Serotonin (5-HT), especially in the intestine, is known to be involved in cisplatin-induced emesis. In the present study, we investigated the effects of cisplatin on 5-HT release in the ileum and 5-HT concentrations in blood using a microdialysis technique. The dialysis probe was inserted into the wall of the ileum in anesthetized dogs or into the cephalic vein in conscious dogs. The probes were perfused with Ringer solution at a rate of 2  $\mu 1/min$ , and the perfusate was collected at 20-min intervals. In anesthetized dogs, 5-HT levels in the ileum increased gradually beginning immediately after cisplatin administration (3 mg/kg, i.v.) and reached a peak 2-3 hrs later, the period when emesis occurs most frequently. 5-HT levels then decreased and had returned to the baseline levels 5 hrs after dosing, the time when emetic episodes stop. The increase in 5-HT levels was confirmed in conscious dogs. 5-HT concentrations in blood increased synchronously with the occurrence of emesis. Furthermore, an immunohistochemical study revealed that the number of 5-HT-immunoreactive cells in the ileum was increased by cisplatin. These results strongly suggest that increases in the synthesis and release of 5-HT in the enterochromaffin cells are intimately involved in cisplatin-induced emesis.

LOCOMOTOR EFFECTS OF MICROINJECTIONS OF KAINIC ACID INTO THE MEDIAN RAPHE (MR), DORSAL RAPHE (DR), VENTRAL TECMENTAL AREA (VTA), AND THE PONTINE RAPHE NUCLEUS (NRP). M.R. Pitzer\* and D. Wirtshafter. Dept. Psychology, Univ. of Il. at Chicago, Box 4348, Chicago, Il.

We have previously reported dose dependent decreases in feeding, drinking, and both spontaneous and methylphenidate-induced locomotion subsequent to intra-median raphe (MR) injections of the glutamate analogue kainic acid (KA). The current series of experiments was designed to investigate the anatomical specificity of KA-induced suppression of activity within the midbrain. Microinjections of KA (0,5,10,20ng) were made into the MR, DR, VTA, and the NRP of animals previously injected with d-amphetamine. The data revealed a pronounced suppression of activity following MR injections and to a lesser extent, following DR injections. Much smaller effects were observed from injections at the remaining sites. These current findings suggest that the MR is the most sensitive site in the midbrain tegmentum for the suppression of locomotion by kainate receptor stimulation. Preliminary work has suggested these effects may be partially mediated by serotonin.

DISCRIMINATIVE STIMULUS PROPERTIES OF ELTOPRAZINE AND FLESINOXAN IN RATS AND PIGEONS. A.van Hest\*, B.Olivier, J.Mos, A.M. Van der Poel, C.E. Ybema and J.L. Slangen. CNS Pharmacology, Solvay Duphar B.V., P.O.Box 900, 1380 DA Weesp, The Netherlands.

The 5-HT<sub>1A</sub> receptor agonist flesinoxan and the 5-HT<sub>1A,1B</sub> receptor agonist eltoprazine, have clear stimulus properties in rats and pigeons and can be easily trained to discriminate either compound from vehicle. The flesinoxan cue in both species (0.5 mg/kg i.p. in rats; 0.25 mg/kg p.o. in pigeons) seems exclusively mediated by activation of the 5-HT<sub>1A</sub> receptor. In rats ipsapirone, 8-OH-DPAT, gepirone and yohimbine generalize to the flesinoxan cue, whereas buspirone and idazoxan partly substitute for flesinoxan. The 5-HT<sub>1A</sub> activity of the  $\infty$ -adrenergic antagonists yohimbine and idazoxan could explain their generalization towards flesinoxan. The flesinoxan cue could be antagonized by ( $\pm$ )pindolol, ( $\pm$ )propranolol and (partly) by NAN-190, all presumed 5-HT<sub>1A</sub> receptor antagonists. In pigeons, buspirone, eltoprazine and ipsapirone completely substitute for flesinoxan.

The eltoprazine cue in rats (0.5 mg/kg i.p.) fully generalized to 8-OH-DPAT, TFMPP, RU 24969, (±)pindolol, (±)propranolol and partly to buspirone, flesinoxan, mCPP, mesulergine, idazoxan and fluvoxamine. No antagonism of the eltoprazine-cue was found with any 5-HT<sub>1,2</sub> or 3 receptor antagonist. The stimulus properties of eltoprazine in rats seem to comprise at least a 5-HT<sub>1A</sub> and 5-HT<sub>1B</sub> receptor agonistic component. In pigeons, which do not posses 5-HT<sub>1B</sub> receptors, eltoprazine (5.0 mg/kg, p.o.) generalized to flesinoxan, partly to buspirone (50%) and not to ipsapirone. 5-HT<sub>1A</sub> receptor activation clearly plays a role in the eltoprazine stimulus properties in pigeons, but other mechanisms (5-HT<sub>1C</sub>, 5-HT<sub>1D</sub>) may also be involved.

## 151.16

EFFECTS OF RAPHE LESIONS AND SEROTONIN DEPLE-TION ON PASSIVE AVOIDANCE. <u>D. Wirtshafter\*</u>, Dept. Psychol., Univ. III. at Chicago, Box 4348, Chicago, IL, 60680. Many studies have shown that electrolytic lesions of the median

Many studies have shown that electrolytic lesions of the median raphe nucleus (MR) can produce dramatic disturbances in performance in a variety of learning paradigms. We report here that electrolytic MR lesions produce a marked impairment in the acquisition of several different step-through passive avoidance tasks in which rats were shocked when they crossed from a large, brightly illuminated, to a small dark compartment. A similar impairment was seen whether or not escape from the shocked compartment was allowed and whether an intertrial interval of 30 sec or 24 hr was employed. After criterion was reached, rats were directly placed in the dark compartment of the box, with the shock turned off, and allowed to cross over into the "safe" compartment. Under these conditions, MR lesioned animals showed significantly longer "escape" latencies than did controls. In another study MR lesions failed to alter the acquisition of a one way avoidance task in which rats had to cross from the dark to the light compartment to avoid shock. When tested on passive avoidance of the dark compartment, however, these lesioned animals showed no transfer from the active to the passive avoidance task.

Electrolytic lesions of the dorsal raphe failed to reproduce the effects of MR lesions, as did specific depletions of serotonin produced by systemic treatment with p-chloroamphetamine or intra-MR injections of 5,7-DHT. These findings suggest that the effects of raphe lesions on passive avoidance may result from damage to nonserotonergic cells within the MR.

EFFECTS OF DESIPRAMINE ON THE DRL ANTIDEPRESSANT SCREEN DEPEND UPON HOW LONG THE RATS ARE REQUIRED TO WAIT. J.B. Richards\*, K.E. Sabol, M.J. Baggott, L.S. Seiden. University of Chicago, Department of Pharm/Phys Sci., Chicago, IL 60637.

The differential-reinforcement-of-low-rate-72-s (DRL 72-s) schedule requires animals to wait 72 seconds between lever press responses in order to gain access to a reinforcer (.05 ml water). When required to wait 72-s between responses for reinforcement normal rats typically produce peak (modal) interresponse time (IRT) durations which are less than the 72-s criterion for reinforcement. For rats trained on a DRL-72s scheule, a variety of antidepressant compounds (tricyclics, monoamine oxidase inhibitors, and atypical antidepressants) shift the peak IRT duration toward longer durations resulting in an increase in the number or reinforcers. Three groups of rats were trained on DRL schedules of reinforcement with criterion values of 18s, 36-s, and 72-s. After training, the peak IRT duration for the DRL 18-s group was greater than the criterion (18.3 s). For the DRL 36-s and 72-s groups however, the peak values were less than the DRL criterion values (34.6 s and 58.7 s respectively). The effect of the antidepressant desipramine (DMI) (2.5, 5.0, 10.0 and 20.0 mg/kg) on peak IRT duration was determined. DMI shifted the peak of the IRT distribution to the right - toward longer IRT durations - at all three DRL criterion values. However, the shift to the right was disproportionately larger at the longer DRL criterion values. At the 10.0 mg/kg dose of DMI the peak IRT durations were 19.8, 39.3, and 69.8 s respectively for the DRL 18, 36, and 72-s schedules. DMI increased the number of reinforcers earned at all three DRL criterion values. DMI did not increase dispersion of the IRT distributions indicating that its effects were not due to a nonspecific disruption of responding. The results are not explained well by the hypothesis that DMI changed the rats' perception of time. The results are more consistent with the hypothesis that DMI enhanced the rats' ability to wait between bar press responses. (Supported by: MH-11191; RSA-10562, L. Seiden)

SEASONAL AND STATE-DEPENDENT CHANGES IN REGIONAL BRAIN CONTENT OF MONOAMINES IN THE HIBERNATING GROUND SQUIRREL. A.C. Russo<sup>†</sup>, A. Izquierdo, R.C. Lowry, C. Kay-Nishiyama and T.L. Stanton\*. Dept. of Physical Therapy <sup>†</sup> & Dept. of Physiology, California State University, Long Beach, CA 90840 The levels of 5-HT, NE, and their metabolites were measured by HPLC in regionally dissected brains of summer euthermic (SE), winter euthermic (WE), interbout (I), and hibernating (H) Citellus lateralis. Dramatic state-dependent increases (H>I) were observed in 5-HIAA/5-HT ratios in all 10 brain regions. The concentration of 5-HIAA was also significantly increased in 5 regions of H animals, most notably in the hypothalamus. No seasonal (SE vs WE) differences were noted in the ratio values, but 5-HIAA levels were significantly increased in 8 regions of SE animals. In the NE system, significant seasonal (SE>WE) differences in MHPG and MHPG/NE ratios were noted in 7 regions. Small but significant state-dependent differences (H>I) in the MHPG/NE ratios were also seen in 5 of these regions, all located in the brainstem. MHPG levels did not vary significantly across state in any region. These results demonstrate dynamic seasonal and state-dependent changes in 5-HT and NE neural systems in Citellus lateralis. (Supported by NIH Grant # GM08238)

DIFFERENTIAL ABILITY OF NK-1 AGONISTS TO PRODUCE SCRATCHING AND GROOMING BEHAVIOURS IN MICE. S. Ravard. J. Betschart. V. Fardin. A. Doble\* and J.C. Blanchard. Rhône-Poulenc Rorer, CRVA, 13 Quai J. Guesde, 94403 Vitry, France.
We have compared the effects of different NK-1 agonists to produce

reciprocal hind-limb scratches and grooming in mice. Selective NK-1 agonists used were [Apa<sup>9,10</sup>]SP (0.1-10 μg) [Pro<sup>9</sup>]SP, [Sar<sup>9</sup>,Met(O<sub>2</sub>)<sup>11</sup>]SP and septide (0.0125-1  $\mu g$ ) We have also tested a mixed NK-1/NK-2 agonist, [Lys5,Tyr7,Pro8]NKA(4-10) (0.1-10 μg). Drugs were administered icv to CD1 mice in a volume of 5 µl/mouse. Consecutive to the icv injection, the number of scratches and time spent grooming were measured in a 10min test session. Induction of scratches and intense grooming, behaviours not seen in vehicle-treated mice, was observed with [Pro9]SP. [Sar9,Met(O2)11]SP and septide in a dose-dependent manner. The rank order of efficacy was septide > [Sar9,Met(O2)11]SP > [Pro9]SP. [Apa9,10]SP produced scratches and grooming only at a dose of 10 µg. The mixed NK-1/NK-2 agonist [Lys5,Tyr7,Pro8]NKA(4-10) had no effect in the dose range tested. In contrast to [Pro9]SP and [Sar9,Met(O2)11]SP, results from binding experiments performed on brain preparations have shown that septide exhibits a weak affinity for NK-1 sites. Since septide was more potent than [Pro9]SP and [Sar9,Met(O2)11]SP in our experiments, a mechanism other than NK-1 receptors may account for the present results. It cannot, however, be excluded that differential degradation of these agonists may affect the behaviours observed.

## 152.3

THE ROLE OF SUBSTANCE P IN MEDIAL AMYGDALOID FACILITATION OF DEFENSIVE RAGE BEHAVIOR IN THE CAT. A. Steinberg, M.B. Shaikh\* and A. Siegel, Department of Neurosciences, N. J. Medical School, Newark, N. J. 07103.

The present study tested the hypotheses that: (1) the medial amygdala (ME) facilitates feline defensive rage behavior (DR) and; and (2) substance P (SP) is utilized as a neurotransmitter in the pathway from the amygdala. In phase I of the experiment, stimulating electrodes were implanted into the ME and cannula-electrodes were implanted into the medial hypothalamus (MH) from which DR could be elicited by electrical stimulation. Response latencies for DR were significantly (p<.01) lowered following dual stimulation of the ME and MH relative to single stimulation of the MH alone. In phase II, following the I.P. administration of the NK1 antagonist, CP 96,345, in doses of 0.05, 2.0, and 4.0 mg/kg, dose and time dependent decreases in ME-induced facilitation (by as much as 30% at the highest dose level) were observed. In phase III of the study, CP 96,345 was microinjected directly into DR sites within the MH in doses of 0.05, 0.50, 2.5 and 5.0 nmoles. Again, dose and time dependent decreases in ME-induced facilitation of DR (by as much as 50% for the highest dose level) were noted. The results suggest that ME facilitates DR by acting through an SP mechanism at the level of the MH. [Supported by NIH Grant NS 07941-22].

APOMORPHINE- AND OXYTOCIN-INDUCED PENILE ERECTION AND YAWNING: ROLE OF SEXUAL STEROIDS. M.R. Melis, A. Mauri & A. Arqiolas\*. B.B. Brodie Dept. Neurosci Cagliari Univ. 09124 (agliari Italy)

A. Mauri & A. Argiolas\*. B.B. Brodie Dept. Neurosci., Cagliari Univ., 09124 Cagliari, Italy.

In intact male rats, apomorphine (APO) (80 µg/kg s.c.) and oxytocin (OXY) (30 ng i.c.v.), induce penile erection (PE) and yawning (Y). Castration prevented both APO and OXY responses. In castrated rats, testosterone (T) (100 µg/kg s.c. once a day for 3 days) restored PE while estradiol (E) (10 µg/kg s.c. once a day for 3 days), restored Y induced by APO or by OXY. 5-dihydrotestosterone (5DHT) and progesterone (P) (100 µg/kg s.c. once a day for 3 days) were ineffective. E + 5DHT partially restored APO-induced Y and PE, while E + P restored only Y. In intact rats, P increased, and E decreased, respectively, APO-induced Y. Both steroids were ineffective on APO-induced PE. T and 5DHT were ineffective on both APO responses. E effect was prevented by the antiestrogen tamo-xiphen (1 mg/kg s.c. once a day for 3 days), which per se failed to modify APO responses, by T or by P. Similar results were found with OXY-induced Y and PE, except that Y was prevented by E much less than that induced by APO. The results suggest that sexual steroids modulate PE and Y induced by APO and by OXY in a way that depends on the endocrine status of the animals.

## 152.2

SUBSTANCE P PATHWAY FROM THE MEDIAL AMYGDALA TO MEDIAL HYPOTHALAMIC DEFENSIVE RAGE SITES. M.B. Shaikh, A. Steinberg, and A. Siegel\*. Department. of Neurosciences, New Jersey Medical School, Newark, N. J. 07103.

We have recently shown that the medial amygdala (ME) powerfully facilitates defensive rage behavior (DR) in the cat. This study tested the hypothesis that the underlying neurochemical substrate includes a substance P (SP) pathway from the ME to the medial hypothalamus (MH) from which DR is elicited. Cannula-electrodes were implanted into DR sites in the MH and microinjections of the retrograde tracer, Fluoro-Gold (8% in 0.5  $\mu$ l), were placed into these sites. Following survival periods of 6-8 days, animals were sacrificed and the tissue was processed for immunoreactivity for SP-positive cells and fibers. Large numbers of retrogradely labelled cells were identified in the ME. Likewise, high concentrations of SP-positive cells were observed in ME. Of particular significance was the presence of large numbers of cells in the ME labelled for both Fluoro-Gold and SP. Such labelled cells were most highly concentrated in the dorsal aspect of ME -- sites which facilitate DR. In addition, dense quantities of SP-positive axons and preterminals were noted in the region of the MH from which DR is elicited. These findings provide further evidence that the pathway from ME to MH, which facilitates DR, utilizes SP as a neurotransmitter. [Supported by NIH Grant NS 07941-22].

## 152.4

LEARNING ENHANCED BY SUBSTANCE P IN RATS WITH HIPPOCAMPAL LESIONS AND GRAFTS OF FETAL NERVOUS TISSUE.

J.P. Huston\*(1), K.Klapdor (1) and U.Sprick (2)

(1) Inst. Physiol. Psych., Univ. Düsseldorf, Germany

(2) Dep. Biopsychol., Ruhr-Univ. Bochum, Germany

Grafting of fetal nervous tissue into the CNS may improve performance of brain damaged animals. The present study was undertaken to examine the interaction of the neurokinin Substance P (SP) with the effects of fetal grafts on the consequences of bilateral hippocampal lesions. It is known that SP has memory enhancing, rewarding, and neurotrophic effects.

One week after bilateral kainic acid injections into the hippocampus rats received suspension grafts of fetal tissue at the sites of their lesions. Spatial learning was tested weekly in a Morris water-maze. SP (at 5 and 50 µg/kg) was injected peripherally, daily 5 hours after the learning trial over a 9 weeks period. Animals with grafts performed superior to non-grafted animals. SP injections (50 µg/kg) facilitated performance in both grafted and non-grafted animals.

SP also inhibited seizure activity in the rats with hippocampal lesions over the whole period of nine weeks.

# 152.6

APOMORPHINE-, OXYTOCIN- AND ACTH-INDUCED PENILE ERECTION AND YAWNING: ROLE OF EXCITATORY AMINO ACIDS (EAAs). A. Argiolas, R. Stancampiano & M.R. Melis\*. B. B. Brodie Dept. Neurosci., Cagliari Univ., 09124 Cagliari, Italy.

The effect of the EAA receptor antagonists MK-

The effect of the EAA receptor antagonists MK-801, CPP, CNQX and AP-4 on penile erection (PE) and yawning (Y) induced by the dopaminergic agonist apomorphine (APO), oxytocin (OXY) and ACTH 1-24 was studied in male rats. Systemic (0.1-0.4 mg/kg i.p.) and i.c.v.(10-50 µg) MK-801 prevented dose-dependently PE AND Y induced by APO (80 µg/kg s.c.), by OXY (30 ng i.c.v.) or by ACTH 1-24 (10 µg i.c.v.). MK-801 prevention of PE and Y was parallel to the appearance of a complex behavioral syndrome characterized by head weaving, body rolling, hyperlocomotion and ataxia. A similar prevention of PE and Y, especially in the number of PE, was also found with high, but not low doses of CPP and CNQX, which impaired normal motor activity. AP-4 was ineffective at all doses tested. All the above compounds failed to modify PE and Y when injected into the paraventricular nucleus of the hypothalamus, the brain area most sensitive to APO and OXY for the induction of PE and Y. The results suggest that EAAs do not play an important role in the expression of PE and Y induced by the above compounds.

GONADAL STEROIDS ALTER VASOTOCIN RECEPTOR CONCENTRATIONS IN AMPHIBIAN BRAINS. S.K. Boyd. \* Department of Biological Sciences, University of Notre Dame, Notre Dame, IN 46556.

Since arginine vasotocin (AVT) levels are sexually dimorphic in the bullfrog (Rana catesbelana) brain, we used in vitro autoradiography with JH-vasopressin to determine whether sexual differences also exist in concentrations of putative receptors for this peptide. Receptor concentrations were greater in female bullfrogs, compared to males, in the amygdala pars lateralis and hypothalamus. Levels were greater in male bullfrogs in the pretrigeminal nucleus and auditory dorsolateral nucleus. Next, bullfrogs of both sexes were gonadectomized and given implants of DHT or estradiol. In the amygdala, gonadectomy significantly reduced receptor concentrations in males and females while estradiol therapy restored concentrations to control levels. In the pretrigeminal nucleus, castration of males significantly decreased receptor number and these effects could be reversed by either DHT or estradiol treatment. Ovariectomy and steroid therapy had no effect on pretrigeminal receptors in female bullfrogs. Likewise, these treatments did not alter receptor levels in the hypothalamus or dorsolateral nucleus of either sex. These receptor populations may represent the sites where AVT interacts with gonadal steroids to alter sexually dimorphic behaviors in the bullfrog.

## 152.9

VASOPRESSINERGIC NEURAL CIRCUITS IN GOLDEN HAMSTERS. Y. Delville\*, G.J. DeVries, and C.F. Ferris. Physiol. Dept., Univ. of Mass. Med. Ctr., Worcester, MA 01655, and Neuroscience and Behavior Program, Univ. of Mass., Amherst, MA 01003.

In golden hamsters, the anterior hypothalamus, the lateral septum and the midbrain central grey are target sites for vasopressin in the regulation of a stereotypic behavior: flank marking. As a first approach to study the underlying neural network controlling this behavior, Phaseolus vulgaris leucoagglutinin, an anterograde tracer, was injected within the anterior hypothalamus, which contains vasopressinergic neurons. Projections originating from this area were observed within the entire limbic system, particularly within the lateral septum, hippocampus, preoptic area, central amygdala, midbrain central grey, and the nucleus solitarius. Interestingly, these sites also contain high affinity vasopressin receptors and vasopressinimmunoreactive fiber terminals. These results suggest that the neural network controlling vasopressin-induced flank marking may originate from the anterior hypothalamus. This hypothesis is being tested through combined retrograde tracing and immunocytochemistry for vasopressin.

# 152.11

ARE SEX DIFFERENCES IN HAMSTER FLANK MARKING MEDIATED BY VASOPRESSIN (AVP) WITHIN THE MEDIAL PREOPTIC-ANTERIOR HYPOTHALAMUS (MPOA-AH)? A.C. HENNESSEY\*, K.L. HUHMAN & H.E. ALBERS. Lab. of Neuroendocrinol. & Behavior, Depts. of Biol. & Psychol., Georgia State Univ., Atlanta, GA 30303.

Female hamsters flank mark more than males in response to the odors of conspecifics. Since AVP activity within the MPOA-AH is critical for the control of hamster flank marking, we investigated whether these sex differences may be mediated by differences in AVP activity within the MPOA AH. In experiment 1, immunohistochemical analysis revealed no significant differences in AVP-IR cell counts within the BNST, MPOA-AH, SON, PVN and SCN in male (n = 6) and female (n=6) hamsters. In experiment 2, males (n=8) and females (n = 8) were implanted with guide cannulae aimed at the MPOA-AH and were microinjected with AVP (0.009) 0.09, 0.9 or 9.0 µM) on four consecutive days. AVP stimulated flank marking in a dose-dependent manner in both male and female hamsters (p < 0.01). No significant sex differences in AVP-stimulated marking were found. These data suggest that sex differences in odor-stimulated flank marking are not due to sex differences in AVP availability or release within the MPOA-AH. (NSF BNS-8910863).

ESTRADIOL ALTERS THE BEHAVIORAL RESPONSE OF THE MPOA-AH TO ARGININE VASOPRESSIN (AVP) IN SYRIAN HAMSTERS. K.L. HUHMAN\* & H.E. ALBERS. Lab. of Neuroendocrinology & Behavior, Depts of Biol. & Psychol., Georgia State Univ., Atlanta, GA 30303.

Vasopressin (AVP) in the medial preoptic-anterior hypothalamus (MPOA-AH) is known to be important in the control of flank marking, a form of scent marking seen in hamsters. In males, there is evidence that testosterone influences the frequency of flank marking by altering the response of the MPOA-AH to AVP. The purpose of this experiment was to determine if estradiol alters the response of the MPOA-AH to AVP in female hamsters. Hamsters (N = 26) were ovariectomized and implanted with blank Silastic capsules or with capsules containing estradiol benzoate (EB). Four weeks later, each hamster was implanted with a guide cannula into the MPOA-AH and was given microinjections of AVP (0.09, 0.9, 9.0, & 90.0  $\mu$ M in 100 nl saline) over four testing days. AVP-induced flank marking was significantly higher in hamsters implanted with EB capsules than in hamsters receiving blank implants. These data support the hypothesis that gonadal hormones influence flank marking by altering the response of the MPOA-AH to AVP. (Supported by NSF BNS-8910863)

CHANGES IN VASOPRESSIN PATHWAYS OF PRAIRIE-VOLE MALES RELATED TO REPRODUCTION. M.Bamshad\*, M.A.Novak, G.J. De Vries. Program of Neuroscience and Behavior and Dept. of Psychology, Univ of Massachusetts., Amherst, MA 01003.

Prairie-vole males display paternal behavior. We have previously found that, in comparison to virgin males, parental males have a lower density of the vasopressin immunoreactive (AVP-ir) fiber plexus in the lateral septum and lateral habenular nucleus, which presumably is derived from the bed nucleus of the stria terminalis (BNST) and medial amygdaloid nucleus (MA). It is not clear whether AVP-ir projections get less dense before or after the birth of pups.

We compared AVP-ir fiber density in the lateral septum and lateral habenular nucleus and the paraventricular nucleus of the thalamus and medial preoptic area among prairie-vole males and females that were either housed separately or housed together for 72 hrs, or until 10 or 18 days into the gestation period, or until six days after the birth of pups. Under all these conditions, AVP-ir fiber density in the lateral septum and lateral habenular nucleus was much denser in males than in females. In males, the lowest density was found at 72 hrs after being housed together. An intermediate density was found at 10 days in the gestational period and at 6 days after birth of pups. An equally high density was found in sexually inexperienced males and in males that were housed together for 18 days. In females, no changes in AVP-ir fiber density were found. In addition, in both sexes no differences were found in the AVP-ir fiber density in the paraventricular nucleus of the thalamus and the medial preoptic area. These data indicate that the AVP-ir projections from the BNST and MA of males become less dense after mating and once again after the pups are born. This suggests that these projections may not only play a role in becoming parental but may also underlie some of the behavioral changes seen in prairie voles after mating.

EEFECT OF VASOPRESSIN ON CIRCADIAN ACTIVITY AND BODY TEMPERATURE IN FOOD-RESTRICTION STRESS.
G. R. Nadzam, C. H. Wideman\*, and H. M. Murphy\*.
John Carroll University, Cleveland, OH 44118.

Male, vasopressin-containing, Long-Evans (LE) and vasopressin-deficient, Brattleboro (DI) rats were maintained in individual cages while telemetered activity (Am) and core body temperature (Tb) data were collected. The rats were exposed to a 12:12 light-dark cycle with a room temperature of 23 ± 1 °C and allowed to habituate for 12 to 14 days with ad-lib food and water. The habituation period was followed by an experimental period in which a stress of 23h of food restriction per day was introduced. A 1h feeding period was initiated 1h after the beginning of the light cycle. While circadian rhythms of Am and Tb were nearly identical between DI and LE rats during habituation, the experimental period produced marked differences. Food stress resulted in a marked increase in DI activity, but resulted in an overall decrease in LE activity. Initially, LE peak Tb per day was significantly elevated and was followed by a gradual daily decrease in trough Tb. In spite of the dramatic increase in DI Am, peak Tb per day was only slightly elevated from the habituation period, but trough Tb per day decreased more than 0.5°C per day until death.

EVIDENCE THAT CELLS IN THE LUMBAR REGION OF THE SPINAL CORD PROJECT TO THE NUCLEUS PARAVENTRICULAR OF HYPOTHALAMUS. L.Y. Yang and L.G. Clemens\* Neuroscience Program and Department of Zoology, Research Center, Michigan State Biology University, East Lansing, MI 48824

We have demonstrated that neurons of paraventricular nucleus of the hypothalamus (PVN) project to the sexually dimorphic, lower lumbar region (Wagner and Clemens, Brain of the spinal cord Research 539:254-262, 1991). The present study extended this analysis by examining whether neurons in the lumbar region of the spinal cord project to the Fluorogold (4%, 0.1uL) was stereotaxically injected into the PVN. Fluorogold-labelled cell bodies were found in the lumbar region of the spinal cord. When combined with previous studies, this experiment demonstrates that reciprocal connections between the PVN and the lumbar region of the spinal cord. (NSF Grant: BNS-9109292)

CHRONIC OXYTOCIN INFUSIONS AFFECT CNS OXYTOCIN RECEPTORS MEDIATING SOCIAL BEHAVIOR. Diane M. Witt\*& Thomas R. Insel. Lab. of Neurophysiology, NIMH, Poolesville, MD 20837

The central release of oxytocin (OT) has been implicated in the neural mediation of both male and female sexual behavior. The current studies examined the effects of chronic central administration of OT studies examined the effects of chronic central administration of OI on (1) male sexual and social behavior, and (2) brain OT receptors. Either artificial cerebrospinal fluid (CSF) or OT was centrally infused (via osmotic mini-pump) to gonadally-intact male rats. Behavioral observations were made on males paired with either ovariectomized or estrous females during a 6-hour time period. The durations of physical contact were doubled in pairs containing OT-infused males, even in the absence of sexual interactions. OT-infused males also showed significantly higher levels of anogenital sniffing of females and autogrooming, however sexual behavior *per se* was unaffected by chronic OT. Chronic OT had no effect on body temperature, analgesia or exploratory behavior in an open field. Subsequently, analgesia of exploitatory behavior in an open field. Subsequently, brains from these animals were processed for *in vitro* receptor autoradiography, using [1251]-OTA. OT receptor binding was decreased in every target field by 50 %, even 24 hours after pump removal, suggesting an OT receptor down-regulation. These findings suggest that chronic OT in male rats has behavioral effects which suggest that curonic O1 in male rats has behavioral effects which enhance adult social (non-sexual) interactions possibly through alterations in olfactory and somatosensory information processing. Alterations in OT receptors, in response to prolonged OT stimulation, may provide insights into mechanisms by which central OT affects neurotransmission.

OXYTOCIN PROJECTIONS FROM THE PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS TO LOWER LUMBAR SPINAL CORD AND THE DISTRIBUTION OF OXYTOCIN FIBERS IN THE REGION OF THE SPINAL NUCLEUS OF THE BULBOCAVERNOSUS IN MALE AND FEMALE RATS. A.E. Ackerman\* and L.G. Clemens, Department of Zoology and Neuroscience Program, Michigan State University, East Lansing, MI

Neuroscience Program, Michigan State University, East Lansing, Ivi 48824.

Oxytocin-immunoreactive (OT-IR) neurons are found within the paraventricular nucleus (PVN) of the hypothalamus and project throughout the CNS, including the spinal cord, (Cechetto, D.F. and Saper, C.B., Comp. Neurol. 272: 579, 1988). We recently demonstrated loss of neurophysin-immunoreactive fibers in the sexually dimorphic lower lumbar cord (L<sub>0</sub>-L<sub>0</sub>) following PVN lesions in male rats (Wagner, C.K. and Clemens, L.G., Unpublished observations). In the present study, we extend this analysis of PVN projections to L<sub>0</sub>-L<sub>0</sub> by comparing the distribution of PVN, OT-IR neurons in male and female rats. This comparison was made using PVN tissue from rats injected with 0.5µl of 4% Fluorogold into segments L<sub>0</sub>-L<sub>0</sub>. Following 1-2 weeks, animals were perfused and immunohistochemistry for OT was performed on 30µm sections through PVN. In addition to comparing the distribution of double labelled cells in PVN, other male and female rats were used to compare the density of OT-IR fibers within lower lumbar cord. Results demonstrate that OT-IR fibers, presumably originating in the PVN, project to the sexually dimorphic lower lumbar segments of the spinal cord in both male and female rats. # DRUGS OF ABUSE: BENZODIAZEPINES AND BARBITURATES

DIFFERENTIAL REGULATION OF THE BEHAVIORAL EFFECTS OF CHLORDIAZEPOXIDE. J.S. Shumsky\* and J. Lucki. Departments of Pharmacology and Psychiatry, University of Pennsylvania, Philadelphia, PA 19104

Chronic administration of the benzodiazepine (BZ) receptor agonist, chlordiazepoxide (CDP), produced tolerance to its motor impairing effects but no tolerance to its anxiolytic or amnesic effects. Male Sprague-Dawley rats were pretreated for 14 days with 25 mg/kg CDP (IP, b.i.d.) or saline and chronic treatment was maintained throughout the experiments. Tolerance to the ataxic effects of CDP on the rotorod was observed as a 9-fold shift to the right in the cumulative dose-effect curve between chronic CDP- and saline-treated animals. Anxiolytic effects were examined using operant behavior reinforced under a multiple schedule with unpunished (RI 80-s) and punished (CRF with incremental shock intensities) components. Tolerance developed to CDP's effects on unpunished responding, as shown by a 7-fold shift to the right in the dose-effect curve. Conversely, tolerance did not develop to the effects of CDP on punished responding. In addition, baseline responding was elevated by chronic CDP treatment throughout the experiment, also indicating a lack of tolerance to CDP's anxiolytic effects. Furthermore, no tolerance developed to the amnesic effects of CDP in a model of memory impairment using the radial arm maze. These results are consistent with the effects of chronic BZ treatment in humans and suggest a homologous regulation of drug effects, potentially mediated by regional differences in BZ receptor subtype regulation or composition. Supported by USPHS grant DA 05186.

EVIDENCE FOR DISCRIMINATION OF BENZODIAZEPINE WITH-DRAWAL BY RATS. D. A. Lytle and M. W. Emmett-Oglesby\*, Dept. of Pharmacology, TCOM, Fort Worth, TX 76107

This experiment determined whether withdrawal from benzodiazepine dependence could be trained as a discriminative stimulus. Rats were chronically maintained on a nutritionally-complete liquid diet that contained 100mg/kg/day of chlordiazepoxide (CDP); diet was administered in two portions daily. Subjects were trained to discriminate a benzodiazepine antagonist, flumazenil (FLUM), 2.5mg/kg, from vehicle using a food-reinforced two-lever choice paradigm. Flumazenil substituted for FLUM over a broad generalization gradient (ED50 = 0.045mg/kg). The anxiogenic drug pentylenetetrazole (PTZ) substituted for FLUM, and pentobarbital (20mg/kg) shifted the dose-effect curve of FLUM to the right. Twenty-four hr. after termination of CDP-diet, vehicle substituted for FLUM. This substitution of vehicle for FLUM was dose-dependently blocked by CDP and abecarnil. At 14 days after termination of CDP-diet, both vehicle and FLUM failed to substitute for FLUM; however, PTZ fully substituted for FLUM at that time. These data show that the FLUM discriminative stimulus is dependent on the presence of chronic CDP, and the results support the hypothesis that FLUM produced a discriminative stimulus based upon precipitated withdrawal from CDP dependence. The substitution of vehicle for FLUM at 24-hr after termination of CDP is consistent with the occurrence of spontaneous withdrawal that substituted for a discriminative stimulus based upon precipitated withdrawal. Supported by grant DA RO1-3521.

EFFECTS OF DIAZEPAM ON SCHEDULE CONTROLLED BEHAVIOR IN A RADIAL MAZE MODEL OF FORAGING. G.R. Sessions\*, J.J. Pilcher, and E.L. Closser Gomez. Walter Reed Army Institute of Research, Washington, D.C. 20307-5100.

The effects of diazepam on scheduled controlled behaviors and motor performance was studied in a novel radial-arm maze model of foraging. Rats were allowed one hour access to a radial maze where delivery of food was controlled by concur-rent fixed interval (FI) schedules of reinforcement in each of 8 arms, ranging from 55 to 759 sec. Diazepam (0.625-10.0 mg/kg ip) produced dose-dependent decreases in measures of performance, but reference memory for the relative contingencies associated with the eight individual FI schedules was relatively unaffected. The patterning of responding on the individual schedules, however, was disrupted at doses lower that those which produced frank motor deficits. observed effects on schedule controlled behaviors in this complex task may be attributable to diazepam-induced alterations in response timing, due to impairments in either working memory for time or internal clock mechanisms. The radial time or internal clock mechanisms. maze foraging model provides a useful paradigm for simultaneous drug testing for behavioral effects on motoric and complex learned behaviors.

## 153.5

CHARACTERIZATION OF THE DISCRIMINATIVE STIMULUS (DS) EFFECTS OF MIDAZOLAM (MDZ) USING A 3-LEVER DRUG DISCRIMINATION PARADIGM IN RATS. C.A. Sannerud\*1, N.A. Ator2, & S.R. Goldberg1, <sup>1</sup>NIDA-Addiction Research Center, Baltimore, MD 21224 and <sup>2</sup>Johns

Hopkins University School of Medicine, Baltimore, MD 21224.
Discrimination procedures are useful to characterize a drug's behavioral effects and to evaluate its mechanisms of action. In the present ioral effects and to evaluate its mechanisms of action. In the present study, 12 rats were trained to discriminate 2 doses of the benzodiarepine (BZ) agonist MDZ (0.32 mg/kg & 3.2 mg/kg MDZ, s.c.) and no-drug (ND), in daily sessions consisting of multiple discrete 20 min trials: 15 min timeout (TO), 5 min FR 10 schedule for food. At the start of each TO, rats received either 0.32 MDZ mg/kg, 3.2 mg/kg MDZ or sham treatment. During tests, vehicle or a dose of test drug was given at the start of each TO; 10 responses on any lever produced food. MDZ produced dose-dependent increases in 0.32 and 3.2 mg/kg MDZ lever responding; this effect was dose-dependently antagonized by flumazenil. Diazepam and triazolam produced similar patterns of seneralization. Chlordiazepoxide, lorazepam, and flurazepam did not by Humazenii. Diazepam and triazolam produced similar patterns of generalization. Chlordiazepoxide, lorazepam, and flurazepam did not produce 3.2 MDZ lever responding up to rate-decreasing doses. Clonazepam produced only ND lever responding in 4/10 rats. Other tests suggested that the DS effects of 3.2 MDZ are BZ-like, and not mediated by sedative or muscle-relaxant effects. The DS effects of 0.32 mg/kg MDZ in this context appeared to be less specific than 3.2 mg/kg MDZ and different than the profile seen in animals trained in 2lever tasks. The DS effects produced by the 2 MDZ doses were qualitatively different and may not reflect simply magnitude differences.

FULL AND PARTIAL BENZODIAZEPINE AGONISTS AND PRIMATE VOCAL COMMUNICATION IN AVERSIVE AND POSITIVE SOCIAL CONTEXTS. Weerts EM.\* Miczek KA. Psychology Dept., Tufts Univ., Medford, MA 02155, USA

In socially relevant situations squirrel monkeys emit a rich repertoire of calls that range in frequency from 0.1 to 16 kHz. These calls consist of specific structural and functional components and may represent intense affective expressions within the social context. During brief periods of isolation from their mother or social group, juveniles (11-30 mo.) exhibit behavioral agitation and emit numerous calls or "peeps". These calls are slightly reduced by partial social contact and are markedly reduced by full physical contact with mother. The benzodiazepine anxiolytics, chlordiazepoxide (1-10 mg/kg,i.m.) and Ro16-6028 (0.1-30 mg/kg, i.m.), reduced peeps and explosive motor behaviors in a manner similar to full contact with mother. Interestingly, vocalizations associated with quiet affiliative behavior are also susceptible to benzodiazepine modulation. Adults with full visual, auditory and olfactory contact with the social group engage in vit, twitter and cackle calls when exposed to light stimuli signaling subsequent access to highly preferred or standard foods. Chlordiazepoxide reduced these types of calls at the same doses that reduced isolation peeps, but increased feeding. Vocal communications in squirrel monkeys may convey subtle and intense affect that are sensitive to anxiolytics.

EFFECTS OF DIAZEPAM ON PERFORMANCE AND MEMORY IN A RADIAL MAZE MODEL

J.J. Pilcher\*, G.R. Sessions, and E.L. Closser-Gomez. Walter Reed Army Institute of Research, Washington, D.C. 20307-5100.

The effects of diazepam on performance and memory were studied in an eight-arm radial maze paradigm designed to be sensitive to the disruption of working memory. Moderately food-deprived rats (n = 10) were trained to obtain a food reward at the end of each arm of the maze. Working memory errors were counted when a rat revisited an arm after obtaining the reward. Latency measures were used as a measure of overall task performance. On drug trials the rats were injected with 0, 1.25, 2.5, or 5 mg/kg diazepam (1.p., counterbalanced order, 2 replications for each dose) 30 min prior to the start of a trial. Diazepam produced a small but significant increase in working memory errors at 5 mg/kg. The drug had no significant effects on latency to complete the trial, average choice latency or in number of pellets obtained. This study shows that working memory deficits induced by dizzepam are independent of generalized performance decrement or motoric impairments.

HORMONE-RELATED DIFFERENCES IN NEURAL ADAPTATIONS TO CHRONIC BENZODIAZEPINE EXPOSURE. M.A. Wilson\* and R. Biscardi. Dept. Pharmacology, Univ. S. Carolina Sch. of Med., Columbia, SC 29208.

The gonadal hormone milieu modifies both the anticonvulsant tolerance and the GABA receptor changes associated with prolonged benzodiazepine (BZ) treatment in rats (Wilson & Biscardi, Eur.J.Pharm., in press). The current studies compare adaptations in physiological GABA/BZ responses induced by chronic BZ exposure in intact MALE and ovariectomized (OVX) rats. GABA sensitivity and BZ responses were assessed in single substantia rats. GADA sensitivity and be responses were assessed in single substantial ingra pars reticulata (SNr) neurons using electrophysiological techniques and in cortical synaptosomes with <sup>36</sup>chloride flux analysis.

Chronic diazepam exposure (DZ; 3 wk) reduced the subsequent effects of diazepam on SNr activity in MALE (F=3.9, p<0.01), but not OVX (F=0.62,NS), rats. Diazepam (0.25 mg/kg,iv) decreased SNr firing rates 24+9% (N=6) below basal values in DZ-treated MALES, compared to a  $57\pm9\%$  (N = 5) decrease in MALE controls. In contrast, DZ (0.25mg/kg,iv) decreased SNr firing similarly in OVX control and DZ-treated groups  $(41 \pm 15\% \text{ and } 34 \pm 17\%, \text{ Ns} = 4)$ . In MALES, chronic DZ treatment did not alter basal SNr activity, but caused a compensatory increase in firing rate after RO15-1788 administration. In OVX DZ-treated rats, basal firing rates were nonsignificantly decreased compared to controls and no Ro15-1788induced increase was observed. In both MALE and OVX rats, chronic DZ exposure did not affect iontophoretic GABA sensitivity and a slight decrease in responses to iontophoretic BZ was observed. Chronic DZ exposure also increased GABA-activation and reduced BZ modulation of cortical <sup>36</sup>chloride influx in OVX, but not MALE, rats. These results suggest that gonadal hormones modify the neural adaptations associated with chronic BZ exposure in a region-specific manner. (Supported by DA05932)

DIFFERENTIAL EXPRESSION OF BENZODIAZEPINE ANTICONVULSANT CROSS-TOLERANCE ACCORDING JO TIME FOLLOWING FLURAZEPAM TREATMENT. H.C. Rosenberg, T.H. Chiu and E.I. Tietz. Dept. of Pharmacology, Med. Coll. Ohio, Toledo OH 43699.

Chronic benzodiazepine (BZ) treatment can cause tolerance, and cross-tolerance to other BZs. In studies of the anti-pentylenetetrazol (PTZ) effect of BZs, the demonstration of tolerance depended on the BZ given acutely to test for tolerance (Pharmacol. Biochem. Behav. 39:711, 1992) and the BZ used for chronic treatment (FASEB J. 5: Al211, 1991). In this study, the time course of tolerance reversal was studied in rats treated one week with flurazepam (FZP). Groups were tested 12 hr, 2 and 7 days after ending FZP treatment. BZ effect was measured by the increase in convulsive threshold during a constant i.v. PTZ infusion. In controls, the BZ doses used increased PTZ clonus threshold approximately 3-fold. 12 hr after 1-week FZP treatment, all BZs were significantly less effective, showing tolerance. 48 hr after the 1-week FZP treatment, tolerance to clonazepam was no longer present, but was still robust for both diazepam and FZP. Rats tested a week after the 1-week FZP treatment were no longer tolerant. The results suggest differences in the way these BZs interact with their receptors, allowing differential expression of tolerance between clonazepam vs FZP and diazepam. Moreover, the molecular basis for the differential interaction of the BZs with their receptors must have been altered by FZP treatment. Supported between 12 and 48 hr after the end of treatment. Supported by DAO2194.

CENTRAL, NOT PERIPHERAL, BENZODIAZEPINE RECEP-CENTRAL, NOT FERTIFIERAL, BENEVITALISM TOR ANTAGONIST PRODUCES ANXIETY-LIKE STIMULUS
THE DEATERDAM-DEPENDENT RATS. C.M. HAIRIS, Dept. IN DIAZEPAM-DEPENDENT RATS. C.M. Harris The peripheral benzodiazepine receptor an-

tagonist PK 11195 (PK) has been reported to precipitate overt signs of diazepam-withdrawal similar to those precipitated by the central-type receptor antagonist flumazenil (FL) (Martinez et al., Pharmacol., Biochem. Behav. 41:461, 1992). To determine whether PK also produces anxiety-like subjective effects, 13 rats were trained to discriminate the anxiogenic drug PTZ, 20 mg/kg, from saline in a 2-lever operant task with food reward, and then tested with PK. Prior to chronic diazepam, neither PK nor FL (up to 40 mg/kg each) substituted for PTZ. After 3-4 days of diazepam (240 mg/kg per day in the diet) PK, 10 and 15 mg/kg (doses up to 3 times those reported to precipitate with-drawal) still did not substitute for PTZ, while FL, 10 mg/kg did. These preliminary results suggest that the the anxiety symptom of benzodiazepine withdrawal may be mediated selectively by the central-type benzodiazepine re-

DAILY FLUMAZENIL (FLU) DOSING DURING CHLORDIAZE-POXIDE (CDP) DEPENDENCE INDUCTION ATTENUATES FLU PRECIPITATED (PWD) BUT NOT SPONTANEOUS WITHDRAWAL

PRECIPITATED (PWD) BUT NOT SPONTANEOUS WITHDRAWAL (SWD). N.R. Boisse, L.P. Martin, J.J. Guarino and G.M. Samoriski. Dept. of Pharm. Sci., Northeastern University, Boston, MA 02115.

Several labs reported periodic benzodiazepine (BZ) receptor antagonist FLU during chronic BZ dosing attenuates FLU PWD. Indeed, Gallager et al (Eur J Pharm 132: 31, '86) suggested intermittent FLU as a therapeutic approach to preventing BZ dependence & WD. However, none monitored SWD which is a more relevant criterion than PWD for BZ WD in man. To re-evaluate FLU in preventing BZ WD rats were made dependent on CDP 75 mg/kg. BZ WD in man. To re-evaluate FLU in preventing BZ WD, rats were made dependent on CDP 75 mg/kg, po bid daily for 5 wks; chronic controls received water. Two hrs after AM CDP doses, FLU 25 mg/kg or vehicle were given po. After the last CDP dose (4-6 hrs), PWD was elicited by FLU 25 mg/kg, ip & monitored for 60 mins by treatment blind observers. SWD was monitored daily x 14 days. The WD score (sum of all grades for 20 WD signs) and AUC for PWD and SWD were compared. Co-treatment WD score (sum or all grades for 20 WD signs) and AUC for PWD and SWD were compared. Co-treatment with FLU attenuated PWD by 35% while SWD was unchanged. Clearly, the PWD results are not predictive of SWD and imply differences in molecular mechanisms underlying BZ SWD vs PWD. These results don't support intermittent FLU as a tool to prevent BZ SWD in man. (BRSG SO7-RR-05830-03)

GENETIC SELECTION FOR REPLICATE LINES OF DIAZEPAMSENSITIVE AND -RESISTANT MICE. E.J. Gallaher\*, M.L.
Helms, S.E. Gionet. VA Medical Center and Oregon Health Sciences
University, Portland OR 97201.
We have previously reported the genetic selection of mice for
diazepam sensitivity. In the earlier study we used a fixed-speed
rotarod and a pass-fail test to monitor the duration of diazepam
impringent. DS (carcitive) and DB (resitival) price ware chounter.

impairment. DS (sensitive) and DR (resistant) mice were shown to differ with respect to CNS sensitivity rather than the rate of diazepam elimination. However, this procedure includes the possibility that differences in innate rotatod performance or diazepam elimination contribute to the observed difference between DS and DR mice.

We have recently developed replicate lines using within-family.

We have recently developed replicate lines using within-family selection. An accelerating rotarod was used and each mouse was pretested to determine its baseline rotarod ability. All mice were then injected with 40 mg/kg diazepam ip and tested for rotarod performance at 30 min. Selection for mating was based on the decrement from baseline. Since all mice are tested at the same time, this protocol eliminates the possible confounds of innate rotarod ability and diazepam elimination rate.

The sensitive and resistant lines were found to diverge

significantly by the third generation, with additional divergence in subsequent generations. Correlated behaviors (seizure threshold, anxiolysis, sedation, muscle relaxation) will be examined during the course of selection to determine which of these benzodiazepine

effects segregate concomitantly with rotarod impairment. Supported by the VA Medical Research Service.

CENTROMEDIAL AMYGDALOID LESIONS BLOCK THE ANXIOLYTIC EFFECT OF DIAZEPAM DURING RESTRAIN OR SWIM INDUCED STRESS. I. Zarco de Coronado, M. de J. Vivar Estudillo, M. A. Barrios Figueroa, M. de L. Palacios Pérez. Biology School. U.A.P. and Physiology Department. Medical School. U.N.A.M. Apdo. Postal 70250. MEXICO.

Emotional stress induce anxiety. The centro medial amygdaloid nucleus (CMA) contains GABA A receptors and benzodiazepine (BDZ) component. To study the role of CMA in anxiolytic effects of diazepam, rats with electroliti-cally produced CMA lesions and sham operated controls were used. After five operative days (food and water intake ad libitum), ip diazepam (8mg/Kg B.W.) was injected two hours prior to swimming in water mantained at 31\*C. or restrain stress.

The experimental animals showed more difficult, incoording ted, and shorter time of swimming behavior. There was lesser gastric ulcerations in the control animals. Beside, lesioned animals increase body weight more than controls. These data indicate that diazepam anxiolysis requires intact CMA to bind adequate GABA receptors.

## 153.12

EFFECTS OF CHLORDIAZEPOXIDE ON SEPTAL SINGLE UNIT ACTIVITY FOLLOWING PAVLOVIAN CONDITIONING: A RE-GIONAL COMPARISON. C.E. Strickland, E. Thomas and E. Yadin. Dept. of Psychology, Bryn Mawr College, Bryn Mawr, PA 19010 and Dept.

of Psychiatry. Medical College of Pennsylvania, Philadelphia, PA 19129.
Single unit activity was recorded from several regions of the septal area in male Sprague-Dawley rats using chronically implanted miniwires. Following Pavlovian conditioning there was a decrease in activity in the dorsolateral (LSD) and ventrolateral septum (LSV) when a stimulus signaling footshock (CS+) was presented. Few consistent changes were observed in the intermediate lateral septum (LSI) and medial septum (MS). Gross movement was also recorded using a video tracking system. Different behavioral patterns developed as a result of conditioning and depended on the type of CS presented. Chlordiazepoxide (CDP, 10mg/kg i.p.) produced an increase in baseline unit activity (as measured during the ten second period prior to CS presentation) in the LSD and LSV and a decrease in the LSI and MS areas. CDP also appreciably reduced the effects of CS+ on unit activity in LSD and LSV. These results are consistent with other results in our laboratory which suggest that activity in the lateral septum may mediate the action of anxiolytic drugs. The results also indicate that the lateral and medial septum may have reciprocal functions with regard to anxiety.

DIFFERENCES IN DURATION OF INHIBITION OF CORTICAL AND HIPPOCAMPAL PROTEIN SYNTHESIS FOLLOWING AN ACUTE ADMINISTRATION OF LORAZEPAM, <u>V.Carson</u><sup>1\*</sup>, <u>M.Carson</u><sup>1</sup>, and <u>S.Tewari</u><sup>2</sup>. 1 Dept. of biology, Chapman Univ., Orange, CA 92666 and 2 Dept. of Psychiatry and Human Behavior, College of Med., UCI, Irvine, CA 92717.

Benzodiazepine derivatives such as Lorazepam (LRZ) interfere with memory consolidation as well as act as anxiolytics. We have found that the degree of inhibition of protein syntheses differs in cortices and hippocampi following an acute administration of LRZ. The time course of these effects was then investigated. An administration of LRZ. The time course of these effects was then investigated. An experimental group of Sprague-Dawley rats received 1 mg/kg LRZ via intra-gastric intubation and a control group of rats received 1 ml H<sub>2</sub>O/kg. Two subgroups were trained in a water maze 50 or 70 min. after intubation and sacrificed 5 min. after training. A third subgroup was sacrificed 24 hours after intubation. Response latencies were significantly greater in LRZ rats at 70 but not 50 min. Free and membrane bound polysomal RNAs were isolated from the pooled cortices or hippocampi of these rats. The effects of LRZ treatment on the translational abilities of the rollstoned RNAs were detained when the pooled cortices of the rollstoned RNAs were detained when the pooled cortices of the rollstoned RNAs were detained when the pooled cortices of the rollstoned RNAs were detained when the pooled cortices of the rollstoned RNAs were detained when the pooled cortices or the pooled cortices of the rollstoned RNAs were detained when the pooled cortices or hippocamping the pooled cortices or the pooled cortices or hippocamping the pooled cortices or the pooled cortices or the pooled cortices or hippocamping the pooled cortices or the pooled cortices or hippocamping the pooled cortices or the pooled cortices or hippocamping the pooled cortices or the pooled cortices or hippocamping the pooled cortices or hippocamping the pooled cortices or hippocamping the pooled cortices or the pooled cortices or hippocamping the pooled cortices or hippocamping the pooled cortices or hippocamping the pooled cortices or the pooled cortices or hippocamping the pooled cortices or hippocamping the pooled cortices or hippocamping the pooled cortices or hippocamping the pooled cortices or hippocamping the pooled cortices or hippocamping the pooled cortices or hippocamping the pooled cortices or hippocamping the pooled cortices or hippocamping the pooled cortices or hippocamping the pooled cortices or hippocamping the pooled cortices or hippocamping the pooled cort hippocampi of these rats. The effects of LRZ treatment on the translational abilities of the polysomal RNAs were determined using a mRNA dependent rabbit reticulocyte lysate system containing <sup>14</sup>C leucine. Free polysomal RNAs from cortices of LRZ treated rats displayed impaired protein synthesis only 24 hrs. after treatment, while bound cortical polysomal RNAs displayed impaired synthesis at all three time points. In contrast, free polysomal RNAs from hippocampi displayed impaired protein synthesis at all 3 time points while bound polysomal RNAs from hippocampi displayed inhibition only 55 and 75 min. after treatment. Free polysomas are associated with the production of extendes the protein proteins and bound polysomes are associated with the production of cytoplasmic proteins and bound polysomes are associated with the production of membrane proteins. These results imply that LRZ affects cortical and hippocampal protein synthesis differently.

HISTOLOGICAL ALTERATIONS OF THE CEREBELLAR CORTEX OF MOUSE FETUSES EXPOSED "IN UTERO" TO DIAZEPAM. A. Márquez-Orozco\* R. Andrade-Martinez , Ma.C. Márquez-Orozco and M.V. Gazca-Ramírez. Embryol. Dept. Sch of Med. Natl. Univ. of Mexico. Mexico 04510 D.F.

Diazepam (DZ) accumulates in the fetal cerebral and cerebellar cortices. We investigated DZ effects upon the development of the cerebellar DZ effects upon the development of the derebellar cortex of mouse fetuses DZ-exposed during gestation. Single daily doses of DZ (2.7 mg/kg/b wt) were s.c. administered to one group (DZ), from the 6th to 17th day of pregnancy. An other from the 6th to 17th day of pregnancy. An other group received 0.9% saline solution and a third was non-treated. At day 18th all females were killed with CO<sub>2</sub> atmosphere to remove the fetuses. Their cerebellums were fixed with 2.5% glutaraldehyde, post-fixed in 0804 and embedded in epoxic resine. The semifine sections were stained with toluidine blue and observed under the fotonic microscope. In the DZ fetuses the cerebellar cortex revealed a significant delay in cerebellar cortex revealed a significant delay in the differentiation and neuroblastic migration it evidenced by their accumulation in the germinal external granular layer, the molecular layer, and the density of the internal granular layer (p < 0.05). The delay in neuroblastic differentiation could explain the behavioral alterations observed in newborn mice exposed prenatally to DZ.

## 153.17

Sensitivity of substantia nigra reticulata (SNR) neurons to GABA and benzodiazepines (BZs) during chlordiazepoxide (CDP) withdrawal. R.F. Cox\*, G.T. Pollard, and C.M. Wang. Burroughs Wellcome Co., Research Triangle Park, NC 27709.

BZs can cause dependence and withdrawal signs in lab animals and humans. We used single-unit extracellular recording to study SNR neuronal

activity and responses to GABA and BZs during CDP withdrawal.

Rats (10/group) were given CDP (75 mg/kg/day p.o.) or vehicle for 5 weeks and tested 5 days after the last dose. Recordings were made in each rat to: (1) count spontaneously active SNR neurons in 6 electrode penetrations and measure firing rates, (2) measure the current-response to iontophoretically applied GABA (0.01M, pH 4), and to (3) GABA with concurrently applied flurazeparm (0.1M, pH 4, 2-5 nA) and (4) determine the dose-response to i.v. diazepam.

There was no difference between the number or firing rate of SNR cells in CDP-treated rats  $(1.9 \pm 0.1 \text{ cells/track}, 20.9 \pm 2.3 \text{ spikes/sec}, N=9 \text{ rats})$  and vehicle-treated controls  $(2.3 \pm 0.2 \text{ cells/track}, 20.7 \pm 1.6 \text{ spikes/sec}, N=9)$ However, GABA sensitivity was significantly reduced over the range of ejection currents (2-20 nA) in CDP-treated rats. Currents to eject GABA for ejection currents (2-20 nA) in CDP-treated rats. Currents to eject GABA for nhibiting firing by 50% (150) were 13.7 nA for CDP-withdrawal rats and 7.6 nA for vehicle (N=11-22 cells in 9 rats/group). Nevertheless, neuronal sensitivity to BZs was unchanged. Co-application of flurazepam shifted the GABA 150 from 13.7 to 9.2 nA in CDP-withdrawn rats and from 7.6 to 3.1 nA in controls. Diazepam (0.25-1 mg/kg i.v.) reduced SNR firing by 82% in CDP-withdrawn rats (ED50 0.25 mg/kg, N=7) and by 83% in controls (ED50 0.23 mg/kg, N=7). 0.23 mg/kg, N=7).

Our results demonstrate a modest, but significant reduction of GABA

sensitivity for SNR neurons during withdrawal from chronic CDP.

TOLERANCE AND SENSITIZATION TO THE BEHAVIORAL EFFECTS OF TRIADIMEFON, A NOVEL STIMULANT. A.R. Allen\* and R.C. MacPhail. Dept. of Psych., UNC-CH, Chapel Hill, NC 27514 and Neurotoxicology Div., US EPA, RTP, NC 2711.

Triadimefon (TDF) is a fungicide which has been shown to produce many of the behavioral effects associated with stimulant drugs. Previous work in our laboratory has shown that tolerance can develop to the effects of TDF on schedule-controlled behavior when chronically administered. The present experiment was conducted in an effort to determine whether tolerance would develop to the effects of TDF only when administered prior to the session, as is reported for stimulants. The acu effects of TDF (30 -170 mg/kg, 30 min presession, i.p.) were determined in 24 male Long-Evans rats performing under a multiple FR 10 FI 3-min schedule of milk reinforcement. Rats were then divided into three groups (N=8). A dose of TDF for chronic treatment was selected for each rat that was based on the acute effects of TDF. One group received this dose daily before each session; a second group received this dose after each session and the third group received vehicle before and after each session. Following 30 days of treatments, TDF dose-response functions were redetermined and compared to the acute TDF dose-response functions. Tolerance developed to the effects of TDF on FR overall response and run rates in rats that received TDF presession, but only at the dose that they had received daily Rats that received TDF postsession were sensitive to the effects of several doses of TDF on performance in both schedule components. No overall change in the effectiveness of TDF on performance was seen in the rats receiving vehicle daily These results indicate that repeated administration of TDF can result in either tolerance or sensitivity, depending upon the temporal relationship between treat and the test session. It is possible that the tolerance in rats receiving presession TDF may have countered changes that otherwise would have resulted in sensitivity.

EFFECTS OF PRENATAL DIAZEPAM ON THE RUNNING BEHAVIOR IN ADULT MICE. Ma.C. Márquez-Orozco\*\*, A. Márquez-Orozco and I. Zarco de Coronado. Embryol. and Physiol. Depts. Sch of Med. Natl. Univ. of Mexico. Mexico 04510 D.F.

Previous results in newborn mice indicated impaired motor activity administration of diazepam. after prenatal
. The underlaying administration of disceptam. The differences involved both peripheral and central alterations in motor regulation. This study analyzes the locomotor activity of 8-weeks old mice prenatally exposed to diazepam.

Diazepam (Valium), 2.7 mg/kg/b.w.,

intraperitoneally injected to pregnant mice (days 6th to 17th). Control animals received 0.9% saline solution. The offsprings were maintained for 8-weeks (food and water intake ad libitum).
Running activity in a cilinder was evaluated in both groups. Experimental animals showed both groups. Experimental animals snowed significant decreased motor activity (p < 0.05). These results indicate that long lasting effects produced by prenatal diazepam include reduction in the recovery capacity after damage.

## 153.18

CHANGES IN GABA ERGIC RECEPTOR FUNCTION IN PENTOBARBITAL-DEPENDENT RATS. A. Nabeshima. I. Saito. H. Ozawa. N. Takahata. Dept. of Neuropsychiat. Sapporo Med. Col., Sapporo, JAPAN Changes in GABA ergic receptor function were studied in pentobarbital (PB)-dependent rats. Physical dependence on PB in male Lewis rats was induced by using the drug-admixed food (DAF) method. The GABA dependent 36Cl influx into cerebral cortical synaptosomes of rats was significantly decreased at the time of PB withdrawal (PB-dependent rats) and was significantly increased 20 hrs after PB withdrawal (PB-withdrawal rats). 3H-Muscimol binding to low affinity sites of GABA, receptors was to low affinity sites of GABA<sub>A</sub> receptors was significantly decreased in the PB-dependent rats. Although <sup>3</sup>H-flunitrazepam (FZ) binding to the cortical membrane was not changed, the enhancement of GABA-dependent <sup>36</sup>Cl influx induced by the addition of FZ disappeared in Induced by the addition of F2 disappeared in the PB-dependent rats. Additions of picrotoxinin and bicuculline had no effect on the GABA-dependent <sup>36</sup>Cl influx in the PB-dependent rats. These results suggest that physical dependence on PB leads to change of the GABA binding site associated with changes in the GABA/benzodiazepine/chloride channel coupling.

Chronic MDMA administration down-regulates CCK but not tyrosine hydroxylase mRNA in neurones of the rat substantia nigra. Marcus Rattray\*. Glen Wotherspoon, Dawn Savery, Sharon Averill and John V. Priestley. Divisions of Biochemistry and Physiology, United Medical and Dental Schools, University of London, St Thomas's Hospital, London SE1 7EH, U.K.

Abuse of the psychotropic drug, methylenedioxymethamphetamine (MDMA) is widespread. Chronic administration of MDMA causes selective neurodegeneration of serotonin neurones whilst levels of dopamine are relatively unaffected by MDMA.

We have measured the effect of MDMA on cholecystokinin and tyrosine hydroxylase messenger RNA expression which are co-expressed in a subgroup of substantia nigra neurones. Using 35S-labelled oligonucleotide probes and liquid emulsion techniques, we measured mean grain densities (grain area/cell area) over positive neurones from control animals and MDMA treated animals. Twenty-four hours after the last of eight injections of MDMA (10 mg/kg, i.p.) administered over four days, CCK mRNA levels were reduced to 40% of control levels (MDMA treated level = 13.52 ± 0.68 (n=463), control level = 32.34 ± 1.00 (n=533)). In sections from the same animals, tyrosine hydroxylase mRNA levels were relatively unchanged (MDMA treated level = 32.87 ± 0.94 (n=407), control level = 29.16 ± 0.79 (n=396)). Two weeks after the last dose, CCK mRNA levels remained depressed (43% of control levels). The effect was dose-related since three injections of MDMA (10 mg/kg, i.p.) administered over two days produced a smaller reduction in CCK mRNA levels vero wood days produced a smaller reduction in CCK mRNA levels 24 hours after the last injection (75% of control levels) and, two weeks after the last injection in CCK mRNA levels and to chronic atypical psychosis in man, since CCK or its antagonists can modulate these behaviours.

IDENTIFICATION OF AP-1 BINDING PROTEINS IN NORMAL AND METAMPHETAMINE-TREATED MOUSE BRAINS BY IN SITU DNA BINDING METHOD. N.Miki,\* X.-B.Wang, Y.Watanabe and M.Hirata. Dept. of Pharmacology, Osaka Univ. Med. Sch, Osaka 565, Japan.

We developed a novel method for detecting specific DNA-binding proteins in situ (In situ DNA binding method, ISDB). Using an oligo-DNA probe containing AP-1 consensus sequence, we examined the distribution of AP-1 binding proteins in mouse brains and its changes induced by metamphetamine. The specific bindings to AP-1 element showed regional distribution coincided with that of jun/fos in the brain and the binding pattern was clearly different from that of SP-1 whose pattern was clearly different from that of SP-1 whose site is recognized by the other transcription factors. Antibody against jun which recognizes a DNA-binding domain markedly reduced AP-1 binding but not SP-1 binding. Gel shift assay with the nuclear extracts from individual regions of brain paralleled with data of ISDB method. Distribution of AP-1 binding proteins was greatly different from that of control brain, when this method was applied for the mouse brains intoxicated with metamphetamine acutely or chronically. These results suggest that ISDB method is useful and These results suggest that ISDB method is useful and convenient for visualizing distribution of a specific DNA binding protein in vivo.

# 154.5

TRANSCRIPTION FACTOR GENE EXPRESSION DURING RAT AMPHETAMINE WITHDRAWAL: CORRELATIONS WITH NOVELTY RESPONSES AND DOPAMINE LEVELS. A.M. Persico\*, C.W. Schindler+, R. Zaczek#, M.T. Brannock and G.R.Uhl, Labs. of Mol. Neurobiol. & Behav. Pharm./Genetics-ARC/NIDA, & Depts. Neurol. & Nsci., JHUSM; & DuPont Merck Pharm.#; Box 5180, Baltimore MD. 21224.

Changes in transcription factor gene expression could participate in the behavioral and neurochemical alterations induced by chronic psychostimulant use. Rats injected with 7.5 mg/kg d-amphetamine sulfate bid for 14 days display enhanced expression of c-fos, fos-b, fra-1, jun-b, c-jun and zif 268 mRNAs that manifests tolerance during treatment and cross-tolerance with saline injection stress. Withdrawal decreases expression of each factor; this begins 12 hours after the last injection and largely recovers to control levels by 54 hours. These results show temporal correlations with the onset of decreased stereotypy time on a novelty test and with modest decreases in striatal dopamine levels; each begins 12 hours after the last injection. Interestingly, dopamine levels are also normal by 54 hours after withdrawal, while novelty response alterations last longer. Decreased novelty responses noted during amphetamine withdrawal are thus accompanied by decreased levels of dopamine and reduced expression of genes encoding several transcription factors. These effects each return to baseline values more rapidly than the abnormal behavioral responses, however.

PHOSPHORYLATION OF NEUROMODULIN (GAP-43) AFTER AN AMPHETAMINE-SENSITIZING REGIMEN AND ACUTE AMPHETAMINE. M. E. Gnegy\*. P. Hong and S.T. Ferrell. Dept. Pharmacology, Univ. MI Sch. of Med., Ann Arbor, MI 48109-0626.

An increase in stimulus-induced DA release and synaptosomal calmodulin (CaM) occur in rat striatum after withdrawal from a sensitizing regimen of amphetamine (A). The CaM-binding protein, neuromodulin (NM), promotes neurotransmitter release and dissociates CaM upon phosphorylation by protein kinase C (PKC). To assess whether these processes were altered in A-sensitization, the *in vivo* phosphorylated state of NM was examined by a back phosphorylation assay, SDS-PAGE and autoradiography. Purified striatal synaptic membranes were phosphorylated by PKC and [<sup>32</sup>P]ATP. Female, Sprague-Dawley rats received a 4 wk-escalating dose regimen of A or saline (S); a challenge dose of 1 mg/kg A or S was given 4 weeks after the last dose of A to create 4 groups: S-S, S-A, A-S, A-A. EGTA in the homogenizing buffers reduced endogenous dephosphorylation. In vitro PKC-mediated back-phosphorylation of NM was significantly reduced in S-A, A-S and A-A groups compared to S-S controls. [32P] content of the cut bands was: S- $293 \pm 5$ ; S-A,  $231 \pm 15$ , A-S,  $201 \pm 16$ , A-A,  $199 \pm 11$ , N = 6 (ANOVA, p < 0.001). Anti-NM immunoblots showed no change in NM levels in any group. These results suggest that acute A (as in the S-A group) increases NM phosphorylation and this change endures 4 wks after repeated A. We have found an effect of 10  $\mu$ M A on NM phosphorylation in  $^{32}\text{Pi-incubated}$  synaptosomes. Since sensitization can be induced with one dose of A, it is possible that phosphorylation of NM could contribute to events leading to an increase in CaM, release of DA and A-induced behavioral sensitization. Funded by NIDA grant, DA05066.

## 154.4

C-FOS EXPRESSION IN MOUSE STRIATUM (STR) IS INDUCED BY AMPHETAMINE (AMPH). K.T. Finnegan\*1,2, R. Karler2, C.E. Inturrisi<sup>3</sup>, Departments of Psychiatry<sup>1</sup>, Pharmacology<sup>2</sup>, Univ. Utah Sch. Med., Salt Lake City, UT 84132; Department of Pharmacology<sup>3</sup>, Cornell U. Med. Coll., New York, NY 10021.

Previous studies (Karler et al., Life Sci. 45:599, 1989) have indicated that NMDA receptors may be involved in the behavioral sensitization associated with amphetamine-induced stereotypy. We have measured c-fos mRNA in total cellular RNA extracts of individual mouse STR (N=5) using a quantitative solution hybridization assay. One hr after D-AMPH, 16 mg/kg ip, c-fos mRNA levels were increased nearly 10 fold above controls (saline =  $0.56 \pm 0.7 \text{ pg/}\mu\text{g}$ RNA, AMPH =  $5.2 \pm 0.7$ ). Pretreatment with MK-801 (MK) or haloperidol (HAL) 0.5 mg/kg ip 30 min prior to AMPH significantly reduced the induction of c-fos mRNA (AMPH + MK =  $2.5 \pm 0.2$ , AMPH + HAL =  $1.7 \pm 0.2$ ). The results provide quantitative information on the ability of a dose of AMPH that produces stereotypy to induce c-fos mRNA in mouse striatum, a structure implicated in the psychomotor actions of AMPH. The demonstration that a dopamine (HAL) or an NMDA antagonist (MK) can attenuate c-fos induction suggests that the measurement of c-fos mRNA, an unambiguous indicator of c-fos gene expression, may be useful in identifying brain regions and neuroeffector systems associated with AMPH's behavioral effects. Supp. in part by DA-00346, DA-01457, DA-07239.

MULTIPLE EXPOSURE TO D-AMPHETAMINE SENSITIZES C-FOS EXPRESSION IN RAT STRIATUM. Jennifer M. Klug.
Sunny Y. Lu, Robert B. Norgren and Andrew B. Norman. Dept. of
Psychiatry, University of Cincinnati College of Medicine, Cincinnati, Ohio 45267.

Exposure of animals to psychomotor stimulants such as amphetamine or cocaine induces an increase in the behavioral effects of these drugs on subsequent exposure. D-amphetamine stimulates the transcription of the immediate early gene c-fos in rat striatum and, therefore, the fos protein can act as a neurochemical marker of postsynaptic responses to d-amphetamine. We investigated fos induction in rat striatum following multiple exposure to d-amphetamine. Male Sprague Dawley rats received an initial injection of either d-amphetamine (5 mg/kg i.p.)(n=7) or an equal volume of saline (n=8) and three days later all rats were administered a second injection of d-amphetamine (2.5 mg/kg i.p.). Three hours post-injection, rats were perfused and brain sections processed for immunocytochemistry for fos. In striatum from rats challenged twice with d-amphetamine there was a significant increase in the total number of fos immunoreactive nuclei and in the intensity of staining compared to that observed in striatum of rats receiving a single challenge of d-amphetamine. Thus, there was an apparent sensitization of the response of striatal cells with respect to fos induction following multiple exposure to d-amphetamine suggesting a possible postsynaptic component of the sensitization response. This change in gene expression may reflect a mechanism by which long term changes in sensitivity to psychomotor stimulants may be produced. (Supported by RO3 MH45253)

## 154 7

MULTIPLE EXPOSURES TO APOMORPHINE SENSITIZES C-FOS EXPRESSION IN 6-HYDROXYDOPAMINE LESIONED RAT STRIATUM. Wayne Quellette, Jennifer M. Klug, Heidi C. Landen, Herbert R. Thompson and Andrew B. Norman. Department of Psychiatry,
University of Cincinnati College of Medicine, Cincinnati, OH 45267.
The sensitization to the behavioral effects of psychomotor stimulants has

been suggested to be mediated via an increase in the release of dopamine in the basal ganglia. However, in dopamine deafferented rats there is a behavioral sensitization following multiple challenges with apomorphine implying that a postsynaptically mediated sensitization response also exists. Dopamine receptor mediated stimulation of c-fos induction can represent a marker of post-synaptic responses. We, therefore, investigated fos induction in rat striatum following multiple exposure to apomorphine. Male Sprague-Dawley rats received unilateral 6-hydroxydopamine (6-OHDA) lesions and were divided into two groups. The first group (n=7) received three injections of apomorphine (0.25 mg/kg sc) separated by three day intervals. The second group (n=6) received two saline injections followed by an injection of apomorphine (0.25 mg/kg sc). Three hours post-injection the rats were perfused and brain sections were processed for immunocytochemistry for fos. In 6-OHDA lesioned striatum from rats challenged three times with apomorphine, there was a significant increase in the total number of fos immunoreactive nuclei and in the intensity of staining as compared to that observed in rats receiving the single challenge of apomorphine. Thus, there was an apparent sensitization in the response of cells with respect to c-fos induction in 6-OHDA lesioned striatum following multiple exposure to apomorphine. These data indicate that the sensitization in lesioned striatum following multiple challenges with apomorphine can be independent of dopaminergic input and may be mediated by postsynaptic mechanisms. ## 154.9

CONDITIONED INCREASES IN LOCOMOTOR ACTIVITY IN MICE PRODUCED BY AMPHETAMINE OR COCAINE ARE ANTAGONIZED BY MK-801, BUT NOT BY SCH-23390 OR SPIPERONE. G.P. Vincent $^{\pm}$ S. Williams, and J. Sepinwall, Neurobiology Research, Hoffmann-La Roche Inc., Nutley, NJ 07110.

Groups of mice (n=16/group) were tested in locomotor activity cages for lh on each of two consecutive days.

Drugs were given ip (mg/kg) as shown below.

|     | Day 1              |               | Day 2               |
|-----|--------------------|---------------|---------------------|
| Gp. | 15' Before Activit | y 1h Post     | 15' Before Activity |
| SSC | Saline             | Saline        | Cocaine (10)        |
| SCC | Saline             | Cocaine (40)  | Cocaine (10)        |
| CSC | Cocaine (40)       | Saline        | Cocaine (10)        |
| SSA | Saline             | Saline        | Amphetamine (3)     |
| SAA | Saline             | Amphetamine ( | 10) Amphetamine (3) |
| ASA | Amphetamine (10)   | Saline        | Amphetamine (3)     |

Groups CSC and ASA on Day 2 exhibited increases in motor activity compared to the other four groups. This behavioral sensitization could be antagonized by the NMDA behavioral sensitization could be antagonized by the wink antagonist MK-801 (lmg/kg), but not by the dopamine  $D_1$  antagonist SCH 23390 (0.04lmg/kg) or the  $D_2$  antagonist spiperone (0.04lmg/kg), when given immediately after the Day 1 test. MK-801 was much less active when given 2 after the Day 1 session. Thus, NMDA receptor blockade, but not  $D_1$  or  $D_2$  blockade, may interfere with long term memory formation processes that underlie conditioned activity increases produced by amphetamine or cocaine.

# 154.11

EFFECT OF d-AMPHETAMINE ON THE EXTRACELLULAR CONCENTRA-TIONS OF DOPAMINE AND GLUTAMATE IN IPRINDOLE TREATED RATS. J. F. Nash\* and B. K. Yamamoto. Dept. of Psychiatry and Neuroscience, Case Western Reserve University, Cleveland, OH 44106-5000

The effect of d-amphetamine on the extracellular concentrations of dopamine (DA) and glutamate (GLU) was studied in iprindole treated rats using in vivo microdialysis. d-Amphetamine (18.4 mg/kg, ip) significantly increased the extracellular concentration of DA in the anteromedial striatum. Treatment with iprindole (10 mg/kg, ip) had no effect on the absolute increase in DA efflux but significantly prolonged the increase in the extracellular concentration of DA. d-Amphetamine administration increased the extracellular concentration of GLU only in iprindole treated rats. The increase in GLU efflux began 4-6 hr after d-amphetamine administration and the maximal increase was observed 8-12 hr after drug administration. Each rat was sacrificed 7 days after the dialysis study and the concentration of DA was determined in the contralateral striatum. Consistent with previous studies, d-amphetamine significantly decreased DA content in the contralateral striatum of iprindole treated rats without affecting the concentration of serotonin. Pretreatment with α-methylparatyrosine (150 mg/kg) significantly attenuated d-amphetamineinduced DA efflux and the long-term (7 day) depletion of DA in the striatum. Haloperidol (1 mg/kg) had no effect on d-amphetamine-induced DA efflux but completely blocked the depletion of DA observed 7 days later. The extracellu-lar concentration of GLU was measured in both cases and will be presented. These data are suggestive that acute increases in the extracellular concentration of GLU plays a significant role in the depletion of DA produced by d-amphetamine in iprindole treated rats.

PHARMACOKINETIC / PHARMACODYNAMIC ANALYSIS OF D-AMPHETAMINE AND D-METHAMPHETAMINE. W.P. Melega\* A.E. Williams, D. Schmitz, E.D. Stefano, A.K. Cho Division of Nuclear Medicine and Dept of Pharmacology, UCLA School of Medicine, Los Angeles, CA 90024

Plasma and brain profiles of the kinetics and metabolism of damphetamine (Ampt) and d-methamphetamine (MAmpt) were correlated with the magnitude of the drug-evoked dopamine release as measured with microdialysis

Ampt or MAmpt (1.0, 2.5, 5, 10 mg/kg, iv), was administered to chloral hydrate anesthetized rats. Striatum, cortex, cerebellum and plasma levels were quantitated from 5 to 120 min; brain levels increased proportionally with increases in plasma levels for both compounds; regional differences among brain regions were not observed. For MAmpt, metabolites consisted of amphetamine and para-hydroxymethamphetamine, the latter being more concentrated in striatum relative to cortex or cerebellum.

Pharmacodynamic profiles were obtained in parallel studies with microdialysis in the anterior striatum. Extracellular dopamine (DA) was assayed between 5 and 90 min post-drug. At 2.5 mg/kg, the MAmpt-induced DA release was greater than that from equimolar Ampt; whereas at 5 mg/kg, equimolar doses of MAmpt and Ampt produced comparable effects.

Maximal DA release (at 10-20 min) lagged behind peak brain levels (at 5-10 min) of either compound. DOPAC and HVA levels decreased (0-90 min) but at 5 min post-drug, a small increase in DOPAC was observed; HIAA was not affected

## 154.10

METHAMPHETAMINE-INDUCED ALTERATIONS IN DOPAMINE AND SEROTONIN NEURONS IN FETAL RAPHE CULTURES.

Barbara A. Bennett', Joseph M. Paris and Julie R. Pecora, Dept. Physiology and Pharmacology, Bowman Gray School of Medicine., Wake Forest Univ., Winston-Salem, NC 27157-1083.

Methamphetamine (METH) and its structural analogues have been demonstrated to be neurotoxic to CNS dopamine (DA) and serotonin (5-HT) neurons both in vivo and in vitro. Our laboratory has been involved in an extensive characterization of mesencephalic cultures and the effects of exposure to METH as determined by both neurochemical and immunochemical indices. We have initiated studies of the midbrain raphe nuclei which contain 5-HT as well as DA neurons. The purpose of the present studies was to extend our previous findings and compare them with METH-induced alterations in cultured fetal raphe cells. Fetal rat brains (E19) were removed and the rhombencephalon obtained and dispersed into single cells. METH (10<sup>4</sup> M) was added to the cultures on day 2 and fresh daily thereafter. The effects of chronic METH exposure on [<sup>3</sup>H]-DA and [3H]-5-HT uptake was determined after 5 days of drug treatment. Additional cultures were fixed with 5% acrolein and the presence of TH-and 5-HT-containing cells was determined by immunocytochemistry. Results indicate that chronic METH exposure decreased DA and 5-HT uptake (approximately 40 and 30%, respectively). Preliminary immunocytochemical studies suggest that METH administration also results in a reduction in the number of TH and 5-HT immunopositive cells. These results, like those found with mesencephalic cultures, suggest that chronic METH exposure can induce alterations in raphe aminergic neurons. Supported by DA-05073 (BAB) and DA-05381 (JMP).

DOPAMINE RELEASE FROM A9 AND A10 NEURONS INDUCED BY ADMINISTRATION OF 4-METHYLAMINOREX AND AMPHETAMINE. W.F. Eberle, C.S. McNeish, C.R. Ashby, R.Y. Wang, and R.E. Strecker\*. The novel stimulant drug 4-methylaminorex (4-MAX) has properties similar to amphetamine in reports of its use in humans, and in drug discrimination paradigms with animals. The present study used microdialysis sample collection and quantitative neurotransmitter analysis by HPLC to quantify 4-MAX and amphetamine induced changes in dopamine (DA) release in the nucleus accumbens (NAS), frontal cortex (FC), and caudate-putamen (CP) of awake freely moving rats. Route of drug administration included both intraperitoneal (i.p.) injections and intra-ringer administration of d-amphetamine and the four isomers of 4-MAX According to previous studies, the four isomers of 4-MAX differ in potency as follows: trans(4S,5S) > cis(4S,5R) = cis (4R,5S) > trans(4R,5R). Our results from the presentation of these compounds (at a concentration of 10<sup>-5</sup>M) in the ringer solution into the NAS resulted in increases of DA release quite consistent with their expected potencies. Specifically, the trans 4S,5S and the cis 4R,5S isomer produced large increases (7.1 and 6.8 fold respectively), which were quantitatively similar to d-amphetamine, while the less active trans 4R,5R isomer produced only a 2.4 fold increase in DA release. Parallel electrophysiology studies by Ashby and Wang have suggested that the trans 4S,5S isomer of 4-MAX is more potent in suppressing cell firing in the NAS and FC (projection area of the A10 DA neurons). Following i.p. injections of the various 4-MAX isomers, a preliminary analysis indicated that there was no large difference between 4-MAX-induced increases in DA levels in the CP versus the NAS. Supported by PHS award DA07456.

AMPHETAMINE-INDUCED CHANGES IN MONOAMINE RELEASE IN AWAKE (MACACA FASCICULARIS) AS ASSESSED BY IN VIVO MICRODIALYSIS. <u>C.W. Berridge\*</u>, <u>R. Kuczenski, D.S. Segal, S.L. Foote</u>. Univ. Calif., San Diego, CA 92093.

Guide cannulae for microdialysis probes were permanently implanted over primary motor cortex (n=4), parietal cortex (n=4), and caudate nucleus (n=4) in an adult male monkey using MRI-determined stereotaxic coordinates. recovery, the monkey was habituated to daily chairing. Each dialysis experiment involved chairing the monkey 3-4 hr/day for 4 consecutive days. On day 1, dialysis probes were inserted into 2-3 sites and on days 2-4 samples were collected prior to and following amphetamine (AMPH; 0.25 mg/kg, sc) administration. Experiments were separated by 1-Dopamine (DA) was present in samples from caudate (60-150 fmol/sample) and motor cortex (2-7 fmol/sample) but not detectable (< 1.5 fmol) in parietal cortex; AMPH increased DA concentrations approximately 10-fold in caudate and motor cortex. Norepinephrine (NE) was detectable in parietal (2-4 fmol/sample) and motor cortices (2-5 fmol/sample); AMPH increased NE in samples from both regions approximately 10-fold. The DA catabolites HVA and DOPAC were present in all regions. Concentrations of HVA were approximately 10-fold greater than those of DOPAC. A delayed AMPH-induced decline in these catabolites was These results demonstrate the feasibility of using microdialysis in cortical and subcortical structures in awake nonhuman primate.

REPEATED MICRODIALYSIS MEASUREMENTS OF CAUDATE EXTRACELLULAR DOPAMINE IN THE VERVET MONKEY:
EFFECT OF AMPHETAMINE. C.W. Bradberry \*, J. Nobelitti, R.
Innis R. Malison. Depts. of Psychiatry and Laboratory Medicine, Yale
University School of Medicine, New Haven, CT and the VA Medical
Center, West Haven, CT 06516.

We have performed repeated microdialysis experiments in the vervet

monkey, examining the effect of intravenous ampletamine on extracellular DA in the caudate nucleus. MRI-directed stereotaxic extracellular DA in the caudate nucleus. Mixt-directed stereotaxic placement of a guide cannula assembly was utilized in order to accurately position microdialysis probes. All experiments were performed by acute placement of a microdialysis probe in the isoflurane-anesthetized animal. Basal levels of extracellular DA were 18.8 ± 3.5 fmol/microliter (corrected for probe recovery), corresponding to an estimated extracellular concentration of 18.8 nM. Intravenous amphetamine sulfate excited in a provincial 23 feel increase in extracellular denomine with an resulted in a maximal 22-fold increase in extracellular dopamine, with an apparent  $\mathrm{ED}_{50}$  of 0.3 mg/kg (salt weight). Careful use of sterile apparent LES on the microdialysis probe placement. For comparison, a series of experiments was performed in the chloral hydrate anesthetized rat. Probes were placed acutely into the lateral striatum. In the rat, intravenous amphetamine sulfate resulted in a maximal 40 fold increase in extracellular dopamine, with an apparent ED50 of 1.1 mg/kg. These results indicate an enhanced sensitivity of the primate to amphetamine in comparison to the rat, and establish the utility of the procedures for the study of psychostimulant action in the primate.

Supported in part by the Yale-VA Alcholism Research Center, MH-14092, DA 04060, and MH44866.

LESIONS OF THE PEDUNCULOPONTINE TEGMENTAL NUCLEUS BLOCK DRUG-INDUCED REINFORCEMENT, BUT NOT AMPHETAMINE-INDUCED LOCOMOTION. M.C. Ol<u>mstead</u> and K.B.J. Franklin\*. Dept. Psychology, McGill University, Montreal, Canada, H3A 1B1 It has been proposed that the positive reinforcing and

motor activating effects of drugs involve the activation of a single neural substrate. If this is true, manipulations that effect drug reinforcement should also effect the locomotor responses to a drug injection. To test this hypothesis, we examined the role of the pedunculopontine tegmental nucleus (PPTg) in drug reinforcement and stimulant induced locomotion.

In three separate experiments, rats were prepared with NMDA (.5 ul of .1M solution) or sham lesions of the PPTg. In two experiments, sham and lesioned animals were tested for the development of a conditioned place preference (CPP) to morphine (2 mg/kg X 3 pairings) or amphetamine (1.5 mg/kg X 3 pairings). Ten days later, spontaneous motor activity (SMA) was assessed following saline or amphetamine (1.5 mg/kg s.c.). The third group of drug-naive animals were tested for SMA only. Lesions of the PPTg blocked the development of a CPP to both morphine and amphetamine. In contrast, lesions had no effect on saline or amphetaminestimulated SMA.

The PPTg appears to be involved in the reinforcing effects of amphetamine and morphine, but is not necessary for the expression of amphetamine-induced SMA.

IN VIVO MICRODIALYSIS AND CHRONOAMPEROMETRY: TIME-RELATED EFFECTS OF AMPHETAMINE ON RAT STRIATAL DOPAMINE EFFLUX AND LOCOMOTION. A.G. Phillips, \* A. Coury, L.J. Atkinson and C.D. Blaha. Dept. Psych., Univ. British Columbia, Vancouver, BC, Canada V6T 1Z4.

Amphetamine (AMP, 2 mg/kg s.c.) effects on striatal dopamine (DA) efflux (CA: chronoamperometric 1 s pulse/30 s; MD: microdialysis-HPLC sample/900 s, 1.5 ul/min) and locomotor activity (photocell counts/10 min) were assessed 24 hr after bilateral implantation into rat striata of a CA electrode (CE: 150 um stearate+carbon paste surface) and MD probe (MP: 0.34x4 mm). AMP effects on DA for MD are given as a percentage of pre-AMP basal DA values (100%). In order to compare CA and MD measures of AMP effects on DA, a second study derived a mean value (100%) for basal DA oxidation current 24 hr after implantation into rat striatum of a parallel side-by-side CE MP assembly. By virtue of MD drainage properties (Blaha et al., Soc Neurosci 17, 1991), perfusion (5 ul/min) of the MP maximally decreased baseline CA currents 9±0.4 nA (n=33). AMP effects on CA signals are thus given as a percentage of this mean basal DA current value. At the nadir of this decrease, the CE selectivity to DA was tested by serial perfusion of the MP with 10, 5, and 0.05 mM of ascorbate, DOPAC, and DA, respectively. Only DA reversed the MD-induced decrease in the CA signal. In the first study, MD and CA measures of AMP effects on DA efflux were similar in total duration (210 vs 230 min) and peak-time (30-45 vs 45-55 min) but differed in the magnitude of increase above baseline (475% vs 200%), respectively. These time course measurements of DA efflux correlated well with AMP action on locomotor activity (600% peak increase in 45 min with baseline recovery in 210 min) and demonstrate that both in vivo methods may be used to study the role of central DAergic systems in mediating specific behaviors. The disparity in magnitude of AMP effects may be due, in part, to the MP extraction process and its impact on steady-state concentrations of neurochemicals in the surrounding interstitial fluid.

THE EFFECTS OF ESCALATING DOSES OF d-AMPHETAMINE (AMPH) ON LATERAL HYPOTHALAMIC INTRACRANIAL SELF-STIMULATION (ICSS). E.M. Munn\* and R.A. Wise, Center for Studies in Behavioral Neurobiology, Department of Psychology, Concordia University, Montreal, Canada, H3G 1M8.

It has been suggested that the transient behavioural depression observed following treatment with escalating, non-neurotoxic doses of AMPH may represent an animal model of the human withdrawal "distress syndrome" (Paulson et al., Psychopharmacology, 1991, 103, 480-492). The effects of this injection paradigm were assessed in rats trained to lever press for lateral hypothalamic electrical stimulation. The animals were pretreated with either saline or AMPH twice a day 5 days a week for 6 weeks. Ratefrequency curves were collected weekly on the seventh day (-36 hrs after the last AMPH injection) during this period and for an additional 3 weeks following the termination of drug treatment. Animals receiving AMPH showed a progressive elevation of ICSS threshold whereas their asymptotic rate of responding decreased from baseline levels. These effects were transitory and 3 weeks later there were no significant differences in these measures. A subsequent AMPH challenge (1 mg/kg IP) reduced the ICSS threshold to the same degree in both groups. These observations suggest that the behavioural depression seen during AMPH withdrawal is accompanied by an attenuation of the rewarding effects of electrical stimulation. Unlike locomotion, however, AMPH pretreatment does not enhance the facilitating effects of subsequent AMPH on ICSS.

CHOLINERGIC-DOPAMINERGIC INTERACTIONS IN THE SHELL AND CORE REGIONS OF NUCLEUS ACCUMBENS. R.M. Booze\* and M.L. Smith, Department of Pharmacology, University of Kentucky Medical Center, Lexington, KY 40536-0084.

The mesocorticolimbic dopamine system has been recognized as an important neurobiological substrate for cocaine abuse. In these experiments, we have used (1) ChAT immunocytochemistry and 3-D computer reconstruction to localize cholinergic neurons within the nucleus accumbens and (2) quantitative receptor autoradiography/in situ hybridization to localize dopamine receptors in the shell and core regions of the nucleus accumbens.

Adult male Sprague-Dawley rats were perfused with 4% paraformaldehyde. The brains were sectioned (40 µm) and tissue sections collected through the nucleus accumbens. Serial sections were processed for ChAT-IR using standard ABC immunocytochemical detection techniques. Computerized 3-dimensional reconstructions were generated of the ChAT-IR interneurons in the dorsal striatum and nucleus accumbens. In a separate series of animals, cryostat-cut (16 µm) adjacent sections were collected through the rostral, mid, and caudal nucleus accumbens for D-1 and D-2 receptor autoradiography/in situ hybridization

We found that ChAT-IR neurons were preferentially localized to the shell (dorso-medial) region of the nucleus accumbens. The shell region of nucleus accumbens also contained the highest levels of dopamine D-1 receptors and D-1 mRNA. In contrast, D-2 receptors and D-2 mRNA were predominant in the rostral nucleus accumbens and the core region. These findings suggest (1) that cholinergic interneurons serve to link the dopaminergic inputs from the VTA (A10) with GABAergic efferent neurons of the nucleus accumbens shell region and (2) the anatomical heterogeneity of the nucleus accumbens should be considered in determining the actions of cocaine. (Supported by DA 06638)

Amphetamine, cocsine and nicotine induce c-fos expression in different subnuclei of ventral tegmental area (VTA). Hideo Kiba, Ying Pang and A. Jayaraman\* Dept. of Neurology, LSU Med. School., New Orleans, LA 70112

The euphoric and reinforcing properties of drugs of abuse have been speculated to be mediated by VTA dopaminergic neurons. Induction speculated to be mediated by VIA dopaminergic neurons. Induction of c-fos is an immediate and early response in the cascade of molecular events that ultimately lead to long-term alterations in gene expression in neurons. To identify the precise subsets of VTA neurons that mediate the acute effects of some common drugs of abuse, the pattern of expression of c-fos gene was mapped in VTA with immunocytochemical methods. Amphetamine (5mg/kgi.p) resulted in Fos-Li in supramamillary area, parabrachialis pigmentosus, rostral linear nuclei, caudal VTA and retrorubral areas. Fos-Li was also prominent in the rostral and lateral areas of substantia nigra pars reticularis (SNpr). Neurons with Fos-Li were moderately labeled in nucleus paranigralis, but were absent in caudal linear nucleus and substantia nigra pars compacta (SNpc). Cocaine (7.5-30 mg/kg.i.p) resulted in prominent Fos-Li in paranigralis, caudal VTA, parabrachialis pigmentosus, and rostral linear nuclei. Only few cells of interfasicular and caudal linear nuclei contained Fos-Li. Many cells of rostromedial SNpc contained Fos-Li, but SNpr was free of labeled cells. Nicotine (0.3-1.4 mg/kg.,s.c.) resulted in prominent Fos-Li in interpeduncular nucleus, medial terminal nucleus of accessory optic tract and caudal linear nucleus of VTA. These results suggest that different drugs of abuse may mediate their acute (and possibly their reinforcing) properties via different subset of VTA nuclei. Supported by Smokeless Tobacco Research Council.

DRUGS OF ABUSE: COCAINE AND DEVELOPMENT

## 155.1

CHRONIC PRE AND POSTNATAL EXPOSURE TO COCAINE PRODUCES AN ALTERATION IN THE RELEASE OF DOPAMINE AND ACETYLCHOLINE IN THE DEVELOPING RAT PUP.

Sherrel Howard\*, David Blank, Rose Dao, C.LeRoy Blank Department of Pharmacology and the MRRC, UCLA, Los Angeles, CA and Department of Chemistry, University of Oklahoma, Norman, OK

Chronic exposure to cocaine produces a behavioral sensitization. The neurochemical basis for this behavioral sensitization has not been determined. In this study, pregnant rats were injected with cocaine (5 mg/kg s.c.) daily from day 10 (sperm + = day 0), through weaning (postnatal day 21). Dopamine and acetylcholine were measured simultaneously, using in vivo microdialysis coupled with HPLC-EC for DA and GC/MS for ACh. Experiments were performed in the rat pups at 10-12, 21-22 and 34-36 days postnatal.

A challenge dose of cocaine (5 mg/kg) was given after a stable baseline was achieved. In pups chronically exposed to cocaine, basal release of DA was reduced 50%. However, the release of DA increased by approxiamately 400% after cocaine challenge.

In the 10-12 day pups the development of basal release of ACh was delayed. At 20-22 days, basal release of ACh was reduced by approximately 50% of control. This reduction in basal release was not altered after a cocaine challenge

These finding provide a neurochemical basis for the behavioral sensitization seen after cocaine administration as well as the learning or motor

# 155.3

PERINATAL EXPOSURE TO COCAINE OR FLUOXETINE INTERACTS WITH GENDER IN PREDICTING THE ACOUSTIC STARTLE RESPONSE FOLLOWING 80HDPAT AND MCPP INJECTION IN ADULT RATS. H. E. Hughes\*, E. A. Grose and D. L. Dow-Edwards. Laboratory of Cerebral Metabolism, Department of Pharmacology, SUNY Health Science Center, Brooklyn, N.Y., 11203.

It is likely that perinatal cocaine exposure impacts upon the development of multiple neurotransmitter systems. The acoustic startle response (ASR) in rats has been shown to be under dopaminergic and serotonergic control. Cocaine has been shown to block the presynaptic uptake of both amines and to alter ASR. This study compared the first ASR in response to 5-HT receptor agonists in adult rats that received cocaine or fluoxetine during a postnatal period of serotonergic development. Sprague-Dawley rats were mated in our animal facility. At birth, litters were culled to four males and four females. During postnatal days 11-20, each litter received daily sc injections of 25 mg/kg cocaine, 25 mg/kg fluoxetine or water. At 21 days, pups were weaned and housed with same sex littermates. At 76-80 days, rats were ASR tested for 30 min (121 trials) on two consecutive days. The startle stimulus was a 40 msec burst of 116 dB white noise. On Day 1 of testing, no test drug was used. On Day 2, subjects received a single sc injection of 0.5 mg/kg 80HDPAT (5-HT1A agonist), 5.0 mg/kg MCPP (5-HT1B agonist) or saline ten min before testing. While postnatal treatment did not effect ASR on day 1 of testing, preliminary analysis of the data indicate that perinatal exposure to cocaine, but not fluoxetine, decreased first trial amplitude in response to MCPP in males. This finding suggests that the long-term effects of cocaine on ASR were not primarily due to cocaine's effects on 5-HT reuptake. Supported by ADAMHA grant #DA04118.

## 155.2

CHARACTERIZATION OF DOPAMINE AND SEROTONIN TRANSPORTERS IN AN ACUTE FETAL RAT STRIATAL PREPARATION. C.E. Hyde and B.A. Bennett, Dept. Physiology and Pharmacology, Bowman Gray Sch. Med., Wake Forest Univ., Winston-Salem, NC 27157.

Monoamine transporters have been implicated in the mechanisms underlying the behavioral effects of various abused drugs. Psychomotor stimulants decrease the uptake of amines by binding to and inhibiting transporter-mediated uptake. Studies have shown that the ability of cocaine to inhibit dopamine (DA) uptake correlates positively with its reinforcing effects. However, little is known about the role of serotonin (5-HT) transporters in the behavioral response to cocaine. In this study, we characterized the DA and 5-HT transporters in an acutely dispersed rat striatal preparation utilizing various neuronal uptake inhibitors. Brains from fetal rats (E19) were removed and the striatum was obtained and dispersed. This preparation is a crude homogenate, consisting primarily of cell bodies with both pre- and postsynaptic elements. DA and 5-HT uptake were performed using 15nM [3H]-DA and 15nM [<sup>3</sup>H]-5-HT respectively. Kinetic analysis of the data revealed high affinity uptake mechanisms. Relative inhibition potencies of the DA transporter was as follows: nomifensine>amfonelic acid> mazindol> CFT> dopamine> methamphetamine > cocaine >> bupropion > (-)norcocaine. Studies with the serotonin transporter revealed the following relative potencies: fluoxetine> CFT> mazindol> cocaine>> methamphetamine. Hill plot coefficients indicated one binding site for the dopamine transporter. The data indicate that the transporters in this preparation exhibit high affinity for inhibition, and their kinetics resemble those observed in synaptosomal or homogenate preparations. This novel preparation is currently being used to examine fetal and neonatal alterations in transporter function after in utero exposure to various abused drugs. Supported by DA-05073 (BAB).

# 155.4

RELEASE OF 3H-5HT FROM SYNAPTOSOMES BY COCAINE: A COMPARISON BETWEEN FETAL AND MATERNAL TISSUE. J. Bell III'2, P.M. Whitaker-Azmitia', C. Clarke', E.C. Azmitia', and H.K. Kramer'. 'Dept. of Psychiatry, SUNY at Stony Brook, Stony Brook, NY 11794 and 'Dept. of Biology, New York University, NY, NY 10003.

Our laboratories have previously reported that gestational cocaine (COC)

administration significantly disrupts the serotonergic (5-HT) system. In adults, it is believed that these drugs exert their effects by inhibiting 5-HT re-uptake and/or promoting its release. However, these effects have never been clearly demonstrated in fetal rats making it difficult to determine how these drugs may be damaging to the fetal brain. This study investigated the ability of COC to cause release of 5HT from fetal synaptosomes, and then compares these results to release measured in the maternal brain.

Sprague-Dawley fetuses were removed by cesarian section on embryonic day 16 (E-16) and their brains removed. Fetal and maternal whole brain synap ere prepared and tested simultaneously. Concentration curves were established for both ages to reveal the COC dosages that best induced release.

In vitro COC resulted in a bi-phasic release of <sup>3</sup>H-5HT in the fetal brain at

107M (100.1% of total release) and a second at 104M and 103M (95.15% and 100% of total release). Conversely, significant release only occurred in the maternal brain at COC concentrations above 10<sup>4</sup>M (100% of total release).

These results indicate that COC may activate a high-affinity release response in the fetal brain. This site may be the product of an immature 5-HT transporter and only present during the early stages of ontogeny. We are currently investigating the effects of other drugs such as fenfluramine and 3,4-methylenedioxymethamphetamine (MDMA) on this system due to their ability to produce significant synaptosomal release of serotonin. ACTIVITY AND RESPONSIVITY TO COCAINE FOLLOWING THIRD TRIMESTER COCAINE EXPOSURE IN RATS. S. Barron', D.H. Kaiser, K.A. Spalmacin, L.S. Hansen, Psychology Department, University of Kentucky, Lexington, KY

Department, University of Kentucky, Lexington, KY 40506.

This study was designed to look at the effects of third trimester cocaine exposure on activity and response to cocaine using a rodent model. Subjects were rat pups artificially-reared (AR) from postnatal (pn) days 4 - 10 with gastrostomy tubes. Treatment groups included two doses of cocaine (20 mg/kg/day and 40 mg/kg/day), an AR control and a suckled control. Subjects were tested at either PN 21 or PN 65. Subjects were placed in a running wheel for a 30 min baseline measure. This was followed by injections of saline on day 1 (ip) and 20 mg/kg cocaine hydrochloride on day 2. Activity was recorded for an additional 60 min. At PN 21, baseline hypoactivity was observed in both sexes at the higher cocaine dose and in females at the lower dose. There was no evidence of hypoactivity at PN 65. Neonatal treatment did not interact with cocaine-induced activation. However, there was a pronounced age effect since all PN 21 groups showed cocaine-induced increases in running wheel activity which contrasted with adults. These findings suggest a developmental difference in the responsivity to cocaine-induced activation, third trimester cocaine exposure resulted in changes in baseline activity which may be age-dependent and sex-dependent. However, there was no evidence of later sensitivity to the activating effects of cocaine. (Supported, in part, by NIDA DA06049).

## 155.7

POSTNATAL BIOCHEMICAL AND NEUROENDOCRINE DEFICITS IN SEROTONIN SYSTEMS FOLLOWING IN UTERO EXPOSURE TO COCAINE.

SEROTONIN SYSTEMS FOLLOWING IN UTERO EXPOSURE TO COCAINE. T.M. Cabrera. J. Yracheta, A.D. Levy, O. Li, K. Kunimoto, H. Kusters, G. Kindel, I. Hanin, L.D. Van de Kar and G. Battaglia. Department of Pharmacology, Loyola University Chicago, Stritch School of Medicine, Maywood, IL 60153. During fetal brain development, serotonin (5-HT) acts as a trophic factor regulating the development of 5-HT neurons and 5-HT target tissues. Since cocaine alters 5-HT neurotransmission, we hypothesized that exposure to cocaine during fetal development could result in long-term postnatal dysfunction of 5-HT systems. Pregnant rats, administered either saline or cocaine (15 mg/kg, ors-ni systems. Pregnant rats, administered eitner saline or cocaine (1s mg/kg, s.c., b.i.d.) from gestational day 13 through 20, comprised 3 treatment groups (sal-inj/ad-lib fed; sal-inj/pair-fed; & cocaine-injected). All progeny were fostered to non-treated lactating dams. On postnatal day (PD) 30 (males & females) and PD 70 (males), rats received a single injection of either saline or the 5-HT releaser p-chloroamphetamine(PCA) to determine the functional integrity of presynaptic 5-HT neurons. HPLC data indicated no significant differences in certical E-HT or 5-likh centert among the mela process groups of either PD0. presynaptic 5-HT neurons. HPLC data indicated no significant differences in cortical 5-HT or 5-HIAA content among the male progeny groups at either PD30 or PD70. Likewise, PD30 female cocaine progeny exhibited no differences in cortical 5-HT or 5-HIAA content from controls. However, deficits in the ability of PCA to deplete cortical 5-HT content were observed in male but not female cocaine progeny. Consistent with these biochemical data, radioimmunoassay of trunk blood revealed deficits in the ability of PCA to increase plasma adrenocorticotrophic hormone (-40%), plasma renin activity (-52%) & renin concentration (-60%) in male progeny. In contrast to these hormone data, but consistent with the HPLC data, no deficits in PCA-mediated increases in plasma renin were observed in female coraine progeny. Both the biochemical and consistent with the HPLC oata, no deficits in PCA-mediated increases in plasma renin were observed in female cocaine progeny. Both the biochemical and neuroendocrine data indicate in utero cocaine-induced long-term functional deficits in brain 5-HT systems in male progeny. These deficits appear to be, in part, due to dysfunction of the presynaptic 5-HT terminal, although the present data do not preclude the possibility of postsynaptic modifications as well. (Supported in part by Loyola University and by DA04865)

# 155.9

INCREASED SEROTONIN IMMUNOREACTIVITY IN STRIATUM AND CORTEX OF ADULT RATS TREATED PRENATALLY WITH COCAINE M.S. Manley'. D.Jackson, L.D.Manley. S.J.Young. and P.M.Groves. Dept. of Psychiatry, School of Medicine, University of California, San Diego, La Jolla, CA 92093-0603

Previous studies involving administration of stimulant drugs to pregnant female rate.

have shown effects on monoaminergic systems in their offspring. In particular, administration of cocaine during the last week of gestation has been shown to cause a serobonin (5-HT) hyperinnervation in the striatum of immature offspring. We examined 5-HT innervation in the cortex and striatum of adult rats (>250g) prenatally treated with HT innervation in the cortex and striatum of adult rats (>250g) prenatally treated with cocaine. Groups of pregnant Long-Evans females received either saline or cocaine hydrochioride (15 mg/kg qd, 15 mg/kg b.i.d. or 40 mg/kg qd s.c.) during the last week of gestation. Pups were weaned at 27 days, then were sacrificed as adults by transcardial perfusion with 4% paraformaldehyde (PF) under Nembutal anesthesia (100mg/kg). Brains were removed, postfixed 4 hrs in PF, cryoprotected, then sectioned. 5-HT was detected using a rabbit polyclonal antibody against 5-HT (incstar) followed either by a standard avidin-biotin method, or fluorescein-conjugated secondary antibody. Measurements of 5-HT labelling in neostriatum and cortex were obtained using an image analysis system. Material was also examined with a confocal laser scanning microscope (Bio-Rad). Adult male rats treated prenatally with cocaine showed significantly increased 5-HT staining in neostriatum and cortex compared to saline controls. Preliminary results 3-H1 stanting in resolvaturin and cortex compared to sating controls.

an adult females similarly treated with cocaine showed a trend toward increased 5-HT in the cortex, but not in the striatum. These results suggest that alterations in 5-HT innervation as a consequence of prenatal exposure to cocaine persist into adulthood. Data will also be presented on 5-HT fiber morphology and distribution. Supported by DA 02854 and PHS 5T32 MH18398.

Gonadal Hormones Modify the Effects of Acute and Chronic Cocaine Administration on Paced Responding F. van Haaren \*, Univ. of Florida, Gainesville, FL 32611.

Intact and gonadectomized male and female Wistar rats were exposed to a two component multiple schedule to investigate whether or not the presence and absence of gonadal hormones would differentially affect the behavioral effects of acute and chronic cocaine administration. High response rates were maintained by a tandem (RI 30-s, DRH 0.5-s) schedule in one component, low rates by a tandem (RI 30-s, DRL 5-s) schedule in the other component. Acute cocaine administration (1-30 mg/kg, IP) decreased high and low rates at intermediate doses (5.6, 10.0 mg/kg). At 17.0 mg/kg responding was eliminated in intact and ovariectomized female rats and castrated male rats, but not in intact male rats. Chronic administration of a behaviorally active dose of cocaine produced sensitization to the rate-decreasing effects at doses exceeding the chronic dose of cocaine. High and low response rates were controlled by stringent schedule contingencies which may have prevented the observation of other differences.

## 155.8

EFFECTS OF PRENATAL COCAINE EXPOSURE ON STRIATAL TYROSINE HYDROXYLASE IMMUNOREACTIVITY. D. Jackson\*. M.S. Manley. L.D. Manley. S.J. Young. and P.M. Groves. Dept. of Psychiatry, Univ. of California at San Diego, La Jolla, CA, 92093-

0603.

The effects of prenatal exposure to cocaine on CNS dopaminergic systems remains controversial in that evidence supports models for both dopamine (DA) repletion and depletion effects of cocaine. A variety of factors may contribute to altered DA transmission, including toxicity to monoaminergic systems or changes in DA synthesis, release, and receptors. We examined changes in TH labeling in the striatum of 20 day old Long-Evans rats following prenatal exposure to cocaine. Pregnant females were injected with cocaine hydrochloride (15 mg/kg b.i.d., s.c.) or saline during embryonic days 15-21. Animals were perfused and post-fixed with 4% paraformaldehyde. Brains were removed, cryoprotected, then cut with a freezing microtome. Tissue was processed for tyrosine hydroxylase (TH) immunoreactivity with a sheep anti-Th polycloral followed by standard a vidin-hobin staining methods. Brightfield images and density measurements were obtained from dorsal, mid-, and ventral striatum using an image analysis system. TH-positive patches in the most dorsal aspect of the striatum of offsoring of saline control mothers were soarse (mean-SEM = 2.35-53). Prenatal exposure using all initiage analysis system. In-possive parties in the most toolsal asystem of inspiring of official scaline control mothers were sparse (meant\_SEM = 2.35±,53). Prenatal exposure to cocaine elevated the number of patches in both female (6.1±61, n=4, p=.002) and male (5.6±61 n= 4, p=.009) rats relative to saline controls. This finding may be related to observations that another monoaminergic drug, amphetamine, unmasks striatal patches in adult rats (Ryan et al., 1988). In contrast, density measurements of the TH labelling in striatal matrix were reduced by 33% in cocaine-exposed female rats relative to controls while males were unaffected. These results suggest that prenatal cocaine exposure produces different effects on patch and matrix regions. Prenatal treatment with cocaine produces a persistent enhancement of TH-positive patches. Loss of TH staining in cocaine-treated female rats may reflect sex-dependent terminal degeneration or decreased expression of TH in the matrix. Supported by grants NIDA DA 02854 and NSF BNS 9006155

# 155.10

PRENATAL COCAINE EXPOSURE HAS MINIMAL EFFECTS ON DEVELOPMENT AND ADULT BEHAVIOR IN RATS. L.W. Means\*, E.W. Bass Jr., T.J. Fernandez and B.A. McMillen. Psych. & Pharm. Depts., East Carolina Univ., Greenville, NC 27858.

To examine the developmental and behavioral effects of

prenatal exposure to cocaine, female Sprague-Dawley rats were given cocaine (15mg/kg s.c. b.i.d.) (group C) or an equivalent volume of saline (group S) throughout gestation. Half of the dams receiving saline were pairfed with dams receiving cocaine (group SPF). At birth litters were culled to 5 male and 5 female pups, and half of the litters from each group were placed with untreated surrogate mothers. One male and one female from each litter was tested on cork gnawing (age 30 days), runway acquisition and response to a novel alley (60 days), CRF FR, and DRL performance (90 days), and response to a plus maze (120 days). The C dams gained less weight during gestation than did the other dams (p<.05), and the C and SPF offspring had delayed eye opening compared to the S pups. In the plus maze, C offspring made more arm entries and spent more time in the open arms than did S offspring (p<.05). Also, due to two outliers, group C male pups had longer latencies during runway acquisition and exposure to the novel alley than pups in the other groups (p<.05). The groups did not differ on any other developmental or behavioral measure. Prenatal cocaine exposure produces minimal developmental and behavioral effects in rats. (DA 04895)

THE EFFECTS OF PRENATAL EXPOSURE TO COCAINE ON THE DISCRIMINATIVE PROPERTIES OF COCAINE IN ADULT RATS. <u>C.J.</u> <u>Heyser', L. Rajachandran, N.E. Spear, and L.P. Spear</u>. Center for Developmental Psychobiology and Dept. of Psychology, SUNY, Binghamton, NY, 13902-6000

Adult male rats prenatally exposed to cocaine and control offspring were trained to discriminate 10 mg/kg cocaine hydrochloride (HCI) from saline in a two-lever discrimination procedure to examine sensitivity to the discriminative (interoceptive) properties of cocaine. Offspring were derived from Sprague Dawley dams that received daily subcutaneous injections of 40 mg/kg/3cc cocaine HCI (C40) from Gestational Day 8-20, pair-fed control dams receiving saline injections (PF), and nontreated control dams (LC). Following training, dose response curves were generated to a variety of substitute doses of cocaine HCI and the time course (to peak discriminability) of cocaine was assessed. No differences were observed among the prenatal treatment groups in bar press acquisition or the number of sessions to reach criterion. Cocaine was generalized to the cocaine training stimulus in a dose-dependent manner in all prenatal treatment groups. However, linear regression analysis of the dose response curves (Probit) indicated a significant shift to the right in the dose response curve for animals gestationally exposed to cocaine (ED50 = 2.70 mg/kg) when compared with LC (1.67 mg/kg) and PF (1.77 mg/kg) offspring. No differences were observed among the prenatal treatment groups in the temporal parameters of cocaine, with peak discrimination occurring 15 min following injection. Taken together these data suggest that offspring gestationally exposed to cocaine are less sensitive to the discriminative

stimulus properties of cocaine.

Binghamton, NY 13901.

CONCENTRATIONS OF DOPAMINE D-1 AND D-2 RECEPTOR AND ENKEPHALIN mRNAs IN RAT CAUDATE AND NUCLEUS ACCUMBENS AFTER PRENATAL COCAINE TREATMENT. A. de Bartolomeis\*, M.C. Austin, L.P. Spear\*, D. Pickar, J.N. Crawley. Experimental Therapeutics Branch, NIMH, Bethesda, MD 20892 and \$Department of Psychology, State University of New York

The effects of prenatal cocaine treatment on D-1, D-2 and enkephalin messenger RNA were investigated in rat forebrain. Pregnant Sprague-Dawley rats were administered one of the following treatments from gestational day 8 to gestational day 20: A) subcutaneous (sc) injection of cocaine hydrochloride 40 mg/kg/3cc; B) 0.9 % saline injection sc and pair fed to the cocaine group; C) no injection and ad libitum access to lab chow; D) saline injection and diet of 60% lab chow and 40% cellulose. Offspring were sacrificed at postnatal day 21 and the brains processed for in situ hybridization histochemistry. Coronal tissue sections were hybridized with oligonucleotides probes for D-1, D-2 and enkephalin genes, of the anterior to the posterior caudate nucleus and the nucleus accumbens. Quantitative analysis of the autoradiographic images demonstrated no significant differences in mRNA concentrations between experimental groups in any of the areas quantitated. These findings suggest that prenatal cocaine exposure does not change the transcription of D-1, D-2 or enkephalin genes in juvenile rats.

# 155.15

EFFECTS OF CHRONIC PRENATAL COCAINE ON THE ONTOGENY OF THE DOPAMINE UPTAKE COMPLEX (DAUC). L.M. Collins\* and J.S. Meyer. Dept. of Psychology, Neuroscience and Behavior Program, Univ. of Massachusetts, Amherst, MA 01003.

Cocaine has been hypothesized to block catecholamine uptake by binding to the transporter complex. Withdrawal from repeated cocaine exposure has been found to decrease [3H]mazindol labeling of the dopamine transporter in adult rat nucleus accumbens (Sharpe et al., Eur. J. Pharmacol. 203:141, 1991), whereas chronic administration of Ldeprenyl resulted in an upregulation of the dopamine transporter (Wiener et al., Eur. J. Pharmacol. 163:191, 1989). To assess the effects of in-utero cocaine exposure on the DAUC, pregnant Sprague-Dawley rats were subjected to either daily s.c. injections of cocaine HCl (40 mg/kg/day from gestational day 11 through 21) or to s.c. implantation of two capsules each containing 80 mg of cocaine base from gestational day 19 through 21. Quantitative autoradiography with [3H]GBR 12935 was used to quantify DAUC density in the corpus striatum, nucleus accumbens, and other forebrain structures, as well as in the substantia nigra and ventral tegmental area. Data will be presented comparing cocaine-exposed and control offspring at postnatal days 1, 5, 10, 30 and 60. Supported by DA-06495.

ONTOGENY OF NEURONS CONTAINING TYROSINE HYDROXYLASE (TH) IN FETAL MACAQUE BRAIN. O.K. Ronnekleiv\*. Oregon Regional Primate Research Center, Beaverton, OR 97006, and Dept. of Physiology, OHSU, Portland, OR. 97201.

The development and distribution of neurons containing immunoreactive (IR)-TH (the rate-limiting enzyme involved in the synthesis of donamine) have been examined in brain sections from days 38 to 60 fetal rhesus macaques. By day 38 of gestation, cells and fibers positive to TH were found in the mesencephalic flexure and the zona incerta. The IR-TH staining was greatly increased by days 40 and 41 of gestation. At this time increased number of IR-TH neurons were found in the mesencephalic flexure and the zona incerta; in addition, neurons were present in the preoptic area (POA) and the hypothalamus. A ventral and a dorsal fiber path could also be distinguished that projected towards the developing POA and nucleus accumbens (NAc), and the striatum, respectively. Large bundles of IR-TH extended in a dorso-ventral direction at the level of the optic chiasm in the day 41 fetal macaque. These bundles resembled those of the migrating GnRH neurons within the nasal septum. The number of IR-TH cells and fibers were further increased in the days 50 - 60 fetuses. We have initiated studies to explore the effects of maternal cocaine use (3mg/kg, four times a day) on the early development of dopamine neurons in fetal macaques, (Supported by PHS grant DA07165).

# 155.14

EFFECTS OF PRENATAL COCAINE TREATMENT ON POSTNATAL DEVELOPMENT OF NEOCORTEXIN WHITE MICE: IMMUNOCYTOCHEMISTRYOF CALBINDIN-AND PARVALBUMIN-POSITIVE POPULATIONS OF GABAERGIC NEURONS. <u>E. Yablonsky-Alter\*, I. I. Glezer C. Carter and M. Juvan</u>. Dept. Pharmcol., Dept. Cell Biol. Anat. Sci., CUNY Med. Sch., Dept. Biology, CCNY of New York, New York, NY 10031.

GABAergic neurons-positive to calcium-binding proteins, calbindin D28-k (CB) and parvalbumin (PV) were studied immunocytochemically in the neocortex of developing white mice (line DC-1) prenatally treated with cocaine. Experimental group of ten pregnant white mice were daily injected intra-peritoneally with cocaine solution in dosage 10 mg per I kg. Control group of eight pregnanat mice was injected daily with saline. The injections in both groups were applied through the whole gestation period (21-22 days) and were stopped at birth of pups. The pups were sacrificed after intracardial perfusion with 0.5% of glutaraldehyde/ 2.5% formaldehyde in the following days after birth: 3, 7, 10-11, 15 and 20. In the first ten postnatal days the difference between control and experimental groups of animals was statistically insignificant. However, at day 15 numerical density of CB- and PV-positive neurons sharply deacreased in experimantal group and remained significantly (p < 0.001) lower than in control group of animals in later ontogenetic stages. Thus, treatment of pregnant mice with cocaine causes changes in quantitative and qualitative distribution of GABAergic cortical neurons in their offsprings. These effects became visible in critical period of postnatal development, when all important sensory systems (especially, visual and sensory-motor) became fully functional. # 155.16

NORMAL STRESS RESPONSE BUT DECREASED CELLULAR IMMUNE RESPONSE IN MALE RATS PRENATALLY EXPOSED TO COCAINE. K. Bulloch., D. Torres and R.F. McGivern. Univ. Cal. San Diego and San Diego State Univ., San Diego, CA 92120.

Previous work from our laboratory has shown that exposure of fetal rats

to cocaine during the last week of gestation significantly decreases thymus weight during development. In an initial evaluation of T cell function in these animals, we have examined the ability of thymocytes and splenocytes to respond to the T cell mitogen, concanavalin A (range 0.1 to 1.0 ug/well). Cells were removed from 30-32 day old male representatives born to 6 Sprague-Dawley dams administered cocaine (10 mg/kg, sc) twice daily from days 15 through 21 of gestation. Six control dams were injected with saline. Pups were weaned on day 24 and group housed by sex and treatment under a 12/12 hr light cycle. Thymus, but not spleen weights weighed significantly less in cocaine exposed males when indexed to body weight (p < 0.01). Con-A induced proliferation of thymocytes derived from cocaine exposed rats was 4-6 fold less than controls (P<0.01). Proliferation in splenocytes was approximately half of that observed in controls (p < 0.05). Subsequent restraint stress studies in 35 days old littermates revealed normal basal and stress-induced levels of corticosterone. Overall, these results reveal marked reductions in Con-A stimulated cellular proliferation in animals prenatally exposed to cocaine which cannot be attributed to circulating glucocorticoids. Current studies are underway to examine potential cocaine induced alterations in the development of autonomic innervation of immune organs. (NIDA, DA04490 to RFM).

EVIDENCE FOR AN ENHANCED PSYCHOPHARMACOLOGICAL RESPONSE TO MU RECEPTOR STIMULATION IN ANIMALS PRENATALLY EXPOSED TO COCAINE. G. A. Goodwin\*, F. Athalie, and L. P. Spear. Department of Psychology, Center for Developmental Psychobiology, State Univ. of NY at Binghamton, Binghamton, NY

Prior work has revealed that weanling offspring of Sprague-Dawley dams given 40mg/kg cocaine during gestation exhibit an increase in [3H]naloxone binding in autoradiograms of numerous brain regions (Hammer, et al., 1991). This increase in opiate binding was associated with an increase in responsiveness to the opiate agonist morphine when assessed in 10 day old (P10) offspring using morphine related suppression of isolation-induced ultrasounds as the response measure (Goodwin, Moody, & Spear, 1991). In the study reported here, P10 offspring gestationally exposed to cocaine and control offspring were injected i.c.v. with opiate agonists specific to the mu (0, .0005, .01 µg/5µl DAMGO) and delta (0, 0.3, 3.0 µg/5µl DPDPE) opiate receptors and tested for ultrasound production. Offspring exposed to cocaine were observed to be more sensitive to DAMGO than control animals. No differences were seen between prenatal treatment groups when animals were given DPDPE, although this may be due to a floor effect as the doses of DPDPE used strongly suppressed ultrasound production in all animals. These results suggest that the enhanced response to morphine seen in animals given prenatal exposure to cocaine is in part the consequence of increased activity at the mu receptor, whereas conclusions about responsiveness at the delta receptor are difficult to draw at this point. [Supported by NIDA Grants R01 DA04478 and K02 DA00140].

INTRAVENOUS COCAINE (C) ADMINISTRATION IN PREGNANT RATS: PROGENY DEVELOPMENT AND BEHAVIOR. P.M.

Kunko\*, D. Moyer and S.E. Robinson Dept. of Pharmacology and Toxicology, Med. Coll. of Virginia., Richmond, VA 23298-0613.

Use of cocaine (C) among pregnant women appears widespread. Developmental consequences for the offspring of these substance abusers are as yet unknown. The current study examined developmental and behavioral endpoints in the offspring of pregnant rats administrated Cinary and College of the control of ministered C intravenously (IV), which may more closely mimic the route of drug use in humans. Rats in the treatment group were injected IV with C (6 mg/kg) or saline on days 8 - 20 of gestation. An untreated control group was also included. This procedure produced no differences in weight gain or litter characteristics (litter size, resorptions) in the C group. Pups were sexed and weighed at birth, litter size reduced to 10, and fostered to untreated mothers. Pups were weighed daily and several developmental endpoints were assessed. On postnatal day 21 (P21) one male and one female from each litter were tested in an open field following an injection of C (10 mg/kg, IP), saline, or no treatment. Ferale pups from C treated dams weighed significantly less than controls, but this difference was resolved by P2. Both C and saline exposed pups gained weight less rapidly than pups from untreated dams. C exposed pups exhibited a trend for developmental delay in most assessments though significant differences were only found for negative geotaxic response and day of eye opening. On day P21, C exposed pups exhibited significantly more vertical movement following C challenge than did either control group. C exposed pups differed in the quality of their behavior, exhibiting more stereotypic or repetitive activity than the control groups. (NIDA Grant DA04746) several developmental endpoints were assessed. On postnatal day 21

COCAINE TREATMENT ALTERS MATERNAL AND AGGRESSIVE J.M. Johns\*, L.I. Zimmerman, L.R. Li and C.A. Pedersen. Dept. of Univ. of North Carolina, Chapel Noonan, L. Li Psychiatry, Univ. Hill, N.C. 27599.

Cocaine abuse by pregnant women is well documented. We studied the effect of chronic and acute cocaine treatment on maternal behavior and acute cocaine treatment on maternal behavior and aggression in rats. Gravid rats received one of three treatments; s.c. injections b.i.d. of saline or 15 mg/kg cocaine throughout gestation or one 15 mg/kg cocaine injection 30 min prior to testing sessions. Frequency, duration and latency of 11 maternal behaviors were recorded for a 30 min period beginning 30 mins following delivery of a dam's last pup. The same measures for 11 maternal aggressive behaviors were recorded on lactation day 6 for a ten min period during which a smaller male intruder was present in the cage. Fewer cocaine treated than saline dams had a crouch latency of (95.005, Fisher's Exact test). More chronic cocaine than saline dams displayed 8 or more bouts of aggressive posture and fight attack on the maternal aggression test (p<.025 Fisher's Exact test). Maternal behavior and aggression were altered by cocaine treatment. (HD 25255) Exact test). Maternal behavior and aggresswere altered by cocaine treatment. (HD 25255)

## 155.20

CHANGES IN BETA ADRENERGIC RECEPTORS FOLLOWING POSTNATAL COCAINE (COC) EXPOSURE. M.A. Kosek\*, G.A. Ordwav, R.M. Kliegman, Department of Pediatrics, Pharmacology and sychiatry, Case Western Reserve University, Cleveland, Ohio 44106.

Because COC blocks neuronal catecholamine reuptake, we hypothesized that it may interfere with development of the brain monoamine system resulting in persistent changes in beta adrenergic receptor density. We measured central beta adrenoceptors in Sprague Dawley rat pups after chronic exposure to COC HCl (20mg/kg s.q. TID) or 0.9% saline in equivalent volume from birth to 15 days. Pups were sacrificed and the binding of <sup>125</sup>I-iodopindolol to brain beta-1 and beta-2 receptors were analyzed using quantitative autoradiography. At 15 days (after a oneday washout period) binding was significantly reduced in beta-1 receptors in the COC exposed group ranging from 18-40%. However, at 27 days (after a 12-day washout period) total beta receptor binding was moderately increased and statistically significantly in the COC group of 19%. In summary, there was a decrease in beta adrenoceptor density following chronic neonatal exposure that appears to show a compensatory rebound and elevation after withdrawal of COC. Whether these changes are sustained and effect behavior are subjects of future studies.

# DRUGS OF ABUSE: OPIOIDS

CLONIDINE ATTENUATES CONDITIONED PLACE AVERSION TO NALOXONE-PRECIPITATED OPIATE WITHDRAWAL. T. A. Kosten\*, PhD. Dept Psychiatry, Yale Univ School Medicine, New Haven, CT 06519.

Previous research shows that clonidine (CLON), an alpha-2 antagonist, attenuates the severity of opiate withdrawal signs in humans and in animals. Although CLON reduces some overt signs of withdrawal, its relief of subjective aspects of withdrawal has been questioned. We tested whether CLON affected conditioned aversion to opiate withdrawal in rats with conditioned place aversion (CPA) and conditioned taste aversion (CTA) paradigms. Rats were made morphine dependent by a subcutaneous morphine pellet implant Withdrawal was precipitated 72 hr later by naloxone (NLX) injection (0.05 mg/kg, s.c.) which was paired with a saccharin solution (0.001 M) and with one side of the place apparatus. Vehicle injections were paired with an HCl solution (0.001 M) and the other side of the place apparatus. CTA was assessed with a 2 bottle preference test and CPA was assessed by measuring the time shift away from the NLX paired side compared to baseline preference. Six rats received CLON (0.4 mg/kg, i.p.) injections 5 min prior to NLX and 6 received vehicle CLON. The vehicle CLON group showed a significant shift away from the NLX paired side (-8.0  $\pm$  0.8 min) compared to the CLON group (1.4  $\pm$  1.9 min). Both groups showed a significant CTA to the NLX paired saccharin (57% and 34% intake) compared to controls (85% intake) and some mild opiate withdrawl signs. No CPA or CTA to NLX was shown in nonmorphine dependent rats. Thus, conditioned aversion paradigms are sensitive measures of opiate withdrawal seventy which is mediated, in part, by the alpha-2 noradrenergic system. Additional groups will be run to test the magnitude and specificity of the CLON effect on NLX CPA.

Supported by NIDA grant #P50-DA04060.

INCREASED EEG SPECTRAL POWER DURING ACTIVE PERIODS ACCOMPANIES MORPHINE WITHDRAWAL K. Grasing\* and 0.T. Lin, Departments of Medicine and Clinical Pharmacology, Robert Wood Johnson School of Medicine, New Brunswick, NJ 08903.

After nicotine withdrawal, EEG alpha frequency is diminished in human subjects with a heavy smoking history. We hypothesized that diminished arousal may also occur during opioid withdrawal. Three, adult male Sprague-Dawley rats were implanted with cortical EEG electrodes and intravenous catheters. Morphine and saline were administered as 12 hour infusions on alternate days. Each subject received two morphine infusions of 1.0, 3.0, and 10 mg/kg-Cortical EEG was continuously nour. Cortical EEG was continuously digitized and analyzed by FFT. On days during which saline was infused, EEG spectral power was diminished during daytime inactive periods but increased during active nighttime hours. Theta activity did not differ significantly during withdrawal periods. Although opioid withdrawal has been associated with increased waking time and reduced EEG amplitude, opposing effects can be observed during active behavior.

EFFECT OF 11-50 488H INDUCED TOLER ANCE AND ARSTINENCE ON MET-ENKEPHALIN LEVELS IN BRAIN, SPINAL CORD PITUITARY AND PERIPHERAL TISSUES OF THE RAT. G.A. Tejwani, A.K. Rattan, K.L. Koo, S.A. Tjioe\* and H.N. Bhargava, Dept. Pharmacology, Ohio State Univ., Columbus, OH 43210 and Dept. Pharmacodynamics, Univ. Ill. at Chicago, Chicago, IL 60612

Male Sprague-Dawley rats were injected with U-50,488H (25 mg/kg, ip) or its vehicle twice a day for 4 days. Tolerance to the analgesic and hypothermic effect of U-50,488H developed as a result of this procedure. On day 5, rats from vehicle and U-50,488H treated groups were divided into 2 groups each. Rats from one group were sacrificed (abstinent rats) while n the other were injected with either vehicle or U-50,488H and sacrificed 1 hr later (tolerant rats). Brain, spinal cord, pituitary gland, plasma, adrenals, kidneys and heart were collected. Brain was dissected into 7 regions namely hypothalamus, cortex, hippocampus, pons and medulla, midbrain, amygdala and corpus striatum. Levels of met-enkephalin were determined by the RIA. Tolerance to U-50,488H was associated with increases in levels of metenkephalin in the hippocampus but decreases in the adrenals. Changes were not seen in other brain regions, spinal cord and other peripheral tissues. On the other hand, abstinence from U-50,488H was associated with increases in the levels of met-enkephalin in the hypothalamus and heart. Thus tolerancedependence and abstinence from U-50,488H alters met-enkephalin levels in the selected part of the CNS and periphery (Supported by a grant DA-02598 from the National Institute on Drug Abuse)

#### 156.5

EFFECT OF STRESS ON MORPHINE AND FENTANYL SELF-ADMINISTRATION IN TWO BEHAVIORAL PARADIGMS IN RATS. Y. Shaham, and N.E. Grunberg\*. Medical Psychology Dept. USUHS, Bethesda,

Clinical and epidemiological studies suggest that stress increases opioid use and relapse. Unfortunately, these human studies are correlational and do not establish a causal link. Recently (Shaham et al. 1992), we reported that immobilization (IM) stress increases oral opioid self-administration (SA) in a home cage setting by male rats during initiation and maintenance phases. The present experiments were designed to extend these findings: 1) to the relapse phase of the addiction process, and 2) to electric shock stressor and operant lever pressing for the drug. Experiment 1 examined the effect of IM stress (15 min/day) on oral opioid (morphine [0.5 mg/ml] or fentanyl [25 ug/ml]) SA after 2 months of opioid SA followed by 3 weeks of a drug-free period. Stressed rats increased their opioid preference and manifested a more severe withdrawal syndrome as compared to control rats not exposed to stress. Experiment 2 examined the effect of electric footshock (10 min/day) on fentanyl (75 ug/ml) SA in operant conditioning chambers. After one month of initiation of fentanyl SA, the animals were tested for lever pressing for fentanyl under fixed-ratio-4 and progressive ratio schedules of reinforcement for 30 min/day. Shock stress caused an increase in drug SA as compared to a non-stress condition. These results indicate that the effect of stress to increase opioid SA can be generalized to the relapse phase of the addiction process and can be detected by an operant conditioning paradigm. Therefore, rat SA paradigms can be used to examine mechanisms underlying the effect of stress on opioid use.

MK-801 INHIBITS THE DEVELOPMENT OF MORPHINE TOLERANCE IN THE RAT AT SPINAL SITES. HB Guistein,\* KA Trujillo, and H Akil. Dept. of Anes. and MHRI, Univ. of Michigan, Ann Arbor, MI

The development of morphine tolerance is a significant clinical problem in anesthesiology and other fields. Recent studies have shown that the non-competitive NMDA receptor antagonist MK-801 inhibits the development of morphine tolerance in rats (Science, 251:85-87, 1991, Brain Research, 547:77-81, 1991). Understanding the basic mechanisms underlying this inhibition could have important theoretical and clinical implications. The present study was undertaken to determine whether this

effect could be mediated at spinal sites.

Sixteen male Sprague-Dawley rats underwent a T-8 level spinal transection under chloral hydrate anesthesia. Animals were allowed to recover for one week following surgery, and baseline tail flick measurements were obtained. Animals were then implanted with one 75 mg morphine pellet and an osmotic minipump infusing either MK-801 (0.1 mg/kg/day) or saline. On day 3, 3 additional morphine pellets were implanted in each animal. Tail flick latencies were measured 4 hours after pellet

implantations and daily thereafter.

The data showed that MK-801 significantly inhibited the development of morphine tolerance in spinal transected rats. Also, one half of the rats in the MK-801 group died after receiving 3 morphine pellets, and the surviving rats appeared sedate. These changes were not observed in the saline-treated rats.

sedate. These changes were not observed in the saline-treated rats.

These data suggest that MK-801 inhibits the development of morphine tolerance at spinal sites. However, the data do not exclude the possibility that supraspinal sites may contribute to this inhibition in the intact animal. The data also suggest that the enhancement of morphine-induced lethality by MK-801 observed in previous studies (Pharmacology, Biochemistry and Behavior, 38:673-675, 1991) also occurs in spinalized animals. The mechanism of this synergism is unclear, and is currently under investigation. These results may have important implications both for understanding mechanisms of tolerance development and for the clinical management of natients requiring long term parcotic therapy. of patients requiring long term narcotic therapy.

MODIFICATION OF DYNORPHIN (1-13) LEVELS IN CENTRAL AND PERIPHERAL TISSUES OF K-OPIATE TOLERANT AND ABSTINENT RATS. H.N. Bhargava, A.K. Rattan, K.L. Koo and G.A. Tejwani\*, Dept. Pharmacol., Ohio State Univ., Columbus, OH 43210 and Dept. Pharmacodynamics, Univ. Ill. at Chicago, Chicago, IL 60612.

Male Sprague-Dawley rats were rendered tolerant to and physically dependent on U-50,488H, a k-opiate agonist, by injecting 25 mg/kg of the drug intraperitoneally twice a day for 4 days. Two sets of rats were used rats labeled as tolerant-dependent were injected with U-50,488H (25 mg/kg) on hour before sacrificing on day 5 whereas the abstinent rats were sacrificed on day 5 without the injection of U-50,488H. Of all the tissues examined, pituitary gland had the highest level of dynorphin (1-13), whereas heart had the lowest level. The levels of dynorphin (1-13) increased in hypothalamus hippocampus and pons and medulla of U-50,488H tolerant-dependent rats whereas in abstinent rats, the levels of dynorphin (1-13) were elevated only in the midbrain. The levels of dynorphin (1-13) in the pituitary gland of U-50,488H tolerant-dependent or abstinent rats were unchanged. In peripheral tissues, the levels of dynorphin (1-13) in the heart of U-50,488H tolerantdependent rats were increased. In the abstinent rats they were elevated in the adrenals, spleen, and the heart but were decreased in the kidneys. Compared to morphine tolerant-dependent and abstinent rats were observed and may explain many pharmacological differences in the µ- and k- opiate induced tolerance-dependence and abstinence processes (Supported by a grant DA-02598 from the National Institute on Drug Abuse).

#### 156.6

THE EVOLUTION OVER TIME OF OPIATE DEPENDENCE AND ABSTINENCE IN RATS. L.H. Gold\*, L. Stinus and G.F. Koob. Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA and Psychobiologie des Comportements Adaptatifs, INSERM Unité 259, Bordeaux, France.

Opiate withdrawal is a common occurrence in human opiate addicts that is not life threatening but is considered to be a significant factor which may prompt drug taking behavior in these opiate dependent individuals. Animal models can be used to study the time courses for the evolution of dependence and the development of the abstinence profile. In the following studies rats were made dependent by either implantation of 2 morphine pellets sc (75 mg morphine base) or 2 daily injections of morphine sulfate (5-10 mg/kg escalating dose/injection, ip) for 10 days. Withdrawal was evaluated by either cessation of morphine injection or an injection of the opiate antagonist, naloxone (1 mg/kg, sc). Morphine implanted rats exhibited analgesia as measured in a taildip assay, from 2-36 hrs post-implant, while hyperalgesia was measured in rats undergoing spontaneous withdrawal from 12-78 hrs following the last morphine injection. Rating of the abstinence syndrome following naloxone injection revealed significant withdrawal signs by 3 hrs post-implant which became increasingly intense up to 24 hrs post-implant. Withdrawal could be precipitated for at least 12 days post-implant, while by 18 days post-implant only minimal signs were observed. These results suggest that opiate abstinence develops gradually and follows the time course of the development of tolerance.

## 156.8

INHIBITION OF MORPHINE TOLERANCE BY PHENCYCLIDINE. K.A. Truillo\* and H. Akil. Mental Health Research Institute. University of Michigan. Ann Arbor, Michigan, 48109-0720.

We have previously reported that the non-competitive N-methyl-D-aspartate (NMDA) receptor antagonist MK-801 inhibits the development of tolerance to the analgesic actions of morphine without affecting pain responsiveness on its own, and without altering acute morphine analgesia (these findings have now been replicated by at least two other groups). In addition to tolerance, we observed that this drug interferes with the development of physical dependence on morphine. These findings led us to suggest that NMDA receptors are involved in the behavioral and neural plasticity associated with long term opiate administration. However, although MK-801 is a potent and selective NMDA receptor antagonist, in order to definitively conclude that NMDA receptors are involved in opiate tolerance and dependence it must be demonstrated that other NMDA receptor antagonists produce similar effects. In the present experiments we examined the ability of phencyclidine (PCP), another potent non-competitive NMDA receptor antagonist, to inhibit tolerance to the analgesic actions of morphine in rats. PCP (1.0 mg/kg i.p.) or saline was administered 30 minutes prior to morphine (10 mg/kg s.c.) or saline, once each day for 9 consecutive days. The tail-flick test was used to assess analgesia, 60 minutes following the second injection, on odd-numbered days. PCP, in the absence of morphine, was found to have no effects on pain responsiveness. However, this drug significantly attenuated the development of tolerance to the analgesic actions of morphine. The effects of 1.0 mg/kg of PCP were very similar to those of 0.1 mg/kg of MK-801, matching very closely the relative affinity of these drugs for the NMDA receptor. These results support our suggestion that NMDA receptors are important in the development of opiate tolerance. Further studies are underway examining the effects of other NMDA receptor antagonists in opiate tolerance and dependence.

NALOXONE INDUCED A RELEASE OF NPFF FROM SPINAL CORD OF

NALOXONE INDUCED A RELEASE OF NPFF FROM SPINAL CORD OF MORPHINE TREATED RATS. J.-M. Zhu, and H.-Y.T. Yang. Lab. of Biochem. Genetics, NIMH, Neuroscience Center at St. Elizabeths, Washington, D.C. 20032.

Neuropeptide FF (FLFGPQRF-Nh2, NPFF), an endogenous peptide with morphine modulating activity, is highly localized in superficial laminae of dorsal spinal cord. Previously, using an in vitro superfusion of isolated rat spinal cords, we have demonstrated that NPFF can be released from the spinal cord in response to stimulation with 56 mM KCl or spinal cord in response to stimulation with 56 mM KCl or substance P. Recently there are studies suggesting the involvement of NPFF in both morphine tolerance and dependence Thus in this study, the effect of morphine on the release of NPFF was investigated using an  $\underline{\text{in vitro}}$  superfusion of isolated rat spinal cord. We found that Naloxone caused a significant increase of NPFF efflux from the spinal cord of morphine treated rat. In contrast naloxone exerted only a very slight or no effect on the NPFF efflux from the spinal cord of control rat. Furthermore, amounts of NPFF release induced by naloxone seem to correlate with durations of morphine treatments. The results of this study strongly suggest an important role for NPFF in morphine dependence.

## 156.11

MORPHINE INDUCED TOLERANCE AND DEPENDENCE ARE CONTEMPORARY TO LARGE VARIATIONS OF F8Fa LEVELS, AN ANTI-OPIATE NEUROPEPTIDE. Simonnet G., Allard M., Gold\*\* L.H and Stinus\* L. INSERM U.176 and \*U.259, Rue C. St Saëns Bordeaux 33076 France. \*\*Dept of Neuropharmacology, The Scripps Research Institute, La Jolla, CA.

Tolerance may be an adaptative process which limits excessive effects of morphine and leads to dependency. Since no clear opiate receptor reduction may underlie the hyposensitivity to chronic morphine, an alternative hypothesis postulates a role of "antiopiate" peptides in the development of tolerance. F8Fa is a FMRF-NH2 like peptide which may counteract the effects of opiates via F8Fa specific receptors (Allard et al., 1989). The administration of morphine could stimulate antiopiate systems such as F8Fa, as part of a homeostatic mechanism. To test this hypothesis, tail-flick latency, physical dependence and CNS F8Fa levels (R1A) were measured at different times after implantation of morphine pellets (2x75mg; NIDA). Three hours after morphine pellet treatment, the analgesic effect was maximum and then decreased rapidly during the following 12 hours. As early as three hours post-implant, rats displayed naloxone-precipitated withdrawal. F8Fa levels were measured in spinal cord, displayed naloxone-precipitated withdrawal. Para levels were measured in spinal cord, brainstem and hypothalamus. We observed a slight decrease (-25% to -45% according to structures) one hour after morphine pellet implantation followed by a drastic increase of F8Fa levels (+60 to +140%) between 3 and 6 hours. F8Fa levels rapidly return to baseline after 24-36 hours, this evolution parallels the development of morphine tolerance and dependence. These data suggest that the activation of F8Fa anti-opiate neurons following chronic exposure to morphine may explain, at least in the property morphine descendence. part, morphine dependency

## 156.13

ANALOG OF NEUROPEPTIDE FF ATTENUATES MORPHINE TOLERANCE ANALOG OF NEUROPEPTIDE FF AITENUALED FROM J.R. Lake\*, K.M. Hebert, K.D. Deshotel, D.D. Hausam, W. Witherspoon, K.R. Arcangeli, K.P. Payza<sup>1</sup> and D.H. Malin.
Univ. of Houston-Clear Lake, Houston, TX 77058 and <sup>1</sup>NIMH
Neuroscience Ctr. at St. Elizabeths, Washington, D.C. 20032.
Neuropeptide FF (NPFF, F8Fa) appears to play a role in opiate tolerance since antibody against NPFF attenuates tolerance. Desamino-YFLFQPQRa (daY8Ra) was synthesized as a possible NPFF antagonist. It reverses behavioral effects of NPFF injection and attenuates morphine dependence. The present study assessed whether daY8Ra has a similar effect on opiate tolerance. Twelve rats were rendered tolerant by 7 days s.c. infusion of 0.53mg/kg/hr morphine via 1 Alzet osmotic minipump. They were then tested for pain sensitivity (tail flick, 15s cut-off) and injected i.c.v. with 600ng daY8Ra in saline or with saline alone. Thirty-eight mins. later they were injected with 6µg morphine i.c.v. and retested at 5, 12, 20 and 28 mins. after morphine. Morphine analgesia scores were computed as % of maximal effect. For purposes of comparison, 6 non-tolerant rats were challenged with 6µg morphine. Tolerant rats pretreated with saline never reached more then 6% of maximal morphine analgesia, while tolerant rats pretreated with daY8Ra ultimately reached 90% The two groups differed significantly, p<.01, at each time interval. Morphine analgesia was generally comparable in non-tolerant rats and tolerant rats pretreated with daY8Ra. In contrast, the same pretreatment with day8Ra did not affect analgesic response to i.c.v. morphine in 12 opiatenaive rats. (Supported by NIDA DA06554 & Tx Adv. Tech. Prog.)

EFFECT OF MORPHINE ON DEVELOPMENT IN XENOPILS EMBRYOS. Q. Xu, S. Spector\*. Dept. of Psychiatry, Vanderbilt Univ. Sch. of Med. Psychiatry, Vanderbilt Univ. Sch. of Med., Nashville, TN 37232. The incidence of fetal birth defects is

greater in these mothers who abuse opiates. This also can be demonstrated in pups from rats treated with morphine during gestation. Our studies used Xenopus embryos as a model to understand the mechanism for the defects. Embryos were incubated with varying concentrations of morphine  $10^4$  to  $10^{10}$  M. Concentrations of  $10^4$  M proved to be toxic and lower concentrations can cause morbidity and deformed tadpoles also. To investigate the neurological effects we used the Homeobox gene XIHbox6 as the marker for the neuro-system differentiation and development. We measured mRNA amount using northern blot to evaluate the expression of the gene. The results show morphine at concentrations from  $10^4$  to  $10^{-8}$  M increased the mRNA. It suggests that at the molecular level morphine may influence the differentiation and development of the neuro-system by an action on the Homeobox gene XIHbox6.

#### 156.12

ENHANCED ANTIOPIATE ACTIVITY IN CYCLOPROPLOGS OF FMRFamide. L.S. Corriere, T.M. Benson, J.R. Lake, D.A. Smith, R.K. Baugher, K-K. Ho', K. Burgess', K. Payza<sup>2</sup> and D.H. Malin\*. Univ. of Houston-Clear Lake, Houston, TX 77058, Rice Univ., Houston, TX 77251 and <sup>2</sup>NIMH, St. Elizabeths, Washington,

D.C., 20032.
FMRFa is a molluscan peptide which has antiopiate activity in a number of test systems. Two conformationally constrained peptidomimetics of FMRFa containing stereoisomers of 2,3-methanomethionine were synthesized. This study determined the antiopiate potency of FMRFa and its two cycloproplogs in precipitating opiate abstinence syndrome in rats infused s.c. for 7 days with 0.27 mg/kg/hr morphine sulfate via one Alzet osmotic minipump. Each rat received third ventricle injection of one of five doses (0.25-25.0ug) of FMRFa or one of its cycloproplogs. The rat was then observed for 20 mins. on a standard checklist of opiate abstinence signs (teeth chatter, writhes, wet shakes, etc.). Both of the cycloproplogs were approximately 50 times more potent than FMRFa itself. ANOVA of abstinence scores revealed a significant effect of conformation, p $\zeta$ .01, and a significant effect of dose, p $\zeta$ .05. The interaction effect (conformation x dose) was not significant. The mechanism of this heightened potency requires further investigation, since one of the cycloproplogs binds with less affinity than FMRFa to FMRFa receptors and mammalian neuropeptide FF receptors. (Supported by NIDA DA06554 and Texas Advanced Technology Program).

## 156.14

OPIATE WITHDRAWAL IN VIVO INDUCES LONG-TERM GLUTAMATE DESENSITIZATION IN LOCUS COERULEUS NEURONS: EX VIVO RECORDINGS IN RAT BRAIN SLICES J. H. Kogan\* and G. K. Aghajanjan. Depts. of Cellular & Molecular Physiology, Psychiatry, & Pharmacology, Yale Univ. School of Medicine, New Haven, CT 06508.

An increase in excitatory amino acid (EAA) activation contributes to the high firing rates of locus coeruleus (LC) neurons observed in vivo during naltrexoneprecipitated withdrawal (Rasmussen and Aghajanian, 1989). The initially elevated firing rates rapidly decline within the first 2-4 hours of precipitated withdrawal (Rasmussen et al., 1991). In the present study we investigated whether EAA responses were altered in LC brain slices prepared from rats chronically treated with morphine and withdrawn with naltrexone in vivo for 1 hour prior to slice preparation. The responses to glutamate, but not carbachol, were substantially reduced in cells from opiate-dependent, withdrawn, animals. In contrast, responses were not reduced in cells from opiate-dependent, non-withdrawn animals. The glutamate desensitization in the cells from the withdrawn animals was most pronounced in the first hour after slice preparation and gradually recovered over several hours. A similar long-term glutamate desensitization (LTGD) phenomenon could also be induced in vitro by prolonged applications (5-30 min) of glutamate (0.5-1 mM) which recovered within several hours. There was cross-desensitization between LTGD induced in vivo and in vitro indicating a common mechanism. Induction of LTGD in vitro was blocked by the non-selective glutamate antagonist kynurenic acid (10  $\mu$ M) but not by the selective NMDA antagonist AP-5 (100  $\mu$ M). These results suggest that LTGD in LC neurons results from increased glutamate release and may contribute to the early rapid decline in the elevated firing rates during naltrexone-precipitated opiate withdrawal.

NEUROCHEMICAL CORRELATE OF SHORT-TERM TOLERANCE TO MORPHINE AND POSSIBLE MODULATION BY IBOGAINE. D.W. Johnson and S.D. Glick.\* Dept. of Pharmacology and Toxicology, Albany Medical College, Albany, N.Y. 12208.

Two regimens of morphine pretreatment were compared in terms of the extent to which tolerance occurred to the locomotor depressant effect of morphine. Rats pretreated with the first regimen (30 mg/kg, 1x/day for 4 days, i.p.) did not differ in their response to the locomotor depressant effect of a single i.p. dose of 30 mg/kg morphine on day 5, compared to saline pretreated control animals. Rats pretreated with the second regimen (30 mg/kg 2x/day for 3 days, then 1x on day 4, i.p) showed tolerance (i.e., higher activity counts) after the day 5 morphine injection compared to saline pretreated controls. Using in vivo microdialysis, neurochemical correlates of tolerance were sought: the morphine-induced increase in extracellular DOPAC levels in the striata of rats pretreated with the tolerance-producing regimen of morphine administration was markedly reduced (p < .005) compared to saline-pretreated controls; no such change occurred in the nucleus accumbens. These data suggest that tolerance to morphine-induced locomotor depression is preferentially due to an effect in the striatum. The effect of ibogaine, a putative anti-addictive agent, on morphine tolerance is being investigated.

SELECTIVE BREEDING FOR OPIOID SELF-ADMINISTRATION IN RATS. K.R. Carlson\*, M.S. Moolten and C.M. Saulnier.
Pharmacology Dept., U. Massachusetts Medical Center, Worcester, MA 01655.

We are breeding lines which show a preference (P) or aversion (A) for drinking the potent opioid etonitazene (ETZ), and a randomly-bred (R) control line. The rats were offered only 2.5 \( \mu g/ml \) ETZ for 4 days; all lines drank equivalent amounts (21-23 ml), and exhibited stereotyped gnawing indicating that they were receiving behaviorally effective doses. They were then given a water-ETZ (2.5 \( \mu g/ml) \) choice for 7 days. A custom fluid-delivery apparatus negated the influence of position preferences; these rats drank equally from the two spouts when both contained water (F<1.0). The rats showing the most extreme choice behavior appropriate to their lines (P or A) were bred in brother-sister pairs, and breeders were chosen randomly from the R line.

By the second selected generation (S2) the lines had diverged significantly in the percent of total fluid consumed containing ETZ (P=37.7%, A=23.8%, R=31.0%; F=11.1, p<0.0001). This trend was enhanced in the S3 generation (P=42.9%, A=18.9%, R=30.8%; F=14.7, p<0.00001).

S2 rats were also given a choice between water and increasing concentrations of ethanol (3-25%). There were no differences between the lines (F<1.0) in percent of total fluid drunk containing ethanol, and an inverted-U relationship was found between concentration and percent (F=43.5), indicating that ethanol was a reinforcer for all the lines. These data suggest that we are breeding selectively for ETZ preference and not for a generalized tendency to drink psychoactive drugs such as ethanol.

OPIOID CONTROL OF CCK RELEASE FROM THE SPINAL CORD OF MORPHINE-TOLERANT AND NON-TOLERANT RATS. J.J. Benoilel, S. Bourgoin, A. Mauborgne, M. Pohl, L. Lantumey\*, M. Harmon and F. Cesselin. INSERM U 288, CHU Pitié Salpètrière, 91 Boulevard de l'Hôpital,

Cesselin. INSERM U 288, CHU Pitlé Saipètrière, 91 Boulevard de l'Hôpital, 75013 Paris, France.

Behavioral studies suggest that activation of central CCKergic systems could be involved in opioid tolerance. This led us to examine the possible influence of opioids on the spinal release of CCK like-material (CCKLM) in naive or morphine-tolerant rats. The Ca<sup>2+</sup>-dependent K+-induced overflow of CCKLM from slices of the dorsal part of the lumbar enlargement from naive rats was reduced by 0.1 μM-10 μM DAGO (μ opioid agonist) or 0.01-3 μM DTLET (∂ agonist), unaffected by 1 μM U 50488 H (κ agonist), and enhanced by 10 μM DTLET. Naloxone (1 μM) and U 50488 H (π agonist), and enhanced by 10 μM DTLET. Naloxone (1 μM) and U 50488 H (π agonist), and enhanced by 10 μM, λ a matagonist) inhibited both the inhibitory and excitatory effects of DTLET but not those of DAGO. This suggests the involvement of two subtypes of λ receptors, and the existence of k/μ, but not k/λ interactions, in the opioid control of spinal CCKLM release. Low concentrations of morphine (0.01-0.1 μM) significantly reduced CCKLM release. Complementary experiments, where the effects of 10 μM morphine were investigated in the presence of 1 μM naloxone, 50 μM ICI 154129 and/or 1 μM norbinaltorphimine (κ antagonist), indicated that the reduction in CCKLM release due to the stimulation of λ receptors. In morphine-tolerant rats the inhibitory effects of 10 μM DAGO and 3 μM DTLET on spinal CCKLM release disappeared. In contrast, the stimulatory effect of 10 μM DTLET on the peptide release persisted. These data strongly support the klea that spinal CCKergic systems are activated in morphine-tolerant rats.

LOW OPIATE CONCENTRATIONS CAN AUGMENT SYNAPTIC TRANSMIS-SION IN NUCLEUS ACCUMBENS VIA DISINHIBITION. S.G. Madamba\*, Z. Nie and G.R. Siggins, Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037

The nucleus accumbens (NAcc) is thought to be involved in the reinforcing properties of opiates. Our previous intracellular studies of a slice preparation of NAcc (Yuan et al., Neurosci. Lett. 134: 223, 1992) showed that  $0.1-1~\mu M$  concentrations of opiates specific for  $\mu$ ,  $\delta$  and  $\kappa$  receptors all reduced the size of both excitatory and inhibitory postsynaptic potentials (EPSPs and IPSPs) in NAcc neurons, with no effect on resting membrane properties. The  $\mu$  receptor agonist [D-Ala², NMe-Phe⁴ Glyol]-enkephalin (DAGO) was the most potent in reducing synaptic potentials. In the present study, we tested the effects of superfusion of lower concentrations of DAGO (30-50 nM) on the size of EPSPs in neurons of the NAcc slice, using intracellular recording. These concentrations again had no effect on membrane potentials or input slope resistance. In contrast to the effects of higher concentrations, 50 nM DAGO increased the size of EPSPs in 7 of 8 NAcc neurons tested (to 112-146% of control), with recovery on washout; EPSP size was decreased in the other neuron. With 30 nM DAGO, EPSP amplitudes were increased in 2 cells, decreased in 2, and unchanged in another. Because higher opiate concentrations were previously seen to reduce IPSPs as well as EPSPs, we tested the possibility that the EPSP increases at low DAGO concentrations might be due to an indirect action via covert IPSP reduction. In slices continually superfused with 30  $\mu$ M bicuculline to block GABA<sub>A</sub> receptors, DAGO 50 nM decreased EPSP size in all 5 cells studied (to 34-81% of control); in 4 cells the effect was reversed by 0.5 µM naloxone. These data suggest that  $\mu$  receptor agonists at low concentrations can augment EPSPs in the NAcc, probably by diminishing the IPSPs more effectively than EPSPs, thus removing the opposing or shunting effects of the IPSPs.

ACUTE EFFECTS OF BUPRENORPHINE ON CEREBRAL GLUCOSE UTILIZATION IN HUMAN SUBSTANCE ABUSERS.
S.L. Walsh\*, J.M. Stapleton, K.L. Preston, J.T. Sullivan, R.F. Dannals, R. Grayson, R.L. Phillips, G.E. Bigelow, D.R. Jasinski and E.D. London, Johns Hopkins School of Medicine and NIDA Addiction Research Center, Baltimore, MD 21224.

Baltimore, MD 21224.

Buprenorphine (BUP), an opioid with mixed agonist/antagonist properties, is currently being investigated as a potential treatment for opiate addiction. We used the PET [18F]fluorodeoxyglucose (FDG) method to characterize the biochemical and neuroanatomical effects of BUP in brain, in a double-blind, placebo-controlled, crossover study. Volunteers were 6 healthy opioid-experienced males, ages 27-36 years, who were not physically dependent on opiates at the time of study. Subjects participated as inpatients in two PET scans following the administration of placebo and BUP (1.0 mg, i.m.), 15 minutes before FDG. BUP reduced glucose metabolism (range 13-27%) in many brain regions. Significant decrements occurred in cortical areas and limbic structures, including hippocampus and amygdala; more caudal brain structures also showed decreases in metabolism. BUP produced typical opiate effects, including pupillary constriction and subjective reports of "liking" and "good effects". BUP produced significant changes in arterial concentrations of oxygen (1 21%) and carbon dioxide († 17%), which may have contributed to the observed decrease in glucose metabolism. Several drugs with known abuse potential, including alcohol, cocaine and morphine, have been shown to produce global decreases in glucose utilization when given acutely. The present data demonstrate that BUP produces global reductions in cerebral glucose utilization, consistent with a commonality in the effects of euphoriants on cerebral metabolism. SYSTEMIC ADMINISTRATION OF THE SUBSTANCE P ANALOGUE, DIME-C7, POTENTIATES THE DEVELOPMENT OF SENSITIZATION OF THE BEHAVIORAL ACTIVATING EFFECTS OF MORPHINE. M.L. Forgie\*. C. Archambault. D. Rodaros and J. Stewart. Center for Studies in Behavioral Neurobiology, Psychology Dept., Concordia University, Montréal, Québec, Canada, H3G 1M8.

Repeated administrations of morphine (MOR) produce long-lasting sensitization of the behavioral activating effects of the drug, thought to be mediated by long-lasting changes in the mesolimbic dopamine (DA) system. Substance P (SP) neurons provide positive excitatory feedback system. Substance P (SP) neurons provide positive excitatory feedback on DA neurons and could thereby contribute to sensitization. Further, SP has been shown to be reinforcing in several learning paradigms. We investigated the interaction of SP with MOR in producing behavioral sensitization. Animals received either MOR (10 mg/kg, i.p.) or its vehicle (1 ml/kg) in conjunction with either the SP-analogue DiMe-C7 (32.6 µg/kg, i.p.) or its vehicle (5 ml/kg). Locomotor activity was measured for 2 h, every 2 days on 5 occasions. In tests for sensitization, all animals received MOR (5.0 mg/kg) or DiMe-C7 (32.6 µg/kg). In a second parallel experiment, DiMe-C7 (3 µg/side) or its vehicle (0.5 µl/side) were administered bilaterally into the ventral termental area (VTA). When both injections were systemic, animals venicle (0.5 µ/side) were administered bilaterally into the ventral tegmental area (VTA). When both injections were systemic, animals that had previously been exposed to both DiMe-C7 and MOR showed greater sensitization to a challenge injection of MOR than did animals that had been exposed to MOR alone. This potentiation was not observed when DiMe-C7 was applied directly to the VTA at this dose. These data suggest that SP can potentiate sensitization to MOR, but the VTA may not be the site of this effect.

INTERACTIONS BETWEEN CANNABINOIDS AND STEROIDS IN THE RAT HIPPOCAMPUS. J.C. Eldridge\*¹, Hong-Yu Hu¹, P.J. Extrom¹, and P.W. Landfield². Department of Physiology & Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157-10831 and Department of Pharmacology, University of Kentucky Chandler Medical Center, Lexington, KY 40536-0084<sup>2</sup>

In previously published reports (Eldridge, et al., Brain Research 534:135, 1990; Steroids 56:226, 1991), we demonstrated that cannabinoids (THC) could interact with glucocorticoid (GC) binding to GC receptors in the rat hippocampus. In the present studies, cytosols were incubated with [ $^{3}$ H]- $^{4}$ THC and a small but significant competition was exerted by excess unlabeled THC or CORT, but not by other steroids. A large amount of the total binding was not saturable and appeared to be non-specific. Sucrose gradients of cytosols incubated with [3H]-THC demonstrated a slight but displaceable association in the 85 region. Additional displaceable binding, plus a large amount of non-saturable binding, was located in the 4-5 S region. In a separate study, analyses were conducted of mRNA for glial fibrillary acidic protein (GFAP), which has been shown to be specifically suppressed in hippocampus after GC administration (Nichols, et al., Mol. Brain Res. 7:1, 1990). Tissue RNA extracts were hybridized to [22P]-labeled antisense probe prepared after amplification of a clone furnished to us by the authors. Dot blot radioactivities were quantified with a Betagen® scanner. Treatment of adrenalectomized rats with 5 mg THC suppressed hippocampal GFAP mRNA within 24 hr. Continued daily injections maintained suppression, although an accommodation was evident by 4 days. These results support our earlier proposal (Landfield, et al., Brain Research 443:47, 1988) that cannabinoids may exert glucocorticoid agonist effects on rat hippocampus. ## 157.3

SYNTHETIC CANNABINOID ANALOGS ENHANCE A FAST POTASSIUM CONDUCTANCE IN CULTURED HIPPOCAMPAL NEURONS. S.A. Deadwyler\*, T.A. Edwards, J. Mu, B.A. Bennett and R.E. Hampso Gray School of Medicine, Wake Forest Univ., Winston-Salem, NC 27157

The recent discovery of the cannabinoid receptor in brain has provoked intense speculation regarding its major physiological action on CNS neurons. Herkenham et al. (J. Neurosci. 11:563-583, 1991) have provided autoradiographic evidence for the possible existence of presynaptically located cannabinoid receptors in both the substantia nigra (pars reticulata) and in the hippocampus (outer molecular layer of the dentate gyrus). The studies to be described investigate the physiological action of cannabinoids in cultured (18-20 day embryonic) hippocampal neurons. Whole cell patch clamp recordings revealed a profound modulation of fast-inactivating, voltage-sensitive "A" current in hippocampal neurons by both the Pfizer (CP-55,940, CP-55,244, levonantradol) and Sterling Drug Co. (WIN-55,212-2) synthetic cannabinoid receptor agonists. Potassium currents provoked by two different voltage-step protocols examined activation and inactivation of "A" currents before and during local pipette perfusion of the cannabinoids in TTX treated cultures. "A" current activation was enhanced while inactivation was decreased in cells exposed to the analogs. Moreover, the potency for producing these effects matched the receptor binding and subsequent biochemical potencies of these compounds reported by others (Howlett et al. TINS 13:420-423 1991; Pacheco et al. JPET 257:170-183, 1991). Comparisons to a similar action of baclofen to produce ese same effects on "A" current via the GABA-B receptor (Gage, TINS 15:46-51, 1992) showed the synthetic cannabinoids to be 100 fold more potent than baclofen.

## 157.5

CHRONIC CANNABINOID ADMINISTRATION ALTERS CANNABINOID RECEPTOR BINDING IN RAT BRAIN: AN AUTORADIOGRAPHIC STUDY Angelica Oviedot, John Glowa and Miles Herkenham\*. Section on Functional Neuroanatomy, NIMH, Bethesda, MD 20892. †Howard Hughes Medical Institute-NIH Research Scholar

The active ingredient of marijuana is  $(-)-\Delta^9$ -tetrahydrocannabinol  $(\Delta^9\text{-THC})$ .  $\Delta^9\text{-THC}$  and other natural and synthetic cannabinoids such as CP-55,940 produce catalepsy in animals in a receptor-mediated fashion. To test the hypothesis that tolerance to repeated administration might be mediated by changes in receptor binding characteristics, we used quantitative *in vitro* autoradiography of [<sup>3</sup>H]CP-55,940 binding to striatal brain sections of rats treated either chronically or acutely with  $\Delta$ 9-THC, CP-55,940, or cannabidiol, an inactive cannabinoid. In the chronic condition, rats were given daily i.p. injections of  $\Delta^9$ -THC (10 mg/kg), cannabidiol (10 mg/kg), or CP-55,940 (1, 3, or 10 mg/kg) for two weeks and sacrificed one-half hour after the last injection. In the acute condition, animals received a single dose (10 mg/kg) just prior to sacrifice. Rats showed rapid tolerance to the cataleptic effects of  $\Delta^9$ -THC and CP-55,940, assayed in an open field test on days 1, 7, and 14. Densitometry of  $[^3H]$ CP-55,940 binding showed that  $\Delta^9$ -THC and CP-55,940 treated animals had decreased binding in all structures measured at a selected striatal level. Displacement curves using varying competing concentrations of CP-55,940 permitted analysis of binding kinetics. Alterations seen in the acute condition were attributed to changes in affinity (Kd), whereas the major changes in the chronic condition were attributed to a lowering of capacity (Bmax). These results express that there are the competitive the part of the strength of the control of the strength of the results suggest that tolerance to cannabinoids results at least in part from agonist-induced receptor down-regulation.

GLUCOCORTICOID AGONIST-LIKE EFFECT OF DELTA-9-THC ON IMMUNOREACTIVE CALBINDIN UPREGULATION IN CAI HIPPOCAMPAL NEURONS. J.L. Geddes, J.C. Eldridge and P.W. Landfield\*, Dept. of Pharmacology, Univ. Kentucky Col. of Med., Lexington, KY 40536 and Dept. of Physiology and Pharmacology, Bowman Gray Sch. Med., Wake Forest Univ., Winston-Salem, N.C. 27157
Glucocorticoids have been shown to increase rat hippocampal neuronal loss during brain aging, possibly by elevating inward calcium currents (cf. review in Landfield and Eldridge, Acta Endocrinol., 1991, 125: 54-64). Because the molecular structure of delta-9-tetrahydrocannabinol (THC) strongly resembles that of glucocorticoids, the effects of THC on hippocampal cell loss and on hippocampal glucocorticoid receptors were studied. THC was found to increase neuronal loss in young rats, and to downregulate the hippocampal type II glucocorticoid receptor (GR) (cf. review in Eldridge et al, Steroids, 1991, 56: 226-231).

The present study was undertaken to determine whether THC interacts with the GR as an agonist or an antagonist. We have investigated the effects of corticosterone (CORT) and THC on immunoreactivity of the calcium binding protein, Calbindin-28K (CaBP). In the hippocampus, the upregulation of CaBP is CORT-dependent. Young (3-5 mo-old), adrenalectomized rats were dosed with THC, CORT or vehicle. CORT induced a consistent increase in the CaBP staining intensity in CA1 and CA2 pyramidal neurons, but not in CA3 and CA4, as measured by average optical density values using a computer-assisted digital image analyzer (p < 0.04). This indicates that CORT upregulates CaBP through the type II GR, which is found in high density in CA1 and CA2.

In addition, 1-2 weeks of THC treatment induced an increase in CaBP immunoreactivity in CA1, indicating a partial type II GR agonist-like effect of THC in the hippocampus. This effect may account for aspects of chronic THC-mediated neurotoxicity. (Supported by DA-03637, DA-06218).

CANNABINOID INDUCED ALTERATIONS IN REGIONAL CEREBRAL BLOOD FLOW IN THE RAT. A. S. Bloom\*, S. Tershner, S. A. Fuller, E. A. Stein. Departments of Pharmacology and Psychiatry, Medical College of Wisconsin, Milwaukee, WI 53226.

The cannabinoid receptor has a wide but heterogeneous distribution in the mammalian brain. However, the functional role of these receptors is not yet well understood. We have therefore examined the effects of  $\Delta^0$ -tetrahydrocannabinol (THC) and its active metabolite 11-OH-THC on regional cerebral blood flow (rCBF) in the rat to determine their functogonal cerebral blood flow (ICBF) in the fat to determine their func-tional sites of action. Conscious rats were injected iv with either THC (0.5, 1, 4, 16 mg/kg) or 11-OH-THC (4 mg/kg) 30 min prior to sacri-fice. rCBF was determined using [14C]Iodoantipyrine. Changes were observed in 14 of 33 areas measured. Significant dose-related decreases in rCBF were produced by THC in 10 areas including the CA1 and CA3 regions of the hippocampus, frontal and medial prefrontal cortex and the nucleus accumbens. Thresholds for these effects ranged from 0.5 to 4 mg/kg. 11-OH-THC also decreased rCBF in these areas. In contrast, a significant biphasic increase (4 mg/kg peak effect) in rCBF was seen in the arcuate nucleus and posterior hypothalamus. Other areas such as the medial septum, ventral tegmental area, caudate, temporal, parietal and occipital cortex and cerebellum were unaffected. Monitoring of cardiovascular and blood gas parameters revealed significant decreases in heart rate and increases in pCO<sub>2</sub>. The decrease in rCBF produced by the cannabinoids in the presence of increased pCO<sub>2</sub> suggests a direct drug effect on the brain. It is significant that the areas where rCBF is altered are involved in major behavioral and physiological effects of the cannabinoids such as impairment of short-term memory and endocrine function. (Supported in part by NIDA grants DA03725 & DA05012)

AGE DEPENDENT CHANGES IN HUMAN BRAIN CANNABINOID RECEPTOR DISTRIBUTION I. Kerman. O. Bar-Peled and A. Biegon\*, Weizmann Inst. Sci., Rehovot, Israel and Lawrence Berkeley Lab., UC Berkeley, CA 94720

Lifespan changes in cannabinoid receptors and the presence of these recepotrs in the human fetal brain may explain age-dependent these recepotrs in the human fetal brain may explain age-dependent changes in drug seeking behavior and the selective effects of marijuana exposure during pregnancy. Cannabinoid recepotrs were examined by quantitative autoradiography of sections of humn brains obtained postmortem, using [3H]CP55,940 (N.E.N, specific activity 104 Ci/mmole) as a ligand. Normal fetal brains (N=5, gestational age 18, 20, 22 and 24 weeks) were obtained from voluntary abortions. Normal adult human brains (N=16, age range 18 to 78) were obtained from the medical examiner's office in NYC and Jaffa. The radioligand (5nM) was incubated with the sections for 3 hours at room temperature followed by 2X90 min wash at 4°C. Non specific hinding was determined in the ax90 min wash at 4°C. Non specific binding was determined in the presence of 10μM unlabeled THC. Dried sections were exposed to tritium sensitive film for 1 to 4 weeks. Autoradiograms and tritium standards were quantified using a computerized image analysis system and the NIH Image software. Cannabinoid receptors exhibit a widespread but heterogeneous distribution in the human brain. The highest levels are found in the substantia nigra. High densities are also found in globus pallidus, caudate, putamen, cerebellum, hippocampus and cortex. A significant negative correlation (R=0.69, p<0.003) between binding and age was found in the cingulate cortex. Fetal brains contained moderate densities of receptors in cortex and hippocampus and very low levels in the basal ganglia, suggesting age dependent changes in human brain cannabinoid receptor distribution.

APPROACHES TO THE DETERMINATION OF THE CENTRAL SITES OF ACTION OF CANNABINOIDS. E.S. Onaivi\*, P.J. Little and B.R. Martin. Dept. of Pharmacology, MCV-VCU, Richmond, VA 23298 and \*Stanford University, CA, U.S.A.

The administration of Δ9-THC to rodents alters some of the

behaviorial measures in a manner indicative of psychoactivity. The aim of this study was directed towards the localization of the central sites of action of cannabinoids. Male ICR mice were subjected to standard stereotaxic surgery for the implantation of guide cannulae to allow microinjection of cannabinoids or its vehicle bilaterally into the ventricles or other selected brain structures. The ICV injection of  $\Delta^9$ -THC or the analog (-)- ACD reduced locomotor activity (LA) and rectal temperature (RT) and enhanced the tail flick (TF) and immobility responses: the (-)-ACD compound being more potent. The ICV injection of lower doses of 5' TMA Δ8-THC (3-9 μg) was effective only in the production of analgesia and catalepsy but did not alter the LA and RT. There was no significant changes in RT and TF tests following the injection of similar doses of  $\Delta^9$ -THC (50-150 µg) into to tho wing the injection of similar doses of  $\Delta^2$ -FIG. (30-130 µg) find the center of the nucleus accumbens (ACB) except for the induction of catalepsy and a slight decrease in LA. In contrast, the injection of similar doses of  $\Delta^9$ -THC into the central nucleus of amygdala (ACE) failed to alter mouse LA, RT, TF and catalepsy tests. Therefore, the mesolimbic ACB but not the ACE may be an important site contributing to the modification of motor activity and induction of catalepsy by some cannabinoids. The importance of other brain sites in these behaviors and other cannabinoid subjective effects remains to be determined. Supported by NIDA grant #DA-03672.

## 157.9

HALOPERIDOL BLOCKS THE RESPONSE-REINSTATING EFFECTS OF HEROIN REINFORCEMENT IN AN OPERANT RUNWAY PARADIGM. A.Ettenberg\*, L. MacConell and T.D. Geist. Behavioral Pharmacology Laboratory, Dept of Psychology, Univ. California, Santa Barbara, CA 93106

The motivating actions of drug reinforcers have been demonstrated in studies where previously extinguished operant behaviors are reinstated following a single "prime" with the original reinforcer. In the present study, male albino rats were trained to traverse a straightalley for a reinforcer consisting of five iv injections of 0.06 mg/kg heroin. Once the alley-running had been established, the heroin reinforcer was removed and the operant behavior permitted to extinguish. On treatment day, animals were injected 45 min prior to testing with 0.0, 0.75 or 0.15 mg/kg of the dopamine receptor antagonist, haloperidol. A single trial was then conducted during which some animals continued to experience extinction conditions while others were injected with the heroin reinforcer. The effects of these manipulations were determined during an additional single trial conducted 24 hrs later when the subjects were no longer drugged. While heroin did lead to a reinstatement in operant responding, this effect was dose-dependently prevented by pretreatment with haloperidol. These data suggest that the motivating properties of opiate agonist drugs can be attenuated during dopamine receptor

PROPERTIES OF NEURONS RECORDED IN THE RODENT NUCLEUS ACCUMBENS, IN VIVO: RELATIONSHIP TO BEHAVIORAL STATE AND HEROIN SELF-ADMINISTRATION Sieven J. Henriksen\*. Clifton W. Callaway. S. Stevens Negus. George F. Koob. Dawn E. Miller, Greta I. Berg. Linda R. Friedman and Catherine C. Engberg. Department of Neuropharmacology, The Scripps Research Institute, La Jolla, California 92037.

The nucleus accumbens septi (NAcc) is a complex brain structure increasingly implicated in the acquisition and expression of reinforced behaviors. There is strong evidence suggesting that the NAcc, including some of its efferent and afferent connections, are critical for the brain processes leading to self-administration of both psychostimulant and narcotic analgesic drugs in rats. In order to investigate the cellular substrate of these behavioral events we have recorded from identified NAcc neurons in unanesthetized, freely-moving rats and have attempted to correlate their discharge with on-going behaviors, state changes and episodes of heroin self-administration. Single accumbens neurons were recorded with either tungsten microelectrodes or nichrome micro-wires assembled in a moveable microdrive. With this configuration we have been able to record the firing patterns of 80 NAcc neurons for tens, of minutes up to several hours. The patterns of responsivity of these neurons to afferent stimulation appeared similar to what we have previously observed in anesthetized preparations. In contrast to the anesthetized rat NAcc neurons in the awake, freely moving rat demonstrated considerable spontaneous activity (4.08 ± 3.86 Hz) with both positive and negative correlations with behaviorally associated theta activity recorded from cortical EEG electrodes. However, there was no correlation of NAcc discharge rate and locomotor behavior, per sé. The rate of firing of these neurons declined during transition to slow-wave sleep (1.77 ± 1.68 Hz) another theta-related state. In one animal lever trained to self-administer heroin (0.02 mg/injection thro

EFFECT OF B-FNA I.C.V. ON HEROIN SELF-ADMINISTRATION IN NON-DEPENDENT RATS AND IN SITU OPIOID BINDING. T.J. MARTIN, S. I. DWORKIN and J. E. SMITH\*. Center for Neurobiology of Drug Abuse. Dept. Physiology and Pharmacology. The Bowman Gray Sch. of Med./Wake Forest Univ. Winston-Salem, NC 27157. β-FNA has been shown to be an irreversible antagonist of μ opiate administered β-FNA on the reinforcing properties of opiates was investigated and compared to effects on opiate binding sites. Male Fisher 344 rats (250-300g) were implanted with intravenous jugular Fisher 344 rats (250-300g) were implanted with intravenous jugular catheters and guide cannulae into each lateral ventricle. The animals were then trained to self-administer heroin (18 μg/kg/inf) on a fixed-ratio 10 schedule during 4 hr sessions. Saline was substituted for heroin twice prior to administration of 40 nmol of β-FNA. Prior to administration of β-FNA the animals self-administered 33.8 (2.0) mean (s.d.) infusions/session. Saline substitution resulted in 9.3 (0.3) infusions/session. The number of infusions/session 1, 2, 3, 4, 7 and 14 days after β-FNA administration was 12 (11), 7 (1), 8.5 (4.5), 10.5 (3.5), 20.5 (2.5) and 39 (0) infusions/session, respectively. Binding to μ opiate receptors was assessed in 20 μm brain slices using [3H]DAMGO. Administration of 40 nmol of β-FNA i.c.v. was found to decrease the Bmax by 38.2% 24 hr later while having no effect on the Kd. The Bmax was found to be 46.2 and 97.3% of control 7 and 14 days after β-FNA treatment, respectively. Therefore, β-FNA produces a temporary loss in μ binding sites correlated with attenuation of heroin reinforcement. Supported by NIDA grants DA-01999 and P50-DA06634.

MICRODIALYSIS ASSESSMENT OF NUCLEUS ACCUMBENS DOPAMINE AND METABOLITES DURING IV HEROIN SELF-ADMINISTRATION AND EXTINCTION. P. Leone, R. Rivest and R.A. Wise, Center for Studies in Behavioral Neurobiology, Concordia University, Montreal, Quebec, Canada, H3G 1M8.

Opiates are known to increase dopaminergic impulse flow and to elevate dopamine turnover in nucleus accumbens; the aim of the present study was to determine whether such effects occur with self-selected doses of intravenous (IV) heroin. Rats with nucleus accumbens guide cannulae were trained to self-administer heroin hydrochloride (0.2 or 0.3 mg/kg/inj) on a FR-1 schedule of reinforcement. Extracellular dopamine and metabolites were sampled at 20-min intervals by microdialysis and measured using high performance liquid chromatography (HPLC) with electrochemical detection. Dopamine and DOPAC levels increased approximately 300% during 3-h self-administration sessions; dopamine levels fell quickly, and DOPAC levels more slowly, during response "extinction" when heroin injections were terminated at the end of the sessions. The fell is described by the during vibration and the sessions. of the sessions. The fall in dopamine levels during extinction occurred at a time of accelerated lever-pressing ("extinction burst") thus indicating that the elevated dopamine levels were not a simple consequence of behavioral arousal or the initiation of goal-directed behavior. These data offer clear evidence that rewarding doses of heroin are sufficient to disinhibit the mesolimbic dopamine system and produce elevated dopamine release similar to that seen during amphetamine or cocaine self-administration. Inasmuch as dopaminergic actions in nucleus accumbens are rewarding in their own right, dopaminergic actions appear to make an important contribution to the abuse liability of IV heroin.

LOCALLY-INDUCED OPIATE WITHDRAWAL MODESTLY ACTIVATES NORADRENERGIC LOCUS COERULEUS (LC) NEURONS IN VIVO. H. Hirata\*, H. Akaoka<sup>1</sup> and G. Aston-Jones. Dept. Mental Health Sci., Hahnemann Univ., Philadelphia, PA 19102; <sup>1</sup>INSERM U171, St. Genis-Laval, France.

Hyperactivity of LC neurons during opiate withdrawal (OW) is thought to contribute to opiate abuse. Recently, we and others showed that the bulk of LC activation during OW resulted from increased excitatory amino acid (EAA) input to the LC from the ventrolateral medulla. It has also been reported that LC neurons in slices from morphine treated rats exhibited modest OW-induced hyperactivity. Here, we tested whether OW induced locally in the LC activated these neurons in vivo.

we tested whether OW induced locally in the LC activated these neurons in vivo.

Adult Sprague-Dawley rats were continuously administered morphine via an osmotic minipump for 6 days (approx. 45 mg/kg/day). Under halothane anesthesia impulse activity of individual LC neurons was recorded using double barrel glass micropipettes. A solution of methyl naloxone (MeNLX) was microinfused (60-140 nl) from one barrel to induce local OW in the LC while recording LC discharge. None of 7 neurons tested were activated by local injection of 10 mM MeNLX. However, the discharge rate of neurons recorded with such MeNLX pipettes was significantly higher than that of neurons recorded in opiate-treated animals without this drug in the pipette (2.1±0.3 vs. 0.8±0.1 spikes/sec). To ascertain if leakage of MeNLX had elevated LC activity and prevented further activation with microinfusion of MeNLX, we used pipettes containing a much lower concentration of NLX (1 µM). Each of 10 neurons tested with 1 µM NLX were modestly activated (from 0.8±0.1 to 1.7+0.2 spikes/sec). However, some of this increase could result from anagonism of 1.7±0.2 spikes/sec). However, some of this increase could result from antagonism of morphine circulating in the animal. Additional calculations revealed that the discharge of LC neurons recorded after microinfusion of 10 mM MeNLX was higher than that of morphine-naive rats (2.1±0.3 vs. 1.3±0.2 spikes/sec, n=7 and 19, respectively). Our results indicate that 1/3 or less of this increase results from local OW mechanisms within the LC area, while the remaining 2/3 or more derives from OW in brain areas outside of the LC (largely or entirely EAA inputs from the ventrolateral medulla). Supported by PHS grants DA 06214 and NS 24698.

EXPRESSION OF FOS PROTEIN IN CENTRAL CATECHOLAMINE NEURONS DURING OPIATE WITHDRAWAL. H. Akaoka\* 1, Y. Zhu, M.T. Shipley<sup>2</sup> and G. Aston-Jones. Hahnemann Univ., Philadelphia, PA 19102; <sup>1</sup>INSERM U171, St. Genis-Laval, France; <sup>2</sup>U. Cincinnati, Cincinnati, OH 45267

Previous studies have strongly implicated central catecholamine (CA) neurons in drug abuse and withdrawal mechanisms. We studied the distribution of CA neurons stimulated during opiate withdrawal using double immunocytochemistry for Fos protein, a metabolic marker, and tyrosine hydroxylase (TH). Adult male for Fos protein, a metabolic marker, and tyrosine hydroxylase (TH). Adult male Sprague-Dawley rats were injected with morphine twice daily for 4 days in escalating doses of 5, 10, 20 and 30 mg/kg per injection. Opiate withdrawal was precipitated on day 5 with naltrexone (1 mg/kg). Control groups included: chronic morphine - saline; chronic saline - saline; and chronic saline - naltrexone. Two hrs after the last injection animals were processed for Fos and TH immunoreactivity (ir). Opiate withdrawal induced Fos-ir in several regions of the brain stem, doubly labeled cells were consistently found in the ventrolateral medulla (A1 and C1 neurons), nucleus tractus solitarius (NTS; most prominently in mid-NTS), and locus coeruleus (mostly in rostral and dorsal regions). Numerous non-TH-ir neurons in the NTS also expressed Fos protein after withdrawal. Fewer, or no, doubly labeled cells were found in the A5 or A7 cell groups or in rostral parts of the dorsal medulla. In control groups, there were few or no Fos-positive cells in any of these areas. From the midbrain to the olfactory bulbs, no TH-ir cells contained a detectable level of Fos protein regardless of the pharmacological treatment, except a subpopulation of cells in protein regardless of the pharmacological treatment, except a subpopulation of cells in the vicinity of the supramammalary nucleus which were doubly labeled even in control groups. In withdrawn animals numerous TH-negative neurons in the hypothalamus and olfactory bulb expressed Fos-ir. These results indicate that opiate withdrawal induces Fos in noradrenergic or adrenergic cells in the medulla and pons, but not in more rostrally-located dopaminergic neurons, suggesting that activation of noradrenergic neurons, but not dopaminergic neurons, is importantly involved in opiate withdrawal. Supported by PHS grants DA 06214, NS 24698 and NS 20643.

### 157.15

EFFECTS OF PRENATAL METHADONE EXPOSURE ON POSTNATAL PRODYNORPHIN AND VASOPRESSIN mRNA EXPRESSION IN THE RAT SUPRAOPTIC NUCLEUS. <u>I.W.</u>

EXPRESSION IN THE RAT SUPRAOPTIC NUCLEUS. J.W. Nemitz\*Dept. of Anatomy, WV School of Osteopathic Medicine, Lewisburg, WV 24901.

Pregnant Sprague-Dawley rats were made physically dependent to methadone (9mg/kg/day) using subcutaneous osmotic minipumps (Alza). The pregnancies were brought to term and the methadone exposed rat pups were sacrificed at different postnatal days by decapitation. Frozen serial coronal sections (20um) obtained at the level of the hypothalamus were processed for in situ hybridization, using 35S-oligonucleotide probes (DuPont), and emulsion autoradiography.

Arginine-vasopressin (AVP) mRNA levels were decreased in the supraoptic nucleus (SON) of methadone exposed rat pups as compared to controls during the first postnatal week. Increases in prodynorphin (DYN) mRNA levels were observed in the adjacent SON sections of neonates exposed to methadone. No labeling for an enkephalin mRNA probe was observed in the SON of either methadone exposed or control pups. Previous work of either methadone exposed or control pups. Previous work or either methadone exposed of control pups. Previous work provided evidence that prenatal methadone exposure results in a decrease in oxytocin mRNA expression in hypothalamic nuclei that is rapidly reversed postnatally. The present data indicate that prenatal methadone exposure also inhibits the expression of AVP mRNA in the SON, but for a longer postnatal period. Furthermore the concurrent increase in DYN levels in the SON as a result of methadone exposure is consistent with a proposed modulatory role for DYN. Supported by WVSOM funds.

## 157.17

REWARD-SPECIFIC BLOCKADE OF MORPHINE'S EFFECT ON BRAIN-STIMULATION REWARD BY PIMOZIDE BUT NOT SCH 23390. M. Sarkar\*, D. Huston-Lyons and C. Kornetsky. Boston Univ. Sch. of Med, Boston, MA 02118.

To further test the hypothesis that dopamine plays an important role in the rewarding effects of morphine sulfate (MS) (2.0 mg/kg sc), we compared the ability of the specific D1 antagonist, SCH 23390 (SCH) (0.00125 - 0.02 mg/kg sc), and the D2 antagonist, pimozide (PIM) (0.05 - 0.4 mg/kg ip), to block the threshold lowering effect of MS on brain-stimulation reward (BSR) to the MFB-LH. Thresholds were determined in 7 male F-344 rats using a discrete trial, rate-independent method. PIM, reversed MS's effect at doses (0.1 - 0.2 mg/kg) that did not significantly alter the threshold alone, suggesting that PIM induced a reward-specific blockade. SCH, in contrast, also reversed MS's effect, but only at doses (>0.01 mg/kg) that significantly raised the threshold when injected alone, suggesting a non-specific blockade of the rewarding effects of MS. Similar non-specific blockade by PIM is seen only at higher doses (>0.2 mg/kg). Thus, to the extent that BSR is a model of drug-induced euphoria, these data suggest that MS's rewarding effects are modified in a reward-specific manner by moderate doses of the D2 antagonist, PIM, and only in a nonspecific manner by the D1 antagonist, SCH. (Supported by NIDA Grant DA02326 and DA00099 to CK).

β-ADRENERGIC ANTAGONISTS BLOCK WITHDRAWAL SIGNS IN MORPHINE AND COCAINE DEPENDENT ANIMALS, G. C. Harris\* and G. Aston-Jones. Department of Mental Health Sciences,

Harriss and G. Aston-Jones. Department of Mental Health Sciences, Hahnemann University, Philadelphia, PA 19102.

Male Sprague-Dawley rats were treated chronically with either cocaine (20 mg/kg/ip/14 days), morphine (incrementing doses of 10 mg/kg/ip) per day up to 80 mg/kg and maintained on 60 mg/kg/day) or saline. During morphine and cocaine abstinence (48 hrs), dependent rats showed increased anxiety in defensive business produces be the business of the control of and cocaine abstinence (48 hrs), dependent rats showed increased anxiety in a defensive burying paradigm by showing a 4 fold (p < .01) increase in burying time relative to saline injected animals (n = 6 per group). This withdrawal-induced increase in burying was blocked by both the  $\beta 1$  and  $\beta 2$  antagonist, propranolol (15 mg/kg), as well as, the specific peripheral  $\beta 1$  antagonist, atendolol (15 mg/kg). These drugs (20 - 30 mg/kg) also significantly reduced the aversion to an environment paired with naloxone administration (200 µg) in morphine dependent animals (n = 5). Finally, these drugs (20 - 30 mg/kg) eliminated many signs of naloxone-precipitated (500 µg) and abstinence withdrawal, such as: wet dog shakes, teeth chatter, writhing and diarrhea (n = 7). These data suggest that many symptoms of writhing and diarrhea (n = 7). These data suggest that many symptoms of opiate withdrawal and some symptoms of cocaine withdrawal can be alleviated through the blockade of peripheral \(\beta\)1-adrenergic receptors. Supported by NIDA Grants DA05387-03 and DA06214.

DOPAMINE D, RECEPTOR SUPERSENSITIVITY WITHOUT RECEPTOR UP-REGULATION IN MORPHINE ABSTINENT RATS. P.L. Reddy, Veeranna and H.N. Bhargaya\*, Dept. Pharmacodynamics, Univ. Ill. at Chicago, Chicago, IL 60612.

Rats were rendered tolerant to and physically dependent on morphine by implanting 6 morphine pellets during a 7-day period. Each pellet contained 75 mg morphine base. Rats which served as controls were implanted with an equivalent number of placebo pellets. Rats were sacrificed brain and spinal cord were isolated. Brain was dissected into 7 regions. Bmax and Kd values of <sup>3</sup>H-spiroperidol to bind to dopamine D, receptors in brain regions and spinal cord of morphine tolerant (pellets left intact at time of sacrificing) and abstinent (pellets removed 18 hr prior to sacrificing) rats were determined. <sup>3</sup>H-spiroperidol bound to tissue membranes at a single high affinity binding site. The B<sub>max</sub> and K<sub>d</sub> values of <sup>3</sup>H-spiroperidol were unaffected in brain regions and spinal cord of morphine tolerant or abstinent rats. Spontaneous withdrawal of morphine resulted in significant increases in motor activity and stereotypic movements. Dopamine D, receptor agonist, 2-bromo-α- ergocriptine induced behaviors were of greater intensity in morphine abstinent rats than in placebo controls. Previously, we had demonstrated that behavioral supersensitivity of D, receptors in morphine abstinent rats involved up-regulation of receptors. Evidence is, thus provided for the behavioral supersensitivity of dopamine D2 receptors without receptor up-regulation (Supported by NIDA grant DA-02598).

## 157.18

CHRONOAMPEROMETRIC MEASUREMENTS OF DOPAMINE LEVELS IN RAT NUCLEUS ACCUMBENS DURING HEROIN SELF-ADMINISTRATION.

RAT NUCLEUS ACCUMBENS DURING HEROIN SELF-ADMINISTRATION.

E. Kiyatkin\*, R.A. Wise and A. Gratton, Douglas Hosp, Res. Ctr, McGill Univ. & Ctr Studies Behav. Neurobiol., Concordia Univ., Montreal, Canada.

Heroin has powerful habit-forming or "reinforcing" properties in humans and in lower animals. Mesolimbic dopamine (DA) neurons that innervate nucleus accumbens (NAcc) are thought to mediate the reinforcing effects of many abused drugs, including heroin. In the present study, high-speed chronoamperometry was used to monitor, on 5-6 consecutive daily recording sessions, DA-dependent electrochemical signals in NAcc of rats allowed to lever-press for intravenous heroin (100µg/kg/injection). The electrochemical signal increased gradually after the first drug infusion each day and electrochemical signal increased gradually after the first drug infusion each day and remained at this elevated level for the rest of the session at which time transient changes in the signal that were time-locked to operant responses were observed. Each response for heroin was preceeded by a reliable increase and followed by a comparable decrease in the electrochemical signal. Doubling the expected dose of heroin reliably potentiated the decrease in signal which then gradually returned to the elevated plateau. Blocking access to the lever at the end of the session caused the electrochemical signal to first increase slightly then to gradually return to the pre-drug baseline; naloxone (1.0 mg/kg i.p.) accelerated the decline of the signal. The present results are generally consistent with the stimulant action of opiates on mesolimbic DA neurons. However, they also suggest a more complex role of this system in opiate reinforcement than has been previously predicted. While extracellular DA levels in NAcc were tonically elevated during heroin self-administration, reinforcement of operant responding by the drug was accompanied by a decrease in extracellular DA, whereas increased DA efflux was more closely associated with the behavioral arousal that preceded each response. Supported by FCAR, NIDA and NSERC.

INVOLVEMENT OF MESOLIMBIC DOPAMINE NEURONS IN THE INITIATION OF SENSITIZATION TO MORPHINE. <u>Michael Jeziorski\* and Francis J. White</u>, Neuropsychopharmacology Lab, Lafayette Clinic, Cellular and Clinical Neurobiology Program, Dept. of Psychiatry, Wayne State University School of Medicine, Detroit MI 48207.

Repeated daily administration of morphine at a moderate dose induces sensitization to the acute stimulatory effects of morphine upon locomotion. Single unit electrophysiological studies have revealed that the basal firing rate of dopamine (DA) neurons within the ventral tegmental area (VTA), the nucleus most extensively implicated in the initiation of this sensitized response, is increased in morphine-sensitized rats (4.7 ± 0.2 Hz) in comparison to control (3.5 ± 0.2 Hz). This elevation persists to a lesser degree in rats withdrawn for 7 days from repeated morphine treatment (4.2 ± 0.2 Hz), mimicking the persistent behavioral response to morphine. We have previously shown that development of the behavioral sensitization produced by 14 day morphine treatment (10 mg/kg/day, i.p.) is blocked by administration of the NMDA receptor antagonist MK-801 (0.25 mg/kg/day, i.p.) prior to each morphine injection. Coadministration of MK-801 and morphine for 14 days also attenuates the increase in basal firing rate of DA cells (4.0 ± 0.2 Hz). Because the actions of morphine within the VTA are likely mediated via GABAergic interneurons, the possibility that alterations in the responses of these neurons are associated with the increase in DA cell activity was also evaluated. DA cells in morphine-sensitized rats displayed a slightly enhanced sensitivity to iontophoretic application of GABA (0.1 M, pH 4.0). Preliminary recordings of non-DAergic neurons within the VTA revealed inhibitory responses to iontophoretic morphine (0.02 M, pH 4.0) which were attenuated in morphine-sensitized rats. #### PSYCHOTHERAPEUTIC DRUGS: CLOZAPINE AND DOPAMINE ANTAGONISTS

#### 158.1

CLOZAPINE AND HALOPERIDOL IN A NOVEL MODEL FOR ASSESSING ANTIPSYCHOTIC POTENCY. N.R. Swerdlow and M.A. Geyer. UCSD Dept. of Psychiatry, La Jolla, CA 92093

Startle is inhibited or "gated" when the startling stimulus is preceded 30-500 msec earlier by a weak prepulse. "Prepulse inhibition" (PPI) is deficient in schizophrenics and in rats treated with dopamine (DA) agonists. We have reported that the ability of neuroleptics to restore PPI in DA-stimulated rats is a sensitive and specific predictor of clinical antipsychotic potency. The DA agonist apomorphine (APO) potently disrupts PPI, and the ability of neuroleptics to reverse this APO effect correlates highly (0.99) with clinical potency. In the present study, we compared the effects of typical and atypical antipsychotics in this model. Haloperidol and clozapine restored PPI in APO-treated rats; haloperidol followed simple monotonic dose-responsivity, while clozapine exhibited a previously reported "inverted-U" doseresponse curve, restoring PPI at low doses, but not high doses. Similarities and differences were also noted in the ability of these drugs to enhance baseline startle gating (increase prepulse effectiveness), and to restore PPI after intra-accumbens DA infusion. The restoration of PPI in DA-activated rats is a predictive model that is sensitive to both typical and atypical antipsychotics, and may also identify important differences in the abilities of these agents to rectify deficits in sensorimotor gating.

## 158.3

THE DOPAMINE D4 AND D2 RECEPTORS: COMPARISON OF NEUROLEPTIC BINDING AFFINITIES. L.M. Figur, D.L. Evans, N.C. Stratman and R.A. Lahti.\* CNS Diseases Research, Upjohn Laboratories, Kalamazoo, MI 49001.

The dopamine D4 receptor, which is considered to be a variant of the D2 receptor, has recently been cloned and then expressed into COS-

The dopamine D4 receptor, which is considered to be a variant of the D2 receptor, has recently been cloned and then expressed into COS-7 cells. Receptor binding studies demonstrated that clozapine, which an effective antipsychotic agent but atypical in that it lacks the usual side effects of typical antipsychotic agents, has high selectivity for the D4 vs. the D2 receptor (H.Van Tol et al., Nature 350:610, 1991).

Comparative binding studies have been carried out for a number of interesting dopaminergic agents using membranes from the CHO-D2 and COS-7-D4 cells and 3H-YM-09151-2 as the ligand. It was found that clozapine is selective for the D4 vs. the D2 receptor by a factor of 2.8. Other compounds with D4 selectivity (K, D2/K, D4) were (+)apomorphine (8.7), (+)-NPA (2.4) and melperone (1.3). Compounds with selectivity for the D2 receptor (K, D4/K, D2) were trifluoperazine (30.1), chlorpromazine (11.9), thioridazine (8.2), SDZ-208-912 (3.9), haloperidol (3.3), and loxapine (2.9). Compounds such as AJ-76 (1.1) and (-)3-PPP (1.6) exhibited low selectivity for the D2 receptor.

The findings are of considerable interest not only because of the selectivity of the atypical antipsychotic agent clozapine for the D4 receptor but because of the selectivity of the typical antipsychotic agents such as chlorpromazine, trifluoperazine, and haloperidol for the D2 receptor. Results may be interpreted to indicate that D2 selectivity confers side effect liability (EPS and TD) and D4 selectivity confers antipsychotic efficacy on neuroleptics.

### 158.2

PROPRANOLOL DOES NOT SUBSTITUTE FOR CLOZAPINE IN CLOZAPINE-TRAINED RATS IN A TWO-LEVER DRUG DISCRIMINATION PROCEDURE. A.D. Compton\*, B.M. Kelley, J.L. Wiley, and J.H. Porter. Virginia Commonwealth University, Richmond, Virginia 23284.

Although clozapine (CLZ) acts at several types of receptors in vitro and in vivo, the mechanism of action for its discriminative stimulus properties has not yet been determined. Previous research has shown that drugs acting at D1 and D2 dopamine receptors, at 5-HT1A, 5-HT2, and 5-HT3 serotonin receptors, and at alpha nor-adrenergic receptors fail to substitute for CLZ in CLZ-trained rats. The present study examined the effects of propranolol, a beta nor-adrenergic receptor blocker, in stimulus substitution tests with CLZ-trained rats. Six adult male Sprague-Dawley rats (85% BW), trained to discriminate CLZ (5 mg/kg, i.p.) from vehicle in a two-lever drug discrimination procedure, were tested in 15 min sessions under an FR3O schedule of food reinforcement. Stimulus generalization tests with CLZ (1.25, 2.5, 5, & 10 mg/kg, i.p.) produced dose-dependent generalization from the training dose. Propranolol (2.5, 5, 10, 20, 25, & 30 mg/kg, i.p.) produced less than chance levels of responding on the CLZ lever; although, interestingly, 2 of the 6 animals generalized completely across the 4 highest doses. Thus, the exact mechanism of CLZ's discriminative stimulus properties remains to be determined.

## 158.4

EFFECTS OF HALOPERIDOL(HAL) AND CLOZAPINE(CLOZ) ON THE ABILITY OF COCAINE TO INCREASE DOPAMINE RELEASE IN RAT STRIATUM (STR) AND NUCLEUS ACCUMBENS (NA) AS MEASURED BY IN VIVO BRAIN MICRODIALYSIS. Baoling Chai<sup>6</sup> and H Y. Meltzer, Case Western Reserve Univ.Sch.of Med., Cleveland, OH 44106

The effects of two antipsychotic agents HAL and CLOZ on DA release and metabolism(dihydroxyphenylacetic acid, DOPAC) in the Str and the N.A. of freely moving rats were investigated using in vivo microdialysis. Cocaine(5 mg/kg,s.c.) produced equivalent increases in DA (221% and 244% of baseline level at the maximum level) and decreases in DOPAC(42% and 35%) efflux in the Str and the N.A., respectively. HAL(2mg/kg,s.c.) 30min prior to cocaine(5 mg/kg,s.c.) increased cocaine-induced DA release(380% and 615%) together with a 210% and 207% increase in DOPAClevel in the Str and the N.A. CLOZ (20mg/kg,s.c.) 30 min prior to cocaine (5mg/kg,s.c.) increased cocaine-induced DA release(456%), produced137% increases in DOPAC levels in the N.A. only. These results suggest that both types of antipsychotics facilitate DA efflux due to cocaine. This would counteract their ability to block the euphoric effects of cocaine. However the D1, D2, and D4 antagonist properties of CLOZ and D2 antagonist properties of HAL would block the effects of DA.

ACTIONS OF CLOZAPINE AND HALOPERIDOL ON THE EXTRACELLULAR LEVELS OF EXCITATORY AMINO ACIDS IN THE PREFRONTAL CORTEX AND STRIATUM: A COMPARISON TO DOPAMINE. K.D. Youngren, D.A. Daly, and B. Moghaddam, Department of Psychiatry and Interdepartmental Neuroscience Program, Yale Univ. Sch. of Med., and VA Medical Center, West Haven, CT, 06516.

The technique of intracerebral microdialysis was employed to assess the effects of clozapine and haloperidol on the extracellular levels of excitatory amino acids, aspartate and glutamate, in the striatum and prefrontal cortex of conscious rats. Haloperidol (0.5 mg/kg s.c.) had no significant effect on the levels of excitatory amino acids in either region. Clozapine (12.5 mg/kg s.c.) was without a significant effect in the striatum; however, it significantly extracellular concentration of both decreased the aspartate and glutamate in the prefrontal cortex. We have previously reported that acute and chronic treatment with clozapine alters the outflow of dopamine in the prefrontal cortex to a greater degree than in the striatum. Thus, it seems that clozapine has preferential actions on extracellular levels of both excitatory amino acids and dopamine in the prefrontal cortex. The effect of chronic clozapine, as well as higher doses of acute clozapine, on the outflow of excitatory amino acids is currently investigation.

#### 158.7

CLOZAPINE AT HIGH CONCENTRATIONS INTERACTS WITH THE CANNABINOID RECEPTOR. <u>D.M. Evans\* and A.C. Howlett.</u> Dept. of Pharmacological and Physiological Science, St. Louis Univ. Sch. of Med., St. Louis, MO 63104.

Previous reports have indicated that acute intraperitoneal injection of the neuroleptic clozapine into male Swiss-Webster mice produces hypothermia and ataxia in these animals (Menon et al., Life Sci. 43, 1791-1804 (1988)). Furthermore, bilateral microinjection of clozapine into rat brains results in catalepsy (Fog, R. Int. Pharmacopsychiatr. 10, 89-93 (1975)). These effects are characteristic of animals exposed to cannabinoid drugs (Compton et al., Marijuana, Intnatl. Res. Rep. 1987, pp. 213). In order to determine whether clozapine could interact with the cannabinoid receptor, we assessed the ability of this compound to inhibit the binding of the synthetic cannabinoid [3H]CP55,940 to rat brain membranes in vitro using a standard filtration assay. Clozapine produced a dose-dependent decrease in the specific binding of this ligand whilst its vehicle at the appropriate concentrations was without effect. The IC<sub>50</sub> for inhibition by the neuroleptic approximated  $50\mu M$ . Furthermore, clozapine was able to inhibit adenylate cyclase activity in membranes prepared from N18TG2 neuroblastoma cells. Inhibition of forskolinstimulated cyclase activity by 41% was observed in the presence of  $200\mu M$  clozapine. The data would suggest that, at very high concentrations, some of the effects of clozapine may, at least in part, be due to interaction with central cannabinoid receptors

Supported by NIDA grants DA-03690 and DA-06912.

## 158.9

ANTAGONISM OF THE DISCRIMINATIVE STIMULUS EFFECTS OF THE SELECTIVE HIGH-EFFICACY D<sub>1</sub> AGONIST SKF 81297 BY THE ATYPICAL NEUROLEPTIC CLOZAPINE IN SQUIRREL MONKEYS. <u>S.</u> Rosenzweig-Lipson\* and J. Bergman. Harvard Medical School/NERPRC, Southboro, MA 01772.

Recent evidence suggests that the behavioral effects of the atypical neuroleptic clozapine may be related to its blockade of D<sub>1</sub> receptors. In the present study, the D<sub>1</sub>-related actions of clozapine were evaluated in squirrel monkeys trained to discriminate the selective, high-efficacy D, agonist SKF 81297 (0.3 - 1.0 mg/kg) from saline in drug discrimination procedures. Monkeys were trained under a 10-response fixed-ratio schedule of stimulusshock termination to respond differentially on left and right levers depending on whether drug or saline was injected. Incremental doses of SKF 81297 (0.01 - 1.0 mg/kg) produced dose-related increases in responding on the drug-associated lever in all monkeys. Pretreatment with the selective D antagonist SCH 39166 (0.03 - 0.1 mg/kg) resulted in a dose-dependent rightward shift of the SKF 81297 dose-effect curve, indicative of surmountable antagonism. Pretreatment with clozapine (0.3 - 3 mg/kg) blocked the discriminative-stimulus effects of SKF 81297. However, the effects of clozapine appeared to differ in individual monkeys. In some cases, clozapine produced a rightward shift of the SKF 81297 dose-effect by SKF 81297 up to 3.0 mg/kg. The present results indicate that the behavioral effects of clozapine in monkeys involve its D, receptor-mediated actions. Supported by USPHS Grants DA03774, DA00499, MH07658, and RR00168.

EFFECT OF SCOPOLAMINE (Scop) ON CLOZAPINE (CLOZ) AND HALOPERIDOL (HAL) INDUCED DOPAMINE (DA), EFFLUX IN THE STRIATUM (STR), NUCLEUS ACCUMBENS (NA) AND PREFRONTAL CORTEX (PFC). H. Y. Meltzer', B-L. Chai and B. Yamamoto, Department of Psychiatry, Case Western Reserve University School of Medicine, Cleveland, OH 44106

CLOZ, an atypical antipsychotic drug (APD), is a potent anticholinergic agent. Nevertheless, in a recent in vivo voltammetric study (Rivest and Marsden, 1991), SCOP, another potent anticholinergic agent, inhibited the CLOZ-, but not the HAL-induced increase in dihydroxyphenylacetic (DOPAC), the DA metabolite, in the rat STR and NA. We now report that CLOZ 20 mg/kg and HAL 1 mg/kg, significantly increased STR DA release as measured by in vivo microdialysis in awake freely moving rats (159.0% and 226.3, respectively). SCOP, 1 mg/kg, had no effect on basal DA release but significantly reduced the effect of CLOZ (69.5%) but not HAL (228.7%) on STR extracellular DA. SCOP treatment also did not affect the ability of CLOZ to increase the release of DA in the NA or PFC. SCOP also did not block the ability of thioridazine (144.8%), another APD with strong anticholinergic properties which has been thought to be atypical, to enhance the release of DA in the STR. These results suggest CLOZ increases striatal DA efflux by an acetylcholine-dependent mechanism which can be blocked by SCOP. CLOZ may be an indirect cholinomimetic agent and a selective antagonist of specific muscarinic receptors. These results suggest that an effect of CLOZ on the cholinergic system to modulate STR DA release may be related to its better profile of effects on the extrapyramidal system compared to typical APD.

BEHAVIORAL EFFECTS OF CHRONIC CLOZAPINE ARE ALTERED BY IBOTENIC ACID LESIONS OF THE RAT MEDIAL PREFRONTAL CORTEX G. Hussain, G.E. Jaskiw\*, H.Y. Meltzer-Psychobiol. Dept., Case Western Reserve Univ., Cleveland, OH 44106 / Brecksville VAMC, OH.

Frontal cortex lesions which spare much of the only modestly medial prefrontal cortex (MPFC) influenced the behavioral effects of chronic clozapine (CLZ) treatment (Abstr. Soc. Neurosci. 1991, p 99). However, CLZ may exert unique actions within the MPFC. We now induced ibotenic acid (IA) lesions in the MPFC of male Zivic-Miller rats (220-250 gr). After 21d, rats began a 21d treatment with haloperidol (HAL) 2 mg/kg/d, clozapine (CLZ) 20 mg/kg/d or vehicle in drinking water. 3d after the end of chronic treatment, apomorphine 0.75 mg/kg sc was administered and behavior visually assessed. As expected, HAL pretreatment increased biting but reduced stationary behavior. Compared to SHAM/CLZ animals, IA/CLZ rats also displayed more oral stereotypies and were generally more active. These data indicate that actions within the MPFC may contribute to some of the atypical effects of CLZ. Supported by NARSAD.

## 158.10

EFFECTS OF LOCAL ADMINISTRATION OF CLOZAPINE IN THE RAT STRIATUM AND PREFRONTAL CORTEX ON DOPAMINE LEVELS. E.A. Pehek\*and B.K. Yamamoto. Dept. of Psychiatry, Case Western Reserve Univ. Sch. of Med., Cleveland, OH 44106

Previous research has demonstrated that systemic administration of the atypical antipsychotic clozapine increased extracellular dopamine (DA) levels in the rat brain and this increase was greater in cortical and limbic areas relative to the caudate-putamen (CP). However, it has not been determined whether these effects were due to direct actions of clozapine on DA nerve terminals in these regions or, alternatively, on their midbrain cell bodies of origin. The aim of the present study was to compare the effects of local infusions of clozapine in nerve terminal and cell body areas on DA levels in the medial prefrontal cortex (MPFC) and CP. In vivo microdialysis coupled with HPLC/EC was used to measure extracellular DA every 30 min. in the freely moving rat. After basal DA stabilized, a 1.0 mM solution of clozapine was infused through the probe for one hour and samples were collected for three hours. Data were expressed as percentages of the average baseline values. Administration of clozapine directly into the cortex increased cortical DA levels (239% during the first 30 min. of drug application, 244% during the second 30 min, and 189% 30 min. after termination of the infusion). Likewise, striatal administration increased DA levels in the CP (286%, 156%, and 66%, respectively). These results suggest that systemically administered clozapine may increase DA via direct actions on DA nerve terminals. Further research will examine the effects of clozapine infusions into regions A9 and A10 of the midbrain and will contrast striatal with cortical effects.

CLOZAPINE AND HALOPERIDOL DIFFERENTIALLY EFFECT COGNITIVE ACTIVATION IN SCHIZOPHRENICS AS MEASURED BY REGIONAL CEREBRAL BLOOD FLOW (rGBF) PET. D. Z. Press\*, K. F. Berman, T. Noga, L. B. Bigelow, J. L. Ostrem, D. R. Weinberger, HHMI-NIH RSP and Clinical Brain Disorders Branch, NIMH-DIRP St. Elizabeth's Hosp., Washington, D.C.

Atypical neuroleptics such as clozapine (CLZ) differ from standard neuroleptics such as haloperidol (HAL) both in their pharmacology and their clinical efficacy. Because of the widely varying pharmacologic differences, the basis for the clinical differences remains elusive. To investigate the neural systems underlying these differences we examined cortical physiology with the H<sub>2</sub>15O method of positron emission tomography (PET) in schizophrenics both while on CLZ (titrated clinically, mean dose 533 mg/day) and on HAL (.4 mg/kg/day) in a crossover, counterbalanced design.

rCBF measurements were taken while subjects performed cognitive tasks (including the Wisconsin Card Sort [WCS], Raven's Progressive Matrices [RAV] and a novel Delayed Alternation [DA] task) and matched sensory-motor control tasks. 15 transaxial slices were acquired with axial and in-plane resolution of 6.5mm after reconstruction. rCBF data were normalized, and both studies were resliced so that they were registered to a single MRI. Regions of

interest were defined on the MRI and then applied to both PET studies.

Results from the first 6 subjects show that in the basal ganglia, there was a trend towards decreased blood flow while on CLZ as compared to HAL for almost all tasks. During DA and RAV there was more activation (task - control) in the left dorsolateral prefrontal cortex while on CLZ than on HAL (p<.05, p<.10 respectively). No such trend was seen during the WCS. On the right a less significant trend in the opposite direction (HAL>CLZ) was seen. CLZ and HAL may have differing effects on tasks mediated by different neural systems

IDENTIFICATION OF PD 139899 AS A NOVEL DOPAMINE AUTORECEPTOR AGONIST WITH ANTIPSYCHOTIC-LIKE ACTIVITY. L.D. Wise\*, D.J. Wustrow, W.J. Smith III, L.T. Meltzer, T.A. Pugsley, T.G. Heffner, Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co. Ann Arbor MI 48106.

Research Division, Warner-Lambert Co. Ann Arbor MI 48106. PD 139899 was selected from a novel series of aminoalkyl-cyclohexylindoles with dopamine (DA) autoreceptor agonist activity. Structure-activity studies indicate that a trans-cyclohexylethyl side chain and a pyridylpiperazinyl amino moiety provide optimal activity within this series. PD 139889 displays high affinity for DA D2 receptors in vitro with an IC50 of 3 nM. In rats PD 139899 activates brain DA autoreceptors as evidenced by reversal of gamma-butyrolactone-stimulated brain DA synthesis and inhibition of nigrostriatal DA neuron firing. Consistent with the profile of other DA autoreceptor agonists, PD 139899 reduces spontaneous locomotor activity (LMA) in mice (ED50 = 1.4 mg/kg IP) but even at much higher doses does not attenuate stimulation caused by the direct DA agonist apomorphine. In rats, PD 139899 inhibits LMA (ED50 = 2.4 mg/kg PO) but does not cause the LMA activation indicative of stimulation of postsynaptic DA receptors in brain, even at high multiples of its LMA ED50. cause the LMA activation indicative of stimulation of postsynaptic DA receptors in brain, even at high multiples of its LMA ED $_{50}$ PD 139899 also does not elicit stereotypy even in the presence of a DA D $_{1}$  agonist. In squirrel monkeys PD 139899 inhibits conditioned avoidance responding after oral dosing (ED $_{50}$  = 1.0 mg/kg). Collectively, these results indicate that PD 139899 is a potent DA autoreceptor agonist with antipsychotic-like effects in resolving later. preclinical tests.

## 158.15

COMPARISON OF PARTIAL DOPAMINE D<sub>2</sub> AGONISTS WITH NEUROPHYSIOLOGICAL AND BEHAVIORAL TESTS.

COMPARISON OF PARTIAL DOPAMINE D<sub>2</sub> AGONISTS WITH NEUROPHYSIOLOGICAL AND BEHAVIORAL TESTS. A.E. Corbin\*, C.L. Christoffersen, K.A. Serpa, I.N. Wiley, L.T. Meltzer and T.G. Heffner, Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co., Ann Arbor, MI 48106. Dopamine (DA) D<sub>2</sub> agonists inhibit locomotor behavior in rodents by direct effects on brain DA autoreceptors and may also act via antagonist-like partial agonist actions at brain DA postsynaptic receptors. In order to estimate partial agonist activity of DA D<sub>2</sub> agonists, drugs were compared for maximal inhibition of substantia nigra DA neuron firing and for ability to antagonize the locomotor stimulatory effect of a low postsynaptic dose of the DA agonist apomorphine in rats. For neuronal firing, relative intrinsic activity was: apomorphine, quinpirole > EMD 38362, PD 128483 > terguride > SDZ 912 > haloperidol (inactive). Whereas DA agonists and antagonists inhibited spontaneous locomotor activity (SLA), partial DA agonists and DA antagonists were also effective at reversing apomorphine-stimulated locomotor activity (ALA). The ratio of ALA ED<sub>50</sub> / SLA ED<sub>50</sub> was used as an estimate of intrinsic activity, corrected for potency, for the behavioral data. This ratio was 1 or less for DA antagonists and greater than 100 for full DA agonists such as quinpirole. Ranking of compounds on the basis of ALA/SLA ratio gave the results: quinpirole, B-HT 920, (+)-3-PPP > SEMD 38362, PD 128483 > terguride, SDZ 911, (-)-3-PPP > SDZ 912, remoxipride & other DA antagonists. These results indicate close agreement between neurophysiological and behavioral measures of partial DA D<sub>2</sub> agonist activity.

CHRONIC HALOPERIDOL TREATMENT REDUCES GLUTAMATE RECEPTOR BINDING IN LIMBIC STRUCTURES OF RAT BRAIN T.Kakigi\* X.M.Gao, O.Shirakawa, C. Maryland, MPRC, Baltimore MD 21228 C.A.Tamminga University of

Haloperidol is a neuroleptic drug with potent antagonist activity at the dopamine D2 receptor. It is used chronically in the treatment of schizophrenia, with broad antipsychotic activity. Chronic haloperidol treatment causes spontaneous oral dyskinesias called vacuous chewing movements (VCMs) in rat. To understand the pathophysiology of these movements and the extended mechanism of its antipsychotic effect, we have studied neurochemical effects of chronic haloperidol. Previously, we have reported regional changes in D<sub>1</sub>, D<sub>2</sub>, and GABA-A receptors with chronic haloperidol and their correlation with VCMs. Here we report the effects of chronic haloperidol on glutamate receptor subtypes. Animals were treated with haloperidol (1.5mg/kg/day) in their drinking water for 6 months. NMDA receptors were quantified using <sup>3</sup>H-glutamate, AMPA receptors, using <sup>3</sup>H-AMPA, both with standard technique. Our results show that chronic haloperidol treatment decreases the <sup>3</sup>H-AMPA binding in the nucleus accumbens, subiculum and entorhinal cortex, and decreases the NMDA sensitive <sup>8</sup>H-glutamate binding in the CA1, posterior cingulate, parietal cortex, and amygdala. Results from kainate and metabotropic glutamate receptor quantification will be reported. It appears that drug treatment effects glutamate receptors in certain limbic related structures while showing no effect in neocortical areas. We report regionally selective, not generalized, modulation of glutamate receptors by chronic haloperidol. We propose that this is related to the functions of haloperidol which do not show tolerance; and, may be pertinent to postmortem studies in schizophrenia.

## 158.14

CHARACTERIZATION OF PD 139899: A NOVEL DOPAMINE AUTORECEPTOR AGONIST WITH ANTIPSYCHOTIC-LIKE ACTIVITY. T.G. Heffner\*, A.E. Corbin, L.W. Cooke, M.D. Davis, S.B. DeMattos, L.M. Georgic, R.G. MacKenzie, F.W. Ninteman, T.A. Pugsley, S.Z. Whetzel, J.N. Wiley, D.J. Wustrow and L.D. Wise. Parke-Davis Pharmaceutical Research Division, Warner-Lambert Company, Ann Arbor MI 48106.

PD 139899 exhibited effects characteristic of a dopamine (DA) autoreceptor agonist and partial DA D₂ agonist in preclinical tests. In addition to DA D₂ receptor affinity, PD 139899 had weak affinity for DA D₁ receptors as well as 5HT₂ receptors and had modest affinity for sigma, 5HT₁A and α₁-adrenergic receptors. The affinity for D₂ receptors was reduced 4-fold by sodium and GTP, a larger shift than seen with DA antagonists but smaller than seen with full DA agonists. PD 139899 also caused DA agonist-like inhibition of forskolin-stimulated adenylyl cyclase activity in GH4C1 cells transfected with the human DA D₂ receptor. Like other DA agonists, PD 139899 inhibited GBL-stimulated striatal DA synthesis in rats and the maximal effect was reduced by pretreatment with the receptor alkylating agent EEDQ. Like DA antagonist antipsychotics, PD 139899 inhibited locomotor activity in rats and caused long-lasting inhibition of conditioned avoidance in squirrel monkeys. But, in contrast to DA antagonists, PD 139899 inhibited striatal DA synthesis and reduced DA overflow as measured with intracerebral microdialysis (ICMD) in rats and squirrel monkeys. Efficacy in rats and reduced DA overflow as measured with intracerebral microdialysis (ICMD) in rats and squirrel monkeys. Efficacy in rats was maintained in the GBL and ICMD tests during repeated dosing. These findings demonstrate a DA autoreceptor agonist/partial DA agonist mechanism of action for PD 139899 and provide evidence of antipsychotic-like effects.

## 158.16

IDENTIFICATION OF THE ACTIVE CONFORMATION OF A NOVEL SERIES OF BENZAMIDE DOPAMINE D2 AGONISTS. D.J. Wustrow, W.J. Smith III, D.M. Reynolds, L.D. Wise, R.G. MacKenzie, T.A. Pugsley, T.G.Heffner, L.M. Georgic\* and T. Mirzadegan, Parke-Davis Pharmaceutical Research Division, Warner-Lambert Company, Ann Arbor Michigan 48106

The benzamide PD 137510 was shown to be a dopamine (DA) autoreceptor agonist (Soc. Neurosci. Absts. 17: 689, 1991). In order to probe the conformation of the ethylene chain connecting the cyclohexylbenzamide and pyridylpiperazine portions of PD 137510, a series of rigid analogs were prepared. PD 140222 was identified as being more potent in the DA D2 binding assay (IC50 73 nM Vs 443 nM) than PD 137510. PD 140222 also exhibited potent activity in the mouse locomotor activity screen (ED<sub>50</sub> 0.10 mg/kg). The inherent conformational stability in PD 140222 suggests the conformation of PD 137510 which is bound by the D2 receptor. The agonist activity of these molecules was further evaluated using inhibition of forskolin-stimulated cAMP accumulation in GH<sub>4</sub>C<sub>1</sub> cells transfected with the human D2 receptor. The results will be discussed in terms of a hypothetical model of the D2 receptor.

ALTERATIONS IN DOPAMINERGIC AND GABAERGIC MECHANISMS OF THE VENTROLATERAL STRIATUM OF RATS PRETREATED WITH DIFFERENT REGIMENS OF CHRONIC NEUROLEPTICS: A MICRODIALYSIS STUDY. A.S. Keys\* and G.D. Ellison, UCLA, Department of Psychology, Los Angeles, CA. 90024-1563

Rats given longterm neuroleptic exposure develop dramatically different oral syndromes depending upon whether the neuroleptic is administered continuously or once weekly. The present study utilized microdialysis procedures to examine alterations in the ventrolateral striatum. This area was selected because of its known involvement in the circuitry that mediates bucco-lingual movements of rats pretreated with chronic haloperidol for over a year in these two different regimens. Levels of DA and its metabolites in addition to GABA were assayed using HPLC with electrochemical detection. A time-linked measure of activity was collected on-line during dialysis collection and correlated with probe infusion action. The response to intrastriatal infusions of the selective dopamine d-2 antagonist, raclopride or the GABA agonist, muscimol, in addition to i.p. injections of haloperidol were examined. The results suggest that while differences in response to challenge infusions, as measured by DA and metabolite levels, exist between the control and both neuroleptic treated groups, some differences in the recovery of DA metabolites after challenge infusions exist between the two neuroleptic regimen groups.

#### 158.19

WAY-124,486: CHARACTERIZATION OF A SERIES OF AMINOMETHYLBENZODIOXANS AS DOPAMINE AUTORECEPTOR AGONISTS. G.P. Stack. K.L. Marquis. N.T. Scherer. Y.H. Kang. T.B. Spangler. R.A. Scerni. T.D. Gardner. A.T. Shropshire. R.F. Kucharik. M.J. Piesla. M. Abou-Gharbia\*. T.H. Andree. Wyeth-Ayerst Research, CN 8000, Princeton, N.J. 08543. A series of aminomethylbenzodioxan derivatives was examined both

A series of aminomethylbenzodioxan derivatives was examined both in vitro (for D2 agonist and antagonist affinity) and in vivo (in the GBL rat model of DOPA accumulation) for the ability to function as dopamine autoreceptor agonists. The compounds were further characterized behaviorally for their effect on mouse locomotor activity, for the ability to induce (either alone or with the D1 agonist SKF 38393) stereotypy or climbing or to antagonize apomorphine-induced effects, and for the inhibition of conditioned avoidance responding. Structural elements examined include a variety of alkyl, aralkyl and aryloxyalkyl substitutions on nitrogen, hydroxy, alkoya, alkyl and halo substitutions on the benzodioxan moiety, and the chirality of the aminomethyl function. Dopamine autoreceptor activity was optimized by a hydroxyl function in the 7 position, alkylation of the amine with a 3-(3-aminophenoxy)propyl group and an S configuration at the asymmetric center. These studies (Wasik et al., Gardner et al., Uzzle et al., this meeting) led to the identification of WAY-124,486 (1) as a dopamine autoreceptor agonist with a preclinical antipsychotic profile.

## 158.21

WAY-124486: A PSYCHOPHARMACOLOGICAL PROFILE OF A DOPAMINE AUTORECEPTOR AGONIST ANTIPSYCHOTIC. T.D. Gardner. A.T. Shropshire. R.F. Kucharik. M.J. Piesla, G. P. Stack, and K.L. Marquis\*. Wyeth-Ayerst Research, CN 8000, Princeton, NJ 08543. WAY-124486, a benzodioxanmethylamine which inhibits DOPA accumulation in

WAY-124486, a benzodioxammethylamine which inhibits DOPA accumulation in the rat (Wasik  $et\,al.$ , this meeting), was evaluated in behavioral studies for its potential antipsychotic activity. WAY-124486 reduced mouse locomotor activity with an ED50 = .08 mg/kg ip and .03 mg/kg sc. One hour after oral administration, the potency estimate improved when mice were fasted (ED50 = 17 mg/kg po) versus free-fed (no effect up to 30 mg/kg po). When fasted and tested immediately, WAY-124486 reduced activity with an ED50 = 5.8 mg/kg po. Disruption of mouse rotorod performance (MED = 10 mg/kg ip) was potentiated when combined with ethanol (MED = 1 mg/kg ip). Similarly, traction reflex deficit occurred at an ED50 = 4.4 mg/kg ip. WAY-124486 blocked apomorphine-induced stereotypy and climbing in mice at an ED50 = 27.3 mg/kg ip and 1.6 mg/kg ip, respectively. At doses up to 30 mg/kg ip, WAY-124486 dinduced contralateral turning (MED = 1 mg/kg ip) in unilaterally 6-OHDA-lesioned rats. WAY-124486 blocked rat conditioned avoidance responding with AB50s of 5.2-11 mg/kg ip. WAY-124486 disrupts prepulse inhibition of acoustic startle. Thus, the dopamine autoroceptor agonist WAY-124486 exhibits a preclinical profile which predicts antipsychotic activity.

#### 158 18

ACUTE ADMINISTRATION OF HALDOL AUGMENTS DOPAMINE'S POSTSYNAPTIC EFFECTS. T.I.Lidsky\* & S.P.Banerjee. Inst. Basic Res., S.I., N.Y. Haloperidol (Hal) can either diminish or

haloperiooi (Hai) can either diminish or facilitate dopaminergic activity by blocking, respectively, postsynaptic or presynaptic D2 receptors. Hal's net effect will be the sum of its pre- and postsynaptic influences. Electrophysiological techniques were used to assess the effects of acute Hal administration on evoked activity in the striatum. Enhanced dopaminergic activity, caused by intravenous cocaine (Coc) or substantia nigra (SN) stimulation, suppressed striatal responses. Hal also caused suppression; dopamine depleting lesions in the SN blocked the effects of Coc were not attenuated by Hal. Indeed, the suppressive effects of Coc were not attenuated by Hal. Indeed, the suppressive effects of Coc and Hal were additive. Thus, acute administration of Hal actually augments dopaminergic activity due to strong presynaptic actions and weak postsynaptic blocking effects. This must be taken into account in attempting to understand the mechanisms underlying the neural changes evoked by chronic Hal administration that allow this drug to have antipsychotic potency.

#### 158.20

WAY-124,486: A NEUROPHARMACOLOGICAL PROFILE OF A DOPAMINE AUTORECEPTOR AGONIST ANTIPSYCHOTIC. T.P. Wasik. R. Scerni. T. Spangler. G.P. Stack. E.A. Muth. and T.H. Andree\* CN 8000, Princeton, N.J. 08543 Wyeth-Ayerst Research,

WAY-124,486, an aminomethylbenzodioxan, has been investigated in a series of neurochemical assays to determine its ability to function as a dopamine autoreceptor agonist. *In vitro* receptor-binding studies using male Sprague-Dawley rat striatal homogenates have shown WAY-124,486 to have a very high affinity for D<sub>2</sub> agonist binding (IC<sub>50</sub> = 0.58 nM; quinpirole as radioligand). At D<sub>2</sub> (antagonist), 5-HT<sub>1A</sub>, alpha<sub>1</sub>, D<sub>1</sub> and 5-HT<sub>2</sub> receptors, WAY-124,486 possessed the following IC<sub>50</sub> values (nM): 47, 15, 6, 2006, 8308. WAY-124,486 was capable of inhibiting *in vitro* DOPA accumulation in rat striatal tissue silces up to 90%, with an ED<sub>50</sub> of 6.2 μM. A submaximal dose of WAY-124,486 (10 μM) that produced a 65% inhibition of *in vitro* DOPA accumulation was partially reversed (80%) by 100 μM haloperidol, a D<sub>2</sub> antagonist. In experiments designed to test the direct effect of WAY-124,486 on soluble tyrosine hydroxylase (TH), WAY-124,486 in concentrations up to 1 mM was unable to block TH activity. Simultaneously run positive controls of dopamine and apomorphine @ 1 mM, however, produced a 100% inhibition. A forskolin-activated *in vitro* model to analyze the regulation of dopamine synthesis through receptor-mediated control of the phosphorylation of tyrosine hydroxylase is currently under development. In the *in vivo* rat NSD/GBL model WAY-124,486 (10 mg/kg, sc) produced a 64% inhibition of DOPA accumulation that was completely reversed by pre-treatment with raclopride (5 mg/kg, sc). The ability of WAY-124,486 to displace quiniprice binding and to suppress both *in vivo* and *in vitro* DOPA synthesis, the latter of which is not mediated by direct action on TH and is reversed by D<sub>2</sub> antagonists, provides strong evidence for the hypothesis that the effects of WAY-124,486 to insplace the mediated through dopamine autoreceptors. Neurophysiological (Uzzle et al., this meeting) and behavioral studies (Gardner et al., this meeting) further support these conclusions. This ability of WAY-124,486 to regulate dopami

## 158.22

ACUTE EFFECTS OF WAY-124486, A NOVEL DOPAMINE AUTORECEPTOR AGONIST, ON A9 AND A10 DOPAMINE (DA) NEURONAL ACTIVITY. C. W. UZzle\*, K. L. Marquis, T. H. Andree, G. P. Stack and J. T. Haskins. Wyeth-Ayerst Research, CN 8000, Princeton, NJ 08543-8000

WAY-124486 (S)-3-[[[3-(3-aminophenoxy)propyl] amino]methyl]-2,3-dihydro-1,4-benzodioxin-6-ol dihydro-chloride binds with high affinity to the dopamine (DA) D2 receptor subtype and is a functional agonist in both in vitro and in vivo models. Neurochemical studies have shown this agent to inhibit DA synthesis (Wasik, this meeting) and behavioral studies have shown selectivity for the DA autoreceptor versus postsynaptic DA receptor (Gardner, this meeting). It was therefore of interest to compare the agonist effects of WAY-124486 (WAY) with those of apomorphine (APO) on central DA neuronal activity. Standard neurophysiological methods were used for recording. Following acute i.v. administration, both APO and WAY inhibited AlO (VTA) spontaneous neuronal activity. The ID50s were 15.63 µg/kg and 23.66 µg/kg, respectively. These values are not statistically different. When challenged with the D2 antagonist haloperidol, the agonist effects of both APO and WAY were completely reversed. These data are evidence that the agonist effects of APO and WAY on the AlO DA autoreceptor are mediated via D2 receptors. Additional testing is underway to determine the effects of APO and WAY on y (SNC) spontaneous neuronal activity and to compare these effects with those observed in AlO.

#### 158 23

EFFECT OF CHRONIC ANTIPSYCHOTIC TREATMENT ON EXTRACELLU-LAR DOPAMINE AND GLUTAMATE CONCENTRATIONS IN THE RAT STRIATUM. B.K. Yamamoto\* and M.A. Cooperman. Depts. of Psychiatry and Neuroscience, Case Western Reserve Univ., Cleveland. OH 44106

The effect of chronic treatment with haloperidol or clozapine on basal concentrations and K+-stimulated dopamine and glutamate efflux in the striatum were studied using in vivo microdialysis in the awake-behaving rat. Male rats were injected IP once daily for 21 days with haloperidol (0.5 mg/kg), clozapine (20 mg/kg) or vehicle. One day after the last injection, dialysis probes were inserted into the striatum via a guide cannula. Basal concentrations of dopamine were not significantly different between treatment groups. However, depolarization-induced dopamine release with 80 mM K was significantly attenuated in the haloperidol compared to clozapine or vehicle-treated rats. In contrast to the dopamine concentrations, basal concentrations of extracellular glutamate were significantly higher following chronic treatment with haloperidol. K\*-stimulated glutamate efflux was unaffected by haloperidol or clozapine when compared to vehicle-treated animals. Basal and stimulated taurine levels were not affected by chronic antipsychotic drug treatment. These data are suggestive of a depolarizationinactivation of dopamine nerve terminals in striatum as revealed by an attenuation of the local K+-induced stimulation of dopamine efflux. These results also provide new evidence for a role of extracellular glutamate in discriminating the neurochemical effects of chronic treatment with typical and atypical antipsychotic drugs. Experiments are currently in progress to investigate the effects of chronic neuroleptic treatment on basal and K+stimulated dopamine and glutamate efflux in the nucleus accumbens and medial prefrontal cortex.

MODULATION OF CAI HIPPOCAMPAL NEURONAL EXCITABILITY BY INHIBITION OF GABA UPTAKE WITH NIPECOTIC ACID. A.A.Oyelese, J.D.Kocsis\*&R.H.Mattson, Dept of Neurology and Sect. Neurobiology, Yale Medical School, New Haven, CT 06510; and VAMC, West Haven, CT 06516.

The rationale for the use of nipecotic acid (NPA) in clinical trials as an antiepileptic is based on its role as a GABA uptake inhibitor; inhibiting GABA uptake from the synaptic cleft is suggested to prolong its inhibitory effects on post-synaptic membranes, decreasing the hyperexcitability associated with seizure disorders. Synaptic activity was studied by stimulating Schaffer collateral afferents while recording intracellularly from CA1 neurons and extracellularly (field potentials) from the stratum radiatum in rat hippocampal slices. NPA (1.0 mM) application produced a hyperpolarization with a decrease in amplitude of both the EPSP and IPSP in CA1 neurons. With prolonged application (1 hr), neurons tended to slowly repolarize possibly due to GABA receptor desensitization and GABA clearance. These findings were corroborated by the field recordings which showed a decrease in both population EPSP amplitude and a late positivity which corresponds to IPSP activity. Following return to normal Krebs' solution, field potentials showed persistent burst discharge. Intracellular recordings revealed a repolarization and increase in EPSP amplitude with the appearance of burst discharge. This hyperexcitability upon NPA washout may be explained by increased uptake of GABA by glia on the removal of NPA and decreased GABA release by GABAergic interneurons secondary to prolonged depletion of stores by NPA. These results indicate that NPA modulates the excitability of CA1 neurons in agreement with reduced GABA uptake and secondary to accumulation of GABA.

Supported in part by the NIH and Department of Veterans Affairs.

IN VITRO AND IN VIVO EFFECTS OF ANTICONVULSANT DRUGS ON PERIPHERAL BENZODIAZEPINE RECEPTORS OF HUMAN LYMPHOCYTES. C.Ferrarese\*, C.Marzorati¹, M.Perego¹, G.Bianchi, G.Moretti¹ and L.Frattola. Dept. of Neurology, University of Milan, S.Gerardo Hospital, Monza, and (1)Scientific Institute E. Medea, Bosisio Parini, ITALY.

We investigated possible effects of antiepileptic drugs on peripheral benzodiazepine receptors (PBR) of human lymphocytes. Drug activities were evaluated on *in vitro* binding of PBR ligands <sup>3</sup>H-PK11195 and <sup>3</sup>H-Ro5-4864. Possible modifications of PBR density and affinity in lymphocytes incubated with drugs *in vitro* or taken from patients under anticonvulsant medications were also investigated.

Various concentrations of phenobarbital (PB), diphenylidantoine (DPH), carbamazepine (CBZ) and valproic acid (VPA) were added to the binding mixture or incubated overnight with lymphocyte primary culture, and subsequently washed before binding experiments. Lymphocytes prepared from 40 epileptic patients under various treatments and from 10 untreated controls were processed to assess PBR density and affinity in intact cells and in membrane preparations.

Displacement curves of antiepileptic drugs revealed that CBZ and PB may bind to PBR at concentrations similar to plasma therapeutic levels, while various drugs did not affect receptor density and affinity after overnight incubation. On the contrary, long-term treatment in epileptic patients induced different modifications of PBR densities.

Such findings may reveal a role of PBR in mediating immuno-endocrine effects of antiepileptic drugs.

ANTICONVULSANT ACTIVITY OF CENTRALLY ADMINISTERED D-CYCLOSERINE IS ANTAGONIZED BY 7-CHLOROKYNURENIC ACID. <u>S.L. Peterson</u>\*. Dept. of Medical Pharmacology and Toxicology, Texas A&M University Health Science Center, College Station, Texas 77843.

Previous studies in this laboratory have shown the anticonvulsant activity of systemically administered D-cycloserine (DCS) in maximal electroshock seizures (MES) to be stereospecific and antagonized by 7-chlorokynurenic acid. The purpose of the present study was to characterize the activity of DCS in MES after intracerebroventricular (icv) administration.

MES was induced in male Wistar rats by passing a 60Hz, 150mA and 0.2 sec duration current through saline-soaked corneal electrodes. Seizure severity was quantified by tonic hindlimb extension. The animals were implanted with icv injection guide cannulas 4-7 days prior to testing.

The time of peak anticonvulsant activity for DCS occurred 2 hours after icv administration. The approximate  $\mathrm{ED}_{50}$  for icv administration at 2 hours was 5  $\mu$ mole. The anticonvulsant activity of 10  $\mu$ mole DCS (icv) was completely antagonized by 100 nmole 7-chlorokynurenic acid administered icv 5 min prior to seizure test.

The antagonism by 7-chlorokynurenic acid is evidence that DCS may act at the strychnine-insensitive glycine receptor to inhibit MES. (Supported by NIH grant 24566).

THE EFFECTS OF PHENYTOIN (PHT) ON 4-AMINOPYRIDINE (4AP)-INDUCED CHANGES IN NEUROTRANSMITTER AMINO ACIDS (AA) IN RAT HIPPOCAMPUS IN VITRO. I.M. Kapetanovic\*. W.D. Yonekawa and H.J. Kupferberg. Epilepsy Branch, NINDS, NIH, Bethesda, MD 20892.

The balance between the effects of inhibitory (GABA) and excitatory [glutamate (GLU) and aspartate (ASP)] neurotransmitter AA may be important in the pathogenesis and potential treatment of epilepsy. Newly synthesized (NEW) AA may be more closely related to neuronally active pools than to total tissue concentrations. 4AP, a voltage dependent potassium channel inhibitor, causes tonic-clonic and electrographic seizures in vivo and evokes epileptiform activity in the in vitro hippocampal preparation. This study examined the effects of 4AP on AA levels in hippocampal slices and a subsequent response to PHT and other anticonvulsants. Isotopic enrichment, after incubation with 13Csglucose, was used to measure NEW AA. Basal and NEW AA were quantitated by GC-MS of the dimethyl t-butyl silvl derivatives. As would be expected, 4AP (50  $\mu$ M) stimulated production of NEW AA (46, 102, and 31% in GABA, ASP, and GLU, respectively). The effect of 4AP was reversed by 60 μM PHT (corresponding to therapeutic plasma PHT concentration). Similar findings were seen in preliminary studies with several candidate antiepileptic drugs. PHT also inhibited the production of NEW AA in control (non-4AP stimulated) slices, but to a lesser degree. This study shows predictable response of NEW AA to convulsant and anticonvulsant agents and this approach will be evaluated further in terms of mechanistic and screening potential.

DIFFERENTIAL EFFECTS OF ANTICHOLINERGIC DRUGS AGAINST SOMAN SEIZURES. J.H. McDonough\*, T.-M. Shih, and N.L. Adams, USAMRICD, APG, MD 21010.

The nerve agent soman can produce prolonged seizures and brain damage. We have reported that scopolamine exhibits a time-dependent effective-ness in terminating soman-induced seizures. We examined atropine, benactyzine and trihexyphenidyl examined atropine, benactyzine and trihexyphenidyl to see if they also showed time-dependent effects. Rats implanted with cortical and depth electrodes were pretreated with the oxime HI-6 (125 mg/kg, IP), to prolong survival, 30 min before soman (180 ug/kg, SC). At 5, 20 and 40 min after the onset of EEG seizure activity the rats were treated IV with an anticholinergic drug. Anticonvulsant ED50s (mg/kg) for each drug are presented below.

5 MIN 20 MIN 40 MIN

5 MIN 20 MIN 0.07 8.04 40 MIN >>51.20 SCOPOLAMINE 3.02 39.17 ATROPINE not tested 0.98 BENACTYZINE 0.14 5.62

Although all drugs showed time-dependent doseeffect profiles, only trihexyphenidyl and
benactyzine were capable of terminating seizures
at all times tested. Trihexyphenidyl has N-methyld-aspartate (NMDA) antagonist properties which may account for its anticonvulsant effectiveness at long seizure durations. The results indicate that benactyzine may also possess anti-NMDA activity.

FLUNARIZINE LIMITS SUSTAINED REPETITIVE FIRING IN VITRO: A POSSIBLE MECHANISM ANTICONVULSANT EFFICACY. FOR

Cheung and E.W. Harris. Dept. of Biology, Fisons Pharmaceuticals, Rochester, NY 14623.

Flunarizine, a potent calcium channel antagonist, has been found to possess anticonvulsant efficacy. Despite the wide spectrum of Ca<sup>2+</sup> channel blocking activities observed in vitro, there is no evidence that the anticonvulsant activity of flunarizine is mediated via neuronal Ca<sup>2+</sup> channels. The convulsant profile of mediated via neuronal Ca<sup>+-</sup> channels. The similarity in the convulsant profile of flunarizine and phenytoin suggests that they may have a common mechanism of action. Like phenytoin, flunarizine blocks neuronal Nathannels in a use- and voltage-dependent manner, as demonstrated by its ability to limit high-frequency sustained repetitive firm in spinal cord cultured neuronacy (with an IC yealne) in the cord cultured neurones (with an IC<sub>50</sub> value in the submicromolar range). In addition, flunarizine has also been shown to displace [3H]batrachotoxin binding in the rat brain synaptosomes ( $IC_{50} = 0.69 \mu M$ ). Both electrophysiological and biochemical evidence suggests that the anticonvulsant action of flunarizine may be the mediated by blocking the neuronal voltage-activated Na channels.

## 159.9

CLASSIFICATION OF NIGRO-TECTAL NEURONS BASED ON RESPONSES TO BENZODIAZEPINE. X. Weng and H.C. Rosenberg, Dept. of Pharmacology, Med. Coll. of Ohio, Toledo OH 43699.
Previous work showed that microinjection of GABA agonists and benzodiazepines (BZs) into substantia nigra had varying effects on different experimental seizures. An explanation was suggested by the observation that nigral neurons were differentiated by their responses to iontophoretic BZ. As some studies suggested that the nigrotectal pathway was critical in seizure modulation, we hypothesized that the varying effects of intranigral drug on seizures might result from the different responses of nigro-tectal neurons to BZ. Male, Sprague-Dawley rats were anesthetized with chloral hydrate. Nigro-tectal neurons were identified by antidromic activation. Multi-barreled glass electrodes were used to record spontaneous activity of single neurons. GABA and BZs were applied iontophoretically, using several currents for each. Recording sites were marked for later confirmation. As a function of increasing current, both BZs and GABA decreased the rate of neuronal discharge. Most nigro-tectal neurons could be increasing current, both BZs and GABA decreased the rate of neuronal discharge. Most nigro-tectal neurons could be completely silenced by GABA, but with widely varying sensitivities. Based on the maximum effect obtained with BZs, the neurons could be divided into categories. Twelve neurons were inhibited > 75%, while 13 neurons were maximally inhibited < 55% by BZs. This suggested that nigro-tectal neurons can be differentiated by their responses to BZs. The GABA-A/BZ receptors of these neurons will be studied. Supported by DA02194.

#### 159.6

ANTICONVULSANT EFFECTS OF DIAZEPAM OR MK-801 AGAINST SOMAN SEIZURES. T.-M. Shih\*, J.H. McDonough and N.L. Adams. USAMRICD, APG, MD 21010.

Both diazepam and MK-801 can modulate seizure activity induced by soman. In this study we investigated whether these drugs showed a time-dependent effectiveness as a function of seizure duration as did anticholinergic drugs. (See accompanying abstract for preparation and procedures) panying abstract for preparation and procedures.) panying abstract for preparation and procedures.) A fixed dose of each drug, 2X the ED50 for terminating the seizure at 2.5 min, was used. Diazepam (0.6 mg/kg, IV) or MK-801 (0.088 mg/kg, IV) was quite effective in terminating soman seizures at 5 and 20 min. At both times each drug suppressed spike amplitude and produced profound behavioral depression (ataxia). However, they also enhanced the lethal effects of soman by depressing enhanced the lethal effects of soman by depressing respiration (particularly MK-801). In many cases, seizure activity reoccurred after 1-3 hrs of suppression. In another experiment, scopolamine (0.4 mg/kg, IV) was given at the 20 and 40 min seizure durations followed 2 min later by diazepam or MK-801. Scopolamine protected against the respiratory effects of both drugs, but did not modify the characteristic anticonvulsant or behavioral effects. We conclude that there was no time-dependence to the effectiveness of these two

#### 159.8

CONVULSANT ACTION AND BINDING PROPERTY OF THE PERIPHERAL-Type BenZoDIAZEPINE, Ro 5-4864, IN El MICE. Y. Nakamoto, M. Yoshii and K. Yamamoto\*. Dept. of Neurophysiology, Tokyo Institute of Psychiatry, Tokyo 156, Japan.

It is well known that "central-type" benzodiazepines

drugs unlike that observed with anticholinergics.

(BDZs) such as diazepam and clonazepam act as potent anticonvulsants, whereas "peripheral-type" BDZs such as Ro 5-4864 act as convulsants. Unlike receptors for the central-type, those for the peripheral-type remain to be characterized for their biological roles including proconvulsant action. In the present study, we have investigated how peripheral-type BDZ receptors contribute of epilepsy, based on behavioral experiments and binding assays. Adult El mice (25-30g) and the control, DDY mice (30-35g), were used. Threshold of seizure in El mice was determined weekly for each animal. Ro 5-4864 induced seizures in El mice at 10 mg/kg or higher doses (i.p.). In DDY, the action of Ro 5-4864 was three-times less optent. The seizures induced by Ro 5-4864 were inhibited by PK 11195 (10-15 mg/Kg, i.v.), an antagonist for the peripheral-type BDZ receptor. PK 11195 also raised the threshold of seizure in El mice. Binding assays revealed slight decreases in Bmax's of 3H-flunitrazepam and 3H-Ro 5-4864 in the cerebral cortex of El mice. The results suggest that peripheral-type BDZ receptors in the brain play a proconvulsant role in the El mouse, possibly with an altered distribution of both types of BDZ receptors.

## 159.10

FCE 26749: A NEW AND POTENT ANTICONVULSANT ACTIVE IN EXCITOTOXIN SEIZURE MODELS. M. Varasi\*, R. Maj. A. Bonsignori, N. Carfagna, R. McArthur and R. Fariello. CNS/CVS Research, Farmitalia Carlo Erba, Erbamont Group, 20014 Nerviano, Italy FCE 26749 [(S)-(+)-2-(4-Benzyl-aminobenzyl) amino-propanamide], exhibits potent FCE 26749: A NEW AND POTENT ANTICONVULSANT ACTIVE

amino-propanamide], exhibits potent anticonvulsant activity in excitotoxin seizure models. On the basis of oral  $\mathrm{ED}_{50}$  doses determined 60 min after in the rotarod (217 mg/kg) and antagonism of maximal electroshock seizures (9.5 mg/kg) tests, FCE 26749 was selected for further study. FCE 26749 (-60 or -180 min) in mice antagonized the tonic convulsions (ED $_{50}$ 's = 48 and 80 mg/kg; po) induced by NMDA (225 mg/kg; sc).

80 mg/kg; po) induced by NMDA (225 mg/kg; sc). Seizures and status epilepticus (SE) in rats induced with kainic acid (KA 10 mg/kg;ip) was antagonized by both diazepam (20 mg/kg;ip) [6/10 and 7/10 rats protected from seizures and SE respectively]) and FCE 26749 (0.5 [1/6, 1/6], 1.0 [4/6, 4/6] and 3.0 [9/12, 10/12] mg/kg;ip) administered 15 min before KA. In cortical membrane preparations, FCE 26749 showed little displacement (pKi < 5) of selective ligands for the NMDA, MK-801, glycine, kainate or quisqualate receptor sites. These results indicate that FCE 26749 is a broad spectrum anticonvulsant agent in seizure models resistant to chronic treatment.

Opiate antagonists have selective effects on morphineinduced potentiation of picrotoxin-induced seizures.  $\underline{\mathtt{W}}$ Notes, J. Thomas, V. Kenigs, A. J. Kastin, G. A. Olson\*, and R. D. Olson. Department of Psychology, University of and R. D. Olson. Department of Psychology, University of New Orleans, New Orleans, LA 70148

The present study evaluated the efficacy of the opiate

antagonists Tyr-MIF-1 (Tyr-Pro-Leu-Gly-NH<sub>2</sub>), MIF-1 (Pro- $\text{Leu-Gly-NH}_2$ ), and naloxone against morphine-potentiated picrotoxin-induced seizures. 40 male rats were injected IP with saline, naloxone (3 mg/kg), Tyr-MIF-1 (3.0 mg/kg), or MIF-1 (3.0 mg/kg). After 15 min, they were injected IP with saline or morphine (50 mg/kg). After another 15 min, they received a SC injection of picrotoxin (3.0 mg/kg). The rats were then observed for 45 min and scored on several parameters of different categories of seizures An ANOVA yielded a significant main effect for the number of focal seizure episodes, p<.05, with all combinations of morphine, except the naloxone+morphine group, increasing the number of focal episodes but not differing from each other. Naloxone reduced the number of focal seizures to a level comparable to that of saline. The incidence of generalized clonic seizures was significanct, p<.05, and displayed a similar pattern of effects among the groups. Finally, morphine increased the duration of akinetic seizures relative to saline; consistent with their known antiopiate activity, the effect was reduced by all three antagonists. The results suggest that the opiate system interacts with picrotoxin-mediated seizure mechanisms.

CARBAMAZEPINE AND PHENYTOIN INHIBIT NMDA RE-CARBAMAZEPINE AND PHENYTOIN INHIBIT NMDA RECEPTOR-MEDIATED CURRENTS IN THE RAT HIPPOCAMPUS. T.Dalkara, C.Ayata, G.Erdemli and R.Onur.
Depts. of Neurology and Pharmacology, Hacettepe Univ.
Fac. of Medicine, Ankara, TURKEY. (SPON: EMA).
Involvement of NMDA receptors in epileptic activity
is well established. A recent paper\* reporting inhibition
of NMDA currents in cultured spinal neurons by carba-

of NMDA currents in cultured spinal neurons by carba-mazepine (1 to 50 µM) prompted us to examine the effects of 4 antiepileptic drugs on the NMDA receptor activity in the rat hippocampus, in situ. The NMDA receptor activity was evoked by high frequency (5-7 pulses at 100 Hz and 0.1 train per sec.) fimbrial/commissural stimulation. Carbamazepine (n=4) and phenytoin (n=5), at a dose (10 mg/kg) which is protective against maximal electroshock seizures, decreased the amplitude of NMDA receptor-mediated component of the field potential (NMDA-FP) by 51±16 % and 41±7 %, respectively, whereas phenobarbital and diazepam (10 mg/kg tively, whereas phenobarbital and diazepam (10 mg/kg i.v.) had no appreciable effect. Local application of carbamazepine and phenytoin by pressure injection also inhibited the NMDA-FF by 27±6 % (n=4) and by 25±6 % (n=4), respectively. Extracellular DC potential shifts produced by iontophoretically applied NMDA in stratum radiatum were also antagonized by pressure injection of carbamazepine (70±21%, n=3) and phenytoin (81±27 %, n=9) but not of phenobarbital or diazepam. These data suggest that inhibition of the NMDA receptor-mediated currents may contribute to the antiepileptic action of carbamazepine and phenytoin. carbamazepine and phenytoin.

SYMPOSIUM. RECENT ADVANCES IN NEUROPEPTIDE BIOSYNTHESIS: MOLECULAR AND CELLULAR BIOLOGY OF NEUROPEPTIDE PROCESS-ING ENZYMES. Lloyd D. Fricker, Albert Einstein Coll. of Med. (Chairperson);
Nabil G. Scidah, Clinical Research Inst. of Montreal;
Betty A. Eipper, Johns
Hopkins Univ.; Stanley J. Watson, Univ. of Michigan.

Hopkins Univ.; Stanley J. Watson. Univ. of Michigan.

The field of neuropeptide biosynthesis has undergone an explosive growth in the last few years. Major advances have occurred in the area of neuropeptide-processing endopeptidases; a family of endopeptidases have been identified (furin, PC-1, PC-2, and others). Recent studies on two other neuropeptide-processing enzymes, carboxypeptidase E and the amidating enzyme, have yielded many new results and some surprises; for example, the 'amidating enzyme' is two separate enzymes produced from a single protein precursor, which work together to form C-terminal amide groups. These recent findings will be presented, along with a concise review of the field. Nabil Seldah will discuss the cloning of PC-1 and PC-2, and the expression of these enzymes in a variety of cells. The substrate specificities and biochemical properties of the enzymes will be presented. The regulation of the expression of these enzymes in a variety of cells. The substrate specificities and biochemical properties of the enzymes will be presented. The regulation of the enzymes will also be discussed, with a focus on the significance for neuropeptide biosynthesis. Lloyd Fricker will present the cloning of the carboxypeptidase E gene and analysis of the promoter. The regulation of carboxypeptidase E mRNA and enzyme activity will be discussed, along with the implications of this regulation on the processing of neuropeptides in neurons and in non-neuronal cells. Betty Elpper the processing of neuropeptides in neurons and in non-neuronal cells. Betty Elpper will describe the two enzymes whose sequential action is required for peptide amidation, and the single gene encoding both enzymes. The importance of tissue specific alternative mRNA splicing and post-translational proteolytic processing in the generation of soluble and integral membrane forms of these enzymes will be presented. Protein domains which affect the routing through neuroendocrine cells will also be discussed. Stan Watson will present the distribution of PC-1, PC-2, furin, CPE, and PAM in brain and other tissues. Emphasis will be placed on whether the enzymes are present exclusively in neuronal cells. The distribution of each enzyme will be compared with the other enzymes, and with the distribution of known neuropeptides, with a focus on the implications for neuropeptide-processing.

TOLERANCE TO THE ANTICONVULSANT EFFECTS OF PENTOBARBITAL: GREATER TOLERANCE WITH AN ASCENDING-DOSE REGIMEN. L.E. Kalynchuk\*, C.K. Kim, J.P.J. Pinel and T. Kippen. Dept. of Psychology, University of British Columbia, Vancouver, B. C., Canada. V6T 124.

In clinical practice, it is common to initiate anticonvulsant therapy at a low dose and to increase it until a therapeutically effective dose is reached. On the basis of the drug-effect theory of tolerance (see Pinel, Kim & Mana, 1990), we predicted that this regimen would promote tolerance development and thus interfere with anticonvulsant therapy. The present study was undertaken to determine the degree of tolerance development to the anticonvulsant effects of pentobarbital with four different dose regimens in amygdala-kindled rats. After kindling, the rats (35 male, Long-Evans) received a convulsive stimulation once every 48 hr for the duration of the experiment. Following five baseline stimulations, the rats received one of four treatments of pentobarbital 1 hr before each of the 20 stimulations of the tolerance-development phase: a constant low dose (10 mg/kg), an ascending dose regimen (10 mg/kg to 20 mg/kg), a constant high dose (50 mg/kg), or saline. On the tolerance test, all rats received a test dose (20 mg/kg) of pentobarbital 1 hr before stimulation. The ascending dose rats displayed significant tolerance to the anticonvulsant effects of pentobarbital whereas the low and high dose rats did not. These results provide further support for the and mgh dose has do not. These results provide future support drug-effect theory of tolerance, and suggest that initiating anticonvulsant therapy at doses high enough to block key neural components of convulsions may result in little tolerance to anticonvulsant effects. (Supported by an NSERC grant to JPJP)

SYMPOSIUM. REGENERATION OF VERTEBRATE SENSORY RECEPTORS. E.W. Rubel, Univ. of Washington (chair); P.A. Raymond, Univ. of Michigan; A.I. Farbman, Northwestern Univ.; H.H. Zakon, Univ. of Texas

Loss of sensory function in man and other vertebrates is usually due

to destruction or degeneration of the receptor epithelium. The ability to regenerate these receptor surfaces varies markedly across vertebrate classes and across different receptor organs. In this symposium we will explore structural, functional and cellular events associated with the regeneration of vertebrate receptor cells for hearing, balance, vision, olfaction, and electroreception. E. Rubel will discuss recent experiments on regeneration of hair cells in the inner ear of birds. P. Raymond will consider regeneration of rods and cones in the retinas of fish and amphibians. A. Farbman will discuss regeneration of chemoreceptors in mammals. H. Zakon will examine electroreceptors in fish. The emphasis of each presentation will be on recent data attempting to further define the cellular events leading to proliferation and differentiation of the regenerated receptor epithelium.

AUDITORY MIDBRAIN CELLS IN GOLDFISH: TRANSFORMATIONS OF PERIPHERAL INPUT. R.R. Fay and J. Lu. Dept. Psychology and Parmly Hearing Institute, Loyola Univ. of Chicago, IL 60626.

Single units from the torus semicircularis (TS) were studied using pipet and indium electrodes in response to tones. Iso-level response areas (RA) were obtained for frequencies between 75 and 1250 Hz. Peristimulus time (PST), inter-spike interval (ISI), period histograms, and scatterplots of inter-spike interval versus spike time (ISIT) were obtained from >150 TS units for comparison with >200 single fibers of the auditory (saccular) nerve (ANF). TS units show less spontaneous activity, greater average sensitivity, sharper tuning (Q10dB up to 5), steeper tuning curve slopes(>200 dB/octave), and more diversity in PSTH patterns than ANFs. While all ANFs phase-lock to the acoustic waveform, only a subset of TS units show phaselocking. TS units that phaselock robustly tend to produce one spike/cycle (entrain) for up to 200 ms with less average error (temporal jitter) than ANFs (ISI standard deviations <40 µs). Some TS units phaselock at both positive and negative phases of the stimulus waveform, as is the case for ANFs. Robustly phaselocked TS units are probably inputs from medullary nuclei. Nonphaselocked TS units fall into several categories based on PSTH shape, similar to some mammal cochlear nucleus units: onset, buildup, pauser, primary-like, and choppers. Choppers have regular interspike intervals (shown in ISIT) that are not phaselocked to the stimulus. Some ANFs show onset and pauser patterns, but not buildup or chopper patterns. In iso-level functions, the frequency producing the most spikes (BF) tends to converge toward 500 Hz as level is raised in ANFs, but not in TS units. This "BF constancy" results in a more secure and robust rate code for frequency in the TS than in the periphery. The origins of this important transformation are being investigated using more complex stimuli. [Supported by NIH, NIDCD]

REPRESENTATION OF TONAL CONSONANCE AND DISSONANCE IN THE TEMPORAL FIRING PATTERNS OF AUDITORY NERVE FIBERS: RESPONSES TO MUSICAL INTERVALS COMPOSED OF PURE TONES VS. HARMONIC COMPLEX TONES

MILTramo\*, P.A. Cariani, and B. Delgutte Dept of Neurobiology, Harvard Med Sch, Boston, MA 02115, and Eaton-Peabody Lab, Mass Eye & Ear Infirmary, Boston, MA Tonal dissonance has been attributed to fluctuations in amplitude that give rise to the sensation of beats and roughness. To investigate how beats and roughness are represented in the temporal discharge patterns of auditory nerve fibers, we recorded the responses of single units in Dial-anesthetized cats to stimuli associated with varying degrees of consonance and disconance. Stimuli were presented at 60 dB, SPI and represented in the temporal discharge patterns of auditory nerve fibers, we recorded the responses of single units in Dial-anesthetized cats to stimuli associated with varying degrees of consonance and dissonance. Stimuli were presented at 60 dB SPL and consisted of: 1) two simultaneous pure tones whose frequencies were in the ratios of 1:2 (musical fifth), 2:3 (fourth), 15:16 (minor second), and 32:45 (tritone); and 2) two simultaneous complex tones with fundamental frequencies at the same ratios, each composed of six equal-amplitude harmonics. Post-stimulus time histograms (PSTH) and all-order interspike interval distributions (autocorrelation histograms, AH) were computed. For the pure tone minor second, the most dissonant of the pure tone intervals, the envelope of PSTH for all fibers showed broad local maxima and minima separated by the difference frequency. This beating pattern was reflected in AH by a broad maximum near the difference frequency. For no other pure tone interval was this beating pattern found. For harmonic complex intervals, beating patterns were observed when fiber characteristic frequency (CF) was near two closely spaced components. For the complex intervals, relatively weak beating patterns were found only for a small number of units whose CFs were near the most closely spaced components. AH showed prominent peaks at the common fundamental period of these harmonic complexes. For the complex intervals, relatively weak beating patterns were found only for a small number of units whose CFs were near the most closely spaced components. AH showed prominent peaks at the common fundamental period of these harmonic complexes. For the complex intervals, relatively weak beating patterns were found only for a small number of units whose CFs were near the most closely spaced components. AH showed prominent peaks at the common fundamental period of these harmonic complexes. For the complex intervals, and provide physiological support for the hypothesis that the dissonance of complex tones reflects t

COMPARISON OF C-FOS EXPRESSION WITH 2-DEOXYGLUCOSE-UPTAKE IN THE AUDITORY AND PREFRONTAL CORTEX AFTER ACOUSTIC STIMULATION, CLASSICAL CONDITIONING OR ACTIVE AVOIDANCE TRAINING

W. Zuschratter, K. Wehner, T. Herdegen, B. Hose\* and H. Scheich Inst. of Zoology, Technical University Darmstadt, Germany;

<sup>2</sup>II. Inst of Physiology, University Heidelberg, Germany

\*\*TI. Inst of Physiology, University reductioning, Germany Previous studies using the "C-2 deoxyglucose method as marker for elevated electrical activity have shown a complex functional organisation of the auditory cortex of gerbils (Meriones unguiculatus) with a parcellation into at least 7 cortical fields, most of which contain tonotopic maps (Scheich, Current Opinion in Neurobiology 1991, 1: 236-247). The 2 DG method was also successful to demonstrate changes in the frequency representation after aversive conditioning (Simonis and Scheich, Eur. I. Neurosci. Suppl. 3, p156, 1990). In the present study we combined 2 DG autoradiography with the immunocytochemical detection of the proto-oncogene c-FOS to analyze the relationship of the two markers in the auditory and prefrontal cortex after acoustic stimulation (900-1100 Hz, frequency modulated, 70 dB/SPL), classical auditory conditioning and active avoidance training avoidance training.

Compared to naive controls the tone stimulated and conditioned animals showed an increased c-FOS expression in various subfields of the auditory and prefrontal cortex, with the strongest labeling in the active avoidance group, c-FOS expression in some areas corresponds to the 2 DG patterns both in terms of spatial extent and experience dependent activation. This indicates a certain yet complex relationship between the functional measures which depend on the brain area.

INTRACELLULAR RECORDINGS FROM NEUROBIOTIN-LABELED PRINCIPAL CELLS IN BRAIN SLICES OF THE GUINEA PIG MSO. P.H. Smith and M.I. Banks. Depts. of Anatomy and Neurophysiology and Neuroscience Training Program. Univ. of Wisconsin, Madison, WI. 53706.

We recorded intracellularly from principal cells in the medial superior olive (MSO) of 10 to 20 day-old guinea pigs. Above threshold, cells fired one or a few action potentials at the onset of a depolarizing current pulse. At higher currents, repetitive firing could be elicited. A large hyperpolarizing pulse could generate a membrane potential "sag" back toward rest. Shock stimuli at the brainstem midline could evoke a short latency epsp and a strychnine-sensitive ipsp. As shock strength increased the ipsp currents could act to reduce epsp duration and thus "sharpen" the epsp peak. Shocking the brainstem lateral to the ipsilateral lateral superior olive could elicit similar events. So far, injected cells have been located in the ventral, higher frequency half of the MSO. The dendritic configuration was typically bipolar in the coronal plane. The thick primary dendrites could branch close to the cell body forming multiple thick dendrites that would rarely branch as they headed medially or laterally. In one cell these large thick dendrites terminated in tufts of string-like appendages. In other cells only a few small appendages accentuated the dendritic termination. The dendritic tree could extend for considerable distances outside the MSO-proper. The axon arose from a primary dendrite or cell body and headed dorsally within the body of the MSO. When the axon could be followed past the dorsal aspect of the MSO, axon collaterals were given off that terminated in the dorsal, lower frequency regions of the MSO.

Supported by NIH First Grant NS26285.

CORRESPONDENCE OF FUNCTIONAL TOPOGRAPHIES IN CAT PRIMARY AUDITORY CORTEX FOR ACOUSTIC AND ELECTRIC COCHLEAR STIMULATION. M.E. Raggio. C.E. Schreiner\* and M.M. Merzenich. Coleman Laboratory, Dept. Otolaryngology, University of California, San Francisco, CA 94143-0732.

The evaluation of electrically-evoked physiological patterns

The evaluation of electrically-evoked physiological patterns in auditory cortex, and their subsequent changes with meaningful stimuli in an animal model, represents a first attempt at defining the role of cortical representation and representational plasticity in the speech perception of cochlear implant patients. The effects of peripheral electrical stimulation on the primary auditory cortex (Al) of cats was evaluated and compared with the functional topographies for constituting attimulation in the series of the cortex of the

evaluated and compared with the functional topographics for acoustical stimulation in the same animal.

A 'map' of the spatial distribution of neuronal responses in AI of adult cats to basic acoustical stimulus properties such as frequency, bandwidth, and intensity, was obtained with 50 to 100 microelectrode penetrations. The cat was then implanted 100 microelectrode penetrations. The cat was then implanted with a four electrode pair cochlear prosthesis in the scala tympani, and the spatial distribution of response thresholds and temporal responses, with stimulation of each electrode pair, was then mapped at the same locations. The resulting alignment of acoustic and electrical response patterns electrical sensitivity profiles that were cochleo-appropriate. Comparison of electrical response with acoustic response thresholds revealed an revealed electrical sensitivity thresholds with inverse correlation, i.e. acoustically more sensitive locations were electrically relatively insensitive. (NIDCD N01-0-2401)

FREQUENCY TUNING OF THE HUMAN AUDITORY CORTEX M. Sams\* and Salmelin. Low Temp. Lab., Helsinki Univ. Technol. 02150 Espoo, Finland.

We employed magnetoencephalographic (MEG) recordings to study frequency tuning of the human auditory cortex. A test sound of 1 or 2 kHz (100 ms, 50 dB SPL) was delivered once per second to the subject's left ear, together with a continuous masker. The masker was either white or notched noise. The notch widths ranged from very wide (4000 Hz) to those inside the critical band. A measurement was started by finding the level of the white-noise masker which just rendered the sound inaudible. Thereafter the masker level was kept constant. The test sounds with different maskers were delivered in separate blocks, in random order.

The N100m response to test stimuli, originating in the auditory cortex, was recorded with a 24-channel neuromagne-

The perceived intensity of the test stimulus increased with the notch width. A parallel effect was seen in the N100m amplitude, plotted as a function of the notch bandwidth. The shapes of the curves measured for the l-kHz and 2-kHz test sounds resembled those obtained in psychoacoustical experiments studying the shape of auditory filters. The reults show that frequency tuning of the human auditory cortex can be studied noninvasively by MEG.

SITE OF PLASTICITY IN THE BRAINSTEM OF THE BARN OWL: REGULATION OF INHIBITION IN RESPONSE TO EARLY MONAURAL OCCLUSION. <u>I. Mogdans\* and E.I. Knudsen</u>, Dept. Neurobiology, Stanford University, Stanford CA, 94305.

Monaural occlusion during early life causes adaptive changes in the tuning of units to interaural level differences (ILD) in the barn owl's optic tectum and inferior colliculus. In order to identify the site of plasticity in the auditory pathway, we investigated whether these changes reflect adjustments at the first site of binaural interaction: the posterior division of the nucleus ventralis lemnisci lateralis (VLVp; functional equivalent of the mammalian LSO). VLVp units are excited by sound in the contralateral ear and inhibited by sound in the ipsilateral ear (EI units). Within the nucleus, the strength of inhibition decreases systematically from dorsal to ventral to create a map of ILD.

We compared the maps of ILD in the left and right VLVp of owls raised with one ear plugged. Using dichotic stimulation and two independent measures for the strength of inhibition, we found that units in the VLVp ipsilateral to the occluded ear were inhibited more strongly than units at comparable depths in the contralateral VLVp, indicating a relative shift in the ILD maps. Moreover, the slope of the gradient of inhibition along the dorsoventral axis of VLVp was steeper on the contralateral side. In contrast, excitatory response functions had thresholds and slopes that were the same on the two sides of the brain. These findings indicate that the brain alters the sensitivity of VLVp units to ILDs by regulating the strength of inhibition, and that plastic changes in VLVp are largely responsible for the adaptive changes in ILD tuning observed at higher levels in the auditory pathway.

OUANTITATIVE ELECTROENCEPHALOGRAPHIC (OEEG) CORRELATES OF HUMAN AUDITORY-CORTEX ANATOMICAL ASYMMETRIES QUANTIFIED USING MAGNETIC RESONANCE IMAGING (MRI): EARLY RESULTS IN THE CNS PROJECT. J. L. Lauter\* and E. Plante, Univ. of Oklahoma Health Sciences Cntr., Oklahoma City OK 73190; and Univ. of Arizona, Tucson AZ 85721.

A number of studies, using dissection, CT, and MRI, have described anatomical asymmetries in human auditory cortex around the Sylvian fissure, concluding that some degree of asymmetry is the norm, while symmetry is predictive of pathology, e.g., in language processing. However, there are no physiological data "bridging" between these observations of anatomy on the one hand vs. behavior on the other. Fight neurologically normal young adults were examined with a cross-section of our Coordinated Noninvasive Studies (CNS) Project test battery, including MRI and a qEEG session with both resting and activation conditions. Distinct correlations between MRI and qEEG measures related to periSylvian asymmetries, such as qEEG power asymmetry and coherence, suggested that some purportedly neurologically normal subjects are at risk for subtle neurological dysfunction. MRI/qEEG measurements in a second group (four more neurologically normal by report, and three patients: one with a history of stuttering, and two with central-auditory complaints) both supported and extended the original predictions. In general, the data suggest that a variety of "neurologically silent" disorders, such as stuttering, mild learning disorder, centralauditory processing disorder, and substance abuse, may be associated with distinct patterns of anatomical/electrophysiological characteristics in periSylvian cortex.

## 166.11

REGRESSIVE EVENTS IN THE DEVELOPING AUDITORY SYSTEM: CALBINDIN-D28K IMMUNOREACTIVITY IN THE SUPERIOR OLIVARY COMPLEX OF RATS. E. Friauf . Dept. Animal Physiology, Univ. of Tübingen, 7400 Tübingen, Germany.

Calcium-binding proteins, such as calbindin-D28k (CaBP), are widely distributed in the brain and may function to protect neurons against an excess of intracellular calcium. Using monoclonal antibodies against CaBP, we have investigated the distribution of this protein in the superior olivary complex of developing rats. Consistent with the findings of others (e.g., MR Celio 1990, Neuroscience 35:375-475), strong CaBP immunoreactivity was found in virtually all somata of the medial nucleus of the trapezoid body (MNTB). Furthermore, immunoreactivity was present in boutons around the neurons of the lateral superior olive (LSO), the nedial superior olive, the superior paraolivary nucleus, and the lateral nucleus of the trapezoid body, whereas the somata themselves were unlabeled. As these nuclei are known to receive input from MNTB principal neurons (c.f., I Sommer et al., this meeting), it is likely that at least some of the immunoreactive boutons represent terminals of MNTB neurons.

During development, CaBP immunoreactivity in MNTB somata can first be burning development, Cabr immunoreactivity in MN1B somata can first be detected at postnatal day 8 (P8), i.e., about four days before the onset of physiological hearing. Surprisingly, heavily immunoreactive LSO neurons are also present at that age. They can be seen throughout the neonatal life and are even present prenatally. Around P6, immunoreactivity in LSO neurons becomes most intense and subsequently decreases until somatic labeling can no longer be found after P21. The transient appearance of CaBP in the LSO shows that there are regressive events during the development of the auditory system and suggests that intracellular calcium may have to be regulated precisely in LSO neurons at a time when synaptic contacts are likely to be rearranged. Supported by the DFG (Fr 772/1-2).

FREQUENCY DOMAIN ANALYSES REVEALED CONNECTIONS BEYOND STIMULUS LOCKING IN THE AUDITORY THALAMUS A.E.P. Villa\*, D.R. Brillinger and F. de Ribaupierre, Institut de Physiologie, UNIL, CH 1005 Lausanne, Switzerland and Department of Statistics, UC Berkeley, Berkeley, CA 94720

Single unit spike trains were simultaneously recorded in the auditory sector of the thalamic reticular nucleus (RE) and medial geniculate body (MGB) of nitrous oxide anesthetized cats. Second order analyses to measure sector of the thalamic reticular nucleus (RE) and medial geniculate body (MGB) of nitrous oxide anesthetized cats. Second order analyses to measure association between 129 pairs of spike trains, A and B, one in RE and one in MGB were carried out. Each unit was studied during spontaneous activity and acoustically evoked activity by white noise bursts. Time domain analyses give the short term firing rate of the B train at a certain time lag after an A spike. This analysis provides an unsatisfactory description of the association between the units if rate effects exist in the presynaptic spike trains. This is particularly true for the bursty units within RE. In a different approach frequency domain coherences were estimated. These reflect the degree of linear time invariant association between the cells as a function of frequency. This method can be extended and the partial coherence analysis removing the effects of the point process corresponding to the stimulus onset carried out. Almost half of the pairs (16/34) exhibit a significant difference between partial coherence and coherence during spontaneous activity. The frequencies concerned by these modifications were below 30 Hz in the vast majority of these pairs (75%). These results support the role of RE in selective filtering of the incoming auditory input (Villa et al. Exp. Brain Res. 86:506, 1991). Analyses of the spike trains in the frequency domain led to a physiologically meaningful conclusion: many functional connections in the auditory thalamus are modulated by the stimulus but not necessarily time-locked to its onset.

EARLY ONSET OF SYNAPTIC TRANSMISSION TO NEURONS IN THE SUPERIOR OLIVARY COMPLEX OF THE RAT. K. Kandler and E. Friauf. Dept. Animal Physiology, Univ. of Tübingen, 7400 Tübingen, Germany

Neurons of the rat cochlear nucleus already project to the superior olivary complex (SOC) two days prior to birth, i.e. about two weeks before the ear canals open and physiological hearing starts. Until now it was unknown whether these afferent connections to the SOC function during this period, when the auditory system is still devoid of physiological input. We addressed this question by recording intracellulary from young SOC neurons (postnatal days 2-19) in vitro while electrically stimulating afferent fibers in the ventral acoustic stria (VAS) ipsilaterally and contralaterally. Physiologically characterized neurons identified by intracellular injection of biocytin.

Stable recordings lasting over several hours were obtained from neurons

located in the medial nucleus of the trapezoid body, the lateral superior olivary nucleus, the superior paraolivary nucleus, and periolivary nuclei. The neurons had resting potentials from -45 to -73 mV and generated action potentials with amplitudes up to 62 mV during depolarizing current injections. Neurons with resting potentials more negative than -50 mV were not spontaneously active. Stimulation of the VAS resulted in excitatory and inhibitory postsynaptic potentials. Already at P2, EPSPs were able to give rise to action potentials. In most cases, the EPSPs could be blocked by CNQX (20 µM), suggesting that they were mediated by glutamate acting on non-NMDA receptors. EPSPs were observed after ipsilateral stimulation, whereas EPSPs or IPSPs occured after contralateral stimulation. These data indicate that ipsilateral and contralateral inputs converge on SOC neurons shortly after birth and that bilateral synaptic interactions can already take place at least ten days before the onset of hearing. Supported by the DFG (Fr 772/1-2) and the GKN Tübingen.

## 166.12

THE PITCH OF COMPLEX SOUNDS IS SIMPLY CODED IN INTERSPIKE INTERVAL DISTRIBUTIONS OF AUDITORY NERVE FIBERS. P.A. Cariani. B. Delguite, and NY,S. Kiang.\* Massachusetts Institute of Technology and Eaton-Peabody Laboratory, Massachusetts Eye and Ear Infirmary, 243 Charles St., Boston, MA 02114.

Temporal theories of pitch perception state that the perceived pitch corresponds to the most frequent interspike interval present in the auditory nerve. In order to assess the physiological plausibility of such models, we recorded from auditory nerve fibers in Dialanesthetized cats, using a wide variety of complex stimuli which have been extensively studied in psychophysical pitch experiments. Stimulus pitches ranged from 80 to 480 Hz.

We computed "autocorrelograms" representing the distribution of all (1st, 2nd, 3rd,...) interspike intervals in a single fiber and summed 40-80 individual autocorrelograms covering a wide CF range to estimate an interval distribution for the entire auditory nerve. For harmonic stimuli having unambiguous pitches (single-formant vowels and harmonic tone complexes), the most frequent intervals in the aggregate autocorrelogram corresponded to the fundamental period and the pitch period. For inharmonic stimuli with ambiguous pitches (sinusoidally-amplitude modulated (SAM) and quasi-frequency-modulated (QFM) 640 Hz tones), the aggregate distributions showed multiple peaks of roughly equal height at interspike intervals corresponding to the periods of the multiple pitches that would be heard by humans. Interval distributions for psychophysically-similar SAM and QFM tones were similar. Stimuli with weaker pitches (SAM) broadband noise and SAM 6400 Hz tones) had less salient peaks in their interval distributions relative to backround.

We also found physiological correlates for the phenomenon of "pitch dominance", wherein the pitch of a tonal complex of lower harmonics (3-5) is heard over the slightly different pitch of a tonal complex of higher harmonics (6-12) of a slightly different fundamental wh

BRAINSTEM PATHWAYS AND BRANCHING PATTERNS OF BIOCYTIN-LABELED OLIVOCOCHLEAR NEURONS IN THE MOUSE. M.C. Brown\* and K.D. Whitley. Depts. of Physiol. and Otol. and Laryngol., Harvard Medical School, and Eaton-Peabody Lab., Mass. Eye & Ear Infirmary, Boston, MA 02114.

Olivocochlear (OC) neurons transmit feedback information from the superior olivary complex in the brainstem to the organ of Corti in the cochlea. We traced OC axons by retrogradely labeling them with extracellular injections of biocytin into the spiral ganglion in CD-1 mice. Tissue was processed with an ABC kit or with an anti-biotin antibody. Two groups of somata were labeled in the brainstem. Lateral olivocochlear (LOC) somata were located entirely within the ipsilateral lateral superior olive. Medial olivocochlear (MOC) neurons were located bilaterally in the medioventral periolivary nuclei, and rarely within the lateroventral and dorsal periolivary nuclei. LOC neurons gave off thin axons (diam. 0.5 to 0.7 µm) whereas MOC neurons generally gave off thicker axons (diam. 0.7 to 1.4 µm). From the somata, the axons traveled dorsally to the region of the facial genu, at which point the fibers from contralateral somata crossed the midline. The thick and thin fibers were intermingled from near the ipsilateral facial genu to the ipsilateral vestibular nerve, where they left the brain. There were a few examples of bilaterally projecting thick fibers. Axon branches from thick fibers were often given off to the cochlear nucleus (basal and apical injections) and to the inferior vestibular nucleus (basal injections only). Thin fibers gave off a few branches to the ventral part of the lateral superior olive. Brainstem branches from olivocochlear neurons are a means by which the OC system can exert influence on diverse areas within the central nervous system as well as on the organ of Corti.

## PAIN: PHYSIOLOGY AND BEHAVIOR

#### 167.1

ADULT HUMAN AND MONKEY DORSAL ROOT AND TRIGEMINAL GANGLION NEURONS: PATCH CLAMP RECORDINGS OF RESPONSES TO NOXIOUS STIMULATION

<u>S.L. Ingram<sup>1</sup></u>, <u>K.J. Burchiel<sup>2</sup></u> and <u>T.K. Baumann<sup>1,2,\*</sup></u>, Department of Pharmacology<sup>1</sup> and Division of Neurosurgery<sup>2</sup>, Oregon Health Sciences University, Portland, OR 97201

The mechanisms that are responsible for transduction in primate nociceptors are not known. We studied the membrane responses to capsaicin, resiniferatoxin, and HEPES-buffered physiological salt solution (HBSS) titrated to pH=6.0. Heat stimuli were applied as HBSS (pH=7.35) heated to between 40 and 50°C. Whole-cell tight-seal recordings were made from adult human DRG neurons and monkey (Macaca mulatta) trigeminal ganglion neurons, either acutely dissociated or grown in culture for several days. Some responded to all three chemicals, others only to lowered pH. Responses consisted of a depolarization and action potential discharge (current clamp recordings) or a net inward current (up to -3.2 nA) and action current discharge (voltage clamp recordings). In a given neuron, inward currents evoked by capsaicin (10  $\mu$ M) and resiniferatoxin (100 nM) had similar amplitude. Some capsaicinsensitive neurons were exposed to heated HBSS to which they also responded with a prolonged net inward current, sometimes associated with action current discharge. Thus these neurons respond to a variety of stimuli known to produce burning pain in humans and should prove valuable in studies of nociceptive transduction.

## 167.3

PLASTICITY OF MECHANICAL HYPERALGESIA IN CHRONIC NEURALGIA AND ACUTE CHEMOGENIC PAIN M.Koltzenburg, L.K.Wahren and H.E. Torebjörk, (SPON: ENA) Dept. of Neurology, Univ. of Würzburg, Germany, Dept. of Clinical Neurophysiology, Academic Hospital, Uppsala, Sweden

Brush-evoked pain (allodynia) is a hallmark of neuropathic pain and can be experimentally evoked by percutaneous application of the irritants capsaicin (1% in 70% ethanol) or mustard oil (100%) which specifically excite nociceptors and sensitize them to heat. Differential nerve blocks (compression of the superficial radial nerve) determined that the ongoing pain of neuralgia (n = 5) and the burning experimental pain (n = 14) is conducted by unmyelinated primary afferents whilst brush-evoked pain is signaled by low threshold mechanosensitive Aß-fibres.

Following induction of acute chemogenic pain and in some neuralgia patients, the severity of brush-evoked pain depends critically on persistent C-fibre activity. When nociceptors are sensitized to heat, innocuous warming of the skin from 35° to  $40^{\circ}\text{C}$  raised the level of chemogenic pain (as meassured on visual analogue scales) from  $37\pm4$  to  $59\pm8\%$ . Simultaneously, the severity of brush-evoked pain increased and there was a close correlation between both pains in neuralgia (r=.94) and after mustard oil (r=.81). Ongoing chemogenic pain and nociceptor discharge (as evidenced by microneurographic recordings) are abolished by mild cooling and sympatholytic therapy can rapidly eliminate the ongoing pain in some patients. In the absence of background pain, tactile stimuli are no longer painful. The rapid malleability of brush-evoked pain indicates that the central sensitizations which permit allodynia cannot be sustained by central nervous processes alone. This could mean that an abnormal nociceptor function is the primary cause of neuropathic pain and that central changes ensue as normal physiological responses to nocicptive inputs.

#### 167.2

PARASPINAL NOCICEPTIVE PRIMARY AFFERENTS.

G.M.Bove, A.R.Light\*. Dept. of Physiology,
Univ. of NC, Chapel HIll, NC 27599.

Though the paraspinal tissues possess

Though the paraspinal tissues possess putatively nociceptive elements, nociceptive afferents from this area have not been fully characterized. Single paraspinal Group IV nociceptive afferents from the rat proximal tail were characterized by their C.V. and response to mechanical stimuli. Their receptive fields (RFs) were located through microdissection. Individual fibers were activated from multiple tissues, such as muscle, tendon sheath, and along fascia associated with nerves supplying these structures. Individual RFs within muscle were found to have multiple punctate receptive areas, with mechanical thresholds between 1.5 and 8.5 gm. Background discharge was increased in several units, possibly due to sensitization from repeated mechanical stimulation. These data suggest that individual deep paraspinal nociceptors have multiple functional branches responsive to mechanical stimulation, and that these branches lie in different tissues. This contrasts with the reported discrete receptive fields supplying individual nociceptive Group IV muscle afferents. (Supported by NINDS NS16433 and FCER 90-6-1)

## 167.4

SUSTAINED GRADED PAIN AND HYPERALGESIA FROM EXPERIMENTAL TISSUE ACIDOSIS IN HUMAN SUBJECTS K.H. Steen & P.W. Rech\*. Dept. of Dermatol., Univ. of Bonn, D-5300 Bonn 1; Dept. of Physiol. & Biocyb., D-8520 Erlangen, Germany. Nociceptors in rat skin are tonically excited and sensitized by hydrogen

Nociceptors in rat skin are tonically excited and sensitized by hydrogen ion concentrations that normally appear in inflamed or ischaemic tissues (Steen et al. 1992, J. Neurosci 12: 86-95). Previous psychophysiological investigators, however, concluded algogenic actions of low pH solutions in human skin to be transient (Keele & Armstong 1964, Substances producing pain and itch. London: Arnold).

We used a motorized syringe pump to infuse an isotonic phosphate buffer solution (pH 5.2) at room temperature via sterile filter and cannula into the palmar forearm skin of human subjects (n=6, age 26-42, either sex). This resulted in a localized burning pain sensation (edema and flare response) that was sustained as long as a constant flow was maintained. Flow rates between 1.2 and 12 ml/h were needed to reach individual pain ratings around 20% of a visual analog scale (VAS) extending from "pain-threshold" to "unbearable pain". Increasing the flow in multiples of this basic rate led to approximately log-linear increases in individual pain ratings with reasonable congruence of the slopes. A constant infusion for 30 min of pH 5.2 at a rate producing pain ratings around 20% VAS led to a localized change in mechanical sensitivity. The touch threshold increased - as it did with control infusion of buffered saline (pH 7.4). The punctate force producing a threshold sensation of pain, however, dropped under pH 5.2 from 64 mN (median value, range 45.3-128 mN) to 5.7 mN (range 1.4-32 mN); the final level was usually reached within 15 min.

We conclude that experimental tissue acidosis provides a controllable and harmless method to produce sustained graded pain and hyperalgesia to mechanical stimulation (DFG grant Ste 593/1-1 and Re 704/1-6).

QUANTITATIVE EVALUATION OF SENSORY DISTURBANCES ACCOMPANYING MUSCULOSKELETAL PAIN. P.Hansson, U.Lindblom and E.Kinnman\*.Dept. of Neurology, Karolinska Hospital, S-104 01 Stockholm, Sweden.

Patients with nociceptive musculoskeletal pain sometimes report paresthesia and numbness in or near the pain area although no evidence nor suspicion of peripheral nerve, plexus or root involvement is present. Patients with lateral epicondylalgia and lumbosacral musculoskeletal pain have been examined using quantitative sensory testing (QST) for touch, temperature and pain, to elucidate if such pain may interfere with somatosensory transmission, and perhaps regularly is associated with sensibility disturbances.

Slight hypo- and/or hyperesthesia was encountered in patients with epicondylalgia, however, not of a dignity that it could be mistaken for neuropathic hyperpathia. Single patients with ongoing musculoskeletal pain in the lumbosacral region presented a more pronounced sensory dysfunction profile, mimicing that found in patients with neurogenic pain, but still possible to differentiate by the non-neuroanatomical distribution and transitory nature. Clinically, some patients with musculoskeletal pain and sensory symptoms and/or signs of sensory dysfunction present a diagnostic challenge.

THE EFFECTS OF PRIOR LOCAL ANESTHESIA ON THE EXPRESSION OF THE DEAFFERENTATION SYNDROME FOLLOWING C5 - T2 GANGLIONECTOMIES IN THE RAT B. Iskandar, E. Rossitch, Jr.\* J. Ovelmen-Levitt, and B.S. Nashold, Jr., Div. Neurosurgery, Duke U. Med. Ctr., Durham, N.C. 27710.

There has been controversy as to the importance of injury discharge at the time of nerve sectioning in the subsequent development of a defferential principle of the control of

There has been controversy as to the importance of injury discharge at the time of nerve sectioning in the subsequent development of a deafferentation pain syndrome. A deafferentation syndrome (DS) has been produced in rats by C5 - T2 ganglionectomies. This was expressed by biting (SM) in the anesthetic, completely denervated zone; and scratching (SCR) in the partially innervated region of the affected limb. In order to reduce or eliminate possible injury discharges, we have applied a long-acting local anesthetic (Marcaine) to the dorsal root ganglia in 9 rats (LAM) for 10 minutes prior to the ganglionectomies. The resultant deafferentation syndrome was then compared to that of 8 ganglionectomy only controls (LAC). Seven of the animals in each group have been observed for at least 30 days post-op. The SM was assessed by means of a point count system, and the extent of scratching noted. Compared to controls, the animals pretreated with Marcaine exhibited the following: 1) the onset of SM was not significantly delayed, but 2) the extent of SM was reduced at 30 days post-op, and 3) the pattern of SM was different. The mean SM score of the LAC rats at 30 days was 9.0 +/- 2.6, while it was 3.1 +/- 0.83 for the LAM animals. Scratching, however, was found to be more severe in the LAM rats. We conclude that nerve discharges at the time of sectioning may play a role in the expression of the deafferentation syndrome which follows dorsal root ganglionectomies.

## 167

LOW-THRESHOLD NEURONAL ACTIVITY OF SPINAL DORSAL HORN NEURONS INCREASES DURING REM SLEEP IN CATS. K. Kishikawa\*, J.G. Collins, H. Uchida, Y. Yamamori. Dept. of Anesthesiology, Yale Univ. Sch. Med., New Haven, CT 06510

Extracellular recordings of single spinal dorsal horn neurons (n = 19) were made in physiologically intact, awake, drug-free cats during EEG confirmed wakefulness and sleep stages [control awake, drowsy, slow wave sleep, rapid eye movement (REM) sleep]. Both the size of the receptive field (RF) area that was sensitive to light touch and the neuronal response to brushing of that RF area were determined. We were able to accurately map the RF size of 7 neurons during REM sleep. The low-threshold RF size of all seven neurons was increased (mean % increase ± S.D. 52.9 ± 25.6) during REM sleep as compared with control. We studied the response to RF brushing in 15 neurons during REM sleep. Eight of the 15 neurons demonstrated an increased response to brushing during REM sleep, 3 neurons were depressed and 4 unchanged. Response to brushing during drowsy and slow wave sleep states was studied in 16 and 12 neurons, respectively, in each group 4 neurons showed a decreased response to brushing. No other changes were observed. The effects of the intravenous anesthetic propofol (7.5 mg/kg) were studied in 10 neurons after determining sleep effects. The receptive field size was decreased by a mean of  $45 \pm 26.6\%$  after propofol administration. Seven of these 10 neurons had had their RF size increased during REM sleep. The response to brushing was also decreased by propofol. These results demonstrate that modulation of sensory information within the spinal dorsal horn varies with stages of sleep. Of particular interest, it appears that tonic inhibition of afferent input is reduced during REM sleep. These results also suggest that anesthetic-induced changes in spinal dorsal horn neuronal activity are not simply due to an anesthetic induced loss of consciousness. (Supported in part by NIH GM-29065)

ADENOSINE INHIBITS CNQX-SENSITIVE EPSCs EVOKED BY DORSAL ROOT STIMULATION <u>J.Li and E.R.Perl\*</u>, Dept. of Physiology Univ. of North Carolina, Chapel Hill, NC 27599

The effect of adenosine (ADE) on synaptic transmission between dorsal root input and neurons of the substantia gelatinosa(SG) was examined in vitro in transverse spinal cord slices (500µm)from hamster. Drugs were applied through bath superfusion. Excitatory post-synaptic currents (EPSCs) evoked by stimulation of the dorsal roots in whole cell patch recordings were judged to be monosynaptic if the latency was constant at near-threshold excitation. Most of the recorded EPSCs were reversibly blocked by CNQX(2-5µM). More than 1/2 of the recorded EPSCs were inhibited by ADE(30-300µM), an inhibition which could be suppressed by theophylline. ADE depressed all polysynaptic EPSCs; however, it did not affect some monosynaptic EPSCs; however, it did not affect some monosynaptic EPSCs. N<sup>6</sup>-cyclohexyl-adenosine, a specific A1 agonist, was 10<sup>3</sup> more potent than ADE. ADE produced hyperpolarization of some SG neurons; however ADE did not alter quantal size of spontaneous EPSCs but decreased the spontaneous EPSC frequency. Thus, in spinal SG, ADE appears to inhibit CNQX-sensitive EPSCs initiated by peripheral input, at least partially, through presynaptic A1 adenosine receptors and to have important actions on SG interneuronal transmission. ORGANIZATION OF LAMINA I TERMINATIONS IN THE POSTERIOR THALAMUS OF THE CYNOMOLGUS MONKEY.

A.D. Craig.\* Div. of Neurobiology, Barrow Neurological Institute, Phoenix, A.Z. 98012.

Lamina I nociceptive and thermoreceptive neurons constitute half of the spinothalamic (STT) and trigeminothalamic projections, and their axons ascend in the lateral STT classically associated with pain and temperature sensibility. Previous PHA-L work has identified termination sites in both the lateral and medial thalamus of the cat and the monkey. In this study, the dense projection to the PO/SG region at the caudal aspect of VP of young (ca. 2 kg) monkeys has been examined with multiple fluorescent labeling (using Texas Red, FITC and AMCA). Following iontophoretic injections in lamina I at the trigeminal, cervical or lumbar level in anesthetized animals, (red, green or biotinylated) dextran was found to anterogradely label this projection (but not one other) similarly to PHA-L; thus, double anterograde labeling from different levels was performed in 8 monkeys. In addition, endogenous calbindin or parvalbumin was labeled immunohistochemically with a third fluorochrome. Lamina I terminal fibers are topographically organized within a discrete region identifiable in all planes of section by a confined plexus of calbindin-positive fibers. This region corresponds to a cytoarchitectonic zone that can be resolved in adjacent thionin-stained sections. Control cases indicate that lamina V terminations occur more rostrally in an adjacent region that is part of VP.

These observations support the hypothesis originated by Head and Holmes (1911) that a discrete portion of lateral thalamus subserves the discriminative aspect of specific pain and temperature sensation. (Supported by NIH grant NS25616)

HUMAN CEREBRAL PROCESSING OF NOXIOUS AND INNOCUOUS STIMULI. R.C. Coghill,\* J. Talbot, A. Evans, A. Gjedde, E. Meyer, G.H. Duncan and M.C. Bushnell. U. Montréal and Montreal Neuro. Inst., Montréal, Qué

The role of human cortex and thalamus in the processing of painful stimuli is currently in dispute. Using positron emission tomography (PET), we demonstrated increases in cerebral blood flow (CBF) in the left primary and secondary somatosensory cortex (SI & SII) and in the left cingulate cortex, all contralateral to the presentation of painful heat (48.2°C) stimuli [Science,251:1355 (1991)]. Other imaging studies have shown activation of left cingulate cortex and thalamus by mildly painful heat (≈46°C) stimuli [Jones et al., Proc.R.Soc.Lond., 244:39 (1991)], but have failed to observe activation of SI or SII [Jones et al.; Apkarian et al., Life Science, (in press)]. Studies using only innocuous vibrotactile stimuli have generally reported activation of SI and/or SII contralateral to the stimulus site. The current study sought to clarify the roles of SI and other brain regions in the processing of somatosensory stimuli by replicating our previous findings, investigating the laterality of nociceptive activation, and comparing the effects of noxious heat and innocuous vibrotactile stimulation within the same group of subjects. Changes in CBF were evaluated by PET following the bolus injection of oxygen-labelled water (H<sub>2</sub><sup>15</sup>O) in nine human volunteers. Each underwent scans during the presentation of painful heat (48°C), vibrotactile (150 Hz), and control (35°C) stimuli (12 five-sec repetitions per scan) to the left forearm. We have confirmed significant pain-related increases in CBF in the regions approximating anterior cingulate, SI and SII, all contralateral to the stimulated forearm. In agreement with Jones et al., we also observe pain-related activation in contralateral thalamus. In contrast, significant vibrotactile-related activation appears restricted primarily to contralateral SI and SII. Although similar regions of SI and SII are activated by both vibrotactile and painful stimuli, it appears that mildly painful stimuli are not adequate to elicit detectable CBF changes within these regions. Supported by the Canadian MRC.

## LEARNING AND MEMORY: SYSTEMS AND FUNCTIONS—NEUROPSYCHOLOGY I

## 168.1

ON THE DEVELOPMENT OF DECLARATIVE MEMORY. R. McKee\* and L.R. Squire. VA Med Ctr & UCSD Psychiatry Dept, La Jolla, CA 92093. Infantile amnesia, i.e., the unavailability of recollections from the first three years of life, has traditionally been explained in terms of repression or retrieval failure. Another possibility, based on the idea of multiple memory systems, is that the limbic-diencephalic brain of multiple memory systems, is that the Imbic-diencephalic brain structures that support declarative memory are late-developing and that declarative memories are not formed early in life. By this view, the learning abilities of infants reflect nondeclarative forms of memory (e.g., skills and habits). We studied the performance of normal subjects and amnesic patients on the visual paired-comparison task, which has been used to demonstrate memory in infants. Based on a procedure recommended by B. Malamut, subjects viewed 24 pairs of pictures (2 identical items/pair) and later viewed another 24 pairs of pictures (one novel item and one old item in each pair). Normal subjects exhibited a tendency to look at the novel item in each pair that persisted for a few hours. This tendency was not observed in amnesic patients, indicating that the effect of famiarity on viewing time depends on the limbic-diencephalic structures that are damaged in amnesia and essential for declarative memory. These results and findings in infant monkeys with surgical lesions (Bachevalier, 1990) suggest that visual paired-comparison performance in human infants is supported by declarative memory. If so, performance on this task reflects an early capacity for declarative memory, and the absence or prolonged postnatal development of this system cannot explain infantile amnesia. It is more likely that infantile amnesia results from slow maturation of the neocortex where long-term declarative memories are thought to be stored.

## 168.3

INTACT PROTOTYPE LEARNING BY AMNESIC PATIENTS: EVIDENCE FOR PARALLEL LEARNING OF ITEM-SPECIFIC AND GENERAL INFOR-MATION B.J. Knowlton\* & L.R. Squire. VA Med Ctr. and Dept. of Psychiatry, UCSD, La Jolla, CA 92093.
When subjects study a list of items, they not only

learn about the specific items, they also acquire generic information about the items as a group, e.g., a concept about the category that the items belong to. Most theories of concept learning suppose that category-level knowledge is derived from long-term memory for the items that are studied. Our study shows that category-level knowledge can develop normally in the absence of memory for individua items. Amnesic patients and control subjects were shown 40 dot patterns that were distortions of a prototypic pattern. After 5 min, subjects were told that the patterns belonged to a single category and were then shown new patterns (4 repetitions of the prototype, 40 distortions of the prototype, and 40 random patterns). Subjects classified each pattern as to whether it did or did not belong to this category. Control subjects and amnesic patients performed identically. In contrast, in a second study, control subjects were significantly better than amnestc patients at recognizing which specific patterns had been presented. There was also a significant interaction (p<.05) of task (classification or recognition) and group (controls vs. amnesics). The results indicate that category-level knowledge about items can develop independently of declarative knowledge about the items themselves.

### 168.2

IMPLICIT LEARNING OF ONE-TRIAL COLOR-WORD "ASSOCIATIONS" IN AMNESIC PATIENTS. G. Musen\* & L.R. Squire, VA Med Ctr, & UCSD Psychiatry Dept., La Jolla, CA 92093. Evidence for implicit and rapid learning of verbal associations has been difficult to obtain (Musen & Squire, submitted). We reasoned that <u>nonverbal</u> associations might be more readily detected because the attributes to be associated can be more completely integrated (i.e., a word printed in a color such that the "association" is between two features of the same stimulus). We used a color naming task in which 84 words that were strongly associated with particular colors (e.g., banana) were printed in incongruous colors (e.g., blue banana). Amnesic patients and control subjects were given 5 seconds to view each item and were asked to form an image of the word in the color in which it was printed. At test, subjects were asked to name the colors of 84 test items as rapidly as possible. One third of the items remained in the same color as during study (old), 1/3 were in a different color (recombined), and 1/3 of the words had not appeared at study (new). If new "associations" are not appeared at study (new). acquired, then recombined items should be named more slowly than old items. Both groups of subjects named the colors of the old items significantly more rapidly than the recombined or new items (control subjects: old = 968 ms, recombined = 1029 ms, and new = 1019 ms; amnesic patients: 1029, 1115, and 1112, respectively). Thus, implicit learning of new nonverbal associations (or conjunctions of features) can occur after a simple study trial features) can occur after a single study trial.

## 168.4

IMPAIRED PERCEPTUAL PRIMING AND INTACT CONCEPTUAL

IMPAIRED PERCEPTUAL PRIMING AND INTACT CONCEPTUAL PRIMING IN A PATIENT WITH BILATERAL POSTERIOR CEREBRAL LESIONS. M.M. Keane\*, H. Clarke, and S. Corkin. Dept. of Brain and Cognitive Sci. and Clinical Research Ctr., MIT, Cambridge, MA 02139. Dissociations among repetition priming effects in patients with Alzheimer's disease (AD) have revealed that priming is not mediated by a single mechanism. We have proposed that perceptual priming (normal in AD) is supported by memory processes localized to posterior (peristriate) cortices that are relatively preserved in AD, and that conceptual priming (impaired in AD) is supported by memory processes localized to more anterior cortices that are compromised in AD. In the present study, we tested this hypothesis by examining priming in a patient with a severe visuoperceptual impairment consequent to a head injury that caused bilateral posterior cerebral lesions and required a right anterior temporal lobectomy. The hippocampus was spared bilaterally. We predicted that the lesions in this patient would compromise the neural substrate of perceptual priming processes and would spare the reural substrate of conceptual priming processes and would spare the neural substrate of conceptual priming processes. Consistent with the first prediction, the patient showed no priming in perceptual identification of words or pseudowords, and reduced priming in within-modality (visual) word-stem completion. Consistent with the second prediction, he showed normal priming in cross-modality (auditory-visual) word-stem completion, and normal priming in category exemplar production. Recognition memory was normal. Coupled with prior findings in AD, these results represent a double dissociation with prior infutings in AD, tiese results represent a double dissociation between perceptual and conceptual priming. Further, they constitute the first demonstration of impaired perceptual priming in the face of normal recognition memory. Our findings provide strong evidence for the existence of two cortically mediated memory systems, each supporting a distinct component of repetition priming. These systems are independent of the limbic-diencephalic system supporting recall and recognition.

NO DREAMS - NO MEMORY: THE EFFECT OF REM SLEEP DEPRIVATION ON LEARNING A NEW PERCEPTUL SKILL A.Karni<sup>1,2</sup>, D.Tanne<sup>2</sup>, B.S.Rubinstein<sup>1</sup>, J.J.M.Askenasi<sup>2</sup> and D.Sagi<sup>1</sup>, <sup>1</sup>Dept. of Appl. Math., Weizmann Inst. of Sci., Rehovol and <sup>2</sup>Dept. of Neurology, Sheba Med. Cent., Tel-Hashomer, ISRAEL.

of Appl. Math., Weizmann Inst. of Sci., Rehovot and \*Dept. of Neurology, Sheba Med. Cent., Tel-Hashomer, ISRAEL.

Is REM sleep important for memory consolidation? We combine a novel perceptual skill learning paradigm with specific sleep stage deprivation technique, to investigate the effect of REM sleep deprivation on memory consolidation. The paradigm we use induces a remarkable long-term, retinal input specific, improvement in a basic visual discrimination task which is highly specific for simple physical attributes of the sensory input (retinotopy, monocularity, orientation). This implies discrete, highly specific, local plasticity within the primary visual cortex induced by sensory experience (PNAS 88:4966, 1991). Furthermore, learning in this paradigm is not immediate - it takes about 8-10 hours to "consolidate". It is then not forgotten for at least one year.

Our 2AFC psychophysical masking paradigm was used to measure texture target discrimination thresholds, in consecutive sessions, before and after sleep with polysomnography in a sleep laboratory. Each session was made of some 1000 stimulus presentations where the subjects were required to identify the orientation of a target made of 3 line elements differing only in orientation from the background. Each subject underwent 2 nights of baseline recording followed by 2 nights of sleep stage deprivation, effected by forced arousal (bell or speech) after recording an epoch of the relevant sleep stage.

Results: 1)Performance was improved by 52% (mean, 4 nights) after a normal (6-7 hours) night sleep. 2) REM deprivation (down to 6% of total sleep time) disrupts consolidation (improvement by 0-9%, 2 nights). 3)REM stage 3-4 sleep deprivation (down to 6% of total sleep time) does not affect normal consolidation (48% improvement, 2 nights). 4)Both types of deprivation did not affect performance on an already trained task.

Depriving REM sleep severely retards processes involved in consolidating the effects of practice ("learning how"). This implies, that proce

IMPAIRED FEELING AND AUTONOMIC ACTIVATION FOR VISUAL BUT FOLLOWING DAMAGE TO RIGHT
D. Tranel\* H. Damasio and A.R. STIMULI INFEROTEMPORAL CORTEX. <u>Damasio</u>. Div. of Behav. Neurol. & Cogn. Neurosci., Univ. of Iowa Col. of Med., Iowa City IA, 52242.

A patient (CB-1614) with a lesion in the right

inferotemporal (IT) region developed defects in learning of faces, places, and routes. We conducted experiments in which skin conductance responses (SCRs) were recorded while CB-1614 viewed two randomly ordered series of stimuli. (1) Nonverbal: emotionally-charged (target) and neutral (nontarget) pictures. (2) Verbal: high-emotional (target) and levermotional (nontarget) words (there were neutral (nontarget) pictures. (2) Verbal: high-emotional (target) and low-emotional (nontarget) words (there were 10 targets and 30 nontargets in each set). CB-1614 had normal SCRs to basic "startle" stimuli (e.g., loud noise). Her SCRs to the nonverbal target stimuli were severely impaired. By contrast, she produced normal SCRs (X-1.68 uS) to the verbal targets. The findings indicate (X=1.68 uS) to the verbal targets. The findings indicate a defect in visually-triggered "emotionality," restricted to nonverbal stimuli. It is interesting to note that the patient's self-report matched the SCR results: she reported a lack of feeling when viewing previously disturbing or exciting stimuli (e.g., watching a provocative movie), but normal feelings when reading this type of material. The results suggest that the right IT region plays a role in triggering somatic states to visual-nonverbal stimulation.

## 168.9

RECALL OF UNEXPECTED STIMULI WHILE TEMPORAL CORTEX IS SUPPRESSED WITH COLD. <u>James A. Horel</u>\*, Department of Anatomy and Cell Biology SUNY HSC Syracuse NY, 13210.

While visual learning is readily disrupted by suppressing inferotemporal cortex (IT) with cold, effects on recall are difficult to produce. Perhaps exposure to the stimuli before the cold is applied causes the animals to withdraw the information from IT. This predicts that if the animal is presented with a visual discrimi-nation that it did not expect during suppression with cold, it would not be able to withdraw this information and could not do the task. One of two well-known discriminations was presented to two well-known discriminations was presented to three monkeys for 10 trials and then the cold was turned on and left on for 60 trials without affecting performance. The unexpected discrim-ination was then introduced and performance was nation was then introduced and performance was at chance for 50 trials, whereupon the discrimination was shifted back to the expected pair and performance returned to nearly normal. The same result obtained with expected and unexpected stimuli reversed. This suggests that information the animals anticipate using may be withdrawn from IT and placed in a working memory that is not suppressed by IT gooling (Suppressed by IT gooling) that is not suppressed by IT cooling. (Supported by NS 18291)

VERBS BUT NOT NOUNS: DAMAGE TO LEFT TEMPORAL CORTICES IMPAIRS ACCESS TO NOUNS BUT NOT VERBS. A.R. Damasio\* D. Tranel and H. Damasio. Div. of Behav. Neurol. & Cogn. Neurosci., Univ. Iowa Col. of Med., Iowa City IA, 52242.

In a task designed to elicit the production of *verbs* (n=220), three patients with left temporal damage consistently produced the correct target words, performing no differently from normal controls. However, in a similar task designed to elicit the production of nouns (n=360), both patients performed quite defectively, nouns (n=360), both patients performed quite defectively, scoring many standard deviations below controls (word frequencies were comparable in the verb and noun sets). The lesions are located outside traditional language areas (left frontoparietal operculum, posterior temporal region, inferior parietal lobule), whose damage is associated with aphasia. The damage is in left anterior and middle temporal lobe (areas 28, 35, 36, 20, and 21). We propose that this sector contains systems for the We propose that this sector contains systems for the retrieval of (1) proper nouns, and of (2) common nouns which denote entities of some but not all conceptual categories. Those systems are not involved in verb retrieval, nor in the implementation of word-forms. Instead, those systems perform a two-way lexical mediation role, e.g., they promote the reconstruction of a word-form triggered by activation of the conceptual structure of the entity that is denoted by that word; they can operate in reverse. We suggest that verb access requires systems in left parietofrontal cortices. requires systems in left parietofrontal cortices.

### 168.8

METABOLIC ACTIVATION OF HIPPOCAMPUS AND DORSOLATERAL PREFRONTAL CORTEX BY A SPATIAL WORKING MEMORY TASK: RELATIONSHIP TO DURATION OF DELAY. R.A. Adoock\*, H.R. Friedman & P.S. Goldman-Rakic, Sect Neurobiol, Yale Univ Sch Med, New Haven CT.

Both hippocampus (HPC) and dorsolateral prefrontal cortex (PFC) have been implicated in performance of spatial memory tasks in monkeys.

Previous studies from this laboratory show that glucose utilization (LCGU) in Previous studies from this laboratory show that glucose utilization (LCGU) in both areas is enhanced in monkeys performing spatial working memory (SWM) tasks as compared to monkeys performing tasks that do not specifically engage SWM (e.g., Friedman & Goldman-Rakic, J. Neurosci. 8:4693, 1988; Soc. Neurosci. Abstr. 17:1135, 1991). PFC lesions produce impairments on SWM tasks at delays as short as 5s (e.g., Goldman & Rosvold, Exp. Neurol. 27:291-304, 1970); however, studies of HPC lesions have shown that performance is impaired only at longer delay intervals, i.e., 15s and longer (e.g., Zola-Morgan & Squire, Behav. Neurosci. 99:22-34,1985). We used the 2DG method to assess a) whether LCGU in the HPC increases with delay period as predicted by the lesion studies, and b) whether LCGU in the PFC is similarly affected or is less dependent on delay, as lesion studies might suggest.

delay, as lesion studies might suggest.

Monkeys were trained on spatial delayed alternation: two each at 15s and 30s, and three at 5s delay. 14C-2DG (100mCi/kg) was injected for the 45 min 2DG test session, and blood samples were taken for later determination of LCGU using a computerized imaging system. Contrary to prediction, both areas showed overall trends toward increased LCGU at shorter delays. In the HPC, LCGU was enhanced by 24% in the 5s group compared to the 30s group, and 22% over the 15s group. In PFC, LCGU was 33% greater in the 5s group vs the 30s group and 12% greater than the 15s group. These results suggest that for this SWM task, delay duration is not the most important determinant of LCGU for either area and must be reconciled with conflicting data from lesion studies. Supported by MH 33546 conflicting data from lesion studies. Supported by MH 38546.

## 168.10

IMPAIRMENT OF LONG-TERM MEMORY AND SPARING OF SHORT-TERM MEMORY IN MONKEYS WITH LESIONS OF THE HIPPOCAMPAL FORMATION. P. Alvarez-Royo\*, S. Zola-Morgan, and L. R. Squire. UCSD Depts. of Neuroscience and Psychiatry, La Jolla, Ca 92093, and

V.A. Medical Center, San Diego, Ca 92161.

During the last decade, an animal model of human amnesia has been developed in the monkey. Studies using this model have identified structures in the medial temporal lobe that are essential for forming long-term memory (i.e., the hippocampus and the entorhinal, perirhinal and parahippocampal cortices). Recently, an important aspect of these studies has been questioned by Ringo (1991). He suggested that the data from the delayed nonmatching to sample (DNMS) task, which has been extensively used in these studies, have been analyzed in a potentially misleading way

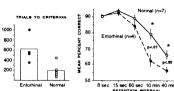

extensively used in these studies, have been analyzed in a potentially misleading way and do not support the idea that medial temporal lobe damage produces a selective impairment in long-term memory while sparing short-term memory.

One problem has been that most of the studies analyzed by Ringo were not designed to directly compare short-term and long-term memory. We addressed this issue directly using a computer-controlled apparatus to test monkeys on an automated version of the DNMS task with delays ranging from 0.5 seconds to 10 minutes. We previously reported that monkeys with lesions of the hippocampal formation that include parahippocampal cortex (the H<sup>+</sup> lesion) learned the task normally with a delay of 0.5 seconds but preferred significantly worse than a propule of comparing the state of the second significantly worse than a propule of comparing the second significantly worse than a propule of comparing the state. of 0.5 seconds, but performed significantly worse than a group of normal animals at delays longer than 30 seconds. In that experiment, however, the delays were presente sequentially. Therefore, differential forgetting or practice with the nonmatching rule could have affected the results. These two groups have now been retested on the could nave arrected the results. Intese two groups have now been retested on the DNMS task using a mixed-delay paradigm. The H<sup>+</sup> animals performed normally at a short delay (1 second) and were impaired at long delays (1 and 10 minutes). These data strongly reinforce the idea that the H<sup>+</sup> lesion affects only long-term memory and leaves short-term memory intact. Accordingly, they provide strong confirmation in the monkey of the long-standing idea, based primarily on findings from humans, that short-term memory is independent of medial temporal lobe function.

SELECTIVE ENTORHINAL CORTICAL LESIONS IMPAIR LEARNING AND MEMORY IN THE MONKEY. B.W. Leonard\*, D.G. Amaral, S. Zola-Morgan and L.R. Squire, Salk Institute, San Diego, CA. 92186, Dept. of Psychiatry, UCSD, La

Bilateral medial temporal lobe lesions in monkeys and humans result in a profound impairment of learning and memory. Human neuropsychological studies indicate that damage limited to the hippocampus proper is sufficient to impair memory function. The entorhinal cortex (EC) is an anatomically distinct component of the hippocampal formation that acts as an interface through which the hippocampus and other hippocampal fields communicate with the neocortex As part of an ongoing program designed to determine the relative contributions to memory function of the separate components of the medial temporal lobe, we have prepared a group of monkeys (M. fascicularis) with aspiration lesions intended to include only the EC. Learning and memory were assessed postoperatively with a standard battery of tests. Here we report the results from 4 monkeys on the visual, trial-unique delayed non-matching to sample (DNMS) test. EC animals were impaired at learning DNMS at a standard 8 sec delay (p<.01). Across longer retention intervals, performance of EC animals was also impaired (group effect, p=.056; group X retention interval interaction, p<.05; based on the

4 longest delays). These results show that bilat-eral lesions intended to damage entorhinal cortex and spare perirhinal and parahippocampal cortices are sufficient to impair memory function.

### 168.13

SEVERE RETROGRADE AMNESIA IN A PATIENT WITH TRAUMATIC BRAIN INJURY. H.J. Markowitsch<sup>1</sup>, Pasquale Calabrese<sup>1,2</sup>, Michael Haupts<sup>2</sup> and W. Gehlep<sup>2</sup> (SPON: European Neuroscience Association), Dept. Psychology, University of Bielefeld, D-4800 Bielefeld, Neurology Dept., University Hospital Langendreer, D-4630 Bochum, Germany

We describe a 45-year old patient who at the age of 41 years fell from a horse and received severe head injury. The patient was comatose for 6 weeks. His brain damage included the ventral half of the right frontal lobe, the temporal polar horns bilaterally, and (as contre coup), the area of the left temporo-parietal cortex.

The patient, a former industrial manager, was of average

intelligence, had a normal short-term memory span, but severe problems in the long-term memory domain, especially in the retrieval of remote memories. He was given a comprehensive test battery to assess his intelligence, learning and memory, his emotional status, problem solving abilities, and language functions. The memory tests included priming tasks, skill learning, and tests of his old memory.

We conclude from our results that similar to the case described by Kapur et al. (Brain, 1992, 115, 73ff), the temporo-polar cortex may play a crucial role for long term memory retrieval.

#### 168.12

RETROGRADE AMNESIA IN RHESUS MONKEYS: DIFFERENTIAL RETENTION OF HABITS AND MEMORIES? <u>R. C. Saunders.</u>\*Clinical Brain Disorders Branch, NIMH, St Elizabeths Hospital, Washington, D.C. 20032. Retention of information acquired prior to the onset of amnesia has been difficult to evaluate in human amnesic subjects. In animals we can evaluate retrograde amnesia more easily because we can control and assess retention of information learned before and after the onset of the amnesia. In experiment 1 monkeys (Macaca mulatta) were trained on several lists of 20 object discrimination pairs in two ways. A list for concurrent discrimination learning was presented either multiple times (5 to 10) during a single testing session or only once (24 hr concurrent). Learning of each list was to the same 90% criterion level. One list of each type was presented at 8-9 month, 4-5 month, and 1 month intervals before the removal of the medial temporal lobe area. Retention of object discriminations tested before surgery was at a high level averaging 84.5%, with no differences between lists. In contrast, post-op retention was dramatically reduced to near chance levels on all lists (58%) and were not differentiated by type of training or by length of interval before the onset of amnesia. In experiment 2, monkeys were given several object discrimination pairs to be learned one at a time. After reaching a 90% performance level they were over-trained for 500 trials before surgery. Monkeys showed perfect post-op retention on each pair. In experiment 3 a paired-comparison recognition memory task was used (Saunders, et al., Neurosci. Abstr., 1990). In contrast to the results of experiment 2, post-op retention of pre-operatively acquired information was at chance (55%). These data taken together demonstrate that 1) a severe retrograde amnesia may be present and not temporally-limited, and 2) retrograde amnesia after medial temporal lobe removal may show a selective defect for 'memories' and not 'habits' similar to that seen in anterograde amnesia.

## VISUAL CORTEX: ANATOMICAL STUDIES

THE INHIBITORY INPUT TO THE PERIKARYON AND INITIAL AXON SEGMENT OF THE LAYER II/III PYRAMIDAL CELL OF RAT VISUAL CORTEX. A. PETERS, Department of Anatomy and Neurobiology, Boston Univ. Sch. of Med., Boston, MA 02118.

The inhibitory input to the cell body and initial axon segment of pyramidal cells is complex. It is provided by at least four different types of local circuit neurons, all of which are GABAergic. The chandelier cells provide input to the axon initial segment, and the other neuronal types provide input to the cell body. Their terminals are distinctly different and because of their characteristics they have been termed large, medium-sized and dense terminals (Peters and Harriman, J. Neurocytol., 19:154, 1990). To determine the origins of these terminals, their features have been compared with those of labelled neurons. It is then evident that the medium-sized and dense terminals resemble those of multipolar neurons with unmyelinated axons, while the dense terminals resemble those of VIP-positive bipolar cells. The source of the large terminals could not be determined. From an analysis of 50 profiles of layer II/III pyramidal cells it is calculated that the average neuron of this type forms 65 axosomatic synapses. 43 of these synapses are medium-sized and are provided by the axon terminals of the medium-sized multipolar neurons, while 12 of the synapses are of the dense kind, which are associated with bipolar cells. The remaining 10 synapses are formed by large terminals. How the inhibitory inputs provided by the different types of non-pyramidal cells differ in function is not known. Supported by NIH grant NS 07016.

## 169.2

FUNCTIONAL AND STRUCTURAL TOPOGRAPHY OF LATERAL INHIBITORY CONNECTIONS IN CAT VISUAL CORTEX (AREA 18) <u>Z.F.Kisvárday¹\*</u>, <u>D.-S.Kim²</u>, <u>U.T.Eysel¹</u>, <u>T.Bonhoeffer²</u> ¹Dept. Neurophysiol. Ruhr-Univ.Bochum, PO Box 102148, F.R.G. ²Max-Planck Inst.Brain Res., 6000 Frankfurt 71,

GABAergic large basket cells in layers III-V provide long-range horizontal connections over several mm. In order to know the relationship between the axonal topography of large basket cells and the topography of orientation specificity over their influenced area we used a combination of optical imaging and single cell tracing in the same tissue. A craniotomy was made above area 18 at Horsley-Clarke co-ordinate A5 and an area of 9.6x7.2 mm<sup>2</sup> of the exposed cortex was studied with the optical recording technique, revealing orientation domains. Then, at several sites, biocytin was extracellularly delivered in to the superficial layers using positive current of 0.7-0.9 μA at 1 Hz.

The labelling was revealed with the ABC method, axonal fields of 3 biocytin labelled large basket cells were reconstructed from adjoining large horizontal sections in layer III. The distribution of these axonal fields was compared with the distribution of the orientation map of the same area. For alignment, identified electrode penetrations were used as landmarks.

The results show that the axonal field of each large basket cell establishes inhibitory connections over regions representing the whole range of orientations, similar and different, to that of the parent soma. It is thus reasonable to assume that the same large basket cell provides so-called isoas well as cross-orientation inhibition depending on the topography of its target cells in relation to the topography of the orientation map.

Z.F.K. and U.T.E are supported by the Deutsche Forschungsgemeinschaft.

Biocytin injections, guided by optical imaging, reveal relationships between functional architecture and intrinsic connections in monkey visual cortex. R. Malach, Y. Amir, E. Bartfeld and A. Grinvald Weizmann Inst. Rehovot, Israel 76100. How are the patterns of intrinsic horizontal connections related to the functional architecture of the cortex? In this study we explored the relationship between patterns of intrinsic connections and the detailed functional architecture. Our approach combined the techniques of tract tracing and optical imaging. Tracing of intrinsic connections with the anterograde tracer biocytin revealed an intriguing diversity of stereotyped patterns of clustered projections. These patterns ranged from highly asymmetric, oval shapes to nearly symmetric "rosette"—like forms. Similarly, individual clusters varied greatly in their shape and size. High resolution optical imaging provided detailed maps of ocular dominance columns and iso-orientation domains which formed pinwheel—like structures around orientation singularity points. Furthermore, optical imaging enabled us to select the precise sites of biocytin injections in the functional map. Our results provide examples of remarkable specificity of intrinsic connections between functional domains. Interestingly, injections that overlapped singularity points, including all orientations, did not produce diffuse labeling. Rather, clear cut, clustered projections were observed. These clusters overlapped with a diverse set of neighboring functional columns.

## 169.5

INTRINSIC CONNECTIONS OF OWL MONKEY STRIATE CORTEX: DIFFERENCES BETWEEN CYTOCHROME OXIDASE (CO) BLOBS AND INTERBLOBS. <u>V.A. Casagrande \* J.A. Maviny-Hudson, and J.G. Taylor</u>. Depts. of Cell Biol. and Psych., Vanderbilt Univ., Nashville, TN 37232

Previous work showed that the CO-blobs in layer III of striate cortex in 2 diurnal (macaque and squirrel monkey) and 1 nocturnal (bushbaby) primates receive indirect input (via layer IV) from both the LGN parvocellular (P) and magnocellular (M) pathways (Casagrande et. al., '90; Lachica et.al. '92). However, connections of interblobs showed species differences; in the diurnal simians interblobs receive indirect input only Lacinca et.a. 92). However, connections of interbloos snowed species differences; in the diurnal simians interblobs receive indirect input only from the P pathway while in the nocturnal prosimian interblobs receive input only from the M pathway. We asked if the species differences in interblob connections were a reflection of phylogenetic (simian verses prosimian) or visual niche (diurnal verses nocturnal) differences. We made HRP or biocytin injections into layer III of 6 nocturnal simians (owl monkeys) and compared the laminar patterns of retrogradely labeled cells. Results show that, as in the other primates, injections in either blob or interblob layer IIIA in owl monkey labeled cells mainly in IIIB and V, and injections into blob centers in IIIB labeled cells in both  $1V\alpha$  (M target) and  $1V\beta$  (P target), as well as cells in the other subdivisions of layer III, and layers V and VI. In contrast, following interblob IIIB injections, the majority of labeled cells were restricted to  $1V\alpha$ , as in the bushbaby. Many cells were also labeled in IIIA, dorsal divisions of V and VI. Results suggest that CO blobs in primates get input from all LGN pathways and are concerned with basic aspects of vision that transcend primate niche specializations. Interblobs receive either M input (via  $1V\alpha$ ) in nocturnal primates or P input (via  $1V\beta$ ) in diurnal primates suggesting that interblobs perform a function that must take into account visual niche requirements. Supported by EYO1778 (VAC) and core grants EY08126, HD15052.

## 169.7

OPTICAL IMAGING OF ORIENTATION MAPS IN V1, V2, AND MT OF NEW WORLD MONKEYS. R. B. H. Tootell\*, D. Malonek and A. Grinyald, Depts. Neurobio., Harvard Med. Sch., Boston, Mass. 02115 and Weizmann Inst., Rehovot, Israel 76100.

The many visual cortical areas exposed on the lateral surface of Aotus (owl) and Saimiri (squirrel) monkeys are ideal for exploration of cortical functional organization by imaging of exploration of cortical functional organization by imaging of intrinsic signals. In this study, the main stimulus was an achromatic, moving (2-10°/sec) rectangular wave grating, presented binocularly at or near zero disparity, at different directions/orientations (45° apart). Such stimuli produced orientation-specific patches in V1 and V2 similar to those previously observed in macaque; a 180° representation with a center-to-center spacing of 500 um and 750 um, respectively. In owl monkey MT, such stimuli also produce radially-arranged functional maps, with center-to-center spacings of 800 um. These images were sufficiently robust so that iso-orientation maps were obtained by subtracting a "blank" stimulus, rather than a grating at the orthogonal orientation. Tests with other stimuli (see Malonek et al, 1992) suggested that the organization is specific for orientation rather than axis-of-motion, and that it coexists with other architectures, including one for direction.

To begin exploring the relationship between these optical maps and earlier DG data on the functional organization of owl monkey

and earlier DG data on the functional organization of owl monkey MT (Tootell and Born, 1990), DG and optical maps of orientation were successfully obtained in MT in the same monkey, in response to identical stimuli. Supported by EY07980 and the Schilling Foundation.

CORRELATION BETWEEN PATTERNS OF LATERAL CONNECTIVITY AND PATTERNS OF ORIENTATION PREFERENCE IN MONKEY STRIATE CORTEX.

G. G. Blasdel, T. Yoshioka , J.B. Levitt, J.S. Lund. Department of Neurobiology, Harvard Medical School, Boston, MA 02115; Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15261

We explored structure function correlations in differentially imaged regions of macaque striate cortex by making small iontophoretic injections of biocytin into the upper layers. Most of the resulting injections were 100-200 µm across, and gave rise to patchy projections that spread as far as 2.3 mm laterally. After each animal had been perfused, and the injections had been recovered, patterns of transport and orientation were compared. In some cases patchy projections were found in regions that preferred similar orientations; in others they occurred in regions that preferred different orientations. One possible explanation for this is that injections into slightly different vertical compartments label different circuits. It is also conceivable that patterns of transport such as these are driven by constraints other than orientation preference. Iso-orientation slabs appear correlated with the anisotropic spread of projections since both appear elongated along axes perpendicular to the ocular dominance columns (see Blasdel, 1992; Yoshioka et al, 1992). CYTOSKELETAL PROFILE OF NEURONS INVOLVED IN THE M AND P PATHWAYS OF THE MACAQUE VISUAL CORTEX. S. B. Kupferschmid<sup>1\*</sup>, R. Gattass<sup>2</sup>, L. G. Ungerleider<sup>2</sup>, J. H. Morrison<sup>1</sup>. <sup>1</sup>Fishberg Research Center for Neurobiology, Mt. Sinai School of Medicine, NY, NY 10029; <sup>2</sup>Lab. of Neuropsychology, NIMH, Bethesda, MD 20892

A monoclonal antibody directed against a non-phosphorylated neurofilament

A monoclonal antibody directed against a non-phosphorylated neurofilament protein, SMI32, labels pyramidal cells in the monkey visual cortex in areal specific patterns. In V1, SMI32-immunoreactivity (ir) labels the cells of layer 4B and the Meynert cells of layer 6. In visual association areas V2, V3, V4 and MT, the SMI32-ir neurons are predominantly in layers 2 and 3. Area MT is unique in having a band of SMI32-ir neurons in layer 6. Because SMI32 also labels the retinal alpha ganglion cells and the magnocellular cells of the lateral geniculate nucleus in addition to the MT projecting cells of V1, SMI32 may be a selective marker of components in the M pathway of the monkey visual cortex. To test this hypothesis we made injections of distinct retrograde tracers into areas V4 and MT of 2 cynomolgus monkeys. The brains were processed for the immunofluorescent distribution of SMI32 and the proportion of double labeled cells (SMI32+ retrograde labeled/hotal retrograde labeled) was quantified on a regional and 29% double labeled, respectively, and from layers 2 and 3 of V2 to MT 74%. The projection from layers 2 and 3 of V2 to V4 was 49% double labeled; from V3 to V4 47%. Of the cells in V2 containing both FB and DY labels, 92% were also recognized by SMI32. These cells probably represent at least part of the anatomical basis for the physiologically identified magnocellular contribution to V4 (Nealey et al., '91). Preliminary studies (Kupferschmid et al., '91) have shown that cells basis for the physiologically identified magnocellular contribution to V4 (Nealey et al., '91). Preliminary studies (Kupferschmid et al., '91) have shown that cells projecting back to V1 and V2 from V4 and MT have a much lower proportion of SMI32-ir. Thus, our data suggest forward and feedback pathways differ in cytosketal profiles and that the M pathway has a particularly high representation of SMI32-ir neurons. Supported by AG06647 and AHAF.

RELATIONSHIP OF ISO-DIRECTION AND ISO-ORIENTATION MAPS REVEALED BY OPTICAL IMAGING IN OWL MONKEY AREA MT. D. Malonek\*, R.B.H. Tootell and A. Grinvald, Depts. of Neurobiology, Weizmann Inst. of Science, Rehovot 76100, Israel, and Harvard Med. School, Boston, Mass. 02115.

Previous electrophysiology and deoxyglucose studies suggest that several columnar systems co-exist in the primate area MT. To clarify the yet-unknown relationship between the functional architecture of various functional domain, we used optical imaging based on intrinsic signals.

To generate iso-direction maps, random dots moving at different directions, covering 360°, were used as a visual stimuli. We found that cells in MT selective for direction of motion are clustered, forming what we term iso-direction domains. Inspecting the spatial distribution of direction domains, 180° apart, revealed that they did not overlap. This result suggests a 360° organization, in agreement with previous electrophysiological and double-label 2-DG studies.

To explore the relationship between iso-direction and isoorientation domains we stimulated with gratings having different orientations and different directions of motion. Iso-orientation (termed "axis-of-motion" in other studies) maps were first generated. We found that iso-orientation domains produced by opposite directions of motion exhibited a large overlap. To obtain the iso-direction maps, from gratings rather than from random dots stimuli, we calculated the difference between two maps from random dots stimuli, we calculated the difference between two maps resulting from gratings moving in opposite direction. Such maps were periodic, but were weaker (2-3 fold) than the iso-orientation maps. The present results, indicating large overlap of clusters responding to different axis-of-motion, are thus different from the model of the functional architecture of area MT in another primate species, suggested by Albright et al., (1984). Supported by the Schilling Foundation.

WIDESPREAD FEEDBACK CONNECTIONS FROM AREAS V4 AND TEO. K.S. Rockland, \*1 K.S. Saleem, 2 and K. Tanaka 2. Dept, of Neurology, Univ. of Iowa, Coll. Med., Iowa City, IA 52242 and RIKEN, Wako,

Feedback connections in the ventral visual pathway from TE to V1 are generally thought to be serial and reciprocal in nature. That is, area TEO projects densely to V4. In turn, area V4 projects densely back to TEO projects densely to V4. In turn, area V4 projects densely back to V2. In order to characterize further these feedback connections, PHAL injections were made in V4 or TEO in two macaque monkeys. Injections in area V4 (wentral prelunate gyrus:PLG) in fact demonstrated dense connections to area V2, to what is probably V3 (in the depth of the LS), and also to a large sector of dorsolateral V1. Connections to areas V2 and V3 concentrated in layers 1, 2, and 6, with occasional terminations in 3a or 5. Those in area V1 were in layer 1, but could occur in layers 2, 6, or 5. Connections from area TEO were directed to area V4 in the ventral PLG. There, they terminated densely in layers 1, 2, 3a, and 6, and occasionally in 5. Sparser connections were directed to area V2 and to area V1 (lin the ventralateral operculum). Connections V1 were in layer 1; those to V2 in layer 1 and occasionally 2 and 5. Three serially reconstructed axons in V1 (from TEO, n=1; or from V4, n=2) traveled 4-7 mm in layer 1. Injections of fluorescent dyes into V1 and V2 confirmed the connections from areas V4 and TEO (abeled neurons were mainly in layers 6 and 3a). We conclude that feedback connections from V4 and TEO are widely distributed rather than merely reciprocating feedforward connections. These connections all target layer 1, but additional layers can be involved, possibly as a function of distance (EY07058 and NS19632, and the Carver Trust) V2. In order to characterize further these feedback connections. PHA-L

EXTENSIVE VISUAL FEEDBACK CONNECTIONS FROM VENTRAL

EXTENSIVE VISUAL FEEDBACK CONNECTIONS FROM VENTRAL INFEROTEMPORAL CORTEX. K.L. Douglas\* and K.S. Rockland. Dept. of Neurology, Univ. of lowa, Coll. Med., lowa City, IA 52242.

Previous work has demonstrated that inferotemporal cortex in the macaque projects densely to area V4. In order to investigate further this relatively inaccessible cortex, injections of PHA-L were made in ventral area TE (in the depth of the occipitotemporal sulcus:OTS). As expected, this injection produced labeled axons in the dorsal prelunate gyrus (primarily layer 1) and in more posterior regions of the OTS (primarily in layers 1, 2, 3a, and, to a lesser extent, 5 and 6). There were also, nowever, labeled axons in dorsolateral V1 (layer 1) and V2 (layers 1, 2, and, sparsely, 5). Serial reconstruction of one axon in V1 showed 3 branches primarily in layer 1, with 2 of these continuing into V2. Branches measured 2.8, 4.8, and 5.6 mm dorsoventral (DV) x 1.5-2.4 mm AP. A second axon, in V2, had a single trunk which traveled in layer 1 for 7.0 mm DV x 1.8 mm AP. There was a short collateral (0.3 mm) in layer 5. This axon branched in the white matter to send a separate 1 for 7.0 mm DV x 1.8 mm AP. There was a short collateral (0.3 mm) in layer 5. This axon branched in the white matter to send a separate collateral to a second focus within V2 (layers 1 and 2). Injections of fast blue into V1 and diamidino yellow into V2 confirmed the connections from cortex in the OTS (labeled neurons were mainly in layers 6 and 3a). A few double-labeled neurons were evident. As V1 is not reported to project to anterior TE cortex, we conclude that feedback connections need not be strictly reciprocal. These connections all target layer 1, but shorter-distance connections, in particular, seem to have more involvement of other layers (NS19632, EY07058 and the Carver Trust)

MODULAR SEGREGATION OF VISUAL PATHWAYS IN OCCIPITAL AND TEMPORAL LOBE VISUAL AREAS IN THE MACAQUE MONKEY.

D. J. Felleman\*, E. McClendon and Ki Lin, Dept. of Neurobiology and Anatomy, University of Texas Medical School, Houston, TX, 77030.

Area V4 consists of modules which receive input from either thin or interstripe compartments of V2 (DeYoe et al., '88; Zeki and Shipp, '89) and from segregated regions of occipital and temporal cortex (DeYoe and Sissola, 91). V4 outputs to the PIT are also organized into segregated, interdigitated modules (Felleman and McClendon, 91). We now wish to determine: 1) how many types of modules are contained within V4 or PIT, 2) what are their relative sizes, 3) what are their inputoutput relationships, and 4) whether other V4 targets contain segregated modules. In the current experiments, 2 fluorescent retrograde tracers were injected into V4 sites separated by 2-4 mm. The precise patterns of labeling were digitized from unfolded, tangential sections of occipital and temporal cortex and were correlated with patterns of cytochrome oxidase and mycloarchitecture. V4 injections were characterized by their inputs from V2 thin- or interstripe compartments. In 2 cases, segregated clusters of labeled cells were found in the same V2 stripe, suggesting that V4 contains more than 2 types of modules. PIT projections to V4 arose from several clusters of cells of variable size, ranging from 6-8 mm across to less than 2 mm. V4 "interstripe" injections tended to label large, irregular zones in PIT, while dual V4 "thin-stripe" injections labeled several smaller foci in PIT and interdigitating zones of VOT. In 2 cases, WGA-HRP was also injected into PIT to determine the specificity and reciprocity of occipito-temporal pathways and to correlate the pattern of intrinsic connections in PIT to the extrinsic V4 pattern. This led to exquisite patterns of local, patchy, reciprocal connections which extended 5 mm or more from the injection sites. WGA labeled terminals and cell clusters in PIT, VOT, V3A and V4 often coincided with V4 fluorescent labeled cell clusters, thus demonstrating the reciprocity and specificity of these modular connections. CALCIUM-BINDING PROTEINS DEFINE SPECIFIC CORTICAL AND SUBCORTICAL COMPONENTS OF THE DOLPHIN VISUAL SYSTEM. I.I. Glezer\*, P.R. Hof and P. J. Morgane. Dept. Cell Biol. Anat. Sci., CUNY Med. Sch., New York, NY 10031 Sch., Mt. Sinai Med. Sch., Fishberg Ctr. for Neurobiology, New York, NY 10029 and Worcester Fndn. Exp. Biol., Shrewsbury, MA 01545.

The calcium-binding proteins, calbindin D-28k (CB), calretinin (CR) and parvalbumin (PV) were studied immunohistochemically in primary visual cortex and subcortical structures (lateral geniculate nucleus, LGN and superior colliculus, SC) of dolphin (Tursiops truncatus) and macaque (Macaca mulatta). In the dolphin, in magno and parvicellular layers of the LGN almost all neurons are CB-positive; CR-positive neurons are found only in magnocellular layers, whereas PV-positive neurons are very sparse. The same relationships between the three calcium-binding proteins are found in the SC. Thus, specific subcortical pathways in the dolphin visual system are subserved mostly by CB- and CR-positive neurons. This correlates with the high concentrations of CB and CR-positive neurons in the upper cortical layers (I and II) which are considered major thalamocortical input layers in dolphin neocortex. Sparsely distributed PV-positive neurons are found mostly in layer IIIc/V. The rarity of PV-positive neurons in visual cortex and specific subcortical nuclei correlates with the general agranularity of the dolphin neocortex and absence of layer IV. In contrast, in the macaque, predominant thalamocortical neurons are PV-positive, whereas specific CB-positive neurons are much less numerous. These findings may reflect significant differences in phylogenesis of sensory systems between highly adapted aquatic and terrestrial mammals. <sup>1</sup>Fidia Research Labs and <sup>2</sup>Ad-Skaper\*1 Faccil. vanced Technology Division, Fidia S.p.A., Abano Italy.

CNTF is a multifunctional protein which promotes neuronal survival and also controls cell division of neuronal precursors, neurotransmitter and glial cell differentiation. Because trophic factors may influence excitotoxin-associated neurodegeneration, CNTF was examined for its ability to alter glutamate-induced hipfor its ability to alter glutamate-induced hippocampal injury. Using cell cultures prepared
from E18 rat hippocampus, recombinant human
CNTF limited the loss of pyramidal neurons subsequently exposed to 200uM glutamate from DIV
5-6 (ED50: 5 ng/ml). CNTF was equally effective
when added at least 48hr prior to glutamate.
Subthreshold amounts (2-3 ng/ml) of CNTF and
10uM monosialogangliosides (GMl or its inner
ester form siagoside) given together were
almost as active as 30 ng/ml CNTF in preventing
glutamate-induced death. Facilitation of such
trophic factor effects by gangliosides makes
the latter useful tools in the study of CNS
plasticity and repair processes. plasticity and repair processes.

## 170.2

CILIARY NEUROTROPHIC FACTOR (CNTF) PREVENTS AXOTOMY-INDUCED DEGENERATION OF ADULT RAT SUBSTANTIA NIGRA DOPAMINERGIC NEURONS. T. Hagg\* and S. Varon

Dept. of Biology 0601, University of California San Diego, La Jolla, CA 92093 After a discrete but complete stereotactical transection of the adult rat nigrostriatal pathway with an extrusion micro-knife, approximately half of the substantia nigra compacta dopaminergic neurons undergo degeneration over a 2 week time period. The extent of degeneration was quantified by counting in the compacta region the number of neurons immunostained for their transmitter enzyme tyrosine hydroxylase and the number of cresyl violet/Nissl stained neurons larger than 10 µm in diameter. To test trophic factors which might affect the nigral degeneration we designed an infusion-cannula where solutions can be continuously administered directly into the brain tissue between the transection and the injured substantia nigra neurons. A 2-week infusion with vehicle did not cause excessive damage or alter the extent of the axotomy-induced degeneration. In sharp contrast, infusion with recombinant human CNTF (a gift from California Biotechnology, Mountainview CA) almost completely prevented the disappearance of cresyl violet stained neurons. However, CNTF did not prevent the loss of staining for tyrosine hydroxylase. This finding appears similar to that seen previously with the axotomized septal cholinergic neurons, where CNTF prevented their degeneration and losses of low affinity NGF receptor, but not the loss of choline acetyltransferase (Hagg, Neuron 8:145-158, 1992). These results provide evidence that CNTF is a general neurotrophic or neuroprotective factor and may have relevance for the future treatment of Parkinson's disease which is caused by degeneration of these substantia nigra neurons. Support: NINCDS grant NS-16349 and 27047.

EXPRESSION OF HUMAN CILIARY NEUROTROPHIC FACTOR B-GALACTOSIDASE DURING DEVELOPMENT.

F. Altruda, G. Stefanuto E. Hirsch, L.Silengo, L. Callegaro<sup>1</sup>, and A. Negrol\* Dept. of Genetics, University of Turin

<sup>1</sup>Advanced Technology Div., Fidia S.p.A. Abano Terme, Italy. Ciliary Neurotrophic factor (CNTF) is not only a potent survival factor for a variety of embryonic neurons in culture, but also influences the differentiation of both developing neurons and glial cells. In order to evaluate the possible role of CNTF in neurous system development, it is important to determine which cells produce CNTF and when they begin to do so. Expression of CNTF has been previously examined using probes for its mRNA and immunoreactive protein. We have attempts a more precise analysis by use of transgenic animals. The 5' flanking region of the human CNTF gene was used to direct expression of a bacterial Bgalactosidase reporter gene in various subset of neurons in transgenic mice. The spatial and temporal patterns of expression of these transgenes during embryogenesis and in adults will be reported.

### 170.5

EXPRESSION OF INSULIN-LIKE GROWTH FACTOR BINDING PROTEINS IN HUMAN NEURONAL CELLS. E. Feldman, A. Randolph, D. Yee and D. Martin. Univ. of Michigan Med. Center, Ann Arbor, MI 48109, <sup>1</sup>Univ. of Texas Health Sci. Center, San Antonio, TX 78284.

SH-SY5Y neuroblastoma cells provide a good in vitro model for examining the action of the neuronal mitogen, insulin-like growth factor II (IGF II). SH-SY5Y cells express IGF II, which acts as an autorrine growth factor to promote SH-SY5Y cellular growth. IGF II action is modulated by a family of high affinity binding proteins, designated IGFBPs. IGFBPs influence IGF II receptor binding and regulate IGF distribution among tissue compartments.

In the present study, we examined the gene and protein expression of IGFBPs in

SH-SY5Y cells cultured in the presence and absence of serum. In some experiments,  $\gamma$ -interferon was added as a neuronal differentiating agent. After collecting conditioned media, total RNA was analyzed by RNase protection or Northern blotting. Dr. S. Shimasaki, La Jolla, CA and Dr. D. Powell, Houston, TX, provided the human cDNA clones IGFBP 2,4,5 and 1,3, respectively. Under all conditions, IGFBP 2 was the major transcript present with four fold less gene expression of IGFBP 4 and 5. No IGFBP 1 or 3 mRNA was detected on Northern analysis or RNase protection. Ligand blotting demonstrated abundant IGFBP 2 in conditioned media, with lesser amounts of IGFBP 4. Cells grown in serum free conditioned media, with lesser amounts of IGFBF 4. Cells grown in serum free media had a 30-fold increase in IGF II gene expression, with no corresponding change in IGFBP 2 gene expression. In the presence of y-interferon, IGF II gene expression decreased two-fold while IGFBP expression increased. These findings suggest a differential regulation of IGF II and IGFBP gene expression during neuronal growth.

Supported by NIH grant NS01381 (EF), R29CA52592 (DY) and NIH grant NS07222-09 (DM).

## 170.7

ESTROCEN REGULATION OF THE INSULIN-LIKE GROWTH FACTOR-I (IGF-I) SYSTEM IN THE RAT PITUITARY. K.M. Michels\*, W-H. Lee. A. Seltzer, S. Zorad, C.A. Bondy and J.M. Saavedra. Section on Pharmacology, LCS, NIMH and the Developmental Endocrinology Branch, NICHHD, NIH, Bethesda, MD 20892.

We used in vitro binding of [1251]IGF-I and quantitative autoradiography along with in situ hybridization of riboprobes for IGF-I, type 1 IGF receptor and binding protein 2 (BP2) to investigate the effect of ovariectomy and estrogen replacement on the pituitary IGF system of rats.

Ovariectomized (OVX) and male rats had less binding in the anterior and posterior pituitary compared to estrus phase females. Estrogen replacement restored binding to levels similar to the intact female. Binding was highest during proestrus and significantly lower through the rest of the cycle.

No change in IGF-I receptor mRNA was detected. Expression of the BP2 mRNA was lower in the male and OVX female anterior and posterior pituitary compared to the estrogen-replaced female and was highest at proestrus. IGF-I mRNA expression in the anterior pituitary was lower for males and OVX compared to estrus phase females while no difference was detected in the posterior pituitary. Estrogen replacement restored mRNA expression to that seen in intact females. IGF-I mRNA expression was highest at estrus and proestrus and lowest at metestrus.

These results show that, in the pituitary, estrogen independently regulates, and is necessary for full expression of, several components of the IGF-I system.

STIMULATION OF INSULIN-LIKE GROWTH FACTOR-II EXPRESSION IN HUMAN NEUROBLASTOMA CELLS. D.M. Martin, and E.L. Feldman. Department of Neurology and The Neuroscience Program, The University of Michigan, Ann Arbor, MI 48104.

Insulin-like growth factor II (IGF-II) has been implicated in regulating proliferation and differentiation of cultured neuroblasts. In human fetal brain and in neuroblastoma cells, IGF-II mRNA is highly expressed and may act as an autocrine growth or survival factor. In the current study, we report increased expression of IGF-II mRNA and protein in the human increased expression of IGF-II mRNA and protein in the human neuroblastoma cell line SH-SY5Y after exposure to serum-free media (SFM). Using Northern analysis, we observed a two-fold increase in the 6.0 kb IGF-II mRNA transcript after 24 hours in SFM. Levels of this IGF-II mRNA transcript returned to basal three days after addition of media containing 10% calf serum. IGF-II mRNA increased 30-fold after a three day incubation in SFM. The increase in IGF-II mRNA after exposure to SFM was most dramatic at lower plating densities. In addition to changes in mRNA, we observed a four-fold elevation of IGF-II protein after a three day incubation in SFM, measured by radioimmunoassay of conditioned SFM. SH-SY5Y cells SFM, measured by radioimmunoassay of conditioned SFM. SH-SYSY cells continue to divide in SFM, based on time lapse photography and a steady rise in <sup>3</sup>H-thymidine incorporation over a three day incubation period in SFM. Taken together, our data support a role for IGF-II in autocrine mediated growth of neuronal cells, and suggest a feedback mechanism for IGF-II

D. Martin is supported by NIH grant NS07222-09. E. Feldman is supported by NIH grant NS01381.

INSULIN AND IGF-I INDUCE RAPID AND SUSTAINED CHANGES IN CFOS mRNA EXPRESSION IN CULTURED FETAL NEURONS. K.A. Heidenreich\* and L. J. Robinson. Dept. of Pharmacol., Univ. of Colo. Hlth. Sci. Ctr., and the Denver VA Med. Ctr., Denver, CO 80262

Insulin and IGF-I support the growth and differentiation of fetal neurons in culture. One of the earliest cellular changes elicited by many growth factors is the induction of immediate early genes. this study, we examined the ability of insulin and IGF-I to induce c-fos, a prominent member of the immediate early gene family, in post-mitotic neurons from day 8 chick forebrains cultured in fetal calf serum. Northern analysis of total RNA using a full-length 32P-labeled mouse cDNA probe (1.8 kB) revealed a single mRNA species of 2.2 kB induced 3-4 fold by insulin, IGF-I, and TPA (0.1µM). The dose-dependent induction of c-fos mRNA by insulin and IGF-I (1-250 ng/ml) was detected within 5 min and remained elevated in the presence of growth factor for at least 3 hr. Inhibition presence of growth factor for at least 3 hr. Inhibition of protein synthesis by cycloheximide (100µM) also increased c-fos mRNA levels and was synergistic with insulin and IGF-I. Basal levels of c-fos mRNA were very low and constant during the 5 days of culture. These data suggest that insulin and IGF-I support neuronal differentiation in part by the induction of transcriptional programs initiated by c-fos.

## 170.8

CO-REGULATION OF TGFS-1 AND FIBRONECTIN mRNA IN RESPONSE TO BRAIN INJURY. G.M. Pasinetti\*, N.R. Nichols, Dugich-Djordjevic M.M., Morgan T.E., Laping N., and C.E. Finch. Andrus Gerontology Center and Dept. of Biological Sciences, University Southern California, Los Angeles, CA 90089-0191 Striatal responses to cortical deafferentation in

adult rat brain include elevation of fibronectin (FN) mRNA and TGFR-1 mRNA 3 and 10 days postlesioning as assessed by northern blot hybridization assay. <u>In situ</u> hybridization combined with immunocytochemistry confirmed northern blot data. Striatal TGFE-1 mRNA signal co-localized with immunostained microglia (OX-42, CR3 complement receptor) which overlapped anatomically with the distribution of degenerating afferent fibers. FN mRNA signal was sparsely distributed in the deafferented striatum and overlapped with the distribution of increased FN immunoreactivity associated with blood vessels and with punctate deposits in the striatal neuropil on adjacent tissue sections. In hippocampus, TGFE-1 mRNA and FN mRNA showed a similar coordinated schedule of changes by 3 and 10 days after colchicine injection, as assessed by <u>in situ</u> hybridization assay. This study suggests in vivo co-regulation and differential cellular distribution of FN and TGF&-1 mRNA following brain injury. Intracerebral infusion of TGF%-1 will ascertain the functional role of TGF%-1 on FN mRNA. Supported by United Parkinson Foundation and Alzheimer Association to GMP and NIH grant AG-7909, AG-9793 to CEF.

LOCALIZATION OF ACIDIC FIBROBLAST GROWTH FACTOR IN SPECIFIC SUBCORTICAL NEURONAL POPULATIONS. F.P. Eckenstein\*, A.Stock, K.Kuzis, R.Nishi and W.R.Woodward. Dept. of Cell Biology&Anatomy, Dept. of Neurology, Oregon Health Sciences Univ., Portland OR 97201.

The effects of fibroblast growth factors (FGF) in vitro include the stimulation of mitogenesis in a variety of non-neuronal cell types and the promotion of the survival of various central and peripheral neuronal populations. The precise physiological role of FGFs in vivo is currently not known. As a step toward understanding the role of FGFs in the nervous system we determined the distribution of acidic FGF (aFGF) in the rat central nervous system (CNS). The levels of aFGF in dissected areas of the nervous system were quantified using a biological assay method and the cellular distribution of aFGF was determined in tissue sections using immunohistochemical methods. Acidic FGF was found to be localized within specific neuronal populations in the CNS and was absent from non-neuronal cells. Neurons found to contain aFGF immuno-reactivity were: magnocellular neurons in the septal area and nucleus basalis, some additional defined neuronal cell groups in the subcortical telencephalon, specific neuronal populations in the hypothalamus, the thalamus, the substantia nigra, the reticular formation, the pons, motor and sensory neurons. Only a very limited number of neurons in cerebral cortex and hippocampus contained aFGF immunoreactivity. A significant overlap of neuronal populations known to express the low-affinity nerve growth factor receptor (LNGFR) with populations containing aFGF-immunoreactivity was demonstrated by staining neighboring tissue sections for aFGF or LNGFR

Supported by NIH AG07424, NS17493 (FPE), NS25767 (RN), the March of Dimes (FPE), and the Oregon Medical Research Foundation (WRW).

## 170.11

CYTOKINE DEVELOPMENTAL REGULATION OF IMMORTALIZED HIPPOCAMPAL NEURONAL PROGENITOR CELLS. M.F. Mehler', R. Rozental, M. Dougherty, D.C. Spray, and J.A. Kessler. Albert Einstein College of Medicine. Bronx. New York 10461.

The mechanisms governing progressive neuronal lineage commitment and successive stages of terminal differentiation are largely unknown. Significant parallels exist between "neuropoiesis" and hematolymphoid development, the latter regulated by an array of multifunctional cytokines. To establish an experimental system to study a possible role for cytokines in neuronal development, we investigated growth factor requirements for differentiation of a well-defined neuronal precursor population. Dissociated murine embryonic (E17) hippocampal cells were immortalized using retrovirally-mediated gene transfer with a temperature-sensitive mutant form of the SV40 large T antigen. Clonal cell lines propagated at 33°C exhibited immature cellular forms that expressed the neuronal precursor protein nestin. These cells, when cultured at 39°C (with breakdown of thermolabile large T) in defined media supplemented with selected interleukins, exhibited neurite outgrowth, immunoreactivity for the 200 kD phosphorylated form of neurofilament and appearance of action potentials that were tetrodotoxin (TTX)-insensitive. Pretreatment of cultured cells with basic fibroblast growth factor or concurrent application of transforming growth factor alpha resulted in further morphologic maturation and the generation of action potentials and inward current in response to depolarizing steps that were reversibly sensitive to TTX administration. These studies demonstrate the feasibility of utilizing clonal neuronal progenitor cell lines for the characterization of successive stages of neuronal maturation. Further, they suggest that cytokines which control selective stages of hematopoiesis may also regulate the maturation of neurons from their progenitor cells.

MOLECULAR CLONING OF BOVINE GLIAL GROWTH FACTORS

M. Marchionni, F. Danehy, D. Misumi, M. Chen, A. Goodearl, I. Hiles, M. Otsu, P. Stroobant, M. Waterfield, E. Gamzu\*, and D. Gwynne Cambridge NeuroScience, Inc., Cambridge, MA and Ludwig Institute for Cancer Research, London, UK

and Ludwig Institute for Cancer Research, London, UK.
Glial growth factors I and II are potent mitogens for
cultured Schwann cells and are present during limb regeneration in
the newt (see Brockes et al (1987) Meth. Enz. 147, 217). These
factors may have therapeutic utility in treatment of peripheral
neuropathies and in nerve regeneration following injury. Bovine
pituitary GGF-I and GGF-II were purified to apparent homogeneity
leading to several novel peptide sequences (Goodearl et al,
unpublished). Using sets of degenerate oligonucleotide probes
that represented similar peptide sequences found in both the
GGF-I and the GGF-II preparations, one 20 kb bovine genomic
DNA was identified and cloned. Five distinct mRNAs have been
isolated by RT-PCR reactions and by screening cDNA libraries
from bovine posterior pituitary. Sequence analysis show multiple
splicing patterns and that these mRNAs contain several GGF-I
and GGF-II peptide sequences suggesting that this gene encodes
GGF-I and/or GGF-II. Selected clones have been expressed to
verify activity. Comparisons to sequence databases indicate that
the GGFs represent a new family of growth factors. Southern
blot analysis at reduced stringency suggests the presence of
related sequences in several mammalian genomes. In situ
hybridization studies are in progress to elucidate further the
expression pattern of GGF-coding sequences.

NEURONAL SURVIVAL: COMBINATORIAL EFFECTS OF FGF, DEPOLARIZATION AND SUBSTRATES. M.F. Schmidt\* and S.B.Kater. Program in Neuronal Growth and Development, Dept. of Anatomy and Neurobiology, Colorado State University, Fort-Collins, Colorado 80523

This study tests the survival promoting effects of specific agents alone, and in combination, in E10 chick ciliary ganglion neurons. Three classes of agents were used: Trophic factors (FGF), depolarization (high potassium) and surface substrate (laminin and Collagen IV). We found that while depolarization and FGF could independently promote survival, their effect was supra-additive when presented in combination. Furthermore, FGF and depolarization were shown to promote survival via separate pathways. These survival promoting effects showed striking differences depending upon the substrate. Although neither laminin (4.3+0.9% survival: at 24 hours) nor collagen (3.7±0.8% survival) promoted survival on their own, FGF mediated survival was highly dependent upon substrate: FGF survival on laminin was 76.5±1.8% and only 6.6±0.9% on collagen. In contrast, depolarization mediated survival did not appear to be substrate dependent (survival was 85.4±3.4% on collagen and 93.7±2.4% on laminin). Interestingly, although FGF was not able to promote survival on a collagen substrate, when added together with depolarization, FGF dramatically enhanced depolarization mediated survival (P<0.001), suggesting that depolarization may prime cells to respond to FGF. Taken together, this study reports two findings that are consistent with the growing idea that neuronal survival is regulated by the complex interactions with several different cues. First, we show that FGF and depolarization act through different pathways and act synergistically when added in combination. Second, we show that substrate can act as an important modulator of the combinatorial action of various survival promoting agents.

### 170.12

PURIFICATION AND PROTEIN SEQUENCING OF GLIAL GROWTH FACTORS -I AND -II . A.D.J. Goodearl\* J.B. Davis, N.F. Totty, J.J. Hsuan, O.T. Nguyen, M.D. Waterfield, M. Otsu and P. Stroobant Ludwig Institute for Cancer Research, 91 Riding House Street, London W1P 8BT (UK)

Glial Growth Factor (GGF) has been identified as an active component present in extracts of brain in many vertebrates, and also bovine pituitary glands, that stimulates cell division in rat Schwann cells and cortical astrocytes. GGF activity has been observed in certain human Schwann cell tumours and is also expressed in a nerve-dependent fashion during limb regeneration in the newt (Brockes (1987) Meth. Enz. 147 217 and refs. therein).

Purification of GGF from whole bovine pituitary glands

Purification of GGF from whole bovine pituitary glands was undertaken using a Schwann cell proliferation assay to measure GGF activity. Two protein species were identified, named GGF-I (approx. MW 33 kDa) and GGF-II (approx. MW 59 kDa) and were purified to apparent homogeneity as judged by silver stained SDS-PAGE. Both purified proteins are mitogenic for neonatal rat Schwann cells at subnanomolar concentrations in vitro, effects potentiated by cAMP-elevating agents.

Considerable amounts of peptide sequence from both preparations have been obtained including a highly homologous peptide sequence found in each preparation, suggesting that these molecules are related at the primary structure level. Computer database searches have revealed no significant sequence similarities between the GGFs and other growth factors. GGF-I and GGF-II may thus represent founding members of a new family of mitogenic growth factors in the nervous system.

BIOCHEMICAL ISOLATION AND CHARACTERIZATION OF MUSCLE DERIVED DIFFERENTIATION FACTOR (MDF): A NOVEL FACTOR(S) WHICH INDUCES EXPRESSION OF THE TYROSINE HYDROXYLASE GENE IN NON-CATECHOLAMINE NEURONS IN CULTURE. L. Jacoviti\* and X. Du. Dept. of Neurology, Hahnemann Univ., Philadelphia, Pa., 19102.

Our previous studies have demonstrated that incubation of brain non-catecholamine neurons overnight with the soluble portion of an extract of rat straiat muscle cells (L6 clonal line) will dramatically induce the appearance of the catecholamine (CA) enzyme tyrosine hydroxylase (TH) in brain non-CA neurons grown in culture (lacovitti et al., 1989, 1991). Because of its ability to direct the biochemical differentiation of these neurons without affecting cell survival, the substance(s) responsible for this activity has been termed muscle-derived differentiation factor(s) or MDF. We have recently used bovine heart to isolate and biochemically characterize MDF. Standard purification procedures, including ammonium sulfate fractionation, DEAE-cellulose ion exchange chromatography, sulfate sephadex G-100 chromatography, ultrafiltration and immobile phase chromatography have been utilized. Column fractions have been bioassayed in culture: mouse striatal neurons have been incubated with individual column fractions overnight. Cultures are then fixed and the number of TH containing neurons determined immunocytochemically. These procedures have yielded a 20,000 fold purification of MDF: the final products, as determined by SDS-PAGE under nonreducing conditions, include 84kD, 82kD, 78kD and 64kD molecular weight species. Inductive activity could not be electroeluted from the gel. We are therefore raising polyclonal antisera against each of these four molecules for neutralization studies. The ability to directly neutralize biological activity or to prevent TH induction following immunoprecipitation with a specific antibody is critical for the final identification of MDF. Supported by NIH NS24204-04 and the Ben Franklin Foundation.

MECHANISM OF DARK ADAPTATION: SUSTAINED ACTIVATION OF THE VISU MECHANISM OF DARK ADAPTATION: EVIDENCE FOR SUSTAINED ACTIVATION OF THE VISUAL CASCADE BY BLEACHED PHOTOPIGMENT MC Cornwall and GL Fain. Dept Physiol, BU Sch Med, Boston, MA 02118 & Depts ophthal & Physiol Sci, UCLA, LA, CA 90024. Using methods pioneered by Hodgkin and Nunn (J. Physiol. 403:439-471, 1988), we have examined the effects of steady backround intensity (I<sub>B</sub>) and bleaching on the velocities of the PDE and cyclase in rods isolated from the retina of the tiger EVIDENCE

in rods isolated from the retina of the tiger salamander. Backgrounds accelerate both PDE and salamander. Backgrounds accelerate both PDE and cyclase velocities. This effect increases with increasing  $I_B$  (and so with decreasing receptor sensitivity,  $S_F$ ). PDE and cyclase velocities are also increased by the bleaching of a substantial fraction (>10%) of the visual pigment. The acceleration of enzyme velocites by bleaching persists in darkness in an isolated rod as long as we have waited (1-2 hours) and is accompanied by a sustained decrease in  $S_F$ . The increases in PDE and cyclase velocities (and the decrease in  $S_F$ ) can be we have waited (1-2) hours) and is accompanied by a sustained decrease in  $S_p$ . The increases in PDE and cyclase velocities (and the decrease in  $S_p$ ) can be reversed by the addition of liposomes containing 11-cis retinal. These experiments indicate that l1-cis retinal. These experiments indicate that bleached pigment (probably just opsin) activates PDE, though with an efficiency perhaps 10<sup>4</sup> that of Rh. They also suggest that the mechanisms of desensitization by bleaching and backgrounds may share some fundamental similarities.

QUANTITATIVE FITS OF AN AMACRINE MODEL OF DIRECTIONAL SELECTIVITY TO RABBIT DATA. N. M. Grzywacz\* and F.R. Amthor. Smith-Kettlewell Inst., 2232 Webster St., San Francisco, CA 94115 and Dept. Psychol. and NRC, Univ. Alabama at Birmingham.

and Γ.K. Allinuft. Similar Sectional Section 1. Albama at Birmingham.

On-Off directionally selective (DS) ganglion cells of the rabbit retina respond in a DS manner to edge motions spanning as little as 3 to 5 μm. Their directionality is maintained over at least three decades of speed. When stimulated with periodic gratings, these cells' preferred-direction is invariant to spatial frequency, except sometimes for high-spatial frequencies, which in any event elicit small responses. We show that a recently proposed model of retinal directional selectivity (Borg-Graham and Grzywacz, 1992) accounts for this robust directionality. The model postulates that an amacrine-cell dendrite receives excitatory and inhibitory synapses throughout its length. This dendrite would then make an excitatory symmetric synapse via its distal end onto the DS ganglion cell. The inhibitory synapses would have slow, sustained kinetics and would be of a shunting-inhibition type.

The model accounts for the DS responses to small motions through the pattern of activation of inhibitory synapses. During null-direction motion, their position between the excitatory synapses and the amacrine dendrite's output allows them to shunt out almost all excitatory currents. Furthermore, speed robustness results from sustained inhibitory synapse activation during arbitrarily slow null-direction motions.

sustained inhibitory synapse activation during arbitrarily slow null-direction motions. While the spatial period of periodic gratings is larger than the dendrite, preferred-direction responses remain strong. However, the model's inhibition reduces them at high spatial frequencies and the preferred direction changes to reduce the spatial ingli spatial inequencies and the preferred infection changes to reduce the spatial requency along the original preferred—null axis. In addition to these results, this model is consistent with apparent-motion, pharmacological, and patch-clamp data (Borg-Graham and Grzywacz, 1992). We conclude that this symmetric-inhibitory asymmetric-amacrine model can account for retinal directional selectivity.

GLUTAMATE, GABA AND GLYCINE IMMUNOREACTIVITY IN THE MACAQUE MONKEY RETINA

M. Kalloniais¹ and RE. Marc\*²: ¹Department of Optometry, University of Melbourne, Parkville 3052, Australia and ²Sensory Sciences Center, University of Texas, 6420 Lamar Fleming, Houston, Texas 77030.

The putative neurotransmitters, glutamate, GABA and glycine are though to mediate "fast" synaptic transmission in the vertebrate retina. It is still uncertain whether these three neurotransmitters are found in the majority of retinal neurons and if distinct subpopulations of neurons, for example, some bipolar cells or ganglion cells, are exclusively GABAergic or glycinergic. We conducted serial section postembedding silver-intensified immunogold detection of anti-glutamate, anti-GABA and anti-glycine immunoglobulin binding in the monkey retina.

All photoreceptor cells (rods and cones) were immunoreactive for glutamate. Of all

anti-glycine immunoglobulin binding in the monkey retina.

All photoreceptor cells (rods and cones) were immunoreactive for glutamate. Of all the somas located in the inner nuclear layer (INL.) [N=344], 73% were immunoreactive for only one of the three neurotransmitters. Within the central retina, all horizontal cells were immunoreactive for GABA with no glutamate immunoreactivity. Bipolar cells bodies were immunoreactive for glutamate, and as in previous studies, distinct subpopulations of bipolar cells were weakly immunoreactive for GABA or glycine. From the serial sections, it was possible to show that these bipolar cells were always also strongly immunoreactive for glutamate. Cell bodies in the amacrine cell layer were immunoreactive for either GABA or glycine, with a small population of cells being immunoreactive for both [1%]. Co-localization of the neurotransmitters in the INL were; glutamate and GABA (8%) and glutamate and glycine (8%). Two distinct groups of presumed GABA ergic amacrine cells were observed; one showing no glutamate immunoreactivity and the other showing weak glutamate immunoreactivity. Cell bodies in the ganglion cells using an anti-glutamine antibody, with a subpopulation of large soma ganglion cells (3%) also being weakly immunoreactive for GABA. The subpopulation (9%) of displaced amacrine cells in the GCL were only immunoreactive for GABA. No glycine immunoreactive cell bodies were found in the GCL.

In the CCL.

Virtually all the neural cells (90%) in the INL and all the cell bodies in the GCL were immunoreactive for one or more of the "fast" neurotransmitters. The cell bodies showing no immunoreactivity in the INL (10%) probably reflect Müller's cell bodies. We conclude that the vast majority retinal neurons use one or more of these three putative neurotransmitters for "fast" neurotransmission.

COBALT IONS OF LOW LEVELS SELECTIVELY BLOCK ROD

COBALT IONS OF LOW LEVELS SELECTIVELY BLOCK ROD PATHWAY IN CARP RETINA. X.L.Yang\*and L.L.Yuan. Shanghai Institute of Physiology, Chinese Academy of Sciences, Shanghai 200031, China It is well established that synaptic transmission in the outer plexiform layer of the retina is generally blocked by extracellular cobalt ions of high levels (more than 1 mM). In superfused isolated carp retinas we found superfused, isolated carp retinas we found, however, that cobalt ions of low levels (8-12  $\mu$ M) showed differential effects on rod and cone showed differential effects on rod and cone synaptic activity. With the application of 10  $\mu$ M cobalt, the rod-driven horizontal cells hyperpolarized and their light responses were suppressed, whereas neither membrane potential nor light responses of the cone-driven horizontal nor light responses of the cone-driven horizontal cells were affected. Furthermore, scotopic ERG b-waves, which have dominant contribution from the rods were suppressed by 10  $\mu$ M cobalt, but cone-contributed photopic b-waves remained unaffected. These results suggest that the rod pathway in the outer plexiform layer is selectively blocked by cobalt of the low concentrations. The glutamate-isolated receptor potentials (PIII) were unaffected by 10  $\mu$ M cobalt in either scotopic or photopic conditions. in either scotopic or photopic conditions, indicating that cobalt must act on the synapse between the rods and rod horizontal cells.

NEUROTENSIN MODULATES QUANTAL TRANSMISSION BETWEEN PAIRS OF RETINAL AMACRINE CELLS. E. Gleason, S. Borges and M. Wilson\*. Department of Zoology, University of California, Davis, CA 95616.

Synaptic transmission between isolated pairs of GABAergic amacrine cells has been examined in sparse cultures of chick retina. In normal saline (3mM, [Ca]<sub>O</sub>), discrete quantal outward currents can be observed in the presence of TTX when the postsynaptic cell is voltage-clamped at 0mV and the presynaptic cell is held negative to -40mV, or else left unclamped. Quantal currents rise quickly (less than 3 msec) and decay with a mean time constant of 17 msec. Mean peak quantal conductance was about 254 pS, equivalent to the simultaneous opening of only 15, 17 pS GABA<sub>A</sub> channels. A net flux of 32x10<sup>3</sup> Cl<sup>2</sup> ions crosses the membrane per mV of driving force.

While the time intervals between spontaneous quanta are generally random (Poisson distribution), bath applied neurotensin (300 nM) causes quanta to arrive in periodic bursts separated by tens of seconds. Fura-2 ratio imaging of amacrine cells reveals that neurotensin induces [Ca]<sub>i</sub> oscillations that are prevented by the phospholipase inhibitor 4'-bromophenacyl bromide, or by the phospholipase C inhibitor U-73,122 but not its inactive analog U-73,343. In addition, the protein kinase C inhibitor H-7, has no effect on the induced [Ca], oscillations. These results suggest that neurotensin, a peptide that has been localized in some amacrine cells of the retina, modulates release of GABA through IP<sub>3</sub> control of intracellular calcium in postsynaptic cells. Were this control of calcium local, it might provide a functional explanation for the reciprocal and serial synapses common in the inner retina. Supported by EY04112.

NBOX SELECTIVELY BLOCKS THE NULL RESPONSE MECHANISM OF DIRECTIONALLY SELECTIVE RABBIT RETINAL GANGLION CELLS. E.D. Cohen\* and R.F. Miller Dept. Physiol., Univ. of Minnesota., Minneapolis, MN 55455

We examined the role of NMDA and non-NMDA EAA receptors on on-off directionally selective ganglion cells in a superfused retina eyecup preparation of the rabbit. When the non-NMDA antagonists NBQX (1-10µM) or DNQX (10 µM) were bath applied to the retina, direction selectivity to a moving slit was abolished and the DS ganglion cell responded equally well to preferred and null movement. However, NBQX/DNQX did reduce, by 20-40%, the number of impulses when compared to the magnitude of the preferred discharge under control conditions. Similar to the findings of Massey and Miller (J.Neurophys.63:1 '90) application of the NMDA antagonist D-AP7 (200-250 µM) had no effect on the DS mechanism, but did reduce the number of impulses evoked by moving stimuli. The combination of NBQX and D-AP7 abolished the light-evoked responses of DS cells. It appears one action of NBQX/DNQX is to force the preferred response to be subserved by NMDA receptors. In contrast, the inhibition underlying the null response appears to depend more critically on NBQX/DNQX sensitive mechanisms. Presumably the NBQX-sensitive inhibitory site is at the level of amacrine cells. Intracellular recordings from amacrine cells show that the light evoked responses of these neurons typically become more transient in NBQX/DNQX raising the possibility that differences in phasic-tonic response components could contribute to loss of the null mechanism in the DS ganglion cell. This idea, together with other competing hypotheses are presented. Supported by NIH grants F32EY0617 to E.D.C. and R01EY03014 to R.F.M.

DIRECT VISUALIZATION OF THE DENDRITIC AND RECEPTIVE FIELDS OF MOTION SELECTIVE RETINAL GANGLION CELLS. G. Yang and R.H. Masland.\* Harvard Medical School, Boston MA 02114.

Directionally selective ganglion cells receive excitatory inputs from the starburst amacrine cells. Other

things being equal, the receptive field of a directionally selective ganglion cell should thus equal the width of its dendritic arbor plus the width of all of the starburst cells that synapse upon it. We used a new experimental technique to compare the ganglion cells' dendritic and receptive fields.

Isolated rabbit retinas with ganglion cells labeled by retrograde transport of Fast Blue were mounted in a fluorescence microscope. The activity of a directionally selective ganglion cell was recorded extracellularly (with the microscope off) and its receptive field plotted, using stimuli projected via the microscope condenser. The identified cell was then injected with Lucifer Yellow. The boundary of the receptive field was then projected through the same optical system, so that it appeared superimposed

upon the dendritic arbor of the injected cell.

For a sample of 33 directionally selective ganglion cells, the mean diameter of the receptive field center exceeded the diameter of the dendritic field by  $8.0\pm2.4\%$ . This is much less than the spread of the overlapping starburst amacrines at the eccentricities studied. Either the spread of activity along the amacrine cell's dendrites or their synaptic connectivity must be quite limited.

### 171.9

RABBIT RETINAL GANGLION CELL SURROUND MECHANISMS: PHYSIOLOGY AND PHARMACOLOGY.

DK MERWINE<sup>1</sup> & FR AMTHOR<sup>2</sup>\*. <sup>1</sup>Optom DK MERWINE & FR AMTHOR\*. 10pto Psychology/NRC, U. Alabama B'ham 35294 1Optometry,

We have previously shown that surround stimulation lowers the slope of the center mechanism's response vs contrast function consistent with a nonlinear center-surround interaction. In addition. the function's saturation level is reduced with no change in threshold. These data can be fit with a shunting-inhibition model originally developed for ON-OFF DS cells (Amthor & Grzywacz, 1991).

We have now analyzed the pharmacological mechanisms of surround inhibition in rabbit retinal ganglion cells. Both 3 μM strychnine or picrotoxin increase the cell's spontaneous or picrotoxin increase the cell's spontaneous activity; however, strychnine, a glycine antagonist, is shown to lower, while the GABA antagonist, picrotoxin, raises the response function's saturation level. Strychnine also reduces the effectiveness of the surround, while picrotoxin has no effect on surround inhibition inhibition.

(Supported by EY05070, EY07033(T32), and ONR N00014-91-J-1280).

## 171.11

CORRELATIONS IN THE RESPONSES OF RETINAL GANGLION CELLS TO VISUAL STIMULI.

L. Lagnado, M. Meister and D. A. Baylor\*. Dept. of Neurobiology Stanford University, Stanford, CA 94305 and Dept. of Cellular and Developmental Biology, Harvard University, Cambridge, MA 02138.

As a first step in analyzing how the ganglion cell population encodes visual information, we have attempted to determine whether different cells respond to visual stimuli independently of each other.

A multielectrode array was used to record action potentials from the ganglion cell layer of the isolated salamander retina under spatially uniform ilumination modulated in intensity as a 1Hz square-wave. The cross-correlogram between the spike trains of two cells often showed a central peak 20-40 ms wide, containing up to twenty times as many spikes as the corresponding interval one stimulus period removed. The excess correlation decreased with increasing separation between the cell bodies, declining to roughly half at 200µm. Similar correlations were observed in darkness and during flickering white noise stimuli. The excess correlations are not expected if a common light stimulus were processed independently by different ganglion cells. Instead, the results indicate that ganglion cells may receive input from a common stochastic signal source. The short time scale of the correlations suggests that the signal does not arise from shared photoreceptor inputs. The correlations may be generated by reciprocal connections between ganglion cells or common input from spiking

NOISE ANALYSIS OF ß GANGLION CELL MICROCIRCUITRY Michael A. Freed\* LNP, NINDS, NIH, Bethesda, MD 20892 The ß ganglion cell in sublamina ½ of the cat retina has an Oncenter receptive field similar to those of presynaptic bipolar cells. This suggests bipolar cells contact ganglion cells at excitatory, sign-conserving synapses. We used an eyecup preparation to test this idea: we impaled with intracellular electrodes 2 On-ß ganglion cells. Flashing, red slits of light (1 s, 647 nm) produced depolarizing center responses and also increased voltage noise variance. This suggests presynaptic neurons open channels with a reversal potential positive to the dark potential, and thus are predominantly excitatory. Two intervals of noise (250 ms, 512 points) were extracted from each digitized response: one during the sustained portion of the response and one in the dark. Although somatic splking was inactivated by somatic depolarization, lower amplitude events persisted. These were probably spikes from the initial segment, and would confound noise analysis. To avoid this hindrance, only those intervals of noise which had symmetrical, unimodal, amplitude distributions were studied further. The changes in voltage noise variance  $(\Delta\sigma^2 = 10 \text{ nV}^2)$  and mean voltage  $(\Delta V=1 \text{ mV})$  indicated an elementary event amplitude  $(=\Delta G^2/\Delta V)$  on the order of 10  $\mu V$ . Assuming the time course of the elementary events was determined by the time constant of the cell  $(=\Delta G^2/\Delta V)$  on the order of 10  $\mu V$ . Assuming the time course of the elementary events was determined by the time constant of the cell (=10 ms), the frequency of elementary events  $(=\Delta V^2/\Delta\sigma^2 \tau)$  was about  $10^4 \text{ s}^{-1}$ . The frequency of captured photons was about  $10^9 \text{ s}^{-1}$  (area = 70  $\mu$ m x 400  $\mu$ m; 1=6.3 log(photons  $\mu$ m  $^2 \text{ s}^{-1}$ )). This suggests, under mesopic conditions, elementary events are not captured photons but either channels or synaptic quanta. These results support previous results (1991 Neurosci Abst #143.6) by indicating infr

## 171.10

REDOX MODULATION OF GLYCINE-EVOKED CURRENT IN RAT RETINAL GANGLION CELLS. Zhuo-Hua Pan\* and Stuart A. Lipton. Department of Neurology, Children's Hospital and Program in Neuroscience, Harvard Medical School, Boston, MA 02115

Disulfide bonds and/or sulfhydryl group(s), which exist on all known ligand-gated channels, have been shown to play an important functional role in the regulation of neurotransmitter responses (e.g., for NMDA-evoked currents, see S.Z. Lei et al., *Neuron*, June 1992). We report here that glycine responses are also modified by sulfhydryl reagents. The whole-cell patch clamp technique was used to examine the reagents. The whole-cell patch clamp technique was used to examine the effects of sulfhydryl reagents on glycine-induced current of solitary rat retinal ganglion cells in vitro. Extracellular application of the disulfide reducing agent dithiothreitol (DTT; 2-5 mM) significantly suppressed responses evoked by glycine (10-100 µM), while the oxidizing agent 5,5-dithiobis-2-nitrobenzoic acid (DTNB; 500 µM) slightly potentiated the responses. The DTT effect was not voltage dependent; nor did it interfere with inhibition by strychnine (100 nM). Similar to DTT, reduced glutathione (GSH; 5 mM) decreased glycine-evoked currents. In contrast, oxidized DTT (2-5 mM) or oxidized glutathione (GSSG; 5 mM) modestly enhanced glycine responses. N-ethylmaleimide (NEM; 1-10 mM), which irreversibly alkylates sulfhydryl groups, enhanced glycine-induced currents, especially after applying DTT to expose free sulfhydryl (-SH) groups. Taken together, these results suggest that regulatory sulfhydryl group(s) exist on the extracellular surface of the glycine receptor, influencing physiological function.

## 171.12

THE CONTRAST GAIN CONTROL OF PRIMATE M GANGLION CELLS: Spatial Organization And Temporal Properties.

E.A.Benardete. E.Kaplan\*, 8 J.D.Victor. Rockefeller University, and Cornell University Medical College, NY, 10021

Previously, we have shown that the temporal frequency response of

primate retinal ganglion cells (RGCs) that project to the magnocellular layers of the LGN (M cells) is modified by the overall contrast in the visual stimulus (Benardete et al., Vis. Neurosci. '92). Work on the cat retina established that a similar process, the contrast gain control, was responsible for this change in dynamics (Shapely & Victor, 1981). Here we investigated the spatial extent and the temporal frequencies that influence the contrast gain control.

RGC activity was monitored as synaptic (S) potentials in the LGN of anesthetized and paralyzed macaque monkeys. The contrast of sinusoidal gratings and/or a spot and an annulus produced on a CRT was temporally modulated with a sum of 8 sinusoids in order to calculate temporal transfer functions. In addition, we used a hybrid m-sequence method to measure the impulse response of various parts of the M cell receptive field (Benardete et al., ARVO '92).

Experiments with sinewave gratings show that the contrast gain control signal comes from retinal elements with a fine spatial scale (similar to the receptive field center or smaller). These elements cover a large area of the receptive field, coextensive with the classical receptive field center and surround. Experiments with small, centered spots and annuli suggest that the contrast signal is pooled from a large number of these elements to modify the M cell temporal frequency response. We are using data from the spatial and temporal analyses to construct a model that accounts for the dynamical properties of the M cel

PERMEATION OF CALCIUM IONS THROUGH KAINATE RECEPTOR-COUPLED CHANNELS IN RAT RETINAL GANGLION CELLS. Dongxian Zhang\* and Stuart A. Lipton. Dept. of Neurology, Children's Hospital and Program in Neuroscience, Harvard Medical School, Boston, MA 02115.

The Ca2+ permeability and current-voltage (I-V) relation of non-NMDA receptor subunits is controlled by a glutamine to arginine substitution in the second transmembrane segment (Verdoom et al., Science 1991;252;1715; Hume et al., ibid. 253:1028). Non-NMDA receptors permeable to Ca<sup>2+</sup> have been found in several types of neurons, including retinal bipolar cells (Gilbertson et al, ibid. 251;1613). We investigated the permeation of Ca<sup>2+</sup> through kainate receptor-coupled ion channels in cultured rat retinal ganglion cells (RGCs) by using patch-clamp and calcium-imaging techniques. With physiological Hanks' solution in the bath and CsCl/TEACl in the patch pipette, RGCs displayed a nearly linear I-V curve for kainate responses. In 5/27 RGCs, with extracellular Na+ replaced by the impermeant ion Nmethyl-D-glucamine and Ca<sup>2+</sup> as the only permeant cation, an inward current was observed at a holding potential of -60 mV. The reversal potential shifted to -45 mV in 2.5 mM external [Ca<sup>2+</sup>], and to near 0 mV potential sinited to -45 int vin 2.5 intwesternal [Ca<sup>2+</sup>], and to flear of intvin 70 mM external [Ca<sup>2+</sup>]. In contrast, for 22/27 RGCs no Ca<sup>2+</sup> influx was observed. The permeation of Ca<sup>2+</sup> through kainate-gated channels in a subpopulation of RGCs was further supported by fura-2 calcium imaging measurements showing that kainate increased intracellular [Ca<sup>2+</sup>] in a subpopulation of RGCs independent of their voltagedependent Ca<sup>2+</sup> channels. Therefore, glutamate may affect [Ca<sup>2+</sup>]<sub>i</sub> in RGCs via both NMDA- and non-NMDA-gated ion channels.

X - TYPE CAT GANGLION CELLS SHOW NONLINEAR OSCILLATIONS OF THE GENERATOR POTENTIAL DETERMINING THE REGULARITY OF SPIKE BURSTING. A. W. Przybyszewski\*, M. J. M. Lankheet, and W. A. van de Grind Dept. of Physiology, Freie Universitaet Berlin, Arnimallee 22, 1000 Berlin 33, Germany & Utrecht Biophysics Research Institute, Utrecht University, Padualaan 8, 3584 CH Utrecht,

The classification of ganglion cells into X - and Y - types is based on the linear and nonlinear spatial summation properties (Enroth-Cugell and Robson, 1966). It will be shown that the generator potential of Xtype ganglion cells shows strong nonlinear behaviour in the time

Ganglion cell activity was recorded intracellularly in the optically intact in situ eye. The light stimuli were spots of different sizes modulated sinusoidally in intensity. The mean illumination level was in the photopic range. Recorded signals were convoluted with the wavelet function (Przybyszewski, 1991) to separate the generator potential (GP) from the spikes. Fourier analysis of the GP of on-center Xganglion cells showed resonance for a frequency between 8 and 16Hz, and for 0.7 deg spot size. The analysis of the GP in 3D phase-space showed other faster oscillations which were local and not directly synchronized in time with the stimulus. The GP of X-cells is strongly nonlinear for the spot sizes comparable to the size of the receptive field center, temporal frequency 8Hz and for the high light intensities (53 530cd/m<sup>2</sup>). Such oscillations are very similar to those described by the van der Pol equation. The strong nonlinearities uncovered in the GP of X-cells produce the observed precise timing of spike bursts.

## EXCITATORY AMINO ACIDS: RECEPTORS III

## 172.1

DEVELOPMENTAL EXPRESSION OF NMDA RECEPTOR SUBTYPES. H. Monver\* and P. Seeburg. Center for Molecular Biology, Heidelberg, Germany.

A new family of NMDA receptors whose members (NR2A, NR2B and NR2C) are between 55% and 70% identical but only 20% identical to other excitatory amino acid receptor subunits has been cloned and characterized recently (Monyer et al., Science, in press). Heteromeric channels formed from one of these subunits plus NMDAR1 (Moriyoshi et al., 1991, Nature 354:31) differ in their gating behavior, Mg2+ sensitivity and the effect of glycine. There is an abundant but differential expression of all subtypes in the adult and developing rat brain as visualized by in situ hybridization. We have now identified a new subtype, NR2D. NR2D is heavily expressed in the embryonic rat brain and spinal cord followed by a substantial decline during development. The physiological properties of this subunit will be discussed

#### 172.2

Ca2+ PERMEABILITY OF RECOMBINANT NMDA RECEPTOR CHANNELS. N.Burnashev, H.Monyer, R.Schoepfer and P.Seeburg\*. MPI für Med. Forschung and ZMBH, 6900 Heidelberg, Germany.

Ca2+ permeability was measured for heteromeric NR1/NR2A and NR1/NR2C receptor channels assembled from recently cloned subunits transiently expressed in 293 cells using patch clamp techniques in whole-cell mode. The reversal potentials for the NMDA-activated whole-cell current shifted from about 0 mV in normal, high Na+ extracellular solution positive potentials around +20 mV in high (110 mM) Ca2+ extracellular solution for both receptor subtypes. The reversal potentials in high Ca2+ extracellular solution are close to those of native NMDA receptor channels in these conditions and they are identical to reversal potentials determined for homomeric AMPA selective GluR-channels engineered to carry asparagine at the Q/R site in the putative TM II segment. Point mutations in homologous position in NMDA receptors revealed that this site is involved in control of Ca<sup>2+</sup> permeability.

## 172.3

SINGLE CHANNEL ANALYSIS OF A MUTANT NMDA RECEPTOR WITH ALTERED ION-CHANNEL PROPERTIES FOR MAGNESIUM IONS. R.Schoepfer\*, P.Seeburg, T.Kuner N.Burnashev, W.Günther and P.Ruppersberg. ZMBH and MPI für Med. Forschung, 6900 Heidelberg, Germany

Ionotropic glutamate receptors are divided into two classes: NMDA (N-methyl-D-aspartate) and non-NMDA receptors. Recent molecular cloning of subunits for both classes defines them as members of one gene family.

The NMDA receptors display several distinctive features: The channels are highly permeable for Ca2+. Mg2+ in the extracellular milieu causes a voltage dependent block of the ion channel. This Mg<sup>2+</sup> property is considered to be of major biological significance and is thought to be involved in some

cases of long term potentiation.

The abstract by N.Burnashev presents a NMDA receptor subunit mutant in the presumed channel lining segment with altered Ca2+ properties. We analysed this mutant with respect to the magnesium block. Wild-type and mutant NMDA receptor subunits were first expressed transiently in 293 cells. Agonistinduced whole cell currents were measured and Mg2+ dependent parameters determined. For single channel analysis recombinant receptors were expressed in Xenopus oocytes and analyzed by patch-clamping.

We found that the mutant has altered Mg2+ dependent channel properties.

## 172.4

CHROMOSOMAL LOCALIZATION OF GLUTAMATE RECEPTOR GENES: CANDIDATES FOR FAMILIAL AMYOTROPHIC LATERAL SCLEROSIS AND OTHER NEUROLOGICAL DISORDERS OF MICE AND MAN

CANDIDATES FOR FAMILIAL AMYOTROPHIC LATERAL SCLEROSIS AND OTHER NEUROLOGICAL DISORDERS OF MICE AND MAN P. Gregor\*-1, M.F., Seldin², R., Reeves³, E., Jabs⁴, X., Yang¹, J.M., Rochelle², B.F., O'Hara⁴, & G.R., Uhl¹.5. ¹Lab. of Mol. Neurobiol., Natl. Inst. on Drug Abuse, Depts. ³Physiol., ⁴Pediatrics, \*Neurol. & Nsct., Johns Hopkins U., Box 5180, Baltimore, MD 21224; ²Dept. Med., Duke U., Durham, NC 27710; ⁴Dept. Biol. Scl., Stanford U., CA 94305. To seek genes underlying hereditary neurological disorders, eight glutamate receptor (GluR) genes were localized to mouse chromosomes by genetic linkage using interspecific backcrosses, and two of these were also assigned to human chromosomes.

The mouse Glur-5 gene was mapped to Chr 16 using a mouse GluR5-3 cDNA that appears to encode a novel C-terminal isoform of GluR5 (Bettler et al., Neuron 5: 583). The gene is 3.9 centiMorgans (cM) telomeric to the App gene and 2.4 cM centromeric to Sod·1. The strong conservation of this linkage group between mouse and man predicted that the homologous GLUR5 gene would be found on human Chr 21q21-q22.1. Localization to Chr 21 was confirmed by analysis of human-rodent somatic cell hybrids. The GLUR5 gene thus becomes a candidate for a familial form of amyotrophic lateral sclerosis (ALS; Lou Gehrig's disease), which has been mapped telomeric to APP and close to D21S58 on Chr 21 (Siddique et al., N. Engl. J. Med. 20:1381). The expression of the rodent Glur-5 gene GLUR5 could also play a role in Down's syndrome pathophysiology.

A clone of mouse CluR6c cDNA, encoding a novel C-terminal isoform of subunit GluR6 (Egebjerg et al., Nature 351: 745), was mapped to mouse Chr 10, close to loci that are defined by neurological mutants waltzer and Jackson circler. Glur-1 maps close to shaker-2, vibrator, tipsy and spasmodoc on Chr 11; Glur-2 is close to shaker-2, vibrator, tipsy and spasmodoc on Chr 11; Glur-2 is close to spastic on Chr 3; and Glur-7 is near clasper on Chr 4.

HETEROGENEITY OF Ca<sup>2+</sup>-PERMEABLE AMPA/KA RECEPTORS IN CULTURED PURKINJE NEURONS. <u>J.R. Brorson\*</u>, <u>S.J. Gibbons</u>, and <u>R.J. Miller</u>. Department of Pharmacological and Physiological Sciences, The University of Chicago, Chicago IL 60637.

We have shown that in cultures of rat cerebellar neurons enriched for Purkinje cells, most of the neurons express Ca<sup>2+</sup>-permeable non-NMDA receptors activated by kainate (KA). Whole-cell sustained currents were evoked by bath application of non-NMDA agonists in Na+-free solution with potencies of AMPA> domoate> KA; EC50 values were 4.3, 19, and 171 µM, respectively. Domoate and KA values were 4.3, 19, and 171 µM, respectively. Domoate and KA evoked much larger maximal sustained Ca<sup>2+</sup> current responses than those evoked by AMPA (mean currents of 211, 224, and 38 pA, respectively), consistent with the rapid inactivation produced by AMPA. The magnitudes of currents evoked by domoate from cell to cell correlated closely with those evoked by KA, whereas those evoked by AMPA did not. Furthermore, coapplication of AMPA with 100µM KA in most cells diminished, but in some cells increased, the Ca<sup>2+</sup> currents relative to those evoked by KA alone. Fura-2 Ca2+ imaging also suggested that the Ca<sup>2+</sup> influxes induced by applications of KA and AMPA in Na+-free media did not correlate closely. These results are best explained by the expression of Ca<sup>2+</sup>-permeable non-NMDA receptors heterogeneous in their agonist selectivity. GluR1 and GluR2/3 expression have been immunocytochemically identified in these cells; the detection of Ca<sup>2+</sup>-permeable KA/AMPA receptors may be explained on the basis of certain combinations of these subunits.

B-AMYLOID (25-35) OR SUBSTANCE P (1-11), BUT NOT B-AMYLOID (1-40), STIMULATE [3H]MK-801 BINDING TO RAT CORTICAL MEMBRANES IN THE PRESENCE OF GLUTAMATE AND GLYCINE. D.O. Calligaro\*. P.J. O'Malley and J.A. Monn. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

Laboratories, Eli Lilly and Company, Indianapolis, IN 46285. We have observed that substance P (1-11) is able to simulate [3H]MK-801 binding in the presence of submaximal concentrations of glutamate and glycine. Substance P (1-11) has sequence homology with *B*-amyloid (25-35). This 11 amino acid segment has been reported to mediate the neurotrophic and neurotoxic effects of *B*-amyloid (1-40) on cultured neurons. This study examined whether *B*-amyloid protein is also able to activate the NMDA operated ion channel when measured by the open channel blocker [3H]MK-801. Micromolar concentrations of *B*-amyloid (25-35) or substance P (1-11) stimulated [3H]MK-801 binding in the presence of low concentrations of glutamate (1 uM) and glycine (0.02 uM). Full length *B*-amyloid (1-40), up to 100 uM, had no effect. Similar to other NMDA receptor complex antagonists (5,7-dichlorokynurenic acid, CGS-19755 and arcaine), substance P -[D-Arg1,D-Trp7,9,Leu11] completely inhibited the stimulated [3H]MK-801 binding. Substance P (6 uM) increased the IC50 of 5,7-dichlorokynurenic acid, but not that of CGS-19755 on [3H]MK-801 binding, suggesting a glycine site interaction. These data may help explain some of the reported effects of *B*-amyloid proteins on cultured neurons. Whether these observations have any relevance to Alzheimer's disease will remain unclear until more in known about the presence of *B*-amyloid fragments in vivo.

## 172.9

DISTRIBUTION OF NMDA RECEPTORS ON DENDRITES OF RAT HIPPOCAMPAL NEURONS.T. A. Benke\*† and K. J. Angelides† . Departments of Molecular Physiology and Biophysics† and Neuroscience . Baylor College of Medicine, Houston, TX 77030.

The NMDA subtype of glutamate ligand-gated ion channels is unique in its ability to permit the influx of calcium ions upon activation. Calcium is thought to act then as a second messenger. Since the activation of the NMDA class of glutamate ligand-gated ion channels is implicated in a number of processes such as synaptic plasticity, epilepsy, and ischemic cell death, the location of these receptors on neurons may be critical to their understanding.

Using Bodipy-conantokin-G, a fluorescent derivative of conantokin-G which specifically blocks NMDA-type glutamate receptors, and a lipophilic membrane permeable dye (Dil) to outline dendritic morphology, we have examined the distribution of these receptors in living cultured hippocampal CA1 neurons and in hippocampal slices. Digital imaging shows that NMDA receptors are clustered and segregated on cell somata and at regions of dendrites associated with synaptic contact sites. Fluorescence photobleach recovery (FPR) studies of these clusters shows that 25% of the receptors are mobile in the membrane. This feature could provide the neuron with additional plasticity by the recruitment of receptors to active zones. Confocal microscopy of slices shows that NMDA receptors are

active zones. Confocal microscopy of slices shows that NMDA receptors are associated with some but not all dendritic spines.

Using the latest information available on NMDA channel kinetics, we are incorporating this anatomical information into mathematical models of different neurons from the hippocampus to gain more insight into how the distribution of NMDA receptors that we have determined can affect the integrative properties of neurons. These models provide information on the time and voltage dependent changes of intracellular calcium concentration, which provides a direct conceptual link with how the distribution of NMDA receptors is involved in calcium dependent

#### 172.6

EVIDENCE THAT ASTROCYTES POSSESS FUNCTIONAL CA<sup>2+</sup> PERMEABLE KAINATE RECEPTORS <u>James A Holzwarth\*<sup>1</sup>, James R</u> <u>Brorson<sup>1</sup>, Simon J Gibbons<sup>1</sup>, Robert J Wenthold<sup>2</sup>, and Richard J Miller<sup>1</sup> <sup>1</sup>Dept. of Pharm and Physiol Sciences The University of Chicago Chicago, II 60637. <sup>2</sup>Lab of Neuro-Otolaryngology NiH Bethesda, Md.</u>

Astrocytes are a heterogeneous population of cells. Some types of astrocytes have been shown to possess excitatory amino acid receptors of both metabotropic and ionotropic types. The present study was undertaken to determine if astrocytes express kainate receptors which are permeable to Ca<sup>2+</sup> ions. We cultured glia from various regions of the brain, and these cells were replated for greater purity. We then examined cells for kainate responses using the intracellular Ca<sup>2+</sup> indicator, fura-2.

In subsets of astrocytes from both the cortex and the hippocampus, we observed responses to kainate (30µM) using both fura-2 microfluorimetry and imaging. These cells responded with an increase in  $[Ca^{2+}]_i$  to kainate, even in the absence of extracellular Na<sup>+</sup>. The magnitude of the response in Na<sup>+</sup> free medium was similar to that seen in Na<sup>+</sup> containing medium. These results suggest that this  $Ca^{2+}$  influx is not a consequence of the activation of voltage gated  $Ca^{2+}$  channels by Na<sup>+</sup> dependent depolarization, but rather is via  $Ca^{2+}$  permeable kainate receptors. Quisqualate failed to give a  $Ca^{2+}$  mobilization response in the same cells, but in another set of cells did give a  $Ca^{2+}$  mobilization response.

In some cortical and cerebellar astrocytes we observed staining using antibodies for the GluR4 receptor, but little evidence for the GluR1, 2 and 3 receptor subunits. In contrast in neurons we observed staining using antibodies for the GluR1 and 2/3 receptor subunits, but there was little evidence for GluR4 in comparison to astrocytes. It has been reported that GluR4 containing receptors which lack GluR2 subunits are permeable to Ca<sup>2+</sup>. Since glia seem to lack GluR2 subunits and possess the GluR4 subunit, these reults suggest a possible basis for the kainate induced Ca<sup>2+</sup> influx seen in these cells.

#### 172.8

PHOSPHORYLATION AND REGULATION OF GLUTAMATE RECEPTORS. I.R. Soderling\*. H. Yamamoto, E. McGlade-McCulloh, S.E. Tan, and D. Brickey. Vollum Institute, Oregon Health Sciences University, Portland, OR 97201.

Regulation of glutamate receptor/ion channels may be important in synaptic plasticity. This study was designed to investigate whether glutamate receptors (GluR) can be regulated by phosphorylation. Purified CaM-kinase II and PKC (10-100M), but not PKA, catalyzed rapid in vitro phosphorylation of GluR which had been immunoprecipitated from Sf9 cells expressing GluR1. In isolated synaptosomes, stimulation of CaM-K II and PKC, but not PKA, stimulated phosphorylation of GluRs. These results are consistent with the existence of consensus phosphorylation sites for PKC and CaM-K II, but not PKA, on the major intracellular loop of GluRi-4. Using whole-cell patch clamp recording from cultured hippocampal neurons, "run-down" of kainate current was partially prevented by inclusion of 5mM Mg²+/ATP in the recording pipette. Kainate current was further enhanced by protein phosphatase inhibitors when Mg²+/ATP was in the pipette; 1.25µM okadaic acid in the perfusion medium or 10µM microcystin-LR in the pipette. We are currently exploring the effects of PKC and CaM-K II in the recording pipette. The above results are consistent with regulation of glutamate ion channels by protein phosphorylation. Supported by NIH grant NS27037

## 172.10

EXPRESSION OF ENDOGENOUS NMDA RECEPTOR MRNA WITHOUT FUNCTIONAL CHANNELS IN PC12 CELLS. Nikolaus J. Sucher\*, David L. Deitcher, Hilmar Bading, Michael E. Greenberg, Connie L. Cepko & Stuart A. Lipton, Dept. of Neurology, Children's Hospital, Dept. of Genetics, Dept. Microbiology & Molecular Genetics; Harvard Medical School, Boston, MA 02115.

Recently, the cloning of a cDNA encoding the rat NMDA receptor (NMDAR1) has been reported (Moriyoshi et al., Nature 354,31;1991). Expression of NMDAR1 mRNA has been demonstrated by in situ hybridization, we found that NMDAR1 mRNA is expressed at high levels in rat pheochromocytoma (PC12) cells. An NMDAR1 probe hybridized to a band of ~4.4 kb with RNA from undifferentiated as well as nerve growth factor-treated PC12 cells. A ~4.4 kb band was also detected in hippocampal RNA but not in RNA from astrocytes or rat adrenals from which PC12 cells presumably arose. No hybridization to PC12 RNA was detected with a probe for the non-NMDA receptor GluR1. To investigate whether PC12 cells translate NMDAR1 mRNA into functional receptors, we performed patch-clamp recordings and fura-2 digital Ca²+-imaging. However, we could not detect NMDA-evoked whole-cell currents or increases in intracellular Ca²+ in PC12 cells. Thus, detection of NMDAR1 mRNA by northern or in situ hybridization does not necessarily indicate that a functional receptor is being made. Moreover, our results indicate that the expression of NMDA-operated channels may be regulated by post-transcriptional mechanisms. The discovery that PC12 cells express NMDAR1 mRNA may afford the possibility of studying in a widely available cell line the transcriptional and post-transcriptional regulation of the NMDA receptor.

NMDA RECEPTORS ON BRAIN CAPILLARY ENDOTHELIAL CELLS ARE COUPLED TO ORNITHINE DECARBOXYLASE. H. Koenig<sup>1</sup>, M. Spatz<sup>2</sup>, \*, C.Y. Lu<sup>1</sup>, A.D. Goldstone<sup>1</sup>, J.J. Trout<sup>1</sup>, Neurol. Svc, VA Lakeside Med. Ctr., Dept. of Neurol., Northwestern U. Med. Sch., Chicago, 11 60611, & <sup>2</sup>LNNS, NINDS, NIH, Bethesda, MD 20892.

We recently reported evidence showing the presence of NMDA receptors on rat brain capillaries (BC) (Soc. Neurosci. Abstr. 17:7, 1991). BC NMDA receptors are coupled to ornithine decarboxylase (ODC), the regulatory enzyme of polyamine synthesis, upmodulate capillary transport of  $^{45}\text{Ca}^2$ , 2-[ $^{3}\text{H}$ ] decayglucose & horseradish peroxidase in a Ca $^{2+}$ & polyamine-dependent manner, & mediate blood-brain barrier breakdown induced by cold injury. We have now investigated endothelial cells (EC) cultured from neonatal & adult rat cerebral capillaries. The basal ODC activity of 4 h serum-deprived neonatal & adult BCEC was approx. 200 & 100 pmol/h/mg respectively. NMDA (50  $\mu\text{M})$  evoked a rapid (<15 sec) increase in ODC activity which peaked (2-fold) at 2 min, & was still elevated at 5 min. NMDA-induced activation of ODC was concentration-dependent with a maximum response at 50  $\mu\text{M}$ , & was blocked by the competitive NMDA antagonist 2-amino-5-phosphonovalerate (AP5, 200  $\mu\text{M}$ ) & the ODC inhibitor  $\alpha$ -difluoromethylornithine (DFMO, 10 mM). These results demonstrate that NMDA receptors are expressed in cultured BCEC, are coupled to ODC, & thus regulate polyamine synthesis. (Supported by the VA Research Service & NHB grant NS 18047)

#### 172.12

ANALYSIS OF THE mRNA ENCODING THE AMPA RECEPTOR IN SINGLE FURKINJE CELLS.E. AUDINAT, B. LAMBOLEZ, P. BOCHET, J. ROSSIER\* and F. CREPEL Lab. Neurobiologie, CNRS, 91405 Orsay and Inst A. Fessard, CNRS, 91198 Gif/Yvette, France.

Several subunits of the AMPA subtype of the glutamate receptor have been recently cloned. These subunits named GluR1, 2, 3 and 4 exist in two versions (flip and flop) generated by alternative splicing. The AMPA receptor is likely to be a pentameric structure composed of combinations of the GluR1-4 subunits. However, the subunit composition of native AMPA receptors involved in single neuron responses is still unknown. To answer this question we combined whole cell recording and amplification, by means of the polymerase chain reaction (PCR), of the mRNAs harvested from the single neuron under investigation. Purkinje cells from cerebellar slice cultures were recorded in the whole cell configuration of the patch clamp technique. The cell cytoplasm was then collected into the patch electrode and the pipette content used for reverse transcription and PCR amplification of the mRNAs encoding the AMPA receptor subunits of each recorded neuron. Our results show that each single Purkinje cell expresses the mRNAs encoding the five following subunits: the flip and flop versions of GluR1 and GluR2 as well as GluR3flip, GluR2 being the most abundant. GluR3flop and GluR4flip were scarcely expressed in half of these neurons whereas GluR4flop was never detected. This suggests that the AMPA receptors of single Purkinje cells are heterogenous with respect to their subunit composition.

## RECEPTOR MODULATION, UP AND DOWN REGULATION I

#### 173.1

PHOSPHORYLATION AND DESENSITIZATION OF THE HUMAN  $\beta_2$ -ADRENERGIC RECEPTOR EXPRESSED IN SF9 CELLS. P. Chidiac, B.Mouillac, M. Caron, M. Dennis and M. Bouvier\*. Département de Biochimie, Université de Montréal, Montréal, Canada.

Postranslational modifications, such as phosphorylation and palmitoylation, are involved in  $\beta_z$ -adrenergic receptor ( $\beta_zAR$ ) regulation. Such modifications are difficult to study in mammalian cells due to the relative scarcity of the receptor protein. Recombinant baculovirus expression in Sf9 cells provides an alternative system which allows purification of large amounts of proteins. We have used this system to express an epitope-tagged human  $\beta_2AR$  (c-myc $\beta_2AR$ ). The epitope consists of 10 amino acids from human c-myc protein and is attatched to the N-terminus of the  $\beta_2AR$ . The c-myc $\beta_2AR$  displayed the appropriate pharmacology as determined by binding assays, and promoted an isoproterenol-sensitive activation of adenylyl cyclase. Stimulation of the cells by 1 µM isoproterenol for 10-30 minutes resulted in desensitization of the agonist-stimulated adenylyl cyclase activity, with decreases of up to 40% in maximal enzymic stimulation. This desensitization profile could be partially mimicked by the membrane-permeable cAMP analogue dibutyryl cAMP, suggesting the involvement of protein kinase A. The desensitization of the response was accompanied by an agonist-promoted increase in phosphorylation level of the c-mycβ<sub>2</sub>AR. The increase was observed both in alprenolol-sepharose affinity-purified receptors and in receptors immunoprecipitated with an anti-c-myc monoclonal antibody (9E10). Sf9 cells infected with recombinant baculovirus encoding G protein-coupled receptors thus provides a useful system to study aspects of regulation and post-translational modification of these receptors.

#### 173.2

SUBTYPE-SPECIFIC INTRACELLULAR SORTING OF ADRENERGIC RECEPTORS. M. von Zastrow. R. Link. Daunt, X.-M. Guan\* and B.K. Kobilka. Dept. of Molecular and Cellular Physiology, HHMI, Stanford Med. Ctr., Stanford, CA 94305. A remarkable feature of the G protein-coupled receptor superfamily is the conservation of multiple subtypes, some of which have nearly identical functional properties. These observations raise the question of whether other functional parameters, apart from ligand binding and G protein coupling, may differentiate receptor subtypes. Simultaneous immunocytochemical localization of B2 and different epitope-tagged a2 adrenergic receptor subtypes expressed in the same cells revealed that these receptors differ substantially from one another in their intracellular targeting and in the regulation of their sorting by agonists. One a2 receptor subtype was colocalized with \$2 receptors in the plasma membrane of untreated cells. Treatment of cells with the common adrenergic agonist norepinephrine resulted in a rapid sorting of  $\beta_2$  receptors to endosomes without redistribution of  $\alpha_2$  receptors. Another  $\alpha_2$  receptor subtype was localized to both the plasma membrane and a vesicular intracellular compartment which was distinguishable, in the same cells, from vesicles containing internalized  $\beta_2$  receptors. Subtype-specific sorting reveals an additional dimension of functional complexity in the G protein-coupled receptor superfamily.

## 173.3

HOMOLOGOUS DOWN-REGULATION OF M<sub>1</sub> AND M<sub>2</sub> MUSCARINIC ACETYLCHOLINE RECEPTORS IN TRANSFECTED FIBROBLAST B82 CELLS. Hongbing Wei, Henry L. Yamamura and William R. Roeske\* Departments of Pharmacology and Internal Medicine, The University of Arizona Health Science Center, Tucson, AZ 85724.

Murine fibroblast cell lines which had been transfected with the m1 or m2 genes were used to study the homologous regulation of mAChR. The cells were pretreated with (+)cismethyl-dioxolane (CD), carbachol (CCh), (-)YM796 or atropine for up to 24 hours. The muscarinic full agonist CD resulted in the loss of the M2 binding sites more rapidly than that of the M<sub>1</sub> binding sites measured by [3H](-)MQNB binding. After 24 hr exposure of the cells to CD, the densities of the M1 and M2 receptors decreased 76-78%, and the M<sub>1</sub> receptor mediated phosphoinositide hydrolysis or the M2 receptor mediated inhibition of forskolin-stimulated cAMP formation was attenuated. A 24 hr exposure of the cells to the M1 selective muscarinic partial agonist, (-)YM796, induced a 45% reduction in the density of the  $M_1$  receptors without significantly alterating the functions of the M1 and the M2 receptors. The antagonist atropine did not influence the densities of the M1 or M2 receptors. These results suggest that the M2 receptors may be more sensitive to homologous down-regulation than the M<sub>1</sub> receptors in the early stages of exposure to CD. The M<sub>1</sub> selective partial agonist (-)YM796 induced down-regulation of the M1 receptors but did not significantly influence the M2 receptor density or the M1 and M2 receptors. Supported by USPHS grants.

## 173.4

INTERNALIZATION OF MUSCARINIC RECEPTORS IN RESPONSE TO PHORBOL ESTER AND AGONIST. P.S. Goldman\* and N.M. Nathanson, Dept. of Pharmacology, Univ. of Washington, Seattle, WA 98195.

Previous studies in our lab and in others have indicated that activation of protein kinase C (PKC) by phorbol ester causes internalization of m1 but not m2 receptors. PMA caused greater internalization of m1 but not m2 receptors when expressed transiently in COS-7 cells. The effects of internalization by PMA and carbachol were measured with a chimeric m1/m2 receptor in which the 17 amino acids at the carboxy terminal end of the third cytoplasmic loop up to the carboxy terminal end of the m1 receptor have been replaced with the corresponding region of the m2 receptor. The m1/m2 receptor did not internalize in response to PMA suggesting that the carboxy terminal end of the m1 receptor is important in PKC activated internalization. The m2 but not the m1 receptor was internalized in response to carbachol when expressed in COS-7 cells. These data suggest that the mechanisms for PMA- and carbachol-induced internalization of the m1 receptor are different, and that a part of the mechanism involved in m1 agonist-induced internalization is not carbachol in COS-7 cells implying that the carboxy terminal end of the m2 receptor is sufficient for the m2 specific pathway for internalization of the receptor by agonist. Studies are underway to further localize the regions responsible for PKC-and agonist-mediated internalization and to determine if phosphorylation of the receptors is required for internalization.

Recent studies have shown that tyrosine residues located in the carboxy terminal tail of a number of different receptors are involved in the internalization and or downregulation of these receptors by agonist. Mutant mAChRs in which single tyrosine residues in their carboxy tails were replaced internalized normally in response to agonist and current work involves determining the ability of these mutant receptors to be downregulated.

AGONIST-DEPENDENT PHOSPHORYLATION OF THE SEROTONIN IC RECEPTOR IN RAT CHOROID PLEXUS AND XENOPUS OOCYTES. J. Hurley', J. Liu, L.S. Bye, M. Baez' and L. Yu Dept. of Med. and Mol. Genetics, Indiana Univ. School of Medicine, Indpls, IN 46202; 'Lilly Research Laboratories, Lilly Corp. Center, Indpls, IN 46285.

The serotonin 1c (5-HT<sub>1c</sub>) receptor, a G protein-coupled receptor, is present at very high density in choroid plexus, where its function and regulation are not well understood. The 5-HT<sub>10</sub> receptor contains putative phosphorylation sites for several protein kinases and may be regulated by phosphorylation in a manner analogous to other G protein-coupled receptors. Two methods were used to address this question. Freshly dissected rat choroid plexus was incubated in radiolabeled inorganic phosphate prior to treatment with 5-HT. Xenopus oocytes expressing the mouse 5-HT<sub>1C</sub> receptor were injected with [γ-32P]ATP 10 min. prior to vehicle or 5-HT treatment. Membrane proteins were analyzed by SDS-PAGE and autoradiography. Time and dosedependent increases in phosphorylation of the 5-HT<sub>1C</sub> receptor were observed. Anti-peptide antibodies directed against the mouse 5-HT<sub>1C</sub> receptor, which recognize both the mouse and the rat receptors, were used to identify the phosphorylated receptor. These methods should be useful to investigate the role of phosphorylation in the regulation of serotonin receptor function.

## 173.7

SELECTIVE UP-REGULATION OF ALPHA-2B ADRENOCEPTORS AFTER BRAIN NORADRENERGIC LESIONS. G.A. Ordway\*, J.D. Brodkin, and S.M. Jaconetta. Depts. of Psychiatry & Pharmacology, Case Western Reserve Univ. & MetroHealth Med. Ctr., Cleveland, OH 44109.

The location and function of alpha-2 adrenoceptors are poorly understood. Both alpha-2A and alpha-2B subtypes have been described in rat brain, and have high and low affinity, respectively, for oxymetazoline (OXY). determined the effect of lesioning catecholaminergic neurons on concentra-tions of OXY-sensitive and OXY-insensitive binding of <sup>3</sup>H-rauwolscine in rat brain. OXY competition curves are GTP-sensitive so all binding was performed in the presence of 250 uM GTP. Competition curves for inhibition of  $^{3}$ H-rauwolscine binding by OXY in rat cerebral cortex were best described by a two-site model (p < 0.005). OXY demonstrated a 100-fold difference in affinity for its high and low affinity binding sites (IC50<sub>H</sub> = 20 nM; IC50<sub>L</sub> = 2086 nM). Binding to OXY-sensitive and OXY-insensitive alpha-2 receptors was determined in rat cerebral cortex 3 weeks following intraventricular injections of saline (SHAM), 6-hydroxydopamine (6OHDA), and 6OHDA with desipramine pretreatment to protect noradrenergic neurons (6OHDA+DMI). Binding to OXY-sensitive alpha-2A-like adrenoceptors was not affected by either lesion (in fmol/mg protein: SHAM 12+2; 6OHDA 9+2; 6OHDA+DMI 10+2). In contrast, OXY-insensitive alpha-2B-like binding was elevated (+32%, p<0.01) in 6OHDA lesioned rats compared to sham-lesioned rats and to 6OHDA+DMI rats (in fmol/mg protein: sham 30+2; 6OHDA 40+2; 6OHDA+DMI 30+2). OXY-insensitive alpha-2B-like adrenoceptors are selectively up-regulated in cortex following destruction of noradrenergic neurons. Lack of change in OXY-sensitive alpha-2A-like adrenoceptors suggests that either these receptors are not synaptic, or alternatively, that these receptors are located on and post-synaptically to noradrenergic neurons.

## 173.9

THE EFFECT OF NEUROTENSIN ON DOPAMINE TRANSMISSION IN THE STRIATUM: EVIDENCE FOR A SUBSTRATE OF NEURONAL PLASTICITY BASED ON PRE-AND POSTSYNAPTIC NEUROTENSIN-DOPAMINE RECEPTOR INTERACTIONS. W.T.O'Connor\*, K.Fuxe, T.Antonelli, P.Osborne, S.Tanganelli, L.F.Agnati & U.Ungerstedt. Depts. of Pharmacology, Histology and Neurobiology, Karolinska Inst., Stockholm, Sweden.

The major mechanism underlying the neuroleptic action of the tridecapeptide neurotensin (NT) appears to be an interaction with dopamine (DA) receptor mechanisms based on biochemical binding and behavioral experiments. In vivo microdialysis was used in conscious rats to investigate the effects of local perfusion with NT on the sensitivity of striatal DA D1 and D2 receptors for their selective agonists by monitoring extracellular DA and GABA levels in the awake unrestrained male rat. Perfusion with NT (10nM) counteracted the inhibitory effects of the DA D2 agonist pergolide (500nM) on DA and GABA levels. In contrast, NT (10nM) significantly enhanced the reduction of DA levels after perfusion with the D1 agonist SKF 38393 (5000nM) and this combined treatment also resulted in a significant increase in the extracellular striatal levels of GABA. These results provide in vivo evidence that NT regulates central DA transmission by reducing pre and postsynaptic DA D2 and enhancing D1 receptor sensitivity possibly through an antagonistic NT/D2 receptor-receptor interaction. heteroregulation has the potential to substantially increase the plasticity within the DA synapse.

A NOVEL ARRESTIN EXPRESSED IN CEREBRAL CORTEX IS SIMILAR TO THE BETA-ADRENERGIC ARRESTIN. C.M. Craft 1, D.H. Whitmore 2, R. Gonzalez, Jr. 1.1 Lab. Mol. Neurogen., Dept. of Psychiatry, U TX Southwestern Med. Sch. & VA Med. Ctr, Dallas, TX 75235, 2Dept. Biology, U TX, Arlington, TX 76019.

Arrestin (AR) proteins, S-antigen (SAG) and  $\beta$ -adrenergic arrestin (βAR), are involved in the inactivation of light-activated rhodopsin and homologous desensitization of  $\beta$ -adrenergic receptors after receptor phosphorylation. Differential expression of mRNAs and proteins encoding multiple ARs occurs in retina, pineal gland, cerebral cortex, cerebellum and sympathetically innervated tissues. Although antigenic epitopes are shared and highly conserved between members of the family, separate genes encode the individual members. Primers designed from these conserved domains between SAG and BAR generated products by polymerase chain reaction (PCR) amplification of cDNAs synthesized from mRNA from cerebral cortex and pineal. subclones of SAG and BAR were detected; plus a unique AR (CAR) was isolated independently from both mRNAs. carboxy terminus (200 amino acids) of CAR shares 74% identity with BAR. Alternative processing of CAR excludes a conserved SAG/BAR 3' exon and modifies the predicted secondary structure. CAR's distribution, evolutionary relationship with the other ARs, and interaction with membrane receptors are being examined.

## 173.8

IRREVERSIBLE BLOCKADE OF DOPAMINE RECEPTORS BY FLUPHENAZINE-N-MUSTARD INCREASES D<sub>2</sub> DOPAMINE RECEPTOR MRNA AND PROENKEPHALIN mRNA IN RAT STRIATUM. J.F. Chen\*, Z.H. Oin and B. Weiss. Div. of Neuropsychopharmacology, Dept. of Pharmacology, Medical College of PA, Philadelphia, PA 19129.

An understanding of the long-term factors that influence dopamine and neuropeptide systems at the level of gene expression is a key to uncovering the role of these systems in dopamine-associated diseases. This study examined the effects of irreversible blockade of dopamine receptors by fluphenazine-N-mustard (FNM) on D<sub>1</sub> and D<sub>2</sub> dopamine receptors, D<sub>1</sub> and D<sub>2</sub> dopamine receptor mRNAs and proenkephalin mRNA in rat striatum. Sprague-Dawley rats were reated with FNM (20 µmole/kg, i.p.) daily for 5 days. The animals were sacrificed 20 hr after the last injection, and brain sections at the level of the corpus striatum were prepared, D<sub>1</sub> and D<sub>2</sub> dopamine receptors were detected by receptor autoradiography, using [<sup>3</sup>H]-SCH23390 and [<sup>3</sup>H]-spiperone, respectively. D<sub>1</sub> and D<sub>2</sub> dopamine receptor mRNAs and proenkephalin mRNA were determined by in situ hybridization histochemistry, using radiolabelled oligodeoxynucleotide probes. FNM treatment caused a 90% reduction in D<sub>2</sub> dopamine receptors and a significant increase in D<sub>2</sub> dopamine receptor mRNA in striatum. By contrast, FNM treatment caused only a 20% inhibition of D<sub>1</sub> dopamine receptors and no significant change in D<sub>1</sub> dopamine receptor mRNA in striatum. FNM treatment also significantly increased proenkephalin mRNA in striatum. FNM treatment also significantly increased proenkephalin mRNA in striatum. FNM treatment also significantly increased proenkephalin mRNA in striatum. These results showing that transcripts for the D<sub>2</sub> dopamine receptor and proenkephalin are increased following irreversible blockade of dopamine receptors suggest not only that these systems can be modulated by dopaminergic input but also that these two systems interact at the level of gene expression. (Supported by MH42148).

## 173.10

Chronic Elevation of Protein Kinase A (PKA) Enhances GABAA Receptor Currents Composed of  $\alpha\beta\gamma$  Subunits and Not  $\alpha\beta$  Subunits. T.P. Angelotti\* $\nabla$ , M.D. Uhler\*, and R.L. Macdonald\* $^{\#}$  $^{\textcircled{Q}}$ , Depts. of Pharmacology $\nabla$ , Biochemistry\*, Neurology\*, and Physiology\* $^{\textcircled{Q}}$ , Univ. of Michigan, Ann Arbor, MI 48109.

Expression of α1, β1, and γ2S GABAA receptor (GABAR) subunit cDNAs in L929 (intermediate PKA), Cα12 (high PKA), and RAB10 cells (low PKA) produced functional GABAR with similar GABA and diazepam pharmacology, as assayed by whole-cell patch clamp analysis. The major difference was the magnitude of the currents; GABARs expressed in Cα12 cells were 3-4 times larger than those expressed in the other two cell lines, at all concentrations of GABA. Co-expression of only  $\alpha 1$  and  $\beta 1$  subunits in the same cells produced non-cooperative GABA concentration-response curves, but no enhancement of currents were seen in Ca12 cells. Substitution of a  $\beta1$  subunit mutagenized to remove the consensus PKA phosphorylation site (Ser409 --> Ala) also produced functional GABARs in all three cell lines after expression with  $\alpha 1$  and  $\gamma 2S$  subunits. This result suggested that the mutation did not effect expression. More importantly, the size of the whole-cell currents in all three cell lines were similar; the mutation reversed the enhancement seen in  $C\alpha 12$  cells. Single-channel patch clamp analysis of the expressed  $\alpha 1$ ,  $\beta 1$  (WT or Mutant), and  $\gamma 2S$ GABARs in all three cell lines revealed similar main and subconductance levels, and open, closed, and burst durations.

MOLECULAR CLONING AND CHARACTERIZATION OF A MOUSE AND RAT GENE ENCODING THE NPY-1 RECEPTOR. C.Eva\*, R.Sprenge1°, A. Oberto, S. Ricci Gamalero and E. Genazzani. Institute of Pharmacology, Univ. of Torino, Italy and °ZMBH, Univ. of Heidelberg, Germany,

Neuropeptide Y is an important central and peripheral modulator of neural and endocrine functions that interacts with at least two distinct receptors, named Yl and Y2. We isolated from a rat cDNA library a novel G proteincoupled receptor belonging to the neuropeptide receptor family. Expression patterns of the receptor encoding mRNA in rat brain showed significant similarities with the localization of the Y1 receptor. Transient expression of this G protein-coupled receptor in 293 cells reveals the ligand binding selectivity of a Yl receptor with high affinity for the selective analog (Leu31, Pro34) NPY, NPY stimulation of this receptor leads to a decrease of cAMP content, stimulation of membrane phospholipids and mobilization of intracellular calcium. The analysis and sequencing of the NPY-1 receptor gene, isolated from a mouse genomic library, shows that this gene lacks introns in the coding region and that regulatory elements potentially important for transcription can be found in the sequence of the putative promoter of this gene.

## 174.3

SUBSTITUTED NPY ANALOGUES EVOKE Y1 AND Y2 RECEPTOR-MEDIATED REPONSES: IDENTIFICATION OF SIGNAL EPITOPES. Lars Grundemar\*<sup>1,2</sup>, John L. Krstenansky<sup>3</sup> and Rolf Håkanson<sup>2</sup>, Departments of <sup>1</sup>Clinical Pharmacology and <sup>2</sup>Pharmacology, Univ. of Lund, Lund, Sweden and <sup>3</sup>Marion Merrell Dow Res. Inst. OH, USA.

A series of substituted neuropeptide Y (NPY) analogues were studied with regard to their ability to activate Y1 receptors (guinea pig caval vein) and Y2 receptors (rat

An anlogue with increased alpha-helicity in the 14-30 region, ESALL-NPY was about equipotent with NPY (1-36) at Y1 and Y2 receptors, respectively. Centrally substituted, linear NPY analogues with 8-aminooctanoic acid (Aoc) in the mid molecule region (hairpin loop), (Aoc <sup>8-17</sup>)NPY and (Aoc<sup>5-24</sup>)NPY), were rather potent at the Y2 receptor, however, being 30-100 times less potent than NPY at the Y1 receptor. A shorter peptide, (Aoc<sup>2-27</sup>)NPY, was virtually inactive at either receptor type. Cyclic analogues (with S-S bonds bringing N- and C-termini together) of (Aoc. \*17)NPY, C7-NPY of (Aoc. \*20)NPY, C5-NPY and of (Aoc. \*4)NPY,C2-NPY were about 10 times less potent than NPY at the Y2 receptor, and 25-50 times less potent at the Y1 receptor. The cyclic analogues appeared more potent than the corresponding linear analogues at the Y1 receptor, but equipotent at the Y2 receptor. A truncated C2-NPY analogue, (Des-S3, Des-K4)C2-NPY was 20

times less potent than NPY at the Y2 receptor, however, inactive at the Y1 receptor.

The results suggest that fairly extensive N-terminal truncation of the NPY molecule does not greatly impair recognition by the Y2 receptor, while the Y1 receptor needs an intact N-terminal end in order to become fully activated. Some centrally truncated analoges were rather potent at the Y1 and Y2 receptors, implying that the hairpin loop is not essential for receptor recognition. Conceivably, it may impose constraints on the N- and C-terminal ends, thereby facilitating Y1, but not Y2 receptor activation

## 174.5

CLONING OF A POTENTIAL NEW SUBTYPE OF THE BOMBESIN/GRP RECEPTOR FAMILY FROM THE HUMAN COLON ADENOCARCINOMA CELL LINE WiDr. E. Giladi\*, S. Nagalla and E.R. Spindel, Division of Neuroscience, Oregon Regional Primate Research Ctr, Beaverton, OR 97006

The bombesin like peptides comprise a large family of peptides common to amphibians and mammals that function as growth factors, neurotransmitters and paracrine hormones. Three subfamilies of bombesin-like peptides have been described; the bombesin/GRP subfamily, the ranatensin/NMB subfamily and the phyllolitorin subfamily. To date two mammalian bombesin-like peptides and their cognate receptors have been characterized, gastrin-releasing peptide (GRP) and neuromedin B (NMB). The phyllolitorins have so far only been characterized in amphibians. Recently, Cardona et al. (Br.J.Cancer 63:14,1991) reported that the WiDr colon carcinoma cell line showed a strong calcium response to phyllolitorin. In order to characterize the bombesin receptor subtype from WiDr cells, poly(A) RNA was prepared and injected into Xenopus oocytes and phyllolitorin induced changes in intracellular calcium were measure luminometrically. A 2-3-fold increase compared to control oocytes was measured. RNA size-fractionated on sucrose gave up to a 6-fold incre in light output in specific RNA fractions. A cDNA library constructed from the fractionated RNA fractions was screened with the human GRP receptor probe and one hybridizing phage was isolated. Sequence analysis revealed this cDNA encoded the C-terminus of a receptor highly related to the GRP and NMB receptors. Amino acid homology was 88% and 64% with the human GRP and NMB receptors, respectively. RNA blot analysis showed hybridization to a 9.5 kb band in WiDr RNA, the same size as the GRP receptor mRNA. Studies are currently in progress to isolate the entire cDNA to allow expression of this receptor and characterization of its pharmacologic specificity.

HIGH LEVEL EXPRESSION OF NEUROPEPTIDE Y (NPY) BIN-DING SITES IN CELLS INFECTED WITH A RECOMBINANT VACCINIA VIRUS. P. Walker \*, M.Munoz, M.-C. Combe, E. Grouzmann, H. Herzog#, L. Selbie#, J.Shine#, H.R. Brunner, B.Waeber and R.Wittek¶. Division of Hypertension, CHUV, 1011 Lausanne, Switzerland. #Gavran Institute, Sidney, Australia, ¶Institute of Animal Biology, 1015 Lausanne Switzerland.

Neuropeptide Y (NPY) is a 36 amino acid peptide first isolated by temoto<sup>1</sup>. Numerous studies point to a role of NPY in cardiovascular regulation. NPY effects are mediated through stimulation of specific cell surface G protein-coupled receptors. The sequence of a human NPY receptor as recently been published. To allow biochemical studies of the receptor and its interaction with the ligand, we have developed a potent expression system for NPY receptors using recombinant vaccinia virus. A NPY receptor cDNA was fused to a strong vaccinia virus promoter and NPY receptor cDNA was fused to a strong vaccinia virus promoter and inserted into the viral genome by homologous recombination. Recombinant viruses were isolated and tested for their ability to induce NPY binding site expression following infection of several mamalian cell lines. Using saturation and competition binding experiments we measured a B max of 5 to 10 X10<sup>6</sup> NPY binding sites / cell with a Kd of about 20 nM. Crosslinking studies identified a single labelled protein of 45 KD in agreement with the size of the receptor deduced from the nucleic acid sequence. Labelling of infected cells with a fluorochrome-labelled NPY indicated that the recombinant protein intergrates into the cell membrane 1 K.Tatemoto, Proc.Natl Acad.Sci.USA.,79, 5485-5489, 1982

LOCALIZATION OF HIGH AFFINITY Y2 RECEPTORS FOR NEUROPEPTIDE Y AND PEPTIDE YY IN THE RAT POSTERIOR PITUITARY

S. P. Sheikh, E. L. Stuenkel, J. D. Mikkelsen, P. J. Larsen, M. Treiman', T. W. Schwartz and M. Møller. Dept. of Clinical Biochemistry, J. Larsen, M. Rigshospitalet 6321, and Depts. of Medical Anatomy & Physiology, Panum Inst. University of Copenhagen, Denmark, and Dept. of Physiology, University of Michigan, Ann Arbor, MI 48109.

NPY has been reported to regulate secretion of several

transmitters and hormones in the hypothalamo-pituitary axis. To investigate whether NPY affects pituitary hormone secretion by a direct effect on pituitary nerve terminals we looked for NPY receptors on the rat pituitary gland. Receptor autoradiographic techniques at the light microscopic level revealed specific labeling in the posterior but not anterior lope. Using a preparation of isolated posterior nerve terminals a NPY receptor of surprisingly high affinity with  $K_d = 14$  pmol  $\pm 9$  (n = 8) and  $B_{max} = 494 \pm 68$  fmol/mg protein was observed. Data from inhibition experiments utilizing specific NPY analogues and fragments classified these binding sites as belonging to the Y2 type of NPY and PYY receptors (n = 6). By contrast, primary cell cultures of rat pituicytes did not specifically bind the PYY radiolabel. Thus, NPY and PYY receptors are present on the pituitary nerve terminals, and not on cultured pituicytes. In order to identify the structure, that contains the NPY binding sites we used the technique of receptor autoradiography at an electron microscopic level. Preliminary data shows that specific autoradiographic silver grains are localized over a distinct population of nerve terminals, whereas others are not labeled. We are currently in the process of identifying vasopressin and oxytocin immunoreactive nerve terminals on the receptor autoradiographs

## 174.6

EXPRESSION OF THE GASTRIN-RELEASING PEPTIDE (GRP) AND GRP RECEPTOR GENES IN DEVELOPING RHESUS MONKEY LUNG. K. Li\*, S.R. Nagalla and E.R. Spindel Oregon Regional Primate Research Center, 505 NW 185th Ave., Beaverton OR 97006.

High levels of the mammalian bombesin-like pentide gastrin-releasing peptide (GRP), is expressed in developing human lung. Rabbits and rats do not show this developmental pattern of expression and, thus, cannot be used to characterize the role of GRP in lung development. In this study we investigated the expression of the GRP and GRP receptor genes in fetal, neonatal and adult rhesus monkey lung. By RNA blot analysis, GRP mRNA was first detectable in fetal monkey lung at 63 days gestation, reached highest levels at 80 days gestation and then declined to near adult levels by 120 days gestation. In monkey lung, in situ hybridization localized GRP mRNA to neuroendocrine cells just as in human fetal lung. A surprising finding in this study was that during early stages of development (between 63 to 80 days gestation) GRP mRNA was present not only in the neuroendocrine cells, but also in cells of budding airways. Immunohistochemical studies showed that bombesin-like immunoreactivity was present in neuroendocrine cells, but not in the budding airways. Thus, the GRP mRNA is apparently present but not translated in airway progenitor cells. This is similar to the many human lung neoplasms which also express but do not translate the GRP mRNA.

PCR was used to clone a fragment of the monkey GRP recepto RNAse protection analysis using this probe demonstrated that the GRP receptor is expressed in monkey lung by 63 days gestation, plateaus from 80 to 140 days gestation and only low levels are present in adult lung. *In situ* hybridization suggested that GRP receptors are expressed in the airway epithelial cells. Thus, both a source of GRP and target cells to respond to GRP are present in developing monkey lung.

EXPRESSION CLONING AND PHARMACOLOGICAL CHARACTER-IZATION OF A RAT BRAIN SOMATOSTATIN RECEPTOR cDNA. H. Lübbert\*, F.-W. Kluxen, C. Bruns, D. Hoyer, L. Rohrer, R. Schüle, K. Kaupmann.
Preclinical Research, Sandoz Pharma Ltd., 4002 Basel, Switzerland.

We have used an expression-cloning strategy to isolate a cDNA encoding a somatostatin receptor from rat cortex and hippocampus. A positive clone was identified by autoradiography after binding of radio-labeled somatostatin to COS-1 cells previously transfected with pools of cDNA clones. The deduced amino acid sequence of the receptor displays sequence and structural homology to the family of G-protein coupled receptors. After expression of or cDNA in COS cells a single high affinity binding site was found with a K<sub>D</sub> of 51 pM and a B<sub>max</sub> of 157 fmol/mg protein. Several somatostatin receptor types have been postulated based on pharmacological criteria. The affinity of various SRIF analogs to the receptor cloned here analyzed and resembled closely their effects on growth hormone release from pituitary cells. The distribution of the RNAs encoding this and other somatostatin receptors has been analyzed in rat tissues, tumors and cell lines by in situ hybridization, RNA blotting and quantitative RT-PCR analyses. Of the tissues examined, the mRNA encoding the above mentioned somatostatin receptor was found in hippocampus, cortex, and pituitary as well as in a pancreas tumor and an exocrine pancreas derived cell line, AR4 2J, but not in kidney. Thus, the pharmacology and tissue distribution of this receptor corresponds to that described for the somatostatin receptor type which inhibits growth hormone release. Similar characterizations are performed for other cloned somatostatin receptor types.

#### 174.9

<u>Desensitization of Human Endothelin A and Neurokinin A Receptors</u> R. Kris \* C. Cyr. S. Josiah and V. Chu. N.Y.U. Med. Center, 550 1st Ave. New York, N.Y. 10016

Endothelin is the most potent endogenous vasoconstrictor known at this time and is implicated in several normal and abnormal physiological conditions including the pathogenesis of myocardial infarction, broncho-constriction, high blood pressure and acute renal failure. The human endothelin receptor A (ETA) has recently been cloned and belongs to the rhodopsin-like superfamily of receptors that contain seven putative hydrophobic transmembrane domains.

The response of G-protein coupled receptors is modulated by homologous desensitization. The endothelin response is probably tightly regulated since it is such a potent vasoconstrictor. The extent of desensitization and resensitization of endothelin responsiveness was therefore studied. Human neurokinin A (NKA) and human serotonin II (5-HT2) receptors were utilized for comparison to ETA in desensitization experiments. These three receptors are coupled to G proteins which mediate phosphotidyl-inositol hydrolysis.

Xenopus laevis oocytes injected with the three different receptor mRNAs all show homologous desensitization but exhibit variable rates of recovery. Human 5-HT2 receptors recover within 2 to 5 minutes while human NKA receptors recover after 20 to 30 minutes. The human ETA receptors have a prolonged desensitization period lasting 2 to 3 hours. Such a prolonged recovery period is unique to this class of receptors and may serve to regulate some of the deleterious effects of the receptor.

## 174.11

MOLECULAR CHARACTERIZATION OF THE NK1 ANTAGONIST SPECIES SELECTIVITY ON RAT AND HUMAN RECOMBINANT RECEPTORS. L. Pradier\*. L. Emile. E. Habert. L. Mercken. J. Le Guern.V. Moras. I. Loquet. J. Clot. V. Fardin. A. Doble. J.F. Mayaux. Rhône Poulenc Rorer, 13 Quai J. Guesde, 94400 Vitry, France.

The neuropeptide Substance P, member of the tachykinin family, is a potent vasodilatator and smooth muscle contractant. SP has also been proposed as a candidate for pain neurotransmission. Recently, two non-peptide competitive antagonists for NK1 receptors, the high affinity SP receptors, have been described: CP96345 and RP67580. Unlike SP, those compounds show strong species selectivities in binding studies with RP67580 being more potent on the rat NK1 receptor and CP96345 on the human receptor (Fardin et al., 1992, Brit. J. Pharm. 105:80P). However, the recent cloning of the NK1 receptor from the two species has revealed few differences in their primary sequences. have used a transient expression system in COS1 cell line to study the binding properties of recombinant rat and human NK1 receptors as well as multiple rat/human hybrids. Point mutants were also constructed in order to identify the respective residues involved in the strong and apposite species selectivities observed in binding. This opposite species selectivities observed in binding. study has allowed a fine characterization of the residues involved in the ligand binding cleft on the NK1 receptor.

#### 174.8

EVIDENCE FOR A NONCLASSICAL NK-1 RECEPTOR ON MICROGLIA F.C. Martin\*. P.A. Anton. J.A. Gornbein. F. Shanahan. and J.E. Merrill Depts. of Neurology, Medicine, and Biomathematics, School of Medicine, University of California, Los Angeles, CA 90025

This study examined whether microglia possess SP receptors. Microglia isolated from primary rat brain cultures were incubated with Bolton-Hunter labeled I- $^{125}$  SP and various concentrations of cold SP or cold analogs. Results were analyzed by an exact weighted nonlinear regression. The data best fit a single receptor model with a  $\rm K_d$  of  $5.3 \times 10^{-7} M_{\odot}$ 

(SE  $\pm$  0.4x10<sup>-7</sup>M) and 35,000 (SE  $\pm$  3500) binding sites per cell. The binding site bound NK-1 selective agents such as the peptide SP methylester and the nonpeptide CP-96,345, while failing to bind NK-2 or NK-3 selective analogs. The binding heirarchy was not typical for NK-1 receptors, however, with SP>SP methylester, very weak binding for physalaemin and none for neurokinin A. The K<sub>d</sub> was also much larger than for classical NK-1 receptors. Similar results have been reported for macrophages (Hartung et al., 1986, J. Immunol., 3856-3863). These data indicate the presence of a nonclassical NK-1 receptor on microglia and other cells of monocytemacrophage lineage.

DIFFERENT BINDING EPITOPES FOR SUBSTANCE P AND THE NON-PEPTIDE ANTAGONIST, CP-96,345 ON THE NK1 RECEPTOR. U. Gether A. T.E. Johansen A. R.M. Snider B. J.A. Lowe III B. S. McLean B\*, S. Nakanishi C. and T.W. Schwartz A. ALab of Molecular Endocrinology, Rigshospitalet 6321, Univ of Copenhagen, Denmark, BDept of Medicinal Chemistry, Central Research, Pfizer Inc., Groton, CT 06340 and CInst. for Immunology, Kyoto Univ. Japan

Immunology, Kyoto Univ. Japan.

Non-peptide ligands for neuropeptide receptors are being discovered in many systems through file screening programs. However, the structural basis for their binding to the peptide receptors is unknown, since they have no chemical resemblance to the natural peptide ligands. CP-96,345 is a selective, high affinity non-peptide antagonist of the NK1 (substance P) receptor. We constructed a series of chimeric receptors by systematically exchanging segments of the NK3 receptor with homologous segments of the NK3 receptor, which normally does not bind the non-peptide ligand. In this way a domain of the NK1 receptor was localized which was not only necessary but also sufficient for high affinity binding of the non-peptide antagonist as transfer of this domain to the NK3 receptor conveyed CP-96,345 binding activity. By exchanging smaller segments of the NK1 receptor with corresponding NK3 segments, it was found that CP-96,345 binds to two subdomains around the junction between extracellular loop 2 and the top of transmembrane segment V and a small, third domain just outside the top of transmembrane segment VI. The binding of the peptide ligands, substance P and eledoisin, was unaffected by these chimeric exchanges. It is concluded that major epitopes for the binding of CP-96,345 are localized at the top of transmembrane regions V and VI of the NK1 receptor and surprisingly, that these epitopes are not important for the binding of the natural ligand, substance P.

A NOVEL GABA RESPONSE FROM ROD-DRIVEN

HORIZONTAL CELLS OF THE WHITE PERCH RETINA. H. Qian and J. E. Dowling\*. Biol. Lab. Harvard Univ. Cambridge, MA 02138. GABA is the main inhibitory neurotransmitter in the central nervous system. Two classes of GABA receptors (GABA<sub>a</sub> and GABA<sub>b</sub>) have been identified and their responses extensively studied. Here, v report a GABA response from rod-driven horizontal cells (H4) of the white perch retina that does not fit either class.

Whole-cell patch clamp recording techniques were used to monitor GABA-induced membrane currents from solitary rod-driven horizontal cells. When the recording pipette was filled with KCl and the cell held at -70 mV, an inward current of ~100 pA was induced by the application of 100 uM GABA to the cell. The response was characterized by a slow time course of recovery (time constant of 15.9 sec at -50 mV) and it did not desensitize during prolonged (30 sec) exposure to GABA. A membrane conductance increase accompanied the response. The reversal potential followed closely the chloride equilibrium potential when extracellular chloride was replaced by isethionate. This finding, coupled with the fact that the response was blocked by picrotoxin, indicates this GABA response is mediated by the opening of chloride channels. The response could not be elicited with either muscimol or baclofen, and it was not blocked by bicuculline, phaclofen or hydrosaclofen, agents that interact with GABAa or GABAb receptors. However, the response could be evoked in H4 horizontal cells by cis-aminocrotonic acid (CACA), a putative agonist of a third class of GABA receptor, termed GABA<sub>C</sub> receptors (Draw et al., Neurosci. Lett. 52:317, 1984) and observed in oocytes expressing retinal RNA (Polenzani et al., PNAS 88:4318, 1991)

### 175.3

SYNCHRONOUS ACTIVITY INDUCED BY 4-AMINOPYRIDINE (4AP) IN THE HUMAN NEOCORTEX MAINTAINED IN VITRO. M.Avoli\*, D. Mattia, G.G.C. Hwa and A.Siniscalchi. MNI & McGill University, Montreal, QC, Canada

Extracellular and intracellular recordings were made in vitro from slices of human neocortex obtained from patients who underwent surgery for epileptic or non-epileptic conditions. Regardless of the type of pre-existing pathology, perfusion with medium containing the convulsant 4AP (50µM) induced the appearance of spontaneous, mainly negative-going, field potentials that lasted 200-500 ms, occurred at 0.05-0.1 Hz and attained largest amplitude  $800\text{-}1,000~\mu\text{m}$  from the pia. This type of activity persisted in the presence of the excitatory amino acid receptors antagonists CPP and CNOX, but was abolished by the GABA<sub>B</sub> agonist baclofen (50-100 $\mu$ M). 4AP-induced field potentials were associated intracellularly with a sequence of events that depending on the membrane potential could consist of: (ii) initial EPSP; (iii) short-lasting hyperpolarization; (iii) long-lasting depolarization (LLD; 4-30mV; up to 800 ms); and (iv) late, long-lasting hyperpolarization LLH). Perfusion with the excitatory amino acid receptor antagonists CPP and CNQX blocked the early EPSP, but did not modify the other components of the sequence that was thus initiated by a hyperpolarization. LLDs disappeared during perfusion with the  $\mathsf{GABA}_\mathsf{A}$  antagonist bicuculline methiodide (BMI, 5-10 $\mu$ M). In the presence of BMI spontaneous, LLHs (400-600ms) that were presumably due to the activation of post-synaptic GABA<sub>B</sub> receptors still occurred. These results indicate that in the human neocortex: (i) 4AP induces synchronous, spontaneous events that mediated by GABA presumably released from inhibitory interneurons; (ii) this mechanism does not require the participation of excitatory synaptic potentials, but (iii) it is under the control of pre-synaptic GABA<sub>8</sub> receptors.

## 175.5

MODULATION OF SYNAPTIC GABA CURRENTS IN BRAIN SLICES: NON-STATIONARY FLUCTUATION ANALYSIS. Y. De Koninck\*. T.S. Otis and I. Mody. Dept. of Neurology & Neurological Sciences, Stanford Univ. Sch. of Med., Stanford, CA.

Spontaneous inhibitory postsynaptic currents (sIPSCs) were recorded using whole-cell patch clamp techniques in dentate gyrus granule cells of 400 µm thick hemisected coronal adult rat brain slices maintained at 34-35°C. The recordings were made in the presence or absence of 1 µM tetrodotoxin with fast glutamatergic transmission blocked by CNQX and D-AP5. Our previous studies have shown that such sIPSCs are solely generated by activation of GABAA receptors, and are modulated by temperature, barbiturates, benzodiazepines and intracellular  $Ca^{2+}$  concentration ( $[Ca^{2+}]_i$ ). We have now examined the kinetics of the subsynaptic receptor/channels based on a non-stationary fluctuation analysis

method (Robinson et al., Biophys. J., 59: 290, 1991).

Under control conditions (V<sub>b</sub> = -60 to -80 mV) the average monoexponential decay time constant (t<sub>D</sub>) of sIPSCs was 4.9 ms and the corresponding mean open time of the constant  $(t_D)$  of sirses was 4.9 ms and the corresponding mean open time of the channels  $(t_{open})$  was 1.4 ms. At room temperature (22-23°C),  $t_D$  was 22.9 ms while  $t_{open}$  was 2.6 ms. Modulation of sIPSCs decay kinetics by Napentobarbital (PB) and by increases in  $[Ca^{2+}]_i$  was investigated at 34-35°C. PB (50  $\mu$ M) increased  $t_D$  to 24.3 ms and  $t_{open}$  to 2.6 ms. During recordings with  $Ca^{2+}$ -filled (1-10  $\mu$ M) buffered or 20-50  $\mu$ M unbuffered) patch electrodes,  $t_D$  and t<sub>open</sub> progressively (30 min) increased to 9.5 ms and 2.0 ms respectively without accompanying changes in sIPSC rise time or amplitude. In addition, a nonationary fluctuation analysis was performed on isolated stimulus-evoked

GABA<sub>B</sub> receptor mediated responses.

TWO GABAA SYNAPTIC RESPONSES IN THE RAT HIPPOCAMPUS. R.A.

TWO GABA<sub>A</sub> SYNAPTIC RESPONSES IN THE RAT HIPPOCAMPUS. R.A. Pearce. Departments of Anesthesiology and Anatomy, University of Wisconsin, Madison, WI 53706.

Molecular biological and biochemical studies have shown that multiple GABA<sub>A</sub> subtypes exist, but corresponding physiological differences in synaptically evoked currents have not been described. Here, two anatomically segregated GABA<sub>A</sub> subtypes exist, but corresponding physiological differences in synaptically evoked currents have not been described. Here, two anatomically segregated GABA<sub>A</sub> synaptic responses in rat hippocampal CA1 neurons are described that have distinct physiological, pharmacological, and functional properties.

Monosynaptic GABA<sub>A</sub> IPSCs in hippocampal CA1 cells in vitro were recorded with single electrode voltage clamp using standard sharp electrodes filled with CsAc or CsCl and QX-314 (50 μM) to block the GABA<sub>A</sub> phase of the evoked response. APV (40 μM) and CNQX (20 μM) were added the perfusion medium to block excitatory synaptic transmission. The decay phase of the IPSC in response to stratum radiatum stimulation was best fit by the sum of two exponentials with time constants 3-8 ms and 30-70 ms, and both components were blocked by bicuculline (10 μM). The relative amplitudes of the fast and slow current decay components (GABA<sub>A, fast</sub> and GABA<sub>A, slow</sub>) depended on stimulus location: stimulation near or directly on stratum pyramidale evoked GABA<sub>A, fast</sub>, whereas stimulation of stratum laculnosum-moleculare evoked GABA<sub>A, slow</sub>. Reversal potentials of the two components were the same with CsAc electrodes. With CsCl electrodes GABA<sub>A, slow</sub> was shifted by a smaller amount than GABA<sub>A, fast</sub>, suggesting that it enters at a more distal edentric location. Furosemide (600 μM) selectively and reversibly blocked GABA<sub>A, fast</sub> with furosemide resulted in an enhanced EPSP and multiple action potentials in intracellular current clamp recordings, and double population spikes in extracellular recordings. However, the early IPSP remained, and

PROPERTIES OF SYNAPTICALLY ACTIVATED, WHOLE-CELL GABAR CURRENTS. T.S. Otis\*, Y. De Koninck, and I. Mody, Dept. of Neurology & Neurol, Sciences, Stanford Univ. Sch. of Med., Stanford, CA.

Monosynaptically evoked GABA<sub>B</sub> currents were recorded in the presence of 10 μM CNQX, 40 μM D-AP5, and 75 μM picrotoxin with wholecell voltage clamp techniques in dentate gyrus granule cells of 400  $\mu$ m thick, coronal, adult rat brain slices maintained at 34-35°C. Molecular layer coronal, adult rail shoes maintained at  $S_{-}$  50. Molecular layer stimulation evoked slow outward currents (at  $V_h \approx RMP$ ) sensitive to the GABA<sub>B</sub> antagonist CGP 35348 (200-800  $\mu$ M). The conductance was also blocked by 2-OH-saclofen, intracellular Cs<sup>+</sup> or QX-314. Peak GABA<sub>B</sub> current was linearly related to V<sub>h</sub> in the range from -110 mV to -49 mV, and reversed at -97.9 mV with a mean slope conductance of 1.52 nS. The kinetics of the current could be fit by the product of fourth power exponential activation and double exponential inactivation processes. The mean activation time constant was 45.2 ms, while the mean inactivation time constants were 110.2 ms and 516.2 ms. The kinetics were not voltage dependent (Vh: -45 mV to -95 mV), and  $Q_{10}$  values ranged from 1.8 to 2.3.

Paired pulse depression (PPD) of the GABA<sub>B</sub> current was similar in time course and magnitude to the PPD of the GABAA current. The time course of the PPD differed from that of the postsynaptic GABAB current. The PPD was not voltage dependent, nor were the kinetics of a test current altered by a preceeding conditioning current. Similarly, partial (50%) blockade of the current by CGP 35348 had no effect on the kinetics. These results are consistent with the hypothesis that PPD results from a presynaptic mechanism, which must be different from the postsynaptic GABA<sub>B</sub> conductance. ZINC INDUCES SPONTANEOUS BURSTING OF INHIBITORY NEURONS IN RAT NEOCORTEX. J.J. Hablitz\* and F.M. ZHOU. Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, AL 35294.

Zinc is a negative modulator of NMDA and GABA receptors in cultured neurons. We have examined the effect of zinc on synaptic potentials in rat neocortical slices. Intracellular recordings were obtained from layer II-III pyramidal neurons. At RMP, weak stimulation produced EPSPs while stronger stimulation produced EPSP-IPSP complexes. IPSPs were depolarizing since RMPs were > -80 mV. Bath application of 50-300  $\mu$ M zinc did not affect weak EPSPs nor I-V relations. IPSPs were enhanced in amplitude and duration while responses to iontophoretically applied GABA were not affected by zinc. When EPSPs were blocked by excitatory amino acid (EAA) receptor antagonists, directly evoked IPSPs were enhanced by zinc and giant GABA, and GABA, mediated IPSPs occurred spontaneously. Giant depolarizing GABA, mediated events could trigger action potentials in some neurons. Picrotoxin (100 µM) greatly reduced or blocked the depolarizing events. All effects of zinc were reversible upon washing. These results demonstrate that zinc has a novel effect in neocortical neurons, namely, an enhancement of GABA-mediated synaptic responses. The occurrence of spontaneous giant IPSPs in the presence of EAA blockers suggests that GABAergic neurons can be synchronized by a non-EAA mechanism. (NS18145)

FUNCTIONAL AND PHARMACOLOGICAL PROPERTIES OF  $\alpha_1\beta_2\gamma_2$  AND  $\alpha_3\beta_2\gamma_2$  ISOFORMS OF THE RAT GABA, RECEPTOR. P. Avenet, P. Granger, C. Faure-Halley, D. Graham, S. Arbilla, H. Depoortere B. Scatton and S.Z. Langer. Dept. of Biology, Synthélabo Recherche (L.E.R.S), 31 Ave. P.V-Couturier, 92220 Bagneux, France.

Recombinant  $\alpha_1\beta_2\gamma_2$  (R- $\alpha_1$ ) and  $\alpha_5\beta_2\gamma_2$  (R- $\alpha_5$ ) forms of the GABA receptor were expressed in human embryonic 293 kidney cells by transfection with GABA, subunit cDNAs and investigated using the whole cell configuration of the patch-clamp technique. At a holding potential of -20 mV, fast superfusion with GABA (1-300 μM) elicited CI currents in 44 out of 89 R- $\alpha_1$  cells (mean intensity 125 pA, GABA 1  $\mu$ M, n=13) and in 41 out of 92 R- $\alpha_3$  cells (mean intensity 70 pA, GABA 1 µM, n=13). The GABA concentration dependency for both recombinant receptors was similar (K<sub>D</sub>=3 μM). Both receptor types slowly desensitized with 1-10 µM GABA and showed a faster desensitization with 100-300 µM GABA which could be resolved into two exponential components. In 40% of the R- $\alpha_1$  cells and 41% of the  $R\text{-}\alpha_{5}$  cells, diazepam and zopiclone (1  $\mu\text{M})$  potentiated the GABA (1 μM) induced current by a factor ranging between 1.2 and 2.6. Zolpidem (1 μM) increased the Cl current to a similar extent in R-α, recombinants but had no effect in R- $\alpha_5$  cells. Thus, although R- $\alpha_1$  and R-α<sub>5</sub> receptors exhibit similar functional properties, zolpidem, unlike diazepam and zopiclone, does not interact with GABA, receptors containing the  $\alpha_5$  subunit.

## 175.9

PROTRACTED DIAZEPAM TREATEMENT INDUCES A DOWN REGULATION OF GABA<sub>A</sub> RECEPTOR FUNCTION. P. GIUSTI\*, N. ASTI<sup>§</sup>, M.M. ZANELLATO<sup>§</sup> and R. ARBAN<sup>§</sup>. Department of Pharmacology, University of Padova, 35131 Padova, <sup>§</sup>FIDIA Research Laboratories, 35031 Abano Terme (PD), Italy.

GABAA receptor down regulation was assayed in rats undergoing a chronic treatment with diazepam. Changes were measured in the anticonvulsant action of this benzodiazepine (BZ) against a slow intravenous infusion of bicuculline (0.11  $\mu$ mol/min), or the  $\beta$ -carboline ester  $\beta$ -CCM (0.28  $\mu$ mol/min) to assess the functional state of GABA binding site and the coupling between the BZ modulatory sites with the GABA binding sites, respectively. Animals receiving protracted doses of diazepam (8.75, 17.5, 35, and 88  $\mu$ mol/kg; 3 time day, p.o.) showed increased sensitivity to the convulsant actions of bicuculline and  $\beta$ -CCM when compared to naive animals receiving the same doses of diazepam. Tolerance to the anticonvulsant effect of diazepam against bicuculline and  $\beta$ -CCM-induced seizures occured after 68, 35, 9, and 4 days, respectively in animals repeatedly treated with 8.75, 17.5, 35, and 88  $\mu$ mol/kg. The Kd and the Bmax values for diazepam in vivo binding in the forebrain and the drug plasma levels (measured by HPLC) did not differ between control and treated animals.

The results are consistent with the hypothesis that chronic diazepam treatment may be accompained by an alteration in the molecular mechanisms underlying sentivity of the GABAA receptor complex to GABA and BZs.

CHARACTERIZATION AND FUNCTIONAL EXPRESSION OF THE PROMOTER FOR THE HUMAN  $\beta_1^1$  SUBUNIT OF THE GABAA RECEPTOR, <u>S.I. Russek and D.H. Farb.</u> Department of Pharmacology and Experimental Therapeutics, Boston University School of Medicine, Boston, MA 02118.

The remarkable heterogeneity and ubiquitous distribution of the GABAA receptor in the central nervous system distinguishes it as part of an important neurotransmitter system that is amenable to the study of receptor function and regulation. Genes coding for the subunits of the GABAA receptor are differentially expressed in the CNS. A number of the GABAA receptor genes display a preferential expression in only one region of the brain, while expression in other brain regions is barely detectable (Wisden et al., (1992) J. Neurosci. 12: 1040). In particular, the highest expression of the β1 gene is seen in the hippocampus, making it a prime candidate for the study of region specific gene regulation. Using a novel form of the polymerase chain reaction (PCR), we have isolated a 600 bp region upstream to the 5' end of the reported full length human β1 cDNA (Schoffeld et al., (1987) Nature 328: 221). This PCR product was cloned into a reporter vector that contains the gene for firefly luciferase. Transfection of the reporter construct into primary cell cultures of embryonic chick brain demonstrates that there is a functional promoter in the 600 bp PCR product. We have identified several possible regulatory elements that may be necessary for the expression of the β1 gene in the vertebrate nervous system.

## 175.10

FULL AND PARTIAL MODULATION OF NEUROSTEROIDS ON GABA ACTION IN NATIVE AND RECOMBINANT GABAA RECEPTORS. G. Puia. I.Ducic, S. Vicini\* and E. Costa. FGIN, Georgetown University, Washington, DC.

Certain naturally occurring steroids (neurosteroids) have been found to modulate GABAA receptor function. In previous studies, we have shown that the neurosteroids 3α-OH-DHP (5α-pregnan-3-α-ol-20-one) and THDOC (5α-pregnan-3-α-21-diol-20-one) potentiate GABA-activated Cl currents elicited on native or recombinant heterooligomeric ( $\alpha\beta$ ,  $\alpha\beta\gamma$ ) as well as homomeric ( $\beta$ ) GABAA receptors. Using the patch-clamp technique, we describe the modulation by 3a-OH-DHP and pregnenolone sulfate (PS) of GABA anionic current in cells expressing recombinant GABA $_{\lambda}$  receptors including different molecular forms of  $\alpha$  $(\alpha 1 \text{ through } \alpha 6) \text{ and } \gamma \, (\gamma 1 \text{ through } \gamma 3) \text{ subunits. With our experimental conditions}$ we fail to show important differences in neurosteroid efficacy and potency in relation with the structural GABAA receptor differences. Furthermore,  $3\alpha\text{-OH-DHP}$ and 3β-OH-DHP compete in modulating GABA- activated Cl currents both in native and in  $\alpha 1\beta 1\gamma 2$  GABAx receptors . Moreover the activity of  $3\alpha\text{-OH-DHP}$  and diazepam, barbiturate and PS summates algebrically. Since the modulation by PS and 3α-OH-DHP are independent of each other, we suggest that the "putative" sites for the allosteric positive and negative modulation of GABA action by the two compounds may be different. Interestingly in cortical neurons and reconstituted  $\alpha 1\beta 1\gamma 2$  receptors PS has a biphasic modulatory action ; i.e. at  $1\mu M$  decreases by 43± 10 % while at 10 nM potentiated by 35 ± 5 % (mean ± SE, n=5 cells) GABA-activated Cl currents. Evidence for differential binding characteristics of neurosteroids in frontal cortex and spinal cord (Gee and Lan, Mol. Pharm. 1991 40:995) prompted us to further investigate and to describe the modulation by neurosteroids of GABA-activated Cl currents in outside-out macro-patches excised from diverse brain regions.

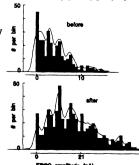

## LONG-TERM POTENTIATION I

## 176.1

INCREASED PRE- AND POSTSYNAPTIC QUANTAL MEASURES DURING LTP IN CA1 HIPPOCAMPUS. R. Malinow. A. Jones and D. Liao. Dept Physiology and Biophysics, University of Iowa, and Dept Mathematics, Reed College.

The modification responsible for long-term synaptic potentiation is not known. To elucidate possible changes we have resolved quantal levels of transmission before and after induction of LTP. LTP was induced by pairing presynaptic

activity (with no change in stimulus frequency) and postsynaptic depolarization. The potentiated transmission could be completely blocked with APV (n=10). After induction of LTP, we find an increase in both quantal content and quantal amplitude, consistent with combined pre- and postsynaptic modifications. On average, 61% of LTP can be accounted by presynaptic enhancement. The increase in either quantal amplitude or quantal content varies significantly among different experiments, but is inversely correlated with its initial value. These results may help to reconcile the different views concerning the site of LTP expression.

Amplitude distributions before and during LTP. Note amplitude axis change.

## 176.2

ALTERED RESPONSES TO PRESYNAPTIC MANEUVERS DURING LONG-TERM POTENTIATION OF MINIATURE EPSC FREQUENCY IN CULTURED HIPPOCAMPAL NEURONS. A. Malgaroli & R. W. Tsien, Department of Molecular and Cellular Physiology, Stanford CA 94305.

Recordings of miniature excitatory postsynaptic currents (minis) were made from hippocampal cells in culture to gain new information about presynaptic changes during the expression of LTP. LTP of mini frequency was induced by direct application of glutamate or hypertonic solution (0 Mg<sup>2+</sup>) (Malgaroli & Tsien, Nature in press). Like the amplitude of evoked responses, the frequency of minis was strongly increased. The rise in mini frequency (TTX present) was induced by activation of postsynaptic NMDA receptors and persisted up to the end of the recording. The potentiation was not abolished by removal of externa  $Ca^{2+}$ , indicating that it cannot be avalained by indicating that it cannot be explained by a sustained elevation of Ca2 entry. We wondered whether the synaptic enhancement might result from increased efficiency of other steps in neurosecretion, such as those controlling vesicle availability or vesicle fusion. To gain insights into the nature of the presynaptic change, we monitored quantal vesicular release induced by variations in the tonicity of the bathing medium, a classical presynaptic intervention. Before potentiation, brief challenges with hypertonic solutions (500-600 mosm)increased mini frequency 50-100-fold above basal levels; hypotonic media (250 mosm) produced only a mild decrease. During mini frequency potentiation, the fold response to hypertonicity was much reduced while the fold response to hypotonic media was accentuated. Thus, the top of the dose-response curve is little changed. while the foot of the tonicity dose-response curve appears to be shifted toward lower values. The fact that hypertonicity occludes the mini frequency potentiation indicates that both interventions act along the same presynaptic secretory pathway. A possible explanation of the shift in the tonicity dose-response curve would be an increase in the sensitivity of the secretory machinery to [Ca2+]i

# Approaches to Quantal Analysis at the CA3-CA1 Synapse in Rat Hippocampal Slices

Felix E. Schweizer\*, Julie A. Kauer, David D. Friel, Richard W. Tsien. Stanford University Medical Center, Stanford, CA 94305

We tried to apply the methods of quantal analysis (QA) to study long-term potentiation (LTP) at the CA3-CA1 synapse in the rat hippocampus. To this goal we constructed amplitude distribution histograms of EPSCs recorded with whole cell voltage clamp from CA1 pyramidal cells. For a majority of experiments there was at least one epoch containing 100-1000 EPSCs from which histograms exhibiting equally spaced peaks could be constructed. Inclusion of more events in the histograms made the peaks less pronounced or let them disappear altogether. We broke the experiment apart into consecutive independent epochs and tried to evaluate whether the peaks reflect sampling artifacts or whether they reflect quantal behavior of the synapse(s). To test for equally spaced, quantal peaks we measured the maximal power in the Fourier spectrum of either mean-subtracted histograms or of the crosscorrelation between two halves of the dataset. To determine the statistical significance of peaks in the entire experiment, we carried out Monte Carlo simulations. Samples taken from either smooth or peaky, simulated distributions were taken, histograms constructed and the respective scores determined. The distribution of scores from simulated peaky and smooth simulations showed considerable overlap, indicating that sampling artifacts can introduce spurious peaks into smooth datasets and smooth out peaks in genuinely peaky datasets. Experiments in which peaks are statistically significant will yield information about quantal size, quantal content and the statistic of release.

# A NOVEL ACTION OF ENDOGENOUS OPIOIDS IN THE INDUCTION OF HIPPOCAMPAL MOSSY FIBER LTP.

S.H. William \* & D. Johnston, Division of Neuroscience, Baylor Colllege of Medicine, Houston, Tx 77030.

The mossy fiber system of the rat hippocampus contains a high concentration of both dynorphin and enkephalin. Previous studies have suggested these peptides are important for mossy fiber LTP induction, possibly acting by producing disinhibition during high frequency stimulation (HFS). We have tested this hypothesis in the hippocampal slice preparation.

Intracellular recordings were made from CA3 neurons at 32–34°C. GABAA inhibitory synapses were blocked by 10  $\mu\rm M$  bicuculine and picrotoxin. The NMDA antagonist APV was routinely added to the saline. The percentage change in EPSP or EPSC amplitude was determined by comparing pretetanus values to 15 min post-tetanus. In control slices LTP was elicited in 12/15 experiments. In contrast if  $1\,\mu\rm M$  naloxone (NAL) was added prior to HFS, LTP was obtained in only 2/9 experiments. The mean increase in EPSP amplitude in control was 75±18%, compared to the a small decrease of 13±4% in the NAL group. If slices were given HFS prior to NAL perfusion, LTP was not affected, indicating that the action of naloxone is specific to the induction step of LTP. NAL did not affect LTP induction in the commissural/associational input to CA3 (n = 4, no APV present). These data suggest that endogenous opioids are important modulators of induction of mossy fiber LTP. The mechanism of action of opioid peptides, however, appears to be independent of GABAA-type inhibition, counter to previous proposals. These data suggest that the opioids released from mossy fiber terminals can act via a previously unsuspected and extremely novel mechanism. (MH44754, NS11535.)

## 176.7

INCREASE IN POSTSYNAPTIC NON-NMDA RECEPTOR SENSITIVITY INDUCED BY NMDA IN HIPPOCAMPAL SLICES.

T. Manabe and R.A. Nicoll' Depts. Pharmacol. and Physiol., UCSF, San Francisco, CA 94143.

NMDA application enhances excitatory synaptic transmission in the CA1 region of the hippocampus. Although this enhancement is generally transient, recent reports indicate that it is closely related to long-term potentiation (LTP). We have shown that during NMDA-induced potentiation an increase in the size of miniature EPSCs (mEPSCs) occurs, which correlates with the change in the size of evoked responses. Furthermore, the NMDA-induced enhancement of mEPSC size shares two key properties with LTP: it requires postsynaptic depolarization and a rise in the concentration of postsynaptic calcium.

An increase in mEPSC size is usually interpreted as resulting from an increase in postsynaptic transmitter sensitivity. However, it could also be explained by an increase in the amount of transmitter in presynaptic vesicles. To address this issue we repeatedly applied AMPA, a selective non-NMDA receptor agonist, to the dendritic region of CA1 pyramidal cells in guinea pig hippocampal slices before and after NMDA application. The response to AMPA, monitored by whole-cell voltage clamping, showed a significant increase during NMDA-induced potentiation of mEPSC size. Thus, it is concluded that NMDA-induced potentiation in hippocampal slices is mediated, at least in part, by an increase in postsynaptic sensitivity. The results also suggest that LTP, during which mEPSCs increase in size, is expressed, in part, by a similar mechanism.

#### 176 A

CHANGES IN PAIRED-PULSE FACILITATION (PPF) SUGGEST PRESYNAPTIC INVOLVEMENT IN THE EXPRESSION OF LTP IN HIPPOCAMPAL AREA CAI. P.E. Schulz & D. Johnston, Dept. of Neurology & Div. of Neuroscience Baylor Col. of Med. Houston, Ty 77030

Neurology & Div. of Neuroscience, Baylor Col. of Med., Houston, Tx 77030.

Despite intensive investigation, there is still disagreement as to the locus of change underlying LTP expression. It has been hypothesized that if LTP expression includes a presynaptic locus, then changes should be observed in other forms of presynaptic potentiation. PPF is a potentiation of a second population excitatory postsynaptic potential (pEPSP) when it follows shortly after a first and is thought to be mediated presynaptically by residual calcium. Thus, if LTP expression includes a presynaptic locus, then PPF may be partially occluded by LTP. Extracellular recordings were made in rat hippocampus area CA1, in  $375\mu m$  thick slices, with picrotoxin and 3.0 or 4.5mM [Ca<sup>2+</sup>]<sub>e</sub> in the bath. Increased extracellular calcium and post-tetanic potentiation (PTP) are thought to increase pEPSPs via a presynaptic mechanism. It was confirmed that both forms of potentiation decreased PPF indicating that PPF expression is sensitive to changes in transmitter release. Slices were repeatedly tetanized until LTP was saturated at a single stimulus intensity that initially yielded a 1.3mV pEPSP. PPF was compared between baseline and after LTP saturation LTP saturation was associated with a decrease in PPF. The decrease in PPF associated with LTP was additive with the decrease associated with increased  $[\mathrm{Ca^{2+}}]_{e}$  and PTP. Once LTP was saturated, further tetani were not associated with additional changes in PPF suggesting that the PPF changes were related to LTP. PPF at baseline, and the change in PPF between baseline and saturation, did not correlate with the magnitude of LTP expressed. We conclude that the mechanism of LTP expression includes at least a presynaptic locus, but these results do not exclude possible additional postsynaptic mechanisms. #### 176.6

A PHYSIOLOGICAL ROLE FOR DYNORPHIN AT MOSSY FIBER SYNAPSES IN THE HIPPOCAMPUS. M. G. Weisskopf\*, R. A. Zalutsky and R. A. Nicoll Depts. Pharmacol. and Physiol., UCSF, San Francisco, CA 94143-0450.

In the hippocampal slice preparation tetanic stimulation delivered in s. granulosum of the dentate gyrus produces robust long-term potentiation (LTP) of synaptic transmission at the mossy fiber-CA3 synapse. Such stimulation also produces a transient depression, lasting 10-20 minutes, in a second, separate set of mossy fiber-CA3 synapses.

We have used field potential recording of mossy fiber synaptic action in the CA3 region to elucidate the mechanism of this heterosynaptic depression. Dynorphin A, the most abundant opioid peptide in mossy fibers, when applied exogenously (100 - 500 nM), reduced mossy fiber synaptic responses, but had no effect on the responses evoked by commissural/associational afferents. The dynorphin-induced depression is likely to result, at least in part, from a presynaptic action, since the depression is associated with an increase in paired-pulse facilitation. In addition, dynorphin had no effect on the excitability of CA3 pyramidal cells recorded intracellularly. Finally, the tetanus-induced heterosynaptic depression was blocked by naloxone, indicating that this effect is largely mediated by a synaptically released endogenous opioid peptide.

In summary, high frequency stimulation of mossy fibers releases, in addition to glutamate, an opioid peptide, most likely dynorphin, which diffuses to neighboring mossy fiber synapses and inhibits the release of glutamate. Such an action would provide a transient inhibition surrounding the potentiated pathway.

## 176.8

EFFECTS OF PRESYNAPTIC MODULATION OF SYNAPTIC TRANSMISSION AND LTP ON DUAL-COMPONENT EXCITATORY SYNAPTIC CURRENTS IN THE HIPPOCAMPUS. D. J. Perkel\* and R. A. Nicoll Depts. Pharmacol. and Physiol., UCSF, San Francisco, CA 94143.

NMDA and non-NMDA ionotropic glutamate receptors are thought to be colocalized at postsynaptic sites. A postsynaptic modification, or a change in transmitter concentration in the synaptic cleft could change the relative receptor contributions to synaptic events, since the two receptor types have very different sensitivities to glutamate. It is not known whether changes in release probability affect cleft transmitter concentration, and controversy exists over the effects of LTP on the two receptor components of synaptic events. We have used "blind" whole-cell recording from guinea pig CA1 pyramidal cells in slices to examine the effect of presynaptic manipulations or of LTP on Schaffer collateral synaptic currents. Postsynaptic neurons were held at +30 mV to allow simultaneous measurement of the two components and to reduce space-clamp artifacts.

Reduction of synaptic currents by 4-fold by baclofen (10  $\mu$ M), or similar enhancement by theophylline (50-100  $\mu$ M) led to parallel changes in late (NMDA) and early (non-NMDA) components. LTP was induced by pairing synaptic stimuli with depolarization to +30 mV. In cells that showed LTP (as measured upon return to +80 mV), there was a marked increase in the ratio of non-NMDA to NMDA receptor contribution. In cells not showing LTP, a small parallel increase (25%) in both components was seen, similar to the growth of the NMDA component in cells showing LTP, likely due to frequency facilitation caused by starting stimulation.

Our data suggest that pharmacological modulation of release is all-ornone at individual synaptic clefts. In contrast, LTP could result from a postsynaptic change or a change in cleft transmitter concentration.

NMDA RECEPTOR-INDEPENDENT POTENTIATION OF SYNAPTIC TRANSMISSION IN HIPPOCAMPAL CA1 CELLS. <u>D.M. Kullmann, T.</u> Manabe, D.J. Perkel, S. du Lac\* & R.A. Nicoll. Depts. Pharmacol. & Physiol., UCSF, San Francisco, CA 94143.

Calcium influx via NMDA receptor gated channels is necessary for the induction of long-term potentiation (LTP). To assess whether a rise in postsynaptic calcium is *sufficient*, we have attempted to maximize calcium influx into CA1 cells via voltage-sensitive calcium channels, in the presence of 50 mM D-2-amino-5-phosphonovaleric acid (D-APV) to block NMDA receptors. Using either conventional intracellular recording or whole-cell patch-clamping *in vitro*, a transient potentiation of excitatory transmission from stratum radiatum stimulation was obtained by delivering repeated depolarizing pulses to the postsynaptic cell. This potentiation typically decayed to baseline within 30 minutes and did not require presynaptic stimulation during the voltage steps. It was, however, greatly enhanced by raising the extracellular calcium concentration from 2.5 to 4 - 5 mM, or by including an ATP regenerating system in the patch-pipette solution: a 2 - 3 fold potentiation of transmission was reliably obtained, but this still decayed with a similar time course. The potentiation was completely abolished by including the calcium chelator BAPTA in the pipette solution, or by adding 20 mM nitedipine to the perfusion medium, confirming that a rise in intracellular calcium was necessary. If D-APV was omitted from the extracellular solution. and LTP was elicited by pairing presynaptic stimulation with postsynaptic depolarization, this did not reduce the amplitude of the transient potentiation produced by depolarizing pulses delivered after a delay of 20 minutes.

Calcium influx via dihydropyridine-sensitive channels can lead to a potentiation of transmission, but this differs from LTP in several respects. upported by the NIMH and Human Frontiers Science Program Organization

## 176.11

THE TIME COURSE OF INCREASED POSTSYNAPTIC CALCIUM NECESSARY FOR LTP REVEALED BY PHOTOSENSITIVE CALCIUM CHELATORS. B. Lancaster\*, R.S. Zucker & R.C. Malenka#. Dept. of Molec. & Cell Biology, U.C. Berkeley, CA 94720 and # Depts. of Psychiatry and Physiology, U.C. San Francisco, CA 94143.

Experiments were performed to quantify the temporal limits of the rise in postsynaptic Ca<sup>2+</sup> which is required for LTP induction. This was achieved by manipulation of the timing between the LTP-inducing tetanus and an instantaneous increase in Ca<sup>2+</sup> buffering capacity produced by rapid, flash photolysis of the photolabile chelator diazo-4 (Adams et.al., J. Am. Chem. Soc. 111:7957)

In hippocampal area CA1 two independent pathways were stimulated and simultaneous recordings were made of field epsps and intracellular epsps using the whole cell configuration (Cs gluconate based solution, pipette tips filled with 1.0-2.5 mM diazo-4). Photolysis was induced with a xenon arc flashlamp. If a tetanus (1 sec, 100-200 Hz) to the control path produced LTP, a tetanus was given to the test path within 2 minutes. Photolysis of diazo-4 after the control tetanus prevented induction of LTP by the test pathway in the same cell (n=16) whereas field epsps showed LTP. The minimum delay for photolysis which did not affect LTP induction was 2.5 secs from the start of the tetanus. Photolysis immediately at the end of a tetanus blocked LTP (n=5). Intermediate (1.0-2.0 secs) delays gave mixed results including a decrementing, short term potentiation. The results indicate that a tetanus-induced rise in postsynaptic Ca<sup>2+</sup> lasting 2.0-2.5 secs is sufficient to generate LTP.

We thank Drs. S. Adams and R. Tsien for providing diazo-4. Supported by NS15114 to RSZ and MH45334, MH00942 to RCM.

EXAMINATION OF TEA-INDUCED SYNAPTIC ENHANCEMENT REVEALS THE ROLE OF Ca<sup>2+</sup> CHANNELS IN THE INDUCTION OF LTP IN AREA CA1 OF RAT HIPPOCAMPUS. Y.-Y. Huang and R.C. Malenka. Depts. of Psychiatry & Physiology, U.C. San Francisco, CA 94143.

The role of voltage-dependent Ca<sup>2+</sup> channels (VDCCs) in the induction of LTP in area CA1 of rat hippocampal slices was determined by examining the relationship between the synaptic enhancement induced by application of tetraethylammonium (TEA; 25 mM) and tetanus-induced LTP. As previously reported (Aniksztejn & Ben-Ari, Nature, 349:67), the TEA-induced synaptic enhancement (TEA-SE) was unaffected by blockade of NMDA receptors with D-APV (25-50 μM). It was blocked by the VDCC antagonist nifedipine (10-12 μM) or by intracellular injection of the Ca<sup>2+</sup> chelator BAPTA and could be mimicked by direct activation of VDCCs with repetitive depolarizing current pulses (Perkel et al., Soc. Neurosci. Abst. 17:2). Nifedipine had no effect on tetanus-induced (100 Hz, 1 sec), NMDA receptor-dependent LTP.

Saturation of LTP with repetitive tetani reduced the magnitude of TEA-SE (by

Saturation of LTP with repetitive tetani reduced the magnitude of TEA-SE (by 55%; n=9). Similarly, increasing synaptic transmission by applying TEA reduced the magnitude of subsequent tetanus-induced LTP (by 61%; n=7). Like LTP, the TEA-SE did not significantly affect paired-pulse facilitation (ISI=50 msec).

TEA-SE did not significantly affect paired-pulse facilitation (ISI = 50 msec). These results suggest that dihydropyridine sensitive VDCCs do not normally contribute to the induction of LTP even though their repetitive activation can result in an increase in synaptic strength. The mutual occlusion of TEA-SE and LTP suggest that they either share a common expression mechanism or activate a common intracellular process. One hypothesis to explain these results is that VDCCs are absent from dendritic spines and do not contribute significantly to the rise in Ca<sup>2+</sup> required for LTP induction. However, repetitive activation of VDCCs may cause a large rise in Ca<sup>2+</sup> that overcomes endogenous buffering mechanisms and editing represents within the spine. The lack of computer coefusion of some and activates processes within the spine. The lack of complete occlusion of one form of synaptic enhancement by the other raises the possibility that there may also be some mechanistic differences between TEA-SE and LTP.

DENDRITIC Ca2+ ACCUMULATIONS ACCOMPANYING TEA-INDUCED LTP IN HIPPOCAMPAL CA1 NEURONS IN BRAIN SLICE. J.J. Petrozzino\*. S.-C. Sun. and J.A. Connor. Roche Institute of Molecular Biology,

Roche Research Center, Nutley, NJ 07110.

Brief exposure of hippocampal slices to tetraethylammonium (TEA) induces  $\text{Ca}^{2+}$ -dependent, NMDA receptor-independent LTP (LTPK) of synaptic transmission (Aniksztejn & Ben-Ari, Nature 349:67-69, 1991). We combined microfluorometric fura-2 imaging of guinea pig hippocampal CA1 pyramidal cells with intracellular and field recordings to evaluate the spatio-temporal distribution of postsynaptic Ca<sup>2+</sup> during LTP<sub>K</sub>. Test stimuli were applied at 0.05 Hz to stratum radiatum in the presence of 100 μM D,L APV at both 23 and 35 °C. TEA (15-25 mM, 10 min) produced increases in the initial slope of both the field and intracellular EPSP (EPSP $_{\rm f}$  and EPSP $_{\rm i}$ , respectively) measuring 183±12% (EPSP<sub>f</sub>; mean±SEM, n=8) and 250±35% (EPSP<sub>f</sub>; n=5) of control. LTP<sub>K</sub> was followed for 30-120 min (EPSP<sub>f</sub>) and 30-80 min (EPSPi) after TEA washout. During TEA exposure cell firing was intense, and dendritic and somatic Ca2+ levels were transiently elevated to 1-5  $\mu$ M from resting levels of <100nM (8/10 cells tested). In 6 of these 8 cells, Ca<sup>2+</sup> returned to near basal levels within 2-20 min of TEA washout. Application of TEA in APV-free saline produced LTP of similar amplitude and duration, but more sustained Ca2+ elevations were observed. These results establish that large, transient postsynaptic  $Ca^{2+}$  accumulations accompany LTP<sub>K</sub> in hippocampal CA1 pyramidal cells, and support a role for postsynaptic Ca2+ in the induction of LTPK

## BRAIN METABOLISM AND BLOOD FLOW II

PROTEIN KINASE C (PKC) AND CEREBRAL VASODILATORY RESPONSES IN THE STREPTOZOTOCIN (STZ)-TREATED RAT. D.A. Pelligrino\* and A. Sharp. Dept. of Anesthesiology, Univ. of Illinois-Chicago, Chicago, IL 60616

Previous work indicated a selective impairment of cerebral vasodilatory respon-

in chronically hyperglycemic, diabetic (CHD) rats. This suppression appears to include 2 separate receptor-mediated vascular relaxation processes: 1) endothelium-derived nitric oxide (NO) release (e.g., mediated by muscarinic or purinergic-P<sub>2</sub> receptors) and 2) an NO-independent mechanism, mediated by the β-adrenergic receptor (β-AR). In this study, we tested the hypothesis that chronic hyperglycemiainduced PKC activation can account for the suppression in both 1 and 2. Male S-D rats were prepared and studied under fentanyl/ $N_2O$  anesthesia, paralysis, and mechanical ventilation. The reactivity of pial arterioles (40-60  $\mu$ m in diameter), observed through a closed cranial window, was assessed using intravital micros py/videometry. Vessel diameters were measured with a video micrometer, in CHD (5 mo. post-STZ) vs non-diabetic (ND) rats. These measurements were made at the (3) no. post-32 vs non-traoeute (ND) rats. These measurements were made at each of the following periods of cortical suffusions of artificial CSF solutions (37° C; PCO<sub>2</sub>, PO<sub>2</sub>, pH constant; infusion rate = 1 ml/min), with or without added test agents: a) 10 min CSF; b) 10 min sodium nitroprusside (SNP) (10<sup>4</sup> M); c) 10 min acetylcholine (Ach) (10<sup>4</sup> M); d) 10 min CSF; e) 10 min isoproterenol (ISO) (10<sup>4</sup> M); d) 20 min CSF; e) 30 min of the PKC inhibitor staurosporine (STAURO) (10<sup>-7</sup> M); h) repeat be (includes STAURO in CSF). In ND rats, Ach, ISO, and SNP produced increases in arteriolar diameters of 12, 15, and 26%, respectively. In CHD rats, Ach and ISO produced 5% and 1% reductions, respectively, in diameters, but SNP induced a 31% increase. In the presence of STAURO, the Ach and ISO responses were partially restored (Ach = +6%, ISO = +9%) and the SNP response was unaffected (+30%). STAURO produced no changes in Ach or ISO responses in ND rats. These results suggest that PKC activation in CHD rats suppresses receptor-dependent NO release and desensitizes β-ARs.

HYPOTHERMIC CEREBRAL VASODILATION IS MEDIATED BY HYPOTHERMIC CEREBRAL VASODILATION IS MEDIATED BY NITRIC OXIDE (NO). J.W. Kuluz<sup>1</sup>, R. Prado, B. Watson, M Ginsberg, R. Busto, A. Martinez\*, C Schleien¹. Depts Pediatrics¹ and Neurology. Univ of Miami School of Medicine, Miami, FL 33136

We have found that selective brain cooling (SBC) increases CBF in rats to 115±26% above baseline. To test whether this response is mediated by NO, we measured CBF in rats by laserdoppler at baseline. for 30 min after a 15mg/kg

mediated by NO, we measured CBF in rats by laser-doppler at baseline, for 30 min after a 15mg/kg infusion of L-NAME (a potent NO synthase inhibitor), during 20 min of SBC and during 30 min of rewarming (RW) while rectal temp was kept 37-38°C. Mean CBF, MAP and brain temp (BT) for each 5 min period was compared to baseline by ANOVA (\*p<.05). Results: L-NAME increased MAP by 12% and decreased CBF by 25%. During SBC, CBF increased to 98±7% of baseline, or 31% above CBF after infusion of L-NAME. During RW, CBF decreased to baseline.

INHIBITORS OF NITRIC OXIDE SYNTHESIS ATTENUATE THE CEREBROVASODILATION ELICITED BY WITHOUT AFFECTING LOCAL METABOLISM Neurology, Univ. of Minnesota, Minneapolis, MN 55455.

Nitric oxide (NO), is an important neural signal and a potent vasodilator that may regulate the cerebral circulation. We have recently demonstrated that inhibition of NO synthesis substantially attenuates the cerebrovasodilation elicited by hypercapnia, an effect that is stereospecific and reversed by co-application of arginine (PNAS, synthesis substantiary attentiates the exteriovasionation electical by hypercapina, are effect that is stereospecific and reversed by co-application of arginine (PNAS, 89:3913, 1992). In this study we sought to determine whether NO-synthase inhibitors attenuate the cerebral blood flow (CBF) response to hypercapina by decreasing local cerebral glucose utilization (ICGU). Rats were anesthetized (chloralose 80mg/kg) and artificially ventilated. Arterial pressure and blood gases were monitored. The sensory cortex was exposed and superfused with aerated Ringer (pH 7.3-7.4; 37C°) with or without the NO-synthase inhibitor N°-nitro-L-arginine (L-NA). CBF was measured autoradiographically at the site of superfusion using 14-C-iodoantipyrine or 14-C-2-deoxyglucose as tracers, respectively. At normocapnia, CBF was 83±19 ml/100g/min at the site of superfusion and 90±14 in the contralateral cortex (p>0.00.5). L-NA superfusion (1mM) decreased resting local CBF from 83±19 to 55 ml/100g/min (p<0.001; n=5). However, L-NA did not affect resting ICGU (Ringer: 69±8µmoJ/100g/min; L-NA: 81±7; p>0.05). During superfusion with Ringer, hypercapnia (pCO<sub>2</sub>=61±4mmHg) increased CBF bilaterally and symmetrically (+161±30%; n=5; p<0.001 ANOVA). L-NA attenuated the CBF increases elicited by hypercapnia by 87±6% (n=5) while the local cerebrovasoditation elicited by topical papaverine (1mM) (n=5) was unaffected (+213±15; p>0.05 from Ringer). Thus, NO nypercapina by 8720% (n=3) while the local cerebrovasodilation elected by topical papaverine (ImM) (n=5) was unaffected (+2131-15; p=0.05 from Ringer). Thus, NO synthesis is required for maintaining resting CBF and for the cerebrovasodilation elicited by hypercapina. Since NO-synthase inhibition does not affect ICGU, these effects are independent of local metabolic activity. The results add further support to the hypothesis that arginine-derived NO is also involved in the regulation of the circulation of the brain. PRESERVATION OF CEREBROVASCULAR DILATION FOLLOWING CORTICAL SPREADING DEPRESSION IN ANESTHETIZED RABBITS. David W. Busija. Dept. of Phys. & Pharm., Bowman Gray Sch. of Med., Wake Forest Univ., Winston-Salem, NC 27157
We examined responses of rabbit pial arterioles to three different stimuli

before and after induction of cortical spreading depression (CSD). In urethane-anesthetized rabbits equipped with a closed cranial window, we measured pial arteriolar diameter during baseline conditions, during topical application of 107M calcitonin-gene related peptide (CGRP), topical application of 10<sup>4</sup>M acetylcholine, and inhalation of 10<sup>9</sup>K CO<sub>2</sub> in air (arterial hypercapnia), before CSD and 30, 60, and 120 after CSD. CSD was induced by localized application of a 5% KCl solution anterior to the arteriole being measured. Average baseline diameter was approximately 100µm. During CSD, arteriolar diameter increased to a peak value that was  $51\pm5\%$  above baseline (n=26). Prior to CSD, arteriolar diameter changed  $47\pm7\%$  (n=9) during hypercapnia,  $42\pm10\%$  (n=7) during  $10^{-7}M$ CGRP, and 61 ± 13% (n = 6) during 104M acetylcholine. After CSD, arterioles dilated during hypercapnia by  $36 \pm 7\%$  (n = 8) after 30 minutes,  $44 \pm 9$  (n = 6) after 60 minutes, and  $61 \pm 10\%$  (n = 5) after 120 minutes. Following CSD, arterioles dilated during CGRP (10-7M) application by  $55 \pm 10\%$  (n = 7) at 30 minutes,  $51 \pm 19\%$  (n = 8) during 60 minutes, and  $30 \pm 5\%$  (n = 5) at 120 minutes. After CSD, acetylcholine ( $10^4$ M) dilated arterioles by  $53 \pm 7\%$  (n = 9) at 30 minutes,  $41 \pm 6\%$  (n = 13) at 60 minutes, and  $53 \pm 15\%$  (n = 10) at 120 minutes. Arteriolar responsiveness was not changed significantly to any of these stimuli by prior CSD. We conclude, that dilator capacity of pial arterioles is still intact in urethane-anesthetized rabbits following CSD. (Supported by HL46558 and HL30260)

AN ELECTROPHYSIOLOGICAL CORRELATE RELATED TO SPONTANEOUS AND EVOKED ELEVATIONS OF CEREBRAL BLOOD FLOW IN RAT CEREBRAL CORTEX. E. Golanov\* and D.J. Reis. Div. of Neurobiol., Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York,

In the cerebral cortex, blood flow (rCBF) is regulated by intrinsic neural networks many of which, when excited, increase rCBF independently of metabolism. To identify electrophysiological correlates associated with spontaneous and/or induced changes in rCBF, rCBF was measured over parietal cortex by laser doppler flowmetry (LDF). Forty five rats were paralyzed, ventilated and anesthetized with 1.5% isoflurane, measuring EEG and arterial pressure. During steady-state conditions, rCBF spontaneously oscillates with brief elevations of rCBF (147.1+2.6% of control) lasting 11.7<sub>4</sub>0.5 sec. The average periodicity was 0.1-0.025 Hz. Oscillations of rCBF were always associated with a characteristic pattern of EEG activity consisting of bursts of high-amplitude (0.75+0.04 mV), low frequency (5.6+0.2 Hz) activity varying in burst duration. The onset and peak of each oscillation followed the onset of each burst with constant latencies (1.7±0.1 and 3.8±0.1 sec, respectively). The frequency of bursts and the oscillations co-vary with depth of anesthesia. Bursts of EEG appear simultaneously and synchronously in different cortical areas. Stimuli increasing rCBF independently of metabolism (e.g. hypoxia, hypercapnia, or brainstem or cerebellar stimulation) simultaneously and proportionally increase EEG bursts to fusion and rCBF. We conclude that spontaneous oscillations of rCBF are tightly coupled to a burst event in the cerebral cortex. This appears triggered by a subcortical pacemakers providing synchronous and simultaneous patterns of cortical neuronal activity. The results suggest the existence of cortical neurovascular modules related to mediating primary vasodilation.

BREAKTHROUGH OF CEREBRAL BLOOD FLOW (CBF) WITH HYPERTENSION: EVIDENCE FOR ACTIVE CEREBRAL VASODILATATION. W.T. Talman\*, D. Nitschke Dragon, H. Ohta. Dept. of Neurology, VAMC and Univ. of Iowa, Iowa City, IA 52242.

Acute elevation of mean arterial pressure (MAP) above 150 mmHg leads to loss of autoregulation, rapid decrease of resistance (CVR) and increase of CBF. We have shown that breakthrough in rats is nearly eliminated by sinoaortic denervation (SAD). We have extended those studies to determine if pharmacological attenuation of the baroreflex interferes with breakthrough as does SAD and if nitric oxide (NO) may mediate vasodilatation with breakthrough. Changes in CBF were assessed by laser flowmetry during control periods and during infusion of phenylephrine (PE), angiotensin II (All), or vasopressin (AVP) in 15 intact rats; during infusion of PE in 13 rats after SAD; and during infusion of PE in 11 intact animals after an i.v. bolus of L-nitroarginine (LNA). Animal temperature, arterial pCO<sub>2</sub> and pO<sub>2</sub>, and rate of rise of MAP were carefully controlled. Breakthrough of CVR and CBF occurred in intact rats when MAP was raised to 160±8 or 179±3 mmHg by PE or AVP respectively but did not occur in intact rats treated with All or with PE after LNA despite equal or greater increases of MAP. Breakthrough also did not occur in rats after SAD, which, like treatment with All, eliminated baroreflex responses to increased MAP. Rats with SAD and removal of the superior cervical ganglia bilaterally likewise did not demonstrate breakthrough. Change in pulse pressure from basal to maximal levels of MAP, change in MAP with respect to time, and pCO<sub>2</sub> did not significantly differ between groups where breakthrough occurred and those where it did not. Thus. breakthrough of autoregulation during acute hypertension may be dependent on the arterial baroreflex and mediated by release of NO. Support: VA Merit Review and Clinical Investigatorship (WTT) and NIH HL32205 and HL14388.

CORTICAL CEREBRAL BLOOD FLOW (CBF) CYCLING. John L. Williams, Mary Shea, Datong Wei, and Stephen C. Jones.\* Cerebrovascular Research Laboratory, Cleveland Clinic Foundation, Cleveland, OH 44195.

Temporal oscillations of CBF and of other cerebral parameters have been noted with a frequency of 0.1 Hz, but only in a small fraction of the animals. Suspicion that this phenomena is dependent on the type of anesthesia led us to investigate the occurrence of CBF cycling with changes in mean arterial blood pressure (MABP) with different anesthetics.

Fifteen Sprague-Dawley rats (370 ± 8 g, SEM) were anesthetized with either pentobarbital (n=5, 40-50 mg/kg), or halothane (n=5, 1-0.5%). Body temperature was maintained at 37°C. Femoral arterial and venous catheters were placed, and a trachectomy was performed, permitting artificial ventilation with 30% O<sub>2</sub> and 70% N<sub>2</sub>. A closed cranial window was formed over a 3 mm diameter craniotomy. MABP (126 ± 3 mmHg), PaCO<sub>2</sub> (36 ± 2 mmHg), PaCO<sub>2</sub> (139 ± 6 mmHg), and pH (7.43 ± 0.03) were controlled and stabilized. CBF was determined using laser Doppler flowmetry. MABP was transiently and repeatedly lowered by exanguination. Fast Fourier analysis of selected 60 s flow recordings (n=38) was performed.

exisanguination. Fast Fourier analysis of selected 60 s flow recordings (n=38) was performed.

CBF cycling was observed, independent of the type of anesthesia, in 14/15 animals. In 13 animals, cycling was induced when MABP was reduced to 71 ± 3 mmHg. The mean frequency and amplitude were 0.102 ± 0.004 Hz and 6.5% ± 0.7%. There were no correlations over the entire group between frequency or amplitude and MABP.

These oscillations occur at MABPs that are near the lower limit of autoregulation. At this pressure, CBF oscillations would suggest that vasoconstrictive and dilatory forces are no longer in balance, but alteratively wing for control.

vying for control.

REGIONAL CEREBRAL BLOOD FLOW, PLASMA CATECHOLAMINES, AND EEG DURING HYPOGLYCEMIA AND RECOVERY. R.M. Bryan,\* M.Y. Eichler, C.N. Niederman, T.D. Johnson, W.T. Woodward, and J. Williams. Department of Anesthesiology, Baylor College of Medicine, Houston, TX. 77030.

Regional cerebral blood flow (rCBF), plasma catecholamines (PC), and EEG were measured during the onset of insulin-induced hypoglycemia (HG) and recovery. Male Long-Evans rats were fasted overnight and surgically prepared using isoflurane. Each rat was immobilized by securing the hindquarters with a plaster cast and allowed to recover from anesthesia. Regional CBF (using 14 isopropyliodoamphetamine), PC, and EEG were measured during control conditions (plasma glucose, PG,=171 mg/dl), HG (PG=29 mg/dl), five (PG=213 mg/dl), and 30 (PG=134 mg/dl) minutes of recovery (IV injection of glucose). The EEG showed a characteristic high-amplitude, slow-wave pattern during HG. Plasma epinephrine in the normoglycemic control rats was 529 pg/ml and increased by 4.5 times when PG had fallen to 50 mg/dl. Plasma epinephrine (E) steadily decreased toward baseline over the next 90 minutes as the HG became more severe. Unlike E which showed a very large increase during the early stages of HG, plasma norepinephrine (NE) significantly increased by 60% only during the latter stages of HG (PG=35-40 mg/dl). NE remained elevated during much of the recovery period. Regional CBF increased 55-82% in most regions, but did not change in regions lacking a blood-brain barrier. During the recovery, rCBF returned to normal within five minutes in those regions where it had increased. We conclude that (a) rCBF immediately returns to normal values upon recovery from HG; and (b) increases in E are probably not responsible for the increase in rCBF during hypoglycemia since it peaked and was returning toward baseline when rCBF increased.

Pituitary adenylate cyclase activating peptide (PACAP): a VIP-like peptide with vasodilator actions in the cerebral circulation P.J. Goadsby\*, R. Ekman† and L. Edvinsson‡ Department of Neurology, The Prince Henry Hospital, Sydney AUSTRALIA and Departments of Otorhinolaryngology† & Experimental Research‡, Malmo General Hospital, Malmo SWEDEN.

Pituitary adenylate cyclase activating peptide (PACAP) is a VIP-like peptide that has been recently isolated from ovine hypothalamus. VIP, peptide histidine isoleucine (PHI), PACAP, PACAP-related protein secretin and glucagon all belong to a super-family of neuroendocrine peptides with generally vasodilator properties. The existence of PACAP in neurons in the central nervous system raises the possibilty that, like VIP, it may be present in nerves on cerebral vessels. To study cerebral blood flow cats were anesthetised with α-chloralose (60mg/kg, ip) and prepared for physiological monitoring including cardiovascular parameters to assess the need for supplemental anesthesia. Cerebral blood flow (CBF) was measured using laser Doppler flowmetry (CBF<sub>LDF</sub>; Goadsby, Am J Physiol, 260;R255,1991). PACAP was injected directly into the brain in 1μl aliquots. To examine the cerebral vessels cats were deeply anesthetised and brain vessels harvested. Double immunostaining for VIP and PACAP using rabbit antibodies was used. Local injection of 1μl of vehicle did not significantly alter resting CBF although injection of PACAP resulted in a concentration-dependent increase in CBF<sub>LDF</sub> with a mean maximum increase of 18±6% at 5μg in 1μl. The double staining technique revealed that PACAP-immunoreactive nerve fibers are a subset of VIP-immunoreactive fibers. These data represent an initial characterisation of the distribution and action of a novel VIP-like vasodilator peptide, PACAP, in the cerebral circulation.

INCREASED EXPRESSION OF CORTICOTROPIN RELEASING FACTOR IN INFERIOR OLIVARY NEURONS EVOKED BY OPTOKINETIC STIMULATION (OKS) IN THE RABBIT N.H. Barmack and P. Errico, RS Dow Neurological Sciences Inst., Good Samaritan Hosp. & Medical Ctr., Portland, OR 97209

Neurons located in the dorsal cap (DC) of the inferior olive are excited by low velocity optokinetic stimulation (OKS) in the posterior-anterior direction of the contralateral eye. These visual olivocerebellar neurons have been implicated in the modification of eye movements. A neuropeptide, corticotropin releasing factor, CRF, has been found in all olivary neurons. Prolonged, unidirectional, binocular OKS increases the level of CRF mRNA in DC neurons by a factor of 12. Using an antibody to CRF, we have studied the expression of CRF in DC neurons after prolonged OKS. Rabbits were partially restrained within an optokinetic drum that rotated at an angular velocity of 5 deg/sec. An antiserum to rat CRF was used to immunohistochemically label brainstem sections of stimulated rabbits. The density of reaction product within individual olivary neurons in slidemounted sections was analyzed with a computer-based densitometer. Binocular OKS for 48 hr caused a 20-70% increase in the optical density of "stimulated" DC neurons, measured relative to the optical density of control olivary neurons in the same section. This elevated expression of CRF lasted approximately 48 hr. If there was a delay of 18 hr following binocular OKS prior to sacrifice, during which the rabbits were deprived of pattern vision then both DCs were densely labeled. Monocular OKS for 48 hr in the anterior-posterior direction caused no change in CRF expression in either DC. But, if a "null-stimulated" eye was densely labeled. We infer that stopping prolonged "null-stimulated" eye was densely labeled. We infer that stopping prolonged "null-stimulated" eye was densely labeled of the DC or more peripherally in the optokinetic pathway.

SPATIAL PROPERTIES OF FLOCCULUS NEURONS IN THE DECEREBRATE CAT. K.D. Powell\*, K.J. Ouinn, L.D. Barke, B.W. Peterson, J.F. Baker. Dept. of Physiology, Northwestern Univ., Chicago, IL 60611.

An intact flocculus is necessary for VOR adaptation. We are studying the spatial properties of neurons in the anterior third of the flocculus. Response properties are more complex than previously expected. Responses of 34 neurons were recorded during 0.5 Hz rotations in 4-11 vertical planes and yaw in decerebrate cats to calculate a plane of maximum activation. Connections were determined by electrical stimulation of bilateral labyrinth and ipsilateral superior vestibular nucleus. Contrary to expectation, only three of the 34 neurons had a preferred plane of activation within 20° of the plane of the ipsilateral anterior canal-contralateral posterior canal pair. All three had type II response to rotation. Three neurons were primarily horizontal canal neurons, two type II and one type I response. One neuron's response plane was within 20° of the ipsilateral posterior canal-contralateral anterior canal pair plane and was type II. The remaining neurons received convergent input from two canals (21 neurons) or 3 canals (5 neurons). Many of the 34 neurons were activated by labyrinth stimulation at 4-6ms, often on top of a N3 field potential suggesting that they were Purkinje cells. In some cases this identification was supported by complex spikes and/or histological reconstruction. Velocity step tests were performed on 9 neurons. Only 4 of 9 neurons had push-pull responses, 2 type I and 2 type II. One neuron was type III and none were type IV. The remaining 4 neurons responded only in one direction, excitatory (3 neurons) or inhibitory (1 neuron) to ipsilateral rotation. The signals in the flocculus, rich in convergence and complicated response patterns, could provide the substrate for VOR direction adaptation and phase shifts. Supported by DC01559, EY06485, EY07342.

COMPLEX SPIKE ACTIVITY OF PURKINJE CELLS IN THE PIGEON FLOCCULUS: RESPONSES TO ROTATIONAL FLOWFIELDS PRODUCED BY A PLANETARIUM PROJECTOR. D.R. Wylie and B.J. Frost. Dept. of Psychology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

The flocculus receives visual signals from the accessory optic system, which is involved in the analysis of visual flowfields resulting from self-motion and the production of compensatory movements to maintain gaze stabilization. We recorded the complex spike activity of floccular Purkinje cells in anesthetized pigeons in response to optokinetic stimuli produced by a rotating "planetarium projector". This projector consisted of a light inside a cylinder which was pierced with numerous small holes. A pen motor oscillated the cylinder about its long axis. This apparatus was placed above the bird's head and the resultant rotational flowfield was projected onto screens surrounding the bird. The rotation axis of the planetarium could be placed at any orientation in space. Two types of responses were found. VA or yaw neurons (n = 43) were maximally excited by rotation of the planetarium about the vertical axis in the direction producing forward and backward motion in the ipsilateral and contralateral eyes, respectively. Rotation about the vertical axis in the opposite direction maximally inhibited VA neurons, and rotation about horizontal axes generally resulted in no modulation. H-135i neurons (n = 34) were maximally excited by counterclockwise (as viewed from the bird's ipsilateral eye) rotation of the planetarium about a horizontal axis at 135° azimuth on the ipsilateral side (beak = 0° azimuth). Clockwise rotation about this axis maximally inhibited H-135i neurons, and rotation about orthogonal axes, (i.e. the vertical axis or a horizontal axis at 45° azimuth on the ipsilateral side), did not produce modulation. These results suggest that the reference frame of the optokinetic signals to the flocculus is similar to that of the vestibular canals. That is, VA and H-135i neurons would respond best to optic flow resulting from a head rotation maximally stimulating the ipsilateral horizontal canal and the ipsilateral anterior canal, respectively.

TRANSIENT CEREBELLAR CLIMBING FIBER ACTIVITY DURING MOTOR LEARNING: RELATIONSHIP TO KINEMATICS. C.L. Ojakangas\* and T.J. Ebner, Depts. of Neurosurgery, Physiology & Grad. Program in Neuroscience, Univ. of Minnesota, Mpls., MN 55455.

Cerebellar Purkinje cells were recorded during a visually guided twodimensional arm movement task in which primates used a manipulandum to place a cursor in target boxes displayed on a video screen. When the relationship between the cursor and hand position was altered, the animals adapted their movements to the new gain over 100-200 trials. The peak tangential velocity and movement amplitude gradually changed to match the new gain while the time to peak velocity remained constant. Complex spike (CS) activity increased during the learning process just prior to or after movement onset, the same time period in which the kinematics were scaled. To determine the relationship of the CS occurrence to the kinematics and simple spike (SS) discharge, the movement trials were sorted into complex spike and non-complex spike trials for 20 cells with significant CS responses. Arm kinematics and simple spikes were aligned on the CS occurrence. For the non-CS trials a Monte-Carlo type simulation was done to achieve a comparable alignment of the data. Results indicate that the CS is followed by a change in the tangential velocity. Both increases (30%) and decreases (55%) have been observed. In 75% of the cells changes in velocity preceded the CS activity. These changes in velocity were accompanied by differences in the SS activity in the CS and non-CS trials. These results suggest a role for the CS in the detection and/or correction of small errors in the movement characteristic of learning. Supported by NIH Grant R01-NS18338.

PURKINJE CELL EYE AND HEAD VELOCITY SENSITIVITY ARE NOT ALTERED DURING VOR ADAPTATION. R. Baker, A. M. Pastor R. R. de la Cruz. and J. I. Simpson\*, Dept. Physiology and Biophysics, NYU Med. Ctr., New York, NY 10016.

Electrical stimulation of the goldfish vestibulo-cerebellum produces conjugate ipsilateral horizontal eye movements. Biocytin injection into Purkinje cells, identified by climbing fiber responses to visual motion, demonstrated a characteristic soma-dendritic arborization, recurrent axon collaterals and projections to the vestibular nuclei. To further elucidate the role of the vestibulo-cerebellum in motor execution and/or learning, Purkinje cell simple spike discharges were quantified in terms of eye and head velocity sensitivity during the optokinetic reflex and visual cancellation of the VOR, respectively. Purkinje cells could be classified into three distinguishable, but overlapping, groups. For the first group, discharge frequency was largely correlated with eye velocity, and in the second group, with head velocity. The third group consisted of two sub-types that had nearly equal sensitivity to eye and head velocity, but in one case, at a VOR gain of 1.0, signals cancelled, and in the other, they added. Purkinje cells representative of all three groups were recorded for 3-24 hrs during eye/head velocity modification of VOR gain from -0.6 to 2.5, representative of all three groups were modulation of Purkinje cells representative of all three groups were from ance. However, the eye and head velocity sensitivity characterizing each Purkinje cell remained constant irrespective of the VOR gain state. These findings demonstrate that Purkinje cell activity is correlated with movement execution, even throughout acquisition of the adapted VOR response. The invariance of Purkinje cell sensitivity to head and eye velocity clearly indicates that VOR learning must occur in the brainstem pathways, not in the vestibulo-cerebellum.

RHYTHMIC OLIVO-CEREBELLAR CONTROL OF SKILLED TONGUE MOVEMENT IN RELATION TO PATTERNED HYPOGLOSSAL NERVE ACTIVITY. J.P. Welsh\*, E.J. Lang, I. Sugihara and R. Llinás, Dept. Physiology & Biophysics, NYU Medical Center, 550 First Avenue, NY, NY 10016.

We have combined simultaneous recordings of the activity of the medial and lateral branches of the hypoglossal nerve (XIIn) with multi-electrode recording of Purkinje cell complex spikes (CSs) during conditioned tongue profursion in the rat. Rats were trained to protrude their tongue 6 mm in response to a tone in order to obtain water spinforcement. The coverages of the tone rester dispure productions and the contraction of t rat. Rats were trained to protrude their tongue 6 mm in response to a tone in order to obtain water reinforcement. The occurrence of the tone reset olivary rhythmicity and subsequently produced rhythmic CS activity in ensembles (25-30) of Purkinje cells whose frequency varied in different rats (n=4) from 6-8 Hz. The frequency of olivocerebellar oscillation produced by the tone in each of the rats predicted within 0.3 Hz (96% accuracy) the rhythm of the tongue protrusion. Cross-correlation of the CS activity of cell ensembles with different movement parameters indicated that rhythmic CS fring was more highly correlated to the time that the tongue leaves the target than to either the time of tongue arrival or mouth opening. The medial and lateral branches of the XIIn manifested highly patterned activity consonant with their respective roles in protrusion and retraction. Both branches manifested 2 burst of activity during the movement, the latter of which occurred within 20 ms of the time of maximal protrusion. CSs reliably preceded the second burst in the lateral XIIn by 30 ms. Because the time the tongue remains at the target varies (15-70 ms), the 30 ms. Because the time the tongue remains at the target varies (15-70 ms), the finding that CSs are more tightly time-locked to tongue withdrawal than to tongue arrival indicates that CSs are not driven by the immediate sensory consequences of the tongue contacting the target. Rather, rhythmic olivo-cerebellar activity engaged by the conditioned stimulus prior to movement makes available a central oscillation that is used by the motor system of the trained rat to coordinate patterned and precisely timed motor activity when the tongue reaches the target. (Supp. NS08844 and NS13742).

DIFFERENCES IN THE PROPERTIES OF SIMULTANEOUSLY RECORDED RESPONSES IN THE CEREBELLAR NUCLEI DURING THE ACQUISITION AND PERFORMANCE OF SEQUENTIAL FORELIMB MOVEMENTS IN THE CAT. <u>I.R.</u> Bloedel\*, V. Bracha, M.S. Milak, F. Kolb, J.D. McAlduff, Barrow Neurological Institute, Phoenix, AZ 85013.

Experiments were performed using chronic multiple single unit recordings to test the hypothesis that neurons in the various cerebellar nuclei are modulated differently during the acquisition and performance of complex forelimb movements. In this task cats reached for a manipulandum on cue and moved it through one of a variety of templates. Each template required the execution of 2-3 straight movements performed sequentially in varying directions. straight movements performed sequentially in varying directions. Recordings were performed simultaneously across the cerebellar nuclei with 24 microwires coupled to a newly developed adjustable electrode system. The kinematics of the ipsilateral forelimb movements were assessed using an active LED system and EMG was recorded from specific forelimb muscles. Data processing techniques were developed to represent graphically the changes in neuronal activity in each nucleus as the tasks were learned and subsequently activity in each nucleus as the tasks were learned and subsequently performed. To date the data show that the activity of dentate neurons is highly related to specific features of the movement sequence. Neurons in the fastigial nucleus discharge primarily in a broad monotonic manner beginning just prior to the lift off of the reaching limb. During learning, the amplitude of the responses in each nucleus was related to specific phases of task acquisition. However, qualitative features of the responses only changed minimally. NIH Genet Pol. NS(2)058 Grant R01 NS21958.

THE ABILITY OF MOTOR CORTEX STIMULATION TO EVOKE VIBRISSAL MOVEMENTS IS MODULATED BY A 10 HZ SIGNAL ARISING IN THE INFERIOR OLIVE. E. J. Lang\*, I. Sugihara, and R. Llinás. Dept. of Physiology & Biophysics, New York University Medical Center, 550 First Avenue, New York, N.Y. 10016.

Synchronized and rhythmic activity in the olivocerebellar system has been shown to facilitate activity generated in other brain regions, increasing the probability of movement execution. This suggests that the ability of motor cortex activation to generate movements should depend on its phase relationship to olivary activity. Thus, if the motor cortex is stimulated at a frequency different from the 10 Hz frequency of the IO, beating patterns reflecting the difference between the two frequencies should occur. Trains of 500 µsec pulses were applied to the motor cortex using a bipolar stimulating electrode. The evoked vibrissal movements were recorded using a high speed VCR. The pattern of vibrissal movements depended on the frequency of the stimulation. In control animals 10 Hz trains produced movements whose amplitudes tended to increase monotonically throughout the train, 20 Hz trains produced alternating large and small amplitude movements, and 25 Hz trains produced four small amplitude movements for each large one. These beating patterns can be explained as the interference between the train

frequency and a 10 Hz signal.

To demonstrate that the 10 Hz modulation arises from the IO we microinjected picrotoxin and lidocaine into the IO. Picrotoxin injections synchronize olivary activity and slow the oscillation frequency to 5-6 Hz. Injections of picrotoxin led to changes in the beating patterns as would be predicted from changing the IO's frequency from 10 to 5 Hz. Lidocaine injections abolished the beating patterns. Furthermore, beating patterns were absent when the IO had been destroyed by 3AP. NIH grant NS13742.

THE ROLE OF CAT RED NUCLEUS DURING REACHING CM, Horn\*, P.L.E, van Kan and A.R, Gibson. Barrow Neurol. Inst.,

Reaching out and grasping an object is accompanied by high rates of neural discharge in the intermediate cerebellum and its output target, the magnocellular red nucleus (RNm). In contrast, simpler movements made while operating single joint manipulanda fail to elicit high discharge rates. Here, we report the results of several experiments designed to analyze the role of the RNm in the control of reaching.

Five cats were trained to reach out and retrieve a lever while we recorded neural discharge in RNm. To date, we have recorded 130 forelimb neurons, and essentially all discharged at high rates during various phases of the reach. Patterns of discharge are highly characteristic for individual cells, and several classes are recognizable. The response patterns for two of the cell classes are reciprocal and match the EMG patterns of specific distal forelimb muscles (extensor digitorum communis and palmaris longus). In contrast, no close correspondence between patterns of neural

discharge and activation patterns of proximal muscles is apparent.

Reversible inactivation of the RNm with either lidocaine or GABA severely alters reaching behavior. Interestingly, reaching out and grasping is impaired whereas the retrieval of the lever is relatively normal. Often, the cats must make several attempts to grasp the lever, and the grasp itself has a heavy reliance upon the wrist rather than the toes or claws. These results indicate that the output of the intermediate cerebellum through the RNm is especially important for limb coordination required to seach and grasp. important for limb coordination required to reach and grasp

PARALLEL FIBER INPUT MODULATES PURKINJE CELL RESPONSES TO ASCENDING FIBER GRANULE CELL INPUT.

Div. of Biology 216-76, Caltech, Pasadena, CA 91125.

We have constructed a detailed compartmental model of a Purkinje cell, based upon anatomical and physiological data. We used this model to explore the response to synchronous synaptic inputs, expected to result from activation of synapses from the ascending part of the granule cell axon, during continuous background asynchronous inputs from the

cell axon, during continuous background asynchronous inputs from the parallel fibers. Dendritic Ca<sup>2+</sup>-channels amplify synaptic inputs so that the response is independent of the dendritic location of synchronous inputs, i.e. the cell will always fire an action potential within 10 ms (De Schutter and Bower, Analysis and Modeling of Neural Systems 1992). To quantify these effects, we examined the somatic EPSP caused by synchronous synaptic inputs at 6 locations in a model with active dendritic membrane and a passive soma. Averaged peak amplitudes of EPSPs (100 samples) were 2.3 to 4.8 mV, corresponding to an amplification of 1.4 to 4.9 compared to a completely passive model. EPSPs from distal inputs were amplified more than those from proximal inputs, so that attenuation of distal inputs was greatly diminished compared to from distal inputs were amplified more than those from proximal inputs, so that attenuation of distal inputs was greatly diminished compared to the passive model. However, the amplitude of single EPSPs was quite variable, with an average standard deviation of 52%. The random, asynchronous excitatory and inhibitory inputs to the model are the only possible source of this variability. The modulation by parallel fibers was independent of the location of the synchronous inputs. For identical patterns of random inputs the size of EPSPs generated from different problems of the property inputs to the control of the synchronous inputs. ent synchronous input locations was correlated by 78 to 98% Supported by Fogarty fs F05 TW04368 to EDS and NIH grant NS 22205 to JMB.

CEREBELLAR ATAXIA WITHOUT CHANGES IN FUSIMOTOR (y) CONTROL OF PROPRIOCEPTION. M. Gorassini\*, A. Prochazka & J.L. Taylor. Div. Neuroscience, University of Alberta, Edmonton, AB, CANADA

The cerebellum has been implicated in the control of muscle spindle sensitivity via the y fusimotor system12. This has never been confirmed in intact animals, though abnormal motor cortical responses to proprioceptive input seen in monkeys with cerebellar dysmetria3 are consistent with aberrant fusimotor control. Disordered proprioceptive feedback could well contribute to dysmetria or hypotonia. To test these ideas, we studied the firing of 8 muscle spindle afferents (7 la, 1 ll) in 5 intact cats before and during 4-6 min blockade of interpositus or dentate nuclei (1.5-2.5 µL, 2% Lidocaine). Spindle sensitivity was assessed in three situations. Before blockade in the resting cat it was low, indicating little y action; in gait, moderate Ia and II sensitivity and bias suggested moderate γ, action; in imposed movements, Ia sensitivity was high, indicating strong \( \gamma\_d \) action<sup>4</sup>. During unilateral interpositus blockade, marked ataxia and dysmetria occurred in ipsilateral limbs. Despite aberrant EMG's in parent muscles, spindle sensitivities in the three situations described above were normal, except for reduced y<sub>4</sub> action in imposed movements in one case. The lack of effect of cerebellar dysfunction was unexpected and suggests that the cerebellar interpositus and dentate nuclei are not primarily responsible for fusimotor control. Furthermore, the results show that severe dysmetria and ataxia can occur in the presence of normal proprioceptive feedback. 1) Gilman, S. (1969) Brain, 92:621-638. 2) Vitek, J.L. A NEW INDEX OF CEREBELLAR DYSMETRIA IN HUMANS. Jacoby, D. Rotella, W. Darling, M. Rizzo\*. Departments

of Neurology and Exercise Science, The Univ. of Iowa, Iowa City, IA 52242.

We evaluated aspects of limb trajectory, timing, and accuracy in 3-D space in 6 patients with cerebellar lesions. We used an optoelectronic technique (the WATS-MART system) to evaluate their ability to smoothly transport each hand from a midline start position to distal targets located on the right, middle and left. The digitized data were low-pass filtered at 10 Hz. The onset and termination of movements were determined by velocity threshold criteria. As expected, the limb on the side of the cerebellar lesion performed much worse, and exhibited intention tremor primarily in the deceleration phase. The major finding was that the endpoint variability of the initial movement towards the target with the hand ipsilateral to the lesion was 3-25 times greater than for comparable movements with the contralateral limb. Nevertheless, the durations of and exhibited intention tremor primarily in the decelerthese movements were similar for each limb. Endpoint variability of the initial movement to targets appears to provide a sensitive quantitative index of cerebellar dysmetria in humans.

MECHANISMS OF DISTRIBUTING SODIUM CHANNELS IN MYELINATED AXONS. <u>Barry W. Hicks\* and Kimon J. Angelides</u>, Dept. of Molecular Physiol. and Biophysics, Baylor Coll. of Med., Houston, TX 77030.

In mature, myelinated axons, sodium channels (NaChs) reach a density as high as 5,000/μm<sup>2</sup> at the node of Ranvier with an internodal density of <100/μm<sup>2</sup>. How are NaChs accumulated and maintained at the node? It has been reported that NaCh distribution on axons of sensory neurons is altered in the presence of Schwann cells (SCs), and that NaChs may travel by surface the presence of schwann cells (SCs), and that NaChs may travel by surface lateral diffusion to axonal sites after insertion into the somal plasma membrane of olfactory neurons. To test this hypothesis and explore the mechanisms responsible for SC-dependant NaCh redistribution, we examined the movement of surface NaChs on living dorsal root ganglion neurons in the absence and presence of SCs. Previous FPR studies on cultures of these neurons indicate that only about 20% of the NaChs are mobile. The time scale for most FPR experiments is in the seconds to minutes range. In contrast, production of compact myelin can take 2-3 weeks in culture. To determine if the small mobile fraction detected by FPR is capable of traveling large distances on the axonal surface, NaCh movements were examined in a large distances on the axonal surface, NaCh movements were examined in a longer time frame using time-lapse fluorescent video microscopy. Movements of individual NaChs were probed with a monoclonal antibody to the NaCh covalently bound to fluorescent latex microspheres. Bulk NaCh movements were examined by labeling channels with the same antibody and Fab fragments of TRITC conjugated goat anti-mouse antibodies. After bleaching large regions on the axonal surface with an argon laser, fluorescence recovery was filmed. In both cases little movement of NaChs on the axonal surface was observed. Although localized redistribution on the axon may occur, these results suggest that the high nodal density of NaChs does not arise by diffusion of channels from the soma to the distal regions of the axon.

THREE-DIMENSIONAL IMAGING OF LIVING NEURONS AND GLIA WITH THE ATOMIC FORCE MICROSCOPE. V. Parpura\*, E. Henderson and P. G. Haydon. Signal Transduction Training Group, Dept. of Zoology and Genetics, Iowa State Univ., Ames, IA 50011.

The atomic force microscope (AFM) collects information from a substrate by scanning a small probe over the surface of interest. Measurements of the deflection of the probe are displayed as a topographic map. The AFM can image samples at extremely high, and in some cases atomic, resolution and has sufficient dynamic range to allow imaging of molecules to a group of cells. In this study we have used the AFM to directly image hippocampal neurons and glia. Using chemically fixed cells it was possible to reconstruct threedimensional cell structure and detect subcellular features such as the nucleus, mitochondria and filaments. Imaging of neuronal growth cones revealed that their height increases in a step-like manner.

We have found it possible to image living cells with the AFM. By repeatedly scanning a single living cell we observed the movement of filaments beneath the cell membrane. Additionally, by controlling the force applied to the scanning tip, nanosurgery was performed to selectively sever neurites or to remove cells from the culture substrate. Neurons and glia were differentially sensitive to the tip-applied forces, neurons being removed with 5-36 nN (n=5) and glia with a force of 60-84 nN (n=5). Thus, the atomic force microscope offers the opportunity to gain three-dimensional information about living cells, to observe the behavior of cellular components by imaging through the intact cell membrane and to perform nanosurgery.

HEMOSTASIS REGULATION IN GUINEA PIG BRAIN. Mark Fisher\*, Milo Lipovac, Aldana Martin, Vicky Wong, Berislav Zlokovic.

Departments of Neurology and Neurological Surgery, USC School of Medicine, Los Angeles, CA 90033 (USA).
Abnormalities of hemostasis are prominently associated

with ischemic stroke. However, little is known of hemostasis regulation in brain. We are investigating hemostasis proteins and their regulation in the brain of the young (six weeks of age) guinea pig. As part of an on-going study, we have used acetone-fixed frozen sections taken from cerebral hemispheres of two animals. lium of blood vessels of all sizes expressed von Willebrand Factor and stained consistently using antibody to tissue plasminogen activator (provided by Nicholas Seeds, U. of Colorado). Brain parenchyma was immunoreactive for tissue factor while this procoagulant protein was infrequently observed in association with blood Brain sections were not immunoreactive for tumor necrosis factor-alpha, an important regulator of hemostasis in vitro. In summary, these findings appear to represent baseline expression of several important endothelial and hemostasis-related proteins in guinea pig brain. guinea pig subjected to a variety of stroke risk factors should prove useful for understanding brain-hemostasis interactions and their relation to stroke. (Supported by NIH RO1 NS20989 and TRDRP 2RT0071)

AN MRI-BASED STEREOTACTIC ATLAS FROM 250 YOUNG NOR-MAL SUBJECTS. A.C. Evans, D.L. Collins and B. Milner.\* Montreal Neurological Institute, 3801 University St., Montréal H3A 2B4, Québec.

Blood flow (CBF) subtraction studies of cognitive activation with PET have increased rapidly in recent years, usually using young healthy volunteers. 3-D image data are mapped into a standardized anatomical coordinate space (Talairach and Tournoux, 1988). The Talairach atlas consists of single sections at 4mm intervals obtained post-mortem from a single brain, that of a right-handed 60-yr old European female. We have constructed an average 3-D brain volume from MRI data (64 2mm-thick planes: T1 sequence) acquired from 250 young healthy volunteers (age  $23.4 \pm 4.0$  ; 179 males ; 71 females). All data were mapped into Talairach space by identification of the bicommissural plane and resampled on to a 3-D grid with spacing of 1.34mm x 1.72mm x 1.50mm in X,Y and Z. Following intensity normalization, the average young normal brain was obtained by voxel summing. Separate maps were also produced for males and females. All major features were clearly defined and the atlas exhibits remarkable detail in the central regions where the dorsomedial nucleus of the tha thalamus was visible. The mean position of the primary sulci, e.g. central, cingulate, occipitoparietal, calcarine, were well-defined while the more variable secondary cortical anatomy was, as expected, less apparent. Known left-right size differences in frontal and occipital lobes (petalia) were confirmed. This database is a first step in the construction of a 3-D probability map of gross neuroanatomy across a large population.

RADIOIODINATED 5-IODO-6-NITROOUIPAZINE IN VIVO LIGAND FOR BRAIN SEROTONI
TERMINALS. A. Biegon, C. A. Mathis, S. Taylor and W. Jagust

Lawrence Berkeley Laboratory, Univ. Calif. Berkeley, CA 94720.
The feasibility of using radioiodinated 5-iodo-6-nitroquipazine (INQUIP) as an in vivo imaging agent for brain serotonin terminals and uptake sites was examined by ex vivo autoradiography in the rat. Following the tail vein injection of 25µCi [125]INQUIP (specific activity 2135Cifmmole = 100µCi/ka) animals uptake sites was examined by the site of th 2175Ci/mmole, -100μCi/kg), animals were decapitated and their brains removed, frozen and sectioned in 20μ sections, which were apposed to tritium sensitive film for 7-21 days with commercial 125I standards. Autoradiograms were quantified using a computerized image analysis system. Initial brain uptake was high  $(1.5 \pm 0.2\%)$  injected dose/g brain at 5 min, n = 3) and the proportion of specific binding increased with time up to 12 hours postinjection. Thus, the frontal cortex-tocerebellum radioactivity concentration ratios increased from  $1.2 \pm 0.1$  at 5 min to  $11 \pm 1$  at 12 hrs (n = 3). The distribution of radioactivity by 4-6 h following injection was similar to the distribution of serotonin uptake sites and terminals derived from in vitro autoradiographic and immunohistochemical studies. Coinjection of paroxetine (2mg/kg), a selective 5HT uptake blocker, resulted in a ~95% decrease in brain selective 5HT uptake blocker, resulted in a ~95% decrease in brain radioactivity. INQUIP brain uptake was also substantially blocked by coinjection of fluoxetine and sertraline (2mg/kg) but not by LSD (0.4mg/kg) nomifensine, GBR12909 or DMI (2mg/kg). A lesion of serotonin terminals (2X10mg/kg PCA i.p.) resulted in a ~90% decrease in brain radioactivity. These results support the use of suitably labeled INQUIP for in vivo SPECT imaging of serotonergic terminals in the human brain.

IDENTIFICATION OF A NOVEL NEURON SPECIFIC NUCLEAR

IDENTIFICATION OF A NOVEL NEURON SPECIFIC NUCLEAR PROTEIN BY GENE TRAPPING IN ES CELLS AND CHIMERA TRANSGENESIS. W. Jing, and A. Peterson\*. Laboratory of Developmental Biology, Royal Victoria Hospital, H5, McGill University, 687 Pine W., Montreal, Quebec, Canada H3A 1A1

We have employed a gene trapping approach using mouse embryonic stem (ES) cells to identify genes that, on the basis of their temporal and spatial expression patterns, may play important roles in nervous system development. The gene trap construct contains a promoterless LacZ gene ligated at its 5° end to a splice acceptor site derived from the mouse En-2 gene. This construct also contains, as a positive selectable marker, a neof gene driven by the B-actin promoter. positive selectable marker, a neor gene driven by the  $\beta$ -actin promoter. Integration of this construct into an intron of a gene expressed in ES cells in the correct orientation and frame results in a fusion transcript encoding a protein with  $\beta$ -galactosidase activity. Four such  $\beta$ galactosidase positive clones have been obtained (1/450 neor colonies) and one, when injected into mouse blastocysts, produces chimeras in which the trapped gene is expressed throughout the nervous system and in no other tissue. All neuronal populations in both the central and peripheral nervous system contain positive cells, indicating that the trapped gene is expressed pan-neuronally. Moreover, the protein encoded by this gene contains a nuclear localization signal suggesting the possibility that it plays a role in the function or organization of neuronal nuclei. Molecular characterization of this gene is in progress and is expected to reveal further clues to its normal function and ultimately, to the regulatory elements that confer its pan-neuronal expression profile.

F5 PROTEIN, A NOVEL MARKER OF ACTIVATED T CELLS, IS LOCALIZED IN DENDRITES AND PERIKARYA OF MATURE NEURONS

MATURE NEURONS

M. Arai\*. I.A. Cohen, and M.B. Prystowsky. Departments of Neurology and Pathology, Univ. of Penn., Philadelphia, PA 19104

F5, a cDNA clone with novel sequence, was initially isolated from IL-2 stimulated helper T cell line. Using Northern blot and in situ hybridization, we demonstrated that F5 mRNA is expressed exclusively in lymphoid tissues and in mature neurons within the nervous system. An open reading frame of 1125 bp encodes a 42 kDa protein with multiple potential phosphorylation sites. The objective of this study was to elucidate the biochemical properties of the F5 protein.

Antiserum was raised against C-terminal 18 amino acid peptide of the deduced F5 protein. This antibody detected a single band with apparent molecular weight of 42 kDa on Western blot of mouse brain extract. It specifically bound to an in vitro translation product with 42 kDa. Subcellular fractionation of adult mouse brain demonstrated that F5 immunoreactivity was present in membrane fractions, especially in synaptosome/ mitochondria fraction, but almost absent in cytosolic synaptosome/ miochondria fraction, but almost absent in cytosonic fraction. Immunoperoxidase staining showed that within the neurons, perikarya and dendrites were stained but axons were not. C-terminal peptide, which contains a consensus sequence for a protein kinase C (PK-C) phosphorylation site, served as a substrate for an PK-C assay.

F5 is a novel class of specific marker for mature neurons. The C-terminus of the F5 protein can be phosphorylated by PK-C. The biochemical properties and intracellular localization of the F5 protein suggests that it functions in receptor anchoring or signal transduction.

EXPRESSION OF A NEWLY IDENTIFIED PROTEIN TYROSINE KINASE IN THE DEVELOPING MOUSE RETINA Xianjie Yang and Constance Cepko\*, Department of Genetics, Harvard Medical School, Boston, MA 02115

Protein tyrosine kinases play critical roles in transducing environmental signals to cells. We have cloned a putative protein environmental signals to cells. We nave cloned a putative protein tyrosine kinase from a neonatal mouse cDNA library. The 4.2 Kb cDNA clone encodes the mouse homolog of the human JAK-1 kinase, which represents a new class of non-receptor protein tyrosine kinases. The main feature of this class of kinases is the presence of an additional phosphotransferase-like domain immediately N-terminal to the highly conserved tyrosine kinase catalytic domain. Analyses of mRNA using Northern blots indicate that the RNA level of mouse JAK-1 increases between embryonic stages and neonatal stages in the eye and brain. In situ hybridization studies analyzing the mRNA expression pattern using different regions of the JAK-1 cDNA are correlated with polyclonal antibody generated against a mouse JAK-1 fusion protein. As early as embryonic day 14, JAK-1 can be detected in axons of mouse retinal ganglion cells. In the adult mouse retina, JAK-1 is expressed in the retinal ganglion cells, amacine cells and horizontal cells. This pattern of expression is also observed in the chick retina. In the adult brain, JAK-1 is expressed most abundantly in the olfactory bulb, which correlates with a high level of expression in an olfactory cell line (OBL21). Thus, JAK-1, a newly identified protein kinase with two catalytic domains, is expressed in the mouse central nervous system, and may play a role in the differentiation of a subset of neurons.

CHARACTERIZATION OF NOTCH HOMOLOGUE CDNAS FROM GOLDFISH RETINA. S. A. Sullivan, B.L. Largent\*, & P.A. Raymond. Dept. of Anatomy & Cell Biology, University of Michigan, Ann Arbor, MI 48109.

Mutations at the Notch locks affect the developmental fate of cells in the neurogenic region of the Drosophila embryo, and in the developing retina of the adult fruit fly. Several vertebrate Notch homologues have been identified and shown to be expressed in developing nervous systems. In Xenopus tadpole retinas, Xotch mRNA localizes to a zone of cell proliferation and differentiation. The goldfish retina differs from that of amphibians in that it grows throughout adult life, and retains the capacity to regenerate after injury. New cells arise from two sources: all retinal cell types except rod photoreceptors arise from the germinal zone (which corresponds to the proliferation zone of Xenopus tad-poles); rods are produced at scattered points throughout the retina from proliferating rod precursor (RP) cells. During normal retinal growth RP cells produce rods exclusively, but in regenerating retinas RP cells can assum different fates. We are interested in the factors influencing the developmental fates of germinal zone cells and of RP cells. Using low-stringency library screening with Xotch probes concomitantly with the PCR, we have cloned two Gotch cDNAs. Clone 8X1 contains 150bp that encode part of the EGF-like repeat region [amino acid identity = Notch 69%; Xotch 90%; Rat 85%; Human 87%]. Clone 10X1 contains 1100bp encoding the entire cdc10/ankyrin-like repeat region [amino acid identity = Notch 58%; Xotch 65%; Rat 69%; Human 67%]. Preliminary digoxygenin-labelled RNA in situ studies reveal significant

levels of Gotch expression in the adult goldfish retina. Supported by NIH RO1EY04318 (P.A.R.) and T32EY07022 (S.A.S.)

Neuroepithelial stem cells: identification and differentiation in vitro and in vivo.
R. McKay\*, D. Collazo, M. Cunningham, T. Hayes, R. Josephson, M. Marvin, C. Vicario, L. Zimmerman, E 25-435, MIT, Cambridge, MA 02139.

The central nervous system in vertebrates is derived from a sheet of epithelial precursor cells. Fate mapping and transplant experiments show that the immediate precursors to neurons are multipotential cells that commit to a specific fate occurs in the hours immediately following the last S phase of the stem cells. These data lead to a model where the many cell types in the brain are a consequence of the response of multipotential stem cells to local signals in the of multipotential stem cells to local embryonic neuroepithelium. The specific expression of the nestin promoter allows these cells to be identified and manipulated in transgenic mice. Neurotrophins interact with stem cells in both transcements and cerebellum. Transplants of hippocampus and cerebellum. Iransplants of primary and immortal stem cells suggest that the extracellular signals drive these cells to appropriate neuronal fates. These results suggest that stem cells can be manipulated in powerful new ways.

ESTABLISHMENT AND CHARACTERIZATION OF A NEURONAL CELL LINE OBTAINED BY c-myc IMMORTALIZATION OF MOUSE MESENCEPHALIC CELLS. U. di Porzio\*, L. Colucci and A. Tino. International Institute of Genetics and Biophysics, C.N.R., V. Marconi, Naples, Italy
A cell line was obtained from E11 mouse mesencephalon

in primary cell cultures (di Porzio et al. Nature 288, 370, 1980) by infection with replication defective retrovirus produced in w 2 fibroblasts containing mouse c-myc and neomycin resistance genes under MoLTR (Blondel et al. Oncogene 5:857-Selection of transformed cell was carried in medium containing 400  $\mu\,\text{g/ml}$  G-418. Five clones were isolated; their growth rate was initially rather slow. Subsequently, a few clones with fast duplication time in 10% FBS were isolated (mes-c-myc-fast-A and -B). Without FBS these cells practically ceased to divide and about 50-60% acquired a neuron-like morphology whereas the remaining population showed less distinct morphology. Both cell types were vimentin-positive in the presence or absence of serum, but only the neuron-like population grown without serum was stained with anti-neurofilamnet (NF) antibodies. NF expression was confirmed by PCR amplification using specific

primers for the gene encoding for the 200 kDa NF subunit.

Phenotypic expression under different gowth conditions will be shown. This cell line can provide a useful tool to study CNS neuron differentiation, and neuron replacement in aging brain and CNS degenerative diseases.

# 180.9

PHENOTYPIC CHARACTERIZATION OF C6 GLIAL CELLS. D.E. Coyle\*. Depart. Anesthesia, Univ. of Cincinnati Col. of Med., Cinti., OH 45267-0531.

The C6 glial cell line has been used as a model system for the study of glial derived neurotrophic factors and the regulation of glial cells by extracellular substrates and growth factors. This cell line has been reported to express a glioblastic phenotype during early passages which can be influenced to express either astrocytic or oligodendrocyte phenotype. Later passages appear to be more committed to the astrocytic phenotype. The C6 cell line, however, has not been characterized by its antigenic phenotypic expression. In this study, the characterization of the expression of glial fibrillary acidic protein (GFAP), A2B5, galactocerebroside (GalC), fibronectin and laminin was determined from C6 cells grown under serum and serum-free conditions

C6 cells were grown in DMEM with 10% fetal bovine serum or in Opti-MEM-I supplemented with 27 nM Sodium selenite, 20 nM progesterone and 10 uM hydrocortisone (passage 41-43). The serum-free cultured cells were grown on 8 ug/cm rat tail type I collagen. After fixation (with or without permeabilization) the cells were exposed to a specific antibody and detected by use of either immunohistochemical or immunofluorescent techniques

Under both culture conditions the C6 cells were GFAP, A2B5, GalC, laminin and fibronectin positive. However, the GFAP expression of the C6 cells exhibited a population of darkly staining and lightly staining cells. C6 cells cultured under these conditions expressed a mixed oligodendrocyte-type 2 astrocyte phenotype. A cell population which expresses this phenotype (O4/GalC/GFAP) has been reported to occur, although infrequently, in primary human temporal lobe white matter cultures (Armstrong et.al. J. Neurosci. 12:1538-1547,1992). This project was supported by BRSG S07 RR05408-30 awarded by the Biomedical Research Support Grant Program, National Center for Research Resources, National Institutes of Health.

IMMORTALIZED, TEMPERATURE-SENSITIVE, DIENCEPHAL-IC CELLS EXPRESS MAP2 AT A NON-PERMISSIVE TEM-PERATURE, BUT NOT AT THE PERMISSIVE TEMPERATURE FOR TRANSFORMATION. K.Shimoda\*, K.Takahashi\*\* and J.W.Commissiong#. Tottori West Hosp\*, and Div.Neurol., Inst.Neurol.Sci.\*\*, Tottori Univ. Sch.Med., Yonago 683, Japan. #LMCN-NINDS-NIH, Bldg 10/5N214, Bethesda, MD 20892.

Cells from the diencephalon of the E13 rat Cells from the diencephalon of the El3 rat fetus were grown in culture and tranfected with SV40 large T antigen temperature-sensitive mutant, carried by a retrovirus vector (sai2 producer cell line: a kind gift from Dr. C. Cepko). The cell were selected with Geneticin, and cultured for 4 weeks. Those cells expressing MAP2 were identified by immunocytochemistory at a nonpermissive temperature(33-35°C), but not at the permissive temperature. The cloned cells differentiated at the non-permissive temperature, and divided at the permissive temperature. The cloned cell line stained negative for neurofilament (68kD), GFAP, vimentin and TH and positive for c-fos, \(\beta\)-tubulin, tau, MAP2 and SV40LT. This cloned, temperature-sensitive cell line could become a useful molecular biological model for become a useful molecular biological model for studies of neuronal differentiation. It might also prove to be of value as a source of donor cells for neuronal transplantation in models of neurodegenerative diseases.

MICROGLIA PROGENITOR CELLS IN ASTROGLIA CULTURES. J. Neuhaus, A. Richardson, G. Blevins, E.M. Abd-El-Basset and S. Fedoroff.\* Department of Anatomy, University of Saskatchewan, Saskatoon, SK \$7N OWO

When mouse astroglia cultures of newborn mice were nutritionally deprived for up to 10 days, macrophage-like cells identified as microglia developed (Hao et al., Int. J. Dev. Neurosci. 9:1-14, 1991). Such cultures contained microglia progenitor cells which did not express Mac-1 or F4/80 and could not be distinguished from astroglia. It seems that microglia progenitor cells do not proliferate, but give rise to microglia by transformation. Once the microglia are formed then in the presence

by transformation. Once the microglia are formed then in the presence of CSF-1 they proliferate extensively and assume a specific phenotype. Using limiting dilution analysis, it was found that in the presence of astroglia-spent medium, 2% of the cells formed microglia; in the presence of CSF-1, 3.8%; and 12.5% in the presence of CSF-1 and a STO cell feeder layer. CSF-1 and a feeder layer or still unknown factor(s) produced by mesodermal cells, appear to be required for the formation of microglia. Analysis of microglia formation in osteopetrotic mice (op/op) which lack CSF-1, also indicated that a factor in addition to CSF-1 is required for microglia formation.

to CSF-1 is required for microglia formation.

Thus, in cultures initiated from newborn animals at least 12.5% of Thus, in cultures initiated from newborn animals at least 12.5% of the cells are microglia progenitor cells which transform into macrophage-like cells in the presence of trophic factors and proliferate when CSF-1 is present.

# 180.10

NEUROTROPHIN-3 IS BOTH MITOGENIC FOR NEURAL CREST (NC) CELLS AND STIMULATES SURVIVAL AND/OR NEURONAL DIFFERENTIATION OF POSTMITOTIC NC PROGENITORS. C. Kalcheim\*, A. Rosenthal\*\*, C. Carmeli and O. Israeli. Dept. Anat. & Embryol. Hebrew Univ.-Hadassah Med. School. Jerusalem 91010. Israel. \*\*Genentech, Inc. South San Jerusalem 91010. Israel. Francisco, CA 94080. U.S.A.

Neurotrophin-3 (NT-3) is mitogenic for cultured avian NC cells (Kalcheim et al, PNA'S 89, 1661-65, 1992). We now report that this factor also promotes the surivial and/or differentiation of a subset of postmitotic NC precursors into neurons expressing the HNK-1, A2B5 and neurofilament epitopes. NC cells derived from 48 hr clusters were grown on top of mesodermal cells. As early as one day after coculture, a 2-fold increase in neuronal number over controls was measured upon treatment with 1 number over controls was measured upon treatment with I mg/ml NT-3. No further stimulation was obtained when higher factor concentrations were used. Localization experiments using specific anti NT-3 antibodies which do not cross react with either NGF or BDNF, revealed that NT-3 immunoreactivity is expressed by neuroepithelial cells of quail neural tubes both in vitro and in sections of E3 and E4 embryos. Staining was also evident on the fibers of developing central neurons, i.e; in the early marginal zone and ventral roots. We propose that NT-3, a factor expressed in the early avian CNS, has multiple effects both on the proliferation and differentiation of distinct NC cells, which depend on the state of commitment of the responsive progenitors.

NON-NEURONAL CELLS INHIBIT CATECHOLAMINERGIC DIFFERENTIATION OF PRIMARY SENSORY NEURONS. G. Fan\* and D. M. Katz. Department of Neurosciences, Case Western Reserve University, Cleveland, OH 44106

Sensory neurons exhibit marked phenotypic heterogeneity, including expression of diverse transmitter traits. To elucidate underlying developmental mechanisms, we are studying expression of the catecholamine synthesizing enzyme tyrosine hydroxylasc (TH) in sensory ganglion cells of the rat. Although some mature sensory neurons are catecholaminergic (CA), most ganglion cells only transiently express TH during early embryogenesis (E10.5-15.5; Katz & Erb, 1990; Jonakait, et al., 1984). The lack of CA expression at later stages appears to be due to modulation of this phenotype by factors related to cell aggregation (Katz, J. Neurosci. 11: 3991, 1991). For example, 20-40% of E16.5 trigeminal (TG) and jugular ganglion neurons express TH in dissociate cell culture even though TH is not detectable *in vivo* at this age. Moreover TH levels are inversely related to cell density, a four-fold increase in density leads to a 30-50% drop in the percentage of TH cells. This density-dependent effect appears to be mediated by ganglionic non-neuronal cells (NNC), because 1) plating E16.5 TG neurons at low density on top of NNC monolayers mimicked the effect of high cell density, 2) treatment with NNC conditioned-medium (NNCM) reproduced the effect of coculture with NNC and 3) plating neurons at high density in the absence of NNC had no effect on TH levels. The inhibitory effect of NNCM was mimicked by Ciliary Neurotrophic Factor (CNTF, 10 ng/ml) and Leukemia Inhibitory Factor (LTF, 5-20 ng/ml), two peptides known to inhibit TH expression in sympathetic neurons, suggesting that these or related molecules, may mediate NNC effects on the sensory CA phenotype. Ganglionic NNC may therefore play an important role in shaping sensory transmitter diversity by modulating expression of specific molecular phenotypic traits. Supported by HL-42131 (DMK) and the Dysautonomia Foundation.

NEUROFILAMENT EXPRESSION AND PRIMARY NEURONS IN THE EMBRYONIC ZEBRAFISH. R.C. Marcus\*, L. Stec and S.S. Easter, Jr. Dept. of Biology and Neuroscience Program, University of Michigan, Ann Arbor, MI 48109.

Neurofilaments (NF) are neuron-specific intermediate filaments useful as markers of neuronal differentiation. We examined NF expression in the embryonic zebrafish using an antibody generated against rat NF (RMO44, kindly provided by V. Lee). Labeled embryos at 24, 36, 48 and 72h post fertilization, were viewed as wholemounts and in sections.

At 24h many identified neurons were labeled in the spinal cord; Rohon-Beard cells, CaPs, some RoPs and MiPs, and CoPAs. Two bilateral pairs of neurons were labeled in the hindbrain, Mauthner cells and a pair further rostral in rhombomere two. Neurons in the trigeminal ganglion were also labeled. By 36h labeled reticulospinal neurons were located in seven clusters in the hindbrain. In the midbrain, 2-3 cells in the nucleus of the MLF labeled per side. At 48 and 72h there were more labeled neurons in the trigeminal ganglion, hindbrain clusters and in the nucleus of the MLF, but except for one or two axons traced rostral of the nucleus of the MLF at 48h, no other label was found in the mid and forebrains.

Labeled cells correspond closely, but not exclusively, to "primary neurons", a developmentally distinct population of cells. Cells in the mid and forebrains are generated and extend axons at times similar to labeled neurons in the hindbrain and spinal cord, indicating that RMO44-labeling does not depend on neuronal birthdate or axonal outgrowth. The restricted labeling pattern of the antibody makes it a useful marker for the study of identified neurons and may provide a useful addition to the study of primary neurons.

Supported by NIH grants EY00168 and EY07022, and NSF 027832.

#### 180.12

THE EVALUATION AND PURITY OF MYOBLAST CULTURES FROM CHILDREN vs. ADULTS BY IMMUNOSTAIN AND FLOW CYTOMETRY. Q. Fang\*, M. Dockter, P.K. Law. Cell Therapy Research Foundation, Memphis, TN 38117 and Dept. of Medicine, University of Tennessee, Memphis, TN 20162

Myoblast Transfer is an experimental therapy being developed for hereditary myopathies. Its success relies on the purity and vigor of the donor myoblasts. The selection of donor thus becomes an important factor.

Muscle biopsies obtained from ten donors, aged between eleven to forty, were processed for myoblast culture. Purity of the ten cultures were assessed by immunostain with Leu 19, a monoclonal antibody that reacts with human myoblasts and regenerating muscle fibers, using the FACS flow cytometry.

| Donor | Age(yr) | Myoblast Purity(%) |
|-------|---------|--------------------|
| 1     | 40      | 81.23              |
| 2     | 12      | 93.56              |
| 3     | 15      | 93.74              |
| 4     | 11      | 96.46              |
| 5     | 31      | 75.12              |
| 6     | 13      | 97.83              |
| 7     | 18      | 92.20              |
| 8     | 36      | 86.68              |
| 9     | 12      | 95.86              |
| 10    | 35      | 89.22              |
|       |         |                    |

Myoblast purity was between 75.12% and 89.22% from father donors. It was between 92.20% and 97.83% from brother donors. The result indicates that purer myoblast cultures can be obtained from younger donors. (Supported by PHS NS 26185 to PKL.)

MULTIPLE MECHANISMS FOR THE INDUCTION OF ECTOPIC SENSILLA IN THE WING OF *DROSOPHILA*. S.S.Blair• and E.Rulifson. Dept. Zoology, U. Wisconsin, Madison. WI 53706.

The positioning of sensilla precursors in the developing wing blade of *Drosophila* is thought to arise through a multi-step process: positional information roughly defines patches of proneural cells; these cells express proneural genes (scute and achaete) rendering them competent become sensilla; refinement defines single or multiple sensilla within these patches; finally, the sensillar and non-sensillar identity of the cells is maintained. Mutations can thus result in the formation of ectopic sensilla by interfering with different steps in this process. We examined the timing and localization of several mutations in order to understand their effects in terms of this model.

We have found that hairy and Hairy wing act late in development, interfering throughout the wing with maintenance after normal sensillar specification has taken place. Notch, on the other hand, induces ectopic sensillar cells only within regions corresponding approximately to regions of proneural gene expression; Notchie experiments suggest that Notch is required for maintenance as well as refinement. Finally, shaggy induces the formation of novel proneural regions, apparently interfering with expression or interpretation of positional information; the ectopic expression of the margin-specific gene vestigial in shaggy clones is consistent with a novel partial transformation towards a marginal identity

CROSS-LINKING OF MEMBRANE-ASSOCIATED GM1 BY B SUBUNIT OF CHOLERA TOXIN MODULATES [Ca<sup>2+</sup>]i AND DIFFERENTIATION IN SENSORY NEURONS. D. Milani\*. M.-C. Minozzi, L. Petrelli, D. Guidolin, S.D. Skaper and P.E. Spoerri. Fidia Research Laboratories, Abano Terme, Italy.

Research Laboratories, Abano Terme, Italy.

The B subunit of cholera toxin, which binds specifically to GMI ganglioside on cell surfaces, has been shown to modulate intracellular free calcium concentration,  $[\text{Ca}^{2+}]$ i, and cellular growth. To explore a role of such changes in  $[\text{Ca}^{2+}]$ i in the growth regulatory function of cell-associated GMI in neurons, chicken embryonic day 8 dorsal root ganglion neurons were exposed to B subunit. Incubation of naive cultures with lug/ml of B subunit produced modest increases in  $[\text{Ca}^{2+}]$ i in 37% of cells, as measured by fura-2 imaging. GMI pretreatment of cells for 48 h increased even further the elevations in  $[\text{Ca}^{2+}]$ i and the percentage of responding neurons observed after B subunit exposure. Such changes in  $[\text{Ca}^{2+}]$ i were accompanied by fine alterations in morphology, mostly affecting the branching of neurites; these effects were more pronounced in GMI-pretreated neurons. Immunogold electron microscopy using anti-B subunit depicted extensive aggregations of immunoreactive gold particles on neuronal surfaces, especially in cells treated with GMI. These results suggest that modification of cell membrane ganglioside distribution together with modulation of  $\text{Ca}^{2+}$  homeostasis can influence differentiation of neuronal cells.

ASSEMBLY OF THE 66-kDa NEUROFILAMENT PROTEIN (NF-66) in vitro AND ITS ASSOCIATION WITH NF-L, NF-M and NF-H PURIFIED FROM BOVINE SPINAL CORD. B.J. Balin\* and M.E. Miller, Med. Coll. of Penn., Dept. Path. & Lab Med, Div. Neuropath., 3200 Henry Avenue, Phila., PA 19129. NF-66, also known as alpha-internexin, has been characterized as a 66-kDa

mammalian neurofilament (NF) protein whose expression in developing rat brain precedes that of the low molecular weight NF protein (NF-L). NF-66 is thought to assemble into 10nm-diameter intermediate filaments in vitro, although the nature of the assembly process remains unclear. Likewise, the ability of NF-66 to associate and/or polymerize with the low (NF-L), middle (NF-M) and high (NF-H) M, NF proteins has not been delineated. Therefore, this study was initiated to determine the reassembly properties of NF-66 regarding its formation into 10nm filaments and its polymerization capabilities with other well-characterized NFs. NF-66 was isolated from bovine spinal cord using established biochemical extraction and isolation procedures (Balin et al., Brain Research (1991) 556:181-195), and purified utilizing HPLC DEAE anion exchange and hydroxyapatite column chromatography. Initial experiments of the reassembly of NF-66 (0.8mg/ml) against 0.1M MES buffer, pH 6.8 at room temperature for 2hr revealed that ~10 nm-diameter filaments of varying length were formed. Immunoelectron microscopy revealed labeling of these filaments by a monoclonal antibody to intermediate filament antigen (IFA). Furthermore, our preliminary studies of the association of NF-66 with GFAP, a type III intermediate filament, indicate that NF-66, indeed, may co-assemble with other 10nm-diameter intermediate filaments. Co-assembly experiments utilizing monoclonal antibodies to NF-66 and NF-L, NF-M and NF-H are in progress to determine the exact nature of NF-66 assembly and/or association with other NFs. These studies suggest that NF-66 can self-assemble in vitro under defined conditions and that the interactions of NF-66 with other NFs may prove important to the development of the axonal NF network. Supported by PHS grant AG10160.

KINESIN IS REQUIRED FOR NEURONAL MORPHOGENESIS J.R.Mancillas\* and G. DeFeo. Dept. of Anatomy and Cell Biology, UCLA School of Medicine, BRI & Molecular Biology Inst. UCLA, Los Angeles, CA 90024.

Differentiated neurons display a unique, complex cytoarchitecture and a high degree of regional specialization. Converting differentially expressed genetic information into a distinct neuronal morphology requires the well regulated spatial distribution of macromolecules and cellular organelles. To evaluate the role of the motor protein kinesin in the translocation of components required for neuronal differentiation, we analyzed the morphology of neurons in specimens of C. elegans containing mutations in the gene encoding the kinesin heavy We observed abnormalities in axonal morphology (frequent prominent varicosities and variations in caliber), neurite length, neuritic branching patterns, microtubule distribution, and axonal trajectories. E.M. analysis reveals cytoskeletal abnormalities associated with some of the defects observed, suggesting inappropriate assembly of the cytoskeletal scaffold during neurite extension and branching. Our findings suggest previously unreported roles for kinesin in the development or maintenance of neuritic structure and in the formation of the stereotypical patterns of axonal projections. Since the base of the growth cone is the primary site of neurite assembly, kinesin may be involved in the establishment of the precise spatial arrangement of cytoskeletal proteins during neuronal morphogenesis by translocating cellular constituents essential for normal growth cone dynamics or by a direct participation in the interactions between cytoskeletal elements when the neuritic scaffold is being erected.

DEVELOPMENTAL TIME COURSE OF THE EXPRESSION OF A NEURON-SPECIFIC  $\beta$ -TUBULIN IN FROG. V.L. Miller\*, A. Frankfurter and S.A. Moody. Depts. Neuroscience, Biology and Anatomy & Cell Biology, Univ. Virginia, Charlottesville, VA 22908.

 $\beta$ -Tubulins are encoded by several genes whose proteins are distinguished by unique sequences at the carboxy terminus. Class III  $\beta$ -tubulin is neuronspecific in mammals and birds, but antibodies that specifically recognize this isotype do not stain frog or fish brain. A gene that encodes a neuron-specific  $\beta$ -tubulin in frog recently has been sequenced (Good et al. 1989 Nucleic Acids Res. 17:8000), and is homologous to the mammalian Class II \(\beta\)-tubulin: human: YQQYQDATADEQGEFEE<u>EGEEDEA</u>
Xenopus: YQQYQDATADEQGEFEEEE\*DEA Developmental Northern analysis shows that the mRNA for this gene is first detectable at Xenopus stage 17, during neural tube closure (Richter et al. 1988, PNAS 85:8086). Using an antibody raised against a peptide sequence (underlined above) in the C-terminus of mammalian Class II \(\beta\)-tubulin (Banerjee et al.,1988,J.Biol.Chem.263:3029) we stained a developmental series of Xenopus embryos with standard PAP-immunohistochemical procedures. Protein staining is not detected until st 21 (closed neural tube), where it appears in the longitudinal and commissural tracts of the hindbrain and spinal cord, and in the trigeminal ganglion cells and their processes. The only other cell bodies detected were those of Rohon-Beard and extramedullary cells. Staining in the axonal tracts was coordinated with their known time course of development. Retinal ganglion cells and axons stained by st 38. The pattern of staining in the tadpole (st 41-48) was in peripheral neuron cell bodies and axons, central neuron axons only, and a few scattered cells in the gut. This antibody is an excellent marker of pioneer axons in the frog. Our results suggest that in embryonic frog Class II, rather than Class III,  $\beta$ -tubulin is the neuron-specific gene product. Supported by HD07192, NS23158 and NS21142.

MAP 2-IMMUNOREACTIVITY AND CYTOCHROME OXIDASE-ACTIVITY IN THE RETICULAR NUCLEUS OF THE HUMAN FETAL THALAMUS. N. Ulfig (SPON: European Neuroscience Association) Dept.Anatomy, J.W.Goethe-University, D-6000 Frankfurt/M., F.R.G.

Microtubule-associated proteins (MAP) play an important role in assembly and stabilization of microtubules. Three subforms are distinguished within the MAP group 2: high-molecular-weight MAP 2a and 2b are only found in mature neurons. low-molecular-weight MAP 2c is found in immature neurons. MAP 2 is found in soma and dendrites. Dendritic development is controlled by afferent input. Functional synaptic input can be demonstrated indirectly with the aid of cytochrome oxidase (CO)-activity (Wong-Riley, TINS 12: 94-101, 1989). Frozen sections of human fetal thalami (age: 15th-23rd week) are incubated with anti-MAP 2 (marks all MAP 2-subforms) and anti-MAP 2ab. In unfixed cryostat sections CO-activity is demonstrated histochemically. In the 16th week the distribution of MAP 2- and MAP 2ab-immunoreactive structures in the reticular nucleus is similar so large amounts of MAP 2c are no longer visible. Adjacent thalamic nuclei reveal much more MAP 2 than MAP 2ab-immunoreactive structures which indicates that considerable amounts of MAP 2c are present. In numerous reticular neurons a high CO-activity is detectable in the 16th week whereas adjacent thalamic nuclei reveal only a very slight activity. In the 20th week the other thalamic nuclei do no longer show significant amounts of MAP 2c, they display higher amounts of CO-activity so these nuclei are later differentiated than the reticular nucleus. (Support: P.C.Weill-Stiftung)

DELETION OF KINESIN HC TAIL DOMAIN SELECTIVELY DISRUPTS ITS ROLE IN NEURONAL MORPHOGENESIS N. Patel\* G. DeFeo and J. R. Mancillas. Molecular Biology Inst. UCLA, and Dept. of Anatomy and Cell Biology, UCLA School of Medicine, Los Angeles, CA 90024

Kinesin heavy chain (KHC) consists of 3 domains: a motor domain containing the microtubule-binding and ATPase sites, a stalk implicated in dimerization and a tail domain believed to be the site of interactions with transported organelles and macromolecules. We have cloned and sequenced the C. elegans homologue of KHC, unc-116, and analyzed the phenotype of 2 mutant alleles. Kinesin defective mutants display an 80% penetrant embryonic lethality, gross morphological abnormalities, severe impairments in various behaviors and a discrete set of abnormalities in neuronal cytoarchitecture. A weak mutant allele, e2281, displays only mild abnormalities in locomotion and defects in neuronal morphology. We have identified the e2281 mutation as a transposon (TC5) insertion into the coding region of unc-116. The site of insertion was localized between Rodll and the tail domain. Sequence analysis suggests that the mutant gene encodes a truncated protein product missing the entire tail domain, which is replaced by 19 amino acids encoded in the transposon. The restricted phenotype of e2281 suggests that absence of the tail domain causes the defects in neuronal morphogenesis in all alleles. They may be due to the disruption of kinesin-mediated interactions between cytoskeletal elements in the growth cone that require the tail domain. Translocation of cellular components involved in functions not disrupted in e2281 may be mediated by the Rod II region of the stalk domain.

PROCESS FORMATION BY MAP 2-TRANSFECTED NON-NEURONAL CELLS TREATED WITH CYTOCHALASIN. B. Weisshaar, K. Edson and A. Matus\*. Friedrich Miescher Institute, 4002 Basel, Switzerland.

The neuron-specific microtubule-associated protein MAP2 and the embryonic version MAP2c are believed to influence neuronal morphogenesis by promoting the formation and stabilization of microtubules in neuronal processes. To investigate the underlying molecular mechanism, rat cDNAs for both high-molecular weight MAP2 and low-molecular weight MAP2c were expressed in non-neuronal cells by transfection. In the human hepatoma cell-line PLC, which does not express endogenous MAP2, the exogenous MAP2 protein binds to microtubules and leads to their bundling in a concentration dependent manner. If MAP2-transfected cells were then treated with the actindepolymerizing drug cytochalasin B, processes formed on these cells. These processes contained bundled microtubules, and time-lapse video microscopy suggested that the processes push out from the cell-body when the cortical actin cytoskeleton is depolymerized. Process formation was completely reversible when cytochalasin was washed out from the culture medium. This suggests that MAP2 does not only promote the formation and stabilisation of microtubule bundles, but also that these bundles have an inherent ability to lead to process formation when they are not inhibited by the cortical actin cytoskeleton.

REDISTRIBUTION OF DREBRIN TO SUBMEMBRANOUS REGION FROM CYTOPLASM BY NEURONAL DIFFERENTIATION. H.Asada', T.Shirao'\*, M. Toda', S. Toya', and K. Uyemura', Department of 'Physiology and 'Neurosurgery, Keio University School of Medicine, Tokyo 160, JAPAN

Drebrins are developmentally-regulated actin-binding proteins (Shirao,et al, NeuroReport, 1992). In this study, we demonstrated that cultured human SY5Y neuroblastoma cells contain drebrin E (embryonic type), by Western blotting analysis of two-dimensional gel electrophoresis. Confocal microscopy demonstrated that patchy drebrin immunoreactivity appeared scattered in the cytoplasm of control cells. Two weeks after retinoic acid treatment (10<sup>-5</sup>M), expression of neurofilament proteins was increased in differentiated SY5Y cells. In parallel with this neuronal differentiation, subcellular localization of drebrin changed to submembranous regions. This drebrin subcellular localization was consistent with those in primary cultured neurons. A close relationship between drebrin and F-actin in subcellular localization was observed. F-actin within undifferentiated SY5Y cells was continuously present in stress fibers and drebrin was discontinuously present in the same regions. In differentiated SY5Y cells, however, drebrin was localized continuously with F-actin. F-actin in the submembranous region, which binds to drebrin, was more stable against cytochalasin-D, an actin depolymerizing agent, than F-actin, which does not bind to drebrin, in the stress fibers. INDUCTION OF CELL PROCESS OUTGROWTH WITH SUBMEMBRANOUS ACTIN FILAMENTS IN FIBROBLASTS BY DREBRIN A OVER-EXPRESSION. T. Shirao, H. Asada, P. Kaub, K. Yamaguchi\* and K. Uyemura. Department of Physiology, Keio University School of Medicine, Tokyo 160; Natl. Inst. for Physiol. Sci. Okazaki 444, JAPAN.

Neuron-specific actin-binding protein, drebrin A, was expressed in parallel with neurite outgrowth and synapse formation during brain development (Dev. Brain Res. 29: 233,1986). In adult it localized in the dendrite (Brain Res. 413:374,1987). Over-expression of drebrin A in fibroblasts induced the formation of highly branched processes from the cell perimeter (NeuroReport, 3:109,1992). We proposed that drebrin plays important roles in neuronal morphogenesis and in remodeling of neuronal connections in the adult. To investigate cellular functions of drebrin A, fibroblast cell lines were transfected with a drebrin A expression plasmid, which contained either the B-actin promoter or the metallothionein promoter. In the transfected cells, expressed drebrin A is co-localized with F-actin. Transfected cells that expressed a large amount of drebrin A changed the subcellular localization of actin filaments and extended a number of processes from a round cell body. The percentage of process-bearing transformants is in parallel with induction of drebrin A expression by cadmium ion. Thus we conclude that drebrin A contributes directly to neurite outgrowth. [Supported by grant from the Ministry of Education, Science and Culture in Japan.]

DEVELOPMENTAL DIFFERENTIATION OF EMBRYONIC HUMAN MESENCEPHALIC DOPAMINERGIC NEURONS IN VIVO AND IN VITRO. P. Almqvist\*, F. Souverbie, E.-B. Samuelsson, H. Pschera¹, Å. Seiger and E. Sundström. Depts. of Geriatric Medicine and Obstetrics & Gynecology¹, Karolinska Institute, Huddinge University Hospital, S-141 86 Huddinge, Sweden.

The present study emphasize to characterize the morphological and neurochemical differentiation of mesencephalic dopaminergic neurons from human embryos, derived from elective first trimester abortions. Mesencephalic tissue was taken for analyses of dopamine (DA) content using HPLC-ED and for tyrosine hydroxylase (TH) immunohistochemistry, as well as for primary culture. TH-immunoreactive neuroblasts were first seen in the ventral mesencephalon at 5 weeks postconceptional age. Detectable levels of DA were found at the same age and increased exponentially during the first trimester.

Mesencephalic cells and cells from target areas (striatum, cerebral cortex) were cultured in separate but connected wells in order to supply dopaminergic neurons with diffusible, trophic factors. Basic fibroblast growth factor (bFGF) added to the growth medium was found to further improve survival and differentiation of TH-immunoreactive cells. Dissociated, mesencephalic primary cultures were plated at 5 - 9 weeks of gestational age and maintained in vitro for several weeks without even brief exposure to antibiotics. TH-immunoreactive neuroblasts with large rounded cell somata, each with a single axonal process and several minor neurites, were detected in cells from 5 week old embryos after 1 week in culture. Neurites extended successively with time in culture, developed varicosities and formed an extensive network. TH-positive cells migrated rapidly to associate with highly proliferative supportive cells. Mesencephalic tissue older than 8 weeks did not survive in long-term culture. For detection of monoamines, cultured mesencephalic cells were harvested and subjected to HPLC-ED analysis. With addition of TH-cofactor tetrahydrobiopterin (BH<sub>Q</sub>) to the culture medium, DA could be detected at 5 + 2.5 weeks, at an approximate concentration of 0.5-1 ng/500-1000 TH-immunoreactive neurons. In conclusion, TH-expression and DA-synthesis are maintained in 5 - 8 week old mesencephalic cells during differentiation in vitro.

DIFFERENTIATION AND NEUROFILAMENT EXPRESSION IN IMMORTALIZED CELL LINES DERIVED FROM RAT MESENCEPHALON. H. Takashima\*, M. Marone †, H. M. Geller † and W. J. Freed. NIMH Neurosci. Centr. at St. Elizabeth. Washington D.C. 20032. †Dep. of Pharmac. UMDNJ-RWJMS, Piscataway, NJ 08854.

Several immortalized cell lines have been established from the E12-E14 ventral mesencephalon of the rat using a retroviral vector containing the temperature-sensitive mutant (tsA58) of SV40 large T antigen. At the permissive temperature (33°C) most clones appeared polygonal with only occasional short processes and were positive for SV40 T antigen. Several of the clones stopped growing at the nonpermissive temperature (39.5°C) and extended processes. A cell line derived from E14, designated K1, was confirmed to be a single clone by Southern blotting. One subclone (K1S) which shows contact inhibition developed neurofilament-positive processes at 39.5°C. When differentiation was further stimulated with a mixture of bFGF. IBMX and dibutyryl cAMP at 39.5°C with 10% FCS, this clone developed elongated processes and a neuron-like multipolar morphology. Expression of neurofilament was promoted by adding conditioned medium from rat brain culture. Another subclone (K1K) which does not show contact inhibition developed a similar morphological change including development of processes, when cultured with bFGF, IBMX and dibutyryl cAMP, but was negative for neurofilament. Characterization of neurofilament expression in additional clones isolated from E12-E13 rats is in progress. Supported in part by NIH grant P01 NS 21469.

COMPLEX EXTRACELLULAR MATRIX BUT NOT LAMININ INCREASES VESICLE DENSITY IN SYNAPTIC PROFILES OF SYMPATHETIC NEURONS IN VITRO. M. Loegering, D. Higgins, + and M.I. Johnson\*. Univ. of Ariz. Col. of Med., Tucson, AZ 85724 and SUNY +, Buffalo, NY 14214.

Although well-studied at the neuromuscular junction, the role of extracellular matrix (ECM) in synaptogenesis in the autonomic nervous system has received little attention. Our previous studies found that complex ECM increases vesicle numbers in axonal varicosities of cultured sympathetic neurons. These studies have now been extended to include an analysis of the effect of a major component of ECM, laminin.

Nonglial-cell-containing dissociated embryonic rat sympathetic neurons were grown on polylysine or laminin adsorbed to polylysine. Polylysine cultures received either defined medium or defined medium containing 50  $\mu$ g/ml of ECM (Matrigel, Collaborative Research, Inc.). Laminin grown cultures remained on defined medium. After 3 weeks, the cultures were processed for electron microscopy and subjected to analysis by stereology. Vesicle density within varicosities found in polylysine or laminin cultures (on defined media) was less than neurons treated with ECM (1820  $\pm$  186 or 1766  $\pm$  261 vs. 5903  $\pm$  544 vesicles/ $\mu$ M³; mean SEM; p < .000l). Varicosities along the axons were increased with ECM treatment (2.5  $\pm$  0.5 vs. 0.8  $\pm$  .2 varicosities/mm; p < .004). More varicosities (I.28  $\pm$  .24) were found within 3  $\mu$ M of an index varicosity in the ECM group than in the polylysine group (.45  $\pm$  .12; p < .002). Varicosity clustering on laminin, however, was similar to the ECM group  $(1.75 \pm .14 \text{ per index varicosity; p} > 0.05)$ . We conclude that laminin appears to affect clustering of varicosities but some other component(s) contained in the ECM result in the vesicle density changes. AGRIN EXPRESSION IN THE DEVELOPING RAT M. Ferns. J. Campanelli, W. Hoch, F. Rupp, R. Scheller, & Z.Hall\*. Dept. Physiol. UCSF, SF, CA 94143-0444 and HHMI, Dept. Molecular. & Cellular Physiol. Stanford Univ. Stanford, CA 94305

and HHMI, Dept. Molecular. & Cellular Physiol. Stanford Univ. Stanford, CA 94305.

Agrin, a component of the synaptic basal lamina at the adult neuromuscular junction, is thought to be the neurally-derived factor responsible for the initial clustering of AChRs at developing synapses. Agrin expression is not limited to motoneurons however, raising the question of whether agrin in other cells of the CNS or in muscle also participates in synaptogenesis, or serves other functions. To address these questions we have examined agrin gene and protein expression in brain, spinal cord and muscle in the developing rat. Northern blotting of tissue extracts at all stages revealed a single agrin transcript of 8.2 kb in the three tissues, with the mRNA being more abundant in brain and spinal cord than in muscle. In each tissue, the transcript was at its highest levels prenatally and declined during the postnatal period. Interestingly, whilst expression of the transcript in spinal cord was relatively constant during the time of initial synapse formation (embryonic day [E)14-birth), expression in limb muscle peaked early in neuromuscular development, at E16. The agrin protein was identified as a single band of 200kD in immunoblots, and in preliminary experiments showed a pattern of expression corresponding to that seen for the mRNA. Immunostanting of limb sections showed that agrin immunoreactivity is initially widespread within early stage muscles [E14-16] and with development progressively becomes restricted to the synaptic regions. We conclude that agrin expression in the spinal cord and brain is highest during synaptogenesis. Muscle also expresses agrin during this period, although its widespread, extrasynaptic distribution prenatally suggests that it may have roles other than in clustering of receptor. Such different biological activities and roles for agrin may be related to the occurrence of multiple forms of the protein generated by alternative RNA splicing.

BIOCHEMICAL CHARACTERIZATION OF A PUTATIVE AGRIN RECEPTOR FROM *TORPEDO* ELECTRIC ORGAN <u>Jianyi Ma\* and Justin R. Fallon</u>, Worcester Fdn. for Exper. Biol., Shrewsbury, MA. 01545

The putative agrin receptor is a plasma membrane protein that binds agrin and is likely to mediate agrin-induced AChR clustering on cultured myotubes. Our previous biochemical characterization of the putative agrin receptor from *Torpedo* electric organ indicates that this receptor is an integral membrane protein distinct from the AChR that is selectively concentrated in postsynaptic-rich membrane fractions. Here, we report the further biochemical characterization of the putative agrin receptor. Agrin binding to postsynaptic-rich membranes is unaffected by pretreatment of the membranes with phosphatidylinositol phospholipase C. The solubilized putative agrin receptor from *Torpedo* electric organ selectively binds to several lectins that recognize galactose, Nacetylglucosamine and a-linked mannose, but not to lectins that recognize fucose. In addition, agrin, but not the putative agrin receptor binds to heparin, indicating that agrin binding to membranes is not homophilic. We have determined the optimal conditions of calcium concentration, pH, ionic strength and detergent for agrin binding to the solubilized putative agrin receptor. Agrin affinity columns bind the putative agrin receptor, but not the AChR. Taken together, these results indicate that the agrin receptor is a transmembrane glycoprotein that is distinct from agrin itself and the AChR. We are currently using agrin affinity methods to identify and purify this receptor. Supported by the NIH and the March of Dimes.

AGRIN GENE EXPRESSION IN DEVELOPING CHICK CILIARY GANGLION.

W.S. Thomas\*§, D.K. O'Dowd†§, M.A. Smith.

Dept. Anat. and

Neurobiol§: Dept. Dept. and Cell Biol † HC Irvine. CA 92717

W.S. Inomas\*\*, D.R. O Dowq\*, M.A. Smith, Dept. Anat. and Neurobiol\*, Dept. Dev. and Cell Biol.†, UC Irvine, CA 92717.

We are interested in identifying factors that regulate agrin gene expression. As a first step, we have begun to examine agrin expression in chick ciliary ganglion (CG), a parasympathetic ganglion whose normal targets include both smooth and striated muscle cells in the eye. Using oligonucleotide primers derived from a chick brain agrin cDNA (Tsim et al., 1992) we have identified agrin transcripts in embryonic CG by PCR. Previous studies have shown that active and inactive forms of agrin are products of alternate splicing of a single gene. Transcripts encoding active agrin contain a 33bp exon that is absent from those encoding inactive forms of the protein (Ruegg et al., 1992). Our PCR analysis indicates that CGs express mRNAs containing and lacking this 33bp exon, consistent with the presence of both active and inactive forms of agrin in the ganglion. We also report the presence of a transcript that contains an additional 24bp exon, contiguous with the 5' end of the 33bp sequence, that may also encode an active agrin protein. In situ hybridization demonstrates that agrin transcripts are present as early as 8d and throughout embryonic development in both neurons and glial cells in the ganglion. In addition, levels of expression of transcripts that contain the 33bp exon alone, are high at 8d in ovo and decline with development. These studies demonstrate that the agrin gene is expressed in parasympathetic neurons that innervate striated and smooth muscle cells. Expression levels of at least one agrin transcript are developmentally regulated, the highest level coincident with the onset of synapse formation in the periphery. Supported by NIH NS-27563.

### 182.6

AGRIN GENE EXPRESSION IN ADULT RAT CNS AND ITS REGULATION BY SEIZURE ACTIVITY. L.T. O'Connor\*, J.C. Lauterborn, C.M. Gall, and M.A. Smith. Dept. of Anatomy and Neurobiology, University of California, Irvine, CA 92717.

Agrin is an extracellular matrix protein thought to play a critical role in development and maintenance of the neuromuscular junction. Detection of agrin mRNA in brains of adult electric rays and embryonic rats and chickens raises the possibility that agrin may also play a role in synaptogenesis in the CNS. As a first step towards understanding agrin's role in the CNS, we have used probes derived from a rat agrin cDNA (Rupp et al., 1991) to analyze the regional and cellular distribution of agrin mRNA in the adult rat brain and to examine whether changes in synaptic activity can influence its expression. Northern blot analysis shows a single band of approximately 8kb present in RNA isolated from all regions of adult brain examined. Consistent with this observation, in situ hybridization studies using 35S-labelled cRNA probes reveal that agrin mRNA is widely distributed throughout the adult brain; expressed in cholinergic as well as non-cholinergic areas. We have also observed that levels of agrin mRNA can be influenced by seizure activity. For seizure studies, an electrolytic lesion is placed in the hilus of the dentate gyrus that induces a period of recurrent limbic seizures for 8-10 hrs. Rats sacrificed 24hrs postlesion exhibited increased levels of hybridization in the caudate, septum, and intermediate layers of neocortex but markedly reduced levels in superficial layers of neocortex and piriform cortex. These findings demonstrate that agrin is widely expressed in adult CNS and its expression can be influenced by changes in synaptic activity induced by seizures. Supported by NIH NS-27563 to M.A.S., NS-07351-01 to L.T.O., and NS-26748 to C.M.G.

METABOLIC KINETICS OF ENDOGENOUS NERVE GROWTH FACTOR.
K. Siminoski and B. Tobin. Department of Medicine,
University of Alberta, Edmonton, Alberta, Canada T66 252.
Nerve growth factor (NGF) is produced in most tissues of
the body and is supplied locally to target neurons. To
assess the endogenous whole-body utilization and metabolism
of NGF, we have administered tracer doses of <sup>125</sup>I-labelled
growth factor to 5 rats and monitored serum levels for up to
4 days. Intact NGF was determined by TCA precipitability.
Intact NGF was cleared from plasma with 3 slopes,
consistent with 2 distinct non-plasma NGF compartments. An
average endogenous NGF molecule was in the body 1120+/-270
min, of which 70+/-20 min were spent in the blood. After
first entering the circulation, NGF exited and subsequently
re-entered 1.8+/-0.4 times. Fractional catabolic rate was e-entered 1.8+/-0.4 times. Fractional catabolic rate was

re-entered 1.8+/-0.4 times. Fractional catabolic rate was 1.3+/-0.3%/min.

NGF metabolites accumulated until about 4 hours, and represented a maximum of 4.4+/-0.4% of the administered NGF dose. Subsequently, degraded NGF disappeared from plasma with 2 sequential slopes, the final one paralleling the terminal slope of intact NGF clearance. Radiolabel accumulation in urine lagged behind plasma disappearance; all urine NGF was degraded, and the excretion rate was directly related to serum levels of degraded NGF.

We have demonstrated that radiolabel tracer methods may

We have demonstrated that radiolabel tracer methods may be useful in assessing whole body NGF kinetics. Accurate analysis requires monitoring intact NGF for at least 36 hours, and the degraded NGF pool at least 72 hours.

### 183.3

ACUTE AND CHRONIC INTRAVENTRICULAR INFUSIONS OF NMDA INDUCE BONF AND NGF mRNA SELECTIVELY IN RAT DENTATE GYRUS GRANULE CELLS. B.J. Gwag\* and J.E. Springer. Department of Neurology, Hahnemann University School of Medicine, Philadelphia, PA 19102-1192.

Events associated with seizure activity and kindling increase mRNA expression of Events associated with seizure activity and kindling increase mRNA expression of nerve growth factor (KOF) and brain-derived neurotrophic factor (BDNF)- a member of the NGF family of neurotrophins- in the central nervous system (CNS). Recently, we found that activation of NMDA receptors induces NGF mRNA expression exclusively in dentate gyrus (DG) granule cells. This increase in NGF gene expression was observed in the absence of both seizure activity and neurotoxicity. The present study investigated whether gene expression of BDNF is also influenced by excitatory transmission via NMDA receptor activation. We also tested whether the expression of mRNA for these two neurotrophins is influenced by long-term (7 dwas) influence of NMDA.

days) infusions of NMDA.

In the first set of experiments, a single, non-toxic dose of NMDA was infused into the lateral ventricle of adult rats, and levels of BDNF mRNA were analyzed over a 24 the lateral ventricle of adult rats, and levels of BDNF mRNA were analyzed over a 24 hour period using in situ hybridization histochemistry. NMDA infusions maximally induced the expression of BDNF mRNA in DG granule cells at 4 hours following infusions, and returned to control levels within 24 hours. In addition, the induction of BDNF mRNA by NMDA was blocked by prior treatment with AP5 (an NMDA antagonist). In the long-term infusion experiment, animals received a single permanent intraventricular cannula attached to an osmotic minipump containing NMDA or AP5. Following 7 days of NMDA infusions, BDNF mRNA levels were significantly enhanced in DG granule cells, while only a slight increase in NGF mRNA levels was observed. The gene expression of both neurotrophins was unchanged following acute or chronic infusions of AP5. These studies provide further evidence that the regulation of genes encoding NGF and BDNF in DG granule cells can occur through NMDA receptor activation. Supported by PHS grants AG-08969 can occur through NMDA receptor activation. Supported by PHS grants AG-08969 and NS-30248 (JES).

LOCAL AND DISTANT SOURCES OF NERVE GROWTH FACTOR (NGF)
MAY PROVIDE TROPHIC SUPPORT FOR NGF-DEPENDENT

MAY PROVIDE TROPHIC SUPPORT FOR NGF-DEPENDENT CHOLINERGIC BASAL FOREBRAIN NEURONS. J.M. Conner and S. Yaron, Department of Biology, 0601, UCSD, La Jolla, CA 92093

The idea that NGF primarily acts as a target derived trophic agent was established in the PNS and accumulating evidence has suggested that a similar role may exist within the CNS. Our previous attempts to localize NGF within the normal adult rat CNS by immunohistochemical methods demonstrated that NGF immunoreactivity (NGF-ir) was exclusively found in the mossy fiber region of the hippocampal formation and within the NGF-dependent basal forebrain cholinergic neurons. A lack of staining among potential NGF sources within cholinergic basal forebrain innervation territories suggested that cells which produce NGF did not accumulate the antigen in quantities large enough to be detected by our immunohistochemical techniques. In the present investigation, an attempt was made to force the accumulation of NGF within the cell bodies of NGF producing cells by pretreating animals with the neuritic transport inhibitor, colchicine. Following a 48 hour colchicine treatment, NGF-ir cells were detected within all cholinergic basal forebrain innervation territories-including cortex, olfactory bulb and hippocampal formation. In addition, numerous NGF-ir neurons were detected within the medial and lateral septum, horizontal limb of the diagonal band/magnocellular preoptic region, and NGF-ir neurons were detected within the medial and lateral septum, horizontal limb of the diagonal band/magnocellular preoptic region, and nucleus basalis. Colocalization of NGF and low affinity nerve growth factor receptor within the same section further demonstrated that NGF-ir neurons within the basal torebrain were not the NGF-sensitive cholinergic ones. These results indicate that NGF producing cells are distributed among all basal forebrain cholinergic cell populations, as well as within their innervation territories, and suggest that both local and distant supplies of trophic factors may play a role in supporting NGF-dependent cholinergic cell populations of the basal forebrain. Supported by NINCDS grants NS-16349 and NS-27047.

INSULAR CORTICAL GRAFTS WITH NGF ACCELERATES RECOVERY OF LEARNING AND REESTABLISH THE CHAT ACTIVITY. Tapia, J.C. López, N. Jiménez and F. Bermúdez-Rattoni. Instituto México, D.F.

It has been demonstrated that insular cortex (IC) involved in the acquisition of Conditioned Taste (CTA) and Inhibitory Avoidance (IA) tasks. We have recently shown that cortical brain grafts produced a significant recovery of the ability to learn after 60 days post-graft in IC lesioned rats. In the present work we evaluated the role of the nerve growth factor (NGF) in the recovery of CTA and IA by cortical grafts. Results showed that IC, but not occipital grafts with NGF promote recovery of learning at 15 days post-graft in both tasks. Biochemical analysis showed that choline acetyltransferase (ChAT) activity in the homotopic but not heterotopic grafts plus NGF, had a similar pattern of activity as the intact control animals. Measures of glutamic acid decarboxylase (GAD) activity at 15 days post-graft did not show any differences between groups. These findings show any differences between groups. These findings suggest that NGF should be associated with homotopic grafts, to produce a faster and stable recovery of learning abilities in IC lesioned rats. Moreover the ACh, but not GAD activity may play an important role in the grafts mediated behavioral recovery.

ANGULAR BUNDLE STIMULATION INDUCES NEUROTROPHIN GENE EXPRESSION IN DENTATE GYRUS GRANULE CELLS. <u>I.E. Springer\*</u>, B.J. Gwag, and F.M. Sessler, Departments of Neurology (JES and BJG)

and Physiology and Biophysics (IES and FMS) Hahnemann University School of Medicine, Philadelphia, PA 19102-1192.

We have previously demonstrated that N-methyl-D-aspartate (NMDA) receptor activation increases NGF mRNA expression exclusively in dentate gyrus granule cells. The induction of NGF mRNA, which occurs following intraventicular or interbiasement inferiors to extend to the observed for intraventicular or intrahippocampal infusions, is observed in the absence of seizure activity, and is timeand dose-dependent. In the dentate gyrus, NMDA receptors are present primarily in the
outer third of granule cell dendrites, and innervated by putative glutamatergic afferents
projecting from entorhinal cortex via the angular bundle and perforant path.

Because the neurotrophins NGF and BDNF are thought to influence the function
and survival of basal forebrain cholinergic neurons, we hypothesize that the activity of

and survival of basal forebrain choinergic neurons, we hypothesize that the activity of entorhinal cortical afferents on hippocampal formation play an important role in transneuronal plasticity. To test this, rats received unilateral high frequency stimulations of the angular bundle and the expression of NGF and BDNF mRNA was analyzed using in situ hybridization histochemistry. Some of the stimulation parameters used in this study were sufficient to produce long-term potentiation (LTP), but not seizure activity. At lower intensities of angular bundle stimulation, gene expression of both neurotrophins was induced exclusively in ipsilateral dentate gyrus granule cells. At higher intensities of stimulation, induction was observed bilaterally, with a greater hybridization signal occurring on the ipsilateral side. Pretreatment with AP5 (NMDA antagonist) effectively blocked induction of NGF and BDNF mRNA, but pretreatment with CNQX (non-NMDA antagonist) had no such effect. These studies demonstrate that activation of angular bundle, using parameters sufficient to produce LTP, results in the increased expression of mRNA encoding NGF and BDNF. We speculate that NMDA receptor stimulation in vivo may ultimately impact the function and survival of neurotrophin-sensitive cholinergic neurons. Supported by PHS grants AG-08969 and NS-30248 (JES).

HUMAN NERVE GROWTH FACTOR (NGF) SELECTIVELY IMPROVES SPATIAL MEMORY DEFICITS IN AGED RATS IMPROVES SPATIAL MEMORY DEFICITS IN AGED RATS VIA STIMULATION OF THE BASAL FOREBRAIN CHOLINERGIC SYSTEM (BFCS). C.A. Fleischman', M.C. Gustilo', A.L. Markowska', L.K. Gorman', L.E. Burton', D. S. Olton', D.L. Price and V.E. Koliatsos\*. Neuropathology Lab. and 'Dept. of Psychology, The Johns Hopkins University, Balto., MD 21205. Genentech Inc., San Francisco, California.

In rats, NGF ameliorates age-associated decline in certain types of memory (Nature 329)

decline in certain types of memory [Nature 329: 65, 1987]. The present study extends the previous findings and establishes the selectivity of NGF effects. Fisher-344 rats, pretested on two tasks of spatial memory and on tasks assessing sensorimotor skills, were treated with recombinant human NGF for one month and subsequently retested. Significant improvement was observed in spatial memory but not in sensorimotor skills. ChAT activity in not in sensorimotor skills. ChAT activity in hippocampus and neocortex and sizes of cholinergic neurons in all sectors of the BFCS were significantly increased. Effects of NGF on catecholaminergic and intrinsic cortical markers will be discussed. The present findings emphasize the potential of NGF as a therapeutic agent for disorders involving the BFCS, including Alzheimer's disease.

BEHAVIORAL EFFECTS OF NERVE GROWTH FACTOR (NGF) IN BOTH YOUNG AND AGED RATS. D.S. Olton\*, A.L. Markowska, V. Koliatsos, R. Henshaw, S. Sinco, L.E. Burton, And D. Price. Department of Psychology and Laboratory of Neuropathology, The Johns Hopkins University, Baltimore, MD 21218; Genentech Inc., San Francisco, CA 94080.

The behavioral effects of nerve growth factor (NGF) were assessed in Fischer-344 rats in three tests: recent memory in a T-maze, place learning in a water maze, and sensorimotor skills. Each rat was trained in each task, given continuous infusion of NGF via an osmotic minipump or a control procedure (CON), and tested again three-four weeks later. Two doses (total amount infused) of NGF were given: 60 and 240 micrograms. Two age groups were tested: 4 months old (4MO) and 23 months old (23MO). The resulting four groups are identified by an abbreviation giving first the age and then the procedure. In 23MO-NGF rats, both doses improved performance in the place learning task and the recent memory task, but not sensorimotor skills. In 4MO-NGF rats, the low dose of NGF did not improve performance. These data indicate that continuous infusion of NGF can have significant behavioral effects

PHARMACOLOGICAL STIMULATION REVEALS NGF-INDUCED INCREASES

PHARMACOLOGICAL STIMULATION REVEALS NGF-INDUCED INCREASES OF HIPPOCAMPAL CHOLINERGIC FUNCTION MEASURED IN VIVO IN RATS WITH PARTIAL FIMBRIAL TRANSECTIONS. E.O. Junard, P.A. Lapchak, D.J. Jenden, and F. Hefti, USC, Andrus Ger. Ctr., and Dept. Pharmacol., UCLA, Los Angeles, CA.

Recent pharmacological studies have shown that chronic recombinant human (rh) NGF treatment enhances hippocampal cholinergic markers measured in vitro following partial fimbrial transections. The present study determined whether the effects of chronic rhNGF administration are also evident when hippocampal cholinergic function is measured in vivo. Partial fimbrial transections did not significantly alter the levels of ACh or [H]ACh in the hippocampus, possibly due to functional compensation by surviving cholinergic terminals. In animals chronically treated with rhNGF (icv, 1.0 µq god for 21 days) the levels of ACh, choline, [H]ACh and [H]choline accumulated in the hippocampus on the lesioned side were not different from those on the unlesioned side where not different from those on the unlesioned side where not different from those on the unlesioned side. However, lesion and/or rhNGF-induced changes in cholinergic parameters became evident when animals were challenged using stimulants. First, in rhNGF-treated animals administered pentylenetetrazole (10mg/kg) 2 minutes prior to measuring in vivo cholinergic parameters, we observed an increase (422-505\*\*s) in the hippocampal content of [H]choline in both lesioned and unlesioned hippocampi. However, there was no concomitant increase in the level of [H]choline in both lesioned and unlesioned hippocampi. However, there was no concomitant increase in the level of [H]choline in both lesioned and unlesioned hippocampi. However, there was no concomitant increase in the level of [H]choline in both lesioned and unlesioned hippocampi. However, there was no concomitant increase in the level of [H]choline in both lesioned side. These results suggest that rhNGF-induced differences in the functional perfo

INCREASED EXPRESSION OF NGF AND bFGF mRNAs IN RAT BRAIN FOLLOWING MAXIMAL ELECTROSHOCK . P. Follesa, K. Gale and I. Mocchetti . Depts. Anatomy & Cell Biology and, Pharmacology, Georgetown Univ., Med. Center, Washington DC

Pharmacology, Georgetown Univ., Med. Center, Washington DC 20007.

Little is known about the regulation of neurotrophic factor biosynthesis in the mature CNS. We have previously found that focally evoked seizures rapidly increase nerve growth factor (NGF) and fibroblast growth factor (bFGF) mRNAs in selected brain regions. In this study, we examine the effect of maximal electroshock (MES)-evoked seizures on the regional pattern of NGF and bFGF mRNA expression. Three MES seizures (induced via corneal electrodes) were evoked at 20 min intervals. Each seizure lasted for not more than 15 sec. 5 h after the first MES, 2-4 fold increases in bFGF mRNA and NGF mRNA were observed in both hippocampus and entorhinal cortex. Previous evidence has implicated corticosteroids in the regulation of growth factor expression. To determinate the role of corticosteroids in the mediation of the MES effect on NGF and bFGF mRNA to the same extent as that observed in sham operated rats, indicating that adrenal steroids are not required for the seizure-evoked increase in NGF and bFGF mRNA. Our results, together with our previous findings, suggest that the induction of NGF and bFGF mRNA following convulsive seizures is associated with the activation of neuronal circuits. This induction may represent an adaptive response which may be important for protecting and mantaining the integrity of the brain circuitry. Supported by H.H.S. grants NS29664, NS 20576.

DEVELOPMENTAL EXPRESSION OF trk mRNA IN THE RAT BASAL FOREBRAIN Y. LI, D.M. HOLTZMAN, R. RIOPELLE, AND W.C. MOBLEY\*, Dept. of Neurology and the Neuroscience Program, UCSF, San Francisco, CA 94143, Dept. of Neurology, Queens Univ. of Kingston, Ontario, K7L3N6

Recent data indicate that the product of the trk gene, p140trk, is a critical component of the NGF receptor. We studied trkmRNA expression in rat basal forebrain in postnatal day (PD) 0, 4, 7, 11, 16, 21, 30, and adult animals, using *in-situ* hybridization histochemistry. Frozen sections of rat brain (18 mm) were hybridized utilizing radio-labeled sense and antisense trk riboprobes. Trk mRNA was first detected at low levels at PD 0 and slightly increased by PD 7. A sharp increase of rrk mRNA was seen at PD 11, and high levels of expression were maintained through PD 21. By PD 30, mRNA levels began to decrease and reached lower levels in adult animals. Studies on choline acetyltransferase (ChAT) mRNA showed similar expression patterns in the same region. Trk expression correlated well with the specific activity of NGF high affinity binding. Our findings indicate that trk expression in the rat CNS is developmentally regulated and that its pattern of expression is consistent with it serving as part of the high affinity NGF receptor.

NERVE GROWTH FACTOR CONJUGATED TO AN ANTI-TRANS-FERRIN RECEPTOR ANTIBODY CROSSES THE BLOOD BRAIN BARRIER: EVIDENCE FROM INTRAOCULAR SEPTAL TRANS-PLANTS. ACh. Granholm C. Bäckman, B. Hoffer, L. Walus, F. Bloom and P. Friden, 1Dept. Basic Science, School of Dentistry, and 2Dept of Pharmacology, University of Colorado HSC, Denver, CO 80262, <sup>3</sup>Alkermes, Inc., 26 Landsdowne Street, Cambridge, MA 02139, and <sup>4</sup> Dept. Neuropharmacol., Scripps Clin. and Res. Fnd., La Jolla, CA 92037. Nerve Growth Factor (NGF) has been shown to affect survival of cholinergic neurons in the medial septal nucleus. However, the delivery of this protein to the brain is impeded by the blood brain barrier (BBB). Our purpose was to investigate if an anti-transferrin receptor antibody (OX-26) could function as a carrier of NGF across the BBB. Fetal rat septal tissue (E18) was grafted into the anterior eye chamber of adult albino rats. An intact BBB was found in the grafts two weeks postgrafting. The experimental group was injected intravenously with OX-26-NGF conjugate, and the control groups with 1)saline, 2)NGF and 3)OX-26 at 2,4,6 and 8 weeks postgrafting. The growth of grafts treated with OX-26-NGF was significantly enhanced as compared to all control groups. After eight weeks the grafts were studied using immunohistochemistry with choline acetyltransferase, laminin and neurofilament antibodies. The overall densities of nerve cells and glia were similar in all groups. However, the survival rate of cholinergic neurons in OX-26-NGF treated grafts appeared to be much higher than in controls. These results suggest that the delivery of NGF across the BBB can be achieved using an anti-transferrin receptor antibody as a carrier.

INCREASED HIPPOCAMPAL NGF-LIKE ACTIVITY FOLLOWING MEDIAL SEPTAL LESIONS IS DETECTED BY A BIOASSAY BUT NOT BY AN ELISA. K.A. Crutcher\*, S. Liang and J. Weingartner. Department of Neurosurgery, Univ. of Cincinnati, Cincinnati, OH 45267.

Nerve growth factor-like immunoreactivity (NGF-LI) has been reported to increase in the rat hippocampal formation (hf) following septal denervation, an increase that may contribute to sympathohippocampal sprouting. The increase has been found in separate laboratories using either an ELISA or a bioassay. However, there are discrepancies between these reports, particularly regarding the magnitude and duration of the increase as well as its specificity. We used both a sensitive 2-site ELISA and a bioassay to monitor hf NGF-LI following septal lesions. The ELISA uses monoclonal and a polyclonal antibody raised against mouse NGF (Saffran et al., '89). The bioassay employs E9 chick sympathetic ganglia grown for 18 hours in the presence of: medium (Ham's F12) alone, mouse NGF, hippocampal extract (from control or septal-lesioned rats) or extract plus anti-NGF antibodies (the same poly clonal antiserum used in the ELISA). No increase in hf NGF-LI was detected with the ELISA at either 1 or 2 weeks following a septal lesion. In contrast, bioassay measurements demonstrated a significant increase in NGF-like biological activity at both survival times. This discrepancy between the ELISA and bioassay could be due to differences in the sensitivity of the two assays. However, both procedures reliably detect concentrations of purified mouse NGF as low as 30 pg/ml. A more likely explanation is that the bioassay detects NGF-like biological activity not detected in the ELISA. Whatever the underlying cause, the discrepancy between the two assays emphasizes the importance of using both methods to assess alterations in tissu levels of putative neuronal growth factors. (Supported by NIH #NS17131.)

DISTRIBUTION OF [ $^{125}$ ]rhngf following bolus intracerebroventricular (icv) delivery in rat brain <u>R. H.</u> Soriano\*J. Briggs 2, L. B. Jakeman, G. Bennett 1, T. Hotaling 3, P. Cossum 3, C. A. Altar and T. Nouven 2. Neuroscience Research, <sup>1</sup>Medicinal and Analytical Chem. <sup>2</sup>Pharm.Res. and Dev.,and <sup>3</sup>Safety Evaluation, Genentech, Inc. South San Francisco, CA 94080.

In order to evaluate the distribution of rhNGF delivery in the brain, iodinated rhNGF ([ $^{125}$ ]rhNGF) was delivered as a bolus injection of 1.64 pmoles/3  $\mu$ l over 15 minutes into the left intracerebral ventricles (ICV) of 220 g male rats. Brains were removed after 24 hours, sectioned and exposed to film for 60 days. Positive labelling appeared in the cholinergic nuclei (medial septum, vertical and horizontal limbs of diagonal band of Broca, and substantia ventical and nonzontal limbs of diagonal band of broca, and substantial inominatal) of all brains treated. A co-injection of approximately 100-fold excess concentration of non-labeled rhNGF blocked the labelling of these cholinergic areas suggesting specific receptor mediated uptake. Label was also localized to the left ventricular ependymal cells but was not competed by an excess of non-labeled ligand. Emulsion autoradiographs of adjacent brain sections revealed silver grains on cells in the forebrain nuclei which were counterstained with an antibody to the cholinergic marker choline acetyltransferase suggesting that label was retrogradely transported to the NGF dependent cholinergic cell bodies in the nuclei. Thus, forebrain cholinergic nuclei can specifically and bilaterally accumulate [125]]rhNGF following a bolus injection.

EFFECTS OF NEONATAL VISUAL CORTEX DAMAGE ON NERVE GROWTH FACTOR RECEPTOR EXPRESSION IN THE CAT RETINA.

J.-T. Xue and P. D. Spear\* Department of Psychology and Center for

Neuroscience, University of Wisconsin, Madison, WI 53706.

Damage to visual cortex (VC; areas 17, 18, and 19) in newborn kittens results in changes as far peripheral as the retina. Some retinal ganglion cells degenerate, and remaining ganglion cells send increased projections to the geniculate wing (retino-recipient zone of the pulvinar) and make anomalous synaptic connections in the lateral geniculate nucleus. We have begun to investigate the roles that growth factors play in these changes. In the present study, we examined the distribution of nerve growth factor receptors (NGFr) in the retina using immunohistochemical labeling with monoclonal antibodies to the NGFr. The antibodies were NGFR2 (Marano et al., 1987) and XIF1 (Clagett-Dame et al., 1990); results were similar.

Kittens received unilateral VC damage on the day of birth and survived 2 wk to >6 mo. NGFr labeling was compared in the two hemiretinae of each eye. In both hemiretinae of all animals, bands of label were present in the inner and outer nuclear layers, and diffuse labeling was present in the ganglion cell layer. This probably was Müller-cell labeling, reported by In all animals with up to 8-wk survival, there also was heavy pericellular labeling in the ganglion cell layer of the hemiretina projecting to the damaged hemisphere. The labeling included large cells presumed to be ganglion cells. Preliminary results suggest that the heavy pericellular

labeling is not seen in animals with longer survivals (12 wk or more).

The results thus suggest that neonatal VC damage increases or maintains NGFr on retinal ganglion cells during a time when enhanced retinofugal projections develop. This raises the possibility that nerve growth factor is involved in compensatory changes after early VC damage.

INFLUENCES OF NEUROTROPHINS ON DORSAL ROOT AXON BRANCHING IN VIVO. W.D. Snider, L. Zhang\*, and I. Silos-Santiago. Dept. of Neurology, Washington University Medical School, St. Louis, MO, 63110. NGF promotes profuse neurite outgrowth from DRG explants in vitro. The function of this neurite-promoting activity during normal development is unknown. One way to address this issue is to assess the influence of exogenous NGF on dorsal root axonal arborizations during embryonic development in vivo. We have, therefore, injected embryonic rats with 10mg/kg of NGF in utero on days E15 and E16, and assessed dorsal root axon branching on E17 with the lipid solu-

We have found that these NGF injections have pronounced effects on dorsal root axon growth in the spinal cord. Prominent axon bundles were apparent in the lateral regions of the dorsal horn which were not observed in control animals. Axons from these bundles penetrated gray matter and were longer than axons in the superficial dorsal horn in control animals. Axons in the most lateral region grew all the way across the midline and ramified extensively in the contralateral dorsal horn. These NGF-stimulated fibers, however, did not grow into the intermediate zone and ventral horn and thus were roughly constrained to their normal target fields. In contrast to axons in the lateral region, Ia fibers entering medially were less prominently if at all affected by exogenous NGF

These results show that exogenous NGF stimulates dorsal root axon branching in the developing mammalian spinal cord in vivo. Furthermore, the influence of NGF may be selective for certain classes of dorsal root afferents. Influences of more recently identified neurotrophins in this same paradigm are under study.

DENERVATION OF DOPAMINERGIC NEURON WITH 6-HYDROXYDOPAMINE INCREASES NERVE GROWTH FACTOR CONTENTS IN RAT BRAIN. T. Nabeshima\*1, A. Nitta¹, T. Hasegawa¹, M. Hiramatsu², T. Kameyama², Y. Furukawa³ and K. Hayashi³. ¹Dept. Neuropsychopharmacol. & Hosp. Pharm., Nagoya Univ. Sch. Med., Nagoya 466, Japan, <sup>2</sup>Dept. Chem. Pharmatol., Fac. Pharmac. Sci., Meijo Univ., Nagoya 468, Japan and <sup>3</sup>Dept. Mol. Biol., Gifu Pharm. Univ., Gifu 502, Japan.

Nerve growth factor (NGF) is a trophic protein for the magnocellular cholinergic neurons. We have reported that dopamine (DA) regulates NGF synthesis and secretion in cultured mouse astroglial cells. These results suggest that DA is one of the molecules responsible for regulation of NGF synthesis in brain. Therefore, it is important to investigate whether dopaminergic (DAergic) neurons affect to NGF contents in the various brain regions to clarify the mechanism of NGF synthesis and secretion. In this study, we measured NGF contents by EIA method in the rat brain following selective lesion of DAergic neurons by injection not fail that notwing selective resolute Date Retrieved in the of 6-hydroxydopamine (23 μg/rat), neurotoxin for DA neurons, into the nigra, where cell bodies of DAergic neurons are present. DA content dramatically decreased to 3 % of the control level 0.5 day, recovered to approximate 30 % of that 1 day and kept this level until 28 days after lesion. The increase of NGF contents was found in the parietal cortex and hippocampus and it continued 0.5-28 days after the lesion. Mechanism of regulation for NGF synthesis is not clear in the present. However, from these results, it is suggested that DAergic neuronal system has some roles in NGF synthesis.

### 183.16

NERVE GROWTH FACTOR EXPRESSION IN MOUSE SUBMANDIBULAR GLAND CELLS IN VITRO. M. Fahnestock\* and O. Lu, Dept. of Biomedical Sciences, McMaster University, Hamilton, Ontario L8N 3Z5, Canada.

Nerve growth factor (NGF) biosynthesis is regulated in a tissuespecific manner, and very high amounts of this neurotrophic molecule are found in the submandibular gland (SMG) of the mouse. Mouse SMG NGF is also hormonally regulated. We have developed two in vitro cell culture systems allowing us to study the mechanism and regulation of expression of NGF in SMG cells.

The first cell culture system uses primary cells from the SMG of male Swiss-Webster mice. These cells are grown in a collagen gel matrix in the presence of dihydrotestosterone, hydrocortisone, and triiodothyronine, and are primarily granular convoluted tubule cells (EM Durban, In Vitro Cell. Dev. Biol. 26:33, 1990). We show, using a mouse superior cervical ganglion bioassay, that these cells secrete NGF into the medium (7-10 ng/ml after 4 days) for at least one week.

The second cell culture system uses the mouse SMG cell line SCA-9 (T Barka et al, Lab. Invest. 42:656, 1980). We demonstrate that this cell line secretes biologically active NGF under a variety of growth conditions. In particular, SCA-9 cells do not require the addition of hormones to the medium to attain a level of NGF secretion of approximately 5-10 ng/ml.

# 183.18

NERVE GROWTH FACTOR AND NERVE GROWTH FACTOR RECEPTOR DISTRIBUTION IN TOUCH DOMES OF ADULT RAT SKIN - AN IMMUNO CYTOCHEMICAL STUDY. K.B. English\* and N. Stayner. Dept. Physiol., Univ. Utah Sch. Med., Salt Lake City, Utah 84108

The distribution of nerve growth factor (NGF) and nerve growth factor

receptor (NGFR) was examined in touch domes from adult rat hairy skin. These mechanosensitive structures are trophically dependent upon their afferent nerve supply, and likely serve as targets for regenerating type I afferent nerves (Horch, Neurosci Lett 32:281-284, 1982).

Tissue was immersed in cold isopentane, transferred to embedding medium (OCT) and snap frozen in liquid nitrogen (NGF staining), or fixed with freshly prepared 4% paraformaldehyde (PLP), prior to cryoprotection in sucrose and immersion in OCT. The primary antisera employed were rabbit anti-2.5S NGF (1:4,000; AB927, Chemicon) and mouse anti-rat NGFR (1:20; Clone 192, Boehringer Mannheim [BM]). Secondary antisera were goat anti-rabbit 1gG rhodamine conj (1:400; BM), and rabbit anti-mouse IgG fluorescein isocyanate conj (1:300, Serotec). Appropriate controls, including abolition of NGF staining following pre-incubation of NGF antiserum with 2.5S NGF (20 nM, Chemicon), were conducted to verify antisera specificity. Immunoreactivity for NGF was intense and sharply restricted to the

keratinocytes (excluding the stratum corneum) of the epidermis of touch domes. The epidermis surrounding touch domes and in tylotrich hair follicles associated with them was not stained. Merkel cells were immuno-negative for NGF but expressed positive staining for NGFR as did type I nerve

The presence of NGF and NGFR in touch domes may be relevant to their proposed neurotrophic and/or neurotropic role during nerve regeneration nd development. Supported by NIH grant 07983.

THE UPREGULATION OF NGF RECEPTOR mRNA EXPRESSION ASSOCIATED WITH COLLATERAL SPROUTING OF SENSORY AXONS IS BLOCKED BY IN VIVO ANTI-NGF TREATMENT. K. Mearow\*, Y. Kril and J. Diamond, Dept of Biomedical Sciences, McMaster University Medical Centre, Hamiltion, Ont. L8N 3Z5.

The collateral sprouting of intact cutaneous sensory neurons has been shown to be dependent on the presence of NGF. In our initial studies of the molecular events occuring in the DRG neurons undergoing sprouting or regeneration, NGF-R<sup>P5</sup> mRNA was shown to be upregulated in the sprouting, but not the regenerating, neurons. We have now extended this work to examine both NGF-R<sup>P5</sup> and NGF-R<sup>®</sup> mRNA expression in DRG neurons undergoing sprouting and in DRG neurons whose sprouting has been prevented through in vivo exposure to anti-NGF antiserum during the course of the experiment. The sprouting paradigm was set up by isolating intact dorsal cutaneous nerves (DCNs); the remaining intact DCNs will sprout into the denervated areas of skin. Animals were treated with either control serum or sheep anti-NGF antiserum, and at varying times after the initial surgery (1, 2, 4, 6, 8, 10, 12 days), animals were perfused, the appropriate DRGs were removed and frozen. Cryosections of these DRGs were taken and used for in situ hybridization (ISH) with <sup>3</sup>S-labeled riboprobes for NGF-R<sup>P5</sup> and NGF-R<sup>at</sup>; hybridized slides were emulsion-coated and exposed for 13 weeks.

coated and exposed for 1-3 weeks.

The results indicate that NGF-R<sup>75</sup> mRNA is increased by 8 days postop in DRGs from control serum-treated animals, and that this increase is restricted to the smaller neurons. In contrast, in DRGs from anti-NGF-treated animals, NGF-R<sup>75</sup> mRNA was maintained at control levels. Preliminary results for NGF-R<sup>76</sup> expression indicate an increase in expression at days 4-6 postop, followed by a decline to initial levels; there is no change in trk mRNA in DRGs from anti-NGF treated animals. It seems likely that increased NGF in the denervated skin lead to increased expression of NGF-R in neurons in which collateral sprouting is evoked. Supported by the Canadian NCE Network for Neural Regeneration and Recovery of Function, and NSERC.

NGF DOES NOT REGULATE GAP 43 mRNA LEVELS IN ADULT RAT DORSAL ROOT GANGLION NEURONDS. M.Hu-Tsai, C.J.Woolf<sup>1</sup>, P.Emsou<sup>2</sup> and J.Winter<sup>3\*</sup> <sup>1</sup>Dept. of Anatomy, UCL, Gower Street, London, WCIE, 6BT. <sup>2</sup>MRC, Cambridge, CB2 4AT. <sup>3</sup> SIMR, 5 Gower Place, London, WCIE, 6BN.

GAP 43 synthesis coincides with axon outgrowth and its levels decline with the cessation of axon elongation (Skene, 1989, Ann. Rev. Neurosci. 12:127-56). Increased amounts of both GAP 43 mRNA and protein after sciatic nerve cu or crush suggest that a target-derived suppressive factor may regulate GAP 43 synthesis. Among the candidates for such a factor is NGF which controls GAP 43 expression in PC12 cells (Costello et al., 1990, J. Neurosci. 10(4):1398-1406). To determine the effects of NGF on GAP 43 gene expression on primary sensory neurons, we examined GAP 43 mRNA in adult rat dorsal root ganglion (DRG) neurons in culture in the presence of either NGF or anti-NGF antiserum using non-isotopic in situ hybridization with an alkaline phosphatase-linked cDNA probe. The results were quantitated at single cell level with a Seescan videoanalysis imaging system. The timecourse of GAP gene expression over 1 week in culture show approximately 50% of DRG neurons are GAP 43 positive, in the presence of NGF or anti-NGF when examined after only 1h in culture. The number of GAP positive neurons increases steadily to approximately 95% at 7 days in the presence both of NGF or anti-NGF. In contrast, 95% of neurons cultured from ganglia that have been preaxotomized 4 days earlier in vivo are positive for GAP 43 mRNA after 1 h in vitro. Furthermore, the number of SP mRNA positive neurons drops from 12% (in the presence of NGF) to 0% (anti-NGF) after 1 week of growing in culture. In conclusion, our results show that GAP 43 mRNA levels in adult rat DRG neurons are independent of NGF, since the presence or absence of NGF does not affect GAP 43 mRNA levels. NGF may not be involved in initiating regeneration in sensory neurons.

#### 183 9

NGF-DEPENDENT PERIPHERAL NERVE SPROUTING IS CORRELATED WITH INTRASPINAL SPROUTING AND FUNCTIONAL SYNAPTOGENESIS. <u>B.A. Urschel\* and J. Diamond.</u> Department of Biomedical Sciences, McMaster University, Hamilton, Ontario, Canada, L8N3Z5.

We examined the possibility that in the adult rat, the NGF-dependent collateral sprouting of undamaged nociceptive nerves in skin will be correlated with intraspinal sprouting of primary nociceptive afferents, and that this involves a functional synaptogenesis within the ipsilateral dorsal horn. Since the immediate early gene cfos is induced in spinal neurons post-synaptic to nociceptive afferents in resp noxious stimuli, an analysis of the pattern of c-fos induction in the spinal cord allows the functional connectivity between nociceptive afferents and spinal interneurons to be evaluated. Cutaneous nerve fields were "isolated" (by surrounding denervation) to induce peripheral nerve sprouting, but in some of the animals sprouting was prevented by daily injections of antibodies to NGF (anti-NGF). 16-21 days later the contralateral field was isolated to provide an "acute" control side. On day 22 (prior to the onset of peripheral sprouting on the acute side), nociceptive field sizes were determined, and the spinal cords processed for c-fos immunoreactivity. Increased functional synaptogenesis on the "sprouting" side was anticipated to increase the ratio of the number of c-fos positive cells/section on that side relative to the number on the acute (control) side. In unoperated animals, and in animals where peripheral sprouting was blocked by anti-NGF treatment, the ratio was not significantly different from 1.0. In the animals with peripheral sprouting the ratio was 1.8, a significant increase (p<0.0001). Thus intraspinal sprouting and synaptogenesis appears to correlate with peripheral nerve sprouting. The intraspinal sprouting will now be confirmed morphologically with substance P and CGRP immunoreactivity, and the possible involvement of centrally-originating NGF will be examined by intrathecal anti-NGF administration. Suppported by the Canadian Centres of Excellence for Neural Regeneration and Functional Recovery.

THE NEUROPEPTIDE VIP: AN AUTOCRINE REGULATOR OF CELL GROWTH. A. DAVIDSON\*, E.DICICCO-BLOOM, I.BLACK, M.DRAOUI, F.ZIA, G. LILING, M. FRIDKIN, D.E. BRENNEMAN, T.M. MOODY AND I. GOZES, CHEM. PATH, SACKLER MED. SCH., TEL AVIV UNIV., ISRAEL; NEUROSCI. CELL BIOL. UMONJ-ROBERT MOOD JOHNSON MED. SCH. PISCATAMAY, NJ08854; BIOCHEM. MOL. BIOL. GEORGE WASHINGTON UNIV. MASHINGTON DC20037; ORGANIC CHEMISTRY, MEIZMANN INST., ISRAEL; SECT. DEV.MOL.PHARMACOL., LAB. DEV. NEUROBIOL. NICHO, NIIH, BETHESDA, MO20892.

THE GENE ENCODING VASOACTIVE INTESTINAL PEPTIDE (VIP) IS EXPRESSED IN THE RAT EMBRYO WITH A PEAK AT EMBRYONIC DAY 16 (E16) (GOZES ET AL., NEUROCHODOCRINOLOGY 47:27;1988), SUGGESTING A ROLE IN DEVELOPMENT. PREVIOUS STUDIES IMPLIED THAT VIP CAN SERVE AS A PARACRINE GROWTH FACTOR, STIMULATING GLIAL PROLIFERATION AND CONSEQUENT NEURONAL SURVIVAL (BRENNEMAN ET AL., PNAS 83:1159,1986; J. NEUROSCI. RES.25:386,1990). WE NOW SHOW THAT VIP FUNCTIONS AS AN AUTOCRINE GROWTH FACTOR IN NEUROGENESIS AS WELL AS IN CANCER PROMOTION.

IN THE DEVELOPING SYMPATHETIC MERVOUS SYSTEM, VIP MRNA WAS EXPRESSED AT HIGH LEVELS IN E15.5 SUPERIOR CERVICAL GANGLIA, WITH LOWER LEVELS AT BIRTH, A PATTERN CONSISTENT WITH PREVIOUS ANALYSIS OF VIP CONTENT. IMPORTANTLY, THE PEAK OF EXPRESSION CORRELATES WITH THE FUNCTION OF VIP AS A REGULATOR OF MITOSIS, DIFFERENTIATION AND SURVIVAL OF SYMPATHETIC NEUROBLASTS (PINCUS ET AL., NATURE 343:564,1990). FURTHERMORE, OUR OBSERVATIONS INDICATED THAT A MOVEL VIP ANTAGONIST (GOZES ET AL., ENDOCRINOLOGY 125:2945,1989; JPET 257:959,1991) INHIBITED VIP-INDUCED MITOGEMESIS IN SYMPATHETIC NEUROBLASTS. IN ADDITION TO NEURONAL CELLS, A NUMBER OF CANCER CELL LINES EXHIBITED VIP AUTOCRINE BEHAVIOR. IN THE NON-SMAL CELL LUNG CANCER LINE NCI-HB33, VIP MRNA WAS DETECTED AND VIP STIMULATED COLOMY FORMATION THAT WAS INHIBITED BY THE ANTAGONIST. IN RELATED STUDIES, VIP MRNA WAS DETECTED IN ABOUT 50% OF LUNG CARCINOID CELL LINES TESTED. THE LINE NCI-H727 DISPLAYED THE HIGHEST COMTENT OF VIP MRNA, WHICH WAS INCREASED BY FORSKOLIN AS WELL AS THE PHORBOL OPM. IN CONCLUSION, VIP FUNCTIONS AS AN AUTOCRINE REGULATOR OF PROLIFERATION.

ONTOGENY OF TACHYKININ SYSTEMS OF THE RAT CAUDATE-PUTAMEN: IMMUNOCYTOCHEMISTRY AND IN SITU HYBRIDIZATION. L. Zhang, L. R. Lucas, J.E. Krauset, J. T. Weber\* and R. E. Harlan, Department of Anatomy, Tulane Medical School, New Orleans, LA 70112 and Department of Anatomy and Neurobiology, Washington University School of Medicine., St. Louis, MO†.

Louis, MO†.

The tachykinins, substance-P (SP) and neurokinin-B (NKB), are expressed in the caudate-putamen (CPu) and project to dopaminergic neurons in the substantia nigra and GABAergic neurons in the globus pallidus, respectively. To understand the independence of these two tachykinin systems, the ontogeny of SP and NKB in the rat CPu has been studied using both immunocytochemistry and in situ hybridization. Pups were studied at embryonic days E16, E18, E20 and E22 and postnatal days P0, P5, P10, P15 and P45. Immunocytochemistry was performed using antisera specific to SP and a NKB-related peptide, peptide 2 (PP2) on brain sections across all ages. On sections from P0, P5, and P10, in situ hybridization was performed using cRNA probes to locate neurons expressing the SP or NKB genes. At E16-E22, SP immunoreactive (ir) cell bodies were concentrated in the ventral lateral aspect of the CPu. At rostral levels, SP-ir cell bodies were not evident at E22 or later ages, while SP-ir fiber systems formed distinct patches beginning at E20. SP-ir patches became most obvious at P15, and declined in intensity at P45. At caudal levels, SP-ir cell bodies continued to be evident as late as P10. In contrast, PP2-ir, which also originated in the ventral lateral aspect of the CPu, was not detected until P10-P15. In situ hybridization indicated that the neurons containing SP-mRNA were concentrated in patches throughout the CPu at P0, P5, and P10. Expression of the NKB gene was not evident in the CPu until P10 when a few labeled cells were seen in the ventrolateral region. The marked developmental differences between SP and NKB suggest independence of function of these two tachykinins in the CPu. Supported by NIH Grant # NS 24148

DEVELOPMENTAL EXPRESSION OF CORTICOTROPIN RELEASING FACTOR MESSENGER RNA IN THE OVINE BRAIN. C. Keiger 1, J.C. Rosel, G. Brewer 2 and W.K. O'Steen 3\*, Bowman Gray School of Medicine, Wake Forest University, Dept. of Physiology and Pharmacology 1, Dept. of Microbiology and Immunology 2, and Dept. of Neurobiology and Anatomy 3.

Corticotropin Releasing Factor (CRF) is a neuroendocrine regulator of the hypothalamic-pituitary-adrenal axis. Using a quantitative RNase protection assay with an ovine antisense RNA probe, we determined the regional localization and expression of CRF mRNA at different gestational ages in the fetal sheep brain.

The amount of CRF mRNA in 75µg of total RNA was measured from the hypothalamus (HYPO), cerebral frontal cortex (CFC), hippocampus (HHPPO), amygdala (AMYG), and brainstem (BS) of 98 to 139 day gestation (DG) fetal sheep. The results are shown in the table below.

| AGE  | HYPO   | CFC    | HIPPO & AMYG | BS     |
|------|--------|--------|--------------|--------|
| 98DG | 0.48pg | N.D.   | N.D.         | N.D.   |
| 99   | 0.45   | 0.83pg | 0.56pg       | 0.45pg |

# FUNCTIONAL EVIDENCE FOR V2 VASOPRESSIN RECEPTOR EXPRESSION IN CULTURED HIPPOCAMPAL NEURONS. A. Brownson\* and B. D. Brinton. Depart of Molecular Pharmacology and

Toxicology, and Depart of Neurobiology, University of Southern California, Los Angeles, CA 90033

Pharmacological studies have suggested the existence of a V<sub>2</sub> vasopressin (AVP) receptor in the CNS but to date there has been no direct evidence of AVP-induction of cAMP in neurons. Our experiments using cultured hippocampal nerve cells have revealed AVP-induction of cAMP via V<sub>2</sub> receptor activation in embryonic neurons. Hippocampal nerve cells from E18 rat pups were cultured onto PEI coated dishes in serum containing medium. Following 1-5 days in culture neurons were exposed to AVP or other peptides. AVP induced a dose dependent accumulation of cAMP in cultured hippocampal neurons that was maximal at 250 nM. The dose response revealed an inverted-U shape function in that higher concentrations of AVP showed a decline in cAMP levels. The time course for AVP-induction of cAMP formation was maximal at 15 min and was also characterized by an inverted-U shape function. Peptide specificity studies indicated that the vasopressin metabolites, AVP[4-8] and AVP[4-9] were more potent than the parent peptide in stimulating cAMP formation while oxytocin was equally as effective as AVP. The receptor linked to adenylate cyclase was, however, specific in that the V<sub>1</sub> agonist Phe<sup>2</sup>,Orn<sup>8</sup>Vasotocin did not induce cAMP formation at any of the concentrations tested whereas DAVP, a selective V2 agonist showed a clear dose dependent induction of cAMP formation. The ability of AVP to induce cAMP formation was maximal at 4 days in culture. These data are the first biochemical evidence for expression of a V2 receptor in neurons and suggests that the V<sub>2</sub> receptor may play a critical role during development of the CNS. Supported by NIH grant MH46036 to R.D.B.

CGRP-PHENOTYPE IS REGULATED BY RESINIFERATOXIN IN DEVELOPING DORSAL ROOT GANGLION NEURONS D.V. Agoston<sup>1</sup>, W.J. Nyhus<sup>1</sup>, A. Szallasi<sup>2\*</sup>, G. Jakab<sup>3</sup> Lab. of Developmental Neurobiology, NICHD<sup>1</sup>, NCI<sup>2</sup>, Lab. of Experimental Neuropathology, NINDS3, NIH, Bethesda MD 20892

Resiniferatoxin (RTX), an ultrapotent analog of capsaicin has been reported to release neuropeptides (calcitonin gene-related peptide (CGRP), substance P, etc.) from the central and peripheral terminals of primary afferent fibers. In order to determine the susceptibility of developing sensory neurons to this neurotoxin and to study the developmental regulation of CGRP gene expression we treated primary dissociated dorsal root ganglion (DRG) cell cultures with 0.3-30 nM of RTX. Immunocytochemical analysis revealed that RTX treatment produced rapid, dose-dependent enhancement of CGRP biosynthesis in small and medium sized neurons; however a number of large neurons also showed detectable immunoreaction. The diameter of CGRP-immunoreactive nerve fibers and their varicosities markedly raised probably due to the increased peptide transport and release. This treatment (maximum 48 hours) caused neither significant loss of neurons nor visible degenerative changes at the light microscopic level. The increase of CGRP release and the subsequent upregulation of the CGRP biosynthesis provoked by RTX may simulate physiological processes evoked by pathological metabolic changes e.g. ischemia or acidosis.

DIFFERENTIAL TIMING AND SEXUAL DIMORPHISM OF VASOPRESSIN GENE EXPRESSION IN THE DEVELOPING RAT BRAIN. P. Szot\* and D.M. Dorsa, GRECC, Seattle VAMC, WA 98108 and Dept. of Pharmacology, Univ. Washington, Seattle, WA 98195.

Neurons which express the vasopressin (VP) gene are located within

hypothalamic nuclei including the paraventricular nucleus (PVN), supraoptic nucleus (SON) and suprachiasmatic nucleus (SCN), and are involved in the hormonal action of the peptide. Extrahypothalamic VP neurons are also present in he bed nucleus of the stria terminalis (BNST) and the medial amygdala (MA), and are thought to be involved in the neurotransmiter actions of the peptide.

In situ hybridization was performed using a 48 base oligonucleotide to the In situ nyoridization was performed using a 48 base oligonucleotide to the glycopeptide portion of the VP gene to measure levels of VP mRNA in 1,3,5,7,14,21,35 and 60 day old male and female Long-Evans (LE) rats in the 5 areas described above. VP mRNA in the PVN, SON and SCN was detectable in day 1 rats, but was only half the level measured in the adult. VP mRNA levels increased rapidly after day 1 and reached adult levels at 35 days. The development of the extra-hypothalamic nuclei was much slower than in the hypothalamic nuclei, and demonstrated the sexual dimorphism known to exist these nuclei. In male rate VP mRNA was not detected with recent days. hypothalamic nuclei, and demonstrated the sexual dimorphism known to exist in these nuclei. In male rats, VP mRNA was not detected until postnatal day 3 for BNST and day 5 for MA. Both areas displayed a rise in cell number until postnatal day 7 for BNST and 14 for MA, reaching a plateau until day 21; followed by a significant increase to adulthood. VP gene expression in LE female rats developed at a significantly slower rate than males and was not detected until day 14 in the BNST and 35 for MA. We suggest that the pattern and timing of VP gene expression in BNST and MA neurons is the result of the organizational and activational effect of testosterone in the developing rat being (Support by the VA and NS 20311) brain. (Support by the VA and NS 20311)

INVOLVEMENT OF THE CAMP RESPONSE ELEMENT IN TISSUE AND AGE SPECIFIC REGULATION OF THE SOMATOSTATIN GENE. C.L. Szymeczek-Seay\* and D.E. Millhorn, University of North Carolina, Chapel Hill, North Carolina 27599

DNA-protein binding studies from our laboratory have indicated a role for the cAMP response element (CRE) in tissue- and age- specific regulation of the somatostatin (SOM) gene. Early studies of the regulation of the SOM gene, performed in tissue culture systems, showed that the CRE bound the cAMP response element binding protein and was involved in the cAMP responsiveness of the gene. Our work, which involves the isolation of nuclear protein from tissue and surement (by gel shift assay) of its capacity to bind to the CRE, demonstrates that protein from brain and non-brain tissues, and protein from brain regions of different ages, form varied types and levels of protein-CRE complexes. The binding of proteins to the CRE, a putative cis-acting element, suggests a role for these proteins as transcriptional activators of the SOM gene. suggests that the different types of protein-CRE complexes we observe with proteins from varied tissues and ages may be partly responsible for the different levels of SOM mRNA observed at different developmental ages in different tissues. Protein from liver, a non-brain, non-SOM expressing tissue, forms a complex with the CRE which is distinctively different from the complexes formed with proteins from other low-expressing tissues (i.e.adult cerebellum) or from high expressing tissues (adult diencephalon and adult pancreas). When proteins from SOM expressing tissues are extracted from rats of different ages and bound to the CRE, one observes a characteristic DNA protein complex for each particular tissue, but the levels of protein binding vary, and indeed are absent in both cerebellum and diencephalon at 28 days of age. Therefore our data suggests that the CRE may be mediating more than just the cAMP responsiveness of SOM, and perhaps more importantly, that it is possible to dissect out the mechanisms by which gene expression, hitherto studied primarily in cell culture, is operating in a native, physiological milieu.

A NOVEL TRANSCRIPT HOMOLOGOUS TO SUBSTANCE P RECEPTOR mRNA IN THE DEVELOPING RAT SPINAL CORD. Paul A. St. John 1,\*, Sherry L. Stephens 1, Linda Nunan 2, and Josephine Lai<sup>2</sup>, Depts. of Anatomy 1 and Pharmacology 2, Univ. of Arizona, Tucson, AZ Previous work from one of our laboratories [St. John and Stephens

(1992) Dev. Biol. 151:XXX] showed that neurons dissociated from the E14 rat spinal cord express receptors for substance P (SPRs) within 24 hr in vitro, and that the number of SPRs increases steadily in culture for about 1 week. We now have measured levels of SPR mRNA in the rat spinal cord during in vivo development. Poly(A)+ RNA prepared from the spinal cords of rats at ages E14 through birth and from adults was hybridized under stringent conditions to a <sup>32</sup>P-labeled cRNA probe derived from the Cterminal 588 bases of the rat SPR cDNA (generously provided by J.E. Krause, Washington Univ.) and analyzed by ribonuclease protection. The results showed that mRNA for the SPR is already present in the rat spinal cord at E14, before the end of neurogenesis. The protected 588-base fragment showed a 35% increase in abundance from E14 to E20, and a further 3-fold increase in the adult. A second protected fragment of approximately 470 bases was also detected at all ages examined. At E14, this band was 2.5-fold more abundant than the 588-base band, but its level decreased 6-fold by E20. In the adult rat spinal cord, this 470-base fragment constituted a minor signal. Two lines of evidence suggest that the second fragment does not arise from degradation or cross-hybridization with mRNA for other known neurokinin receptors. We are considering the possibilities that the 470-base fragment is derived from an alternatively spliced mRNA or from a slowly spliced nuclear transcript. Supported by NSF 8808506, NIH NS29657, ADCRC WC9311, and AHA IG-2-44-91.

ACTIVITY DEPENDENT ALTERATIONS IN SUBSTANCE P AND CGRP IMMUNOREACTIVITY IN NEURONS AND FIBERS IN THE EMBRYONIC CHICK SPINAL CORD. B. Mendelson.\* Dept. of Anatomy, U. of Ark. for Med. Sci., Little Rock. AR 72205.

In some regions of the nervous system, changes in patterns of neural activity can after synaptic connectivity during development. To ask if patterned activity is important for the appropriate formation of neural circuitry in the spinal cord, dubocurarine (dtc) was administered to developing chick embryos and subsequently neuropeptide immunoreactivity was examined. In the chick, dtc directly affects spinal cord circuits, preventing the alternating bursts in motoneuronal pools. In the present study 2-3 mg/d of dtc was administered beginning at embryonic day 5 (ES). At later stages (E8-E18) the expression of the neuropeptides substance P (SP) and calcitonin gene-related peptide (CGRP) was assayed immunohistochemically and compared to similar immunostaining in Tyrodes-treated control embryos processed in parallel. Dtc-treatment caused a decrease in SP-like immunoreactivity (SP-LI) in a particular subset of neurons. Following the treatment, interneuronal SP-LI was dramatically reduced as was the SP-LI in most fibers in the dorsal horn. However, a specific subpopulation of fibers that project from lateral to medial just ventral to lamina 2 were much more intensely immunostained after dtc-treatment. Following dtc-treatment, motoneuronal CGRP-LI was decreased, but a subpopulation of fibers located ventral to lamina 2 projecting to the midline were more heavily immunostained in a similar fashion to the SP-LI fibers. Therefore, normal patterns of neural activity appear to be necessary for the appropriate expression of certain neuropeptides and the altered pattern of activity produced by dtc-treatment affects only a specific subpopulation of neurons. EFFECT OF CURARE ON ENKEPHALIN mRNA IN THE DEVELOPING CHICK BRAIN. M.A. Young, L.K. Garner, B.M. Mendelson<sup>2</sup>, and B.M. Davis\*. Dept. of Anatomy and Neurobiology, Univ. of Kentucky Med. Cntr., Lexington KY 40536; 2Dept. of Anatomy, Univ. of Arkansas Med. Sch., Little Rock. AR 72205.

Sch., Little Rock, AR 72205.

Application of curare during development has been shown to prevent motoneuron (MN) cell death. Studies in our laboratories have shown that spinal cord mRNA production in the developing chick is down-regulated following curare application. In the study presented here, in situ hybridization was used to examined the ontogeny of the mRNA coding for the prohormone for enkephalin (ENK) in the chick brain. In addition, embryos were treated with Tyrode's buffer, Img, 2mg or 3mg of curare per day from st 25 through st 39 followed by Northern analysis of whole brains. ENK mRNA can be detected in the developing basal ganglia and in the area of the acc. occulomotor nucleus by st 25 (E5). By st 26 heavily labeled cells are also seen in the diencephalon, rostral mesencephalon and immediately ventral to the ventricular zone. By st 30, most of the ENK positive nuclei that can be found in older embryos are present. These include all nuclei described as ENK positive by immuno studies, plus additional cell groups, e.g. clusters of ENK mRNA positive cells flanking the anterior commisure and fasciculus prosencephali lateralis. Curare treatment often retarded the maturation of the embryos by 0.5-1 stage by day 14 (the time when brains were removed). However, no difference was seen in the amount of total RNA/mg wet wt. Northern analysis showed a significant decrease in the amount of ENK mRNA in chicks treated with 2.0 or 3.0 mg curare/day. Supported by NIH NS25617 to BMD.

ONTOGENY OF THE PROENKEPHALIN SYSTEM IN THE RAT AMYGDALA: DETECTION BY IN SITU HYBRIDIZATION. D. D. Song\* and R. E. Harlan. Dept. of Anatomy, Tulane Univ. School of Medicine, New Orleans, LA, 70112.

Medicine, New Orleans, LA, 70112.

In situ hybridization was performed on coronal cryostat sections through the amygdala on embryonic day 14 (E14), E16, E18, E20, postnatal day 0 (P0), P5, P10, P15 and P20, using a random-primer labeled (35S) 435 bp cDNA complementary to nucleotides encoding amino acids 56 to 200 of rat proenkephalin. Earliest expression of PPE mRNA in the amygdala occurred at E16 in the central nucleus (Ce), immediately ventral to concurrent PPE expression in the ventrolateral concurrent PPE expression in the ventrolateral concurrent PPE expression in the central nucleus (Ce), immediately ventral to concurrent PPE expression in the ventrolateral concurrent PPE expression in the ventrolateral concurrent PPE expression in the Central nucleus (Ce).

compiementary to nucceoudes encouing amino acids 36 to 200 of rat preenkephalin.

Earliest expression of PPE mRNA in the amygdala occurred at E16 in the central nucleus (Ce), immediately ventral to concurrent PPE expression in the ventrolateral caudate-putamen (CPu). Expression in the Ce was of moderate intensity. By E18, PPE expression in the Ce had increased and also occurred in the sublenticular substantia innominata (SLSI) at high levels. By E20, heavy labelling of cell bodies was also found in the posterior portion of the medial amygdala and in the intramedullary gray. By P0, weak labelling was observed in the lateral division of the bed nucleus of the stria terminalis (BSTL). By P5, an adult-like distribution was present. In addition to the already mentioned nuclei, heavy labelling of thensely packed cells was also present in the intercalated nucleus, moderate labelling in the BSTL, and weak labelling in the cortical (Co), basomedial (BM), anterior portion of the medial (MeA), and ventral portion of the basolateral (BLV) amygdaloid nuclei. By P10, the intensity of labelling in the SLSI had decreased to a moderate level as seen in the adult. By P15, labelling in the BM and BLV had increased to moderate level as seen in the adult. By P15, labelling in the BM and BLV had increased to moderate levels. By P20, PPE expression in the MeA had increased to heavy amounts and in the Co to moderate amounts. PPE expression in the amygdala was essentially adultike both in distribution and intensity by this age. A continuum of prominent and early PPE expression in the ventrolateral CPu, Ce, medial amygdala, SLSI, and BSTL may suggest that these structures are related as parts of a common neuroanatomical system. Supported by NS24148 (REH).

EFFECT OF ACTIVITY ON ENKEPHALIN AND SUBSTANCE P mRNA IN THE DEVELOPING CHICK SPINAL CORD. L.K. Garner\*, B.M. Mendelson², K.M. Albers, M. Kindy and B.M. Davis. Depts. of Pathology & Anatomy and Neurobiology, Univ. of Kentucky Med. Cntr., Lexington KY 40536; 2Dept. of Anatomy, Univ. of Arkansas Med. Sch., Little Rock, AR 72705.

Synaptic contections in the central nervous. Numerous studies have used curare to block synaptic connections in the central nervous. Numerous studies have used curare to block synaptic activity to study its role in development. In our experiments, ontogeny of the mRNAs for the prohormones coding for substance P (SP) and enkephalin (ENK) was determined for the chick spinal cord. In addition, curare was applied to chick embryos during the period that primary afferents innervate the dorsal horn to study changes in expression of these mRNAs associated with decreased activity. ENK mRNA first appears in the dorsal horn at approximately stage (st) 25 and in the region of the intermediate laminae at 27. By st 38 ENK mRNA was localized to the dorsal horn, intermediate laminae and column of Terni. SP mRNA was first seen in the dorsal root ganglion at st 30. By st 38 it was localized to the dorsal and ventral horn, and dorsal root and sympathetic ganglia. To examine the effect of decreased activity, chick embryos were treated with Tyrode's buffer, 1mg, 2mg or 3mg of curare per day from st 25 through st 39. In sith hybridization showed a dose dependent down-regulation for both ENK and SP mRNA in the majority of the gray matter and dorsal root ganglia (for SP). However, SP mRNA expression in the ventral horn did not appear to be affected by curare treatments. These results were confirmed by Northern analysis. Supported by NiH NS25617 to BMD.

Developmental-Specific Changes in Opioid Peptide Gene Expression and AP-1 Proteins in Rat Hippocampi after Seizures. K.R. Pennypacker\*, M.K. McMillian, J. Douglass, and J.S. Hong. Natl. Inst. of Environ. Health Sci. Lab of Mol. and Integ. Neurosci. Research Triangle Park, NC 27709

Administration of the seizure-inducing drugs, kainate (KA) and pentylenetetrazol (PTZ) to adult rats causes an increase in AP-1 proteins and opioid gene expression in the hippocampus. We analyzed hippocampi from postnatal day 7 (P7) and postnatal day 14 (P14) rat pups after KA and PTZ treatment for AP-1 transcription factors and opioid peptide gene expression. At both ages, the rats exhibited seizure behavior. Neither AP-1 proteins nor opioid peptide genes were affected in the hippocampus from P7 rats; however, there was a high basal level of AP-1 DNA binding. At P14, both KA and PTZ treatment increased AP-1 protein expression in the hippocampus, but only KA increased preproenkephalin and neither drug treatment affected preprodynorphin. These data suggest that the neuronal pathways involved in seizure behavior are completed early in development, while the pathways that regulate the induction of AP-1 protein and opioid peptide genes are not intact until P14 or later. Expression as well as seizure-induction of the preproenkephalin gene in the rat hippocampus occurs earlier than the preprodynorphin gene.

# 184.14

G PROTEINS AND ALTERED NEURONAL PLASTICITY IN MORPHINE EXPOSED RATS. A.Gorio, A.M.Di Giulio, M.L. Malosio, C. Finco, A.Bertelli, and P.Mantegazza. Dept. of Medical Pharmacol., Univ. of Milano, Italy.

Perinatal exposure to morphine affects neuronal plasticity in the rat brain. In morphine-exposed animals the  $% \left( 1\right) =\left( 1\right) \left( 1\right$ regeneration of neurotoxin injured serotoninergic axons is markedly impaired, as well as the collateral sprouting of serotonin (5-HT), dopamine (DA) and met-enkephalin (ME) axons triggered by the neonatal lesion of noradrenergic nerve terminals. By in situ hybridization we have monitored the gene expression of specific molecules. The striatal morphine induced ME increase is correlated by a parallel increase of preproenkephalin A mRNA, while, in the same area, the reduced levels of DA are correlated by a reduced expression of D1 receptors. Morphine causes also significant increase of Gs protein expression throughtout the brain and a parallel increase of the protein amount detected by western blotting. G2i and Go subunits are apparently unaffected. Morphine exposure markedly reduces synapsin 1 expression. All these changes are normalized by neonatal 6-OHDA lesion, as if the denervation stimulus would counteract morphine effects. The data suggest a new role for G proteins in neuronal plasticity.

EFFECTS OF PRENATAL COCAINE ON THE DEVELOPMENT OF CEREBRAL CORTEX OF DUTCH BELTED RABBITS L. Jones, I. Fischer, P. Levitt\* . Dept. Anatomy & Neurobiology. Medical College of PA, Philadelphia, PA, 19129.

of PA, Philadelphia, PA, 19129.

There is clinical evidence of profound developmental behavior anomalies experienced by children who have been exposed to cocaine prenatally. This study was undertaken to establish possible structural correlates in the developing brain. Pregnant rabbits were treated with cocaine intravenously starting on the 8th day of gestation to the 29th day, using a dosage of 4mg/kg twice a day. The progeny were taken on various postnatal (P) days between birth to P14. Specific cellular changes were compared during development using a variety of immunocytochemical markers. Anti-glial fibriliary acidic protein (GFAP) was used to examine astrocyte differentiation; anti-neurofilament-H (NF-H) was used to assess axons; anti-microtubule-associated protein 2 (MAP2) to assess dendrites. At all ages examined there were no differences between cocaine-treated and normal animals in the distribution or number of GFAP or NF-H positive profiles, suggesting normal glial and axonal development. In contrast, MAP2 staining revealed short, tortuous apical dendrites of pyramidal neurons in the cerebral cortex. This was evident at birth and at all ages examined. Other structural proteins present in dendrites, such as a and b tubulin, also showed similar staining patterns with the corresponding antibodies. The proteins present in dendrites, such as a and b tubuin, also showed similar staining patterns with the corresponding antibodies. The data suggest a profound and specific effect of prenatal cocaine exposure on dendritic development, perhaps by altering growth patterns and/or molecular assembly of dendritic proteins. (Supported by NIDA grant DA06871-01)

#### 184.17

EFFECTS OF LOCAL ADMINISTRATION OF AMPHETAMINE ON NEOSTRIATAL DOPAMINE RELEASE AS MEASURED BY IN VIVO MICRODIALYSIS IN DEVELOPING AND ADULTS RATS. R.A. Gazzara\* and S.L. Andersen. Center for Developmental Psychobiology and Dept. of Psychology, SUNY-Binghamton, Binghamton, NY 13902-6000.

Amphetamine (AMPH) produces atypical responses when administered to immature organisms. For example, Trent et al. (Eur. J. Pharmacol. 204: 265, 1991) have shown that AMPH produced a increase in firing rate in nigral dopamine (DA) neurons in rat pups at postnatal days (PND) 1-6 compared with a decrease in firing rate in adult rats. In an attempt to further elucidate the neurochemical mechanisms that may underlie these AMPH effects during development, we have employed in vivo microdialysis to determine the effect of locally-administered AMPH on the extracellular level (ECL) of DA in the neostriatum of PND 5 pups and adult rats.

In urethane-anesthetized PND 5 pups and adult rats, baseline levels of DA were measured during perfusion with artificial cerebrospinal fluid (aCSF). Subsequent to establishment of baseline levels, increasing doses of AMPH (conc. in µM: 0.01, 0.1, 1, 10, 100, 1000; dissolved in aCSF) were perfused sequentially through the dialysis probe. The  $0.01~\mu M$  dose produced an increase in ECL of DA in the adult rats, but had no effect in the PND 5 pups. The 0.1 µM dose produced an increase in ECL of DA in the PND 5 pups, however this increase was smaller than in the adult rats. At all doses tested, AMPH produced a greater increase in ECL of DA in adult rats than in PND 5 pups AMPH-induced increases in ECL of DA plateaued at the 100 and 1000 μM doses in the PND 5 pups, whereas no such plateau was seen in the adult rats

These results suggest that AMPH is much more efficacious in releasing DA from nigrostriatal terminals in adult rats than in developing rats.

Supported by NIH BRSG Grant S07RR07149-17.

MOLECULAR MECHANISMS OF GERMINAL MATRIX VASCULAR MATURATION.

YASCULAR MATURATION.

LR. Ment\* W.B. Stewart, M.F. Einat, C.C. Duncan and F.H. Ruddle.

Yale University Sch. of Medicine, New Haven, Ct. 06510.

Intraventricular hemorrhage (IVH) or hemorrhage into the germinal matrix (GM) occurs in over 45% of neonates of less than 34 weeks gestational age. There is evidence that the risk period for IVH is the first 4to 5 days after birth; this risk period is independent of gestational age. We have used the newborn beagle pup as a model for this vascular disorder of the GM. The risk period for IVH in this model is also the first four days. Our previous work has shown that laminin deposition increases markedly during this period. The aim of the present study was to test the hypothesis that maturation of the vessels was regulated by activation of a number of genes during the first few days of life. We isolated microvessels from the germinal matrix of 1 and 10 day old isolated microvessels from the germinal matrix of 1 and 10 day old pups. A cDNA library was prepared for each age and a differential screen was performed to look for gene expression that was present at day 10 but not at day 1. The screens were performed on 10,000 pfu using probes made from poly A plus RNA isolated from the GM microvessels of 1 and 10 day old pups. Nine positive clones were identified. A second screen was performed and the inserts of the positive clones were amplified by PCR. The cDNA insert of one positive differential band was sequenced and found to be homologous to carboxynentidase E a vasoartive protein known to be present in to carboxypeptidase E, a vasoactive protein known to be present in brain. These data indicate a perinatal induction of genes related to both structural and functional maturation of the vessels.

LOCAL PERFUSION OF (-)SULPIRIDE VIA MICRODIALYSIS ALTERS
K\*-EVOKED DOPAMINE RELEASE IN THE NEOSTRIATUM OF DEVELOPING AND ADULT RATS. S.L. Andersen\* and R.A. Gazzara. Center for Developmental Psychobiology and Dept. of Psychology, SUNY-Binghamton, Binghamton, NY 13902-6000.

A within-subject dose-response analysis of (-)sulpiride was conducted in urethane-anesthetized 5, 10-11, 15-16, and 21-22 day old rat pups and adult rats. (-)Sulpiride was administered locally via a microdialysis probe located in the neostriatum. After establishment of a baseline for K\*-evoked release of dopamine (DA), increasing doses (0.1, 1, 10, 100 μM in artificial cerebrospinal fluid) of (-)sulpiride were sequentially perfused during subsequent samples of K+-evoked DA release. Samples were collected every 15 min and DA was measured by HPLC-ED.

While presynaptic DA autoreceptors are able to modulate K+-evoked DA release following local perfusion of the D-2 agonist quinpirole (Andersen and Gazzara, Soc. Neurosci. Abstr. 17: 364, 1991), unexpected results were obtained using the D-2 antagonist (-)sulpiride. Local perfusion of (-)sulpiride produced significant dose-dependent increases in K\*-evoked DA release in the 5, 10-11, and 15-16 day old rat pups only. In contrast, (-)sulpiride produced decreases in K+-evoked DA release in the 21-22 day old pups and the adult rats at all doses tested.

These results suggest that locally-administered (-)sulpiride produces agedependent effects on K\*-evoked DA release in the neostriatu Supported by NIH BRSG Grant S07RR07149-17.

### 184.18

EFFECTS OF DEVELOPMENTAL AGE IN RATS ON THE RELATIVE CONTRIBUTION OF LEUCINE RECYCLED FROM THE DEGRADATION OF PROTEIN TO THE PRECURSOR POOL FOR PROTEIN SYNTHESIS

Y. Sun\*, G. E. Deibler, & C. Beebe Smith. LCM, NIMH, Bethesda, MD 20892.

The autoradiographic determination of rates of cerebral protein synthesis with L-[1-14C]leucine (Smith et al, PNAS 85:9341, 1988) takes into account recycling of unlabeled leucine derived from protein degradation into the precursor pool for protein synthesis. The degree of recycling can be evaluated by measuring  $\lambda$ , the ratio of the steady state leucine specific activity in the precursor pool (tRNA-bound) to that of the plasma. We have shown previously that in adult rat brain recycling does occur and that the value of  $\lambda$  is significantly less than 1.0. As a prelude to studies of the developmental time course of regional rates of protein synthesis we have evaluated  $\lambda$  for the whole brain at 10, 14, 21, & 35 days of age. Rats were administered, i.v., a programmed infusion of [3H]leucine designed to achieve and maintain for 60 min a constant arterial plasma [3H]leucine specific activity. The [3H]leucine specific

| Age (days)                            | N | Value of \( \lambda \) |  |
|---------------------------------------|---|------------------------|--|
| 10                                    | 2 | $0.41 \pm 0.02$        |  |
| 14                                    | 6 | $0.52 \pm 0.01$        |  |
| 21                                    | 5 | $0.53 \pm 0.02$        |  |
| 35                                    | 4 | $0.58 \pm 0.01$        |  |
| Adult*                                | 9 | $0.58 \pm 0.01$        |  |
| Values are means ± SEM.               |   |                        |  |
| * Sun et al., J Neurochem (in press). |   |                        |  |

activities were measured in the tRNA-bound extracts of brain and in the acid-soluble fraction of timed plasma samples; the values of  $\lambda$  are shown in the table. Values are lowest in the 10 day old rats and increase with developmental age until 35 days at which time the value of  $\lambda$  is the same as that of adult rats. These results show that early in development a greater fraction of the precursor leucine pool is derived from protein breakdown. These values of λ can now be used in the determination of rates of cerebral protein synthesis in developing rats.

REGULATION OF ASTROCYTE DEVELOPMENT BY INTERLEUKIN-1 AND TUMOR NECROSIS FACTOR. Y. Aizenman\*, D. Maciejewski, J. Holliday, F.E. Bloom and R. Milner. Department of Neuropharmacology, Scripps Research Institute, 10666 N.
Torrey Pines Rd., La Jolla, CA 92037.

We have investigated the effect of Interleukin-1β (IL) and

Tumor Necrosis Factor-α (TNF) on the mRNA levels of 3 proteins important in astrocyte development and function: Glial Fibrilary Acidic Protein (GFAP), Glutamine Synthetase (GS), and S100. To prevent indirect effects of cytokines via the microglia they were eliminated from the astrocytic cultures as follows: astrocytes were grown in vitro for 7 days, followed by shaking (200 RPM) for 6 hrs in serum free medium containing L-leucine methyl ester (10mM). After an overnight incubation with 10% serum and repetition of the shaking procedure, the cultures were found to be devoid of microglia as detected by florescent Low Density Lipoprotein. Treatment of these purified astrocyte cultures for 24 hrs with IL(10units/ml) caused an increase in the mRNA levels of GFAP, GS and S100. These findings taken together with the increase of IL during astrocyte development in vivo suggest a critical role of this cytokine in astrocyte differentiation. GFAP mRNA, a moderate decrease in S100 mRNA, and no change in GS mRNA. These observations are consistent with the idea that, unlike IL, TNF is not a differentiating factor but a proliferative one for astrocytes. (Supported by MH47680)

GIANT TWO-DIMENSIONAL GEL ELECTROPHORESIS REVEALS POTENTIALLY NOVEL PROTEINS RELEASED BY INTERLEUKIN-18 (IL-18) TREATED ASTROCYTES. J. W. Chang\*, D. A. Young, P. D. Coleman, and M. K. O'Banion. Depts. of Neurobiology and Anatomy, Medicine, and Neurology, Univ. of Rochester Med. Critr., Rochester, NY 14642.

Neurology, Univ. of Rochester Med. Critr., Rochester, NY 14642.

Astrocytes are known to secrete factors important for normal neuronal development, survival, and recovery following injury or disease. Failure of these astrocytic responses may play a role in selected neuronal deficits noted in Alzheimer's disease. IL-18, a cytokine that is produced by microglia may be a mitogen for astrocytes and is known to influence the release of astrocytic factors. To more fully characterize this response we have utilized high resolution giant two-dimensional (2-D) gel electrophoresis to investigate the secretion of newly synthesized proteins in primary cultures of rat astrocytes treated with recombinant human IL-18.

Two-D gel separations of <sup>35</sup>S-labeled proteins recovered from the media at selected times after IL-18 traveled at least three groups of IL-18.

at selected times after iL-18 treatment revealed at least three groups of IL-18 induced proteins: Group A, a doublet at 24-25 kDa, pl 5.6; Group B, 4 isoforms at 50-53 kDa, pl 6.2-6.5; and Group C, consisting of about 10 isoforms at 125-130 kDa, pl 6.3-7.1. Of these, groups A and C represent nearly *de novo* inductions (at least 25-fold) while group B was induced by about 5-fold. The induction of group B proteins occurred within 3 h of IL-18 treatment whereas inductions for the other groups were not observed until 8 h. Based on its location on the 2-D gels we speculate that group B is plasminogen activator inhibitor type 1, that has been previously shown to be induced by IL-18. Studies to determine the identity of these and the other IL-16 induced proteins are underway. Their further characterization and molecular cloning may reveal novel molecules that play a role in neuronal/glial interactions. [Supported by LEAD award AG09016 and RO1 AG01121 to P.D.C.

NON-NEURONAL LOCATION OF GABA, AND NMDA RECEPTORS IN EARLY POSTNATAL RAT CEREBELLUM. G.D. Pratt, J.- M. Fritschy & H. Mohler Inst. of Pharmacology, Univ. of Zurich, CH-8006 Zurich, Switzerland.

The involvement of both GABAergic and glutamatergic receptors in the structural development of the cerebellum has been investigated by immunocytochemical receptor-mapping. Polyclonal antibodies to cDNAderived peptides of the rat NMDA receptor and to the GABA, receptor  $\alpha_1$ ,  $\alpha_3$ ,  $\delta$  sub-units plus a monoclonal antibody (bd17) recognising both  $\beta_2$  and  $\beta_3$  sub-units were incubated with free-floating sections and processed using the avidin-biotin immunoperoxidase technique. In Purkinje cells, at PN1, staining was evident for all five antibody categories with immunoreactivity (IR) increasing up to PN10. Thereafter,  $\alpha_1$  and  $\alpha_3$  subunit-IR in these neurones persisted until PN21 and whereas bd17 and NMDA receptor-IR was much weaker by comparison,  $\delta$  IR was completely lost. Both molecular and granular cell layers were strongly immunoreactive for the  $\alpha_1$ ,  $\delta$  and bd17 antisera at PN21. Conversely, NMDA receptor IR was more pronounced in the molecular layer than the granular cell layer. In the external granular layer, stained filamentous parallel processes corresponding to Bergmann glia were inalientious parallel processes corresponding to berginaling like were recognised selectively by antibodies to the  $\alpha_3$ ,  $\delta$  and NMDA receptors (most strikingly up to PN10), but not to  $\alpha_1$  and bd17. Non-neuronal elements in white matter and the developing molecular layer were stained by bd17 up to PN10. At PN21, Bergmann glia, although faint, were still apparent for  $\alpha_3$  but not obvious for  $\delta$  IR. In summary, during the period of cerebellar granule cell migration, Bergmann glial cells show selective expression of both excitatory and inhibitory receptors which are possibly involved in regulatory trophic neuronal/glial interactions.

PROLIFERATIVE EFFECT OF IGF-I ON IFAP-70/280kD-CONTAINING IMMATURE ASTROCYTIC CELLS IN CULTURE. H.-Y. Yang\*, N. Lieska, P.-Y. Chien, V. Kriho and G.D. Pappas. Department of Anatomy and Cell Biology, University of Illinois, Chicago, IL 60612.

We have recently demonstrated that four differentiation-specific subtypes of non-stellate astrocytes can be defined in primary cultures of neonatal rat brain by use of intermediate filament (IF) cytoskeletal markers, specifically an early marker, IF-associated protein (IFAP)-70/280kD [Brain Res. 573(1992), 161]. Because of the expression of insulin-like growth factor-I (IGF-I) in fetal rat brain and its known proliferative and differentiation effects, it is hypothesized that IGF-I may be implicated in macroglial development. Due to the early developmental nature of IFAP-70/280kD, an increased proportion of IFAPcontaining cells would be indicative of a proliferative effect of IGF-I in the system. To test this, primary cultures were established from neonatal rat brain and maintained in serum-containing medium for two weeks prior to transfer to: 1) serum-free medium, 2) serum-free medium plus IGF-I (100ng/ml), or 3) regular serum medium. Two days later, the phenotypic composition of the cells was determined by double-label immunofluorescence microscopy to delineate: IFAP(I) GFAP(G)\*, I\*G\*, and I'G cells. The IGF-I group exhibited twice as many non-stellate cells as the serum-free control due to a two-fold increase in the number of I'G' cell types and a three-fold increase in the minor number of I'G' cells. It was concluded that IGF-I is mitogenic for the two IFAP\* cell types. Moreover, based on the observation of mitoses among the IFAP cells and the less differentiated state indicated by the IFAP marker, IGF-I appears not to have a maturation effect on those astrocyte stages. Supported by NIH grant NS26395.

NUCLEAR LOCALIZATION OF CREATINE KINASE (CK) IN CULTURED ASTROCYTES (AST) BY CONVENTIONAL AND CONFOCAL MICROSCOPY: ROLE IN PROLIFERATION. P. Manos\* and J. Edmond. Dept. Biol. Chem., MRRC, UCLA Sch. of Med., Los Angeles, CA 90024

CK is an enzyme important in brain energy homeostasis. The subcellular localization of CK was examined in primary cultures of AST using immunofluorescent labeling methods and detection by both standard fluorescence and confocal laser-scanning microscopy. Using standard microscopy, the pattern of CK staining was uniform throughout the cell cytoplasm and appeared to stain the nuclear region intensely. Staining of CK in the nuclear region colocalized with the Hoechst nuclear stain. The structural details of CK in the nuclear region were examined in serial optical sections taken through the cell monolayer with a confocal microscope. CK staining was present in each section and had a granular, particulate pattern indicating a nucleoplasmic distribution. Nuclear CK was examined in AST cultured at either a low or high cell density; 92% of the low density AST contained intense CK-stained nuclei, whereas only 47% of the high density confluent AST had intense CK-stained nuclei. The rate of DNA synthesis was 8-fold higher in low density AST than in high density AST. A nuclear fraction from low density AST cultures had higher CK activity than that prepared from high density cultures. These data demonstrate the presence of high CK in the nucleus of proliferating AST and suggest a preferential localization of CK to the nucleus to meet the energy demands of cell division and/or nuclear function.

REGULATION OF POTASSIUM CHANNEL mRNA'S IN RAT SCIATIC NERVE. S.Y. Chiu, A. Messing, M. Behan', and S.S. Scherer. Dept. of Pathobiological Sci., Dept. of Neurophysiology, Univ. of Wisconsin, Madison, WI 53706; Dept. of Neurophysiology, Univ. of Pennsylvania, Philadelphia, PA 19104.

Recent electrophysiological studies suggest that potassium channel expression in Schwann cells, at least at the cell body, changes during myelination. However, it is unclear whether channel expression is regulated at the whole-cell level, since a major portion of the cell membrane is electrically sealed from recordings by tight myelin wrappings. We addressed this issue by examining the regulation of mRNA levels for two potassium channel genes, MKI and MK2, in rat sciatic nerves during development and following injury. In Northern blot analysis of total RNA extracted from P2 to adult nerves, probes generated from CDNA clones for these channel genes recognize single transcripts of ≈8.6 kb for MK1 and ≈11.3 kb for MK2; the level of expression is higher for KK1 than MK2. The hybridization signal shows a developmental change that is similar for both channel genes; it increases from P2 to 214, then declines again in the adult. Permanent nerve transection in adult animals results in a dramatic reduction in mRNA levels for both potassium channel genes which lasted up to 58 days posttransection. When the nerve is crushed so that regeneration can occur, KK1 and MK2 expression initially declines, but subsequently regains the pre-crush levels. The patterns of potassium channel genes regulation resemble those of myelin-specific genes such as P,. These results provide the first direct evidence that the expression of some potassium channel genes in Schwann cells is dependent on association with axons.

GLIAL CALCIUM SIGNALING IN INTACT MAMMALIAN WHITE MATTER. S. Kriegler and S.Y.Chiu\* Graduate Program in Biophysics & Dept. of Neurophysiology, University of Wisconsin, Madison, WI 53706.

In slice cultures of gray matter, neuronal activities trigger [Ca<sup>2+</sup>]<sub>i</sub> spiking and [Ca<sup>2+</sup>]<sub>i</sub> waves in glial network, presumably via substances, like glutamate, released at synapses. Here we examine glial [Ca2+]; signaling in mammalian white matter lacking neuronal cell bodies and synapses. Rat optic nerves (P2, P7, P14) were stained with fluo-3 and confocal images of [Ca<sup>2+</sup>]<sub>i</sub> recorded at ~25°C or ~37°C. Glial cell bodies showed spiking or sustained [Ca<sup>2+</sup>]; response to bath-applied glutamate (100-500 μM). Metabotropic glutamate agonist trans-ACPD elicited transient, sometimes spiking, [Ca<sup>2+</sup>]<sub>i</sub> responses, whereas ionotropic agonists kainate and AMPA elicited a DNQX-sensitive, mostly sustained [Ca2+]i response. Transient and spiking glial [Ca<sup>2+</sup>]; responses were also elicited by adenosine or ATP (10-50 µM). Repetitive nerve stimulations (10-20 Hz) elicited [Ca<sup>2+</sup>]<sub>i</sub> spiking in 10-20 % of glial cells in P-7 nerves; glial spiking typically occurred 20-45 sec after onset of nerve stimulations. At 37°C, the frequency for glial [Ca2+]; spiking increased from 0.06 Hz to 0.11 Hz when axonal stimulation was increased from 10 to 20 Hz (n=17). This activity-dependent glial spiking was inhibited by 10 µM TTX, could not be mimicked by increasing the bath K+ by 20 mM in unstimulated nerves alone, and occurred when nerves were stimulated in the absence of bath calcium. We suggest that glial [Ca<sup>2+</sup>]<sub>i</sub> spiking in white matter is mediated by non-vesicular release of neuroactive substances, possibly through reversal of transporters when Na+ and K + gradients are altered by prolonged nerve activity.

EVIDENCE THAT UPREGULATION OF THE mRNA FOR GLIAL FIBRILLARY ACIDIC PROTEIN DOES NOT DEPEND ON THE SYNTHESIS OF AN IMMEDIATE EARLY GENE PRODUCT. M.R. Smith\* and O. Steward. Department of Neuroscience, University of Virginia,

Charlottesville, VA 22908.

Entorhinal cortex (EC) lesions lead to a dramatic upregulation of glial fibrillary acidic protein (GFAP) mRNA in the hippocampus (Steward et al., J. Neurosci., 10:2373-2384, 1990). Similar increases are also observed after hippocampal seizures (Steward et al., Proc. Natl. Acad. Sci., 88: after improcampal selective (steward et al., Froc. Nat. Nat. (1982). 6819-6823, 1991). The regulation of GFAP gene expression is important in reactive astrogliosis but little is known about the mechanisms involved. The present study evaluates whether GFAP gene induction occurs as a result of activation of immediate early genes (IEGs). Gene induction via IEGs occurs as a result of the rapid synthesis of IEG proteins, which then act as transcription factors. Previous studies have shown that protein act as transcription factors. Previous studies have shown that protein synthesis inhibitors reduce gene induction via IEGs by reducing the increases in the IEG products (Mocchetti et al., Proc. Natl. Acad. Sci., 86:3891-3895, 1989). Thus, we evaluated whether inhibition of protein synthesis blocked the increases in GFAP mRNA after EC lesion. Adult male Sprague-Dawley rats received a subcutaneous injection of anisonycin (100 mg/kg) in order to inhibit protein synthesis. Twenty minutes later, the EC was destroyed electrolytically. GFAP mRNA levels were assessed 4.8, 12,24, and 48 hours after the EC lesion using dot blot hybridization. GFAP mRNA levels increased 2-3 fold by 12 hours postlesion and 5 fold by 24 hours postlesion in both drug-treated and control animals. There were no significant differences in the GFAP mRNA levels between the two groups at any of the time points. These results suggest that upregulation of GFAP mRNA is not dependent on induction of immediate early genes. Supported by NIH #NS29875 to OS. MRS received predoctoral fellowship support from NIH #NS07199.

Distribution of Myosin and Cytokeratin Immunoreactivity within the Regenerating Electric Organ of the Gymnotiform fish Sternopygus. J.M. Patterson<sup>2</sup> and H.H.Zakon. Dept. of Zoology, University of Texas at Austin, Austin, Texas 78712

Weakly electric gymnotiform fish produce an electric field using an electric organ (EO) located in the tail. The EO is comprised of large multi-nucleate electrocyte cells, which have been shown to possess morphological characteristics indicative of a myogenic ontogeny. The electrocytes are surrounded by a peripheral ring of skeletal muscle fibers that lie just under the skin. We have sought to study the changes in myofibrillar and cytoskeletal proteins which occur during the differentiation of new electrocyte cells as the EO regenerates after amputation. Seven days after removal of the terminal portion of the tail, which includes EO, muscle, nerve and other tissues, a regeneration blastema forms at the wound site. Previous work has shown that blastemal cells are progeny of myogenic satellite cells located between electrocyte cells and between skeletal muscle fibers (Patterson & Zakon, 1990). During the next 14 days, blastemal cells differentiate into electrocytes, skeletal muscle, and other tissues found within intact EO. We have shown in the mature EO that electrocytes are labeled with the monoclonal antibody AE1, an anti-acidic cytokeratin Ab, while the peripheral muscle fibers are selectively labeled by MP20, an anti-myosin monoclonal antibody.

To look at the expression of these cell-specific epitopes over time, we have conducted a time course experiment in which regenerating EO from three fish were obtained at each of the following times post-amputation: 3 days, 6 days, 10 days, 14 days, and 21 days. At each time point, the distal regeneration blastema/stump was removed, frozen, and sectioned longitudinally for immunohistochemistry.

Changes in MP20 expression occur prior to blastema formation. At three days post-amputation, myosin, which is never expressed in mature electroc

for immunohistochemistry.

Changes in MF20 expression occur prior to blastema formation. At three days post-amputation, myosin, which is never expressed in mature electrocytes, is seen within intact electrocyte cells near the wound margin. MF20 staining indicates that this myosin is of a particulate nature; it is not organized into any contractile machinery. At 6 days, just as the blastema is forming, no MF20 nor AE1 labeled cells are present. At 10 days post-amputation, small, heavily-labeled MF20-positive cells predominate in the distal region of the blastema; occasional AE1-positive cells are seen in this area. Proximally, large (>200 microns in length) AE1-positive/MF20-positive cells extend from near the wound margin into the blastema. Based on their size and position, we believe these larger proximal cells represent primordial electrocytes. By 21 days, these regenerated electrocytes no longer express the myosin epitope. Thus, it appears that regenerating electrocytes transiently express a muscle-like phenotype during differentiation, and that EO amputation can cause these cells to revert to this earlier form.

Patterson, J. M. & Zakon, H. H. (1990) Soc. for Neurosci. Abs. Vol. 16, p. 1327.

ACTIVATION OF c-FOS IN GLIA OF DEVELOPING OPTIC NERVE K.J. Mack\*, S. Kriegler, S. Chang, and S.Y. Chiu. Depts. of Neurology, Biophysics, and Neurophysiology, University of Neurology, Biophysics, and Neurophysiology, University of Wisconsin, Madison, WI. Recent experiments with developing optic nerves have

demonstrated a stimulation-dependent calcium elevation in glia. To investigate if other glial cell events are associated with optic nerve stimulation, an immunohistochemical analysis for immediate early genes was performed in optic nerves.

In unstimulated optic nerves, an antibody to c-fos related antigens demonstrated positive cell body staining at P2, P7, and P14. Adult optic nerves showed no specific staining. The nuclear staining was most prominent at P7, and occurred in the cell bodies of presumptive glia.

Optic nerves from P7 animals were exposed for 5 to 30 min to a solution of 300 uM glutamate, latter maintained in a glutamate free solution for 2 hours, and then quickly frozen. Glutamate-treated nerves showed an increased expression of c-fos related antigens compared to control nerves.

Finally, optic nerves received 15-20 Hz electrical stimulation for 5 to 15 minutes. Two hours after this stimulation, increased immunoreactivity for c-fos related antigens was demonstrated.

These studies indicate that developing (P7) optic nerves show a baseline expression of immediate early genes, and activation through glutamate or electrical nerve stimulation results in an increased expression of these transcription factors. These results suggest that axonal activity affects early gene transcription in glia of the developing optic nerve

FISH GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP) CLONING AND EVIDENCE OF THE PRESENCE OF GFAP TRANSCRIPT IN THE FISH OPTIC NERVE. I. Cohen. Y. Shani and M. Schwartz\*. Department of Neurobiology, The Weizmann Institute of Science, 76100 Rehovot, Israel.

During development, astrocytes support axonal elongation. With maturation, concomitant changes occur in the ability of astrocytes to support axonal growth and in the type of intermediate filaments expressed by them. Controversy exists as to whether the fish optic nerve expresses GFAP and thus whether its astrocytes differ from those of the brain and spinal cord, as well as from astrocytes of optic nerves of other species. In this work we use a molecular approach to show, for the first time, the work we use a morecular approach to show, for the first time, the presence of a GFAP transcript in the fish optic nerve. A cDNA library originating from fish brain was constructed in \(\lambda\)g110 and screened with mouse GFAP probe. Two partial cDNA clones, which appeared to encode for two different forms of GFAP, were isolated and sequenced. The partial coding region of one clone (# 1) contained 214 amino acids and that of the other (# 3) contained 211 amino acid. other (# 3) contained 211 amino acids. There were several mismatched nucleotides between the two clones, but only five amino acids were found to be different: histidine/glutamine, asparagine/serine, alanine/threonine, valine/alanine, and lysine/asparagine. In the 3' noncoding regions the differences between the clones were more pronounced. In clone # 1 this region contained 573 base pairs (bp) starting from the polyA+ tail, while in clone # 3 it contained 805 bp but the polyA+ tail was not approached. Additional differences in the 3' noncoding region included nucleotide mismatches, as well as several deletions in clone # 3. The fish GFAP was found to contain approximately 2.7 bp and thus closely resembled the mammalian GFAP in size. Using the isolated fish GFAP clones, we were able to detect a GFAP transcript of 2.7 bp in the fish optic nerve.

# 185.12

ASTROCYTES AND THEIR CONDITIONED MEDIA REDUCE BLOOD BRAIN BARRIER LEAKAGE AND DECREASE EXPRESSION OF INHIBITORY ECM MOLECULES IN ASTROGLIAL SCARS. I. Silver\*, K. Morigiwa and K. Maier. Dept. of Neurosciences, Case Western Reserve University, Cleveland, OH 44106
Precritical period astrocytes (PA) of the mammalian CNS appear to provide a supportive substrate for neurite outgrowth and to differ in their functional properties from mature astrocytes (MA). We have previously shown that PA, but not MA, suppress astroglial scarring and may suppress blood brain barrier (BBB) leakage in an in vivo CNS lesion model in adult rats. We have also demonstrated that the expression of putative inhibitory ECM molecules, chondroitin-6-sulfate proteoglycan (CSPG) and tenascin/cytotactin (TN), increase in CNS gray matter lesions in adult but not in neonatal rats. Here, we examined whether PA reduce CSPG and TN expression as well as BBB leakage in adult CNS lesions, and if so, whether diffusible factors or cell contact were responsible for the effect. Purified astrocyte cultures were made from neonatal rat cortex, seeded onto Millipore filters after 3 days (PA) or 30 days (MA) of aging in culture, and implanted into the forebrain of adult rats. Filters were also immersed in P3 and P30 astrocyte conditioned media pulsated in N2 media. The controls were implanted with filters immersed in DMEM/F12 or N2 media or with boiled dead astrocyte membranes (DA). After a 9 day survival period the animals were either intravenously injected with Evans Blue dye or HRP and perfused through the ascending aorta. The brains were processed to visualize dye and marker leakage or stained with antibodies to albumin and to GFAP, CSPG, TN and laminin to determine the degree and nature of the scarring. PA and PA conditioned media but not MA conditioned media implants, whereas MA and DA increased the leakage. The leakage was correlated with the degree of scarring and location of CSPG and TN. These results suggest that diffusible factors of PA may reinstate the

CHARACTERIZATION OF MURINE TENASCIN MRNA ISOFORMS AND ANALYSIS OF THEIR DEVELOPMENTAL EXPRESSION BY IN SITU HYBRIDIZATION.

U. Dörries\* and M. Schachner. Dept. of Neurobiology, Swiss Federal Institute of Technology, CH-8093 Zurich, Switzerland.

The extracellular matrix molecule tenascin is, in the mouse, expressed as a group of polypeptides with molecular weights between 190 and 240 kD, depending on the tissue and the developmental stage analyzed. This heterogeneity has been shown to be, at least in part, caused by alternative splicing in the region of the fibronectin type III (FNIII) repeats. According to Northern blot analysis, the regulation of the splicing process appears to be tissue-specific and developmentally regulated. To characterize mRNA isoforms present in the mouse central nervous system, we applied PCR to cDNA from mouse brains of embryonic and postnatal stages. In addition to the isoforms already described, we could identify additional splicing variants, amongst which we found an as yet undescribed FNIII repeat which showed 97% homology to the eleventh FNIII repeat of hexabrachion, the humantenascin homologue.

In order to further analyze the spatiotemporal expression of individual isoforms, we applied in situhybridization to sections of mouse embryos of different developmental stages, after amplified fragments were doned and isoform-specifical goxigenin labelled cRNA probes were generated. Analysis of the hybridization signals revealed that the expression of all tenascin mRNA isoforms described here is dependent on the developmental stage of the embryo and regulated in a tissue-specific manner.

CHARACTERIZATION OF JANUSIN (J1-160/180) mRNA EXPRESSION IN BRAIN. B. Fuss\*. E. Wintergerst. M. Schachner. Dept. Neurobiology, Swiss Federal Institute of Technology, Honggerberg, 8093 Zürich, Switzerland.

Janusin (formerly designated J1-160/180) has been shown to be highly related to tenascin by cDNA sequence analysis. The common structure of these extracellular matrix molecules is characterized by a cystein-rich N-terminal region, followed by EGF-like repeats, fibronectin type III (FNIII) repeats and a domain homologous to fibrinogen. In contrast to tenascin, which is expressed by astrocytes, fibroblasts and Schwann cells, janusin is described as an oligodendrocyte-derived protein. In addition to adhesive substrate properties both proteins display repulsive properties towards neurons and growth cones. For janusin, but not for tenascin, the neuronace sell recognition molecule F3/11 is involved in the initial recognition process.

The existence of alternatively spliced FNIII repeats, resulting in isoforms that are expressed in a tissue-specific and developmentally regulated manner have been previously demonstrated for tenascin. By using PCR with cDNAs from rat brain, we could identify alternative splicing in the region of the FNIII repeats which generates at least two janusin isoforms which could constitute the difference between the 160 kD and 180 kD protein components. In situ hybridization with janusin-specific cRNA probes confirms the expression of janusin by oligodendrocytes with a peak at around postnatal days 8 to 15, previously shown by Northern blot analysis, and suggesting a possible role during myelination. Surprisingly, there are additional signals detectable in non-oligodendroglial cells, most probably basket cells of the cerebellum. The structural homology between janusin and tenascin including the position of alternatively spliced exons could indicate that both proteins are derived from a common ancestor, although they are expressed by different cell types.

IMMUNOREACTIVITY OF REGENERATING OPTIC FIBERS OF GOLDFISH WITH MONOCLONAL ANTIBODIES AGAINST MAMMALIAN HEAVY NEUROFILAMENT. E.I. ANDERSON and R.L. MEYER\*. Developmental Biology Center, UC Irvine, Irvine, CA 92717 Two monoclonal antibodies against heavy neurofilament

Two monoclonal antibodies against heavy neurofilament were found to be reactive against regenerating optic fibers in goldfish. The monoclonal antibody NE14 was found to selectively stain fibers growing from retinal explants in culture. In retinal sections of regenerating optic fibers NE14 immunoreactivity was selective for optic fibers. Sections of tectum innervated by regenerating optic fibers show enhanced staining compared to the normal optic fibers, although some staining of the tectal cells was also observed. Immunoblotting of a tectum homogenate identified a prominent band in the cytoskeletal fraction, but it was below 10 KD, which is too low to be a neurofilament protein.

In tectum, monoclonal antibody RT 97 was also found to selectively stain for regenerating optic fibers. Moreover, it selectively stained fibers that projected to, or fibers within, the stratum marginale. Immunoblotting with RT 97 identified no prominent bands in the cytoskeletal fraction, but one prominent band was seen in the cytosolic fraction at about 160 kD. Supported by NIH EY6746.

EXPRESSION AND DISTRIBUTION OF MICROTUBULE-ASSOCIATED PROTEINS IN DRG NEURONS AFTER SCIATIC NERVE LESION IN ADULT RAT. F. Nothias\*, M. Murray, A. Tessler and I. Fischer. Dept. Anatomy and Neurobiology. Med. College of PA. Philadelphia. PA 19129.

Anatomy and Neurobiology, Med. College of PA, Philadelphia, PA 19129. Microtubule-associated proteins (MAPs) are major structural components of the neuronal cytoskeleton whose expression is regulated during brain development. MAP1B is present predominantly in growing axons. Tau is also present in axons and exhibits multiple isoforms that include embryonic, adult and a PNS-specific "big-tau". Sciatic nerves were transected to determine the expression and distribution of MAP1B and tau during axonal regeneration in adults. A polyclonal antibody that recognizes all MAP1B isoforms showed staining in adult DRG neurons as well as in their central and peripheral branches. A monoclonal antibody recognizing only the phosphorylated isoform of MAP1B (MAP1B-P), showed immunostaining in axons but not in perikarya. After sciatic nerve lesion, MAP1B-P immunoreactivity increased in injured sciatic nerve, but not in dorsal roots. The cell body of axotomized neurons remained devoid of immunostaining. The polyclonal antibody showed no changes in staining after axotomy. MAP1B-P is therefore restricted to axons. Its increase during axonal regeneration may reflect changes in postranslational modifications of MAP1B suggesting that MAP1B-P plays a role during regeneration of adult axons. Monoclonal antibodies that recognize the known forms of tau stained small and medium DRG neurons intensely. The large neurons were weakly or not immunostained. Axon staining was also selective. No changes were observed after sciatic nerve lesion. These results suggest that the distribution of "big-tau" is not uniform in adult DRG neurons and it is not affected by axotomy. Supported by grants NIH-NS 24707, APA-FB1-9102, USAMRDC 51930002.

# 186.3

EXPRESSION OF MAP1B AND TAU DURING REGENERATION OF NEWBORN AND ADULT RAT DRG NEURONS IN CULTURE. Y. Sagot, A. Tessler\*, and I. Fischer. Dept. of Anatomy and Neurobiology, Medical College of Pennsylvania, Philadelphia, PA 19129

Both adult (Ad) and newborn (NB) DRG neurons are able to regenerate neurites in culture. We have compared the expression of MAP1B and tau, two prominent microtubule associated proteins, in cultured Ad DRG and NB DRG using immunocytochemical analysis. MAP1B is present in perikarya and neurites of Ad DRG neurons throughout the 7 days of culture. A monoclonal antibody directed against the phosphorylated isoform of MAP1B shows that this isoform is initially localized to cell bodies. During regeneration of neurites it accumulates in the distal end of neurites including the growth cones. The staining decreases with time in the cell bodies of neurons with long neurites. Similar patterns of staining are observed in NB DRG. These results indicate that phosphorylated MAP1B is associated with growing axons and may play a role in axonal regeneration of NB and Ad DRG neurons. The expression of tau was examined using antibodies that recognize the known forms of tau including "big-tau", an isoform that is present only in adult PNS. In Ad DRG culture, tau immunoreactivity is initially localized to cell bodies and the proximal ends of neurites. After seven days in culture some neurons show tau staining in both cell bodies and neurites, while others do not. This pattern may reflect the heterogeneity of the neuronal populations found in Ad DRG in vivo. In contrast, tau is present in all of the NB DRG cell bodies and neurites during all stages of their growth in culture. These results suggest that tau may be required for early events of regeneration in NB DRG but not in Ad DRG neurons. This may reflect changes in the expression of tau isoforms (e.g. "big tau") during development. Supported by grants FB1-9102, NS24707, USAMRDC51930002.

# 186.4

DISTRIBUTION OF MICROTUBULE ASSOCIATED PROTEINS IN ADULT AND EMBRYONIC MOUSE RETINAL EXPLANTS. C.A. Bates\* and R.L. Meyer. Developmental Biology Center, UC Irvine, Irvine, CA 92717

Microtubule associated proteins (MAPs) are developmentally regulated proteins involved in microtubule polymerization and stabilization. We have asked whether MAPs in regenerating adult mouse retinal ganglion cell axons recapitulate the pattern of MAPs seen during development.

Adult and embryonic day 15 (E15) mouse retinal segments were explanted onto laminin coated coverslips and incubated in serum free media. Using a variety of monoclonal antibodies (Mabs), we stained adult and E15 explants for early (MAP5) and late (MAP1, MAP2, MAP2a+b, tau) MAPs. E15 explants were strongly immunoreactive for MAP5. Mabs to MAP2 and tau lightly stained axons and cell bodies, probably due to MAP2c and juvenile tau which are found in developing neurons. MAP1 and MAP2a+b labeling was faint or absent. In adult explants, both perikarya and axons were immunoreactive for MAP1. MAP2 and MAP2a+b mainly labeled perikarya and fibers within the explant while tau stained axons on the substrate. MAP5 immunoreactivity was variable, ranging from light labeling to labeling as intense as that seen in E15 explants.

In summary, retinal explants maintain their adult complement of MAPs, with high levels of MAP1, and tau and MAP2 segregated into axons and perikarya respectively. The exception is MAP5 which labels some adult axons at levels similar to that seen in E15 axons. Supported by NS26750 (RLM).

NEUROFILAMENT PROTEINS IN REGENERATING FROG OPTIC AXONS. Y. Zhao and B.G. Szaro\*. Departm Biological Sciences, S.U.N.Y., Albany, NY 12222. Patterns of neurofilament protein (NF-P) Department

expression and the phosphorylation of NF-H and NF-M at K-S-P residues are similar in developing and regenerating PNS axons. This may be important for axonal growth, since injured mammalian CNS axons, which do not regenerate, exhibit novel patterns of cytoskeletal gene expression different from regenerating PNS axons. optic nerve of the frog, Xenopus laevis, is one of the few vertebrate CNS projections capable of fully regenerating. To determine whether the pattern of NF-P expression and phosphorylation in regenerating frog optic axons resembles that of development, we stained optic nerves with antibodies to NF-Ps after an orbital nerve crush. NF-Ps reappeared during the second week after injury. As in developing optic axons, the appearance of and NF-M-immunoreactivity preceded that of NF-L and NF-H; and NF-M was hypophosphorylated. By 3 weeks, staining with all antibodies, except for anti-NF-H, was as intense as in uninjured nerves. The similarity in NF-P expression and phosphorylation between generating and embryonal optic axons supports the idea that such changes in NF-Ps reflect a reorganization of the axonal cytoskeleton that is essential for growth.

MAPI EXPRESSION IN DORSAL ROOT GANGLION (DRG) NEURONS DURING DEVELOPMENT AND REGENERATION. N. Taleghany\* and M.M. Oblinger, Dept. Cell Biology and Anatomy and The Neuroscience

High molecular weight microtubule-associated proteins (MAPs) are important regulators of microtubule dynamics and have been postulated to play essential roles in regulating neuronal morphology and neurite outgrowth. We and others have previously shown that increases in tubulin gene expression accompany successful axonal regeneration in peripheral sensory neurons but accompany successful axonal regeneration in peripheral sensory neurons but little information exists about the expression of the various MAPs during this process. In the present study we examined the hypothesis that during regeneration of adult DRG neurons, MAP gene expression reverts to a pattern that reflects earlier developmental events. We examined mRNA and protein levels of two related genes, MAPla, a "late" MAP in brain, and MAPlb, an "early" MAP in brain during postnatal development of normal DRG neurons and during axonal regeneration of adult DRG neurons. For developmental studies, DRGs were obtained from pups between 1-21 days of age; for axotomy studies, unilateral sciatic nerve crushes were done on anesthetized adult male rats and the L4 and L5 DRGs were harvested 1-28 days later. In situ hybridization, immunocytochemistry, northern blotting and western blotting analyses revealed L4 and L5 DROs were narvested 1-28 days later. In stul hypothization, immunocytochemistry, northern blotting and western blotting analyses revealed that MAP1a and MAP1b expression during development of DRG neurons was similar to the patterns reported in brain. The axotomy experiments revealed that adult DRG neurons did not revert to earlier developmental patterns of MAP1 gene expression during axonal regeneration. For example, MAP1b expression was not augmented in regenerating DRG neurons, suggesting that the reorganization of MAP gene expression after axotomy is more complex than a simple reversion to an earlier developmental pattern.

Acidic fibroblast growth factor prevents shrinkage of cholinergic neurons of nucleus basalis magnocellularis following cortical devascularization D. Maysinger, B.C. Figueiredo, P. Piccardo, P.B.S. Clarke and A.C. Cuello Dept of Pharmacology and Therapeutics, McGill University, Montreal, Canada,

The ability of acidic fibroblast growth factor (aFGF) to elicit a trophic respons was first tested in rat septal cultures. Treatment with aFGF (0.1µg/ml) moderatelly increased the staining and length of glial processes immun for glial fibrillary acid protein (GFAP). Subsequently groups of rats (n=6) were trained in a spatial memory task (Morris water maze) and then were submitted to unilateral cortical devascularization, resulting in a 1X1 cm<sup>2</sup> area of neocortical infarction, and in retrograde degeneration the nucleus basalis magnocellularis (nBM) shown by ChAT immunocytochemistry (ICC). Animals were tested 24 days post-lesion for retention of the memory tasks and were sacrificed at 30 days. Intraventricular administration of aFGF (12 µg/day for 7 days via minipump), starting just before lesion, reduced NBM cholinergic cell degeneration (assessed by morphometric ChAT ICC and radioenzymatic assay for ChAT activity) and prevented the lesion-induced impairment in the memory retention test. The morphometric analysis of ChAT immunoreactive neurons in the nBM (ventral and dorsal midportions) showed significant reduction of the cell body shrinkage and of the cholinergic fiber degeneration. The most striking difference in the memory retention test between aFGF-treated (or sham-operated) and vehicle-treated decorticated subjects was observed in the first trial compared to the following trials in the first day and in the first day compared to the trials in the following days. Supported by Center of Excellence and Medical Research Council (Canada). 'CNPq and UFC (Brazil).

MICROTUBULE ASSOCIATED PROTEINS IN THE REGENERATING PERIPHERAL NERVOUS SYSTEM. I.W. Fawcett, G. Ma thews\*, M. Goedert and A. Matus. Physiological Laboratory, Cambridge University, England, MRC Laboratory for Molecular Biology, Cambridge, England and Friedrich Miescher Lab., Basel, Switzerland.

Some MAP proteins, particularly MAP5 and Tau, are abundant in axons and their growth cones during embryogenesis. Because of their effects on tubulin polymenrization and stabilization it is likeley that they play an important role in the process of axogenesis. Some axons, particularly those in the peripheral nervous system, are able to regenerate when cut in adulthood, although regenerative growth may be much less vigourous than embryonic growth. We have examined the disribution of MAPs in the sciatic nerve and its neurons of origin during embryogenesis and regeneration.

All normal sciatic nerve axons stain for MAP-5, and none stain for MAP-2. Tau is found in many very fine axons which do not stain for neurofilament, but is undetectable in many large diameter axons: many of these fine axons must be sensory, since neurones and axons which contain Tau and not neurofilament are plentiful in dorsal root ganglia. MAP-1 is present in all axons, but staining is more intense in the finer fibres.

MAP-5 and Tau but not MAP1 are present in axons and neurones

in the hindlimb region of E14 rat embryos, including their growth cones.

In regeneration the pattern of MAP distribution does not change: MAP-5 is present in all axons, including their growth cones, MAP-1 is also present in all axons. Tau staining is intense in many regenerating axons, but fibres which stain for neurofilament but not Tau can be found. MAP staining in motoneurones does not change in regeneration.

TUBULIN AND NEUROFILAMENT EXPRESSION IN REGENER-ATING ADULT RAT RETINAL GANGLION CELLS ANALYZED BY IN SITU HYBRIDIZATION. L. McKerracher\*, C. Essagian and A.J. Aguayo. Centre for Research in Neuroscience, Montreal General Hospital and McGill University. Montreal, Quebec, H4A 2P1.

Transected retinal ganglion cell (RGC) axons in adult rats regrow when the CNS environment of the optic nerve (ON) is replaced with a peripheral nerve (PN) graft. To investigate the expression of tubulin and NF in RGCs after ON transection in the presence or absence of a PN graft, we hybridized β-tubulin and NF probes to cryostat sections of injured retinas at various times after axotomy or 20 days after PNgrafting. Regenerating RGC were identified by retrograde labeling from the caudal end of the graft. A reduction in signal intensity for both tubulin and NF was observed after axotomy, and quantitative autoradiography confirmed that the mRNA levels were decreased in RGCs relative to contralateral controls. In the PN-grafted retinas the overall signal intensity with both probes was also reduced; however, some RGCs hybridized intensely for \( \beta\)-tubulin. Retrograde labeling revealed that such B-tubulin "hotspots" corresponded to the somata of regenerating RGCs. Because in such retinas the B-tubulin signal did not increase in the unlabeled RGCs we suggest that active axonal regrowth into the PN graft rather than other putative influences arising from the graft play a key role in this change in neuronal gene expression.

# 186.10

GAP-43 AND NGF-RECEPTOR EXPRESSION IN ADULT RAT THAI AMUS AFTER INITIRY OR PERIPHERAL NERVE IMPLANTATION. G.Campbell\*, E.Vaudano. A.P.Davies. P.N.Anderson, A.R.Lieberman, D.J.Schreyer Dept. of Anatomy, University

College London, Dept. of Physiology, Queen's University, Kingston, Canada. Many neurons undergoing regeneration increase their expression of the growth associated protein GAP-43, and, in some cases, the low affinity NGF receptor (NGFr). It is not known whether the upregulation of these proteins is simply a response to It is not known whether the upregulation of these proteins is simply a response to axotomy or whether the upregulation is necessary for, or is a consequence of, regeneration. We have studied whether injury alone is a sufficient stimulus to increase levels of GAP-43 and NGFr protein and mRNA in thalamic neurons of adult rats. Either a stab wound was made into, or a tibial nerve was grafted into the thalamus of anesthetized adult rats. After 4-177 days brains were processed for LM and EM immunocytochemisty with monoclonal antibodies 9-1E12 (which recognizes all forms of GAP-43) and 192-1gG (for NGFr) or for in situ hybridization using radio-labelled oligonucleotide probes for GAP-43 and NGFr mRNAs.

At 7-12d large numbers of GAP-43+ axonal sprouts were present in the thalamus adjacent to the grafts and small numbers close to the lesion. GAP-43+ sprouts were present in the graft at 12-40d. A few GAP-43+ neuronal perikarya were present in the thalamus close to the stab wound at 7-12d and many were GAP-43+ near the grafts at 9-12d. Preliminary hybridization data show that GAP-43 expression was increased in the thalamus close to the lesion at 7d whereas GAP-43 mRNA levels were not elevated near the graft/brain interface at 7d but were at 12d. In the thalamus close to grafts, but

near the graft/brain interface at 7d but were at 12d. In the thalamus close to grafts, but not lesions, NGFr+ sprouts were clearly present at 7-12d. NGFr+ neurons were present in caudal thalamus adjacent to the lesions at 7d but were not clearly identifiable adjacent to the grafts at any survival time. However, NGFr mRNA was greatly increased around the graft tip in caudal thalamus at 7d. In conclusion, a stab wound is a sufficient stimulus to increase the expression of GAP-43 and NGFr in some thalamic neurons. However, in the presence of a substrate permissive for axonal growth the upregulation of GAP-43 is both delayed and prolonged. The increased expression of NGFr in some neurons near the lesion or graft suggests that these cells may be responsive to neurotrophic factors related to NGF.

CHANGES IN mRNA LEVELS OF NEUROTENSIN,  $\alpha$ -AND  $\beta$ -CGRP, AND GAP-43 IN RAT HYPOGLOSSAL NUCLEUS AFTER THE H. Kiyama\*, N. Kobayashi, and M.Tohyama NERVE INITIRY

Anatomy & Neuroscience, Osaka Univ. Med. Sch., Osaka, JAPAN.

Neurotensin(NT), α- and β-CGRP, and GAP-43 mRNA expressions were observed in the rat hypoglossal motor neurons when unilateral hypoglossal nerve was either resected or crushed. For the detection of these mRNAs an in situ hybridization histochemical method using an alkaline phosphatase labeled oligonucleotide probe was used. The decrease of NT and B-CGRP mRNA level in the operated side after the decrease of N1 and p-corr many level in the operated side after the nerve injuries was observed, and the duration of the gene down regulation was much longer in NT mRNA than in  $\beta$ -CGRP. The  $\beta$ -CGRP mRNA level observed in the resected side could recover by a month, while it took almost two months for NT mRNA to recover the normal while it took amost two moints for H linking to fectore the homested level. Similar observation could be seen in case of crush, but the recovery of these mRNAs was quicker—than in the resected case, probably because of the extent of nerve damage. GAP-43 mRNA gene expression was contrary upregulated by the injuries. The tempora profile in the upregulation of GAP-43 mRNA level was similar to that of NT. The temporal regulation of  $\alpha$ -CGRP mRNA expression after the The temporal injuries apparently demonstrated different pattern. Nerve crush caused a few weeks upregulation of the message, however the however the caused a few weeks upregulation of the message, nowever the resection showed a quick transient upregulation within a few days and later a delayed increase of mRNA after about a month. Moreover the gene expression in the contralateral side was also transiently observed for about three weeks. These findings suggest the existence of different ways of gene regulation for NT,  $\alpha$ - and  $\beta$ -CGRP, and GAP-43 mRNAs during the regeneration of the hypoglossal motor neuron, but the profound reason for these difference is subject to more investigations.

ENHANCED EXPRESSION OF GAP-43 IN RETINAL GANGLION CELLS BY AN INTRAVITATIONS PERIPHERAL NERVE GRAFT AFTER INTRAOBBITAL AXOTOMY IN HAMSTERS 2 T.F.Ng , K-F.So and S.K.Chung\* . 1 Dept. of Anatomy, 2 Inst. of Molecular Biology, Univ. of

Hong Kong. HONG KONG.

GAP-43 expression in retinal ganglion cells (RGCs) are studied by immunocytochemical techniques using polyclonal antibody against GAP-43 (kind gift from Dr. Benowitz). Number and soma area of GAP-43 expressing cells are measured at various time courses (1-56 days) after optic nerve (ON) is cut 2mm from optic disc intraorbitally (n=32) or after intraorbital ON cut with a vital (n=40) or a nonvital (freeze and thaw, n=24) intravitreal peripheral nerve (PN) graft. When the ON is not damaged, no immunore-activity to GAP-43 is observed in retinas with (n=4) or without (n=25) a vital intravitreal PN graft. However, expression of GAP-43 is observed in RGCs in the ON cut animals and in the animals with ON cut and intravitreous implantation of a vital or non-vital PN graft. The time course of the immunoreactivity of GAP-43 is similar for the ON cut group (5-21 days post-axotomy) and the group receiving non-vital PN graft (5-28 days post-axotomy) but they are both different from the group receiving a vital PN graft (3-56 days post-axotomy). Thus our results show that a PN graft implanted close to RGC soma seems to influence the expression of GAP-43 so that it is expressed close to the optic disc. These changes of expression of GAP-43 may be important for enhancing axonal regeneration.

MRNA LEVELS OF PLASMINOGEN ACTIVATORS IN REGENERATING RAT

Sciatic Nerve. N.Kalderon\* and D.Belin+. The Rockefeller Univ. New York, NY 10021 and +Dept. of Pathology, Geneva Univ. Sch. of Med., Geneva, Switzerland.

Schwann cell plasticity during peripheral nerve regeneration and its regulation by the regroving severed axons are investigated on the molecular level. Plasminogen activators (PA) are key enzymes controlling a cascade of experiments. tivators (PA) are key enzymes controlling a cascade of ex-tracellular proteolysis, thus playing an important role in regulating cell and tissue plasticity. We previously determined that undifferentiated Schwann cells express determined that undifferentiated Schwann cells express high levels of PA activity, primarily of the urokinase type (u-PA). Here, the regulation of mRNA levels of both u-PA and tissue type PA (t-PA) during rat sciatic nerve regeneration were determined. Two distinct migrating cell populations, consisting mostly of de-differentiated Schwann cells that are either accompanied or unaccompanied by the regenerating evens were applied. These are obby the regenerating axons, were analysed. These are obtained by suturing the stumps of the transected nerve to each end of an empty silicone tubing; the cells from both each end of an empty silicone tubing; the cells from both stumps start migrating into this chamber during the 2nd week postinjury. The severed axons regrow from the proximal stump and follow the Schwann cells reaching the distal stump cells a week later. In the adult sciatic nerve no u-PA mRNA was detected while low levels of t-PA mRNA were found. High levels of both u-PA and t-PA mRNA were found in the migrating cell populations of the two stumps (11 days postinjury). These data strongly argue that the expression of both PA genes is up-regulated by axotomy in (11 days postinjury). These data strongly argue that the expression of both PA genes is up-regulated by axotomy in de-differentiated, migrating Schwann cells.

EARLY CHANGES IN FAST AXONALLY TRANSPORTED PROTEINS REFLECT DIFFERENTIAL REGULATION IN CRUSHED RAT OPTIC NERVE. L. Wodarczyk and G. W. Perry.\* Program in Comp Brain Sciences, Florida Atlantic University, Boca Raton, FL. 33431

The ability of RGCs of lower vertebrates to successfully regenerate their axons following optic nerve crush is attributed to both intrinsic factors, such as the ability to respond to damage through upregulation of fast axonally transported protein (FTPs), and extrinsic factors, such as a growth-permissible environment provided by the glial cell population. Increases in some FTPs (e.g. GAP-43) have been reported in rat RGCs following optic nerve crush; nonetheless, axon outgrowth is limited and subsequently aborted. This suggests that the characteristic failure of nammalian RGCs to regenerate is not due to an inherent inablity to respond to damage. Moreover, an appropriate glial environment will sustain directed axonal growth. This study examines how extensive the changes in FTPs are in response to RGC damage and how comparable these changes are to those that occur in lower vertebrate RGCs.

The left optic nerves of male Sprague-Dawley rats were crushed intraorbitally (4-5 nm distal to the eye) 2 and 5 days prior to intraocular injection of 35S-methion Following 5 hr labelling, experimental and control optic nerves were dissected and subjected to 2D-gel analysis. Quantification of Jahelled FTPs seen in fluorographic patterns from crushed nerves show both increased and decreased labelling in a broad range of FTPs. These changes are not unlike those seen in lower vertebrate optic nerves shortly after crush. We conclude that rat RGCs are capable of initiating the metabolic responses necessary for regeneration to begin. However, these and subsequent responses may eventually be suppressed by the presence of growthinhibitory factors in the rat optic nerve.

Supported by NIH Grant EYO6449.

EXPRESSION OF GAP-43 IS NOT INCREASED FOLLOWING CENTRAL AXOTOMY OF ADULT RAT DORSAL ROOT GANGLION NEURONS. David J. Schreyer\* and J.H. Pate Skene. Dept. of Physiology, Queen's University, Kingston, Canada K7L 3N6, and Dept. of Neurobiology, Duke University, Durham NC 27710
Peripheral nerve injury results in increased synthesis of GAP-43

and its accumulation in the injured peripheral and uninjured central axon branches of dorsal root ganglion (DRG) neurons (Schreyer & Skene, '91; J. Neurosci. 11:3738-3751). We sought to determine if the injury-associated mechanism which triggers increased GAP-43 synthesis is confined to one axon branch. Immunocytochemistry using monoclonal antibody 9-1E12 was used to monitor GAP-43 expression in uninjured adult rats, in rats two weeks after peripheral nerve crush lesions, and in rats two weeks after dorsal root crush Immunocytochemical labelling intensity was quantified from digitized images of DRG tissue sections.

Approximately half of DRG neurons were found to constitutively expresses GAP-43 in adult rats in the absence of axon injury. This constitutive GAP-43 expression ranged in magnitude from barely detectable to high, but was restricted to small DRG neurons. Following sciatic nerve lesions 1 cm. peripheral to the ganglion, virtually all DRG neurons, large and small, were found to express high levels of GAP-43. Following dorsal root lesions 1 cm. central to the ganglion, no increase in GAP-43 expression by DRG neurons above that seen in uninjured animals was detected. Thus, the injury-associated increase of GAP-43 expression in DRG neurons appears to be regulated principally by a mechanism operating through peripheral, rather than central, axon branches.

# 186.16

NCAM EXPRESSION DURING TASTE BUD DEGENERATION AND REGENERATION. D. V. Smith\*, R. Klevitsky, R. A. Akeson, and M. T. Shipley. Depts. Otolaryngology - Head Neck Surg., Pediatrics, Anatomy & Cell Biol., Univ. Cincinnati Coll. Med. and Children's Hosp., Cincinnati, OH 45267

Taste cells are continuously renewed throughout life and are trophically dependent on the peripheral gustatory nerves that innervate them. We and others have shown that the neural cell adhesion molecule (NCAM) is expressed by taste cells and their nerve fibers. In early development, NCAM molecules contain high levels of polysialic acid (PSA), which regulates the degree of cell-cell interaction mediated by NCAM. Here we have characterized the reappearance of both NCAM polypeptides and PSA in the rat vallate papilla at several points in time following bilateral crush of the glossopharyngeal (IXth) nerve using monoclonal antibodies (mAbs) to NCAM polypeptides (mAb 3F4) and to PSA (mAb 5A5).

In non-lesioned controls, NCAM is distributed on a subset of cells within the taste buds and on nerve fibers throughout the tongue, including those innervating the gustatory epithelium. By contrast, PSA is present only on nerve fibers, including a small number that enter the vallate taste buds. In the first week following bilateral IXth nerve crush, NCAM expression gradually diminishes in the gustatory epithelium; its expression returns upon reinnervation by the IXth nerve. PSA expression also diminishes in the IXth nerve after crush and reappears as the nerve regenerates. We hypothesize that PSA will be downregulated in afferent fibers as they enter the gustatory epithelium. These results suggest that NCAM is involved in the differentiation of epithelial cells into taste receptors and in the interactions between IXth nerve fibers and taste receptor cells

PROTEOGLYCANS OF REGENERATING NERVE, <u>J. F. Challacombe\*</u> and <u>J. S. Elam</u>, Program in Neuroscience, Florida State University, Tallahassee, Florida 33306

Our previous studies demonstrated the enhanced axonal transport of \$^5S\_0\_4labeled proteoglycans in the regenerating goldfish optic system (Coughlin and Elam, Br. Res. 493, 326 (1989), Challacombe and Elam, Soc. Neurosci. Abs. 17, 49 (1991)). We have extended these studies to assess the distribution of transported proteoglycans in sequential optic tract extractions consisting of: (1) isotonic buffer followed by hypotonic buffer (soluble fraction), (2) 1M NaCl (peripheral membrane-associated), (3) 1% Triton (integral membrane), and (4) 1% Triton-1M NaCl (integral membrane-anchored). Distribution of total transported radioactivity among these extracts for unoperated controls was 35.9% soluble, 15% NaCl extracted, 20.6% Triton extracted, 21.6% Triton-NaCl extracted, and 6.9% unextracted. For 21 day regenerating tracts the values were 27.7% soluble, 13.8% NaCl extracted, 24.3% Triton extracted, 27.5% Triton-NaCl extracted, and 6.7% unextracted. As assessed by DEAE-cellulose ion-exchange chromatography, the proportion of total radioactivity in proteoglycans for each of these extracts showed a regeneration-correlated increase. However, the distribution of total transported proteoglycans among the various extracts indicated little difference between regenerating and unoperated controls. Gel filtration of transported proteoglycans of negenerating nerve are distributed among soluble and membranous compartments in a pattern similar to intact nerve, but with some change in the overall proteoglycans ize range. ANALYSIS OF C-JUN mRNA AND PROTEIN IN DORSAL ROOT GANGLIA AFTER SCIATIC NERVE TRANSECTION. M. De León\*, R. Nahin, S. Inagaki, B. Allen and M.A. Ruda. NAB, NIDR, NIH, Bethesda, MD 20892

NIDR, NIH, Bethesda, MD 20892

The effect of nerve injury and regeneration on transcription factors in dorsal root ganglia (DRG) neurons was examined. Adult rats were anesthetized and the sciatic nerve transected. DRG at 8 hours, 1, 2, 3 and 7 days after transection were collected, their mRNA extracted and Northern blots performed using a 32P-labeled 51-mer oligonucleotide probe complementary to bases 2810-2861 of rat c-Jun. The constitutive expression of c-Jun mRNA was very low in DRG. Induction of c-Jun mRNA was observed by 1 day after nerve transection, with a 6 fold peak at three days and returning to control levels by day seven. In situ hybridization using the same oligonucleotide probe demonstrated c-Jun mRNA induction in small,- medium- and large-sized DRG neurons. Immunocytochemistry demonstrated Jun protein in nuclei of DRG neurons. DNA gel mobility shift experiments showed a single DNA-protein complex was increased in ipsilateral as compared to contralateral DRG extracts. The amount of DNA-protein complex was reduced by Jun protein antisera, but was not altered when treated with a Fos antibody. These data suggest that c-Jun may play an important role in transcriptional regulation of DRG neurons in the response to neuronal injury and regeneration.

# 186.21

INSULIN-LIKE GROWTH FACTORS REGULATE THE RATE OF SCIATIC NERVE REGENERATION. G.W. Glazner, S. Lupien, J.A. Miller, and D.N. Ishii. Physiology Depts., Colorado State Univ., Fort Collins, CO 80523; Amgen, Inc., Thousand Oaks, CA 91320.

Prolonged denervation results in atrophy and degeneration of organs, and the slow rate of mammalian nerve regeneration is a risk factor for permanent paralysis. It is, therefore, of interest to identify the endogenous factors that can influence the rate of peripheral nerve regeneration. Insulin-like growth factors (IGFs) can enhance neurite outgrowth in vitro, and IGF-II gene expression is implicated in the development and regeneration of neuromuscular synapses. We report that local infusion of IGF-II near a site of sciatic nerve crush significantly increased (P < 0.01) the rate of regeneration in rats. On the other hand, local infusion of an anti-IGF antiserum caused a sustained reduction in rate (P < 0.01) for 6 days, showing that the spontaneous rate of regeneration was continuously dependent on nerve IGF activity. IGF-II mRNA content was increased per poly(A)<sup>+</sup> RNA (P < 0.03) as well as per nerve (P < 0.001) in deafferented nerves. These results support the hypothesis that IGFs help regulate the rate of peripheral nerve regeneration. ENHANCED EXPRESSION OF A PROTEOGLYCAN ON AXOTOMIZED TROCHLEAR MOTOR NEURONS. P. Jannuzzelli\* Y. Wang, A. Pimenta, I. Fischer, P. Levitt and E. H. Murphy, Department of Anatomy and Neurobiology, Medical College of Pennsylvania /EPPI, Philadelphia, PA 19129.

A monoclonal antibody, 8B3, recognizes a surface chondroitin sulfate proteoglycan associated with the soma and dendritic processes of a sub-population of neurons, including cranial and spinal motor neurons. In this study, we examined the effect of a peripheral nerve cut on 8B3 immunoreactivity in axotomized cranial motor neurons. In adult cats, the trochlear nerve was exposed and severed peripherally. Following this type of lesion, some trochlear motor neurons (TMNs) die. The surviving motor neurons regenerate and reach their target in 4 weeks (Murphy, et.al. 1990 J.Comp.Neurol.292:524-536). In the normal adult cat, 8B3 labelling is observed along somata and dendritic processes throughout the trochlear nucleus. One week after axotomy, the level of 8B3 immunoreactivity in the lesioned nucleus increases compared to the normal side. At longer survival times, the difference in staining intensity between the lesioned and normal nucleus remains, with 8B3 immunoreactivity in the lesioned nucleus elevated for as long as 14 weeks post-axotomy, the longers survival time examined.

(Murphy,et.al.1990 J.Comp.Neurol.292:524-536). In the normal adult cat, 8B3 labelling is observed along somata and dendritic processes throughout the trochlear nucleus. One week after axotomy, the level of 8B3 immunoreactivity in the lesioned nucleus increases compared to the normal side. At longer survival times, the difference in staining intensity between the lesioned and normal nucleus remains, with 8B3 immunoreactivity in the lesioned nucleus elevated for as long as 14 weeks post-axotomy, the longest survival time examined.

One possible explanation for this finding is that TMNs expand their dendritic arborization in response to injury. We examined this possibility using a monoclonal antibody to microtubule-associated protein 2 (MAP2) on alternate sections through the trochlear nucleus. MAP2 has been shown to be localized specifically to neuronal cell bodies and dendrites. As early as one week post-axotomy, the density of MAP2 positive dendritic processes decreases in the lesioned nucleus and this decrease is even more pronounced at longer survival times, suggesting that axotomy results in a reduced number of dendritic processes in the axotomized trochlear nucleus. These findings suggest that 8B3 immunoreactivity is rapidly increased on axotomized TMNs, and may reflect an important role for the 8B3 proteoglycan in the functional recovery of regenerated motor neurons. TESTOSTERONE EFFECTS ON TUBULIN GENE EXPRESSION IN REGENERATING HAMSTER FACIAL MOTOR NEURONS (HFMN). K.J. Jones¹ and M.M. Oblinger ²\*, Dept. Physical Therapy¹, Univ. Illinois at Chicago, Chicago, IL 60612 and Dept. Cell Biology and Anatomy², Chicago Med. Sch., North Chicago, IL 60064.

We have previously shown that testosterone propionate (TP) differentially regulates the regenerative properties of injured HFMN through an enhancement of the nerve cell body response to injury. In this study, the hypothesis that TP increases the rate of regeneration by altering cytoskeletal gene expression was tested. Adult intact male hamsters were subjected to right facial nerve axotomies. One-half of the axotomized animals received 2 subcutaneous implants of TP, and the other half were shamimplanted. At 2 and 7 days postoperative (dpo), the animals were sacrificed and either cryostat sections collected for in situ hybridization or total RNA was isolated from the facial nuclear groups for northern blot analysis. Hybridizations with cDNA probes to class II beta-tubulin and alpha1-tubulin mRNAs were done. The autoradiograms from in situ hybridizations were quantitatively analyzed using a computerized image analysis system and the northern blots were assessed by densitometry. The results from both series of experiments revealed that axotomy induced significant increases in the levels of both tubulin mRNAs by 7 dpo, and that testosterone augmented the expression of tubulin mRNAs in the axotomized neurons. Supported by NIH grants NS28238(KJJ) and NS21571 (MMO).

INDUCTION OF NEUROTROPHIC FACTORS GENE EXPRESSION IN THE KAINIC ACID LESIONED THALAMUS. M.P. Junier \*, M. Peschanski. CJF INSERM 9102, Fac de Médecine, 8 rue du Général Sarrail, 94010 Créteil, France.

Kainic acid injection in the ventro-basal nucleus of the thalamus (VB) triggers a complete neuronal loss while sparing afferents to the lesioned nucleus. The lesion is followed by a dramatic cellular rearrangement leading to the sequential proliferation of activated microglia, reactive astrocytes and Schwann cells. These different glial cells are putative sources of neurotrophic factors and their appearance at the lesion site is correlated with the initial maintainance of axonal projections issued from the dorsal column nucleus (DC). Along the weeks the number of projections issued from the DC decreases although some are still identified 18 months post-lesion. To unravel some of the cellular mechanisms allowing long term maintainance of axonal projections at the lesion site, we sought to determine the timing of neurotrophic factor gene expression in the lesioned VB. Messenger RNA was extracted from both lesioned VB and its intact contra-lateral counterpart. Using ribonuclease protection assays VB mRNAs were hybridized to a riboprobe complementary either to TGF alpha, or NGF, or low affinity NGF receptor (LNGFR) mRNAs. Both TGF alpha and NGF message were detectable in intact VB. TGF alpha mRNA levels did not vary as compared to the controlateral VB up to 40 days post-lesion. At this time TGF alpha mRNA levels increased over contra-lateral VB levels. On the opposite, NGF mRNA levels tended to decrease in the lesioned VB until resuming 40 and 60 days post-lesion to quantities similar to those observed in the contra-lateral intact VB. At the same time points LNGFR mRNA were detected in the lesioned VB. Previous studies suggest that at least two cell types could account for the increased expression of TGF alpha and NGF genes: reactive astrocytes (for both TGF alpha and NGF mRNA are under current investigation. These results suggest that cellular rearrangement induced by kainic acid lesion of the VB is accompanied with the induction of neurotrophic factor genes expression susceptible to exert trophic effects on axona

MODULATION OF CALBINDIN EXPRESSION IN PUTATIVE RENSHAW CELL AFTER SCIATIC NERVE LESION. P.P. Sanna 1\*, M. R. Celio<sup>2</sup>, F., E. Bloom 1 and M. Rende<sup>3</sup>. <sup>1</sup>Department of Neuropharmacology, The Scripps Research Institute, La Jolla, CA, USA; <sup>2</sup>Institute of Histology, University of Fribourg, Fribourg, Switzerland; 3Institute of Human Anatomy, A. Gemelli Medical School, Rome, Italy. A subpopulation of calbindin-immunoreactive (CB-IR) neurons in lamina VII of the spinal cord has been proposed to be Renshaw cells, the anatomical substrate for recurrent inhibition. We used sciatic nerve crush to disrupt the activity of motorneurons and presumably of local interneurons. One week after sciatic nerve crush, CB-IR neurons had virtually disappeared ipsilaterally, between L4-L6, but were still immunoreactive controlaterally and cranially to the lesioned levels. Similar effects were produced by intramuscular administration of botulinum toxin. The time course for the onset of these changes was consistent across animals. CB-IR neurons reappeared during reinnervation of muscle along a rough cranio-caudal gradient and appeared normal within 6 to 8 weeks after the crush. However, a significant degree of inter-animal variation was observed in the timing and pattern of their reappearance on the lesioned side. The slower conduction velocity of  $\alpha$ -motorneurons, their reduced activity and the reduction of their input on Renshaw cells may result in reduced activity of these latter neurons and hence in reduced need for Ca++ buffering power. The present results suggest that the CB expression in putative Renshaw cells of the anterior horn is plastic and that its maintenance depends on motorneuron electrical activity. The fact that similar changes occurred in CB-IR neurons following intramuscular botulinum toxin emphasizes the critical nature of neuro-muscular transmission in the expression of CB.

EXTRINSIC DENERVATION INDUCES CHANGES IN NEUROPEPTIDE AND PHOSPHORYLATED HEAVY NEUROFILAMENT IMMUNOREACTIVITY IN SUBMUCOSAL PLEXUS OF GUINEA PIG ILEUM A.M. Yunker\* and J.J. Galligan Dept. Pharm. and Tox. and Neuroscience Program, Michigan State University, E. Lansing MI 48824

Following extrinsic denervation of the small intestine there are changes in surviving nerve fibers associated with submucosal arteries. The purpose of this surviving nerve incers associated with submucosal arteries. The purpose of this study was to further describe the changes in neuropeptide immunoreactivity (ir) and to determine if denervation alters phosphorylated heavy neurofilament (pNF-H)-ir. Tissues were obtained 1,710, or 24 weeks after denervation, denervation was verified using glyoxylic acid to reveal neuronal stores of norepinephrine, and tissues were processed using immunohistochemical methods. In normal animals submucosal arterioles were innervated by extrinsic sympathetic and calcitonin gene related peptide (CGRP)-/substance P (SP)-ir ensory nerve fibers; submucosal enteric nuclei and axons contain pNF-H-ir. One week after denervation extrinsic nerves were not detected: furthermore One week after defervation extrinsic rieves were not detected, intrinsingly splin or vasoactive intestinal peptide (VIP)-ir nerve fibers were found associated with arterioles. SP-ir decreased, VIP-ir increased in the submucosal plexus, and pNF-H-ir was reduced. Seven weeks after denervation, SP-ir nerve fibers had formed a sparse perivascular plexus and multiple VIP-ir nerve fibers were found with arterioles. Neuropeptide-ir of ganglia was similar to control, but PNF-H-ir in nuclei was decreased and nerve fibers were not immunoreactive. Ten weeks after denervation, meandering SP-ir fibers were associated with arterioles, sympathetic nerve fibers returned to ganglia, and nuclear pNF-H-ir was normal. Finally, twenty-four weeks after denervation extrinsic nerve fibers were associated with arterioles and nerve fibers contained pNF-H-ir. This study concludes denervation induced changes in neuropeptides and pNF-H may represent an adaptive response to allow normal intestinal function in the absence of extrinsic control. THE INITIAL STAGES OF NEURAL REGENERATION ARE DEPENDENT UPON INTRACELLULAR CALCIUM LEVELS V. Rehder and S.B. Kater, Program in Neuronal Growth and Development, Dept. of

Anatomy and Neurobiology, Colorado State University, Ft. Collins, CO 80523

The ability of a neuron to repair a transected process through the generation of new outgrowth has been the topic of investigations dating back to Ramon y Cajal. There are, undoubtedly, several stages, from the repair of the existing axon to the reformation of appropriate connections, that have to be considered analytically in order to understand functional regeneration. We focus on the earliest stages of regeneration, namely, the formation of a new growth cone from a transected process.

Motivated by the finding that the motility of neuronal growth cones can be Motivated by the inding that the motility of neuronal growth cones can be completely inhibited by high intracellular calcium levels, we examined whether the proximal stump of a severed neurite is also influenced by potentially inhibiting levels of intracellular calcium ([Ca2+]i). To test this hypothesis, we severed individual neurites after elevating their [Ca2+] it ovarying degrees and asked whether this would influence the probability of formation of a functional neuronal growth cone. The formation of a new growth cone was a rapidly occurring event in standard culture medium. The time course and absolute degree of growth cone formation, however, were highly dependent on [Ca2+]i. If transections were performed after experimentally increasing [Ca2+]i by either depolarization or via calcium ionophores, regeneration became gradually slowed and less complete, indicating that regeneration is fastest and most successful at basal levels of intracellular calcium. Likewise, when is raisest and most successful at oasal levels or intractituar calcium. Likewise, when decreasing the extracellular calcium concentration, the time course of growth cone formation was also continuously slowed and the percentage of regenerating neurons decreased. These findings may bear significantly on studies attempting to optimize conditions for neuronal regeneration. Either a transient rise in the intracellular- or a decrease in the extracellular-calcium concentrations will contribute to impaired regeneration and possibly to neuronal cell death. Since both of these events can be simultaneously observed after neuronal injury and in certain types of neurological diseases, they may prove to be important factors in determining the degree to which neuronal regeneration can be expected to occur.

### 186.26

Neurotransmitter Receptor Modulation Following Unilateral L1-S2 Deafferentation. S.Croul'\*, A.Sverstiuk\*, W.Battisti\* and M.Murray\*. Depts.

Pathology\* and Anatomy/Neurobiology, Med.Col.Penna., Phila., Pa. 19129

Following surgical deafferentation of the spinal cord, cut dorsal roots do

not regenerate, but spared projections compensate for this loss by forming collateral sprouts and thereby modifying the synaptic organization of the dorsal horn. Locomotor functions recover with a time course and pattern which parallel and may therefore in part be accounted for by these changes in synaptic organization. Light microscopic immunocytochemistry has shown sprouting by organization. Ight interception infinition experientially has shown sproung by selected undamaged intraspinal projections including those that express the transmitter substance P (SP) (Wang SD et.al., J.Comp.Neurol. 304;555-568, 1991). Quantitative immunoelectron microscopy supports these results by demonstrating loss and consequent recovery of SP containing terminals (Zhang et.al.,Soc. for Neurosci. Ab., 1991). Effects on second order neurons in the dorsal horn may include modulation of neurotransmitter receptors which parallel these afferent changes. To test this hypothesis, adult rats were subjected to L1-S2 unilateral dorsal rhizotomy and sacrificed at 0.5, 1, 2, 6, or more than 20 weeks after surgery. Spinal cords from 3 rats per time point were cryosectioned and used to evaluate changes in the receptor binding density of the SP (NK1) receptor in the dorsal horn. NK1 binding density was increased in lamina II of the deafferented side by 1 week after surgery by a factor of 1.5 compared to the control side. It remained elevated at 2 and 6 weeks( 2 times control) but returned to control values by 20 weeks. N -methyl-D-aspartate(NMDA) receptor binding using H-MK801 shows clear binding to the dorsal horns in rat lumbar spinal cord. Clarification of the magnitude, time course and cellular localization of the changes will help to define the second order neuronal response to spinal deafferentation and its impact on functional recovery. # CALCIUM CHANNELS: PHYSIOLOGY I

# 187.1

CALCIUM CHANNEL STABILITY IN LARGE NEURONAL INSIDE-OUT

PATCHES. B.D. Johnson and L. Byerly.\* Dept. of Biol., USC, L.A., CA 90089.

One of the most universal properties of Ca<sup>2+</sup> channels is their tendency to "wash out" or "run down" during whole-cell voltage-clamp recording. Washout can be reduced or prevented by using the perforated patch technique, or by including such intracellular components as ATP, cyclic AMP, and kinases in the recording electrode. Although restorative, these additions to the recording electrode may have multiple effects within the cell. To address the issue of Ca<sup>2+</sup> channel lability in a neuronal preparation, we have developed a large, inside-out patch technique similar to that described by Hilgemann (1990; *Nature* 344, 242-5). These large patches provide an easily quantifiable macroscopic Ca<sup>2+</sup> channel current of 20-100 pA and clear access to the cytoplasmic side of the channel. Patch electrodes with an inner diameter of 5-10  $\mu$ m, dipped in a mixture of oils and filled with 4 mM Ba²¹-Tris saline, are sealed (5-50 GΩ) to acutely isolated neurons from the snail Lymnaea stagnalis. In the cell-attached configuration,  $I_{Ba}$  (measured in standard Lymnaea saline) appears stable over the period of observation (up to 30 minutes). Following excision into a low Ca<sup>2+</sup> solution (2 nM) containing 1 mM Mg<sup>2+</sup>. has declines rapidly with a t of 75 seconds (N=11). Future work will determine if higher free Ca<sup>2+</sup>, G-proteins, or agents involved in phosphorylation (ATP, cAMP, kinases, phosphatase inhibitors) will stabilize I<sub>Ba</sub> in this cell-free preparation. If I<sub>Ba</sub> can be stabilized sufficiently, this preparation will be used to determine the sensitivity of these Ca<sup>2+</sup> channels to intracellular Ca<sup>2+</sup>. This work was supported by NINDS grant NS28484.

EFFECTS OF TEMPERATURE ON Ca CHANNELS IN CHICK SENSORY NEURONES. P. Acerbo, M. Nobile and C. Marchetti\*. Ist. di Cibernetica e Biofisica, CNR, 16146 Genova, Italy. We investigated the effects of the temperature on Ca channels in cell-attached patches, in chick dorsal root ganglion neurones. In 110mM BaCl<sub>2</sub>and at T=20°C, chick dorsal root from Vh=-50mV, we observed three different types of HVA calcium channels: one BayK-sensitive channel, "L" (conductance 23pS); a BayK-insensitive, fast inactivating channel, "FI"(13pS); a BayK-insensitive not-inactivating channel with similar conductance but different kinetics from FI. When the temperature was changed from 15°C to 30°C, all three conductances increased with Q<sub>10</sub> 1.4,1.32,1.28 respectively and the mean open time of the three channels decreased. Moreover, both FI and L channels inactivated faster at 15°C than at 30°C; FI channel activity was concentrated during the first 20ms at 30°C, while at 15°C openings were distribuited on the the channel the channel openings were distribuited on the whole trace; as a consequence, during a 150ms trace, the open probability was lower at higher temperature. In averaged traces of about 50 individual records the peak current increased with  $\Omega_{10}$  1.35 (L) and 1.64 (FI). These data are in agreement with our previous results on whole-cell currents. (Pflug. Arch. 415, 1990)

MODAL GATING OF L-TYPE CALCIUM CHANNELS IN RAT CEREBELLAR NEURONS. D. Pietrobon and L. Forti. C.N.R. Mitoc. Physiol. Center, Univ. of Padova, 35100 Padova, Italy. Gating of single L-type calcium channels in rat cerebellar granule cells is complex and shows some peculiar properties not previously reported in other cells. The same L-type channel can have two different acting partners. The loss frequent which Po previously reported in other cells. The same L-type channel can have two different gating patterns. The less frequent "high-Po gating" (g=27 pS, 90 mM Bā') is similar to the previously described activity with the typical short openings (mode 1) and some rare long-openings (mode 2). The transitions between modes 1 and 2 have voltage dependent rate constants similar to those reported in cardiac cells (Pietrobon and Hess, 1990, Nature 346:651). In the presence of (+) 202-791 the mean open time is ~10 ms at 20 mV. In contrast, the more frequent "low-Po gating" (g=24 pS) has a mean open time of only 2 ms at 20 mV in the presence of agonist, and shows almost no activity in its absence (mode 1) except for some openings with mean open time ~1-2 (mode 1) except for some openings with mean open time ~ 1-2 ms (mode 2). In the range 0-30 mV the open probability of the "low-Po gating" does not increase, closed times do not become shorter and open times appear to shorten with voltage. Positive prepulses induce very long openings at negative voltages. The resulting average current shows a typical rising phase after the prepulse, which we show not to be due to recovery from inactivation, but rather to the peculiar voltage dependent properties of the open-closed transitions inside mode 2. These properties of the "low Po gating" result in minimal calcium influx during depolarization and potentiated calcium influx upon repolarization. Supported by Fidia Research Laboratories.

DIFFERENT VOLTAGE-DEPENDENT CALCIUM CHANNELS AT PRE- AND POSTSYNAPTIC STRUCTURES IN HIPPOCAMPAL AREA CA1. L.G. Wu\* and P. Saggau. Div. of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

We investigated the pre-versus postsynaptic distribution of different types of voltagedependent calcium channels in the Schaffer collateral/commissural pathway (SCC) synapsing on CA1 pyramidal cells in hippocampal slices of guinea pigs. Synaptic structures were selectively loaded with the calcium indicator Fura-2 AM (Saggau et al., Biophys J 61, 1992). Pre- and postsynaptic calcium transients (pre-Ca<sup>2+</sup>, post-Ca<sup>2+</sup>) were optically recorded from the region of apical dendrites of area CA1, by single-pulse stimulating either orthodromically via SCC or antidromically via alveus (alv). The effects of different types of calcium channel blockers on pre-Ca<sup>2+</sup>, post-Ca<sup>2+</sup>, field EPSP (fEPSP), and population spike (pop) were investigated and preliminary results are summarized in the following table (=: no significant change; ---: no data).

|                           | orthodromic sum of SCC |              | antidromic stim of alv |           |     |
|---------------------------|------------------------|--------------|------------------------|-----------|-----|
|                           | pre-Ca <sup>2+</sup>   | <b>fEPSP</b> | post-Ca <sup>2+</sup>  | post-Ca2+ | pop |
| ω-conotoxin (1 μM)        | -45%                   | -85%         | -98%                   | -20%      | =   |
| Nifedipine (10 µM)        | =                      | =            | =                      |           |     |
| Nimodipine (40 µM)        | =                      | +20%         | +15%                   | +12%      | =   |
| Phenytoin (100 µM)        | -10%                   | -30%         |                        |           |     |
| NiCl <sub>2</sub> (50 µM) | =                      | =            |                        |           |     |

Our results suggest the existence of N-type (oCTX-sensitive), but not L-type (dihydropyridine-sensitive) calcium channels in presynaptic terminals. The dosetempore curve of  $\omega$ CTX showed with 1  $\mu$ M a saturating reduction of about 45% of pre-Ca<sup>2+</sup>, which suggested the existence of another type of calcium channel in the presynaptic terminals. Phenytoin, a T-type channel blocker, decreased pre-Ca2+ reversibly, and delayed the orthodromic volley. The decreasing effect of  $\omega$ CTX on post-Ca<sup>2+</sup> induced by antidromic stimulation was reversible, suggesting the existence of either N-type or T-type calcium channel in the apical dendrites of CA1 pyramidal cells. Supported by grants of the Cain Foundation and the Whitaker Foundation to P. Saggau.

# 187.7

CHARACTERIZATION OF CALCIUM CHANNELS IN RAT BRAIN SYNAPTOSOMES USING STOPPED-FLOW FLUORIMETRY AND M.M.Thomas\* and S.M.J.Dunn. Dept. of Pharmacology, Univ. of Alberta, Edmonton, Canada T6G 2H7

The functional properties of voltage-dependent calcium channels have been measured in synaptosomal preparations from rat brain. Synaptosomes were equilibrated in low potassium (5 mM) buffer and loaded with the fluorescent calcium chelating dye, Fura 2, by incubation with the membrane permeant acetoxymethyl ester Depolarization-dependent uptake of calcium was measured in stopped-flow experiments by following the fluorescence changes of the entrapped dye. Rapid mixing with a high potassium (30 mM final) buffer resulted in an increase in intrasynaptosomal calcium concentration as measured by a quench in Fura 2 fluorescence at 390 nm. The magnitude of the quench was dependent on extrasynaptosomal potassium concentration and was completely blocked by the inorganic calcium channel blockers, cadmium, cobalt and lanthanum with EC50 values of 7.1  $\mu$ M, 11.6  $\mu$ M and 0.8  $\mu$ M respectively. The observed quench was unaffected by the neuronal N-type calcium channel blocker,  $\omega$ conotoxin GVIA (1  $\mu$ M). The dihydropyridine antagonist nitrendipine did not affect the observed quench over the concentration range, 10 nM to 10 µM. However, another dihydropyridine derivative, nimodipine blocked approximately 25% of the flux response. Supported by AHFMR and NIH GM-42375.

A NON T-, N- OR L-TYPE CALCIUM CHANNEL MEDIATES RELEASE OF TRANSMITTER FROM CEREBELLAR GRANULE CELLS IN TISSUE CULTURE. R.D. Randall\* and W. Raabe. Depts. Neurology, Physiology and Neuroscience Graduate Program, VA Med. Ctr. and U. of Minnesota, Minneapolis, MN 55417.

The characteristics of the calcium channel responsible for transmitter release from cerebellar granule cells were investigated in rat cerebellar neurons grown in primary tissue culture. Whole cell patch voltage clamp recordings were obtained from large (  $\geq$  15  $\mu m$ Ø) cerebellar neurons, presumed to be Purkinje cells. Excitatory postsynaptic currents (EPSCs) were elicited by stimulation of a

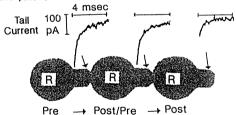

nearby granule cell ( $\leq 8 \ \mu m \varnothing$ ) with an unpolished patch pipette. Removal of Ca<sup>2+</sup> from the extracellular solution, substitution of Ba<sup>2+</sup> for Ca<sup>2+</sup>, or addition of Cd<sup>2+</sup> (20  $\mu$ M) abolished evoked EPSCs but not action potential independent miniature EPSCs. This demonstrates the Ca<sup>2+</sup>-dependence of transmitter release and that Ca2+ does not significantly contribute to the postsynaptic currents examined. Addition of T-, N- and L-type calcium channel antagonists Ni<sup>2+</sup> (500  $\mu$ M),  $\omega$ -conotoxin GVIA (1  $\mu$ M) or nifedipine (1  $\mu$ M) failed to abolish evoked EPSCs. These observations indicate that the calcium channel mediating the release of excitatory synaptic transmitter from cerebellar granule cells is not of the T-, N- or Ltype. This suggests the existence of an uncharacterized calcium channel.

ANTEROGRADE AND RETROGRADE EFFECTS OF SYNAPSE FORMATION ON CALCIUM CURRENT DISTRIBUTION IN PRE- AND POST-SYNAPTIC CELLS. F. Fernandez-de-Miguel\* R.L. Cooper, W.B.
Adams and J.G. Nicholls
Biocenter, CH-4056 Basel, Switzerland

Leech Retzius cells were plated as triads, with the tip of one Retzius cell touching the soma of another. Ca<sup>++</sup> current distribution was measured by loose-patch clamp recording. With three cells arranged in a row, the last of the cells was purely postsynaptic. It showed a dramatic reduction in Ca<sup>++</sup> tail currents in the initial segment compared to tail currents in either the first cell, (purely presynaptic) or the second cell of the chain (postsynaptic to the first cell and presynaptic to the third). These results show that neurons upon which chemical synapses have formed express different Ca<sup>++</sup> currents depending on whether they themselves have formed presynaptic terminals on other cells. This change in current distribution is accompanied by marked differences in growth patterns.

# 187.8

UNITARY CALCIUM CHANNEL CURRENTS RECORDED FROM SYNAPTIC VARICOSITIES OF EMBRYONIC XENOPUS MOTONEURONS IN VITRO. S.D. Meriney. B. Yazejian and A.D. Grinnell. Jerry Lewis Neuromuscular Res. Ctr., UCLA School of Med., Los Angeles, CA 90024. Presynaptic calcium channels are of critical.

Presynaptic calcium channels are of critical importance in the regulation and modulation of chemical transmitter release. However, due to their relatively inaccessible distribution in the presynaptic membrane, with rare exception, they have been difficult to study directly. We have studied unitary calcium channel currents in varicose synaptic regions of Xenopus motoneuron neurites using the cell-attached patch-clamp configuration. Primary nerve-muscle cultures were prepared from stage 19-21 embryos. For isolation of single calcium channels, cultures were bathed in a normal frog Ringer and the patch pipette was filled with 100 mM BaCl<sub>2</sub>, 10 mM Hepes, 2  $\mu$ M TTX, and 100  $\mu$ M 3,4 DAP. In two-day old cultures, we have measured two voltage-gated conductances (10-12 pS and 17-19 pS), both of which were resistant to dihydropyridine agonist modulation. In addition, we have evidence for a third conductance smaller than 10 pS. Supported by grants from the NIH (NS06232) NSF

(BNS8919841) and The Council For Tobacco Research.

KINETICS AND VOLTAGE DEPENDENCE OF THE HIGH THRESHOLD CALCIUM CURRENT IN RAT NEOCORTICAL NEURONS. A.M.Brown, P.C. Schwindt\* and W.E.Crill Dept. of Physiology & Biophysics, Univ. of Washington Sch. of Med., Seattle, WÁ 98195

High threshold (HT) calcium currents were recorded in pyramidal neurons acutely isolated from sensorimotor cortex of 14-28 day old rats using the whole cell patch clamp configuration. The HT current consists of dihydropyridine-sensitive, ω-conotoxin-sensitive and residual components (Sayer et al, Neurosci. Letts. 120, 1991). Kinetics were derived from the time course of current onset and offset Kinetics were derived from the time course of current onset and offset (tails); the voltage dependence of activation (m<sub>oo</sub>) was derived from tail current amplitude. While nifedipine (5 µM) and ω-conotoxin (10 µM by puffer pipette) partially suppressed the peak current, these agents altered neither time constants nor voltage dependence. Hence, the HT current of these neurons is composed of kinetically the HT current of these neurons is composed of kinetically homogeneous subcomponents. Current onset was best fit by m² kinetics. Tail time constants increased with depolarization and fit m² kinetics only negative to -30 mV. The measured instantaneous current-voltage relation (IIV) was steeper than predicted by the constant field equation. The former but not the latter predicted a constant permeability over the range of potentials measured (-20 to +25 mV). Using m² kinetics and constant permeability, measured peak currents could be reconstructed from independently measured parameters (m, time constants, IIV). Supported by ONR N0014-90-5-1627, NS 16792, and W.M.Keck Foundation.

WHOLE CELL PATCH CLAMP RECORDING OF CALCIUM CHANNELS IN BULLFROG DORSAL ROOT GANGLION CELLS USING INTRACELLULAR ARGININE. Alice M. Holohean, Carlos A. Rodriquez, John C. Hackman and Robert A. Davidoff\*, VA Medical Center and Department of Neurology, University of Miami School of Medicine, Miami, FL 33101.

Medicine, Miami, F.L. 33101.

Whole cell current recordings were made from acutely dissociated *R. catesbiana* dorsal root ganglion cells using the following solutions: *Intra-cellular* (mM): 110 CsCl or 110 L-arginine, 10 EGTA, 5 MgCl<sub>2</sub>, 40 HEPES, 2 ATP, 0.3 GTP; pH 7.4 adjusted with CsOH; *Extracellular*: 135 TEA-Cl, 10 Glucose, 10 HEPES, 0.0007 TTX, 5 CaCl<sub>2</sub>; pH 7.4 with TEA-OH. Depolarizing step pulses of 5-10 mV from holding potentials (Hp) of -40 to -100 mV were used to examine Ca<sup>2+</sup> currents. Two populations of cells with high casual cases (CsC) were statistically associated as the contraction of the con

of cells with high or low/medium capacitances (Cm) were studied.

Using Cs in the intracellular solution, at Hp of -80 mV, there were no significant differences between the high Cm (90±3 pF) and low/medium rm (53.53+3.60 pF) cells for either current density (0.018+0.004 nA/pF and 0.017+.004 nA/pF, respectively) or reversal potential (38+4 mV and 37±4 mV, respectively). Small outward currents, presumably produced by Cs were observed at higher depolarizing voltages and were blocked by Čadmium.

When Cs was replaced by L-arginine (Xu, 1991), both the current density (0.037±.006 nA/pF for high Cm cells and 0.031±0.007 nA/pF for low/med Cm cells) and the reversal potential (49±5 mV and 53±6, high and low/med Cm cells, respectively) increased significantly. Outward currents were minute and rarely observed. (Supported by VAMC Funds MRIS #1769 and #3369 and USPHS grant #17577).

HETEROGENEITY OF CALCIUM CHANNELS OF DIFFERENT RAT SYMPATHETIC NEURONS. Chu Chen and Geoffrey G. Schofield.\* Department of Physiology, Tulane University School of Medicine, New Orleans, LA 70112.

It has been speculated that the electrophysiological and pharmacological characteristics of ion channels of sympathetic neurons may be dependent upon the end organ innervated by the neurons. In the present study we tested this possibility by investigating the properties of Ca2+ currents of superior cervical ganglion (SCG) and paravertebral ganglion (PVG) neurons removed from the same rats by using the whole-cell patch clamp technique. SCG and PVG ( $T_{10}$ - $L_2$ ) neurons from adult male Sprague-Dawley rats were isolated by an enzymatic dispersion method and  $Ca^{2+}$  currents were recorded using external and internal (pipette) solutions designed to isolate Ca2+ currents. Ca2+ current inhibition induced by norepinephrine (NE, 5 µM) was larger in SCG than that in PVG (P<0.01). Normalized tail current activation curves demonstrated that both SCG and PVG neurons could be fitted to a double Boltzmann equation. The activation curve of Ca2+ currents from SCG neurons was shifted more hyperpolarized compared with the curve of PVG neurons. In addition, Ca2+ channel density, expressed as maximal tail current normalized to cell capacitance, was higher in PVG than that in SCG. The differences in the biophysical properties of Ca<sup>2+</sup> currents and sensitivity to NE in different populations of sympathetic neurons may reflect the heterogeneity of Ca2+ channels in neurons that innervate different tissues.

LOW VOLTAGE-ACTIVATED (LVA) CALCIUM CURRENT IN BULLFROG DORSAL ROOT GANGLION (DRG) CELLS USING INTRACELLULAR L-ARGININE. J.C. Hackman\*, C.A. Rodriquez, A.M. Holohean and R.A. Davidoff, VAMC and Dept Neurology, Univ of Miami School of Medicine, Miami, FL 33101.

Acutely dissociated R catesbiana DRG cells were used for whole cell Ca<sup>2+</sup> current recordings. Measurements of cell size and capacitance

indicated at least a bimodal distribution. ≈ 50% were small-medium in

relation and diameter: 36.3 ± 1.0 μ; mean capacitance: 48 ± 1 pF. Larger cells; mean diameter: 44.4 ± 1.7 μ; mean capacitance: 95 ± 2 pF.

The following solutions were used: *Intracellular* (mM): 110 CsCl or 110

L-arginine, 10 EGTA, 5 MgCl<sub>2</sub>, 40 HEPES, 2 ATP, 0.3 GTP; pH 7.4 adjusted with CsOH; *Extracellular*: 135 TEA-Cl, 10 Glucose, 10 HEPES, 0.0007 TTX, 5 CaCl<sub>2</sub>; pH 7.4 adjusted with TEA-OH. Depolarizing step pulses of 5-10 mV from holding potentials (Hp) of -40 to -100 were used to examine high voltage (HVA) and LVA currents. Inward currents evoked using this protocol readily distinguished HVA currents at Hp of -50 mV and LVA currents at Hp of -80 mV. A ratio of the current evoked

of the Adult of the peak current was obtained from the I-V curve from Hp of -80 mV and used as a measure of LVA current.

When Cs was used, the amount of LVA Ca<sup>2+</sup> current was not significantly different for different cell sizes if Ca<sup>2+</sup> was used as the current carrier. Because Cs has been found to produce an outward current through Ca<sup>2+</sup> channels, L-arginine was substituted (Xu, 1991). With Lunough Ca<sup>-</sup> channels, L-arginine was substituted (Xu, 1991). With Larginine, the amount of LVA current was significantly greater in small-medium cells compared to larger cells (21% vs 12%). This may be explained by the larger Ca<sup>2+</sup> currents seen in L-arginine as compared with Cs. (Supported by VAMC Funds MRIS #1769 and #3369 and USPHS grant #17577).

VOLTAGE CLAMP ANALYSIS OF CALCIUM CURRENTS IN ACUTELY-ISOLATED ADULT RAT NEOSTRIATAL NEURONS D.J. Surmeiër, J. Bargas and A. Howe, Dept. of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, Memphis, TN

Calcium currents are of importance to a variety of cellular functions including short- and long-term regulation of excitability. Recently, we have shown that cultured neostriatal neurons express both low-voltage activated (LVA) and high-voltage activated (HVA) currents (Bargas et al., Brain Res., 541 (1991) 70-74). We have found that adult neurons differ from cultured neurons in that adult neurons rarely express LVA currents and have heterogeneous HVA currents.

Neurons were acutely isolated from juvenile and adult rats using conventional procedures. In brief, 400  $\mu m$  frontal sections were enzymatically treated (pronase E, 1.5 mg/ml) for 30 minutes at 35 C in oxygenated HEPES-buffered salt solution (pH=7.3). After washing, striata were mechanically dissociated in a low Ca (200 µM) medium and plated for recording. Recording used conventional whole cell techniques

In the majority of adult neurons (>90%, n=130), only HVA calcium currents were observed. In 5 mM calcium or barium, currents activated near -40 mV and peaked near 10 mV. These currents could be separated pharmacologically into two components. One component was blocked by the dihydropyridine antagonist nifedipine (Ki=126 pM, n=15) or ω conotoxin (1-10  $\mu$ M, n=10). The other component of the current was resistent to block by either dihydropyridines or  $\omega$ -conotoxin. This work was supported by USPHS grant NS 28889.

ROLE OF NERVE-MUSCLE CONTACT IN EXCITATION-SECRETION COUPLING. D. B. Gray\*, C. Rossi, S. Kom, and G. Pilar. Department of Physiology and Neurobiology, Univ. of Pilar. Department of Physi Connecticut, Storrs, CT 06269.

In chick ciliary ganglion (CG) neurons, K+ evoked secretion of acetylcholine (ACh) is mediated by Ca++ influx at terminals in the iris and choroid coat of the eye and in cocultures with muscle. The calcium pharmacology of ACh release has been shown to vary with presence of target and developmental age (Gray et al., Neuron 8: 715, 1992). At embryonic day 14 evoked ACh release from CG neurons cocultured with muscle is mediated by calcium influx through channels which are inhibited by nifedipine. In cultures of CG neurons cultured without muscle, this release is not sensitive to nifedipine. This dependence on the presence of muscle does not appear to be mediated by soluble trophic factors released by the muscle. Neurons cultured alone were either exposed to media conditioned by muscle or grown on aclar cover slips to prevent contact between neurons and muscle, and placed in muscle cultures for 24 hrs. Nifedipine was unable to inhibit evoked release in either condition. However, evoked release from st. 40 CG neurons grown on lysed myotube membranes for 24 hrs was reduced by 50% (p< .05) by 10 uM nifedipine. These results suggest that contact of neurons with muscle cell membrane can induce the coupling of L-like channels to ACh secretion. We are currently examining the pharmacology of whole cell calcium currents to determine if changes in the coupling of channels to secretion observed above may be mediated by differential expression of calcium channels in these cells. Supported by NIH grant to G. Pilar #5R01 NS 10338.

TWO COMPONENTS IN VOLTAGE AND TIME DEPENDENT INACTIVATION OF HVA CALCIUM CURRENTS IN PITUITARY CELLS. I. Nussinovitch\*, E. Keller and O. Matzner. Dept. of Anatomy, Hebrew Univ. Sch. of Med., Jerusalem. Israel.

Influx of calcium through voltage sensitive channels is an important step in the regulation of hormone secretion from pituitary cells. Two populations of voltage sensitive calcium channels have been described in these cells; low voltage-activated (LVA) and high voltage-activated (HVA) channels. It is known from studies on pituitary cells and neurons that HVA calcium currents are partially inactivated when holding potential (Vh) is changed from -80 mV to -40 mV. In the present study we examined the kinetics of this inactivation. Experiments were performed with the whole-cell mode of the patch-clamp technique on two types of rat pituitary primary cultures: anterior cells (somatotrophs) and intermediate cells (melanotrophs). HVA calcium currents were recorded from pituitary cells in response to voltage steps (200 ms) to 0 mV first from Vh=-80 mV and then from Vh=-40mV (frequency 0.1Hz). The change in Vh from -80 mV to -40 mV completely and immediately blocked LVA currents and elicited a slow time dependent inactivation of the HVA calcium currents. We found that this inactivation of the currents can be described as the sum of two exponential decays with the average time constants of 38 ± 16 and 248 ± 102 seconds (mean ± S.D., n=8) for the sustained currents(measured at the end of the voltage step). Similar values were obtained for the inactivation of peak calcium currents.

These two time constants of inactivation may reflect inactivation of two

These two time constants of inactivation may reflect inactivation of two different HVA channel subtypes or alternatively, inactivation of two different states of the same HVA channel in pituitary cells.

FURTHER DIVERSITY OF LVA Ca CHANNELS WITHIN BURST FIRING NEURONS OF THE CNS: LONG LASTING CURRENTS IN RAT LATERAL HABENULAR CELLS. J.R. Huquenard, M.J. Gutnick, and D.A. Prince. Dept. of Neurology & Neurological Sciences, Stanford Univ. Medical Center, Stanford, CA 94305.

We previously demonstrated differences in transient, low-voltage-activated (LVA) Ca currents between two different burst-firing cell types in the thalamus, namely thalamocortical relay (TCs) cells and neurons of the reticular nucleus (nRt). These differences lead to distinct, cell-specific burst-firing patterns: TCs have relatively short bursts, while nRt bursts are prolonged. In vitro voltage recordings from lateral habenular (IHB) cells have demonstrated Ca-dependent bursts comparable to those in nRt. Another similarity to nRt is the propensity of IHB cells to fire an oscillatory series of bursts in response to appropriate stimuli. We hypothesized that the LVA current in IHB cells would be similar to or equivalent to that in nRt, and different from that in TCs. We obtained whole-cell voltage clamp recordings (n=29) from acutely isolated rat (age 6 34 days) IHB cells, and found they possess Ca-dependent LVA currents that differ from those in both nRt and TC cells. Important differences from previously described LVA currents included an inactivation process with prominent slow and fast components, equivalent permeability to Ba and Ca, and activation rates intermediate between those in nRt and TC cells. The LVA current in IHB cells was similar to that of other cell types in terms of sensitivity to divalent cations, succinimide anticonvulsants, and amiloride. We conclude that there is a remarkable diversity in LVA currents within the CNS. Furthermore, we hypothesize that slow activation and inactivation of LVA currents may be important for the generation of rhythmic Ca-burst oscillations. Supported by NIH grants NS06477 and NS12151.

PROTEIN KINASE INHIBITORS BLOCK THE PHORBOL ESTER INDUCED INCREASE IN CALCIUM CURRENTS EXPRESSED BY RAT BRAIN RNA IN XENOPUS OOCYTES. J.L. Costantin, M.D. Mauk\* and M.N. Waxham, Dept. of Neurobiology and Anatomy, Univ. of Texas Medical School, Houston TX 77225

Waxnam. Dept. of Neurobiology and Anatomy, Univ. of Texas Medical School, Houston TX 77225

RNA from five-week old rat forebrain expresses voltage-activated, cadmium-sensitive, nifedipine (DHP), ω-Conotoxin and BAY K-8644 insensitive Ca<sup>2+</sup>-currents in Xenopus oocytes. Two electrode voltage clamp was employed and current sweeps were elicited by a voltage step from -90mV (holding potential) to +10mV. Using a Cl<sup>-</sup>-free, 40mM Ba<sup>2+</sup> recording solution after 24 hours in Cl<sup>-</sup>-free ringers, we recorded a 56% increase in peak Ba<sup>2+</sup> current 14 minutes after the addition of 100nM Phorbol 12,13-Dibutyrate (PDBu). 100-1000nM of the inactive analog to PDBu, 4α-Phorbol 12,13-Dibutyrate (4α-PDBu) did not increase these voltage-activated Ba<sup>2+</sup>-currents. DHP and ω-Conotoxin also remained ineffective after PDBu treatment. Kinase inhibitors K-252a and staurosporine reduced the increase in Ba<sup>2+</sup>-currents elicited by PDBu. K-252a (2.1 and 1.1uM) inhibited the PDBu induced increase by 55% and 43%, respectively, normalized to PDBu. Staurosporine reduced the PDBu increase by 55%. Thus, we conclude that the action of PDBu is mediated through the action of protein kinases, most likely protein kinase C (PKC), and not through non-specific membrane effects. We are currently exploring the action of more specific peptide inhibitors of PKC on this PDBu effect and are investigating the effect of injecting purified PKC directly. The DHP and ω-conotoxin-insensitive currents expressed here are similar to those that have been shown to be largely P-type, due to their sensitivity to funnel web spider toxin (Lin et al., PNAS 87, 4538-4542,(1990). It is unclear to us why oocytes would preferentially express a P-type channel over L- or N- channel types. Oocytes are a good preparation for injection of purified kinases or peptide inhibitors of kinases to look at phosphorylation regulation of a largely P-type current.

HIGH- AND LOW-THRESHOLD CALCIUM CURRENTS COEXIST IN MAGNOCELLULAR NEUROSECRETORY CELLS (MNCs). T.E. Fisher', S.H.R. Olict, and C.W. Bourque. Center for Research in Neuroscience, Montreal General Hospital and McGill University, Montreal, Canada.

MNCs release oxytocin and vasopressin from axon terminals in the neurohypophysis. While calcium influx is known to be important for neurosecretion, as well as the regulation of electrical activity in these cells, somal voltage-gated calcium currents have not been characterized in MNCs. Whole cell voltage-clamp recordings from the somata of acutely dissociated MNCs from adult rats have revealed multiple subtypes of voltage-gated calcium current. In media containing 2mM Ca2+, 40mM TEA, 4mM 4-AP, and 0.2  $\mu M$  TTX, voltage steps from -100mV to voltages positive to -70mV elicited a rapidly activating (τ≈5-10ms) and inactivating (t≈20-40ms) inward current. At higher potentials (above -35mV) additional inward currents appeared consisting of both an inactivating component and a non-inactivating nifedipine-sensitive component. Addition of 20-100 µM Ni2+ caused a selective and reversible inhibition of the low-threshold component. These data suggest that MNC somata express "T"-, "N"-, and "L"-like calcium currents. Interestingly, previous voltage clamp studies of the isolated nerve terminals of these cells found no evidence for "T"type currents (Lemos & Nowycky, 1989). Taken together, these results suggest that somata and terminals can differentially regulate the expression of calcium channels. Supported by FCAR and MRC.

N-TYPE CALCIUM CHANNEL INACTIVATION IS ENHANCED BY PHOSPHORYLATION. M. A. Werz. K. S. Elmslie and S. W. Jones. Department of Physiology & Biophysics, Case Western Reserve University School of Medicine, Cleveland, OH 44106.

Effects of phosphatase and protein kinase inhibitors on the predominantly N-type calcium current of bullfrog sympathetic ganglion were investigated using the whole cell configuration of the patch clamp technique. Calcium currents of cells dialyzed with 1  $\mu\text{M}$  okadaic acid, a phosphatase inhibitor, initially showed inactivation similar to controls but over time the majority (15 of 17) developed a rapidly inactivating component. After 50 to 70 minutes of cell dialysis, 5 to 11% (mean 8%) of current inactivated over 50 msec in controls, compared to 5 to 60% (mean 29%) for cells treated with okadaic acid. The difference is predominantly attributable to the development of a component inactivating with a time constant of 15 msec in cells dialyzed with okadaic acid, 10 times faster than the most rapidly inactivating component in controls. To determine whether okadaic acid was affecting phosphorylation, additional agents were studied. Nor-okadone, an inactive analog, did not alter the rate of inactivation compared with controls. Calyculin-A, a phosphatase inhibitor structurally dissimilar to okadaic acid, increased the rate of inactivation though less potently. Staurosporine, a protein kinase inhibitor, completely blocked the increase of inactivation by okadaic acid. Thus, the observed enhanced inactivation is likely to result from phosphorylation of the calcium channel or of a nearby site. The phosphorylation state of N-channels may underly the spontaneous shifting between inactivating and non-inactivating modes of gating (Plummer & Hess, *Nature*, **351**, 657-659, 1991) and the variability among published reports of N-channel inactivation rates

NYSTATIN PATCH MEASUREMENT OF CALCIUM INFLUX ACTIVATED BY MUSCARINIC AGONIST IN NEUROBLASTOMA CELLS. C. Mathes and S. H. Thompson. Hopkins Marine Station, Stanford University, Pacific Grove, CA 93950 and Interdepartmental Program in Neurosciences. BRI. UCLA, LA CA 90024.

Neurosciences, BRI, UCLA, LA CA 90024.

Production of cGMP following muscarinic receptor activation in N1E-115 cells requires calcium influx. We measured this calcium influx during voltage and current clamp experiments with the nystatin whole-cell patch configuration. Bath administration of carbachol activated a 3-10 pA current in cells held at -60 mV. The current was unaffected by the nicotinic AChR blocker curare (10 µM). The current increased during hyperpolarizing voltage steps. This indicates that it results from an increase in conductance and therefore is different from block of M-current. In current clamp experiments carbachol activated a 3-5 mV depolarization and broadened calcium spikes elicited by anode break. The external saline contained (in mM): 25 CaCl<sub>2</sub>, 90 Tris-HCl, 10 TEA-Cl, 0.8 MgCl<sub>2</sub>, 5 glucose, 25 HEPES and pH 7.4 -7.5 at 30° C. The internal saline contained 100-200 µg/ml nystatin dissolved in (mM): 16 CSCl, 70 CS<sub>2</sub>SO<sub>4</sub>, 5 MgSO<sub>4</sub>, 10 HEPES, 100 sucrose and pH 7.2. GABA B RECEPTOR MODULATION OF HIGH VOLTAGE ACTIVATED BARIUM CURRENTS IN ACUTELY DISSOCIATED RAT HIPPOCAMPAL NEURONES. I.M. Stanford, S.J. Caddick, H.V. Wheal and J.E. Chad. Dept. of Physiology and Pharmacology, Univ. of Southampton, SO9 3TU, UK.

Postsynaptic activation of GABA B receptors in the central nervous system (CNS) activates a potassium conductance responsible for the late inhibitory post synaptic potential. In peripheral neurones the GABA B receptor agonist baclofen also inhibits Ca'+ currents (I<sub>Cb</sub>) (Dolphin A.C. and Scott R.H., 1987, J.Physiol. 386, 1-17). In cultured CNS neurones it has been reported that baclofen reduces an 'L' type I<sub>Ca</sub> in cerebellar granule cells (Wojcik W.J. et al., 1990, Neuropharm. 10, 969-972) and 'N' and 'L' type I<sub>Ca</sub> in hippocampal pyramidal neurones (Scholz K.P. and Miller R.J., 1991, J. Physiol 444, 669-686).

Whole cell voltage clamp of acutely dissociated hippocampal neurones from 12 day old rats, allows the study of voltage activated currents without the space clamp problems associated with other preparations. The neurones retain their morphology so that CA1 pyramidal cells may be easily identified. After pharmacological blockade of typical sodium and potassium conductances, Ba<sup>++</sup> currents (I<sub>BL</sub>) were activated from a holding potential (HP) of -80mV. There was little evidence of low voltage activated, T type currents, even when stepping from a HP of -100mV.

The  $I_{\rm Be}$  exhibited conventional activation and inactivation kinetics. Application of  $20\mu M \pm$  baclofen reduced peak current, for a maximal response, by 26% (n=5) without apparent effect on the voltage dependence of activation. The activation kinetics were slowed, increasing the latency to peak current by 11% (n=5). There was no apparent effect on inactivation. This preliminary data indicates GABA B receptors may directly inhibit post synaptic  $Ca^{++}$  currents, thus reducing pyramidal cell excitability by increasing spike threshold. A similar mechanism may also be involved in presynaptic inhibition of transmitter release.

Supported by MRC studentships to I.S and S.J.C and S.E.R.C. project grant (J.C.)

NMDA-INDUCED CALCIUM TRANSIENTS ARE ATTENUATED BY VOLTAGE-SENSITIVE CALCIUM CHANNEL ANTAGONISTS G.A. Skeen and H.S. White Anticonvulsant Drug Development Program

Dept. of Pharmacol. & Toxicol., Univ. of Utah, S.L.C., UT, 84108 The N-methyl-D-aspartate (NMDA)-preferring glutamate receptor is thought to be associated with an ion channel permeable to calcium (Ca2+), but distinct from voltage-sensitive Ca2+ channels (VSCC). The present investigation indicates that NMDA-preferring channels and VSCC's may be associated. Specifically, T- and L-type VSCC antagonists nickel (Ni2+) and nitrendipine (NT) respectively, were examined for their ability to block NMDA-evoked Ca2+ transients of mouse cerebellar granule cells. Primary cultures of granule cells were grown on 25 mm cover slips and maintained for 7-9 days. Mature cover slips were loaded with the Ca2+-sensitive fluorescent probe indo-1 (5 \(\mu\)M) for 20 min. Intracellular Ca2+ transients were evoked by the co-perfusion of 100  $\mu$ M NMDA and 100  $\mu$ M glycine, or by perfusion of 1 mM L-glutamate (GLU). Agonist solutions (NMDA, GLU) were prepared in magnesium-free buffer, and were perfused over the cells for 3 min to evoke intracellular calcium transients. Drug effects were studied by application of drug solutions with an agonist for 2 min following 1 min of agonist alone. Hence, each cover slip served as its own pre-drug control. NMDA-evoked transients were blocked completely by 10 nM MK-801. Ni2+ (100  $\mu$ M) and NT (10  $\mu$ M) individually attenuated NMDA-induced responses by 40-60%. In combination, Ni2+  $(100 \mu M)$  and NT  $(10 \mu M)$  attenuated the NMDA transient by >80%. GLU-evoked transients were decreased by 60% with MK-801 (10 nM) alone. The subsequent combination of Ni2+ (100  $\mu$ M) and NT (10  $\mu$ M) with MK-801 (10nM) produced no additional attenuation. These data suggest that Ni2+ and NT may exert their effects on GLU and NMDA-evoked calcium transients in a manner similar to MK-801. Furthermore, these results suggest that VSCC's and NMDA-associated ion channels may be coupled. (Supported by NIH grants 2-RO1-NS22200 and GM07579)

CHOLINERGIC ENHANCEMENT OF LOW VOLTAGE-ACTIVAT-ED (LVA) CALCIUM CHANNELS IN DISSOCIATED MEDIAL SEPTUM/DIAGONAL BAND (MS/nDB) NEURONS. W.H. Griffith\*, I.D. Hood and M.J. Davis, Depts. of Medical Pharmacol. & Toxicol. and Medical Physiology. College of Medicine, Texas A&M University, College Station, TX 77843.

Cholinergic regulation of voltage-dependent Ca2+ channels may result in either enhancement or inhibition depending upon cell type, species of Ca2+ channel and/or second messenger systems involved. We have previously shown that cholinergic cells in the MS/nDB have LVA channels. We extend that work to show that LVA channels in some cells are specifically enhanced by carbachol (10  $\mu$ M). LVA currents were recorded using the cell-attached patch clamp recording configuration from acutely dissociated MS/nDB neurons of adult guinea pigs. Isotonic K-aspartate was used to zero the cell's resting potential and barium (100 mM) inside the pipette was used as the charge carrier across the Ca2+ channel. Holding potentials were -100 or -80 mV with test potentials to -40 or -30 mV. The open probability (NP<sub>a</sub>) of LVA channels was increased in a population of cells (36.9  $\pm$  2.2%, n=3); whereas no increase was seen in two other cells. Ensemble averages of LVA channels were also enhanced by carbachol (6 of 10 cells). These results show that in a population of MS/nDB cells, LVA channels are enhanced by carbachol (10  $\mu$ M). Supported AG07805 (WHG) and HL46502 (MJD)

DOPAMINE INCREASES VOLTAGE ACTIVATED CALCIUM CHANNEL CURRENTS IN CULTURED WHITE BASS HORIZONTAL CELLS. C. Pfeiffer-Linn and E.M. Lasater. Dep'ts. Physiology and Ophthamology, Univ. of Utah, Salt Lake City, UT. 84108.

H<sub>2</sub> cone horizontal cells in the white bass retina contain D1 receptors linked to adenylate cyclase and are innervated by dopaminergic plexiform cells. We have examined the effect of dopamine on voltage sensitive L-type sustained calcium currents on the H<sub>2</sub> cone horizontal cells using the whole cell patch clamp technique on cultured cells.

Isolated identified  $\rm H_2$  horizontal cells were held at -70mV and stepped in 10mV increments from -70 to +70mV or ramped over this range. Calcium currents were enhanced using 10mM extracellular calcium or barium in saline which pharmacologically suppressed Na\* and K\* currents. Pressure ejected dopamine increased the sustained voltage dependent calcium currents in these cells by as much as 200% ( $\rm EC_{50}$ =7 $\mu$ M) without affecting its voltage dependence. This increase in calcium current is minicked by the D1 receptor agonist, SKF 38393 ( $\rm 1\mu$ M). The D1 receptor antagonist, SCH 23390 ( $\rm 10\mu$ M), blocked the effect of 10 $\rm \mu$ M dopamine completely.

The effect of dopamine on horizontal cells has been linked to increased adenylate cyclase activity. In this study, the membrane permeant cyclic AMP derivative, 8-(4-chlorophenylthio)-cyclic AMP, mimicked the effect of dopamine on the voltage sensitive calcium current. These results indicate that dopamine is acting through the D1 receptor on H<sub>2</sub> horizontal cells to activate a cyclic AMP mediated pathway which modulates voltage sensitive calcium channels to increase calcium influx. INCREASE OF L-TYPE CALCIUM CURRENT BY BASIC FIBROBLAST GROWTH FACTOR IN ACUTELY ISOLATED NEURONAL CELLS FROM RAT VENTREOMEDIAL HYPOTHALAMUS. N. Matsuki\*, H.Koike and H.Saito. Dept. of Chem. Pharmacol., Faculty of Pharmaceut. Sci., The Univ. of Tokyo, Tokyo 113, Japan.

Whole-cell calcium currents were recorded from acutely isolated neuronal cells of the ventromedial hypothalamus from neonatal rat. Three types of Ca currents were recorded. Low threshold current (Ttype) was activated at -40 to 0 mV when holding potential (HP) was -90 mV and inactivated rapidly. But only 10 % of the cells had this current. One of high threshold currents was slowly inactivated (Ltype) and suppressed by nicardipine (10<sup>-5</sup>M). The third current had intermediate inactivation rate and was activated when HP was more negative than -60 mV. This current was thought to be N-type, but ωconotoxin (10-5M) did not specifically suppress it. Effects of basic fibroblast growth factor (bFGF) on the Ca currents were investigated. At 10 ng/ml bFGF increased the L-type current in about 10 % of the cells studied. But other two currents were not affected. Although there was a great heterogeneity among the cells, neurotrophic and neuromodulatory effects of bFGF can be partly attributed to the augmentation of the L-type Ca current.

CONCENTRATION DEPENDENCE OF TRANSMITTER EFFECTS ON CALCIUM CURRENT KINETICS IN FROG SYMPATHETIC NEURONS. K. S. Elmslie\* & S. W. Jones. Dept. Physiol. & Biophys., Case Western Reserve Univ., Cleveland, OH 44106.

Several neurotransmitters act through G proteins to slow the activation kinetics of N-type calcium currents. If the shift in kinetics reflects binding and unbinding of a G protein to the calcium channel, the time constant for slow activation might depend on the concentration of activated G protein. Lopez & Brown (Neuron 7:1061-1068, 1991) found such an effect, but Kasai (J. Physiol. 448:189-209, 1992) did not. We have reexamined this by comparing large and small effects of transmitters (or GTP- $\gamma$ -S). No clear changes in time constants have been found (see Figure). Either the slow activation process does not involve G protein binding, or the binding step is not rate limiting in our conditions.

Figure: Difference currents, between records taken before (\*) and after (\*\*) the effect of chicken II luteinizing hormone-releasing hormone was reversed by a step to +70 mV. The % inhibition of current by LHRH during 1 nA the prepulse to -10 mV is indicated. The largest effect was from the first application of LHRH to this cell; the others were at different times during a second application of LHRH.

INTERLEUKIN-18 INHIBITS CALCIUM CHANNEL CURRENTS IN ISOLATED HIPPOCAMPAL CA1 NEURONS. C. R. Plata-Salamán \* and J. M. H. ffrench-Mullen?, 'Univ. of Delaware, Newark, DE 19716 and 'Dept. Pharmacology, ICI Pharmaceuticals, ICI Americas Inc., Wilmington, DE 19897.

The effect of recombinant human interleukin-18 (rhIL-18) on voltage-gated

The effect of recombinant human interleukin-18 (rhIIL-18) on voltage-gated Ca<sup>2+</sup> channel currents was examined in enzymatically dissociated CA1 neurons from adult guinea pig hippocampi using the whole-cell patch clamp technique. The external solution contained 3 mM Ba<sup>2+</sup> (I<sub>B-</sub>) and the internal solution NMG-CI, CS<sup>2+</sup> BAPTA and Mg<sup>2+</sup>-ATP. I<sub>B+</sub> was examined with 10 ms to 200 ms depolarizing command steps from a holding potential of -80 mV to a test potential of -10 mV. Compounds were applied by rapid superfusion. RhIL-1β rapidly depressed only a fraction of both peak and late Ca<sup>2+</sup> currents (measured 5 ms prior to the end of step) in a concentration-dependent manner. Depression of the peak current was (mean % depression): 2.4 (n=5), 9.4 (n=13), 19.4 (n=9), 19.8 (n=12), 21.9 (n=9) and 22.5% (n=10) at 0.98, 1.97, 7.9, 15.8 and 31.2 pg/10 μl rhIL-1β. Depression of the late current was: 4.2, 15.9, 28.5, 31.2, 32.4 and 32.7%. The apparent K<sub>D</sub>'s were 2 pg/10 μl and an nH of 2.8 for both peak and late current. At concentrations >1.97 pg/10 μl, the block was irreversible but with no further effect on the remaining current. Application of greater concentrations (up to 2 ng/10 μl) did not result in further depression of the inward Ca<sup>2+</sup> current (n=10). The depressive effect of rhIL-1β was completely blocked by the concomitant application of a specific rhIL-1 receptor antagonist (R & D Systems, MN) in concentrations 25-fold higher than rhIL-1β. The antagonist alone (49.3-197 pg/10 μl) had no effect. This demonstrates a specific and direct action of rhIL-18. These results show that IL-1β depresses the voltage-gated Ca<sup>2+</sup> channel currents at pathophysiological concentrationis (21.97 pg/10 μl). This may play a role in: 1) the regulation of neuronal excitability; 2) the induction of neurological manifestations during disease; and 3) in the induction and/or progression of neurological manifestations during disease;

# 188.11

A DIHYDROPYRIDINE-SENSITIVE T-TYPE CALCIUM CURRENT REQUIRED FOR ADRENOCORTICOTROPHIC HORMONE (ACTH)-STIMULATED CORTISOL SECRETION J.J. Enveart\*@, B. Mlinar@, J.A. Enveart, and B.A. Biaqi#, Depts. of Physiology#, Pharmacology and the Neuroscience Program@, The Ohio State University, Columbus, OH 43210-1239.

Many neurons and endocrine cells express multiple Ca²+ channels which couple membrane depolarization to secretion. Cortisol secretion by adrenal zona fasciculata (AZF) cells is stimulated by the pituitary peptide ACTH in a Ca²+-dependent manner. Ca²+ channels in these cells have not been described, and their role in cortisol secretion is not clear. The whole cell version of the patch clamp technique was used to identify and characterize Ca²+ channels in enzymatically-dissociated bovine AZF cells. Nearly every cell (84 of 86) expressed only a low voltage activated, rapidly inactivating T-type Ca²+ current. Kinetics of T current activation and inactivation were described by a Hodgkin-Huxley model of m⁴n form. The rates of T current activation, inactivation, deactivation, and reactivation approached maximum voltage independent values at extreme potentials.

Ca²+ current in AZF cells was blocked by the T channel selective antagonist penfluridol and by the dihydropyridine antagonist nimodipine with  $\rm IC_{60}$ s of 300 nM and 3  $\mu\rm M$  respectively. At the same concentrations, these antagonists also inhibited ACTH-stimulated cortisol secretion measured over periods ranging from 3 to 48 hours. Cortisol-secreting cells of the adrenal gland are unusual among secretory cells in expressing only T-type Ca²+ channels which are sensitive to dihydropyridines and required for ACTH-stimulated cortisol production.

ACTION OF GTP-7-S ON CALCIUM TAIL CURRENTS IN RAT DORSAL RAPHE NEURONES. J.S. Kelly\* and R.H. McAllister-Williams. Dept. of Pharmacology, Univ. of Edinburgh, 1 George Square, Edinburgh, Scotland, EH8 91Z.

Serotonin has been shown to cause an inhibition of high-threshold calcium currents in dorsal raphe neurones (Penington et al, 1991, J. Neurosci, 11, 3594). In common with other vertebrate neurones, intracellular application of the non-hydrolysable GTP analogue, GTP-y-S, is able to mimic the action of the transmitter. We have investigated a possible further action of GTP-y-S on calcium tail currents.

Whole cell patch clamp current recordings were made from acutely isolated adult rat dorsal raphe neurones, with barium as the charge carrier. Currents were elicited by voltage jumps from -100 to -10 mV for 150 ms, and tail currents examined as the voltage was returned to -100 mV. All measurements were made at 20°C.

The time constant of single exponential curves fitted to the tail currents was 3.03 +/-0.33 ms, n=38 (mean +/- standard error) in the control situation. When 200 µM GTP-y-S was included in the patch pipette solution this increased significantly to 3.85 +/-0.27 ms, n=23 (p < 0.005, Mann-Whitney-Wilcox test). To help examine which component of the calcium current was responsible for this increase, cadmium was applied to the bath solution. While 200 µM cadmium produced an 87 +/-3% reduction in the current amplitude, the magnitude and rate of the tail current were not diminished (n=6). However, 2 mM cadmium produced a 95% reduction in current amplitude, and completely abolished the tail currents (n=2).

In addition to inhibiting high threshold current, it appears that GTP-y-S also produces

In addition to inhibiting high threshold current, it appears that GTP-Y-S also produces a retardation of calcium tail current kinetics. The type of current underlying this action would appear to be relatively cadmium insensitive. This would normally be explained as low threshold or 'T' type current (Fox et al, 1987, J. Physiol. 394, 149), however, one would expect such current to have fully inactivated during the 150 ms voltage jump. It is therefore not clear exactly which type of calcium current underlies the prolonged tail current produced by GTP-Y-S.

INTERLEUKIN-18 INHIBITION OF CALCIUM CHANNEL CURRENTS IN ISOLATED HIPPOCAMPAL CA1 NEURONS: PHARMACOLOGY AND MODE OF ACTION. J. M. H. ffrench-Mullen'\* and C. R. Plata-Salamán', 'Dept. Pharmacology, ICI Pharmaceuticals, ICI Americas Inc., Wilmington, DE 19897 and 'Univ. of Delaware, Newark, DE 19716.

The mode of action of recombinant human interleukin-1ß (rhIL-1ß)-induced inhibition of the voltage-gated calcium (Ca²-) channel currents was examined in enzymatically dissociated hippocampal CA1 neurons from adult guinea-pig using the whole-cell patch clamp technique. RhIL-1ß showed no change in the peak I-V relationship at 1.97, 7.9 and 31.2 pg/10  $\mu$ I (m=4). The time course of activation was speeded up (n=3) but there was no change in voltage-dependent activation by rhIL-1ß (n=2). The rate of deactivation of the current was unaffected (m=3). Peak current remaining in presence of  $\omega$ -conoloxin (CgTX, GVIA; 10  $\mu$ M) block was potentiated 11.9, 19.9 and 26.9%, while the late current (measured 5 ms prior to the end of step) was potentiated 8.9, 13.6 and 19.9% at 1.97, 7.9 and 31.2 pg/10  $\mu$ I rhIL-1ß (n=4, each) respectively. Peak and late currents in the presence of nifedipine (10  $\mu$ M) were minimally affected. In the presence of CgTX plus nifedipine, the peak current was potentiated 17 (n=3), 17.6 (n=9) and 19% (n=4) at 1.97, 7.9 and 31.2 pg/10  $\mu$ I rhIL-1ß. Similar potentiation was observed in the late current; (±)BAY K 8644 (1  $\mu$ M) potentiation of the Ca²- current was blocked by rhIL-1ß 7.9 pg/10  $\mu$ I). With GTP- $\gamma$ 5 (100-500  $\mu$ M) in the recording pipette, rhIL-1ß had minimal effect on the peak current, whereas it suppressed the late current 12.1, 25.3 and only 9.3% at 1.97, 7.9 and 31.2 pg/10  $\mu$ M in the electrode, rhIL-1ß potentiated the peak current by 9.3, 12 and 9.9% at 1.97, 7.9 and 31.2 pg/10  $\mu$ M in the lectrode, rhIL-1ß fin=5), whereas the late current was not affected (n=5). These results suggest that at pathophysiological concentrations (≥1.97 pg/10  $\mu$ M), rhIL-1ß depresses a fraction (L-type) of the Ca²- current in hippocampal CA1 neurons via G-protein(s).

NIMODIPINE BLOCK OF L-TYPE CALCIUM CHANNELS IN A PRIMARY CULTURE OF RAT HIPPOCAMPAL NEURONS.

P.E. TanPiengco and R.T. McCarthy, Miles, Inc., West Haven, CT 06516.

West Haven, CT 06516.

Nimodipine inhibits L-type calcium channel current with high affinity in rabbit peripheral neurons but comparable high-potency block has not yet been demonstrated in central neurons. Wholecell and cell-attached patch recordings were used to characterize voltage-dependent calcium channels in a primary culture of hippocampal neurons from neonatal rat pups. Whole-cell and cell-attached patch recording after 2-4 days in culture failed to detect dihydropyridinesensitive current. However after 6-14 days in culture, these cells expressed a 22 pS [110 Ba<sup>22</sup>] conductance L-type channel which was resistant to inactivation by depolarized holding potentials (V<sub>h</sub> = -30 mV) and enhanced by the calcium channel agonist BAY k 8644 (30-90 nM). Nimodipine inhibition of these calcium channels was dosedependent. At 100 pM, nimodipine reduced the activity of L-type channels while at 10 nM the drug completely inhibited sustained L-type current (T<sub>i</sub>= 150-160 msec; n=5). Direct effects of nimodipine on L-type calcium channels in central neurons may contribute to the therapeutic effects of nimodipine in central neurons.

IDENTIFICATION OF DIHYDROPYRIDINE BINDING REGIONS WITHIN THE  $\alpha1$  SUBUNIT OF CARDIAC CALCIUM CHANNELS. H. Nakayama\*, A.Kuniyasu, M.Taki and Y.Kanaoka, Faculty of Pharm. Sci., Hokkaido Univ., Sapporo, 060 Japan.

To identify regions which are involved in the formation of the dihydropyridine (DHP) receptor site of cardiac L-type calcium channels, the alpha 1 subunit of the channel complex was specifically labeled with a novel DHP-type photoaffinity probe, [3H]diazipine which binds to the receptor with higher affinity than to the skeletal muscle receptor. Photolabeled regions were identified by probing labeled proteolytic fragments with several anti-peptide antibodies recognizing different segments of the alpha 1 sequence. A part of the alpha1-associated [3H]diazipine label was contained in the 3 kDa tryptic fragment derived from the loop between segments S5 and S6 in domain III. This homologous region to the skeletal muscle channel which we have proposed to contribute to formation of the transmembrane pore (PNAS, 88, 9203-7, 1991), is also considered to play such a role. Another part of the labeling occurred in a fragment that is not highly homologous to the skeletal muscle counterpart and contains a transmembrane segment of domain IV. Our data suggest that the cardiac DHP receptor is also formed by close apposition of two discontinues regions of the alpha1 subunit sequence in domain III and IV. It is proposed that amino acid residues at the putative extracellular surface in the loop connecting segments IIIS5 and IIIS6 fold into the extracellular end of transmembrane segment in domain IV to contrib-ute to formation of the DHP receptor site.

# NIMODIPINE INHIBITS EFFULX OF 45Ca2+ FROM RAT BRAIN SYNAPTOSOMES.

Wan K. Kim-Park\* and Efrain C. Azmitia, Department of Biology New York University, New York, New York 10003

A known L-type Ca<sup>2\*</sup> channel blocker, nimodipine has been shown to

A known L-type Ca\* channel blocker, nimodipine has been shown to modulate neuronal development, plasticity and aging. The possible role of nimodipine was tested on "5Ca\*-uptake using rat brain synaptosomes. A micro-assay system has been developed to measure "5Ca\*-uptake into synaptosomes. Using 96-well plate and a total volume of 150ul, preincubated (at 30°C for 15 min) synaptosomal aliquot was added to prewarmed buffer containing <sup>45</sup>Ca for 1-30 sec. The uptake is stopped by quenching buffer containing 12 mM EGTA. The uptake was linear over 1-30 sec in resting and stimulating buffer. Nimodipine at a dose of 1 nM, stimulated <sup>45</sup>Ca<sup>2+</sup> uptake in resting buffer (5mM K+) and stimulating buffer (68.5mM K+) significantly (p<0.05). The stimulation was the greatest at 1 sec and by 30 sec the stimulation was not seen. This paradoxical stimulation of  $^{45}$ Ca-uptake by nimodipine was either due to an increase in uptake or a decrease in release.

At a dose of 1nM, nimodipine inhibited <sup>45</sup>Ca efflux from the preloaded synaptosomes. The inhibition was more pronounced during 1 sec incubation in stimulating buffer than resting buffer. These results suggested that the L-type Ca<sup>2+</sup>-channels can permit the reverse flow of Ca<sup>2+</sup> depending on the membrane potential and Ca2+ equilibrium. The study is supported by NIDA contract (271-90-7403).

LIPOPHILIC AMINO ALCOHOLS WITH CALCIUM CHANNEL BLOCKING ACTIVITY. A S. Sipahimalani\*, J L. Werth, R H. Michelson, A K. Dutta. S. M. N. Efange and S. A. Thayer, Departments of Pharmacology and Medicinal Chemistry, Univ. of Minnesota, Minneapolis, MN 55455.

A series of novel lipophilic amino alcohols, analogs of the anticholinergic drug vesamicol, were evaluated for  ${\rm Ca^{2+}}$  channel blocking activity. The effects of these drugs on depolarization-induced intracellular free  ${\rm Ca^{2+}}$  concentration ([ ${\rm Ca^{2+}}$ ]i) transients were examined in single NG108-15 cells and dorsal root ganglion (DRG) neurons in culture, using Indo-1 based microfluorimetry. Structure-activity studies indicated that features required for Ca<sup>2+</sup> channel blocking activity were distinct from those required for anticholinergic activity. In particular, the anticholinergic activity, but not the Ca2+ channel blocking activity, was enantioselective. One the most active compounds 3-(3-bromophenyl)-2-hydroxy-1-[1-(4-phenylpiperidinyl)]propane was characterized in more detail. This compound inhibited the dihydropyridine-sensitive Ca<sup>2+</sup> channel response in NG108-15 cells, evoked by depolarization with 50 mM K+, with an IC50 of 5  $\mu$ M. In DRG neurons, it inhibited the [Ca<sup>2+</sup>]<sub>i</sub> transients elicited by field potential stimulation, which are mediated by all three Ca<sup>2+</sup> channel subtypes. A key element required for Ca<sup>2+</sup> channel blocking activity was the presence of an electron withdrawing substituent on the pendant phenyl ring. These lipophilic amino alcohols may provide a chemical starting point for the development of more potent compounds with broad-spectrum Ca2+ channel blocking activity.

L-TYPE CA+2 CHANNEL ANTAGONISTS ENHANCE NEUROTRANSMITTER RELEASE. H.K. Kramer', E.P. Chiopelas, H.M.

Akbari, and E.C. Azmitia. Dept. of Biology, New York University, NY, NY 10003.

Recent studies have indicated the presence of unique N and L Ca+2 channel Recent studies have indicated the presence of unique N and L Ca channel subtypes to be found in heterogenous distribution throughout the brain. It has been suggested that while the N channel regulates Ca<sup>12</sup> influx that is coupled to neurotransmitter release, it appears that the L-subtype may play an important role in regulating internal Ca<sup>12</sup> levels during and after depolarization. This study examined the effects of the L-channel antagonist nimodipine (NIM) on the release of <sup>3</sup>H-5HT induced by K<sup>+</sup>, phorbol 12-myristate 13-acetate (PMA), and 3,4-methylenedioxymethamphetamine (MDMA).

Rat forebrain synaptosomes were loaded with <sup>3</sup>H-5HT (50nM) and incubated in normal or Ca<sup>+2</sup>-free buffer. Release of <sup>3</sup>H-5HT was tested with KCL (30mM), PMA (10<sup>6</sup>M), MDMA (10<sup>6</sup>M), and NIM (10<sup>9</sup>M) either alone or in combination. In normal buffer, NIM had no effect on PMA or MDMA-induced release, however, it did significantly (p<0.01) potentiate 30mM KCL induced-release. In Ca''-free buffer, NIM did not alter KCL or MDMA-induced release, but did significantly augment (p<0.05) PMA-induced release.

These results indicate that NIM elicits its effects by blocking the efflux of Ca\* through the L-channel. Consequently, L-channels appear dually sensitive to both terminal Ca+2 concentration and electromotive force. In summary, our data shows that a function of the L-type channel in synaptosomes is to fine tune internal Ca<sup>+2</sup> levels in order to promote a brief release of neurotransmitter, and to allow the efflux of Ca+2 after the membrane potential has become positive. THE EFFECT OF POLYAMINES ON VOLTAGE-ACTIVATED CALCIUM CHANNELS. M. D. Herman\*, E. Reuveny, and T. Narahashi. Dept. Pharmacol.&Neurosurg., Northwestern Univ. Med. Sch., Chicago, IL 60611

The polyamines have been implicated to modulate cytoplasmic calcium

concentration and are correlated with selective neuronal vulnerability in cerebral ischemia. In order to determine whether the polyamines modulate voltage-activated calcium channels, whole-cell and single-channel patch clamp experiments were performed with N1E-115 mouse neuroblastoma cells. L-type calcium channel currents showed a 34 ± 21% increase (n=6 cells) during external application of 1 mM putrescine. There was no change in the kinetics of the current and no shift in the

currents snowed a 34 ± 21% increase (n=o cens) during external application of 1 mby putrescine. There was no change in the kinetics of the current and no shift in the current-voltage relation along the voltage axis. T-type calcium channel currents were not affected by 1 mM putrescine. External application of 1 mM spermine and 1 mM spermidine had no effect on T- and L-type calcium channels.

In order to test whether the effect of putrescine is mediated by a second messenger, specific protein kinase C and cyclic AMP-dependent protein kinase inhibitors, staurosporine and KT5720, respectively, were applied prior to putrescine. Staurosporine 200 nM prevented the increase of the L-type calcium current by 1 mM putrescine, whereas a 200 nM KT5720 did not inhibit the putrescine effect. The increase of L-type channel currents by putrescine may be mediated by protein kinase.

The effect of putrescine on single L-type calcium channels was studied using the cell-attached configuration of the patch champ technique. Putrescine 5 mM applied to the external solution caused an increase in open time of the single channel openings longer than 3 ms increased from 6 to 76, and the number of channel openings longer than 9 ms increased from 6 to 76, and the number of channel openings longer than 9 ms increased from 6 to 77 in 345 depolarizing steps compiled from three cells. This single channel study supports the idea that putrescine acts on the cytoplasmic side of the membrane. Putrescine is the only polyamine elevated in ischemia, and does not affect the NMDA-receptor mediated channel. This suggests that the putrescine-induced enhancement of the L-type calcium channel activity may alternative the putrescine is the entire external solution of the L-type calcium channel activity may alternative the putrescine is the entire resident and the putrescine is the collinear of the L-type calcium channel activity may alternative the external solution calcium channel activity may alternative the collinear calcium channel activity may alternati that the putrescine-induced enhancement of the L-type calcium channel activity may play an important role in calcium related neurotoxicity.

DM-9384, A NOOTROPIC AGENT, INTERFERES WITH THE INHIBITORY ACTION OF OPIATES ON N-TYPE CALCIUM CHANNELS IN NG108-15 CELLS. S.Watabel\*, M.Yoshii², H.Yamaguchi¹ and S.Ashida¹. Explor. Res. Lab. II, Daiichi Pharmaceutical Co.,Ltd., Tokyo 134, Japan and 2Dept. of Neurophysiol., Tokyo Inst.

of Psychiatry, Tokyo 156, Japan.
We have previously reported that DM-9384 (nefiracetam), a newly-developed cognitive enhancer, facilitates a long-lasting (type II or N/L-type) Ca channel current in NG108-15 cells. DM-9384 also diminishes an inhibitory effect of DM-9384 also diminishes an inhibitory effect of 15 cells. DM-9384 also diminishes an inhibitory effect of enkephalin on the type II current. These DM-9384 actions can be mimicked by elevating the intracellular level of cAMP (Yoshii et al., Soc. Neurosci. Abstr. 17, 774, 1991). In the present study, we have further examined the effect of DM-9384 on the type II channel by isolating N-type component from L-type. The membrane was held at -50 mV to inactivate a transient (type I or T-type) current. Nifedipine (5-10  $\mu$ M), an L-type channel blocker, reduced type II currents more than 50% and prevented the action of DM-9384 (I  $\mu$ M). When Leu-enkephalin (50 nM) was applied in the presence of nifedipine, the type II currents were DM-9384 (1  $\mu$ M). When Leu-enkephalin (50 nM) was applied in the presence of nifedipine, the type II currents were further reduced. The inhibitory effect of enkephalin was reversed by DM-9384 (1  $\mu$ M). This DM-9384 action was mimicked by forskolin (10  $\mu$ M) and dibutyryl cAMP (1 mM). The results suggest that DM-9384 interferes with the inhibitory action of opiates on N-type Ca channels via cAMP system.

SITE OF ACTION OF COGNITIVE ENHANCER DM-9384 THAT ENHANCES CONGLASTING CALCIUM CHANNEL CURRENTS IN NG108-15 CELLS.

M. Tanaka<sup>4</sup>. Dept. of Neurophysiology, Tokyo Inst. of
Psychiatry, Tokyo 156, Japan and Explor. Res. Lab. II,

3Medical Devel. Dept., Devel. Res. Lab., Daiichi Pharma-

3Medical Devel. Dept., <sup>4</sup>Devel. Res. Lab., Daiichi Pharmaceutical Co.,ttd., Tokyo 134, Japan.

We have reported recently that DM-9384 (nefiracetam), a nootropic agent, can facilitate long-lasting (type II or N/L-type) Ca channel currents in NG108-15 cells (Yoshii et al., Soc. Neurosci. Abstr. 17, 774, 1991), and that the effect results from an increase in the intracellular level of cAMP (Murashima et al., Neurosci. Res. Suppl. 16, SG1, 1991). In the present study, we have further investigated the site of action of DM-9384 using the whole-cell patch-clamp technique. DM-9384 (1 μM), when applied intracellularly through the patch electrode, enhanced type II currents as usually seen when annlied externally. Then. currents as usually seen when applied externally. Then, proconvulsant agent pentylenetetrazole (PTZ) and Ro 5-4864 were applied in order to alter intracellular Ca $^{2+}$ . PTZ (10  $\mu\text{M})$  did not affect the DM-9384 action, whereas Ro 5-4864 (10  $\mu\text{M})$ , which reduced type II currents, diminished the effect of DM-9384. When inhibitory G-proteins were activated by Leu-enkephalin (50 nM) or intracellularly applied GTPYS (50  $\mu\text{M})$ , the action of DM-9384 appeared more consistently. The results suggest that the site of action of DM-9384 is inside the cell, and regulated by G-protein systems rather than intracellular Ca $^{2+}$ . currents as usually seen when applied externally.

THE EFFECT OF HOLOLENA CURTA VENOM CONSTITUENTS ON Ca2-INFLUX IN MAMMALIAN AND AVIAN SYNAPTOSOMES. Paul M. Lundy\*, Anita Hong and Robert Frew, Defence Research Establishment Suffield, Box 4000, Medicine Hat, Alberta, Canada, TlA 8K6: NUROS Corp, 2020 Lundy Ave., San Jose, Canada, T1A 8K6: CA, USA, 95131.

Canada, T1A 8K6: 'NUROS Corp, 2020 Lundy Ave., San Jose, CA, USA, 95131. Hololena curta venom (HC) potently inhibits  $\text{Ca}^{2^+}$  influx and neurotransmitter release from rat synaptosomes. The constituents of the venom responsible for this activity and the channel on which they act were investigated. Crude venom was separated into 3 approximate molecular weight ranges by use of a Centricon micro-concentrator followed by reversed phase HPLC purification using a Vydac  $C_{\text{IR}}$  column. The eluent was fractionated at 1 min intervals. Sixty fractions were collected for each mol. wt. range. The biological activity of the eluted fractions was measured by their ability to inhibit  $K^+$  evoked synaptosomal  $\text{Ca}^2$  influx. Two separate biologically active areas were found, one containing material in the range of 4,000 daltons and another of about 8,000 daltons.  $\text{Ca}^2$  influx in rat brain synaptosomes was inhibited by crude venom (1:2,500), both fractions and  $\text{CaCl}_1$  (0.1 mM) but was unaffected by the N channel inhibitor  $\omega$ -CgTX. In chicken brain synaptosomes,  $\text{Ca}^2$  influx was inhibited by both fractions, crude venom (1:2,500),  $\text{CdCl}_1$  (0.1 mM) and also  $\omega$ -CgTX (1  $\mu$ M). The results provide pharmacological evidence for the existance of a high voltage activated  $\text{Ca}^{2^+}$  channel in rat brain which does not correspond to the N or L designation. Synthetic FTX (0.1 mM) failed to affect  $\text{Ca}^{2^+}$  influx in either tissue. HC appears to contain constituents which block the N channel as well as the  $\omega$ -CgTX resistant channel.

Lambert-Eaton Syndrome IgG Inhibits Calcium Channels Involved in Exocytosis in Small-Cell Lung Cancer Cells. Michael P. Viglione\*, Thomas I. O'Shaughnessy and Yong I. Kim. Departments of Biomedical Engineering, Neurology, University of Virginia Health Sciences Center, Charlottesville, VA 22908.

The Lambert-Eaton syndrome (LES) is an autoimmune neuromuscular disorder. Patient weakness is a consequence of the blockade of presynaptic calcium channels resulting in a deficient release of ACh at the neuromuscular junction (NMJ). Frequently, LES patients also develop small-cell lung cancer (SCLC). It is currently thought that SCLC is the antigenic stimulus for the production of the autoantibodies which cross-react with Ca<sup>2+</sup> channels at the NMJ. We have previously shown that LES IgG can inhibit both I<sub>Cs</sub> (Kim & Neher, Science 239:405, 1988) and exocytosis (Kim et al., J. Physiol., 446:245P)

in bovine adrenal chromaffin cells. SCLC cells (NCI-H146) were incubated with serum from an LES patient or SCLC cells (NCI-H146) were incubated with serum from an LES patient or from a healthy individual for 24 hours (1 mg/ml IgG). After achieving the whole-cell configuration, cells were given a 500 msec depolarizing stimulus to +10 mV (V<sub>x</sub>=80 mV). Five pulses were applied to all cells at a frequency of 0.2 Hz. We simultaneously recorded I<sub>ca</sub> and the resulting changes in membrane capacitance due to each depolarization with 10 mM [Ca<sup>2+</sup>]<sub>o</sub>.

LES serum was able to reduce both the peak I<sub>ca</sub> and the I<sub>ca</sub> measured at the end of the stimulation by ~40% (p<0.05). Exocytosis, as measured by interestical in prombrane capacitance was advanced by interestical intermediate in prombrane capacitance was advanced by interestical intermediate.

increases in membrane capacitance, was reduced by slightly >50% (p<0.05) in the LES-treated cells. Thus, LES autoantibodies are capable of reducing  $I_{Ca}$ in SCLC cells which participate in exocytosis. As the release of ACh is reduced at the NMJ in patients with the syndrome, it may be that the Abs which reduce secretion from SCLC cells are the ones which block the presynaptic Ca<sup>2+</sup> channels at the NMJ. (Supported by NIH grant NS18607 and the Miserular Dystrophy Association) the Muscular Dystrophy Association).

PGE1-ACTIVATED CALCIUM CHANNELS IN NIH 3T3 CELLS. Y. Shin, E. Ito, K. Oka, C. Collin and F. Gusovsky\*. LBC, NIDDK and LMCN, NINDS, NIH Bethesda, MD 20892.

Calcium mobilization was studied in single NIH 3T3 cells preloaded with the fluorescent probe fura-2. Dose-response relationships were obtained for the ability of different PGs in generating increases in intracellular calcium. The doseresponse relationships were in good agreement with the potencies of these compounds in stimulating phosphoinositide breakdown. PGE1 was remarkable since it was completely ineffective in inducing phosphoinositide breakdown even at 10  $\mu M$ . However, PGE1 induced maximal increase in intracellular calcium at a concentration of 1  $\mu M$ . A time course indicated that PGE1-induced calcium increase has a faster onset of action than PGF2α-induced response. In the absence of extracellular calcium, PGF2 $\alpha$  elicits maximal calcium increase through the release of IP3 and subsequent release of calcium from intracellular stores. In a remarkable contrast, PGE1-induced calcium response is completely eliminated in the absence of extracellular calcium, suggesting the involvement of a calcium channel in PGE1-mediated action. PGE1 also induces a large increase in cyclic AMP accumulation in NIH 3T3 cells. However, neither forskolin, which activates adenylate cyclase directly, nor IBMX, a phosphodiesterase inhibitor, induce any change in intracellular calcium. PGE1-induced calcium influx was inhibited with divalent cations (cobalt, cadmium, nickel) at  $100~\mu\text{M}$ , with the L-type calcium channel blocker nifedipine at 100~nM and with methoxyvcrapamil at 1 µM. However, neither divalent cations nor nifedipine affected PGE1induced cyclic AMP accumulation. The results suggest that PGE1 induces increases in intracellular calcium through the activation of calcium channels that share the pharmacology of L-type calcium channels.

CHARACTERIZATION OF ANTIBODIES AGAINST A CANDIDATE. PRE

SYMAPTIC CALCIUM CHANNEL SUBUNIT OF TORPEDO.

A. Mastrogiacomo and C.B. Gundersen, Department of Pharmacology and Brain Research Institute, UCLA School of Medicine, Los Angeles, California 90024.

ne, Ios Angeles, California 90024.
The omega-conotoxin-sensitive, N-type Ca<sup>2+</sup>channel has been implicated in the regulation of neurotransmitter release at a number of vertebrate synapses (see: Miller, Science 235; 46-52). This laboratory has recently cloned the cDNA encoding a candidate, N-type, Ca<sup>2+</sup>channel subunit from Torpedo nervous tissue (C.B. Gundersen and J.A. Umbach, submitted 2+ Neuron). This protein is designated CCCS, for candidate Ca channel subunit. To facilitate the biochemical isolation and tissue localization of CCCS, antisera against synthetic peptides (from the deduced primary structure of CCCS) have been produced in rabbits. Antiserum against the C-terminal 12 residues specifically immunoprecipitate CCCS produced by in vitro translation in rabbit reticulocyte lysate. On Western blots of the in vitro translation of CCCS, a protein of about 27 KD is recognized by immune serum but not by pre-immune serum. Binding of antibodies to this 27 KD band is abolished by excess C-terminal peptide of CCCS. When this abolished by excess C-terminal peptide of CCCs, when this antiserum is used to probe Western blots of a microsomal fraction of Torpedo electroplax a protein of about 34 KD is specifically identified. We are examining in more detail the tissue and subcellular distribution of this antigen. Moreover, we are investigating the basis of electrophoretic mobility shift of the antigen that is detected in in vitro translation versus tissue. translation versus tissues.

Dihydropyridine-sensitive Ca2+ Channels Participate in Exocytosis in Small-Cell Lung Cancer Cells. Thomas J. O'S. Jughnessy, Michael P. Viglione and Yong I. Kim\*. Departments of Biomedical Engineering, Neuroscience & Neurology, University of Virginia Health Sciences Center, Charlottesville, VA 22908.

Small-cell lung cancer (SCLC) is an aggressive cancer frequently associated with the paraneoplastic disorder, Lambert-Eaton Syndrome (LES). The presence of SCLC is thought to be the antigenic stimulus for the production of autoantibodies which inhibit presynaptic Ca<sup>2+</sup> channels at the neuromuscular junction. Therefore, it is of interest which type(s) of Ca<sup>2+</sup> channels underlie secretion in these cells.

The effects of 10 μM nicardipine, 1 μM ω-conotoxin (CgTx) or vehicle were studied on the calcium currents (Ic) and exocytosis in SCLC cells (NCI-H146), as measured by increases in membrane capacitance, using the patch-clamp technique. A series of 5 depolarizations 500 msec in duration was applied to each cell from  $V_{h} = -80 \text{ mV to } +10 \text{ mV}.$ 

Nicardipine was able to reduce  $I_{\text{Ca}}$  at the end of the stimulation by more than 50%(p<0.005) while inhibiting the peak by less than 10%. Exocytosis, however, was reduced by 60% (p<0.05).  $\omega$ -conotoxin reduced both the peak and plateau  $I_{\rm c_b}$  by approximately 25%. While a clear effect on secretion was not obvious, about half of the CgTx-treated cells displayed reduced  $I_{cx}$  and exocytosis compared to controls. Therefore, it appears that calcium ions mediating exocytosis in SCLC cells enter through DHP-sensitive and possibly  $\omega$ -CgTx-sensitive Ca2+ channels. It is not certain, however, whether LES antibodies are interacting with DHP-sensitive or ω-CgTx-sensitive Ca<sup>2+</sup> channels to reduce exocytosis in SCLC cells. (Supported by NIH grant NS18607 and the Muscular Dystrophy Association).

PROFILE OF DUAL Ca2+ AND Na+ CHANNEL BLOCKERS ON KCI- AND VERATRIDINE-INDUCED SYNAPTOSOMAL [Ca2-], INCREASE

Wurster and D.J. Dooley\*. Department of Neuroscience, Parke-Davis Pharmaceutical Research Division, Warner-Lambert Co., Ann Arbor, MI 48106.

A common feature of many synthetic compounds developed as blockers of neuronal Ca2+ channels or Na+ channels is that they are active on both channel types. The determination of structural properties that favor specificity for one channel type requires the assessment of relative channel selectivities using uniform experimental conditions. We have investigated rat neocortical synaptosomes loaded with Fura 2 for this purpose, and tested the effects of channel blockers on increases in synaptosomal [Ca<sup>2+</sup>], induced by veratridine or depolarizing concentrations of KCI. The increase in [Ca<sup>2+</sup>], caused by veratridine consisted of a sustained plateau after a relatively slow rise. K\*-depolarizations consisted of a sustained plateau and a relativity sich most file of the state of th was almost entirely blocked by tetrodotoxin, whereas the response to K\* was unchanged. Thus, the response to K\*-depolarization appears devoid of Na channel activity, whereas that of veratridine reflects both a Na and a Carchannel component. A determination of IC<sub>w</sub>'s of several dual Na and Carchannel blockers (e.g. flunarizine, RS 87476, R 58735) revealed that they were 3- to 9-fold more potent on the plateau induced by 10 μM veratridine than on the peak evoked by 33 mM KCl. They also inhibited the delayed plateau in K\*-depolarization by ~ 85%. The latter result indicates that the sustained [Ca²¹], increase in K\*-depolarization may be caused by Ca2\* channel activity; alternatively, if the increase is due to the depolarization-driven electrogenic Na<sup>3</sup>/Ca<sup>33</sup> exchanger as is often assumed, then this exchanger must be considered to be susceptible to inhibition by the dual channel blockers.

# 188.27

A NOVEL SUBSTITUTED GUANIDINE BLOCKER OF GLUTAMATE RELEASE. N.L. Reddy, S. Katragadda, D. Daly, J.B. Fischer, L-Y Hu, A.G. Knapp, L. Margolin, W. McGowan and S.M. Goldin, Cambridge NeuroScience, Cambridge MA; Cambridge NeuroScience & Dept. of Biol. Chem., Harvard

In ischemic brain tissue, blockade of presynaptic calcium channels in glutamatergic nerve terminals should attenuate the excessive release of glutamate leading to nerve cell death. A novel rapid kinetic method was used to resolve kinetic components of Ca-dependent, K\*-stimulated H-glutamate release from rat brain nerve terminal preparations (synaptosomes) *in vitro*: a "phasic" component (decay const. <200 msec) and a more persistent component. A family of substituted guanidines were evaluated for their ability to block K\*-stimulated H-glutamate release and \*Ca uptake into rat brain. synaptosomes. The ability to block glutamate release of compounds initially tested (at [10 AM]) correlated well with their ability to block the persistent but not the phasic component of Ca dependent glutamate release. A synthetic effort targetted to develop more potent and selective blockers of glutamate release led to CNS 1145. CNS 1145, at [3-10 M], selectively blocked the persistent vs. the phasic component of glutamate release; it was more potent in its ability to block glutamate release than predicted from its ability to block synaptosomal \*Ca uptake. In whole cell recordings of frog dorsal root ganglia and N1E-115 neuroblastoma cells, respectively, CNS 1145 blocked N-type Ca channels and TTX-sensitive Na channels at [2-20 

M]. CNS 1145 reversibly blocked excitatory synaptic transmission in hippocampal slice preparations. A dual action on presynaptic Ca channels and additional sites is one possible explanation for the relative potency of CNS 1145 as a glutamate release blocker. Selective block of the persistent vs. phasic Ca-dependent glutamate release may be a desirable characteristic for a neuroprotective agent.

LAN-1 HUMAN NEUROBLASTOMA CELLS RECOME RESPONSIVE TO MEMBRANE DEPOLARIZATION AND MAITOTOXIN INDUCED [Ca+ INCREASE AFTER RETINOIC ACID-INDUCED DIFFERENTIATION. L. Annunziato\*, A. Bassi, G.F. Di Renzo and A. Fatat Sect. of Pharmacology, Dept. Human Comm. Science, II S of Med, Univ of Naples, Naples ITALY.

LAN-1 is a neuroblastoma cell line devoid of  $Ca^{++}$ channels activated by membrane depolarization or by Ca<sup>++</sup> channels activators like maitotoxin (MTX) or BAY K8644. Since cell differentiation can be accompanied by functional expression of ion channels, LAN-1 cells were exposed for 1-7 days to  $10\mu\mathrm{M}$  retinoic acid (RA) and [Ca<sup>++</sup>]; was monitored by fura-2 single-cell [Ca<sup>++</sup>]<sub>i</sub> was monitored by fura-2 single-cell microfluorimetry. Morphological differentiation already became evident at the 3th day of RA exposure. By contrast, already after 1 day of RA treatment, LAN-1 cells showed [Ca<sup>++</sup>]<sub>i</sub> elevation in response to depolarizing concentrations of R<sup>+</sup>. This effect was still present after 3,5,7 days of RA-induced differentiation. Interestingly, even maitotoxin, a toxin described as an activator of Voltage Sensitive Calcium Channels (VSCC) in different neuronal cell types, became effective in stimulating [Ca++] i increase in single LAN-1 cells. These results seem to suggest that: 1.Differentiation of LAN-1 cells induced by RA can induce the appearance of Ca<sup>++</sup> channels activated by depolarizing stimuli 2. MTX beaves as a rather selective activator of VSCC since it is inactive in undifferentiated cells. (Supported by 40% and 60% MURST founds and CNR grants to L.A. and G.F.D.R.)

MAMMALIAN VOLTAGE-GATED CALCIUM CHANNEL CURRENTS ARE BLOCKED BY AP\*. D. Büsselberg", B. Platt', D.O. Carpenter and H.L. Haas'. 'Univ. Düsseldorf, Physiologie II, Moorenstr. 5, W-4000 Düsseldorf 1, FRG, and <sup>2</sup>Wadsworth Labs, and School of Public Health, Albany, NY 12201.

Aluminum is the third most abundant element in nature. Aluminum in dialysis patients can cause dementia and has been suggested to play a role in Alzheimer's partents can cause tementar and has been suggested to play a 100 m Arinemer's disease. Neurons from dorsal-root ganglia (DRG) of 2 to 4-day-old rat pups were cultured. Voltage activated calcium channel currents, carried by  $Ba^{2+}$ , were recorded using the whole cell patch clamp configuration. Patch pipette electrodes had resistances between 2 to 5 M $\Omega$ . Electrodes were filled with (in mM): CsCl 140; HEPES 10; EGTA 10; MgCl<sub>2</sub>\*6 H<sub>2</sub>O 4 and Na-ATP 2. The external solution had the following composition (mM): TEA Cl 135; HEPES 10; glucose 10; BaCl<sub>2</sub> 10; MgCl<sub>2</sub> 1; TTX 0.002; pH was adjusted to 7.1-7.4. Neurons were routinely clamped -45 mV to +35 mV for 75 m

Al3+ blocked sustained and transient components of voltage activated calcium Al<sup>+</sup> blocked sustained and transient components of votage activates cartein channel currents of DRG cells. Although solutions surrounding the neuron completely exchanged within 10-30s, a steady state blockade of calcium channel currents was reached within 1-5 min. Upon wash there was little or no recovery. Threshold concentration for blockade was 5-10  $\mu$ M Al<sup>3+</sup> and a total blockade (>80%) of the calcium channel current was reached with concentrations of 200  $\mu$ M Al<sup>3+</sup> or higher. The IC<sub>50</sub> was 83 μM Al<sup>3+</sup> and the Hill slope was around 3. degree of blockade was very pH dependent and was greater at higher concentrations of H<sup>+</sup>. Frequently, we observed a depolarizing shift in the peak of the current-voltage relation after applying Al<sup>3+</sup>. The degree of the shift depended on the concentration of Al<sup>3+</sup> but differed from cell to cell. We conclude that Al<sup>3+</sup> is a potent and irreversible blocker of voltage activated calcium channel currents.

### cAMP and Calcium Regulate Nicotinc Acetylcholine Receptor Subunit RNA Levels

K.G. Chahine, J.Staple and D. Goldman\*

Department of Biological Chemistry and Mental Health Research Institute
The University of Michigan, Ann Arbor, Michigan 48109.

During development of the neuromuscular junction there is a switch in expression of nAChR genes from an embryonic- $(\alpha_2\beta\gamma\delta)$  to an adult-type (α2βεδ). Embryonic-type genes are expressed throughout the muscle fiber prior to innervation. However, after innervation, extrajunctional expression of these genes is suppressed by nerve induced muscle activity and the adult-type receptors are expressed beneath the neuromuscular junction. The mechanisms by which this regulation is transduced to the genome is not known. We have developed a rat primary muscle culture system that suppresses the expression of the embryonic-type receptors when stimulated to contract with extracellular electrodes. The expression of the adult-type e-subunit and the muscle creatine kinase genes were unchanged. We are using this *in vitro* culture system to characterize the signal transduction systems mediating the effects of nerve induced electrical activity on embryonic-type nAChR gene expression. We report here that agents that increase intracellular levels of cAMP can reverse the suppressive effect electrical activity has on the  $\alpha$ -,  $\beta$ -,  $\gamma$ - and  $\delta$ - subunit The adult-type ε-subunit and the muscle creatine kinase RNAs were unchanged under the same conditions. Furthermore, increasing intracellular levels of calcium with the calcium ionophore A23187 decreases the levels of the  $\alpha$ -,  $\beta$ -,  $\gamma$ -,  $\delta$ - and  $\epsilon$ -subunit, but not muscle creatine kinase, RNAs in cultures made inactive with tetrodotoxin. Currently, we are investigating the possible roles of other second messenger systems, as well as, continuing to study the pathways by which cAMP and calcium mediate their effects on the expression of the nAChR subunit RNAs. This work was supported by grants from NIH and MDA.

SODIUM BUTYRATE- AND CYCLIC AMP-DEPENDENT REGULATION OF NICOTINIC ACETYLCHOLINE RECEPTOR EXPRESSION IN RMO AND BC3H-1 MUSCLE CELL LINES. <u>Linda Lucero</u>, <u>Ronald J. Lukas</u>\* and <u>Merouane Bencherif</u>. Division of Neurobiology, Barrow Neurological Institute, Phoenix, AZ 85013.

Sodium butyrate (NaBu) or dibutyryl cyclic AMP (dbcAMP) treatments induce rapid, 90% downregulation of muscle-type nicotinic acetylcholine receptor (nAChR) expression in total particulate fractions of BC3H-1 mouse non-fusing muscle cells in concert with substantial (alphal, betal or delta) or complete (gamma) inhibition of nAChR subunit gene transcription. Here, we demonstrate that these effects are accompanied by downregulation ( $\geq 60$ %) of cell surface nAChR expression and loss (≥ 90%) of nAChR-mediated function. Comparable effects are observed on functional nAChR expression by the rat fusing muscle cell line, RMO. Whereas downregulatory effects of NaBu or dbcAMP are evident within 6 hr of drug treatment and persist for at least 5 days, treatment of BC3H-1 cells with forskolin or with 8-(4-chlorophenylthio)-adenosine 3':5'-cyclic monophosphate induces functional downregulation and losses of cell surface nAChR that downregulation and losses of cell surface nature that persist for only 1-2 days and reverse to control values 5 days after drug exposure. Continuing studies using the BC3H-1 and RMO systems are designed to test the hypothesis that motor neuronal influences on muscle cell development involve modulation (perhaps via co-released calcitonin gene-related peptide) of muscle cell cyclic AMP levels

TRANSIENT CO-EXPRESSION OF ACETYLCHOLINE RECEPTOR SUBUNIT AND MYOD1 mRNA IN CULTURED MUSCLES. X, Su. S. Berman\*, T. Sullivan and S. Bursztain. Mailman Research Center, McLean Hospital and Harvard Medical School, Belmont, MA 02178.

We have quantified mRNA levels of acetylcholine receptor (AChR) subunits and the myogenic transcription factor MyoD1 in chicken muscle primary cultures by a nonradioactive. PCR-based method. We first prepared total RNA from cells and cRNA standards from cDNA clones. As controls, known amounts of cRNA of a foreign gene were added to both the cellular RNA and cRNA. After cDNA synthesis and PCR, signals were detected by the chemiluminescence method. The amount of mRNA in a sample was deduced from the cRNA standards after correction for its system efficiency determined from the control cRNA. With this method, we measured mRNA levels of  $\alpha$ ,  $\gamma$  and  $\delta$  subunits of AChR and MyoD1 in chicken primary muscle cultures. We found peaks for all the mRNAs studied on Day 2 when myoblasts began to fuse. The RNA returned to nearly basal levels afterwards. After myotube formation,  $\alpha$  subunit mRNA had a second peak on Day 6 but  $\gamma$  and  $\delta$  subunits' mRNA had second peaks on Day 7. Among the three subunits,  $\delta$  subunit mRNA was expressed the least. On the other hand, MyoD1 mRNA remained at basal level during Day 6 and Day 7, suggesting that MyoD1 was not required for the AChR gene expression after cell fusion. The data indicate that gene expression for each AChR subunit during muscle development is differentially regulated by mechanisms which are being investigated.

CYTOSKELETAL MECHANISMS IN THE REGULATION OF MUSCLE-TYPE

CYTOSKELETAL MECHANISMS IN THE REGULATION OF MUSCLE-TYPE NICOTINIC ACETYLCHOLINE RECEPTOR (nAChR) EXPRESSION BY TE671/RD CELLS. Merouane Bencherif\* and Ronald J. Lukas, Barrow Neurological Institute, Phoenix, Arizona 85013

Treatment of TE671/RD human cells with inhibitors of actin polymerization (cytochalasins A, B, C, D, E, H, or J at concentrations of 5 ug/ml) produces a two- to five-fold increase in nAChR per unit of total membrane protein (B<sub>max</sub> for 123 - Labeled o-bungarotoxin binding) with no change in AAChR affinity (K,) or muscarinic receptor density. These achieved obtained to the state of the state results reflect an up to 10-fold increase in intracellular nAChR whereas cell surface receptor density is unchanged or slightly decreased. Functional studies using a  $^{86}{\rm Rb}^+$ efflux assay indicate that cell surface receptors are fully responsive to agonist, and Northern blot analysis shows a 4 to 5-fold coordinate increase in the expression of mRNA encoding alphal, betal, gamma or delta subunits. When co-treated with non-labeled alpha bungarotoxin to block surface nAChR, cytochalasin up-regulation was still observed suggesting that it does not require transit of nAChR through a cell surface pool. The magnitude of nAChR up-regulation following chronic exposure to nicotine (lmM) is similar to but not additive with that of-cytochalasin treatment. These data support a role for microfilaments in the regulation of nAChR expression.

DEGRADATION RATE OF MUSCLE ACHR EXPRESSED IN XENOPUS OOCYTES. E. Liu. O. Hamill. T. Podleski\* and M.M. Salpeter. Neurobiology & Behavior, Cornell University, Ithaca, NY 14853.

The Xenopus oocyte system has proven very useful in studying properties of proteins expressed from injected mRNAs, and much has been learned about the physiological role played by the different subunits of the acetylcholine receptor (AChR). We were interested in using the Occupies system to study the regulation of turnover of muscle AChRs. Using culturing conditions for prolonged maintenance of oocytes (developed by Quick, Naeve, Davidson, and Lester, Biotechniques in press), functional AChRs were expressed from mouse and Torpedo α β  $\gamma$  and  $\delta$  subunit mRNAs, and their degradation rates determined. Resting potentials were used as a criterion for oocyte viability.

We found that when the oocytes were maintained at  $16^{\circ}$ C, degradation  $t_{1/2}$  values of  $4.7 \pm 0.5$  (n=7) and  $5.6 \pm 0.6$  (n=3) days were obtained for the mouse and Torpedo AChRs respectively. These values are slower than the  $\sim 1$  day half life seen for embryonic AChRs in mouse myotubes at  $37^{\circ}$ C. and closer to the value of  $\sim 2$  1/2 days previously reported for AChR in *Xenopus* myotomal muscles at  $20^{\circ}$ C (Brehm et al., J. Neuroscience 3:101-107, 1983). We suggest that when properly maintained, the Xenopus oocyte system is usable to study conditions which may regulate AChR degradation. The role of temperature, subunit composition, and associated proteins will be examined.

FUNCTIONAL NICOTINIC RECEPTORS ARE EXPRESSED IN C3H 10T1/2 CELLS TRANSFECTED WITH THE cDNA FOR MyoD, A MYOGENIC REGULATORY FACTOR. R. Odeh\*, J. Philie, M. Szyf and M. Quik. Dept. Pharmacol., McGill U., Montreal, Que., Canada, H3G 1Y6.

Evidence now indicates that MyoD represents a transcriptional activator for muscle-specific genes including those for nicotinic acetylcholine receptor (nAChR) subunits. MyoD binding sites are present in the 5' flanking regions of DNA of the α and γ subunits of the nAChR and their presence is required for the expression of these subunits in muscle cells. The present studies were designed to investigate whether transfection of a non-muscle cell line with MyoD could induce the expression of a functional muscle nAChR. A mesodermal stem cell line C3H 10T1/2 was stably transfected with MyoD cDNA. Myogenic clones were isolated which formed myotubes in fusion medium. The presence of a nicotinic  $\alpha$ -bungarotoxin ( $\alpha$ -BGT) receptor population was demonstrated by saturable  $^{125}I-\alpha$ -BGT binding which was of high affinity (K<sub>d</sub> of 1.5 nM). Time course studies showed that the receptors increased to a plateau level by 8 days in culture. Subsequent studies demonstrated the presence of carbachol-stimulated <sup>22</sup>Na uptake suggesting that the receptor was functional. Moreover, function correlated well with the levels of <sup>125</sup>I-α-BGT binding. Both <sup>125</sup>I-α-BGT binding and carbachol-stimulated <sup>22</sup>Na uptake were potently inhibited by α-BGT and d-tubocurarine (IC<sub>so</sub>s of 2 nM and 250 nM, respectively). Thus, this receptor has a pharmacological profile characteristic of a muscle nAChR. To conclude, MyoD not only binds to 5 flanking regions of specific nAChR subunit genes ( $\alpha$  and  $\gamma$ ), but as shown in the present studies results in the expression of nAChRs which are functional. (Supported by MRC Canada.)

DIFFERENTIAL EFFECT OF SPONTANEOUS ACTIVITY ON ACETYLCHOLINE RECEPTOR STABILITY IN PRIMARY RAT MUSCLE CELL CULTURES. J.P. O'MALLEY & M.M. SALPETER\* Section of Neurobiology & Behavior, Cornell University, Ithaca NY 14853
Cultured rat myotubes express acetylcholine receptors (AChRs) that decay with a

double exponential indicating the existence of two populations of receptor. Approximately 80 % have a 11/2 of ~ 1 d and 20 % have a 11/2 of ~ 3 d. These half-lives are similar to those reported for rapidly degrading (R<sub>f</sub>) and slowly degrading (R<sub>S</sub>) AChRs at denervated neuromuscular junctions (Shyng & Salpeter J. Neurosci. 10:3905-3915). Like the AChRs at the denervated neuromuscular junction, the myotube  $R_S$  AChRs are stabilized to a degradation  $t_{1/2}$  of 8 d by cAMP analogues, while the degradation  $t_{1/2}$  of the  $R_F$  AChRs are unaffected.

In this study AChRs were labeled with [125I]-α-bungarotoxin on day 4 or day 10 of culture (i.e. before or after the myotubes become spontaneously active on day 6) and the loss of labeled receptors measured for the next 13 days. We found that the  $R_{\rm S}$ AChRs inserted in quiescent 4 day old myotubes had a t1/2 of 3 days which did not change throughout the 13 day sampling period. However the Rs AChRs inserted in active 10 day old myotubes decayed with a  $t_{1/2}$  of 8 days. In both cases the  $R_\Gamma$  retained their  $t_{1/2}$  of 1 day. Because our results show that myotubes can simultaneously have some Rs which degrade with a  $t_{1/2}$  of 3 d and others with a  $t_{1/2}$ of 8 d, we suggest that the degradation rate of the Rs AChR depends on the time a which they were inserted, i.e before or after the initiation of activity, and does not simply slow down as the myotube ages.

We conclude that spontaneous muscle activity can maintain the stability of newly inserted  $R_S$  AChRs but does not stabilize them once they are in an accelerated state. In that respect spontaneous activity differs from cAMP which does stabilize the

N-GLYCOSYLATION OF NICOTINIC ACETYLCHOLINE RECEPTOR SUBUNITS IS REQUIRED FOR EFFICIENT INTRACELLULAR TRANSPORT OF ASSEMBLED RECEPTORS. <u>Vaughn M. Gehle\* and</u> Katumi Sumikawa. Dept. of Psychobiology, Univ. of California,

Neglycosylation site on the four subunits of the Conserved N-glycosylation site on the four subunits of the Torpedo nicotinic AChR does not prevent subunit assembly, but rather causes changes in both degradation rates of mutant subunits and transport of accembled recorders (Mod. Project Page 11: 17.25) and transport of assembled receptors (Mol. Brain Res. 11: 17-25, 1991). These results were obtained by directed mutagenesis of the Asn residue in the N-glycosylation consensus sequence (Asn-X-Ser/Thr) to an Asp residue. Additional experiments to determine how the negative charge associated with the Asp affected our results are reported here. For these experiments, we created additional mutant subunits by changing the Ser or Thr residues to Ala. These second mutant subunits were tested for assembly and degradation rate by immunoprecipitation of the subunits expressed in Xenopus oocytes. Functional studies the subunits expressed in Xenopus oocytes. Functional studies were also performed using voltage-clamp techniques and  $\alpha$ -bungarotoxin binding assays. Our results demonstrate that the degradation rate changes seen previously were mainly due to the addition of the negative charge while the decrease in transport of receptors to the surface membrane was caused by the loss of the carbohydrate moiety. Thus, for the four subunits of the Torpedo AChR, glycosylation of the nascent peptides serves mainly to aid in efficient transport of assembled receptors to the cell surface membrane.

TUNICAMYCIN INCREASES DESENSITIZATION OF JUNCTIONAL AND EXTRAJUNCTIONAL ACH RECEPTORS EXPRESSED IN XENOPUS OOCYTES BY A MECHANISM INDEPENDENT OF BLOCKING N-GLYCOSYLATION.

Tomoyuki Nishizaki and Katumi Sumikawa\*. Dept. of Psychobiology, Univ. of California, Irvine, CA 92717-4550.

In muscle cells, it was shown that tunicamycin (TU), an inhibitor of protein N-glycosylation, reduced the appearance of functional ACHBE in the please of superpensations wither by blocking

functional AChRs in the plasma membrane either by blocking the assembly of AChR subunits or increasing the rate of degradation of AChR molecules. In Xenopus oocytes injected with AChR mRNAs and treated with external TU alone, Nglycosylation was only partially blocked. Therefore, in these oocytes relatively large membrane current responses to ACh still could be observed. Interestingly, extrajunctional and junctional mouse muscle AChRs expressed in oocytes in the presence of TU desensitized more rapidly than the corresponding AChRs synthesized in the absence of TU. The two types of AChR expressed in non-TU-treated oocytes could two types of ACnH expressed in non-10-treated oocytes could be distinguished by their different rates of desensitization, but TU diminished this difference. The effect of TU on the AChR desensitization appeared to be reversible and co-application of TU with ACh also caused a similar effect on desensitization of these AChRs, suggesting the effect of TU was mediated by a mechanism independent of blocking N-glycosylation.

A SMALL CONDUCTANCE ACh CHANNEL IS PRESENT FOLLOWING RECOVERY FROM DESENSITIZATION AT STAUROSPORINE-TREATED SNAKE ENDPLATES. <u>I.C. Hardwick\* and R.L. Parsons.</u> Dept. of Anatomy & Neurobiology, The University of Vermont, Burlington, VT 05405.

Pretreatment of snake twitch muscle fibers with staurosporine, a protein kinase inhibitor, decreased the extent of AChR recovery from carbachol-induced desensitization (Hardwick et al., Brit. J. Pharm. <u>104</u>:879, 1991). Here induced desensitization (Hardwick et al., 1911. J. Pharm. 104,879, 1991). Here we show that the decrease of recovery by 0.5 $\mu$ M staurosporine, determined by a decrease in MEPC amplitude, was dependent on the duration of carbachol exposure. Following a 1 min. exposure to 540 $\mu$ M carbachol, staurosporine-treatment did not alter AChR recovery from desensitization. However, with a 5-10 min. exposure to carbachol, staurosporine pretreatment significantly decreased MEPC amplitude during recovery for periods up to 1 hr. The decrease in MEPC amplitude was not associated with a shift in the reversal potential. Single channel measurements of ACh-activated currents from cell-attached patches demonstrated that a single class of ACh-activated currents with a slope conductance of 45-49 pS was present at both control and staurosporine-treated endplates. Following recovery from a 5 min. exposure to  $540\mu$ M carbachol, small amplitude ACh-activated channels were recorded at staurosporine-treated preparations in addition to the large conductance channels. The reversal potential of the small conductance channels was similar to that of the large conductance channels. The small channels was similar to that of the large conductance channels. The small conductance channels were not present following recovery from desensitization at control endplates. We propose that the staurosproine induced decrease in extent of recovery is due to the presence of small conductance channels which in control preparations are converted to large conductance channels by a staurosporine-sensitive protein kinase. GABA. ANTAGONISTS PICROTOXIN AND BICUCULLINE ALTER NICOTINIC ACETYLCHOLINE CHANNEL KINETICS IN CULTURED

EMBRYONIC RAT MYOTUBES Q.Y.Liu, V.Smallwood and J.L.Barker Lab of Neurophysiology, NINDS, NIH, Bethesda, MD 20892.

The effects of GABA, receptor antagonists picrotoxin (PTX) and bicuculline (BIC) on nicotinic acetylcholine receptor (AChR) in cultured embryonic rat myotubes were first recorded in the cell-attached patchclamp mode. This embryonic AChR current was of low conductance (slope conductance: 35.4  $\pm$  0.6 pS), long lasting (open time constant,  $\tau_{\rm s}$ : 6.3  $\pm$  0.5 ms) type (with 2  $\mu M$  ACh in the pipette) as reported previously. Its reversal potential (RP) was at  $+60.8 \pm 3.3$  mV pipette potential (Vp). In our experimental conditions, the ratio of the total time the channels stayed in the open state over the total recording time of 25 seconds (Toper/Trecording was  $31.3 \pm 4.1\%$ . 50 µM PTX significantly decreased  $\tau_0$  of the channel to  $1.7\pm0.1$  ms (-73.0% as compared with control, p < 0.01) and  $T_{oper}/T_{recording}$  to  $19.3~\pm~3.0\%$  (-38.3%, p < 0.05) without significantly affecting its conductance (34.3 $\pm~0.6$  pS) or RP (+55.1 $\pm~4.3$  mV Vp). BIC in the same conductance (34.3  $\pm$  0.6 ps) or Rr (+35.1  $\pm$  4.5 mV vp). Bit in the same concentration was less powerful in decreasing  $\tau_o$  but more powerful in decreasing  $T_{open}/T_{recording}$ ,  $\tau_o$  and  $T_{open}/T_{recording}$  in BIC were 4.2  $\pm$  0.6 ms (-33.3%, p < 0.05) and 11.4  $\pm$  3.0% (-63.6%, p < 0.01), respectively. Channel conductance and RP in BIC (33.7  $\pm$  0.7 pS and +63.3  $\pm$  2.5 mV Vp, respectively) were not significantly different from control. The effects of PTX and BIC were also recorded with the whole-cell voltage clamp technique. 50  $\mu$ M PTX and BIC significantly decreased whole-cell embryonic AChR currents to 77.4  $\pm$  6.9% (p < 0.05) and 63.1  $\pm$  4.6% (p <0.01) of control values, respectively. We conclude that GABA, receptor antagonists PTX and BIC can alter embryonic AChR channel kinetics in rat skeletal myotude without changing their unit conductance or ion selectivity.

SECOND MESSENGER MODULATION OF ACETYLCHOLINE RECEPTOR CHANNELS IN MYOTUBES FROM dy MICE. Alfredo Franco-Obrégon\* and Jeffry B. Lansman. Department

of Pharmacology, UCSF, San Francisco, CA. 94143.

The activity of nicotinic acetylcholine receptor channels recorded from cell-attached patches from dy myotubes differs from that recorded from wild type myotubes in two ways. First, spontaneous openings of acetylcholine receptor channels are observed at a much greater frequently in dy myotubes. Secondly, the sensitivity of acetylcholine receptor channels to acetylcholine appears to be reduced in dy

myotubes when compared to wild type myotubes.

Excising patches of myotube membrane from the surface of dy myotubes results in a steady drop in spontaneous activity, suggesting that diffusible cytosolic second messengers are responsible for maintaining spontaneous openings. Adding bromo-cAMP or Forskolin to cultures of wild type myotubes results in an increase of spontaneous channel openings and a concomitant reduction in the responsiveness of acetylcholine receptor channels to acetylcholine, mimicking the dy dystrophic condition. We propose that the dy phenotype could arise as a result of a defect of the adenylate cyclase signalling pathway.

SPERMIDINE AND PUTRESCINE MODULATE THE FUNCTION OF THE PERIPHERAL NICOTINIC ACETYLCHOLINE RECEPTOR. M.M. Froes-Ferrao\*1, M.C. Heluy-Dantas1, E.X. Albuquerque1.2 & R. Rozental1. Lab. Mol. Pharmacol., IBCCF, UFRJ, Rio de Janeiro, Brazil 21944; Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201.

Spermidine and putrescine are ubiquitous polyamines and much experimental evidence indicates their role in cell development. Their possible actions on membrane receptors were indicated by the findings of Anis et al. (J. Pharmacol. Exp. Ther., 254:764, 1990) showing that spermidine displaces  $\alpha$ -bungarotoxin and histrionicotoxin from their binding sites on the nicotinic acetylcholine receptor (nAChR). Here, we further evaluated the interactions of these polyamines on single channel currents generated by the activation of the nAChR applying the cell-attached patch-clamp technique to single fibers isolated from the interosseal muscle of the frog Leptodactylus ocellatus. Neither spermidine nor putrescine applied to the single muscle fibers at concentrations up to 10 \( \mu \text{M} \) induced any single channel current. However, spermidine and putrescine (1-100  $\mu$ M) both increased the number of flickers of single channel currents elicited by 0.4 µM acetylcholine (ACh). addition, these polyamines decreased the mean open time and prolonged the burst duration of the ACh-activated single channel currents, in a concentration- and voltage-dependent manner. Our findings taken altogether suggest that putrescine and spermidine interact with a site most likely located within the ion channel of the nAChR. Therefore, these data support the idea that these polyamines play a key role in the regulation of the activation of the nAChRs. Support: FINEP, UFRJ/UMAB Mol. Pharmacol. Training Program and CNPq.

CHARACTERIZATION OF A NON-MOTILE ZEBRAFISH MUTANT, nic, THAT LACKS FUNCTIONAL ACETYLCHOLINE RECEPTORS. Diane Sepich, Robert Ho, and Monte Westerfield\*, Institute of Neuroscience, University of Oregon, Eugene, Oregon.

One of the first signs of neuromuscular synapse formation is the clustering of acetylcholine receptors (AChRs) beneath the nerve terminal. To study steps in synapse assembly, we are characterizing a mutation in zebrafish, *nic* [b107] which blocks the expression of clustered and functional AChRs in muscle cells.

During normal development, zebrafish muscle requires contact with a neuron to cluster AChRs. The *nic* defect could block either the neuron's ability to signal the muscle or the muscle's ability to respond. We tested in which cell the mutation acts by transplanting precursor cells from labeled wild-type donor embryos into mutant embryos. After axon outgrowth and synaptogenesis, we visualized the AChRs with rhodamine-αbungarotoxin. Wild-type muscle cells transplanted into mutant embryos clustered AChRs. In contrast, mutant muscles failed to

cluster AChRs even when innervated by wild-type motoneurons.

To test whether the mutation alters the AChR alpha subunit gene or its expression, we isolated the corresponding zebrafish cDNA and performed Southern analysis. A restriction fragment length polymorphism in the alpha subunit cDNA is linked to the mutation. We conclude that the *nic* defect acts solely within the muscle cell to

block AChR synthesis or clustering and may be due to a mutation within the alpha subunit gene. Supported by NIH NS21132 and HD22486.

ANTIBODIES AGAINST THE LEVAMISOLE ACETYLCHOLINE RECEPTOR OF THE NEMATODE C. ELEGANS. J.R. Romeu<sup>1</sup>, K.S. Helmer<sup>1</sup>, J.T. Fleming<sup>2</sup> and J.A. Lewis<sup>1</sup>.\* IDivision of Life Sciences, University of Texas at San Antonio, San Antonio, TX 78249 and 2MRC Laboratory of Molecular Biology, Cambridge, England CB2 2QH

Mutations conferring resistance to the nicotine analog levamisole identify acetylcholine receptor (AChR) mutants of the nematode C. elegans. Mutation of the AChR blocks the toxic muscle-hypercontracting effects of levamisole. By transposon tagging and by crosshybridization with the Drosophila AChR subunit gene ard, several genes associated with levamisole resistance have been cloned and sequenced. By homology to  $\underline{\text{Drosophila}}$  and vertebrate subunits,  $\underline{\text{unc-38}}$  encodes an alpha subunit and  $\underline{\text{unc-29}}$  encodes a non-alpha subunit. Mutations have been isolated in each of these genes that block levamisole agonism with little effect on motor behavior, suggesting the binding site of the nicotine analog may be between subunits. Efforts are underway to identify the amino acid residues altered in the mutants. A monoclonal antibody that we raised against highly purified receptor shows punctate, synapse-like staining in the dorsal and ventral nerve cords where muscle arms receive innervation from motorneurons (G. Ruvkun, pers. comm.). Similar staining occurs in the central neuropil. Because the staining is weak, polyclonal antibodies are being raised against unc-38 and unc-29 fusion proteins. Our goal is to identify mutants affecting synapse formation.

# EXCITATORY AMINO ACIDS: EXCITOTOXICITY II

#### 190.1

EXCITATORY AMINO ACIDS IN GLAUCOMA: A POTENTIALLY NOVEL ETIOLOGY OF NEURONAL LOSS IN THIS OPTIC NEUROPATHY. Evan B. Dreyer\* & Stuart A. Lipton. Departments of Ophthalmology and Neurology, Harvard Medical School, Children's Hospital, Boston, MA 02115 The optic neuropathy secondary to glaucoma has generally been ascribed to an intraocular pressure higher than the nerve can tolerate. Traditional wisdom has held that glaucomatous damage occurs at the lamina cribrosa, by either a mechanical or vascular etiology. Glaucoma does, however, injure retinal ganglion cells, which are bona fide neurons of the CNS. This suggests that other neurotoxic etiologies -- in particular excitatory amino acids -- known to play a role in CNS damage, may contribute to the neuronal loss seen in glaucoma. We therefore analyzed amino acid levels in vitreous specimens from patients with open angle glaucoma, as well as controls. Vitreous specimens were selected because of the proximity of the vitreous to the retinal ganglion cell layer. Vitreous was obtained from fifteen patients and twelve controls at the time obtained from fifteen patients and twelve controls at the time obtained from fifteen patients and twelve controls at the time obtained swith a greater than three year history of open angle glaucoma was 22.3±2.8 μmols/litre, as compared to 12.6±1.8 μmols/litre in controls. No significant difference was found in other amino acids between these two groups. Given the known neurotoxic effects of glutamate, this suggests that this excitatory amino acid may play a role in retinal ganglion cell death in glaucoma. Furthermore, this raises the possibility of alternative therapeutic modalities for limiting ganglion cell loss.

A HUMAN IMMUNODEFICIENCY VIRUS (HIV)-DERIVED PEPTIDE AUGMENTS NMDA-INDUCED BRAIN INJURY IN PERINATAL RATS. Faye S. Silverstein\*, Madhavan Nair, Stanley Schwartz and John D.E. Barks. University of MichiganMedical School, Ann Arbor, MI, 48109

University of MichiganMedical School, Ann Arbor, MI, 48109
In vitro data suggest that HIV neurotoxicity may be mediated, in part, by activation of NMDA-type excitatory amino acid (EAA) receptors. We examined the impact of co-injection of an HIV-derived peptide ("env-gag") with NMDA on the severity of NMDA-mediated injury in perinatal rodents. "Env-gag", a recombinant HIV fusion peptide (derived from gp41 and p24) has potent bioactivity in vitro . 7 day old rats received injections of: env-gag, NMDA, or both co-injected, into right striatum [through cortex and dorsal hippocampus (HIP)]; controls received NMDA co-injected with an E. Coli-derived peptide (m=6). Neuropathology was assessed 5 days post-injection, and graded from "0"=normal to "3"=severe damage in HIP and striatum and/or thalamus; HIP cross-sectional areas were also measured. Env-gag alone caused no injury. 37 animals received 5 mmol NMDA [alone or with env-gag (1 or 50 ng, LOW DOSE or 100 ng, HIGH DOSE), and injury was detected in 22/29 survivors. In animals that received NMDA + 100 ng env-gag neuropathology scores were highest [means: 2.3 vs .1.4 at "Low dose" vs. 1.1 with NMDA alone, p=0.01 Kruskal-Wallis (KW)] and reductions in right HIP area were most pronounced (mean reduction in area -28 % vs -13 % vs -8% with NMDA alone, p=0.02, KW). Co-injection of the expression vector peptide with NMDA did not influence the severity of NMDA-mediated damage.

Thus, these data provide evidence that an HIV-derived peptide increased EAA-induced neuropathology in vivo. and strongly support the hypothesis that locally secreted HIV peptides may potentiate the neurotoxicity of endogenous EAA neurotransmitters in HIV-infected brain.

ASSESSMENT OF INTRASTRIATAL INJECTIONS OF QUINOLINIC ACID. M. Levivier\*, S. Holemans², D. M. Gash³, S. Przedborski⁴, J-M. Maloteaux², and J. Brotchi¹. ¹Dpt of Neurosurgery, Univ. Libre de Bruxelles - Hôp. Erasme, B-1070 Brussels; ²Dpt of Neurochemistry, Univ. Catholique de Louvain, B-1200 Brussels, ¹Dpt of Neurobiology & Anatomy, Univ. of Rochester Med. Center, Rochester, NY 14642; ⁴Dpt of Neurology, Columbia Univ., New York, NY 10023.

Quinolinic acid (QA) lesions of the striatum are used as a rat model of Huntington's disease. In order to evaluate mechanisms by which transplants protect against excitotoxicity [Pearlman et al., Exp. Brain Res., 84:303-310, 1991], we analyzed the protective effect the NMDA-glutamate receptor antagonist MK-801 against striatal QA toxicity using behavioral and neurochemical measures.

Seven days after QA injection (100 nmol in 1 µl), saline pre-treated rats showed marked apomorphine-induced rotations toward the lesioned side, while MK-801 (10 mg/kg, i.p., 30 min prior to the QA injection) pre-treated animals showed no significant rotations. In saline pre-treated rats, QA injection caused significant decreases in [PH]MK-801-labeled NMDA receptors, [PHSCH23390-labeled dopamine D1 receptors, [PH]spiperone-labeled dopamine D2 receptors and [PH]hemicholinium-3-labeled high affinity choline uptake sites, as well as a marked increase in [PH]PK11195-labeled glial cells. Except for [PH]hemicholinium-3 binding, these changes were almost completely prevented by MK-801 pre-treatment. Scopolamine (0.25 mg/kg, i.p., 10 min. prior to the MK-801 injection) completely prevented QA-induced [PH]hemicholinium-3 binding loss. Histological assessment confirmed the protective effect of MK-801 on striatal neurons, but all groups of animals showed major cortical damage on the side of the QA injection.

This study shows that most QA-induced striatal damage may be prevented by

This study shows that most QA-induced striatal damage may be prevented by MK-801; however severe cortical damage is present in both saline and MK-801 pre-treated rats. This study also provides some evidence that QA toxicity on cholinergic neurons might result from interactions between NMDA and muscarinic receptors.

MK801 INCREASES BRAIN CELL CULTURE YIELDS. D.J. Leszczyszyn', J.S.Hong and M.K.McMillian, LMIN/NIEHS/ NIH, MD14-06, Research Triangle Park, NC 27709 Neuroprotective effects of NMDA receptor antagonists during striatal and hippocampal cell preparations were examined in neonatal Fischer 344 rats. Viable cell yield for each tissue increased 2.5-fold after 1-2 hours of MK801 (10 mg/kg i.p.) pretreatment. Injection of MK801 was critical. Adding MK801 to dispersing solutions was only 40% as effective at increasing cell yields. PCP (10 mg/kg i.p.) was 50% as effective as MK801. The competitive NMDA receptor antagonist CPP (50 mg/kg i.p.) only slightly increased cell yield unless also added to the dispersing solution; under this condition CPP was fully as effective as MK801, confirming involvement of NMDA receptors. The protective effect of MK801 was not due to anesthesia or hypothermia. L-type Ca2+ channel blockade, nitric oxide synthesis inhibition, and dextromethorphan and ketamine did not produce major increases in viable cell yields. The protective effect of MK801 was restricted to the neonatal period; no pronounced increase in cell yields were observed in 7 day old rats. Our results show that NMDA antagonists greatly increase neonatal striatal and hippocampal cell yields for culture and, more importantly, suggest that a large population of NMDAsensitive cells are lost during routine culture of these tissues.

EXCITOTOXIC NMDA RECEPTOR ACTIVATION RESULTS IN INHIBITION OF CAM KINASE II ACTIVITY IN RAT CORTICAL CELL CULTURE. <u>S.B. Churn\*</u>, <u>S. Sombati</u>, and <u>R.J DeLorenzo</u>. Department of Neurology, Medical College of Virginia, Richmond, VA 23298.

Excitotoxic activation of glutamate receptors results in a delayed neuronal necrosis which is thought to be calcium dependent (J Neurosci 1987;7:369). In addition, the NMDA glutamate receptor subtype has been implicated as mediating the glutamateinduced delayed neuronal cell death (J Neurosci 1988;8:185). CaM kinase II, is a neuronally enriched, calcium-regulated enzyme which is inhibited in models of excitotoxicity such as stroke (Stroke 1990;21:1715)and epilepsy (Epilepsy Res 1991;9:211). Therefore, we examined whether selective excitotoxic activation of the NMDA glutamate receptor would result in inhibition of CaM kinase II activity.

Cortical cells cultured for 14 days from embryonic (E15) rats were exposed to 10 μM glycine plus 100 μM NMDA or 500 μM glutamate for 10 minutes. Following 60 minutes recovery, the cells were harvested and studied for CaM kinase II activity under standard conditions. Non-excitotoxic (2 minute) exposure to glutamate did not result in inhibition of CaM kinase II. Glutamate exposure for 10 minutes resulted in an extended neuronal depolarization (END) and significant inhibition of CaM kinase II activity (66.4 ± 4.9% of control), which was blocked with the co-administration of MK-801 (20  $\mu$ M). The glutamate induced inhibition was observed within 10 minutes after excitotoxic glutamate exposure and was observed at all time points measured. Furthermore, removing calcium from the culture medium resulted in almost complete protection from glutamate-induced inhibition of CaM kinase II. Excitotoxic exposure of neurons to NMDA resulted in greater than 50% inhibition of CaM kinase II activity. The results suggest that excitotoxic activation of the NMDA glutamate receptor subtype results in a calcium-dependent inhibition of CaM kinase II.

THE EFFECTS OF CALCIUM ANTAGONISTS AND MILD HYPOTHERMIA ON HIPPOCAMPAL GLUTAMATE CONCENTRATIONS FOLLOWING REPEATED ISCHEMIA. M. Matsumoto, M. S. Scheller, and M. H. Zornow. Dept. of Anesthesiology, Univ. of California, San Diego, CA 92093-0629

This study compared the effects of the calcium antagonists S-emopamil and nimodipine, with mild hypothermia (32°C) on extracellular concentrations of glutamate following transient cerebral ischemia. Hippocampal glutamate concentrations were measured in rabbits (n=17) using in vivo microdialysis. Administration of drugs (S-emopamil 1 mg/kg bolus, 0.1 mg/kg/min infusion or nimodipine 10 μg/kg bolus, 1 μg/kg/min infusion), or institution of hypothermia was initiated prior to the first ischemic insult. Animals were subjected to two 7.5 min episodes of global ischemia separated by a one hour interval of reperfusion. Ischemia was produced by neck tourniquet inflation (20 psi) with hypotension (< 50 mmHg). Each episode of ischemia resulted in significant increases in the hippocampal concentrations of glutamate in all groups. Peak concentrations of glutamate were significantly lower in the S-emopamil and the hypothermia group (p< 0.05, by 2-way ANOVA). Magnitude of the effect of S-emopamil approaches that provided by mild hypothermia. These findings suggest a possible mechanism for the reported neuroprotective properties of phenylalkylamines.

| Table. Extracellular giutamate concentration Mean ± OLIM (µM) |           |                |                |  |
|---|-----------|----------------|----------------|--|

NEURONAL CELL DEATH IN ORGANOTYPIC CULTURES OF RAT HIPPOCAMPUS IS PREVENTED BY GLUTAMATE RECEPTOR ANTAGONISTS. <u>Lucas D. Pozzo Miller\* and Dennis M.D. Landis.</u> Depts of Neurology and Neurosciences, Case Western Reserve University, Cleveland, OH 44106

A consistent pattern of neuronal cell death occurs in organotypic slice cultures from rat hippocampus during the second and third weeks in vitro. In most slices studied after 7 days in vitro, there is little evidence of cell death. However, neuronal degeneration is present in most slices studied at 14 days, and persists in a few cultures studied at 21 days. At 14 and 21 days, slices with relatively mild cell degeneration contained degenerating neurons in the CA3 region. In slices with more extensive damage, cell death spreads along the pyramidal cell layers into CA1 and CA4. To investigate the causes of the spontaneous neuronal death in vitro, we compared the extent of cell loss in cultures exposed to 3mM kynurenic acid, 100µM D-APV, or 10.5mM Mg<sup>↔</sup> (In all cultures, Ca++ was 1.1mM). Cultures were treated from 7 to 21 days in vitro, and the medium was changed at 48 hour intervals. The extent of cell death was estimated by morphological criteria in cultures fixed with aldehydes, embedded in plastic, and sectioned to  $0.5\mu$  thickness. Both high magnesium and kynurenic acid prevented cell death at 14 days in vitro. The extent of cell death was markedly decreased by treatment with APV, but was still apparent. These observations indicate that studies of cell death in this in vitro system will have to take into account spontaneously occurring neuronal cell death. Moreover, the fact that astrocytes in these cultures share characteristics with reactive astrocytes may reflect the continuing cell destruction over the first three weeks in vitro.

NMDA-INDUCED FODRIN TURNOVER IN VIVO: ASSOCIATION WITH NEURONAL INJURY AND DISSOCIATION FROM CONVULSIONS.

M.S. Miller\*, P. M. Fritz, M. Lewis and D. Luttinger, Sterling Winthrop Pharmaceutical Research Division, Rensselaer, NY 12144.

Elevations in intracellular Ca" have been implicated

Elevations in intracellular Ca" have been implicated in the etiology of neuronal injury following exposure to excitatory amino acid agonists (EAAs). Increased intracellular Ca" can activate calpain, a Ca"-dependent protease which is capable of hydrolyzing cytoskeletal proteins, including fodrin. Degradation of the cytoskeleton may contribute to EAA-induced neuronal injury. A previous study (Siman et al., 1989) demonstrated increases in fodrin turnover (FTO) in adult rat brain and prolonged convulsions following icv injection of NMDA. CPP, a competitive NMDA antagonist, blocked NMDA-induced FTO without affecting convulsions suggesting a dissociation. In the present study, neonatal rats were treated intrastriatally with single doses of NMDA. FTO, convulsions, and neuronal injury were subsequently quantified. Test agents were administered ip 30 min. prior to NMDA. MK-801 produced dose-related inhibition of FTO, convulsions, and neuronal injury with no selectivity (ED50 approx. 0.3 umol/kg for each). The anticonvulsant, chlordiaze-poxide, produced dose-related inhibition of convulsions (MED 30 umol/kg) without reducing FTO or neuronal injury at doses up to 100 umol/kg. Thus, NMDA-induced FTO in vivo is associated with neuronal injury and not convulsions. These data extend the dissociation between convulsions and FTO/neuronal injury.

### 190.8

DEVELOPMENT OF GLUTAMATE-INDUCED EXCITOTOXICITY IN EXPERIMENTAL THIAMINE DEFICIENCY. A.S. Hazell and A.M. Hakim. Cerebrovascular Research Unit, Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada H3A 2B4

Cerebral microdialysis has been used to investigate the role of extracellular glutamate (glu) in the development of the selective histological lesions characteristic of thiamine deficiency.

Male Sprague Dawley rats (300 g) were placed on a thiamine deficient diet with administration of pyrithiamine. A 1 mm dialysis probe was implanted by stereotaxic means into the ventral posterior medial thalamus, a vulnerable region of the brain, in pre-symptomatic (day 13) animals showing no evidence of behavioural changes (n=4). Samples were collected for 48 h at 12 h intervals, following which a second probe was introduced into the same region on the contralateral side with sampling in a similar manner. The dialysates were then subjected to HPLC analysis for determination of glu content.

Side to side comparison of this amino acid showed no significant difference. Progression of the disorder resulted in an increase in extracellular glu compared with pre-symptomatic values, rising to 200-300% which coincided with the onset of the acute symptomatic stage of the illness (loss of righting reflexes) 36 h later. Subsequently, levels of glu were observed to fall below basal values.

The reason for these alterations in glu is unclear at this time, although several processes may be involved including edema, a failure of glial and neuronal uptake mechanisms, and cell death. In experimental thiamine deficiency, the fate of vulnerable regions of the brain may be determined by the temporal profile of increased glu release rather than its absolute concentration.

NEUROTOXIN-INDUCED INTRACELLULAR CA<sup>2+</sup> OSCILLATIONS ARE BLOCKED BY CA<sup>2+</sup> CHANNEL AND NMDA RECEPTOR ANTAGONISTS. <u>T. M. Piser\*, and S. A. Thayer.</u> Department of Pharmacology, University of Minnesota Medical School, Minneapolis MN, 55455.

Oscillations in intracellular free Ca<sup>2+</sup> concentration ([Ca<sup>2+</sup>]<sub>i</sub>) were evoked by exposure of single rat hippocampal neurons to HIV-1 envelope protein (gp120; 200 pM). Intracellular free [Ca<sup>2+</sup>]; was recorded from single cells grown in primary culture using indo-1 based microfluorimetry. gp120-induced [Ca2+]i oscillations were completely and reversibly blocked by the NMDA receptor antagonist CGS197 (10 μM), the voltage-gated Ca<sup>2+</sup> channel blocker nitrendipine (1 μM), and tetrodotoxin (1 µM) (n=4). Spontaneous [Ca<sup>2+</sup>]; transients observed in these cultures were also glutamatergic, as indicated by complete block with the non-NMDA glutamate receptor antagonist CNQX (10 μM). But in contrast to those induced by gp120 spontaneous oscillations were insensitive to nitrendipine. Removing Mg<sup>2+</sup> from the media evoked [Ca<sup>2+</sup>]<sub>i</sub> oscillations with similar pharmacology to the gp120-evoked [Ca2+]; transients; Mg2+-free [Ca<sup>2+</sup>]<sub>i</sub> oscillations have been shown to be neurotoxic. We hypothesize that neurotoxins such as gp120 convert "normal" dihydropyridine-insensitive synaptic activity into excitotoxic dihydropyridine-sensitive activity. We have observed the recruitment of nitrendipine-sensitive, action potential-mediated Ca2+ influx in the presence of the K+ channel blocker TEA (2 mM), suggesting a potential mechanism for the induction of nitrendipine sensitive glutamatergic neurotransmission.

GAMMA-ACETYLENIC GABA CAUSES EXCITOTOXIC LESIONS IN THE RAT HIPDOCAMPUS O.G. McMaster\* H. Baran F.Du. H.-O. Wu. IE.D. French and R. Schwarcz. Maryland Psych. Res. Center, Baltimore, MD 21228 and Dept. Pharmacol., Univ. Arizona Coll. Med., Tucson, AZ 85724.

Camma-acetylenic GABA (GAG) shares many pharmacological properties with aminooxyacetic acid (AOAA). While both

compounds are blockers of GABA transamination, they also inhibit kynurenine aminotransferase, the biosynthetic enzyme of the neuroprotectant kynurenic acid. Intrahippozyme of the neuroprotectant kynurenic acid. Intranippo-campal injections of GAG (60-240 nmoles/1  $\mu$ 1), similar to AOAA injections (Exp. Neurol., 113:378, 1991), caused ex-citotoxic lesions in rats. GAG appeared to be approxi-mately equally toxic to CA3/hilar neurons and CA1 <u>pyramids</u> while CA2 neurons and granule cells were clearly less vulnerable. Choline acetyltransferase activity, a marker of extrinsic afferents, remained unchanged in GAG-lesioned tissue, indicating the axon-sparing nature of the insult. Moreover, GAG lesions were prevented by the NMDA receptor antagonists MK-801 and AP7. However, unlike AOAA lesions, GAG lesions were independent of the anesthetic used during surgery. Upon iontophoretic application, GAG, like AOAA, did not excite CAI/CA3 cells. Taken together, GAG-induced lesions share many characteristics of AOAA lesions but subtle differences exist. GAG and AOAA seem to belong to a new family of excitotoxic agents which produce lesions indirectly by metabolic derangement and/or inhibition of kynurenate production. Supported by grant NS 16102.

SELECTIVE VULNERABILITY IN FOCAL ISCHEMIA DEPENDS ON EARLY CUMULATIVE EXPOSURE TO GLUTAMATE. H. Osuga. AM. Hakim\*. Cerebrovascular Research, Montreal Neurological Institute and Hospital, Montreal, Quebec, Canada, H3A 2B4. <a href="Introduction">Introduction</a> The simultaneous permanent occlusion of the middle cerebral artery and the internal carotid artery results in infarction of the striatum first followed by the overlying cortex. The aim of this study was to evaluate the changes in extracellular glutamate concentration in this model in both striatum and cortex using microdialysis. We hypothesized that glutamate levels would rise in proportion to the ischemic vulnerability of the brain region.

Amaterial and Methods>Day 1: Male Sprague-Dawley rat weighing 250-300g were anesthetized with 2% halothane and mounted on Kopf stereotaxic device. After making two bur holes, two microdialysis probes(OD 0.5mm, membrane length 1.0mm, Carnegie Medicine) were implanted into left caudate nucleus and parietal cortex. Day 2:The probe-implanted rat was anesthetized and left femoral artery was canulated to monitor blood pressure and blood gas. The proximal middle cerebral artery was then coagulated and ipsilateral carotid artery was ligated. During and after surgery, Ringer's solution was perfused at 4µ/min and dialysate was collected at 5 min intervals. The glutamate concentrations in dialysate were measured by HPLC.

HPLC. <Results>The pre-occlusion glutamate level in dialysate was  $1.03\pm0.47\mu\text{M}$  in striatum and  $1.00\pm0.41\mu$  mM in cortex. Immediately after occlusions, glutamate levels rose first in striatum then in cortex. Peak glutamate concentration in striatum (7.28 ±3.60  $\mu$ ) and cortex (5.64 ± 2.24  $\mu$ ) after ischemia were not significantly different. the cumulative integral of glutamate vs. time was obtained and was significantly higher in striatum than in cortex during the first hour of ischemia(p <0.05). At longer durations of ischemia, this parameter was not significantly different between striatum and cortex.

iscrientia, utils parameter was not obtained.

<Conclusion > We conclude that in this model striatum is more vulnerable than cortex to ischemic insult because it is exposed to higher cumulative levels of glutamate in the first hour, but both regions eventually infarct because their total exposure to glutamate is identical.

CARBAMAZEPINE-INDUCED NEUROTOXICITY IN CULTURED CEREBELLAR CARBAMAZEFINE-INDUCED NEUROTOXICITY IN CULTURED CEREBELLAR GRANULE CELLS: EVIDENCE FOR AN INTERACTION WITH NMDA GLUTAMATE RECEPTORS. X.-M. Gao\* and D.-M. Chuang. Biological Psychiatry Branch, NIMH, Bethesda, MD 20892 We have recently demonstrated that carbamazepine (CBZ) induces a concentration-dependent delayed neurotoxicity in

cerebellar granule cells and that NMDA exposure blocks neurotoxicity by an NMDA receptor-mediated mechanism (Gao & Chuang, Neurosci. Lett. 135:159-162, 1992). The present study was undertaken to investigate possible mechanisms underlying CBZ-induced neurotoxic effects. Treatment of cerebellar granule cells with 100  $\mu$ M CBZ for 3 days was found to selectively increase NMDA-induced phosphoinositide (PI) turnover, with a concomitant decrease in PI response to carbachol, norepinephrine and 5-HT, largely because of CBZ-induced neuronal death. 3H-MK-801 binding to NMDA receptors in intact cells was also increased fol lowing a 3-day treatment with CBZ with an  $EC_{50}$  of about 30 $\mu$ M. Moreover, NMDA-induced release of preloaded  $^3$ H-D aspartate (which labeled glutamate uptake pool) was significantly enhanced by long-term treatment with 100  $\mu\rm M$  CBZ, but basal release was reduced. CBZ displaced  $^3\rm H-MK-$ 801 binding to intact cells by an  $IC_{50}$  of approximately 28  $\mu\text{M}$ , but its long-term neurotoxicity was unaffected by the presence of NMDA antagonists MK-801 (10  $\mu$ M) and APV  $(200~\mu\text{M})$ , although these two antagonists effectively prevented the neuroprotective effects of NMDA against CBZ neurotoxicity. Our results suggest that an indirect allosteric interaction of CBZ with NMDA receptors contributes to CBZ-induced neurotoxicity.

EFFECTS OF CO-INJECTION OF GLUTAMATE (Glu) AND INHIBITORS OF SODIUM-DEPENDENT Glu UPTAKE (SDGU) INTO STRIATUM. B.A. McLaughlin, D.R. Lynch, and M.B. Robinson\*, Children's Seashore House; Depts. of Ped., Pharm., and Neurol., U. of PA, Phila., PA, 19104.

Substantial evidence suggests that excessive activation of excitatory amino acid (EAA) receptors contributes to the neuronal degeneration observed after a variety of CNS insults. SDGU transport is presumed to prevent the accumulation of extracellular EAAs in the normal brain. Previous studies show that dihydrokainate, a weak inhibitor of transport activity, does not cause toxicity in vivo. DL-threo-hydroxyaspartate (THA), a 50-fold more potent inhibitor of SDGU, has been co-injected with Glu. Striatal toxicity was observed in one study (McBean, J. Neurochem.44:247,1985), but not in another (Mangano, Brain Res.Bull 10:47,1983). In the present study, neurotoxicity of EAAs was examined by stereotactically injecting compounds into the striatum (1 or  $2\mu$ L, pH = by streetactically injecting compounds into the strictum (1 of  $2\mu$ L, pr = 7.4). Four days later, choline acetyltransferase (ChAT) and glutamic acid decarboxylase (GAD) were measured. As previously reported, kainate (6 nmol) caused seizures, circling, barrel rolling and reductions in ChAT (37 ± 4) and GAD (35 ± 4). Glu (1  $\mu$ mol) was co-injected with either THA (1 µmol) or another potent uptake inhibitor, L-trans-pyrrolidine-2,4-dicarboxylate (1 µmol). At these doses, Glu alone or in combination with these uptake blockers caused neither the behavioral effects observed with kainate, nor the reductions in GAD or ChAT. At these concentrations of SDGU inhibitor, synaptosomal and glial uptake should be dramatically inhibited (Bridges, Neuro.Sci.Abs.17:393, 1991 & unpubl.). These studies suggest that unlike kainate toxicity, Glu toxicity is limited in this experimental paradigm. (Pew, Sloan, GM34781)

SYSTEMIC NEONATAL NMDA ADMINISTRATION RESULTS IN SYSTEMIC NEONATAL NMDA ADMINISTRATION RESULTS IN BEHAVIOURAL DEFICITS IN THE ADULT RAT. J. Kleim, M. Saari\*, S. Kish, L. Ridley, B. Fairey, G. McClenaghan and M. McIsaac. Neuroscience Research Unit, Nipissing University, 100 College Dr., North Bay, Ontario, P1B 8L7.

This study examined the effects of systemic neonatal NMDA administration on the behavioural and physiological development of the rat. On Day 7 postpartum, approximately 160 rats were randomly

and physiological development of the fact. On Day postpartum, approximately 160 rats were randomly allocated to one of four drug treatment groups; Saline, 2mg/Kg, 3mg/Kg or 4mg/Kg of NMDA with equal numbers of male and female animals in each. Those in the NMDA groups received a single rhose in the NMDA groups received a single subcutaneous (s.c.) injection of either 2mg/Kg, 3mg/Kg or 4mg/Kg of NMDA in a saline vehicle. Subjects in the saline group received an equivalent volume of physiological saline (0.9%, NaCl, s.c.). On Day 12, open field activity levels were measured on half of the animals and body and brain weights were taken. Behavioural testing on the remaining animals began on Day 56 postpartum and included tail flick, rotor rod, Morris water maze and open field activity. The animals were sacrificed on Day 70 and body and organ weights were obtained. Analysis of Variance (ANOVA) revealed significant effects of the drug treatment on Day 12 body and brain weights and on adult tail flick, rotor rod and Morris water maze performance. No drug effects were observed on adult body or organ weights.

NEURONAL LOCALIZATION OF QUINOLINIC ACID IN THE RAT BRAIN. J.R. Moffett\*, P. Kok, V. Padis G. Suvannavejh, S. Gaudet, and M.A.A. Namboodiri. Dept. of Biology, Georgetown Univ. Washington D.C. 20057.

Quinolinic acid (QUIN) has attracted increased attention in recent years

as an excitotoxin possibly involved in neurodegenerative disorders such as Huntington's disease. Recent findings also indicate that many chronic infections, including AIDS, are associated with increased concentrations of QUIN in selected areas of the brain. To understand the mechanism of action and role of QUIN in the nervous system, a knowledge of its cellular localization is essential. In the present study, we have accomplished this by an immunohistochemical approach using highly specific antibodies against QUIN. Polyclonal antibodies against QUIN were raised by immunizing a rabbit with QUIN conjugated to protein or adsorbed to colloidal gold. Immunohistochemistry of carbodiimide fixed tissue from rat brain demonstrated that neurons are the most immunoreactive elements for QUIN. Among the most immunoreactive neurons were pyramidal cells of neocortex, pyriform cortex and hippocampus. This direct immunohistochemical approach provides a new tool for studying QUIN-mediated neurotoxicity. Further, the present results strengthen the candidacy of QUIN as an endogenous agonist of the NMDA receptor system. (Supported by NIH grant DK37024 and program project NS 28130).

CHRONIC INTRASTRIATAL DIALYTIC ADMINISTRATION QUINOLINIC ACID REVEALS SELECTIVE SPARING NADPH-DIAPHORASE NEURONS.

J. B. Becker 1 R.L. Albin 2 Depts of 1 Psychology <sup>2</sup>Neurology, University of Michigan, Ann Arbor, MI 48104.

2-Neurology, University of Michigan, Ann Arbor, MI 48104.
Huntington's disease (HD) is marked by striatal atrophy resulting from loss of medium spiny neurons. Striatal neurons that contain NADPH-diaphorase are selectively spared in HD. One theory of HD suggests that selective neuronal loss results from excitotoxic effects of the excititory amino acid quinolinic acid (QUIN) in the striatum. Using a microdialysis probe mated to an Alzet 2002 mini-osmotic pump (Bazzett et al, 1991, J. Neurosci. Meth. 40:1), we administered 220 µl of phosphate buffered saline containing 0.880 nmoles, 3.3 µmoles O2 µl of phosphate buffered saline containing of week period. Animals that received 3.3 µmoles QUIN had significant striatal atrophy that could be attributed to two distinct areas of neuronal loss. First, an area of recrossis grunned by alack of an area of necrosis surrounded the probe area, and was marked by a lack of neurons and dense gliosis. The region surrounding the necrotic area was a marked by a significant reduction in nissi stained cells, with no change in the density of NADPH-diaphorase staining neurons compared to the intact striatum. In addition, there was a reduction in cytochrome oxidase staining that closely matched these two areas of cell loss. The striata of animals that received 880 nmoles QUIN appeared identical to those that received vehicle. The striata of animals that received 8.8 μmoles QUIN showed venicle. The stratad of animals that received to a finite score some surrounding structures of the striatum and some surrounding structures. Dialytic delivery of QUIN produces an area of selective neuronal destruction of that resembles selective neuronal loss seen in HD. This selective neurodegeneration produced by chronic exposure to QUIN more closely models the course of HD.

THE NEUROTOXIN QUINOLINIC ACID: DIFFERENTIAL MODULATION OF BRAIN AND BLOOD LEVELS. J.B. Erickson\*, E.M. Flanagan, S.Y. Chang, M. Salter, and J.F. Reinhard, Jr. The Wellcome Research Laboratories Research Triangle Park, NC 27709 USA, and Beckenham, Kent BR3 3BS U.K. Quinolinic acid (QA) is an endogenous NMDA receptor agonist and a

neurotoxin. It is synthesized as a product of tryptophan (Trp) metabolism, and in the liver it is a precursor for the synthesis of NAD. Much is known about the hepatic synthesis of QA, but very little is understood about the formation of this substance in the brain. We examined the differential accumulation of QA in serum and brain of both rats and mice following peripheral administration of several biosynthetic precursors to QA. Quinolinate was quantitated using GC/MS with biosynthetic precursors to QA. Quinolinate was quantitated using GC/MS with [13C-U]QA as an internal standard. In rats, the i.p. administration of Trp (0.5 to 2 mmol/kg) elevated brain QA 5 to 50 fold over that of the control levels 2 to 4 hours post injection. Serum QA was similarly increased but reached maximal levels at earlier time points than did brain QA. In contrast, anthranilate (AA) did not elevate either brain or plasma QA. In mice, Trp, kynurenine, 3-hydroxykynurenine, 3-hydroxyanthranilate, and AA (each at 0.3 mmol/kg) resulted in QA brain levels of 142, 651, 14700, 589, and 78 % of control respectively. Trp, kynurenine, and 3-hydroxyanthranilate also elevated serum QA, but in control the brain 3 hydroxylanterine did not simificantly allowed serum QA. Trp, kynurenine, and 3-hydroxyanthranilate also elevated serum QA, but in contrast to the brain, 3-hydroxykynurenine did not significantly elevate serum QA. Anthranilate raised serum QA approximately 2-fold but did not elevate brain QA. Rat liver homogenates but not rat brain homogenates formed <sup>3</sup>H<sub>2</sub>O when incubated with (3,5-<sup>3</sup>H]AA, suggesting that AA is hydroxylated in the periphery but not in the brain. The results suggest that brain and peripheral blood QA are differently controlled, as implied from the observed species differences, and in the brain, anthranilate is not an efficient intermediate for QA formation.

THE NEUROTOXIN QUINOLINIC ACID IS SELECTIVELY ELEVATED IN SPINAL CORDS OF RATS WITH EXPERIMENTAL ALLERGIC ENCEPHALOMYELITIS (EAE).

JF. Reinhard, Jr.\*, E.M. Flanagan, J.B. Erickson, O.H. Viveros, S.Y. Chang. The Wellcome Research Laboratories, 3030 Cornwallis Rd., Research Triangle Park, NC 27709, USA EAE is an animal model of multiple sclerosis (MS) in which demyelination and paralysis are evident. Quinolinic acid (QA), an NMDA receptor agonist, is an endogenous neurotoxin formed from tryptophan. The role of endogenous neurotoxins in EAE, or MS, is unknown.

Lewis rats were immunized with guinea pig myelin basic protein, in Freund's adjuvant, intradermally. The rats were killed 12-15 days later, when hindlimb paralysis was evident, and their tissues assayed

for QA by GC/MS, using [<sup>13</sup>C-U]quinolinate as the internal standard. In five separate experiments, basal levels of QA in spinal cord (8.03 ± 0.93 fmol/mg tissue) were markedly elevated (to 94.70 ± 11.08 fmol/mg tissue). Brain tissue (cortex and corpus callosum), plasma, and liver contents of QA were not altered in EAE. Thus, the alterations in QA appear to be specific for the affected tissue. It is not currently known whether QA contributes to the demyelination found in EAE. However, it is entirely possible that the increase in QA in the spinal cord may contribute to the disability by altering NMDA receptor function. If QA is pathogenic in EAE, this finding could have therapeutic implications for MS.

# EXCITATORY AMINO ACIDS: ANATOMY AND PHYSIOLOGY I

Nitric Oxide (NO) Donor Actions on NO-Synthase Containing Neurons of the Mesopontine Tegmentum in vitro. R. Sanchez\* and C.S. Leonard, Center for Neural Science, NYU 6 Wash. Pl., NY, NY 10003.

The effects of the nitric oxide (NO) generating compounds, sodium nitroprusside (SNP) and isosorbide dinitrate (ISDN), on responses to nitroprusside (SNP) and isosorbide dinitrate (ISDN), on responses to NMDA were studied in the nitric oxide synthase (NOS) -containing neurons of the pedunculopontine (PPT) and lateral dorsal tegmental (LDT) nuclei using intracellular recording methods in a guinea pig brain slice preparation. NOS-containing neurons were identified by combined intracellular injection of biocytin and NADPH-diaphorase staining, which identifies brain NOS (Dawson et al, '91, PNAS:88). Focal application of NMDA produced an increase in firing rate and membrane depolarization which was strongly inhibited by SNP (300μM), while ISDN (up to 600 μM) had no systematic effect. Control experiments showed the SNP action to be specific for NMDA receptor-mediated showed the SNP action to be specific for NMDA receptor-mediated responses since SNP had no effect on the responses to focal glutamate application, nor on the synaptic potentials evoked by local electrical stimulation in control Ringer containing 3 mM Mg++. Also, SNP had no effect on the Ca++-spike evoked by brief current injection in the presence of TTX, TEA, and 4-AP, thus excluding a nonspecific block of Ca++-channels as a possible mechanism of action. Since ISDN did not have a similar effect, it appeared that the response blockade by SNP was not mediated by NO. Further experiments showed that the SNP effect was mimicked by potassium ferrocyanide, thus suggesting it was largely an action of the liberated ferrocyanide. Thus, the multiple actions of SNP must be considered in interpretations of studies which use this agent strictly as an NO-donor. Supported by NS27881.

CGMP AND NITRIC OXIDE SYNTHESIS IN THE STRIATUM OF THE RAT: AN IMMUNOCYTOCHEMICAL APPROACH. J. DE VENTE, A.N.M. SCHOFFELMEER' and H.W.M. STEINBUSCH. Dept. of Pharmacology, Faculty of Medicine, Free University, 1081 BT Amsterdam, The

We studied the relationship between the cellular components in the striatum synthesizing nitric oxide (NO) and the cellular structures responsive to NO by synthesizing cyclic GMP.

Striatal tissue slices (300 µm) were prepared and incubated in vitro. Drugs were added to the slices and incubations were terminated by adding the formaldehyde fixative. Slices were processed for immunocytochemistry as described (De Vente et al, Eur. J. Neurosci 2:845 (1990). NOS was demonstrated using an antibody against rat brain NOS (courtesy Dr. S. Moncada, Wellcome Research Institute). cGMP was visualized using an antibody directed against formaldehyde fixed cGMP.

NOS in the striatum was found in relatively few cell somata with abundant es containing numerous varicosities. cGMP ICC after stimulation of the soluble guanylate cyclase with nitroprusside (0.1 mM, 10 min) showed cGMP in a dense fiber network with numerous varicosities. Very few cell bodies were found that showed some cGMP-immunoreactivity. After stimulation with NMDA (0.1 mM, 2 min) cGMP was found accumulated in a dense varicose fiber network; this was sensitive to inhibition by 0.1 mM  $N^{\rm G}$ -nitro-arginine methyl ester and by 50  $\mu$ M AP-5. No cell somata were positive for cGMP after stimulation with NMDA. It is concluded that in the striatum there is a close correlation between the localization of NOS and the soluble guanylate cyclase, and between the activation of NMDA receptors, the activation of NOS and the production of cGMP.

NITRIC OXIDE IN RETINA: RELATION TO EXCITATORY AMINO ACIDS & EXCITOTOXICITY. W.J.Nicklas\* & G.D.Zeevalk. Neurology Dept. UMDN.I-RWJ Med.Sch., Piscataway, N.J.08854.

UMDNJ-RWJ Med.Sch., Piscataway, N.J.08854.
The excitatory amino acids (EAAs), glutamate (glu), NMDA and kainate(KA) increase cGMP in chick retina. Guanylate cyclase can be stimulated by several mechanisms, one of which is through activation of NO synthase and formation of nitric oxide(NO). This study was done to determine if NO pathways exist in retina and are linked to EAAinduced increases in cGMP. Exposure of embryonic day 15 retina from chick for 10min to either 1mM glu,  $100\mu$ M NMDA or  $100\mu$ M KA increased cGMP content 2-3fold. The environmental neurotoxins domoic acid (DO,  $20\mu$ M), 8-oxalyl-amino-L-alanine (BOAA,  $200\mu$ M), but not B-methyl-amino-L-alanine (BMAA,3mM), also increased cGMP. The NO synthase inhibitor L-nitro-N-arginine(L-NNA,100µM) completely blocked the increases in cGMP induced by the above glu-agonists. Glu agonist induced increases in cGMP were receptor mediated. MK-801 a NMDA receptor antagonist blocked NMDA and glu-stimulated cGMP formation, whereas, CNQX, a KA/AMPA receptor antagonist blocked cGMP increases produced by KA, BOAA and DO. To examine the involvement of NO pathways in NMDA-mediated toxicity, the ability of L-NNA to protect against both acute and delayed excitotoxic damage, from a 60min exposure to NMDA, was assessed. Acute excitotoxicity, monitored by swelling-induced GABA release at 60min and delayed cell death, determined by LDH release following a 24hr recovery period, vere unchanged by the presence of L-NNA. These studies show that NO pathways exist in retina and link EAA receptor activation to cGMP formation, however, this pathway may not play a role in NMDAmediated excitotoxicity.

LOCAL ADMINISTRATION OF QUINOLINIC ACID IN THE RAT HIPPOCAMPUS INDUCES EXPRESSION OF c-FOS AND NGFI-A H.W.G.M. H. Boddeke<sup>1</sup>, L. Massieu<sup>2</sup>, P.H. Kelly<sup>1\*</sup> and J.M. Palacios<sup>3</sup>. 1 Preclinical Research Sandoz Pharma LTD., Basle, Switzerland, 2 Instituto de Fisiologia Celular, UNAM, 04510- Mexico D.F., México, 3 Laboratorios Almiralli, Barcelona, Spain.

We have studied the effect of intrahippocampal administration of quinolinic acid on the temporal expression of mRNAs encoding the immediate early genes c-fos and NGFI-A, by in situ hybridization histochemistry.

After administration of quinolinic acid (120 nmol) to the left hippocampus, expression of mRNA of both IEGs was transiently stimulated. Maximal expression was found between 1 and 3 hours. mRNA of both early genes was simultaneously expressed in the ipsilateral and contralateral sides in the granule cell layer of the dentate gyrus, the pyramidal cell layer of the CA1 and CA3 fields as well as in the cortex. After pretreatment with the non-competitive NMDA antagonist MK-801 (2 mg/kg i.p. -30 min) the increased expression of both IEGs was partially prevented in the hippocampus and completely in the cortex. No inhibition was observed after treatment with the AMPA antagonist NBQX (30 mg/kg i.p. -15, -5 and +10 min). The present results show that the effect of quinolinic acid is mediated by NMDA and not by AMPA receptors.

## 191.7

NMDA RECEPTOR MEDIATED PLASTICITY IN THE DORSAL HORN AFTER PERIPHERAL NERVE INJURY. Stephen B. McMahon\* & 'Gary R. Lewin Dept. Physiology, UMDS (St. Thomas'), London SE1 7EH. 'Neurobiology & Behavior, SUNY, Stony-Brook, New York, NY 11794.

In adult rats one sciatic nerve was sectioned and the cut ends entubated leaving a 1 mm gap to maximally disrupt the spatial organization of regenerating afferents. The receptive field (RF) properties of dorsal horn cells in medial L5 were studied up to 10 weeks later, under urethane anaesthesia. When cutaneous reinnervation was incomplete (4-5 weeks), RFs were diffuse and relatively large (mean size 210  $\pm$  23 mm²) significantly larger than on the contralateral control intact side (118  $\pm$  17 mm², p-0.005). After 10 weeks (complete reinnervation) RFs had reduced in size to 139  $\pm$  17 mm² (p<0.001 cf 4/5 week data, and p>0.8 cf intact data), and usually consisted of one contiguous area. Thus, with time, dorsal horn cells only a subset of afferents, those with adjacent peripheral RFs.

We also studied RF properties in animals that had additionally received the NMDA receptor antagonist MK801 continuously for a four week period before the terminal experiment (0.015 mg/kg/hr, via an implanted cemotic pump). In intact animals, MK801 treatment resulted in a small, but nonsignificant, increase in RF size (162  $\pm$  17 mm³). In contrast, 8-9 week lesioned animals treated with MK801 had extremely large RFs (456  $\pm$  41 mm³, p<0.001 cf lesioned, untreated animals).

We suggest that when the peripheral topography of primary sensory neurons is disrupted (following regeneration), coincident activity in afferents that newly innervate adjacent peripheral territory strengthens the central connectivity of these afferents (acting via NMDA receptors) at the expense of other inputs, and so results in the emergence of restricted contiguous RFs. Supported by a NATO twinning grant.

REGULATION OF TETRAHYDROBIOPTERIN BIOSYNTHESIS IN CULTURED NEURONS BY CAMP-DEPENDENT GENE EXPRESSION.
K. Hirayama, and M. Zhu and G. Kapatos. Cellular and Clinical Neurobiology Program, Dept. of Psychiatry, Wayne State University School of Med., Detroit, MI. 48201

Tetrahydrobiopterin (BH4) is the essential cofactor for the biosynthesis of monoamines and nitric oxide. To investigate the possible regulation of BH4 biosynthesis by cAMP-dependent mechanisms we have used monolayer cultures of hypothalamic (HYP) and mesencephalic (MES) neurons derived from day 15 rat embryos and maintained in the absence of glia. Fourteen-day MES and HYP cultures were treated with different concentrations of 8-bromo-cAMP (8BrcAMP, 0-5 mM) for 24 hours. BH4 levels were increased in a concentration-dependent manner in both cultures although the increase was greater in HYP than MES. Incubation with forskolin or IBMX produced a similar increase in BH4. The time course of the 8BrcAMP effect was maximum at 24 hours. Analysis of BH4 turnover indicated that 8BrcAMP increased BH4 levels by stimulating BH4 synthesis without altering degradation. The increase in BH4 levels was completely prevented by inhibitors of gene transcription and translation. GTP cyclohydroxylase 1 (GTPCH1) is the first and rate-limiting enzyme in the BH4 biosynthetic pathway. GTPCH1 mRNA was increased by 8BrcAMP in both culture systems. These data demonstrate that cAMP increases BH4 levels by increasing BH4 biosynthesis. This increase in BH4 biosynthesis appears to be due to an increase in GTPCH1 gene expression. (Supported by NIH NS26081)

#### 191.6

THE NMDA RECEPTOR ANTAGONISTS CPP AND MK-801 EXERT DOSE AND GENOTYPE-DEPENDENT DIFFERENTIAL EFFECTS ON LONG-TERM HABITUATION TO NOVELTY IN TWO RAT STRAINS. M.P. Pellicano, F. Siciliano and A.G. Sadile (SPON: European Brain and Behaviour Society). Dip. Fisiologia Umana & Funzioni Biologiche Integrate "F. Bottazzi", Univ. Naples "Federico II", I-80138 Naples, Italy.

A series of experiments was designed to investigate the role N-methyl-D-aspartate (NMDA) receptors play in behavioral plasticity. Adult male rats of the Naples High-Excitability (NHE) and Naples Low-Excitability (NLE) lines, selectively bred for arousal to spatial novelty, were given i.p. the NMDA receptor antagonist CPP (0.01 - 5mg/Kg) or MK-801 (0.01 - 2.5 mg/Kg), or vehicle soon after a 10min-test in a Làt-maze. Retention was run one week later. Habituation of activity and defecation score was monitored by the between-test decrement (LTH) in the frequency of corner-crossings and rearings (with prevailing cognitive and non-cognitive meaning, respectively) and of fecal boli. The results indicate that (i) in the NLE-rats, both isosteric and allosteric blockers facilitate LTH of cognitive components at low doses of the isosteric blocker, and, conversely, that (ii) in the NHE-rats, isosteric blockade at low doses facilitates LTH of cognitive components in the entire exposure, whereas allosteric blockade by high doses of MK-801 impair LTH of cognitive components, and facilitate LTH of emotional components. The dose and genotype-dependent differential effects of NMDA receptor antagonists lend support to their hypothesized modulatory role in behavioral plasticity. Moreover, the dissociation between LTH of cognitive and non cognitive components suggests a role of NMDA receptors in their parallel processing, as suggested earlier (Behav.Brain Res., 39:187, 1990).

# 191.8

LATERAL VENTRICULAR (LV) N-METHYL-DL-ASPARTATE (NMA) ADMINISTRATION ELICITS ACTH SECRETION IN FETAL SHEEP AT 125-130 DAYS GESTATION (dGA). P.W. Nathanielsz\* & T.J. McDonald Laboratory for Pregnancy and Newborn Research, Dept. Physiology, College of Veterinary Medicine, Cornell University, Ithaca, New York 14853.

The fetal paraventricular nucleus (PVN) plays a central role in control of increased ACTH secretion in fetal sheep in response to hypoxemia and hypotension as well as preceding parturition (McDonald & Nathanielsz, Am.J.Ob.Gyn.165:764). The transmitter(s) that activates PVN control of ACTH secretion via CRH and AVP is not known. Aspartate is an excitatory central nervous system responses interval.

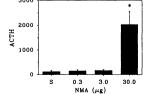

Hypothesis: NMA, the mixed aspartate analog given to the fetus via the LV would stimulate ACTH release.

Methods: A LV catheter (LVC) was placed in 4 fetal sheep at 119-121 dGA. At 125-130 dGA either saline (8) or NMA (0.3 - 30  $\mu$ g in S) was administered as a single injection via the LVC, one dose per day only. Fig 1. shows cumulative fetal ACTH responses over 30 min.

Results: 30  $\mu$ g NMA via the fetal LVC stimulated ACTH secretion p<0.05vs S.

Conclusions: NMA stimulates ACTH release from the fetal pituitary at site(s) of action to be determined.

Fig. 1 Percent change of ACTH from baseline in 4 fetal sheep at 125-130 dGA given NMA via a LVC as a single injection. \*p<0.05vs S.

N-METHYL-D,L-ASPARTATE (NMA) MODULATES LUTEINIZING HORMONE (LH) BUT NOT GROWTH HORMONE (GH) SECRETION FROM PIG PITUITARY CELLS. C.R. Barb\*, J.B. Barrett, G.B. Rampacek and R.R. Kraeling. 1USDA-ARS, and University of Georgia, Athens, GA 30613.

Administration of NMA to pigs increases GH and suppresses LH secretion. Cultures of anterior pituitary colls from luteal (LHT. as).

suppresses LH secretion. Cultures of anterior pituitary cells from luteal (LUT; n=5), follicular phase (FOL; n=3) and OVX (n=6) pigs were treated with NMA ( $10^{-4}$ ,  $10^{-6}$  or  $10^{-8}$  M) or 2-amino-5-phosphonopentanoic acid (AP5;  $10^{-4}$ ,  $10^{-6}$  or  $10^{-8}$  M) to determine if NMA affects the pituitary directly. Secreted LH and GH were measured at 4 h after treatment. Basal LH and GH secretion (control): (1) were 11 + 0.6 AAA + 2 1 and 1.6 + 1.2at 4 h after treatment. Basal LH and GH secretion (control; C) were 1.1  $\pm$  0.6, 4.4  $\pm$  2.1 and 5.6  $\pm$  1.3 ng/well and 5.2  $\pm$  1.2, 7.5  $\pm$  1.2 and 5.2  $\pm$  1.7 ng/well for FOL, LUT and OVX, respectively. Relative to C,  $10^{-4}$  M NMA increased (P<.05) LH secretion 3.2- and 3.9-fold in FOL and OVX cultures, respectively. The NMA-antagonist AP5  $10^{-4}$  M, inhibited (P<.06) the effect of  $10^{-4}$  M NMA in FOL cultures, but not in OVX cultures. GnRH increased (P<.05) LH levels 2.2-, 1.7- and 2.6- fold in FOL, LUT and OVX cultures, respectively. Neither NMA nor AP5 altered basal GH secretion. However, GHRH increased GH secretion 1.8-fold in all cultures. Therefore, excitatory amino acids stimulate LH secretion, but not GH directly at the acids stimulate LH secretion, but not GH directly at the pituitary.

## 191.11

RELEASE OF AMINO ACIDS IN THE DORSAL HORN OF RAT SPINAL CORD INDUCED BY ELECTRICAL STIMULATION OF SCIATIC NERVE V. Paleckova', J. Palecek, D. J. McAdoo, and W. D. Willis Marine Biomedical Institute, UTMB, Galveston TX-77555 - 0843

Extracellular concentrations of nine amino acids (AA's - aspartate, glutamate,

asparagine, serine, glycine, threonine, alanine, taurine and glutamine) in the dorsal horn of 17 Sprague Dawley rats were determined using in vivo microdialysis in acute experiments under urethane anesthesia. Basal levels of AA's were determined from samples of the perfusing solution - artificial cerebrospinal fluid (ACSF) collected 2 hours after the fiber insertion. Then samples during and after the stimulation of both sciatic nerves at C-fiber strength (20-30 V, 1 Hz, 0.5 ms) were obtained. CNOX (non-NMDA antagonist; 2 mM) and tetrodotoxin (TTX; 10µM) were added to the perfusion ACSF (approximate gradient across the membrane was 10:1) in 6 and 5 experiments respectively. The level of AA's in ACSF samples was determined using high pressure liquid chromatography (HPLC). Differences in the AA levels were statistically evaluated using Kruskal-Wallis analysis and the Wilcoxon paired test.

The basal extracellular concentrations of AA's corrected for fiber efficiency (µM ± S.E., n=17): Asp 2.9±0.4; Glu 3.8±1.1; Asn 1.66±0.4; Ser 3.2±0.6; Gly 6.5±1.3; Thr 9.1±1.8; Ala 5.0±1.1; Tau 9.6±3.2; Gln 132.5±55.2. During the control stimulation while perfusing with normal ACSF the concentration of all the AA's but glutamine significantly increased from the prestimulation level. All the AA's but taurine returned to the baseline level after the stimulation. We did not find a significant increase in the concentration of AA's during the nerve stimulation when CNQX or TTX were present in the ACSF.

Our data support a role for AA's in neurotransmision in the spinal cord dorsal horn. This work was supported by NS 11255, NS 09743 and a grant from Bristol-Myers Squibb Corp.

TIME COURSE OF SEIZURE-INDUCED INHIBITION OF ENZYMATIC HYDROLYSIS OF NAAG. J.L. Meyerhoff<sup>1\*</sup>, D.L. Yourick<sup>1</sup>, R.E. Carter<sup>2</sup>, and J.T. Coyle<sup>3</sup>. <sup>1</sup>Dept. Medical Neurosciences, Walter Reed Army Inst. Res., Washington, DC 20307; <sup>2</sup>Dept. Pharmacology and Molecular Sci., Johns Hopkins Univ. School of Medicine, Baltimore, MD, 21205; 3Dept. Psychiat., Harvard Medical School, Belmont, MA 02178.

N-acetylated- $\alpha$ -linked acidic dipeptidase (NAALADase), is a membrane-bound peptidase which hydrolyzes the endogenous neuropeptide N-acetyl-aspartyl-glutamate (NAAG) to N-acetyl-aspartate (NAA) and the excitatory amino acid, glutamate. We have previously reported that, 48 hours after the last of a series of 5 daily electrically stimulated convulsions, NAALADase activity is significantly suppressed in the entorhinal cortex (Meyerhoff et al., Brain Res. 505:130-134, 1989). In an effort to determine the time course of this suppression, we measured brain regional NAALADase activity at 1, 6, 24, 48 and 96 hours after a series of 5 electrically stimulated convulsions. Suppression was seen in entorhinal cortex at all time points Although there is evidence that NAAG might neurotransmitter, this dipeptide could also function as a precursor form of glutamate, which is liberated by the dipeptidase. The suppression of NAALADase activity might decrease availability of glutamate in certain CNS synapses in these rats, and might represent a homeostatic mechanism to reduce excitability. This finding might be relevant to understanding the mechanisms of the therapeutic and/or amnestic effects of electrically stimulated seizures

THE LIH RESPONSE TO NMDA DECLINES DURING NMDA-INDUCED PRECOCIOUS PUBERTY. C. Smyth\*, M. Wilkinson, Depts. of Obst. and Gynecol., Physiol. and Biophys., Dalhousie University, Hallfax, N.S. B3H

Daily injections of the glutamate agonist NMDA reliably induce precoclous puberty in female rats (Neurosci. Abstr.106.7 (1991). A restricted injection schedule of NMDA (20 mg/kg/day; age 24 -28 days) similarly advances the day of first ovulation (V.O.). (CON:  $34.2 \pm 0.6$  (n=10); NMDA (24 to VO):  $29.8 \pm 0.4$  (n=10); NMDA (24 to 28):  $29.4 \pm 0.5$ 

(n=10); NMDA (24 to VO): 29.8 ± 0.4 (n=10); NMDA (24 to 28): 29.4 ± 0.5 (n=10)). The pituitary-ovarian (P-O) axis is also stimulated by dally NMDA injections as shown by an estrogen-dependent rise in uterine weights between day 24 and 30. Stimulation of the P-O axis by dally injections of GnRH (5 ng/100 g), which gives an LH response equivalent to NMDA (20 mg/kg), does not advance puberty. Therefore, the stimulation of the P-O axis by NMDA is secondary to its effects on the maturation of the hypothalamus.

We have shown that there is a decline in the LH response to NMDA as female rats approach puberty (J. Neuroendocr. (1992). Using the restricted NMDA model of precoclous sexual maturation we now show that the normal decline in the LH response to NMDA occurs sooner in the treated than in the control group (p-d.001). An LH dose-response curve for NMDA at age 28 days demonstrates that the NMDA-treated group is less responsive to NMDA than the control group (p-d.001). The source of NMDA desensitization is not located in the pituitary as an LH dose response curve for GnRH at age 28 days is identical in the NMDAdose response curve for GnRH at age 28 days is identical in the NMDA-treated and control groups. In conclusion, since NMDA induces precoclous puberty it is possible that the decline in hypothalamic response to NMDA is a necessary event in sexual maturation. SEXUAL DIFFERENCES IN N-METHYL-D-ASPARTATE RECEPTOR-MEDIATED REGULATION OF TUBEROINFUNDIBULAR DOPAMINERGIC NEURONS IN THE RAT. E.J. Wagner, K.E. Moore and K.J. Lookingland. Dept. of Pharm. & Tox., Michigan State Univ., E. Lansing, MI

Dopamine released from tuberoinfundibular nerve terminals in the median eminence inhibits the secretion of prolactin from the anterior pituitary. The purpose of the present study was to examine the effects of N-methyl-D-aspartate purpose of the present study was to examine the effects of N-methyl-D-asparatae (NMDA) receptor blockade on prolactin secretion and on the activity of tuberoinfundibular dopaminergic (TIDA) neurons [estimated by either the accumulation of 3,4-dihydroxyphenylalanine (DOPA) 30 min after the administration of the decarboxylase inhibitor NSD-1015 or the concentration of the dopamine metabolite 3,4-dihydroxyphenylacetic acid (DOPAC) in the median eminence] in male and female rats. The NMDA receptor antagonist MK-801 (1.0 mg/kg; s.c.) markedly reduced plasma levels of prolactin in both male and female rats. MK-801 also produced a dose-dependent decrease in DOPA accumulation, and a time-dependent decrease in DOPAC concentrations in the median eminence of female rats. In contrast, MK-801 had no effect on DOPA accumulation or DOPAC concentrations in the median eminence of male rats. Removal of the tonic stimulatory effects of prolactin on TIDA neurons in female rats by immunoneutralization of endogenous prolactin did not prevent MK-801 from decreasing DOPA accumulation. In the median eminence of ovariectomized female rats, however, MK-801 was unable to decrease DOPA accumulation. These results suggest that NMDA receptor activation tonically stimulates TIDA neurons in female but not in male rats by a prolactin-independent mechanism, and that ovarian hormones modulate this NMDA receptor-mediated regulation of TIDA neuronal activity. (Supported by ADAMHA Grant MH 42802.)

MK-801-INDUCED HYPERMOTILITY IS DEPENDENT ON DOPAMINERGIC NEUROTRANSMISSION IN THE NUCLEUS ACCUMBENS (NA). L.J. Wallace\*, D.L. Willins, and N.J. Uretsky. College of Pharmacy, The Ohio State University, Columbus, Ohio 43210.

Systemic administration of the non-competitive NMDA receptor antagonist, MK-801, in rats stimulates locomotion. The present experiments investigate the role of central dopamine (DA) transmission in this response. Depletion of catecholamine stores with reserpine (5 mg/kg, 18 hrs) or  $\alpha$ -methyl-p-tyrosine (250 mg/kg, 4 and 1 hour) markedly inhibited the locomotor response to MK-801 (0.1 mg/kg, sc). While the D-1 DA receptor antagonist, SCH23390 (0.03 mg/kg, sc) did not reverse the locomotor response to MK-801, the D-2 receptor antagonist, eticlopride (0.03 mg/kg, sc) decreased this response. In combination these antagonists reduced the locomotor response to a greater extent than did eticlopride alone. The hypermotilty response to MK-801 was also inhibited by the administration of either SCH23390 or eticlopride into the nucleus accumbens (NA). The administration of MK-801 (10  $\mu$ g) into either the ventral tegmental area (VTA) or the NA stimulated a marked locomotor response, which was attenuated by the systemic administration of DA receptor antagonists. These results demonstrate the importance of central DA transmission in the hypermotility response to MK-801 and suggest a role for endogenous DA in the NA in this response. These results further suggest that MK-801 may act either at the level of the VTA or NA to stimulate locomotion.

Dros-METHYLIMIDAZOLEACETIC ACID EFFECTS ON GLUTAMATE AND ASPARTATE EXTRACELLULAR LEVELS IN BRAIN REGIONS OF FREELY MOVING RATS. P. Blandina\*1,2, G. Cherici<sup>1</sup>, F. Moroni<sup>1</sup> and J. P. Green<sup>2</sup>. <sup>1</sup>Dip. di Farmacologia Preclinica e Clinica, Universitá di Firenze (I) and <sup>2</sup>Dept. of Pharmacology, Mount Sinai School of Medicine, C.U.N.Y., New York, NY 10029.

The severity of Parkinson's disease was correlated with the cerebrospinal fluid levels of pros-methylimidazoleacetic acid (p-MIAA), an endogenous substance in brain and other tissues (Prell et al., J. Neural Transm. 3:109-125, 1991). However, no causal relationship has been established. The possible contribution of the excitatory amino acids to the neural toxicity in Parkinson's disease prompted us to investigate p-MIAA effects on glutamate (GLU) and aspartate (ASP) release, using a microdialysis technique. Perfusion flow rate was 2 µl/min. Twenty four hours after implantation with dialysis fiber, striatum, hippocampus or cortex of male Wistar rats (200g) released spontaneously in the micromolar range GLU and ASP, measured with HPLC coupled with fluorescent detection. p-MIAA (1-0.01 mM), given through the dialisys fiber, increased concentration-dependently GLU baseline up to three-fold in striatum, but not in hippocampus and cortex. In none of these regions p-MIAA increased ASP baseline, p-MIAA effect was not mimicked by its isomer tele-methylimidazoleacetic acid (1 mM). p-MIAA (1 mM) did not influence the uptake of GLU by striatal slices. The presence of stereo-, region-specific and direct releasing mechanism(s) is suggested.

PHTHALLIC ACID LESIONS OF RAT BASAL FOREBRAIN-DIFFERENTIAL EFFECTS ON CHOLINE ACETYLTRANSFERASE IN CORTEX AND AMYGDALA. R.J. Boegman\*, J. Cockhill, K. Jhamandas, R.J. Beninger, Pharmacology & Toxicology and Psychology, Queen's University, Kingston, Ontario, Canada K7L 3N6.

Phthallic acid excites cells in rat cerebral cortex and provokes acetylcholine release from striatal slices in vitro (Stone, Br. J. Pharmacol. 81 175, 1984; Lehmann et al. J. Pharmacol. Exper. Therap. 232 873 1985). We have previously observed that cholinergic neurons in the nucleus basalis (nb) projecting to the cortex or amygdala show characteristic excitotoxic responses depending on the neurotoxin infused. We demonstrate here the effects of phthallic acid on cholinergic neurons of the nb. Phthallic acid (50-750 nmoles/0.5 µl) was unilaterally infused into the nb of male Sprague Dawley rats (275-300 g). After seven days the cortex and amygdala were assayed for choline acetyltransferase (ChAT) activity. A 60% reduction in ChAT activity of the amygdala was obtained at doses between 100 and 300 nmoles. In contrast the ChAT activity of the cortex remained unaltered until a dose of 750 nmoles was infused; at this dose a 55% reduction was obtained. Phthallic acid-induced neurotoxicity was antagonized by kynurenic acid and APV suggesting an NMDA receptor mediated mechanism. In addition, phthallic acid was not neurotoxic in 12 day old rat pups, indicating that a presynaptic input is required for its neurotoxic effect.

THE COMPETITIVE NMDA ANTAGONIST, LY274614, ALTERS MORPHINE TOLERANCE BUT NOT OPIOID RECEPTORS OR MORPHINE'S DISTRIBUTION. P.J. Tiseo\*, J. Cheng, G.W. Pasternak and C.E. Inturrisi. Depts. of Pharmacology and Neuroscience, Cornell U. Med. College, New York, N.Y. 10021. Co-administration of LY274614 (LY) with morphine

significantly attenuates the development of morphine tolerance in rats. Furthermore, morphine tolerant animals infused with LY (sc at 24 mg/kg/24 hrs) regained their analgesic sensitivity to morphine whether co-administration of morphine was continued or discontinued. The tolerance produced by morphine and prevented by LY results in a 10fold shift of the morphine dose-response curve and appears to be primarily pharmacological and not behavioral Steady-state plasma morphine levels were not significantly different after 7 days of co-administration of LY compared to saline. Infusion of LY for 7 days did not increase the affinity or density of mu, delta, kappa, or kappa, opioid receptors in rat brain homogenates as assessed by ligand binding assays. Furthermore, the  $\rm IC_{50}s$  for LY in  $mu_1$ ,  $mu_2$ , delta, kappa, or kappa, ligand binding assays were greater than 10 uM. These results indicate that LY can prevent or reverse the development of morphine tolerance without reducing the analgesic response, altering morphine's systemic distribution or upregulated opioid receptors. The ability of LY to alter the development and maintenance of tolerance is presumed to be mediated at NMDA receptors. (Supported in part by DA01457 and DA02615.)

DEXTROMETHORPHAN AND DEXTRORPHAN BUT NOT DTG PREVENT

DEXTROME HORPHAN AND DEXTRORPHAN BUT NOT DTG PREVENT MOTION SICKNESS IN CATS. J.B. Lucot\*, Dept. Pharmacol., Wright State Univ., Dayton, OH 45435.

Ten to twelve female cats susceptible to motion sickness were tested biweekly in a motion device modelled after a Ferris wheel. Tests lasted for 30 min followed by one min of observation at rest. The sigma ligand DTG had no significant effect on motion sickness over DTG had no significant effect on motion sickness over the dose range of 0.03 to 3.0 mg/kg given SC. Dextromethorphan significantly decreased motion sickness over the same dose range. Dextrorphan, a metabolite of dextromethorphan, was roughly 10X more potent than dextromethorphan at suppressing motion sickness. High doses of dextromethorphan and dextrorphan but not DTG produced slight ataxia of the hindlimbs without significantly impairing the righting reflex or the vestibulo-ocular reflex. The relative effects of these drugs on different receptors leads to the suggestion that blockade of NMDA/PCP but not sigma receptors can suppress motion sickness. suppress motion sickness.

EFFECTS OF BTS 54 505, A METABOLITE OF SIBUTRAMINE ON XCITATORY AMINO ACID AND MONOAMINE EVOKED RESPONSES IN THE RAT DORSOLATERAL GENICULATE NUCLEUS (dLGN). G. Scott, G.P. Luscombe<sup>1</sup> & R. Mason\*. Dept. of Physiol. & Pharmacol., Queens Medical Centre, Nottingham NG7 2UH, UK. <sup>1</sup>Boots Pharmaceuticals Research Dept., Nottingham NG2 3AA, UK.

Tricyclic antidepressants have been shown to produce an open channel block of NMDA receptors similar to MK-801 and ketamine. Here we report the effects of BTS 54 505, the primary amine metabolite of the non-tricyclic putative antidepressant sibutramine, on NMDA-, 5-HT- and NA-evoked responses in the rat dLGN in vivo. Male Lister hooded rats were anaesthetised with urethane (1.3-1.5g.kg<sup>-1</sup>, i.p.) and seven-barrelled micropipettes were used to record extracellular neuronal activity and for ionophoresis. BTS 54 505 inhibited NMDA-evoked activity in the dLGN [mean  $ED_{50} \pm S.E.M: 17 \pm 7nA$ , n=8] but had no effect on AMPA-evoked activity. BTS 54 505 was ejected at a current (20nA; 120s) that had no effect on basal firing rate and the effect of ionophoresed 5-HT (10mM, 0-30nA) and NA (0-40nA) were compared before and during BTS 54 505 application. The recovery time, i.e. the period required by the neurone to recover by 50% (RT $_{50}$ ) from termination of the ionophoretic ejection, was used as an index of the efficacy of the transmitter uptake process. BTS 54 505 prolonged the suppression of firing by 5-HT [mean RT<sub>50</sub>  $\pm$  S.E.M:(control) 13.0  $\pm$  2.0s;(BTS 54 505) 65.7  $\pm$  24.3s; n=6] and also prolonged the potentiation of firing by NA (mean RT $_{50}$   $\pm$  S.E.M.(control) 29.0  $\pm$  1.7s;(BTS 54 505) 130.8  $\pm$  6.7s; n = 6]. The magnitude of 5-HT- and NA-evoked responses was unaffected by BTS 54 505. These studies show that BTS 54 505 is a potent inhibitor of NA and 5-HT uptake and that elevation of endogenous 5-HT levels by uptake block does not contribute to the inhibition of NMDA-evoked activity by BTS 54 505

DL-(TETRAZOL-5-YL) GLYCINE: POTENCY AND EFFICACY IN MK801 BINDING AND NOREPINEPHRINE RELEASE. W.H.W. Lunn\*, D.D. Schoepp D.O. Calligaro. C.R. Salhoff and P.J. O'Malley. Lilly Research Laboratories, Eli Lilly and Company, Lilly Corporate Center, Indianapolis, Indiana 46285.

N—NH DL-(Tetrazol-5-yl) glycine is the simplest (tetrazol-5-yl) α-mino acid. It has been shown to be a highly active NMDA

amino acid. It has been shown to be a highly active NMDA agonist (Schoepp, et al., Eur. J. Pharmacol. 203:237-243, 1991). With a view to better establishing potency and efficacy we have measured the stimulatory effect of DL-(tetrazol-5-yl) glycine, (TG), on [3H] MK-801 binding, comparing it to responses seen with other NMDA agonists L-glutamic acid (GA), cismethanoglutamate (CMG), and NMDA. The EC<sub>50</sub> values for the four compounds were 0.07, 0.12, 0.18 and 6.86 µM, respectively. TG and GA exhibited approximately equal efficacies, in that they each caused a 60% increase in specifically bound [3H] MK801 at the maximally effective concentration of 10 µM. CMG was somewhat less efficacious, with a 40% rise, whilst NMDA only led to a 25% increase at the 10 µM concentration.

Occupation of the NMDA receptor by agonists leads to the release of norepinephrine (NE) from the neurons involved. TG, CMG, and NMDA were investigated in this capacity, their relative potencies being indicated by

investigated in this capacity, their relative potencies being indicated by respective  $EC_{50}$  values of 2.03, 16.5 and 75  $\mu M$ . TG was the most efficacious of the three, since it resulted in a maximal release of 90% of the efficacious of the three, since it resulted in a maximal release of 90% of the total [<sup>3</sup>41] NE at 3 μM, whereas that evoked by CMG or by NMDA was only 50% under the same conditions. The NE release in response to TG was completely abolished by LY274614 and 5,7-dichlorokynurenate, competitive and noncompetitive NMDA antagonists respectively. NMDA receptor activation would, then, seem to be causative in the NE release. These and previously obtained data define TG as the most potent α-amino acid selective NMDA agonist found to date. This probably accounts for its extreme neurotoxicity (see following abstract).

THE NMDA AGONIST D,L-(TETRAZOL-5-YL)GLYCINE IS AN EXTREMELY POTENT IN VIVO EXCITOTOXIN. D.D. Schoepp W.H.W. Lunn. C.R. Salhoff, and J.W. McDonald. Lilly Research Laboratories, Eli Lilly and Company,

and J.W. McDonald. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, Indiana 48285

D.L. (Tetrazol-5-yl)glycine (TG) is a highly selective NMDA agonist with nanomolar in vitro potency (Schoepp et al., Eur. J. Pharmacol 203: 237-243, 1991). Receptor binding experiments showed that TG has 2- and 42-times greater affinity at NMDA receptors than cis-methanoglutamate (CMG) and NMDA, respectively. Electrophysiological experiments suggested that among these NMDA agonists, TG was more toxic to neurons relative to its NMDA receptor affinity. In this study, the in vivo excitotoxic potency of TG was compared to CMG and NMDA. Adult (250-300g) and neonatal (7 day-old) rats received stereotaxic unitateral intrastriatal injections of compounds. In adult rats TG produced marked loss of striatal GABA neurons (as indexed by glutamic acid decarboxylase activity (GAD)) and ACh neurons (as indexed choline acetyltransferase (ChAT) activity). Dose-response showed that TG was about 100- and 500- times more potent than CMG and NMDA, respectively. In neonatal rats, TG produced significant brain damage as indicated by brain weight losses 5 days later. TG was about 50-and 150-times more potent than CMG and NMDA, respectively, in the neonate.

|                 | Calculated Dose (nmoles) |      |      |
|-----------------|--------------------------|------|------|
|                 | TG                       | CMG  | NMDA |
| Adult Rat       |                          |      |      |
| GAD (50% loss)  | 0.433                    | 61.3 | 197  |
| ChAT (50% loss) | 0.458                    | 17.1 | 205  |
| Neonatal Rat    |                          |      |      |
| 20% Damage      | 0.12                     | 7.0  | 18   |

The in vivo excitotoxic potency of TG relative to other NMDA agonists indicates that this compound has high efficacy and potency at the NMDA receptor. TG may be a very useful agent to probe further the in vivo role of NMDA receptors in brain pathology.

### 192.7

EFFECT OF GLYCINE AND NMDA RECEPTOR LIGANDS ON RAPID TOLERANCE TO ETHANOL. J.M. Khanna\*, H. Kalant, A. Chau and G. Shah. Department of Pharmacology, University of Toronto, and Addiction

Research Foundation, Toronto, Canada MSS 1A8.

We recently reported that NMDA receptor antagonists [(+)MK-801 and ketamine] prevent rapid tolerance to EtOH-induced hypothermia and motor impairment (tilt-plane test) in rats tested repeatedly on the first EtOH exposure ("intoxicated practice"). The role of the NMDA system in rapid tolerance was now defined further. (1) On day 1, rats received either saline (S) or D-cycloserine (CS; 3 mg/kg), an agonist at the glycine receptor, 30 min before EtOH (2.3 g/kg IP) or S. At the end of tilt-plane testing they were given EtOH (0.7 g/kg) or S, together with CS (3 mg/kg) or S. On day 2, only the EtOH + CS group showed rapid tolerance to EtOH alone (2.3 g/kg). (2) (+)MK-801 (0.25 mg/kg) pretreatment totally blocked the facilitation of rapid tolerance by CS. (3) To examine whether the effect of the NMDA system on tolerance was paradigm-specific, two groups of rats were given S or EtOH on day 1 but one group received  $\underline{no}$  testing, while the other was handled at the times corresponding to testing in the original experiments (dummy tests). EtOH dosage was 4 g/kg IP (2 or 2.3 g/kg before testing, and 2 or 1.7 g/kg respectively at the end of testing) on day 1. On day 2, half of each group was tested for hypothermia and half on the tilt-plane. The dummy testing group showed rapid tolerance, but the non-tested group did not. Ketamine pretreatment (1 mg/kg), which was previously found to block rapid tolerance in the "intoxicated practice" paradigm, did <u>not</u> block tolerance in the dummy test group. These results confirm the role of the glycine-NMDA system in rapid tolerance, and suggest that it is specific for some adaptation that occurs during intoxicated practice.

## 192.9

FURTHER STUDIES ON THE INTERACTION OF PENTAMIDINE WITH THE NMDA RECEPTOR. I.J. Reynolds, K.D. Rothermund, D.M. Zeleski, K.A. Hartnett and E. Aizenman, Depts. Pharmacol. and Physiol., Univ. of Pittsburgh, Pittsburgh PA 15261.

We have previously shown that pentamidine is a non-competitive antagonist of the NMDA receptor in vitro (J.Neurosci. 12:970, 1992). The goal of these studies was to investigate the mechanism of action of pentamidine and several of its analogues. Using [3H] dizocilpine binding to rat brain membranes we compared pentamidine to Zn2+. Spermidine had marked allosteric effects on the inhibition of [3H] dizocilpine binding by Zn2+, while having minor effects on pentamidine concentration response curves. We also found that the affinity of Zn2+ could be significantly reduced by the histidine modifying reagent diethylpyrocarbonate. DEPC also prevented Zn2+ from slowing the dissociation of [3H] dizocilpine. As DEPC had no effect on the action of pentamidine we conclude that pentamidine and Zn2+ bind to distinct sites on the NMDA receptor complex.

While pentamidine is neuroprotective at  $5\mu M$  it becomes directly toxic above  $30\mu M$  after prolonged exposure. We examined several analogues of pentamidine (Tidwell et al. J.Med.Chem. 33:1252, 1990) for their protective and toxic properties. Of the six drugs tested two were equally toxic to pentamidine, while one was slightly toxic and three showed no toxicity at  $30\mu M$ . However all compounds inhibited [3H] dizocilpine binding and NMDAinduced [Ca2+]; changes, and two drugs tested were also neuroprotective. This shows that the effects of pentamidine on the NMDA receptor and its toxicity are unrelated, and that it may be possible to find pentamidine-related drugs that have a wider margin of safety.

ELECTROCHEMICAL INTERACTIONS OF NMDA AND NOREPINEPHRINE IN THE CEREBELLUM OF RATS. Y. Wang and J.C. Lin. Department of Pharmacology, National Defense Medical Center, Taipei, Taiwan, R.O.C.

In the present study, we used high-speed (5Hz) chronoamperometric recording techniques using Nafion-coated carbon fiber electrode coupled with pressure ejection of NMDA (n-methyl-d-aspartate) to investigate the effects of NMDA on noradrenergic (NE) nerve terminals. Adult male rats were anesthetized with urethane and placed on a stereotaxic frame. NMDA or NE were applied stereotaxic frame. NMDA or NE were applied directly to the cerebellum through the multibarrel pipette. We found that local application of NMDA (1 mM, <200 nl) produced an increase of NE overflow in the cerebellum. In addition, the clearance/ diffusion of locally-applied NE was also enhanced by NMDA. This effect was antagonized by systemic injustice of decimalized by systemic injustice of decimalized. temic injection of desipramine (25 mg/kg, i.p.). Taken together, these data suggest that NMDA enhances NE turnover in the NEcontaining nerve endings in the cerebellum.

## 192.8

BLOCKADE OF THE DEVELOPMENT OF CHRONIC TOLERANCE TO ETHANOL BY (+)MK-801. J. Francis', P.H. Wu, J.F. Liu, S.J. Mihic, A.D. Lê and H. Kalant, Department of Pharmacology, University of Toronto, Toronto, Ontario Canada M5S 1A8.

Previous studies indicated that learning and memory play important roles in the development of tolerance to ethanol (EtOH). (+)MK-801 has been shown to impair learning and might thus also block the development of tolerance to EtOH. Rats were trained to criterion on the moving belt, a complex motor coordination test. Acute injection of (+)MK-801 (an NMDA channel blocker) in doses of 0.05-0.25 mg/kg i.p. produced dose-related impairment on this test. A dose of 0.1 mg/kg, that had negligible effect by itself, potentiated the acute effects of EtOH, shifting the ED $_{\infty}$  from 1.75 to 1.0 g/kg. In a chronic experiment, half of the rats then received (+)MK-801 (0.1 or 0.25 mg/kg i.p.) or saline daily, followed 30 min later by EtOH (1.8 g/kg, i.p.) and 3 practice runs on the belt, and 1 hr later a second dose of (+)MK-801 (0.1 increasing to 0.2 mg/kg by increments of 0.05 mg/kg every 4th day) or saline. The other half received the same drugs but EtOH followed the practice. (+)MK-801 (0.25 mg/kg plus a second dose of the drug) blocked the functional tolerance to EtOH in both groups, but (+)MK-801 (0.1 mg/kg) did not. Tolerance to MK-801 did not occur over 2 wks of treatment. Results indicate that NMDA receptors are involved in development of chronic tolerance to EtOH, as shown previously with rapid tolerance. The interpretation of these data is not wholly clear, and an important question is unresolved. Both EtOH and (+)MK-801 inhibit the NMDA receptor-ion channel complex and produce motor impairment, but chronic EtOH treatment produces functional tolerance whereas chronic (+)MK-801 treatment prevents the development of tolerance. Supported by NIAAA grant AA08212-03.

## 192.10

THE PRESENCE OF FREE D-SERINE IN RAT BRAIN. A.Hashimoto\*,
T Michibawa T Havashi. N.Fujii, K.Harada, T.Oka and K. Takahashi. Div. of Mental Disorder Res., Natl. Inst. of Neurosci., NCNP, 4-1-1, Ogawa-Higashi, Kodaira, Tokyo 187 Japan and Group of Cell and Information, Precursory Res. for Embryonic Science and Technology, Research Development Corporation of Japan, 2-5-2, Nagata-cho, Chiyoda-ku, Tokyo 100, Japan.
Free amino acid enantiomers in rat brain extracts were

analyzed as their N,O-pentafluoropropionyl isopropyl analyzed as their N,O-pentafluoropropionyl isopropyl derivatives by gas chromatography. A peak X, which exhibited the same retention time as the derivative of authentic D-serine, was detected in the brain extracts. Electron impact and positive chemical ionization mass spectra of the peak X of the brain extracts were identical to those of authentic D-serine. The content of free D-serine and the ratio of D-serine/total serine in the brain were estimated to be 0.27 µmol/g and 0.23, respectively. These data provide the first evidence that substantial quantities of free D-serine are present in mammalian brain tissues and suggest that free D-serine in rat brain may be a novel candidate of an endogenous ligand for the strychnine-insensitive glycine binding site for the N-methyl-D-aspartate receptor.

CYCLOHEXYLADENOSINE ATTENUATES N-METHYL-D-ASPARTATE-INDUCED PURINE RELEASE. V.M. Sciotti\* and D.G.L. Van Wylen. Departments of Pathology and Physiology, SUNY-Buffalo School of Med. and Bio, Sci., Buffalo, NY 14215.

Activation of N-methyl-D-aspartate (NMDA) receptors

Activation of N-methyl-D-aspartate (NMDA) receptors leads to increased neuronal activity. Adenosine depresses the neuronal activity associated with excitatory amino acids. We investigated the effects of NMDA on cerebral interstitial fluid (ISF) adenosine (ADO), inosine (INO), and hypoxanthine (HYP) in the presence and absence of N<sup>g</sup>-cyclohexyladenosine (CMA), an ADO A<sub>1</sub> receptor agonist. Microdialysis probes were implanted bilaterally in the caudate nucleus of halothane-anesthetized rats (n=4) and perfused with artificial cerebrospinal fluid (CSF). Following baseline collections, the probe on one side of the brain was perfused with CSF containing  $10^{-3}$ M NMDA, while the probe on the other side of the brain was perfused with  $10^{-3}$ M NMDA +  $10^{-7}$ M CHA. Dialysate levels are shown below (mean±SEM). \*p<0.05 vs baseline, \*p<0.05 vs opposite side.

|          | $ADO(\mu M)$       | $INO(\mu M)$       | $HYP(\mu M)$       |

CHA prevents the NMDA-induced increase in ISF purines, possibly by acting presynaptically to inhibit neurotransmitter release or postsynaptically to interfere with membrane excitability. Supported by NIH HL-40878.

## 192.13

COMPETITIVE NMDA RECEPTOR ANTAGONISTS, CGP 39551 AND CGP 37849, DO NOT IMPAIR SPATIAL MEMORY AT ANTIEPILEPTIC DOSES IN RATS. A. Ylinen\*, J. Sirviö, T. Hartikainen and P.J. RIEKKINEN. Dept. of Neurology, Univ. of Kuopio, Kuopio,

Several NMDA receptor antagonists have been shown to have anticonvulsive properties in experimental models of epilepsy. However, in most of these experiments the animals have exhibited ataxia and other side effects at anticonvulsive doses, especially the non-competitive NMDA receptor antagonists have been shown to cause impairment of memory. In the present experiments we studied the effects of two competitive NMDA receptor antagonists, CGP 39551 and CGP 37489 administered systemically at anticonvulsive doses, on the acquisition of water maze task. In contrast to MK 801 which was used a reference compound, CGP 39551 and CGP 37849 did not impair spatial memory at an EO $_{50}$  dose in the maximal electroshock test (MES) (p>0.1). CGP 39551, but not CGP 37849, slightly impaired spatial memory at double this dose (p=0.001) and, both of drugs caused impairment at four times higher dose than the ED $_{50}$  in MES (p< 0.001). The present results suggest that there is a larger therapeutic window of these new competitive NMDA antagonists compared to MK 801 and emphasize the possibility to develop NMDA receptorantagonizing antiepileptic drugs.

## 192.15

POTENTIATION OF NEUROLEPTIC ACTIVITY BY POSITIVE MODULATORS OF NMDA FUNCTION. O. Gandolfi\*, R. Dall'Olio and A. Poli. Department of Pharmacology, University of Bologna, Via Irnerio n. 48, I-40126 Bologna, Italy.

According to the view that N-methyl-D-aspartate (NMDA) agonists could be seen as putative therapeutic agents in schizophrenia, the present study was aimed at investigating whether the NMDA positive modulator D-cycloserine (DCS) could show neuroleptic activity. When given alone, DCS (3, 6, 12 mg/kg i.p.) failed to affect the stereotyped behaviour induced by 0.5 mg/kg. s.c. apomorphine. Nevertheless, when DCS (3 mg/kg) was administered in combination with the D1 or the D2 antagonists SCH 23390 or YM 09151-2 respectively at doses which by themselves were ineffective in blocking apomorphine induced behaviour, a neuroleptic effect occurred. Furthermore, the positive NMDA modulator allowed (-)sulpiride, that "per se" never antagonized the apomorphine--induced stereotypy, to exhibit a full neuroleptic activity. The dose of DCS which potentiated antipsychotic effect of dopaminergic blockers also counteracted hypermotility induced by the NMDA negative modulator MK-801 (0.25 mg/kg), indicating the specificity of DCS effect. The results suggest that DCS could be a useful supplement in the therapy of psychotic disorders.

#### 192.12

DIFFERENTIAL EFFECTS OF COMPETITIVE AND NON-COMPETITIVE NMDA ANTAGONISTS ON THE CAMP ACCUMULATION, DOPAMINE RELEASE IN VIVO AND PREPULSE INDUCED INHIBITION OF ACOUSTIC STARTLE RESPONSE

K. Wedzony, K. Golembiowska and A. Pilc\*. Institute of Pharmacology, Polish Academy of Science, 31-343 Krakow, 12 Smetna street, Poland.

Therapeutic potentials of NMDA receptors antagonists recently evidenced by experiments with MK-801 are limited by its phencyclidine like effects. Therefore, in spite of the heuristic value of analysis based on MK-801 a need arises for further studies reevaluating the therapeutic potentials with compounds which are devoided of PCP like properties. In the present study we analyzed, the impact of competitive and non-competitive antagonists CGP37849 and MK-801 in three experimental paradigms: release of dopamine in the rat prefrontal cortex, prepulse induced inhibition of acoustic startle response (PPI) and forskolin stimulated accumulation of cAMP. It was found that MK-801 induced a pronounced, dose dependent elevation of dopamine release in the rat prefrontal cortex, while the effects of CGP37849 in this respect were week and inconsistent. MK-801 opposite to CGP37849 abolished the PPI, but in contrast, CGP37849 attenuated the amplitude of acoustic startle response. The forskolin-induced cAMP accumulation was enhanced in a dose dependent manner by MK-801 whereas CGP37849 was devoided of any significant effect on forskolin-induced cAMP accumulation. Therefore, CGP37849 as a new putative therapeutic agent markedly differs form MK-801 concerning its influence on dopaminergic and noradrenergic systems of rat brain.

### 192.14

4-CHLORO-3-HYDROXYANTHRANILIC ACID IS A RELATIVELY POOR INHIBITOR OF QUINOLINIC ACID PRODUCTION IN THE RAT BRAIN IN VIVO. J.L. Walsh\*, H.-Q. Wu and R. Schwarcz. Maryland Psych. Res. Center, Baltimore, MD 21228. Quinolinic acid (QUIN) has been speculatively linked to the pathogenesis of several neurological, psychiatric and neuroviral diseases. In the mammalian brain, QUIN appears

Quinofine acid (Quin) has been specifiatively linked to the pathogenesis of several neurological, psychiatric and neuroviral diseases. In the mammalian brain, QUIN appears to be synthesized exclusively by enzymatic conversion of 3-hydroxyanthranilic acid (Adv. Exp. Med. Biol., 294:185, 1991). 3-Hydroxyanthranilic acid oxygenase blockers are therefore of potential therapeutic value. 4-Chloro-3-hydroxyanthranilic acid (4-Cl-3HANA) is known to be a highly potent, reversible inhibitor of brain QUIN synthesis in vitro (K<sub>i</sub>: 6 nM; Biochem. Pharmac., 42:985, 1991). We have now assessed its potency in unanesthetized rats in vivo. 3-Hydroxyanthranilic acid (30  $\mu$ M) was introduced to the hippocampus by microdialysis, and extracellular QUIN was determined hourly in the dialysate. Various concentrations of 4-Cl-3HANA (3  $\mu$ M-3 mM) were introduced by the same route after attainment of steady-state QUIN levels, and the drug was discontinued after 3 hours. Total inhibition of de novo QUIN synthesis was seen only at the highest dose used (IC $_{\infty}$  -300  $\mu$ M), and QUIN concentrations returned to steady-state levels within 3 hours after drug discontinuation. Using the same experimental paradigm, i.v. injection of 14 mg/kg 4-Cl-3HANA caused a 44  $\pm$  9% decrease in extracellular QUIN levels within 3 hours (maximal effect). Supported by USPHS grant NS 16102.

## 192.16

EFFECTS OF STRYCHNINE-INSENSITIVE GLYCINE
RECEPTOR LIGANDS ON DISCRIMINATIVE STIMULUS
EFFECTS OF N-METHYL-D-ASPARTATE (NMDA) CHANNEL
ANTAGONISTS. J. M. Witkin and T. D. Steele.
Drug Development Group, Psychobiology Lab, NIDA
Addiction Res. Center, Box 5180, Balt. MD 21224.
Glycine acts as a co-agonist for activation

Glycine acts as a co-agonist for activation of the NMDA receptor ion channel through a strychnine-insensitive receptor, which is a potential target for novel therapeutic agents (eg. anticonvulsants, antidepressants). We evaluated the behavioral effects of glycine receptor ligands in rats trained to discriminate either (+)-MK-801 or phencyclidine (PCP) from saline, to predict whether they might induce PCP-like subjective effects in humans. The partial agonist, 1-aminocyclopropane-carboxylic acid (ACPC), did not mimic the discriminative stimulus effects of either (+)-MK-801 or PCP. Antagonists of the strychnine-insensitive glycine receptor, 7-chlorokynurenic acid or (+)-3-amino-1-hydroxypyrrolid-2-one [(+)-HA-966] also did not substitute for the discriminative stimulus effects of MK or PCP. These data suggest that functional antagonists of the strychnine-insensitive glycine receptor will be devoid of the subjective side-effects characteristic of NMDA channel ligands.

NEUROPROTECTIVE EFFECTS OF CARVEDILOL, A NEW ANTIHYPERTENSIVE, AT THE N-METHYL-D-ASPARTATE RECEPTOR. P.G. Lysko\*, K.A. Lysko, and G. Feuerstein. Dept. of Pharmacology, SmithKline Beecham Pharmaceuticals, King of Prussia, PA 19406.

Carvedilol was found to be neuroprotective ( ${\rm IC}_{50}$ =1.1 $\mu$ M) against glutamate-induced excitotoxicity in our model system of energy-stressed rat cerebellar granule cell neurons which rapidly succumb to glutamate via N-methyl-D-aspartate (NMDA) receptor-mediated events. Carvedilol was also a potent inhibitor of neuronal lipid peroxidation (LPO) induced by Fe<sup>2+</sup>/vitamin C-generated hydroxyl radical (73% inhibition at 10 $\mu$ M). However, this protective action did not seem to apply to glutamate-induced excitotoxicity in the granule cells, since glutamate neurotoxicity was not associated with the formation of LPO products (thiobarbituric acid-reactive substances). Rather, carvedilol inhibited NMDA/glycine-induced increases in intracellular calcium ([Ca<sup>2+</sup>]<sub>1</sub>), as measured in Fura-2/AM-loaded neurons, diminishing [Ca<sup>2+</sup>]<sub>1</sub>), as measured in Fura-2/AM-loaded neurons, diminishing [Ca<sup>2+</sup>]<sub>1</sub>), as measured in 59% (n=8) with a 50% inhibitory concentration of 0.8 $\mu$ M. Prior addition of 5 $\mu$ M dihydropyridines did not shift the dose-response of carvedilol, but did significantly lower the NMDA/glycine-stimulated response to 64% of untreated (n=8, p=0.014). Furthermore, carvedilol displaced  $^{3}$ [H]MK-801 binding to rat cortical membranes with a K $_{0}$  of 29, 4 ± 2.2 $\mu$ M (n=6, LIGAND analysis). These data therefore suggest that, in addition to its antihypertensive and anti-lipid peroxidative functions, carvedilol has neuroprotective activity as a non-competitive inhibitor at the NMDA receptor and may have therapeutic value in cerebral ischemia and stroke.

#### 192.18

P-9939, A NOVEL NEUROPROTECTIVE AGENT. A.M. Szczepanik, R. Kosley, Jr., M. Li, R. Dunn, F. Camacho, R. Fishkin, K.M. Brooks, F. Wirtz-Brugger, L. Leonard, L.L. Martin, C.A. Wilmot\*. Neuroscience Strategic Business Unit, Hoechst-Roussel Pharmaceuticals, Inc., Somerville NJ 08876-1258.

Competitive and noncompetitive NMDA antagonists protect against neuronal loss due to ischemia or excitotoxin-induced lesions

Competitive and noncompetitive NMDA antagonists protect against neuronal loss due to ischemia or excitotoxin-induced lesions in animal models. Glycine antagonists, via an allosteric site associated with the NMDA receptor, are also neuroprotective. P-9939 [2-amino-N-(1H-indol-1-yl)acetamide HCl] was characterized as a low efficacy glycine partial agonist. P-9939 inhibited [ $^3$ H]glycine binding (IC $_{50}$  36  $\mu$ M) and exhibited biphasic effects on ( $^3$ H]TCP binding, with stimulation at low concentrations (EC $_{50}$  3.6  $\mu$ M, producing 40% of the maximal effect of glycine at 100  $\mu$ M) and inhibition at high concentrations (IC $_{50}$  780  $\mu$ M). Unlike the prototypical partial glycine agonist D-cycloserine (DCS), P-9939 was not a cognitive enhancer in passive avoidance (rat, 10-40 mg/kg, ip) and impaired performance at doses  $\geq$  100 mg/kg. Biological testing of P-9939 also included behavioral studies, cerebellar cGMP in mice and electrophysiology in the Xenopus oocyte expression system. P-9939 partially protected against NMDA-induced rat striatal lesions in single or multiple doses, as measured with the markers ChAT and GAD, whereas DCS had no effect. These data suggest that P-9939 may have therapeutic potential in pathological conditions associated with excitotoxic mechanisms.

### PEPTIDES: RECEPTORS II

## 193.1

CLONING OF A CANDIDATE PEPTIDE RECEPTOR FROM HYPOTHALAMUS HOMOLOGOUS TO NEUROMEDIN RECEPTORS. S.K. Welch. B.F. O'Hara. E.L. Sutin. L. Bitting. D. Edgar\*. and T.S. Kilduff, Sleep Research Ctr., Stanford Univ., Stanford, CA 94305.

As part of our study of the hypothalamic suprachiasmatic nuclei (SCN), we are using PCR with degenerate primers to clone and identify members of the G-coupled neurotransmitter receptor family expressed in this nucleus. One of our novel clones is a candidate peptide receptor most similar to receptors for the tachykinins, neuromedin K, substance P, and substance K. RNA was isolated from rat SCN, reverse transcribed, and PCR amplified with degenerate primers homologous to conserved transmembrane domains (TMD) of the receptor family. PCR products were subcloned and partially sequenced. Clone UHR-1 (Unknown Hypothalamic Receptor-1) encodes TMD 3-6 of a candidate receptor which is 28% identical to the tachykinin receptors. We obtained a 3.7 kb cDNA from a hypothalamic library. Hydropathy analysis of the inferred amino acid sequence suggests seven TMDs, 2 potential glycosylation sites, and two consensus sites for protein kinase phosphorylation. The cDNA has a 1.5 kb 3' untranslated region, 2 polyadenylation sites, and a (GA)-rich repeat. Hybridization to a Southern blot of rat, human, and mouse DNAs suggests a single UHR-1 gene and a small number of related sequences. The tissue distribution of UHR-1 is being examined by Northern blotting. A 4.2 kb mRNA is expressed in rat hypothalmus, pituitary, cerebellum, cortex and midbrain, and a 2.5 kb message is apparently expressed in several peripheral tissues. We are also using in situ hybridization to examine expression of this receptor in the brain. (Research supported by the UpJohn Company)

# 193.3

PROGRESS TOWARDS CLONING OF A NOVEL SOMATOSTATIN RECEPTOR. H. Kong\*, M. Theveniau, C.M. Spencer, C.W. Murray, J.H. Eberwine and T. Reisine. Dept. of Pharmacology, Univ. of PA Sch. of Med., Philadelphia, PA 19104-6084

Previous work from our group supports the hypothesis that multiple somatostatin (SRIF) receptors are expressed in mammals. Recently, three SRIF receptor genes have been cloned from human and mouse libraries. However, biochemical and pharmacological studies indicate that at least one more SRIF receptor subtype has yet to be cloned. We had previously developed an antibody (Ab) directed against a rat brain SRIF receptor. This Ab detects a 60 kDa protein in rat brain and the mouse cell line AtT-20. It does *not* cross-react with any of the recently cloned SRIF receptors transiently expressed in COS cells. Therefore, this anti-SRIF receptor Ab was used to screen an AtT-20 cell expression library. Clones identified by the Ab were analyzed and the inserts sequenced. A 2 kb insert has been isolated that has several hydrophobic regions. No significant similarity to other sequences in the GenBank database has been observed. Northern analysis revealed that this clone hybridizes with RNA from AtT-20 cells but not RNA from COS cells (which do not normally express SRIF-R). In order to obtain full length coding region, this clone is currently being used to screen other cDNA libraries. [Supported by grants NiMH MH 48518 and MH 45533 (T.R.) and training grant MH 14654 (C.W.M.).]

#### 193.2

MULTIPLE GENE TRANSCRIPTS OF THE SOMATOSTATIN RECEPTOR (SSTR): TISSUE-SELECTIVE DISTRIBUTION AND CAMP REGULATION. Y.C. Patel', G. Kent, C.B. Srikant, and R. Panetta-Fraser Laboratories, McGill University, Royal Victoria Hospital, Montreal, Quebec, Canada H3A IAI.

mRNA transcripts of 2 recently cloned SSTR subtypes have been reported to be selectively expressed in the human intestine (SSTR1:mRNA of 4.8 kb) or brain and kidney (SSTR2:mRNAs of 8.5, 2.5 kb) (PNAS 89:251, 1992). The presence of mRNAs encoding for these receptors in normal pituitary and adrenal cortex or in pituitary tumor cell lines, all of which represent major SSTR positive tissues, has not been reported. In the present study we have characterized the expression of gene transcripts homologous to the SSTR2 sequence in rat pituitary, adrenal, and other tissues, and in AtT-20 mouse pituitary tumor cells. Total RNA was analysed by Northern blot under moderate stringency with a full length human SSTR2 cRNA probe. Expression of a 2.3 kb mRNA was detected in cerebral cortex, hypothalamus, anterior pituitary, adrenal cortex, stomach, pancreas, and colon. This message was found in low abundance in kidney, but was undetectable in liver, lung, testes, and muscle. The presence of an additional 2.8 kb mRNA species was evident only in pituitary, hypothalamus, and adrenal cortex. Furthermore, selective abundance of the 2 mRNAs was seen in pituitary (2.8 kb > 2.3 kb), and hypothalamus (2.8 kb < 2.3 kb). AtT-20 cells expressed a single 2.3 kb transcript which showed a significant 2 fold increase with forskolin stimulation. The reported 4.8 kb mRNA selective for SSTR1 was not observed in any tissue in these studies.

CONCLUSIONS: (i) Two closely related transcripts of SSTR2 of 2.3, 2.8 kb are expressed either singly or together in a tissue-selective manner in the rat. (ii) The 2.3 kb mouse pituitary mRNA is regulated by cAMP.

## 193.4

CHARACTERIZATION OF TWO CLONED SOMATOSTATIN RECEPTORS. S. Rens-Domiano', S. Law, Y. Yamada, S. Seino, G. Bell and T. Reisine. Dept. Pharmacology, Univ. of Pennsylvania, Phila. PA 19104 and HHMI, Univ. Chicago.

Somatostatin is a neuropeptide that induces a variety of physiological responses by interacting with specific cell surface receptors. Several lines of evidence have suggested that multiple SRIF receptors exist. Two of these, called SRIF<sub>1</sub> and SRIF<sub>2</sub>, can be differentiated by their ability to bind MK 678 and CGP 23996-like compounds with high affinity, respectively. Recently, two SRIF receptor genes (SSTR1 and SSTR2) were cloned from human and mouse genomic libraries. We have characterized the pharmacology of these two cloned receptors expressed in CHO cells. Both cloned receptors could be labeled by [125]Tyr<sup>11</sup>-SRIF and bound SRIF with high affinity. SSTR1 was also able to bind CGP 23996-like compounds, but not MK 678. In contrast, SSTR2 bound MK 678 with high affinity, but was insensitive to CGP 23996like compounds. High affinity agonist binding to SSTR2 was abolished after agonist pretreatment, whereas SSTR1 did not desensitize. GTP $\gamma$ S and pertussis toxin treatment decreased high affinity agonist binding to SSTR2, while agonist binding to SSTR1 was not altered, suggesting that only SSTR2 couples to pertussis-toxin sensitive GTP-binding proteins. These results demonstrate that these two cloned receptors are pharmacologically distinct and can be differentially regulated. The data also suggests that the cloned SSTR1 receptor is similar to the previously characterized SRIF2 receptor, and the cloned SSTR2 receptor is similar to SRIF<sub>1</sub>. Currently, the function of these two cloned receptors is unknown, since forskolin-stimulated adenylyl cyclase activity was not inhibited by SRIF in cells either stably (CHO) or transiently (COS-7) expressing the two cloned receptors. Both of these cloned receptors are glycoproteins, and like brain SRIF receptors, high affinity agonist binding was decreased after removal of sialic acids by neuraminidase indicating a role for sialic acids in high affinity agonist binding. Supported by NIMH grants 45533 and 48518 and NAMI (TR) and NRSA postdoctoral fellowship (NS 09002) and NARSAD (SRD).

PROPERTIES OF THE CLONED MOUSE SSTR3 SOMATOSTATIN RECEPTOR. S.F. Law\*, K. Yasuda, S. Rens-Domiano, C.D. Breder, C.B. Saper, T. Reisine and G.I. Bell. Graduate Group in Cell Biology, Dept. of Pharmacology, Univ. of PA Philadelphia, PA 19104, HHMI and Depts. of Biochem. Mol. Biol.,

Pharm., Physiol. Sci., and Neurol., Univ. Chicago, III. 60637.
Recently, two somatostatin (SRIF) receptor genes have been cloned (Yamada et al. PNAS 89:251, 1992) and have been referred to as SSTR1 and SSTR2. We have cloned a novel third member of the SRIF receptor family and have referred to it as SSTR3. The receptor has approximately 50% amino acid identity with the other two receptors. It binds SRIF, SRIF-28 and the SRIF analog CGP 23996 with high affinity but expresses low affinity for the SRIF agonists MK 678 and SMS-201-995. The receptor can be desensitized when continuously exposed to agonist. Furthermore, SSTR3 couples to perfussis toxin sensitive G proteins and mediates SRIF inhibition of adenylyl cyclase activity. These findings indicate that both the pharmacological and functional properties of SSTR3 differ from the other cloned SRIF receptors. Interestingly, both SSTR3 and SSTR2 couple to pertussis toxin sensitive G proteins but only SSTR3 functionally couples to adenylyl cyclase. Studies are underway to determine the regions of the receptors needed for G protein association and coupling to adenylyl cyclase. Supported by MH-45533 and 48518.

## 193.7

## DEVELOPMENTAL STUDIES OF THE 60 KDa SOMATOSTATIN RECEPTOR IN THE RAT BRAIN

Magali Théveniau\*, Karen Raynor and Terry Reisine.

Dept. Pharmacol. Univ. of Pennsylvania, PA 19104.

The neuropeptide somatostatin (SRIF) is present in various tissues and widely distributed throughout the nervous system. A number of studies have shown that SRIF is developmentally regulated. The purpose of our work is to determine using specific antibodies for the 60 kDa brain SRIF receptor whether the SRIF receptor is also developmentally regulated. Our preliminary results using an immunoblotting procedure demonstrate that the level of the 60 KDa SRIF receptor is not changed during the development in the whole brain as well as in subregions such as the hypothalamus, cerebral cortex, hippocampus and striatum. However, regulation of the expression of the SRIF receptor is observed in the cerebellum after birth. From P3 to P8 the SRIF receptor has reached maximal level of expression and then dramatically disappears. These results are particularly interesting since major modifications of the cell distribution in the cerebellum take place at this time of the distribution in the cerebellum take place at this time of the development. Studies are in progress to determine which cells in the cerebellum as well as in the other brain regions (such as the cerebral cortex where cell migration also takes place during development) express the SRIF R during development. Using pharmacological and immunological approaches we will attempt to determine which subtypes of the SRIF R are regulated.

Supported by NIMH grants MH45533 & 48518 and the Human Frontiers Scientific Program grant LT-475/90.

# 193.9

CLONING AND EXPRESSION OF A RAT SOMATOSTATIN RECEPTOR ENRICHED IN BRAIN. X.-J. Li<sup>1</sup>, M. Forte<sup>2</sup>, R.A. North<sup>2</sup>, C.A.

Ross<sup>1</sup> and S.H. Snyder<sup>1</sup>\*. Johns Hopkins University School ENRICHED IN BRAIN. A.-J. LI. M. FOTTE, K.A. NOTELY, C.A. ROSS<sup>1</sup> and S.H. Snyder<sup>1</sup>\*. <sup>1</sup>Johns Hopkins University School of Medicine, Department of Neuroscience, 725 N. Wolfe Street, Baltimore, MD 21205; <sup>2</sup>Vollum Institute, The Oregon Health Sciences University, Portland, OR 97201.

A cDNA encoding a rat somatostatin (SRIF) receptor was identified by use of degenerate oligonucleotide primers and polymerase chain reaction (PCR) amplification of cDNA prepared from transcripts expressed in rat brain. complete cDNA encodes a protein of 391 amino acids with complete CDNA encodes a protein of 391 amino acids with seven potential transmembrane domains. Expression of the cDNA product in transfected COS-7 cell lines provides the same high affinity of binding to [1251-Tyr11]-SRIF-14 as that of rat cerebral cortex tissues. However, the binding of [1251-Tyr11]-SRIF-14 to cloned rat SRIF receptor is not displaced by MK678, a SRIF analog that partially displaces [1251-Tyr11]-SRIF-14 binding sites in membranes of rat cerebral cortex. Northern analysis and <u>in situ</u> hybridization indicate that mRNA (4.0 kb) for cloned rat SRIF receptor is preferentially expressed in rat brain regions such as cerebral cortex and hippocampus with no detectable expression in most peripheral organs. This pattern contrasts with the exclusive peripheral expression of a recently cloned human SRIF receptor. The cDNA probe of rat receptor detects mRNA from mouse brain but not from human cerebral cortex and cerebellum.

#### 193.6

ONTOGENY OF SOMATOSTATIN RECEPTOR SUBTYPES IN RAT BRAIN. K. Raynor\*, M. Theveniau, and T. Reisine, Dept. of Pharmacology, Univ. of PA, Phila., PA, 19104.

Adult rat brain expresses at least two receptor subtypes for the neuropeptide somatostatin (SRIF). SRIF<sub>1</sub> receptors are sensitive to hexapeptide SRIF analogues such as MK 678, whereas SRIF2 receptors are insensitive to hexapeptide analogues. To determine whether expression of SRIF receptors subtypes is developmentally regulated in the rat brain and cerebellum, we labelled SRIF1 and SRIF2 receptors with [125I]MK 678 and [125I]CGP 23996, respectively, in membranes of rat brain from embryonic day 13 (E13) to postnatal day 18 (P18). Embryonic rat brain (E13, E16) express exclusively SRIF<sub>1</sub> receptors which show a 3-fold increase in levels from E13 to E16. The level of SRIF<sub>1</sub> receptors continues to rise with a peak at P2 (representing a 10-fold increase relative to E13) after which the level remains relatively constant. In contrast, SRIF2 receptors are not present in embryonic brain, but appear by P2. The level of SRIF2 receptors rises steadily to P8 after which the level is maintained. Pharmacological characterization of SRIF1 and SRIF2 receptors in membranes from P13 shows that these receptors are indistinguishable from those expressed in adult rat brain. SRIF<sub>1</sub> and SRIF<sub>2</sub> receptors are also expressed in the postnatal rat cerebellum and show parallel increases in levels to P5 followed by a decrease to lower levels by P16. The pattern of expression of SRIF<sub>1</sub> receptors identified by radioligand binding parallels results found by immunoblotting with antibodies to a 60 kDa rat brain SRIF receptor.

Autoradiographic studies are underway to delineate the localization of SRIF receptor subtypes during development. [Supported by grants NIMH MH 48518 and MH

## 193.8

PROPERTIES OF SOMATOSTATIN1 RECEPTOR SUBTYPES IN AtT-20 CELLS. M. Tallent\*. K. Raynor, M.A. Dichter, and T. Reisine. Depts. of Pharmacology and Neurol. and Inst. of Neurol. Sci.,

Univ. of PA, Philadelphia, 19104.

We have recently identified two subtypes of somatostatin (SRIF) receptors in the rat brain which can be distinguished by their affinity for the agonist MK 678. SRIF1 receptors bind MK 678 with high affinity whereas the SRIF2 receptor is insensitive to this peptide. Characterization of SRIF receptors in AtT-20 cells now show that two subclasses of the SRIF1 receptor are expressed in this cell line. Both receptors have a high affinity for MK 678. However SRIF1a receptors do not bind a putative somatostatin antagonist (SA), and high affinity agonist binding in these receptors is abolished upon continuous exposure to MK 678. SRIF1b receptors bind SA and are less sensitive to regulation by exposure to MK 678. Both MK 678 and SA inhibit forskolin stimulated cAMP formation and potentiate an inward rectifier K+ current in AtT-20 cells. suggesting that the SRIF1b receptor is coupled to adenylyl cyclase and a K+ channel. MK 678, but not SA, can inhibit a high voltage activated Ca++ current in AtT-20 cells suggesting that SRIF1a receptors may selectively couple to Ca++ channels in these cells. These preliminary results suggest that the subtypes of SRIF1 receptors couple to different cellular effector systems. Studies are underway to further investigate the pharmacology and functional properties of these two receptors and to determine whether they couple to different G proteins. Supported by MH 45533, 48518, and GM 34781.

## 193.10

MOLECULAR CLONING AND CHARACTERIZATION OF FOUR MEMBERS OF THE SOMATOSTATIN RECEPTOR GENE FAMILY. L.L. Demchyshyn. J. Comess, R.K. Sunahara. P. Seeman. H.H.M. Van Tol. C.B. Srikant. Y.C. Patel. and H.B. Niznik.\* Dept. of Pharmacology and Psychiatry, University of Toronto: Fraser Laboratories, Royal Victoria Hospital, Montreal, Canada, H3A 1A1 and the Mol. Neurobiol Lab., Clarke Institute of Psychiatry, Toronto. Canada, M5T 1R8.

Somatostatin receptors are members of a superfamily of G-linked receptors which act as biochemical modulators in the release of hormones receptors which act as biochemical modulators in the release of hormones and other secretory proteins. Pharmacological and biochemical evidence suggest the existence of various receptor subtypes selective for somatostatin-14 and somatostatin-28. PCR amplification of human genomic DNA with degenerate oligonucleotide primers constructed to conserved segments of transmembrane domains 3 and 6 followed by high stringency hybridization screening yielded four genomic clones, HG2-3, HGA1-22, HGA2-22 and HG9-2. Nucleotide sequence analysis indicates two intronless genes encoding 391 and 369 amino acid proteins displaying affinity for somatostatin-14 which have recently been characterized as SSTR1 and SSTR2. These have been functionally expressed in mammalian fibroblast cell cultures. A third gene. SSTR3. characterized as SSTR1 and SSTR2. These have been functionally expressed in mammalian fibroblast cell cultures. A third gene, SSTR3, encodes for a 407 amino acid protein displaying considerable homology within the seven putative transmembrane domains to SSTR1 (72%) and SSTR2 (57%). Northem blot analysis of various brain regions reveals a transcript size of approximately 4.0 kb. The fourth gene displays transmembrane homology of 50%, 75%, and 55% to SSTR1, SSTR2 and SSTR3 respectively. Northern blot analysis has revealed no discernable message within brain regions for this gene.

CHARACTERIZATION OF A cDNA ENCODING A BOVINE SOMATOSTATIN RECEPTOR AND REGIONAL DISTRIBUTION IN BRAIN. W. Xin\* M.-L. Wong, J. Rimland, E.J. Nestler and R.S. Duman. Laboratory of Molecular Psychiatry, Departments of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

Somatostatin, a tetradecapertide

Somatostatin, a tetradecapeptide, is widely distributed in the central nervous system and peripheral tissues where it has a number of actions most notable being regulation of neuroendocrine function. Using degenerate primers for the third and sixth transmembrane domains of G protein-coupled receptors and the polymerase chain reaction, we have cloned a somatostatin receptor from bovine locus coeruleus. DNA sequencing of this receptor cDNA revealed greater than 93% homology at the nucleotide level and greater than 99% identity between the predicted amino acid sequences of the bovine receptor and the human and mouse somatostatin receptor subtype 2 (SSTR2).

Northern blot analysis showed that the bovine SSTR2 cDNA hybridizes to a unique 2.2kb transcript in different bovine brain regions with highest density in cerebral cortex, cerebellum, and thalamus and lower levels in neostriatum, locus coeruleus, dorsal raphe, and in peripheral tissues. In addition, bovine SSTR2 also hybridizes to a rat 2.2kb transcript as well as a larger transcript (>7kb) with levels of expression similar to that in bovine brain. To further characterize expression similar to that in booine brain. To further characterize expression of SSTR2, in situ hybridization on rat brain slices is being carried out using bovine SSTR2 cDNA as the probe. The full-length cDNA of bovine SSTR2 is being subcloned and expressed in mammalian cell lines to study the functional and ligand binding properties of this

## 193.13

SEQUENCE AND LOCALIZATION OF A RAT HOMOLOGUE OF A NEUROPEPTIDE Y RECEPTOR cDNA. M-L. Wong\*, W. Xin, E. J. Nestler, R. S. Duman. Lab. of Molecular Psychiatry, Depts of Psychiatry and Pharmacology, Yale Univ. School of Medicine, New Haven, CT 06508.

Northern blot analysis of a NPY receptor mRNA sequenced by our laboratory (Rimland et al. Mol. sequenced by our laboratory (idiniant et al. Mol. Pharmacol. 40:869, 1991) from bovine locus coeruleus, referred to as LCR1, is regionally distributed in both brain and peripheral tissues. Spleen is a peripheral organ particularly enriched in LCR1 mRNA and for that reason

a spleen tissue library was obtained for this study.

We used the full length LCR1 cDNA as a probe to screen a poly dT/random primed rat spleen library to isolate the rat homologue of that NPY receptor. The rat LCR1 has a sequence homology of approximately 85% when compared to the bovine clone. NPY has been implicated in a variety of physiological and pharmacological actions including cardiovascular, gastrointestinal, and neuroendocrine modulation. The rat LCR1 cDNA clone will be particularly useful for studies of the regulation and function of NPY receptors.

# 193.15

isolation and characterization of human cDNA clones related to the NPY/PYY Y1 receptor.

I. Lundell, A. G. Blomqvist, F. Yee#, H. Yoo#, C. Söderberg\*, C. Wahlestedt# and D. Larhammar, Dept. of Medical Genetics, Uppsala University, S-75123 Uppsala, Sweden. # Dept. of Neurology and Neuroscience, Cornell University Medical College, New York, N. Y.

We have recently described the isolation and characterization of a human NPY/PYY Y1 receptor cDNA clone (Larhammar et al, J. Biol. Chem., 1992). The NPY/PYY receptor family includes at least two additional pharmacologically distinct receptors called Y2 and Y3. In order to isolate Y1related receptors we screened a human fetal brain cDNA library at low stringency conditions. Several clones were isolated. Sequencing revealed that at least three clones correspond to partially and/or aberrantly processed Y1-receptor transcripts.

We have identified two introns in the Y1 gene, one in the 5'-untranslated region and one immediately after the segment encoding transmembrane region 5. One of the cDNA clones has an L1 repeated element fused to the splice acceptor of exon 2. The other two clones also begin with Y1unrelated DNA, but joined to different positions in the coding region, presumably corresponding to cryptic splice acceptor sites. One of the latter clones also still contains intron 2. This is in agreement with our RT-PCR analyses on mRNA from several cell lines, some of which displayed a larger Y1-related product, as sequencing revealed this to correspond to Y1 mRNA retaining intron 2. Although intron 2 is only approximately 100 nucleotides, it cannot be translated as a termination codon precedes exon 3. Based upon cDNA clone frequency, the aberrantly processed Y1 transcripts may correspond to more than 5% of the total Y1 mRNA in human fetal brain.

ISOLATION OF NOVEL G-PROTEIN COUPLED RECEPTOR CDNAs FROM LOCUS COERULEUS AND VENTRAL TEGMENTUM BY PCR. J.D. Alvaro', E.J. Nestler, and R.S. Duman. Interdepartmental Neuroscience Program, Laboratory of Molecular School Med., New Haven, CT 06508.

Studies in our laboratory have focused on the function of the locus

coeruleus (LC) and ventral tegmentum (VT), two brain regions which have been implicated in drug addiction and a number of other psychiatric disorders. In continuing our efforts to identify G-protein coupled receptors localized in these regions, we have used degenerate oligonucleotide primers corresponding to highly conserved regions within the third and sixth transmembrane domains of the receptor superfamily to PCR amplify both bovine LC and rat VT double stranded cDNA. As seen on an agarose gel, the subsequent PCR reactions yielded greater than 9 cDNA bands for the LC and more than 5 bands for the VT. The reaction mixture for the LC was blunt-end cloned into pBluescript, and the VT reaction mixture was subcloned into the pCR1000 TA vector. Preliminary sequence data on individual clones receptor fragments have been amplified in each brain region. The novel cDNAs display hydropathicity plots indicative of G-protein coupled receptors and retain a number of highly conserved residues found in other members of the receptor superfamily. Northern blot analysis of these cDNAs is under way to determine the regional distribution of each clone, and cDNA libraries will be screened to isolate full length clones for each putative receptor.

## 193.14

NEURON-SPECIFIC CLONING OF G PROTEIN-COUPLED RECEPTORS IN THE POND SNAIL LYMNAEA STAGNALIS. C.P. Tensen\*, C.C. Gerhardt, E.R. van Kesteren, R.J. Planta, E. Vreugdenhil and H. van Heerikhuizen. Department of Biochemistry and Molecular Biology, Vrije Universiteit, De Boelelaan 1083, 1081 HV Amsterdam, The Netherlands.

Signal transduction pathways mediated by G protein-coupled receptors, play an important role in several neuronal processes (information processing, learning, behaviour, etc). The cloning of cDNAs that encode vertebrate neuronal signal transduction components has revealed the existence of several large superfamilies of polypeptides which share primary sequence homology and which have similar secondary structures. Despite these extensive molecular studies, however, little is known about the precise in vivo interaction of specific members of the different superfamilies.

Aiming at the elucidation of such interactions in well-characterized neurons that are amenable to experimental manipulation, we have focussed our attention on the central nervous system (CNS) of the pond snail, Lymnaea stagnalis. The limited complexity of the CNS, the large size of its neurons (50-200 µm) and the multidisciplinary expertise on a number of identified neurons make the Lymnaea CNS a well-suited model system

We have carried out cell-specific cDNA cloning by using RNA isolated from (groups of) individual well-characterized neurons from the Lymnaea CNS. Thus, we have cloned and characterized a number of different cDNAs encoding signal transduction components, including G protein-coupled receptors (both "classical" neurotransmitter receptors as well as putative neuropeptide receptors). The predicted structural properties of some of these proteins, the expression of the corresponding genes and their potential role in neuronal signal transduction will be discussed.

## 193.16

Cioning and functional expression of a human neuropeptide receptor of the Y1 subtype

A. G. Blomqvist\*, F. Yee#, H. Yoo#, E. E. Jazin, C. Wahlestedt# and D. Larhammar, Dept. of Medical Genetics, Uppsala University, S-75123 Uppsala, Sweden. #Department of Neurology and Neuroscience, Cornell University Medical College, New York, NY

Neuropeptide Y (NPY) and peptide YY (PYY) are structurally related peptides that function as a neurotransmitter and gastrointestinal hormone, respectively. At least three distinct NPY and/or PYY receptors, called Y1, Y2, and Y3 have been identified pharmacologically. We describe here a human Y1 cDNA clone isolated from a fetal brain library. The Y1 receptor consists of 384 amino acids and has the characteristic seven transmembrane regions of G-protein-linked receptors. In the region spanning the transmembrane regions, it displays 30% sequence identity to the tachykinin receptors but only 22% identity to the recently described bovine NPY receptor Mol. Pharmacol. 40, 869-875

Nothbern blot analysis revealed a mBNA of 3.5 kb in the human

Northern blot analysis revealed a mRNA of 3.5 kb in the human neuroblastoma cell line SK-N-MC. Southern blot analysis indicated that the Y1 gene is present in the genome as a single copy. When expressed in COS1 kidney cells the Y1 receptor, HY1-5, binds <sup>125</sup>I-labelled NPY and PYY with displacement patterns typical for a Y1-receptor, i.e. PYY≥NPY≥[Leu³1, Pro³4]NPY>NPY2-36>NPY13-36. NPY and PYY stimulation of HY1-5 accelerated <sup>45</sup>Ca²+ release and inhibited forskolin

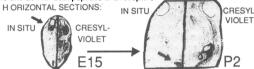

stimulated adenylate cyclase activity.

The results are in agreement with the expected characteristics of a NPY/PYY-receptor of the Y1 subtype.

DISTRIBUTION OF NPY/PYY AND THEIR G-PROTEIN COUPLED RECEPTORS IN THE DEVELOPING RAT BRAIN. E.E.Jazin. S.Söderström#. C. Wahlestedtt. T. Ebendal#, and D. Larhammar. Dept. of Medical Genetics, and #Dept. of Dev.Biol., Uppsala University,S-751 23 Uppsala, Sweden. †Dept. of Neurology and Neuroscience, Cornell University Medical College, N.Y., N.Y., U.S.A.

Neuropeptide Y (NPY) is involved in a variety of functions including eating

Neuropeptide Y (NPY) is involved in a variety of functions including eating behavior, blood pressure control, memory retention, and sexual behavior. While NPY is expressed through-out the brain, its homolog, peptide YY (PYY), which has similar biological functions as NPY, is only found in selected brainstem neurons in addition to gut endocrine cells. At least three different receptors named Y1, Y2 and Y3 have been characterized pharmacologically. We have cloned the rat and human Y1 receptor (J.Biol.Chem., in press) and the human and rat homologs of a published suggested bovine NPY receptor of the Y3 subtype (Mol. Pharmacol. 40:869-875). We are studying the distributional correlation of the two peptides and the receptors in different parts of the brain during rat development by in situ hybridization. The figure shows the change in distribution of the NPY-Y3-receptor candidate reactivity from embryonic day 15 (E15) when the labeling is more evident-in the developing striatum (arrow), to postnatal day 2 (P2) when labeling was observed in the hindbrain (arrow) and retina. Similar experiments are now being conducted at embryonic days 9, 11, 13, 16, and 20 and postnatal day 2, 15 and 30 with both peptides and receptors.

## 193.19

CLONING AND CHARACTERIZATION OF ET-3 SPECIFIC RECEPTOR FROM XENOPUS MELANOPHORES. S. Karne\*, C. K. Jayawickreme, and M. R. Lerner. Howard Hughes Medical Inst., Depts. of Internal Medicine, Phar. & Neuroscience, Yale Univ. School of Med, New Haven, CT 06510

Endothelins belong to a family of potent vasoactive peptides consisting of three isopeptides, ET-1, ET-2, and ET-3. Vasopressor activity, radioligand binding and cross-linking affinity studies have suggested the existence of multiple, possibly three, receptor subtypes. Recently, two subtypes of endothelin receptors, which belong to the G-protein coupled receptor family, have been cloned: (1) ETA, which is specific for ET-1 and (2) ETB, which is non-selective.

We report here the cloning of an endothelin receptor which is specific for ET-3. The existence of such a subtype, termed ETC, has been demonstrated in cultured bovine endothelial cells and in cultured rat anterior pituitary cells. While studying the endogeneous G-protein coupled receptor pathways in Xenopus dermal melanophores, we observed that these cells contained a receptor highly specific to ET-3. Using the polymerase chain reaction and degenerate oligonucleotides to conserved regions of other G-protein coupled receptors, we isolated and sequenced a unique fragment from the melanophores. This fragment was used to screen and isolate a clone of 2.2 kb in length, which has the characteristic seven transmembrane domains of other G-protein coupled receptors. Sequence comparison of this clone with those in GenBank revealed that this clone is highly homologous to the endothelin receptors only.

#### 193.18

VARIANT TRANSCRIPTS OF THE MOUSE GONADOTROPIN RE-LEASING HORMONE RECEPTOR GENE W. Zhou\*1, M. Tsutsumi¹, S.C.Sealfon¹,² ¹.Fishberg Center for Reserch in Neurobiology and ². Dept. of Neurology, Mount Sinai School of Medicine, New York, NY 10029.

We have isolated a cDNA from a gonadotrope cell line which encodes a functional mouse GnRH receptor (clone WZ25). The predicted receptor structure has seven transmembrane (TM) domains, characteristic of G-protein coupled receptors, but lacks a typical intracellular C-terminus. Library screening has identified three additional transcripts which contain deletions in comparison with the functional receptor. Clone WZ34 contains a deletion at +909 eliminating TM VII and the C-terminus. The deletion in clone WZ15 encompasses most of TM IV-VI (+ 523 to +739) and alters the reading frame, leading to a premature stop codon. Clone WZ16 is identical to the cDNA for the functional receptor until TMVI (+739), at which point a mouse repetitive sequence is encountered. Synthetic RNA transcripts from the deletion containing clones, unlike clone WZ25, did not induce a response to GnRH when injected into Xenopus oocytes. The identification of these transcripts suggests that the mouse GnRH receptor is a complex gene. The mechanism of generating these transcripts, their tissue specificity and their functional significance remain to be determined. (supported by NSF 91-06877).

## 193.20

PHARMACOLOGY OF THE CLONED RAT NEUROTENSIN RECEPTOR EXPRESSED IN 293 CELLS, Barbara S. Slusher\*, Anna E. Zacco, John A. Maslanski, Tyrrell E. Norris, and Michael W. McLane. Department of Pharmacology, ICI Americas, Wilmington, DE 19897.

A cDNA clone for the rat neurotensin receptor (NTR) was isolated, sequenced, functionally expressed in 293 cells and pharmacological and second messenger studies were conducted. Poly(A)+ RNA from rat ventral tegmental area was reverse transcribed and subjected to nested PCR using specific NTR primers (Tanaka et al., 1990). The resulting 1.3 kb cDNA was isolated, cloned into a phagemid vector and sequenced to ensure that it was devoid of mutations. Subsequently, the NTR cDNA was subcloned into the eukaryotic expression vector pRC-CMV and the resulting plasmid was transiently transfected into 293 cells. The binding of [3H]neurotensin to membranes prepared from the NTR cDNA-transfected cells displayed specificity and saturability, with an apparent Kd of 0.54 nM. We compared several neurotensin analogs for their ability to inhibit 0.5 nM [3H]neurotensin binding. The apparent half-maximal concentrations for the inhibition (ICso) of binding for neurotensin 8-13, [gln4]-neurotensin, neurotensin pseudopeptide H-[Ψ8,9] (Lugrin, 1991), neurotensin, acetylated neurotensin 8-13, xenopsin, neuromedin N, LANT-6, and [D-Tyr]neurotensin was 0.19 nM, 0.30 nM, 0.70 nM, 1.6 nM, 1.7 nM, 3.2 nM, 15.9 nM, 18.5 nM, 9.3 µM, respectively. Neurotensin 1-8, neurotensin 1-11, and [D-Typ11]neurotensin (1 μM) had no effect on receptor binding, consistent with the observation that the C-terminal portion of neurotensin contains the structural requirements for receptor binding. Levocabastine (1 µM) also had no effect, suggesting that the cloned receptor was the high affinity NTR. We also tested the cloned NTR for second messenger associations. Neurotensin (100nM) stimulated an increase in [3H]inositol phosphates in the NTR cDNA-transfected cells to approximately 3-fold over basal; no stimulation was observed in non-transfected cells. Pharmacological characterization of this response is ongoing.

BINDING PROFILE OF CGRP<sub>1</sub> SELECTIVE ANTAGONIST, [ $^{125}$ I] Tyr $^0$  hCGRP $\alpha_{8-37}$ , IN RAT BRAIN. <u>D. van Rossum'\*</u>, <u>D. Ménard'</u>, <u>A. Fournier'</u>, <u>S. St-Pierre'</u> and <u>R. Ouirion'</u>. (1) Douglas Hospital Research Centre and Department of Pharmacology & Therapeutics, McGill University, Montréal, Québec, Canada (2) INRS-Santé, Pointe-Claire, Québec, Canada.

Based on the differential potencies of the fragment hCGRP $\alpha_{8:37}$  and the analog  $[Cys(ACM)^{2,7}]hCGRP\alpha$  in peripheral tissues, we have proposed the existence of two classes of Calcitonin Gene-Related Peptide (CGRP) receptors, the CGRP<sub>1</sub> and CGRP<sub>2</sub> subtypes (Dennis et al., JPET, 1989, 1990). The binding characteristics of [1251] Tyr<sup>0</sup> hCGRPa<sub>8-37</sub>, a CGRP antagonist with preferential affinity for CGRP, receptor subtype, were studied in an attempt to visualize the distribution of CGRP, sites in rat brain, using an autoradiographic method. Specific [1251] Tyr<sup>0</sup> hCGRPa<sub>8-37</sub> binding (70%) was regionally distributed in rat brain, with the highest level of binding present in the cingulate cortex, nucleus accumbens, amygdaloid body, caudate putamen (tail), habenular nuclei, temporal cortex, pontine nuclei, superior and inferior colliculus, cerebellum (molecular layer), inferior olive and spinal vestibular nuclei. Competition assay in rat brain membrane preparations revealed one high affinity binding component with a  $K_i$  of 15 nM and a total receptor population of 1.2 pmol/mg protein. These results demonstrate the potential usefulness of [ $^{125}$ l] Tyr $^0$  hCGRP $\alpha_{8-37}$  as a radioligand to label rat brain CGRP sites. Supported by the MRC of Canada.

## 194

ONTOGENY OF CHOLECYSTOKININ RECEPTORS IN THE BRAZILIAN OPOSSUM BRAIN. M.C. Kuehl-Kovarik\*, L.R. Ross, S. Spencer, and C.D. Jacobson. Department of Veterinary Anatomy and Neuroscience Program, Iowa State University, Ames IA 50011

We have studied the distribution of cholecystokinin (CCK) receptors in the brain of the developing marsupial, Monodelphis domestica. Receptors were localized in tissue sections using Bolton-Hunter I125labelled CCK, as we have described previously (Neurosci, Abst. 17:807, 1991). Silver grains were evident in the trigeminal ganglion and nuclei, facial motor nucleus (VII), vagus nerve, and presumptive nucleus of the solitary tract by postnatal day 5 (5PN). By 10PN, the hypothalamus, presumptive interpeduncular nucleus, and specific amygdaloid nuclei labelled as well. As evidenced by specific binding, receptors in the cortex, cerebellum, and cerebellar nuclei were also identified. Receptors in portions of the limbic system, ventromedial hypothalamic nucleus, and spinal trigeminal nucleus were found by 15PN. The forming reticular thalamic nucleus demonstrated dense labelling in the 15PN animal that decreased with age and was absent in the adult. By 25PN, the caudateputamen and ventral tegmental nucleus contained CCK receptors. In general, labelling in the 35PN animal closely resembled that of the adult. It is interesting that VII contains high levels of I<sup>125</sup>-labelled CCK (as confirmed by tract tracing studies) and that the density of labelling is even greater in younger (10 and 15PN) animals. This is the first report of CCK binding in the facial motor nucleus. These results indicate that CCK may play a unique role in the nursing neonatal marsupial. Studies are underway to determine if this labelling pattern is unique to this marsupial.

CHOLECYSTOKININ AFFECTS MULTIPLE CURRENTS IN SYMPATHETIC NEURONS OF CELIAC GANGLION H. Xian, J. S. Coggan, S. R. Knoper and D. L. Kreulen\* Dept. of Pharmacol. and Inter. Med., Coll. of Medicine, Univ. of AZ, Tucson, AZ 85724

Cholecystokinin (CCK), a peptide neurotransmitter in mammalian prevertebral sympathetic ganglia, is involved in regulation of gastrointestinal activities. Previous studies have demonstrated that CCK octanentide (26-33) sulfated (CCK8-S) induces a slow membrane depolarization via activation of CCK-A receptors in guinea-pig celiac ganglion neurons in primary culture. We further studied the mechanism of CCK-induced depolarization in these cells with whole-cell voltage clamp technique. CCK8-S (250 nM - 1 mM) by pulse application (1.5 sec) induced a concentration- and voltage-dependent inward shift in holding current in voltage-clamped neurons (Vh: -30 mV to -90 mV). In some cells, the inward shift was biphasic. The reversal potential of CCK-mediated inward shift in holding current was near EK (-80 mV). The inward shift in holding current was blocked in the presence of 2 mM barium in the bath, indicating that CCK-induced inward shift in holding current may be mediated by change of potassium conductance, i.e., decreasing an outward potassium current. However, in some cells, CCK8-S increased an inward current at hyperpolarizing potentials (-50 mV to -120 mV). These studies suggest that CCK-induced slow membrane depolarization may involve the regulation of multiple currents. HL-27781, DK-36289 and Lilly Research Labs.

CCK<sub>A</sub> RECEPTORS MEDIATE PHOSPHATIDYL-INOSITOL TURNOVER IN AR 4-2J CELLS. <u>K. G. Pratt.</u> <u>D. Bryce\*. and S. H. Zorn.</u> Central Research Div., Department of Neuroscience, Pfizer Inc, Groton, CT 06340.

AR 4-2J rat pancreatoma cells reportedly express both CCKA and CCKB receptors. In these cells, the octapeptide CCK-8 and other CCK peptide fragments have been previously shown to induce PI turnover, and it has been suggested from these studies that this response may be mediated through a stimulation of  $CCK_A$  receptors. The present study was undertaken to characterize the effect of CCK-8 on PI turnover in AR 4-2J cells by studying the effects of selective CCKA and CCKB receptor antagonists on CCK-8 stimulated inositol phosphate (IP) accumulation. AR 4-2J cells, prelabelled with [3H]myo-inositol, were exposed to various concentrations of CCK-8 and 10 mM lithium in the presence and absence of selective CCKA and CCK<sub>B</sub> receptor antagonists. CCK-8 produced a dose-dependent stimulation of IP accumulation (EC50 ~1nM). The response to 10nM CCK-8 was completely blocked by the selective CCKA receptor antagonist L-364,718 with an IC<sub>50</sub> < 100 nM. In contrast, the selective CCK<sub>B</sub> antagonist L-365,260 was less potent in this regard producing only a 40% reduction of the CCK-8 response at a concentration of 1 µM. These data are consistent with the notion that CCK stimulation of PI turnover in AR 4-2J cells is mediated by a selective interaction with CCKA and not CCKB receptors.

## 194.7

EXCITATORY EFFECTS OF CCK-8 IN THE RAT NUCLEUS TRACTUS SOLITARIUS (NTS). H. Rhim\*, S.R. Glaum & R.J. Miller, Dept. of Pharm. and Phys. Sci., University of Chicago, Chicago, IL. 60637.

Cholecystokinin (CCK) is a major intestinal hormone which

Cholecystokinin (CCK) is a major intestinal hormone which plays an important role in satiety and gastric motility. It is also known that this neuropeptide is involved in the central control of anxiety, feeding behavior and nociception. Two major CCK receptor types, CCKA and CCKB, have been found in the brain. Both CCK receptors coexist in the rat NTS, which is an important relay center for the integration of peripheral and central neuronal activities related to gastrointestinal, cardiovascular and respiratory

In order to study actions of CCK in the NTS, we conducted experiments using whole cell patch clamp recording in rat brain stem slices. Application of CCK-8(S) (100nM-10µM) produced excitatory effects including depolarization and increased spontaneous excitatory synaptic activity. Under voltage clamp conditions, CCK-8(S) induced an inward current and increased spontaneous synaptic activity in a dose related manner between 10 nM and 10µM. These excitatory effects were partially blocked by the selective CCKB receptor antagonist, LY-288513. Excitatory postsynaptic currents (EPSC), evoked by the stimulation in the tractus solitarius, were not affected by CCK-8(S) (100nM, n=4). These data suggest that CCK receptor activation may be involved in regulating gastrointestinal and other reflex systems in the NTS.

#### 194.4

RELATIONSHIP BETWEEN RADIOLIGAND ANTAGONIST/AGONIST BINDING RATIOS AND FUNCTIONAL EFFICACY OF CHOLECYSTOKININ RECEPTORS IN RAT PANCREAS. S. Patel, K.L. Chapman, A.J. Smith and S.B. Freedman. Merck Sharp and Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Eastwick Road, Harlow, Essex, CM20. 2QR, U.K.

We have examined whether the ability of agonists to distinguish between high and low affinity states of the cholecystokinin (CCK-A) receptor in rat pancreas can be predictive of relative efficacy. Radioligand binding studies were performed using the agonist  $\binom{1}{2}$  I]Bolton Hunter CCK-8S (50pM) and the antagonist [<sup>3</sup>H]devazepide (0.2nM) in rat pancreatic membranes. Phosphatidyl-inositol (PI) turnover and amylase secretion was measured in rat pancreatic acini. CCK-8S and caerulein exhibited high antagonist/agonist binding ratios (340 and 160 respectively) and were full agonists in the PI and amylase assays, whereas devazepide and the CCK-B antagonist L-365,260 displayed ratios close to unity (1 and 2.4 respectively) and were without agonist efficacy in either functional assay. The peptoid CCK-B antagonist CI-988 had a higher binding ratio of 15 and was a full agonist in the amylase assay, an effect reversed by devazepide (100nM). Thus, antagonist/agonist binding ratios for compounds acting at CCK-A receptors are predictive of functional activity. Furthermore, it is possible for an agent to be an antagonist at CCK-B receptors yet an agonist at CCK-A receptors.

#### 194.6

CHARACTERIZATION OF NOVEL CCK ANALOGS USING THE SMALL CELL LUNG CANCER CELL LINE, H345. D.G. Witte. A. M. Nadzan, M. Rodriguez†, J. Martinez†, and C. W. Lin\*. Neuroscience Research Division, Abbott Laboratories, Abbott Park, IL 60064. †CCIPE-Faculté de Pharmacie, Montpellier, France.

The interaction of the novel CCK analogs JMV-180, JMV-320, JMV-332 and A-63387 with CCK-B/gastrin receptors on small cell lung cancer (SCLC) cells was investigated. JMV-320 and JMV-332, conformationally restrained cyclic analogs of the C-terminal hepta- and hexapeptides of CCK, respectively, and A-63387, a conformationally restrained analog of the C-terminal tetrapeptide of CCK, are CCK-B/gastrin selective ligands. JMV-180, Boc-Tyr(SO<sub>3</sub>)-Nle-Gly-Trp-Nle-Asp-2-phenylethyl ester, is a CCK-7 analog which is non-selective for CCK-A and B receptors. JMV-180, JMV-320 and JMV-332 potently inhibited specific binding of 1251-CCK-8 to CCKB/gastrin receptors expressed on the SCLC cell line NCI-H345 (H345) with IC50 values of 4.9, 1.8 and 7.0 nM, respectively. JMV-320 and JMV-332 stimulated intracellular calcium ([Ca<sup>2+</sup>]<sub>1</sub>) release in a dose-dependent manner. In contrast, JMV-180 did not stimulate (Ca<sup>2+</sup>]<sub>1</sub> but inhibited the [Ca<sup>2+</sup>]<sub>1</sub> release elicited by 10 nM CCK-8 in a dose-dependent manner. These data indicate that JMV-320, JMV-332 and A-63387 function as CCK-B/gastrin receptor antagonists while JMV-180 functions as a CCK-B/gastrin receptor antagonist in H345 cells.

## 94.8

PURIFICATION AND CHARACTERIZATION OF A MEMBRANE-BOUND CHOLECTSTOKININ-BINDING PROTEIN FROM HUMAN BRAIN.R.LU.\*
M-C Liu.Y.Gu.Q.Shen and Y.Yu.Department of Neurobiology,
Shanghai Medical University, Shanghai 200032, P.R. China

A membrane-bound cholecystokinin octapeptide(CCK-8)-binding protein was purified from human brain cortex using column affinity chromatography on immobilized sulfated tyrosine and CCK-8. The purified protein was electrophoresis homogenity with an apparent molecular weight of 35,000 as determined by sodium dodecyl sulfate-polyacrylamide gel electrophoresis under reducing conditions. Using immobilized CCK-8 fragment as ligands, the 35-KDa protein was found to bind CCK-8 (sulfated and nonsulfated form) and Asn-Tyr(SO3)-Met, but not to bind Asn-Tyr-Met-Gly and Met-Gly-Trp-Met-Asp-Phe, suggested that either sulfated tyrosine or enough length of the peptides was necessary for the binding. The binding between CCK-8 and CCK-binding protein was PH-dependent, being strong from PH 5.5 to 7.5, beyond this range becoming weaker. Divalent cations Ca<sup>2+</sup>, Mg<sup>2+</sup> and Mn<sup>2+</sup> with 5 mM of concentration added in the assay mixture significantly promoted the binding. The seventeen amino acid sequence of N-terminal of the CCK-binding protein was almost same as mitochondrial malate hydrogenase of pocine heart.

AUTORADIOGRAPHIC ANALYSIS OF GASTRIC INHIBITORY POLYPEPTIDE BINDING SITES IN THE RAT BRAIN, Andrew M. Kaplan and Steven R. Vigna\*, Depts. of Cell Biology and Medicine, Duke University Medical Center, Durham, NC 27710.

Synthetic porcine gastric inhibitory polypeptide (GIP) was iodinated and purified by MPLC and used to localize GIP binding sites in frozen sections of rat brain. Saturable binding was present in several brain regions including cortex, anterior olfactory nucleus, lateral septal nucleus, subiculum, inferior colliculus, and inferior olive. Saturable 125I-GIP binding was time-dependent, reversible, high affinity, and specific for GIP. Peptides with amino acid sequences similar to GIP such as secretin, vasoactive intestinal polypeptide, glucagon, and peptide histidine isoleucine did not inhibit saturable 125I-GIP binding. Saturable 125I-GIP binding was not observed in other rat organs surveyed such as spinal cord, pituitary, stomach, small intestine, colon, pancreas, liver, heart, and skeletal muscle. We conclude that a saturable 125I-GIP binding site with the pharmacological properties of a GIP receptor is expressed in certain regions of the rat brain.

#### 194.11

DISTRIBUTION OF <sup>125</sup>I-GALANIN BINDING SITES IN THE ADULT AND DEVELOPING BRAZILIAN OPOSSUM BRAIN. <u>J. K. Elmquist\*, A. Kao, M. C. Kuehl-Kovarik, and C.D. Jacobson</u>. Department of Veterinary Anatomy and Neuroscience Program, Iowa State University, Ames, IA 50011.

We have previously described the distribution of galanin (GAL)-like immunoreactivity in the adult and developing Brazilian opossum brain. In this study immunoreactivity was shown to be present in several areas of the brain as early as postnatal day 1 (1PN), when neurogenesis is actively taking place in Monodelphis domestica. To understand the functionality of these results, the elucidation of GAL binding sites in the brain of adult and developing brains was accomplished using 125 I labelled GAL as described previously for cholecystokinin (Neurosci. Abst. 17:807). The distribution of GAL receptors in the adult brains was very similar to that which has been reported in other species including the rat. In the 1 PN brains, light binding was detected in the forming brainstem in the presumptive solitary and spinal trigeminal nuclei. Outside the brain moderate binding was seen in the vagus nerve. By 5 PN, light to moderate binding was detected in the forming ventral hypothalamus and amygdala. Moderate to dense binding was seen in the forming midbrain and brainstem at this age. By 11 PN, dense binding was observed in the basal hypothalamus, septum, amygdala, tectum, and medulla. The pattern seen at 25 and 60 PN was comparable to that seen in the adult. In summary, we have found that GAL receptors as evidenced by receptor autoradiography, are detectable as early as 1-5 PN. Coupled with the presence of immunoreactivity at this stage of development, our results indicate that GAL may be playing a role in development and differentiation of the opossum.

A POTENT NON-PEPTIDE ANTAGONIST OF NEUROTENSIN RECEPTORS: EVIDENCE IN THE GUINEA-PIG BRAIN. D.GuIly¹·M.HeauIme¹·P.Kitabgl²·P.Soubrie¹·W.Rostène³ and G.Le Fur¹¹¹SANOFI RECHERCHE 31036 Toulouse, and 34082 Montpellier, France; ²IPMC-CNRS 06560 Valbonne, France; ³INSERM U.339 Hôpital St Antoine 75012 Parls, France.

Neurotensin (NT) has been shown to possess several neuromodulatory roles on brain functions, mediated by an interaction of NT with specific membrane receptors. However, the lack of specific NT receptor antagonist has prevented the study of the specificity of these physiological actions. The present data describe the properties of one such potent and selective non-peptide antagonist in the guinea-pig brain. SR 48692 competitively inhibited 125INT specific binding to homogenates from adult guinea-pig brain with an IC50 of 1nM. Autoradiographic data obtained on sections at both striatal and midbrain levels confirmed that increasing concentrations of SR 48692 produced a dose-dependent decrease of 125INT labeling. 1µM SR 48692 totally inhibited 125INT binding in both ventral tegmentum and substantia nigra and was found to be more potent than unlabeled NT Itself. Stimulation of 3H-dopamine release from striatal sections induced by 10 nM NT was dose-dependently counteracted by SR 48692 with an efficacy (IC50 0.5nM) quite similar to its binding affinity. In contrast, up to 100 nM, SR 48692 did not affect the spontaneous and K+-evoked release of 3H-dopamine indicating a lack of agonistic effect of the compound. SR 48692 is the first non-peptide antagonist of NT receptors described so far, which offers the possibility to study the physiological roles of NT.

STRUCTURAL CHARACTERIZATION OF VARIOUS FRAGMENTS AND ANALOGS OF CALCITONIN GENE-RELATED PEPTIDE. <u>A. Fournier\* 1, M. Mimeault¹, S. St-Pierre¹, Y. Dumont² and R. Quirion², ¹INRS-Santé, Université du Québec, Pointe-Claire (QC), Canada and ²Douglas Hospital Research Centre, McGill University, Verdun (QC), Canada.

Biological studies using the fragment hCGRP<sub>8-37</sub> and the linear analog [Cys-(Acm)²-²]hCGRPα suggested a heterogeneity of CGRP receptors. Moreover,</u>

conformational analysis of hCGRPα and its related fragments and analogs, proposed the presence of a helical stretch in the molecule, involving amino acid residues 8 to 18. Therefore, we evaluated the biological effects of hCGRP $\alpha$  and homolog peptides in relation to their structural characteristics. Thus, hCGRPa exhibited potent agonistic properties in the guinea pig atrium and rat vas deferens bloassays. However, the opening of its disulfide bridge gave an analog ([Cys(Acm)<sup>2,7</sup>]hCGRPα) almost inactive in the guinea pig atria but still showing substantial agonistic effects in the rat vas deferens. On the other hand, hCGRP<sub>8-37</sub> displayed potent antagonistic properties in the guinea pig atrial pre paration while it was much less potent in inhibiting the rat vas deferens twitch response. Structural analyses showed that the removal of valine-8 in the fragment hCGRP<sub>8-37</sub> did not alter the  $\alpha$ -helix stability nor the antagonistic properties of the fragment. However, subsequent deletion of N-terminal amino acids resulted in an important decrease of antagonistic potency as well as in a substantial reduction of the  $\alpha$ -helix content. Thus, it suggests that the  $\alpha$ -helix content might play a predominant role in the interaction between the so-called CGRP, receptor and its ligand. On the other hand, helical stability does not appear as a highly critical parameter for the CGRP<sub>2</sub> receptor. Indeed, although [Cys-(Acm)<sup>2,7</sup>]hCGRP $\alpha$  exhibited 77% of the helical content of hCGRP $\alpha$ , it displayed a relative potency of only 2% in the vas deferens preparation. Supported by the MRCC.

SR 48692: A POTENT NON-PEPTIDE ANTAGONIST OF NEUROTENSIN RECEPTORS IN MURINE BRAIN. P. Kitabgi\*1, C. Labbé-Jullié<sup>1</sup>, J. Mazella<sup>1</sup>, D. Gully<sup>2</sup>, M. Poncelet<sup>2</sup>, P. Soubrié<sup>2</sup>, G. Le Fur<sup>2</sup>, A. Brouard<sup>3</sup>, D. Pelaprat<sup>3</sup> and W. Rostène<sup>3</sup>. <sup>1</sup>IPMC-CNRS, 06560 Valbonne, France; <sup>2</sup>SANOFI RECHERCHE, 31036 Toulouse, France; <sup>3</sup>INSERM U339, Hôpital St-Antoine, 75012 Paris, France.

St-Antoine, 75012 Paris, France.

The CNS actions of the tridecapeptide neurotensin (NT) have been extensively studied in the rat and mouse. However, the lack of NT antagonist has hampered the elucidation of its central physiological roles. Here we demonstrate that SR 48692 is a potent and selective non-peptide NT antagonist in murine brain. SR 48692 inhibited the specific binding of 1251-NT to adult rat and mouse brain homogenates with IC50 values of 35-80 nM. In the presence of 10 µM levocabastine (LC) which selectively and totally blocks NT binding to its low affinity binding sites in adult rat and mouse brain, IC50's were decreased to about 5 nM. In cultured rat mesencephalic neurons, new-born mouse brain homogenates, and membranes from COS 7 cells transfected with the cloned high affinity rat brain NT receptor, systems all devoid of LC-sensitive NT binding sites, IC50's for SR 48692 binding ranged from 4 to 13 nM. Altogether, these data show that in murine brain SR 48692 binds preferentially and with high potency to the functional, high affinity, LC-insensitive NT receptor. Unitateral intrastriatal injections of 10 pg NT in mice induced contralateral rotations which were dose-dependently inhibited by prior p.o. or i.p. administration of SR 48692. Time-course studies with a maximally effective dose of 80 µg/kg (p.o.) showed that SR 48692 antagonism was significant as soon as 30 min post-injection, maximal (85%) 1 to 2 h post-injection and still significant after 8 h. These data demonstrate that SR 48692 has a good oral bioavailability, crosses the blood brain barrier and exerts long-lasting NT antagonism in vivo.

## 194.14

THE NONPEPTIDE NK-1 ANTAGONIST CP-96,345 MODULATES [3H]NITRENDIPINE BINDING TO L-TYPE CALCIUM CHANNELS IN RAT CARDIAC AND CORTICAL MEMBRANES. A.W. Schmidt\*, S. McLean and J. Heym. Central Research Division, Pfizer Inc., Groton, CT. 06340-1596.

Pfizer Inc., Groton, CT. 06340-1596.

Recently, we reported that the nonpeptide NK-1 antagonist CP-96,345 and its 2R,3R enantiomer CP-96,344 interact with L-type calcium channels (Eur. J. Pharmacol., in press). CP-96,345 and CP-96,344 inhibit [3H]desmethoxyverapamil binding to rat cardiac membranes with Ki values of 25 ± 2 and 28 ± 4, respectively. In addition, these compounds produced a dose-dependent enhancement of [3H]nitrendipine ([3H]NITR) binding in rat cortex with a 3-fold increase in specifically bound [3H]NITR obtained at a concentration of 10 μM CP-96,345 or CP-96,344. The benzothiazepine calcium channel antagonist diltiazem (DLT) is reported to enhance [3H]NITR binding by allosteric modulation of the dihydropyridine (DHP) binding site (Janis et al., 1987). Both CP-96,345 and CP-96,3444 inhibit [3H]DLT binding to rat cardiac membranes with Ki values of 43 ± 10 and 31 ± 10, respectively. To further investigate the interaction of CP-96,345 and CP-96,3444 with the DHP-sensitive calcium channel site, saturation studies were carried out in rat cardiac and cortical membranes to determine if the Kd or Bmax of [3H]NITR changed in the presence of 10 μM CP-96,345, 10 μM CP-96,344 or 10 μM DLT. In rat cortical membranes, the Kd for [3H]NITR increased 4-fold in the presence of 10 μM CP-96,345, or CP-96,344. In the presence of 10 μM DLT, the Kd for [3H]NITR increased 2-fold. No change in Bmax was observed in experiments with either CP compound or DLT. Similar results were obtained using rat cardiac tissue. These results are in agreement with previously reported data for DLT.

USE OF SELECTIVE ANTAGONISTS TO DISSOCIATE THE CENTRAL CARDIOVASCULAR AND BEHAVIORAL EFFECTS OF NEURO-KININS ON NK<sub>2</sub> and NK<sub>3</sub> RECEPTORS IN THE RAT. P. Picard<sup>1</sup>, D. Regoli<sup>2</sup> and R. Couture<sup>\*1</sup>, Dept. Physiology, Faculty of Medicine, Université de Montréal, Montréal, Qué., Canada H3C 3J7 and <sup>2</sup>Dept. Pharmacology, Sherbrooke University, Sherbrooke, Qué., Canada, JIH 5N4.

The effects of intracerebroventricular (i.c.v.) injection of highly selective and potent NK<sub>2</sub> (SR-48968) and NK<sub>3</sub> (R-487, [Phe<sup>7</sup>, $\beta$ -Ala<sup>8</sup>]NKA(4-10)) receptor antagonists were assessed on the cardiovascular and behavioral responses elicited by the i.c.v. injection of substance P (SP), neurokinin A (NKA) and [MePhe<sup>7</sup>]-neurokinin B (NKB) in the conscious freely moving rat. SP, NKA and [MePhe<sup>7</sup>]-NKB (25 pmol) induced mean arterial pressure and heart rate increases of the same magnitude that reached a maximum at 2-3 min post-injection. The cardiovascular responses lasted for about 30 min and were associated with typical behaviors (face washing, grooming, digging, sniffing, rearing and wet dog shakes). The cardiovascular and behavioral responses (except for wet dog shakes) elicited by NKA were significantly and dose-dependently reduced by 0.65 - 6.5 nmol SR-48968. However, the latter antagonist had no effect on the SP or [MePhe<sup>7</sup>]-NKB mediated responses. R-487 (0.65 pmol) inhibited the cardiovascular response and wet dog shakes produced by [MePhe7]-NKB only. SR-48968 and R-487 were devoid of cardiovascular and behavioral activity and blocked in a reversible manner. These results suggest that the central effects of NKA and [MePhe7]-NKB are mediated by specific receptors, different from those activated by SP, and which appear to belong to NK2 and NK3 receptor subtypes, respectively. [Supported by the MRC of Canada].

TACHYKININ INDUCED PHOSPHATIDYLINOSITOL HYDROLYSIS IN TRANSFECTED CHINESE HAMSTER OVARY CELLS R. Raddatz\* P. Blount, R.M. Snider, J.E. Krause, Dept. Anatomy and Neurobiology Washington University School of Medicine, St.Louis, MO 63110 and Central Research Division, Pfizer Inc Groton. CN 66340

We are interested in the functions of Substance P (SP) in target tissues and in the cellular mechanisms by which SP mediates its diverse biological roles. Chinese hamster ovary (CHO) cells transfected with the CDNA for either rat NK-1 or rat NK-2 receptors expressing approximately 250,000 high affinity binding sites for 1251-V1-SP per cell or 280,000 high affinity binding sites for 1251-NPy per cell, respectively, have been established as model cell systems to examine the kinetics of ligand binding and tachykinin-induced second messenger responses (Takeda et al., 1992). In this study we further characterize tachykinin-induced second messenger responses. In NK-1 receptor transfected CHO cells SP induces a rapid and transient rise in IP3 concentration as measured by a mass assay. However, flux through the inositol phosphate pathway continues for at least 30 minutes, and then plateaus, as evidenced by the accumulation of 3H-inositol phosphates (IPs) in cells prelabelled with 3H-myo-inositol. The addition of the SP antagonist CP-96,345 at 15 minutes after SP stimulation results in a rapid cessation of further 3H-IPs accumulation indicating that the receptor is repeatedly activated during this time. In cell lines expressing various densities of NK-1 receptor the amount of 3H-IPs produced is correlated with receptor number. In the CHO cells expressing NK-1 receptors NKA is a full agonist with similar kinetics of response as compared to SP induced 3H-IPs. NKA also elicits a similar 3H-IPs response from CHO cells expressing the NK-2 receptor type. A cell line expressing both NK-1 and NK-2 receptors at similar numbers of high affinity sites has been used to characterize responses in cross-stimulation experiments. These studies indicate that following maximal stimulation with SP, NKA can cause additional IPs accumulation while readdition of SP elicits no further response. We conclude that these transfected cell lines represent useful model systems to examine tachykinin receptor functions.

## 194.19

DISTRIBUTION OF TRH-RECEPTOR MRNA IN THE RAT BRAIN: AN IN SITU HYBRIDIZATION STUDY L. Cala L. Giardino: S. Ceccatelli R.P. Elde and T. Hökfelt.

<sup>1</sup> Institute of Human Physiology, University of Cagliari, Italy and

Dept. of Histology and Neurobiology, Karolinska Institutet, Stockholm, Sweden, 104 01.

Using in situ hybridization histochemistry we have investigated the distribution of thyrotropin releasing hormone receptor (TRH-r) mRNA in the central nervous sytem of adult male rat. Coronal sections were hybridized using synthetic oligonucleotide probes complementary to mRNA for TRH-r. Among the investigated areas of the forebrain, a strong TRH-r mRNA labeling was seen in the medial portion of the nucleus accumbens, septal nuclei, bed nucleus of the stria terminalis, nucleus of the horizontal limb of the diagonal band, primary olfactory cortex, paraventricular thalamic nucleus, medial anterior cortical, central nuclei of the amygdala and ventral hippocampus. A moderate TRH-r mRNA labeling was seen in the medial preoptic areas and in the hypothalamus. In the medulla oblongata, a dense TRH-r mRNA labeling was found in the hypoglossal and in the ambiguus nuclei. A moderate labeling was seen in the vagal complex, particularly around the area postrema. The results show that the TRH-r, just as the TRH peptide, has a wide distribution in the central nervous system.

NK-3 TACHYKININ RECEPTORS LOCALIZED ON MIDBRAIN DOPAMINE (DA) NEURONS. A. Jon Stoessi\*, Clinical Neurological Sciences, Univ. of Western Ontario. London. Ontario. Canada N6A 5A5.

Although there is a prominent SP-containing projection from the striatum to the substantia nigra (SN), the SN is devoid of SP receptors. Studies using nonselective tachykinin ligands have suggested the presence of NK-3 binding sites in this region. We have demonstrated preferential stimulation of DA-mediated behaviours following stereotactic infusion of the NK-3 agonist senktide into the SN or ventral tegmental area (VTA). In the current study, we have sought more direct evidence for DA neuronal localization of NK-3 receptors. Unilateral destruction of ascending DA pathways was accomplished by stereotactic infusion of 6-OHDA (8 ug/2 ul) into the medial forebrain bundle of male Sprague-Dawley rats (n = 4). 2 weeks after surgery, the animals were sacrificed. 10 um coronal cryostat sections through the striatum and SN were incubated with [3H]senktide to delineate NK-3 sites. In order to verify the efficacy of the lesion, adjacent sections were incubated with [°H]mazindol and the sections were opposed to °H-sensitive film. Following development, the film was analyzed using quantitative densitometry and side-to-side comparisons were made using paired t-tests. 6-OHDA lesions resulted in profound loss of [3H]mazindol binding in both midbrain and striatum (STR). There was a 42% decrease of [ $^{3}$ H]senktide binding in the lesioned SN ( $\rho$ <0.03), but only a 12% decrease in the VTA ( $\rho$ =n.s.). There were non-significant decreases of [ $^{3}$ H]senktide binding ipsilateral to the lesion in the dorsomedial (20%), ventromedial (15%) and ventrolateral STR (20%), but a more substantial decrease (40%, *p*<0.05) in the dorsolateral STR. These findings suggest that NK-3 receptors are located on DA neurons of the SN, and possibly on their terminals in the STR. Binding sites in the VTA may be on non-DA neurons

THE EXTRACELLULAR DOMAIN OF THE NEUROKININ-1 RECEPTOR IS REQUIRED FOR HIGH AFFINITY BINDING OF PEPTIDES. Tung Ming Fong', Hong Yu, Ruey-Ruey C. Huang & Catherine D. Strader. Dept. of Mol. Pharmacol., Merck Research Laboratories, PO Box 2000, Rahway, NJ, 07065

The neurokinin-1 receptor binds neurokinin peptides with

The neurokinin-1 receptor binds neurokinin peptides with the potency order of substance P > substance K > neurokinin B. Elucidating the molecular basis of differential peptide selectivity will require the localization of the binding domain on the receptor. In the present report, mutagenesis and heterologous expression experiments reveal that a segment of the extracellular N-terminal sequence of the neurokinin-1 receptor is required for the high affinity binding of substance P and related peptide agonists. Substitution of amino acid sequence at the N-terminal region affects the binding affinity of both intact peptides and a C-terminal substance P fragment. Glycosylation of the receptor does not change the peptide binding affinity. In addition, substitution of the valine-97 residue in the rat neurokinin-1 receptor by a glutamate residue increases the binding affinity of neurokinin B but not substance P or substance K, suggesting that the second extracellular segment is involved in peptide selectivity. These results indicate that the extracellular domain of neurokinin-1 receptor plays a critical role in peptide binding.

## 194.20

QUANITATION OF NEUROTENSIN RECEPTOR mRNA USING POLYMERASE CHAIN REACTION. B. Myers\*, A. Levey and C.B. Nemeroff, Depts. Pharmacology, Neurology and Psychiatry, Emory Univ. Sch. Med., Atlanta, GA 30322.

Neurotensin (NT) is an endogenous neuropeptide hypothesized to be involved in the pathophysiology of schizophrenia and the mechanism of action of antipsychotic drugs. NT concentrations are specifically increased in the nucleus accumbens and caudate following antipsychotic drug treatment. Recently, a neurotensin receptor cDNA (NT-R) was cloned from rat brain by Nakanishi et al (1991). In order to study the regulation of NT-R gene expression, we have developed a method to quanitate NT-R mRNA with the polymerase chain reaction (PCR). Using as little as 100 pg of NT-R cDNA inserted in the plasmid pBluescript II KS+, we were able to amplify, using PCR, segments of the NT-R cDNA encoding the putative C-terminus (141 base pairs), the third cytoplasmic loop (132 base pairs) and a 500 base pair segment encoding the third cytoplasmic loop to the C terminus. Amplification of 100pg-40ng of NT-R cDNA demonstrated a proportional increase in the amount of ethidium bromide staining after electrophoresis on agarose gels. These same NT-R segments were amplified from total rat brain mRNA and poly-A mRNA by reverse PCR. This assay will allow us to quantitate changes in NT-R mRNA levels following treatment with antipsychotic drugs, and potentially, in humans with neuropsychiatric disease. (NIMH MH-39415)

ISOLATION OF A MEMBRANE PROTEIN FROM RAT LIVER WITH PROPERTIES OF THE PUTATIVE SIGMA RECEPTOR/BINDING SITE. G.K. Ehrlich, \*G. Singh¹, G. Lem¹, D.I. Schuster¹, H. Tiedge², J. Brosiug², and R.B. Murphy². ¹ Department of Chemistry and Center for Neural Science, New York University, N.Y., NY 10003 and ²Fishberg Research Center for Neurobiology, Mt. Sinai School of Medicine, Gustave Levy Place, N.Y., NY 10029.

The sigma receptor/binding site, a putative receptor protein which is found in brain and liver, has been purified from a detergent-solubilized rat liver membrane preparation by affinity chromatography. An affinity column was constructed using an oximino derivative (OB 101) of the neuroleptic haloperidol, which is known to have high affinity for the sigma site. The ligand was linked through a spacer arm to agarose. The affinity column selectively retained a single 28 kDa polypeptide, which could be eluted from the column with 1  $\mu$ M haloperidol. A control affinity column, was prepared from an oximino derivative of a ketone which did not associate with the sigma receptor/binding site. The control column did not selectively occlude this 28 kDa component. The affinity purification, followed by transfer to wheat germ agglutinin-agarose and elution with N-acetyl-D-glucosamine, resulted in ca. 3,000-fold purification of the 28 kDa component. The enantiomeric benzomorphans, levaliorphan (50 nM) and dextrallorphan (50 nM), were used to elute the affinity column; only dextrallorphan, which potently associates with the sigma receptor/binding site, removed the 28 kDa component, with levallorphan did not. The purified 28 kDa component was homogeneous on SDS-PAGE and is, as isolated, N-terminal blocked. The observed molecular mass is in accord with that of the sigma receptor/binding site observed by others using photoaffinity labeling. (Supported by NIDA DA 05728 (RBM) and New York University.)

## 195.3

Sigma Binding in Brain and Liver from Rats Deficient In Cytochrome P450-2D1. A.L. Jewell\*, P.J. Wedlund and L.P. Dwoskin. College of Pharmacy, University of Kentucky, Lexington, KY 40536-0082.

Substrates for cytochrome P450-2D1 exhibit a high affinity for sigma binding sites suggesting that sigma sites may be associated with the cytochrome P450-2D1 isozyme. contrast to male and female Sprague Dawley (SD) rats, both male and female Dark Agouti (DA) rats do not express the P450-2D1 gene product. In the present study, binding of the selective sigma ligand (+)[3H]3-PPP, in whole brain and liver homogenates from female DA and control female SD rats was examined. If a subpopulation of sigma sites are associated with the P450-2D1 enzyme, then the number  $(B_{\text{max}})$  of sigma binding sites is predicted to decrease in female DA rat brain and liver compared to control female SD rat tissues. present study demonstrates a significant decrease (63 and 74% of control female SD values) in  $B_{\text{max}}$  with no alteration in affinity  $(K_0)$  of  $(+)[^3H]3$ -PPP binding in female DA rat brain and liver, respectively. These results suggest that a portion of sigma sites in brain and liver may be associated with cytochrome P450-2D1. (Supported by University of Kentucky Medical Center Small Research Grant.)

## 195.5

IDENTIFICATION AND CHARACTERIZATION OF SIGMA RECOGNITION SITES ON ESTABLISHED TUMORS AND TUMOR CELL LINES. <u>I. E. Taylor\* and S. R. Keyes</u>, Biomeasure Inc., 9-15 Ave E., Hopkinton, MA 01748

Although sigma recognition sites are widely expressed in neural, endocrine, and immune tissues, the functional significance, except for a possible psychotropic action, and the cellular transduction mechanisms associated with these binding sites are unclear. Recently, Bem et al. (Cancer Res. 51:6558,1991) observed that fresh surgical specimens of various human tumors were enriched in sigma binding sites compared to control nonmalignant tissue, which indicates a possible role in neoplastic cell proliferation and tumor growth. While examining the therapeutic potential of various neuropeptides, opioids, and opioid-related compounds as antitumor agents, we also observed that established in vivo tumors and clonal tumor cell lines were highly enriched in sigma recognition sites. For the five tumors or tumor cell lines examined thus far for [<sup>3</sup>H]DTG binding, the following receptor concentrations (fmol/mg protein) were observed:

 $\begin{array}{lll} \text{C6 rat glioma} & 9483 \pm 426 \\ \text{A549 human non-small cell lung} & 6556 \pm 2811 \\ \text{NCI-H69 human small cell lung} & 4879 \pm 103 \\ \text{B16 mouse melanoma} & 1816 \pm 154 \\ \text{AR42J rat pancreas} & 178 \pm 13 \\ \end{array}$ 

The rank order of potency for the ability of various sigma ligands to compete with  $[^3H]DTG$  binding was similar for each tumor: haloperidol > DTG > BMY 14802 > 3-PPP > PCP. However, the absolute potencies for some of the ligands were less than that observed in membranes prepared from guinea-pig brain. These results may indicate the possibility of receptor heterogeneity. Preliminary evidence obtained from growth experiments also showed that haloperidol and DTG inhibited the proliferation of B16 cells in vitro.

#### 195.2

LACK OF CHANGES IN SIGMA RECEPTORS IN THE BRAINS OF GENETICALLY DYSTONIC RATS. A. D. Weissman\* D. J. McCann\* J. F. Lorden\* and T.-P. Su\* 1. Neuroscience Branch, NIDA Addiction Research Center, P. O. Box 5180, Baltimore, MD 21224; 2Dept. Psychol., Univ. Alabama, Birmingham, AL 35294.

Sigma receptors have been proposed to play a role in either the etiology or expression of dystonic symptoms in rats and this effect may be predicted at experite briging in Malters at all. Niverseless.

Sigma receptors have been proposed to play a role in either the etiology or expression of dystonic symptoms in rats and this effect may be mediated at specific brain loci (Walker et al., Neurology 38:961). Consonant with this hypothesis is a report of alterations in sigma receptors (↑B<sub>max</sub> and ↑K<sub>d</sub> for [³H]DTG) in brains of genetically dystonic rats (Bowen et al., Eur. J. Pharmacol., 147:153). [³H]DTG is now known to label two distinct binding sites in rat bain, termed "sigma-1" and "sigma-2." The present study was initiated to evaluate the relative contribution of these two sites to the reported differences in brains of dystonic rats. Sigma-1 sites were defined by 5 nM (+)[³H]SKF-10,047 in the presence of 300 nM MK-801 (included to block binding to PCP receptors). Sigma-2 sites were labeled with 5 nM [³H]DTG in the presence of 1 μM (+)SKF-10,047 (included to block binding to sigma-1 sites). Preliminary results did not reveal compelling differences between dystonic and normal brains under either of our selective assay conditions.

In an attempt to replicate the earlier report of alterations of sigma binding in this strain of dystonic rats, we performed [<sup>3</sup>H]DTG saturation experiments. The results failed to confirm a difference between normal and dystonic litermates. These data question the relative importance of sigma sites in this animal model of dystonia.

### 195.4

CHARACTERIZATION OF SIGMA SUBTYPE BINDING IN GUINEA PIG BRAIN MEMBRANES. J.B. Fischer\*, K.J. Burke Howie, J.A. Dunn, S.Y. Ablordeppey¹ and R.A. Glennon¹. Cambridge NeuroScience, Cambridge, MA 02139 and ¹Dept. Med. Chem., Med. Coll. Virginia, VCU, Richmond VA 23298.

The literature contains a number of suggestions of subtypes of the Sigma receptor. Hellewell and Bowen (Brain Res. 527:244, 1990) proposed characteristics for two putative subtypes, named Sigma<sub>1</sub> and Sigma<sub>2</sub>. The primary distinction between these two sites is the affinity of the (+) isomers of the benzomorphan opiates for the binding sites. We have developed separate assays for these two sites using [³H](+)pentazocine (courtesy of Dr. S. Hurt, DuPont/NEN) for the Sigma<sub>1</sub> site, and [³H]DTG (which labels both sites with about equal affinity) in the presence of unlabeled (+)pentazocine for the Sigma<sub>2</sub> site. (+)Pentazocine showed the highest Sigma<sub>1</sub> selectivity (500-fold). Haloperidol and (+)3-PPP were marginally Sigma<sub>1</sub> selective (10-20 fold). No compounds were found to have high Sigma<sub>2</sub> selectivity; however several compounds had slightly higher affinity for the Sigma<sub>2</sub> site (BMY 14802, rimcazole, ifenprodil). In a series of related, novel Sigma ligands a broad range of selectivities was also found, allowing preliminary structure-activity analysis for the two sites. The development and use of selective ligands for these Sigma receptor subtypes should allow a better understanding of the functional roles of these receptors.

## 195.6

ZINC IS A POTENTIAL ENDOGENOUS LIGAND FOR ONE FORM OF THE HALOPERIDOL-SENSITIVE SIGMA RECEPTOR. Mark Connor\* Terrell Patterson and Charles Chaykin, Dept of Pharmacology, Univ of Washington, Seattle WA 98195.

We have identified two components in brain extracts able to displace radioligand binding to the haloperidol-sensitive  $\sigma$  receptors. Ionic zinc displaces the non-selective o ligand 1,3-di(2-[5-3H]tolyl)guanidine ([3H]-DTG) from two binding sites in rat brain membranes. The Ki of Zn<sup>2+</sup> for the cation sensitive ( $\sigma_2$ ) site was  $48 \pm 14 \,\mu\text{M}$ , and for the cation-insensitive (σ<sub>1</sub>) site, the Ki was 2.4 ± 0.5 mM. Ionic zinc is present in synaptic vesicles in the brain and may function to regulate binding at the  $\sigma_2$  site. To test this hypothesis, we measured the effects of metallothionein peptide 1, a specific zinc chelator, on the radioligand displacement caused by the stimulated release of putative endogenous σ ligands in the rat hippocampus. High frequency, focal electrical stimulation of the hilar region of the hippocampus caused a decrease in the specific binding of [3H]-DTG and [3H]-(4)-pentazocine to  $\sigma$  sites. The decrease in [3H]-DTG binding was largely blocked by metallothionein, whereas the decrease in [3H-(+)-pentazocine binding was unaffected. These results suggest that Zn2+ may act as an endogenous ligand at σ2 sites in the rat hippocampal slice, and suggest that there are other endogenous ligands for  $\sigma$  sites that can be released by focal electrical stimulation. In addition, we have isolated a trypsin-sensitive substance from rat brain that displaces both (3H)-DTG and [3H)-(4)pentazocine from haloperidol-sensitive or binding sites. The substance was recovered from acid extracts of brain by ion exchange chromatography and further purified by C18 HPLC. The functional significance of these two endogenous factors remains to be established. Supported by MH46501.

MULTIPLE BINDING SITES FOR SIGMA LIGANDS IN RAT SPLEEN. B.B. Whitlock and S.A. Wolfe, Jr. Department of Medical Microbiology and Immunol., Ohio State Univ., Columbus, OH 43210.

In previous studies we detected high concentrations of  $\sigma$  receptors in rat spleen, and found that  $\sigma$  agonists suppressed in vitro immune activities such as mitogen- and antigen-driven lymphocyte proliferation. However, the rank order of drug immunosuppressive potency did not correlate well with the pharmacology of the  $\sigma$  receptor. Therefore, we hypothesized that additional binding sites for  $\boldsymbol{\sigma}$  agonists may be active in immune cells. In the present investigation we have examined rat spleen for such additional binding sites. In competition studies, a major fraction of d-[ $^3$ H]pentazocine and d- $^3$ -( $^3$ - $^3$ - $^4$ ) studies, a major fraction of  $a^{-5}$ -[5H]pentazocine and  $a^{-3}$ -[3-H]) hydroxyphenyl)N-(1-propyl-2,3-[3H]) piperidine  $(d^{-[3H]-3}$ -PPP) binding was not sensitive to 10-4 M haloperidol, but was blocked by 10-5 M d-N-allylnormetazocine (d-NANM, or SKF<sub>10,047</sub>). In contrast, specific binding of the  $\sigma$  ligand [3H]-1,3-di-(2-tolyl) guanidine ([3H]DTG) was completely blocked by either 10-5 M haloperidol or 10-4 M d-NANM. DTG competed for [3H]haloperidol-labeled of receptors, but [3H]DTG also labeled additional sites in rat spleen that had lower affinity for d-benzomorphans than do o receptors. From these observations, it appears there are at least three binding sites for  $\sigma$  ligands in rat spleen: 1) the well-described  $\sigma$  receptor, 2) a haloperidol-sensitive site that binds d-pentazocine, d-NANM and DTG, and 3) a relatively haloperidol-insensitive site that binds d-3-PPP and d-NANM. The non-o binding sites were more prevalent in rat spleen than in cerebellum. The role of these additional binding sites in immune modulation by  $\boldsymbol{\sigma}$  agonists is yet to be determined.

MULTIPLE SIGMA BINDING SITES IN GUINEA-PIG BRAINS. Nicholson, J.H. Connick\*, L. France, G. Hanlon and P.K. Fox. Organon Labs., Newhouse, Lanarkshire ML1 5SH, U.K. Evidence is accumulating for multiple sigma sites in the mammalian CNS. Mussachio et al. (Eur. J. Pharmacol., 1991, 206: 261-264) have suggested that  $^4$  sites (R1-R4) are present. We have addressed this problem and have examined sigma site - G protein coupling in guinea-pig brain membranes. DTG, (+)3PPP and dextromethorphan displaced [3H]-DTG (3.4 nM) with low Hill slopes of 0.5, 0.6 and 0.6, respectively. In the presence of Gpp(NH)p (100  $\mu$ M), the [3H]-DTG specific binding was reduced by 31.7%, the Hill slope of (+)3PPP was increased to near unity, the ability of dextromethorphan to displace DTG was virtually abolished and the Hill slope for DTG remained low (0.7), indicating the presence of at least two binding sites. Gpp(NH)p apparently removes a dextromethorphan/DTG high affinity site, corresponding to R1 of Mussachio et al. (1991). two binding sites for DTG remaining in the presence of Gpp(NH)p may be R3 and R4, dextromethorphan has a low affinity for these sites. R2, a dextromethorphan high affinity site, does not appear to be labelled by [3H]-DTG as this compound has a low affinity and dextromethorphan is ineffective in the presence of Gpp(NH)p. The present study suggests that DTG binds to at least three sites in guineapig brain at least one of which is G protein linked. the presence of R2 is assumed, the present study is in agreement with the model of Mussachio et al. (1991).

## 195.11

DESIGN OF DIVALENT LIGANDS AS PROBES FOR & RECEPTOR TOPOGRAPHY. 4-PHENYLPIPERIDINYL AND 4-PHENYLPIPERAZINYL ALKYL-SPACED 5,5-DIPHENYLHYDANTOINS (PHENYTOIN). R. L. Hudkins. 1 and D. L. DeHaven-Hudkins<sup>2</sup>. 1 Albany Molecular Research, Watervliet, NY 12189 and 2 Dept. Enzymology & Receptor Biochemistry, Sterling Winthrop Pharmaceuticals Research Division, Malvern, PA 19355.

Divalent ligands are defined as molecules which incorporate two discrete pharmacophores linked through a spacer. Recently we have demonstrated that the anticonvulsant phenytoin (5,5-diphenylhydantoin) allosterically modulates  $\sigma$  binding to the [ $^3\mathrm{H}](+)$  pentazocine-labeled  $\sigma$  site, which suggests that phenytoin may bind to a distinct site near the competitive ligand site. Since the may bind to a distinct site near the competitive ligand site. Since the 4-phenylpiperidine moiety has been proposed to be the  $\sigma$  site pharmacophore, the rationale for the design of this series was to probe the spatial relationship of the allosteric or lipophilic phenylpine site with the competitive  $\sigma$  binding site. A series of 4-phenylpiperidines and 4-phenylpiperazines linked via a methylene chain to the N-3 nitrogen of 5,5-diphenylhydantoin was prepared and evaluated for affinity at  $[^3H](+)$ pentazocine- and  $[^3H]DTG$ -labeled  $\sigma$  sites. The compounds with a two carbon chain had weak affinity for both sites. However, as the distance was increased to six carbons a progressive increase in binding affinity was observed. The carbons a progressive increase in binding affinity was observed. The 4-phenylpiperidine derivative spaced by six carbons showed potent affinity for both  $[^3H](+)$ pentazocine-  $(K_i = 0.59 \text{ nM})$  and  $[^3H]DTG$ -  $(K_i = 3.02 \text{ nM})$  labeled sites. An hypothesis, the synthesis and structure-affinity relationships will be presented.

SIGMA-1 AND SIGMA-2 BINDING SITES OF RAT KIDNEY. W.D. Bowen\*, G. Feinstein, and J.S. Orringer. Unit on Receptor Biochemistry and Pharmacology, Laboratory of Medicinal Chemistry, NIDDK, NIH, Bethesda, MD

There is now evidence from several laboratories for the existence of two subtypes of sigma sites, termed sigma-1 and sigma-2 (*Trends Pharmacol. Sci.* 13: 85-86, 1992). We have previously shown using photoaffinity labeling and ligand binding that rat liver contains both of these sites (Soc. Neurosci. Abstr. 16: 370, 1990). Here, we characterize sigma binding sites in rat kidney. 16: 370, 1990). Here, we characterize sigma binding sites in rat kidney. [3H]DTG (which labels sigma-1 + sigma-2 sites) labeled sites with Kd = 45.8 nM and Bmax = 1,190 fmol/mg protein. [3H](+)-Pentazocine (selective for sigma-1) labeled sites with Kd = 23.3 and Bmax = 229. Both ligands gave linear Scatchard plots. Competition studies revealed that sites labeled by [3H]DTG and [3H](+)-pentazocine had profiles which differed mainly in affinity [9H]DTG and [9H](+)-pentazocine had profiles which differed mainly in affinity for (+)-benzomorphans. For [9H](+)-pentazocine-labeled sites: haloperidol > (+)-pentazocine > (+)-3-PPP > (+)-SKF 10,047 > (-)-SKF 10,047. When [9H]DTG binding was carried out in the presence of 1 uM dextrallorphan (a condition which masks labeling of sigma-1 receptors): haloperidol = (-)-pentazocine > (+)-3-PPP > (+)-pentazocine = (-)-SKF 10,047 >> (+)-SKF 10,047. All curves were monophasic. The ratio of Bmax values for [3H](+)-pentazocine and [3H]DTG would suggest that rat kidney contains only 20% sigma-1 sites and 80% sigma-2 sites. Thus, without masking, [3H]DTG gave an overall sigma-2 profile and (+)-benzomorphans exhibited biphasis curves. The ratio of sigma-1 to sigma-2 in rat kidney is similar to the ratio in rat liver, which is 25% sigma-1 and 75% sigma-2. However, the density of each site in kidney is 10-fold lower compared to liver, and is more comparable to the densities found in rat brain. Also, the relative density of sigma-2 in rat brain is lower than in liver and kidney. The wide distribution of sigma-1 and sigma-2 sites in brain, liver, kidney, and other peripheral tissues suggests important cellular functions for these sites.

## 195.10

ALLOSTERIC MODULATION OF THE BINDING OF (3H)(+)PENTAZOCINE ALLOSTERIC MODULATION OF THE BINDING OF [\*H](+)PEN IAZOCINE
TO  $\sigma$  SITES BY PHENYTOIN. D.L. DeHaven-Hudkins\*.<sup>1</sup>, F.Y. FordRice<sup>1</sup>, J.T. Allen¹ and R.L. Hudkins². ¹ Dept. Enzymology & Receptor
Biochemistry, Sterling Winthrop Pharmaceuticals Research
Division, Malvern, PA 19355 and <sup>2</sup>Albany Molecular Research, Watervliet, NY 12189.

The allosteric modulation of  $\sigma$  recognition sites by phenytoin (diphenylhydantoin) has been proposed based on the ability of phenytoin to stimulate binding of various  $\sigma$  ligands, as well as to slow dissociation from a sites and to shift o sites from a low- to a high-affinity state (Craviso & Musacchio, *Mol. Pharmacol.* 23: 629, 1983; Karbon et al., *Eur. J. Pharmacol.* 193: 21, 1991; McCann & Su, J. Pharmacol. Exp. Ther. 257: 547, 1991).

Phenytoin stimulated the binding of the  $\sigma\text{-selective}$  ligand  $[^3H](+)\text{pentazocine}$  in a dose-dependent manner, with maximal stimulation of binding observed at a final concentration of 250 µM phenytoin. The affinities of eleven structurally diverse  $\sigma$  reference compounds were determined in the presence or absence of 250  $\mu$ M phenytoin. The affinities of caramiphen, dextromethorphan, dextrorphan, (+)3-PPP and (+)SKF-10,047 were three- to eightfold higher in the presence of phenytoin. In contrast, the affinities of benzetimide, BMY 14802, carbetapentane, DTG, haloperidol and (+)pentazocine were unchanged in the presence of phenytoin. The relative sensitivity of  $\sigma$  compounds to allosteric modulation by phenytoin is not a property of all  $\sigma$  compounds, and may provide an in vitro basis for distinguishing  $\sigma$  subtypes and for predicting  $\sigma$  effects in vivo.

# 195.12

SIGMA LIGANDS HAVE REDUCED ABILITY TO INHIBIT THE MUSCARINIC PHOSPHOINOSITIDE RESPONSE IN CELLS DEFICIENT IN SIGMA-1 RECEPTORS. J.M. Cutts' and W.D. Bowen. Unit on Rec. Biochem. Pharmacol., Lab. of Medicinal Chemistry, NIDDK, NIH, Bethesda, MD 20892. We have previously shown that micromolar concentrations of sigma ligands inhibit the ability of muscarinic cholinergic agonists to stimulate phosphoinositide (PPI) turnover in rat brain synaptoneurosomes, with a rank

order of potency suggesting mediation through sigma-1 receptors (*Pharmacol. Rev.* 42: 355-402, 1990). However, sigma ligands bind to muscarinic receptors with micromolar affinity, and this has clouded the issue of sigma-1 receptor involvement in this effect. A way to test the requirement for sigma-1 receptors is to examine the effect of sigma ligands in cells which possess a muscarinic PPI response, but which do not possess a high density. possess a miscarnic PPT response, but which do not possess a high density of sigma-1 receptors. PC12 pheochromocytoma and N1E-115 and SK-N-SH neuroblastomas contain a high density of sigma-2 sites [as well as a novel binding site for (+)-pentazocine; see Vilner et al., this meeting], but low to negligible density of sigma-1 sites (*Brain Res.* 527: 244-253, 1990; *Soc. Neurosci. Abstr.* 17: 593, #236.15, 1991). In PC12 and N1E-115 cells, DTG and (+)-pentazocine inhibited 10 uM oxo-M-stimulated PPI turnover with similar potency as in rat brain synaptoneurosomes. However, BD737, BD1008, and dextrallorphan had considerably reduced potency compared to borrow, and extranoprian lad consolerably reduced potency compared to brain synaptoneurosomes, and reduced haloperidol was essentially inactive. In SK-N-SH cells, all of the above sigma ligands showed reduced potency, Furthermore, while the inhibition seen in synaptoneurosomes is non-competitive, the inhibition observed in SK-N-SH and N1E-115 cells was competitive. Thus, unless sigma-1 receptors are present, only a weak competitive inhibition is observed. Implications for inhibition seen in the brain are: 1) at low concentrations of sigma ligand, heterologous, non-competitive inhibition is mediated by sigma-1 receptors, 2) at higher concentration, a component of the inhibition may be due to direct interaction of sigma ligands with muscarinic receptors, 3) sigma-2 sites do not appear to be involved.

α<sub>1</sub>-ADRENERGIC ACTIVATION OF PHOSPHOLIPASE C IN XENOPUS OOCYTES IS MEDIATED VIA THE NATIVE GTP-BINDING PROTEIN, G. E.M.Landau\*, R. Iyengar, G.Omri, C.L.Ma, R.Premont and R.D.Blitzer. Department of Psychiatry, Bronx Medical Center and Departments of Psychiatry and Pharmacology, Mount Sinai Medical Center, New York, NY 10029.

The cloned  $\alpha_1$  receptor was expressed in Xenopus oocytes as previously described (Omri et al. NS abstracts 16,539;1990). The coupling of the receptor to the Xenopus phospholipase C was monitored by measuring the amplitude of the norepinephrine-induced, Ca<sup>2</sup>-dependent chloride current. The coupling of the receptor to phospholipase C was sensitive to pertussis toxin (PTX), but large concentrations of PTX and long exposure times were required to see an effect. Thus, to get a reduction of the response to norepinephrine by 70-80%, the oocytes needed to be exposed to 2 ug PTX for 72 hours or to 10 ug for 24 hours. The response to norepinephrine was enhanced by injecting the oocytes with 50 nl of a 50 nM solution of holo-G<sub>o</sub>, but not by injection of G<sub>i</sub> or vehicle. Finally, in oocytes form 5 different donors, the response to norepinephrine was reduced by 33-64% by injecting the oocytes with antisense nucleotides designed to inhibit the synthesis of Xenopus  $G_{ao}$ . The responses were compared to those seen in oocytes injected with the corresponding sense nucleotides and were measured 6 to 24 hours after the nucleotide injection. We conclude that the coupling of the cloned  $\alpha_1$  adrenergic receptor to phospholipase C in the oocyte is mediated via Go. The low sensitivity of the response to treatment with PTX may be an intrinsic property of Xenopus G.

PHARMACOLOGIC CHARACTERIZATION OF ALPHA-2-ADRENERGIC RECEPTOR HETEROGENEITY IN RAT BRAIN. M.F. O'Rourke\*, R.C. Pleus, L.J. Iversen, and D.B. Bylund. Dept. of Pharmacology, University of Nebraska Medical Center, Omaha, NE 68198-6260.

Four pharmacological alpha-2 adrenergic receptor subtypes have been identified using tissues and cell lines which express only one receptor subtype. In the rat, three alpha-2 adrenergic receptors have been cloned: RG20; RG10; and RNG. These clones correspond pharmacologically with the D, C, and B alpha-2 adrenergic receptor subtypes, respectively (Bylund, FASEB J. 6:832, 1992). In this study we characterized the alpha-2 adrenergic receptors in rat brain. We used [3H]RX821002 and [3H]rauwolscine to label receptors in membranes of rat cerebral cortex and cerebellum. Inhibition curves were generated using rauwolscine, BAM 1303, oxymetazoline, spiroxatrine, prazosin, ARC-239, and SKF 104078. The data are consistent with the conclusion that two alpha-2 adrenergic receptors, the D and C subtypes, are expressed in these areas of the brain. Approximately 80% of the alpha-2 receptors are the D subtype and 20% the C subtype. (Supported in part by NIH Grant GM 40784.)

## 196.5

IN SITU HYBRIDIZATION STUDY OF ALPHA AND BETA ADRENERGIC RECEPTORS IN THE RAT HYPOTHALAMUS.

S. Ceccatelli\* A.P. Nicholas and T. Hökfelt. Dept. of Histology and Neurobiology, Karolinska Institutet, Stockholm, Sweden, 104 01.

Noradrenergic and adrenergic input to the hypothalamus have been shown to influence the activity of neurons in this area of the brain via activation of alpha and beta adrenoceptors. In the present study, we have designed specific 48-mer oligoprobes to the recently-described DNA sequences of the rat alpha-1A, alpha-1B, alpha-2A, alpha-2B, alpha-2C, beta-1 and beta-2 adrenoceptors to localize hypothalamic cells that manufacture the mRNA for these receptor subtypes using the in situ hybridization technique. Complementary DNA probes were made on a DNA synthesizer to the following nucleotide sequences: 1167-1241 of rat alpha-1A, 1420-1467 of rat alpha-1B, 949-996 of rat alpha-2A (RG20), 1196-1243 of rat alpha-2B (RNG), 868-915 of rat alpha-2C (RG10), 1401-1448 of beta-1 and 2999-3046 of beta-2 receptors. All probes then were labelled at the 3-end using terminal deoxynucleotidytransferase and [35S] dATP. The hypothalamus was rapidly removed, frozen, sectioned on a cryostat (14 µm), air dried and transferred to humidified boxes at 42° C for 18 hrs with 1 X 10° cpm of an end-labeled DNA oligonucleoide probe diluted in a hybridization solution consisting of 0.02% Ficoli, 0.02% polyvinyl µm), air dried and transferred to humidified boxes at 42° C for 18 hrs with 1 X 10<sup>6</sup> cpm of an end-labeled DNA oligonucleoide probe diluted in a hybridization solution consisting of 0.02% Ficoll, 0.02% polyvinyl pyrrolidone, 1% sarcosyl, 0.2 M sodium phosphate (pH 7), 10% dextran sulfate, 200 mM dithiothreitol and 500 µg/ml heat-denatured salmon sperm DNA. The sections then were washed 4 X 15 min in SSC at 55° C, dehydrated, dipped in Kodak NTB2 photographic emulsion and exposed for 6-12 weeks before development. In the hypothalamus, the paraventricular nucleus labeled strongest with the alpha-2A probe, followed in intensity by labeling with the alpha-1B, alpha-2C and beta-2 probes. Adrenalectomized and thyroidectomized animals were also examined for differences in hypothalamic labeling intensity compared to controls.

DEVELOPMENTAL EXPRESSION OF THE ALPHA-1A, ALPHA-1B AND ALPHA-1C ADRENERGIC RECEPTOR SUBTYPE mRNAs IN THE RAT BRAIN. <u>S. K. McCune\*</u>, M. M. Voigt and J. M. Hill. Lab. of Developmental Neurobiology, NICHD, NIH, Bethesda, MD 20892. The ontogenic expression of three alpha-1 adrenergic receptor subtypes, in E14, E16, E19, P0, P8, P14, P21 and adult brains, was

examined by in situ hybridization using oligonucleotide probes derived from the non-homologous regions of the receptors. The alpha-1A subtype mRNA was expressed at low levels in the prenatal and P0 cortex. Specific expression in the olfactory bulb, cortex, hippocampus and reticular nucleus of the thalamus was detected in the P8 animal and persisted through adulthood. Detectable levels of mRNA were present in other thalamic nuclei only at P8 and P14. The alpha-1B receptor subtype mRNA was present in the E19 cortex, diagonal band, amygdala, pineal, mammillary nuclei, dorsal raphe and intensely in brainstem nuclei. By P0, the thalamus and globus pallidus were also visualized. With aging, the thalamic signal intensified while the expression in the globus pallidus and brainstem nuclei diminished. The alpha-1C subtype had limited expression. Low levels of mRNA were detected in E14 cortex and P0 olfactory bulb, but significant expression in the olfactory bulb, cortex and hippocampus was not seen until P8. Expression increased in olfactory bulb and hippocampus with age. The widespread nature of the expression of these alpha-1 adrenergic receptor subtypes in cortical, thalamic and limbic regions supports a role for adrenergic receptors in cognitive and affective functions. The ontogenic variations in distribution and intensity of expression may dictate changing physiologic and pharmacologic responses to catecholamines.

### 196.4

IMMUNOCYTOCHEMICAL LOCALIZATION OF  $\alpha_{2A}$ -,  $\alpha_{2B}$ - AND  $\alpha_{2C}$ -ADRENERGIC RECEPTORS IN BRAINS OF RAT AND MONKEY. C-G. Go1\*, C. Aoki1, O. Cartano1, H. Kurose2 & R. Lefkowitz2.1 Center for Neural Science, New York Univ., NY, NY, 10003 & Howard Hughes Med. Inst., Duke Univ. Med. Ctr, Durham, NC, 27710.

Three human genes, C-10, C-2 and C-4, with pharmacologic properties of  $\alpha_2\text{-adrenergic}$  receptors  $(\alpha_2AR)$  have been isolated in recent years (rev. by Lomasney et al., 1991, Biochim. Biochphys. Acta 1095: 127). Based on their rank orders of potency for adrenergic ligands and their tissue distribution, these genes have been assigned to the  $\alpha_{2A}$ ,  $\alpha_{2B}$  and  $\alpha_{2C}$  subtypes, respectively. Using rabbit antisera that were raised against GST-fusion proteins corresponding to the intracellular third loop of these receptor molecules (Kurose et al., ms in preparation), we show that the three subtypes of  $\alpha_0 AR$  are differentially distributed across brain regions and are differentially conserved between primates and rodents. Immunoreactivity (ir) to the C-10 (02) gene product is readily detectable as punctate profiles within neuronal perikarya of the cerebral cortex, hypothalamus and locus coeruleus of the monkey (n=7). Ir is detectable but weaker within the corresponding regions of rat brain (n=10). Electron microscopy revealed that punctate profiles correspond to saccules that are removed from synaptic regions of the perikaryal plasma membrane. Ir to C-2 ( $\alpha_{2B}$ ) is pronounced within perikarya and dendrites of cerebellar Purkinje cells of monkey but not of the rat. Rat brain tissue is most immunoreactive to anti-C-4 ( $\alpha_{2\text{C}}$ ). Nuclei with pronounced C-4-ir include the olfactory nerve, amygdala, piriform cortex, hypothalamus and area postrema. Supported by EY08055 and 2-SO7-RR07062-26 to CA.

## 196.6

BEHAVIORAL AND NEUROPHARMACOLOGICAL ASSESSMENT OF α2-ADRENOCEPTOR DENSITY AND FUNCTION FOLLOWING EEDQ TREATMENT. M.J. Durcan P.F. Morgan. M. Van Etten, and M. Linnoila. Laboratory of Neurogenetics, NIAAA, Bethesda, MD 20892.

N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDQ) is a potent and irreversible antagonist of  $\alpha_2$ -adrenoceptors. The repopulation of these receptors following EEDQ treatment to male NIH Swiss mice was investigated receptors following EEDQ treatment to male NIH Swiss mice was investigated both behaviorally and neuropharmacologically.  $\alpha_2$ -adrenoceptor turnover was assessed by investigating the binding of the selective  $\alpha_2$ -adrenoceptor antagonist, (2-{2-methoxy-1,4-benzodioxany|)} imidazoline ( $^{3}$ H-RX821002) to mouse whole brain tissue 1, 2, 4, 8, 12 and 16 days following treatment with EEDQ (2 mg/kg, i,p.). One day following EEDQ treatment  $^{3}$ H-RX821002 binding is reduced to 25% of control levels and this returns to approximately 75% by day 16. The time taken for the binding sites to return to 50% of control levels was calculated to be 5.25 days. In a separate experiment the behavioral response to the  $\alpha_2$ -adrenoceptor agonist medetomicline was investigated at the same time points following EEDQ ( $\alpha_2$  mg/kg i.p.) treatment behavioral response to the  $\alpha_2$ -adrenoceptor agonist medetomidine was investigated at the same time points following EEDQ (2 mg/kg, i.p.) treatment using the holeboard test of directed exploration and locomotor activity. Medetomidine (0.1 mg/kg) caused a highly significant (p <.01) reduction in both exploratory head-dipping and locomotor activity. The reduction in both head-dipping and locomotor activity was significantly (p <.05) attenuated in animals pretreated with EEDQ 1, 2 or 4 days earlier; longer durations of EEDQ pretreatment did not result in significant attenuation of medetomidine-induced sedation. EEDQ treatment alone did not significantly affect either of the holeboard measures. The loss of  $\alpha_2$ -adrenoceptors can be dose dependently prevented by the administration of RX821002 prior to EEDQ treatment. This protection can be observed both in the binding of <sup>3</sup>H-RX821002 and in the behavioral responses to medetomidine. These results suggest that there is a significant receptor reserve for the sedative effects of the  $\alpha_2$ -adrenoceptor agonist medetomidine in mice.

#### 196 7

[3H]DEXMEDETOMIDINE, AN ALPHA-2 ADRENERGIC RECEPTOR AGONIST, BINDS ALSO TO A NON-ADRENERGIC IMIDAZOLE-PREFERRING SITE IN RAT CNS. M.K.T. Savola, J.-M. Savola 1 and A. Marjamäki\*. Dept. of Pharmacology, Univ. of Turku, and 1 R&D, Pharmaceuticals, Orion Corp. Farmos, Turku, Finland.

The imidazole derivative dexmedetomidine (DMD) is a potent and selective α2-adrenergic receptor (AR) agonist. This compound has been tritiated to high specific activity (about 70 Ci/mmol) and we characterised binding of [3HIDMD in the cerebral cortex and spinal cord of the rat. Saturation analysis of binding showed two affinity sites when DMD or detomidine were used to define nonspecific binding in these tissues. Compared to values when epinephrine was used to define non-specific binding, presence of a non-adrenergic binding site (NAIBS) was evident in both tissues, the proportion of NAIBS being greater in the rat spinal cord. Interestingly, saturation analysis in presence of Gpp(NH)p showed only one affinity site in both tissues indicating binding to a G-protein coupled receptor. Inhibition experiments with a number of α-AR agonists and antagonists and other neurotransmitter receptor ligands indicated specific binding of  $[^{9}H]DMD$  to  $\alpha_2$ -ARs in rat cerebral cortex. However, epinephrine could inhibit binding of  $[^{9}H]DMD$  to cerebral cortex by 80% and in spinal cord maximally by 50%. Furthermore, clonidine, rauwolscine, and yohimbine could inhibit binding by 50% but the imidazole derivatives DMD, detomidine, atipamezole, and *I*-medetomidine, and the imidazoline derivative idazoxan (at high concentration) inhibited totally binding in the spinal cord.

We conclude that [<sup>3</sup>H]DMD has very complex binding characteristics in rat

CNS. It binds to  $\alpha_2$ -ARs without substantial affinity to other classical cns. It binds to ag-Ans without substantial allimity to other classical neurotransmitter receptors. However, [<sup>3</sup>H]DMD binds also to a NAIBS which seems to be different from those identified with [<sup>3</sup>H]p-aminoclonidine or [<sup>3</sup>H]idazoxan but resembling that identified with [<sup>3</sup>H]atipamezole.

IN VIVO ELECTROCHEMICAL STUDIES OF THE EFFECTS OF A75200 ON EXOGENOUS NE CLEARANCE IN THE CEREBELLUM OF THE ANESTHETIZED RAT. J. A. Grebb G.A. Gerhardt, C. van Horne, A.M.Y. Lin, P.C. Bickford, J. DeBernardis, M. Pierce and J.F. McKelvy. Depts. of Pharmacology and Psychiatry, Univ. of Colorado Health Sci. Ctr., Denver, CO and Abbott Laboratories, Abbott Park, IL.

A75200,(±)-(R',3R')-3-phenyl-1-(1',2',3',4'-tetrahydro-5',6'methylenedioxy-1- naphthalenyl)methyl)-pyrolidine, methanesulfonate is a racemic mixture which is a potent alpha-2 antagonist, and an inhibitor of the uptake of norepinephrine (NE) into catecholamine-containing neurons. These properties of this new drug support the hypothesis that this compound has potential as a novel antidepressant agent. The purpose of the present study was to investigate the effects of A75200 on NE-containing neurons in vivo in the anesthetized rat using electrochemical recording techniques. NE was locally applied, either alone or following applications of A75200 or nomifensine (50-100 nanoliters of a 400 micromolar solution), into the cerebellar cortex of the anesthetized male Fischer 344 rat by pressure ejection from double-barrel micropipettes. The clearance of NE from the extracellular space was measured using rapid chronoamperometric measurements with Nafion-coated carbon fiber electrodes which were positioned 300 microns from the micropipette tips. Both A75200 and nomifensine were seen to significantly increase the amplitude and prolong the time course of locally-applied NE. A75200 is currently being evaluated in clinical trials to investigate whether it will be useful as an antidepressant.

TIMING OF NORADRENERGIC DEPLETION AND OCCURRENCE OF DARK CELLS IN HIPPOCAMPUS AFTER SUBCUTANEOUS ADMINISTRATION OF DSP4 OR 6-OHDA AT NEONATE.

Y.-P. Lee\*, M.-Y. Min and H.-M. Hwang. Dept. of Anatomy, Chang Gung Medical College, Taoyuan,

Taiwan 33333, R.O.C.

Previous study indicated that subcutaneous

injection of 6-OHDA or DSP4 after birth caused noradrenergic depletion, up-regulation of beta-adrenergic receptors and occurrence of dark cells in adult rat hippocampus. To investigate possible association among these events, they were examined by immunohistochemistry, receptor binding assay and microscopy respectively at different developmental ages after treatment. During the normal development, noradrenergic innervation into hippocampus was not apparent until P15. Beta-adrenergic receptor activity also revealed similar developmental pattern. After drug treatment at PO, depletion appeared to be in effect immediately. No innervation was found in hippocampus at any age. In contrast, n increase of beta-adrenergic receptor activity was found to be increased until P15. Microscopy indicated that no dark cells occur until P60 or P90. Therefore, occurrence of dark cells may not be an immediate consequence of noradrenergic depletion. (supported by NSC81-0412-B182-01)

ALPHA-2 ADRENERGIC RECEPTORS AND TYROSINE HYDROXYLASE IN THE LOCUS COERULEUS OF P VS NP AND HAD VS LAD RATS. B.H. Hwang\*, G.-M. Wang, L. Lumeng and T.-K. Li. Indiana University School of Medicine, and VAMC, Indianapolis, IN 46202.

Locus coeruleus (LC) is rich in tyrosine hydroxylase (TH) and possesses a high density of alpha-2 adrenergic (A2) receptors. Ethanol administration causes changes of central monoamine neurons, but whether LC is involving in alcohol-drinking preference (AP) is not known. To explore this question, selectively bred alcohol-preferring (P) and -nonpreferring (NP) rats, as well as high alcohol-drinking (HAD) and low alcohol-drinking (LAD) rats nigh alcohol-drinking (HAD) and low alcohol-drinking (LAD) rats were studied. Cryostat sections were cut, 125I-iodoclonidine was used to label A2 receptor binding, and TH antibody and 125I-secondary antibody were applied to assess TH content in the LC. Quantitative autoradiographic analyses showed that the TH content in the LC was substantially lower in P rats (24.8% reduction) than in NP rats. There was also a significant reduction (18.7%) of A2 receptor binding in P rats as compared with NP rats. However, HAD rats exhibited a higher (17.2%) TH content in the LC than LAD rats, and A2 receptor binding was similar in HAD and LAD rats. Similar A2 receptor binding was also seen in the solitary nucleus, area postrema and dorsal motor nucleus of the vagus in the P vs NP rats, and HAD vs LAD rats. Collectively, the above results suggest that adrenergic systems in the LC are not directly associated with AP. Supported in part by grant AA07611 and NS25087.

### 196.10

IMPACT OF PHENYLPROPANOLAMINE AND CIRAZOLINE ON EXTRACELLULAR NOREPINEPHRINE IN RAT PARAVENTRICULAR HYPOTHALAMUS: A MICRODIALYSIS STUDY. P.J. Wellman\*, A. Morien and B.T. Davies. Dept of Psychology, Texas A&M University, College Station, TX 77843-4235, USA. Adrenergic receptors within rat paraventricular hypothalamus (PVN) are known to modulate feeding behavior. In particular, activation of α2-adrenergic receptors via drugs such as clonidine enhances feeding whereas activation of α1-adrenergic receptors via drugs such as phenylpropanolamine (PPA) and cirazoline (CZ) inhibits feeding. The neuropharmacology of PPA and CZ is incompletely known. Whereas both compounds are thought to exert direct action at α1-adrenergic receptors, their activity at the α2-adrenergic receptor is unknown. One means to determine whether a compound acts as an agonist or antagonist at the α2-adrenergic receptor involves in vivo microdialysis measures of extracellular norepinephrine (NE) with rat PVN. α2-adrenergic agonists suppress extracellular PVN NE whereas antagonists enhance PVN NE. Ratswere implanted with a concentric microdialysis probe within PVN and then treated with either vehicle (n=5), 20 mg/kg PPA (n=8) or 0.2 mg/kg C2 (n=4) with dialysates taken for 60 min before and 60 min after drug treatment. Extracellular NE was suppressed by 55% over a 60 min period in rats treated with 20 mg/kg PPA whereas 0.2 mg/kg CZ slightly increased extracellular NE by 20% within the first 40 min after injection. These results suggest that, at systemic doses that suppress feeding, PPA acts as an α2-agonist within the PVN whereas CZ has minimal action at the α2-adrenergic receptor.

EFFECT OF AGENTS THAT INCREASE BRAIN NOREPINEPHRINE (ME) RELEASE ON BRAIN EXTRACELLULAR cAMP LEVELS. S.M. John and E.A. Stone. Dept. Psychiatry, New York Univ. Sch. Med.,

RELEASE ON BRAIN EXTRACELLULAR CAMP LEVELS. S.M. John and E.A. Stone. Dept. Psychiatry, New York Univ. Sch. Med., New York, NY 10016

Previously we have shown that administration of exogenous NE produces an increase in extracellular levels of cAMP in the frontal cortex of the rat. We have also shown that some stimuli that increase endogenous brain NE release such as handling stress and infusion of amphetamine produce increases in cAMP levels. In the present experiment we examined the effects of additional stimuli that increase NE release on this response. Rats were implanted with microdialysis probes in the prefrontal cortex and 48 hrs later perfused while subjected to treatments known to enhance brain NE release. It was found that i.p. administration of yohimbine and desmethylimipramine (DMI) both tended to increase cAMP levels however the responses were highly variable. I.P. injection of saline by itself had no effect but did produce a reliable increase in cAMP level if the dialysis probe was first perfused with a phosphodiesterase inhibitor. Local administration of DMI via the probe increases cAMP levels. The results suggest that stimuli that increase endogenous NE release may be capable of producing detectable increases in brain extracellular cAMP levels but the optimal conditions for detecting this response remain to be determined. Supported in part by grants AFOSR 89-0208, MH45265 and MH08618.

AUTORADIOGRAPHIC LOCALIZATION OF BETA-ADRENERGIC RECEPTORS IN THE SONGBIRD VOCAL CONTROL SYSTEM

J. M. Casto\*, P. Absil, J. Balthazart, & G.F. Ball Dept. Psychology, Johns Hopkins Univ. Baltimore, MD 21218; Univ. of Liège, Belgium

Beta-adrenergic receptors have been implicated in learning and memory processes in several species. Noradrenergic activity in the songbird vocal control system may be related to song learning and production. We therefore localized β-adrenergic receptors in three to song tearning and production. We therefore localized p-adrenergic receptors in firther avian species; two species that exhibit vocal learning (zebra finches and European starlings) and one that does not learn its vocal behavior (Japanese quail ). Receptors were labeled using [ $^3$ H] CGP 12177, a non-selective  $\beta$  receptor ligand.  $\beta$ 1 and  $\beta$ 2 subtypes were specified by selectively inhibiting either  $\beta$ 2 receptors with the addition of ICI 118551 (to visualize  $\beta$ 1 receptors) or  $\beta$ 1 receptors with the addition of atendol (to visualize  $\beta$ 2 receptors). Total non-specific binding was determined by the addition of propranolol. In general,  $\beta$ 2 receptors were present in higher densities than  $\beta$ 1 receptors in all three species. general,  $\beta$ 2 receptors were present in higher densities than  $\beta$ 1 receptors in all three species. Three vocal control nuclei: the caudal part of the ventral hyperstriatum (HVc), the robust nucleus of the archistriatum (RA) and the magnocellular nucleus of the anterior neostriatum (MAN) were well defined by the high density of both the  $\beta$ 1 and the  $\beta$ 2 subtype in comparison to the surrounding tissue. These areas are not discernible in the quail brain based on an examination of either Nissl stained sections or the autoradiograms. In all three species, the cerebellum, the hippocampus, the optic tectum, the nucleus rotundus, nucleus mesencephalicus lateralis, pars dorsalis and and many parts of the diencephalon exhibited high receptors densities. There was a qualitative difference between the high density of receptors in the sonobint telencephalon as compared to the low density in the telencephalon. receptors in the songbird telencephalon as compared to the low density in the telencephalon of quail. Although these species differences exist, immunohistochemical visualization of tyrosine hydroxlase did not reveal major differences in the distribution of cell bodies containing catecholamines suggesting that the telencephalic receptors of songbirds receive their inputs from specialized projections orginating from catecholaminergic cell groups that are common to all bird species.

LOW AFFINITY 8-ADRENERGIC RECEPTOR IN CANINE ADRENAL MEDULLA. K.Clarkson, J.Tobin, K.Kubos, D.Hanley\*, M.Breslow. The Johns Hopkins Medical Institutions, Department of Anesthesiology/CCM, Baltimore, MD 21205.

Drugs active at adrenergic receptor sites modulate adrenal medullary function. To determine beta receptor binding constants and density, a canine adrenal medulla homogenate was incubated at 37°C, pH 7.4, in 10mM Tris, 130mM NaCl, 1mM ascorbate for 1hr with increasing concentrations of 125Icyanopindolol (125I-CYP), with and without 150 µM 1-propranolol to differentiate total and nonspecific binding. Total and bound ligand were separated by vacuum filtration. <sup>125</sup>I-CYP binding was 75-90% specific and separated by vacuum intradistributions. Part binding was 37-90 specific asturable. Analysis of the data with the curve fitting program, LIGAND, was consistent with a single binding site, apparent  $K_D$  750pM. Receptor density (Bmax) was 100 fmol/mg protein. Competition experiments using increasing concentrations of 1-propranolol revealed a  $K_i$  of 900nM. These data suggest the presence of a low affinity <sup>125</sup>I-CYP binding site in canine adrenal medulla. We hypothesize that this is a  $\beta$ -adrenergic receptor since  $\beta$ adrenergic agonists stimulate in vivo and in vitro catecholamine secretion from adrenal medullary tissue(1.2)

### CATECHOLAMINES: RELEASE

### 197.1

ELECTROPHYSIOLOGICAL AND NEUROCHEMICAL EFFECTS OF (-)HA-966: EVIDENCE FOR PATTERN-DEPENDENT MODULATION OF DOPAMINE RELEASE. P.D. Shepard and B. Moghaddam. MD Psychiatric Res. Cntr, Baltimore, MD 21228 and VA Med. Cntr., West Haven, CT 06516. (±)1-hydroxy-3-aminopyrrolidone-2((±)HA-966) is known to cause a rapid

and selective increase in striatal dopamine (DA) levels; an effect that has been attributed to the drug's ability to block the spontaneous activity of nigrostriatal DA-containing neurons (Shepard and Lehmann, JPET 261:387, 1992). Although the racemic form of HA-966 has been used extensively as a noncompetitive NMDA antagonist, the resolved enantiomeric forms of the drug possess disparate pharmacological effects. In the present series of experiments, single unit recording and microdialysis techniques were used to assess the neurochemical and electrophysiological effects of (-)HA-966 on nigrostriatal DA-containing neurons in chloral hydrate anesthetized rat. Low i.v. doses of DA-containing neurons in chloral hydrate anesthetized rat. Low 1v. doses of (-)HA-966 failed to significantly affect DA neuronal firing rate (1 mg/kg (n=8): control:  $3.9 \pm 0.4$  Hz, post(-)HA-966:  $3.5 \pm 0.4$  Hz, 3 mg/kg (n=8): control:  $5.2 \pm 0.7$  Hz, post(-)HA-966:  $4.7 \pm Hz$ ). Higher doses of the drug (10 - 30 mg/kg) produced a rapid and dose-dependent cessation in neuronal firing in 8 of 10 cells tested (latency to 50% inhibition - 10 mg/kg;  $5.9 \pm 1.5$  min; 30 mg/kg;  $3.2 \pm 1.4$  min). Interestingly, doses of (-)HA-966 which failed to affect firing rate, "normalized" DA neuronal firing pattern as evidenced by a significantly decrease the variability (coefficient of variation) associated with interspike interval distributions (1 mg/kg: pre-drug:  $50.1\pm6.6$  %, post-drug:  $36.5\pm6.8$  %, Wilcoxan signed rank test, P<0.02; 3 mg/kg: pre-drug:  $42.5\pm6.5$  %, post-drug:  $23.3\pm4.5$  %, P<0.02). Preliminary results from *in vivo* dialysis experiments suggest that these changes are accompanied by a significant reduction in striatal DA release. Taken together, these data support the hypothesis that alterations in neuronal firing pattern can modulate DA release in forebrain areas.

## 197.3

APOMORPHINE AND QUINPIROLE INHIBIT DOPAMINE RELEASE BY DIFFERENT MECHANISMS: ROLE OF DOPAMINE SYNTHESIS

A. Töröcsik and M.J. Zigmond. Department of Cellular & Behavioral Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

Apomorphine and quinpirole inhibit the efflux of dopamine (DA) from striatal slices. However, whereas this inhibition usually is attributed to an action of D2 agonists on release-modulating autoreceptors, apomorphine has a catechol-like structure and has been reported to inhibit tyrosine hydroxylase (TH). Thus, we wished to compare the mechanism by which these two agonists inhibit DA efflux and to determine whether inhibition of TH plays any role in the impact of apomorphine on DA release. Striatal slices were superfused in a modified Krebs bicarbonate buffer. Electrical field stimulation (5 Hz for 4.5 min) was applied and endogenous DA release was assessed using HPLC. Both apomorphine and quinpirole reduced the overflow of DA in a concentra-tion-dependent manner. No statistical difference was found between the maximal effects of apomorphine (1 μM, -84%) and quinpirole (1 μM, -75%). However, whereas sulpiride (10  $\mu$ M) strongly antagonized the effect of 1  $\mu$ M quinpirole on DA overflow (-91%), this D2 antagonist only partially antagonized the effect of 1  $\mu$ M apomorphine (-21%). No further inhibition of DA overflow was noted when sulpiride was applied at a 10-fold higher concentration. To assess the impact of another drug known to inhibit TH, we examined the effect of 3-iodotyrosine (2 mM). This drug almost completely abolished the overflow of endogenous DA from striatal slices (-95%), although tissue DA content remained high. Our results suggest that apomorphine, but not quinpirole, has an inhibitory influence on DA release that is not mediated by autoreceptors but instead reflects an inhibition of DA synthesis. They also indicate that inhibition of DA synthesis can markedly reduce release in vitro despite the continued presence of DA in tissue. (Supported in part by USPHS grant NS19608.)

### 197.2

COMPARISON OF A NOVEL D1 RECEPTOR ANTAGONIST, SCH 39166, WITH SCH 23390 AND HALOPERIDOL ON THE IN VIVO RELEASE OF DOPAMINE AND ITS METABOLITES FROM THE RAT STRIATUM USING MICRODIALYSIS. C.E. Tedford', G. Crosby, W. Billard and R.D. McQuade. Schering-Plough Research Institute, Bloomfield, New Jersey, 07003

In vivo microdialysis was utilized to investigate the effects of various dopamine receptor antagonists on dopamine release in the rat striatum. course and dose response curves were compared between D1 and D2 receptor antagonists on dopamine, DOPAC, HVA and 5-HIAA release. SCH 39166, a novel benzonaphthazepine analog, and SCH 23390, a benzazapine derivative, were compared as selective D1 receptor antagonists. Additionally,

the selective D2 receptor antagonist, haloperidol was tested.

Male Sprague Dawley rats were implanted with guide cannulae, a minimum of 24 hr prior to in vivo microdialysis. On the day of the experiment, the microdialysis probes were implanted into the left striatum at the stereotaxic coordinates from bregma of + 0.2 mm, -3.0 mm lateral and 6.0 mm ventral. Subsequently, the striatum was perfused with Kreb's buffer (2.0 µl/min) for 60 min prior to obtaining a baseline level of catecholamine release. Four 10 min samples were collected for baseline determinations and the rats were then administered drug, ip. Animals were perfused for the next 3 hours and samples were collected every 10 min.

samples were collected every 10 min. Haloperidol, the D2 receptor antagonist produced a robust dose-dependent increase in DOPAC and HVA release. A dose of 1 mg/kg of haloperidol produced an increase of over 200% of DOPAC, that was seen throughout the collection period. Lower doses of haloperidol also produced significant increases in DOPAC and HVA. In contrast, SCH 39166 produced a smaller increase in DOPAC that was significantly different from control only at the highest dose (10 mg/kg, ip). Minimal or no effects on DOPAC and HVA levels were seen at lower doses. No effect was seen on 5-HIAA release at any of the doses used. Similar findings were seen with the other D1 receptor selective antagonist, SCH 23390.

## 197.4

PREFRONTAL CORTICAL CONTROL OF MESOLIMBIC DOPAMINE CELL FIRING AND TRANSMITTER RELEASE. TH. Svensson, S. Murase, J. Grenhoff\*, G.Chouvet+ and F.G. Gonon+. Dept. Pharmacology, Karolinska Institute, 104 01 Stockholm, Sweden; and +INSERM U171/CNRS URA 1195, 69310 Pierre Bénite, France.

The putative influence of the medial prefrontal cortex (PFC) on mesolimbic dopamine (DA) activity was studied with single cell recording and in vivo voltammetry techniques in the chloral in vivo voltammetry techniques in the chloral hydrate-anaesthetized male rat. Microinfusion of glutamate (25 nmol) in PFC enhanced burst firing of DA cells in the ventral tegmental area (VTA) and increased DA release in nucleus accumbens. Microinfusion of lidocaine (38 nmol) in PFC decreased burst firing in VTA-DA cells and DA release in accumbens. Firing rate and regularity of firing of VTA-DA neurons were unaffected by both treatments. treatments.

The present results indicate a tonic stimulatory input from the PFC to mesolimbic DA neurons. tory input from the PFC to mesolimbic DA neurons. This input seems to specifically control burst firing and burst-related transmitter release of DA neurons, underlining the role of burst firing in DA function. PFC control of DA neurons might be involved in incentive behavior and in negative schizophrenic symptomatology associated with dysfunction of the PFC.

DIFFERENTIAL EFFECTS OF MAO INHIBITORS ON L-DOPA-INDUCED DA RELEASE IN THE STRIATUM OF INTACT AND 6-OHDA-TREATED RATS. S.R. Wachtel, H. Ramasubramaniam, and E.D. Abercrombie. Ctr. Molec. and Behav. Neurosci., Rutgers Univ., Newark, NJ 07102

The present study examined the roles of MAO-A and MAO-B in the metabolism of dopamine (DA) formed from exogenous L-DOPA in the striatum of intact and 6-OHDA-lesioned rats. Since MAO-A in the striatum is preferentially localized in DA nerve terminals, it was hypothesized that the metabolic action of this enzyme could account in part for the relatively small effect of L-DOPA on extracellular DA in intact striata compared to DA-depleted striata. In vivo microdialysis, in freely moving rats, was used to monitor the extracellular level of DA in the striatum, as well as the metabolites, DOPAC and HVA. Pretreatment of intact rats with clorgyline (2 mg/kg), an irreversible, selective inhibitor of MAO-A, increased L-DOPA-induced (50 mg/kg) DA release by 2442% and decreased DOPAC and HVA by 71% and 73%, respectively. In rats with 6-OHDA lesions, clorgyline had no significant effect on the increase of DA and its metabolites elicited by L-DOPA. Pretreatment with Ro 19-6327 (1 mg/kg), a reversible, selective inhibitor of MAO-B, did not significantly affect basal or L-DOPA-induced changes in striatal DA or its metabolites in either intact or 6-OHDA-lesioned rats. Pretreatment with the irreversible inhibitor of MAO-B, deprenyl, at a dose devoid of amphetamine-like effects on DA release (1 mg/kg), also did not significantly affect L-DOPAinduced DA release in the striatum of either intact or 6-OHDA-lesioned rats. These results indicate 1) MAO-A efficiently metabolizes DA formed from exogenous L-DOPA within DA terminals, 2) destruction of DA terminals eliminates this action of MAO-A, and 3) the loss of DA terminals does not unmask or enhance metabolism of DA by MAO-B. [Supported in part by a NRSA from NINDS (SRW), USPHS grant NS19608, and The American Parkinson's Disease Association (EDA)1

## 197.7

OPIOID MODULATION OF [3H]DOPAMINE RELEASE FROM EMBRYONIC RAT VENTRAL MESENCEPHALIC CULTURES. Smith J.A.M., Loughlin S. E. and Leslie F. M.\* Dept. of Pharmacology, University of California, Irvine

Endogenous opioids play an important role in the regulation of ventral mesencephalic dopaminergic neurons. However, the precise mechanism underlying opioid modulation of dopamine function has not been determined. In the presen study, a dissociated cell culture model of embryonic ventral mesencephalon was established in order to define the actions of selective opioids on dopamine release at the cellular level. Ventral mesencephali were dissected from rat brains at embryonic day 15. Cells were enzymatically and mechanically dissociated and plated in serum-containing media. At 8 days in vitro, each of the major morphological types of dopaminergic cell was represented in these cultures. These cells exhibited specific uptake of <sup>13</sup>Hldopamine, which was subsequently released, in a calcium-dependent manner, in response to a double pulse of elevated extracellular potassium. There was a dose-dependent increase in [3H]dopamine release with increasing concentrations of a dose-dependent increase in [1-r] doparime release with increasing concentrations of extracellular potassium. Spontaneous and potassium-evoked [3-H] dopamine release was inhibited by kappa, but not mu or delta, opioid agonists. The selective kappa agonist U69593 produced a dose-dependent inhibition of spontaneous and evoked dopamine release. The inhibitory effect of U69593 was blocked by the non-selective opiate antagonist naloxone and the selective kappa opioid antagonist nor binaltorphimine. Kappa opioid inhibition of potassium-evoked [<sup>3</sup>H]dopamine release was maintained in the presence of tetrodotoxin. These results provide evidence for a presynaptic localisation of functional kappa receptors on the terminals of ventral presynaptic tocation of nutrotial kappa receptors on the terminates of ventual mesencephalic dopamine neurons. Embryonic rat ventral mesencephalic cultures represent an appropriate model to further characterise kappa opioid modulation of neurotransmitter release. Supported by NS19319, NS26761 and American Parkinson Disease Association SCC.

## 197.9

EFFECTS OF BENZODIAZEPINE AND GABA, RECEPTOR ANTAGONISTS ON STRIATAL EXTRACELLULAR DOPAMINE LEVELS: AN IN VIVO MICRODIALYSIS STUDY. R.J.Gruen\*, B.Moghaddam, A.Coale, and A.J.Friedhoff. New York Univ., NY, NY 10016, Yale Univ. School of Medicine, New Haven, CT 06510.

The present study was designed to examine whether ligands which bind at the GABA/benzodiazepine receptor complex have a tonic modulatory effect with regard to striatal dopamine (DA) transmission. We therefore examined the effects of local administration of Rol5-1788, a benzodiazepine (BZ) receptor antagonist, and SR 95531, a novel GABA, receptor antagonist, on restracellular dopamine  $(DA_{\{a\}})$  levels in the striatum of anesthetized and awake adult rats. Administration of Ro15-1788 resulted in a dose-dependent increase in  $DA_{\{a\}}$  in both anesthetized and awake animals. The Ro15-1788induced increase in  $DA_{[\bullet]}$  was blocked by coadministration of the BZ diazepam, as well as GABA. Local administration of SR 95531 also resulted in a dosedependent alteration in DA[e] in anesthetized and awake animals. The SR 95531-induced increase in  $\mathrm{DA}_{\{\mathbf{e}\}}$  was blocked by coadministration of GABA. It has been suggested that the effects of excitatory amino acids on striatal DA activity <u>in vivo</u> are mediated, in part, by inhibitory neurons (Moghaddam & Gruen, 1991). The results of the present study provide support for the idea that GABA has a tonic inhibitory effect on striatal DA transmission. Supported, in part, by MH-08618 (AJF).

#### 197.6

EFFECTS OF THREE NEW COMT INHIBITORS ON STRIATAL DOPAMINE METABOLISM IN VIVO. S. Kaakkola, P.J.
Lindsberg\* and R.J. Wurtman. Dept. of Brain and
Cognitive Sciences, M.I.T., Cambridge, MA 02139.
In vivo microdialysis was used to examine the of three new COMT inhibitors, Ro 40-7592, CGP 28014, and OR-611 (entacapone), on extracellular levels of dopamine, DOPAC, HVA, and 5-HIAA in rat striatum. A dose of 30 mg/kg of each compound was injected i.p. to male Sprague-Dawley rats under chloralose/urethane anaesthesia. Dialysis samples were collected for 20 min periods over 260 min and assayed by HPLC. All the three inhibitors significantly increased the efflux of DOPAC and decreased that of HVA. Ro 40-7592 was the most potent followed by CGP 28014. OR-611 was the least potent. Ro 40-7592 and CGP 28014 tended to increase the extracellular levels of dopamine whereas OR-611 had no effect. None of the COMT  $\,$ inhibitors changed significantly the efflux of 5-HIAA.

The results show that both Ro 40-7592 and CGP 28014 are potent centrally-active COMT inhibitors whereas OR-611 is principally a peripherally-active inhibitor. COMT inhibitorscan considerably modify brain dopamine metabolism and may be of clinical significance in therapy of e.g. Parkinson's disease.

### 197.8

THE EFFECTS OF HYDRALAZINE AND NITROPRUSSIDE ON STRIATAL MONOAMINE AND AMINO ACID NEUROTRANSMITTER SYSTEMS: SIMULTANEOUS MEASUREMENT OF DRUG, NEUROCHEMICALS, AND METABOLITES IN MIGRODIALYSIS PERFUSATES. P. Garnache<sup>1+</sup>, E. Ryan<sup>1</sup>, J. Yu<sup>2</sup>, T. Maher<sup>2</sup>, and I. Acworth<sup>182</sup> <sup>1</sup>ESA, Inc., 45 Wiggins Avenue, Bedford, MA 01730 and <sup>2</sup>Department of Pharmacology, Massachusetts College of

MA 01730 and <sup>2</sup>Department of Pharmacology, Massachusetts College of Pharmacy, Boston, MA 02115.

We have studied the effects of peripheral administration of hypotensive agents on striatal extracellular levels of neurotransmitters and metabolites using *in vivo* microdialysis in the anesthetized rat. Animals were cannulated for arterial blood pressure monitoring and I.v. drug administration. Automated derivatization, column switching, and HPLC using coulometric array detection permitted simultaneous determination of monoamines, their metabolites, and neuroactive amino acids from each perfusate sample. Hydralazine (10mg/kg, bolus) produced a marked increase (> 10 -fold) above basal levels of aspartate (ASP), dopamine (DA), GABA, glutamate (GLU), glycine (GLY) and taurine (TAU). Smaller increases, or no change, was evident for 8 other amino acids. The acid metabolites of the monoamines decreased to ca. 1/5th of the basal levels. Interestingly, a chromatographic peak corresponding to an external hydralazine standard was evident only in the post-treatment perfusate samples. To examine whether these results were mainly associated with hydralazine's hypotensive effects, another hypotensive agent was examined. Nitroprusside was infused at a rate which maintained blood pressure between 2/3 and 1/2 of baseline. This produced relative changes in the analyte levels similar to baseline. This produced relative changes in the analyte levels similar to

These experiments show that hydralazine can traverse the blood-brain barrier and that specific effects of these drugs may involve several transmitter systems. Furthermore, this analytical technique may be useful for direct pharmacokinetic and neuropharmacological studies.

## 197.10

EFFECT OF BLOOD PRESSURE (BP) ALTERATIONS ON STRIATAL DOPAMINE (DA) RELEASE IN ANESTHETIZED RATS: A MICRODIALYSIS STUDY. J.Yu, K.C.Gariepy, I.N. Acworth, T.J. Maher\*. Mass. Coll. of Pharm., Boston, MA 02115 and ESA, Inc., Bedford, MA 01730 Significant evidence supports a role for CNS monoamines in cardiovascular regulation. We measured, using microdialysis, striatal ECF levels of DA and its metabolites DOPAC and HVA. Dialysate DA, DOPAC, and HVA, as well as BP were recorded during infusion of nitroprusside (NPR), hydralazine (H), phenylephrine (PHE), or methoxamine (MX) and after mechanical hemorrhage (HEM). H and NPR increased striatal DA levels by 123 ± 52 and 56 ± 11 fold as BP decreased by 50% and 57%, respectively. DOPAC and HVA levels decreased by 60% and 50% after injection of H, however little effect was seen after NPR. PHE increased striatal DA by 2 fold as BP increased by 70%, however, effect was seen after NPR. PHE increased striatal DA by 2 fold as RP increased by 70%, however, another all agonist MA did not increase striatal DA despite a 150% BP increase. IV infusion of MX with H to maintain BP, produced only a slight increase in DA (47%). Cessation of MX infusion increased DA by 22 fold as BP decreased by 40%. HEM induced-hypotension also increased striatal DA by 9 fold. Changes in striatal DA accompany hypotensive insults and may constitute reflex hypotensive insults and may constitute reflex mechanisms and/or result from decreased cerebral blood flow

ENHANCED STRESS-INDUCED DOPAMINE RELEASE IN THE PREFRONTAL CORTEX IN AMPHETAMINE SENSITIZED RATS. T. Hamamura and H.C. Fibiger\*. Division of Neurological Sciences, Department of Psychiatry, University of British Columbia, Vancouver, B.C., Canada V6T 1Z3

Chronic administration of amphetamine (AMPH) can produce a syndrome that strongly resembles idiopathic psychosis in humans. There is also evidence that former AMPH abusers are particularly vulnerable to psychotic relapse upon exposure to psychological stress or acute re-exposure to the drug. The present study examined the possibility that dopaminergic mechanisms in the prefrontal cortex are involved in these phenomena. Rats received injections of saline (14 days) or AMPH (2 mg/kg 7 days and 4 mg/kg 7 days i.p.). After 7 days of drug abstinence, extracellular dopamine (DA) concentrations were measured in the prefrontal cortex and nucleus accumbens using in vivo microdialysis in freely moving rats. Mild foot shock stress (0.4 mA 10 sec/min 20 min) produced significantly greater increases in extracellular DA concentrations in the prefrontal cortex of AMPH pretreated rats than in controls. In contrast, compared to controls an AMPH (2 mg/kg) challenge produced significantly greater increases in extracellular DA concentrations in the nucleus accumbens but not in the prefrontal cortex. These results are consistent with previous reports by demonstrating that chronically pretreated rats exhibit an augmented dopaminergic response in nucleus accumbens upon re-exposure to AMPH. They also suggest that the mesocortical dopaminergic system is involved in cross-sensitization between AMPH and stress, but not in AMPH behavioral sensitization. EFFECTS OF THE INHIBITION OF DOPAMINE UPTAKE ON SYNAPTIC TRANSMISSION AND ON EXTRACELLULAR CATECHOLAMINE CONCENTRATIONS WITHIN THE SUPERIOR CERVICAL GANGLION OF THE RAT. C.G. Acosta-Farrar\* 2.P. Pantano<sup>3</sup>, J.H. Ashe<sup>1,2</sup>, W.G. Kuhr<sup>3</sup>.

Departments of Neuroscience<sup>1</sup>, Psychology<sup>2</sup> and Chemistry<sup>3</sup>, University of Colifornic Biogeoide CA 03651

Departments of reduces refer-7 sychology—and chemistry—chircusty of California, Riverside, CA 92521.

The objective of this study was to investigate the effects of dopamine uptake inhibitors on synaptic transmission and on stimulation induced changes in extracellular catecholamine concentrations within the superior cervical ganglion (SCG) of the rat. This was accomplished using both electrophysiological and electrochemical recording techniques.

electrochemical recording techniques.

Following incubation of the ganglion with the dopamine uptake inhibitor, GBR-12909 (5µM), the amplitude of the slow-inhibitory postsynaptic potential was selectively reduced. The amplitudes of the fast-excitatory postsynaptic potential and the slow-excitatory postsynaptic potential were not changed following GBR-12909 incubation. During the same time, the preganglionic volley also remained unchanged.

unchanged.

In separate experiments fast-scan cyclic voltammetry was used to examine stimulation induced changes in extracellular catecholamine concentrations within the SCG. In the presence of GBR-12909, an increase in oxidative current was recorded during and for a short period following electrical stimulation (1 to 20 Hz for 0.5 to 1.0 s) applied to ganglionic afferents. This suggests that an increase in the extracellular concentration of an oxidizable substance(s) had occurred. Voltammetric analysis suggests that a catecholamine(s) was the principle substance generating this oxidative current. In GBR-12909-free medium, stimulation-induced changes in oxidative currents were inconsistent and could not be identified as originating from catecholamine oxidation.

These results are consistent with the possible release of catecholamines either from small intensely fluorescent cells and/or principal cells within the SCG as a result of preganglionic nerve stimulation.

SIMULTANEOUS MONITORING OF ELECTRICALLY STIMULATED RELEASE AND REUPTAKE OF NOREPINEPHRINE FROM MULTIPLE REGIONS OF RAT BRAIN. <u>K.M. Mitchell</u> and R.N. Adams. Dept. of Chemistry, University of Kansas, Lawrence, KS 66045.

The aim of the present work was to quantitatively compare the temporal characteristics of norepinephrine (NE) release and reuptake in multiple regions of rat brain innervated by locus-coeruleus noradrenergic neurons. Chronoamperometry at a carbon fiber electrode allowed real time detection of NE overflow in the extracellular fluid elicited by electrical stimulation of the dorsal bundle ascending from the locus coeruleus in the urethane anesthetized rat. The kinetic parameters determined from the experimental data were used to accurately simulate the evoked responses using a model developed previously to characterize electrically stimulated dopamine overflow (Wightman et al., Brain Res. Rev. 15: 135, 1990).

Norepineprine release and reuptake were examined in the following brain regions: anterior ventral thalamus, lateral geniculate, stria terminalis, substantia innominata and cingulate cortex. All of the brain regions showed slight differences in the amount of NE release and rates of uptake. However, cortical responses were strikingly different with significantly smaller rates of uptake than in subcortical regions.

ESTROGEN MODULATION OF STIMULATED DOPAMINE RELEASE MEASURED BY IN VIVO VOLTAMMETRY. T.L Thompson\* and R.L. Moss. Dept. Physiology, UT Southwestern Medical Center, Dallas, TX 75235.

Estrogen (E) modulation of dopaminergic (DA) neurons is well

documented. In vitro experiments have demonstrated that E can increase DA turnover and release, as well as alter both pre- and post-synaptic DA receptors (Levesque et al. 1989, Fernandez-Ruiz et al. 1989, Becker 1990). Particular interest exists in elucidating the role of E on the modulation of nigrostriatal and mesolimbic dopaminergic neurons. In the present study we examined the effect of E on in vivo  $K^+$  stimulated DA release in ovariectomized rats using high speed voltammetry (5Hz, IVEC-5). Nafion coated multifiber carbon expoxy electrodes, attached to multibarrel glass pipets, were lowered into the striatum and nucleus accumbens of urethane anesthetized rats. DA release was stimulated by pressure ejection of KCI (70mM) from one barrel of the micropipet. Both genomic (E primed, Sug, 48hrs) and non-genomic (E pressure ejected 15min. prior to K<sup>+</sup>) mechanisms were studied. E priming: 1.) caused a slight reduction in the total amount of DA released; 2.) resulted in an increase clearance of DA; and 3.) decreased the disparity between the amount of DA released on the right and left sides of the accumbens which was observed in control animals. In contrast, there was no change in the magnitude nor time course of stimulated DA release measured over 1hr after a single ejection of E (1x10<sup>-5</sup>g/ml) in the striatum or the accumbens. Basal DA release was not effected by E infusion. These data suggest that E modulation of nigrostriatal and mesolimbic DA neurons may be due at least in part, to an alteration in reuptake mechanisms and that this modulation requires long term exposure. PHARMACOLOGICAL CHARACTERIZATION OF MONOAMINE RELEASE IN THE HIPPOCAMPUS: AN IN VIVO MICRODIALYSIS STUDY. K. Garlepy<sup>1</sup>, L. Acworth <sup>182\*</sup>, J. Yu<sup>2</sup>, and T. Maher<sup>2. 1</sup>ESA Inc., Bedford, MA 01730 and ssachusetts College of Pharmacy, Longwood Ave., Boston, MA 02155.

I. Acworth <sup>162-8</sup>, J. Yu.\*, and T. Maher.\* 'ESA Inc., Bedford, MA 01730 and <sup>2</sup>Massachusetts College of Pharmacy, Longwood Ave., Boston, MA 02155. The ability to routinely and accurately measure different neurotransmitters concurrently in a single brain region using one analytical system has always been desirable. We have developed a method capable of simultaneously quantitating norepinephrine (NE), dopamine (DA), and serotonin (5HT) at subpicogram levels, in under 8 minutes using conventional HPLC coupled to coulometric electrochemical detection. We have used microdialysis perfusion to examine the effects of a variety of receptor agonists on the ECF levels of monoamines in the hippocampus. Bats were anethetized with urethane and had a precalibrated 3mm "loop" type probe stereotaxically implanted into the right hippocampus. Basal concentrations of NE, DA, and 5HT were found to be approximately 2.25, 1.05, and 4.6 pg (per collection) respectively. The peripheral administration of the ∞ 2 agonist clonidine (0.3 mg/hg i.p.) caused a major decrease in NE levels by approximately 70% within 40 minutes. Clonidine also decreased DA levels but had little effect on those of 5HT. The subcutaneous administration of the D2 agonist, apomorphine (0.5 mg/hg in 0.1 μM ascorbate), decreased DA levels by greater than 75%. More interestingly, NE levels decreased to below detection limits. In a separate experiment the 5HT agonist (±)-8-Hydroxy-2-(di-n-proplyamino) tetralin (8-OH-DPAT) (2 mg/hg i.p.) caused a major decrease in 5HT levels by greater than 50% while levels of NE increased.

These data suggest that the measured chemicals be neuronal in origin. Using this method, it is possible to examine potential interaction between transmitter systems. By assaying for monoamines only improved sensitivity to approximately 300 fg can be obtained.

LOCAL CONTROL OF THE RELEASE OF NOREPINEPHRINE IN THE CNS: THEORY AND RESULTS. C.R. Collazo, E.A. Witte, and R.T. Marrocco \*. Inst. of Neuroscience, Univ. of Oregon, Eugene, OR 97403.

The notion of transmitter release regulated not only by electrical activity in the

parent neuron but also by mechanisms in the vicinity of the terminal bouton has received increasing support (e.g., Nelson, et al, 1980). We have recently proposed two mechanisms, levels of extracellular K+ and glutamate (glu), to account for the local control of norepinephrine release in the visual cortex of anesthetized macaque monkeys. Here, we present key elements of the theory and some recent empirical

The cerebral cortex receives specific inputs from the thalamus and from the locus coeruleus (LC). Local control theory asserts that activity in cortical neurons modulates the release of norepinephrine (NE) from locus ceruleus terminals. Several specific predictions may be made: a) the ocular dominance and orientation selectivity of both intrinsic activity and NE release should be similar, b) exogenous K+ or glu should enhance stimulus-evoked electrical activity and NE release for both approriate and inappropriate visual stimuli; c) focal electrical stimulation of the lateral geniculate nucleus should excite V1 neurons and evoke NE release at retinotopically matched sites but not at mismatched sites; d) pharmacological blockade of LC somata should not block the release of NE produced by activation

of intrinsic neurons or by local application of K+ or glu.

Predictions (a) and (b) have been empirically verified (Marrocco et al, 1987). Recent results from our lab suggest that reversible blockade of LC does not prevent local release of NE in parietal association cortex of anesthetized albino rats, thus supporting prediction (d). Our data thus suggest that local control mechanisms may modulate local NE release in visual cortex. Supported by the McDonnell-Pew Foundation.

OMEGA CONOTOXIN (ωCT) AND α2-ADRENOCEPTOR AGONISTS (AAA) IMPAIR SYNAPTIC TRANSMISSION IN THE PERIPHERAL SYMPATHETIC NERVOUS SYSTEM (SNS) BY N-TYPE CALCIUM CHANNEL BLOCKADE (N-CCB). H.K. Schedewie, N. Boban, J.P. Kampine\* and Z.J. Bosnjak , Department of Anesthesiology, The Medical College of Wisconsin, Milwaukee, WI 53226

We have previously shown that wCT and AAA, like dexmedetomidine (DMT), impair synaptic transmission in the peripheral SNS by N-CCB. The present investigation was designed to further delineate the site(s) and mechanism(s) of these ωCT and DMT actions. 10 stellate ganglia (SG) were isolated from adult mongrel dogs, desheathed and superfused with Krebs' buffer at pH 7.4 and 37°C. Compound action potentials (CAP) were generated by supramaximal stimulation of the preganglionic T3 ramus and were recorded from the ventral ansa subclaviae. The percent CAP change from control was measured after SG superfusion in the following order with DMT-ATI-DMT-ωCT-ATI in a first set of experiments versus DMT-ATIωCT-DMT-ATI in a second set. Superfusate drug concentrations of ωCT 64x10<sup>-9</sup>M and DMT 10<sup>-6</sup>M were those determined in dose-response studies to cause maximal CAP depression; the concentration of the α2-antagonist atipamezole (ATI) 10-6M was selected to be equimolar to DMT. Results: 1) DMT caused rapid onset CAP depression, that did not resolve by washout alone until specifically reversed by ATI; 2) ATI reversal of CAP depression was prompt and complete; 3) ωCT caused slow onset CAP depression, that was not reversible by washout or ATI; 4) ωCT administered subsequent to DMT caused insignificant additional CAP depression suggesting that both ωCT and DMT act on the N-CC; and 5) ATI was able to reverse the CAP depression resulting from the combined effect of DMT followed by  $\omega CT$ , but failed to reverse the effect of ωCT followed by DMT. This suggests that DMT and ωCT may have close interactions at the receptor complex that controls calcium transport across N-CC.

## SEROTONIN RECEPTORS: MOLECULAR BIOLOGY

## 198.1

CLONING AND CHARACTERIZATION OF A SEROTONIN RECEPTOR FROM LYMNAEA STAGNALIS K.S. Sugamori, R.K. CLONING AND CHARACTERIZATION OF A SEROTONIN RECEPTOR FROM LYMNAEA STAGNALIS K.S. Sugamori, R.K. Serotonin is a major neurotransmitter in molluses that is involved in many behaviours such as learning and memory. We have cloned a serotonin receptor (5HTlym) from the pond snail *Lymnaea stagnalis* using a strategy based on the high homology of genes encoding members of the superfamily of G-protein coupled receptors and the polymerase chain reaction. The receptor protein is composed of 509 amino acids and displays high homology to the mammalian 5HT, family of serotonin receptors and to the *Drosophila* serotonin receptors. Northern blot analysis revealed the presence of two mRNA species of 2.3 and 3.2 kb in the central nervous system of *Lymnaea*. Membranes prepared from COS-7 cells transiently expressing the receptor bound [1H]-LSD in a saturable manner with high affinity (Kd-0.9 nM), and exhibited a distinct pharmacological profile. The rank order of potency for inhibition by various serotonergic agonists and antagonists is as follows: methothepin>lisuride > LSD > clozapine > ergotamine > metergoline > 5CT > SCH23390 > 5HT > quipazine > ketanserin > noradrenaline > dopamine. The pharmacological profile displayed by 5HTlym suggests that this invertebrate serotonin receptor represents a novel 5HT receptor that cannot be classified according to the classification scheme used to define mammalian serotonin receptors.

EXPRESSION OF RECOMBINANT SEROTONIN RECEPTORS IN THE BACULOVIRUS-INSECT CELL SYSTEM. Eric M. Parker\*, Darcy A. Grisel and Lawrence G. Iben. Department of Biophysics and Molecular Biology, Bristol-Myers Squibb Co., Wallingford, CT 06492

Three human serotonin receptor subtypes (5-HT<sub>1A</sub>, 5-HT<sub>1Dα</sub> and 5-HT<sub>1Dβ</sub>) have been expressed in the baculovirus-insect cell system. Sf9 cell membranes containing the 5-HT<sub>1</sub>A receptor displayed both high (KD=1.0 nM) and low (KD=26 nM) affinity binding sites for the agonist radioligand [3H]8-OH-DPAT. GTPγS (100 μM) decreased radioligand binding to the high affinity site by 80%. The 5-HT<sub>1A</sub> receptor produced by the insect cells had the appropriate affinity for a variety of standard ligands. Western blots of insect cell membranes containing the 5-HT1A receptor revealed 4-5 immunoreactive bands at 40-50 kDa. In contrast, insect cell membranes containing the 5-HT $_{1D\alpha}$  and 5-HT $_{1D\beta}$  receptors displayed a single high affinity binding site for the radioligand [ $^3$ H]5-CT ( $K_D$ =0.5 nM in both cases). Binding to these receptors was relatively insensitive to the inclusion of guanine nucleotides and/or NaCl in the binding assay (20-30% inhibition). The ligand binding properties of the two 5-HT<sub>1D</sub> receptors expressed by the insect cells is similar. Metergoline is the most selective compound identified thus far (10 fold higher affinity for the 5-HT  $_{1D\alpha}$  receptor). It is concluded that serotonin receptors can be successfully expressed in the baculovirus-insect cell system. These receptors apparently can interact with G proteins in the insect cell membrane and thus can be detected with available agonist radioligands. This system should be a useful for the production of high levels of receptors for purification and pharmaceutical screening.

MOLECULAR ANALYSIS OF SEROTONIN RECEPTORS IN

MOLECULAR ANALYSIS OF SEROTONIN RECEPTORS IN APLYSIA C.Bessho\*,T.Shirai and T.Manabe# Dept. of Physics, Kyoto Sangyo Univ. and #Dept. of Physiology, Kyoto Univ. Sch. of Med., Kyoto 603

In Aplysia gill withdrawal refrex, serotonin (5HT) evokes presynaptic facilitation of sensory to motor neuron synapses. The 5HT receptors were analyzed by their functional expression of the gill mRNAs in <u>Xenopus</u> oocytes and assayed by electrophysiological method. The application of 5HT to mRNAs injected oocytes elicited an oscillatory current after a delay. The reversal potentials of the reversal potentials of the reversal potentials of the reversal potentials. tial of this current corresponded with that of chrolide current. The cDNA libraries from Aplysia abdominal ganglia were probed with the cDNA coding a human 5HT-1A receptor (G21, a gift from Dr. Lefkowitz, J.) at low stringency. The isolated cDNAs were amplified by PCR with degenerate primers corresponding to consensus DNA sequences of the third and sixth transmembrane segments of G protein-coupled receptors. The amplified DNA fragments (400-600 b.p) were subcloned in the vectors. The insertion DNAs were sequenced by Sanger's method. We are screening Aplysia cDNA libraries with the DNA fragments homologous to G21 for full length clones.

RECEPTOR RESERVE MASKS PARTIAL AGONIST ACTIVITY OF DRUGS IN A CLONED RAT 5-HT<sub>18</sub> RECEPTOR EXPRESSION SYSTEM. N. Adham. B. Ellerbrock, P. Hartig, R. Weinshank and T. Branchek. Synaptic Pharmaceutical Corporation, Paramus, N. J. 07652

We have previously cloned and characterized a rat 5-HT<sub>18</sub> receptor (Adham et al., 1992) and subsequently observed several divergences from the expected pharmacological actions of known drugs at these receptors. For example, the β-adrenergic antagonists propranolol and pindolol (reported to be partial agonists or antagonists at native 5-HT<sub>18</sub> receptors) were found to be full agonists at the cloned 5-HT<sub>18</sub> receptors were found to be full agonists at the cloned 5-HT<sub>18</sub> receptor, and dition, the EC<sub>80</sub> values for agonists (determined by measuring drug-induced inhibition of forskolin-stimulated cAMP release) were lower than expected from the measured K, values determined from (1\*B)liodocyanopindolol binding (e.g. 5-HT: EC<sub>80</sub> -0.49 ± 0.043, n = 6; Ki = 5.3 ± 0.82, n = 49. To investigate the degree of receptor reserve, we used the irreversible receptor antagonist N-ethoxycarbonyl-2-ethoxy-1,2-dihydroquinoline (EEDO). EEDO treatment shifted the dose-response curve for 5-HT to the right by 5-8 fold accompanied by a reduction (20-50%) in maximal response. Furchgort analysis revealed a very steep hyperbolic relationship between receptor occupancy and response for 5-HT with 96 ± 1.4% (n = 3) receptor reserve at the 50% maximal response curves for pindolol. The maximal responses were reduced and a linear relationship was found between receptor occupancy and response for this compound. According to classical receptor theory, these data indicate that pindolol acts as a partial agonist relative to 5-HT but due to the large number of receptors present, the difference in the intrinsic activities of the two drugs is masked. Therefore, one has to be cautious when interpreting functional data in transfected systems that may possess large receptor reserves.

CLONING AND CHARACTERIZATION OF A NOVEL 5-CT INSENSITIVE (5HT<sub>rE</sub>) RECEPTOR. M. <u>Teitler\*, K. J. Miller and B.J. Hoffman\*</u>, Dept. of Pharmacology and Toxicology, Albany Medical College, 47 New Scotland Avenue, Albany, N.Y. 12208.\*Lab. Cell Biol., NIMH, Bethesda, MD.

Multiple serotonin receptors have been detected, originally using Multiple serotonin receptors have been detected, originary using radioligand binding methodologies and second messenger systems, and more recently using recombinant DNA technology. These multiple receptors have been sub-divided into four families: SHT<sub>1</sub>, SHT<sub>3</sub>, and SHT<sub>4</sub> receptors, based on various pharmacological criteria. The potency of the tryptamine derivative 5CT (5-carboxy-amidotryptamine) was at one time used to define receptors belonging to the SHT<sub>4</sub> receptor family. However in 1989 a receptor was detected using radioligand binding methodology that fulfilled other criteria for a 5HT, receptor, but displayed low affinity for 5CT. This receptor was designated "5HT, $_{\rm E}$ " (1). Recently the sequence of a clone displaying properties typical of a G-protein coupled receptor and displaying a fairly high degree of homology with previously cloned 5HT receptors was reported (2). In order to determine the properties of the receptor coded for by this sequence primers were designed 5' and 3' to the coding region, and the human gene was amplified by PCR. After subcloning, stable transfectants were produced. Preliminary data suggests that this receptor displays high affinity for 5HT ( $\sim$ nM) and low affinity for 5CT ( $\sim$ µM). Detailed pharmacological properties of this clone will be presented. (Supported by PHS grant no. MH40716)

LIGAND BINDING DOMAINS OF THE RAT 5HT<sub>1c</sub> RECEPTOR DETERMINED BY SINGLE SITE MUTATION. S. Leonhardt ', B.J. Hoffman ^ and M. Teitler, Dept. of Pharmacology & Toxicology, Albany Medical College, Albany, N.Y. 12208; ^ Laboratory of Cell Biology, NIMH, Bethesda, MD, 20892.

5HT<sub>1C</sub> and 5HT<sub>2</sub> receptors appear to be closely related from a pharmacological as well as molecular viewpoint, displaying similar pharmacological profiles, identical second messenger systems and a high degree of amino acid sequence homology. However there are striking differences in the interactions of 5HT with 5HT<sub>10</sub> and 5HT, receptors: 5HT is generally 10-fold more potent in stimulating responses mediated through  $5\mathrm{HT}_{,\mathrm{C}}$  receptors than in stimulating responses mediated through  $5\mathrm{HT}_2$  receptors. The affinity and potency of  $5\mathrm{HT}$  for the  $5\mathrm{HT}_{,\mathrm{C}}$  receptor appears to be similar to other members of the  $5\mathrm{HT}_{,\mathrm{T}}$ -receptor family. In aligning the seven transmembrane domains of the cloned mammalian 5HT, and 5HT, receptor families we noticed an arginine residue identical in all 5HT receptors displaying high affinity and potency for 5HT. In the mammalian 5HT<sub>2</sub> receptor and in the 5HT<sub>DROSOPHILA</sub>, receptors with affinities for 5HT in the micromolar range, the arginine has been replaced by glutamine and glycine, respectively. Using recombinant PCR we have constructed a mutant 5HT<sub>1C</sub> receptor with a glutamine residue in transmembrane domain IV. We predict that mutating the arginine residue of the  $\mathrm{5HT_{1C}}$  receptor to a glutamine will significantly decrease the affinity and potency of 5HT for the  $\mathrm{5HT_{1C}}$  receptor. The results of these and other site-specific mutagenesis studies should reveal the molecular determinants of 5HT affinity and potency at serotonin receptors.

## 198.9

DESENSITIZATION OF THE 5-HT<sub>3</sub> RECEPTOR IS ALTERED BY A SINGLE AMINO ACID SUBSTITUTION. J.L. Yakel\*, A. Lagrutta, J.P. Adelman, R.A. North. Vollum Institute, Oregon Health Sciences University, Portland, OR. 97201

The cloned 5-HT<sub>3</sub> receptor (Maricq et al., Science: 254,

432, 1991) was expressed in Xenopus oocytes to study the relation between primary structure and the kinetics of desensitization. 5-HT (300 nM to 100  $\mu$ M) evoked an inward desensitization. 5-HT (300 nM to 100  $\mu$ M) evoked an inward current at -60 mV, which became larger with hyperpolarization and reversed near 0 mV. The current decayed by 50% during the continual application of 5-HT (30  $\mu$ M) in 47  $\pm$  3 sec (mean  $\pm$ s.e.m.; n=13). The site-directed mutant L286F, whereby the leucine at position 286 was replaced by phenylalanine, desensitized much faster (the current decayed by 50% in 1.2  $\pm$  0.1 sec (n=9)), while the L286T mutant (a leucine-to-threonine substitution) desensitized much slower (the current decayed by  $19 \pm 4$ % [n=9] during a 1 min application of 5-HT). The concentration of 5-HT that produced a half-maximal current was not greatly altered by these mutations. The direction of these changes in desensitization kinetics is similar to that observed for the neuronal nicotinic receptor expressed in <u>Xenopus</u> oocytes (Revah et al., <u>Nature: 353</u>, 846, 1991), in which smaller, more polar amino acid substitutions at the equivalent podesensitization. position reduced the kinetics

Agonist Activity of Sumatriptan and Metergoline at the Serotonin 5-HT<sub>1D8</sub> Receptor: Evidence for a Role of a 5-HT<sub>1D</sub> Receptor in the Anti-Migraine Action of Sumatriptan.

K.J. Miller\*, A. King L. Demchyshyn\*, H. Niznik\*\*, and M. Teitler. \*Dept. of Pharm/Tox, Albany Medical College, Albany, NY 12208 and Dept. of Psychiatry+ and Pharmacology#, University of Toronto, and the Molecular Neurobiology Laboratory\$, The Clarke Institute of Psychiatry, Toronto, Ontario M5T-1R8.

We have recently cloned a novel human 5-HT<sub>10</sub> receptor subtype termed 5-HT<sub>108</sub>. CHO K1 cells expressing the serotonin 5-HT<sub>108</sub> receptor were assayed to determine the second messenger of this receptor. Cyclic AMP radioimmunoassays revealed that the  $5\text{-HT}_{100}$  receptor is negatively coupled to adenylate cyclase in this cell system, typical of the  $5\text{-HT}_1$ ptor sub-family. A maximum of 50% inhibition of forskolin stimulated cAMP production was obtained with 5-HT, receptor agonists which was blocked by the non-selective 5-HT receptor antagonist methiothepin, no stimulatory activity was detected. The novel anti-migraine drug sumatriptan, a putative 5-HT $_{1D}$  selective compound, acted as an agonist at the 5-HT $_{1DB}$  receptor (EC $_{5D}$ =317±90). Most notably metergoline, a putative 5-HT, receptor antagonist, did not block the effects of 5-HT and was found to be acting as an agonist at the 5-HT<sub>1D8</sub> receptor (EC<sub>50</sub>=98 $\pm$ 9). The ability of metergoline to act as an agonist may explain why it does not inhibit 5-HT and sumatriptan induce contraction of dog saphenous vein and other large conducting arteries. These results suggest that the 5-HT<sub>1DB</sub> receptor may be the site of action of sumatriptan in preventing migraine, and that metergoline's actions on the dog saphenous vein are not contradictory to that hypothesis, as previously reported. (Supported by MH 40716 to M.T.)

REGULATION OF mRNA FOR 5-HT2 RECEPTORS IN P11 CELLS BY AGONISTS. R. C. Ferry\*. R. Artymyshyn and P. B. Molinoff. Dept. of Pharm, Univ of Penn. School of Med., Phila., PA 19104 In several experimental paradigms, central 5-HT2 receptors exhibit anomalous regulatory responses. Paradoxical changes in the number of 5-HT2 receptors following various drug treatments and experimental manipulations may be the result of unique regulatory mechanisms or may arise from complexities of *in vivo* studies. To investigate the anomalous regulation of the 5-HT2 receptor, this laboratory has isolated a cell line (P11 cells) which expresses a high density of 5-HT2, receptors coupled to stimulation of phosphatidylinositol hydrolysis. We have previously used this cell line as a model system to demonstrate that in contrast to reports of studies carried out *in vivo*, antagonists at this receptor, including ketanserin and mianserin, do not alter the density of 5-HT2 receptors. Both full (5-HT) and partial (LSD, DOI) agonists, however, down-regulate the receptor with similar efficacy, an effect that has been observed *in vivo*. The mechanisms responsible for agonist-induced regulation of 5-HT2 receptor are not known. Changes in 5-HT2 receptor messager RNA (mRNA) could occur and may be responsible for agonist-dependent changes in the density of receptor. To quantify 5-HT2 receptor mRNA in P11 cells, a ribonuclease protection assay was used. A 200-bp cDNA insert encoding a portion of the i3 loop of the 5-HT2 receptor was amplified from full-length 5-HT2 receptor cDNA using the polymerase chain reaction. This insert was ligated into pGEMTZ-(f-4) to generate a recombinant plasmid that was used as a template to generate radiolabeled riboprobes specific for the 5-HT2 receptor. Exposure of P11 cells to 5-HT led to a time- and dose-dependent increase in 5-HT2 receptor mRNA. A significant increase in levels of receptor mRNA was seen as early as 30 min after exposure to 10 µM 5-HT and was maximal at 1.5 hr (> 2-Fold). An increase in 5-HT2 recepto

5-HT1B and 1D RECEPTORS IN MAMMALIAN BRAIN: VISUALIZATION 5-HT1B and 1D RECEPTORS IN MAMMALIAN BRAIN: VISUALIZATION OF THEIR MRNAS AND BINDING SITES BY IN SITU HYBRIDIZATION AND LIGAND BINDING AUTORADIOGRAPHY. R. Cortés¹\*, G.Mengod¹, B. O'Dowd², F. Artigas¹, and J.M. Palacios³. ¹C.I.D., Centro Investigación y Desarrollo, C.S.I.C., Jordi Girona, 18-26, 08034 Barcelona (Spain), ²Dept. of Pharmacology, University of Toronto, Ont. Canada M5S 1A8. ³Research Institut Almirall Laboratories, Cardener, 68-74, 08024 Barcelona

Cloning of the genes coding for 5-HT1B and 5-HT1D recep tors in several mammalian species has shown that these receptors, although presenting marked species differences in their pharmacology, are homologous members of a sub-family of 5-HT receptors. We have used oligonucleotide probes from the sequences of the 5-HTLB and 1D genes to visualize the distribution of these two receptors mRNAs in the rat and other mammalian species including man. In parallel, the distribution of putative 5-HTIB and 1D sites has been studied using receptor autoradiography with ligands such as  $^{3}$ H 5-HT,  $^{125}$ I -GTI and  $^{125}$ I CYP in the presence of selective displacers in all the species examined. Both receptors were predominant in the basal ganglia but not in the subs tantia nigra. Furthermore, both receptors mRNAs were also expressed in the nucleus raphé dorsalis.5-HT1B receptor mRNA was much more abundant than 1D in the other brain regions. Mismatches between mRNA and binding sites were observed. These studies indicate areas in the mammalian brain where 5-HT1B receptors can be studied separately from 1D sites.

EXPRESSION IN BACTERIA OF RECOMBINANT HUMAN SEROTONIN RECEPTORS OF THE 5-HT<sub>1A</sub> AND 5-HT<sub>1D</sub> SUBTYPE. <u>W.H.M.L. Luyten\*. I. Yan de Weyer. W. Gommeren and J.E. Leysen</u>. Department of Biochemical Pharmacology, Janssen Research Foundation, Beerse, B2340 Belgium.

The coding region of a human 5-HT1<sub>A</sub> receptor clone, purchased from TULCO (Durham, North Carolina, U.S.A.), was inserted into the pMalp bacterial expression vector (New England Biolabs, Massachusetts, U.S.A.). A full-length human 5-HT1<sub>D</sub> receptor cDNA was amplified by the polymerase chain reaction and also inserted into the pMalp vector. Both constructs generate MalE fusion proteins, whose N-terminus should be translocated to the periplasm. Bacteria harbouring these expression constructs were maintained in rich media supplemented with flucose (1%) and ampicillin (100 μg/ml). Induction of early log-phase cultures with isopropyl-β-D-thiogalactopyranoside led to a rapid flattening of the growth curve and progressive expression of the abovementioned receptor proteins as judged by radioligand binding. Maximal expression was reached after 3-4 hours for the 5-HT1<sub>D</sub>-receptor.

The 5-HT $_{1A}$  receptor, measured with 2-(N,N-di/2,3(n)- $^3$ H]propylamino)-8-hydroxy-1,2,3,4-tetrahydronaphtalene (8-OH-DPAT), displayed an affinity of 10-20 nM when expressed in bacteria, compared to 0.5-1 nM when expressed in the HA-7 eukaryotic cell line or measured in rat hippocampal membranes and 1.5-3 nM when the non-hydrolysable GTP-analogue GppNTp was added to the latter two preparations. For a large number of reference compounds the affinity ( $K_1$ , calculated from experimentally derived IC50s) was 10-100-fold lower in bacteria, compared to the HA-7 cells or hippocampal membranes. However, for ergotamine, spiperone and metitepine, affinities were comparable in the three systems. The 5-HT $_{1D}$  receptor, measured with 5-hydroxy( $G^{-3}$ H]tryptamine, displayed an affinity of  $\pm$ 5 nM when expressed in bacteria or COS cells, compared to  $\pm$ 0.5 nM when measured in calf substantia nigra membranes.

The  $K_i$ s for sumatriptan and metergoline were comparable in the three systems. Most likely, the measured affinity differences result from differences in the presence of or interaction with appropriate G-proteins, which allosterically modulate receptor affinity for agonists.

CLONING AND FUNCTIONAL EXPRESSION OF A NOVEL RAT 5-HT, -LIKE RECEPTOR. T.W. Lovenberg 1. M.G. Erlander 1. B.M. Baron 2. M.W. Dudleg 2. P.E. Danielsen 1. J.E. Burns 1. C.M. Craft 3. J.G. Sutcliffe 1. Dept. Mol. Biol., The Scripps Res. Inst., L. a. Jolla, CA 92037. 2 Marion Merrell Dow Res. Inst., Clincinnati, OH 45215. 3 Univ. Texas Southwestern Med. Sch., Dallas, TX 75235. In order to identify new members of the 5-HT receptor family, we used a

In order to identify new members of the 5–HT receptor family, we used a polymerase chain reaction (PCR) with highly degenerate primers corresponding to conserved transmembrane domains three and five of known 5–HT receptors. This approach resulted in two novel sequences, MR77 and MR22 (For description of MR22, see abstract of Erlander et al.). PCR-amplified cDNA was used to isolate a full length genomic clone (MR77) containing an intronless open reading frame encoding a putative 366 amino acid protein related to the rat 5–HT $_{1,1}$ , 5–HT $_{1,2}$ , dog 5–HT $_{1,1}$ , and human S31 receptors with 34%, 46%, 32%, and 56% overall identity, respectively. Greater than 90% of the binding of  $\left[^{122}\right]I-LSD$  to membranes prepared from MR77—transfected CosM6 cells could be inhibited by 100 uM 5–HT (IC $_{50}$  = 59 nM). Binding data both confirms the similarity to the 5–HT $_{1,1}$  breceptor (sumatriptan IC $_{50}$  = 64 nM) and helps to differentiate the two binding sites [e.g., MR77 appears to be insensitive to 5–Carboxyamidotryptamine (5–CT)]. The amino acid structure of MR77 (long TM 5–6 intracellular loop and a short C-terminal tail) suggested that it may be coupled to the inhibition of adenylate cyclase through a  $G_{1}$ —like G—protein. In HeLa cells cotransfected with MR77 and the hamster Beta-adrenergic receptor, 5–HT (10 uM) inhibited isoproterenol stimulated cAMP accumulation (32%). Together, this data suggests that MR77 is a novel 5–HT receptor in the 5–HT subfamily. The initial pharmacological characterization indicates that MR77 is similar to the 5–HT $_{12}$  receptor by virtue of its low affinity for 5–CT. Further studies should clarify the correct classification of this unique receptor.

## 198.15

GENERATION OF A cDNA PROBE SPECIFIC FOR THE 5-HT<sub>1B</sub> RECEPTOR IN THE OK CELL, AN OPOSSUM KIDNEY CELL LINE. D.R. Cerutis, \* N.A. Hass and D.B. Bylund, Dept. of Pharmacology, Univ. of Nebraska Med. Ctr., Omaha, NE 68198-6260.

Serotonin is a neurotransmitter which mediates a wide range of effects by interacting with multiple receptor subtypes. Previous studies from our laboratory have demonstrated the presence of the serotonin 5-HT<sub>1B</sub> receptor in the OK cell line, an established renal proximal tubule epithelial cell line. In order to generate a probe for this receptor, the published sequences of the canine 5-HT<sub>1D</sub> and the rat 5-HT<sub>1B</sub> were used to design degenerate primers directed at the first and sixth transmembranes (TM) domains. OK cell RNA was isolated using standard guanidinium thiocyanate methodology. Approximately 2  $\mu$ g of this RNA was reverse transcribed using AMV reverse transcriptase, and the resulting cDNA's were subjected to 30 cycles of PCR with the above primers. The resulting product of about 0.8 kb is consistent with the calculated size of this region. This product was cloned into pBluescript KS+ (Stratagene) and sequenced by the dideoxy chain termination method. This cDNA fragment exhibits > 90% similarity (within the TM domains) at the amino acid level with the published mouse and rat 5-HT<sub>1B</sub> receptors. This fragment was radiolabeled and used as a probe on an OK cell mRNA Northern blot, showing a message size of about 6 kb. This fragment is currently being used to screen an OK cell  $\lambda$ gt11 cDNA library. (Supported by NIH grant MH47334).

### 198.12

A NOVEL 5-HT RECEPTOR SUBFAMILY MEMBER HIGHLY ENRICHED IN THE HIPPOCAMPUS. M.G. Erlander 1, T.W. Lovenberg B. M. Baron M.W. Dudley L.K. Cannon P.E. Danielson J. J.E. Burns C.M. Craft J.G. Sutcliffe Dept. Mol. Biol., The Scripps Res. Inst., La Jolla, CA 92037. 2 Marion Merrell Dow Res. Inst., Cincinnti, OH 45215. 3 Univ. Texas Southwestern Med. Sch., Dallas, TX 75235.

We have used a polymerase chain reaction (PCR)—based strategy to isolate novel cDNA clones of mRNAs encoding 5–HT receptor—like proteins (seven transmembrane family). By using degenerate primers specific to known 5–HT receptors, we isolated two PCR cDNAs from rat brain designated MR22 and MR77 (for description of MR77 see abstract of Lovenberg et al.). A single fullength clone was initially isolated from rat hypothalamus cDNA; MR22 encodes a 370 amino acid protein with 30–34% overall sequence identity with known catechol and 5HT receptors. The tissue distribution of MR22 mRNA is highly enriched in hippocampus (10–20 fold greater) when compared to hypothalamus thalamus and pons and MR22 mRNA is not detectable in cortex, striatum, cerebellum as well as liver, kidney and heart. Transient expression of MR22 cDNA in CosM6 cells suggests that MR22 encodes a 5–HT receptor in that > 80% Air CosM6 cells suggests that MR22 encodes a 5–HT receptor in that > 80% he binding of  ${1}^{125}||-\text{LDS}||$  could be inhibited by 100 uM 5–HT (IC $_{50}=20$  1 uM). In addition, binding was sensitive to 5–carboxyamidotryptamine (IC $_{50}=20$  30 nM) and methiothepin (IC $_{50}=82$  nM), but insensitive to sumatriptan (IC $_{50}=20$  30 nM) and methiothepin (IC $_{50}=30$  2 nM), but insensitive to sumatriptan (IC $_{50}=30$  2 nM). The pharmacological data suggest that MR22 cDNA encodes a novel 5–HT receptor and may represent a unique 5–HT receptor subfamily.

## 198.14

QUANTITATIVE ESTIMATION OF 5HT<sub>2</sub> RECEPTOR mRNA IN RAT GLIOMA C6BU-1 CELLS BY THE RT-PCR METHOD. M. Ikeda\*, M. Mikuni, K. Saitoh, C. Yamazaki and K. Takahashi, Div. Mental Disorder Res., Natl. Inst. Neurosci. NCNP, Kodaira, Tokyo 187, Japan

We have previously shown that 4-hour treatment with 5HT attenuated 5HT-stimulated Calcium mobilization and 24-hour treatment with dexamethasone enhanced it in rat glioma C6BU-1 cells. To evaluate the transcriptional regulation of 5HT2 receptor in C6BU-1 cells, we applied RT-PCR method to quantify it's mRNA. Total RNA from C6BU-1 cells was extracted by the method of Gough. Priming with random hexamers was used to synthesize cDNA. To normalize sample-to-sample variations, we co-amplified B-actin cDNA. One primer of each set was radiolabeled by 5' end-labeling. excess amplification of B-actin cDNA, primer set for amplification of B-actin cDNA was added after 15 cycles. The products of PCR were removed after various cycles and fractionated by polyacrylamide gel. Radioactivity was measured by the Bioimaging analyzer (Fujix BAS2000). Work is in progress to determine the effect of 5HT and dexamethasone on the transcriptional regulation of 5HT2 receptor gene.

## 198.16

CLONING OF A HUMAN PSEUDOGENE RELATED TO THE 5-HYDROXYTRYPTAMINE 1D RECEPTOR GENE. T. Nguyen. P.H. Wu. A. Marchese, W.M. Burnham\* and B.F. O'Dowd. Addiction Research Foundation and Department of Pharmacology, University of Toronto, Toronto, Canada M5S 1A8.

In an effort intially planned to isolate novel adenosine receptors, we prepared degenerate primers based on the third and sixth transmembrane (TM) regions of A1 and A2 receptors. The gene structure of these adenosine receptors had not been reported, however, many G protein-coupled receptors are encoded on single exons. The primers were used to amplify genomic DNA in the polymerase chain reaction, and DNA in the size range 350 to 1000 bp was subcloned. One of these clones, BD-20 with an insert size of 350 bp, contained some sequence homologous to the serotonin receptors. BD-20 was used to uman genomic library, and nineteen probe binding phage were plaque purified. Deduced amino acid sequence of one of these clones (TN-1) possessed six TM regions most closely homologous to the 5HT1D receptor, however, several stop codons and deletions were present in the coding region suggesting that TN-1 could not encode a functional receptor. Sequence analysis revealed that the sequence of TN-1 following TM 6 was disrupted by insertion of an Alu element, including a poly A tract of 20 bp. Northern blot analysis using clone TN-1 in rat and human showed the presence of mRNA transcripts in many organs, including brain. However, Northern analysis using clone BD-20 (lacking the Alu repeat) did not show any detectable hybridization. We have previously reported the presence of two dopamine pseudogenes in the G protein coupled receptor gene family, however, this report is the first of a serotonin pseudogene.

MOLECULAR CLONING AND CHARACTERIZATION OF A cDNA ENCODING A SEROTONIN-RELATED G PROTEIN-LINKED RECEPTOR. Y. Shen\* F.J. Monsma. Jr., C.R. Gerfen. L.C. Mahan P.A. Jose, and D.R. Sibley. Experimental Therapeutics Branch, NINDS and Laboratory of Cell Biology, NIMH, NIH, Bethesda, MD 20892.

We have recently cloned a cDNA encoding a novel G protein-coupled receptor which exhibits high homology to serotonin receptors. This sequence was initially identified as a cDNA fragment which was amplified from rat kidney proximal convoluted tubule mRNA using the polymerase chain reaction (PCR). Northern blot analysis with this fragment reveals an ~3.6 kb transcript with the following rank order of abundance in CNS tissues: hypothalamus > hippocampus = mesencephalon > olfactory bulb = cerebral cortex > olfactory tubercle > striatum. In peripheral tissues, this mRNA is most abundant in the spleen. In situ hybridization analysis confirms the Northern blot data and also reveals a high level of transcript in the thalamic reticular nucleus. Isolation and sequencing of a full-length clone obtained from a rat hippocampal library revealed a long ORF encoding a 404 residue protein the sequence of which is most closely related to the serotonin receptor family. Within the 7 putative transmembrane spanning regions, this receptor exhibits 60% - 43% identity with the following receptors: SHT0pc01 > SHT1p > SHT1q > D1A > D2 > SHT2c. The rat hippocampal cDNA also appeared to contain 72 bp of incompletely spliced intronic sequence located in the 2nd intracellular loop. PCR amplification and sequencing of hippocampal mRNA using primers flanking this region confirmed the presence of two alternatively-spliced forms of mRNA, one of which represents a correctly spliced transcript. This latter PCR product was subsequently used in the construction of a correctly spliced full-length clone for expression analysis. Thus far, transient expression of this clone in Cos-7 cells has not produced specific radioligand binding activity using a variety of ligands. Further identification of this receptor subtype using functional assays is currently being attempted.

CLONING AND EXPRESSION OF A NOVEL SEROTONIN RECEPTOR SUBTYPE. Frederick J. Monsma. Jr. Yong Shen. Lawrence C. Mahan, and David R. Sibley. Experimental Therapeutics Branch, NINDS and Laboratory of Cell Biology, NIMH, NIH, Bethesda, MD 20892.

We have utilized the polymerase chain reaction (PCR) technique to

We have utilized the polymerase chain reaction (PCH) technique to selectively amplity G protein-coupled receptor cDNA sequences from rat striatal mRNA. One cDNA fragment was identified which exhibits high homology with previously cloned catecholamine receptors. Sequencing of a full-length clone isolated from a rat striatal cDNA library, using this fragment, revealed an open reading frame of 1308 bp encoding a 436 residue protein with seven hydrophobic regions representing putative transmembrane spanning domains. Within these hydrophobic regions, this receptor was found to exhibit 44% - 36% identity with the following receptors: D1\_A = D1\_B> D\_2 = D\_3 = D\_4 > 5HT\_2 > 5HT\_1C > 5HT\_1Da > 5HT\_1A > 5HT\_1DB. Northern blot analysis revealed an ~3.8 kb transcript with the following rank order of abundance in CNS tissues: striatum >> olfactory tubercle > cortex > hippocampus. Expression of the full-length cDNA in Cos-7 cells resulted in the appearance of high affinity and saturable [ $^{125}$ I]-LSD binding ( $K_d = 3$  nM). Among all endogenous biogenic amines tested, only 5-HT completely inhibited [ $^{125}$ I]-LSD binding a K i of = 300 nM. The rank order of potency for inhibition of [ $^{125}$ I]-LSD binding by other serotonergic agonists was: 5-MT > 5-HT > 5-CT > TFMPP > mCPP >> 8-OH-DPAT. The rank order of antagonist binding was: mianserin >> (-) propranolol >SCH 23390 > ketanserin = spiroperidol. As a group, ergoline derivatives displayed the highest affinities: lisuride > lergotrile > bromocriptine > dihydroergotamine > 2-Br-LSD > dihydroergocriptine. This pharmacological profile does not appear to correlate with any previously described 5-HT receptor subtype. The functional properties of this novel 5-HT receptor are currently under investigation.

# HISTAMINE AND OTHER BIOGENIC AMINES

## 199.1

EFFECTS OF HISTAMINE ON HYPOTHALAMIC 5-HYDROXYTRYPTAMINE NEURONS IN THE RAT A.E. Fleckenstein\*, K.J. Lookingland and K.E. Moore Dept. Pharmacology and Toxicology, Michigan State Univ., East Lansing, MI 48824

Although substantial evidence demonstrates histamine neurotransmitter in the mammalian central nervous system, the central functions of the amine remain uncertain. The purpose of the present study was to examine the influence of histamine on 5-hydroxytryptamine (5HT) neurons in the rat hypothalamus by measuring the concentration of neurotransmitter (5HT), its synthesis [accumulation of 5-hydroxytryptophan (5HTP) after administration of a decarboxylase inhibitor] and metabolism [concentration of 5-hydroxyindoleacetic acid (5HIAA)] in brain regions containing terminals of these neurons. The intracerebroventricular administration of histamine increased 5HTP accumulation, dose- and timedependently decreased 5HT levels, and either increased or had no effect on 5HIAA concentrations in various hypothalamic nuclei. The H, antagonist mepyramine maleate blocked, whereas the H2 antagonist zolantidine dimaleate did not affect the ability of histamine to increase hypothalamic 5HIAA and decrease 5HT concentrations, respectively. These results indicate that exogenously administered histamine has a stimulatory effect on hypothalamic SHT neurons through an action at the H<sub>1</sub>, but not the H<sub>2</sub> receptor. Depletion of neuronal histamine by the histidine decarboxylase inhibitor o-fluoromethylhistidine decreased basal 5HIAA levels. This suggests that histamine may tonically activate hypothalamic SHT neurons in male rats (supported by NIH grant NS 15911 and a fellowship from the Pharmaceutical Manufacturers Association Foundation).

# 199.3

CHARACTERIZATION OF HISTAMINE RELEASE USING SUPERFUSED SLICES OF RAT HYPOTHALAMUS. <u>A. Rodrigues. A. Fink-Jensen\*. P.D. Suzdak.</u> Novo Nordisk A/S, CNS Division, DK-2760 Maaloev, Denmark.

Pharmacological studies have demonstrated the presence of presynaptic histamine  $\rm H_3$  receptors (Arrang et al., Nature 302, 1983) in addition to the postsynaptic H, and  $\rm H_2$  receptors. The release of histamine (HA) from the hypothalamus of male rats was measured using superfused brain slices preloaded with 150  $\mu$ Ci [ $^3$ H]-histidine. The amount of de novo synthesis [ $^3$ H]-HA in the superfusates and tissue was determined by cation-exchange chromatography (H. Timmerman et al., Eur. J. Pharmacol. 138, 1987)

The release process was shown to be  $Ca^{2+}$ -dependent and stimulated by high levels of K\*. The  $H_3$  agonist  $R-\alpha$ -methylhistamine inhibited, in a concentration-dependent manner, the histamine release evoked by 30 mM K\* with an approx.  $IC_{50}$  of 300 nM and a maximal inhibition of 70%. This effect was fully antagonized by 1  $\mu$ M of Thioperamide, an  $H_3$  receptor antagonist.

It is concluded that histamine modulates its own release from hypothalamus neurons by interacting with  ${\rm H_3}$  histamine autoreceptors similarly to other brain regions.

## 199.2

HISTAMINE AND METHYLHISTAMINE IN SEIZURE-PRONE RATS. L. Tuomisto\*, K. Onodera, M. Ylinen, U. Tacke, M.M. Airaksinen. Dept. of Pharmacology and Toxicology, Univ. of Kuopio, Finland, SF-70211
Brain histaminergic system has been implied as

Brain histaminergic system has been implied as one of the neurotransmitter systems modifying the response of audiogenic seizure (AGS) sensitive rodents to audiogenic stimulation. Lowered histamine (HA) levels have been found in the brains or specified brain areas of genetically epilepsy prone deermice and KM rats. This study was aimed to locate possible differences in histamine turnover between the KM strain and the resistant Wistarhomologue (W). All KM but no W rats studied responded (ARS 5) to 10 KHz, 110 dB sound 1 week earlier. Male rats were decapitated 4 hours after HA synthesis inhibitor alfa-fluoromethylhistidine (FMH, 100 mg/kg i.p.) or saline. Histamine and tele-N-methylhistamine (MH) were analysed (HPLC and GC-MS, resp.) in 11 brain parts. FMH lowered HA levels both in KM and W rats, but after FMH the overall HA level was lower in KM rats (p=0.000, ANOVA). Interestingly, there were regional differences in MH/HA ratio with higher values in KM rats: hippocampus (p=0.008, t-test), amygdala (p=0.005) and dorsal cortex (p=0.001). The dissimilar turnover of HA in brain aregulatory role for HA in seizures.

## 199.4

CHARACTERIZATION OF GLUTAMATERGIC REGULATION OF HISTAMINE RELEASE FROM RAT HYPOTHALAMUS.

K. Okakura-Mochizuki<sup>1</sup>, A. Yamatodani \*2, T. Mochizuki<sup>1</sup>, A. Horii<sup>3</sup> and H. Wada<sup>1</sup>. Departments of <sup>1</sup>Pharmacol. II, <sup>2</sup>Molec. Physiol. and <sup>3</sup>Otolaryngol., Faculty of Med., Osaka Univ., Suita, Osaka 565, Japan.

A microdialysis method was used to study the effects of glutamate (Glu) on in vivo release of histamine from the anterior hypothalamic area of urethaneanesthetized rats. Infusion of 1mM Glu caused about 150% of histamine release over the basal release. N-methyl-D-aspartate (NMDA, 100 µM) caused a similar increase. Glu-evoked histamine release was completely blocked by D(-)-2amino-5-phosphonopentanoic acid (APV, 100μM), a specific antagonist of NMDA-receptors. APV alone also reduced histamine release. Infusion of TTX (100nM) reduced histamine release, but had no effects on Glu-evoked release. These results clearly indicate that Glu enhances histamine release through NMDA-receptors located on histaminergic nerve terminals, and suggest the presence of tonic glutamatergic regulation of the release. On the other hand, kainic acid (KA, 50µM) caused delayed increase of histamine to about 180% of the basal release. KA-induced histamine release was reduced by APV while the increase was not blocked by 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX, 10μM) or 6,7-dinitroquinoxaline-2,3-dione (DNQX, 100μM), antagonists of non-NMDA receptors. In the presence of TTX, KA caused no significant increase in histamine release. These results suggest that the increase of histamine release is induced by Glu which is enhanced by KA.

CISTERNAL CSF VOLUME AND HISTAMINE CONCENTRATION IN LEWIS RATS WITH EXPERIMENTAL AUTOIMMUNE ENCEPHALOMYELITIS. Edward L. Orr\*. Sushanta Mallick. Martin T. Taylor. and Jean H. deSchweinitz. Dept. Anat. & Cell Biol., Texas College of Osteopathic Maddicine. End World TX 75107.

Medicine, Fort Worth, TX 76107
Lewis rats with experimental autoimmune encephalomyelitis (EAE) exhibit significant changes in brainstern and spinal cord histamine and water content (edema) in concert with the clinical course of EAE. To determine if CSF levels of histamine (HA) are also altered in EAE, we measured the concentration of HA present in CSF obtained from the cisterna magna of control and EAE rats. EAE was induced by inoculation of female Lewis rats with an emulsion of guinea pig spinal cord homogenate (gpsch) in complete Freund's adjuvant; control rats received an identical inoculum lacking gpsch. Beginning on day 7 post inoculation (pl), rats were monitored daily for clinical signs of EAE. Whole spinal cords, brainsterns, and samples of cisternal CSF were obtained from anesthetized control and EAE rats on days 7, 9, 11, 14, and 16 pi. The tissues and CSF samples were stored frozen until assayed for HA using radioenzymatic methods.

Significant changes in spinal cord and brainstem HA and wet weight occurred in parallel with the clinical course of EAE. Similarly, CSF concentrations of HA also fluctuated in concert with the clinical course of EAE. This increase in CSF HA was accompanied by a significant decrease in the volume of CSF one could obtain from the cistema magna. These results indicate that cisternal CSF HA concentration parallels the changes in CNS HA levels which occur during EAE in Lewis rats. In addition, the decrease in CSF volume obtained from the cistema magna of rats with clinically significant EAE is consistent with the significant CNS edema observed in rats with EAE. (Supported by a grant from the National Multiple Sclerosis Society.)

### 199.7

Measurement of histamine in brain by gas chromatographymass spectrometry. E Douyon, AM Morrishow and GD Prell\*; Department of Pharmacology, Mount Sinai School of Medicine of CUNY; New York, NY 10029 USA Levels of histamine are often measured in brain tissue, diasylates or

Levels of histamine are often measured in brain tissue, diasylates or cerebrospinal fluid. However, residual presence of drugs used to probe histaminergic function may affect histamine methyltransferase (HMT) used to measure histamine by the radioenzymatic method. Also, recovery of histamine may be problematic. To overcome these difficulties we developed a method to measure histamine by GC-MS. Internal standard, d4-histamine, is added to aqueous sample homogenates or standards (0.1-100ng). Samples are basified, extracted into butanol-chloroform, then back extracted into 0.1N HCl, and dried. Following derivatization with heptafluorobutyryl anhydride in toluene, the reaction is quenched with TRIS. The organic layer is retained, dried with Na2SO4, then derivatized with ethylchloroformate. The monoheptafluorobutyryl-N-ethoxycarbonyl derivative of histamine (MW 379) is separated on a polycyanopropylphenylmethylsiloxane capillary column. Protonated molecular ions m/z 380 and 384 were acquired utilizing methane-positive chemical ionization (CI) GC-MS selected ion monitoring (SIM) for derivatives of histamine and d4-histamine, respectively. Electron impact ionization yielded ions at m/z 94, 306, 379 and 98, 310 and 383 for derivatives of histamine and d4-histamine, respectively. Measurements of levels of histamine in whole brains or brain regions of rats using CI-SIM or the radioenzymatic method gave comparable results. This GC-MS method is particularly useful for measuring histamine in samples containing HMT inhibitors such as metoprine or tacrine or other tetrahydroacridines. (NS-28012)

## 199.9

BRAIN HISTAMINE LEVELS AND HISTIDINE DECARBOXYLASE ACTIVITY IN MAST CELL DEFICIENT RATS(WS/WS). K. Maeyama, H. Onoue, E. Sakurai, T. Kasugai, Y. Kitamura and T. Watanabe. Dept. of Pharmacology, Tohoku University School of Medicine, Sendai 980, Dept. of Pathology, Osaka University Faculty of Medicine, Suita 565. Japan.

of Medicine, Suita 565, Japan.

In the brain, there are at least two types of histamine storing cells, i.e. neurons and mast cells, and histamine derived from mast cells has hampered studies of neuronal histamine. In 1978, Kitamura et al. found that W/W' mice are deficient in mast cells, and last year they found that similar rats(Ws/Ws) which have mutation of c-kit receptor are completely deficient in mast cells. To clarify the contribution of non-mast cell histamine in the brain, histamine contents and the activities of histidine decarboxylase(HDC), a histamine-synthesizing enzyme, in Ws/Ws and congenic (+/+) rats were compared. Histamine levels in the forebrain, midbrain, pons-medulla and cerebellum of Ws/Ws rats are 0.25, 1.17, 0.31 and 0.12 nmoles/g, respectively and 60.9, 107, 80.7 and 64.4 % of each tissue of congenic +/+ rats. HDC activities of brains of Ws/Ws are not different from those of +/+ rats.

It is concluded that the brain histamine in Ws/Ws rats represents non-mast cell histamine and these mutant rats will be useful for pharmacological research of functions of neuronal histamine.

Aknowledgement: Ws/Ws rats were kindly donated by Drs. K. Kondo and A. Niwa(Lab. of Experimental Animal, Yagi Memorial Park, Gifu, Japan).

#### 199.6

Histamine metabolites in CSF of patients with schizophrenia: their relationships to other aminergic transmitters and ratings of schizophrenic behavior.GD.Prell<sup>1</sup>, IP.Green<sup>1\*</sup>, CA.Kaufmann<sup>2</sup> J.Khandelwal<sup>1</sup>, D.Kirch<sup>2</sup>, M.Linnoila<sup>3</sup>, and RJ.Wyatt<sup>2</sup>; <sup>1</sup>Dept. Pharmacology, Mount Sinai School of Medicine, NY, 10029; <sup>2</sup>NIMH Neuroscience Center, at St. Elizabeth's Hospital, Washington, D.C. 20032; <sup>3</sup>DICBR, NIAAA, Bethesda, MD 20205 USA
Levels of the histamine metabolites, tele-methylhistamine (t-MH) and

Levels of the histamine metabolites, *tele*-methylhistamine (t-MH) and *tele*-methylimidazoleacetic acid (t-MIAA), other aminergic transmitters and their metabolites were measured blindly in cerebrospinal fluid from 36 inpatients with chronic(RDC) schizophrenia(SZ) and 7 neurological inpatients (controls). In both groups, patients' mean ages, durations of illness, and periods of withdrawal from medication were similar. Mean t-MH level of controls was similar to t-MH levels seen previously in healthy volunteers. The mean t-MH level in patients with SZ was 2.5-fold higher (p<0.001) than controls; 25 (74%) had levels that exceeded the range of controls. There was no difference (p>0.05) in levels of other analytes between the two groups. Those taking (n=10) or withdrawn (n=26) from neuroleptics had nearly the same mean levels of t-MH; each was higher than controls (ANOVA: p<0.05). Among all SZ patients, levels of t-MH, t-MIAA and their sum correlated positively with levels of HVA, DOPAC, NE, MHPG and 5-HIAA; but only t-MH levels correlated with positive scores on the Brief Psychiatric Rating Scale (BPRS) (r<sub>S</sub>=+0.45, p<0.02). Negative scores alone did not correlate with any substance. However, among patients with predominantly deficit schizophrenia (ratio neg/pos BPRS scores >2), the ratio correlated (r<sub>S</sub>=+0.82,p<0.02) only with levels of t-MH. These results suggest increased histaminergic activity in brains of patients with chronic SZ. (Supported by MH-31805 and NS-28012)

### 199.8

Characterization of the Putative Promoter for the Histidine Decarboxylase Gene and Regulation by Steroid Hormones in Rat Brain. C.A. Zahnow\* and D.E. Millhorn, University of North Carolina, Chapel Hill, N. C. 27599.

The biogenic amine, histamine, is synthesized from L-histidine by the enzyme Histidine Decarboxylase (HDC). 1.3kb of the putative promoter region for the HDC gene was amplified via the polymerase chain reaction from a 9kb gene fragment and cloned into M13mp19 for sequence analysis. resembling a TATA box, SP1 sites, AP1 and AP2 sites, octamers, CTF/NF-1 and glucocorticoid response elements (GRE) have been identified based upon homology to sequences known to be recognized by sequence-specific transcription factors. Our previous data suggested that HDC mRNA levels are regulated by high (1mg) doses of dexamethasone, and dihydrotestosterone. This regulation may be occurring at the level of the gene through actions on the GRE. It is necessary, however, to determine whether lower, physiological doses of these steroid hormones are also able to regulate HDC mRNA levels. HDC mRNA (2.6kb) was detected via Northern blot analyses in both the hypothalamus and hippocampus. However, the only neuronal source thus far identified for HDC mRNA is found in the hypothalamus (Mol.Cell Neurosci., 1: 1990) In an effort to rule out the possibility that HDC mRNA may be axonally transported (EMBO J.,10: 1991) from the hypothalamic cell bodies to the hippocampus, colchicine, a blocker of axonal transport, was injected into the lateral cerebral ventricle of 44 day old rats and the animals were sacrificed 24 hours later. Northern blot analysis revealed an approximate three fold decrease in hypothalamic HDC mRNA in the colchicine treated rats as compared to PBS treated rats. Treatment did not block the presence of mRNA in the Hippocampus. This suggests that HDC mRNA is transcribed within a cell type in the Hippocampus.

## 199.10

DURATION OF STRESS CAN AFFECT HISTAMINE LEVELS IN INTACT AND ADRENALECTOMIZED RATS. A. Gillich,\* & M. J. Meaney. Douglas Hospital Res. Ctr., Depts. of Neurology & Neurosurgey, and Psychiatry, McGill Univ., Montreal H4H 1R3, Canada. Central histamine (HA) has been thought to regulate ACTH release, however, no consistant relationship has been found between HA and the exposure to stress. We examined HA levels in several rat brain areas using cold restraint stress for 15 min or for 2 h. In the paraventricular nucleus, median eminence, supraoptic nucleus, suprachiasmatic nucleus, posterior hypothalamus, and the dentate gyrus, HA levels increased after 15 min of stress with a decrease in HA following 2 h of stress. Other areas such as the frontal cortex, septal nucleus, bed nucleus, periventricular nucleus, mammallary bodies, ventromedial nucleus, and the CA1 and CA3 cell fields demonstrated progressive decreases in HA with longer periods of stress. In all areas examined, lower HA levels were seen following 2 h stress when compared to controls or 15 min stress. In sebsequent experiments, 15 min stress with adrenalectomy (7 days prior to testing), attenuated changes in HA levels in the posterior hypothalamus, mammallary bodies, and median eminance. In the suprachiasmatic nucleus and the supraoptic nucleus, adrenalectomy enhanced the decrease in HA followed by 2 h stress. Both effects were reversed with a low basal level of corticosterone replacement. These results show that 1) HA responds to stress in brain regions known to regulate ATCH release, 2) the histaminergic response can depend upon the duration of the stress, and 3) circu-lating corticosterone can affect these

CLONING OF A HISTAMINE H, RECEPTOR. 1H. Fukul, Yamashita, 2K. Sugama, 1Y. Horio, Fujimoto, 1Y. Abe, 1H. Mizuguchi, 1N. Inagaki, 1H. Wada, 1Dept. Pharmacol. II, Faculty of Meosaka Univ. and 20saka Bioscience Institute, Su and Med.. 565. Japan. Histamine acts as a neurotransmitter in the brain. The  $H_1$  subtype of histamine receptors expressed on

cells mediates histaminergic neurotransmission. Although the second messenger of the H<sub>1</sub> receptor was extensively investigated, little was known about the molecular structure the histamine known about the molecular structure the histamine H<sub>1</sub> receptor. We cloned a cDNA encoding the H<sub>1</sub> receptor from a cDNA library of bovine adrenal medulla using in vitro transcription and electrophysiological assay with Xenopus oocytes. The H<sub>1</sub> receptor cDNA clone was 2,960 nucleotide long and encoded a protein of 491 amino acids with seven putative tansmembrane domains and a characteristically large third intracellular loop. Binding affinities to histamine receptor related compounds of the H<sub>1</sub> receptors expressed in COS-7 cells were comparable with those of native H<sub>1</sub> receptors in comparable with those of native H<sub>1</sub> receptors in bovine adrenal medulla. Northern blot analysis showed a band of 3.0-kb nucleotides corresponding to a histamine H<sub>1</sub> receptor mRNA in various bovine tissues including cerebral cortex, lung, intestine, adrenal medulla, uterus and spleen.

## 199.13

BIOCHEMICAL AND BEHAVIORAL EFFECTS OF CDD-2016, A NOVEL H3 ANTAGONIST. S. Ghodsi-Hovsepian\*, W. Hoss, A. Khan, G.J. Durant, A. El-Assadi, W.S. Messer, Jr., #R.C.A. Frederickson, Center for Drug Design and Development, University of Toledo, Toledo, OH 43606 and #Gliatech, Inc., 23420 Commerce Park Rd., Beachwood, OH 44122.

Histamine H<sub>3</sub> receptors are autoreceptors that control the synthesis and release of histamine from nerve endings. A role for brain histamine is indicated in several brain functions, including sleep, arousal and cognition. The ability to regulate pharmacologically the levels of brain histamine raises the possibility of developing therapies based on H<sub>3</sub> receptors as a target and suggests new strategies for the

therapies based on H<sub>3</sub> receptors as a target and suggests new strategies for the treatment of neurological disorders. The compound CDD-2016 was synthesized as part of a program to develop novel H<sub>3</sub> antagonists. The biochemical and behavioral properties of CDD-2016 were compared to thioperamide, a potent and selective H<sub>3</sub> antagonist. The inhibition of the binding of 1 nM [ $^3$ H\_10-M\_cmethylhistamine, a selective H<sub>3</sub> agonist, was used to assess binding to H<sub>3</sub> receptors in rat brain membranes. CDD-2016 displayed an IC50 value of 23  $\pm$  6 nM compared with a value of 4.0  $\pm$  0.6 nM for thioperamide. (R)- $\alpha$ -methylhistamine, a highly selective H<sub>3</sub> agonist, produced a dose-dependent increase in sleep one hour after i.p. injection in the range of 15 to 35 mg/kg in mice. Both thioperamide (20-70 mg/kg), and CDD-2016 (40-80 mg/kg) were able to inhibit the soporific effects of (R)- $\alpha$ -methylhistamine, respectively. (R)- $\alpha$ -methylhistamine inhibited the release of histamine from nerve endings in a dose-dependent manner over the range of 10 nM to 1 mM. Both thioperamide and CDD-2016 increased histamine release from nerve endings in the range of 10-100 nM and completely reversed the inhibition of histamine release induced by 1  $\mu$ M (R)- $\alpha$ -methylhisted increase from nerve endings in the range of 10-100 nM and completely reversed the inhibition of histamine release induced by 1  $\mu$ M (R)- $\alpha$ -methylhisted increased instamine release induced by 1  $\mu$ M (R)- $\alpha$ -methylhisted increased instamine release induced by 1  $\mu$ M (R)- $\alpha$ -methylhisted increased instamine release induced by 1  $\mu$ M (R)- $\alpha$ -methylhisted increased instamine release induced by 1  $\mu$ M (R)- $\alpha$ -methylhisted increased instamine release induced by 1  $\mu$ M (R)- $\alpha$ -methylhisted increased instamine release induced by 1  $\mu$ M (R)- $\alpha$ -methylhisted increased instamine release induced by 1  $\mu$ M (R)- $\alpha$ -methylhisted increased instamine release induced by 1  $\mu$ M (R)- $\alpha$ -methylhisted increased instamine release induced by 1  $\mu$ M (R)- $\alpha$ -methylhisted increased in the methyli

and completely reversed the inhibition of histamine release induced by 1  $\mu M$  (R)- $\alpha$  methylhistamine.

In summary, the data indicate that CDD-2016 is a potent and effective antagonist for H<sub>3</sub> receptors. CDD-2016 binds with high affinity to H<sub>3</sub> receptors, blocks the soporific effects of an H<sub>3</sub> agonist in vivo and the inhibition of histamine release by an H<sub>3</sub> agonist in vitro. Supported by a grant from Gliatech, Inc. to the University of

## 199.15

EVIDENCE FOR AGONISTIC ACTION OF PICOLINIC ACID ON STRYCHNINE-SENSITIVE GLYCINE RECEPTOR IN THE CENTRAL NERVOUS SYSTEM. T. Kaneko\* T. Tonohiro. M. Tanabe and N. Iwata New Lead Res. Lab., Sankyo Co., 2-58, Hiromachi 1-chome, Shinagawa-ku, Tokyo, 140 Japan. Picolinic acid (PA), when administered iontophoretically, suppresses spinal

interneurons through activation of strychnine-sensitive glycine receptors (Brain Res., 516, 332-334, 1990). In this study, in order to define further profiles of PA, effects of PA and related compounds on motor functions were compared with those of indole-2-carboxylic acid (ICA) which is reported to be an antagonist for strychnine-insensitive glycine receptors coupled with NMDA receptors.

Both compounds were administered systemically in the present experiments. In mice, PA and ICA suppressed chemically induced convulsions in different manner, at lower doses than those that exerted muscle relaxant effect. PA selectively inhibited strychnine-induced convulsion although ICA reduced all the convulsions following injections of strychnine, bicuculline and pentylenetetrazol. Among PA derivatives, when injected systemically, PA methy ester (mPA) showed the strongest protection against strychnine. In cats anesthetized with  $\alpha$ -chloralose, PA and mPA inhibited spinal monosynaptic reflex (MSR) as well as polysynaptic reflex (PSR), whereas ICA depressed PSR sparing MSR. In spinal preparations, suppression of MSR by mPA was unchanged although effect on PSR diminished. Strychnine, when injected after mPA, accelerated recovery of MSR from depression by mPA. On the other hand, ICA failed to show any inhibition in spinal preparations. Furthermore, intracellular recording from feline spinal motor neuron detected hyperpolarization following mPA injection. Conceivably, PA directly inhibits the reflex pathway in the spinal cord, whereas ICA exerts the effect via inhibitory action on supraspinal structures in the brain. PA, specially in its methyl ester form, seems to be useful as a systemically injectable agonist for strychnine-sensitive glycine receptors.

APPARENTLY COOPERATIVE BINDING TO G PROTEIN-LINKED RECEPTORS LABELED BY [<sup>3</sup>H]HISTAMINE. W.G. Sinkins and J.W. Wells.

Faculty of Pharmacy, University of Toronto, Toronto, Ontario, Canada, MSS 2S2.

Tritiated histamine labels two classes of sites in membranes from guinea-pig cerebral cortex. GMP-PNP reduces capacity at both classes with little or no effect on affinity  $(K_{\rm Pi})$  at the sites that remain. The Hill coefficients of 26 histaminergic ligands range from 0.78 to 1.54 among agonists, and from 0.66 to 1.26 among antagonists. The data reveal elements of both H<sub>2</sub> and H<sub>3</sub> specificity, but the abiguity cannot be attributed to a mixture of gene products Fourteen compounds were studied at 1.4 nM and 11 nM [<sup>3</sup>H]histamine; in such experiments, the radioligand is both a second independent variable and an In terms of distinct and independent sites, the relative internal control. In terms of distinct and independent sites, the relative capacities  $(F_i)$  and the inferred affinity of  $i^3$ H)histamine  $(K_{\rm P}_i)$  differ from ligand to ligand; since the discrepancies persist for any number of classes, the model can be rejected unequivocally. All 26 compounds were studied at 1.4 nM  $i^3$ H]histamine, and two hyperbolic terms  $[i.e., F'|K_i/(K_i + |L|)]$  are required for 6 agonists and 6 antagonists;  $F'_i$  varies widely from ligand to ligand. Agonists reveal a correlation between log  $(K_2/K_1)$  and  $F'_1$ ,  $(K_1 < K_2)$ ; antagonists reveal a correlation between log  $(K_2/K_1)$  and  $F'_2$ . Antagonists thus appear to promote the state to which they bind more weakly. This paradox and Hill coefficients significantly greater than 1 argue against a ligand-regulated equilibrium between two states of mutually independent sites. High values of  $n_H$  suggest that binding is cooperative, and ligand-related anomalies in the inferred binding of  $i^3$ H]histamine are largely avoided by a model in which one equivalent of bound [<sup>3</sup>H]histamine are largely avoided by a model in which one equivalent of bound ligand affects the binding of a second. The failure to identify an unambiguous pharmacological specificity may reflect the failure to assess binding in the correct mechanistic context. The approach described here is generally applicable to the evaluation of different models for binding at equilibrium.

INTERACTION OF DOPAMINERGIC FIBERS WITH GABAERGIC INTERNEURONS IN RAT MEDIAL PREFRONTAL CORTEX. S.L. Vincent\*, R.P. Molloy, F.M. Benes. Department of Psychiatry and Program in Neuroscience, Harvard Medical School and Mailman Research Center, McLean Hospital, Belmont, MA 02178.

The anatomical relationship between dopamine (DA)-containing fibers

and GABAergic interneurons was investigated in rat medial prefrontal cortex (mPFC) using a double immunofluorescent method. Rats were perfused intracardially with a solution containing 5% glutaraldehyde and 1% Na-metabisufite in 0.1 M cacodylate-HCl buffer, pH 7.4, at room 1% Na-metabisufite in 0.1 M cacodylate-HCl buffer, pH 7.4, at room temperature. Sections (40-µm-thick) were cut on a Vibratome and were incubated in a solution containing 1:100 rabbit anti-dopamine antibody and 1:500 mouse anti-GABA antibody, followed by 1:100 dilutions of FITC-conjugated donkey anti-rabbit and rhodamine-conjugated donkey anti-mouse antibodies. The mPFC was viewed with either epiflucrescence or confocal laser scanning microscopy to asses the degree to which DA-immunoreactive (DA-IR) fibers were in close apposition to GABA-IR neuronal cell bodies. Two types of interaction were identified: (1) fibers with a calculator with a context with a con with a single terminal varicosity in contact with a soma, (2) fibers en passage with multiple varicosities making contact either around or across a soma. From an examination of all visualized GABA-IR cells in coronal souria. From an examination of an visualized AGAFA to Certs in Cutofial sections of mPFC it was determined that the frequency with which DA-IR fibers formed close appositions was 7%, 39%, and 75% for layers I, I/I/II, and V/VI, respectively. This gradient of interaction frequency parallels the density of DA afferents to rat mPFC which are most dense in the deeper density of DA anterents to tall infer which are misst dense in the deeper laminae. Overall, these data suggest that GABAergic interneurons may be targets of mesocortical DA afferents and support the idea that an interaction between DA and GABA may play a role in the intrinsic circuitry of rat mPFC. Supported by MH 00423, a Stanley Award, and the Scottish Rite Foundation.

## 199.16

A SHORT, NOVEL, G-PROTEIN COUPLED RECEPTOR ISOLATED BY PCR USING mRNA EXTRACTED FROM THE OVINE PARS TUBERALIS. P. Barrett\*, A. MacDonald, R.J. Helliwell and P.J. Morgan. Rowett Research Institute, Aberdeen AB2 9SB, U.K.

The ovine pars tuberalis is an important target for the pineal hormone, melatonin. The receptors for melatonin are located on 80-90% of the cells that constitute this tissue. These receptors have been shown to be high affinity receptors coupled to the inhibition of adenylate cyclase through a  $G_i$  heterotrimeric protein complex. Homology between most of the G-protein coupled receptor superfamily is sufficient

to design degenerate oligonucleotide primers which will hybridize to DNA sequence homologies in these genes and therefore may be amplified using thermostable DNA polymerases to produce sufficient amount of DNA for sequencing and probes.

Applying the PCR technique to cDNA reverse transcribed on mRNA extracted from the ovine pars tuberalis, a number of receptor sequences were detected. One amplified fragment with G-protein coupled receptor sequence similarity was used to screen a genomic DNA library in \( \lambda \text{EMBL3} \). A clone was identified containing a 20kb insert. A 6kb SacI fragment was subcloned into pUC19 and sequenced by primer walking. The identified clone contained an open reading frame of 870bp, encoding a protein of 290 amino acids. The coding sequence is preceded by a sequence which conforms to the consensus sequence proposed by Kozak and ends with a TAA stop codon

A hydrophobicity plot reveals seven hydrophobic regions which correspond to the transmembrane domains, and these domains contain many of the highly conserved residues found in other receptor sequences. The receptor has the unusual characteristics of a very short loop between transmembrane domains 4 and 5, and a short if nonexistent N-terminal cytoplasmic domain. A database search reveals only limited homology with the ligand unidentified receptor edg1 and with the histamine H2 receptor. In situ hybridization and Cos cell transfection assays are being used to identify the ligand for this receptor.

FIRST CHARACTERIZATION OF 6-HYDROXYTRYPTAMINE IN THE RAT MIDBRAIN BY USING SPECIFIC ANTIBODIES. H.Dabadie1, M. Geffard\*1, C.Berrier<sup>2</sup> and J.C.Jacquesy<sup>2</sup>. <sup>1</sup>Laboratoire d'Immunologie et Pathologie, Université de Bordeaux II, 33076 Bordeaux, France. <sup>2</sup>Laboratoire de Chimie XII C.N.R.S., Université de Poitiers, 86022 Poitiers, France.

The visualization of serotonin (5-HT), 5-methoxytryptamine and tryptamine in the rat midbrain has been made possible by the development of antibodies raised against these conjugated molecules. It has been suggested that 6-hydroxytryptamine (6-HT) might be also a neurotransmitter in this region. In order to test this hypothesis, 6-HT was synthesized and antibodies were raised in the rabbit. The high avidity (IC50 = 5 x 10<sup>-9</sup> M) and specificity (cross reactivity ratio between 6-HT-glutaraldehyde(Gl-bovine serum albumine (BSA) and 5-HT-G-BSA the most immunoreactive compound was 1,500) rendered these antibodies reliable tools for specific molecular detection of 6-HT in the G-fixed tissues. In the dopaminergic region 6-HT-immunoreactivity was noted in the substantia nigra but was particularly intense in the red nuclei where it seems to be localized in the magnocellular division in the form of large 6-HT neurons. In contrast there were few 6-HT neurons in the raphe neurons. In contrast there were rew 6-H1 neurons in the raphe nuclei. Thus, 6-HT may be a new putative neurotransmitter existing in the ReN, alongside of the other neurotransmitters already described in this region, in the nigrorubral pathway and in the rubral projection from the dorsal raphe nuclei.

ACTIONS OF FMRFamide-RELATED PEPTIDES FROM Fusinus ferrugineus ON IDENTIFIED CENTRAL NEURONS OF Helix aspersa. M.L.Chen and R.J. Walker\*. Dept. of Physiology and Pharmacology, Univ. Southampton, Southampton SO9 3TU, UK.

FMRFamide-related peptides have been isolated from ganglia of the mollusc, F. ferrugineus which exhibit biological activity. This study investigates the action of Fusinus peptides, GSLFRFamide, GSFFRFamide and FMRFamide, and the fragments, LFRFamide and RFamide, and their structure-activity relation. Experiments were performed on neurons, F1 and F2, of suboesophageal ganglia from snail, H. aspersa, using intracellular recording and two electrode voltage clamp. On F1, FMRFamide, GSLFRFamide and LFRFamide all exert inhibition due to an increase in K permeability, with thresholds 1 , 1 and 5-10  $\mu M$  respectively, order of potency: FMRFamide ≥ GSLFRFamide > LFRFamide. On F2, FMRFamide is excitatory increasing Na+ permeability. In contrast, GSLFRFamide and LFRFamide are inhibitory, thresholds 0.05 and 0.5 µM, respectively. Pressure ejection of GSLFRFamide on F2 induced an outward current, reversal potential -70/75 mV, which was augmented in K+-free saline and blocked with 1 mM TEA and 100 µM 4-AP. GSFFRFamide and RFamide at 30 µM were inactive on F1 and F2. We conclude GSLFRFamide and FMRFamide act at different receptors and LFRF may be crucial for bioactivity.

## 200.3

STRUCTURAL FEATURES OF APLYSIA BAG CELL PEPTIDES WHICH ARE IMPORTANT FOR REGULATION OF BAG CELL ADENYLATE CYCLASE R.W. Berry\* and R. Sanger Redman. Dept. Cell, Molecular and Structural Biology, Northwestern Univ., Chicago, II. 60611.

The bag cell peptides,  $\alpha$ -,  $\beta$ -, and  $\gamma$ -BCP, are a set of structurally related peptides which are produced and secreted along with egg-laying hormone by Aplysia bag cell neurons. Among their functions is the modulation of bag cell discharges, as they can influence bag cell excitability by altering cAMP levels. These effects can be excitatory or implibitory depending on temperature. We have found that these actions excitability by altering cAMP levels. These effects can be excitatory or inhibitory, depending on temperature. We have found that these actions can be reproduced *in vitro* in adenylate cyclase assays, performed in the presence of 200 mM CI. In an attempt to define the structural features responsible for enzyme stimulation and inhibition, we have assayed each of the naturally-occurring BCP's, as well as synthetic peptide analogues. At 30° C, each of the BCP's stimulates enzyme activity, just as they elevate cAMP in intact bag cells at elevated temperature. Each stimulates to a maximum of 30%, with potency decreasing in the order  $\alpha(1-7) > \gamma \ge \beta$ . Alpha(1-7) and  $\gamma$  inhibit enzyme activity at 15° C, a temperature at which these peptides reduce cAMP levels in intact cells. The  $\beta$  peptide does not share this property but its stimulation of the enzyme is reduced at which these peptides reduce cAMP levels in intact cells. The  $\beta$  peptide does not share this property, but its stimulation of the enzyme is reduced at the lower temperature. The synthetic peptide RLRF, which corresponds to  $\alpha(3$ -6),  $\beta(1$ -4), and  $\gamma(1$ -4), mimics  $\beta$ , but is less potent. The synthetic dipeptides FY [ $\alpha(6$ -7)], FH [ $\beta(4$ -5)], and FD [ $\gamma(4$ -5)] are ineffective in this assay at 1 mM. These results suggest that binding of the RLRF sequence which is shared by all of the BCP's is sufficient to stimulate adenylate cyclase at 30°, and an electronegative residue immediately C-terminal to RLRF apparently both increases potency and enables the peptide to cause adenylate cyclase inhibition at 15°.

## 200.2

IN VITRO RELEASE OF IR-MET-ENKEPHALIN IN A WHOLE PERIOESOPHAGEAL GANGLION OF Helix aspersa.

F. PELLICER, M.ASAI, M.LEON-OLEA, M. SANCHEZ-ALVAREZ.

INSTITUTO MEXICANO DE PSIQUIATRIA, MEXICO, 14370 D.F. The existence of opioid peptides in the nervous system of molluscs has been demonstrated by different techniques: identification of receptors (1), inmunohisto-chemistry (2), RIA (3), and by behavioral experiments (4). However, the opioid peptide release has not been described. In the present work we study the IR-met-enkephalin (IR-ME) in vitro release from a single whole perioesophageal ganglion. Nine ganglia were dissected and their geaf ganglion. When ganglia were dissected and their connective tissue was removed. The ganglia were immersed in a Ringer solution (inmM- NaCl, 75; KCl, 2.5; CaCl2, 10; MgCl2, 5; glucose, 5; Hepes, 5; pH, 7.45). Each ganglion was depolarized with 40 mM of KCl during 10 min, in presence of Phe-Al a (1 mM) as inhibitor. and perfusates were processed as previously described (3). The results expressed as IR-ME pM/g wet tissue, showed a basal release of 23+4; with high K+ pulse 81+16; post pulse 37+18. The results suggest that in the whole ganglion the in vitro opioid peptide release mechanism is functionally present. (1) Osborne, N. N. et al. J. Phar. ## 200.4

MODULATION TRANSMISSION MODULATION OF NEUROMUSCULAR TRANSMISSION BY EXCITATORY AND INHIBITORY MOTOR NEURONS IN APLYSIA. P. L. Church\* and P. E. Lloyd. Committee on Neurobiology, The University of Chicago, Chicago, Il 60637.

Buccal muscle I3a is innervated by two excitatory motor

neurons, B3 and B38 and the cholinergic inhibitory motor neuron, B47. B38 synthesizes the SCPs and B47 synthesizes myomodulin A (Mma). Application of the SCPs or Mma (10nM) to the muscle enhanced B3-evoked EJPs. We monitored the modulation of B3-evoked EJPs in response to stimulation of B38 and B47 using paradigms designed to release the peptide cotransmitters. When B38 was stimulated in a series of extended bursts during B3 interburst intervals, subsequent B3-evoked EJPs were enhanced, an effect that is due at least in part to release of peptide cotransmitters (SCPs) from B38 during extended bursts. Stimulation of B47 evoked IJPs in I3a. However, extended B47 stimulation during B3 interburst intervals enhanced subsequent B3-evoked EJPs. These results suggest that when B47 is stimulated in short bursts the primary effect is inhibition due to cholinergic IJPs, but when B47 is stimulated in extended bursts, release of Mma contributes to the enhancement of subsequent B3-evoked EJPs. Supported by NRSA 1-F31-MH10240-01 to PJC and NS 23569 to PEL.

MODULATION OF ACh RELEASE FROM NEUROMUSCULAR SYNAPSES IN APLYSIA. G. A. Phares\* and P. E. Lloyd. Committee on Neurobiology, University of Chicago, Chicago, Il 60637.

Buccal muscle 15 is innervated by the cholinergic motor neuron, B15. This neuron also synthesizes modulatory neuropeptides: the SCPs and buccalins. release of peptide cotransmitters from terminals of B15 has been studied in detail.

We have previously demonstrated that terminals of B15 can be loaded with [3]Hacetylcholine ([3]H-ACh) by stimulation of buccal nerve N3 while I5 is bathed in [3]H-choline ([3]H-Ch; Lloyd, 1991). The [3]H-ACh is released upon subsequent stimulation of B15, and most of the released label is recovered as [3]H-ACh since nearly all of the acetylcholine esterase activity is found in hemolymph which is washed from the muscle prior to labeling.

Using this system, we have begun to study the modulation of [3]H-ACh release from B15. After loading B15 terminals with [3]H-Ch, I5 was placed into a microperfusion chamber and superfused with artificial sea water. Superfusate collected for periods of 3 min. At the beginning of every third collection period B15 was stimulated for one minute with 4 s bursts and 3 s interburst intervals at either 12.5 or 15 Hz. Recovery of [3]H-ACh due to stimulation was determined by subtracting the average radioactivity in the bracketing rest periods from that collected during a stimulation period

Serotonin (5-HT: 1 uM) caused a transient increase in the [3]H-ACh recovered during 15 Hz stimulation, but only slightly increased recovery at 12.5 Hz. The recovery of [3]H-ACh increased nearly 2-fold for the first stimulation period in 5-HT at 15 Hz, however, this effect was reduced in following stimulation periods although 5-HT was still present. In 1  $\mu$ M buccalin [3]H-ACh recovery was substantially reduced with stimulation at 12.5 Hz, but only moderate reductions were seen for stimulation at 15 Hz. It appears that frequency of stimulation is an important factor in determining the effects of modulators on ACh release.

### 200.7

PRESENCE AND BIOLOGICAL ACTIVITY OF A GnRH-LIKE PEPTIDE IN THE NERVOUS SYSTEM OF HELISOMA TRIVOLVIS. J.P. Chang\*, S. Patrick, C.J. Price and J.I. Goldberg. Dept. of Zoology, University of Alberta, Edmonton, Alberta, T6G 2E9.

Gonadotropin-releasing hormone (GnRH) constitutes a family of neuropeptides found throughout the vertebrates. While a GnRH-like peptide (GLP) has also been isolated from yeast ( $\alpha$ -mating factor), the presence of GnRH has not been clearly demonstrated in several invertebrate phyla. In this study, we tested the hynothesis that GLPs are invertebrate phyla. In this study, we tested the hypothesis that GLPs are present and functional in the CNS of the gastropod mollusc, *Helisoma trivolvis*. The presence of GLP was examined by three methods. 1) In immunofluorescence of GLP was examined by three methods. 1) In immunofluorescence studies using four antibodies generated against different GnRHs, select neurons and putative neurosceretory cells were specifically and consistently labelled throughout the CNS. 2) Reverse-phase HPLC and RIA analysis revealed a GLP which co-migrates with mammalian (m)GnRH. 3) In bioactivity experiments, extracts of Helisoma trivolvis CNS stimulated gonadotropin release from dispersed goldfish pituitary cells in culture. Two functional assays were carried out to examine the potential biological roles of GLPs in *Helisoma*. 1) Addition of mGnRH arrested neurite outgrowth in a subpopulation of dissociated *Helisoma* neurons in culture. 2) Intracellular recordings of left-parietal and visceral ganglion neurons revealed diverse electrophysiological responses to mGnRH. These effects were attenuated by a mGnRH antagonist. Taken together, these results strongly suggest that GLPs are important neuropeptides in the molluscan CNS.

PUTATIVE CARDIOVASCULAR ROLE FOR MET-ENKEPHALIN AND α-PEPTIDE IN LYMNAEA STAGNALIS. N.M. Ewadinger\*, N.I. Syed, R.L. Ridgway, A.G.M Bulloch and K. Lukowiak. Dept. of Med. Physiology, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

(Supported by NSERC grants to JPC and JIG.)

We have previously shown that two identified, well-characterized cells, Visceral Dorsal 1 (VD1) and Right Parietal Dorsal 2 (RPD2), in the CNS of Lymn moreactive to a polyclonal met-enkephalin (ME) antibody. Others have shown these cells to also be immunoreactive to an  $\alpha$ -peptide antibody. In this study, we found these cells and their fibers to be immunoreactive to a monoclonal ME antibody. Using dot blot analysis, no cross-reactivity between either  $\alpha$ -peptide and ME antibody or between ME peptide and  $\alpha$ -peptide antibody was observed. Therefore, the two peptides may co-exist within these identified neurons.

Since VD1 and RPD2 innervate the heart, it is possible that both peptides have

a functional role in cardiovascular regulation. We used an isolated heart preparation to test the effects of ME and α-peptide on the myogenic heart of Lymnaea. During perfusion, effects on heart rate, amplitude, and tonus were examined. Distinct effects of ME (more variable) and  $\alpha$ -peptide (consistently excitatory) were recorded. In 27 out of 35 trials, ME was excitatory at concentrations from 108 to 105 M. Reliably, α-peptide at concentrations from 10° to 10° M caused an increase in both frequency and amplitude of contractions. These results suggest that both ME and  $\alpha$ peptide may function in modulating the heart of Lymnaea.

Supported by MRC (Canada). We would like to acknowledge Dr. J. Van Minnen for supplying the α-peptide and the α-peptide antibody. Drs. C. Cuello and A. Côté for providing the monoclonal ME antibody. Drs. B. Brezden and D. Gardner for the use of their heart perfusion system.

RELEASE OF NEUROPEPTIDES FROM IDENTIFIED APLYSIA NEURONS IN CULTURE IS NOT SENSITIVE TO THE PATTERN OF STIMULATION. M.D. Whim\* and P.E. Lloyd. Dept. Pharm. Physiol. Sci. & Comm. on Neurobiol. Univ. Chicago, Chicago, IL 60637.

Aplysia buccal neurons B1 and B2 contain the 2 neuropeptides SCPA and SCPB. When placed in primary culture, these cells grow an extensive neuritic field. Newly synthesized peptides can be labeled by the addition of  $[^{35}S]$ -met to need. Newly symmestized periods can be address by the address of interest the culture medium, and using a combination of HPLC and liquid scintillation counting, the SCPs can be shown to be released in a stimulus and Ca-dependent fashion (Lloyd et al, 1986). We used this preparation to investigate how peptide release from individual cells varied with the pattern of stimulation. Initially, total spike number was kept constant while spike pattern was varied. We observed no difference in the amount of labeled SCPs released when the cells were stimulated tonically at 3 Hz compared to 6 Hz for 500 msec every other 500 msec. We then compared 1 Hz tonic stimulation with 6 Hz for 500 msec repeated every 2.5 sec. There was again no difference in the amount of labeled peptide released. Finally we examined the effect of increasing spike number. When cells were stimulated tonically at 1,3 or 5 Hz we observed a linear relationship between spike number and amount of peptide released. Reducing the calcium in the superfusate by 50% resulted in a reduction in peptide release but did not markedly alter this linear relationship. These results suggest that the release of the SCPs from B1 and B2 in culture is insensitive to the stimulation pattern, in contrast to the release of the SCPs from B15 in yivo which have been shown to be very sensitive to the stimulus paradigm (Whim and Lloyd, 1989; Cropper et al, 1990). PHARMACOLOGICAL PROFILE OF GLUTAMATERGIC INFLUENCES IN THE BUCCAL CPG HELISOMA TRIVOLVIS. E.M. Quinlan and A.D. Murphy Dept. of Biological Sciences, University of Illinois at Chicago, Chicago, Illinois 60608

Feeding behaviors in Helisoma are controlled by a CPG comprised of three subunits (S1-S2-S3). S2 inhibition of S1 and S3 plays a fundamental role in the temporal organization of this CPG. Previous data suggests the S2 neurons are glutamatergic, and that glutamate has direct effects on isolated motoneurons. There are at least two pharmacologically distinct glutamate receptors on identified buccal neurons. The receptor mediating S2 excitation and glutamatergic depolarization resembles a vertebrate kainate receptor. In contrast, S2 inhibition and glutamatergic hyperpolarizations were not blocked by ionotropic glutamate receptor antagonists, nor 24 hour incubation in pertussis toxin (2-6 ug/ml). lmM external TEA or 1mM 4-AP were also ineffective. However, prolonged exposure to quisqualate ameliorates the S2 ipsps and produces a desensitization to the hyperpolarizing effects of glutamate, ibotenate and quisqualate. Blocking S2 psps changes the timing of action potential bursts in other CPG neurons and motoneurons, allowing us to unravel the temporal organization of this multifunctional CPG.

## 200.10

ISOLATION AND CHARACTERIZATION OF MYOMODULIN-CARP-RELATED PEPTIDES (MCRPs) IN MOLLUSCS. W. Lesser', M.J. Greenberg, K.E. Doble, T.D. Lee, C.G. Morgan, N.A. Pennell and D.A. Price.
Whitney Laboratory, University of Florida, St. Augustine, FL 32086-8623.

Augustine, FL 32086-8623.

The MCRPs are a family of neuropeptides that regulate muscle contraction in molluscs, e.g., Aplysia (K. R. Weiss et al.), Fusinus, and Mytilus (Y. Muneoka et al.). We have used RIA (with antisera kindly provided by Weiss) to monitor HPLC purification of similar pertides from a clam (Morcouria) and a small control of the co peptides from a clam (Mercenaria) and a snail (Helix aspersa). Of the MCRPs isolated, the sequences of four have been determined by FAB mass spectrometry and microsequencing: i.e., GGFSMLRLamide and GGHAMLRLamide from the clam; and polymers and microsequencing. and pQLSMLRLamide and GGSGMLRLamide from the snail. We have also determined the relative amounts and distributions of the peptides in individual organs. In the cerebral, visceral, and pedal ganglia of the clam the MCRPs are 5 to 100 times more concentrated than in other tissues. Moreover, immunohistochemistry reveals different staining patterns within each tissue. Supported by NIH HL28440 and NSF grants DIR-8901337 and DIR-9200417.

CHARACTERIZATION OF AN ALKALINE PHOSPHATASE LOCALIZED IN THE CENTRAL NERVOUS SYSTEM OF APLYSIA CALIFORNICA. T. Daza and J.K. Ono\*, Dept. of Biological Science, California State University, Fullerton, CA 92634.

Alkaline phosphatase (AP) is commonly used in

Alkaline phosphatase (AP) is commonly used in histochemical studies as a reporter enzyme for depositing a chromogen. However, the Aplysia CNS contains a high level of endogenous AP localized in glial cells surrounding neurons and nerve connectives. Several inhibitors of mammalian AP's were tested on the Aplysia enzyme. Our results show that the Aplysia AP is unlike any one of the several mammalian APs, but in general, is similar to the Liver/Bone/Kidney AP in mammals, which is thought to be the most primitive type. The possible involvement of this AP in transport of neurotransmitters and neurotransmitter precursors into neurons is being investigated.

STRUCTURE-ACTIVITY STUDIES OF THE MYOACTIVE HISTIDINE-RICH BASIC PEPTIDE FROM THE R3-R14 NEURONS OF APLYSIA. S.L. Knock, G.T. Nagle, A. Kurosky, S.D. Painter.\* Marine Biomedical Institute and Department of Human Biological Chemistry and Genetics, Univ. of Texas Medical Branch, Galveston, TX 77555.

The histidine-rich basic peptide (HRBP), a 43-residue peptide product of the R3-R14 neurons of Aplysia californica, excites the heart and enhances gut motility in vitro. Six peptides were synthesized for structure activity studies; they corresponded to residues 1-43, 6-43, 13-43, 18-43, 23-43 and 32-43 of the native peptide. Each was purified by reversed-phase HPLC. The identity of each peptide was confirmed and the amount of material quantified by amino acid compositional analysis. Biological activity was assessed in an in vitro bioassay using A. californica crop muscle. The longer peptides, corresponding to residues 6-43, 13-43 and 18-43, were approximately equipotent with HRBP(1-43). In each case, the threshold was 3-10 x 10<sup>4</sup> M. The shorter peptides [HRBP(23-43) and HRBP(32-43)] were inactive at 10<sup>4</sup> M, suggesting that the NH<sub>2</sub>-terminal region of the peptide is not critical for HRBP biological activity. (Supported by NIH NS07185 and NS29261).

## TRANSMITTERS IN INVERTEBRATES II

## 201.1

DIFFUSIONAL PROPERTIES OF EXTRACELLULAR SPACE IN OPTIC LOBES OF THE INVERTEBRATE SEP1A. K. T. POILET . C. Nicholson. R. Williamson and N.J. Abbott. The Marine Biological Association of the United Kingdom, Citadel Hill, Plymouth, PL1 2PB, UK.

Diffusion of molecules within the extracellular space (ECS) of the brain is an important tissue characteristic, likely playing a role in distribution of informational substances, nutrients and metabolic products. The diffusion characteristics of ECS can be defined by tortuosity ( $\lambda$ ), which indicates hin Irance of diffusion, and volume fraction ( $\alpha$ ), a measure of the proportion of the tissue that is ECS. Studies of diffusion in vertebrate brain indicate a typical  $\lambda$  of 1.6, and  $\alpha$  of 0.2 (20%) (e.g. Rice and Nicholson, J. Neurophysiol., 65: 264, 1991). To determine whether invertebrates have similar ECS diffusion values we studied slices of the optic lobes from Sepia officinalis (cuttlefish).

Slices (400  $\mu m$  thick) of optic lobe were cut with a McIlwain tissue chopper and bathed in cooled, oxygenated artificial seawater. Measurements of diffusion were made by iontophoresing tetramethylammonium ions via a microelectrode and recording the concentration with an ion selective microelectrode located 100  $\mu m$  or more away. Values of  $\alpha$  and  $\lambda$  were estimated by fitting a suitable diffusion model to the data. Analysis of 54 measurements in Sepia optic lobe showed  $\lambda=1.86\pm0.37$  (mean  $\pm$  standard error) and  $\alpha=0.29\pm0.18$ . These data are comparable to those from vertebrate brain slices, suggesting similar ECS architecture in both vertebrates and invertebrates.

## 201.3

LOCALIZATION AND PHYSIOLOGICAL ACTION OF THE NOVEL HOLOTHURIAN PEPTIDE GFSKLYFamide. L. Díaz-Miranda\* and J. E. García-Arrarás. Department of Biology, University of Puerto Rico, Río Piedras, P. R. 10031.

The heptapeptide Gly-Phe-Ser-Lys-Leu-Tyr-Phe-NH<sub>2</sub> (GFSKLYFamide: GFS) was recently purified and characterized from gut extracts of the sea cucumber Holothuria glaberrima. This represents one of the first peptides to have been isolated from the phylum Echinodermata and the first from the class Holothuroidea. We have prepared antisera against synthetic GFS and have used them, through indirect immunohistochemistry, to map its distribution in H. glaberrima. Our results revealed that, in the intestine, GFS is expressed in a nerve plexus, where cell bodies are primarily found in the serosa, and a fiber network is associated with the muscular layer. Additional nerve fibers expressing this peptide can be seen in the submucosal layer. Immunoreactive cell bodies showing long processes are also found in the mucosa.

The location of nerve fibers expressing GFS, particularly those closely apposed to the longitudinal muscle cells, suggests that this neuropeptide is involved in regulating the digestive physiology of H. glaberrima. We have used intestinal strips of H. glaberrima to test the potential actions of this peptide. Changes in the tension of the muscle in response to GFS and other peptides were measured under partially isometric conditions. GFS induces a dramatic relaxing action of the muscle tension in a dose-dependent manner. Structure-activity relationships show that the FMRFamide-related peptide, FLRFamide, but not FMRFamide, mimics the action of GFS. In summary, we provide histochemical and pharmacological evidence that indicates that the peptide GFS is present and might be acting as a neurotransmitter in H. glaberrima. ## 201.2

L-GLUTAMATE AND GABA: THEIR EFFECTS ON AFFERENT RESTING ACTIVITY IN THE CEPHALOPOD STATOCYST.

Y.J. Tu and B.U. Budelmann. Marine Biomed. Inst., Univ. Texas Med. Branch, Galveston, TX 77555.

The effects of bath application of excitatory amino acids and GABA on the resting activity (RA) of afferent fibers were studied in the isolated Sepia officinalis statocyst. L-Glutamate (threshold 10.5M) and its agonists quisqualate and kainate (thresholds 10-6M) increased the RA in a dosedependent manner, while D-Glutamate had no effect. Also, no obvious excitatory effects for NMDA and L-aspartate, nor any antagonistic effect of the selective NMDA-receptor antagonist 2-amino-5-phosphonovaleric acid (AP-5) were seen. The spider toxin argiotoxin-636 (threshold 10<sup>-10</sup>M), 2amino-4-phosphonobutyric acid (AP-4), glutamic acid diethyl ester (GDEE), and  $\gamma$ -D-glutamylaminomethyl-sulfonic acid (GAMS) had inhibitory effects on the RA and were effective antagonists of L-Glutamate (and its non-NMDA agonists). GABA and the GABA-A agonists muscimol and isoguvacine inhibited the RA. The GABA-A antagonists bicuculline and picrotoxin increased the RA, or reversed the inhibitory effects of GABA and GABA-A agonists. The GABA-B agonist baclofen had no significant effect on the RA.

The data favor the hypothesis that L-Glutamate (via non-NMDA receptors) is a potent excitatory transmitter or modulator of the activity of the afferent fibers in the cephalopod (Sepia) statocyst, and that endogenous GABA (via GABA-A receptors) has a tonic inhibitory effect.

Support by NIH grant HAR 5 R01 EY 08312-02.

# 201.4

FMRFamide-RELATED PEPTIDES IN THE FLATWORM BDELLOURA CANDIDA. Kevin L. Blair\*, David A. Price, and Peter A.V. Anderson. Whitney Laboratory, University of Florida, St. Augustine, FL 32086.

FMRFa-related peptides are defined loosely as any putative neuropeptide that is detectable with an FMRFa-directed assay using techniques such as immunocytochemistry, RIA, or bioassay. Bdelloura candida, an ectoparasite on horse shoe crab, is a model platyhelminth neuro- and muscular-electrophysiology. Immunocytochemistry of whole mounts of brain, whole body, and dispersed brain in culture reveals staining with antisera to FMRFamide, Antho-RFamide and Antho-RWamide. Acetone and acidified acetone (1% TFA) extracts of Bdelloura were fractioned by reverse phase HPLC with linear gradients of ACN in aqueous TFA, HFBA and PO<sub>4</sub><sup>3</sup>, with the resulting fractions being tested by RIA between each fractionation. Based on differential detection with the antisera: Q2, S-253, and Yang's, as many as seven different fractions are expected to yield unique peptides. Fractions 57-58 of the acidified acetone extract have been purified to yield a partial sequence of XMFDSPPQVYSPSNFX..? where the identity of X is not clear. Supported by NSF Grant BNS 9109155 to PAVA.

THE SEQUENCE OF A G PROTEIN-COUPLED RECEPTOR FROM JELLYFISH NEURONAL TISSUE. D.A. Price \*, P.A.Y. Anderson, M.A. Holman, W. Lesser and M.J. Greenberg. The Whitney Lab of the University of Florida, St. Augustine, FL 32086.

Coelenterates (jellyfish and their kin) are the most primitive animals possessing a nervous system, so we are interested in comparing their neural specific molecules to those of higher animals. Using PCR with degenerate primers based on conserved regions of known G-protein linked receptors, we have isolated a putative receptor clone from a cDNA library prepared from neuronally enriched tissue of a jellyfish (Cyanea).

The deduced amino acid sequence of this clone is most similar to those of the tachykinin and NPY receptors. Indeed, the computer program Clustal (PCGene) groups this receptor into a distinct clade which includes the *Drosophila* and mammalian tachykinin and NPY receptors. An array of neuropeptides that have been isolated from coelenterates (primarily by Grimmelikhuijzen and colleagues) have in common the C-terminal sequence Arg-X-amide where X is Ala, Asn, Ile, Phe, Pro or Trp. Since NPY shares this motif, with X = Tyr, we suppose that some of the similarities in sequence among this clade of receptors may reflect similarities in ligands bound. We are currently using two approaches to functionally characterize this *Cyanea* receptor. First, we are attempting to express the receptor in yeast. Second, we are trying to localize it by in-situ hybridization. Support: NSF BNS9109155 (PAVA); NIH HL28440 (DAP & MJG).

### 201.7

IS ACETYLCHOLINE AN INHIBITORY TRANSMITTER IN HEART INTERNEURONS OF THE LEECH?

<u>Joachim Schmidt & Ronald L. Calabrese</u>\* Dept. of Biology, Emory University, Atlanta, GA 30233

Inherent tonic activity of heart motor neurons (HE cells) in the leech is organized into rhythmic bursts of action potentials by rhythmic inhibitory input from interneurons of the heartbeat pattern generator, HN cells (Calabrese, 1979). HN cells in the third and fourth ganglion not only form synapses with motor neurons but also form reciprocal inhibitory synapses across the ganglion, thereby constituing half center oscillators. IPSPs in HE and HN cells appear to be Cl<sup>-</sup> mediated (Nicholls & Wallace, 1978; Calabrese, 1979).

Synaptic transmission between HN cells and between HN cells and HE cells is blocked by bicuculline methiodide. GABA when applied focally onto the somata of HN cells or when added to the supefusate, has no effect on the membrane potential of HN cells. Acetylcholine (ACh) or the ACh agonist carbachol hyperpolarize HN cells and HE cells when applied focally onto their somata or into the neuropil or when added to the superfusate. IPSP-like responses elicited by focal application of carbachol onto the somata of HN cells and HE cells are blocked by bicuculline methiodide. Focal application of carbachol onto the somata of HN cells and HE cells increases membrane conductance. IPSP-like responses elicited by focal application of carbachol onto the somata of HN cells and HE cells are reversed when Cl' is injected into the cells. The results indicate, that HN cells use ACh as an inhibitory transmitter, that the postsynaptic receptors for ACh are blocked by bicuculline methiodide and that inhibition of HN cells and HE cells is mediated by an increased Cl' conductance. (NIH NS24072).

# 201.9

A COMPARISON OF THE MICROSTRUCTURE OF CHOLECYSTOKININ-LIKE IMMUNOREACTIVITY IN THE STOMATOGASTRIC GANGLION OF THREE DECAPOD CRUSTACEA. A.E. Christie<sup>1</sup>, D. Baldwin<sup>2</sup>, K. Graubard<sup>2\*</sup> and E. Marder<sup>1</sup>. <sup>1</sup>Dept. of Biology, Brandeis, Univ., Waltham, MA 02254 and <sup>2</sup>Dept. of Zoology, Univ. of Washington, Seattle, WA 98195.

We used confocal microscopy to compare the microstructure of cholecystokinin (CCK)-like immunoreactivity (using monoclonal antibodies C36-9H and C37-4E; Christie et al., Soc. Neurosci Abst. 17:278) in the stomatogastric ganglion of the crab, Cancer borealis and the lobsters, Homarus americanus and Panulirus interruptus. While the superficial appearance of each species' ganglion varies dramatically, the general patterns of peptidergic immunoreactivity remain constant; staining is generally within the peripheral neuropil. C36-9H and C37-4E immunoreactivity consists of individually distinguishable blobs, the majority of which can be resolved as varicosities running along fine neurites. Both antibodies label varicosities ranging in cross-sectional area from <1µm² to 20µm² in each of the species studied. In C. borealis, C36-9H also labels blobs with cross-sectional areas >20µm². Some blobs have substructures consisting of regional variations in staining density.

The overall shape of labeled blobs is species dependent. In *C. borealis* and *P. interruptus*, C36-9H blobs appear relatively spherical, while in *H. americanus* the majority of larger varicosities  $(>10\mu\text{m}^2)$  are spindle-shaped. The localization of staining within the ganglion also varies. For example in *C. borealis* C36-9H labeled blobs of  $<20\mu\text{m}^2$  cluster in the posterior periphery of the ganglion, rarely invading the central core; while in *P. interruptus* staining is most prevelant in the anterior of the ganglion with occasional ramification in the central core. The results of this study indicate that the microstructure of homologous peptidergic neuropil differs among species of decapod crustacea. Supported by NS 17813(EM), NS 15697(KG), NS 25505(KG) and the Human Frontier Science Program.

#### 201.6

EFFECTS OF FMRFamide RELATED PEPTIDES ON WHOLE CELL CURRENTS IN IDENTIFIED MOTOR NEURONS OF A JELLYFISH. N. Grigoriev and A. N. Spencer\*. Department of Zoology, University of Alberta, Edmonton, Alberta, Canada T6G 2E9.

A family of neuropeptides with the carboxy-terminal Gly-Arg-Phe-NH<sub>2</sub> have recently been isolated and sequenced from coelenterates. Two of these peptides are specific to the hydromedusa *Polyorchis penicillatus*: Pol-RFamide I (<Glu-Leu-Leu-Gly-Gly-Arg-Phe-NH<sub>2</sub>) and Pol-RFamide II (<Glu-Trp-Leu-Lys-Gly-Arg-Phe-NH<sub>2</sub>). Polyclonal antisera to these peptides stain a subset of neurons in both peripheral regions associated with smooth muscle, and in neurons apposed to a network of motor neurons (SMNS) in the nerve-rings (CNS). *In vivo* studies indicate that RFamide peptides are able to cause long duration excitation of these neurons in the absence of any obvious depolarization.

These neurons can be identified in cultures of nerve-rings and whole-cell voltage clamp studies undertaken. Peptides were applied by "spritzing" onto cells through a pipette with an opening of approx. 1µm. Application of 2 x 10<sup>-5</sup>M FMRFamide caused a selective inhibition (30 to 40%) of the sustained (I<sub>K</sub>-like) potassium current Based on preliminary experiments using forskolin it appears that this peptide acts through a cAMP-dependent mechanism. This modulation of a voltage activated potassium current may account for the increased excitability seen in vivo. Other cultured cells, probably myoepithelial cells, exhibit a variety of ligand-gated responses to pulses of RFamide and Pol 1-RFamide, including fast inward and outward currents.

## 201.8

THE DISTRIBUTION AND MICROSTRUCTURE OF PEPTIDERGIC IMMUNOREACTIVITIES IN THE STOMATOGASTRIC GANGLION OF THE CRAB, CANCER BOREALIS. D. Baldwin<sup>1\*</sup>, A.E., Christie<sup>2</sup>, E. Marder<sup>2</sup> and K. Graubard<sup>1</sup>. <sup>1</sup>Dept. Zoology, Univ. of Washington, Seattle, WA 98195 and <sup>2</sup>Dept. of Biology, Brandeis, Univ., Waltham, MA 02254.

Proctolin, FMRFamide-like, red pigment concentrating hormone (RPCH)-like and cholecystokinin (CCK)-like (using the monoclonal antibodies, C36-9H and C37-4E; Christie et al., Soc. Neurosci Abst. 17:278) immunoreactivities within the stomatogastric neuropil were examined using confocal microscopy. Staining consists of individually distinguishable blobs, often identifiable as varicosities running along (and probably enclosed within) fine neurites. A subpopulation of the labeled blobs has a substructure composed of variations in staining density. All immunoreactivities contain blobs ranging in cross-sectional area from < |μm² to 20μm². FMRFamide-like, RPCH-like and C36-9H staining also show a population of blobs >20μm².

Peptidergic immunoreactivity is largely confined to the peripheral and intermediate regions of the neuropil with very limited staining seen in the central core. Peripheral and intermediate labeling varies in three-dimensional distribution in an antibody specific manner. For example, C37-4E immunoreactivity extends past the main neuropil invading the area around and between the neurons immediately posterior to the neuropil. The appearance of the labeled regions also varies. For example, C37-4E staining produces an open, honey-combed appearance, while proctolin staining leaves less open space. Supported by NS 17813(EM), NS 15697(KG), NS 25505(KG) and the Human Frontier Science Program.

## 201.10

DYNAMICS OF INTRADENDRITIC CALCIUM IN A SEROTONIN-EVOKED PLATEAU-GENERATING CRAB MOTONEURON B. Zhang\*1, K.R. Delaney², D.W. Tank² and R.M. Harris-Warrick¹
1). Section of Neurobiology and Behavior, Comell University, Ithaca, NY 14853; 2). Biological Computation Research Department, AT&T Bell Laboratories, Murray Hill, NJ 07974.

A set of serotonergic/cholinergic mechanosensory cells, the gastro-pyloric receptor (GPR) cells, exert a variety of neuromodulatory effects in stomatogastric ganglion of the crab, Cancer borealis. GPR stimulation evokes a plateau potential of about 15 mV lasting many seconds in the dorsal gastric (DG) motoneuron. Both GPR stimulation and serotonin (5-HT) application produce a slow inward current (SIC) by evoking a conductance decrease (of Ik-Ca) and a conductance increase (of Ih) (Kiehn & Harris-Warrick 1992) and possibly other as yet unidentified currents

dorsal gastric (DG) motoneuron. Both GPR stimulation and serotonin (5-HT) application produce a slow inward current (SIC) by evoking a conductance decrease (of Ik-Ca) and a conductance increase (of Ih) (Kiehn & Harris-Warrick, 1992) and possibly other as yet unidentified currents. Several lines of evidence indicate that Ca plays an important role in generation of the DG plateau. The 5-HT-induced SIC persists in TTX-containing saline, but is reduced when the cell is voltage-clamped in the presence of 20 mM TEA (Ik-Ca blocker). Extracellular Cd (200 µM) reduces the amplitude of the plateau leaving a 3-5mV depolarization that lasts several seconds. This suggests that reduction of Ik-Ca, together with increased Ih, may trigger the plateau, but Ca influx is required for full expression of the plateau response. Intracellular injection of the Ca chelator EGTA slows the rising phase of the plateau and prolongs its duration. These results are consistent with a 5-HT-induced Ca-dependent inward current(s) contributing to the plateau.

current(s) contributing to the plateau.

We are using quantitative fura-2 imaging of dendritic Ca in the presence and absence of excess Ca buffers to determine whether the time course of Ca accumulation and recovery correlates with the amplitude or time course of the 5-HT-induced plateau. Sponsored by NIH NS17323 to RHW.

Neurones in the head ganglia of the nematode Ascaris suum: A possible functional correlate for the nervous system of C.elegans. L. Holden-Dye and R.J. Walker. (SPON: Brain Research Association\*). Dept. of Physiol. and Pharmacol., Bassett Crescent East, University of Southampton, Southampton, SO9 3TU, U.K.

Stretton et al. have pioneered the use of the large parasitic nematode Ascaris suum as a functional correlate for the extensively studied nematode C. elegans. We have used a whole mount preparation of Ascaris head ganglia to intracellularly label neurones and record their electrical properties. These have been combined with immunocytochemical studies to indicate the possible neurotransmitter content of the neurones. Neuropeptide immunoreactivity, particularly FMRF-amide-like, is widespread. The neurones have membrane potentials of about -30 mV, and a relatively high input resistance for their size e.g. 24 megohm for a 100µm cell. Many of the neurones have distinctive morphologies that are similar to neurones in C. elegans. All the neurones identified so far in the ventral ganglia are similar to those of C.elegans in that they are monopolar and send projections into the nerve ring. Varicosities resembling sites for transmitter release have been observed in this region. These studies will be used to identify simple neuronal circuits in Ascaris. Supported by the Wellcome Trust.

## 201.13

THE REGULATION OF A MUSCARINIC CURRENT IN AN IDENTIFIED INSECT MOTONEURON. B. A. Trimmer\*. Department of Biology, Tufts University, Medford, MA 02155.

In larval Manduca sexta, brief (500 ms) bursts of activity from mechanoreceptors on the prolegs and ventral body wall evoke slow, long-lasting (5-20 s) depolarizations (sEPSPs) in the identified proleg motoneuron, PPR. The sEPSP has muscarinic pharmacology and can be mimicked by microinjection of the muscarinic agonist, oxotremorine-M (oxo-M), into the neuropil. Both oxo-M and the sEPSP increase PPR's excitability by depolarization and by lowering its spike threshold. Using a single electrode voltage clamp, it has been determined that the muscarinic current (Iox) underlying these effects is voltage-sensitive, TTX-insensitive and carried predominantly by sodium. The regulation of lox and the roles of G-proteins and second messengers in insect neurotransmission is now being investigated.

lox requires the presence of extracellular calcium and is sensitive to agents that affect calcium channels. Hence, nifedipine (40 μM), cadmium (100-400 μM), cobalt (4 mM), magnesium (20 mM) and high concentrations of calcium itself (10 mM), inhibit Iox. These results suggest that Iox requires, or is regulated by, the entry of calcium.

The injection of PPR's soma with agents that affect G-protein turnover have implicated G-proteins in the control of Iox. Using antibodies that recognize subclasses of mammalian G-proteins, Western blotting analysis of Manduca nerve cord homogenates reveals a protein, approximately 39 Kd in size, that is immunologically related to  $Go\alpha$ . The potential role of this and other G-proteins in the muscarinic modulation of identified neurons is being investigated by

immunohistochemistry and ligand binding studies.

Supported by a Sloan Foundation Fellowship and NIH Grant NS30566.

ALLATOSTATIN-IMMUNOREACTIVE NEURONS IN THE COCKROACH DIPLOPTERA PUNCTATA AND THE SPHINX MOTH MANDUCA SEXTA. N.T. Davis\*, H. Agricola, R. Feyereisen, and J.G. Hildebrand. ARL Div. of Neurobiol., Univ. of Arizona, Tucson, AZ 85721.

The allatostatins are a family of neuropeptides that have been shown to inhibit the release of juvenile hormone by the corpus allatum (CA) in cockroaches. Antisera against each of two principal allatostatins, the tridecapeptide (AS-A1) and the octadecapeptide (AS-B2), were used for the immunocytochemical identification of allatostatin-like immunoreactive (ASLI) neurons in the cockroach Diploptera punctata. ASLI neurosecretory cells located in the brain and projecting to the corpora cardiaca were stained, and these cells appeared to function in the control of juvenile hormone release. In addition, median neurosecretory cells and neurohemal organs of the ventral ganglia were stained, indicating the possible release of allatostatin-like neurohormones at sites remote from the CA. ASLI interneurons were stained throughout the CNS, suggesting that allatostatin-like peptides may serve as neuroeffectors within the CNS. In addition, projections of ASLI neurons to the midgut, hindgut, and salivary glands and intrinsic neurosecretory cells in the lining of the midgut were stained, indicating that allatostatin-like peptides may be involved in the control of visceral movements and secretion. Comparable neurosecretory cells, interneurons, and efferent visceral neurons were stained in the CNS of larvae and adults of the sphinx moth Manduca sexta, indicating that ASLI neuropeptides may occur in insects other than cockroaches.

AMINO ACID SEQUENCE AND MOLECULAR ANALYSIS OF INSECT CARDIOACTIVE PEPTIDES. P.K. Loi, C.C. Cheung, T.D. Lee, and N.J. Tublitz, Inst. of Neurosci., Univ. of Oregon, Eugene, OR 97403 and Div. of Immunol., Beckman Res. Inst., City of Hope, Duarte CA 91010.

The CNS of the tobacco hawkmoth, Manduca sexta, contains several myoactive neuropeptides, the Cardioacceleratory Peptides (CAPs), that are functionally well characterized (Tublitz et al., TINS, 1991). The CAPs have different stage-specific actions, modulating gut contractility in embryonic and larval stages via local release while acting as cardioregulatory neurohormones in the adult moth. Here we report on a series of studies to elucidate the primary structure of the CAPs

Previous biochemical studies using HPLC isolated two distinct peaks, CAP, and CAP2, which had different retention times but similar CAP-like bioactivities. Refinements to our extraction and chromatography procedures coupled with the use of a syringe pump microbore HPLC system enabled further purification of the CAPs. CAP2, when subjected to a 5-step chromatographic procedure, fractionated into at least three separate peaks, CAP<sub>20</sub>, CAP<sub>20</sub>, and CAP<sub>2c</sub>. Similar analyses on CAP<sub>1</sub> also revealed multiple bioactive peaks. Conventional sequencing and FAB-MS analysis of CAP, yielded a primary amino acid sequence of PFCNAFTGCamide, which is completely homologous to crustacean cardioactive peptide (CCAP). Biochemical and pharmacological analyses, in which synthetic CCAP and native CAP, co-chromatographed on 5 different HPLC steps and produced identical dose-dependent responses on the isolated *Manduca* heart bioassay, provided confirmation of the sequence. The primary sequences for  $CAP_{2a}$  and  $CAP_{2c}$  have also been tentatively established but have not yet been confirmed. Both appear to be short peptides (<10 residues) with a N-terminal pyro-glu and an amide at the C-terminus. These latter two sequences, if confirmed, share these features with the arthropod peptide family that includes the adipokinetic hormones in insects and red pigment concentrating hormone in crustaceans. Supported by grants from NIH and NSF.

ECLOSION HORMONE RELEASE AND ITS REGULATION BY ECDYSONE: CHANGES IN THE EXCITABILITY OF THE VM CELLS AT ECDYSIS. R.S. Hewes\* and J.W. Truman. Dept. of Zoology, University of Washington, Seattle, WA 98195.

In the tobacco hornworm, Manduca sexta, declining titers of ecdysteroids trigger eclosion hormone (EH) release, and EH in turn stimulates ecdysis, a highly stereotyped behavior used to shed the old cuticle at the culmination of each molt. Intracellular recordings from the EH containing cells (VM cells) before, during, and after hormone release may provide much of the essential groundwork for resolving the mechanisms by which changes in ecdysteroid titers stimulate ecdysis. We have recorded from the VM cells during the molt from the 4th to the 5th larval instar, since at this time they are easily identifiable under a dissecting micro-It has been possible to confirm their identity with the colocalization of iontophoretically injected biocytin and immunocytochemical staining with an anti-EH antiserum. The most dramatic change seen in the VM cells associated with EH release was a decrease in threshold. In intermolt animals, and up to about 90 min before ecdysis (at which time EH release begins in intact animals), the VM cells required depolariation of 10-30 mV from rest to elicit firing. Threshold voltage then rapidly declined so that by 30 min before ecdysis the threshold had dropped to 0 mV, and the cells fired tonically (2-3 Hz) at rest. Within 2-5 h  $\,$ after the onset of ecdysis behavior, threshold increased again to intermolt values.

ISOLATION AND DISTRIBUTION OF cDNAs WITH HOMOLOGY TO Na+-DEPENDENT NEUROTRANSMITTER TRANSPORTERS. L.A. Dowd\* H.O. Nguyen, J.D. Sinor, M. Mercugliano, D.B. Pritchett, and M.B. Robinson, Children's Seashore House; Depts. Pediatrics and Pharmacology, Univ. of Pennsylvania; Phila., PA 19104

The cDNAs for the GABA, NE, 5-HT and DA transporters have recently been cloned. Since their sequences are highly homologous, these transporters may belong to a gene family. We designed degenerate oligonucleotides directed towards two conserved regions of the rat GABA and human NE transporters and used these as primers for the polymerase chain reaction. Using these PCR products, a rat brain cDNA library was creened for other homologous sequences. We isolated 79 cDNAs which were different from the cloned GABA transporter and characterized 12. Based on restriction digests, most of these 12 cDNAs were unique from the already cloned transporters and were also distinct from each other.

were also distinct from each other. Four of these cDNAs were larger than 3.0 kB and were thought to be full-length clones. Full-length RNA probes from 3 of the 4 cDNAs demonstrated labelling of specific brain regions with *in situ* hybridization histochemistry. cRNA transcripts from clone 29.2 hybridized to mRNA in the substantia nigra pars compacta and ventral tegmental area. RNA transcripts from clone 44.1 hybridized to subregions of the brainstem, while clone 45.2 hybridized to neurons in multiple brain regions, including hippocampus (CA1, CA3, and dentate gyrus) and middle layers of the cortex.

We have also used the original degenerate oligonucleotides in the polymerase chain reaction with the 4 cDNAs as template. Each produced a DNA fragment of approximately 600 bp. This is the distance present between the two regions

We have also used the original degenerate oligonucleotides in the polymerase chain reaction with the 4 cDNAs as template. Each produced a DNA fragment of approximately 600 bp. This is the distance present between the two regions the oligonucleotides were directed against in the already cloned transporters, suggesting that our 4 cDNAs may be other members of a growing transporter family. (Supported by the Pew Foundation and Grant #GM-34781).

## 202.3

CLONING AND EXPRESSION OF A TAURINE TRANSPORTER FROM RAT BRAIN. K.E. Smith\*, L.A. Borden, C.-H.D. Wang, P.R. Hartig, T.A. Branchek, and R.L. Weinshank. Synaptic Pharmaceutical Corporation, 215 College Road, Paramus, N.J. 07652.

Pharmaceutical Corporation, 215 College Road, Paramus, NJ 07652.

A complementary DNA clone encoding a taurine transporter was isolated from rat brain by low stringency hybridization with the rat GABA transporter CDNA (GAT-1; Guastella et al., 1990). The nucleotide sequence predicts a protein of 604 amino acids with significant homology to previously cloned neurotransmitter transporters. The functional properties of the CDNA were examined by transient transfection of COS-7 cells. The transporter displays high-affinity for taurine (K\_=40µM) and is dependent on external sodium and chloride for transport activity, similar to taurine transport in vivo. \$\beta\$-alanine, a structural analog of taurine, and GABA significantly inhibit specific taurine transport, while glycine, glutamate, norepinephrine, dopamine, betaine, and L-methionine have no effect. Localization studies demonstrate that the transporter mRNA is present in a variety of peripheral tissues as well as the brain and retina. The cloning of an additional member of the inhibitory amino acid transporter family will facilitate the study of structure\function relationships for this class of molecules as well as the understanding of the physiology of taurine transport in the nervous system.

## 202.5

ISOLATION AND CHARACTERIZATION OF A cDNA ENCODING A NEW MEMBER OF THE SODIUM-DEPENDENT NEUROTRANSMITTER TRANSPORTER SUPERFAMILY. <u>Eugenia M. C. Jones</u> Committee on Neurobiology and Howard Hughes Medical Institute and <u>Robert A. McCrea\*</u> Committee on Neurobiology, Department of Pharmacology and Physiology, University of Chicago, Chicago, Illinois 60637

Sodium-dependent neurotransmitter transporters comprise a superfamily of integral membrane proteins. Degenerate oligonucleotide primers based on regions of amino acid similarity between the GABA and norepinephrine transporters were used to amplify related sequences in bovine retina RNA. Sequence analysis of fifteen PCR products revealed three clones encoding the bovine GABA transporter (there is 94% amino acid identity with the rat brain GABA transporter) as well as a novel member of this superfamily designated as TL-15 having 51%, 58%, 59%, 61% and 62% amino acid identity with the betaine, norepinephrine, serotonin, GABA, and dopamine transporters, respectively. Of the remaining 11 clones, six encoded clusterin and five were not related to any sequences in the GenBank database. RNA blotting indicated that TL-15 hybridized to a single transcript of about 4.4 kb that was present in retina and brain, but not in liver. In situ hybridization showed that TL-15 mRNA was localized to the inner nuclear layer of the bovine neural retina. A similar pattern of hybridization was noted using the bovine GABA transporter cDNA clone. Studies are underway to complete the cloning of this new member of the Na-dependent neurotransmitter transporter superfamily and to identify its ligand. Supported by NRSA 5F31MH09973-02 BPN-02

#### 202.2

EXPRESSION OF SODIUM-SENSITIVE ATP-DEPENDENT [\*H]DOPAMINE UPTAKE IN A MOUSE CELL LINE TRANSFECTED WITH CLONED HUMAN GENOMIC DNA. A.J. Eshleman, J.C. Fernando, A.T. Eldefrawi\*, M.E. Eldefrawi, and R.J. Hickey. Dept. Pharmacol. & Exp. Therap. & the Molecular & Cellular Biology Program, Univ. Md. Sch. Medicine, Baltimore, Md. 21201.

The transfection into mouse fibroblasts of cloned human genomic DNA contained in a cosmid vector has resulted in the identification of mouse cell lines exhibiting sodium-sensitive ATP-dependent uptake of [3H]dopamine (DA). All cells which exhibited [3H]DA uptake had specific [³H](-)-2-β-carbomethoxy-3-β-(4-fluorophenyl)tropane 1,5-naphthalene disulfonate ([³H]CFT) binding which was inhibited by micromolar concentrations of desipramine, imipramine, and cocaine. The presence of human DNA in the cell lines was verified by probing Southern blots with the human Alu sequence (pBlur8). A human S. nigra lambda cDNA library was screened with an oligonucleotide probe for the highly conserved region of the first transmembrane domain of the human norepinephrine and rat DA transporters (TM1). The positives were rescreened with a probe made by PCR using the nigral cDNA and two primers, the TM1 and another for the rat DA transporter protein terminus. These clones are being sequenced, and selected clones are being expressed in Cos cells. Positive clones will be used to probe Southern blots of the DNA of the mouse cell lines. (supported by grants to: RJH DRIF 30417; and DA07369; and to M.E.E. DA03680)

### 202.4

EXPRESSION OF GABA TRANSPORTER mRNA IN THE RAT CENTRAL NERVOUS SYSTEM. N. Brecha, C. Weigmann, and E. Messersmith\*. Depts. of Anatomy & Cell Biology and Medicine, Brain Research Institute, and CURE, UCLA School of Medicine and VAMC-Wadsworth, Los Angeles, CA 90073.

GABA transporters play an important role in the termination of synaptic activity in the nervous system. The present study evaluates the distribution and developmental resultation of a birth efficient.

GABA transporters play an important role in the termination of synaptic activity in the nervous system. The present study evaluates the distribution and developmental regulation of a high affinity GABA transporter in the nervous system using in situ hybridization histochemistry. Tissue sections were incubated in antisense or sense RNA, washed at high stringency, and processed for autoradiography. GABA transporter mRNA is abundantly distributed along the entire neuroaxis. Prominently labeled structures include the olfactory bulb, septal nuclei, basal forebrain nuclei, cortex, hippocampus, substantia nigra, superficial layers of the superior colliculus, interpeduncular nucleus, pontine nuclei, cerebellar cortex, spinal trigeminal nuclei and the spinal cord. These studies are in agreement with previous descriptions of the distribution of GABA or L-glutamate decarboxylase immunoreactivity in the central nervous system. Developmental studies show that at birth low levels of GABA transporter mRNA are present in the olfactory bulb, cerebellar cortex, and brainstem nuclei. Other forebrain structures begin expressing GABA transporter mRNA during the first postnatal week. These studies indicate that there is a temporal regulation in the expression of this GABA transporter mRNA.

We thank Dr. J. Guastella for providing the GAT-1 cDNA. Supported by NEI grant EY 04067 and VA Medical Research Funds.

## 202.6

DOPAMINE TRANSPORTER PROTEIN: SOLUBLE FRAGMENTS, PHOSPHORYLATION PATTERNS, & MOLECULAR MODELING. C.K. Surratt. S. Yuhasz. M. Amzel. M.T. Brannock, M. Takemura\* and G.R. Uhl. Lab. Mol. Neurobiol., ARC/NIDA & Depts. Neurol, Nsci, Biophysics, JHUSM, Box 5180, Baltimore, MD 21224.

Efficient expression of dopamine transporter (DAT) proteins can allow production of antibodies, study of phosphorylation and other post-translational modification patterns, and possibly even allow protein crystallization for X-ray structural studies. Bacterial expression of a DAT fusion protein yielded little recoverable product. Expression of rat and human cDNA segments encoding the N-, C-, and second extracellular domains yielded ca. 100 µg peptide/L, with homogeneous material eluted from a single affinity purification step. In preliminary studies, the N- terminal fragment was phosphorylated in vitro by protein kinase A. These transporter fragments can elicit polyclonal antibody responses in rabbits. Molecular modelling studies of transporter putative transmembrane helices, in combination with studies of the effects of specific mutations, have yielded insights into possible transporter protein structural motifs and its potential modes of interaction with cocaine, dopamine, and transporter-dependent dopaminergic neurotoxins.

DOPAMINE TRANSPORTER 1 mRNA DENSITIES DIFFER AMONG NEURONS OF DIFFERENT DOPAMINERGIC NUCLEI. C. Cerruti\*S. Shimada, D. Walther, M. Kuhar & G. Uhl. Labs. Mol. Neurobiol. & Mol. Pharm. ARC/NIDA & Depts. Neurol. Nsci & Psych., JHUSM, Box 5180, Baltimore, MD. 21224.

Cloning cDNAs encoding the rat dopamine transporter (DAT1) allows assessment of the regional and cellular bases of its expression in the rat brain. Oligonucleotides and a full-length cDNA complementary to DAT1 mRNA hybridize to a 3.7 kb mRNA prepared from the rat midbrain that is absent in cerebral cortex or cerebellum. In situ hybridization using specific oligonucleotides reveals dense hybridization in neurons of the rat substantia nigra compacta, intermediate densities in ventral tegmental area subdivisions and A11, and very low levels in arcuate, olfactory bulb, retina and solitary tract. Different dopaminergic (or putative L-DOPAergic) cell groups thus display different levels of DAT1 dopamine transporter expression. Interestingly, the rank order of expression in several of these groups is parallel to the extent of cell loss in Parkinson's disease (compacta > VTA > arcuate).

#### 202.9

PRIMARY STRUCTURE AND FUNCTIONAL EXPRESSION OF A CHOLINE TRANSPORTER EXPRESSED IN THE RAT NERVOUS SYSTEM. P. Schloss. W. Mayser and H. Betz\*. Dept. of Neurochemistry, Max-Planck-Institute for Brain Research, Deutschordenstr. 46, D-6000 Frankfurt 71, Germany

Re-uptake of neurotransmitters into the presynaptic terminal is mediated via high-affinity, sodium-dependent transport proteins. These are thought to form a new family of integral membrane polypeptides, which share a common predicted transmembrane topology and significant amino acid identity (30-65%). We have performed polymerase chain reaction (PCR) with degenerate oligonucleotides deduced from the sequence of the GABA transporter (GAT1). This led to the isolation of cDNAs encoding a choline transporter (CHOT1), as shown by functional expression in *Xenopus* oocytes. [<sup>3</sup>H]Choline uptake in oocytes was of high affinity (Km ≈10 μM) and strictly sodium dependent. Amplification by PCR revealed significant amounts of CHOT1 transcripts in brain, cerebellum, spinal cord and, to a lesser extent, heart, but only very low expression in lung, kidney and muscle.

# 202.11

DOPAMINE TRANSPORTER mRNA CONTENT IN RAT SUBSTANTIA NIGRA: COCAINE-RELATED DECREASE. Yue Xia\*, Dennis J. Goebel, Gregory Kapatos and Michael J. Bannon. Departments of Psychiatry (Cellular and Clinical Neurobiology Program) and Pharmacology, Wayne State University School of Medicine, Detroit, MI. U.S.A.

The function of the dopamine transporter is to terminate synaptic transmission in dopaminergic neuronal systems. It is also a primary site of action for such psychostimulant drugs as cocaine and amphetamine. To investigate some of the effects of these drugs on dopamine transporter gene expression, we have taken advantage of the high level of sequence homology between our human dopamine transporter partial cDNA clone and the corresponding sequence in the rat. Using the human clone to make antisense RNA probe, dopamine transporter mRNA in the rat substantia nigra has been successfully visualized by in situ hybridization and quantitated by nuclease protection assay. A preliminary assessment of the effects of cocaine on rat nigral dopamine transporter mRNA content has shown that repeated drug administration (15 mg/kg, twice a day for 6.5 days) produces a >40% decrease in transporter mRNA compared with controls. In contrast, neither acute cocaine administration (4 hr before sacrifice) nor repeated administration followed by 72 hr of abstinence had any effect on nigral dopamine transporter mRNA levels. This suggests that one of the effects of dopamine transporter blockade may be the downregulation of neuronal dopamine transporter gene

#### 202.8

CELLULAR LOCALIZATION OF mRNA FOR A NOREPINEPHRINE UPTAKE TRANSPORTER IN NEURONS AND ENDOCRINE CELLS OF RAT AND MONKEY: AN *IN SITU* HYBRIDIZATION STUDY

R. Elde, B. Meister, M. Eriksson\* and T. Hökfelt. Dept. of Histology and Neurobiology, Karolinska Institute, P.O. Box 60400, 104 01 Stockholm, Sweden

Noradrenergic neurotransmission is terminated by reaccumulation of norepinephrine into the presynaptic terminal by an uptake system. A cocaine- and antidepressant-sensitive human norepinephrine transporter (NET) was recently cloned and Northern-blot analysis has shown presence of NET in brain stem and adrenal gland (Pacholczyk et al.; Nature 350:350, 1991). In the present study we have synthesized 48-mer oligonucleotide probes from the coding region of the human NET complementary to oligonucleotides 143-190 (probe 1) and 1861-1908 (probe 2). NET mRNA was visualized by in situ hybridization in the central and peripheral nervous system and adrenal gland of rat and monkey (Macaca fascicularis). Intense hybridization with the NET probes was demonstrated in neurons of the locus coeruleus and in several norepinephrine-containing cell groups of the lower brain stem. Virtually all cells in the superior cervical, inferior and superior mesenteric ganglia contained NET mRNA. Less intense hybridization with the NET probes was demonstrated in chromaffin cells of the adrenal gland, whereas ganglion cells within the adrenal medulla exhibited intense hybridization signal. No NET mRNA was detected in cortex cerebri, hypothalamus, spinal cord, dorsal root ganglia, retina, kidney or pancreas. This study demonstrates presence of NET mRNA in neurons previously known to store and release norepinephrine. Studies on changes in cellular NET mRNA expression may be of importance in order to identify neurons where function is altered in affective disorders and in addiction to cocaine.

(Supported by grant DA 06239 and from the Swedish MRC 04X-2887).

#### 202.10

DOPAMINE TRANSPORTER mRNA CONTENT IN HUMAN SUBSTANTIA NIGRA: ABRUPT AGE-RELATED LOSS. Michael S. Poosch', Yue Xia, Dennis J. Goebel, Bader Cassin, Gregory Kapatos and Michael J. Bannon. Departments of Psychiatry (Cellular and Clinical Neurobiology Program) and Pharmacology, Wayne State University School of Medicine, and Wayne County Medical Examiner's Office, Detroit, MI. U.S.A.

Neurotransmitter transporters provide the primary means for terminating synaptic transmission in monoaminergic neuronal systems. Additionally, they constitute a major site of action for psychostimulant drugs and, in the nigrostriatal system, for the uptake of neurotoxins that induce parkinsonism. In this study, a human dopamine transporter (DAT) partial cDNA clone was obtained via reverse transcription of human substantia nigra RNA followed by polymerase chain reaction using primers based on the published sequence for the human norepinephrine transporter. The cloned sequence subsequently was found to exhibit 87% nucleic acid identity (89% amino acid identity) with the sequence for transmembrane domains three through five of the rat homolog. This clone was used to quantitate age-related changes in human DAT mRNA by nuclease protection assay. The postmortem content of DAT mRNA in the nigrae of 18-57 year-old subjects was found to be relatively constant; however, in subjects >57 years of age, an abrupt decline (>95%) in nigral DAT mRNA was observed. In situ hybridization experiments confirmed this profound loss of DAT gene expression in melanin-positive (presumptive dopamine) nigral neurons. In contrast, the tyrosine hydroxylase mRNA content of these samples declined in a more uniform manner with increasing age. These data provide evidence that compensatory changes may be occurring in human dopamine neurons consequent to the normal aging process.

# 202.12

EFFECT OF PROTEIN KINASE C ON GABA TRANSPORTER EXPRESSED IN XENOPUS OOCYTE. N. Saito\*, T. Koga, I. Osawa, and C. Tanaka Dept. of Pharmacology, Kobe University School of Medicine, Kobe 650, Japan.

The synaptic neurotransmission is terminated by rapid re-uptake of the neurotransmitter into the presynaptic terminals from the synaptic cleft. GABA, a major inhibitory neurotransmitter, is also transported into glial cell or neuronal cells by variety of the pharmacological kinetics. The cDNA for GABA transporter was isolated and the significant homology between the various neurotransmitter transporters has been identified. However, the modulation of these transporter activities has not yet been elucidated. The presence of multiple putative phosphorylation sites in GABA transporter suggests that the activity of transporter may be regulated by phosphorylation. We have cloned a cDNA for GABA transporter from rat brain library and the effect of various kinases on the GABA transporter was examined in the brain synaptosomal fraction and in the Xenopus Oocytes. The activation of protein kinase C reduced the high affinity uptake of GABA into brain synaptosome but not effected on the low affinity uptake. Similarly, the activation of protein kinase C inhibited the GABA transporter which is expressed in Xenopus Oocyte by injection with the synthesized mRNA for GABA transporter. Using site directed mutagenesis, the regulation site of the transporter activity was also examined.

IODINATED DERIVATIVES OF TETRABENAZINE FOR MAPPING MONOAMINE STORAGE SITES. M.P. Kung D.Canney Y.Z. Guo , J.Billings and H.F. Kung Depts. of Psychiatry and Radiology, Univ. of Pennsylvania, PA 19104

Monoaminergic neurotransmission has been implicated in various neurological and psychiatric disorders. Pharmacological characterization of these neuronal systems could be greatly facilitated by the use of specific radioligands. J³HJReserpine and [³HJdihydrotetrabenazine ([³HJTBZOH]) have been evaluated as in vitro probes for the vesicular monoamine transporter. Development of iodinated ligands with higher specific activity and selectivity for monoamine vesicular transport sites would be useful as presynaptic monoamergic markers for radioligand binding and autoradio-graphic studies. Starting with TBZ, an iodinated derivative, iodovinyltetrabenazine (I-TBZ), was synthesized in modest overall yield (28%). Subsequently, the "cold" and [125]I-TBZ were prepared from the tributyltin derivative by iododestannylation. The racemic mixture was then resolved on a HPLC chiral column into peak A and peak B (absolute configuration not determined). In vivo evaluation of peak A & peak B showed that, despite their similar high liphophilicity, peak A displayed specificity for the rat striatum compared to peak B. This selective in vivo uptake in rat brain after an i.v. injection could also be blocked by TBZ pretreatment. In vitro radioligand binding studies (rat striatal membrane preparations) indicate that peak A (but not peak B) of [125]I-TBZ binds selectively to a homogenous site corresponding to TBZ site with a Kd value of 0.3nM. The high binding affinity and selectivity of I-TBZ (peak A) suggests that this agent warrants further investigation as a potentially useful tracer for studying CNS vesicular monoamine transport sites. (Supported by Nihon Medi-Physics Inc.)

TRANSPORT OF ACETYLCHOLINE DRIVEN BY AN ARTIFICIALLY-INDUCED PROTON GRADIENT. M. L. Nguyen and S. M. Parsons\*. Neuroscience Research Institute, University of California, Santa Barbara, California 93106.

Cholinergic synaptic vesicles purified from electric organ that are hyposmotically lysed and resealed in buffers of pH 5.1-5.8 transiently take up [<sup>3</sup>H]acetylcholine (ACh) when the external pH is suddenly shifted to 7.8. Less [<sup>3</sup>H]ACh is taken up when the internal pH is lower or higher than 5.1-5.8. Uptake of the [<sup>3</sup>H]ACh is due to the artificial proton gradient, whereas the subsequent efflux of the [<sup>3</sup>H]ACh is due to the decay of the proton gradient, which was monitored by the change in absorbance of acridine orange. Uptake is blocked by vesamicol, which is an allosteric ligand of the ACh transporter. Vesamicol added at the peak of uptake blocks efflux of the [<sup>3</sup>H]ACh. A 100-fold excess of nonradioactive ACh added at the peak of uptake does not stimulate efflux of [<sup>3</sup>H]ACh. Vesamicol-sensitive uptake is composed of osmotically sensitive component is blocked by low temperature but the osmotically insensitive component is not. [<sup>3</sup>H]Choline and [<sup>3</sup>H]-N-methylcarbamoylcholine are not transported, but they are rapidly bound to the ACh transporter in a vesamicol-sensitive manner. The pH jump approach to inducing active transport of ACh will simplify study of the transporter by removing the dependence of transport on the V-type ATPase.

STRUCTURE-ACTIVITY RELATIONSHIPS OF SEROTONIN TRANSPORT. Albert S. Chang, Sharon M. Chang, Charles L. Densmore\* and Diane M. Starnes. Center for Biotechnology, Baylor College of Medicine, The Woodlands, TX 77381.

A transfectant cell model of high-affinity serotonin transport was used to assess the inhibitory potencies of 5-HT/tryptamine structural analogues in order to assess the significance of 5-HT structural domains in transport interaction. One finding of this study is that methyl substitution at indole-7 position led to enhanced inhibitory potency, suggesting enhanced transport interaction. Further, the discerned SARs are consistent with the hypothesis that the terminal amino group (on the ethylamine side chain) has to be spatially coordinated with the hydroxyl group in order to be recognized by the transport system; the necessary spatial coordination is provided by the aromatic indole nucleus. This hypothesis also seemed to apply to nontricyclic antidepressant (NTCA) structures, including fluoxetine, paroxetine, citalopram and sertraline. Molecular modelling analyses revealed that the same spatial coordination of an electronegative group (attached to an aromatic system) away from an amino group, as observed in 5-HT, also existed in the NTCA structures. Thus, a common pharmacophore structure seems to exist within structurally diverse inhibitors of 5-HT transport. This pharmacophore presumably accounts for antidepressant interaction with the 5-HT transport system.

CHRONIC ESTRADIOL AND PROGESTERONE TREATMENTS AFFECT RAT STRIATAL DOPAMINE UPTAKE SITES. T. Di Paolo\* and M. Morissette. Mol. Endocinol., CHUL Res. Centre, G1V 4G2 and Sch. Pharm., Laval Univ., G1K 7P4, Québec, CANADA.

The effects of chronic estradiol (E2) and progesterone (P) treatments to ovariectomized (OVX) rats on striatal DA uptake sites were investigated on

The effects of chronic estradiol (E2) and progesterone (P) treatments to ovariectomized (OVX) rats on striatal DA uptake sites were investigated on tissue homogenates and by quantitative autoradiography with [³H]GBR-12935 binding. Treatments were started the day after ovariectomy for 2 weeks and consisted of E2 (10 μg/0.2 ml), P (0.72 mg/0.2 ml), E2+P or the vehicle. One saturation curve of [³H]GBR-12935 binding was performed using the striatal tissue of each animal. The steroid treatments left affinity (Kd) of [³H]GBR-12935 striatal binding unchanged (OVX: 0.823 ± 0.028 nM). In contrast, the density of these binding sites was significantly increased by these steroids alone or in combination to a similar extent (about 20%): OVX, 4742 ± 287; E2, 5547 ± 287; P, 5822 ± 425; E2+P, 5616 ± 272 fmol/mg of protein. By autoradiography, [³H]GBR-12935 at 2nM was chosen for binding on striatal coronal section (10 μm). No dorsal-ventral or lateral-medial differences were observed for the effects of steroids on [³H]GBR-12935 binding. In anterior and medial striatum, E2 and E2+P treatments increased significantly [³H]GBR-12935 binding (about 25% for E2-treated animals and 45% for E2+P-treated animals) whereas P treatment led to a non-significant increase of binding sites (about 20%). In posterior striatum, all treatments examined produced a significant increase of [³H]GBR-12935 binding (E2, 27%; P, 24%; E2+P, 40%). Chronic exposure to E2 and/or P was shown here to increase striatal DA uptake sites density. The hormonal modulation of DA uptake sites could be involved in the gender related differences in cocaine-induced behavioral sensitization. Supported by the MRC of Canada.

EFFECTS OF ANGIOTENSIN II (ANG II) ON INOSITOL PHOSPHATE (IP) HYDROLYSIS IN THE BRAIN OF FEMALE RATS. M K.Steele\* and R K.Riemer, UCSF, Depts of Physiology and Obstetrics and Gynecology, San Francisco, Ca. 94143
Ovarian hormones modify the central effects of Ang II on LH and

Ovarian hormones modify the central effects of Ang II on LH and prolactin release. The present experiments tested whether estrogen modifys the intracellular second messenger system of Ang II in the hypothalamus from female rats.

Animals were ovariectomized and treated with either vehicle or ethynylestradiol (25 µg/rat) sc for two days. Whole hypothalamic

Animals were ovariectorized and treated with either Ventice or ethynylestradiol (25 µg/rat) so for two days. Whole hypothalamic halves and pituitaries were incubated in Krebs Henseleit buffer with <sup>3</sup>H myoinositol. After incorporation of the label, the tissue was stimulated for varying periods of time with 10<sup>-5</sup>M Ang II.

Ang II stimulated IP production in pituitaries from both untreated and estrogen treated animals. The stimulation was seen by 2 min and lasted

Ang II stimulated IP production in pituitaries from both untreated and estrogen treated animals. The stimulation was seen by 2 min and lasted for up to 30 min. No stimulation of IP production was seen in hypothalami from untreated animals. In contrast, in hypothalami from estrogen-treated rats, a maximal stimulation was observed at 2 min, which discinated by 6 min.

estrogen-treated rats, a maximal stimulation was observed at 2 min, which dissipated by 6 min.

These results show that, similar to that seen in the periphery, Ang II stimulates IP production in the brain. Under the conditions of this experiment, this response is short lived and seen only after in vivo estrogen treatment. Modification of Ang II second messenger systems may provide a mechanism by which ovarian hormones modify the efficacy of Ang II on pituitary hormone secretion in female rats (Steele, et al, 1991).

## 203.

ENFLURANE INHIBITS MOUSE AND HUMAN BRAIN PHOSPHOTIDYLINOSITOL-LINKED ACETYLCHOLINE AND SEROTONIN RECEPTORS EXPRESSED IN XENOPUS OOCYTES. L.-H. Lin\*and R. A. Harris. Dept. of Pharmacology, UCHSC, Denver, CO 80262; Veterans Admin. Med. Res. Serv., Denver, CO 80222.

Modulation of IP<sub>3</sub>-mediated signal transduction pathways by the inhalational anesthetic enflurane was studied in *Xenopus* oocytes expressing mouse and human cortical mRNA. We found that enflurane significantly inhibited ion currents activated by ml muscarinic and 5-HT<sub>1C</sub> receptors in a concentration dependent manner, with large inhibition (80-89 %) on low and small inhibition (8-44 %) on high concentrations. Similar effects were found with both mouse and human receptors. To investigate the sites of enflurane action, ion currents induced by intracellular injections of GTP-\(\gamma\)-S and IP<sub>3</sub> were examined. Enflurane strongly suppressed the GTP-\(\gamma\)-S-activated current. The results suggest that an inhalational anesthetic can disrupt the function of mouse and human brain PI-linked receptors by selective inhibition on the G protein activity. On the other hand, the results suggest that enflurane exerts little effect on the IP<sub>3</sub>-activated Ca<sup>2+</sup>-dependant Cl-channels. Together, specific modulation of membrane proteins by enflurane suggests that proteins are the target sites of action for anesthetics.

INHIBITION BY ETHANOL OF METABOTROPIC RESPONSES TO SEROTONIN AND ACETYLCHOLINE IN XENOPUS OOCYTES. E. Sanna\* and R.A. Harris. Dept. of Pharmacology, Univ. of Colorado Hlth. Sci. Cntr. and Denver VAMC, Denver, CO 80262.

In voltage-clamped Xenopus oocytes microinjected with mouse whole brain mRNA, serotonin (5HT) and acetylcholine (ACh) acting through 5HT<sub>1C</sub> and M<sub>1</sub> receptors, respectively, evoke membrane responses through a common biochemical cascade. This involves G-protein-mediated phospholipase C activation, production of IP<sub>3</sub>, release of intracellular Ca<sup>2+</sup> and opening of Ca<sup>2+</sup>-dependent Cl<sup>-</sup> channels. The effect of ethanol (EtOH) on these metabotropic responses was studied. ErOH (25-200 mM) inhibited in a dose-related manner currents evoked by both 5HT (0.1  $\mu$ M) and ACh (1  $\mu$ M). The maximal effect (-50% for ACh, and -65% for 5HT) was observed at 150 mM ErOH. Moreover, EtOH (100 mM) produced rightward shifts of both 5HT and ACh dose-dependent curves. To clarify the site of action of EtOH, IP<sub>3</sub> and GTP-y-S were injected intracellularly. EtOH (100 mM) did not significantly alter the Ca2+-dependent Cl- currents elicited by either IP3 (200 fmols) or GTP-y-S (20 pmols). Treatment of oocytes for 12-18 hrs with 400 nM staurosporine (Stau), a PKC inhibitor, prevented the inhibition by EtOH of 5HT and ACh-induced responses. Moreover, in Stau-treated oocytes EtOH alone was able to induce Cl- currents which were abolished by intracellular EGTA or at a clamping potential of -20 mV. These data suggest that the inhibition by EtOH of metabotropic responses induced by 5HT and ACh in Xenopus oocytes might be mediated by an alteration of PKC activity, or alternatively, that EtOH effect requires an activated PKC. The role of PKC on EtOH action will be further discussed

### 203.5

STUDIES OF AGONIST STIMULATION OF EXOGENOUS PHOSPHO-INOSITIDE HYDROLYSIS BY PHOSPHOLIPASE C - β IN RAT BRAIN MEMBRANES. P. Kurian and F.T. Crews\*. Department of Pharmacology. University of Florida College of Medicine, Gainesville, FL 32610-0267.

A number of neurotransmitters have been shown to activate phospholipase C (PLC) resulting in the hydrolysis of membrane PidIns(4,5)P2, leading to the formation of Ins(1,4,5)P3 and diacylglycerol. To investigate the mechanism of receptor coupling to PLC, membranes were prepared from various regions of rat brain and incubated with a mixture of [3H]PtdIns (3\* %), [3H]PtdIns(4)\* [10.4 %) and [3H]PtdIns(4,5)P2 (2.6%) which is comparable to that found in intact tissue. GTPγS stimulated the formation of [3H]Ins(1,4,5)P3 (GTPγS stimulated [3H]Ins(1,4,5)P3 formation was enhanced by carbachol (220 %) and 5-HT (210 %). Norepinephrine, glutamate and quisqualate did not stimulate [3H]PtdIns(4,5)P2 hydrolysis in the presence of GTPγS. SAX-HPLC separation of [3H]Insoitol polyphosphates indicated that there was only one isomer of InsP3, Ins(1,4,5)P3, the expected product of PtdIns(4,5)P2 hydrolysis. No Ins(1,34,5)P4 was formed in this assay. Two isomers of InsP1 were formed, Ins(1)P1 and Ins(4)P1. Both GTPγS - carbachol and IµM Ca2+ stimulated Ins(1)P1 and Ins(4)P1 formation. These isomers could be formed by direct hydrolysis of [3H]PtdIns substrate and/or phosphatase activity within our membrane preparation. Both GTPγS-carbachol stimulation and Ca2+ stimulated the formation of Ins(1)P1 (from PtdIns) and Ins(4)P1 (from PtdIns(4,5)P2 bydrolysis at a = 3 nM, increasing to a maximum at = 1 μM. The presence of GTPγS and carbachol appeared to left shift the calcium concentration effect curve for Ins(1,4,5)P3 formation. Membranes from cerebellum showed a large stimulation of PtdIns(4,5)P2 hydrolysis with GTPγS and Ca2+. In contrast to cortical membranes where carbachol and 5-HT enhanced GTPγS stimulated PtdIns(4,5)P2 hydrolysis with GTPγS and Ca2+. In contrast to cortical membranes shove G

EFFECTS OF U50.488, A KAPPA OPIOID RECEPTOR AGONIST, ON PHOSPHOINOSITIDE HYDROLYSIS IN RAT HIPPOCAMPUS. M. Mosaddeghi, J. M. Moerschbaecher\*, D. Paul. Dept. of Pharmacology and Alcohol and Drug Addiction Center, L.S.U. Medical Center., New Orleans, LA. 70112.

Hydrolysis of membrane phosphoinositides (PI) is proposed as a signal transduction mechanism mediating effects of several cell surface receptors. This study examined effects of kappa opioid receptor agonist U50,488 on PI hydrohysis in hippocampus. Tissue slices, labelled with [3H]inositol, were stimulated with KCl and PI hydrolysis were measured in the presence of LiCl. KCl-stimulated PI hydrolysis in a concentration dependent manner (EC<sub>50</sub>=20 mM) with maximal PI hydrolysis of 0.37 dpm released/dpm incorporated. U50,488 (0.1-1000 mM) did not affect PI hydrolysis. However, U50,488 diminished KCl-stimulated PI hydrolysis in a concentration dependent manner (IC<sub>50</sub>=100 uM). One mM U50,488 completely abolished 27.4 mM KCl-simulated PI hydrolysis. Time course experiments showed that 100 uM U50,488 did not stimulate PI hydrolysis upto 60 min incubation, whereas, KCl stimulated PI hydrolysis in a timedependent manner. U50,488 inhibited KCl-stimulated PI hydrolysis after 30 min or longer incubation. The kappa selective antagonist norbinal torphimine (nor-BNI) (100 uM) blocked the inhibitory effect of 300 uM U50,488 on KCl-stimulated PI hydrolysis. Nor-BNI alone did not alter PI hydrolysis. These data suggest that kappa opioid receptor agonists may exert their central effect, at least in part, by modulating PI hydrolysis. This study supported by NIH-BRSG SO-RR-5376 and DA03573.

INHIBITION BY ALUMINUM OF AGONIST-STIMULATED INOSITOL PHOSPHATE RELEASE IN SLICES FROM RAT HIPPOCAMPUS AND CORTEX. T.J. Shafer\*, W.R. Mundy, V. Dulchinos and H.A. Tilson, Neurotoxicology Division, HERL, U.S.EPA, Research Triangle Park, NC 27711.

Effects of aluminum chloride (0.1 to 1000  $\mu$ M) on inositol phosphate (IP) release stimulated by carbachol (CARB), norepinephrine (NE) or quisqualate (QUIS) were examined in rat hippocampal and cortical slices. Release of IPs was measured in the presence of Li<sup>+</sup> by incubation of slices with agonist for 30 min, followed by isolation of <sup>3</sup>H-IPs by ion-exchange chromatography. In the absence of agonist, Al<sup>3+</sup> significantly reduced basal release of IPs only at 1000  $\mu$ M. In cortical slices, the effect of Al<sup>3+</sup> on maximal agonist-stimulated IP release was significantly different from the effect of Al<sup>3+</sup> on agonist-stimulated IP release in hippocampal affected from the effect of AP\* on agonist-stimulated it release in hippocampal slices. For CARB-stimulated release,  $[AP^+]$  of 50  $\mu$ M and greater significantly inhibited IP release in cortical slices.  $1000 \mu$ M AP\* reduced IP release by 55%. In hippocampal slices;  $1000 \mu$ M AP\* significantly inhibited CARB-stimulated IP release by 40%. Similar effects of AP\* were observed for NE-stimulated IP release. For QUIS-stimulated release,  $1000~\mu M~Al^{3+}$  significantly inhibited IP release in hippocampal slices. However, in cortical slices a biphasic effect of  $Al^{3+}$  was observed. 500 and  $1000~\mu M~Al^{3+}$  significantly inhibited IP release, whereas 10 and 50  $\mu$ M AP\* significantly potentiated QUIS-stimulated IP release. In both hippocampal and cortical slices, 500  $\mu$ M Al3\* significantly inhibited CARB or NE stimulated IP release at all agonist concentrations (1 to 10000  $\mu$ M) tested. Thus, Al<sup>3+</sup> inhibits agonist-stimulated IP release in a non-competitive manner. These results suggest that: 1) differences in the sensitivity to Al<sup>3+</sup> exist in the hippocampus and cortex and, 2) Al<sup>3+</sup> does not interfere directly with agonist binding to the receptor, but interacts with other components of receptor-stimulated phosphoinositide hydrolysis possibly including G-proteins, phospholipase C and regulatory or modulatory influences such protein kinase C or Ca2+.

#### 203.6

EFFECTS OF ACUTE AND CHRONIC TREATMENT WITH HALOPERIDOL, LITHIUM AND VALPROATE ON PHOSPHOINOSITIDE TURNOVER IN RAT BRAIN SLICES. R.Li. L.L.Wing. R.J.Wyatt. and D.G.Kirch\*. Neuropsychiatry Branch, NIMH, Neuroscience Center at St. Elizabeths, Washington D.C. 20032 and Division of Clinical Research, NIMH, Rockville, MD 20857.

Haloperidol (HAL), lithium (LI) and valproate (VAP) have been shown to be effective in the treatment of bipolar disorder. While these medications treat Haloperidol (HAL), lithium (LI) and valproate (VAP) have been shown to be effective in the treatment of bipolar disorder. While these medications treat the same disease, it is unclear whether they work through a common mechanism. The effects of acute (single dose) and chronic (2 weeks and 4 weeks) treatment with HAL, LI and VAP on agonist-induced inositol phosphate (IP) formation were examined. Acute treatment with HAL, LI and VAP had no effects on carbachol- and norepinephrine(NE)-stimulated IP accumulation in both the frontal cortex and striatum, while acute HAL or HAL and LI combined (HAL/LI) reduced cortical and striatal IP basal levels. Four week treatment with HAL, LI and VAP each attenuated carbachol-induced IP formation in the striatum while a significant decrease in the frontal cortex was found only after HAL, LI and HAL/LI treatment. A similar reduction in NE-stimulated IP accumulation was found after HAL and LI treatment for 4 weeks in the frontal cortex, while HAL and VAP each produced a reduction in striatum. Two week treatment with HAL caused a significant reduction in carbachol-stimulated IP accumulation in the frontal cortex and striatum and a decrease in NE-sensitive IP formation in the frontal cortex. While regional and time-dependent differences in IP effects were observed, our data indicate that chronic treatment with HAL, LI or VAP may result in a down-regulation of receptor-mediated IP formation. This suggests that the common action of these drugs on IP systems may be an important factor underlying their mood-stabilizing effect.

## 203.8

PHOSPHOINOSITIDE HYDROLYSIS IN HIPPOCAMPAL SLICES: MODULATION BY GLUCOCORTICOIDS. K. Kolasa\*, L. Song and R. S. Jope. Dept. of Psychiatry and Behavioral Neurobiology, Univ. of Alabama, Birmingham, AL 35294.

Adrenal steroid hormones have many complex effects on the brain, influencing metabolism, signal transduction and behavior. Because physocorticoids can directly affect the limbic system especially the

glucocorticoids can directly affect the limbic system, especially the hippocampus, we investigated hippocampal phosphoinositide (PI) hydrolysis after adrenalectomy (ADX).

PI hydrolysis induced by norepinephrine(NE), quisqualate, or ACPD, but not by carbachol, was 50% greater in hippocampal slices from ADX (14 days) rats compared with controls. No effects of ADX on PI hydrolysis were detected in cortical or striatal slices. The enhanced response to NE in hippocampal slices after ADX was observed throughout the effective concentration range of NE, was not influenced by in vitro corticosterone or cyclic AMP, and was not due to impaired inhibition of the to impaired inhibition of the response to NE which was elicited by activation of protein kinase C or by an inhibitory concentration of

quisqualate.

These findings indicate that ADX either removes an inhibitory influence of glucocorticoids on the PI system in the hippocampus or that the neurodegeneration of granule cells in the dentate gyrus following ADX is associated with neurotransmitter-selective increases in PI hydrolysis. These data provide further evidence that glucocorticoids modify signal transduction in the brain and extends their known influence to the PI second messenger system. Investigations of the effects of glucocorticoid administration on hippocampal PI hydrolysis are currently in progress.

HYDROLYSIS OF [3H]PHOSPHATIDYLCHOLINE IN CYTOSOL AND MEMBRANES FROM RAT BRAIN. M.S. Baird\* L. Song and R.S. Jope. Dept. of Psychiatry and Behavioral Neurobiology, Univ. of Alabama, Birmingham, AL 35294.

Phosphatidylcholine hydrolysis apparently occurs in a manner analogous to phosphoinositide hydrolysis in the transduction of signals

to form second messengers. The functions and control mechanisms associated with phosphatidylcholine hydrolysis remain to be clarified.

We adapted methods used by others to measure the hydrolysis of

exogenous [3H]phosphatidylcholine incubated with rat cerebral cortex membrane and cytosolic fractions. Both preparations induced hydrolysis of [3H]phosphatidylcholine for at least 60 min, but the rate was higher in the cytosol compared with membranes. GTP<sub>1</sub>S enhanced hydrolysis in both fractions, supporting the existence of a regulatory G-protein.

Seizures were induced in rats by administration of LiCl (3 mmol/kg) 20 hr prior to pilocarpine (30 mg/kg). After 1 hr cytosolic fractions were prepared and they were found to hydrolyze [3H]phosphatidylcholine at a lower rate than controls, whereas no difference was observed in membranes.

These data show that both cytosolic and membrane fractions

contain enzymes that hydrolyze exogenous [3H]phosphatidylcholine, that a G-protein may influence this activity, and that the activity is reduced in the cytosol after seizures induced by lithium and pilocarpine. Studies are underway to identify the enzymes responsible for [3H]phosphatidylcholine hydrolysis and to study the regulation of this process.

# 203.11

STUDIES ON <sup>3</sup>H-INS[1,2,6]P<sub>3</sub> AND OTHER <sup>3</sup>H-INOSITOL PHOSPHATE BINDING SITES IN RAT BRAIN. <u>Heahyun Yoo, Anneli Lindahl, Erol</u> Veznedaroglu\* and Claes Wahlestedt. Division of Neurobiology, Department of Neurology and Neuroscience, Cornell University Medical College, New York, NY 10021 and Perstorp Pharma, S-284 80 Perstorp, SWEDEN.

We have studied binding sites of tritiated inositol phosphates (InsPs) in rat brain membranes in an attempt to assess differences and similarities in binding characteristics amongst various tritiated and unlabeled InsP analogs. The present study focused on a novel analog, <sup>3</sup>H-Ins[1,2,6]P<sub>3</sub> (PP-56), whose binding characteristics were compared with those of previously studied analogs, <sup>1</sup>e. <sup>3</sup>H-Ins[1,4,5]P<sub>3</sub>, <sup>3</sup>H-Ins[1,3,4,5]P<sub>4</sub> and <sup>3</sup>H-InsP<sub>6</sub>, While all four tritiated InsPs displayed specific binding, marked differences in optimum binding conditions were observed. 3H-Ins[1,2,6]P3 was found to bind to a single population of sites with a  $\rm K_0$  of 70 nM. The binding of  $\rm ^3H$ -Ins[1,2,6]P $_{\rm 3}$  to rat brain membranes, as well as to cultured vascular smooth muscle and endothelial cell membranes, was greatly enhanced at acidic pH (optimum pH 5) and reduced by alkali ions (while Ca<sup>2+</sup> had little effect). The conditions favoring <sup>3</sup>H-Ins[1,2,6]P<sub>3</sub> binding while Ca had little effect). The containts favoring P-Ins[1,3,4,5]P<sub>4</sub> binding. In contrast, we found <sup>3</sup>H-Ins[1,4,5]P<sub>3</sub> and <sup>3</sup>H-InsP<sub>4</sub> to display different pH and ionic requirements for optimum binding, as previously demonstrated also by several other groups. The present data, therefore, suggest the possibility that Ins[1,2,6]P<sub>3</sub> exerts its reported antiinflammatory and antihypertensive actions by interacting with membrane binding sites/receptors, abundantly present not only in smooth muscle and endothelial cells, but also in brain. These sites are only in smooth muscle and endomelial cells, but also in brain. These sites are probably distinct from  ${}^{3}H$ -Ins[1,4,5]P $_{3}$  as well as  ${}^{3}H$ -InsP $_{6}$  preferring sites. Interestingly, Ins[1,2,6]P $_{3}$  showed binding characteristics quite similar to those of Ins[1,3,4,5]P $_{4}$ , an agent believed to activate Ca $^{2}$  permeable channels, raising the possibility that Ins[1,2,6]P $_{3}$  might affect these same channels.

# 203.13

DISTRIBUTION OF CYTOSOLIC G-PROTEIN IN BRAIN AND OTHER RAT TISSUES; EVIDENCE FOR ROLE IN THE ACTIVATION OF CYTOSOLIC PLC BY A MECHANISM OTHER THAN GTP HYDROLYSIS. T Akompong\* RL.Spencer and B. S.McEwen. Lab. of Neuroendocrinology, Rockefeller University, New York, New York 10021. The G-proteins are involved in the transduction of signals initiated by hormones, neurotransmitters and drugs. We examined the distribution of two G-proteins; Gia and Gsa in the membrane and cytosol of rat tissues by western blot analysis. The levels of  $\text{Gi}\alpha$  in the membrane were much analysis. The levels of Gia in the membrane were much higher in brain regions than the peripheral tissues. In contrast the highest levels of Gia in the cytosol were found in spleen and thymus. The two species of Gsa (GsL, and GsH,) were distributed in a tissue dependent fashion in both membrane and cytosol. The effects of calcium, nucleotides, G-protein antibodies and protein phosphatase inhibitors on cytosolic PI-PLC activation were also examined. Calcium in the micromolar range stimulated PLC activity by 10 fold over basal. The calcium stimulated activity was inhibited up to 70 % by antibodies to Gil. GTP and its non-hydrolyzable analogues had no effect on both basal and calcium stimulated PI-PLC activity. NaF which is used to turn on G-protein mediated processes, inhibited the calcium stimulated activity in a dose dependent manner. Our data suggests a mechanism of dependent manner. Our data suggests a mechanism of regulating cytosolic PI-PLC by cytosolic G-proteins that is independent of G-protein hydrolysis required for other G-protein regulated systems.

## 203.10

SUSTAINED CALCIUM INFLUX INDUCED BY A NON-METABOLIZABLE INOSITOL TRISPHOSPHATE IN <u>XENOPUS</u> OOCYTES <u>Y. Yao</u> and I. Parker. Lab. Cellular and Molecular Neurobiology, Dept. Psychobiology, University of California, Irvine,

Ins(1,3,4,5)P<sub>4</sub> (formed by metabolism of Ins(1,4,5)P)<sub>3</sub>) has been suggested to play a role in phosphoinositide-mediated Ca<sup>2+</sup> influx (Irvine, R. F. <u>FEBS Lett.</u> 263, 5-9, 1990). To test this hypothesis we injected <u>Xenopus</u> oocytes with a synthetic analogue, 3-Deoxy-3-fluoro-Injected <u>Xenopus</u> oocytes with a synthetic analogue, 3-Deoxy-3-fluoro-Ins(1,4,5)P<sub>3</sub> (3-F-Ins(1,4,5)P<sub>3</sub>), which cannot be metabolized to  $lns(1,3,4,5)P_4$ .  $Ca^{2+}$  influx was monitored by applying hyperpolarizing pulses to transiently increase the driving force for  $Ca^{2+}$  entry, while recording fluo-3 fluorescent signals and  $Ca^{2+}$ -activated chloride currents. Intracellular injection of 100 fmol 3-F-Ins(1,4,5)P<sub>3</sub> (about 100nM final intracellular concentration) induced intracellular  $Ca^{2+}$  release followed by a gradually developing  $Ca^{2+}$  influx in a manner specific to  $lns(1,4,5)P_3$ . However, in correct to the transient of the residual property of the propert release followed by a gradually developing  $Ca^{-1}$  influx in a manner similar to  $Ins(1,4,5)P_3$ . However, in contrast to the transient responses (several minutes) seen with  $Ins(1,4,5)P_3$ ,  $3-F-Ins(1,4,5)P_3$  responses lasted several hours, suggesting it is metabolized slowly, if at all. This result indicates a mechanism for  $Ca^{2+}$  influx independent of  $Ins(1,3,4,5)P_4$ . In some oocytes loaded with  $3-F-Ins(1,4,5)P_3$ , of  $Ins(1,3,4,5)P_4$ . In some oocytes loaded with 3-F-Ins(1,4,5)P<sub>3</sub>, hyperpolarizing or depolarizing steps evoked damped sinusoidal oscillations of  $Ca^{2+}$ -dependent chloride current, suggesting that oscillations of intracellular  $[Ca^{2+}]$  can be induced by sudden changes in  $Ca^{2+}$  flux across the membrane. The ability of 3-F-Ins(1,4,5)P<sub>3</sub> to activate a sustained  $Ca^{2+}$  influx should make it a useful tool for studying mechanisms of  $Ins(1,4,5)P_3$ -mediated  $Ca^{2+}$  influx.

PRODUCTION AND CHARACTERIZATION OF MONOCLONAL ANTIBODIES FOR αo G-PROTEIN. <u>A.G.Faulk-Greenwood\*, X. Li and R.S. Jope</u>. Dept. of Psychiatry and Behavioral Neurobiology, Univ. of Alabama, Birmingham, AL 35294 and <u>S.M. Mumby</u>, Dept. Pharmacology, Univ. Texas Southwestern Medical Center, Dallas, TX 75235.

Guanine nucleotide-binding proteins (G-proteins) mediate many receptor-coupled signal transduction mechanisms. Of the several identified G-proteins, Go is present in brain in the highest concentration and shows some selectivity for nervous tissue. Although several functions for Go have been postulated, definitive evidence of its roles lags behind that obtained for several other Gretients. In order to feelilitate studies of Go a mencellocal articles. proteins. In order to facilitate studies of Go, a monoclonal antibody was prepared against the α-subunit.

G-proteins were purified from bovine brain and monoclonal antibodies were prepared by conventional techniques. Western blots with purified G-proteins or brain membranes were used to characterize the monoclonal antibodies. One monoclonal antibody, 1C, reacted specifically with  $\infty$ . 1C recognized human and bovine  $\infty$  equally well, and recognized rat, mouse and guinea pig αο to a lesser extent. Native as reacted better with 1C than did denatured as. Purified, concentrated 1C reacted maximally with 0.5 µg bovine Go at a dilution of 1:5,000. Several other monoclonal antibodies directed against bovine and rat purified G-proteins are currently being characterized. The development of several specific monoclonal antibodies should facilitate studies of the regulation and function of G-proteins.

SECOND MESSENGER REGULATION OF THE SYNAPTIC VESICLE PROTEIN p65 (SYNAPTOTAGMIN) IN RAT SYMPATHETIC GANGLIA IN VITRO. K.F. Greif\*, H. Fahl and E. Lederman. Dept. of Biology, Bryn Mawr College, Bryn Mawr,

We have demonstrated previously (Linderman and Greif, 1990) We have demonstrated previously (Linderman and Greit, 1990) that depolarizing agents increase levels of the synaptic vesicle protein, p65 (synaptotagmin), in neonatal rat superior cervical ganglia (SCG) in explant culture. We are investigating the role of second messengers in the signalling pathway. Neonatal SCGs are maintained in explant culture in defined medium. After two days in culture, SCGs are treated with cAMP, Ca<sup>2+</sup> and protein kinase C (PKC)-associated pharmacological agents for 48 hours. Levels of 1955 are determined by radioinmunoassay. p65 are determined by radioimmunoassay.

Cholera toxin and forskolin, which elevate cAMP levels, both

increase p65 levels. The magnitude of the increase is similar to that increase post seveis. The magnitude of the increase is similar to that produced by depolarization with veratridine, a Na<sup>+</sup>-channel ionophore. Surprisingly, 8-Br-cAMP, a nonhydrolysable form of cAMP, blocks the veratridine response, and has no effect on its own. Levels of p65 are slightly increased by the Ca<sup>2+</sup>-ionophore, A23187. The phorbol ester TPA, which activates PKC, does not appear to increase p65 levels. These results suggest that at least two second messenger pathways contribute to depolarization-associated transsynaptic regulation of p65.

Supported by NSF Grant BNS 88-19763 to KFG.

STIMULATION OF M<sub>1</sub> MUSCARINIC RECEPTOR-MEDIATED PHOSPHO-INOSITIDE TURNOVER BY ALKOXY-1,2,5-THIADIAZOLE DERIVATIVES OF ARECOLINE IN THE RAT BRAIN. S. Periyasamy\*, W. S. Messer, Jr., S. Roknich, #P. Sauerberg, W. Hoss, Dept. of Medicinal & Biological Chemistry, University of Toledo, Toledo, OH 43606 and #Pharmaceuticals Research, Novo Nordisk A/S, Novo Nordisk Park, DK-2760 Måløv, Denmark
A series of alkoxy-1.2.5-thiadiazole derivatives of arecoline (alkoxy-TZTPs) was

A series of alkoxy-1,2,5-thiadiazole derivatives of arecoline (alkoxy-TZTPs) was synthesized in an effort to develop M<sub>1</sub> muscarinic agonists. The ligands, including 3-butenyloxy, 2-butynyloxy, cyclopropylmethyloxy, and hexyloxy, stimulated phosphoinositide (Pl) turnover in the rat hippocampus. The dose-response curves were biphasic, compared with arecoline, which was monophasic. The maximal effects were approximately 200% stimulation for each derivative with the exception of the 3-butenyloxy compound (85%), compared with arecoline (207%) and carbachol (450%). The cyclopropylmethyloxy and hexyloxy compounds were shown to be partial agonists as expected. In addition, the maximal PI turnover response of arecoline and the hexyloxy compound together was the same as the response of each separately. Pirenzepine was substantially more potent than AF-DX 116 for inhibiting the responses of arecoline were similar. The magnitude of the PI response for the hexyloxy analog was highest in hippocampus, amygdala, neostriatum and cortex and lowest in cerebellum and pons-medulla. Molecular mechanics calculations predicted a conformational preference for the anti form with the alkyloxy substituent oriented away from the nitrogen in the tetrahydropyridine ring. The data are consistent with the hypothesis that the thiadiazoles distinguish between M<sub>1</sub> and M<sub>3</sub> receptors linked to PI turnover. It also is suggested that the anti conformer is active at M<sub>1</sub> receptors. The work was supported by a contract from Lilly Research Laboratories and by NS 23929, NS 25765, NS 23598 and NS 01493.

## HYPOTHALAMIC-PITUITARY-ADRENAL REGULATION: GLUCOCORTICOID AND MINERALOCORTICOID RECEPTORS

#### 204.

DIFFERENTIAL MINERALOCORTICOID (MR) AND GLUCOCORTICOID (GR) RECEPTOR EXPRESSION IN LEWIS and FISCHER RATS. C. C. Smith. R. J. Omeljaniuk. H. J. Whitfield, Jr.\* S. Aksentijevich. E. Zelazowska. P. W. Gold and E. M. Sternberg. Clinical Neuroendocrinology Branch, National Institute of Mental Health, Bethesda, MD 20892; Currently: Dept. of Biology, Lakehead University, Ont. Canada P7C 3B2; Dept. of Internal Medicine, Northwestern University, Chicago, IL 60611.

There has been debate in the literature regarding the precise effects of glucocorticoids upon hippocampal and hypothalamic-pituitary-adrenal (HPA) glucocorticoid receptor expression. Results vary depending upon the tissue studied as well as the mode and dose of glucocorticoid replacement. LEW/N and F344/N rats represent two rat strains whose differential inflammatory and behavioral responses to stress are related to their differential HPA axis responsiveness. They lie at two extremes of the spectrum of corticosterone (Cort) responses to stressful stimuli: chronically HPA hypor-responsive LEW/N compared to chronically HPA hyper-responsive F344/N. Thus it might be expected that the amount of MR and GR binding, and the levels of their corresponding mRNA's in various tissues in LEW/N and F344/N rats might reflect the overall integrated levels of Cort to which these receptors have been exposed. We have found that while the binding affinity (Kd) of MR and GR varies between tissues, there is no strain difference in Kd. Receptor number (Bmax), however, varied not only between tissues, but also between strains. MR Bmax in the hippocampus and pituitary was lower in LEW/N compared to F344/N, whereas GR Bmax in LEW/N thymus was greater than that F344/N. MR and GR mRNA levels in the hippocampus parallelled receptor binding data in the two strains. The findings reported here support the notion that these strains represent an excellent physiologic model for assessing the effects of repeated exposure to relatively low versus relatively high levels of Cort during stress. These differences may contribute to the differential inflammatory disease and stress responsiveness of the two strains.

METHAMPHETAMINE-INDUCED DECREASE IN NEURAL GLUCOCORTICOID RECEPTORS. M.T. Lowy\*. Dept. of Psychiatry, Case Western Reserve University, Cleveland, OH 44106

Methamphetamine (MA) is a potent psychostimulant which is neurotoxic to dopamine (DA) and serotonin (5-HT) neurons. Glucocorticoid receptors (GR) are extensively co-localized in monoamine neurons. The present study was designed to determine if MA could decrease neural GR and to relate such effects to DA and 5-HT levels. MA (6.25, 12.5 and 25 mg/kg) was given every 2 hrs for a total of 4 doses. Rats were adrenalectomized 6 days later and subsequently sacrificed 24 hr later. MA produced dose-related decreases in GR in the striatum, hippocampus, frontal cortex and hypothalamus. Hippocampal mineralocorticoid receptors were not affected by MA. 5-HT was also decreased in all 4 brain regions, whereas DA was decreased only in the striatum. MA did not decrease GR in cerebellum and had no effect on DA and 5-HT in this region. Similarly, MA did not decrease GR or 5-HT levels in the spleen. In contrast, MA decreased pituitary GR, but did not alter DA or 5-HT levels in the pituitary. These results demonstrate that MA produces a decrease in GR in a variety of brain areas, which is related to 5-HT depletions. MA-induced decrease in neural GR may have significant implications for the rewarding and neurotoxic effects of this abused drug. Supported by MH44699.

NORADRENERGIC REGULATION OF CORTICOSTEROID RECEPTORS IN DIFFERENT BRAIN STRUCTURES. S. Maccari, P.V. Piazza, H. Simon, L. Angelucci and M. Le Moal\*. INSERM U259 - Rue Camille St Saëns, 33077 Bordeaux France and Farmacologia II, Univ. Roma, P.le A. Moro, 2 00185 Rome, Italy.

The effects of corticosteroids on various brain functions, including the negative feedback control of hypothalamo-pituitary-adrenal (HPA) axis activity, are mediated by two types of receptors (type I or mineralocorticoid and type II or glucocorticoid) in the central nervous system. Although receptor number, especially the number of type II receptors, is thought to be regulated by circulating levels of corticosterone, a direct neural control of these receptors has been hypothesized. In order to demonstrate neuronal control of corticosteroid receptors, we tested the effect of 6-OHDA lesionig of noradrenergic systems at the level of the pedunculus cerebellaris superior produced in adrenalectomized animals in which corticosterone levels were maintained within normal limits by corticosterone replacement implants. Both receptors were studied in hippocampus, hypothalamus and amygdala. The results indicate that: 1) the noradrenergic system regulates corticosteroid receptors; 2) this control depends on the brain region studied. The type I receptor number was enhanced in hippocampus and reduced in hypothalamus and amygdala. The type I receptor affinity was unaltered. The type II receptor number was increased only in the hypothalamus while the affinity of this type of receptor was increased in hippocampus. These different effects of NA lesioning on corticosteroid receptor types may derive from an action on different noradrenergic receptors. Activation of  $\beta$  NA receptors may increase corticosteroid receptors and activation of nentre and that salbutamol increase the type II corticosteroid receptor numbers my decrease these receptors. We have tested this hypothesis by the administration of phenylepryne ( $\alpha_1$  agonist) and salbutamol ( $\beta$  agonist). In the hippocampus we found that salbutamol increase the type II corticosteroid receptor numbers. In conclusion, central NA neurons appear to regulate the plasticity of the two corticosteroid receptors in a different and complex way. This findings may elucidate the mechanisms con

CONFOCAL MICROSCOPY OF GLUCOCORTICOID AND MINERALO-CORTICOID RECEPTORS (GR, MR) IN CULTURED HIPPOCAMPAL NEURONS AND ASTROCYTES. D. L. Barker\*, R. Giuliano, Z. Krozowski, M. C. Bohn. Molecular Dynamics, Sunnyvale, CA 94086 and Dept. Neurobiology and Anatomy, Univ. Rochester Med. Ctr., Rochester, NY 14642.

and Anatomy, Univ. Rochester Med. Ctr., Rochester, NY 14642.

Confocal laser scanning microscopy (CLSM) was used to study the subcellular localization of GR and MR in dissociated neurons and astrocytes prepared from whole E18 rat hippocampus and grown in defined or serum-containing medium. CLSM permits sensitive visualization of fluorescently tagged antibodies against these rare proteins in both thin (0.5 µm) optical sections and in-focus projections of whole cells. Immunofluorescence (IF) was combined with propidium iodide staining to yield dual-labeled images of receptor localization and cell nuclei. Antisera included a monoclonal to rat liver GR, BUGR2, provided by R. Harrison, and an affinity-purified polyclonal, MR4, raised against a fusion protein, expressed in E. coli, from a construct of a 168 amino acid portion of the N-terminus of human MR and elutathione transferase.

In astrocytes fixed in the presence of corticosterone (CORT,  $10^{-6}$ M, 30 min), both GR-IF and MR-IF were concentrated in nuclei, whereas only MR-IF was observed in nuclei in the absence of CORT. In neurons fixed in the absence of CORT, GR-IF was observed in the nuclei of some neurons, but not others. MR-IF was uniformly distributed over nuclei, cytoplasm and processes regardless of the presence or absence of CORT. Serum has no effect on the localization of either receptor. These observations suggest that the subcellular localization of MR and GR is differentially regulated. In addition, the translocation of GR appears to be regulated by a different ensemble of factors in neurons and glia. (Supported by NIH grant NS20832 and Molecular Dynamics.)

GLUCOCORTICOID RECEPTOR (GR)) AND MINERALOCORTICOID RECEPTOR (MR) MRNA REGULATION IN NEURONS AND ASTROCYTES. M.C.Bohn\*, S.Hussain, R.Guiliano, M.K.O'Banion and D.Dean.

Neurobiol. & Anatomy, Univ. of Rochester Med. Ctr., Rochester, NY 14642.
Glucocorticoids produced by the adrenal cortex act through two receptors, GRI and MR, to influence gene expression in the brain. Previous studies have shown that both neurons and glia are targets for glucocorticoid action. To establish defined *in vitro* systems to study glucocorticoid effects, we have used the RNAse protection assay to compare levels of mRNAs coding

have used the RNAse protection assay to compare levels of mRNAs coding for GR and MR in neurons prepared from embryonic E18 rat hippocampus and type 1 astrocytes prepared from newborn rat cortex.

Protected bands corresponding to GR mRNA and MR mRNA are observed in both neurons and astrocytes. Neurons grown for 5 days express approximately equal amounts of MR mRNA and GR mRNA. In vivo, levels of the two messages are also approximately equal in E18 hippocampus, but in postnatal day 10 hippocampus, MR mRNA is 4-5 fold higher than GR mRNA. In contrast, in astrocytes, GR mRNA levels are 5-fold those of MR mRNA. Both messages are easily detected in 2.5µg of total RNA from neurons, whereas 1µg of polyA-RNA is needed to detect MR mRNA in astrocytes. These results suggest that the absolute abundance of the two messages, as well as their relative abundance, is different in neurons and astrocytes.

Study of the effects of culture conditions on mRNA levels showed that the ratio of MR/GR mRNA is significantly higher in neurons grown in the presence of 1% serum or medium conditioned by astrocytes, than in serum-free defined medium. This increase is due to an increase in levels of MR mRNA

without a change in GR mRNA levels. Addition of 10<sup>-6</sup>M corticosterone for 48 hours also increases the MR /GR mRNA ratio in neurons.

These studies suggest that the expression of GR and MR is differentially regulated and is quantitatively influenced by age, cell type and extracellular factors.

POSTNATAL HANDLING IN THE RAT ALTERS HIPPOCAMPAL GLUCOCORTICOID RECEPTOR GENE EXPRESSION. S.

POSTNATAL HANDLING IN THE RAT ALTERS HIPPOCAMPAL GLUCOCORTICOID RECEPTOR GENE EXPRESSION. S. LARCQUE. D. O'Donnell, C. Gianoulakis\*. J.R. Seckl and M.J. Meaney. Douglas Hos. Res. Ctr., Depts of Psychiatry, and Neurology & Neurosurgery, McGill Univ, Montreal, Canada H4H 1R3 and Dept of Medicine, Univ of Edinburgh, Edinburgh, Scotland EH4 2XU Postnatal handling of rat pups alters the development of hypothalamic-pituitary-adrenal responses to stress. This effect is, in part at least, mediated by the effect of handling on glucocorticoid receptor (GR) density in the hippocampus, a critical target site for the negative-feedback effects of glucocorticoids on HPA activity. In order to study the molecular basis for the difference in GR binding we examined GR mRNA as well as mineralcorticoid receptor (MR) mRNA expression in hippocampal sections from adult animals that were either handled (H) and nonhandled (NH) for the first three weeks of life. mRNA expression was determined using in situ hybridization with cRNA probes and quantified by counting silver grains over invidual hippocampal neurons. There was a highly significant increase in GR mRNA expression in each of the hippocampal cellifields of the H animals (dentate gynus= +64%; CA1= +62%; CA3= +53%; CA4= +45%). By contrast, there were no significant changes in MR mRNA expression as a function of postnatal handling. Handling had no effect on hippocampal neuron density or volume. These studies demonstrate that early handling selectively alters GR mRNA expression in the hippocampus. the hippocampus.

HIPPOCAMPAL GLUCOCORTICOID AND MINERALOCORTICOID RECEPTOR GENE EXPRESSION IS UNALTERED IN ALZHEIMER'S DISEASE. I.R. Seckl\*, D. O'Donnell<sup>1</sup>, M.I. Meaney<sup>1</sup>, C Yates<sup>2</sup> and G. Fink<sup>2</sup>. Dept. Med., West. Gen. Hosp., Edinburgh, <sup>1</sup>Douglas Hosp. Res. Ctr., McGill Univ., Montreal, Canada and <sup>2</sup>MRC Brain Metabolism Unit, Edinburgh, UK.

Glucocorticoids acting at the hippocampus via two types of intracellular receptor are thought to mediate shut-off of the hypothalamic-pituitaryadrenal axis. Excess glucocorticoids exert direct and indirect neurotoxic actions on hippocampal neurons. Since glucocorticoid hypersecretion with failure of central feedback occurs in Alzheimer's disease (AD) it has been proposed that a primary reduction in hippocampal glucocorticoid receptor expression leads to failure of feedback, hypercortisolemia and hence further neuronal loss. However, we have recently found that lesions of the cholinergic innervation of the hippocampus - known to be severely affected in AD - increase corticosteroid receptor gene expression in specific subregions of the hippocampus. We have now examined glucocorticoid (GR) and mineralocorticoid receptor (MR) gene expression in individual neurons in human postmortem hippocampus, using in situ hybridization in 5 patients with mild-moderate AD (81±3y) and 7 controls (81±7y) without neurological disease. We found similar distributions of MR and GR mRNA expression in control hippocampal neurons, with high expression in dentate gyrus and CA2-4, but significantly lower expression in CA1. There were no differences in GR or MR mRNA expression between AD and control hippocampus in any subregion. These data do not suggest a primary deficiency of biosynthesis of hippocampal corticosteroid receptors in AD. In view of reports of elevated glucocorticoid levels in AD, the maintainance of hippocampal GR and MR gene expression in AD may reflect loss of the cholinergic innervation.

DIFFERENTIAL DISTRIBUTION OF TYPE I CORTICOSTEROID RECEPTOR mRNA VARIANTS IN THE RAT HIPPOCAMPUS. S.P. Kwak\*H. Akil, and S.J. Watson. Mental Health Research Institute, University of Michigan, Ann Arbor, MI

Three forms of the mineralocorticoid receptor mRNA, alpha, beta, and gamma, are expressed in the rat hippocampus. These subtypes share a common protein coding domain but differ in their 5'UT sequence. The subtypes of MR mRNA are transcribed from the same gene, although it appears that the variants are transcribed by separate promoters flanking each 5'UT exon and subsequently spliced onto the common exon coding for the MR protein. Interestingly, the 5'UT exon is spliced onto the protein-coding exon 3bp upstream of the putative initiator ATG, but the Kozak sequence is faithfully retained in each case. The physiological relevance of multiple MR mRNA transcripts in the hippocampus is not clear, although it is conceivable that their expression may be differentially regulated since they have separate transcriptional units, and their translational efficiency may be different since they possess varying 5'UTs. To test these possibilities, we determined whether the three variants are loaded on polysomes and therefore translated into proteins; we also examined the mRNA distribution within the hippocampus. We found all three species to be bound by polysomes, indicating that they are all involved in MR protein synthesis. In situ hybridization revealed that the three forms are differentially distributed within the CA fields. The alpha form was enriched in the CA2-3, fasciculum cinereum, and the indusium gresium while other two forms were evenly distributed in CA1-3. These results suggest that the multiple forms of MR mRNA are functionally relevant and are expressed differentially among the subregions of the hippocampus. (work supported by NIMH grant # MH42251).

REGULATION OF MINERALOCORTICOID RECEPTOR mRNA EXPRESSION IN HAMSTER HIPPOCAMPUS BY PHOTOPERIOD.

B.B. Turner', S.J. Lance, and L.I. Holtsclaw. Dept. of Physiology, College of Medicine, E. Tenn. State Univ., Johnson City, TN 37614.

The secretion ratio of cortisol (F) to corticosterone (B) in hamsters decreases following 8 weeks exposure to short day photoperiods (Krey et al. Nauresci. Abert. 15:715). An increase in MB hieritory was also al, Neurosci. Abstr. 15:715). An increase in MR binding was also observed at 8 weeks. Since F is the putative principal ligand of MR in brain, it has been proposed that the decrease in F results in enhanced MR binding though up-regulation. In this study, we test this hypothesis by measuring the expression of MR mRNA at a time prior to the reported change in adrenal secretion. Male golden syrian hamsters (n=10) were exposed to either long day length (14:10) or short day length (10:14) for 18 days. A plasmid containing a 1047 bp sequence (p95; from P. Patel) of the DNA binding region of rat MR was amplified. The transcribed cRNA was radiolabelled with 35S-UTP and sections were hybridized overnight with the riboprobe. The density of the film autoradiographs was quantitiated using image analysis. Some sections were also dipped in NTB-2 emulsion for cellular localization of silver grains. Two-way analysis of variance indicated a significant effect of photoperiod (P<0.0001). The hamsters exposed to short day length had about 40% more MR mRNA in their hippocampi than did long day animals. Post-hoc Scheffe tests indicated a significant photoperiod effect for 7 of the 8 hippocampal regions. We conclude that changes in brain MR mRNA expression precede, rather than follow, changes in adrenal secretion; hence, changes in receptor number are not the result of decreased F synthesis. Supported by NIH S07 RR05959.

LOCALIZATION OF ANGIOTENSIN AND NICOTINAMIDE ADENINE DINUCLEOTIDE PHOSPHATE DIAPHORASE (NADPH-d) IN RAT HYPOTHALAMUS J. Calka, C.H. Block\*, and G.T. Pauer The Research Institute of the Cleveland Clinic Foundation, Cleveland, OH 44195

Immunoreactive (ir) angiotensin (Ang)-(1-7) is found in magnocellular neurons of the paraventricular (PVN) and supraoptic nuclei (SON) with a distribution pattern similar to vasopressin. Recently, nitric oxide synthase, the enzyme which forms nitric oxide from arginine has been demonstrated in these magnocellular hypothalamic nuclei using NADPH-d histochemistry. Further, nitric oxide participates in neuronal plasticity, evidenced by its role in long-term potentiation. We have demonstrated prominent morphologic changes of Ang-(1-7)-ir in the dehydrated rat hypothalamo-neurohypophysial system. Thus, the present study addressed whether there exists an anatomical relationship between the Ang-(1-7) and nitric oxide systems that may subserve plasticity in hypothalamus.

Perfusion-fixed hypothalamic tissue from adult male rats was sectioned at 30 µm. Brain sections were processed for immunocytochemical localization of Ang-

(1-7), and subsequently for histochemical localization of NADPH-d.

Microscopic examination of hypothalamus revealed a limited degree of colomicroscopic examination of hypothalanus revealed a finited degree of color calization of NADPH-d and Ang-(1-7)-ir in magnocellular neurons of SON and PVN. Throughout all levels of SON, approximately 5% of the neurons were found to be labeled with both NADPH-d and Ang-(1-7). In PVN at rostral levels, 2 separate cell populations were observed which contained either Ang-(1-7) or NADPH-d. However, at mid-levels through the PVN, a small number of double-labeled cells were viewed in the lateral aspect of PVN. Double-labeled cells were

seldomfound at caudal levels of the PVN.

This pattern of colocalization of Ang-(1-7)-ir and NADPH-d in magnocellular neurons of the SON suggests that nitric oxide may be involved in the morphologic changes that are observed in hypothalamus during dehydration. Future studies to examine this possibility are proposed.

PREABSORPTIVE SIGNALS INHIBIT VASOPRESSIN (AVP)

PREABSORPTIVE SIGNALS INHIBIT VASOPRESSIN (AVP) SECRETION IN RATS DURING HYPOVOLEMIA. M.G. Scheidler\*, J.G. Verbalis and E.M. Stricker. Depts. of Behavioral Neuroscience and Medicine, University of Pittsburgh, Pittsburgh, PA 15260.

Plasma volume deficits induced by sc injection of polyethylene glycol (PEG) solution in adult rats stimulates neurohypophyseal secretion of AVP and oxytocin (OT), and also enhances thirst and salt appetite. Eight hours after sc PEG treatment rats implanted with a remote pyloric noose (to prevent gastric emptying of ingested fluid) drank water in proportion to induced volume deficits but they consumed no 0.5 M Nacl. In blood samples taken minutes after drinking, only basal levels of AVP were found despite hypovolemia, whereas AVP were found despite hypovolemia, whereas asma OT was elevated appropriately. In other plasma OT was elevated appropriately. In other studies PEG-treated rats were additionally fitted with a gastric fistula, to drain the ingested fluids. In this situation, rats drank 20-45 ml of water per hr for several hours but no saline. Again, plasma OT was elevated whereas plasma AVP Again, plasma OT was elevated whereas plasma AVP was not. The results are consistent with previous reports in other species that dehydration-induced AVP secretion is inhibited by drinking. However, pituitary secretion of OT is not similarly inhibited, consistent with its association with inhibition of salt appetite in hypovolemic rats.

IN SITU HYBRIDIZATION ANALYSIS OF HYPOTHALAMIC MACNOCELLUAR NEURONS FOLLOWING AXONAL INJURY PRODUCED BY PITUITARY STALK COMPRESSION IN RATS. J. Dohanics\*, T. G. Sherman. G. E. Hoffman and J. G. Verbalis, Univ. of Pittsburgh, Pittsburgh, PA, 15261

Pituitary stalk compression (SC) causes almost complete disappearance of vasopressin (AVP) and oxytocin (OT) from the neural lobe and increased water intake characteristic of diabetes inspidius. Similar to neurolobectomy and pituitary stalk transection, the axonal injury produced by SC also leads to death of substantial proportions of AVP (=60%) and OT (=30%) neurons in the supraoptic (SON) and paraventricular (PVN) nuclei. In this study we investigated the effect of SC on expression of AVP and OT mRNAs in the PVN and SON via in situ hybridization histochemistry. to determine whether the tigated the effect of SC on expression of AVP and OT mRNAs in the PVN and SON via in situ hybridization histochemistry, to determine whether the surviving neurons manifested increases in AVP and OT gene expression to compensate for the loss of neurosecretory units. Adult male rats received SC (n=4) or sham surgery (n=4) 21d prior to euthanasia by decapitation. AVP and OT contents of neurointermediate lobe (NIL) homogenates were determined by RIA. Hypothalamic blocks were serially sectioned to 14 µm using a cryostat. Sections were hybridized with specific AVP and OT exon C [35]S-labeled cRNA probes. Grains were counted in visually identified neurons using Optimas Bioscan software and were corrected for cell area. NIL AVP and OT contents in SC rats were 1.8% and 0.9% of sham operated rats. but plasma Optimas Bioscan software and were corrected for cell area. NIL AVP and OT contents in SC rats were 1.8% and 0.9% of sham operated rats, but plasma [Na\*] concentrations were similar in both groups (141.0±0.1 vs. 141.7±0.7, NS). Magnocellular AVP and OT mRNA grain counts/cell area were not significantly different between the sham-operated (n=1006 neurons counted) and the SC rats (n=1178 neurons counted). These data suggest that under conditions where a normal plasma osmolality can be maintained by increased water intakes, there is no significant compensatory increase in AVP and OT mRNA expression in the magnocellular neurons that survive axonal injury. It remains to be determined, however, whether the surviving neurons respond normally to acute and chronic osmotic challenges, as well as whether synthetic activity at the time of SC is related to magnocellular neuronal survival.

The Effect of Lesions of the Median Preoptic Nucleus on Augmentation of Vasopressin and Oxytocin mRNA Levels in Response to Chronic Osmolality. M.L. Volkov and J.T. McCabe Uniformed Services University of the Health Sciences, Bethesda, MD

The median preoptic nucleus (MnPO) is an osmosensitive afferent of the supraoptic nucleus (SON) in rats. With changes in plasma osmolality, it influences the release of both vasopressin (VP) and oxytocin (OT) from the SON and MnPO lesions will attenuate VP release that normally follows acute hypertonic saline administration (Gardiner, et al. '85; Mangiapane et al. '83). Through the use of quantitative in situ hybridization, we found that lesions that destroy >70% of the ventral aspect of the MnPO effectively diminished augmentation of VP mRNA levels in SON neurons during chronic hyperosmolality induced by a salt-loading regimen, whereas levels of VP mRNA under basal conditions of water availability were not different in lesioned and controls animals. In comparison to nonlesioned rats, MnPO lesioned rats had higher levels of OT mRNA under basal conditions, and did not show as great an augmentation of OT mRNA levels as a consequence of salt-loading. These results indicate that presynaptic inputs from forebrain regions mediating plasma osmolality affect not only the release of VP from the posterior pituitary, but are also involved in the modulation of intracellular processes determining VP and OT synthesis. WATER DEPRIVATION INDUCES WIDESPREAD CHANGES IN GLUTAMATE RECEPTOR DENSITIES IN BRAIN: IMPLICATIONS FOR EXCITATORY PATHWAYS WHICH REGULATE WATER BALANCE. R.B. Meeker\*, R.S. Greenwood, S.P. McGinnis and J.N. Hayward, Department of Neurology and Neurobiology Curriculum, University of North Carolina, Chapel Hill, NC 27599

Glutamate synapses are thought to provide excitatory input to vasopressin neuroendocrine cells for the release of vasopressin in response to dehydration. Two days of water deprivation result in an increase in the density of glutamate binding sites in the hypothalamus with no corresponding change in  $K_D$ . This increase is thought to reflect compensatory changes within systems involved in the regulation of water balance; principally the supraoptic nucleus (SON). Autoradiographic mapping studies in Long-Evans rats deprived of water for 48 hrs using [3H]glutamate as a ligand verified specific increases in glutamate binding sites in the supraoptic nucleus in water deprived rats relative to nondeprived controls. However, both increases and decreases in glutamate receptor density of equal or greater magnitude were noted in other brain regions. Increases in receptor density were found in the SCN, PVN, amygdala and hippocampus. Decreases in receptor density were found in the tuberculum olfactorium, lateral septum, diagonal band of Broca, arcuate and ventromedial hypothalamus. Thus, glutamate receptors appear to be widely used and highly dynamic within fluid balance regulatory circuits, increasing or decreasing in response to changes in activity. Increases in receptor density were associated with the magnocellular neuroendocrine cells and general limbic circuits whereas, reduced receptor densities were found in areas known to provide synaptic input to the region of the SON. Supported by NIH Javits Award NS 13411.

# 205.6

HYPOOSMOLALITY INHIBITS NEUROHYPOPHYSEAL EXPRESSION OF C-FOS AND FOS-RELATED ANTIGENS IN RATS. J.G. Verballs. A.G. Robinson and G.E. Hoffman, Departments of Medicine and Physiology, University of Pittsburgh, Pittsburgh, PA 15261.

Previous studies from this and other laboratories have shown that neurohypophyseal neurons express c-Fos protein following stimuli that cause reuronypophysea neurons express or cap protein rollowing sumuli that cause secretion of vasopressin (AVP) and/or oxytocin (OT). Hyperosmolality is one such stimulus known to increase secretion and synthesis of AVP and OT, and to stimulate robust expression of c-Fos protein in magnocellular neurons. Because hypoosmolality inhibits secretion and synthesis of AVP and OT in rats, we studied expression of c-Fos and fos-related antigen (FRA) immunoreactivity (IR) in hypoosmolar rats. Hypothalamic sections (25 um) from perfused brains were stained using antisera to c-Fos protein (Oncogene Sciences) and FRA (M. hyposmolar for 7 d (pNa=109±1 mmol/L, n=5) had complete absence c-fos IR and markedly reduced levels of FRA IR. Additional hypoosmolar rats were Infused Iv with 1.5 M NaCl @ 1.0 cc/h and blood was collected for plasma sodium (pNa), AVP and OT before perfusion after 0, 2, 4, 6, and 8 h. During correction of hypoosmolality, magnocellular neurons expressed both c-Fos and FRA IR as early as 2 h (pNa=122±1 mmol/L, n=5), and maximally by 4-6 h (pNa=135±4 mmol/L, n=10). Magnocellular c-Fos and FRA expression preceded increased plasma levels of AVP, though not of OT. Therefore: 1) hypoosmolality downregulates neurohypophyseal proto-oncogene expression as well as AVP and OT secretion and synthesis; and 2) subsequent increases in plasma osmolality rapidly induce proto-oncogene expression of both c-Fos and FRA's, for AVP neurons even before measurable pituitary secretion occurs. The latter suggests that during some conditions c-Fos/FRA expression can detect magnocellular neuronal activation before neurosecretion occurs.

ARGININE VASOPRESSIN (AVP) LEVELS AFTER DAILY INFUSIONS OF ANTISENSE OLIGONUCLEOTIDES INTO THE SUPRAOPTIC NUCLEUS (SON). L.M. Flanagan\*, M.M. McCarthy, P.J. Brooks, D.W. Pfaff, and B.S. McEwen. The Rockefeller University, 1230 York Avenue, New York. NY 10021 USA.

Synthetic antisense oligonucleotides have been shown to reduce synthesis of proteins by blocking translation in vitro. In the present experiment we used the hypothalamic-neurohypophyseal system as an in vivo model for antisense pharmacology. Antisense 5' AVP mRNA just downstream from the translation start codon (n=4) or a scrambled sequence control oligonucleotide (n=3) was infused into the bilateral SON (100 ng in 0.5  $\mu$ l/side/min). After 10 daily infusions, the antisense treatment decreased AVP levels in the pituitary by 60%, and in the SON by 75%, whereas it increased AVP levels in the paraventricular nucleus (PVN) several fold. Compared with the scrambled sequence oligonucleotide control injections, antisense increased plasma osmolality, and decreased urine osmolality at the time of sacrifice. Histological analysis confirmed the location of the cannula tip near the SON. Oxytocin (OT) levels were somewhat reduced in the pituitary, but were elevated in plasma which suggests osmotic stimulation of OT neurons (Brimble, 1978). The increase in the level of AVP in the PVN may result from a compensatory mechanism activated by episodes of diabetes insipidus due to impaired synthesis of AVP in the SON. These preliminary results suggest that antisense oligonucleotides can provide a useful tool for studying control of neuropeptide synthesis in vivo. Supported by NIH grant NS07080 and postdoctoral fellowship NS09026.

GLUTAMATERGIC EXCITATION OF RAT SUPRAOPTIC NEURONS FOLLOWING OSMOTIC STIMULATION OF THE ORGANUM VASCULOSUM LAMINA TERMINALIS (OVLT). C.W. Bourque\* and D. Richard. Center for Research in Neuroscience, Montreal General Hospital, Montreal, Canada.

Osmotically-evoked hormone release by the axon terminals of magnocellular neuroendocrine cells (MNCs) is partly mediated by the OVLT. Intracellular recordings obtained in rat hypothalamic explants examined the nature of OVLT's contribution to the osmoregulation of supraoptic MNC firing. Local hypertonic stimulation (<30 mOsm) excited 14/17 OVLT neurons, a response which was temporally associated with a dramatic increase in the frequency of spontaneous EPSPs and spike discharges recorded in 19 of 23 MNCs. A fast excitatory connection between the OVLT and MNCs has been proposed on the basis that electrical stimulation of the OVLT elicits a CNQX-sensitive compound EPSP in MNCs (Yang & Renaud, S.N. Abs 1991). Confirming the specificity of this connection, computer averaging during recordings obtained from 7/18 pairs of neurons revealed a tight correlation between spike discharge in OVLT neurons and the occurrence of an EPSP in MNCs. Bath-application of kynurenic acid (200 µM) or CNQX (10-25 µM) reversibly abolished evoked EPSPs (n=6), as well as the OVLT-mediated hypertonic activation of supraoptic MNCs (n=4). We conclude, therefore, that glutamatergic synapses onto MNCs relay osmosensitive information arising within the OVLT. Supported by MRC, FCAR and the Heart and Stroke Foundation of Canada.

INTERACTION OF NEUROTRANSMITTERS AND NEUROMODULATORS ON SUBFORNICAL ORGAN NEURONS H. A. SCHMID, F. SCHÄFER, E. SIMON. Max Planck Institute f. Physiol. and Clin. Research, 6350 Bad Nauheim, FRG.

The subfornical organ (SFO), a circumventricular organ lacking a blood-brain barrier, is known to participate in osmoregulatory responses in mammals and birds. Blood borne and brain intrinsic Angiotensin II (AII) has been shown to affect the activity of SFO neurons. In this study we investigated the possible interaction of AII with various Atrial Natriuretic Factor (ANF) analogs and cholinergic and noradrenergic agonists on spontaneously active duck SFO neurons in an in vitro slice preparation. AII (0.1 µM) excited over 70% of the SFO neurons, while ANF, which antagonizes AII in vivo, has no effect, neither alone, nor on the AII induced excitation. Isoproterenol (10 µM) and ACh (30 µM) increased the activity of 85% and 40% of the neurons, whereas clonidine decreased it in 85%. Coapplication of ACh and Isoproterenol together with AII had additive excitatory effects. These results suggest a high degree of signal integration of osmoregulatory important substances within the SFO. Supported by DFG Si 230/8-1

VOLUME CHANGES REGULATE A CATIONIC CURRENT TO TRANSDUCE OSMOSENSITIVITY IN SUPRAOPTIC NEURONS. Stéphane H.R. Oliet\*and Charles W. Bourque.

Centre for Research in Neuroscience, Montreal General Hospital and McGill University, Montreal, Canada H3G 1A4.

The membrane potential and electrical activity of rat supraoptic neurons are known to be modulated by changes in plasma osmolality. Whole-cell patch-clamp experiments on acutely dissociated supraoptic neurons were performed to characterize the mechanism mediating this endogenous osmosensitivity. The amplitude of a non-selective cationic current (NSC; E<sub>mv</sub>≈-41 mV) was found to be proportional to changes in external osmolality (-30 to +30 mOsm; 1.4 %NSC/mOsm; R=0.99; n=17). Experiments using a confocal laser scanning microscope revealed that changes in cationic conductance were directly correlated (R=0.88) with changes in cell volume. Comparable volume changes directly elicited by pressure (≈1 mmHg) applied through the patch electrode also modulated a cationic current, cell potential and firing rate (n=11). Reversal potential analysis and ionic substitutions revealed that the currents modulated by pressure and external osmolality were, in fact, the same. We conclude that volume-sensitive cationic channels transduce osmosensitivity in rat supraoptic neurons. Supported by the MRC and Heart and Stroke Foundation of Canada

ATRIAL NATRIURETIC FACTOR (ANF) MODULATES EXCITATORY TRANSMISSION FROM THE ORGANUM VASCULOSUM OF THE LAMINA TERMINALIS (OVLT) TO THE SUPRAOPTIC NUCLEUS (SON). D. Richard\* and C.W. Bourque, McGill University, Montreal, Canada H3G 1A4.

Previous studies have implied that ANF modulates the osmotic

Previous studies have implied that ANF modulates the osmotic regulation of neurohypophyseal hormone (NH) release via an action at receptors which are presynaptic to magnocellular neurosecretory cells (MNCs). One possible site for such action may be at the glutamatergic OVLT→SON synapse, which relays osmotic information arising within the OVLT. To study the effects of ANF at this synapse, we obtained intracellular recordings from SON MNCs in rat hypothalamic explants. Electrical stimulation of the OVLT (80 μA; 200 μs) evoked a fast glutamatergic EPSP in each of 20 MNCs tested. In control conditions, voltage-current analysis revealed that the conductance underlying evoked EPSPs (G<sub>EPSP</sub>) ranged from 0.5 to 1.7 ns. Bath-application of ANF<sup>1-28</sup> (50-100 nM; n=10) or dibutyryl cGMP (0.5-1 mM; n=3) reversibly decreased the evoked G<sub>EPSP</sub> by 41.1±3.6%. Bath applied ANF was also found to reversibly abolish the synaptic activation of MNCs following local hypertonic (5-30 mOsm/Kg) stimulation of the OVLT (n=3). These results indicate that ANF may modulate the osmoregulation of NH release via an inhibitory action at the OVLT—SON synapse. Supported by the MRC, FCAR and the Heart & Stroke Foundation of Canada.

Furosemide Alters Development in Neonatal Rats. <u>G. Watkins, J. Diaz\*, E. Taylor, and M. Rolfs, Dept. of Psychology, Univ. of Washington</u>, Seattle, WA 98195.

Furosemide (Lasix), a powerful diuretic, is routinely used in human neonates. We examined the acute and chronic effects of Lasix on water compartments in the neonatal rat.

In the acute study, 4 day old rat pups were randomly assigned to one of three groups: 1) Lasix (IP, 15 mg/kg every 2 hours)), 2) saline (IP, every 2 hours), or 3) non-inject controls. After 24 hours all animals were sacrificed. In the chronic study, pups were randomly assigned to one of three groups: 1) gastrostomy-fed, receiving Lasix via a chronic indwelling subcutaneous catheter, 2) gastrostomy-fed, receiving saline via chronic indwelling catheter, and 3) mother-reared, non-injected. Lasix and saline were given at doses modeling a steady-state condition in humans. After seven days of treatment, all the animals were sacrificed. For both studies, wet and dry whole brain, kidney, and spleen weights were recorded for all animals. Acute Lasix treatment resulted in a significant decrease in body

Acute Lasix treatment resulted in a significant decrease in body weight and a significantly smaller brain to body weight ratio. In addition to a significant decrease in body weight, chronic Lasix treatment also resulted in significantly smaller wet brain weights, and significantly heavier wet and dry kidney weights. There was no difference in spleen weights.

Lasix, when administered in a dosing regimen which mimics that given neonatal infants, changes the fluid dynamics of the developing brain. Whether this directly affects neuronal development and results in long-term neurological sequelae remains to be determined.

MODULATION OF CATECHOLAMINE RELEASE BY INTERLEUKIN-2 (IL-2) IN MOUSE HYPOTHALAMUS. F. Villemain\*, D. Seto, U.K. Hanisch, R. Quirion and A. Beaudet. Montreal Neurol. Inst. and Douglas Hosp. Res. Center, Montreal, Canada, H3A 2B4.

Immunohistochemical and in situ hybridization experiments from our laboratory have previously demonstrated the presence and expression of IL-2 in mouse brain (Neurosci. Abstr., 1991, 475-20). In normal CD-1 mice, high concentrations of IL-2 and Tac antigen (low-affinity subunit of IL-2 receptorlimmunoreactivity were detected within the arcuate nucleus/median eminence complex of the hypothalamus. Electron microscopic studies indicated that both antigens were contained in a subpopulation of arcuate neurons. In addition, double labeling studies indicated that some of the Tac immunoreactive cells also stained positively for tyrosine hydroxylase, suggesting that endogenous IL-2 might act upon hypothalamic monoamine neurons. To test this hypothesis, the effect of IL-2 on endogenous catecholamine release was investigated in hypothalamic slices superfused for 30 min in Krebs buffer (KB) and stimulated 40 min with high-K+ (25 mM) KB in the presence or absence of low (10.9M) or very low (10<sup>-12</sup>M) concentrations of recombinant IL-2 (Boehringer). The superfusate was collected over the entire duration of the experiment and analyzed for dopamine (DA), noradrenaline (NA) and metabolites using an HPLC system. At low concentrations of IL-2, the evoked NA efflux was significantly reduced at the very onset of stimulation. At very low concentrations, the inhibitory effect only became apparent after 30-min of stimulation. A slight, but non significant inhibition of dopaminergic release was also evident after stimulation at low concentration of the cytokine. These results support the role of neuronal IL-2 in the modulation of monoamine release in the ventrobasal hypothalamus. Supported by HFSP and MRC.

NEUROLOGIC DISEASE INDUCED IN TRANSGENIC MICE BY THE ASTROCYTE-SPECIFIC EXPRESSION OF INTERLEUKIN-6. <u>J.L. Campbell</u>, <u>M.B.A. Oldstone and L. Mucke\*</u>. Dept. Neuropharmaclogy, The Scripps Research Institute, La Jolla, CA 92037.

Cytokines, including interleukin-6 (IL-6), are known to have a spectrum of CNS effects. Although inappropriate expression of cytokines within the CNS has been reported in a variety of CNS diseases including multiple sclerosis, AIDS dementia complex (ADC) and Alzheimer's disease their precise pathogenetic role in these diseases remains unknown. We have investigated this question by using a transgenic approach to target the inappropriate expression of IL-6 to astrocytes in the CNS of mice.

The complete cDNA encoding for IL-6 was inserted in the first exon of the murine glial fibrillary acid protein (GFAP) genomic DNA. Following microinjection of the GFAP-IL6 into the germline of mice, a number of transgenic offspring were found to have a phenotype characterized by growth retardation, tremor, hunched posture, ataxia, hind-limb weakness and seizures. In all such mice high levels of IL-6 transgene expression were found in the brain. No disease phenotype was seen in nontransgenic littermates nor in transgenic mice without detectable IL-6 gene expression. Histopathological examination of the brain in IL-6 expressing mice was on the whole unremarkable except for the presence of occasional scattered perivascular mononuclear cell accumulation in cerebellar fissures and some neovascularization. Neither dysmyelination nor neuronal loss were evident. However, immunocytochemical staining and northern blot analysis revealed the presence of a pronounced astrocytosis present in hippocampal, formation-cerebellum and white matter tracis.

Therefore overexpression of IL-6 by astrocytes in the CNS of mice produces a severe neurological disease in association with marked astrocytosis - these features have similarly to some human CNS diseases eg. ADC. This model should prove extremely valuable for elucidating the role of cytokines in neuropathogenesis.

INTERLEUKIN-2 MODULATES THE EVOKED RELEASE OF [3H]DOPAMINE FROM MESENCEPHALIC CELLS IN PRIMARY CULTURE. R. ALONSO\*, J. DIORIO, R. OUIRION and P. BOKSA. Douglas Hospital Research Centre, Dept. of Psychiatry, McGill University, 6875 Lasalle Blvd, Montreal, Quebec, Canada, H4H 1R3.

Beside its immunological functions, Interleukin-2 (IL-2) is known to interact with several neuronal systems. In particular, our laboratory previously showed that IL-2 modulates the release of acetylcholine in the rat hippocampus (Seto et al, Neurosci.Soc.Abstr., 1991). It has also been suggested that IL-2 is involved in the regulation of striatal dopaminergic transmission (Lapchak, Soc.Neurosci.Abstr., 1991). In an attempt to further investigate the interaction of IL-2 with dopaminergic neurons, we evaluated the effects of this cytokine on [³H]dopamine (DA) release from rat cultured mesencephalic cells. Since this cell culture model contains a high proportion of GABAergic neurons, modulation of [³H]GABA release by IL-2 was also investigated, IL-2 (10¹⁴-10³-8 M) modulated K<sup>‡</sup>-induced [³H]DA release with a biphasic dose response curve. Very low concentrations (10¹¹2 M) of IL-2 increased, while higher (10³-8 M) concentrations (10¹²2 M) of IL-2 also increased NMDA (5x10³-5 M)-induced [³H]DA release while 10³-8 M IL-2 had no effect on the NMDA response. IL-2 alone did not modify spontaneous [³H]DA release. Under our experimental conditions, the release of [³H]GABA evoked by K<sup>†</sup> or by NMDA is mostly Ca²+-independent. IL-2 did not modulate the [³H]GABA release evoked by either K<sup>+</sup> or NMDA. This study demonstrates that low concentrations of IL-2 selectively interact with dopaminergic neurons in cultured mesencephalic cells to modulate [³H]DA release evoked either by K<sup>+</sup> depolarization or NMDA receptor activation. Mesencephalic cell cultures should provide a useful model to further investigate the mechanisms involved in these IL-2 effects. Supported by MRC of Canada.

CORTICOTROPIN RELEASING HORMONE INCREASES PLASMA LEVELS OF INTERLEUKIN - 6. Z.A. Kronfol\*. B. Gosnell. M. Kluger. Departments of Psychiatry and Physiology, University of Michigan Medical Center, Ann Arbor, MI 48109

Several reports have now confirmed the existence of complex and bidirectional interactions between the central nervous system and the immune system. We have earlier reported that open field stress increases core body temperature along with a rise in plasma levels of interleukin - 6 (IL-6). Since many of the effects of stress can be mimicked by corticotropin releasing hormone (CRH), we hypothesized that CRH injections would be accompanied by similar increases in the plasma levels of IL-6, and that this effect will be blocked at least in part by the CRH antagonist x-helical CRH. To test this hypothesis, we injected male Sprague-Dawley rats in which we had previously placed intracerebro-ventricular cannulae with either CRH (10,µg) or saline ICV. Twenty or sixty minutes later, the animals were sacrificed and plasma levels of IL-6 were measured using a B9 bioassay. The same experiments were later repeated with two additional groups: one group receiving both indicated a significant increase in the plasma levels of IL-6 in the CRH-treated group. The group receiving both indicated that CRH and CRH had somewhat lower levels of IL-6. These results indicate that CRH given ICV, like stress, is accompanied by significant elevations in the plasma levels of IL-6, and that this effect of CRH can be partially reversed by indicated CRH.

HISTAMINE INDUCES INTERLEUKIN 6 RELEASE FROM THE HUMAN ASTROCYTOMA CELL LINE, U-373 MG. D.C. Waters, R.F. Bruns\*, J.J. Howbert, and B.D. Gitter. Depts. of Central Nervous System Research and Biochemical Pharmacology Research, Lilly Research Laboratories, Eli Lilly and Co., Indianapolis, IN 46285.

Eli Lilly and Co., Indianapolis, IN 46285.

Histamine is a mediator of allergic, inflammatory, and immune responses. Although it is produced by neurons and mast cells in the brain, histamine's potential role as a mediator of CNS inflammation has not been described to date. Histamine receptors linked to phosphoinositide hydrolysis have been identified on primary rat astrocytes and human astrocytoma cell lines. Since astrocytes have been shown to secrete inflammatory mediators such as prostaglandins and cytokines, we studied the ability of histamine to induce the secretion of interleukin 6 (IL-6) and prostaglandin E2 (PGE2) by human U-373 MG astrocytoma cells. Histamine stimulated IL-6 release in a concentration-dependent manner, reaching 50% of the maximum response at 10μM. However, histamine did not stimulate PGE2 production at concentrations as high as 50μM. Detectable levels of IL-6 were produced approximately 1 hour after stimulation and peaked after 24 hours. IL-6 release induced by histamine was inhibited by the H1 antagonist, pyrilamine (IC<sub>50</sub> ~5nM), but was not affected by the H2 antagonist famotidine or the nonpeptide substance P antagonist (±)CP-96,345 at concentrations ≥ 5μM indicating that the IL-6 response was specifically mediated through H1 receptors. In addition, histamine-stimulated phosphoinositide (PI) turnover was also inhibited by pyrilamine, suggesting that IL-6 secretion was linked to this second messenger. Histamine in the CNS may, therefore, contribute to neuronal inflammation by inducing astrocytes to secrete IL-6, a key mediator of immune and inflammatory

SYMPATHECTOMY ENHANCES INTERLEUKIN-2 (IL-2)-INDUCED PROLIFERATION BY SPLENOCYTES FROM SPONTANEOUSLY HYPERTENSIVE RATS (SHR). Edwin S. Purcell\* and Vincent H. Gattone, II. Department of Anatomy and Cell Biology, University of Kansas Medical Center, Kansas City, KS 66160.

The SHR is known to possess increased sympathetic innervation of a number of tissues and a T cell immunological deficiency. We have previously described increased catecholaminergic innervation of the thymic parenchyma and splenic white pulp (Purcell and Gattone, Exp Neurol, in press, 1992) and an impaired proliferative response of splenocytes to IL-2 (Purcell and Gattone, Anat Rec 229:70A, 1992) in SHR as compared to Wistar-Kyoto (WKY) and Fischer 344 (F-344) rats. To determine if there is a causal relationship between the increased innervation and the immune dysfunction, we performed neonatal sympathectomy using a combination of guanethidine and NGF-antisera. At 12 weeks of age, splenocytes were obtained and cultured with or without 50 units/ml recombinant human IL-2. Subsequently, cells were pulsed with tritiated-thymidine and thymidine incorporation was determined by scintillation counting. The stimulation index (cpm of stimulated cells/cpm of unstimulated cells) of sympathectomized SHR displayed a significantly higher stimulation index than sham treated control SHR (con 1.28  $\pm$  0.17/symX 1.97  $\pm$  0.27 , p  $\leq$  0.05). Sympathectomy did not enhance the robust proliferative response of WKY splenocytes to IL-2 (con 3.85  $\pm$  $1.06/\text{sym} \times 3.41 \pm 0.52$ ). However, it did increase the responsiveness of F-344 splenocytes (con  $2.00 \pm 0.34/symX$   $3.54 \pm 0.24$ , p  $\leq 0.05$ ) to a level similar to the WKY. These results suggest that noradrenergic innervation contributes to the immune deficit of the SHR by decreasing the proliferative response to IL-2. Supported by MH46511.

ANOREXIC EFFECTS OF MICROINJECTION OF INTERLEUKIN-1β (IL-1β) INTO THE VENTROMEDIAL HYPOTHALAMUS (VMH) OF THE RAT. S. KENT\*, F. RODRIGUEZ, K.W. KELLEY and R. DANTZER. INSERM U.176, rue Camille Saint-Saëns, 33077 Bordeaux Cedex, France (SK, FR and RD); Dept. of Animal Sciences, Univ. of Illinois, Urbana, IL 61801

(KWK).

II.-1 is a cytokine that is released by activated macrophages and monocytes and mediates many of the local and systemic responses to monocytes and mediates many of the local and systemic responses to inflammation. Intracerebroventricular injections of IL-1β produce anorexia, however, the specific site(s) of action within the central nervous system have not been elucidated. We report here that bilateral infusion of recombinant human IL-1β (Glaxo, Geneva; 5 and 30 ng) into the VMH of adult male rats dose-dependently induces anorexia in two animal models. (1) Daily consumption of food and water were measured in rats fed ad libitum. IL-1β (5ng) reduced food intake to 56 (p<0.01) and drinking to 70 % (p<0.05) of baseline. Larger decreases were observed after infusion of 30ng. Amounts returned to near control levels after 24 h. Body weight was reduced for 2 d post-IL-1β. (2) Rats were food-restricted and trained on an operant schedule (FR10) for food reinforcement. They were tested for 5 min before injection of IL-1β and then retested 1, 2, 4, 8, and 24 h later. Both doses produced profound decreases in responding, with maximal effects 2-4 h post-injection. Four h post-infusion responding was reduced to 15±7 % (5ng) and 3±3 % (30ng) of baseline (p<0.01). These results suggest that the VMH may serve as a central site of action for the depressive that the VMH may serve as a central site of action for the depressive effects of IL-1β on food intake. (Supported by DRET (RD) and ONR (KWK))

INTERLEUKIN-6 AND TUMOR NECROSIS FACTOR INDUCTION BY CENTRAL ENDOTOXIN M. G. De Simoni\*, C. Gemma, A. De Luigi, A. Manfridi and P. Ghezzi. Istituto di Ricerche Farmacologiche "Mario Negri", via Eritrea 62, 20157 Milan, ITALY.

Our previous studies 1 have shown that intracerebroventricular (icv) interleukin 1 (IL-1) induces high levels of circulating interleukin 6 (IL-6) indicating that central IL-1 is able to induce cytokine-mediated actions in the periphery. To better elucidate the communication between brain and periphery, the present study analyses the effects of central endotoxin (LPS) administration on cytokine production. Different doses of LPS have been injected to rat cerebral ventricles and serum IL-6 and tumor necrosis factor (TNF) have been mesured. Central LPS resulted in more marked induction of circulating IL-6 than the same dose of LPS given systemically, the maximal response being obtained in both cases 2 hours later. Differently from IL-1 central injection, LPS-induced IL-6 was not prevented by IL-1 receptor antagonist indicating that LPS central effect is not mediated by IL-1.

Serum TNF levels have also been measured following central and

systemic LPS injection: also in this case the icv administration was more efficient than the systemic one. The time-course analysis indicated that the peak of TNF induction is delayed after icv compared to systemic injection. LPS icv (but not intraperitoneus) induced IL-6 and TNF in various brain areas

The data show that central endotoxin administration induces high circulating levels of IL-6 and TNF indicating the existence of a pathway that could explain how lesions confined to the central nervous system result in systemic alterations

INTERLEUKIN-2 ENHANCES SCOPOLAMINE-INDUCED . AMNESIA IN THE MOUSE. M. Bianchi and A.E. Panerai Dept. Pharmacol. University of Milano, School of Medicine, 20129, Milano, Italy.

Evidence has been reported that IL-2 exerts several neuromodulatory effects, including the inhibition of acetylcholine release in specific CNS regions and a dose dependent inhibition of long-term potentiation in the rat hippocampus (1,2). These observations might explain the memory impairment observed in patients during immunotherapy with IL-2 (3).

We evaluated the effects of human rIL-2 on scopolaminewe evaluated the effects of numan ril-2 on scopolamine-induced amnesia for a passive avoidance response in mice (4). Pre-training i.p. administration of 1250 or 2500 l.U. of the cytokine significantly potentiates the amnesic effect of scopolamine 1mg/kg i.p.. Higher (5000-10000 l.U.) or lower (625 l.U.) doses of IL-2 were completely ineffective. The post-training administration of IL-2, as well as IL-2 alone, does not affect memory retention.

Our results are in agreement and further extent the electrophysiological and clinical observations, and suggest that the pharmacological modulation of the cholinergic system could be useful in order to reduce some neurological side todal be disent in order to reduce some hearthing lical side effects of IL-2 on learning and memory.

EFFECT OF IL-18 INJECTIONS IN PGE2-SENSITIVE mPOA HEAT GAIN SITES OF ADX RATS WITH mPOA CORTICOSTERONE REPLACEMENT. G.E. Resch\*. Schl. Biol. Sci., Univ. Missouri at Kansas City, Kansas City, MO

The literature shows the loss of body temperature during cold stress that occurs in adrenalectomized (Adx) rats was restored with whole body corticosterone (Cort) replacement. In our previous reports Cort was replaced in PGE2-sensitive thermogenic sites within the medial prooptic area (mPOA) and tolerance to cold was restored in Adx rats. PGE2 injections into the mPOA sites that normally elicit a rise in colonic temperature (Tc) in intact rats failed to do so in Adx rats. The response was restored with mPOA Cort replacement indicating the PGE2 response was Cort-dependence. Some evidence indicates IL-1B acts via a PGE2 mechanism, consequently in this report the pyrogenic effects of IL-1B were tested for a similar cort-dependence. Stainless steel guide tubes (24 ga) were implanted under ketamine + acepromazine anesthesia in the mPOA and PGE2 injected stepwise dorsal to ventral to identify PGE2-sensitive thermogenic sites as previously reported. Cold tolerance tests were used to verify effective Adx. IL-18 (1 au) was then injected into these sites in 5 intact rats and in 5 Adx rats, before and again after 6 to 8 days of Cort injections into mPOA sites(100ng 2X/day). IL-1B elicited a 0.57°C +/- 0.69) rise in Tc in Adx rats, (0.92°C +/- 0.28) in the intact controls and 1.42°C +/- 0.41) in 8 day Cort replaced rats (P<.05, Adx vs Rpl) These data do not appear consistent with Chowers report of Cort attenuation of a pyrogen fever; however site specificity and differences in methods may account for the data. Compared with previous PGE2 responses, Adx attenuated the IL-1ß response but did not abolish it. These data support the notion of IL-1B acting through a PGE2 transduction mechanism, how incomplete blockade of IL-18 by Adx suggests IL-18 may operate through more than one mechanism of action. Supported by AFOSR 870297.

ELEVATED TUMOR NECROSIS FACTOR-ALPHA LIKE ANTIGEN LEVELS (TNFL) IN BRAINS OF DYSTROPHIC HAMSTERS. E. H. Schlenker & J. A. Burbach. Depts. of Physiology and Pharmacology & Lab. Medicine, USD School of Medicine, Vermillion, SD 57069.

The BIO 14.6 dystrophic hamster (DH) like patients who have euthyroid sick syndrome have low serum triiodothyronine (T3) levels. Mooradian and coworkers (J Clin Endocrin Met 71:1239,1990) reported that such patients also exhibited elevated serum tumor necrosis factor-alpha (TNF) levels. The purpose of this study was to test the hypothesis that DH have elevated TNFL levels. Measurements of TNFL were made using recombinant murine TNF ELISA. Because TNF in hamsters has not been fully characterized, we chose to call the antigen that cross-reacted in the ELISA tests TNFL. We used normal hamsters (NH) as a negative control and normal hamsters injected i.p. with 5ng/kg endotoxin (EH) as a positive control. Values were expressed as pg of TNFL/mg protein for brain, spleen and lung from animals in the 3 groups are presented below.

|        | NH $(n=3)$      | EH (n=4)     | DH (n=4)     |
|--------|-----------------|--------------|--------------|
| Brain  | $0.25 \pm 0.14$ | 2.41 ± 0.38  | 2.02 ± 0.41  |
| Spleen | $1.97 \pm 0.73$ | 16.53 ± 3.42 | 19.50 ± 7.10 |
| Lung   | 126 + 077       | 20.20 . 1.04 | 16.41 + 2.70 |

Lung 1.26  $\pm$  0.77 20.28  $\pm$  1.84 16.41  $\pm$  2.70 The results indicate that both EH and DH have elevated TNFL levels relative to those of NH in all 3 tissues evaluated (P<0.03, Mann-Whitney Test). The physiological significance of the association of low T3 levels and elevated TNFL levels in DH needs to be investigated further.

484

PROSTOGLANDINS MEDIATE ACTH SECRETION IN RESPONSE TO TUMOR NECROSIS FACTOR-α (TNF). J.G. McCoy, S.G. Matta, S.E. Nicol\*, and B.M. Sharp. Minneapolis Medical Research Foundation and Depts. of Med., Hennepin County Medical Center and Univ. of Minn., Mpls., MN 55404

We have previously shown that the cytokines II-1B and TNF- $\alpha$  given i.v. stimulate the release of pituitary ACTH to a comparable magnitude, with the same time course. However, II-1B acts within the hypothalamus, whereas TNF- $\alpha$  has no direct central effect when administered i.e.v. or adjacent to the median eminence. no direct central effect when administered i.e. v. or adjacent to the median eminence. To determine if prostaglandins (PGs) might be mediators of the interaction between TNF- $\alpha$  and the hypothalamo-pituitary-adrenal axis, indomethacin (Indo, 1 mg/kg, i.v.) was administered prior to TNF- $\alpha$  (1µg/rat, i.v.) in freely mobile, alert rats. While Indo alone had no significant effect on plasma ACTH levels [at 20 min peak (mean±sem): 26±13 pg/ml compared to buffer 26±10 pg/ml], it completely blocked the response to TNF- $\alpha$  from 29±54 pg/ml to 22±8 pg/ml. This dose of Indo had no effect on the ACTH response to CRF 1 µg/kg i.v.(at 10 min: CRF alone = 461±69 pg/ml; Indo/CRF = 403±76 pg/ml), demonstrating that there was odirect inhibition of injustrus response to the content of the hope respected the no direct inhibition of pituitary responsiveness. Since it has been reported that Indo elevates plasma corticosterone (B) levels, the blockade of TNF-stimulated Indo elevates plasma corticosterone (B) levels, the blockade of 1Nr-stimulated ACTH release by Indo could be due to a rapid feedback inhibition by B, rather than a direct involvement of PGs. However, in additional experiments, inhibition of ACTH secretion by Indo was shown to be dose-dependent, whereas plasma B levels were elevated to the same degree, independent of Indo dose. Furthermore, Indo failed to block the ACTH response to an unrelated ACTH stimulus - insulinrailed to block the AC1H response to an unrelated AC1H stimulus - insulinduced hypoglycemia (area under response curve: Insulin alone = 3113142794 pg x min/ml; Indo/Insulin =  $32919\pm3582$  pg x min/ml). In adrenalectomized, B-replaced rats, TNF (1 µg/rat, i.v.) elevated ACTH to the same levels seen in sham animals. Indo inhibited these ACTH responses to the same extent in both groups. Thus, Indo inhibited the ACTH response to TNF- $\alpha$  by a mechanism independent of corticosterone feedback. These results demonstrate that circulating TNF- $\alpha$ stimulates ACTH secretion through a PG-dependent mechanism.

#### 206.14

SELECTIVE MODULATION OF EVOKED HIPPOCAMPAL ACETYLCHOLINE RELEASE BY CYTOKINES

U.-K. Hanisch\*, D. Seto, and R. Ouirion, Douglas Hospital Research Centre and Department of Psychiatry, McGill University, Montreal, Quebec, Canada.

Signalling peptides of the immune system, i.e. cytokines, also exert effects on glial and neuronal cells. Produced in the CNS or having access to brain targets via passage of the blood-brain barrier, cytokines may control neuronal activity, especially when intrinsic or circulating cytokines are elevated (i) upon challenge of an immune or inflammatory response, (ii) during immunotherapy, or (iii) as a consequence of injury or pathologic processes. By means of superfusion and static incubation of rat brain slices interleukin-2 (IL-2) was shown to modulate the evoked release of acetylcholine (ACh) from hippocampus and frontal cortex, but not from striatal tissue (Soc.Neurosci.Abstr. 1991: 313.13). For the hippocampus, the dose-response relation has a biphasic profile, with inhibition at 1 nM and transient augmentation at 0.1 pM. Subsequently, we investigated the specificity of the IL-2 effect in experiments involving other cytokines, including tumor necrosis factor (TNF). Although several cytokines, like IL-1, IL-3, IL-5, and IL-6, were ineffective at nanomolar concentrations in modulating hippocampal ACh release, we obtained some evidence for a TNFB-mediated inhibition. Taking together, the data suggest a preferential sensitivity of hippocampal ACh release to a modulation by IL-2. (Supported by the FRSQ, the MRCC, and the HFSPO.)

# REGULATION OF AUTONOMIC FUNCTION: GASTROINTESTINAL AND VISCERAL AFFERENTS

THE WEANLING RAT LATERAL HYPOTHALAMIC SYNDROME: INTERMEDIARY METABOLISM. L.Bernardis\*.J. Natale.C. Fink and A.Awad.
DVAMC Buffalo, Dept. Med., SUNY/Buffalo 14215 and Nutrition
Program, SUNY/Buffalo, Buffalo NY 14214.
Weanling rats with ventromedial hypothalamic nucleus

lesions show dramatic changes in intermediary metabolism of liver, epididymal fat pad (PAD) and diaphragm (DIA) in the presence of normophagia, normal body weight (BW) and presence of normophagia, normal body weight (BW) and obesity even in the absence of the pituitary gland. No data are available on the weahling rat with lateral hypothalamic lesions (LHAL rat), which shows severe reductions in food intake (FI) and BW. LHAL rats were maintained for 1 mo. post-op (POP). One control (CON) group was fed ad libitum (CONAL), another CON group was pair-fed/gained to LHAL (CONPFPG). Incorporation of 14C-U-glucose into CO<sub>2</sub> (OXID) was significantly (SIG) elevated in liver of LHAL vs CONAL but was normal vs CONPFPG. In PAD, OXID was SIG elevated in LHAL rats vs CONAL, but was also higher than in CONPFPG. No SIG differences were found in DIA. BW and FI were SIG reduced in LHAL vs CONAL and most LHAL rats had to be gavaged for 10 POP days when they began to eat chow pellets. The liver data suggest that the metabolic changes might be due to the severe hypophagia that is seen in LHAL rats, but the PAD data indicate an effect independent of FI that results in enhanced catabolism.

MICROINJECTIONS OF ANTI-TRH ANTIBODY IN THE DORSAL VAGAL COMPLEX INHIBIT STOMACH CONTRACTIONS PRODUCED BY LATERAL HYPOTHALAMIC LESIONS. C.V. Grijalva\*, J. Landeira-Fernandez, M. Prince, G. Ohning, T. Garrick. CURE, BRI, & Depts. of Psychology, Psychiatry, and Medicine, UCLA, Los Angeles, CA 90024.

Lateral hypothalamic (LH) lesions induce stomach erosions which are related to vagally-mediated increases in high amplitude gastric contractions (Garrick et al. Gastroenterology 99: 1990, 1213). Microinjections of anti-TRH antibody (TRHa) in the dorsal vagal complex (DVC) block stomach contractility induced by glutamate injections in the raphe pallidus nucleus (RPa) (Prince et al. Gastroenterology, 1992). The present study examined whether TRHa into DVC would also block the increase in contractility following bilateral electrolytic LH lesions. In three groups of urethane anesthetized rats, gastric contractions were measured with extraluminal force transducers and analyzed by computer. After a 30 min baseline period, LH lesions were performed in two groups. One hour later one, LH group received bilateral injections of TRHa (1.6  $\mu$ g/ 0.1  $\mu$ l) into DVC. The second LH group was injected with an equal volume of BSA vehicle. The third group received a bilateral injection of glutamate (100 pmole/  $0.1~\mu$  l) into RPa and one hour later TRHa was infused into the DVC. Both LH lesions and glutamate injections evoked high amplitudes contractions. Vehicle produced a short term suppression of gastric contractions but the magnitude of the suppression was greater in groups treated with TRHa. Gastric contractions in TRHa-treated LH lesioned rats remained suppressed for over 45 min. These results suggest that LH lesions may induce gastric contractions by activating DVC through the release of TRH. (UCLA PZ-06; CNPq)

BLOCKADE OF GABA RECEPTORS IN THE HYPOTHALAMIC DORSOMEDIAL NUCLEUS (DMN) CAUSES PARASYMPATHETICALLY-MEDIATED INCREASES IN JEJUNAL AND COLONIC MOTILITY IN ANESTHETIZED RATS. J. A. DiMicco<sup>2</sup> and B. Greenwood. Dept. of Pharmacology and Toxicology, Indiana University School of Medicine, Indianapolis IN 46202, and Eli Lilly and Co., Indianapolis, IN 46285

In our previous studies blockade of GABA, receptors in the DMN of the rat induces cardiovascular and behavioral changes resembling those associated with emotional stress. Another consequence of emotional stress is altered gastrointestinal (GI) motility. The purpose of the present study was to test the hypothesis that microinjection of the GABA antagonist bicuculline methiodide (BMI) into the DMN of anesthetized rats would produce changes in intestinal and colonic motility. Male rats (250-350 gms) were anesthetized with equithesin. A femoral artery was cannulated for recording of arterial pressure, and heart rate was monitored using a cardiotachometer triggered by the systolic pulsation. Motility was monitored manometrically using saline-filled cannulae placed in the jejunum and colon and connected via pressure transducers to a chart recorder. In some animals, loose ligatures were carefully placed around the cervical vagi for later transection. Microinjection of BMI 15-30 pmol/15 nl into the DMN resulted in increases in both jejunal and colonic motility in addition to the marked tachycardia and moderate increases in arterial pressure previously reported. The enhanced motility was characterized by increases in both amplitude and frequency. The time course paralleled that for the associated tachycardia. In a given animal, the BMI-induced stimulation of GI motility appeared to be reproducible and dose-related. Section of the cervical vagi blocked the increases in jejunal but not colonic motility, whereas intravenous injection of atropine blocked both responses. These observations suggest that: (1) disinhibition of neurons in the DMN of the rat increases jejuna

PEPTIDE YY MICROINJECTED INTO THE DORSAL VAGAL COMPLEX INHIBITS CENTRALLY STIMULATED PANCREATIC SECRETION. D.C. Whitcomb, J.T. Curtis, E.M. Stricker and A.F. Sved\*. Departments of Medicine and Behavioral Neuroscience, Univ. Pittsburgh, Pittsburgh, PA 15261

Peptide YY (PYY) is a hormone that is released from the distal intestine in the presence of luminal nutrients. PYY inhibits pancreatic secretion, gastric acid secretion, gastric emptying and intestinal motility. Recent studies suggest that PYY inhibits the vagal component of pancreatic secretion at a site proximal to the pancreas (Putnam, AJP 256:G698-G703, 1989). PYY receptors are present in the dorsal vagal complex (DVC) and circulating PYY can bind to at least some of these receptors (Hernandez, Gastroenterol. 100:A827, 1991). The present study sought to determine whether activation of these receptors by microinjection of PYY into the DVC can inhibit centrally stimulated pancreatic secretion. Male rats were anesthetized with urethane (1.5 mg/kg) and the pancreatic duct was cannulated so that pancreatic secretion could be collected without bile. The rat was placed in a stereotaxic frame and the dorsal surface of the medulla surgically exposed. After the basal pancreatic secretory rate was determined, 2-deoxyglucose (2DG 50 mg/kg iv) was injected to centrally stimulate pancreatic secretion. After 30 minutes, PYY (100 nl of a 0.5  $\mu$ M solution) or artificial CSF was injected into the DVC bilaterally. 2DG caused a significant (>3x), long lasting increase in pancreatic secretion. Injection of PYY but not CSF into the DVC caused an immediate inhibition of centrally stimulated pancreatic secretion to, or below initial baseline levels. Pancreatic flow typically returned to pre-PYY levels within 20 minutes. These data support the hypothesis that PYY inhibits vagal dependent pancreatic secretion, in part, by acting directly at the DVC.

DISTRIBUTION OF GASTRIN-RELEASING PEPTIDE IMMUNO-REACTIVITY IN THE DORSAL VAGAL COMPLEX IN RATS.

R.B. Lynn\*, R.R. Cooperman and R.R. Miselis, Dept. of Medicine,

Biology, Univ. of Pennsylvania, Philadelphia, PA 19104.

Gastrin-releasing peptide(14-27)(GRP), also referred to as bombesin,
injected into the dorsal vagal complex(DVC) or intracerebroventricularly

Gastrin-releasing peptide(14-27)(GRP), also referred to as bombesin, nijected into the dorsal vagal complex(DVC) or intracerebroventricularly inhibits the increase in gastric function in response to numerous stimuli. To determine the neuroanatomic circuitry mediating this inhibitory response we used immunohistochemistry to better define the location of GRP-immunoreactive(IR) fibers and cell bodies within the DVC. GRP fiber and terminal labeling was heavy in the dorsal motor nucleus of the vagus(DMV) and medial subnucleus of the nucleus of the solitary tract (NTS), in contrast to very light labeling in the centralis and gelatinosus subnuclei. Moderate labeling was also found in the dorsal, interstitial, lateral, commissural - caudal to the area postrema(AP) and the rostral intermediate subnucleus central to the AP and the dorsomedial, periventricular portion of the NTS. In colchicinized animals, numerous cell bodies were labeled and were located in the medial and dorsal subnuclei of the NTS. GRP-IR fibers and cell bodies were seen in a number of other areas of the brain with the heaviest labeling in the suprachiasmatic and medial parabrachial nuclei. In conclusion, GRP immunoreactivity in the DVC conforms to the particular subnuclear boundaries we have described in reporting the viscerotopic organization of the NTS. Labeling is abundant in areas of the NTS that receive afferents from the cecum and esophagus.

CATECHOLAMINERGIC CONNECTIONS TO VISCERAL MOTO-NEURONS ESTABLISHED BY TRANSNEURONAL TRANSFER OF PSEUDORABIES VIRUS FROM INDIVIDUAL VISCERA. M. Yang, S.M. Altschuler\*, X. Zhao, L.W. Enquist, and R.R Miselis. Dept. of Animal Biology, School of Veterinary Medicine, University of Pennsylvania, Philadelphia, PA 19104.

It has not been possible to map the distribution of catecholaminergic (CA) neurons as a function of their relationship to specific visceral organs. With viral transneuronal tracers and double labeling it is possible to determine which CA neurons of the brainstem connect to autonomic motoneurons innervating specific organs and whether they influence visceral function via parasympathetic or sympathetic routes. The stomach, esophagus or cecum of a rat was injected with Bartha pseudorabies virus. Some stomach injected rats had a high complete subdiaphragmatic vagotomy preceding the injection. After survival times of 4 to 6 days the brains were processed for double immunoflorescence for viral antigen and either DBH or PNMT CA enzymes. No apparent topology emerged within any CA neuron grouping in relation to a specific viscus. In all cases the stomach injections resulted in the most double labeled neurons in any CA grouping compared to the esophagus or cecum. Vagotomy preceding a stomach injection blocked double labeling in A1, A2, and caudal C2. There was less double labeling in C1, rostral C2, C3, and A6. There was no change in A5.

THYROTROPIN RELEASING HORMONE ANALOGUE AND SEROTONIN INTERACT WITHIN THE DORSAL VAGAL COMPLEX TO POTENTIATE GASTRIC ACID SECRETION. D. M. McTigue, R. C. Rogers\* and R. L. Stephens Jr.. Ohio State University, Dept. of Physiology, Columbus OH 43210.

The brainstem raphe nuclei send projections to the dorsal vagal complex [(DVC); i.e. the nucleus tractus solitarius and the dorsal motor nucleus]. These vagal nuclei play integral roles in releaves controlling visceral function. The raphe projections to the

The brainstem raphe nuclei send projections to the dorsal vagal complex [(DVC); i.e. the nucleus tractus solitarius and the dorsal motor nucleus]. These vagal nuclei play integral roles in relexes controlling visceral function. The raphe projections to the DVC contain the putative transmitters thyrotropin releasing hormone (TRH) and serotonin (5HT). Co-localization of these agents suggests a possible interaction between these compounds involving the DVC neurons. In this study, the effects of 5HT and a TRH analogue, RX77368, on vagal control of gastric acid secretion were studied. Microinjection of RX77368 (0.66 pmol in 10nl) into DVC evoked a significant increase in acid output. 5HT (8pmol in 10nl) microinjected into the DVC produced no change in gastric acid secreted. When the same doses of RX77368 and 5HT were co-injected, the amount of acid secreted was significantly greater than that due to RX77368 alone. Vehicle control injections into the DVC produced no change in the acid output. Injection of atropine methyl nitrate i.p. eliminated the elevation in acid secretion due to co-injection of RX77368 and 5HT suggesting vagal cholinergic influence over the stomach is involved. The results of the study suggest 5HT amplifies the effects of TRH on DVC neurons. Supported by NS24530 (RCR) and DK42880 (RLS).

FOREBRAIN MODULATION OF GASTROINTESTINAL FUNCTION IS MOST DIRECT THROUGH PARASYMPATHETIC INNERVATION. R. R. Miselis\* L. W. Enquist, X. Zhao and M. Yang, Dept. Animal Biology, School of Veterinary Medicine, University of Pennsylvania, Philadelphia, PA 19104

The use of pseudorabies virus (PRV) as a transneuronal tracer enables labeling brainstem and spinal cord autonomic neurons in a viscerotopic manner with short survival times following injections of specific viscera. With increasing survival times the virus passes transneuronally into central afferent sources to the autonomic motoneurons (Miselis et al., Soc. Neurosci. Abst., 17:1361, 1991 and Card et al J. Neurosci. 10: 1990). Transneuronally labeled neurons occur specifically throughout the visceral neuraxis including forebrain sites such as the paraventricular nucleus of the hypothalamus (PVN), bed nucleus of the stria terminalis, central nucleus of the amygdala and the insular cortex. To determine the major route by which PRV travels retrogradely to the forebrain sites, the stomachs of rats were injected at multiple sites with Bartha (Ba - an attenuated strain of PRV), total volume - 6 µl of 9 x108 pfu/ml with or without a high complete subdiaphragmatic vagotomy preceding the injection. Rats survived 4 to 6 days before being sacrificed. The vagotomy blocked the transport of the virus to the CNS via the parasympathetic route. The cut prevented major labeling ontinued to occur in the intermediolateral cell column of the spinal cord and brainstem sites known to project to the sympathetic outflow. This indicates that the great majority of forebrain modulation of gastrointestinal function is most directly applied through parasympathetic innervation of the gut (assumes both systems can be infected by Ba). The data also continue to support the contention that the virus is moving most rapidly by transsynaptic means rather than by nonspecific spread. Supported by NIH Grant GM 27739

FOS EXPRESSION IN THE FERRET BRAINSTEM AFTER EMETIC STIMULI. F.M. Boissonade , K.A. Sharkey and J.S. Davison. Dept. Medical Physiology, University of Calgary, Calgary, Alberta T2N 4N1 Canada

The aim of this study was to map central pathways involved in the emetic reflex by examining the expression of Fos within the ferret brainstem after emetic stimuli. All experiments were performed on halothane anaesthetized ferrets. Local anaesthetic was infiltrated S.C. prior to all skin incisions. The trachea and left carotid artery were cannulated, blood pressure (BP) monitored and rectal temperature maintained at 38°C. Animals were paralysed and ventilated. In 7 animals electrodes were positioned on the supradiaphragmatic vagal crossing branch, 4 were stimulated, 3 were unstimulated controls. In 6 animals chronic duodenal cannulae were inserted 14 days prior to experimentation. On the day of the experiment animals were prepared as described above and given intraduodenal injections of either 1.5M saline n=3) or normal saline (n=3). Animals were deeply anaesthetized 1h after the onset of the stimulus and perfused fixed with 4% paraformaldehyde. Forty µm frozen sections were incubated with a polyclonal Fos antibody for 48h and tissue was reacted using the ABC technique. For both types of stimulation, induction of a fictive emetic episode was verified by a dramatic increase in BP following application of the stimulus. After electrical stimulation, dense Fos labelling was observed in the medial subnucleus (mn) of the nucleus of the solitary tract (NTS) and moderate labelling in the dorsal/dorsolateral (d/dln) and interstitial (ni) subnuclei of NTS. Labelling was also moderate in the dorsal motor nucleus of the vagus (DMNX), area postrema (AP) and the subnucleus gelatinosus (sg) of NTS. Hypertonic saline induced dense Fos expression in a more discrete region, consisting of the medial portion of the sg and the AP. Labelling was moderate in the mn and sparse in DMNX. In controls, virtually no staining was observed in the dorsal vagal complex. Supported by the Canadian MRC and AHFMR.

# 207.10

SPINAL INPUT TO INTESTINE-SENSITIVE NEURONS IN THE DORSAL MOTOR NUCLEUS OF THE VAGUS (DMNV). X. Zhang\*, W.E. Renehan and R. Fogel. Division of Gastroenterology, Henry Ford Hospital, Detroit, MI 48202.

We have recently shown that 92% of the DMNV neurons which could be driven by a subdiaphragmatic vagal stimulating electrode were inhibited by moderate intestinal distention. Our data suggested that vagal primary afferents excited neurons in the nucleus of the solitary tract which then inhibited the neurons in the DMNV. It is possible, however, that spinal afferents also contribute distention-related information to the vagal complex. To explore this important issue, we recorded the responses of DMNV neurons to intestinal distention in animals which had undergone complete transection of the subdiaphragmatic vagus nerve. Influx and efflux catheters were placed in a 60-70 cm loop of small intestine and normal saline was perfused through the lumen at low pressure. The intestine was distended by raising the efflux catheter to 20 cm above the level of the animal. This manipulation increased intraluminal pressure by 9.0 (SE = 0.63) mm Hg and increased the circumference of the intestine from 16.9 (SE = 0.04) to 21.6 (SE = 0.02) mm. Glass micropipettes filled with 6% HRP or 2% Neurobiotin (Vector Labs) in Tris-KCl buffer were used to intracellularly label physiologically-characterized distention-sensitive neurons in the DMNV. In contrast to the results obtained in normal animals, only one of the 20 labeled DMNV neurons in the vagotomized animals was inhibited by distention. Ten of the 20 neurons were excited by the stimulus and 9 showed no response. The results suggest that an ascending pathway(s) from the spinal cord provides distention-related information to the DMNV. This pathway would seem to oppose the circuit which includes vagal primary afferents, but the vagal afferent circuit is dominant in the intact animal.

Distribution of 5-HT, substance P and CGRP-containing vagal afferent

Distribution of 5-HT, substance P and CGRP-containing vagal afferent fibres in the rat dorsal medulla. R.M. Sykes, K.M.Spyer' and P.N. Izzo (SPON: European Neuroscience Association) Dept. Physiology, Royal Free Hosp. Sch. Med., Rowland Hill St., London, NW3 2PF, U.K. Evidence supports the presence of a wide variety of putative neurotransmitters in sensory neurones of the vagus nerve, based on immunocytochemical and in situ hybridization studies on the perikarya of the nodose ganglia. Although these studies suggest a chemical heterogeneity they are unable to provide information regarding the central organization of a particular group of chemically identified afferents. This study examines the presence of 5-HT, substance P or CGRP in the central fibres of the vagus and companes their distribution.

central fibres of the vagus and compares their distribution.
Vagal afferents anterogradely labelled following the injection of choleratoxin into the nodose ganglia and its subsequent immunofluorescent detection together with immunofluorescent detection of 5-HT, substance P or CGRP using different fluorochromes. Areas of the nucleus tractus solitarius (NTS), dorsal vagal motonucleus (DVN) and area postrema (AP) were scanned using a confocal microscope and the resulting images examined for fibres both anterogradely labelled and containing immunoreactivity for one of the putative neurotransmitters studied.

Afferents containing 5-HT were detected mainly in the AP and the adjacent NTS as well as in the ventral NTS. Afferent fibres containing CGRP were found primarily in the more caudal aspects of the NTS and DVN. Substance P-containing afferents were surprisingly few in number

and did not appear to be associated to any particular region.

These results, together with previous demonstrations of a viscerotopic organization of vagal afferents suggest that afferents innervating different organs contain different putative neurotransmitters.

Supported by grants from the MRC and BHF.

# GLUTAMATE RELFASE IN THE CAT NUCLEUS TRACTUS SOLITARIUS (NTS): AN IN VIVO MICRODIALYSIS STUDY. RE Allchin, TFC Batten\*, PN McWilliam and PFT Vaughan. Cardiovascular Studies, The University, Leeds LS2 9JT, U.K. Biochemical and pharmacological evidence (eg. Perrone, 1981,

Brain Res. 230: 283-293) suggests glutamate may be the neuro-Brain Res. 230: 263-293) suggests glutamate may be the neuro-transmitter utilized by synaptic terminations of vagal afferent fibres in the NTS. By EM immunohistochemistry we have also shown high levels of glutamate in terminals in the NTS (Batten & Saha, 1991, Soc. Neurosci. 17: 243.11). We have now used *in vivo* microdialsis to examine glutamate release into the extracellular fluid of the NTS of cats anaesthetized initially with halothane, then pentobarbitone (5 mg/kg/hr i.v.). A microdialysis probe (CMA/12, 1 mm membrane) was inserted into the medial NTS at area postrema level and was perfused with Krebs Ringer at 25 µl/min postrema level and was periused with Kreos Kinger at 2.5 μl/min during a 2 h stabilization period, then at 2.5 μl/min during the collection periods (25 min per sample). In vitro recovery of glutamate for individual probes varied from 3.5% to 7.5% at this perfusion rate. Basal glutamate release was compared with release during electrical stimulation of the vagus (20 Hz). Each brain was fixed for histological verification of the probe position. Samples were analyzed by HPLC with electrochemical detection, using OPA derivatization (Kehr & Ungerstedt, 1988, J. Neurochem. 51: 1308 1310). Experiments so far (n=10) have failed to show any consistent or significant increase in glutamate release with vagal stimulation. This casts doubt on the idea that glutamate is a neurotransmitter in vagal afferents, and raises the possibility that glutamate measured/localized in the NTS may have a metabolic role.

# 207.15

# VAGAL INNERVATION OF THE RAT PANCREAS: AFFERENT AND EFFERENT PATTERNS COMPARED. TL. Powley\*, C.L. Stanwyck, D.L. Kim, and M-C. Holst. Purdue Univ., W. Lafayette, IN 47907.

Although it is well established that the vagus innervates the pancreas, little is known about the intrapancreatic pathways, target tissues, or endings of vagal fibers. In separate animals, the carbocyanine dye Dil was injected into the left or right nodose ganglion or bilaterally into the dorsal motor nucleus of the vagus. Animals were injected intraperitioneally with fluorogold to label the dorsal motor nucleus, nodose ganglia, and pancreatic ganglia and islets. After the rats were sacrificed, each pancreas was blocked into a standard series of whole mount samples from the head and the tail. These samples were surveyed with epifluorescence and confocal microscopy. Afferent fibers were most numerous in the head of the pancreas near the common bile duct and its branches, where they occurred in many (up to 42±8%) of the nerve bundles. Afferents from left and right vagi were equally numerous in the different regions and followed similar courses. Afferents terminated most prominently as fine puncta within the interlobular ganglia of the pancreas. Whole mounts near ducts in the head had the highest percentage (up to 22±6%) of vagally innervated ganglia. In comparison, vagal efferents were found in a similar number of nerve bundles following the same course as the afferents. The percentages of ganglia innervated by efferents in the different regional samples also paralleled those observed for the afferents (see also Br. Res. 553: 336-341, 1991). Overall, the density of vagal afferents and efferents is consistent with the conclusion that the pancreas receives modest numbers of fibers from the vagus. Finally, the innervation pattern suggests that the vagal branches supplying the proximal duodenum are also the source of parasympathetic connections with the pancreas, an organization which may reflect the embryological derivation of the pancreas from duodenum. (DK27627)

## 207.12

SOLITARY TRACT NUCLEUS AS A RELAY IN THE VAGAL CORTICAL ASCENDING SYSTEM IN RATS. S. Ito\*. Dept. Physiol., Kumamoto Univ. Med. Sch., Kumamoto, 860 Japan.

Both the A- and C- vagal afferents project to the granular insular cortex (GI), presumably through polysynaptic processes at the solitary tract nucleus (NTS), to evoke surface positivenegative field potentials (PNs) (Neurosci.Abstr. 243,10,1991). To clarify the input-output organization of the NTS, the present study 1) mapped vagally evoked field potentials (FPs) at the NTS and 2) stimulated various sites in the NTS to evoke PNs in the GI in SD rats anesthetized with chloralose or barbiturate, immobilized with tubocrarine, and artifitially ventilated. A-af-ferent-evoked FPs were restricted laterally in the NTS while C-afferent-evoked FPs were distribthe NTS while C-afferent-evoked FPS were distributed broadly throughout it. Stimulation less than 1  $\mu$ A at the lateral part of the NTS evoked a PN at the GI. The threshold increased as the stimulation site moved medially; it was more than 100  $\mu$ A at the midline. These results suggest that the caudal NTS is differentiated along the mediolateral axis; the lateral part serves as the relay for both the afferents in the cortical ascending system, but the visceral information processed in the medial part does not contribute to the thal-amocortical projection.

## 207.14

VAGAL INNERVATION OF RAT LIVER, BILE DUCTS, PORTAL VEIN, AND ASSOCIATED PARAGANGLIA: AN ANTEROGRADE TRACING STUDY. H.-R. Berthoud\*, M. Kressel, and W.N. Neuhuber, Pennington Medical Res.Ctr., LSU, 6400 Perkins Rd., Baton Rouge, LA 70808, USA, and Anatomy Institute, Univ. of Zürich, Winterthurerstr. 190, 8057 Zürich, Switzerland. In order to investigate the distribution and structure of the vagal liver

innervation, abdominal vagal afferents and efferents were selectively labeled by injecting WGA-HRP (Neuhuber, JANS 20:243-255,1987) or Dil (Berthoud et al., JCN 319:261-276,1992) into the nodose ganglia, and DiA into the dorsal motor nucleus, respectively.

Vagal afferent fibers produced numerous terminal-like structures on both intra and extrahepatic portions of the larger bile ducts, on limited regions of

the portal vein, and in most of the paraganglia of the hepatic vagal branch and hilus. Varicose vagal efferent fibers were present within the fascicles of the vagal hepatic branch and fine terminal-like structures in a small fraction of the paraganglia. No efferents were found to terminate on the few neurons paraganglia. No erretents were tound to terminate on the few heurons embedded in nerves or paraganglia, and neither vagal afferents nor efferents were found in hepatic lobules and parenchyma. In contrast, an abundance of vagal efferent and afferent fibers and terminals with distinctive distribution patterns and structural characteristics were present in esophagus and gastrointestinal tract. While about two thirds of the vagal afferent fibers that originate in the left nodose ganglion and are contained in the hepatic branch bypass the liver hilus area on their way to the gastroduodenal artery, a significant number (approx. 10% of the total) of vagal afferents that does innervate the area, originates from the right nodose ganglion, and projects through the dorsal celiac branch and the periarterial plexus of the common hepatic artery.

It is concluded that vagal intralobular hepatic innervation is largely absent

in rats, and that the putative hepatic vagal nutrient and osmoreceptors are located either in the portal vein, bile ducts, or the hepatic paraganglia. Roche Foundation Grant No. 788, and Hartmann-Müller Stiftung No. 765.

# 207.16

VAGAL AFFERENTS END ON INTERSTITIAL CELLS OF CAJAL AT THE GASTRODUODENAL JUNCTION OF THE RAT. M.C. Holst, E.A. Baronowsky and T.L. Powley, Purdue University, West Lafayette, IN 47907.

Although Caial described interstitial cells in all layers of the gastrointestinal tract, only those in muscle have been well characterized, and little is known about the source(s) of axons contacting them. A combination of a double staining paradigm with laser scanning confocal microscopy provides high resolution and specific information on these cells. In this study vagal afferents of the pyloric region were labeled by injections of the fluorescent carbocyanine dye Dil into the nodose ganglia (left, right or both). Additional animals had injections of Dil in the dorsal motor nucleus of the vagus and/or DiA in the nodose ganglion with or without supranodose vagotomy. Intraperitoneal injections of fluorogold labeled neurons throughout the enteric nervous system, the dorsal motor nucleus of the vagus and the nodose Dil labeled vagal afferent fibers in transverse or longitudinal sections (140 µm) or whole mounts of the antrum, pylorus or duodenum were located with a fluorescent microscope. Stacked serial confocal images of muscle, submucosa or mucosa reveal fine afferent fibers and clusters of puncta forming a dense covering over the body and processes of interstitial cells of Cajal. In addition to forming such complexes, vagal afferents also supply puncta or endings to a multiplicity of other sites including the bases of epithelial cells, gastric glands, Brunner's glands, duodenal crypts, and ganglion cells in the myenteric and submucosal plexuses. Although interstitial cells are commonly considered part of an intrinsic network with a pacemaker function, the rich and ubiquitious nature of the vagal afferent/interstitial cell complexes suggests these structures may also participate in sensory functions. Supported by NIH DK27627.

NADPH DIAPHORASE ACTIVITY IN AUTONOMIC NEURONS WHICH INNERVATE THE RAT ANOCOCCYGEUS MUSCLE. B. Galloway, J. Bordegaray, W.G. Dail and S.L. Rogers\*. Dept. of Anatomy, Univ. of NM, School of Medicine, Albuquerque, NM 87131.

The anococcygeus muscle of the rat is supplied by parasympathetic nerves which may contain acetylcholine and vasoactive intestinal polypeptide, yet neither of these neurotransmitters is responsible for inhibition of this muscle. Relaxations of the anococcygeus can be blocked by compounds which interfere with nitric oxide (NO) formation. Since it has been suggested that NADPH diaphorase activity may be a marker for neurons which synthesize NO, the present study reports on the localization of this enzyme. Intramural neurons of the anococcygeus were moderately to intensely stained for NADPH diaphorase. Staining was limited to the cell soma with no evidence of a fiber plexus in the anococcygeus or a reaction in proximal processes of the cell body. Neurons in the pelvic plexus showed the same range of staining intensity as those in the anococcygeus, while there was no staining of retrogradely labeled neurons of the sympathetic chains. The results further support the hypothesis that neurons which synthesize NO may be characterized by a high NADPH diaphorase activity.

AN ULTRASTRUCTURAL STUDY OF SEROTONINERGIC INPUTS TO NEURONS OF THE MYENTERIC PLEXUS OF THE GUINEA-PIG ILEUM. H.M. Young\* and J.B. Furness. Dept. of Physiology, University of Melbourne, Parkville, Victoria, 3052, Australia.

The serotonin-immunoreactive (IR) neurons in the myenteric plexus of the guinea-pig ileum are descending interneurons. In this study we determined whether these serotonin-IR interneurons selectively provide input to any sub-population of myenteric nerve cell bodies.

Myenteric ganglia were processed for pre-embedding immunocytochemistry for serotonin. Serial ultrathin sections were taken through one ganglion from each of two animals. In one ganglion, a sample region was chosen that contained the cell bodies of 43 neurons. We counted the number of serotonin-IR terminals that formed close contacts or synapses with every cell body in the sample area. The sample included the cell bodies of 3 Dogiel type II and 2 serotonin-IR neurons. Each of the Dogiel type II cell bodies received only one close contact each from a serotonin-IR terminal. In contrast, one of the serotonin-IR cell bodies received 4 synapses and 10 close contacts, and the other received 5 synapses and 17 close contacts from serotonin-IR terminals. Other nerve cell bodies received varying numbers of synapses and close contacts from serotonin-IR terminals. In another ganglion the Dogiel type II cell bodies also received very few serotonin-IR inputs whereas the serotonin-IR cell body received many synapses and close contacts from serotonin-IR terminals. It is probable that serotonin interneurons form descending chains.

NON-M1 CHOLINERGIC RETICULAR MECHANISMS PRODUCE A STATE-DEPENDENT DECREASE IN PARABRACHIAL NEURON DISCHARGE. K.A. Gilbert and R. Lydic. Dept. of Anesthesia, Penn. State University, College of Medicine, Hershey, PA, 17033. Some parabrachial nuclear complex (PBNC) neurons reveal altered

Some parabrachial nuclear complex (PBNC) neurons reveal altered discharge rates during sleep, but mechanisms mediating state-dependent changes in PBNC cell firing rate are not understood. Microinjection of the mixed cholinergic agonist carbachol (0.4 µg) into the medial pontine reticular formation (mPRF) of awake cats produces a state (DCarb) that is similar to rapid eye movement sleep. Recent reports suggest that the cholinoceptive mPRF contributes to state-dependent changes in PBNC cell discharge (Gilbert & Lydic, Neurosci.Letts., 120: 241-244, 1990). Encouraged by these findings, this study sought to examine which populations of mPRF cholinergic receptors could contribute to state-dependent changes in PBNC cell discharge. Long-term recordings from a single PBNC neuron revealed a decreased firing rate during DCarb (32.7 Hz) compared to waking (63.4 Hz). A similar decrease in discharge rate was observed following mPRF microinjection of the acetylcholinesterase inhibitor neostigmine (6.3 µg). Similar nicotine injections (0.35 and 3.5 µg) did not alter PBNC cell discharge. Pretreatment of the mPRF with the mixed cholinergic antagonist atropine (5.0 µg) blocked the carbachol-evoked decrease in PBNC cell discharge. An equimolar dose of the M<sub>1</sub>-specific antagonist pirenzepine failed to block the DCarb-induced decrease in PBNC cell discharge. These results suggest that activation of an mPRF non-M<sub>1</sub> receptor subtype is required to produce both the DCarb state and the concommitant decrease in PBNC cell discharge.

GABA INHIBITS CAUDAL HYPOTHALAMIC NEURONS THAT ARE STIMULATED BY HYPOXIA IN SPONTANEOUSLY HYPERTENSIVE AND WISTAR-KYOTO RAT BRAIN SLICES. C.A. Shonis' and T.G. Waldrop. Department of Physiology & Biophysics, College of Medicine, University of Illinois, Urbana, IL 61801.

A GABAergic input onto caudal hypothalamic neurons modulates basal respiratory drive and several cardiorespiratory reflexes. Recent studies from this laboratory have shown that neurons in this same hypothalamic region are stimulated by hypoxia in vivo and in vitro. The purpose of the present study was to determine if caudal hypothalamic neurons that are stimulated by hypoxia are also inhibited by GABA. Extracellular single unit recordings of hypothalamic activity were performed in a rat brain slice preparation; brain slices (400 µm thick) were placed in an interface chamber that was perfused with nutrient media equilibrated with 95% OJ5% CO, Neuronal responses to hypoxia (10% OJ5% COJ85% N<sub>2</sub> or 5% COJ95% N<sub>3</sub>) and to GABA (10 mM) were recorded from slices taken from both Wistar-Kyoto (WKY) and spontaneously hypertensive (SHR) rats. Hypoxia increased the discharge frequency by over 200% in >70% of the caudal hypothalamic neurons studied. Most of the neurons that were stimulated were inhibited following removal of the hypoxic stimulus. GABA depressed the discharge frequency of most (>70%) of the hypothalamic neurons that were stimulated by hypoxia. Similar results were obtained for SHR and WKY neurons. These results demonstrate that caudal hypothalamic neurons that were stimulated by hypoxia are also sensitive to GABA. Thus, GABA-sensitive neurons in the caudal hypothalamus may be involved in the cardiorespiratory responses to hypoxia in both spontaneously hypertensive and normotensive rats. (Supported by NIH 38726 and IL Affiliate-AHA).

EFFECTS OF GABAA RECEPTOR ANTAGONISTS ON THE RAPHE MAGNUS-INDUCED RESPIRATORY INHIBITION IN CATS.

M. Aoki\* and Y. Nakazono. Dept. Physiology, Sapporo Medical College, Sapporo 060, Japan

We previously reported that chemical as well as electrical stimulation of the medullary raphe magnus (NRM) induces marked depressant actions on respiratory activities in the medulla and the spinal cord in cats. In the present study, we examined the possible involvement of putative transmitters in the stimulation induced inhibition by observing the actions of receptor antagonists on the responses to stimulation of the NRM. Cats were anesthetized with pentobarbital sodium (initial dose of 30 mg/kg, i.v.) and artificially respirated. Spontaneous respiratory neuron activities and phrenic nerve discharges were maintained. Putative transmitters mediating these effects were assessed by systemic injection and iontophoretic application of various antagonists of serotonin, GABA, opiates etc. The NRM-induced respiratory inhibition was specifically blocked following injection of the GABA<sub>A</sub> receptor antagonists (picrotoxin 0.8-1.25, bicuculline 0.13-0.25 mg/kg). Iontophoretically applied picrotoxin (5 mM, 50-200 nA) and bicuculline (5 mM, 100-300 nA) significantly reduced the NRM-induced inhibition. Iontophoretic application of the GABA<sub>B</sub> receptor antagonist 2-OH saclofen (10 mM) showed little blocking action on the NRM-induced inhibition. This study provided evidence for the involvement of a GABAA receptor-mediated system responsible for the NRM-induced respiratory inhibition.

GABA-B ACTIVATED K\* CHANNELS IN CULTURED BULBOSPINAL NEURONS FROM NEONATAL RATS. P.G. Wagner, Y. Sun, and M.S. Dekin. Sch. Biological Sciences, Univ. of Kentucky, Lexington, KY 40506.

Activation of GABA-B receptors has been shown to directly inhibit the activity of medullary respiratory neurons in vivo (Lalley, Brain Res., 376:392, 1986). To determine the mechanism of action underlying this effect we have studied the properties of GABA-B activated channels in cultured bulbospinal neurons from the dorsal (DRG) and ventral (VRG) respiratory groups of the neonatal rat. Bulbospinal neurons were labeled with fluorescent latex beads injected into the phrenic motor nucleus prior to being placed in culture (Wagner and Dekin, Neurosci. Abstr., 17(1):619, 1991). Using the patch clamp technique in the cell attached configuration, bath application of the GABA-B agonist baclofen (100uM) caused the expression of outward currents in both DRG and VRG neurons. The appearance of these currents was slow in onset (> 3 minutes) and they disappeared when the patch was excised in the inside-out configuration. I-V relationships for the GABA-B activated channel were obtained in bath solutions containing 140 mM KCl to zero the membrane potential. In all cells, the I-V relationship displayed outward rectification at membrane potentials positive to -50 mV. The single channel conductance was 90.4 p8 ± 2.6 (n = 12). When the concentration of K\* in the pipette was altered, the reversal potential for these currents followed the predicted equilibrium potential for K\*. These data suggest that GABA-B receptors on DRG and VRG bulbospinal neurons are coupled to a large conductance K\* channel via a second measenger system. In addition, the outward rectification of the GABA-B activated channels suggests that they modulate the repetitive firing activity of these neurons during depolarization but have little effect on quiescent or actively inhibited neurons. (Supported by NIH grants HL40369, HL02314, and RR07114).

THYROTROPIN-RELEASING HORMONE INHIBITS GABA-B ACTIVATED K+ CHANNELS IN CULTURED BULBOSPINAL NEURONS OF THE NEONATAL RAT. M.S. Dekin, P.G. Wagner, and Y. Sun, Sch. of Biological Sciences, Univ. of Kentucky, Lexington, KY 40506

In an accompanying report, the GABA-B agonist baclofen was shown to activate a K+ conductance in cultured dorsal (DRG) and ventral (VRG) respiratory group neurons (Wagner et al., this volume). In whole animal studies it has been suggested that the neuropeptide thyrotropin-relhormone (TRH) antagonizes the respiratory depression caused by the central administration of GABA (Hedner et.al., Acta. Physiol. Scand., 117:427, 1983). It was of interest, therefore, to determine the effects of TRH on the activity of the GABA-B activated K+ channel. All recordings were done using the patch clamp technique in the cell attached configuration. An example of GABA-B activated K+ channels recorded in a DRG neuron during bath application of 100 uM baclofen is shown below (top trace). Addition of 1 uM TRH to the bath reduced the channel activity (middle trace). This effect was fully reversible upon vashout of TRH (lower trace). Channel open time probabilities were 19% in baclofen, 3% in baclofen and TRH, and 17.8% in the baclofen wash. TRH did not alter either the single channel conductance or the mean channel lifetime. These data demonstrate that TRH inhibits GABA-B

activated K+ modulating either GABA receptor OF associated second messenger system. (Supported by NIH Grants HI 40360 Scale: 3 pA, 24 ms

## 208.7

NON-NMDA NEUROTRANSMISSION IN THE MEDIAL NUCLEUS TRACTUS SOLITARIUS (mNTS) IS NOT INVOLVED IN ALL AFFERENT-EVOKED INSPIRATORY TERMINATION REFLEXES, D.R. Karius\*, L. Ling, and D.F. Speck. Dept. of Physiology, Univ. of Kentucky, Lexington, KY 40536.

Reflex termination of inspiration can be elicited by stimulation of the vagus (X), superior laryngeal (SLN), and intercostal (ICN) nerves. Neurotransmission at non-N-methyl-D-aspartate (non-NMDA) receptors in the mNTS is required in the production of the Breuer-Hering reflex in the rat, as well as the inspiratory termination produced by SLN stimulation in the cat. This study tested the hypothesis that non-NMDA neurotransmission in the mNTS of cats is required for inspiratory termination elicited by X or ICN stimulation. Adult cats were decerebrated, vagotomized, paralyzed and ventilated. One or both SLN, the right X, and a left ICN (T6-8) were cut and placed on stimulating electrodes. After recording control thresholds for eliciting inspiratory termination from each nerve, the non-NMDA antagonist DNQX (10 mM, 200-700 nl) was ejected into the mNTS. Each reflex was tested 10, 30 and 60 minutes after ejection. The inspiratory termination elicited by vagal stimulation was abolished by ejections ipsilateral to the stimulated nerve. The X-elicited termination persisted after ejections into the contralateral (left) mNTS, although the termination elicited by the left SLN was abolished. Inspiratory termination elicited by ICN stimulation persisted with no change in threshold following ipsilateral, contralateral and bilateral ejections, even though X- and SLN-evoked terminations were severely attenuated or abolished. This study indicates that non-NMDA transmission in the mNTS, although required for X- and SLN-elicited terminations, is not required for all inspiratory terminating inputs. (Supported by NIH PO1 40369).

IONIC MECHANISMS INVOLVED IN THE GENERATION AND MODULATION OF RESPIRATORY RHYTHM IN VITRO. S.M. Johnson\*, J.C. Smith, G.D. Funk, & J.L. Feldman, Systems Neurobiology Lab, Dept of Physiological Science, UCLA, Los Angeles, CA, 90024-1527

Neurons with voltage-dependent, pacemaker properties in the pre-Bötzinger Complex (preBötC) of ventral medulla, have been proposed to be the kernel of the respiratory oscillator (*Science* 254 '91). To test for

Bötzinger Complex (preBötC) of ventral medulla, have been proposed to be the kernel of the respiratory oscillator (Science 254 '91). To test for involvement of cationic conductances in respiratory rhythm generation, ion channel blockers and neuromodulators were applied to rhythmically active medullary slices of neonatal rats Perturbations of the rhythm in the slice were analyzed from whole-cell recordings of respiratory neurons and recordings of oscillatory motor output.

Increasing concentrations of K<sup>+</sup> channel blockers in the bath solution increased the frequency of rhythmic motor discharge, eventually disrupting the rhythm. In contrast, activation of neurotransmitter receptors (5HT<sub>1</sub>A, GABAB, and c<sub>2</sub> adrenergic) known to be coupled to K<sup>+</sup> conductances (via G-proteins) reduced the discharge frequency; prior application of blockers of inward rectifying K<sup>+</sup> conductances prevented these effects. In the preBötC, respiratory pacemaker neurons received excitatory synaptic drive and exhibited 10-20 mV membrane potential oscillations that increased in frequency with depolarization. These oscillations had a rapid upstroke, a slowly declining plateau-like potential upon which action potentials were either expressed or shunted, and a rapid repolarization to resting potential.

These data suggest that in preBötC cells: (i) An inward-rectifying K<sup>+</sup> conductance potentially coupled to the G-protein second messenger system in part sets the baseline membrane potential and bursting frequency (ii) A strong, slowly inactivating cationic conductance provides the major inward current during the depolarization phase. Support: HL02204 & HL40959 (ICS); HL08524 (SMI).

NMDA RECEPTOR BLOCKADE AT THE VENTROLATERAL SUBNUCLEUS OF THE NUCLEUS TRACTUS SOLITARIUS (VLNTS) PRODUCES IN-SPIRATORY APNEA. I. Berger, W.H. Panico, J. McManigle, W. Norman, S. Vitagliano, P. Hamosh, K.L. Dretchen\*, R.A. Gillis and A.M. Taveira da Silva. Georgetown University, Washington, D.C. 20007.

Our purpose was to determine whether blockade of excitatory amino acid (EAA) transmission at the VLNTS affects respiratory activity. Studies were conducted in chloralose anesthetized cats while monitoring respiratory minute volume(VE), tidal volume, respiratory rate inspiratory time(Ti), expiratory time and end-tidal CO2(FECO2). Bilateral microinjections (coordinates:-1.2R;2.6L;1.7D) of the N-methyl-D aspartate (NMDA) receptor antagonist CPP (2.25nM; N=8) produced significant increases in Ti  $(+4.1\pm1.6 \text{ sec}, P<0.05)$  and FECO2 $(+1.3\pm0.2\%, P<0.05)$  and decreases in VE $(-75\pm14\text{ml}/\text{min}, P<0.05)$ and  $F(-3.5\pm0.7 \text{ breaths/min}, P<0.05)$ . Appendix breathing and inspiratory apnea ranging from 15 to 80 seconds were seen in all cats. Microinjection of the NMDA receptor antagonist AP-7 (225nM; N=3) into the VLNTS also produced apneustic breathing and inspiratory apnea. Microinjections of the non-NMDA receptor antagonist CNQX (0.05nM;N=3) had no effect on respiratory activity. We conclude that an endogenous EAA at the VLNTS acting at NMDA receptors plays an important role in breathing.

SYNERGISTIC ROLES FOR NMDA AND NON-NMDA RECEPTORS IN BRAINSTEM RESPIRATORY CONTROL IN ADULT RATS. C.A. Connelly\* and J.L. Feldman. Systems Neurobiology Laboratory, Dept. of Physiological Science, UCLA, Los Angeles, CA 90024-1527.

biology Laboratory, Dept. of Physiological Sciencé, UCLA, Los Angeles, CA 90024-1527.

Effects of NMDA and non-NMDA excitatory amino acid (EAA) receptor antagonists on the generation and transmission of central respiratory drive were examined in anesthetized adult Wistar rats. Respiratory-modulated neuronal impulses from Bötzinger (Böt), pre-Bötzinger (preBöt) and rostral ventral respiratory group (rVRG) neurons were recorded extracellularly with single or multibarrel electrodes also used to microinject antagonists to non-NMDA (CNQX, 1mM in saline) or NMDA (CPP, 1mM in saline) receptors. Diaphragm electromyogram activity was recorded to monitor respiration. Bilateral microinjection of CNQX (18-54 pmol/side) into brainstem sites containing inspiratory-modulated preBöt and/or rVRG neurons increased the rate of spontaneous breathing in 5/8 rats. Concomitant with these increases, inspiratory timing and burst amplitude became variable in 4 rats. Apnea occurred in 6/7 rats when CNQX microinjection in these regions was combined with systemic MK-801 administration (0.5-1.0 mg/kg) to block NMDA channels. When MK-801 was not administered, bilateral microinjection of both types of EAA receptor antagonists (CPP and CNQX, 18 pmol/ea) into rVRG and/or preBöt markedly perturbed respiratory pattern and timing in 6 rats. Within 1-5 minutes, 5 of these rats developed apnea which lasted 1/2 to 2 hours; arterial pressure was unaffected. Although antagonism of non-NMDA receptors in preBöt and rVRG subregions may substantially perturb the respiratory pattern, breathing is sustained unless NMDA-mediated excitatory transmission through these regions is also impaired. Research supported by NIH grant HL 37941. CAC was supported by the Parker B. Francis Foundation.

NADPH-DIAPHORASE REACTIVE NEURONS WITHIN PONTO-MEDULLARY CARDIORESPIRATORY NUCLEI OF THE RAT. H.H. Ellenberger\*, J. Groomer & J.L. Feldman, Systems Neurobiology Lab, Dept. of Physiol. Science, UCLA, Los Angeles, CA, 90024-1527

Lab, Dept. of Physiol. Science, UCLA, Los Angeles, CA, 90024-1521 We performed a neuronal labeling study to determine whether nitric oxide (NO) is utilized as a neuromessenger within cardiorespiratory regions of rat brainstem. We labeled nicotinamide adenine dinucleotide phosphate diaphorase (NADPH-dontaining neurons (Hope et al., PNAS, 88:1991). NADPH-d labeled cell somata and/or terminals were located in many regions of caudal brainstem, including portions of all reticular nuclei, somatic and visceral sensory nuclei, and cranial nerve motor nuclei. With respect to cardiovascular control, labeled cell bodies and terminal varicosities filled the rostrocaudal extent of many parts of the nucleus of the solitary tract, including commissural, dorsal, dorsomedial, medial, ventral and ventrolateral subnuclei. The dorsal motor nucleus of the vagus contained labeled ventuolateral solution to the waste month of the value contained labeled terminals and lightly labeled cell bodies. Nucleus ambiguus (NA) contained labeled terminals, especially in the rostral compact division. The intermediate reticular nucleus of the lateral tegmental field (intl.TF) was prominently labeled, with many darkly stained neurons, axons and terminals in the region extending ventrolaterally darkly stained neurons, axons and terminats in the region extending ventrolateral to NA) contained fewer, lightly stained somata and terminals. Many darkly stained neurons were located in the lateral paragigantocellular nucleus extending dorsomedially into the ventral gigantocellular nucleus in rostral medulla. Many darkly stained neurons and terminals were located within the rostral raphe obscurus. Labeled terminals formed a dense horizontal sheet ventral to the facial nucleus in Labeled terminals formed a dense horizontal sheet ventral to the facial nucleus in the region of retrotrapezoid nucleus. Labeled cell bodies and terminals were scattered within the pontine LTF and concentrated within discrete portions of lateral and medial parabrachial and Kölliker-Fuse nuclei. These results indicate that NO may be released at pre- or postsynaptic sites to act as a neuromessenger within the brainstem to modulate cardiorespiratory function. Supported by NIH Grant HL 2704.1

NITRIC OXIDE INVOLVED IN THE PONTINE RESPIRATORY FUNCTION OF CATS. L. Ling, D.R. Karius and D.F. Speck\*. Dept. of Physiology, Univ. of Kentucky, Lexington, KY 40536.

Previous studies from our laboratory demonstrated that apneusis could be produced by bilateral microinjection of MK-801 (an NMDA receptor-associated channel blocker) into the pontine respiratory group (PRG), indicating that NMDA receptors in the PRG were necessary for the pontine pneumotaxic mechanism. The close relationship between NMDA receptors and nitric oxide in the central nervous system suggests that nitric oxide production by these NMDA-sensitive neurons within the PRG may be involved in respiratory control. Ten adult cats were anesthetized, decerebrated, decerebellated, paralyzed and ventilated. Bilateral microinjection of N,-nitro-L-arginine (L-NNA, 1 mM, 200 - 600 nl, inhibitor of nitric oxide synthase) into the PRG significantly prolonged the time of inspiration (Ti) in all animals when lung inflation was withheld. Four cats showed complete apneusis after the injection. Na-nitro-Darginine (1 mM, inactive enantiomer) injections at the same sites did not change the no-inflation Ti. The effect of L-NNA on the noinflation Ti could be partially reversed by bilateral microinjection of L-arginine (10 mM, nitric oxide synthase substrate) in 3 cats. We conclude that endogenous formation of nitric oxide from L-arginine in the PRG region is involved in the normal function of the pontine pneumotaxic mechanism. (supported by NIH P01 40369)

## 208.13

EFFECTS OF MORPHINE AND STRYCHNINE ON RECIPROCAL RESPIRATORY MOTOR ACTIVITY IN THE ISOLATED FROG BRAINSTEM. N. Kimura\*, S.F. Perry and J.E. Remmers. Dept. of Medical Physiology,

Univ. of Calgary, Calgary, AB, Canada T2N 4N1.

The role of opioids and of inhibitory amino acids in respiratory control was studied in the frog, Rana pipiens, using two isolated brainstem preparations. Both were superfused with oxygenated HEPES buffer. An in vitro preparation, consisting of the brainstem alone, showed spontaneous bilateral bursting activity in the trigeminal, yagal and hypoglossal nerve rootlets. An in situ preparation, consisting of the brainstem plus the ventral half of the skull and nerve branches to respiratory muscles, showed a coordinated discharge pattern resembling the respiratory motor output reported in vivo. The sternohyoid branch of the hypoglossal nerve (Hsh) showed an augmenting discharge pattern which alternated with a short burst from the main branch (Hm). This reciprocal activity became synchronous when the preparation was exposed to 10  $\mu$ M strychnine. The laryngeal branch of the vagus nerve (X1) showed a biphasic discharge pattern, an early component commencing near the end of the Hsh burst and extending to the peak of the Hm burst, and a late component following the peak of the Hm burst. Bath application of 5 to 20  $\mu$ M morphine prolonged the interburst interval or abolished the burst discharge of the nerve rootlets. Morphine prolonged the Hsh burst duration and decreased the amplitude of Hsh and of the late component of XI, but had no obvious effect on the Hm burst. These morphine-induced effects were antagonized by 2.5 to 10  $\mu M$  naloxone. The results suggest that respiratory motor output in the frog involves strychnine-sensitive synaptic inhibition and is modified by the opioid system as in mammals. (MRC grant MA 9719 to JER)

EFFECTS OF SUBSTANCE P AND CP-96,345 ON RESPIRATORY PATTERN GENERATION IN THE IN VITRO FROG BRAIN. S.F. Perry\*, N. Kimura and J.E. Remmers. Dept. of Medical Physiology, Univ. of Calgary, Calgary AB, Canada T2N 4N1

Substance P (SP) increases the amplitude and/or frequency of neural activity related to breathing in mammalian in vitro or decerebrated in situ preparations, and the binding of SP to its NK1 receptor is effectively blocked by the nonpeptide antagonist CP-96.345. In order to investigate the role of SP in respiratory pattern generation we superfused the isolated brainstem of the leopard frog, *Rana pipiens*, with HEPES-buffered, 10<sup>-13</sup> M - 10<sup>-6</sup> M solutions of SP, NK1 antagonist or a combination of the two, while recording from the trigeminal, facial, vagal and hypoglossal cranial nerve rootlets using suction electrodes. These nerves innervate the respiratory muscles in the frog. SP reduced respiratory frequency in a dose-dependent manner from 10.9 M upward, while eliciting high-frequency, low-amplitude bursts reminiscent of buccal pumping activity during the breathing pauses. Amplitude also increased in the trigeminal but not in the vagus nerve. NK1 antagonist (from 10.9M upward) applied alone tended to increase breathing frequency, but when applied together with SP, failed to completely block the frequency-reducing effects and low-amplitude activity caused by the latter. We conclude that the effect of SP on the frequency of respiratory activity in the frog brainstem preparation is opposite to that reported for mammalian preparations. SP thus appears to be an important neuromodulator but is not essential for central respiratory pattern generation in tetrapods. This research was supported by MRC grant MA 9719 to JER.

INHIBITION OF PROTEIN SYNTHESIS ATTENUATES THE FEVER INDUCED BY HYPOTHALAMIC MACROPHAGE INFLAMMATORY PROTEIN-1. W.M. Zawada, R.D. Myers, W.D. Ruwe\*. Dept. Physiol. & Biophys., Univ. of Arkansas for Med. Sci., Little Rock, AR 72205 and Dept. Pharmacology., East Carolina Univ. Sch. Med., Greenville, NC 27858.

Macrophage inflammatory protein-1 (MIP-1), a novel cytokine composed of  $\alpha/\beta$  subunits, is released from macrophages during infection. When injected IV in rabbits and into the anterior hypothalamic preoptic area in rats, MIP-1 causes an intense fever which is not blocked by indomethacin. The purpose of this study was to determine sensitivity of ventral septal area (VSA) to MIP-1 and the role of protein synthesis in the MIP-1 fever. Guide cannulae were implanted bilaterally above the VSA and medially above the 3rd ventricle in male Sprague Dawley rats. Bilateral microinjections into the VSA of MIP-1 in a dose of 14pg/0.5µl per site caused a biphasic elevation in core temperatures (T<sub>2</sub>) to micronjections into the VSA of MIP-1 in a dose of 14pg/0.3 $\mu$  per site caused a biphasic elevation in core temperatures (T<sub>o</sub>) to  $0.9\pm0.2^{\circ}$ C within 1 hr and to  $1.5\pm0.2^{\circ}$ C in 3 hrs which persisted for over 6 hrs. The infusion of  $80\mu g/10\mu$ l of an inhibitor of protein synthesis, anisomycin (ANI), into the 3rd ventricle either 10 or 30 min before the microinjections of MIP-1 attenuated significantly the rise in T<sub>o</sub> for 1 to 3 hrs. These results coincide with the findings that ANI inhibits both endotoxin- and IL-18 induced fevers. Further, synthesis of new protein factor(s) may be requisite for the induction and maintenance of a nonrequisite for the induction and maintenance of a non-cyclooxygenase fever. [Supported in part by NIH NS26045 and cyclooxygenase fever. NSF IBN-91-21656].

RELEASE OF AVP IN THE VSA OF 1 KIDNEY - 1 CLIP GOLDBLATT HYPERTENSIVE RATS. M.L. Earle, T. Horn, R. Landgraf & Q.J. Pittman, Medical Physiology & Neuroscience Research Group, University of Calgary, Calgary, Alberta, CANADA. & Section of Biosciences, University of Leipzig, Leipzig, GERMANY

Release of the peptide arginine vasopressin (AVP) within the ventral septal area (VSA) is inversely correlated to fever height. 1K-1C Goldblatt hypertensive rats display reduced fevers, and in the present study we have tested the hypothesis that this is due, in part to an overactive AVP system. We have therefore measured AVP release in the VSA during the development and maintenance of hypertension. Using male Sprague-Dawley rats (80-100g), following an initial baseline blood pressure recording (using tail-cuff plethysmography), the 1K-1C surgery or sham surgery was performed. In addition, guide cannulae were implanted for push-pull perfusions in the VSA and for icv injections of PGE1. Either 4 or 18 days following this surgery, the blood pressures were taken after which the animals were anaesthetized with urethane, rectal temperature was measured and push-pull perfusates of the VSA were collected before and after icv injection of PGE1 (50 or 100 ng) or vehicle, at 30 minute intervals. The perfusate was then lyophilized and the AVP content measured using a specific radioimmunoassay. We found the level of fever produced in the 1K-1C hypertensive rats to be significantly (p<0.05) lower than that produced in the normotensive rats (n≥9) at both day 4 and 18. However, neither baseline levels nor PGE1 stimulated release of AVP in the VSA differed between normotensive and hypertensive animals. Supported by Alberta Heart & Stroke Foundation & NATO Collaborative Research Grant.

TEMPERATURE RESPONSES OF MICE TO ENDOTOXIN OR POLY-INOSINIC:POLYCYTIDYLIC ACID. W. Kozak, C. A. Conn. and M.J. Kluger\*, Department of Physiology, Univ. of Michigan Medical School, Ann Arbor, MI 48109.

There are reports that mice, in contrast to other laboratory species, are not capable of developing fevers after injection of endotoxin (LPS) or polycytidylic:polyinosinic nucleotide (Polyi-C).
However, it has been shown that murine cells stimulated with LPS ex vivo" can produce cytokines known as endogenous pyrogens in other mammals.

When body temperature (Tb) and activity (Act) were measured using blotelemetry, unrestrained male Swiss Webster mice kept at 31  $\pm$  1°C ambient temperature responded with fever, accompanied with decreased activity, to ip Injection of 2.5 mg/kg LPS. Injection of LPS in mice was followed by a fall in body temperature (ΔTmax - 0.87± 0.14°C) lasting for 3 h, and Tb reached a peak after 24 h of LPS injection (△Tmax +2.04±0.11°C). The mice recovered to normal circadian rhythm of Act and Tb within 48 h of injection. In contrast, injection of Poly I:C (2.5 mg/kg, ip) led to a fall in Tb of -1.89 ±0.16°C, which was of similar magnitude to that seen during

±0.16°C, which was of similar magnitude to that seen during influenza infection, with no ensuing fever. Indomethacin (5 mg/kg), which had no effect on Tb in control mice, blocked LPS fever, and resuited in a prolonged, magnified post-injection fall in Tb. Antiserum against mouse tumor necrosis factor (TNF) significantly enhanced LPS-induced fever and inhibited the initial fall in Tb. These data are consistent with the hypothesis that rodents can produce cryogens that may limit the magnitude of Tb increase during fever, and TNF may play a role in this negative feedback. BIPHASIC THERMAL RESPONSE TO CLONIDINE (CLO) MICROINJECTED INTO THE PREOPTIC AREA (iPOA): DIFFERENT GENESIS OF THE TWO PHASES. A. A. Romanovsky, O. Shido, A. L. Ungar, and C. M. Blatteis\*. Dept. of Physiology and Biophysics, Univ. of Tennessee, Memphis, TN 38163.

The iPOA microinjection (µinj) of agents often causes local injury, inducing prostaglandin (PG)-mediated core temperature (T<sub>C</sub>) rises. However, the iPOA print of the response CLO capacityle workers. The Tall. To

The IPOA microinjection (Linj) of agents often causes local injury, inducing prostaglandin (PG)-mediated core temperature ( $T_c$ ) rises. However, the iPOA µinj of the  $\alpha_2$ -agonist CLO generally evokes a  $T_c$  fall. To study the contribution to this response of an unavoidable traumatic injury, we implanted cannulas iPOA into guinea pigs and, 7 days later, measured their  $T_c$  during 7 h without treatment (time-control) or 2 h before and 5 h after the bilateral µinj (in 1 µl of pyrogen-free saline [PFS]) of: (a) CLO (0, 0.5, 1.5 or 5 µg); (b) CLO (0.5 µg) 20 min prior to the PG synthase blocker indomethacin (INDO, 0 or 10 mg/kg in 0.1 ml of PFS, im); or (c) the  $\alpha_2$ -antagonist rauwolszine (RAU, 0 or 1 µg) 10 min prior to CLO (0.5 µg). The  $T_{ambient}$  was  $23^{\circ}$ C. Compared with the time-control (no significant change in  $T_c$ ), the iPOA µinj of CLO caused a biphasic hypo/hyperthermic response. Both the magnitude and the duration of the initial  $T_c$  fall were dose-dependent:  $-0.4 \pm 0.1^{\circ}$ C and 60 min for 0.5 µg;  $-0.9 \pm 0.1^{\circ}$ C and 70 min for 1.5 µg; and  $-1.2 \pm 0.1^{\circ}$ C and 90 min for 5 µg. During the second phase of the response,  $T_c$  increased to a dose-independent level (1.0-1.5°C) where it remained until the end of the experiment PFS produced a gradual  $T_c$  rise from the outset. The hypothermic phase was completely blocked by RAU, while the hyperthermic phase was significantly attenuated by INDO, but insensitive to RAU. These results confirm our earlier conclusion that the thermal response to the iPOA µinj of an agent, whether hyper- or hypothermizing, is contaminated by an artifactiagent, whether hyper- or hypothermizing, is contaminated by an artifactitious, PG-mediated, T<sub>c</sub> rise consequent to nonspecific brain tissue injury. SYNAPTIC INTERACTIONS OF HYPOTHALAMIC TEMPERATURE SENSITIVE AND INSENSITIVE NEURONS John D. Griffin\* and Jack A. Boulant. Department of Physiology, Ohio State University, Columbus, OH 43210.

The rostral hypothalamus is important in thermoregulation and contains both temperature sensitive and temperature insensitive neurons. Studies indicate that hypothalamic warm sensitive neurons are intrinsically thermosensitive; but, little is known about synaptic interactions within local neuronal networks. To study these interactions, whole-cell recordings were made of neuronal intracellular activity in rat hypothalamic tissue slices. The frequencies of action potentials and postsynaptic potentials (i.e., EPSPs and IPSPs) were recorded during changes in tissue temperature. warm sensitive and temperature insensitive neurons display very different dendritic morphologies, both types of neurons receive excitatory and inhibitory synaptic inputs. Moreover, the predominent synaptic inputs come from temperature insensitive neurons, suggesting that warm sensitive neurons primarily affect cells outside of this local neuronal network. (Support by NIH NS14644; NS07291; Am. Heart, Ohio.)

IMPAIRED BARORECEPTOR RESPONSES AND FEVER. Y.Takahashi, W.L. Veale\* Neuroscience Research Group, University of Q.J.Pittman, Calgary, Calgary, Alberta, CANADA.

Recent studies indicate a possible interaction between fever and cardiovascular Electrolytic lesions of the rat NTS (the site of baroreceptor reduced endotoxin fever. In the present study baroreceptor afferents in the Aortic Depressor Nerve (ADN) and Carotid Sinus Nerve (CSN) were severed to determine whether these may play a role in fever regulation in the adult rat. Bilateral ADN, CSN transections and sham surgeries were performed on male Sprague-Dawley rats. Intracerebroventricular and intravenous cannulae and temperature telemetry devices were also implanted. Following a 2 week recovery, groups of rats (n=7) were given icv injections of PGE<sub>1</sub> (75 & 150 ng), icv IL-18 (24 units) or iv injections of E.coli endotoxin (50 ug/kg) and fever responses were monitored. At the end of the experiment baroreceptor denervation was confirmed by testing rats under urethane anesthesia for their cardiovascular responses to iv phenylephrine and nitroprusside. All denervated rats displayed <20 bpm change in heart rate in responses to >75mmHg alterations in blood pressure.

Statistical analysis (2-way Anova for repeated measures) showed no significant difference between control and denervated rats in febrile responses to 75 ng denervated rats than in controls. Therefore it appears that functional baroreceptor denervation does not necessarily interfere with the development of fever in rats

HYPOTHALAMIC NEURONAL NETWORKS FOR THERMOREGULATORY VASCMOTOR CONTROL, K.Kanosue\*, M.Yanase-Fujiwara and T.Hosono. Dept. of Physiol., Dept. of Obst. & Gynecol., Osaka Univ. Med. Sch., Suita, Osaka 565, Japan. Warming of one side of a rat's preoptic area and ante-

rior hypothalamus (POAH) causes skin vasodilation on both sides of the body. The present study evaluated the extent to which signals from POAH thermosensitive sites cross the midline within and below the POAH. Hind-paw vasomotor responses to unilateral POAH warming were measured for ure-thane anesthetized (1.2g/kg, i.p.) rats in which the POAH had been midsagittally transected and for rats in which one side of the hypothalamus had been coronally transected just below the POAH. Unilateral POAH warming produced bi-lateral paw vasodilation in midsaggittaly transected rats but the ipsilateral dilation occurred at lower threshold. Unilateral POAH warming usually produced bilateral vasodi-lation in unilaterally transected rats and the threshold stimulus temperature eliciting vasodilation was always lower for the paw of the intact side regardless of which side of the POAH was warmed. These results show that information controlling thermoregulatory vasomotion crosses the midline both inside and outside the POAH. Furthermore, local unilateral transection of the medial forbrain bundle (MFB) had the same effect as the unilateral transection of the whole hypothalamus, while the transection medial to the MFB had no effect. Vasomotor signal from the POAH would descend through the MFB.

EXPRESSION OF C-FOS IN THE RAT HYPOTHALAMUS AFTER

EXPRESSION OF C-FOS IN THE RAT HYPOTHALAMUS AFTER THERMAL AND FLUID CHALLENGES. P.A. MASON\*. L.K. WEIGEL\*, G.A. MICKLEY\*, B.L. COBB\* AND N. MIRRO\*. Operational Technologies, Department. of Biology, Trinity University, Nadiofrequency Radiation Branch (OEDR), Armstrong Laboratory, Brooks AFB, TX 78235-5301, Systems Research Laboratories.

Expression of the immediate-early gene C-fos occurs in response to a variety of stressors. Thermal stress was delivered by exposing rats to a 600 MHz electromagnetic field (SAR = 10 W/kg) for 20 min. Since thermal challenges may produce changes in blood flow and blood chemistry, we attempted to mimic such alterations using intra- and extracellular dehydration. Rats were water restricted for 48 hr or intraperitoneally injected with 35% polyethylene glycol (PEG)/0.7% NaCl, 35% PEG/4% NaCl or 4% NaCl. C-fos was expressed throughout the hypothalamus in response to the electromagnetic field. Water restriction produced C-fos expression in the periventricular nucleus. PEG produced C-fos expression in the paraventricular nucleus whereas C-fos was expressed in the supraoptic nucleus in response to 4% NaCl. The combination of PEG and 4% NaCl produced C-fos expression in both the paraventricular nucleus and the supraoptic nucleus. Results indicate that there is selective regional expression of the C-fos protein within the hypothalamus in response to these stressors.

ELECTRICAL STIMULATION OF THE POSTERIOR HYPOTHALAMUS OF ANESTHETIZED RATS KEPT AT 37°C EVOKES SUSTAINED SHIVERING TO INCREASE CORE TEMPERATURE.

I. Halvorson and J.A. Thornhill', Dept. of Physiology, Univ. of Saskatchewan, Saskatoon, Sask., Canada, S7N 0W0.

Experiments were conducted to determine if sustained shivering could be induced by electrical stimulation of the CNS (i.e. posterior hypothalamus, PH) in anesthetized rats kept at 37°C as normally occurs with cold cutaneous stimulation. Male Long Evans rats, anesthetized with urethane (1.5 g/kg ip) were instrumented with an indwelling femoral arterial catheter (blood pressure, heart rate monitored), bipolar needle recording electrodes into the gastronemius muscle (differential EMG changes), thermistor probes for monitoring colonic (core), surface (tail), subcutaneous (abdominal) and gastronemius muscle temperatures, and an insulated stimulating monopolar pin electrode advanced towards the PH (for electrical stimulating of this locus using 0.5 msec pulses of 50 Hz for 30 sec, using currents of 100-300 µA). For the first time it was demonstrated that electrical stimulation of the PH can evoke sustained, current-related increases in EMG electrical activity (shivering) in the gastronemius muscle, immediate graded increases in gastronemius muscle, immediate graded increases in gastronemius muscle temperature which caused subsequent increases in core temperatures, responses all similar to cold cutaneous stimulation also applied to these animals.

EFFECTS OF SUSTAINED COLD EXPOSURE ON PLASMA LEVELS OF TSH AND CORTICOSTERONE IN AGED 344/N FISCHER RATS. G. Cizza, K. Fukuhara, R. Kvetnansky, A. Moazzez, M.A. Kling\*, G.P. Chrousos, and P.W. Gold, National Institutes of Health, Bethesda, MD, 20892.

The hypothalamic-pituitary-adrenal (HPA) axis is traditionally considered to be the

The hypothalamic-pituitary-adrenal (HPA) axis is traditionally considered to be the neuroendocrine system most responsive to stressful stimuli, while the hypothalamic-pituitary-thyroid (HPT) axis is thought to be much less responsive to external stimuli. However, cold exposure is well-known to activate the HPT axis, though its effects of cold exposure on both HPT and HPA function. Because we have shown that aged rats demonstrate both a central hypothyroidism and hypoadrenalism, we also explored the effects of aging and cold-stress mediated changes in HPA and HPT function. To accomplish these tasks, 3-4 month (mo) and 24 mo old 344/N Fischer rats (344/N) effects of aging and colo-stress mediated changes in HPA and HP1 function. 10 accomplish these tasks, 3.4 month (mo) and 24 mo old 344NN fischer rats (344NN) (6-7 animals each group) were exposed at 10:00 hr for 24 hr to 40°C or room temperature. Blood was collected by tail artery cannulae at times -15′, 30′, 2, 4, 8, 12, and 24 hr, and immediately replaced with saline. Plasma was assayed by RIA for thyroid-stimulating hormone (TSH), and corticosterone (B). Basal TSH and B plasma levels were not different between age groups. Cold exposure significantly increased TSH plasma levels (p < 0.0001 by ANOVA followed by Scheffe test) in both age groups but more in younger animals. B levels were only subtly increased by cold stress in both young and old animals (ANOVA p < 0.1; t test at 30′ time-point corrected by Bonferroni: young p <0.007, old p < 0.07), with older animals showing the greater but more variable response. We conclude that cold-stress activates the HPT axis more robustly than the HPA axis in the rat. The lack of a profound cold-stress effect on the HPA axis could reflect the known capacity of cold to inhibit the ACTH secretagogue, vasopressin, a peptide that ordinarily lowers body temperature. The attenuated plasma TSH responses to cold-stress in older rats are compatible with their known centrally-mediated hypothyroidism; similarly, their exaggerated B responses to cold-stress are compatible with our previous data showing that, in the context of central adrenal insufficiency, the resultant hypocorticosteronism promotoes disinhibition of pituitary-adrenal responses to centrally-acting stressors despite a relative CRH deficiency.

CONDITIONING REVERSES NOREPINEPHRINE -INDUCED HYPOTHERMIA IN THE COLD. C. Chancellor-Freeland\* E. Sohn, and A. Ettenberg. University of California, Santa Barbara, Santa Barbara, CA 93117 Research in our laboratory has demonstrated that while acute

norepinephrine produces hypothermia when administered in cold environmental temperatures, repeated injections produce an attenuation of this response. The present study examines the potential role of Pavlovian conditioning in the repeatexposure effect of norepinephrine on body temperature. Male albino rats were used in a four day conditioning paradigm. For days 1-3, nine rats received i.p. administration of norepinephrine (100 ug/kg) in the test environment (5°C), norepinephrine (100 ug/kg) in the test environment (5°C), followed by a saline injection in the home cage (23°C). A second group was injected with saline in the test environment, followed by norepinephrine in the home cage. On day 4, both groups received the drug challenge in the test environment. Colonic temperature measurements revealed a mild hyperthermic response in the norepinephrine-test environment group. In contrast, animals with previous norepinephrine-home cage pairings exhibit hypothermia, despite identical handling, cold exposure, and number of injections. These data suggest that the norepinephrine-induced hyperthermia observed in the cold environments, is at least in part related to Payloyan conditioning. part related to Pavlovian conditioning.

IN VITRO THERMOSENSITIVITY AND C-Fos IMMUNOREACTIVITY OF RAT NUCLEUS REUNIENS NEURONS. K.A. Travis\*,
A.M. Zardetto-Smith, M.Z. Cicha, H.J. Bockholt and
A.K. Johnson. Depts. of Psychology and Pharmacology. The University of Iowa, Iowa City, IA 52242.

Functional studies suggest that the nucleus reuniens of the thalamus (Re) may receive temperature information and serve as a site of integration of peripheral sensory information. <u>In vivo</u> c-Fos immunoreactivity (c-Fos IR) is increased in Re following noxious peripheral heat stimuli (Bullitt, <u>J. Compar Neurol.</u> 296:517-530, 1990).

<u>In vitro</u> neuronal activity was recorded from Re neurons

in horizontal tissue slices (350-400 um) of male Sprague Dawley rats exposed to a change in perfusate temperature  $(32-42^{\circ}C)$ . A separate group of tissue slices (n=24) were evaluated for induction of c-Fos IR in Re in response to a heat stimulus (40-41°C; 10-20 min).

Of the Re neurons tested for thermosensitivity (n=52): 21.2% were warm sensitive, 1.9% were cold sensitive and 21.2% were warm sensitive, 1.9% were cold sensitive and 76.9% were temperature insensitive. Compared to control tissue slices (incubated 120 min, 37°C), moderate to heavy c-Fos IR was visualized in the Re, posterior hypothalamus and median preoptic nucleus of the hypothalamus in tissue slices exposed to the heat stimulus.

The single unit responses and the induction of c-Fos IR in the Re in the slice preparation following temperature changes indicate that Re is part of a circuit integrating thermal information. (Supported by F32HL08442)

EFFECTS OF SERCTONIN ON SIGNAL TRANSMISSION IN HIBERNATING AND COLD-ACCLIMATED HAMSTER HIPPOCAMPAL SLICES. Horrigan and J. M. Horowitz. Dept. of Animal Physiology, Univ. of Calif. Davis, CA 95616.

Previously, the temperature dependence of serotonergic modulation of CA1 pyramidal cells in response to Schaffer

collateral stimulation has been described in euthermic animals. Here the response from cold-acclimated and hibernating hamsters is examined. Population spike amplitude was measured before, during and after bath administration of 10  $\mu$ M 5-HT at a bath temperature of 20 $^{\circ}$ C (J. Comp. Physiol. A. 167:79-88, 1990). In slices from cold-acclimated hamsters, 5-HT reduced population spike amplitude by 54% (n=5), and in slices from hibernating hamsters this modulatory inhibition was also present -spike amplitude was depressed 81% (n=9). This initial inhibition, seen immediately following application of 5-HT, is blocked by spiperone, a 5-HT<sub>1A</sub> receptor antagonist. Serotonin binding to a second receptor type (possibly a 5-HT<sub>4</sub> receptor) enhances the population spike amplitude seen as a rebound in spike amplitude after 5-HT is removed from the bath. In slices from cold-acclimated animals the rebound was a 13% (n=3) enchancement over control amplitudes, and in slices from hibernating animals the overshoot was 19% (n=7). Thus, at 20°C 5-HT remains fully effective as a robust neuromodulator of hippocampal neural activity in slices from cold-acclimated and hibernating animals. [NASA grant NAGW-1458].

THERMOREGULATORY DYSFUNCTION IN RATS EXPOSED TO ACTIVITY-STRESS. N.S. Morrow\*, P.J., Geiselman, G. Ohning, and D. Novin, Depts. of Psychiatry, Psychology, UCLA, Los Angeles, CA 90024, CURE, West Los Angeles Veterans Administration Center, Los Angeles, CA 90073, & Dept. of Psychology, Louisiana State Univ., Baton Rouge, LA 70803.

Using telemetric monitoring, the relationship between core body temperature.

Using telemetric monitoring, the relationship between core body temperature, wheel running and gastric erosion formation was examined in female rats housed in activity cages. Rats were sacrificed when body temperature fell to 35.0°C or 30.0°C. A third group was rewarmed with a heat lamp when body temperature dropped to 35.0°C. Group differences in CNS localization of thyrotropinreleasing hormone were also examined. Results indicated that the extent of thermoregulatory disturbances on Day 1 of deprivation was predictive of length of survival. Rewarming the animals significantly extended survival time and attenuated erosion formation. Thermoregulatory disturbances appear to underlie the development of excessive wheel running and gastric ulceration (NIMH Fellowship 5T32MH17140, NSF BNS-9196142, and UCLA Univ. Research Grant SF86).

THERMAL STRESSORS PRODUCE NON-UNIFORM BRAIN TEMPERATURE GRADIENTS AND ALTERATIONS IN LOCAL CEREBRAL GLUCOSE UTILIZATION (LCGU).G.A. Mickley\*1, B.L. Cobb¹, C.D. Rose² and S.T. Farrell¹. ¹Armstrong Laboratory, Brooks AFB, TX 78235; ²Trinity University, San Antonio, TX 78235

and S.I. Farrell. 'Armstrong Laboratory, Brooks AFB, IX 78235; ZTrinity University, San Antonio, TX 78235

Last year (Cobb et al., Soc. Neurosci. Abstr., 17/2, 1991, 1460) we reported that certain brain nuclei (e.g., lateral hypothalamus) exhibit significantly different LCGUs depending on the hyperthermic agent (hot-moist air or 5.6 GHz microwaves) used to produce a cephalic temperature rise. After midbrain temperature was raised 2°C, we used the 2-Deoxyglucose method (Sokoloff et al., Neurochem., 28, 1977, 897-916) to determine rat LCGU during a 45-minute period of stable hyperthermia. Here, we extend these studies by determining precise local temperatures present in brain structures with either similar (e.g., caudate putamen), or dissimilar (e.g., hypothalamus) LCGUs during exposure to microwaves or hot air. As before, both hyperthermic treatment groups produced similar midbrain and tympanic temperatures. Further, we determined that both hyperthermic methods produced similar hypothalamic and caudate temperatures during the time period of stable hyperthermia when LCGUs were measured. However, microwaves caused a more-rapid rise in the temperature of both caudate and hypothalamus than did hot air exposure. These data suggest that stable differences in local brain temperature may not fully explain the disparity between microwave and hot-air-induced LCGUs. Instead, this difference in LCGUs may be influenced by local temperatures that increase at dissimilar rates or by a variety of inputs from non-uniformly heated afferents.

CALCITONIN GENE-RELATED PEPTIDE AND SUBSTANCE P IMMUNOREACTIVE NERVE FIBERS IN THE DURA MATER OF CAT AND RAT: AN IMMUNOELECTRON MICROSCOPIC STUDY U. Hanesch, K. Meßlinger, M. Baumgärtel, R.F. Schmidt\*

U. Hanesch, K. Meßlinger, M. Baumgärtel, R.F. Schmidt\*
Dept. of Physiology, University of Würzburg, D-8700 Würzburg, FRG
The durae mater encephali of the rat and the cat are richly innervated
by calcitonin gene-related peptide (CGRP) and substance P (SP) immunoreactive nerve fibers that originate mainly in the ipsilateral trigeminal
ganglion. Part of them may participate in nociception and generation of
headaches. To characterize the putative sensory nerve endings morphologically, whole mount preparations of the dura mater were processed
immunocytochemically for light microscopic and ultrastructural exami-

In rat and cat CGRP- and SP-immunopositive nerve fibers formed a dense network around dural blood vessels. However, a considerable number of the peptidergic nerve fibers terminate in the dural connective tissue with complex tree-like endings. In both species CGRP immunoreactive nerve fibers were found much more abundant than SP-positive fibers. In the cat, however, the dura mater generally showed less immunoreactive nerve fibers. Electron microscope immunolabelling revealed that CGRP and SP immunoreactivity is mainly found in thin unmyelinated nerve fibers located at blood vessels and within dense collageneous tissue.

The data show that small diameter unmyelinated nerve fibers of the supratentorial dura mater, a part of which is SP and CGRP immunoreactive, innervate blood vessels but also cross the dense connective tissue terminating in free endings far away from vessels. The peptidergic nerve fibers in both locations may be involved in neurogenic inflammation.

PELVIC AND NON-PELVIC INNERVATION OF MALE RAT PUDENDAL NERVE. Pacheco, P.\*; R.A.Lucio; J.Manzo; M.Martínez-Gómez; P.Carrillo and M.A.Camacho. Depto.Fis.IIB-UNAM; Inst. Neuro-Etología, Univ. Veracruzana: CIPA Univ. Autón Tlaycala Mévico.

Veracruzana; ITB-UNAM; INST. Neuro-Etologia, Univ. Veracruzana; CIRA, Univ. Autón. Tlaxcala. México.

The L6-S1 trunk forms two major nerves, pelvic and pudendal (PN). The PN gives off branches to: coccygeus muscle (CB); penis (DPN); scrotal and tail base skin (SAB); and the anastomotic branch that constitutes a bridge-like structure which forms part of the sacral plexus. From the bridge emerges branches to: obturator muscle (OB); penile muscles (MB); scrotal basal skin (SBB); and semitendinosus muscle (StB). CB, OB, MB and StB electrical stimulation produces contraction of respective muscles. Scrotal basal skin activates SBB, while scrotal apical and tail base skin activates SAB. Stimulation of penis and prepuce evokes DPN activity. Through the anastomotic branch PN evokes obturator and penile muscles contraction and flexion of the third foot finger. CONCLUSIONS: PN is compound of fibers that travel through sciatic nerve (third foot finger); sacral plexus (basal scrotum, penile and obturator muscles); and its own branches to coccygeus muscle, penis and prepuce (dorsal penile nerve) and apical scrotum.

ORIGIN AND PATHWAY OF PENILE CALCITONIN GENE-RELATED PEPTIDE (CGRP)-IMMUNOREACTIVE (-I) AFFERENT NERVES. C.H. Harris, W.G. Dail, R.E. Papka, J.G. Wood, N.E. Traugh, and D.L. McNeill. Dept. Anat. Sci., Univ. Okla., Okla. City, OK 73190 & Dept. Anat., Univ. New Mexico Sch. Med., Albuquerque, NM 87131.

The penis receives an abundant innervation by CGRP-I primary afferent nerve

The penis receives an abundant innervation by CGRP-I primary afferent nerve fibers. In this study, the location of penile CGRP-I afferent perikarya and the pathway by which CGRP-I fibers reach the penis were examined in male Sprague-Dawley rats. To identify perikarya, the retrograde tracer fluorogold (FG) was injected into the dorsum of the penis. Ten days post-injection, rats were perfused and the L4-S2 dorsal root ganglia (DRG) were removed, sectioned and immunostained for CGRP. To identify pathways of CGRP-I nerve fibers, rats received either a bilateral transection of the hypogastric nerves, pelvic splanchnic nerves or pudendal nerves. Ten days later, penises were removed and immunostained for CGRP. Additional rats received a transection of the left pudendal nerve followed immediately by an injection of FG into the penis. Following a 10 day survival, the L4-S2 DRG were removed, sectioned and immunostained for CGRP. FG-labeled perikarya were confined to the L6 DRG and approximately 40% of FG-labeled perikarya were CGRP-I. No diminution of CGRP immunostaining in the penis was observed following transections of the hypogastric or pelvic splanchnic nerves. However, CGRP immunostaining in the penis was eliminated following bilateral pudendal nerve transections. In rats receiving a transection of the left pudendal nerve and a FG injection, no labeled perikarya were present in the L6 DRG. These data suggest that the pelvic splanchnic or hypogastric nerves do not possess a CGRP-I afferent fiber component. Instead, CGRP-I fibers reach the penis primarily via the pudendal nerves and are presumably somatic in nature. Supp. by the PVA Spinal Cord Res. Fnd., OCAST and the Amer. Fnd. for Urol. Dis.

ELECTRON MICROSCOPY OF POLYMODAL RECEPTORS OF THE TESTICULAR TUNICA VASCULOSA

D. Anderson. L. Kruger T. Kumazawa¹. K. Mizumura¹ and Y. Yeh. Dept. of Anatomy and Cell Biology and the Brain Research Institute, UCLA Medical Center, Los Angeles, CA 90024. ¹The Institute of Environmental Medicine, Nagoya University, Nagoya, Japan.

Receptive fields of polymodal receptor axons were delimited by von Frey hair stimulation during sustained electrophysiological study in vitro of single units of the dorsal spermatic nerve of the dog, dominated by unmyelinated axons. The sample included A delta and C fibers, selecting for zones of low innervation when feasible and marking the surround of the receptive field with fine insect pins inserted perpendicularly through the tunica albuginea. The blocks were trimmed and embedded for serial analysis of functionally characterized endings. Most receptive fields revealed one or more Remak bundles containing several unmyelinated axons. Profiles with aggregates of dense vesicles and mitochondria as well as exattered spherical clear vesicles were common and often constituted varicosities of continuing axons. Axon terminals, identified by serial tracing, usually end at the surface of the bundle, not surrounded by Schwann cell processes but covered by basal lamina; these generally contain numerous tightly-packed clear spherical vesicles, less numerous granular vesicles, and a few dense-core vesicles with distinct halos. Free axons are rare compared with terminals at the periphery of a thin axonal bundle

extending beyond the receptive field. Supported by NIH grant NS-5685.

DISTRIBUTION OF CALBINDIN D-28K AND PARVALBUMIN-IMMUNOREACTIVE SENSORY NEURONS INNERVATING VISCERAL AND SOMATIC STRUCTURES IN THE RAT. <u>C. N. Honda\*</u> Dept. of Cell Biology and Neuroanatomy, Univ. of Minnesota, Minneapolis, MN 55455.

Calcium binding proteins have been localized to subpopulations of

neurons in both the peripheral and central nervous systems. In this study, immunohistochemical and retrograde tracing techniques were combined to compare the distribution of the calcium-binding proteins parvalbumin (PV) and calbindin-D28k (CaBP) in somatic and visceral sensory neurons.

Dorsal root ganglion (DRG) cells were retrogradely labeled by the application of Fluorogold (FG) to sural, gastrocnemius, and pelvic nerves. Adjacent pairs of DRG sections were then immunostained for PV or CaBP using a secondary antibody conjugated with cyanine 3.18 (CY3). Counts of neuronal profiles labeled singly with FG or CY3 and double-labeled with FG/CY3 were obtained from reconstructions of each DRG section examined. The distribution of calcium binding proteins localized to sensory neurons projecting through each peripheral nerve is summarized below as the percentage (range) of FG-labeled neurons immunoreactive for each calcium binding protein. Colocalization of PV and CaBP was negligible.

| Nerve (DRG)          | % PV       | % CaBP     |
|----------------------|------------|------------|
| Sural (L4-6)         | 17 (7-27)  | 24 (14-34) |
| Gastrocnemius (L4-5) | 27 (18-37) | 22 (17-26) |
| Pelvic (L6-S1)       | 0          | 23 (18-27) |

The distribution of PV and CaBP suggests that these two proteins may be differentially involved in calcium-dependent processes particular to somatic and visceral sensory neurons. Supported by NIH grant NS25658.

## 210.7

DISTRIBUTION OF SACRAL AFFERENT FIBERS IN CAT PARASYM-PATHETIC GANGLIA, URINARY BLADDER AND URETHRA. J. Krier\* and J. McRorie. Lansing, MI 48824 Dept. Physiol., Mich. State Univ.

The peripheral distribution of afferent fibers (AF) from sacral dorsal root ganglia (SDRG) to pelvic nerve (PN), pelvic plexus (PP)-urinary bladder (UB) ganglia, UB and urethra (Ur) was studied in cat with the anterograde transport of wheat germ agglutinin-horseradish peroxidase (WGA-HRP). WGA-HRP was injected into SDRG (S1-S3) bilaterally or ipsilaterally. Glutaraldehyde background fluoterally or ipsilaterally. Glutaraldehyde background fluorescence was used to visualize neuronal somas within PP and UB ganglia. When SDRG were injected ipsilaterally, anterogradely transported WGA-HRP was detected ipsilaterally in the PN and branches of the PN to the PP, but bilaterally in PP-UB ganglia. Nonvaricose AF were detected in 28 of 30 PP ganglia (n=3) and in 37 of 42 UB ganglia (n=4). Some single AF and afferent bundles were in close proximity to neurons. For UB, AF were distributed to neck, trigone, apex, anterior and posterior regions of bladder musculature. A dense innervation occurred in neck serosa. musculature. A dense innervation occurred in neck serosa, musculature. A dense innervation occurred in neck serosa, external muscle layers and in mucosa-submucosa. For Ur mucosa, AF were oriented parallel to the long axis of mucosal cells. In Ur submucosa, AF were oriented longitudinally, obliquely, and circumferentially. For Ur circular-longitudinal smooth muscle and striated muscle, AF were oriented parallel to the long axis of muscle cells. Our data show sacral AF in parasympathetic ganglia and in pelvic visceral organs. (DK-29920)

CHARACTERIZATION OF DISTENSION-SENSITIVE SACRAL PRIMARY AFFERENTS INNERVATING THE COLON OF THE RAT. G.F. Gebhart\* and J.N. Sengupta. Department of Pharmacology, The University of Iowa, Bowen Science Building, Iowa City, IA 52242.

Single-unit activity was recorded from the left S<sub>1</sub> dorsal rootlet. Eight fibers that responded to colorectal distension (CRD; 80 mmHg, 20 s) and demonstrated an evoked-response to pelvic nerve stimulation were selected for further study. Of 8 fibers, 7 had ongoing resting activity and one was silent. The mean resting activity was 9.7 ± 2.9 impulses/s. Repeated CRD (80 mmHg, 20 s) for 10 triple at 4 min intervals evoked responses that were producible trials at 4 min intervals evoked responses that were reproducible. There was no evidence of facilitation or inhibition of subsequent responses. All fibers demonstrated slow adaptation during the 20 s responses. All noers demonstrated slow adaptation during the 20 s period of distension. The stimulus-response function (SRF) to graded CRD (5 to 100 mmHg) was studied in 7 fibers, all of which demonstrated linear increases in firing. The mean maximum response of the fibers to 100 mmHg CRD was 29.4 ± 10.5 impulses/s. Three fibers were tested for response to i.a. bradykinin (BK) and all 3 responded. BK administration at a short interval (5 min) produced rapid tachyphylaxis, but tachyphylaxis to BK could be avoided if given at 20 min intervals. The concentration-response function to BK  $(0.05-300~\mu g/kg, i.a.)$  was studied in one fiber which showed maximum in response at 50  $\mu g/kg$ . The conduction velocity was measured in three fibers; two fibers were C-fibers and one was an

RESPONSES OF UTERINE RECEPTORS TO MECHANICAL AND

RESPONSES OF UTERINE RECEPTORS TO MECHANICAL AND CHEMICAL STIMULI IN THE CAT. H.C.Han<sup>1\*</sup>, S.K.Hong<sup>1</sup>, Y.W.Yoon<sup>1</sup> and J.M.Chung<sup>2</sup>. Dept. of Physiology, Med. Coll., Korea Univ., Seoul, KOREA and Marine Biomed. Inst., Depts. of Anat. & Neurosci. and of Physiol. & Biophys., Univ. Texas Med. Br., Galveston, TX, 77550, U.S.A.

This study was done to examine the sensory function of uterine afferent fibers in the cat.

Single unit recordings were made from fine filaments dissected from the hypogastric nerve in 21 cats anesthetized with α-chloralose. The mechanical stimuli were applied to the receptive field by von-Frey hair and stretching of intrauterine latex balloon. As a chemical stimulus, algesic substances (e.g. bradykinin etc.) were injected into the uterine artery. Uterine contractility was continuously monitored.

The majority of uterine afferent fibers were unmyelinated C fibers and the remaining were thinly myelinated A-δ fibers. The threshold to mechanical stimuli was variable from 0.3 g to 18 g of von Frey hair and some of the low threshold units were synchronously activated with spontaneous uterine contraction. Most of the units we tested were excited by one or more algesic chemicals and the response was accompanied by intense uterine contraction. There were some evidence indicating that at least some uterine receptors can be excited directly by these chemicals.

The results suggest that there are at least two populations of uterine receptors, low threshold mechanoreceptors and mechanical nociceptors. In addition some of them are likely polymodal receptor.

EFFECT OF DORSAL RHIZOTOMY AND MK-801 ON BLADDER AFFERENT NEURONS AND FIBERS. D.L. McNeill\*, C.H. Harris, R.L. Shew and R.E. Papka. Dept. of Anat. Sci., Univ. of Okla. Hith. Sci. Ctr., P.O. Box 26901, Oklahoma City, OK 73190

Suprasacral lesions of the spinal cord result in marked decreases in the density of calcitonin gene-related peptide (CGRP)-immunoreactive (-1) primary afferent nerve fibers in the rat bladder which is ameliorated by post-surgical treatment with the NMDA receptor antagonist MK-801. In post-surgical treatment with the NMDA receptor antagonist MK-801. In this study, the potential of MK-801 to restore bladder CGRP-I nerve fibers following a decentralizing lesion, i.e., dorsal rhizotomy (DR) was examined. In addition, the effect of DR and MK-801 on the number of CGRP-I primary afferent neurons was determined. Group 1 rats served as intact controls. Group 2 rats were anesthetized and the L6 and S1 dorsal roots were transected bilaterally. Group 3 rats underwent a similar surgery, but received a daily i.p. injection of MK-801 (1.0 mg/kg) for 14 days. On post-surgical day 14, rats were reanesthetized, the bladder and the L6 and S1 dorsal root cancilia (DRC) were removed and recogned for CCRP. post-surgical day 14, rats were reanesticized, the bladder and the Lo and SI dorsal root ganglia (DRG) were removed and processed for CGRP immunoreactivity. The density of CGRP-I nerve fibers in each bladder was quantified by image analysis. In bladders from Group 2 rats, the density of CGRP-I fibers was significantly reduced from that observed in control rats. In Group 3 rats receiving MK-801, no improvement in the density of CGRP-I nerve fibers was observed. Counts of CGRP-I neurons in the DRG were not significantly different between the 3 groups. These data suggest that decentralization by rhizotomy significantly reduces the density of peripheral CGRP immunostaining and interferes with the restorative potential of MK-801. In addition, DR with or without MK-801 failed to alter the number of primary afferent neurons expressing CGRP. Supp. by the PVA Spinal Cord Res. Found., OCAST and the Amer. Found. for Urol. Dis.

OF OXYTOCIN INTO SPINAL CORD SUPERFUSATES IN RESPONSE TO VAGINOCERVICAL STIMULATION IN RATS. J.L. Steinman\*, J.T. Winslow 1, G. Sansone, C. Gerdes, B.R. Komisaruk and T.R. Insel<sup>1</sup>, Institute of Animal Behavior, Rutgers-The State Univ., Newark, NJ 07102 and <sup>1</sup>NIMH, Laboratory of Neurophysiology, Poolesville, MD 20837

Oxytocin (OXY)-containing terminals have been identified in laminae I and X of the spinal cord in rats. The present study assessed whether vaginocervical stimulation (VS) evokes the release of OXY at the spinal cord level. OXY concentrations in spinal cord superfusates (5 min samples) were measured before, during and after VS (300 g force, on 30 sec-off 30 sec for 5 min) in 8 intact urethane-anesthetized rats. concentration of OXY, measured using radioimmunoassay, was significantly elevated 10-15 min after VS (Mann-Whitney U test, p=.037, 1-tailed) compared to samples collected 10-15 min pre-VS. Pre-VS values ranged from 0.4 to 2.1 pg/ml (mean ± sem =  $1.1 \pm 0.1$ ) whereas post-VS values ranged from 0.5 to 15.7 pg/ml (2.7 ± 1.0). There was a 130% increase in OXY after the first application of VS over pre-VS values; when administered a second time, 45 min later (n=6), VS produced a 53% increase over pre-VS values. The hormonal state of these animals was not determined; we are currently investigating whether estrogen influences the release of oxytocin in response to VS.

EXPRESSION OF C-FOS PROTEIN IN LUMBOSACRAL SPINAL CORD IN RESPONSE TO VAGINOCERVICAL STIMULATION (VS) IN RATS. <u>S.Chinapen\*, J.M., Swann, J. L. Steinman, and B.R. Komisaruk</u>. Inst. Animal Behavior and Dept. Biol. Sci., Rutgers-The State Univ., Newark, NJ 07102.

The pattern of VS-evoked expression of the proto-oncogene cfos in lumbar 5-sacral 1 spinal cord segments of ovariectomized adult Sprague Dawley rats was mapped using immunocytochemistry. Mechanostimulation (10 sec on/10 sec off for 5 min) was applied to the vaginal cervix of experimental rats and to the perineum of control rats (400 and 100g force, respectively) during gentle restraint. Two hours after stimulation all rats were euthanized, perfused, and the spinal cord was removed, sectioned and immunolabeled for c-fos. Using 1-tailed multiple ttests, the total number of neurons expressing c-fos was significantly greater in the experimental (n=4) than control (n=3) group (t=2.9 p=0.04). The experimental group showed a significantly greater number of c-fos-activated cells than the control group in laminae I (t=3.3; p=0.03), IV (t=3.0; p=0.02), V-VI (t=3.3; p=0.03) and X (t=2.6; p=0.04). The distribution of neurons activated by VS corresponds to that of cell bodies: a) of ascending pathways (spino-bulbar, -hypothalamic and thalamic), b) of para-sympathetic preganglionics, and c) receiving synaptic input from descending spinopetal pathways. Supported by Grant GM 08223-08 and Sigma Xi.

LOCALIZATION OF VIP RECEPTOR SITES IN THE CAT SACRAL SPINAL CORD (SSC).

T.J. Brown\*, M.S. O'Dorisio, M.S. Beattie, J.C. Bresnahan. Dept. of Cell Biol., Neurobiol. & Anatomy; and Dept. of Pediatrics, Ohio State University, Columbus, OH 43210.

VIP has been localized to a prominent visceral afferent pathway in the SSC. We have examined the binding characteristics, localization, and effects on cAMP production of VIP in the cat SSC. Synaptosomal fractions were used in competitive binding experiments to determine the affinity (Kd) and number (Bmax) of 1251-VIP binding sites. Binding of 1251-VIP binding sites. Binding of 1251-VIP to SSC membranes was dependent on the amount of membrane protein over the range of 75-400 ug. Competitive binding showed a Kd = 3.19±2.33 nM, Bmax = 0.11±0.08 nM, n=3. VIP has been reported to stimulate cAMP production in homogenates derived from rat cerebral cortex; while luM forskolin stimulated cAMP in SSC, luM VIP did not. Sections (20um) from the SI region of the cord were incubated with 0.2 nM 1251-VIP. Autoradiograms revealed specific binding in laminae I,II, and X, with distinct binding to motoneurons in IX. The results suggest that there are relatively few VIP receptors in SSC, and that these are concentrated in regions corresponding to VIP-containing afferents, and on motoneurons. Supported by NS-10165, and NCI-CA41997.

# 210.15

NEURONAL RESPONSES TO STIMULATION OF UTERUS, CERVIX AND VAGINAL CANAL IN THE RAT GRACILE NUCLEUS. C.H. Hubscher and K.J. Berkley. Dept. Psychology, Florida St. Univ., Tallahassee, FL 32306.

The present study examined input from female pelvic reproductive organs to the gracile nucleus using electrophysiological techniques. Seventeen female rats in estrus were anesthetized with either ketamine/xylazine (10) or urethane (7). Recordings were made from a total of 112 single units located either rostral to (n = 44), at the level of (n = 44) or caudal to (n = 24) the obex. Testing was as follows: gentle brushing of the caudal body surface, gentle probing of the cervix and inflation of water-filled latex balloons in the uterus and vaginal canal to levels at the threshold for provoking escape responses in conscious rats. Almost all neurons had excitatory cutaneous receptive fields (95.5%) to the brush stimulus. Of these, 49.5% also responded with excitation or inhibition to one (27.1%) but sometimes more than one (22.4%) of the visceral stimuli; 23.4% to uterus, 29.9% to vagina and 14.0% to cervix. Although viscerally-responsive neurons were found throughout the entire gracile nucleus, they were particularly concentrated dorsomedially at the level of obex. These results taken together with similar data for spinal cord and thalamus (Guilbaud et al., 1991; Hubscher et al., 1991 - Soc. Neurosci. Abs.) indicate that the internal reproductive organs have a surprisingly large potential for influencing the properties of somatosensory neurons. Supported by NIH grant R01 NS11892.

QUANTITATIVE ANALYSIS OF VIP-IMMUNOREACTIVE TERMINALS IN CAT SACRAL SPINAL CORD.

Q. Li, J.C. Bresnahan,\* M. G. Leedy, and M.S. Beattie. Dept. Cell Biol., Neurobiol. and Anat., Ohio State Univ., Columbus, OH 43210

The purpose of the present study was to provide a detailed quantitative analysis of VIP immunoreactive (VIP-IR) synaptic terminals in different regions of the cat sacral spinal cord. VIP-IR elements were labelled using the ABC technique in sections of cat S1-S2 spinal cord. VIP-IR elements were seen in the tract of Lissauer, laminae I, II, V, lateral VII, X and rarely in IX. The ultrastructural features of VIP-IR terminals (n=292) were analyzed and compared in different regions (Lamina 1&II, lamina V&VII in the sacral parasympathetic nucleus [SPN], and lamina X. VIP-IR terminals contained clear synaptic vesicles (73% round; 22% pleomorphic; flat 5%). Almost all terminals (97.95%) also contained DCVs (range 1-128 / terminal; X = 17.11). 45% of the VIP-IR terminals were observed in glomerular structures in 1&II, 26% in the SPN and 8% in X. Overall, 41.78% of the VIP-IR terminals exhibited synaptic contacts, most occurring in laminae 1&II (50.35%), with less in the SPN (34.4%) and X (29.17%). The most common post-synaptic targets were small dendritic profiles and other axon terminals. Only a few labeled terminals were found to synapse on proximal dendrites or somata in any area examined. Supported by NIH grant NS-10165

# 210.14

Cervix-responsive neurons at thoracolumbar and lumbosacral regions of spinal cord receive convergent uterine (76% and 42%, respectively) and cutaneous (100%) input. The present study addressed the issue of source of uterine and cervical input to these two separated spinal regions. Neuronal recordings pre- and post- dorsal root cuts (31 and 71 units, respectively) from 10 spinalized, decerebrate unanesthetized rats in estrus were obtained. The search stimulus was a simultaneous distension of both uterine horns using water-filled latex balloons. Hypogastric nerve input was removed by cutting the T13-L3 dorsal roots bilaterally. Pelvic nerve input was removed by culting the L6-S2 dorsal roots bilaterally. At L1, neurons still responded to gentle cervix stimulation after removal of the pelvic (6 rats) or hypogastric nerve inputs (1 rat). Neurons in this area also continued to respond to uterine stimuli after removal of the pelvic nerve input but were lost after removal of hypogastric input. Obvious changes, however, occured in the detail of responses of individual neurons at L1 as a result of these manipulations. At L6 (4 rats), neuronal responses to uterine stimulation were lost after removal of hypogastric input. Those to gentle cervix stimulation remained after such removal but disappeared after subsequent removal of pelvic nerve input. These results demonstrate that the main source of uterine influence at both L1 and L6 is derived from the hypogastric nerve whereas the main source of cervix input at L1 and L6 is derived from both the hypogastric and pelvic nerves. Since some neurons still responded to uterine or cervical stimuli when all nearby roots were cut, it was apparent that neurons could be influenced by inputs 3-6 segments away. Supported by NIH grant RO1 NS11892.

VENTROBASAL NEURONAL RESPONSES TO UTERINE AND VAGINAL DISTENSION AND TO UTERINE SUPRAFUSION WITH PROSTAGLANDINS (PGF2a) AND BRADYKININ. <u>K.J.</u> Berkley, <u>G. Guilbaud</u>\*, <u>J.M. Benoist</u> and <u>M. Gautron</u>. INSERM, U. 161, 2 rue d'Alesia 75014 Paris, France.

Previous studies demonstrated the existence of neurons in and near the ventrobasal complex (VB) of anesthetized rats responsive to uterine and vaginal mechanical stimulation (Guilbaud et al., 1991). Most of these neurons had somatic receptive fields, particularly to noxious pinch stimuli, and were located at the rostral and dorsal edges of VB. This study examined responses of these neurons to graded stimulation of the uterus and vagina as well as to suprafusion of the uterus with the inflammatory mediators PGF2a and bradykinin (BK). Fifteen estrous virgin rats were anesthetized with halothane (0.7%) and nitrous oxide (67%) in oxygen and paralyzed (pancuronium bromide). Latex balloons were inserted in each uterine horn and the vagina, and a catheter was secured over the uterine body. The rostral 1/3 of VB was searched with a glass microelectrode filled with pontamine sky blue in saline. The first neuron encountered responsive to pinching the contralateral hindnew or tail was further examined, first by graded distension of one uterine horn (50 - 225 ul) and then graded distension of the vagina (0.5 - 1.25 ml) and finally by suprafusion with 1 ug (in 1 ml) of PGF2a and then 1 ug (in 1 ml) BK. To avoid sensitization, only one neuron was studied per rat. The responses of 11 neurons to uterine distension increased dramatically above background levels at 200 - 225 ul distension. In contrast, the stimulus-response function of 9 neurons to vaginal distension was more linear, with firing levels gradually increasing from 0.5 to 1.25 ml. These response patterns were nearly identical to escape response probabilities obtained in previous behavioral studies. Of 10 neurons tested, 6 responded to PGF2a; of 13 neurons tested, 7 responded to BK. Taken together, the results support the hypothesis that neurons in and near VB are involved in visceral nociception arising from female pelvic reproductive organs. Supported by EPHE (France) and NIH grant NS 11892.

REPRESENTATION OF BLADDER, COLON AND ESOPHAGUS IN THE LATERAL THALAMUS OF THE SQUIRREL MONKEY. J. Brüggemann\* T. Shi. R.A. Stea. R.T. Stevens, and A.V. Apkarian. Dept. of Neurosurgery, SUNY Health Science Center, Syracuse, New York

of Neurosurgery, SUNY Health Science Center, Syracuse, New York 13210.

The lateral thalamus is emerging as an important area for processing the discriminative aspects of innocuous and noxious somatic stimuli. However, little is known about its role in the coding of visceral information. Here we report on the response properties of visceroceptive neurons in chloralose- and nembutal-anesthetized squirrel monkeys. Extracellular single unit recordings were performed in the lateral thalamus. The skin, muscles, and joints were stimulated with innocuous and noxious stimuli. The urinary bladder, the distal colon and the lower esophagus were distended with pressures up to 100 mmHg.

Of 87 thalamic neurons studied in 4 animals 73 were visceroresponsive. Of these 63 were located in VPL and its border, 7 in ZI and the reticular n. and 3 in VPI and VL. For 5 neurons visceral specific responses were demonstrated. With respect to their somatic receptive fields 44 visceroresponsive units were non-nociceptive and 22 were nociceptive (2 not tested). Due to the search strategy most somatic receptive fields of these neurons were located on the hindlimb and tail. Lateral thalamic neurons exhibited a high degree of viscero-visceral convergence: 18 (of 56) received inputs from all 3 viscera, 25 from 2 and 13 only from one viscus. Excitation and inhibition were seen from all 3 viscera. The incidence of both response patterns was comparable for all 3 organs and unrelated to Excitation and inhibition were seen from all 3 viscera. The incidence of both response patterms was comparable for all 3 organs and unrelated to the viscero-visceral convergence or the location of the somatic receptive fields. Neurons with colon input tended to be located more dorsally in VPL, but a viscerotopic arrangement was not obvious. Somatic nociceptive inputs were not predictive of visceral nociceptive inputs.

The results indicate that the lateral thalamus is a major viscero-somatic link, albeit the organization of the visceral representation in VPL is extremely different from that of the somatic organization.

## 211.1

RESPONSES OF UPPER THORACIC SPINAL CORD NEURONS TO ESOPHAGEAL DISTENSION IN THE RAT.

ESOPHAGEAL DISTENSION IN THE RATI.

I. Euchner,\* J.N. Sengupta, G.F. Gebhart, S.T. Meller. Dept. of Pharmacology, University of Iowa, Iowa City, IA, 52242

Previously it has been shown that graded esophageal distension (ED) with a Swan Ganz catheter inserted orally into the thoracic esophagus of rats

a Swan Ganz catheter inserted orally into the thoracic esophagus of rats elicits pseudoaffective responses (pressor and visceromotor responses). The purpose of the present study was to characterize the responses of neurons in the upper thoracic spinal cord (T<sub>2</sub>-T<sub>3</sub>) to graded ED.

In 34 pentobarbital anesthetized and pancuronium paralyzed male Sprague-Dawley rats (425-500 g), graded ED (0.5 - 1.5 ml, 30 s) produced excitatory, inhibitory and biphasic excitatory-inhibitory responses of T<sub>2</sub>-T<sub>3</sub> neurons. Responses to ED were graded; the extrapolated threshold for responses of all units was 0.4 ml. Cutaneous receptive fields, only responsive to noxious pinch were located in the thoracic, axcillar region or responses of all units was 0.4 ml. Cutaneous receptive fields, only responsive to noxious pinch, were located in the thoracic, axcillar region or on the forearm. One neuron responded to non-noxious and noxious movement of the forearm joints; no somatic input was found for 3 neurons. Recording depth ranged from 242 to 1404  $\mu$ m and histological reconstruction revealed that neurons were distributed throughout lamina I-VII. Antidromic activation from C<sub>2</sub>-C<sub>4</sub> showed ascending projections of 7/32 neurons tested ED tripically produced a intensity dependent decrease. 7/12 neurons tested. ED typically produced a intensity-dependent decrease in arterial blood pressure, but intraveneous sodium nitroprusside ( $24 \mu g/kg$ ) did not change the activity of neurons that responded to ED. Reversible spinalization with a  $C_2$ - $C_4$  cold block revealed tonic descending influences on neurons responding to ED.

These data complement and extend earlier work and establish that ED is a reproducible and reliable stimulus for the study of thoracic visceral

# 211.3

THE NOCICEPTIVE RESPONSES TO GASTRIC ARTERY ADMINISTRATION OF ACETYLCHOLINE IN THE RAT ARE MEDIATED BY VAGAL AFFERENTS. S.T. Meller,\* J.N. Sengupta, I. Euchner and G.F. Gebhart. Department of Pharmacology, University of Iowa, Iowa City, IA 52242, USA.

Administration of serotonin (5-HT), histamine (HA) and acetycholine (Ach) to visceral organs such as the heart have been reported to be algesic. However, other than the accompanying report on BK, there have been no systematic studies of the effects of gastric administration of algesic agents. Therefore, the aims of this study were to determine whether administration of 5-HT, HA or Ach into the gastric artery are noxious stimuli, and to evaluate which afferents mediate these effects.

Administration of HA (1-100  $\mu$ g/kg), 5-HT (1-100  $\mu$ g/kg) or Ach (1-100 μg/kg) into the gastric artery of awake, chronically-catheterized rats produced a rapid, dose-dependent decrease in arterial blood pressure and an accompanying tachycardia. Within 1 s after administration, Ach but not HA accompanying tachycattor. Within 15 after administration, Act out for IA or 5-HT, in doses greater than 50 µg/kg produced a distinct pseudaffective response that consisted of a pronounced hunching behavior accompanied by agitation, scratching of the abdomen and a contraction of the facial musculature that lasted for 5-6 s. In addition, administration of 100 but not  $10 \mu g/kg$  Ach produced a passive avoidance behavior that was significantly different from saline. The passive avoidance behavior and the pseudaffective, but not the cardiovascular responses to Ach were abolished by chronic bilateral transection of the subdiaphragmatic vagus.

These data suggest that the gastric artery administration of Ach, but not HA or 5-HT, is a noxious visceral stimulus that activates subdiaphragmatic vagal afferents.

# 211.2

THE NOCICEPTIVE RESPONSES TO GASTRIC ADMINISTRATION OF BRADYKININ IN THE RAT ARE MEDIATED BY SYMPATHETIC AFFERENTS. J.N. Sengupta, \* S.T. Meller and G.F. Gebhart. Department of Pharmacology, University of Iowa, Iowa City IA, 52242. USA

Bradykinin (BK) is a potent algesic substance when administered to cutaneous tissues, muscle or to the viscera. However, there have been no systematic studies of the effects of gastric administration of BK, or its role in gastric pain. Therefore, the aims of this study were to determine whether administration of bradykinin into the gastric artery is a noxious stimulus and

administration of oradystim into the gastric artery is a noxious stitutus and to evaluate which afferents mediate these effects.

Administration of BK (0.05-10  $\mu g/kg$ ) into the gastric artery of awake, chronically-catheterized rats produced an almost instantaneous dose-dependent increase in arterial blood pressure and an accompanying tachycardia. Within 1 s after administration, doses of BK greater than 1  $\mu g/kg$  produced a distinct pseudaffective response that consisted of a hunching behavior accompanied by scratching of the abdomen, writhing and a contraction of the facial musculature that lasted for 5-10 s. In addition, gastric artery administration of 1 or 10  $\mu$ g/kg BK produced a passive avoidance behavior that was significantly different from saline. The greater dose of BK produced a more rapid acquisition of the avoidance behavior. The passive avoidance behavior and the pseudaffective but not the cardiovascular responses were unaffected by prior (48-72 h) transection of the subdiaphragmatic vagus nerves

These data suggest that gastric artery administration of BK is a noxious visceral stimulus possibly acting through sympathetic afferents.

# 211.4

C-FOS EXPRESSION IN SPINAL NEURONS AFTER NON-NOCICEPTIVE AND NOCICEPTIVE STIMULATION OF THE LOWER URINARY TRACT. <u>L. Birder\* and W.C. de Groat</u>, Depts. Pharmacology and Behavioral Neuroscience, Univ. Pittsburgh, Pittsburgh, PA 15261

Spinal neurons receiving afferent input from the lower urinary tract (LUT) of urethane-anesthetized rats were identified by increased c-fos gene expression using immunocytochemical techniques to detect c-fos protein Non-nociceptive stimulation (NNST) of the LUT induced by saline distension of the bladder increased c-fos positive neurons primarily in the region of the sacral parasympathetic nucleus (SPN), whereas nociceptive stimulation (NST; intravesical infusion of 1% acetic acid) produced the majority of c-fos positive neurons in the dorsal commissure region. MK801, an NMDA antagonist, in a dose (3.5 mg/kg; i.v.) that completely blocked reflex bladder activity did alter the c-fos response to NNST but reduced by 50% the number of active cells induced by NST. Pretreatment with capsaicin (CAPS) in a dose (125 mg/kg, s.c.) that increased bladder capacity by 35% did not alter the number of c-fos positive cells induced by NNST but reduced by 90% the number of cells induced by NST. These data indicate that non-nociceptive as well as nociceptive stimuli to the LUT increase c-fos expression in spinal neurons and that the two stimuli activate different populations of afferents (CAPS - sensitive and CAPS - resistant). Glutamic acid acting via NMDA receptors appears to play a role in the central processing of nociceptive input from the LUT.

CENTRAL PROJECTION OF ELECTROPHYSIOLOGICALLY IDENTI-FIED TESTICULAR THIN-FIBER AFFERENTS. K. Mizumura\*, Y. Sugiura and T. Kumazawa. Dept. Neural Regulation, Res. Inst. Envi-

ron. Med, Nagoya Univ., Nagoya 464-01, Japan
The spinal projection pattern of the testicular polymodal receptor (PMR) was studied by intracellular injection of PHA-L. Recordings were carried out in L1 DRG in 2-3 months old puppies under pentobarbital anesthesia (35 mg/kg). One A- $\delta$  (3.7 m/s) and two C-fiber (0.9 and 1.7 m/s) testicular PMRs were labeled good enough to trace their central terminations. The mean diameters of labeled C-DRG neurons were 40.7 µm and 36.8 µm. After entering into the spinal cord, axons of C-PMRs divided into rostral and caudal daughter axons that extended over 20-24 mm (about 3 spinal segments), and issued 15 and 16 branches. Majority of branches ran in/along the lateral surface, two in the middle, and one along the medial surface of the dorsal horn. Terminal swellings and en passant enlargements were observed mainly in laminae I, V, and VII, and some in lamina II. A- $\delta$  PMR had the similar termination pattern to C-PMRs except that interval issuing branches was shorter (13 branches over 10 mm) and its rostral daughter axon ran further rostrally (traced for 3.6 mm) in Lissauer tract after issuing all branches. Only two branches were found running just above the central canal in an another A-δ neuron in which termination could be only partially traced. The density of terminals of testicular thinafferents was lower and their rostro-caudal spread was wider than those reported in cutaneous C-PMRs. These results suggest that testicular afferents have diffuse and wide spreading influences on the spinal neurons.

# 211.7

SPECTRAL ANALYSIS OF BACKGROUND ACTIVITY AND NO-XIOUS HEAT-EVOKED RESPONSES OF SPINAL DORSAL HORN NEURONS IN THE RAT. A. EBLEN-ZAJJUR\* AND J. SANDKÜHLER.

II. Physiologisches Institut, Universität Heidelberg, F.R.G.

Rhythmic discharges are a characteristic feature of many neurons throughout the CNS. Little, if anything is known about the role of rhythmicity for the encoding of nociceptive information. Here, we report that a large proportion of nociceptive and non-nociceptive neurons in the spinal cord display rhythmic background activity. This rhythmicity is largely depressed during noxious skin stimulation.

Multiple neuron recordings were made via single electrode in the lumbar spinal cord of pentobarbital anesthetized rats. Single neuron discharges were identified using a template matching algorithm and were analyzed after stationarity test. test. To evaluate rhythmicity of background activity (BA) and heat-evoked responses (HER) during stationarity phase (48°C, 100 s), auto-correlation (AC) and auto-spectral (AS) analysis was performed, a specific stochastic method for spectral analysis of point processes. The BA of a total of 135 neurons was analyzed. Twenty seven (20%) of which were non-nociceptive (class 1), 85 (62.9%) were multireceptive (class 2) neurons. Fifty four of all neurons (40%) had rhythmic activity. The distribution of the fundamental frequencies has a bimodal shape. The first peak 0.5-2 Hz consisting of 12 neurons overlaps with the respiratory rhythm (1-2 Hz) the second one at 6-13 Hz (16 neurons) is not related to the cardiac rhythm (5 Hz). Class 1 neurons have a higher incidence of rhythmicity (59.3%) than class 2 neurons (34.1%, p< 0.01). Only one (5%) of the 20 neurons with a projection to C2 had rhythmic BA. Activation of heat-sensitive nociceptors within the cutaneous receptive field of class 2 neurons had a strong antirhythmic effect in 12/21 (57.1%) neurons. No changes in spectral pattern were observed in non-rhythmic neurons. It is concluded that rhythmicity exist in sensory neurons of the spinal dorsal horn which is affected by activity in primary afferent nociceptors.

DIFFERENTIAL EFFECTS OF OPIOID AND ALPHA2 NORAD-RENERGIC AGONISTS ON METABOTROPIC AND OTHER GLUTAMATE RECEPTORS.

L. Lichtblau.\* K. Kitto and G.L. Wilcox. Department of Pharmacology, University of Minnesota, Minneapolis, MN 55455, U.S.A.

Excitatory amino acids, which act on glutamate receptors, induce biting and scratching behavior in rodents when injected intrathecally. Whereas and scratching behavior in rodents when injected intrathecally. Whereas most glutamate receptor ligands (e.g., NMDA and AMPA) act on ligand-gated cation channels to produce their effects, the glutamate receptor agonist (+/-)-1-amino-1,3-cyclopentane-trans-dicarboxylic acid (ACPD) acts through a G-protein-coupled metabotropic glutamate receptor. When injected intrathecally, biting and scratching behaviors were elicited in a dose dependent manner by NMDA (0.03 - 0.5 nmol), AMPA (1.0 - 10.0 ng) and ACPD (0.03 - 1.0 μg). However, the ability of the μ- and δ-opioid agonists DAMGO and DPDPE, respectively, and the α, noradrenergic agonist IK 1430-18 to block the behavior varied for the three glutamate agonist, UAVIOO and DPPE, respectively, aim the to include light agonist, UAVIOO and DPPE, respectively, aim the top include light agonist. White is the behavior varied for the three glutamate receptor agonists. Behavior induced by NMDA was only reversed by DAMGO whereas bitting and scratching induced by AMPA was only reversed by UK14304-18. ACPD-induced bitting and scratching was reversed dose-dependently by DAMGO, DPDPE and UK14304-18. As we had observed earlier (Kitto and Wilcox, Soc. Neurosci Abstr. 137.11 1001), the behavior revoked by ACPD and its reversed by

17:71, 1991), the behavior produced by ACPD and its reversal by DAMGO, DPDPE and UK14304-18 was almost identical to that seen with the neurokinin peptide Substance P (SP). The relationship between the metabotropic glutamate receptor and the SP neurokinin receptor suggests an intimate association between these two signaling systems. One can speculate that these receptors share a common cellular localization or signaling mechanism. (Supported by KO2-DA-00145, RQ1-DA-04274 and -01933)

VAGAL AND CARDIOPULMONARY SYMPATHETIC AFFERENTS EXCITE UPPER CERVICAL (C1-C3) SPINOTHALAMIC TRACT (STT) CELLS IN MONKEYS. MJ. Chandler, Q.-G. Fu, R.D. Foreman. Dept. Physiology & Biophysics, Univ. of Okla. HSC, Okla. City, OK 73190.

Myocardial ischemia activates vagal and sympathetic cardiac afferent fibers. Anginal pain classically involves sympathetic afferent fibers that enter T<sub>1</sub>-T<sub>4</sub> spinal cord segments to activate STT cells. Vagal afferents generally inhibit STT cells in C<sub>4</sub>-S<sub>2</sub> segments. After sympathectomies, angina still may be referred to the neck and inferior jaw. The purpose of this study was to determine a neurophysiological basis for this pain referral. We hypothesized that vagal afferents excite C1-C3 STT cells. In 15 anesthetized monkeys, 40 C1-C<sub>3</sub> STT cells were identified by antidromic activation from lateral or medial thalamus. Left cardiac, recurrent laryngeal, and thoracic vagus branches were stimulated electrically; left stellate ganglion was stimulated electrically to activate sympathetic cardiopulmonary (CP) afferents; somatic fields were mapped by brushing hair and pinching skin and muscle. Cardiac vagus input excited 10/26 cells tested; recurrent laryngeal input excited 9/28 cells; thoracic vagus excited 21/37 cells and excited/inhibited 1 cell depending on stimulus parameters. Sympathetic CP input excited 25/39 cells, inhibited 1 cell and excited/inhibited 1 cell. Somatic receptive fields generally included or were confined to the neck; 22 cells were excited by innocuous and noxious stimuli (WDR), 15 cells required noxious stimuli (HT) and 2 cells were low-threshold (LT). We conclude that both vagal and sympathetic CP afferents can increase activity of C<sub>1</sub>-C<sub>3</sub> STT cells with somatic fields located on or near the neck. This viscerosomatic convergence may account for referral of pain to the neck region during myocardial ischemia. (Supported by NIH grant HL22732).

THE ROLE OF NITRIC OXIDE IN SPINALLY MEDIATED HYPERALGESIA IN MOUSE AND RAT K. F. Kitto, J. E. Haley, M. Cook, P. Dosha and G. L. Wilcox\*. Department of Pharmacology and Graduate Program in Neuroscience, University of Minnesota, Minneapolis MN 55455

N-methyl-D-aspartate (NMDA) receptors may be involved in long term potentiation (LTP), "wind-up" and hyperalgesia. Nitric oxide (NO) also appears to participate in these phenomena. The present study was designed to determine whether NO participates in central hyperalgesia following

MDA receptor activation in spinal cord.

Male ICR mice were injected intrathecally (i.t.) with NMDA (0.3 μg/5 μl) and nociceptive effects were measured with the tail flick test (baseline 3.9 s ± 0.1). In male Sprague-Dawley rats, i.t. injection of L-NAME (N<sup>w</sup>-Nitro-L-arginine methyl ester, a NO synthase inhibitor, 1 mg/10μl, i.t.) was immediately followed by a left hindpaw injection of 2.5% formalin (50μl). Over the next 50 min rats were observed for flinching and licking/biting of the formalin-injected paw.

NMDA-induced hyperalgesia (-0.75 s  $\pm$  0.17 SEM at 10 min) in mice was completely blocked by 4 h pretreatment with L-NAME but not with its inactive stereoisomer D-NAME. L-NAME was effective both intrathecally and systemically and its effects could be partially reversed by coadministering the NO precursor L-arginine (90-300  $\mu$ g i.t.). Concurrent administration of hemoglobin (600  $\mu$ g i.t.), which purportedly inactivates extracellular NO, also blocked NMDA-induced hyperalgesia. Intrathecal sodium nitroprusside (0.1-3  $\mu$ g i.t.), which spontaneously degrades to NO and ferrocyanide, was hyperalgesic for up to 3 hr (-0.75 s  $\pm$  0.1 SEM at 90 min) in the tail flick test. In the rat, L-NAME inhibited the flinching and licking/biting behavior elicited by intraplantar injections of formalin. These results indicate that spinal NO production is necessary for increased synaptic efficacy following nociceptive input or NMDA receptor activation in rodent spinal cord. FUNCTIONAL PROPERTIES OF SPINOMESENCEPHALIC TRACT CELLS AND UNIDENTIFIED NEURONS IN THE LUMBOSACRAL SPINAL CORD OF THE RAT. S.H. Park\*and R.P. Yezierski. Department of Neurological Surgery and The Miami Project, University of Miami, Miami, FL 33136.

The present study was carried out in order to characterize the functional properties of two different populations of neurons in the lumbar spinal cord of urethane anesthetized rats. Extracellular single-unit recordings were made from unidentified neurons as well as cells antidromically activated from midbrain stimulation sites, including the deep layers of the superior colliculus, periaqueductal gray, and midbrain reticular formation. Recording sites were located in laminae I-VIII and X of spinal segments L4-L6. For each cell receptive field properties, including responses to calibrated mechanical stimuli, were

Thus far, 20 SMT cells and 31 unidentified neurons have been studied. Single SMT units were classified into four groups: wide dynamic range (58%), deep/tap (21%), high threshold (11%) and non-responsive (10%). Unidentified neurons included wide dynamic range (58%), deep/tap (23%), low threshold (16%), and high threshold (3%). Simple excitatory receptive fields were found for most SMT and unidentified cells recorded in laminae I-IV. Large complex inhibitory and/or excitatory fields were commonly found for cells in laminae V-VIII and I

In conclusion, the results of the present study have shown rat SMT cells to have functional properties similar to those described in other species. Furthermore, it is suggested that sensory neurons in the rat dorsal horn have a functional role that is different from ventral horn neurons in relation to the integration and proc of sensory input, including that derived from noxious mechanical stimuli. Supported by NS19509, NS28059 and the Miami Project.

BLOCKADE OF NOCICEPTIVE INPUTS TO DORSAL HORN NEURONS BY 6-CYANO-7-NITROQUINOXALINE-2,3-DIONE (CNQX): AN INTRACELLULAR STUDY USING THE RAT SPINAL CORD-HINDLIMB PREPARATION.

J.A. Lopez-Garcia and A.E.King (SPON: Brain Research Association). Department of Physiology, University of Leeds, Leeds LS2 9NQ, U.K.

The role of non-NMDA receptors in synaptic transmission from cutaneous mechanoreceptors to dorsal horn neurones has been assessed using the selective antagonist CNQX.

Intracellular data were obtained from 40 dorsal horn neurons responding to noxious stimulation (pinch) of the hindlimb skin, 14 cells were 'nociceptive specific' and 26 cells were 'multireceptive'. The response to pinch consisted of an initial large amplitude depolarization (8-16 mV) typically followed by long duration (up to 20s) slowly decaying EPSPs. In 27 cells the depolarization elicited cell firing but in 13 neurons the excitatory potentials were entirely subthreshold. Superfusion of CNQX (2-5 mV) to 13 dorsal horn neurons (9 'multireceptive' and 4 'nociceptive specific') reduced the amplitude (80-90%) of the depolarization in response to pinch and completely abolished cell firing. This effect was reversible. In the 'multireceptive' neurones the response to light touch was also antagonized by CNQX.

These data support a fundamental role for non-NMDA receptors in the transmission of noxious sensory information

These data support a fundamental role for non-NMDA receptors in the transmission of noxious sensory information to second order dorsal horn neurons in the mammalian spinal cord.

This research is supported by the Wellcome Trust.

DIFFERENTIAL EXPRESSION OF C-FOS IN TRIGEMINAL SUBNUCLEUS INTERPOLARIS AFTER CHEMICAL AND THERMAL CORNEAL STIMULATION IN THE RAT. [LD, Meng, D.F. Bereiter and D.A. Bereiter\*. Section of Neurobiology and Dept of Surgery, Brown Univ/RI Hospital, Providence, RI 02903

The pathways that underlie autonomic responses to noxious corneal stimuli are uncertain. In the rat, the magnitude of select autonomic responses to corneal stimulation is stimulus-dependent. For example, plasma ACTH increases significantly after the application of the specific c-fiber irritant mustard oil (MO) to the cornea, whereas noxious corneal heat has little effect on ACTH. Both stimuli increase arterial pressure and heart rate in a similar fashion. This study examined if the differential ACTH response to MO and to noxious corneal heat was associated with a difference in the distribution of fos-like immunoreactivity (FLI) within the spinal trigeminal nucleus (Vsp). In addition, projection sites for FLI positive neurons to autonomic areas were studied using the retrograde tracer fluorogold (FG). The distribution of FLI within subnucleus caudalis (Vc) and interpolaris (Vi) was quantified in barbiturate-anesthetized rats after noxious corneal heat (52 °C, 20 s pulses for 15 min) or after 20% MO applied to the cornea. After 2h survival, rats were perfused and FLI was visualized by the avidin-biotin method. Bilateral injections of FG (100-200nl, 2%) into medial hypothalamus or parabrachial regions 7-10 days prior to MO stimulation was used to assess the projections of Vsp cells. Noxious corneal heat caused an increase in FLI mainly in uncertain. In the rat, the magnitude of select autonomic responses to corneal parabrachial regions 7-10 days prior to MO stimulation was used to assess the projections of Vsp cells. Noxious corneal heat caused an increase in FLI mainly in the ipsilateral superficial laminae of caudal Vc. Although MO induced a similar increase in FLI in caudal Vc, a high percentage of FLI positive neurons also were present ipsilaterally within the ventral pole of the periobex Vi. FG injections into medial hypothalamus labeled many cells in ventral Vi, while injections into parabrachial areas labeled many cells in Vc. These results suggest that the difference in ACTH response to noxious stimuli may be related to the activation of second order neurons in periobex Vi. Supported by NIH grant NS26137.

VISUALISATION OF CAPSAICIN SENSITIVE DORSAL ROOT GANGLION CELLS AND THEIR CENTRAL TERMINALS. L. Nagy, L. Urban<sup>1</sup>, K. Matesz, J. Winter<sup>1</sup>, A. Dray<sup>1</sup>, M. Antal<sup>a</sup> and C. J. Woolf<sup>2</sup>. Department of Anatomy, University Medical School, Debrecen, 4012, Hungary; 'Sandoz Institute of Medical Research, London, WC1E 6BN, UK; 'Department of Anatomy, University College London,

Capsaicin selectively activates a sub-population of unmyelinated and thin myelinated primary afterents (Holzer, Pharmacol, Rev. 43:144, '91). In this study a method used to show capsaicin sensitive cells in vitro (Winter, Neurosci, Lett. 80:134, '87) has been modified to demonstrate the distribution of these neurons in the intact DRG and their central terminal fields in the spinal cord.

Lumbar segments of hemisected spinal cords with DRGs attached were dissected from young rats anaesthetised by Enfluorane and transferred into a buffer containing (in mM) sucrose:139; NaCl:57.5; KCl:5; MgCl<sub>2</sub>: 2; CaCl<sub>2</sub>:1; glucose:12; HEPES:10; CoCl.:5. Tetrodotoxin (400nM) was added to stop cell firing. Cobalt entry into cells through receptor activated Ca channels was induced by capsaicin (2µM). The Co ions taken up by the capsaicin sensitive cells were reacted with H,S to form CoS. After fixation and sectioning the CoS precipitate was intensified by a silver developer. Fifteen percent of the total DRG cell population was stained with cobalt. The

diameter of labelled cells was in the range of 10-30µm, while unlabelled neurons measured between 10-50 µm. In the spinal cord stained fibres and terminals formdense network around lamina I cells. In lamina II and in the medial part of lamina III fine fibres and a number of labelled boutons were found. From the lateral border of the superficial dorsal horn labelled fibres looped around to the lateral part of lamina

The selectivity of this technique provides a powerful new tool to identify the cell bodies and central terminals of a particular class of chemosensitive nociceptors. I. Nagy was supported by the Wellcome Trust

TEMPOROMANDIBULAR JOINT STIMULATION IN THE RAT INDUCES C-FOS IN THE CAUDAL SPINAL TRIGEMINAL NUCLEUS. <u>C. B. Hathaway\*</u>. J.W. Hu and D.A. Bereiter, Dept. of Surgery, RI Hosp/Brown Univ., Providence, RI 02903 and Fac. of Dentistry, Univ. Toronto, Toronto, Ont., Canada M5G 1G6.

Central neural mechanisms underlying sensory and autonomic responses to nociception in deep craniofacial structures are not well-defined. This study nocception in oeep cramotactal structures are not well-defined. This studies examined the distribution of c-fos protein in brainstem neurons following injection of 10  $\mu$ l of 20% mustard oil (c-fiber-specific irritant) into the left temporomandibular joint (TMJ) of barbiturate-anesthetized rats. The protoncogene c-fos is known to be induced rapidly and transiently in neurons by synaptic activity. Animals were processed for fos-like immunoreactivity (FLI) at 2h and 5h after injection using the avidin-biotin method. To assess the effect of adrenal and 5h after injection using the avidin-biotin method. To assess the effect of adrenal steroids on FLI induced by TMJ stimulation, adrenalectomized (ADX) animals were included in the 2h group. Nuclei showing FLI were found throughout the trigeminal subnucleus caudalis (Vc) and in the caudal subnucleus interpolaris (Vi). Induction of FLI was greatest pisilaterally in superficial laminae of the dorsal horn near the Vc/CI junction (i.e. > 4 mm caudal to obex) and bilaterally in dorsal and ventral pockets in Vi about 1 mm caudal to the obex. About 20% of dorsal horn FLI cells were found in the deeper laminae of Vc. FLI in sections rostral to the obex was rare. At periobex levels, significant FLI was also seen bilaterally in the paratrigemial nucleus, solitary tract nucleus, inferior olive, and ventrolateral medulla. Treatment effects were mainly changes in quantity rather than location of FLI. At all rostrocaudal levels, FLI was reduced at 5h survival when compared to 2h survival. ADX generally promoted an increase in FLI over that of the intact group particularly in the contralateral Vc and Vi. Ipsi-vs. contralateral differences in FLI varied with rostrocaudal position and survival time suggesting differences between sites in the nature and/or degree of response to TMJ stimulation. Extensive FLI induction from obex to cervical cord may indicate a functional diversity in the trigeminal involvement with the processing of nociceptive information from the TMJ. Supported by NIH grant NS26137.

A NEW RAT TOOTH STIMULATION MODEL: EVOKED REFLEX AND TRIGEMINAL (V) BRAINSTEM NEURON RESPONSES. J.W. Hu\*, X. Zhou, C.L. Kwan, R. MacMillan and B.J. Sessle. Fac. of Dentistry, Univ. of Toronto, Ont. M5G 1G6, Canada.

We have developed a new technique to implant bipolar stimulating electrodes into the rat maxillary first molar tooth in order to study dental neural pathways and avoid well-known problems of current spread associated with the use of the rat incisor. The mean (± S.D.) threshold of the tooth-evoked digastric jaw-opening reflex (JOR) in 29 anaesthetized rats was 1.1 ± 0.8 mA and its shortest supra-threshold latency was 4.8 ms. For thresholds < 1.5 mA, a prolonged stable JOR threshold lasting > 4 hours was observed. Brainstem neuronal activity was recorded in the V subnuclei oralis and caudalis in 8 and 10 of these rats, respectively. Neurons (n = 278) were classified according to their cutaneous mechanoreceptive field properties as low-threshold-mechanoreceptive (LTM), wide dynamic range (WDR) and nociceptive-specific (NS) neurons and tested for incidence, threshold and latency of molarevoked responses. Data were as follows:

Oralis LTM Caudalis LTM Caudalis WDR + NS

The findings represent the first documenting reflex and neuronal responses evoked by rat molar stimulation. Supported by NIH Grant DE04786.

DISTRIBUTION OF FOS-LIKE IMMUNOREACTIVITY IN THE MEDILLARY AND UPPER CERVICAL DORSAL HORN PRODUCED BY STIMULATION OF

DURAL BLOOD VESSELS IN THE RAT. A.S.Trassman.\*, Y.Mineta & B.P.Vos.
Pain Physiology Lab., Massachusetts General Hospital, Charlestown, MA 02129.
Previous studies indicate that sensory signals from cranial blood vessels (superior sagittal sinus and middle meningeal artery) converge on central neurons that also receive nociceptive inputs from facial skin. In order to investigate further the central organization of afferent pathways from vascular and cutaneous tissues, the distribution of fos-like immunoreactivity in the medullary and upper cervical dorsal horn produced by dural vascular stimulation was compared with that found in previous studies following mechanical, thermal, and chemical stimulation of cutaneous facial sites.

and chemical stimulation of cutaneous facial sites.

Dural stimulation was carried out under Brevital anesthesia in rats that had received a chronic surgical exposure of the transverse and superior sagittal sinuses 2-4 days earlier. The exposed dural surface was stimulated for 30-60 minutes with either mechanical stroking with a blunt probe), chemical (capsaicin or formalin), or electrical (10mA, Imsec pulses) stimuli. Animals were perfused two hours after the end of stimulation and C4 to the obex was processed for fos-like immunoreactivity.

Dural stimulation produced a pattern of labelling in the dorsal horn that was similar for all of the stimulus modalities and that differed from the pattern produced by cutaneous facial stimulation. The dural-induced labelling in the dorsal horn was evenly distributed across a large rostrocaudal distance that extended from the midlevel of caudalis to the level of caudal C2 or rostral C3. In the transverse plane, the labelling was distributed primarily in the ventral (i.e., ophthamic) half of the dorsal horn. This is a broader, more diffuse distribution than was found with stimulation of any sincle facial site, and corresponds to a recion that ventral (i.e., ophthalmic) half of the dorsal horn. This is a broader, more diffuse distribution than was found with stimulation of any single facial site, and corresponds to a region that represents approximately the dorsal half of the head and face from the intraural line to the beginning of the snout. The labelling was most heavily concentrated in lamina I, with less labelling in lamina III-IV, and very tittle labelling in lamina II. This laminar pattern differs from that found with noxious facial stimulation, which produces heavy labelling in both lamina I and II. These results suggest that the dural afferent pathway may differ significantly in its central organization from sensory pathways that originate from facial skin.

POSTSYNAPTIC TARGETS OF CGRP IMMUNOREACTIVE VARICOSITIES IN LAMINA II OF THE RAT SPINAL TRIGEMINAL NUCLEUS: AN IMMUNOCATOCHEMICAL AND INTRACELLULAR LABELLING STUDY IN FIXED TISSUE SECTIONS J.V. Priestley' and S. Averill. Departments of Physiology & Biochemistry, U.M.D.S. St. Thomas's Medical School Campus, London, England SEI 7EH Small diameter trigeminal and dorsal root ganglion cells can be divided into two major populations according to whether they express the neuropeptide calcitonin generelated peptide (CGRP) or express an oligosaccharide which can be recognized by the monoclonal antibody (LA4) and the lectin Griffonia simplicifolia IB4. As part of ongoing research on the central terminations of these two populations, we have investigated the cell types in lamina II (LII) which are contacted by CGRP terminals.

100 µm sections of the spinal trigeminal nucleus were cut on a vibratome from rat medulla perfusion fixed with 4% paraformaldehyde. Under visual guidance, LII neurons were injected intracellularly with lucifer yellow. The dye filled the cell body, proximal and distal dendrites, spines, and occasionally also part of the axon. Injected cells were photo-oxidised, drawn at high magnification, and then cut into 30 µm sections on a freezing microtome. Sections were stained for CGRP using Ni enhanced PAP immunocytochemistry, embedded in Durcupan, and examined directly and after resectioning into 1.5 µm sections.

Stalked cells, islet cells and intermediate cell types were identified. Where dendrites passed through areas of CGRP immunoreactive terminals, contacts between them were observed. For example both stalked and islet cells which were located primarily in inner LII received contacts on their dendrites where they penetrated outer LIII. No simple relationship was observed between innervation density and cell type.

DIFFERENTIAL EFFECTS ON TRIGEMINAL NOCICEPTIVE SUBNUCLEUS CAUDALIS NEURONES OF INFLAMMATORY IRRITANT APPLIED TO CUTANEOUS VERSUS DEEP TISSUES. X.-M. Yu\* J.W. Hu and B.J.

Sessle. Fac. of Dentistry, Univ. of Toronto, M5G 1G6 Canada.

We recently showed that injection of the inflammatory irritant mustard oil into the tongue muscle induces a significant and reversible expansion of both cutaneous and deep mechanoreceptive fields (RFs) of nociceptive skin/mucosa+deep convergent (S+D) neurones in subnucleus caudalis, and that the expansion is significantly greater for deep RFs. The present study tested if the relative expression of this cutaneous and deep RF neuroplasticity might depend on the specific source of the inflammatory irritation (i.e. cutaneous versus deep). Mustard oil  $(5\mu)$  injected into the tongue muscle of anaesthetized rats produced a significant (p<0.01)cutaneous and deep RF expansion, although there was no significant difference in incidence of expansion between S+D neurones with (n = 8) or without (n = 11) a documented tongue input. As a control, mustard oil injected into the gastrocnemius muscle did not change either cutaneous or deep RF properties of caudalis S+D neurones (n=3). When mustard oil was applied to the facial cutaneous region overlapping the deep RF but outside the cutaneous RF of another 7 caudalis S + D neurones, no deep RF expansion occurred but a significant (p<0.05) expansion of the cutaneous RF was documented for 6 of the 7 neurones. Thus, the mustard oil-induced expression of neuroplasticity in S+D neurones may depend on whether deep or cutaneous regions are the source of the inflammatory irritation. The changes in both cutaneous and deep RF properties by deep injections of mustard oil, as opposed to the more limited changes with its cutaneous application, may explain clinical reports of greater sensory disturbances in pain conditions involving deep tissues than those involving cutaneous tissues. Supported by NIH grant DE09559.

RESPONSE PROPERTIES AND LOCATIONS OF AXONS OF LUMBO-SACRAL SPINOTHALAMIC (STT) AND SPINOHYPOTHALAMIC (SHT) TRACT NEURONS IN RATS. J.T. Katter, R.J. Dado and G.J. Giesler, Jr. Dept. of Cell Biol. & Neuroanat., Grad. Prog. in Neurosci., Univ. of Minn., Minneapolis, MN 55455.

Many neurons in sacral spinal cord are labeled after injections of retrograde tracers into the thalamus or hypothalamus. These neurons are located in regions that receive inputs from primary afferent fibers innervating lumbosacral dermatomes and pelvic visceral structures. We recorded extracellularly from neurons in L6-S2 that initially were activated antidromically with low currents ( $\leq$ 30 uA) from either the contralateral posterior thalamus (n=18) or the contralateral hypothalamus (n=6) in rats of both sexes. Recording points were concentrated in the dorsal part of nucleus proprius, and a few were located in the lateral reticulated area and the area around the central canal. Most receptive fields (RFs) included the perineum. Nine of thirteen neurons tested responded to hair movement within their RFs and did not show increased responses to increasingly intense mechanical stimuli including noxious stimuli. These nine neurons were classified as low threshold (LT) neurons. Two of the four LTs tested also responded to colorectal distention. None of the five LTs tested responded to heat or cooling. These results suggest that some STT neurons in lumbosacral cord of rats transmit information about innocuous cutaneous and visceral stimuli. Using microantidromic mapping techniques, axons of 14 neurons were found in the contralateral lateral funiculus in cervical cord: ten were located in the ventral lateral funiculus (VLF), one in the dorsal lateral funiculus (DLF) and three at the border between the VLF and DLF. Almost all axons were located near the lateral edge of the cord. This supports the idea that STT axons are arranged somatotopically with sacral axons located laterally. Supported by NS29276 and MH10059.

C-FOS EXPRESSION IN THE LUMBAR SPINAL CORD OF THE DEVELOPING RAT INDUCED BY NOXIOUS STIMULI. D. Yi and G. A. Barr\*. Biopsychology Doctoral Program, Dept. of Psychology, Hunter College-CUNY, NY, NY 10021 and Dept. Developmental Psychobiology, , New York State Psychiatric Institute, NY, NY 10032.

There are a number of important unanswered questions regarding how pain is processed during early development. In this study, we used the c-fos oncoprotein as a marker to examine the development of pain systems in the spinal cord of infant rats using different types of noxious stimuli. One to two-day-old unanesthetized rat pups were injected with 15  $\mu$ l of 10 % formalin into the right hindpaw and were sacrificed 2 hours later. The spinal cord was processed for immunocytochemistry using a commercial antibody for the c-fos protein. c-Fos-like immunoreactivity was found ipsilaterally in the superficial dorsal horn and in lamina V of the lumbar spinal cord. At 14 days of age, under light methoxyflurane anesthesia, the right hindpaw was submerged in the hot water bath, 52 °C, four times for 10 seconds each at 5 minute intervals. Pups were sacrificed 2 hours after the termination of the stimulation. Ipsilateral c-fos -like labeling was observed in the medial portion of the superficial layer of the lumbar enlargement of the spinal cord. The results obtained from the younger animal are consistent with previous results that suggest that the processing of noxious stimulation occurs at least at the level of the dorsal horn shortly after birth. The differences observed in the pattern of c-fos labeling for the two age groups could either be due to the age difference or to the difference in the type of noxious stimulus used. Further studies are examining those differences.

# PAIN MODULATION: COGNITIVE, AUTONOMIC AND ENDOCRINE

MORPHINE ATTENUATES THE HABITUATION OF NOVELTY-INDUCED HYPOALESIA. J. Rochford's E. C'Brien. Douglas Hospital Research Center, , McGill University, Verdun, Quebec, H4H 1R3, Canada.

Exposure to novel stimuli, such as a nonfunctional hot plate apparatus, has been shown to induce hypoalgesia. With repeated exposure, novelty-induced hypoalgesia (NIH) habituates. The present experiments were conducted to determine the effect of morphine administration on the rate of habituation

habituation.

Male, Wistar rats (275-300g) were administered 5 mg/kg morphine (Group MORI) or saline (Group SAL) prior to being exposed to a nonfunctional hot plate apparatus for three days. On the fourth day all rats were administered saline and tested for pain sensitivity on a functional (48.5°, 50.0° or 52.0° C) hot plate. This four day sequence was then repeated twice more. Paw lick latencies (PLLs) declined over repeated tests. However, the rate of decline was retarded in group MOR (as indicated by longer PLLs), suggesting that morphine attenuated the habituation of NIH. Futher experiments have demonstrated that (1) the hypoalgesic efficacy of morphine is lower in group MOR than in group SAL; (2) both the attenuation of NIH and the lowered hypoalgesic response to morphine are not observed if animals are exposed to a stimulus other than the hot plate apparatus. Thus, morphine administration alone is not sufficient to account for these effects, they require both morphine administration and exposure to the plate apparatus; (3) the both morphine administration and exposure to the plate apparatus; (3) the longer PLLs observed in group MOR are not affected by pretreatment with 7

mg/kg natirexone; (4) morphine attenutes the habituation of NiH within a dose range of 5-20 mg/kg.

These data indicate that morphine administration can influence changes provoked by learning on a stress-induced hypoalgesic response, and that such an influence in turn afters the pain inhibiting properties of the drug itself.

BILATERAL LESIONS OF THE CENTRAL OR BASOLATERAL NUCLEUS OF THE AMYGDALA ATTENUATE THE ANALGESIA THAT RESULTS FROM FEAR-INDUCING STIMULI. B.M. Morrison and C.A. Sorenson\*. Neuroscience Program, Amherst College, Amherst, MA 01002.
The roles that the central (CNA) and basolateral (BLA)

nuclei of the amygdala play in analgesia induced by environmental challenges were investigated through selective bilateral electrolytic lesions (mean destruction: 93.5 percent of CNA or 68.5 percent of Either lesion attenuated the analgesia, as measured by the tail-flick apparatus, that resulted from cat exposure or classically conditioning an environment Cat exposure and classical conditioning to footshocks, were chosen as the environmental challenges because they induce fear through unconditioned and conditioned means, Previous experiments had determined that respectively. the BLA is involved in the analgesic response to conditioned fear, but this experiment is the first to show that lesions of the BLA attenuate unconditioned fear-induced analgesia. This result, along with the equal magnitude of attenuation of analgesia that resulted from CNA and BLA lesions, support the hypothesized role of the BLA as providing a sensory input to the CNA. addition, the manipulations that reduced analgesia in this experiment have been shown in other studies to reduce fear, indicating that cat exposure and classical conditioning may induce analgesia through a fear mechanism.

ADRENALECTOMY BLOCKADE OF OPIATE ANALGESIA IS NOT DUE TO STRESS-INDUCED RELEASE OF HORMONES. L Sutton, M. Fleshner, S.F. Maier\* & L. Watkins. Department of Psychology, University of Colorado, Boulder, CO 80309 USA.

Psychology, University of Colorado, Boulder, CO 80309 USA.
Inescapable tail shock (Sk) produces 3 sequential analgesic states as numbers of Sks (5 s. 1 mA) increase: an early opiate (after 2 Sks), a nonopiate (after 5-40 Sks) & a late opiate (after 80-100 Sks). We tested if adrenalectomy (ADX) would affect any of these analgesias &, if so, whether such blockade(s) was due to shock-induced release of adrenal hormones.

We first tested ADXs vs. shams 2 wks post-surgery. Rats received 7 mg/kg naltrexone or saline 15 min before testing baseline pain sensitivity (tail flick [TF]). Sk began right after baseline testing. TF latencies were recorded after 2, 5, 10, 20, 40, 60, 80 & 100 Sks. Both ADX & naltrexone blocked 2 Sk & 80-100 Sk opiate analgesias. The fact that 2 Sk analgesia was blocked implied that Sk-induced hormone release could not be critical, since release is minimal at this time. Since steroids are tonically required for synthesis of various neurotransmitters, perhaps this was the mechanism involved.

If this idea were correct, then it should be possible to test ADX rats shortly after surgery, before long-term changes in neurotransmitter levels have

after surgery, before long-term changes in neurotransmitter levels have occurred. In this case, despite no circulating adrenal hormones, no reduction in either 2 or 80-100 Sk analgesia should occur. This is indeed what we observed at 48 hrs after ADX. Thus, stress-induced release of adrenal hormones cannot account for the effects observed at 2 wks after surgery.

To determine whether basal levels of cortical or medullary factors are critical, rats were tested 2 wks after ADX, after receiving chronic basal adrenal replacement in their drinking water. Basal steroid replacement abolished the

effect of ADX at 2 wk post-surgery.

In sum, these data call for a re-evaluation of the suggestion that some forms of analgesia can be classified as hormonally mediated. Instead, it may be that such analgesias simply rely on neurotransmitters which require adrenal steroids for their synthesis.

HYPOALGESIA IN RESPONSE TO NOISE STRESS IS BLOCKED BY LESIONS OF THE AMYGDALA AND PERIAQUEDUCTAL GRAY P.S. Bellgowan, & F.J. Helmstetter, Department of Psychology, University of Wisconsin, Milwaukee, WI

Prior studies have demonstrated that a single brief exposure to moderately intense (75-95 dB) white noise is sufficient to activate opioid-mediated antinociceptive systems in the rat. This form of stress-induced hypoalgesia is attenuated by systemically administered benzodiazepines and may represent a response to anxiety, sensitization or fear. Our recent data indicate that a neural circuit which includes the amygdala, periaqueductal gray and rostral medulla is critical for the expression of hypoalgesia in response to auditory stimuli that have been paired with footshock during Pavlovian conditioning This study was conducted to find out if this same neural circuit is responsible for hypoalgesia following noise stress. Male rats received small bilateral electrolytic lesions of the central or lateral nuclei of the amygdala or the ventrolateral periaqueductal gray. Following several baseline radiant heat tail flick (TF) trials subjects were exposed to a single 60s presentation of 90 dB white noise. TF testing continued at 2 min intervals for 12 min. In all cases, baseline TF latencies for lesioned animals did not differ from corresponding groups of sham-operated controls. Control rats showed a time-dependent hypoalgesia following noise. The elevation of TF latency following noise ntation was abolished or attenuated in all lesion groups. These results support the idea that anxiety-related hypoalgesia and defensive behavior share a common neural substrate.

THE EFFECT OF CONDITIONED STRESS AND MORPHINE ON GLUCOSE UTILIZATION IN THE RAT. Gescuk, B. \* Lang, S. and C Kornetsky, Boston Univ. Sch. of Med. Boston, MA 02118.

This experiment determined the effects of morphine sulfate (MS) on local cerebral metabolic rates for glucose (LCMR<sub>glu</sub>) in male F-344 rats previously exposed to chronic, escapable footshock (conditioned stress or CS). Four groups of animals were studied: control-saline, control-MS, CS-saline, and CS-MS. The two CS groups were exposed to 11 days of half hour sessions of footshock. LCMR<sub>glu</sub> experiments were carried out without stimulation in the same shock-chamber. All animals were given MS (4mg/kg sc) or saline 7 days, 3 days, and 10 min prior to the start of the experiment. The only significant effects of CS compared to saline control were decreases in the diagonal band and medial habenula. MS significantly decreased metabolic activity in 22 brain regions. In several of these regions medial nabenula. In Significantly decreased medabulic activity in 22 brain regions. In several of these regions, MS in the presence of CS caused a further decrease in LCMR<sub>glu</sub> when compared to MS alone. However, there were significant increases in 3 thalamic nuclei: anteroventral, significant increases in 3 thalamic nuclei: anteroventral, gelatinosus, and parafasicular. Interestingly, in the hippocampus (dentate gyrus, CAl), MS alone caused significant increases in  ${\rm LCMR_{glu}}$ ; but, in the presence of CS, MS decreased metabolism. These results suggests that the effects of MS on brain activity can vary (especially in thalamic nuclei, hippocampus, and some limbic regions) as a result of exposure to a stressful environment. (Supported by grant DA02326 and DA00099 to CK).

HYPERALGESIA BY SUCKLING IN LACTATING RATS IS ADRENAL GLAND MEDIATED. Martinez-Gómez,M.\*; Y. Cruz; P.Carrillo; A.Loranca; F.Mena and P.Pacheco
CIRA,Univ. Autón. Tlaxcala; Instituto de NeuroEtología, Univ. Veracruzana; IIB-UNAM, MEXICO.

As compared with virgin rats Tail Flick

Latency (TFL) shows reduction during the three thirds of lactation. Hormonal condition, suckling, pups presence and mammary gland emptying seem to participate in this phenomenon. Present study participate in this phenomenon. Present study analyzes this possibilities. After pups separation (6 hs) mothers showed TFL higher than those during suckling. Pups presence did not reduce TFL in both lactating and virgin rats in which maternal behavior was induced. On the other hand, in these virgin rats pups presence and suckling-like stimulation increased TFL. Milk ejection blockade by ducts glued did not impeded suckling hyperalgesic effect (SHE). An hour after suckling a second period performed by new and hungry pups (when mammary glands still are emptied) produced SHE again. Ovariectomy on day 7 or 14 of lactation did not alter the low levels of TFL. Adrenalectomy on day 14 of lactation increased TFL to virgin or weaning levels. CONCLUSIONS: During lactation suckling determines hyperalgesia through adrenal activation.

INVOVEMENT OF PITUITARY BETA-ENDORPHIN IN ANAL-RETALENDORPHIN IN ANALOGESIA PRODUCED BY STIMULATION OF HYPOTHALAMIC ARCUATE NUCLEUS. Q.-Z. Yin, F.Gu, M.-Y. Zhu, N.Zhang and L. Met \* Lab.of Neurobiology, Su-Zhou 215007, P.R.China.

Previous studies have demonstrated that hypothalamic arcuate nucleus(ARC) stimulation could result in a naloxone-reversible analgesia accompanied by an elevation of brain  $\beta$ -endorphin  $(\beta extsf{-END})$  level. As the ARC isone of the nuclei in hypophysiotropic area and the pituitary  $\beta$ -END can flow retrogradely via portal vessel system into the brain, hypophysectomy and dexamethasone block were used in this experiment to investigate the role of pituitary  $\beta$ -END in analgesia produced by ARC stimulation. Sham ARC stimulation. produced by ARC stimulation. Sham ARC stimulation and sham hypophysectomy were performed as control. As previously, electrical stimulation of ARC produced a marked analgesia with concomitant increase of brain  $\beta$ -END level. The analgesia could be blocked by dexamethasone injection. After hypophysectomy ARC stimulation could neither produce analgesia nor increase the brain by ARC stimulation and flow retrogradely into the brain to result in the analgesia.

PHYSIOLOGIC RESPONSE AND PERCEPTION OF PAIN IN THE AGED. F Porter, JP Miller, J Morris, L Berg\* Washington University School of Medicine, St Louis, MO 63110.

As a prelude to a study of pain in the aged with dementia, ECG and respiration were continuously recorded during undisturbed BASEline (13.2+3.0min). PREParation (tourniquet/cleansing/needle visualized) (.8 ± .8mln), required VENIpuncture (1.6 ± .3mln), and undisturbed RECovery (10+2.6min) from 48 (33 female; 45 white) visually intact, non-demented, ≥65 yr old (X=76±5 yrs) adults. Physiologic response was assessed by change in heart rate (HR), HR variability (HRV), heart period (HP), and respiratory rate (RR). Anxiety, pain and fearfulness were rated by subjects on 10-point visual analog scales and correlated with physiologic responses. A battery of neurocognitive tests was administered to assess cognitive performance. Significant increases in HR and RR and decreases in HRV and HP occurred in response to PREP. In contrast, HR and RR decreased and HP increased significantly from PREP to VENI yet differed at VENI from BASE. All measures returned towards BASE during REC. Poorer cognitive performance was associated with less physiologic response to PREP and greater physiologic response to VENI. Magnitude of physiologic response was not associated with age. Mean anxiety at PREP was 2.7; mean pain rating at VENI was 1.1. Magnitude of Price was 2.7; mean pain rating at VENI was 1.1. Magnitude or physiologic response to VENI was significantly related to ratings of pain sensitivity and fearfulness at BASE. We conclude that: 1) a cognitively based event (PREP) elicits greater magnitude physiologic response than does a mild physiologic insult (VENI); and 2) cognitive performance is does a finite physiologic lister (VENI), and 2) cognitive performance is differentially related to the magnitude of physiologic response to cognitive vs physical events. These data suggest that cognitive preparation may reduce response to pain among older adults. (Supported by 5P50AG05681 and AG06815)

FORMALIN INDUCED PAIN DOES NOT AFFECT ACTH AND CORTICOSTERONE PLASMA LEVELS IN RAT. A.M. Aloisi and G. Carli. Ist. Fisiologia Umana, Università di Siena, via Laterina 8, I-53100 Siena, ITALY.

It was the aim of the present research to eva luate the amount of Corticosterone (C) and ACTH release during a condition of persistent pain, indipendently from others environmental factors Male Wistar rats were group-housed, familiarized with the open field and tested during the dark phase. Groups varied according to a) treatment: formalin (50 µl at 0.1 and 10%), sham injection, restraint (30 min) and control; b) time of blood collection (30 and 60 min after treatment). Pain levels, assessed according to licking duration, flexion and paw jerk were higher in the 10% than in 0.1% formalin group. C displayed the same levels in formalin treated, sham injected as well as in control group, being elevated in the restraint one. ACTH was found increased 30 min after formalin (10%) and in the restraint group with respect to all the others. In conclusion, it is possible to elicit tonic pain without a clear involvement of the pituitary-adrenal axis.

EFFECTS OF LESIONS OF THE ROSTRAL MEDULLA AND VENTRAL PERIAQUEDUCTAL GRAY ON ANTINOCICEPTIVE AND CARDIOVASCULAR CONDITIONAL RESPONSES

S.A. Tershner \*& F.J. Helmstetter, Department of Psychology, University of Wisconsin, Milwaukee, WI 53211 Upon presentation of an auditory stimulus that has been paired with footshock rats will respond with hypoalgesia and a transient increase in mean arterial blood pressure. The present study was designed to determine if the performance of these Pavlovian conditional responses is dependent on the rostral ventral medulla (RVM) and periaqueductal gray (PAG). Independent groups of subjects were first exposed either to paired or unpaired presentation of an auditory stimulus and footshock. After training all rats were prepared with chronic femoral catheters for measurement of arterial blood pressure (AP). Separate groups of rats within the paired and unpaired training conditions were given electrolytic lesions of the RVM or PAG. Control rats had electrodes lowered but no current was passed. Following adaptation to restraint subjects were tested using the radiant heat tail flick (TF) test. In non-lesioned animals that received paired training, presentation of the auditory signal resulted in significant elevation of TF latency and AP. Unpaired controls did not show these responses. Lesions of the ventrolateral PAG, and RVM lesions that primarily involved the n. raphe magnus and n. paragigantocellularis eliminated hypoalgesia but did not affect conditional elevations in AP. These data support the idea that the PAG and RVM are critical structures in the neural circuit subserving hypoalgesia as a conditional response.

Vesicoanal (VA) reflex activity in the rat: a model of urinary bladder (BL) irritation. M.A. Muhlhauser\* and K.B. Thor. Lilly Research Laboratories, Eli Lilly and Co., Indianapolis, IN 46285
Irritation of the BL activates "silent nociceptors". While c-fos

Irritation of the BL activates "silent nociceptors". While c-fos expression is used to monitor BL nociceptor activity, the technical limitations complicate pharmacological experiments. Thus, the following model was developed. BL of urethane-anesthetized rats were cannulated through the dome for cystometrogram recording. Anal (AS) and urethral (US) sphincter EMG activity were recorded. AS potentials were of 2 types, short (1-3 msec) and long (10-50 msec) duration that were succinylcholine- and methylscopolamine-sensitive, respectively, indicating striated and smooth components. US activity was completely succinylcholine-sensitive. During saline infusion, BL contractions always evoked US activity but only occasionally striated AS activity. (AS smooth muscle activity was never correlated with BL activity and is not discussed further.) In every rat, infusion of 0.5% acetic acid (AA) produced robust increases (2-4 fold) in striated AS activity (i.e. VA reflex), which was highly-correlated with BL activity. Topical BL application of capsaicin (CAP) desensitized the AA-induced increase in AS activity. In saline-infused BL, topical CAP mimicked the AA-induced BL-related increases in AS activity. CAP pretreatment (50-125 mg/kg s.q., 4-5 days prior) eliminated AA-induced increases in AS activity. Finally, analgesic compounds, i.e. cholinergic agonists and substance P antagonists, reduced the AA-induced increase in AS activity. These studies indicate that striated AS activity is a sensitive indicator of BL nociceptor activity and that the VA reflex model is useful for pharmacological studies aimed at suppressing these nociceptors.

CARDIOPULMONARY INPUT TO PUTATIVE PAIN MODULATORY NEURONS IN THE ROSTROVENTRAL MEDULLA. C.L. Thurston, and A. Randich, Dept. Psychology, Univ. of Alabama at Birmingham, Birmingham, AL 35294.

Neurons in the rostroventral medulla (RVM) have been classified based on their response to a noxious stimulus and the evoked withdrawal reflex. ON cells are excited and OFF cells are inhibited by noxious stimuli. We recently showed that ON cell activity is negatively correlated and OFF activity is positively correlated with mean arterial blood pressure (MAP). The present study demonstrated that increases in MAP excites OFF cells and inhibits ON cells whereas decreases in MAP inhibits OFF cells and has no effect on ON cells. In rats with bilateral sinoaortic deafferentations, spontaneous correlations between RVM neurons and MAP are still evident. However, experimentally-produced changes in MAP do not affect RVM neural activity. These data suggest that ON and OFF cells not only receive baroreceptor input, but also either produce changes in MAP or receive input from other neurons that produce changes in MAP.

Central cholinergic inhibition of the vesicoanal (VA) reflex model of urinary bladder irritation. K.B. Thor\* and M.A. Muhlhauser, CNS Research, Lilly Research Laboratories, A Division of Eli Lilly and Co., Indianapolis. IN 46285

Indianapolis, IN 46285
Previous studies showed that endogenous and exogenous cholinergic muscarinic (Ach-M) agonists can suppress somatic nociception. The present studies were conducted to determine if Ach-M systems can suppress visceral nociception. Bladders of urethaneanesthetized rats were cannulated thru the dome for continuous-infusion cystometrogram recordings. EMG electrodes were inserted into the anus and the peri-urethral musculature for recording sphincteric activity. Infusion of 0.5% acetic acid into the bladder produced modest increases in bladder and urethral sphincter activity and pronounced increases in anal sphincter activity (i.e. VA reflex). Oxotremorine (OXO, 1-30 µg/kg iv) and compound 296182 (0.01-1.0 mg/kg iv), centrally-active cholinergic agonist and partial agonist, respectively, produced a dose-dependent inhibition of the anal sphincter activity (to 10% of control) that was reversed by atropine (ATR, 1-3 mg/kg), but not by doses of methylscopolamine (MSC, 1-30 ug/kg) that did block carbachol-(1µg/kg), 296182- and OXO-induced bradycardia. This indicates that OXO- and 296182-induced inhibition of the VA reflex was centrally mediated. Furthermore, ATR (but not MSC) given alone transiently (15 min.) increased anal sphincter activity, indicating that endogenous acetylcholine was partially suppressing the VA reflex via tonic muscarinic mechanisms. Finally, physostigmine, but not neostigmine, also suppressed the VA reflex in a dose-dependent, ATR-sensitive manner, reinforcing the proposal of endogenous Ach-M suppression of the VA reflex.

RELEASE OF & ENDORPHIN-IR FROM BRAIN IS REGULATED BY A HYPOTHALAMIC NMDA RECEPTOR F.W. Bach, T.L. Yaksh, and M. Lauritzen\*, Dept. Anesthesiology, University of California San Diego, La Jolla, CA 92093-0818

β-endorphin (β-EP) is located in cell bodies in the arcuate nucleus of the hypothalamus and its major projections to the periaqueductal gray area in the brainstem are believed to play a role in antinociception. Systematic studies of the pharmacology of receptors governing the release of β-EP are lacking. We examined the effects of the glutamate receptor agonist NMDA on the release of β-EP-ir from arcuate nucleus neurons and on the motor response to a noxious heat stimulus. Rats were anesthetized with halothane. A microinjection cannula was stereotaxically implanted in n. arcuatus, and perfusion with artificial CSF was established through cannulae in the lateral ventricle and cisterna magna. Rats were kept at 1-1.2% halothane after the operative procedure. After 30 min of perfusion 0.5 μl of drug or saline was injected, followed then by collection of three 10 min post-injection CSF samples. Antinociception was evaluated by the latency to tail flick after dipping the tail in water heated to 52.5°C immediately before and 4 min after injection. Ten μg, but not 1 μg NMDA significantly increased the release of β-EP-ir (2-way-ANOVA, p-0.001), as compared to saline. Pretreatment with 1.5mg/kg MK-801 i.p. blocked the β-EP-ir release. The tail dip response was blocked by injection of 10μg NMDA in 10/12 rats, by 1μg NMDA in 6/9, by MK-801+10μg NMDA in 1/6, and by saline in 0/9. These results suggest a possible role for glutamatergic input into β-EP cells in the hypothalamus, as part of a system which regulates the antinociceptive response to a high threshold stimulus. (Supported by Fogarty Fellowship grant no.1 F05 TW04551-1 ICP (AHR-5))

AUTONOMIC SENSITIVITY AND REACTIVITY IN HUMAN PAIN.
A.C.N. Chen\* NeuroCognition Inst. Los Angeles, CA 91402
Human pain responsiveness was previously demonstrated in a tonic pain model of cold pressor test (Chen, PAIN 37:143-160, 1989) whereby healthy subjects clearly being categorized into pain sensitive (PS) and pain tolerant (PT) groups. This report extends the observation of differences in EEG activities (Chen, PAIN 37:129-141, 1989) to the autonomic activities between the PS and PT groups under the cold pressor test. The PS group (n=11) endured a mean+/-s.e. of 48.82+/-3.05 sec while the PT group (n=23) could tolerate the entire 3 min of the tonic pain test (t=35.22; pc.0000). The PS group rated a VAS score of 78.69+/-5.99 vs 58.29+/-4.08 for the PT group (t=2.77; pc.007). Autonomic sensitivity and reactivity showed significant differences in these two groups. At the resting baseline state, PS showed marked higher diastolic blood pressure (82.08+/-3.45 mmHg) than that (66.52+/-0.49 mmHg) of the PT group (t=3.65; pc.0009). In response to the cold pressor test, the PS and PT groups exhibited significant opposite patterns of systolic blood pressure change (decrease of 6.18+/-2.91 vs increase of 1.13+/- 2.06 mmHg, respectively; t=2.05, pc.048). Most strikingly, the diastolic blood pressure displayed a drastic contrast between the PS and PT groups (decrease of 9.83+/-3.72 vs increase of 11.04+/-2.74 mmHg, t=4.51, pc.0001). Further, in the group as a whole, the resting systolic blood pressure was found inversely correlated with the subjective pain rating upon the cold pressor test, primarily through the influence of the PT group alone. These results taken together indicates that the autonomic sensitivity and reactivity can differentiate the individual differences in human pain responsiveness. Plausible neurobiologic mechanisms for the autonomic sensitivity and reactivity can differentiate the individual differences in human pain responsiveness. AUTONOMIC SENSITIVITY AND REACTIVITY IN HUMAN PAIN.

#### 213.1

PRIMATE FRONTAL CORTEX: EFFECT OF INSTRUCTIONAL SIGNIFICANCE ON ACTIVITY FOLLOWING IDENTICAL VISUAL CUES S.P. Wise\*and D. Boussaoud. Lab. Neurophysiology, NIMH, Poolesville, MD

We examined neuronal activity in dorsal (PMd) and ventral (PMv) premotor cortex and in prefrontal (PF) cortex of two rhesus monkeys. Each monkey fixated a 0.2° white square in the center of a video display while depressing a switch located between two touch pads. Red or green squares (2x2°) served as cues. On each trial, a spatial/attentional cue (SAC) was presented for 0.8 s. The SAC consisted of one square, red or green, and its location indicated where a relevant motor instructional cue (MIC) would appear 1.8 to 3.3 s later. The MIC consisted of either one square (red or green) or both a red and green square presented simultaneously. A green square at the previously cued location instructed a forelimb movement to the right touch pad; red instructed movement to the left. At the offset of the MIC (duration 1 to 3 s), the monkey had to execute a forelimb movement within 1 s (and could break

Because the SAC could occur in different locations, a MIC with two squares could be physically, retinotopically and craniotopically identical, but instruct diametrically opposite limb movements. Thus, we tested the hypothesis that task-related activity reflects the direction of limb action rather than the sensory stimuli that guide movement

Our results from a sample of 91 frontal neurons show that the majority in PMd (65%), but only a small minority in PF (18%), have phasic and tonic activity that depends on the motor significance of the stimulus. In PMv, 41% of tested neurons show such a movement effect. Thus, for most cells in PMd, the activity during the MIC and before the onset of movement reflects the direction of the upcoming movement and appears to code for aspects of action rather than the sensory signals that guide the act. By contrast, cells in PF appear to have activity more closely linked to the instructing stimuli, whereas PMv cells have intermediate properties.

# RELATIONS OF SINGLE CELL ACTIVITY TO MOVEMENT PARAMETERS IN MOTOR CORTEX AND AREA 5. A.P. Georgopoulos\* and J. Ashe. Brain Sciences Center, Veterans Affairs Medical Center, Minneapolis, MN 55417.

The relations of ongoing single cell activity in the arm area of the motor cortex and area 5 to parameters of evolving arm movements in 2D space were determined using a multiple linear regression model in which the trial-by-trial time course of cell activity, at time  $t+\tau$ , was expressed as a function of the position, velocity and acceleration of the hand at time t, and of a constant corresponding to the visually defined target direction;  $\tau$  was a time lag (-100 to +200 ms). We analyzed the impulse activity of 290 motor cortical and 207 area 5 cells recorded previously in our laboratory. (a) In all cases, the regression model above was statistically significant (F-test, P < 0.05) at the lag with the highest  $R^2$ . (b) The median  $R^2$  was 0.55 and 0.46 for motor cortex and area 5, respectively. (c) The median lag at which the highest  $R^2$  observed was -110 ms and +20 ms for motor cortex and area 5, respectively. (d) For the motor cortex, velocity was the most important parameter in accounting for variation in cell activity in 41.72% of the cells, followed by the constant target direction (41.38%), position (8.62%), and acceleration (8.28%). For area 5, the most important parameter was velocity (47.34% of cells), followed by the constant target direction (33.82%), position (14.01%) and acceleration (4.83%). (Supported by NIH.)

# FUNCTIONAL CLASSIFICATION OF CELLS IN PRIMATE MOTOR CORTEX BASED ON SPIKE TRAIN ANALYSES.

M. Taira\* and A.P. Georgopoulos. Brain Sciences Center, Veterans Affairs Medical Center, Minneapolis, MN 55417.

In extracellular recordings, the cell type (e.g. pyramidal or local interneuron) is unknown. We developed a statistical technique to classify spike trains to a minimum of cell types. We analyzed spike trains from 1,925 cells recorded in our laboratory while monkeys held their arm in a stable posture preceding the onset of a visual target. First, we used a clustering analysis to identify the measures that would separate most effectively the cells into 3 groups. These were the mean firing rate, the trimean of the inter-spike interval (ISI) distribution, the percent of ISI < 20 ms, and a composite measure of bursting activity. This classification was then validated using a discriminant analysis which showed that 96.3% of the cells were correctly classified in their respective groups. The 1st group (59.6% of cells) had low discharge rate, high trimean ISI, small percentage of ISI < 20 ms, and low bursting. The 2nd group (19.3%) had low discharge rate, high trimean ISI, intermediate percentage of ISI < 20 ms, and high bursting. The 3rd group (21.1%) had high discharge rate, low trimean ISI, high percentage of ISI < 20 ms, and low bursting. These groups are very similar to those distinguished by other investigators in the neocortex: low frequency or bursting (presumably pyramidal) and high frequency (presumably local interneurons). Finally, the percentage of directionally tuned cells was very similar in all three cell groups. This finding suggests that directional operations are distributed in the motor cortex among presumably pyramidal and local interneurons.

# 213.4

MOTOR CORTICAL ACTIVITY PRECEDING A MEMORIZED MOVEMENT TRAJECTORY WITH A 90° DIRECTIONAL BEND. J. Ashe\*, N. Smyrnis, M. Taira, T. Georgakopoulos, J.T. Lurito, and A.P. Georgopoulos. Brain Sciences Center, Veterans Affairs Medical Center, Minneapolis, MN.

Two monkeys were trained to make a previously memorized arm movement with a 90° directional bend, first up and then to the left ( ), following a waiting period. They held a 2D handle over a spot of light at the center of a planar working surface. When this light went off, the animals were required to hold the handle there for 0.6-1 s and then move it up-and-to-the-left to receive a liquid reward. There were no external go signals. Following 20 trials of making the memorized movement trajectory, 5 trials of visually triggered movements in 8 radially arranged directions were performed. activity of 143 arm-related single cells in the motor cortex was recorded extracellularly during performance of the task. 58% of these cells changed activity during the waiting period. During the waiting period, the neuronal population vector began to grow in length approximately 170 ms following the time at which the center light went off. The population vector pointed first in the direction of the endpoint of the movement (N) and then changed direction gradually during the remainder of the waiting period towards the direction of the initial (†) component of the upcoming movement. (Supported by NIH, HFSP.)

ARE EXTENT AND FORCE INDEPENDENT MOVEMENT PARAMETERS? Alexa Riehle<sup>1</sup>, William A. MacKay<sup>2</sup>\*, <sup>1</sup>Cognitive Neuroscience Lab., CNRS, 31 ch. J. Aiguier, 13402 Marseille 09, France; <sup>2</sup>Dept. of Physiology, University of Toronto, Toronto M5S 1A8, Canada.

Movement extent and force can be independently controlled in motor performance. Therefore, independent representations of extent and force should exist in the CNS. To test this hypothesis, two levels of frictional resistance were applied to a manipulandum by means of which wrist flexion movements of two extents were performed. A first, preparatory signal (PS) provided complete, partial or no information about extent and/or force of the movement, which had to be performed in response to a second response signal (RS). The activity of about 400 neurons of the primary motor cortex (MI), the premotor cortex (PM), the primary somatosensory cortex (SI) and the parietal cortex (PA) was recorded in two monkeys. Preliminary analysis of the data suggests that different neuronal processes underly the programming of force and extent. On the one hand, partial information about either movement parameter shortened reaction time, when compared with the condition of no prior information. On the other hand, there were, among others, two discrete populations of neurons, one related only to extent, the other only to force. Furthermore, we conducted trial-by-trial correlation analyses between reaction time and neuronal activity during the preparatory period for all conditions of prior information. The mean correlation coefficient was significantly higher in the condition of information about movement extent than of information about force, and it was significantly higher in MI/PM than in SI/PA.

CORRELATIONS OF PRIMARY MOTOR CORTICAL SINGLE-UNIT ACTIVITY WITH EMG DURING A BEHAVIORAL TASK. J. L. Adams\* and A. B. Schwartz. Barrow Neurological Institute, 350 W. Thomas Road, Phoenix, Arizona 85013.

We compared single-unit activity in the primary motor cortex to EMG activity of the proximal arm muscles as a monkey (Macaca mulatta) performed drawing movements. We were particularly interested in the way this correlation evolved throughout the course of the movement. In macaques the corticospinal pathway to proximal arm muscles is multisynaptic. This indirect linkage as well as intratrial nonstationarity make it difficult to apply standard cross-correlation analysis.

One of the problems in detecting correlation between two time-varying neurological signals over a long time period (> 30 msec) is that any rhythmic variation within the individual signals will tend to contribute to the correlation between the signals. This was especially important in our experiments, since the movements the monkeys were performing were periodic, complicating the structure of cross-correlations. This was solved by using the impulse response function which removes the periodic changes.

In order to visualize the changes between motor cortical activity and proximal-arm EMG, the impulse response function was calculated in overlapping 350 msec windows throughout the task. Simulated spike trains and EMG patterns were also tested with this analysis. The correlation between spikes and EMG could be examined for particular epochs in the simulation. As well as the impulse response function, standard cross-correlation and spike-triggered averages were calculated. In the collected data we found that most of the cortical cell - muscle pairs showed transient correlation through each movement.

DIRECTIONALLY TUNED RESPONSES IN PRIMATE PREFRONTAL CORTEX COMPARED WITH THOSE IN MOTOR AND PREMOTOR CORTEX R.E. Kettner\* and J.K. Marcario, Department of Psychology and Program in Neural Science, Indiana University, Bloomington, IN 47405

To study the input, storage, and conversion of directional variables into coordinated movement, rhesus monkeys were trained to view a sequence of two target lights at randomly selected target locations, to delay their response during a delay period when eye and body position was fixed, and to then press the remembered target buttons in the proper order to receive a juice reward. Directional responses were defined using circular regression techniques and were categorized based upon the existence of statistically significant tuning during sensory (s), delay (d), and movement (m) periods. Thus, a neuron with tuned responses during the s and m periods was termed an sm neuron. Based upon 203 prefrontal and 254 motor/premotor cortex neurons that showed significant tuning, the percentages (prefrontal, motor/premotor) of m (43%, 44%), sd (2%, 2%), sm (10%, 13%), s (4%, 6%) and dm (20%, 18%) neurons were approximately equal for the two cortical areas. In contrast, d (12%, 5%) responses were more common in the prefrontal cortex, and sdm (6%, 16%) neurons were more common in the motor/premotor cortex. Our past studies of the motor and premotor cortex suggests that there is a diversity of sensory-motor responses during this task across the extent of motor/premotor cortex. The present results extend this idea to the prefrontal areas studied. While there were more d responses in prefrontal and more sdm responses in motor/premotor cortex, the similarities between these two areas is even more striking. Of particular interest is the large number of m and dm response in both areas that suggest activity correlated with the execution of arm movements to targets in space. NEURONAL SPECIFICATION OF DIRECTION AND DISTANCE DURING REACHING IN THE PREMOTOR AREA AND PRIMARY MOTOR CORTEX OF MONKEYS. Q.-G. Fu\*, J.I., Suarez and T.J. Ebner, Depts. of Neurosurgery & Physiology, Univ. of Minnesota, Mpls., MN 55455

In two primates we studied the activity of 186 neurons in the premotor area and motor cortex during a reaching movement. The task involved reaching to 48 targets in the horizontal plane (8 different directions at 6 distances). The neuronal activity before the onset of movement (PT) and during the movement (MT) was analyzed. Based on a cosine tuning function the majority of neurons were related to movement direction either in PT (73.7%) or in MT (68.3%). The cell's preferred direction did not change with movement distance. Using a simple linear regression model many cells had a significant relationship with distance in PT (46.8%) and in MT (68.8%). Distance modulation was not correlated with a cell's preferred movement direction. Both the correlation coefficient and the regression slope were distributed uniformly over the movement directions relative to a cell's preferred direction. Using a multivariate regression model based on distance, direction as well as interaction terms, a continuum of response types were described ranging from 1) cells with only direction encoding, 2) cells with only distance encoding and 3) cells requiring both distance and direction to describe the response. The model accurately predicted the response profile in 79.3% of the cells. The results show in the premotor area and primary motor cortex both direction and distance are encoded in parallel. Supported by Grant NSF/BNS-8707572 and the Human Frontier Science Program.

COMPARISON OF RESPONSES FROM CORTICAL AREAS 4 AND 6 DURING DRAWING. A. Kakavand and A.B. Schwartz\*, Barrow Neurological Institute, 350 West Thomas Road, Phoenix, AZ 85013.

Single-unit activity was recorded from two cortical areas as a monkey drew spirals on a touch screen with its contralateral arm. The spirals consisted of three cycles in which the radius changed at a fixed rate per degree of rotation; the largest radius was 6 cm and the smallest 1.5 cm. While isolation of each neuron was maintained, the animal drew the spiral from outside inward and in the opposite direction. Each task was repeated 5 times. In addition, each neuron was tested in a different task ('center->out') that determined whether the cell had a direction of movement to which it fired most rapidly, a preferred direction, and whether the activity of the cell could be fit with a cosine tuning function (directionally tuned). Responses from direction specific cells should occur in opposite portions of the cycle when the spirals were drawn from outside inward compared to the trials when they were drawn from the inside outward. On the contrary, location specific cells should tend to fire in the same part of the cycle regardless of the movement direction.

All cells in this experiment were modulated during the drawing tasks and tested with manipulation of the body to insure that they were related to proximal arm movement. In dorsal Area 6 the activity patterns of 78 cells were found to be directionally tuned during the center->out task. Only three of these cells could be clearly classified as directional during the spiral task. Twelve of these units were clearly location specific. In contrast, of the 81 directionally tuned cells in Area 4, 21 showed clear directional sensitivity during the spiral task while only three were location specific. Thus, location specific cells are more likely to be found in Area 6 while those responsive to direction tend to occur in Area 4. (NIH-NS26375)

# 213.10

COMPARISON OF PREFRONTAL NEURONAL RESPONSE PROFILES WITH THOSE OF THE MOTOR AND PREMOTOR CORTICES IN MONKEY. J.K. Marcario\* and R.E. Kettner. Department of Psychology and Program in Neural Science, Indiana University, Bloomington IN 47405.

Previously we have described the categorization of response profiles of neurons recorded in the motor and premotor cortices of rhesus monkeys performing a movement-sequence delayed response task (Marcario & Kettner, 1991; Kettner & Marcario, 1991). The task consisted of an initiation period (I), a sensory period (S), an uninstructed delay period (D), and a movement period (M). Each neuron was categorized according to whether it had statistically significant increases in average firing rate during each of the four task periods. In the motor and premotor cortices, the largest number of neurons were primarily movement related (I, 10%; IM, 24%; M, 21%). Other categories were less common. Categories above 1% were: S (10%); D (8%); SD (9%); IS (6%); DM (3%). All categories were distributed throughout motor and premotor cortex. To date, analyses of 355 neurons from prefrontal areas immediately anterior

To date, analyses of 355 neurons from prefrontal areas immediately anterior to premotor cortex suggest a larger number of IS (11%), ISM (3%), and SM (5%) responses and a smaller number of SD (1%) and IM (14%) responses than in the motor and premotor cortices. Other major categories were similar to those in motor and premotor cortices. In particular, there was still a good number of M (18%) and I (8%) responses, which indicates cells active when the monkey is moving to remembered target buttons. It is interesting to note that neurons categorized as SD units were much more prevalent in the motor and premotor cortices than in the prefrontal cortex. These results agree with the companion abstract in suggesting both similarities and differences in responses recorded across motor, premotor, and prefrontal cortices. (Supported by NSF grant BNS-8919867)

TEMPORAL PRIORITY AND LONGER PROCESSING TIME OF PREMOTOR CORTEX OVER NEARBY AREAS IN RECEIVING VISUAL CUES IN PRIMATES. K. Okano. Y. Inoue\* Department of Physiology, Hokkaido University School of Medicine, North 15, West 7, Sapporo, 060, Japan. Neuronal activities in the premotor cortex (PM, n=41cells), supplementary motor area (SMA, n=43), and precentral motor cortex (MC, n=53) were recorded while monkeys performed a visually trionered task. Kendall's partial correlation coefficient

visually triggered task. Kendall's partial correlation coefficient analysis was applied to the data to determine whether changes in neuronal activity were dependent on visual-stimulus or movement-onset. The proportion of cells in which neuronal activity changes were significantly related to visual-stimulus was 22% in PM cells, 7% in SMA cells, and 0% in MC cells.

Cross correlation analysis was performed on 31 pairs of neurons recorded with a single electrode. Neuronal related correlograms which were constructed by subtracting the shuffled correlograms from the gross correlograms had either a positivity or negativity, asymmetric to the zero time, and declined gradually (8/31). Presynaptic cells showed longer periods between onset of activity changes and the onset of the key pressing (mean±sd; 48.8±39.4 ms). Furthermore, PM cells had a longer processing time than nearby areas (PM/non PM: 3/5cells, t-Test, P=0.04). This suggests that the PM possesses the temporal priority over, and has longer processing time than the nearvy areas in receiving visual cues in primates.

ACTIVITY OF SINGLE NEURONES IN PRIMATE FACE SOMATOSENSORY CORTEX SI DURING TONGUE PROTRUSION MOVEMENTS IN DIFFERENT DIRECTIONS. L.-D. Lin\*, G.M. Murray, J.W. Hu, and B.J. Sessle Fac. of

Dentistry, Univ. of Toronto, Toronto, Ont., M5G 1G6, Canada. We recently reported (J. Neurophysiol. 67, '92) that neuronal population coding of tongue movement direction may be a feature of face motor cortex (MI). The aim of this study was to determine if neuronal activity in face SI also can be related to movement direction. Two monkeys (M. fascicularis) were trained to perform a tongue-protrusion task at each of 3 directions, with a force transducer positioned at 0° or 30° to the left or right of the midline. Extracellular recordings were then made from 47 single SI neurones with a mechanoreceptive field involving tongue, lip, or periodontium. The firing rates of 38 neurones (81%) was significantly altered during the tongue-protrusion task performed by the monkey in 1 or more directions (repeated measures ANOVA; p<0.05). The firing rate of 27 of these neurones (71%) varied significantly with the direction of tongue protrusion. Of 24 such 'direction' neurones studied during all 3 directions, 19 exhibited a single direction for which the firing rate was significantly greater than for any other direction; the highest firing rate in 18 of the 19 occurred at one of the two asymmetrical positions. The location of occurred at one of the two asymmetrical positions. The location of the neuronal mechanoreceptive field however could not predict the presence of directional selectivity of neurones or the preferred direction. This suggests that, in accordance with recent findings in face MI, coding of movement direction may also be a feature of face SI. Supported by Canadian MRC.

DISCHARGE OF PARIETAL NEURONS DURING STATIC POSTURES, I. FORCE DEPENDENCE. SI Helms Tillery\*, JF Soechting. TJ Ebner, Depts of Physiology and Neurosurgery, Univ Minnesota, Minneapolis, MN 55455

Well-controlled movement requires the use of information provided by somatic receptors, inputs from which first arrive in cortex at the primary somatosensory cortex (SI). The signals thought to be most relevant to the encoding of posture arise largely from muscle, joint, and tendon receptors. These receptors have complex discharge properties in relation to movement, with components related to muscle length and force, as well as joint angle and angular velocity. Therefore, it is important to determine the extent to which discharge in SI neurons can be accounted for in terms of posture without taking into account the forces used to maintain the posture. Parietal neurons were recorded while a monkey performed two tasks involving placement of the hand at locations specified by a robot arm. The monkey either 1) grasped a manipulandum which provided support for the arm, or 2) pressed a switch in the face of the manipulandum which did not provide support. We found that the discharge of many neurons is modulated in a consistent manner with changing location of the hand in space, but that the nature of that modulation was often different in the two tasks.

MODULATION OF THE ACTIVITY OF SMA NEURONS DURING PREHENSION. G. Cadoret\*S. Mellah and A.M. Smith, C.R.S.N, Université de Montréal, Québec, Canada H3C 3J7

A M.fascicularis monkey learned to grasp, lift and hold an instrumented device between the thumb and forefinger, and to hold it stationary for 1 second within a position window. The instrumented device allowed the grip and lifting (load) forces as well as the object position to be accurately measured. The texture and weight characteristics of the device could be changed to examine the scaling of grip and load forces during lifting. On selected blocks of trials, a predictable force-pulse perturbation was introduced during the holding phase to produce a slip force on the fingers. This perturbation invariably induced a reflex increase in grip force and, with repetition, a gradual preparatory increase in the static grip force which preceded the perturbation. Single units were recorded in the controlateral SMA in the different conditions of texture, weight and perturbation. Although many SMA neurons had modulated activity during grasping, only 7 cells could be further identified with the control of hand muscles by their response to microstimulation or by the presence of receptive fields on the palm or fingers. However, of these 7 cells, only one demonstrated a reflex response to the perturbation whereas the 6 others had increased activity related to the anticipation of the perturbation. Supported by MRC of Canada and FCAR du Québec.

THE ACTIVITY OF VIBRATORY-RESPONSIVE MONKEY PRIMARY SOMATOSENSORY CORTICAL NEURONS IS MODULATED PRIOR TO HAND MOVEMENT. M. A. Lebedev and R. J. Nelson\*. Dept. of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, 875 Monroe Avenue, Memphis, TN 38163.

Primary somatosensory (SI) cortical neurons may be entrained to the frequency of vibratory stimuli presented to the hand as go-cues for wrist movements. While these neurons initially convey high fidelity information about vibratory stimuli, it is unclear if they do so for the entire period before movement. Recent studies suggest that the activity of SI neurons is modulated prior to both movement and EMG onset. Four adult rhesus monkeys (Macaca mulata) were trained to make hand flexion and extension movements in response to vibratory stimuli applied to the palm. They were also trained to maintain wrist position following the same vibratory cues. Accordance with the NIH Guide for Care and Use of Laboratory Animals, revised 1985 was kept. The discharge patterns of 10, 15, 38 and 8 Area 3a, 3b, 1 and 2 neurons have been analyzed. Most had receptive fields on the hand, wrist or forearm. The records for each neuron were split into two cases, one for each movement direction. The vast majority showed changes in mean firing rate and stimulus frequency synchronization that occurred before movement. Most changes lead movement onset by 80ms or more and EMG activity by ~20ms. Cases were split into three groups based on changes in firing rate. Some 60%, 37%, 38% and 50% of the Area 3a, 3b, 1 and 2 cases showed increased discharge before movement. Of the cases for the respective areas, 20%, 33%, 32% and 19% showed mean discharge rate decreases before movement. The rest did not alter firing rate before movement. However, spikes related to single stimulus cycles occurred earlier as the onset of movement approached. A model was constructed that could explain the observed changes in mean discharge rate, synchronicity and spike occurrence.

DISCHARGE OF PARIETAL NEURONS DURING STATIC POSTURES, II. RELATION TO POSTURAL PARAMETERS JF Soechting\*, SI Helms Tillery, TJ Ebner. Depts of Physiology and Neurosurgery, Univ Minnesota, Minneapolis, MN 55455

One of the possible uses of kinesthetic information in arm movement is to provide feedback about the position of the arm. The posture of the arm, however, can be described in any of a number of possible coordinate systems (eg. Soechting and Ross, Neurosci 13: 595, 1984). To address the question of coordinate representation of posture in the brain, we have recorded from parietal neurons in an awake monkey while the animal placed its hand at various locations in its progressive process. brain, we have recorded from parietal neurons in an awake monkey while the animal placed its hand at various locations in its workspace specified by a robot arm. The posture of the arm during performance of the task was recorded by a video system and the locations of the shoulder, elbow, wrist, and hand in three-dimensional space reconstructed from the images. The discharge observed in single neurons was then related to various possible descriptions of the posture of the arm. The firing frequency of any neuron typically depended in a nonlinear manner on the postural parameters, regardless of which set of parameters was chosen. However, it was possible to identify simplified parameter sets (eg. a plane in space) which could account for the observed discharge. The degrees of freedom required to describe the discharge could thereby be reduced while still accounting for complexities in the cells' spatial properties.

SELECTIVITY OF HAND-MOVEMENT-RELATED NEURONS OF THE PARIETAL CORTEX FOR SHAPE, SIZE AND ORIENTATION OF OBJECTS AND HAND GRIPS. H. SAKATA, A. MURATA, G. LUPPINO, M. KASEDA and M. KUSUNOKI\*. Department of Physiology, Nihon University School of Medicine, Itabashi-ku, Tokyo 173, Japan.

In the inferior parietal lobule of the monkey, there is a group of neurons that is specifically related to hand movements. We found many neurons preferred a particular type of manipulandum, and most of them received both visual and motor signals (Taira et al, Exp. Brain Res. 83:29, 1990). In order to study the selectivity of these neurons for the spatial characteristics of objects and hand grips, we trained the monkey to grasp and pull a set of objects of different shapes (sphere, cube, cylinder, plate and ring), sizes and orientations, and recorded the activity of parietal neurons during grasping or fixation of objects

Many of the hand movement-related neurons were preferentially activated during grasping an object of a particular shape. Several neurons showed categorical selectivity in shape, e.g. some cells preferred round objects such as spheres and cylinders to angular objects such as cubes and plates. Some cells were selective for the size of objects and grips, but others were selective only for shape, independent of size. Some cells were selective in orientation of the plate or ring, either vertical, horizontal or diagonal. Only some neurons responded to viewing the object alone but rest of them required the view of grasping hand to be activated.

These results suggest that the parietal neurons integrate visual and motor signals to discriminate the pattern of active hand movements and play an important role in the matching of the hand posture with the object to be grasped.

# TRANSMISSION OF PRELIMINARY PERCEPTUAL INFORMATION TO

THE MOTOR CORTEX.

<u>Jeff Miller<sup>1</sup>, Alexa Richle<sup>\*2</sup>, Jean Requin<sup>2</sup>, <sup>1</sup> Dept. Psychol., UCSD, La Jolla, CA 92093-0109; <sup>2</sup> Cogn. Neurosci. Lab., CNRS, 13402 Marseille 09, France</u>

Single neurons were recorded in the primary motor cortex of one monkey to discriminate between discrete models of sensorimotor information processing, in which one stage begins only when the earlier stage finishes, and continuous models, in which the gradual transmission of information implies that one stage can begin before the earlier stage finishes. The monkey had to perform wrist extension/flexion movements. The visual display provided a two-dimension stimulus: side (an easy discrimination between left and right targets), which determined movement direction, and distance (a difficult discrimination between proximal and distal targets), which determined whether or not the movement was to be made. 116 directionally selective neurons were classified into three classes: sensory neurons (activity change time-locked to the stimulus), motor neurons (time-locked to movement onset), and sensorimotor neurons (having two response components, the first time-locked to the stimulus and the second time-locked to movement onset). Activity changes of sensory neurons were similar in GO and NOGO trials, those of motor neurons were weaker in NOGO trials than in GO trials, and sensorimotor neurons behaved in such a way that, in NOGO trials, the first component remained whereas the second component was reduced, compared to GO trials. Thus the results substantiate the conclusion from reaction time and event-related potential studies that preliminary perceptual information may reach the motor system before stimulus analysis is completed. However, it does not end the debate between discrete vs continuous models, since the interpretation of results depends upon the stage mapping conception of cortical organization. Supported by ONR grant N 00014-89-J1557

SENSORY TO MOTOR TRANSFORMATION WITHIN AREA 5 OF THE POSTERIOR PARIETAL CORTEX (PPC) OF THE MONKEY. M. Akamatsu<sup>1</sup>, T. Hasbroucq I. Mouret and J. Seal\*. Industrial Products Research Institute, Tsukuba, Japan<sup>1</sup> and Lab. of Cognitive Neuroscience, C.N.R.S., BP 71, Marseille, France.

The aim of our work was to study the neuronal mechanism of sensory to motor transformation within area 5 of PPC using single neuron recordings in monkeys performing a sound-triggered forelimb movement. We studied the changes in neuronal activity that occurred after the sensory cue and before the onset of movement on a trial by trial basis. Although the onset of change remained relatively stable on a sensory to motor gradient, the peak in neuronal activity became less sensory and more motor as it occurred later in the reaction time. This suggests that peak activity of these neurons is involved in sensory to motor transformation. To investigate the transformation mechanism, time from onset to peak in neuronal activity, amplitude and rate of increase in neuronal activity were estimated using new methods of data analysis. Plotting these parameters against reaction time gave scatter diagrams each with a characteristic form. The relation between these parameters and reaction time could be simulated in a neuron model with variable amplitude of input, rate of increase in activity and threshold with inhibition after a fixed delay. This model gave scatter diagrams similar to the real data.

WIDELY DISTRIBUTED NEURON ACTIVITY IN PRIMARY MOTOR CORTEX HAND AREA DURING INDIVIDUATED FINGER MOVEMENTS. M.H.Schieber\* Depts. of Neurol. & Neurosurg., Anat. & Neurobiol., Wash U. Sch. Med., St. Louis, MO, 63110.

Classic surface stimulation studies implied a somatotopic representation of movements of different fingers in the primary motor cortex (MI) hand area. Recent ICMS studies, however, suggest a diffuse representation. But during movements of a given finger performed actively by the subject, are active neurons confined to a particular sub-region of the hand area, or are they present articular sub-region of the hand area, or are they present

throughout?

Single neuron activity was studied in the MI hand area of 2 rhesus monkeys trained to perform individuated flexion and extension movements of each finger or the wrist. Conventional techniques were used to record all isolable, task-related neurons without differentiating between pyramidal tract (PT) and non-PT neurons. Though some neurons discharged with only 1 of the 12 movements, most neurons discharged in relation to 2 or more movements. Such neurons could discharged in relation to 2 or more movements, such neurons could be related to various combinations of movements, not necessarily to movements of adjacent digits, or to flexion and extension movements of the same digit(s). Three-dimensional reconstruction revealed that the region containing neurons related to any one individuated finger ent was virtually coextensive with the region containing neurons related to any other.

Neurons participating in any given individuated finger movement thus appear to form a network spread throughout the MI hand area. The network generating any given finger movement overlaps extensively and shares many neurons with the network generating any other.

MOVING A SINGLE FINGER OR MOVING ALL FINGERS: AN ACTIVATION PET STUDY OF CORTICAL MOTOR AREAS. Ph. Remy, M. Zilbovicius, L. Raynaud, A. Syrota, Y. Samson\*, CEA Service Hospitalier F. Joliot, 91406 Orsay, France. We used PET to test the hypothesis that an individuated movement of a single finger involves a greater number of cortical neurons, and perhaps more motor areas, than a less complex movement of all fingers (M.H. Schieber, TINS, 1990, 13: 440). Eight normal volunteers had rCBF measurements with PET (H2<sup>15</sup>O) in three conditions: 1) Rest; 2) All finger movement: repeated flexion-extension of the all five fingers; 3) Medius movement: flexion-extension of the medius only. All movements were self-paced, and subjects were untrained. Four regions of interest were defined on individual MRI in the cerebral cortex contralateral to the fingers movements, and superimposed on PET images: primary sensorimotor cortex superimposed on PEI images: primary sensorimotor cortex (SM), supplementary somatosensory area (SMA), premotor cortex (PM), parietal associative cortex (area 7). All finger condition activates SM (7.9±3.2%, p<0.001) and no other region. medius condition activates both SM (+10.6±3.7%, p<0.001) and SMA (+5.2±5.1%, p<0.01). The rCBF increase was significantly larger in the medius condition than the one found in all finger condition in both SM (p<0.05) and SMA (p<0.001). Our results support the hypothesis that more neurons of the primary support the hypothesis that more neurons of the primary motor cortex may be involved in movements of individual finger than in combined movement of all fingers. They also show that SMA is involved in the realization of an unusual and difficult single digit movement. (Supported by AP-HP, Paris).

INTRACORTICAL MECHANISMS FOR THE RECRUITMENT OF MOTOR CORTEX NEURONS, P. Istvan, P. Kirchberger & P. Zarzecki\*, MRC Group in Sensory-Motor Physiology, Department of Physiology, Queen's University, Kingston, Ontario, Canada, K7L 3N6

During behaviour, motor cortex neurons are recruited in discharge patterns that vary according to the projection targets of their output axons. It is not known how these distinctive discharge patterns are determined, especially for neurons located close together but projecting axons to separate targets. One mechanism is that nearby neurons are affected by distinct patterns of input from pathways projecting into cortex from extrinsic sources (Zarzecki, Somatosens Mot Res 8:313,'91). However, because the majority of synapses upon output neurons are of intracortical origin, the local circuitry must also be considered.

We investigated the effects of intracortical neurons upon motor cortex output neurons in anesthetized cats. Corticospinal, corticorubral, corticoreticular and corticothalamic neurons were invaded antidromically and spontaneous discharges of three to five additional neurons were recorded simultaneously with the same or a second nearby electrode. Individual neurons were identified and sorted by their characteristic spike waveforms. Discharges of each waveform-identified neuron were cross-correlated with discharges of the invaded neuron or neurons recorded at the same site. Several different shapes of correlograms were found. The most common same site. Several universe mappes of correlograms were found. The most common correlograms had symmetrical peaks centered at zero time, evidence of shared input. Increased probability of discharge of the output neuron that was delayed after the trigger spike was interpreted as serial coupling. Some correlograms were flat. The correlograms generated for each output neuron using the three to five waveform-identified neurons at the same recording site were usually different from one another. This result suggests that intracortical neurons contribute to the selective recruitment of neurons from within clusters of projection neurons.

CONTROL OF THE DISTAL MUSCULATURE IN INDIVIDUALS WITH CALLOSAL AGENESIS. P. Servos\*, L.S. Jakobson, M.A. Goodale, & M. Lassonde, Department of Psychology, University of Western Ontario, London, Ontario, and \*\*Département de Psychologie, Université de Montréal, Montreal, Quebec.

Supported by the Medical Research Council of Canada.

Classic work with split-brain monkeys suggests that the reaching limb can be controlled by either cerebral hemisphere but that finger control is largely crossed (Haaxma & Kuypers, 1975). Accordingly, acallosal subjects (AS) should have no difficulty grasping objects in the visual field ipsilateral to the hand used, but should have great difficulty forming their grasp in crossed space. Recently, however, it has been suggested that human callosotomy patients can exercise substantial degree of ipsilateral control for the thumb and index finger (Trope et al., 1987). This suggests that AS should show good grip formation throughout the visual field.

In the present study, we carried out a kinematic analysis of reaching and grasping movements executed by 4 AS and 4 matched controls. Ss maintained central fixation while reaching with either hand for objects placed in left, central, and right space. Relative to controls, AS took longer to complete reaches directed into contralateral space, and spent proportionately more time decelerating. Moreover, unlike controls, their grip formation appeared to be impaired in all regions of space. Contrary to the predictions mentioned above, these results suggest either that prehension requires cooperation between the hemispheres, or that the corpus callosum in normal Ss exerts a facilitatory influence on intrahemispheric processing (Lassonde, 1986). Supported by grants from MRC (Canada).

A COMPARISON OF HEMISPATIAL NEGLECT FROM FRONTAL EYE FIELD AND POSTERIOR PARIETAL LESIONS IN THE MONKEY. Douglas P. Crowne\* and Linda W. Mah, Department of Psychology, University of Waterloo, Waterloo, Ontario, CANADA N2L 3G1

Observation of monkeys with unilateral frontal eye field (FEF) and posterior parietal lesions suggests that the neglect syndromes may be partially distinct. Ipsilaterally-deviated gaze, impaired head and eye movements, and ipsiversive circling are characteristic of FEF but not parietal lesions. There is also a question of their relative severity. This experiment quantitatively compared visual neglect and recovery in monkeys with unilateral FEF, parietal, and principal sulcus (control) lesions. Neocortical lesions of these 3 regions were produced in 9 macaque monkeys, and they were tested for their ability to detect and respond to brief visual stimuli in varying field eccentricities. Both FEF and parietal lesions resulted in neglect. Recovery from the FEF lesion occurred by the 3rd postoperative week, but neglect was strongly evident in the parietal animals in the 8th week. A second homologous lesion produced a more severe and enduring neglect of contralateral stimuli and also reinstated neglect in the hemifield affected by the first lesion. These data confirm symptoms of visual neglect from parietal lesions and are consistent with differentiated functions of the FEF and posterior parietal cortex in directed attention.

PYRAMIDAL TRACT LESIONS AND SKILLED REACHING IN THE RAT. Whishaw\*, I.O., Tetzlaff, W., Pellis, S.M., Gorny, B., Dept. Psychology, Univ. Lethbridge, Lethbridge, AB, Canada, T1K 3M4

A number of contemporary theories associate the pyramidal tract with distal movements, especially independent finger movements. Such movements are not pronounced in rats, yet the size of the rat corticospinal projections as a ratio of cortical volume is among the highest of all mammals. We reexamined the role of the pyramidal tract in a skilled reaching for food task with the purpose of determining whether it is also involved in other aspects of limb movements. High speed videorecording, movement notation, and kinematic methods were used to describe the movements. Rats with selective lesions to the pyramidal tract, just rostral to the decussation, were studied over a prolonged recovery period. Although success in limb use was only decreased if a difficult reaching task was used, the rats did have enduring impairments in limb use. Impaired movements included limb aiming, paw pronation and supination, and food release. Successful reaching was accomplished by compensatory movements of the body and modifications in reaching style. Since aiming and pronation involve upper arm movements and supination involves both arm and wrist movement, the pyramidal tract is involved in both proximal and distal limb movements. Since digit closing to grasp was unaffected but opening to release food was affected, some aspects of distal movements are lost while others are spared. The results suggest a general association between the pyramidal tract and skilled movements irrespective of the location of the controlled body part.

FORCE-RELATED NEURONAL ACTIVITY IN TWO DIFFERENT REGIONS OF THE PREMOTOR CORTEX IN THE ALERT MONKEY.

M.-C. Hepp-Reymond\*, M.A. Maier, F. de Luca, H.X. Qi

Brain Research Institute, University of Zurich, CH-8029 Zurich, Switzerland In the lateral area 6, neurons related to finger movements have been described by several groups. The question was raised whether the activity of such neurons may encode grip force exerted between thumb and index finger

We have explored the premotor region in one monkey trained to produce fine-graded forces in a step-tracking task, with two or three consecutive force steps presented in a random manner. Task-related neurons were found in two subregions of area 6, 150 in the most lateral part of the arcuate premotor area (APA) and 162 on the convexity rostral to area 4. The neurons of both regions shared several properties similar to those of area 4, such as firing patterns and receptive field characteristics. A large population of tonic and phasic-tonic neurons increased or decreased their firing rate with force increase. In lateral APA, 63 neurons had clear receptive fields on the fingers, and 26/40 with tonic activity showed highly significant positive or negative correlations between firing rate and isometric force. All these neurons were located in sites where microstimulation elicited discrete movements of the digits for currents of 7 to 30 uA. In the convexity, 92 neurons also had receptive fields on the hand and from a sample of 25 neurons, 14 had positive significant correlations in contrast to a single negative one. These neurons were clustered in a small region where microstimulation occasionally triggered motor reactions of the digits. For some neurons in both regions, the covariation with force was conditional, depending on the expectation of the reward at the end of the trial.

In conclusion, coding of force is present in area 6 neurons located in two circumscribed regions. Thus, the division of area 6 into subregions according to their connectivity is supported by the present functional study

POSITRON EMISSION TOMOGRAPHY STUDIES OF CEREBRAL GLUCOSE UTILIZATION IN MONKEYS PERFORMING VISUO-MOTOR INTEGRATION TASKS. J. Quintana\*. A. Alazraki. Z. Allen. R. Woods. S. Cherry. J.C. Mazziotta. L.R. Baster and M.E. Phelps. Depts. of Neurology, Psychiatry, Div. of Nucl. Med., and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024. Positron emission tomography (PET) was used to study local cerebral glucose utilization (ICGU) in a rhesus monkey performing a visually guided motor grasping task while seating in a primate chair, its two hands resting on a horizontal plastic plate. The task consists of grasping a small piece of food reward presented at the bottom of one of four narrow grooves carved in different directions on a vertical plastic panel. Performance requires a target-oriented combined arm/hand reaching movement with a precise coupled position of the thumb and the forefinger. Fluorine-18 deoxyglucose (FDG) was administered intravenously (i.v.) or orally immediately before the animal was exposed to either a repeated performance or a control stable situation during the tracer uptake period (30 or 75 min for the intravenous or oral administration routes, respectively). During the control experiments no movement was required: the monkey sat in the chair in front of the panel and the food reward was administered directly into the mouth. The scanning was carried out on a high resolution Siemens-CTI animal PET device. Differences in regional glucose metabolism due to specific performance-related responses were analyzed by subtracting control from stimulation PET emission data. Results showed an increase in ICGU during task performance after i.v. FDG in posterior parietal (15%), premotor and motor areas of the hemisphere contralateral to the used hand. In addition, smaller increases in he ipsilateral preoccipital parieto-temporal area were seen. No differences in ICGU into sea areas were observed between the post-oral and post-i.v. FDG control situations. However, a marked increase in ICGU

INTERMEDIATE LINKS IN THE CORTICO-CORTICAL
CONNECTIONS FOR VISUAL REACHING.

Most reaching movements are to visual targets yet the pathways through

which the arm regions of the frontal lobe receive visual information are unknown. To address this issue, we have injected multiple retrogradelytransported tracers into the shoulder-related region extending from area 4 to transported tracers into the shoulder-feated region extending from area 4 to dorsolateral area 6, as identified by single-cell recordings in macaque monkeys performing a reaching task. Within the frontal lobe, the arm-related region of dorsolateral area 6 projects to the border region between areas 4 and 6. This intermediate region, in turn, projects to the arm region of area 4. The parietal lobe inputs to these frontal areas originate from the cortex forming the medial crown of the intraparietal sulcus (areas 2 and 5), the medial bank of the intraparietal sulcus (area MIP), and from a region extending from the most posterior part of the medial bank of intraparietal sulcus onto the mesial aspect of the hemisphere (areas MDP and 7m). Injections restricted to area 4 retrogradely labeled neurons in areas 2 and 5. Injections in the border region between areas 4 and 6 labeled neurons mainly in MIP, but also in areas 5, MDP, and 7m. Injections in area 6 labeled neurons mainly in MDP and 7m, but also in the adjacent MIP. Other studies have previously shown the existence of direct projections from visual area PO to MIP and 7m (Blatt et al., J.Comp.Neurol. 299:421-445, 1990; Cavada and Goldman-Rakic, J.Comp.Neurol. 287:393-421, 1989). The projections shown in our study from these parietal areas provide an anatomical substrate by which visual information may influence the frontal lobe mechanisms for the control of arm movement.

CLUSTERED INTRINSIC CONNECTIONS AMONG REPRESENTATION ZONES IN THE CAT MOTOR CORTEX. A. Keller \*. Department of Anatomy, USUHS, Bethesda, MD 20814.

Patterns of intrinsic connections in the cat motor cortex were studied using intracortical microstimulation (ICMS) and extracellular dye injections. ICMS was used to identify cortical sites at which low threshold stimulation (< 20 μA) evoked movements or muscle contractions. The forelimb, hindlimb, and icial representations were discreetly segregated within the motor cortex. facial representations were discreetly segregated within the motor cortex. Within each of these representation zones, identical movements could be elicited from several non contiguous sites. In each cat, a single small injection of either fluorescent latex beads, HRP, or PHA-L was made into a single site from which wrist flexion was evoked. The distribution of retrogradely labeled somata and anterogradely labeled axons and axon terminals were then correlated with the physiologically defined motor maps. Labeled somata and terminals were distributed in dense clusters across the forelimb representation zone. A more diffuse distribution of somata and terminals occurred within the hindlimb representation area, and only scant labeling was found within the representation of facial musculature. Within the forelimb representation representation area and terminals occurred within zones representation of somata and terminals occurred within zones representation clusters of somata and terminals occurred within zones representing movements – in different directions – of digits, wrist, elbow, and shoulder. Tracing of individual PHA-L labeled axons revealed that each intracortical axon forms a number of terminal clusters, and that different clusters of the same axon terminate in zones representing different movements. These data indicate that extensive intracortical connections mediate reciprocal synaptic interactions among groups of cells involved in the execution of different movement segments. These clustered, horizontal connections may be used for coordinating the activity of different cortical representations for the execution of complex movements, and may also be involved in the pliability of motor representation maps. Supported by NIH grant # NS-31078.

EXPANSION OF DISTAL FORELIMB REPRESENTATIONS IN PRIMARY MOTOR CORTEX OF ADULT SQUIRREL MONKEYS
FOLLOWING MOTOR TRAINING. G.W. Milliken\*, R.J. Nudo, R. Grenda, W.M. Jenkins and M.M. Merzenich. Dept. of Neurobiology & Anatomy, Univ. of Texas Med. Sch., Houston, TX 77030 and Keck Center for Integrative Neuroscience, Univ. of Calif. at San Francisco, San

We examined consequences of motor training on the functional topography of primary motor cortex. In normal squirrel monkeys, a detailed map was derived in the zone of representation of hand, wrist, and arm contralateral to the preferred hand using intracortical microstimulation techniques and sterile operative procedures. After a post-operative recovery period, monkeys underwent behavioral training. The task required the animals to retrieve small food pellets from four graded wells on a Plexiglas board. The smallest well required the controlled insertion of only one or two digits into the food well to retrieve pellets. The animal's skill at pellet retrieval was significantly improved by only a few days of intensive training. Training continued for 10-11 days. Within two days after the final retrieval session, a second detailed map of motor hand representations was derived.

In each case, post-behavior maps revealed significant changes in the topographies of movement representations marked by expansion of the cortical sectors representing movements involved in the task. By contrast, in control animals, distal forelimb representations were relatively unchanged. These experiments confirm that the functional representations of primary motor cortex are remodeled by use, throughout life. Supported by NIH NS27974 (RJN), NS10414 (MMM) and the Whitehall Foundation (RJN).

THALAMIC INPUT TO AREA F3 (SMA-PROPER) AND TO AREA F6 (PRESMA) IN THE MACAQUE MONKEY.

M. Matelli\* G. Luppino\*, R. Camarda\* and G. Rizzolatti \*(SPON: European Brain and Behavior Society) Istituto di Fisiologia Umana Universita' di Parma Via Gramsci 14 I-43100 Parma Italy.

Recently we showed that the mesial sector of area 6, generally considered ecentry we snowed that the mestal sector of area 6, generally considered coextensive with the so called Supplementary Motor Area (SMA), is composed by two different areas: F3 (SMA-proper) and F6 (pre-SMA) (Luppino et al. J. Comp. Neurol. 311:463-482,1991). On the basis of the neurophysiological properties of the two areas, we proposed that, in motor control, F6 plays a hierarchically higher

The present experiments were aimed to verify this proposal by studying the thalamic input to the two areas. Neural tracers (WGA-HRP, FB, TB and DY) were injected in F3 and F6, following their physiological identification with intracortical microstimulation, in four monkeys. The results were the following. The main input to F3 comes from basal ganglia recipient nuclei: VLo (major contribution), VLm, and VApc. A substantial input arrives also from cerebellar recipient nuclei: VLc, and, to a lesser extent, the caudal part of VPLo. Almost no labelling was observed in area X of Olszewski. Finally, an input arrives to F3 also from the caudal part of MD. The main thalamic input to F6 originates from VApc and area

caudal part of MD. The main thalamic input to F6 originates from VApc and area X. Other projections come from VLc and the caudal part of MD. Intralaminar nuclei and, at a much lesser extent, the posterior thalamus project to both F3 and F6. Taken together these data allow us the following main conclusions: a) F3 and F6 are both targets of basal ganglia and cerebellar outflow. b) The thalamic origins of this outflow is markedly different. c) As far as the basal ganglia are concerned, F3 is a part of the so called "basal ganglia motor loop", whereas, F6 belongs to the "basal ganglia complex loop". This differential basal ganglia input provide further evidence in favour of a higher hierarchical role of F6 in respect to F3. (Supported by a Grant from Human Frontier Science Program)

TOPOGRAPHY OF MOTOR CORTEX REORGANIZATION H.Henningsen, M.Daffertshofer, M. Syren, S. Knecht(I), R. Diehl and J. Röschke\* Depts. of Neurology, Univ. of Heidelberg (Mannheim) and Düsseldorf(I).FRG

Previous studies have shown that after limb amputation there is a use dependent enlargement of motor cortex areas projecting to muscles proximal to the amputation. In order to determine whether in humans such changes conform with motor homunculus topography we performed transcranial magnetic stimulation (TMS) in 10 patients (pts) (4 pts aged 34.8 +/- 7.2 ys with forearm and 6 pts aged 33.2 +/- 6.8 ys with finger amputation). TMS (at 1.5 twitch threshold) mapping was carried out by consecutively placing an eight shaped coil on 80-120 frontal-parietal scalp positions, 0.5 cm apart from each other. EMG responses were recorded from the biceps and (in finger amputees) the extensor indicis

In finger amputees, off-line analyses of scalp position and EMG response did not show enlargement of the scalp "biceps-field", i.e. the area giving biceps motor responses (>100 uV) to TMS. However, pts with forearm amputation showed a significant enlargement of the biceps field in comparison to their unaffected side (p<0.01). In our 4 pts this enlargement resulted from a lateral extension of the field. The forearm is also located more laterally in the human motor homunculus. Therefore the topography of the enlargement of TMS "biceps-fields" strongly suggests, that motor cortex, formerly projecting to the forearm, is used for output to proximal stumb muscles after amputation.

PLASTICITY IN THE CEREBELLO-THALAMO-CORTICAL PATHWAYS. L. Rispal-Padel\*, E.-M. Meftah and M. Pananceau. Equipe "MSM" - CNRS - 13009 Marseille - France.

The cerebello-thalamo-cortical pathway (C.T.C.) may be temporarily involved in the learning of new movements (ITO, 1984). The exclusion of the ventrolateral nucleus (VL) of the thalamus does not affect the performance of learned movements, but makes it impossible for subjects to acquire new movements (FABRE and BUSER, 1980). Moreover, acquire new movements (FABRE and BUSER, 1980). Moreover, simultaneous high frequency stimulation of both the sensory cortex and the VL induced long term potentiation of thalamic input to motor cortical neurons (BARANYI and FEHER, 1979; IRIKI et al., 1989). It was therefore proposed to investigate whether any plasticity in the C.T.C. connections could be observed after classical forelimb flexion conditioning in cats.

A classical conditioning of the X-type effectively produced changes in the conditioned motor response about

A classical conditioning of the type effectively
produced changes in the conditioned motor response about
ten days after the beginning of the the conditioning
procedures. The probability of the occurrence of this
motor response as well as its amplitude were increased.
Motor cortical evoked potentials induced by the
conditioned stimulus were also modified. Increasing the
excitatory cerebellar inputs was found to affect one or
two motor cortical sites, whereas the activation of the
other cortical sites was decreased.

other cortical sites was decreased.

These motor and evoked cortical potential modifications were seen to be correlated.

MAGNETIC TRANSCRANIAL CORTEX STIMULATION TO DOCUMENT MOTOR FUNCTION RECOVERY AFTER STROKE. M.A.Lissens\* and W.B.McKay. Dept. Physical Medicine and Rehabilitation, University Hospitals of Leuven, Belgium, and Division of Restorative Neurology and Human Neurobiology, Baylor College of Medicine, Houston, TX 77030.

Information about the integrity of the corticospinal tracts can be obtained by transcranial stimulaiton of the motor cortex. We performed transcranial stimulation using a magnetic stimulator in stroke patients with hemiplegia, in the acute phase and at one month intervals during the motor activity recovery. A case report is presented of a 36-year old female who suffered from a hemorhagic stroke with left hemiplegia. During the first three weeks no motor evoked potentials (MEP's) were obtained anywhere. After one month in the left abductor pollicis brevis muscle a very small MEP of only 50 microvolts (uV) with a slightly delayed latency time was obtained, after two months the amplitude was 140 uV, after three months 450 uV and after four months 1650 uV with a nearly normalized latency time. At this last examination a small response was also obtained in the abductor digiti minimi muscle.

The increase of the initially very small MEP amplitudes and normalization of the originally delayed latency times correlated remarkably with the recovery of motor function.

This clearly demonstrates that MEP's can be used as a

quantitative parameter of motor activity recovery, and moreover can motivate patients during rehabilitation.

THREE-DIMENSIONAL RECONSTRUCTION OF SERIAL SEC-TIONS USING FOURIER DESCRIPTOR ANALYSIS. J.P. Ray\*, L.S. Hibbard, and J.L. Price. Anatomy and Neurobiology, and Neurology and Neurological Surgery. Washington University School of Medicine, St. Louis MO 63110.

Our studies of the anatomical organization of the primate prefrontal cortex have used flattened, two-dimensional (2-D) maps of cortex from serial coronal sections using a contour line unfolding technique (Van Essen and Maunsell, *J. Comp. Neurol.*, 191:255, 1980). We are developing computational methods for unfolding the cortex. Preliminary to unfolding is the accurate three-dimensional (3-D) reconstruction of the serial sections. We have adapted Fourier Descriptor (FD) techniques (Zahn and Roskies, IEEE Trans. Comput., C21: 269, 1972) to align sections represented by xy-coordinates from tracings of the pial surface and layer IV. After linear interpolation, the N traced coordinates are combined as u(n) = x(n) + jy(n), n = 0, 1, ..., N-1, in a Fourier series equal to the FD a(k)

$$a(k) = \sum_{n=0}^{N-1} u(n) exp(-j2\pi kn/N). \quad 0 \le k \le N-1.$$

The differences between the FDs of adjacent sections dictate the translation and rotation necessary to align the sections. If a(k), b(k) are the complex FDs for coordinate sets u(n), v(n), then the x- and y-translations are given by the differences [Re(b(0))-Re(a(0))]. [Im(b(0)-Im(a(0))], respectively. The rotational misalignment and the coordinate starting point offset are extracted from the phase differences of the lower order terms by linear regression. (Support: McDonnell Center for the Studies of Higher Brain Function. Small Grants Program.)

AN UPDATED VERSION OF McCUILLOCH'S MAP OF THE CEREBRAL CORTICAL AREAS OF THE MACAQUE SUGGESTS A COMPLETE CIRCLE OF VISUAL AND OCUL OMOTOR AREAS SURROUNDS A CORE OF SENSORIMOTOR CORTEX E.J.Neafsey\*. Dept. of Cell Biology, Neurobiology & Anatomy, Loyola Univ. Medical Center, Maywood, IL 60153. In 1944 Warren McCulloch published a two dimensional map of the cortical areas in macaque cortex (Physiol Rev 24). His map differed from current flat' maps (Van Essen, Kaas, etc.) because his map had no artificial breaks or cuts but rather simply stretched' the limbic cortical areas at the medial edge of the hemisphere. The figure below illustrates an attempt to incorporate some of our present knowledge of macaque cerebral cortical organization into a McCulloch map. The shaded ring of cortical areas can all be classed as visual or oculomotor, based on the work of Van Essen, Kaas, and others. Note in particular that when areas 23 and 24 are included, the ring becomes complete. Several studies have found that area 24 has an oculomotor function and also projects to the superior colliculus (Leichnetz et al. Neuroscience (1981) 6:10/23); area 23 has recently been reported to be responsive to the position of the eye in the orbit and to the occurrence of saccades (Musil et al (1991) NS Abstr 17:442). The central core encircled by the ring contains the neurons that give rise to the pyramidal tract (Toyoshima and Sakai, J Hirnforsch (1981) 32:257). Frontal lobe at upper left, corpus callosum around top, hippocampus at bottom. Suggestions invited.

# ASSOCIATION CORTEX AS A DARWINIAN WORKSPACE: Corticocortical Axons Suggest Cloning from Hexagonal Engrams. WILLIAM H. CALVIN, Univ. of Washington, Psychiatry NJ-15, Seattle WA 98195

The brain might shape up more complex mental images on the milliseconds-tominutes time scale, using principles similar to how new species are shaped up in millennia and novel antibodies in weeks. Darwinism signifies 1) patterns (genes or memes) that make copies of themselves, where 2) different patterns compete with one another for hegemony over a territory, their relative success biased by 3) a manyfaceted environment; further, 4) variants on successful patterns are frequently introduced, occasionally finding a new niche or improving the fit to an existing one. Selective survival may occur without #1 and #4, but is not appropriately termed darwinism. Here I show that association cortex has the essential anatomy (standard axon lengths in layer III pyramids) for a true darwinian workspace. 1) Spatiotemporal patterns of neuronal activity could clone themselves; because chaotic firing patterns in similar hexagons synchronize, NMDA-like coincidence facilitation can recruit corresponding points in adjacent unorganized cortex. A hexagonal mosaic ensues. Approach/avoidance and remembered environments can 2) promote one pattern over another in boundary disputes. 3) An active pattern may resonate with an underlying synaptic pattern, one engram of many in the 0.5mm hexagon. I identify situations where copying errors are corrected, others that 4) encourage variants. Recombination occurs; such composite hexapixels might represent categories, ensembles, and sequences. Active patterns ("phenotypes") can be cloned even if novel, successful ones later imprinted in the static connectivity (Lamarckian "genotypes"). Subcortical managers might set good-enough criteria for memorization and overt action, serve to speed evolution via "climatic changes." While darwinian procedures seem particularly appropriate for judging novel plans, they may also generate shortcut algorithms that recognize the routine and extrapolate the present situation into one's next act.

# VESTIBULAR SYSTEM: NEUROCHEMISTRY

FOS-DEFINED ACTIVATION OF THE INFERIOR OLIVE DURING CENTRIPETAL ACCELERATION IN UNILATERAL LABYRINTHECTOMIZED RATS. G. D. Kaufman\*, J. H. Anderson†, A. J. Beitz. Departments of Veterinary Biology and Otolaryngology†, University of Minnesota, St. Paul, MN 55108 USA.

Polyclonal Fos antibody was used to identify activated neurons in rat brainstem following 90 minutes of centripetal acceleration at 2 G. Long-Evans rats were restrained with the head fixed inside metal cones in darkness and positioned ~50 cm eccentric from the axis of rotation which was earth vertical. Unilateral chemical labyrinthectomies (UL) were performed by middle ear injection of sodium arsanilate, and the rats were sacrificed 24 hours (acute) or 14 to 18 days (chronic) later. When chronic restrained rats with UL were positioned with their long axis tangential (left or right position) to the arc of rotation, the dorsomedial cell column (DMCC), and the beta (IOB) subnuclei, exhibited Fos expression only when the lesioned side was towards the axis of rotation. In acute rats the DMCC was labeled similar to the chronic rats, but the IOB on the side toward the axis of rotation was labeled for both orientations of the rat. Fos activity patterns in other vestibular-related nuclei revealed different patterns in response to the centripetal stimulus, depending on the time since UL, and the orientation of the animal. The vestibulo-ocular reflex, measured with the dual search coil technique, was also quantified. The results suggest that a subset of the otolith receptors was responsible for DMCC and IOB activation. The DMCC might play an important role in adapting to a new gravito-inertial reference, whereas the IOB may be more critical in initial compensation to the UL. Supported by NASA/NGT-50563, NIH DC01086, DC00110, DA06687.

INFLUENCE OF NMDA ANTAGONIST ON VESTIBULO-OCULAR REFLEX ADAPTIVE GAIN DECREASES. T.L. Carter\*1, R. Baker2 and I.G. McElligott<sup>1</sup>. <sup>1</sup>Dept. of Pharmacology, Temple University School of Medicine, Phila., PA 19140, and <sup>2</sup>Dept. of Physiology and Biophysics, N.Y.U. Medical Center, New York, NY 10016

Antagonists to the NMDA receptor interfere with neuroplastic electrophysiological and behavioral changes regulated by the central nervous system. More specifically, previous work in our laboratory has shown that the NMDA antagonist MK-801 interferes with adaptive vestibulo-ocular reflex (VOR) gain increases (Soc Neurosci. Abstr. 17 #127.9, 1991). In order to test the generality of this finding, goldfish were trained to decrease VOR gain after a systemic (i.M.) injection of MK-801 (Img/kg). Goldfish were restrained in the center of a cylindrical test aquarium (dia. = 27.5 cm) which was sinusoidally rotated about the vertical axis at 1/8 Hz  $\pm$   $20^\circ$  (vestibular stimulus). Projection of visual stimuli (random dot pattern) onto the wall of the stimulus). Projection of visual stimuli (random dot pattern) onto the wall of the aquarium at the same frequency, amplitude, and in phase with the vestibular stimuli produced VOR gain decreases (towards 0X). The gain of the VOR was assayed by measuring the movements of both eyes using the electro-magnetic search coil technique. Fish were trained to decrease VOR gain over a 3 hour period during which time the VOR in both the light and the dark was measured at 15 minute (1st hour) and 30 minute intervals (2nd and 3rd hour). The systemic injection (I.M.) of fish Ringer's solution (control) or MK-801 (Img/kg; experimental) did not alter non-adapted VOR gain when measured prior to adaptive training. Furthermore, control and MK-801 injected animals produced identical adapted VOR gain decreases measured during the training neriod. For poth the control and the experimental groups, the onset of VOR training period. For both the control and the experimental groups, the onset of VOR gain decrease was immediate and had the same initial rate of gain decrease (0.4/hour). gain decrease was immediate and had the same initial rate of gain decrease (0.4/hour). This result is in sharp contrast with that of our previous experiments which demonstrated that systemic injection of MK-801 delays the onset and reduces the rate of adaptive VOR gain increase. These results would indicate that the site of adaptive VOR gain decrease is located at a non-NMDA sensitive area while the site of adaptive VOR gain increase is located at a NMDA sensitive area. (Supported by a grant from NIDCD-NIH # DC 01094).

LOCALIZED MICROINJECTION AND DIALYSIS OF NMDA ANTAGONIST IN THE VESTIBULO-CEREBELLUM DURING ADAPTIVE VESTIBULO-OCULAR REFLEX GAIN CHANGE. J. G. McElligott\* and T. L. Carter, Dept. of Pharmacology, Temple Univ. Sch. of Med., Philadelphia, PA 19140.

The vestibulo-ocular reflex (VOR) has been studied as a model system for investigating neuroplasticity within the central nervous system. Two areas involved in this reflex, the vestibulo-cerebellum and the vestibular nucleus, have been proposed as sites responsible for adaptive VOR gain changes. Our previous studies (Soc Neurosci. Abstr. 17 #127.9, 1991) have found that MK-801, an NMDA antagonist, when administered systemically (LM), delays the onset and reduces the initial rate of VOR adaptive gain increases. In order to determine if the vestibulo-cerebellum is an NMDA sensitive site, MK-801 was administered directly into this region. VOR gain changes were measured by means of the electro-magnetic search coil technique. Goldfish were presented with sinusoidal vestibular stimulation by rotating them about the vertical axis (1/8 Hz @ ± 20°) while restrained within a cylindrical test aquarium (dia. = 27.5 cm). Gain increases were produced by projecting visual stimuli (random dot pattern) onto the wall of the test aquarium. These stimuli were presented at the same frequency and magnitude but 180° out of phase with the vestibular stimuli. In all cases, there was no change in the non-adapted VOR gain measured in the light or the dark before and after intra-cerebellar application of MK-801. In addition, the onset and the initial rate of adapted gain change in control and MK-801 microinjected animals (1 to 638ng @ 1.5 ng/nl) was also equal in both groups. A second study using microdialysis probes (dia. = 150 µM, length = 3 mm) was carried out in order to increase the amount of MK-801 available to the vestibulo-cerebellar region. Using this technique, MK-801 was delivered continuously during the entire period of VOR adaptation. Again, there was no difference in the onset time and the initial rate of VOR adaptive gain increase between the experimental and the control infused animals. These results suggest that the vestibulo-cerebellar region is not an area in the goldfish brain where the NMDA antagonist, MK-801, interfe

IN SITU HYBRIDIZATION OF GLUTAMATERGIC RECEPTORS, GLUTAMATE DECARBOXYLASE AND CHOLINE ACETYLTRANSFERASE ENZYMES IN RAT VESTIBULAR NUCLEI C. de Waele\*, M. Abitbol, C. Menini, M. Chat, J. Mallet, P.P. Vidal Lab. de Physiologie Neurosensorielle, CNRS, UPR2, Paris, FRANCE and Lab. de Neurobiologie cellulaire et moléculaire, CNRS, Gif sur Yvette, FRANCE.

Histological distribution of NMDA and metabotropic receptor mRNAs was determined in the vestibular nuclei of the adult rat. Both NMDA and trans-1-amino-cyclopentane-1,3-dicarboxylate (t-ACPD), a specific agonist of glutamate metabotropic receptors, previously had been shown to depolarize strongly medial central vestibular neurons (Vibert et al., Soc. Neurosci. Abst.128.22, 1991). Specific radioactive oligonucleotides were used to probe sections of rat vestibular nuclei according to in situ hybridization methods. Dense labelling of NMDA mRNA appeared in several brainstem regions including the medial, lateral, inferior and superior vestibular nuclei. In addition, these nuclei showed intermediate levels of metabotropic receptor mRNA labellings. In a second step, we studied the localization of mRNAs that encode two forms of glutamic acid decarboxylase (GAD1 and GAD2) and choline acetyl transferase. The findings indicate that both GAD mRNAs were present in all subpopulations of central vestibular neurons. Our data also confirm previous electrophysiological studies which have demonstrated the role of GABA in modulating medial vestibular neuron resting discharges.

CGRP IN THE VESTIBULAR AND COCHLEAR EFFERENT NEURONS IN THE CHINCHILLA. P. Popper\*, R.A. Wong Marco, L.F. Hoffman, P.A. Wackym and P.E Micevych. Dept. of Anatomy & Cell Biology, Laboratory of Neuroendocrinology, and Division of Head and Neck Surgery, UCLA School of Medicine, Los Angeles, CA 90024.

The distribution of calcitonin gene-related peptide immunoreactivity (CGRPi) among efferent vestibular and cochlear neurons in the chinchilla was investigated. Fluorogold (40 µl, 4% in saline) was injected through the oval window into the inner ear of anesthetized young male chinchillas (6-12 months old). Four days postinjection, the animals were anesthetized and perfused through the heart with 4% paraformaldehyde in phosphate buffer. Alternate 20 µm thick brainstem sections were processed for CGRPi using a fluorescent method. Alternate sections were processed for in situ hybridization using a radiolabeled RNA probe complementary to the 3'end of the aCGRP mRNA. At the levels of the descending facial nerve and the genu of the facial nerve, virtually all of the Fluorogold labeled cells in the perigenual nuclei (group E vestibular efferents) extending to the medial aspect of the medial vestibular nucleus contained CGRPi. All the Fluorogold labeled cells around the dorsal third of the parvocellular reticular nucleus (PCR) and most of the Fluorogold labeled cells in the lateral superior olivary nuclei (cochlear efferents) contained CGRPi. More caudally, 50% of the Fluorogold labelled cells in the PCR had CGRPi. Fluorogold labeled cells in the dorsal lateral aspect of the perifacial zone were not CGRPi. Supported by DC00008 and DC01404.

NEUROGENETIC CLASSIFICATION OF PROJECTION NEURONS IN THE RAT VESTIBULAR NUCLEI. Y.Kitao, S.Okoyama, T.Moriizumi\* and M.Kudo. Dept.of Anatomy, Sch.of Med., Kanazawa 920. JAPAN University. Kanazawa 920. JAPAN

Kanazawa University, Kanazawa 920, JAPAN.

The vestibular nuclear complex is divided into four subnuclei cytoarchitecturally. Each subnucleus may contain the vestibulo-spinal (Sp), the vestibulo-oculomotor (III) and the vestibulo-thalamic (Th) projection neurons. Present study attempts to make a classification of the projection neurons according to their proliferation periods by combining nuclear bromodeoxyuridine (BrdU) and retrograde cytoplasmic fluorescent dye labeling. 1) The Sp neurons in the medial nucleus were produced through E12-E14 with peak on E13, while most of the SP neurons in the lateral nucleus were generated on day E12. In the inferior nucleus, the Sp neurons arose over days E12 and E13.

2) The III neurons were generated from days E12 to E13 predominantly on E12 taking no different temporal course among subnuclei. 3) The Th neurons were produced on days E13 and E14 without temporal differences among the subnuclei either. The results suggest that the targets of the projections can be destined by the proliferation periods of the neurons.

LOCAL INJECTIONS OF \$\text{B-NORADRENERGIC}\$ SUBSTANCES IN THE CEREBELLAR ANTERIOR VERMIS OF CATS AFFECT ADAPTATION OF THE VESTIBULOSPINAL REFLEX (VSR) GAIN. \$\text{Q.Pompeiano\*}\$ \text{P.Andre, P.d'Assanio and D.Manzoni.}\$ Dept. of Physiol. Biochem., Univ. of Pisa, 56127 Pisa, Italy.

Dept. of Physiol. Biochem, Univ. of Pisa, 56127 Pisa, Italy.

In precollicular decerebrate cats sinusoidal roll tilt of the head at 0.15 Hz,±10' was associated with roll tilt of the body in the same direction and at the same frequency, but at the peak amplitude of 12.5'; this stimulus led to 2.5' of neck rotation, which was thus outphase with respect to head rotation. During a 3 hr period of sustained vestibular and neck rotation, the gain of the VSR recorded from the triceps brachii and tested every 15 min progressively increased to reach the mean value of 240.7±41.8,S.E.X of the control (n=11 experiments). This adaptive process was followed up to 1 hr after stimulation. Injection into the zone B of the cerebellar anterior vermis of the 8-adrenergic antagonists propranolol or sotalol (0.25µl at 8µg/nl saline) produced only slight and short-lasting changes in the basic amplitude of the VSR, but decreased or prevented the occurrence of the adaptive changes which affect the VSR gain during sustained head-neck rotation (n=11 experiments). The same agents also suppressed the increase in gain of the VSR which occurred during sustained roll tilt of the whole animal (at 0.15 Hz,±10') leading to selective stimulation of labyrinth receptors (n=2 experiments); moreover, the 8-adrenergic agonist isoproterenol (0.25µl at 8µg/µl saline) enhanced this adaptive process (n=4 experiments). In conclusion, the results obtained indicate that adaptive changes affect the gain of the VSR in decerebrate cats. Such processes are facilitated by the noradrenergic afferent system acting on Purkinje cells of the cerebellar vermis through 8-adrenoceptors.(NIH grant NS 07685-23 and ASI 1991 RS77).

NMDA RECEPTOR-MEDIATED CALCIUM INCREASE IN RAT MEDIAL VESTIBULAR NUCLEI. Y.Takahashi. M.P.Takahashi. T.Tsumoto\* K.Doi and T.Matsunaga. Dept. of Neurophysiology, Biomedical Research Center and Dept. of Otorhinolaryngology, Osaka University Medical School, Suita, 565 Japan

Osaka University Medical School, Suita, 565 Japan An activity-dependent change in synaptic efficacy in the vestibular nuclei may underlie mechanisms of vestibular compensation, and an entry of Ca²+ into postsynaptic sites through N-methyl-D-aspartate(NMDA) receptor-linked channels is suggested to play a role in such plasticity of the vestibular system. To test this possibility, we measured changes in [Ca²+], with fluorometry using a Ca²+ sensitive indicator, rhod-2, in slice preparations of the medial vestibular nuclei (MVN) of young rats (postnatal 4-7 days) following electrical stimulation of afferent pathways and analysed effects of NMDA receptor antagonists on these measures. Single shock stimulation of vestibular afferents or commisural fibers did not induce sizable increase of [Ca²+], in the standard medium. In the Mg²+-free medium, however, the fluorescence increased by 3-6 % in response to single shock stimulation, and this increase was blocked by an application of an NMDA receptor antagonist, D.L-2-amino-5-phosphonovaleric acid (APV) (100µM). However, a non-NMDA receptor antagonist, CNQX (10µM) was ineffective. In the standard medium, the fluorescence also increased during tetanic stimulation (30Hz for 3.3 sec) of both pathways by 5-15%. APV reduced such a tetanus-induced increase by 27±11% in case of afferent tetanus and 20±14% in case of commisural tetanus (n=24). A blocker for NMDA receptor-linked channels, MK801 (20µM), also reduced the tetanus-simulation of vestibular afferents and commisural fibers may induce an influx of Ca²+ into MVN neurons partly through NMDA receptor-linked channels in young rats.

LOSS OF INTEGRATOR FUNCTION AFTER INJECTION OF GABAERGIC SUBSTANCES INTO THE PREPOSITUS HYPOGLOSSI NUCLEI (PPH). J.Yokota, H.Reisine\*, and B.Cohen. Depts. Neurol. & Physiol. Mt. Sinai Sch. Med. NY 10029

We have previously shown that velocity storage is most probably generated in the vestibular nuclei (VN) and not in PPH (Yokota et al. 1992). Consistent with this electrical stimulation of PPH of alert cynomolgus monkeys caused ipsilateral eye deviations or nystagmus with ipsilateral horizontal slow phases from 30-45°/s. Peak slow phase velocities were 10-20°/s less than from stimulation of VN or from OKAN. There was no after-nystagmus after PPH stimulation. After microinjections of muscimol (1  $\mu g/\mu l$ ), the eyes were shifted to the contralateral side, and gaze holding was poor in the ipsilateral field. There was horizontal spontaneous nystagmus with contralateral slow phases. The time constant of the ipsilateral VOR was shortened, although the gain was preserved. Ipsilateral OKAN disappeared; contralateral OKAN was normal. Steady state velocities were lost for ipsilateral but not contralateral OVAR. Vertical eye movements were unaffected. After injection of bicuculline into PPH, changes in eye movements were transient. Animals were unable to hold contralateral gaze positions, and the eyes were shifted to the ipsilateral side. There was horizontal spontaneous nystagmus with ipsilateral slow phases. The time constant of the horizontal VOR was reduced contralaterally with preservation of gain. Contralateral OKAN and OVAR disappeared transiently. We conclude that muscimol sensitive GABA. receptors are utilized in PPH in the process related to V-T-P integration. They also appear to play a role in producing horizontal slow phases of nystagmus generated by velocity storage. Supported by NS00294 and EY01867.

EFFECTS OF AMINO ACIDS ON MEDIAL VESTIBULAR NEURONES IN GUINEA PIG BRAINSTEM SLICES. N. Vibert, M. Serafin, A. Khateb, P.P. Vidal' and M. Mühlethalet\*, Department. of Physiology, CMU, 1211 Geneva 4, Switzerland and "Laboratoire de Physiologie Neurosensorielle, CNRS UPR 02, 75270 Paris Cedex 06, France.

Geneva 4, Switzerland and \*Laboratoire de Physiologie Neurosensorielle, CNRS UPR 02, 75270 Paris Cedex 06, France.

Using intracellular recordings in brainstem slices, we have recently identified in the guinea-pig medial vestibular nucleus (MVN) two main neuronal cell types (A and B MVNn) differing by their intrinsic membrane properties. Both cell types were found to be extremely sensitive to inhibitory (IAA) and excitatory (EAA) amino acids. Almost all MVNn were consistently depolarized and excited by selective EAA agonists, including AMPA (45 out of 46 MVNn), NMDA (49 out of 52 MVNn) and trans-ACPD (73 out of 73 MVNn). In contrast, L-AP4 had no effect in either cell type (8 out of 8 MVNn), The effects of AMPA and trans-ACPD persisted in presence of TTX, and in a low calcium/high magnesium medium known to block synaptic transmission. NMDA responses also persisted in presence of TTX. Almost all MVNn had their firing rate reduced by IAA, including GABA (35 out of 39 MVNn), muscimol (selective GABA A agonist, 83 out of 83 MVNn) and baclofen (selective GABA B agonist, 61 out of 65 MVNn). Whereas for baclofen this inhibition was associated with a membrane hyperpolarization, in the case of muscimol and GABA it could occur concomitantly with either a membrane depolarization (in about half of the cases in A as in B MVNn) or hyperpolarization. The effects of IAA analogs persisted on both cell types in presence of TTX and in low calcium/high magnesium solution, but the depolarizing responses eventually obtained in normal medium were all reversed to hyperpolarizing ones. Since the application of bicuculline always induced a membrane depolarization, we suggest that GABA in the MVN can play a role either directly (postsynaptic hyperpolarizing action) or indirectly (through presumed inhibitory interneurones). These data confirm the major physiological importance of both EAA and IAA as transmitters in the medial vestibular nucleus (supported by the Swiss NSF).

## VESTIBULAR SYSTEM: MORPHOLOGY AND PHYSIOLOGY

## 216.1

CONTRIBUTION OF REGULAR AND IRREGULAR DISCHARGING SEMICIRCULAR CANAL AND OTOLITH AFFERENTS TO LOW FREQUENCY VOR. <u>A.A. Perachio\*</u>, <u>D.E. Angelaki and C.L. Strunk</u>, Dept. of Otolaryngology, Univ. of Texas Medical Branch, Galveston, TX 77555.

The functional significance of the diversity in the dynamic characteristics of regular and irregular discharging vestibular afferents and their role in different motor outputs has recently been addressed (Highstein et al., I/IP 58:719-738, 1987; Minor & Goldberg, I/N 11:1636-1648, 1991). Minor & Goldberg have shown that the vestibular nerve input to the high frequency VOR comes almost entirely from regular semicircular canal afferents. The present study examines the relative contribution of regular and irregular vestibular afferents to the low frequency VOR by selectively ablating irregular afferents with 100 uA anodal (inhibitory) currents delivered bilaterally to both labyrinths in squirrel monkeys. Eye movements were monitored using EOG electrodes. The contribution of regular and irregular semicircular canal afferents to the low frequency VOR was examined with 3 and 5 sec duration pulses of anodal currents delivered bilaterally at various intervals during a step of angular velocity about an earth-vertical axis. The relative role of a functional ablation of irregular otolith afferents was examined with 3 and 5 sec duration anodal currents delivered bilaterally during the steady-state toolith-induced ocular response evoked with off earth-vertical axis rotation (OVAR). In contrast to the effects seen during high frequency VOR, ablation of irregular afferents significantly decreases eye velocity during on-axis rotations. The effect is transient and only lasts during the period of electrical stimulation. In addition, ablation of vestibular afferents decreases the steady-state eye velocity during OVAR. This supports previously proposed models that have suggested a role for irregular otolith afferents in the generation of that response. (Hess, Biol. Cyb. In press, Angelaki, Biol. Cyb. In press, 1992). Supported by NASA NAG 2-26 Grant and NIH Grant DC00385.

DIFFERENCES IN CILIARY BUNDLE MORPHOLOGY OF TYPE I AND TYPE II VESTIBULAR HAIR CELLS. L.L. DiCaprio\* and E.H. Peterson. Neurobiology Program, Ohio University, Athens, OH 45701.

Vestibular hair cells are classically divided into two types based on somatic structure and afferent innervation. Hair cell ciliary bundles also exhibit anatomical diversity, which may affect their mechanical properties, and we ask whether the morphological properties of ciliary bundles vary with hair cell type.

We visualized hair cells in transverse sections through the crista of a turtle, *P. scripta*, using DIC optics or confocal microscopy; the confocal material was double labeled, using dextran rhodamine for afferent terminals and Bodipy phallacidin for hair bundles. We identified type I hair cells by the presence of a calyx. Our results indicate that the ciliary bundles of type I cells have a significantly wider base (from kinocilium to shortest stereocilia) and a greater proportion of short stereocilia than adjacent type II bundles.

Such differences in bundle width could be due to variation in numbers, spacing, or width of individual stereocilia. Scanning electron microscopy of the hair cell apical surface indicates that differences in ciliary number account for at least 70% of the observed variation in bundle thickness. Thus, type I hair cells have significantly more stereocilia than type II cells at the same location on the sensory surface.

Ciliary number is thought to be a major determinant of bundle stiffness. Our results suggest that type I bundles will be stiffer, and will require a greater force to deflect them, than adjacent type II bundles. Thus, type I and type II hair cells may be preferentially responsive to different amplitudes of head acceleration. Supported by NIH-NIDCD DC00618.

#### 216.2

MORPHOLOGICAL FEATURES OF SINGLE INHIBITORY MEDIAL VESTIBULOSPINAL AXONS RECEIVING HORIZONTAL SEMICIRCULAR CANAL INPUT. Y. Shinoda\*, S. Kakei, Y. Sugiuchi and T. Kawasaki. Dept. of Physiol., Sch. of Med., Tokyo Med. & Dent. Univ., Tokyo, 113, Japan.

Dent. Univ., Tokyo, 113, Japan.

Single horizontal canal-related type-I medial vestibulospinal tract (MVST) axons were visualized by intraaxonal injection of horseradish peroxidase (HRP) and their morphological features were analyzed in terms of axonal branches reconstructed on serial sections, target motor nuclei, and synapses at an electronmicroscopic level. MVST axons were electrophysiologically identified in anesthetized cats as secondary MVST axons descending in the ipsilateral MLF to the upper cervical cord. In the same cats, motoneurons of different neck muscles were retrogradely labelled with HRP. MVST axons running in the ventral funiculus gave off multiple axon collaterals at multiple segments of the upper cervical cord. Terminal boutons were mainly distributed in laminae VII-IX and also in laminae IV-VI. Single MVST axons terminated in the ventromedial, spinal accessory, and dorsomedial nuclei. In these nuclei, terminal boutons of these axons appeared to make contact with cell bodies and proximal dendrites of retrogradely-labelled motoneurons of various sizes. Electronmicroscopic analysis confirmed direct syaptic contacts on the motoneurons and showed the existence of symmetric synapses and pleomorphic vesicles in the synaptic boutons.

CONTRIBUTION OF INDIVIDUAL VERTICAL SEMICIRCULAR CANAL PAIRS TO ESTIMATION OF YAW EYE VELOCITY DURING PITCH WHILE ROTATING. M.Dai, T.Raphan, J-I.Suzuki, S.Yakushin, Y.Arai, B.Cohen\* Mt. Sinai School of Med, Brooklyn College of CUNY, Teikyo Univ Sch Med, Tokyo Women's Medical College

Pitching the head while rotating about a spatial vertical axis (PWR) generates continuous horizontal nystagmus whose steady state eye velocity is related to rotational head velocity. This has been shown to be dependent on the integrity of the vertical semicircular canals. Here we studied PWR of a canal plugged animal, but with its right anterior and left anterior semicircular canal (RALP) left intact. Pitching the monkey in the plane of the intact canals, induced vertical and roll eye velocity, but no horizontal component. As the pitch plane was positioned away from the intact canal plane, a horizontal component appeared. The pitch plane that induced the maximal steady state horizontal eye velocity was orthogonal to the plane of the intact canals. A significant steady state eye velocity was achieved with pitch periods ranging from approximately 4 to 25 sec. The data suggest that steady state horizontal head velocity is estimated as a mathematical inner product of the vertical semicircular canal signal with the otolith signal. This signal activates velocity storage to induce steady state eye velocity (Raphan et al, 1983). The direct vestibular pathways from the intact semicircular canals contribute to the modulation in eye velocity. Thus, PWR provides the brain with a way to estimate yaw head velocity in the absence of the lateral semicircular canals. AFFERENT AND EFFERENT RESPONSES FROM MORPHOLOGICALLY IDENTIFIED FIBERS FROM THE POSTERIOR SEMICIRCULAR CANAL OF THE TURTLE. A.M. Brichta and J.M. Goldberg. Dept. Pharm. Physiol. Sci., Univ. Chicago, Chicago, IL 60637

Units innervating the posterior semicircular canal in the isolated head of the turtle, Pseudemys scripta, were divided into three groups based on their discharge regularity and on their gains and phases re head velocity of their responses to sinusoidal head rotations (0.1-1 Hz), (Soc. Neurosci Abstr 17: 312). Group 1 consist of regular and irregular units encoding head velocity. Phase leads increase from =0\* in the most regular units to ≈45° in the most irregular units. Gains increase only 1-3 fold between 0.1-1 Hz Group 2 are irregular units whose phases are nearer head acceleration (~60°) and whose gains grow =5 fold over the same frequency range. Group 3 are irregular units responding near head jerk. Phases are ≈ 150° and gains increase 10-50 fold as

Intra-axonal labeling was used to characterize the peripheral terminations. Groups 1 and 2 are bouton units innervating the peripheral zone of either posterior hemicrista. The first group are located nearer the planum semilunatum, while the second group are found near the torus. The third group go to the papilla neglecta, a small end organ located at the posterior canal-utricular junction . Calyx units, found in shifar tend organ vacated at the posterior canal-vulctual pinction. 

— <u>any nime</u>, round in the central zone, are a fourth group: they are silent at rest, but otherwise resemble group 1 units. Recordings were also made in intact animals. <u>Discharge properties of</u> all four groups were almost identical in the intact and isolated preparations. Efferent axons were electrically activated in the anterior ramus of the VIIIth nerve. Group 1 afferents were invariably excited by efferent stimulation, while many group 2 afferents

The results suggest that the isolated turtle ear provides an excellent opportunity to study sensory transduction and efferent control in a vestibular end organ. (Supported by ONR Contract N00014-88-k-0381).

VESTIBULO-OCULOMOTOR CONNECTIVITY IN AN ELASMOBRANCH, THE ATLANTIC STINGRAY, <u>D. SABINA</u>. R.L. Puzdrowski\* and R.B. Leonard, Marine Biomedical Institute, University of Texas Medical Branch, Galveston, TX 77555.

The organization of the oculomotor complex in elasmobranchs

is different from other vertebrates in that the motorneurons for is different from other vertebrates in that the motorneurons for the medial rectus lie contralateral to the innervated muscle. Based on this, Graf and Brunken ('84) postulated that in elasmobranchs all excitatory vestibulo-ocular neurons should project to the contralateral extraocular motor neurons. To examine this possibility, 0.1- $0.2\mu$ 1 injections of 2% wheatgerm HRP-20% HRP were made unilaterally into the oculomotor nuclear complex of stingrays. After survival times ranging from 8-23 days, the animals single as. An extensive the statement of the statement o the descending were predominantly contralateral. The labeled cells in the magnocellular nucleus were similar in size to those in the descending, and also were predominantly contralateral to the injection. Based on this distribution of vestibulo-ocular neurons, we hypothesize that the neurons in the anterior nucleus are inhibitory and those in the contralateral descending nucleus are excitatory. PROJECTIONS OF THE INDIVIDUAL VESTIBULAR END-ORGANS IN THE BRAINSTEM OF THE SQUIRREL MONKEY. \*A. Newman, Y. Naito, W.S. Lee Beykirch, V. Honrubia. UCLA Sch. of Med., Los Angeles, CA 90024.

Beylaird, V. Honnubia. UCHA Sch. of Med., Los Angeles, CA 90024.

The CNS projections of primary afferent neurons from individual vestibular receptors were studied using borseradiah peroxidase (HRP) or biocytin labelling in 14 ears from seven adult squirel montheys. The technique for labelling individual end-organs was similar to that used in the chinchilla [1].

The specificity of labelling was verified by examining the location of the labeled fibers and cell bodies in the vestibular nerve and Scarpa's ganglion. Labelled primary afferents in the vestibular nerve root exhibited a receptor-dependent segregation. Fibers from the horizontal semicircular canal (HSC) and the superior semicircular canal (SSC) were found rostrally and those from the posterior semicircular canal (FSC) and the sacculus (SAC) were found in the caudal area. Utriculus (UTR) fibers were sinuated between those areas. A bundle of fibers, probably vestibular efferents, were identified immediately rostral to the UTR fibers. The primary afferent fibers bifurcated into an ascending and descending longitudinal fiber tract of secondary branches at the lateral border of the vestibular nuclei. The secondary fibers from individual endorgans occupied specific locations in that: the UTR fibers were domal to the SSC and the HSC fibers: the PSC fibers were found most medially and the SAC fibers occupied the lateral-most area. The secondary UTR fibers overlapped considerably with those of the SSC and the HSC. Receptor dependent segregation of fibers was more prominent in the descending tracts than in the ascending tracts.

tracts.

Projection areas of the tertiary branches of various endorgans exhibited considerable overlap within the major vestibular nuclei. However, differences in the projection patterns could be identified. Within all these nuclei, the SAC projected primarily laterally, the SSC and the UTR ventromedially to the SAC and the HSC projected slightly medially to the SSC area. The PSC projected most medially. The UTR and the SAC sent numerous fibers to the cerebellum. Fibers from the semicircular canals were found projecting through the rostrodorsal region of SN, presumably also projecting to the cerebellum.

BRAINSTEM ARCHITECTURE OF VESTIBULAR AXONS FROM THE POSTERIOR SEMICIRCULAR CANAL. J.A. Huwe\* and E.H. Peterson. Neurobiology Program, Ohio University, Athens, OH 45701.

Previously we described the architecture of peripheral terminals in the posterior crista in a turtle, P. scripta (Brichta and Peterson, '92, Ann. N.Y. Acad. Sci.). In the present study we are developing a parallel classification of the central axons of these afferents. We use a palatal approach to the posterior ampullary nerve and label primaries with biotinylated dextran amine. We use long survival times to allow complete filling of the smallest central processes, reconstruct individual axons, and compare them with the total projection from the posterior canal.

All axons bifurcate upon entering the brainstem and emit ascending and descending branches. Some bear varicosities distal to the bifurcation, at their entrance to the brainstem. At the level of the bifurcation, some

axons emit clusters of varicosities in the ventrolateral nucleus.

Ascending branches give off varicose collaterals in the dorsolateral and superior vestibular nuclei (Weston, '36) and deep cerebellar nuclei before entering the cerebellum. Most cerebellar fibers run sagittally, bearing mossy rosettes and smooth varicosities; the axons differ markedly in diameter (0.3-1.8 μm).

Descending branches, at the level of the ventromedial nucleus, emit collaterals that pass under the ventricle and reach the MLF or run in fascicles along the ependymal border. Some axons also have branches that run longitudinally through the descending nucleus as far as the obex. Our data suggest that there are morphological differences between the central processes of vestibular afferents as there are between their peripheral terminals. Supported by NIH-NIDCD DC00618.

## 216.8

THE INTERSTITIAL NUCLEUS OF THE VESTIBULAR NERVE IN THE CHINCHILLA. MORPHOLOGICAL ASPECTS AND PRIMARY AFFERENT INNERVATION. K. Beykirch, A. Newman, L.F. Hoffman, W.S. Lee, Y. Naito, J.P. Segundo\*, V. Honrubia, Victor Goodhill Ear Research Center, UCLA Div. of Head and Neck Surgery, Los Angeles, CA 90024

The interstitial nucleus of the vestibular nerve (IN) was investigated in the

chinchilla using tolutione blue staining to elucidate the soma morphology, while HRP and biocytin tract tracing techniques [Lee et al :Cell Biol Internat Rep 13:635-636,1989] were used to study the afferent innervation from the individual vestibular receptors. The IN was dorsolateral to the spinal trigeminal nucleus, and ventromedial to the ventral cochlear nucleus and resides completely within the vestibular nerve root in the brainstem. It extends rostrocaudally for 0.8 to 1.0 mm. The IN was ellipsoid with its long axis in a rostral dorsomedial to caudal ventrolateral direction. Its long axis was 1.1 to 1.4 mm, parallel to the vestibular primary afferent fibers. It was approximately 0.2 to 0.25 mm in width in the mid-portion. One selected specimen contained 424 neurons ranging in size from 4 - 40 microns, with the larger ones (>20 microns) in the dorsomedial aspect of the IN throughout the rostrocaudal extent.

The individual vestibular endorgans innervated specific regions of the IN. Fibers

from the endorgans innervated by the superior vestibular nerve (anterior semicircular canal, ASC; horizontal semicircular canal, HSC; turicle, UTR) were located in the rostral portion of the IN. The ASC fibers were most rostral. More caudal, the HSC fibers were dorsolateral and the UTR fibers were ventromedial. The receptors innervated by the inferior vestibular nerve (posterior semicincular canal, PSC; sacculus, SAC) were located in the caudal portion of the IN. Fibers from the PSC were located rostral and medial to the fibers from the SAC which were located most caudal. The SAC innervated a larger area of the IN than any of the other receptors. The innervation patterns were predominantly axodentritic with boutons en passant, though some axosomatic contacts were observed via boutons termineax. (Work supported by NIDCD grant DC00008 and NIDCD grant DC01404.)

# 216.10

MONOSYNAPTIC INPUT FROM THE CEREBRAL CORTEX TO THE VESTIBULAR BRAINSTEM NUCLEI IN THE RAT W. Guldin\*, S. Mirring, and O.-J. Grüsser Dept. Physiology, Freie Universität Berlin, Arnimallee 22, 1000

The cortical input to the brainstem vestibular nuclei in the rat was investigated by means of the retrograde flourescence tracers rhodamine dextran, FITC-dextran and fast blue. For determining the loci of the injections, single unit recordings were carried out under natural vestibular stimulation conditions with a turntable. Recordings were done in anaesthetized animals.

The vestibular brainstem nuclei receive direct input from different cortical areas, such as the border region of the prefrontal and cingular cortex (Cg3 and Cg2), a region of Fr3 adjacent to the Par1 region, and the Par1 region itself. A band of labelled units was found, running from the middle part of area Par2 into the temporal area T1 (nomenclature according to Zilles). Some labelled units were located at the dorso-caudal border of the insular cortex. The distribution pattern of cortical cells connected directly to the vestibular brainstem nuclei of rats is similar to that found in different primates (Macaca fascicularis, Saimiri sciureus, Callithrix jacchus). The question of homology to vestibular cortical regions in primates will be discussed. (Supported in part by the Deutsche part Forschungsgemeinschaft Gr 161)

MORPHOLOGY OF THE EXCITATORY DISYNAPTIC EXTRA-MLF ANTERIOR CANAL PATHWAY IN THE CAT. Y. Uchino, M. Sasaki, N. Isu, M. Hirai, M. Imagawa, K. Endo and W. Graf\*. Tokyo Medical College, Shinjuki-ku, Tokyo, Japan and Lab. Physiol. Neurosensorielle, CNRS, Paris, France.

The three-neuron vestibulo-ocular reflex arc provides the fastest link between the vestibular receptor cells and the extraocular muscles for the generation of compensatory movements. We have now determined by intracellular application of horse radish peroxidase (HRP) the morphology of excitatory second-order neurons of the anterior canal system that course outside the medial longitudinal fasciculus (MLF) towards their target sites. Cell somata of these neurons were located in the superior vestibular nucleus. The main axon ascended through the deep reticular formation beneath the brachium conjunctivum to the level of the rostral extent of the nucleus reticularis tegmenti pontis (NRTP) where it also crossed the midline. Small collaterals branched into the superior central nucleus of the raphe and the adjacent reticular formation. The main axon then reached the caudal edge of the red nucleus from where it coursed back towards the oculomotor nucleus. Within the oculomotor nucleus, collaterals reached superior rectus and inferior oblique motoneurons. Some axon branches recrossed the midline within the oculomotor nucleus and targeted superior rectus motoneurons on that side. The signal content and spatial tuning characteristics of this vestibulo-oculomotor neuron remain to be determined.

VESTIBULAR INPUTS TO RAPHE-SPINAL NEURONS IN THE CAT: IMPLICATIONS FOR AUTONOMIC AND MOTOR CONTROL. P.S. Bolton, T. Goto and B.J. Yates. Laboratory of Neurophysiology, The Rockefeller Univ., New York, NY 10021.

Caudal medullary raphespinal neurons (RSN) include cells which mediate motor, antinociceptive and autonomic We previously showed that over 70% of RSN with either slow (5 m/s or less) or more rapid conduction velocities responded to vestibular nerve stimulation. the present study we determined the nature of vestibular inputs to RSN by analyzing their responses to sinusoidal whole body tilts in vertical planes (delivered at 0.02-1 Hz).

Experiments were conducted on decerebrate cats which were baroreceptor-denervated, vagotomized and had a spinal transection at  $C_8$ . Floating electrodes for antidromic stimulation were placed in  $C_3$ - $C_4$ . Over 70% of RSN whose firing rate was modulated by whole body tilts had response gains that remained flat across stimulus frequencies, suggesting that their vestibular inputs came principally from otolith organs. For most cells (over two-thirds), the plane of body rotation which produced maximal excitation was nearer pitch than roll.

The present data suggest that changes in head position in the sagittal plane (pitch) may influence autonomic and motor function via the raphe nuclei.

Supported by NIH grants DC-00693 and NS-02619.

CENTRAL PROJECTIONS OF CANALICULAR PRIMARY AFFERENT NEURONS: CORRELATIONS WITH PERIPHERAL INNERVATION LOCUS AND PHYSIOLOGIC CHARACTERISTICS. L. F. Hoffman and V. Honrubia, Goodhill

Ear Ctr., Div. of Head & Neck Surgery, UCLA School of Medicine, L.A., Ca. 90024. Individual primary afferent neurons innervating the bullfrog's anterior and horizontal semicircular canal cristae were intracellularly labeled with horseradish peroxidase or biocytin following electrophysiologic characterization. Subsequent to histochemical processing of nerve and brainstem, the central projections of each afferent were reconstructed and evaluated with respect to innervation locus within the crista and physiologic characteristics.

The crista-specific central projections of primary afferent neurons sampled in the present study were found to reflect the combined characteristics of crista innervation locus and physiology. Large axon-diameter primary afferents that originated in the central isthmus region of the crista were found to project to some areas of the brainstern vestibular nuclei that were independent of projections from afferents of comparable axon diameter originating in the more peripheral, planar regions. For example, the central region of the ventral vestibular nucleus (i.e. at the level of the vestibular nerve root) received projections from isthmus originating afferents, where projections from planar-originating afferents were not observed. Conversely, the superior vestibular nucleus was originating afferents were not observed. Conversely, the superior vestibular nucleus was found to receive projections from the planar-originating but not the isthmus-originating afferents. Other areas of the vestibular nuclei appeared to receive projections from afferents originating in both crista regions. These included the rostrodorsal and caudodorsal regions of the descending vestibular nucleus. These patterns of central innervation are independent of axon diameter and spontaneous activity characteristics. Though the isthmus-originating afferents exhibited generally higher gains than those innervations that planar gains the protocological innervating the planar regions, the most marked physiologic difference between these afferents was in their response phase to 0.05 Hz acceleration sinusoids. Isthmusoriginating afferents exhibited phases closer to stimulus acceleration simusoids. Stimusoriginating afferents exhibited phases closer to stimulus acceleration compared to planar-originating afferents. The central projections of smaller caliber planar-originating afferents exhibited differences from larger afferents innervating comparable crista loci, concommittant with marked differences in their physiologic characteristics. (Supported by NIDCD DC01404.)

# 216.14

A QUANTITATIVE ULTRASTRUCTURAL STUDY OF THE NEONATAL CHICK TANGENTIAL NUCLEUS AFTER VESTIBULAR NERVE TRANSECTION. E.M. Aldrich and K.D. Peusner\*. Department of Anatomy, Washington University School of Washington, DC 20037.

The mechanism of vestibular compensation, the recovery from deficits after unilateral vestibular nerve lesion, has yet to be determined. Past studies have implicated synaptic terminal sprouting in recovery of function. Behavioral studies of hatchling chicks after vestibular neurectomy have shown that compensation occurs over 7-10 days (Aldrich and Peusner, 1989). We have completed a quantitative ultrastructural analysis of the tangential nucleus (TN/lateral vestibular nucleus) in these animals. The TN principal cells receive large calyciform endings from colossal vestibular fibers. Axons project to abducens and spinal motor neurons (Cox and Peusner, 1990). Following vestibular terminal degeneration, no change was detected in percent soma covered by terminals, mean terminal length, number of terminals per 100  $\mu m$ , or distribution of synaptic terminal lengths up to 8 weeks after lesion. There was no evidence of TN neuron death. The results suggest that physiologic mechanisms should be investigated. Supported in part by NIH grants NS18108 and DC00970.

INTRINSIC DETERMINANTS OF RAT MOTONEURON REPETITIVE

INTRINSIC DETERMINANTS OF RAT MOTONEURON REPETITIVE FIRING PATTERN. F. Viana\*, D.A. Bayliss and A.J. Berger. Dept. of Physiol. & Biophys., Univ. of Washington Sch. of Med., Seattle, WA 98195.

Together with recruitment of silent motoneurons, the pattern and frequency of discharge of individual motoneurons determine the smooth gradation of force generated by a muscle. Intrinsic properties of different neuronal types greatly influence their repetitive firing response to excitatory inputs. We studied the repetitive firing behavior of neonatal rat (PO-P14) hypoglossal motoneurons (HMs) (n=50) in brainstem slices. Transduction properties were studied by measuring the repetitive firing response to intracellularly injected depolarizing

measuring the repetitive firing response to 2-s depolarizing current pulses. All HMs fired repetitively in response to 2-s depolarizing current pulses. Repetitive firing threshold current ( $l_{\rm thr}$ ) averaged  $0.6\pm0.3$  nA and minimal steady firing rate ( $l_{\rm thr}$ ) was  $13\pm6Hz$ . A good correlation was found between  $1/l_{\rm min}$  and AHP duration (r=0.83). Also,  $l_{\rm thr}$  was correlated with  $R_N$  (r=0.74). The steady-state f-1 relationship was linear, with a single slope ( $30\pm10$  Hz/nA). The f-1 slope weakly correlated with  $R_N$  (r=0.38) and with AHP duration (r=0.44). Neonatal HMs were classified according to 3 repetitive firing patterns: 1) Type D HMs were characterized by spike-frequency adaptation (SFA). The time course of SFA was complex with an early (<1s) and late phase; the early phase accounted for more than 80% of the total adaptation. During a train of action potentials, the AHP amplitude summated in Type D HMs. 2) Type I HMs were characterized by spike-frequency acceleration. This firing pattern was well fitted with a single exponential function (r=90 ms). In Type I HMs, AHP amplitude decreased during trains of spikes. Block of the Ca<sup>2+</sup>-dependent AHP conductance transformed the I pattern into a D pattern. 3) Type NM (non-modulated) HMs had no change in firing rate during long pulses.

no change in firing rate during long pulses.

In summary, the pattern and frequency of discharge of neonatal HMs to steady synaptic input may not be specified by the characteristics of synaptic drive alone, but may also be a function of motoneuronal intrinsic properties. (NIH NS 14857)

EARLY POSTNATAL CHANGES IN RAT HYPOGLOSSAL MOTONEURON RESPONSES TO THYROTROPIN-RELEASING HORMONE (TRH) AND SEROTONIN (5-HT) IN WITRO. D.A. Bayliss. F. Viana and A.J. Berger. Dept. Physiol. & Biophys., University of Washington, Seattle, WA 98195.

Normal maturation of a motoneuronal system may involve changes in motoneuron intrinsic properties or in effects of neuromodulators on those

motoneuron intrinsic properties or in effects of neuromodulators on those properties. The innervation of motoneurons by the coexisting neuromodulators TRH and 5-HT is derived mainly from the caudal raphe nuclei. In raphe neurons, TRH mRNA is developmentally regulated; barely detectable at birth, it rises steadily to near adult levels by P21 [FASEB J. 4:A1109, 1990). Therefore, we determined the motoneuronal response to TRH over this same postnatal period. Conventional intracellular recordings of hypoglossal motoneurons (HMs) in brainstem slices of adult rats (>P21) revealed that TRH (1-10 µM) caused a depolarization and decreased input conductance (G<sub>N</sub>) in all HMs (n=71). The response was more variable in neonatal HMs (P0-P21); in some, the effect of TRH was similar to that in adult HMs (depolarization with decreased G<sub>L</sub>.) whereas in oepolanzation and decreased input conductance  $(U_N)$  in all HMS (n=1)1. The response was more variable in neonatal HMS (P0-P21); in some, the effect of TRH was similar to that in adult HMS (depolarization with decreased  $G_N$ ), whereas in others, TRH was either without effect or caused a slight depolarization with no change in  $G_N$ . We grouped neonatal HMS according to the effect of TRH on  $G_N$ . The percentage of HMs exhibiting "adult-like" responses  $(G_N \text{ to } < 85\% \text{ of control})$  increased from 25% (28) at P0-P2 to 50% (4/8) at P3-P5, 62.5% (5/8) at P6-P8 and 100% (14/14) by P14-P21. Thus, the response to TRH in HMS changed over the early postnatal period. The response of HMS to 5-HT also appeared to change during development. 5-HT  $(100 \, \mu\text{M})$  caused a depolarization with no effect on  $G_N$  in young HMS  $(\leq P8, n=11)$ . Also, 5-HT decreased the amplitude of the spike after-hyperpolarization (AHP) in most young HMS (9/11) that resulted in an increased slope of the curve relating firing frequency to injected current (f-1) curve. By contrast, in older HMS  $(\geq P20)$  studied to date (n=4), 5-HT caused a depolarization with decreased  $G_N$ . It had little effect on the AHP and caused a parallel leftward shift in the f-1 curve. Thus, although 5-HT depolarized both young and older HMS, the mechanisms involved were different. (NIH NS14857 & Francis Families Foundation)

NOREPINEPHRINE (NE) EXCITES HYPOGLOSSAL MOTONEURONS. M.A. Parkis, D.A. Bayliss, and A.J. Berger\*. Department of Physiology & Biophysics, University of Washington School of Medicine, Seattle, WA 98195.

The presence of NE-containing axons and processes in the hypoglossal motor nucleus was first reported by Levitt and Moore (J. Comp. Neurol. 186:505-528, 1979). A subsequent study supported this finding by showing that the hypoglossal motor nucleus contains fibers and varicosities strongly immunoreactive to tyrosine hydroxylase and dopamine β-hydroxylase, but not to phenylethanolamine N-methyltransferase (Brain Res. Bull. 21:305-312, 1988). Although NE has been reported to excite hypoglossal motoneurons (HMs) (Soc. Neurosci. Abstr. 8:958, 1982), little is known about the mechanism of this excitation.

We characterized the electrophysiological response of HMs to NE in vitro using conventional intracellular recording from HMs in 400-500 µm brainstem slices taken from juvenile (<30 d.o.) rats.

In all cells recorded to date (n = 11 HMs), NE (50 or 100  $\mu$ M) applied in the bathing medium or by pressure-injection caused a reversible depolarization, increased input resistance ( $R_N$ , mean increase of 41  $\pm$  13%, n = 8 cells), and a lowering of rheobase. Analysis of action potentials generated by injecting brief (2-msec) current pulses revealed that in three HMs, NE diminished the amplitude of (2-insec) united pairs recent that in the rinks, the infilms at the amplitude of the medium-duration afterhyperpolarization (mAHP, avg. decrease of  $34 \pm 15\%$ ). The mAHP of two others was unchanged. Those cells that showed a decrease in mAHP amplitude in response to NE also showed a corresponding increase in the

slope of the relationship between steady-state firing frequency and injected current. The increased  $R_N$  accompanying the depolarizing response suggests that the effect of NE involves closure of  $K^+$  channels present in the membrane of HMs. (Supported by NIH grant NS 14857).

REDUCTION OF Na+-K+ ATPase ACTIVITY DOES NOT REDUCE THE LATE ADAPTATION OF MOTONEURON DISCHARGE. A. Sawczuk

and M.D. Binder\*. Dept. of Physiology & Biophysics, Univ. of Washington, Seattle, WA 98195.

In response to a constant-current stimulus, motoneurons display a pronounced reduction in firing rate during the first second of discharge (early adaptation) followed by a more gradual decline in frequency that continues over tens of seconds or even several minutes ("late adaptation"; Granit et al. J. Physiol. 169: 1963). The early adaptation is related to an increase in the K+ conductances associated with the AHP, but increase in the K<sup>+</sup> conductances associated with the AHP, but late adaptation appears to involve additional mechanisms. One such mechanism might be a gradually increasing hyperpolarizing current generated by the electrogenic sodium pump (Kernell and Monster. Exp. Brain Res. 46:1982). To test this hypothesis, we injected long (>60 s), suprathreshold depolarizing current pulses into hypoglossal motoneurons in brainstem slices of young (3-7 weeks) rats before and after adding ouabain (4-20  $\mu$ M) to the bathing solution. Prior to the addition of ouabain, the membrane potential displayed marked post-discharge hyperpolarization (-11 $\pm$ 2 mV). The addition of ouabain substantially reduced this hyperpolarization (64.44%), but did not reduce the extent this hyperpolarization (64 $\pm$ 14%), but did not reduce the extent of late adaptation. We are currently investigating other potential contributors to late adaptation such as Na+ channel inactivation and slowly-activated K<sup>+</sup> currents. NIDR grant DE00161 and NIH grant NS26840) (Supported by

CORRELATED AND UNCORRELATED FLUCTUATIONS OF MOTONEURON EXCITABILITY DURING MONOSYNAPTIC REFLEXES. 1.-P. Gossard, M. K. Floeier, S. J. Schiff, Y. Kawai and R. E. Burke\* Lab. of Neural Control, NINDS, NIH, Bethesda, MD 20892 and Children's Hospital National Medical Center, Washington, DC 20010.

Rall and Hunt (J. Gen Physiol. 39:397, 1956) showed that fluctuations of monosynaptic reflexes (MSRs) result from correlated and independent variations in motoneuron (MN) discharge probabilities. We have re-examined this phenomenon in unanesthetized decerebrate and decerebrate-low spinal cats with respect to: 1) the probability profiles of individual MNs recorded simultaneously in teased ventral root filaments as functions of population MSRs in the rest of the same ventral root; 2) correlations between group Ia EPSPs and baseline membrane potential recorded intracellularly in a homonymous motoneuron and MSR fluctuations and MN probability profiles; and 3) the effects of conditioning inputs in muscle, skin, and descending afferent systems. Results to date suggest that: 1) individual MNs show different levels of uncorrelated probability fluctuations, with a tendency to greater indepedence among higher threshold cells; 2) increased MSRs after post-tetanic potentiation is sometimes accompanied by changes in mean unit firing probabilities; 3) conditioning extensor MSRs with stimulation of flexor group I afferents that generate presynaptic inhibition produces little change in average MN firing probabilities despite marked inhibition of population response; and 4) conditioning input in skin afferents that generate short latency excitation in extensor motor pools can produce relatively large shifts in probability profiles in some triceps surae MNs in relation to population MSRs. In general, shifts in MN probability profiles were not accompanied by changes MSRs. In general, sinis in Are probability profites were not accompanied by clarifying in variance. These observations suggest that the relative excitability of individual MNs within a particular motor pool during MSRs not only vary independently of overall pool excitability but can differ between MNs, presumably due to differences in the organization of synaptic inputs among MNs within the pool.

EXCITATORY AMINO ACIDS (EAA) INVOLVED IN MIXED CHEMICAL AND ELECTRICAL SYNAPTIC TRANSMISSION IN FROG SPINAL CORD.

M.-S. Rioult-Pedotti and H.P. Clamann, Dept. of Physiology,

University of Bern, 3012 Bern, Switzerland
Synapses between primary afferents and motoneurons (MNs) in amphibians provide joint electrical and chemical transmission. To study properties of the electrical coupling in isolation competitive antagonists of EAAs were used to block chemical transmission. Responses to supramaximal dorsal root stimulation were recorded from ventral roots and intracellularly in lumbar MNs of isolated frog

Evoked excitatory postsynaptic potentials (epsps) were of long duration (up to 1s) which often evoked action potentials. 100  $\mu$ M D-2-Amino-5-phosphonopentanoic acid (D-APV) abolished spike activity and a late epsp component. At temperatures between 17-20°C MN responses were entirely blocked by 40  $\mu$ M 6-Cyano-7-nitro-quinoxaline-2,3-dione (CNQX) while at low temperature, 8-12°C, an early (<1ms) component with a steep rise time and two decay rates, fast and slow remained. This component was blocked by arachidonic acid which uncouples gap junctions.

It is concluded that glutamatergig transmission in the amphibian spinal cord is mediated by NMDA and non-NMDA receptors and that the electrical coupling is temperature labile. (Supp.: SNF Grant

SHORT-TERM SYNCHRONIZATION OF MOTORNEURONS DEPENDS ON MAP OF EXCITATORY CONNECTIONS. F.A. Dodge, IBM Research, T.J. Watson Center, Yorktown Heights, NY 10598.

During tonic reflexes, the fluctuations in synaptic drive resulting from the convergence of many excitatory

interneurons (EIN) would be expected to show some degree of correlation among motorneurons (MTN) in a given pool: if all the EIN projected globally to all the MTN like the spindle Ia afferents, then the fluctuations would be highby correlated in all MTN; but if the EIN projected locally only to near neighbors as is know for identified inhibitory interneurons, then the fluctuations in widely separated MTN would be completely uncorrelated. A correlated depolarizating fluctuation would tend to synchronize any tonically firing MTN whose membrane potential is approaching threshold at that time; hence, we might expect a map of the strength of short-term synchronization (C-SYNC) to

strongly reflect the map of connectivity of the EIN.
Using a mathematical model that realistically simulates a motor pool (Neurosci. Abstr. 17:647, 1991), I have found that C-SYNC (measured as the probability of synchronized firing in excess of chance) is a stochastic variable whose expected values can be predicted from the correlation coefficient and the magnitude of the synaptic noise in the two MTN, weighted by a factor that depends on how closely their mean spike rates match. The model reveals practical limitations to mapping connectivity by C-SYNC.

ACCELERATION OF MOTONEURON DISCHARGE RATE BY HYPERPOLARIZING CURRENT TRANSIENTS. R.K. Powers and M.D. Binder. Dept. of Physiology & Biophysics, Univ. of Washington, Seattle, WA 98195.

A change in somatic voltage produced by an injected or synaptic current transient alters the discharge probability of a spontaneously-firing neuron by changing the difference between the membrane potential and the spike voltage threshold (e.g. Ashby and Zilm. Exp. Brain Res 47: 33, 1982). Conventional models of this process predict that a depolarizing current transient will advance the occurrence of the subsequent spike and that a hyperpolarizing current transient will delay it. We have tested the effects of hyperpolarizing current transients on repetitive discharge in cat lumbar motoneurons by superimposing short (5 ms), hyperpolarizing injected current pulses on long (10 s), suprathreshold, depolarizing current steps. In a few cells, the addition of a hyperpolarizing current pulse paradoxically advanced the occurrence of the subsequent spike. In these cases, it appears that the hyperpolarizing transient produces a decrease in spike voltage threshold that exceeds its effect on somatic membrane potential. We are currently investigating the mechanisms underlying this variation in spike threshold using several motoneuron models. These results suggest that at times a hyperpolarizing synaptic input may increase rather than decrease the rate of dischare of the postsynaptic cell. (Supported by NIH grants NS26840 and NS25206)

MECHANICAL PROPERTIES OF THE TONGUE: EFFECTS OF WHOLE AND PARTIAL HYPOGLOSSAL NERVE STIMULATION IN RAT. <u>E. E. Gilliam and S. J. Goldberg\*</u>. Department of Anatomy, Medical College of Virginia-Virginia Commonwealth University, Richmond VA 23298.

The rat's tongue like man's is composed of extrinsic and intrinsic muscles which function to protrude and retract the tongue. The hypoglossal nucleus as well as the nerve are basically "compartmentalized" into protrusive and retrusive subdivisions (nucleus) or branches (nerve) so that the individual muscle groups may be activated in a coordinated manner. This study was designed to begin the examination of the tongue's mechanical properties in detail.

Male Sprague-Dawley rats (200-350 g) were anesthetized with urethane (1.3 g/kg), tracheotomized, and the XIIth nerve was exposed using a ventral approach. The whole nerve or one of its branches was stimulated with bipolar, sibre wire electrodes. A silk suture was placed at the apex of the tongue and attached to a sensitive strain gauge after the animal was stereotaxically placed. A preload of =4 g was found to be optimal. Stimulation of the whole nerve unilaterally with single stimuli (2X threshold) produced a net retrusive force of 8-10 g, 13-18 ms twitch contraction times, and =20 ms half decay times. Tetanic stimulation at 50 to 150 Hz, in 10 Hz increments, for 200 ms yielded 22-27 g tensions and fusion frequencies from 90-110 Hz. Stimulation of the lateral division at 2X threshold produced a retrusive force of 6-10 g, 14-19 ms twitch contraction times, and =13 ms half decay times. Tetanic stimulation resulted in 21-25 g tensions and fusion frequencies of =100 Hz.

In a separate study, stimulation of the medial branch of the nerve was done and two strain gauges were placed at 30° to each side of the midline of the tongue so that lateral tongue deviations could be recorded. A preload of ≈2.0 g was used on each strain gauge. Low intensity stimulation yielded protrusion with 0.4-0.5 g twitches, ≈14 ms twitch contraction times, and ≈11 ms half decay times. Tetanic fusion occurred at ≈100 HZ with ≈1.5 g tensions. Current studies involve monopolar stimulation of restricted areas of the XIIth nucleus with glass electrodes (≈10-15µ tip diameter). Areas of the nucleus which produce protrusion and retrusion have been identified.

QUANTITATIVE ANALYSIS OF RAT MOTONEURON MORPHOLOGY. X.Y. Chen\* and J.R. Wolpaw. Wadsworth Labs, New York State Dept of Health and State Univ of New York, Albany, NY 12201.

As part of developing H-reflex conditioning in rat as a model for learning (Wolpaw & Chen, this vol), we are analyzing the elements of the reflex pathway (motoneurons and Ia afferent connections).

Fourteen physiologically identified rat triceps surae (TS) motoneurons (MNs) were intracellularly stained with HRP and reconstructed with a Eutectic system. Somata were in ventral horn of L4-5 and averaged 35 $\mu$ m diameter and  $995\mu$ m² area in sagittal section. Each had 6-12 primary dendrites. Dendritic fields extended widely through and beyond ventral horn and accounted for 97-99% of neuronal surface area. Ventral extent was positively correlated with soma distance from ventral border of ventral horn. Total dendritic lengths, surface areas, and volumes were 33-78mm, .14-.36mm², and 63-266x10³ $\mu$ m³, respectively. Primary dendrites averaged 21 branch points, 22 terminations, and 43 branch segments. Their diameters averaged 5.6 $\mu$ m and correlated with total lengths, surface areas, volumes, number of terminations, and maximum segment orders. Tapering averaged 0.21 $\mu$ m/100 $\mu$ m. Rall's ratio,  $(\sum (d_{\text{daughter}})^{3/2})/(d_{\text{parent}})^{3/2}$ , averaged 1.2. Compared to cat TS MNs, these rat TS MNs had smaller somata,

Compared to cat TS MNs, these rat TS MNs had smaller somata, fewer primary dendrites, and smaller total dendritic surface areas and lengths. However, they had more dendritic segments and terminations. Thus, their dendritic fields were more complex. (Supported by NIH NS22189 and Paralyzed Veterans of America Spinal Cord Research Foundation.)

## 217.13

EFFECTS OF H-REFLEX CONDITIONING ON MOTONEURON PROPERTIES. J.S. Carp\*, X.Y. Chen and J.R. Wolpaw. Wadsworth Labs, NYSDOH/SUNY, Albany, NY 12201.

Monkeys (Macaca nemestrina) can increase or decrease the triceps surae (TS) H-reflex (HR), the electrical analog of the monosynaptic stretch reflex. Such conditioning changes the spinal cord (<u>TINS</u> 13:137, 1990). In order to define this plasticity and its role in the behavioral change, intracellular recordings were performed in 504 TS motoneurons (MNs) in animals in which one leg's HR had been trained up (HR†; n=9) or down (HR‡; n=10), and in 14 naive animals. Animals were deeply anesthetized throughout and sacrificed by overdose.

Differences were found among MNs from trained and control sides of conditioned animals and from naive animals. These data, together with HR data from awake behaving animals and nerve volley data from anesthetized animals, give three different views of HR conditioning effects. For example, HRs and nerve volleys are larger/smaller on the trained side of HR†/HR↓ animals, while the opposite is seen with EPSPs. Control side HRs and MN properties are similar to those in naive animals, while control side nerve volleys are smaller/larger in HR†/HR↓ animals than in naive animals. The differences in these views presumably reflect differences in animal state and experimental method, and suggest that HR conditioning changes the spinal cord at multiple sites. (Supported by NIH NS22189 and Paralyzed Veterans of America Spinal Cord Research Foundation.)

SYNAPTIC MORPHOLOGY OF PRIMATE TRICEPS SURAE MOTONEURONS: INITIAL STUDIES. <u>K.A. Starr\* and J.R. Wolpaw.</u> Wadsworth Labs, NY State Dept Health & State Univ NY, Albany, NY 12201.

In order to define anatomical changes associated with operant conditioning of the primate triceps surae (TS) H-reflex, the electrical analog of the stretch reflex (TINS) 13:137-142, 1990), we are examining in monkeys (Macaca nemestrina) the synaptic contacts on TS motoneurons at the electron microscopic (EM) level. Motoneurons are labeled by retrograde transport of cholera toxin-HRP and visualized with tetramethylbenzidine (Olucha et al. 1985) stabilized with DAB (Rye et al. 1984). Somatic and dendritic synaptic contacts are analyzed by size and shape of synaptic vesicles, subsynaptic specializations, number of active zones, and location.

Initial analysis of data from two naive (i.e., untrained) animals reveals five categories similar to those of Conradi (1969). F-type boutons, with flattened or pleomorphic vesicles, make up 62% of the population and S-type boutons, with spherical vesicles, make up 18%. Both types range in size from 0.8-3.3 $\mu$ m. Larger C-type boutons (1.2-6.4 $\mu$ m), with postsynaptic subsurface cisterns, make up 11% of the population, and M-type boutons (3.4-4.9 $\mu$ m), with multiple active zones and subsynaptic dense bodies, make up 6%. P-type boutons, which are presynaptic on M-type boutons, are 0.8-1.1 $\mu$ m and make up 3% of the population. (Supported by NIH NS22189.)

#### 217.12

QUANTITATIVE ANALYSIS OF PRIMATE MOTONEURON DENDRITIC MORPHOLOGY. D.M. Maniccia, C.L. Lee\*, and J.R. Wolpaw. Wadsworth Labs, NY St Dept Health & St Univ NY. Albany, NY 12201 & Dept Physiol, UNC, Chapel Hill, NC 27599.

In order to define the spinal cord plasticity associated with operant conditioning of the primate triceps surae (TS) H-reflex (TINS 13:137, 1990), we are analyzing the components of the reflex pathway, the motoneurons and their primary afferent connections, at the light and electron microscopic levels. In the present work, physiologically identified TS motoneurons are intracellularly stained with HRP and reconstructed by camera lucida and with a Eutectic system.

TS motoneurons are clustered in dorsolateral quarter of L6-7 ventral horn. Dendritic fields are elliptical with longest axis rostral-caudal and shortest axis medial-lateral. Dendritic extent is not correlated with soma diameter. However, number of dendritic segments per neuron is correlated with soma diameter, and number per dendrite is correlated with primary dendrite diameter. Thus, larger motoneurons have more complex, but not more widespread, dendritic trees. The most complex neuron analyzed to date has 271 segments and 141 terminations.

analyzed to date has 271 segments and 141 terminations.

Compared to dendritic fields of cat TS motoneurons, those of primate TS motoneurons appear to be more elliptical, and more variable in complexity and extent. (Supported by NIH NS22189 & Paralyzed Veterans of America Spinal Cord Research Foundation.)

## 217.14

H-REFLEX CONDITIONING IN THE RAT: INITIAL STUDIES. <u>J.R. Wolpaw\* and X.Y. Chen.</u> Wadsworth Labs, NY State Dept of Health and State Univ of NY, Albany, NY 12201.

Operant conditioning of the H-reflex (HR), which has been demonstrated in primates, is a new experimental model for defining the CNS substrates of learning (TINS 13:137-142, 1990). In order to increase the practical and theoretical potential of this model, we are seeking to establish it in the rat.

Male Sprague-Dawley rats (300-400gm) are chronically implanted with fine-wire EMG electrodes either in right triceps surae (TS) or in right intrinsic foot plantar flexors (IFF), stimulating cuff on right posterior tibial nerve, and bipolar stimulating electrode in left median forebrain bundle. Electrodes connect to a head-mounted tether cable. Monitored by computer, each rat learns to keep background EMG in a specific range. At a random time, nerve cuff stimulation at M response threshold elicits the HR. In control mode, reward (60Hz intracranial stimulation, 20-40µA,250-500ms) begins 200ms later. In HRup or HRdown mode, reward occurs only if the HR is above or below criterion. Rats usually perform more than 7,000 trials/24hrs.

Initial results suggest that rats can increase HR amplitude in response to the HRup mode. As in primates, change progresses over days and weeks. The normally small amplitude of the TS HR complicates use of the HRdown mode. Thus, current efforts focus on the typically larger IFF HR. (Supported by NIH NS22189 and Paralyzed Veterans of America Spinal Cord Research Foundation.)

ALTERED SYNAPTIC TRANSMISSION FROM IA AFFERENTS AND TO MOTONEURONS, BOTH CROSS-INNERVATING THE SURAL NERVE OF CATS. J.B.  $\operatorname{Munson}^{\star 1}$ , R.D.  $\operatorname{Johnson}^{1}$ , J.S.  $\operatorname{Taylor}^{1}$  and  $\operatorname{L.M. Mendell}^{2}$ . Univ of Florida &  $^{2}\operatorname{SUNY}$  at Stony Brook.

Cats whose medial gastrocnemius nerve had been crossunited into the sural nerve 24 months before were anesthetized and prepared for intracellular recording of omposite EPSPs from triceps surae motoneurons, which were characterized by rheobase, duration of AHP and input resistance. Peripheral nerves were activated with single shocks (0.5 and 18 Hz) and bursts (32 shocks at 167 Hz, 2 sec interburst interval), and the resultant EPSPs were averaged. As reported (<u>JNphys 65</u>: p590), the EPSPs in low-rheobase motoneurons exhibited more depression during high-frequency stimulation than EPSPs in high-rheobase motoneurons. AHP duration was also a useful predictor of this behavior, but input resistance was less reliable. Motoneurons with axons in the sural nerve developed large EPSPs which were prone to more profound high-frequency depression than those in controls. Similar, perhaps profound changes were noted when crossed afferents were activated and their synaptic effects evaluated in normal The EPSP amplitude/depression correlation reflects a property of the synapse; thus we surmise that the change occurs in the synapse itself, probably at a presynaptic locus. These changes could result from alterations in activity levels, trophic factors, or both. Supported by NIH: NS-15913, NS-14899, NS-16996, NS-27511.

PAD PATTERNS OF REGENERATED GROUP I AFFERENTS AFTER PERIPHERAL NERVE CRUSH IN THE CAT. M. Enriquez, I. Jiménez\* and P. Rudomin. CINVESTAV. México.

In normal cats group Ia and ID muscle afferents have different PAD patterns involving activation of separate sets of last-order interneurons (J. Neurophysiol. 56:987, 1987). Sectioning or crushing cutaneous fibers in the periphery transiently abolishes their PAD (J. Physiol. 313:287, 1981). We have examined in 6 cats the intrafiber PAD elicited in functionally identified group I fibers 6-10 months after crushing the medial gastrocnemius nerve. 16/39 fibers (79.6±20.1 m/s) were classified as "in parallel" based on their responses to vibration, ramp stretch and twitch. Group I PBSt volleys produced PAD in 14/16 fibers (1.1±0.83 mV). This PAD was reduced by conditioning stimulation of the sural (SU) nerve in 6/14 fibers to 52:29% and by the reticular formation (RF) in 5/13 fibers to 77:8%. In 5/13 fibers RF produced PAD (0.39±0.16 mV). 9/39 fibers (84.8±11.3 m/s) were classified as "in series". 8/9 fibers were depolarized by PBSt (1.010.87 mV), 3/8 by SU (0.51:0.93 mV) and 6/9 by RF (0.62:0.62 mV). 14/39 fibers (64±13.4 m/s) were not physiologically activated, but in 9/14 fibers PBSt produced PAD (0.35:0.33 mV) and SU in 5/12 (0.34±0.15 mV), which is smaller than the PAD elicited in functionally regenerated fibers. The PAD patterns of regenerated fibers appear not to be different from those of fibers in intact animals, except for a larger number of Ia fibers in intact animals, except for a larger number of Ia fibers in intact animals, except for a larger number of Ia fibers in intact animals, except for a larger number of Ia fibers in intact animals, except for a larger number of Ia fibers with PAD induced by RF (10/48 in intact cats). We conclude that the specificity of the connections of PAD mediating interneurons is resumed following the functional regeneration of the afferent fibers. PAD OF PERINEAL AFFERENTS EVOKED BY STIMULATION OF SENSORY AFFERENTS AND DURING MICTURITION IN THE CAT. M.J. Angel, D.A. McCrea\*, D. Fyda, S.J. Shefchyk Depts. of Physiology and Medicine, Univ. of Manitoba. Winnipeg, CANADA R3E 0W3.

During micturition, activity in the external urethral sphincter (EUS)

decreases, and excitatory sphincter reflexes are suppressed. We are exploring the possibility that during voiding, a reduction in transmitter release from tonically active sensory perineal afferents decreases the excitation of EUS motoneurons. The present experiments determine the effectiveness of peripheral nerve stimulation in evoking primary afferent depolarization (PAD) of dorsal penile (sensory pudendal, PUD) and superficial perineal (SFP) afferents. In addition, PAD of these same afferents during micturition was recorded. Experiments were performed on both decerebrate and α-chloralose anaesthetized male cats. Antidromic action potentials of single afferents were evoked by intraspinal micro-stimulation and recorded in the PUD and SFP nerves. Stimulus current was automatically controlled and PAD inferred from a decrease in the current required to maintain a firing probability of 0.5. All hindlimb cutaneous afferents, especially those in posterior tibial and SFP nerves, produced substantial PAD of PUD afferent terminals. Hindlimb muscle afferents were much less effective. In general, low threshold (<2T) afferents evoked the greatest PAD of fast conducting perineal afferents (>35m/s). During micturiton PAD occurred in 15% of the fibres; primary afferent hyperpolarization (PAH) was observed in 8% of the fibres. The presence of PAH suggests that a tonic level of PAD may be modulated during micturition. These results support the notion that some of the reduction in EUS motoneuron excitation during voiding may be mediated by changes in perineal afferent transmitter release. Supported by the MRC of Canada.

SELECTIVE CONNECTIVITY OF LAST-ORDER INTERNEURONS MEDIATING PAD OF GROUP ID FIBERS ACCORDING TO THE MUSCLE OF ORIGIN. J.R. Equibar\*, J.N. Quevedo, I. Jiménez and P. Rudomin. Dept. of Physiol. CINVESTAV and ICURP, México.

Although it seems well established that different last-order interneurons mediate PAD of Ia and Ib fibers (J. Neurophysiol, 50:743, 1983), the question remains on whether there is any selectivity in their connections according to the muscle of origin of the target afferent fibers. We have explored the effects of conditioning microstimulation ( $\mu$ S) of the intermediate nucleus simultaneously on the intraspinal threshold of six pairs of single group I afferents. Stimulating pulses were delivered in alternation through two micropipettes placed in the intermediate nucleus to produce antidromic responses in two single group I (Ia-Ib or Ib-Ib) afferents, one from a GS and the other from a PBSt nerve filament. Stimulus current was automatically adjusted to elicit antidromic firing with a constant probability (0.5). Intraspinal  $\mu S$ (<10  $\mu A$ ) delivered at short conditioning testing time intervals (2-5 ms), produced a monosynaptic PAD in the fiber closest to the stimulating micropipette but not in the other fiber, even though PBSt group I conditioning stimulation produced a substantial PAD in both fibers. Our results suggest that a separate presynaptic control can be exerted by last order PAD mediating interneurons on group I fibers arising from different muscles. DIFFERENTIAL EFFECTS OF RETICULO-SPINAL STIMULATION ON

DIFFERENTIAL EFFECTS OF RETICULO-SPINAL STIMULATION ON THE INTRASPINAL THRESHOLD OF CUTANEOUS AND MUSCLE AFFERENTS IN THE ISOLATED FROG NEURAITS. H. GONZÁLEZ, I. Jiménez and P. Rudomin\*. Dept. of Physiol. CINVESTAV, and Fac. de Ciencias, UNAM. México D.F.

In a previous study (Exp. Brain Res. 88:106,1992), we showed in the isolated nervous system of the frog that stimulation of the reticular formation (RF) depressed the DRPs elicited by stimulation of dorsal and ventral roots and suggested that this depression was due to inhibition of PAD of muscle spindle afferents. In isolated preparations with ventral roots sectioned, glass micropipettes (1-3 MQ) were introduced at L10 segmental level, in the dorsal horn and in the motor nucleus, to produce an (1-3 MΩ) were introduced at L10 segmental level, in the dorsal horn and in the motor nucleus, to produce antidromic responses in cutaneous (gluteus and superficial peroneus) and muscle (tibial) nerve afferents, respectively. RF stimulation (4 pulses 200 Hz, 10-20 µA, 80 ms before the excitability test pulse) increased the antidromic responses elicited in cutaneous nerves (36-104%, n=6). This effect occluded with the PAD elicited in the same fibers by stimulation of dorsal or ventral roots (n=6). In contrast, RF stimulation produced no changes in the antidromic responses of muscle afferents but inhibited the PAD produced in them by stimulation of dorsal (16-31%, n=5) or ventral roots (10-23%, n=5). It is suggested that, like in the cat, descending inputs may inhibit the PAD of muscle spindle afferents and produce PAD in cutaneous afferents. The effect of RF stimulation on Golgi tendon afferents remains to be elucidated. Partly supported by NIH 09196 and CONACYT 0319-N9107.

FAILURES OF TRANSMISSION IN THE MONOSYNAPTIC EPSPS ELICITED BY SINGLE PRESYNAPTIC NEURONS IN SINGLE RAT TRIGEMINAL MOTONEURONS IN-VIVO AND IN-VITRO. Paul D. Grimwood, Kwabena Appenteng and John C. Curtis. SPON: Brain Research Association. Dept. of Physiology, Univ. of Leeds, Leeds, UK.

For each of a sample of 15 EPSPs, elicited by trigeminal spindle afferents and interneurones trigeminal motoneurones pentobarbitone anaesthesia, we have determined both the percentage of sweeps which contained EPSPs triggered by the pre-synaptic neurone, and the incidence of randomly triggered EPSPs. have subtracted the two estimates to produce a corrected incidence of occurrence of EPSPs triggered by the presynaptic neurone. Corrected triggered by the presynaptic neurone. Corrected incidences of failure have ranged from 8 to 96%, and the incidence was linearly related ( $r^2 = 0.97$ ) to the amplitude of the averaged EPSP. Similar experiments performed in-vitro have revealed, that for individual presynaptic neurones, linear relationships also exist between these two parameters. We conclude that for averaged EPSPs of less than approximately 150  $\mu$ V. differences in amplitude of the EPSPs 150  $\mu$ V, differences in amplitude of the EPSPs can primarily be accounted for by differences in the incidence of failures of transmission.

THE INFLUENCE OF CONSTRAINTS ON THE KINEMATICS OF A NATURAL PREHENSION TASK. R.G. Marteniuk\*, B. Steenbergen, L.E. Kalbfleisch. Human Motor Systems Lab, Simon Fraser University, Burnaby, B.C. V5A 1S6.

Motor Systems Lab, Simon Fraser University, Burnaby, B.C. V5A 186.

Acquiring coordination, according to Bernstein (1967), is 'the mastery of the redundant degrees of freedom'. In solving a novel or complex movement problem (brought about by the relational influence of diverse constraints, e.g. task constraints, organismic constraints), the organism is required to reorganize it's coordination system such that a minimum number of degrees of freedom remain to be actively controlled. In the present study of natural prehension, a multiple degrees of freedom task was used to examine this notion. The kinematics of the movement were examined as a function of task (grasping a full cup versus an empty one), and organismic (hand used) constraints. Seven right handed subjects were required to reach and grasp a cup (the transport phase) and place it on a designated target (the placement phase) using either their preferred or non-preferred hand. Kinematic analysis revealed a and grasp a cup (the transport phase) and place it on a designated target (the placement phase) using either their preferred or non-preferred hand. Kinematic analysis revealed a precision effect, displayed through increased movement times in the full cup condition, found to be principally due to an increase in the low velocity phase of the movement for the transport phase. Differential lengthening of the pre-peak velocity time was evident for the placement component of the movement. Subsequent analysis of the rate of angular change of the shoulder, elbow and wrist joints demonstrated that, for both transport and placement low velocity phases of movement, a precision effect existed such that for the full cup condition significantly less joint movement occurred. Results however, could not confirm the notion of a fixed relationship between the transport and grasp component in a prehension task (Jeannerod, 1981, 1884; Wing et al., 1986; Wallace and Weeks, 1988). It is argued that the specific coordination relationship is an emergent result of the imposed task constraints in coordination relationship is an emergent result of the imposed task constraints in relation to the dynamics of the system. Furthermore as it has been shown that the retained to the dynamics of the system. Furthermore as it has been shown that the imposed task constraints had considerable impact on the length of the low velocity phase of the movement, it is argued that joint freezing was implemented in order to solve the movement task at hand. Hence, minimization of the degrees of freedom to be actively controlled is used as a strategy through which more complex movement problems can be solved.

RAPID ADAPTATION OF ARM MOVEMENT ENDPOINT AND TRAJECTORY TO CORIOLIS FORCE PERTURBATTONS. OLIS FORCE PERTURBATIONS. J.R. Lackmer\* and P. Ashton Graybiel Spatial Orientation Laboratory, Brandeis University, Waltham, MA 02254.

Subjects pointing to a visual target in a rotating room () ppm,CCW() showed deviations in movement trajectories and endpoints in the direction of the (rightward) Coriolis forces generated by their arm movements. Initial errors were 47±34mm rightward for fast (305±68ms duration) movements and 38±27mm for slow (730±111ms duration). Trajectories and endpoints returned to normal within 40 movements even though subjects were denied visual and tactual error feedback. Adaptation proceeded quasi-exponentially and was about twice as rapid for fast movements as slow. Movements made after the room was stopped showed mirror-image trajectories and endpoint errors to those initially induced by the Coriolis forces during rotation. Initial post-rotation errors were 36±37mm and 27±25mm leftward for fast and slow movements, respectively. Re-adaptation took approximately the same number of movements as adaptation to rotation had. The findings imply that discrepancies between actual and intended arm trajectories - likely determined by comparing correlated patterns of alpha-gamma motoneuronal co-activation and muscle spindle feedback with expected feedback patterns - lead to adaptive compensations to

generate straight movements. Supported by NASA Grant NAG9-515.

## 218.5

SIMILAR TRAJECTORIES FOR SLOW MOVEMENTS TOWARDS A TARGET AND SLOW MOVEMENTS IN A "STRAIGHT" LINE.

J.B. de Graaf, A.C. Sittig, and J.J. Denier van der Gon. (SPON: European
Neuroscience Association) Delft University of Technology, Jaffalaan 9, 2628 BX

Previously we showed that the trajectories of slow arm movements towards visual targets are systematically curved [1]. A possible cause for this curvature is an incorrectly internally represented target position. This would cause a bias in initial movement direction, which is corrected for during the move ment. Another possible cause is that the whole movement trajectory that is followed is internally represented as a straight line. In this study we tested these hypotheses. Five normally sighted subjects and four congenitally blind subjects had to move their arm slowly and accurately in a straight line (Exp 1) or towards a target (Exp 2). Stimuli were used to suggest a starting direction (Exp 1) or to indicate a target position (Exp 2). The sighted subjects performed both experiments with visual stimuli and visual feedback (condition A), and with tactile stimuli and excluded vision (condition B). The blind subjects were presented tactile stimuli. The results show that 1) the curvature of the trajectories when moving in a straight line is comparable to the curvature of the trajectories when moving towards a target position, 2) the trajectories in condition A are significantly curved, and 3) the trajectories are significantly curved for the congenitally blind subjects, but not for most normally sighted subjects in condition B.

We conclude that 1) the curved movement trajectories are internally represented as straight lines, and 2) for the normally sighted subjects the curvature of the trajectories is influenced by the absense of visual information, although the curvature is not caused by visual information processing. MAKING CONTACT: TARGET SURFACES AND POINTING IMPLEMENTS FOR 3D KINEMATICS OF HUMANS PERFORMING A FITTS' TASK. C. L. MacKenzie, School of Kinesiology, Simon Fraser University, Burnaby, BC, V5A 1S6, Canada

Following Fitts' law, kinematics of aiming movements are used for inferences about underlying planning/control. We defined "precision effect" as the relative lengthening of the deceleration phase of movement with decreases in target size (MacKenzie, Marteniuk, Dugas, Liske & Eickmeier, 1987). Having noted changes in impact velocity, the purpose was to examine effects of target surface and pointing implement on 3D kinematics.

Eight adults made aiming movements. Conditions for Index of Difficulty (ID) included: 2 amplitudes (30, 40 cm) and 4 target diameters (1, 2, 4, 8 cm). These were factorially combined with 2 implements (index finger tip or pen tip) and 2 target types (hole or solid target). On each trial, subjects placed the pointer on a constant start position. At the "Ready, GO" signal, subjects moved as quickly and as accurately as possible to the target. The Optotrak system (Northern Digital, Waterloo) collected 3D coordinates at 200 Hz.

MT results replicated Fitts' Law. Kinematic differences among the pointing implement and target surface conditions showed: the pen was faster, with greater, earlier peak kinematic values than the finger tip; a greater proportion of time after peak velocity with the pen than the finger; the hole target had lower peak kinematic values and a greater proportion of time decelerating than the solid target. Results are discussed in terms of task requirements, contact forces in interaction with objects, and subject initiated deceleration control (see also Milner & Ijaz, 1991; Teasdale & Schmidt, 1991).

### 218.4

MODIFICATION OF FAST ARM MOVEMENT EMG PATTERN BY CORTICAL MAGNETIC STIMULATION

M. Pause, J. Mohm, R. Tauber, K.-H. Mauritz\* Dept. of Neurology, Universitaet Wuerzburg, Dept. of Neurorehabilitation Freie Universitaet Berlin, Germany.

It was shown by Day et al. (Brain 112, 1989) that magnetic stimulation of the human motor cortex before a fast target movement delays the entire triphasic EMG pattern, while stimulation after the beginning of the agonist burst delays only the antagonist and later bursts. We reexamined this paradigm with the question as to whether cortical stimulation results only in a delay or in a deletion of a fixed EMG sequence.

Four subjects performed fast elbow extension movements (30 deg) towards a target

in a device where the position of the arm and the rectified EMG of the triceps and biceps muscles were synchronously measured. Magnetic stimulation which was focussed on a region evoking responses predominantly in these muscles was triggered by the onset of the first agonist burst with a systematic variation of the stimulus delay from 0 to 280 ms. In a second series the arm movement was initiated by an acoustic signal, and the stimulus was positioned within the reaction time, i.e. in different intervals before the beginning of the voluntary EMG bursts.

With the second paradigm a minimum interval between stimulation and EMG onset

with the second paradigm a minimum interval develent stituturion and EMO onset was noted with increasing duration at higher stimulation intensities. Apart from a critical period where the stimulation occurs obviously within 15 ms before the beginning of the agonist burst, the general triphasic pattern and the movement were unchanged suggesting a mere temporal shift. With stimulation after the onset of the agonist burst, a delay of the antagonist burst was also observed relating to the poststimulus silent period, but the amplitude and duration of the delayed burst was markedly re-

duced as if a part of the burst would have been cut off. The movement was modified according to this but was additionally disturbed by the evoked response.

We conclude that an EMG pattern of a simple movement can be delayed without essential changes to the pattern, when magnetic stimulation occurs before the EMG onset while a similar shift of the antagonist burst only is not possible. Stimulation after the beginning of the pattern interrupts the antagonist burst and partially cancels the EMG activity. This result is compatible with the assumption of a fixed motor program.

## 218.6

DISTURBANCE OF SPATIOTEMPORAL PATTERNS OF EXPLORATORY FINGER MOVEMENTS IN PATIENTS WITH PARIETAL LESIONS F.Binkofski, E. Kunesch, H.-J. Freund\*, Dep. of Neurology, University of Düsseldorf, 4000-FRG

In normal subjects exploratory finger movements during object recognition are In normal subjects exploratory finger movements during object recognition are characterized by a typical spatial pattern of the digital scan path and by regular temporal sequencing of the finger movements that are preformed at a naturally preferred frequency below 2Hz (Kunesch et al., Exp. Brain Res., 78: 539-546, 1989). In order to study the impact of lesions of parietal cortex (PC) on this sensorimotor task, we analysed the temporal and spatial characteristics of exploratory finger movements during recognition of stereometric objects in blindfolded normal subjects (n=17) and patients with lesions of PC (n=8) using a 2-camera Selspot position analysis system. For comparison 6 patients with premotor damage and clinically normal hand function were examined. In order to provide quantitative assessment of the dysfunction of exploratory movements three parameters were defined: 1.preferred frequency and 2.regularity of the digital palpation, 3.movement space of the thumb. In frequency and 2.regularity of the digital palpation, 3.movement space of the thumb. In PC lesions with clinical disturbance of stereognostic functions (n=5) the movement frequencies on the affected hand were lower (mean: 0.49Hz, sci: 0.25) than in normal subjects (mean: 1.22Hz, sci: 0.21). The index of regularity calculated as area under peak divided by area under the remainder of the spectrum was lower than in normal subjects (normals: 0.83, sd: 0.05, PC: 0.47, sd: 0.20). Movement trajectories in PC lesions were grossly deranged and thumb movements more expanded in space (PC mean movement space: 23.0cm<sup>3</sup>, sd: 26; normals: mean: 8.3cm<sup>3</sup>, sd: 2.6). The results of the unaffected hand in PC were similar to that in normals. In the cases with PMC lesions preferred movement frequencies were slightly lower (mean: 1.04Hz, sd: 0.27), and the regularity index was severely affected (mean: 0.53, sd: 0.30), but movement space and pattern of the thumb were within the normal range. These results indicate that the PC contributes to the motor programs for explorative and manipulative finger movements, whereas the PMC is involved in the temporal organization and the regularity of digital palpation.

ARM MOVEMENT ENDFOINT ERRORS INDUCED BY CORIOLIS STIMULATION. P. DiZio\* and J.R. Lackner. Ashton Graybiel Spatial Orientation Laboratory, Brandeis University, Waltham, MA 02254.

We measured pointing movements to a visual target in an otherwise dark slow rotation room with a WATSMART system. Subjects attempted to touch a target about 35cm straight ahead, starting with the fingertip on the axis of rotation. During rotation (10rpm), reaching movements generated lateral Coriolis forces (C<sub>2</sub>) proportional to arm velocity which acted without local contact forces. Before and after the movements, virtually no unusual forces were present. Thirteen subjects made fast (305±68ms duration) movements and 11 slow (730±111ms duration). All initial movements and 11 slow (730±111ms duration). All initial movements exhibited path and endpoint deviations in the direction of C<sub>1</sub>. The lateral endpoint error was 47±34mm for fast movements and 38±27mm for slow. Peak lateral error was only 5±13mm greater than the endpoint error for fast movements and 8±19mm greater for slow. Movements were also foreshortened by about 25mm. When again stationary, subjects accurately mimicked their aberrant trajectories and endpoints. In other observations, when subjects pointed in the air above the target surface, endpoint errors were reduced by 65% for slow but not fast movements. The discrepancies between these and other findings on load compensation likely relate to the tactile cues on the arm unavoidable with other methods.

MECHANISM UNDERLYING SHIFTS IN INTERLIMB MOVEMENT PATTERNS IN INFANCY: A PERTURBATION STUDY. D. Corbetta\* and E. Thelen. Department of Psychology, Indiana University, Bloomington, IN 47405.

The development of reaching in infancy is marked by successive shifts between bimanual and unimanual limb coordination. Little is known about the mechanisms of early interlimb coupling and the dramatic shifts in coordination patterns. We report on two experiments designed to (1) identify developmental shifts in the manual strategies used for reaching and (2) test bilateral symmetry coupling by changing the task and the limb weighting. In the first experiment, small and large balls requiring uni- or bilateral reaches were presented at midline. In the second experiment, infants' preferred arms were weighted.

Five infants were tested longitudinally from 5 to 8 months, using WATSMART to record trajectories of hands and shoulder and ball position. In the second experiment, we also recorded EMG activity of biceps, triceps and deltoid.

Shifts in the manual strategy used for reaching occurred around 7 months old. At this age, infants shifted from unilateral to bimanual strategies with the large ball or from bimanual to unimanual with the small ball. Weight perturbations provoked compensatory contralateral activity that shifted the coordination into symmetry if originally asymmetric or broke the symmetry of an originally symmetrical pattern.

These results suggest that the development of manual strategies in reaching depends on the underlying strength of the bilateral activity that links both sides of the body as a single system.

## 218.11

HOW DOES THE CEREBELLUM CONTROL COMPOUND MOVEMENTS? H.P. Goodkin\* and W.T. Thach. Depts of Anatomy and Neurobiology and the IWI Rehab Res Institute. Wash Univ Sch of Med, St. Louis, Mo 63110.

A rhesus monkey was trained to perform 2 single digit tasks - flexion of the thumb or index finger cued by separate LED commands - and a two digit task - simultaneous! The intent was to combine two simple movements into a third compound synergic movement. This would appear to be the critical test of the hypothesis that the cerebellum may control compound and not simple movements (Thach, et al, Ann Rev Neurosci, 15, 1992).

Injections of 3 ul (Sug/ul) muscimol were placed into the cerebellar dentate nucleus. Muscimol did not significantly impair the monkey's ability to perform any of the instrumented finger tasks. The only consistent measurable effect was a delay in reaction time of 20 to 50 milliseconds affecting the thumb and index finger during both the single and two digit tasks. A reaction time delay was never seen purely in the two digit tasks. Nor was the relative timing between the thumb and index finger during the two digit task significantly changed. However, the performance of natural compound movements was affected. The monkey's reaches overshot the target (usually unaccompanied by tremor), and he could not use a precision pinch and would substitute single digit strategies. In this experiment, the dentate nucleus was not necessary for the control of the instrumented single or two digit finger tasks but was necessary for the control of the natural compound tasks. This finding further supports our hypothesis that the cerebellum preferentially controls compound movements. The finding that the instrumented 2 digit "compound" movement was unaffected raises the possibilities that the monkey performed this task as 2 simple movements simultaneously and independently or that the compound movements need to be made to "natural" visual targets.

Longitudinal Study of EMG Activation Relative to Reaching Kinematics and Kinetics in the first Year  $\,$ 

Spencer, J., Kamm, K. & Thelen, E.\* Department of Psychology, Indiana University, Bloomington, IN 47405.

In the first year of life, infants learn to reach objects with speed and precision. This study reports on the muscle activation patterns associated with the onset of reaching and the relation between muscle patterns and kinematic and kinetic measures of reaching skill improvement. We observed the reaches of one infant weekly from 3 to 30 wk of age, then bi-weekly to 52 wk. We recorded 3-D kinematic data from the joint centers of both arms and calculated kinetics using inverse dynamics. In addition, we collected EMG (750Hz) with surface electrodes placed over the muscle bellies of: anterior deltoid (AD), upper trapezius (UT), biceps (B), triceps (TI) and erector spinae (ES).

The infant initiated reaches from different starting positions and

The infant initiated reaches from different starting positions and background movement conditions throughout the first year, generating a wide variety of kinematic, kinetic and EMG patterns. Despite this variability, a coactivation pattern was present at all ages. Reaches were initiated by UT contraction, followed by co-activation of AD, BI, and TRI. The infant rarely used this co-activation pattern in his spontaneous movements prior to the onset of stable reaching at 12 wk. He used the pattern inconsistently during a period of exploration and rapid improvement in reaching skill from 12 to 21 wk. By 22 wk, co-activation was the predominant pattern. In this later stage of reaching skill, the co-activation pattern was coupled with a stable sub-set of kinematic and kinetic patterns.

We suggest that the infant successively discovered this stable strategy of reaching with reaching practice and that it represented an efficient way of controlling the underlying force dynamics of the reach movement.

### 218.10

LONGITUDINAL ANALYSIS OF REACHING KINETICS IN THE FIRST YEAR OF LIFE. R. Zernicke<sup>1\*</sup>, K. Schneider<sup>2</sup>, and E. Thelen<sup>3</sup>, 'Department of Surgery, University of Calgary, Calgary, AB, Canada, T2N 4N1, <sup>2</sup>Munich Technical University, Munich, Germany, <sup>3</sup>University of Indiana, Bloomington, IN, USA, 47405

During the first year of life, human infants undergo dramatic changes in motor control-as well as limb mass and geometry-and must learn to coordinate an array of muscular and passive forces to reach for an object. To better understand these changes in motor control, we quantified the upper-extremity kinematics, inverse dynamics, and intralimb coordination during development as an infant reached (or attempted to reach) for a toy. The infant's movements were recorded weekly from 3-30 wk of age and bimonthly thereafter until 1 yr of age. In early reaches (5-22 wk), the infant principally used flexor muscle torques at both the shoulder and elbow to counteract the gravitational extensor torque. Muscular torques at the shoulder and elbow became more tightly coupled during weeks 48-51. Muscle-power profiles at the elbow and shoulder joints were quite variable in the early weeks (5-22), but a pattern emerged at later ages with first power generation at both elbow and shoulder joints followed by a combined shoulder joint power generation and elbow joint power absorption. By the last month of the first year, there was a triphasic relationship between elbow- and shoulder-joint muscle power: generation at both elbow and shoulder, then elbow absorption and shoulder generation, followed by power absorption at both the elbow and shoulder joints. Of the torque components due to mechanical interactions among limb segments, inertial torques related to upper-arm and forearm angular accelerations and the linear acceleration of the shoulder joint were most prominent throughout the first year. Elbow and shoulder muscle torques were modulated with respect to the interactive torques, particularly as the hand approached the toy. Although hand trajectories stabilized sooner, refinements in intersegmental dynamics continued throughout the first year. Supported by a grant from NIH (HD 22830).

## 218.12

PRISM ADAPTATION IN THROWING IS SPECIFIC FOR ARM AND TYPE OF THROW. W.T.Thach\*, H.P.Goodkin, J.G.Keating, and T.A. Martin, Depts of Anatomy, Neurology, and The IWJ Institute for Rehabilita. Research, Washington University Medical School, St. Louis, Mo. 63110.

In throwing, eyes (and head) fixate the target. Donning wedge prisms (bases right) bends the optic path right, and gaze shifts left to fixate the target. The arm throws in the direction of gaze—left of the target. With practice, the throw shifts right, away from gaze direction, closer to and finally on-target. When the prisms are removed, gaze is now on-target, the arm throws right of target an amount almost equal to the original leftward error, and each throw shifts left closer to and finally on-target (Thach et al, 1991). How specific is this adaptation to the task and to the body parts?

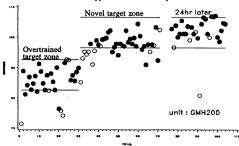

In one experiment, subjects threw with 1) one arm, 2) the other arm, 3) the first arm with prisms, 4) the other arm, and 5) the first arm. Prism adaptation occurred in all subjects in the throwing arm (3), did not affect or abate with throws by the other arm (4), and readapted during throws by the first arm (5). In a second experiment, subjects threw 1) underhand, 2) overhand (same arm), 3) over hand with prisms, 4) underhand, and 5) overhand. On wearing prisms all subjects adapted the overhand throw (3). In 6 subjects, subsequent underhand throw showed no effect of prior overhand adaptation (4). In these subjects, prior overhand adaptation persisted in subsequent overhand throws despite intervening underhand throws, and readapted with repeated overhand throws (5). Two subjects showed carryover from prior overhand adaptation (3) to underhand throw which disappeared with underhand throwing (4), and the amount of residual overhand adaptation (5) was less.

amount of residual overhand adaptation (5) was less.

Thus, in most subjects adaptation involved one task and not another task, although many or the same body parts participated in both tasks. This implies separate central channels for adaptation of muscle actions for each task.

ADAPTATION OF A BALLISTIC MOVEMENT TO A NOVEL ENDPOINT IS ENDURING. J.G. Keating\* and W.T. Thach. Dept. of Anatomy and the IWJ Rehab. Res. Ins., Washington Univ. Sch. Med. St. Louis, MO 63110.

We have described an inactivation map of cerebellar cortex produced by systematically injecting muscimol into cerebellar cortex of a Rhesus Monkey. Inactivation of a small area of cortex resulted in prevention (2ul of 5ug/ul) or a marked slowing (2ul of 1ug/ul) of adaptation with no significant change in task performance (Soc. Neurosci. Abs. 551.3, 1991). We now show that normal adaptation is enduring: the adapted state is maintained for at least 24 hours. We conclude that the cerebellar can cortex play an essential role in producing changes of at least this duration in this type of movement adaptation.

End points of ballistic movements are plotted vs. trial number. The first trials 24 hours later end in the adapted target zone, not the overtrained control zone.

#### 218.15

EFFECTS OF PRACTICE ON REPRODUCING MOVEMENT DISTANCE AND LOCATION S. Jaric D. B. Ilic D. M. Corcos. G. L. Gottlieb, M. L. Latash\*.

Institute for Medical Research, Belgrade, Yugoslavia, University of Illinois at Chicago, IL 60608 and Rush Medical Center, Chicago, IL, 60612.

Movements can be controlled by a shift in a command related to joint equilibrium position r from an initial value r<sub>in</sub> to a final value r<sub>f</sub> at a rate ω within a

time  $\tau$ . If a subject learns a movement to a final position, he needs to remember only one value at the control level,  $r_f$  and shift r at a rate  $\omega$  (an  $r/\omega$ -strategy). If the subject is asked to learn a movement over a certain distance, he needs to remember two values,  $\tau$  and  $\omega$ , the product of which gives movement distance (a  $\tau/\omega$ -strategy), since distance itself does not have a single-valued representation at the control level. This control scheme predicts that movements performed by the r/\omega-strategy will be

This control scheme predicts that movements performed by the t/ω-strategy will be more accurate and consistent than those performed by the t/ω-strategy.

Two groups of subjects (n=6) practiced rapid, self terminating movements to a target. One group of subjects performed 500 movements over a fixed distance from seven different initial starting positions over 36° (a t/ω-strategy). The other group of subjects performed 500 trials to the same final location from the same seven different initial positions with actual movement distance ranging from 24° to 48° (an r/ω-strategy). Then, the subjects were tested under conditions of both distance and location reproduction. The indices of variability are:

√CE<sup>2</sup>+VE VE CE Dis Dis 4.9 8.36 6.29 Dis

Performed Loc 1.8 3.8 3 2.3 3.49 4.44

All three indices of variability show that location is better reproduced than distance and are consistent with predictions of the equilibrium point hypothesis. This work was supported by NIH grants NS 23593, AR 33189, NS 28176 as well as by HHS grant IF-012 through the US-Yugoslav board of scientific cooperation and a grant from the Serbian Research Foundation.

## 218.17

• THE STUDY OF CONSTRAINED AND PARTIALLY CONSTRAINED REACHING MOVEMENTS • I. Won and N. Hogan.\* Department of Mechanical Engineering, Massachusetts Institute of Technology, Cambridge, MA 02139.

In early forms of the equilibrium prictinology, standings, massatusets in the state of the price target position was required to provide a simple and complete explanation for experimental observations [Bizzi et al., 1984]. In later work these virtual trajectories were shown through simulations to be remarkably competent in describing unconstrained two joint arm movements. [Flash and Hogan, 1985].

To experimentally test this notion of virtual trajectories in two-joint movements, a new experimental paradigm was designed. Human subjects grasped the instrumented handle of a two-link robot manipulandum and performed specified point-to-point planar arm trajectories. Computer-controlled clutches were used to subtly change the movements by constraining the trajectory to be along an arc of radius equal to the length of one link of the manipulandum. Targets points were arranged to lie along the arc so that the subject could complete the movement even when constrained Three situations were tested: (1) unconstrained throughout movement, (2) constrained through the entire movement, and (3) initially constrained and then released during movement.

Experimental results showed significant forces during the constraint strongly oriented so as to restore the hand to the unconstrained hand path. In addition when released from the constraint, these forces caused a strong tendency to return the hand to the unconstrained path before the end of the movement was reached. The presence of these restoring forces (even when considering the anisotropy of the end-point arm stiffness) implies that an attractor point exists between the start and target points for a significant portion of the movement. These results extend earlier single-joint results [Bizzi et al., 1984] to the multi-joint case and provides further support for the theory that a single process underlies posture and movement.

KINEMATICS OF HAND AND ARM ORIENTATIONS IN REACHING AND GRASPING. M.Flanders\* and J.F.Soechting. Dept. Physiology, Univ. Minnesota, Minneapolis, MN 55455.

Grasping an object involves a coordinated posture of the arm, the wrist and the hand which is related to the object's location and We have begun to study the kinematic orientation in space. transformations between the parameters defining object location and orientation and those defining arm and hand posture. We presented subjects with a target (a rod 20 cm in length). In some experiments we asked them to remember the object's location and orientation and to move the arm to the remembered target location so as to grasp the virtual target with a power grip or with a precision grip. There were no appreciable consistent errors in subjects' performance on this task. Their performance was comparable when we asked them to reproduce only the hand configuration adequate for grasping, i.e to maintain their arm at the side rather than to move to the target's location. In another series of experiments we left the target in view and also asked the subjects to reproduce only the hand configuration. In this experimental situation, there were appreciable and consistent errors in hand orientation. Subjects appeared to orient the hand relative to the arm in a manner that would have been appropriate had the arm reached the target location rather than remaining at the subject's side. These errors suggest that hand orientation is defined in a reference frame fixed to the arm and not in a reference frame fixed in space.

### 218.16

LOCATION AND DISTANCE CODING IN OPEN LOOP POINTING IN A DEAFFERENTED PATIENT. Bard, C.<sup>1</sup>, Fleury, M.<sup>\*1</sup>, Teasdale, N.<sup>1</sup>, Paillard, J.<sup>2</sup>, Forget, R.<sup>3</sup>, & Lamarre, Y.<sup>3</sup>. Université Laval, Québec.<sup>1</sup> CNRS, Marseille.<sup>2</sup> Université de Montréal.3

We tested the ability of a deafferented patient and two neurologically normal subjects to produce alternate wrist pronations and supinations without vision of their moving limb. For 30 seconds, subjects, holding a handle centered on the axis of their right forearm, performed pointings between two visible targets to the left or right of the vertical. From a 0° initial position, subjects pointed at targets, and verbally indicated the end of their movement. The verbal signal triggerred the lighting of the next target immediately or 8 seconds later. Both normal subjects and the patient showed an ability to time the end of their movements with accuracy. The patient produced as stable amplitudes as normals for both delays, confirming recent findings (Larue et al., 1992). Yet, unlike normals, the patient was unable to move her arm to the spatial location of the target. She exhibited an important shift in all series of movements. Rather than an agonist/antagonist length/tension ratio, the deafferented patient seems to modulate her "effort" proportionnaly to the required distance between two targets.

## 218.18

SENSORIMOTOR COORDINATION DURING WRIST MOVEMENT IN NORMAL AND DEAFFERENTED SUBJECTS. M.F. Levin\*, Y.Lamarre and A.G. Feldman. Centre de Recherche, Institut de réadaptation de Montréal, CRSN, Université de Montréal, Montreal, Quebec. Canada H3S 2J4.

We examined the relative roles of central and peripheral mechanisms in movement production. Predictions of equilibrium-point model of motor control were compared to EMG, net joint torque and kinematic data from normal (n=8) and deafferented (n=1) subjects who made fast 30° wrist flexion movements. The forearm was nobilized and the hand was clamped at the metacarpals to minimize grasping. After training with no load, the load was randomly presented during the first 700 or 300 ms after which it was suddenly removed. Loading resulted in an undershoot of the target which was regained after the load was removed. In the second experiment, subjects trained to reach the target with the load. In subsequent trials, when the load ted, subjects overshot the target. Subjects trained with vision was randomly not preand in experimental trials, they performed movements with and without visual feedback. They were instructed not to correct errors arising from loading or unloading. In spite of the presence of muscle coactivation, wrist stiffness associated with the final position was significantly less for the deafferented subject (0.033-0.084 Nm/deg with vision, 0.022-0.063 Nm/deg without vision) than for normal subjects (0.115-0.269 Nm/deg). This subject was also unable to consistently reproduce the final joint position and had a longer time to peak velocity. Both normal and deafferented subjects produced movements by shifting the torque/angle characteristic to the final position by means of reciprocal (R) commands and by increasing its slope by means of coactivation (C) commands. The low movement precision in the deafferented subject can be explained by a loss of the positional frame of reference for R commands normally provided by muscle afferents and diminished effectiveness of C command due to the absence of peripheral feedback.

COORDINATION BETWEEN ARM AND TRUNK MOTION DURING RAPID POINTING MOVEMENTS. TR Kaminski\*, C Bock & AM Gentile. Dept. of Movement Science, Teachers College, Columbia Univ., New York, NY, 10027 Previous multijoint pointing studies have limited the distance travelled by the hand to

Previous multijoint pointing studies have limited the distance travelled by the hand to within arm's length and have focused on the linkage between the shoulder and elbow joints (Kaminski and Gentile, 1986; 1989). In the present study, the amplitude of hand displacement varied so that successful completion of the movement required the use of 2, 3 or 4 joints (albow shoulder sample-transic him)

movement required the use of 2, 3 or 4 joints (elbow, shoulder, scapulo-thoracic, hip).

Four seated subjects performed pointing movements to a target at five distances; two within and three greater than arm's length. 2-D kinematic analysis indicated that regardless of the number of segments involved, the hand moved along the same path and its velocity profile was smooth and bell-shaped. However, the joint configuration at any given point along that path varied depending on the target location. There was a distal to proximal organization to joint movement cessation: elbow joint stopped first, followed by shoulder, then hip. Thus, for movements beyond arm's length, the pattern of hand motion remains the same while the coordination between the joints is altered.

SPATIO-MOTOR MAPPING DURING DRAWINGS IN 3D ISOMETRIC CONDITIONS. J.T. Massey\*, G. Pellizzer, and A.P. Georgopoulos. Brain Sciences Center, VAMC, Minneapolis, MN 55417; Dept. of Physiology, Univ. of Minnesota, Minneapolis, MN 55455; and Dept. of Neuroscience, The Johns Hopkins Univ., Baltimore, MD 21205.

Soechting et al. (Neuroscience, 17: 295, 1986) described that free hand drawings of circles were characteristically distorted when traced in the sagittal plane. They suggested that the sensorimotor mapping between the motion of arm orientation angles and the intended wrist trajectory is not as well valid for all planes of space. We investigated whether distortions occur when circles are drawn in isometric conditions, that is when the trajectory is defined in the force space. Normal human subjects were asked to exert forces continuously on a 3D isometric manipulandum in order to draw circles in specified planes in the force space. The drawings were performed at a selfchosen pace in the presence or absence of a visual feedback cursor and a visual template. We found that: (a) the orthogonal components of force were modulated in a close to sinusoidal fashion, (b) the phase relation was clustered around 90°, (c) the force amplitude varied relatively more than the timing, (d) these characteristics were not affected by the plane of drawing or by the presence or absence of visual feedback. The results indicate that, in isometric conditions, there were no more distortions for circles drawn in the sagittal plane than for those drawn in other planes. These results suggest that, unlike the movement case, the force modulation is adequately mapped to the intended spatial outcome independently of the plane of drawing. Therefore the distortions observed with free hand drawings in the sagittal planes are likely related to constraints of movement execution. (Supported by NSF and ONR).

AMYGDALAR NEURONAL RESPONSES DURING CROSS-MODAL ASSOCIATION TASK IN AWAKE RATS.

T. Uwano, H. Nishijo, T. Ono, K. Nakamura\*, and K. Torii¹
Dept. Physiol., Fac. Med., Toyama Med. & Pharmaceu. Univ., Toyama 930-

01, and ÉRATO, R&D Corp. of Japan, Yokohama 221, Japan.

The amygdala (AM) receives information from various sensory modalities via the neocortex, and directly from the thalamus. Lesion of the AM decreases emotional responses to various sensory stimuli. In this study, single unit activity was recorded in the AM and ventral parts of the striatum in awake rats. Rats were trained to acquire glucose or intracranial self-stimulation reward, or to avoid electric shock or tail pinch, by identical behavior, licking. Each unconditioned stimulus was associated with a cue tone stimulus (CTS), a light, or an air-puff. The neurons were also tested with various sounds, somatosensory stimuli, and taste solutions through intraoral canulae. Of 645 neurons was recorded, 245 responded to one or more sensory stimuli, and 65 of these responded exclusively to an auditory, a visual, a somatosensory, or an oral sensory stimulus. Most receptive fields of somatosensory neurons included some parts of the head and/or neck. Some auditory specific neurons were tested for extinction, and responses to CTS were diminished when reward was eliminated. Eight multimodal neurons responded to specific combinations of various sensory stimuli. Of these, two responded only to ingestion of glucose and the corresponding CTS. When CTS for electric shock was associated with glucose, these neurons became responsive to the CTS. The results suggest that the AM is one of the foci of convergence of various sensory information, and suggest its involvement in cross-modal and stimulus-affect association.

### 219.2

CGRP-IMMUNOREACTIVE TERMINALS IN THE LATERAL NUCLEUS OF THE AMYGDALA FORM ASYMMETRIC AND SYMMETRIC SYNAPTIC JUNCTIONS. C. Farb\*, C. Aoki, and J.LeDoux. Center for Neural Science, NYU, NY, NY 10003

Projections from medial geniculate body (MGB) to lateral amygdala (AL) have been implicated in the classical conditioning of emotional responses to acoustic stimuli (LeDoux,1990). Recent anatomical studies (Yasui et al., 1991) have suggested that calcitonin gene-related peptide (CGRP) plays a role in neurotransmission in this pathway. In order to elucidate role of this peptide in synaptic transmission, CGRP immunoreactivity in the AL was examined at the electron microscopic level. CGRP-like immunoreactivity was seen in axon terminals, soma, glia and dendrites. Immunoreactive terminals contained many small clear vesicles and 1-5 dense-core vesicles. Labeled terminals formed both asymmetric (excitatory?) and symmetric (inhibitory?) synaptic junctions. Asymmetric synapses were almost always observed on dendritic spines while symmetric synaptic junctions were localized almost exclusively on soma or proximal portions of dendrites. CGRP immunoreactivity in soma and initial-segment axons was seen in vesicles of membrane-bound organelles. These observations are consistent with the possibility that both local inhibitory interneurons and excitatory projection neurons use CGRP in neurotransmission. Since neuroactive peptides are often co-localized with other transmitters, it is possible that CGRP plays a modulatory role neurotransmission in the AL. (Supported by MH 38774 & MH46516).

OVERLAPPING AND DIVERGENT PROJECTIONS OF CA1 AND THE VENTRAL SUBICULUM TO THE AMYGDALA. R.G. Phillips\* and J.E. LeDoux. Dept. of Psychology & Center for Neural Science, New York University, NY, NY 10003.

In recent studies we implicated the hippocampus and amygdala in contextual fear conditioning and suggested that projections from hippocampus to the amygdala are critical. Studies using horseradish peroxidase as a retrograde marker indicate that cells in the ventral CA1/subiculum region of the hippocampal formation project to the amygdala. In the present study we determined whether ventral CA1 and subiculum have differential projections to the amygdala using anterograde and retrograde tracing. and retrograde tracing. The anterograde tracer phaseolus-vulgaris lecouaglutinin (Pha-L) was iontophoretically injected into either ventral subiculum or ventral CA1. Injections in subiculum resulted in a dense projection to the ventromedial part of the lateral nucleus (ALvm), basomedial nucleus (BM), medial nucleus, and intra-amygdala part of the bed nucleus of the stria terminalis, whereas injections in CA1 resulted in transport to the ALvm and BM, but also to the basolateral nucleus (BL). Following iontophoretic injections of FluoroGold in AL or BM, retrogradely labeled cells were found both in the ventral subiculum and CA1, whereas injections of BL resulted in retrograde transport only to CA1. Thus, ventral subiculum and CA1 have overlapping and divergent projections to the amygdala. Processing of contextual information in fear conditioning may be mediated by all or a subset of these projections. Supported by MH38774 and MH46516.

## 219.4

AMYGDALA EFFERENTS MEDIATING FEAR-POTENTIATED STARTLE: REFRACTORY PERIODS, CONDUCTION VELOCITIES, AND SYNAPSES. B.A. Pollard and J.S. Ycomans. Dept. of Psychology, University of Toronto, Toronto, Canada, M5S-1A1.

Pathways from the amygdala via the caudal ventral amygdalofugal pathway (VAF) have been shown to mediate fear-potentiated startle (Davis, 1991). In the present study, we examined the subsequent connections from VAF to medulla using electrical stimulation and electrolytic lesions. Stimulation of VAF, midbrain, or medulla (two 0.1 ms pulses, 100 to 820 uA) produced an unconditioned startle in behaving rats. Refractory periods ranged from 0.4 to 0.8 ms in VAF sites, and from 0.2 to 0.5 ms in midbrain and medulla sites. To determine connections between sites, 'collision tests' were carried out by delivering a single pulse to one site, and a second pulse to another site. Results suggested ipsilateral midbrain and medulla were connected by axons with a mean conduction velocity of 66 m/s. Ipsilateral VAF and midbrain sites appear to be connected by strong synapses transmitting from VAF to midbrain, with a synaptic delay of less than 0.8 ms. No collision was observed between contralateral sites.

These rats were then conditioned by pairing light with footshock. After fear-conditioning, bilateral lesions via the midbrain electrodes (0.5 mA for 30 s) abolished fear-potentiated acoustic startle, but had no effect on acoustic startle alone. In addition, electrical stimulation of VAF sites could no longer elicit startle behavior, while electrically-evoked startle from medulla sites was decreased but not eliminated.

These results suggest that fear-potentiated startle is synaptically mediated between VAF and midbrain, with fast axons from midbrain to medulla. (Supported by NSERCC grant A7077 to J.S.Y.)

GABA-Immunoreactive Terminals Make Synaptic Contact With Identified Projection Neurons in the Rat Extended Amygdala. N. Sun\* H. Yi and M.D. Cassell Department of Anatomy(N.S. and M.D.C.) and Central EM Research Facility(H.Y.), University of Iowa, Iowa City, IA

Recent neuroanatomical studies have suggested that the central nucleus of the amygdala(Ce), lateral bed nucleus of the stria terminalis(BNST) and the dorsolateral sublenticular substantia innominata(SI) comprise the central amygdala(Ce), lateral bed nucleus of the stria terminalis(BNST) and the dorsolateral sublenticular substantia innominata(SI) comprise the central division of the extended amygdala(CEA). One of the common features of these regions is that they all project to brainstem autonomic nuclei. Previous studies in this laboratory have suggested that intrinsic GABAergic connections seem to link the subdivisions of the CEA which have similar brainstem projection targets and that GABAergic terminals form "basket-configurations" surrounding presumed projection neurons. The present study was designed to determine whether GABAergic terminals make synaptic contact with identified projection neurons in the rat CEA. We combined retrograde transport of HRP-WGA with postembedding immunogold staining for GABA. After injections of HRP-WGA into either dorsal medulla or parabrachial complex of Sprague Dawley rats, neuronal cell bodies in the different subdivisions of the Ce, BNST and SI were peroxidase-labeled. Ultrathin sections from Ce, BNST and SI were immunostained with GABA antisera, using a secondary antibody conjugated to 10nm gold particles. Peroxidase-labeled neurons and their dendrites received synaptic contact from colloidal gold-labeled terminals immunoreactive for GABA. The GABAergic axons contained pleomorphic vesicles and formed symmetric synapses(Gray type II) on the target neurons. The present study demonstrates a widespread GABAergic innervation, largely of intrinsic origin, on CEA neurons projecting to brainstem autonomic nuclei, suggesting a strong GABAergic inhibitory influence on CEA outputs. Supported by NS25139.

#### 219.7

DISTRIBUTION OF GABA AND PARVALBUMIN IMMUNOREACTIVE CELLS AND FIBERS IN THE MONKEY AMYGDALOID COMPLEX. A. Pitkänen\* and D. G. Amaral, Dept. of Neurology, Univ. of Kuopio, Kuopio, Finland and The Salk Institute, La Jolla, CA 92037.

The aim of this study was to examine the organization of inhibitory interneurons in the primate amygdaloid complex. Coronal sections from the brains of three M. fascicularis monkeys were immunohistochemically processed with monoclonal antibodies directed either against GABA or parvalbumin. GABA and parvalbumin immunoreactive (GABA-ir and PARV-ir, respectively) neurons consisted of at least three distinct cell types (small stellate cells; medium to large multipolar cells; and fusiform cells). All labeled neurons appeared to have aspiny or sparsely spiny dendrites. In general, there was a greater number of GABA-ir cells than PARV-ir neurons was found in the deep amygdaloid nuclei (lateral, basal and accessory basal nuclei) than in the more superficial regions such as the central, medial and anterior cortical nuclei. GABA-ir cells were more homogeneously distributed within the deep nuclei than PARV-ir neurons; the latter showed marked variations in intranuclear distribution. The distribution of fibers and terminals demonstrating PARV-ir was similar to the distribution of labeled cells. The highest density of GABA-ir fibers and terminals, however, occurred in the central and medial nuclei rather than in the deep nuclei. Since there was substantial overlap of the distributions of GABA-ir and PARV-ir cells and since they demonstrated similar morphologies, it is likely that the PARV-ir cells form a subset of the GABA-ir cell population.

## 219.9

IBOTENATE LESIONS OF THE ROSTRAL CENTRAL AMYGDALOID NUCLEUS PRODUCE A MARKED DEFICIT IN DRINKING PASSIVE AVOIDANCE BEHAVIOR IN RATS MORE EASILY UNDER PENTOBARBITAL THAN KETAMINE ANESTHESIA. G.D. Coover\* and R.C. Meyer. Department of Psychology, Northern Illinois University, DeKalb, IL 60115. The rostral third of the central amygdaloid nucleus

The rostral third of the central amygdaloid nucleus (rACE) appears to be the most effective target for electrolytic lesions that are "anxiolytic" as assessed by marked deficiency in passive avoidance of drinking (Coover, Soc. Neurosci. Abstr., 16:473). However, ibotenate (IBO) lesions of apparently comparable size did not produce such a marked deficit (Coover, Murison, and Jellestad, Physiol. Behav., in press). The present study examined three doses of IBO under pentobarbital or ketamine-xylazine anesthesia. ketamine-xylazine anesthesia.

A marked deficit in drinking passive avoidance was obtained with a 4  $\mu$ G dose of IBO (in .4  $\mu$ L pH 7.4 phosphate buffer), but not with doses of 1 or 2  $\mu$ G, and only in rats anesthetized with pentobarbital. Vehicle-injected controls required 24  $\pm$  2 (M  $\pm$  SE) footshocks of incrementing intensity to avoid a water spout for 5 min. incrementing intensity to avoid a water spout for 5 min. In contrast, the group injected with 4  $\mu G$  IBO under Nembutal required 42  $\pm$  3 footshocks, which is comparable to rats lesioned electrolytically, 45  $\pm$  2 footshocks. The 4  $\mu G$ /ketamine group required 33  $\pm$  3. Lesser rACE lesion-induced behavioral deficits with IBO under ketamine (p < .05 collapsed across dose) may reflect ketamine's antagonism of IBO at the NMDA receptor.

THE PROJECTIONS FROM THE ANTERIOR CINGULATE AND PRECENTRAL AGRANULAR CORTICES TO THE AMYGDALA IN THE RAT. G.D. Fisk\*\*, T. van Groen and J.M. Wyss. Dept. of Cell Biology and \*Psychology, Univ. of Alabama, Birmingham, AL 35294-0019

Several studies in the rat demonstrate that the anterior cingulate (area infraradiata; anterior, IR $\alpha$ ; posterior, IR $\beta$ ) and precentral agranular (Preag) cortices project to the amygdala. The present study characterizes the termination pattern of these projections using the anterograde tracers Phaseolus vulgaris leucoagglutinin and Fluororuby. The ventral areas of  $IR\alpha$  (i.e.,  $IR\alpha\alpha$  and  $IRb\alpha$ ) project predominantly to medial and ventral parts of the amygdaloid complex, specifically medial, basomedial, cortical and central nuclei, the caudal half of the basolateral nucleus and the periamygdaloid cortex. IRaa projects most densely to the medial and the cortical nuclei, and IRb $\alpha$  projects most densely to the medial nucleus and the caudal half of the basolateral nucleus. In contrast to IRa $\alpha$  and IRb $\alpha$ , dorsal IR $\alpha$  (i.e., IRc $\alpha$ ) and rostral Preag project primarily to the lateral and basolateral nuclei and avoid the more medial and ventral areas of the amygdala. IR $\alpha$  projects to the entire basolateral nucleus, but Preag projects only to the rostral half of the basolateral nucleus. Injections in IR $\beta$  or caudal precentral agranular cortex do not label axon terminals in the amygdala. Thus, nearly all projections to the amygdala from the IR and Preag cortices arise from the rostral portions of these cortical areas, with ventral IR $\alpha$  projecting primarily to ventral and medial areas of the amygdala, and dorsal IR $\alpha$  and Preag projecting to lateral areas of the amygdala. The preponderance of ventral IR $\alpha$  projections to the medial and central amygdaloid nuclei suggests that ventral IRα influences cardiovascular and affective functions, at least in part, via this pathway.

### 219.8

DISTRIBUTION OF DIFFERENT TYPES OF AXON TERMINALS TO NEURONS IN THE MEDIODORSAL THALAMIC NUCLEUS (MD) OF THE RAT. M. Kuroda and J.L. Price. ¹Dept. Anat., Toho Univ. Sch. Med., Tokyo 143, Japan, ²Dept. Anat. & Neurobiol., Washington Univ. Sch. Med., St. Louis, MO 63110

The Golgi electron microscopic study was undertaken to determine the

distribution of axon terminals synapsing onto each order dendrite of MD neurons identified by the gold-toning procedure.

In our previous study, four types of axon terminals have been demonstrated in MD; 1) small axon terminals with round synaptic vesicles (SR type), 2) large axon terminals with round vesicles (LR type), 3) small to medium axon terminals with picomorphic vesicles (SMP type), 4) large axon terminals with picomorphic vesicles (LP type). Both SR and LR types of boutons establish asymmetric synaptic contacts, whereas SMP and LP terminals are observed to make synaptic junctions of symmetric specialization. The present study provided evidence that there was no significant difference on the distribution of synaptic organization formed by each type of boutons synapsing along each order of dendrites in different parts of MD, although it was noticeable that each part differed in the number and percentage of each type of boutons. Primary dendrites carried LR, LP and SMP terminals with high proportional density of large-sized boutons regardless of synaptic morphology. No SR terminals were found to make synapses with primary dendrites in each part. Secondary and tomate synapses with primary dendrites in each part. Secondary and tertiary dendrites were covered with all types of axon terminals. Higher order dendrites more than tertiary ones were crowded predominantly with SR boutons, but they also carried LR as well as SRP terminals. In addition, SRP boutons were often found to form symmetric contacts with cell bodies. Thus, MD neurons were covered at least with either SRP or LP terminals, which have been shown to be extrinsic inhibitory inputs, at any orders of their dendrites.

The results of the present study suggest that neurons in each part of MD receive the same sets of axon terminals at each order dendrite, though sources of afferent inputs vary with different parts of MD. Supported by NIH research grant DC 00093.

## 219.10

A NEW SUBDIVISION OF THE PERIAQUEDUCTAL GRAY (PAG) BASED ON DIFFERENT MYELIN CONTENT: A HIGH RESOLUTION LM STUDY G.Holstege\*, D.H.Croon, and P.O.Gerrits. Dept. Anatomy, University of Groningen, The Netherlands.

Reports on the myelin content in the periaqueductal gray (PAG) are scarce and confusing. In the nineteenth century Schütz described a rostrocaudally orientated tract in the ventral part of the PAG (Bundle of Schütz or dorsal longitudinal fasciculus). In the nineteen thirties in transverse sections radiating fibers were described running to the periphery of the PAG and adjoining tegmentum.

Using a new glycol methacrylate-resin (GMA) embedding technique

for high resolution light microscopy, a cytoarchitectonic map of the normal rat PAG was made, which precisely defines myelin division patterns. Large semi-thin sections stained with Sudan Black B showed excellent morphologic detail with finest myelin sheaths preserved.

The results show that five main areas with myelinated fibers can be distinguished: I. centrally a thin subependymal layer, containing few, thin myelinated axons. This layer is surrounded by area II with ros-

trocaudally orientated fibers. The number and the thickness of these fibers increase towards the periphery of this zone; area III contains tangentially oriented fibers running to the periphery of the PAG and adjacent tegmentum; area IV is located in the dorsolateral part of the PAG with very few, mostly tangentially orientated fibers; area V is located ventrally and contains a mixture of rostrocaudally oriented fibers and fibers belonging to the visuomotor system.

THE ORGANIZATION OF PROJECTION FROM THE CINGULATE CORTEX TO THE THALAMIC RETICULAR NUCLEUS. A MULTIPLE TRACER - EM STUDY. D.A. Lozsadi\*, R.W. Guillery; Dept. Human Anatomy, University of Oxford, OX1 3QX, UK.

Although it has previously been reported that cingulate cortex (Cg) sends afferents to the thalamic reticular nucleus (TRN) (Cornwall, 1990. Exp.Br.Res. 80. 57), the apparent lack of input from the TRN to the anterior thalamic nuclei (Steriade, 1984. J.Comp.Neur. 229. 531) suggests that cingulate connections with thalamus differ from those of primary sensory cortical areas. As a first step in an analysis of the pathways linking Cg and thalamus single pressure injections of WGA-HRP, biocytin, neurobiotin or double injections of fluorescent dextrans were made into the rat Cg cortex. All tracers except WGA-HRP present a complete image of the anterogradely labelled structures. The cortico-thalamic fibres enter the thalamus rostrally and give off collaterals throughout the medio-lateral extent of the rostral sector of TRN. The secondary axons are either a few microns long or form more complex branches and terminate in a bouton-like swelling. Correlated electron microscopy demonstrates that these structures are synaptic terminals filled with reaction product, and contact dendritic shafts with asymmetrical synapses. Double tracing experiments show, that there is significant overlap in TRN, of terminals from distinct cortical areas.

Thus we conclude that there is a widespread projection from Cg to TRN, the terminals contact dendritic shafts showing the morphology of excitatory synapses.

DENERVATION OF FRONTAL CORTEX IN RATS BY RE LESIONS OF THE LATERAL INTERNAL MEDULLARY LAMINA (L-IML). Yueping Zhang & R.G. Mair\*. Dept. Psychol., Univ. New Hampshire, Durham, NH 03824.

In rats, RF lesions of the L-IML produce DNMTS deficits comparable to pyrithiamine-induced thiamine deficiency (PTD). Lesions of either the anterior or posterior portions of the L-IML have no such effect. Previously, we have shown that PTD treatment produces thalamic lesions centered on the IML and is associated with widespread Layer IV cortical denervation. To determine the possible cortical substrates of the L-IML induced deficit, we mapped Layer IV denervation in rats following PTD treatment (N=9) or RF lesions producing complete or partial L-IML destruction (N= 21). Whereas PTD denervated widespread areas of cortex, L-IML lesions denervated layer IV selectively in frontal cortical areas that are innervated by the mediodorsal nucleus of thalamus. Anterior and posterior lesions of the L-IML produced distinctive patterns of Layer IV denervation.

Univ., Shiga 520-01⁴, Japan aFGF, which is released from ependymal cells in the brain by glucose, has memory facilitating effects in rodents, when tested by two tasks, the passive avoidance and the Morris water maze task. We examined relations between aFGF, LTP in rat hippocampal slices, and transcription factor, zif 268

water maze task. We examined relations between aFGF, LTP in rat hippocampal slices, and transcription factor, zif 268 gene expression. Population spikes evoked by stimulation of the stratum radiatum were recorded from the CA1 pyramidal neuron layer. When continuous perfusion of the slices with aFGF of 0.5, 1.0 and/or 2.5 ng/ml concentrations was started 30 min before brief tetanic stimulation, dose-dependent enhancement of LTP occurred. The perfusion of aFGF immediately after or 10 min after tetanic stimulation did not enhance the LTP. No increase of zif 268 related protein was absented in the rat hippocampus with in alwayse 2th pefore enhance the LTP. No increase of zil 268 related protein was observed in the rat hippocampus with i.p. glucose 2hr before acquisition trial in the passive avoidance task. No increase of zif 268 mRNA was observed when examined 30 min after application of i.p. glucose. The present results suggest that aFGF can influence synaptic efficacy, and that zif 268 gene expression is not related to memory facilitation by aFGF.

NEURONAL ACTIVATION OF BDNF AND trkB mRNA EXPRESSION IN RAT HIPPOCAMPUS AND ASSOCIATION TO SPATIAL LEARNING. T. Falkenberg, P. Emfors. A. Mouhammed. H. Persson and N.

Lindefors\* Departments of Pharmacology, <sup>1</sup>Medical Chemistry, and <sup>2</sup>Geriatric

Lindefors\* Departments of Pharmacology, <sup>1</sup>Medical Chemistry, and <sup>2</sup>Geriatric Medicine, Karolinska Institutet, S-104 01 Stockholm, Sweden The involvement of the hippocampus in cognitive functions such as learning and memory is well established and members of the nerve growth factor family of neurotrophic factors, has been implied of importance in memory related neuronal survival and plasticity. Using in situ hybridization increased expression of brain-derived neurotrophic factor (BDNF) mRNA in the CA1 subfield in the rat hippocampus is shown to be associated with improved spatial memory in the Morris water maze. Furthermore, chemical stimulation of cholinergic and glutamatergic afferents, respectively, is shown to induce BDNF mRNA expression in several regions of the hippocampus. The trkB gene, a member of the trk gene family of tyrosine kinase transmembrane receptors known to mediate cell growth and differentiation, encodes a potential component of a cell surface receptor for BDNF. In order to further elucidate the hippocampal increase in BDNF mRNA expression, following cognitive challenge and afferent transsynaptic stimulation, trkB mRNA expression was subsequently investigated. An injection of quisqualate into the medial septal nucleus caused an and afferent transsynaptic stimulation, trkB mRNA expression was subsequently investigated. An injection of quisqualate into the medial septal nucleus caused an increase both in the dentate gyrus and in the CAI and CA3 regions, and was completely prevented by scopolamine or diazepam pretreatment. In contrast, activation of afferents in the entorhinal cortex resulted in a significant increase only in the dentate gyrus, prevented by diazepam but not scopolamine. Our results show a differential afferent influence on trkB mRNA expression and suggests a relative importance of a cholinergic component in regulating the expression which is not evident in regulation of BDNF mRNA expression where a glutamatergic component seem more manifest. This could mean that septal and cortical afferents to the hippocampus cooperatively regulate the amount of functional trkB-BDNF receptor complexes able to mediate neurotrophic actions. Experiments are currently in progress to determine if cognitive challenge influences hippocampal trkB mRNA expression.

## 220.3

C-FOS AND C-JUN PEPTIDES COEXPRESS IN THE RAT BRAIN IN A DIFFUSE, TIME AND NMDA-DEPENDENT MANNER FOLLOWING EXPOSURE TO NOVELTY. A.G. Sadile<sup>2\*</sup>, M.Papa, M.P. Pellicano<sup>2</sup> and H.Welzl<sup>3</sup>. Ist. Anatomia Umana Normale; <sup>2</sup>Dip. Fisiologia Umana "F.Bottazzi", Univ. Naples "Federico II", Naples, I; Inst. Behav. Biology, ETH, Zürich, CH.

The neural consequences on gene expression of exposure to a spatial novelty were mapped in the rat brain by antibodies against the immediate early gene (IEG) products c-fos and c-jun. Adult male Sprague-Dawley rats were tested for 10 min in a Lat-maze, and corner-crossings, rearings, and fecal boli were counted. Rats were sacrificed at different time intervals (0.5, 2, 6 or 24 h) thereafter. Unexposed handled rats or rats exposed for three days to the maze were used as controls. The latter showed a low and scattered basal positivity In the *exposed* rats, extensive *c-fos* and *c-jun* positive cells were the granular and pyramidal neurons of hippocampus, and later neurons in all layers of sensorimotor cortex and the granule cells of the cerebellar cortex. The positivity was stronger in rats exposed for the first time to the maze. The fos and jun-like immuno-reactivity was time-dependent, since it was present between 2 and 6 h after the first exposure, and it was NMDA-dependent, being prevented by reference in the exposure, and it was *NMDA-dependent*, being prevented by pretreatment with the competitive NMDA receptor antagonist CPP at a high (5mg/Kg) but not at a low dose (0.1mg/Kg). The results indicate that exposure to spatial novelty involves activation of the hippocampal formation, followed by that of the cerebral and cerebellar cortex. In conclusion, although its physiological resolution does not allow to dissect specific and non specific effects, IEG brain mapping reveals diffuse, distributed changes in gene expression associated with a non-associative task, supporting the neural network hypothesis of information processing at different organizational levels of the

## 220.4

AN INTRAPERITONEAL INJECTION OF ISOTONIC SALINE INDUCES NMDA-DEPENDENT DIFFUSE CHANGES IN *C-FOS* AND *C-JUN* PEPTIDES IN THE RAT BRAIN. M.Papa, M.P.Pellicano<sup>2</sup>, H.Welzi<sup>3+</sup> and A.G.Sadile<sup>2</sup>. Ist. Anatomia Umana Normale; <sup>2</sup>Dip. Fisiologia Umana "F.Bottazzi", Univ. Naples "Federico II", Naples, I; 3Inst. Behav. Biology, ETH, Zürich, CH.

The aim of this study was to map the neural consequences of an acute blockade of N-methyl-D-aspartate (NMDA) receptors on gene expression in the rat brain by antibodies against the immediate early gene (IEG) products c-fos and c-jun. Adult male Sprague-Dawley handled rats were given an i.p. injection of the competitive NMDA receptor antagonist CPP at a high (5mg/Kg) or at a low dose (0.1mg/Kg). The controls were given an equivalent volume of 0.9% saline solution or no injection. They were all sacrificed 2 h later. Non perfused brains were processed for immunocytochemistry by the double-antibody technique with where processed on immunocytochemisms by the condensation by the displayed with a witin-biotin and diaminobenzidine as revealing method. Rats receiving saline or 0.1mg/Kg of CPP showed a diffuse positivity for c-fos and c-jun in the reticular formation, thalamus, amygdala, the granular and pyramidal neurons of the hippocampus, in all layers of sensorimotor cortex and in the granule cells of the cerebellar cortex. Rats receiving 5.0mg/Kg of CPP showed few, sparse positive cells comparable to non injected controls. C-fos and c-jun appeared co-localized in the same neurons. Thus, the injection-related stress, associated with pain, short lasting restraint and contextual cues, induced IEG expression that was prevented by the isosteric blockade of NMDA receptors at a high but not at a low dose of antagonist. The existence of a pre-wired neural network is inferred, which involves different organizational levels of the CNS, is activated by different arousal eliciting mechanisms, e.g. by novelty or painful stimuli, like i.p. injection in this case, and it is likely to be necessary for information processing and storage. Nonetheless, the informational content intrinsic to this activated network is beyond the physiological resolution of brain mapping by IEG.

PARALLEL PROCESSING BY CAMP AND CALCIUM DURING HABITUATION IN PC12 CELLS. P. T. Martin and D. E. Department of Molecular and Cell Biology, Koshland, Jr.\* Department of Molecula University of California, Berkeley CA 94720.

Habituation of norepinephrine secretion in PC12 cells serves as a model for understanding the molecular mechanisms of simple memory processes in neurons. We have investigated habituation in response to repetitive stimulation with high potassium (high K+) and acetylcholine (Ach). For both stimuli, habituation occurred as a result of repetitive stimulation and was identified with decreased calcium levels as habituation progressed. Habituation to both high K+ and Ach was decreased by cAMP through a mechanism independent of calcium elevation. The extent to which habituation was decreased by cAMP depended on the timing of cAMP elevation, and was different for high K+ and Ach. cAMP levels did not change during repetitive stimulation with high K+ or Ach, but both high K+ and Ach reduced cAMP levels when they were elevated by N-ethylcarboxamidoadenosine. These results demonstrate that calcium and cAMP increase norepinephrine secretion through parallel mechanisms, and that calcium serves as a negative feedback on cAMP elevation, under some selected circumstances. This is the second example of parallel processing in the PC12 cell line (McFadden, P. N. and Koshland, D. E., Jr. (1990) Neuron 4, 615-621.), and suggests that parallel processing by second messengers may be a general strategy used by single neurons.

#### 220.7

PKC IN THE HIPPOCAMPUS IS ALTERED BY SPATIAL BUT NOT CUED DISCRIMINATIONS. S.Golski\*, J.L.Olds, M.Mishkin, D.S.Olton, D.L.Alkon. Dept. of Psychology, Johns Hopkins Univ., Baltimore, MD 21218.

Protein kinase C (PKC) may play a role in neuronal plasticity, including learning and memory. Changes in membraneassociated PKC were determined by quantitative autoradiography of tritiated phorbol ester ([3H]PDBu) in rats given four different behavioral tests. Cage (CA) rats remained in their cages. The three other groups swam in a water tank surrounded by explicit controlled stimuli. The swim-stimuli group (SS) did not have a discrimination to learn; each SS rat swam for periods of time yoked to a rat in the discrimination groups. The remaining rats learned a discrimination with either space (SD) or a cue (CD) as the relevant stimulus to locate the submerged platform. The SD group had lower PKC levels in the hippocampus than the other groups (p<.03, SD vs. CA,SS,CD). [3H]PDBu binding in nCi/g (and standard error) for the hippocampal region for each group was: CA=21.3(1.9); SS=21.4(2.2); SD=16.2(.6); CD=21.3 (1.6). The SD group also had lower PKC levels in the CA1, CA3, and dentate gyrus subfields of the hippocampus. These data suggest that hippocampal PKC is involved in spatial memory and support the conclusions from lesion data, which indicate the hippocampus is required for performance in the SD but not the CD.

## 220.9

CHOLINERGIC MODULATION OF THE INPUT/OUTPUT FUNCTION OF RAT PIRIFORM CORTEX PYRAMIDAL CELLS.

M.E. Hasselmo\* and E. Barkai, Dept. of Psych., Harvard Univ., Cambridge, MA 02138.
Cholinergic modulation of the excitability of cortical pyramidal cells may enhance the learning of afferent input (Hasselmo et al., J. Neurophysiol. 67:1230-1246). However, the effect of cholinergic modulation on the full f/I curve (spiking frequency / injected current) has not been described experimentally. This has led to inaccurate models of cholinergic modulation as shifting the slope of an input/output function which is stable over time. Here we show that a cholinergic agonist increases the slope of the ffl curve more for later intervals (during adaptation), while leaving the initial spiking response unchanged. In brain slice preparations of piriform cortex, we tested the ffl curve of pyramidal cells

(n = 32, mean Vm = -74.3 mV, mean spike height = 102 mV) using a 1 sec. intracellular current injection at a range of amplitudes. Adaptation increased the interspike interval and decreased the f/I slope at later stages of current injection. 14 of 32 neurons showed strong adaptation (no spikes after 250 msec. at  $2 \times 10^{-2}$  x threshold current). When possible, the slope of the  $10^{-2}$  curve at different intervals was computed with least-squared error. The mean slope was 138.5 ±25.8 Hz/nA (n=9) for the 1st spike interval, 34.2 ±4.4 Hz/nA (n=15) for the 3rd spike interval, and 13.6 ±1.5 Hz/nA (n=15) after 250 msec. of current injection.

Perfusion with the cholinergic agonist carbachol decreased adaptation, increasing the slope of the 3rd spike interval from 30.6 ±4.4 Hz/hA to 39.0 ±10.7 Hz/hA, and the slope after 250 msec. from  $9.97 \pm 2.4$  Hz/nA to  $18.24 \pm 5.9$  Hz/nA (n = 6). The mean number of spikes at 1.5 x threshold current went from 6.9  $\pm$ 1 to 10.9  $\pm$ 2 (n=8). Biophysical simulations allow this modulation to be linked to effects on potassium currents described in voltage clamp preparations. Carbachol (100µM) also suppressed the IPSPs elicited by afferent fiber stimulation, thereby increasing the spiking response to previously subthreshold afferent fiber stimulation. In models of cortical associative memory function, adaptation allows a strong initial response to afferent input during recall, with weakening response during feedback excitation. During learning, cholinergic modulation of adaptation could allow afferent input to drive neuronal responses in a strong and sustained manner.

LATERALIZATION OF MEMBRANE-ASSOCIATED PKC DISTRIBUTION IN RAT OLFACTORY CORTEX SPECIFIC TO OLFACTORY LEARNING BUT NOT AUDITORY LEARNING. LL Olds. \*.U. Bhalla., D.L. McPhie, J. Bower, D.L. Alkon. Computational Neuroscience Institute of Technology, Pasadena CA. 91125, Neural Systems Section, NINDS, NIH, Bethesda MD

The critical role of protein kinase C in the sequence of molecular events subserving associative memory formation has been delineated by several independent laboratories including our own in recent years. Most of these studies have concentrated on changes in the activity or distribution of the enzyme within the mammalian hippocampus. Here we present evidence for learning-specific changes in the distribution of the enzyme within the rat olfactory cortex.

Briefly, operant conditioning was used to train thirsty rats to push paddles for a water reward. For the experimental group (GROUP OLF), training involved two odors (A and B) and an auditory stimulus (C). C was randomly presented independent of whether A or B was presented in a trial. Responding to A and B by pressing the appropriate paddle was rewarded. Control animals (GROUP AUD) received the same three stimuli. In this case A and B were presented to the animal during each trial however their presentation did not have any contingent relationship to reward. For the control animals, reward was given for pressing the appropriate paddle for either C or no C during the trial. Saggital brain sections were analyzed in a manner such that the analyst did not know the experimental groups using quantitative computerized autoradiography for 3H-phorbol12,13-dibutyrate as previously described (Olds et al. SCIENCE 1989). GROUP OLF animals showed a statistically significant increase in the left to right ratio of specific binding within the olfactory cortex when compared to GROUP AUD controls (1.257±.118, vs. 0.965±.084; N=5,6, p<0.04 Two Tailed Student T test). In contrast, the hippocampus did not show significant changes in the lateralization of PKC, though the specific binding for both groups was higher than naive controls.

While lateralization of cortical function has been previously reported for both cortical and subcortical structures within the rat brain, this is the first instance to our knowledge of such a lateralization in olfactory cortex. In addition, this study supports the evolving hypothesis that PKC is at a nexus of molecular events in associative learning

### 220.8

ASSOCIATIVE LEARNING POTENTIATES PROTEIN KINASE C SYNAPTOSOMES ACTIVATION IN RABBIT OF HIPPOCAMPUS. K.Sunayashiki-Kusuzaki', D.S.Lester, B.G.Schreurs and <u>D.L.Alkon.</u> Neural Systems Section, NINDS, National Institutes of Health, Bethesda, MD, 20892.

We have previously documented findings correlating changes in protein kinase C (PKC) localization in the hippocampus and classical conditioning of the rabbit nicitating membrane response (NMR). We have further investigated the nature of these PKC changes and report here that the activation of PKC was significantly potentiated in purified synaptosomes (SPMs) obtained from microdissected regions (CA1, CA2-3) of the rabbit hippocampus that had undergone classical conditioning. The nonstimulated levels of membrane and cytosol PKC levels in SPMs were similar in naive or unpaired control and conditioned animals. Stimulation of SPMs by the combined action of depolarization (40 mM KCI) and phorbol ester (100 nM, phorbol myristate acetate) potentiated the level of membrane-associated (activated) PKC 2- to 3-fold in SPMs of conditioned animals only (p < 0.01; Dunnett's test). This response was not found in isolated postsynaptic density fractions prepared from the SPMs, suggesting that this change in the PKC activation properties was specific to the presynaptic plasma membrane. Additionally, there was no difference in the total PKC activities of the SPMs from the different behavioral conditions supporting the notion that the change is in the PKC activation mechanism. It is proposed that there are long term changes in the synaptic membrane in the CA1 and CA2-3 regions of one of the intrinsic lipid PKC activators; diacylglycerol or arachidonic acid. The difference in this biochemical entity may play an important role in memory recall by maintaining a different membrane state that will facilitate subsequent conditioned stimulus-induced PKC activation.

## 220.10

TIME DEPENDENT MODULATION OF HIPPOCAMPAL SYNAPTIC STRENGTH BY SEPTAL CHOLINERGIC INPUT. T.C.Foster\* & T.C.Dumas Dept. of Psychology, U.

The septohippocampal fibers (SH) provide the major cholinergic input to the hippocampus. Previous research indicates that exogenous acetylcholine (ACh) decreases the amplitude excitatory postsynaptic potentials (EPSPs) in the hippocampus. The present study demonstrates that activation of SH can also influence synaptic strength. Anesthetized influence synaptic strength. Anesthetized (Nembutal) rats were implanted with stimulating electrodes in the medial septum and CA3 hippocampal commissures. A recording electrode was positioned to transverse the CA1 region. SH activation (20 ms, 400 Hz) resulted in a short latency (50 ms) increase and longer latency (peak 200 ms) decrease in EPSP slope and an increase in the population spike area. Slope fluctuations were associated with an immediate decrease and late increase in the Immediate decrease and late increase in the paired-pulse (ISI 50 ms) facilitation ratio. SH modulation of synaptic strength was reduced by scopolamine (1mg/kg IP). Population spike facilitation was not altered by scopolamine. Results indicate that septal cholinergic input can alter hippocampal synapses. FRS 441335

LEARNING-INDUCED CHANGES IN DENTATE NEURONAL ACTIVITY AND IN GLUTAMATE RELEASE ARE BLOCKED BY THE NMDA RECEPTOR ANTAGONIST AP5. C. Rédini-Del Négro and S. Laroche\*.

Laboratoire de Neurobiologie de l'Apprentissage et de la Mémoire, C.N.R.S., URA-1491, 91198 Gif-sur-Yvette, France.

Learning a tone (CS)-shock (US) association in rats is accompanied by rapid and persistent changes in dentate cell activity in response to the behaviorally significant CS (Behav. Brain Res. 1983, 9:381-387), and is followed by a long-lasting increase in glutamate release in the dentate gyrus (Eur. J. Neurosci. 1990, 2:534-543). Here we report that both cellular and synaptic changes associated with learning require the integrity of the NMDA receptor. Rats were implanted with a cannula and recording electrodes in the dentate gyrus and with a stimulating electrode in the perforant path. The cannula was connected to an osmotic mini-pump delivering AP5 (4mM) or saline (.5µl/hr) for 8 days, during which animals were submitted to 4 daily sessions of 8 paired or unpaired tone-shock trials. In experiment 1, neuronal activity to the of 8 paired or unpaired tone-shock trials. In experiment 1, neuronal activity to the CS was recorded in 25 rats. AP5 perfusion, which was shown to block tetanus-induced LTP, reduced significantly the early component of the cellular response, and completely abolished the sustained CS-evoked cell discharge that was normally seen in conditioned controls or in rats receiving saline infusion. Neither spontaneous activity, nor the reactivity of these cells to a loud and novel tone were affected by AP5. In experiment 2, we examined whether the NMDA receptor is involved in the induction of learning-associated changes in glutamate release, as has been shown in LTP. Slices of the dentate gyrus were prepared from 25 rats submitted to 4 conditioning or pseudoconditioning sessions to examine K+-stimulated release of radiolabeled glutamate in the presence of absence of Ca2+. The increase in K+-stimulated, Ca2+-dependent release of glutamate observed in conditioned rats was not affected by saline, but was suppressed by the infusion of AP5 during conditioning. These results support the hypothesis that an NMDA-dependent conditioning. These results support the hypothesis that an NMDA-dependent synaptic plasticity similar to LTP occurs during learning and is necessary for the full development of the hippocampal component of the CS-US associative representation. Supported by grants from HFSP and the EEC (SC1-CT910685).

### 220.13

CIRCULATING CATECHOLAMINES AND MEMORY RETRIEVAL; PHYSIOLOGICAL SIGNIFICANCE AND ADRENERGIC RECEPTOR STATE-DEPENDENCY. B. Bohus, S.M. Korte, B. Roozendaal and J. Borrell. Dept. of Animal Physiology, Univ. of Groningen, Haren, The Netherlands and Cajal Institute of Neurobiology, CSIC, Madrid, Spain (SPON: European Brain and Behaviour Society).

Abundant evidence suggests that epinephrine of adrenal origin assures an optimal condition to consolidation of memory in the rat. The physiological significance of this hormonal action is supported by behavioral findings in adrenalectomized (ADX) or adrenomedullectomized (ADXM) rats with or without epinephrine (E) or norepinephrine (NE) replacement therapy. The present experiments have been designed to investigate the role of circulating E and NE in retrieval of memory. Therefore, plasma levels of E and NE were determined during learning and retrieval of various conditioned responses. In addition, the effects of ADX and ADXM and the effects of E and NE administration on the memory retrieval were studied in a one-trial learning inhibitory avoidance paradigm. The results show (a) the conditioned catecholamine response in various situations appears to be an increment of both E and NE levels; (b) the proactive impairment of memory retrieval by ADX or ADXM is normalized by the administration of E but not of NE before the retrieval; (c) postlearning administration of subthreshold E potentiates the effect of preretrieval E in AD rats; (d) postlearning NE induces NE to affect behaviour during retrieval, but (e) postlearning E fails to prime for retrieval NE actions and postlearning NE does not sensitize for retrieval E. The conclusion of the latter experiment is that the effect on the same population of adrenergic receptors during both consolidation and retrieval of memory is an essential requisite for affecting the expression of conditioned behaviour.

ESTRADIOL ACTS AS AN INTER-AGENT TO ACCELERATE EXTINCTION OF CONDITIONED TASTE AVERSIONS. <u>Y.Wang. D.L.Yuan and K.C. Chambers</u> Department of Psychology, USC, Los Angeles, CA.
Exposure to a substance that has US properties before

acquisition or extinction of a conditioned taste aversion (CTA) can attenuate acquisition and accelerate extinction. This effect is called inter-agent disruption. We have suggested that estradiol (E) accelerates extinction by acting as an inter-agent. If this is the case, then the dose of E that accelerates extinction should induce a CTA when used as a US and exposure to E before extinction should accelerate extinction. In study 1, gonadectomized (CK) females were implanted with 10 mm empty or E-filled silastic capsules after consumption of a 10% sucrose solution. The capsules were removed 18 hours later. Two days after the first sucrose exposure, they again were given access to the sucrose solution. The sucrose consumption of the E-treated females decreased whereas that of the untreated females did not change. a CTA was induced in GX females with 0.15 M LiCl (10 ml/kg) after access to a 10% sucrose solution. Two days after acquisition, the females were implanted with 10 mm empty or E-filled capsules. The capsules were removed 8 days later. Daily extinction trials were initiated the next day. The extinction rates of the females given E before extinction were significantly faster than those of the females given no hormone. These data are consistent with the hypothesis that E acts as an inter-agent. BRSG

THE DOPAMINE D1 AGONIST SKF 82958 REINFORCES OPERANT CONDITIONING OF HIPPOCAMPAL CA1 CELLULAR BURSTING. B. G. XUE AND L. STEIN\*. Department of Pharmacology, UCI School of Medicine,

CA 92717. In our cellular analog of operant conditioning, hippocampal CA1 bursting activity is reinforced by local micropressure applications of dopamine, cocaine or the dopamine D2 agonist N0437, but not by the partial D1 agonist SKF38393. Furthermore, dopamine's reinforcing action is blocked by co-administration of sulpiride (D2 antagonist) but not by SCH23390 (D1 antagonist), accordingly, it was concluded that dopaminergic reinforcement of CA1 bursting is exerted mainly at D2 receptors (Stein, L and Belluzzi, J D. Neurosci & Biobehav Rev,13:69-89,1989). Here we report excellent CA1 operant conditioning when the full dopamine D1 agonist SKF 82958 was used as reinforcement. A single-barrelled glass micropipette for simultaneous recording and pressure injection was filled with SKF 82958 (5, 10 and 20 µM in 185mM saline) and aimed at spontaneously active pyramidal cells in the used as reinforcement. A single-barreined glass micropipetie for simulaneous recording and pressure injection was filled with SKF 82958 (5, 10 and 20 μM in 165mM saline) and aimed at spontaneously active pyramidal cells in the CA1 layer of hippocampal slices. During reinforcement periods, the pressure injector was activated for 10 ms at 15 p.s. immediately after each burst to deliver an approximately 10 μ-diameter droplet of drug to the vicinity of the cell body. The frequency of bursts was rapidly increased by the 5 and 10 μM doses of SKF 82958, but not by the 20-μM dose. When administered independently of bursting, the effective doses of SKF 82958 did not increase and often suppresed the bursting rates, thus providing a control for nonspecific pharmacological stimulation or facilitation. In other experiments, co-administration of SCH 23390(+) (10μM) eliminated or largely suppressed the reinforcing action of SKF 82958 (10 μM). These in vitro results indicate that activation of dopamine D1 receptors can reinforce hippocampal CA1 bursting activity, and are consistent with recent behavioral data demonstrating that intravenous SKF82958 is avidly self-administered by the rat (Self and Stein, Brain Res. in press).

CENTRAL AMYGDALOID NOREPINEPHRINE INFUSION ENHANCES LATER RETENTION IN ROMAN HIGH-AVOIDANCE AND LOW-AVOIDANCE RATS. B.Roozendaal, J.M.Koolhaas and B.Bohus\* (SPON: European Brain and Behaviour Society), Univ. of Groningen, Dept. of Animal Physiol., P.O.Box 14, 9750 AA Haren, The Netherlands.

Memory-enhancement of posttraining norepinephrine given into the CEA was investigated on active and passive behavioral components in a shockwas intestigated to active and passing. Genetically selected Roman high-avoidance (RHA/Verh) and low-avoidance (RLA/Verh) rats, displaying active or passive coping strategies in response to emotional stressors, were active or passive coping strategies in response to emotional stressors, were used. Upon the presentation of the electrified probe during acquisition, both lines spent comparable time in burying behavior. The RLA/verh rats, but not the RHA/verh rats, also displayed substantial immobility. During the retention test, the CSF-treated RLA/verh rats predominantly displayed immobile behavior during the presentation of the nonelectrified probe, whereas the RHA/Verh rats showed neither burying nor immobility. In the RLA/Verh rats norepinephrine (NE) infusion in the high dose (200 ng), and not in the low dose (20 ng), enhanced immobility without affecting the active response. On the other hand, NE given into the CEA of RHA/Verh rats caused a dose-dependent appearance of the conditioned active behavioral component without affecting immobility. The present results suggest a phenotype-dependent effect of intra-amygdaloid NE on memory processes. Differential release of NE in the CEA in the two strains may determine the expression of retention behavior.

## 220.16

REVERSAL OF AGE-RELATED COGNITION DEFICITS IN AUTOIMMUNE MICE BY 647U, A POTENTIAL NEW NOOTROPIC. H. Lal, P.L. Prather, R.R. Luedtke\*, and M. J. Forster. Department of Pharmacology, Texas College of Osteopathic Medicine, Fort Worth, TX 76107

Autoimmune NZB/BINJ mice exhibit accelerated age-related declines in performance of habituation retention and active and passive avoidance paradigms [Drug Dev. Res, 24:1, 1991]. We evaluated the potential for 647U, a novel drug with antidepressant and cognition-enhancing activity, to improve these spontaneously occurring, age-related deficits. One-way active avoidance training consisted of daily sessions until a performance criterion had been attained. Pre-session administration of 647U at all doses tested (10, 20 and 40 mg/kg) significantly improved both acquisition and retention of the avoidance response. Habituation training consisted of 9 daily 20-min locomotor activity tests where 647U was given immediately after training on days 1 through 4. A dose of 10 but not 20 or 40 mg/kg of 647U produced significant session-related decreases in time spent in the center zone, whereas vehicle treated animals showed no habituation. In contrast, all doses of 647U administered prior to single step-through passive avoidance trial were ineffective in increasing the mean latency to enter the dark chamber at a 24-h retest. The current findings indicate that 647U is efficacious in reversing some of the autoimmune-related learning and memory deficits exhibited spontaneously by NZB/BINJ mice.

DECREASE IN ASSOCIATIVE LEARNING IN OLDER SPONTANEOUS HYPERTENSIVE RATS. E. Hong\* and A. Meneses. Dept. of Pharmacology and Toxicology, CINVESTAV-IPN, Mexico city. Spontaneous hypertensive rats SHR and their respective controls, the Wistar Kyoto (WKY) rats are frequently used for the study of arterial hypertension. It has been reported that SHR score poorly in learning tasks, therefore, it seems of interest to make a systematic study correlating hypertension and age with learning in SHR and WKY rats of different ages, ranging from 3 to 24 months-old. For this purpose, food-deprived rats, to 85% of their weight were trained on autoshaping during six days. Animals were retrained one month later. Animals were individually trained to find 15 pellet in the food magazine, once that the animal ate the food, a session began. The learning task consisted in illumination of a retractable lever for 8 sec (conditioned stimulus) followed by delivery of a food pellet (unconditioned stimulus) each 60 sec. If the animal pressed the lever (conditioned respones) the trial was shortened and the lever was retracted, the light was turned off and the unconditioned stimulus was delivered. The younger animals learned faster and achieved a greater score than older ones. SHR took a longer time to learn and showed lower scores than WKY rats. The present results suggest that both factors, ageing and hypertension decrease the associative learning.

### LEARNING AND MEMORY: PHARMACOLOGY-OPIOIDS

#### 221.1

EXPLICIT AND IMPLICIT MEMORY DISSOCIATED BY ANESTHETIC TECHNIQUE. R. C. Cork, J. F. Kihlstrom and S. R. Hameroff\*. Univ. of Arizona Health Sciences Center, Anesthesiology, Tucson, AZ 85724.

Explicit memory entails conscious recollection of some event; implicit memory refers to a change in a subject's behavior attributable to such an event, without conscious recollection of the event. These two types of memory are dissociable with amnesic syndrome and posthypnotic amnesia. This study tested for implicit and explicit memory in surgical patients with two commonly used, qualitatively different, anesthetic techniques.

Human Subjects Committee approval and informed consent were obtained. After barbiturate induction of anesthesia, patients were maintained during surgery with either isoflurane (a volatile fluorocarbon) or sufentanil (a synthetic opiate) with N<sub>2</sub>O while one of two lists of commonly associated word pairs was continuously played to the patient via headphones. Patients were tested for free recall, cued recall, recognition, and free association (the one test for implicit memory) after surgery in the recovery room and again two weeks later. Repeated-measures ANOVA was used, p<0.05.

Testing was completed for 25 of 30 patients in the Isoflurane Group and 25 of 36 patients in the Sufentanil/N<sub>2</sub>O Group. Patients receiving isoflurane were more likely to produce target items from the critical list, presented during surgery, than they were from the control list, a significant priming effect (p<0.05). Sufentanil/N<sub>2</sub>O resulted in no observable priming effect.

Results showed that isoflurane spares implicit memory, while sufentanil/N<sub>2</sub>O does not. Opiates inhibit release of neurotransmitters much better than do volatile anesthetics at clinical levels. Could implicit memory be pre-synaptic and explicit memory post-synaptic? Nitric oxide (NO) has been implicated as a retrograde signal in learning (post-synaptic → pre-synaptic). Could N<sub>2</sub>O block pre-synaptic NO actions?

## 221.3

THE SEPTAL, BUT NOT THE AMYGDALOID, OPIATE SYSTEM IS INVOLVED IN SPATIAL WORKING MEMORY IN AN APPETITIVELY MOTIVATED TASK. R.Q.Wan', L. Gorman, K. Pang, and D.Olton, Dept. of Psychology, The Johns Hopkins University, Baltimore, MD. 21218.

The oplate system in both the septum and amygdala can influence memory. Previous studies have typically examined the role of these oplate systems in mnemonic function by using different tasks. Thus, dissociations of the effects of these oplate systems on memory processes are difficult to interpret because many variables differ among behavioral tasks. The present experiment examined the hypothesis that the septal and amygdaloid oplate systems may be involved in different mnemonic processes by keeping all aspects of the experimental procedure the same except for the neuroanatomical location of the oplate manipulation, the medial septal area (MSA) or the central amygdaloid nuclei (CAN). The role of both oplate systems in spatial working memory was tested by using an appetitively reinforced T-maze alternation task. A within-subjects experimental design was used. β-endorphin (β-END, 250 and 1000 ng) or muscimol (MUS, 20 ng) was infused into MSA, and β-END (1000 ng) or MUS (20 ng) was infused into CAN immediately prior to testing, infusions of β-END and MUS into the MSA, but not into the CAN, impaired choice accuracy. Infusion of either compound did not impair general activity as indicated by the amount of time to complete one session. These results suggest that the oplate system mediates different mnemonic processes in different neuroanatomical areas.

### 221.2

DYNORPHIN<sub>(1-13)</sub> IMPAIRS MEMORY FORMATION FOR BOTH AVERSIVELY AND APPETITIVELY MOTIVATED LEARNING IN CHICKS. <u>P.J. Colombo\*, K.R. Thompson, J.L. Martinez Jr., E.L. Bennett, M.R. Rosenzweig.</u> Dept. of Psychology, Univ. of California, Berkeley, CA 94720.

Administration of the endogenous opioid peptide dynorphin<sub>(1-13)</sub> impairs acquisition of memory for aversive training in the two-day-old Golden sex-linked cockerel (Colombo et al., 1990). We examined whether this effect on memory formation is general to both aversively and appetitively motivated learning. Two- or four-day-old White Leghorn cockerels were injected bilaterally with dynorphin<sub>(1-13)</sub> into the intermediate medial hyperstriatum ventrale - a region important for memory formation in the chick - and trained on either a one-trial peck-avoidance (PA) task, or an appetitive visual discrimination (AVD) task; retention was tested at 24 h. In two-day-old chicks, dynorphin was amnestic for PA training at 0.01 mM. In four-day-old chicks, administration of 0.03 mM and 0.1 mM dynorphin<sub>(1-13)</sub> impaired memory formation for AVD and PA training, respectively. Thus, the effects of dynorphin on memory formation in the chick are similar for both aversive and appetitive conditioning.

Supported by NRSA DA05492 to PJC, NIDA DA04795 to MRR and JLM, and DA04195 to JLM.

## 221.4

INTERACTION BETWEEN  $\beta$ -ENDORPHIN AND THE NORADRENERGIC SYSTEM IN THE MODULATION OF MEMORY STORAGE JL.McGaugh\*. I.B.Introini-Collison and L.A.Ford, Center for Neurobio. of Learning & Memory and Dept. of Psychobio., U. of Calif., Irvine. CA 92717.

Intra-amygdala injections of  $\beta$ -noradrenergic ( $\beta$ -NE) receptor agonists facilitate memory storage in a dose-dependent manner. Opioid receptor antagonists facilitate memory, while opiates and opioid peptides impair memory. Propranolol, a  $\beta$ -NE receptor antagonist, blocks the memory enhancing effects of naloxone, suggesting that such effects are mediated by an increased release of norepinephrine (NE). These experiments examined further the interaction between the noradrenergic and the opioid peptidergic systems in the amygdala in modulating memory storage. Male Sprague-Dawley rats (180g, 50-days old on arrival) were trained in inhibitory avoidance (IA) and Morris water maze (MWM) tasks. Injections were given immediately post-training for IA and 5 minutes pre-training for MWM. In the first experiment, rats were given clenbuterol (10.0 or 30.0 ng) concurrently with  $\beta$ -endorphin (0.1 ng) through cannulae previously implanted bilaterally in the amygdala. In both the IA and the MWM, clenbuterol prevented the memory impairing effects of  $\beta$ -endorphin. In the second experiment, rats were given concurrent subeffective doses of propranolol (0.3 μg) and  $\beta$ -endorphin (0.03 ng) intra-amygdally. Neither propranolol nor  $\beta$ -endorphin affected memory when given alone. However, when given together, these doses of propranolol and  $\beta$ -endorphin significantly impaired memory. Considered together the findings of these experiments are consistent with the view that opioid peptides impair memory by decreasing the release of NE in the amygdala.

INTRA-AMYGDALA INJECTIONS OF MORPHINE IMPAIR AVOIDANCE LEARNING: ATTENUATION WITH CONCURRENT AMYGDALA INJECTIONS OF GLUCOSE. M.E. Ragozzino\* and P.E. Gold. University of Virginia, Charlottesville, VA 22903. Dept. Psychology.

Recent findings from several laboratories demonstrate that modest increases in circulating glucose levels modulate memory processes in rodents and humans. One brain area sensitive to direct glucose administration is the medial septum. For example, intraseptal glucose injections attenuate memory impairments after intraseptal morphine injections, contributing to the view that glucose may act functionally to antagonize opioid actions. The present experiment examined whether, as seen with medial septum, memory processing was susceptible to morphine and glucose injections into the amygdala. Rats were tested for inhibitory avoidance and spontaneous alternation performance. Bilateral morphine (4.0 nmol) injections into the amygdala prior to training impaired later retention of inhibitory avoidance training. Concomitant administration of Intra-amygdala glucose (16.6 nmol) attenuated the morphine-induced inhibitory avoidance deficit. Intra-amygdala injections of morphine did not significantly affect spontaneous alternation performance. Thus, both the amygdala and medial septum are sensitive to direct injections of glucose. In both brain regions, glucose attenuates memory deficits after morphine administration. The nature of the deficits, however, varied by task. Injections of morphine into medial septum substantially impaired both spontaneous alternation and inhibitory avoidance performance. Morphine injections into the amygdala impaired inhibitory avoidance learning but had no effect on spontaneous alternation performance. #### 221.6

RELATIVE SALIENCE OF ENVIRONMENTAL AND DRUG CUES AS CONDITIONED STIMULI.

N. M. Bormann and D. A. Overton\*. Department of Psychology, Temple University, Philadelphia, PA 19122.

An exp. was conducted to compare the relative salience of

environmental (metal box) cues and morphine (6 mg/kg, i.p.) induced cues as conditioned stimuli (CS) when each was paired with a footshock unconditioned stimulus (US), to produce a conditioned suppression of drinking (CR) in water deprived rats. Before training, baseline measures of water consumption were taken 10 min after oaseine measures of water consumption were taken 10 min after morphine and saline injections. Then 6 groups (6 rats each) were exposed to the following conditioning procedures: Groups 1 & 2 were placed into a metal box 90 min before saline-> US and morphine-> US pairings, respectively; Groups 3 & 4 were respectively placed into the box 5 min after saline and morphine injections and received shock 5 min later. Groups 5 & 6 were placed into the box 10 boxes. into the box 5 min after saline and morphine injections and received shock 5 min later; Groups 5 & 6 were placed into the box 19 hours before morphine > US and saline > US pairings. For 20 days after conditioning, Ss received drinking test sessions after saline injections in a novel plastic box in order to extinguish any fear in response to the technican and/or injection procedure. Then during subsequent tests Ss were exposed to morphine in the plastic box, to the metal box alone, and to morphine in the metal box before drinking tests. box alone, and to morphine in the metal box before drinking tests. When exposed to morphine in the plastic box, only Group 5 suppressed drinking. When exposed to the metal box alone, Groups 3 and 4 suppressed significantly more than all other groups. When exposed to morphine in the metal box, Groups 1-4 exhibited a profound suppression of drinking. This exp. demonstrates that morphine cues can act as a CS for fear, but that environmental cues presented up to 90 min before US presentation are more salient as CS than morphine drug cues. Supported by NIDA grant DA02405.

## LEARNING AND MEMORY: PHARMACOLOGY-MONOAMINES

#### 222.1

ONDANSETRON IMPROVES SHORT-TERM MEMORY AND BLOCKS CHOLINOMIMETIC-INDUCED EMESIS IN RHESUS MONKEYS. H.J. Normile,\*1 H.J. Altman, 1 M.J. Callahan, 2 R.E. Davis2. 1Wayne State University School of Medicine, Detroit, MI 48207 and <sup>2</sup>Parke-Davis Pharmaceutical Research, Warner-Lambert Co., Ann Arbor, MI 48106

The serotonin antagonist Zacopride reverses cholinomimetic-induced emesis in the ferret. We have extended these findings demonstrating that another 5-HT<sub>3</sub> antagonist Ondansetron blocks cholinomimeticinduced emesis in young rhesus monkeys. In addition, Ondansetron improves cognitive performance of aged but not young monkeys at doses similar to those blocking emesis in this species. Pretreatment of young rhesus monkeys with Ondansetron dose dependently decreased the severity of emesis associated with administration of the partial muscarinic agonist CI-979. At one of these doses Ondansetron reliably improved delayed matching-to-sample performance of aged but not young rhesus monkeys. Ondansetron, however, did not enhance attention/vigilance or reverse scopolamine-induced impairments in attention. These results are consistent with previous reports demonstrating cognitive enhancement following administration of 5-HT<sub>3</sub> receptor antagonists and confirm the ability of this class of agents to block cholinomimetic-induced emesis in a second species. Thus, Ondansetron may be useful in ameliorating the GI disturbances commonly associated with cholinomimetic therapy in man. At the same time, combined use of cholinomimetics and 5-HT3 antagonists may exert synergistic effects on cognitive performance. The combined use of these agents should be considered in treating age-related memory disorders including Alzheimer's disease.

## 222.3

T-MAZE ALTERNATION DEFICITS IN METHAMPHETAMINE-TREATED RATS. Cooper, B.G., A.E. Butt, & G.K. Hodge. \* Department of Psychology, University of New Mexico, Albuquerque, NM 87131-1161.

High doses of methamphetamine (MA), which are neurotoxic to dopamine.

rgic and serotonergic neurons, cause lasting changes in behavior. We examined performance in a T-maze alternation task in MA-treated rats previously tested in an operant conditioning paradigm. Operant conditioning results suggested that these animals were unable to modify learned behaviors when task parameters changed (Cooper, Butt, Hardy, & Hodge, Soc. Neuroscience Abstr., 1991). Since alternation tasks require modification of previously reinforced behaviors and MA treatment disrupts performance when response requirements change, it was expected that MA-treated animals would show impaired learning.

Animals received four subcutaneous injections, two hours apart, of either saline (n=7) or MA (10 mg/kg, n=9; 12 mg/kg, n=8). Eight months post-injection, animals were trained in a T-maze alternation task. Each of eight daily trial consisted of a forced run and a choice run. In the forced run, animals were allowed access to one arm, while access to the other arm was blocked. Animals were reinforced upon entering the unblocked arm where they were held for 20 seconds. Then, in the choice run, animals were allowed to choose between the two arms but were rewarded only for entering the previously blocked arm.

Animals were trained to an a priori criterion of seven correct choices per block, for three consecutive blocks, with a perfect score in the third block. Mean number of days required to reach criterion were recorded for each group.

MA-treated animals in the 12 mg/kg group took significantly longer to reach criterion compared to controls (p<.05). Results suggest that MA-treated animals have difficulty adjusting their behavior when reinforcement contingencies change. ### 222.2

SEROTONIN DEPLETION IMPAIRS THE PERFORMANCE OF RATS IN SPATIAL WORKING MEMORY TASK. J.Sirviö\*, P.Jäkälä, P. Riekkinen Jr. and P.J. Riekkinen. Dept. of Neurology, Univ. of Kuopio, Kuopio,

The present study investigated the role of the serotonergic system in working memory. The effects of serotonin depletion in brain induced by p-chlorophenylalanine (PCPA, 3x500 mg/kg, ip) on the performance of rats in a continuous operant delayed non-matching to position (DNMTP) task were studied. PCPA treatment impaired behavtask were studied. PCPA treatment impaired behavioural activity (lengthened response latencies, decreased number of trials completed) of rats which had been trained for DNMTP task before the treatment. The percent correct responses were not significantly decreased at any delays (0-16 seconds) tested. Neurochemical analysis showed that frontal and hippocampal serotonin was markedly decreased (>97%) in PCPA treated rats as compared to controls. The present results support compared to controls. The present results support the hypothesis that brain (cortical and hippo-campal) serotonin is involved in the general organization of behavior, but they do not suggest any important role for serotonin in spatial working memory.

DOPAMINERGIC MODULATION OF LATENT INHIBITION IN PREWEANLING RAT PUPS. <u>C.A. Moody\* and L.P. Spear</u>, Dept. Psychology and Center for Developmental Psychobiology, SUNY, Binghamton, NY 13902-6000

The role that dopaminergic neurotransmission plays in the regulation of latent inhibition (LI) was examined in postnatal day 18-19 Sprague-Dawley rat pups. Animals received a single subcutaneous (s.c.) injection of 0, 0.05, 0.1 mg/kg haloperidol or 0, 0.25, 0.5 mg/kg d-amphetamine, 45 or 15 min respectively, prior to the preexposure period which consisted of 0 (0P), 3 (3P), or 9 (9P) min of exposure to banana odor. Twenty min following preexposure or an equivalent amount of time in a holding cage for animals not receiving preexposure, pups received 30 sec of exposure to banana odor during which three 3 sec 1.5 mA footshocks were delivered. Unpaired (UP) animals received footshocks 20 min prior to banana odor exposure. Five min after conditioning (or odor exposure for the UP group), animals were given a 1 min odor preference test between banana and a novel odor (lemon). Time spent on the banana side of the test apparatus was recorded. Non-preexposed animals (0P group) spent significantly less time on banana side relative to their UP counterparts. LI was observed following 9, but not 3, min of preexposure. Similar to observations in adult animals, the high dose of amphetamine disrupted the LI observed in the 9P group. Conversely, haloperidol, typically shown to enhance LI in adult animals, disrupted LI in the 9P pups at the high dose of haloperidol. Studies are currently underway to determine whether this haloperidol-induced disruption in LI is a dopamine autoreceptor-mediated effect. [Supported by NIDA Grants R01 DA04478, and K02 DA00140].

D1 AND D2 ANTAGONISTS PRODUCE DIFFERENTIAL EFFECTS ON AMPHETAMINE-PRODUCED ENHANCEMENT OF RESPONDING FOR CONDITIONED REWARD IN RATS. R. Ranaldi\* and R.J. Beninger. Dept Psych, Queen's Univ, Kingston, Canada, K7L 3N6.

Dopamine (DA) D1 receptors may play a role in reward. The effects of D1 and D2 antagonists on amphetamine (AMPH)-produced enhancement of responding for conditioned reward (CR) were evaluated. Rats were exposed to two levers, one producing a 3-s lights-off (LO) stimulus and the other a tone (T), for 5 40-min sessions (S). The levers were then removed and, during 4 Ss, rats were exposed to 80 presentations of LO (on a random time 45-sec schedule) paired with food. Testing consisted of two Ss with the levers again present. Results showed that the saline group increased responding for LO more than for T from pre- to postpairing, confirming that LO became a CR. AMPH (0.1 to 5.0 mg/kg, ip, 5 min before test Ss) dose-dependently enhanced responding specifically for the CR. SCH 23390, a D1 antagonist (5.0 and 10.0 ug/kg, sc, 2 h before test Ss), shifted the locus of rise in the AMPH ose-response function toward higher AMPH doses. Metoclopramide, a D2 antagonist (1.0 to 7.5 mg/kg, ip, 1 h before test Ss), did not affect the locus of rise but reduced the asymptote of the AMPH dose-response function. These results provide strong support for the hypothesis that reward-related learning may involve a DA signal at D1 receptors. (Funded by N.S.E.R.C.)

#### 222.7

INFLUENCE OF CHRONIC BETA-BLOCKER ANTIHYPERTENSIVES ON AROUSAL-MODULATED WORKING MEMORY IN ELDERLY ADULTS. K.A. Franklin and R.A. Jensen\*, Biopsychology Laboratory, Department of Franklin and R.A. Jensen\*. Biopsychology Laboratory, Depart Psychology, Southern Illinois University, Carbondale, IL 62901-6502.

Level of arousal influences learning and memory. Under conditions of arousal (i.e., sympathetic activation) there is increased release of adrenal catecholamines (CAs) which have primarily peripheral actions since they do not freely cross the blood-brain-barrier. McGaugh (McGaugh, J.L., 1990, Psychological Science, 1(1), 15-25) proposed that these substances, by affecting peripheral receptors, may modulate memory through alterations in arousal level which, in turn, affect the memory consolidation process. We have demonstrated that moderate increases in arousal, induced by having human subjects squeeze a hand dynamometer, enhance long-term memory (LTM) in young adults in a variety of tasks. Elderly adults are commonly treated for hypertension. Those who chronically take Beta-blockers may have impaired capacity to modulate memory processes through the release of adrenal CAs. We tested normotensive elderly subjects, elderly hypertensive subjects who chronically take Beta-blockers, and those who take Ca<sup>2+</sup> blockers or anglotensin-converting enzyme inhibitors (ACEIs). Male and female subjects (mean = 70.7 years) were given a series of reading comprehension tests of working memory and were asked to squeeze the hand dynamometer during the consolidation/retrieval interval. The arousal manipulation produced enhance ment of LTM in normotensives, a smaller enhancement in those taking Ca2 blockers or ACEIs, and no enhancement in those taking Beta-blockers. These findings suggest that elderly individuals chronically taking Beta-blockers may be unable to benefit from the memory-modulating effects of arousal, and that medications taken in an attempt to attenuate some of the physiological symptoms of aging may actually contribute to cognitive decline in aging.

## 222.9

PRAZOSIN ENHANCES RECOVERY OF SPATIAL LEARNING IN ANIMALS WITH HIPPOCAMPAL SYMPATHETIC INGROWTH. L.E.

Animals with hispocampal sympathetic ingrowth. Leg. Harrell\*, A. Peagler and D. Parsons. Depts. of Neurology and Psychology. VA and University of Ala., Birmingham, Al. 35294

We have previously reported that the detrimental effects of hippocampal sympathetic ingrowth (HSI), a neuronal rearrangement induced by hippocampal cholinergic denervation via medial septal lesions (MSL), on spatial learning were ameliorated by phentolamine ( $\alpha$ -antagonist) treatment. In this study, we sought to determine the role of  $\alpha_1$ -receptors. Adult male rats underwent training on a radial-8-arm maze, with all arms batted, until learning criterion was achieved. Animals were then randomized to 1 of 3 groups: Controls--sham MSL + sham Gx (ganglionectomy); MS--MSL + sham Gx (HSI group); MSGx--MSL + Gx (no HSI). Two days following surgery, testing on the maze was initiated. Prior to the beginning of each daily trial, \(^1/2\) of the animals in each of the groups received prazosin (1 mg/kg IP), while \(^{1/2}\) received saline. Testing continued until criterion was reachieved. Prior to surgery, the number of trials to achieve learning criterion was similar among all groups. Following surgery, in the saline treated groups, MS animals required significantly more trials (41.2  $\pm$  10.5 M  $\pm$  SE) to achieve criterion than MSGx animals  $(23.5 \pm 4.3)$ , who were more impaired than CON  $(9.7 \pm 2.7)$  (p <.01). Prazosin normalized performance of the MS group  $(10.7 \pm 2.5)$  but was without effect on the MSGx  $(24.0 \pm 4.0)$  or CON  $(20.8 \pm 8.9)$ groups. These results 1) confirm that HSI has a detrimental effect on recovery of spatial learning and 2) suggest that the detrimental effect of HSI is mediated through  $\alpha_1$  receptors.

EVALUATION OF CHANGES IN DOPAMINERGIC SYSTEMS AS A BASIS OF LEAD-INDUCED LEARNING IMPAIRMENTS. J. Cohn\* and D.A. Cory-Siechta Environ. Health Sci. Ctr., Univ. Rochester Med. School, Rochester, NY 14642

LEAD-INDUCED LEARNING IMPAIRMENTS. J. Cohn\* and D.A. Cory-Slechta Environ. Health Sci. Ctr., Univ. Rochester Med. School, Rochester, NY 14642

Even very low-level lead (Pb) exposures are known to impair learning and other behavioral functions. The neurotialogical bases of these effects remains obscure, although alterations in neurotransmitter systems have been proposed as one possibility. Using drug discrimination procedures, this laboratory previously reported both a D1 and D2 dopaminergic (DA) supersensitivity in rats exposed to Pb postweaning. To determine whether this DA supersensitivity in flight underlie Pb-induced learning impairments, the effects of acute administration of the tyrosine hydroxylase inhibitor alpha-methyl paratyrosine (AMPT), the D1 agonist SKF3893 and the D2 agonist quinipirole were compared in control and Pb-exposed rats (0, 50 or 250 ppm in drinking water from weaning) working under a multiple schedule of repeated acquisition (RA) and performance (P). The RA component of the schedule required rats to learn a new 3-member sequence of responses during each experimental session (Center Right Left, RLC, CLR, RCL, or LRC), while the correct sequence of responses for the P component was constant across sessions (LCR). Each of these components alternated twice during the daily experimental session, yielding two RA components (RA1, RA2) and two P components (P1, P2). In control rats, AMPT had little effect on accuracy, which declined by about 25% only in the RA2 component, Quinprole produced dose-related decreases in accuracy of 20-30% in RA2, P1 and P2, indicating non-specific performance impairments rather than selective learning deficits. SKF38393 also resulted in dose-related decreases in accuracy of 20-30% which occurred in all four components (RA1, RA2, P1, P2), but which was statistically significant only in RA1 and RA2 where rates declined with dose. Pb exposure did not systematically alter any of the observed effects of the DA compounds upon accuracy. It did, however, modify the alter

#### 222.8

POST-TRAINING D-AMPHETAMINE ENHANCES WIN-SHIFT RADIAL MAZE RETENTION: EVIDENCE FOR A CENTRAL ACTION ON MEMORY. M. G. Packard\*, C. L. Williams, J. L. McGaugh. Center for Neurobio. of Learning & Memory and Dept. of Psychobio., U. of Calif., Irvine,

CA 92717.

Peripheral post-training injection of the indirect catecholamine agonist D-amphetamine (D-AMP), enhances memory in both aversive and appetitive learning tasks. Previous evidence suggests that the retention enhancing effects of D-AMP seen in tasks using aversively motivated training is mediated by an action of the drug in the periphery. For example, post-training injection of 4-OH amphetamine, an analog with limited capacity to cross the blood-brain barrier, enhances retention in an inhibitory avoidance task. The present experiments examined the contribution of the peripheral effects of D-AMP memory enhancement in an appetitive win-shift radial maze task. On each daily trial in an 8-arm radial maze, male Sprague-Dawley rats (275-300 g) were allowed to obtain food from 4 randomly selected maze arms before being removed from the maze. After a delay, the rats were returned to the maze for a retention test in maze. After a delay, the rats were returned to the maze for a retention test in which only those 4 arms not visited prior to the delay contained food. On the which only those 4 arms not visited prior to the delay contained food. On the experimental day, the rats were injected (s.c.) with drug or vehicle immediately after completion of the first 4 choices, and a retention test was given after a delay of 18 hours. Injection of 1.0 mg/kg D-AMP enhanced retention relative to saline injected controls, while doses of 0.5 and 2.0 mg/kg were ineffective. Furthermore, injections of 1.0 mg/kg D-AMP administered 2 hours post-training did not affect retention. In contrast to the memory enhancement observed following administration of D-AMP, post-training injection of 4-OH amphetamine (0.5, 1.0, 2.0, and 4.0 mg/kg), did not enhance retention. The findings indicate that peripherally administered D-AMP enhances win-shift retention in the radial maze by acting, at least in part, directly on brain processes. ## 222 10

ALPHA-2-ADRENERGIC MODULATION OF SPATIAL MEMORY PERFORMAN-CE IN AGED BUT NOT IN ADULT RATS BY MEDETOMIDINE. S.Carlson, H.Tanila, P.Rämä, E.Mecke and A.Pertovaara. Dept. of Physiol., Univ.Helsinki, Helsinki, Finland

The role of alpha-2-adrenergic mechanisms in spatial memory performance was studied in rats using a highly selective alpha-2-adrenoceptor agonist medetomidine and antagonist atipamezole. The effect on working memory was studied in a T-maze using a delayed alternation task. Testing was performed in two stages, at the age of 8.3 months (mean) and again at the age of 17.6 months (mean). The drugs/saline control were administered i.m. in a double blind fashion.

A low (3 ug/kg) and a high (30 ug/kg) dose of medetomidine improved the performance of the aged rats in the memory task, but a medium dose (10 ug/kg) had no effect. Thus, the non-monotonic dose-response curve of medetomidine resembled that of guanfacine. There was no effect on the younger rats. At the low dose of medetomidine the rats showed no signs of sedation, whereas the high dose was sedative. Atipamezole (0.3-3.0 mg/kg) had no significant effect in the memory task.

Since medetomidine, even at a low dose, has a beneficial effect on the memory performance of aged rats, it could be a good candidate for the treatment of age-associated memory dysfunction.

EVIDENCE THAT NORADRENERGIC (NE) ACTIVITY PLAYS A ROLE IN DISTRACTIBILITY. B.J.Strupp\* & M.D.Bunsey. Division of Nutritional Sciences and Department of Psychology. Cornell University. Ithaca. NY 14853.

Psychology, Cornell University, Ithaca, NY 14853. The putative modulation of attentional processes by endogenous NE was examined by pharmacologically manipulating this system with idazoxan (IDZ), a drug that blocks  $\alpha_2$  receptors. The drug (0, 0.5 & 1.0 mg/kg, s.c.) was administered to rats prior to testing in two automated discrimination tasks designed to assess different aspects of attention. While IDZ did not affect vigilance or impulsivity, a significant negative correlation was observed between distractibility under the high dose and distractibility in the control condition (p=.001). The animals that were the most distractible in the nondrug state were the least distractible when treated with IDZ and vice versa. Further analyses indicated that IDZ primarily affected the animals' tendency to respond prematurely when presented with distractors. The fact that a single dose produced qualitatively different effects on distractibility indicates that IDZ's neurochemical effects interacted with the activity of a neurochemical system(s) that plays an endogenous role in modulating this cognitive process.

#### 222.13

THE ROLE OF NOREPINEPHRINE IN CONSOLIDATION OF EARLY OLFACTORY MEMORIES. R.M. Sullivan\* and D.A. Wilson, Devel. Psychobiology Lab., Dept. Psychology, University of Oklahoma, Norman, OK 73019

Norepinephrine has been shown to be critically involved in olfactory associative learning in newborns. NE blockade during training prevents acquisition of learned behavioral responses to the conditioning odor and their neural correlates. NE is not necessary, however, for expression of the learned responses once they are acquired. In mature animals, levels of NE during the immediate post-training period can influence the consolidation of previously learned associations. The present experiment examined whether NE consolidation processes also occur early in development.

Wistar rat pups were trained on PN5 in a classical conditioning paradigm with citral odor (CS) and intra-oral infusions of milk (UCS). Pups were randomly assigned to either the PAIRED, UCS only or CS only conditions. Immediately following training, pups in each group were injected with either saline, or the B-receptor antagonists propranolol (10 or 20 mg/kg) or timolol (3 mg/kg). Pups were tested for conditioned behavioral odor preferences on PN6.

The results suggest that post-training blockade of NE impairs early olfactory learning.

IMPROVED ATTENTION FOLLOWING METHYLPHENIDATE HYDROCHLORIDE (RITALIN) IN AN ANIMAL MODEL OF ATTENTION-DEFICIT HYPERACTIVITY DISORDER

## TERIE SAGVOLDEN

Department of Neurophysiology, University of Oslo, Norway. SPON: European Brain and Behaviour Society

Attention-Deficit Hyperactivity Disorder (ADHD) is a disease characterized by attention problems and over-activity. ADHD is frequently treated with psychomotor stimulating drugs. Spontaneously hypertensive rats (SHR) are hyperactive and may be used as an animal model of (ADHD). The present study investigated attention processes of SHR by using a time-discrimination task. In this task, the subject had to space its responses by at least 16 s in order to be eligible for a reinforcer. However, not all responses with sufficient interresponse time qualified, as the reinforcer was set up on the average only every 120 s.

SHR timed their responses less effectively than WKY thereby showing an attention-like deficit. The lowest dose of methylphenidate improved the time discrimination of controls, but only to a very limited degree compared to the effects of low doses of this drug on the behavior of SHR which virtually normalized their time discrimination. Thus, methylphenidate did not have a "paradoxical" effect since both groups are effected similarly by the drug, but SHR are less sensitive compared to WKY.

EXAMINATION OF ALPHA<sub>2</sub>-ADRENERGIC AGENTS ON COLD-INDUCED IMPAIRMENT OF DELAYED MATCHING-TO-SAMPLE PERFORMANCE IN RATS. <u>Q. A. Morgan, S.T. Ahlers, D. Shurtleff, M.O. Thornton\*</u>. Naval Medical Res. Inst., Bethesda, MD 20889-5055.

Modulation of alpha<sub>2</sub>-adrenergic receptors has been reported to effect working memory performance. The present study examined the effects of clonidine and idazoxan administration in rats, both alone, and under conditions in which performance was impaired by exposure to cold air stress. A delayed matching-to-sample (DMTS) task was used to measure working memory. Under the DMTS task rats were required to respond on one of two levers cued by an illuminated light above the lever on the front wall of an operant chamber. Following a variable delay ranging from 1-16 sec, both lights were illuminated and rats were required to correctly respond on the lever previously cued for a food reward. Rats responded on the back wall lever during the delay interval to prevent position bias. Clonidine (0.005-0.05 mg/kg), idazoxan (2.0 or 5.0 mg/kg), or saline, administered (ip) in a mixed sequence, were given 30 min before a 75 minute session in which rats performed the DMTS task (180 trials). During test sessions the ambient air temperature was either 24°C or 2°C. Administration of clonidine produced dose-dependent impairment of matching accuracy across all of the delays when rats were exposed to 24°C. Idazoxan did not impair matching accuracy at any dose under normothermic conditions. Exposure to 2°C impaired matching accuracy at all delays. Low doses of clonidine (0.005 and 0.01 mg/kg) reduced cold-induced impairment of matching accuracy whereas high doses were ineffective. Idazoxan, at doses up to 5.0 mg/kg, did not alter the effect of cold stress on matching accuracy.

SOCIAL EXPERIENCE ALTERS RATS' RESPONSES TO ODORS FROM DSP-4-TREATED RATS. C. Cornwell-Jones\*, T. Palfai, A. Krause, A. Friedberg, A. McCausland, C. Harfenist, C. Andrew, and T. Kuntz. Psychology Department, Syracuse University, Syracuse, NY. 13244.

Injecting rats with the NE neurotoxin DSP-4, alters the odors the rats produce, as measured by responses of control rats to those odors. The present experiments investigated whether such responses were influenced by the age of the treated animals, or by prior exposure to their odors. Within the period ending on postnetal day 2, male Sprague-Dewley rats were injected subcutaneously with either 50 ug/g of DSP-4, or water. They were housed with the dam in mixed water/DSP-4 litters until weaning. After weaning, some of these litters were divided into separate water-only and DSP-4-only living groups. The remaining litters were divided into water-only and mixed water/DSP-4-treated groups.

Odor preference tests using home-cage bedding as stimuli indicated that juveniles, but not infants, neonatally treated with DSP-4, produce odors that are distinguishable from controls. Mixed groups of water/DSP-4-treated juveniles produce odors which are more aversive to rats housed in the mixed condition than to other rats. These findings suggest that the aversion develops through association with some other negative stimulus within the home-cage, and not because the mixed odors act as an aversive pharagement.

SONG-SELECTIVE AUDITORY NEURONS EMERGE DURING VOCAL LEARNING IN THE ZEBRA FINCH. AJ.Doupe\* and M. Konishi. Division of Biology, Caltech, Pasadena, CA 91125.

Auditory experience and feedback are essential for normal birdsong learning Auditory experience and feedback are essential for normal birdsong learning. Young male birds first hear and memorize a parent tutor song during a stage called sensory learning. Later, during motor learning, they gradually match their own vocalizations to the song memory, using auditory feedback. Therefore, there must exist brain mechanisms for auditory recognition of song and song-like vocalizations, and for providing feedback to the vocal motor system. The neural circuit containing the song nuclei X, DLM, and L-MAN is a possible site for such mechanisms. It plays a crucial but unknown role during song development, and in

circuit containing the song nuclei X, DLM, and L-MAN is a possible site for such mechanisms. It plays a crucial but unknown role during song development, and in adult finches all three of these nuclei contain song-selective auditory neurons: these cells respond more robustly to the bird's own song than to songs of conspecific individuals, and they are sensitive to the temporal order of song. We therefore investigated this circuit in juvenile birds, at a stage when it is essential to learning. We used single unit recordings to characterize the auditory response properties of song nuclei of young male finches of 30-35 days of age, a time when sensory learning is underway and motor learning is just beginning. Each of these birds had been exposed to only one tutor, the male parent, whose song was included in the acoustic stimuli presented during the experiment. We found that X and L-MAN do contain complex auditory neurons at this early stage. Their properties are strikingly different from those in adults, however. These neurons respond to a variety of conspecific songs as robustly as to the tutor song, and they respond well to the tutor song even when the temporal order is reversed.

The presence of auditory neurons in this circuit in young birds suggests that one of the essential functions of this pathway may be the auditory feedback crucial to normal song learning. Moreover, the highly song-selective properties of the adult forebrain song nuclei are not present in young birds, and must emerge during development, in parallel with song acquisition. Further studies of these neurons will reveal which facets of learning their selectivity reflects and may shed light on their critical role in normal song development.

### 223.3

ACTIVITY OF SYRINGEAL MUSCLES DURING SONG IN MIMIC THRUSHES. F. Goller and R. A. Suthers\*. Medical Sciences, Indiana Univ., Bloomington, IN 47405.

Simultaneous recordings of sound, air sac pressure, bronchial flow and electromyograms of ventral (m. syringealis ventralis) and dorsal (m. syr. dorsalis) syringeal muscles were made during song in brown thrashers (Toxostoma rufum). Most vocalizations are preceded by strong electrical activity in dorsal, and usually also in ventral, muscles as subsyringeal pressure rises. In neither of these muscles is the EMG prominently correlated with the termination of sound. Electrical activity varies with the frequency characteristics of the vocalizations. Ventral muscles are essentially inactive during simple notes which have little frequency modulation. High pitched FM notes are typically accompanied by high amplitude, long duration EMG's in both ventral and dorsal muscles and by a reduction in the rate of syringeal airflow. Sounds with rapid sinusoidal frequency modulation are accompanied by alternating EMG bursts in the dorsal and ventral muscles, as well as by oscillations in the rate of syringeal airflow and the amplitude of the vocalization. Unilaterally produced vocalizations are often accompanied by similar EMG patterns in the left and right ventralis muscle. The phonating side of the syrinx therefore could not be reliably deduced from bilateral recordings of the EMG. (PHS R01 NS29467-01)

CONNECTIVITIES OF MIDBRAIN VOCAL CONTROL NUCLEUS AND HYPOTHALAMUS: CONTRIBUTION OF ENKEPHALINERGIC PATHWAYS. M.-F. Cheng\* and M. Zuo. Institute of Animal Behavior, Rutgers University, Newark, NJ 07102 Recent studies in the ring dove (<u>Streptopelia risoria</u>)

have shown that the female's nest-coo calls stimulate her follicular growth. This causal relationship implicates the hypothalamus (Hy), a projection target of the nest-coo control neucleus, the medial n. intercollicularis (mICo). We have used PHAL as an anterograde marker to identify terminal fields in the hypothalamus. We found: one direct projection to the Hy and the other via auditory pathways. One pathway leaving ICo travels medially to the central gray, descends along 3rd ventricle and terminate in the lateral hypothalamus (LHy) and anterior medial hypothalamus (AM). Distribution patterns of immunoreactive enkephalin cell bodies and fibers suggest that LHy/AM projection may be an enkephalinergic pathway. Fluorogold injection was restricted to LHy/AM region and the sections were processed for retrogradelly labelled cell bodies and metenkephalin immunoreactivity. The 2nd pathway travels laterally and enters the lateral ICO then descends to the lateral lemniscus and follows the auditory pathway to the area adjacent to the OV (thalamic auditory relay), an area previously shown to send projection to the posterior hypothalamus. Parallel enkaphalinergic pathways suggest this too an enkephalinergic pathway.

NEURONS IN FIELD L OF BUDGERIGARS PREFER SPECIES SPECIFIC CALLS TO WHITE NOISE K. Mori and G. Striedter. Division of Biology, 216-76, California Institute of

Technology, Pasadena, CA 91125.

Budgerigars (Melopsitacus undulatus) are capable of discriminating between their own calls and those of cagemates. In an attempt to investigate the neuronal correlates of this behavior, we studied the characteristics of neuronal responses in field L to species specific behavior, we studied the characteristics on reformed responses in lieur L to species specific calls as well as to synthetic noise and tones. Adult budgerigars were kept together for several weeks before their calls were recorded. A stereotaxic head pin was affixed to the skull under Xylaziner/Ketamine anesthesia several days prior to the recording session. Extraoellular activity of single neurons was isolated in field L under Urethane anesthesia (1.4 g/kg). Simuli consisting of white noise and various calls were delivered to the bird during search, and more than 160 auditory single units were isolated. Units preferring calls to nois search, and nitrol training sanger unity shipter units where isolates child prefer in the war were further tested with tone bursts, frequency sweeps and modified calls. Recording sites were later confirmed histologically. We found that more than half of the single units eresponded more vigorously to its own calls or cagemates' calls than to white noise. Of these units, approximately 90% responded to pure tone bursts of various frequencies. However, half of them did not respond to white noise, which suggests that there is inhibitory interaction among different frequencies. Ninety-five percent of the neurons preferring calls responded among dimerent requences. Ninety-live percent of the neutrons pretering calls responsed to at least one upward or downward frequency sweep ranging from 5 kHz/s to 320 kHz/s. Twenty percent responded predominantly to only one of the calls in our stimulus set, although the frequency-time spectrograms of some of the calls were similar. Forty-one percent of the units tested with forward and reverse calls showed differential responses. Although some of these persponses could be explained by the unit's selectivity for direction and speed of frequency sweeps, there were cases where further analysis with modified and synthetic calls revealed more complex signal processing such as interfrequency inhibition in the time domain, and interval tuning for consecutive frequency sweeps. These properties were specific enough to allow neurons to respond to only a single call in our stimulus set.

### 223.4

RIGHT SIDE DOMINANCE FOR SONG CONTROL IN THE ZEBRA FINCH. H. Williams\*, L.A. Crane, T.K. Hale, M.A. Esposito, and F. Nottebohm. Biology Dept., Williams College, Williamstown, MA 01267, and The Rockefeller University Field Research Center, Millbrook, NY 12545.

Left-side hemispheric dominance for song control, similar to that described for human speech, has been found in several songbird species. We unilaterally denervated the syrinx or unilaterally lesioned the forebrain nucleus HVC (known to be important for song control) of adult male zebra finches. Disruptive effects on song were greater after right side than after left side operations. After denervation of the right half of the syrinx, the fundamental frequencies of all syllables within a song converged on a value near 500 Hz, and classification by type of nearly all syllables was altered. In contrast, the syllables produced after denervation of the left side of the syrinx largely maintained their after denervation of the left side of the syrinx largely maintained their pre-operative frequencies, and fewer syllables changed in type. Syllable frequency and syllable structure were less affected by HVC lesions than by syringeal denervation. However, the stereotyped structure of normal zebra finch song was impaired after HVC lesions, and was more strongly affected by right side than left side operations. Although it is apparent both centrally and peripherally, right side dominance for song production in zebra finches may be tied to different aspects of vocal control at different levels of the song system.

Other songbird species with lateral asymmetry for vocal

Other songbird species with lateral asymmetry for vocal communication have left side dominance for song control, the reverse of zebra finches. The need for a dominant side may be more important than the side of dominance.

NUCLEUS Uva MIGHT BE PART OF A FEEDBACK CIRCUIT FOR SONG PROCESSING

S. Okuhata and F. Nottebohm\*, The Rockefeller University, New York, N.Y.

A motor theory of song perception has been proposed to explain the presence of vigorous auditory responses in HVC and other nuclei of the motor pathway for song production. This proposal would require the existence of a pathway to carry feedback from vocal motoneurons, e.g. those in RA and nXIIts, to higher brain centers involved in song discrimination. The thalamic nucleus Uva projects to the neostriatal nuclei NIf and HVC of the song system, and stimulation of Uva elicits

neostriatal nuclei NIt and HVC of the song system, and stimulation of Uva elicits strong responses in the descending motor pathway for vocalization from HVC to nXIIts (Williams, 1989). Because of its anatomical position and physiological properties, Uva might be a component of such a feedback circuit. In order to examine the function of Uva, single unit recordings were performed in awake zebra finches. Antidromic responses to HVC stimulation were used to identify Uva neurons. Most identified Uva neurons respond to sound with a latency of 18-50 ms and some also respond orthodromically to RA stimulation with a latency of 15-25 ms. In addition, respiratory rhythm is observed in Uva. In order to determine the possible sources of these responses, fluorescent beads were injected into Uva unilaterally and backfilled neurons were observed in both the pistiateral and contralateral medulla. The area of backfilled neurons overlapped injection of the control to the current and the control to the control to the current of the cur Thus, the motor pathway for song production forms a loop that sends information back to HVC. This loop and Uva could play an important role in song acquisition, song production and song perception.

NUCLEUS UVAEFORMIS CONTRIBUTES TO THE TEMPORAL PATTERN OF VOCAL PRODUCTION IN SONGBIRDS. D.S. Vicario\* and H. Williams. The Rockefeller University, York, NY 10021 and Williams College, Williamstown, MA 01267.

Birdsong is a learned vocal behavior used in intraspecific communication. The motor pathway serving learned vocalizations includes forebrain nuclei NIf. HVC and RA; RA projects to midbrain and brain stem areas that control the temporal and acoustic features of song. Nucleus Uvaeformis of the thalamus (Uva) sends input to two forebrain nuclei. NIf and HVC, but heretofore has been thought not to be important for song production.

We have used three experimental approaches to re-examine Uva's function in adult male zebra finches. 1) Electrical stimulation applied to Uva activates HVC and the vocal motor pathway, including tracheosyringeal motor neurons that innervate the bird's vocal organ. 2) Bilateral lesions of Uva affect the normal temporal organization of song; specifically, damage to the dorso-medial "horn" of Uva seems to account for the effects. 3) Chronic multi-unit recordings from Uva during normal song and calls show bursts of pre-motor activity that lead the onset of individual syllables, and also larger bursts that appear to signal the occurrence of repeated song phrases.

Together, these results clearly implicate Uva in the production of

learned vocalizations. The lesion and recording data further suggest that Uva may contribute more to the temporal structure than to the acoustic characteristics of song. (Supported by MH40900 and DC00553).

## 223.9

A VOLUMETRIC STUDY OF THE SONG CONTROL NUCLEI OF MALE AND FEMALE STARLINGS. S.L. RICH\*1, F. GOLLER2 and D.R. SENGELAUB1 Program in Neural Science<sup>1</sup> and Medical Sciences Program<sup>2</sup>, Indiana University, Bloomington, IN 47405.

While song is considered to be largely a male-specific behavior, both male and female starlings (<u>Sturnus vulgaris</u>) have the capability to produce an elaborate and varied song repertoire (Adret-Hausberger and Jenkins, <u>Behav.</u> 107:156 '88; Hausberger and Black, <u>Ethol. Ecol. Evol.</u> 3:337 '91). The neuroanatomical basis for this complex song in starlings has not been examined in detail, but investigation of song production in other birds has revealed a set of discrete brain nuclei involved in vocal behavior (Nottebohm et al., <u>J. Comp. Neurol.</u> 165:457 76). These nuclei are generally sexually dimorphic, and both the relative size and degree of dimorphism correlate with song behavior (Nottebohm et al., Brain Res. 213:99 '81; Brenowitz et al., Brain Res. 343:104 '85). In this study the size of telencephalic nuclei involved in song were compared in male and female starlings.

Brains from 2 male and 5 female adult starlings were frozen sectioned (60 μm), stained with cresylecht violet, and examined with light microscopy. Three principal song nuclei (HVc, Area X, and RA) were identified, their perimeters traced, and volumes determined. In all cases the volumes displayed a marked sexual dimorphism, with male:female ratios of 5.11 in HVc, 3.28 in RA, and 2.89 in Area X. Ratios of Area X and HVc to RA are consistent with volumetric measurements taken in birds with similar song dimorphisms. The similarity of the relative sizes and dimorphisms of the song control nuclei of starlings with other species is interesting given the complex vocal ability of starlings and their dynamic vocal repertoire.

## 223.11

SEXUAL DIMORPHISM IN THE VOLUME OF SONG CONTROL NUCLEI OF EUROPEAN STARLINGS: ASSESSMENT BY A NISSL STAIN AND AUTORADIOGRAPHY FOR MUSCARINIC

CHOLINERGIC RECEPTORS D.J. Bernard\* J.M. Casto, & G.F. Ball Dept. of Psychology, Johns Hopkins Univ. Baltimore, MD 21218

In European starlings (Sturnus vulgaris), male song is more complex than female song and is produced at a higher rate. In order to investigate the degree to which this behavioral dimorphism is reflected in the brain, we compared the volume of song control nuclei (SCN) of male and female photosensitive starlings in brain sections stained with cresyl violet. Area X is approximately 2.2 times larger in males than in females. Other SCN, such as the robust nucleus of the archistriatum (RA) and the caudal part of the ventral hyperstriatum (HVc) are approximately twice as large in males as in females. This sex difference agrees well with studies on other songbird species where the degree of behavioral dimorphism parallels the volumetric dimorphism in the SCN. Previous work has suggested that there are several neurochemical markers of the SCN that also demonstrate this volumetric dimorphism. We therefore assessed the volume of the SCN using autoradiographic methods. Area X is well defined by a high density of muscarinic cholinergic receptors in comparison to the surrounding caudate. We localized muscarinic cholinergic receptors by film autoradiography in alternate sections with the use of  $[^3H]$  N-methyl scopolamine (NMS) as the ligand. The density of cholinergic receptors defined the boundaries of area X in good agreement with the Nissl stain: the volume of area X as defined by NMS binding was found to be approximately 2 times larger in males. Thus the cholinergic innervation of area X in starlings is sexually dimorphic.

GABA-LIKE IMMUNOREACTIVITY IN THE SONG SYSTEM OF THE ZEBRA FINCH. W. Grisham\* and A.P. Arnold. Dept. of Psychology and Brain Research Institute, UCLA, Los Angeles, CA 90024.

To increase our knowledge of the neurotransmitters that might be involved in the learning or the production of birdsong, we studied the distribution of GABA-like immunoreactivity (GABA-LIR) in the song control regions of the zebra finch brain. Eight male and 4 female brains were fixed with 1% paraformaldehyde/1.25% glutaraldehyde, sectioned at 40 $\mu$ , and incubated with a GABA-gluteraldehyde antibody (Chemicon). Binding was visualized using an avidin-biotin system with diaminobenzidine as a chromagen.

Area X of males and the LPO of females had many densely packed, small light to moderate GABA-LIR somata. Males had intense neuropil GABA-LIR in Area X, but females did not. Both males and females had scattered neurons in MAN with GABA-LIR. HVC in males usually had intense neuropil GABA-LIR and large, densely-packed somata with moderate GABA-LIR. HVC had no detectable GABA-LIR in females. RA in males had intense neuropil GABA-LIR and large, widely-scattered neurons with intense GABA-LIR. The RA of females had no detectable neuropil GABA-LIR and consisted of small, densely-packed somata with light GABA-LIR. RA neurons with GABA-LIR were significantly larger in males than in females. ICo had small, densely packed neurons with light GABA-LIR in both sexes. These data suggest that GABAergic neurons may be involved in the learning and/or production of song. Supported by NIH NS09040 to W.G. & DC00217 to A.P.A.

### 223.10

MK801 BINDING DECLINES STEADILY WITH AGE IN A NUCLEUS INVOLVED IN AVIAN SONG LEARNING. S.M. Aamodi\*, E.J. Nordeen, and K.W. Nordeen. Dept. Psych., U. Rochester, Rochester, NY 14627.

N-methyl-D-aspartate (NMDA) receptors are linked to various forms of experience-dependent plasticity and early learning. Recently, physiology and autoradiography have revealed this receptor type in brain regions controlling song learning and production in zebra finches (Poephila guttata). We hav song learning and production in zeroa intense (*roepinia gantala*). We have shown that in one nucleus involved in song learning, the lateral magnocellular nucleus of the anterior neostriatum (IMAN), binding of the NMDA receptor antagonist <sup>3</sup>H-MK801 is much greater in males at 30 days, at the beginning of song learning, than in adulthood, after song learning is complete. To understand better how this regional decline in NMDA receptor binding relates to vocal learning, we have elaborated its timecourse and begun to examine how it is affected by auditory manipulations that could extend the period during

which song learning can occur.

Using autoradiography, <sup>3</sup>H-MK801 binding was measured in IMAN of 30d, 55d, 80d, and adult (4-6 mos and 7-20 mos) males. Binding declined steadily 30d, out, and adult (42- mos and 7-20 mos) mates. Similar gets the steadily between 30d and adulthood, but did not differ between the two adult groups. Values were 0.176 ± 0.012 pmol/mg tissue at 30 days, 0.125 ± 0.003 at 55 days, 0.104 ± 0.002 at 80 days, and 0.080 ± 0.005 in adults. Since song learning can be extended by restricting early auditory experience, we also examined MK 801 binding in the IMAN of males raised either deaf or isolated from conspecific song. In 80d deaf males, binding in the IMAN  $(0.107\pm0.007 \, \text{pmol/mg})$  was no different from binding in age-matched controls. However, in two 80d males isolated from hatching, MK801 binding was higher  $(0.126\pm0.013)$ , and more comparable to levels in 55d control birds. Additional birds are currently being examined to confirm this finding.

## 223.12

AXONAL CONNECTIONS OF A FOREBRAIN NUCLEUS IN MALE ZEBRA FINCHES. E.F. Foster\* & S.W. Bottjer. Dept. Biol., USC, Los Angeles, CA 90089.

The Higher Vocal Center (HVC) is a telencephalic nucleus known to be essential for song production in adult birds. HVC receives afferent inputs from two telencephalic nuclei, mMAN and NIf, and a thalamic nucleus, Uva. Our goal was to map the afferent and efferent projections of one of these nuclei, mMAN, in adult male zebra finches. mMAN was electrophysiologically by stimulating HVC and recording antidromic multicellular activity in the anterior neostriatum. Borders of evoked activity were used to define mMAN and pressure micro-injections of DiI were made in the center of the field of activity. Injections produced light afferent label in HVC, confirming the pathway from mMAN, with fiber label in the LH tract. A small cluster of retrogradely labeled cells were found in the thalamus, directly dorsal to the song nucleus DLM, with fiber label in the FPL tract. Injections dorsal and lateral to mMAN did not label these cells. Results indicate that mMAN receives only one afferent input and makes only one efferent projection. The role of mMAN in vocal behavior is not vet known.

BLOCKING STEROID HORMONES DURING SONG LEARNING EXTENDS THE SENSITIVE PERIOD FOR LESIONS OF LMAN IN JUVENILE MALE ZEBRA FINCHES. S.D. Brown\* and S.W. Bottjer. Univ. of Southern California, Los

Lesions of the telencephalic nucleus IMAN disrupt song learning in juvenile male zebra finches (< 70 days old) but have no effect on stereotyped song produced by older birds. Blocking steroid hormones in juvenile birds also prevents normal development of learned vocal behavior; delayed exposure to testosterone in such birds beyond the normal period of vocal learning permits delayed development of normal song. This finding raises the possibility that low levels of steroid hormones may also extend the period during which IMAN Is required for learning to produce specific song patterns.

To test this idea, male zebra finches were castrated at 20 days of age and

received continuous exposure to an anti-androgen (flutamide) or an antiestrogen (tamoxifen) until adulthood (> 90 days). IMAN was then electrolytically lesioned, and song behavior was recorded pre-operatively and for six to eight weeks following surgery. Lesions of IMAN resulted in immediate deficits ranging from severely disrupted song consisting of only one or two notes to more subtle changes in which several notes that were consistently produced pre-operatively were deleted from the final song. Normal siblings that received IMAN lesions at matched ages showed no behavioral deficits. Thus, preventing development of stable song behavior by blocking access to sex steroid seems to extend the period during which the neural circuit that includes IMAN is essential for song learning.

EXPRESSION OF AN IMMEDIATE EARLY GENE IN SONGBIRD BRAIN: ANATOMY, CONNECTIONS AND EFFECTIVE STIMULI. C. V. Mello, F. Nottebohm and D. F. Clayton\*, Lab. of Animal Behavior, Rockefeller Univ., New York, NY 10021 & Dept. of Cell & Structural Biology, Univ. of Illinois, Urbana, Il 61801

ZENK is the canary homolog of an immediate early gene which is highly responsive in neurons to membrane depolarizing which is highly responsive in neurons to membrane depolarizing signals. We have recently shown that ZENK is rapidly induced in discrete regions of the forebrain of songbirds after presentation of tape-recorded birdsong (PNAS, in press). In particular, a high ZENK induction was observed in the caudo-medial neostriatum (NCM) and the medial hyperstriatum ventrale (HV), with a preference for conspecific over heterospecific song. We show here that ZENK induction in response to birdsong also occurs in more lateral areas of the feesbring is additionally the appreciations additionally the appreciations of the description of the second constant the forebrain, including: a) the neostriatum adjacent to and possibly including subregions of the auditory Field "L"; b) the neostriatum adjacent to HVC (shelf); c) the archistriatum adjacent to RA (cup); d) adjacent to HVC (shelf), by the archistratum adjacent to KV (cup), d) portions of the caudal paleostriatal complex; e) other forebrain areas whose connections are not yet known. We have established the time-course of this genomic response and are now further studying its specificity by testing the effects of various auditory stimuli, such as specificity by testing the effects of various auditory stimut, such as bird's own song played forwards and backwards, conspecific and heterospecific songs, and white noise. We are also using neuroanatomical tract-tracing methods to establish the connections of areas where a high ZENK induction occurs and their possible relation to auditory areas and to the song control circuit.

## 223.17

YOUNG MALE SONGBIRDS IMITATE THE MALE-TYPICAL VOCALIZATIONS OF SINGING MOTHERS. H.B. Simpson\* and D.S. Vicario. The Rockefeller University, New York, NY 10021.

In zebra finches, only the males sing and young males learn their song and long call during a limited period in development by imitating adult male models. Females produce a variety of communication calls; these are acoustically simpler and are not learned. The present work investigated whether it is primarily the gender of the parent or the type of vocalizations produced that determines which parent will be imitated when a young bird is exposed to both a mother and father that sing.

Females with learned, male-like song and long calls were produced by early treatment with estradiol. Two such females were paired with singing males, one of which had a male-typical long call, while the other was chosen because he happened to produce a female-like long call. These pairs were placed in individual breeding cages and given successive cohorts of foster chicks to raise (each cohort consisted of 4 chicks < 11d old). The young were removed at 60-80 days of age. Their vocalizations were recorded after 100 days of age. The two pairs raised 7 clutches containing a total of 12 males.

Songs and calls were displayed as sonograms and compared to both foster parents' vocalizations. Analysis showed that young males copied only one parent's song but were as likely to copy the song of their female (n=5) as of their male (n=7) foster parent. Males who copied their mother's song copied her male-like long call as well (5/5). In contrast, only 1 of 7 males that copied their father's song also copied the father's long call; he came from the pair where both parents produced male-like calls. The other males produced calls with unusual leatures (4/7) or copied the mother's call (2/7). These data suggest that young birds do not select models by their sex or plumage; male and female parents can be equally good tutors, if they produce male-typical vocalizations. (Supported by MH40900

CHEMICAL LESIONS OF A THALAMIC NUCLEUS DISRUPT SONG DEVELOPMENT IN MALE ZEBRA FINCHES. K.A. Halsema\* & S.W. Bottjer. Dept. Biol., USC. Los Angeles, CA 90089.

Previous studies indicate that discrete portions of the neural song system in male zebra finches play a critical role in the development of song, but not in the production of the stable adult vocal pattern. Damage to either IMAN or Area X in juvenile males producing an unstable vocal pattern severely disrupts song development, whereas the same type of lesion in adults does not result in any change of the stereotyped song pattern. Area X projects trans-synaptically to IMAN through the thalamic nucleus DLM. In order to evaluate the contribution of DLM to the development of song behavior, we lesioned the dorsal thalamic region containing DLM using ibotenic acid. As in the case of IMAN lesions, damage to DLM disrupted song behavior only in those males producing an unstable vocal pattern at the time of lesion. Chemical ablations of DLM in young males between 50 to 60 days of age producing an unstable song resulted in an abnormal adult vocal pattern consisting of a highly repetitive sequence of 1 to 3 poorly modulated syllable types. The same lesion in 70 to 80 day old males did not interfere with further development of the relatively stable vocal pattern. Interestingly, in contrast to lesions of DLM's target (IMAN), damage to this thalamic nucleus produced no immediate disruption of the vocal pattern. Rather, abnormal song patterns develop gradually following the lesion. This difference in the immediacy of the disruption may reflect a modulatory role for DLM neurons in the motor development of sona.

# PROGRESSIVE DEVELOPMENT OF THE PROJECTION FROM HVC TO AREA X IN CANARIES. Alvarez-Buylla A., and Mateo, A. Rockefeller University, New York, N.Y. 10021.

The high vocal center (HVC) in canaries plays an important role in the production of learned song. Two main efferent pathways originate from the HVC. Large HVC neurons that project to area X are born before hatching or soon thereafter. Small projection neurons that connect HVC to RA are born throughout juvenile development and adulthood. Here we studied the development of the projection interconnecting the HVC to area X. Male canaries of 1, 2, 4, 8, and 13 months were injected with the retrograde tracer Fluoro-Gold(FG) in area X. HVC volume, as revealed by FG, doubled between 2 and 4 months (0.11±0.02mm<sup>3</sup> to 0.24±0.02mm<sup>3</sup>). The density of HVC-area X cells was  $287\pm 36$ ,  $307\pm 54$ , and  $276\pm 61$  cells /mm  $^2\pm 4$  sd at 1,2 and X cells was 28/£ 36, 30/£34, and 2/6£61 cells /mm £ sq at 1,2 and 4 months and dropped to 161±46 by 8 months. Dil crystals placed into the HVC of canaries of different ages revealed that the size of area X and the density of innervation from HVC increases dramatically also between 2 and 4 months. The projection neurons interconnecting HVC and area X are part of a circuit important for song aquisition. These results indicate that between 2 and 4 months HVC becomes a major afferent to area X, perhaps inducing it to grow and differentiate. While these projection neurons are born early, their and differentiate. While these projection neurons are born early, their axons wait 2-4 months to form a mature projection to area X. The influence of HVC on the circuit required for song aquisition may become more important at later stages in juvenile development.

## 223.18

DEVELOPMENT OF VOCAL LEARNING IN THE BUDGERIGAR. E. F. Powell, R. J. Dooling\*, S. M. Farabaugh. Department of Psychology, University of Maryland, College Park, MD 20742.

Vocalizations of ten budgerigars (Melopsittacus undulatus) were sampled from day of hatching to four weeks post-fledging. Food begging calls recorded in the nest box showed changes with age in peak frequency, frequency modulation (FM), and duration. Peak frequency decreased from hatching until asymptotic weight was reached (22 days). FM changed dramatically with age as food-begging calls progressed from nearly pure tones, to simple sinusoidal modulations, to repeated, complex, individually distinctive patterns of modulation. Call duration was invariant with age in birds from two small clutches but increased significantly in birds from a large clutch from 200 ms (at hatching) to average of 500 ms (at 20 days of age). Within a week of fledging, each bird produced a contact call consisting of a shortened version of its final food-begging call recorded in the nest box. These calls were of roughly the same duration across birds (188 ± 36 ms). By three weeks post-fledging, budgerigars were highly social, their contact call repertoire often contained more than one call type, and there was sharing and imitation among the calls of parents, fledglings, and other social companions.

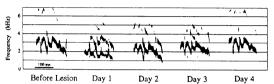

The decrease in peak frequency with age is probably related to the lengthening of the vocal tract while the increase in FM may be related to the maturation of basic syringeal coordination. Changes in duration and FM of begging calls may also reflect differential parental reinforcement of nestling begging behavior. This interaction may mark the earliest stage of vocal learning where an association between the nestling's vocal behavior and a feeding response from its parents are formed and strengthened. These early associations may be precursors of more complicated associations affecting the production, perception, and learning of contact calls in social encounters throughout adulthood. (supported by NIH - DC00198).

THE EFFECT OF SYRINGEAL DENERVATION ON CALL PRODUCTION IN THE BUDGERIGAR. James T. Heaton, Susan M. Farabaugh, and Steven E.

Brauth\*. Department of Psychology, Univ. of Maryland, College Park, MD 20742.

In the budgerigar, the left and right tracheosyringeal nerves were sectioned in order to provide insight into the role of the hypoglossal nuclei in the control of call production. Pre- and post-surgical distance or contact calls were examined for quantifiable changes in peak frequency, fundamental frequency, frequency modulation, and duration. After resecting a portion of either the right or left ts nerve above the anastomosis, both peak frequency and fundamental frequency of distance calls dropped markedly on day 1 post-surgery, while call structure itself remained largely unchanged. Peak and fundamental frequencies returned to normal by day 4 (see figure below).

Vocalizations produced after bilateral syringeal denervation were abnormal, consisting entirely of poorly modulated broadband harmonic series. Significantly, individual call durations as well as the rhythm and patterning of vocalizations resembling warble song after both unilateral and bilateral ts nerve resection were remarkably similar to pre-surgical values, thus suggesting that the control of spectral and temporal aspects of budgerigar distance calls are associated with different neural circuits.

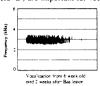

#### 223.20

EFFECT OF FOREBRAIN AUDITORY LESIONS ON CALL DEVELOPMENT IN BUDGERIGARS. William S. Hall, James T. Heaton, Paul L. Cohen & Steven E. Brauth, Dept. of Psychology, University of Maryland, College Park, MD 20742-4411.

Lesions were placed in forebrain auditory structures including nucleus basalis (Bas), nucleus ovoidalis (Ov) and Field "L" in budgerigars at 3-5 weeks posthatching and as adults. The calls of birds sustaining Bas lesions before fledging or as adults were markedly abnormal in that they showed little frequency modulation and individual distinctiveness. Call durations, however, were similar for lesioned and unlesioned birds (see figure below).

In contrast to the effects of Bas lesions, Ov-lesioned birds produced calls in which temporal as well as spectral features were highly abnormal. Calls of Ov birds were often very long (e.g. 0.5 - 1 sec.), showed little frequency modulation and did not possess any of the distinctive spectral features exhibited by cagemates. Significantly, the calls of Field "L"-lesioned birds were similar to those of siblings and cagemates, although call durations were more variable. This implies that other thalamic auditory projections, either to subpallial fields or to areas adjacent to Field "L", are important for vocal learning.

ENVIRONMENTAL STIMULI AFFECT MEMORY AFTER LEARNING THAT FOOD IS INEDIBLE IN APLYSIA FASCIATA. M. Schwarz\* & A..J. Susswein. Dept of Life Sciences, Bar Ilan University, Ramat Gan, Israel 52 900

We have examined whether exposure to a novel stimulus affects memory after learning in Aplysia fasciata. Previous work has shown that presence of a conspecific in the medium during training affects the ability to learn that a specific food is inedible. In absence of a conspecific, learning is impaired. We now demonstrate that brief exposure to a medium lacking a conspecific immediately after training erases memory of the learning, even when animals are returned to an environment having a conspecific. Controls that are handled or transferred to a new medium containing a conspecific show normal memory. Exposure as brief as 1 hour to an environment lacking a conspecific is sufficient to abolish memory. After memory is abolished, animals are fully able to re-learn and remember that a food is inedible, but behave like naive animals when re-trained. Thus, the brief experience does not impair the ability to learn, only the memory of a previous learning. We also examined whether lack of a conspecific interferes with memory even when animals receive this experience 24 hrs after the training. This experience affected memory, but not as severely as immediate exposure. To examine whether the effect on memory is caused by exposure to any behaviorally-significant new environment, or is specific to exposure to an environment lacking conspecifics, animals were transferred immediately after training to a medium of 120% seawater, or were exposed to an alternate food. These experiences did not affect memory. The effect of a conspecific on memory was also examined in sexually immature Aplysia, which presumably are insensitive to pheromones released by conspecifics. Lack of a conspecific did not abolish memory. These data indicate that memory in *Aplysia* is affected by posttraining treatments, as it is in vertebrates.

### 224.2

PLASTICITY IN A SENSORY-MOTOR PATHWAY OF THE LOBSTER STOMATOGASTRIC NERVOUS SYSTEM. R. Nargeot, M. Moulins and F. Nagy\* Lab. Neurobiol. Physiol. Comp. Université de Bordeaux I. CNRS. Arcachon 33120. France.

A fundamental question in neurobiology is understanding

A fundamental question in neurobiology is understanding how activity of the central nervous system can be durably modified by sensory information. To address this problem we study a well-known "simple" model, the crustacean stomatogastric nervous system.

Recent work on this system in <u>Palinurus</u> has shown that a sensory input pathway conveyed by the ventral posterolateral nerve (<u>vpln</u>) is able to induce a short-term inactivation (loss of burst-generating oscillatory behaviour) of a motoneuron (VD) belonging to the pyloric network. We find that with repetitive stimulation of the <u>vpln</u> in vitro, the duration of VD inactivation remains constant. However the prior conditioning stimulation of the contralateral-vpln.

Several cellular elements concerned in this phenomenon have now been identified. We have a situation in which the cellular mechanisms implicated in the induction and maintenance of change in efficacy of the sensory-motor pathway can be studied.

## 224.3

CONTRASTING EFFECTS OF KNOWN NEUROTRANSMITTERS ON VISUAL-VESTIBULAR RESPONSES IN HERMISSENDA R.F. Rogers(\*) <sup>1</sup>, D.M. Fass<sup>1</sup>, S.M. Specht<sup>2</sup>, and L.D. Matzel<sup>1</sup>

<sup>1</sup>Department of Psychology, Rutgers University, New Brunswick, NJ 08903; <sup>2</sup>Department of Psychology, Lebanon Valley College, Annville, PA 17003

In the marine mollusk Hermissenda, stimulation of vestibular hair cells induces a hyperpolarization in ipsilateral B photoreceptors which is mediated by an outward K\* conductance that reverses at a membrane potential between -70 to -80mv. We attempted to further characterize this interaction using pressure microapplication of putative neurotransmitters known to exist within this nervous system. GABA, Acetylcholine (ACH), Serotonin (5-HT), Histamine (HIST), and Dopamine (DA) (25µM) were pressure applied to both the terminal branches and the cell bodies of the B photoreceptor. The observed effects were as follows: (1) Both GABA and ACH (but not 5-HT, HIST, or DA) induced a hyperpolarization of the B photoreceptor when applied to the terminal branches. GABA is believed to mediate the visual-vestibular interaction while ACH mediates the interaction between photoreceptors. The GABA response was gradual in onset and prolonged (10-20 sec), while ACH resulted in a rapid hyperpolarization of short duration (1-2 sec). (2) Hair cell-induced hyperpolarization of the B cell was attenuated by 60-90% when stimulation of the hair cells was preceded by GABA or ACH pressure microapplication to the terminal branches, indicating activation of a common conductance. (3) Pressure application of 5-HT (but not GABA or ACH) onto the B cell bodies led to a brief and rapid depolarization (5-10mv) which was accompanied by a transient increase in spike height (1-4mv). This result suggests a possible modulation of the visual-vestibular interaction by 5-HT. (4) Finally, we investigated the possibility that these synaptic events were Gprotein mediated. Iontophoretic injection of GDP-BS completely blocked the visual-vestibular interaction following 20-30 min of injection.

CELLULAR ANALYSIS OF LONG TERM HABITUATION OF TAIL-INDUCED SIPHON WITHDRAWAL IN APLYSIA CALIFORNICA. M. Stopfer\*. Y. Tal and T.J. Carew. Departments of Psychology and Biology, Yale University, New Haven, CT.
Long term memory for habituation in the tail-induced siphon withdrawal reflex (T-SWR) in Aphysia can be confined to one side of the body (Stopfer et al., 1991). This lateralization of memory is kely due to a bilaterally symmetric sensory system which mediates the T-SWR. Here we report that long term memory for habituation can also be lateralized in a reduced preparation that is amenable to a cellular analysis, and we provide a preliminary description of amenable to a cellular analysis, and we provide a preliminary description of some of the cellular components contributing to the T-SWR.

Preparations consisting of the tail and mantle organs connected to the CNS (n=13) first received baseline stimuli delivered via implanted electrodes in

the tail, and the duration of T-SWR was measured. Next, habituation training was delivered to one side of the tail: 4 blocks (90 min apart) of 30 stimuli each

was delivered to one side of the tail: 4 blocks (90 min apart) of 30 stimuli each (ISI=30 sec) were given. Bilateral tests were conducted (blind) 24 hr after training. Trained-side test scores were significantly decremented relative to their own pre-scores (p<0.01), whereas control-side scores were not. Thus, this preparation exhibits lateralized long term habituation like intact animals. As a first step in a cellular analysis we have characterized the responses of tail sensory neurons (SNs) in the pleural ganglia to the identical stimulus employed in behavioral studies. SNs respond to the tail stimulus with an action potential barrage equal in duration to the tail stimulus with an action potential barrage equal in duration to the tail stimulus (100msec). When tail stimuli were delivered at an ISI that habituates the T-SWR, there was no significant change in action potential number or latency. There was, however, a gradual increase in spike width. Motor neurons that receive monosynaptic EPSPs from SNs often fired to stimuli too weak to elicit responses in the SNs and often received input 50-75msec before the SNs, indicating the presence of an additional, lower-threshold, sensory pathway. We are currently examining long term changes in the tail SNs and their synaptic output, as well as the low-threshold pathway, following lateralized long term habituation.

LEARNED MODIFICATION OF HEAD WAVING BEHAVIOR IN APLYSIA WITH AVERSIVE REINFORCEMENT. K. Fitzgerald\*, C.A. Takacs and T.J. Carew. Depts. of Psychology and Biology, Yale University, New Haven, CT 06520. Head waving in Aplysia is a spontaneously occurring exploratory behavior consisting in part of alternating lateral flexions of the neck. Animals can learn to modify this behavior in response to stimuli such as light or food. We report here that Aplysia can also learn to modify the lateral component of head waving following presentation of local electric shock to one anterior tentacle (AT; the ATs are symmetric structures that project bilaterally from the head).

Animals were suspended in a seawater tank and their baseline head waving

behavior was monitored for 10 min. Next, during a 10 min training phase, a series of shocks was delivered to one of the ATs. In a subsequent 10 min test period, animals spent significantly less time flexing toward the side on which the AT had received shock (mean change 85±22 sec, p<.002, n=20).

We have begun to investigate the neural mechanism of this modulation by examining the effects of AT shock on identified central neurons. Cerebral examining the effects of A1 shock on identified central neutrons. Cerebral ganglion mechanoafferent sensory neurons (SNs), which innervate the ATs (Rosen et al., 1979), exhibited significant spike broadening in response to AT shock (p<.04, n=5). Furthermore, the effect of AT shock was side-specific: SNs spialteral to site of shock exhibited significantly greater broadening than contralateral SNs (30 s after shock, mean difference 31±2.2%, p<.0001, n=5). Since these SNs are likely to participate in the head withdrawal reflex, the modulation that we observe suggests that AT shock could, in addition to its effects on head waving behavior, produce side-specific sensitization of head

We are currently assessing the modulatory effects of AT shock on neural circuitry involved in head waving. For example, AT shock appears to inhibit pedal ganglion MNs that innervate the neck region. In addition, we are cploring the use of AT shock as an aversive reinforcer for operant conditioning of head waving behavior.

DISTRIBUTION OF APGWamide-LIKE AND FMRFamide-LIKE INMUNOREACTIVE NEURONS INNERVATING THE PENIS AND THE DART SAC IN MESOCEREBRUM OF THE SNAIL HELIX ASPERSA. G. Li and R. Chase. Dept. Biology, McGill Univ., Montreal, Quebec, H3A\_1B1, Canada.

The penis and the dart sac are innervated by the nervus penis (NP) and the nervus cutaneus pedalis primus dexter (NCPD), respectively. Electrophysiological evidence suggests that right mesocerebrum neurons are capable of commanding penis eversion and dart release. It is also known, from immunohistochemistry, that two major peptides in the mesocerebrum are APGWamide and FMRFamide. APGWamide-like immunoreactive substance was observed in the penis but not in the dart sac (Griffond et al.). We therefore hypothesized that mesocerebrum cells projecting to the penis contain APGWamide, while cells projecting to the dart sac contain FMRFamide.

A double-label study was conducted. The NP or the NCPD  $\,$ was backfilled with Neurobiotin, later conjugated with Rhodamine-Avidin. Tissue sections were immunoreacted with antisera for APGWamide or FMRFamide, later conjugated with FITC. Primary results indicate that the mesocerebrum neurons backfilled from NP may contain either APGWamideneurons backfilled from NP may contain either APCWamide—like peptide or FMRFamide—like peptide, and neurons backfilled from the NCPD may likewise contain either FRMRamide—like peptide or APGWamide—like peptide. A quantitative analysis using confocal laser scanning microscopy is in progress.

## 224.9

FUNCTIONAL UNCOUPLING OF CHOLINERGIC INHIBITORY INTERNEURONS PLAYS AN IMPORTANT ROLE IN SHORT-TERM SENSITIZATION OF APLYSIA GILL AND SIPHON WITHDRAWAL REFLEX (GSWR). L.-E. Trudeau\* and V.F. Castellucci. Lab. de Neurobiologie et Comportement. Inst. Rech. Clin. de Montréal, Montréal, (Québec), Canada. H2W 1R7.

Polysynaptic transmission between sensory and motor neurons of the neuronal network mediating the GSWR is important for the expression and plasticity of this simple behavior. We have investigated the importance of cholinergic inhibitory interneurons in this network. Central application of the nicotinic blocker d-tubocurarine (d-TC) (100  $\mu$ M) potentiates evoked gill contractions (422% increase, n = 5) and siphon nerve-evoked compound EPSPs recorded in motoneurons (189% increase, n = 10). Excitatory interneurons receive excitation followed by powerful inhibitory input upon siphon nerve stimulation. Application of d-TC blocks this rapid inhibition and prolongs the excitation (205% increase in area, n = 5). Heterosynaptic facilitation of compound EPSCs in motoneurons is reduced in preparations already disinhibited by pre-treatment with d-TC. Facilitation of sensory-motor synapses is however unaffected. These data indicate that (1) transmission through the GSW neuronal network is gated by a feedback inhibitory mechanism, and (2) a reduction of cholinergic inhibition onto excitatory interneurons may be a mechanism by which transmission within the GSW network is increased during various forms of learning such as sensitization. They also place new emphasis on the important role of inhibitory interneurons in determining the plastic properties of neuronal networks.

5-HYDROXYTRYPTOPHAN ELICITS SUSTAINED CPG ACTIVITY FOR RHYTHMIC SHELL MOVEMENTS IN LYMNAEA STAGNALIS. E.A. Kabotyanski, W. Winlow, D.A. Sakharov, L. Bauce and Ken Lukowiak. Neuroscience Research Group, University of Calgary, AB Canada T2N 4N1.

Knowledge regarding the intrinsic and network properties of neurons that form central pattern generators (CPG's) are critical to our understanding of the neural basis of rhythm generation. However, in many in vitro reduced preparations CPG's are strongly inhibited and thus unuseful. Here we report a method to obtain ongoing CPG activity in Lymnaea. The injection of 5 hydroxytryptophan (5HTP),  $100 \mu g/g$  after a 20-30 min delay induces stereotyped, rhythmic lengthwise shell movements. The effect persists for approximately 2h, and includes an increase of ciliary locomotion velocity as well as the suppression of defensive reflexes. Rhythms possessing similar characteristics were obtained in semi-isolated and isolated CNS preparations. Following 5HTP injection there is a dramatic increase both in serotonin levels (HPLC assay) of the CNS and in firing of pedal 5HTergic cells, that correlate well with the behavioural effects. The CPG responsible for rhythmic shell movements in Lymnaea appears to be 5HT dependent and the application of 5HTP is a useful tool to enable us to investigate further how this rhythm is generated. Supported by ESF and MRC (Canada).

RECOVERY OF TAIL MECHANOSENSORY FUNCTION IN APLYSIA FOLLOWING CRUSH OF NERVE P9. I. Steffensen and C.E. Morris\*, Loeb Institute (and Biology Dept.) University of Ottawa, OCH, Ottawa, Ontario, K1Y 4E9.

The tail withdrawal reflex in Aplysia is mediated by mechanosensory afferents carried in nerve P9. Using a combination of scanning electron microscopy and immunofluorescence against class III B-tubulin to follow the tail afferents, we concluded that a certain class of epidermal structures - tufts of cilia surrounded by microvilli - probably constitute the sensory terminals. If this interpretation is correct, crushing the nerve carrying the afferents should both abolish the tail withdrawal reflex and destroy the epidermal endings. Moreover, recovery of the reflex should coincide with regeneration of the epidermal endings. video-monitoring the post-crush recovery of the tail withdrawal reflex and following the status of the epidermal endings with the above morphological techniques. The two P9 nerves are crushed about 1.5 cm from the pedal ganglia through a single ~1 cm incision which is reclosed with a cyanoacrylate adhesive. Both locomotory functions (P9 also carries tail motor efferents) and the withdrawal response are abolished by this procedure; recovery is evident within 2-3 days. Supported by the NCE for Neural Regeneration, Canada.

## 224.10

INTERNEURONAL PLASTICITY CONTRIBUTES SIGNIFICANTLY TO ENHANCED MOTOR NEURON FIRING DURING SENSITIZATION OF THE APLYSIA SIPHON-WITHDRAWAL REFLEX. J.R. Lieb Jr.\* and W.N. Frost. Dept of Neurobiology & Anatomy, Univ of Texas Medical School, Houston Tx 77225.

Physiological studies have shown that four different circuit modifications

occur during sensitization of the Aplysia siphon-withdrawal reflex. How much each site contributes to the sensitized response is currently unclear because individual circuit modifications cannot be readily introduced or removed in physiological experiments. In an effort to explore the importance of these sites of plasticity in sensitization, we have constructed a realistic computer simulation of the siphon-withdrawal circuit, consisting of the LE sensory neurons, the L29, L30, and L34 interneurons, and the LFS motor neurons.

In this study, our goal was to evaluate the relative contribution of sensory neuron versus interneuron sites of plasticity. In sensitization, the sensory neuron synapses undergo presynaptic facilitation. Doubling these connections in the simulation produced an enhancement of both the phasic and longlasting components of the LFS motor neuron firing response to a simulated siphon stimulus. The increase in long-lasting LFS firing was due to increased interneuronal recruitment by the sensory neurons. Sensitization also involves a decrease in the L30-L29 and L30-L34 inhibitory synapses, and an increase in the L29-LFS excitatory synapse. Adding these interneuronal modifications to the simulation resulted in a further enhancement of both the phasic and long-lasting components of the LFS firing response. These results support the idea that the enhancement of siphon withdrawal seen in sensitization is due to the combined action of a distributed set of circuit modifications. While the interneuronal changes reinforce the sensory neuron facilitation, they may also have an additional, specialized role in biasing the sensitized response toward movements produced by LFS neurons, rather than other types of motor neurons.

INTRACELLULAR AND PATCH-CLAMP RECORDING IN THE NEMATODE C. ELEGANS. S. R. Lockery\*, C. M. Loer and T. J. Sejnowski. Computational Neurobiology Lab., Salk Institute, La Jolla, CA 92186.

Although a complete anatomical circuit is available for the nematode C. elegans, further progress in understanding the neuronal basis of behavior has been hampered by the inability to make electrophysiological recordings. Using quartz sharp electrodes and conventional patch pipettes, we explored the feasibility of recording from identified muscles and neurons in C. elegans. Worms were affixed to coverslips, maintained in Ascaris saline, and observed using an inverted microscope with Nomarski optics. Quartz electrodes driven through the cuticle lost 50% of their initial resistance but remained sharp. Dye fills (Lucifer Yellow) of a number of cells were obtained including an amphid sheath cell, individual body muscles, and pharyngeal muscle cells. In some preparations, pharyngeal muscles were dye coupled, while in others they were not. Pharyngeal contractions could sometimes be produced by passing depolarizing current. To facilitate patch recording, cells were exposed by making a slit in the cuticle over the nerve ring. Cells were pludged to be neurons on the basis of size, appearance of the nucleus, and presence of one or two processes. As previously shown by D. Raizen and L. Avery (personal communication), gigaohm seals (5-20 G) could readily be formed and single channel currents observed. Seals were stable and lasted over an hour. Thus, it is likely that sharp electrodes can be used to record from muscles and whole-cell recordings can be used to study the intrinsic properties of neurons in C. elegans.

### 224.13

LASER ABLATION OF CIRUIT ELEMENTS IN C. ELEGANS. S.R. Wicks\* and C.H. Rankin. Department of Psychology, University of British Columbia, Vancouver, B.C., Canada. V6T 1Z4.

The nematode C. elegans exhibits a broad behavioral repertoire despite possession of rather limited nervous system. The anatomical connectivity of all 302 neurons in the nematode nervous system has been described at the synaptic level by serial section electron microscopy (White et al. 1986). Furthermore, a specific subcircuit of 85 neurons—the touch withdrawal circuit—has been shown to underlie the worm's response to touch (Chalfie et al. 1985). In response to a vibration, the worm will react by either accelerating or reversing. This response has been termed the tap withdrawal reflex and is potentially a more sensitive measure of sensorimotor integration than response to touch. The neural bases of this behavior were investigated by circuit analysis.

In these studies we attempted to define the functional role of each of the neurons in the circuit by systematically laser ablating these identified cells. The response of these worms to tap then was assessed. To determine the function of a cell, in some worms the cell of interest was killed and the effect of its loss on the behavior was assessed; in other worms the cell of interest was left intact but cells in all alternative pathways were killed. An example of our results is that, in the intact circuit, the head-touch cells (ALMs) are required for the reversal response to tap. In the absence of the head-touch cells, the tail-touch cells mediate an acceleration response to tap.

## 224.15

THE RELATIONSHIP BETWEEN DISHABITUATION AND HABITUATION IN C. ELEGANS. C.D.O. Beck\*, B.S. Broster and C.H. Rankin. Department of Psychology, University of British Columbia, Vancouver, B.C., Canada, V6T 1Z4.

Dishabituation is the facilitation of a previously habituated response. It is not clear whether the mechanism underlying dishabituation reverses the process underlying habituation or whether dishabituation is a separate facilitatory process superimposed on habituation. To investigate the relationship between habituation and dishabituation we compared dishabituation to another process that alleviates habituation, ie. spontaneous recovery.

In one set of experiments we habituated the tap withdrawal response in C. elegans at either a 10 s or 60 s interstimulus interval and dishabituated half of the animals with a 60 V shock. When we compared the recovery following dishabituation to normal recovery we found that at a 10 s ISI dishabituation produced a transient increase in recovery, whereas at a 60 s ISI dishabituation resulted in a consistent and longer lasting advantage. In another set of experiments, again using a 10 and 60 s ISI we examined differences in rehabituation between animals dishabituated, or allowed to recover. The dishabituation group rehabituated slightly faster with a 10 s ISI, but was no different from the recovery group with a 60 s ISI. The extent to which dishabituation is similar to recovery seems to vary with ISI, which may be a reflection of ISI dependent differences in the interplay of mechanisms underlying habituation and dishabituation.

#### 994 19

ISOLATION OF LEARNING SPECIFIC MUTANTS IN CAENORHABDITIS ELEGANS. N. Kumar\*, J.Y.M. Wen, G.Morrison, J. Parker and D. van der Kooy, Neurobiology Research Group, Dept. of Anatomy, University of Toronto, Toronto, Ontario, M5S 148.

The nematode Caenorhabditis elegans is an ideal model system in the search for the molecular and cellular basis for associative learning and memory because of its well characterized genetics, neuroanatomy and development. Using C. elegans we developed a classical conditioning paradigm in order to search for learning impaired mutant lines. The assay utilizes the chemotaxic responses to the conditioning stimuli (CS) Na+ (Na CH3COO) and Cl- (NH4Cl), and to E. coli (a food source) as an unconditioned stimulus (US). The animals were conditioned by presenting one of the CS ions (CS+) paired with the US followed by an exposure to the other CS ion (CS-) in the absence of the US. Testing consisted of placing approximately 100 of the conditioned animals between point gradients of each CS (in the absence of the US) and allowing them to migrate towards one of the gradient centers. CS levels on testing were balanced such that naive animals displayed equal preferences for either CS ion. Conditioned animals showed a significant preference for the CS+ ion that previously predicted the presence of food

predicted the presence of food.

Wild type animals were mutagenized using the chemical mutagen EMS and then F2 animals were segregated into clonal lines (C. elegans is a hermaphrodite). These lines were then assayed for classical conditioning using the procedure described above. To date we have isolated 2 mutant lines of animals that, following conditioning, display only the naive preferences for the CS+ and CS- ions. However, these mutant animals seem to possess normal sensory and motor functions. When the unconditioned preferences for either of the CS ions or for the US are tested in accumulation assays, mutant animals display normal preferences compared to wild type controls. Thus, the 2 lines of mutant worms may be specifically impaired in their ability to make associations between the CS+ and the US.

#### 224.14

HABITUATION OF TWO REFLEXES MEDIATED BY A SINGLE CIRCUIT IN C. ELECANS. C.H. Rankin\*, B.D.G. Hartnett and S.R. Wicks, Department of Psychology, University of British Columbia, Vancouver, B.C., Canada. V6T 124.

An important question in the analysis of the neural substrates of habituation is whether response decrement is due to habituation of a single cell or at several cells within an identified circuit. C. elegans offers both a clearly defined behavior and an experimentally tractable nervous system to investigate this question. In this worm, the tap withdrawal circuit consists of two interconnected subcircuits, head-touch induced backward movement and tail-touch induced forward movement. Although both subcircuits are activated by tap, backward movement is the predominant response of wild-type worms. Using laser ablation techniques and mutants lacking specific cells in the circuit we manipulated input to the tap withdrawal circuit by removing either the head-touch or the tail-touch receptors. We then compared the dynamics of the habituation of accelerations produced in the absence of headtouch receptor input with those of the reversals produced in the absence of tail-touch receptor input. A comparison of these curves with the habituation dynamics of control animals allowed an assessment of the role of each of the subcircuits in habituation in the intact animal. We found that worms lacking functional tail-touch receptors habituate more slowly and to a lesser degree than control worms. Our results suggest that habituation of the tap withdrawal response in C. elegans occurs in at least two cells.

## 224.16

AN EXPLORATION OF LONG-TERM MEMORY IN C. ELEGANS. T. M. Marion\*, C. D. O. Beck, and C. H. Rankin, Dept. of Psychology, Univ. of British Columbia, Vancouver, BC V6T 1Z4.

The nematode Caenorhabditis elegans may be used as a simple systems model of the dynamics of memory. C. elegans is capable of long-term retention (over 24 hrs) of habituation training with vibrational stimuli at a 10 s interstimulus interval (ISI) (Rankin et al., 1990). We investigated the dynamics of long-term habituation by varying ISI, number of stimuli and training schedule. The stimulus used was a train of six taps (8.5 Hz, delivered to the plate holding the worm) shown in previous experiments to evoke the reversal response (swimming backward for a short distance) in experimentally naive animals. Worms received habituation training (60 s ISI): a) 40 stimuli (Massed training), b) four 10 stimuli blocks separated by 60 min. (Distributed training), c) 10 stimuli, and d) a single stimulus. All worms received 10 stimuli on day 2 (at least 24 hrs later) as a test of retention of habituation training. A preliminary analysis of the data suggests that both massed and distributed training with 40 stimuli or one stimulus did not. Further research will explore the effects of retention interval, interstimulus interval, and context on long-term memory.

PRESENTATION OF THE STIMULI PREVIOUSLY ASSOCIATED WITH SOCIAL STRESS, INCREASE THE EXPRESSION OF THE CFOS ONCOGENE. C.A.Cohen\* T.S. Zaccheo, K.A. Miczek, and R.M. Kream. Department of Psychology, Tufts University, Research Building, 490 Boston Ave., Medford, MA 02155, Department of Anesthesiology, Tufts University School of Medicine, 136 Harrison Ave., Boston MA 02111 and the Department of Electrical Engineering, Tufts University, Halligan Hall, Medford, MA 02155.

Previously, we have reported that exposure to social stress increases cFos gene expression peaked at one hour after the stress and the density of met-enkephalin stained fibers peaked at three hours after stress in the periaqueductal gray region of the brainstem. In the current experiment, the time course was extended to 24 hours post-stress and in addition we were interested in assessing the effect of re-exposure of the intruder to the salient stimuli associated with the original encounter, but physical contact with the resident did not occur. An intruder male rat was placed into the home cage of a resident and subsequently exposed to attack and threat. Once the animal showed unambiguous signs of submission, the intruder was placed into a protective cage for one hour while being exposed to attack and threat. Once the animal showed unambiguous signs of submission, the intruder was placed into a protective cage for one hour while being exposed to the threat of an attack. No physical harm could come to the intruder at this time. The intruders were perfused with saline followed by 4% paraformaldehyde, at various time intervals after the initial social stress experience or re-exposure to the salient stimuli associated with the stressful encounter. The brains were removed and placed in fixative for two hours followed by a solution of 20% sucrose and 0.1M phosphate buffer where they remained until sectioning. The control animals were handled in the same manner as mentioned above. All brains were sectioned (32 µm) and prepared for immunohistochemistry using antibodies for Fos and met-enkephalin. Preliminary data suggest that re-exposure to the relevant stimuli associated with the social stress experience is sufficient to increase Fos expression in the brainstem 24 hours after the encounter. These changes are being monitored via radioimmunoassay and molecular biological techniques.

SELECTIVE INDUCTION OF FOS RELATED ANTIGENS FOLLOWING THE INITIATION OF SOUND STRESS R.P. Dilts\* and M.C. Boadle-Biber, Dept. of Physiology, Medical Coll. of Virginia/VCU, Richmond, VA 23298-0551

The immediate early gene products FOS and FOS related antigens (FRA) have been proposed as an index of cellular activity within the CNS (Sagar and Sharp, Science; 1988). In an attempt to delineate the neuronal circuitry involved with the activation of serotoninergic neurons within the dorsal raphe following sound stress, FRA immunoreactivity (FRA-IR) was localized. At 0.5, 1 and 2 hours following the initiation of sound stress, rats were anesthetized with equithesin and perfused with 4% buffered paraformaldehyde. Rats placed in sound chambers but not exposed to sound stress served as controls. Frozen sections were processed to detect FRA-IR nuclei using DAB/imidazole reaction product with strepavidin labelled peroxidase (Jackson Immuno Research, West Grove, PA). Five antibodies which recognize different epitopes within FOS proteins have been utilized, each yielding a different distribution of FRA-IR. FRA antisera (1:5,000) directed towards the conserved M2 sequence (amino acids 127-152) in FOS, a gift from M. Iadorola, produced the greatest number of labelled nuclei. Regions in which sound stress produced more FRA-IR nuclei than controls included: the region of the B7 serotonin neurons within the dorsal raphe and surrounding central gray, the central and basolateral nuclei of the amygdala, the lateral habenula and the ventral subiculum as well as the entorhinal cortex within the hippocampal complex. Numerous neurons were found within the hypothalamus which did not appear to be restricted to cytoarchitectural boundaries. Regions with FRA-IR nuclei within the hypothalamus included the lateral hypothalamus, cona incerta, the anterior paraventricular area (magnocellular and parvocellular), arcuate nucleus and medial preoptic area. This data suggest that FRA are differentially expressed within selected nuclei following exposure to sound stress and provide a useful index to identify neuronal populations involved with the activation of the ascending serotoninergic system. EVIDENCE FOR THE ACTIVATION OF ASCENDING SEROTONINERGIC SYSTEMS DURING SOUND STRESS IN RATS M.C. Boadle-Biber\*, T. Phan and R.P. Dilts Medical Coll. of Virginia/VCU, Richmond, VA 23298-0551

Tryptophan Hydroxylase (TrpH) is the rate-limiting enzyme in serotonin (5-HT) biosynthesis, requiring tryptophan, free oxygen and tetrahydrobiopterin co-factor to produce 5-hydroxytryptophan (5-HTP). Sound stress increases 5-HT turnover as measured by the ratio of the metabolite 5-HIAA to 5-HT as well as TrpH activity measured ex vivo. The purpose of these studies was to determine whether sound stress enhances 5-HTP accumulation in vivo. Rats (200-300g) were weighed, given an injection (I.P.) of saline, gepirone (10mg/kg) or tryptophan (100mg/kg) and placed in a sound stress chamber in groups of 4 animals. After 1 hour of sound stress, rats were given the decarboxylase inhibitor NSD-1015 (m-hydroxybenzylhydrazine, 200mg/kg I.P.) and sacrificed 30 minutes later. Brains were dissected and the midbrain, hippocampus, caudate and cortex frozen on dry ice. 5-HTP, as well as tryptophan, 5-HT and 5-HIAA were measured using HPLC-EC. Results were analyzed using ANOVA (p< 0.01) and means subsequently compared using Newman-Keul's test. Sound stress significantly increased 5-HTP in the midbrains and hippocampus (F<sub>3,12</sub> = 13.04 & 11.59: 703.4 ± 29.4 & 261.4 ± 26.9 ng/g, wet wt. ± S.E.M., respectively) compared with non-stressed controls (423.5 ± 84.1 & 157.1 ± 12.9). Gepirone, a 5-HT1a agonist, blocked the increase in 5-HTP and had no effect on non-stressed controls (401.2 ± 43.5 & 132.4 ± 10.6). Preliminary results indicate that tryptophan loading 1-hour before the administration of NSD-1015 increases 5-HTP, 5-HT and 5-HIAA. However, sound stress with tryptophan loading further increases 5-HTP accumulation. These results support the hypothesis that sound stress increases TrpH activity in vivo and provides further support for the activation of serotoninergic neurons during sound stress. NIH Grant NS14090 to M.C.B<sup>2</sup>.

#### 225.2

INDUCTION OF C-FOS mRNA IN THE BRAIN AND ANTERIOR PITUITARY GLAND OF THE RAT FOLLOWING INTRODUCTION TO A NOVEL ENVIRONMENT. R.J. Handa' and K.R. Nunley Dept. of Cell Biol., Neurobiol., and Anat. Loyola Univ., Stritch School of Medicine, Maywood, IL

To determine some of the rapid genomic changes which can occur following novelty stress, we examined the induction of cFOS mRNA in the brain and anterior pituitary gland following the introduction to a novel open field (OF) environment. Adult male Fischer 344 rats (Harlan Inc., Indianapolis IN) were placed into the OF (48"x48") for 20 minutes. Rats were sacrificed following removal from the OF, or were returned to their home cage and sacrificed 30, 45. or 60 min. later. Control rats were sacrificed immediately upon initial removal from their home cage. Brains were frozen in isopentane for subsequent analysis by In Situ Hybridization (ISH) histochemistry, or dissected and homogenized in GITC to obtain total RNA for analysis by Northern blot hybridization. C-FOS mRNA was examined using a radiolabelled oligonucleotide probe complementary to nucleotides 138-185 of rat c-FOS mRNA. Northern blot hybridization of total RNA showed hybridization to a single 2.3 Kb species of mRNA. C-FOS mRNA was low or absent in all brain areas examined from home cage animals. Following the introduction to the open field, large increases in cFOS mRNA were detected in the medial frontal cortex, piriform cortex and hippocampus with greatest levels achieved 30 min after removal from the open field. In the anterior pituitary gland, cFOS was highest after 20min in the open field and declined The timecourse c-FOS induction in the ant. pituitary correlates well with rapidly. The three-one-core mount in the ani. producty correctes were winted the ACTH secretory response to novelty stress. Additional areas of GFOS induction, as demonstrated by ISH were the paraventricular n., septohypothalamic n., anteroventral preoptic n. and layers 2,3 and 5 of the parietal and cingulate cortex. These data demonstrate some of the brain areas which are undergoing rapid genomic activation following behavioral paradigms such as the introduction to the open field environment. NSF BNS9109226

STRESS INDUCED c-FOS PROTEIN IN THE BRAIN: TEMPORAL-SPATIAL PATTERNING. L. Weimore\*, W. Wan and D.M. Nance. Departments of Physiology and Pathology, Univ. of Manitoba, Winnipeg, MB., R3E 0W3, Canada.

The c-fos oncogene protein was used as an indicator of neuronal activation following exposure of adult male S/D rats to intermittent footshock. Animals were given scrambled footshock (1.6mA) on a variable interval schedule (ITI=3.5min) for 60 min. Each 5 sec shock was preceeded by a 15 sec warning tone which terminated with shock onset. Rats were sacrificed and the brains removed at 0, 2, 6, 12 and 24 hours post shock. Alternate sections were processed for c-fos protein immuno-reactivity (Oncogene Sci) using the PAP technique. The expression was found to be both temporally dependent and regionally specific. Relative to controls, elevated levels of c-fos protein were detected at 0 (maximal) and 2 hours (moderate) post shock, but declined and remained at basal levels at the 6, 12 and 24 hr intervals. In all animals, significantly elevated c-fos expression was detected in the intermediate and ventral divisions of the lateral septal area(LSA), bed nucleus of the stria terminalis, prooptic area(POA), paraventricular nucleus of the hypothalamus, amygdala, locus coeruleus, A1 and A2 cell groups of the brainstem. Other hypothalamic and limbic regions exhibited increased c-fos expression of a more variable nature. Additional experiments were performed to determine the duration of footshock exposure required to induce these changes in c-fos expression. Following 15 minutes of shock, increases in c-fos protein was detected in all brain regions examined except for the A1 and A2 cell groups. The data indicate that c-fos expressions is transient and occurs in distinct neuronal regions which actually constitute a highly interconnected neuronal circuitry involved in an animals adaptive response to a stressor. Given the limbic system involvement in this response and its previous association with psychological phenomenon, future studies will determine the conditionability of stress induced c-fos expression. Additionally, the neurochemical specificities of neurons induced to express c-fos by footshock will be determined. Supporte

NMDA LESION OF AMYGDALA BLOCKS PSYCHOLOGICAL STRESSSR-INDUCED ACTIVATION OF PREFRONTAL DOPAMINE AND SEROTONIN SYSTEMS: A BEHA VIORAL, NEUROHUMORAL, AND NEUROCHEMICAL STUDY OF CONDITIONED FEAR IN THE RAT L.E.Goldstein. A.M.Rasmusson. B.S.Bunney. R.H.Roth\*, Yale University School of Medicine. New Haven. CT. 06510

L.E. Goldstein, A.M.Rasmusson, B.S. Bunney, R.H.Roth\*, Yale University School of Medicine, New Haven, CT 06510.

We have characterized a model of fear conditioning in the rat. Prior to conditioning, male Srague-Dawley rats were bilaterally lesioned with N-methyl-D-aspartate (NMDA); saline was used as control. Lesion and control injections were aimed at the basolateral-central nuclei of the amygdala. After recovery, all animals were tested in our conditioned fear model during the dark phase. On Day 1, the rat is placed in the testing environment for a 30 min nabituation phase (PR1). This period is immediately followed by a 30 min conditioning period (PR2) in which 10 pairings of a 5 sec non-startle eliciting white noise tone and a co-terminating 0.5 sec 0.4 mA footshock are delivered. On Day 2, the rat is reexposed to the testing chamber and presented with ten tones over another 30 minute period (PR3). Rats are sacrificed immediately after PR3 and the brain dissected for neurochemical analysis of tissue dopamine (DA), serotonin (5HT), and metabolite levels by HPLC-ED. Animal behaviors are remotely coded for locomotion, grooming, defecation, freezing, and ultrasonic vocalization (UV). Previous studies using this model have shown that these parameters are under strong stimulus control. NMDA lesion of the amygdala blocked the conditioned metabolic activation of both DA and 5HT in the prefrontal cortex, serum corticosterone elevation, and UV. In addition, PR3 freezing behavior was dramatically suppressed. Other lesion abnomabilities include hyperkinesis and failure to retrieve a gauze pad placed on top of the home cage (stimulus-response uncoupling). These data suggest that the amygdala plays a role in (1) the metabolic activation of the prefrontal DA and 5HT systems and (2) the coordination of such behaviors as ultrasonic vocalization and freezing in reponse to a psychological stressor. SEROTONERGIC AGONISTS ENHANCED LONG-TERM EFFECTS

SEROTONERGIC AGONISTS ENHANCED LONG-TERM EFFECTS OF STRESS ON BEHAVIOR IN THE RAT. E. Grauer\*, Y. Kapon, E. Segev and B.A. Weissman. Israel Inst. Biol. Res., Ness-Ziona, Israel.

Prior exposure to stress affects performance in various tests, especially in those associated with aversively motivated behavior. One interpretation of this phenomena assumes that anxiety generated by stress generalizes to impair other behaviors. Evidence of serotonergic (5-HT) involvement in anxiety suggest that the phenomena may be modulated by 5-HT agonists. (5-HT) involvement in anxiety suggest that the phenomena may be modulated by 5-HT agonists. Rats exposed to 2 hrs of immobilization and cold stress were tested 24 hrs later for changes in an open field activity. Stress alone had no effect on this behavior. At doses that had no overt effect on the behavior of naive animals, buspirone (5 mg/kg, ip) and 8-OH-DPAT (0.25 mg/kg, ip) significantly reduced open field activity of animals with prior exposure to stress. Since the behavioral impairment was detected 24 hrs following stress exposure, 5-HTIA receptors were characterized at that time by equilibrium binding study of [3H]8-OH-DPAT in 5-HTIA receptors were characterized at that time by equilibrium binding study of [3H]8-OH-DPAT in the forebrain. An increase in the density of binding sites observed in stressed animals may account for their behavioral suppression. This atypical behavioral profile is in accord with human data suggesting initial anxiogenic activity of buspiron.

CHRONIC STRESS ALTERS DENDRITIC MORPHOLOGY OF HIPPOCAMPAL NEURONS IN THE RAT Bruce S. McEwen\*, Yoshifumi Watanabe, Elizabeth Gould, and Heather A. Cameron Lab. of Neuroendocrinology, Rockefeller University, 1230 York Ave., N.Y., N.Y. 10021

Elevated levels of circulating glucocorticoids for 3 weeks decrease the number of dendritic branch points and the length of dendrites of CA3 pyramidal cells (Woolley et al., <u>Brain Res.</u>, 1990); and 3 months of treatment with excess glucocorticoids reduce pyramidal cell number in this region (Sapolsky et al. J.Neurosci. 1985). In order to determine whether chronic stress results in similar changes in rat hippocampal neurons, we performed a morphological analysis of Golgi-impregnated hippocampal neurons on the brains of unstressed control rats and rats subjected to short term (7 day) and chronic (21 day) restraint stress. Adult male Sprague Dawley rats were assigned to one of the following groups: 1) 7 days of 6 hours per day stress in wire mesh restrainers, 2) short term unstressed hours per day stress in wire mesh restrainers, 2) short term unstressed controls, 3) 21 days of 6 hours per day stress in wire mesh restrainers, or 4) chronic unstressed controls. The rats were perfused and the brains were processed for single-section Golgi impregnation as previously described (Woolley et al., 1990). Chronic stress resulted in significant decreases in the number of dendritic branch points and the length of dendrites in the apical dendritic tree in the CA3 pyramidal neurons; no significant differences were noted in the basal dendritic tree of rats subjected to chronic stress. No changes in the apical or basal dendritic trees of CA3 pyramidal cells were observed with 7d restraint stress. Whether these decreases in the number of dendritic branch points and the length of dendrites lead to cell death remains to be determined. Supported by MH41256 and The Health Foundation.

STRESS ALTERS THE NONLINEAR RESPONSE CHARACTERISTICS OF HIPPOCAMPAL DENTATE GRANULE CELLS IN THE ANESTHETIZED RAT. M.J. Mana, M.J. Zigmond, and T.W. Berger. Depts. of Behavioral Neuroscience and Psychiatry, Univ. Pittsburgh, Pgh, PA 15260; Dept. of Biomed. Eng. and NIBS Program, Univ. of Southern California, Los Angeles, CA.

Chronic stress elevates norepinephrine (NE) synthesis and release in the hippocampus. However, the effect of these changes on the electrophysiological activity of hippocampal neurons is unknown. We used nonlinear systems analytic procedures to study the effect of chronic cold stress on the dynamics of dentate granule cell responses to perforant path stimulation. A train of impulses with random (Poisson) interimpulse intervals (ISI; mean frequency = 2 Hz) was used as the input. First, second, and third order kernels describing the relationship between ISIs and the amplitude of evoked granule cell population spikes were computed.

The average population spike amplitude for all impulses in a train (first order kernel) was not significantly altered in stressed rats. However, chronic stress did alter second order nonlinearities, which reflect the influence of any preceding impulse on the response to the most current impulse as a function of ISI. In unstressed rats, granule cell responses were inhibited for ISI = 0-50 ms, but 0-70 ms in stressed rats. In unstressed rats, facilitation occurred for ISI = 50-300 ms (maximum = 105% of first order kernel; ISI = 90 ms), whereas stressed rats displayed facilitation for ISI = 70-200 ms (maximum = 65% at ISI = 110 ms). And in unstressed rats, suppression occurred for ISI = 300-400 ms, whereas stressed rats displayed suppression for 200-400 ms and 500-700 ms. Stress also changed third order nonlinearities, which reflect the influence of any two preceding impulses that is not described by the lower order kernels. Interestingly, the  $\alpha$ -2 antagonist yohimbine (4 mg/kg, ip), which increases hippocampal NE, partially reversed the stress-related changes in second and third order nonlinearities--suggesting that these changes reflect a decrease in basal NE modulation of hippocampal excitability. Supported by MH43947, MH00343, AFOSR, ONR, & MRC of Canada (MJM).

I HE EFFECT OF INESCAPABLE SHOCK ON SHUTTLE-BOX ESCAPE PERFORMANCE, CONDITIONED FEAR, AND ANXIETY IN RATS WITH LESIONS OF THE DORSAL RAPHE NUCLEUS OR CENTRAL NUCLEUS OF THE AMYGDALA. R. E. Grahn\*, B.A. Kalman, L. Sutton, L.H. Silbert, E.P. Wiertelak, L.R. Watkins, and S.F. Maier. Dept. of Psychology, University of Colorado, Boulder, CO 80302. THE FFFECT OF INESCAPARIJE SHOCK ON SHUTTLE-BOX

Exposure to inescapable shock (IS) produces behavioral sequelae Exposure to inescapable shock (IS) produces behavioral sequelae including poor escape performance, enhanced conditioning of fear and anxiety. We investigated the role of the dorsal raphe nucleus (DRN) and central nucleus of the amygdala (CeA) in producing these phenomena. Sprague-Dawley rats were restrained or given IS one week after receiving electrolytic lesion of either the DRN, the CeA, or sham surgery. Subjects were tested 24 hr after restraint or IS in a shuttle-box escape task. This session began with a 10 min period during which baseline freezing was measured. Freezing is defined as a complete absence of movement except for that required for respiration and is considered to be a measure of fear conditioned to the contextual cues present in the shuttle-box (Fanselow & for that required for respiration and is considered to be a measure of fear conditioned to the contextual cues present in the shuttle-box (Fanselow & Lester, 1988). Rats were then exposed to a single shock and freezing was measured for 20 min. Escape from shock in the shuttle-box was subsequently measured. Four days after escape testing subjects were observed on a elevated plus maze for five min. Lesions of the DRN, but not the CeA, eliminated the interference with escape learning that is normally produced by IS. In addition, DRN and CeA lesions reduced freezing behavior, both before and after footshock. Both also reduced anxiety as measured by performance on an elevated plus maze. These findings support a recently proposed hypothesis (Maier, 1992) concerning the role of the DRN and CeA in mediating the effects of exposure to uncontrollable stressors. Current studies address the role of stressor controllability and serotonergic pathways that originate from the DRN.

EFFECTS OF CORTICOSTERONE & STRESS ON SPATIAL LEARNING, HIPPOCAMPAL PLASTICITY & NEURON LOSS. S.R. Bodnoff<sup>1,2\*</sup>, A. Humphreys<sup>3</sup>, G.M. Rose<sup>3,4</sup> & M.J. Meaney<sup>2</sup>.

Concordia Univ. & <sup>2</sup>Douglas Hospital Research Centre, McGill Univ., Montreal, Canada, 'Dept. of Pharmacology, UCHSC & 'Medical Research Service, VAMC, Denver, CO, U.S.A.

We have previously demonstrated that chronic exposure to elevated levels of corticosterone (CORT) in mid-aged rats impairs acquisition in a spatial learning task (Bodnoff et al., Neuroscience Abst., 1991). The present studies examined CORT effects upon spatial learning under 2 conditions: (i) long-term pellet implants & (ii) chronic social stress. The pellets produced stable levels of CORT for 3 months (medium dose: 10-15 ug/dl; high dose: 25-30 ug/dl). High-dose rats demonstrated significantly slower acquisition in the Morris swim maze relative to the medium dose and controls. We also studied rats living in a stressful environment (mixed-sex housing in which males were rotated twice weekly), a manipulation which increased a.m. CORT levels approximately 3-fold relative to controls. After 6 months, a subtle but significant acquisition impairment was seen in the stressed rats. Moreover, this deficit was absent in stressed rats that were adrenalectomized and given low CORT replacement. These behavioral impairments will be discussed in the context of markers of synaptic plasticity and hippocampal neuron loss.

## 225.12

LESIONS OF THE FASCICULUS RETROFLEXUS (FR) PRODUCE A DEFICIT IN SPONTANEOUS ALTERNATION BEHAVIOR.

A. DiCamilio. M. Murray. and F. Haun\*. Dept. of Anatomy & Neurobiology, Medical College of Pennsylvania, Philadelphia, 19129.

In investigating the functions of the habenula-interpeduncular (Hb-IPN) system, we have found that removing the Hb input to the IPN by making bilateral FR lesions produces a chronic elevation in circulating levels of stress bilateral FR lesions produces a chronic elevation in circulating levels of stress hormones in adult rats. We tested whether a spontaneous behavior of these animals, a tendency to explore alternate arms of a T-maze, might also be affected. Adult female rats meeting a 70% criterion of spontaneous alternation (SA) between two reinforced arms of a T-maze, first trial forced) received either sham lesions, bilateral (BL), or unilateral (UL) lesions of the FR. The sham group (n=6) alternated at a mean rate of 77.3% pre-operatively and 80.7% post-operatively. In contrast, both types of FR lesion significantly decreased post-operative SA to chance levels: SA rate was reduced from 77.8% to 57.3% in the BL group (n=6) and from 86.6% to 56.5% in the UL group (n=6). This elimination of spontaneous alternation was accompanied by the post-operative appearance of a response (side) bias, although the direction of the bias (left or right arm of the maze preferred) was not predictable by the side of the unilateral lesion. These results demonstrate that FR lesions alter a spontaneous behavior in a way that previously has been associated with hippocampal or thalamic damage. We suggest that a deficit in spontaneous alternation may reflect a stress-induced change in exploration strategy. Supported by NiH grants NS28856 (FH) and NS16556 (MM).

ATTENUATION OF ENDOCRINE AND BEHAVIORAL RESPONSES TO SOCIAL CONFLICT STRESS IN RATS BY MICROINIECTION OF CYTOTOXIC ANTIBODY TO CORTICOTROPIN RELEASING FACTOR AND RICIN A CHAIN TOXIN WITHIN THE PARAVENTRICULAR NUCLEI. E. Menzaghi, S.C. Heinrichs, E. Merlo Pich, F.J.H. Tilders and G.F. Koob. Torrey Pines Rd., La Jolla CA 92037 and Department of Pharmacology, Free University, 1081 BT Amsterdam, The Netherlands.

Previous work has demonstrated that non-linked cellular toxins (Ricin A chain and monensin) added to a cytotoxic IgG2a monoclonal antibody to Corticotropin Releasing Factor (CRF-MAb) specifically affect some CRF neurons after central injection into the hypothalamic paraventricular nuclei (PVN). Since the CRF neurons of the PVN are involved in mediating the endocrine responses to stress, we attempted here to evaluate the long-term effects of CRF-MAb/toxins injection in the PVN on behavioral and endocrine reactivity to a social stressor. Social interaction stress was induced in naive intruder rat by brief social defeat and non-injurious exposure in the home cage territory of an aggressive resident rat. Social defeat produces a specific CRF-dependent release of plasma ACTH and an increase in emotionality of the intruder rat measured with the Elevated Plus-Maze. Two weeks after bilateral intra-PVN injection of CRF-MAb/toxins intruder rats were exposed for twenty minutes to resident animals. CRF-MAb/toxins caused a significant 63% reduction of the ACTH release induced by the resident/intruder interaction and blocked the anxiogenic effect of stress on open arms exploration in the Elevated Plus-Maze. These data point to the possible involvment of CRF neurons within the PVN in mediating not only the endocrine responses but also some behavioral responses to social interaction stress in the rat. The intracerebral microinjection of CRF-MAb/toxins may prove to be a valuable tool for dissecting the contribution of CRF neurons to the pattern of stress responses (Research grant NIADDK Am 26741 to G.F. Koob).

## 225.15

Corticotropin Releasing Factor (CRF) Injected in Region of the Central Nucleus of the Amygdala (CNA) Increases Tryptophan Hydroxylase (TrpH) Activity and 5-HTP Accumulation but not Serotonin Turnover. K.C. Corley\*, R. Dilts, T-H. Phan and M.C. Boadle-Biber. Dept. Physiol., Va Commonwealth University, Richmond, VA 23298. TrpH is the rate-limiting enzyme in 5-HT synthesis that converts

TrpH is the rate-limiting enzyme in 5-HT synthesis that converts tryptophan to 5-HTP. An acute, 1-h exposure to sound stress (SS) produces ex vivo an increase in TrpH activity (Brain Res., 482: 306, 1989) which can be mimicked by intracranial injection of CRF into the region of the CNA (Neurochem, Int., 20, 81, 1992). However, unlike SS, CRF does not increase tissue levels of 5-HIAA or the ratio of 5-HIAA/5-HT, both indices of enhanced 5-HT turnover. The present study was undertaken to determine if intracranial injections of CRF enhance the in vivo conversion of tryptophan to 5-HTP, as found for SS (Soc. Neurosci, Abstr., 1992). CRF (0.5 µg per side) or vehicle via bilateral guide cannulae implanted 7-10 days earlier under surgical anesthesia was injected into the region of the CNA of rats, and 15 min later they were given a decarboxylase inhibitor (NSD 1015, 200 mg/kg i.p.). The accumulation of 5-HTP over a 30 min period was later assayed in the cortex and midbrain by HPLC-EC. Compared with vehicle controls, significant (P < 0.01) increases of 5-HTP were found [cortex: 119.6 ± 0.5 vs. 202.5 ± 3.7 ng 5-HTP/g ± SEM; t(3) = 17.2; midbrain: 338.4 ± 3.4 vs 684.8 ± 49.9 ng 5-HTP/g ± SEM; t(4) = 6.9]. Questions remain as to how to explain the failure of CRF to mimic the increased 5-HT turnover produced by SS. However, both the enhanced accumulation of 5-HTP in vivo and the increased TrpH activity ex vivo in response to CRF resemble that of SS and suggest common neural events. Supported by NIH Grant NS14090 to MCB-B.

## 225.17

STRESS-INDUCED RELEASE OF CORTICOTROPIN RELEASING FACTOR IN THE AMYGDALA MEASURED BY IN VIVO MICRODIALYSIS, E. Merlo Pich\*, G.F. Koob, S.C. Sattler, F. Menzaghi, M. Heilig, S.C. Heinrichs, <sup>1</sup>W. Vale and F. Weiss. <sup>1</sup>The Salk Institute, and Department of Neuropharmacology, Scripps Research Institute, 10666 N. Torrey Pines Rd., La Jolla, CA 92037.

The amygdala is a part of the limbic system that mediates behavioral, autonomic and neuroendocrine responses to stressful stimuli. Anatomical studies showed that corticotropin releasing factor (CRF)-containing cell bodies and terminals are densely distributed in the central amygdaloid nucleus (Ce). The observation that ICV administration of CRF induces behavioral and autonomic changes resembling the stress response suggests that the CRF-amygdaloid system may be important in the mediation of some component of this response. To test this hypothesis we used the intracranial microdialysis technique for the measurement of immunoreactive CRF measurement in awake, freely moving rats recently developed in our laboratory (Merlo Pich et al, Soc Neurosci Abstr 542.7, 1991). Male Wistar rats were surgically implanted with a chronic guide cannula one week before the experiment. Microdialysis probes were inserted 12 h prior to sampling. For the experiment the flow rate was 3.0 µl/min, and fractions were collected at 20 min intervals. Basal values of CRF were estimated to be  $2.13 \pm 0.44$  fmol/sample. Immobilization stress (20 min) transiently increased CRF levels to 12.7 ± 3.4 fmol/sample. Perfusion with the depolarizing agent 4 aminopyridine (10 mM) induced a 3-fold increase in CRF, suggesting that the sampled CRF was of synaptic origin of CRF release. Histological verification was performed by immunocytochemistry to visualize the probe traces with respect to CRF neurons in the Ce. The evidence of stress-induced release of CRF in Ce in conjuction with behavioral evidence that local injections of the CRF antagonist α-helical-CRF (250 ng) in the rat Ce attenuate the effects of stress on the Elevated Plus-Maze suggests that the CRF amygdaloid system is involved in the mediation of the stress response.

IN SITU HYBRIDIZATION OF VASOPRESSIN AND CORTICOTROPIN RELEASING FACTOR IN RAT HYPOTHALAMUS FOLLOWING EXPOSURE TO STRESSORS. R.L.Galli\* & H.R.Lieberman. Military Performance and Neuroscience, U.S. Army Research Institute of Environmental Medicine, Natick, MA 01760, & \*Boston University, Boston, MA 02215

Vasopressin (VP) and corticotropin releasing factor (CRF) interact to stimulate the release of adrenocorticotropic hormone (ACTH) from the anterior pituitary during the physiological response to stress. VP and CRF synthesizing cells have been anatomically localized to specific subpopulations within nuclei of the hypothalamus. Nonisotopic in situ hybridization was performed to investigate changes in VP and CRF mRNA at the single cell level. Adult male Fisher 344 and Sprague-Dawley rats were stressed by restraint or by swimming. Digoxigenin-11-dUTP (Boehringer Mannheim Biochemicals) labeled oligonucleotide probes were hybridized to 10u coronal sections cut at the level of the hypothalamus. The pattern of changes in VP and CRF mRNA expression in the different hypothalamic nuclei in response to the two stressors was examined and compared to no-stress control VP mRNA increased in the supraoptic (SON) and paraventricular (PVN) nuclei of Fisher rats and in the PVN of Sprague-Dawley rats following one hour of restraint stress.

MUSCARINIC RECEPTORS MEDIATE THE EFFECT OF ACETYLCHOLINE ON NEURONS OF THE BED NUCLEUS OF THE STRIA TERMINALIS. <u>J.H. Casada and N. Dafny.</u> Dept. Neurobiol. and Anat., The University of Texas Medical School at Houston, TX 77225.

The bed nucleus of the stria terminalis (BNST) is considered to be essential in mediating the effects of the limbic system on ACTH secretion, a hallmark of stress. Electrical stimulation of BNST has also been shown to produce stresslike changes in corticosterone secretion, behavior and autonomic activity. Previous experiments have shown that acetylcholine (Ach) is excitatory to certain BNST neurons, thus suggesting that BNST Ach may play a role in the expression of the stress response. This study was designed to determine the type of receptor mediating the effect of Ach on BNST neurons. Twenty-one rats (200-350 g) were anesthetized with urethane (1.25 g/kg, i.p.), and action potentials were recorded from single BNST neurons using a recording microelectrode mounted on multibarrel microiontophoresis pipettes filled with Ach, atropine (Atr), and hexamethonium (Hex). 45% of BNST neurons showed a dose-dependent monophasic increase in firing rate in response to Ach. Atr, a muscarinic antagonist, blocked the effects of Ach in all neurons tested, while Hex, a nicotinic antagonist, did not alter Ach responses. Since amygdala stimulation (AmygS), like Ach is excitatory to BNST neurons, each of the neurons was also tested for responsiveness to AmygS and for the ability of Atr to block responses to AmygS. Atr had no effect on the responses of BNST neurons to AmygS, and there was no correlation between neurons responsive to Ach and those responsive to AmygS. Thus, this experiment shows that the excitatory effect of Ach on BNST neurons is mediated by muscarinic receptors and is consistent with the possible role of BNST Ach in modulating the endocrine and autonomic effects of stress.

## 225.18

AFFERENT AND EFFERENT PROJECTIONS OF BARRINGTON'S NUCLEUS, A CORTICOTROPIN-RELEASING FACTOR (CRF)-CONTAINING PONTINE NUCLEUS. M.E. Page\*. P.H. Luppi. G. Aston-Jones. and R.J. Valentino. Dept. of Mental Health Sci., Hahnemann Univ., Philadelphia, PA 19102. LIS A

Barrington's nucleus contains a substantial number of CRF-immunoreactive neurons (Suttin and Jacobowitz, 1988), suggesting that in addition to its role in micturition it may be important in stress responses. However, the afferent and efferent connections of this nucleus have not been completely identified. To characterize the anatomic connections of this nucleus in detail the anterograde and retrograde tract tracer, cholera toxin b subunit (CTb) was iontophoresed (0.5 µA, 5 min) into Barrington's nucleus of 3 halothane-anesthetized rats and rats were perfused 10 days later. Visualization of CTb with streptavidin-HRP immunohistochemistry revealed numerous retrogradely labeled cells in the periaqueductal gray (PAG), the lateral hypothalamus and cortical layers 4 and 5. A smaller number of cells were retrogradely labeled in the nucleus of the solitary tract, the nucleus paragigantocellularis, the dorsal motor nucleus of vagus, medial vestibular nucleus and paraventricular nucleus of the hypothalamus. Anterograde labeling indicated that in addition to the previously described descending projections to the sacral spinal cord, Barrington's neurons project to the ventrolateral PAG and the lateral mammillary nucleus in the hypothalamus. Additional possible connections are also being examined. These results demonstrate that Barrington's neurons receive projections from brain regions of diverse function and that these neurons project to supraspinal regions that are involved in functions other than micturition. Exposure of rats to 30 min. inescapable footshock (1.5 mA, 0.5 ms, 0.033 Hz) increased Fos protein immunoreactivity of CRF-immunoreactive neurons of Barrington's nucleus suggesting that these neurons are activated by stress. Taken together with natomic findings, these results implicate a role for Barrington's nucleus in stress responses. Supported by MH00840, MH40008 and NS 24698.

EFFECTS OF DORSAL OR MEDIAN RAPHE INJECTIONS OF 8-OH-DPAT ON RESPONSE INHIBITION. P.J. Fletcher\*, Sect. Biopsychology, Clarke Inst. Psychiatry, Toronto, Ontario, Canada M5T 1R8.

Although it is well established that brain 5-hydroxytryptamine (5-HT) is important for behavioural inhibition few studies have systematically compared the effects of separately manipulating dorsal raphe (DR) and median raphe (MR) 5-HT activity on response inhibition. These experiments were undertaken to examine further the effects of reducing brain 5-HT on response inhibition, and to assess the relative importance of 5-HT efferents arising from the DR and MR in mediating such inhibition. Adult male rats, equipped with a single stainless steel guide cannula aimed at either the DR or MR, and reduced to 85% free-feeding body weight were used. Rats were tested for their ability to withold responding (bar pressing for 45 mg food pellets) following raphe injection of various doses of 8-OH-DPAT, which suppresses 5-HT raphe neuronal activity. Three operant paradigms were used: extinction of a previously rewarded response (EXT: reward omission), omission training (OT: requiring cessation of responding to receive reward) and performance of a golnogo discrimination (involving alternate signalled periods of reward, S+, and extinction, S-). Rats injected with 8-OH-DPAT in the MR showed increased responding during EXT (0.2 and 1µg) and OT (1µg); DR injections were ineffective in both paradigms. Injections of 8-OH-DPAT into the DR (0.2,1 and 5µg) or MR (5µg) reduced accuracy of responding in the golnogo task. In the case of DR injections this was due to reductions in responding during S+periods, but in the case of MR injections responding was increased during S-periods. The results suggest that suppressing 5-HT function leads to difficulties in restraining behaviour, particularly when rewards are expected (EXT and OT). These effects appear to be mediated by 5-HT neurons arising from the MR, rather than the DR.

#### 226.3

SPECIES DIFFERENCES IN SENSORIMOTOR REACTIVITY AND LOCOMOTOR ACTIVITY FOLLOWING REPEATED ADMINISTRATION OF THE 5-HYDROXYTRYPTAMINE1 (5-HT1) AGONISTS (±)-8-HYDROXY-DPAT (8-OH-DPAT) OR L-(M-CHLOROPHENYL) PIPERAZINE (mCPP). M. Schmidt'. D. Helton. C. Murphy-Farmer, and J. Tizzano. Lilly Research Labs, Eli Lilly and Company, Greenfield, IN, 46140.

Single doses of 5-HT<sub>1a</sub> agonists decrease startle amplitude while 5-HT<sub>1b</sub> agonists increase startle amplitude in mice. In contrast, single doses of 5-HT<sub>1</sub> agonists produce effects in rats opposite to those seen in mice. In this study, drug-related changes in auditory startle and locomotor activity were compared in rats and mice following repetitive dosing (5 days) with the 5-HT<sub>1a</sub> receptor agonist, 8-OH-DPAT (1, 3, 10 mg/kg, ip), or the preferential 5-HT<sub>1b</sub> agonist, mCPP (1.25, 2.5, 5 mg/kg, ip). Auditory startle was assessed on days 1-5, while activity levels were measured on days 1 and 5. Changes in auditory reactivity produced by single doses of 8-OH-DPAT or mCPP in mice were only slightly reduced following repetitive doses. Similarly, increases or decreases in reactivity produced by single doses of

8-OH-DPAT or mCPP in rats were not altered following repetitive dosing. In contrast, although 8-OH-DPAT or mCPP decreased locomotor activity in both species initially, repetitive dosing with 8-OH-DPAT resulted in activity levels at or above control levels by the fifth day in both species. However, both rats and mice continued to show decreased activity levels on the fifth day of dosing with mCPP. These data indicate that drug-related changes resulting from repetitive dosing with 5-HT<sub>1</sub> agonists may depend on the intrinsic activity of the compound at 5-HT receptors, the species examined, or the type of behavioral assessment.

## 226.5

8-OH-DPAT IN THE MIDBRAIN CENTRAL GRAY, BUT NOT THE DORSAL RAPHE NUCLEUS, INHIBITS FEMALE LORDOSIS BEHAVIOR. M. Droge\*, M. Caldarola-Pastuszka, and L. Uphouse. Department of Biology, Texas Woman's University, Denton, Texas, 76204.

Sexually receptive female rats were infused intracranially

Sexually receptive female rats were infused intracranially with 500-2000 ng 8-hydroxy-2-(di-n-propylamino)tetralin (8-OH-DPAT) into the midbrain central gray (MCG), in the vicinity of the dorsal raphe nucleus (DRN), or directly into the DRN. When cannulae were located within the DRN, there was little evidence of change in lordosis behavior but a decrease in locomotor activity was commonly observed. In contrast, when cannulae were located anterior, ventromedial or lateral to the DRN, inhibition of lordosis behavior was rapid and robust. Both the lordosis-to-mount ratio (LIM) and the quality of the lordosis reflex were reduced following the infusion. The MCG receives lordosis-facilitating input from the ventromedial nucleus of the hypothalamus and from ascending sensory pathways and contributes information to descending motor systems involved in the lordosis response. Thus the MCG is a critical link in the completion of the estrogen-dependent lordosis reflex. The present results suggest that 5-HT<sub>1A</sub> receptors in the MCG prevent the completion of this reflex. Supported by NIH RO1 HD28419

#### 226.2

ATTENUATION BY PROPRANOLOL OF 8-OH-DPAT-INDUCED REDUCTION OF LORDOSIS BEHAVIOR. M. Andrade, S. Montanez, M. Caldarola-Pastuszka, J. Hines\*, and L. Uphouse. Department of Biology, Texas Woman's University, Denton, Texas, 76204.

After a 10 min pretest for sexual receptivity, proestrous rats were injected i.p. with 0.15 mg/kg 8-hydroxy-2-(di-n-propylamino)tetralin (8-OH-DPAT). Inhibition of lordosis behavior occurred within 15 min. Treatment with 1 or 2 mg/kg (-)propranolol, 30 min before 8-OH-DPAT, significantly attenuated the effects of 8-OH-DPAT. I.p. injection of 2 mg/kg propranolol 30 min before bilateral infusion of 200 ng 8-OH-DPAT into the VMN failed to reduce the inhibition produced by 8-OH-DPAT. However, simultaneous infusion with 1000 ng propranolol and 200 ng 8-OH-DPAT per cannulae site did attenuate the effects of 8-OH-DPAT. These results provide further evidence for the inhibitory effects of VMN 5-HT<sub>1A</sub> receptors in female lordosis behavior.

#### 226.4

NON-RECIPROCAL CROSS-TOLERANCE BETWEEN LSD AND 8-OH-DPAT IN RATS <u>K.M. Krebs and M.A. Geyer</u>\*. UCSD Dept Psychiatry, La Iolla CA 92093

Like other hallucinogens, LSD (d-lysergic acid diethylamide-25) has characteristic effects on rats' behavior, including decreases in locomotor activity and investigatory holepokes and rearing. Because LSD is an agonist at both 5HT-1A and 5HT-1C/2 receptors, it is unclear which behavioral effects are influenced by actions at which receptor sites. Because there are no selective 5HT-1A antagonists with which to address this question, LSD's specific 5HT-1A effects are difficult to assess. An alternative method is the use of tolerance and cross-tolerance regimens. In the present study, rats were pretreated with either saline, the 5HT-1A-selective agonist, 8-hydroxy-2/di-npropylamino)tetralin (8-OH-DPAT) (0.5 mg/kg sc) or LSD (60 μg/kg sc), every 12 hours for 5 days. 36 hours later, rats were tested in a Behavioral Pattern Monitor (BPM) after either saline, 0.5 mg/kg 8-OH-DPAT, or 60 μg/kg LSD. The BPM is a 30.5 x 61 cm chamber, with 10 holes. Infrared photobeams assess holepokes, quantify movement, and chart the pattern of locomotor behavior. As expected, tolerance to the decreases in locomotor activity produced by acute 8-OH-DPAT occurred when rats were pretreated with 8-OH-DPAT. However, only partial tolerance to LSD was found, perhaps due to the latency between preteatment and behavioral testing. Interestingly, pretreatment with LSD produced no cross-tolerance to LSD, but pretreatment with LSD produced no cross-tolerance to LSD. Our interpretation of these findings is that the LSD pretreatment was less effective than the 8-OH-DPAT protreatment at producing adaptive changes in 5HT-1A receptor function and therefore failed to produce cross-tolerance with 8-OH-DPAT. However, the 8-OH-DPAT retreatment supports the hypothesis that LSD's effects in this model reflect a combination of 5HT-1A and 5HT-1C/2 effects.

## 226.6

REDUCTION OF FEMALE LORDOSIS BEHAVIOR FOLLOWING VENTROMEDIAL HYPOTHALAMIC INFUSIONS WITH 5-OH-DPAC OR 5-MeO-DPAC. M. Caldarola-Pastuszka, J. Williams\* and L. Uphouse. Department of Biology, Texas Woman's University, Denton, Texas, 76204 and Department of Biology, Southeastern Oklahoma State University, Durant, Oklahoma, 74701.

Intact, female rats were implanted with bilateral cannulae directed stereotaxically into the ventromedial nucleus of the hypothalamus (VMN). Following recovery from surgery, rats were tested on proestrous for sexual receptivity. Following a pretest, rats were infused i.c. with 400 ng, 1000 ng or 2000 ng of either 5-OH-3-dipropyl-aminochroman (5-OH-DPAC) or 5-methoxy-3-dipropyl-aminochroman (5-MeO-DPAC). Some inhibition of lordosis behavior and considerable resistance to attempts by the male to mount were evident at 400 ng of the drugs; significant suppressions of lordosis behavior occurred at 2000 ng. The chroman derivatives were less effective than 8-OH-DPAT, but more effective than 5-HT, in suppressing lordosis behavior following VMN infusions. Therefore, these studies suggest that the 5-HT<sub>1A</sub> sites within the VMN may be responsible for serotonin's inhibition of lordosis behavior. Supported by NIH RO1 HD28419 and GM08256.

NEONATAL ACTH 1-24 TREATMENT INCREASES HYPOTHALAMIC SEROTONIN INNERVATION IN THE FEMALE RAT. S.E. Alves\*, H.M. Akbari, E.C. Azmitia and F.L. Strand. Department of Biology and Center for Neural Science, New York University, New York: NY 10003.

Administration of ACTH 1-24 to neonatal female rats during the first week postnatal causes delayed reproductive maturation and decreased female sexual behavior among these animals tested as virgins (60 days of age)<sup>1</sup>. This treatment also increases hypothalamic serotonin (5-HT) fiber density as measured by high-affinity specific 5-HT uptake at postnatal day 7 and at adulthood (days 80-90)<sup>1</sup>. As 5-HT is believed to have an inhibitory effect on female sexual behavior through 5-HT,, receptor activation within the medial basal hypothalamus, this current study investigates whether early postnatal ACTH 1-24 alters 5-HT innervation and/or 5-HT<sub>1x</sub> receptor number within this hypothalamic region. Female Sprague-Dawley rat pups were injected s.c. with either ACTH 1-24 (0.1mg/kg) (donated by Organon, Inc.) or saline vehicle once daily from postnatal day one (day of birth) to day 7. Animals were perfused transcardiacally (n=4 per subgroup) on day 7 and immunohistochemical staining for 5-HT and the 5-HT, receptor was performed using antibodies against 5-HT and the 5-HT, a receptor. 5-HT fiber density within the medial base hypothalamus was increased in ACTH treated animals compared to controls. This increase in 5-HT innervation was apparent within the ventromedial nucleus (VMN), the primary region responsible for the control of female sexual behavior in the rat. There does not appear to be a difference in  $S+HT_{1A}$  receptor immunoreactivity at postnatal day 7 between ACTH and saline treated animals. We are currently investigating these parameters in adult animals. Based on this study we suggest that 5-HT innervation into the developing female hypothalamus is susceptible to postnatal manipulation with ACTH 1-24 and that the resulting change in this monoamine fiber density within the VMN during development may be responsible for the observed deficits in reproductive behavior. This study was supported by the Council for Tobacco Research.

FLUOXETINE INDUCED INHIBITION OF MALE RAT SEXUAL BEHAVIOR:

POSSIBLE ROLE OF THE NUCLEUS PARAGIGANTOCELLULARIS.

D. Yells¹, M. Prendergast¹, S. Hendricks² \*, M. Nakamura², D. Fitzpatrick², E. Rosa-Molinar². ¹Department of Psychology, University of Nebraska at Omaha and ²Department of Psychiatry, University of Nebraska Medical Center, Omaha, NE 68182.

We have previously found that male rats with bilateral lesions of the nucleus paragigantocellularis (PGi) display profound changes in copulatory behavior when tested until sexually exhausted. researchers (Marson & McKenna, 1990) have demonstrated that the PGi contains 5HT-immunoreactive neurons and neurons that project to the spinal nucleus of the bulbocavernosus. We hypothesized that inhibition of male rat copulatory behavior following administration of the 5HT reuptake blocker fluoxetine may be mediated by neurons originating in the PGi. In Experiment 1, male rats received systemic injections of either 0, 5, 10, or 20 mg/kg of fluoxetine 45 min prior to being tested for sexual behavior in an exhaustion paradigm. There was a significant reduction in both latency to exhaustion and number of ejaculations to exhaustion for rats receiving the highest dose. Additionally, animals displayed dose dependent increases in mount frequency, ejaculation latency, post-ejaculatory interval, and intercopulatory interval and decreases in copulatory efficiency. These changes were especially noticeable just prior to exhausion. In Experiment 2, we are investigating whether the fluoxetine induced inhibition of copulatory behavior can be reduced or eliminated following bilateral lesions of the PGi.

## 226.11

PHARMACOLOGICAL DEPLETION OF CATECHOLAMINES MODIFIES COVERT ORIENTING IN RHESUS MONKEY. E.A. Witte, M.E. Lickey\*, and R. T. Marrocco. Institute of Neuroscience, Univ. of Oregon, Eugene, OR 97403

Catecholamine depletion in humans using the alpha-2 adrenergic agonist clonidine and the dopaminergic antagonist droperidol affects attentional processing in a covert target detection (CTD) task (1). We sought to replicate these results with Rhesus macaques using a CTD task very similar to that used previously (1). In addition to using i.m. clonidine and droperidol to deplete catecholamine levels, we used guanfacine, another alpha-2 adrenergic agonist, and normal saline controls.

During the CTD task, rhesus monkeys pressed a bar to illuminate a fixation spot in the center of a video monitor. Fixation was monitored with the scleral search coil method. Following a random delay interval, a peripheral cue was presented to one, both hemifields, or omitted on some trials. A target was presented to either the left or right hemifield at intervals of 100, 400, or 700 msec after the cue. The cue was presented to either the same hemifield as the target (valid condition); the opposite hemifield (invalid condition), to both hemifields (neutral condition), or was omitted (no-cue condition). The monkey's reaction times (RTs) to target detection were measured.

The primary effect of catecholamine depletion was a significant reduction in invalid trial RTs compared to those for saline control trials. No general drowsiness or impairment of saccadic eye movement frequency was seen. This result implies that the neural systems underlying human and non-human primates are quite similar in the degree to which they depend on normal levels of central nervous system catecholamines. Supported by the McDonnell-Pew

FLESINOXAN, A 5-HT1A AGONIST, IN THE MPOA INCREASED EX COPULA SEMINAL EMISSIONS AND PENILE REFLEXES IN RATS. L.A. Lumley\*, J. Moses, R.C. Eaton, and E.M. Hull. Psychology Dept., SUNY at Buffalo, Buffalo, NY 14260.

Initially serotonin was believed to inhibit male sexual behavior. However, systemically administered selective 5-HT1A agonists have been reported to facilitate male sexual behavior by decreasing the ejaculatory latency, the postejaculatory interval, and the number of intromissions before ejaculation (reviewed in Ahlenius, 1991). We recently reported that flesinoxan (FLES) microinjected into the medial preoptic area (MPOA) facilitated male sexual behavior by decreasing ejaculation latency and postejaculatory interval (Lumley et al., 1990)

In a resent experiment on ex copula genital reflexes in restrained supine male rats FLES (10 ug/.5ul) into the MPOA significantly increased the number of seminal emissions (p<.03) and reduced the latency to reflex (p < .001). In addition, FLES increased the total number of penile reflexes (p < .04), in particular E2's (p < .02), erections characterized by tumescence of both the base and the tip of the glans.

These data may explain why FLES in the MPOA facilitated

copulation. The increase in penile reflexes and seminal emissions may be related to the increased copulatory rate and decreased ejaculatory threshold.

Supported in part by NIMH grant MH-40826.

#### 226.10

REDUCED SENSITIVITY TO 8-OH-DPAT-INDUCED SUPPRESSION OF LORDOSIS BEHAVIOR WITH REPEATED ESTROGEN PLUS PROGESTERONE PRIMING. 上 Uphouse\*, M. Caldarola-Pastuszka, S. Montanez, and A. Jackson Department of Biology, Texas Woman's University, Denton, Texas, 76204.

Ovariectomized rats were injected with 25 µg estradiol followed 48 hr later by 500 µg progesterone. The rats were tested for sexual receptivity 4-6 hrs later following either i.p. treatment with 0.15 mg/kg 8-hydroxy-2-(di-n-propylamino)tetralin (8-OH-DPAT) or a bilateral ventromedial hypothalamic (VMN) infusion of 200 ng 8-OH-DPAT. Either treatment reduced lordosis behavior. Repetition of the treatment one week later produced little suppression of lordosis. When rats were primed for two weeks with estradiol plus progesterone prior to treatment with 8-OH-DPAT, there was still an attenuation of the effects of 8-OH-DPAT, but less than when 8-OH-DPAT accompanied the first week's priming. These findings suggest that repeated treatment with relatively high doses of gonadal hormones can reduce the sensitivity of 5-HT receptors to 8-OH-DPAT. They also suggest that activation of 5-HT1A receptors can lead to a subsensitivity to 8-OH-DPAT, present at least a week later Supported by NIH RO1 HD28419 and GM08256.

## 226.12

BEHAVIORAL AROUSAL POSSIBLE AFTER PROCAINE INJECTION INTO EITHER LOCUS COERULEUS OR NUCLEUS ACCUMBENS, BUT NOT BOTH. B.E.Morton + , R.M.Chesire, W.E.Winn + , B.E.Digman, and M.K.Peterman,

Depts. of + Biochemistry and Psychology, University of Hawaii, Honolulu, HI 96822.

Although the locus coeruleus (LC) is commonly believed to be the organ of arousal, attention, alerting, orienting, vigilance, or sympathetic nervous system activation, it is well known that intense behavioral arousal can originate from either of two different motives: reward or punishment. An alternative and more utilitarian distinction for the function of the LC is the view that it is the organ of alarm (B.E.Morton, Biol. Psychol., submitted). Clearly, while excitation of LC alarm may lead to arousal, etc., this does not mean it is the actual structure producing arousal.

Confirming this view, we found, using rats (Long-Evans, about 400g, mixed sex, n=6), that injection of 0.5 ul 0.733M procaine HCL, pH 7.4, into both precannulated LC did not abolish arousal. Instead, it produced a reversible display of those behaviors usually appearing to maximize attainable reward, but not the alarm-driven behaviors commonly associated with threats to survival (6/6). Conversely, 0.5 ul procaine, injected into both n. accumbi (NA), reversibly inhibited behaviors activated by reward seeking, but not by survival threats (6/6). Furthermore, 0.5-1.0 ul procaine injections into both LC, and both NA, caused temporary (2-10 min) immobilization of most responses characteristic of either alarm or reward (4/6).

Thus, although LC inactivation resulted in temporary reductions in signs of alarmdriven "fear" (thigmotaxis, grooming, and freezing), LC inhibition simultaneously enhanced "fearless" active exploration. In contrast, inhibition of the NA resulted in signs of alarm, such as increased grooming, piloerection, and vocalization, along with increased overall movement that was highly thigmotactic. Yet, temporary inhibition

of both pairs of brain structures brought movement almost to a complete halt.

These results suggest that neither the LC nor the NA are required for arousal.

Rather, either of these systems, by producing the foundational motives of alarm or reward, can independently stimulate the downstream organs of arousal and behavior.

ALPHA-2 ADRENOCEPTOR ANTAGONISTS FACILITATE PLAY INDEPENDENT OF ANY ACTION AT NON-ADRENOCEPTOR IMIDAZOLINE BINDING SITES. S.M. Siviy and A.E. Fleischhauer. Department of Psychology, Gettysburg College, Gettysburg, PA 17325.

Previous work has demonstrated that idazoxan, an alpha-2 adrenergic antagonist, increases play in juvenile rats (Siviy et al., Psychopharmacology, 100:119-123). In addition to acting at alpha-2 adrenoceptors, idazoxan has also recently been reported to bind with high affinity to non-adrenoceptor imidazoline binding sites. Therefore, the extent to which idazoxan facilitates play through it's action as an adrenoceptor antagonist is unclear. RX 821002 is a derivative of idazoxan which has minimal affinity for imidazoline binding sites, while having high affinity for alpha-2 receptors. In the present study, the effects of both idazoxan and RX 821002 on roughand-tumble play were assessed in juvenile rats. Male and female rats (30-45 days old) were housed individually and given daily 5 minute opportunities to play. One group of rats were injected with either saline or one of four doses of idazoxan (1, 2, 4, 8 mg/kg) 30 minutes prior to a play session. Another group of rats were injected with either saline or one of four doses of RX 821002 (0.05, 0.1, 0.2, 0.4 mg/kg). Frequency of dorsal contacts and pinning were used to assess levels of play. Both idazoxan and RX 821002 increased pinning in a dose-dependent manner, while having no effect on dorsal contacts. For idazoxan, the maximal increase in pinning was observed after 4 mg/kg, while for RX 821002 the maximal increase was after 0.2 mg/kg. These data provide further support for a direct action of alpha-adrenoceptors in the modulation of mammalian playfulness.

ACTIVITY OF LOCUS COERULEUS (LC) NEURONS IN BEHAVING MONKEYS VARIES WITH CHANGES IN FOCUSED ATTENTION. \_J. Rajkowski\*, P. Kubiak. & G. Aston-Jones. Div. Behavioral Neurobiol., Dept. Mental Health Sci., Hahnemann University, Philadelphia, PA 19102.

Our previous results revealed that sensory responses of LC neurons in behaving

Our previous results revealed that sensory responses of LC neurons in behaving monkeys are selectively elicited for attended stimuli in a discrimination task (Aston-Jones et al., Prog. Brain Res. 8: 501, 1991). Here we report that tonic LC discharge also varies in close correspondence with attentiveness.

Johns et al., Prog. Brain Res. 5: 301, 1991. Here we report that tonic LC discharge also varies in close correspondence with attentiveness.

Discharge of individual LC neurons was recorded from 2 cynomolgus monkeys performing an attentional task (oddball visual discrimination). The results of activity during this task are presented in an accompanying abstract (Kubiak et al., this volume). This task required that the animal foveate a central fix spot to initiate each trial of stimulus presentation; proper response to target stimuli resulted in juice reward. Such foveation is effortful and reflects attentiveness to the task. During drowsiness there was typically no task performance and LC activity was very low (< 0.5 spikes/sec). We observed that during continuous alertness and task performance the frequencies of both LC discharge and foveation fluctuated over short (10-30 sec) and long time intervals (10-30 min). The long-term changes in LC discharge were consistently inversely correlated with task behavior, such that slightly elevated LC activity (by 0.5 to 1 spike/sec) was accompanied by decreased foveation frequency and poorer task performance. Correlation analyses revealed that this relationship was highly significant (of the 6 cells quantitatively analyzed to date, typically r = -0.5, p < 0.001). In addition, even short-term increases in LC tonic activity often corresponded to marked, short-lasting reductions in foveation frequency. These results suggest that focused attentiveness varies with tonic LC discharge corresponds with labile attention and restlessness; optimal focusing of attention occurs with intermediate levels of tonic LC activity. Additional studies are underway to test whether fluctuations in tonic LC activity cause or reflect changes in attentiveness. Supported by AFOSR grant 90-0147.

# ASPHYXIA-INDUCED LESION OF THE LIMBIC SYSTEM

<sup>a</sup>Rochellys Diaz\*, <sup>c</sup>B, Bjelke, <sup>b</sup>P, Bolme, <sup>c</sup>S,O, Ögren & <sup>a</sup>K, Andersson.

<sup>a</sup>Dept. Internal Medicine and <sup>b</sup>Dept Pediatrics, Karolinska Institutet, Huddinge Hospital, 141 86 Huddinge, Sweden, <sup>c</sup>Dept. Histology & Neurobiology, Karolinska Institutet, Box 60 400, 104 01 Stockholm, Sweden

Asphyxia to male Sprague-Dawley rat pups was induced by a delayed cesarean section. An immunohistochemical and functional analysis was carried out on the pups at an age of 3 weeks. By means of immunohistochemistry the nigro-striatal dopamine system was studied. It was demonstrated that asphyxia time-dependently produced an increase in the number of tyrosine hydroxylase immunoreactive (TH-IR) nerve cell bodies of the substantia nigra, while the TH-IR nerve terminal levels in the caudata nucleus were unchanged. Following mild asphyxia increases in rearing and locomotion were found, while severe asphyxia resulted in a reversal of these behaviours. Treatment with the glutamate antagonist MK801 on normal animals resulted in an enhanced rearing and locomotion response. Asphyxia abolished this response indicating that asphyxia induced disturbancies in glutamate-innervated neuronal pathways of the limbic system. Increases in rearing and locomotion behaviours may be regarded as an animal analogue for the hyperkinetic syndrom in MBD-children. The observed behavioural changes may thus indicate an important role of neuronal pathways containing glutamate for the development of the hyperkinetic syndrom in MBD-children.

TONIC AND SENSORY-EVOKED ACTIVITIES OF NORADRENERGIC LOCUS COERULEUS (LC) NEURONS IN PRIMATE VARY WITH DISCRIMINATION PERFORMANCE IN A VIGILANCE TASK. F. Kubiak J. Rajkowski. G. Luthin\* and G. Aston-Jones, Div. Behavioral Neurobiol., Dept. Mental Health Sci., Hahnemann University, Philadelphia, PA 19102.
Previous studies indicate that the LC regulates vigilance, or attentiveness to

Previous studies indicate that the LC regulates vigilance, or attentiveness to sensory stimuli. Consistent with this idea, we have recently reported that monkey LC neurons typically respond preferentially to target stimuli in a vigilance task (Aston-Jones et al., Prog. Brain Res. 88: 501, 1991). We extended this analysis to include changes in discrimination performance and basal discharge rates of LC neurons.

Individual LC neurons were recorded in 2 cynomolgus monkeys performing a vigilance task which required bar release within 700 msec of a target stimulus (10 % of trials) but no response to non-target stimuli (90% of trials). Stimuli were horizontal or vertical bars presented on a video screen, one of which occurred per trial immediately after foveation of a central fix spot. The mean baseline discharge rates of LC neurons were typically between 1 and 4 spikes/sec. During prolonged task performance (more than 30 min), each of 15 LC neurons analyzed to date alternated between two levels of tonic activity which differed by 0.5 - 1.5 spike/sec; animals were continuously alert throughout the task. These episodic changes in LC activity corresponded to altered task performance such that epochs of elevated discharge were accompanied by decreased discrimination, reflecting lowered attention to task stimuli. In addition, LC neurons appeared to be unresponsive to both target and non-target task stimuli during such periods of elevated discharge. In contrast, when LC activity resumed the lower level of discharge, discrimination performance markedly improved and neurons exhibited the typical phasic activation by target stimuli. Thus, a strong relationship exists among tonic LC discharge rate, sensory responsiveness of LC neurons and vigilance performance. These and other results (see Rajkowski et al., this volume) support a role for the LC in attention and vigilance. Additional work is underway to determine how these changes in LC activity contribute to the accompanying changes in attention. Supported by AFOSR grant 90-0147.

IS MELATONIN INVOLVED IN NEURAL SIGNALLING OF PHOTO-INDUCED HATCHING OF HALIBUT (HIPPOGLOSSUS HIPPOGLOSSUS) LARVAE?

A.Bogsnes, J.V.Helvik, B.T.Walther\* Lab. of Marine Mol. Biology, Univ. of Bergen, HiB, N-5020 Bergen, NORWAY. Hatching of halibut larvae normally takes place after 14 days of devel-

opment, but may be delayed for at least two weeks by continuous exposure to white light of 50 lux. Synchronous hatching of such photo-arrested larvae may be induced by 20 minutes in darkness <0.1 lux. This signal causes irreversible secretion of the proteolytic hatching enzyme. The vast majority of such larvae hatch within 90-120 minutes. Since light appears to act as a physiological stimulus, we consider this hatching-regulation to be mediated by CNS. Melatonin is an indolic compound known to be influenced by light/dark cycles. In order to investigate the possible role of melatonin in this regulatory pathway, we have established an HPLC method allowing us to measure nine different indolic compounds in the metabolic pathway of tryptophan, including serotonin and melatonin, in the range of 0.1-0.5 pmole pr. sample. Larvae immediately prior to normal hatching show a significant activity in the serotonergic system by turnover to 5-hydroxy indole acetic acid (5-HIAA). Serotonin is present at slightly lower levels during darkness, even if the level of 5-HIAA remains unchanged. Lower amounts of larval serotonin when dark may be accounted for by the synthesis of an additional compound, e.g. melatonin. Larval melatonin is as yet only indicated, but its presence and fluctuation at such minute levels must be validated by further sample purification and concentration. At these developmental stages catecholamines are present, but their turnover is low and not dependent upon photic treatment at hatching. These findings attest to the likelihood of early serotonergic functions in halibut larvae at hatching. As the pineal develops early, such serotonergic function may relate to pineal sensing of light.

NERVE GROWTH FACTOR (NGF) TREATMENT REDUCES THE INHIBITORY EFFECTS OF AGUTE ETHANOL ON CALCIUM CHANNELS IN PC12 CELLS. D. Mullikin-Kilpatrick\* and S. N. Treistman. Department of Pharmacology, Univ. of Massachusetts Medical Center, Worcester, MA 01655.

To gain insight into the development of alcohol toler-

ance, we have examined the effects of acute ethanol on voltage-activated calcium channels in undifferentiated (UND) and NGF-treated PC12 cells, using voltage clamp techniques and nystatin-perforated patch recording. roscopic currents were evoked from holding potentials (Vh) of -90 mV and -40 mV, using barium as charge carrier. presence of non-inactivating currents, and the inhibition of the currents by nifedipine, indicated that the currents or the currents by hiredipine, indicated that the currents were carried mainly through L-type channels in both UND and NGF-treated cells. 25 mM ethanol reversibly inhibited currents evoked from  $V_{h_1}$  -90 mV, by ~ 10% and from  $V_{h_2}$  -40 mV, the inhibition was ~23% and this was significantly less (P<0.05) than the inhibition seen in UND cells. NGF treated cells were not significantly different from UND cells in their steady-state inactivation characteristics in the absence of ethanol. Steady-state inactivation curves were shifted in the hyperpolarizing direction by 25 mM ethanol in UND cells and this may be one of the mechanisms by which acute ethanol acts. In contrast, the lack of this shift in NGF-treated cells may explain why, in comparison to UND cells, currents in these cells are inhibited less by acute ethanol. Supported by ADAMHA grant AA05542

EFFECTS OF ALCOHOL EXPOSURE ON GENE EXPRESSION DURING SYNAPTOGENESIS IN RAT BRAIN. <u>A.E.Ryabinin.</u> <u>D.M.Gonzalez#. T.Melcer#. E.P. Rilev#.M.C. Wilson\*</u>. Dept. Neuropharm., The Scripps Research Institute, La Dolla, CA 92037 #Center for Families at Risk San Diego State Univ. S.D. CA 9201

Neuropharm., The Scripps Research Institute, La Jolla, CA 92037, 
#Center for Families at Risk, San Diego State Univ., S.D., CA 920120 
Artificial rearing of rat pups with alcohol during the first two weeks 
after birth leads to specific cell loss and behavioral disorders and is 
regarded as an adequate animal model for human Fetal Alcohol 
Syndrome (reviewed by J.R. West, Alcohol Drug Res., 1987 and 
E.P.Riley, Alcohol.Clin.Exp. Res., 1990). The present investigation 
was carried out using this model in order to find gene targets for 
alcohol that could mediate abnormal brain development. SpragueDawley rat pups were artificially reared with 6 g/kg/day alcohol during 
postnatal days 6-10. Gene expression was analyzed using Northerm 
blots, RNase protection assays, In situ hybridization and 
Immunohistochemical staining. Changes in c-fos expression were 
observed after this treatment. Since expression or c-fos is low at this 
stage of development, preproenkephalin expression was studied as 
a marker for c-fos targeted gene expression. Preproenkephalin mRNA 
level increased in cortex of rat pups reared with alcohol, but not in 
sham operated animals or those artificially reared with maltose, 
indicating specificity of this response to alcohol. Changes in expression of 
genes encoding presynaptic proteins SNAP-25 and Synapsin I were 
also observed after alcohol treatment as well as in expression of 
"housekeeping" genes cyclophillin and glyceraldehyde phosphate 
dehydrogenase, whereas β-actin expression did not change after this 
treatment. These results suggest that alcohol may disrupt normal 
patterns of gene expression which underlie brain development.

NMR EVIDENCE FOR ETHANOL-INDUCED REDUCTION IN MOBILITY OF WATER MOLECULES FROM FISH BRAIN. W. R. Klemm\*, L. K. Misra, Hung Cao, C. F. Hazlewood. Dept. Vet. Anat. Public Health, Texas A&M, College Station, TX 77843 and Baylor College of Medicine and Rice University.

NMR can measure the dynamics of water protons after they have been energized by radio waves. The time needed to dissipate absorbed energy (T1 relaxation time) is longer for "free" water than it is for water that is associated with macromolecular structures of cells. Here we report T1 data from brain tissue of fish. Fish were randomly assigned in one group exposed for 5 min to alcohol (ethanol, 400mM) in their fish-bowl water and in another group having no alcohol added to their water. Brains from 6-8 fish were pooled for each sample, with four samples per group. Alcohol decreased the T1 values of brain an average of 11% (control mean  $\pm$  S.D.: 833  $\pm$  17 msec; intoxicated: 740  $\pm$  11 msec). The decrease was highly significant statistically (two-tailed P < 0.002). The speed at which this occurs suggests that the dehydration is not an indirect consequence of inhibition of anti-diuretic hormone.

This acute reduction in T1 is consistent with the idea that alcohol-induced dehydration is a mechanism of intoxication (Alcohol, 1990, 7: 49-59; Alc. clin. exp. Res. 1992, in press).

INHIBITION OF (Na,K)-ATPase IN RAT BRAIN BY ACUTE ETHANOL TREATMENT, L. H. Farber\*, N. Anlar, and G. J. Siegel. Dept. of Neurology, Hines VA Hospital, and Loyola-Stritch Medical School, Hines, IL 60141

Ethanol produces complex effects throughout the nervous system involving neural transmission, metabolism, membrane permeability and ion flux. The acute effects of ethanol, in vivo, on (Na,K)-ATPase, the membrane bound enzyme critical to the regulation of ion gradients, membrane potential, and transport of neurotransmitters, amino acids and sugars, are not well understood.

We have investigated the effect of an acute dose of ethanol on (Na,K)-ATPase activity in the brain stem, cerebellum and cerebrum of the rat over time. Adult Sprague-Dawley rats (330-340 gm.) were injected 1.P. (1 ml of 30% (approx. 5.15 M) ethanol/80 gm. weight) twice, 24 hours apart, sacrificed at 90 minutes or 3 hours after the second injection, and their brains were rapidly removed, dissected and frozen in liquid nitrogen. At 90 minutes, in complete homogenates, a 20-30% inhibition of (Na,K)-ATPase activity was found from all areas of the brain, being most pronounced in the cerebellum. At 3 hours after injection, the brain stem (Na,K)-ATPase activity returned to control values. A similar inhibition was seen in washed microsomal membrane fractions from the cerebellum and cerebrum at both 90 minutes and 3 hours after injection. No effect was observed at either time point in the brain stem microsomes.

These data suggest that acute effects of in vivo ethanol on brain (Na,K)-ATPase are measurable and are different in washed microsomal membranes as compared to homogenates. Additionally, the time course for these effects may vary with the brain region. We plan to expand our study of the time course and dose response for in vivo ethanol in different brain areas.

CHRONIC ETHANOL ADMINISTRATION RESULTS IN TOLERANCE DEVELOPMENT IN POLY-PI TURNOVER IN MOUSE BRAIN. T. A. Lin, J. P. Zhang and G. Y. Sun. Biochemistry Dept., University of Missouri, Columbia, MO 65212

Many neurotransmitters and hormones in brain are known to transduce signals through interaction with receptors that are coupled to the poly-phosphoinositide (poly-PI) pathway. In turn, this leads to the release of inositol trisphosphate, a second messenger for mobilization of intracellular calcium stores. An in vivo procedure to assess the poly-PI turnover in brain by first prelabeling brain inositol metabolites with [3H]inositol and subsequently using lithium (6-8 gm/kg, i.p.) to block inositol phosphatase activity has been developed in this laboratory. Acute ethanol administration caused a dosedependent inhibition of the poly-PI turnover activity in brain. As compared to pair-fed controls, mice given ethanol (3-4 gm/kg) twice daily by gavage for 3 weeks developed tolerance to the ethanolinduced inhibition of poly-PI turnover. Blood ethanol levels in the two groups were not different. Chronic ethanol mice also showed a more rapid recovery of the poly-PI activity as compared to the pairfed controls. Furthermore, an increase in poly-PI turnover activity could be observed in the chronic ethanol mice 7-9 hrs after the last dose, correlating to the time of withdrawal hypersensitivity. These results suggest that the poly-PI turnover activity in brain can be a useful measure for assessing ethanol induced tolerance development in mice (Supported by AA-06661 from NIAAA)

ACUTE EFFECT OF ETHANOL AND MK-801 ON THE EXCITABILITY OF THE HIPPOCAMPAL DENTATE GYRUS IN THE FREELY MOVING RAT. Q. Prospéro-García\*, D. R. Miller, P. Robledo and S. J. Henriksen. Dept. Neuropharmacology, The Scripps Research Inst. La jolla, CA 92037.

Previous work has shown that ethanol and MK-801 can antagonize the electrophysiological actions of N-methyl-D-aspartic acid (NMDA) in several experimental hippocampus preparations. In this study the effect of ethanol and MK-801 alone, and in combination, was evaluated for their effects on hippocampal field potentials of chronically implanted freely-moving rats. Paired-shocks (20-160 msec interstimulus interval, ISI) were delivered to the perforant pathway. The amplitude of the conditioning population spike (P1) in the dentate gyrus evoked by the primary shock and the test population spike (P2) evoked by the secondary shock was measured. The ratio of these populations spikes (P2/P1\*100) was determined and considered as an index of inhibition of P2. This index was determined during wakefulness under the effect of saline, ethanol (1.5 g/kg, i. p.), MK-801 (0.1 mg/ kg, sc) or ethanol+MK-801. Results showed that in the saline group, P2 is inhibited at ISI = 20 msec and disinhibited P2 at every interstimulus interval, whereas MK-801 showed a biphasic effect, disinhibiting at ISI = 20 msec and inhibiting at ISI = 60 and 80 ms. The combination of these drugs resulted in ISI-dependent effects that suggest both antagonistic as well as synergistic actions of ethanol on NMDA pharmacology.

ETHANOL-INDUCED DEGENERATION OF DENTATE GYRUS

ETHANOL-INDUCED DEGENERATION OF DENTATE GYRUS, ENTORHINAL CORTEX AND OTHER OLFACTORY RELATED AREAS IN RATS: EFFECTS OF CO-ADMINISTRATION OF MK-801, DNQX, OR NIMODIPINE. T.D. Corso\*, E.J. Neafsey, and M.A. Collins, Biochem. & Anatomy Depts., Loyola Med. School, Maywood IL 60153.

We previously reported neurodegeneration in rats maintained with high blood ethanol levels (BELs) above 300mg% for 4 days (Corso et al., Abst. Soc. Neurosci. (1991) 17:1458). We visualized the degeneration with the de Olmos cupric-silver staining method. Postulating that cupric-silver staining method. Postulating that the degeneration involves the influx of calcium, we have attempted to prevent the degeneration by simultaneous treatment with nimodipine (a calcium channel blocker), DNQX (AMPA/KA type glutamate receptor antagonist), or MK-801 (an NMDA type glutamate receptor antagonist). Surprisingly, MK801 alone (4 days) caused degeneration in the same areas as ethanol, and when combined with nontoxic BELs (100 mg%), the damage was significantly increased. Nimodipine or DNQX alone did not induce damage, and neither agent significantly altered the amount of ethanolinduced degeneration caused by 300-400 mg% BEL); co-treatment at higher BELs is under study. Support by LUMC Potts Award. we have attempted to prevent the degeneration by

CHRONIC ETHANOL EFFECTS ON IMMUNOHISTOCHEMICAL MARKERS OF CHOLINERGIC SEPTOHIPPOCAMPAL INTEGRITY.
M.A. King, B.E. Hunter, and D.W. Walker\*, Dept. of Neuroscience, University of Florida and VAMC Gainesville, Florida 32610

We have been examining the effects of chronic ethanol consumption on the cholinergic septohippocampal system with emphasis on the possible mechanistic involvement of nerve growth factor. Male rats were treated for 28 wks, with a nutritionally supplemented liquid diet containing ethanol or isocalorically substituted sucrose in a pair feeding paradigm. Eight weeks later the rats were sacrificed and coded brain sections were stained using choline acetyltransferase (CHAT) and nerve growth factor receptor (NGFR) immunohistochemistry. Labelled neurons in the medial septum and diagonal band of Broca were counted and the area and volumes of these regions were measured. Preliminary data indicate that 37% fewer CHAT+ neurons were counted in alcohol animals. Combined with a 20% decrease in area this represents a 27% decrease in neuronal density. NGFR+ neuronal density was decreased less markedly (16%) in the alcohol animals. These results are consistent with the hypothesis that even with adequate nutritional intake chronic alcohol consumption produces a deficiency in nerve growth factor function. As with other treatments that interfere with NGF reception, an initial decrease in chat expression may presage the actual loss of cholinergic neurons. Neuronal morphometry and other neuronal type markers are currently being used to explore this hypothesis further Supported by the Veterans Administration and NIAAA grant AA00200.

## 227.11

EFFECT OF ETHANOL AND ACETALDEHYDE ON 8-ENDORPHIN SECRETION IN PRIMARY CULTURES OF RAT HYPOTHALAMIC NEURONS. B.V. Reddy, S. Minami and D.K. Sarkar\*. Dept of VCAPP, Washington State University, Pullman, WA 99164-6520.

Central opioid peptides are known to be involved in the neurological and behavioral complications of alcoholism. The cellular mechanism involved in ethanolregulated opioid activity is presently elusive because of a lack of reliable experimental models. We have previously shown that the fetal hypothalamic neurons can be grown viably in long-term primary cultures. The cultured neurons were often electrically excitable, possessed voltage-activated ionic conductance and secreted B-EP in response to well-defined physiological challenges, suggesting that the culture system can be useful in determining the regulation of hypothalamic B-EP activity. In this study, we characterize the effect of ethanol and its metabolite acetaldehyde on the hypothalamic β-endorphin (β-EP) secretion from the cultured hypothalamic neurons. Incubation of the cultures with a 50 mM dose of ethanol maintained a constant level of ethanol for a minimum period of 6 h. This and other lower doses of ethanol (6, 12.5 and 25 mM) did not produce any significant effect on cell morphology, viability, DNA or protein content. However, these doses of ethanol (6-50 mM) produced a dose-dependent effect on 8-EP release from the cultured neurons for a period of 2 to 3 h. The ethanol metabolite acetaldehyde also produced a concentration-dependent stimulatory effect on B-EP secretion. Comparison of the ethanol and acetaldehyde e curves revealed that acetaldehyde are more potent than ethanol in inducing B-EP release from the cultured neurons. These results suggest that ethanol and its metabolite acetaldehyde stimulates B-EP release from the hypothalan neurons, and that the neuron culture system can be useful for studying the cellular mechanisms of ethanol action. (Supported by NIAAA grant # RO1-AA08757).

EFFECT OF ETHANOL ON WORKING MEMORY: INVOLVEMENT OF THE SEPTOHIPPOCAMPAL PATHWAY. B. Givens\* and D.S. Olton. Departments of Psychology, Ohio State Univ., Columbus, OH 43210 and Johns Hopkins Univ., Baltimore, MD 21218.

Low doses of ethanol can impair working memory and alter neural activity in the septohippocampal pathway. The present study used a within-subjects analysis to determine the extent to which changes in hippocampal theta rhythm, an electrophysiological measure of septohippocampal function, were correlated with impairments of working memory. Rats were pre-operatively trained to criterion performance on one of two tasks: spatial alternation or conditional discrimination. Post-operatively, rats were tested 10 min after injection of ethanol (0.0, 0.25, 0.5 or 1.0 g/kg i.p.). In both tasks, ethanol had a dose-dependent effect on choice accuracy and on hippocampal theta rhythm. At 0.5 g/kg, ethanol reduced choice accuracy and suppressed hippocampal theta activity. At 1.0 g/kg, ethanol also affected the time required to complete the task and reaction time. The selective effect of ethanol at 0.5 g/kg on working memory is similar to that observed after microinfusion of the GABA agonist muscimol into the medial septal area, the origin of the septohippocampal pathway. The results are discussed in terms of possible interactions of ethanol with GABAergic regulation of the medial septal area.

ETHANOL DECREASES NEUROTRANSMISSION IN RAT NUCLEUS ACCUMBENS IN VITRO: NALOXONE REVERSAL. Z. Nie, X. Yuan, S.G. Madamba and G.R. Siggins\*. Dept. of Neuropharmacology, The Scripps Research

The nucleus accumbens (NAcc) has been shown to be an important brain region for the rewarding effects of addictive drugs such as opiates and ethanol. We recently showed that opiate peptides selective for  $\mu$ ,  $\delta$  and  $\kappa$  receptors superfused onto NAcc neurons in a slice preparation reduced both excitatory and inhibitory postsynaptic potentials (EPSPs and IPSPs), with naloxone reversal (Yuan et al., Neurosci. Lett. 134: 223, 1992). Therefore, we used intracellular recording in this rat NAcc slice preparation to investigate ethanol actions (methods as described by Yuan et al.). We recorded from a total of 50 neurons within the NAcc core, with pipettes usually containing K-acetate. Resting membrane potentials (RMPs) averaged -83 mV; spike amplitudes averaged 95 mV. Ethanol 22 - 66 mM had little effect on resting membrane properties, but reduced EPSPs evoked by stimulation of the peri-tubercle region ventral to NAcc. Ethanol 22 mM (n=10), 44 mM (n=12), and 66 mM (n=8) all significantly (by ANOVA) decreased the EPSPs to 77% (P < 0.0002), 65% (P < 0.0045) and 72% (P < 0.0093) of control, respectively. One cell tested with 11 mM ethanol showed no effect. To confirm a direct ethanol action on EPSPs, 5 cells were tested in the presence of 30 µM bicuculline to block IPSPs. In these cells ethanol 44 mM still decreased the EPSP size, suggesting IPSPs are not involved in this effect. As ethanol mimicks opiates in reducing EPSPs without effect on RMPs in the NAcc, we applied the opiate antagonist naloxone together with ethanol. Naloxone 2  $\mu$ M (n=9) significantly reversed ethanol (44 mM) reduction of EPSPs (P < 0.02 by ANOVA and Newman-Keuls). Thus, our data show a striking similarity between mechanisms of ethanol and opiate effects in NAcc and suggest that

ethanol may act indirectly via some opiate mechanism. Supported by grants from NIAAA (AA06420) and NIDA (DA03665).

ENHANCED ALCOHOL INTAKE IN FAWN-HOODED RATS AFTER WITHDRAWAL FROM ALCOHOL. A H. Rezvani\*, P. Garges, and D. Overstreet. Skipper Bowles Center for Alcohol Studies and Dept. of Psychiatry, University of North Carolina School of Medicine, Chapel Hill, N.C. 27599-7175.

Fawn-Hooded (FH) rats have been proposed as a novel animal model of human alcoholism with genetic serotonin (5-HT) impairment. These rats possess a peripheral and central 5-HT abnormality and exhibit a high preference for alcohol in a free choice situation (Rezvani et al., 1990). To further investigate their alcohol drinking behavior, the following experiments were carried out. FH rats were given free access to food, water and a solution of 10% alcohol for at least 15 days. Food, water and alcohol intakes were recorded every 24 hr during the experiments. After establishment of a stable baseline, alcohol was withdrawn for 24 hr. This cycle, (alcohol exposure-24 hr alcohol abstinence-alcohol exposure), was repeated several times in the same group of rats. The results indicated that when FH rats have free access to food, alcohol and water, they drink a significant amount of alcohol (>5g/kg). Twenty-four hr forced abstinence from alcohol induced a significant incre their alcohol intake for at least one day after re-exposure to alcohol.

Compared with pre- and post-abstinence, the amount of water intake during abstinence increased significantly, but total fluid intake and food intake did not change. Administration of fluoxetine, a 5-HT uptake inhibitor, and other serotonergic compounds on the day of abstinence or on the day after abstinence significantly affected the amount of alcohol intake. These data support the proposed idea that FH rats have an endogenous preference for alcohol which can be enhanced by forced abstinence and that the serotonergic systems in the brain may be involved in alcohol-seeking behavior in this strain of rat. (Partially supported by Grant no. 9103 from NCARA to Dr. Rezvani).

CONSUMPTION OF SWEET, SALTY, SOUR AND BITTER FLAVORED SOLUTIONS BY SELECTIVELY-BRED ALCOHOL PREFERRING P AND NONPREFERRING NP LINES OF RATS. RB STEWART\*, RN RUSSELL, T-K LI and JM MURPHY, Indiana University Medical School and VAMC; Purdue School of Science Indianapolis, IN 46202

To determine whether selective breeding for high and low oral ethanol consumption is associated with different oral ethanol consumption is associated with different preferences for non-pharmacological solutions with various flavors, the self-administration of a range of concentrations of sucrose (0.5-64.0 g/100 ml), NaCl (0.025-3.2 g/100 ml), citric acid (0.008-2.048 g/l), and sucrose octaacetate (0.002-0.512 g/l) was studied in P and NP rats. Separate groups of 7-8 rats from each line were used to test each of the four flavors. The flavor solutions were presented continuously with water always available and the concentration was doubled every 48 hr. available and the concentration was doubled every 48 nr.

Although rats from both lines showed a strong preference for
the sucrose solutions, P rats consumed greater amounts than

NP rats at most of the concentrations tested (0.5-16.0 g/100 ml,
p<0.05). Rats of the NP line drank more NaCl solution than P rats but the effect was not as robust as that seen with sucrose and the difference was significant only at one of the NaCl concentrations (0.4 g/100 ml, p<0.05). The P and NP rats did not differ in citric acid or sucrose octaacetate intake at any of the concentrations tested. Selective breeding for oral ethanol preference and nonpreference in these lines of rats appears to be associated with differences in the self-administration of sweet and salty flavored solutions. (AA08553 and AA07611)

#### 227.15

ETHANOL SELF-ADMINISTRATION IN TRANSGENIC MICE. C.J. Meliska\*, A. Bartke, J.L. Vandergriff, and R.A. Jensen. Departments of Psychology and Physiology, Southern Illinois University at Carbondale, Carbondale, IL 62901-6502.

Evidence suggests that central dopaminergic (DA) mechanisms mediate the rewarding effects of ethanol and various other drugs of abuse. Genetic alterations in DA function may also modulate susceptibility to ethanol self-administration. For example, altered hypothalamic DA turnover rates occur in transgenic (T) mice expressing various growth hormone (GH) genes (Steger, R.W. et al., 1991, Neuroendocrinology, 53, 365-372). In particular, male MT/bovine GH T mice show elevated DA turnover relative to T females and non-T littermate controls. Using a two-bottle choice paradigm, we presented tap water and an ascending series of ethanol concentrations (2.2, 4.6 and 10.0%, v/v), for 4 to 6 days per concentration, to 90-day-old male and female T mice and matched [EtOH/(EtOH+H<sub>2</sub>O)] of male T mice were higher at 4.6% (0.67 vs. 0.49, p = .035), and at 10.0% (0.71 vs. 0.36, p = .012) than in non-T males, suggesting that T mice with elevated central DA function may be more prone to self-administer ethanol than controls. Thus, T mice expressing GH genes may provide a useful model for studies of the role of DA function in ethanol selfadministration and ethanol abuse.

## 227.17

ALCOHOL-ILLNESS ASSOCIATIONS IN THE SELECTIVELY BRED HIGH ALCOHOL DRINKING (HAD) AND LOW ALCOHOL DRINKING (LAD) RATS. R.L. Elder\*, N.B. Elder. P.J. Bice, S.A. Bailey and S.W. Kiefer. Department of Psychology, Kansas State University, Manhattan, KS 66506-5302.

Selectively bred HAD and LAD rats obtained from Indiana University were used to examine the acquisition and extinction of an alcohol aversion. Each subject was given two pairings of a 6% (v/v) alcohol solution followed by the intubation of a .15 M LiCl solution. On the day following the second acquisition trial, animals were tested for taste reactivity to 6% alcohol. The animals then received seven extinction trials with the alcohol solution, each trial given every other day. Analysis of the taste reactivity data showed that HAD rats produced significantly fewer aversive responses than LAD rats. The groups did not differ in ingestive reactivity. Although both HADs and LADs showed strong alcohol avoidance on the initial extinction test, the HAD rats consumed significantly more alcohol over the course of the seven extinction trials. These results suggest that, while HAD rats acquired an avoidance of alcohol when it was paired with illness, the avoidance did not appear to entail a shift in palatability nor was it as durable as that found in LAD rats.

COMPARISON OF ALCOHOL-PREFERRING (P) AND -NONPREFERRING (NP) RATS IN A FORCED-SWIM STRESS TEST. C.D. Godfrey, S.L. Jing, R.B. Stewart, J.C. Froehlich and J.M. Murphy\*. Dept. Psychology, Purdue Sch. Sci., Dept. Med. & Inst. Psychiat. Res., Indiana U. Sch. Med., IUPUI, Indianapolis, IN 46202.

Rats of the P and NP lines have been selectively bred

for alcohol preference and nonpreference. P and NP rats were compared in a swim test to determine if differences in response to an inescapable stressor are associated with genetic differences in alcohol preference. Alcohol-naive adult male P and NP rats (n=10/line) were placed in a round tub filled with ambient temperature tap water (21°C). The rats were unable to touch the bottom or escape from the tub. Behavior was videotaped for 10 minutes on each of two consecutive days and scored for time spent actively swimming or immobile. During both daily sessions, rats of the NP line were less active than P rats and spent approximately 50% (p<0.05) more time immobile. The effect of desipramine (10 or 20 mg/kg) or saline on behavior in the swim test was investigated in satine on behavior in the swim test was investigated in separate groups of P and NP rats. Both doses of desipramine significantly (p<0.05) attenuated time spent immobile in the P and NP rats, but the attenuation was greater in rats of the NP line. Hence, desipramine served to eliminate the line difference in time spent immobile. Compared with NP rats, P rats may be more anxious and/or less susceptible to despair in response to an inescapable stressor. (Supported by AA08553, AA08312 and AA07611)

TRH ANTAGONISM OF ETHANOL-INDUCED SEDATION IN ALCOHOL-PREFERRING (P) AND -NONPREFERRING (NP) RATS. Morzorati\*, Y. Morrow, M.J. Kubek, Depts. Psych., Med. & Anat. & Regenstrief Inst., Indiana Univ. Sch. Med. Indianapolis, IN 46202

Sleep time (ST) is significantly shorter in P rats

compared with NP rats following a single, sedating dose of ethanol. Intracerebroventricular (icv) administration of TRH antagonizes ethanol-induced sedation in a number of species. The present study was undertaken to determine if P and NP rats are differentially sensitive to TRH in reversing sedation produced by ethanol. Adult alcohol-naive male rats were injected ip with ethanol, 3g/kg, and tested for loss of righting reflex. TRH (5, 20, 40ug) or saline was infused icv (10ul) and ST was calculated. TRH dose-dependently decreased ST in both lines of rats (35-80% in NP rats and 40-50% in P rats). All doses of TRH were effective in NP rats, while only the 2 highest doses were effective in P rats. TRH was approximately twice as potent in NP rats compared with P

These data agree with those indicating that TRH reverses the sedating effects of ethanol. NP rats are more sensitive to TRH than P rats. This may be due to an increase in receptor affinity or a decrease in TRH metabolism in the NP rats. (Supported by AA07611).

TASTE REACTIVITY AND CONSUMPTION AS MEASURES OF ALCOHOL PALATABILITY IN HIGH ALCOHOL DRINKING (HAD) AND LOW ALCOHOL DRINKING (LAD) RATS. N.B. Elder\*, P.J. Bice, and S.W. Kiefer. Department of Psychology, Kansas State University, Manhattan, KS 66506-5302.

Selectively bred, alcohol naive HAD rats and LAD rats (obtained from Indiana University) were tested for taste reactivity to five concentrations of alcohol (5%, 10%, 20%, 30%, and 40% v/v), sucrose, and quinine. After the reactivity tests, a two-bottle consumption test with 10% (v/v) alcohol and distilled water was given for 21 days to verify HAD or LAD status. A second taste reactivity test was conducted at the end of the alcohol access period. The initial reactivity results showed no significant differences between naive HADs and LADs in their responses to alcohol, sucrose, or quinine. However, after the three week access period, significant group differences in taste reactivity did appear. The reactivity of LAD rats remained stable relative to the first test but HAD rats showed a significant increase in ingestive responding and a significant decrease in aversive responding and a significant decrease in aversive responding. Our results replicated an identical study with alcohol preferring (P) and alcohol nonpreferring (NP) rats in that experience with alcohol increased its palatability for rats that consumed high amounts of alcohol.

GENETIC SELECTION FOR RAT LINES THAT SHOW A HIGH AND LOW TASTE PREFERENCE FOR ALCOHOL. P.J. Bice\* and S.W. Kiefer, Dept. Psychology, Kansas State University, Manhattan KS 66506-5302.

Rat lines were selectively bred to determine if the taste preference for alcohol (as measured by taste reactivity) was heritable and to examine possible correlated responses to taste. In this project, outbred rats were given an intraoral infusion of alcohol and the resulting orofacial responses were videotaped and analyzed. Based on the number of ingestive responses made to alcohol, two male-female pairs were selected to start a high ingestive responding line (LIR), and a control line. After one generation of selection, heritability for the total realized response difference between the HIR and LIR lines was estimated to be .43. Statistical analysis of the ingestive responses to alcohol for the S, generation revealed a significantly more ingestive responses to alcohol for the S, generation the P, and S, generations were also given two-bottle consumption tests. Although the HIR rats consumed more alcohol than the LIR rats, the relationship between consumption and taste reactivity revealed no significant phenotypic correlations. correlations.

BRAIN 125I—RTI—55 AND 3H—CFT BINDING IN NORMAL AND COCAINE—ABUSING HUMAN SUBJECTS
K.Y. Little,\* Kirkman J.A., Carroll F.I., Duncan G.E.

Cocaine causes its behavioral and subjective effects by binding to Cocaine causes its behavioral and subjective effects by binding to sites on monoaminergic transporters and inhibiting normal synaptic reuptake. Both RTI–55 and CFT are cocaine congeners which bind to the cocaine binding site and can be radiolabeled. Initial studies with 125I–RTI–55 indicate two binding sites ( $K_D=58\,\mathrm{pM},55\%$  binding;  $K_D=1.9\,\mathrm{nM},45\%$  binding) which are displaced by other dopamine—selective transporter—binding ligands, including CFT and GBR 12909, but with a 10–fold shift to the right. 125I–RTI–55 binds with high affinity to apparent serotonergic sites in the midbrain, but is only slightly displaced by fluoxetine in the striatum. In addition high affinity 175I–RTI–55 fluoxetine in the striatum. In addition high affinity 1251—RTI—55 binding (5—500 pM) was found unaltered in striatum from six -abusers, but there was a trend to increased binding at 2.5 nM. Conversely, 3H–CFT demonstrated significantly increased binding in the striatum of cocaine—abusers at 5 and 10 nM concentrations. Further evidence exploring the hypothesis that RTI-55 and CFT selectively label distinct cocaine binding sites will be presented. Evidence of altered binding in other brain regions of cocaine-abusing subjects will also be presented.

DOPAMINERGIC RECEPTOR SUBTYPE REGULATION IN COCAINE-INDUCED

DOPAMINERGIC RECEPTOR SUBTYPE REGULATION IN COCAINE-INDUCED PSYCHOSIS AND SUDDEN DEATH: AN AUTORADIOCRAPHIC STUDY. R. Toiba, A. I. Ruttenber, C. V. Wetli, W. Lee Hearn, I. Staley and D. C. Mash\*. Depts. of Neurology, Pharmacology, Biochemistry and Pathology, University of Miami School of Medicine and the Dade County Medical Examiner Dept., Miami, FL., 33101 and the University of Clorado School of Medicine, Denver, CO, 80262. Fatal cocaine intoxication presenting as an excited delirium has been reported in recreational users. Prodromal signs and symptoms of the cocaine intoxication include bizarre and violent behavior and hyperthermia. The cocaine overdose cases selected for receptor autoradiographic analysis were ones in which cocaine users presented with a psychotic reaction, died suddenly with respiratory arrest, and had low toxic levels of cocaine in blood. For quantitative autoradiographic studies, the D1 receptor subtype was labeled with 1 nM [3H]-SCH23390 and the D2 receptors was decreased significantly in the anterior sectors of the caudate and the putamen in the cocaine overdose cases as compared to controls cases. Significant decreases in D1 receptor numbers were observed also over the entorhinal cortex (Brodmann area 28) and within the cortical nucleus of the amygdala. No alteration in the density of D1 or D2 dopaminergic receptors were detected over the nucleus accumbens. The number (BMAX) and affinity (KD) of D2 dopaminergic receptors was unchanged throughout the anterior to posterior extent of the nucleus accumbens. The number (BMAX) and affinity (KD) of D2 dopaminergic receptors was unchanged throughout the anterior to posterior extent of the striatum. Within the hypothalamus, no group differences were seen in the density of the D1 receptor sites. In contrast, a significant decrease in the Bmax was determined for the D2 dopaminergic receptor within the anterior and preoptic nuclei of the hypothalamus. These results may be relevant to an understanding of the contribution of selective alterations in D1 and D2 receptor subtypes in central dopaminergic temperature regulation. D1 and D2 dopaminergic receptors mediate opposite effects on thermoregulation, with the D1 receptor mediating a prevailing increase, while the D2 receptor mediates an opposing decrease in core body temperature. The selective down-regulation in the density of the D2 dopaminergic receptor subtype within the hypothalamus may explain the hyperthermia associated with cocaine-induced excited delirium and sudden death. (DA06227)

 $[^{125}I]RTI$ -55 BINDING TO THE DOPAMINE TRANSPORTER IN COCAINE OVERDOSE DEATHS. I. Staley, R. Toiba, A. I. Ruttenber, C. V. Wetli, W. Lee Hearn, D.D. Flynn\* and D. C. Mash, Depts. Neurology, Pharmacology, Biochemistry and Pathology, Univ. of Miami School of Medicine and the Dade County Medical Examiner Dept, Miami, FL. 33101 and the Univ. of Colorado School of Medicine, Denver, CO, 80262.

Fatal excited delirium has been reported in recreational cocaine users

Fatal excited delirium has been reported in recreational cocaine users having significantly lower blood levels of cocaine than those usually associated with cocaine overdose deaths. Although the neural mechanisms underlying cocaine-induced psychosis and sudden death are not known, they may be related to the differential regulation by cocaine of neuroamine transporters and receptors. The cocaine analog [1251]RTI-55 is a potent ligand for the dopamine transporter (Boja et al., Eur.J. Pharm. 194:133, 1991). We have characterized the binding of [1251]RTI-55 to the dopamine transporter assayed in human brain membranes. Saturation analysis reveals multiple sites in the putamen with KD. values of 0.33 mM (BMAX = 165 pmol/g tissue) and assayed in human brain membranes. Saturation analysis reveals multiple sites in the putamen with KD values of 0.33 nM (BMAX = 165 pmol/g tissue) and 1.85 nM (BMAX = 473 pmols/g tissue). Competition studies demonstrate the following rank order of potency: GBR 12935 > mazindol  $\geq$  cocaethylene  $\geq$  (-)-cocaine > fluoxetine  $\geq$  desipramine > (+)-pentazocine > (+)-cocaine. Cocaine competed for [125]]RTI-55 binding sites in control putamen in a biphasic manner with 56% of the sites diplaying high affinity (IC50 = 60 nM) and the remaining sites with low affinity IC50 = 530 nM). Preliminary studies demonstrate that the density of [125]]RTI-55 binding to the high affinity site in the putamen was reduced in the excited delirium subgroup of cocaine the nontrivible of the putamen was reduced in the excited delirium subgroup of cocaine overdose deaths as compared to control values (p < 0.025). Homologous competiton revealed no alteration in the affinity of the binding sites assayed in the frontal cortex and putamen. Autoradiographic studies are underway to visualize the neural distribution and density of [1251]RTI-55 binding sites in cocaine overdose deaths. (Supported by DA06227)

mRNA ALTERATIONS IN THE BASAL GANGLIA OF HUMAN COCAINE ADDICTS. Y.L. Hurd\*, M. Herman, J. Kleinman and M. Herkenham. NIMH, Clinical Brain Disorder Branch, Neuroscience Center at St. Elizabeth's Hospital, Washington, D.C. 20032 and Section on Functional Neuroanatomy, Bethesda, MD 20892.

Molecular changes in the basal ganglia of human subjects with recent cocaine use were revealed in discrete neuronal convictions by in circumstances.

cocaine use were revealed in discrete neuronal populations by in situ hybridization histochemistry. Cocaine subjects had a history of repeated cocaine use and had cocaine and/or cocaine metabolites on board at the time of death. Cocaine subjects were compared to control subjects that had both a negative history and toxicology of cocaine use. Synthetic oligodeoxyribonucleotide probes as well as cDNA riboprobes were used to selectively label cells expressing the transcript for enkephalin, dynorphin, glutamic acid decarboxylase, somatostatin, substance P, neuropeptide Y, tyrosine hydroxylase, and subtypes of dopamine and glutamate receptors. In the human striatum dynorphin-containing cells were predominantly localized to the patch compartment, enkephalincontaining cells were predominantly localized to the matrix compartment, while substance P-containing cells were localized to both compartments. In cocaine users enkephalin mRNA levels were found to be decreased in the caudate and putamen while dynorphin mRNA levels were found to be increased (primarily in the patch compartment of the putamen). No significant alterations were observed in the gene expression of substance P, somatostatin, neuropeptide Y, or the dopamine D1 receptor. Selective alterations in other transmitter systems in the basal ganglia were also apparent. Disruption of systems altering sensorimotor and cognitive function as well as neurochemical evidence of "craving" is hypothesized.

#### MAZINDOL TREATMENT OF COCAINE ABUSERS Susan Stine, MD, PhD\*

We have studied Mazindol, a dopamine uptake blocker, in the treatment of cocaine addicts. It is hypothesized that mazindol a commonly available anorectic agent may compete with cocaine at the active site and inhibit cocaine use and craving.

There is preliminary evidence from a pilot study that mazindol is effective in decreasing cocaine use in cocaine abusers. The present study is a 12 week double-blind, randomized placebo-controlled treatment protocol. All subjects meet DSM III R criteria for current cocaine dependence, are in good health, heet DSM III K retirent for current cocanie dependence, are in good nearly, between the ages of 20 and 60 and report minimum of 14 gms of total cocaine use during the 12 weeks prior to seeking to treatment. Patients who meet DSM III R criteria for substance dependence disorder other than cocaine or meet criteria for major psychiatric disorder other than depression and anxiety disorder are excluded. Subjects receive 2 mg/day of mazindol (or matching placebo tablets) and receive weekly relapse prevention therapy.

The primary outcome measures are cocaine use as determined by urine toxicology and self report, and "desire to use" measured by a standard scale. Other psychological symptoms as well as serum indicators of dopaminergic function (plasma homovanillic acid and prolactin levels) are obtained as runction (plasma nomovanilus acto and pronactin levels) are obtained as hypothesis generating exploratory analyses as well as indicators of imbalance between groups. 24 subjects have been recruited to date and 11 of those have completed the study (active mazindol n=5, placebo n=6). No significant effect has been observed on cocaine use (urine toxicology or self-report) or desire to use. No difference between groups has been observed for depression or anxiety and mazindol has made no effect on these parameters. This study is ntinuing and data will be presented with a larger number of subjects ( goal is 60 subjects).

COCAINE SENSITIZATION IN ROMAN HIGH AND LOW AVOIDANCE RATS IS MODULATED BY SEX AND GONADAL HORMONE STATUS M. Haney\*, N. Castanon, M. Cador, M. Le Moal and P. Mormède, INSERM U 259, INRA, Université de Bordeaux II, Brance Bordeaux FRANCE

Roman high avoidance (RHA) and Roman low avoidance (RLA) male rats differ in reactivity to stressful stimuli and sensitivity to amphetamine. The following experiment compares the interaction between sex and gonadal hormone status on the acute and chronic effects of cocaine in the two strains. Adult male and female, RHA and RLA rats were housed in same-sex groups of three. Half the animals were gonadectomized (GDX) while the others were left intact. Sixteen days after gonadectomy, all rats were habituated to an activity cage (1 hr) and then administered cocaine hydrochloride (10 mg/kg IP) during the dark phase of the light cycle. Activity was measured for 2 hrs. This procedure was repeated twice/week for 5 weeks. Overall, RHA rats had higher baseline activity levels and were more sensitive to acute cocaine-induced locomotor enhancement than RLA rats. Following repeated administration, sensitivity to cocaine increased 100-500% above the response to the first injection; the per cent change was greatest in the RLA strain, such that sensitized RLA rats no longer differed from RHA rats in their response to cocaine. Within each strain, females were more sensitive to acute cocaine than males, particularly during proestrus. Females became more sensitized to repeated cocaine administration than males. GDX did not modulate the effects of acute cocaine, but did significantly attenuate cocaine sensitization in males and females of both strains. Therefore, the factors of sex and gonadal hormone status similarly modulated cocaine sensitization in RHA and RLA rats. In addition, strain differences in acute cocaine sensitivity diminished with repeated drug administration, due to the greater degree of sensitization in RLA rats.

## 228.9

ACUTE COCAINE TREATMENT LEVELS IN THE HIPPOCAMPUS. DECREASES OXYTOCIN C.H. Walker, J.M. Prange\* and C.A. Johns, J.D. Caldwell, A.J. Prange\* and C.A. Pedersen. Dept. of Psychiatry, Univ. of North Carolina, Chapel Hill, N.C. 27599.

Oxytocin (OXT) has been suggested as an endogenous mediator of the effects of cocaine

endogenous mediator of the effects of cocaine and estrogen. We studied the effects of acute cocaine treatment on OXT using twenty female Sprague-Dawley rats (250-275g) that were ovariectomized and one week later received either two consecutive days of s.c. injections b.i.d. of saline or 15 mg/kg of cocaine HCL in conjunction with 10µg of estradiol benzoate i.m.. On the third day the animals were killed and tissues taken for measurement of oxytocin by RIA. The whole hippocampus, ventral tegmental area (VTA) and amygdala were removed from each animal and analyzed for OXT immunoreactive animal and analyzed for OXT immunoreactive content. Mean picograms per area and per mg tissue were compared for the two groups using an tissue were compared for the two groups using an analysis of variance. Acute cocaine treatment significantly reduced oxytocin levels in the hippocampus both in picograms/area (1,17-F=7.49, p<.01) and in picograms/mg (1,17-F=4.89, p<.04). Levels in the VTA and amygdala were not significantly different between groups.

TREATMENT OF NEGATIVE SYMPTOMS AND CRAVING IN COCAINE-ABUSING SCHIZOPHRENICS WITH MAZINDOL, R. M. Johnson, J. J. Erdos\*, J. P. Seibyl, D. Miles, D. S. Charney, J. H. Krystal, Schizophrenia Biological Research Center, West Haven VA Med. Center and Dept. of Psychiatry, Yale Univ., New Haven, CT 06510.

Despite the high prevalence and significant morbidity associated with cocaine abuse in schizophrenic patients, there has been little study or effective pharmacotherapies for this population. This study evaluates the efficacy of the dopamine reuptake blocker, mazindol, in the treatment of cocaine-abusing schizophrenics. METHODS: Outpatients meeting DSM-III-R criteria for schizophrenia and concomitant cocaine abuse on a stable dose of neuroleptics were enrolled in a 4 week baseline and 8 week double blind placebo-controlled augmentation trial of oral mazindol at a dose of 2 mg/d. The patients were rated with the following outcome measures on a weekly basis; PANSS, AIMS, Webster Scale for Extrapyramidal Symptoms, Cocaine-Craving Scale, and selfreported cocaine use. Additionally, twice weekly urine toxicology screens were done. RESULTS: In an ongoing study, 4 subjects showed an 11% reduction in negative symptoms on placebo and a 37% reduction in negative symptoms on active mazindol as measured by the PANSS. Although none of the 4 subjects completely stopped cocaine use, mazindol appeared to have an advantage over placebo in decreasing the amount of craving and frequency of cocaine use. IMPLICATIONS: If effective in a larger sample, mazindol may be useful in the treatment this refractory subset of schizophrenic patients. It also may provide clues to neurobiological aspects of cocaine use in this population.

COCAINE-INDUCED TURNING BEHAVIOR IN RATS WITH UNILATERAL LESION OF THE DOPAMINE PROJECTION: EFFECT OF FETAL MESENCEPHALIC TRANSPLANTS D. Masco® & K. Gale, Department of Pharmacology,
Georgetown University Medical Center, Washington, DC 20007
Cocaine elicits strong asymmetrical locomotor activity in rats

with unilateral 6-hydroxydopamine lesion of the dopaminergic (DA) nigrostriatal pathway. This rotational behavior is directed toward the lesioned side (i.e. ipsiversive). In the present study, fetal brain tissue containing DA cells, was grafted over the DA-denervated striatum in order to provide a partial reinnervation of the striatum, and the transplanted rats were subsequently evaluated for their response to cocaine. After transplantation, a strong contraversive rotational behavior in response to cocaine was observed; this was never

observed in lesioned rats without transplant or with sham transplant.

We also examined the effect of <u>repeated</u> exposure to cocaine on the turning behavior in lesioned rats with and without transplants. Following daily administration of cocaine (25 mg/kg per day for 5 days) marked "sensitization" to cocaine was observed: We found an increase of 3-4 fold in a) the rate of ipsiversive turning in lesioned rats without transplants and b) in the rate of contraversive turning in rats with transplants. These data suggest that the transplant-reinnervated striatum responds in an exaggerated fashion not only to the acute effects of cocaine but also to the actions of cocaine responsible for the development of sensitization.
