (Supported by BNS-8718938 and 8958169, and NIH NS-25915).

BOTH STEADY AND FLASHING DIFFUSE LIGHT INCREASE 2-DG UPTAKE IN GROUND SQUIRREL BUT NOT IN RAT VISUAL CORTEX. B.M.

OPTAKE IN GROUND SQUIRREL BUT NOT IN RAT VISUAL CORTEX. R.M. COOPER\*. Behavioural Neuroscience Research Group, Dept. Psychology, University of Calgary, Calgary, Alberta, Canada T2N 1N4.

Diffuse light significantly affects visual cortex activity in the diurnal primate but not in the nocturnal cat, rabbit or rat. Thus, "luxotonic" units, i.e. cells which respond to diffuse light, are readily detectable in recordings made from macaque striate cortex but are rarely encountered in cat and rabbit cortex (Kayama et al., <u>J. Neurophysiol.</u>, 42: 1495, 1979). Similarly, diffuse cortex (Kayama et al., <u>J. Neurophysiol.</u>, 42: 1495, 1979). Similarly, diffuse light stimulation elevates 2-DG uptake in monkey (Tootell et al., <u>J. Neurosci.</u> 8: 1569, 1988) but not in rat (Cooper & Thurlow, <u>Exp. Neurol.</u>, 113: 79, 1991) visual cortex. Cones play a more important role in the vision of the diurnal macaque than they do in the more nocturnal cat, rabbit and rat. As a further test of whether the degree of cone vision might be correlated with the degree of the cortical effects of diffuse light, 2-DG uptake was examined in the strongly diurnal ground squirrel (Richardson's), a rodent with an almost completely cone retina. The awake and freely moving squirrels were tested with one eye covered by a white diffusing mask and the other eye with an occluding black mask; hemispheric differences in 2-DG uptake in monocular visual areas were used to assess effects. In contrast to the rod-dominated rat, both steady diffuse light (illumination supplied by 500 w halogen lamps) and flashing diffuse light (10 microsecond flashes from Grass photostimulator set at 5 hz and ~1.5 million CP intensity) did elevate monocular area 17 2-DG uptake in the cone-dominated squirrel. Apparently Grass photosumulator set at 5 nz and ~1.5 million CP intensity) did elevation monocular area 17 2-DG uptake in the cone-dominated squirrel. Apparently then, even within the relatively closely related rodent group, whether or not diffuse light information is important to cortical activity may be related to whether or not an animal has a rod- or a cone-dominated retina. The cortical processing of diffuse light (or intensity) information may be more important to an animal retinally specialized to function visually under bright light

CONDITIONAL DENDRITIC OSCILLATOR IN A LOBSTER MECHANORECEPTOR NEURON. D. Combes J. Simmers and M. Moulins Lab. de Neurobiol. Physiol. Comp., Univ. Bordeaux I & CNRS, Place Peyneau, 33120 Arcachon, France

Although many neurons of the CNS possess endogenous bursting properties, to date such non-linear behavior has not been demonstrated in peripheral neurons. Here we report oscillatory burst-generating properties in a primary sensor neuron and show that the oscillator is located in the dendritic membrane of the cell close to its distal receptor terminals. This element, the Anterior Gastric Receptor (AGR), is a unique mechanoreceptor neuron belonging to the stomatogastric nervous system of *Homarus gammarus*. Due to its large geometry and accessibility for multiple recording *in vit*ro, we have been able to demonstrate (a), a spiking capability in the dendrites of AGR that is dependent on Na<sup>+</sup> ions (b), these autogenic dendritic impulses can occur in rhythmic bursts superimposed upon voltage-dependent oscillations in membrane potential (c), this non-linear property imparts considerable integrative complexity to the transfer of mechanosensory information from AGR's receptor terminals to its central axon, in that sensory coding is mediated by changes not only in the frequency of ongoing dendritic bursts but also in the duration of individual bursts and their inherent spike frequencies

Furthermore, the expression of dendritic bursting in AGR is not invariant, but can switch spontaneously to autoactive tonic firing. Although the basis for this change in endogenous behavior is not yet known, local application of F1 peptide  $(10^{-7} \mathrm{M})$  to AGR's dendritic membrane can reversibly alter its activity pattern from tonic firing to a bursting mode. We are currently employing this FMRFamiderelated peptide, which is known to be present in the lobster stomatogastric nervous system, to examine the functional significance of a conditional sensory oscillator in the control of its postsynaptic targets.

THE SINUS GLAND NEUROSECRETIONS MODULATE THE RESPONSE TO MONOCHROMATIC LIGHT IN THE COMPOUND EYE OF THE CRAYFISH. V. Inclán-Rubio\* and R. Mora-Mora. Depto. de Fisiología, Fac. de Medicina, A.P. 70-250, 04510 México, D.F. MEXICO. It has been demonstrated the ability the monochromatic light has to evoke phase changes in the ERG circadian rhythm in crayfish. The retinular screening pigments (RSP) and the distal pigment light-adapting hormone (DPLH) participate in these responses. It is well known that the application of white light induces the depletion of DPLH content inside the sinus gland (SG). However, the relation-ship between the application of a specific wavelenght and the content of DPLH in the SG is unknown. In this work, we determined that LM application in crayfish induces modifications in the amount of DPLH contained in the eyestalk. We worked with 5 experimental groups of Procambarus bouvieri submitted to different light (30 s): I:465nm, II:565 nm and III:630nm, IV:white light) and V:darkness. After illumination, the eyestalks were removed to prepare extracts injected in crayfish previously dark-adapted. The effect was evaluated through glow area. Results: the extracts of crayfish that were submitted to darkness induced a reduction in the glow area of 48%; blue light-46%; and green light-33%. White and red light without changes. These results show: A) a selective effect of the LM used over the content of the SG neurosecretions that movilize the retinal screening pigments.

# SEGMENTALLY HOMOLOGOUS NEURONS AND INFORMATION FLOW IN THE LOCUST CNS. G.S. Boyan,\* Zoology Institute, Rheinsprung 9, CH-4051 Basel, Switzerland

This study focusses on the synaptic properties of an array of neurons which are among the progeny of neuroblast 7-4 in consecutive ganglia along the ventral nerve cord of the locust. Intracellular recordings have been performed from pairs of homologous neurons within the array, and between members of the array and other non-related pre- and postsynaptic cells. A neuronal network is described in which all the postsynaptic cells belong to the lineage of NB 7-4 in their respective segment. Information flow within the network is highly directional as shown by the fact that the segmental homologs receive common synaptic drive from one and the same presynaptic interneuron. Homologous neurons within one particular segment receive synaptic inputs from common sets of presynaptic cells; and this criterion may complement morphological features in identifying other putative progeny of the neuroblast in the adult. Despite their common inputs serially homologous members of the array output to different motor pathways. An analysis of the information flow to and from this neuronal network aims at a better understanding of motor activity along a segmentally distributed nervous system. Supported by the Swiss Nationalfonds.

DEVELOPMENTAL CHANGES IN THE ELECTROTONIC STRUCTURE OF THE CRICKET NEURON MGI CONTRIBUTE TO CHANGES IN SYNAPTIC EFFICACY OF IDENTIFIED AFFERENTS. A.A.V. Hill. R.K. Murphey, D.H. Edwards. Neuroscience and Behavior Program, Univ. of Massachusetts, MA. 0.1003.

The amplitude of EPSPs from identified sensory neurons that make monosynaptic connections with MGI decreases during postembryonic development (Chiba et al., Science, 240, 901, 1988). This change in EPSP amplitude could be due to a passive phenomenon such as the growth of the postsynaptic cell or an active phenomenon such as a retraction of the presynaptic terminals. In order to assess the effect of growth of the postsynaptic cell on EPSP amplitude we constructed compartment models of MGI at different developmental stages. The models were based on Lucifer Yellow fills of MGI imaged with a scanning confocal microscope and reconstructed 3-dimensionally. An important parameter, the specific membrane resistance was estimated from the MGI's time constant determined from its response to current injection. We simulated synapses of the same strength in models of MGI at various stages of development by modelling a synapse as a conductance change with a given waveform. We found that the growth of MGI leads to a decrease in EPSP amplitude that is significantly less than the decrease reported for identified sensory neurons. This suggests that the change in EPSP amplitude is only partially due to passive changes in the electrotonic structure of MGI.

IONIC CURRENTS UNDERLYING RAPID SENSORY ADAPTATION IN THE COCKROACH TACTILE SPINE. Päivi H. Torkkeli and Andrew S. French\*.

Department of Physiology, University of Alberta, Edmonton, Alberta T6G 2H7, Canada.

The cockroach, *Periplaneta americana*, femoral tactile spine contains a single mechanosensory neuron. The neuronal soma is at the bottom of the spine lumen, and a sensory dendrite passes through the spine wall. Intracellular recordings were made from the neuronal soma by advancing glass microelectrodes ( $\sim$ 40 M $\Omega$ , 3 M KCl) down the lumen of spines cut just above the sensory dendrite. Membrane currents during step changes in membrane potential were measured by two techniques: (1) a switching single-electrode voltage-clamp amplifier, and (2) a computer-controlled process in which the current through a balanced microelectrode was adjusted iteratively to give a voltage step.

Depolarizing steps of 1-5 mV from resting potential produced an inward current which decayed with at least two time constants. Preliminary evidence indicates that these are comparable to the time constants of  $\sim 100$  ms and  $\sim 1000$  ms with which the threshold has previously been shown to change during adaptation.

Supported by the Medical Research Council of Canada.

DEVELOPMENT OF FILIFORM HAIRS AND ITS SPECIFIC CONNECTIONS TO A PROJECTION INTERNEURONE IN LOCUSTS. <u>H.J.Pflueger</u> , A.Czizek¹ and <u>M.Burrows</u>². Freie Universitaet, Neurobiologie, Koenigin-Luise Str. 28-30, D(W)-1000 Berlin 33, FRG¹ and Dept. of Zoology, Cambridge, CB2 3EJ, UK².

The development of the projection pattern of identified filiform hairs on the prosternum was studied from the first instar to the adult locust. In adults these hairs make direct, high gain, monosynaptic connections to two projection interneurones, one in each connective, which activate motor neurones of wing steering muscles. In adults eight filiform hairs on one half of the ventral prosternum connect only with the contralateral interneurone, and accordingly only project into the contralateral neuropile of the prothoracic ganglion. Two filiform hairs on one proepisternum connect only with the ipsilateral projection interneurone, and correspondingly these project into the ipsilateral neuropile only. The projection pattern of the two filiform hairs on each proepisternum changes only with respect to number of side branches and varicosities.

Identified filiform hairs on the ventral prosternum of first to third instar larvae project into the ipsi- and contralateral neuropile. However, from the fourth stage onwards, ipsilateral branches are retracted and contralateral ones extended and increased in size. In accordance with these morphological observations, direct synaptic connections of ventral prosternal hairs with the ipsilateral interneurone were only found up until the third instar but not in later instars. The synaptic gain of the ipsilateral connection was much less than that of the contralateral connection

FUNCTION, PHYSIOLOGY AND AXONAL PROJECTIONS OF THE CHEMORECEPTORS OF DIPTERAN WINGS. S. Hannaford\* and J. Palka, Dept. of Zoology, Univ. of Washington, Seattle WA

Most flies have a set of multiply innervated bristles on their wings, which appear to be contact chemoreceptors. We find that they are widely conserved among the Diptera, present in members of the most primitive as well as the most advanced families. Despite this they remain largely uncharacterized. We have been studying the function of these sensilla in Drosophila melanogaster. Stimulation of the wing with a drop of sugar solution elicits a proboscis eversion reflex (PER), the first step in feeding behavior. This response is concentration dependent and sugar specific. When a high concentration of NaCl is added to the stimulating sugar solution the PER is inhibited. These behaviors are similar to those elicited by stimulating the tarsal and labellar taste hairs. We have also examined a number of mutants in which the inhibiting effect of salt application to the tarsi and labellum is known to be defective; in all cases wing evoked PER is affected as well. These behavioral results suggest that the wing chemosensilla are responsive to both sugar and salt and are capable of modulating feeding behavior. Preliminary electrophysiological recordings confirm that the receptor neurons are sensitive to salt and sugar. Dye fills show that the central projections of the wing chemosensilla differ from those of the tarsal sensilla; they occupy a discrete area in the mesothoracic neuropil and fail to project to the subesophageal ganglion. We are now looking for possible functional organization of the wing neuropil.

THE DIFFUSION OF SMALL MOLECULES IS REGIONALLY RESTRICTED IN THE RETINA OF THE COMPOUND EYE OF THE BLOWFLY.M. Järvilehto', M. Syrjäkallio-Ylitalo and M. Weckström. Depts. of Zool. and Physiol., Univ. of Oulu, 90570 OULU, Finland Histologically the layer of the retinular cell

Histologically the layer of the retinular cell bodies appears as a diffusionally uniform space. We studied the diffusion in the retina of white-eyed blowfly chalky with two different methods: Dye diffusion and deep pseudopupil (DPP) changes affected by intraretinally applied KI or CaCl2 solution. For the diffusion test a small excised ventral or dorsal area of the eye was covered with a drop of test substance, i.e. Toluidine Blue (1% FW 306), Methyl Blue (1% FW 799.8), KI (1 M, FW 166), CaCl2 (1 M, FW 111). The substances were allowed to diffuse passively into the retina from a continuous supply. The changes of the DPP were stored on a video tape. The DPP of the other eye served as a control. The diffusion isoprofiles (DIP) show that the test substances are unevenly diffusing throughout the retina. The effect clearly depends on the type of the test substance and its concentration. The DIPs show that the test substances diffuse always first to lateral parts of the eye and finally to the opposite dorsal/ventral central region.

EFFECTS OF BANG-SENSITIVITY MUTATIONS UPON MECHANO-SENSORY BRISTLE RESPONSE IN DROSOPHILA. J. E. Engel\* and C.-F. Wu. Biology Dept., Univ. of Iowa, Iowa City, IA 52242.

Drosophila bearing mutations of the genes bang-sensitive (bas<sup>1</sup>), bang-senseless (bssMW1), or easily-shocked (eas<sup>2</sup>), become paralysed when subjected to mechanical shock ("bang-sensitivity"). Because the mechanosensilla may be involved in the bang-sensitivity phenotype, we monitored the sensory neuron response to step deflections of the anterior postalar (APA) thoracic macrochaete in mutant and wild-type (Canton-S) flies. The results provide a first glimpse at a common physiological effect of these mutations in a class of identified neurons.

The response to a step stimulus is phasic, decaying to a tonic baseline. The phasic response may be described by  $y = A \cdot t^{-k}$ , where k characterizes the rate of decay (adaptation). In wild-type sensilla deflected strongly enough to produce a saturating, maximal response, k = 0.37. Adaptation rate (k) in mutant sensilla was similar. However, during the first 100 msec of a saturating response, wild-type sensilla produced  $33.3 \pm 5.5$  spikes (X  $\pm$  SD, n = 16). The maximal response was lower in mutants:  $eas^2 = 27.3 \pm 5.0$  (n = 7),  $bssMW1 = 19.6 \pm 3.2$  (n = 7),  $bss^2 = 18.1 \pm 2.9$  (n = 7). This was not likely due to prior fatigue, since two of the mutants fatigued normally following the initial response: given 1000 msec stimuli every 5 seconds, wild-type responses dropped to 84% at the second stimulus, and remained there for subsequent stimuli:  $eas^2$  and bssMW1 also dropped to 84% and 83%, respectively.  $bas^2$  did not fatigue, remaining at 100% of initial response. Thus, in these bangsensitivity mutants, adaptation and (in  $eas^2$  and bssMW1) fatigue were normal, but the maximal response was deficient. This suggests deficits in a rather specific mechanism in these mutants, which may also act at other sites in the nervous system, and thereby lead to the bang-sensitivity phenotype.

ELECTRICAL PARAMETER CHARACTERISATION OF FLY PHOTORECEPTORS IN MUSCA DOMESTICA. S. Gagné\*, M. Liu. Lab. of Vision and Logical Systems, Laval Univ. Elec. Eng. Dept., Québec, Qué. Canada G1K 7P4.

The so called R1-R6 photoreceptors of the fly (musca domestica), looking in the same direction of space, joined together in a closed structure (cartridge) in the first neuropile (lamina) when feeding, by numerous chemical synapses, two large monopolar cells (LMCs). It is believed they make electrical synapses between nearest neighbours while making their close encounter with LMCs. The nature of the return path for the receptor current is not completely characterized but it is taught to be through a high electrical resistance formed by the cartridge. It is possible to take advantage of the symmetrical 3D receptor arrangement of the resulting circuit and to evaluate, with relatively simple experiments, its electrical parameters. It appears, the cartridge offers a large electrical resistance for the return current when a single receptor is stimulated but, is considerably reduced when all receptors are responding, which is the normal case of operation. It seems this fact could be a valuable design principle, that is, built a high electrical barrier first and, let the current from many sources, control its final value. In this way, the building contingencies are less severe from the developmental phase to the final structural arrangement. Another well known effect for the barrier: its averaging and voltage reference point for operating the LMC synapses is also considered.

A COUPLED OSCILLATORY OUTPUT FROM AN INSECT AUDITORY RECEPTOR. S.R. Shaw.\* D. S. MacIntosh and K.M. Kokic', Psychology and Neuroscience Dalbousic University Halifax Nova Scotia Canada

Neuroscience, Dalhousie University, Halifax, Nova Scotia, Canada. Subgenual organs (SGOs) in insect legs evolved originally as extremely sensitive contact vibration detectors, but in cockroaches are bimodal, with an additional sensitive direct response to airborne sound, best around 2 kHz. The SGO is suspended in haemolymph from a thin accillular membrane between a tracheal air-sac and the wall of the tibia. An unusual feature is that the impulses from the ca. 26 sensilla appear to synchronize during each burst, and furthermore fire at a constant frequency  $f_R$  of ~300 Hz, regardless of sound intensity. The origin of this apparent response resonance is of interest as an early step in mechanotransduction. Electrical coupling is an unlikely cause, since neither sensilla nor axons contact each other initially. No change in the effective frequency  $f_R$  follows the replacement of air in the tracheae with He-O2, excluding a Helmholtz resonance in the subgenual air-sac as a causal factor. It is possible that a common mechanical drive coordinates the responses, if the parts of the SGO vibrate in unison at 150 or 300 Hz, in the local fluid environment. The large numbers of microtubules in the cells of the SGO might supply the requisite stiffening, and topical injections of colchicine do lower  $f_R$ . But colchicine is effective only at high initial concentration (> 5 mM), high K<sup>+</sup> has similar effects, taxol has none, and the temperature coefficient  $(Q_{10})$  of  $f_R$  is ~2, pointing away from a simple mechanical origin for  $f_R$ . A source of intrinsic oscillation at a similar frequency in different sensilla could also account for both synchronization and frequency invariance, if a common mechanical trigger supplied initial coordination of the responses. To clarify the mechanism, preliminary intracellular recordings were made, and correlate with impulses recorded from leg nerve 5. These recordings rule out frequency doubling at 150 Hz from opposing groups of sensilla to generate a 300 Hz response, but so far have failed to yield evidence of a voltage-dependent resonance. A DIFFERENTIAL INCREASE IN VISUAL SENSITIVITY CORRELATED WITH BIOLUMINESCENT FLASHING ACTIVITY IN TWO SPECIES OF FIRELIES ADAPATED TO DIFFERENT PHOTIC NICHES. Abner B. Lall, Department of Biology, Howard University, Washington DC 20059.

Based on the bioluminscent flashing activity, North American firelies can be divided into two groups: a) those which restrict their luminescent activity to a short period at twilight (twilight-active) and b) those which are active all night (dark-active). Thresholds for visual sensitivity in the compound eyes was monitored over long periods (24-48 hr) by recording ERGs elicited by constant intensity 550 nm flashes. In the dark-active firefly Photuris versicolor, the day-time responses were small (< 0.5mV) while the night-time responses were "5-6X larger than their day-time counterpart. This nightly increase in the amplitude of the ERG amounted to an increase in visual sensitivity on average 4.1 log units(N=5). In the twilight-restricted firefly Photinus pyralis, the amplitude of day-time ERG responses were large ("10mV) and increased only 3-4 mV at twilight. This increase in the amplitude corresponded to on average 1.8 log units (N=5) increase of the visual sensitivity. Supported by Howard University Faculty Research Support and NSF grant # NSF 9013076.

CENTRAL DISTRIBUTION OF THE TERMINALS OF PERIPHERAL SENSORY CELLS OF APLYSIA. Y. Xin. K. R. Weiss and I. Kupfermann\*. Cntr. for Neurobiol. & Behav., Columbia Univ. and the NYS Psychiat. Inst., New York, NY 10032; and Dept. of Physiol. and Biophys., Mt. Sinai Sch. of Med., New York, NY 10029.

Psychiat. Inst., New York, NY 10032; and Dept. of Physiol. and Biophys., Mt. Sinai Sch. of Med., New York, NY 10029.

The nerves of all central ganglia contain thousands of very small axons which number considerably more than the number of central neurons, suggesting that the small axons may originate from chemosensory and perhaps mechanosensory cells whose cell bodies are located in the periphery. The central terminations of presumptive sensory cells was studied by exposing peripheral structures to \$35 methionine or H³ leucine. Following a 24 hr incubation that permitted synthesis and axonal transport of labelled proteins, the central termination of presumptive sensory fibers was determined by autoradiography on sectioned material. Axons from the upper lip region terminate bilaterally in the cerebral, buccal and pleural ganglia, with fibers extending into the pleural abdominal connectives. Axons from the lower lip region terminate in the cerebral and buccal ganglia. Axons from mid-lip, mid-anterior tentacle nerve and terminate bilaterally within the cerebral ganglia, with slightly different distributions for the 3 branches of the anterior tentacle nerve and terminate bilaterally within the cerebral ganglia, with slightly different distributions for the 3 branches. Axons from the rhinophore terminate bilaterally in the cerebral and pleural ganglia, with fibers extending into the pleural abdominal connectives. The rhinophore also send fibers into the ipsilateral eye nerve, suggesting that light sensitive receptors in the rhinophore may directly communicate with the eye. Fibers from the siphon terminate in the abdominal ganglion. The feeding command-like neuron CBI-2 was filled iontophoretically with Lucifer yellow before radiolabelling of the upper lip. Combined fluorescent microscopy and autoradiography revealed that processes of CBI-2 and axons from the upper lip are present in the same small region of the cerebral ganglion, suggesting that CBI-2 may receive direct inputs from peripheral sensory cells. The ove

SOMATOSTATIN IN THE BRAIN OF THE POLYCHAETE ANNELID, NEREIS DIVERSICOLOR. E.I. Pinkhasov and S.C. Feldman\*. Depts. of Neuroscience and Anatomy, Cell Biology & Injury Science, New Jersey Medical School, Newark, N.J. 07103.

Somatostatin (SS) is a neuropeptide which has been shown

by us to be present in several higher invertebrates and is primarily associated with sensory or integrative processing areas. Complex annelids such as the Polychaetes show, for the first time, ganglia which are believed to correspond to

fore-brain, mid-brain and hindbrain regions.

In this study we examined the distribution of SSimmunoreactive (I-SS) neurons and fibers in the prostomium of the polychaete annelid Nereis diversicolor. I-SS was localized in the prostomia (heads) of 5 animals by immunocytochemistry using a well-characterized antiserum to the peptide. The prostomium is characterized by layers of presumed sensory neurons under the cuticle and dorsal to the eyes, as well as several central ganglia and extensive commissures and tracts. I-SS was identified in neurons in the dorsal epithelium, in a very few small cells in the optic ganglia and in several fiber tracts, including the optic nerve. The most striking feature was the presence of large numbers of I-SS neurons in the ciliated sensory cells just under the cuticle and in the large, pigmented cells in the epithelium directly covering the eyes. The presence of SS in these sensory layers and in the optic ganglia and tract suggest an early evolutionary association of the peptide with sensory function.

BEHAVIORAL CONSEQUENCES OF REDUCING OLFACTORY INPUT TO THE BRAIN. M.A. Butler, M.A. Willis\*, L.P. Tolbert, & E.A. Arbas. ARL Division of Neurobiology, University of Arizona, Tucson, AZ 85721.

Glomeruli are a common element of olfactory systems in a large number of animals, from humans to insects. They comprise spherical knots of nerve fibers where sensory axons and target neurons synapse. The aim of this study was to investigate the role of glomeruli in processing olfactory information, using behavioral and histological techniques. Previous studies have indicated that various degrees of glomerulus formation in the antennal lobes of the brain of the moth Manduca sexta can be effected by reducing the number of sensory axons that grow into the antennal (olfactory) lobe during development. Therefore, we surgically reduced the number of antennal segments in developing animals to produce animals with reduced numbers of glomeruli. The odor-stimulated behaviors of normal and experimental adult moths were observed and quantified in a wind tunnel, where the moths were challenged to fly upwind to the source of an attractive odor. Some of the moths that developed with reduced olfactory input flew upwind to the odor source. The flight behavior of these individuals was similar to the odor-mediated flight typically observed from normally developing moths. The histology of the moths' antennal lobes was then analyzed to determine the extent of formation of glomeruli. We found that the antennal lobes of more than half of the respondents were mostly aglomerular. There are a few isolated glomeruli, however, in at least one antennal lobe of each moth that developed with reduced antennal input and displayed odor-mediated behavior. This suggests that either a small number of glomeruli is sufficient to process the information necessary for this behavior or that glomerular organization may not be important for this fundamental odor-mediated behavior.

MODULATORY EFFECTS OF 5-HYDROXYTRYPTAMINE ON INTERNEURONS IN THE ANTENNAL LOBE OF THE SPHINX MOTH MANDUCA SEXTA. P. Kloppenburg and J. G. Hildebrand. ARL Division of Neurobiology, University of Arizona, Tucson, AZ 85721. Among the ca. 1200 neurons in each antennal lobe (AL) in Manduca sexta

is a single 5-hydroxytryptamine (5HT)-immunoreactive neuron. Each of these neurons has extensive ramifications in the ipsi- and contralateral protocerebrum and arborizations throughout the glomerular neuropil of the contralateral AL (Kent et al., J. Neurobiol. (1987) 19:451-465; Homberg and Hildebrand, Cell Tissue Res. (1989) 258:1-24). Combined Combined immunocytochemical and ultrastructural studies suggest that this neuron may provide centrifugal (descending) input to the AL (Sun et al., accompanying abstract). We have begun to examine the physiological role of 5HT (serotonin) in AL interneurons by means of intracellular recording.

The responses of local interneurons induced by electrical stimulation of the antennal nerve (a depolarization sometimes leading to firing of action potentials) are enhanced by superfusion of the AL with 5HT (10<sup>4</sup>M). Preliminary results show low concentrations (10<sup>4</sup>M) of 5HT decrease the width of spontaneous spikes, whereas high concentrations (10-4M) lead to within of spontaneous spikes, whereas high concentrations (or My) lead as spike broadening. In some neurons, electrical stimulation of the antennal nerve evokes a complex response that includes a brief hyperpolarization of the cell membrane. This hyperpolarization can be enhanced by a low concentration of 5HT (10°M). These effects of 5HT can be reversed by washing with saline for ca. 10 min. The spontaneous activity of AL neurons generally remains unaltered by 5HT.

The changes in membrane properties and the receptors that mediate these 5HT effects are currently under examination (Mercer et al., accompanying

abstract).

OLFACTORY INTERNEURON OSCILLATIONS: OPTICAL AND ELECTRICAL MEASUREMENTS OF INTRINSIC AND ODOR-MODULATED ACTIVITY. A. Gelperin\*, R. Gervais, K. Delaney, M. S. Fee, J. Flores, D. W. Tank and D. Kleinfeld, Biol. Computation Research Dept., AT&T Bell Laboratories, Murray Hill, N.J. 07974

The intrinsic dynamics of the central network of rhythmically active olfactory interneurons in the terrestrial mollusc Limax maximus has been recorded with and without odor input using a nose-brain preparation. The spatially-averaged membrane potentials of cells and fibers in the procerebral (PC) lobe were measured optically after staining the preparation with Di-4-ANEPPS. The local field potential was recorded with a patch pipette. Phase differences in the peak depolarization of the with a patch pipetie. Phase differences in the pear depolarization of the oscillatory activity (T=1.4s) were apparent in multisite optical records. Sequences of CCD derived images revealed a wave-like propagation of depolarization, with velocity ≥3 mm/s, from apex to base of the PC coincident with the oscillation (Fig.) Mild odor stimulation transiently increased the activity in local regions of the PC while strong odor could, in addition transiently increased the activity in local regions of the PC while strong odor could, in addition, transiently alter the frequency of the oscillation.

ULTRASTRUCTURAL CHARACTERISTICS OF THE 5HT-IMMUNOREACTIVE NEURON IN THE ANTENNAL LOBE OF MANDUCA SEXTA. X. J. Sun', L. P. Tolbert, and J. G. Hildebrand. ARL Div. of Neurobiol., Univ. of Arizona, Tucson, AZ 85721.

In each of the two antennal lobes (ALs), the primary olfactory centers, of the brain of Manduca sexta, one neuron displays 5-hydroxytryptamine (5HT)-like immunoreactivity, and this cell persists throughout the post-embryonic life of the insect. The morphology of this neuron was described by Kent et al. (J. Neurobiol. (1987) 19:451-465): its cell body resides in the AL, and without further ramification in the AL, it sends processes into the ipsi- and contralateral protocerebrum and finally into the contralateral AL. The arborizations of the neuron in the contralateral AL are distributed in most or all of the glomeruli. what role(s) this neuron may play in processing of olfactory information is not clear. We report here the ultrastructural characteristics of the 5HT-immunoreactive neuron, in the AL of the adult female moth, revealed using peroxidase-antiperoxidase and immunogold labeling methods. The membrane of the cell body was highly indented and the cell body, very rich in endoplasmic reticulum, Golgi apparati, and clusters of dense-cored vesicles. No synapses were found on the unbranched neurite in the ipsilateral AL, although dense-cored and small clear vesicles were present. The neurites of the neuron in the contralateral AL, however, did participate in synapses. The branches within the AL glomeruli, among the finest in those neuropil modules, participated in synapses in the glomeruli at very low frequency: 66% of the documented synapses (29) were output synapses and 34% were input synapses, and among them, most appeared to be dyadic synapses in single sections. Our observations suggest that this neuron is a very active cell and may play a feedback regulatory role in the

processing of olfactory information in the AL.

# 135.20

MODULATORY EFFECTS OF 5-HYDROXYTRYPTAMINE ON VOLTAGE-GATED CURRENTS IN CULTURED INSECT OLFACTORY NEURONS. A.R. Mercer, J.H. Hayashi, and J.G. Hildebrand\*. ARL Div. of Neurobiol., Univ. of Arizona, Tucson, AZ 85721.

5-Hydroxytryptamine (5HT or serotonin) modulates the activity of antennal-lobe (AL) neurons in the brain of the sphinx moth Manduca sexta (Kloppenburg and Hildebrand, accompanying abstract). To understand better the mechanisms that underlie the actions of this biogenic amine in vivo, we have used whole-cell patch-clamp techniques to analyze the effects of 5HT on membrane currents in AL neurons grown in culture. AL neurons can be dissociated and cultured from animals at all 18 stages of adult development. A subset of neurons, identified on the basis of morphological characteristics, were found to respond to 5HT in a constant and predictable way. 5HT caused reversible reduction of both an A-type K+ current and a more slowly activating K+ current resembling the delayed rectifier. Modulation of K currents may underlie the 5HT-induced increases in neuronal excitability and broadening of action potentials observed in some AL neurons in vivo.

In cells taken from pupae at stage 5 of adult development, 5HT modulates an inward Ca++ current that does not appear to be affected by 5HT in cells taken from pupae at a later stage in development (stage 9). The ability of 5HT to modulate specific membrane channels may play a role not only in olfactory information processing but also in the growth and development of AL neurons during metamorphosis of this insect.

### The Differential Laminar Distribution Of Cells In Prefrontal Cortex Projecting To The Mediodorsal Nucleus. D.F. Siwek and D.N. Pandya, E.N.R.M. VA Hospital, Bedford, MA 01730

Neurons in the deep layers of each area in the prefrontal cortex (PFC) project to the three subdivisions of the mediodorsal nucleus of the thalamus (MD). Horseradish peroxidase and retrograde fluorescent tracers were injected into MD to assess the laminar distribution of corticothalamic neurons in the different architectonic areas of PFC. The laminar distribution pattern of these cells follows the progressive architectonic differentiation of the PFC.

Although cortical projections to MD arise from cells in lavers V and VI. the relative distribution of those neurons is not the same for each prefrontal area. Less differentiated areas of the PFC (Pro, areas 13, 14, 25 and 32) are weakly laminated, have a poorly granulated layer IV and have small pyramidal cells in layer III. MD projecting cells in these areas are concentrated in layers Vb and VI. PFC areas 9, 10, 11, 12 have intermediate cytoarchitectonic features including well defined laminae, modest granularity in layer IV and large pyramidal neurons in layer III. The corticothalamic neurons in these areas are located mainly in layer Vb, somewhat in layer VI and occasionally in layer Va. Areas 46 and 8 of the PFC are the best differentiated, with six well-defined laminae, clear layer IV and abundant large layer III pyramidal cells. Neurons projecting to MD in these areas are located mainly in layer Vb, regularly in layer Va and occasionally in layer VI. The variation in the laminar distribution of MD-projecting neurons in PFC parallels the progressive elaboration of cytoarchitectonic features of the PFC. Thalamic projections from the least differentiated areas of PFC arise from mainly from layers Vb and VI, whereas thalamic projections in the best differentiated areas arise mainly from layer Vb, Va and somewhat from layer VI. (Supported in part by NIH 16841).

OVERLAP OF THALAMO-ACCUMBENS AND THALAMO-AMYG-DALOID PROJECTION NEURONS WITH PEPTIDERGIC FIBERS IN THE DORSAL MIDLINE THALAMUS OF THE RAT. <u>L. J. Freedman\*1</u> and <u>M. D. Cassell<sup>2</sup>.</u> <sup>1</sup>Neuroscience Program and <sup>2</sup>Department of Anatomy, University of Iowa, Iowa City, IA 52242.

Many of the afferents to the dorsal midline thalamus are peptidergic. Differences in the distribution of these fibers might suggest a topography whereby different neurochemically defined inputs influence groups of midline thalamic neurons projecting to different basal forebrain targets. We previously have shown that peptides are distributed in three basic patterns. Enkephalin and several other peptides are found in fibers in dorsal and ventral paraventricular thalamus (PV). αMSH and neuropeptide Y fibers are found in laterodorsal PV. Vasopressin fibers are found in medial PV.

To test how well these patterns of peptidergic fibers are aligned with the distribution of neurons projecting to specific basal forebrain targets, we combined retrograde tracing with fluorogold and red fluorescent microspheres with immunohistochemical localization of peptidergic fibers. We placed injections of these tracers in the core and shell of the nucleus accumbens and in the central amygdaloid nucleus. We observed that enkephalin fibers overlapped best with cells best projecting to the shell or core of the nucleus accumbens. aMSH fibers overlapped best with cells projecting to the shell of the nucleus accumbens. Vasopressin overlapped best with cells projecting to the central amygdaloid nucleus. This arrangement suggests a "labelled line" arrangement whereby specific inputs to the midline thalamus influence specific outputs to the basal forebrain.

THE THALAMIC PARAFASCICULAR PROJECTION TO THE SUBTHALAMIC NUCLEUS: A GLUTAMATERGIC EXCITATORY PATHWAY. <u>I.FEGER, S.MRAOVITCH\* AND M.MOUROUX</u> Lab. de Pharmacologie Faculté de Pharmacie, Paris and \* Lab.Rech.Cérébrovasculaires, Paris, France.

A thalamic projection to the subthalamic nucleus (STN) arises from the intralaminar parafascicular nucleus (Pf). We recorded unit activity within the STN to electrical and/or chemical Pf stimulation in anesthetized (ketamine) rats in order to investigate the nature of the thalamosubthalamic transmission. Electrical Pf stimulation (single square shock, 0,1 msec, 20-60 μA) elicited in the STN an initial single spike (latency: 3,7 ± 0,2 msec), an inhibitory period lasting for 6-9 msec, a secondary firing burst (2 to 5 spikes, latency 11,8 ±0,5 msec, discharge rate: 150 to 250 Hz) followed by a complete depression of the spontaneous activity. The initial excitation remains after section of cortico-subthalamic projection and/or pallidal lesion. Microinjection of he excitatory aminoacids receptors antagonist, kynurenic acid into the STN suppress the initial spike but not secondary burst in dose (0,035, 0,1 and 0,3 μg, in 200 nl) dependant manner. Long-lasting cholinergic stimulation of the Pf (microinjection of carbachol: 10 μg in 100 nl) elicited and maintained elevated firing rate of the STN (105±14%) for more than 30 min demonstrated during unit recording (n = 8) and/or 2-deoxyglucose experiments (n=5). These results suggest that the STN neurons are monosynaptically driven by the Pf efferents output ant that thalamosubthalamic synaptic transmission may implicate excitatory amino acid glutamate.

#### 136.2

ARCHITECTONIC SUBDIVISIONS OF THE VENTROLATERAL THALAMUS (VL) IN OWL MONKEYS (AOTUS TRIVIRGATUS): COMPARISON OF NISSL, ACHE AND CO PATTERNS.

1. Stepniewska\* T.M. Preuss, and J.H. Kaas. Dept. of Psychology, Vanderbilt University, Nashville, TN 37240.

As part of investigations of thalamic connections of motor and premotor cortex, we used Nissl stains and histochemical procedures for cytochrome oxidase (CO) and acetylcholinesterase (AChE) to help identify nuclei in the ventrolateral thalamus of owl monkeys. Material was obtained from 15 brains cut in frontal, parasagittal or horizontal planes.

We were able to distinguish most of Olszewski's divisions of VL, although we use a modified nomenclature to designate them. These divisions were much more readily distinguished in AChE than in Nissl or CO. The anterior part of VL (VLo of Olszewski) contains darkly stained neurons of medium size arranged in characteristic clusters. VLo is also characterized by AChE-rich perikarya embedded in dark matrix of AChE-rich neurites. The posterior part of VL can be divided into three subdivisions. The principle portion, VLp (VPLo of Olszewski), is composed of large, darkly stained cells, sparsely distributed among bundles of fibers. VLp has a patchy pattern of neuropil that stains darkly for AChE and CO. More medially, VLx (area X of Olszewski) contains smaller, lighter and more uniformly distributed neurons. VLx stains lightly and evenly for AChE. CO staining in VLx is moderate, uniform, and similar to VLp. Dorsally, VLd (VLc of Olszewski) consists of densely packed neurons that are smaller than these in VLp and VLx. VLd stains darkly for both AChE and CO. (Supported by NS 16446)

### 136.4

CHOLINERGIC INNERVATION OF THE HUMAN THALAMUS.
S. Heckers\*, C. Geula, M-M. Mesulam. Harvard Medical School,
Boston, MA 02215.

The cholinergic innervation of the human thalamus was studied with an antibody against the enzyme choline acetyltransferase (ChAT). All thalamic nuclei displayed ChAT-positive axons and varicosities. Only the medial habenula contained ChAT-positive perikarya. Intralaminar nuclei (central medial, central lateral, and paracentral), the reticular nucleus, midline nuclei (paraventricular and reuniens), some nuclei associated with the limbic system (anterodorsal nucleus and medially situated patches in the mediodorsal nucleus) and the lateral geniculate nucleus displayed the highest level of ChAT-positive axonal varicosities. The remaining sensory relay nuclei and the nuclei interconnected with the motor and association cortex displayed a lower level of innervation. The contribution of basal forebrain afferents to the cholinergic innervation of the human thalamus was studied with the aid of nerve growth factor receptor (NGFr) immunoreactive axonal staining. The anterior intralaminar nuclei, the reticular nucleus, and especially medially situated patches in the mediodorsal nucleus displayed a substantial number of NGFr-positive varicose axons, presumably originating in the basal forebrain. Rare NGFr-positive axonal profiles were also seen in many of the other thalamic nuclei.

These observations suggest that nuclei affiliated with limbic structures and with the ascending reticular activating system are likely to be under particularly intense cholinergic influence. While the vast majority of thalamic cholinergic input seems to come from the upper brainstem, some nuclei also appear to receive substantial cholinergic innervation from the basal forebrain.

INTRACELLULAR ANALYSIS OF A SLOW RHYTHM IN RETICULAR THALAMIC NEURONS. <u>B. Curró Dossi\*</u>, <u>D. Contreras and M. Steriade</u>, Lab. of Neurophysiology, Laval Univ. Sch. of Med., Quebec, Canada G1K 7P4. Thalamic relay cells oscillating at delta (1-4 Hz) or slower frequencies become

Thalamic relay cells oscillating at delta (1-4 Hz) or slower frequencies become synchronized by stimuli applied to cortical foci not directly related to the recorded cells (Steriade et al., J. Neurosci. 1991, 11:3200-3217). This finding led to the hypothesis that reticular thalamic (RE) cells are implicated in the synchronizing process. Here we report the results of intracellular recordings from RE neurons of urethane-anesthetized cats displaying a slow rhythm (–0.3 Hz) similar to that observed in neocortical cells (Steriade et al., this meeting).

The slow rhythmicity observed in RE cells was constituted by long depolarizing plateaus and spike trains recurring periodically every 3 to 5 s. These plateaus were diminished and eventually blocked by hyperpolarization as well as by QX-314. The slow rhythm of RE neurons was closely correlated with EEG complexes, and transitions from synchronized to less synchronized EEG states were paralleled by the disappearance of RE-cells' oscillations.

Recordings of RE cell-couples revealed that simultaneously recorded RE cells may be synchronized within the 0.3 Hz rhythm. However, in other instances, RE neurons tonically fired at 10-40 Hz (see also Contreras et al., this meeting), regardless of the EEG synchronization and of the slow rhythm in the simultaneously recorded cell.

We propose that RE cells, driven by the cortex, fire at the slow rhythm and, in turn, synchronously trigger long-lasting hyperpolarizations in thalamic relay cells. This would explain the periodic recurrence at 0.3 Hz of a hyperpolarization-activated intrinsic delta oscillation (1-4 Hz) in thalamic relay neurons.

ELECTROPHYSIOLOGICAL PROPERTIES OF RETICULAR THALAMIC CELLS. D. Contreras\*, R. Curró Dossi and M. Steriade. Lab. of Neurophysiology, Laval Univ. Sch. of Med., Quebec, Canada G1K 7P4.

Neurons of the reticular thalamic (RE) nucleus are implicated in processes of synchronization and rhythm generation within thalamocortical systems. To explore the intrinsic properties of RE neurons, we performed intracellular recordings in the

anterolateral districts of the RE nucleus in urethane-anesthetized cats.

Upon injection of depolarizing current pulses, 82% (n=41) of the recorded cells responded with tonic firing at rest (≈-60mV) and with spike-bursts at a V<sub>m</sub> more negative than -75 mV. Transition in firing pattern, from tonic to bursting, occurred argadually. During the pulse, the discharge frequency started to increase at -65 mV and reached a maximum of 250 Hz, with a peculiar burst morphology, at a  $V_{\rm m}$  between -75 and -85 mV. The graded nature of spike-bursts in RE cells suggests that low-threshold spikes are generated in multiple dendritic foci and eventually summate, giving rise to somatic spike-bursts. In some cells, bursting behavior was seen as high-frequency dendritic spikes, with an amplitude of 3 to 7 mV, which could

trigger somatic spikes or plateau potentials.

By contrast, 18% (n=9) of cells fired only in the single-spike repetitive mode. By contrast, 18% (n=9) or cells fired only in the single-spike repetitive mode. These non-bursting cells showed a high propensity for sustained regular firing (8-10 Hz) at rest, even during deeply synchronized EEG patterns, and increased their firing rates up to 40-50 Hz upon slight DC depolarization. The apparent lack of bursting behavior in this neuronal type can be related to a similar absence of spike bursts in ventral lateral geniculate neurons (Crunnelli et al., 1987) with which RE neurons share a common embryological origin.

LAMINAR ORIGIN OF STRIATAL AND THALAMIC PROJECTIONS OF THE

LAMINAR ORIGIN OF STRIATAL AND THALAMIC PROJECTIONS OF THE PREFRONTAL CORTEX IN RHESUS MONKEYS. E.H. Yeterian\* and D.N. Pandya. Dept. of Psychology, Colby College, Waterville, ME 04901, E.N.R.M. V.A.M.C., Bedford, MA 01730, and Boston Univ. Sch. of Med. Corticostriatal and corticothalamic projections of the prefrontal cortex have been shown to have specific, similar distributions. For example, the medial and orbital prefrontal regions are related to the medial portions of both the head of the caudate (HCN) and of the mediadorsal (MD) nuclei. To compare the laminar distribution of striatal and thalamic projection neurons, fluorescent retrograde tracers (Diamidino Yellow and Fast Blue) were injected into topograpically similar portions (e.g., medial sectors) of both nuclei in the same animal. Consistent with earlier studies, projections to common topographic sectors of the HCN and MD nuclei were found to arise from similar architectonic regions. The laminar origins of these projections, however, were distinctive. Although the projection neurons leading to the HCN and MD nuclei were located predominantly in infragranular cortical layers V and VI, with occasional cells noted in layer III, the bulk of striatal neurons was observed in layer Va, with fewer cells in layer Vb. In contrast, thalamic projection neurons were found mainly in layer VI, with a smaller number in layer V. Only occasional double-labeled cells were observed, suggesting segregation of striatal and thalamic projections. The suggesting segregation of striatal and thalamic projections. The differential laminar patterns of neurons projecting to the striatum and thalamus suggest that these structures receive independent rather than collateral forms of information from the prefrontal cortex. THE MARGINAL DIVISION IN THE NEOSTRIATUM OF THE CAT. S.Y.Shu\*, X.H.Bao and Z.W.Xu. Dept. of Neurobiology, Zhu-Jiang Hospital, Guangzhou, 510282, China.

In our previous studies, a new subdivision, the marginal division(MrD) was found in both rat and monkey striatums(Shu et al, J.of Chemical Neuroanatomy, 1988. Shu and Bao, Soc Neurosci Abstr. Vol.16,1990). The division is located at the caudomedial extent of the striatum surrounding the rostrolateral border of the globus pallidus. It exhibits special cellular organization, immunohistochemical reactivity and fiber connections.

The present abstract reported our investigation on the marginal division in the cat striatum. Nissl staining, histochemarginal division in the cat striatum. Misa; staining, miscra mistry and immunohistochemistry methods were used. A modified DAB-nickel method(Shu et al, Neurosci. Lett. 1988) was used to enhance the visualization of the immunohistochemistry reaction product.A band of scattering large fusiform neurons was observed at the medial border of the putamen surrounding the lateral edge  ${\sf constant}$ of the globus pallidus in the cat striatum. Some of them are AchE positive, or Enk-, or SOM-, or CCK-immunoreactive. SP-, L-Enk-, 5-HT-, NT- and SOM-immunohistochemistry positive fibers and terminals were found more densely packed in this band than the rest of the striatum. The location of the band, the morphology and immunoreactivity of the neurons and the immunoreactivity logy and lumunoreactivity of the neurons, and the lumunoreactivity of the fibers and terminals in the band proved that there is also a marginal division in the cat striatum. This study indicates that the marginal division is probably an universal structure in the striatum of the vertebrate.

SIMULATED ENTRAINMENT OF THALAMOCORTICAL CELLS BY REPETITIVE CORTICAL SHOCKS. W. W. Lytton\*, T. J. Sejnowski, and M. Steriade, University of Wisconsin, Madison, WI. 53792, The Salk Institute, La Jolla, CA, 92037, Laval University, Quebec City, Canada, G1K7P4.

Intrinsic properties and synaptic input both aid in determining the major oscillatory behaviors of thalamocortical relay cells: the 8-10 Hz spindle oscillations seen in early sleep and the 1-3 Hz slow oscillations seen in slowwave sleep. We simulated the effects of cortical shocks, including both the initial excitatory component and feedforward inhibition. We were able to match intracellular recordings by placing both synapse types at sites about 100 microns out on the dendrites, with activation of GABA<sub>A</sub> feedforward inhibition at 30 ms following the EPSP and activation of GABA<sub>B</sub> at 50 ms. In order to obtain the smooth transition between EPSP and IPSP observed electrophysiologically, we had to activate multiple GABA<sub>A</sub> inputs over a 20 ms range of time intervals. A low-threshold spike followed the inhibition. Cortical shocks could reset the phase of either the spindle-frequency oscillations seen at resting membrane potential  $(V_m)$  or the slow waves occurring with D.C. hyperpolarization. The slower rhythm could also be entrained by rapid repetitive cortical stimulation to above 10 Hz in the model, though the responses were subthreshold for sodium spikes above 7 Hz. Cortical stimulation could not slow the frequency. Simulated repetitive cortical shock with the thalamocortical neuron model at resting  $V_m$  produced repeated damped oscillations at spindle frequencies.

ENK+ AND SP+ STRIATAL NEURONS AND THEIR INTERACTION AT THE EM LEVEL. E.J. Karle\*, K.D. Anderson and A. Reiner. Dept. of Anatomy & Neurobiology, Univ. of Tennessee, Memphis, TN, 38163.

Although information is available on the synaptic inputs to medium spiny striatal neurons, little is specifically known regarding enkephalin-containing (ENK+) versus substance P-containing (SP+) striatal neurons and the interaction between them. Therefore, we are investigating this issue in pigeons, in whom ENK+ and SP+ perikarya,

dendritic shafts and spines, and terminals can be readily labeled.

Immunohistochemical single-label studies within the striatum revealed that most ENK+ and SP+ terminals formed symmetric synapses with unlabeled perikarya, dendritic shafts and spines. The ENK+ and SP+ input to spines showed noteworthy differences. ENK+ terminals were more likely than SP+ terminals to target spines. Of those terminals contacting spines, SP+ terminals typically made symmetric synaptic contact at the bases of spines, whereas ENK+ terminals often wrapped around the spines. Double-label EM study of ENK+ input to SP+ structures, using silver-intensified immunogold and diaminobenzidine as two distinct markers, showed that SP+ neurons received input from ENK+ terminals at their perikarya, dendritic shafts and spines.

These results show that the collaterals of ENK+ and SP+ striatal projection neurons form synaptic specializations with other neurons within the striatum, with many ENK+ terminals clearly contacting SP+ structures. Since we have previously shown similarities between basal ganglia in pigeons and in mammals, the present results should also be true of striatal medium spiny neurons in mammals. by NS-19620 & NS-28721 (A.R.)

PALLIDOTHALAMIC AFFERENTS OF THE MEDIAL AGRANULAR CORTEX IN THE RAT: A COMBINED PHA-L AND CTB TRACING STUDY. S.T. Sakai\*, K. Bruce and M. Park, Dept. of Anatomy, Michigan State University, East Lansing, MI 48824. Pallidothalamic input to the supplementary motor area is

thought to provide an important link in motor control pathways in primates. However, similar data in non-primate species are lacking primarily due to questions regarding the comparability of cortical and thalamic regions. Although the rat medial agranular cortex (AGm) is thought to contain the supplementary motor area, the source of the ascending inputs to AGm by way of the thalamus remains unclear. Our purpose was to determine if the AGm receives afferents originating from the entopeduncular the AGm receives afferents originating from the entopeduncular nucleus (EP). The pallidothalamic and thalamocortical projections were determined using a double-labeling paradigm in which pressure injections of Cholera toxin subunit B (CTB) were made into different sectors of AGm. At the same time, iontophoretic injections of Phaseolus vulgaris leucoaggluitin (PHA-L) were made into EP. The tissue was processed using a sequential immunohistochemical protocol. The majority of retrogradely labeled CTB neurons were found in the ventral anterior lateral nucleus (VAL) and the ventromedial (VM) nucleus. Dense plexuses of PHA-L label were also observed in VAL, VM and the lateral habenular nucleus (LHb). The greatest coincidence of both CTB labeled cells and PHA-L anterograde label was in the anterolateral portion of VAL and in VM. This pathway may provide an anatomical substrate for the motor control functions of the AGm in the rat. (Supported by the College of Human Medicine BRSG).

THE CINGULOSTRIATAL PROJECTION IN THE MONKEY:

THE CINGULOSTRIATAL PROJECTION IN THE MONKEY:
TOPOGRAPHY AND RELATIONSHIP TO CHEMICAL
ORGANIZATION. M.M.Mizobuchi\* and S.N.Haber. Dept. of
Neurobiology and Anatomy, Univ. of Rochester, Rochester, NY 14642
The ventral portion of the striatum is considered to receive input from
structures related to the limbic lobe, the dorsolateral region receiving
information from sensorimotor cortex. As part of a larger study to understand
the organization of limbic-related striatal input, we injected tritiated amino acids
and Lucifer yellow (L.Y) into areas 25, 32 and rostral 24 of the limbic-related
insultar curve and certacted these refeated between the state of the strictions. cingulate gyrus and contrasted these striatal projections to ones arising from area 23, a motor-related part of the cingulate gyrus. Routine autoradiography and immunocytochemistry were carried out on 50 µm sections throughout the striatum. To compare the cortical terminal fields to acetylcholinesterase (AChE)-poor "striosomes", enkephalin (ENK)-positive, or calcium binding protein (CaBP)-negative patches, compartments adjacent to the autoradiography were processed for AChE, ENK or CaBP staining. A dense patchy distribution of labelled fibers from area 25, 32 is observed in the medial patchy distribution of labelled fibers from area 25, 32 is observed in the medial part of the caudate head, nucleus accumbens and rostromedial putamen. Caudally, label continues in the medial part of the body of the caudate. No terminal fields are seen in the caudal part of the putamen. The terminal fields from area 24 expand to more central part of the striatum than those from area 25 and 32. The terminal fields from area 23 are in the dorsolateral caudate head and the central part and lateral edge of the putamen. There are no terminals in the nucleus accumbens. The results show an anterior-posterior cortical relationship corresponding to the medial-lateral alignment of terminal fields in the striatum. The distribution of each marker varies. Comparison between terminal fields and "striosomes" reveal inconsistent matches, however, interminal fields in the striatum of the partic comparison between terminal fields in the striatum of the partic comparison between terminal fields in the striosomes professible to the partic comparison between terminal fields professible prof general the limbic-related cortices preferentially project the matrix compartment in AChE staining. THE INTEGRATIVE ROLE OF THE SUBSTANTIA NIGRA IN BASAL GANGLIA CIRCUITRY. S.N Haber\* and E. Lynd-Balta. University of Rochester School of Medicine & Dentistry, Rochester, New

Several cortical- basal ganglia- thalamo-cortical circuits are thought to exist based on the topography of cortical inputs to the striatum, and striatal projections to the globus pallidus. The organization of the striato- nigro- striatal loop in relation these different functional circuits has not been explored. This study was undertaken to determine the organization of dopaminergic neurons projecting to the striatumwith

regions of the striatum. Adjacent or single sections were dual stained to visualize retrogradely labeled neurons and afferent terminals in the substantia nigra.

The results demonstrate that there are both reciprocal and non-reciprocal connections between the substantia nigra and distinct regions of the striatum. For example, when a retrograde and anterograde tracer were placed in adjacent regions of the dorsolateral striatum, terminal labeling and retrogradely labeled neurons overlapped extensively in the ventrolateral part of the substantia nigra. However numerous retrogradely labeled neurons were also found in the medial aspect of the substantia nigra, which is devoid of dorolateral striatal inputs. This medial region of the substantia nigra is known to receive inputs from the ventral striatum and the ventral pallidum. The combination of an anterograde and retrograde tracer in the ventral pallidum and dorsolateral striatum respectively, confirm this overlap of

ORGANIZATION OF DOPAMINERGIC STRIATAL PROJECTIONS IN RELATION TO PEPTIDERGIC INNERVATION OF THE SUBSTANTIA NIGRA IN PRIMATE. E. Lynd-Balta\*, and S.N. Haber. Department of Neurobiology and Anatomy, University of Rochester School of Medicine, Rochester, New York 14642.

The dopaminergic neurons of the pars compacta that project to the striatum occupy a large area of the substantia nigra in the primate. A dorsal and ventral tier of cells have been identified with distinct characteristics. The substantia nigra is also heavily innervated by different neuropeptides, presumably due to striatal inputs. We have examined the organization of the dopaminergic neurons projecting to the striatum with respect to neuropeptide staining patterns in the substantia nigra.

The retrograde tracers horseradish peroxidase conjugated to wheat germ agglutinin and Lucifer yellow were injected into different areas of the striatum. Dual immunocytochemical staining for the tracer and specific peptides, i.e. Substance P and enkephalin, was performed on single sections to determine the relationship between neurons projecting to different functional areas of the striatum and the peptidergic innervation of the substantia nigra. For example neurons projecting to the ventral striatum are found in the dorsal tier of dopaminergic neurons, clearly separate from enkephalinergic or Substance P immunoreactivity. The results indicate that neurons projecting to distinct areas of the striatum may be influenced differently by striatal peptidergic inputs.

Supported by NIMH MH 45573 7NIH NS22511.

respect to the topography of inputs from distinct striatal areas in the primate.

A combination of retrograde and anterograde tracers were injected into different

ventral pallidal inputs and dopaminergic neurons projecting to the dorsolateral striatum in the dorsomedial substantia nigra. The substantia nigra may allow different areas of the striatum to communicate via the organization of its afferent and efferent projections. Taken together these studies suggest that the ventral striatum may modulate the dorsolateral striatum via the connections of the substantia nigra. Supported by MINH MH45573 7NIH NS22511.

BRAINSTEM CHEMOSPECIFIC AFFERENTS TO PRIMATE PALLIDUM. A. Charara, R. Boucher\* and A. Parent. Centre de recherche en neurobiologie, Hôpital de l'Enfant-Jésus, Québec, Canada, G1J 1ZA. Previous studies from this laboratory have shown that neurons of the substantia nigra pars compacta, pedunculopontine nucleus and dorsal raphe nucleus project to the pallidum in primates. The aim of the present study was to analyze the organization of projections from these brainstem nuclei to the pallidal complex in the squirrel monkey (Saimiri sciureus) by combining retrograde transport methods (cholera toxin B) with immunohistochemical techniques for tyrosine hydroxylase, calbindin D-28k, 5-hydroxytryptamine and choline acetyltransferase. After injection of cholera toxin B into the pallidum, retrogradely labeled neurons were found in the substantia nigra pars compacta, labeled neurons formed a compact group medially and a more diffuse group laterally. The majority of these neurons did not display immunoreactivity for calbindin. In the dorsal raphe nucleus, retrogradely labeled neurons occurred both centrally and dorsally. Many of these neurons displayed immunoreactivity for serotonin. In the pedunculopontine nucleus, retrogradely labeled neurons were found both ventrally and dorsally to the superior cerebellar peduncle. Some of them were also immunoreactive for choline acetyltransferase. These findings reveal that dopaminergic, serotoninergic and cholinergic neurons of the brainstem directly influence the output neurons of the basal ganglia at the pallidal level in primates. Investigations aiming at determining the exact distribution and proportion of these various brainstem chemospecific neurons projecting to the pallidum are presently under way. [Supported by MRC, FRSQ and FCAR].

# 137.2

CHOLINERGIC NEURONS EXPRESS BRAINSTEM JTAMATE-LIKE IMMUNOREACTIVITY IN THE SQUIRREL MONKEY. B. Lavoie\* and A. Parent. Centre de recherche en neurobiologie, Hôpital de l'Enfant-Jésus, Québec CANADA G1J 1Z4 A previous study in rodents revealed that numerous cholinergic

(NaDPH-d positive) neurons in the brainstem display glutamate (GLU) immunoreactivity (IR). In this study we used single and double immunohistochemical procedures with antibodies against choline acetyltransferase (ChAT) and GLU to localize these two types of neurons in the brainstem of squirrel monkey (Saimri sciureus). Cholinergic neurons are largely confined to the pedunculopontine (PPN) and laterodorsal (LDT) tegmental nuclei, the parabigeminal nuclei, and the IIIth and IVth cranial nerve nuclei. Comparisons of adjacent sections immunostained for either GLU or ChAT revealed that the pattern of distribution of GLU-like neurons is similar to that of ChAT neurons, except that GLU-like neurons are scattered over a larger sector of the brainstem. GLU IR is mainly found in large neurons of PPN and LDT as it is also the case for ChAT IR. However, smaller GLU-like neurons are also present in this area. GLU IR is also found in neurons of the IIIth and IVth cranial nerve nuclei and in the parabigeminal nucleus. The analysis of double-immunostained sections reveals that both GLU and ChAT are colocalized in numerous neurons of the brainstem. However some neurons display only GLU or ChAT immunoreativity and the ratio of the three subpopulations varies from one cholinergic group to the other. Since PPN and LDT neurons are known to exert a powerful effect on various forebrain neuronal populations, our results suggested that this influence could be mediated by both acetylcholine and glutamate. [Supported by MRC]

ANATOMICAL ANALYSIS OF THE VENTRAL STRIATUM IN THE MACAQUE MONKEY. D.P. Friedman L.J. Porrino, and S. Vinsant. Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157. The ventral striatal region (VSR) includes the nucleus accumbens,

olfactory tubercle (OT) and a portion of the ventral putamen. Although this region has been distinguished from the dorsal striatum on a variety of anatomical and functional grounds, it has not yet been systematically described in the monkey. We have combined histochemistry, immunocytochemistry, and receptor localization in a first step to understand the regional anatomy of the VSR.

Both rhesus and cynomolgus monkeys were deeply anesthetized and either perfused with 4% paraformaldehyde or left unperfused before the brains were removed. Sections from perfused brains were incubated to reveal acetylcholinesterase (ACHE) or with antibodies against tyrosine hydroxylase (TH), calbindin (CALB), or neurotensin (NT). Sections from unperfused brains were incubated with [<sup>3</sup>H] SCH23390 to reveal D1 dopamine receptors, or [<sup>3</sup>H] sulpiride to reveal D2 receptors.

In the VSR, all markers revealed a narrow medial compartment that extended in a ventrolateral arc from the floor of the 3rd ventricle into the region of the OT. A larger, more lateral compartment could be distinguished from the dorsal striatum by relatively light TH immunoreactivity (IR) and a less dense population of D1 and D2 binding sites. Caudally, ACHE and TH and CALB-IR failed to distinguish the medial compartment from the OT.

These findings suggest that in the monkey the VSR is distinguishable from the dorsal striatum and that it consists of 2 compartments, a medial (shell) region that may include at least the caudal part of the OT, and a more lateral (core) region located largely in the ventral putamen.

DUALITY IN THE GABAERGIC OUTPUT SYSTEM OF THE BASAL GANGLIA IN THE RAT. B.A. Flumerfett\*, N. Rajakumar and K. Elisevich, Dept. of Anatomy, University of Western Ontario, London, Ontario, Canada.

The substantia nigra pars reticulata (SN-R) and the entopeduncular nucleus (EPN) form the main output centers of the basal ganglia, providing GABAergic projections to the thalamus, lateral habenula (LH), superior colliculus (SC) and pedunculopontine tegmental nucleus (PPN). Although many cells within the SN-R and EPN have been described as modality specific, the morphological similarity of the output neurons precludes their identification on a structural basis. Calcium binding proteins have been used successfully to verify neuronal heterogeneity in other regions of the brain. The present study was undertaken to investigate parvalbumin (PAR) immunoreactivity in the SNR and the EPN to provide a possible basis for characterizing their neurons. Adult Wistar rats were anesthetized with sodium pentobarbital and the retrograde tracer fluorogold or the anterograde tracer fluororuby was injected into the VL or VM nucleus of the thalamus, LH, SC, PPN, SN-R or EPN. After a one week survival period the rats were perfused with 4% PFA, and frozen transverse sections through the brain were cut (40µ) and processed with an indirect immunofluorescence method using antibodies to PAR or GAD. The results revealed that the majority of neurons in the SN-R and a significant number of neurons in the EPN contained PAR colocalized with GAD. Double-labeled neurons were found in the mid-portion of the EPN whereas they were distributed throughout the rostrocaudal extent of the SN-R except its medial part. The PAR immunoreactivity was seen in every output pathway of these centers. These results indicate the neurochemical heterogeneity of the basal ganglia output neurons and suggest multiple functions for each of these pathways. (Supported by MRC Canada).

COMPARTMENTALIZATION OF CHOLINERGIC INNERVATION OF THE HUMAN STRIATUM. D.J. Holt. S. de Lacalle. and C.B. Saper\*. Depts. of Pharm. & Physiol. Sci. and Neurology, Univ. of Chicago, Chicago, IL 60637.

The extraction is a light control of the contr

The striatum in humans, as in other mammals, may be divided into anatomically distinct compartments based upon the distribution of neurochemical markers. Diseases and pharmacological interventions in neurochemical markers. Diseases and pharmacological interventions in the human striatum that alter the dopaminergic system may change the expression of these neurochemical markers and therefore perhaps the compartmentalization itself. To investigate this possibility, it will be necessary first to determine the neurochemical compartmentalization of the normal striatum in humans. We examined the striatum from a series of human brains that were obtained at autopsy and fixed by perfusion through the carotid artery with a solution of 4% paraformaldehyde and 0.2% picric acid. Frozen sections were stained using an antiserum against human placental choline acetyltransferase (Hersh) with an immunoperoxidase and silver intensification method. We identified three distinct levels of density of cholinergic innervation in the human striatum, rather than the two (striosome and matrix) that the human striatum, rather than the two (striosome and matrix) that have been reported in other species. In general, the compartment containing the lowest density of innervation filled much of the nucleus accumbens and extended into small, circumscribed areas in the putamen. The medium density compartment included small, circum-scribed areas in the dorsal caudate nucleus and background regions in the putamen and ventral caudate. The heaviest density compartment accounted for much of the background in the caudate nucleus. Thus, the medium density compartment often appeared as "striosomes" in the caudate, but "matrix" in other regions of the striatum. Our observations indicate that the compartmentalization of the human striatum may be more complex than the two-compartment model used to describe the striatum in other mammals.

CHEMICAL COMPARTMENTALIZATION OF THE RAT GLOBUS PALLIDUS. K. Elisevich\*, N. Rajakumar and B.A. Flumerfelt, Dept. of Anatomy, University of Western Ontario, London, Ontario, Canada.

Striatal neurons projecting to EPN and SN contain SP and dynorphin colocalized with GABA, while those projecting to GP contain enkephalin (ENK) colocalized with GABA. Recent observations that two-thirds of striosomal neurons contain ENK/GABA, and that the content of ENK in SN and EPN is significantly low suggest a substantial projection from the striosomal compartment to GP. Therefore, it was undertaken to study the distribution of neurochemical markers in GP to identify separate areas that receive inputs from the two striatal compartments. Adult female Wistar rats were anasthetized with sodium pentobarbital and perfused with 4% PFA in PB (pH 7.4). Frozen transverse sections  $(40\mu)$  were cut through the striatum and GP. Serial sections were immunolabeled for calbindin (CB) and adjacent sections through GP were also processed for single labeling with antibodies to SP, ChAT, leu-ENK or parvalbumin employing the indirect immunocytochemical technique using DAB, or double labeling using immunofluorescence.

The results confirm a complete absence of immunoreactivity (IR) for CB in striosomes and in the dorsolateral part of the striatum. GP showed a moderate density of CB-IR. A continuous area devoid of CB-IR was seen extending throughout the rostrocaudal extent of GP, and was most conspicuous in the lateral aspect of the rostral part. The CB-negative area had parvalbumin containing neurons whereas the CB-positive area contained most of the ChAT- and SP-IR, and ENK was seen in both areas. The data indicate a compartmentalization of the GP that corresponds to the compartmental projections from the striatum. (Supported by MRC Canada).

ORGANIZATION OF THE EFFERENT PROJECTIONS OF NEOSTRIATAL COMPARTMENTS IN THE RAT. N. Rajakumar\*, K. Elisevich and B.A. Flumerfelt, Dept. of Anatomy, University of Western Ontario, London, Ontario, Canada.

The striatum can be divided into neurochemically distinct striosome and matrix compartments that receive discrete projections from allocortical and neocortical areas respectively. Although different projections from the striosome and matrix have been ovserved, details concerning their organization are not available. In the present study the efferent connections of the striatal compartments are investigated to elucidate their functional Adult female Wistar rats were anasthetized with sodium.
The retrograde tracer fluorogold or the anterograde tracer organization. pentobarbital. fluororuby was iontophoretically injected into the dorsolateral or medial striatum, calbindin positive or negative parts of GP, rostral or caudal parts of EPN, SN-C, SN-R and medial or lateral parts of STN. After a one week survival period the rats were perfused with 4% PFA in PB (pH 7.4). Transverse sections were processed with an indirect immunofluorescence technique using antibodies to TH, calbindin (CB) or parvalbumin (PAR). The results confirm the existence of a striosome input to SN-C and a segregated projection from striosome and matrix compartments to habenulofugal neurons of the rostral EPN and thalamofugal neurons of the caudal EPN respectively. dorsolateral striatum is reciprocally connected to the CB negative parts of GP whereas the medial striatum projects mainly to the CB positive areas of GP. The PAR-containing GABAergic neurons in the CB negative part of GP provide the main GP-EPN, GP-SN and GP-striatal projections whereas PAR negative GABAergic neurons in the CB positive part of GP provide the main GP-STN projection. The data suggest multiple levels of interaction in the efferent projections of neostriatal compartments. (Supported by MRC Canada).

CO-LOCALIZATION OF DOPAMINE D1 AND D2 RECEPTOR mRNAs IN THE RAT NEOSTRIATUM. J. Lester<sup>1</sup>, J.S. Fink<sup>2</sup>, N. Aronin<sup>3</sup>, M.DiFiglia<sup>1</sup>. Labs. of Cellular Neurobiology<sup>1</sup> and Molecular Neurobiology<sup>2</sup>, Massachusetts General Hospital, Boston, MA 02114, and Dept. of Medicine<sup>3</sup>, Univ. of Massachusetts. Med. Ctr., Worcester, MA 01655.

By ligand binding autoradiography, D1 and D2 dopamine receptors are highly concentrated in the striatum. Some physiological studies suggest that these receptors are co-localized and may functionally interact to mediate the effects of dopamine. However, other results based on mRNA localization have suggested that these receptor subtypes are contained predominantly in non-overlapping striatal output pathways. In order to determine more accurately the extent of cellular co-localization of D1 and D2 receptor mRNAs in the striatum, we used in situ hybridization in serial 4 µm frozen sections with <sup>35</sup>S labeled cDNA probes. Hybridized and emulsion-dipped sections were exposed for 12 weeks. After development, sections were photographed in dark field and 35 mm negatives were printed at 7x. In the photographs, fiber bundles were used as landmarks to accurately localize the position of the same labeled neuron in each section. Section pairs treated with the same cDNA probe were compared to those treated with different probes (D1 vs D2). Quantitative results based on the analysis of 1,775 cells showed that striatal neurons expressing D1 or D2 receptors were equally distributed throughout the caudate-putamen and that both receptors were colocalized in 26% (mean percents ranged from 11% to 36% per region examined) of the total neurons expressing one or the other receptor subtype. Results confirm previous reports that most striatal neurons do not appear to contain both receptors. Nevertheless, those neurons expressing both receptor subtypes represent a sizeable minority and it will be of interest to determine their neurotransmitter\neuropeptide content. (Supported by NIH NS 16367 to MD and NSF BNS8819989 to NA).

DISTRIBUTION OF NMDA RECEPTOR mRNA IN RAT NEOSTRIATAL NEURONS. P. Ge<sup>1</sup>, H. Aizawa<sup>1</sup>, J. Lester<sup>2</sup>, E. Sapp<sup>1</sup>, N. Aronin<sup>3</sup>, J.-P. VonSattel<sup>1</sup> and M. DiFiglia<sup>2\*</sup>. Laboratories of Neuropathology<sup>1</sup> and Cellular Neurobiology<sup>2</sup>, Massachusetts General Hospital, Boston MA 02114 and Dept. of Medicine<sup>3</sup>, Univ. Mass. Med. Ctr., Worcester, MA 01655.

Glutamate, the neurotransmitter of the corticostriatal pathway, mediates its effects through multiple receptor subtypes in striatal neurons. Although previous studies using ligand binding and excitotoxic lesions with NMDA receptor agonists suggest that NMDA receptors may be widely distributed to most striatal cells, there is no direct evidence about the extent of neuronal distribution of this receptor subtype in the striatum. Using <sup>35</sup>S oligonucleotide probes, we examined the localization of NMDA receptor mRNA in the rat caudate-putamen using in situ hybridization. Frozen sections from the anterior striatum were hybridized with labeled oligomers directed to different regions of the predicted mRNA sequence of the NMDA receptor recently reported (Moriyoshi et al., Nature, 1991). Sections treated with antisense probes showed specific labeling over medium and large-sized neurons throughout the striatum. Sense probes produced no specific hybridization signal. The density of labeled cells was determined with camera lucida by recording the location of cells in 1.6 mm<sup>2</sup> fields throughout the mediolateral and dorsoventral extent of the caudate-putamen. The density of labeled cells was compared to total striatal neurons recorded in adjacent counterstained sections which had not been used for in situ hybridization. Results from 141 fields counted in six sections showed that 88% of all neostriatal neurons express the NMDA receptor and that 88% of medium-sized cells and 49% of large neurons were labeled. Results provide evidence that the NMDA receptor is expressed by most striatal neurons. (Supported by NS16367 to JPV and MD).

VENTRAL PALLIDAL NEURONS PROJECT TO BOTH THE VENTRAL STRIATUM AND THE MEDIODORSAL NUCLEUS OF THE THALAMUS IN THE RAT. H. Kuổand H.T. Chang, Dept. of Anatomy and Neurobiology, College of Medicine, The Univ. of Tennessee, Memphis, 875 Monroe Ave., Memphis, TN 38163.

Previous studies have shown that some neurons in the ventral pallidum (VP) project to the ventral striatum (VS) and some VP neurons project to the mediodorsal nucleus of the thalamus (MD). Since these two groups of projection neuron in VP appear to occupy similar locations and have very similar morphology, it is possible that the same individual VP neuron projects to both VS and MD. In order to study the relationship between these two types of VP projection neurons, two different retrograde tracers were used in double-labeling experiments. One retrograde tracer, FluoroGold (FG), was injected into VS, and the second retrograde tracer, cholera toxin B (CTB), was injected into MD in the same animal. Immunofluorescence reactions were performed on brain sections such that CTB-containing neurons were labeled by Texas Red conjugated secondary antibody. Our results showed that both FG and CTB labeled cells were found in VP. Careful examination revealed that some of the FG labeled cells were also labeled by CTB. This result indicates that some individual VP neurons project to

SPECIFICITY IN THE EFFERENT PROJECTIONS OF THE NUCLEUS ACCUMBENS IN THE RAT: COMPARISON OF THE ROSTRAL POLE PROJECTION PATTERNS WITH THOSE OF THE CORE AND SHELL D.S. Zahm\*and Lennart Heimer! Dept. of Anat. & Neurobiol., St. Louis U. Sch. Med., St. Louis, MO, 63104 and 'Depts. of Otolaryngol., Head & Neck Surg. & Neurosurg., U. VA Sch. of Med., Charlottesville, VA 22908

The efferent connections of the rostral pole of the rat accumbens were examined with PHA-L, for comparison with the projection patterns of the accumbal core and shell. Injection sites and transported PHA-L were evaluated with the aid of adjacent sections processed for substance P or calbindin immunoreactivities. Lateral rostral pole is more "core-like" and projects to the rostroventral globus pallidus, subcommissural ventral pallidum, entopeduncular nucleus and contiguous lateral hypothalamus, ventral tegmental area, dorsal pars compacta and, modestly, to the pars reticulata and lateral mesencephalic tegmentum. Medial rostral pole is more "shell-like" and projects to the subcommissural ventral pallidum, preoptic region, lateral hypothalamus, ventral tegmental area, dorsalmost pars compacta, retrorubral field, lateral midbrain tegmentum, pedunculopontine tegmental nucleus and central grey. The medial rostral pole contributes some projections to preoptic and sublenticular regions, but not to the bed nucleus of the stria terminalis. Concentrations of calbindin immunoreactive cells in the core and lateral rostral pole correlate with the origin of the "basal ganglia-like" projections, suggesting that core and rostral pole calbindin immunoreactive cells contribute principally to basal ganglia-like projections and that cells lacking calbindin immunoreactivity contribute more to the innervation of hypothalamus and midbrain tegmentum, i.e., that projection specificity, possibly in combination with topographic constraints, defines the patterns of projections from the accumbens. PRE-AND POSTSYNAPTIC LOCALIZATION OF THE DOPAMINERGIC DI RECEPTOR IN THE BASAL GANGLIA. D. Zhou<sup>1\*</sup>, O. Huang<sup>1</sup>, N. Aronin<sup>2</sup> and M. DiFiglia<sup>1</sup>. Laboratory of Cellular Neurobiology<sup>1</sup>, Dept. of Neurology, Mass. General Hospital, Boston, MA 02114 and Dept. of Medicine<sup>2</sup>, Univ. of Massachusetts Medical Center, Worcester, MA 01655.

Based on ligand binding and mRNA localization studies, D1 dopamine receptors are highest in the basal ganglia where they may play an important role in modulating the activity of D2 receptors and in mediating stereotypic behaviors. Although the subcellular distribution of D1 receptors is unknown, a variety of studies suggest that they may be involved in mediating the actions of dopamine both pre- and postsynaptically. Using a purified rabbit polyclonal anti-peptide antibody (see also Q. Huang et al., this meeting), we examined the localization of D1 receptors at the light and electron microscopic level with the immunoperoxidase method. Results showed that in the neostriatum immunoreactive D1 was localized to 49% of neurons which included both medium spiny and medium aspiny types. Reaction product was seen in discrete patches primarily at postsynaptic sites within spines, spine necks, and dendritic shafts. Small axon terminals which formed synapses mostly with dendritic spines were also labeled. In the globus pallidus and substantia nigra, pars reticulata, D1 immunoreactivity was abundantly distributed to the axoplasm of myelinated and unmyelinated fibers and preterminal axon endings which were apposed to unlabeled axon terminals. In addition, small patches of immunoreactive product were found in cell bodies and at plasma membranes within dendrites. Results provide the first direct evidence that the D1 receptor is widely distributed to pre- and postsynaptic sites in all three areas of the basal ganglia. (Supported by NIH NS 16367 to MD and NSF BNS881989 to NA).

THE CORTICONIGRAL PROJECTIONS IN THE RAT: A BIOTIN-DEXTRAN ANTEROGRADE TRACING STUDY. A. Naito and H. Kita\*. Dept. of Anatomy and Neurobiology, College of Medicine, University of Tennessee Memphis, Memphis, TN 38163 U.S.A.

The existence of corticonigral projections remains a debated issue. Several studies suggest the frontal cortex projects to the substantia nigra (SN) pars compacta, while others suggest this projection is not prevalent. We have studied this projection using a biotin conjugated dextran anterograde nervetracing technique. Biotin-dextran (2%) dissolved in 0.01M phosphate buffer (pH 7.2) was pressure injected into the cerebral cortex of 20 male Sprague-Dawley rats (280-390g). After a survival period of 5-8 days, rats were fixed with 4% paraformaldehyde and the brain was sectioned sagitally. Sections were processed for visualization of biotin-dextran containing fibers using the ABCmethod with DAB-Ni reaction. The same sections were further processed for tyrosine hydroxylase (TH) immunohistochemistry for identification of the SN pars compacta area. A large number of the stained fibers with small boutons was found in both the compacta and the reticulata parts of the SN after injection in the frontal cortex, yet only a fibers were found after an injection in the other cortical areas. The present findings indicate 1) that the corticonigral projects exists; 2) that these terminations are not limited to the compacta part; and 3) that the main projection arises from the frontal cortex.

VENTRAL PALLIDOSTRIATAL PROJECTIONS IN THE RAT: RECIPROCATION OF THE STRIATOPALLIDAL PROJECTIONS OF THE ACCUMBAL SUBTERRITORIES Judith S. Brog<sup>®</sup> and D.S. Zahm Dept. of Anat. & Neurobiol., St. Louis U. Sch. Med., St. Louis, MO, 63104

The nucleus accumbens comprises three subterritories: core, shell and rostral pole, which give rise to striatopallidal projections that define ventral pallidal subterritories. Shell projects selectively to a histochemically distinct ventromedial part of the subcommissural ventral pallidum (VPm). Core projects massively to a dorsolateral ventral pallidal subterritory (VPI) and less robustly to VPm and the rostromedial part of the globus pallidus (GP). The rostral pole projection involves primarily VPm but also, to a lesser extent, VPI and the rostromedial GP. We now report that components of the ventral pallidostriatal pathway (Kuo and Chang, Soc. Neurosci. Abstr. 17:453, 1991) reciprocate the striatopallidal projections from the accumbal subterritories. Immunohistochemically detected retrograde labeling was evaluated in the pallidal complex following injection of Fluoro-Gold (FG) into the core, shell or rostral pole. Substance P and calbindin 28 kD immunoreactivities were used to delineate subterritories in the ventral pallidum and accumbens. Following FG injections in the shell, FG cells were present only in VPm. When the injections were restricted to the core, FG cells were present in VPm, VPl, and the rostromedial GP. Rostral pole injections resulted in large numbers of FG cells in VPm and significantly fewer in VPl and the rostromedial GP. The divergent pathways from core and rostral pole, and their reciprocation by the neurons in VPm, VPI and GP, contrasts with the marked selectivity of the interconnections of the shell and VPm. These data are additional evidence that both specificity and topographic constraints contribute to projection patterns in the ventral basal ganglia. Supported by NIH NS-23805 & T32 NS-07254.

SUBTHALAMIC AND PEDUNCULOPONTINE INPUTS TO THE SUBSTANTIA NIGRA IN THE RAT: A DOUBLE LABEL EM STUDY. M, Damlama\* and J,M, Tepper, Aidekman Research Center, Center for Molecular and Behavioral

Neuroscience, Rutgers, The State University of New Jersey, Newark, NJ 07102.

Both the subthalamic (STN) and pedunculopontine (PPN) nuclei are considered to be important in the regulation of motor function, and both of these nuclei have been shown to project to the substantia nigra but the identity of their postsynaptic targets has not been demonstrated. Therefore, anterograde transport of biocytin combined with tyrosine hydroxylase (TH) immunohistochemistry was performed to investigate the relationship of these afferent inputs to dopaminergic neurons. The tissue was

processed for sequential light and electron microscopic analysis.

At the light microscopic level, both the STN and PPN were seen to give rise to numerous fine, varicose axons and axonal boutons in the substantia nigra. Whereas the STN input was densest in the pars reticulata, that from the PPN was densest in the pars compacta. At the EM level, the terminal boutons of STN and PPN origin had an average area of 0.43±0.06 μm<sup>2</sup> (SEM) and 0.53±0.07 μm<sup>2</sup>, respectively. The terminals contained small round vesicles, and 1-3 mitochondria. All boutons observed to form synaptic contacts formed asymmetrical synapses, the overwhelming majority of which were onto small TH negative dendrites of approximately 1  $\mu$ m in diameter. The average length of the active zone was 0.36±0.05 µm for PPN, and 0.44±0.13 µm for STN terminals. Most of the terminals contained one active zone but occasionally PPN terminals synapsed with more than one element. Although terminals of PPN and STN origin were quantitatively similar, PPN terminals were less tightly packed with vesicles than STN terminals, and unlike the latter, they contained some large dense core vesicles in addition to the more numerous small round vesicles. In summary, although numerous axonal boutons were seen in close apposition to TH+ material at the LM, the majority of synapses originating from STN and PPN were onto TH- dendrites at the EM level. STRIOSOME / MATRIX AFFILIATIONS OF PREFRONTO-STRIATAL PROJECTIONS IN THE MONKEY. Frank Eblen, and Ann M. Gravbiel, Dept. of Brain & Cognitive Sciences, M.I.T., Cambridge, MA 02139

To identify the prefrontal afferents to the striosome and matrix compartments of the monkey striatum, intracortical injections of the anterograde tracers, [35S]-methionine and HRP-WGA, extending through all layers were placed in the left prefrontal cortex of 6 adult female monkeys (Maccaca fascicularis). Polar, dorsolateral, lateral orbital and caudal orbito-proisocortical sites were injected, and tracer distributions in the ipsilateral striatum were studied in relation to striatal compartments marked by stains for acetylcholinesterase activity and enkephalin-like

The projection fields in all cases were patchy and topographically organized, with striatal labeling from dorsolateral injection sites more dorsolateral than that from ventral and orbital sites. The strongest labeling was in the head of the caudate nucleus and the anteroventral putamen. Predominant labeling of the matrix occurred with injections in the principal sulcus and anterolateral orbital cortex. Labeled projections from the frontal pole were also mainly to matrix along the medial edge of the caudate nucleus, but they showed some overlap with striosomes. In striking contrast, injections of caudal orbital cortex and proisocortex caudal to areas 12 and 13 led to prede labeling of striosomes through most of the fields of labeling. Weaker matrix labeling occurred, especially in the ventromedial caudate nucleus and putamen.

These findings demonstrate that different parts of the primate prefrontal cortex project preferentially to striosomes and to matrix, and suggest that the caudal orbital cortex and contiguous proisocortex is one major source of projections to striosomes Supported by NIH Javits Award NS25529 and Deutsche Forschungsgemeinschaft (Eb 127/1-1).

PALLIDAL TERRITORY OF THE MONKEY THALAMUS: CELL TYPES AND GABAERGIC STRUCTURES. H. Yi, I. Rachman, K. Kultas-Ilinsky\* and I.A. Ilinsky. Dept. of Anatomy, Univ. of Iowa Coll. Med., Iowa City, IA 52242.

The densicellular part of the ventral anterior nucleus (VAdc) represents the major projection zone of pallidal efferents and projects itself to the premotor cortex. VAdc is characterized by clusters of varying size neurons but it is not clear how many cell types are present in these clusters and what is the ratio of individual cell types.

To elucidate this we made WGA-HRP injections in the area 6 of one hemisphere and applied the same tracer to the surface of the cortex at symmetric location in the contralateral hemisphere in two adult Rhesus monkeys. Thalamic neurons retrogradely labeled from both tracer locations (PN) were then compared as to their sizes cytological features and immunocytochemical properties. For the latter, postembedding immunocytochemical procedure with antibody to GABA was carried out on the tissue processed for HRP and embedded in Epon.

PN displayed bimodal distribution of soma sizes with majority of cells being of small to medium size. These predominated in clusters. The mean size of neurons projecting to superficial layers of the cortex did not differ significantly from those of cells projecting to all cortical layers. The GABA positive cells represented distinct population: they were significantly smaller than PN, displaying minimal size overlap with the latter and did not become labeled from cortex. The distinct cell types differed also with respect to the density and distribution of GABAergic input as well as other ultrastructural features.

Our results suggest existense of three types of neurons in the pallidal territory of the thalamus: two types of PN, which differ in size, and some cytological properties but not cortical layers they project to, and small GABA containing cells which are similar to interneurons in other thalamic nuclei. The data suggest that synaptic and neuronal organization of the pallidal afferent territory of the thalamus differs from that of the nigral and cerebellar projection zones. Supported by RO1NS 24188.

CEREBELLO- AND PALLIDO-THALAMOCORTICAL PROJECTIONS TO THE PRIMARY MOTOR CORTEX: BODY MAPS. J.E. Hoover' and P.L. Strick. Research Service, VAMC and Depts. of Neurosurgery & Physiology, SUNY-HSC, Syracuse, NY 13210

We injected a retrograde strain of herpes simplex virus type 1 (HSV-1) into the "face", "arm", and "leg" representations of the primary motor cortex of monkeys to label the origin of cerebellar and basal ganglia projections to these sites. We found neurons labeled by retrograde transneuronal transport in restricted regions of the dentate nucleus and the internal segment of the globus pallidus (GPI). Surprisingly, projections to the primary motor cortex originate from only 30% of the volume of the dentate and only 15% of GPI. Thus, the majority of the output from these two subcortical nuclei is directed to areas other than the primary motor cortex. The distribution of neuronal labeling in the dentate and GPi varied with the cortical injection site. Within the dentate, neurons labeled after virus injections into leg motor cortex were located rostral to those labeled by injections into arm motor cortex, whereas the neurons labeled after injections into face motor cortex were located caudal to those labeled from arm motor cortex. Within GPi, neurons labeled after virus injections into leg motor cortex were located dorsal to those labeled by injections into arm motor cortex, whereas the neurons labeled after injections into face motor cortex were located ventral to those labeled from arm motor cortex. Thus, these observations provide evidence for at least one map of the body in the dentate and one in GPi. Supported by VA Medical Research Service and USPHS 2957, 24328.

INPUT-OUTPUT MODULARITY OF MOTOR AND SOMATOSENSORY PROCESSING IN THE PRIMATE BASAL GANGLIA. A. W. Flaherty A. M. Graybiel<sup>1</sup>. <sup>1</sup>Dept. of Brain and Cog. Sci., M.I.T., Cambridge, MA 02139, and <sup>2</sup>Harvard Medical School, Boston, MA 02115.

In the extrastriosomal matrix of the striatum, cortical inputs and pallidal outputs are clustered in discrete zones ("matrisomes"). To determine the relationships between these input and output modules, we made electrophysiologically-guided injections of anterograde tracers (35S-methionine and WGA-HRP) to label inputs to the striatum from body part representations in motor and somatosensory cortex, and in the same brains injected retrograde tracers (cholera toxin and WGA-apoHRPgold) into the internal and external segments of the globus pallidus (GPi and GPe).

1) Divergent inputs to the striatum from body part representations in cortex can reconverge on specific locations in GPe and GPi. Anterograde and retrograde injections in corresponding parts of cortex and GP labeled multiple overlapping matrisomes. Dispersed sets of input matrisomes can thus act together as output matrisomes, and specific loci in GPe and GPi may reintegrate information from distributed sets of matrisomes concerned with the same body part. 2) GPe and GPi contain small input modules that may convey cortical information in parallel. Matrisomes projecting to some regions of GPe and GPi are selectively avoided by sensorimotor cortical inputs, yet these GP regions are very near those receiving sensorimotor matrisome inputs. 3) Striatal outputs to GPe and to GPi are not rigidly segregated in different matrisomes. Small retrograde injections in GPe and GPi each label multiple matrisomes, and these sometimes overlap. Within the areas of overlap, however, few striatal neurons contain both retrograde labels, suggesting that striatal projections to GPe and GPi are nonetheless distinct at the neuronal level.

Overall, the systematic convergence and divergence of matrisome connections may allow the putamen to sort cortical information into particular channels through both GPe and GPi. (NIH R0125529 and the Human Frontier Science Program.)

THREE DIMENSIONAL REPRESENTATION OF BASAL GANGLIA AND CEREBELLAR PROJECTION ZONES IN THE PRIMATE THALAMUS. I.A. llinsky\*.A.W. Toga\* and K. Kultas-Ilinsky. Dept. of Anatomy, Univ. of Iowa Coll. of Med., Iowa City, IA 52242 and \*Dept. of Neurology, UCLA Sch. of Med., Los Angeles, CA 90024.

The topographic relationships of nigral pallidal and cerebellar projection zones within the correct below how here the projection zones.

The topographic relationships of nigral pallidal and cerebellar projection zones within the primate thalamus have been a subject of long existing controversy until recent unequivocal demonstration of their complementarity (Ilinsky and Kultas-Ilinsky, 1987, JCN, 262:331-364). The segregation of these subcortical afferent systems is clearly seen along the anterior-posterior axis in sagittal sections, whereas it is less obvious in the frontal section plane. One of the reasons for the latter is difficulty in making accurate comparisons and adjustments of frontal section planes from different experiments due to variations in cutting angles. The situation has been further agrayated by the fact that experciple districtions within the motor. further aggravated by the fact that cytoarchitectonic distinctions within the motor thalamus are not always obvious and hence can not be routinely used as a reliable criterion. Therefore, it is important to reveal the spacial relationships of major subcortical afferent systems, since these may have major functional implications.

succorrical arrerent systems, since these may have major functional implications. The purpose of the present study was to generate computer reconstructed images of nigral, pallidal and cerebellar projection zones in frontal plane of section using their outlines obtained in experimental studies utilizing sagittal sections (Ilinsky and Kultas-Ilinsky, 1987). The task of converting one section plane to another was accomplished by three-dimensional computer reconstructions from serial sections cut

accomplished by three-dimensional computer reconstructions from serial sections cut in one plane followed by re-slicing in the plane of choice (Toga, 1990). The present study revealed more complex topographic relationships between nigral, pallidal and cerebellar afferent domains in frontal section plane as compared to those observed in the sagittal plane. In particular, the interdigitation of these domains was much greater than previously thought. This may have contributed to the mentioned above segregation vs. overlap controversy of topographic relationships between the major motor-related afferent systems.

ORGANIZATION OF CONTACTS FROM VESTIBULOSPINAL AXONS ON THE DENDRITIC SURFACE OF DORSAL NECK MOTONEURONS IN THE CAT. P.K. Rose\*, T. Corneil, R. Nirula and T. Jones, MRC Group In Sensory Moto

Physiology, Queen's University, Kingston Ontario K7L 3N6
It is well established that the vast majority of synaptic contacts on spinal motoneurons are located on the dendritic tree. However, the arrangement of synapses from identified afferents on the dendritic tree is poorly understood. The goal of the present experiments was to describe the distribution of contacts made by axon terminals of vestibulospinal axons on the dendritic trees of individual spinal motoneurons. The method of anterograde transport of phaseolus vulgaris leucoagglutinin was used to visualize the boutons of phaseous valgars leaves gradually was used to vascause the boulders of vestibules pinal axons arising from the lateral or descending vestibular nuclei. The dendritic trees of dorsal neck motoneurons were stained intracellularly with horseradish peroxidase. All contacts consisted of a clearly discernible bouton that, at the light microscopic level, appeared to be a direct apposition with a dendrite. Despite the presence of over 5,000 boutons within the volume of ventral horn that contained dendrites of a single motoneuron, contacts were few, ranging from 12 to 26 on the three motoneurons examined in detail. These contacts were not randomly arranged, but instead, were either concentrated on proximal dendrites directed medially or laterally (1 motoneuron) or were evenly distributed along the proximal and distal regions of dendrites travelling rostrally or caudally (two motoneurons). Regardless of the medial, lateral, rostral or caudal orientation of the dendrites, most contacts were found deep in the ventral horn, within motoneuron nuclei. These results suggest that synapses on dorsal neck motoneurons from vestibulospinal neurons are arranged in specific patterns which may form a substrate for nonlinear interactions with other inputs received by dorsal neck motoneurons. (Supported by the Canadian MRC and

### 138.3

IDENTIFICATION OF POSTSYNAPTIC TARGETS OF CORTICAL AFFERENTS IN THE RAT DORSAL COLUMN NUCLEI G.Q. Chang\*, J.G. Valtschanoff, and A. Rustioni

Dept. of Cell Biology & Anatomy, and Dept. of Physiology, University of North Carolina, Chapel Hill, NC 27599.

To test the hypothesis that sensorimotor cortex controls the activity of projecting neurons in the dorsal column nuclei (DCN) via GABAergic interneurons we studied the relationship between identified cortical terminals and their postsynaptic targets. WGA-HRP was injected bilaterally in the somatosensory contex of 8 anesthetized Sprague-Dawley rats. Fifty µm thick Vibratome sections containing DCN were reacted with TMB/tungstate to reveal peroxidase, and studied under bright and dark field. For EM observations, selected sections containing the anterograde label were osmicated and wafer-embedded in Epon-Spurr. Thin sections from these were collected on nickel mesh grids and stained for GABA, using postembedding immunogold techniques and different antibody concentrations. The areas of the labeled terminals, postsynaptic dendrites other terminals and dendrites, and glia processes were measured; gold particles were counted and their densities were calculated for each profile

In the caudal medulla, the anterograde labeling was concentrated in the gracile, cuneate and external cuneate nuclei. At EM level, it was in the form of electron-dense crystals and amorphous deposits inside small domeshaped terminals containing numerous clear round vesicles. These terminals were negative for GABA. The profiles postsynaptic to cortical terminals were predominantly small dendrites and dendritic spines with areas up to 1 µm<sup>2</sup>. In about 50% of the cases these dendrites contained higher densities for GABA then the background. Thus, the preliminary results suggest that cortical afferents in the DCN contact GABAergic as well as non-GABAergic neurons.

A TOPOGRAPHICAL COMPARISON OF RAPHE NUCLEI PROJECTIONS TO ANTERIOR CINGULATE & AREA Fr2 OF PREFRONTAL CORTEX IN THE RAT. G. Behzadi M. Janahanadi and N. Rajaee. Physiology Dept., Shahid Beheshti Med. Sci. Univ. Tehran, TRAN. (Spon: Brain Research Association.)

Morphofunctionally, the anterior cingulate (ACg) is related to limbic system and area Fr2 is considered as a supplementary somatomotor cortex. Physiological studies indicate the implication of raphe-cortical projections in the regulation of learning, memory and movement. To compare the abundancy of the raphe nuclei projections to ACg and Fr2 prefrontal regions on the basis of their site of origin, We used retrograde transport of WGA-HRP followed by TMB reaction. The injection of tracer in area Fr2 resulted in labeling of dorsomedian and ventromedian neuronal groups of anterior dorsal raphe nucleus (DR). But in the median level of DR, numerous labeled neurons were found in the lateral wing of DR. Median raphe nucleus (MnR) innervated more rostral part of Fr2 from its median part. Rostral and caudal linear raphe (RLi, CLi) contained a few scattered labeled neurons. The rostral part of ACg was heavily innervated by ventromedian part of anterior DR and lateral wing of the rusted part of ACg was heavily innervated by ventromedian part of mns end only a few terminals to ACg. The separate neuronal groups in rostral, ventral and lateral part of DR and median MnR project mostly to caudal ACg. RLi and CLi contained many labeled cells in comparison to their projections to area Fr2. Our data reveals that the strong connections of raphe nuclei (especially DR & MnR) to these specific prefrontal areas, arised mainly from separated neuronal groups and/or some of their common projections may occur via collateral axons.

CENTRAL PROJECTION PATTERNS OF INTRA-AXONALLY-LABELLED TRIGEMINAL SECONDARY MUSCLE SPINDLE AFFERENTS. REVERS DONGA, DEAN DESSEM and RICHARD MESZLER.\* Department of Physiology, School of Dentistry, University of Maryland, Baltimore, MD, 21201 USA.

Axons of jaw-muscle spindle afferents were labelled with HRP in the tract of the mesencephalic nucleus of the fifth nerve in rats anaesthetized with pentobarbital. Four axons with dynamic indices ≤ 20 imp/s during ramp and hold stretches that followed sine wave stretches were classified as secondary jaw-muscle spindle afferents. Incoming axons of all labeled secondary jaw-muscle spindle afferents bifurcated into the tracts of the mesencephalic nucleus and Probst and had somata throughout the rostrocaudal extent of the mesencephalic nucleus. These axons could be followed for approximately 4 mm. Most labelled somata were pseudounipolar although one possessed a clear dendritic process. The heaviest density of boutons was in the region dorsal to the trigeminal motor nucleus. All secondary spindle afferents had relatively fewer boutons in the fifth nerve motor nucleus. In addition, processes given off from the tract of Probst, at the level of the facial nucleus, had sparce boutons in the reticular formation. These results suggest that the strongest projection of secondary jaw-muscle spindle afferents is dorsal to the trigeminal motor nucleus with weaker but direct projections also to the trigeminal motor nucleus and the reticular formation. Supported by NIH DE10132.

NUCLEAR ORIGINS OF RETICULOTHALAMIC PROJECTIONS IN RATS

NUCLEAR ORIGINS OF RETICULOTHALAMIC PROJECTIONS IN RATS D.B.Newman\* and C.Y. Ginsberg Dept. of Anatomy and Cell Biology, USUHS, Bethesda, MD 20814-4799 Nuclear origins of reticulothalamic projections in rats were studied using WGA-HRP and Fluoro-Gold. Tracer injections were made into the intralaminar (IL), ventrolateral, mediodorsal (MD), and ventral posterolateral (VPL) nuclei. Counts of retrogradely-labeled cells were done on 19 select cases. The strongest reticulothalamic projections were to IL and lateral MD; the weakest to VPL. The strongest reticulothalamic projections arose from midbrain cell groups, including cuneiformis, subcuneiformis, and the pedunculopontine nucleus. Strong pontine projections arose from pontis oralis pars medialis, pontis caudalis pars beta, and the dorsomedial tegmental area. A medullary trans-nuclear field encompassing paragigantocellularis dorsalis and dorsal parts of gigantocellularis and parvocellularis contained many labeled cells. Reticulothalamic projections were ipsilateral from the midbrain, bilateral from the pons, and contralateral from the medulla. Within a given reticular nucleus, thalamic-projecting neurons were similar in their morphology to those projecting to the spinal cord, cerebral cortex, and cerebellum.

PROJECTIONS FROM THE PERIAQUEDUCTAL GRAY TO THE SPINAL CORD. L. J. Mouton\* and G. Holstege. Dept. Anatomy and Embryology, Faculty of Medicine, Rijksuniversiteit Groningen, The Netherlands.

Motoneurons represent the final output of the motor system. They are located in spinal cord and caudal brainstem. Recently it has become evident that the mesencephalic periaqueductal gray (PAG) takes part in the motor system. The question arises whether there exist direct projections from the PAG to the cat spinal cord and where such projections terminate.

In ten cats HRP was injected in the spinal cord each at a different spinal level. Prior to the injection a hemisection was made rostral to the injection site. In order to identify and count the retrogradely labeled PAG neurons every fourth 40 µm transverse section of the PAG was incubated using the TMB method. In the anterograde study injections of <sup>3</sup>H-leucine or WGA-HRP were made in the lateral PAG. The autoradiographic tracing and TMB incubation method were used to visualize the labeled fibers in the spinal cord.

The results show that there exist neurons in the lateral and ventrolateral PAG projecting throughout the length of the spinal cord. The average diameter of these neurons is 33 µm, which is about twice as large as the PAG neurons projecting to the caudal raphe nuclei. The PAG-spinal cord neurons are mainly located between A 1.6 and P 0.2. Their number varies from a few hundred (upper cervical cord) to a few single neurons (sacral cord). The neurons project to the medial part of the ventral cervical cord, containing inter and motoneurons innervating axial and proximal muscles. A small number project to the intermediolateral cell column of the upper thoracic cord. likelihood these PAG projections play a role in defensive behavior.

MONDAY PM

AFFERENT PROJECTIONS FROM THE SPINAL CORD TO THE PERIAQUEDUCTAL GRAY IN THE CAT. V.G.J.M. van der Horst\* and G. Holstege. Dept. Anatomy, University of Groningen, The Netherlands.

The periaqueductal gray (PAG) not only plays an important role in nociception control, but also in motor activities, related to emotional behavior. The PAG is strongly influenced by higher limbic structures such as hypothalamus and amygdala, but it also receives input from the spinal cord. In order to obtain a precise description of the spinal cord-PAG projection in the cat, a combined retrograde and anterograde tracing study was done to determine the number and location of the

spino-PAG neurons and their precise termination area in the PAG. In the retrograde tracing study unilateral injections of WGA-HRP were made in the PAG. In order to identify and count the retrogradely labeled spinal cord neurons, all segments of the spinal cord were cut in transverse 40  $\mu$ m thick sections and every fifth section was incubated using the TMB method. In the anterograde tracing study HRP was injected at different spinal levels after a hemisection was made just rostral to the injection site. The TMB incubation method was used to visualize the labeled fibers in the PAG.

The results show that the spino-PAG projections are bilateral with a clear contralateral preponderance. Spino-PAG neurons are not evenly distributed along the different segments. They are most numerous at upper cervical and sacral levels and to a lesser extent at upper and mid thoracic levels. At sacral levels they are mainly located in the area of the intermediolateral cell column. The anterograde study shows that fibers originating from neurons at different spinal cord levels project to different areas of the PAG, suggesting a somatotopical organization of spinal cord projections to the PAG.

DIVERSITY OF FORM (AND FUNCTION?) OF COLLATERALS ORIGINATING FROM VESTIBULOSPINAL AXONS IN THE CAT. A.H. Donevan\*, J.A. MacDonald, P.K. Rose. MRC Group in Sensory Motor Physiology, Queen's University, Kingston Ontario Canada K7L 3N6

Neurons in the upper cervical spinal cord are one of the primary targets of vestibulospinal axons. In the present experiments, the anterograde tracer, phaseolus vulgaris leucoagglutinin, was used to visualize the collaterals of single vestibulospinal axons in the upper cervical spinal cord of the cat. A total of 27 collaterals that arose from 23 different axons were examined in detail. All axons originated from cells in the medial and descending vestibular nuclei and travelled in the ipsilateral ventral funiculus. Almost half of the collaterals formed bushy arborizations. The boutons of these collaterals were usually widely distributed in the ventromedial nucleus, medial and central parts of lamina VIII, medial parts of lamina VII and occasionally the spinal accessory nucleus and lateral parts of laminae IV, V and VI. A small number of axon collaterals with bushy arborizations terminated in a single lamina, either VII or VIII. Bushy collaterals usually arose from large diameter (3.0 - 6.0 μm) axons located in the medial part or base of the ventral funiculus. Other collaterals had a string-like appearance with several short side branches. Some of these formed a line of terminals that extended from lamina IX to lamina V. Other string-like collaterals only terminated in one or two laminae, usually laminae VII, VIII or IX. Most of the string-like collaterals arose from small diameter (0.5 μm to 1.0 μm) axons that were found in the medial part of the ventral funiculus or just ventral to the base of the ventral horn.

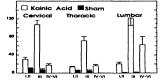

the ventral norm. The rich diversity of these collaterals suggests that vestibulospinal projections in the ipsilateral ventral funiculus are composed of multiple subdivisions. Each subdivision is distinguished by its innervation of specific interneurons or selected combinations of interneurons and motoneurons. (Supported by the Canadian MRC and MDA)

MAP OF SPINAL NEURONS ACTIVATED BY CHEMICAL STIMULATION IN THE VENTROMEDIAL MEDULLA OF THE AWAKE, DRUG-FREE RAT J. SANDKÜHLER\* & K. BETT II. Physiologisches Inst., Univ. Heidelberg, F.R.G.

The ventromedial medulla (VMM) is a major source for medullospinal neurons modulating sensory input and motor output of the spinal cord. Here we used the expression of the proto-oncogene c-fos as a cellular marker of spinal neurons

Under deep pentobarbital anesthesia 13 S.D. rats were implanted with a guide cannula (.45 mm o.d.) to allow insertion of an injection cannula (.23 mm o.d.) into the VMM. For one week before and another week after the surgery the animals were daily allowed to adopt to the experimental environment and procedures. At the day of the experiment the animals were injected either with saline (0.9 %, 100 nl) or kainic acid (0.2 mmol in 100 nl). Five minutes before and 15 minutes after the injection the animals were placed into a Perspex chamber  $(40 \times 40 \text{ cm})$  and their behavior war recorded on video tape. One hour after stimulation the animals were perfused with phosphate buffered saline and paraformaldehyde, the spinal cord was removed and postfixed overnight and cut in 25  $\mu$ m cross sections through the cervical (C) and lumbar (L) enlargement and the mid-thoracic (T) cord. The c-FOS protein was detected by immunocytochemistry(avidin-biotinmethod, primary antibody at 1:40.000).

In the figure the total numbers of FOS-positive cells per 5 sections are given. It is shown that stimulation in the VMM activates a large number of neurons throughout the spinal cord, predominantly in lamina III. Supported by a grant from the DFG (SA 435).

PATHWAYS OF THE CORTICOSPINAL TRACTS PROJECTING TO

PATHWAYS OF THE CORTICOSPINAL TRACTS PROJECTING TO LUMBAR CORD IN THE RAT. A. Chen, R. Melinek, J.-J. Kim¹, J.H. Kim¹, The Miami Project To Cure Paralysis, Dept. of Neurol. Surg., Univ. of Miami, Miami, FL 33136 ¹ Dept. of Anat., Chosun Univ., Kwangjoo, Korea The majority of rat corticospinal tract (CST) axons project contralaterally to the ventralmost part of the dorsal column (DC) in the spinal cord and terminate in lamina III-VI of the dorsal horn (DH). The purpose of this study was to determine whether there are ventral and lateral CST projections to lumbar cord, and what is their terminal distribution. The anterograde tracer, PHA-L, was iontophoretically injected into the hindlimb area of the unilateral sensorimotor cortex of female Sprague-Dawley rats. Fourteen to 21 days later, the cortex and LC were sectioned and processed for ABC immunoperoxidase staining. As expected, the majority of labelled CST axons were located under the contralateral DC and in Jamina III-VI of DH. In addition they were found in Jamina III-VI of DH. In addition they were found in Jamina III-VI of DH. In addition they were found in Jamina III-VI of DH. In addition they were found in Jamina III-VI of DH. In addition they were found in Jamina III-VI of DH. In addition they were found in Jamina III-VI of DH. In addition they were found in Jamina III-VI of DH. In the Market Addition of the Market Addition of the Market Addi DC and in lamina III-VI of DH. In addition they were found in laminae I and II, as well as in the intermediate zone and lamina X. Some of the labelled axons were

as well as in the intermediate zone and lamina X. Some of the labelled axons were 2located bilaterally in the dorsolateral funiculi. A small number were also found in the ipsilateral ventral funiculus of LC. Interestingly, the ventral CST entered the ipsilateral ventral horn (VII), projected near large neurons (possibly motoneurons), and exhibited boutons en passant and terminaux.

For retrograde tracing, a radiofrequency lesion was made to the dorsal CST at the T8 level. One week later Fast Blue (FB) and Fluoro-gold (FG) were injected unilaterally into the cord, rostral and caudal to the lesion site. FB, FG and double labelled cells were observed bilaterally in the cerebral cortex. These results labelled cells were observed bilaterally in the cerebral cortex. These results indicate that there are CST projections through the dorsolateral and ventral funiculi, and that single neurons in the cerebral cortex project to lumbar as well as cervical cord.(Supported by N1H Grant NS28059, The Miami Project Research Fund, and GE International Scholar Training Fund)

INTRA-CORD MAPPING OF FIELD POTENTIALS EVOKED BY EXTRAPYRAMIDAL SYSTEMS IN THE RAT. B.R. Park<sup>1+</sup>, J-H. Sohn, R.

EXTRAPYRAMIDAL SYSTEMS IN THE RAT: B.R. Park\*\*, J-H. Sohn, K. Melinek, M.S. Kim¹, A. Chen, J.H. Kim The Miami Project To Cure Paralysis, Dept. of Neurol. Surg., Univ. of Miami, Miami, FL 33136, ¹ Dept. of Physiol., Won Kwang Univ., Iri, Korea Somatosensory evoked potential (SSEP) and motor evoked potential (MEP) monitoring has been used to evaluate the integrity of ascending and descending pathways in the spinal cord (SC), and thus to assess pathways involved in spinal cord injury (SCI). However, several studies report a poor correlation between functional recovery of locomotion and electrophysiological assessment. The purpose of this study was: (1) to assess electrophysiologically conduction. functional recovery of locomotion and electrophysiological assessment. The purpose of this study was: (1) to assess, electrophysiologically, conduction pathways of the extrapyramidal system in the rat and (2) to predict the pathways involved in SCI. The medullary reticular nucleus (RIN), lateral vestibular nucleus (VN), and red nucleus (RN) of adult Sprague-Dawley rats were stimulated using microelectrodes. Laminectomies were performed at the C3, T12 and L2 cord level. Field potentials (FPs) evoked by stimulation of each motor nucleus were recorded using a glass microelectrode filled with 2 M NaCI. To construct a cross-sectional map of the FPs, the recording was made in 7 tracks equally spaced across the SC. In each track, the FPs were recorded at seven equally spaced points from ventral to dorsal cord. Following VN stimulation, 1 or 2 short duration biphasic waves followed by a longer duration positive wave were monitored mainly in the ventral cord. Stimulation of RtN resulted in FPs with similar characteristics to those observed after VN stimulation, but their laterocy was much shorter. FPs eenerated cord. Stimulation of RtN resulted in FPs with similar characteristics to those observed after VN stimulation, but their latency was much shorter. FPs generated by RN were monitored mainly in the dorsolateral funiculus and intermediate zone of the grey matter. The first wave component generated by each nuclei follows high frequency stimulation and is eliminated or significantly reduced by specific lesions placed above the recording site. Conduction velocities for the extrapyramidal systems were vestibulospinal tract, 37 m/sec, rubrospinal tract, 39 m/sec, and reticulospinal tract, 44 m/sec. REDEFINING RED NUCLEUS: ANTEROGRADE PROJECTIONS FROM RED NUCLEUS TO THE INFERIOR OLIVARY NUCLEUS

IN RAT. D.Yu\* and P.R.Kennedy. Neuroscience Lab, Georgia Tech, Atlanta, GA 30332.

To confirm the retrograde labelling of red nucleus neurons from targets such as the inferior olivary nucleus (Yu et al., Soc. Neurosci. Abstr., 17(1) 469, 1991), anterograde studies were undertaken.

Hoth WGA-HRP and PHA-L were injected stereotaxically into the red nucleus of adult female Long Evans rats. 5 to 15 nl of WGA-HRP stereotaxically into the female Long Evans rats. 5 to 15 nl of wear-makere pressure injected while meniscus movement was observed. WGA-HRP or PHA-L were also train injected using 2.5 uh monophasic cathodal pulses 100 ms in duration at 5 Hz for 10, 5 or 2.5 mins. Standard perfusion and tissue processing techniques were used.

Both tracers revealed terminal stippling contained within the boundaries of the inferior olivary nucleus (ION). Evidence of fibers in the brainstem was also seen. The very small brainstem was also seen. The very small injection sites associated with PHA-L injections within red nucleus resulted in terminal labeling confined to specific sub-divisions of ION.

These anterograde tracing studies corroborate the retrograde studies in providing evidence for the existence of a rubro-clivary projection in the rat. Supported by NS grant 24602.

CONNECTIONS OF TURTLE RED NUCLEUS AND CEREBELLAR NUCLEI STUDIED IN VITRO WITH NEUROBIOTIN AND BIOCYTIN. R. Sarrafizadeh\*, J. Keifer, and J. C. Houk. Dept. of Physiology,

Northwestern Univ. Medical School, 303 E. Chicago Ave., Chicago, IL 60611.

Neurobiotin and biocytin transport rapidly in both anterograde and retrograde directions in mammalian systems (Kita and Armstrong, J. Neurosci. Meth. 37: 141, 1991). Rapid transport of these tracers and the viability of the isolated turtle (Chrysemys picta) brainstem-cerebellum enabled us to study the afferent and efferent connections of the chelonian red nucleus (RN) and cerebellar nuclei (CN) in vitro.

connections of the chelonian red nucleus (RN) and cerebellar nuclei (CN) in vitro.

Turtles were anesthetized with brevitol sodium (10 mg/Rg i.p.) and perfused with heparinized oxygenated physiological saline. The midbrain and rostral spinal cord segments were then placed in oxygenated physiological saline, and 15-25 nl of neurobiotin or biocytin (4%) dissolved in 1M KCl and 0.25M TRIS buffer was pressure injected into RN or CN. Transport times ranged from 16-22 hours. Coronal sections were washed, incubated with ABC reagent, and reacted with DAB.

Neurobiotin and biocytin transport in both anterograde and retrograde directions. Retrogradely filled soma, dendrites, and axons were clearly visible, as were anterogradely labelled fibers and to a lesser extent terminals. RN injections resulted in dense retrograde label and some terminal label in the contralateral CN. A contralaterally descending rubrospinal tract and a smaller ipsilateral rubro-olivary pathway could also be seen. Cells in the ipsilateral superior reticular formation, several subdivisions of the contralateral trigeminal nucleus, and the dorsal column nuclei were retrogradely filled. Spinothalamic axons were visible ipsilaterally in the ventromedial spinal cord. Following CN injections sparse retrograde label and dense terminal label could be seen in the contralateral RN. Cells in the ipsilateral ventrolateral medulla (tentatively identified as the lateral reticular nucleus) and spinal nucleus of the trigeminal nerve, and in the contralateral inferior olive and dorsal

column nuclei were also retrogradely labelled.

These data provide an anatomical basis for the concept of a turtle cerebellorubral recurrent network, in which positive feedback sustains bursting that is initiated by sensory inputs relayed in dorsal column nuclei and the spinothalamic system.

CELLS OF ORIGIN AND FUNICULAR COURSES OF PROPRIOSPINAL AXONS DESCENDING IN THE TURTLE HINDLIMB ENLARGEMENT. A. Berkowitz\* and P.S.G. Stein, Department of Biology, Washington University, St. Louis, MO 63130.

University, St. Louis, MO 63130.

Sherrington and Laslett found descending propriospinal axons spread throughout the spinal white matter of the dog in 1903 (J. Physiol. 29:58-96). Nevertheless, it has been popularly believed in recent decades that such fibers are concentrated in fasciculi proprii in the inner zones of the lateral and ventral funiculi (see A. Brodal, *Neurological Anatomy*, 1981). We have recently recorded from many descending propriospinal axons throughout the lateral funiculus and dorsal funiculus of the turtle (Abstr. Soc. Neurosci. 17:123, 1991). We now describe retrograde labeling of spinal neurons with descending axons, following injections of horseradish peroxidase into portions of each funiculus in the middle of the hindlimb enlargement of the turtle spinal cord. Following each injection, labeled cell bodies were found in the ipsilateral dorsal horn, intermediate zone, and ventral horn, as well as the

contralateral intermediate zone and ventral horn, in the 7 mid-body and rostral hindlimb enlargement segments examined. Quantitatively, however, injections in each region of white matter gave rise to a characteristic distribution of labeled cells. Injections in either the dorsal funiculus or the dorsomedial part of the lateral funiculus labeled cells predominantly in the ipsilateral dorsal horn and intermediate zone. Injections in the lateral part of the lateral funiculus labeled mostly ventral horn cells bilaterally. Ventral funiculus injections labeled mainly contralateral cells, in the ventral horn and intermediate zone. Thus, there are consistent patterns in the funicular distributions of descending propriospinal axons. These distributions are much wider than other accounts suggest. Supported by NSF Grant BNS-8908144 to PSGS.

DISTRIBUTION OF THE SPINO-THALAMIC CELLS WITH COLLATERALS TO THE RED NUCLEUS IN THE CAT. Y. Padel M. Daadi, M. Gavioli and F. Condé. Equipe "Mécanismes M. Gavioli and F. Condé. Equipe Sensori-Moteurs", CNRS, 13009 Marseille, France
The cells at origin of the rubros

rubrospinal corticospinal pathways receive a short latency somesthetic input through a ventral spinal pathway. The present study was to check if the afferents to the red nucleus (RN) are collaterals of fibres which terminate in the thalamus.

A double labelling neuroanatomical method was used: fluorescent markers were stereotaxically injected in the RN (the fast blue (FB) which labels the cytoplasm of afferent cells) and in the caudal part of the thalamus

the diamidino yellow (DY) which colors the nuclei).

Three groups of retrogradly labelled neurones were observed in the spinal cord: spinothalamic, spinorubral and doubly labelled cells. 80 % of the total population of FB labelled cells are located bilaterally in the four uppermost segments, in the VIIth and VIIIth Rexed lamina. They are mostly on the contralateral side in the cervical and lumbar enlargements.

and lumbar enlargements.

These data lead to the conclusion that the spino-rubral input is transmitted for a large part (at least 56 %) through collateral branching of spino-thalamic fibres. This organization suggests that the same somatic information is sent in parallel to the two motor structures at the origin of the "lateral descending system" of Lawrence and Kuypers (1968) which controls limb matricity is a the red pulsus and the great cortical spinor to the structure of the red pulsus and the proper cortical spinor to the structure of the red pulsus and the great cortical spinor to the structure of the spinor to the structure of the spinor to the structure of the spinor to t motricity i.e. the red nucleus and the motor cortex.

ASSESSMENT OF CERVICAL SPINAL CORD FUNCTION USING MAGNETIC MYOTOMAL MEPs. LR Ray', YP Zhang, RD Linden, CB Shields and JR Johnson. Depts. of Anatomical Sciences & Neurobiology, Orthopedic Surgery, and Surgery (Neurological), U of L, Louisville, KY 40292. The objective of this study is to determine whether myotomal motor evoked potentials (MEPs) may be reliably elicited in normal subjects and in spinal cord injured patients.

injured patients.

Transcranial MEPs were elicited following stimulation with a Cadwell Magneto-Electric Stimulator (MES-10) using a prototype skullcap coil. Stimulus intensity was set at 20, 40, 60, and 80% of the stimulator output (peak magnetic flux = 2 Tesla, pulse width=70 µsec). MEPs were recorded bilaterally from the sternocleidomastoid (SCM), deltoid (DEL), brachioradialis (BRR), flexor carpi ulnaris (FCU), abductor pollicis brevis (APB), and first dorsal interosseus (FDI) muscles. These muscles were selected because their innervation is primarily from a single spinal cord level: SCM=64, DEL=C5, BRR=C6, FCU=C7, APB=C8, and FDI=T1. Single responses were replicated. The bandpass filter was 3-3,000 Hz and the timebase was 100 msec with a 10 msec pre-stimulus delav.

Normative data was obtained from 10 adult volunteers. Suprathreshold transcranial magnetic stimulation reliably elicited compound muscle action potentials in all muscles tested. At 80% output of the stimulator, the mean onset latencies of the MEP responses were SCM= 7.38 ± 2.54 ms, DEL= 11.64 ± 1.11 ms, BRR= 16.07 ± 3.28 ms, FCU= 16.36 ± 1.93 ms, APB= 21.66 ± 1.50 ms, and FDI= 22.38 ± 1.75 ms. The maximum peak-to-peak amplitudes were SCM= 3118 ± 1458 µV, DEL= 1148 ± 726 µV, BRR= 1192 ± 393 µV, FCU= 1517 ± 748 µV, APB= 5142 ± 2339 µV, and FDI= 6298 ± 2996 µV. Clinical data was obtained from 3 cervical spinal cord injured patients. The presence of myotomal MEPs correlated well with the clinical assessment of the level of the lesion, as well as the laterality of neurological deficit.

This study demonstrates that myotomal MEPs are easy to elicit and are reproducible. Myotomal MEPs may aid in the precise localization of the level of motor deficit following spinal cord injury. Normative data was obtained from 10 adult volunteers. Suprathreshold

EVIDENCE THAT SYNAPTIC TRANSMISSION IN LUMBAR PROJECTION NEURONES IS SUPPRESSED DURING ACTIVE SLEEP. P.J. Soja\* & J.-I. Oka. Faculty of Pharmaceutical Sciences, UBC, Vancouver, BC, Canada V6T 123.

Despite numerous studies describing the central mechanisms controlling lumbar spinoreticular (SRT) and spinothalamic tract (STT) neurones, little is known regarding the excitability of these cells across naturally occurring behaviors, e.g., sleep vs. wakefulness (see monograph by Willis & Coggeshall, 1991). The present study was performed in the chronic, unanaesthetized cat to provide an overall assessment of the cellular excitability of lumbar spinal cord projection neurones as a function of behavioral state. Axons of SRT/STT projection neurones form a tight compact bundle which is located in close proximity to the facial motor nucleus (MotVII). The amplitude of the orthodromic field potential elicited by stimulation of the contralateral sciatic nerve was compared with the amplitude of the antidromic motoneurone field potential recorded within MotVII (see Soja, Soc. Neurosci. Abst., 17: 644, 1991) during wakefulness (W), quiet sleep (QS), and active sleep (AS).

The peak amplitude, latency-to-peak, and half width of the orthodromic field potential elicited by sciatic nerve stimulation (0.05msec, 0.5mA, 0.5Hz) during W was 0.78mV, 27.5msec and 29.5msec, respectively. These waveform parameters did not differ significantly between W and QS; however, the amplitude was reduced by 77% to 0.18 mV throughout AS when compared to preceding episodes of QS or W. The amplitude of the antidromic response was also reduced by 46% during AS when compared to QS or W. During W or QS, glycine was iontophoretically applied to the site where both field potentials recorded and the effects of the drug were then assessed on each type of opotential. Glycine markedly suppressed the antidromic response and exerted no effect on the orthodromic response during this state.

The present results suggest that the orthodromic response and exerted no

INTRACELLULAR STUDIES OF LUMBAR NEURONES IN THE CHRONIC CAT. 1-1. Oka\* & P.J. Soja. Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada V6T 1Z3.

Little is known about the activity of individual lumbar sensory neurones across the sleep/wakefulness cycle. The present report describes the first stage of ongoing studies designed to address this issue, namely the feasibility of performing intracellular analyses of lumbar neurones in the chronic, unanesthetized cat during drowsy wakefulness (W) or quiet sleep (QS).

Two adult cats were prepared for chronic intracellular recording of lumbar neuronal activity using methodologies developed previously (Physiol. Behav., 27: 355-362, 1981). Bevelled glass micropipettes filled with 2M K\*-citrate were lowered into the spinal cord. The electrodes were lowered in tracks 0.75-1.0mm medial to those where the sciatic motor pools were first located. In these medial tracks, a 3-6mV negative going field potential (latency-to-peak: 3.3msec, half-width: 1.7msec) could be recorded in response to sciatic nerve stimulation (0.05ms, 0.3-0.5mA, 0.3Hz). Fifteen neurones were recorded intracellularly at spinal cord depths corresponding to the presence of this field potential. The membrane potential and spontaneous action potential amplitude of the impaled cells ranged from -45 to -55mV and 50 to 88mV, respectively. Graded sciatic nerve stimulation evoked complex polysynaptic EPSPs leading to action potential bursts and/or IPSPs; however, no antidromic spikes were evoked in any of these cells. Current pulses (200µsec) injected intracellularly revealed post spike afterhyperpolarizations consisting of a fast early component followed by a slower sustained component unlike those recorded from motoneurones in the same preparation (see J. Neuroscience, 11: 2804-2811, 1991). High-gain DC records revealed the marked presence of spontaneous synaptic activity during QS or W.

These results corroborate previous work performed in acute preparations; they also sugges

ORDER OF REM SLEEP FIRING RECRUITMENT CORRELATES WITH SOMA SIZE OF PONTINE RETICULAR FORMATION NEURONS: INTRACELLULAR RECORDING AND LABELING IN THE NATURALLY SLEEPING CAT.

K. Ito, M. Yanagihara, S. Higo, L. Dauphin, D. Fuchs, & R. W. McCarley\*. Lab. Neurosci., Dept. Psych., Harvard Med. Sch. /VAMC, Brockton Ma 02401.

Acute intracellular labeling studies in our laboratory have examined the projections of giant cell field pontine reticular formation (FTG) neurons. Type I neurons had primarily reticulo-spinal projections, relatively few collatograls, and most had soma diameters  $\geq$  47.5 µm. Type II neurons projected to brainstem reticular sites, often had collaterals, and had soma diameters < 45.7 μm. The present study used intracellular recording and intracellular labeling (PhAL, biocytin, or neurobiotin) in naturally sleeping, chronic cats to determine if the "lead time" of onset of markedly increased discharge rate prior to REM was correlated with soma size. Soma diameter was determined from digitizer measurements of cross-sectional area (inter- and intra-rater variation < 5%), and done blind to the physiology. RESULTS. Diameters of the 14 labeled neurons ranged from 42.9  $\mu m$  to 87.9  $\mu m$ . Within this size range there was a strong positive linear correlation (Pearson's r = 0.64, p < 0.02) between diameter and "lead time", which ranged from 0.25 min to 5.88 min. That larger neurons had longer "lead times" was contrary to our expectation that smaller neurons, which might be Type II neurons with abundant reticular projections, would show earlier recruitment. It was also expected from the inverse size dependence of recruitment order in alpha motoneuronal pools. Earlier recruitment of larger neurons may reflect a stronger cholinergic excitatory

GABA- AND SEROTONIN-ERGIC INNERVATION OF MEDULLARY POSTINSPIRATORY NEURONS IN THE CAT. S.W. Schwarzschert. M. Maschket, T. Rudolph and D.W. Richter\* Center of Anatomy† and Center of Physiology and Pathophysiology Univ. Göttingen. W-3400. FRG.

Physiology and Pathophysiology, Univ. Göttingen, W-3400, FRG.

In mammals, the respiratory rhythm is generated by a network of medullary respiratory neurons. Postinspiratory neurons (PINs) seem to act as general inhibitors establishing a third, postinspiratory phase in the rhythm (Richter et al 1982). In the anaesthetized adult cat we HRP-labeled bulbar PINs intracellularly in the caudal medulla. These PINs were not antidromically activated by vagal nor by spinal cord stimulation. The somata of 11 labeled PINs were located in the ventral respiratory region in or in close vicinity to the ambigual nucleus. Cell bodies were multipolar and showed extensive dendritic branching. Axons travelled dorsomedially and crossed midline ventral to the central canal. Identified axon-collaterals preferentially terminated along the ipsilateral ambigual nucleus. They terminated with boutons, which in EM proved to represent axo-dendritic and axo-somatic synapses on multipolar neurons. Immunocytochemistry revealed a dense network of 5-hydroxy-tryptamine-immunoreactive (5HT-IR) fibers in the ventrolateral respiratory region. Fine 5HT-IR terminals with multiple small boutons terminated as close appositions to proximal and distal dendrites of HRP-labeled PINs. At cell bodies of PINs, however, 5HT-IR terminals were only sparsely detected. In contrast, postembedding immunocytochemistry showed multiple GABA-IR-boutons on the somata of PINs.

boutons on the somata of PINs.

Our findings verify intensive synaptic interconnections of PINs within the ventrolateral medulla, thus providing the structural basis for their proposed role as functionally important interneurons of the respiratory network. The dense GABA-ergic innervation corresponds with their pronounced post-synaptic inhibition by chloride inward currents through GABA-A-receptors (Haji et al 1986, Richter et al 1986). The 5HT-innervation of PINs explains parts of the modulatory serotoninergic influence on central respiration. S. b. DFG

THE EFFECT OF TOOTH MECHANORECEPTOR STIMULATION ON TRIGEMINAL MOTOR UNIT ACTIVITY Dean Dessem\* and Revers Donga. Dept. Physiology, Univ. Maryland Dental School, Baltimore, MD 21201

Motor unit firing in the muscles of mastication was recorded while graded forces were applied to maxillary teeth to examine the reflex effects of mechanical stimulation on various trigeminal motoneurons. Responses were recorded while horizontal or vertical forces (0.05N to 4N) were applied to the maxillary canine tooth in four cats anesthetized with pentobarbital or decerebrated. The afferent volley produced by mechanical stimulation was monitored via an electrode placed at the brainstem entry point of the trigeminal nerve. The reflex effects of ipsi- and contralateral tooth displacement were observed in twenty-two masseter, temporalis or medial pterygoid motor units using histogram analysis. Peristimulus histograms (100-500 sweeps; 1ms binwidth) were generated from the spontaneous firing of jaw-elevator motor units during the application of force. Motor unit firing was inhibited at forces less than 0.5N and this inhibition increased as the magnitude of force applied to the tooth was increased to 4.0N. Using these forces a jaw-opening reflex was never produced. Contralateral as well as ipsilateral jaw-elevator motor unit firing was inhibited for periods up to 45ms. The reflex effects on contralateral motor unit firing occurred at higher forces with slightly longer latencies. Motor units tested with both horizontal and vertical forces showed higher thresholds for modulation with vertical forces. Motor unit responses were modified by intravenous strychnine (0.35mg/kg) suggesting a glycinergic component to this reflex pathway. These results imply that the reflex effects produced by applying small forces to the teeth have different synaptic strengths to different jaw-elevator motoneurons. This reflex diversity may contribute to the precise control of jaw movement. Supported by DE10132

EFFECT OF TRACHEOSTOMY UPON RESPIRATION CYCLE DURING ELECTRICALLY INDUCED VOCALIZATION IN DECERBERATE CATS. T. Sakamoto, Y. Yamanaka, K. Wada, Y. Nakajima and Y. Tamai\*. Dept. of Physiol., Sch. of Med., Chiba Univ., Chiba, JAPAN 260

To determine the functional role of laryngeal and vagal afferents upon the coordination of laryngeal and ventilatory muscles during vocalization induced by a pontine electrical stimulation (0.2ms, less than 60  $\mu\text{A}$ , 60Hz, for 5-10s), tracheostomy was performed to bypass respiratory airflow.

Under halothane nitrous gas anesthesia, the cats were decerebrated at the precollicular-postmammilary level, and balloon catheter was inserted into the opening of a T-shaped tube, which was inserted into the trachea, to open and close the T-shaped tube at various timing of respiration. The same catheter was employed to monitor the subglottic pressure.

During continued tracheostomy, the respiratory cycle became shorter, although the pontine stimulation induced coordinated activation of laryngeal and ventilatory muscles. The sudden opening of prepared tracheostomy during expiration decreased the subglottic pressure and terminated the vocalization, however, the expiration phase continued until a termination of lung deflation. This suggested that the feedback inputs from the laryngeal mucosa or other upper airway tract were less important than the vagal inputs to determine a respiratory rhythm during vocalization.

CARDIOVASCULAR NEURONS MEDIATING SOMATOSYMPATHETIC REFLEX IN ROSTRAL VENTROLATERAL MEDIALA Y.S. Goo, S.J. Kim  $\spadesuit$  and J. Kim  $\spadesuit$ \* Dept. of Physiology, College of Medicine, Chungbuk National Univ. Cheongju 360-763 and Seoul National Univ.  $\spadesuit$ , Seoul 110-460, Korea Neurons having a close functional association with cardiac

Neurons having a close functional association with cardiac rhythm were found in the rostral ventrolateral medulla(RVLM). In the present study we intended to demonstrate that some of these cardiovascular neurons (CVN) can mediate the somatosympathetic reflex (SSR). Sixty-one neurons, showing spontaneous discharge, were identified as CVN in cats anesthetized with  $\alpha$ -chloralose by using post R-wave spike histogram and spike-triggered averaging of the sympathetic nerve discharge. Since peripheral nerve stimulation could orthodromically activate these neurons to elicit SSR with a resultant change in arterial blood pressure (ABP), simultaneous measurements of the spike frequency (SF) and ABP were successfully made in 12 neurons while stimulating the sciatic nerve. Stimulation with C-intensity (10 mA, 0.5 ms) at a high frequency (20-50 Hz) increased SF of 10/12 neurons with a concommitant rise in ABP, while that of 2/12 neurons decreased. Although stimulation with A $\delta$ -intensity (1 mA, 0.1 ms) at a low frequency (1 Hz) did not always significantly decrease ABP, an increased SF was observed in 7/12 neurons during depressor response. Some (2/12) neurons showed a decreased SF with depressor response and 3/12 neurons showed no measurable change in both ABP and SF. These results suggest that SSR can be mediated by functionally different classes of CVN present in the RVIM: the increased activity of pressor and depressor neurons facilitating, and respectively, inhibiting the reflex.

A COMPARISON OF THE DISTRIBUTION AND MORPHOLOGY OF NEURONS IN RAT TRIGEMINAL NUCLEUS ORALIS PROJECTING TO FACIAL, HYPOGLOSSAL AND TRIGEMINAL MOTOR NEURONS. D. J. Sohn, W. M. Falls\* and L. A. Smith. Dept. Anatomy, Michigan State University, East Lansing, MI 48824.

Retrograde HRP transport was used to examine and com-

pare the overall distribution and morphology of neurons in rat trigeminal nucleus oralis (Vo) projecting to facial (VII), trigeminal (VMO) and hypoglossal (XII) motor nuclei. Injections into VII and VMO labeled neurons in ventrolateral (VL) and dorsomedial (DM) subdivision throughout the middle third of Vo. Labeled VL neurons outnumbered those in DM by a 2:1 ratio. VL and DM neurons projecting to VII had spherical somata with an average cross-sectional area of  $239\mu\text{m}^2$ . VL and DM neurons projectional area of  $239\mu\text{m}^2$ . ting to VMO had large and small spherical-shaped somata with average cross-sectional areas of  $407\mu m^2$  and  $175\mu m^2$ , respectively. Injections in XII labeled nearly equal numrespectively. Injections in XII labeled nearly equabers of VL and DM neurons in the middle third of Vo.  ${\sf V}$ Neurons with spherical-shaped cell bodies were found in each subdivision and had average cross-sectional areas of  $185 \mu m^2$ . Scattered VL and DM neurons with pyramidal-shape. Scattered VL and DM neurons with pyramidal-shaped cell bodies were observed following all three injections. These results suggest that there are morphologically distinct populations of neurons in the middle third of VL and DM projecting to VII, VMO and XII. VL projects densely to VII and VMO with VL and DM providing equal innervation of XII. Vo involvement in complex orofacial reflexes is suggested. Supported by NIH/BRSG to C.O.M.

WHOLE-CELL RECORDINGS OF IONIC CURRENTS UNDERLYING THE FIRING PATTERN OF NEURONS OF THE GUSTATORY AREA OF THE RAT NUCLEUS TRACTUS SOLITARII. <u>F.J. Tell and R.M. Bradley</u>\*. Sch. of Dentistry, Univ. of Michigan, Ann Arbor, MI 48109.

Four groups of neurons within the rostral nucleus tractus solitarii (NTS) have been previously distinguished (Bradley and Sweazey, J. Neurophysiol., 67, 1992). Depolarizations induced a repetitive discharge in Group I, II and III neurons and a burst of spikes in group IV neurons. Moreover, after hyperpolarizations Group I neurons produced irregular firing and a long delay occurred in the initiation of discharge in Group II neurons. Hyperpolarizing pulses often elicited burst of spikes in Group I, III and IV neurons. Voltage clamp recordings of rostral NTS neurons in rat brainstem slices revealed that Group II neurons posses an early transient outward current which is turned on by negative voltage step commands. Application of 4-aminopyridine (1-2 mM) significantly reduced this current. For neurons exhibiting a burst of spikes following hyperpolarization, application of cobalt (2-4 mM) strongly reduced both its duration and frequency. In addition, a small inward current was elicited after negative step commands from rest. Results suggest that Group II neurons posses an A-like potassium current the activation of which delays the initiation of action potentials. An inward calcium current may underlie the bursting responses of the other neurons groups. Physiological activation of these conductances might play an important role in the processing of taste information by the rostral NTS. N.I.H. Grant DC000288

AUDITORY INPUT TO THE PEDUNCULOPONTINE NUCLEUS. N.B. Reese\*, E. Garcia-Rill and R.D. Skinner, Department of Anatomy, University of Arkansas for Medical Sciences, Little

Previous studies have shown that the P1 potential, a middle latency auditory evoked response induced by click stimuli in the intact cat, is blocked by lesions of the cholinergic pedurculopontine nucleus (PPN) and by administration of the muscarinic antagonist scopolamine (Buchwald et al. 1986, 1989). We recently showed that this middle latency potential is evident at the level of the PPN in the decerebrate cat and rat (Reess, 1991). The present studies were conducted on precollicular decerebrate, paralyzed cats. Auditory click stimuli were delivered by earphones attached to hollow ear bars and depth auditory evoked stimuli were delivered by earphones attached to hollow ear bars and depth auditory evoked potentials (3 Hz - 3KHz bandpass) and single unit responses were recorded. Recording sites were localized by Fast Green deposits in the region of histochemically (MADPH diaphorase positive) identified cholinergic PPN neurons. A total of 26% of PPN neurons were found to respond to click stimuli at a similar latency to the P1 potential (15.1± 3.8 msec), and 19% were found to respond at a shorter latency to the P1 potential (15.1± 3.8 msec), and 19% were found to respond at a shorter latency (8.0±3.2 msec), while 55% showed no auditory responses. A series of cats (n=6) and rats (n=4) underwent similar procedures except that the P1 was recorded only from the surface of the interior colliculus during auditory click stimulation at 0.2 Hz for 2 hrs. The brains were then fixed and processed for immunocytochemical labelling for c-fos early gene expression and histochemically for NADPH diaphorase labelling of cholinergic PPN cells. Between 40% and 73% of cholinergic PPN neurons also were c-fos positive. Linstitutated (surrical) controls showed minimal labelling.

of cholinergic PPN ceils. Between 40% and 75% of cholinergic PPN returns also were chose positive. Unstimulated (surgical) controls showed minimal labelling.

These studies suggest that some neurons in the PPN respond to auditory stimulation at a latency similar to that of the P1 and long-lasting auditory stimulation induces cfos expression in a significant proportion of PPN cells. In addition, preliminary evidence 
suggests that the auditory input to the PPN is modulated during episodes of spontaneous

STUDY OF RETICULOSPINAL NEURONES AND THEIR SENSORY INPUTS DURING ACTIVE AND FICTIVE SWIMMING IN A LAMPREY SEMI-INTACT PREPARATION. S.Coghlin\*, N.Bussières and R.Dubuc, Dép. Kinanthropologie, U. du Québec à Montréal H3C 3P8 and Centre de Recherche en Sciences Neurologiques, U. de Montréal H3C 3J7, Canada.

Reticulospinal (RS) neurones in lampreys show rhythmic membrane potential collections of this conduction of the latent with

oscillations during fictive locomotion and this modulation originates at least partly from spinal cord locomotor networks (Dubuc and Grillner, Brain Res 1989 483 196). To study the rôle of movement related feedback and sensory inputs to RS neurones under more natural conditions, we have used a semi-intact preparation of young adult *Petromyzon marinus*. The rostral one-third of decerebrated animals (12-14 cm) was dissected isolating the brain and spinal cord with their underlying cranium and notochord. The remaining two-thirds were left largely intact with only a medial incision to expose the dorsal surface of the spinal cord. The rostral part of the preparation was then pinned down to the Sylgard bottom of a double depth recording chamber where the tail had unrestricted movement in the deeper recording chamber where the tail had unrestricted movement in the deeper reservoir filled with cold Ringer. Bouts of swimming (20-30 cycles) occurred spontaneously or after pinching the tail. Ventral roots (fictive swimming) and EMG (active swimming) were recorded and the pattern of activity in both was well coordinated. Intracellular recordings of RS cells showed rhythmic membrane potential fluctuations which required the presence of distinct bouts of fictive locomotion in the rostral ventral roots. Cutaneous electrical stimulation evoked large synaptic responses in RS neurones which consisted of a mixed excitation and inhibition. Mechanical stimulation of the skin in a preparation where the animal was eviscerated opened along the ventral midline and pinned flat, elicited excitatory responses in RS cells with greater responses in the large Müller neurones. This robust preparation provides an opportunity to examine more closely the response of RS cells to sensory and proprioceptive inputs. HYPOGLOSSAL SENSORY FEEDBACK MODULATES MOUTH OPENING DURING FEEDING IN TOADS. K. C. Nishikawa\* and C. Gans. Department of Biological Sciences, Northern Arizona University, Flagstaff, AZ 86011.

High-speed videography, electromyography, deafferentation, and electrical stimulation experiments were used to investigate how sensory feedback from the tongue, which enters the brain through the hypoglossal nerve, influences mouth opening during feeding behavior in the marine toad (Bufo marinus). Behavioral observations demonstrate that bilateral transection of the hypoglossal nerves prevents mouth opening during feeding. Before transection, the mandibular depressors become active 87 ms before the mandibular depressors. After transection, the depressors and levators become active simultaneously. Electrical stimulation experiments showed that hypoglossal sensory feedback inhibits both tonic and phasic activity of the jaw levators. This feedback system appears to coordinate jaw and tongue movements during feeding in toads. Similar experiments on other anuran species show that hypoglossal sensory feedback is a derived feature of anuran feeding behavior. Supported by NSF grant #BNS 8909937 to KCN.

RETICULOSPINAL NEURONS AND DESCENDING INITIATION PATHWAYS FOR LOCOMOTION IN THE

ALD. MCCLellan and G.R. Davis, Div. of Biol. Science, Univ. of Missouri, Columbia, MO 65211

The Lamprey, the lateral spinal tracts are important for the descending initiation of locomotion (McClellan, 1988). In this study the pathways in which reticulospinal neurons project were examined using a more sensitive which reticulospinal neurons project were examined using a more sensitive tract-tracing method than previously employed in our laboratory. In larval lamprey, various partial lesions of the spinal cord were made either at the level of the third or fifth gill. After 5-7 days the behavioral capabilities of the animals were tested. At 7-10 days post-lesion, which in control experiments was found to be sufficient time to allow cut axons to seal, HRP was applied at 25% body length, and after 12-14 days the brains and spinal cords where removed and processed using the Hanker-Yates protocol developed by M.E. Selzer. Focal application of HRP to the spinal cord indicated that descending axons usually remained in the same spinal tracts after leaving the brain. In control animals without partial lesions, a total of about 1200 labeled brainstem neurons were distributed in one diencephalic, two mescnephalic, there istabile, two bulbars one lateral, and three yeads cell groups. Animals

three isthmic, two bulbar, one lateral, and three vagal cell groups. Animals with spinal hemisections were able to locomote, and Mauthner cells and brainstem neurons in subdivisions of the isthmic and vagal nuclei had crossed descending axons. The remaining brainstem neurons had ipsilateral axons. Animals with both lateral spinal tracts lesioned usually could not initiate Animals with book lateral spinal tracts lesioned usually could not initiate locomotion, and mostly large Muller reticulospinal neurons and some mesencephalic and vagal neurons were labeled. Animals with medial spinal lesions were able to locomote, and most brainstem neurons other than Muller cells were labeled, particularly in the isthmic, bulber, and vagal cell groups. These results support the notion that reticulospinal neurons in the isthmic, Inese results support the notion that reticulospinal neurons in the istumic, bulbar, and vagal cell groups with exons in the lateral spinal tracts are important for the initiation of locomotion. In addition, axons of neurons in several cell groups appear to descend in intermediate areas of the spinal cord including both lateral and medial subdivisions of the spinal cord. Supraspinal control in learn ANATOMICAL AND PHYSIOLOGICAL STUDY OF VESTIBULOSPINAL NEURONES IN LAMPREYS. N.Bussières\* and R.Dubuc. Dép.

reticulospinal (RS) and the vestibulospinal (VS) systems. RS neurones are known reticulospinal (RS) and the vestibulospinal (VS) systems. RS neurones are known to play a key rôle in the control of locomotion but less is known about VS neurones which are located in three nuclei: the posterior, the intermediate and the anterior octavomotorii nuclei (OMI n., OMP n. and OMA n.). This study was aimed at characterizing the morphology of VS cells, their axonal projections as well as some of their inputs. Anatomical data were obtained using retrograde tracers such as cobaltlysine (in vitro), HRP (in vivo), as well as with intracellular filling with Lucifer Yellow. Our results show that VS cells of the OMI n. (50-60 cells; 15-60 µm) are anatomically segregated, the smallest being found at the rostral and the caudal poles of the nucleus. Most of these cells have a dendritic tree projecting laterally within the alar plate. They have several axonal branches projecting rostrally in the basal plate and one caudally, reaching the ipsilateral spinal cord where it travels either within the intermediate or medial tract. The OMP n. contains between 20 and 30 VS cells (25-80 µm), many of which are deprived of dendrites. Their axon and 30 VS cells (25-80 µm), many of which are deprived of dendrites. Their axon projects to the contralateral basal plate where it bifurcates: one or two branches project rostrally and one or two caudally, with a larger branch projecting to the medial tract of the contralateral spinal cord. The spinal projection of some VS cells of the OMI n. and OMP n. reaches further caudally than the gills as demonstrated by HRP injections. Cells of the OMA n. project only to the very rostral contralateral spinal cord and the caudal brainstem. VS neurons were recorded intra-cellularly within the OMI n. and the OMP n. They receive mixed chemical and nic synaptic inputs from vestibular afferents; the chemical component is blocked using kynurinate (4mM) suggesting EAA transmission. Other inputs from dorsal and/or lateral columns are presently under study. (Supported by MRC Canada, FCAR and FRSQ Québec).

GLUTAMATE METABOTROPIC RECEPTORS MODULATE SYNAPTIC INPUTS TO RETICULOSPINAL NEURONES OF THE LAMPREY. S. Alford and R. Dubuc' Dép. Kinanthropologie, U. du Québec à Montréal, H3C 378 and CRSN, U. de Montréal, Montréal, H3C 37, Québec.

Reticulospinal (RS) neurones are important for the initiation and control of locomotion. They receive inputs from several sources, the spinal locomotor networks and the periphery. Application of the glutamate receptor agonist N-methyl-D-aspartate significantly reduces the excitatory transmission from vestibulospinal inputs to RS neurones (Bussière et al 1992, Brain Res. in press). This study was extended to investigate the mechanisms involved and the possible rôle of this depression. Whole-cell patch clamp recordings were made from RS neurones with patch pipettes containing principally Cs' Methane sulphonate in isolated brains of Petromyzon marinus. Stimulation of the brainstem alar plate over axons of vestibular neurones activated a compound EPSC in the RS neurone. The application of NMDA (50 µM) caused a depression in amplitude (to 56 ± 5 % sem of control n = 12) of the EPSC, which was unaffected by the application of the competitive antagonist ketamine, suggesting a possible presynaptic effect of NMDA. Pretreatment of the brainstem for 24 hrs with pertussits toxin (A compound that inactivates certain classes of G protein) eliminated the this depressant action of NMDA indicating that NMDA acts at a metabotropic site in this case. Application of the glutamate metabotropic receptor agonist 15-3R ACPD (20 µM) also caused a depression of the RS EPSC (to 67 ± 5 % sem of control) in addition to causing an increase in synaptic noise recorded from the neurone. On washout an enhancement of the EPSC amplitude was then recorded. To test for a physiological role of these receptors paired pulse stimuli were used. Responses to the second stimulus were depressed up to 30 s following the initial stimulus. Application of NMDA (50 µM) eliminated this depression by more effectively depressing the f

EFFECTS OF INHIBITORY AMINO ACID AGONISTS ANTAGONISTS ON LOCOMOTOR RHYTHMICITY IN THE RAT SPINAL CORD IN VITRO. K.C. Harder, B.J.Schmidt. Dept. of Medicine and Physiology,

University of Manitoba, Winnipeg, Canada R3E 0W3.

Little is known about the role of inhibitory neurotransmitters in mammalian locomotor networks, although recent studies by Kudo et al. (Neurobiol. Basis of Human Locomotion 1991) suggest glycinergic systems are required for side-to-side coordination in fetal rats. In the present series, the effect of GABA and glycine receptor activation and blockade during pharmacologically induced locomotion was studied using isolated spinal cords of 1-7 day old rats. Rhythmic activity was recorded bilaterally from flexor (peroneal) and extensor (tibial) nerves.

The GABA, agonist muscimol (5-15 uM), GABA, agonist baclofen (1-10 uM), and glycine (1500 μM) abolished NMDA and ACH-induced rhythmic activity. In the absence of NMDA or ACH, antagonists of GABA<sub>A</sub>, GABA<sub>B</sub>, and glycine (bicuculline 20 μM, hydroxysaclofen 1400 μM, and strychnine 20 μM) failed to induce sustained rhythmic activity, although responses to afferent stimulation were markedly enhanced. Locomotor rhythm was unaffected by GABA<sub>B</sub> antagonists (hydroxysaclofen 400 μM, phaclofen 2000 μM), but bicuculline (4-20 μM) and strychnine (4-20 µM) enhanced phasic discharge and converted left-right and flexor-extensor alternating patterns into highly synchronous rhythms, the frequency of which depended on the concentration of NMDA or ACH. AP5 (30 µM) abolished the activity. Single isolated lumbar hemi-segments also demonstrated strychnine and bicuculline enhanced rhythmic bursts. Bilateral synchrony persisted after splitting the lumbar cord by mid-sagittal section, even when only 1 supralumbar spinal cord segment remained bilaterally intact. The results suggest that inhibitory amino acid transmission is not essential for establishing rhythmic oscillation in spinal networks but may mediate reciprocal antagonism that coordinates inter and intralimb locomotor patterns. (Supported by MRC Canada)

CONVERGENCE OF EXCITATORY Ib AND DESCENDING LOCOMOTOR PATHWAYS IN THE CAT. R.M. Brownstone\*, B.R. Noga, & L.M. Jordan. Dept. Physiology, University of Manitoba, Winnipeg, Manitoba, Canada R3E 0W3.

During fictive locomotion, oligosynaptic excitation from selected extensor Ib afferents to extensor motoneurones replaces the usual autogenetic inhibition (see Gossard et al, SFN Abst 1990). Stimulation of these Ib afferents has profound effects on locomotion, resetting the rhythm and initiating an early extensor phase, likely by exciting the extensor component of the spinal locomotor network (extensor half-centre). Stimulation of the mesencephalic locomotor region (MLR) produces locomotion and short-latency PSPs in motoneurones which are normally modulated through the step cycle, giving EPSPs during extension and IPSPs during flexion in extensor motoneurones (Shefchyk & Jordan, J. Neurophysiol. 1985). If these shortlatency PSPs and Ib EPSPs are effected via common interneurones, spatial facilitation should be demonstrable with appropriate stimulation. The current study vas undertaken to test this hypothesis.

Fictive locomotion was initiated in decerebrate cats by stimulation of the MLR, with intracellular recordings from motoneurones (see Brownstone et al, 1992). A condition-test protocol was employed with electrical stimulation of the

MLR and ipsilateral group I (likely Ib) afferents from plantaris.

The short-latency MLR PSPs in ipsilateral extensor motoneurones were facilitated by Ib stimulation both during extension and particularly during flexion. Whereas a short-latency IPSP from the MLR is usually seen during the flexor phase, an EPSP was instead observed with the addition of Ib stimulation.

It can be concluded that there are populations of interneurones involved in the central generation of the extensor phase of locomotion which receive excitatory input from both the MLR and Ib afferents. These Ib interneurones are those involved in the recently described Ib excitatory pathway, rather than those of the classical autogenetic inhibitory pathway.

INTERACTION BETWEEN MAUTHNER NEURONS AND THE SWIMMING PATTERN GENERATOR IN XENOPUS TADPOLES. M. T. Lee\* and A. M. Olin. Dept. of Biology, Carleton College, Northfield, MN 55057.

The Mauthner (M) cells are paired reticulospinal neurons of fish and amphibians. Their firing triggers a short-latency body bend that is the earliest component of an escape behavior. We have studied the effects of M cell firing on later motoneuron activity in the isolated CNS of Xenopus laevis tadpoles at NF stages 51-58. M axons were stimulated in the spinal cord with intracellular microelectrodes, while motor activity was recorded via suction electrodes on ventral roots (VRs).

The brain and spinal cord in vitro spontaneously produce episodes of rhythmic VR activity, in which bursts of impulses occur alternately on opposite sides of the cord. Typical episodes last for several seconds, consist of approx. 5-10 cycles, and repeat at intervals of 15-30 sec. Longer episodes (20-300 cycles) have also been recorded. Cycle periods range from approx. 100 to several hundred msec; the shorter cycle periods overlap with the range of swimming periods in intact tadpoles at the same stages. We refer to these episodes as flictive swimming. Similar episodes are also generated by the isolated spinal cord. When the cord is separated into right and left halves (with the brain still attached), alternating VR activity is replaced by long barrages of spikes that occur synchronously in left and right VRs.

Direct activation of either M axon in the isolated CNS consistently elicits a large compound action potential (CAP) in ipsilateral VRs at a latency of 2-5 msec, followed within 15-40 msec by an episode of fictive swimming that resembles spontaneous episodes. The first burst in an M cell-evoked episode nearly always occurs in contralateral WRs; a brief period in which motoneurons are activated bilaterally is sometimes interspersed between the ipsilateral CAP and the contralateral burst. Stimulation of an M axon during an ongoing episode can increase the in

ACTIVITY IN THE ANTERIOR CORRELATED WITH HINDLIMB EXTENSION INITIATED BY LOCOMOTOR STIMULATION OF THE HYPOTHALAMUS OF THE ANESTHETIZED RAT. D.R. Epuru, A. Salyapongse, H.M. Sinnamon. Neuroscience. & Behavior Prog.,

Wesleyan University, Middletown, CT 06457.

To identify neurons that might mediate locomotor initiation, the anterior midbrain was mapped for responses to ipsilateral stimulation (3-4 sec trains of 30-50 uA pulses) of the perifornical area which produced bilateral hindlimb stepping by Nembutal-anesthetized rats. We varied pulse frequency to make the first hindlimb extension occur at different latencies. Type I neurons, considered the best candidates for an initiation role, had peak responses correlated in time with the onset of extension. Type II neurons had peak responses early in the train that were uncorrelated with the extension onset. Of Type I responses, the ratio of increases to decreases was 9:1; for Type II, the ratio was 2:1. To date, with more than 450 sites tested, Type I neurons (n=36) were most common in a 1-mm wide band that included the red or nucleus and the tegmentum lateral to the central gray. Type II neurons (n=30) were found throughout the anterior midbrain. Few responses of any type were found in the VTA.

DIFFERENTIAL RECOVERY OF LOCOMOTION AFTER COMPLETE HEMISECTION D. M. Basso\*, K. Ziegler, M. E. Goldberger, Dept. of Anatomy & Neurobiology. Medical College of Pennsylvania, Philadelphia, PA 19129

Cats with spinal cord hemisections sparing the dorsal columns recover segmental (bipedal) and supraspinal (overground) locomotion (McBride & Goldberger, Society for Neuroscience, 1989). We extended these studies by examining the effect of complete hemisection (dorsal column included) on recovery of these types of locomotion.

Two cats were trained to perform bipedal and overground locomotion and their spinal cords were then hemisected at T-13/L1. Five weeks of postoperative training began the day after surgery. A high speed Motion Analysis (TM) system generated pre- and postoperative hindlimb angular excursions and phase plane diagrams ipsilateral to the hemisection which were used to examine recovery of locomotion in that limb. Complete hemisection had a more deleterious effect on bipedal than on overground locomotion as noted by: 1) a longer time course of recovery; 2) persistent deficits in swing; 3) greater decomposition of ankle movement; and, 4) hypermetria in knee and ankle flexion. The results suggest that recovery of segmentallytlexion. The results suggest that recovery of segmentally-mediated locomotion is more impaired by axotomy of the ascending collaterals of dorsal root ganglion cells than is recovery of supraspinally-mediated locomotion. (Supported by NS16629 & NS24707).

A SINGLE ACTION POTENTIAL IN A RETICULOSPINAL NEURON CAN RESET THE FICTIVE SWIMMING RHYTHM IN GOLDFISH. J.R. Fetcho\*. Dept. Neurobiology and Behavior. SUNY at Stony Brook, NY 11794.

Fish can produce escape movements in the midst of swimming, indicating that the neural networks mediating escape and swimming must sometimes interact. I studied these interactions in goldfish. Fictive swimming was elicited by stimulation of the midbrain of decerebrate, paralyzed goldfish and the motor pattern was monitored by recording extracellularly from branches of ventral roots. Escape movements in fish are initiated by the firing of an identifiable reticulospinal neuron, the Mauthner cell (M-cell). An intracellular microelectrode was used to fire a single action potential in the Mauthner axon (M-axon) at different times during the swimming rhythm to activate part of the escape network in the midst of swimming. Firing the M-axon produced a burst of activity in an ipsilateral ventral root regardless of whether that root was in an active or silent phase of the swimming rhythm. The single M-axon spike sometimes reset the swimming rhythm dramatically, so that swim bursts following the M-axon spike were shifted in different trials by roughly 20 to 50 % of a cycle relative to when they would be expected to occur based upon the pre M-axon burst pattern. These results indicate that the M-axon can override the output from the swimming network and also has a very powerful influence on the central pattern generator for swimming . Supported by NIH NS26539.

In larval lamprey the brainstem and spinal cord interact to produce a novel motor output A.H. Cohen. R. Pitts. J.C. Presson\* and L. Guan. Department of Zoology, University of Maryland, College Park, MD 20742

In adult lampreys, brainstem neurons can activate the spinal pattern generator for locomotion; after locomotion begins, the brainstem neurons themselves become periodically active, apparently being driven by the bursting spinal neurons. In larval lampreys, this interaction is likely but has not yet been shown. In the larval lamprey, we tested the effect of the brainstem-spinal cord interaction, since fictive locomotion in the larval spinal cord is unstable making it likely to be sensitive to the potential positive feedback between brainstem and spinal cord.

Without the brain, the Isolated larval lamprey spinal cord, stimulated by bath applied D-glutamate, produces a sequence of motor patterns: a slow often Irregular rhythm, followed by disorganized activity lasting about 45 minutes, often ending in relatively regular rapid bursting qualitatively similar to adult fictive locomotion. With the lower brainstem present, after 30-40 minutes D-glutamate elicits a novel pattern. Rostral and caudal segments burst at different frequencies, only episodically becoming phase locked at a single stable frequency. Two hours after drug application, the segments can still be seen to display this pattern. After removing the brainstem, the spinal cord stabilizes like controls to a single fast frequency 30-45 minutes after drug application. Thus, in the larval lamprey the brainstem and spinal cord strongly interact during generation of locomotion. The brainstem is not simply maintaining the rostral segments at a faster frequency as has been suggested by others. The comparison to adult lamprey, the details of the interaction, and the possible mechanisms remain to be determined. Support by grants NIMH #MH44809 and NSF #BNS9009570 to AHC.

THE ROLE OF APAMIN SENSITIVE POTASSIUM CHANNELS IN THE LAMPREY LOCOMOTOR NETWORK. R. H. Hill, J. L. Schotland T. Matsushima and S. Grillner, Nobel Institute for Neurophysiology, Karolinska Institute, Stockholm, Sweden.

Several factors have been identified which control burst duration in the lamprey locomotor network. One important mechanism is spike frequency adaptation in network interneurons which is dependent on the slow afterhyperpolarization (sAHP) mediated by calcium dependent potassium channels ( $K_{Ca}$ ).

Apamin, which is a highly specific blocker of small conductance K<sub>Cs</sub> channels, sharply reduced the sAHP in all lamprey spinal neurons observed. This is similar to the effect of 5-HT in this and previously reported studies (Wallén et al., 1989; Matsushima and Grillner, 1992). Thus, apamin sensitive K<sub>Cs</sub> channels contribute to the sAHP and 5-HT may block, directly or indirectly, the same type of K<sub>Cs</sub> channel. Bath application of excitatory amino acids to the lamprey spinal cord can induce

Bath application of excitatory amino acids to the lamprey spinal cord can induce rhythmic bursting which alternates between left and right similar to the motor output during swimming (Wallén and Williams, 1984). Under these conditions spike frequency adaptation associated with the sAHP in interneurons is thought to have a key role in burst termination. Apamin was applied to spinal cords during fictive locomotion induced by kainate. This resulted in a clear decrease in the frequency of ventral root bursting. 5-HT application had similar results on burst frequency during fictive locomotion. During fictive locomotion induced by NMDA (150  $\mu$ M), in which other burst terminating factors also contribute, apamin reduced the average frequency of bursting, but to a lesser extent.

Thus, regulation of K<sub>Cs</sub> channels may be an important mechanism for control of the locomotor network. 5-HT is an endogenous transmitter of the lamprey spinal cord and likely exerts some of its effects on the network by this mechanism (Wallén et al., 1989; Christenson et al., 1989). Activation of GABA<sub>B</sub> receptors has been shown to reduce calcium entry and diminish the sAHP (Matsushima et al., 1992) and may represent another endogenous system utilizing a similar mechanism.

NEURAL NETWORK SIMULATION OF LOCOMOTION IN LAMPREY. J.T. Davis\* and L.E. Moore. Dept. of Physiology & Biophysics, University of Texas Medical Branch, Galveston, TX 77555-0641

Neurons of the lamprey central pattern generator have been shown (Grillner et al Ann. Rev. Neurosc. 14:169 1991) to display a periodic activity that maintains a constant phase relation to the onset of the ventral root burst. During fictive swimming some fraction of the neurons in the circuit remain subthreshold. These subthreshold membrane potentials were signal averaged over twenty or more oscillations to obtain representative waveforms of a single cycle for different excitatory amino acid (EAA) agonists. In kainate induced fictive swimming the estimated synaptic input of a neuron was correlated with the shape of its subthreshold oscillation. In NMDA or glutamate induced fictive swimming some features of the subthreshold record could not be accounted for by synaptic input. It is postulated that these features are due to membrane mechanisms induced by activation of the NMDA membrane receptor. This hypothesis was tested using simulations of kainate, glutamate, and NMDA induced fictive locomotion. Simulations were done using a modified form of the neuronal model developed by the Grillner group (Brodin et al J Neurophysiol. 66:473, 1991; Ekberg et al Biol. Cyber. 65:81, 1991). The simulations show that in kainate induced fictive swimming all of the subthreshold shape features can be attributed to the synaptic input. In contrast, in NMDA or glutamate induced fictive swimming, membrane mechanisms generate additional shape features in the subthreshold waveform. In addition to generating the waveform of subthreshold oscillations, the simula-tions also reproduce the experimentally determined dependence of the oscillation frequency on EAA concentration. Supported in part by DHHS-R01-MH45796.

Comparison of archetype of interneuron in kainate induced swimming and simulation of kainate induced swimming.

Evidence for long-distance coupling between segmental oscillators is inferred from the intrinsic variability of fictive swimming in the lamprey Ichthyomyzon unicuspis. T. Kiemel <sup>1</sup>, N. Mellen <sup>2</sup>, and A. H. Cohen <sup>3</sup> · <sup>1</sup>Mathematical Research Branch, NIDDK, NIH, Bethesda MD, 20892; <sup>2</sup> Department of Psychology, Cornell University, Ithaca NY 14853; <sup>3</sup> Department of Zoology, College Park MD 20742. Data from 16 locations along 50 segments of isolated

Data from 16 locations along 50 segments of isolated spinal cord of the lamprey lchthyornyzon unicuspis have been analyzed to infer properties of the functional anatomy of the central pattern generator (CPG) for locomotion. Our analysis suggests that long-distance connections between segmental oscillators play a role in the coordinating system. The relative phase model of the lamprey CPG (Cohen, Holmes and Rand, 1982) with noise has been used to interpret the data. This approach associates each recording location with an oscillator whose state is given by its absolute phase. Coupling between oscillators is a function of relative phase, linearized around a travelling-wave solution. Noise has been introduced into the model using independent autocorrelated stochastic processes to force the oscillators. A maximum-likelihood estimation of parameters in the model has been performed based on experimental burst onset times. The results indicate that the model requires long-distance connections in order to best account for the experimental data.

ROLE OF THE LATE AFTERHYPERPOLARIZATION IN FICTIVE SWIMMING IN THE LAMPREY. J.T. Buchanan\* and D.P. Meer. Dept. of Biology, Marquette University, Milwaukee, WI 53233. The role of the late after-spike hyperpolarization (I.AHP) in the

The role of the late after-spike hyperpolarization (l.AHP) in the firing properties of lamprey spinal neurons and in fictive swimming was tested by bath application of apamin, a selective blocker of the sk calcium-activated potassium current. Membrane potentials of identified classes of interneurons and motoneurons were recorded intracellularly in the isolated spinal cord. Apamin (0.2 to 1µM) reversibly reduced the l.AHP of all four neuronal classes tested [74±19% (±SD) reduction, n=24] without affecting resting potential or other aspects of the action potential. The interneurons tested were two classes involved in fictive swimming (lateral interneurons and CC interneurons) and a class of intraspinal stretch receptors (edge cells). The reduction of the l.AHP increased the steepness of the firing frequency vs. input current (F-I) relationship. During fictive swimming, however, apamin (1 to 10µM) had no significant effect on ventral root burst rate, burst intensity, or intersegmental phase lag (n=7).

It was also shown in the present experiments that motoneurons and

It was also shown in the present experiments that motoneurons and interneurons exhibit l.AHPs during fictive swimming in the absence of apamin. Intra-axonal recordings of neuronal firing during fictive swimming revealed that most cells tend to fire at frequencies below 10Hz, which is a region of the F-I curve unaffected by apamin. These results suggest that the l.AHP has little role in fictive swimming in the lamprey due to the relatively low rates of neuronal firing, and that mechanisms other than spike adaptation must account for burst termination in the lamprey swim cycle.

DOPAMINERGIC MODULATION OF FICTIVE SWIMMING IN LAMPREYS. <u>D.McPherson\* and C.Kemnitz</u>. Dept. of Biology, Marquette Univ., Milwaukee, WI 53233.

We have used an in vitro preparation of the spinal cord to test we have used an *in vitro* preparation of the spinal cord to test dopamine (DA) as a potential modulator of the central pattern generator for swimming in lampreys. The motor program for swimming was elicited by bath application of D-glutamate or N-methyl-DL-aspartate (0.2-0.5 mM), and activity was recorded extracellularly from spinal ventral roots through suction electrodes. Bath application of dopamine at low concentration (0.1-1 µM) consistently increased the swim cycle rate by about 20%, while 10 µM dopamine produced cycle rates similar to control values. Higher concentrations of dopamine (31.6-1000 µM) caused dose-dependent reduction of cycle rate, with about 50% reduction at 31.6 µM. These data suggest that dopamine has two distinct modulatory effects, accelerating swimming at low concentration, and slowing it at higher concentrations. The general features of fictive swimming, such as left-right alternation, rostral-caudal phase lag, and the ratio of burst left-right alternation, rostral-caudal phase lag, and the ratio of burst duration to cycle period, were relatively unaffected by low to moderate [DA] (0.1-31.6  $\mu$ M). In rectified ventral root recordings, the mean amplitude of bursts during swimming was slightly depressed by low [DA] (0.1-10  $\mu$ M), and significantly augmented by higher concentrations (31.6-100  $\mu$ M). Immunocytochemistry with antibodies to DA indicates it is present in cells and processes in the spinal cord, providing a source for dopaminergic modulation in vivo.

STRIATO-THALAMO-CORTICAL CIRCUIT FOR HALOPERIDOL ACTION IN VIVO IN HUMAN BRAIN: PET/FDG ANALYSIS., C.A. Tammingat H.H. Holcomb, E. Gastineau, D. Medoff. University of Maryland, MPRC, P.O. Box 21247, Baltimore, MD 21228

Haloperidol (HAL) is a potent antipsychotic drug, whose action is

mediated by D2 receptor blockade. HAL actions at the postsynaptic DA receptor produce its functional effect, first on that postsynaptic neuron, then on subsequent projection neurons, eventually influencing entire neuronal circuits. PET with FDG is a technique which can reflect regional functional changes in neuronal activity produced by a drug at all sites where they occur, integrated over the incorporation period of the sites where they occur, integrated over the interpolation period of ligand. Eleven schizophrenic subjects were studied on (4 weeks) and off (4 weeks) HAL using PET/FDG. Images were volumetrically (4 weeks) HAL using PET/FDG. Images were volumetrically reconstructed and resampled along the same planes; then analyzed using traditional ROIs; scaled data from the two scans were compared in the data analysis. Results show a significant HAL-induced increase in the regional cerebral metabolism of glucose (rCMRglu) in caudate and putamen; then in the striatal projection area, the globus pallidus, rCMRglu was decreased by drug. In thalamus, the next projection area, HAL increased rCMRglu. And in two cortical areas, the frontal cortex and cingulate, the drug decreased rCMRglu. These data are not readily understandable by postulating a primary HAL effect in each of these sites. Rather, we suggest that HAL has its primary and direct functional effect in the striatum, ie caudate and putamen. Thereafter, HAL action is mediated through basal ganglia and thalamus, to neocortex in a predictable fashion, through the described cortical-subcortical circuits (TINS 13:266, 1990). These data suggest the potency of these striato-thalamo-cortical pathways, in information transmission to cortex.

SYNCHRONIZED EARLY-INSPIRATORY PHRENIC UNIT ACTIVITIES IN DECEREBRATE CATS. W.-X. Huang\*, M.I. Cohen, R. Barnhardt and C.N. Christakos, Dept. of Physiol., Albert Einstein Col. Med., Bronx NY 10461. Synchronization of phrenic (PHR) nerve and unit activities was studied in 8

decerebrate, paralyzed, and vagotomized cats, by simultaneously recording discharges of two or three PHR single fibers (n = 151) and of the left and right PHR nerves. Short-time-scale (2-ms bins) cycle-triggered histograms (CTH) always showed a distinct burst in whole PHR activity at the onset of neural inspiration (I). This burst arose mainly from the summation of the first spikes of early-I (onset delay < 80 ms) PHR units (80/151). 60 of these 80 units of early-I (onset delay < 80 ms) PHR units (80/151). 60 of these 80 units showed an oscillation in the CTH that was locked to the onset of I. In 40 of a total of 71 pairs of early-I PHR units, each unit showed such an early-I oscillation. For spectral analyses, the I phase was divided into two halves. 1) First half of I. 31/40 pairs had significant coherence peaks in the range of medium frequency oscillation (MFO) (14.4 ± 6.4 S.D. Hz, coherence value 0.17 ± 0.11 S.D.). The coherent frequency was usually close to the initial rates of the rhythmic and augmenting unit discharges. By comparison, only 15/40 pairs showed coherence in the range of high frequency oscillation (HFO) (70.4 ± 19.5 S.D. Hz). 2) Second half of I. The oscillations in the CTHs that were locked to the start of I became weaker or disappeared; and only 13/40 pairs showed significant MFO coherences, which were lower (0.08 ± 0.03 S.D.) than in the first half. In contrast, a larger proportion (24/40) of significant HFO coherences was observed than in the first half. Thus, the rhythmic firing of many early-I PHR units is locked to the start of I, resulting in significant coherences in the MFO range between unit pairs; and this transient synchrony of PHR unit spikes near the start of I can account, in part, for MFO coherences (unit-PHR and PHR-PHR) that are sometimes observed. (Christakos et al., J. Neurophysiol. 66, 674-687, 1991). (Supported by N.I.H. Grant HL-27300.)

NEUROCHEMICAL MECHANISMS FOR GENERATION AND TRANSMISSION OF LOCOMOTOR RHYTHM IN VITRO A. Lev-Tov<sup>1</sup>. I.C. Smith & B. I. Schmidt\*. Systems Neurobiology Lab, Dept. of Physiological Science, UCLA, Los Angeles, CA 90024-1527. Dept. of Anatomy, The Hebrew University Medical School, Jerusalem, Israel.

Neurochemical mechanisms involved in generation of locomotion were studied in the in vitro isolated spinal cord, or spinal cord-hindlimb preparation from 0-4 day old rats. Locomotor pattems were characterized by suction electrode recordings from homologous lumbar ventral roots, EMG recordings from hip and ankle flexor and extensor muscles, and sharp-electrode intracellular recordings from lumbar motoneurons. Locomotor patterns could be induced by bath application of NMDA; glutamate + the glutamate uptake inhibitor DHK or DHK alone; dopamine; acetylcholine + detrophonium (choline esterase inhibitor) or edrophonium alone. Although there were differences in the detailed patterns of motoneuron and muscle activation with each of the neurochemicals tested, alternating rhythmic patterns characteristic of quadruped stepping were induced in homologous ventral roots as well as in flexor and extensor muscles, in all cases. Intracellular recordings from lumbar motoneurons showed that each of the neurochemicals induced an initial tonic activity accompanied by membrane Intracellular recordings from lumbar motoneurons showed that each of the neurochemicals induced an initial tonic activity accompanied by membrane depolarization (10-15 mV) which was then transformed into rhythmic activity with large rhythmic depolarizing drive potentials (5-15 mV) imposed on the repolarized resting membrane potential. Block of NMDA and non-NMDA receptors with APV and CNQX, respectively, or activation of AP4 receptors, reduced the depolarizing rhythmic drive to subthreshold levels in a dose-dependent manner without affecting the cycle timing. Our findings indicate that multiple neurochemical mechanisms can generate an organized locomotor pattern. We suggest that activation of excitatory amino acid receptors is required for transmission of the rhythmic locomotor drive to motoneurons, but not for its generation. THREE-DIMENSIONAL IMAGING OF THE CEREBELLORUBRAL NETWORK OF TURTLE USING ANATOMICAL DATA FROM IN VITRO NEUROBIOTIN AND BIOCYTIN TRACER STUDIES. L. He\*. R. Sarrafizadeh. T. Skimina and J. Houk. Department of Physiology, Northwestern University Medical School, Chicago, Illinois 60611-3008.

Medical School, Chicago, Illinois 60611-3008.

Neurobiotin and biocytin can be used in an in vitro turtle brainstem-cerebellum preparation to characterize recurrent feedback connections thought to comprise the cerebellorubral network (Sarrafizadeh et al. this meeting). Because of the small molecular size of these tracers good retrograde cell fills together with detailed information concerning axon locations and dendrite arborization patterns may be obtained. Our goal is to three-dimensionally reconstruct the cerebellorubral interconnections by imaging serial sections from anatomical studies performed in an in vitro turtle (Chrysemys picta) brainstem-cerebellum preparation.

Images are captured by light field microscopy with a CCD camera, after which the section boundaries are manually traced and cell, axon, and dendrite positions are located. Sections are aligned using anatomical landmarks and the third dimensional coordinate is assigned to each section. Using the method of triangulation, a three dimensional model of the tissue surface is constructed. Each cell is modelled with a

dimensional model of the tissue surface is constructed. Each cell is modelled with a sphere marking its center and axon bundles and dendritic processes are recreated with curves which follow their trajectories in space. The boundaries of different nuclei are marked with polyhedrons which form a convex hull covering all labeled cells in that nucleus. Realistic three-dimensional images of the tissue are subsequently created using surface rendering techniques. These three-dimensional images may be created to reflect the rotation of the tissue in space giving the observer different perspectives

This technique may be used to reconstruct the three-dimensional structure of the different postulated components of the cerebellorubral network, namely the red nucleus, the lateral cerebellar nucleus, and a nucleus in the lateral cerebellar zone. Furthermore, reconstruction of the recurrent connections between these nuclei may be used to demonstrate global and local neuroanatomical information which would be difficult to grasp from serial sections alone.

STATE-DEPENDENT SYNCHRONIZED FAST RHYTHMS IN NEURAL NETWORKS (INSPIRATORY AND SYMPATHETIC). M.I. Cohen\*, C.N. Christakos, R. Barnhardt, W.-X. Huang and W.R. See. Dept. Physiol., Albert Einstein Col. Med., New York, NY 10461.

Fast rhythms in unit and population discharges have been observed in various neural systems, such as the inspiratory (I) and sympathetic (symp). The properties of such rhythms (amplitude, frequency, phase) may reflect network interactions, as suggested by spectral, coherence,

and crosscorrelation analyses applied to I and symp activities.

I motor nerve (e.g., phrenic) and medullary I unit discharges exhibit, in addition to the respiratory rhythm, faster rhythms in the range 50-100 Hz (high-frequency oscillations, HFO). a) There are high coherences between HFOs in different I nerves, indicating a common brain-stem origin of these rhythms. b) The great majority of medullary I neurons have HFO, which are highly coherent with I nerve HFOs. c) Different types of I neuron have different phase relations of unit to I nerve HFOs. d) HFO properties vary with time in the I phase, with respiratory afferent inputs, and with state (e.g., between respiration and fictive vomiting). These properties suggest that the system HFOs are due to interactions (possibly via excitatory and

inhibitory loops) between neurons of the inspiratory pattern generator. Symp nerve discharges also have fast rhythms, albeit on a slower time scale: spectral peaks occur in two ranges, 2-6 Hz and 9-11 Hz. There are high coherences between different symp nerve activities as well as between medullary unit and nerve activities. These rhythms also vary with time in the central respiratory cycle, as well as with state (e.g., baroreceptor activation). These features suggest that symp rhythms arise from interactions in sympathetic-generating networks. (Supported by N.I.H. Grant HL-27300.)

An Electrophysiological Topography of the Rat Corticostriatal Projection. G.E. Glynn!\* & B.K. Yamamoto<sup>2</sup>. Parke-Davis, Ann Arbor, MI 48105. Pept. of Psych. Case Western Res. Univ. Clev., OH 44106.

Anterograde degeneration, amino acid transport and striatal biochemical changes due to cortical ablations indicate that a corticostriatal topography exists. The aim of this study is to examine the physiological significance of these projections using quantitative electrophysiological techniques. Bipolar stimulating electrodes delivering a biphasic pulse ( 800-1000  $\mu$ A, 0.2 msec ) were implanted in the frontal, motor, hindlimb, auditory, visual, occipital and somatosensory areas of the rat cortex. Multiple unit activity was measured in 7 dorsal and 7 ventral areas of the striatum for a period of 25 msec prior to and after the delivery of a stimulus to a cortical site. Stimulation of each cortical site produced a unique regional pattern of striatal activation. The degree of activation (max = 800  $\pm$  300% s.e.m.) was also stimulation site dependent. All areas except the frontal ctx produced a greater dorsal than ventral activation. A rostrocaudal topography was evident. These are the first results to show a quantitative 3 dimensional corticostriatal topography.

A NEW MULTI-CONDITIONAL STATISTICAL MEASURE FOR DETECTING SPATIO-TEMPORALLY CORRELATED FIRING PATTERNS IN MULTIPLE SPIKE TRAINS. D. C. Tam. Dept. of Biological Sciences, University of North Texas, Denton, TX 76203.

A multi-conditional statistical measure is developed to extract the conditions under which firing in neurons occur in recorded spike trains. It is well-known that firing of action potentials in a neuron could depend not only on a single input but also on multiple inputs to the neuron. Thus, specifically designed statistical measures are needed to correlate the specific timing relationship of the multiple inputs to a neuron with its firing probability. This multi-conditional statistic measures the firing probability of the next spike for a neuron in relation to the firing times of spikes in other spike trains. Thus, this statistic detects the spatio-temporal conditions under which a neuron will fire. The probability distribution function (p.d.f.) of firing is estimated by the statistics relative to the pre-firing interspike and cross-intervals. Once the multi-conditional probability distribution function (c.p.d.f.) is established, this statistic can be used to detect what spatio-temporal firing patterns of other neurons are related to the firing probability of a neuron. Since precise synaptic inputs to a neuron cannot be easily established experimentally in multi-unit recordings, this conditional statistic can be used to detect which of the *n* recorded neurons contribute to the combinatorical firing probability. Thus, the combinatorics can be used to isolate which sub-groups of neurons are correlated with the firing probability of a neuron and which are not. It can also provide statistical inference on the interactions in firing of spikes in the sub-group of correlated neurons that may be considered as a functional unit. The ability to detect neural functional units and their firing relationships is crucial in the interpretation of physiological functions performed by neuronal networks using multi-unit spike train analysis. USING THE ASYMPTOTIC KOLMOGOROV ENTROPY TO IDENTIFY DETERMINISTIC ORDER IN MULTI-UNIT SPIKE TRAINS. G. T. Kenyon\* and D. C. Tam Division of Neuroscience, Baylor College of Mathicine Neuron TY 7020

College of Medicine, Houston, TX 77030.

We describe a method for testing the hypothesis that, within a neural population, the sequence of firing times is deterministic (chaotic), characterized by a finite Kolmogorov entropy, K, and thus that such sequences may encode behaviorally significant information. We contrast this with the alternative hypothesis that the sequence of firing times is stochastic, characterized by an infinite K, implying that behaviorally significant information can only be encoded in the firing rate. To compute K, an ensemble of digitized firing patterns is first obtained by overlaying the multi-unit spike trains with a series of spatial-temporal grids, each aligned along a different reference spike, and denoting the occurrence of one or more events in a grid square by a 1 (0 otherwise). The spike train entropy, H, is estimated by the average over the logarithms of the occurrence frequencies of all digitized firing patterns in the ensemble. K is then given by the asymptotic value of the rate of the marginal increase in H as the grid resolution and pattern size are increased. Starting from an explicit expression for a train of uncorrelated events, we show that for any reasonably smooth stochastic process, K grows logarithmically with increased temporal resolution (for a sufficiently large, fixed pattern size). A sufficient criterion for identifying an underlying deterministic order is therefore that K asymptotes to a finite value as the temporal resolution is increased. We also consider renormalized spike trains, obtained by selecting every nth event from each reference spike and rescaling the time axis by the same factor. The renormalized spike train can be used to investigate temporal structures at longer time scales, such as burst patterns or slow oscillations. Stereotypical results are illustrated through the analysis of computer generated spike train data. A parallel algorithm for extracting the spike train entropy, which on the CM-2 exhibits near linear scaling with both ensemble size

# FAILURES OF ANTIDROMIC INVASION OF EMBRYONIC RAT DRG-SOMATA DURING HIGH FREQUENCY STIMULATION.

Chr. Lüscher\*, J. Streit and H.-R. Lüscher, Dept. of Physiology, University of Berne, Berne, Switzerland

Impulse conduction along branching axons might be an integrative instead of a simply transmittive process, since it has been shown that impedance mismatch can lead to failure of impulse propagation. In order to investigate the presence of such a process in spinal cord circuits, we have examined the reliability of antidromic invasion of action potentials from central unmyelinated axons into the somata of DRG cells in organotypic rat embryonic spinal cord cultures. Somatic membrane potentials were recorded during extracellular stimulation of the central axons of DRG cells. By localized stimulation at various sites along the axons the conduction velocity was measured to be 0.2-0.6m·s<sup>-1</sup>; the chronaxie 150µs. With stimulation at 1 Hz four possible responses were observed in different cells: action potentials (AP), complete failure and two intermediate responses indicating propagation failures at different sites along the axons. In cells with reliable conduction propagation failures could be induced by hyperpolarizing or depolarizing the cells through current injections. The reliability of conduction was increased when the extracellular Ca<sup>++</sup> concentration was lowered from 5mM to 1mM., but was decreased by Cd<sup>++</sup> (1.5mM). Failures again appeared after several stimuli at 10 Hz but never when applying paired stimuli 100ms apart. The frequency dependent propagation failures were more pronounced in high extracellular K (10mM). These findings show that the safety factor for impulse propagation in embryonic DRG axons is low.

MULTI-UNIT SPIKE DISCRIMINATION USING WAVELET TRANSFORMS. G. Zouridakis\* and D. C. Tam\*. \*Dept. of Electrical Engineering, University of Houston, Houston, TX 77204-4793, and \*Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

In multi-unit extracellular recordings, action potentials from different neurons can be identified by their characteristic waveforms recorded at each electrode. We employed wavelet transforms (WTs) to extract unique features of the spikes corresponding to individual neurons, and then used these features for spike discrimination.

In analogy to the Fourier transform, where a signal is expressed as a weighted sum of sines and cosines, the WT represents a signal by a weighted sum of basis functions, called wavelets. The basis functions are obtained by scaling and time shifting a single prototype (a spike, in our case). The WT not only provides information about the frequency content of a spike at every time instant (like the spectrogram), but also allows both the time and the frequency resolutions to vary. Thus, typical features associated with spikes from different neurons can be identified more readily in the WT domain.

Spike discrimination starts with spike detection, which is accomplished by setting criteria in the time domain (such as amplitude-threshold crossing and peak detection) or in the WT domain. Then, feature extraction is performed in the WT domain, where typical patterns are determined by computing the ratios of the weighting coefficients that correspond to individual spikes. Different patterns in the WT domain correspond to different spikes in the time domain. These "signatures" are then used to separate spikes into distinct classes that correspond to different neurons.

The performance of the method is evaluated using both simulated data and extracellular recordings from actual neurons.

and extracellular recordings from actual neurons.

WORKING MEMORY IN SMALL INHIBITORY-FEEDBACK NEURAL NETWORKS: NOISE, BISTABLE NEURONS AND CODING OF SCALAR VALUES. A.B. Kirillov, C.D. Myre' and D.J. Woodward. Biographics, Inc., and Dept. of Physiology and Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157.

We reported earlier that an inhibitory-feedback network inspired by neostriatal circuitry may exhibit bistable neuronal firing and spontaneous switching phenomenon. In the presence of excitatory noise, some neurons switch "on" and generate streams of impulses while other neurons remain quiescent. In time, the existing "on' neurons spontaneously switch "off" and other neurons switch "on". In this work we examined the nature of bistability and memory phenomenon using simple models consisting of several (2 to 7) totally interconnected neurons with symmetrical inhibitory synapses. A network with spontaneously active neurons and minimal noise settles in a specific pattern of "on" and "off" neurons, and the active neurons establish stationary phase relationships. A pattern of "on" and "off" states can be set by excitatory stimulation. The network then sustains the pattern, thus working as a memory register. Whereas the two-neuron network acts as a common flip-flop binary device, networks with several neurons can be made to store a scalar value in the form of a summed subset of neurons in "on" state. Neuroanatomy suggests that neostriatal circuitry is designed to operate in this mode. Increased noise causes switching which washes out this form of memory trace or allows expression of long term memory patterns stored as synaptic strengths. Our analysis shows that the ability of the network to exhibit memory properties depends on the complex of physiological parameters, including duration of afterhyperpolarization, strength and the time duration of inhibitory post-synaptic potentials and the temporal pattern of noise. Our hypothesis is that inhibitory-feedback networks may operate as a form of local temporary scalar memory in a motor control system. Support from the Texas Adv. Res. Prog., Biol. Humanics Found., MH44337, DA02338 and AFOSR 90-146.

PHYSIOLOGICAL PROCESSING STRATEGIES OF SINGLE NEURONS W.E. Faller\*, S. Shah and M.W. Luttges. Aerospace Engineering Sciences,

University of Colorado, Boulder, Colorado 80309-0429.

Sampling biases, for large neurons, are especially worrisome for the analysis of Sampling biases, for large neurons, are especially worrisome for the analysis of simultaneous single-unit recordings where the results are commonly assumed to infer network information processing strategies. Since a majority of the cells recorded are large, it is unclear whether the results from such analyses yield an accurate picture of the network function. To address this problem we developed a method for determining the size of each individual neuron obtained using paired-electrode sets. The technique assumed that recorded spike amplitudes decreased with the inverse of distance squared while spike angles (widths) increased linearly with distance from the cellular source to the recording electrodes. Starting with the recorded spike amplitudes and angles for each cell a numerical algorithm was iterated to estimate the true value of the amplitude and angle minus these distance effects. The resolved amplitudes were a direct, consistent estimate of the size of each recorded neuron. Using this technique simultaneous single-unit recordings from 57 neurons were analyzed. The results indicated that the ratio of small to large cells was roughly 2:1. Histologically, however, a ratio of small to large cells on the order of 10:1 would have been expected. A sampling bias for the recording of large cells was apparent. Since the technique determined the size of each individual cell, however, apparent. Since the technique determined the size of each individual cell not population studies were effected by such sampling biases. The population statistics for the small and large cell groups were calculated for the mean firing frequency, standard deviation of the firing period and both the number of functionally" inhibitory and "functionally" excitatory connections per cell. Small and large cells were shown to make different contributions to the processing of information in this network of neurons. Small cells on average showed a slightly lower mean firing rate, more than twice as many functionally inhibitory connections with other cells and fewer functionally excitatory connections.

ELECTROPHYSIOLOGY AND MORPHOLOGY OF RAT SUBICULAR NEURONS IN VITRO. A.J.R. Mason\*. University Department of Pharmacology, Oxford, OX1 3QT, UK.

Although the subiculum is an important output structure of the hippocampus, the membrane properties of its neurons have received little attention. Horizontal slices of the hippocampus and parahippocampal region were maintained at 34 °C in an interface chamber. little attention. Horizontal slices of the hippocampus and parahippocampal region were maintained at 34 °C in an interface chamber. Intracellular recordings were made with conventional, sharp micropipettes. A metal, bipolar, stimulating electrode on the slice surface was used to evoke synaptic potentials. Analysis of the data from 23 neurons gave values for resting potential of -64 +/- 6 mV (mean +/- SD), input resistance of 28 +/- 9 MΩ, and membrane time constant of 12.7 +/- 3.6 ms. Action potentials (APs) had peak amplitudes above rest of 102 +/- 7 mV, and widths at base of 1.2 +/- 0.1 ms. Nineteen of the cells responded to depolarising current pulses with an initial burst of 2-4 APs riding on a depolarising pulses of sufficient strength and duration evoked trains of single APs after the initial burst. Burst-firing was resistant to blockade of excitatory synaptic transmission with a mixture of CNQX (10 μM) and AP5 (50 μM) but was abolished by maintained depolarisation to just below firing levels, suggesting that burst-firing is an intrinsic membrane property. Stimulation of CA1 oriens/alveus or the molecular layer of the subiculum evoked a biphasic synaptic potential. The depolarising component was abolished by CNQX and AP5, leaving a hyperpolarisation. Intracellular injection of biocytin into 10 neurons revealed pyramidal morphology with spiny dendrites. Most basal dendrites projected into the white matter and most apical dendrites extended across the molecular layer to the hippocampal fissure.

INTRACELLULAR RECORDINGS FROM MEDIAL SEPTAL PACEMAKER NEURONS DURING HIPPOCAMPAL THETA RHYTHM. E. S. Brazhnik and S. E. Fox\*, SUNY Health Sci. Ctr., Dept. of Physiology, Brooklyn, NY 11203.

Medial septal bursting cells project to the hippocampus and pace the theta rhythm. Many of the septohippocampal (S-H) cells are cholinergic, others are GABAergic. Two classes of S-H rhythmically bursting neurons have been identified by their sensitivity to muscarinic antagonists (e.g. atropine). The rhythmicity of one class is abolished by atropine, the other is unaffected. This study provides evidence that the atropine-sensitive S-H neurons are cholinergic.

Rats were anesthetized with urethane (1.0 g/kg, i.v.). A 3 mm hole was made in the skull and the septum was exposed by aspiration. The cavity was filled with mineral oil and capped with wax to seal around the shaft of micropipets filled with K-acetate (Rg: 50-100 Mn). Hippocampal macroelectrodes recorded the theta rhythm.

Recordings from 24 septal cells showed resting potentials greater than 40 mV (x= 58 mV). Nine rhythmic neurons were recorded during theta. Of these, four had short action potential (AP) durations, consistent with those of noncholinergic septal cells (Markram & Segal, Brain Res. 513: 171, 1990). These neurons fired rhythmic neurons recorded during theta, AP durations were longer, as were afterhyperpolarizations. These properties are consistent with those reported for cholinergic S-H cells. Like the atropine-sensitive S-H neurons, these usually fired only 1 to 3 spikes/cycle. One of these cells was tested with scopolamine (0.5 mg/kg i.v.), whereupon its rhythmic bursting ceased. These data support the hypothesis that muscarinic antagonists abolish the rhythmicity of cholinergic S-H neurons, leaving the GABAergic S-H neurons unaffected. (Supported by NIH NS17095.)

BLOCKADE OF EXCITATION REVEALS INHIBITION IN DENTATE HILAR NEURONS IN RAT HIPPOCAMPAL SLICES. H.E. Scharfman." Neurology Research Center, Helen Hayes Hospital, West Haverstraw, NY, 10993-1195, and Departments of Pharmacology and Neurology, Columbia University, NY, NY.

To understand the relative contributions of excitation and inhibition to dentate hilar activity, hilar cells were recorded intracellularly in rat hippocampal slices and their spontaneous and evoked activity were analyzed pharmacologically. Despite evidence of GABA-immunoreactive terminals on hilar neurons, and the ability to evoke robust IPSPs in other neurons in the same slice, both spontaneous activity and evoked responses in most hilar neurons were solely excitatory. The AMPA/kainate receptor antagonist CNQX blocked spontaneous potentials and responses to perforant path stimuli of all spiny hilar neurons as well as most aspiny hilar neurons. The NMDA receptor antagonist APV had relatively little effect, even when [Mg²¹], was lowered to 0.5 mM. When combined CNQX and APV application blocked hilar and granule cell excitation, IPSPs were revealed, but only after raising stimulus intensity. These IPSPs were mono- or biphasic, and reversal potentials were near -65 and -80 mV, respectively.

These results suggest that, at least in slices, hilar cells are ordinarily excited and after excitation is blocked inhibitory influence is unmasked. The hyperpolarizing inhibition that is revealed appears to be similar in mechanism to the type of inhibition exerted on hippocampal and dentate principal cells. The neurons that may be responsible for hilar cell inhibition are the local GABAergic interneurons that have dendrites in the molecular layer, and/or the somatostatin/neuropeptide Y-immunoreactive hilar cells with axons in the molecular layer, although it is not yet proven that the latter are inhibitory.

The balance of excitation and inhibition is fundamental in allowing normal signal processing while preventing seizure activity. A possible example of inapp

signal processing while preventing seizure activity. A possible example of inappropriate emphasis on excitation appears to exist in the hilus of the rat fascia dentata, with the possible consequence of predisposing the dentate and hippocampus to epileptiform behavior.

ORIGINS OF THE HIPPOCAMPAL THETA RHYTHM: ENTORHINAL AND SEPTAL CONTRIBUTIONS. <u>S. E. Fox, J. Brankack and M. Stewart</u>, SUNY Health Sci. Ctr., Depts. of Physiology and Pharmacology, Brooklyn, NY 11203.

Single unit data from all hippocampal subfields, entorhinal cortices, and septal nuclei suggest a picture of EEG generation that accounts for the thetarelated firing throughout the hippocampal formation. Excitatory lateral ento-rhinal inputs: 1) generate much of the phasic current sinks located in str. lacunosum/moleculare of CA1 and the distal molecular layer of the dentate (accounting for the EEG negativity at the fissure), and 2) modulate granule and pyramidal cell excitability, as tested via apical synaptic activation. Excitatory medial entorhinal (MEC) inputs: 1) generate a phasic mid-molecular layer sink in the dentate (peaking on a phase nearly opposite to the LEC-generated current sinks), and 2) drive dentate granule cells, forming the first segment of the tri-synaptic pathway. Dentate neurons drive the CA3/4 pyramids, which activate CA1 pyramids, completing the tri-synaptic pathway. The absence of phasic MEC-generated current sinks in CA1 and CA3/4 indicate that thetarelated firing by pyramidal cells is not due to direct MEC afferents

Medial septal afferents entrain entorhinal and hippocampal projection cells with rhythmic excitatory (cholinergic) and inhibitory (GABAergic) inputs to interneurons. In walking rats, however, hippocampal interneuron firing is driven, in addition, by potent recurrent and feed-forward activation from projection cells. Here, rhythmic septal GABAergic inputs are most important for synchronizing interneurons (hence the atropine-resistance of the walking theta rhythm). In urethane anesthetized rats, where rhythmicity of projection cells is notably less, the rhythmic excitation via cholinergic septal afferents domin-ates interneuron firing (hence the atropine-sensitivity of the urethane theta rhythm, and the differences in hippocampal projection cell and interneuron firing phases). [Supported by NIH grants NS17095 and NS09175.]

EVIDENCE FOR SUPRAMAMMILLARY CONTROL OF THE FREQUENCY OF RETICULARLY-ELICITED HIPPOCAMPAL RHYTHMICAL SLOW-WAVE ACTIVITY (THETA). I.J. Kirk\*, B.J. Logan and N. McNaughton. Department of Psychology and the Neuroscience Research Centre, University of Otago, Dunedin, New

The present study assessed the role of ascending systems in the production of hippocampal rhythmical slow-wave activity (RSA). RSA was elicited in urethanized and freely-moving rats by high frequency (100 Hz.) stimulation in the reticular formation (RF). Procaine hydrochloride (0.5 µl., 20% w/v) was microinfused at various caudo-rostral extents between the pontine RF and the medial septum/ diagonal band (MS/DB), and its effect on the frequency and amplitude of reticularly-elicited RSA determined by spectral methods. It was found that, in the region of the medial forebrain bundle or in the MS/DB, procaine reduced the amplitude of elicited RSA but had no effect on its frequency. In the RF, up to the level of the caudal diencephalon, procaine principally reduced the frequency of elicited RSA. In a relatively restricted zone in the supramammillary (SUM) region, procaine reduced both the amplitude and frequency of reticularly-elicited RSA. These results suggest that the frequency of reticularly-elicited RSA may be encoded in the SUM, rather than in the MS/DB as has previously been suggested.

EFFECTS OF Mk-801 ON HIPPOCAMPAL REG SPIKES IN THE RAT. M. Oguri, M. Takita and Y. Sugiyama Department of Biometrics Faculty of Science, Toho University, Tokyo 253, Japan.

In the normal rat, highly conspicious spikes are superimposed on spontaneous hippocampal EEG activity during behaviors not accompanied by rhythmical slow activity such as immobility and slow wave sleep. From the point view that hippocampus contains much glutamic acid, NMDA receptor might take part in inducing hippocampal EEG spikes. The present study was undertaken to investigate the effects of MK-801, an antagonist for NMDA receptor of Glu on the spontaneous EEG spikes in the CA1 region of rat hippocampus. Bundles of guide tubing and macroelectrode wewe placed in the CA1 region of rat hippocampus, together with electrodes to record cortical EEG, nuchal EMG and eye movements. MK-801 were microinjected through Hamilton syringe with Gazel infusion pump. Microinjections and electrophysiological recordings were conductedunder the head-restrained condition. MK-801 injection suppressed distinctively the appearance of hippocampal REG spikes in awake state, while the hippocampal EEG in slow wave sleep still showed conspicious spikes. It is suggested that the effects of antagonistic function of MK-801 on NMDA receptors might be different among sleep states.

HIPPOCAMPAL-RETROHIPPOCAMPAL INTERACTIONS DURING

HIPPOCAMPAL RETROHIPPOCAMPAL INTERACTIONS DURING SHARP WAVES. J.J. Chrobak\*, R. Urloste and G. Buzsakl. Ctr.for Mol. and Behav.Neurosci. Rutgers University, Newark, NJ 07102. Hippocampal sharp waves (SPW) may play an important role in memory consolidation processes. These hippocampal field potentials reflect excitatory potentials in the CA1 dendritic region driven by CA3 input. During SPW's, there is a relatively synchronous activation of CA3, CA1 and subicular neurons. The present study examined the activity of retrohippocampal (subiculum, presubiculum, parasubiculum and entorhinal cortex) neurons during SPW's. Retrohippocampal neurons were observed that exhibited a transient increase in activity concurrently with hippocampal SPW'S (see figure).

These data indicate that the SPW-associated increase in intrahippocampal excitability is associated with a sequential or concurrent increase in the excitability of retrohippocampal neurons. The emerging picture suggests a transient increase in the activity of a network of neurons from CA3 through to the entorthinal cortex. This network event could provide the synaptic drive to potentiate synaptic connections within this temporal lobe circuitry and may represent ongoing memory consolidation processes.

ALPHA2 MODULATION OF TYPE 1 AND TYPE 2 HIPPOCAMPAL THETA IN THE FREELY MOVING RAT. R. S. Sainsbury\* and L. A. Partlo. The University of Calgary, Calgary, AB, Canada T2N 1N4.

Changes in both type 1 and type 2 theta were examined following infusions of detomidine (alpha 2 agonist) or procaine (local anaesthetic) into one of three brain sites in the freely moving rat: the hippocampus, median raphe nucleus (MRN) and the locus coeruleus (LC). Detomidine infused into the hippocampus had an attenuating effect on type 1 theta, while type 2 theta remained unchanged. Infusions of detomidine into the MRN produced no apparent effects on type 1 theta, while a release/driving of type 2 theta was noted. No changes were observed following detomidine infusions into the LC. Procaine infusions into all three brain sites had no effect on type 1 or type 2 theta. The results of this work suggest the hippocampus as being the site of action responsible for the attenuation of type 1 theta following detomidine infusions. The MRN is likely responsible for the release/driving of type 2 theta.

Axon arborization of CA3 pyramidal cells in vivo: an intracellular labeling study. X-G. Li. J. M. Tepper\*, Jandó, G. Buzsáki Center for Neuroscience, Rutgers, The State University of New Jersey, Newark, NJ 07102

Twenty CA3 pyramidal cells in 60 rats were physiologically characterized and filled with biocytin in urethane anesthetized rats. CA3 pyramidal cells arborized most extensively in CA1, followed by CA3, in line with previous observations. Bouton density was similar in both regions (mean interbouton distance: 4.89 μm). The axon length of a the analysis of the strength o contact 20,000-30,000 neurons. Two cells, with horizontal dendrites and numerous thorny excresences at the CA3c-hilus border ("mossy-like" cells) were also labeled. These neurons also projected to CA3 and CA1. All neurons had axon collaterals in the hilus and some of the terminals reached the border of the granule cell layer. Three CA3c pyramidal cells in the ventral hippocampus had extensive projections to the inner third of the dentate molecular layer (!), and to CA3 and CA1. Based on these findings, we suggest that (a) CA3 pyramidal cells have wider projections than hitherto suspected, (b) there is a bidirectional communication between hippocampal CA3 and the dentate gyrus, and (c) CA3 projections in the dorsal and ventral hippocampus are qualitatively different.

PHYSIOLOGICAL CLASSIFICATION OF HIPPOCAMPAL FEEDBACK AND FEEDFORWARD INTERNEURONS . R. Urioste\*, I. J. Chrobak, G. Buzsáki, Ctr. for Mol. and Behav. Neurosci., Rutgers University, Newark, NJ 07102.

Analysis of the network interactions between the principal and non-principal hippocampal neurons reveals important intrinsic and extrinsic control. Particularly important are the feedback (recurrent) and feed forward inhibitory influences of interneurons on pyramidal cells. Extracellular analysis of interneuron activity and its correlation with spontaneous sharp waves (SPW) is a physiological way of classifying interneuronal subtypes. We examined the possible correlations between interneuronal firing and SPW-associated population bursts of pyramidal cells in the awake rat. Three patterns of interneuron activity were observed: (i.)interneurons excited during SPWs (via recurrent CA1, or feedforward CA3, pyramidal activity); (ii.) a subclass of interneurons exhibiting relationship to the population activity; (iii.) a small subset of interneurons inhibited during SPWs (possibly by extrinsic, subcortical input or by lateral inhibition mediated by neighboring interneurons). These findings underscore the importance of normal physiological activity in the classification of hippocampal network elements participating in neuronal cooperativity.

The dentate spike: a new network pattern reflecting synchrony. A. Bragin, G. Jando, Z. Horvath interneuronal Buzsáki\* Center for Molecular Neuroscience, Rutgers University, Newark, NJ 07102

Field potentials and unit activity was recorded in the dentate area of the rat using single and multiple microelectrodes. During behavioral immobility and drowsiness large amplitude (2-4 mV), short duration (<25 ms) field spikes were observed. (2-4 mV), short duration (<25 ms) field spikes were observed. Two-dimensional potential maps of the dentate spike (DS) showed largest amplitude positivity in the hilar area with a reversal in the outer molecular layer. This depth profile was distinctly different from the simultaneously recorded potentials evoked by stimulation of the perforant path. Simultaneous recordings from left and right hili revealed that DSs occurred with zero time lag in the two hemispheres. Recordings with multielectrode arrays spanning several mm along the longitudinal axis of the hippocampus showed very high coherence of DSs. Cross-correlation histograms of unit firing in the hills showed prominent peaks during DS while firing in the hilus showed prominent peaks during DS, while simultaneously recorded CA3c pyramidal cells and putative mossy cells were inhibited. To date, we did not find a reliable relationship between DSs and hippocampal sharp waves which also occur during behavioral immobility. We hypothesize that DSs are due to synchronous discharge of hilar inhibitory interneurons. The mechanism of interneuronal synchrony has yet to be discovered.

A CURRENT SOURCE DENSITY (CSD) ANALYSIS OF STIMULUS INDUCED FIELD POTENTIALS IN RAT DENTATE GYRUS SLICES FOLLOWING ENTORHINAL LESION. R. Nitsch\*(1), H. Clusmann (2), and U. Heinemann (2), (1) Centr. of Morphology, Univ. Clinic Frankfurt, 6000 Frankfurt/M. 70, FRG and (2) Inst. of Neurophysiol., Univ. Cologne, 5000 Köln 41, FRG

Following ipsilateral entorhinal lesion sprouting of remaining afferents (eg. commissural fibers) into the hippocampal termination zones of the degenerated perforant path fibers has been reported suggesting a compensatory replacement of excitatory synaptic input. Conversely, peripheral dendrites of inhibitory interneurons retract from these zones, which might result in altered inhibition. In order to study the functional consequences of adaptive changes following lesion we analyzed field potential responses to stimulation of the inner and middle molecular layer and to stimulation of mossy fibers in the hilus. In addition we performed a current source density analysis (CSD) of the stimulus induced field potentials in slices obtained from normal and animals 55 days post lesion. Stimulation of the inner molecular layer caused large field EPSPs with small if any generation of population spikes in the granule cell layer both in normal and lesioned animals. In lesioned animals responses evoked by stimulation of the middle molecular layer cause smaller field potentials than in normal animals. The CSD analysis revealed a shift of current sinks induced by stimulation of either the inner or the middle molecular layer to a common site. Activation of mossy fibers does not reveal alterations of evoked potentials following lesion. These results suggest that the postlesional reorganisation, i.e. sprouting of remaining afferents is not effective in functionally compensating for the loss of entorhinal input.

FUNCTIONAL THREE-DIMENSIONAL DISTRIBUTION OF ENTORHINAL PROJECTIONS TO DENTATE GRANULE CELLS OF THE IN VIVO RABBIT HIPPOCAMPUS. Andrew J. Nowak\* and Theodore W. Berger, Dept. of Behavioral Neuroscience, Univ. of Pgh, Pittsburgh, PA 15260; Dept. of Biomedical Engineering and Program in Neural, Informational and Behavioral Sciences, Univ. of Southern California, Los Angeles, CA, 90089

Anatomical mapping studies have indicated that the distribution of entorhinal projections to dentate granule cells is extensive along both the septotemporal and transverse axes of the hippocampus (see review by Amaral & Witter, 1989, Neurosci, 31), in contrast to electrophysiological studies which have emphasized an organization primarily oriented with respect to the transverse axis and a restricted septotemporal distribution (Andersen, et al., 1971, Exp. Brain Res., 13). To examine the three-dimensional extent of the granule cell field excited by perforant path fibers, we stimulated the perforant path through electrodes in the angular bundle of halothane anesthetized rabbits and recorded simultaneously the resulting extracellular field potentials generated along the septotemporal and transverse axes of the dentate gyrus using multiple electrode arrays. Laminar profiles of field potentials and current source density analyses revealed widespread activation of granule cells and systematic changes in population spike latency and amplitude across both axes of the hippocampus. Additionally, results indicated the activation of two distinct subpopulations of granule cells as judged by the existence of bimodality in the distribution of population spike

To minimize stimulation of multiple subpopulations of perforant path fibers, additional experiments utilized focal stimulation of layer II and III cells in the entorhinal cortex. Present results show systematic changes in the gradient of entorhinal activation of dentate granule cells in a septal-temporal direction, as revealed by: 1) a decrease in the peak latency and an increase in peak amplitude of somatic EPSPs; and, 2) decrease in the slope of dendritic EPSPs. (Supported by MH18273 to AJN and by ONR, AFOSR, MH00343 to TWB).

NEURONAL FIRING AS DIFFERENTIABLE MANIFOLDS EMBEDDED IN NEURONAL FIRING RATE SPACE. <u>James B. Ranck Jr.</u>\* Dept of Physiology, SUNY-Brooklyn, NY 11203.

If the discharge of a single neuron is converted into a firing rate, the possible firing of a whole class of neurons can be described as an n-dimensional space, where "n" is the number of neurons in the class. In addition to anatomical and biochemical criteria, part the current definition of a neuronal class, is that the neurons fire under similar circumstances. Therefore, the actual firing of a class of neurons in not n-dimensional, but rather a smaller dimension, "m". If there is a clean relation between the firing of the neuronal class and the external world, the firing can be expressed mathematically as an m-dimensional differentiable manifold embedded in an n-dimensional firing rate space. For instance, the firing of head direction cells is a one dimensional manifold without boundary, topologically equivalent to a circle. The firing of an ideal without optimary, topinogramy equivalent to a critic. The firing of hippocampal place cell is a 2-dimensional manifold with boundary. The firing of visual and somatosensory neurons up to primary sensory cortex is a more complicated topological structure and requires a bundle structure. This approach allows us to topological structure and requires a bundle structure. Ints approach anlows us to consider many different topological structures embedded in firing rate space, some of which have behavioral consequences. There is an algorithm by which one can determine the dimension of a manifold from the firing of many neurons of a class recorded simultaneously, independent of the relation of the firing to the external world.

Under certain restricted, but fairly general conditions (which include consideration of persistence of effects) maps can be written between manifolds which express how the inputs to a class of neurons cause the firing of the output. By composing these maps the relation of the firing of a class of neurons to the outside world can be written. These composed maps show that a differentiable manifold is not only a description of the firing of a class of neurons, but also can reflect causal relations in brain. This analysis shows that the brain is a dynamical system, which can be analyzed with with this approach. (Supported by NIH NS14497.)

ANATOMICAL AND ELECTROPHYSIOLOGICAL EVIDENCE FOR ANATOMICAL AND ELECTROPHYSIOLOGICAL EVIDENCE FOR CONVERGENCE OF MONOSYNAPTIC AND DISYNAPTIC ENTORHINAL INPUT TO CA3. Theodore W. Berger\* and Mark F. Yeckel. Dept. of Biomedical Engineering, and Program in Neural, Informational, and Behavioral Science, University of Southern California. Los Angeles, CA 90089. We have demonstrated previously that stimulation of entorhinal axons results in monosynaptic excitation of dentate granule cells, and CA3 and CA1 pyramidal neurons.

In addition, CA3 and CA1 pyramidal neurons are excited at longer latencies consistent with polysynaptic activation through the trisynaptic pathway. Based on these findings what polysynapure activation intrough the insynaptic painway. Based on finese intimings we have proposed that excitatory input from the entorhinal cortex initiates a two-phase feedforward excitation of pyramidal cells, with the dentate gyrus providing feedforward excitation of CA3, and with both the dentate and CA3 providing feedforward excitation of CA1. An implicit assumption of this model is the convergence between mono- and on CAT. All implicit assumption of this model is the convergence between mono- and multisynaptic entorhinal input to any one subpopulation of pyramidal neurons. Therefore, anatomical and electrophysiological experiments were performed using New Zealand white rabbits to examine the extent to which the topography of monosynaptic entorhinal input to CA3 parallels that of disynaptic input via mossy fiber axons.

Two general strategies were attempted with both methodologies: i) afferent pathways were examined individually and the spatial distribution of monosynaptic and

reconstructed multisynaptic circuitry were compared, ii) connectivity was examined as a function of transsynaptic transport or propagation of activity, and compared to monosynaptic innervation. Anatomical experiments utilized WGA-HRP with enhanced sensitivity for the detection of transsynaptic transport. Electrophysiological characterization included analysis of the latencies for evoked responses, laminar profiles, and pharmacological manipulation of cellular responsivity. In general, the results of these experiments demonstrate a considerable overlap for mono- and disynaptic input to CA3 from the entorhinal cortex; however, differences in topographies for the direct and indirect pathways to CA3 also indicate that the extent of convergence varies as a function of the septotemporal axis and CA3 subfield (CA3a-c). These findings indicate that the number of cells receiving convergent input will be influenced by the degree of synchronous discharge among granule cells

FUNCTIONAL EVIDENCE FOR GREATER GABAA RECEPTOR-

FUNCTIONAL EVIDENCE FOR GREATER GABA, RECEPTOR-MEDIATED INHIBITION IN VENTRAL VERSUS DORSAL in vitro HIPPOCAMPAL DENTATE GYRUS. Choi Choi\* and Theodore W, Berger, Dept. of Behavioral Neuroscience, Univ. of Pittsburgh, Pgh., PA 15260, and Dept. of Biomedical Engineering, and Program in Neural, Informational, and Behavioral Sciences, Univ. of Southern California, Los Angeles, CA 90089.

Interneurons within the hippocampal dentate gyrus containing y-aminobutyric acid (GABA) provide feedforward and feedback inhibition of dentate granule cells. The time course of this inhibition overlaps with the time course of processes which facilitate granule cell responses to perforant path input. In the in vitro slice, facilitative processes predominate. Previously, we evaluated the interaction of inhibitory and facilitative effects using nonlinear systems analysis.

Slices of 600 µm thickness were cut transverse to the longitudinal axis of the hippocampus from the dorsal and ventral thirds of the hippocampus. The perforant path projection to dentate granule cells was stimulated with a train of electrical impulses having randomly determined interimpulse intervals. The relationship between the interimpulse intervals and amplitudes of the evoked population spikes were expressed as the kernels of an orthogonalized functional power series. The first order kernel represents the average population spike amplitude to all impulses in the train. The second order kernel represents the facilitation and suppression of the population spike amplitude due to any preceding impulse with interval delta (A).

population spike amplitude due to any preceding impulse with interval delta  $(\Delta)$ . In the previous study, we found that second order kernels for dorsal slices showed a larger facilitation at short  $\Delta$  values than those from ventral slices. In the present study, we used identical experimental and analytical procedures to test the hypothesis study, we used identical experimental and analytical procedures to test the hypothesis that dorsal slices have less inhibitory input on the granule cells. We compared the second order kernels of both dorsal and ventral slices with and without 10 µM bicuculline in the bathing media. The responses from ventral slices showed a greater change in second order kernel facilitation after the addition of bicuculline than responses from dorsal slices. This result suggests that greater GABAergic feedforward and/or feedback inhibition exists in the ventral dentate gyrus. Supported by ONR, AFOSR, MH45156, and MH00343.

STIMULATION OF THE CONTRALATERAL DENTATE DISINHIBITS PERFORANT PATH INPUT TO HIPPOCAMPAL GRANULE CELLS T.A. Blanpied\* and T. W. Berger Dept. Behav. Neuroscience, Univ. Pittsburgh, Pgh. PA 15260, and Dept. of Biomedical Engineering and Program in Neural, Informational, and Behavioral Sciences, Univ. Southern California, Los Angeles, CA 90089

Stimulation of the glutamatergic perforant path (PP) input to the dentate gyrus initiates EPSPs in granule cells which are truncated by IPSPs resulting from feedforward and/or feedback excitation of local GABAergic interneurons. GABA released after a stimulus can serve to reduce subsequent inhibition of granule cells by acting on terminal autoreceptors. Because stimulation of the contralateral dentate gyrus also excites ipsilateral dentate GABAergic neurons, we have investigated whether this separate, commissural input disinhibits granule cell responses to PP activation.

Using rabbits anesthetized with halothane, the PP was stimulated with paired suprathreshold impulses (20 ms interval) which inhibited a population spike response to the second stimulus. Preceding contralateral stimulation affected the first and second responses over separate contralateral-PP interval ranges. The first population spike was greatly inhibited with intervals of 5–40 ms, but was facilitated with intervals of 50–500 ms. The second population spike was facilitated with intervals of 5–40 ms (i.e. paired pulse inhibition was eliminated) and also could be facilitated with an interval of 200, but not 75 or 400 ms. Next, short bursts of stimulation subthreshold for the induction of LTP were applied to the PP either alone or preceded by 200 ms by contralateral stimulation (1–30 impulses, 1–10 Hz). No LTP was induced. However, longer trains of contralateral stimulation facilitated the induction of LTP. Thus, these experiments demonstrate functional interactions of the GABAergic systems activated by PP and contralateral stimulation. Possible mechanisms underlying this disinhibition include activation of presynaptic GABA<sub>B</sub> receptors or reduction of the driving force on PP stimulus-evoked GABA<sub>A</sub> inhibition. (Supported by an NSF Predoctoral Fellowship to TAB, and by ONR, AFOSR, MH45156, and MH00343)

STIMULATION OF PREFRONTAL CORTEX FACILITATES CA1 AND DENTATE POPULATION SPIKES BUT NOT EPSPS. N. Coniglio, B.Y. Yang, T.W. Berger and D.J. Weisz.\* Departments of Behavioral Neuroscience and Neurological Surgery, University of Pittsburgh, Pittsburgh, PA 15260

In electrophysiological studies the influence of prefrontal cortex on population responses elicited in the hippocampus were investigated in rabbit. In the first set of experiments stimulation was applied to many sites within the prefrontal cortex prior to the elicitation of a granule cell population spike or EPSP in the dentate gyrus. Facilitation of the spike but not EPSP was observed at stimulation sites along the medial wall of the prefrontal cortex. The same basic results were obtained when prefrontal stimulation preceded the elicitation of spikes and EPSPs in CAl pyramidal cells.

These results suggest that medial structures in the prefrontal cortex facilitate dentate granule cell and CAl pyramidal cells by acting at the cell body layer.

DURATION OF LINDANE-INDUCED CHANGES IN DENTATE EVOKED RESPONSES DEPENDS ON INPUT PATH. K.-S. Dai, D.E. Woolley\*, L. Zimmer and Z.A. Hasan. Dept. of Animal Physiology, Univ. of Calif., Davis, CA 95616.

Limbic electrodes were positioned under surgical anesthesia in the rat for later study in the freely behaving state, in order to relate behavior and evoked potentials. After recovery from surgery a single dose of lindane was administered and the time course of the resulting minimal seizure activity was compared with that for changes in evoked potentials recorded in the dentate gyrus (DG). Seizure activity peaked between 45-120 min. Amplitude of the dentate population spike (PS) evoked by stimulation of the medial-dorsal perforant path (DPP) was increased prior to onset of seizures, was maximally increased at 1 h, was still increased at 4-6 h, but was within normal limits by 8 h. PS amplitude was increased in the absence of a change in the initial slope of the population slow wave (SW), as if EPSP-spike (E-S) coupling was enhanced, perhaps because of a reduction in feedforward inhibition. Amplitudes of the first and second SWs evoked in the DG by paired-pulse stimulation (48 ms interstimulus interval) of the prepyriform cortex (PPC) were also increased before seizures appeared and were near maximal values by 1 h; thereafter, however, amplitudes, especially of the second SW, remained high with only a slight decline during the 48 h of the study. The long-lasting increase in amplitude of the PPC-evoked DG response after administration of lindane appears to represent a form of LTP and contrasts with the relatively rapid return to normal of the DPP-evoked dentate PS amplitude.

FIMBRIAL INPUT TO HIPPOCAMPAL CA3 PYRAMIDAL CELLS STUDIED USING A COMBINED ANATOMICAL AND ELECTROPHYSIOLOGICAL APPROACH. D.A. Henze\*, W.E. Cameron & G. Barrionuevo. Depts of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, Pittsburgh, PA 15260

It has been previously shown that the induction of LTP at the mossy fiber/CA3 cell synapse is associated with LTP of fimbrial inputs converging onto the same CA3 pyramidal cell (Bradler & Barrionuevo, 1989, 1990). However, the anatomical and electrotonical location of fimbrial synapses onto CA3 cells has not been well characterized. This study examined the anatomical and electrotonic locations of these synapses in transverse slices (300-400  $\mu$ m) prepared from rat hippocampus. Intracellular recordings from CA3 pyramidal cells were obtained using neurobiotin-filled micropipettes. Neurobiotin was iontophoresed into the cell after measuring input resistance, time constant, and rise time and decay time of fimbrial EPSPs. A double-barreled pipette was used to deposit a small quantity of biocytin into the fimbrial stimulus site. Labeled cells and fimbrial fibers (and their synaptic swellings) were reconstructed in three dimensions using the Eutectic Neuron Tracing System. The electrotonic length of the dendrites for each cell was calculated from geometry and specific membrane resistance. The locations of individual fimbrial synaptic swellings in the s. oriens were determined relative to the average electrotonic distance from the bottom of the CA3 cell body layer. Results showed that the CA3 cell basilar dendrites reach their peak branching complexity at a distance of 80 to 100 um from the soma. This anatomical distance corresponds to an electrotonic distance of 0.1 to 0.2 length-constants. This region of the s. oriens exhibiting the greatest pyramidal cell dendritic surface area is coextensive with the region of highest number of fimbrial fiber synaptic swellings. PHYSIOLOGICAL EFFECTS OF PULSED, FOCUSED ULTRASOUND ON THE RAT HIPPOCAMPAL SLICE. <u>C.Georgiades</u>, <u>P.C.Rinaldi\*</u>, <u>J.P.Jones</u>, <u>L.Price and F.Reines</u>. Departments of Neurosurgery, Radiological Sciences and Physics, University of California, Irvine, CA 92717.

Pulses of focused ultrasound have been found to cause physiological changes in mammalian Peripheral and Central Nervous Systems (CNS). Specifically in single nerve as well as population responses, ultrasound was found to cause a change in the magnitude of the evoked response and a reduction in the stimulus-response delay. In this study the rat hippocampal slice was employed to study the effects of pulsed, focused ultrasound on the mammalian CNS. The magnitude of evoked field potentials as well as response latency were studied. Emphasis was placed on eliciting a reversible enhancement or reduction in the response magnitude, toward a goal of using pulses of focused ultrasound to stimulate or inhibit mammalian CNS cells in a non-invasive manner. In 500 micron slices, classical field potentials were recorded during ultrasound irradiation and compared to control responses. Pulsed, focused ultrasound caused a 30-80% reduction in the antidromic cell population spike and a 20-60% reduction in the orthodromic cell population spike. Complete recovery was noted for most cases with partial recovery for the remainder. Enhancement was also observed in a number of experiments, however reliable reproduction of these results has not yet been achieved.

Two previous studies from our group utilizing different ultrasonic transducers noted the following: first, a 10-25% reduction with complete recovery and second, a more significant reduction with only partial recovery. In conclusion, ultrasound has the ability to significantly alter the physiology of mammalian CNS cells in a reversible manner. Furthermore, the reversibility and direction of response magnitude change show a dependency on the parameters of ultrasound, such as center frequency, pulse rate and power.

INVAGINATION OF PYRAMIDAL CELL DENDRITES BY AXONS AND OTHER DENDRITES IN THE ADULT HIPPOCAMPAL CA1 REGION. N. L Desmond' and C. A. Scott. Dept. of Neurosurgery, Univ. of Virginia, Charlottesville, VA 22908.

Serial section 3-D reconstruction of normal adult hippocampal CA1 s. moleculare has revealed nonsynaptic invaginations of pyramidal cell dendrites by protrusions from dendrites and unmyelinated axons. These dendritic and axonal protrusions are completely engulfed by the invaginating dendrite. Two normal adult rats were perfused with a mixed aldehyde fixative, and hippocampal sections were prepared conventionally for electron microscopy. Serial thin sections (silver to gray) of CA1's, moleculare were photographed. Whorled membranes and clustered vacuoles were occasionally identified in dendrites and were reliably associated with a protruding axonal or dendritic finger in adjacent sections. These fingers were thin (ca. 50-100 nm) and were in clear continuity with the parent axon or dendrite on only 1 or 2 serial sections. The protruding fingers were, however, quite long (ca. 1  $\mu$ m). In the case of protruding unmyelinated axons, the axon sometimes also formed a normal appearing synapse on the engulfing dendrite. The protruding dendritic fingers appeared to contain actin and were often associated with ribosomes, endoplasmic reticulum, spine apparatus, and/or mitochondria. Interestingly, pairs or triads of dendrites protruded reciprocally into one another. The functional significance of these structures is unknown. Interesting possibilities include growth of distal pyramidal cell dendrites in the mature hippocampus and nonsynaptic communication between a pair of dendrites or an axon and a dendrite.

# 142.3

THE DENTATE AREA OF THE DOMESTIC PIG. I.E. Holm\*. Inst. of Neurobiology, Univ. of Aarhus, DK-8000 Aarhus C, Denmark.

Supported by NIH NS26645 to NLD and NS15488 to W. B Levy

The hippocampal region of rodent brains is widely used as experimental model in studies of ischaemic brain damage and temporal lobe epilepsy. In order to enhance the clinical relevance of such studies, we are currently attempting to establish an experimental model involving the domestic pig. Since no comprehensive description of the pig hippocampus was available we have studied the Timm staining pattern, the distribution of somatostatin-(SS-li), neuropeptide Y- (NPY-li), cholecystokinin- (CCK-li), met-enkephalin-(ENK-li), and substance P- (SP-li) -like immunoreactivity. The present report deals with the dentate area which was seen to be relatively large in comparison with other species and possess a complex cytoarchitecture with a clear lamination of the dentate hilus. This lamination was reflected in the Timm staining pattern by a particularly intense staining of the superficial part of the hilus. NPY and CCK-li cell bodies were present in the deepest part of the granule cell layer and in the hilus, whereas SS-li cell bodies were only seen in the hilus. SS and NPY-li fibers were present in large numbers forming particularly dense fiber plexus in the molecular layer and in the superficial part of the hilus. SS, NPY, and CCK-li puncta were present in the molecular layer. Except for a few SP-li cell bodies in the hilus, ENK and SP-li cell bodies were very faintly stained and were rarely encountered. ENK-li puncta were present in large numbers forming an intensely stained layer in the inner third of the molecular layer, but were otherwise absent. SP-li puncta were present in abundant numbers in the superficial part of the hilus surrounding the hilar neurons. Considerable septotemporal variation was observed for all neuropeptides. The distribution of SS, NPY and CCK-li in the pig hippocampus largely resembles that of other mammals, whereas the distribution of ENK and SP-li differs markedly from that observed in other species

# 142.5

RECIPROCAL CONNECTIONS BETWEEN THE SUBICULULM, FIELD CA1 AND THE ENTORHINAL CORTEX IN THE RAT Nobuaki Tamamaki\* and Yoshiaki Nojyo, Dept. of Anatomy, Fukui Medical School, Fukui 910-11 Japan In the formation of short term memory and its conversion into long term memory, the entorhinal cortex relays information from the neocortex to the hippocampus and from the hippocampus to the neocortex. In order to obtain a perspective on the communication, fluorescent tracer, Dil was applied into the entorhinal cortex closest to the rhinal sulcus, and labeled neuronal elements were investigated in the dorsal hippocampus. Dil showed the same anterograde labeling pattern revealed by other tracers in the dorsal hippocampus. When the injection of Dil involved deep layers of the entorhinal cortex, the anterograde labeling of the subicular neurons and the CA1 neurons. Distribution of labeled cells completely correspond to the distribution of labeled fibers. The labeled cells might receive input from the labeled fibers in the str. lacnosum-moleculare or in the molecular layer. I conclude that the output from a point of the entorhinal cortex to the subiculum and field CA1 converges on the subiculum and then returns to the same cortical column of the entorhinal cortex.

#### 142.2

SPINY HILAR NEURONS OF THE RAT IN VIVO. <u>I. Soltesz\* and M. Deschênes.</u> Centre de Recherche en Neurobiologie, Université Laval, Quebec, Canada.

The importance of the hilus in regulating the input-output operations of the hippocampus both in health and excitotoxic diseases has been recognized, and correlated *in vitro* studies provided important information about the physiological features of hilar neurons. However, we need to learn more about the *in vivo* characteristics of these cells.

Intracellular recordings were obtained from six spiny hilar neurons in the anaesthetized rat using electrodes filled with a K-salt and biocytin. One multipolar cell, which has been reconstructed, was located 5.2 mm posterior from the bregma (P=5.2). Its membrane characteristics, as well as the high level of spontaneous activities mainly consisting of EPSPs, were similar to those reported for mossy cells by Scharfman et al. The high background activity resulted in some degree of jitter in the intracellular membrane potential's phase relation to the EEG theta rhythm. The cell had giant spines on its proximal dendrites and simple spines on its distal dentrites. One dendrite entered the molecular layer and ended in its outer region. Some axon collaterals displayed boutons in the hilus, others entered the granule cell layer and within 200 µm of the soma 3 main branches could be seen studded with boutons in the inner one third of the molecular layer, running parallel with the granule cell layer. Axons in the molecular layer were present up to P=6.2 towards the temporal pole and to P=3.8 towards the septal pole of the hippocampus. It is suggested that spiny hilar neurons might influence a number of other cells both in the same hippocampal 'lamella' (Andersen et al, '71) and considerable distances away in the septotemporal axis (Amaral & Witter, 1989).

### 142.4

PERFORANT PATHWAY PROJECTIONS TO THE AMMONS HORN AND THE SUBICULUM IN THE RAT. AN ELECTRON MICROSCO-PICAL PHA-L STUDY. M.P. Witter\*, B. Jorritsma Byham and F.G. Wouterlood. Department of Anatomy & Embryology, Vrije Universiteit, Amsterdam, The Netherlands.

Light microscopical studies have provided evidence that the perforant pathway (PP) distributes to all subfields of the hippocampal formation. Electron microscopical (EM) analysis has shown that PP fibers make synaptic contacts in the dentate gyrus (DG) and CA3, but failed to find such evidence in CA1. The PP projection to the subiculum has not been studied at the EM level. Since the terminal distribution of the PP in the latter two fields shows a marked topography, the negative observations in CA1 might be the result of a sampling problem. We therefore reinvestigated these PP projections at the EM-level in female Wistar rats using the sensitive anterograde tracers Phaseolus vulgaris-leucoagglutinin and biotinylated dextran. As a reference, the projections to CA3 were also analyzed.

In all subfields, labeled fibers had rather small diameters of approximately 0.4  $\mu$ , whereas many unlabeled fibers showed diameters up to 0.8  $\mu$ . Labeled boutons were observed in the molecular layers of all hippocampal subfields and without exception, they formed asymmetrical synapses predominantly with spines. The largest diameter of labeled boutons measured approximately 0.8  $\mu$ .

The present results show that the PP indeed terminates in all hippocampal subfields and that in a previous study the terminals in CA1 simply may have been missed because of the topography of the PP. We further conclude that the projections to the DG and CA3 on the one hand and to CA1 and the subiculum on the other, although they originate from different cell layers in the EC, do not differ with respect to the gross morphology of their terminals.

# 142.6

PATTERNS OF CONNECTIVITY IN THE HIPPOCAMPAL FORMATION OF THE RAT. D.Chan\*, D.AI Dulaimi & J.O'Keefe. Dept. of Anatomy, University College London, Gower St., London WC1E 6BT, UK

The retrograde fluorescent tracers Fast Blue and rhodamine microspheres were used to map the topography of four pathways in the hippocampal formation of the rat, namely the CA3→CA1 and CA3→CA3 pathways and the direct projections from the entorhinal cortex to CA3 and CA1. Injections were delivered under electrophysiological control and the hippocampus was dissected and straightened along the septotemporal (ST) axis before sectioning.

The pattern of backfilling in CA3 following CA1 injections indicates that this projection is organized as a series of bands diagonal to the ST axis of the hippocampus. In contrast the CA3→CA3 association pathway is organized in bands parallel to the ST axis. Taking into account the organization of the mossy fibre pathway orthogonal to the ST axis, these results suggest a lattice arrangement for the intrahippocampal pathways similar to the crossing fibre arrays proposed by Tamamaki and Nojyo (1991).

Different populations of cells in the entorhinal cortex project to the CA3 and CA1 fields. While the former arises from cells across the entire extent of the entorhinal cortex and is organized topographically with respect to the ST axis, the latter arises from a delimited population of cells around the rhinal fissure and shows no obvious organization.

ULTRASTRUCTURAL RELATIONS OF SEPTAL TERMINALS WITH NEUROPEPTIDE Y-CONTAINING NEURONS IN THE DENTATE GYRUS. T.A. Milner\* and E. Veznedaroglu. Div. of Neurobiology, Dept. of Neurology and Neuroscience, Cornell Univ. Med. Coll., New York, NY 10021.

The ultrastructural relations of terminals arising from the medial septal and diagonal band nuclei (i.e., the septal complex) with neurons containing neuropeptide Y (NPY) was examined in the rat dentate gyrus. The septal complex of adult male rats was injected with 1% ibotenic acid (150 nl). Following a 2 - 4 day survival, the hippocampal formation was processed for the immunocytochemical demonstration of NPY. Electron microscopic analysis revealed that terminals with the morphological characteristics of anterograde degeneration, in particular an increase in osmiophilia, were most abundant in the hilus of the dentate gyrus. In this region, degenerated terminals (n = 105) were mostly small (0.2 - 0.4  $\mu$ m in diameter) and formed both asymmetric and symmetric synapses with small dendrites. The degenerated terminals were associated with (1) one unlabeled perikaryon or dendrite (48%); (2) one NPY-containing perikaryon or dendrite (20%); (3) the same unlabeled or NPY-labeled perikaryon or dendrite as an NPY-containing terminal (10.5%). The remaining degenerated terminals were either directly apposed without glial intervention to unlabeled and NPY-immunoreactive terminals (10.5%) or lacked associations with any neuronal processes in the plane of section analyzed (11%). These findings provide cellular substrates for direct synaptic regulation as well as presynaptic modulation of hippocampal NPY containing neurons by septal terminals. ### 142.9

CONVERGENCE OF LIMBIC INPUT TO THE CINGULATE MOTOR CORTEX IN RHESUS MONKEY. R.J. Morecraft\* and G.W. Van Hoesen.

Depts.of Anatomy and Neurology, Univ. of Iowa, Iowa City, IA. 52242 Limbic system influences on motor behavior are widespread, ranging from the initiation of action to the motivational pace of motor control. Motor abnormalities are also a common feature of psychiatric illness. Several subcortical limbic-motor entry points have been defined in recent years but cortical entry points are understood poorly, despite the fact that a part of the limbic lobe, the cingulate motor cortex, contributes axons to the corticospinal pathway. Using fluorescent tracers in monkeys, we investigated the limbic input to area 24c and adjacent area 23c. We summarize here several intrinsic limbic sources that have as a target the cingulate motor cortex. Cortical input to both areas 24c and 23c arise from cingulate areas 24a, 24b, 23a and 23b, retrosplenial cortex and temporal areas 35, TF, TH and TPO. Areas 24c and 23c were also interconnected strongly. The dysgranular part of orbitofrontal cortex and insula project primarily to area 24c while the granular part of orbitofrontal cortex and insula project primarily to area 23c. Cortical areas 25 (the anterior cingulate gyrus), 28 (the entorhinal cortex) and 38 (the temporopolar cortex) project only to area 24c. Subcortical telencephalic afferents to areas 24c and 23c originate from the claustrum, nucleus basalis and lateral basal nucleus of the amygdala. In addition, a few neurons in the cortical, accessory basal and medial basal nuclei of the amygdala project to area 24c. Since our observations indicate that a variety of telencephalic limbic structures project to areas 24c and 23c, and it is known that areas 24c and 23c project to the spinal cord, red nucleus and primary and supplementary motor cortices, it seems reasonable to conclude that cortex lining the lower bank and fundus of the cingulate sulcus forms a strategic cortical entry point for limbic influence on the motor system. (Support: NS 14944)

PATHWAYS MEDIATING THE CHOLINERGIC INNERVATION OF THE RETROSPLENIAL CORTEX AS REVEALED BY ChAT IMMUNO-CYTOCHEMISTRY. Y.J. Li<sup>1</sup>, P.L. Faris<sup>2</sup>, B.K. Hartman<sup>2</sup>, and W.C. Low<sup>1,34</sup>, Departments of 'Neurosurgery, 'Psychiatry, and 'Prysiology, and 'Program in Neuroscience, University of Minnesota Medical School, Minneapolis, MN 55455

Previous studies from our laboratory using retrograde tracers provided evidence for a septal innervation of the retrosplenial cortex (RSC) via the fornix pathway. In the present study we have used choline acetyltransferase (ChAT) immunocytochemistry to demonstrate that this innervation is cholinergic in nature. We studied the pattern of cholinergic fiber innervation in the RSC of normal rats, rats with cingulum lesions, and rats with fornix lesions. In normal rats we found that the RSC exhibited two patterns of fiber orientation, one was perpendicular to the cortical surface, the other was parallel to the cortical surface. The fibers that ran perpendicular in direction originated from cholinergic interneurons found in layer IV. The fibers that ran parallel to the cortical surface formed a distinct laminar pattern with the highest density of ChAT positive fibers in layers I and IV, moderate staining in layers III and V/VI, and light staining in layer II. Cingulum lesions alone reduced the density of staining but did not alter the general laminar pattern. Fornix lesions, however, dramatically abolished all of the parallel fibers and the laminar pattern of innervation leaving a few scant perpendicularly oriented fibers. We conclude that the fimbria-fornix, in addition to the cingulum bundle, is also involved in mediating the cholinergic projection from the medial septal nucleus and the diagonal band of Broca to the RSC. (Supported by NIH RO1-NS-24464).

COLLATERAL PROJECTIONS FROM THE RAT HIPPOCAMPAL FORMATION TO THE LATERAL AND MEDIAL PREFRONTAL CORTEX.

R.W.H. Verwer\*, R.J. Meijer and J.F.M. van Uum. Netherlands Institute for Brain Research, Meibergdreef 33, 1105 AZ Amsterdam, The Netherlands. The subiculum and field CA1 of the hippocampal formation

The subiculum and field CA1 of the hippocampal formation (HF) have a direct projection to the ipsilateral medial prefrontal cortex (mPFC). Indications exist that the lateral PFC (1PFC) also receives fibers from these hippocampal areas. With respect to the functions of the PFC it is important to know the distribution of the cells of origin of these fibers and whether collateral connections exist. Rats received an injection of diamidino yellow into the mPFC and of fast blue into the 1PFC. The distribution of cells projecting to the mPFC was similar as found previously by Swanson (Brain Res., 217 (1981) 150). The cells sending axons to the 1PFC were mainly found in the pyramidal layer of CA1 and subiculum. They were located in the posterior septal part, the entire intermediate part and the anterior temporal part of HF. The numbers of cells having collateral projections and of those projecting to the 1PFC only were comparable. In the splenial and temporal HF the total number of cells projecting to 1PFC was considerably lower than that of the neurons innervating mPFC. The septal part hardly contained double labeled cells, while neurons projecting to the 1PFC were slightly more numerous than cells connecting the mPFC. The hippocampal projection to the frontal cortex may be more diverse than is generally assumed.

### 142.10

CONNECTIONS OF RETROSPLENIAL CORTEX (CINGULATE GYRUS) IN MACACA FASCICULARIS STUDIED WITH WGA-HRP.

R. Insausti\*, M.T. Herrero, A.M. Insausti and M.T. <u>Sobreviela</u>. Dept. of Anatomy, Univ. of Navarra, Pamplona, Spain.

The retrosplenial cortex (RSC, areas 29 and 30) forms the caudal extension of the cingulate cortex. Reported data relate RSC to memory, emotion and attention through connections with the frontal, temporal and parietal cortices. Some of these connections are established through more rostral portions of the cingulate cortex. We made a series of experiments to get a comprehensive view of the RSC connections in the monkey.

Five monkeys were anesthetized, the medial surface of the hemisphere exposed and 200-300 nl. of a 1% WGA-HRP solution injected with an air pressure system. 48 h later, animals were deeply anesthetized and perfused. Serial, 50  $\mu m$  sections through the brain were collected and reacted.

Preliminary analysis shows reciprocal connections with association cortices of the dorsolateral (areas 10, 46, 9) and orbital (areas 11, 12 and 13) portions of the frontal lobe, temporal lobe (dorsal bank of the superior temporal sulcus, layer V of caudal entorhinal cortex and TF), cingulate cortex (areas 32, 24, 25 and 23), posterior parietal cortex (area 7) and cortex of the rostral calcarine sulcus adjacent to area 17.

# 142.12

PROJECTIONS FROM THE ANTERODORSAL AND ANTEROVENTRAL NUCLEUS OF THE THALAMUS TO THE RETROSPLENIAL AND HIPPOCAMPAL CORTICES. T. van Groen and J.M. Wyss. Dept of Cell Biology, University of Alabama, Birmingham, AL 35294

Birmingham, AL 35294
Previous studies suggested that the anterodorsal (AD) and the anteroventral nuclei (AV) of the thalamus projected to the retrosplenial granular cortex (Rg); but, preliminary evidence from our retrograde tracing studies suggests that many AD and AV axons extended beyond Rg. In this study we used anterograde tracers to characterize the projections of AD and AV in detail. Injections into the middle part of AD reliably labeled axon terminals in Rgb, Rga, subicular, and caudal entorhinal and perirhinal cortices. In contrast, injections into AV consistently labeled terminal fields only in Rgb, Rga, and subicular cortices. Both the AD and AV projections were topographically organized, such that rostral parts of each nucleus projected to caudal parts of each cortical areas, whereas caudal parts of each nucleus projected to rostral parts of cortical areas. Further, the axons of AD and AV terminated in distinct layers in each cortical region. In Rgb and Rga, AD axons ended in layers I and III-IV, but AV axons terminated in layers Ia and IV. In postsubiculum AD terminals were in layers I, II/III, and V, whereas AV terminals were in layer I and V. In presubicular and parasubicular cortices both AD and AV terminals were predominantly distributed in the deep layers (i.e., layers V-VI); however, AV terminals were also in layer I. The AD projection to the caudal entorhinal and perirhinal cortices ended in the deep layers (i.e., layers V-VI). These results demonstrate that the cortical projections from AD and AV are very similar, but the differences in laminar organization suggest that each nucleus innervates a distinct group of dendrites in each cortical region.

DEVELOPMENT OF DENDRITIC BUNDLING IN THE RETROSPLENIAL GRANULAR CORTEX IN THE RAT. J. M. Wyss\*, M. Liumsiricharoen and T. van Groen. Department of Cell Biology, University of Alabama at Birmingham, Birmingham, AL 35294.

Apical dendrites in layer II of the retrosplenial granular cortex (Rg) of the rat bundle together tightly in near in layer Ic and Ib and then unbundle in layer Ia, where they arborize receive their primary input, i.e., the axonal terminals of the anteroventral thalamic nucleus. In the present study, the developmental time course of the bundling has been characterized in brains in which the retrograde tracer fluorogold was injected into the contralateral cortex. Both Nissl and fluorogold material suggest that the neurons reach layer II of Rg between postnatal day (P) 1 and 3. By P5 the first presumptive bundles are present, and in these bundles, 10-20 apical dendrites group together in layer Ic and Ib, but few of these dendrites reach layer Ia. Also on P5 many of the apical dendrites of the layer II neurons bifurcate in layer Ic. Between P9-P12, apical dendrites that compose the dendritic bundles begin to reach layer Ia and initially arborize in this sublayer. Around P15 these apical dendrites begin to arborize extensively in layer Ia, and the interbundle spaces become much more obvious. Finally, by P21 the dendritic bundles are morphologically mature and not structurally different from those in adult Rg. At this stage, very few, layer II apical dendrites lie outside of the dendritic bundles, almost none of the dendrites branch in layer Ib or Ic, and virtually all dendritic spines on these apical dendrites are located in layer Ia. These results suggest that the initial development of the dendritic bundles in Rg is coincident with the arrival of the anteroventral thalamic nucleus input to these dendrites, suggesting that common forces underlie the development of both.

### 142.15

MESOLIMBIC DOPAMINERGIC INNERVATION OF THE HIPPOCAMPUS IN THE RAT. C. Pacitti, E. Campana, R. Innocenzi, A. Gasbarri\*. Lab. of Human Physiology, Sch. of Med., 67100 L'Aquila, Italy.

The present study offers a description of the projections from the ventral tegmental area (VTA-A10) to the hippocampus (HPC) in the rat. In the first part of our research we used <u>Phaseolus vulgaris</u>-leucoagglutinin (PHA-L) and retrograde fluorescent tracers. Following injections of PHA-L into VTA anterogradely labeled fibers were mainly found in the ventral subiculum, adjacent CA1 field and dorsal subiculum. Few labeling was also observed in the CA3 field and dentate gyrus. The distribution of VTA neurons projecting to the HPC was also examined by injecting retrograde fluorescent tracers (Fluoro-Gold, Fast Blue and Nuclear Yellow) in several hippocampal areas. In the second part of this study we combined the retrograde neuronal tracer technique with the tyrosine hydroxylase (TH) immunocytochemistry to evaluate the percentage of dopaminergic (DA) VTA cells projecting to the HPC. We injected Fluoro Gold (FG) in several areas of either ventral or dorsal HPC (CA1, CA3, subiculum, dentate gyrus). Sections containing retrogradely FG labeled neurons were either mounted directly as controls or incubated with TH antiserum revealed with IgG-TRITC. The quantitative evaluation of retrogradely labeled and TH stained cells showed that the VTA-HPC projection was partially DA (about 15%) and partially crossed (about 10%). Our results show that the most abundant VTA-HPC projections originate from the upper and lower edges and the lower half of the VTA. The terminal fields in the HPC i.e., ventral subiculum, adjacent CA1 and dorsal subiculum, also contain the major quantitivity of DA cells and match with the hippocampal areas projecting towards the nucleus accumbens (Acb). Since Acb and its DA innervation would play an important role in the locomotor initiation and goal-directed behaviors, the input from the HF is considered to be able to influence this behavioral phase

CALCIUM-CALMODULIN-DEPENDENT PROTEIN KINASE TYPE II mRNA EXPRESSION IS ALTERED BY RECURRENT LIMBIC SEIZURES. K.D. Murray.\* § C.M. Gall. § D.L. Benson and P.J. Isackson. # § Dept. of Anatomy and Neurobiology, University of Calif., Irvine, CA 92717, ¶ Dept. Neurosci., Univ. of Virginia Sch. of Med, Charlottesville, VA 22908 and #Dept. of Biochemistry and Molecular Biology, Mayo Clinic, Jacksonville, Fla, 32224
Calcium-calmodulin-dependent protein kinase type II (CAM II israe) in a thicking for being protein kinase type II (CAM II)

Calcium-calmodulin-dependent protein kinase type II (CAM II kinase) is a ubiquitous forebrain protein which has recently been shown to be modulated by neuronal activity. Specifically, CAM II kinase mRNA is increased in visual cortex of monocularly deprived monkeys (Benson et al., 1991) and hippocampus of Alzheimer's diseased brains, both expected to have reduced levels of physiological activity. To further investigate the regulation of CAM II kinase by activity, in situ hybridization of a riboprobe complimentary to 350 bases of monkey CAM II kinase mRNA aws examined in rat forebrain following recurrent seizures. In adult rats an electrolytic lesion was placed in the dentate gyrus hilus, this triggers = 10 hrs of intermittant limbic seizures. At 12hrs following lesion placement, CAM II kinase mRNA levels were dramatically decreased in the dentate gyrus granule cells and pyramidal cells of region CA1, bilaterally, and remained below control levels as long as 30hrs postlesion. Decreased mRNA content also was detected in superficial layers of piriform cortex and neocortex. These results provide evidence for the negative regulation of CAM II kinase expression by physiological activity and reinforce the interpretation that decreases in activity underlie increased CAM II kinase expression in Alzheimer's brain. (Supported by NIHAG00538)

#### 142.1

ELECTROCHEMICAL DETECTION OF MONOAMINES IN THE HIPPOCAMPUS. <u>A.K. Wiser\* and G.M. Rose.</u> Medical Research, VAMC, and Dept of Pharmacology, UCHSC, Denver, CO.

The purpose of this study was to investigate the composition and distribution of monoaminergic signals in the hippocampus of pentobarbital anesthetized Sprague Dawley rats. Carbon fiber (35 micron diameter) electrodes were Nafion-coated to minimize the contribution of monoamine metabolites or ascorbate to the electrochemical signals. Releases were evoked by local microejection of an iso-osmotic calcium/potassium (2.5 mM/70 mM) solution or by electrical stimulation of the commissural path. Signals were detected at two different potentials, 0.25 V and 0.5 V, in an attempt to discriminate between the noradrenergic and serotoninergic contributions to the evoked signals.

Responses were obtained to both types of stimulation; those following electrical stimulation were smaller than the potassium-evoked signals. Potassium evoked responses were reproducible at intervals of 15 minutes or greater. Signals obtained at 0.5 V were consistently larger than the ones obtained at 0.25 V, indicating that the former contained both noradrenergic and serotoninergic components. Further studies using selective neurotoxins to confirm this conclusion are in progress. Only small differences in signal amplitude were found as the electrode was lowered from the stratum pyramidale to the stratum radiatum of the CA1. No obvious relationship was found between electrochemical signals and the occurrence of long term potentiation following high frequency stimulation of the commissural path.

### 142.16

NEURAL CONNECTIONS FROM HIPPOCAMPUS TO NUCLEUS ACCUMBENS TO SUBPALLIDAL AREA MAY CONTRIBUTE TO LOCOMOTOR ACTIVITY C. T. Tsai. Department of Biology, National Changhua University of Education, Changhua, Taiwan, ROC.

Neural connections of hippocampus-Nucleus Accumbens-Subpallidal area have been demonstrated by behavioral technique. Locomotor activity recorded in an automated activity cage was increased substantially by unilateral injection of carbachol, a cholinergic agonist, into the dentate gyrus of hippocampus; this increase of activity was reduced significantly after the injection of glutamate antagonist, GDEE into the ipsilateral nucleus accumbens. In the other hand, this hyperactivity elicited by the injection of carbachol was also reduced by injection of GABA into subpallidal area. In another observation, the increase of locomotor activity was re corded following the injection of dopamine into nucleus accumbens; then this increase of locomotor activity indcued by dopamine was attenuated by the injection of GABA into subpallidal area. These observations suggest that neural connections from hippocampus to nucleus accumbens to subpallidal area may contribute to locomotor activity.

# 142.18

DOSE-DEPENDENT EFFECTS OF INTRACEREBROVENTRICULAR KAINIC ACID ADMINISTRATION ON SUBCORTICAL GLUTAMATE CONCENTRATIONS. M. E. Bardgett\*, C. T. Wrona, J. W. Newcomer, J. G. Csernansky. Psychiatry Dept., Wash. Univ. Sch of Med., St. Louis, MO 63110.

Glutamate concentrations and/or monoamine turnover in the rat dorsal hippocampus, corpus striatum (CS), and nucleus accumbens (NA) were quantified one week after intracerebroventricular (ICV) administration of the excitotoxin, kainic acid (KA). Three doses of KA were employed (1.4, 3.8, and 5.2 nM) which have been shown previously to produce progressively greater levels of hippocampal cell loss. Adult male rats were sacrificed one week following bilateral ICV KA infusion, brain regions dissected, and glutamate/monoamines assayed by HPLC-EC. Exposure to the high KA dose reduced glutamate concentrations in the dorsal hippocampus. When compared to the low KA dose, the moderate dose was also found to decrease glutamate levels in the dorsal hippocampus. Glutamate levels, as well as dopamine and serotonin turnover, were not altered in the NA and CS of KA-treated animals. The results indicate that basal glutamate concentrations are altered in the dorsal hippocampus at one week post-KA infusion, while basal glutamate/monoamine levels in other subcortical brain regions remain unchanged. We are currently examining other indices of subcortical neurochemical functioning at one week following ICV KA administration and at other post-infusion time points.

INTRINSIC CONNECTIONS OF THE HIPPOCAMPAL FORMATION

INTRINSIC CONNECTIONS OF THE HIPPOCAMPAL FORMATION IN THE HUMAN BRAIN. C. Lim. J. Kordower. E. Mufson and C.B. Saper. Depts. of Pharm. & Physiol. Sci. and Neurology, Univ. of Chicago, Chicago, IL 60637 and Dept. of Neurology, Rush Medical College, Chicago, IL 60642.

The hippocampal formation plays a critical role in the consolidation of long-term memory, especially in humans. The intrinsic connections of the hippocampal formation have received intensive study in rodents, but rather less attention in monkeys, and virtually none at all in humans. We therefore have studied the intrinsic connections of the human hippocampal formation using a lipid soluble fluorescent tracer, dil and several related compounds. Either crystals or injections of 15-45 nl of a 1% solution of tracer in EtOH, DMSO or dimethylformide were placed into various hippocampal fields in formalin-fixed blocks of post-mortem human brain. Following incubation of 3-12 months at 45° C. tissue was sectioned on a freezing microtome, mounted, and coverslipped with a water-based mounting medium (Dako).

We observed several pathways that have not previously been reported in non-human material. Injections placed into the granule cell layer of the dentate gyrus labeled fibers that ran through the alveus and stratum oriens of the CA3 field, to a terminal area in the outer part of the pyramidal layer of CA2. Injections into the molecular layer of the dentate gyrus labeled fibers in the classical perforant pathway, which penetrated the subiculum/distal CA1 to innervate the superificial part of the dentate and CA fields molecular layer.

perforant pathway, which penetrated the subiculum/distal CA1 to innervate the superificial part of the dentate and CA fields molecular layer. A large contingent of fibers, however, appeared to turn anterolaterally, running through the deep stratum lacunosum of CA1 before before turning into the plane of section and joining the fibers in the superficial molecular layer. These observations suggest that the intrinsic pathways of the human hippocampal formation may differ from the classical conceptualization based on data in other species.

A MOLECULAR APPROACH TO HIPPOCAMPAL PHYLOGENY. S. Shafqat\*, A.D. Roses and J.R. Gilbert. Departments of Neurobiology and Medicine (Neurology), Duke University Medical Center, Durham, NC 27710.

In brain evolution, the hippocampal formation first appears in higher order vertebrates. In order to recognize its phylogenetic forerunners, therefore, additional markers of hippocampal identity must be developed that are independent of conventional morphology. We have are independent of conventional morphology, we have decided to approach this question by (i) isolating genetic transcripts preferentially expressed in the human hippocampus and (ii) characterizing their molecular homologs in a diverse range of species. A human hippocampal subtraction library was prepared from hippocampal and neocortical (post-central gyrus) cDNA pools using a protocol based on aqueous hybridization and biotin-avidin extraction. Subtracted cDNAs were directionally cloned into phagemid pSPORT (BRL) to yield an initial library of ~600 clones. Screening of this library with subtracted, unsubtracted and control probes has highlighted 43 clones that are putatively hippocampus-specific. Preliminary analysis of four 'best-signal' clones by Northern blot and dideoxy sequencing has revealed a hippocampus-enriched species with partial homology to the mRNA for the human dopamine D4 receptor. This and other transcripts confirmed to be overrepresented in the hippocampal formation will be used as in situ hybridization probes to identify hippocampal homologs in submammalian brains.

MORPHOLOGICAL EVIDENCE FOR LEFT-RIGHT ASYMMETRIES IN THE HUMAN HIPPOCAMPUS. Dahlia W. Zaidel\*, Margaret M. Esiri, and John M. Oxbury. Dept. of Psychology, UCLA, and Dept. of Neuropathology, Radcliffe Infirmary, Oxford.

Neuronal densities in surgically removed left or right

hippocampal tissue of temporal lobe epilepsy patients were determined in CA1, CA4, and the dentate gyrus. We examined 14 left and 13 right hippocampi. Mean counts showed no statistically significant left-right asymmetry in CAl and the dentate gyrus but did show previously unreported lower densities in the right CA4 than in the left. Another new finding is the asymmetry in regional intercorrelations: Positive (high and significant) r values among the 3 subfields were obtained only in the left hippocampus. In addition we confirmed presence of positive r value between CAl and age of onset of habitual epilepsy, on either side. With respect to the subfields studied here, the findings suggest regional interdependence within the left hippocampus and regional independence within the right

ENKEPHALINERGIC AND TYROSINE HYDROXYLASE IMMUNOREACTIVITY IN THE PRETECTAL AREA AND VENTRAL MESENCEPHALON OF CARTILAGINOUS FISHES. C.A. Meade. S.L. Stuesse\*, and W.L.R. Cruce. Neurobiology Dept., Northeastern Ohio Universities College of Med., Rootstown, OH 44272.

There are two pathways between basal ganglia and tectum by which visuomotor control may be regulated in vertebrates: via a pretectal area characterized by enkephalin positive (ENK+) cells or via the substantia nigra (SN). The pretectal pathway is present in several nonmammals including geckoids and snakes (Medina and Smeets, 1991). The SN pathway is in mammals, birds and several reptiles. The SN in mammals has two divisions: pars compacta (TH+ cells) and pars recticulata. The pars reticulata projects to the tectum. The presence of a SN or of ENK+ cells in the pretectal area may be indicative of ventral or dorsal mesencephalic pathways, respectively. The distribution of ENK+ and TH+ cells in the midbrain of cartilaginous fishes was determined using antibodies against TH or ENK. Two sharks, Squalus acanthias and Heterodontus francisci, two rays, Myliobatis californica and Raja sp., and a holocephalian, Hyrdrolagus colliei, were studied. The holocephalian is in a sister group to other cartilaginous fishes. Hydrolagus had pretectal ENK+ cells but no TH+ cells in the ventral mesencephalon. The other cartilaginous fishes had TH+ cells in the ventral mesencephalon, SN and ventral tegmental nucleus, but lacked ENK+ cells in the pretectal area. Thus Hydrolagus may have a visuomotor pathway through the dorsal mesencephalon while the other cartilaginous fishes may have a pathway through the ventral mesencephalon (NIH grant NS25895).

SOME CONNECTIONS OF THE TORUS LONGITUDINALIS IN THE

SOME CONNECTIONS OF THE TORUS LONGITUDINALIS IN THE OSTEOGLOSSOMORPH TELEOST, Xenomystus nigri. M.R. Braford, Jr.\*, A.A. Jensen and R.W. Russell. Biology Department and Neuroscience and Biopsychology Program, Oberlin College, Oberlin, OH 44074

In X. nigri (but not in all teleosts) the torus longitudinalis (TL) comprises three cell layers—from ventral to dorsal—A, B and C. HRP and/or DiI injections of the TL, tectum, valvula and corpus of the cerebellum, and specific portions of the diencephalon and telencephalon revealed different patterns of connectivity for the three revealed different patterns of connectivity for the three layers. Major sources of input to the TL arise from tegmental cell groups including nucleus Q and a nucleus we have designated as S that lies ventrolaterally adjacent to the granule cell layer of the cerebellum near the junction of the valvula and the corpus. Q and S both project heavily to layer B. Cell bodies of layers B and A are retrogradely labeled after injections in the tectum. retrogradely labeled after injections in the tectum. Cell bodies of layer C are retrogradely labeled after injections of a caudal nucleus (PGp) of the preglomular complex of the thalamus. Injections of the TL that include layer C result in anterograde labeling of terminals in PGp. Injections of PGp also result in anterograde labeling of terminals in a parvocellular group (DLa) within the lateral part of the area dorsalis of the telencephalon. Injections of DLa retrogradely label cell bodies in PGp. These data suggest that a toro-thalamo-telencephalic pathway is present in  $\underline{\mathbf{X}}$ .  $\underline{\mathbf{nigri}}$ . Support: NSF 8820858 & Oberlin College.

Acoustic Areas in the Hindbrain and Midbrain of the Goldfish. C.A. McCormick, D.V. Hernandez, M.R. Braford, Jr. Dept. Biology, Oberlin College, Oberlin, OH 44074

The projections of each inner ear endorgan and of various medullary and midbrain areas were determined in the goldfish, Carassius auratus, using horseradish per oxidase. Otic endorgan projections were largely similar to those in the related otophysan Ictalurus. In both species the medial portion of the descending octaval nuc. extends dorsally towards the cerebellar crest. In Carassius, these dorsomedial cells do not reach the ventridescending nuc. in Carassius receives afferents from the saccule and lagena and projects to a higher-order, presumably acoustic population which lies at the ventricle medial to the facial nerve tract. Both this ventricular population and the dorsomedial descending nuc. project to a superficial, medial zone of the torus semicircularis which is largest at caudal levels. The primary lateral line nucleus, nuc. medialis, projects to a toral population which lies partly ventral, and partly lateral, to the superficial medial toral zone. The anterior octaval nuc. contributes few, if any, axons to the torus semicircularis. The efferents of a previously identified superior olive (Echteler, S.E. [1984] J. Comp. Neurol. 230) may not be restricted to the presumed acoustic zone of the torus. Supported by NSF BNS 8820098, NSF BNS 880858, and the Department of Biology, Oberlin College.

CENTRAL PROJECTIONS OF THE SPLANCHNIC NERVE IN THE CATFISH, ICTALURUS PUNCTATUS. L.E. Goehler\* Dept. C&S Biology, U. of Colorado Sch. of Med., Denver, CO 80262.

Vertebrate splanchnic nerves provide both autonomic (sympathetic) and

sensory innervation of the coelomic viscera. In mammals and birds, splanchnic preganglionic neurons lie in the lateral horn or pericentral grey of the thoracic and upper lumbar spinal cord. The location of preganglionic neurons in fish has not been determined. Splanchnic sensory nerves in mammals terminate in laminae 1 and 5 of the spinal dorsal horn. These areas receive convergent visceral and somatic sensory information, an arrangement that complicates characterizing splanchnic sensory information. This experiment used the neuroanatomical tracer, dil, to determine the location of splanchnic motor neurons and the area of termination of splanchnic visceral sensory fibers in channel catfish. After dil was placed on the splanchnic nerves, labeled neurons occurred both in paired ganglia situated at the junction of the celiaco-mesenteric artery and the aorta, and in the dorsal root ganglia of the first three spinal segments. In the spinal cord, labeled neurons lie in the pericentral grey and dorsal part of the ventral horn at the level of the second through fourth spinal segments. Except for the rostral location, these neurons are situated in a similar position as preganglionic neurons in mammals and birds. The processes of labeled neurons of the dorsal root ganglia enter the spinal cord with the dorsal roots, and travel in a tract adjacent to the lateral border of the dorsal horn, to terminate in a nucleus of the ventromedial dorsal horn. This nucleus recieves few somatic sensory inputs, suggesting that in contrast to mammals, visceral and somatic sensory information in catfish are processed in separate regions of the dorsal horn.

THE LOCUS COERULEUS IN THE SUNFISH: NEURONAL NUMBER, NEURONAL MORPHOLOGY AND PROJECTION PATTERN. P.M.Ma\*Dept. of Neurobiology, Harvard Medical School, Boston MA 02115.

In fish, the locus coeruleus (LC) is a group of large noradrenergic neurons located in the brainstem isthmus. The number of neurons and their morphology were studied with immunocytochemistry using antibodies directed against tyrosine hydroxylase or dopamine-\(\theta\)-hydroxylase. In the Sunfish (Lepomis spp.), each LC contains an average of 12 neurons. The number of neurons ranges between 8 - 17 among fish, but the number between the two sides is similar for each individual. The average diameter of LC cells is a similar for each individual. The average diameter of LC cells is similar for each individual. The average diameter of LC cells is similar for each individual. The average diameter of LC cells is a similar for each individual. The average diameter of LC cells is a similar for each individual. The average diameter of LC cells is a similar for each individual. approximately 40  $\mu$ m. They form a compact cluster below the floor of the 4th ventricle. The dendritic arbors of LC neurons are oriented primarily dorsomedially and ventrolaterally. Axons from these cells appear to be braided and leave the LC ventrolaterally, bifurcate, and project both rostrally and caudally. Some of the rostral projections can be traced to the nucleus isthmus, the optic tectum, and the telencephalon. The relatively large size, consistent location, and characteristic projection pattern of LC neurons in the Sunfish provide a possible model system for electrophysiological studies of central noradrenergic function. LC neuronal number was also studied in several other species of fishes. In general, each species has a characteristic average number of neurons. The number ranges from about 24 neurons in the goldfish to about 6 neurons in the zebrafish. (Supported by NIMH grant MH-47368).

THE OCULOMOTOR SYSTEM OF A BLIND CAVE FISH, S.E. Fish\* and P. Ghosh. Department of Anatomy and Cell Biology, Marshall University School of Medicine, Huntington, WV, 25755-9350.

The Mexican Characin, Astyanax jordani, has a greatly reduced eye commensurate with evolutionary adaptation to a cave environment. The vestigial optic cyst is buried beneath the skin suspended by the usual set of six oculomotor muscles. In order to determine the extent to which the extraocular motor system is intact, the muscles were examined in paraffin sections of the cave fish's head, and CNS motor neurons projecting to the muscles were traced with HRP. For comparison, similar experiments were performed in the cave fish's direct evolutionary ancestor, the normally sighted river fish, Astyanax mexicanus.

Cave fish extraocular muscles contained slightly reduced numbers of muscle fibers. Muscles of both fish consisted of partially segregated populations of large and small fibers, identified elsewhere as white and red types, with a shift toward an increased distribution of smaller ones in the cave fish. Patterns of muscle innervation from brainstem nuclei were the same as in most other vertebrates studied. Within limitations of the HRP technique, extraocular motor neurons in the brainstem of the two fish were comparable in number and gross morphology.

The contrast between a greatly reduced eye and a relatively intact oculomotor system has implications for theories of regressive evolution in caves. These findings could be explained by several mechanisms, including the possibility that there is greater selection pressure against an eye. DISTRIBUTION OF SECONDARY OLFACTORY FIBERS IN THE CHINOOK SALMON. S. Matz\* Institute of Neuroscience, University of Oregon, Eugene, OR 97403

Juvenile salmon "imprint" to their homestream odor prior to their migration out to the ocean. During their return journey, they use this olfactory information to locate their natal stream. The aims of this study were to localize forebrain areas that receive input from the olfactory bulb in juvenile chinook salmon (Oncorhynchus stahwytscha). We injected a concentrated solution of a carbocyanin dye, Dil, unilaterally into the olfactory bulb.

The results of this study are consistent with that reported in the literature. Labeled fibers travelling in a dorsolateral tract terminated in DI and Dp and coursed through the anterior commissure to the contralateral hemisphere. Labelling was also present in Vv, Vd, Dc, Dm and in the preoptic area (POA). The presence of labeled fibers in Dm and in the POA is of particular interest. Fibers in the POA course near neurons that contain hypothalamic releasing factors. Although we have not determined synaptic contact between olfactory fibers and hypophysiotropic neurons, the possibility exists that the activity of these neurons may be modulated by olfactory input.

The existence of labeled fibers in Dm was enigmatic since olfactory fibers and hypophysiotropic neurons, the possibility exists that the activity of these neurons may be modulated by olfactory input.

The existence of labeled fibers in Dm was enigmatic since olfactory fibers and hypophysiotropic neurons are to very discrete parts of Dm, which raises the possibility of a topographical projection pattern. In order to confirm the origin of the labeled fibers in Dm, Dil was injected into this region and retrogradely labelled cell bodies were found in the olfactory bulb. This work was supported by NIH Systems Physiology Training Program (GM07257).

AN HRP STUDY OF PATHWAYS LINKING THE SUPRACHIASMATIC NUCLEUS TO BASAL FOREBRAIN NUCLEI IN HYLA CINEREA.

Allison\* and W. Wilczynski. Dept. of Psychology, University of Texas, Austin, TX. 78712.

In frogs, the preoptic area (POA), ventral hypothalamus (VH), and striatum (St) receive auditory input related to reproduction. To investigate the pathways by which the photoperiod cues involved in reproduction might reach these nuclei, HRP was iontophoretically injected into either the optic nerve (ON, n=3), POA (n=8), VH (n=10), or St (n=3) of male green treefrogs (Hyla cinerea). After a 4 day survival, the injected animals were sacrificed under anesthesia and the brains ex tracted, fixed, cut at 40 µm, mounted, and reacted with standard techniques using TMB as the chromogen. ON fibers coursed dorsally from the optic chiasm, entered the ventromedial region of the ipsilateral SCN, and terminated within the nucleus. A number of cells in the ipsilateral periventricular portion of the SCN were well labeled after POA injections. In contrast, HRP deposits in VH labeled SCN cell bodies in more dorsolateral portions of the nucleus. Finally, striatal HRP injections resulted in labeled cells in the ventrolateral corner of the rostral SCN. Thus, in treefrogs, the SCN receives a direct retinal input and separate suprachiasmatic areas may relay this retinal information to basal forebrain nuclei which also receive biologically important auditory input. (Supported by NIMH grant RO1 MH45350).

HYPOTHALAMIC AND EXTRAHYPOTHALAMIC DISTRIBUTION OF ARGININE VASOTOCIN IMMUNOREACTIVITY IN A URODELE AMPHIBIAN. C.A. Lowry\*, L.J. Miller, L.E. Muske, and F.L. Moore. Dept. of

Zoology, Oregon State University, Corvallis, OR 97331-2914.

Using immunocytochemical techniques, we determined the distribution of arginine vasotocin immunoreactive (AVTir) cell bodies and fibers in the brain of rough-skinned newts (Taricha granulosa). In males collected in March, AVTir cell bodies were found in the following hypothalamic and extrahypothalamic areas: cell bodies were found in the following hypothalamic and extrahypothalamic areas: olfactory bulb, medial pallium, caudal ventral cellular prominence, caudal striatum, amygdala pars medialis, anterior preoptic area, ventral preoptic area, magnocellular preoptic area, posterior preoptic area, ventral thalamus, ventral hypothalamus, nucleus visceralis superior, and nucleus posterior tecti. Highest densities of AVTir fibers were found in the medial pallium, lateral pallium, amygdala pars medialis, all regions of the preoptic area and hypothalamus, isthmic tegmentum, and interpeduncular nucleus. Moderate densities of AVTir fibers were found in the striatum nucleus. were found in the striatum, nucleus accumbens, amygdala pars lateralis, ventral thalamus, dorsal thalamus, habenula, tegmentum dorsale mesencephali, nucleus thatamus, dorsai thatamus, noemula, tegmentum dorsaie mesencephan, nucleus tuberalis posterioris, eminentia subccrebellaris tegmenti, nucleus visceralis superior, corpus cerebelli, tegmentum trigemini, tegmentum facialis, and nucleus motorius tegmenti. This distribution of AVTir cell bodies and fibers is more widespread than previously reported in other amphibians and is consistent with the conclusion that, in addition to its hormonal function, AVT functions as a neurotransmitter within the brain to regulate multiple behavioral responses. Supported by NSF BNS-8909173.

PHYLOGENETIC, ONTOGENETIC AND EXPERIMENTAL EVIDENCE SUGGESTING THAT INNER EAR EFFERENT CELLS ARE REROUTED FACIAL MOTONEURONS. B. Fritzsch\* and D. H. Nichols. Div, Anat., Creighton Univ., Omaha, NE 68178.

An efferent innervation exists in all vertebrate inner ears except hagfish. In lampreys and frogs cells of origin are ipsilateral to the ear and adjacent to the facial motoneurons (Fritzsch et al., Neurosci. Lett. (1989) 96:241). In other vertebrates, efferent perikarya to the inner ear are bilaterally distributed but remain located in proximity to the facial nucleus. In addition, the pathways of the axons of both facial and efferent populations show parallel variation (presence or absence of a genu). During development of chickens and mice the facial motoneurons and efferents to the ear are coextensive in the same rhombomere before they simultaneously migrate to their final positions. Thus proximity in original position, similarity of fiber pathways and timing of migration are consistent with the interpretation of efferents being redirected facial motoneurons. After transplantation of the otocyst in Xenopus into the dorsal fin a few spinal motoneurons could be backfilled from this ear. This is experimental evidence consistent with an evolutionary scenario in which formation of an otocyst may have caused motoneurons of the facial nucleus to project to the ear instead Supported by the NIH. of nearby somites.

# 143.13

GNRH IMMUNOREACTIVITY IN THE BRAIN OF THE BROWN ANOLE, ANOLIS SAGREI, L.S. Demski and D.E. Wright. Div. of Natl. Science, New College of the Univ. of S. Florida, Sarasota, FL 34243; Dept. of Anatomy and Neurobiology, Univ. of Kentucky Medical Center, Lexington, KY 40536.

Reproduction and sexual behavior have been well studied in lizards (Crews, J. Exp. Zool., 4:164-166), yet a clear understanding of the neuroendocrine systems underlying these behaviors is lacking. In particular, the neuropeptide gonadotropin-releasing hormone (GnRH) has been examined in only a limited number of reptiles, and the results have been contradictory. For this reason, we have examined GnRH systems in the lizard, Anolis sagrei using antiscra that recognize several GnRH forms. Populations of GnRH-immunoreactive (ir) neurons were observed in four different areas: the ventral periventricular meter area, septum, posterolateral anterior hypothalamus, and midbrain tegmentum. Dense ir-fibers were present in the septum, medial and dorsal cerebral cortex, ventral hypothalamus, infundibulum, tegmentum, cerebellum, dorsal and ventral medulla. Fewer ir-fibers were observed in the optic tectum and spinal cord. Irneurons and fibers were absent in the olfactory nerve, bulb, and rostroventral forebrain. Thus, our data supports the view that reptiles lack a terminal nerve, at least in relation to GnRH systems. Moreover, preoptic and midbrain GnRH neurons in the anole appear similar to those observed in other vertebrates, while the presence of GnRH neurons in the posterolateral hypothalamus may be uniquely shared only with birds (Millam et al., Soc. Neurosci. Abst. 257.12)

PRESUMPTIVE HOMOLOGUE OF THE MAMMALIAN STRIATONIGRAL CABAERGIC PATHWAY IN THE FROG BRAIN. I.Kratskin\*, J.Pierre, J.Reperant and J.P.Rio. Lab. of Neuromorphology, INSERM U-106, 75651 Paris, France; Smell and Taste Center, Univ. of Pennsylvania, Philadelphia, PA 19104, USA.

A large number of striatopallidal neurons in amniotes use gamma-aminobutyric acid (GABA) as a neurotransmitter and project to the substantia nigra. The question of the possible existence of similar GABAergic projections in an anamniote brain remains open. In the current study, double labeling with horseradish peroxidase (HRP) retrograde axonal tracing (diaminobenzidine-cobalt technique) and GABA immunohistochemistry (avidin-biotin method) and postembed ding GABA immunogold staining of the tegmentum have been used. After unilateral iontophoretic application of HRP into the rostral mesencephalic tegmentum of the frog, Rana temporaria, numerous retrogradely labelled GABA-immunoreactive (GABA-IR) cell bodies were observed in the dorsal and ventral striatum. In thin sections of the tegmentum, there were many GABA-IR myelinated fibers and axon terminals in the region of the anterodorsal, posterodorsal and superficial isthmal reticular nuclei. These axon terminals contained small pleiomorphic and large dense core synaptic vesicles and established symmetrical synaptic contacts with GABA-immunonegative dendrites. This study suggests that GABAergic striatomesencephalic projection system is an ancestral feature of the brain in terrestrial vertebra-

SEQUENCE AND ATLAS OF LHRH mRNA AND PEPTIDE IN DEVELOPING AND ADULT XENOPUS: EVIDENCE FOR CONSERVED DOMAINS IN GRRH-ASSOCIATED PEPTIDE (GAP) AND DELAYED LARVAL ONSET. W.P. Hayes\*, S. Wray, Y.P. Loh and J.F. Battey. Labs. of Dev. Neurobiology (NICHD) & Neurochemistry (NINDS), NIH, Bethesda, MD 20892.

To identify mechanisms responsible for the diversification of neuronal fate in brain, we are using neuropeptide genes as phenotypic markers and analyzing cell-cell interactions underlying their expression onset in frog embryos. In Xenopus, in situ hybridization showed that the adult-like brain patterns of POMC and TRH cells arise locally in the neural tube before brain nuclei form (Hayes and Loh, 1990, Development 110:747). Similarly, in mammals, the first GnRH cells were found to be born in the nasal placode from which they migrate into forebrain (Wray et al. 1989, PNAS 86:8132).

To ultimately determine if removal of the placode eliminates all or part of the GnRH system, the full-length GnRH cDNA was cloned for Xenopus using the RACE protocol. Expectedly, the 396-base mRNA, comprising 5'-UTR,

the RACE protocol. Expectedly, the 396-base mRNA, comprising 5'-UTR, signal peptide, prohormone and 3'-UTR, showed the amino acid sequence of

signal peptide, prohormone and 3'-UTR, showed the amino acid sequence of GnRH was identical to the mammalian decapeptide; however, unlike the GnRH cDNA reported recently for fish (Bond et al. 1991, *Mol. Endo.* 5:931), frog also showed high homology in the flanking GAP region, with conserved domains yielding up to 42% identity to mammals, but only 4% to fish. Serial section *in situ* hybridization and immunocytochemistry showed 250-350 GnRH cells in adult forebrain, with over 70% in the anterior preoptic area, and massive projections to the median eminence. Further, this gene was not expressed by midbrain cells shown by others to be immunoreactive for the fish form of LHRH, and only a single mRNA could be detected by Northern blotting. Interestingly, neither GnRH mRNA nor peptide was found until the late larval period, indicating that, unlike in mammal, this gene may be suppressed during early frog development. Studies are in progress to show suppressed during early frog development. Studies are in progress to show where and how this neuropeptide system arises in *Xenopus*.

ABNORMAL DEVELOPMENT OF GnRH NEURONAL SYSTEMS IN THE STERILE EYELESS MUTANT AXOLOTL.

T.J. Maccagnan and L.E. Muske\*. Biology Dept., Franklin &
Marshall College, Lancaster PA 17604.

A recessive allele, "eyeless" induces a sterile and eyeless phenotype in the axolotl, Ambystoma mexicanum. To evaluate whether sterility of mutants is linked to deficits in GnRH development, paired mutant and phenotypically normal siblings were sacrificed at 6 week intervals between ages 4 and 12 months and their brains processed in tandem for immunocytochemistry, using anti-mammalian GnRH 635-5 (courtesy Dr. L. Jennes) and a commercial avidin-biotin-HRP secondary antibody system. We examined GnRH immunoreactivity (ir) in: (1) the medial septum/POA, locus of GnRH cell bodies that arise from the olfactory placode and nervus terminalis (TN); (2) the hypothalamic-hypophyseal (H-H) tract, locus of GnRH axons to the median eminence and pituitary; (3) the posterior tubercle (TP) of the caudal diencephalon, locus of GnRH neurons that develop independently of the TN and placode. In 4 month old juveniles, there are GnRHir cell bodies in the septum/ POA and a few axons in the H-H tract, and no detectable differences between normals and mutants. Between 6 and 12 months, ir-GnRH increases dramatically in the H-H tract of normals, but not mutants. Normal axolotis have about twice the number of GnRHir cell bodies in the TP as mutants at all ages examined. Results support the interpretation that early stages of GnRH development, including centripetal migration of GnRH neurons from the placode, occur normally in mutants, but that maturation of GnRH neuroendocrine pathways, and normal development of the TP GnRH system, is blocked. Supported by Franklin & Marshall College Committee on Grants

DISTRIBUTION AND INNERVATION OF ELECTRO-RECEPTORS IN A SOUTH AMERICAN TYPHLONECTID CAECILIAN. R.G. Northcutt\* and K.C. Catania. Neurobiology Unit, SIO, and Dept. of Neurosci's., Sch. of Med., UCSD, La Jolla,

The morphology and distribution of lateral line organs in juvenile and adult Typhlonectes natans were determined from flat mounts of skin from the head and trunk and from scanning electron microscopy. These methods confirm earlier observations that this caecilian species lacks neuromasts but does possess approximately 200 ampullary organs on each side of the head (Fritzsch and Wake, J. Herpetol., '86). These organs are not distributed randomly but form distinct lines of receptors, which can be homologized to the supraorbital, infraorbital, oral, otic and preoperculomandibular lateral lines of other amphibians and fishes. The innervation of the ampullary organs was determined by gross dissection, Sudan Black staining of the cranial nerves in cleared specimens, and serial transverse sections of whole heads. Anterodorsal, anteroventral, and otic lateral line nerves can be recognized. The anterodorsal nerve innervates the ampullary organs of the supraorbital and infraorbital lines; the anteroventral organs of the supraorbital and intraorbital lines; the anteroventral nerve innervates the receptors of the oral and preoperculomandibular lines; and the otic lateral line nerve innervates the organs of the otic line. These results indicate that Typhlonectes does not possess postotic receptor lines or the three additional lateral line nerves that occur primitively and are seen in other caecilians, such as larval ichthyophids, and in many larval salamanders. Supported in part by NIH NS24669.

REPTILIAN POST-SYNAPTIC DORSAL COLUMN SYSTEM. M.B. Pritz\* and M.E. Stritzel. Div. Neurol. Surg., Univ. Calif. Irvine Med. Ctr., Orange, CA 92668

Both mammals and birds possess a postsynaptic dorsal column system (PSDCN) which requires at least one synapse in the spinal cord before the dorsal column nucleus (DCN) is reached. We asked whether a PSDCN system was present in reptiles, Caiman crocodilus.

Several experiments were performed to identify the PSDCN in Caiman. First, a cytoarchitectonic analysis of the spinal cord was undertaken to identify its laminar organization utilizing a schema similar to that described by Rexed. Second, terminations of dorsal root fibers in the dorsal portion of the upper cervical cord and in the brachial and lumbar enlargements were investigated by anterograde HRP and orthograde degeneration techniques.
Dorsal root fibers terminated in lamina I to VI in these Third, placements of HRP into the dorsal cord revealed a fiber path that entered the dorsal funiculus to terminate in the DCN. Fourth, HRP injections into the DCN revealed retrogradely labeled neurons in lamina IV and lamina V in the cervical, thoracic, and lumbar dorsal cord.

These data document a PSDCN system in Caiman which represents a second path whereby non-facial somatosensory information can reach the DCN. The presence of a PSDCN system in Caiman suggests that this neural circuit is phylogenetically ancient and may well be a feature common to all amniotes

DISTRIBUTION OF PEPTIDE IMMUNOREACTIVE CELL BODIES IN THE HYPOTHALAMUS OF THE PIGEON. M.L. Berk\* and S.E. Smith. Dept. of Anat. and Cell Biol., Marshall Univ. Sch. of Med., Huntington, WV 25755.

Immunocytochemical data can provide information on the organization of avian hypothalamic cell groups, and serve as a basis for comparison to mammalian cell groups. The present survey of the distributions of cholecystokinin (CCK), calcitonin-gene related peptide (CGRP), leucine-enkephalin (LENK), a-melanocyte stimulating hormone (a-MSH), neuropeptide Y (NPY), neurotensin (NT), somatostatin (SS), substance P (SP), and vasoactive intestinal peptide (VIP) immunoreactive cell bodies was undertaken to achieve this goal. A routine immunoperoxidase avidin-biotin technique was used to identify peptide containing cell bodies in colchicine treated pigeons.

The medial preoptic area has many CGRP, LENK, NT, and SP immunoreactive cells. The periventricular preoptic area has SS immunoreactive cells. The lateral preoptic area contains several NT and VIP immunoreactive cells, and some LENK and SS cells. The anterior lateral hypothalamic area has many VIP, LENK, and NPY cells. The tuberal nucleus is principally composed of numerous a-MSH, NPY, and NT containing cells, while fewer LENK, SP, VIP, CCK, and CGRP cells are located in this nucleus. The ventral part of the posterior medial hypothalamic nucleus has several o-MSH, NPY, and NT immunoreactive cells, and the posterior lateral hypothalamic nucleus contains several CCK, SP, and VIP cells. The stratum cellulare internum in the caudal hypothalamus is composed of many CGRP and VIP immunoreactive cells. The lateral mamillary nucleus contains many CCK cells. The presence of specific populations of peptide immunoreactive cells will aid in the demarcation of avian hypothalamic cell groups. Supported by NSF R11-8922106.

THE PECULIAR VASCULARIZATION OF THE NEURAL COMPLEX OF THE MESENCEPHALIC TRIGEMINAL NUCLEUS IN MAUREMYS CASPICA (TURTLE).

Paz Doel<sup>\*</sup> R., Fernández E., Gcia. Cordovill R., Fdez. Soriano J. Departamento de Biología Celular. Facultad de Biología. Universidad Complutense, Madrid. Spain.

A Neural Complex can be identified in the A Neural Complex can be identified in the mesencephalon of Mauremys caspica by using optic and electron microscopy. This Neural Complex is placed along the sagittal ventricular tectal ridge and consists of both the medial neuronal population of mesencephalic trigeminal nucleus and the mesencephalic trigeminal nucleus and the deeply modified underlying ependyma. One of the most relevant features of this deeply modified underlying ependyma. One of the most relevant features of this neurohemal formation is its peculiar vascular network provided, in some specific regions, of sinusoids and fenestrate capillaries in very close relationship with the neurons and the cerebro spinal fluid. The peculiar vascularitation of this Neural Complex is very similar to that of the circumventricular

LOCALIZATION OF SPINAL CORD MOTONEURONS INNERVATING SUB-UNITS OF THE PECTORALIS MUSCLE IN THE ALLIGATOR. J.A.

Peterson, C.K. Haun\*and I. Tan. Dept. of Anatomy & Cell
Biology, USC School of Medicine, Los Angeles, CA 90033.

Recent studies of neuromuscular organization in birds and mammals suggest that muscles consist of discrete subunits innervated by topographically distinct populations of motoneurons. This study investigates whether neuromuscular subunits/compartments occur in a lower tetrapod, Specifically, the study Alligator mississippiensis. Specifically, the study examines the organization of spinal cord motoneurons innervating discrete subunits of the pectoralis muscle, which were previously determined by histochemistry, architecture, electromyography and nerve stimulation. Motoneuron cell bodies were identified by retrograde labeling with HRP or Fluoro-Gold. The anterior and middle/posterior subunits of the muscle are innervated by neurons extending from the caudal portion of spinal nerve  $8\ \text{to}$  caudal  $9\ \text{and}$  from cranial 9 to caudal 10, respectively. This result provides further evidence that muscular compartments occur in lower vertebrates. The topographic organization of the pectoralis is similar to that described previously for birds, suggesting that it may be possible to: i) establish compartment homologies among species, and ii) frame evolutionary hypotheses in terms of selection on neuromuscular compartments.

COMPARISON OF TYROSINE HYDROXYLASE(TH) VS. DOPAMINE (DA) SPECIFIC ANTIBODY PROCEDURES FOR MAPPING DA-CONTAINING PERIKARYA THROUGHOUT THE CHICK BRAIN. W.J. Kuenzel, J. Kirtinitis and W. Saidel\*. Poultry Sci. Dept., Univ. of Maryland, College Park, MD 20742.

A polyclonal antibody to TH (dilution 1:200) was compared to a monoclonal antibody against DA (dilution 1:200). Beginning at the caudal region of brainstem and moving rostrally, the n. tractus solitarius (S)/vagal complex showed immunoreactivity (ir). With TH, many perikarya immunostained within the S. In contrast none was found using an antibody against DA, however many fibers were immunostained. A small chain of perikarya were found that immunostained with DA directly ventral to the origin of the IXth and X nerves. The n. reticularis subtrigeminalis immunostained. Moving rostral to the midbrain, the n. tegmenti pedunculo-pontinus, pars compacta (substantia nigra) had large numbers of perikarya ir to TH. In contrast, fewer perikarya were found ir to DA in that n. The most intense staining for DA was found in the area ventralis of Tsai (AVT). A few scattered neurons within the central gray immunostained with both TH and DA. The sixth nucleus that immunostained with both TH and DA was found at the caudal extent of the hypothalamus just dorsal to the supramamillary decussation, the n. intramedialis (nI). Both dorsal and ventral projections were observed the latter appeared to travel to the median eminence. The last group of DA neurons (cerebrospinal fluid contacting neurons) was found within a circumventricular organ, the paraventricular organ. Supported by USDA grant \$90-37240-5506 and MAES competitive grant.

EARLY SEXUAL MATURATION INDUCED IN CHICKS BY NEUROPEPTIDE Y: BIOGENIC AMINE AND NEUROANATOMICAL EFFECTS.

EARLY SEXUAL MATURATION INDUCED IN CHICKS BY NEUROPEPTIDE Y: BIOGENIC AMINE AND NEUROANATOMICAL EFFECTS. G.S.Fraley and W.J. Kuenzel\*. Poultry Science Dept., University of MD; College Park, MD 20742.

Neuropeptide Y (NPY) was administered intracerebroventricularly to immature male chicks to determine its effects on sexual maturation. Male broiler chicks were cannulated within the lateral ventricle at three weeks of age. Chronic injections of 5.0 ug NPY were injected for four consecutive days during the fourth week and repeated the fifth week of age. At six weeks of age sexually mature respondant birds were selected on the basis of advanced secondary sex characteristics and compared with groups of nonrespondant and control animals. Birds were then injected with 100 mg/kg body weight hydroxybenzylhydrazine, an amino acid decarboxylase blocker, to ascertain levels of L-DOPA as well as other biogenic amines. After thirty minutes, the brains were removed and prepped for HPLC analysis. Micropunches of the preoptic area (POA), paraventricular nucleus (PVN), bed nucleus of the pallial commissure (nCPa), and median eminence (ME) were analyzed. Results showed an increase in dopamine (DA) and L-DOPA in both the ME and POA, but a decrease in DA within the PVN. Also, an increase in DA metabolites were seen in the PVN and nCPa. These results are interpreted as an increase in dopaminergic activity within the ME and POA suggesting a localized stimulatory affect on gonadoytropin releasing hormone (GnRH) neurons, while a decrease in dopaminergic activity in the PVN and nCPa. Thas results and cPa. These results are interpreted as an increase in dopaminergic activity in the PVN and nCPa. Thas neurons wifecally induced precocious puberty (Fraley et al, 1991). Thus, NPY could be an initiator of cascading events including the localized stimulatory action of DA on GRRH neurons. Supported by USDA Grant \$\frac{90}{90} - 37240 - 5506.

IMPLICATIONS OF NEURON REDUCTION IN CETACEAN AND SIRENIAN CORTEX: T\_Deacon." R. Reep. 2 C\_Marshall 2 & J.Moore. Anthrop. Harvard U., Cambridge, MA 02138 2 Physiol., U. of Florida, Gainsville, FL 32610 3 Neuronal cell counts with respect to surface area in the cerebral cortices of four cetacean and one sirenian species are compared with those of six terrestrial mammal species. The four cetacean species (2 mysticetes and 2 odontoctes) and the one sirenian species all have cell numbers reduced to approximately 40% of the corresponding cell numbers in the cortices of the terrestrial mammals (including a marsupial). Two possible developmental causes of this cell reduction are 1) underproduction of cortical plate neurons from germinal cells or 2) high post-milotic cell death of cortical plate neurons. No direct evidence is available for either mechanism, however, the cetacean cortical plate is unusually thin for brain size, whereas the sirenian cortical plate appears unusually thick, compared to terrestrial mammals. Sirenian brains also exhibit a clearly differentiated layer IV in some regions, whereas cetacean brains do not. This suggests that the cetacean pattern may be a consequence of selective cell death. Truncation of cortical plate neurogenesis would have significant consequences for cell types, axon-target atfinities, and laminar designation within the cerebral cortex, since the liming and order of cell production in the cortical plate determines both target position within the mature cortex and also the laminar specificity of function and connectivity. If the generation of cortical plate cells is somehow shut off alter generating only 40% of the normal complement, then there may be no cells that would otherwise differentiate to express the characteristics of cells in upper cortical layers: the targets for specific thalamic afferents and the sources and targets for the majority of corticacontical connections. This would severely impact oortical cells reduction pattern by these independent, long aquatically ad

NEUROANATOMIC VARIABILITY OF RAT BRAINS J.R. Absher, A.W. Toga, P.K. Banerjee, R.C. Collins\*, and E.M. Laboratory of Neuro Imaging, Dept of Neurology, UCLA School of

We report an analysis of intersubject variability in Spraque-Dawley rats and compare the "average" rat brain from 5 subjects to the Paxinos and Watson compare the "average" rat brain from 5 subjects to the Paxinos and Watson rat brain atlas. Coronal planes were obtained after in situ freezing, and sagittal planes were obtained from the 3D data set. The Paxinos and Watson atlas data set was reconstructed from the individual images, corresponding exactly to the sagittal planes taken from each subject. Eleven brain regions were traced on each plane. Region area, perimeter, and percent overlap (of subject and atlas brain regions) were determined for all brain regions. A 3D model was derived by triangulation, and surface area, volume, and center of mass were determined. Translational and rotational "correction factors" were each subtact to fit the individual data sets to the the Paxinos and Watson and mass were determined. Translational and rotational correction factors were calculated to fit the individual data sets to the the Paxinos and Watson atlas data set. "Average" translational and rotational correction factors were also derived. The results reveal substantial intersubject variability in location (center of mass) and orientation (rotation about the center of mass) for most brain regions.

DISTRIBUTION OF CHAT IMMUNOREACTIVE PERIKARYA AND FIBERS IN THE PIGEON BRAIN. L. Medina\* and A. Reiner Dept. Anat. & Neurobiol., Univ. of Tennessee, Memphis, TN 38163.

In order to provide a complete description of the cholinergic systems of the pigeon (White Carneaux) CNS, brain sections were processed for choline acetyltransferase (ChAT) immunohistochemistry using a rabbit anti-chicken ChAT primary antiserum (kindly donated by Dr. Epstein, Univ. Wisconsin).
Within the telencephalon most ChATi neurons are confined to the

basal regions, such as striatum, globus pallidus, ventral pallidum, diagonal band nucleus and septum. Further caudally, ChATi cell bodies are present in the preoptic region, several hypothalamic nuclei, the thalamus, the medial habenula, the pretectum (adjacent to the posterior commissure), tectal layer 10, central gray, nucleus of Darkschewitsch, ventral tegmental area, parvocellular and semilunar isthmic nuclei, nucleus dorsalis lemnisci lateralis, pontomesencephalic tegmentum, reticular formation, descending trigeminal nucleus, medial vestibular nucleus, nucleus cuneatus externus, and all cranial nerve nuclei. Cholinergic fibers and varicosities are widespread over the brain. Prominent plexi are seen in the hyperstriatum accessorium, striatum, intrapeduncular nucleus, all retinorecipient neuropiles, and lateral spiriform, intercollicular and interpeduncular nuclei. The ChAT distribution in the pigeon brain largely resembles that of other vertebrates, indicating that the cholinergic systems have been highly conserved during evolution. DOLPHIN PERIPHERAL VISUAL TRACT IN CHRONIC UNILATERAL OCULAR ATROPHY: COMPLETE DECUSSATION APPARENT. B.J. Tarpley, J.B. Gelderd\*, S. Bauserman & S. H. Ridgway. Depts. of Vet. Anat., Anat. & Med. Neurobiol., Pathology, Texas A&M University, College Station, TX 77843 and NRaD., San Diego, CA. 92152

Components of the peripheral visual pathway were examined in two bottlenose dolphins *Tursiops truncatus*, each with unilateral ocular degeneration of three years or more duration. In both dolphins, the optic nerve associated with the blind eye (right eye in Tg419 and left eye in Tt038) appeared translucent upon gross examination. This translucency was also evident in the optic tract contralateral to the affected eye. Many axons, primarily myelinated, were identified in the left optic nerve of Tg419 while essentially none were seen in the right optic nerve. In T1038, axons were found in association with the right optic nerve and left optic tract but were essentially absent in the left optic nerve and right optic tract. The optic chiasm of Tt038, examined by light microscopy in serial horizontal section, appeared near its center to be arranged in segregated, alternating pathways for the decussation of right and left optic nerve fibers, while the exterior portions of the chiasm were dedicated ventrally to fibers from the left optic nerve and dorsally to fibers from the right optic nerve. Because of this architectural arrangement, the right and left optic nerves appeared to overlap as they crossed the optic chiasm with the right optic nerve coursing dorsal to the le optic nerve. At light and electron microscopic levels, optic nerves and tracts lacking axons were well-vascularized and dominated primarily by astrocytes. Although extensive postmortem change precluded accurate fiber counts, the essential absence of axons in one of the optic tract pairs (right in Tt038 and left in Tg419) appears to support the concept of complete decussation of right and left optic nerve fibers at the optic chiasm in the bottlenose dolphin. TOPOGRAPHY OF CORPUS CALLOSUM FIBERS IN THE RAT. M.F. Novotny\* and D.P. Crowne. Department of Psychology. University of Waterloo, Waterloo, Ontario, Canada, N2L 3G1,

The topographical relationship between callosal fibers and their cortical origins in the adult rat were examined using a lipophilic tracer. Dil crystals were inserted into the frontal cortex of whole fixed brains, and onto discrete sectors of the corpus callosum. The results confirm the rostral-caudal sectoring of the corpus callosum, with axons in the anterior callosum originating from the corresponding frontal cortex. Commissural projections displayed a vertical band organization mainly occupying layers III and V. The results may provide insights for anatomical and behavioural studies interhemispheric communication.

EVIDENCE FOR A UNIQUE POPULATION OF PYRAMIDAL NEURONS

EVIDENCE FOR A UNIQUE POPULATION OF PYRAMIDAL NEURONS IN BROCA'S AREA. T.L. Hayes\* and D.A. Lewis. Depts. of Behav. Neurosci. and Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA 15216. In the left hemisphere, Brodmann's regions 44 and 45 (Broca's area) are believed to support motor speech, whereas in the right hemisphere, the role of these regions remains unknown. Hemispheric differences in the characteristics of the layer III pyramidal neurons of those regions have been reported, including greater dendritic arborization (Scheibel 1984) and larger neuron size (Soc Neuro Abstr 17:1021, 1991) in the left hemisphere. In a sample of 11 cases, we have confirmed our previous finding that the cross-sectional area of the largest layer III pyramids is greater in left than in right area 45 (p <.0001). In every case the mean size of these neurons in the left hemisphere was greater than that in the right, and in eight cases this difference was statistically significant (7-38% greater in the left than in the right). This difference was specific to the largest pyramids, as there was no hemispheric difference in the mean size of all layer III pyramidal neurons in area 45. Immunohistochemical studies have demonstrated that large in area 45. Immunohistochemical studies have demonstrated that large pyramidal neurons in area 45 contain non-phosphorylated neurofilament protein (NFP). However, no hemispheric differences were found in the size of the largest NFP-positive layer III pyramids. Comparisons of the Nissl and NFP findings suggest that the largest pyramids in left area 45 may be morphologically and chemically distinct from those in the homotopic region in the right hemisphere. Other studies to examine the chemical specificity of these neurons are underway. These findings suggest that area 45 of the left hemisphere contains a unique population of large pyramidal neurons, which may be specialized for the language functions mediated by this region.

THREE DIMENSIONAL RECONSTRUCTIONS OF THE CAUDAL SUPERIOR TEMPORAL REGION IN HUMANS SHOW NO ASYMMETRIES IN CORTICAL SURFACE AREA W.C. Lofus, C.E. Thomas, M.J. Tramo<sup>†</sup>, R.L. Green<sup>††</sup>, R.A. Nordgren and M.S. Gazzaniga\*. Ctr

for Neurobiology, University of California, Davis, CA 95616, †Dept of Neurobiology, Harvard Medical School, Boston, MA 02115, ††Dept of Psychiatry, Dartmouth Medical School, Hanover, NH 03755.

In order to consider whether left hemisphere specialization for language is associated with hemispheric asymmetries in gross cortical morphometry, the surface area of the caudal superior temporal region was measured from magnetic resonance scans of 10 young, normal, right-handed subjects. Planar map measurements of the full extent of the infrasylvian cortical surface caudal to measurements of the full extent of the infrasylvian cortical surface caudal to Heschl's gyrus were first obtained by summing the length of the convolutions across contiguous coronal sections. A leftward asymmetry was found (mean left=7.18, mean right=5.57, p-0.007). This region was then measured using 3D reconstructions that take into account the intrinsic curvature of the cortical surface and the oblique portions of the posterior sylvian fissure. No asymmetry was found (mean left=6.91, mean right=6.67, p=0.719). Finally, the 3D model allowed us to measure the combined surface area of Heschl's gyrus, caudal superior temporal gyrus, and adjacent parainsular cortex. Again, no left-right asymmetry was found (mean left=29.81, mean right=29.29, p=0.678). These findings indicate that: 1) measurements of the caudal superior temporal region from serial coronal sections that do not explicitly model the tilt of the ascending sylvian ramus with respect to the rostrocaudal axis are biased in favor leftward asymmetry; and 2) three dimensional reconstructions of the caudal

of leftward asymmetry; and 2) three dimensional reconstructions of the caudal superior temporal region reveal no left-right asymmetry of cortical surface area. Supported by ONR N00014-89-1-3035, NIH/NINDS P01 NS17778-10, the McDonnell-Pew Foundation and 1 K08 DC00071 (MJT).

LATERALIZED DIFFERENCES IN MORPHOLOGICAL

LATERALIZED DIFFERENCES IN MORPHOLOGICAL COLUMNS OF AREA Tpt. D. Buxhoeveden\* and E. Armstrong, University of Chicago, Chicago, TL 60637 and A.F.I.P. Washington, D.C., 20306. Selected algorithms from a method that analyzes the size and shape of cell columns in the cortex was used to study laterality in the posterior language area, Tpt. Gross anatomical differences exist between the two hemispheres here, but little is known about asymmetry at the histological level. Comparisons were made between 7 human, 5 chimpanzee and 4 rhesus monkey brains. All were normal adult or young adult. Nissl stained coronal sections were digitized on a computer imaging system.

In human brains, the morphological columns on the left side are farther apart and there is slightly more non-neuronal space at the periphery of individual columns than on the right. The cell arrangement is less vertically oriented in the left hemisphere than in the right in lamina III, but is more vertical in all the other lamina. The chimpanzee brains show no laterality in these features. The rhesus brains have an asymmetry in lamina III that runs counter to that of the human Tpt. Cell columns in the rhesus left hemisphere are more vertically oriented and are closer together than in the right. No difference in the peripheral space was observed.

BROCA'S REGION: ANATOMICAL AND FUNCTIONAL ASYMMETRIES. S.F. Witelson\* and D.L. Kigar. Dept. of Psychiatry, McMaster Univ., Hamilton, Ont., Canada, L8N 3Z5

Frontal cortical regions related to language production were measured for their extent and right-left asymmetry and the relationship of these anatomic measures to psychological measures of hemispheric functional asymmetry. Previously, we demonstrated that variation in gross structure in posterior language gyri surrounding the Sylvian fissure (SF) was associated with handedness and, by inference, with functional asymmetry (Witelson & Kigar, Abst. Soc. NSc, '90; '91). The structure-function relationship was observed in men; not women. We focused on frontal regions in this study for two reasons:

(1) they are very asymmetric functionally in the mediation of speech and this could be represented by an asymmetric structure; (2) handedness may be associated in women with frontal region morphology. There have been a few studies of right-left asymmetry of inferior frontal regions (variably defined) which, in general, indicate nonsignificant asymmetry. We defined Broca's region as the region bounded by the precentral sulcus, the anterior horizontal ramus of SF, the inferior frontal fissure and SF, and studied this region in 67 postmortem brains (24° and 43°), whose hand preference [consistent-righthand (CRH) or nonCRH] was tested prior to death. Statistical analyses revealed that Hemisphere was not a significant main factor. Handedness was, with nonCRH having greater frontal regions. This relationship held only for men. In addition, in men, Handedness interacted with direction of asymmetry. These results are consistent with the bilateral differences found in posterior brain regions between CRH and nonCRH men, and again indicate a perplexing lack of relationship of handedness with structural variation in women compared to men. Implications for the neural substrate of varying patterns of cognition will be discussed. Supported by US NINDS.

THE FIBER COMPOSITION OF THE HUMAN CORPUS CALLOSUM. F. Aboitiz. A.B. Scheibel\* and E. Zaidel, Brain Research Institute and Department of Psychology, UCLA, Los Angeles CA 90024.

The densities of fibers of different sizes were calculated in

ten regions of the corpus callosums of twenty human brains (ten females, ten males, ages 25-68) under light microscopy. Large fibers (>3um in diameter) are least dense in the anterior corpus callosum (genu), and increase in density posteriorly towards the middle and posterior midbody, where posteriorly towards the middle and posterior midbody, where somatosensory and auditory areas apparently project, respectively. Towards the posterior corpus callosum (splenium), the density of large fibers decreases, but in the posterior pole of the callosum, where visual areas project, there is a local increase in their density. So far, the highest density of large-diameter fibers was in the region presumably connecting auditory areas. Thin fibers (>0.4 um in diameter) show a pattern exactly complementary to that of large fibers, being most dense in the genu and decreasing their density toward the posterior midbody. Their density increases when entering the splenium, to show a local decrease in the posterior pole of the callosum. Across subjects, the density of callosal fibers had no significant correlation with callosal area and therefore an increased callosal area indicated an increased total number of fibers crossing through. No sex differences in the fiber crossing through. No sex differences composition of the corpus callosum were found.

# 144.6

WHAT IS ANOMALOUS IN THE DYSLEXIC PLANUM? C. M. Leonard\*a,b, K.K.S. Voellerb, L.J. Lombardinoc, J.C. Honeymand, and O.F. Agee<sup>4</sup>, Depts. of Neuroscience<sup>4</sup>, Psychiatry<sup>6</sup>, Communication Processes<sup>c</sup> and Radiology<sup>4</sup>, University of Florida, Gainesville, FL 32610.

Post mortem studies of dyslexics have revealed symmetry of the planum

temporale due to increased growth on the right. We asked which bank of the planum was responsible. Computer-based measurements of average planar length were made on thin sagittal images from MR scans of 12 controls [(C): ages 14-52]; 9 dyslexics [(D): ages 15-65]; and 10 unaffected relatives of the ages 19-52], 9 dystexics [(D): ages 19-65]; and 10 unaffected relatives of the dyslexics [(R): ages 6 - 63]. All three groups had leftward asymmetry in the temporal bank  $(T-P)^{4}(T+P)^{4}.5]=17\%$ , 48%, and 40%, respectively) and rightward asymmetry in the parietal bank (-18%, -67%, and -45%, respectively). We confirmed Galaburda's finding of an anomalous right planum, although, in our subjects, the anomaly was restricted to the parietal bank. The dyslexic group had a significantly larger proportion of tissue devoted to the parietal bank: [intrahemispheric T/P asymmetry = 81%, 2% and 19%, to the particul bank: [intrahemispheric 17] asymmetry = 81%, 2% and 19%, respectively (D vs C: p < 0.02, R vs C: p > 0.10, post-hoc Duncan)]. There were no significant differences on the left (T/P asymmetries of 108%, 101%, and 98%, respectively). When the data on anomalous intrahemispheric asymmetry were combined with data on left and right sided perisylvian anomalies (extra or missing gyri), 7 dyslexics, 2 relatives and no controls were found to have bilateral anomalies. Interpretation: Visuospatial functions are localized in the parietal lobe while auditory functions are localized in the temporal lobe. The reversed T/P asymmetry found in dyslexic families could reflect cognitive biases for spatial strategies that are not suited to the sequential analysis of language. The risk of dyslexia increases with additional left-sided perisylvian anomalies that interfere with normal language processing.

VISUAL ATTENTION DEFICITS IN AUTISTIC ADULTS WITH CEREBELLAR AND PARIETAL ABNORMALITIES. <u>J.Townsend'</u>, <u>E.Courchesne, B.Egaas</u>. (UCSD Psychiatry, Neuroscience Depts.) Children's Hospital, Neuropsychology Research Lab, 8001 Frost St., San Diego, CA 92123.

A model of visual-spatial attention developed by Posner and Petersen (1990) proposes that brain systems involving posterior parietal cortex, the lateral pulvinar nucleus, and the superior colliculus guide the orienting of visual attention in space. Studies using a behavioral test that follows attentional cuing with a simple visual target, have shown patterns of deficits in orienting of spatial attention in humans with specific brain lesions, suggesting involvement of the posterior parietal cortex in the disengagement of attention; the superior colliculus in the moving of attention; and the lateral pulvinar in the engagement of attention. We tested autistic subjects from a group with cerebellar and, in a subset, parietal abnormalities, using several variations of the Posner spatial task. Autistic patients showed a unique pattern of responses with two important findings. First, compared to controls and other autistic patients, autistic patients with parietal abnormalities were extremely slow to respond to targets when their attention had been cued to the location opposite the target (a deficit similar to that seen in patients with parietal injury), with a strong correlation between the level of behavioral impairment and MRI quantitative estimates of parietal damage. In the second major finding, both groups of autistic subjects had significantly slowed responses when the cue to target delay was short (100 msec), but in the context of normal attention-related response patterns (i.e. faster response to validly than invalidly cued targets). This time-related delay has not been reported for other patient groups (e.g. parietal, frontal, midbrain, thalmic lesions), but is similar to time-related delays in attention shifts reported in patients with autism and with acquired cerebellar damage.

SELECTIVE ATTENTION AND THE ANTERIOR CINGULATE: A DEVELOPMENTAL NEUROANATOMICAL STUDY. B.J. Casey, J. Giedd, Y. Vauss, C.K. Vaituzis and J.L. Rapoport\*. Child Psychiatry Branch, NIMH, Bethesda, MD 20892.

Selective and divided attention measures were correlated with MRI measures of the anterior cingulate in 14 right-handed normal children between the ages of 8 and 16 years. Parasagittal slices from a 3-D T1 weighted (TR=400, TE=12) data set (1 X 1 X 1.5 mm) were used to obtain whole brain and cingulate measurements. A dual visual and auditory detection task and a visual discrimination task were used to assess divided and selective attention. Selective attention measures were correlated with age ( $\mathbf{r} = .76$ ,  $\mathbf{p} < .005$ ,  $\mathbf{r} = .81$ ,  $\mathbf{p} < .005$ ), but not whole brain area. There were significant correlations between the selective attention measures and the anterior cingulate measures ( $\mathbf{r} = .66$ ,  $\mathbf{p} < .01$ ,  $\mathbf{r} = .74$ ,  $\mathbf{p} < .005$ ), especially the right anterior cingulate ( $\mathbf{r} = .62$ ,  $\mathbf{p} < .025$ ,  $\mathbf{r} = .75$ ,  $\mathbf{p} < .0025$ ). The results are consistent with recent PET findings of activation in the right anterior cingulate during selective attention and provide additional support for proposed structure/function relationships in the anterior attention system.

OBJECT AND LOCATION RECOGNITION MEMORY IN PRETERM AND FULLTERM INFANTS. T. Wilcox, L. Nadel\* and R. Rosser. Dept. of Psychology, Univ. of Arizona, Tucson, AZ 85721.

This study (1)investigated the relative development of

This study (1)investigated the relative development of the object vision and location vision systems (inferior temporal and posterior parietal areas; Underleider & Mishkin, 1982); and (2)determined the effect of alterations in early experience on their development. 18 healthy preterm (PT) infants and 21 fullterm (FT) controls were tested on an object recognition task (Visual Paired Comparision) and a location recognition task (Visual Search). The mean chronological age for the PT infants was 3.9, 5.9 & 7.9 mos; for the FT controls it was 2.5, 4.5 & 6.5 mos. For both tasks delay intervals of 5, 10, & 30 secs were used according to the age of the subjects.

Both PT and FT infants evidenced location recognition

Both PT and FT infants evidenced location recognition memory at all ages; there were no differences between the groups. However, the PT infants performed better than the FT infants on VPC. They evidenced a stronger preference for novelty at each age tested. This finding can be explained by the older chronological age of the PT infants. The fact that the PT infants did not also perform better on VS suggests that location recognition abilities may be more affected by premature birth than object recognition abilities. This is consistent with converging neural and behavioral evidence that the spatial ("magno") system may be a more rudimentary and earlier developing system than the object ("parvo") system.

PARIETAL LOBE ABNORMALITIES DETECTED BY MAGNETIC RESONANCE IN PATIENTS WITH INFANTILE AUTISM. <u>E.Courchesne</u>, <u>G.Press, R.Yeung-Courchesne</u>. (UCSD Dept. Neuroscience) Children's Hospital, Neuropsychology Research Lab, 8001 Frost St., San Diego, CA 92123.

Autism is a neurologic disorder that severely disrupts the development of higher cognitive functions. Cerebellar maldevelopment beginning between prenatal and early postnatal life has been detected by autopsy and radiologic analyses in autistic patients. Increased cell packing density in limbic structures reflecting developmental arrest by 3 years of age has also been seen at autopsy in several cases. Whether the cerebrum is affected is unknown. The MR scans of 21 healthy autistic subjects (ages 6-32 years) were examined for evidence of cerebral abnormality. Cortical volume loss in the parietal lobes was seen in 7 autistic patients; in 4 cases, cortical volume loss extended either into the adjacent superior frontal or occipital lobe. Additional abnormalities detectable by MR included white matter volume loss in the parietal lobes (3 patients), and thinning of the posterior body of the corpus callosum (2 patients). Abnormalities were bilateral in all but one patient. Three also met neuroradiologic criteria for cerebellar hypoplasia (as previously reported by our group). The mesial, lateral and orbital regions of frontal lobes, temporal lobes, limbic structures, basal ganglia, diencephalon and brainstem were normal in all autistic subjects. These results indicate that the parietal lobes are reduced in volume loss may be by consequence of a progressive age-related focal parietal volume loss may be by consequence of a progressive age-related focal parietal volume loss may be by consequence of a progressive age-related focal parietal volume loss may be by consequence of a progressive age-related focal parietal volume loss may be by consequence of a progressive age-related focal parietal volume loss may be by consequence of a progressive age-related focal parietal volume loss may be by consequence of a progressive age-related focal parietal volume loss may be by consequence of a progressive age-related focal parietal volume loss may be by consequence of a progressive age-related focal manufactures and/or causality to

DEVELOPMENT OF PLACE MEMORY IN CHILDREN AS MEASURED IN A DRY MORRIS MAZE. W.H. Overman\*, L. Carter, S. Thompson, Dept. of Psychology, U.N.C.at Wilmington, N.C. 28401.

The Morris maze has been used to measure place learning and memory in rodents (Morris, R.G.M., 1980, Learn. & Motiv., 12, 239-260). We adapted this maze for use with children by filling a large pool with plastic chips to a depth of 60 cm. Children, ages 2 to 12 years, spent 5 trials per day, for 3 days, searching for a candy filled box that was always hidden in the same location. Results were that latency to find the goal box decreased significantly across three test days for each age group and the latency had an inverse relation to age of subject. The same result was found when the dependent measure was distance traveled to find the goal. By the third day, older children followed direct paths to the goal. After their last trial children were asked (in another room) to locate the goal position in a scale model of the test room and maze. On this task, children below age 7 were significantly inferior to older children. Taken together these data suggest that cognitive mapping ability continues to mature up until at least age 7.

# 144.12

NCTR OPERANT TEST BATTERY (OTB) PERFORMANCE IN CHILDREN: CORRELATION WITH IQ. M.G. Paule, D. J. Blake, R.R. Allen and P.H. Casey. C.A.R.E., Dept. of Pediatrics, Arkansas Children's Hospital, Little Rock, AR 72205 and Div. of Neurotoxicology, National Center for Toxicological Research, Jefferson, AR 72079-9502.

In order to determine whether aspects of operant performance are related to subject IQs, OTB data obtained from 109 61/2 year old children were compared to their IQ scores obtained at age 5. Tasks in the nickel-reinforced, multiple schedule OTB and the specific function(s) they are thought to model include: Progressive Ratio (PR), motivation; Conditioned Position Responding, color and position discrimination; Incremental Repeated Acquisition (IRA), learning; Delayed Matching-to-Sample (DMTS), short-term memory and attention; and Temporal Response Differentiation (TRD), time perception. Endpoints included response rates (RR), accuracies (ACC), and percent task (PTC) completed. Highly significant correlations were noted between several OTB measures (e.g., CPR ACC, r=0.60, p<0.0001) and IQ, whereas other OTB measures (e.g., PR endpoints) did not correlate at all. These data demonstrate that: a) certain aspects of OTB responding are associated with subject IQ; b) certain OTB measures are not reflective of IQ and thus apparently measure other aspects of brain capacity. Since operant methodology is easily used for assessing the behavior of animal subjects, it should now be possible to quantitate aspects of 'animal IQ' using the NCTR OTB.

PLASMA COBALAMIN LEVELS ARE ASSOCIATED WITH INFORMATION PROCESSING SPEED IN A LONGITUDINAL STUDY OF HIV-1 DISEASE. G Shor-Posner\*, R Morgan, F Wilkie, RS Beach, E Mantero-Atienza, and MK Baum. Univ. of Miami Sch. of Med., Miami, FL 33101

Our recent studies indicate that HIV-1 infected individuals with low plasma cobalamin (vitamin B<sub>12</sub>) levels (<240 pg/ml) demonstrate significantly poorer performance on measures of information processing, as compared to those with adequate vitamin B<sub>12</sub> status (Arch Neurol; 1992, In press). The present longitudinal study examined the impact of change in vitamin  $\rm B_{12}$  status, over 12 month intervals, in relationship to the speed of accessing highly overlearned name codes as measured by the Posner Letter Matching Test in HIV-1 infected homosexual men (n=84, CDC Stage II, III, IV) evaluated for up to 30 months. Autoregression analysis indicated that normalization of vitamin B<sub>12</sub> status, from deficiency to adequacy was associated with faster processing speed, while change from adequacy to deficiency, in contrast, was associated with slower reaction time (p < 0.002). These findings, which are independent of CD4 status and zidovudine treatment, suggest that vitamin B<sub>12</sub> deficiency may be an important cofactor in cognitive changes observed during HIV-1 infection. Clinical trials are needed to confirm that restoration of adequate plasma vitamin B<sub>12</sub> levels improve information processing speed in HIV-1 disease.

## 144.15

MRI STUDY OF WHITE MATTER CHANGES IN CYSTINOSIS. Barbara L. Hodge, John R. Hesselink\*, Doris A. Trauner\*. Departments of Neurosciences and \*Radiology, University of California at San Diego, San Diego, California.

In an attempt to learn more about brain-behavior relationships, we used MRI scans to correlate structural changes in brains of children used MRI scans to correlate structural changes in brains of children with cystinosis, with the known cognitive deficits associated with this disorder. Children with cystinosis, an autosomal recessive disorder of cystine metabolism, have a specific visual processing deficit on a background of normal IQ. Previous MRI studies have reported cortical atrophy in people with cystinosis.

MRI scans were done on nine children with cystinosis (age range: 5 to 14 years) and on nine age- and sex-matched normal controls using a G.E. Signa 1.5-Tesla unit. The radiologist who examined the

scans was blind to the status of each of the subjects.
Six of the nine children with cystinosis had evidence of subcortical abnormalities. Four had changes consistent with defective myelina-tion and two had white matter volume loss. All of the controls had normal scans.

The metabolic defect in cystinosis may preferentially affect white matter. No other conditions were present that might have caused these changes. The visual processing deficits seen in children with cystinosis may thus result from the disruption of the subcortical connections between different brain regions.

# 144.17

SUSTAINED ATTENTION DEFICITS AND WHITE MATTER CHANGES (MRI) IN PATIENTS WITH PHENYL-KETONURIA J. Pietz, C. Benninger\*, U. Meyding-Lamade Childrens Hospital University of Heidelberg, D-6900 Heidelberg, INF150, FRG

Phenylketonuria (PKU) is an autosomal recessive disorder of amino acid metabolism. By the early institution of a phenylalanine restricted diet the severe impairment of brain development can be prevented. We investigated 32 early treated PKU patients (mean age 19.8 years) with cranial magnetic resonance imaging (MRI) and with a continuous performance task (CPT) to determine the level of sustained attention. In addition IQ testing (WAIS-R) was performed. All 32 patients showed testing (WAIS-R) was performed. All 32 patients showed lesions (high signal intensities in T2-weighted images) in the white matter of the central nervous system. A subgroup of 6 patients were found to be severely affected subgroup of 6 patients were found to be severely affected with extension of the lesions to the frontal, temporal and subcortical white matter. These patients showed distinct deficits in the CPT and had lower IQs in comparison to the other patients. Within the patients with a mild (N=15) or moderate (N=11) degree of MRI changes the extent and/or location of these lesions (mainly within the posterior and parietal hemispheres) was not correlated with CPT and IQ results.

NEUROCOGNITIVE AND NEUROIMAGING CHARACTERISTICS OF HIV-1 INFECTION. R. C. Verma.\* J. O. Harker, M. P. Gan, L. R. Bennett, F. D-L. Jones, G. Mathisen, F. Kjournehr, M. A. Mandelkern, W. H. Blahd. J. Ropchan. Olive View-UCLA Medical Center, Sylmar, CA 91342

This study was undertaken to determine the frequency and correlation of Inis study was undertaken to determine the frequency and correlation of neurocognitive (NC) and neuroimaging (NI) abnormalities in HIV-1 infection. HIV-1 seropositive subjects (27 in Group A, symptomatic, and 14 in Group B, asymptomatic) and 14 high risk seronegative subjects (Group C) underwent NC testing (n=55), CT/MRI (n=44), I-123-iodoamphetamine SPECT cerebral perfusion imaging (n=48), and F18-flourodeoxyglucose PET brain scans, FDG, (n=19). Subjects with focal neurological lesions were excluded. NC tests included 22 measures of memory, reasoning, motor function, and conntive flexibility.

Global NC impairment (GNCI) score was computed by expressing the number of abnormal (±1.5SD) NC tests as a percent of the total tests given to each subject. Cortical atrophy on CT/MRI, cortical perfusion deficits on SPECT, and striatal FDG metabolism on PET brain scans were graded on a scale of 5 to 8, 5

being normal and 8 being marked abnormality.

The mean ±SD of CD4 cell count/cmm and NC and NI measures were:

CD4 GNCI Atrophy +Cort. Perf. ↑Str. Perf. ↑Str. FDG 225±136 36%±29 771±179 5%±7 9%±7

A 225±136 36%±29 6.3±0.8 6.5±0.8 5.4±0.6 5.8±1.0
B 771±179 5%±7 5.5±0.8 6.8±1.0 5.2±0.7 4.7±1.0
C 9%±7 5.4±0.7 6.2±0.8 5.0±0 5.2±0.7 4.7±1.0
Group A demonstrated a significantly higher GNCI (p< 0.001), cortical atrophy (p< 0.012) and 1striatal perfusion (p< 0.028) than Group B or C or B and C.
A modest correlation was demonstrated between CD4 cell count and GNCI (r = -0.44), cortical atrophy (r = -0.39) and striatal FDG (r -0.58). Overall, there is a significantly higher frequency of neurocognitive impairment, cortical atrophy and striatal hyperperfusion in subjects with symptomatic HIV-1 infection and these measures correlate with disease severify as measured by CD4 status.

## 144.16

WEIGHTED LINEAR ESTIMATOR PROCEDURES FOR NEUROMAGNETIC SOURCE RECONSTRUCTION I. Gorodnitsky, J.S. George\*, H.A. Schlitt and P.S.Lewis. Los Alamos National Laboratory, MS: M-715, Los Alamos, NM, 87545 The goal of neuromagnetic source reconstruction is high resolution 3-D mapping of the current distribution within the brain. A useful computational strategy for current reconstruction involves a basis matrix which specifies the signal at each sensor produced by a set of orthogonal unit current vectors associated with each volume element (voxel) in the reconstruction space. Given such a matrix, the forward calculation is a simple linear combination of the basis vectors associated with each of the component currents. However, expressed in this manner, the neuromagnetic inverse problem is ill-posed and typically underdetermined. The Moore-Penrose pseudoinverse provides a linear algebraic inverse calculation that simultaneously minimizes chi-square and the Euclidean norm of the component currents. Such 'minimum norm' reconstructions often produce diffuse and superficial current distributions because voxels nearer the sensor array can account for more power in the data with less current than deeper voxels. Our approach overcomes the superficial bias of minimum norm procedures by using weights chosen to compensate for the distance dependence of procedures by using weights chosen to compensate for the distance dependence of magnetic signal strength. In our procedure, the Euclidean norm of the set of basis vectors associated with each source voxel is normalized, and the weighted basis matrix is used for the reconstruction. We also apply a Bayesian weighting strategy in an iterative pseudoinverse computation, to address the bias of the linear estimator procedure toward diffuse solutions. At each successive iteration the previous solution is accepted as a priori knowledge and is used to weight the reconstruction. This strategy produces a progressively more focal current distribution while accomodating distributed current sources, and appears to effectively reduce the problems associated with the under-determined linear system. Procedures based on singular value decomposition, hierarchical reconstruction strategies and nantomical constraints can be employed in the hierarchical reconstruction strategies and anatomical constraints can be employed in the context of this algorithm to handle problems associated with noisy data, and modeling arrors associated with the discrete volumetric grid used for current reconstruction. The weighting strategy also provides a natural mechanism to incorporate estimates of source location based on other analyses or other functional imaging techniques.

CEREBRAL ACTIVATION STUDIED WITH PET AND (O-15)-BUTANOL: METHODOLOGICAL CONSIDERATIONS M. Ingvar, L. Eriksson, T. Greitz, S. Stone-Elander, C. von Euler, and P. af Trampe The Karolinska Hospital/Institute, Karolinska Pharmacy and the University of Stockholm, Stockholm, Sweden

A total of 32 cerebral blood flow (rCBF) studies have been performed A total of 32 cerebral blood flow (rCBF) studies have been performed in four healthy volunteers with the aim of investigating methodological aspects of brain activation studies. Four rCBF studies while reading aloud and four studies while reading silently were performed in each subject. During a period of three minute, the volunteer read words from a semantically balanced list presented on a screen in front of him. Each word was presented every 1.5 s, starting 20 s before the bolus injection of 30 mCi (0-15)-butanol. The uptake of the flow tracer was followed for 100 s with time frames of 10 s using a Scanditronix (GE) PC2048-15B positron camera system. The arterial concentration of the flow tracer was monitored every second for two minutes with a Scanditronix automatic blood sampling system. Scanditronix automatic blood sampling system. A computerized atlas was adapted to the individual rCBF images. By A computerized atlas was adapted to the individual rCBF images. By using transformations that are inverse to those used to adapt the atlas, the individual rCBF images were reformatted to the atlas coordinate system. Average and error images were generated for the group as well as for each individual allowing intra- and inter-individual comparisons. Maps of the difference between the two activation states divided by the error were calculated both for the individual cases and the group. Areas of robust activations, for ex Brodman area 04, with "reading silent" as the reference state and the frontal cortex with "reading aloud" as the reference state, were found for the group and for each individual. This is in agreement with findings of DH Ingvar.[J. Human Neurobiol 4,127(1983)]. Our results indicate that intra-individual averaging is a powerful tool for reducing noise in activation studies. activation studies

ATTENTION TO LOCATIONS IN SPACE: THE NEUROPHYSIOLOGY OF EARLY SELECTION S. Johannes, H.C. Hughes\* & G.R. Mangun. Medizinische Hochschule

H.C. Hughes\* & G.R. Mangun. Medizinische Hochschule Hannover, 3000 Hannover, Germany; Dartmouth College, Hanover, NH & University of California, Davis, CA.

Previous studies of spatial attention have shown that attended visual stimuli produce amplitude enhancements of sensory event-related potentials. This has been interpreted as a facilitation of visual processing. We investigated whether attention more effectively modulates the processing of weak sensory signals, as well as whether these attention-sensitive ERP components (P1 & N1) respects to excellent descents. N1) represent serially dependent visual processes, or instead

parallel processing channels.

Stimuli consisted of low and high luminance bars which were randomly flashed 5 deg. to the right and left of fixation. Subjects attended to stimuli at one location while ignoring those at the other location

The overall amplitude of the occipital PI component was affected by both luminance and attention, but neither the absolute magnitude of the attention effect, nor the peak latency differed as a function of luminance. In contrast, for the occipital-temporal NI component, luminance affected the latency of the NI peak, but not the amplitude or latency of the attention effect observed in this time range. These data suggest partial dissociations between sensory processes and the effects of attention on early ERP components. Further, they suggest that the PI and NI components are differentially affected by attention and that they may reflect activity in parallel processing streams.

## 145.3

THE SPATIAL FREQUENCY CONTENT OF THE STIMULUS PATTERNS DOES NOT EXPLAIN FACE-RESPONSIVE COMPONENTS IN VISUAL EVOKED POTENTIALS

W. S. Seidler\*, O.-J. Grüsser Dept. of Physiology, Freie Universität Berlin, Arnimallee 22, W-1000 Berlin 33, Germany

In previous studies face-responsive components were found in man and primate visual evoked potentials (EP's). Photographs of faces, tools, houses, flowers, other parts of the body etc. were used as stimuli (slide projection).

Differences in face-responsive EP-components were also found when adult human-faces, human-baby-faces, adult animal-faces and animal-baby-faces were used as stimuli. Fourty slides of each category were projected in recording sessions with 16 subjects (9 female and 7 male, EEG-recordings from F3, T5, Cz, Oz, T6, F4, reference: linked mastoids).

The most prominent and significant differences were found in the EP's recorded through Cz-T6. The greatest differences at this recording site occured between EP's aroused by human-baby-faces and adult animalfaces as well as between human-baby-faces and animal-baby-faces. The differences in EP's evoked by human-baby-faces and adult human-faces were smaller but still significant. There were no significant differences in the EP's related to adult animal-faces and animal-baby-faces.

The two-dimensional spatial frequency distributions of the stimuli (Fourier transforms) were computed and averaged for the 4 stimulus categories. The spatial frequency content (nearly identical for the four stimulus categories) can not explain the differences in EP's. (Supported in part by a Forschungsgemeinschaft, Gr 161). grant of the Deutsche

ESTIMATING NEURAL GENERATOR POWER AND FIELD CLOSURE FROM INTRACRANIAL CURRENT SOURCE DENSITY (CSD) PROFILES. C.E.Tenke\*, M.Steinschneider and C.E.Schroeder, Dept. Biopsychology, NYS. Psychiatric Institute, NY, NY and Depts. Neurology and Neuroscience, Albert Einstein College of Medicine, Bronx, NY

CSD profiles computed at low spatial sampling resolution provide a useful preliminary description of the neural populations and temporal activity patterns underlying surface-recorded event-related potentials (ERPs). Although localizing capacity improves as spatial resolution is increased, the CSD also becom more sensitive to sharply localized activity that may not be reflected in the ERP recorded at the scalp. We have reported that closed field contributions may be separated from volume conducting activity by comparing CSD profiles computed using two differentiation grids (Tenke and Schroeder, 1990; 1991). The present study extends the applicability of this approach by quantifying overall activity generated in cortical and subcortical sensory structures in the monkey. Three measures of effective amplitude were examined: root mean square (RMS), standard deviation (SD) and mean absolute value. Findings for the Flash-ERP of the lateral geniculate nucleus (LGN) include the following: 1) peak power generation is coincident with the surface N25 (14-29ms), and suffers little cancellation locally; 2) a lower amplitude, sustained resp includes oscillatory activity (25-60ms), which is cancelled locally in the LGN. While the standard deviation waveform has the advantage of allowing direct statistical comparisons, all methods produce similar results if the mean CSD waveform is approximately zero. This approach may provide an additional means for determining the relative contributions of the activity patterns within specific neural structures to the surface-recorded ERP. (Supported by MH36295, MH06723 and DC00657)

ORIENTING ATTENTION IN SPACE: ELECTRO-PHYSIOLOGICAL STUDIES OF CONTROL MECHANISMS.

G.R. Mangun\*, Department of Psychology and Center for Neurobiology, University of California, Davis, CA 95616.

The mechanisms of attentional orienting and selective sensory processing were examined in a trial-by-trial spatial cuing task. Subjects were cued by a left or right pointing arrow to orient covert attention to a lateral field location in order to discriminate a target stimulus. Event-related potentials (ERPs) were recorded in response to both the cue and the target. During the cue-target interval, two effects were observed. The first was in the latency range of 250-350 msec post-cue and was manifest as a relative negativity over the parietal-temporal scalp contralateral to the direction of the cue. The second effect was observed only over the right hemisphere between 300-500 msec latency; the response to the left cue was more negative than the response to the right cue. This effect was composed of an early negativity (300-400 msec) over right anterior scalp regions, and a later negativity (400-500 msec) over right occipital-temporal scalp sites. The target stimuli elicited enhanced occipital P1 (100-140 msec) and N1 (160-200 msec) peaks when the target appeared at the cued location.

These findings suggest that lateralized executive orienting mechanisms are activated in the response to the attention-directing cues, as first shown by Harter and colleagues (1987). Further, the present data indicate a specialization of the right hemisphere for some aspects of the orienting process. One result of such mechanisms is the preparation of cortical sensory areas for the differential processing of attended and ignored stimuli, thereby leading to improved perceptual representations of, and responses to the target stimuli.

## 145.4

SHIFTING OF VISUOSPATIAL ATTENTION: AN EVENT-RELATED POTEN-TIAL STUDY S. Yamaguchi\*, H. Tsuchiya, S. Kobayashi, T. Tsunematsu, Third Div. of Internal Medicine, Shimane Med. Univ., Izumo 693, JAPAN

Distinct neural systems are involved in sustained and phasic attentional mechanisms. Both hemispheres may separately contribute to phasic attentional allocation while the right hemisphere has superiority in tasks demanding voluntary sustained attention. The current study was designed to clarify the nature of voluntary attention shifts by recording event-related potentials (ERPs) during a visual discrimination task Five visual stimuli were sequentially presented one at a time in a straight line from the periphery through the fovea to the opposite periphery while subjects fixed their eyes to the fovea. The first four stimuli were identical in color and shape. The fifth stimuli was presented with a different color or shape from the preceding four stimuli, or without any changes. In some trials, the fifth stimuli was presented at the spot shifted from the point expected from the four preceding stimuli. Subjects pressed a button when the fifth stimuli changed in color and were obliged to shift their attention from the expected spot to the remote spot immediately after the shifting stimuli were

The fifth stimuli generated a positive-going resolution of the CNV for all stimulus types. An additional positive component (P260) was observed in the ERP elicited by the shifting stimuli. This component had a maximal amplitude at the frontal scalp site and was preceded by a small negative component (N180) maximal at the parietal temporal site. The P260 amplitude depended on the degree of shifting distance and direction. Stimuli with larger shifting generated larger amplitudes associated with shorter latencies. Left-to-right shifting of stimulus spot generated amplitudes in the right hemisphere and vice versa. The N180 amplitude was maximal at the posterior temporal site contralateral to stimulus side. These results suggest that N180/P260 potentials may index the shifting of overt visuospatial attention, and support the notion of separate contribution of each hemisphere on phasic attentional shifting across visu-

SPATIAL AND TEMPORAL PATTERNS OF HUMAN BRAIN ACTIVITY DURING VISUAL SPATIAL ATTENTION, G.V Simpson' and J. Foxe. Depts. of Neurology & Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

We examined the brain regions and their temporal activation patterns underlying visual processing in a spatial attention task. Event related brain potentials (ERPs) were recorded from 50 scalp sites while subjects performed a visual spatial attention task. Small white rectangles were randomly presented at a rapid rate to the left and right of fixation. Subjects attended to the stimuli in one visual field and responded only to the rare smaller rectangles on that side while ignoring all stimuli in the other visual field. Current source density (CSD) maps were calculated and a spatiotemporal generator analysis (BESA) was used to estimate the locations and temporal activation patterns of the active brain regions generating the ERPs. MRIs of each subject's head and brain were used to maximize the accuracy of the spherical volume conductor model used in BESA, and to visualize and evaluate the active brain regions corresponding to the BESA results. CSD maps revealed multiple foci during the P1 and N1 ERP components. The major foci were: at lateral-occipital scalp (contralateral to the eliciting stimulus), followed by a similar focus on the ipsilateral side, a dorsal frontal focus, then dorsolateral posterior foci on both sides. BESA/MRI results revealed the generator complexity underlying the CSD foci and provided an estimate of the active brain generators and their temporal patterns of activation. BESA/MRI results support sequential and overlapping activation of the following brain regions: contralateral (to the stimulus) occipital extrastriate cortex, then ipsilateral extrastriate cortex, anterior cingulate/medial frontal cortex, bilateral dorsolateral parietal cortex and medial parieto-occipital cortex. In those subjects with large enough responses preceding the P1 (60-90 msec), BESA/MRI and CSD suggest a striate source. These spatial and temporal patterns of activation provide some evidence for both serial and parallel flows of processing in cortical areas ranging from striate to frontal and parietal regions during visual spatial attention

THE EFFECT OF PREPARATORY PERIOD ON REACTION TIMES AND P3 LATENCIES IN NEWLY LEARNED AND OVERLEARNED S-R INCOMPATIBILITY TASKS <u>C. A. Christensen\* and K. J. Drake</u>. Dept. of Psychology, Vassar College, Poughkeepsie, NY 12601.

Pfefferbaum, Christensen, Ford & Kopell (1986) found that P3 latency was prolonged on incompatible trials in a S-R incompatibility task, suggesting that P3 latency may reflect aspects of response processing in that task. This conflicts with the widely held hypothesis that P3 latency reflects the duration of stimulus evaluation alone. The P3 prolongation was observed only when compatible (C) and incompatible (I) trials were tested in separate blocks, however. They speculated that the more rapid responding observed during blocked trials may reflect concurrent stimulus evaluation, response selection and execution, conditions which may predispose to prolonged P3 latencies on I trials. In a study of 16 Ss we evaluated this possibility by testing C and I trials together but cued the trial type either 1 or 2 sec in advance of the stimulus words RIGHT or LEFT. We predicted that P3 latency would not be prolonged on I trials with the 1 sec preparatory interval (a finding obtained by McCarthy & Donchin, 1981) but would be observed with a longer period of preparation. The longer preparatory interval produced only marginal effects on RT and P3 latency. As expected, reaction times (RTs) were prolonged on I trials with both intervals (~70 msec), but contrary to the prediction, P3 latency was prolonged at both intervals as well (~30 msec). A second set of 16 Ss was tested in the same task but using two nonsense words instead of the overlearned stimuli LEFT and RIGHT. The findings of the two studies were not significantly different suggesting that the incompatibility effects on RT and P3 latency are robust.

## 145.9

BRAIN VARIABILITY, INDIVIDUAL DIFFERENCES, AND TASK PERFORMANCE OVER TIME. G. W. Lewis\* & D. L. Ryan-Jones. Navy Personnel Research and Development Center, San Diego, CA 92152-6800.

Brain variability has been shown to be inversely related to short-term task and

job performance in both neuroelectric (ERP) and neuromagnetic data. This research addresses relationships between brain variabilty and performance on a 400 trial, 2 letter visual discrimination task which lasted about 24 minutes. ERP data were analyzed from site PZ for 69 male subjects (23 +/- 3 yrs). Data were recorded from 200 ms prestimulus to 1000 ms poststimulus. ERPs were separated into 25 windows, and trials were separated into 8 blocks of 50 epochs each. The first 10 epochs in each block were used to obtain the ERPs. Trial-to-trial variability (TTV) was the summed variance of each of the 154 points in the 10 epoch average of each block. Two groups [high decrement (HD), N=34, low decrement (LD), N=35] were determined from the regression line slope of correct hits. TTV was significantly greater for the HD than the LD from the start of the task, and increased throughout the testing session. The ERP prestimulus TTV showed large statistically significant group differences. The large, and increasing poststimulus TTV of the HD over the LD suggested that the HD may have less adaptation to the task than the LD. This difference in ERP variability probably was not due to attentional factors as the N1 amplitudes were not statistically significant over time. The large group differences in TTV were maximal during prestimulus, early (50-200 ms), and late (850-1000 ms) poststimulus, but were not statistically significant in the 200-850 ms interval. These data suggested that the HD group may be showing a decreased ability to suppress irrelevant background information which would result in a decreased stimulus sensitivity over time. However, the significantly greater TTV in the HD group in the prestimulus records also suggested that the HD individuals may be showing inherently greater processing variability. This abstract does not necessarily reflect the views of the Navy Department.

ATTENTIONAL DEVELOPMENT DURING MATURATION AS ASSESSED WITH SCALP ENDOGENOUS POTENTIALS AND RELATED MEASURES. S.F. Gilson', J.W. Rohrbaugh, J.M. Stapleton, K.Y. Sirocco, G.L. Brown, J.L. Varner, M.J. Eckardt. National Institute on Alcohol Abuse and Alcoholism, Bethesda, MD 20892; National Institute on Drug Abuse, Addiction Research Center, Baltimore, MD 21224; Dept. of Psychiatry, Washington Linix, St. Louis MD 63110.

on Drug Abuse, Addiction Research Center, Baltimore, MD 21224; Dept. of Psychiatry, Washington Univ. Sch. of Med., St. Louis, MO 63110.

The maturation of attention was studied using event-related potential (ERP) and choice reaction time (RT) measures, obtained from 24 children without significant medical diagnosis and without psychiatric diagnosis. Subjects were grouped according to age (8.0 to 13.0, and 13.1 to 18.0 years) and sex. Dichotic listening tasks were designed to elicit several ERP components related to different attentional and cognitive processes; these included N2, P3, Processing Negativity (PRN), and Mismatch Negativity (MMN). ERPs were recorded from midline and lateral central scalp sites.

central scalp sites.

RT and ERP measures showed pronounced developmental changes. Young children had slower RTs and made more errors. Atthough P3 was not affected by age, the younger children produced larger N2, PRN and MMN components. This effect occurred in the absence of any discernible N1 component, attesting to the independence of the attention-related components from the exogenous N1. Performance and P3 amplitude diminished rapidly over time when the task was difficult, at the same rate for younger and older children. The N2 component also diminished but at a faster rate in younger children. No decrement over time was observed for PRN or MMN. These results provide evidence regarding the maturational course of attention, and suggest that the course may not be a linear progression from simple to complex processing.

ERP CORRELATES OF WITHIN SESSION VARIATIONS IN DISCRIMINATION PERFORMANCE. D. Ryan-Jones. G. Lewis. & D. Wetzel\*. Navy Personnel Research and Development Center, San Diego, CA 92152-6800.

Large individual differences in choice reaction time (RT), and response accuracy (HITS) are often seen on relatively simple psychophysiological tasks under conditions in which only minor differences would be expected. Many subjects may exhibit significant performance variability over trial blocks. These changes in performance have been attributed to mechanisms such as learning, adaptation, habituation, fatigue, and changes in cognitive strategies. Although average RT, and HITS may be significantly correlated, it is not clear how ERP amplitude, and latency measures covary with changes in performance over trials for these two behavioral measures. The purpose of this study was to investigate the ERP correlates to changes in performance. ERP activity was recorded from site Pz for 119 male subjects during a 400 trial, 2-letter visual discrimination task which lasted 24 minutes. Behavioral and ERP data were analyzed with respect to eight 3-minute blocks of 50 trials, as well as P3 amplitude and latency at the single epoch level. Variables of interest included absolute performance (HITS and RT), block-to-block performance variability (HSE and RTSE), and rate-of-change in performance over blocks (HSLOPE and RTSLOPE). For the grand averages, HITS and HSE were correlated with P1, N1, P2 and P3 amplitudes, and HSLOPE as correlated with early SW amplitude in grand average ERPs. In contrast, RTTOTAL, and RTSE were correlated with P2, P3, and early SW amplitudes amplitude. For the single-epoch P3 measures, the P3 amplitude was correlated with HITS and RT, and P3 latency was correlated with HITS, HSE, RT, and RTSE. The data suggest that RT and HIT measures are not equivalent measures of performance, and that the two measures may be mediated by different cognitive mechanisms. This abstract does not necessarily reflect the views of the Navy

THETA-ACTIVITY RELATED TO PERFORMANCE <u>S.J.Lauk-ka\*</u>, <u>J.Lindqvist</u>, <u>T.Järvilehto, Yu.I.Alexandrov</u>. Laboratory of Developmental Neuropsychology, University of Oulu, Kasarmintie 4, SF 90100 Oulu, Finland.

Oulu, Finland.

Frontal midline theta-activity reported to appear during mental task (Ishihara et al., 1972) was investigated during goal-directed behavior. In a simulated traffic situation subject had to find the right way for driving a'car' through a set of roads in a computer game. During driving two interdependent decisions had to be made at two crossroads. Feedback about quality of performance was given after each trial. Duration of trial was 10 s. EEG was recorded from Fz.

formance was given after each trial. Duration of trial was 10 s. EEG was recorded from Fz.

Theta-activity during consecutive phases of behavior was analysed. Theta periods were timelocked with the instants of decisions.

Correct driving at crossroads was associated with significantly more theta than the wrong one. The results demonstrate a relation between the appearance of theta and quality of performance in dependence on the phase of behavior.

MATURATIONAL CONSTRAINTS ON CEREBRAL SPECIALIZATIONS FOR LANGUAGE PROCESSING: ERP AND BEHAVIORAL EVIDENCE IN BILINGUAL SPEAKERS. C.M. Weber-Fox\*, H.J. Neville. The Salk Institute, LaJolla, CA 92037.

Recent evidence from event-related brain potentials (ERPs) suggests that cerebral organization is highly specialized for processing functionally distinct aspects of language. ERPs elicited by words that convey the meaning of a sentence (semantics) are distinct in timing and distribution from the ERPs elicited by words that specify the relationship between words in a sentence (syntax). Further, unique patterns of ERP responses were found to distinguish between three types of syntactic processing. Our goal was to investigate the hypothesis that different maturational constraints may affect distinct functional specializations of language systems within and between the hemispheres. Subjects were 61 adult Chinese/English bilinguals who were exposed to English at different points in development: 1-3, 4-6, 7-10, 11-13, and after 16 years of age. The language simuli were 240 sentences which included semantic anomalies, three types of syntactic violations (phrase structure, specificity and subjacency constraints), and their controls. ERPs were recorded as the randomized sentence stimuli were presented on a monitor one word/\$40ms. Subjects judged whether or not each sentence was a "good English sentence." Our findings indicate that age of exposure to a language significantly determines functionally distinct aspects of language processing, and that different aspects of language processing are not uniformly affected by delays in exposure. Behavioral and ERP (N400) responses to semantic stimuli were found to be least vulnerable to delays in exposure (>11 yrs). The ERP and behavioral responses to each of the three types of syntactic stimuli showed earlier (<11 yrs), but not uniform, sensitivities to delays. Our findings are consistent with the view that maturational changes significantly determine the capabilities of humans to acquire language and constrain the development of relevant functional cerebral specializations for language. (NIH DC00054, NIH DC00128)

CONFIGURAL AND FEATURAL PROCESSING OF FACES: ERP AND BEHAVIORAL EVIDENCE I.D. Sarfaty\*, D. Mills, P. Knaudt, and H. J. Neville. UCSD Dept. of Neuroscience, La Jolla, Ca 92093, and The Salk Institute, San Diego, Ca. 92037

Previous research has shown that inverted faces are more difficult to recognize than are upright faces. This 'inversion effect' is disproportionately greater for faces than for other types of stimuli. These findings have been interpreted to indicate that adults employ configural analysis for the recognition of upright faces and featural analysis for the recognition of inverted faces. Clinical and behavioral research have also suggested that the right hemisphere is superior for configural analysis in general, and for

the right hemisphere is superior for configural analysis in general, and for the recognition of upright faces in particular.

We sought physiological evidence concerning these hypotheses and recorded event related potentials (ERPs) from midline and lateral sites in 20 normal adults. Pairs of faces (upright or inverted) were sequentially presented, and subjects were required to make an identity discrimination.

Subjects were faster and more accurate in their responses to the upright faces. Difference ERPs formed by subtracting the ERPs to matched from ERPs to mismatched stimuli revealed that the identity mismatch effect for ERPs to mismatched stimuli revealed that the identity mismatch effect or upright faces was characterized by an asymmetrical negativity (larger over the right hemisphere) beginning around 250 msec. with an antero-central distribution. By contrast, the effect for inverted faces was a symmetrical positivity that onset around 500 msec., with a posterior distribution. ERPs recorded in response to upright and inverted faces thus differed in latency, amplitude, polarity, and distribution. These data support the

hypotheses that a) the right hemisphere is preferentially involved in the recognition of upright faces and b) the recognition of upright faces and b) the recognition of upright and inverted faces is mediated by different neural systems that may be organized for configural and featural processes, respectively. (NIH DC00481)

EVENT-RELATED POTENTIALS CORRELATE OF IMPLICIT AND EXPLICIT MEMORY OF FACES. S. Hertz, P. Porjesz, H. Begleiter\* and D. Chorlian. Neurodynamics Lab., SUNY HSC @ Brooklyn, Brookyln, NY 11203

We have conducted an electrophysiologic experiment to assess the effects of priming in both implicit and explicit face matching paradigms. Subjects were shown a series of pictures of faces interspersed with scrambled pictures of faces of equal size, position and luminance; intermittantly, the same face or scramble would be repeated. During the implicit task, subjects were asked to differentially press buttons to the face and scramble. Subjects were then asked to identify faces from hand held pictures mixed with faces not previously presented to test recognition and ensure that the implicit task was truly implicit. During the explicit task, subjects were presented with the e series of faces and scrambles but this time instructed to press one button to immediately repeated faces or scrambles and another button to different faces and scrambles. For both tasks, recordings were made from 32 EEG electrodes placed according to the 10/20 system, along with an electrode placed over an eye to monitor eye movements. Correct trials were sorted and averaged according to the combination of stimulus and preceeding stimulus: face/same face, face/different face, face/scramble, scramble/same scramble, scramble/different scramble and scramble/face. Reaction times were recorded. We observed a series of evoked potentials consisting predominantly of a P160, N180 and P240 with a posterior, bitemporal distribution and an amplitude maximum over the right posterior temporal region. Implicit and explicit priming effects were present predominantly over bilateral, anterior, mid and posterior temporal regions and reflected by reduction of the P240 amplitude. This P240 am plitude effect was more pronounced for the explicit task. These data reflect a novel set of neurophysiological observations on implicit and explicit memory for faces Supported in part by the New York State Office of Mental Retardation and Develop-

EVENT-RELATED POTENTIALS ASSOCIATED WITH SHIFTING VISUAL ATTENTION IN NORMAL CHILDREN AND CHILDREN WITH CEREBELLAR LESIONS. N. A. Akshoomoff\*, and E. Courchesne. Depts. of Psychology and Neurosciences, UCSD, La Jolla, CA 92093, and Neuropsychology Research, Children's Hosp. Res. Ctr., San Diego, CA 92123.

Event-related potentials (ERPs) were recorded while 8 normal children

(ages 7-11) and 5 children with cerebellar lesions as a result of removal of a cerebellar astrocytoma (ages 8-11) were presented with randomized sequences of centrally located form and color stimuli on a computer screen In the shift attention experiment, subjects responded to the target stimulus in one category (form or color), shifted their attention to the other stimulus category, and responded to the first target stimulus in that category. The target thus served as a cue to shift attention. In the focus attention experiment, subjects maintained their attention and responded to the target stimulus in one category. The frontal Nc component was found to be more negative when normal children maintained their attention than when they shifted their attention. The posterior P3b component was similar in amplitude across both experiments in normal children. Difference waves betwe focus and shift attention revealed a posterior positive component longer in latency than the P3b (labeled the Shift Difference or Sd wave). The present data demonstrate that children have ERPs that are similar to adults when they rapidly shift their attention. Compared to normal children, the patients with cerebellar lesions had abnormally small P3b and Sd responses to the signal to shift attention and were significantly impaired in their ability to rapidly shift attention. Both the reduced cognitive ERPs and reduced capacity to rapidly shift attention in these patients have important implications for the role of the cerebellum in cognitive operations, and suggest that cerebellar damage affects operations that may be primarily mediated by the cerebral cortex

SIGNALING IN DISTRIBUTED NEURAL SYSTEMS. V. Menon. EEG Systems Lab., 51 Federal St., San Francisco, CA,94107

A theoretical study of nonlinear interaction between neuronal populations was undertaken to gain insight into the functioning of distributed neural systems. Temporal characteristics of the interaction are studied using, in addition to numerical simulations, simplified relations between the frequency, amplitude, and phase of the response

Signaling between populations is shown to give rise synchronization, desynchronization, and resynchronization (with a large jump in frequency and spatial phase difference) of the oscillatory activity as the latency of the reentrant signal is varied. During the desynchronized phase, the temporal response is chaotic and the two-population correlation is reduced substantially. This phenomenon represents a rapid (correlation-dependent) switching mechanism. The study further reveals topological effects - (1) spatial amplitude modulation and (2) existence of stabilizing (closed loop) and

destabilizing (open loop) circuits.

These spatio-temporal features are likely to be important in cognitive processing.

NON-LINEAR CORTICAL DYNAMICS ("CHAOS") AND MENTAL COMPLEXITY. N. Birbaumer\*, W. Lutzenberger & Elbert. Inst. of Medical Psychology, Univ. of Tübingen, Tübingen, Germany, 74.

EEG-recordings from 16 cortical sites during mental tasks with different complexity were recorded in 52 healthy subjects with above average (IQ>100) and below average (IQ<100) intellectual ability. EEGs were analyzed with conventional power-spectra and (non-linear) dimensional analysis using the algorithm of Farmer et al (83) to determine phase space dimensions of extended time series such as the EEG.

Tasks were of sensory (tactile and visual discrimination) and verbal (alliteration) nature, all tasks were performed "invivo" and in imagination. Several imagery tasks were used. Results demonstrate higher dimensionality ("fractal complexity") during non-task rest conditions in intelligent subiects and increased frontal complexity during imagery compared to "in-vivo" tasks. Conventional EEG analysis did not show meaningful differences

INTRACEREBRAL MEASURES OF LATERALIZED PROCESSING IN HUMANS: EFFECTS OF VISUAL FIELD, RESPONSE HAND AND PROCESSING STAGE. "J.M. Clarke", "P. Chauvel. "J.-M. Scarabin, "E. Haloren." Laboratoire de Neurosciences, INSERM CJF90-12 & "INSERM U335, Univ. Rennes I, 35033 Rennes, France.
Intracerebral recordings were acquired from 17 epileptic patients while they performed a lateralized visual discrimination task. Across these neurosurgical candidates, a total of 115 'depth' electrodes were implanted for seizure localization, permitting recordings from over 1,000 cortical and limbic sites. While maintaining central fixation, subjects responded to rarely occurring targets (e.g. a "o"), but not to frequent nontargets (e.g. a "+"), presented to the four corners of a CRT screen.

A series of visual components (N170-P200-N260) were recorded in a cocipital and posterior inferotemporal cortices, which were larger (by 20-30 µV) and usually earlier (by about 20 ms) for stimuli presented to the visual field (VF) contralateral to the side of the electrode. An unmistakable visual quadrant effect (260 ms peak latency) was apparent in one patient in putative visual area 19. 'Cognitive' P3-like components to rare stimuli (300 to 500 ms peak latency) were reliably recorded in limbic and orbitofrontal locations, and sometimes in parietal sites. When present, the P3s were elicited by either VF with equal amplitudes. Hippocampal P3s showed VF latency effects, being typically 20 ms earlier for contralateral presentations. Finally, a late negative-going component (400 to 600 ms onset) was common for medial and lateral peri-rolandic sites, and was usually undifferentiated by VF or response hand. Clearly lateralized somatosensory and motor responses (500-650 ms peak latency) were recorded in one electrode that coursed through the somatomotor strip.

latency) were recorded in one electrode that coursed through the somatomotor strip.

For this task, it appears that only early visual input and final motor output stages are lateralized. Both cerebral hemispheres appear to be equally engaged for intermediate cognitive stages even though this type of task probably can be performed by a single hemisphere. CONDITIONING STIMULUS PREEXPOSURE MODIFIES PRE-TRAINING HIPPOCAMPAL ACTIVITY. S.D. Berry\*, R.L. Borgnis, and L.J. Dreshfield. Psych.Dept., Miami Univ., Oxford, OH 45056.

To clarify the role of the hippocampus in classical conditioning, we examined the effects of prior exposure to conditioning stimuli on patterns of hippocampal activity and the acquisition patterns of hippocampal activity of the acquisition patterns of hippocampal activity. related to acquisition rates in rabbits. New Zealand White rabbits were implanted with stainless steel extracellular microelectrodes under anesthesia (ketamine 50mg/kg), xylazine 10mg/kg). Group P was exposed to the stimuli prior to the onset of classical jaw movement conditioning. Group C was not pre-treated. One minute samples of unit and slow wave activity from CA1 were recorded before and after each session. Slow wave frequency analysis showed that there session. Slow wave frequency analysis showed that there were no differences between groups prior to adaptation to the apparatus (F (1,9)=0.67, p).44). After the preexposure phase but before the beginning of conditioning, the groups had significantly different frequency distributions (F (1,9)=11.22, p<.006). Such variations have been shown to precede differences in the rate of behavioral learning and in the development of conditioned unit activity (Berger, Berry, & Thompson, 1986). This result suggests that the effects of stimulus preexposure alter the behavioral effects of stimulus preexposure alter the behavioral state of the animal prior to (as well as in response to) the occurrence of the conditioning stimuli, and that the hippocampus participates in the hypothesized reduction in stimulus salience.

Changes in Conditioning-Related Neuronal Activity in Rabbit Lobule HVI of Cerebellar Cortex During Backward, Unpaired and Forward Conditioning. T. J. Gould\* & J. E. Steinmetz. Dept of Pysch., Prog. in Neural Science. Indiana University, Bloomington, IN 47405

At least two areas of the cerebellum are believed to be involved in conditioned stimulus (CS)-unconditioned stimulus (US) association during classical conditioning; lobule HVI and the interpositus nucleus. The goals of the present study were to examine multiple unit HVI activity during two scenarios: 1.) Backward conditioning (US-CS) paired presentation) followed by forward conditioning (CS-US paired presentation), and 2.) Unpaired training and subsequent forward conditioning. Twelve animals received 5 consecutive days of backward conditioning followed by forward conditioning until treathed a conditioning criterion for two days. Tone CSs and airpuff USs were used. Four additional animal received 5 days of explicitly unpaired training followed by forward conditioning until reaching criterion for two days. In some HVI recording sites, a significant increase in US-related activity was seen over the five days of backward training and these sites all showed well-sculpted amplitude-time course models of the learned response during forward training. In other sites, a significant decrease in US-related activity was seen over the five days of backward training and these sites did not show amplitude-time course models of the learned response during forward training. Both of these patterns were seen to a lesser extent in animals receiving explicitly unpaired training. During both backward and unpaired training, activity was largely concentrated early in the trial but across forward training large amounts of activity in both the early CS period and US period decreased as activity in the late CS period increased. These data demonstrate that several patterns of excitatory, multiple-unit, conditioning-related activity in cerebellar cortex can be observed as training cons

SINGLE-UNIT ACTIVITY IN VENTROLATERAL PONS DURING CON-DITIONING OF THE RABBIT NICTITATING MEMBRANE RESPONSE. M. J. Hirl and J.W. Moore. Dept of Psychol, Univ of Mass, Amherst, MA

This study examined the activity of single-units in the ventrolateral pons during differential classical conditioning of the rabbit nictitating membrane (NM) response. We were particularly interested in the response of units in the pontine reticular formation (RF) and dorsolateral pontine nuclei (DLPN). Moore et al., (Biol. Cybern., 62:17, 1989) present a brain implementation of a model of NM conditioning which purports parallel learning in cerebellar cottex and brainstem with RF as a possible brainstem site. For RF to be a site of parallel learning, it must receive US information, and thus should contain units which respond to US. The model assumes that DLPN propagates CS information to cerebellar cortex. CR-related activity in DLPN is not predicted by the model's implementation, given the motor program originates efferent

McCormick et al., (Brain Research, 271:73, 1983) investigated multi-unit recordings from RF and DLPN. Both showed activity closely coupled to the conditioned stimulus (CS) and CR. They did not observe activity to the un-

conditioned stimulus (US).

We trained rabbits to differentially respond to a reinforced CS+ and nonreinforced CS- (tones of 1200 and 600 Hz, 80 dB, 350 ms). The US was a single pulse of DC current applied to the periorbital region of the right eye. Under anesthesia rabbits were prepared for subsequent recording by exposing the dura and cementing a recording chamber in place. RF units were responsive to events during conditioning, 39% were coupled to CSs, 33% to US, and 28% to CRs. Thus far, we have found no units in DLPN with activity related to CRs. Our results support the the model's implementation

LONG-TERM DEPRESSION AND CLASSICAL CONDITIONING OF THE RABBIT NICTITATING MEMBRANE RESPONSE: AN ASSESSMENT USING THE RABBIT CEREBELLAR SLICE. B. G. Schreurs\* and D. L. Alkon. Neural Systems Section, NINDS, NIH, Bethesda, MD 20892.

Long-term depression (LTD) has been proposed as a mechanism underlying

classical conditioning of the rabbit nictitating membrane/eyelid response (NMR). However, LTD in cerebellar slices has only been obtained in the presence of GABA inhibitors which abolish disynaptic ipsps, and even then the temporal sequence of events (climbing fiber - parallel fiber) has been the reverse of that used in classical conditioning (CS-US)

Based on intradendritic Purkinje-cell recordings obtained from rabbit cerebellar slices, we report that stimulation (80  $\mu$ s, 4 Hz, 30 s) of parallel fibers in the absence of GABA inhibitors produced a small, brief depression of parallel fiber epsp amplitude (-10%, 4 min, n=17) that then became a longer lasting potentiation (20%, 12 min). However, if parallel fibers were stimulated during depolarization-induced local dendritic calcium spikes, significant, prolonged depression emerged (-35%, 17 min, n=19, p <.001). Presentation of climbing fiber and parallel fiber stimulation in either an LTD or classical conditioning-like order (80 µs, 4 Hz, 30 s, 50 ms interstimulus interval) without GABA inhibitors produced brief, weak depression (-20%, n=10; -15%, n=13, respectively). Presumeably, the depolarization and consequent calcium influx into the Purkinje-cell dendrite produced by climbing fiber synaptic potentials were less effective than the prolonged, direct depolarization induced by current injection through the recording electrode. Finally, stimulation of parallel fibers at frequencies used in in vivo conditioning experiments (100 Hz) produced profound, longlasting epsp depression. The depression occurred in the absence of climbing fiber stimulation and was reminiscent of transmitter rundown.

# 146.4

A POSSIBLE MECHANISM FOR ASSOCIATIVELY DECREMENTING US PROCESSING IN RABBIT EYEBLINK CONDITIONING T. Canli\*, J. Anthony, and N.H. Donegan. Dept. of Psychology, Yale Univ., New Haven, CT. 06520.

and N.H. Donegan. Dept. of Psychology, Yale Univ., New Haven, CT. 06520. The cerebellar interpositus nucleus (IP) and red nucleus (RN) are activated by a conditioned stimulus in eyeblink conditioning, and are thought to be involved in decrementing US processing and contribute to the Kamin blocking effect and conditioned diminution of the UR (Donegan et al., 1989, Psy. Learn. & Motiv. 1989, 23, 109). Support comes from the finding that electrical stimulation of the IP or the RN shortly before a periorbital shock-US decrements the unconditioned eyeblink response in rabbits (Canli, Whitney, & Donegan, Neurosci. Abstr., 1991). This decrement was observed both ipsi- and contralateral to the stimulation site. The present experiment was designed to assess the extent to which the decremental effect of IP stimulation is relayed through the RN. We combined electrical stimulation of the IP with chemical inactivation of the RN, using the excitatory amino acid antagonist glutamyl-glycine (0.5 ul. 50 nmol), Fourteen New Zealand male rabbits antagonist glutamyl-glycine (0.5 µl, 50 nmol). Fourteen New Zealand male rabbits were implanted with a pair of unipolar stimulating electrodes in the region of the left IP, and a guide/infusion cannula targeted at the right RN. The effect of IP stimulation was tested for 22 trials (10 US-alone, 10 Stim ->US, 2 Stim-alone sumulation was tested for 22 mas (10 05-acione, 10 3mil ->05, 2 5mil-acione trials; parameters as in Canli et al., 1991). Subjects then received infusions of glugly (day 1) or aCSF (day 2) into the RN. Testing was then resumed for another 78 trials (35 US-alone, 35 5tim->US, 8 5tim-alone trials). Infusion of glu-gly into the RN significantly attenuated IP stimulation-induced UR diminution, regardless of RN significantly attenuated IP stimulation-induced UR diminution, regardless of whether diminution was observed jps-ior contralateral to the IP stimulation site. Thus, the decremental effect of IP stimulation on eyeblink UR amplitude appears to be relayed through the RN. The same subjects were then tested for the effect of chemical stimulation of the RN in response to repeated facial shock-USs, using the excitatory amino acid kainate (0.2  $\mu$ l, 235 pmol). Chemical stimulation of the RN bilaterally decremented the average cyeblink amplitude, suggesting that activation of the RN, not fibers of passage, affected US processing; possibly directly, via crossed rubrospinal projections, and indirectly, via uncrossed rubrobulbar projections .

CONDITIONED POTENTIATION OF THE RAT EYEBLINK REFLEX. N. H. Donegan\*1 and T. H. Brown<sup>1,2</sup>. Depts. of Psychology<sup>1</sup> and Cellular and

Molecular Physiology<sup>2</sup>, Yale University, New Haven, CT. 06520.

The eyeblink reflex has proven useful for neurobiological studies of Pavlovian conditioning (Donegan et al, *Psychol. of Learn. and Motiv. 23*, 109, 1989). Although most of the work has been done on restrained rabbits, recent studies have begun to explore eyelid conditioning in unrestrained rats (Skelton, Behav. Neurosci. 102, 586, 1988). The use of rats may be superior for studies that

Neurosci. 102, 586, 1988). The use of rats may be superior for studies that require the same species to be used for both in vivo and in vitro analysis.

The lid closure during a reflex blink is generated by a passive downward force plus active contraction of the orbicularis occuli (00) muscle. Reflex eyeblinks were elicited by electrically stimulating the fifth cranial nerve. Stimulation was delivered through a bipolar electrode that was uninsulated on the inner surface of a cuff that surrounded the nerve. The EMG response was measured with a monopolar electrode that was implanted in the oo muscle. The amplified EMG was filtered at 0.3 kHz and 5 kHz, digitized at 5 kHz, and rectified. The EMG response was roughly 100 times greater than the recording noise (about 20  $\mu$ V).

Stimulation of the fifth nerve produced two distinguishable EMG responses. The R1 response had a short latency (6 - 6.5 ms) that was relatively invariant over trials. The R2 response had a lower threshold and longer latency (15 - 20 ms) that was quite variable. In response to 1 Hz stimulation, the R2 amplitude ins) has was quite variance. In response of 1 rea summation, the R2 amplitude diminished whereas the R1 amplitude remained invariant. We are currently examining the modulatory effects of fear conditioning on the R1 and R2 amplitudes. Of particular interest is the possible role of the amygdala in conditioned potentiation of the eyeblink reflex (cf. Harden et al, Soc. Neurosci. Abstr. 16, 269, 1990). Supported by NIH and the Whitehall Foundation

RETENTION OF NM VISUAL CONDITIONING AFTER VISUAL DISCONNECTION OF THE CEREBELLUM. I. Steele Russell\*, Anatomy, Texas A&M University, College Station, TX. 77843.

A mid-sagittal section of the optic chiasma in the rabbit will leave intact only the ipsilateral retinal ganglion cell fibers. All retinal NOT projections are destroyed.

Rabbits were trained on both brightness and pattern discriminations in the 2-choice situation, and then to both a light and a tone CS using NM response. The optic chiasma was cut, and they were tested for retention in both situations. All animals showed rapid re-learning of both visual tasks, clearly establishing the point that all animals could see.

Without exception all animals with complete section of the optic chiasma showed no retention of the Pavlovian visual conditioning. They were also unable to relearn it. In contrast rapid and acquisition of NM responses was obtained to the tone CS, showing that the failure of visual conditioning was not due to a motor impairment. With incomplete chiasma section there was a graded relationship between the amount of crossed fibre sparing and the amount of OKN and NM conditioning. When the chiasma-section was complete there was neither any OKN nor any NM conditioned responding. All animals conditioned to the auditory CS, independent of the amount of chiasma fibre sparing.

This argues that the same oculomotor circuitry that is controlling the OKN and VOR is also involved in visual conditioning of the NM response. Thus it is possible that lesions of the cerebellum affect Pavlovian conditioning either by disrupting the oculomotor control system that mediates the expression of the learning, or because it destroys the neural site of memory storage. Where only one measure is taken of conditioning, which involves an oculomotor response system, these two theoretical alternatives are inseparable.

## 146.9

HIPPOCAMPAL LESIONS DISRUPT LATENT INHIBITION. B.A Christiansen and N. A. Schmajuk\*. Department of Psychology, Northwestern University, Evanston, IL 60208.

The effect of hippocampal lesions on latent inhibition of the classically conditioned eyeblink response in rats was examined with a procedure described by Schmajuk and Christiansen (1990). Male, Long-Evans hooded rats received either sham (S), cortical control (CC) or hippocampal (HL) lesions. Animals were assigned to either the or hippocampal (HL) lesions. Animals were assigned to either the preexposed (PRE) or the non-preexposed condition (SIT). PRE animals received 100 CS-alone presentations per day for four consecutive days following habituation. SIT animals remained in the experimental chamber without stimulus presentations during the preexposure phase. On the fifth day animals received 50 CS-alone presentations (or 25 minutes in the SIT condition), followed by 50 CS-US pairings. All groups received four additional days of conditioning (100 trials per day). The conditioned stimulus (CS) was a 85 dB, 500 ms, 1,200 Hz tone; the unconditioned stimulus (US) was a 5psi, 150 ms air puff; the interstimulus interval was 350 ms; and the intertrial interval was 30 s.

Both CC and S groups, but not the HL group showed latent inhibition. On the final day of training, PRE control animals exhibited significantly fewer CRs than SIT control animals (F [1, 17] = 5.76, p <0.5). Conversely, PRE HL and SIT HL animals did not differ in the number of CRs generated (F [1, 17] = 1.64, p > .05). Furthermore, a comparison between HL and control animals revealed a significant interaction between lesion type and treatment (F [1, 17] = 4.80, p < .05). (Supported by ONR Grant N00014-91-J-1764.)

# 146.11

MODULATION OF ACTIVITY IN THE MEDIAL GENICULATE NUCLEUS DURING AUDITORY TRACE CONDITIONING.

K.N. O'Connor and J.W. Moore\*. Dept of Psychol, Univ of Mass, Amherst,

In classical trace conditioning the acquisition of a CR is dependent on neural coding of the CS following its termination. There is evidence that the medial or magnocellular region of the medial genicualate nucleus (mMGN) is one area where this coding may occur; it is essential to the acquisition and maintenance of successful discrimination of auditory stimuli in the conditioning of bradycardia in rabbits (Jarrel, et al., Brain Res, 382:199, 1986), and multi-unit reponses to reinforced tones in this region increase during conditioning in comparison to non-reinforced tones (Disterhoft & Olds, J. Neurophys, 35:665, 1972)

Single cell activity was recorded from the MGN during differential trace conditioning of the rabbit nictitating membrane response (NMR). Rabbits were first trained to discriminate between a reinforced CS+ and nonreinforced CS- (tones of 600 or 1200 Hz) 150 ms in duration followed by a 200 ms trace interval. The US was electrostimulation to the periorbital region of the eye. The rabbits were then prepared for subsequent recording; under anesthesia the dura was exposed, and a recording chamber cemented in place

Responses of cells in the mMGN tend to be transient and related to the type of CS, primarily showing greater modulation in firing rate to the CS+. Presentation of probe CSs of varying duration suggest a relationship between these responses and NMR timing and topography.
(Supported by AFOSR grant 89-0391 and NSF grant BNS 88-10624)

LESIONS OF THE MEDIAL PREFRONTAL CORTEX IMPAIR REVERSAL OF CLASSICALLY CONDITIONED EYEBLINK RESPONSES IN RABBITS. Chachich\* and D.A. Powell. VA Medical Center, oia, SC 29201 and Department of Psychology, Columbia. University of South Carolina, Columbia, SC 29208.

The medial prefrontal cortex (mPfc) is important flexible response strategies, such as those involved in the Wisconsin Card Sorting Task. This study extends the findings that the mPfc is involved in non-perserverative responding to classical eyeblink (EB) conditioning

The mPfc of rabbits was bilaterally aspirated bregma to the olfactory bulbs. In sham operated animals a skull flap was removed, but no lesion was made. Both groups received differential EB conditioning (304 & 1216 Hz tones were CSs and paraorbital shock was the US), until responding to the CS+ was 30% greater than to the CS- over two consecutive days. Reversal training then began, in which the reinforced CS+ and nonreinforced CSwere switched. Again reversal was terminated when the rabbits responded to the CS+ at a 30% higher

than to the CS- over two consecutive days.

mPfc lesions had no effect on the original discrimination, but when compared to the sham operated control animals, lesioned animals showed an impairment in These results thus suggest reversal learning (p<.01). These results thus suggest that the mPfc is necessary for conditioned reversal of the EB response.

EXCITABILITY TO INTRACELLARLY INJECTED DEPOLARIZING CUR-RENT OF CORTICAL NEURONS SHOWING PRE-MOVEMENT SPIKE ACTIVITY IN CONSCIOUS RATS TRAINED TO LICK TO A LIGHT CUE STIMULUS. C.D. Woody\* and E. Gruen. UCLA Med. Ctr., MRRC, BRI, Los Angeles, CA 90024.

Rats were trained to lick water after the onset of a light cue stimulus. Extracellular and intracellular recordings of unit activity were made from the rostral cor-tex during performance of the behavior. Averages of activity were made a) synchronized to the light onset and b) synchronized to the first lick after light onset (by b) synchronized to the first fick after fight onset (by back averaging). Neural excitability was measured by the number of spikes elicted by intracellularly applied, 80 ms, 1 nA, depolaring pulses. Mean (n = 74 units) increases in activity > 3Z above background activity were found to be temporally correlated with production of the licking rather than responding to the visual cue. No differences rather than responding to the visual cue. No differences in excitability were found between 28 cells showing increased pre-lick activity (mean 4.14 spikes/pulse) and 14 other cells that did not (4.28 spikes). The results favor the hypothesis that a mechanism other than the tonic excitability changes found to support Pavlovian conditioning supports the increased lick activity in these cells and the large, previously reported EPSPs that precede licking, or that the adaptations occur in cells prior to these along the involved sensorimotor pathways. (Supp. HD05958. We thank M.P. Kristensen for his contributions to this study and G. Cheng and R. Folia for technical assistance.)

SIMULTANEOUS SINGLE UNIT RECORDING IN THE ACOUSTIC THALAMUS AND THE AMYGDALA THROUGHOUT HABITUATION, DIFFERENTIAL ACQUISTION, AND EXTINCTION OF THE RABBITS CONDITIONED HEART RATE. M.D. MEEDITON. P.M. McCabe\*. E.J. Green. and N. Schneiderman. Department of Psychology and Neurosciences Program, University of Miami, Coral Gables, Fl. 33124.

Previous research has shown that the posterior acoustic thalamus and the amygdala are critical regions for the acquisition and expression of classically conditioned heart rate (HR) using acoustic conditioned stimuli (CS). It has been demonstrated that single units in the medial subnucleus of the medial geniculate nucleus (mMG) and the amygdaloid central nucleus (ACe) exhibit associative changes in response to acoustic CSs. The purpose of the present study was to examine simultaneous single unit responses in the acoustic thalamus and the amygdala. Following recovery, each animal received one conditioning session that included habituation, differential acquisition, and extinction trials. During differential HR conditioning two tonal CSs (2 s; 560 or 1350 Hz) were presented, one of which was paired with a corneal airpuff unconditioned stimulus (US; 0.5 s; 15 N/cm²). The results focus on two areas of the posterior acoustic thalamus, the mMG and the posterior intralaminar nucleus (PIN). Within the amygdala, most recorded cells were in ACe. The areas mMG, PIN, and ACe were found to contain cells which show short latency (<100 ms) responses to the initial presentation of both tones. During differential conditioning, units in these regions exhibited differential responding to the tones. Differential responses developed gradually, and in some cases were correlated with the magnitude of the HR response on an individual trial basis. Extinction was associated with a decrease in differential responding in the mMG (PIN, and, ACe. Cells in these areas also exhibited short latency responses to the US alone. These findings provide evidence that associative changes in unit responding occur in t

DISCRIMINATION TRAINING INDUCES SELECTIVE RECEPTIVE FIELD (RF) PLASTICITY IN THE AUDITORY CORTEX DURING BOTH EASY AND DIFFICULT TASK. Jean-Marc Edeline\* & Norman Weinberger, Center Neurobiology of Learning and Memory and Dept Psychobiology, UC IRVINE CA 92717.

Dept Psychobiology, UC IRVINE CA 92717.

CS frequency-specific RF plasticity develops in the auditory cortex (ACx) during classical conditioning to a single tone (Br. Res. 372: 357, 1986; Br. Res. 536:271, 1990). We report here the effects of discrimination training at two levels of task difficulty. RF (single unit n=9, cluster n=32) were determined before and after a single session of tone shock training. The CS+ and the CS- (6 s in duration) were pure tone frequencies selected to be in the cells' RF without being the pre-training best frequency (BF). A clear behavioral discrimination (conditioned bradycardia to the CS+ only) was observed after completion of training in the easy task, while the same animals failed to discriminate (they showed similar bradycardia to the CS+ and the CS-) when the 2 frequencies were closer during the difficult task. However, at both levels of task difficulty, selective RF plasticity was observed in the ACx. Responses to the CS+ increased while responses to the pre-training BF and to the CS- decreased . These changes were large enough to shift the BF to the CS+ frequency in 49% cases (20/41). The shifts to the CS+ frequency were maintained and even stronger 1hr. post training. These results suggest that selective RF plasticity is not tightly linked to behavioral performance but rather reflects highly selective acquisition of information. SINGLE UNIT CS-SPECIFIC RECEPTIVE FIELD PLASTICITY IN THE AUDITORY CORTEX IN AVOIDANCE TRAINING. <u>D. A.</u>

J. S. Bakin and N. M. Weinberger. Cntr. Neurobiol. Learn. & Neurophysiological studies of learning in behaving subjects have benefitted from cluster recordings (CC). For example, classical and instrumental conditioning produce CS-specific receptive field (RF) plasticity in guinea pig primary auditory cortex (AC) (Bakin et al, Neurosci. Abst., 1988, 14, 862; Bakin & Weinberger, Br. Res., 1990, 536, 271). However, as CL consist of contributions from an indeterminate number of single unit waveforms (SU), the extent to which highly specific plasticity develops within SU in the primary AC and the degree to which CL consists of heterogenous SU plasticity are unknown. To resolve these issues, and also to determine if RF plasticity at the level of SU develops for instrumental conditioning, we plasticity at the level of SU develops for instrumental conditioning, we used waveform sorting algorithms to obtain SU and CL simultaneously from the primary AC of guinea pigs trained to avoid shock in a running wheel (CS = 10 sec tone, 30-60 trials in one session to a criterion of consistent avoidance). RF were obtained before and after training. We found highly specific RF plasticity within SU, e.g., increased response to CS frequency and decreased response to pretraining best frequency. Also, different patterns of plasticity were observed for SU within cluster recordings. Therefore, highly specific RF plasticity is a property of single cortical cells and cells within the same locale (which yield CL) can exhibit different dynamics due to learning. Supported by ONR can exhibit different dynamics due to learning. Supported by ONR N00014-91-J-1193.

LONG-LASTING CS-SPECIFIC RECEPTIVE FIELD PLASTICITY IN AUDITORY CORTEX IS EXPRESSED UNDER ANESTHESIA. Roxanna Javid, Branko Lepan, Gabriel K Hui and Norman M Weinberger\* Cntr. Neurobiol. Learn. Mem. & Dept. Psychobio. Univ. California, Irvine, Ca., 92717.

Receptive field plasticity in sensory neocortex during development and after peripheral denervation has been observed in anesthetized subjects. Brief learning experience (classical conditioning) induces subjects. Brief learning experience (classical conditioning) induces frequency specific receptive field (RF) plasticity in the auditory cortex (AC) of the cat (Diamond and Weinberger, Br. Res. 372:357, 1986) and guinea pig (Bakin and Weinberger, Br. Res. 536:271, 1990) in the waking state. This plasticity is characterized as increased response to waking state. Inis plasticity is characterized as increased response to the CS frequency and decreased responses to other frequencies, including the pretraining best frequency (BF). This experiment determined if such RF plasticity established in the waking state can be expressed under general anesthesia. We obtained frequency RFs in expressed under general anestnesia. We obtained frequency KFS in guinea pigs under Nembutal (Nem) or Ketamine/Xylazine (K/X) anesthesia, before and repeatedly after (1 hr. – 8 wks.) a 20-30 trial session of non-BF tone-shock pairings. CS-specific RF plasticity was found in 6/7 (86%) Nem and 6/8 (75%) K/X subjects. In several cases, this plasticity lasted 8 wks. after training. Therefore, learning-induced CS-specific RF plasticity transcends the state under which it was established and can be expressed under anesthesia for very long retention periods. The extent to which RF plasticity in development and following injury involves learning remains to be determined. Supported by ONR # N0014-91-J-1193.

THE DIRECTION OF THE CONDITIONED NATURAL KILLER CELL RESPONSE CAN BE RE-DIRECTED WITH INDOMETHACIN AND/OR HANDLING. C. Rogets\*, V.

INDOMETHACIN AND/OR HANDLING. C. Rogers\*. V. Ghanta. C-M. Hsuch. N. Hiramoto, and R. Hiramoto. Departments of Biology and Microbiology, University of Alabama at Birmingham, Birmingham, Alabama 35294.

We have used the pairing of camphor odor conditioned stimulus (CS) and injection of poly I:C unconditioned stimulus (US) in a short 3 day single trial conditioning paradigm. Conditioning was done by exposing mice to the CS/US combination on day 0 and reexposing the conditioned animals to the CS on day 2. This results in a conditioned aumentation of the natural siller (NK) call in a conditioned augmentation of the natural killer (NK) cell response. Indomethacin treatment and/or handling stress induced by simply measuring rectal temperature was found to dramatically alter the direction of the conditioned NK cell response. Conditioning of indomethacin treated mice produced a conditioned suppression of the NK cell response mimicking a conditioned tolerance response. If handling stress was superimposed on day 2 the conditioned suppression response was replaced by a conditioned augmentation of the NK cell response. Even with one trial conditioning, drugs and handling stress can serve as additional cues to alter the direction of the conditioned response. The studies also show that the conditioning of the fever response is independent of conditioning of the NK cell response.

GONADAL STEROIDS AND CHOLINE INTERACT DURING DEVELOPMENT TO IMPROVE RADIAL-ARM MAZE PERFORMANCE AND INCREASE HIPPOCAMPAL NGF IN ADULT RATS. E. Gorry!, R. Loy?, J.K. Blusztain?\*, W.H. Meck, & C.L. Williams. College of Physicians and Surgeons! and Depts. of Psychology, Columbia Univ.4 and Barnard Colleges, New York, NY 10027; Canandaigua VAMC and Dept. of Neurology, Univ. Rochester, Rochester, NY 14620; Dept. of Pathology, Boston Univ. School of Medicines, Boston, MA 02118.

Recent work has shown that choline chloride administered during

Recent work has shown that choline chloride administered during ED 12-17 and PD 16-30 produces a long-term enhancement of visuospatial memory in male rats. In female rats choline is less effective in producing a memory improvement. To determine whether sensitivity to choline is influenced by endogenous perinatal gonadal steroids in male rats, choline-treated (ED 12 - PD 30) and control rats were either castrated or given sham surgery within 24 hrs of birth. At 50 days the sham surgery rats were castrated. Training on a 12-arm radial maze with 8 baited and 4 unbaited arms revealed an enhancement of overall with 8 batted and 4 undatted arms reveated an enhancement of overail choice performance by neonatally intact choline-treated male rats compared to the other 3 groups. Following behavioral training, 4 subjects from each of the groups were sacrificed, hippocampal regions dissected, frozen, homogenized, and assayed by ELISA for NGF. Hippocampal NGF was significantly elevated in neonatally intact choline-treated rats. Neonatally castrated rats did not show the cholineinduced increase in NGF. These data suggest that organizational effects of perinatal choline on spatial memory may be dependent upon exposure to neonatal steroids. Both factors may play a role in regulating NGF levels in the developing hippocampus. (Supported by PO1 AG09523)

SELECTIVE DEVELOPMENTAL ACCELERATION OF RELATIONAL CUE NAVIGATION AND REDUCTION OF AGE-RELATED IMPAIRMENTS IN SPATIAL PROCESSING BY PRENATAL SUPPLEMENTATION WITH CHOLINE, N. L. Dallali\*, W. H. Meck! & C. L. Williams<sup>2</sup>, Departments of Psychology, Columbia University<sup>1</sup> and Barnard College<sup>2</sup>, New York, NY 10027.

Choline supplementation during prenatal development has been

Choline supplementation during prenatal development has been shown to enhance rats' spatial memory as adults. Because prior studies have focused on adult behavior as a consequence of these organizational changes occurring during infancy, the impetus for the current study was to look at these effects as they appear developmentally and to examine the longevity of memory enhancement into old age. A comparison of water maze performance for prenatal choline-treated (embryonic days 12 to birth) versus untreated Sprague-Dawley male and female rats was made at three time-frames spanning postnatal days 18-28. The results indicated that the development of relational, but not proximal, cue use is advanced by as much as three days for choline-treated rats. Due to the involvement of the hippocampus in relational cue use, these results support previous indings that this late developing structure is sensitive to prenatal choline supplementation. Additionally, repeated-acquisition water maze testing with these same groups of rats at 21 months showed that the level of age-related impairments in spatial working-memory function was significantly reduced for both male and female rats treated prenatally with choline. These data support the proposal that prenatal choline supplementation offers advantages for hippocampal-dependent memory function across the entire lifespan. (Supported by PO1 AG09523)

CHOLINE SUPPLEMENTATION DURING PRENATAL DEVELOPMENT INOCULATES AGAINST THE AGE-

DEVELOPMENT INOCULATES AGAINST THE AGE-RELATED DECLINE IN SPATIAL MEMORY OF 24 - 26 MONTH OLD RATS. W.H. Meck & C.L. Williams\*. Depts. of Psychol., Columbia Univ. & Barnard College, New York, NY 10027. Male Sprague-Dawley rats were supplemented with choline during embryonic days 12-17 by adding choline chloride to the drinking water of their dams. Dams consumed 1 mmol/day. Controls received choline-free water. When these rats were trained on a 12-arm radial maze (with 8 baited and 4 unbaited arms) at 90 days of age, prenatal choline-treated rats made fewer working and reference memory errors than controls. rats made fewer working and reference memory errors than controls throughout training (Days I-30). During reacquisition of this maze task at 24 months of age, prenatal choline-treated rats were more accurate in their choice performance than age-matched controls. Following this retraining phase, rats (now 26 months old) were tested on a retention-interval task where a delay (1.25, 2.5, 5, or 10 hrs) was inserted between the 4th and 5th correct choice. After waiting in their home cage, the rats were placed back on the maze to complete the trial. Performance during delay trials was evaluated relative to performance during normal training sessions which were interspersed with delay trials. All rats showed a reliable increase in both working and reference memory errors as a function of the length of the retention interval. Choline-treated rats showed a significantly lower rate of forgetting than control rats as indexed by working memory errors and made reliably fewer reference memory errors at all delays. These data demonstrate that prenatal choline supplementation causes permanent organizational changes in brain and behavior that appear to reduce or delay the normal age-related impairment in spatial memory. NEUROCHEMICAL SUBSTRATES OF MEMORY: IMPLICATIONS OF CHRONIC PHYSOSTIGMINE INFUSION. R.A. Booth, D.J. Jenden\*, R.W. Russell, K.M. Rice, M. Roch and A.S. Chang, Dept of Pharmacology and Brain Research Institute, UCLA, Los Angeles CA 90024.

Osmotic minipumps were implanted subcutaneously in rats to deliver

physostigmine (PHY) (1.5 mg.kg<sup>-1</sup>.day<sup>-1</sup>) for 49 days. Neurochemical, physiological and behavioral variables were measured. Using a modified radiometric method, brain and blood ChE activity were ~20% of control and did not change significantly during the infusion. Acetylcholine (ACh) and choline (Ch) levels and ACh turnover were estimated in cerebral cortex (CTX), hippocampus (HIP) and striatum (STR) by measuring  $[^2H_0]$ - and  $[^2H_4]$ -Ch and ACh 1 min after IV  $[^2H_4]$ -Ch (20  $\mu$ mol.kg<sup>-1</sup>). Levels of total ACh in CTX, HIP and STR rose significantly by 20, 13 and 7%  $(p \le 2.7 \times 10^2)$  and levels of total Ch fell significantly by 13, 8 and 10%  $(p \le 3.7 \times 10^2)$ . [<sup>2</sup>H<sub>4</sub>l-Ch uptake and [<sup>2</sup>H<sub>4</sub>l-ACh synthesis were affected differentially. The greatest decrease in ACh synthesis was seen in HIP (-14%;  $p = 1.0 \times 10^{-3}$ ); the mole ratio of [ $^2H_4$ ]-ACh was reduced by 25% ( $p < 10^{-4}$ ) in HIP and by 12% ( $p = 1.6 \times 10^{-3}$ ) in CTX. Ch uptake was less only in the CTX (-14%:  $p = 1.2 \times 10^{-2}$ ). Core body temperature and weight fell after day 1 of infusion but showed tolerance, returning to control levels by 14 days. Rates of habituation in rearing and locomotion were significantly reduced at 13 days ( $p < 10^{-4}$ ). Retention in the conditioned avoidance paradigm was impaired after 14 days of PHY infusion when the infusion began 1 day after training. At 14 days, controls showed positive transfer of memory ( $p = 4.0 \times 10^{-4}$ ) and made fewer errors than the experimental animals ( $p = 7.4 \times 10^{-7}$ ). Overall, the neurochemical changes were greatest in CTX and HIP, regions associated with higher cognitive function. neurochemical variables did not change during treatment, physiological and behavioral tolerance are presumably the result of other processes, perhaps receptor down-regulation. Supported by DAMD-88-C-8045 and MH 17691.

E2030, A NOVEL ACETYLCHOLINESTERASE INHIBITOR (2): BEHAVIORAL STUDIES ON THE CENTRAL CHOLINERGIC SYSTEM. H. Ogura, K. Uchikoshi, Y. Furuya, T. Kosasa, Y. Yamanishi Tsukuba Research Laboratories, Eisai Co. and T. Kaneko\*. Tsukuba-shi, Ibaraki 300-26, Japan.

Ltd., Tsukuba-shi, Ibaraki 300-26, Japan.
These studies, using behavioral tests in rats, were undertaken to explore the effects of E2030, a newly synthesized acetylcholinesterase inhibitor, on the central cholinergic system. E2030 and tetrahydroaminoacridine (THA) elicited yawning significantly at more than 4 mg/kg, p.o. E2030 caused only mild fasciculation, a peripheral cholinergic sign, at the highest dose, 16 mg/kg, p.o., whereas THA produced the symptom at more than 4 mg/kg, p.o. Scopolamine, but not methylscopolamine, inhibited E2030-induced yawning and haloperidol partially blocked it. p.o. Scopolamine, but not methylscopolamine, inhibited E2030-induced yawning and haloperidol partially blocked it, suggesting that central cholinergic and, in part, dopaminergic mechanisms may be involved in E2030-induced yawning. Secondly, we examined the effects of E2030 on scopolamine-induced impairment in two different learning tasks, the 8-arm radial maze and the 3-panel runway. Scopolamine (0.5 mg/kg, i.p.) disrupted both performances, i.e. increased errors. Pretreatment with E2030 significantly counteracted scopolamine's effect at 1 mg/kg, significantly counteracted scopolamine's effect at 1 mg/kg, p.o., in the two tasks. THA antagonized the deficit at 2 mg/kg, p.o., in the two tasks. I HA antagonized the deficit at 2 mg/kg, p.o. in the radial maze, but was not effective in the 3-panel runway at the range of 1-3 mg/kg. These results indicate that E2030 has a potent cholinergic activity and is more centrally selective than THA.

SUPPLEMENTATION WITH CHOLINE IN UTERO REDUCES BRAIN CHOLINE ACETYLTRANSFERASE (CAT) ACTIVITY DURING POSTNATAL DEVELOPMENT IN THE RAT. D.A. Jackson 1, W.H. Meck<sup>2</sup>, C.L. Williams<sup>3</sup> & J.K. Blusztain<sup>1</sup>. <sup>1</sup>Dept. of Pathology, Boston Univ. Sch. of Med., Boston, MA 02118; Depts. of Psychology, <sup>2</sup>Columbia Univ. & <sup>3</sup>Barnard College, New York, NY 10027.

Supplementation of rats with choline during embryonic days (ED) 12-17 has been shown to facilitate spatial memory processes in adulthood. Therefore we hypothesized that supplemental choline may alter the development of the brain cholinergic system. Sprague-Dawley rats consumed 1 mmol/day of choline chloride in their drinking water during days 12-17 of pregnancy in addition to the choline in their chow. Controls received choline-free water. All of the pups were cross-fostered to control females. CAT activity, determined at postnatal day (PD) 35, was significantly reduced in rats supplemented with choline, by 14.1% and by 8.8% in the striatum and in the hippocampus, respectively. Cortical CAT activity tended also to be reduced. At PD90, the average CAT activity was lower in rats supplemented with choline in utero than in controls, although this effect was not significant in any of the above brain regions. The overall reduction of CAT activity in ED12-17 choline supplemented animals was statistically significant (p-0.01) by three-way ANOVA using choline treatment, age, and brain region as the independent variables. The results confirm our previous observations obtained with rats treated with choline during the ED12-PD30 period and indicate that the reduced CAT activity in the developing brain, in rats supplemented with choline perinatally, provides a biochemical correlate of the behavioral effects of this treatment. (Supported by P01 AG09525.)

E2030, A NOVEL ACETYLCHOLINESTERASE INHIBITOR (1): NEUROCHEMICAL STUDIES ON THE CENTRAL NERVOUS SYSTEM. . Yamanishi\*, T. Kosasa and T. Kaneko, Tsukuba Res. Lab., Eisai Co. Ltd., 5-1-3 Tokodai Tsukuba-shi, Ibaraki 300-26,

E2030, 3-{2-[1-(1,3-dioxolan-2-ylmethyl)-4-piperidyl] ethyl }-2H-3,4-dihydro-6-methoxy-1,3-benzoxazin-2,4-dione hydrochloride, is a novel acetylcholinesterase (AChE) inhibitor. The *in vitro* IC<sub>50</sub> of E2030 for AChE was 155.4 nM. E2030 inhibited AChE 2700-fold more selectively than butyrylcholinesterase. The mode of inhibition was non-competitive and the inhibition was reversible. In an ex vivo study, E2030 (80 mg/kg, p.o.) showed slight but significant inhibition of brain AChE in rats. The compound increased the rat brain acetylcholine (ACh) content and counteracted the decrease in ACh content induced by scopolamine or a descrease in Achi enucleus basalis magnocellularis, dose-dependently, at doses of 5-20 mg/kg, p.o. The microdialysis studies revealed that E2030 increased the extracellular ACh, norepinephrine and dopamine metabolites (DOPAC and HVA) in the brain of rats. These results indicate that E2030 increases ACh content not only in the intact but also in the cholinergic hypofunction models of rats, and furthermore, that E2030 may stimulate monoamine metabolism. serve as a new type of acetylcholinesterase inhibitor for Alzheimer therapy.

GLYCERYLPHOSPHORYLCHOLINE PREVENTS SCOPOLAMINE-INDUCED AMNESIA AND ENHANCES CHOLINERGIC TRANSMISSION IN HIPPOCAMPAL THE RAT. C.Missale\*, S.Sigala, P.Rizzonelli, E.Zanelli, and P.F.Spano. Inst. of Pharmacology, Univ. of Brescia Sch. of Med., Brescia, Italy.

The effects of L-α-glycerylphosphorylcholine

The effects of L-Q-glycerylphosphorylcholine (GPC) on scopolamine-induced memory impairment and on hippocampal acetylcholine (Ach) release were investigated in rats. Oral administration of GPC 3h before aquisition of a passive avoidance response prevented the learning impairment induced by scopolamine (1 mg/kg). Similarly, the retrograde amnesia induced by scopolamine was also completely blocked by the drug. These effects were dose-dependent (50-600 mg/kg) with a maximum at 300 mg/kg. The effects of oral GPC administration on [3H]ACh release in rat hippocampal slices were then studied. K+-stimulated [3H]ACh release was highly potentiated by the drug. The dose-response and time curves of this effect were superimposable on those found in the behavioural test with a maximum with the drug given at 300 mg/kg 3h before killing. The data suggest that the behavioural effects of GPC may be related to its property to increase hippocampal ACh release.

TIME-GRADIENT OF POST-TEST VULNERABILITY TO SCOPOLAMINE-INDUCED AMNESIA IN MICE: CORRELATION WITH THE TIME-COURSE OF MEMORY TEST-INDUCED ACTIVATION OF ASCENDING CHOLINERGIC PATHWAYS. T.P.Durkin\* and A. Toumane. Lab. Neurosciences Comportementales et Cognitives, CNRS URA n° 339, Univ. Bordeaux I, Av. des Facultés, 33405 Talence, France. Our previous studies showed that the initial session of acquisition of

Our previous studies showed that the initial session of acquisition of a concurrent spatial discrimination reference memory task in mice induces a long-lasting (up to 3 hrs) post-test activation of the cholinergic neurones of the ascending septo-hippocampal and nBM-cortical cholinergic pathways (Toumane et al., 1988, Behav. Brain Res. 30, 225-234). In order to reply to the question: is this testing-induced activation of cholinergic neurones a critical step for long-term retention of information?, we have conducted a study examining the effect of blockade of central muscarinic receptors at various times post-test. In comparison to groups injected with either scopolamine-MBr or saline, the injection of scopolamine-HCl (1 mg/Kg i.p.) during the period 30sec-3hrs post-test produced significant deficits in 24 hr. retention performance (amnesia). The severity of this amnesia decreased progressively as a function of the time of treatment following learning. No such amnesia was observed if the scopolamine injection was delayed from between 3-6 hrs post-test, attesting to the absence of any significant long-term pro-active effects of scopolamine on the ability to perform the retention test. These results show that there exists a time window of up to three hours post-learning for vulnerability to the amnesiant effects of scopolamine. This time window corresponds to the time course of the testing-induced activation of the ascending cholinergic pathways observed previously, and more particularly, to that of the nBM-cortical cholinergic pathway.

POST-TRAINING INSULIN ATTENUATES SCOPOLAMINE-INDUCED AMNESIA. C. MESSIER\*, J. SIE, and C. DESTRADE. Lab. de Neurosci. Cognitives et Comport., URA. CNRS n° 339, Université de Bordeaux I, FRANCE and \* School of Psychology, U. of Ottawa, (ONT) CANADA KIN 6N5.

Scopolamine is a well-known amnestic drug. Most of the

Scopolamine is a well-known amnestic drug. Most of the agents that attenuate scopolamine amnesia can also improve memory when injected alone. We report here that insulin can abolish scopolamine-induced amnesia even though insulin per se has little memory-improving action. Male Balb/c mice were trained in an appetitive bar-pressing task. Immediately after the mice had completed 15 trials, scopolamine hydrochloride was injected (0.1, 0.2, 0.3, 0.6, 1.0 mg/kg i.p.) either alone or in conjunction with insulin (0.8 I.U./kg, s.c.). The retention of the animals for the training was tested the next day. The 0.6 and 1.0 mg/kg doses of scopolamine (but not the lower doses) produced an amnesia for the bar-pressing task training. This amnesia was significantly attenuated by the insulin injection. However, the injection of insulin alone had no effect on memory processes. These results show that insulin can protect from scopolamine amnesia. It is not clear by which mechanisms insulin has this action since insulin has been shown to reduce acetylcholine (ACH) turnover. This reduction should have accentuated the effect of scopolamine which effectively depletes acetylcholine stores. However insulin may also modulate scopolamine amnesia through its CNS receptors.

DIFFERENTIAL INVOLVEMENT OF STRIATAL REGIONS IN MEMORY CONSOLIDATION: EFFECTS OF CHOLINERGIC BLOCKADE. G. Quirarte, M.A. Guevara, and R.A. Prado-Alcala. Psychol. Sch., Univ. of Guadalajara, Physiol. Dept., Med. Sch., and Psych. Sch., Natl. Univ. of México, México, D.F. 04510.

Cholinergic blockade of the general area of the anterior caudate-putamen (CPU) produces amnesia. We now re-

Cholinergic blockade of the general area of the anterior caudate-putamen (CPU) produces amnesia. We now report the effects of atropine injections into each of four discrete regions of the anterior CPU (dorsomedial, dorso-lateral, ventromedial, and ventrolateral), and into three regions of the posterior CPU (dorsomedial, dorsolateral, and ventral). Rats were trained in a passive avoidance task and 2 min. later injected, unilaterally, with atropine  $(60~\mu\text{g/J}\mu\text{l})$  into one of the seven regions. Appropriate control groups were also studied. A test of retention was given 24 hours later. A strong amnesic effect was found in the ventral regions, a milder amnesia in the dorsal-anterior regions, and no effect in the postero-dorsal CPU. (Supported by DGAPA IN202791 and CGEP).

EFFECTS OF BICUCULINE ON SCOPOLAMINE-INDUCED S. E. Cruz-Morales\*and R.A. Prado-Alcala. Behav. Pharmacol. Program, ENEP-Iztacala and Physiol. Dept., Med. Sch., Natl. Univ. of Mexico, P.O.B. 314, Tlalnepantla, Edo. de Mexico, 54030, México.

The aim of this experiment was to study the interaction of GABAergic and cholinergic systems in memory processes. Male Wistar rats (250-350 g) were trained with 2.5 mA, on a passive avoidance task and tested 24 hr later. The rats were assigned to one of 17 groups: two groups were injected 5 min post-training (ip) with scopolamine (SCP) (4 or 8 mg/kg); six groups with bicuculline (BI) (0.25, 0.5, 1.0, 2.0, 4.0 or 6.0 mg/kg) six groups received 8 mg/kg of SCP in combination with BI (0.25, 0.5, 1.0,2.0, 4,0 or 6.0 mg/kg); and three control groups, one injected with isotonic saline, an intact group and a group with no shock. SCP induced amnesia in a dose dependent way; BI induced amnesia with low doses. Except the group with 1.0 of BI, all combinations of BI and SCP reversed the SCP-induced amnesia. (Supported by CONACYT P228CCOX891608)

## 147.12

GALANIN MIMICS SCOPOLAMINE IN DISRUPTING DELAYED NON-MATCHING TO SAMPLE (DNMTS) IN RATS <u>J.K. Robinson\* and J.N. Crawley.</u> NIMH, Building 10, Room 4N214, Bethesda, MD 20892.

The neuropeptide galanin coexists with acetylcholine in the rat medial septal region and inhibits cholinergic functions in vitro and in vivo (Fisone, et al, PNAS, 1987). The water maze, T-maze, and operant DNMTS are memory paradigms sensitive to lesions of the septo-hippocampal pathway and to cholinergic antagonists, especially scopolamine. In the present study, the effects of galanin (.5, 2, and 5 ug, i.c.v.) and scopolamine (.06, .12, .25, and 1.0 mg/kg, i.p.) on spatial DNMTS were compared. Both compounds impaired choice accuracy in a dose-dependent but delay-independent manner, but did not alter the frequency of sample-phase discrimination errors. Both compounds decreased trial completion rate and moderately decreased retention-interval VI lever pressing at the largest dose. The effects of intraventricularly administered galanin and intraperitoneally administered scopolamine therefore appear to be qualitatively analogous in this spatial memory paradigm.

# 147.14

EFFECT OF FR121196, A NOVEL COGNITIVE ENHANCER, ON THE MEMORY IMPAIRMENT OF RATS IN PASSIVE AVOIDANCE, WATER MAZE AND RADIAL ARM MAZE TASKS. N. Matsuoka\*, N. Macda, M. Yamazaki, Y. Ohkubo and I. Yamaguchi. Basic Research Group, Tsukuba Research Laboratories, Fujisawa Pharmaceutical Co., Ltd., 5-2-3 Tokodai, Tsukuba, Ibaraki 300-26, JAPAN

We investigated effects of FR121196 in various animal models of dementia, and the results were compared with those of methamphetamine and physostigmine. FR121196 (N-(4-acetyl-1-piperazinyl)-4-fluorobenzenesulfonamide), a newly introduced cognitive enhancer, ameliorated the failure of memory retention in passive avoidance task seen in young male rats subjected to scopolamine treatment, nucleus basalis magnocellularis (NBM) lesion or in aged rats (24-26 months old) with bell-shaped dose-response curves in doses ranging from 0.1 to 10 mg/kg. Similar dose-response curves were obtained with methamphetamine (0.1-10 mg/kg). On the other hand, physostigmine (0.01-1.0 mg/kg) attenuated the amnesia in scopolamine-treated rats but hardly affected that in NBM-lesioned or aged rats. In the water maze task, FR121196 significantly restored the acquisition deficits of spatial memory observed in young animals with NBM lesion or in aged rats. In the radial arm maze task, behavioral indices of spatial memory, such as first correct choices and numbers of errors, were impaired following an injection of scopolamine or lesions of medial septum (MS) or fimbria-fornix (FF). FR121196 ameliorated the scopolamine-induced spatial memory deficit with a bell-shaped dose response curve, while methamphetamine rather tended to aggravate the deficit. These two drugs had little effect on the memory deficits in MS- or FF-lesioned rats. On the other hand, physostigmine ameliorated the memory deficits in scopolamine-treated and MS-lesioned rats but not in FF-lesioned rats. These results suggest that intact septo-hippocampal cholinergic neurons are necessary for FR121196 to ameliorate the memory deficits.

AF64A IMPAIRS TASTE AVERSION AND SPATIAL LEARNING IN A MORRIS WATER MAZE TASK. K. Opello \*, S. Ackerman, R.W. Stackman, T.J. Walsh, Dept. of Psychology, Rutgers Univ. New Brunswick, NJ 08903.

AF64A (ethylcholine aziridinium ion) produces a long-term hypofunction of the cholinergic septohippocampal pathway and spatial working memory deficits. However, the effects of AF64A on non-spatial memory and reference memory have not been well-characterized. The following studies examined whether AF64A would differentially affect the acquisition or extinction of a non-spatial task; conditioned differentially affect the acquisition or extinction of a non-spatial task; conditioned taste aversion (CTA), or the performance of spatial or non-spatial reference memory tasks in the Morris water maze. Male Sprague Dawley rats were injected (icv) with either 2 ul artificial CSF or 2.5 nmol/side AF64A. During CTA water-deprived rats were injected (i.p.) with either 0.15 M LiCl or the NaCl vehicle, either immediately (0 delay) or 4 hrs (4 hr delay) after exposure to a preferred 0.2 % saccharin solution. At the 0 delay condition the AF64A-treated group exhibited a comparable aversion to the saccharin solution on the first day of testing but an accelerated extinction of the CTA. In contrast, with the 4 hr delay the AF64A group exhibited a significantly attenuated CTA but a rate of extinction that was comparable to the controls. Cognitive impairments in these animals were further assessed using both a standard spatial Morris water maze task and a non-spatial cued-version of the task. AF64A spatial motifies water maze task and a non-spatial tued-version of the task. Arrowa significantly impaired acquisition of the spatial task as evidenced by longer escape latencies and pathlengths and less time spent in the target quadrant during a one minute probe trial. However, AF64A had no effect on the acquisition or performance of the cued version of the task. These cognitive deficits were associated with a significant, 42% decrease in high affinity choline uptake in the hippocampus and with no alterations of uptake in the striatum. These data demonstrate that AF64A produces memory impairments that depend upon the temporal and spatial demands of the task.

## 147.17

ESTABLISHMENT AND IMPLEMENTATION OF AN AUTOMATED SYSTEM FOR EVALUATING A DELAYED MATCH-TO-SAMPLE TASK IN STUMPTAIL MACAQUE MONKEYS. N. L. Katz\*, D. C. Jolly, R. F. Schlemmer, Jr., H. J. Haigler and J. M. Davis. Dept. of Pharmacodynan College of Pharmacy, University of Illinois at Chicago, Chicago, IL 60612 and Research Dept., Illinois State Psychiatric Institute, Chicago, IL 60612.

We will describe a computer controlled system used to train and test stumptail macaque (<u>Macaca arctoides</u>) monkeys on a delayed match-to-sample (DMTS) task and present preliminary data collected thus far. The DMTS is an operant behavioral procedure which requires monkeys to discriminate a particular stimulus from several choices at varying time intervals after its initial presentation. The data from a DMTS allow quantitative assessment of attention to environmental stimuli, reaction time, and recent memory function. In 2 young adult female monkeys trained to criterion performance, the percentage of correct matches (i.e., success ratio) declined only slightly as a function of delay length, indicating involvement of memory in performing the task. Furthermore, in these animals, 0.015 mg/kg im of the acetylcholine antagonist scopolamine (SCO) did not affect DMTS performance at acety/cnoine antagonist scoporamine (SCO) due not affect DMTS performance at delay intervals less than 5 sec. Higher doses of SCO consistently reduced the success ratio at 2, 5, and 10 but not 0 sec delay. The amnestic effect of SCO was attenuated by the cholinergic agonist physostigmine (PHY). This computer controlled implementation of the DMTS shows promise as a means for studying neuropharmacologic modulation of memory and attention, and for the pre-clinical screening of drugs for the treatment of dementia and other age-, disease-, or traumarelated cognitive dysfunctions. Also, the stumptail macaque is a highly social species. Extensive systematic studies of the effects of drugs on the social behavior of the stumptail macaque are routinely conducted in this laboratory. The DMTS paradigm should complement studies of drug-induced changes in free ranging social and solitary behavior

ADMINISTRATION OF MUSCARINIC RECEPTOR ANTAGONISTS MODULATE HIPPOCAMPAL ACETYLCHOLINE RELEASE: POSSIBLE RELATION TO MEMORY PROCESSES. A. Wilson\*, J. Richard, R. Quirion, & N.M. White. Douglas Hospital Research Centre and Department of Sychology, McGill University, 1205 Dr. Penfield Avenue, Montreal, Quebec, Canada H3A 1B1

Previous evidence indicates that peripheral post-training injections of a selective cholinergic M2 receptor antagonist, AFDX 384, enhances retention on a task sensitive to lesions of the hippocampal system (win-shift). The extent to which subcutaneous injections of AFDX 384 modulates the release of acetylcholine in the CA1 region of the hippocampus was examined using the in vivo microdialysis technique. Male Long-Evans rats were dialyzed using Ungerstedt ringer buffer containing physostigmine (75 uM) and ACh levels were determined using gas chromatography-mass spectometry. Doses of AFDX 384 which improved performance in the win-shift task (1.0 mg/kg) did not significantly alter measurable hippocampal ACh release; higher doses of the drug increased ACh release to a minor extent (125% and 150% over basal levels, 10.0 and 2.0 mg/kg respectively). For comparison, we observed that at 5.0 mg/kg atropine sulfate increased ACh release 500% over basal levels. These results indicate that peripheral injections of rather selective M2 receptor antagonists such as AFDX 384 are able to modulate ACh release in the CA1 region of the hippocampus, but that the effective doses mediating the memory modulating effect and ACh release in hippocampus do not coincide. This may be due to the sensitivity of the methods used here which only monitor ACh overflow. While preliminary evidence indicates that intrahippocampal injections of AFDX 384 also enhance retention on the win-shift task we cannot rule out the possibility that the memory modulating effect of peripheral injections of the drug are mediated by other mechanisms.

## 147.16

A POTENTIAL PRIMATE MODEL OF DISRUPTIVE BEHAVIOR OF DEMENTIA. C.K. Fleming, R.F. Schlemmer, Jr., J.E. Young, N.L. Katz, and J.M. Davis\*. Dept. of Pharmacodynamics, Univ. of Illinois at Chicago and Research Dept., Illinois State Psychiatric Institute, Chicago, IL 60612.
The centrally active antimuscarinic scopolamine (SCOP) has been used

to model dementia because it induces a disruption of short-term memory in humans and animals. In our laboratory SCOP, 0.01-0.03 mg/kg, disrupts responding in the delayed match-to-sample paradigm in monkeys. This study was designed to examine the behavioral effects of SCOP in free-ranging aged vs. non-aged adult monkeys. Parallel experiments were conducted in two stumptail macaque (Macaca arctoides) social colonies of 4 females and 1 male each. The females in one group were aged  $(\geq 20 \text{ yr})$  and, in the other, the females were younger adults (< 20 yr). Following baseline observation, the females from each colony received 7 acute doses of SCOP HBr, 0.001-0.05 mg/kg, in a cross-over design. Each dose was given intramuscularly 15 min prior to a 1 hr behavioral observation session. A blind observer scored the behavior of behavioral observation session. A blind observer scored the behavior of each monkey using a checklist of more than 40 social and solitary behaviors. SCOP induced dose-dependent increases in locomotion and checking (visual scanning) in both age groups; aged monkeys exhibited greater sensitivity to the drug. Social interaction, particularly social grooming initiated by treated monkeys, was disrupted. SCOP induced an increase in distancing of aged monkeys from other colony members increase in distancing of aged monkeys from other cotony memors suggestive of social withdrawal. There was no significant change in aggression. These results suggest that increased locomotion and hypervigilance may exemplify a state of agitation in monkeys; whereas the disruption of social grooming represents a deficit in social interaction. Hence, this paradigm may serve as an animal model for the study of disruptive behavior and social deficits of dementia.

## 147.18

EFFECTS OF AN M, MUSCARINIC AGONIST, YMT96, ON DISTURBANCE OF LEARNING BEHAVIOR IN CEREBRAL ISCHEMIC RODENTS. Kolchiro Takahashi\*, Mitsuko Qovama, Takashi Yamaguchi, Sachiko Saito, Minoru Yamamoto. Applied Pharmacology & Development Laboratories, Yamanouchi Pharmaceutical Co., Ltd., Itabashi-ku, Tokyo 174, Japan.

An M, muscarinic agonist, YMT96((-)-S-2,8-dimethyl-3-methylene-1-oxa-8-azaspiro[4,5]decane L-tartarate monohydrate][11], ameliorates the disturbance of learning behavior in nucleus basalis magnocellularis-lesioned and scoppolamine-treated rats [21]. The present study examined the effects of YMT96 on passive avoidance response in gerbils subjected to 3 repeated 2-min occlusions of the bilateral carotid arteries, and middle cerebral artery-occluded rats (MCA rats). Latency of step-through in the passive avoidance behavior was shortened in both cerebral ischemic rodents. Neuronal despeneration of the CAI region of the hippocampus in ischemic gerbils, and that of cerebral cortex and striatum was observed in MCA rats. YMT96 in a dose of 0.1 mg/kg (p.o.) or doses of 0.1-l mg/kg (p.o.) ameliorated the shortened latency in gerbils and MCA rats. respectively, without affecting spontaneous movement and pain response. Neuronal degeneration was not changed by administration of YMT96. These results suggest that YMT96 improves the disturbance of learning behavior presumably due to activation of Mn receptors in the brain including the cerebral cortices and hippocampus of the cerebral ischemic rodents.

# 147.20

INTERACTION BETWEEN THE MUSCARINIC CHOLINERGIC AND THE D2-DOPAMINERGIC SYSTEMS ON THE MODULATION OF MEMORY STORAGE I.B. Introini-Collison\*. A. Gasbarri. M. Packard and J.L. McGaugh. Center for Neurobio. of Learning & Memory and Dept. of Psychobio., U. of Calif., Irvine, CA 92717.

Evidence exists indicating that both the muscarinic cholinergic and the dopaminergic systems are involved in the modulation of memory storage. Posttraining administration of muscarinic cholinergic receptor agonists acilitate memory while antagonists induce amnesia. The D2 antagonist sulpiride appears to impair memory. The present experiments examined the interaction between the two systems on the modulation of memory the interaction between the two systems on the modulation of memory storage. Male CD1 mice (60 days old) were trained in an inhibitory avoidance and a Y-maze visual discrimination task. Retention was evaluated 48 hrs after training. Sulpiride (10.0, 30.0 or 100.0 mg/kg; ip) impaired retention in both tasks in a dose-dependent manner. In the inhibitory avoidance task, the muscarinic agonist oxotremorine (35.0, 50.0 or 70.0 µg/kg; ip) significantly prevented sulpiride-induced impairment of memory. In the Y-maze visual discrimination task, sulpiride (10.0, 30.0 or 100.0 mg/kg; ip) prevented oxotremorine (35.0, 50.0 or 70.0 µg/kg; ip)-induced memory facilitation. Although both the muscarinic cholinergic and the D2 systems modulate retention of both tasks, the two systems appear to interact differently in influencing retention in the two learning tasks.

NB LESION-INDUCED PA DEFICIT MAY BE MEDIATED VIA AMYGDALA. P. Riekkinen Jr\*, J. Sirviö, M.Riekkinen and P. Riekkinen. Department of Neurology, University of Kuopio, 70211 Kuopio, Finland

The present study was designed to elucidate the role of cholinergic innervation of amygdala (AG) in inhibitory avoidance (passive avoidance, PA) and spatial reference memory (water maze, WM) performance. Nucleus basalis (NB) quisqualic acid lesioning decreased ChAT activity in the AG and frontal cortex, and impaired PA retention and reversal WM performance. AG lesioning impaired PA retention but did not affect PA or WM performance in NB-lesioned rats. Scopolamine (a muscarinic antagonist) and mecamylamine (a nicotinic antagonist) dose dependently impaired PA and WM performance in intact rats. The cholinergic antagonist effects on PA performance were blocked (low antagonist doses) or decreased (high antagonist doses) by lesions of the AG. AG lesions did not modulate the performance impairing effect of cholinergic antagonist on WM performance. The present results suggest that the NB cholinergic projection may modulate the functioning of amygdala via muscarinic and nicotinic receptors.

## 147.23

CHRONIC NICOTINE-MECAMYLAMINE INTERACTIONS AND RADIAL-ARM MAZE PERFORMANCE IN RATS. E.D. Levin\*, S.J. Briggs, N.C. Christopher and J.E. Rose. Nicotine Research Laboratory, Department of Psychiatry, Duke University and VA Medical Centers, Durham, NC 27705

Acute or chronic nicotine administration has been found to improve working memory performance, whereas acute doses of the nicotinic antagonist mecamylamine have been found to impair it. In the current study, the effects of chronic nicotine and mecamylamine on working memory in the radial-arm maze were examined in adult female Sprague-Dawley rats implanted subcutaneously with osmotic minipumps delivering saline (N=12), 12 mg/kg/day of nicotine (N=12), 3 mg/kg/day of mecamylamine (N=11) or these doses of nicotine and mecamylamine (N=12). Replicating our earlier work, nicotine was found to improve working memory performance (p<0.05) Concurrent administration of mecamylamine with nicotine eliminated the facilitation. Surprisingly, unlike acute mecamylamine, chronic mecamylamine did not cause a deficit in memory performance and actually improved memory performance during the first week of administration (p<0.001). This effect subsequently dissipated. These results demonstrate that chronic nicotine-induced facilitation of working memory performance is a robust effect which appropriately is blocked by concurrent administration of a nicotinic antagonist. The facilitation of working memory performance by chronic mecamylamine is an interesting effect which deserves further investigation. (Supported by funding from Abbott Labs.)

## 147.22

MECAMYLAMINE DELAYS ACQUISITION OF THE CLASSICALLY CONDITIONED NM RESPONSE BUT DOES NOT AFFECT NICOTINIC RECEPTOR BINDING IN RABBIT BRAIN. Y.-T.Li'-D.S. Woodruff-Pak', A. Kazmi', & W.R.Kem², Dept. of Psych.', Temple Univ., Phuladelphia, PA 1912. & Dept. of Pharmacol. & Therapeutics', Univ. of Florida, Gainesville, FL 32610.

The septo-hippocampal acetylcholinergic system plays an important modulatory role in classical conditioning of the nictitating membrane (NM) response in rabbit. The effects of low doses (0.5mg/kg, sc) of the nicotinic receptor antagonist, mecamylamine, were compared to vehicle, in 18 young rabbits (7-8 mo.) classically conditioned for 10 sessions in the delay NM conditioning paradigm with a 750 ms interval between the tone CS and corneal airpuff US that were paired or explicitly unpaired. Nicotinic receptor densities were measured by vacuum filtration after incubating the synaptosomal membranes with [3H]methylcarbamylcholine for one hour at O.C. Mecamylamine prolonged acquisition of conditioned responses (CRs) so that young rabbits learned like older rabbits. Mecamylamine-treated young rabbits took a mean of 780 trails to learning criterion, whereas the saline-treated ones attained criterion in 422 trails (T=3.7427;p<.05). The percentage of condition responses (CRs) were also strikingly different ( $F_{(2,15)} = 9.31; p < .003$ ). Motor unconditioned responses were not affected by the compound  $(F_{[2,15]}=1.29;p>.3)$ . Nicotinic receptor concentrations in cerebral cortex, cerebellum, and remaining brain tissues were 40.2, 7.4, and 64.6 fmol/mg membrane protein, respectively for saline-treated rabbits. For mecamylamine-treated rabbits the corresponding  $B_{\text{max}}$  estimates were 40.5, 7.5, and 57.3 fmol/mg protein. The mean estimates of these two groups were not significantly different. Thus, the deleterious effect of mecamylamine upon NM classical conditioning was not accompanied by a measurable change in nicotinic receptor concentration, at least for these three brain regions.

LEARNING AND MEMORY EFFECTS OF LOBELINE, A NICOTINIC AGONIST, IN RATS. M.W. Decker\*, M.J. Majchrzak, and S.P. Americ. Neuroscience Research, Pharmaceutical Products Division, Abbott Laboratories, Abbott Park, IL 60064.

Lobeline crosses the blood brain barrier readily and binds to nicotinic sites, but does not produce the nicotine cue (Reavill et al., 1990, Neuropharmacol., 29: 619), This suggests that the behavioral effects of lobeline and nicotine differ. However, these differences have not been well characterized. Since we have found that nicotine enhances retention of inhibitory avoidance (IA) training in rats (Majchrzak and Decker, 1991, Neurosci. Abstr., 17: 1236) and improves the performance of rats with septal lesions in a spatial discrimination Morris water maze (Decker et al., 1992, Br. Res., 572: 281), we were interested in determining if lobeline had similar effects.

Male, Long-Evans rats were used in these experiments. For the 1A experiment, lobeline (0, .62, 1.9, 6.2, and 19 µmol/kg IP, n=15/group) was administered immediately after training, and retention was assessed 24 h later. Lobeline-treated rats (19 µmol/kg) took significantly (p<.05) longer to enter the shock compartment on the test day than saline-treated rats. In the water maze experiment, rats with radiofrequency and sham lesions of the septal area learned to use spatial cues to discriminate an escape platform from a similar appearing false platform. Lobeline (0, 1.9, and 19 µmol/kg IP) was administered 15 min. before training on each of 4 consecutive days (n=4-5/group). Lobeline significantly improved performance of rats with septal lesions (lobeline by lesion interaction, p<.025), particularly at the lower dose. This finding was confirmed when rats were retrained using new spatial locations and saline and low dose treatments were reversed in a crossover design.

Thus, lobeline's effects on learning and memory may be similar to nicotine's.

Thus, lobeline's effects on learning and memory may be similar to nicotine's. Coupled with previous reports that lobeline does not produce the nicotine cue, one results suggest that nicotinic receptors involved in the modulation of memory processes may be distinct from those involved in producing the nicotine cue.

TEMPERATURE-DEPENDENT BLOCK OF LTP BY THE NO SYNTHASE INHIBITOR L-NARG. Y.-G. Li, M.L. Errington, J.H. Williams and T.V.P. Bliss\*. Nat. Inst. Med. Res., London, NW7, UK.

We have previously failed to detect an effect of the Nitric Oxide (NO) synthase inhibitor Nw-Nitro-L-arginine (L-NARG) on the induction of LTP in area CA1 of rat hippocampal slices maintained at 29°C (Abstr. Soc. Neurosci. 17, 951,1991). We have now confirmed recent reports that L-NARG blocks LTP in CA1 at room temperature CA1 minislices were prepared from male Sprague-Dawley rats (70-100g), and maintained in an interface chamber. At 29°C L NARG (100µM, Sigma) had no effect on the magnitude of tetanicallyinduced LTP; the normalized change in population EPSP slope 60 min post-tetanus relative to pre-tetanus values was 47.8 ± 6.7% in control medium (mean  $\pm$  sem, n=8), and 53.3  $\pm$  7.8% (n=8) in slices exposed to L-NARG for 2-4 hours pre-tetanus. In contrast, at 24°C L-NARG blocked LTP (% change 60 min post-tetanus was -14.9 ± 4.9% (n=8) compared to 29.2± 1.7% in control medium (n=8)). D-NARG (100µM) was ineffective. The block by L-NARG at 24°C was reversed by 1mM arginine. L-NARG did not reduce LTP in dentate minislices at either temperature; this may be related to the presence of bicuculline  $(100\mu M)$  and/or higher concentrations of Mg and Ca in the medium. Haemoglobin (20µM, Sigma) significantly reduced the magnitude of LTP at 24°C but not at 29°C in CA1 minislices and in 5/5 experiments blocked the induction of LTP in the perforant path in vivo. L-NARG (100μM (n=3) or 500μM (n=2)) failed to block LTP in vivo when perfused into the dentate gyrus for 2h pre-tetanus. These data raise doubts about the role of NO in LTP at physiological temperatures.

# 148.

EFFECTS OF GLUCOCORTICOID TYPE 1 AND TYPE 11 AGONISTS ON HIPPOCAMPAL LONG-TERM POTENTIATION. C. Pavlides\*, Y. Watanabe A.M. Magarinos and B.S. McEwen.

The Rockefeller University, New York, NY.

A number of studies have demonstrated that high levels of glucocorticoids (GC), correlate negatively with hippocampal long-term potentiation (LTP). Similar deficits have recently been described with subbasal levels of GC. Thus, optimal plasticity can be obtained at an intermediate level of GC (Diamond et al. 1991). In the present experiments we investigated the effects of specific low affinity (Type I) and high affinity (Type II) GC receptor agonists on LTP in the dentate gyrus granule cell layer (DG). Male, Sprague Dawley rats were ADX 3 days prior to LTP testing. Approx. 2 h before recording, rats were administered (s.c., 10 µg/100 g/body weight) with either RU-28362 (Type II agonist), aldosterone (ALDO; Type I agonist), or the vehicle (propylene glycol). The animals were then implanted, under Chloropent anesthesia, with a stimulating electrode in the perforant path and a recording electrode in the DG. Following baseline recording, high frequency stimulation was applied (10 pulses, 200 Hz, 6X, @ 0.1 Hz) followed by recording for 30-40 min.

followed by recording for 30-40 min.

RU-28362 produced an extremely potent suppression in LTP induction as measured by bot', the pop spike and the EPSP slope. ADX itself also produced a suppressing effect on LTP, in comparison to nonADX controls. ALDO admin. reversed the ADX induced suppression and produced even higher LTP than non operated controls. These results confirm previous observations indicating an opposing modulatory effect of GC, mediated by Type I and Type II receptors. Supported by a Whitehall Foundation grant to CP.

RATS HOUSED IN A COMPLEX ENVIRONMENT EXHIBIT GREATER HILAR LTP THAN INDIVIDUALLY HOUSED LITTERMATES. E.L. Hargreaves\*, F. Boon, and D.P. Cain. Dept. Psych., Univ. Western Ontario, London, Ont

Male rats (n=18) approximately 50 days of age were housed either together in a meter<sup>3</sup> cage filled with ramps, boxes, and toys that were re-arranged on a daily basis, or individually in suspended cages located in the same colony room. After a month of such housing an overall behavioral assessment was undertaken. Some of the findings from this assessment have been reported in brief, elsewhere (rats housed in the complex environment were stronger, swam faster, balanced better, weighed less, drank less, were less neophobic to novel tastes, less aggressive to strange conspecifics, and faster at acquiring the Morris Water-Maze task than their individually housed littermates; however, they were behaviorally similar to their individually housed littermates in their open-field activity levels, food consumption, and retention of the Morris Water-Maze).

Subsequent to the behavioral assessment, rats were surgically implanted, with stimulating/recording electrodes in the perforant-path/dentate-gyrus of the hippocampus for the recording of hilar evoked potentials. After 10 days recovery, the complex housed rats were reintroduced to the environment. Full I/O curves were recorded a month later using behavioral clamping and compared on identical intensities. No differences between the groups on pop-spike amplitude were found. After a further three weeks of housing, rats were matched at approximately 60% of the maximum I/O pop-spike amplitude and electrically potentiated using standard lab parameters. Potentiation was assessed at 0, 1, 3, 24, 72, and 168 Hrs after LTP induction. Results indicate that rats housed in the complex environment (n=6) sustained, and maintained over the 7 day period, higher levels of LTP than their individually housed littermates (n = 8). Supported by a grant from NSERC to DPC.

## 148.5

ASSOCIATIVE LONG-TERM POTENTIATION/DEPRESSION OF SYNAPTIC TRANSMISSION IN CINGULATE CORTEX SLICE.

T.G. Hedberg\*. G.V. Simpson and P.K. Stanton. Department of Neuroscience, Albert Einstein College of Medicine, Bronx, N.Y. 10461.

A persistent increase in synaptic efficacy (LTP) has been demonstrated in hippocampus and neocortex following brief high-frequency stimulation. LTP is associative in nature: synchronous (in phase) activation of convergence to the same neuron can enhance synaptic strength. Alternately, out of phase to the same neuron can enhance synaptic strength. Alternately, out of phase coactivation of separate afferents can elicit enduring synaptic depression (LTD). We used high and  $\theta$  frequency stimulation of callosal (CAL) and subicular (SCT) afferents to characterize synaptic plasticity in superficial (II/III-IV) vs deep (V-VI) laminae of rat cingulate cortex slices. SCT/CAL stimulation allowed both synchronous and asynchronous activation of pyramidal apical and basal dendritic arbors. Trains of 100Hz bursts applied to the CAL yielded persistent (>15-60 min post-stim) decreases in latency (0.6-2.3 msec) and increases in amplitude of population potentials in both laminae. In contrast, 100Hz bursts via SCT yielded LTP in deep laminae only ( $\Delta$ EPSP +51%  $\pm$  7%, n=8). When 5Hz SCT pulse trains were given in or out of phase with 100Hz bursts to CAL, no associative changes in synaptic strength were elicited. However, 5Hz CAL pulse trains elicited associative LTP (AEPSP +24% -3%; n=5) when out of phase and LTD (AEPSP -13% +7% n=9) when out of phase with 100Hz bursts via SCT. Thus, CAL afferents show enhanced capacity for associative plasticity. (Supported by NIMH Creat #45782 and the Office of Name Page 2011) Grant #45752 and the Office of Naval Research)

CLASSICAL CONDITIONING OF EYEBLINK RESPONSE IN TRACE PARADIGM MODIFIES AMPA AND CNQX BINDING IN THE RABBIT HIPPOCAMPUS. A.J. Annala\*, G. Tocco, M. Baudry & R.F. Thompson. Neuroscience Program, University of Southern California, Los Angeles, CA 90089-2520.

Trace classical conditioning of the rabbit eyeblink response requires an intact hippocampus. Because we have observed increased AMPA binding in the hippocampus following classical conditioning of the rabbit eyeblink response in the delay paradigm we were interested in determining whether a similar effect would be observed after trace conditioning.

New Zealand White rabbits were divided into three groups: Paired, Unpaired, and Naive. Rabbits in the paired group received paired presentations of CS (1 KHz 85db 250ms tone) and US (3 psi 100 ms air puff) in a classical conditioning paradigm with a 500 ms trace interval. Rabbits in the unpaired group received explicitly unpaired CS and US presentations. Paired rabbits exhibited significantly increased  $\,^3\mathrm{H}\text{-}\mathrm{AMPA}$  binding in hippocampal CA1 stratum oriens and radiatum/lacunosum, CA3 stratum radiatum/lacunosum, and molecular layer of dentate gyrus. Paired rabbits also exhibited significantly decreased <sup>3</sup>H-CNQX binding in hippocampal CA1 stratum oriens and radiatum/lacunosum, and molecular layer of dentate gyrus.

The results suggest that classical conditioning is accompanied by a change in affinity of the AMPA receptors, and that this cellular modification might play a critical part in learning-induced synaptic plasticity.

REM SLEEP DEPRIVATION EFFECTS LTP IN THE RAT HIPPOCAMPAL SLICE. R.N. Morrissette\*,R.A. Hicks, S.A. Veregge. San Jose State University, San Jose, CA. 95192.

REM sleep (RS) consolidation theory postulates that RS may serve to consolidate learning. Current evidence sug-gests that LTP occurs when animals learn. It is hypothsized that RS deprived (RSd) rats will show enhanced LTP characteristics. RSd was initiated using the platform technique and LTP was elicited and monitored in hippo-campal slices of control and 4-day RSd rats. Four characteristics of the field potential response were measured, as well as, the frequency of occurrence and duration of LTP. Results show a significant increase in population spike amplitudes for the RSd rats as compared to controls. Although these results offer support for the hypothesis, non-significant differences using the other measures weaken this support.

INCREASED EXPRESSION OF GAP-43, SOMATOSTATIN AND NEUROPETIDE Y mRNA IN HIPPOCAMPUS DURING DEVELOPMENT OF HIPPOCAMPAL KINDLING IN RATS.

C. Bendotti\*, G. Tarizzo, A. Vezzani and R. Samanin. Istituto di Ricerche Farmacologiche "Mario Negri", 20157, Milano, Italy.

It has been suggested that during the development of kindling, an animal model of temporal lobe epilepsy and neuronal plasticity, a animal model of temporal lobe epilepsy and neuronal plasticity, a synaptic reorganization occurs in certain neuronal populations of the hippocampus. Recently, we have shown a specific distribution of GAP-43 mRNA, a putative marker of neuritic growth, within the CA3 pyramidal neurons and the polymorph hilar neurons of dentate gyrus of the hippocampus from adult rat (Kruger et al. Mol. Brain Res.,13,267,1992). In this study, using in situ hybridization technique and computer assisted grain counting at cellular level, we investigated whether changes in the distribution and expression of GAP-43 mRNA occured in the hippocampus during the development of electrical occured in the hippocampus during the development of electrical hippocampal kindling. A significant increase of grains number was found in the CA3 pyramidal neurons and hilar polymorph neurons of the dentate gyrus, 48 hours after stage 2 (preconvulsive stage) but not stage 5 (full seizure expression) kindling in the stimulated hippocampus. No modifications in the distribution of GAP-43 mRNA were observed in the hippocampus of kindled rat as compared to sham stimulated animals. We also found a marked increase of somatostatin(SOM) and neuropetideY(NPY) mRNA in the neurons of the hilus of the dentate gyrus at both stages of kindling, 2 days but not 30 days after last simulation. This study suggests that GAP-43 may play a role in the synaptic remodeling occurring during kindling and an isynthesis of SOM and NPY may have a role in epileptogenesis and an increased

ASSOCIATING CHOLINERGIC AND SCHAFFER COLLATERAL STIMULATION INITIATES PROTEIN SYNTHESIS IN CAI PYRAMIDAL CELL DEMDRITES. P. Lipton' & S. Feig. Depts. Physiol. Anat. U. Wisconsin Med. Sch. Madison, WI 53706.

A large body of evidence suggests that protein synthesis in the hippocampus around the time of learning is essential for memory consolidation. One way in which such synthesis might be involved is if associated synaptic inputs activate protein synthesis in the ribosomes which are located in subsynaptic regions of dendrites. Such a process could have great specificity.

Schaffer collaterals in the guinea-pig hippocampal slice were stimulated intermittently at 10 Hz over 20'. The cholinergic agonist carbachol (50 µM) was added to the bath to mimic the effect of cholinergic stimulation. Protein synthesis in pyramidal cell layer dendrites, and somata, was measured autoradiographically, following 3' exposure to (3H)-leucine (to prevent dendritic flow) at the end of the 20'period.

Cycloheximide-dependent (3H) incorporation (protein synthesis) was negligible in the resting state and was not activated by Schaffer collateral stimulation, or carbachol, when administered separately. However, associating the two stimuli increased incorporation in dendrites 3-fold, without increasing uptake of free (3H)-leucine. The increase was cycloheximide-dependent (protein synthesis). There was no effect in cell somata. The increase synthesis in dendrites was completely blocked by the muscarinic antagonist, atropine, and by the NMDA-antagonist, D-APV.

Thus, associating inputs which may occur together during learning initiates protein synthesis in target dendrites of CA1 pyramidal cells. This is dependent on activation of NMDA receptors.

PROGRESSIVE ENTORHINAL LESIONS ACCELERATE HIPPOCAMPAL SPROUTING IN RATS. K.R. Bulsara, J.F. Manibo and J.J. Ramirez\*. Neuroscience Program and Department of Psychology, Davidson College, Davidson, NC 28036.

Previously, we have shown that two-stage (progressive) lesions of the entorhinal cortex (EC) restricted to one hemisphere result in a 300% acceleration in: A) sprouting by the crossed temporodentate pathway (CTD) and B) recovery from spatial alternation deficits following unilateral EC lesions. The purpose of this study was to determine electrophysiologically whether progressive lesions accelerate the rate at which the CTD forms functional synapses.

Animals were assigned to one of four groups: progressive lesion, control, priming lesion, or one-stage lesion. Electrophysiological recordings were made in the dentate gyrus contralateral to the lesion site either 6 or 12 days postlesion.

CTD stimulation in the progressive lesion group resulted in a 250% increase in the evoked population EPSPs of the dentate granule cells when compared to the one-stage group. Thus, the synaptic drive of the CTD in the progressive lesion cases was significantly greater than that of the one-stage group.

Based on our anatomical, behavioral, and electrophysiological data, we propose that progressive EC lesions accelerate the formation of functional CTD synapses that are behaviorally meaningful.

RECEPTIVE FIELD PLASTICITY IN THE ADULT RAT BARREL CORTEX. M.E. Diamond\*. M.A. Armstrong-James. and F.F. Ebner. Institute for Developmental Neuroscience, Vanderbilt University, Nashville, TN 37203.

Experiments were carried out to determine if the receptive fields (RFs) of neurons in layer IV barrels are shaped by changes in sensory experience. All whiskers on one side of the face -- except D2 and one neighbor (D1 or D3) -- were clipped to a length of 3 mm and trimmed daily. After 3-30 days, the responses of single units in barrel D2 of anesthetized rats to stimulation of whisker D2 (the center RF), and 4 whiskers in the surround RF (SRF), D1, D3, C2, and E2, were measured. In "control" rats, cells in barrel D2 responded maximally to whisker D2 at latencies < 10 ms; whiskers in the SRF evoked a less powerful response at longer latencies. The response to whiskers D1 and D3 was symmetric. Strong asymmetry in the RFs of D2 barrel cells developed as early as 3 days after whisker trimming. Responses of D2 cells to D2's "paired" neighbor (D1 or D3) became more powerful and the response to the trimmed neighbor became less powerful: the ratio of response magnitudes for paired/trimmed whisker (D1/D3 or D3/D1) was 2.0. The latency to the paired whisker decreased and to the trimmed whisker increased. The response to SRF whiskers occurred mainly in the 10-20 ms and 20-50 ms poststimulus epochs, but not in the 0-10 ms epoch, indicating that thalamocortical drive was not significantly affected. The results suggest that behavioral pairing of whiskers rapidly potentiates the linkage of the co-active barrels; whereas un-pairing weakens the linkage (Supported by NS-25907, P30-HD15052, and the Wellcome Trust).

# 148.13

ENHANCED DENDRITIC ARBORIZATION AND PRUNING AFTER SENSORIMOTOR CORTEX DAMAGE IN ADULT RATS: ROLE OF THE NMDA RECEPTOR. D.A. Kozlowski\*, T.A. Jones, & T. Schallert. Neuroscience Institute & Department of Psychology, University of Texas at Austin, Austin, TX 78712.

Unilateral damage to the forelimb-representation area of the sensorimotor cortex in adult rats causes a time dependent proliferation of dendritic processes followed by a partial pruning of layer V pyramidal neurons of the homotopic contralateral cortex (Jones & Schallert, 1992). Dendritic growth appears to be linked to a hyper-reliance on the unimpaired forelimb, especially for postural-motor behaviors, whereas dendritic pruning is associated with a return to symmetrical limb use.

whereas denoratic pruning is associated with a return to symmetrical limb use.

Unilaterally lesioned rats were administered an NMDA receptor antagonist, MK801 (1mg/kg, i.p. once every four days), or saline control, during the dendritic pruning phase. MK801 reinstated severe and chronic unilateral posturalmotor asymmetries. These behavioral events may be associated with anatomical changes. Analysis of Golgi-Cox stained tissue in the homotopic cortex of the undamaged hemisphere indicated that MK801 prevented the pruning (that is, enhanced dendritic arborization was maintained). Pruning of adult dendrites may depend on glutamatergic activation of the NMDA receptor and may be important for restoration of function after brain damage.

GLUTATHIONE REDUCES SPATIAL LEARNING DEFICITS IN THE MORRIS WATER TASK AFTER MEDIAL FRONTAL CORTEX LESIONS IN THE RAT. M. S. Weaver\*, T. A. Jones, M. L. Swoboda, T. Schallert, and S. W. Leslie. Institute for Neuroscience, University of Texas, Austin, TX 78713.

The endogenous tripeptide glutathione (GSH; \( \gamma\)-glutamyl-cystein|glycine\) interacts specifically with the NMDA recognition site (Leslie, et al., 1992). This peptide also acts as a free radical scavenger (Halliwell & Gutteridge, 1989). Since both of these processes are linked with attenuation of excitotoxicity, the present study was conducted to evaluate the neuroprotective effects of GSH after brain injury. The influence on spatial learning deficits after medial frontal cortex (MFC) lesions was assessed. Following 5 days of baseline training on Whishaw's learning-set version of the water task, rats sustained bilateral MFC lesions or sham operations, and cannulae were implanted chronically in either the left or right lateral ventricle. Infusions of GSH (10 µl of 20 mM; i.c.v.) or vehicle (a-CSF) were given at 1, 12, and 24 hrs after surgery and then once daily for 7 days. Training was resumed 4 days after surgery and continued for 12 days. As expected (Weaver et al., 1991), bilateral MFC lesions significantly impaired spatial learning ability in the water task. GSH-treated rats were significantly less impaired and had faster rates of recovery than vehicle-treated lesioned animals. Preliminary anatomical results indicate that GSH may protect against lesion-associated shrinkage of the CA1 region. (Funded by NS-23964 and AA-07471).

THE CORTICAL METABOLIC EFFECTS OF TRAINING A SPARED RAT VIBRISSA IN THE ADULT C.L. Hand\*, R.L. Craik, K.M. Gallo, & P.J. Hand, Idaho State U., Pocatello, ID 83209; Beaver College, Glenside, PA 19038; and U. of Pennsylvania. Phila. PA 19104

We are exploring treatment interventions that **maximize functionally-appropriate brain alterations**. This study combined a bilateral spared vibrissa preparation with unilateral associatively-paired (AP) or disassociatively-paired (DAP) training in 19 **adult** rats. Subtotal vibrissa deafferentation involved bilateral sparing of a single whisker (SC3) on postnatal day 45. AP (pairing vibrissa stroking with a 20% honey water positive reinforcer) or DAP (unpaired vibrissa stroking and honey water administration) training on SC3 was initiated on PND 50 for 5 min/day for 30 days. Prior work in **neonatal** rat indicates a robust response of the damaged SC3 system to AP training, but not to DAP training. For neonates, the quantitative [1<sup>4</sup>C]-2DG technique revealed a 65±38% **increase** in the area of metabolic labeling in the AP trained SC3 cortical representation and a 31 ±10% **decrease** in the DAP trained animals. In the **adult**, there was a 40 ± 12% **increase** in the AP trained SC3 cortical representation. Results demonstrate that the **adult** cortical metabolic representation of vibrissae is also dynamically maintained and responds differentially to peripheral interventions. NS22283

ICMS INDUCED EMERGENCE OF NEW SKIN FIELD REPRESENTATIONS IN RAT SOMATOSENSORY CORTEX. F. Spengler\* and H.R. Dinse.

Inst. für Neuroinformatik, Theoret. Biologie, RUB, D-4630 Bochum. Intracortical microstimulation (ICMS) induces short time plasticity in somatosensory cortex of adult rats and monkeys[1]. ICMS alters not only cortical representations and receptive fields, but also neuronal sensitivity functions and transfer properties [2]. The present studies demonstrates that ICMS in addition induces receptive fields beyond the representational borders. Neural activity in deep layer III and IV within the hindpaw representation were recorded in adult Urethan anesthetized rats using 1 or 2 microelectrodes. Low-threshold cutaneous receptive fields were defined by handplotting and quantitative averaging techniques before and after ICMS. First, the rostromedial and caudal borders of the hindpaw representation were mapped in detail. Recordings made outside this region revealed neuronal activity that was neither drivable by cutaneous stimulation nor by stimulation of joint or muscle receptors. ICMS was then applied at a location close to the representational border for several hours. After ICMS, this border region was remapped. The borders of the skin field representations were shifted rostro-medially or caudally resp., up to Imm into zones that were under control not sensitive to tactile stimuli. These results demonstrate that cortical networks are dynamically maintained not only within, but also beyond the representational borders. Further studies are required to clarify the nature of thalamic projection within the border region.

COMPARATIVE PLASTICITY OF SOMATOSENSORY AND AUDITORY COR-TEX IN RAT P.H.Bedenbaugh\*, P.E.Maldonado and G.L.Gerstein Dept. of Physiology, Univ. of Pennsylvania, Philadelphia PA 19104

Ogy, Univ. of Pennsylvania, Philadelphia PA 19104

We have studied plasticity induced by electric intra cortical microstimulation (ICMS) in primary somatosensory and auditory cortex of the rat using essentially identical experimental, recording and analytic procedures. Multi-unit, separable recordings were obtained with various arrays of electrodes, and processed with
appropriate spike shape sorting devices. Recordings and characterization of unit and assembly properties were made before and after a period of supragranular or granular ICMS. This consisted of spaced trains of biphasic 5µA pulses applied through one of the recording electrodes.

- 1. After a period of ICMS the responses in both cortices to appropriate sensory stimulus of cells recorded near but not at the stimulating electrode became more similar to those of cells at the stimulating electrode. These changes grew and subsequently seemed to be reversible with a similar time course of several hours.
- 2. Irregular somewhat bursting firing (< 10 Hz), approximately synchronized across electrodes was observed in both cortices under several anesthetic conditions. This pattern of activity was enhanced by ICMS. Sensory stimulus entrained this bursting behavior for two or three cycles, particularly after the ICMS period.

  3. Cross-correlograms among all simultaneously recorded cells showed that many
- cell pairs increase their correlation of firing after the ICMS period, while a few decrease correlation. This is expressed as changes in peak areas and shapes.

  4. Joint peri-stimulus histograms (JPST) for cell pairs in auditory cortex showed
- 4. John per-sumulus instograms (17-31) for ceil pairs in adunity cortex showed that much of the ICMS related increases in correlated firing occurred during the interstimulus time; less increase occurred during the sensory stimulus response.

  5. Our interpretation of these observations is that (a) ICMS reveals the plastic nature of the sensory map structure, and (b) that ICMS forces an increase of intracortical neuronal coupling. The detailed mechanisms remain to be investigated. NIH MH46428

THICKNESS OF THE MOTOR CORTEX INCREASES FOLLOWING 28 DAYS OF EXERCISE OR MOTOR SKILL TRAINING. B.J. Anderson', P.B. Eckburg, K.I. Relucio' & W.T. Greenough. Dept. of Psych., Neurosci. Prog., Cell Struct. Bio., Univ. of Ill., Urbana, IL 61801, 'Rush Med. College, Chicago, IL 60612.

Voluntary exercise in an exercise wheel in 10 mo, old female rats was previously shown to increase the density of capillaries in the paramedian lobule of the cerebellar cortex, whereas training on an obstacle course caused an increase in both the volume of the molecular layer and number of synapses per neuron (Black, et al., 1990). We investigated the effects of these motor tasks on the thickness of the motor cortex. Six mo. old female littermates were balanced across three treatment conditions each lasting 28 days. The exercise group had free access to a running wheel (running a mean of 150 Km). The acrobatic group traversed an increasingly difficult obstacle course requiring balance and coordination five times a day (travelling a mean of 125 m). Control rats were raised in standard cages and handled daily. Rats were perfused, brains were embedded in celloidin, sectioned at 40 µm and stained with Methylene Blue/Azure II. Motor cortical thickness was measured in four coronal planes between -2.33, & -3 mm posterior to bregma (Paxinos and Watson, 1982). Thickness was measured at 13 medial-lateral positions starting from the midline. At the plane -2.33 mm from bregma the acrobatic group had significantly thicker cortices at four positions. The acrobatic and exercising rats had significantly thicker cortices in the other three planes than the control rats. Although the pattern of differences in thickness are somewhat dissimilar between the acrobatic and exercise groups, both treatments increased cortical thickness. The discrepancy between the exercise effects in this study and those in the cerebellum may reflect the greater amount of exercise performed by the rats in this study. Supported by AG-10154 and MH-18412-05.

CORTICAL PLASTICITY AND NEURONAL ASSEMBLIES IN RAT AUDI-TORY CORTEX P.E.Maldonado\* and G.L.Gerstein Dept. of Physiology, Univ. of Pennsylvania, Philadelphia PA 19104

Neuronal assemblies as defined in terms of cooperativity of neuron firing were studied during cortical reorganization induced by electrical microstimulation Multiple single-unit recordings from rat primary auditory cortex (supragranular layers) were obtained with a linear array of four parlyne-insulated tungsten microelectrodes in ketamine-xylazine and nembutal anesthetized animals. Receptive fields (RF) and after-discharge responses were characterized before and after cortical microstimulation (ICMS) through one of the recording electrodes. Auditory stimuli were free field 50 msec tone burst over the range of 4-40 Khz, 20-30 dB over threshold, randomly presented through a tweeter located 60 degrees at the contralateral side of the site of recording. For RF determination, burst tones occurred every 600 msec; for after-discharges burst tones were given every 2 sec. ICMS were trains of 13 pulses of 5 uA spaced 5 ms, trains repeated every 0.5 sec. We found changes in RFs of cells recorded from the electrodes adjacent to the stimulating electrode which consisted mainly in new sensitivity to the best frequency of cells recorded from the stimulating electrode. In most cases the cells remained with sensitivity to the former best frequency. RF of cells recorded from stimulating electrodes did not change their best frequency. Cross-correlation analysis showed that ICMS changes the distribution of cooperativity of neuron firing between cells located at different recording electrodes. Spontaneous activity shows a rhythmic synchronized pattern of firing between most cells in cortex in the range of 4-8 Hz. synchronized pattern of firing between most cells in cortex in the range of 4-5 Hz. Auditory stimulus response entrained this oscillation; IPST analysis shows significant correlation between cells during interstimulus time, but not during stimulus response time. ICMS increases particularly the correlation of firing during interstimulus interval. Differences between Ketamine and Nembutal anesthesia relate mainly to spontaneous activity, strength of coherent firing and shapes of RFs. Plasticity occurs with both anesthetics. NIH MH46428

ROLE OF NMDA RECEPTOR IN THE BEHAVIORAL EFFECTS OF ENVIRONMENTAL COMPLEXITY. A. Mohammed R. Liljequist, B. Henriksson, N. Latif, T. Pham and B. Winblad. Dept. of Geriatric Medicine, Karolinska Institute, S-141 86 Huddinge, Sweden.

This study examined the involvement of NMDA receptor in environmentally-induced cognitive changes. Juvenile male Sprague-Dawley rats were housed in group cages. They were treated with the noncompetitive NMDA receptor blocker MK-801 (0.16 mg/kg/day, i.p.) or saline and exposed for two hours to a complex environment (EC). Other animals remained in the standard (social) condition (SC) after drug or saline treatment. Drug treatment and exposure to EC were given on alternate days for 4 weeks. All the animals remained in home cages in groups of 4 per cage for 3 months and then tested for motor activity and spatial learning. During the exposure to EC, observation of the animals using a behavioral checklist was carried out at 10 min intervals. Drug treatment caused ataxia, increased locomotion, and decreased rearing with resultant diminished interaction with objects in the complex environment. For saline treated rats EC resulted in higher rearing scores and rapid habituation, as well as superior spatial learning when compared to SC. This EC-SC difference was absent in drug treated rats where the performance of rats from SC was at the level of those from EC. MK-801 treatment modified the effects of both EC and SC. Radioligand binding studies showed that drug treatment decreased [3H]-MK-801 binding situdies snowed that drug treatment decreased [37]-MK-801 binding sites in cortex and hippocampus. These observations demonstrate that the NMDA receptor is critically involved in mediating environmentally dependent cognitive changes, and are in line with the findings implicating NMDA receptors in neuronal plasticity underlying learning and memory.

NEURON SOMA EXCITABILITY: A COMPARATIVE APPROACH BY ANALYSIS OF Na+ CURRENT IN MOLLUSCAN NEURONS. Rhanor Gillette\* and William F. Gilly, Dept. Physiol., Univ. Illinois, Urbana, IL and Hopkins Marine Station, Stanford Univ., Pacific Grove, CA.

The excitability of neuron somata of opisthobranch and pulmonate snails may be exceptional, since the somata of cephalopods and some other molluscs are non-spiking, like those of arthropods and annelids. In most cases, neither the significance nor biophysical basis of these conditions is known. We measured  $\mathbf{I}_{\text{Na}}$  with whole cell patch clamp of acutely dissociated neurons (0-1 day culture, < 100 microns dia.).  $I_{No}$  is not prominent in larger somata of stellate ganglion neurons of *Loligo* (squid) nor *Octopus* until several days in culture. Properties of INa in these cells are similar to squid giant axon. In contrast, small stellate neurons of these species as well as CNS neurons of opisthobranchs Pleurobranchaea and Doriopsella show  $I_{Na}$  of relatively high density.  $I_{Na}$  kinetics in these differ from squid giant axon: 1. Steady-state curves for activation and inactivation are displaced to positive voltages; 2. INS kinetics of activation, inactivation, and deactivation in the operating (intermediate) voltage range are much slower than those of giant axon cells, but are similar at extreme ends of the range. Such findings may relate to the electrical relationship of the soma to the synaptic integrating region of the neuron.

CHEMICALLY MEDIATED DEFENSIVE INKING IN APLYSIA CALIFORNICA.

C. Kicklighter, P.M. Johnson and T.G. Nolen\*, Department of Biology, University of Miami, P.O. Box 249118, Coral Gables, FL 33124.

Ink release by Aphysia in response to noxious stimulation may function as an anti-predator, chemical defense. While this adaptive hypothesis has yet to be tested directly, considerable indirect evidence supports it: Inking involves an elaborate neural releasing mechanism [Carew & Kandel, 1977]; ink release is directed to the site of attack [Walters & Erickson, 1986]; the toxic secondary plant compounds concentrated by the animal in its ink can act as an effective deterrent [Ambrose et al, 1979]; and finally, ink itself elicits escape behaviors in neighboring juvenile Aphysia [Johnson & Nolen, 1991]. Inking is thought to be triggered only by high threshold, noxious stimulation. But we have found that relatively mild handling can elicit inking and that much of this effect appears to be due to chemical components found on the experimenter's skin.

Forty-five 100 gm Aplysia were tested twice, on successive days, for inking in response to gentle exposure of the length of the foot to BARE skin or GLOVED skin. Comparisons were made between BARE vs GLOVED, BARE vs BARE, GLOVED vs GLOVED, and for prior handling effects. BARE skin elicited inking in 43 to 93% of the trials compared to GLOVED skin, ca 20 to 23% (p<0.05). The probability of BARE skin triggering inking increased following handling with either BARE or GLOVED skin (p<0.05 respectively) whereas the probability of GLOVED skin eliciting inking did not change (p>0.05). When mechanical handling effects are accounted for, chemical factors appear to be correlated with increased ink release. Chemical sensitivity to predators is or common in molluses: Saponins and related naturally occurring surfactants in the skin of predators is sufficiently surfactants in the skin of predatory starfish elicit escape behavior in many other gastropods. Currently we are examining the behavioral and neural mechanisms of chemically mediated inking — in response to a variety of natural, sympatric starfish predators — in several species of Aplysia.

ESTIMATION OF THE SIZE OF A FUNCTIONAL GROUP OF INTERNEURONS CONTROLLING ABDOMINAL POSITIONING IN THE CRAYFISH. L.D. Brewer, and J.L. Larimer\*. Dept. of Zoology, Univ. of Texas at Austin, Austin, TX 78712.

at Austin, Austin, TX 78712.

The command system controlling abdominal positioning (flexion and extension) in the crayfish *Procambarus clarkii* has been extensively studied (Larimer 1988 TINS: 11). Several studies indicate that the command elements underlying this behavior are organized into parallel and serial functional groups through extensive synaptic connections (fellies and Larimer 1985, J. Comp. Physiol., 156; Murphy *et al.* 1989, J. Comp. Physiol. A, 165). We devised a method to estimate the number of interneurons which comprise a functional group controlling abdominal restitioning. Exitive abdominal positioning was observed by recording from motor. positioning. Fictive abdominal positioning was observed by recording from motor roots. Single command elements were stimulated intracellularly in isolated, perfused nerve cords. Recordings were also made from rostral and caudal hemiconnectives (1-2 and 5-6) that were divided into bundles. When these command elements were stimulated they activated a number of previously silent interneurons and increased or inhibited the spontaneous activity of others. We then compared spontaneous with evoked activity. The number of recruited interneurons ranged from 4 to 19 (average = 10; n = 10). Vigorous motor output was usually correlated with a greater recruitment of interneurons. Sometimes a stronger motor output was generated either rostrally or caudally; and interneuronal activity was also directionally biased. Occasionally, evoked activity was of such high frequency that individual spikes could not be identified. Therefore, the actual number of recruited individual spixes could not be identified. Therefore, the actual number of recruited cells is probably higher than reported. Finally, since the output of these command elements are usually symmetrical, the interneurons underlying the behavior may be distributed equally in each half of the nerve cord. Since our numbers are based on counts from one hemiconnective the total number of interneurons in a functional group is probably twice that given above. These data support the functional group hypothesis. (Supported by NIH Grant NS 05423, to J.L.L.)

NEURAL ELEMENTS AND MOTOR PATTERNS UNDERLYING EGG PROGRESSION IN CRICKETS.

T.N. Ricciardi and G.A. Wyse\*, Neuroscience and Behavior Program, University of Massachusetts, Amherst, MA 01003.

Sugawara and Loher (1986, J. Insect Physici. 32:179) described the sequence of events underlying egg movements and oviposition in the reproductive system of female crickets. In an attempt to characterize the motor patterns to musculature involved in egg progression, we recorded the EMG activity of the genital chamber (GC) and muscle 2 (M2) in dissected preparations of adult Acheta domesticus. GC and M2 show ongoing rhythmic bursting that appears to represent motor patterns underlying egg movements during chinosition. The automy of motor patterns underlying egg movements during oviposition. The anatomy of motor neurons supplying these muscles was determined by cobalt backfills of the 7th and 8th segment ventral was determined by cobalt backfills of the 7th and 8th segment ventral nerves, and by intracellular dye fills of single motor neurons. These experiments showed that the 7th and 8th segments of the terminal abdominal ganglion (TAG) contain bilaterally paired clusters of motor neurons, as well as cells similar in morphology to dorsal unpaired median (DUM) cells. In situ intracellular recordings of GC motor neurons (GCMN) show rhythmic bursting that is coincident with ipsilateral GC contraction. Intracellular spikes of GCMN cause time-locked excitatory intertical currents in the GC muscle. ipstlateral GC contraction. Intracellular spikes of GCMN cause time-locked excitatory junctional currents in the GC muscle. Some recordings of single GCMN showed various sizes and shapes of spikes, suggestive of multiple sites of spike initiation. It has been hypothesized that chemical mating factors passed via the spermatophore can activate egg progression and oviposition by turning on pattern-generating circuitry in the TAG. Our system is well suited to test such a hypothesis.

PREDICTING INTERNEURON TUNING CURVES FOR DIFFF" .ENT WIND VELOCITIES IN THE CRICKET CERCAL SENSORY SYSTEM Michael Landolfa-frederic Theunissen and Gwen Jacobs Molecular and Cell Biology, and Graduate Group in Biopysics, UC Berkeley, Berkeley, CA.

The cricket cercal sensory system encodes the direction of wind stimuli over a large range of wind velocities. Both the primary sensory interneurons (INs) and the sensory mechanoreceptors exhibit changes in the variance and shape of their directional tuning curves as a function of changes in wind velocity. To determine the extent to which the IN response properties depend upon the characteristics of the afferent input, we predicted the tuning curves of INs using a simple model and compared those results to data obtained from physiological experiments. First, a computer reconstruction of the topographic map of the sensory afferent arbors was created based on their directional sensitivity to wind and receptor density on the cercus. Hypothetical IN tuning curves were then computed based on (1) the position of the IN dendritic arborizations within this map, (2) the shape of the afferent tuning curves and (3) the electoanatomy of the IN. Hypothetical IN tuning curves were computed using afferent tuning curves measured at several different wind velocities. The computed IN tuning curves were very similar to tuning curves measured physiologically at matched wind velocities.

In previous studies, we demonstrated that the position of peak response of the IN depended on features of the dendritic arborization pattern. We have tested these predictions by blocking inputs to specific dendrites through immobilizing mechanoreceptors on one cercus. The observed shifts in directional tuning curves will be discussed in light of the results predicted by the model.

TIMING OF THE COCKROACH ESCAPE RESPONSE AND THE INFLUENCE OF CHOLINOACTIVE DRUGS. S.  $Y^*$  and  $Y^*$  C.M. Comer. Neuroscience Group, Dept. Biol. Sci., Univ. of Illinois, Chicago, IL 60680

The wind-evoked escape response of the cockroach occurs at short latencies and is mediated by giant interneurons in the ventral nerve cord which are putatively cholinergic. A preliminary report (Krähling, Neurosci. Lett., 62: S514, 1985) claimed that the frequency distribution of latencies for wind elicited escape had several peaks, and that cholinergic drugs could selectively shift some of the peaks. We were interested in verifying that the escape response has different latency classes, and also in assessing the sensitivity of escape latency to cholinoactive

We observed the escape responses of adult male Periplaneta americana with a high speed video system (240 pictures/sec). Wind puffs were delivered to the animals under free-ranging conditions. The frequency distribution of latencies observed in normal animals showed two peaks: an early peak (latencies < 44 ms from time of triggering wind machine) and a later peak (latencies > 44 ms). The relative positioning of these two peaks depended, in part, on wind intensity.

Injecting animals with atropine (200 ug/animal), a cholinergic antagonist, diminished the early peak and slightly shifted the later peak to the right. Injecting animals with carbamylcholine (20 ug to 100 ug/animal), a cholinergic agonist, shifted latencies in the opposite direction — it increased the number of trials comprising the early peak and slightly shifted both peaks to the left. These results partially confirm the observation that there exist more than one class of latencies for the wind-evoked escape. In addition, cholinergic agents affect these classes differently.

FUNCTIONAL REPRESENTATION OF WIND DIRECTION IN THE CRICKET CERCAL SENSORY SYSTEM. Jacob Levin and Gwen Jacobs\* Dept. of Molecular and Cell Biology, UC Berkeley, Berkeley, CA. 94720

We are interested in how a topographically mapped sensory system represents the functional characteristics of sensory stimuli anatomically in the nervous system. In the cricket cercal sensory system, mechanoreceptors on the cerci of the animal are sensitive to both the direction and velocity of wind stimuli. They have broad overlapping tuning curves which encode wind stimulus orientation with respect to the animal's body. We have made a 3-D computer reconstruction of the topographic map formed by the sensory receptors in the CNS by staining and reconstructing single sensory afferents encoding all wind directions. These reconstructions preserve the precise spatial location and the density distribution of terminals within each afferent arbor. Our results show that overlap between the arbors of different afferent types decreases exponentially with separation between tuning curves. Thus, wind direction may be represented in a continuous fashion within the map. To examine this observation in detail, a vector field map consisting of density-weighted average sensitivity vectors at each point in the map was generated, enabling us to visualize how the representation of wind direction changed with position in the map. We have found that the map is composed of two large regions within which the direction of peak sensitivity changes in a continuous fashion. There are, however, abrupt changes in the vector field between these two regions. A similar reconstruction technique was performed on the sensory interneurons. By convolving the IN dendritic arbor with the afferent vector field we were able to illustrate how interneurons construct their receptive fields by sampling different regions of the topographic map.

WIND VELOCITY ENCODING BY SPIKES IN INTERNEURONS OF THE CRICKET CERCAL SENSORY SYSTEM: QUANTIFICATION BY THE REVERSE RECONSTRUCTION TECHNIQUE. F.E. Theunissen.and L.P. Miller. Mol. & Cell Biology Dept., University of California, Berkeley 94720.

The activity patterns of primary sensory interneurons in the cricket cercal sensory system encode information about the direction and velocity of air current stimuli in the animal's immediate environment. In previous work the statistical principles of information theory were used to calculate the maximum directional accuracy attainable from the probabilistic response ensemble of four low velocity interneurons from this system. Here we quantified the accuracy with which the velocity aspect of wind stimuli are encoded in this class of interneurons.

The dimension of the velocity space was too large to allow estimation the conditional probability of the spike train given a particular wind waveform. Instead, the "reverse reconstruction" technique (Bialek et al. Science 1991) was used to estimate the equivalent measure of signal to noise. For our case, we calculated the filter which yielded the best estimate the air current stimulus velocity from the recorded interneuronal spike trains. The effective noise was defined as the difference between the reconstructed stimulus waveform and the actual stimulus waveform. From this signal to noise ratio, the quality of the velocity encoding was characterized by calculating the information theoretic measure of transinformation. We found that the shape of the filter derived for the interneuron, as well as the quality of the associated stimulus reconstruction, were very different from those of the primary sensory afferents in our system (obtained in an earlier study.) This reflects aspects of neural processing carried out between these layers.

THE SUBLEMNISCAL PREPACEMAKER NUCLEUS (SPPN) MODULATES THE FREQUENCY OF THE MEDULLARY PACEMAKER NUCLEUS IN THE GYMNOTIFORM FISH, EIGENMANNIA.

Walter Metzner \*, UCSD 0202, La Jolla CA 92093 and UCR Dept.Biology, Riverside CA 92521

Eigenmannia is able to raise or to lower the frequency of its medullary pacemaker to shift its own electric organ discharge (EOD) frequency away from similar interfering frequencies of its neighbors (= jamming avoidance response, JAR). These frequency shifts are generated by the diencephalic prepacemaker nucleus (PPn-G/CP) and by the sublemniscal prepacemaker nucleus (SPPn), respectively. Activation of the PPn-G/CP raises the pacemaker frequency through AMPA-mediated excitation of cells in the pacemaker nucleus. The SPPn, on the other hand, appears to maintain a stable pacemaker frequency through tonic, NMDA mediated excitation of pacemaker cells. As a consequence, a GABA-mediated inhibition of the SPPn causes a drop in the pacemaker frequency. Therefore, the motor side of the JAR appears to be controlled according to a push-and-pull principle.

POSSIBLE IONIC MECHANISMS UNDERLYING THE CONTROL OF PACEMAKING IN THE WEAKLY ELECTRIC FISH, HYPOPOMUS. J. E. Spiro\*and W. Heiligenberg. Departments of Biology and Neuroscience, UCSD, La Jolla, CA 92093.

Hypopomus discharges an electric organ in its tail which is driven by a signal from an endogenous oscillator, the medullary pacemaker nucleus. In different behavioral contexts, the otherwise regular discharge is modulated to produce a number of distinct output patterns. We are investigating the ionic mechanisms underlying these modulations in an intact preparation as well as in a newly developed whole-brain in vitro preparation by recording intracellulary from the pacemaker cells while inducing changes of the rhythm by stimulating previously characterized presynaptic regions in the diencephalon. Prior investigations have shown that glutamate serves as the transmitter and that the various modulations result from a specific placement of the subtypes of the glutamate receptor complex on the two cell types that make up the pacemaker nucleus.

We have found that the pacemaker is especially sensitive to cesium which has been shown in other preparations to block an inward current that is activated by hyperpolarization, and is implicated in the control of pacemaking (termed If or Ih). Cesium at 1-5mM slows the pacemaker rhythm without affecting spike shape and may impede slow modulations. We suggest that one mechanism for the control of frequency of the pacemaker may involve modulation of this current, which sets the slope of the pacemaking potential, and therefore increases or decreases the interpulse interval.

LOCAL CIRCUITRY WITHIN THE ELECTROSENSORY LATERAL LINE LOBE (ELLL) OF STERNOPYGUS: ROLE OF POLYMORPHIC NEURONS J.A. Matsubara\* and J. Zhang. Depts. of Anatomy and Ophthalmology, University of British Columbia, Vancouver, British Columbia, CANADA, V5Z 3N9.

High frequency weakly electric fish, Apteronotus and Eigenmannia, exhibit a well known behavioral reflex, the jamming avoidance response (JAR). This behavior apparently allows these species to electrolocate in the presence of noise generated by the electric organ discharges of neighboring conspecifics. Neuronal processing underlying the JAR relies heavily on the amplitude and phase coding pathways. A closely related low frequency species, Sternopygus, does not exhibit JAR behavior. Furthermore, earlier anatomical studies showed that the ELLL, a major electro-sensory nucleus receiving both primary afferent and descending inputs, differs markedly between the low and high frequency species, suggesting that microcircuits in the ELLL of Sternopygus may be related to behaviors other than the

In this study, we used intracellular micropipettes to iontophorese lucifer yellow into cells in lightly fixed slices to examine the somatodendritic morphology of selected neurons in the ELLL of Sternopygus. A confocal laser scanning microscope (BioRad MRC 600) was used to collect serial optical sections which were then projected onto a single plane to render a photographic equivalent of a camera lucida image of each neuron. This technique allowed us to study a large number of munohistochemically identified neurons, in combination with retrograde labeling or plant lectin staining, in order to identify cell types and their local connectivity within the ELLL. Our survey revealed a number of new cell types, most of which appear to be modified polymorphic neurons, were far more prevalent in the tuberous subdivisions of Sternopygus when compared to the high frequency species. The dendritic field dimensions of polymorphic, basilar and non-basilar cells near the M/CM, CM/CL and CL/L borders were measured. Dendritic asymmetries were present mostly at the CM/M border. This work funded by NSERC 5-80310 (JM).

CENTRAL PROJECTIONS OF THE LATERAL LINE NERVES IN GYMNAR-CHUS NILOTICUS (GN) IDENTIFIED BY HRP AXONAL TRANSPORT. T. Szabo\*, A. Bass, R.G. Northcutt, M. Ravaille-Veron.Inst. Alfred Fessard, CNRS, F-91198 Gif-sur-Yvette Cedex; Sect. Neurobiol. & Behav., Cornell Univ., Ithaca, N.Y. 14853, USA; Dept. Neurosci. A-001, UCSD, La Jolla, CA 92093, USA. As other weak electric fish GN possesses a posterior (ELL) and an anterior (NM) lateral line lobe (Bass & Hopkins, 1982), the presumed main central projection areas of the lateral line nerves. HRP labeling of the posterior (PLLn) and anterior (ALLn) lateral line nerves demonstrates that indeed both nerves project to the ELL and NM as well as to the eminentia granularis and corpus cerebelli. In the ELL, the ALLn projects to its medial, the PLLn to its lateral half, and both projection fields extend from the ELL's pos-terior pole to its anterior border. Each nerve projects to three distinct ELL cortical regions: to the medial (MZ), dorsal (DZ) and ventral (VZ) cortical zones. Thick fibers of each nerve end in the inner cell layer (IC) of  $\ensuremath{\text{MZ}}\xspace,$ whereas medium sized fibers project to the inner cell layer of DZ and VZ. According to the fiber diametre spectrum, the  $\ensuremath{\mathsf{MZ}}\xspace$  ,  $\ensuremath{\mathsf{DZ}}\xspace$  and  $\ensuremath{\mathsf{VZ}}\xspace$  cortical areas appear to be the projection areas of the three GN electroreceptor types, Gymnarchomast I, II and ampullary receptor (Szabo, 1965), respectively. In addition, fine fibers terminate on the giant cells of the ELL deep fiber layer, which seems to be a particularity

## 149.12

THE EMERGENCE OF ELECTROTONIC CONNECTIONS IN THE DEVELOPING MEDULLARY PACEMAKER NUCLEUS OF APTERONOTID ELECTRIC FISH. W. Heiligenberg\* and G. Kennedy, Neurobiology Unit, Scripps Institution of Oceanography, UCSD, La Jolla, CA 92093

The medullary pacemaker nucleus of gymnotiform electric fish consists of electrotonically coupled pacemaker cells, which generate the oscillation, and pacemaker cells, which generate the oscillation, and relay cells, which transmit the pacemaker signal to the spinal motor neurons of the electric organ. Pacemaker cells form chemical synapses on relay cells in species such as <a href="Hypopomus">Hypopomus</a>, which discharge their electric organ at relatively low rates (in the range of tens of Hz) and are considered 'ancestral' in this regard. The most modern gymnotiform fish appear to be those of the apteronotid family, which discharge at the highest known frequencies (in the range of 1000 Hz), and have converted the ancestral myogenic electric organ to a faster, neurogenic organ. This evolution is repeated in the juvenile development of these fish (Kirschbaum F, Naturwissenschaften 70: 205 (1983)). In addition, adult apteronotid fish have established purely electrotonic junctions between pacemaker cells and relay cells (see junctions between pacemaker cells and relay cells (see reviews in Bullock and Heiligenberg: Electroreception, Wiley (1986)). These connections, however, are 'still' chemical in juvenile apternotids and are then replaced by electrotonic junctions as the fish's initially low pacemaker frequency approaches adult levels.

FAST NMDA TRANSMISSION IN A SENSORY FEEDBACK PATHWAY. J.R.Plant\*, R.W.Turner§ and L.Maler. Dept. of Anat., Univ. of

PATHWAY. J.R.Plant\*. R.W.Turner\$ and L.Maler, Dept. of Anat., Univ. of Ottawa, Canada, K1H 8M5 ;\$Dept. of Physiol. Univ. of Calgary, T2N 4N1 Within the electrosensory system of weakly electric fish, feedback projections constitute a significant yet poorly understood functional component. Two sensory feedback pathways (one direct and one indirect) project back to the first order electrosensory processing nucleus the Electrosensory Lateral Line Lobe (ELL), with spatially discrete zones of synaptic termination in the ventral (VML) and dorsal (DML) molecular layers respectively. While the response characteristics of the projection neurons of the direct tractice stratum librarium (Tel) teachback projection in the bean in the contraction have been synaptic termination in the ventral (vmL) and orderal (DML) molecular layers respectively. While the response characteristics of the projection neurons of the direct tractus stratum librosum (Tst) feedback projection have been investigated Invivo (Bratton and Bastian, 1990), the physiological and pharmacological characteristics of their synaptic terminations in the VML have yet to be fully elucidated. Since these synapses are excitatory in appearance, and NMDA and Non-NMDA receptors have been demonstrated in this region, we investigated the effects of various EAA receptor antagonists on synaptic transmission in the VML Invitro. Under control conditions, electrical stimulation of the Tst evoked a characteristic extracellular field potential in the VML which (1) consisted of both an early (3-10 msec) and late (>10 msec) phase, (2) was restricted to the zone of Tst synaptic termination, (3) was blocked by Mn2+, and (4) was reversibly blocked by focal pressure ejection of the NMDA receptor antagonist CPP (1mM) reduced both the early and late phase of the VML response, and while both phases of the VML response were enhanced under 0-Mg+, this effect was completely blocked by CPP. Under control conditions, CNOX (1mM) completely blocked by CPP. Under control conditions, CNOX (1mM) completely blocked the VML response was seen which was subsequently blocked by CPP. Theses results confirm the existence of fast NMDA receptor mediated synaptic transmission. transmission

INFORMATION CODING BY PRIMARY ELECTROSENSORY AFFERENTS IN APTERONOTUS. M.E. Nelson\*, J.R. Payne,

Z. Xu. Dept. of Physiology and Biophysics, Beckman Institute, Univ. of Illinois, Urbana, IL 61801.

The first stage of information processing in the electrosensory system is the encoding of electrical stimuli by primary electrosystem is the electrical stimuli primary electro-sensory afferents. Natural stimuli give rise to perturbations in the fish's electric field which typically influence a large number of electroreceptors on the body surface. Individual receptors within the region of influence can have varied properties in terms of threshold, gain, dynamic range and temporal filtering properties. In order to understand how sensory information is encoded at the periphery, it is necessary to characterize the distributions of response properties is necessary to characterize the distributions of response properties within the primary afferent population. To address this issue, we characterize response properties in probability coding (P-type) afferents in the brown ghost knife fish, Apteronotus leptorhynchus. We quantify the response properties of individual afferents by fitting we quantify the response properties or individual affective by fitting a time-domain model of primary afferent dynamics to experimentally measured responses to step and sinusoidal amplitude modulations. We use a linear-nonlinear cascade model, consisting of a linear dynamic block followed by a static nonlinearity. The linear part of the model consists of a spontaneous rate term, a tonic gain term, and two phasic components (fast and slow). The output of the linear model feeds into a sigmoidal-type nonlinearity which accounts for the effects of rectification and saturation. The model provides a basis for quantifying how information about the electrosensory world is represented at the electrosensory periphery.

MOVING OBJECT RESPONSES OF PERIPHERAL AND TECTAL MECHANOSENSORY, AND BIMODAL ELECTRO/ MECHANOSENSORY LATERAL LINE UNITS IN WEAKLY ELECTRIC FISH. Bandy Zelick\* and Horst Bleckmann. Biology Dept., Portland State University, Portland, OF

LATERAL LINE UNITS IN WEAKLY ELECTRIC FISH. Randy Zelick\* and Horst Bleckmann. Biology Dept., Portland State University, Portland, OR 97207 and Fak. für Biologie II, Universität Bielefeld, W. 4800 Bielefeld 1, FRG In weakly electric fish Eigenmannia virescens primary lateral line units were very sensitive to small vibrations from a moving object (2.0x 1.5 x 0.6 cm) for object speeds ≥ 2.5 cm/s. Peak spike rate and total number of spikes elicited increased with increasing object speed. In the velocity range tested (2.3 - 20 cm/s) saturation of neural responses did not always occur. Compared to tuberous electroreceptors, object detectability over distance declined more slowly in the mechanosensory lateral line. Opposite directions of object movement often caused an inversion of the main features of the response histogram. Increases in spike frequency became decreases and vice versa. But in terms of peak spike rate or total number of spikes elicited, primary lateral line afferents were not directionally sensitive. Midbrain lateral line units of Apteronotus leptorhynchus had low spontaneous activity and a weak, jittery response to object motion. If the object was set into vibration while moving past the fish, however, the total number of spikes elicited increased and masked object position. In contrast to the peripheral lateral line, many higher order lateral line neurons were direction-sensitive. Highly directional ampullary and tuberous midbrain units were also recorded. The receptive fields of single units demonstrated a somatotopic organization of lateral line input: anterior body areas project to rostral midbrain, posterior body areas project to caudal midbrain. Bimodal lateral line-tuberous or lateral line-ampullary units recorded were OR units, i.e., the units were reliably driven by a unimodal stimulus of either modality. Thus object motion is coded by multimodal mechano- and electrosensory input. Tuberous electrosensory input provides good low-speed information over a shorter range, while the mechanosenso

SOUND PRODUCTION EVOKED BY ELECTRICAL STIMULATION OF THE OYSTER TOADFISH FOREBRAIN. M.A. Perini and M.L. Fine\*
Dept. of Biology, VA. Commonwealth Univ., Richmond, VA

Although sonic pathways in vertebrates are considered homologous, forebrain involvement in sound production has not been investigated in fishes. We targeted potential forebrain structures in and close to the preoptic area based on their role in fish courtship, presence of steroid concentrating neurons and involvement in frog mating call roduction. The agonistic grunt and courtship boatwhistle call were evoked in the nucleus preopticus parvocellularis anterior (PPa) and the supracommissural nucleus of the ventral telencephalon (Vs), an amygdala homologue. Evoked sounds formed a continuum from knock to burst grunts to transition and complete boatwhistles, and sound pressure level (SPL), fundamental frequency and duration increased within the continuum. For all sound types, SPL exhibited smallest, fundamental frequency intermediate and duration widest variation. Boatwhistles exhibited the smallest variation suggesting maximal output of the CNS and sonic muscles, whereas grunt SPLs varied by as much as 18 dB, suggesting recruitment of variable numbers of motor units despite electrical coupling within the sonic motor nucleus.

## 149.16

SEXUAL DIMORPHISM IN CHIRPING BEHAVIOR INDUCED BY ELECTRICAL STIMULATION OF THE WEAKLY ELECTRIC TELEOST, APTERONOTUS LEPTORHYNCHUS. G.K.H. Zupanc<sup>1,2\*</sup> and L. Maler<sup>2</sup>. Abteilung Physikalische Biologie, Max-Planck-Institut für Entwicklungsbiologie, W-7400 Tübingen, F.R.G., and <sup>2</sup>Dept. Anatomy, University of Ottawa, Canada K1H 8M5.

The brown ghost, Apteronotus leptorhynchus, produces quasi-sinusoidal electric organ discharges (EODs) of highly constant frequency and waveform. In the context of aggression, courtship, and mating short-term modulations of the EOD may occur. One common form are "chirps", brief and sharp rises in EOD frequency (T.H. Bullock, Brain Behav. Evol. 2: 85-118, 1969; M. Hagedorn and W. Heiligenberg, Anim. Behav. 33: 254-265, 1985). By stimulating a fish electrically with a sine wave of slightly different frequency than its own EOD, chirps can be elicited under controlled experimental conditions (J. Dye, J. Comp. Physiol. A 161: 175-185, 1987; L. Maler and W.G. Ellis, Behav. Brain Res. 25: 75-81, 1987). In the present study, we used such a stimulation regime consisting of four 30 s trials to examine some of the parameters that may influence the propensity to chirp.

While total length, body weight, relative gonadal weight, and EOD frequency were only weakly correlated with the rate of chirping, the sex of the fish turned out to be a decisive factor. Females, on the average, chirped only 0.5 times per 30 s, and 7 out of 9 female fish tested did not chirp at all during the 30 s stimulation periods. Males, in contrast, generated on the average 21.9 chirps per 30 s, and even the weakest male produced a total of 6 chirps during the four 30 s trials. The difference between males and females is highly significant when comparing the mean chirp rates of individuals (p = 0.0001, Mann-Whitney U Test, 2-tailed, n =9 females and 21 males). We hypothesize that this sexual dimorphism may be caused by differences between males and females in the structure of the prepace-maker nucleus, a diencephalic cluster of neurons controlling chirp-like modulations of the EOD (M. Kawasaki et al., J. Comp. Neurol. 276: 113-131, 1988).

## 149.18

TRANSNEURONAL BIOCYTIN OUTLINES THE VOCAL MOTOR CIRCUIT IN A TELEOST FISH. A. Bass\*, M. Marchaterre, B. Horvath and R. Baker. Neurobiology and Behavior, Cornell Univ., Ithaca, N.Y. 14853; Bodega Marine Laboratory, Bodega Bay, CA. 94923; Physiology & Biophysics, NYU Medical Center, New York, N.Y. 10016.

The plainfin midshipman Porichthys notatus vocalizes by the simultaneous contraction of sonic muscles attached to the lateral walls of the swimbladder. Intracellular staining and recording has demonstrated that each muscle is innervated ipsilaterally by large motoneurons (lm) located in caudal brainstem sonic motor nuclei (SMN). Certain pacemaker neurons (pm) lie ventrolateral along the entire extent of the SMN and innervate it bilaterally, consistent with the hypothesis that they synchronize motoneuron activation. Biocytin was used as a transneuronal tracer to more completely identify the extent and position of pacemaker tracer to more completely identify the extent and position of pacemaker and command neurons. Following ipsilateral injections into the sonic muscle or nerve, 4 groups of biocytin-labelled neurons with a Golgi-like filling of their processes and somata were observed: Im ipsilateral, pm bilateral, 'small' motoneurons (sm) bilateral but restricted to the rostral SMN, and ventrolateral reticular formation neurons (vrf) bilateral but rostral to the SMN. Sm, unlike lm, had extensive dendritic branching lateral to the SMN and possible axonal branching to both sonic muscles. Axons of the vrf ascended and terminated at the level of brainstem auditory and vestibular nuclei. The vrf may be a part of the pacemaker circuitry and include command neurons providing temporal information to sensory-recipient nuclei. Support by NSF, NIH and New York State Hatch Act.

STUDIES OF THE STARTLE REFLEX IN FATHEAD STUDIES OF THE STARTLE REFLEX IN FATHEAD MINNOWS: METHODS AND INITIAL DATA. J.M. Wakeman, M.O. McHenry, I.D. Kendrick and R.L. Seaman\*. Depts. of Biological Sciences and Biomedical Engineering, Louisiana Tech Univ., Ruston, La 71272.

Startle reflexes in fathead minnows

Ruston, La 71272.

Startle reflexes in fathead minnows
(Pimephales promelas) were evoked using brief
(50-100 ms) sinusoidal sound stimuli at
frequencies from 50 to 1000 Hz. The fish were
held within a cylinder along which they could
swim freely but could turn only with difficulty.
An infrared beam at one end of the cylinder was
directed towards an infrared detector at the
other end and responses were digitized at 2000
samples/sec and stored on disk.

Initiation of the startle response occurred
within 8 - 14 ms (mean = 10 ms) following onset
of the stimulus. At frequencies below 700 Hz,
startle responses were elicited in 71% of the
trials. However, the response rapidly weakened
at higher frequencies and no startle response
could be evoked at 1000 Hz.

The techniques and initial data developed
in this study will be applied in subsequent
studies on modification of fathead minnow
startle responses by prepulse stimuli and
chemical exposure.

Supported by a Louisiana Tech Faculty
Development Grant.

CHRONIC VARIABLE STRESS ENHANCES THE STIMULATORY ACTION OF LOW DOSES OF MORPHINE: REVERSAL BY DESIPRAMINE. V.A. Molina\*, C.J. Heyser, and L.P. Spear. Center for Developmental Psychobiology and Dept. of Psychology, SUNY, Binghamton, NY 13902-6000.

The effect of a low dose of morphine on locomotor activity was investigated in rats previously exposed to a chronic variable stress treatment (CVS) with or without concurrent daily administration of desipramine (DMI). Animals given CVS were submitted daily to a different stressor following an injection of either saline or DMI (5 mg/kg, i.p.), whereas control animals were unmanipulated except for the injection process. Following 2 weeks of CVS treatment, control and stressed animals were administered saline or morphine (1.5 mg/kg, i.p.) and their locomotion assessed for 90 min. A substantially greater increase in locomotor activity following morphine administration was observed in chronically stressed rats as compared to control rats. This potentiated locomotor response to morphine in CVS rats was attenuated by DMI pretreatment prior to the daily stressors. These data support the suggestion that a CVS regimen results in sensitization to the low dose stimulant effects of opioid stimulation, and that pretreatment with the tricyclic antidepressant DMI prior to the daily stressor blocks the development of this sensitization.

## 150.3

CHRONIC STRESS DOES NOT AFFECT ARTERIAL BLOOD PRESSURE IN THE RAT. Y. Tizabi\*, V.J. Massari and P.J. Gatti. Dept. of Pharmacol., Howard Univ., Washington, D.C. 20059

In humans, stress or psychological stimulation may be an important factor in the etiology of hypertension. Several studies in the rat have provided evidence in support of this hypothesis. However, these studies have utilized the tail-cuff method for measurement of blood pressure (BP). Since a variety of factors can influence the outcome of measurement by this method, rigorous control of the environment is required. In addition modest changes in BP may be difficult to detect with this technique. This study was designed to correlate the changes in BP, measured by direct intraarterial cannulation, with various durations of stress. Male Sprague-Dawley rats were immobilized for 2.5 hr daily, 5 days a week for 2, 4 or 6 weeks. Twenty four hours after the last stress, rats were anesthetized with urethane (1.5g/kg, i.p.) and the carotid artery was cannulated for BP easurement. The anesthetic urethane was shown not to affect BP. The study verified that the weight gain in stressed animals was considerably lower than in controls. However, no significant difference in BP or heart rate between any stressed group or controls was detected. The mean systolic and diastolic pressures were approximately 92 and 52 mmHg respectively. The mean heart rate was approximately 300 beats/min. Thus, the question of whether chronic stress does indeed result in hypertension in rats requires further clarification. (Supported by American Heart Association/ NCA)

CHRONIC SOCIAL STRESS IN RATS: EFFECTS ON GLUCOCORTICOID SECRETION AND CORTICOSTEROID
BINDING GLOBULIN R.R. Sakai\* S.M. Weiss, D.C. Blanchard,
R.J. Blanchard, R.L. Spencer, A.H. Miller and B.S. McEwen. The
Rockefeller University 1230 York Ave., NY., NY 10021, Mount. Sinai
Medical Center. NY, NY 10029 and The University of Hawaii, 2430 Campus Rd. Hono., HI 96822.

The use of a visible burrow system in the analysis of social interactions in rat colonies has been shown to provide an effective model for the examination of behavioral and neuroendocrine effects of prolonged social stress. In a previous study we showed that dominant male rats within each colony had lower basal plasma corticosterone than subordinate rats after two weeks in the colony situation.

We have extended these studies to show that, in addition to an elevated basal level of corticosterone, the response of subordinate rats after 1 hour of a novel restraint stress was blunted as compared to the

typical elevation in corticosterone seen in control animals.

Levels of serum corticosteroid binding globulin (CBG) were also lowest in subordinates, higher in dominants and highest in singlyhoused controls. Low CBG in subordinates may lead to higher concentrations of free corticosterone in these animals and may explain the increase in receptor activation (decrease in Type II glucocorticoid receptor binding) found in spleen tissue of subordinate rats compared to dominant and control animals.

These data provide further support that subordinate and dominant male rats in a burrow system habitat provide a useful model for the analysis of neuroendocrine effects of prolonged social stress. (Supported by AA0622, MH41256, MH42803, MH47674)

VISCERAL AND BEHAVIORAL HYPERSENSITIVITY CONSEQUENT TO REPEATED STRESSOR EXPOSURES: FURTHER EVIDENCE TOWARD AN ANIMAL MODEL OF PTSD. R.J. Servatius', J.E. Ottenweller, S. Soldan, J.L. Gross, B.H. Natelson. V.A. Medical Center & New Jersey Medical School, East Orange, N.J. 07019.

Human PTSD, a stress-related mental illness, is characterized by persistent post-stressor abnormalities including visceral hyperresponsiveness and exaggerated startle responding. We previously reported an animal model of PTSD exhibited elevated basal corticosterone (CORT) and altered behavior for up to 3 days post-stressor. To extend our analogy to PTSD we examined hypersensitivity in our model. In Experiment 1, rats were exposed to 3 or 1 day(s) of in our model. In Experiment 1, rats were exposed to 3 or 1 day(s) of 40, 2-mA tallshocks. Rats were then given a single tallshock probe 10 days post-stressor. For both repeatedly stressed groups the CORT response to the probe at 15-min and 60-min post-stressor was elevated response to the probe at 15-min and 60-min post-stressor was elevated compared to nonstressed probed rats. In Experiment 2, rats exposed to 3 days of tailshock stress were tested for their startle response to high and low auditory stimuli. Repeatedly stressed rats exhibited an exaggerated startle response to the low stimulus 4 days post-stressor, but at either 1 day or 10 days post-stressor. There were no difference in startle responding to the high stimulus. The hyperresponsiveness in our model, both visceral and behavioral, makes it a prime choice for the study of the etiology and treatment of PTSD. Supported by V.A. Medical Research funds. THE EFFECTS OF CONTINUOUS AND INTERMITTENT (SART) COLD EXPOSURE ON HYPOTHALAMIC-PITUITARY-THYROID AXIS IN RATS. K. Fukuhara<sup>1,3</sup> G. Cizza<sup>2</sup>, R. Kvetnansky<sup>1</sup>, V.K. Weise<sup>1</sup>, H. Ohara<sup>3</sup>, K. Go<sup>3</sup> and LJ. Kopin<sup>1</sup>, NINDS and <sup>2</sup>NIMH, NIH, Bethesda, MD 20892, <sup>3</sup>Inst. of Bio-Active Science, Nippon Zoki, Hyogo, Japan.

Immobilization stress produces an activation of the sympathoadrenal and hypothalamic-pituitary-adrenocortical systems but inhibits the hypothalamicpituitary-thyroid axis activity in rats. Recently, we reported that SART (Specific Alternation of Rhythm in Temperature) stress, i.e. continuous cold exposure interrupted by four hourly intervals of room temperature daily, activates mainly the sympathoneural system in rats. In the present study, we examined the effects of long-term SART and continuous cold on hypothalamic-pituitary-thyroid axis, which is functionally related to the sympathoadrenal system. Male Wistar rats (280-350 g) were exposed to -3 °C for 5 days, either continuously, either with four hourly intervals of room temperature. Plasma TSH and free T3 levels were significantly increased by both SART and cold stress, whereas plasma free T4 levels were not changed. KCI-stimulated TRH in vitro secretion from hypothalamic explants was four times higher in both SART and cold stressed-rats compared to controls (room temperature), whereas basal TRH secretion was not modified by cold exposure. Plasma ACTH and corticosterone levels were not significantly changed in rats exposed to either SART or continuous cold stress for 5 days. These results suggest that the hypothalamicpituitary-thyroid axis is highly activated by continuous or intermittent (SART) cold exposure. It appears that hypothalamic-pituitary-adrenocortical system, which is highly activated by some stressors (e.g. immobilization), is not significantly affected by long-term cold exposure.

NIMODIPINE COUNTERACTS BEHAVIORAL EFFECTS OF LONG TERM CORTICOSTERONE TREATMENT

A. Levy\*, T. Kadar and S. Dachir Israel Inst. for Biological Res., Ness-Ziona, 70450, ISRAEL. Corticosterone (COR) slow release pellets were implanted subcutaneously in young Fischer rats, in an attempt to produce an animal model for the central effects of stress. COR treated rats exhibited cognitive impairments during the initial acquisition stage of the radial arm maze (RAM), and morphological specific damages in their pyramidal hippocampal cells, mainly at CA1 and CA4 regions. In a continuation study, COR and placebo groups were divided into two sub-groups, fed by either regular food or food containing 860 fed by either regular food or food containing 860 ppm of nimodipine. During the second week of this treatment, their activity in a new environment was measured. Placebo-treated rats, explored the new environment and showed a characteristic habituation, leading, two days later, to a low activity in the same maze, while COR treated group regarded it as completely new. COR rats treated with nimodipine behaved during this test as controls. The protection afforded by this test as controls. The protection afforded by this test as controls. The protection allocated  $\omega_1$  nimodipine against morphological and cognitive impairments induced by long term COR treatment will be substantiated using the RAM and histological evaluation (Supported by Bayer AG).

CHRONIC COCAINE CHANGES CHRONIC STRESS-INDUCED ALTERATIONS IN DOPAMINE (DA) AND 5-HT NEUROCHEMISTRY. David J. Mokler', Mark Dixon and Denise Gay Dept. Pharmacol., Univ. New England Col. Osteopathic Med., Biddeford, ME 04005.

The purpose of the present experiment was to examine the effects of chronic cocaine administration on the stress-induced alterations in DA and 5-HT neurochemistry. Male C57Bl/6J mice were exposed to an acoustic stressor (100 dB, 8 kh tone for 1 se on a variable 90 sec interval) during 1 hr sessions for 14 d. Half of each stress group was administered either saline or 25 mg/kg cocaine HCl 3 hours after the end of the session. Five min after the last stress session, animals were decapitated. The CN, mPFC and NA were dissected from frozen slices and analyzed by HPLC. Cocaine and stress produce significant alterations in the levels of DA and metabolites, DOPAC and HVA, as well as, 5-HT and 5-HIAA in the mPFC. Turnover rates were increased for DA by cocaine and cocaine and stress; while 5-HT turnover was increased by cocaine and stress but not the combination.. In the CN, stress decreased DA, HVA, 5-HT and 5-HIAA. Cocaine did not alter the effects of stress. Turnover of DA and 5-HT were not altered by stress or cocaine. Thus chronic exposure to cocaine produces alterations in the response to chronic stress.

FOOTSHOCK-INDUCED EXACERBATION OF

AMPHETAMINE CTA. W.J. Bowers, M.A. Gingras & Z.

Amit\*, Center for Studies in Behavioral Neurobiology, Dept.

Psychology, Concordia University, Montreal, Canada, H3G 1M8.

Stressors have been reported to block the development of

CTA to lithium but not morphine. However, it is unclear if this
effect generalizes to other self-administered drugs. Since cross sensitization exists between amphetamine and stressors, we expected that footshock would augment amphetamine-induced CTA. In experiment 1 rats were placed on a restricted water schedule. On pairing days animals were given .1% saccharin instead of water and were exposed to either footshock or no shock. Half the animals in each group were then injected with either saline or 2mg/kg amphetamine. A second pairing was conducted 2 days later followed by 4 extinction trials on alternate days and access to water on intervening days. Experiment 2 was identical except footshock was given 2 and 4 days preceding the amphetamine-saccharin pairing. On pairing days, half the animals in each shock group received either saline or amphetamine. A second pairing was conducted 2 days later followed by 4 extinction trials as in experiment 1. For both experiments, a CTA was evident on the second pairing day and continued until the third extinction trial. Footshock alone had no effect on saccharin consumption but it did exacerbate the amphetamine-induced CTA evident on the second pairing day.

CHRONIC ABERRANT BEHAVIOR IN THE MENTALLY RETARDED (MR): ANIMAL MODELS, RISK FACTORS AND REPEATED STRESS. <u>C. J. Stodgell\*, P. S. Loupe, & R. E. Tessel</u> Dept. of Pharmacol. & Toxicol. Univ. of Kansas, Lawrence, KS 66045

Certain risk factors appear to contribute to the likelihood that the MR will chronically manifest aberrant behaviors (CAB). Previously our laboratory demonstrated that acute stress (foot shock) can elicit CAB-like behaviors in terministrated intal acute stress (total strick) can elicit CAD-like behavior a rats modeling these risk factors. In the present study we examined the behavioral effects of chronic (repeated) stress in these risk-factor models. Spontaneously hypertensive (SHR), Sprague-Dawley (SD), methylazoxymethanol-induced microencephalic (MAM), and 6-Hydroxydopamine (6-HD) neonatal catecholamine depleted rats were group hydroxydopamine (e-nD) neonatal catecholamine depleted rats were group housed (GH) or socially isolated (SI) for 3 months post weaning. Then, every 3-4 days rats received foot shock (6/2s every 10s/1h X 7 sessions.), The sessions were video taped and behaviors scored (e.g., self injurious behavior, sagression, stereotypy, and hyperactivity). Differences in groups and housing condition were as follows (">" = p< 0.05; lack of housing designation indicates no sig. housing effect). CAGE BITING (aggression); Session 1: SHR-SI>all other group. Session 7: 6-HD-SI>all other groups.

MAINTAINED REARING (stereotypy); Sessions 1 and 7: MAM>all other groups. Session 1 v. 7: Maintained rearing is increased in the MAMS.

LOCOMOTOR ACTIVITY DURING SHOCK (hyperactivity); Session 1: MAM>(SD-SI>SD-GH)=(SHR-SI>SHR-GH)>MAM. Session 1 v. 7: ocomotor Activity is decreased in all of the groups. FREEZING (LEARNED HELPLESSNESS?); SESSION 1: SHR>SD=6-HD>MAM. Session 7: SHR=SD=8-HD>MAM. Session 1 v 7: There is an increase in Freezing behavior in all groups except MAMs. These data support the hypothesis that stress can contribute to both the chronicity and topography of CAB displayed by the MR. (Supported by NICHHD grant 1 PO 1 HD26927)

STRESS: CHRONIC

ESCAPABLE AND INESCAPABLE SHOCK DISRUPT DELAYED ESCAPABLE AND INESCAPABLE SHOCK PRODUCT OF ALTERNATION IN RATS R. Bauman and G. Kant. Dept. of Medical Neurosciences, Walter Reed Army of Medical Neurosciences, Walter Reed Army Institute of Research, Washington, D.C. 20307. In our rodent model of sustained stress, a 12

hour light/dark cycle is maintained in individual living cages where a rat must feed itself by pressing a lever once for each food pellet. A rat in group ES is trained to pull a ceiling chain to avoid/escape signaled footshocks that are schedavoid/escape signaled footshocks that are sched-uled 24 hours/day. In group IS, a rat can not avoid/escape shock; shock delivery is yoked to the delivery of shocks in group ES. In an effort to evaluate the effects of sustained stress on a simple cognitive performance, pellets were delivered only if a rat alternated presses on two levers and a signaled minimum delay of 16 sec elapsed between presses. Compared to rats who were not shocked, mean

Compared to rats who were not shocked, mean percent correct alternation (accuracy) of groups ES and IS was reduced during the dark but not the light period of the first day of shock. The mean accuracy of group IS was most reduced and compared to the accuracy of group ES recovered much more slowly during seven days of sustained shock. These data suggest that this model is sensitive to the differential impairment of cognitive performance by controllable and uncontrollable stress.

CENTRAL ALPHA2 ADRENOCEPTORS AND FOOTSHOCK STRESS. G.B. Kovachich\*, R.E. Poland, A. Frazer & C.E. Aronson, Vet. Affairs Med. Ctr., Phila. PA\*, Harbor-UCLA Med. Ctr., Torrance, CA, Univ. of Pa. School of Med., Phila. PA.

Stress activates the hypothalamic-pituitary-adrenal (HPA) axis leading to augmented release of ACTH and corticosterone (CS), and repeated exposure to the same stressor attenuates this response. Alpha<sub>2</sub> adrenoceptors appear to play a key role in regulation of ACTH and CS adrenoceptors appear to play a key role in regulation of AC1H and CS release, since administration of clonidine alters their release under either basal or stress conditions. We examined the effect of daily exposure of rats to 30 min sessions of intermittent footshock (0.15mA shocks calibrated across 53K Ohms; 0.5sec duration with 0.5sec intervals delivered 15 times every 5 min) for 1, 6 or 10 days on central alpha2 adrenoceptors, measured by quantitative autoradiography using <sup>3</sup>H Idazoxan (3nM). Baseline CS increased slightly, but not significantly, in the strength of the control of auazonan (3nivi). Baseline CS increased slightly, but not significantly, in rats given footshock for 6 days. However, a single initial footshock session increased plasma CS by 209  $\pm$  28% but the same footshock session only increased plasma CS by 47  $\pm$  23% in rats given five prior footshock sessions (p<0.001). This suggests adaptation of the stress response. Central alpha<sub>2</sub> adrenoceptors showed no change in the paraventricular nucleus of the hypothalamus (where CRF producing neurons originate) or in noradrenergic cell body areas A1, A2, or A6, neurons originate) or in noradrenergic cell body areas A1, A2, or A6, either after 1, 6 or 10 days of footshock. By contrast, chronic but not acute exposure of rats to footshock significantly elevated alpha2 adrenoceptors in several areas of the dorsal hippocampus. The results support recent results indicating the importance of the hippocampus in the adaptive response to chronic stress. (Supported by Research Funds from the Veterans Administration).

FEAR-POTENTIATED STARTLE IN POST-TRAUMATIC STRESS DISORDER C.A. Morgan III M.D., C. Grillon Ph.D.\*, M.Davis Ph.D.,

D.S.Charney M.D., Yale University, West Haven VA Medical Center, West Haven, CT, 06516.

Objective studies have given conflicting results as to whether or not startle is increased in Post Traumatic Stress Disorder (PTSD). Normal, increased and reduced startle have all been reported. Increased startle increased and reduced startle have all been reported. Increased startle can be considered as part of a conditioned emotional response to stimuli reminiscent of trauma. A reasonable model for the conditioned emotional response in PTSD is the fear-potentiated startle paradigm in which a central state of fear/anxiety increases the magnitude of the startle reflex. This study was designed to explore both the magnitude and timing of the effect of anticipatory anxiety on startle in combat veterans with PTSD. The eyeblink component of the startle reflex was measured at various times preceding and following the anticipation of electric shock in 9 PTSD subjects and 10 age-matched controls. Results indicate that startle was greater throughout the experiment in the PTSD subjects, compared to the controls. In addition, the magnitude of startle potentiation at the time of shock expectation was larger in the PTSD. compared to the control group. Because data from larger in the PTSD, compared to the control group. Because data from our laboratory indicate normal baseline startle in the same cohort of PTSD subjects when no aversive stimulation is anticipated, these data suggest that exaggerated startle is contextual in PTSD.

STRESSOR CONTROLLABILITY AND PLASMA CHOLESTEROL. Francis

STRESSOR CUPIROLLABILITY AND PLASMA CHOLESTEROL. Flatters

We Brennan, Jr.\*, Linda R. Watkins, & Steven F. Maier. Psychology Department,
University of Colorado, Boulder, CO, 80309, USA.

Elevations in the level of cholesterol in plasma are a risk factor for the
development of Coronary Heart Disease (CHD). We have recently reported
(Brennan, Job, Watkins, & Maier, 1992) that three sessions of inescapable tailshock, one session per day for three consecutive days, is sufficient to increase the total plasma cholesterol levels of rats versus nonshocked controls. Uncontrollable stress produces a myriad of behavioral and physiological changes that do not occur, or occur with a marked reduction in severity, if the physically identical stressor is presented in a controllable manner. Berger, Starzec, Mason, and DeVito (1980) demonstrated that total plasma cholesterol was sensitive to stressor controllability using a 30 day leverpress avoidance paradigm. The purpose of the present study was to explore whether various cholesterol parameters were differentially sensitive to the

controllability of our relatively brief stress procedure.

Male Sprague-Dawley rats were exposed to 3 sessions of either escapable shock mane sprague-12wiey rats were exposed to 3 sessions of either escapable shock, or no shock. Escape subjects could terminate a 1.0 mA shock pulse, delivered to the tail via an attached electrode, by performing a wheel turn response. Each escape subject had a yoked partner that received the identical pattern of shock as his escape partner. Control animals were left undisturbed in their home cages. Escape and yoke subjects received one 100-shock session per day, for three consecutive days. Blood samples were taken prior to stress, and four hours after the conclusion of the third stress session.

Results indicated that stressed groups showed elevated levels of both total cholesterol, as well as LDL and VLDL cholesterol, relative to nonshocked controls. No differences were observed between escape and yoke animals. The fact that cholesterol is sensitive to controllability in more chronic stress regimens (Berger et al., 1980), while the controllability of the stressor is not a relevant variable in our brief stress paradigm, may have implications for the pathogenesis of CHD.

HUMAN RESPONSE TO HIGH DOSE NALOXONE FOLLOWING EXPOSURE TO CONTROLLABLE AND UNCONTROLLABLE STRESS J. Fertig\*, R. Peters, J. Leu, G. Meuller, G. Kamimori. Walter Reed Army Institute of Research, Washington, D.C. 20307

In an attempt to characterize the biochemical and physiological response to naloxone administration following exposure to stress, forty healthy male subjects were exposed to bursts of 95 dB noise while attempting to solve a visual-spatial task under either controllable stress (CS) or uncontrollable stress (UCS) conditions. The stress induction procedure was followed by a double blind infusion of the opiate antagonist naloxone (1.5 mg/kg) or Physiologic reactivity, biochemical response, mood and physical symptoms were monitored throughout the stress induction and drug administration procedures. Naloxone had a highly significant effect on heart rate (p<.0001), plasma cortisol (p<.0001), and immunoreactive beta-endorphin (p<.0001). Diastolic blood pressure, beta-endorphin (p<.0001). Diastolic blood pressure, systolic blood pressure, and plasma norepinephrine which had been differentially elevated by stress were unaffected by the administration of naloxone. Subjects who received naloxone also reported an increased number of physical symptoms as well as disturbances of mood. Results suggest that the opiate antagonist naloxone has a selective effect on the biochemical and physiological responses to stress.

LINKAGE OF STRESS-INDUCED HYPOCALCEMIA, GASTRIC ULCER AND BEHAVIORAL DESPAIR IN WISTAR KYOTO RATS. S. AOU, J. MA and T. HORI, Dept. of Physiology, Fac. of Med., Kyushu Univ., Fukuoka 812, Japan.

Recently the stomach has been suggested as a critical organ for etiology of immobilization-induced hypocalcemia (Aou et al., 1991). Changes in calcium metabolism can affect many physiological functions, however, pathophysiological implication of stress-induced hypocalcemia is unknown. In the present study, stress-induced hypocalcemia was investigated in relation to gastric ulcer and emotional behavior in Wistar Kyoto (WKY) rats which have been known to be vulnerable to behavioral despair and gastric ulcer (Pare, 1989). Wistar rats were used as a control. In forced-swimming test, WKY rats showed significantly longer duration of immobility and shorter duration of struggling than Wistar rats as previously reported. In immobilization stress under water immersion, the WKY rats showed significantly severer gastric ulcer and hypocalcemia than the Wistar rats. The degrees of hypocalcemia and total ulcer length were positively correlated in both strains. The severity of both ulcer and hypocalcemia were positively correlated with the immobility time in the WKY rats, while those were negatively correlated with the struggling time in the Wistar rats. It is concluded that vulnerability to stress-induced hypocalcemia are closely related to gastric ulcer and behavioral responsiveness to the stress condition. Those factors link each other in strain dependent manner. The stress-induced hypocalcemia seems to be an emotionally induced pathological phenomenon associated with formation of gastric ulcer.

## 150.16

NEUROENDOCRINE STRESS RESPONSE IN ADOLESCENT PREGNANCY. A. Chicz-DeMet\*, B. Simon, E.M. DeMet, C.K. Cho and F.M. Crinella. Dept. Psychiatry & Human Behavior, UC Irvine, CA 92717 and State Dev. Res. Inst., Costa Mesa, CA 92626.

Three biochemical stress indices, plasma \(\beta\)-endorphin (\(\beta\)E), ACTH, and cortisol, were studied in 26 adolescent and 59 adult mothers during the third trimester of pregnancy. A multivariate comparison failed to reveal any significant group difference (F=1.11; df=3, 81) although  $\beta E$  levels were marginally elevated (11.6%) in the adolescent group. Plasma ACTH and cortisol levels were significantly correlated in adults (r=0.31; p<0.02), but not adolescents (r=0.10) although the group difference was also not significant. In contrast, adolescent BE levels were significantly correlated with cortisol (r=0.52; p<0.007) whereas adult levels were not (r=0.01), and this group difference was significant (F=5.8; p<0.005). Plasma βE and ACTH levels were significantly correlated in both groups although the regression lines significantly differed (F=6.6; p<0.003). Adjustment of both variables for the influence of feedback regulation on the HPA axis (partialling of cortisol values) significantly improved the model fit in adults  $(F=6.5;\ p<0.02)$  but not adolescents  $(F=0.13,\ df=1,\ 23)$ . The results suggest that stress induced changes in plasma cortisol may be selectively linked to BE increases in adolescent as opposed to adult mothers.

# MONOAMINES AND BEHAVIOR: SEROTONIN

5HT2 RECEPTOR CONTRIBUTION TO THE LOCOMOTOR ACTIVATION

SHT, RECEPTOR CONTRIBUTION TO THE LOCOMOTOR ACTIVATION PRODUCED BY THE AMPHETAMINE ANALOGUE, 3,4-METHYLEREDIOXYMETHAMPHETAMINE (MDMA). J.H. KEHNE\*, H.J. KETTELER, R.A. PADICH, T.C. MCCLOSKEY, C.K. SULLIVAN, AND C.J. SCHNIDT. Marion Merrell Dow Research Institute, 2110 E. Galbraith Rd., Cincinnati, OH 45215.

Understanding the mechanisms of amphetamine and related compounds is critical for their utilization in models of CNS dysfunction. Given data that amphetamines acutely release both 5HT and DA, the present study evaluated the relative roles of these monoamines in the locomotor stimulating effects of the ring-substituted analogue MDMA.

MDMA (0.25-20 mg/kg) dose-dependently stimulated locomotion in rats as measured with photocell activity cages. MDMA stimulation (20 mg/kg; 0-30 min postinjection) was significantly reduced (but not abolished) in rats with severe central 5HT depletions achieved with i.c.v. 5,7-DHT. A similar magnitude attenuation was produced by the highly selective 5HT2 antagonist MDL 100,907 (R(+)-\alpha-(2,3-dimethoxyphenyl)-1-[2-(4-fluorophenylethyl)]-4-piperidinemethanol), or by the DA antagonist haloperidol. In contrast, low dose (2 mg/kg) MDMA locomotor stimulation was reduced by haloperidol but not MDL 100.907. MDMA locomotor stimulation was reduced by haloperidol but

The data suggest that 5HT<sub>2</sub> and DA receptor stimulation both contribute to the early locomotor activating effects of high doses of MDMA.

EFFECTS OF SEROTONERGIC DRUGS ON A 5,7-DIHYDROXYTRYPTAMINE-ASSOCIATED BEHAVIORAL DEFICIT IN RATS PERFORMING ON A DIFFERENTIAL REINFORCEMENT OF LOW RATE-72 SECOND OPERANT SCHEDULE OF WATER REINFORCEMENT. D. C. Jolly\*, J. B. Richards, and L. S. Seiden, Dept. of Pharmacol. and Physiol., University of Chicago, Chicago,

The Differential Reinforcement of Low Rate-72 second (DRL-72s) operant The Differential Reinforcement of Low Rate-72 second (DRL-72s) operant schedule of water reinforcement in rats is a behavioral screening procedure for antidepressant drugs. Chemical lesion of the brain serotonin (5-HT) system disrupts DRL-72s behavior. This experiment was an attempt to discern the 5-HT receptor subtypes involved in the performance of DRL-72s behavior. Trained rats were given bilateral, intracerebroventricular (icv) infusions of 100 µg of 5,7-dihydroxytryptamine (5,7-DHT). A control group received icv infusions of vehicle. After the rats recovered from surgery, DRL-72s performance was continually assessed for a period of 17 weeks. During drug free (baseline) sessions, all measures of the behavior of the control group remained unchanged, but the 5,7-DHT rats showed a behavioral deficit. This behavioral deficit was characterized by increased response rate, decreased erinforcement rate, and but the 5,7-DHT rats showed a behavioral deficit. This behavioral deficit was characterized by increased response rate, decreased reinforcement rate, and disruption of the temporal distribution of DRL-72s responding relative to pre-lesion baseline behavior. The results of 5-hydroxytryptophan administration to the 5,7-DHT treated rats suggested partial amelioration of the DRL-72s behavioral deficit. The 5-HT1A agonist drugs 8-hydroxy-2-di-N-propylaminotetralin (8-OH-DPAT), or 5-Methoxy-dimethyltryptamine (5-MeODMT) reversed the behavioral deficit observed in the 5,7-DHT treated rats. The neurochemical assay results indicated specific depletion of 5-HT in the 5,7-DHT treated rats, in all brain regions examined. These results suggest that 5-HT1A receptors play a significant role in the serotonergic mediation of DRL-72s response timing.

DOPAMINE AND LEARNED HELPLESSNESS: IN VIVO MEDIATION BY SEROTONIN IN FRONTAL CORTEX. F. Petty\*, L. Kramer, L. Wilson, M. Waddill and Y.L. Chae. VA Medical Center and the University of Texas Southwestern Medical School, Dallas, TX 75216.

Learned helplessness (IH) is a maladaptive behavioral depression following inescapable stress (IS) which may be a model of human depression. IH can be induced neurochemically in naive mice by injection of the dopamine (DA) receptor blocker haloperidol (HDL). We have replicated this in the rat, with doses of 10 and 20 mg/kg (but not 5 mg/kg) inducing IH. These doses all produced increased release of DA (measured by in vivo microdialysis), but only 10 mg/kg elevated basal 5-HT release. When HDL was perfused in the microdialysis probe, increased release of both DA and 5-HT was produced by 100 µM HDL. Also, perfusion of DA itself through the probe led to increased release of 5-HT measured in perfusate. Of note is the fact that even at the highest dose intraperitoneal, HDL only produced behavioral depression in 67% of rats (similar to IS). Therefore increased frontal cortex (FC) DA release, known to be a common and non-specific stress effect, may play a necessary but not sufficient role in IH development. Along with previous research, increased FC 5-HT release and subsequent 5-HT depletion cause the subsequent IH.

## 151.5

DIFFERENTIAL EFFECT OF TWO 5HT AGONISTS ON REM SLEEP INITIATION AND PGO GENERATION. R.J. Ross, L.D. Sanford, A.E. Seggos, A.R. Morrison, W.A. Ball\*, and G.L. Mann. Depts. of Anim. Biol., and Psychiatry, Univ. of Penn. and VAMC., Phila., PA 19104

Ponto-geniculo-occipital waves (PGO), identifying markers of REM, appear to be generated by "burst" neurons in mesopontine cholinergic nuclei. Serotonin (5HT) may modulate REM sleep and inhibit PGO generation. We unilaterally infused the relatively specific 5HT, agonist 8-hydroxy-2-(ndipropylamino)tetralin (DPAT; 0.0, 0.002, 0.01, and 0.08 \pm o/0.5\pm i) and the less specific 5HT agonist 1(3-chlorophenyl)piperazine (mCPP; 0.0, 0.02, 0.2, 2.0, and 20.0  $\mu$  g/0.5 $\mu$ l) into the mesopontine peribrachial region (PB) of cats to examine the role of 5HT receptor mechanisms in sleep/wake patterns and PGO generation. Six-hour sleep studies separated by a minimum of 7 days were conducted for each dose. The number of REM episodes (> 1 min) was significantly decreased by DPAT (0.01  $\mu$  g). REM% was decreased 71% by this same dose; however, there was no significant effect on REM episode duration once a cat actually entered REM. A higher dose (0.08  $\mu$  g) did not significantly decrease the number of REM episodes relative to saline, perhaps due to the activation of additional 5HT receptor populations. All doses of DPAT increased aborted REM episodes (<1 min) and periods of increased PGO rate in non-REM (NREM) that did not lead to REM. DPAT did not appear to affect PGO generation (ipsilateral to injection site) independently of its effect on REM; PGO rate/min in REM episodes (≥1 min) was not significantly different from the saline control. REM% and total number of REM episodes (≥ 1 min) were only marginally decreased by mCPP (0.02 and 0.2  $\mu$  g; p < .08) relative to saline. At higher dosages of mCPP (2.0 and 20.0  $\mu$  g) sleep architecture was not discernible from that during saline control, and increases in aborted episodes of REM were not noticed. 5HT in receptor mechanisms have been suggested to regulate REM and waking. We propose that actual REM initiation is regulated by 5HT<sub>M</sub> receptor mechanisms located in PB. Supported by MH-42903, MH-18825 and the D.V.A. Med. Res. Serv.

COMPULSIVE ORAL MOTOR BEHAVIOR INDUCED BY SEROTONERGIC STIMULATION OF THE VENTROLATERAL STRIATUM. S.K. Yeghiayan\* and A.E. Kelley. Department of Psychology, Northeastern University, Boston, MA 02115. Both anatomical and behavioral studies have suggested that the

striatum can be divided into various functional subregions. One area, the ventrolateral striatum (VLS) is thought to play a critical role in oral motor behavior. The striatum is heavily innervated by both dopaminergic and serotonergic neurons arising from the midbrain. The current experiments were aimed at exploring the role of the serotonergic terminals in this region. In Experiment 1, 5-hydroxytryptamine hydrochloride (5-HT) was microinjected into the VLS in pargyline (25 nydrochloride (3-H1) was microinjected into the VLS in pargyline (25 mg/kg i.p.) - pretreated rats and various behaviors were observed using a time-sampling procedure. 5-HT (0, 1, 10, 20, and 30 μg/0.5 μl) induced strong head-down sniffing, biting and licking of cage bars, self-gnawing and mouth movements. In Experiment II, oral stereotypy induced by 5-HT (30 μg/1.0μl) was significantly reduced by intra-VLS microinjection of the nonselective 5-HT antagonist methysergide (15, 30 μg/1.0μl). Furthermore, the secretaria mediated and behavior was 30 µg/1.0µl). Furthermore, the serotonin-mediated oral behavior was also blocked by coadministration of SCH23390 (0.1 mg/kg i.p.), a D1 receptor antagonist, and raclopride (1.0 mg/kg i.p.), a D2 receptor antagonist. These data provide evidence for a role of serotonin within the ventrolateral striatum in repetitive oral motor behavior, and suggest that dopamine may be involved in this effect.

ANXIETY, 5-HT RELEASE AND THE EFFECT OF DRUGS IN THE GUINEA-PIG. A. REX, C. A. MARSDEN AND H. FINK<sup>1</sup> (SPON: GUINEA-PIG. A. REX, C. A. MARSDEN AND H. FINK¹ (SPON: Brain Research Association) Department of Physiology and Pharmacology, University of Nottingham Medical School, Queen's Medical Centre, Nottingham, NG7 2UH, UK, and ¹Institute of Pharmacology and Toxicology, Humboldt University, 1040 Berlin.

In the present microdialysis study exposure of the guinea-pig to the elevated plus maze increased extracellular 5-HT in the frontal cortex; an effect similar to that seen in the rat. Diazepam and the 5-HT1<sub>A</sub> agonist 8-OH-DPAT decreased not only basal

Shiftal to that seem in the lat. Diazepam and the S-HTi<sub>lA</sub> agonist 8-OH-DPAT decreased not only basal extracellular 5-HT but also reduced the increase in 5-HT observed on exposure to the x-maze and produced 'anxiolytic' behaviour. Pretreatment with flumazenil (10.0 mg/kg) and methiothepin (10.0 mg/kg) antagonised the neurochemical and behavioural effects of diazepam and 8-OH-DPAT, respectively. Flumazenil alone also decreased basal extracellular 5-HT and prevented the increase seen when the guinea-pigs were on the x-maze, but had no effect on behaviour. 5-CT, a 5-HT<sub>1D/1A</sub> agonist prevented the increase in extracellular 5-HT but had no anxiolytic profile. The results show that an increase in extracellular 5-HT occurs in the guinea-pig exposed to aversive conditions. While the anxiolytic effects of diazepam in the guinea-pig were associated with decreased extracellular 5-HT, there was no relationship between the decrease in extracellular 5-HT after either flumazenil or 5-CT and behaviour. 5-HT after either flumazenil or 5-CT and behaviour.

ANTAGONISTS AT THE 5-HT3 RECEPTOR CAN REDUCE THE RAT POTENTIATED STARTLE RESPONSE: BUT IS THIS SUPPORT FOR ANXIOLYTIC ACTIVITY? E. W. Anthony\* and M. E. Nevins. Neurological Diseases Research, SEARLE. Skokie, IL 60077.

The ability of drugs to reduce the "conditioned fear" leading to the potentiated startle response in rats is believed to predict anxiolytic efficacy in humans. Clinically-effective anxiolytics, such as the benzodiazepines and buspirone, reduce the potentiated startle response. Antagonists at the 5-HT3 receptor are currently under clinical invetigation for anxiolytic utility: and one report [Glenn & Green, Behav. Pharmacol. 1: 91-94, 1989] found ondansetron to block potentiated startle. The current study was done to determine the effects of three 5-HT3 antagonists on the potentiated startle response. Two conditioning protocols were used: a) 10 conditioning trials on each of two days using 0.5 mA footshock (i.e., the "standard" conditioning protocol), and b) 15 conditioning trials in 1 day using 0.25 mA footshock (which presumably produces a less intense conditioned fear). Ondansetron, (+)-zacopride, granisetron, diazepam and buspirone were evaluated for their ability to reduce the potentiated startle produced by both protocols. While diazepam and buspirone effectively reduced the potentiated startle produced by both protocols, the 5-HT3 antagonists were potently effective only in the modified protocol. Ondansetron and granisetron were ineffective, at doses up to 1 mg/kg, and (+)-zacopride was effective only at the highest dose (1 mg/kg) when the "standard" conditioning protocol was used. These results suggest that the 5-HT3 antagonists may not have the broad spectrum of clinical efficacy characteristic of the benzodiazepines and buspirone.

SEROTONIN RECEPTOR SUBTYPES IN NIPPLE ATTACHMENT IN INFANT S. A. Rabchenuk\* and C. P. Cramer. Dept. of Psychology, Dartmouth College, Hanover, N.H. 03755

One possible mechanism underlying weaning in rat pups is the maturation of the serotonin system. Serotonin antagonists, such as methysergide, enhance suckling in nondeprived rat pups after 15 days of age (Williams, Rosenblatt, & Hall, 1979); but at 3 days, antagonists inhibit suckling (Spear & Ristine, 1982). Conversely, the serotonin agonist quipazine inhibits suckling in deprived rats beginning at 10 days of age. One possibility for these ontogenetic changes may lie in the time of development of different serotonin receptor subtypes. It is not yet known which receptor subtype(s) mediate serotonergic actions on suckling, because previously tested drugs were relatively nonselective. This experiment investigated the effects of selectively-acting serotonin agents in rat pups at different ages.

Nondeprived, Long-Evans rats were tested at different ages before weaning. Eight litters were used in each condition; 4 pups within a litter each received a different dose: Ketanserin, a 5-HT2 receptor antagonist (1.0, 2.5, 5.0 mg/kg); and DOI, a 5-HT2/5-HT1c agonist (1.0, 2.0, 3.0 mg/kg) (IP). Latency to attach to a nipple and total time attached were measured in the following 45-min. observation period. To determine the receptor specificity of the agonist effect, 20-day-olds were subsequently pretreated with ketanserin (5.0mg/kg) 25 min. prior to the administration of DOI (2.0mg/kg).

Ketanserin significantly inhibited nipple attachment in 10-day-old pups, at all doses but had no effect on either measures in 20-day-olds. DOI likewise significantly inhibited nipple attachment in 10-day-old pups. Conversely, DOI had no significant effect on latency to attach in 20-day-olds, but significantly reduced their total time attached. Pretreatment with ketanserin blocked the inhibition of nipple attachment by DOI in 20-day-olds. The inhibition of nipple attachment with DOI thus appears to be via the 5HT2 receptor. The facilitation with nonselective agents in older pups appears to act through a different subtype or combination of subtypes.

A MORE PRONOUNCED INCREASE IN BRAIN TRYPTOPHAN AND 5HIAA IN A TCDD-SUSCEPTIBLE THAN A TCDD-RESISTANT RAT STRAIN BY TCDD.
M. Urikila, R. Pohjanvirta, <sup>1</sup>E. MacDonald and J. Tuomisto'. National Public Health Institute, Division of Environmental Health, P.O.B. 95, SF-70701 Kuopio, Finland and

Department of Pharmacology, University of Kuopio, Kuopio, Finland and Department of Pharmacology, University of Kuopio, Kuopio, Finland 2,3,7,8-Tetrachlorodibenzo-p-dioxin (TCDD) is a potent anorexigen in rats. However, there is an over 300-fold difference in the LD<sub>50</sub>-values for TCDD between two rat strains, Long-Evans (L-E) and Han/Wistar (H/W). This difference is reflected in the degree of hypofagia after TCDD exposure. As central monoamines are putative regulators of feed intake, we compared the effects of TCDD on brain neurochemistry between the rat strains. Rats of both strains were given a single ip dose of TCDD (50 μg/kg; LD<sub>100</sub> for L-E, nonlethal to H/W) or vehicle. Four or 10 days after TCDD exposure, half the rats were injected with α-methyl-p-tyrosine (AMPT), an inhibitor of catecholamine synthesis, or vehicle. Three hr later, the rats were decapitated. Noradrenalin, dopamine and indoleamines (5HT, 5HIAA, tryptophan; from th treated with AMPT) were then determined by HPLC-EC in 9 brain regions. L-E rats decreased dramatically their daily food intake and body weight after TCDD exposure while H/W rats responded only marginally to TCDD administration. Four days after exposure, L-E rats exhibited 36 and 43% elevated levels of the 5HIAA and trypto-phan, respectively. These increases were still present 10 days after exposure. In contrast, the resistant H/W rats exhibited only slightly elevated tryptophan and 5HIAA four days after TCDD, and these changes had levelled off by 10 days after TCDD administration. L-E rats pair-fed for 4 days to their TCDD-treated counterparts exhibited a slight tendency toward increased 5HIAA and tryptophan levels in the brain areas measured. However, this change was clearly less pronounced than that in TCDDtreated L-E rats. TCDD had only a negligible effect on noradrenaline or dopamine metabolism. These findings imply that increased serotonergic activity may be, indirectly or directly, associated with TCDD lethality.

SEEKING RELATIONSHIPS BETWEEN BLOOD CHOLESTEROL AND CSF 5-HIAA IN A MIXED PSYCHIATRIC SAMPLE
D. L. Ringo, K. F. Faull, S. E. Lindley, W. O. Faustman\*,
Stanford/VA Mental Health Clinical Research Center, VA Medical
Center, 3801 Miranda Ave., Palo Alto, CA 94304, USA.

Meta-analysis of treatment studies to reduce blood cholesterol suggests that

decreased cardiac mortality is balanced by increased non-medical mortality (e.g., suicide, violence). A small literature notes an association between low cholesterol and violent/aggressive behavior in humans and animals. Many works have linked diminished serotonergic measures (e.g., CSF 5-hydroxyindoleacetic acid, 5-HIAA) and violent/impulsive acts in humans. These parallel findings have recently led to speculation about lipid/neurotransmitter interactions. We performed two retrospective analyses of 5-HIAA and cholesterol relationships in partially overlapping samples of male psychiatric inpatients (predominantly schizophrenia overlapping samples of male psychiatric inpatients (predominantly schizophrenia and depression). CSF was obtained in patients, free of psychiatric treatment medications, studied over the past 15 years. The initial analysis correlated the closest available routine clinical value of plasma cholesterol with CSF 5-HIAA. No overall correlation was obtained between 5-HIAA and cholesterol (r = 0.13, N = 49). However, an analysis of those patients who had clinical cholesterol samples within 7 days of the CSF collection suggested a trend towards a relationship with 5-HIAA (r = 0.33, P = .08, N = 31). In a second analysis we assayed blood plasma obtained at the time of the CSF collection, stored frozen at -700, from patients obtained at the time of the CSF collection, stored frozen at  $-10^{\circ}$ , from patients studied over the past 5 years. Measures were obtained for total cholesterol, HDL, LDL, and triglycerides. In this partially overlapping sample we were not able to find a significant relationship between 5-HIAA and lipid measures (total cholesterol r = 0.15, HDL r = 0.18, LDL r = 0.07, triglyceride r = -0.01, N = -70). The results do not offer strong support for cholesterol/CSF 5-HIAA relationships. Such relationships may be subtle, and therefore easily obscured by methodological issues (e.g., small sample size, stored samples). Prospective studies may be needed clarify a possible serotonin/cholesterol interaction. Supported by MH-30854.

AGGRESSIVE BEHAVIOR AND BRAIN SEMUJOREAGE AN AGGRESSIVE BEHAVIOR AND BRAIN SEROTONERGIC RESPONSIVITY IN MALE CYNOMOLGUS MACAQUES. R.C. Kyes\*, M.B. Botchin, J.R. Kaplan, S.B. Manuck, and J.J. Mann. Dept. of Comparative Med., Bowman Gray Sch. of Med., Winston-Salem, NC 27157 and Depts. of Psychology and Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA 15260. We examined the relationship between behavioral responsivity and an index of CNS serotonergic activity (serum prolactin response to fenfluramine injection) in

adult male cynomolgus macaques (Macaca fascicularis). Prolactin response to fenfluramine was distributed bimodally. Fifteen low and 15 high prolactin responders were compared. Mean prolactin response was 13.2 ng/ml (SE  $\pm 0.3$ ) for low responders and 44.3 ng/ml (SE  $\pm 1.9$ ) for high responders (p < .001). Behavioral responsivity was assessed by placing the monkeys individually in an open-field enclosure and presenting a series of photographic slides depicting both threatening and nonthreatening stimuli. Monkeys that were low prolacting processed by the processed of th responders displayed significantly more aggressive gestures in response to the threatening slides than did the high prolactin responders (p < .05). No other behaviors differentiated these groups with respect to the threatening slides, nor did animals differ in any behavioral responses to the nonthreatening slides. These data support the hypothesis that high aggressivity is associated with low CNS serotonergic activity, as indicated by a blunted serum prolactin response to fenfluramine.

AUGMENTATION OF THE EFFECTS OF FLUVOXAMINE BY FLESINOXAN IN RATS?: ADDITION IN 2 MODELS OF ANXIETY, ANTAGONISM ON PARAMETERS OF THE 5-HT SYNDROME. A.M. Van der Poel, B.Olivier\*, J.Mos and H.E.Molewijk. CNS Pharmacology, Solvay Duphar B.V., P.O.Box 900, 1380 DA Weesp, The Netherlands.

Recent clinical findings indicate that buspirone adjuvant therapy may be beneficial to OCD and depressed patients treated with 5-HT uptake blockers (e.g. Pigott et al., J.Clin.Psychopharmacol. 12:11-18, 1992). However, supporting animal data are lacking. We therefore studied the effects of combined treatment with the 5-HT<sub>1A</sub> receptor agonist flesinoxan and the 5-HT uptake blocker fluvoxamine on two measures of anxiety (isolation-induced ultrasonic distress calls in pups and shock-induced ultrasonic vocalizations in adults) and a number of parameters of the 5-HT syndrome in rats. Both flesinoxan and fluvoxamine suppress ultrasonic distress calls dose-dependently in pups as well as in adult rats. Combined treatment with marginally effective doses of flesinoxan (pups and adult rats: 0.03 mg/kg IP) and fluvoxamine (pups: 0.3 mg/kg IP; adults 1 mg/kg IP) produced a significant suppression of calling. However, doubling the dose of flesinoxan as well as doubling the dose of fluvoxamine produced similar reductions of calling. Similar additive effects were found with flat body posture, part of the 5-HT syndrome produced by both flesinoxan and fluvoxamine. High doses of flesinoxan (3 mg/kg IP and higher) produce diarrhoea and piloerection. These effects are effectively antagonized by fluvoxamine. On the other hand, high doses of fluvoxamine (15 mg/kg IP and higher) produce immobility and reduce rearing, which effects are effectively antagonized by flesinoxan. If these animal data can be taken as predictive for the clinical situation, it can be concluded that combined treatment with a 5-HT<sub>1A</sub> agonist and a 5-HT uptake blocker yields little advantage over monotherapy with either flesinoxan or fluvoxamine.

## 151.12

EXTREME AGGRESSION AND SOCIAL WITHDRAWAL ARE RELATED TO

EXTREME AGGRESSION AND SOCIAL WITHDRAWAL ARE RELATED TO REDUCED CENTRAL SEROTONERGIC ACTIVITY IN MALE CYNOMOLGUS MACAQUES. M.B. Botchin\*, J.R. Kaplan, S.B. Manuck, and J.J. Mann. Dept. of Comparative Med., Bowman Gray Sch. of Med., Winston-Salem, N.C. 27157 and Depts. of Psychology and Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA 15260.

We examined behavioral differences between monkeys characterized as having low vs high serotonergic responsivity. The subjects were 75 male cynomolgus macaques (Macaca fascicularis), housed in five-membered social groups for 28 months. Behavioral assessment consisted of ad libitum sampling of specific behaviors for 30 minutes, twice a week, for each social group. Extreme aggression was calculated as the ratio of severe forms (bite, grab, chase) to total aggression (including facial threat and displacement). Sociability was assessed by %time spent alone and %time in body contact. The mean of these behaviors over the entire experiment was used in the statistical analyses. Central serotonergic function was assessed by serum prolactin response to fenfluramine HCl injection. The challenge was performed once during the final six months of the study. Mean prolactin response for the low responders was 14.3 ng/ml (SE±1.43) compared to 44.5 ng/ml (SE±1.1) for the high responders. It was observed that the low responders exhibited significantly higher levels of extreme aggression (p < 0.05), less time in body contact with others (p < 0.05), and a trend toward more time alone (p = 0.06). These data support the hypothesis that aggressivity is related to reduced central serotonergic activity. Further, the tendency toward less positive social interaction is also related to reduced central serotonergic activity. central serotonergic activity.

INDOLEAMINE METABOLISM IS AFFECTED BY THE BEHAVIORAL MUTANT <u>JERKY</u> IN <u>XENOPUS LAEVIS</u>. <u>R</u> Tompkins\*, T. Le, B. F. Ferrer, D. C. Reinschmidt, Cell and Molecular Biology Department, Tulane University, New Orleans, LA 70118.

The recessive mutant gene, jerky, of Xenopus laevis causes in the larval stages of homozygous animals a transient abnormal behavioral syndrome characterized by uncoordinated swimming movements which grade toward immobility and paralysis. Onset of the syndrome is first apparent about stage 48 and continues until metamorphosis.

Environmental factors including photoperiod, light intensity, kind of food, and amount of food have been shown to affect the severity of the syndrome. In addition, lithium has been found to have a prophylactic effect on the expression of the motor disturbances. These results point to a centrally acting lesion. Levels of catecholamines and indoleamines in the brains of mutant and normal animals were compared using HPLC with electrochemical detection. Mutant tadpoles consistently had more serotonin (5-HT) in their forebrains than did normal tadpoles with a concurrent rise in the levels of 5-hydroxyindoleacetic acid (5-HIAA), a major metabolite. Differences were more pronounced in tadpoles kept in the light than in those kept in the dark.

INCREASE IN SEROTONIN LEVELS IN THE DOG ILEUM AND BLOOD BY CISPLATIN AS MEASURED BY MICRODIALYSIS. M. Yamamoto\*, H. Fukui, T. Kondo, S. Sato and T. Ando. Drug Safety Research Labs. Takeda Chemical Ind. Ltd., Osaka, 569 Janan.

Labs., Takeda Chemical Ind., Ltd., Osaka, 569 Japan.
