Cocaine produces supraspinal, non-oplate analgesia in rats that is believed to be mediated, at least in part, by dopamine (Lin et al., Brain Res. 479:306, 1989). The purpose of this study was to determine the analgesic properties of several cocaine metabolites and analogs. Also, brain cocaine (COC) levels were measured using GCMS. Adult rats (N=6-12 per group) were injected intracerebroventricularly (kc) with COC, cocaethylene (COCE), benzoylecgonine (BE), norcocaine (NORCOC), ecgonine (EC), tropaine (TROP), tropacocaine (TRPCOC), and ecgonine methyl ester (EME). Analgesia was assessed using a standard hot plate method (Lin et al., 1989). Cocaine (.370 mcM, potency=1.00) and COCE (.075 mcM) both induced short-term analgesia (10 min); COCE was approx. 5 times more potent. Brain COC levels decreased rapidly (30 min) from 70 to 5 ug/g tissue. EC, TRPCOC, and TROP produced analgesia but were less potent than cocaine (18, 62, 8. 11 relative potency, respectively). Both BE and NORCOC produced longer acting analgesia (approx. 60 min.) with potencies similar to COC (1.06 & .860, respectively). EME did not cause analgesia in doses ranging from .3 to 3.7 mcM. The results Indicate that: (1) N-demethylation, hydrolysis of the C2 methyl ester group and addition of a carbon molecule at the C2 methyl ester group and addition of a carbon molecule at the C2 methyl group of cocaine increase its analgesic properties and/or the duration of analgesia; (2) loss of the C3 benzoxy group attenuates analgesic activity, (3) cocaethylene is a fast-acting and potent analgesic; and (4) brain cocaine levels decline rapidly and correlate with the loss of analgesic activity.

INHIBITION OF COCAINE-INDUCED SEIZURES AND ANALGESIA BY ECGONINE METHYL ESTER. G. Schuelke, K. Welr. L. C. Terry , Dept. of Neurology, Medical College of Wisconsin, Milwaukee, WI 53226.

Previous studies in rats showed that cocaine-related tropanold compounds cause thermal (hot plate) analgesia and seizures following intracerebroventricular (icv) injection. These studies showed that several cocaine analogs cause analgesia for up to 60 minutes. Of the tropanoids tested to date, only ecgonine methyl ester (EME) failed to cause seizures, analgesia, or other psychomotor/behavioral effects. The purpose of this study was to determine if EME inhibited cocaine-induced analgesia and seizures. Rats were injected icv with 3.7mcM EME, rested 5, 10, or 15 minutes, given 0.44mcM cocaine icv, and tested for hot plate analgesia. EME caused significant inhibition of cocaine analgesia. Inhibition was not seen when cocaine was injected simultaneously with EME or ≥15 minutes after EME. A similar protocol was used to investigate EME inhibition of cocaine-induced tonic/clonic seizures. In this experiment, 2.37, 1.78, or 1.18mcM of cocaine was injected 2 minutes after EME 3.7mcM icv. EME decreased the duration of seizures induced by 2.37mcM of cocaine cov but did not prevent them. Treatment with 1.78mcM of cocaine produced seizures in 33% (4 of 12) of EME-treated rats vs. 88% (8 of 9) control rats (P=.03) with the average time of seizures being 1.6 minutes in the EME-treated rats and 7.8 in controls. Administration of 1.18mcM cocaine produced seizures in 15% of EME treated rats (N=20) and 56% of saline controls (N=19; P=0.01). The data show that EME inhibits cocaine-induced analgesia and seizures. Time- and concentration-dependency of this inhibition suggest that EME binds competitively to CNS cocaine receptors and blocks at least some of it's central effects. These findings may be of possible clinical significance in the treatment by EME or related compounds of cocaine-induced seizures and other clinical effects.

PHYSIOLOGICAL ACTIONS OF COCAINE IN SENSORY CIRCUITS: II DRUG- INDUCED ALTERATIONS IN RECEPTIVE FIELD PROPERTIES OF RAT SOMATOSENSORY CORTICAL NEURONS. B.D. Waterhouse\* and

OFRAT SOMATOSENSORY CORTICAL NEURONS. B.D. Waterhouse\* and L. Bekavac, Dept. of Physiol. and Biophys., Hahnemann U., Phila., PA 19102 In human subjects cocaine has been reported to produce alterations in sensory perception as well as a generalized state of well being. Although considerable effort has been focused on identifying the neural basis of cocaine's euphorogenic properties, there have been few studies aimed at investigating the drug's influence on sensory signal processing. In a companion study we have reported that systemically administered cocaine (0.25-1.0 mg/kg, i.v.) can enhance rat somatosensory cortical neuronal responsiveness to mechanical displacement of mystacial vibrissae. The goal of the present experiments was to determine if cocaine exerts a uniform facilitating effect on cortical cell responsiveness to stimulation of different portions of its receptive field (RF). Extracellular recordings were obtained from single units in the barrelfield cortex of halothane-anesthetized rats. Cellular responses to mechanical displacement of "central" and "peripheral" whiskers were monitored before and after systemic administration of cocaine (0.25,0.5,1.0 and 2.0 mg/kg i.v.). Control responses to vibrissae stimulation consisted of an initial excitatory burst (E1) sometimes followed by a post excitatory suppression of activity (11) and a Control responses to vibrissae stimulation consisted of an initial excitatory burst (E1) sometimes followed by a post excitatory suppression of activity (11) and a secondary excitatory discharge (E2). For a given cell, displacement of the "central" whisker produced the most robust response whereas equivalent stimulation of an adjacent "peripheral" whisker produced a lesser response. After injection of cocaine at 0.25, 0.5 or 1.0 mg/kg the magnitude of responses to central whisker stimulation were increased or unchanged from control. Over the same dose range stimulation were increased or unchanged from control. Over the same dose range responses to peripheral whisker displacement were progressively reduced, sometimes to the point of complete suppression at 1.0 mg/kg. These results suggest that a net action of systemic cocaine on sensory cortical neurons is to differentially suppress responses from the periphery of the RF while preserving or increasing responses to central RF stimulation. Such drug-induced alterations in the functional dimensions of sensory neuron RF's could lead to changes in sensory perception such as those reported after cocaine self- administration. (NIDA DA05117)

EVOKED POTENTIAL EXCITABILITY CYCLES DURING EARLY COCAINE ABSTINENCE Richard A. Roemer\* and Charles Shagass
Department of Psychiatry, Temple University and Belmont
Center. Philadelphia, PA 19131

We report on somatosensory evoked potential (SEP) excitability cycles, using right median nerve stimulation, recorded in 22 males who were early abstinent chronic cocaine abusers (median 11 days abstinent). They are compared to age-matched male controls in terms of amplitude and topography of 8 SEP events occurring the first 65 msec poststimulus to the conditioning stimulus alone and to pairs of stimuli at seven ISIs. The ISIs ranged from 5 to 90 msec.

Group by Lead differences were found at 10 msec ISI for P14, N19, N31, and P45; at 55 msec ISI for P28, P39, P45, and N65; and at 90 msec ISI for P28, N31, and N65.

These data indicate differences in SEP recovery between anterior and posterior scalp regions in relation to exposure to cocaine. The data support the viability of SEP recovery cycle studies in demonstrating CNS alterations subsequent to chronic cocaine use.

Supported, in part, by DAO6728 and MH12507 We report on somatosensory evoked potential (SEP)

PHYSIOLOGICAL ACTIONS OF COCAINE IN SENSORY CIRCUITS: I. ENHANCEMENT OF RAT SOMATOSENSORY CORTICAL NEURON
RESPONSIVENESS TO VIBRISAE STIMULATION. I. Bekavac\* and B.D.
Waterhouse. Dept. of Physiol. and Biophys. Hahnemann U., Phila. PA 19102
Prominent among cocaine's psychostimulant actions are its ability to heighten
awareness of the sensory surround and induce sensory hallucinations. While many
studies have examined the cellular actions of cocaine in "reward" circuits of the brain,
few have investigated the impact of cocaine on neuronal function in primary sensory circuits. The goal of this study was to characterize the effects of cocaine on somatosensory cortical neuronal responsiveness to peripheral activation of afferent synaptic pathways. Extracellular recordings were obtained from spontaneously active single units in the barrelfield cortex of halothane-anesthetized rats. Sponactive single units in the barrelfield cortex of halothane-anesthetized rats. Spontaneous firing rate and cellular responses to mechanical displacement of a single whisker were monitored before and after systemic administration of cocaine (0.25, 0.5, 1.0 and 2.0 mg/kg i.v.). Control responses to vibrissae stimulation consisted of an initial excitatory burst (E1), a post excitatory suppression of activity (11) and a secondary excitatory discharge (E2). Cocaine effects on spontaneous discharge were variable but generally slight increases in firing rate were noted with low doses, up to 1.0 mg/kg, and marked suppression of activity observed at 2.0 mg/kg. After cocaine injection, E1 responses were unchanged or within (+/-) 20% of control; however, in 9 of 10 cells E2 responses were increased from 50 - 600% above control however, in 9 of 10 cells E2 responses were increased from 50 -600% above control levels. Such facilitation was observed at doses as low as 0.25 mg/kg but most consistently at 0.5 - 1.0 mg/kg; whereas suppression of both evoked responses was seen at 2.0 mg/kg. Cocaine's effects on spontaneous and evoked discharge were rapid in onset with peak effects occurring at 6 min post-injection and recovery to control patterns of discharge observed by 20 min. These results indicate that cocaine consistently exerts a facilitating effect on a specific late component of cortical neuron responses to sensory stimuli. While the specific neural substrates responsible for this effect have not been identified, such findings demonstrate a clear impact of cocaine on sensory signal transmission at dosages which are capable of supporting behavioral reinforcement. (Supported by NIDA DA 05117)

PHYSIOLOGICAL ACTIONS OF COCAINE IN SENSORY CIRCUITS: III. EFFECTS ON INTRINSIC MEMBRANE PROPERTIES OF RAT SOMATOSENSORY CORTICAL NEURONS. F.M. Sessler, \* R.D. Mouradian, C.-S. Lin and B.D. Waterhouse. Dept. of Physiol. and Biophys., Hahnemann Univ., Philadelphia, PA 19102.

C-S. Lin and B.D. Waterhouse, Dept. of Physiol. and Biophys., Hahnemann Univ., Philadelphia, PA 19102.

The somatosensory cortex, a major target area for monoaminergic projections, contains an heterogeneous neuronal population which is believed to express different complements of membrane receptors, signal transduction mechanisms and ions channels. These neurons can be classified according to unique morphology, electrophysiology and synaptic connectivity. This heterogeneity suggest that classes of neurons may be more sensitive to the action of cocaine than others. Thus, it may be necessary to obtain specific information concerning the influences of cocaine on individual cellular components of the cortical circuitry in order to fully comprehend the potential impact of this drug in the signal processing capabilities of a sensory cortical network. To address this question, experiments were conducted using an in yirto brain slice preparation from rat somatosensory cortex. Microelectrodes (3% neurobiotin in 1 M KCl) were used for electrophysiological and morphological characterization of individual layer V cortical neurons. Excitatory postsynaptic potentials (EPSP) were evoked by stimulating the cortical white matter (WM). Cocaine was applied at various concentrations (0.3-100uM) to examine the full spectrum of the drug's effects. Bath application of cocaine did not produce significant changes in membrane potential and input resistance in most of the neurons recorded, whereas cell excitability, as measured by depolarizing current pulses, was increased by drug application in several cases. Cocaine (30-100uM) reversibly decreased the amplitude and duration of EPSPs and also reduced the number of evoked action potentials. At lower doses (1-10uM), cocaine produce denancement of neuronal excitability in response to both, current pulses and stimulation of WM. Preliminary data indicate that cocaine-induced effects may vary across different of the current pulses and stimulation of produce denancement of neuronal excitabilit

METABOLIC RECOVERY DURING COCAINE WITHDRAWAL, B.B. Young\* S.J. Lee, W.S. Pires, E.S. Cooke and R.P. Hammer, Jr., Lab. of Cellular & Molecular Neuropharmacology, Dept. Anatomy & Reprod. Biology, Univ. Hawaii Sch. Med., Honolulu, HI 96822

Withdrawal following chronic cocaine treatment is known to produce

windrawai following chronic cocaine treatment is known to produce short-term reduction of brain metabolic activity (Clow and Hammer, Neuropsychopharmacol., 4: 71-75, 1991). The present study examined metabolic recovery over time during cocaine withdrawal, and following pharmacotherapy with BMY 14802. Adult male rats were treated for 14 days with saline vehicle or cocaine HCl (10 mg/kg) followed by 3 or 7 days of water vehicle or BMY 14802 (10 mg/kg). Regional cerebral metabolic rate (rCMR) was measured using the quantitative method of Scheleff paternal careachies acquired to the data print of MB pulses. Sokoloff; autoradiographic analysis was used to determine rCMR values in 61 brain regions. rCMR was reduced in the infralimbic medial prefrontal cortex after 3 and 7 days of withdrawal. The 3 day withdrawal group showed significant reductions in the nucleus accumbens core and shell, olfactory tubercle, dorsolateral ventral pallidum, globus pallidus, entopeduncular nucleus, central amygdala, lateral hypothalamus, substantia nigra, pars reticulata and central gray compared to the control group, while decreases were observed only in the globus pallidus, entopeduncular nucleus, medial habenula, and entorhinal cortex after 7 days. Treatment with BMY 14802 enhanced metabolic recovery at an earlier time point in most regions. The results suggest that recovery from the metabolic effects of cocaine withdrawal occurs in the mesolimbic system in as little as one week, while sustained deficits are still present in extrapyramidal efferent zones. Treatment with an indirect dopamine agonist can further enhance metabolic recovery. Supported by USPHS awards DA06645, RR08125, and HD01161.

CYTOTOXICITY OF THE COCAINE METABOLITE BENZOYLECGONINE.

CYTOTOXICITY OF THE COCAINE METABOLITE BENZOYLECGONINE.

Y. Lin\* and K.C. Leskawa. Dept. Anatomical Sciences & Neurobiology, School of Medicine, University of Louisville, Louisville, KY 40292.

We have previously reported that the major metabolite of cocaine, benzoylecgonine (BE), increased glycosphingolipid synthesis by glial cells (C6) but not neuronal cells (NG108-15) in culture. This was observed at low BE concentrations (10 µM or less). At higher BE concentrations glycosphingolipid synthesis appeared to decrease, but it was found that this was due to a loss death from the substantiane.

synthesis appeared to decrease, but it was found that this was due to a loss of cells from the substratum. We have recently found that this loss is not due to BE altering substratum interactions of C6 or NG108-15 cells, but that BE exerts cytotoxic effects. This was demonstrated by decreased cell viability, as determined by the activity of mitochondrial dehydrogenases, with increasing BE concentrations (from 0 to 100  $\mu$ M). Also, detached C6 and NG108-15 cells were not viable, as determined by Trypan Blue inclusion and determination of DNA synthesis using  $^{\rm NR}$ 

determined by Trypan Blue inclusion and determination of DNA synthesis using <sup>3</sup>H-thymidine.
Early events in these interactions were studied by examining cells cultivated on the stage of an inverted microscope using differential interference contrast (Nomarski) optics. Retraction of cellular processes within 15 minutes could be observed when both cell types were cultured in the presence of 50 µM BE. Eventual loss of cells could be observed within 3 hours. When the media concentration of BE was reduced to 10 µM, retraction of processes could again be observed, but the time course was slightly longer (30 minutes or more). Cultures of primary astrocytes exhibited similar morphologic reactions. Under these experimental conditions control cells remained viable and extended processes.

These results demonstrate that benzoylecgonine is cytotoxic to both neuronal and glial cells at concentrations near those found in fetal brain following prenatal cocaine exposure.

GENDER DIFFERENCES IN PLACE PREFERENCE INDUCED BY ICV INJECTIONS OF COCAINE. S. Wang\* and G. A. Barr. Biopsychology Doctoral Program, Dept. of Psychology, Hunter College-CUNY, NY, NY 10021 and Dept. Develop. Psychobiology, New York State Psychiatric Institute, NY, NY 10032.

Conditioned place preference (CPP) has been used to study the reinforcing properties of cocaine and other abused drugs. Most investigators have used male rats even though it has been reported that many of the behavioral responses to psychostimulants are gender dependent. In the present experiment, male or female adult rats were injected with cocaine HCl (0, 10, 30, or 100 µg) or saline into the lateral ventricle through indwelling cannulas. Immediately following injection, animals were individually confined into one of two distinguishable sides of a chamber for 30 minutes. Eight hours later, rats were confined to the opposite side and injected with the opposite treatment (cocaine or saline). Training lasted 4 days. On the 5th day, rats were tested for a side preference in a 20 minute test using a three chamber test apparatus. Females demonstrated a dose-dependent preference for the side paired with cocaine, preferring the two highest doses. In contrast, male rats displayed a strong aversion to the side paired with the drug. These effects lasted for several extinction trials. This result was not found when cocaine was injected peripherally. The results indicate a distinct gender difference in the reinforcing properties of cocaine and indicate a central site of action. Further investigation is needed to explain the mechanisms of this result. (Supported in part by DA-06600)

THE SELECTIVE 5-HYDROXYTRYPTAMINE1a AGONIST LY274600 EXACERBATES INCREASES IN SENSORIMOTOR REACTIVITY RESULTING FROM WITHDRAWAL OF CHRONIC NICOTINE. D. Helton\*, K. Rasmussen, D. Modlin, J. Barrett, and J. Tizzano. Lilly Research Labs, Eli Lilly and Company, Greenfield, IN, 46130.

Cessation of chronic nicotine (NI) in rats leads to increased startle responding during the first 5 days of nicotine withdrawal. The present study evaluated the effects of pretreatment with 1) the known anxiolytic diazepam, 2) the 5-HT<sub>1a</sub> agonist LY274600, and 3) NI replacement on auditory startle responding following NI 3) NI replacement on auditory startle responding following NI withdrawal. NI (6 mg/kg/day) was continuously administered for 12 days in rats by surgically implanting osmotic pumps (sc). Diazepam (3 mg/kg, ip), LY274600 (.3, 1, 3 mg/kg, sc), and NI (.01, .03, .1, .5 mg/kg, ip) were given 15 minutes before daily evaluation of startle responding for 5 days following cessation of NI exposure. NI replacement reversed the increased reactivity following the termination of chronic NI for 5 days. In addition, diazepam attenuated the increased reactivity schemes of the characteristic schemes. diazepam attenuated the increased reactivity observed for 5 days at a dose which did not alter startle responding in naive rats. In contrast, the selective 5-HT<sub>1a</sub> agonist LY274600 exacerbated withdrawal at doses which did not alter startle responding in naive rats. These results suggest that  $5\text{-HT}_{1a}$  agonists may not be useful for attenuating the withdrawal symptoms associated with the cessation of chronic NI exposure.

NEUROPHYSIOLOGICAL EFFECTS OF SYSTEMIC NICOTINE ON NEURONS IN THE NUCLEUS ACCUMBENS. <u>C. Hart, A. Strauss, and R.L Hakan</u>\*. Dept. Psychology, UNC-W, Wilmington, NC 28403
Extracellular recordings of single neurons within the

Extracellular recordings of single neurons within the nucleus accumbens (NAS) of halothane anesthetized rats have revealed that systemic nicotine injections (1.0 mg/kg) inhibit the action potentials evoked from normally inactive NAS neurons by fimbria stimulation (Fimbria-driven responses, n= 18/20). These nicotine inhibitions of fimbria-driven NAS action potentials appear to be centrally mediated because they were reversed by subsequent injections of mecamylamine (1.0 mg/kg). reversed by subsequent injections of mecamylamine (1.0 mg/kg, s.c., n=6/6) but not by hexamethonium (2.0 mg/kg, s.c., n=0/6). Nicotine induced inhibitions of NAS fimbria-driven units were followed in some experiments by halperidol (0.5 mg/kg, s.c.), in attempts to reveal the possible role of dopamine in these effects. Halperidol was successful at reversing nicotine inhibitions in only a few cases (n= 2/6). In contrast to the fimbria-driven responses, spontaneously active NAS neurons were not affected by nicotine injections. Iontophoretic studies to further localize the site of this nicotine action on NAS neurons are in progress.

NALOXONE PRECIPITATES NICOTINE ABSTINENCE SYNDROME IN RAT. D.H. Malin, V.A. Carter, J.R. Lake, J.S. Cunningham and O.B. Wilson\*1. Univ. of Houston-Clear Lake, Houston, TX 77058 and <sup>1</sup>Baylor College of Medicine, Houston, TX 77030.

At last year's meeting this laboratory reported a rapid and convenient rodent model of nicotine abstinence syndrome based primarily on frequency of spontaneous behavioral signs resembling those seen in opiate abstinence syndrome. Might there be an endogenous opioid component in nicotine dependence? The present study determined whether a moderate dose of naloxone s.c. could precipitate an abstinence syndrome in nicotine-dependent rats. Fourteen male Sprague-Dawley rats were continuously infused s.c. for 7 days with 9 mg/kg/day nicotine tartrate in saline via one Alzet osmotic minipump. Fourteen rats were sham-operated and remained nicotine-naive. Half of each group received 4.5 mg/kg naloxone s.c. immediately before a 15 minute observation. The remaining rats received saline s.c. All observations were performed under "blind" conditions. Anova revealed significant drug infusion, drug injection and interaction effects. Post hoc analysis (Dunnett's) revealed that the nicotine-dependent + naloxone group exhibited significantly more overall abstinence signs than all other groups, p<.01. This group differed significantly from all others on writhes/gasps, chews, genital licks, and shakes/tremors. (Supported by Neuromedical Technology, Inc.)

## 229 4

EFFECTS OF PRENATAL COCAINE ON ADULT SEXUAL BEHAVIOR AND ON BRAIN CATECHOLAMINES IN RATS. Ilona Vathy and Livia Katay. Dept. Psychiatry, Albert Einstein Coll. Medicine, Bronx, NY 10461.

Female rats exposed to cocaine hydrochloride (C) in utero (10 mg/kg twice a day on days of 11-18 of gestation) were significantly inhibited in their adult sexual behavior when compared to salineexposed (S) controls. In contrast, males exposed prenatally to C exhibited increased mounting and intromitting activity and had shorter post-ejaculatory intromission intervals relative to controls. Examination of the catecholamine content in the hypothalamus, preoptic area (POA), striatum, cortex and cerebellum revealed that prenatal C treatment affects males and females differently. Prenatally C-exposed male rats had significantly higher norepinephrine (NE) and dopamine (DA) levels when compared to S-treated controls. In contrast, NE and DA content in the POA of S and C-treated females were essentially identical. Neither NE nor DA content in other brain regions of C-treated male and female rats were different from Streated controls. These results suggest that prenatal C exposure, which differentially affects adult male and female sexual behavior, also alters the content of catecholamines in the POA in a sexually dimorphic fashion. Supported by NIDA DA 05833.

EFFECTS OF CONTINUOUS COCAINE ADMINISTRATION ON OPIOID-REGULATED ADENYLYL CYCLASE ACTIVITY IN RAT NUCLEUS ACCUMBENS. S. Izerwasser and B.M. Cox. Department of Pharmacology, Uniformed Services University, Bethesda, MD and \*Psychobiology Laboratory, NIDA Addiction Research Center, Baltimore, MD. Cocaine is a psychomotor stimulant that inhibits the reuptake of dopamine

into presynaptic dopaminergic terminals. Pretreatment with cocaine has been shown to alter opioid receptor densities in rat brain. Opioid receptor activation leads to inhibition of adenylyl cyclase activity. To investigate the functional consequences of cocaine-induced opioid receptor changes, functional consequences of cocaine-induced opioid receptor changes, adenylyl cyclase activity was measured in rat nucleus accumbens following continuous cocaine administration. Male Sprague-Dawley rats were chronically treated with either cocaine (50 mg/kg/day, expressed as free base), or saline (0.9% sodium chloride; 24  $\mu$ l/day) via subcutaneously implanted osmotic minipumps. After 7 days, the effects of DAMGO, the selective  $\mu$ -opioid receptor agonist, and the selective  $\delta$ -opioid receptor agonists DPDPE and DSLET were examined on adenylyl cyclase activity in crude membrane preparations of the nucleus accumbens. Adenylyl cyclase activity was measured with a cAMP radioligand binding assay. There was no change in basal adenylyl cyclase activity in the nucleus accumbens of the animals treated with cocaine as compared to those receiving saline. animals treated with cocaine as compared to those receiving saline. Treatment with cocaine, however, led to an increase in the maximal inhibition of adenylyl cyclase by DAMGO but had no effect on DPDPE or DSLET inhibition in the nucleus accumbens. These findings suggest that continuous cocaine administration for 7 days results in a selective increase in  $\mu$ -opioid receptor mediated effector function in the nucleus accumbens (Supported in part by a grant from NIDA to BMC).

#### 229.7

COCAINE'S BEHAVIORAL AND LETHAL EFFECTS UPON THE DEVELOPING CHICKEN FETUS ARE BLOCKED BY TREATMENT WITH THE 5-HT1c/5-HT2 ANTAGONIST RITANSERIN. S.B.Sparber\*, D.G.Kim and E. Kostarczyk, Dept. of Pharmacology, Univ. of Minn., Mpls. MN 55455.

Cocaine, injected late during development of domestic chick fetuses (i.e. day 19 of incubation) reduces motility shortly after injection, reduces hatchability and causes behavioral changes in chicks for up to 2 weeks after hatching(FASEB J. 5:A1588,1991). This laboratory has published numerous reports on the efficacy of 5-HT1c/5-HT2 antagonists against the expression of opiate and quaisiopiate withdrawal. Because of similarities between acute effects of cocaine and withdrawal from opiates (e.g. autonomic activation, aroused CNS) we examined the therapeutic potential of a 5-HT1c/5-HT2 antagonist for its capacity to block one or more of cocaine's effects upon the developing chick fetus. In the P.M. of day 17 of incubation intanserin(0.4 mg/kg egg) or tartrate (0.05M) was injected(20  $\mu$ l) into chick eggs 2 cm below the air cell. In the A.M. of day 18, starting 10 hr after ritanserin, cocaine HCl(22.5 or 67.5 mg/kg egg) was injected and fetal motility was monitored. Moreover, additional eggs were injected and allowed to hatch. This dose of ritanserin blocked the significant reduction in motility 15-20 min after the low dose of cocaine only. It also blocked the reduction in hatchability of both doses of cocaine. These data confirm our hypothesis that some of the acute toxic effects of cocaine in the chick fetus are mediated indirectly by activation of 5-HT1c/5-HT2 receptors. It remains to be determined if potential functional teratogenic effects of cocaine can also be attenuated or prevented by this class of 5-HT antagonists in this species and in mammalian species as well.

## 229.9

REGULATION OF ANDROGEN RECEPTOR IMMUNOREACTIVITY BY ANABOLIC STEROIDS IN INTACT AND CASTRATED MALE RAT BRAINS. C. S. Menard\* and R. E. Harlan, Dept. of Anatomy, Tulane Med. School, New Orleans, LA 70112.

R. E. Harlan, Dept. of Anatomy, Tulane Med. School, New Orleans, LA 70112.

In an attempt to characterize changes in the central nervous system that occur with anabolic steroid abuse in humans, immunocytochemical localization of androgen receptors in the rostral brains of male rats was conducted after the administration of high levels of anabolic steroids. Specifically, 12 castrated and 12 intact male rats received 14 daily injections of sesame oil vehicle or a cocktail of 2mg/kg testosterone cypionate, 2 mg/kg nandrolone decanoate, and 1 mg/kg boldenone undecylenate. Immunocytochemistry was performed with 1 µg/ml IgG-purified polyclonal rabbit 1' antibody (provided by Gail Prins). In intact males treated with sesame oil only, intense moderate nuclear immunocettics indicated the research of actions. lerate nuclear immunoreactivity indicated the presence of androgen receptors intense-moderate nuclear immunoreactivity indicated the presence of androgen receptors in many brain regions, including the cortex, septum, bed nucleus of the stria terminalis, preoptic area, hypothalamus, hippocampus, amygdala, midbrain central gray, substantia nigra, ventral tegmental area, and locus coeruleus. However, in castrated males treated with vehicle, immunoreactivity was reduced or absent, suggesting that endogenous androgen levels are necessary for the normal immunoreactivity of these receptors. In castrated and intact males treated with anabolic steroids, the distribution and number of immunoreactive cells were equivalent to the found in intensity of ceiping of anabolic steroids, the distribution and number of immunoreactive cells were equivalent to that found in intact, oil-treated males. However, the intensity of staining of immunoreactive cells in all anabolic steroid-treated rats was dramatically increased over that seen in intact, oil-treated rats. Therefore, these high levels of anabolic steroids appear to increase androgen receptor immunoreactivity. These results may suggest that androgen receptors in the brain are up-regulated by anabolic steroids. However, regulation of androgen-receptor gene expression must be examined before this relationship can be established. Nevertheless, these results identify the distribution of one central nervous system mechanism modified by anabolic steroids. In addition, the increase in androgen-receptor immunoreactivity induced by anabolic steroids begins to characterize modifications in central nervous system functioning which underlie the characterize modifications in central nervous system functioning which underlie the psychotic, addictive, motoric, and sexual abnormalities reported when athletes abuse anabolic steroids at these high levels. Supported by NIDA Grant # DA-06194.

#### 229.6

CHANGES IN BASAL AND OPIOID-REGULATED ADENYLYL CYCLASE ACTIVITY IN RAT NUCLEUS ACCUMBENS AND CAUDATE-PUTAMEN FOLLOWING REPEATED, DAILY COCAINE ADMINISTRATION. E. M. Unterwald'. S. Izenwasser. T.E. Cote. M.J. Kreek, and B.M. Cox. The Rockefeller University, New York, NY and Uniformed Services University,

Cocaine binds to the dopamine transporter and prevents the reuptake of dopamine into presynaptic dopaminergic terminals. Repeated daily cocaine dopamine into presynaptic dopaminergic terminals. Repeated daily occaine injections have been shown to alter opioid receptor densities in rat brain (Unterwald et al., <u>Brain Res.</u>, in press). Adenylyl cyclase activity was measured in rat accumbens and caudate following repeated cocaine administration to determine the functional consequences of cocaine-induced opioid receptor changes. Male Fischer (CDF) rats were injected daily with saline or cocaine HCI (30 mg/kg/day i.p.) in three equal doses over a two hour period for 14 days. The effects of DAMGO (a selective µ-opioid receptor agonist) and DPDPE (a selective 8-opioid receptor agonist) on adenylyl cyclase activity in the nucleus accumbens and the rostral portion of the caudate-putamen were examined using a cAMP radioligand binding assay in crude membrane preparations. There was a 50% decrease in basal adenylyl cyclase activity in the caudate of animals treated with cocaine as compared to those receiving saline injections. In the nucleus accumbens, however, basal adenylyl cyclase activity was unchanged following the cocaine treatment. those receiving same injections. In the indiceds accombens, however, basal adenylyl cyclase activity was unchanged following the cocaine treatment. DAMGO and DPDPE maximally inhibited approximately 25% and 30%, respectively, of basal adenylyl cyclase in saline-treated animals. Treatment with cocaine attenuated the ability of DPDPE to inhibit adenylyl cyclase in with occarne attenuated the ability of DPDPE to inhibit adenlyif cyclase in both brain regions, but had no effect on the efficacy or potency of DAMGO for inhibiting adenylyl cyclase activity. These results suggest that chronic, repeated cocaine administration results in a selective impairment of 8-opioid receptor mediated effector function in nucleus accumbens and caudate-putamen. [Supported by grants from NIDA (BMC, MJK) and Aaron Diamond Foundation (MJK)].

EFFECT OF A CHIRAL 4-ALKYL SUBSTITUENT IN HALLUCINOGENIC AMPHETAMINES. Robert Oberlender\*, P. V. Ramachandran, Michael P. Johnson, Xuemei Huang and David E. Nichols. Departments of Medicinal Chemistry and Pharmacognosy, Pharmacology and Toxicology, School of Pharmacy and Pharmacal Sciences, and H. C. Brown and R. B. Wetherill Laboratories of Chemistry, Purdue University, West Lafayette, IN

The hallucinogenic amphetamines have recently attracted wide-spread interest, as members of this drug class have become increasingly useful as selective and potent agonists at the 5-HT2 subtype of serotonin receptors. This investigation was directed toward evaluating the effects of chirality in a branched alkyl group at the 4-position of a 2,5dimethoxy-substituted hallucinogenic amphetamine analogue. A pair of novel compounds related to the hallucinogen 1-(2,5-dimethoxy-4methylphenyl)-2-aminopropane (DOM) was prepared containing either the R- or S-2-butyl substituent in place of the 4-methyl group. The synthetic method included an asymmetric hydroboration reaction. No significant difference in the activity of these analogues was observed in male rats for either LSD-like dicriminative stimulus properties or affinity for the agonist-labeled serotonin 5-HT2 binding site. However, both diastereomers had high affinity for the serotonin 5-HT2 receptor, but lower behavioral potency than DOM, suggesting that the 2-butyl homologues might have decreased agonist efficacy.

EFFECTS OF POLYAMINES ON PCP-INDUCED EEG AND BEHAVIOR IN THE RAT. <u>D.F. Sisson', L.R. King and J.E. Moreton, University of Maryland School of Pharmacy, Baltimore, MD 21201.</u>

Phencyclidine (PCP) and PCP-like compounds bind with high affinity to a receptor within the ion channel of the NMDA-receptor complex blocking the channel. Recent studies have shown that the NMDA complex also contains a polyamine binding site. Agonists for the polyamine site, eg. spermine, enhance binding to PCP receptors; inverse agonists, eg. 1,10-diaminodecane (DA-10), decrease binding to PCP receptors; antagonists, eg. diethylenetriamine (DET), block the effects of either agonists or inverse agonists.

We tested the ability of DA-10 (250 nMole) and the polyamine antagonist arcaine (50 nMole), delivered intracerebroventricularly (icv), to attenuate the acute effects of intravenous (iv) PCP administration (1.25 and 2.5 mg/kg). Effects on behavior (locomotion, ataxia and stereotypy) were quantified with a rating scale (0-5). Effects of PCP on EEG power spectrum were measured with a Nicolet Pathfinder II.

Behaviorally, both DA-10 and arcaine significantly reduced PCP-induced ataxia and stereotypy while locomotor response was not affected. Neurally, these agents did not clearly affect PCP-induced augmentation of spectral power in the delta and theta bands of EEG. This dissociation of behavioral and neural effects could indicate that reduced ataxia and stereotypy are produced through mechanisms not specifically related to the PCP receptor. analysis of EEG power spectrum is in progress to determine if subtle neural changes were produced by DA-10 and arcaine.

This work is supported by NIDA grant DA03173.

EFFECTS OF CHRONIC EXPOSURE TO HIGH LEVELS OF TESTOSTERONE ON AGGRESSION AND SEXUAL BEHAVIOR IN MALE RATS. M.Y. McGinnis'. K.T. Thorner and A.R. Lumia. Dept. Cell Biol/Anat, Mount Sinai Sch. Med. New York, NY 10029 and Skidmore Coll., Biopsych. Prog., Saratoga Springs, NY 12866.

The substantial rise in reported abuse of anabolic steroids in humans has revived interest in the behavioral consequences of chronic exposure to androgens. In this experiment, the effects of chronic testosterone propionate (TP) treatment on intermale aggression and sexual behavior was examined in gonadally intact, male, Long-Evans rats. Sexually experienced males received three weekly injections of 1 mg TP, or propylene glycol (PG: control) for ten weeks. Animals were tested weekly for aggressive and sexual behaviors. Results indicate that TP-treated males displayed more dominance postures and fewer subordinate postures toward opponents than did PG-treated controls. The TPtreated rats also showed increases in the display of threats and initiated fewer attacks. There was no difference between groups in the frequency of approaches toward the opponent. These data suggest that the increase in dominance postures by TP-treated males is not due to increased contact with the opponent male (ie. approaches and attacks), but was due to an increase in threats directed toward the opponent. No effect of chronic TP administration on sexual behavior was found. The results suggest that anabolic steroids exert differential effects on aggressive and sexual behavior in gonadally intact male rats.

## PSYCHOTHERAPEUTIC DRUGS: SIGMA RECEPTORS AND ANTIPSYCHOTICS

#### 230.1

SIGMA BINDING IN RAT BRAIN IS DIMINISHED AFTER TREATMENT WITH HALOPERIDOL OR BMY 14802. <u>Diana Marrero.<sup>1</sup> Doris M. Grimes.<sup>2</sup> R. Francis Schlemmer, Jr.,<sup>2</sup> and Duncan P. Taylor\*.<sup>1</sup> Biophysics and Molecular Biology, Bristol-Myers Squibb Co., Wallingford, CT 06492-7660; <sup>2</sup>Pharmacodynamics, University of Illinois, Chicago, IL 60612.</u>

It has been proposed that agents with affinity for the  $\sigma$  binding site may be useful in the treatment of schizophrenia and psychosis. Rats were dosed intraperitoneally with haloperidol (2 mg/kg), the putative sigma antipsychotic BMY 14802 (10 mg/kg) or saline. Statistically significant decreases in the density of  $\sigma$  sites (B<sub>max</sub>) were observed for the binding of (+)-[³H]-3-(3-hydroxyphenyl)-N-(1-propyl)piperidine [(+)-[³H]-3-PPP] in the cortex of rats receiving either drug for 2 weeks or BMY 14802 for 3 weeks. In the cerebellum a trend was observed for a decrease in the B<sub>max</sub> value for  $\sigma$  binding following 2 weeks' treatment with BMY 14802, while no statistical difference was observed in the B<sub>max</sub> values following 3 weeks' treatment with either haloperidol or BMY 14802. No changes were seen in the affinity (K<sub>D</sub>) of  $\sigma$  sites for (+)-[³H]3-PPP with any treatment. These data confirm the work of others on the effect of chronic administration of haloperidol on  $\sigma$  binding and suggest that BMY 14802 may act at  $\sigma$  sites in the cortex and cerebellum in a similar manner after chronic administration.

## 230.3

IN VIVO BINDING OF THE SIGMA/5-HT<sub>2</sub> RECEPTOR ANTAGONIST DuP 734 TO MOUSE BRAIN. M. Watanabe\*, D. Rominger, E.B. De Souza and S. W. Tam. Central Nervous System Diseases Research, The Du Pont Merck Pharmaceutical Company, Wilmington, DE 19880-0400

In vivo receptor binding studies with DuP 734 have been performed to relate the behavioral effects to occupation of brain sigma receptors. DuP 734 administered orally to mice 30 min before i.v. injection of the sigma receptor ligand [3H](+)-SKF 10,047 potently antagonized the binding of [3H](+)-SKF 10,047 to mouse brain sigma receptors in vivo with an ED50 of 0.07 mg/kg, p.o.. Near maximal antagonism of  $[^3H](+)$ -SKF 10,047 binding was obtained at 0.3 - 1 mg/kg, p.o. DuP 734 which corresponds well to the ED50 dose of 0.35 mg/kg, p.o. in the mouse mescaline test. Preliminary in vivo binding studies demonstrated specific binding of [3H]DuP 734 (56 - 72 %) to several brain regions in mice. [3H]DuP 734 binding to cerebral cortex and cerebellum peaked around 45 min after i.v. injection and significant levels of specific binding were maintained when measured up to 4 hr post dose. Results on the pharmacokinetics and pharmacology of in vivo [3H]DuP 734 receptor binding in mouse brain regions will be presented.

#### 230.2

IS THE RAT BRAIN SIGMA RECEPTOR THE SAME AS CYTOCHROME  $P_{450}$ ? HALOPERIDOL DOWNREGULATES SIGMA RECEPTORS BUT NOT CYTOCHROME  $P_{450}$ . S. W. Tam\*, D. Rominger, S. Diamond and G.N. Lam. Central Nervous System Diseases Research and Drug Metabolism and Pharmacokinetics Section, The Du Pont Merck Pharmaceutical Company, Wilmington, DE 19880-0400 Studies were performed to investigate the relationship

Studies were performed to investigate the relationship of sigma receptors with cytochrome P<sub>450</sub>s in rat brain. Rats were chronically treated with haloperidol (5 mg/kg, s.c. daily) for two weeks, then the sigma receptor binding and cytochrome P<sub>450</sub> activities were measured in vitro. The cytochrome P<sub>450</sub> activities in rat cerebral cortical microsomal fractions were labile and were rapidly converted to P<sub>420</sub>. Chronic treatment with haloperidol induced significant down-regulation (73-79%) of sigma receptor binding in cerebral cortex using either [³H](+)-SKF 10,047, [³H](+)-3-PPP or [³H]DuP 734 as sigma ligands, but no significant change in the cytochrome P<sub>420</sub> activities were detected in these tissues. The results suggest that the sigma receptor and cytochrome P<sub>450</sub> may be different entities.

## 230.4

Administration of XJ448, a Novel Selective Sigma Receptor Ligand, Causes Regional Differences in Dopamine Turnover in the Rat. C.M. Krause. C.M. Rominger\*. S.W.Tam and R.Zaczek. The DuPont Merck Pharmaceutical Co., Wilmington, Delaware.

The selective sigma receptor ligand XJ448 has been shown to

The selective sigma receptor ligand XJ448 has been shown to antagonize the inhibition of dopamine neuronal firing induced by (+)-3-PPP. The effects of acute subcutaneous administration of XJ448 on the levels of dopamine, serotonin and their principal metabolites in rats were examined 1 hr after dosing. No changes in serotonin or 5-HIAA were observed after 1,3.9 or 27 mg/kg XJ448. Increases in dopamine turnover as indicated by elevations in the levels of dopamine metabolites DOPAC (16% above control) and HVA (32% above control) were observed in the medial frontal cortex after 3 mg/kg XJ448. Increasing the dose of the drug to 9 mg/kg produced a further increase in dopamine turnover in this region (increases of 40% and 57% above control for DOPAC and HVA, respectively). In other regions of the brain, higher doses of the drug were required to increase dopamine turnover. No increase in the level of DOPAC was observed in striatum, nucleus accumbens, hypothalamus, substantianigra or ventral tegmental area at doses as high as 9 mg/kg of XJ448. In these regions, HVA was only marginally increased (less than 20% over control) at 9 mg/kg of the drug. XJ448 at a dose of 27 mg/kg produced increases in the levels of both dopamine metabolites in all regions studied. In contrast to the effect of XJ448 in preferentially increasing dopamine turnover in the frontal cortex over the striatum, haloperidol (0.1 mg/kg) induced an equal or greater increase in dopamine turnover in the straitum than in the frontal cortex. These results suggest that sigma receptors have a modulatory function on dopamine neuronal activity with a preferential effect in the frontal

SIGMA-SELECTIVE ANTIPSYCHOTIC COMPOUNDS: COMPARATIVE IN-VIVO PROFILES. J.F. McElroy\*, K.A. K.L. Zeller, J.F. Cawley, W.G. Carey, P.J. Gilligan, and G.F. Steinfels. CNS Diseases Research, The Du Pont Merck Pharmaceutical Co., Experimental Station, P.O. Box 80400, Wilmington, DE 19880-0400

Sigma receptors have been implicated in the etiology of psychosis and this receptor may provide a novel target for the discovery and development of antipsychotic agents. XJ448 (4-(2'-(4"-Cyanophenyl)-2'oxoethyl))-1-(cyclopropylmethyl) piperidine, is a high affinity (Ki=9 nM) and selective ligand for the sigma binding site in rodent brain. Sigma receptor antagonists have also been discovered in the laboratories of Bristol Myers-Squibb (BMY14802), Burroughs Wellcome (Rimcazole), Merck (L687,384), and Nova (NPC16377). The present study compares XJ448 to these sigma antagonists in a battery of behavioral animal models that have predictive value for antipsychotic therapeutic activity and side effect liability. XJ448 is orally active in the Mouse Mescaline Scratch (ED50=0.8 mg/kg) and Mouse Isolation-Induced Aggression (ED50=1.5 mg/kg) tests and is weakly active in the Mouse Apomorphine-Induced Climbing test (ED<sub>50</sub>=29.2 mg/kg). XJ448 reverses the inhibition of DA cell firing induced by the sigma agonist (+)-3PPP, consistent with the hypothesis that sigma receptors may modulate DA neuronal cell firing. The order of potency in these efficacy models predictive of antipsychotic therapeutic activity is XJ448 >> Rimcazole & BMY14802 > L687,384 >> NPC16377. None of these sigma compounds produces catalepsy in rats, an animal model predictive of side effect liability. These results suggest that XJ448, might represent a novel antipsychotic drug with little propensity for the motor side effects (e.g., Tardive Dyskinesia) typically associated with antipsychotic drug treatment.

#### 230.7

DUP 734 DIFFERENTIALLY ANTAGONIZES THE LOCOMOTOR STIMULANT EFFECTS OF COCAINE, D-AMPHETAMINE AND APOMORPHINE IN MICE AND RATS. . Cook. J. F. McElroy and K. W. Rohrbach\*, Central Nervous System Disea Research, The DuPont Merck Pharmaceutical Company, Wilmington, DE 19880-

DuP 734 modifies the activity of many agents which are hallucinogens and stimulants. The evidence suggests that DuP 734 does this by modulating the presynaptic dopamine system, possibly through sigma receptors (Tam et al., JPET, submitted; Cook et al., JPET submitted). In the present studies, we tested DuP 734 in comparison with haloperidol and ketanserin for ability to modify the increases in locomotor activity induced by cocaine, D-amphetamine and appromphine. DuP 734 cripificantly induced by the locomotor activity induc significantly antagonized the locomotor stimulant effects of cocaine in both mice and rats. It did this at doses which did not effect baseline locomotor activity. DuP 734 selectively antagonized cocaine induced stimulation of locomotor activity in mice at 0.2 mg/kg p.o. and in rats at 2.3 mg/kg p.o. whereas the doses that decreased spontaneous baseline locomotor activity in mice and rats were 2.3 and >7.7 mg/kg p.o. respectively. DuP 734 antagonized the locomotor stimulant properties of amphetamine in mice at 0.2 mg/kg p.o., whereas in rats, it only antagonized the locomotor stimulant properties of D-amphetamine at doses which decreased baseline spontaneous locomotor activity. Neither haloperidol nor ketanserin antagonized the locomotor stimulant properties of cocaine or D-amphetamine in mice or rats at doses that did not also antagonize spontaneous baseline locomotor activity. DuP 734 did not selectively antagonize the locomotor stimulant effects of apomorphine in either mice or rats. Haloperidol selectively antagonized the locomotor stimulant effects of apomorphine in rats but not in mice. Ketanserin selectively antagonized the locomotor stimulant effects of apomorphine in mice but not in rats. These results suggest a potential use for DuP 734 in the treatment of cocaine abuse which is supported by the observation that DuP 734 (7.5 and 10 mg/kg p.o.) blocked generalization to cocaine in drug discrimination.

## 230.9

CHRONIC FLUPHENAZINE TREATMENT INCREASES GAD67 mRNA LEVELS IN SPECIFIC REGIONS OF THE RAT BRAIN. A.E.Johnson\*, U.Liminga. N.Lindeforsp. L.Gunne. F.-A.Wiesel. Dept. of Psychiatry, Uppsala University, Uppsala, Sweden and ODept. of Pharmacology, Karolinska Institute, Stockholm, Sweden. Chronic neuroleptic treatment is associated with the development of severe motor disturbances collectively known as tardive dyskinesia. Long-term treatment of rats with the neuroleptic fluphenazine decanosate (FLU) increases vacuous chewing movements (VCM), a model of dyskinesia. One transmitter system known to be affected by neuroleptics is the GABA system. The purpose of this experiment was to more closely examine the effects of chronic FLU treatment on GABAergic neurotransmission. Adult female Sprague-Dawley rats received 6 monthly injections of FLU (30mg/kg/month i.m.) or vehicle (N=7/group). Animals were killed 60 days after the last injection. The brains were processed for in situ hybridization histochemistry with an oligodeoxynucleotide probe directed against glutamic acid decarboxylase67 messenger RNA (GAD67 mRNA). The results of behavioral studies showed that throughout the treatment period and one week prior to sacrifice, rats given FLU exhibited significantly more VCM than controls. Autoradiographic analysis indicated that FLU treatment increased GAD67 mRNA levels in the core (101%) and dorsal shell regions (30%) of n. accumbens, caudate putamen (121%) and in the entopeduncular n. (92%). No differences were found in other brain regions including the ventral shell of the accumbens, globus pallidus, cortex or in substantia nigra. These results indicate that chronic neuroleptic exposure can alter GABAergic transmission. Whether these changes are related to the development and expression of VCM remains to be demonstrated. The effect of FLU treatment on GABA-A receptor binding is currently under investigation. These experiments were funded by grants awarded to N.L., L.G. and to F.-A.W. from the Swedish Medical Research Council

Dup 734 blocks the Electroencephalographic (EEG) beta-2 increase induced by (+)-pentazocine in the Long Evans Rat. G. P. ALBERICI\* W. G. Carey, and G. F. STEINFELS. The Du Pont Merck Pharmaceutical Company, Wilmington, DE 19880-0400 USA.

DuP 734 a potent sigma and 5HT2 receptor ligand, with low affinity for the dopamine D2 receptor, is effective in behavioral tests indicating a possible antipsychotic use. DuP 734 was tested in the rat cortical background spectral EEG model. In these studies we used the change spectral EEG model. In these studies we used the change in beta-2 (25-50 Hz) relative power (RP) as our measure of drug activity. (+)-Pentazocine (a potent sigma ligand) at 21.3 mg/kg sc induces an increase in beta-2 RP activity. DuP 734 was administered alone or prior to (+)-pentazocine. DuP 734 by itself shows no significant change in beta-2 RP at behaviorally active doses. However, DuP 734 dose dependantly blocks the (+)-pentazocine induced beta-2 increase. Ketanserin (a 5HT2 antagonist), at 0.3 mg/kg sc, does not block the (+)-pentazocine induced beta-2 RP increase. Based on this evidence, the rat EEG model beta-2 RP measure may have utility as a measure of in vivo sigma receptor activity. utility as a measure of in vivo sigma receptor activity.

#### 230.8

PHARMACOLOGICAL PROFILE OF THE ATYPICAL NEU-ROLEPTIC DRUG EMD 57445 G.D. Bartoszyk\*, H.E. Greiner, J. Harting, M. Stohrer, C.A. Seyfried. E. Merck, Biol. Res., Dept. of CNS-Res., POB 4119, 6100 Darmstadt, Germany.

EMD 57445 ((S)-(-)-5-[4-hydroxy-4-(1,3-benzodioxol-5-yl)-piperidin-1-ylmethyl]-3-(4-methoxyphenyl)-oxazolidin-2-one HCl) exhibited the following binding profile in vitro (receptor and IC50, resp.): σ: 6 nM; D<sub>2</sub>: 5200 nM. Affinity to D<sub>1</sub>, 5HT<sub>1A</sub>, 5HT<sub>1B</sub>, 5HT<sub>1C</sub>, 5HT<sub>1D</sub>, 5HT<sub>2</sub>, 5HT<sub>3</sub>, BDZ,  $\alpha_1$ ,  $\alpha_2$ , NMDA,  $\mu$ ,  $\kappa$ ,  $\delta$ , M<sub>1</sub>/M<sub>2</sub> was ≥ 1 µM. EMD 57445 stimulated rat striatal dopamine synthesis with ED<sub>50</sub>-values of 3.4 mg/kg po and 2.1 mg/kg sc; striatal levels of DOPAC and HVA were increased with threshold doses of 1 and 3 mg/kg sc, resp., but 3MT levels were unaffected. Avoidance behavior in rats was inhibited with ED50-values of 5 mg/kg both po and sc. EMD 57445 reversed dopamine-agonist (apomorphine) induced stereotyped behavior with ED50-values of 1.2 mg/kg po and 0.4 mg/kg sc (climbing mice) and 2.1 mg/kg po and 1.0 mg/kg sc (stereotypies rats), resp.. Only marginal cataleptic activity was observed in rats up to 1000 mg/kg po and 300 mg/kg sc. Chronic application of EMD 57445 for 19 days to rats did not result in supersensitized dopamine receptors. The results characterize EMD 57445 as a potent D2-dopamine antagonist in vivo with high affinity to the σ- and comparably low affinity to the D2-receptor in vitro, a profile shared with some other atypical neuroleptic drugs.

## 230.10

ATYPICAL ANTIPSYCHOTIC-LIKE EFFECTS OF NEUROTENSIN ON MIDBRAIN DOPAMINE CELLS. Jeffrey M. Goldstein\* and Linda C. Litwin. Department of Pharmacology, ICI Pharmaceuticals Group, A Business Unit of ICI Americas Inc., Wilmington, DE 19897.

The acute administration of most antipsychotic (AP) drugs increases the number of spontaneously firing midbrain DA cells located in substantia nigra (A9) or ventral tegmentum (A10), whereas atypical (clozapine-like) APs exhibit a doserelated selectivity for A10. The present study tested the hypothesis that neurotensin (NT) would have a clozapine-like profile in this paradigm. Since NT does not readily cross the blood-brain barrier, it was injected intraventricularly and compared to haloperidol and clozapine injected via the same route. Male Sprague-Dawley rats were anesthetized with chloral hydrate and stereotaxically injected with either NT (1-100 µg), haloperiol (10-30 µg), or clozapine (1-100 µg), and the number of spontaneously firing DA cells determined using standard extracellular recording techniques. NT was found to increase both A9 and A10 DA cells at the 100 µg dose, was selective for A10 at lower doses (3-30 µg), and was inactive at 1 µg. Clozapine had a similar profile of activity, producing selective increases in A10 at doses that were lower then those required to produce equivalent increases in A9. In contrast, haloperidol produced equally extensive dose-related increases in both A9 and A10 at 17.5-30 µg, with no apparent selectivity for either area, and was inactive at 10 µg. It was of interest that both NT and clozapine were found to be more potent than haloperidol after intraventricular administration. The results of this study provide the first evidence that NT itself has an atypical clozapine-like profile. Testing of a more potent analog of NT is now in progress.

SERTINDOLE - A LIMBIC SELECTIVE NEUROLEPTIC WITH POTENT ANXIOLYTIC EFFECTS. C. Sánchez', J. Arnt\*', B. Costall², A.M. Domeney², M.E. Kelly²; 1. H. Lundbeck A/S, Copenhagen, Denmark; 2. University of Bradford, UK.

mark; 2. University of Bradford, UK.

Sertindole is a putative neuroleptic with high limbic selectivity . We have assessed the anxiolytic potential of sertindole in various animal models. Sertindole shows extremely potent effects in social interaction test (unfamiliar and bright light test conditions) in rats (Minimal effective dose (MED) = 0.000023 nanomol/kg) and in test of explorative behaviour in black and white test box in mice (MED=0.00023 nanomol/kg, Potent effects are obtained in human threat test in marmosets (MED=2.3 nanomol/kg) and test of explorative behaviour in black and white test box in rats (MED=1 nanomol/kg). Sertindole exerts a moderate inhibition of isolation-induced aggressive behaviour in mice (ED50=4200 nanomol/kg), and has no effect on footshock-induced ultrasonic vocalization (rat) and shock-induced ultrasonic vocalization (rat). In conclusion, sertindole exerts potent anxiolytic-like effects both in rodents and in the marmoset. The profile of sertindole is different from that of benzodiazepines, which together with a lack of sedative effects may indicate clinical advantages.

### 230.13

EFFECTS OF CHRONIC TREATMENT WITH SM-9018, A POTENTIAL ATYPICAL ANTIPSYCHOTIC, ON BEHAVIORAL DOPAMINERGIC AND SEROTONERGIC SENSITIVITY IN RATS. Y. Ohno\*, K. Okada, K. Ishida, T. Kato and M. Nakamura. Res. Lab., Sumitomo Pharm., Konohana-ku, Osaka 554, Japan. SM-9018 is a novel 5-HT<sub>2</sub>/D<sub>2</sub> receptor antagonist which has

antipsychotic efficacy with few extrapyramidal side-effects. To examine whether chronic SM-9018 induces dopaminergic and/or serotonergic supersensitivity, we studied the behavioral responses to dopamine and 5-HT agonists in rats after 2 weeks of chronic treatment with SM-9018 or with haloperidol (HAL) at a dose sufficient to block D2 receptors (0.1 and 0.3 mg/kg/day s.c., respectively). Four days after withdrawal of the drug, no significant change in apomorphine-induced stereotyped behaviors was observed in the SM-9018-treated group. However, the response to apomorphine was markedly enhanced by HAL treatment. Increase of the dose of SM-9018 to 0.3 mg/kg/day for 2 weeks resulted in a small increase of AP-induced stereotypy, but this action was still weaker than that of HAL. On the other hand, serotonergic behaviors, such as 5-hydroxytryptophan-induced wet dog shakes and 8-OH-DPAT-induced flat body posture, were unaffected by treatment with either SM-9018 or HAL. These results suggest that SM-9018 is weaker than haloperidol in inducing dopaminergic supersensitivity after chronic administration and has low potential for induction of tardive dyskinesia.

# 230.15

POSSIBLE LOSS OF DOPAMINE TERMINALS FOLLOWING SHORT TERM NEUROLEPTIC TREATMENT. S.P. Banerjee,

SHORT TERM NEUROLEPTIC TREATMENT. S.P.Banerjee, E.Alter, L. Zuck & T.I.Lidsky. Pharmacology Dept, CUNY Med., CCNY & Inst Basic Res., S.I., N.Y. Prolonged medication with typical neuroleptics leads to several types of neurological disorders. Some of the symptoms of motor dysfunction, such as the extrapyramidal syndrome, appear after treatments of short duration. Others, such as tardiye dyskinesia, typically appear after treatments of short duration. Others, such as tardive dyskinesia, typically appear after years of medication. In this context, rats were administered haloperidol (Hal) daily (0.5 mg/kg; ip) for 21 days. Endogenous striatal dopamine (Da) levels and numbers of presynaptic uptake sites were assessed by, respectively, HPLC and [3H] mazindol (Maz) binding. Rats that received Hal had reduced Da levels and reduced number of Maz binding sites. MK-801 (0.5 mg/kg, ip) or ganglioside (30 mg/kg, ip) co-administered with Hal in other groups of rats failed to attenuate these effects. These results indicate that short term Hal treatment may cause loss of Da cells and/or terminals. may cause loss of Da cells and/or terminals. This damage, unlike that caused by other modulators of Da activity, is not mediated by interactions with excitatory amino acids.

### 230.12

EVALUATION OF Wy-47,791, A GAMMA-CARBOLINE ANTIPSYCHOTIC CANDIDATE, IN A PRIMATE SOCIAL COLONY MODEL OF PSYCHOSIS. R.F. Schlemmer, Jr.\* and J.M. Davis. Dept. of Pharmacodynamics, University of Illinois at Chicago and Research Dept., Illinois State Psychiatric Institute, Chicago, IL 60612.

Wy-47,791 (Wy), 8-fluoro-2,3,4,5-tetrahydro-2-[2-(4-pyridinyl) ethyl]-1H-pyrido[4,3-b]indole HCl, has been identified as an anti-psychotic candidate in rodent screens. The present study was designed to assess the antipsychotic activity and side effect profile of Wy in a non-human primate social colony model of psychosis. Gevotroline, a gamma-carboline, demonstrated activity in this model similar to known anti-psychotics and with minimal movement disturbances. Wy was tested alone and in combination with the dopamine agonist apomorphy high (APO) which carbonne, demonstrated activity in this model similar to known antipsychotics and with minimal movement disturbances. Wy was tested alone
and in combination with the dopamine agonist apomorphine (APO) which
was used to induce the model psychosis. Four females from a stable social
colony of 5 adult stumptail macaque (Macaca arctoides) received one of
6 doses of Wy, 1-16 mg/kg, for 2 days in a cross-over design. At least 5
days separated each dose regimen. Wy was given n.g. at 0800 and 1630 on
Day 1 and at 0800 on Day 2 of treatment. APO, 1 mg/kg, was given i.m.
at 1015. Two 1 hr observation sessions were conducted daily by a "blind"
observer at 0900 and 1030. Observation of baseline behavior and APOinduced behavioral changes preceded Wy treatment. At doses ≥ 8 mg/kg,
Wy significantly antagonized APO-induced increased submissiveness and
increased checking (visual scanning), behaviors that model paranoia and
hypervigilance respectively. Wy only weakly antagonized APO-induced
stereotypy. Wy alone significantly increased resting time at higher doses.
Wy induced low levels of movement abnormalities in all treated monkeys
at 16 mg/kg. The results demonstrate that Wy has an antipsychotic profile
similar to known antipsychotics and gevotroline in this model at doses
which produce low levels of movement abnormalities, Princeton, NJ).

### 230.14

TARDIVE DYSKINESIA AND NEUROLEPTIC INDUCED IMMUNOLOGIC ANOMALIES. L.L. Wing\*, A. Elkashef, M.F. Egan, T.M. Hyde, D.G. Kirch, R.J. Wyatt and H. Kulaga. NIMH @ St. Elizabeths Hospital, Washington, D.C. 20032.

Neuroleptics such as haloperidol decanoate (HAL) increas the likelihood of free-radical formation which may result

in neuronal changes in brain areas involved in tardive dyskinesia (TD). We examined the effects of chronic HAL alone and in combination with the anti-oxidant, free radical scavenger, Coenzyme Q10 (CoQ), on immunological markers in rats. Rats were treated with either vehicle or HAL (21mg/ kg every 3 wks) alone or in combination with CoQ (50mg/kg day) for 6 months. Rats were divided into TD and no TD groups based on ratings for vacuous chewing movements.

Using flow cytometry in peripheral blood lymphocytes number of cells staining for CD4 was decreased in the HAL-CoQ/no TD group, but increased in the HAL-CoQ/TD group versus controls. Class II MHC staining of a secondary cell population was eliminated in the HAL-CoQ/TD rats. IL-2r staining was increased 4-fold in rats treated with HAL-CoQ/no TD versus controls. In splenic lymphocytes, CD4 staining intensity was increased in the HAL/TD group and cell number decreased in CD8 and Class II MHC stains in the HAL-CoQ/no TD group.

Our findings indicate significant differences in lymphocyte populations following HAL alone versus HAL-CoQ, and in TD versus no TD rats, suggesting immunologic effects of these drugs as covariates of TD.

COMBINATIONS OF SUB-THRESHOLD DOSES OF HALOPERIDOL AND 5-HT1A AGONISTS AND PARTIAL AGONISTS SUPPRESS CONDITIONED AVOIDANCE RESPONDING IN RATS. A.T. Shropshire\* and K.L. Marquis. Wyeth-Ayerst Research, CN8000, Princeton, NJ 08543

Previous work by Wadenberg and Ahlenius (1 Neural Transm [GenSect] 83:43-53, 1991) demonstrated strong interaction between a 5-HT<sub>1A</sub> agonist (8-OH-DPAT) and a DA D<sub>2</sub> antagonist (raclopride) on some critical tests for antipsychotic-like actions and extrappramidal motor effects. They suggested such a 5-HT<sub>1A</sub>/DA D<sub>2</sub> combination might offer new antipsychotic drugs with higher clinical efficacy and fewer extrapyramidal side effects (EPS). In the present study, we examined the effects of doses of haloperidol (0.06 and 0.125 mg/kg sc), which do not suppress conditioned avoidance responding (CAR) in rats, in combination with sub-threshold doses of the 5-HT<sub>1A</sub> agonist 8-OH-DAT (0.13 mg/kg). DPAT (0.1 mg/kg sc), the 5-HT $_{1A}$  partial agonists gepirone (5.0 mg/kg ip) and ipsapirone (2.5 and 5.0 mg/kg ip) and the 5-HT $_{1A}$  weak partial agonist BMY 7378 (1.0 mg/kg ip) on CAR in the rat. When given alone, only the 5.0 mg/kg dose of ipsapirone significantly affected CAR when compared to control data obtained previously. Combination treatments produced significant suppression of CAR in all cases. These findings extend the report of Wadenberg and Ahlenius to the observation that 5-HT<sub>1A</sub> ligands ranging in levels of agonism can enhance apparent antipsychotic effects of D2

THE ROLE OF SEROTONIN RECEPTOR SUBTYPES IN THE EFFECTS OF NEUROLEPTIC DRUGS B.A. Ellenbroek\* E.P.M. Prinssen & A.R. Cools, Psychoneuropharmacol. Res. Unit, P.O. Box 9101, 6500 HB Nijmegen, the Netherlands

Despite the fact that the concept of atypical neuroleptics as well as the first true atypical neuroleptic clozapine was introduced some fifteen years ago, few advances have been made in elucidating the mechanisms underlying such neuroleptic drugs. In the present study we have investigated the role of serotonin receptors in the effects of neuroleptic drugs in the PAW TEST. This test has been extensively validated as an animal model with predictive validity for schizophrenia and it models both the therapeutic efficacy (TE) as well as the extrapyramidal side effects (EPS) of neuroleptic drugs.

The results show that adding a 5-HT<sub>2</sub> antagonist (ketanserin) to the classical neuroleptic haloperidol reduced the EPS without affecting TE. Adding a 5-HT1A agonist (8-OHDPAT) on the other hand reduced both the TE and the EPS. Conversely adding a 5-HT<sub>1c</sub>/5-HT<sub>2</sub> agonist (DOI) to the atypical neuroleptic risperidone increased EPS and to a lesser extent TE. However, adding DOI to clozapine did not affect EPS, but rather led to a strong decrease in TE. These data suggest that (1) distinct serotonin receptors differentially affect the effects of neuroleptic drugs (2) distinct neuroleptics can influence EPS and TE via different working mecha-

LEVELS OF S100\$ PROTEIN IN POST-OPERATIVE BRAIN TISSUE FROM EPILEPTIC PATIENTS. O. Yeralan, C. Rovnaghi, F.A. Boop, L.J. Van Eldik, P.E. Bean and W.S.T. Griffin.\* Depts. of Pediatrics, Anatomy, and Neurosurgery, UAMS, Little Rock, AR 72205; +Dept. of Pharmacology, Vanderbilt U., Nashville, TN 37232.

Gliosis in and around epileptic foci is the most common

neuropathological finding in epilepsy. S100 $\beta$ , a calcium binding protein synthesized and secreted by astrocytes, can stimulate elevation of intracellular calcium in neurons. The levels of S100 $\beta$  are increased in activated astrocytes such as those characteristic of the gliosis observed in some neurodegenerative diseases. S100\beta expression was studied by immunohistochemistry, Western analysis, and Enzyme Linked Immunosorbent Assay (ELISA) in post-operative brain tissue samples from 11 epileptics and in analogous samples taken post-mortem from 5 agematched controls. Compared to control sections, there was an elevated number of S100 $\beta$  immunoreactive astrocytes in tissue sections from epileptics; these astrocytes were activated, i.e., enlarged with prominent processes. By ELISA, the levels of S100 $\beta$  were 500-2,000 ng/mg protein in 7 of 11 patients compared to 100-500 ng/mg protein in the 5 controls. Western analysis of the same tissue yielded similar results. The levels of S100 $\beta$  were found to correlate with the degree of gliosis, the age of the individual, and/or the severity and duration of the disease. Further work is underway to determine if elevated levels of this calcium-binding neurite extension factor might contribute to (i) synaptic reorganization and (ii) neuronal loss characteristic of epilepsy.

CHANGES IN VASOPRESSIN MRNA IN THE PARAVENTRICULAR NUCLEUS AFTER AMYGDALA KINDLING. R.S. Greenwood\*, R.B. Meeker, A. Abdou and J.N. Hayward. Dept. of Neurology and Pediatrics and Neurobiology Curriculum, Univ. of North Carolina Sch. of Med., Chapel Hill, NC 27599.

We have previously shown that resting plasma vasopressin (VP) is elevated and VP mRNA expression is chronically higher in the magnocellular neuroendocrine system after amygdala kindled seizures. In the supraoptic nucleus we have found a two fold increase in VP mRNA in magnocellular neurons 1 to 4 months after kindling was completed. In the present study we sought to determine if all subpopulations of VP-containing neurons in the paraventricular nucleus (PVN) show chronic elevation of VP mRNA. Sprague Dawley rats with amygdala electrodes received daily kindling stimuli until they reached class 4 or 5 kindled seizures. For VP in situ hybridization, 20 um brain sections from kindled and control animals were hybridized with a 30mer oligonucleotide probe specific for vasopressin. Three regions of the PVN approximating the posterolateral posterior magnocellular (pml), the ventral tail of the medial arvicelluar (mpv, mpdv), and the dorsal parvicellular and the dorsal part of the medial parvicellular (dp, mpdd) PVN subdivisions were sampled fo analysis of autoradiographic silver grain density using an image analysis system (Bioquant IV). The magnocellular regions of the PVN in the kindled rats had more VP mRNA than control rats. We were unable to detect a change in VP hybridization in the predominantly parvicellular region in kindled rats.

We conclude that kindling results in vasopressin up-regulation in PVN magnocellular neurons but not in dorsal parvicellular neurons.

Canada, T6G 2H7

Recent reports suggest that numerous neuronal gene products are induced following experimentally-induced seizure. We have tested the hypothesis that neuronal phenotype is altered by stimuli well before seizure itself is induced. Male Sprague-Dawley rats were anesthetized with subcutaneous urethane, placed in a stereotaxic apparatus, and stimulating anestnetized with subordaneous urethane, placed in a stereloxic apparatus, and stimulating and recording electrodes placed in the angular bundle and granule cell layer of dentate gyrus, respectively. Paired test stimuli (2 Hz, 30 V, 100  $\mu$ s 40 msec ISI) elicited granule cell population EPSP and population spike responses that exhibited paired-pulse inhibition on the second pulse. Trains of stimuli (30V, 100  $\mu$ s, 20 Hz, 10s, 1/min) were superimposed on test stimuli for 2-24h. Animals were allowed to recover for a time after

superimposed on test summit for 2-24a. Animals were anowed to recover for a time after stimulation ceased, then brains were prepared for cryotomy and in situ hybridization (ISH) with riboprobes for NPY and  $T\alpha 1$   $\alpha$ -tubulin mRNA's. Stimulus trains induced brief (1-2s) afterdischarges. 4h stimulation resulted in smaller responses to both pulses of test stimuli, and briefer afterdischarges. 24h stimulation resulted in massive disinhibition. After 4 h stimulation, ISH showed NPY mRNA to be resulted in massive disinhibition. After 4 h stimulation, ISH showed NPY mRNA to be elevated in ipsilateral, and some contralateral hilar and CA1/CA3 interneurons, while Tα1 α-tubulin mRNA was elevated in ipsilateral (and some contralateral) dentate granule cells; some elevation in CA3 and CA1 pyramids was seen. After 24h stimulation, levels of NPY and Tα1 α-tubulin mRNA's increased in the same populations of neurons, and the contralateral increases were much greater than after 4h.

Stimuli that do not lead to permanent alterations in the electrical behavior of hippocampus appear to be able to markedly alter neuronal phenotype in specific neurons in hippocampus engages the statement of the property of the property of the property levels of the property of the property levels of the property of the property levels of the property of the property of the property levels of the property of the property levels of the property of the property levels of the property of the property of the property levels of the property of the property levels of the property o

ENHANCED EXPRESSION OF NEUROPEPTIDE Y IN GRANULE CELLS AND IN INTERNEURONS OF THE DENTATE GYRUS AFTER KAINIC ACID-INDUCED SEIZURES IN THE RAT. G. Sperk, B. Gruber, R. Bellmann, S. Greber, (SPON: European Neuroscience Association). Dept. of Pharmacology, University of Innsbruck, 6020-Innsbruck, Austria.

Distribution of neuropeptide Y (NPY) mRNA has been investigated at various time intervals after seizures induced by i.p. injection kainic acid (10 mg/kg). In rats which had experienced a full limbic seizure syndrome high concentetions of NPY mRNA were found in the granule cell layer of the dentate gyrus 24 hours after injection of the toxin. No NPY message was found there in untreated rats. The increase in NPY mRNA declined at later intervals (2 to 30 d after kainic acid). At the same time a loss of NPY expressing cells was observed in the deep hilus of the dentate gyrus. Pyramidal shaped basket cells laying closely to the inner surface of the granule cell layer were spared and exhibited increasing concentrations of NPY message which could be seen even 4 months later. In animals which had received the same treatment with kainic acid without developing motor seizures no NPY mRNA was observed in granule cells after 24 hours. At this time, however, a marked induction of the peptide message was detected in

interneurons throughout the hilus.

These data suggest an early activation of presumably inhibitory NPY containing neurons of the hilus. In animals exposing motor seizures this activation affects granule cells. Although damage of hilar interneurons can be seen presumably GABA-ergic basket cells become long lasting activated. Supported by the Austrian Scientific Reaserch Funds (P8128).

C-FOS-LIKE IMMUNOREACTIVITY AFTER SPONTANEOUS SEIZURES IN RATS. <u>L.E.A.M. Mello\*, A.M. Tan, E.A. Cavalheiro and D.M. Finch</u> Department of Neurology and Brain Research Institute, University of California, Los Angeles, CA 90024, and Departamento de Neurologia, de Fisiologia, Escola Paulista de Medicina, 04023 São Paulio Brazil

Systemic injections of pilocarpine (320-350 mg/kg, i.p., 30 min after 1 mg/kg scopolamine) were used to induce status epilepticus in adult, male Sprague-Dawley rats (150-250 g, seizures controlled after 1 h with 4.0 mg/kg diazepam). After a variable period (4-34 days), the rats entered a phase of spontaneous recurrent seizures (SRS) that lasted for as long as the animals were allowed to survive. SRS were similar to stage 5 kindled seizures, lasting an average of 30-60 sec. To assess fos-like-immunoreactivity (FLI) after SRS, animals were sacrificed 1 h after an SRS was observed, and processed with anti c-fos (Cambridge).

Light microscopic examination of coronal brain sections revealed no

Light microscopic examination of coronal brain sections revealed no neuronal FLI, except in 2 animals. One of these was processed within 10 days of SE induction. The other was processed after an unusual flurry of 5 seizures that occurred in the span of 1 hour. The latter animal showed staining in the piriform and perirhinal cortices, and in scattered locations throughout neocortex. SE was induced in naive animals or reinduced in chronic animals (100 mg/kg pilocarpine dose for the chronic animals), and only the naive animals showed FLI. These results indicate that severe spontaneous seizures can induce FLI. However, they also suggest (1) that most single spontaneous seizures are subthreshold for this technique or (2) that a state of chronic seizures down-regulates c-fos induction. KINDLED SEIZURES FAIL TO INDUCE FOS PROTEIN IN SUBSTANTIA NIGRA PARS RETICULATA <u>C.D. Appleaate\*</u>, <u>D. Piekut and S. Pretel</u>. University of Rochester School of Medicine, Rochester, NY 14642.

FOS immunolabeling is being widely used to identify activated neuronal networks following seizures induced using a variety of experimental models. Despite the demonstrated involvement of the substantia nigra pars reticulata (SNpr) in seizure expression in virtually all seizure models, this structure has not been reported to express FOS protein following seizures suggesting that the networks defined by FOS immunolabeling may be incomplete. In this study we examined the SNpr for FOS labeling at various time points following kindled seizures to establish that the lack of reported labeling is not due to differences in the time course of FOS induction in SNpr. Male rats were kindled from the entorhinal cortex and sacrificed at 1-12h following seizure. Tissue was processed for FOS labeling using standard protocols. No FOS immunolabeling was observed at any time point following seizure in SNpr neurons. The pattern of labeling of other structures was consistent with previous reports and was maximum at 1-3h, decreased at 4-6h and virtually absent at 12h. In a second study, immunolabeling of serum response factor (SRF), a suggested necessary nuclear protein for FOS induction, was examined. All SNpr cells showed nuclear labeling for SRF. Together, results suggest SNpr neurons have at least some of the nuclear machinery for FOS induction but that seizures are not effective stimuli for inducing FOS in these cells.

EXCITATORY AMINO ACID ANTAGONISTS PREVENT SEIZURES AND C-FOS INDUCTION IN A RAT MODEL OF PERINATAL HYPOXIA. <u>I.R. Firkusny\*</u>, <u>H.K. Blume</u>, and <u>F.E. Jensen</u>. Dept. of Neurology, Children's Hospital and Harvard Medical School, Boston, MA 02115.

We have previously shown that hypoxia is acutely epileptogenic in the immature rat (P5-17), and that c-fos immunoreactivity (IR) is present predominantly in neocortex at 4 hrs post-hypoxia. Furthermore, long term seizure susceptibility is increased after hypoxia-induced seizures at P10. This age window corresponds to a period of development when various regions of the brain exhibit a transient increase in NMDA and non-NMDA receptors, while the GABA system is still immature compared to the adult. To determine whether activity at these excitatory amino acid (EAA) receptors might underlie the age-dependent epileptogenicity of hypoxia, the relative efficacy of the systemic pretreatment with the NMDA antagonist MK-801 and the AMPA antagonist NBQX (2,3-dihydroxy-6-nitro-7-sulfamoyl-benzo(F)quinoxaline) were compared to the GABA agonist lorazepam on seizure frequency and c-fos IR in immature rats. Long Evans rats aged P10 were rendered hypoxic in 4%O2 after i.p. pretreatment with saline (n=20), MK-801 (1 mg/kg, n=11), NBQX (20mg/kg, n=10), or lorazepam (1mg/kg, n=10). Compared to saline, pretreatment with MK-801 or NBQX significantly reduced seizures (p < 0.001), while lorazepam did not. In addition, c-fos IR was reduced compared to control hypoxic pups in 63% of MK-801 treated animals and 56% of NBQX treated animals, compared to 44% of lorazepam treated animals. These results suggest that EAA receptors may be involved in the genesis of neonatal hypoxia-induced seizures, and that EAA antagonists may be superior to conventional benzodiazepine anticonvulsants in neonatal seizures associated with hypoxia.

PENTYLENETETRAZOL KINDLING INCREASES VASOPRESSIN MRNA IN THE BNST AND MA OF RATS. J.N. Bicknell\*, P. Szot and D.M. Dorsa. GRECC, Seattle VAMC, WA 98108 and Dept. of Pharmacology, Univ. Washington. Seattle. WA 98195.

Washington, Seattle, WA 98195.

Kindling is an animal model of epilepsy that resembles partial complex seizures observed in humans. Kindling is produced in rats with a periodic administration of a subconvulsant stimuli (chemical or electrical) until clonic/tonic convulsions are observed. The present study was performed to determine if chemical kindling with pentylenetetrazol (PTZ) altered the level of vasopressin mRNA containing neurons of the limbic system including the bed nucleus of the stria terminalis (BNST) and medial amygdala (MA). Chemical kindling was performed by administering PTZ intraperitoneally at a subconvulsant dose (30 mg/kg) every other day for about 4 weeks until stage 5 tonic/clonic seizures were observed. Once kindled the animals were sacrificed 24 hours following the last convulsion. In situ hybridization was performed in control and kindled rats using a 48 base oligonucleotide to the glycopeptide portion of the vasopressin (VP) gene. VP mRNA was not significantly different in hypothalamic VP neurons of the paraventricular, suprachiasmatic and supraoptic nucleus, though the supraoptic nucleus showed a tendency to be higher in the kindled rats compared to the control. In contrast, VP mRNA levels in the BNST and MA of kindled rats was significantly higher (p<0.05 and p<0.10) compared to controls, suggesting a possible role for VP in kindled seizures. Interestingly, VP gene expression in these neurons is regulated by textosterone. Preliminary data has suggested a sex difference in c-fos gene expression in the hippocampus following a PTZ seizure. A possible involvement of VP neuronal systems in gender specific differences in seizurerleated c-fos expression is under investigation. (Supported by NS 20311 and the VA)

EXPRESSION OF PRODYNORPHIN MRNA IN FOS ACTIVATED CELLS IN RAT NUCLEUS TRACTUS SOLITARIUS AFTER INDUCED SEIZURES. Robert K Kanter\*, Jeffery T Erickson. David E Millhorn. University of North Carolina, Chapel Hill, NC 27599

Activation of the c-fos gene occurs in rat hippocampus (Science 1987; 237:192) and nucleus tractus solitarius (NTS) (Ped Res 1992;31:349A) after pentylenetetrazole (Ptz) induced seizures. Fos protein appears to act as a transcription regulatory factor for the proenkephalin (proENK) gene in hippocampus (Science 1989; 246:1622), but other seizure associated Fos target genes and their tissue locations have not been reported. We performed an immunohistochemical and in situ hybridization study to identify neuropeptide genes potentially regulated by Fos in NTS after Ptz (i.p. 45 mg/kg plus 10 mg/kg every 5 minutes until motor seizures occurred). Fos immunoreactive (IR) cells were identified with the avidin-biotin method after incubation with anti-Fos antibody. Cells containing prodynorphin (proDYN), proENK, or c-fos mRNA were identified by autoradiography after in situ hybridization with 35S labeled oligonucleotides. Levels of c-fos mRNA peaked at 1-2 hours, while the number of Fos IR cells peaked at 2-4 hours after seizures in NTS. Control and sham treated (i.p. saline) animals had negligible c-fos mRNA or Fos IR cells in NTS. At 4 hours after seizures, proENK and proDYN mRNA were colocalized with Fos IR in many cells of the NTS. While proENK and proDYN mRNA were detectable in NTS under control conditions, proDYN mRNA level was mildly enhanced by 7 hours, and strongly increased 24 hours postictally. These observations suggest a potential role of the c-fos gene in regulation of proDYN expression in rat brainstem after Ptz induced seizures.

SUPPRESSION OF BASAL LEVELS OF ZIF268 mRNA IN A CHRONIC SEIZURE MODEL. A.J. Cole\* and J.M. Baraban. Depts. of Neurology and Neuroscience, Johns Hopkins University Sch. of Med., Baltimore, MD 21205.

In contrast to the transient expression of several

In contrast to the transient expression of several transcription factors seen in brain after stimulation, zif268 displays significant basal expression in cortex. The functional role of this basal expression is unknown, however it may serve as a marker of normal cortical physiology as it is dependent on afferent synaptic activity (Worley et al., PNAS 1991). We used the maximal electroconvulsive seizure (MES) model to examine the effects of repeated seizures on the basal expression of zif268. Rats were sacrificed at various time points after 10 daily MES and compared to animals that received a single MES. Brains were processed for in situ hybridization, immunohistochemistry, northern blot analysis, and gel shift analysis of transcription factor binding to DNA. Basal levels of zif268 mRNA assayed by in situ or Northern blot were markedly reduced 4-36h after the tenth seizure, but returned to near baseline by 48h. A single seizure caused no supression. Surprisingly, after chronic seizures there was no suppression of zif268 protein levels assessed immunohistochemically or of binding activity to the zif268 consensus sequence in nuclear extracts. This dissociation between mRNA and protein responses suggests that repeated stimulation may affect zif268 expression at both transcriptional and post-transcriptional levels.

DIFFERENCES IN THE PATTERNS OF FOS EXPRESSION FOLLOWING ELECTROCONVULSIVE SHOCK(ECS)-INDUCED GENERALIZED TONIC AND GENERALIZED CLONIC SEIZURES IN C57BL/6J MICE. G.M. Samoriski', C.D. Applegate and D.T. Piekut. University of Rochester Medical Center, Rochester, NY 14642.

Studies suggest that the expression of generalized tonic vs generalized clonic seizures may be mediated by separate brain systems. The goal of this study was to define anatomical pathways that participate in the expression of these two seizure phenotypes using FOS immunocytochemistry (ICC). Seizures were induced in adult C57BL/6J male mice by transcorneal ECS (0.2 sec, variable current). Animals were perfused at 3 hrs and brain sections were incubated in primary antiserum against both FOS and FOS-related antigens. Neurons of the dorsal central gray, deep layers of the superior colliculus and the area surrounding the ventral aspect of the inferior colliculus express FOS after elicitation of tonic hindlimb extension (THE, n = 8) but not after clonic seizures (n = 3). Other brain regions expressed FOS in a graded fashion. The peripeduncular area, substantia nigra pars lateralis, lemniscal/paralemniscal region and ventromedial hypothalamus exhibited robust FOS staining following THE but were noticeably less labeled after a clonic seizure. Forebrain structures were labeled following seizures of either phenotype but more neurons of the anterior piriform cortex expressed FOS following a clonic seizure than after THE. The pattern of labeling was dependent on the seizure phenotype expressed and independent of stimulus intensity. Results suggest both qualitative and quantitative differences in FOS labeling as a function of the seizure phenotype expressed.

### 231.13

LIDOCAINE KINDLING AND REPEATED COCAINE ADMINISTRATION DO NOT ALTER SODIUM CHANNEL-LINKED PHOSPHOINOSITIDE (PI) TURN-OVER IN RAT CORTICAL AND HIPPOCAMPAL SLICES. R.L. Margolis\*, D.-M. Chuang, S.R.B. Weiss and R.M. Post. Biological Psychiatry Branch, NIMH, Bethesda, MD 20892

Repeated administration of a subconvulsant dose of a local anesthetic eventually produces seizures, a phenomenon similar to electrical kindling. Since local anesthetics acutely alter sodium channel conductance, we investigated the possibility that local anesthetic kindling also modulates the function of these channels. Rats received daily injections of lidocaine until seizures were observed. Kindled rats were compared with non-kindled rats receiving lidocaine or saline. Basal-, batrachotoxin (BTX, a voltage-sensitive sodium channel activator)-, and ibotenic acid (IBO, a glutamate receptor agonist)-stimulated PI turnover did not differ among the three groups in slices of either hippocampus (HC) or piriform cortex (PC), though IBO-stimulated PI turnover was much greater in the HC than in the PC. In a second experiment, rats were injected with cocaine or saline daily for six days, and PI turnover was assayed in sliced frontal cortex. Cocaine treatment had no effect on BTX-induced PI turnover, while in vitro cocaine blocked the BTX effect. In vitro addition or one week pretreatment in vivo with carbamazepine did not alter the effect of cocaine on BTX-induced PI turnover. These results demonstrate that local anesthetic kindling does not alter PI turnover coupled to sodium channel activation, and imply that this type of kindling does not influence the function of the BTX binding site of the sodium channel or the coupling of the PI system to this site.

PILOCARPINE-INDUCED SEIZURES: EFFECT ON EXTRACELLULAR EXCITATORY AMINO ACID LEVELS IN RAT HIPPOCAMPUS WITH AND WITHOUT GLUTAMATE UPTAKE INHIBITOR. M.H. Millan, A.G. Chapman, B.S. Meldrum. Institute of Psychiatry, Denmark Hill, London SE5 8AF, U.K.

Microdialysis was performed in the dorsal hippocampus of the freely moving rats during pilocarpine-induced seizures. Dialysis probes were implanted 24h before perfusion with Ringer

Microdialysis was performed in the dorsal hippocampus of the freely moving rats during pilocarpine-induced seizures. Dialysis probes were implanted 24h before perfusion with Ringer solution (3µl/min). 15µl samples were collected and analyzed by HPLC. Extracellular levels of GLU, ASP and GLN were slightly lowered after the i.p. pilocarpine injection (400mg/kg) and during consecutive motor limbic seizures. The GLU uptake inhibitor L-trans-pyrrolidine-2,4 dicarboxylate produced significant increases in GLU (by 67%) and ASP (by 276%) levels. Concentrations of these amino acids were further slightly increased after pilocarpine injection (by 13 and 17% respectively) prior to seizures. After development of seizures ASP and GLU levels were slightly reduced. These results indicate that uptake mechanisms may prevent any increase in extracellular concentration of GLU and ASP associated with enhanced release during the development of seizures.

### 231.12

FUNCTIONAL MAPPING OF BICUCULLINE-INDUCED "FOREBRAIN" AND "BRAINSTEM" SEIZURES: A "C-2-DEDXYGIJCOSE STUDY A. Handforth, R. Peters, B.E. Swartz\* & D.M. Treiman, VAMC Wadsworth and Dept. of Neurology, UCIA, Los Angeles, California 90024.

Studies have suggested that forebrain seizures result in face and forelimb clonus, brainstem seizures in tonic and running-bouncing clonus (Browning and Nelson, <u>Exp Neurol</u> 93:546-556, 1986). We studied the anatomic basis of "forebrain" and "brainstem" seizures, utilizing the "C-2-deoxyglucose (2DG) method in rat. IV bicuculline was infused at 0.25 ug/sec, the rate slowly increased until seizures occurred, at which time 2DG, 30 uCi, was administered as a bolus. Controls (n=5) received vehicle. Following sacrifice at 10 min post-2DG, cut cerebral sections were apposed to X-ray film to form autoradiographs; these were analyzed semiquantitatively with an image analyzer.

were analyzed semiquantitatively with an image analyzer. Rats with "forebrain" type seizures (n=6) showed metabolic activation of forebrain (cortex, thalamus, hippocampus) and of substantia nigra. Of 8 rats with "brainstem" seizure behaviors, 3 displayed activation of mainly brainstem structures, particularly inferior colliculus, periaqueductal gray, substantia nigra, and midbrain-pons reticular formation. Five displayed activation within brainstem plus widespread forebrain areas. These results directly support the concept of "forebrain" and "brainstem" seizures, and also indicate that both areas of cerebrum can simultaneously engage in seizure activity.

### 231.14

ENDURING INCREASE IN MEMBRANE-ASSOCIATED PROTEIN KINASE C ACTIVITY IN THE HIPPOCAMPAL-KINDLED RAT. K. Akiyama<sup>1\*</sup>, I. Kohira<sup>2</sup> and A. Daigen<sup>1</sup>. <sup>1</sup>Dept. of Neuropsychiatry and <sup>2</sup>Dept. of Neurology, Okayama University Medical School, Okayama 700, JAPAN.

In a previous study (A. Daigen et al. Brain Research 545:131-136, 1991), we demonstrated that the membrane-associated protein kinase C (PKC) activity in the amygdala/pyriform cortex (AM/PC) and both the right and left hippocampus (HIPP) of rats kindled from the left HIPP increased significantly four weeks after the occurrence of the last seizure compared with control rats. In the present study, we examined whether the effect of HIPP-kindling on membrane-associated PKC activity would be more enduring, and could be seen after the last partial (stage 1-3) seizure. 15 to 16 weeks after the final kindled full seizure, the membrane-associated PKC activity which was expressed as nmol/min/mg protein increased significantly in the AM/PC and left HIPP compared with control rats. When expressed as pmol/min/mg wet tissue weight, it increased significantly in the right HIPP as well as the AM/PC and left HIPP. The cytosolic PKC activity did not differ in any brain region examined. One week after the final partial seizure, neither the membrane-associated nor the cytosolic PKC activities in any brain region examined in the partially kindled and control groups differed significantly. These results suggest that activation of membrane-associated PKC may be involved in the long-lasting seizure susceptibility induced by kindling.

DEPRESSION OF AMINO ACID AND DOPAMINE CONTENT OF STRIATUM OF AUDIOGENIC-SEIZURE SUSCEPTIBLE (AGS) BALB/C MICE. J. P. Vriend\*and N. A. M. Alexiuk, Dept. of Anatomy. University of Manitoba, Winnipeg, MB, Canada, R3E OW3.

Nigrostriatal connections have been shown to provide a

neuroanatomical substrate for regulating propagation of this audiogenic seizures. Hence, ín concentrations of amino acids, monoamines, and monoamine metabolites were determined in extracts of tissue punches and monoamine of striatum of audiogenic-seizure susceptible (AGS) and resistant (AGR) substrains of Balb/c mice. In situ activity of tyrosine hydroxylase (TH) and tryptophan hydroxylase (TPH) were determined by measuring the accumulation of L-dopa and 5-HTP after administration of the decarboxylase inhibitor, NSD-1015. Concentrations of amino acids and monoamines were detected by a coulometric electrode array system. Highly significant decreases in both excitatory (glutamate, aspartate) and inhibitory (GABA, taurine, glycine) amino acids were observed in tissue extracts of caudate nucleus of AGS mice compared to that of AGR controls. Highly significant decreases in DA content, in content of DA metabolites, and in activity of TH (but not of TPH) were observed in AGS Balb/c mice compared to AGR controls. These data suggest that AGS mice have a defect in the ability to retain amino acids in the intracellular compartment. The data also raise the issue of the role of GABAergic and dopaminergic neurons in regulation of audiogenic seizures.

THE ONTOGENY OF BINDING SITES TO γ-HYDROXYBUTYRIC ACID IN RAT BRAIN. O. Carter Snead III. C.C. Liu. P.K. Banerjee, Div. Neurol. Childrens Hospital Los Angeles, Dept. Neurol. Univ. Southern California, School of Medicine, Los Angeles, CA 90027

3-Horoxybutyric acid (GHB) is a naturally occurring compound which has the ability to induce generalized absence seizures when given to animals. Since generalized absence seizures have a unique developmental profile, we sought to further validate the GHB model of absence seizures in rat by characterizing the ontogeny of the GHB receptor in rat brain, determining the exact time point when the characteristic GHB absence seizure appears during development, and correlating these two ontogenic

Rat pups were sacrificed at ages ranging from the first postnatal day to adulthood, the brains removed, and subjected to [3H] GHB autoradiography (Snead et al, Epilepsy Res. 1990;7:121). In another group of experiments animals over the same age range were implanted with electrodes and an attempt made to induce GHB absence seizures. Binding to [3H]GHB was not detected in brain slices until the 18th postnatal day. At this age the regional distribution of [3H]GHB binding was characteristic of that seen in adult animals, being maximal in cortex and hippocampus. GHB absence seizures did not appear until 18-21 days of postnatal age. This developmental specificity confirms the validity of the GHB animal model of absence seizure. The data also suggest that the GHB receptor itself may be involved in the mechanism of absence seizures in this animal model.

AMINOOXYACETIC ACID CAUSES SELECTIVE NEURONAL LOSS IN LAYER III OF THE RAT MEDIAL ENTORHINAL CORTEX. F. Du Schwarcz, Maryland Psychiatric Research Center Baltimore, MD 21228.

Focal injection of aminooxyacetic acid (AOAA), a nonspecific yet powerful inhibitor of kynurenic acid synthesis, causes NMDA receptor-mediated seizures and selective neuronal damage in the rat hippocampus (Exp. Neurol 113: 378, 1991). We have now examined the possible neuro-degenerative effects of AOAA in another part of the sei-zure circuit, the entorhinal cortex (EC). Assessed 7 days following the injection of 75 µg/0.75 µl AOAA into the medial EC, neuronal loss was consistently observed in layer III of the medial EC in Nissl-stained horizontal sections. Selective neuronal degeneration of the medial EC was observed even when AOAA was injected more laterally. Higher doses of AOAA also killed neurons in layer II and in deep layers. The extent of the lesion along both the medio-lateral and the dorso-ventral axes varied slightly from case to case. Behavioral seizures were noticed between 2-4 hours after AOAA injection in all rats whose brains subsequently showed lesions. Since neuropathological changes in layer III of the EC have been described in neuropsychiatric diseases such as schizophrenia and Alzheimer's disease and may be involved in seizure disorders, the selective ablation of EC neurons described here may provide an experimental model for those pathological conditions.

RESISTANCE TO SEIZURE INDUCED HIPPOCAMPAL DAMAGE FOLLOWING KAINIC ACID SEIZURES IN 5 DAY OLD RATS.

FOLLOWING KAINIC ACID SELECTORS IN 5 DAY OLD RAIS.

E.F. Sperber \* and K.Z. Haas. Departments of Neurology &
Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461

We have previously demonstrated that kainic acid seizures produce age-related neuropathologic and neurophysiologic hippocampal changes age-teated neutopathologic and neutophysiologic inppocampat change in rats. In adult rats, kainic acid seizures result in cell loss in the CA3/CA4 hipppocampal subfields, sprouting of mossy fibers to the dentate supragranular layer and enhanced paired-pulse inhibition in the dentate gyrus. In contrast, 15-16 day old rats appear to be resistant to

dentate gyrus. In contrast, 15-16 day old rats appear to be resistant to these types of seizure induced hippocampal changes.

In this study, we examined the potentially detrimental effect of kainic acid seizures on the hippocampus of 5 day old rats. Five day old rats were administered kainic acid (2.5 mg/kg, IP). They were remained in status epilepticus for at least 30 min. Two to four weeks following the seizure, the brains were examined for hippocampal neuronal loss (cresyl violet stain) and synaptic reorganization of the mossy fibers in the dentate gyrus (Timm histochemistry). The present results indicate that kainic acid induced seizures did not produce hippocampal neuronal loss or synaptic reorganization. These findings extend our previous findings ranne acta mources serzures did not produce hippocampal neuronal loss or synaptic reorganization. These findings extend our previous findings and indicate that immature 5 and 15 day old rats are more resistant to the development of seizure induced hippocampal damage than adult rats. RPILEPSY: BASIC MECHANISMS II

NEURONAL CELL DENSITY CHANGES IN THE HIPPOCAMPUS OF AN EPILEPTIC MUTANT, STARGAZER X. Oiao\* and J.L. Noebes. Developmental Neurogenetics Laboratory, Section of Neurophysiology, Department of Neurology and Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

We have discovered hippocampal mossy fiber sprouting in the molecular layer of the dentate gyrus and CA3 pyramidal cell body region following the onset of inherited spike-wave seizures in the stg mutant. To test the hypothesis that neuronal loss in this region may play an important role in the synaptic reorganization, quantitative measurements of neuronal density and morphology were performed in the adult +/+ and stg/stg hippocampus. Using computerized image analysis, the perimeter measurements (3 mice, 20-24 sections per group) of the dentate gyrus (+/+ 1723.03.04377.27 μm², stg/stg 18937.37±1049.25 μm²) and CA3 regions (+/+ 24933.33±708.09 μm², stg/stg 27712,12±1801.22 μm²) showed no significant difference in area between genotypes (P > 0.05). The density of granule cells (+/+ 11246.03±292.43/mm², stg/stg 11411.77±312.53/mm²) and CA3 pyramidal cells (+/+ 6253.32± 626.51/μm²) stg/stg 98.41±4.00 μm²). In contrast, hilar polymorphic cells are significantly reduced (P < 0.05) in density (28%) and increased (P < 0.05) in volume (23%) in the stg mutant (density 3943.22± 169.24/mm², volume 57.39±2.18 μm²) compared to +/+ (density 5457.84±220.60/mm², volume 46.78±2.29 μm²). Preliminary immunocytochemical staining of glial fibrillary acidic protein did not reveal any obvious difference in the hilar astrocyte population between the mutant and control sections. These data suggest that there is a selective reduction of the hilar cell population in the stg mutant, which may be related to mossy fiber sprouting and spike-wave seizure activity.

Structural impairment in hippocampal neurons following a single epileptic afterdischarge. Z. Horváth\*, M. Hsu, E. Pierre, D. Vadi, F. Gallyas and G. Buzsáki. Center for Molecular and Behavioral Neuroscience, Rutgers, The State University of New Jersey, 197 University Avenue, Newark,

A highly sensitive silver-impregnation procedure was used to reveal whether lasting structural changes can be induced by a brief epileptic afterdischarge. In groups of rats, implanted with perforant path or entorhinal cortex stimulating electrodes and epidural recording electrodes, a single afterdischarge (< 2 min) was induced and the animals were perfused 1 to 16 hour after the electrical seizure. Most silver-impregnated "dark" neurons were present in the strata radiatum-lucidum, pyramidale and oriens of CA3, followed by the hilus and strata oriens and pyramidale of CA1. "Dark" cells were present at all time points in both hippocampi, but not in other structures. The findings suggest that even short epileptic epochs are capable of triggering long-lasting morphological changes and interneurons are more vulnerable than principal cells. We hypothesize that the observed structural changes might explain the cumulative damaging effects of successive epileptic episodes.

EEG PATTERN RECOGNITION BY BACKPROPAGATION NETWORK G. Jando, R. M. Siegel\*, Z. Horvath and G. Buzsaki. Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

A backpropagation network was trained to recognize the high voltage spike-and-wave spindle (HVS) pattern in the rat, a rodent model of human petit mal epilepsy. The spontaneously occurring HVS were examined in 250 rats of the Fisher 344 and Brown Norway strains and their F1, F2 and backcross hybrids (Vadasz et al., this meeting). neitr F1, F2 and backeross hybrids (vadasz et al., this hiereing). Neocortical EEG and movement of the rat were recorded for twelve night hours in each animal and analog data were filtered (low cut: 1 Hz; high cut: 50 Hz) and sampled at 100 Hz with 12 bit precision. A training data set was generated by manually marking durations of HVS epochs in 16 representative animals selected from each group. Training data were presented to backpropagation networks with variable numbers of input, hidden and output cells. The performance of different types of input, hidden and output cells. The performance of different types of networks were first examined with the training samples and then the best configuration was tested on novel sets of the EEG data. FFT transformation of EEG significantly improved the pattern recognition ability of the network. With the most effective configuration (16 input; 19 hidden; 1 output cells) the summed squared error dropped by 80% as compared with that of the initial random weights. When testing the network with new patterns the manual and automatic evaluations were compared quantitatively. HVSs which were detected properly by the network reached 91-99% of the manually marked HVS patterns, while falsely detected events (non-HVS, artefacts) varied between 18% and 40%. These findings demonstrate the utility of backpropagation networks in automatic recognition of EEG patterns. networks in automatic recognition of EEG patterns.

DEGENERATION AND REINNERVATION INTERVALS AS MECHANISMS FOR THE LATENT PERIOD BETWEEN FOCAL DAMAGE AND LATER FOCAL CHRONIC SEIZURES. T. Babb\*, J. Pretorius, F. Cifuentes and G. Mathem. Dept. of Neurology, UCLA School of Medicine, Los Angeles, CA 90024

Mathem. Dept. of Neurology, UCLA School of Medicine, Los Angeles, CA 90024.

One of the most puzzling phenomena in epilepsy is the well-known latent period between damage-induced acute seizures and the establishment of chronic seizures. Historically, the rat kainate model of epileptic hippocampus (HC) has demonstrated rapidly occurring (7-30 days) reactive synaptogenesis of intrinsic circuits (both "excitatory" and "inhibitory"). However, the typical latent period (90-120 days) before chronic HC seizures far exceeds the initial time course of reactive synaptogenesis (as demonstrated by Mathern, et al., 1992, this meeting). We propose that markers for degeneration and reinnervation might suggest mechanisms propose that markers for degeneration and reinnervation might suggest mechanisms that would be impermissive or growth-promoting for functional synaptic reorganization. Results show that at 21 days post-kainate, the bilaterally-dependent spiking was associated with dense dentate supragranular proliferating astrocytes (GFAP) and sprouting (GAP-43) that was related to sprouting by mossy fibers (neo-Timm). At 180 days, when HC EEG seizures and behavioral partial complex seizures occurred, there was a subnormal GFAP band in the supragranular layer which was overlapped by an increased supragranular band of GAP-43 staining. These results suggest that early in reactive synaptogenesis GFAP marks the factors such as degenerating axons, microglia and activated astrocytes that are impermissive to functional synaptogenesis. The GAP-43 may mark neuritic processes that may progress into new supragranular synapses. By 180 days, the absence of supragranular GFAP may mean the impermissive factors were cleared and functional synaptogenesis established, as indicated by the dense GAP-43 band and the HC EEG focal and behavioral seizures. These results suggest that changes in glial functions Synaphogeties restablished, as indicated by the dense CAP 43 and and the fix Experience focal and behavioral seizures. These results suggest that changes in glial functions at deafferented zones may contribute to the latent period by interacting to inhibit or promote functional neoinnervations. Supported by NIH Grant NS02808 and an EFA Fellowship to G.M. GAP-43 was a gift from Dr. Larry Benowitz.

A METHOD FOR 3-D RECONSTRUCTION OF THE CELL-ORGANIZATION IN CORTEX CEREBRI - DEVELOPED FOR THE ANALYSES OF EPILEPTIC CORTEX (WORK IN PROGRESS). T.Skoglund', R. Pascher, M. Rydmark, C-H. Berthold, T. Gustavssson. Dept. of Anatomy and MedNet-laboratory, University of Göteborg, Medicinarg. 3, 413 90 GÖTEBORG, SWEDEN.

The hypothesis that a developmental disturbance underlies epilepsy was put forward in the early 1900's by Alzheimer and Ranke. In order to study if this disturbance could be found in cortex cerebri we developed a system for 3-D reconstruction of the cellorganization in nervous tissue.

During the development of the system we used cortex cerebri from cat. Light microscopical images of consecutive semithin (0.5 um) serial sections of cat motor cortex were digitized into a image analyses system (Teragon 4000) via a CCD-camera attached to a microscope. The image-stack in the computer, containing 914 photographic images, were aligned and analyzed and the coordinates and a classification of the neurons and the glial-cells were saved in a database. The database (i.e. the cortical prism containing about 20.000 cells) could be visualized in a 3-D graphic system (Megatek 9300) where the cells were represented by semi-realistic models. Parameters as celldensity, clustering and lamellar organization could be computed.

We are now applying the same procedure on cortex cerebri from human epileptic cortex. The cortex (in this case area 21) has been removed in the neurosurgical treatment of the patients epilepsy. Instead of Vestopal W we have used LR Gold which makes it possible to do immunohistological classification of the cells. At the conference we will show the results from our studies comparing the cellorganization in epileptic cortex and in normal, nonepileptic human cortex

UNIT RECORDINGS FROM THE CEREBELLUM CORRELATE WITH SPIKE AND WAVE CORTICAL EEG PATTERNS IN THE RAT. Adam Kandel\* and György Buzsáki. Center for Molecular and Behaviora Neuroscience, Rutgers University, Newark, NJ 07102

High voltage spike and wave spindles (HVS) in rodents are regarded as a High voltage spike and wave spindles (HVS) in rodents are regarded as a model of petit mal generalized non-convulsive seizures in humans. In previous studies the ventral anterior (VA) and the ventral lateral (VL) have been implicated as important initiators for neuronal oscillations underlying neocortical HVS. The deep cerebellar nuclei (the only output from the cerebellum) have a heavy projection to the thalamus, mainly to the VAVL. Spike and wave patterns recorded from the frontal cortex of the rat were observed to correlate with unit recordings in the cerebellar of rats. In this study the EEG was recorded with screw electrodes implanted in the calvarian bone over the frontal cortex. A microelectrode drive was placed over the cerebellum above the deep cerebellar nuclei (AP= 11.50-13.50; ML=0.00-1.50) and recordings were attained from 0-8 mm vertical and from 4-6 tracks per animal. Tremor was recorded with a magnet-coil type accelero-mater. Single or multiple units were recorded with 1-3 MO from 4-6 tracks per animal. Tremor was recorded with a magnet-coil type accelero-meter. Single or multiple units were recorded with 1-3 M $\Omega$  tungsten microelectrodes. Units were found to occur in correlation with HVS with the majority of neurons recorded discharged during the wave component, whereas a smaller portion fired in association with the spike component of the HVS. From our data we conclude that cerebellar neurons may contribute to the emergence and/or maintenance of HVS.

PROGRESSIVE HIPPOCAMPAL ELECTROGRAPHIC HYPEREXCITABILITY CORRELATES WITH REACTIVE SYNAPTOGENESIS IN THE RAT KAINATE SEIZURE MODEL. G. Mathern, J. Pretorius, F. Cifuentes, M. Nuwer\* and T. Babb. Dept. of Neurology,

SYNAPTOGENESIS IN THE RAT KAINATE SEIZURE MODEL. G. Mathem. J. Pretorius, F. Cifuentes. M. Nuwer\* and T. Babb. Dept. of Neurology, UCLA School of Medicine, Los Angeles, CA 90024.

Previously, Mathem et al., (Dendron, 1992, vol. 1) showed that bilateral intrahippocampal kainate in rats induced progressive cell loss and mossy fiber sprouting in hippocampia and eventually to subiculum at 4 months. Partial complex seizures were observed at 6 months. This study recorded EEG bilaterally from hippocampus and frontal cortex to relate critical stages of EEG changes to cytologic and circuit alterations in the hippocampi. EEGs were recorded at the time of kainate injection (0.1 µg/µl bilaterally), every 4-6 days using both fast (to resolve interictal spikes) and slow paper speeds (to detect EEG seizures, many of which were observed behaviorally). Minor brain sections were alternately stained for: 1) recent cell death (silver stain), 2) reactive astrocytes (GFAP), 3) cell counts (CV), 4) reactive synaptogenesis (GAP4), 5). "excitatory" sprouting (neo-Timms, AChE), and 6) "inhibitory" sprouting (GAD). Results indicate the pattern of hippocampal EEG changes predicts reactive synaptogenesis and partial hippocampal status lasting only 4-8 hours. For the next 5-7 days there was diffuse background slowing with occasional synchronous spikes. From 7-21 days there was a second period of diffuse, bilaterally synchronous hyperexcitability, and generalized seizures. After day 21 a silent period occurred lasting 90 to 120 days, then bilaterally-independent hippocampal spikes began. At 120 to 180 days, these developed into independent hippocampal spikes began and paroxymal fast activity. This independent hippocampal EEG activity caused complex partial seizures in these animals. Synaptic reorganization paralleled the EEG changes, showing more sprouting as independent EEG activity was seen. Supported by NIH Grant NS02808 and an EFA Fellowship to G.M. EFA Fellowship to G.M.

MK-801 BLOCKED SEIZURE-RELATED HIPPOCAMPAL DAMAGE INDUCED BY ELECTRICAL STIMULATION OF THE DEEP PREPYRIFORM CORTEX. K.Inoue, K.Morimoto\*and S.Otsuki. Dept.Neuropsychiat. Okayama Univ.Med.Sch. Okayama, 700 Japan. A model of status epilepticus (SE), which was induced by intermittent electrical stimulation of the deep prepyriform cortex, has been developed in the conscious rat. SE

was induced in 9 of 16 rats in the drug-free group. Significant cell loss was observed in the hippocampal CA3 ipsilateral to the stimulation site and bilateral CA1 areas in the status subgroup compared with the sham operation group. In addition, there was a significant correlation between the duration of seizure activity subsequent to the stimulation session and the total number of intact pyramidal neurons observed in the bilateral CA1 and ipsilateral CA3 subfields of the status subgroup. There were significant differences between the status and non-status subgroup with respect to the number of afterdischarges (ADs) and the total AD duration during the stimulation sion. Pretreatment with phenobarbital (30mg/kg) prevented the development of SE and hippocampal cell loss comp letely. Pretreatment with MK-801 (0.25 or lmg/kg) also prevented hippocampal cell loss, although it did not block SE generation completely, which suggests dissociation of the mechanisms underlying the development of SE and hippocampal damage. These results indicate that prolonged seizure activity actually causes hippocampal damage and it is critically dependent upon NMDA receptor participation.

GENERALIZED TONIC-CLONIC SEIZURES INDUCED IN RATS BY INTRAVENTRICULAR ADMINISTRATION OF OKADAIC ACID. J.T. Slevin\*, G.R. Barnes, Y.J. Farrar, R.M. Alcala, and T.C. Vanaman. VA and the University of Kentucky Medical Centers, Lexington, KY 40536.

We have shown that rat hippocampal protein kinase C [PKC] and phosphoprotein phosphatase 2A [pp2A] apparently redistribute from cytosol to synaptic plasma membrane [SPM], either following an ECS in vivo or K depolarization of hippocampal slices in vitro. In slices, PKC and pp2A activity crest in SPM at 0.5 and 2 min, respectively, and both return to control values by min, respectively, and both return to control values by 5 min. PKC activity is amplified and pp2A redistribution is attenuated in fully kindled, epileptic rats. We report here that rats administered 7.5 nmoles of the pp2A inhibitor, okadaic acid, through intraventricular cannula experienced generalized tonic-clonic seizures. These were observed, both by electroencephalographic [EEG] recording and behavioral measures, within 5 min of dosing. Dephosphorylation of the synthetic peptide, <sup>32</sup>p-RRATVA, using pp2A partially purified from either hippocampi of animals given okadaic acid or vehicle alone, was no different suggesting, among other possibilities, the inhibitor is rapidly dispersed. These data indicate phosphorylationdephosphorylation events associated with neuronal depolarization may play a central role in epilepsy. [Support: Dept. of Veterans Affairs & NS 21868, NINDS]

# 232.11

INCREASED NUMBER OF GABA, RECEPTORS IN THE LETHARGIC (LI/LIB) MOUSE MODEL OF ABSENCE EPILEPSY. F-H Lin, Z. Cao & D. Hosford. Duke & VA Medical Centers, Durham, N.C. 27705.

Lh/lh mice have a single-locus defect on chromosome 2 and spontaneous absence seizures. Pharmacologic studies appear to indicate a requirement for GABA<sub>b</sub> receptors in the expression of these seizures (Hosford et. al., Soc. Neurosci. 17:170, 1991); electrophysiologic studies show enhanced synaptic activation of GABA, receptors in slices from *lh/lh* mice (Clark et. al., Soc. Neurosci. 17:170, 1991). We used a radioligand binding assay to test the hypothesis that an increase in the affinity (Kd) or number (Bmax) of GABAB

receptors underlies enhanced synaptic activation of these receptors.

We measured [H]-baclofen binding sites to neocortical plasma membranes prepared from lh/lh and wild (+/+) age-matched congenic mice. The  $B_{max}$  was significantly greater (20%) in lh/lh (4.2 pmol/mg protein, n = 43 pairs, p < 0.02) than +/+ mice (3.3 pmol/mg protein) in an age-independent manner. The  $K_a$  (50 nM) was unchanged. Interestingly, the subset of lh/lh mice with greater seizure frequency (40-70 seizures/15 min, measured by bipolar electrodes implanted into neocortex; n = 11) had a significantly greater  $B_{max}$  (p < 0.003) than the subset with lower seizure frequency (1-10 seizures/15 min; n = 11). The increased number of GABA<sub>b</sub> receptors was selective, because binding to NMDA receptors (NMDA-displaceable [<sup>3</sup>H]glutamate binding) and to GABA, receptors ([3H]muscimol binding) was not significantly different in the two strains.

These data support our hypothesis that the increased number of GABA receptors in Ih/Ih mice underlie enhanced synaptic activation of these receptors. Together with evidence that GABA, receptor activation can produce disinhibition (Ogata, Gen. Pharmacol. 2:395-402, 1990), our data also support a role for GABA, receptors in the expression of absence seizures in Ih/Ih mice.

# 232.13

LOSS OF GAD mRNA-CONTAINING NEURONS IN THE HILUS THE DENTATE GYRUS FOLLOWING PILOCARPINE-INDUCED SEIZURES. A. Obenaus\*, M. Esclapez and C.R. Houser. Dept. of Anatomy and Cell Biology and Brain Research Institute, UCLA, and VA Medical Center, Los Angeles, CA 90024.

In situ hybridization methods were used to determine if glutamic acid decarboxylase (GAD) mRNA-containing neurons within the dentate hilus are vulnerable to seizure-induced damage in the pilocarpine model of chronic seizures (Turski et al., Synapse 3:154, 1989). Sprague-Dawley rats (150-200 gm) were injected with pilocarpine (325-350 mg/kg, i.p.) to induce severe behavioral seizures and were studied histologically at 1, 2 and 4 week intervals. In situ hybridization histochemistry, using a digoxigenin labeled GAD cRNA probe, demonstrated a substantial decrease in the number of GAD mRNA-labeled neurons within the hilus of the pilocarpinetreated rats as compared to controls. Supplemental studies, utilizing cresyl-violet staining, neuronal degeneration methods and GFAP immunohistochemistry, suggested that the decrease in GAD mRNAlabeled neurons was related to neuronal loss rather than to a decrease in GAD mRNA levels. The loss of GAD mRNA-containing hilar neurons contrasted with the relative preservation of labeled putative basket cells along the inner border of the granule cell layer. The results suggest that, in this model, a subpopulation of GABA neurons within the dentate gyrus is selectively vulnerable to seizure-induced damage. Supported by VA Medical Research Funds and NS21908.

INHERITANCE OF NEOCORTICAL HIGH VOLTAGE SPIKE-AND-WAVE (HVS) PATTERNS IN RATS. D. Carpi', G. Jando, E. Pierre', D. Vadi', A. Fleischer', A. Lajtha', C. Vadasz', and G. Buzsaki'. Center for Neuroscience', Rutgers University, Newark, NJ 07102; Nathan Kline Institute for Psychiatric Research2, Orangeburg, NY 10962.

Our previous studies on Fisher 344 (F344) and Brown Norway (BN) rats indicated that genetically controlled, spontaneously occurring HVS in rats may serve as an animal model of absence epilepsy. To further investigate the inheritance of HVS patterns, (F344XBN)F<sub>1</sub> hybrids were mated to produce segregating (F344XBN)F<sub>2</sub> rats (N=82). Neocortical activity was recorded in 6-month-old F344, BN,  $\hat{F}_1$ , and  $F_2$  rats for 12 night hours by a computer assisted system. HVS episodes were detected by a backpropagation neural network (Jando et al., this meeting). 74% of the F<sub>2</sub> animals expressed HVS, a proportion that fit well the Mendelian 3:1 ratio expected for monogenic inheritance with complete dominance. However, since occurrence of HVS in F344, BN and F1 groups did not fit this simple Mendelian model, and significant sex differences were also detected in BN, F1, and F2 animals, we suggest that HVS is a treshold trait whose expression is affected by one or more quantitative trait loci, and sex-linked gene effects.

INCREASED HIPPOCAMPAL NMDA RECEPTOR DENSITY IN GENETICALLY

INCREASED HIPPOCAMPAL NMDA RECEPTOR DENSITY IN GENETICALLY EPILEPSY-PRONE RATS. KA Ortiz and D.D. Savage\* Dept. Pharmacology, University of New Mexico School of Medicine, Albuquerque, NM, 87131—5316.

Previous in vitro autoradiographic studies indicated that [3H]—glutamate receptor binding site density is increased in the apical dendritic field regions of hippocampal formation in Genetically Epilepsy-Prone (GEPR-9) rats compared to non-epileptic Sprague-Dawley controls. Using two different radioligands that selectively bind to the NMDA subtype of glutamate receptors is one of the subtypes elevated in GEPR-9 rat hippocampal formation.

Eight-µm-thick histological sections of brain containing either dorsal or ventral hippocampal formation were incubated with either [3H]—MK-801 [12 nM) or [3H]—CGS 19755 [33 nM]. Specific [3H]—MK 801 binding was defined as the difference between [3H]—K8 801 binding in the absence and presence of 200 µM unlabelled ketamine. Specific [3H]—CGS 19755 binding was defined as the difference between [3H]—CGS 19755 binding in the absence and presence of 10 µM unlabelled CGS 19755. Binding was measured in three apical dendritic field regions of hippocampal formation: 1) dentate gyrus s. moleculare, 2) hippocampal Ca<sub>1</sub> s. radiatum and 3) subiculum s. radiatum. Specific [3H]—MK 801 binding was increased by 33% to 47% dorsal hippocampal formation of GEPR-9 rats. Thas compared to controls. Lesser elevations, ranging from 11 to 17% above control, were noted in ventral hippocampal formation of GEPR-9 rats. Specific [3H]—CGS 19755 binding was increased VD-57% in dorsal hippocampal formation of GEPR-9 rats compared to controls. Lesser elevations, ranging from 14 to 23% above control, were noted in ventral hippocampal formation of GEPR-9 rats. This increased MMDA receptor density may contribute to elevated hippocampal glutamatergic neurotransmission and enhanced seizure susceptibility in GEPR-9 rats. Since these GEPR-9 rats were not deliberately convulsed, an alternative interpretation of the bindin

not deliberately convulsed, an alternative interpretation of the binding data is that the GEPR-9 rats may have experienced spontaneous seizures which consequently elevated NMDA receptor density. (Supported by RR08139 and RR05583).

ENHANCED ASPARTATE RELEASE RELATED TO SEIZURES

ENHANCED ASPARTATE RELEASE RELATED TO SEIZURES IN EPILEPTIC (EL) MICE. H.J. Flavin\* and T.N. Seyfried. Biology Dept., Boston College, Chestnut Hill, Ma. 02167.

The release of the putative neurotransmitters aspartate, glutamate, and gamma-aminobutyric acid (GABA) was studied in hippocampal slices from epileptic (EL) and non-seizure control C57BL/6J (B6) and ddy mice. The EL mouse is a genetic model of temporal lobe epilepsy. We previously showed that the endogenous release of aspartate was significantly higher in slices from adult EL mice (many seizures) than B6 mice (Flavin et al., 1991 J. Neurochem. 56, 1007-1011). In the present study, we used young (38 ± 4 days) mice prior to seizure expression in EL mice. The calcium-dependent potassium-induced release was compared between strains. Release of mice prior to seizure expression in EL mice. The calcium-dependent potassium-induced release was compared between strains. Release of endogenous amino acids was measured using liquid chromatography with fluorescence detection and was expressed as pmol amino acid released/min incubation/slice  $\pm$  SEM. No significant differences were found between the B6, ddy and EL mice for the release of glutamate (22.95  $\pm$  2.0;  $32.28 \pm 5.8$ ; and  $25.86 \pm 2.6$ , respectively) or GABA (23.52  $\pm$  0.7; 19.51  $\pm$  3.2; and 21.80  $\pm$  3.2, respectively). Aspartate release, however, was significantly higher in the EL mice (15.79  $\pm$  0.8) than in either the B6 mice or the ddy mice (8.54  $\pm$  1.4 and 8.39  $\pm$  1.7, respectively). Thus, enhanced aspartate release in EL slices is expressed both before and after seizure onset. Further, the enhanced expressed both before and after seizure onset. Further, the enhanced aspartate release may be related to the cause rather than to the effects of seizure activity. (Supported by NIH Grant 23355 and the Michael P. Walsh Fellowship.)

SINGLE GENE CONTROL OF ATP AND GTP HYDROLYSIS IN MOUSE BRAIN K.M. Ding-Allen\*, and T.N. Seyfried Dept. of Biology, Boston College, Chestnut Hill, MA 02167.

In order to discriminate between catalysis by one enzyme or two different enzymes, both RTP and GTP were used as substrates in the Ca2+- or Mg2+- stimulated nucleotide triphosphatase assay in brain microsomes from C57/BL6 (B6) and DBR/ZJ (D2) mice. The total substrate concentration was kept constant while varying the relative concentrations of RTP and GTP. The activity was constant and linear which is consistent with a single enzyme model. Furthermore, competitive inhibition experiments, using non-hydrolyzable RTP or GTP analogs, suggest that the same enzyme hydrolyses both RTP and GTP. Previous studies showed that RTPase and GTPase activities are significantly lower in the audiogenic seizure (RGS) susceptible D2 mice than in the resistant B6 mice. B6D2F; hybrids had RTPase and GTPase activities that were intermediate to those of the parental strains. Rnalysis of eight BXD recombinant inbred (RI) strains showed that RTPase and GTPase activities were inherited together and displayed activities were inherited together and displayed activities were inherited together and displayed solimodal distribution, suggesting single gene control. Hence, the data suggest that a single enzyme, under single gene control, is responsible for the Ca2+- or Mg2+-stimulated hydrolysis of either RTP or GTP in mouse brain. (Supported by NIH Grant 23355 and NIMH NRSR MH18138.)

NORADRENERGIC ABNORMALITIES IN THE CENTRAL NERVOUS SYSTEM OF GENETICALLY EPILEPSY-PRONE RATS: STUDIES WITH MICRODIALYSIS. Q-S. Yan, P. C. Jobe and J. W. Dailey. Department of Basic Sciences, University of Illinois College of Medicine at Peoria, Peoria, Illinois 61656

An expanding body of data supports the concept that the genetically epilepsy-prone rat (GEPR) brain is characterized by a deficiency in the number of noradrenergic terminals, in the amount of norepinephrine (NE) released per terminal and in the capacity of the postsynaptic receptors to compensate for the presynaptic deficits. The present study was designed to provide a direct demonstration of abnormalities in the central noradrenergic transmission of GEPR by using intracerebromicrodialysis. Under anesthesia, guide cannulae were stereotaxically placed over thalami of both severe seizure GEPRs (GEPR-9s) and seizure-resistant control rats. After recovery from surgery, dialysis probes were inserted and the animals were placed individually into a plexiglass chamber where they were allowed to move about freely. Artificial CSF was perfused at 1  $\mu$ L/min and samples were collected for analysis on HPLC with electrochemical detection. After 2-3 hours of sampling, a stable baseline for NE was established and three basal release measures were made. Either desipramine (5  $\mu M$  in artificial CSF) or yohimbine (5  $\mu M$  in artificial CSF) was administered through the dialysis probe for 2 hours and dialysis was continued for another 4 hours. Significantly diminished in vivo NE release from the thalamus was seen after the treatment with either drug in GEPR-9s when compared with seizure-resistant controls. These findings are consistent with the hypothesis that NE deficiencies exist within some brain areas of GEPR and serve as a partial determinant of the abnormal state of seizure predisposition exhibited by these animals. (Supported by UICOM-P Internal Research Grant and NIH NS22672)

NEUROPROTECTION FROM NMDA AND NON-NMDA MEDIATED DAMAGE OF SOMATOSTATIN AND NPY CELLS IN A RAT MODEL OF STATUS EPILEPTICUS. L.P. Penix\*¹ and C.G. Wasterlain² ¹ Epilepsy Research Branch, NINDS, NIH, Bethesda, MD 20892, and ² Brain Research Institute, UCLA.

Somatostatin positive interneurons are selectively lost in the dentate hilus of patients with long standing temporal lobe epilepsy. Somatostatin neurons have also been shown to be vulnerable to non-NMDA but not to NMDA mediated neurotoxicity in cell culture. However, selective mechanisms of hilar neuronal death have not been demonstrated in in-vivo models of epileptic brain damage. We administered the non-competitive NMDA antagonist MK-801 and the competitive non-NMDA antagonist NBQX to rats during a 24 hour perforant path stimulation paradigm described by Sloviter in order to prevent the damage to somatostatin positive hilar interneurons. MK-801 and NBQX were administered i.v. at 100  $\mu$ g/kg/hr and 1.5 mg/kg/hr, respectively. Paired pulse inhibition was lost in each of the three groups. Control animals had 64.7 ± 2.9 % and 50.3 ± 1.5 % loss of SS- and NPY-like immunoreactive interneurons, respectively. Animals treated with MK-801 had 37 ± 5.0 % (p<0.05) and 38 ± 4.4 % (N.S.) loss. Animals treated with NBQX had 30.7 ± 10.3 % (p<0.01) and 18 ± 4.8 % (p<0.05) loss. These data show that antagonism of both NMDA and non-NMDA receptors significantly protect against damage of NPY-immunoreactive hilar interneurons yet only non-NMDA antagonism significantly protects against damage of NPY-immunoreactive lilar interneurons may not be responsible for this particular type of inhibition.

### 232.16

ENHANCED RELEASE OF SOMATOSTATIN (SLI) IN THE RAT HIPPO-CAMPUS IN CHRONIC MODELS OF LIMBIC EPILEPSY:COMPARISON WITH NEUROPEPTIDE Y (NPY). A.Monno, M. Rizzi, A. Galli, M.T. Tacconi\*, R. Samanin and A. Vezzani. Lab. of Neuro-pharmacology, Mario Negri Institute for Pharmacological Research, Milan, Italy.

Spontaneous efflux of SLI from hippocampal slices of rats  $(3.5\pm0.48 \text{ fmol/ml every 10 min})$  was increased 1.5 times in the electrically kindled hippocampus (HP) 48 h after stage 2 and 2 times on average bilaterally one week after stage 5 (p<0.05). Ca<sup>2+</sup>-dependent 50 mM KCl-induced release was enhanced (1.8 times on average, p<0.01)bilaterally at both stages compared to shams (17+1.6 times baseline, p<0.01). The release did not differ 48 h after a single afterdischarge. 50 mM KC1-induced NPY release was enhanced bilaterally at both stages of kindling (4.1+ 0.7 times sham value, p<0.01). One month after 10 mg/kgkainic acid, KC1-induced SLI release was similar to shams in dentate gyrus (DG) slices in rats with behavioral seizures and a two-fold increase in NPY release was found in the DG of the same animals (p<0.05). These peptides role in hippocampal epileptogenesis is worth further investigation.

In order to evaluate a protein-related mechanism underlying epilepto-

In order to evaluate a protein-related mechanism underlying epileptogenesis, we quantitatively analyzed the 70-kDa protein (namely, P70), a specific protein found in the cobalt-induced epileptic focus of rat cerebrum, and examined its effect on the electrocorticogram (ECoG) and cortical neurons in cerebral slices and its immunocytochemical localization in rat cerebrum. Cobalt-induced epileptogenic cortex exhibited a marked induction of P70. Its initiation time was ahead of the generation of epileptogenic activities. The anticonvulsant phenytoin (PHT) attenuated the epileptogenic activities, but failed to suppress protein induction. Injection of this protein into the motor region of normal rat cerebral cortex elicited an epileptiform ECoG and behavioral seizures. It also caused epileptiform activity with paroxysmal depolarization shifts in cortical neurons. These epileptogenic phenomena elicited by P70 were abolished by prior treatment with PHT or phenobarbital. Immunocytochemical analysis with an antiserum against P70 revealed that the reactivity was confined to pyramidal cells only in the region of the focus and was mainly localized on somatic, dendritic, and nuclear membranes and microtubles. These findings suggest the possibility that P70 may be linked to epileptogenesis.

GALANIN INNERVATION WITHIN THE NUCLEUS BASALIS IN DOWN SYNDROME. E.J. Mufson, E.J. Cochran, R. Casanova and J.H. Kordower. Dept. of Neurol. Sci. and Rush Alzheimer's Dis. Ctr., Rush Presbyterian St. Luke's Med. Ctr., Chicago, IL. 60612.

Galaninergic fibers have been reported to hypertrophy in response to cholinergic cell loss within the nucleus basalis (nbM) in Alzheimer's disease (AD). Since brains of patients with Down syndrome exhibit neuropathologic changes similar to AD, we investigated the pattern of galanin innervation within the nbM of these individuals. Paraformaldehyde (4%) immersion fixed 40µ thick sections throughout the entire extent of the nbM of Down patients (ages 46, 47 and 47 years) were singly or concurrently immunohistochemically stained for galanin (GAL), nerve growth factor receptor (NGFR; a marker for basal forebrain cholinergic neurons) and the cytoskeletal markers thioflavin-S, paired helical filament (PHF) and Tau. All cases exhibited cytoskeletal positive neuritic plaques, neurofibrillary tangles and neurites within neo and limbic cortex. The severity of nbM NGFR containing neuron loss ranged from moderate to severe. Numerous cytoskeletal extracellular globose shaped tangles and neurites, but virtually no neuritic plaques, were found within the nbM. GAL immunoreactive (ir) sections revealed positive fibers and only a few small oval shaped atrophic GAL-ir neurons distributed mainly within the anterior regions of the nbM. The extent of the GAL-ir fiber innervation exceeded the levels expected from the number of nbM GAL-ir neurons. In the Down cases, hypoinnervation of GAL-ir fibers was seen in regions containing clusters of NGFR-ir neurons relative to AD and age-matched controls. GAL-ir fibers within the Down nbM were observed mainly in areas devoid or adjacent to clusters of NGFR-ir perikarya. Interestingly, AD and age matched controls exhibited similar GAL-ir fiber innervation in close apposition to NGFR-ir neurons. Support: AG10668, AG09466, AG10161 and IDPHS.

THE FRONTAL CORTEX IN NEURODEGENERATIVE DISORDERS: CELLULAR AND REGIONAL PATTERNS OF VULNERABILITY. E.A. Nimchinsky\*, P.R. Hof, D.P. Perl and J.H. Morrison. Fishberg Rect for Neurobiology, Mount Sinai Sch of Med, New York, NY 10029. We have conducted an analysis of the primary motor, premotor and

We have conducted an analysis of the primary motor, premotor and prefrontal regions (areas 4, 6, and 9) in normal human brain as well as in Alzheimer's disease (AD), amyotrophic lateral sclerosis (ALS), and ALS/Parkinsonism-dementia complex of Guam (ALS/PD). SMI32, an antibody that recognizes nonphosphorylated neurofilament protein stains virtually all of the giant pyramidal (Betz) cells in layer V of area 4, and exhibits a bilaminar staining pattern in areas 6 and 9. Interestingly, the largest of the Betz cells are labeled with an antibody to the calciumbinding protein calretinin (CR). CR has not been found in any other pyramidal cell population. In AD, area 9 shows a reduction of SMI32-immunoreactive (ir) cells and the presence of NFT, while in area 4 SMI32-ir neurons including Betz cells are spared. In ALS, there is a dramatic reduction in the number of SMI32- and CR-ir Betz cells in area 4, without the formation of neurofibrillary tangles (NFT), whereas areas 6 and 9 show no such loss of SMI32-ir cells. In ALS/PD, where NFT preferentially occur in superficial cortical layers, ALS-predominant cases show a loss of cells also in the deep cortical layers of area 4. PD-predominant cases show alterations mostly in superficial layers of area 9 and have intact populations of SMI32- and CR-ir giant cells in area 4. These observations suggest that SMI32- ir pyramidal cells may react to insult with or without NFT formation and express specific regional vulnerability in various neurodegenerative diseases depending upon the particular cortical efferent systems involved as reflected in the relative dominance of cognitive or motor symptoms.

PATHOLOGY OF EPINEPHRINE NEURONS IN ALZHEIMER'S. W.J. Burke\*, N.J. Galvin, H.D. Chung, K.N. Gillespie, A.M. Cataldo, R.A. Nixon. Dept. Neurology, St. Louis Univ. Med. Sch., St. Louis VAMC, St. Louis, MO 63110; McLean Hosp., Mailman Res. Ctr., Belmont, MA 02178

We reported chemical changes but no cell loss in the epinephrine (Epi) C-1 neurons in Alzheimer's disease (AD) (Ann. Neurol.24:532,1988). To examine for histopathological changes in Fot paymons in AD.

We reported chemical changes but no cell loss in the epinephrine (Epi) C-1 neurons in Alzheimer's disease (AD) (Ann. Neurol.24:532,1988). To examine for histopathological changes in Epi neurons in AD we performed the following: 1) Computer assisted analysis of area distribution of 1000 control and 2500 AD neurons from 2 controls 58±15 yrs. and 4 AD 76.7±2.3 yrs. Mean areas and distributions were compared using t and Kalmogorov-Smirnov z tests respectively. 2) Immunohistochemical analysis of: a) Tau-2 and Alz-50 positive C-1 neurons, b) Staining density of cathepsin D in AD and control C-1 neurons. The mean area of AD C-1 neurons was 21% less than controls (AD:328±4 mm² vs control: 416±7; pc0.001). The size distributions differed significantly (p<0.001) with the peak of AD distribution shifted toward smaller neurons. Both Tau-2 and Alz-50 positive neurons were found in C-1. Cathepsin staining density of some AD C-1 neurons appeared increased compared to control and adjacent normal neurons. We conclude that characteristic pathological changes found in other parts of the brain in AD also occur in C-1 neurons.

DISTRIBUTION OF CYTOCHROME OXIDASE (COX) ACTIVITY AND mRNA IN MONKEY AND HUMAN BRAIN. COX mRNA DISTRIBUTION CORRELATES WITH NEURONS VULNERABLE TO ALZHEIMER PATHOLOGY. K.Chandrasekarant. J. Stoll. D.R. Brady and S.I. Rapoport. Laboratory of Neurosciences, NIA, Bethesda, MD 20892.

Differential screening of a frontal pole cDNA library from monkey (Macaca mulatta) brain revealed 3 cDNA clones whose cognate mRNAs are expressed more in fortal pole than in primary visual cortex. The cDNA

Differential screening of a frontal pole cDNA library from monkey (Macaca mulatta) brain revealed 3 cDNA clones whose cognate mRNAs are expressed more in frontal pole than in primary visual cortex. The cDNA clones were identified as mitochondrial (mit) DNA encoded cytochrome oxidase (COX) subunits I, II and III. Each clone showed higher expression of mRNA in association neocortices than in the primary sensory or motor cortices. COX mRNA and COX activity were localized, by in situ hybridization and by enzyme histochemistry, respectively, in regions of monkey and human brain. In monkey cerebral cortex, COX enzyme activity was highest in dendrite-rich neuropil. In contrast, COX mRNA was detected mainly in cell bodies and apical dendrites of medium to large projection neurons. Thus, in the entorhinal cortex, the highest levels of COX mRNA were localized in neuronal cell bodies of layers II and IV, neurons involved in the input and output pathways of the hippocampus, respectively. In superior temporal sulcus, perirhinal and prefrontal cortices, highest levels were detected in cell bodies of layers III and V-VI, presumably neurons involved in corticocortical connections. In normal human brain, similar distributions of COX mRNA were observed. The laminar distribution of COX mRNA corresponded with neurons vulnerable to Alzheimer disease (AD) pathology. In AD brains, there was a significant decrease in COX mRNA in vulnerable brain regions. Preliminary results also showed deletions in mitDNA. These results indicate high levels of a mitochondrial oxidative enzyme, and of the mRNA for its subunit, in brain regions vulnerable to AD pathology. This neuropathology is accompanied by deletions in mitDNA and reduced COX mRNA.

### 233.4

DISTRIBUTION AND CELLULAR ANALYSIS OF MRNA FOR COMPLEMENT COMPONENTS C1Q AND C4 IN ALZHEIMER'S AND NORMAL BRAIN. M. Lampert-Etchells. S.A. Johnson. G.M. Pasinetti and C.E. Finch\*. Andrus Gerontology Center and Dept. of Biol. Sci., Univ. of Southern California, L.A., CA 90089.

Complement mRNAs for components C4 and C1qB are present in AD (Alzheimer's disease) and normal human brain. In a group of 7 AD and

Complement mRNAs for components C4 and C1qB are present in AD (Alzheimer's disease) and normal human brain. In a group of 7 AD and 6 control individuals average C1qB and C4 mRNA concentration (as measured by *in situ* grain density) in AD frontal cortex is increased 2-3 fold. In addition the average number of C1qB and C4 mRNA expressing cells per total cells counted is 3 times higher in the AD group than in the control group. This data along with localization of complement proteins in plaques and tangles, (McGeer, et al. Can. J. Neurol. Sci. 16:516) suggest possible involvement of brain derived complement in the Alzheimer's neurodegeneration. The cellular distribution of C4 and C1qB mRNA in the frontal cortex is stratified. Grain density and the number of labeled cells are highest in layers 1-2 then gradually diminish from layers 3 to 6. No hybridization is seen in white matter. There is no correlation between the frequency of C4 and C1qB mRNA expressing cells and the frequency of plaques in these 7 AD individuals. There is a positive correlation of C4 and C1qB mRNA levels in the same specimen, suggesting coordinate regulation. In contrast, the average grain density of mRNA for the AD/control non-changing clone 17-3, is not positively correlated with that of C4 or of C1qB. Ongoing studies address identification of the cell type responsible for the increased mRNA for C1qB and C4 in AD and whether C1q and C4 mRNAs are made in the same individual cell. Supported by NIH AG-07909 and AG-10673.

# 233.6

SYNAPSE NUMBERS IN THE POSTERIOR CINGULATE CORTEX (AREA 23) IN PATIENTS WITH ALZHEIMER'S DISEASE. S.W. Scheff and D. A. Price. Center on Aging, Dept. Anatomy & Neurobiology, Univ. Kentucky, Lexington, KY 40536.

The cingulate gyrus, a key limbic structure, undergoes neuron loss in Alzheimer's disease (AD) beyond that observed in normal aging. This cortical area plays an important role in emotion, motivation, attention and memory; behaviors known to decline in AD. Several key cortical structures demonstrate a substantial decrement in connectivity in AD as evidenced by a significant loss of cortical synapses. There is a significant enlargement of synaptic apposition length, which correlates with the declines in synaptic numbers; as synapse density declined, synapse size increased. A major exception is the entorhinal cortex (area 28) which receives a major input from the posterior cingulate cortex but fails to show any change in synapse numbers. Because of the extensive connections of the posterior cingulate with other limbic structures and its known involvement in AD, it is important to quantitatively assess its functional connectivity (synaptic density) and to determine the degree of neuropathological changes in AD.

Human brains were obtained at postmortem examination from 10 patients who met the NINCDS-NIA criteria for AD and from 10 agematched controls. All tissues were obtained within 11 hours postmortem. Both lamina III and V were quantitatively assessed for synapse number and size as well as possible correlations to other AD related pathologies. Supported by Alzheimer Association and NIA AG05144.

THE ASSOCIATION OF KERATAN SULFATE PROTEOGLYCAN AND ALZHEIMER'S DISEASE. E. E. Geisert, Jr.\* and R.E. Powers. Department of Cell Biology and UAB Brain Resource Program, University of Alabama at Birmingham, Birmingham, Alabama 35294.

A large keratan sulfate proteoglycan that migrates at over 440 kDa on polyacrylamide gels is present in autopsy specimens of human subjects with Alzheimer type damage. A monoclonal antibody (TED 15) that specifically recognizes keratan sulfate glycosaminoglycan side chain stained sections of temporal lobe (superior temporal gyrus and hippocampus) from young controls (n = 10) aged controls (n = 8) and subjects with AD (n = 8). Immunostaining was completely abolished by pretreatment of hippocampal tissue with keratanase.

Normal appearing astrocytes were stained in all cases. TED 15 immunostained selected neuronal populations that appeared morphologically normal, some damaged neurons and a subpopulation of "soft or immature senile plaques were stained in tissue from aged controls and AD subjects. Neurofibrillary tangles were infrequently stained with TED 15 in AD cases. Amyloid cores, neuritic plaques, dystrophic neurites, granulovacuolar degeneration and hirano bodies A large keratan sulfate proteoglycan that migrates at over 440 kDa

dystrophic neurites, granulovacuolar degeneration and hirano bodies were not stained with TED 15.

These findings document the presence of proteoglycans in the brains of aged humans and subjects with AD suggesting a role for keratan sulfate in age and disease related neuronal damage.

### 233.9

IMMUNOCYTOCHEMICAL EVIDENCE OF ACCELERATED SPECTRIN PROTEOLYSIS IN HIPPOCAMPUS FROM ALZHEIMER DISEASE PATIENTS. M-C de Lacoste\*, C.E. Lewis, C.L. White, J.S. Morrow. Depts. OB/GYN & Pathol., Yale University, New Haven CT & Dept. Pathol., Southwestern Medical Center, Dallas, Texas

It has been hypothesized that accelerated calpain-I mediated proteolysis of specific isoforms of the spectrin-based neuronal cytoskeleton may serve as a mechanism by which neurons are irreversibly damaged in Alzheimer disease (AD). This study was undertaken to test this hypothesis using immunocytochemical techniques and the RA150 antibody that recognizes only calpain-cleaved alpha fodrin. RA150 is made against a synthetic peptide characterizing the C-terminus of the calpain-I cleavage site of the 11th repeat of alpha fodrin (i.e. antigen 150N).

Methods: Standard avidin-biotin immunoperoxidase techniques were used on cryostat-sectioned formalin-fixed blocks of hippocampal tissue from AD and normal brains. Results: In the AD brains, the RA150 immunodecorated a large subset of pyramidal neurons in the CA1 subfield as well as neuritic plaques throughout the hippocampal formation. In contrast, there was considerably less immunostaining in the normal brains. Moreover, in AD brains liquid phase preabsorption of RA150 with the synthetic peptide to the RA150N antigen resulted in a marked decrease in immunoreactivity. In addition, double-labelling techniques using either Thioflavin-S in conjunction with RA150 or RA150 simultaneously with an anti-PHF antibody evidenced colocalization of neurofibrillary tangles and spectrin breakdown products. In brief, data obtained in this study provide evidence of accelerated spectrin proteolysis in AD hippocampus. (Supported by HD 21711 (MCL & CLW)).

# 233.11

Latent Type IV Collagenases in the Hippocampus From Alzheimer and Control Specimens, Jon R Backstrom, Giselle P Lim, Michael J Cullen, and Zoltan A Tokes\*. Departments of Biochemistry, Anatomy and Cell Biology, University of Southern California, School of Med., Los Angeles, CA 90033.

Earlier, we examined the proteinases from hippocampal specimens which could be detected in SDS-polyacrylamide gels containing gelatin (substrate gels). We found an increase in metalloproteinases (MPs) with masses of 280, 130, and 100 kD from the AD specimens relative to the control specimens and no significant difference in the 70 kD MP (J Neurochem. 58: 983, 1992). Therefore, experiments were designed to further characterize the three larger MPs. To this end, we purified MPs from brain extracts and cell cultures. The cells included HL-60 cells which resemble macrophages upon stimulation with phorbol esters and the glioblastoma cell line U-87. The brain and HL-60 MPs cross-reacted with antisera raised against neutrophil metalloproteinases. The Tris-soluble brain fraction and purified MPs were latent and could be activated with an organomercurial compound, which caused a >50-fold increase in latinase activity and fragmentation of the enzymes. Endogenous MP-280 in the Triton-insoluble brain fraction has a higher avidity for the matrix than MP-130 and MP-100 which had similar properties. This finding correlated with the results from gelatin-agarose purification in that a higher concentration of DMSO was necessary to efficiently elute MP-280 from the matrix. Immunohistology revealed that the distribution of MPs and the tissue inhibitor of metalloproteinases (TIMP-1,-2) differed between AD and control tissues. Since serine proteinases are known to activate MPs, we postulate that the accumulation of latent MPs in AD tissues relative to control tissues may be due to an excess of serine proteinase inhibitors which could block their activation. Supported by NIA R01-AG 09681.

TWO DISTINCT SYNAPTIC VESICLE PROTEINS ARE DECREASED IN ALZHEIMER'S DISEASE. A. Pruchnicki, J. Gleeson, W.G. Honer and P. Davies. Departments of Medicine and Pathology, Albert Einstein College of Medicine, New York, NY 10461.

Medicine, New York, NY 19401.

Recent reports have indicated that declining synapse density may contribute to the development of dementia, especially of the Alzheimer's disease type. These studies have employed a limited number of monoclonal antibodies raised to synaptophysin or synapsin (E. Masliah et al. 1991, Am. J. Pathol. 138:235-246). The study reported here examined this issue with both qualitative and quantitative methods. Three monoclonal antibodies believed to be reacting and quantitative methods. I hree monoclonal antibodies believed to be reacting with two different synaptic proteins, were produced, and used to examine four brain regions (W. Honer and P. Davies, 1991, Proc. 3rd IBRO World Congress of Neurosci). Samples were obtained from autopsy specimens from both Alzheimer's disease patients and age-matched controls, confirmed by pathology. Western blot analysis indicated that one antibody (EPI0) reacted with a 38Kd antigen and two others (SP12 and 14) with a distinct lower molecular weight protein. Immunocytochemistry showed a synaptic-like reticular pattern of

weight protein. Imministrytochemistry showed a synaptic-like reticular pattern of staining. Neither Western blotting nor immunocytochemistry gave quantitative data. Elisa analysis, however, was able to show that there were statistically significant decreases, in the range of 25-75%, in synaptic density in hippocampus and temporal cortex, using all three antibodies. Only one of the three antibodies showed a similar significant decrease in occipital cortex and caudate.

These results are consistent with the theory that synapse loss, as measured by control artified a respectively.

several antibody reactivities, occurs in those brain regions most closely associated with Alzheimer's disease.

A combination of classical and stereological neuron counting A combination of classical and stereological neuron counting techniques was used to obtain a preliminary estimate of the relative density of neurons in the hippocampus of 23 histologically-verified male Alzheimer's patients and 22 age-matched controls with no history of dementia. Parrafin-embedded cresyl violet-stained sections from portions of hippocampus removed during routine brain autopsies from 1983-1988 were analyzed with the optical dissector sampling technique. The results suggest that the number of neurons but not the standard cross-sectional volume of the hippocampus was decreased in the CA1-2 and CA3 fields of patients with Alzheimer's dementia. The density of neurons in the CA1-2 area of Alzheimer's patients was significantly decreased by 31% compared to controls, while the density of neurons in the CA4 field of Alzheimer's patients was not significantly different from controls. These results are consistent with previous reports of relatively focal CA1-2 and CA3 hippocampal pathology in patients with Alzheimer's dementia. The minimalist technique used in this study may be useful in obtaining preliminary estimates of neuron density in other be useful in obtaining preliminary estimates of neuron density in other regions of the brain routinely sampled in brain autopsies.

# 233.12

HIPPOCAMPAL SCLEROSIS AS A CAUSE OF DEMENTIA: CLINICOPATH-OLOGICAL STUDY OF PROSPECTIVELY STUDIED ELDERLY SUBJECTS. D.W. Dickson\*, H.A. Crystal, M.K. Aronson and E. Grober. Neuropathology and Neurology, Albert Einstein College of Medicine, Bronx, NY 10461.

Of 90 brains obtained from prospectively studied elderly subjects, 13 had hippocampal sclerosis (HpScl) affecting the CA-1 region of the hippocampus, including 5 men and 7 women. The average age was 86.8 ± 6.2 years. Four cases had co-existing pathology of senile dementia of the Alzheimer type (SDAT), including many senile plaques and neurofibrillary tangles in neocortex. Two cases had substantia nigra and cortical Lewy bodies (LBD), including one case with co-existing SDAT and another with pathological aging. The average Blessed score for the 5 with either SDAT or LBD, or both, was 29.2 ± 4.1, while the remaining 7 cases had a Blessed score of  $16.7 \pm 5.6$ . Of the 7 cases with neither SDAT nor LBD, 4 cases had no other explanation for cognitive impairment besides HpScl. The remaining 3 had ischemic lesions in cortex or cerebral white matter that may have contributed to cognitive impairment. Clinical features included risk factors for cerebrovascular disease, including hypertension (6/12), atherosclerotic vascular disease (6/12), EKG abnormalities (6/12), cardiomegaly (4/12), myocardial infarction by either history, EKG or pathologic confirmation (4/12), congestive heart failure (2/12) and diabetes mellitus (2/12). Memory disturbances were prominent in at least 7 cases. In two cases the onset of memory problems was considered abrupt; one patient was treated with phenytoin for "transient global amnesia." Another patient had a nearly pure amnestic syndrome, before developing global cognitive decline later in his disease course. None of the cases had seizures. CT findings were usually only diffuse cortical atrophy, but 3 had lacunes, 1 had leukoencephalopathy and 1 had severe basal ganglia mineralization. The results show that HpScl is common in elderly demented subjects and is sometimes the best pathological explanation for dementia. It may account for increased risk of demen tia in elderly subjects with history of myocardial infarction noted in other studies.

INCREASED CORTICAL NGF-LIKE ACTIVITY IN ALZHEIMER'S DISEASE: ELISA AND BIOASSAY RESULTS. S.A. Scott\*, J.A. Weingartner, S. Liang, W. Everson <sup>1</sup> and K.A. Crutcher. Departments of Neurosurgery and <sup>1</sup>0B/GYN, University of Cincinnati, Cincinnati OH 45267.

NGF promotes survival of basal forebrain cholinergic neurons in vivo and in vitro, leading to the suggestion that declines in NGF underlie AD-related basal forebrain neuronal degeneration. To test this hypothesis, NGF-like protein levels were measured in AD using a 2-site ELISA. Samples of frontal and occipital cortex from 11 AD and 14 control brains were run using recombinant human NGF (rhNGF; provided by Genentech) as the standard. Neither rhNT-3 nor rhBDNF (provided by Amgen) were detected by this assay; antibody binding specificity was confirmed using Western blots. A 2-fold AD-related increase in NGF-like activity (p<.001) was found in each brain region whether or not the values were corrected for recovery. This increase was unrelated to age or postmortem interval. NGF-like biological activity was also measured in the same tissue samples using E9 chick sympathetic ganglia. Explants were exposed to either rhNGF (detectable as low as 10pg/ml) or brain extracts (1:50 dilution) with or without anti-NGF antibodies at a co (20ug/ml) that completely inhibited the effect of 1 ng/ml of rhNGF. Both AD and control brain extracts stimulated neurite outgrowth and the inhibition of neurite outgrowth by anti-NGF antibodies was significantly greater with AD extracts (>60% growth reduction) than with control extracts (25% reduction).

These data suggest that reduced NGF does not underlie basal forebrain neuronal degeneration in AD. Rather, increased NGF-like activity may represent a response to atrophy of basal forebrain neurons that are affected by a more global neurodegenerative process in this disease. (This work was supported by the Samuel A. Blank Research Fund of the Alzheimer's Association.)

CHARACTERIZATION OF GAP-43 IN LAN-1 NEUROBLASTOMA CELLS.

M. R. Martzen\*. S. Sullivan, J. Cheetham, M. K. O'Banion and P. D. Coleman.
University of Rochester School of Medicine and Dentistry, Depts. of Neurobiology
and Anatomy and Neurology, Rochester, NY 14642.
Growth associated protein-43 (GAP-43) is a phosphoprotein expressed in neurons

at high levels during development and regeneration which persists at lower levels in the normal adult brain. In post-mortem samples from Alzheimer's disease (AD) cases with high neurofibrillary tangle (NFT) density we have observed decreased phosphorylation of membrane-associated GAP-43 and a 6 fold decrease in GAP-43 mRNA. In an attempt to investigate the relationship between GAP-43 and NFT's, we have initiated studies on the effects of cytoskeletal disruption with the human neuroblastoma cell line LAN-1. Retinoic acid (RA) treatment of LAN-1 cells increases GAP-43 message and causes the cells to extend neurites that possess growth cones. Radiolabeling of these chemically differentiated cells with 32Porthophosphate and with <sup>35</sup>S-cysteine/methionine, followed by immunoprecipitation of labeled GAP-43 protein and ultra high-resolution 2D gel electrophoresis of the immunoprecipitate, indicate a minimum of 5 GAP-43 isoforms, three of which are phosphorylated. Preliminary studies also indicate that exposing chemically differentiated cultures to colchicine or cytochalasin B for 24 hours also decreases GAP-43 mRNA. Experiments to define further these GAP-43 isoforms and their modulation by cytoskeletal disruption are currently in progress. Supported by grants AG 01121, AG 03644 and AG 09016 (PDC) from the National Institute on Aging.

CLONING OF HUMAN SCG10: ITS DEDUCED AMINO ACID SEQUENCE AND ABNORMAL EXPRESSION IN ALZHEIMER'S DISEASE. T.Okazaki, H.Wang, C.W. Wuenschell\* L.-C.Lo#, E.Masliaht, T. Saitoht and N.Mori, Div. Neurogerontology, Ethel Percy Andrus Gerontology Center, \*Med. Center, Univ. Southern California, Los Angeles, CA90089. #Howard Hughes Med. Inst., Div. Biol., Caltech, Pasadena, CA91125. ‡Dept. Neurosciences, School of Med., UCSD, La Jolla, CA92093-0624.

SCG10 is a neural-specific, growth-associated protein that is broadly expressed in embryonic central and peripheral neurons in rats. The SCG10 expression in brain is high during prenatal and postnatal development, and low but significant expression persists into adulthood (see the abstract by T. Himi). As a way of studying SCG10 expression in normal and deseased human brains, we cloned analyzed human SCG10 cDNA. By screening a human fetal brain cDNA library with rat SCG10 cDNA probe, we isolated a human SCG10 cDNA clone. In comparison with rat SCG10, the order of only two amino acids was exchanged in the two species with no apparent change in the amino acid composition and probably in the tertiary structure of the protein. It reveals that SCG10 is highly conserved in mammalian evolution, suggesting that it has an important function in neurons. The human SCG10 sequence was highly homologous to the human stathmin (also called p19), which was recently isolated by Sobel and his coworkers. Stathmin/p19 contains at least three serine residues which are phosphorylated presumably by protein kinase A. Amino acid sequences surrounding these three serine residues were conserved in the human SCG10 sequence, suggesting that SCG10 also is a phosphoprotein. Immunohistochemistry using the rat antibody has shown that SCG10 is expressed at different levels in several regions of the nomal human brain, and that levels of SCG10 expression have changed in the brains of Alzheimer's disease. The result implies that abberant expression of SCG10 may be involved in the pathogenesis of Alzheimer's disease, as in the case of other neuronal growth-associated proteins such as GAP-43 and tau.

### 234.2

FIBROBLAST GROWTH FACTOR RECEPTOR 4-LIKE IMMUNOREACTIVITY IN SENILE PLAQUES. O. Yasuhara, A. Matsuo<sup>1</sup>, Y. Hara<sup>1</sup>, I. Tooyama<sup>1</sup>, K. Hanai<sup>1</sup>, P.L. McGeer, H. Kimura<sup>1</sup> and S. C. Sung\*. Kinsmen Lab. of Neurol. Res., U. of British Columbia, Vancouver, Canada, V6T1Z3; <sup>1</sup>Institute of Mol. Neurobiology, Shiga U. of Med. Sci., Otsu, Shiga, Japan

We have previously reported that acidic fibroblast growth factor (aFGF) is expressed in reactive astrocytes surrounding senile plaques in Alzheimer's disease (AD) (Dementia 1991;2:64-70). We now report on the immunohistochemical localization in AD and control brain tissue of FGF receptor 4 (FGFR4) which is specific for aFGF. A polyclonal antibody to the 125-141 FGFR4 amino acid sequence (Partanen et al., EMBO J 1991;10:1347-1356) was prepared in rabbits by immunizing with the synthetic haptenic antigen conjugated to carrier poly-L-glutamate. In cerebral cortices of both AD cases and age-matched controls, FGFR4-like immunoreactivity was observed in capillaries. In addition, senile plaques were positively stained in AD cases. The FGFR4-like immunoreactivity was localized mainly to consolidated plaques. The present study indicates that astroglial aFGF may be involved in plaque formation by binding to both high and low affinity receptors (FGFR4 and heparan sulfate proteoglycan) in senile plaques.

TRANSFORMING GROWTH FACTOR-\$1 IS PRESENT IN PLAQUES IN ALZHEIMER'S DISEASE AND DOWN'S SYNDROME. E.A. van der Wal\*, F. Gómez-Pinilla and C.W. Cotman, Irvine Research Unit in Brain Aging, University of California, Irvine, CA 92717

Transforming growth factor- $\beta$ 1 (TGF- $\beta$ 1), a cytokine synthesized by various tissues, acts as a regulator of the extracellular matrix and has growth related functions. Recent evidence suggests that Alzheimer's disease (AD) and its hallmark, plaques, may be partially caused by an imbalance in trophic support. Plaque-biogenesis may involve growth factors that induce sprouting of neurites towards plaques and/or may modify the extracellular matrix. Accordingly, we examined the distribution of TGF- $\beta$ 1 in the hippocampus and in the entorhinal cortex (EC) from AD and Down's syndrome (DS) human brain tissue. TGF- $\beta$ 1 immunoreactivity was investigated in controls, AD and DS by ABC immunohistochemistry with two anti-TGF- $\beta$ 1 antibodies. The control tissue showed light staining only in fibers. The AD cases displayed TGF- $\beta$ 1 positive immunoreactivity in fibers as well as in plaques. Plaque identity was confirmed by immunostaining with an anti- $\beta$ A4-antibody. The TGF- $\beta$ 1 plaques in AD were mainly located in the dentate gyrus (DG) of the hippocampus. The TGF- $\beta$ 1 immunostained plaques in DS, however, showed a preference for the EC. The TGF- $\beta$ 1 staining pattern within plaques was identical for both AD and DS; strong immunoreactive aggregates intermingled with weak staining. TGF- $\beta$ 1 may play a role in the cascade of events leading to plaque-biogenesis, possibly by directly modulating the extracellular matrix or coordinating the actions of bFGF (also found in plaques).

FAMILIAL INCIDENCE OF DIFFUSE PLAQUES IN AGED DOGS. J.W. Geddes', R. White, E. Patel, V. Bondada, W. R. Markesbery, and M.J. Russell. Sanders-Brown Ctr. Aging, Univ. Kentucky; Inst. Toxicology & Environmental Health and Dept. Anesthesiology, Univ. Calif. Dayis.

Environmental Health and Dept. Anesthesiology, Univ. Calif. Davis.

Aged dogs develop diffuse and possibly neuritic plaques and represent an animal model of plaque formation in Alzheimer's disease. We examined the distribution and incidence of plaques in 38 aged beagle and 22 aged St. Bernard dogs. The results provide evidence for a familial, possibly genetic, influence on the incidence of diffuse plaques.

The dogs lived in controlled laboratory colonies in a study conducted by the United States Department of Energy and did not receive any experimental treatment. At the time of their natural deaths, autopsies were performed and the brains were removed and stored in 10% formalin. The parahippocampal region was embedded in paraffin, sectioned at 8  $\mu m$  and stained using thioflavin-S, the Gallyas method, and the modified bielschowsky method. Twenty-two (58%) of the beagles had diffuse plaques in the parahippocampal region whereas only 2 19% of the St. Bernard's had plaques. Neuritic plaques, neurofibrillary tangles, and neuropil threads were not observed and neuron loss was not evident. The density of plaques was greatest in inferior temporal cortex-perirhinal cortex-entorhinal cortex asubiculum =dentate gyrus-CA1. In beagles from 10 of 11 litters there was congruence ( $\chi 2$ = 5.6, P=0.025). That is, if one animal had plaques, its littermate also had plaques. The results demonstrate breed differences in the incidence of diffuse plaques in aged dogs and a clear familial association of plaques among littermates in aged beagle dogs.

### 235.3

CHARACTERIZATION OF ALZ-50 IMMUNOREACTIVE NEURONS IN THE NORMAL SHEEP STRIATUM. P.T. Nelson\* and C.B. Saper. Depts. of Pharm. & Physiol. Sci. and Neurology, Univ. of Chicago, Chicago, IL 60637

Chicago, IL 60637

Alz-50 is a monoclonal antibody that recognizes the N-terminus of tau molecules in cells undergoing the early stages of neurofibrillary degeneration, and in a limited population of neurons in the brains of normal humans and other mammals. The process that leads to the exposure of the epitope that Alz-50 binds to in normal brain is not well understood, but its elucidation may provide an insight into both normal tau processing and the pathophysiology of Alzheimer's disease (AD). To better characterize the Alz-50 staining of neurons in the normal brain, we examined the Alz-50 simmunoreactive neurons in the normal sheep striatum using immunoblotting as well as immunocytochemistry at the light and electron microscopic levels, and double-staining with Alz-50 and other antisera.

Alz-50 stained a population of medium aspiny neurons in the sheep striatum, as it does in humans. These cells also expressed neuropeptide Y and somatostatin immunoreactivity, as well as NADPH diaphorase activity, but did not stain with antisera against tau,

Alz-50 stained a population of medium aspiny neurons in the sheep striatum, as it does in humans. These cells also expressed neuropeptide Y and somatostatin immunoreactivity, as well as NADPH diaphorase activity, but did not stain with antisera against tau,  $\beta$ -amyloid protein, ubiquitin or heat shock proteins. Alz-50 stained only tau bands on immunoblots, and immunocytochemical staining was blocked by preadsorption with a synthetic peptide corresponding to the N-terminal of tau. The presence of the Alz-50 epitope, which many neurons only express in AD, in a discrete and well-characterized normal cell population may help identify a cellular pathway that is aberrantly triggered during AD.

IMMUNOCYTOCHEMICAL EVIDENCE OF INCREASED SPECTRIN PROTEOLYSIS IN COLCHICINE-TREATED RATS. C.E. Lewis, F. Naffolin\*, M-C de Lacoste. Dept. OB/GYN, Yale Medical School, New Haven CTT 06410

This study was undertaken to determine the effects of colchicine (C), an axoplasmic flow inhibitor, on the spectrin-based neuronal cytoskeleton. Posttranslational modification, i.e., calpain-cleavage of spectrin has been associated with a number of pathogenic conditions including exposure to neurotoxins such as colchicine. We hypothesized that colchicine-treated (CT) animals would exhibit an increased level of spectrin proteolysis. Experimental: C was administered in a single dose (80µg/20µl in saline) into the lateral ventricles of adult female Sprague-Dawley rats 24 hours prior to sacrifice. Standard ABC techniques on vibratome-sectioned (40µm) tissue were utilized using the RA150 antibody. RA150, an antibody made to a synthetic peptide characterizing the Cterminus of the calpain-1 cleavage site of alpha fodrin, serves as a specific marker of spectrin proteolysis. Results: Little or no RA150 immunostaining was observed in untreated controls. In contrast, intense staining was visualized in the CT animals. Comment: These results suggest an increase in spectrin proteolysis in CT animals, further clarifying the mechanisms of C action. They are significant in light of 1) recent evidence that some of the pathological changes found in CT animals mimic those found in Alzheimer disease (AD) (Shigematsu & McGeer, 1992) and 2) data indicating that accelerated calpain cleavage of cytoskeletal proteins may accompany certain neuropathological conditions such as AD. Thus C-induced spectrin proteolysis may assist in studies of these conditions. (Supported by HD13587(FN) & HD21711(MCL). The RA150 antibody was kindly provided by Dr. Jon Morrow).

### 235.2

βA4 ACCUMULATION IN AGED CANINE BRAIN: AN ANIMAL MODEL OF EARLY PLAQUE FORMATION IN ALZHEIMER'S DISEASE.

B.J. Cummings\* \* J.S. Su\*, C.W. Cotman\*, R. White\* and M.J. Russell\*
Department of Psychobiology\*, U.C. Irvine, CA 92717 USA and Depts. of Anesthesiology\* and LEHR\*, U.C. Davis, CA 95817 USA.

The aged canine brain has long been suggested as an animal model of Alzheimer's disease (AD); yet little is known about the components of canine plaques compared to AD plaques. We characterized the subtypes and molecular components of plaques in 8 aged canines (maintained from birth in a laboratory colony) with a variety of techniques: Bielschowsky's, Thioflavin and Congo red staining, as well as with antibodies to  $\beta A_4$  peptide, APP, heparan sulfate (HS), bFGF, C3d, GFAP, Tau-1 and SMI-31. In agreement with earlier reports, we find that  $\beta A_4$  reveals the greatest number of plaques. These "diffuse" plaques were not Congo red nor Thioflavin positive.  $\beta A_4$ -positive plaques were seen in 4 of the 8 dogs. In 3 of the 4 dogs, plaques were embedded in a diffuse linear zone of  $\beta A_4$  immunoreactivity running the length of the mid-molecular layer of the dentate gyrus, suggesting that diffuse  $\beta A_4$  peptide aggregated into plaques. Within the cortex and hippocampus, the majority of  $\beta A_4$ -positive plaques engulfed Nissl-positive neurons. Fewer plaques were detected with Bielschowsky's staining. These were faint, diffuse-brown and rarely contained curly fibers. Neither Tau-1 or SMI-31 revealed dystrophic fibers and plaques did not show bFGF or HS-positive staining, although positively stained neurons similar to those seen in humans were detected. Our data suggest that the trophic and substrate factors (i.e. bFGF and HS) which could help induce neuritic growth are not present in canine plaques. Consequently, little if any neuritic involvement occurs within these canine plaques.

EVALUATION OF MOUSE TRISOMY 16 HIPPOCAMPAL TRANSPLANTS AS A MODEL OF ALZHEIMER'S DISEASE PATHOLOGY. M.J. Savage\*. S. Mistretta. L. Pinsker, and R. Siman. Cephalon, Inc. West Chester, PA 19380 Human trisomy 21 (TS21) is associated with the age-related development of

Human trisomy 21 (TS21) is associated with the age-related development of Alzheimer's-like pathology. In an attempt to develop an animal model of this pathology, we used TS16 mice, which have both phenotypic and genotypic features in common with human TS21. Many genes of human chromosome 21 have homologues located on mouse chromosome 16, including the  $\beta$ -amyloid precusor protein gene. Proteolytic processing of this protein in Alzheimer's disease (AD) leads to formation of the  $\beta$ /A4 protein, the major component of amyloid plaques. If the genes responsible for the AD-like pathology in human TS21 are found on mouse chromosome 16, the TS16 mice might develop similar pathology.

Hippocampal explants from TS16 mice or their euploid littermates at E17 were transplanted into the striatum or lateral ventricle of wild-type neonatal hosts. Transplantation of the hippocampal grafts was necessary since trisomy mice die in utero at about E18. Hosts receiving transplants were allowed to survive from 1-13 months. Brains from these animals were examined by immunohistochemistry for deposits of  $\beta/A4$  protein (using antibodies raised against  $\beta1-28$  or  $\beta3-22$ ) or for neurofibrillary tangles (using anti-Alz 50 or anti-tau 1). Transplants became well-vascularized, and both neuron- and glial-specific stains revealed healthy cells. Methods which readily stained amyloid deposits and neurofibrillary tangles in AD brain failed to detect similiar pathologies in the trisomy transplants at any age, although neurons in both types of transplants expressed the beta-amyloid precursor protein. Intracellular inclusions similiar to those reported recently (Jucker et al., Science (1992) 255:1443) were seen after staining with anti- $\beta/A4$  in both trisomy and euploid hippocampal transplants at long survival times. We conclude that TS16 mouse hippocampal transplants do not develop AD-like amyloid deposits or neurofibrillary tangles by 13 months of age.

NEURONAL CULTURES: A MEANS TO CHARACTERIZE CEREBROSPINAL FLUID ANTIBODIES OF DEMENTIA PATIENTS.

Antibodies in the cerebrospinal fluid (CSF) of Alzheimer's disease (AD)

Antibodies in the cerebrospinal fluid (CSF) of Alzheimer's disease (AD) patients recognize distinctly different structures in the developing rat CNS compared to CSF antibodies from other dementia groups. To rapidly screen and characterize embryonic cell types recognized by CSF antibodies a cell culture system was developed. Cells dissected from E-18 medial septum were dispersed, plated on poly-L-lysine coated sterile micro-16-well modules affixed to a standard laboratory slide and maintained in sterile conditions for 10 days. CSF from 90 AD, 21 multi-infarct dementia (MID), 83 non-specified dementia (NSD) patients and 35 controls were incubated in this 4% PF-fixed cell culture system. Immunocytochemical results revealed that CSF from 30 AD, 1 MID, 4 NSD and 0 controls stained microglial cells in culture. Furthermore, an immuno-EM study revealed that other AD-CSF samples specifically stained glioblasts containing a nucleus with patchy chromatin material. The scanty cytoplasm was characterized by abundant free and poly-ribosomes, isolated cisternae of rough endoplasmic reticulum and a small Golgi apparatus with diluted saccules. The AD-CSF immunoreactivity was specifically localized in the cytoplasmic matrix. These observations suggest that this cell culture system can significantly enhance differential diagnosis of the dementias and sa well to further subgroup AD patients according to whether the CSF contains antibodies directed against, e.g., microglia or glioblasts. Thus, it seems that immune responses play a role in neurodegenerative processes and that antibodies may reflect abnormal proteins, which when identified could improve diagnostic and treatment strategies for AD.

DETECTION OF GLUTAMINE SYNTHETASE IN THE CSF OF ALZHEIMER'S DISEASED PATIENTS: A POTENTIAL DIAGNOSTIC BIOCHEMICAL MARKER Debra Gunnersen \* and Boyd Haley. Division of Medicinal Chemistry and Pharmaceutics, College of Pharmacy, University of Kentucky, Lexington,

Photoaffinity probes have shown changes in specific nucleotide binding proteins in Alzheimer's Diseased (AD) brain (Khatoon,S. et al. 1989, Ann Neurol). If such changes occured in the CSF of AD patients, this could be used as a diagnostic procedure. Testing of CSF with nucleotide photoaffinity analogs identified a 42kD ATP binding protein in the CSF of AD patients that is not observed in CSF from normal patients or other neurological controls. The photolabeling with  $(\gamma^{32}P]2N_3ATP$  shows saturation at  $30\mu M$  and it is specifically abolished by the addition of  $25\mu M$  ATP. Photoinsertion of  $2N_3ATP$  into the 42kD protein is only weakly protected by ADP, AMP, or Adenosine. This data indicates that this is a specific ATP binding protein. This protein was observed in 23 out of 24 AD CSFs examined and absent in 42 of 42 control samples examined. This 42kD protein was identified as glutamine synthetase by the following: similar nucleotide binding properties, co-migration on 2D gels, reaction with a polyclonal  $\alpha$ -GS antibody, and elevated of glutamine synthetase enzyme activity only in the AD CSF. Supported by Eli Lilly and Co. & NIH grant GM-35766-07.

### 236.2

AN ELEVATED LEVEL OF NEURAL THREAD PROTEIN (NTP) IN HUMAN CULTURED OLFACTORY EPITHELIAL NEUROBLAST OF ALZHEIMER'S PATIENTS. J. Chong , B.L. Wolozin', T. Sunderland', H. Ghanbari'\*. Neuropsychiatric markeys R&D, Abbott Laboratories, Abbott Park, IL 60064. Laboratory of Clinical Science, NIMH, Bethesda, MD 20892.

An elevated level of NTP was reported in brains of patients with Alzheimer's disease (AD). As part of our clinical study we have measured NTP level in antemortem cerebrospinal fluid (CSF) in a large patient population (n>400) of AD, normal, psychiatric, neurological, and other dementia patients in order to study the clinical utility of NTP as a potential antemortem marker for AD. The clinically diagnosed AD CSF specimens had much higher NTP levels than those of non-AD. In this communication we report the NTP measurement in human cultured olfactory epithelial neuroblast (B.L. Wolozin et al. J. Mol Neurosci 3:137-146, 1992). The concentration of NTP in the cell homogenates was assayed by microparticle enzyme immunoassay (MEIA). Olfactory neuroblast (ON) from normal and Parkinson's disease patients showed no detectable NTP level while ON from patients with Alzheimer's disease showed elevated NTP level (60-1700 pg/ml of neuroblast homogenates).

Lipid peroxidation is increased in frontal cortex in Alzheimer disease (AD) and in substantia nigra in Parkinson disease (PD), suggesting impaired CNS anti-oxidative mechanisms in these diseases. Ceruloplasmin (CP), transferrin (TF), and ferritin (FT) interact to prevent iron-catalyzed production of free

Lipid peroxidation is increased in frontal cortex in Alzheimer disease (AD) and in substantia nigra in Parkinson disease (PD), suggesting impaired CNS anti-oxidative mechanisms in these diseases. Ceruloplasmin (CP), transferrin (TF), and ferritin (FT) interact to prevent iron-catalyzed production of free radicals. We evaluated CP, TF, and FT in CSF from individuals with AD (n=10), PD (n=14), and normal controls (n=10). CP was significantly increased in AD (p=0.019) but not PD CSF. TF was increased by 39% in AD CSF (26.0  $\pm$  10.3 vs. 18.8  $\pm$  4.0 ug/ml), but this increase was not statistically significant (p = 0.10). FT was not elevated in AD or PD CSF. This study provides no evidence for reduced CNS extracellular anti-oxidative mechanisms in AD or PD. Elevated CP concentrations in AD CSF suggest that extracellular anti-oxidant capacity may be increased, perhaps as a secondary event, in this disease.

# DEGENERATIVE DISEASE: ALZHEIMER'S-TAU

# 237.1

PK40, AN ATP-REGULATED MEMBER OF THE ERK-FAMILY OF KINASES, CONVERTS TAU PROTEIN INTO PHF-TAU AS FOUND IN ALZHEIMER'S DISEASE. P.A. Eden, H. Roder#, W. Schroeder# and V.M. Ingram\*. Dept. Biology, M.I.T. Cambridge, MA 02139 and #Bayer AG, Wuppertal FRG.

The bovine protein kinase PK40 phosphorylates bovine and human TAU at sites including Lys-Ser-Pro motifs. PK40 phosphorylation of TAU is inhibited by a physiologically relevant excess of ATP over magnesium. The hyperphosphorylation of TAU induces electrophoretic and antigenic changes similar to the abnormally phosphorylated form of TAU in the tangles of Alzheimer's Disease (AD). PK40 likely plays a major role in the chronic hyperphosphorylation of TAU in AD and in the formation of neurofibrillary tangles.

We identify PK40 as a member of a family of extracellular signal-regulated kinases (ERKs). Like ERKs, PK40 autophosphorylates at a Tyr residue resulting in an increase in activity. Several ERK proteins similar in size to PK40 were detected in human neuroblastoma cells and are discussed. The significance for AD of TAU hyperphosphorylation and of PK40 regulation is also discussed. We present a model in which somatic mitochondrial DNA mutations provide a mechanism for age-related neurodegeneration.

# 237.2

LACK OF THE CARBOXYL TERMINAL SEQUENCE OF TAU IN GHOST TANGLES OF ALZHEIMER'S DISEASE. R. Endoh, M. Ogawara I. Nakano , T. Iwatsubo & H. Mori\* Department of Neuropathology, Institute for Brain Research, University of Tokyo, Hongo, Tokyo 113, Japan, \*Tokyo Metropolitan Institute of Gerontology, Tokyo 173, Japan, \*\*Tokyo Metropolitan Institute of Neuroscience, Tokyo 183, Japan. Using seven independent antibodies against the amino terminal to the carboxyl terminal sequence of tau, we biochemically analyzed and compared the neuropathogenesis

Using seven independent antibodies against the amino terminal to the carboxyl terminal sequence of tau, we biochemically analyzed and compared the neuropathogenesis of two Alzheimer's disease (AD) brains from the viewpoint of the abnormal processing on tau, the major constituent of paired helical filaments (PHF). One showed typical AD with senile plaques and intracellular neurofibrillary tangles. The other showed advanced AD with senile plaques and virtually the sole of ghost tangles. We confirmed the previous observation that the carboxyl-thirds of tau are tightly associated with PHF isolated in the presence of SDS (Kondo et al, Neuron 1, 827-834,1988). We found the biochemical nature of ghost tangles that lacked the final carboxyl terminal sequence as well as the amino half of tau, unlike intracellular tangles. From these biochemical results taken together with the current evidence for ubiquitin in ghost tangles, we concluded that ghost tangles were extensively processed and irreversibly tranformed into highly insoluble extracellular deposits in AD brains.

DISTRIBUTION AND FUNCTION OF FLUORESCENTLY LABELED BOVINE TAU PROTEIN IN LIVING CELLS. Q.LU \* AND J.G.WOOD. Dept.of Anatomy and Cell Biology, Emory Univ. Sch. of Med., Atlanta.

Bovine tau protein was tagged with fluorescent dye 5 (and 6)carboxy-x-rhodamine-succinimidyl ester and microinjected into cultured Chinese Hamster Ovary (CHO) cells to study the intracellular distribution and function of the fluorescent analog. Xrhodamine tau incorporated rapidly into centrosomes within seconds after microinjection. It labeled distinctly the microtubule network as early as 5~10 minutes following microinjection. In addition, Xrhodamine tau was transported into the nucleus and labeled the nucleolus. Double labeling of the injected cells with DiC6(3) indicated that fluorescent tau can bind to endoplasmic reticulum, most evidently in the cells where injected tau failed to label microtubules strongly. The concentrations of injected X-rhodamine tau ranged from 1.68~5 mg/ml, yet bundling of microtubules was not observed. Studies of nocodazole effects on the microtubules established that X-rhodamine tau stabilized microtubules against depolymerization conditions. Together with the earlier reports that Xrhodamine tau promotes microtubule assembly in vitro (JCB, 115: 384a), we conclude that this fluorescent analog of tau is associated with microtubules and their related structures in living cells, and is competent to stabilize microtubules against microtubule depolymerizing drug treatment. AG 06383; NS 17731.

### 237.5

UNIQUE TAU AND NEUROFIBRILLARY TANGLE DISTRIBUTION

UNIQUE TAU AND NEUROFIBRILLARY TANGLE DISTRIBUTION IN THE HIPPOCAMPAL FORMATION OF PATIENTS WITH FAMILIAL "TANGLE ONLY" DEMENTIA. J. Leverenz. T. Bird. D. Nochlin. S.G. Greenberg. C.B. Saper. Depts. of Pharm. & Physiol. Sci. and Neurology, Univ. of Chicago, Chicago, IL 60637, Depts. of Neurology and Pathology, University of Washington, Seattle, WA 98195 and Burke Med. Res. Inst., White Plains, NY 10605.

The relationship of post-translational modifications of tau protein with the formation of neurofibrillary tangles (NFT) and neuronal death in Alzheimer's disease (AD) remains controversial. It may be possible to obtain insights into the process of NFT formation from the study of unique familial dementing illnesses that demonstrate patterns of tau modification and NFT formation that differ substantially from AD. We have identified such a disorder, characterized by onset in young adulthood of psychotic behavior and dementia (Neurology 42:120, 1992). Classical neuropathological methods reveal moderate numbers of NFT in the cerebral cortex, subiculum, amygdala and brainstem, but no plaque formation. NFT are not seen in the hippocampal CA fields, but cell loss occurs in this location in long standing cases. Immunostaining with antibodies against pathological taus, such as Alz-50 or PHF-1, demonstrated granular neuronal staining in the hippocampus only in the cases with symptoms for > 20 yrs. There appeared to be a progression from Alz-50 staining, to PHF-1 staining, to cell loss, involving first the CAI field, then CA2-3, and finally the dentate granule cells. Antiesra against amyloid or ubiquitin stained NFT in the cortex, but not neurons containing granular Alz-50- or PHF-1-positive material in the hippocampus. Our observations suggest that pathological tau formation, indicated by progression from Alz-50 to PHF-1 staining, may contribute to cell loss, even in the absence of classical NFT formation, but that staining with amyloid or ubiquitin antibodies may occur only after actual NFT formation. of classical NFT formation, but that staining with amyloid or ubiquitin antibodies may occur only after actual NFT formation.

CASEIN KINASE II PHOSPHORYLATION OF TAU AND MAP-2. LA.

CASEIN KINASE II PHOSPHORYLATION OF TAU AND MAP-2. <u>LA. Greenwood\* and G.V.W. Johnson.</u> Department of Psychiatry, University of Alabama at Birmingham, Birmingham, AL 35294-0017.
Casein kinase II (CKII) is a cyclic nucleotide- and calcium-independent protein kinase directed by the presence of acidic or phosphorylated amino acid residues immediately C-terminal to the phosphoacceptor serine/threonine. Recently, CKII has been proposed to play a role in the formation of paired helical filaments, composed largely of excessively or inappropriately phosphorylated tau, found in Alzheimer's Disease brain. In this study, we examined the in vitro CKII phosphorylation of purified bovine tau and MAP-2, and the individual human tau isoform containing three microtubule-binding repeats in the C-terminal half of the molecule (T3).

Tau, MAP-2 and T3, were phosphorylated by CKII to a stoichiometry of

and the individual human tau isoform containing three microtubule-binding repeats in the C-terminal half of the molecule (T3).

Tau, MAP-2 and T3, were phosphorylated by CKII to a stoichiometry of 0.10, 0.80, and 0.05 mol phosphate/mol protein, respectively. The presence of polyethylenimine enhanced CKII catalyzed phosphate incorporation into these substrates approximately 5-fold. Two-dimensional phosphopeptide mapping demonstrated that tau was phosphorylated by CKII primarily on one peptide. Cleavage of phosphorylated tau at cysteine residues revealed that CKII phosphorylated tau predominately on the C-terminal half of the molecule. Two-dimensional phosphopeptide mapping of T3 displayed a different pattern of phosphorylated compared to purified tau suggesting that endogenous phosphorylation may influence CKII phosphorylation of purified tau. However, cleavage of CKII phosphorylated T3 at cysteine residues produced a profile similar to purified tau, in that the phosphate was incorporated predominantly in the C-terminal half of the molecule. Two-dimensional phosphopeptide mapping of MAP-2 phosphorylated by CKII also demonstrated phosphorylation predominately on a single peptide. Site-specific phosphorylation of tau and MAP-2 by CKII may be important for the regulation of their function or alteration in disease states.

INHIBITION OF PROTEIN KINASE C INDUCED ALZ-50 IN THE CULTURE OF HUMAN NEUROBLASTOMA CELLS. L. Zhang. B.L. Wolozin, C.Y. Chen, and T. Sunderland\* Lab. of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892 Aberrant protein phosphorylation has been previously

documented in Alzheimer's disease (AD). Phosphorylation of Tau protein and amyloid precursor protein may play pivotal roles in the pathogenesis of the illness. Both of these processes are thought to involve protein kinase C (PKC) directly and indirectly. To investigate the role of PKC in the pathophysiological processes of AD, we have studied the effects of kinase inhibitors on the induction of Alz-50 immunoreactivity in human NSH neuroblastoma cells. Our preliminary results show that H-7, an inhibitor of PKC, protein kinase A (PKA) and protein kinase G (PKG), induces Alz-50 immunoreactivity, while HA-1004, an inhibitor of PKA and PKG, but not PKC, has no such an effect. Down regulation of cellular PKC by long term incubation with phorbol 12-myristate 13-acetate, gives a similar result as H-7. Together, these data emphasize the importance of PKC in the development of markers of AD pathology.

THE ABNORMAL PHOSPHORYLATION OF TAU AT SER396 IN ALZHEIMER'S DISEASE RECAPITULATES PHOSPHORYLATION DURING DEVELOPMENT AND CONTRIBUTES TO REDUCED MICROTUBULE BINDING SE Merick, GT Bramblett, M Goedert, R Jakes, JQ Trojanowski, and YM-Y Lee\*. Dept of Path and Instit of Neurosci, University of PA, Philadelphia, PA 19104, USA and Medical Research Council Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH, UK.

Paired helical filaments (PHFs), the major building block of Alzheimer's disease (AD) neurofibrillary tangles (NFTs) has been shown recently to be comprised of the microtubule associated protein, tau. However the tau in PHFs differs from normal adult tau by the extent and sites of phosphorylation. One such site, Ser396 (located within a KSPV sequence), was shown to be phosphorylated in PHF tau but not in normal adult tau. To determine whether phosphorylation at Ser396 affects the binding of PHF tau to microtubules (MTs), we performed MT binding assays on 1) isolated and dephosphorylated PHF tau and 2) Chinese Hamster Ovarian (CHO) cells that were transfected with either a normal or mutant tau construct at Ser396. We showed that PHF tau is functionally impaired with respect to its ability to bind to MTs and that this defect correlates with abnormal phosphorylation, including the presence of phosphate on Ser396. We further examined the regulation of phosphorylation at Ser396 and showed that it is phosphorylated in fetal tau isolated from fetal brain but not postnatal human brain. This suggests that phosphorylation of tau at Ser396 and that phosphorylation of tau at Ser396 and that phosphorylation of tau at phosphorylation of tau and phosphorylation of tau. These results support the notion that phosphorylation of tau in AD may recapitulate development when axons extend to their targets, MTs are more flexible, and MT stabilizing proteins such as tau bind to MT with less affinity than in mature neurons.

PHOSPHORYLATION, CALPAIN HYDROLYSIS AND TUBULIN BINDING OF THE RECOMBINANT HUMAN TAU ISOFORM, T3. J.M. Litersky\*, J.A. Greenwood, C.W. Scottf and G.V.W. Johnson. Dept. of

Litersky\*. J.A. Greenwood, C.W. Scottf and G.V.W. Johnson. Dept. of Psychiatry, University of Alabama at Birmingham, Birmingham, AL 35294-0017 and †ICI Americas Inc., Wilmington, DE 19897.

Tau is an integral component of the paired helical filaments (PHFs) in Alzheimer's disease brain. All six isoforms of tau are present in soluble PHFs and appear to be abnormally phosphorylated. In this study we examined the phosphorylation, calpain degradation and tubulin binding of the recombinant human tau isoform, T3 which contains three tandem microtubule binding repeats in the Cterminal region, and no inserts in the N-terminal half of the molecule.

terminal region, and no inserts in the N-terminal half of the molecule.

T3 was phosphorylated by cAMP-dependent protein kinase (cAMP-PK) and Ca++/calmodulin-dependent protein kinase II (CaMKII) more extensively than bovine tau. In contrast, casein kinase II (CKII) phosphorylated T3 to a significantly lesser extent than bovine tau. Phosphorylation of T3 with each of the kinases in the presence of <sup>32</sup>P-ATP and subsequent cleavage at the only cysteine residue within the molecule revealed that CaMKII and CKII phosphorylate residues in the C-terminal of the molecule, while cAMP-PK phosphorylates sites in the N-terminal region, as well as in the C-terminal. Phosphopeptide mapping demonstrated that cAMP-PK and CaMKII phosphorylate the same sites in the C-terminal, while CKII phosphorylates a unique site. T3, which contains no detectable phosphate, was proteolyzed by calpain at a significantly faster rate than bovine or human tau. However, phosphorylation of T3 with cAMP-PK did not alter its susceptibility to calpain hydrolysis in contrast to what was previously observed with bovine tau. Binding of T3 to immobilized bovine tubulin showed that phosphorylation by cAMP-PK significantly reduced T3-tubulin interactions, while phosphorylation of T3 with significantly reduced T3-tubulin interactions, while phosphorylation of T3 with CaMKII did not alter tubulin binding.

### 237 Q

PHOSPHORYLATION STATES OF BOVINE TAU, PORCINE TAU, AND A TAU FRAGMENT BOUND TO ALZHEIMER PHFs. C.W Scott\*, L. Poulter. D. Barratt, C. Wischik and C.B. Caputo. ICI Americas Inc., Wilmington, DE 19897 and MRC Laboratory of Molecular Biology, Cambridge, UK.
PHFs contain modified tau protein (τ) and are present in both of the major

histopathologic lesions of Alzheimer's disease, neuritic plaques and neurofibrillary tangles. We investigated the nature and specificity of τPHF modifications by comparing  $\tau$  extracted from pronase-treated PHFs to  $\tau$ extracted from bovine and porcine microtubules. Each preparation was digested with proteases, fractionated by RPHPLC, and analyzed by mass spectrometry and Edman sequencing. Peptides spanning aa 299-391of the longest human tau isoform (τ4L) were identified in the τPHF sample, although none contained any post-translational modifications. One phospho peptide was identified in the porcine τ digest; the phosphorylated residue was Ser404. Three phospho peptides were identified in the bovine  $\tau$  digest representing aa 40-53, 193-251, 402-417 of τ4L. Nonphosphorylated peptides encompassing the KSPV motif were identified from both porcine and bovine t suggesting that this site was not phosphorylated in vivo However, phosphate-dependent antibodies T3P (kindly provided by Dr. V. Lee) and SMI-34 recognized the porcine and bovine τ samples in a phosphate-dependent manner by immunoblot and ELISA. Thus these antibodies may react with phosphate groups outside the KSPV site. In conclusion, no evidence of post-translational modifications of aa 299-391of τPHF was observed. Direct chemical analysis rather than antibody reactivity is needed to map the locations of aberrant phosphorylation that occur N- and C-terminal to aa 299-391 of rPHF

THE ALZHEIMER-LIKE STATE OF TAU PROTEIN: KINASES AND PHOSPHORYLATION SITES. E.-M.Mandelkow\*, J.Biernat, B.Lichtenberg-Kraag, B.Steiner, H.Wille, G.Drewes, N.Gustke, H.Meyer (a), M.Goedert (b), E.Mandelkow. Max-Planck-Unit for Struct. Mol. Biol., D-2000 Hamburg 52; (a) Inst. physiol. Chem., Univ. of Bochum, D-4630 Bochum; (b) MRC-LMB, Cambridge CB2 2QH, U.K. Tau is a major component of the paired helical filaments (PHFs) of Alzheimer's disease where it is abnormally phosphorylated. Our aim is to analyze the structure and function of tau in normal and pathological conditions. (1) We prepared a kinase from brain capable of transforming normal or recombinant tau into the abnormally phosphorylated. Our aim is to analyze the structure and function of tau in normal and pathological conditions. (1) We prepared a kinase from brain capable of transforming normal or recombinant tau into the Alzheimer state, as judged by several criteria: (i) a reduced electrophoretic mobility in an SDS gel; (ii) reaction with PHF-specific monoclonal antibodies; (iii) alterations in microtubule binding. (2) We determined several abnormal phosphorylation sites in tau, including Serl99 and Ser202. Most sites are Ser followed by Pro, indicating a Pro-directed kinase. (3) We determined epitopes of antibodies sensitive to the PHF-like state of tau. Two of the antibodies tested have epitopes including Serl99 and Ser202; they are phosphorylated when tau is in a PHF-like state. The phosphorylation sites and antibody epitopes were confirmed by site-directed mutagenesis. (4) We probed the function of recombinant tau proteins in vitro, with or without phosphorylation, in terms of microtubule binding or assembly into filaments closely resembling PHFs. - Supported by BMFT and DFG.

POSTMORTEM CHANGES IN CYTOSKELETAL PROTEINS RESEMBLE ALTERATIONS IN ALZHEIMER'S DISEASE. C. Schwab' and J.W. Geddes. Sanders-Brown Center on Aging and Dept.

Anatomy & Neurobiology, Univ. Kentucky, Lexington, KY 40536.

Alzheimer's disease (AD) is characterized by disruptions in the structure and localization of microtubule-associated proteins (MAPs), particularly the tay proteins. Loss of tay from axons and accumulation in somatodendritic compartments, as detected by immunocytochemistry, is one of the earliest identified abnormalities in AD. The mechanisms which lead to the accumulation of tau in the somatodendritic compartment are uncertain. We examined the distribution of tau and other cytoskeletal proteins in the

rat hippocampus at various times postmortem. As early as 30 min postmortem, here was a decrease in tau immunoreactivity in axons and increase in neuronal cell bodies. Similarly, MAP1, MAP2, and MAP5/1B accumulated in the cell body and proximal portion of the apical dendrites and were lost from the distal dendrites. In contrast, the cellular localization of phosphorylated neurofilaments was similar in control and postmortem animals. In Western blots, a loss of MAP1, MAP2, and MAP5 was evident to the contract of the contra by 4h postmortem, whereas the levels of tau were relatively stable. Postmortem accumulation of microtubules, but not of neurofilaments, in the

soma and proximal dendrites was also evident using electron microscopy.

These results suggest that: i) the cytoskeletal alterations observed in AD are not causally related to, but result from, neuronal death; ii) the prominence of tau in AD pathology may reflect its postmortem stability in contrast to other MAPs; and iii) results regarding the levels and distribution of cytoskeletal proteins obtained from postmortem human tissue must be interpreted with caution. (Supported by NIA grant AG10678 to JWG).

INDUCTION OF AMYLOID FIBRIL FORMATION BY TAU PROTEIN. C.B. Caputo\*, C.W Scott, I.R.E. Sobel, and L.A.
Sygowski. ICI Pharmaceuticals Group, ICI Americas, Wilmington, DE 19897.

Paired helical filaments (PHFs) possess amyloid-like properties, contain tau protein ( au) and form intracellularly in neurons in Alzheimer's disease. compared the properties of PHFs with those of the amyloid fibrils (Caputo et al. Arch. Biochm. Biophys. amyloid fibrils (Caputo et al. Arch. Biochm. Biophys. 292:199,1992) formed from C-APP, a synthetic peptide of the last 20 amino acids of  $\beta$ -amyloid precursor protein. C-APP fibrils resembled PHFs morphologically after C-APP was heated at 60° C for 1 h.  $\tau$  considerably enhanced C-APP fibril formation, without influencing its morphology. Bovine  $\tau$ , phosphorylated at 3 sites, was as effective as the shortest, longest, and 4-repeat human  $\tau$  isoforms expressed in E. coli or a fragment containing the tubulin-binding region.  $\tau$  remained bound to C-APP fibrils, as determined by  $\tau$  immunoreactivity of the fibrils upon centrifugation. C-APP fibrils were insoluble in solvents that also do C-APP fibrils were insoluble in solvents that also do not dissolve PHFs such as SDS, guanidine-HCl, triton X-100, and CAPS, whereas both PHFs and C-APP fibrils became soluble using a 6 M guanidine-SCN procedure. conclude that C-APP fibrils share morphological and solubility properties with PHFs and both bind  $\tau$ 

### 237.12

ACID INDUCES HYPERPHOSPHORYLATED FORMS OF TAU PROTEIN IN HUMAN BRAIN SLICES. K.A. Harris, G.A. Oyler, and M.L. Billingsley\*, Dept. Pharmacology,

Penn State University College of Medicine, Hershey, PA 17033
Hyperphosphorylated forms of the microtubule-associated protein tau (tau-P) form paired helical filaments seen in Alzheimer's disease. In fresh tissue slices of human temporal lobe, tau phosphorylation was increased in a dose-dependent manner by treatment with the phosphatase inhibitor okadaic acid (5-20  $\mu$ M). Lower concentrations of okadaic acid (15-125 nM) did not alter tau electrophoretic mobility, suggesting that nM) did not alter tau electrophoretic mobility, suggesting that inhibition of protein phosphatase 2B (calcineurin) was important in generation of tau-P. Treatment with NMDA, quisqualate, or kainate failed to alter tau-P. Immunoreactivity to Alz-50, a monoclonal antibody which recognizes the A68-tau epitope was increased following okadaic acid treatment and comigrated with tau-A68 purified from Alzheimer's brain. In vitro incubation with purified bovine calcineurin dephosphorylated the tau-A68 isoform formed following okadaic acid treatment. Inhibition of calmodulin-dependent protein kinase II using the specific inhibitor KN-62 prevented formation of okadaic acid-induced tau-A68 immunoreactivity in slices. These data suggest that prevented formation of okadaic acid-induced tau-A68 immunoreactivity in slices. These data suggest that the tau-A68 phosphorylation site(s) is regulated by calmodulin kinase II and okadaic acid-sensitive protein phosphatases; alterations in these enzyme activities may be implicated in the pathogenesis of Alzheimer's disease.

AN INVESTIGATION INTO THE ORIGIN OF NEUROPIL THREADS IN ALZHEIMER'S DISEASE CORTEX USING CONFOCAL LASER MICROSCOPY. M.L.Schmidt, J.Murray, & J.O.Trojanowski\*.
Dept.of Path. & Lab.Med., U.of Penn, Sch.of Med. PA 19104

Neuropil threads (NTs) are abnormal processes found in tangle rich grey matter areas of the brains of patients with Alzheimer's disease (AD). Although NTs contain paired helical filaments (PHFs) and share multiple tau epitopes with neurofibrillary tangles (NFTs), the relationship between NTs and tangle bearing neurons is unclear. For this reason, we investigated the origin of NTs using histochemical and immunochemical methods with the aid of a confocal laser scanning microscope. Only a small fraction of NTs (<1%) in 3.5 X  $10^6~\mu m^3$  of cortex could be traced to local cortical neurons with NFTs or to neurons that did not contain NFTs, and no NTs were observed to originate from astrocytes. These results indicate that only a very small percentage of NTs occur in the proximal parts of dendrites that emanate from neurons located within NTrich grey matter, while the majority of NTs appear to reside in the distal parts of dendrites and/or the terminal arborizations of axons. Hence, NTs could disrupt local and long distance neuronal circuitry and thereby contribute to the cognitive impairments seen in AD patients.

### 238.3

MICROGLIA ARE NOT EXCLUSIVELY ASSOCIATED WITH PLAQUE-RICH MICROSLIA ARE NOT EXCLUSIVELY ASSOCIATED WITH PLAQUE-RIC REGIONS OF THE DENTATE GYRUS IN ALZHEIMER'S DISEASE. M.T. Roe¹, C.M. Hulette¹, G. Einstein², B.J. Crain¹-²\* Depts. of Pathology¹ and Neurobiology², Duke Univ. School of Medicine, Durham, NC 27710.

The role of microglial cells in plaque formation in Alzheimer's Disease (AD)

remains uncertain. We studied the relative spatial distributions of plaques a reactive microglia in the molecular layer of the dentate gyrus (DG) of the hippocampus to determine if reactive microglia are confined to the same area as plaques or are more broadly distributed. Tissue from ten AD cases with numer plaques in the DG (Group 1) was compared with tissue from five age-matched AD cases without plaques in the DG (Group 2) and five age-matched control cases (Group 3). Serial sections were immunostained with antibodies to beta-amyloid (for plaques) and L-ferritin (for reactive microglia). Selected cases were immunostained with antibody to glial fibrillary acidic protein (for reactive astrocytes) to ensure that antibody to L-ferritin was not staining astrocytes. Relative spatial distributions of plaques and microglia were determined in the three groups by measuring th distances of plaques and microglia from the top of the granule cell layer (GCL). In plaque-rich regions, reactive microglia were most numerous in the same area as plaques (0.05-0.20 mm from the GCL), but were distributed broadly within the ecular layer (up to 0.45 mm from the GCL). In plaque-free regions in all thre groups, reactive microglia were less common and were distributed uniformly (up to 0.50 mm from the GCL). Therefore, reactive microglia were not exclusively confined to plaque-rich regions since they were distributed more broadly than plaques and were common in plaque-free regions. Reactive microglia thus appear to be associated with both plaque formation and more generalized brain injury in AD. Supported by AG 09216.

THREE DIFFERENT HEPARAN SULFATE PROTEOGLYCAN PROTEIN CORES ARE PRESENT IN THE AMYLOID PLAQUES OF ALZHEIMER'S DISEASE. J. Eisler 1.2\* L. Buee. 2 W. Ding. 2 R. Kisilevsky. 3 S. Narindrasorasak. 3 H. Fillit. M.D. 1.2 1 Fishberg Center for Neurobiology, <sup>2</sup>Ritter Department of Geriatrics, Mount Sinai Medical Center, Box 1070, New York, NY 10029, and <sup>3</sup>Department of Pathology, Queens University, Kingston,

Heparan Sulfate Proteoglycan (HSPG) may play a role in amyloidosis, including Alzheimer's Disease (AD). Both polyclonal antibodies to the basement membrane HSPG named perlecan (MW-600 k Da, protein core ~400 kDa), and monoclonal antibodies (mAbs) 7E12 to another basement membrane HSPG (M.W. ~ 250 kDa, protein core ~ 110 kDa) identify HSPG in amyloid plaques, and also stain occasional neurons in AD as well as normal and abnormal plaques, and also stan occasional neurons in AD as went as formula and admining cerebrovasculature. Immunoblot analysis employing these two purified HSPGs was performed to determine whether these HSPGs share common epitopes or are actually distinct molecules. Results indicate that the mAbs reactive with 110 kDa HSPG protein core do not recognize perfecan, and polyclonal antibodies to perfecan react minimally with the 110 kDa HSPG protein core possibly due to recognition of the heparan sulfate side chains which both molecules have in recognition of the heparan sulfate side chains which both molecules have in common. HSPG was also purified from the supernatant of human neuroblastoma cells (SKNSH), and immunoblot analysis revealed an intermediate weight HSPG (M.W. protein core ~ 150 kDa) recognized by the mAbs to the 110 kDa HSPG but not by the polyclonal antibodies perfecan. In conclusion, while the three proteoglycans do in fact share common heparan sulfate side chains, they probably have distinct protein cores. Therefore, there are at least two types, and possibly three of HSPG in amyloid plaques. In addition, these HSPGs are derived from different cellular sources, particularly vascular addition, these HSPGs are derived from different cellular sources, particularly vascular endothelial cells and neurons.

DOES BRAIN MICROVESSEL PATHOLOGY PROVOKE ALZHEIMER'S DISEASE?

DOES BRAIN MICROVESSEL PATHOLOGY PROVOKE ALZHEIMER'S DISEASE?.

J.C. de la Torre\*. University of Ottawa, Fac.of Medicine, Ottawa, Ontario Canada KiH 8MS.

Previous light microscopic findings and recent ultrastructural studies have demonstrated extensive structural distortions of cerebral capillaries in Alzheimer's brains. Alzheimer's disease (AD) subjects additionally show reduced cerebral blood flow (CBF), glucose metabolism and oxygen utilization which appear inversely proportional to increased disease severity. Other work supports he notion that congophilic angiopathy and glial fibrillary acidic protein (GFAP) in AD brains precede plaques and tangles formation. These and other findings, including our experimental work in rats\*, have led us to develop a hypothetical model which be prefered experienced.

which appears consistent with the pathogenesis and progression of AD.

During aging, brain capillaries (site of the blood-brain barrier) can degenerate progressively During aging, brain capillaries (site of the blood-brain barrier) can degenerate progressively from amyloid deposits, thickened basement membrane, cerebral atrophy, reduced vessel elasticity, genetic predisposition, etc. When structural abnormalities of brain microvasculature begin to interfere with basic laws of fluid dynamics, hemorheological compromise develops. The product of hemorheological compromise results in higher cerebral capillary resistance, blood viscosity, abnormal flow patterns, and shear stress of vessel walls. The net effect is chronic disturbed blood flow to the brain that impairs the delivery of essential nutrients (particularly oxygen and glucose) to cerebral neurons. As ischemic-sensitive neurons lower their oxidative phosphorylation and ATP production to sub-functional levels, they release a diffusible glial mitogen that directly stimulates reactive astrocytosis. These GFAP- reactive glia proliferate quickly in response to brain nijury and can spread to unaffected tissue. It has been suggested that β/ amyloid precursor protein (APP), may be expressed.

reactive glia and microglia following neuronal injury thus providing the nidus of neuritic plaque formation. As brain tissue space is invaded by reactive glia, neuronal cytoskeletal damage results in neurofibrillary tangles.

Evolving microvascular insufficiency also limits the availability of proteases responsible for

the removal of APP and the products of cell injury involved in plaque formation. The linear outcome of this process is slow and progressive neuronal damage, transmission failure and brain tissue death

STRUCTURAL ANALYSIS OF \$\alpha\_1\$-ANTICHYMOTRYPSIN IN ALZHEIMER'S DISEASE. Kelly Johnson-Wood, Cheryl Blomquist. Robin Barbour, Russell Blacher, Fred Esch. Ivan Lieberburg. Lawrence Fritz\*, and Dale Schenk. Athena Neurosciences, South San Francisco, CA. 94080.

Multiple studies have identified  $\alpha_1$ -antichymotrypsin ( $\alpha_1$ -ACT) as a major component of neuritic plaques. Its presence Act) as a major component of neutric plaques. Its presence frequently co-localizes with  $\beta$ -peptide deposition and its synthesis appears to be increased in the brain tissue of Alzheimer's disease patients. Several groups have used this observation to see if total levels of  $\alpha_1$ -ACT in either cerebrospinal fluid or plasma are specifically increased in AD patients. While some investigators have identified an increase, others have not. In an attempt to more fully understand the role of the  $\alpha_1\text{-ACT}$  in Alzheimer's disease, we have developed several monoclonal antibodies to it and have used these antibodies to aid in the purification of  $\alpha_1$ -ACT from plasma and brain tissue of both Alzheimer's disease and The results of this analysis suggestSu control patients. heterogeneity in the molecule that might have relevance to the disease process in Alzheimer's disease.

# 238.6

RESTRICTION ENDONUCLEASE ANALYSIS OF AMYLOID PRECURSOR PROTEIN GENE IN GUAMANIAN PARKINSNONISM-DEMENTIA AND AMYOTROPHIC LATERAL SCLEROSIS. D.C. Guiroy\*, V. R. Nerurkar, I. Wakayama, R.M. Garruto, R. Yangihara, D.C. Gajdusek. Laboratory of Central Nervous System Studies, National Institute of Neurological Disorders and Stroke, NIH, Bethesda, MD 20892

Guamanian parkinsonism-dementia (PD) and amyotrophic lateral sclerosis (ALS) are neurological disorders characterized neuropathologically by abundant neurofibrillary tangles. Codon altering point mutations in the amyloid precursor protein gene, leading to altered tertiary configuration, may explain the predominant intracellular amyloid deposition in these disorders. To determine if point mutations are present in the amyloid protein precursor gene, we studied high molecular weight DNA extracted from brain and lymphocytes of 12 cases of Guamanian PD and 9 cases of Guamanian ALS by polymerase chain reaction using primers 5'GCCTAATTCTCTATAGTCTTAATTCCCAC 3' and 5'GAGCCGATAACGCGTCCATCG 3' of the APP gene. Restriction enzyme analysis of the 319 bp enzymatically amplified product using Bcl I, which is specific for T/GATCA (Valine>Isoleucine), did not reveal a point mutation at codon 717 in Guamanian PD and ALS. Further restriction enzyme analyses and direct sequencing of the amplified amyloid precursor protein gene is underway to determine the presence of point mutations.

LEUPEPTIN INDUCES AN ACCUMULATION OF UBIQUITIN-CONJUCATED PROTEINS AND AMYLOID PRECURSOR PROTEIN (APP) FRAGMENT IN RAT BRAIN. I. Hajimohammadreza, V.E.R. Anderson, J.B. Cavanaqh, B.H. Anderton and P.N. Leigh (SPON: Brain Research Association). Institute of Psychiatry, London SE5 8AF, UK. The processing of APP to  $\beta$ -amyloid may be an early feature of Alzheimer's disease pathology. Little of the processing of APP to  $\beta$ -amyloid say be an early feature of Alzheimer's disease pathology.

The processing of APP to  $\beta$ -amyloid may be an early feature of Alzheimer's disease pathology. Little is known of mechanisms by which  $\beta$ -amyloid is formed but lysosomal proteolysis may be involved. Leupeptin is a potent serine and thiol protease inhibitor which blocks several lysosomal proteases. Infusion of leupeptin into rat cerebral ventricle causes a rapid accumulation of lysosomes appearing in hippocampal and cerebellar neurones first and later in glia. We have demonstrated increased lysosomal immunoreactivity for both ubiquitin and APP following leupeptin infusion, indicating altered proteolytic processing. SDS-PAGE analysis of proteins followed by Western blotting showed an increase in ubiquitin immunoreactivity and a strong APP immunoreactive band at 19 kDa in leupeptin intoxication. This in-vivo model demonstrates that neurones can process APP via the lysosomes. It may indicate that lysosomes are transported from the neuronal perikarya via astrocytes on the way to the vascular bed and pia-arachnoid.

### 238.9

ANTIBODY MAPPING OF ALZHEIMER DISEASE PAIRED HELICAL FILAMENTS USING FREEZE-DRYING/DEEP-ETCH TECHNIQUES. <u>D.M. Appelt\* and B.J. Balin\*</u>, Medical College of Pennsylvania, \*Dept. of Anatomy and Neurobiology, \*Dept. of Pathology & Laboratory Medicine, 3200 Henry Ave., Phila., PA 19129.

Paired helical filaments (PHFs) are the major constituents of neurofibrillary tangles (NFTs), one of the hallmarks of Alzheimer's Disease (AD). Recent evidence suggests that PHFs are comprised of highly phosphorylated tau proteins known as A68 (Lee et al., Science 251:672-678, 1991). The formation of insoluble paired structures from these modified tau proteins into individual PHFs and macromolecular complexes, such as the NFTs, remains to be determined. To clarify these issues, we have utilized freeze-drying/deep-etch electron microscopy techniques of isolated PHFs to obtain stereoscopic images. These images allow us to view the individual filaments as they relate to one another in three dimensions. PHFs were extracted and isolated from AD brains using well-established biochemical techniques. Affinity purification of these PHFs was employed to obtain a contaminant-free population. Monoclonal antibodies to tau and PHF (Tau 1, Tau 14, Tau 46, Tau 60, Alz 50) were used to examine the arrangement of tau and A68 epitopes on each filament. Their labeling patterns suggest that specific epitopes of these proteins are discretely arranged along the PHFs. The arrangement of these epitopes, in particular the amin and carboxyl termini, provides an indication of the structural relationships of tau molecules both on and between the helical strands. This alignment of tau proteins (e.g., parallel/anti-parallel) along the filaments may allow us to determine the potential sites on the tau molecules that interact to form insoluble PHFs and ultimately, the NFTs. Supported by PHS grant AG10160.

# 238.11

DISTRIBUTION OF INTERMEDIATE FILAMENTS IN THE RETINAS OF NORMAL AND ALZHEIMER'S DISEASE DONOR EYES. <u>Kathryn V. Porrello, David R. Hinton and Janet C. Blanks\*</u>. Doheny Eye Institute and Departments of Pathology and Ophthalmology, USC School of Medicine, Los Angeles, CA 90033.

The retinas of patients with Alzheimer's disease (AD) exhibit a selective

degeneration of the ganglion cell layer (GCL) and the nerve fiber layer (NFL). This retinal degeneration is not accompanied by the characteristic neurofibrillary tangles (NFT) and neuritic plaques that are associated with neuronal degenera-tion in AD brains. Evidence suggests that these lesions represent abnormalities in the neuronal cytoskeleton. In particular, NFT contain small segments of neurofilaments (NF) that appear to be abnormally phosphorylated and distributed within the neuron. AD brains also express increased levels of glial fibrillary acidic protein (GFAP), which appears to be related to the astrocytic gliosis that occurs near degenerating neurons. To investigate whether similar cytoskeletal abnormalities exist in AD retinas, the distribution of NF and GFAP was examined in 10 AD and 11 age-matched normal control eyes. Monoclonal antibodies specific for phosphorylated (SMI 31) and non-phosphorylated (SMI 32) epitopes of the 200 kD NF demonstrated a differential distribution of NF within the normal retina. SMI 31 labeled the NFL intensely and produced a laminar pattern in the inner plexiform layer (IPL). SMI 32 labeling was greatly reduced in the NFL and IPL, but sporadically labeled cell somata in the GCL and NFL. In AD retinas, the distribution of SMI 31 labeling of the NFL was greatly reduced compared with controls, and appeared proportional to the degree of optic nerve degeneration. SMI 32 labeling of AD retinas was similar to that of controls. In normal retinas. anti-GFAP labeling was usually restricted to the perivascular astrocytes of the GCL and NFL. In most AD retinas, anti-GFAP labeling appeared to be more extensive compared with controls, and included labeling of the Müller cell processes. These results suggest that the retinal degeneration in AD patients involves cytoskeletal abnormalities

SOLUBILIZATION AND ANALYSIS OF ALZHEIMER DISEASE PAIRED HELICAL FILAMENTS. D.R. Sparkman\*, W.J. Goux, C.L. White III, and S.J. Hill. U.T. Southwestern Med. Ctr., Dallas, TX 75235 and U.T. at Dallas, Richardson, TX

Alzheimer disease is a neurodegenerative disorder that is characterized by neurofibrillary degeneration. The paired helical filaments (PHF) of the neurofibrillary tangles are SDS-insoluble structures, in contrast to the non-tangle SDS-soluble PHF. An abnormal form of tau has been found to be associated with both types of PHF, but does not account for their differences in solubilities. The insoluble PHF core structures have been isolated by SDS extraction and pronase digestion, and solubilized by heating in dimethyl sulfoxide. Analysis by proton nuclear magnetic resonance has demonstrated the presence of a glycolipid component associated with the insoluble PHF. Similar studies of the soluble, non-tangle PHF also detected a glycolipid component, in addition to protein. X-ray microprobe analysis of the two types of PHF support the PHF core structures being predominately nonproteinaceous, in contrast to the non-tangle PHF. The associated of a glycolipid component with the abnormal tau may give rise to soluble PHF, which over time becomes covalently modified to give rise to an insoluble, glycolipid PHF core structure with tau forming the outer fuzzy coat.

ALZHEIMER PAIRED HELICAL FILAMENTS: SHARED EPITOPES WITH TAU AND BETA-AMYLOID. L. McLaughlin\*. G.E. Dean, & F.P. Zemlan Dept. of Molec. Genetics, Biochem. and Microbiol., and the Alzheimer's Research Center, Univ. of Cincinnati, Cincinnati, OH 45627.

Neurofibrillary tangles (NFT) are one of the characteristic neuropathological

Neurofibrillary tangles (NFT) are one of the characteristic neuropathological lesions seen in Alzheimer's diseased brains. These intracellular lesions are seen to consist chiefly of tenaciously insoluble structures called Paired Helical Filaments (PHF). On the basis of limited peptide sequenation and immunological reactivity, PHF is thought to contain abnormal forms of the microtubule-associated protein tau (TAU). This conclusion is based, however, on studies performed with either 1) highly impure preparations of NFT's or 2) a group of soluble proteins known as the A68 proteins whose relationship with PHF has not clearly been established. A purification procedure previously developed in this laboratory has enabled the isolation of the PHF structural proteins resulting in several bands of approximately 56-66 kD (AD 66 proteins) as seen on silver stained PAGE. To determine which regions of TAU are present in PHF we have performed more detailed epitope-mapping studies of these highly purified PHF-derived proteins with antibodies specifically raised against defined regions of the TAU protein. The data from the specific TAU antibodies suggests that only some TAU isoforms are present and that these appear to be abnormally phosphorylated. Immunological studies have also suggested the presence of the amyloid protein (the major proteinacious component of plaques) in PHF. Similar immunological studies with antibodies raised against defined regions of the amyloid precursor protein (APP) were therefore carried out. Results from these experiments show reactivity of the AD 66 proteins with antibodies raised against the carboxy-terminal and the beta-amyloid region of the APP. To rule out the presence of amyloid protein in the PHF-derived proteins will require further investigation.

DISTRIBUTION OF NEUROFIBRILLARY TANGLES AND AMYLOID DEPOSITS IN THE HIPPOCAMPUS AND THE TEMPORAL NEOCORTEX: A STUDY OF ONE YEAR AUTOPSY POPULATION FROM A GERIATRIC HOSPITAL. C. Bouras <sup>1\*</sup>, P. Giannakopoulos<sup>2</sup>, P.R. Hof<sup>3</sup>, N.K. Robakis<sup>3,4</sup>, M. Surini<sup>1</sup>, J.P. Michel<sup>2</sup>, <sup>1</sup>Dept. of Psychiatry, Univ. of Geneva, CH-1225, Switzerland, <sup>2</sup>Institutions Universitaires de Gériatrie, CH-1226 Geneva, Switzerland, and <sup>3</sup>Fishberg Research Center for Neurobiology and <sup>4</sup>Psychiatry Mt Sinai Sch. Med., New York, NY 10029,

Sinai Sch. Med., New York, NY 10029. The brains of 114 cases (68-101 years old) were obtained at autopsy from the Geriatric Hospital of Geneva in 1989. The patients included 47 men (41.2%, 83±7 years old) and 67 women (58.8%, 87±6 years old). The clinical diagnosis was established according to the DSM-IIIR definition of dementia and four clinical groups were retained. Twelve patients presented with degenerative dementia, 18 with other types of dementia (vascular, traumatic or mixed), 22 with slight memory impairment and disorientation, and 62 cases without known neurologic or psychiatric disorders. We assessed quantitatively the distribution of neurofibrillary tangles (NFT) and amyloid deposits (AMLD) using anti-A4 and anti-Tau antibodies in the CA1 field of the hippocampus, in layers II and V of the entorhinal cortex and in layers II-III and V-VI of the inferior temporal cortex. These cortical areas exhibited various degrees of NFT formation and AMLD was present only in 27% to 62% of the cases depending on the areas investigated. For instance, NFT were present in 83% of the cases in the CA1, 92% in the subiculum, 100% in the entorhinal cortex and 91% in the inferior temporal cortex. Moreover, memory impairment and disorientation were correlated with the number of NFT in layer II of the entorhinal cortex (p<0.05), whereas dementia was correlated with the involvement of hippocampal formation and inferior temporal neocortex (p<0.05) suggesting that dementia is linked to the presence of neocortical damage.

LAMINAR AND REGIONAL DISTRIBUTION OF NEUROFIBRILLARY TANGLES AND PICK BODIES IN PICK'S DISEASE. COMPARISON WITH ALZHEIMER'S DISEASE. L. Buée <sup>1\*</sup>, P.R. Hof <sup>2</sup>, A. Delacourte <sup>1</sup>, M. Surini <sup>3</sup>, C. Bouras <sup>3</sup>. IINSERM U156, 59045 Lille, France, <sup>2</sup>Fishberg Research Center for Neurobiology, Mt Sinai Sch. Med., New York, NY 10029, <sup>3</sup>Dept of Psychiatry, Univ. of Geneva, CH-1225, Geneva, Switzerland. The regional and laminar distribution of Pick bodies were analyzed in Fourteen patients with Pick's disease (72 6748 4 year-old PD) showing

fourteen patients with Pick's disease (72.6±8.4 year-old, PD) showing the classical fronto-temporal cortical atrophy. Results were compared to the distribution of neurofibrillary tangles (NFT) from thirteen neuropathologically confirmed Alzheimer's disease (AD) cases (87.3±8.0 year-old) with no Pick bodies. Pick bodies and NFT were stained with an antibody to tau proteins.

In PD patients, Pick bodies were observed in high densities in the fascia dentata, the CA1 pyramidal layers, layers II to V of the entorhinal cortex and in layers II-IIIa and VI of the inferior temporal and superior frontal cortex. A quantitative assessment revealed the highest densities of Pick bodies in fascia dentata, CAI, and inferior temporal layers II-IIIa (500±89, 151±24, 184±71 respectively).

Interestingly, most PD cases showed the presence of NFT in this areas suggesting that PD and AD are likely to coexist more frequently than is susually thought. In addition, NFT exhibited a complementary distribution to that of Pick bodies in neocortical areas, in that they were mostly located in layers III and V.

This suggests that the typical lesions of PD and AD involve different

sets of neurons and that specific elements of cortical circuitry are differentially affected in these conditions. Furthermore, these differences in laminar distribution of lesions in PD and AD may account for some of the clinical features typical of each of these dementing illnesses.

### 238.15

CHARACTERIZATION OF THE ALZ50 EPITOPE IN CEREBRAL CORTEX. D. Parkinson\*, D.Q. McManus and J.C. Morris, Depts. Cell Biology and Physiology, and Neurology, Washington Univ. Med. Sch. St. Louis, MO 63110.

The neurofibrillary tangles (NFTs) characteristic of Alzheimer's disease (AD) appear to be composed of abnormal forms of tau. ALZ50 is a monoclonal antibody that stains NFTs in AD brains. ALZ50 binds to both the abnormal tau in NFTs and normal tau yet does not stain normal brain sections. The ALZ50 epitope has variously been identified as a phosphorylated epitope near the C-terminus of tau, a conformational epitone within 3-4kD of the N-terminus and an 8 residue peptide at the N-terminus. Identification of the ALZ50 epitope may provide insight into the changes in tau that occur in AD.

Tau-enriched extracts were prepared from normal aged and AD cerebral cortex and used for western blotting. Fixation of the blots prior to antibody staining did not reduce ALZ50 staining. This result suggests that the lack of ALZ50 staining of normal brains is not a fixation artefact. Digestion with either acid or alkaline phosphatases changed the mobility of tau bands but there was no effect on ALZ50 staining. These results show that the binding of ALZ50 to its epitope on tau is not phosphorylation-dependent.

ALZ50 did not recognize tau extracted from the brains of non-mammalian species while tau from all mammalian species was stained to a similar extent. Both rat and mouse tau were stained as strongly as bovine, monkey and human tau. These results suggest that the ALZ50 epitope may not be at the N-terminus of tau since this is where there is most sequence divergence between species. Further work is needed to localize the ALZ50 epitope in tau and explain why this antibody stains AD but not normal brains Supported by AG0 5681

### 238.14

DYSTROPHIC NEURITES ARE COMPOSED OF BOTH DENDRITES AND AXONS, AND MAY BE ASSOCIATED WITH EARLY STAGE NEUROFIBRILLARY TANGLES IN ALZHEIMER'S DISEASE

J.H. Su\*. B.J. Cummings and C.W. Cotman. Department of Psychobiology, University of California: Irvine, CA. 92717 USA.

Dystrophic neurites are one of the pathological characteristics of AD. The term "neurite", however, does not identify a fiber's origin. It has been suggested that tau-immunoreactive dystrophic neurites are of dendritic origin (Ihara, 1988; Mckee et al., 1989). Additionally, Weghe et al. 1991 and Yamaguchi et al. 1991 showed that tau-positive neurites were only associated with extracelluar neurofibrillary tangles (NFTs). In the present study, a tau-1 monoclonal antibody (Boerhinger) was used to examine the hippocampal formation in AD tissue. We confirm these previous observations and report two new findings. The tau-1 antibody stained dystrophic neurites of both dendritic and axonal origin. The morphological appearance of these axonal dystrophic neurites was diverse, and was related to the perikaryl origin of the axon. Axonal dystrophic neurites arising from NFTs were readily detected in CA3 and CA1. Axonal neurites were also seen in some axonal fiber tracts and terminal regions. In addition, dystrophic neurites of unknown origin were found not only within extracellular NTFs as suggested above, but also associated with the proximal dendrites of some "pretangle" neurons and intracellular NFTs. We have not determined if the neurites associated with the earliest stages of tangle formation are axonal or dendritic. This study suggests that dystrophic neurites are composed of both dendritic and axonal components and may be associated with "pretangle" neurons and intracellular NFTs prior to the formation of extracellular NFTs. These neuritic changes may . contribute to neuronal dysfunction in Alzheimer's disease.

### 238.16

LIPOPUSCIN CONTENT IN THE NEUROFIBRILLARY BRARING NEURONS OF

DISEASE. A.Stojanovic1, M.J. Ball2\*, A.E. Roher1, Dept. of Anatomy/Cell Biology, Wayne State University School of Medicine, Detroit, MI  $48201^1$  and Depts of Pathology and Neurology, Oregon Health Sciences University, Portland, OR 97201

Lipofuscin is an autofluorescent cellular inclusion in the neuronal perikaryon resulting from the accumulation of metabolic by-products which cannot be further degraded. Thus, it may represent a beneficial cellular mechanism for storing toxic waste. By using computer enhanced morphometry and fluorometric analysis, the amount of lipofuscin was measured in 500 hippocampal neurons (regions CA2 and CA3) with and without neurofibrillary tangles(NPT) in brains of 10 patients with Alzheimer disease(AD), as well as in age matched controls. The mean values for cellular area demonstrate that the lipofuscin content in those cells carrying NFT is only 10% of the total cellular area, whereas in the AD neurons free of NFT and in the age matched controls, lipofuscin amounted to 31% and 33% respectively. The intrinsic autofluorescence of lipofuscin confirmed these inclusions to be three times more abundant in AD neurons without NPT and control cells than in those neurons containing NFT.We propose a breakdown in the capacity for making lipofuscin may result in the neuronal inability to store toxic waste. Such a defect could be responsible for the generation of NPT and ultimately may contribute to neuronal death.(NIH#AG08017.)

# DEGENERATIVE DISEASE: ALZHEIMER'S-CLINICAL OBSERVATIONS

EARLY DETECTION OF HUNTINGTON'S DISEASE. BARLI DETECTION OF HUNTINGTON'S DISEASE.

N. C. Reynolds\*, B. R. Elejalde, R. S. Tikofsky, R. S. Hellman,
B. Blackwell, K. D. Hamsher, R. R. Lebel, and G. R. Winter.

Medical College of Wisconsin, Milwaukee, WI 53226.

Huntington's Disease (HD) is an autosomal dominant, genetic

condition with 100% penetrance, representing a phenotypic expression of DNA located on the short arm of chromosome number 4, yet the actual gene identity remains obscure, most likely representing a deletion of a peptide directly or indirectly involved in the maintenance of extrapyramidal control of motor activity within the basal ganglia. The early detection of at risk members of HD families often takes on special meaning because the clinical syndrome is usually adult onset and at risk individuals need to clearly establish their genetic risk to facilitate decisions concerning vocational and family planning as well as a resolution of deep seated emotional conflicts.

Genetic certainty is established in our at risk family members using several different DNA probes applied to tissue samples from at least the index case, 2 afflicted and 1 non-afflicted family members. We have enhanced our prediction of clinical risk in members. We have enhanced our prediction of clinical risk in ambivalent cases by performing Spect (Ceretec technicium) scaming. The selective lack of perfusion of the caudate appears to be a highly sensitive and very early sign of degenerative changes in this nucleus. Scans of caudate anatomy performed with Magnetic Resonance Imaging (MRI) or Computerized Axial Tomography (CAT) procedures can be falsely negative if caudate mass is maintained by astrocytic proliferation.

# 239.2

**ELECTROPHYSIOLOGIC ANALYSIS OF EXTRAPYRAMIDAL MOTOR** SIGNS (EPS) IN ALZHEIMER DISEASE (AD) COMPARED TO CONTROL SUBJECTS. A.S. Mandir, U. Kischka, J. Ghika, J.H. Growdon from the Department of Neurology, Massachusetts General Hospital, Boston, MA 02114. Present address Emory Univ School of Medicine, Atlanta, GA 30322.

Reports of EPS prevalence in AD are based on subjective clinical ratings and vary greatly. We performed clinical examinations and then employed sensitive, objective measures of rigidity (strain gauge tone arm), bradykinesia (computer determined reaction and movement time: RT & MT), and resting tremor (accelerometers) on 50 AD patients and 40 age MI), and resting tremor (accelerometers) on 50 AD patients and 40 age and gender matched control subjects. No AD patients had other neurologic diagnoses and none was taking medications that would contaminate our measures. Dementia severity was determined by the Blessed Dementia Scale. Clinically, EPS were not present in control subjects and were present in only 2 AD patients. Objective measures, however, demonstrated significant differences between AD and control groups for tone (.096 ± .008 vs .042 ± .004 Nn/degree, ps.001; AD vs .004 NN L (.244, .234; .236; .241 meas. .500) and PT Gontrols, Mean ± SEM), MT (349 ± 23 vs 286 ± 21 msec, p<.03) and RT (350 ± 17 vs 317 ± 20 msec, p<.01). Resting tremor was absent in all subjects. Tone was significantly increased even in a subset of 24 "mild" AD patients (p<.05 from controls) and increased with severity of dementia (p<.05, ANOVA). We conclude that subclinical EPS are present in a large percentage of "pure" AD patients and EPS progress with the severity of

Olfactory Dysfunction in Dementia <u>Claire Murphy\*, Jill Razani, Rani</u> <u>Nijjar, Alicia Garcia and Samuel Jinich (</u>San Diego State University and UCSD Medical Center, San Diego, CA)

Patients with Probable Alzheimer's disease have significant impairments in olfactory function (Murphy et al, Neurobiology of Aging, 1990: Society for Neuroscience Abstracts, 1987, 1989). Patients with Down's Syndrome who live into their 30's and 40's develop plaques and tangles in the same areas of the brain that Alzheimer's patients do and these patients exhibit dementia. In an effort to investigate whether these patients show olfactory dysfunction, we tested Down's Syndrome patients 20-24 years old using standardized psychophysical testing procedures: two-alternative, forced-choice threshold testing for butanol, odor identification using a scratch and sniff test, and a recognition memory test. We found impairment in olfactory sensitivity and odor identification. We also found impairment in odor memory which was highly related to dementia. Some 25-40 % of patients who are HIV+ eventually develop dementia. In order to investigate whether these patients also show olfactory dysfunction, we tested male patients 20-40 years old for butanol threshold as described above. Results suggest that dementia in HIV+ patients is accompanied by diminished olfactory sensitivity. Given the proximity of olfactory projections to limbic and temporal lobe structures involved in memory, further investigation of the performance of patients with various dementias on a variety of olfactory tasks may prove to be informative.

VOLUMETRIC MAGNETIC RESONANCE IMAGING IN ALZHEIMER'S DISEASE: CORRELATIONS WITH DISEASE SEVERITY. Daly E. DeCarli CD, Haxby JV, Soncrant T\*, Schapiro MB, Rapoport SI, Horwitz B, Murphy

We related cognitive decline in males with Alzheimer's disease (DAT) to brain we related cognitive decline in males with Alzienmer's disease (DAT) to brain morphometric changes. Cognitive dysfunction was evaluated by the Folstein Mini-Mental State Examination (MMS) and Wechsler Adult Intelligence Scale. Brain MRI studies were performed on a Picker 0.5 Tesla scanner. We analyzed 7-mick, contiguous slices axial slices (TR 2000 msec, TR 20 msec), and 5mm thick coronal slices. Mean  $(\pm$  S.D) MMS of DAT men was  $16 \pm 7$ ; mean  $(\pm$  S.D) age of DAT men and controls (NC) was  $68 \pm 9$  yr and  $70 \pm 8$  yr respectively. DAT nen had significantly smaller cerebral brain matter and temporal lobe volumes (p< 0.05), and significantly larger volumes in every CSF measure (except right and left cerebral hemispheric peripheral CSF) than controls. The volume of the subcortical nuclei did not differ significantly between groups. Men with mild DAT had significantly smaller cerebral brain matter and temporal lobe volumes and significantly larger lateral ventricles than controls. Total temporal lobe volume significantly larger lateral ventricles than controls. Total temporal lobe volume ditriminated between groups with a sensitivity and specificity of greater than 85%. When peripheral and central CSF volumes were analyzed as a function of dementia severity, both increased significantly (central CSF, r=0.68, p<0.001; peripheral CSF, r=0.68, p<0.002). The slope of ventricular CSF regression (1.6% per point on MMS) was, however, 3 times that of the peripheral CSF slope [0.67% per point on MMS (z=3.37, p<0.0002)] Neuropsychological measures of disease severity in DAT patients were significantly (p<0.05) and appropriately correlated to the normalized volumes of cerebral brain matter and right lateral ventricle. We conclude that in DAT: (i) there is no effect of the disease process over and above the healthy aging process on volumes of caudate, tenticular and thalamic nuclei, (ii) differential expansion of peripheral and central CSF represent different attrophic differential expansion of peripheral and central CSF represent different atrophic processes, and (iii) measurement of temporal lobe brain matter volume provides a relatively sensitive and specific means of discriminating between DAT and NC.

IN VIVO BRAIN GLUCOSE AND PHOSPHORUS METABOLISM IN ALZHEIMER'S DISEASE. Murphy DGM, Bottomley PA, Salerno J, Williams W\*, Schapiro MB, Rapoport SI, Alger J, Horwitz B, NIA, Bldg 10, Rm 6C 414, Bethesda.

ACZELEMBER S DISEASE. Multiply EARL, Bottomicy PA. Saterno J. Williams W-Schapiro MB. Rapoport SI. Alger J. Horwitz B. NIA. Bldg 10, Rm 6C 414, Bethesda.

Positron emission tomography (PET), magnetic resonance imaging (MRI) and magnetic resonance spectroscopy (MRS) were used to study brain glucose and phosphorous metabolism in dementia of the Alzheimer type (DAT) to determine if there are differences in concentrations or ratios of phosphorus metabolites between DAT patients and age/sex-matched healthy controls (NC), if severity of DAT is correlated with phosphorus metabolite concentrations/ratios, and if glucose flux and phosphorus metabolism are related. We studied 9 drug-free, otherwise healthy DAT patients (6 M/3F) and 8 NC (5 M/3F). Mean ages (± 5D) of the patients and NC were 60 ±10 yr and 64±16, respectively. PET, MRI, and MRS were all carried out on the same volume of brain matter (ROI), from 3.5 - 6.5 cm above the inferior orbitomeatal line. MRI and MRS was performed on a 1.5 Teals scanner (General Electric, Milwaukee, WI). ROI volume was determined by quantitative MRI, so concentrations of phosphorus metabolites could be expressed per kg of brain tissue. In MRS, phosphorus concentrations were measured relative to reference vials of phosphonitrilic chloride trimer around the head. Resting regional metabolic rates for glucose (rCMRglc) were obtained using PET (Scanditronix PC-1024-7B, Uppsala, Sweden) with (18F)-2-fluoro-2-deoxy-D-glucose (FDG) in 7 of the DAT patients (5 male, 2 female) and 7 of the NC (5 male, 2 female). Mean rCMRglc was significantly lower in the DAT group than controls (p < 0.01), 5.01 ± 0.9 vs 6.8 ± 0.6 mg/100g/min. However, we found no significant correlation between any phosphorus metabolite concentration/ratio and severity of dementia, or glucose metabolism. We suggest that glucose metabolism is significant correlation between any phosphorus metabolitie concentration/ratio and severity of dementia, or glucose metabolism. We suggest that glucose metabolism is reduced early in DAT (reflecting decreased basal synaptic functioning), and is unrelated to a rate-limitation in glucose delivery, abnormal glucose metabolism, or abnormal coupling between oxidation and phosphorylation. Normal or near normal levels of phosphorus metabolites are maintained at all stages of DAT. Therefore, altered high-energy phosphate levels are not a consequence of reduced glucose metabolism in DAT, and do not play a major role in the pathophysiology of the disorder

### 239.4

Sleep and computerized EEG in Alzheimer's disease: Effects of THA. D Petit, J Montplaisir\*, D Lorrain & S Gauthier

Introduction: Patients with Alzheimer's disease (AD) present a modified sleep architecture and a diffuse slowing of the awake EEG. Since the cholinergic system, which is greatly impaired in AD, is crucial for REM sleep generation, this study aims to determine whether slowing of the EEG is more pronounced during REM sleep than during wakefulness. Another goal is to determine whether the anticholinesterase THA corrects sleep deficits and diminishes EEG slowing in AD patients.

Method: Ten mild to moderate AD patients (mean age: 61 yrs) and ten controls matched for age and sex were studied in the sleep lab for two nights and the intervening day. The following montage was used: F3/C3, F4/C4, T3/T5, T4/T6, P3/O1, P4/O2. Artifact-free samples collected during REM sleep and wakefulness were subjected to spectral analysis. AD patients were recorded again after each of two 2-week treatments with THA and placebo (up to 100 mg/day).

Results: AD patients showed EEG slowing in both states but it was more marked during REM sleep than during wakefulness (F(1,10) = 6.91, p < .025). Spectral analysis of the REM sleep EEG allowed correct classification of 100% of the subjects. It also revealed differences in the degree of slowing in different cortical regions that did not appear in wakefulness. Temporal regions were the most impaired and presented a strong asymmetry in favor of a more impaired left side. THA reduced only REM sleep EEG slowing in frontal (t=5.03, p<.01) and parieto-occipital (t = 4.22, p < .01) regions, when compared to baseline (THA vs placebo = NS). THA produced no change in the sleep variables studied.

Conclusion: Spectral analysis of the REM sleep EEG is a powerful diagnostic tool for AD. It is a sensitive gauge of cholinergic treatment efficacy. The lack of effect of THA was probably due to the low dosages given to avoid hepatotoxicity.

BLOOD-BRAIN BARRIER INTEGRITY IN AGING AND ALZHEIMER'S DISEASE. M. T. Caserta, C. Allen, G. D. Lapin, & D. R. Groothuis, Depts. of Peychiatry. Neurology, Biomedical Engineering Neurology, Biomearca Cology, Northwestern Psychiatry, Neurolo and Neurobiology, Engineering Univ. Med.

and Neurobiology, Northwestern Univ. Med. School, Evanston Hosp., Evanston, IL 60201 Alzheimer's disease (AD) is characterized by increased senile plaques and neurofibrillary tangles in brain. It is not clear if the  $\beta$ -amyloid protein is generated by synthetic processes in the brain or crosses the bloodbrain barrier (BBB). Previous studies about BBB function in AD have been inconclusive. We studied the BBB in 11 elderly patients with a clinical diagnosis of AD; all had no medical or neurological illness. We studied BBB function with a computed tomographic (CT) method (Groothuis et al., Ann Neurol 30: 581,1991) that measures transcapillary transport of meglumine iothalamate. We studied influx (K<sub>1</sub>) in hippocampus, temporal and frontal cortex. In iothalamate. We studied initian (1), hippocampus, temporal and frontal cortex hippocampus, temporal and frontal cortex. In all regions, K, was between 1-3 µl/g/min, which is within the normal range. We conclude that there is no generalized abnormality of the BBB in AD. This does not exclude the possibility of a specific BBB defect with regard to \(\theta-amyloid protein. (Supp. by Washington Square Washington Foundaries and NTM Corne Tool While Is a specific BBB defect) Health Foundation and NIH Grant TO1 MH19151.)

CEREBRAL GLUCOSE METABOLISM IS REDUCED IN PRIMARY VISUAL CORTEX OF ALZHEIMER'S DISEASE (AD) PATIENTS WITH PROMINENT VISUAL IMPAIRMENT: A PET LONGITUDINAL STUDY. E. De Micheli \* P. Pietrini, C. L. Grady, J. V. Haxby, J. Salerno, A. Gonzales-Aviles, S. I. Rapoport and M. B. Schapiro. Laboratory of Neurosciences, National Institute on Aging, NIH, Bethesda MD 20892

Schapiro. Laboratory of Neurosciences, National Institute on Aging, NIH, Bethesda MD 20892.

Prominent visual symptoms (VS) are noted early in the course of AD in a subgroup of pts. To further investigate VS in AD, we yearly determined regional cerebral metabolic rates for glucose (rCMRg(c) with PET and neuropsychological functions over a 3 yr period in two AD pts (58; 64 v.o) with visual disorientation, optic ataxia, and ocular apraxia (AD+VS). Using Mini-Mental Status Examination (MMSE), the two pts. were mildly-demented (MMSE>20) first evaluation, and became moderately-demented during follow-up (MMSE scores: 23, 22, 15 and 22, 19, 13, respectively). PET examinations (Scanditronix PC1024-7B; 6mm FWHM) were performed in the "resting state" with 18FDG. Results were compared with sex- and age-matched healthy normal volunteers (NV; mean age 58 ± 5 SD, range 52-66) and with a group of 16 sex- and age-matched mildly-moderately AD patients (AD; mean age 52 ± 5 SD, range 52-68). Absolute rCMRglc values were measured in mg/100g tissue/min. To reduce inter-subject variability, rCMRglc were "normalized" to mean cerebellar rCMRglc (a region relatively preserved in AD). Compared to NV, the AD+VS pts. showed significant bilateral reductions in absolute rCMRglc (>2 SD, Z-score analysis) in parietal (PA) and occipital association (OCA) areas from the first PET scan and, in the last two PET scans in the calcarine cortex (Cal), too; normalized rCMRglc values were significantly reduced in PA and OCA as well as in Cal at every examination in the AD+VS pts. Compared to AD pts, the two AD+VS pts. showed bilateral rCMRglc reductions in PA and OCA from the first PET scan; one pt. also in Cal at his last PET scan. Neuropsychological testing confirmed visual-spatial deficit along with a global cognitive deterioration. These results extend previous findings, of reduction in OCA in AD+VS pts showed in AD+VS pts, consistent with pathological reports.

IN VIVO <sup>31</sup>P NMR SPECTROSCOPY REVEALS ELEVATED PHOSPHOMONOESTERS AND ALTERED ENERGY METABOLISM IN EARLY ALZHEIMER'S DISEASE R. J. McClure, W.E. Klunk, K. Panchalingam, and J.W. Pettegrew Lab. of Neurophysics, Univ. of Pittsburgh, WPIC, Pittsburgh, PA 15261

Previous in vitro and in vivo 31P NMR spectroscopic studies of Alzheimer's disease (AD) brain have revealed changes in phospholipid and energy metabolism in this dementing illness. In this ongoing, longitudinal study of AD patients at various levels of severity and agematched normal controls, we have completed 55 cognitive and spectroscopic studies on 21 controls and 26 assessments on 12 AD patients. The results showed an elevation of phosphomonoesters (PME) (p=0.005) in the mildly but not moderately demented AD patients as compared to controls. The levels of PME were inversely correlated with measures of severity, suggesting that PME levels in AD may peak even before patients present with an early clinical dementia. The levels of energy metabolites, including phosphocreatine and ADP, appeared to be decreased early in the dementia, suggesting an increased utilization of The latter may signify increased activity at the synaptic membrane, since this is thought to be the major site of ATP utilization in neurons. In vivo 31P NMR spectroscopy is a non-invasive technique that may provide metabolic insights into the pathophysiology of AD and provide a useful tool to monitor the progression and response to experimental therapies in this dementia.

9-Amino-1,2,3,4-tetrahydroacridine (THA), an inhibitor of acetylcholipustersse, has gained interest during

9-Amino-1,2,3,4-tetrahydroacridine (THA), an inhibitor of acetylcholinesterase, has gained interest during recent years as a therapeutic agent for senile dementia of the Alzheimer type. In this report, we examined whether or not THA has a trophic effect on differentiating cerebellar granule cells using the method of {H}inositol incorporation into inositol-containing phospholipid. We found that supplementation with THA (30 µM) of cultures grown in 15 mM K\*-containing medium markedly increased survival and promoted the morphological maturation of cerebellar neurons. We have also characterized this THA-induced trophic effect by the assessments of phosphoinositide responses and saturation binding studies and presented evidence that THA selectively increases the expression of muscarinic cholinergic receptor function in cultured cerebellar granule cells. The present observations may offer a new avenue to investigate the mechanisms of action of THA and related therapeutic agents.

PERIPHERAL AND CIRCULATING IMMUNE COMPLEXES IN PATIENTS WITH DEMENTIA. <u>0. Heinonen1. S. Syriänen2. H. Soininen1. H. Neittaanmäki3. L. Paljärvi2, K. Syrjänen2. M. Kaski4. S. Majuri5. S. Talasniemi6. M. Mäntyjärvi and P. Riekkinen Dept. of Neurol., Pathol., Dermatol. and Microbiol., Univ. of Kuopio, Vaalijala Centr. Inst. 4, Policl. of Develop. Disord. of Kuopio5, Harjula Hospital, Kuopio6, Finland.</u>

An immunohistochemical study was carried out on the skin biopsies of 44 patients with Alzheimer's disease (AD), 15 with multi-infarct dementia (MID), 24 with Down's syndrome (DS) and 19 elderly controls, to study  $\beta$  /A4 expression in skin in coexistence with IgG, IgM and complement factor C3c. Immunopositivity for these proteins was found either separately or colocalized in several localizations in skin significantly more frequently in the AD, MID and DS patients than in controls. These data prompted us to analyse the presence of circulating immune complexes (CIC) in sera of patients with dementia and DS and aged-matched controls using both C1q and conglutinin binding ELISA tests. The probable AD and MID patients had more frequently CIC in their sera as compared to elderly nondemented subjects (ANOVA/Duncan; p < 0.05). The CIC were detected with highest frequency in the series of 10 DS patients, as contrasted to young controls, only 1/10 of which showed C1q binding-positivity. In the AD patients, the cognitive decline (Mini-Mental Status test) correlated significantly with the CIC values of both tests. The study supports the view that systemic autoimmune mechanisms may be involved, at least partly, in a variety of dementing processes.

# 240.1

THE EFFECTS OF SELENIUM AND VITAMIN E DEPRIVATION IN THE MOUSE. R. Philip\* and F. J. Denaro. Department of Neurology, Texas Tech University Health Sciences Center, Lubbock, TX 79430.

Nutritional myopathy, congestive cardiomyopathy have been reported as a consequence of selenium deficiency. Vitamin E deficiency can result in degeneration of axons and myelin degeneration. Selenium deficiency results in decreased activity of glutathione peroxidase activity. This is because selenium is a mandatory element in the formation of glutathione peroxidase. Inhibition of vitamin E and selenium activity may result in observable morphologic changes. The present study histochemically analyzes these morphologic changes. Animals were deprived of either compound or both and were examined at three-month intervals. We then examined them for evidence of neuropathological conditions. In the animals deprived of both selenium and vitamin E, some gliosis of the cortex and striatum was noted, but no neural cell loss. Examination by Bielschowsky stain revealed no inclusion bodies, plaques or tangles. Thioflavin stain did not reveal any plaques. Immunocytochemistry to ubiquitin found occasional positive neurons near the site of vascular changes. Vascular changes were noted and these were accompanied by cuffing. Immunocytochemistry to neurofibrils have not revealed any changes in animals examined at three months.

# 240.2

EFFECT OF ALUMINUM ON CULTURED RAT MICROGLIA. <u>J. Goodwin,</u>
<u>E. Uemura and W.G. VanMeter\*</u>. Dept. of Vet. Anat., Iowa State Univ.,
Ames, IA 50011.

The significance of aluminum and microglial cell changes in Alzheimer's disease (AD) has not yet been determined. One way in which aluminum and microglia may affect the progression of AD is through the effects of Interleukin-1 (II-1). II-1, a cytokine secreted by microglia, is reported to be significantly elevated in the brains of AD patients. We have cultured microglia isolated from the hippocampi of 3-5 day old rat pups. These microglia were exposed to various aluminum compounds in order to elicit the release of II-1. After 24 h, II-1 levels were measured using the mouse thymocyte assay. We have found that aluminum silicate (AISi) causes a significant increase in II-1 release from cultured rat microglia. Other aluminum compounds such as aluminum hydroxide, aluminum potassium sulfate and aluminum lactate also caused increases in II-1 but to a lesser degree. Since AISi is found in the cores of AD plaques, elevated II-1 in AD may be due to AISi-activated microglia.

BEHAVIORAL CONSEQUENCES OF ALF3 CONSUMPTION. R. L. Isaacson\* and J. Varner, Dept. Psychology, SUNY Binghamton, Binghamton, NY 13902-6000.

Excessive aluminum (Al) in the brain has been associated with Alzheimer's disease. Many investigators have attempted to associate high levels of (Al) intake with signs of this disease in animal models. In this study a monomeric fluoroaluminum complex, AIF<sub>3</sub>, was added to the daily water supply of 40 Long-Evans rats 4-5 months of age. They were divided into 4 groups based on the water made available daily for longer than 8 months. The control group received distilled, deionized water. The others received water to which AlF<sub>3</sub> had been added in the following concentrations: 0.5, 5.0, or 50 ppm. Body weights were recorded throughout the study. Testing in an open field for activity levels were assessed twice during the exposure period as were examination of walking patterns based on footprints of the animals. "Spatial memory" was assessed in a Morris water maze. Other tests were administered to determine possible changes in emotionality and/or motoric coordination. general the lowest concentration dose group and the group receiving only water appeared to be similar in performances, and in almost every task these groups appeared to differ from the two higher concentration groups. However, as expected (based on previous reports of individual differences in absorption and retention of Al), considerable variability occurred in the data. Analyses of the Al content by chemical and histologic means are underway. One prominent and potentially significant result is that the group receiving the lowest concentration of AlF3, was most prone to succumbing to diseases during the course of the experiment, more so than the rats receiving the higher concentrations. This may suggest a differential effect on the physiology of the animals at low levels

A WIDESPREAD INCREASE IN THE ACTIVATED ISOFORM OF uCANP IN BRAIN IN ALZHEIMER DISEASE. K.-I. Saito, J. Hamos and R.A. Nixon\*. McLean Hospital and Harvard Medical School, Belmont, MA 02178

Calcium-activated neutral proteinases (CANP) are key enzymes in intracellular signaling cascades and are potential mediators of calcium-induced cell injury. The class of CANP requiring micromolar levels of calcium for maximal activity (uCANP or calpain I) is enriched in neurons and exists in tissues in both a precursor form and one or more autolytically activated forms. In this study, we identified three isoforms of uCANP in postmortem brain regions from 22 Alzheimer patients and 17 controls. As an index of changes in the in vivo activity of the enzyme in Alzheimer disease, we quantified the relative proportions of activated and precursor isoforms of uCANP by immunoassay. In prefrontal cortex, the ratio of k76 kDa activated to 84 kDa precursor isoforms was increased 3-fold. The 84 Kda form in AD brains was decreased (AD, 22.6% vs. control, 37.2%, p < 0.001) and 76 Kda isoform was increased (AD, 41.4% vs. control, 26.6%, p < 0.001). The severity of these abnormalities did not correlate with the postmortem interval or with age of the individual. The ratio of activated to precursor uCANP isoforms was also increased 50% in both cerebellum and putamen (p < 0.001), where degeneration of neurons is considered minimal. Persistent activation of uCANP, which accords with evidence for disrupted calcium homeostasis in AD, could contribute to the altered protein processing and abnormal phosphorylation associated with neuronal degeneration in AD.

### ISCHEMIA: NEUROTRANSMITTERS

CSF MONOAMINES REFLECT BRAIN BIOCHEMISTRY DURING CEREBRAL ISCHEMIA P. Wester.\* R. Busto, W. D. Dietrich, M.D. Ginsberg, M.Y.-T. Globus. CVD Research Center, University of Miami, School of Medicine, Miami, FL 33101. We have tested the hypothesis that cerebrospinal fluid (CSF) monoamines reflect changes in brain extracellular fluid during cerebral inchemic Mede Wieter gr. (270 min.) were objected to automate (120 min.)

ischemia. Male Wistar rats (n=7) were subjected to permanent (120 min) 2-vessel occlusion plus hypotension under brain hyperthermic (39.0 °C) conditions. Dopamine (DA), norepinephrine (NE), serotonin (5HT) and their metabolites were measured in striatum, lateral ventricle and cisterna magna by microdialysis and HPLC. In striatum, ischemia induced an immediate significant increase of all monoamines (DA 430 x baseline values (BL); NE 6 x BL and 5HT 35 x BL, p<0.05 by ANOVA). The increased levels gradually decreased but remained significantly elevated during the ischemic period (p<0.05). The metabolites DOPAC, HVA and 5HIAA showed a significant instant and sustained decrease to 17 - 20 % compared to BL values during ischemia (p<0.05). In the lateral ventricle, significantly increased levels of DA (5 x BL), NE (11 x BL) and 5HT (19 x BL) occured immediately after the onset of ischemia (p<0.05) and remained elevated whereas decreased levels of DOPAC (60% of BL), HVA (31% of BL) and 5HIAA (26% of BL) were monitored (p<0.05). Similarily, in cisterna magna, significantly elevated levels of DA (7 x BL), NE (2 x BL) and 5HT (5 x BL) (p<0.05) and decreased concentrations of DOPAC (65% of BL), HVA (65% of BL) and 5HIAA (71% of BL) were recorded. These data suggest that CSF monoamines and their metabolites reflect changes in striatal extracellular fluid during brain hyperthermic cerebral ischemia. CSF neurotransmitters may thus be important as specific neuronal damage markers during ischemic stroke.

# ATTEMUATION OF POTASSIUM CYANIDE MEDIATED NEURONAL CELL DEATH BY ADENOSINE. C.D. Sturm and K.-W. Yoon\*. Division of Neurosurgery and Surgical Research Institute, St. Louis University School of Medicine, St. Louis, Mo 63110-0250. Glutamate has been shown to play a role in the delayed neuronal cell death seen with ischemia. Attenuation of synaptically released glutamate can be accomplished by modulators such as adenosine and baclofen. We have studied adenosine's ability to attenuate in vitro cell death after exposure to potassium cyanide <KCN> in hippocampal neuronal cell cultures. Using hippocampal cell cultures obtained from 1 d old rats and Trypan blue staining for cell viability counting, we have found that the NMDA specific antagonist MK801 10 µM attenuates the neuronal cell death secondary to exposure to KCN 1 mM for 60 min. Adenosine 10-1000 µM also decreases the neuronal cell death secondary to the same concentration of KCN in a dose dependent manner. This same neuroprotective effect is mimicked using the Al specific agonist N6-Cyclopentyladenosine 10-100 nM. The Al specific agonist N6-Cyclopentyladenosine 10-100 nM. The Al specific acceptor antagonist 8-Cyclopentyl-1,3-dimethylxanthine 10-1000 nM blocks the adenosine neuroprotective effect in a dose dependent manner. We conclude that the neuronal cell death produced by KCN in our experimental model is mediated by glutamate. This neuronal cell death is attenuated by denosine via the Al specific receptor. Our results also strongly suggest that adenosine produces this neuroprotective effect against KCN exposure by attenuating endogenous glutamate release. Supported by KO8NS01547-01.

241.4

DOPAMINE IS INVOLVED IN ISCHEMIA-INDUCED IN-CREASES OF EXTRACELLULAR CAMP IN THE STRIA-R. Prado, R. Busto, E. Martinez, I. Valdés, M.Y.-T. Globus, CVD Research Center, Univ. of Miami, Sch. of Med., Miami, FL, 33101.

Dopamine has been demonstrated to be involved in the development of ischemic neuronal damage in the striatum. The detrimental effect of dopamine may involve activation of second messenger systems, such as the cAMP cascade, which may enhance the susceptibility of striatal neurons to ischemia. In the present study we have evaluated the relationship between ischemia-induced changes in cAMP and dopamine neurotransmission. Microdialysis probes were implanted in both striata, a D-1 antagonist (SCH-23390, 100uM) was administered through one probe and modified Ringer solution through the other. After a stabilization period, rats were subjected to 20 min of ischemia by 2-vessel occlusion plus hypotension. Extracellular samples were collected, from both striata, before during and after ischemia and analyzed for cAMP by radioimmunoassay. Ischemia induced a significant increase in extracellular cAMP (peak levels mean±SD, fmol/min; 13.6±2.7), which was also observed during 4h of recirculation. Treatment with a D-1 antagonist significantly reduced the magnitude of cAMP release during ischemia (1.8±1.3, p<0.01) and completely inhibited the rise during recirculation. These results indicate that ischemia-induced surge in dopamine and activation of D-1 receptors are involved in generation of cAMP during ischemia and recirculation. Further studies will evaluate the importance of this pathway in the detrimental effect of dopamine during ischemia.

CALCIUM DEPENDENCE OF AMINO ACID RELEASE IN THE ISCHEMIC RAT HIPPOCAMPUS L. CANTOR, J.D. JANG\*, & T.L. YAKSH Dept. of Anesthesiology,

University of California, San Diego, La Jolla, CA 92093 Cerebral ischemia causes increases in extracellular levels of amino acid Cerebral ischemia causes increases in extracellular levels of amino acid (AA) neurotransmitters in the hippocampus. The degree of calcium (Ca) dependence of this release is controversial 1.2.3. The present study sought to determine the Ca dependence of release of the AAs glutamate (GLU), glycine (GLY), aspartate (ASP), taurine (TAU), serine (SER) and glutamine (GLN) in the presence of 20 min of ischemia (hypoxia +hypoglycemia) in the rat hippocampal slice. Slices were perfused with either Kreb's with Ca, or Kreb's without Ca, with MgCl2, bubbled with 95%O2/5%CO2 at 200µl/min at 38°C for a 45 min washout period. After 10 min baseline samples were collected, 20 min of ischemia was induced with either dextrose-free Kreb's or dextrose-free. min of ischemia was induced with either dextrose-free Kreb's or dextrose-free, Ca-free, Kreb's with MgCl<sub>2</sub> bubbled with 95%N<sub>2</sub>/5%CO<sub>2</sub>. Control groups Ca-free, Kreb's with MgCl2 bubbled with 95%N2/5%CO2. Control groups received sham perfusate changes. After two 10 min ischemia samples were collected, all perfusates were replaced with the initial solutions and five 10 min reperfusion samples collected. AA content was analyzed by HPLC. Twenty min of ischemia caused increases in levels of GLU, GLY, TAU and SER, but not ASP, as compared to control in the presence of Ca. Ischemia-evoked peak release was Ca dependent for the AA's GLU, GLY, TAU and SER. GLN did not rise in response to ischemia and was lower than control. In this model, a substantial portion of ischemia-evoked AA release is Ca dependent. This supports the hypothesis that regulation of excitatory AA release during ischemia may be achieved by treatments altering nerve terminal Ca flux.

IN VIVO MICRODIALYSIS OF THE BORDER ZONE IN A RAT MODEL OF REVERSIBLE FOCAL ISCHEMIA. Nash', S. Pundik, C.M. Jenkins, S.U. Bhatti and W.R. Selman, Depts. of Neurosurgery and Psychiatry', Case Western Reserve Univ. Cleveland, OH Previous studies have shown that the border zone (BZ) surrounding the

ischemic core is metabolically at risk even if reflow is initiated within 2 h of middle cerebral artery occlusion (MCA). Since the BZ is destined for infarction after only 2 h of ischemia, we examined the possibility that the release of cellular contents including neurotransmitters may contribute to the deterioration of this tissue. A dialysis probe was placed in the cerebral cortex 4 mm lateral to the midline and 1 mm anterior to the Bregma and the tissue was perfused at a rate of 2  $\mu$ l/min for 2 h prior to ischemia. The ipsilateral MCA was occluded and samples were collected at 20 min intervals during 2 h of ischemia and during 1 h of reflow. The brain was frozen in situ, sectioned and the proper positioning of the probe confirmed. Tissue lactate adjacent to the probe site was elevated by 5.8-fold, while ATP levels were depressed to 70% of control. During the ischemic period, lactate levels in the perfusate increased 27%, glucose decreased by 50%, and glutamate increased by over 2-fold. These changes were significantly different from the preischemic values and suggested that the occlusion of the MCA elicited a response typical of that observed after a mild metabolic stress. Despite this relatively mild energy imbalance, the dopamine levels in the perfusate increased more than 16-fold during ischemia, while those for DOPAC and HVA decreased by 50% of more. Serotonin levels did not change despite a marked reduction in its metabolite, 5HIAA. It would appear that brain homeostasis was markedly compromised in the border zone both during and after focal ischemia and these changes could be the triggering events leading to infarction.

PURINE METABOLITE RELEASE DURING CEREBRAL ISCHEMIA AS ASSESSED BY CHRONICALLY IMPLANTED MICRODIALYSIS PROBES. M.C. Grabb, V.M. Sciotti and D.C.L. Van Wylen\*, Department of Physiology, SUNY-Buffalo School of Medicine and Biomedical Sciences, Buffalo, NY 14215.

The purpose of this study was to determine the interstitial fluid (ISF) purine metabolite profile during cerebral ischemia (ISC). Vertebral arteries were cauterized and microdialysis probes were implanted in the caudate nucleus of rats (n=4). After 24 hours, animals were anesthetized with halothane and dialysate samples were collected before (BASE) and during  $90\ \mathrm{min}$  of ISC, induced by bilateral carotid artery occlusion. Cerebral blood flow (CBF; H2 clearance) was reduced from 103.1 to 8.8 ml/min/100g during ISC. Dialysate concentrations of adenosine (ADO), inosine (INO),

5.1±2.4\* 8.4±3.0\* 34.7± 7.8\* 9.9±2.1\* 3.6±1.7 10.3±3.9\* 45.5±13.5\* 11.5±1.4\* 2.1±1.2 9.7±4.1 52.2±15.0\* 11.1±2.7\* TSC 60' 5.0+1.8\* 4.6±1.6\*

ISF levels of all purine metabolites except UA increased progressively during ISC, with HYP being the predominate metabolite. These data indicate that chronically implanted microdialysis probes can be used to assess ISF metabolite and CBF changes during ISC. Supported by NIH HL-40878

ISCHEMIC DAMAGE TO CA1 HIPPOCAMPUS CORRELATES POORLY WITH GLUTAMATE RELEASE DURING ISCHEMIA S. Cho,\*Y. Takeda, and W. Pulsinelli Dept. of Neurology and Neuroscience, Cornell University

Medical School, New York, NY 10021

Excessive excitation of postsynaptic neurons by ischemia-induced release of excitatory neurotransmitters (EN) has been proposed as a principal cause of injury to selectively vulnerable neurons. In prior work (Brain Res., 1990), we showed that transection of fimbria/fornix (F/F) but not of either the perforant (P/P) or Schaffer collateral (S/C) pathways, significantly reduced ischemic damage to CA1 neurons. In the present study we examined whether these same pathway lesions altered the release of EN in the CA1 hippocampus of rats subjected to forebrain ischemia. Ten to 14 days after lesioning the afferent pathways, microdialysis probes were inserted into the CA1 hippocampus and the animals were subjected to 20 min of 4-VO ischemia. The dialysates, collected during ischemia and for 20 min after cerebral reperfusion, were analyzed by HPLC. In hippocampi with F/F lesions previously shown to protect against CA1 damage, the EN concentrations were not altered. In hippocampi with P/P or S/C pathway lesions previously shown not to protect against CA1 injury in this model, the release of extracellular glutamate was significantly reduced. The lack of correlation between CA1 glutamate concentrations and CA1 damage in these pathway-lesioned animals suggests that CA1 injury is largely independent of the extracellular glutamate concentration during ischemia and shortly after reperfusion.

SPINAL CORD ISCHEMIA INDUCES RELEASE OF AMINO ACIDS AND CONCURRENT NEURONAL DAMAGE. M. Marsala\*, L.S. Sorkin and T.L. Yaksh, UCSD, Anesthesiol. Res. Lab., La Jolla, CA 92093

Ischemic induced excitatory amino acid release is postulated to play a

causal role in irreversible neuronal damage. Extracellular changes in amino acid concentrations were measured using a microdialysis fiber inserted transversely through the dorsal lumbar enlargement of halothane anesthetized rats; samples (30 min) were assayed using HPLC with UV detection. After washout and a 1 hr control period, 20 min of reversible spinal cord ischemia was induced by the inflation of a Fogarty catheter passed through the femoral artery to the descending thoracic aorta. This was followed by 2 hr of reperfusion. Rats were perfused with saline followed by buffered formalin, and the spinal cord tissue removed and processed for modified Nauta staining and light level microscopy.

Glutamate concentrations were elevated during the ischemia and returned to control after 2 h of reperfusion. Taurine increased 0.5 h postocclusion, peaked at 1.5 h and remained elevated for the full 2 h. Although not significant, mean glycine concentrations increased within 1 h of recirculation and remained high. No consistent changes were detected in aspartate, asparagine or glutamine concentrations. Apparent interneuronal damage, affecting small and medium sized cells, was found predominantly in laminae II-V. Only occasional small areas of focal ecrosis, located in the dorsolateral dorsal horn and anterolateral ventral horn, were detected.

These results are consistent with a role for glutamate in ischemic spinal cord interneuronal damage and suggest that changes in taurine concentration detected during the early postischemic period can serve as an important indicator of neuronal damage.

# SCHIZOPHRENIA

SMOOTH PURSUIT TRACKING IN ADOLESCENT PSYCHOTICS: EFFECTS OF BACKGROUND ILLUMINATION R.T. Pivik, Ph.D.\*, University of Ottawa, Ottawa General Hospital, Ottawa, Canada, K1H 8L6
Aberrant smooth pursuit tracking performance in adult psychotics shows marked improvement when patients are recorded under dark-adapting conditions. The present investigation assesses the comparability of eye tracking

conditions. The present investigation assesses the comparability of eye tracking performance in adolescent psychotics with published data in adult patients. Eleven Ss with psychotic symptomatology (DSM-III-R, RDC criteria) and 8 normal controls were studied. Ss, matched for age (patients:17.4±1.1 yrs, controls:16.1±0.1 yrs), were free from organicity or medications known to affect eye tracking. Control Ss were free from psychiatric disorders. EOGs were recorded on magnetic tape under light and dark-adapting conditions, while Ss tracked a light oscillating sinusoidally at 45 Hz (10 cycles). The root-mean-square (RMS) error measure was calculated from artifact-free, phase and amplitude adults of target and EOG signals. Data were apracted using ANOVA amplitude adjusted target and EOG signals. Data were analyzed using ANOVA

In the light condition, psychotics showed higher mean RMS and greater variability than controls (M=11.8±6.5% & 8.8±0.67%,respectively). Relative to

variability than controls (M=11.8±6.5% & 8.8±0.67%, respectively). Relative to iight-testing data, psychotics' tracking under dark-adapting conditions showed a mean improvement of 18% and decreased variability (M=9.7±3.8%), and controls slight (3%) increases in mean RMS and variability (M=9.1±1.5%). The absence of statistically significant group differences in these data may relate to the small sample sizes or heterogeneity of the psychotic group. Nine of these Ss experienced their first psychotic episode within an average of 3.2 months (5-6 mos. range) of the recordings, and the results may, therefore, also reflect early stages of physiological dysfunction which intensifies with exacerbation and persistence of psychotic symptomatology. Supported by the Ontario Mental Health Foundation and Health & Welfare Canada.

Force Control Fatigability as a Pathognomonic Sign in Tardive Dyskinesia. P.B. Vrtunski\* K.L. Lewis and H.Y. Meltzer, Microbehavior Lab. VA Medical Center and Case Western Reserve University, Cleveland, OH 44141.

The hypothesis was that response output (button-press) with a target force X at time t would be measurably lower if it were preceded (at time t-1) by a target output of X+Y (a higher force) than if it were preceded by a target output of X-Y (a lower force). Over 150 subjects participated in this study. In addition to schizo-phrenics with and without tardive dyskinesia, three control groups were employed: normal controls, elderly and drug addicts. The test utilized was a target-matching task (90 6-second trials, 10 targets) with force output ranging from 5 to 560 cN. Results indicated that precedent output at t-1 significantly alters force at t, but in the opposite direction from that expected, i.e., X + Y increased the force while X-Y reduced it. Thus, the fatigability effect results in a threshold change rather than an attenuation of output. In group comparisons, the X+Y precedent separates the groups significantly better than the X-Y precedent. Since normal controls and TD schizophrenics were on the opposite ends of the continuum, with non-dyskinetic schizophrenics, drug addicts and elderly (in that order) ranging between them, the X+Y precedent at t-I may have a higher clinical value in the assessment of motor impairment.

TASK SENSITIVE ABNORMALITIES IN PROCESSING NEGATIVITY AND P3 ACTIVITY IN SCHIZOPHRENIC CHILDREN. R.J. Strandburg\*, J.T. Marsh, W.S. Brown, R.F. Asarnow, D. Guthrie and J.

Higa. Dept. of Psychiatry, UCLA, Los Angeles, CA 90024

The Continuous Performance Task (CPT) has been shown to be sensitive to schizophrenic impairments. Multichannel ERP data were recorded from 16 schizophrenic and 16 normal children (SCH & NCH) during performance of easy (detect "8") and hard (detect sequentially recurring digits) versions of the CPT to examine when in the course of CPT processing SCH exhibit deficits. impaired on both versions of the CPT producing fewer hits, more false alarms, and longer reaction times. Their poorer performance was associated with the absence of a normal increase in amplitude for early processingrelated negativities (Np) from non-target to target stimuli suggesting inefficiencies in the allocation of resources for stimulus discrimination and categorization. While P3 amplitude was not significantly smaller in SCH, the pattern of P3 amplitudes obtained for target versus non-target stimuli in easy versus hard versions of the CPT was significantly different in normal and schizophrenic subjects suggestive of SCH deficits during later stages of CPT processing associated with context updating and the evaluation of stimulus significance. No group differences were seen in CNV amplitude, which increased with task demand for both groups. (Supported by NIMH Research Grant MH37665)

### 242.5

THE USE OF EBY-TRANSFORMED LYMPHOID CELLS IN THE STUDY OF SCHIZOPHRENIA. <u>T. Ranson, A. Mezu, J. Lancaster, P. Sweetnam and H. Kulaga\*\*</u>. NovaScreen®, Baltimore MD 21224; \*NIMH, St. Elizabeth's Hospital, Washington, D.C. 20032

Two continuous lymphoid cell lines are now being used to further the studies of schizophrenia at the cellular level. The lines are unique having been established from subjects in the E. Fuller Torrez monozygotic twin studies at the National Institute of Mental Health. Cell lines SLM, schizophrenic twin, and LG, psychiatrically normal twin, were started from EBV-transformed PBMC's, and have been maintained in culture for over one year. Twenty distinct receptor systems have been examined by radioligand binding and minimal or no binding was detected to the GABA, receptor complex, 5HT-1A, 5HT-2, Dopamine-1, Dopamine-2, delta opioid, mu opioid, kappa opioid. Both cell lines express the dopamine-4 receptor and dopamine uptake site as determined by <sup>3</sup>H-clozapine and <sup>3</sup>H-WIN binding, respectively. No apparent alteration in either binding affinities and receptor density were apparent for either receptor. This maybe of interest given the SLM cell line was established while the subject was undergoing Haldol treatment. Chronic drug studies are now underway in vitro to further examine the potential for biochemical alterations as a resulting from drug

ANTICHOLINERGICS MODIFY POSITIVE AND NEGATIVE SYMPTOMS IN SCHIZOPHRENIA R. Tandon.\* J.R. DeQuardo. JF Greden. University of Michigan Schizophrenia Program, Ann Arbor, MI 48109-0120

Anticholinergic drugs have been assumed to have no effects on schizophrenic symptomatology. Studies indicate, however, that anticholinergics may antagonize the beneficial effects of neuroleptics on positive symptoms, and increase positive and decrease negative symptoms in drug-free schizophrenic patients. To further study this issue, we conducted a double-blind placebo-crossover study, comparing the effects of biperiden (a centrally-active agent) and glycopyrrolate (an anticholinergic agent with no central activity) on positive and negative symptoms in twenty otherwise medication-free (minimum two-weeks) schizophrenic (DSM-III-R and SADS/RDC) inpatients. After a three-day period when they received no drugs, they received either biperiden (4 mg po bid) or glycopyrrolate (1 mg po bid) for 3 days and they were then crossed over to the other medication for the next 3 days. The order of drug was randomized. Patients were rated on the BPRS by blind raters at four timepoints: baseline 1, baseline 2-day 4, agent 1-day 7, agent 2-day 10. Post-biperiden ratings were compared to post-glycopyrrolate and baseline ratings. Glycopyrrolate had little effect on any symptom cluster. Biperiden was observed to significantly increase positive symptoms and decrease negative symptoms. Following biperiden withdrawal (in the biperiden-first group), positive symptoms decreased. These data indicate that cholinergic modulation significantly affects positive and negative schizophrenic symptoms and suggest the need for systematic trials of cholinergic and anticholinergic agents in the treatment of positive and negative symptoms of schizophrenia, respectively.

ERYTHROCYTE TRANSKETOLASE ABNORMALITIES IN PATIENTS WITH SCHIZOPHRENIA. M.F. Casanova, B.I. Diamond\*, A.P. Pathiraja and T.H. Nguyen. Med. Coll. of Georgia, Augusta, GA 30912-3800.

SCHIZOPHRENIA. M.F. Casanova, B.I. Diamond\*, A.P. Pathiraja and T.H. Nguyen. Med. Coll. of Georgia, Augusta, GA 30912-3800.

Several authors have reported the presence of periventricular gliosis in patients with schizophrenia (SC). Astrocytosis in these patients occurs regardless of other subcortical pathology. Although some investigators have interpreted these findings as suggesting a previous encephalitis, we believe they are specific for thiamine deficiency. This study examines the probable presence of thiamine deficiency in patients with SC and in addition attempts to elucidate whether the same is secondary to nutritional factors or a comorbid expression of psychosis. Fourteen patients fulfilling DSM IIIR criteria for SC and 13 age-matched controls were used in the study. A nutritional questionnaire, physical examination, and laboratory evaluation excluded the presence of patients with nutritional abnormalities. The NADH-dependent transketolase assay was measured in erythrocyte hemolysates both in the presence (TPP) and absence (TK) of thiamine pyrophosphate. A total of 186 assays were performed. Significant differences among groups were found for TPP activation (t test, p<0.01). Differences were most prominent for the undifferentiated schizophrenic patients. Results from our study indicate that undifferentiated schizophrenic patients have an abnormality of thiamine metabolism which derives from its processing enzyme and is not dependent on nutritional status. Thiamine deficiency may therefore modulate the expression of clinical symptoms in a subset of patients with schizophrenia or may altogether bear witness to a different disease process.

THE SPECIFIC ACTIVITY OF THE SYNAPSIN PROTEINS IS MARKEDLY REDUCED IN THE BRAINS OF SOME SCHIZOPHRENICS. E. M. Dudek, S. Leonard\*, R. Freedman, and M. D. Browning. Dept. of Pharmacology, University of Colorado Health Sciences Center,

E. M. Dudek, S. Leonard\*, R. Freedman, and M. D. Browning. Dept. of Pharmacology, University of Colorado Health Sciences Center, Denver, CO.

The synapsin proteins are a family of synaptic vesicle-associated phosphoproteins that play a role in regulation of transmitter release and participate in synapse formation. We have recently shown that the synapsins may play a role in forms of synaptic plasticity thought to underlie normal cognitive function. We hypothesized that schizophrenia, which is often characterized by morphological deficits and cognitive impairment, might be associated with alterations in the synapsin proteins and examined the levels of synapsin proteins in postmortem hippocampus obtained from 6 schizophrenics and 7 controls. Utilizing a quantitative western blot technique we found the specific activity of synapsins I and Ilb in the seven control brains to be 98.4 ± 11.2 and 79.7 ± 9.4 u/mg-protein, respectively. Two brains from schizophrenic subjects exhibited synapsin levels essentially identical to the control brains. However, in 4 of the schizophrenic samples the concentrations of synapsins I and Ilb were markedly decreased to 31 ± 7.4 and 40.8 ± 5.6, respectively. No significant differences in PMI, age, cause of death, or storage time of postmortem brain could be correlated with the reduction of specific activity in the schizophrenic samples. It is also unlikely that the differences are due to tissue loss in the brains of schizophrenics as our findings relate to the absolute concentration of synapsins in the hippocampus. The data are thus consistent with a deficit in synapsin regulation of synaptic function in the brains of some schizophrenics. some schizophrenics.

ISOLATION OF A TRANSFORMING AGENT FROM HUMAN NEUROBLASTOMA CELLS EXPOSED TO SCHIZOPHRENIC CSF

NEUROBLASTOMA CELLS EXPOSED TO SCHIZOPHRENIC CSF S. Shirabe<sup>1,2</sup>, J.R. Stevens¹\* & J.P. Schwartz².

1) NIMH at St. Elizabeths Hosp., Washington DC 20032 & 2) CNB, NINDS, NIH, Bethesda MD 20892. Schizophrenic (Sch) but not control (Con) CSF contains an agent which can transform the human neuroblastoma cell line SK-N-SH (EP). After transformation, the agent can be detected in culture medium (CM). Centrifugation of CM on a Percoll density gradient indicated that the agent banded with a density of 1.08-1.11 g/ml, suggesting that it is particulate. The agent is sensitive to CHCl, and proteinase K (PK) but resistant tive to CHCl<sub>3</sub> and proteinase K (PK) but resistant to DNase or RNase. Since these results suggested that the agent might be viral in nature, we labeled Sch- and Con-cells with <sup>32</sup>P-phosphorus for labeled Sch- and Con-cells with "P-phosphorus for 16 hr in order to determine whether the particle contained nucleic acid. The CM was treated successively with DNase and RNase; SDS and PK; phenol and CHCl<sub>3</sub> extraction; followed by centrifugation at 100000xg. Agarose gel analysis showed an appox. 25kb band in Sch- but not Con-cell medium which was DNasconcitive DNAsconcil. showed an appox. 25kb band in Sch- but not Con-cell medium, which was DNase-sensitive, RNase-resistant, and could be digested with EcoRI, indicating that it is a double-stranded DNA. These results suggest that the growth-promoting agent derived from Sch CSF may be a DNA virus.

EEG MAPPING OF PSYCHOTIC SYMPTOMS IN ACUTE SCHIZO-PHRENIA. D. Lacroix, P. Rappelsberger, K. Steinberger, K. Thau. H. Petsche. Academy of Sciences, Institut of Neurophysiology, Dept. of Psychiatry, Univ. of Vienna, Währingerstraße 17, A-1090 Vienna, Austria. Dépt. de Psychiatrie, Hôpital Notre-Dame, Univ. de Montréal, 1560 Sherbrooke E., Montréal, Canada H2L 4M1.

EEG were obtained from 18 acutely psychotic patients with eyes closed and opened using 19 scalp electrodes (10/20 system). Signals were recorded against averaged signals from both ear lobes (TC 0.3s, Filter 35 Hz). Spectral parameters such as amplitude and coherence (local and interhemispheric) were computed for 6 frequency bands. For data analysis, patients were subgrouped according to their symptoms using a Brief Psychiatric Rating Scale: group #1 (n=6) differed from group #2 (n=7) with regard only to the presence of hallucinations and group #2 from group #3 (n=4) with regard only to the presence of thought disorders. Patients were drug-free for at least three days. Patients prone to hallucinations (LC) between posterior temporal, parietal and occipital electrode sites, lower LC in frontal regions and higher delta amplitude. Thought disorders (comparison of group #2 and 3) were mostly related to higher LC between frontal, central and anterio-medial temporal sites and to lower LC between left posterior temporal and left parietal sites. These results suggest dysfunctions in brain areas related to cognitive systems (mental imagery, language and executive functions) which may be involved in the expression of symp-

# CLOSED AND OPEN LOOP SMOOTH PURSUIT EYE MOVEMENTS IN SCHIZOPRENIA. A.D. Radant and D.W. Hommer\*, VA Medical Center & U. of WA. Seattle, WA 98108

Two processes, a failure to suppress inappropriate saccades and an inability to match eye velocity to target velocity, impair overall smooth pursuit performance. The relative contribution of each of these inability to match eye velocity to target velocity, impair overall smooth pursuit performance. The relative contribution of each of these processes to the pursuit abnormalities of schizophrenia is not known. To address this issue we used infra-red oculography to measure the eye movements of 20 neuroleptic-treated schizophrenic patients and 31 normal controls during a constant velocity, predictable tracking task (closed loop pursuit) as well as during the initiation of smooth pursuit (open loop pursuit) elicited by two step ramp tasks. The frequency of intrusive saccades was increased (p < .05) and smooth pursuit gain was decreased (p < .001) among the schizophrenic patients while pursuing a predictable target. The frequency of catch-up saccades did not differ between the two groups. One of two measures of open loop gain was significantly lower in the schizophrenic patients, but neither the latency significantly lower in the schizophrenic patients, but neither the latency of pursuit nor the accuracy of the initial saccade during the step ramp tasks differed between schizophrenics and normals. Schizophrenics made slightly more frequent saccades during fixation than controls (p <. 06). Intrusive saccades during fixation predicted closed loop smooth pursuit gain more robustly than did measures of open loop gain. These results suggest that a failure to suppress intrusive saccades may play a results suggest that a failure to suppress intrusive saccades may play a more important role in causing schizophrenic smooth pursuit abnormalities than any deficit in the smooth pursuit system itself. Such a tendency is consistent with dysfunction of prefrontal cortex and/or associated sub cortical structures.

# 242.13

REGIONAL CEREBRAL BLOOD FLOW DURING SINUSOIDAL PURSUIT, FIXATION AND SACCADIC EYE MOVEMENTS IN PATIENTS WITH SCHIZOPHRENIA AND NORMAL CONTROLS. R.E. Litman.
K.F. Berman, T.R. Zeffiro, B. Martin\*, D. Pickar. Lab. of Experimental Therapeutics, National Institute of Mental Health, Bethesda, MD 20892.

Saccadic eye movement abnormalities have been reported during newformance of fivetion and small process.

during performance of fixation and smooth pursuit eye movement tasks in patients with schizophrenia. To investigate the pathoplysiologic mechanisms underlying saccadic dysfunction in schizophrenia, we used oxygen-15 saccadic dysfunction in schizophrenia, we used oxygen-15 water method for measuring regional cerebral blood flow (rCBF) with positron emission tomography in 5 male patients with schizophrenia and 5 age matched male normal controls. rCBF wasmeasured during performance of sinusoidal smooth pursuit, fixation, and visually-guided saccadic eye movement tasks. Data were collected on the Scanditronix PC2048-15B brain tomograph which produces 15 slices with reconstructed resolution of 6-6.5 mm in three planes. rCBF data were normalized (i.e. each pixel of rCBF expressed as a percentage of the whole mean brain metabolism) for data analysis. Group differences in mean rCBF for the frontal eye fields as well as structures which control of saccadic eye movements will be presented for all eye movement tasks. Implications of these findings for the pathophysiology of eye movement dysfunction in schizophrenia will be discussed.

### 242.10

NEGATIVE SYMPTOMS IN OLDER SCHIZOPHRENIC PATIENTS
M.J. HARRIS, D.V. JESTE\* J. KUCK, L.A. MCADANS
Objective: We studied the relationship of negative symptoms of schizophrenia to variables such as psychopathology, cognitive impairment and neuroleptic-induced extrapyramidal symptoms (EPS) in older patients.

Methods: We evaluated 53 outpatients with DSM-III-R schizophrenia and 30 normal controls over the age of 45. The mean (with SD) age of the schizophrenic patients was 59.4 (8.3) years, duration of illness 19.2 (14.1) years, and neuroleptic dose at the time of evaluation 414.8 (666.9) mg chlorpromazine equivalent. The evaluations included the Brief Psychiatric Rating Scale (BPRS), Scales for the Assessment of Positive and Negative Symptoms (SAPS and SANS), Hamilton Rating Scale for Depression, the Mini Mental State Examination (MMSE), the Abnormal Involuntary Movement Scale (AIMS) and Simpson-Angus EPS Scale.

Results: Schizophrenic patients had significantly more negative symptoms than normal controls (p<0.001). In schizophrenic patients, negative symptoms (total SANS score) showed the strongest association with overall psychopathology (total BPRS score, Pearson's r=.37 p<0.02) and symptoms of depression (total Hamilton's score, r=.37 p<0.03). Total SANS score also correlated with the severity of negative symptoms tended to correlate inversely with age, and positively with total SAPS Score. There was no association between total SANS score and chronicity of illness, global cognitive impairment (total MMSE score), neuroleptic dose and tardive dyskinesia.

Conclusions: Negative symptoms in older schizophrenic patients correlated with overall psychopathology, depressive symptoms, and bradykinesia, but not with chronicity, cognitive impairment or neuroleptic dose.

### 242.12

CHANGES IN DISTRIBUTION OF NADPH-DIAPHORASE (NADPH-d) NEURONS IN THE FRONTAL CORTEX OF SCHIZOPHRENICS. S. Akbarian, W.E. Bunney, S.B. Wigal, S.G. Potkin, E.J. Hagman, W.G. Tourtellotte, and E.G. Jones, Dept. of Anatomy and Neurobiology, and Dept. of Psychiatry and Human Behavior, University of California, Irvine, and Dept. of Neurology, University of California, Los Angeles.

Neurons containing the enzyme NADPH-d are selectively spared in chronic

neurodegenerative illness and in neonatal hypoxia/ischemia. We analyzed the topographical distribution and the density of NADPH-d neurons in the gray and white matter of the prefrontal cortex of 6 schizophrenics and 6 controls (matched for age, gender and autolysis time) by using an enzyme-histochemical

Four of the six schizophrenics had a significant decline in the density of NADPH-d neurons in the external and internal cortical layers. By contrast, the density of NADPH-d neurons in deeper regions of the white matter of the same 4 cases was strikingly elevated. These findings fit well into theories about a disturbance of prenatal brain development, affecting cell migration, in schizophrenia, but do not support theories postulating a postnatal brain lesion or a neurodegenerative process as the underlying basis of schizophrenia.

Supported by NIMH grant MH 44188-03 and a DFG fellowship.

SUBSTANCE ABUSE AND THE NEUROBIOLOGICAL ASPECTS OF SCHIZOPHRENIA. W.B.LAWSON\*, and J. CLOTHIER. Dept. of Psychiatry, U. of Arkansas Sch. of Med. and John C. McClellan VAMC, N.Little Rock, AR 72114

Substance abuse is common among schizophrenic patients. Over half may abuse alcohol and nearly 17% may be cocaine abusers. We initiated an 8 week Schizophrenia/Addiction Treatment (SCAT) program with a thorough neuropsychiatric evaluation which included a SCID and clinical DSM IIIR diagnostic assessment, dementia workup, neuropsychological assessment, single photon emission tomography (SPECT) scan, and EEG. All patients abused cocaine, alcohol, or both. They continued their medication but were free from drugs of abuse for at least 7 days. Thus far 28 patients have been studied. Ten of 13 patients have been studied. that required antiparkinsons medication and 4/4 intolerant to haloperidol due to dystonia were cocaine abusers. Tc-90 Single Photon Emission Tomography(SPECT) was done on 17 patients. All, including cocaine and noncocaine abusers, showed hypoperfusion defects with diverse abnormalities and most showed abnormal neuropsychological performance. Left sided and frontal-temporal deficits were most common.

PUPILLARY CONSTRICTION FOLLOWING EYEBLINKS IN NORMAL SUBJECTS AND SCHIZOPHRENIC PATIENTS. I.C. Bruce\*, P.W.F. Poon, S.L. Lai, F.H.Y. Chan, P.W.H. Lee and F. Lieh-Mak. Depts of Physiology, Electrical & Electronic Engineering, and Psychiatry, University of Hong Kong, Hong Kong.

Abnormal pupillary responses have long been noted as one of the 'soft' neurological signs associated with schizophrenia. This report describes results obtained from a portable device for screening populations for such signs.

Subjects (50 controls and 49 schizophrenic outpatients receiving medication) were asked to fixate on a point while images of the left eye were captured on videotape. Subsequently, the video images were digitized (two 40 sec epochs per subject) and pupil area calculated by counting pixels above a threshold level. Eyeblinks were detected as rapid excursions of pupil area to zero, followed by a rapid return, and were used to create average responses of the pupil to eye opening at the end of the blink.

the pupil to eye opening at the end of the blink. Compared to controls, the schizophrenics showed increased blink rates, decreased exposed pupil areas (due to the eyelid partially covering the pupil) and sluggish or absent pupillary responses to eye opening following the eyeblink. It is suggested that these signs, in addition to the tracking defect reported by previous workers and confirmed by our observations, may serve as biological 'markers' for the disease, and that this non-invasive method may be useful in screening populations at risk for developing schizophrenia. ### 242.17

EFFECTS OF CLOZAPINE (CLOZ), LOXAPINE (LOX) AND HALOPERIDOL (HAL) ON SYNAPTIC TRANSMISSION IN THE CA, AREA OF THE HIPPOCAMPUS. A. Baskys, G. Remington, E. Palmer\*, and J. M. Wojtowicz. Clarke Inst. of Psychiatry and Depts. of Physiology and Psychiatry, University of Toronto, Toronto M5T IRR Canada

Among the neuroleptics, Cloz is believed to be least prone to cause movement disorders in schizophrenic patients and is often referred to as "atypical" neuroleptic. To better understand neuronal mechanisms of neuroleptic action, we compared effects of Cloz (50- $100 \,\mu\text{M}$ ) with those of Lox (5-20  $\mu\text{M}$ ) and Hal (1-5  $\mu\text{M}$ ) on synaptic transmission in the area CA1 of the hippocampus. Experiments were done in in vitro slices prepared from 15-35 day old Wistar rats. Extracellular field potential recordings from CA<sub>1</sub> neurons were used to monitor the slope of the dendritic synaptic potential evoked by 0.1 Hz stimulation of Schaffer collaterals. Cloz (50  $\mu$ M) reduced synaptic transmission by 17% (SE=3%, n=6). The response returned to the control level after 10-15 min exposure. Both Lox and Hal increased synaptic transmission by 30-50% (n=5). All effects were concentration-dependent and could be reversed upon wash-out of the drug. These results demonstrate a different action of Cloz on synaptic function. Supported by Sandoz Canada.

SYMPOSIUM. NEW WAVES IN CELL CALCIUM. M.R.Hanley, Univ. of Calif., Davis (Chairperson); K.Campbell, HHMI, Univ. of Iowa Sch.Med.; R.Y.Tsien, HHMI, Univ. of Calif, San Diego; D.Clapham, Mayo Foundation.

The regulation of cytosolic free calcium is a convergent control point in excitable cells for a remarkable variety of processes from secretion to gene expression. Most of the major gene products involved in calcium regulation in excitable cells have been cloned and expressed, permitting evaluation of explicit signalling functions for identified gene products. This Symposium will focus on intracellular calcium homeostasis and its modulation by receptor activity. Repeating themes will be how genetic or pharmacological probes and single-cell imaging have created a new appreciation of the sophistication of calcium control.

The functional and structural definition of intracellular "calcium pools", and their perturbation by drugs or genetic manipulation, will introduce the session (M.Hanley). The release of calcium from stores is mediated by InsP3 and ryanodine-gated calcium channels in brain and skeletal muscle, which will be considered in the context of their complementary functions. (K.Campbell). Insights into the molecular mechanisms of calcium signalling based on the use of novel reagents for detecting or altering intracellular messengers in single living cells will be described (R.Tsien). Lastly, the use of confocal laser microscopy has revealed complex spatial and temporal calcium patterns in Xenopus laevis oocytes expressing ectopic receptors and transduction genes (D.Clapham).

### 242.16

SCHIZOPHRENIA AS A FAILURE OF REGULATION OF COMPUTATIONAL TEMPERATURE. <u>D. K. McFarlane</u>\*, SmartTech Systems Engineering, 1293 Orlando Dr., Haslett, MI 48840.

Advances in computational neuroscience allow exploration into precise mechanisms that may underlie schizophrenia. Of particular interest are simulated annealing models (e.g. harmony theory, Boltzman machines, Alopex) in which the probability distribution of system states is governed by a global parameter T, called computational temperature in view of its similar role in thermodynamic systems: raising T reduces the differences between the probabilities of different system states. An appropriate annealing schedule of raising and lowering T allows these models to simulate normal cognitive processes. The current study aims to display how abnormal annealing schedules may result in behavior common to schizophrenia. In particular, chronically elevated T keeps the system shifting between otherwise improbable states (loose association), early lowering of T will quench the system toward non-optimal states (bizarre ideation, inappropriate affect), and chronically lowered T will result in poverty of thought, flat affect and possibly catatonia. The physiological substrate of T may be dopaminergic projections from the ventral tegmental area to prefrontal and anterior temporal cortex. Thus, anti-dopaminergic neuroleptics act by stabilizing T, alleviating uncontrolled flights of thought but not restoring the fine temporal control required for optimal annealing.

### 242.18

NON-CHOLINERGIC DEMENTIA IN ELDERLY SCHIZOPHRENICS. M. Davidson, V. Haroutunian, P. Knott\*, P.D. Kanof, P. Powchik, L.M. Bierer, D.P. Perl, D.P. Purohit, and K.L. Davis. The Mount Sinai School of Medicine. New York.

Cortical cholinergic deficits have been associated with most dementias of organic origin, such as Alzheimer's disease (AD), and Parkinson's disease. Recent evidence suggests that a large proportion of elderly schizophrenics suffer from cognitive impairments resembling dementia. To determine the neurochemical basis of this dementia, we have quantified cholinergic markers and biogenic amines in six different cortical regions (Brodmann 8, 32, 44, 22, 36, and 17). Schizophrenic cases (SCHIZ, n=24) with no neuropathological evidence of AD were compared to a cohort of nonschizophrenic chronically hospitalized psychiatric cases devoid of AD-like neuropathology (NON-SCHIZ, n=19), neuropathologically verified AD cases (n=10), and a group of elderly controls (NL, n=9). As expected, markers of cholinergic, dopaminergic and serotonergic activity were significantly (ps< 0.01) diminished in most cortical regions of the AD group. Average regional cholinergic marker levels were not affected in the SCHIZ and NON-SCHIZ groups. Choline acetyltransferase activity in Brodmann areas 32 and 36 was negatively and significantly (ps<0.03) correlated with clinical dementia rating (CDR) scores in the NON-SCHIZ cohort, but not in the SCHIZ group. These results suggest that unlike other dementing diseases, the dementia observed in elderly schizophrenics is unrelated to cortical cholinergic marker activity.

SYMPOSIUM. THE ROLE OF SENSORY INFORMATION IN THE GUIDANCE OF VOLUNTARY MOVEMENT. D.I. McCloskey, Univ. New South Wales, and A. Prochazka, Univ. Alberta (Chairpersons); C.J. Vierck, Univ. Florida Col. Med.; J.D. Brooke, Univ. Guelph; P.J. Cordo, Good Samaritan Hosp. & Med. Ctr.; P.R. Burgess, Univ. Utah

The purpose of this symposium is to encourage the development of a

The purpose of this symposium is to encourage the development of a psychophysics of voluntary movement and emphasize the concept that the motor system controls what it senses. To this end, four speakers will present data they believe indicates sensory information is of great importance in the control of voluntary movement. Dr. Vierck will describe the permanent Impairment that occurs in monkey hand control after lesions that interrupt spinal sensory pathways. Dr. Brooke will discuss the importance of sensory information in adjusting to different loads and how ambiguous instructions influence performance. Dr. Cordo will present evidence that kinesthetic sensory information is used to accurately trigger the opening of the hand in a throwing movement. Dr. Burgess will present data jointly collected with Mark Latash and Gerald Gottlieb at Rush Medical Center and show how from a common database it is possible to arrive at either an equilibrium point model of voluntary movement or a quite different sensory guldance model depending on whether one applies the concept that one can control only what one senses. Dr. McCloskey and Dr. Prochazka, the two chairpersons, who will not be speakers, will then lead a thirty-minute general discussion on the subject and prepare a written summary of what in their view has been settled and what needs further attention.

EXPRESSION OF FOS-LACZ CORRELATES WITH CELL DEATH. R.J. Smeyne\*, M. Vendrell, T. Curran, and J.I. Morgan. Roche Institute of Molecular Biology. Roche Morgan. Roche Institute Research Center, Nutley, NJ

Cell death has been shown to be an important component of development in both vertebrates and invertebrates. Current hypotheses regarding the mechanism that both lead to, and underlie cell death include both genetic as well as epigenetic processes. Our laboratory has generated a c-tos-lacZ transgenic mouse that recapitulates expression of the protooncogene c-<u>fos</u>. During examination of embryonic and early postnatal mice we observed Fos-lacZ expression in several positives known to have components that undergo cell death; including the medial edge epithelium of the palate, the enamel knot of the developing incisor, the thymus, ossifying chondrocytes and a small population of ventral horn motor chondrocytes and a small population of ventral horn motor neurons. In order to determine if Fos-lacZ was expressed during periods of cell death, we examined two experimental models: neuronal death in the weaver mutant mouse, and neuronal death induced by kainic acid administration. In the early postnatal weaver cerebellum, expression of Fos-lacZ is observed in the post-mitotic premigratory cell population of the EGL, a site of expression not seen in wild-type mice. Following IP injection of neurotoxic doses of kainic acid, expression of Fos-lacZ was observed in degenerating cells of the hippocampus and amygdala. The kinetics of Fos-lacZ expression first appear several days following injection and remain detectable for approximately 2 weeks. These studies suggest that expression of the proto-oncogene, c-fos, may be involved in, or responsive to, the process of cell death.

AN INCREASE IN NEURONAL CYTOPLASMIC CALCIUM RESULTS IN INTERNUCLEOSOMAL DNA FRAGMENTATION. <u>Raijv Joseph</u>, <u>Wei Li and Enji Han</u>. Dept. of Neurology, Lab. of Experimental Hematology and Stroke, Henry Ford Hospital, Detroit, MI 48202.

Internucleosomal DNA fragmentation, secondary to endonuclease activation, is characteristic of programmed cell death. First noted in thymocytes following treatment with glucocorticoids, DNA fragmentation has also been noted in developing neurons, and in primary neuronal cultures treated with glutamate. As calcium is essential for endonuclease activation, we questioned whether activation of cytoplasmic calcium may directly or indirectly cause DNA activation of cytoplasmic calcium may intensity intensity case briva-fragmentation in neurons. For this purpose, we used PC12 and NCB-20 (Chinese hamster cortical neurons x mouse neuroblastoma, gift from M. Nirenberg, Bethesda, MD) cell lines. The calcium ionophore, A23187, caused a dose-dependent (as low as 10 nM) activation of cytoplasmic calcium and loss of cell viability, in association with DNA fragmentation, in both cell lines. DNA fragments, typical of internucleosomal digestion, were consistently detected in the incubating medium. Release of DNA fragments into the medium was time-dependent and observed within an hour of treatment. preceding loss of cell viability. Furthermore, calcium added directly to PC12 nuclei also produced DNA fragmentation. The mechanism by which an increase in cytoplasmic calcium causes activation of a nuclear enzyme, such as endonuclease, is unknown. Our observation that incubation of PC12 nuclei as enconuclease, is unknown. Our observation that incoduction for 2 nuclei with calcium also results in DNA fragmentation, indicates that calcium may activate endonuclease directly. However, this effect of calcium was less impressive compared to when DNA fragmentation was caused in intact cells by activation of cytoplasmic calcium, suggesting that calcium may also act indirectly for instance through a regulatory protein. In either event a critical change in the concentration of cytoplasmic calcium, either directly or indirectly activates endonuclease, resulting in the fragmentation of genomic DNA, and neuronal death.

CALCIUM-MEDIATED NEURONAL DEGENERATION FOLLOWING SELECTIVE LASER ACTIVATION OF PHOTOACTIVE NANOSPHERES. V.L. Sheen, \*E.B. Dreyer, J.D. Macklis. Dept. of Neurology, Prog. in Neuroscience, Harvard Medical School, Children's Hospital, Boston, MA, 02115.

A model of pathologic neuronal degeneration for studies of development and transplantation is provided by noninvasive, selective, photolytic cell population lesions to targeted neuronal subtypes following intracellular incorporation of cytotoxic chromophores. The histologic time-course of neuronal injury with this approach is prolonged, occurring over several days to weeks, without significant inflammatory response, suggesting features unique to this model and distinct from injury due to chemical toxins such as excitotoxic amino acids. In order to better define the mechanisms involved, resting cytosolic calcium levels were measured in vitro from cortical neurons cultured from C57B/61 mice following laser exposure.

Neurons were targeted by latex nanospheres conjugated with chlorin e<sub>e</sub> as a singlet oxygen producer. Decline of neuronal membrane integrity was studied in parallel by observation of propridium iodide (PI) incorporation, serving as an indicator for progressive cell injury, electrophysiologic decline, and death.

Singlet oxygen production within lysosomal granules caused an irreversible rise in cytosolic calcium, predominantly from influx of extracellular calcium. Time to peak calcium levels depended on the dosage of laser exposure. The increase in cytosolic calcium was observable within minutes following laser illumination. Incorporation of PI followed a slower time course (hours to days). Either the calcium channel blocker, nimodipine (0.1 uM), or calcium-free medium, reduced neuronal death by approximately 50% as assessed by PI incorporation. These results suggest that neuronal degeneration following singlet oxygen production by selective laser activation of photolytic chromophores occurs by both calcium dependent and independent mechanisms. This may be due in part to release of cytotoxic lysosomal contents. HD28478, HD18655, Alzheimer's Assoc, Rita Allen Fdn, and Lion's Fdn.

THE RELATIONSHIP BETWEEN TIME OF BIRTH AND TIME OF DEATH OF CELLS IN THE DEVELOPING RAT RETINAL GANGLION CELL LAYER L. Galli-Resta', M. Ensini and B. Margheritti Istituto di Neurofisiologia CNR 56127 Pisa Italy

In most neural centres, neurons are generated in a limited time window peculiar to the animal species. Many of these cells soon undergo cell death in a predetermined time interval. We have investigated whether a relation exists between the time of birth and the time of death for the cells of the rat retinal ganglion cell On fixed gestational days, BrU, which is incorporated by cells synthesising DNA, was administered to pregnant rats. On each postnatal day between P1 and P20, one or more pups were sacrificed. Retinae were whole-mounted and reacted with an antibody against BrU. In this way we could follow the time course of the total number of cells born on specific gestational ages and find when cells among them die. We have found that, among the cells undergoing naturally occurring cell death in the ganglion cell layer, the earlier the cells are born, the earlier they die.

### 247.4

WALLERIAN DEGENERATION IN THE MAMMALIAN CNS: EARLY DETECTION WITH MAGNETIC RESONANCE IMAGING. F.J. Lexa, R.I. Grossman and A.C. Rosenquist. Univ. of Pennsylvania Sch. of Med., Philadelphia,

Wallerian degeneration is a fundamental response of the nervous system to injury. Although manifestations of this process on magnetic resonance (MR) imaging have been reported in animal models and humans, it remains incompletely characterized. We undertook this study in order to examine the utility of measuring magnetization transfer rates (MTR) for delineating dynamic changes which occur after controlled injury in a feline model in which anatomic pathways are well understood. Using standard neurosurgical techniques all known visual cortical areas in the cat were ablated. Gradient imaging was performed serially at 1.5 Tesla, with and without a saturation pulse to create a magnetization transfer effect. At varying intervals, the animals were sacrificed for histologic analysis with light and electron microscopy.

Within the first two weeks there is a statistically significant increase in MTR relative to the control hemisphere within the white matter connections between the lateral geniculate nucleus (LGN) and the visual cortex (p < .02) at a time when no effects are visually detectable on conventional spin-echo images or light microscopy. Electron microscopy at 8 and 11 days confirmed early changes of Wallerian degeneration. Between 16 and 28 days, this reverses to a decrease in MTR in both thalamo-cortical white matter (p < 0.01) and the LGN (p < 0.05).

This application of magnetic resonance can reliably detect changes at a time when

degeneration is <u>not</u> detectable by other non-invasive imaging techniques or even light microscopy. Furthermore, temporal changes in MTR appear to correspond well with known histologic phases of Wallerian degeneration.

This work was supported by the American Society of Neuroradiology through a Basic Science Fellowship Award to F.J.L. and by N.I.H. grants NS 29029 (R.I.G.) and EY 02654 (A.C.R.).

The Ability of Diphenylpiperazines to Prevent Neuronal Death in Dorsal Root Ganglion Neurons In Vitro after NGF Deprivation and In Vivo After Axotomy Keith M. Rich,\* Innet M. Dubinsky, and Marc E. Eichler Washington University School of Medicine, St. Louis, MO 63110

Flunarizine, a class-IV Ca²\* entry blocker, is an effective cerebral protecting agent in models of brain hypoxia, ischemia, and in metabolic intoxication. Recently, DRG neuronal protection in vivo after sciatic nerve injury and in vitro after NGF withdrawal has been demonstrated with the diphenylpiperazine, flunarizine. We investigated the ability of the diphenylpiperazine, dihydropyridine, benzothiazipine, and phenylalkylamine groups of calcium channel antagonists to prevent neuronal deshi in primary dissociated rat dorsal root ganglion (DRG) neurons in vitro after nerve growth factor (NGF) deprivation and in vivo after sciatic axotomy. Only cinnarizine, a diphenylpiperazine calcium channel antagonist similar to flunarizine, protected DRG from death in vitro and in vivo. In vivo, cinnarizine given subcutaneously (50 mg/kg) protected DRG neurons in rat pups after unilateral sciatic nerve crush on PMD-1. Counts of L./L., DRG neurons in these rats revealed 88% cell survival in control animals (the difference was significant) students t-test, pc 0.0.5). Using an "5-methionine protein synthesis assay, we found that the efficacious dose of cinnarizine in vitro (10 µM) was significantly lower than flunarizine. (b 0 µM); this lower dose may have less toxicity and greater therapeutic value. The role of [Ca\*1] is trophic-factor-induced death remains unclear. DRG neurons in cell culture show as initial fall in [Ca\*1], between 24 and 48 hours after NGF deprivation; this fall occur prior to morphologic changes consistent with death. This decrease in [Ca\*1], is a trophic-factor-induced death remains unclear. DRG neurons is cell culture show as initial fall in [Ca\*2], in neurons "dying" after NGF deprivation. DRG neurons maintained in cell culture for 10 days an

EFFECTS OF DIFFERENT NEUROMUSCULAR BLOCKING AGENTS ON NATURALLY OCCURRING MOTONEURON DEATH DURING DEVELOPMENT IN VIVO. <u>L. J. Houenou', D. M. Prevette and R. W. Oppenheim.</u> Department of Neurobiology & Anatomy, Bowman Gray School of Medicine, Winston-Salem, NC 27157

The formation of normal nerve-muscle connections during vertebrate embryonic development is followed by the degeneration and death of approximately 50% of postmitotic motoneurons (MNs), Previously, it has been shown that the chronic blockade of embryonic neuromuscular activity (motility) with postsynaptic membrane potential stabilizing agents, including d-tubocurarine (dTC), resultes in the survival of virtually all postmitotic MNs (e.g., Pittman & Oppenheim, 1978). In the present study, we have compared the effects of depolarizing, i.e., decamethonium (dMET), and stabilizing, i.e., dTC, neuromuscular blockers on the survival of chick lumbar spinal cord MNs on embryonic day (E)10 following treatment from E6 to E9. The results show that both dMET and dTC significantly decreased embryonic motility to 25% of control. However, dMET did not affect the survival of MNs, while dTC enhanced MN numbers by 80%, compared to controls. Because both dMET and dTC bind to postsynaptic acetylcholine receptors, but at different sites, a group of embryos were simultaneously treated with both agents. In this case, MN survival was comparable to that obtained with dTC alone. Together, our results indicate that depolarizing and stabilizing neuromuscular blockers have different effects on avian MN survival in vivo and suggest that postsynaptic membrane depolarization may be a major factor that controls the fate of MNs during embryonic development. Additional experiments are underway to determine whether dMET treatment affects muscle innervation patterns and whether other depolarizing agents act similar to dMET.

NEURONAL APOPTOSIS: DEVELOPMENT OF A STUDY MODEL FOR THE IDENTIFICATION OF DEATH-RELATED PROTEINS. B. Petmann\* and P. Villa Laboratoire de Neurobiologie Ontogénique, Centre de Neurochimie du CNRS, 5, rue Blaise Pascal, 67084 STRASBOURG Cedex, FRANCE.

Programmed cell death which leads to the selective death of some neurons during development is a well known phenomenon. The idea that cell death is an active process in which the cells actually commit suicide through the biosynthesis of specific proteins is based on the observation that neurons cultured in the absence of their neurotrophic factor and which would therefore normally die, can be rescued by addition of translation inhibitors like cycloheximide. The proteins involved named "killer" proteins remain to be identified.

We have developed a study model consisting in cultures of neurons isolated from chicken ciliary ganglions at embryonic day 8 (CG8). Programmed neuronal death occurs in this ganglion and half of the neurons will die between E7 and E12. In vitro, the CG8 neurons survive only in the presence of a neurotrophic factor, either basic fibroblast growth factor (bFGF) or ciliary neurotrophic factor (CNTF). In their absence, the cells will die within 24-48 hours, but will be saved if cycloheximide or actinomycine D is added. In this system we have studied the biosynthesis of proteins. Fifty microcuries of <sup>35</sup>S methionine were added to the neurons immediately after seding, for 18 hours, in the absence or in the presence of CNTF or bFGF. After 18 h, cells were scrapped, proteins were extracted and submitted to 2D-electrophoresis. We compared the pattern of synthesized proteins on autoradiograms of 4 gels of cells cultured in the absence of trophic factors with 3 gels of cells treated with CNTF and 5 with bFGF. In all the autoradiograms of the untreated cells, we observed a strong stimulation of the synthesis of 4 proteins with molecular weights between 33 and 45 kD and isoelectric points between 5.5 and 6.2. These proteins are hardly visible in the autoradiograms of the treated cells.

We are currently trying to 1) investigate the presence of these proteins in another system of apoptosis (dorsal root ganglionic neurons and NGF); 2) get enough materiel to allow microsequencing or antibody production.

DEATH OF CEREBRAL CORTICAL NEURONS AFTER CLOSE AXOTOMY. P. S. Fishman\* and D. A. Parks. VA Research Lab., Dept. of Neurology, Univ. of Maryland Sch. of Med., Baltimore, MD 21201.

Although the neuronal response to axotomy is highly variable, adult corticospinal neurons survive long after their axons are severed in spinal cord or medullary pyramids. To determine if similar cortical neurons that project across the corpus callosum (transcallosal neurons) survive lesions that sever axons close to the cell body (close axotomy), neurons were first pre-labeled with the fluorescent dyes True Blue or Fluorogold by retrograde transport in adult mice. A uniform field of labeled transcallosal cells was formed by applying a dye-soaked gelatin sponge to a large area of contralateral cortex. Seven days later a stab wound was made through cortex contralateral to the label site dividing the field of pre-labeled transcallosal neurons into 2 groups: 1) neurons medial to the wound with intact axons projecting to the contralateral cortex, 2) neurons lateral to the wound that had undergone axotomy. Animals (20) were sacrificed between 1 and 5 wks after injury, while labeled but uninjured control animals (22) were sacrificed 1 to 7 weeks after labeling. Although control animals showed a variable number of labeled cells, density of labeled cells was uniform over a large area of cortex (4 mm²). In contrast, injured mice had progressive loss of neurons lateral to the stab wound. Loss of labeled neurons was particularly evident when comparing densities of labeled neurons in cortex immediately adjacent to wound sites. There was little direct damage to cortical neurons by the stab wounds, with labeled cell densities medial to the wound within the range of uninjured controls (500-2000 cells/mm²). Directly lateral to the wound cell densities were markedly reduced, with less than 10% of the expected cell density over a region within 1 mm lateral to the wound by 4 wks after injury. There appeared to be a gradual increase in labeled cell density with distances beyond 1 mm from the wound. In transcallosal neurons axotomy within 1 mm of the cell body results in extensive cell death. A minimum amount of axoplasmor remaining

A MODEL SYSTEM FOR CHARACTERIZING CELLULAR AND MOLECULAR EVENTS IN PROGRAMMED NEURONAL CELL DEATH. R. N. Pittman\* A. J. DiBenedetto, and S. Wang. Dept. of Pharmeology, Univ. of Pennsylvania School of Medicine, Philadelphia, PA 19104 Selected sublines of PC12 cells can be grown under culture conditions in which 90-95% of the cells become dependent on NGF for survival. Following removal of NGF in the absence or presence of serum, approximately 85% of the cell death can be blocked with the RNA synthesis inhibitor actinomycin D. This is consistent with the

Selected sublines of PC12 cells can be grown under culture conditions in which 90-95% of the cells become dependent on NGF for survival. Following removal of NGF in the absence or presence of serum, approximately 85% of the cell death can be blocked with the RNA synthesis inhibitor actinomycin D. This is consistent with the activation of cell death genes following removal of NGF. Properties of our PC12 model system are similar to those of primary cultures of sympathetic neurons (Martin et al., 1988; J. Cell Biol. 106:829). Committment to cell death occurs about 14 hrs after the removal of NGF, and can be blocked by KCl, bFGF, and dbcAMP, but not by protease inhibitors, EGF, or the endonuclease inhibitor ATA (DNA laddering, however, does occur following removal of NGF). In Agreement with published studies (Rukenstein et al., 1991; J. Neurosci. 11:2552), PC12 cells also undergo transcription-independent cell death when placed in serum-free medium; however, a large number of differences exist (eg. sensitivity to actinomycin D, KCl, and ATA) between this transcription-independent cell death and the transcription-dependent cell death ecommittment of PC12 cells to a dependence on NGF for survival, identifying cell death genes, and characterizing early transcriptional events in cell death. CORRELATION OF SINGLE CALCIUM CHANNEL OPENINGS AND ACETYLCHOLINE RELEASE FROM THE RELEASE FACE OF A CHOLINERGIC NERVE TERMINAL. E.F. Stanley\*. NINDS Biophysics Lab. NIH Bethesda MD 20892.

We have previously reported the direct recording of single Ca channels from the release face of a cholinergic presynaptic nerve terminal (Neuron 7:585). We now report an attempt to simultaneously detect ACh release.

Calyx-type presynaptic nerve terminals were acutely dissociated and patch electrodes were applied to the release face. The patch pipette included an assay solution that emits photons on exposure to ACh. Patch current and single-photon output were recorded simultaneously. Quantal transmitter release was identified as short bursts (SBs) of photons (>2 photons/0.3 ms). SBs were very infrequent at a -70 mV holding potential. Ramp depolarization increased SBs (p<<0.01), particularly over the voltage range of Ca channel activation. SBs were preceded by calcium channel opening events with a minimal and modal latency of 0.2 and 0.5

CALCIUM OSCILLATIONS AND EXOCYTOSIS IN PITUITARY GONADOTROPES. A.Tse\*, F.W.Tse, W.Almers and B.Hille. Dept. Physiol. and Biophysics, U. of Washington, Seattle, WA 98195.

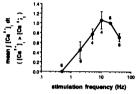

and Biophysics, U. of Washington, Seattle, WA 98195.

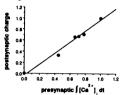

In adult male rat gonadotropes (identified by reverse hemolytic plaque assay), GnRH receptor stimulation induces an oscillatory release of intracellular Ca (Shangold et.al., PNAS 85:6566) from an IP<sub>3</sub>-sensitive store (Tse & Hille, Science 255:462). We examine whether this Ca release stimulates secretion from gonadotropes by simultaneously measuring [Ca], (indo fluorometry) and exocytosis (capacitance measurement). Gonadotropes are whole-cell voltage clamped at -70 or -90 mV (where voltage-gated Ca channels are closed), and a sinusoidal wave of 30 mV (pp) is applied at 800 Hz. GnRH ejected from a puffer pipet results in cyclic elevations of [Ca], at 20-25 °C, the resting [Ca], in gonadotropes is 86 ± 36 nM (mean ± S.D.; n = 12) and the peak elevated [Ca], ranges from 0.49 μM to 3.8 μM. Each cycle of Ca elevation is accompanied by a burst of exocytosis (up to 365 ff/cycle), sometimes followed by endocytosis. These phenomena persist in the absence of extracellular Ca, can be triggered by flash photolysis of caged IP<sub>3</sub> (10 μM) but are largely suppressed by buffering [Ca], with intracellular EG1A or BAPTA. The rate of exocytosis increases initially with the rise of [Ca], but typically reaches a maximum (up to 538 ff/s, corresponding to -400 vesicles/s) before [Ca], peaks. Voltagegated Ca entry induced by depolarizing voltage steps rarely supplies enough Ca for exocytosis. Therefore, oscillatory release of Ca from the IP<sub>3</sub>-sensitive store provides the major control of stimulus-secretion coupling in gonadotropes. (Supported by AM-17803, GM-39520, HD-12629, Mellon Foundation and McKnight Foundation.)

RELEASE OF LHRH IS LINEARLY RELATED TO THE TIME INTEGRAL OF PRESYNAPTIC CA<sup>2+</sup> ELEVATION ABOVE A THRESHOLD LEVEL IN BULLFROG SYMPATHETIC GANGLIA. Y.-y. Peng<sup>2</sup> & R. S. Zucker, Dept. of Molecular & Cell Biology, Univ. of California, Berkeley CA 94720

In the bullfrog sympathetic ganglia, the amount and rate of LHRH release from the preganglionic C terminals evoked by a train of electrical stimulation increased as the stimulation frequency increased from 2 to 20 Hz. At 40 Hz the amount of release decreased to less than that at 20 Hz (Peng & Horn, 1991). Here, the [Ca²\*] iat presynaptic terminal boutons caused by electrical stimulation was directly monitored by fura-2.

We found that as stimulation frequency increased from 0.5 to 40 Hz 1) the peak  $[Ca^{2+}]_Q$  and its rate of rise increased; 2) the decay of  $[Ca^{2+}]_q$  transients followed up to 3 exponentials; 3) release of LHRH was linearly related to  $[Ca^{2+}]_d$  twhere  $[Ca^{2+}]_r > [Ca^{2+}]_r$ . For a given set of boutons on a C cell,  $[Ca^{2+}]_r$  the threshold level of  $[Ca^{2+}]_r$  for LHRH release was estimated from the  $[Ca^{2+}]_r$  evoked by 0.5 Hz stimulation which did not induce release of LHRH. The mean  $[Ca^{2+}]_r$  was 185 nM (m=6). Supported by NIH grant NS15114 to RSZ.

POSSIBLE ROLE DURING EXOCYTOSIS OF SYNAPTOPHYSIN-LIKE Ca<sup>2+</sup>-ACTIVATED CHANNEL IN NEUROSECRETORY GRANULES OF NEUROHYPOPHYSIS. J.R. Lemos\*, C.J. Lee, G. Dayanithi, and J.J. Nordmann. Worcester Found. Exp. Biol., Shrewsbury, MA 01545 & Centre Neurochimie, Strasbourg, France.

A large amplitude channel, from purified bovine neurosecretory granules (NSG), was incorporated into artificial lipid bilayers. This channel opens only in the presence of free Ca<sup>2+</sup>, but is inhibited by relatively high Ca<sup>2+</sup> concentrations. Release of vasopressin from permeabilized neurohypophysial terminals also shows a similar biphasic dependence on Ca<sup>2+</sup>. Release is selectively inhibited by low concentrations of the long-chain alcohol octanol, but not by high concentrations of ethanol, as is the NSG Ca<sup>2+</sup>-activated channel. Furthermore, Ca<sup>2+</sup>-evoked release and channel activity are both inhibited by 10 carbon-long chain TEA-analogs. Most importantly, both the Ca<sup>2+</sup>-activated NSC channel and Ca<sup>2+</sup>-dependent release are inhibited by SY-38: a monoclonal antibody directed against the putative Ca<sup>2+</sup>-binding site of synaptophysin, an integral NSG membrane protein. The close correlation between channel and release properties leads us to conclude that this synaptophysin-like NSG channel may be involved in peptide secretion. (Supported by grants from IREB, NIH, and NSF).

THE ROLE OF VESICULAR MOBILIZATION IN TONIC TRANSMITTER RELEASE AND POTENTIATION IN THE CRAB T-FIBER GIANT SYNAPSE. J.-W. Lin\* and R. Llinas. Dept. Physiology and Biophysics. NYU Medical Center. NY NY 10016.

The crab T-fiber giant synapse is formed between the stretch receptor afferent, T-fiber, and promotor neurons. The presynaptic element, T-fiber, is a non-spiking neuron which releases transmitter tonically. The large size of the presynaptic erminal allowed double eletrode penetration and the active control of membrane potential at the release sites. Following a prolonged (300 ms) presynaptic depolarization, transmitter release activated by test pulses was enhanced. This potentiated transmitter release exhibited kinetic properties that are best described by a model requiring the control of synaptic vesicular mobilization. A mathematical model was constructed that divided the synaptic vesicle population into two groups. The first group is stationary and can be converted into a second, mobile and releasable population. The conversion is dependent upon the activity of the presynaptic terminal, i.e. a prolonged presynaptic depolarization would activate it, by way of calcium influx, in order to maintain tonic release. In addition, this mechanism can account for the potentiation described above. Specifically, as the conditioning pulse is terminated, the tonic transmitter release stops immediately while the vesicle mobilization continues for a brief period. This process leads to an accumulation of releasable vesicles at the release site and potentiated release. At a microscopic level, autocorrelation analysis of the synaptic noise during tonic release revealed an intrinsic periodicity that was not found in the synaptic noise of the squid giant synapse. This periodic behavior presumably reflects a cycling time which determines the rate of repetitive release at individual release sites. (Supported by NIH grant NS13742 and NS07942-02).

### 248.4

CALCIUM MICRODOMAINS IN SQUID GIANT PRESYNAPTIC TERMINALS STUDIED WITH N-AEQUORIN-J. R. Llinás\*. M. Sugimori and R. B. Silver, Dept. of Physiology & Biophysics, NYU Medical Center, 550 First Avenue, NY, NY 10016, and Section and Dept. Physiology, Cornell University, Ithaca, NY 14853-6401.

The presence of specifically located calcium channels at the active

The presence of specifically located calcium channels at the active zone of presynaptic terminals indicates that the calcium-dependent release of transmitter requires high calcium concentration profiles to trigger synaptic vesicle fusion (Llinás, Soc. for Neurosci. Symposia 2:139 1977). Calculations based on presynaptic current measurements indicate that  $[Ca^{2+}]_i$  against the interior plasmalemma surface could rise to  $10^4$  M (Simon & Llinás, Biophys. J. 48:485, 1985). To test this hypothesis a hybrid synthetic n-aequorin-J having a sensitivity to  $[Ca^{2+}]_i$  in the order of  $10^{-4}$  M was injected into the preterminal of the giant synapse of the squid Loligo pealii.

The photon emission by n-aequorin-J following increased  $[Ca^{2+}]_i$  was visualized using a VIM camera operated in the photon counting mode. The results indicated  $[Ca^{2+}]_i$  microdomains on the order of  $10^4\,\mathrm{M}$  occurs at particular sites, or quantum emission domains (QEDs), that correspond in size, number and distribution to the active zones in the squid giant synapse. In addition, QEDs tend to occur as short lasting events that are never continuous in time, suggesting calcium-dependent calcium inactivation of individual active zones. This mechanism may be responsible for the "one vesicle per active zone" rule.

We extend our deep gratitude to Dr. Osamu Shimomura, who kindly provided the n-aequorin-J used in this study. (AFOSR89-0270)

### 248.6

ROLE OF L-TYPE CALCIUM CHANNELS IN SLOW DEVELOPING POTENTIATION IN APLYSIA: S.M. Fredman\*Dept. of Physiology, Meharry Medical College Nashvilla EN 37008

Meharry Medical College, Nashville, TN 37208. Slow developing potentiation (SDP) is a form of enhanced synaptic transmission exhibited at the A-B neuron synapse in the cerebral ganglion of Aplysia. Brief intracellular tetanic stimulation (4x 500 msec @20 Hz) of single A neurons causes a long-lasting (~25 min) increase in EPSP amplitudes in B neurons (Fredman, 1991). Previous results (Fredman, 1990) suggested that SDP was due in part to the presynaptic activation of PKC. Evidence is now presented suggesting that PKC may be acting on L-type Ca<sup>2+</sup> channels. SDP presented suggesting triat. FIX. Thay be acting on 1-type Ca. Challines. Journey required more Ca<sup>2+</sup> than did synaptic transmission alone. Intracellular injection of nonspecific Ca<sup>2+</sup> blockers (Ni<sup>2+</sup>), and Ca<sup>2+</sup> chelators ( EGTA), blocked SDP prior to blocking synaptic transmission. Bathing the cerebral ganglion in 50  $\mu$ M ryanodine to increase Ca<sup>2+</sup> sequestration, reduced SDP without effecting nonpotentiated EPSPs. SDP was also reduced by L-type Ca<sup>2+</sup> channel blockers. Verapamil (150  $\mu$ M) and several dihydropyridines (10-100  $\mu$ M nifedipine, 10-50  $\mu$ M isradipine, 10  $\mu$ M darodipine) all significantly reduced SDP. The dihydropyridines, particularly at high concentrations, had multiple effects. The falling phase of the presynaptic action potentials were broadened resulting in an increase in baseline EPSP amplitudes. Despite this increase, the relative amplitude of EPSPs following tetanizing trains were reduced compared to controls. Taken together these results suggest that SDP is mediated by increased presynaptic Ca<sup>2+</sup> due, in part, to the activation of L-type Ca<sup>2+</sup> channels. In light of previous findings, they suggest that L-type channels may be phosphorylated by PKC, increasing their opening and intracellular Ca2+, thus enhancing synaptic transmission.

This work was supported by NINDS grant NS28199 and NIGMS (MBRS) grant GM08037. Isradipine and darodipine were gifts from the Sandoz Research Inst.

QUANTAL TRANSMITTER SECRETION FROM MYOCYTES LOADED WITH ACETYLCHOLINE. Y. Dan\* and M-m. Poo. Dept. of Biol. Sci., Columbia Univ., N.Y., NY 10027.

Acetylcholine (ACh) was loaded into isolated Xenopus myocyte through a whole-cell recording pipette, which also served to record the myocyte membrane current. Within minutes after the onset of recording (with 10 mM ACh in the pipette), pulsatile inward currents resembling miniature endplate currents (MEPCs) were observed. These MEPC-like events increased in frequency and amplitude with time, and were abolished by extracellular application of curare and -bungarotoxin. The frequency of the events increased markedly after repetitively depolarizing the myocyte membrane potential or after treatment that elevated cytosolic Ca<sup>2+</sup>. These events reflect quantal ACh secretion by the myocyte, and the secretion appeared to be a result of exocytosis of ACh-filled cytoplasmic compartments. The latter notion is supported by the finding that vesamicol, a drug that blocks ACh uptake into synaptic vesicles, reduced the frequency and amplitude of these events, and that cytosolic application of cholinesterases after ACh loading resulted in a gradual disappearance of the events without significant change in their mean amplitude. Finally, evoked ACh secretion was also observed occasionally after applying depolarizing voltage steps to the myocyte, and the efficacy of secretion was improved by elevating external Ca<sup>2+</sup>. Taken together, these results indicate that transmitter secretion does not require secretion pathways unique to neurons, and the essence of presynaptic differentiation may reside in the provision of transmitter supply and synapse-specific proteins whose functions are facilitatory in nature.

QUANTAL ANALYSIS OF EXCITATORY SYNAPTIC TRANSMISSION: THEORY AND EXPERIMENTAL APPROACH FOR DETECTION OF SMALL QUANTA EVENTS. Guosong Liu\* & I.L. Feldman. System Neurobiology Lab., Dept. Physiological Science, UCLA, Los Angeles, CA 90024-1527. Quantal analysis is an important tool for analysis of pre- and post-synaptic mechanisms underlying synaptic transmission. However, the experimental conditions for quantal detection have not been well defined. Our results from analysis of simulated synaptic currents suggest that direct resolution of quantal peaks requires the ratio of quantal peak (q) to quantal standard deviation (σ) > 2.2. We studied the factors that influence this ratio and developed experimental techniques that enhance it.

influence this ratio and developed experimental techniques that enhance it.

For measurement of synaptic current, q/\sigma\text{ratio} is reduced by: slow frequency response of voltage-clamping system (caused by series resistance); distal origin of synaptic current; and high background noise. To distinguish the current amplitude distribution from noise, digital filtering techniques were compared, based on enhancement of q/\sigma\text{ratio} add \text{q}/\sigma\text{ratio} add \text{q}/\sigma\text{ratio} add \text{q}/\sigma\text{ratio} add \text{p}/\sigma\text{ratio} a

PEPTIDES HOMOLOGOUS TO THE RAB3 EFFECTOR DOMAIN STIMULATE NEUROTRANSMITTER RELEASE IN <u>HELISOMA</u> NEURONS. J.E. Richmond\* and P.G. Haydon. Dept of Zoology and Genetics, Iowa State University, Ames, IA 50011.

Small GTP-binding proteins of the rab gene family are involved in vesicular transport through the secretory pathway. Of the rab GTPases, rab3A is selectively expressed in neurons and is associated with synaptic vesicles. In the present study we asked whether perturbation of rab3 affects neurotransmitter release at cultured Helisoma synapses. Using chemical synapses that form between contacting somata we first injected the non-hydrolyzable GTP analogue, GTP S. Under conditions where action nyarolyzable (1) analogue, (1) noter conditions where action potentials were evoked presynaptically, the frequency of spontaneous miniature currents (MIPSC) increased in response to GTP/6, whereas GTP had no effect. To more specifically perturb rab3 we microinjected synthetic peptides with sequences spanning the putative effector domain of rab3A. Injection of rab3AL caused a dose-dependent increase in MIPSC frequency with a half-maximal effect at about 30µM, and a three-fold increase in MIPSC frequency at a concentration of 40-60 $\mu M$ . No significant increase in evoked release was observed. The increased MIPSC frequency was sustained in high  $Mg^{2+}/zero\ Ca^{2+}$  external saline indicating that the enhanced release was not due to an increase in Ca<sup>2+</sup> influx. Injection of the peptide rab3(29-38) caused a similar increase in MIPSC, while injection of a peptide bearing little homology to the rab3 effector domain (ral), had no effect on MIPSC frequency. Together these results demonstrate that manipulations aimed at perturbing rab3-target interactions, modify synaptic transmission and provide evidence for a role of rab proteins in regulating neurotransmitter release.

RELEASE PROPERTIES, FACILITATION AND DEPRESSION OF EXCITATORY SYNAPSES ON DENTATE GRANULE CELLS, STUDIED BY SINGLE AXON ACTIVATION.

Morten Raastad \*, Institute of Neurophysiology, University of Oslo, Norway

The excitatory response to a second stimulus given shortly after an identical first one, can be larger (facilitation), or smaller (depression) than the initial response. In hippocampal slice preparations with blocked inhibition, the synapses between Schaffer-collaterals and CA1 cells demonstrate facilitation, while depression is more commonly seen in the synapses between perforant path fibres and the dentate granule

Double stimulation of single axons (Soc.Neurosci.Abstr 1991, 593.9) was used to study depression and release properties of excitatory synapses on d.g. cells. Reliable activation of one synaptically connected axon was possible by weak electrical stimulation with a small glass electrode, using a range of stimuli around the threshold for the appearance of EPSCs.

Intracellularly recorded single fibre EPSCs from d.g. cells showed considerable variability in amplitude, like the synapses in the CA1 area. Unlike the latter synapses, however, the release probability was near 100% with 2 mM Ca++ and 2 mM Mg++ in the extracellular solution. In this situation, there was a negative correlation between the individual amplitudes of the first and second response, and with a smaller average amplitude of the second response, corresponding well with the observed depression. By reducing the Ca<sup>++</sup> concentration to 1 mM and increasing the Mg<sup>++</sup> concentration to 4.5 mM a clear population of failures appeared in the amplitude histograms. Under these conditions, the average second response was facilitated, corresponding to a reduced number of failures in response to the second stimulus. In conclusion, facilitation required a situation in which the release probability could increase, and thereby overcome the simultaneously present depression. Supported by NAVF/RMF 326.91-031.

IMAGES OF SYNEXIN IN RAT BRAIN: HETEROGENEOUS DISTRIBUTION WITHIN LIMBIC STRUCTURES AS DETERMINED BY COMPUTER-ENHANCED NEURO- IMMUNOCYTOCHEMISTRY, H.B. Pollard\* R. Eicheberrigaray, H. Caohuy, D. L.Alkon, and J. L. Olds, Laboratory of Cell Biology and Genetics, NIDDK; and Neural Systems Section, NINDS, NIH. Bethesda, MD. 20892.

Synexin (Annexin VII) is a calcium-binding protein with membrane fusion and calcium channel properties, which occurs in brain with an additional specific, cassette-exon defined domain of 22 amino acids edited into the unique N-terminal region. The exact function is not known, but we report here that an affinity purified polyclonal antibody directed against the 22 residue peptide from human brain synexin is heterogeneously distributed in the rat brain. The specific localization includes (1) hippocampal pyramidal cells in CA1 and CA3, granule cells of the dentate gyrus, and Schaffer collaterals which are axonal projections of CA3; (2) cingulate cortex, layers 2-6; (3) somatosensory cortex, layers 2-6, including heterogeneous column-like structures; (4) Thalamus, including ventromedial lateral (VML) and ventral posterior medial (VPM) nuclei, which are motor projections to the motor cortex; (5) axons in the corpus callosum; (6) the lateral habenula, which shares with inferior colliculus the highest intensity of deoxyglucose metabolism in rat brain; (7) the ventral aspects of the pars reticularis of the substantia nigra, which contains GABA-ergic terminals from neurons in the caudate-putamen; and (8) axons in the corpus callosum. A second polyclonal antibody against a peptide from the C-terminal domain of synexin prepared in a different animal gave nearly identical distribution in rat brain. High power views demonstrate unambiguously that synexin is enriched in neuronal somata and axons. We conclude that there seems no evidence for molecular heterogeneity in synexin distribution in rate brain, and that furthermore, the distribution seems limited to specific regions of the limbic system and axons.

HEPARIN-BINDING GROWTH-ASSOCIATED MOLECULE (HB-GAM) IN AXON GROWTH AND GUIDANCE. H. Rauvala, J. Merenmies, R. Pihlaskari, E. Raulo, E. Castrén and P. Panula. Institute of Biotechnology and Department of Anatomy, Univ. of Helsinki, Helsinki, Finland, SF-00380.

HB-GAM (p18) was isolated from perinatal rat brain as a developmentally regulated, secretory protein that enhances neurite outgrowth from protein that enhances neurite outgrowth from brain neurons in vitro. Molecular cloning of HB-GAM has revealed a conserved lysine-rich sequence. To characterize the role HB-GAM in brain development, we studied its distribution in developing rat forebrain by in situ hybridization and immunohistochemistry. A strong expression of the HB-GAM mRNA was found in cortical neuroepithelium and in developing layers of the cerebral cortex. The most prominent expression of the HB-GAM protein was found in tracts that follow developing axonal processes in several areas of the brain, for example in cerebral cortex, corpus callosum and fimbriae. To study, whether such tracts of HB-GAM could influence neural patterning, pathways of brain-derived and baculovirus-derived recombinant HB-GAM were created on culture wells. The HB-GAM pathways were found to strongly enhance patterned growth of axons from rat forebrain neurons. We suggest that HB-GAM plays a role in axonal pathfinding in perinatal rat brain.

EXPRESSION OF THE BARRIER-ASSOCIATED PROTEINS EAP-300 AND CLAUSTRIN IN THE DEVELOPING CENTRAL NERVOUS SYSTEM. Craig F. McCabe, Robert M. Beckstead\*, and Gregory J. Cole, Department of Anatomy and Cell Biology, Medical University of South Carolina, Charleston, SC 29425.

Immunohistochemistry of embryonic chick central nervous system (CNS) and immunocytochemistry of retinal cells were performed to compare and map the expression of two barrier-associated molecules. EAP-300 (Embryonic Avian Polypeptide of 300 kDa) and claustrin (a 320 kDa extracellular matrix keratan sulfate proteoglycan) were both transiently expressed in CNS regions that are considered nonpermissive to either neuron migration or axon growth. In the developing spinal cord, EAP-300 and claustrin were both expressed by the marginal zone early in development, and by the roof plate later in embryogenesis. In the developing rhombencephalon, immunoreactivity for both molecules was also observed first in the marginal zone, and later expression was restricted mostly to the midline. In the mesencephalon, EAP-300 and claustrin were also localized to the midline, and this expression represented a continuation of the expression observed in the spinal cord roof plate and hindbrain ventral midline. In the developing retina and cerebellum, EAP-300 and claustrin were differentially expressed. In retina, EAP-300 and claustrin were expressed by Müller cells and the optic fiber layer, respectively. In cerebellum at embryonic day 12 (E12), EAP-300 was expressed by Bergmann glia, but claustrin was not expressed until E15. Immunocytochemical staining of retinal and cerebellar cultures indicated that EAP-300 was expressed by a subset of radial astrocytes, as confirmed by double labeling experiments with a specific marker for radial astrocytes. These data indicate that in the absence of claustrin expression, EAP-300 was expressed by a radial astrocytes during developmental periods of neuron migration. Also, the coexpression of EAP-300 and claustrin in CNS regions considered to be nonpermissive to neurite extension suggests that these two developmentally regulated proteins may be associated with barrier function in the developing CNS. Supported by EY07130.

A HEPARAN SULFATE PROTEOGLYCAN IN DEVELOPING AXONAL PATHWAYS W. Halfter Dept. of Neurobiology, University of Pittsburgh

Two monoclonal antibodies against heparan sulfate proteoglycan (HSPG) were generated by immunizing mice with embryonic chick retina basal laminae (clone 3Al2) and embryonic chick optic nerve (clone 6D2). Both antibodies recognized a new type of HSPG that appears transiently in developing chick axonal tracts. In early stages (E3), the antibodies labeled basal lamina only. During further development, in addition to basal laminae a strong staining of the optic nerve and other fiber tracts in the brain and spinal cord was found. The axonal staining peaked between E8 and E10 and decreased afterwards. By E14, the axonal staining had disappeared, while the labeling of basal laminae persisted. Western blot analysis showed that the antigen had a molecular weight of 600kD that dropped to 250kD upon treatment of the sample with heparitinase or nitrous acid, showing that the antibodies recognized the core protein of a HSPG. Antibodies against HSPG from non-neuronal tissue, such as the EHS mouse tumor, or embryonic chick muscle, did not label axonal tracts, suggesting a unique HSPG in developing nervous tissue. The function of the protein might be to localize adhesion proteins and growth factors to the growing axons before trophic support from the target becomes available.

GROWTH CONES FOLLOW WIDELY DISTRIBUTED DIRECTIONALITY CUES IN THE ZEBRAFISH BRAIN. J.P.Kanki, S. Akhtar, and J.Y.Kuwada\*. Dept. of Biology, University of Michigan, Ann Arbor, MI. 48109-1048.

Growth cones follow precise, cell specific pathways to reach their targets in the zebrafish CNS. To do this growth cones must extend in the correct direction along their appropriate pathways. Directionality cues may be limited to a pathway or be more widely distributed. To determine the distribution of directionality cues, the epiphysial neurons, located laterally at the base of the epiphysis, were transplanted to ectopic sites in the brain of isochronic host embryos and allowed to develop further. Donor cells but not host cells were labeled with FITCdextran by the prior injection of dye at the 1-2 cell stage. This allowed the visualization of the transplanted cells. Epiphysial growth cones normally extend ventrally from the epiphysis. The growth cones of orthotopically transplanted neurons also extend ventrally, indicating that the transplant method does not unduly damage the donor cells or the host environment. Similarly, the growth cones of donor neurons in ectopic sites overwhelmingly extended ventrally although in principle they could have extended in any direction from their ectopic sites. This was true even at a site where host growth cones were known to extend dorsally. These data suggest that directionality cues that epiphysial growth cones can read are widely distributed in the embryonic brain.

F3 NEURONAL CELL ADHESION MOLECULE IS POLARIZED ON AXONS AND ITS SOLUBLE FORM PROMOTES NEURITE OUTGROWTH. G.N.Rougon<sup>1</sup>, P. Durbec<sup>1</sup>, C. Faivre-Sarrailh<sup>1</sup>, J.P. Ternaux<sup>2</sup>\* and G. Gennarini<sup>2</sup>. CNRS 179, Université de Marseille-Luminy; <sup>2</sup> CNRS 418 Marseille; France, <sup>3</sup> Università di Bari, Italy.

Luminy, 2 CNRS 418 Marseille; France, 3 Università di Bari, Italy.

The establishment of the complex network of specific neuronal connections is critically dependent on the correct outgrowth of axons to their cellular targets. The F3 molecule is a member of the immunoglobulin superfamily anchored to membranes by a glycane-phosphatidylinositol, and is predominently expressed on a subset of axons. We investigated its distribution by light and electron microscopy in cerebellum and found that the granule cell axons strongly express F3 as soon as they begin to grow, consistent with a role in promoting directional outgrowth of axonal processes. In adult cerebellum, F3 present at three types of synaptic sites, suggesting it might also play a role in the formation and maintenance of synapses. In each type of synapse F3 is present at only one synaptic site, never at both, indicating that F3 mediates heterophilic interactions. (Faivre-Sarrailh et al. J. Neurosc. 1992. 12; 257-267).

The question as to whether soluble forms of F3, that are detected in developing nervous system, would be functionally active was addressed in vitro on culture of mouse sensory neurons. Preparations enriched in soluble F3 have no effect on neuron attachment and survival but enhance neurite initiation and neurite outgrowth in a dose-dependent manner (Durbec et al. J. Cell Biol. in press). These results suggest that the soluble forms of adhesive proteins with neurite outgrowth promoting properties act at distance of their site of release in a way reminescent of growth and trophic factors.

LASER INACTIVATION OF HNK-I PERTURBS LATERAL LONGITUDINAL FASCICLE FORMATION IN THE ZEBRAFISH HINDBRAIN.

E.M. Shah and D.G. Jay\*. Department of Cell. and Developmental Biology,

Harvard University, Cambridge, MA 02138

During zebrafish development, the trigeminal axons project to the Rohon-Beard axons to form the lateral longitudinal fascicle. The coincident specific expression of the glycosyl moiety, HNK-1, on both of these neuronal subtypes (Metcalfe et al. Devel. 110, 1990) suggests that HNK-1 may be involved in target recognition when these neurons interact. By applying the technique of chromophore assisted laser inactivation (CALI) (Jay and Keshishian., Nature, 348:548, 1990), we have endeavored to characterize the in vivo function of the molecule(s) recognized by the HNK-1 antibody during zebrafish neural development.

HNK-1 antibody during zeorarisn neural development. We have developed an efficient method for vital labeling of the zebrafish neural cell surfaces with HNK-1 antibody. Yolk injections of HNK-1 antibody between 10 and 15 hours post-fertilization result in 89% of the injected embryos exhibiting HNK-1 staining of the trigeminal and Rohon-Beard neuron surfaces at 17 hours post-fertilization. Embryos injected with malachite-green labeled HNK-1 antibody at the 4 somite stage, irradiated at the 14 somite stage and fixed at the 20 somite stage exhibited a perturbation in the normal morphology of the lateral longitudinal fascicle in 55% (10/18) of the cases. We observed either disordered fascicles, differential growth rates of contralateral fascicles and/or failure of the Rohon-Beard and trigeminal axons to meet. Embryos injected with malachite green-labeled HNK-1 antibody, but not irradiated, exhibited perturbations in 14% (5/34) of the cases, while those injected with control reagents and irradiated had perturbations in 20% (2/10) of the cases. These preliminary results using CALI suggest a role for an HNK-1 immunoreactive cell surface molecule in the formation of the lateral longitudinal fascicle in the developing zebrafish.

BEN, A NOVEL ADHESION MOLECULE TRANSIENTLY EXPRESSED DURING AXONAL MIGRATION OF MOTONEURONS AND CLIMBING FIBERS. O. Pourquié, M.E.R. Hallonet, and N.M. Le Douarin\*, Institut d'Embryologie du CNRS et du Collège de France, 49 bis Avenue de la Belle Gabrielle, 94130 Nogent-sur-Marrie FRANCE

Institut d'Embryologie du CNRS et du Collège de France, 49 bis Avenue de la Belle Gabrielle, 94130 Nogent-sur-Mame FRANCE.

We have previously reported the identification by means of a Mab, of a 95-110 kd membrane glycoprotein that we call BEN. This protein is expressed in the chick embryo on various cell types among which hematopoietic and neural cells. We have shown that BEN expression is selectively associated with axonal migration on the peripherally projecting neurons, including the motor and sensory neurons. Its distribution during avian cerebellum ontogenesis was investigated by immunocytochemistry and was suggestive of a selective expression on the climbing fibers. We have used a quali-chick chimera grafting system which enabled us to obtain chimeras with a cerebellum exclusively composed of quail cells whereas the inferior olivary nucleus was composed of chick neurons. These animals where studied in double staining with a Mab which recognizes chick neuronal fibers at the exclusion of quail ones together with antibodies directed against the BEN protein. We could show that the BEN positive fibers were of chick origin implicating that their source was extrinsic to the cerebellum. We conclude that BEN is transiently expressed during cerebellum development on the climbing fibers. Using polyclonal antibodies we have shown that BEN is implicated in neuronal aggregation. Biochemical analysis of the purified protein has revealed that it is heavily glycosylated in a tissue specific manner and bears the HNK-1 epitope. We have cloned a full length cDNA encoding this protein. Analysis of its sequence shows that it is a new member of the Ig superfamily with an original structure. Two neural adhesion molecules SC1 and DM-GRASP that share an identical sequence have been simultaneously identified. These proteins are similar in structure to the human melanoma marker MUC18 and are likely to define a new subgroup of adhesion molecules of the Ig superfamily. We conclude that BEN/SC1/DM-GRASP might represent an avian homolo

# 249.8

RESTRICTED EXPRESSION OF N- AND R-CADHERIN ON NEURITES OF THE DEVELOPING CHICKEN CNS. C. Redies<sup>1,2,4</sup> and M. Takeichi<sup>1</sup> Dept. Biophysics, Fac. Science, Kyoto University, Kyoto 606, Japan, and <sup>2</sup>Dept. Biochem., Max Planck-Institute Dev. Biology, Tübingen, Germany

The expression of two cadherins, N- and R-cadherin, was mapped in the CNS of chicken embryos of 6-11 days incubation. Throughout the neural axis, both molecules are expressed in a developmentally and topographically restricted manner. In the spinal cord, the laterally located fibers of the dorsal funiculus express N-cadherin while the medially located fibers do not. These two fiber systems have a different course within the CNS. In the hindbrain, N-cadherin is expressed by the descending trigeminal (general somatic sensory) tract and R-cadherin by the visceral motor fibers of the vagus and glossopharyngeal nerves. Other tracts and nuclei expressing either N- or R-cadherin are found in the mid- and forebrain.

The possibility that N-cadherin provides a guidance cue for

The possibility that N-cadherin provides a guidance cue for axon migration within the CNS by a homophilic adhesion mechanism was investigated in vitro. Axon outgrowth from E6 sensory ganglia was studied on N-cadherin-transfected neuroblastoma cells. The N-cadherin-positive sensory axons defasciculate and follow the cell-cell borders between transfected cells where high levels of N-cadherin are expressed. These results suggest that the topographically restricted expression of N-cadherin during chick brain development may play a role in guiding N-cadherin-positive neurites along CNS paths which express the same molecule.

SUBSETS OF OLFACTORY AXONS THAT EXPRESS LACTOSERIES GLYCOCONJUGATES ARE ASSOCIATED WITH EXTRACELLULAR LACTOSE-BINDING LECTIN, L-14, AND LAMININ. G. A. Schwarting\* and N. K. Mahanthappa, E.K.Shriver Ctr., Waltham, MA 02254; and and Program in Neuroscience, Harvard Medical School, Boston, MA 02115.

A homogeneously distributed subset of neurons in the mature olfactory epithelium of rats express terminally lactosaminylated glycolipids that react with the monoclonal antibody, 1B2. In adult rats, 1B2+ axons can be detected in the outer portion of the nerve layer of the olfactory bulb (OB), and can be seen branching through the inner portion of the nerve layer into individual 1B2+ glomeruli; about 10% of glomeruli are 1B2+. L-14, a lactose-binding lectin capable of binding laminin-associated 1B2+ glycolipids and polylactosamine, is also expressed in the olfactory system. Immunocytochemistry using antiserum to L-14 (gift of D. Cooper, UCSF) has demonstrated that this lectin is in the outer portion of the OB nerve layer and on structures branching toward the the glomerular layer, overlapping with Blathering toward the the glotheridal layer, overlapping with 182+ regions. We show that 182+ axons and L-14 co-localize with a subset of laminin+ tracks leading to 182+ glomeruli. These data suggest that L-14 may promote non-integrinmediated, laminin interactions with elongating, 182+ olfactory axons.

MAbs #4 & 199 SPECIFICALLY INHIBIT ATTACHMENT OF NG108-15 CELLS TO LOW, BUT NOT HIGH AMOUNTS OF LAMININ. N. R. <u>Smalheiser\* and B. J. Collins</u>. Dept. of Pediatrics, Univ. of Chicago, Chicago, IL 60637.

E14 chick brain membrane proteins were purified by DEAE, con A and SDS-PAGE; a band containing cranin was DEAE, con A and SDS-PAGE; a Dang containing cranin was injected into mice to raise monoclonal antibodies. MAbs #4 and 199 recognize a non-integrin ~125 kDa band (N.S., Trans. Am. Soc. Neurochem. 22: 203 '91) which binds to laminin affinity columns in a calcium—and conformation-dependent manner. MAb #4 Ag is co-expressed with laminin in chick CNS and regenerating goldfish optic nerve

dependent manner. MAD #4 Ag is co-expressed with laminin in chick CNS and regenerating goldfish optic nerve (Collins et al. Eur. J. Neurosci. suppl. 4: 295 '91).

To learn if MAD #4/199 antigens are involved in cell responses to laminin, MADs were purified from hybridoma spent medium (cells grown either in serum-free medium, or containing 10% FCS) by hydroxyapatite and ammonium sulfate precipitation. MADs (100 μg/ml) were added with NG108-15 cells and plated in serum-free medium on plastic Petri dishes treated with laminin (1-5 ng/mm²) and blocked with BSA (0.3%). Short-term (1.5-7 hr) and long-term (16-24 hr) assays gave similar results: Both MAD #4 and 199 inhibited cell attachment to laminin (1 ng/mm²) by 60-70% relative to controls (BSA or mixed mouse IgG, 100 μg/ml), but did not inhibit attachment at all to high laminin (5 ng/mm²), bovine plasma fibronectin (0.5-1 ng/mm²), or polylysine. A MAD against ACAM (GC-4) did not inhibit attachment to any surface tested. These data suggest that MAD #4/199 antigens play specific roles in lamininmediated adhesion. Supported by NS 26055, HD 09402, and the March of Dimes Birth Defects Foundation.

KINETICS AND ULTRASTRUCTURAL 3D RECONSTRUCTION OF DEVELOPING TUBEROUS ELECTRORECEPTORS IN THE ELECTRIC FISH EIGENMANNIA

H.A. Vischer.\* Neurobiology Unit, S.I.O., UCSD, La Jolla, CA 92093-

Epidermal tissue of embryonal and juvenile developmental stages of Eigenmannia, a South American, weakly electric fish, was processed for electron microscopy. Serial thick sections (0.5  $\mu$ m) through developing electroreceptors were photographed with a JEM-1000 High-Voltage Electron Microscope at 1000 kV. Images were subsequently digitized and processed with a reconstruction program on a PC to render 3D pictures. Additional tissue was prepared for histochemistry with Safranin O, a marker for mitotic figures in dividing cells. After the afferent fiber penetrates the basal lamina and invades the receptor primordium, it birfurcates into two classes of branches: 1) Branches that form synaptic contacts with primordial receptor cells and 2) collateral branches that sprout to the periphery of the primordium. These latter collaterals do not form synaptic contacts and degenerate during further development. Synaptic contacts are smaller at early developmental stages than at older stages. On the are smaller at early developmental stages than at older stages. On the other hand, presynaptic ribbons are longer and interconnected at their apical ends in early stages and shorter and solitary after synaptic maturation. Supporting cells derive from receptor-primordium cells and divide within the supporting cell layer. At the periphery of this layer, they differentiate into new primordial receptor cells which subsequently shift upwards to the receptor cell layer and mature.

SURFACE AND CYTOSKELETAL MARKERS OF POSITION IN THE MAMMALIAN NERVOUS SYSTEM. Z. Kaprielian\*, and P.H. Patterson. Division of Biology, 216-76, California Institute of Technology, Pasadena, CA

Spinal cord axons display a rostrocaudal, positional bias in their innervation of sympathetic ganglia and intercostal muscles (Wigston and Sanes, J. Neurosci. 5:1208, 1985). To examine the molecular basis of this positional specificity, mAbs that bind preferentially to rostral sympathetic ganglia were produced. Staining of one of these mAbs, ROCA1 (ROstroCAudal), is highest in produced. Staining of one of mess makes, ROCA1 (ROSTOCAUGA), is nignest in rostral sympathetic ganglia and intercostal nerves and declines in a graded manner in the caudal segments. The staining of another mAb, ROCA2, does not display a rostrocaudal difference. Immunoblot analysis shows that ROCA1 recognizes two antigens in membrane preparations of peripheral nerves and ganglia: (1) a Triton X-100-insoluble 60 kD protein and (2) a Triton X-100-soluble 26 kD protein. The 60 kD antigen is preferentially expressed in rostral intercostal nerves, and is identical to the intermediate filament protein, peripherin. The 26 kD protein, on the other hand, is found on neuronal and glial cell surfaces. N-terminal amino acid sequence data obtained from the affinity purified 26 kD protein indicates significant homology with human CD9, a protein expressed on the surfaces of platelets and pre-B lymphocytes. CD9 mAbs induce platelet aggregation and homotypic adhesion of pre-B cells (Horejsi and Vlcek, FEBS, 288:1, 1991).

nomotypic agnesion of pre-B cells (frotegis and Vices, Feb. 200.1, 1991).

ROCA2 also binds this 26 kD protein in peripheral nerves and ganglia.

Unlike ROCA1, ROCA2 binding does not display a rostrocaudal gradient, suggesting that it is the ROCA1 epitope, and not the 26 kD protein itself, which distributed in a rostrocaudal gradient. (Supported by the McKnight foundation, a Markey internal grant in Developmental Biology, and an individual NRSA.)

MOLECULAR ANALYSIS OF THE CA1 SUB-REGION OF THE HIPPOCAMPUS S. M. Nair , S. A. Mackler, Y. Cao and J. H. Eberwing. Univ of PA Phila PA 19104.

We characterized and compared the relative levels of mRNA expression in CA1

tissue sections to that in single pyramidal neurons from the rat hippocampus by using the antisense RNA (aRNA) amplification procedure. The aRNA generated by this method has previously been shown to represent the poly (A+) RNA population.

Analysis of CA1 sections enables characterization of mRNA populations from

discrete numbers of hippocampal cells, but may not detect those that are unique to subtypes of cells since these sections contain many neuronal and glial cell types. In contrast, we performed a similar analysis in both acutely dispersed single live pyramidal cells and in the live slice preparation, where some synaptic connectivity and glial interactions remain

glial interactions remain.

In-situ transcription (IST) was used to generate cDNAs corresponding to the poly (A+) RNA population from CA1 sections. In separate studies, a patch pipette electrode was used to simultaneously record from cell bodies of single neurons as well as to initiate IST. In each case, the cDNA was made double-stranded and amplified incorporating <sup>32</sup>P-CTP into the aRNA product. The aRNA was used as a probe to screen slot blots containing selected cDNA clones - called 'Expression Profiling'. This permits characterization of the relative mRNA abundances from each preparation.

Among 24 different mRNA species examined in the aRNA population, CA1 tissue sections revealed high relative levels of mRNA expression for a Ca++ channel, as well as for nerve growth factor (NGF) and brain-derived neurotrophic factor (BDNF). Differences between expression profiles of acutely dispersed single CA1 neurons relative to those in fixed tissue sections are likely due to the heterogeneity of cell types. Also, observed differences in patterns of gene expression between dispersed CA1 neurons and those in the live slice preparation may be partly due to the influence of synaptic and glial connectivity on the physiological state of the neuron. Further studies along these lines may help characterize the influence of cellular

interactions on physiological responsiveness at the level of single neurons.

CLONING OF THE DROSOPHILA NEURAL GENE, PASSOVER. S.N. Krishnan, E. Frei, G. P. Swain\* and R. J. Wyman. Dep't. of Biology, Yale University, New Haven, CT 06511

Passover flies fail to jump in response to a light-off stimulus. The mutation disrupts the synapses of the giant fibers, command neurons for this response. njP181, a non-jumping mutant was isolated from a Pelement mutagenesis and found to be allelic to Pas. Revertants of njP181 were obtained; in all revertants the P-element had been excised. Using genomic sequences adjacent to the P- insertion site, a single 2.7 kb cDNA was obtained from 2 million phages. The cDNA spans 60Kb of genomic sequence and straddles a breakpoint that defines the gene. The cDNA has a 5' untranslated sequence of 335 bp, an open reading frame of 1083 bp, and a 3' untranslated region of 1330 bp. The Pelement of njP181 is inserted in the 5' leader sequence 28 bp from the start of the cDNA. The cDNA codes for a putative protein of 361 amino acids with a calculated molecular weight of 42.9 kd. putative protein has the features of an integral membrane protein with a single transmembrane domain. The putative extracellular domain is composed of 256 amino acids, followed by a transmembrane domain of 22 amino acids, as judged by hydropathy analysis. Pas may start a new gene family: the only highly similar gene is l(1) optic ganglion reduced (proteins 46% identical). Both genes are involved in the development of postembryonic neurons. The head capsule, (with eyes and lamina attached) was dissected away from the brain of newly emerged adult flies; in situ hybridization showed strong expression of Pas in two large cells in the same location as the giant fiber somata.

ECTOPIC EXPRESSION OF THE UNC-5 GUIDANCE RECEPTOR IN THE TOUCH NEURONS OF <u>C. ELEGANS</u> STEERS THEIR AXONS DORSALLY ON THE EPIDERMIS. <u>J.G. Culotti</u>, <u>M. Hamelin</u>, <u>Y. Zhou, and I.M. Scott</u>. Samuel Lunenfeld Res. Inst. of Mt. Sinai Hospital, Toronto, Canada M5G 1X5.

The <u>unc-5</u> gene of <u>C</u>. <u>elegans</u> encodes a novel cell adhesion receptor of the immunoglobulin superfamily (UNC-5) which is required to guide dorsal growth cone movements on the epidermis (Leung-Hagesteijn et al., submitted). unc-5 has been shown genetically to require unc-6, which encodes a putative epidermal guidance cue, for dorsal guidance (Hedgecock et al., Neuron 4:61-85,1990; Ishii et al., submitted). We wanted to test whether unc-5 expression in neurons that do not grow dorsally on the epidermis would suffice to steer them in a dorsal direction. When ectopically expressed in the set of touch receptor neurons, which normally extend axons longitudinally or ventrally on the epidermis, unc-5 induces dorsal axon trajectories. These abnormal trajectories depend on unc-6, suggesting that UNC-5 acts to redirect the touch cell axons by utilizing its normal guidance functions. on the epidermis (Leung-Hagesteijn et al., submitted). functions.

DROSOPHILA EMBRYOS MUTANT FOR ZYGOTIC TOLL HAVE ALTERED RP MOTONEURON NUMBERS AND ECTOPIC MOTOR ENDINGS. M. S. Halfon, 1 C. Hashimoto<sup>2</sup> and H. Keshishian<sup>1\*</sup>. <sup>1</sup>Dept. of Biology & <sup>2</sup>Dept. of Cell Biology, Yale Univ., New Haven, CT 06511.

Toll (TI) encodes a transmembrane protein important in dorso-ventral patterning. A  $\pi$  enhancer-trap line has previously shown  $\pi$  transcription in several ventral muscle fibers (Nose & Goodman, 1991. Soc. Neuro. Abs., 17:742), spurring our interest in a possible role of  $\Pi$  in synaptogenesis. We have used anti-TI antibody to characterize zygotic TI protein expression. At embryonic stage 14, TI is expressed on the medial and lateral edges of muscle fiber 7, and is located on membrane contacts between muscle fibers 17 & 16, 16 & 15, and 15 & 28. At stage 15, TI is no longer expressed on muscle fiber 7 and between fibers 17 & 16, and in stages 16 and 17, the only Ti expression in the musculature is between fibers 16 & 15. The spatial pattern is strikingly similar to that of fasciclin III (fasIII), a molecule believed to be involved in axon pathfinding and synaptogenesis. Due to the similarities in faslll and TI expression, we looked at TI localization in a fasili background and fasili localization in a Tr background. Both fasIII and TI are properly expressed in the musculature in the respective backgrounds. In wildtype embryos, there are 3 fasIII positive RP motoneurons. In TI null embryos, ~74% of hemisegments have a wildtype RP number, while 3% have +1 RP, 17% have -1 RP, 1% have -2 RP and 4% have -3 RPs (n=94 hemisegments, 7 embryos). Antibodies against eve and Ubx, which label additional motoneurons, likewise show aberrancies in neuron number. A further TIphenotype is ectopic nerve endings on muscle fibers 6 & 7, which are contacted by the RP3 axon. A similar result is seen when the muscle fibers are denervated by RP ablation (T.N. Chang & H.K., this mtg.). We are investigating whether these aberrant synapses are due to pre- or post-synaptic mechanisms.

# 250.9

THE ROLE OF NEURAL ACTIVITY IN ESTABLISHING NEUROMUSCULAR ENDING MORPHOLOGY DURING DROSOPHILA EMBRYOGENESIS. J.E. Jarecki. M.D.S. Anderson, 2 Y.A. Sunt 3, H. Keshishian 3. Genetics 1 and Biol. 3 Depts., Yale Univ., New Haven, CT 06511 and Div. of Genetics 2, Harvard Medical School, Boston, MA 02115.

The motoneuronal ending anatomy of embryos and larvae is highly stereotyped Mutations that increase neural activity result in more elaborate larval endings (Budnik et al., J Neurosci, 10:3754). Some of these changes probably occur postembryonically. Both muscle area and motoneuron arbors grow dramatically during this period, with bouton number increasing 10 fold and distinct type I and II (large vs small bouton) processes arising by the 2nd larval instar. In addition, activity may also affect embryonic development. In hatchlings motor endings are relatively simple, yet prefigure the mature larval anatomy. However, they also differ in their size and maturity. For example, synapses on muscle fibers 6&7 have more differentiated boutons than those on 12 &13. We have examined the affect of altered activity in embryos, and found that it influences synaptic development. During late embryogenesis coordinated bodywall peristalsis begins. This movement is neurally evoked and mediated by glutamate (M.A., Soc Neurosci Abstr. 16:973). We used both genetic and pharmacological tools to cause paralysis. Argiotoxin 636, an open channel glutamate blocker that acts postsynaptically, had no effect on ending morphology when injected during stage 17. The role of presynaptic activity was assessed using either TTX or the sodium channel mutant paralytic (para), para does not block bodywall penstalsis, and had no affect on ending morphology. However, microinjection of TTX during stage 17 did block penstalsis, suggesting that at least one other sodium channel gene is expressed at this stage. Also TTX retarded maturation on fibers 12 and 13, so that endings resembled growth cones. The affected arbors are 3- to 4-fold more branched than controls and lack boutons. This effect did not occur on muscle fibers 6&7, suggesting fiber-specific differences. These results imply a role for embryonic presynaptic activity in regulating synaptic maturation.

TERMI: A NEURON-SPECIFIC GLYCOPROTEIN LABELS GROWTH CONES AND DEVELOPING SYNAPSES OF AN IDENTIFIED INTERNEURON. T. Meier, S.Therianos, D. Zacharias and H. Reichert\*. Dept. of Zoology, University of Basel, CH-4051 Basel, Switzerland.

TERM1 is a molecular label that is expressed by a pair of individually identifiable developing interneurons in the embryonic nervous system of the grasshopper. During embryogenesis, TERM1 is not expressed by any of the other interneurons in the CNS. The extremely restricted spatiotemporal expression pattern of TERM1 during nervous system development suggests that it may play a role in neuron-specific cell-cell recognition during pathfinding and synaptogenesis.

We have characterized TERM1 at the cellular and biochemical level with the aid of a TERM1-specific monoclonal antibody. Cellular studies involving immuno-electron microscopy show that the TERM1 label is localized on the outer cell surface of the growth cones of the two interneurons during axogenesis. Subsequently, during the phase of synaptogenesis, TERM1 is found at the synaptic terminals of the labeled cells. It is retained at these specific synapses throughout postembryonic life. Immunoprecipitation of TERM1 followed by a biochemical analysis shows that the molecular label is a membrane associated glycoprotein with an apparent molecular weight of 50kD. TERM1 is now being isolated for microsequencing, antibody generation and expression cloning. (Supported by the Swiss NSF).

### 250.8

LASER ABLATION OF EMBRYONIC MOTONEURONS IN DROSOPHILA RESULTS IN ABERRANT LARVAL TARGET MUSCLE INNERVATION. I.N. Chang\* 1 & H. Keshishian, Interdepartmental Neuroscience Program 1 and Dept. of Biology, Yale University, New Haven, CT 06511.

Previous mismatch experiments duplicating or ablating muscle targets implicated cellular recognition of synaptic partners by motoneurons (Chiba et al., Soc Neurosci Abstr 17:213). Here we ablated motoneurons to show that partial or complete denervation induces foreign inputs on muscle targets. We directed the laser through the cuticle at the identified motoneuron RP3 on the left side of every abdominal segment in intact stage 15-16 embryos. Left RP3s were ablated just before or shortly after they made their initial contacts on their targets, contralateral muscle fibers 6 and 7. Unlased right RP3s served as an internal control. We then allowed the embryo to mature to third instar and examined the innervation of muscle fibers 6 and 7. In unlased animals, 6 and 7 innervation includes type I (large varicosity) endings at the middle of the 6-7 cleft; type II (small varicosity) endings are colocalized with the type I's in anterior abdominal segments. Type I endings were missing on the right side of most lased animals, while type II's were either missing or were present but more extensive, sometimes crossing normally restrictive segment borders. Foreign endings were observed at ectopic sites on both muscles 6 and 7; such endings were extremely rare on the control side or in unlased animals. For example, in most right hemisegments of left RP3-lased animals, both type I and II ectopic endings were observed from the transverse nerve. In addition, ectopics were observed branching off from endings on 13, as well as from 15-16 endings, which originate from a separate nerve branch. In all cases, the control side (right RP3s, left musculature) had normal innervation of 6 and 7. Our results show that partial or complete denervation results in novel synaptic inputs from diverse sources

SYNAPTIC COMPETITION AT DEVELOPING APLYSIA
SENSORIMOTOR SYNAPSES IN CELL CULTURE: REGULATION BY
ACTIVITY AND ELECTRICAL COUPLING. D.L. Glanzman.\* Dept. of
Physiological Science, UCLA, Los Angeles, CA 90024.
Recent morphological data indicate that when two Aplysia sensory neurons
are grown together in dissociated cell culture with a single, postsynaptic
motor neuron, the outgrowth of the two sensory neurons tends to occupy
separate postsynaptic regions (Glanzman et al., Neuron 7: 903, 1991). This
morphological segregation of the outgrowth from different presynaptic inputs
may reflect competition between the developing sensory neurons for
innervation of the target motor neuron. To determine whether activity can
affect this apparent competition. electrophysiological experiments were affect this apparent competition, electrophysiological experiments were performed on sensorimotor cocultures, each of which consisted of a motor neuron innervated by two sensory neurons. All sensorimotor cocultures wer 2-3 days old. Each sensory neuron was activated once every 5 min, and the size of the excitatory postsynaptic potential (EPSP) evoked in the motor neuron by the test stimulus was recorded intracellularly. After 3-4 test stimuli, one of the sensory neurons was given a brief tetanus (24-48 pulses at 20-25 Hz). This selective tetanic stimulation tended to suppress the synaptic connection made by the nontetanized sensory neuron with the motor neuron, as indicated by a reduction in the size of the EPSP, when there was little or no electrical coupling between the two sensory neurons. The reduction in the size of the nontetanized sensory neuron's EPSP was prolonged, lasting for up to 30 minutes. By contrast, when the sensory neurons were strongly coupled electrically, selective tetanization of one of the sensory neurons did not result in a prolonged suppression of the nontetanized input. These results indicate that the effect of neuronal activity upon the synaptic competition between sensory neurons in developing Aphysia sensorimotor cocultures can be influenced by the extent to which the presynaptic neurons are electrically coupled.

RETROGRADE CONTROL OF FACILITATION AT AN ECTOPIC

RETROGRADE CONTROL OF FACILITATION AT AN ECTOPIC CENTRAL SYNAPSE. K.A. Killian\* and R.K. Murphey. Program in Neuroscience and Behavior, Univ. of Massachusetts, Amherst, MA 01003.

By transplanting sensory neurons (SNs) of the cricket to ectopic sites, we can induce them to synapse with unusual postsynaptic neurons. We have used these mismatched synapses to try to understand the relative roles of pre- and postsynaptic neurons in determining the temporal

understand the relative roles of pre- and post-synaptic neurons in determining the temporal aspects of transmitter release at a synapse. Interneuron MGI is located in the terminal abdominal ganglion (TAG) where it synapses with SNs of cercal filiform hairs. These synapses facilitate when activated at 100 Hz (G. Davis, Soc. Neurosci. Abstr. 17:1288, 1992). Campaniform sensilla (CS) located on the tibia of the meso-thoracic leg of locust have been shown to form thoracic leg of locust have been shown to form synapses with thoracic interneurons which only exhibit depression during repetitive stimulation (N. Emptage, unpub.). When homologous CS SNs of the cricket are transplanted to the abdomen, they regenerate and synapse with MGI. We have found that when these ectopic synapses are activated at 100 HZ, facilitation is sometimes observed. Thus, we hypothesize that MGI can induce facilitation at these synapses. MOLECULAR CLONING OF THE HUMAN DOPAMINE AND NOREPINEPHRINE TRANSPORTER GENES. K.A. Neve\*, C. Li, R.A. Henningsen, S. Smiley, and A. Janowsky VA Medical Center and Oregon Health Sciences University, Portland, OR 97213

The molecular cloning of cDNA for neurotransmitter transporters

has revealed that they are highly homologous proteins. They are unusual in that each is expressed in a set of neurons that is often quite small and does not overlap with the sets of neurons expressing other neurotransmitter transporters. As a first step towards identifying determinants of cell-specific expression, we are cloning the genes and flanking regions for the dopamine (DAT) and norepinephrine (NET) transporters. DAT and NET cDNAs were cloned by reverse transcription-PCR, and used as hybridization probes to screen a human genomic library. For each cDNA, 19 positive recombinants were selected and plaque-purified, and genomic DNA from the phage clones is being mapped with restriction endonucleases and sequenced. One phage that hybridized with the DAT probe contains a 15-kb DNA insert that has 0.5 kb of intronic sequence at its 3 end.

Upstream from the intron, coding sequence begins within amino acid 96 and continues through the translational start codon. In these amino acids, the human DAT has 91% identity with the rat DAT but only 84% identity with a bovine DAT. A 0.4 kb Sac1-EcoRI fragment ending 24 bp upstream from the start codon has been ragment ending 24 by upstream from the start codon has been subcloned for determination of the transcriptional start site by S1 nuclease protection. Based on a published length of 3.4 kb for a DAT cDNA and 3.6 kb for the message, the promoter should lie within this fragment if there is no intron in the 5'-UTR. (NIDA Contract No. 271-90-7405, VA Merit Review Program)

# 251.3

UPTAKE OF THE NEUROTOXIN MPP+ BY THE CLONED HUMAN AND RAT DOPAMINE TRANSPORTERS. Ch. Pifl, B. Giros, N. Godinot and <u>N.G. Caron</u>\*. Dept. of Cell Biology, Howard Hughes Medical Institute, Duke University Medical Center, NC 27710.

The neurotoxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) produces parkinsonism in humans and subhuman primates but not in rats. A crucial step in the neuroprimates but included the uptake of its toxic metabolite proper MPP<sup>+</sup> by dopamine (DA) neurons as revealed by the protective effect of DA uptake blockers. Since primates but not rodents show a preferential retention of MPTP metabolites in the caudate, their different susceptibility to MPTP neurotoxicity may be due to species differences in the DA transporter systems versus MPP. To test this hypothesis we stably expressed the cloned human and rat DA transporters in Ltk cells; we measured uptake of [3H]DA and [3H]MPP in these cells and, in parallel, in striatal synaptosomes of rats. The DA uptake in clonal cell lines and in striatal synaptosomes showed the rank order of potency of uptake blockers characteristic of a DA transporter. However the cloned transporters had a much lower affinity for MPP $^{\dagger}$  than the transport system in striatal synaptosomes ( $K_m=20-30~\mu M$  vs 200-300 nM). No significant differences between human and rat transporters were observed. We conclude that (1) species differences in susceptibility of humans versus rats to MPTP neurotoxicity cannot be due to differences in the properties of DA transporters and (2) the molecular basis of the high affinity uptake of  $\mathtt{MPP}^+$  in striatal synaptosomes remains to be clarified.

### 251.2

CLONING, PHARMACOLOGICAL CHARACTERIZATION AND DELETION MUTATIONS OF THE HUMAN DOPAMINE TRANSPORTER. B. Giros\*, S. El Mestikawy, Ch. Pifl, N. Godinot and M. G. Caron. Dpt. of Cell Biol. Howard Hughes Med. Inst., Duke University Durham, NC 27710, USA

We have screened a human substantia nigra cDNA library with probes from the rat dopamine transporter. A 3.5 kb cDNA clone was isolated and found to code for a 620 amino acid protein. The hydropathicity analysis suggested the presence of 12 putative transmembrane spanning domains, a characteristic feature of sodium-dependent neurotransmitter carriers. The rat and the human dopamine transporters were found to be 92% homologous. When permanently expressed in mouse fibroblast Ltk- cells, the human clone was able to induce a saturable time- and sodium-dependent dopamine uptake. This transport was blocked by psychostimulant drugs (amphetamine, cocaine, phencyclidine), neurotoxins (6-OH-DA, MPP+), neurotransmitters, antidepressants (amitriptyline, bupropion, desipramine, mazindol, nomifensine, nortriptyline), and various uptake inhibitors (mazindol, GBR 12783, GBR 12909, amfonelic acid). The rank order potencies of the  $K_{\rm i}$  of these substances on the human and the rat dopamine transporter displays a high correlation (r=0.998), when compared under the same conditions, i.e, same

expression vector, same stable cell lines, and experiments run in parrallel.

In order to elucidate the role and function of the different domains of this large transmembrane protein, we have constructed a serie of mutants in which we deleted respectively, the C-terminus tail, the N-terminus tail, or the large second extracellular loop. Interestingly, some of these deletions produce an impairment of the dopamine uptake, without any marked modifications of the <sup>3</sup>H-CFT binding. These findings should allowed the determination of whether binding and transport are dissociable functions of these transporters.

CLONING AND EXPRESSION OF TWO NOVEL GABA TRANSPORTERS FROM RAT BRAIN. <u>L.A. Borden, K.E. Smith, P.R. Hartig, T.A. Branchek, and R.L. Weinshank</u>. Synaptic Pharmaceutical Corporation, 215 College Road, Paramus, NJ 07652

Pharmaceutical Corporation, 215 College Road, Paramus, NJ 07652
Neuronal transmission at GABAergic synapses is terminated by the uptake of GABA into the presynaptic terminal and surrounding astrocytes. The previous cloning of the neuronal GABA transporter (GAT-1; Guastella et al., 1990) revealed that this protein is a member of the 12 transmembrane domain superfamily of transporters. We have now isolated clones from rat brain cDNA which encode two novel GABA transporters. The clones, designated GAT-2 and GAT-3, exhibit 68% amino acid sequence identity to one another, but only 53% identity to GAT-1. When expressed in COS-7 cells both transporters display high-affinity for GABA ( $K_{\rm M}=10\mu{\rm M}$ ), and transport activity is dependent on external sodium and chloride. GAT-2 and GAT-3 display greater sensitivity to  $\beta$ -alanine than does GAT-1, suggesting similarity to the transporter characterized in glial cultures. However, the lack of sensitivity to guvacine, nipecotic acid, and hydroxynipecotic acid indicate that GAT-2 and GAT-3 are distinct from the previously characterized glial transporter. The identification of these novel clones reveals unexpected heterogeneity in GABA transporters.

NEUROTRANSMITTER TRANSPORTER & ORPHAN cDNAs IN RAT MIDBRAIN LIBRARIES: STRUCTURAL VARIANTS IN THIS GENE FAMILY. G. Uhl\*, S. Shimada, A. Persico, P. Gregor, E. Nanthakumar & S. Kitayama. Labs. Mol. Neurobiol., ARC/NIDA & Depts. Neurol. Nsci., JHUSM, Box 5180, Baltimore, MD. 21224.

A sodium dependent neurotransmitter transporter gene family has been defined by GABA, norepinephrine, dopamine (DAT), and serotonin (SERT) transporter cDNAs. While cloning the DAT cDNA, we developed data concerning 20 members of this family identified in screening 5 x 10<sup>5</sup> plaques from a size-selected midbrain cDNA library. 8 of the cDNAs encoded GABAT, 3 DAT, and 1 SERT while 8, including v7-3, were novel. v7-3 and 2 related clones encoded amino acids 60% homologous to other transporters and 12 hydrophobic putative transmembrane domains. The 4th extracellular loop was strikingly long, and displayed N-linked glycosylation sites. v7-3 mRNA was highly expressed in thalamus, hippocampus, olfactory bulb, and cerebellum but not peripheral tissues. Xenopus oocytes injected with mRNAs synthesized from the 8 orphan clones failed to display specific uptake of any of 9 candidate substrates These data suggest diversity in the size and structures of members of this sodium dependent transporter gene family.

### 251.7

OBSERVATION OF TWO VESICULAR COMPARTMENTS IN A SINGLE Yau Yi Lau. Department of Chemistry, Penn State
University, University Park, PA 16802.

A critical hypothesis in single-cell neurophysiology is

the existence of two vesicular compartments for neuro transmitters. Neurotransmitters in the functional compartment are readily available for stimulated release, whereas those in the nonfunctional compartment are thought to act as long-term stores or perhaps for potentiation of response following extremely heavy neuronal stimulation. The bulk of the analytical data suggesting the presence of these two compartments has been obtained by study of tissue levels of neurotransmitters following inhibition of synthesis. We have used capillary electrophoresis in narrow-bore capillaries to examine whole cell levels of dopamine in single large invertebrate neurons. Variation of the sampling conditions apparently leads to selective lysing of vecicles in the functional vs nonfunctional compartments and, in fact, leads to two different peaks for dopamine in a single electropherogram. The first peak is modelled to contain dopamine  $(6.1 \pm 3.0 \text{ fmol } (n=3))$ from the cytosol and in vesicles poised for exocytosis. The second peak is abolished by long lyse times or the application of reserpine and, hence, appears to contain dopamine (19  $\pm$  9.1 fmol (n=3)) from storage vesicles that are not readily releasable.

MECHANISMS OF CALCIUM RESPONSIVE SECRETION IN MEDULLARY THYROID CARCINOMA CELLS. S.A. DeRiemer, H.S. Hsiung, & H. Tamir, Depts. of Anatomy and Biological Sciences, Columbia Univ., NY NY 10032.

The parafollicular C-cells of the thyroid respond to elevations of serum calcium by releasing the calcium-lowering hormone, calcitonin, as well as serotonin (5-HT). Both  $\acute{\rm 5}$ -HT and calcitonin are found in the same secretory granules, and they have been shown to be co-released. Medullary thyroid carcinoma (MTC) cells derived from a human C-cell tumor have been used to analyze the coupling between extracellular calcium and 5-HT secretion. Intracellular calcium levels were determined using fura-2 spectroscopy, and 5secretion. Intracellular calcium levels were opermined using fura-2 spectroscopy, and 5-HT secretion was monitored by HPLC with electrochemical detection. Changes in extracellular calcium from 0.01 - 7 mM produced proportional increases in both intracellular calcium and 5-HT secretion. This suggests that intracellular calcium acts as the mediator for the signals produced by altered extracellular calcium levels. The intracellular calcium levels correlated with 5-HT secretion ranged from 10  $\mu\text{M}$  to 35  $\,\mu\text{M}$ suggesting that the secretory apparatus in MTC cells responds to intracellular calcium suggesting that the sections appearation in other nerve and endocrine cells. Electrophysiological analysis using whole cell patch clamping on MTC cells revealed the existence of a non-inactivating calcium current resembling, but not identical to a dihydropyridine sensitive "L-type" calcium channel. Two of the distinctive properties noted were a slower time course of inactivation (tails) and less of a difference in the conductance of barium vs calcium than expected from a prototypical "L-type" channel. Application of the dihydropyridine antagonist nimodipine (10 -5 M) inhibited stimulated 5-HT release by 80%. This effect was reversed by the dihydropyridine agonist, BAYk8644

IDENTIFICATION OF A cDNA CLONE WITH HOMOLOGY TO THE ADRENAL CHROMAFFIN GRANULE AMINE TRANSPORTER. D.L. Peter, Y. Liu, C. Weigmann, N. Brecha, and R.H. Edwards\*. Department of Neurology, University of California, Los Angeles, 90024.

We have previously isolated a cDNA clone for the chromaffin granule amine transporter using the genetic strategy of selection in MPP+. To identify related vesicular amine transporters in the brain, a rat midbrain cDNA library was screened with this cDNA. Sequence analysis of the positive midbrain clones revealed one with significant homology to the chromaffin granule amine transporter. Northern blot analysis of polyA<sup>+</sup> RNA indicate expression in the midbrain, pons, medulla, and in a midbrain cell line. In situ hybridization analysis of rat brain demonstrate its expression in aminergic populations.

AMPHETAMINE ACTION EXAMINED IN REAL-TIME IN THE GIANT DOPAMINE NEURON OF PLANORBIS. 1D. Sulzer\* 27X, Lau. 2A. G. Ewing and 1S. Rayport. 1Dept. Psychiatry, Ctr. Neurobiology &

Lau. <sup>2</sup>A. G. Ewing and <sup>1</sup>S. Rayport. <sup>1</sup>Dept. Psychiatry, Ctr. Neurobiology & Behavior, Columbia Univ.; Dept. Neuropathology, NYS Psychiatric Inst., NY 10032. <sup>2</sup>Dept. Chemistry, Penn State, University Park, PA 16802. In the weak base model of psychostimulant action (Sulzer & Rayport, Neuron 5;759, 1990), amphetamine (AMPH) disrupts the synaptic vesicle pH gradient, redistributing catecholamines from vesicles to the cytosol; the elevated cytosolic catecholamine in turn promotes release through reverse action of the uptake transporter (Sulzer et al., Soc. Neurosci. Abstr., 1991). To test this mechanism further, we applied ultra-small volume electrochemical and capillary electrophoresis techniques developed by Ewing et al. (this meeting) to the giant dopamine (DA) neuron of the snail Planorbis corneus. By injecting DA or AMPH into the neuron and measuring DA efflux in real time with an extracellular carbon-ring electrode, confirmed that increased cytosolic DA promotes reverse transport. Injection of 20 and measuring DA ethus in real time with an extracellular carooti-ing electrode, we confirmed that increased cytosolic DA promotes reverse transport. Injection of 20 fmol of DA increased extracellular DA by 40 µM; DA release was rapidly and reversibly blocked by nomifensine (10 µM). Injection of 0.8 pmol of AMPH increased extracellular DA by 1.5 µM. These results are the first direct demonstration of reverse transport of neurotransmitter and suggest that AMPH acts intracellularly to release DA. To examine AMPH effects on vesicular DA, we intracellularly to release DA. To examine AMPH effects on vesticular DA, we performed capillary electrophoresis on single neurons.  $100 \, \mu M$  AMPH for 15 min increased DA in the cytosol and in vesicles poised for exocytosis (these are not resolved with this technique) from  $6.1 \pm 3.0$  fmol (n=3) to  $107 \pm 23$  fmol (n=6), whereas DA in reserpine-sensitive vesicles decreased from  $19 \pm 9.1$  fmol (n=3) to below detectable levels (< 10 amol; n=3). These results are inconsistent with an exchange diffusion model, in which AMPH should lower cytosolic DA; rather, the increase in cytosolic DA with a decrease in vesicular DA supports the weak base

# 251.10

EXPRESSION OF THE SMALL GTP-BINDING PROTEIN RAB3A

EXPRESSION OF THE SMALL GTP-BINDING PROTEIN RABA IN THE ADULT RAT BRAIN.

O. Stettler\*, A. Zahraoui, K.L. Moya and B. Tavitian, INSERM U334 and CNRS URA 1285, C.E.A., S.F.H.J., Orsay, and INSERM U248, Paris, France. The ras-related rab genes code for small GTP-binding proteins that are thought to control intracellular membrane trafficking. Some of the rab proteins are localized to the membrane of specific subcellular organelles, and rab3A is associated with small synaptic vesicles. Previous immunohistochemical studies have revealed terminal regions and several sergetific neural circuits which contain rab3A but terminal. regions and several specific neural circuits which contain rab3A, but since the protein is not present in cell bodies, those studies were unable to identify the neurons expressing this small G protein. In this study, we have used in situ hybridization with a specific probe to localize the rab3A mRNA in the adult rat brain and we have found an unique pattern of neurons that express this protein. In the forebrain, rab3A mRNAs were mostly detected in neocortical and limbic areas such as hippocampus, enthorinal cortex and rhinencephalic nuclei, while no significant labelling was observed in the striatum, in the hypothalamus or in several thalamic nuclei. Rab3A expression does not directly correspond to any known neurotransmitter expression pattern nor is it completely superimposable to the pattern of expression of other synaptic vesicle proteins. Our results show that the expression of rab3A is spatially restricted and thus, that the protein exerts its

function in a subset of neurons in the brain.

In combination with previous studies of other synaptic vesicle proteins, the present results suggest that subsets of presynaptic terminals can be characterized at a molecular level by their vesicular proteins, which may impart unique functional properties. The complex combinations of such synaptic components would provide multiple molecular mechanisms for the precise regulation of exocytosis in the brain.

CHICOSE DEPRIVATION INHIBITS NEUROTRANSMITTER RELEASE AND DECREASES UDP-GLUCOSE INDEPENDENT OF ATP. N.A. Veyna\*, and R.B. Marchase, Department of Cell Biology, The University of Alabama at Birmingham, Birmingham, AL 35294

It has been previously established that glucose deprivation diminishes electrical responses prior to a reduction in ATP or other high energy phosphates in both retina (Winkler, J. Gen. Physiol. 77:667-692, 1981) and hippocampal slices (Cox and Bachelard, J. Physiol. 352:91-102, 1984). We suggest that this loss of activity is due to a decrease in vesicular neurotransmitter release. Utilizing a synaptosomal model system we find a 41% decrease in release of [3H]norepinephrine in response to 40 mM KCI after a 20 minute incubation in glucose-free buffer (n=10). Luminometric assays were performed on identically treated synaptosomes to determine ATP and UDP-Glc content. A 78% decrease was seen in UDP-Glc pools (n=6), whereas ATP content was decreased by a statistically insignificant 0.8% (n=6)

When synaptosomes undergo a freeze-thaw permeabilization to allow the introduction of radiolabeled UDP-Glc a single protein of 63 kDa is labeled. This protein, PGP 63, contains glucose in a phosphodiester linkage, and its analogue has previously been implicated in vesicular release mechanisms in *Paramecia* (Satir et al., J. Cell Biol. 111:901-907, 1990). Interestingly, PGP 63 is more robustly labeled when synaptosomes containing radiolabeled

UDP-GIc are depolarized with 40 mM KCl.

DETECTION OF PROTEIN TYROSINE KINASES (TKs) AND THEIR SUBSTRATES IN THE POSTSYNAPTIC DENSITY (PSD) OF ADULT Penhallow<sup>3</sup>, T.W. Kim<sup>1</sup>, Y. Huang<sup>4</sup>, J.L. Adler<sup>2\*</sup>, J. Boelen<sup>3</sup>, R.C. Penhallow<sup>3</sup>, T.W. Kim<sup>1</sup>, Y. Huang<sup>4</sup>, J.L. Xu<sup>1</sup> & I.B. Black<sup>1</sup>, <sup>1</sup>Dept. Neurosci. and Cell Biol., UMDNJ/RWJ Med. Sch., Piscataway, N.J. 08854; <sup>2</sup>Dept. Neurol., Wayne State Univ. Med. Sch., Detroit, M.I. 48201; <sup>3</sup>Bristol-Myers Squibb, Pharma. Res. Inst., Princeton, N.J. 08543

48201; <sup>3</sup>Bristol-Myers Squibb, Pharma. Hes. Inst., Princeton, N.J. 00040 and <sup>4</sup>Div. Neurosci., NYSPI, New York, N. Y. 10032.

Recent studies showing high level of TK activity in adult rat brain suggest that the enzyme(s) may mediate signal transduction in the nervous system. Since abundant evidence indicates that the PSD is crucial for synaptic function, we examined this structure for TKs and substrates. Our results revealed that the specific PTK activator, substrates. Our results revealed that the specific PTK activator,  $\text{Mn}^{2+}/\text{Vanadate}$ , enhanced phosphorylation of several proteins  $(\text{MW}, =\!20\text{ to }250\text{ kDa})$  in the PSD and synaptic membrane (SM). In addition, the presumptive TKs were greatly enriched in the PSD, compared with those in SM or total homogenate (H). Moreover, Western blot analysis using rabbit anti-phosphotyrosine antibody indicated that the PSD isolated from cerebral cortex, cerebellum and olfactory bulb contained several tyrosine-phosphorylated proteins (M.W.=20 to 250 kDa), which appeared to be PTKs and their substrate proteins. These phosphorylated proteins were differentially expressed in these brain regions. We conclude that PTKs and their substrates are present in the PSD and may play roles in synaptic function. (NS10259 and HD23315)

ACETYLCHOLINESTERASE REGULATION IN APLYSIA: EFFECT OF AGE AND CHRONIC SENSORY STIMULATION. B. Peretz\*, M. Srivatsan and B. Hallahan, Dept. of Physiology Univ. of Kentucky Med. Cntr., Lexington, KY 40536.

Acetylcholinesterase (AChE) is a major protein in the hemolymph of Aplysia. It apparently insures a ready supply of choline for the nervous system and may be involved in trophic function. Both age and chronic sensory stimulation (CSS) affect hemolymph AChE activity (Srivatsan et al., 1992). We wanted to find the source of hemolymph AChE and the effect of age and CSS on its source. The central nervous nemotymph Action and the effect of age and CSS of the Source. The Central nervous system (comprised of 4 paired ganglia and the abdominal ganglion) and tissues such as the gill, foot muscle, buccal muscle, liver, heart, and gonad were examined in young (ca 85 days old), mature (ca 170 days old) and old (over 250 days old) animals. Hemolymph had the highest AChE activity of any tissue in the animal, followed by the activity in the gill and foot. With increased age the activity in the two tissues was decreased, and the activity in the nervous system increased. CSS (siphon stimulation for 4 weeks) resulted in decreased AChE activity in the ganglia and other tissues tested in young and mature Aplysia, and increased activity in the ganglia and tissues from old Aplysia. We next tested for release: Pooled ganglia and sections of the gill and foot musculature were subjected to depolarization with high  $K^+$  (ca 100mM) in seawater of (1050 mOsm) for up to 1 hr; little or none was measured in control tissues in seawater (10 mM KCl). Little release was measured from the ganglia. The gill and foot did release AChE in the three age groups. From the gill, released activity/g. tissue for the young was 68.22 ± 39.27 units (n=6); for the mature was  $33.41 \pm 18.12$  units (n=6); and for the old was  $41.77 \pm 18.65$  units (n=4); 1 unit = AChE that hydrolyzes 1µmole of substrate/min. The foot showed an age-related pattern of release similar to the gill. These results indicate that with age and to CSS hemolymph AChE activity reflects the activity in the tissues. And, the gill and foot may be sources of hemolymph AChE. The mechanisms of AChE release into the hemolymph need to be determined. (NIA)

IMAGING OF STIMULATION AND FUNCTIONALLY EVOKED INTRINSIC OPTICAL CHANGES IN MONKEY AND HUMAN CORTEX. D.W. Hochman's G.A. Ojemann, M.M. Haglund, Dept. Neurological Surgery, Univ. of Washington, Seattle, WA 98195

Neurological Surgery, Univ. of Washington, Seattle, WA 98195
In a variety of preparations, it has been demonstrated that changes in the intrinsic optical properties of tissue are associated with neural activity. Using video imaging, we studied stimulation and functionally evoked activity in monkey and human cortex. Pairs of images of macaque visual cortex were acquired during left eye and right eye visual stimulation. Each image consisted of at most 96 frames averaged at 30 Hz. Subtraction of these pairs yielded difference maps of ocular dominance columns (signal/noise: 0.1-0.5). Comparing control images (no visual stimulus) to stimulation images, temporal information regarding the onset and recovery of these optical changes was obtained. Large changes (>15%) were observed in the magnitude of optical absorption of the cortex between control images and stimulation images. After surface electrodes were placed on the cortex of human patients, electrical stimulation evoked large optical changes (>5.0%) in a graded manner near the stimulating electrodes. Negative optical changes were observed surrounding these areas of intense activity. In some cases, epileptiform activity was evoked by the cortical stimulation. The optical changes observed during these afterdischarge episodes corresponded to the electrical activity recorded with surface electrodes. Optical changes were evoked in human cortex during sensory (tongue movement) and language tasks. Both the positive and negative (longue movement) and language tasks. Both the positive and negative optical changes were larger than those evoked by direct electrical simulation (up to 30%). Computer analysis of our images enabled us to follow the temporal characteristics of the optical changes in the vasculature and many cortical areas simultaneously. (Research supported by the Klingenstein Foundation Fellowship to MMH)

OPTICAL IMAGING OF EPILEPTIFORM AND COGNITIVE ACTIVITY IN HUMAN CORTEX. M. M. Haglund\*. G. A. Ojemann. and D. W. Hochman. Dept. Neurological Surgery, Univ. Washington, Seattle, WA 98195.
Optical imaging in animal somatosensory, olfactory, and visual cortices has revealed high resolution maps of functional activity (Orbach et al., 1985; Blasdel and Salama, 1986; Kauer, 1988; Frostig et al., 1990; Ts'o et al., 1991). After obtaining informed consent, similar video imaging techniques were used in patients undergoing awake craniotomies for intractable epilepsy (n = 15). We obtained maps of epileptiform and functional activity from human cortex. Epileptiform activity evoked by bipolar stimulation for 4 sec (60 Hz, 1 msec biphasic pulses, 2-8 mA) was recorded by surface EEG electrodes both within the optical imaging field and outside the field-of-view. The optical changes correlated with the electrical activity recorded from nearby surface EEG electrodes with the intrinsic reflection signals increasing as the intensity and duration of the afterdischarge activity increased.

After cortical stimulation mapping identified sensory/motor cortex and essential language sites (Broca's and Werricke's areas), large optical changes were found in somatosensory cortex during tongue movement. In the anterior language areas, naming evoked optical changes that were localized in the anatomical Broca's area and not in areas of speech arrest identified by surface stimulation. In the posterior language areas for naming, but also secondary language areas. These secondary language areas, not identified by surface stimulation, were verified when the subject's language deteriorated as the surgical removal of cortex neared these areas. The extension of high resolution optical imaging to human cortex will open new areas of investigation into the cortical organization of sensory/motor cortex, language, and cognitive processes. An Electrophysiological Study of Infants' Sensitivity to the sound structure of English Function Words. V.L. Shafer<sup>1,2</sup> D.W. Shucard. 1,3, J.L. Shucard. L.A. Gerken, Departments of Neurology, Linguistics and Psychology, SUNY Buffalo, 100 High Street, (D-6), Buffalo, NY 14203.

A major issue in the study of language acquisition is the age at which infants attend to specific aspects of language structure. Our work explores the possibility that children are sensitive to the phonological properties of function morphemes even before they have begun to produce their first words. Auditory evoked potentials (AEP) to task-irrelevant pairs of tone probes obtained to investigate the sensitivity to English function morphemes of 10- to 12-month-old infants. Infants received three conditions; a baseline condition of only tones; and two experimental conditions consisting of task-irrelevant tone probe pairs superimposed on an unmodified version of a story, and a modified version of the same story in which the function morphemes had been replaced by nonsense forms (e.g. ku, po). The pattern of AEP fast habituation and amplitude asymmetry to the tone pairs were examined across conditions. The following results were obtained: 1) There was a general decrease in amplitude from the baseline to the experimental conditions, and 2) the pattern of fast habituation within each cerebral hemisphere differed across conditions. For example, there was less habituation in the right hemisphere relative to the left hemisphere during the unmodified version of the story. The opposite pattern occurred for the modified version. Furthermore, for the second of the tone pairs, there was a reversal of amplitude asymmetry between the experimental conditions. These findings support the notion that 10- to 12-month old infants are sensitive to the phonological and/or prosodic information carried by function morphemes, and 2) that attentional resources in each cerebral hemisphere are allocated differentially among the three condition.

ELECTROPHYSIOLOGICAL MEASURES OF SEMANTIC PROCESSING IN HUMANS. A.C. Nobre\*, G. McCarthy. Neuropsychology Laboratory, VAMC, West Haven, CT 06516 and Departments of Psychology and Surgery, Yale University.

Event-related potentials (ERPs) were recorded from cortical surface and depth electrodes from patients performing language tasks. The tasks were designed to manipulate semantic processing and involved categorization of linguistic stimuli viewed successively. One task included intermixed pairs of semantically related or unrelated words, while the other included orthographically illegal nonwords (e.g., 'xmwtf'), pseudowords (e.g., 'flepple'), grammatical connectives (e.g., 'therefore'), and concrete nouns. Scalp recordings showed that these manipulations of semantic processing modulated an ERP which occurred near 400 msec (N400) following word onset. Intracranial studies using an anomalous-sentence task have shown that the anterior-medial temporal lobe is one neural generator for N400 (McCarthy & Wood 1984, Soc. Neur. Abs.). Recordings in the anterior-medial temporal lobe during the two categorization tasks also exhibited an N400 that was elicited by concrete nouns and was modulated by semantic priming. Illegal nonwords and grammatical connectives elicited little N400 activity, however, pseudowords did elicit N400. In addition, neocortical stimulation and recordings were performed in patients with electrode grids over the left Electrode sites which caused disruption of naming and comprehension during cortical stimulation, exhibited focal electrophysiological potentials that were modulated by the task manipulations.

SUPPRESSION OF UNATTENDED-CHAMMEL MISMATCH-RELATED ACTIVITY IN HUMAN AUDITORY CORTEX DURING AUDITORY SELECTIVE ATTENTION. M.G.Notdooff\*(1), C.C.Gallen(2), S.R.Hampson(2), S.A.Hillyran(1), C.Pantev(2), and f.E.Bloom(2). Dept. of Neurosci., UCSD, La Jolla, CA 92095-0608 (1), Dept. of Neuropharm., Research Inst. of Scripps Clinic, La Jolla, CA, 92037 (2).

The mismatch negativity (NNN) and the corresponding mismatch megnetic field are elicited by infraquent, physically deviant sounds in a sequence of repetitive auditory attenuit. Previously, Nastaram and colleagues had asserted that this wave was unaffected by attention and thus reflected a strongly automatic feature-analysis and mismatch-detection process. These proposals were called into question by two recent fast-rate dichotic Listening experiments designed to optimize the selective focusing of attention (Woldorff, Hackley, and Hillyard, 1991). In these experiments, the deviant tones (intensity decrements) in the attended ear elicited deviance-related negative (DRI) waves consistent in latency (peaking at 200 msec), waveshape, and distribution with previously described NNNs, but the NNN elicited by the unattended-channel deviants appeared to be highly suppressed.

Me have now recorded the tone-evoked neuromagnetic feleds in an experiment with very similar parameters to one of our previously reported NNN experiments. Like its electrical counterpart, the deviance-related field (DRF) in the unattended channel uses autremely small. In the attended channel Repair was a subjects) uses of substantial amplitude, and, like the auditory-evoked MIOO, could be well-modeled as originating from a focal dipolar source in the auditory cortex on the supratemporal plane (STP). Furthermore, the difference wave derived by subtracting the extremely small unstrended-channel DRF from the attended-channel DRF also showed this pattern of localization.

These neuromagnetic results indicate that the additional deviance-related anon-specific NZb component as proposed by Nastaren (1991),

Fast Habituation of Scalp-Recorded Auditory Evoked Potentials to Paired Tone Stimuli in Infants. J.L. Shucard, D.W. Shucard, V.L. Shafer, L. Ferretti, S. A. Kubow Department of Neurology, SUNY @ Buffalo, 100 High Street, (D-6), Buffalo, NY 14203.

Fast habituation of the averaged evoked potential was described by Callaway (1973) as a general reduction in evoked potential amplitude that occurs to stimuli presented less than 10 seconds apart. When auditory stimuli are presented in pairs, separated by 2 seconds, with an interpair interval of approximately 10 seconds, averaged evoked potentials to the second stimulus may have as little as half the amplitude as that to the first stimulus of the pair. It has been shown that fast habituation depends somewhat on the subject's anticipation of the stimulus, attention to the stimulus, or knowledge of the interstimulus interval. In our laboratory, we have exploited this phenomenon of auditory evoked potential (AEP) fast habituation to study the allocation of cerebral resources under a variety of experimental conditions in infants, children and adults. In this investigation we present data describing the scalp distribution of AEPs associated with paired tone stimuli in infants less than one year of age. AEPs were recorded in awake infants to pairs of auditory tone bursts (100 msec, 600 Hz, approximately 70db) separated by two seconds with an interpair of greater than 6 seconds. Findings showed that 1) there was a marked amplitude decrement from tone 1 to tone 2 in frontal and temporal but not parietal scalp locations; and 2) right hemisphere recordings from frontal and temporal sites but not parietal sites showed higher amplitude responses than left. These findings occurred for AEP components between 100-500 msec. These results indicate that "fast habituation" to paired tone stimuli is present in infants and that it varies with both left to right and rostral to caudal scalp locations. This technique may prove useful for studying the development of orientation and attention in infancy.

PARALLEL DISSOCIATION OF HUMAN RECOGNITION/RECALL AND TWO DISTINCT FRE COMPONENTS THROUGH THE MANIPULATION OF ITEM MEANINGFULNESS. Daniel M. Rice\* & Thomas F. Locke, Andrus Gerontology Center, University of Southern California, Los Angeles, CA. 90089.

In a first experiment, seventeen young adults had 32 channel topographical ERPs while they were engaged in a continuous verbal recognition memory task in which item meaningfulness (moderate frequency words vs. pronounceable nonwords) and item repetition (novel vs. repeat) were manipulated. Items were presented every three seconds on a CRT. Item repetition within 6-18 seconds was associated with 1) an increased positive component over the entire head during the 400-600 msec poststimulus period for both words (p<.008) and nonwords (p<.004), and 2) an increased negative component over the entire head during the 800-1200 msec poststimulus period for words (p<.003), but not for non-words. All of these effects were largest in the posterior leads in this nose reference recording. Because there were no significant differences between recognition performance accuracy or response time for words vs. non-words and because the late negative ERP enhancement to repeated words happened after the average response time, this late negative enhancement would not appear to reflect a process which is necessary for recognition memory. In a second experiment, the identical timing and word/non-word list were employed as in the first experiment, but the items were not repeated verbatim. Instead, the first few letters of each item were repeated. Ten young adult subjects were now asked to recall the item recently seen which uniquely corresponded to the letter cue presented. Words were recalled better than non-words in all ten subjects in this letter cued recall task (p<.0001). These experiments suggest that 1) moderate frequency words are recalled, but not recognized, better than non-words, and 2) a pattern of ERP effects parallels this dissociation.

AMPLITUDE OF EVENT-RELATED POTENTIALS GENERATED IN THE CON-TEXT OF MNEMONIC DEMAND IS DIRECTLY RELATED TO MRI DERIVED HIPPOCAMPAL VOLUME. L. deToledo-Morrell\*, M. Sullivan, D. Charletta, F. Morrell & C. Spanovic. Depts. of Neurol.Sci., Psychol. & Diag. Radiol., Rush Med. Coll., Chgo, IL 60612.

There is some uncertainty about the neural generators of the P300 component of event-related potentials (ERPs). To examine the proposition that the amplitude of the P300 potential elicited under conditions of mnemonic demand reflects the integrity of the hippocampal formation, we studied 21 subjects electrophysiologically and with a high resolution MRI protocol to assess hippocampal volume. Subjects consisted of patients with various dementias, with structural neocortical lesions, aged and young controls. ERPs were recorded referentially during a modified Sternberg memory scanning task with letters as probes as well as during a visual discrimination (oddball) task that did not contain a memory component. Hippocampal volume was computed from MRI scans of gapless coronal slices taken perpendicular to the long axis of the hippocampus. With memory loads of 3-5 letters, P300 amplitude was significantly correlated with hippocampal volume irrespective of diagnosis or age (r=0.812, p<.001). In the same subjects, the amplitude of the P300 potential elicited in the spatial oddball task did not relate to hippocampal volume (r-0.339, p>.05). These results clearly indicate that the neuroanatomical substrate (i.e., the generator site) of the P300 potential may vary depending on the nature of the eliciting task.

RETROACTIVE ENHANCEMENT OF A SKIN SENSATION BY A DELAYED CORTICAL STIMULUS, IN MAN.
B. Libet, E.W. Wright, B. Feinstein and D.K. Pearl. Dept. of Physiology, UCSF, San Francisco, CA 94143-0444, and Dept. of Statistics, Ohio State Univ., Columbus, OH Retroactive or backward masking had been shown earlier with the second peripheral stimulus (they extens) are adelered.

either a second peripheral stimulus (by others) or a delayed cortical stimulus (by us) as the masking agent. We now report that retroactive enhancement can also be produced when a train that retroactive enhancement can also be produced when a train of stimulus pulses to somatosensory cortex (C) follows a skin stimulus (S) by up to 400 msec or more. Two identical stimulus pulses ( $S_1$  and  $S_2$ ) were applied to the same skin electrode,  $S_2$  following  $S_1$  by 5 sec. Subjects reported whether  $S_2$  felt stronger following  $S_1$  by 5 sec. Subjects reported whether  $S_2$  felt stronger than, same as, or weaker than  $S_1$  in the control trials, and with the C stimulus added some time after  $S_2$  in experimental trials.  $S_2$ ·C intervals ranged from 25 msec to 500 msec or more. In control series  $S_2$  was reported same as  $S_1$  in about 2/3 of trials, and stronger than  $S_1$  in 1/3 of trials. With C added,  $S_2$  was reported stronger in about 2/3 of trials and same as  $S_1$  in 1/3, for reported stronger in about 2/3 of trials and same as  $S_1$  in 1/3, for all  $S_2$ -C intervals to 400 msec; difference from controls was significant at p=<.0001. The long  $S_2$ -C intervals effective for retro-enhancement provide strong support for our thesis that the development of a conscious sensory experience, and perhaps awareness of any event, requires a substantial duration of up to 0.5 sec of appropriate cortical activity.

IMPROVED EEG/MEG SOURCE LOCALIZATION BY COMBINING A CORTICAL SURFACE MODEL WITH SPATIO-TEMPORAL CONSTRAINTS. A.M. Dale\*and.M.I. Sereno, Cognitive Science Department, University of California San Diego, La Jolla, CA 92093.

STRAINTS. A.M. Dale and M.I. Sereno, Cognitive Science Department, University of California San Diego, La Jolla, CA 92093.

We recently described a linear approach to the inverse problem of localizing cortical current sources using EEG and MEG data and anatomical constraints (Dale and Sereno, NS Abs., 1991). This technique works well with shallow sources and computationally tractable, even for several thousand source dipoles (required for a minimal tiling of the cortical sheet). Optimal linear inverse operators, however, ypically mis-localize deeper sources. Even with constraints on dipole location and orientation, and noise and source covariance, there are numerous shallower, spread-out solutions in the case of a deep focal source that are also consistent with the data for a single time step. Recently, Mosher et al. (NS Abs., 1991) described an application of the MUSIC algorithm to the source localization problem using constraints arising from the structure of the sensor data over time. We have integrated a MUSIC like constraint into our approach, and show with model studies that we can obtain high spatial resolution with moderate numbers of sensors.

The cortical sheet is first found by orthogonal slice combination, flood-filling, and deformable template refinement (Sereno and Dale, this volume). The sensor spatio-temporal covariance matrix is then estimated using a finite series of timesteps from an averaged evoked response. An eigenvalue decomposition of the sensor covariance matrix and the forward solution are used to obtain estimates of the avainace of each source dipole. These are inserted into the equation for the optimal linear inverse operator as a priori source variance estimates. The inverse operator is then used to calculate a solution for each time step. Our formulation does not require setting an explicit eigenvalue threshold and reduces smoothly to a minimumnom like approach when the eigenvalues are almost equal (as with white noise).

Model studies using a real cortical sheet (~150,000 vertices

COGNITIVE PROCESSING IN A THREE CHOICE REACTION TIME PARADIGM AND ITS MODULATION BY TRANSCRANIAL MAGNETIC STIMULATION (TMS). E. Gomez-Tortosa, A. Pascual-Leone, D.W. Alway, P. Nichelli, M. Hallett and J. Grafman \*. Cognitive Neuroscience and Human Motor Control Sections, NINDS, NIH, Bethesda, MD 20892

Neural processes involved in a choice reaction time (RT) task may vary according

Neural processes involved in a choice reaction time (R1) task may vary according to the number of choices. In a 3-choice RT paradigm we studied 8 right-handed normal volunteers (4 men and 4 women, aged 22 to 50 years). A monitor displayed an asterisk randomly either on the right, on the left, or on both sides of a fixation point. Subjects were asked to respond as fast as possible by pressing either a single key on the same side of the stimulus or both keys at the same time in case of bilateral stimuli. Unimanual RT was equal with right and left hand and significantly shorter stantan. Ominanian RT was equal with right and reft hand and significantly shorter than RT for the faster hand in bimanual responses in all subjects. With bilateral stimuli, 6 subjects responded in >60% of the trials with the sequence "right-left", while two preferred the sequence "left-right". Intermanual interval was about 5 ms for the preferred and 25 ms for the non-preferred sequence, but RT for the first key press in responses with the preferred sequence was approximately 200 ms longer than in those with the non-preferred sequence. There was no significant difference in RT between trials with unilateral stimuli and trials with bilateral stimuli responded with the non-preferred sequence. Subthreshold TMS of the sensorimotor area concurrently with the stimuli induced faster RTs in unimanual contralateral responses and biased all subjects to lead bimanual responses with the contralateral hand despite long intermanual to read offination responses with the contrastateral nand despite long intermanual interval. Although the task encompassed 3 choices, subjects completed it in only 2 processing steps, one for unimanual responses (short RT) and the other for bimanual responses with the preferred sequence (long RT). Bimanual responses with the non-preferred sequence may represent processing errors in which a unimanual response is initiated but corrected in time; this results in short RTs for the first hand but long intermanual intervals. Lateralized TMS speeds up the pre-movement excitability build-up for contralateral hand movements, thus shortening unimanual RT and inducing processing errors for bimanual responses.

### 252.12

A TECHNIQUE FOR RECONSTRUCTING AND FLATTENING THE CORTICAL SURFACE USING MRI IMAGES. M<u>L. Serend and A.M. Dale,</u> Cognitive Science Dept., University of California San Diego, La Jolla, CA 92093.

CORTICAL SURFACE USING MRI IMAGES. M.I. Serend and A.M. Dale. Cognitive Science Dept., University of California San Diego, La Jolla, CA 92093.

In order to more strongly constrain the solution to the inverse problem of localizing cortical current sources using MEG and EEG (Dale and Sereno, this volume), we needed to reconstruct the shape of the entire cortical sheet for individual subjects from MRI images, since this varies substantially among different people. Stacked-section images displayed with interslice interpolation, transparency, and lighting are realistic-appearing, but they lack explicit information about the orientation of a local surface patch. Since manual methods for making a cortical surface model are labor intensive and error-prone, we devised a more automatic, three-stage method for generating a high-quality wireframe cortical surface model.

2-D MRI images have good in "plane resolution (<1mm), but sections are usually thick (3-6 mm), smearing the image of the cortical surface when it is oriented nearly parallel to the stice plane. Therefore three orthogonal series of inversion-recovery sections (needle-shaped voxels) optimized for contrast between the gray and white matter are combined into a single volumetric data set with the same high (subslice) resolution in all directions (cubic voxels) using a linear estimation technique. After automatic skull removal, an initial estimate of the boundary between the cortical gray and white matter is found by recursive flood-filling. White matter (classified by voxel intensity) is initially flood-filled in 3-D from a single seed location. Internal holes and external islands are eliminated by successive "outside in" and "inside out" fills. A single, closed tessellation of the white-matter surface can then be constructed from the faces of filled woxels bordering unfilled woxels.

The surface is refined using a deformable template algorithm. The location of each vertex is updated according to elastic "forces" between neighboring vertices, and repulsive and

PROTEIN KINASE A MODULATES AN ENDOGENOUS VOLTAGE-DEPENDENT CALCIUM CHANNEL IN XENOPUS OOCYTES. Y. Chen, J. D. Pollock\*, Y. Wang, A. DePaoli-Roach, L. Yu. Dept. of Med. & Mol. Genetics, Indiana Univ. Sch. of Med., Indianapolis, IN 46202.

Xenopus oocyte possesses a calcium channel that is activated by membrane depolarization. The calcium influx through this channel activates a calcium-dependent chloride channel and results in a transient outward current  $(T_{out})$ .  $T_{out}$  is increased by cAMP-dependent phosphorylation of the endogenous voltage sensitive calcium channel in *Xenopus* oocyte. Treatment of oocytes with forskolin, IBMX, or cAMP injection increases the magnitude of  $T_{out}$  in a dose- and time-dependent fashion without a change in voltage dependence. The effect of cAMP on  $T_{out}$  is mediated through the activity of protein kinase A (PKA). The effect of cAMP and PKA on the increase of  $T_{out}$  is blocked by a PKA inhibitor PKI as well as a mutant RII, which inhibits PKA in the presence of cAMP. Furthermore, the increase of  $T_{out}$  by cAMP injection can be inhibited by both type I and type II phosphatases. A barium current is augmented by cAMP injection, and the magnitude of the increase is directly proportional to that of  $T_{our}$ . These results suggest that the increase of  $T_{out}$  produced by cAMP-mediated phosphorylation results from a modulation of the endogenous calcium channel in the oocyte.

ACTIVATION OF CHLORIDE CHANNELS IN HUMAN NEUTROPHILS BY TUMOR NECROSIS FACTOR  $\alpha$  VIA CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE. M. A. Schumann P. Gardner, and T. A. Raffin. Division of Pulmonary and Critical Care Medicine, Stanford University School of Medicine,

The mechanism underlying tumor necrosis factor  $\alpha$  (TNF $\alpha$ )-induced intracellular  ${\rm Ca}^{2+}$  changes and activation of CI $^-$  channels in polymorphonuclear neutrophil leukocytes is unknown. By means of the whole-cell patch clamp methodology, we studied the mechanism of activation of Cl $^-$  channels by TNF $\alpha$  in human neutrophils. The current was carried by Cl- ions and was activated by Ca2+ ions. Bath application of ionomycin (1µM) activated the control current significantly. Bath application of TNFa (1000 U) resulted in comparable activation of the current in 80% of tested cells. Both amplitude and activation rate of the current were augmented. The activated current was blocked by 10 µM 5-nitro-2(3-phenylpropylaminobenzoic acid, a potent Cl channel blocker. We found that with the intracellular application of a peptide inhibitor (10  $\mu$ M) having the same sequence as the inhibitory domain of the multifunctional calcium/calmodulin-dependent protein kinase (273-302), the current ceased to activate, from the level of the control, by the exogenous application of either ionomycin or TNF  $\alpha$ . Including 10  $\mu$ M of the neated form (nonactive control; 284-302) of the inhibitory peptide in the pipette did not block the TNF $\alpha$ - (or ionomycin-) induced Cl - current. These results show that Cl<sup>-</sup> channel activation by Ca<sup>2+</sup> in human neutrophils is mediated by Ca2+/calmodulin-dependent protein kinase and this mechanism underlies, in part, the activation of Cl<sup>-</sup> channels by TNFα-induced Ca<sup>2+</sup> changes in these cells.

PKC ACTIVATION PRODUCES SPIKE BROADENING IN SENSORY NEURONS OF JUVENILE APLYSIA PRIOR TO THE DEVELOPMENT OF 5HT-INDUCED BROADENING, E.A. Marcus\* and T.J. Carew. Depts. of Biol. and Psych., Yale Univ., New Haven CT 06520 In tail sensory neurons (SNs) of adult Aplysia, serotonin (5HT) produces both increased excitability and spike broadening. An important component of 5HT-induced spike broadening is mediated by protein kinase C (PKC)-dependent modulation of the delayed rectifier potassium conductance, ikv (Baxter and Byrne, 1990). In development, 5HT-induced spike broadening emerges after 5HT-induced increased excitability (Marcus and Carew, 1990). Here we examined whether the lack of 5HT-induced spike broadening in juvenile Aplysia reflected an inability of 5HT to activate PKC or alternatively an inability of PKC to modulate liv. of PKC to modulate lkv.

Confirming Sugita et al. (1991), we found that activation of PKC via application of phorbol esters (PDAc, 3µM) produced significant spike broadening in adult SNs (x =17.4%, p<0.001, N=13) with no appreciable effect on excitability. We then examined the effects of PDAc on SNs of juvenile on excitability. We then examined the effects of PDAc on SNs of juvenile Aplysia (-19 and ≤ 1.5g) and found that it produced significant spike broadening (x =18.1%, p<0.02, N=8). Moreover, there was no difference between the magnitude of PDAc-induced spike broadening in these juveniles and adults suggesting that the ability of PKC to modulate kiv is fully mature at this stage. In younger juveniles (>0.5g and ≤1g) PDAc did not produce significant spike broadening (x = 3%, ns, N=8) and the effect of PDAc on spike duration was significantly different from that observed in adults (p<0.001). These data suggest that the ability of PKC to modulate kiv is not expressed in these ituacities although be consequent to be functioned within these.

These data suggest that the ability of PKC to modulate like is not expressed in these juveniles although like appears to be functional at this stage.

We propose a model for the sequential development of neuromodulatory pathways which includes 3 steps: initial expression of an ionic conductance, followed by development of the ability to modulate that conductance with specific second messengers, followed still later by development of the ability to activate the second messenger with a specific modulatory neurotransmitter.

THAPSIGARGIN ACTIVATES AN INWARD CURRENT AND SPECIFICALLY INCREASES INTRACELLULAR CALCIUM AT THE SOMATA OF BAG CELL NEURONS IN CULTURE. L.S. Kao. THAPSIGARGIN R. J. Knox.\* E. A. Jonas, J.A. Connor, and L.K. Kaczmarek, Dept. of Pharmacology, Yale University School of Medicine

A rise in intracellular calcium occurs during a long-lasting afterdischarge in Aplysia bag cell neurons. We used thapsigargin, a specific inhibitor of the endoplasmic reticulum Ca² pump to analyse the effects of calcium released from intracellular stores on the electrophysiological responses of bag cell neurons. We used isolated cells that at the time of the experiments had produced considerable new neuritic outgrowth. Using digital imaging of cells loaded with the calcium indicator dye, fura-2, we found that thapsigargin (0.5µM) produced a rapid and sustained elevation of the basal calcium concentration at the soma. Such changes as occurred in neurites appeared to be the result of passive spread from the soma, suggesting that intracellular calcium stores are specifically localized at the soma. Thapsigargin also produced a decrease in the latency for the generation of action Inapsiagin area produced a decrease in the faterity of the generation of action potentials and, in media containing the potassium channel blocker TEA, a sustained depolarization of ~ 10mv. The depolarization was observed when Na\* was replaced by TEA or Tris but not by N-methylglucamine and was insensitive to 10mM Co<sup>2+</sup>, 100µM TTX or to removal of extracellular Ca<sup>2+</sup>. The depolarization was paralleled by the development of a non-rectifying inward current with a reversal potential of around -20mv. Our data suggest that an increase in intracellular calcium at the soma may activate a non-specific cation channel that may contribute to changes in the electrical properties of bag cell neurons at the onset of an afterdischarge.

INDIRECT INHIBITION OF OLFACTORY CYCLIC NUCLEOTIDE-GATED (CNG) CATION CHANNELS BY INTERNAL CALCIUM: PROBABLE ROLE IN SENSORY ADAPTATION. Richard H. Kramer and Steven A. Siegelbaum Ctr. for Neuro. and Behav., HHMI, Columbia Univ. P&S., New York, NY 10032

Olfactory signal transduction involves an odorant-elicited increase in cAMP, which directly activates CNG channels. Adaptation is thought to involve an increase in intracellular Ca<sup>2+</sup>. Here we demonstrate that internal Ca<sup>2+</sup> profoundly inhibits CNG channels in inside-out "macro" patches containing the

protoundly inhibits CNIs channels in inside-out "macro" patches containing the dendrite and cilial from carlfsh olfactory neurons.  $Ca^{2*}\text{-dependent inhibition of the cAMP-elicited current is distinct from the open-channel block produced by Mg^2*. The Mg^2* block is voltage-dependent, occurs only at [Mg^2*] > 100 <math>\mu$ M and is equally effective at all cAMP concentrations. In contrast, the inhibition by internal Ca^2\* has a K<sub>1/2</sub> of 3  $\mu$ M, is voltage-insensitive, and occurs at low cAMP concentrations (e.g. 2.5  $\mu$ M), but not with cAMP levels that saturate channel gating (e.g. 50 µM).

Hence Mg<sup>2\*</sup> reduces the maximal cAMP-elicited current, while Ca<sup>2\*</sup> shifts the activation of CNG channels to higher cAMP levels without altering the maximal response. This shift in sensitivity is characteristic of adaptation in sensory systems.

The inhibition of CNG channels by Ca2+ apparently not direct because 1) the effect "washes out" with time after excision (see Figure), and 2) Ca2+ has no effect on the cloned catfish CNG channel expressed in Xenopus oocytes. Hence we propose that Ca<sup>2+</sup> inhibits CNG channels by interacting with a loosely associated protein distinct from the CNG channel protein.

MODULATION OF AN APLYSIA DIVALENT-PERMEABLE CATION CHANNEL BY ENDOGENOUS KINASE AND THE CATALYTIC SUBUNIT OF PROTEIN KINASE A. G.F. Wilson\*, and L.K. Kaczmarek, Dept. of

Pharmacology, Yale Univ. Sch. of Med., New Haven, CT 06510.

Nonspecific cation channels provide the depolarizing drive underlying bursts of action potentials and also an entryway for cations that mediate secretion. Using bag cell neurons of *Aplysia*, we have studied the modulation of a channel permeable to both monovalent and divalent cations. This channel was present in 50/182 excised patches, but appears only rarely in cell-attached patches. In physiological extracellular solutions (containing in mM: 460 NaCl, 10.4 KCl, 11 CaCl<sub>2</sub>, 55 MgCl<sub>2</sub>, 10 Hepes, pH 7.8), the channel exhibits a slope conductance of 30-35 pS, an extrapolated reversal potential close to 0 mV, and is voltage-dependent, the open probability decreasing with hyperpolarization below -60 mV. We have found that ATP (5 mM, the concentration normally present in intracellular solutions) bath applied to inside/out patches results in an increase in channel activity (n= 4/4), presumably via a kinase closely associated with the channel protein. Further, addition of the catalytic subunit of PKA (1-5 µM) decreases the open probability when the starting open probability of the channel is high (n=6/6), but increases the open probability when the starting open probability is low (n= 3/4). Both effects of the catalytic subunit require ATP and appear to be due to a difference in the behavior of one channel type, since occasionally transitions in activity are observed for single untreated channels. Thus, these effects are best explained by a two phosphorylation site model, where the effect of phosphorylation of the second site depends on whether the first site is phosphorylated. This model is being tested by treating patches with protein phosphatases.

### 253.6

ENHANCEMENT OF Ca AND K CURRENTS BY MODULATORY PEPTIDE COTRANSMITTERS CORRELATED WITH POTENTIATION AND DEPRESSION OF CONTRACTIONS OF THE ARC MUSCLE OF APLYSIA. V. Hezina\*1, E.C. Cropper!, C.G. Evans!, I. Kupfermann² and K.R. Weiss!. ¹Dept. Physiol. & Biophys., Mt. Sinai Sch. Med. and ²Crt. Neurobiol. & Behav., Columbia Univ., New York, NY. The accessory radula closer (ARC) muscle of Aplysia has been studied as representative of the many buccal-mass muscles whose coordinated contractions underlie biting and swallowing. Preservation of the functional integrity of these behaviors even as their frequency and amplitude change, for instance during food-induced arousal, requires coordinated changes in the parameters of these contractions. In the case of the ARC muscle, such modulation is thought to be brought about in large part by appropriate release of peptide cotransmitters of several different families (the small cardioactive peptides (SCPs), myomodulins (MMs), FMRFamide-related peptides (FRPs) and buccalins) from the same two motomeurons whose primary transmitter, ACh, mediates the contractions. At least some of the peptides feed back to presynaptically modulate ACh and cotransmitter release. Another important site of modulation, however, is clearly the postsynaptic ARC muscle itself: contractions elicited by exogenous ACh are potentiated by low concentrations of SCPs and MMs, weakly depressed by high concentrations of SCPs and MMs, weakly depressed by FRPs. We have studied the electrophysiological properties of dissociated ARC muscle fibers to determine whether modulation of ion properties of dissociated ARC muscle fibers to determine whether modulation of ion currents might underlie these effects. Indeed, the pattern of the effects of the peptides on contraction is clearly reproduced in their pattern of effects on two ion currents SCPs and MMs enhance an 'L'-type Ca current, and SCPs and MMs slightly activate a characteristic K current whereas MMs and FRPs activate it strongly. The Ca current characteristic K current whereas  $MM_A$  and FRPs activate it strongly. The Ca current most likely supplies much of the  $Ca^{2*}$  necessary for contraction, while the K current appears well suited to counteract ACh-induced depolarization of the muscle and thus limit activation of the Ca current. It is thus an attractive hypothesis, which we are currently testing more directly, that the enhancement of the Ca current by the SCPs and MMs is in fact the mechanism by which they potentiate ARC muscle contractions, whereas activation of the K current is the mechanism by which the SCPs, MMs and FRPs, to different degrees, depress those contractions.

MECHANISM OF VOLTAGE-DEPENDENT CALCIUM CHANNEL MODULATION BY NEUROTRANSMITTERS IN CHICK SYMPATHETIC NEURONS. A.G. Golard and S.A. Siegelbaum. Ctr. Neurobiol. and Behavior, HHMI, Columbia University, New York, NY 10032

Neurotransmitter inhibition of calcium currents (Ica) can be relieved by large depolarizing prepulses. This effect has been postulated to be due to the voltage-dependent unbinding of a blocking particle (e.g. G protein) to the channel or, alternatively, to reflect a slow voltage-dependent gating step intrinsic to the modulated channel. According to the first hypothesis, the rate of reblock following a depolarizing prepulse should increase with the extent of inhibition (i.e. concentration of blocking particles). We used whole cell patch clamp to study calcium channel inhibition produced by somatostatin (SS) and norepinephrine (NE). At maximal concentrations, both SS (30 nM) and NE (30  $\mu$ M) inhibit Ica by 50% at a test potential of 0 mV. This inhibition is transiently relieved by a 15 msec prepulse to +100 mV. Upon repolarization to -80 mV,  $I_{c_a}$  reblocks with a  $\tau$  of 58.4 $\pm$ 19 msec (n=7) for SS and of  $52.0\pm0.2$  (n=2) for NE. With repeated applications of NE or SS, the extent of inhibition desensitizes and re-block kinetics are significantly slowed (r increases to >100 msec for both NE and SS). These results favor a model in which a blocking particle is freed by depolarization.

CA2+-DEPENDENT REGULATION OF K CHANNELS IN INTACT HUMAN T LYMPHOCYTES. L.C. SCHLICHTER\*, I. CHUNG, P.A. PAHAPILL AND P.A. SCHUMACHER. Playfair Neuroscience Unit, Toronto Hospital, Toronto, Ontario, CANADA, M5T 2S8.

T cell activation is dependent on a rise in intracellular Ca2+ which is comprised of an IP<sub>3</sub>-mediated release from internal stores and a sustained influx across the plasma membrane. The driving force for Ca<sup>2+</sup> influx is maintained by K<sup>+</sup> efflux and two classes of K channels have been identified in T cells; voltage dependent and Ca2+ dependent. However, we have recently determined that the K channels are also regulated by second messenger (kinase) pathways. Since mitogenic stimuli activate both IP3 and protein kinase C pathways, it is not clear which K channels will be active during mitogenic stimulation. Using patch-clamp recordings in the cell-attached and nystatin-permeabilized configurations to preserve cytoplasmic integrity, we have characterized three K channels; an inwardly rectifying 10-25 pS voltage-dependent channel, a similar conductance Ca2+dependent channel and a smaller (~9 pS) Ca<sup>2+</sup>-dependent channel. The voltage-dependent channel is inhibited by a physiologically relevant rise in Ca, over the entire voltage range (-100 to +50 mV). Steady-state activity of this channel is increased at the resting potential by Ca<sup>2+</sup> depletion. Conversely, two types of non-voltage dependent K channels are activated by a rise in  $Ca_i$  (ionomycin, Ca rebound treatment) or by mitogenic lectins which stimulate both the  $IP_3$  and PKC pathways. The larger of the two channels was sensitive to patch excision, hence it may be under-represented in whole-cell or excised patch recordings. Our results are consistent with a major role for Ca-dependent rather than the voltagedependent K channels in maintaining the Ca2+ influx.

ARACHIDONIC ACID INHIBITS SODIUM CURRENTS IN STRIATAL NEURONS. B.A. MacVicar\*, D.D. Fraser, K. Hoehn, and S. Weiss. Neuroscience Research Group, University of Calgary, Calgary, AB, Canada T2N 4N1.

We investigated the effects of arachidonic acid (AA) on neurotransmitter release and on Na currents (INa) in striatal neurons. In cultured striatal neurons, the TTX-sensitive release of [3H] GABA induced by 5  $\mu$ g/ml veratrine was depressed by AA (1-10 µ M) in a concentration dependent manner (up to 65% at  $10~\mu\text{M}$ ). AA did not, however, inhibit the release of [ $^3\text{H}$ ] GABA induced by 56 mM K $^*$  depolarization. This suggested that AA inhibited veratrine-induced release by selectively acting upon the Na channel. We then investigated the action of AA on TTX-sensitive I<sub>Na</sub> studied under whole-cell voltage clamp in either cultured or acutely isolated striatal neurons. AA (10  $\mu$  M) reversibly depressed the peak amplitude I<sub>Na</sub> (45% in culture; 30% in acutely isolated cells) and shifted steady state inactivation by -15 mV in the majority of neurons studied. Na entry was studied in cultured striatal neurons by imaging veratrine-induced changes in SBFI fluorescence, a Na-dependent fluorescent dye. AA (10  $\mu$ M) reversibly inhibited (81%) the veratrine-induced increases in [Na]<sub>i</sub>. We conclude that AA inhibits synaptic transmitter release and Na entry in striatal neurons by depressing I<sub>Na</sub> and shifting steady state inactivation in the hyperpolarizing direction. Supported by Medical Research Council (Canada).

MODULATION OF Ca CURRENTS BY L-GLUTAMATE IN CULTURED HYPOTHALAMIC NEURONS. T.H. Müller\*, H.U. Zeilhofer & D. Swandulla. Max-Planck-Institut biophysikalische Chemie, Göttingen, Germany & Institut für Pharmakologie und Toxikologie, Universität Erlangen-Nürnberg, Erlangen, Germany.

Dissociated hypothalamic neurons taken from foetal rats Elissociated hypothalamic neurons taken from foetal rats (E14) and kept in culture for more than 21 days exhibit both low- (LVA) and high-voltage-activated (HVA) Ca currents and different types of glutamate receptors (Swandulla & Misgeld, J. Neurophysiol. 64:715, 1990; Müller et al., J.Physiol. 450:341, 1992). In the present study we investigated the effect of glutamate on Ca currents recorded in whole-cell configuration. reduced HVA Ca currents in a dose-dependent manner (~50% at 100 μM) whereas LVA Ca currents were not affected. Quisqualate reduced HVA Ca currents with a affected. Quisqualate reduced HVA Ca currents with a tenfold higher potency compared to glutamate. Kainate (5 μM), NMDA (20 μM), AP4 (100 μM) and trans-ACPD (100 μM) were ineffective. The action of glutamate on Ca currents was attenuated by including either the GDP-analogue GDB-β-S, which blocks G-protein activation, or the Ca chelator BAPTA in the pipette solution. The results suggest that glutamate modulates HVA Ca currents by a Cadacacactar activation. dependent mechanism involving G-protein activation. Supported in part by an SFB grant (353) to D.S.

"Dept. of Pharmacol., Oxford Univ., Oxford OX1 3QT, U.K.
Microinjection of a high molecular weight cytosolic
extract from sperm (SF) into unfertilized mammalian eggs
activates sustained Ca2\* oscillations due to a

sensitization of calcium-induced calcium release (CICR). cADPR is a potent Ca2+ releasing agent in sea urchin eggs and may also act on a CICR mechanism. We have found that and may also act on a CICK mechanism. We have found that intracellular application of both these agents induces Ca<sup>2+</sup>-dependent inward currents in cultured rat dorsal root ganglion (DRG) neurones. Cells were voltage clamped at -90mV using the whole cell variant of the patch clamp at -90mW using the whole cell variant of the patch claim technique and SF (0.2-2.0 mg/ml total protein conc.) or cADPR (10-8 - 10-6 M) applied by inclusion in the patch pipette. Extracellular application of SF had no action nor did intracellular application of cytosolic brain extract or serum albumin fraction V. Activity of both agents was abolished by denaturing (heat or freeze/thaw). SF induced activity was attenuated by intracellular ruthenium red and could be triggered or potentiated by activating a series of voltage gated Ca<sup>2+</sup> currents to load the cell with Ca<sup>2+</sup>. However, preincubation with load the cell with  $\text{Ca}^{2+}$ . However, preincubation with caffeine (lmM) did not abolish SF induced activity.

## GENE STRUCTURE AND FUNCTION IV

EXPRESSION OF THE SMALL NUCLEAR RNA-ASSOCIATED PROTEIN SMN IN CELLS IS NOT SUFFICIENT TO DIRECT CGRP SPECIFIC MRNA SPLICING. S.E. Leff\*, M.L. Reed, and M.E. Sanjines. Dept. of Pharmacology, Stanford Univ. School of Medicine, Stanford, CA 94305. The mammalian calcitonin/CGRP gene is alternatively spliced in a

tissue-specific fashion. Currently, there are no tissue-specific transacting splicing factors identified that control or participate in alternative splicing of mammalian mRNAs. However, one small nuclear ribonucleoprotein associated polypeptide, SmN, has been described that is expressed selectively in brain, heart and pituitary, tissues which favor the production of CGRP mRNA from a transgene. We examined whether the ectopic expression of SmN in cells alters the pattern of alternative splicing of a transfected rat calcitonin/CGRP in: 1) HeLa cells, which express no endogenous SmN and; 2) COS cells, which express a relatively moderate level of SmN. In both instances, expression of SmN was not sufficient to significantly increase the production of CGRP mRNA from the rat calcitonin/CGRP gene. However, expression of SmN protein in HeLa cells was associated with a post-transcriptional suppression of Sm B/B' levels that might arise from either an effect on synthesis or degradation of Sm B/B' proteins. Thus the cell specific expression of SmN protein does not appear to be sufficient to direct on CGRP mRNA specific splicing. Current studies are attempting to determine whether SmN expression is necessary for a cell to produce CGRP mRNA efficiently.

Glutamine synthetase (GS) gene expression
confined to astrocytes in the CNS. Previously
series of deletion and site-directed mutants of expression promoter region were generated by PCR, cloned into  $pSV_0CAT$ , and expressed in various cell lines.

pSV<sub>6</sub>/AT, and expressed in various cell lines. We identified three regions of importance for the regulation of GS expression, a site homologous to AP2 located at -222, an enhancer region at -315, and a silencer region at -797. We have shown that these sites are functionally important for GS expression in astrocutes.

astrocytes. We now demonstrate that these regions bind transacting factors using a gel retardation assay with synthetic oligonucleotide probes. Interestingly, the site we identified by homology to the AP2 consensus sequence did not bind any proteins. By extending the site to include an upstream G/C rich region we were able to demonstrate binding with nuclear extracts from astrocytes, however, purified AP2 protein was unable to bind. Thus the site must bind an unidentifed, non-AP2, protein.

We have also been able to show that the two other sites are capable of binding proteins from astrocyte nuclear extracts. The silencer binds a protein which is not present in HeLa nuclear extracts, while the enhancer region binds proteins from both HeLa and astrocyte nuclear extracts.

NICOTINE AND MUSCARINE STIMULATE EXPRESSION OF PNMT PROMOTER CONSTRUCTS TRANSFECTED INTO PRIMARY CHROMAFFIN CELLS. M.J. Evinger", L.M. Hemmick", S. Regunathan", D.J. Reis", and M.E. Ross\*, "Dept. Neurobiol. & Behav., SUNY Stony Brook, "Div. Neurobiol., Cornell Univ. Med. Coll., 'Dept. Neurology, Univ. of Minn.

Exposure of bovine adrenal medullary cells to nicotine or musc stimulates accumulation of phenylethanolamine N-methyltransferase (PNMT) mRNA with each of these chollinergic agonists acting through separate receptor and second messenger systems. We sought to establish whether the effects of these agents are mediated through defined regions in the 5' upstream sequences of the PNMT promoter. Primary cultures of bovine chromaffin cells were transfected with PNMT-CAT or -luciferase promoter-reporter constructs, then exposed to either nicotine (50 uM) or muscarine (100 uM). Both nicotine and muscarine stimulate by 2.5 fold expression of the 3 kb and 0.9 kb constructs but not the 0.3 kb construct. The relative effects of these agonists are comparable for both CAT and luciferase constructs when transfected either by calcium phosphate or electroporation. The muscarinic response appears specific for the m4 receptor subtype: a) only m4 subtype mRNA is expressed in bovine chromaffin cells (Fernando et al., 1991), b) the m4 selective antagonist 4-DAMP blocks muscarine-stimulated expression of PNMT constructs at concentrations that inhibit accumulation of endogenous PNMT mRNA, and c) 4-DAMP relieves muscarinic inhibition of forskolin-stimulated cAMP accumulation in these cultures. This indicates that muscarinic stimulation of the transfected PNMT gene is mediated through a cyclic nucleotide coupled m4 receptor. We therefore conclude that 5' upstream sequences (>-300 bp) in the PNMT gene convey responsiveness to neural stimuli transduced individually through nicotinic and muscarinic receptors on chromaffin cells.

IN VIVO ANALYSIS OF THE RAT PREPROENKEPHALIN PROMOTER

USING AN HSV DEFECTIVE VIRAL VECTOR.

M.G.Kaplitt<sup>1</sup>, L.Lipworth<sup>1</sup>, S.D.Rabkin<sup>2</sup>, and D.W. Pfaff<sup>4</sup>, <sup>1</sup>Laboratory of Neurobiology and Behavior, Rockefeller Univ., New York, NY 10021; <sup>2</sup>Program in Molecular Biology, Memorial-Sloan Kettering Cancer Center, New York, NY 10021.

We have employed a defective herpes simplex viral vector as a gene transfer vehicle, in order to characterize tissue or brain region-specific regulatory sequences in the rat preproenkephalin promoter. Previously, we have demonstrated that a defective HSV vector can transfer and express a foreign gene in the adult rat brain (Mol. Cell. Neurosci. 2:320-330). In this study, the bacterial lacZ gene was placed under the control of a 2.7kb fragment of the rat preproenkephalin promoter. The transcription unit was inserted into our HSV amplicon and the viral vector dvHENK was then created. Following stereotaxic microinjection of the viral vector, blue cells were noted in the ventromedial hypothalamus and the amygdala, two regions known to express endogenous enkephalin. This indicates that the promoter was functional in the vector. The caudate nucleus usually contains the highest level of endogenous preproenkephalin expression in the brain, however no positive cells have been noted in this Other regions are currently being examined. We have also produced defective viral vectors with different fragments of the promoter region, and these are also being tested in vivo. This study demonstrates that promoter analyses, once restricted to tissue culture, can now be performed in vivo using a plasmid-based HSV defective viral vector.

## 254.7

PROMOTER REGIONS INVOLVED IN BASAL AND HORMONE-STIMULATED ACTIVITY OF TYROSINE HYDROXYLASE (TH) GENE. M.K.Stachowiak.
A.Goc. Barrow Neurological Institute, 350 W.Thomas Rd, Phoenix, AZ 85013.

Cardiovascular effects of angiotensin II (All) have been attributed to the stimulation of catecholamine (CA) secretion from sympathoadrenal and central CA neurons. We have shown that stimulation of All receptors in adrenal medullary cells (AMC) increases mRNA level and transcriptional activity of the TH gene, which encodes the rate-limiting enzyme in CA synthesis. All upregulated also c-Fos- and c-Jun and related antigens. To examine mechanisms of All induction of TH gene, and possible role of AP1 factor, we constructed plasmid bearing luciferase reporter gene under control of -428/+21 bp fragment of TH promoter. Deletion mutants were prepared by removing either -194/-54 or -269/-54 promoter regions. Luciferase activity in transiently transfected cells was normalized to the amount of intracellular plasmid DNA. Each construct expressed luciferase in bovine AMC as well as in glia-derived SF763 cells. -194/-54 region of TH promoter may be involved in tissue-spec basal regulation since its deletion enhanced TH promoter activity 5-fold in AMC and 2-fold in SF763. Deletion of further upstream region containing putative AP1 site (deletion -269/-54) reduced expression of luciferase. Incubation of AMC with All induced a 3-fold increase in luciferase expression from the wild type TH promoter. Promoter deletions diminished this stimulation to 2.1-fold (-194-54 deletion) and 1.8-fold (-269/-54 deletion). We conclude that AP1-containing -269/-195 region is important for basal TH promoter activity, and that multiple regions including -269/-54 fragment participate in All regulation. Pretreatment of AMC with All enhanced in vitro binding of nuclear proteins to TH promoter. Binding of Fos-related antigens was observed in extracts from nonstimulated AMC and was enhanced in cells treated with All supporting the roles of AP1 in basal and All-induced expression of the TH gene.

TRANSCRIPTIONAL REGULATION OF SOMATOSTATIN (SRIF) GENE BY A CYCLIC GUANOSINE 3'5' MONOPHOSPHATE (cGMP) MECHANISM IN A CYCLIC GUANDSINE 3 MANUAL OF THE RAT. M.C. Agu
The Periventricular Nucleus Of The RAT. M.C. Agu
Perivent of Physiology. Neuropeptide Division, Southwestern Medical Center, Dallas, TX 75235-9040.

We had previously reported that growth hormone-releasing factor stimulates cGMP and SRIF release without altering cAMP accumulation from median eminences (ME's) incubated in vitro. Therefore, the possible role of cCMP on SRIF release and on the regulation of SRIF mRNA was examined in periventricular nucleus (PeN) of male rats incubated in vitro. SRIF mRNA levels were determined in PeN explants subjected to 2 and 6 hrs culture in Waymouth's medium in the presence of various concentrations (10-9 to 10-6M) of dibutyryl cGMP (dbcGMP); sodium butyrate served as control. Sodium nitroprusside (SNP) was used to activate the guanylate cyclase pathway. Levels of SRIF mRNA were determined by  $\mathbf{S}_1$  nuclease protection assay using a determined determined by  $\mathbf{S}_1$  nuclease protection assay using a [ $^{32}$ P]labelled rat SRIF riboprobe. SRIF release was measured at 30 min and 6 hrs by RIA. After 6 hrs of incubation SRIF mRNA levels and SRIF release were significantly (pc0.025) increased by  $10^{-7}\text{M}$  dbcGMP, whereas sodium butyrate did not modify them. Likewise, SNP ( $10^{-6}\text{M}$ ) augmented (p<0.001) SRIF mRNA levels at 6 hrs. These results indicate that cGMP regulates the expression of SRIF gene in the PeN and they suggest that cGMP may play an important role in the transcriptional regulation of the SRIF gene. (Supported by NIH grant NS26821).

### 254.6

A NOVEL MADS-FAMILY TRANSCRIPTION FACTOR IN HUMAN BRAIN AND MUSCLE TRANS-ACTIVATES VIA THE MEF-2 ELEMENT. D. Leifer\*. D. Krainc. J. McDermott. Y.-T. Yu. R. E. Breitbart. J. Heng. R. L. Neve. B. Nadal-Ginard. and S. A. Lipton. Depts. of Neurology, Cardiology, and Psychiatry, Harvard Medical School, Boston, MA.

We have identified cDNA clones from human fetal brain and muscle

libraries for a novel transcription factor in the MADS family. This noraries for a novel transcription factor in the MADS tamily. This family includes the yeast transcription factor MCM1, plant homeotic genes such as AGAMOUS and DEF A, which have roles in flower morphogenesis, and human gerum response factor, which may regulate muscle-specific genes and immediate-early genes. Our clones occur in several variant forms that appear to result from alternative splicing. Northern blots indicate that our clones are expressed at abundance in human fatal careful containing and schedule muscle and st lower levels. in human fetal cerebral cortex and skeletal muscle, and at lower levels in cerebellum, but not in other regions of the brain or in other tissues. Our cloned proteins bind specifically to the myocyte-specific enhancer binding factor-2 (MEF-2) regulatory element, which has so far been found to be functionally important in a variety of muscle-specific genes. Our proteins also bind a variant MEF-2 element that is present in the promoter of the brain creatine kinase gene. Moreover, our proteins specifically activate transcription of reporter genes containing the MEF-2 element. Gel-shift experiments have confirmed that an MEF-2 activity similar or identical to our cloned proteins is present in human cortex (Krainc et al., this meeting). Our results suggest that these proteins have a role in development not only of muscle but also of human cerebral cortex and cerebellum, perhaps similar to the role of MADS proteins in plant morphogenesis.

## 254.8

THE CYCLIC AMP RESPONSE ELEMENT IS ESSENTIAL FOR BASAL AND INDUCIBLE TRANSCRIPTION OF THE TYROSINE HYDROXYLASE GENE M.K. Lee, J. Carroll, H. Ishiguro, T.H. Joh and K.S. Kim. Cornell Univ. Med. Coll. at the Burke Med. Res. Inst., White Plains, NY 10605.

Adenosine 3', 5'-cyclic phosphate (cAMP) exerts its effects on a variety of responsive genes via a conserved octamer motif 5'TGACGTCA3', cAMP response element (CRE). The tyrosine hydroxylase (TH) gene, encoding the first and rate-limiting enzyme in the biosynthesis of catecholamine neurotransmitters, contains a single copy of the consensus CRE in the proximal 5' region at -45 to -38 bp upstream of the transcription initiation site. Functional analysis of the upstream 2400 bp region using a transient transfection assay in catecholaminergic cell lines identified two upstream domains, -365 to -151 bp and -60 to -39 bp, containing important cis-acting elements for TH transcription. Strikingly, site-directed mutagenesis demonstrated that the TH CRE was essential not only for cAMP-inducible transcription but also for basal transcription of the TH gene. The CRE of the TH gene resides in a position nearest to the TATA (8 base pairs apart) among the known genes containing the CRE. DNA binding assays revealed the presence of two specific DNA/protein complexes using either TH CRE or somatostatin CRE oligonucleotides suggesting that the same CRE binding protein activates both genes. These data suggest that the CRE exerts an important dual role as a basal promoter element and an inducible enhancer for TH transcription. Supported by MH24285.

CAMP-DEPENDENT PROTEIN KINASE (PKA) IS REQUIRED FOR BOTH BASAL EXPRESSION AND INDUCTION OF THE TH GENE. K.S. Kim', D.H. Park, T. Wessel, J.A. Wagner and T.H. Joh Cornell Univ. Med. Coll. at the Burke Med. Res. Inst., White Plains, NY 10605 and New York, NY 10021.

The role of PKA in the expression of TH and the regulation of catecholamine biosynthesis remains controversial. PKA could exert its regulatory function on TH expression at the transcriptional level via the CRE of the TH gene as well as at the post-translational level via the direct phosphorylation of TH molecule. We have found that the CRE located at -45 to -38 bp is crucial both for basal and inducible transcription of the TH gene, suggesting that PKA may have an important role in TH expression. This CRE might also respond to other signal transduction pathways, such as the Ca++/calmodulin-dependent protein kinase. To address this issue, we utilized several PKA-deficient PC12 cell lines (Ginty et al., JBC 23, 15325, 1991). Specifically, the AB11 and A123.7 cell lines that were rendered PKA-deficient by stable expression of the mutant regulatory subunits of PKAI provided a useful model system to assess the functional importance of PKA in catecholamine biosynthesis. We also used the A126-1B2 cell line, a PC12 mutant deficient only in PKAII, which was isolated after chemical mutagenesis (Van Buskirk et al., MCB 5, 1984, 1985). The ABI1 and A123.7 cell lines contained about 15% and 30% activity compared to the wild type PC12, whereas the A126 1B2 line did not show any detectable TH activity. Northern blot analysis indicated that PKA plays an essential role in the expression of TH primarily at the transcriptional level. These observations were supported by in situ hybridization and immunocytochemical analysis. We suggest that PKA is an essential component of the signal transduction pathway for both the basal and inducible expression of TH. Supported by MH24285.

### 254.11

ANALYSIS OF THE GENE PROMOTER OF THE 67,000 Da FORM OF RAT GLUTAMIC ACID DECARBOXYLASE. Michael J. Morales\* & David I. Gottlieb. Anat & Neurobiol, Washington U Sch Med, St. Louis MO 63110.

Glutamic Acid Decarboxylase (GAD) is the key enzyme responsible for GABA biosynthesis. There are two forms of this enzyme, 67,000 Da and 65,000 Da, that are encoded by different genes. To study the genetic regulatory apparatus that governs development of GABAergic neurons, we are examining the transcription of the 67,000 Da form of GAD from rat.

We previously reported the cDNA sequence of GAD. (Wyborski, etc.)

GAD from rat.

We previously reported the cDNA sequence of GADe, (Wyborski, et al., Mol. Brain Res. 8:193-198 (1990)). Further analysis suggested that GAD<sub>1</sub>, mRNA from adult rat brain had multiple 5' ends, ranging from 218 to 250 nucleotides upstream from the translational start site. We obtained a genomic clone from bacteriophage \( \lambda \) that contained the first two exons of the GAD<sub>2</sub>, gene plus 12 kBp of upstream sequence. The translational start site resided on Exon 2, while Exon 1 consisted of 5' untranslated sequence. The sequence of the region upstream of the transcriptional start site revealed four consensus "GC Boxes" within 30 nucleotides of the start site and a "TATA Box" another 125 bp upstream. This distance suggests that the TATA box is not widely used in adult rat brain.

in adult rat brain.

To asses the activity of this putative promoter, we transiently transfected reporter constructs into P19 embryonal carcinoma cells. This cell line, in its undifferentiated state, expresses GAD<sub>6</sub>, mRNA. A 280 bp region that contained the GC Boxes and TATA Box supported expression of the reporter gene. A 2.2 kBp region upstream of the transcriptional start site (including the promoter) increased expression of the reporter 10-fold. An important aspect of P19 cells is that they can differentiate into cells resembling neurons. GAD<sub>6</sub>, transcription is induced approximately 50-fold in differentiated P19 cells (See Abstract by G. Bain, et el.). Stable transfection of reporter constructs containing portions of the GAD<sub>6</sub>, gene into P19 cells, followed by differentiation, should allow us to identify cis-acting elements required for GAD<sub>6</sub>, induction.

CHARACTERIZATION OF A PROTEIN THAT SPECIFICALLY BINDS PHOSPHORYLATED CREB. J.C. Chrivia, R. Kwok\* and R.H. Goodma Vollum Institute, Oregon Health Sciences University, Portland, Oregon 97201-3098.

Transcriptional regulation by cAMP depends in many cases on a DNA elements designated the "cAMP-responsive enhancer," or CRE. CREB, a leucine zipper transcription factor, has been shown to bind the CRE sequence. In response to increased levels of cAMP, CREB is phosphorylated at its consensus site for cAMPdependent protein kinase (PKA). Mutation of this site prevents activation of CREB. How activated CREB induces transcription is unclear but presumably it acts either by directly contacting the core transcriptional machinery or indirectly by binding to an adapter protein.

To identify proteins that interact with the phosphorylated form of CREB, CREB was labeled with  $\gamma^{32}P$  ATP and PKA and used as a probe to screen  $\lambda gt11$ expression libraries. This approach led to the isolation of a cDNA clone for a CREB-binding protein (CBP) of 2440 amino acids (268 KD). Analysis by Western blot confirmed the presence of the 268 KD CBP protein in a number of cell lines, and in addition demonstrated the presence of a shorter 220 KD isoform. Northern blot analysis of rat brain mRNA revealed CBP mRNA of 9 and 10 kb in length. Using immunohistochemical techniques CBP was found to be localized exclusively to the nucleus.

To determine whether CBP interacted with CREB in solution, recombinant CBP was added to a mixture of CREB and radiolabled CRE, and complexes were analyzed by gel shift assay. If non-phosphorylated CREB was used, CBP had no effect on the mobility of the CREB-CRE complex. If CREB was phosphorylated by PKA, addition of CBP supershifted the complex.

We propose that CBP interacts with the activator domain of the transcription

factor CREB, that this interaction requires phosphorylation of CREB by PKA, and this association may alter or mediate CREB activity.

## CATECHOLAMINE RECEPTORS: ADRENERGIC II

## 255.1

CHARACTERIZATION OF THE SIGNAL TRANSDUCTION PATHWAYS OF THE THREE α1-ADRENERGIC RECEPTORS J.W. Lomasney\*, A. Hirakata. Allen. D. Capel. A.D. Proia. M.G. Caron and R.J. Lefkowitz. Depts. Pathology, Ophthalmology, Medicine and HHMI, Duke U. Med. Ctr., Durham, NC 27710.

Many hormones, growth factors and neurotransmitters exert their effects by causing

profound changes in cellular lipid metabolism. Epinephrine (EPI) and norepinephrine have been shown to activate various phospholipases (PL) including PLC, PLA $_2$  and PLD via  $\alpha_1$ -adrenergic receptors (AR). Our laboratory has identified by molecular cloning three distinct  $\alpha_1$ -ARs ( $\alpha_{1A}$ ,  $\alpha_{1B}$ , and  $\alpha_{1C}$ ). The purpose of this study was to determine the interaction of  $\alpha_1$ -AR subtypes with PLC , PLA<sub>2</sub> and/or PLD.

Rat-I fibroblast cell lines which permanently express each of the  $\alpha_1$ -AR subtypes were incubated with either [14C] arachidonate (AA) or [3H] inositol. PLC activation was assessed by isolating inositol phosphates (IP) using anion exchange chromatography. PLD catalyses a transphosphatidylation reaction in which the phospholipid phosphatidyl group is transferred to ethanol (Et) to produce phosphatidylethanol (PEt); the formation of PEt was determined by thin layer phosphatolytetrainol (FEI); the formation of FEI was determined by thin layer chromatography (TLC) and used to assess PLD activity. PLA<sub>2</sub> activity was assessed in the presence of the diacylglycerol lipase inhibitor RHC-80267 by determining the release of AA using TLC. In  $\alpha_{1C}$ -Rat-1 cells, 100  $\mu$ M EPI stimulates the formation of Ps 15 fold, and PEI 27 fold. RHC-80267 markedly reduced monoacylglycerol (MAG) by >90% whereas the EPI-stimulated increase (~2 fold) in AA was not significantly changed, suggesting that the AA is derived from PLA2 catalyzed hydrolysis of phospholipids. All effects were blocked by the  $\alpha_1$  antagonist prazosin. In  $\alpha_{1B}$ -Rat-1 cells, IPs increased 8 fold, PEt 5 fold and AA ~1.5 fold. In  $\alpha_{1A}$ -Rat-1 cells IPs increased 2 fold, however, PEt and AA were minimally increased. These findings suggest differences in the transmembrane signalling pathways of the  $\alpha_1$ -AR subtypes. The  $\alpha_{1C}$ -AR potently stimulates PLC, PLD and PLA<sub>2</sub>, the  $\alpha_{1B}$ -AR less potently stimulates PLC, PLD and the  $\alpha_{1A}$ -AR weakly stimulates PLC and minimally stimulates PLD and PLA2.

RELATIONS BETWEEN  $\alpha_{h}$ . AND  $\alpha_{h}$ . ADRENOCEPTOR SUBTYPES: AN ELECTROPHYSIOLOGICAL ASSESSMENT IN HYPOTHALAMIC NEURONS. L.-M. Kow' and D.W. Pfaff. The Rockefeller University, New York, NY. 10021

We previously found that excitatory neuronal actions and lordosiswe previously found that excitatory neuronal actions and forcossis-facilitating effects of  $\alpha_1$ -agonists, methoxamine and phenylephrine, in ventromedial hypothalamus (VMH) of rats were both blocked by the  $\alpha_{1b}$ -antagonist, chloroethylclonidine (CEC), indicating that the  $\alpha_{1b}$ -subtype is involved in mediating these functions (Brain Res. in press). To investigate whether  $\alpha_{1a}$ -subtype is also involved, effects of  $\alpha_{1a}$ -antagonists, WB-4101 (1-10  $\mu$ M) and 5-methyl urapidil (5-MU, 1-10  $\mu$ M), on the excitatory action of  $\alpha_1$ -agonists on VMH neurons were examined in vitro. Like CEC, both WB-4101 (on 19 cells) and 5-MU (on 16 cells) completely blocked or severely attenuated the  $\alpha_1$ -action on all the neurons tested, but did not block the excitatory actions of carbachol or oxytocin. These together with our previous findings with CEC suggest that all the VMH neurons excitable by previous intends with CLC suggest that all the VMTI neurons excitable by  $\alpha_1$ -agonists possess both  $\alpha_{1a}$ - and  $\alpha_{1b}$ -subtypes. This suggestion was tested in 20 VMH units excited by  $\alpha_1$ -agonists. The excitatory response of each of these units was subjected first to CEC (50-100  $\mu$ M), whose effect is reversible, and then to 5-MU or WB-4101. In each case, the  $\alpha_1$ -action was completely or nearly abolished by either  $\alpha_{1a}$  or  $\alpha_{1b}$ -antagonist alone. These findings not only confirmed that every VMH neuron excitable by  $\alpha_1$ -agonists possess both  $\alpha_{1a}$ - and  $\alpha_{1b}$ -subtypes, but also indicate that both subtypes are necessary for mediating the neuronal action of  $\alpha_1$ -agonists. Thus, in these hypothalamic neurons the  $\alpha_{1a}$ - and  $\alpha_{1b}$ -subtypes appear to be functionally

DIFFERENTIAL EXPRESSION OF THREE  $\alpha_2$ -ADRENERGIC RECEPTOR mRNAs IN RAT BRAIN. <u>M. Scheinin\* J.W. Lomasney, D. Hayden-Hixson, U.M. Schambra, M.G. Caron, R.J. Lefkowitz & R.T. Fremeau Jr. HHMI, Duke U. Med. Ctr., Durham, NC 27710, and BDRC, UNC-CH, Chapel Hill, NC 27599. Molecular cloning has revealed the existence of at least three distinct genes which</u>

encode related  $\alpha_2$ -adrenoceptor ( $\alpha_2$ -AR) subtypes. To begin to relate the receptor subtypes to functional catecholaminergic subsystems, we have determined the distribution of the three corresponding mRNAs in rat brain with in situ hybridization using 35S-UTP- labeled antisense cRNA probes. The distributions of the three mRNAs were strikingly different, but not entirely exclusive.  $\alpha_{2A}$ -AR mRNA (RG20 1) was most abundant in the locus coeruleus (LC), and was also present in several other regions of the brain stem, hypothalamus, and cerebral cortex (most notably layers 2-3 and 6). Expression of α<sub>2C</sub>-AR mRNA (RG10 <sup>1</sup>) was strongest in the striature Labeling was also seen throughout the cerebral cortex, in the dentate gyrus and CA1 region of the hippocampus, and in the olfactory tubercle. Some regions of the hypothalamus and amygdaloid complex, inferior colliculi, pontine nuclei, and scattered, large cells in the granule cell layer of the cerebellum appeared to express both  $\alpha_{2A}$ -AR and  $\alpha_{2C}$ -AR mRNA. Labeling with the  $\alpha_{2B}$ -AR probe (RNG $\alpha_{2}$ ) was largely restricted to several thalamic nuclei. The exclusive presence of  $\alpha_{2A}$ -AR mRNA in the LC, where a large part of the noradrenergic innervation of the brain originates, suggests that this receptor subtype functions as a presynaptic autoreceptor. Since cells expressing  $\alpha_{2A}$  mRNA were also observed in noradrenergic projection areas, including the cerebral cortex, the  $\alpha_{2A}$ -AR appears to mediate postsynaptic signaling, as well. The differential expression patterns of the receptor subtypes suggest different physiological functions for the three  $\alpha_2$ -AR subtypes, warranting more detailed identification and characterization of the involved cell types and neuronal pathways. Such information may provide important clues for targeted drug development

G PROTEINS COUPLED TO ALPHA-2 ADRENERGIC RECEPTORS Y. Okuma and T. Reisine\*. Dept. Pharmacology, Univ. PA, Philadelphia, PA 19104

Alpha2-adrenergic receptors mediate many of the biological effects of epinephrine and norepinephrine. G proteins couple these receptors to cellular effector systems. To identify which G proteins are coupled to alpha2a-receptors (AR), cloned AR stably expressed in LLCPK1 cells were solubilized and AR/G protein complexes were immunoprecipitated with antisera directed against different alpha subunits of G proteins. Immunoprecipittated receptors were detected using a binding assay. Antisera directed against the C-terminal region of Gia and Goa immunoprecipitated AR. Antisera against internal regions of the three subtypes of Gia also immunoprecipitated the receptor. Antisera against beta-36 also immunoprecipitated the receptor but not antisera against beta-35. The binding of agonists to the receptor alters the association of the receptor with G proteins. Following clonidine binding to the receptor, antisera against the C-termin-al region of Gi and Go were less effective in immunoprecipitatin the AR whereas antisera directed against internal regions of Gi, Go or beta-36 were equally effective in immunoprecipitating the agonist-bound and agonist free AR. These findings indicate that Ga and beta-36 remain coupled to the agonist bound AR but a conformational change occurs in the receptor/G protein complex such that the epitope for C-terminal directed Gia and Goa antisera is made inaccessible. Since these conformational changes in the AR/G protein complex occur when agonist bind to the receptor, they may be important for the activation of the AR signal transduction pathway. ## 255.7

EXPRESSION OF FUNCTIONAL IMIDAZOLINE RECEPTORS IN RAT ASTROCYTES. S. Regunathan\*, D.L. Feinstein and D.J. Reis. Div. of Neurobiol., Cornell Univ. Med. Coll., New York, NY 10021.

In many tissues clonidine and structurally related imidazolines bind not only to α<sub>2</sub>-adrenergic receptors (AARs) but also with high affinity to a non-adrenergic imidazoline receptor (IR) which is expressed in several isoforms. In brain, IRs have been identified by membrane ligand binding (Wikberg et al., J. Neurochem. 55:192, 1990) or by autoradiography (Hudson et al., *Br. J. Pharmacol.*, 102:4P, 1991) with regional variability. However, the cellular localization of the IR is not known. We have characterized the binding of <sup>3</sup>H-idazoxan to membranes prepared from primary cultures of rat cerebral cortical astrocytes and neurons obtained from neonatal rat. 3H-idazoxan binds specifically (85% of total binding) to astrocytic membranes. The binding is saturable to a single high affinity site with an apparent K<sub>D</sub> of 4 nM, and a B<sub>max</sub> of 220 fmol/mg protein. Over 80% of binding is to non-adrenergic receptors (not blocked by 10  $\mu$ M epinephrine).  $^3$ H-idazoxan is displaced by cirazoline > idazoxan > clonidine > amiloride >>> rauwolscine = epinephrine consistent with binding to an idazoxan-preferring (I-2) subclass of IRs. In contrast, the binding of 3H-idazoxan to neuronal membranes was only 25% of astrocytes and completely displaceable by epinephrine. Thus, neuronal binding was exclusively to AARs. Incubation of astrocytes with 100 μΜ idazoxan, but not vehicle, increased, by 15-fold, the amount of GFAP mRNA as measured by quantitative PCR. We conclude: (a) astrocytes derived from neonatal rat express IRs of the I-2 subclass; (b) the receptors are functional and can stimulate expression of the GFAP gene; (c) the majority of binding of <sup>3</sup>H-idazoxan observed in cortex is probably astrocytic; (d) since <sup>3</sup>H-idazoxan binding in brain varies topographically these results suggest regional variability in astrocytic phenotypes. In vivo, astrocytes may be a target cell for the actions of imidazolines in brain.

[11C]MK-912 AND [11C]WY26703 AS POSITRON EMITTING RADIOLIGANDS TO LABEL ALPHA-2 ADRENERGIC RECEPTORS IN IVVO: ASSESSING THEIR USE IN RHESUS MONKEY BRAIN. R.C. Pleus\*, C.Y. Shiue, J. Rysavy, H. Huang, J. Sunderland, K. Cornish, L. Bal, M. Frick and D.B. Bylund, Depts. of Pharmacology and Physiology, Univ. of Nebraska Med. Ctr., and Creighton University Ctr. for Metabolic Imaging, Omaha, NE 68198-6260. In humans, alpha-2 adrenergic receptor density is associated with depression and borderline personality disorder. Also, agonists for these

In humans, alpha-2 adrenergic receptor density is associated with depression and borderline personality disorder. Also, agonists for these receptors can lower blood pressure, reduce symptoms of opiate withdrawal, induce anesthesia, and improve cognitive deficits.

Positron emitting ligands for dopaminergic, cholinergic, benzodiazepinergic,

Positron emitting ligands for dopaminergic, cholinergic, benzodiazepinergic, serotonergic, and opioid receptor systems have been developed for positron emission tomography (PET). However, there are no suitable alpha-2 adrenergic receptor ligands currently available for PET studies. We have methylated the desmethyl precursor of two alpha-2 adrenergic receptor antagonists using [¹¹C]Hd\_3¹ to obtain [¹¹C]WY26703 and [¹¹C]MK-912. In vitro analyses of the unlabeled compounds demonstrate that both compounds exhibit subnanomolar affinity for subtypes of alpha-2 adrenergic receptors (i.e., alpha-2A, -2B, and -2C). In vivo studies in rodents demonstrate that both compounds pass the blood-brain barrier and both exhibit specific binding in brain when rats coinjected with atipamezole (alpha-2 antagonist) were compared to those injected with the [¹¹C] radioligand alone. To test these radioligands further, [¹¹C]WY26703 and [¹¹C]MK-912 will be injected into Rhesus monkeys. Brains will be imaged by PET and blood samples will be obtained to assess plasma radioactivity clearance and unchanged [¹¹C]WY26703 and [¹¹C]MK-912. These data will indicate that these two radioligands may have potential use in human PET studies. (Supported by NHH grant GM40784).

### 255.6

SYNTHESIS AND CHARACTERIZATION OF A HIGH AFFINITY RADIOIODINATED PROBE FOR THE IMIDAZOLINE/GUANIDINIUM RECEPTIVE SITE (IGRS). S. Lanier, B. Ivkovic, J. Neumeyer, V. Bakthayachalam, Dept. Pharmacol., Medical Univ. of South Carolina, Charleston, SC 29425. Research Biochemicals Inc., Natick, MA 01760.

Imidazoline and guanidinium compounds recognized by  $\alpha$ -adrenergic receptors (AR) elicit diverse effects in the central nervous system and in peripheral tissues. Many of these responses appear unrelated to interaction with  $\alpha$ -AR or other known receptor systems suggesting the presence of a specific imidazoline/guanidinium receptive site (IGRS). Radioligand binding studies indicate the presence of such a site in brain, kidney and liver. To facilitate the structural analysis of IGRS, we prepared functionalized analogs of cirazoline, a ligand that exhibits high affinity (Ki=0.8nM) for IGRS. Radioiodination of one analog, 2-(3-aminophenoxy)methyl imidazoline (AMPI) generates a high affinity ligand  $^{125}$ I-AMIPI (Kd=2nM) selective for IGRS as determined by binding assays in rabbit kidney membranes.  $^{125}$ I-AMIPI was diazotized and converted to the azide AzIPI, a potential photoaffinity adduct for IGRS. Incubation of rabbit kidney membranes with  $^{125}$ I-AzIPI followed by photolysis results in covalent labeling of a major Mr=51000 and a minor Mr=61000 species as visualized by SDS/PAGE-autoradiography. The labeling of both species is blocked by the imidazoline idazoxan or the guanidinium analog guanabenz but is not effected by coincubation with the  $\alpha$ -AR selective compounds rauwolscine, prazosin or epinephrine. A similar labeling pattern was observed with rat brain membrane preparations. The pharmacological specificity of labeling implicates the Mr=55000/06/1000 species as the ligand-binding subunit of IGRS. The availability of these probes should facilitate efforts to define the functionality of IGRS and a potential endogenous ligand. (Supported by NIH GM 46605-01, NS24821 and CTR2235.)

ISOLATION OF, AND PRODUCTION OF ANTIBODIES TO, THE IMIDAZOLINE RECEPTOR PROTEIN. H. Wang\*, S. Regunathan, M.P. Meeley and D.J. Reis. Division of Neurobiology, Department of Neurology & Neuroscience, Cornell University Medical College, New York, NY 10021.

The imidazolines clonidine and idazoxan bind in brain to  $\alpha_2$ -adrenergic (AAR) and to imidazoline receptors (IR). The structure of the IR is not known. We sought to isolate the IR of bovine adrenal chromaffin cells which express IRs but not AARs (Regunathan et al., *Mol. Pharmacol.* 40:884, 1991). Chromaffin cell membranes were solubilized and receptor proteins purified on para-aminoclonidine- or idazoxan-affinity matrices by elution with idazoxan. A major receptor protein was isolated with an affinity for  $^3\text{H-idazoxan}$  ( $K_0$ : 3.7 nM) comparable to that for the receptor in the intact membrane ( $K_0$ : 4 nM). The number of binding sites of the isolated receptor protein (B\_{max}: 465 pmol/mg protein) was enriched 1000-fold over membrane receptor (350 fmol/mg protein). The rank order of potency for inhibition of  $^3\text{H-idazoxan}$  binding (K) to the isolated receptor protein was: cirazoline  $\geq$  idazoxan > clonidine and amiloride >> rauwolscine  $\approx$  epinephrine which paralleled that of membrane. Immunization of rabbits with the IR protein yielded specific polyclonal antibodies which reacted with IRs, as demonstrated on Western Blot, by immunoinhibition and immunoprecipitation of ligand binding. The anti-IR protein antibodies specifically stained cultured bovine adrenal chromaffin cells as well as subpopulations of rat adrenal medullary cells and neurons and glia in specific areas of rat brain (Ruggiero et al., *Soc. Neurosci. Abstr.*, 1992). We conclude that IRs differ biochemically from AARs and that the binding site is contained in a protein of 70 K<sub>0</sub> which may or may not represent the complete receptor. Antibodies to the IR protein will permit mapping the distribution of IRs in brain and periphery to provide clues to function and provide a probe for isolation and cloning of the IR.

IMIDAZOLINE RECEPTOR-ASSOCIATED BINDING PROTEIN IN CENTRAL NERVOUS SYSTEM. D.A. Ruggiero\*, T.A. Milner, H. Wang, S. Regunathan, M. Anwar and D.J. Reis. Div. of Neurobiol., Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, NY 10021.

We sought to localize in rat brain a specific polyclonal antibody raised in rabbits to an imidazoline receptor-associated binding protein (IRBP) purified from bovine adrenal gland (Wang et al., Soc. Neurosci. Abstr., 1992). IRBP-like immunoreactivity (IRBP-LI) was detected in neurons, neuronal processes and non-neuronal cells by light and electron microscopy (EM) and verified by control studies. Perikarya containing IRBP-LI were uncommon. A prominent cell group was observed in the med. habenular n. Immunostained neuronal processes were anatomically restricted. Labeled punctata were localized: in medulla to dorsal motor vagal n. and n. ambiguus, n. tractus solitarii (NTS; particularly medial n. centralis), superficial lamina of spinal trigeminal n. (and contiguous loci in spinal dorsal horn), dorsal cap of Kooy in inferior olivary n.; in pons to dorsal and external divisions of lat. parabrachial n. and surrounding the locus ceruleus; in <u>midbrain</u> to the lateral interpeduncular nucleus (i.e. component of fasciculus retroflexus); in <u>forebrain</u> to ventrobasal thalamic complex, midline thalamic n., and an arc extending between the central amygdaloid n. and bed nucleus of stria terminalis. Non-neuronal cells containing IRBP-LI included: astrocytes in white and gray matter sometimes aligned with penetrating vessels, and radial, subependymal and subpial glia. By EM, IRBP-LI in the NTS was localized to axons and terminals and astrocytes containing dense bundles of filaments. The results are consistent with a view that, in the CNS, imidazoline receptors are regionally distributed and are expressed both in neurons, particularly presynaptically, and glial cells.

## 255.11

125I-CYANOPINDOLOL (ICYP) BINDING SITES IN THE

TREE SHREW BRAIN. G., Flügge\*, O. Ahrens and E. Fuchs. German Primate Center, Göttingen, FRG.

The ß-adrenoceptor (ß-AR) system in the brain is of special interest because it is affected by antidepressant reatments. When studying B-AR it has to be considered treatments. When studying ß-AR it has to be considered that there are considerable species differences with respect to distribution and density of ß-AR subtypes. We are interested in central nervous catecholaminergic receptors of tree shrews (*Tupaia belangeri*), a species which provides a useful model for investigating effects of psychosocial stress. We therefore localized and quantified ß-AR in the tree shrew brain by *in vitro* autoradiography with ICYP which labels ß<sub>1</sub> and ß<sub>2</sub> subtypes.

Strongest ICYP binding was detected in all layers of the neocortex (mostly  $\beta_1$ ), the superior colliculus (mostly  $\beta_2$ ), and the molecular layer of the cerebellar cortex (mostly  $\beta_2$ ). Moderate binding was found in the inferior colliculus, the molecular layer of the hippocampus, the colliculus, the molecular layer of the hippocampus, the pulvinar nucleus (equal portions of  $\mathbb{B}_1$  and  $\mathbb{B}_2$ ) and the granular layer of the cerebellar cortex (mostly  $\mathbb{B}_2$ ). In contrast to the rat, other regions like the dorsomedial medulla oblongata and the substantia nigra showed only very low binding. In summary, (1) the number of ICYP binding sites in the tree shrew brain is lower than in the rat and (2) the ratio of  $\mathbb{B}$ -AR subtypes differs between the brain regions.

DISTINCT SUB-CELLULAR LOCALIZATION OF IMIDAZOLINE AND α2-ADRENERGIC RECEPTORS IN BOVINE CEREBRAL CORTEX. M.P. Meeley", S. Regunathan, S. Roberts, S. Bramwell and D.J. Reis, Div. of Neurobiol., Cornell Univ. Med. Coll., New York, NY 10021.

The imidazolines clonidine (CLON) and idazoxan (IDA) bind to  $\alpha_2$ -

adrenergic (AAR) and imidazoline receptors (IR) in brain. In several organs, IRs of the IDA-preferring (I-2) subclass are expressed in mitochondria (Parini et al., J. Biol. Chem., 260:155, 1991). To determine whether IRs and AARs are differentially distributed between subcellar compartments in brain, synaptosomes and mitochondria were isolated from fresh bovine cerebral cortex by Percoll density gradients and membranes prepared. Binding of  $^3\text{H-IDA}$  to synaptosomal and mitochondrial membranes was specific (K $_p$  = 8 and 5 nM, respectively). Epinephrine (EPI) (10  $\mu\text{M})$  displaced 80% of binding of  $^3\text{H-}$ IDA to synaptosomal but not mitochondrial membranes. \$\frac{9}{1}\$+IDA was displaced from mitochondria by: cirazoline > IDA >> CLON >> amiloride > EPI = rauwolscine. The order in synaptosomes was: IDA > CLON > rauwolscine > cirazoline > EPI. Displacement of <sup>3</sup>H-IDA to synaptosomes not mitochondria by CLON was inhibited by Gpp(NH)p. <sup>3</sup>H-IDA binding to mitochondria but not synaptosomes was inhibited by K\*. Clonidine-displacing substance (CDS), a purported endogenous ligand for IRs, displaced binding of <sup>3</sup>H-IDA to mitochondrial membranes with high affinity. We conclude: (a) in bovine brain, AARs are localized primarily to synaptosomal membranes and regulated by GTP; (b) IRs, concentrated in mitochondrial membranes, are not G-protein linked and are regulated by K<sup>+</sup>; (c) CDS binds to IRs of brain with high affinity; (d) Since IRs of the I-2 subclass are preponderantly glial (Regunathan et al., Soc. Neurosci. Abstr., 1992) agents interacting with these IRs bind to receptors differentially localized with respect to cellular and subcellular compartments in

# VISUAL CORTEX: NEURONAL RESPONSE PROPERTIES

SPATIAL FREQUENCY CHARACTERISTICS OF LGNd AND 17-18

SPATIAL FREQUENCY CHARACTERISTICS OF LGNd AND 17-18 NEURONS IN ADULT SPLIT-CHIASM CATS. Legother. M. Pitto. F. Legother. Legot recorded under paralysis, local anaesthesia and N<sub>2</sub>O. Stimulation consisted of sinusoidal gratings, swept at optimal orientation, direction and temporal frequency. Results indicated that LGNd cells in the split-chiasm cats were limited to the AI layer and were X- and Y-like. The X-like cells had a higher spatial frequency cut-off than the Y-like cells, as in the normal cat. The visual acuity and contrast threshold of these cells were also similar in the normal and the split-chiasm cats. Cortical recordings show that about one third of the cells are still binocular in the callosal recipient zone. Binocular input originating either from the direct geniculo-cortical or callosal pathways show similar sensitivity to spatial frequency (ranging in different cells from low to high) and contrast thresholds (<10% to <20%). The spatial frequency ranges of both narrow band and low pass cells were similar in the normal and the split-chiasm cats. The high spatial frequency cut-off was lower than in the LGNd both for the direct geniculate and the callosal input. Moreover high spatial frequency cut-off seemed to be related to ocular dominance and not to the source of the visual input. recorded under paralysis, local anaesthesia and N2O. Stimulation consisted of

COLOR RECEPTIVE FIELDS IN MACAQUE V1: THE SPATIAL AND TEMPORAL STRUCTURE OF ISOLATED CONE INPUTS. R. Clay Reid and Laboratory of Neurobiology, The Rockefeller University, NY.

<u>Daniel Y. Ts'o\*</u>. Laboratory of Neurobiology, The Rockefeller University, NY. We have studied the spatial structure of color selective receptive fields in the striate cortex of *Macaca fascicularis*. Optical imaging of the intrinsic signal provided maps of color-selective and highly monocular regions so that cytochrome oxidase blobs could be tentatively identified in vivo. White-noise checkerboard stimuli were used to map the spatiotemporal structure of receptive fields. For some circularly symmetric receptive fields, the spatial and temporal interactions between center and surround were also studied with concentric annuli modulated by white noise. The separate contributions of each of the cone types (L, M, and S: long, medium, and short wavelengthsensitive) were studied with the method of silent substitution.

Red/green parvocellular neurons in the lateral geniculate nucleus have been studied previously with similar stimuli. The antagonistic on and off inputs are segregated by cone type: rarely does one cone type provide spatially opponent linear on and off inputs to a receptive field (Reid and Shapley, Nature, 1992). In the cortex, modified type II cells with strong broadband suppressive surrounds have been reported (Ts'o and Gilbert, J. Neurosci., 1988). Nonlinear suppression made such neurons difficult to study with two-dimensional white noise stimuli. Concentric annuli modulated by white noise were more effective in driving these cells and helped characterized the suppressive nonlinearity.

S cone input to blob cells was not always opposed by the sum of L and M cones signals. Often, the S cone input was opposed by one cone type, usually L, while the other cone type had the same sign as the S cone. (Supported by grants EY06393, EY08240, ONR N00014-91-J-1865 and the Whitaker Foundation).

COLOR PROCESSING IN THE CYTOCHROME OXIDASE-RICH BLOBS AND BRIDGES OF MACAQUE STRIATE CORTEX. C.E. Landisman\* and D.Y. Ts'o. Laboratory of Neurobiology, The Rockefeller University, NY, NY

To better understand the organization of color processing in striate cortex, we have used a combination of optical imaging and electrical recording. Previous work has shown that the cytochrome blobs contain a predominance of monocular color selective cells whereas interblobs contain broadband cells (Livingstone and Hubel, 1984). Subsequently, Ts'o and Gilbert (1988) found clustering of red-green and blue-yellow opponency such that individual blobs seemed dedicated to one or the other. They also observed color selective cells that were in the bridges connecting blobs both within a single ocular dominance columns and across ocular dominance columns

We have shown that color selective regions, as revealed by optical imaging, overlap the monocular blobs as well as span ocular dominance columns. We postulated that such color regions may correspond to two blobs connected by a bridge. Guided by optical maps of color regions and ocular dominance, we targeted sites of color regions spanning ocular dominance columns with electrode penetrations. A series of penetrations across one color region revealed a shift from monocular cells of one eye, to binocular cells, to monocular cells of the other eye. Interestingly, at times a bridge was found to connect a red-green blob to a yellow-blue blob. Histological reconstruction confirmed that the color selective regions correspond to areas of dense cytochrome oxidase staining, which includes both the bridges and the blobs

CLUSTERING OF VISUAL RESPONSE PROPERTIES IN CORTICAL AREA V4 OF MACAQUE MONKEYS. E.A. DeYoe\*, S. Glickman, & J. Wieser; Dept. Cellular Biology & Anatomy, Medical College of Wisconsin, Milwaukee, WI 53226.

To identify physiological correlates of segregated projections to V4 from thin- and inter-stripes of V2, we used long tangential penetrations through the crown of the prelunate gyrus to record neuronal responses to drifting sinusoidal gratings modulated in both luminance and hue. Eight luminance-matched colors were presented at each of 8 spatial frequencies. Responses (spike rates) were analyzed by constructing standard tuning curves for hue and spatial frequency, and by computing a measure of information conveyed by each cell (Optican & Richmond, 1987) about hue and spatial frequency separately or about all 64 stimulus conditions together. In each of 5 penetrations (108 recording sites in 4 animals) passing 3.5-4.5 mm A-P across the prelunate gyrus, we observed clustering of cells that conveyed significant information about hue (>0.2 bit) or frequency (>0.1 bit), or conveyed little information about either parameter (<0.1 bit). The latter cells responded poorly to formal test stimuli but sometimes responded well to more complex figures. Few cells (2 of 108) conveyed significant information about both color and spatial frequency cimultageness for Microscopic (Clusters represented in significant control of the control of (2 of 108) conveyed significant information about both color and spatial frequency simultaneously. Clusters ranged in size from 2-10 successive recording sites spanning 0.25-1.4 mm. These results suggest that V4 contains at least 2, and possibly 3, types of functional subdivisions for the processing of color and form. (Supported by NIH grant EY08406)

## 256.7

EXTRARETINAL SIGNALS IN RELATION TO PARALLEL PATHWAYS IN MACAQUE VISUAL CORTEX. Vincent P. Ferrera and John H. R. Maunsell\* Dept. of Physiology and Center for Visual Science, University of Rochester, Rochester NY, 14642.

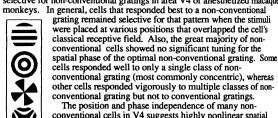

The visual cortex of macaque monkeys has been divided into two functional streams which have been characterized in terms of sensory processing (color/form vs. motion) and in terms of behavioral goals (object recognition vs. spatial orientation). As a step towards unifying these two views of cortical processing, we have compared the behavioral modulation of sensory signals across the two streams in monkeys trained to do a visual short-term memory task. We recorded from individual neurons in areas MT, MST, 7a and V4 while monkeys performed a delayed match-to-sample task using direction of motion as the matching criterion. This task allows us to determine if sensory responses are modulated by extraretinal signals related to the direction of the remembered sample. We sorted responses as a function of the remembered direction and calculated a modulation index, MI = (max. response - min. response)/(max + min). In the motion pathway, we found virtually no extraretinal signals in MT (avg. MI 0.022±0.007 s.e., 29 cells), but progressively stronger extraretinal signals in later stages, i.e. MST (avg. MI 0.234±0.025 s.e., 30 cells) and 7a (avg, MI 0.323±0.04 s.e., 42 cells). In contrast to MT, strong extraretinal signals for direction matching were found in V4 (avg. MI 0.411±0.031 s.e., 56 cells), a relatively early stage of the color/form pathway, even though this pathway is not generally viewed as playing a significant role in motion processing. Some cells in V4 were also tested while the animal performed a color matching task and showed memory-related modulation of their response when either color or direction was used as the matching criterion. We conclude that extraretinal signals related to the matchto-sample task are found earlier and are stronger in the temporal (color/form) pathway than in the parietal (motion) pathway, regardless of the stimulus dimension involved. POSITION AND PHASE INDEPENDENCE OF NEURAL RESPONSES TO NON-CONVENTIONAL GRATINGS IN MACAQUE AREA V4. J. L. Gallant. J. Braun\*, and D. C. Van Essen. Biology Division 216-76, Caltech, Pasadena CA 91125.

We previously reported that a substantial minority (~15%) of neurons in area V4 respond better to non-conventional grating patterns (concentre, burneted) the restain of the production of t

hyperbolic, or radial) than to conventional sine-wave gratings (Gallant et al., Invest. Ophth. Vis. Sci. 1992). We have now investigated the position and phase dependence of neural responses in the subset of cells selective for non-conventional gratings in area V4 of anesthetized macaque

The position and phase independence of many non-conventional cells in V4 suggests highly nonlinear spatial processing. These cells are unlikely to represent an orthogonal set of basis functions derived from differential

geometry and previously proposed on theoretical grounds. Rather, they may represent the local energy associated with complex surface patterns. This may constitute an intermediate stage of form processing, between the low-level processes of V1 and the more complex characteristics of IT.

SENSITIVITY OF MONKEY INFERO-TEMPORAL CELLS TO LUMINANCE, MOTION AND TEXTURE DEFINED PATTERNS. Gy. Sary, R. Vogels\* and G.A. Orban. Lab. Neuro- en Psychofysiologie, Medical School, KULeuven, Belgium.

We investigated whether TE units are sensitive to form attributes

irrespective of the cue that defines this attribute. In one experiment we recorded from 415 TE cells while the monkey was discriminating the orientation of gratings of which the boundaries were defined by a discontinuity in either luminance, direction of motion or texture. We found that from the 145 cells which were tested for all three grating types one third responded to the grating stimuli irrespective of the defining cue. There was no correlation between the sensitivity for the orientation of the luminance, motion or texture boundaries. For those few cells that were significantly orientation tuned for at least two types of boundaries, the preferred orientations tended to match.

In a second experiment, using the same monkey, we presented 8 In a second experiment, using the same monkey, we presented 8 different patterns during fixation (e.g. a cross, star, triangle) and recorded from area TE. The patterns were defined either by a difference in luminance, motion or texture. Several cells responded to the patterns irrespective of the defining cue. Surprisingly, pattern selectivity usually differed according to the defining cue: e.g. selectivity for particular luminance defined patterns but no selectivity for the motion defined patterns. Also, the preference for particular patterns did not necessarily match for the different defining cues. The results of both experiments suggest that in TE sensitivity for form attributes both experiments suggest that in TE sensitivity for form attributes depends on the cue which defines the form attribute. RESPONSES OF INFERIOR TEMPORAL (IT) NEURONS DURING VISUAL SEARCH. L. Chelazzi\*E.K. Miller, J. Duncan, A. Lueschow, and R. Desimone. Lab. Neuropsychology, NIMH, Bethesda MD, 20892.

The responses of IT neurons are known to be modulated by mnemonic and attentional processes. We studied IT responses in the present models of the processes of the processes of the processes of the processes.

two rhesus monkeys performing a visual search task that required both processes. Each trial began with the brief presentation of a sample stimulus at fixation. Following a delay interval of 700-3000 ms, during which fixation had to be maintained, a pair of test ms, during which fixation had to be maintained, a pair of test stimuli was shown 3-5° from the fovea and the animal was required to saccade to the stimulus (target) that matched the sample. Many cells displayed differential sustained firing during the delay interval and for most of them the magnitude of delay activity paralleled the sample preference. When a given sample was predictable from trial to trial, appropriate sample-dependent activity developed well in advance of actual sample presentation. This sustained activity is not an invariant characteristic of Transconnection of the research of the presentation of the second of the part of the sustained activity is not an invariant characteristic of Transconnection of the presentation of the second of the part of the presentation. an invariant characteristic of IT responses in short-term memo an invariant characteristic of 11 responses in short-term memory tasks, however, as it was infrequently seen in a standard matching to sample task with individual test stimuli presented at the fovea. In addition to the delay activity, some cells in the search task responded differentially to the test stimuli depending on their spatial configuration, or depending on the particular sample presented on a given trial, or depending on both factors. We conclude that all of the view information needed for the animal to perform the search the visual information needed for the animal to perform the search task is present in IT, for at least some cells. CODING OF EXTRAPERSONAL VISUAL SPACE IN BODY-PART CENTERED COORDINATES. M. S. A. Graziano\* and C. G. Gross Psychology Department, Princeton University, Princeton, N. J.

Several areas in the macaque brain contain bimodal neurons, which respond both to visual and tactile stimuli. These areas include 6, 7b, and the putamen. They are monosynaptically interconnected, forming a bimodal system. Each area contains a somatotopic map. In addition, the neurons with tactile RFs on the face or the arms often respond to visual stimuli adjacent to the tactile RF, within about 10 cm of the skin. Thus each area contains a somatotopically organized map of the visual space that immediately surrounds the monkey. This system of bimodal areas could code the location of visual stimuli in extrapersonal space.

We recorded from single neurons in these areas in anesthetized, paralyzed macaques. For a class of neurons that had tactile RFs on the arm and visual RFs adjacent to the tactile RFs, when the arm was moved, the visual RF moved with it. Thus, these neurons appear to code the location of visual stimuli in armcentered coordinates. More generally, we suggest that the bimodal cells represent extrapersonal space in a body-part centered fashion, rather than in a head-centered or trunk-centered fashion.

## 256.11

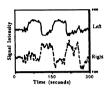

DENTIFICATION OF EARLY VISUALLY EVOKED POTENTIAL COMPONENT SOURCES IN VIVO USING MAGNETIC RESONANCE IMAGING. V. P. Clark, E. Courchesne, S. A. Hillyard, and M. Grafe. Dept. of Neurosciences, School of Medicine, U. C. San Diego, La Jolla, CA 92093-0608. Procedures which are used to characterize and localize the component sources of visually evoked potentials (VEPs) such as the Brain Electrical Source Analysis (BESA) algorithm have been used to make claims regarding functional differences between striate and extrastriate cortical regions in humans. However, considerable inter-subject variability in the topographic position of striate cortex may lead to the erroneous identification of functionally defined regions on the basis of cerebral topographic or cranio-cerebral position alone. Here we present a method using magnetic resonance (MR) imaging to directly identify and differentiate the myeloarchitecture of striate and extrastriate cortex in vivo. A high-resolution MR protocol using a 1.5 Tesla magnet (Signa) was employed. Signal contrast between grey and white matter was enhanced by the use of a 5° surface coil, imaging sequences optimal for detecting grey/white contrast in the occipital lobe, and a large number of excitations to reduce noise. Also, partial voluming of adjacent laminar layers was reduced by using an imaging plane orientation orthogonal to the surface of the cortical region in question, and utilizing the highest possible spatial resolution (i.e., thin slices, small field of view, and a dense spatial matrix). After imaging, the MR data matrix was analyzed to identify upper and lower gray matter boundary locations, and adjacent data points falling within equivalent laminar levels were averaged together. Differences between laminar levels and topographic locations were tested for significance. Using this method, the stria of Gennari (which is a defining myeloarchitectonic feature of striate cortex) and extrastriate cortex were identified and differentiated in vivo. Correspondence of MR signal intens

FUNCTIONAL NEUROIMAGING BY MRI: HUMAN VISUAL SYSTEM I.W Belliveau\*, KK Kwong, JR Baker, CE Stem, R Benson, IE Goldberg, MS Cohen, DN Kennedy, RBH Tootell, PT Fox, TJ Brady, BR Rosen, MGH-NMR Center, Department of Radiology, Massachusetts General Hospital and Harvard Medical School, Boston, MA 02114, PTF at Univ Texas at San Antonio.

Recent advances in our laboratory have yielded high speed MRI techniques that

are sensitive to changes in cerebral blood volume, blood flow, and blood oxygenation (see abstract by Kwong et al.). These non-invasive methods were used to investigate tee abstract by Kwong et al.). These non-invasive methods were used to investigate the functional organization and frequency response of human primary visual cortex. Seven normal subjects underwent dynamic NMR imaging using a prototype high-speed echo planar imaging device (1.5 Tesla GE Signa modified by ANMR, Wilmington, MA). Cortical activation was measured using an oxygenationwilmington, MA). Cortical activation was measured using an oxygenation-sensitive gradient echo imaging sequence sensitive to variations in T2\* (TR = 2000 ms, TE = 50 ms) and a T1-sensitive (blood flow) spin echo inversion recovery sequence (T1 = 1100 ms, TR = 3500 ms, TE = 42 ms). Activated cortical areas are revealed by subtraction of averaged baseline (resting) images from all subsequent images. Frequency response studies were carried out using full-field, bilateral, pattern-flash visual stimulation goggles (Grass Instruments, Quincy MA). The stimulus rate was varied between 2 and 32 Hz. Additional studies were carried out using full-field and hemifield presentation of a counterphased checkerboard stimulus

Functional images exhibit sensitivity to stimulation frequency, and correspond well with previous PET studies. Alternating hemifield experiments show that the cortical response tracks the stimulus cortical response tracks the stimulus presentation (see figure). The ability of this technique to generate high temporal and spatial resolution data should foster greater understanding of the unique structure-function correlates involved in visual processing.

THE BRAIN STRUCTURES INVOLVED IN VISUAL ORIENTATION DISCRIMINATION IN MAN: A PET STUDY. G.A. Orban, P. Dupont, R. Vogels, G. Bormans, J. Nuyts, C. Schiepers and L. Mortelmans. Lab. Neuro- en Psychofysiologie, Medical School, KULeuven and PET Center, Dept. of Nuclear Medicine, UZ GHB, Leuven Poleium.

Leuven, Belgium.

Using positron emission tomography and changes in regional cerebral blood flow measured with (0-15) water we compared the brain structures involved in two types of orientation discrimination tasks: a temporal same-different task and an identification task. In the first task structures involved in two types of orientation discrimination tasks: a temporal same-different task and an identification task. In the first task subjects had to compare the orientation of two successively presented gratings (2-3° orientation difference, median % correct 87). In the second task subjects had to identify the grating presented as vertical or not (1-2° orientation difference, median % correct 83). Control tasks included a detection task and passive fixation task. Grating stimuli were identical in all tasks and were presented foveally. Fixation was controlled by EOG. Data were obtained from 7 right-handed subjects with a CTI-931/8/12 PET scanner. Approval was given by the Ethics committee of the KULeuven Med. School. The analysis of the subtraction images was done with the SPM software (Hammersmith Hospital London) and with technique of Fox and Mintun (J. Nucl. Med. 89).

Comparison of the same different and identification tasks revealed a marked lateralization in the right hemisphere of the significant foci. These included the cuneus, the gyri occipitalis medius, temporalis inferior, fusiformis, parahippocampalis, cinguli anterior, and pulvinar. Activation of the same foci was also observed after subtraction of detection from same-different. Comparison of the identification and detection task revealed in addition to gyrus lingualis and fusiformis several nonvisual structures (e.g. cerebellum, gyrus cinguli). These results suggest that same-different tasks require more visual processing than the simpler identification task, underscoring the task dependency of visual processing.

## NEURAL PLASTICITY II

## 257.1

AUDITORY COMPENSATION OF EARLY VISUAL DEPRIVATION IN THE CAT'S ANTERIOR ECTOSYLVIAN CORTEX. I.P. Rauschecker\* and M. Korte. Neuroethology Unit, NIMH, Poolesville, MD 20837, U.S.A. and Max-Planck-Institut für biologische Kybernetik, W-7400 Tübingen, Germany.

Binocular deprivation (BD) from birth leads to improvement of sound localization in cats. The superior colliculus (SC) in the midbrain tectum is one candidate structure in which the neural basis for this behavioral change could be sought. Indeed, a four-fold increase of auditory-responsive units is found in the SC of visually deprived cats (Rauschecker and Harris, 1983). The major auditory cortical input to SC comes from the anterior ectosylvian cortex (AES), and this projection is

input to Scionite and the attention ecrosystant conex (ALS), and into projection is strengthened in visually deprived cats.

Neuronal responses in AES to visual, auditory, and somatosensory stimuli were studied in normal and visually deprived cats under halothane anesthesia. Just like in the SC, drastically changed proportions of neurons with responses to the different in the 3c., drastically changed proportions on neutrons with responses to the different modalities were found. Neutrons in the fundus of the anterior ectosylvian sulcus (area AEV; Mucke et al., 1982; Olson & Graybiel, 1987), which normally react exclusively to visual stimuli, responded vigorously to auditory and somatosensory stimuli. The few neurons that could still be driven by visual stimulation were now bimodal, responding also to other sensory modalities. No increase of unresponsive

Auditory spatial tuning width for the azimuth of a sound source was compared for neurons in the anterior ectosylvian region of normal and blind-reared cats using broad-band stimuli. A spatial tuning (ST) index was calculated for each cell as the min/max ratio between responses in 7 different azimuthal positions (Rajan et al., 1990). The distribution of ST indices for blind cats was significantly shifted towards smaller values indicating sharper tuning (p<0.001, median and Smirnov tests). In addition, the proportion of omni-directional units was 44% in normal cats and only 14% in visually deprived cats. The half-widths of spatial tuning curves were also significantly reduced in all BD animals. It seems possible that these changes in the cortical AES region form the neural basis for the improvements in sound localization behavior of visually deprived cats and that the changes in the SC are only secondary.

VISUAL INPUTS ROUTED TO THE AUDITORY PATHWAY IN FERRETS: BEHAVIORAL RESULTS. L.S. Carman\*, S.L. Pallas+ and M. Sur. Department of Brain and Cognitive Sciences, M.I.T. Cambridge, MA 02139 <sup>+</sup>Division of Medicine, Baylor College of Medicine, Houston, TX 77030

A retinal projection to the auditory pathway of the brain can be induced in neonatal ferrets by ablating or reducing normal retinal ganglion cell targets (the superior colliculus and lateral geniculate nucleus) and deafferenting the auditory thalamic nucleus (medial geniculate nucleus, MGN) (Sur et al., 1988). This 'rewired' retinal projection confers visual responsivity on cells in the MGN and in primary auditory cortex (A1) (Roe et al., 1990, 1991). We sought to determine (i) whether this rewired projection is capable of mediating behavior, and (ii) whether rewired ferrets perceive a light stimulus presented to the rewired A1 as visual or auditory. Unilaterally rewired ferrets were trained to distinguish between auditory stimuli and a light stimulus presented to the non-rewired hemisphere. The perceptual function of the rewired projection to A1 was then examined by presenting test light stimuli to the rewired hemisphere. Prior isolation of remnant visual thalamus in the rewired hemisphere with ibotenic acid ensured that the visual stimuli activated the rewired pathway. Rewired ferrets consistently responded to test stimuli as though they were visual. To confirm that the responses to test light stimuli were mediated by the rewired projection and its representation in A1, the auditory cortex of rewired ferrets was ablated; ferrets responses were reduced to chance level. These results indicate that the functional modality of a sensory cortical region can be respecified by novel sensory innervation. Supported by EY07719

LEARNED AUDITORY RESPONSES IN THE BARN OWL'S OPTIC TECTUM ARE PREFERENTIALLY SUPPRESSED BY THE NMDA RECEPTOR BLOCKER KETAMINE. M.S. Brainard\*, D.E. Feldman and E.I. Knudsen. Dept. Neurobiology, Stanford University, Stanford, CA 94305.

Space-specific neurons in the barn owl's optic tectum (OT; superior colliculus) are space-specific neurons in the barn owl's optic tectum (O1; superior colliculus) are normally funded to the interaural timing differences (ITDs) which are produced by sounds at the locations of their visual receptive fields. Neurons in owls raised with laterally displacing prisms become tuned for abnormal ITDs corresponding to the locations of their optically displaced visual receptive fields. We have found that these learned responses to abnormal ITDs are strongly suppressed by ketamine.

Owls were raised with prismatic glasses that laterally displaced the visual field.

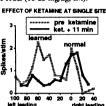

Dwis were raised with prismatic glasses that laterally displaced the visual need. Beginning at 60 days of age, extracellular recordings were used to measure unit tuning for the ITD of sounds delivered via earphones. At some recording sites, units responded both to the ITD which was normal for that location in the tectum ("normal ITD"), and to the ITD which corresponded to the prismatically displaced visual receptive field ("learned ITD"). At those sites, responses to repeated presentations of normal and learned ITDs were monitored for a 20 minute control period, and then for

normal and learned 11Ds were monitored for a 20 minute control period, and then to up to 100 minutes following injection of ketamine HCL (10-25 mg/kg; IM).

Ketamine suppressed responses to learned ITDs by 40 to 90% during the 20 minute period following injection, with gradual recovery over 

3

\*\*EFFECT OF KETAMINE AT SINGLE SITE | The standard of the next hour. In contrast, ketamine had a consistently smaller effect on responses of units to normal ITDs. The same levels of ketamine blocked responses of OT units to iontophoresed NMDA but not quisqualate. These results suggest that NMDA receptors may participate differentially in the expression of responses to the learned versus normal range of ITDs. ### 257.5

AFFERENT STIMULATION IN THE ENTORHINAL CORTEX INCREASES THE CA1 RELEASE OF GABA, GLUTAMATE AND ASPARTATE, IN VIVO, ASSOCIATED WITH INCREASED EXPRESSION OF NGF AND BDNF mRNA IN THE RAT HIPPOCAMPUS. T. Falkenberg\*, W.T. O'Connor, U. Ungerstedt, H. Persson<sup>1</sup>, and N. Lindefors. Department of Pharmacology and <sup>1</sup>Department of Medical Chemistry, Laboratory of Molecular Neurobiology, Karolinska Institutet, P.O. Box 60 400, S-104 01 Stockholm, Sweden

The present study was undertaken to understand the relative role of afferent stimula-

tion in the entorhinal cortex on the synaptic release of neuroactive aminoacids and their involvement in regulation of gene expression of neurotrophic factors. Transmittor release was measured, in vivo, by means of microdialysis in the dorsal CA1 region of the hippocampus in awake freely moving rats as well as behavioural effects following injection of different doses of quisqualate into the lateral part of the lateral entorhinal cortex. The entorhinal cortex is the major source of cortical input to the hippocampal formation and we have shown using a similar paradigm as in this study that afferent transsynaptic stimulation differentially regulate nerve growth factor (NGF) and brain-derived neurotrophic factor (BDNF) mRNA expression. Furthermore, pretreatment with the benzodiazepine receptor agonist diazepam completely prevented the increase in NGF and BDNF mRNA expression seen following afferent activation. Preliminary results indicate that quisqalate injection results in dose-dependent release of GABA, glutamate and aspartate and dose-dependent effects on behaviour, such as increased exploratory behaviour, epileptogenic activity and stereotypic movements. Changes in behavioural activity accompanied changes in basal transmittor levels. Similar effects were also seen after injection of quisqualate into the perinhinal cortex, however, were also seen after injection of quisqualate into the peririnnal cortex, however, epileptogenic activity could not be observed. Experiments are in progress to determine, with in situ hybridisation, if there are transmittor release dependent changes in mRNA levels of NGF and BDNF following afferent activation with different concentrations of quisqualate. Thus we are currently investigating the possibility that changes in release of GABA, glutamate and aspartate differently regulate gene expression of BDNF and NGF that may mediate changes in neuronal plasticity in the hippocampus.

## 257.7

ACTIVITY-DEPENDENT PLASTICITY OF INHIBITORY AND EXCITATORY AMINO ACID TRANSMITTER SYSTEMS IN CULTURED RAT CEREBRAL CORTEX. G.J.A. Ramakers\* H. van Galen, M.G.P. Feenstra, M.A. Corner and G.J. Boer, Netherlands Inst. for Brain Res., Meibergdreef 33, Amsterdam, The Netherlands.

Chronic suppression of spontaneous bioelectric activity in rat cerebral cortex cultures increases neuronal cell death and results in electrophysiological alterations, indicative of changes in the balance between excitatory and inhibitory neurotransmitter systems. To delineate mechanisms that could underlie this disbalance, we investigated the effects of chronic silencing with tetrodotoxin (TTX) on the content and release of glutamate, aspartate and gamma-aminobutyric acid (GABA) in culture. Chronic TTX treatment decreased the content of all amino acids investigated. However, relative to the general neuronal marker NSE (neuron-specific enolase) only GABA was decreased, indicating a disproportionate loss of GABAergic neurons upon chronic silencing. The K+- induced release of GABA, glutamate and aspartate increased about tenfold between 7 and 21 days in vitro in control cultures. Chronic TTX treatment significantly increased the depolarization-induced release of glutamate and aspartate at 7 days in vitro, and at all ages increased the ratio of the evoked release of the excitatory amino acids to that of GABA more than twofold. These observations support the hypothesis that chronic silencing increases the ratio of excitatory to inhibitory synaptic activity through several mechanisms, all of which may be involved in activitydependent functional neuroplasticity in vitro as well as in vivo.

INDUCTION BY SEIZURES OF F1/GAP-43 GENE EXPRESSION IN HIPPOCAMPAL GRANULE CELLS. A. Routtenberg \*1\_P. J. Meberg 1\_and C. M. Gall<sup>2</sup>. 1. Cresap Neurosci. Lab., Northwestern Univ. Evanston, IL 60208. 2. Dept. of Anatomy and Neurobiology, Univ. of California, Irvine 92717

F1/GAP-43 mRNA is highly expressed in pyramidal cells of the adult rat hippocampus, but is nearly absent in the granule cells even at the time of mossy fibe outgrowth in the neonate [Neuroscience 45:721 (1991)]. To determine whether granule cells can be induced to express F1/GAP-43 mRNA, we studied transcript levels after seizures, which are known to increase the expression of other genes [Prog. Brain Res. 83:371 (1990)]. Seizure-inducing electrolytic lesions were made in the hilus with stainless-steel electrodes, and then mRNA levels were measured in contralateral hippocampus by quantitative in situ hybridization. F1/GAP-43 expression was induced in granule cells. Grain density was almost 20-fold higher at 24 hr, as compared to 6 or 12 hr post-lesion. Labeling over granule cells had declined by 48 hr post-lesion; but even at 10 days was still higher than controls This sustained elevation of F1/GAP-43 mRNA expression may be important for the sprouting of mossy fibers shown to occur after seizures in other paradigms. F1/GAP-43 expression also increased 2-3 fold in CA1 pyramidal cells, but the peak expression occurred at 48 hr post-lesion. The changes were attributable to the seizures, as labeling in all cell fields was similar to controls when similar lesions were made with a platinum electrode which does not induce seizures. These data provide evidence that F1/GAP-43 expression can be induced in adult neurons which normally do not express F1/GAP-43. This increased expression by seizures may be a useful paradigm for studying whether regulation of F1/GAP-43 in the mature CNS is by transcription [J. Neurosci. 12:691 (1992)] or mRNA stability [Molec. Cell. Neurosci. 2:402 (1991)]. [Supported by MH25281-18 and AFOSR-90-0240 to A.R. and NS-26748 to C.G.]

### 257.6

BRAIN LOCALIZATION OF ACTIVIN AND INHIBIN IN RATS WITH NEURAL PLASTICITY RESPONDING TO DEFICIENT NUTRIENT CENTRALLY AND DURING INGESTION UNDER PROTEIN OR L-LYSINE DEFICIENCY K. Torii1\* K. Oosawa<sup>2</sup>, M. Funaba<sup>3</sup>, A. Okiyama<sup>1</sup>, T. Murata<sup>2</sup>, M. Takahashi<sup>4</sup> and T. Ono<sup>5</sup>

A Constant and Taliana and Tal selected the Lys solution and their food intake and growth normalized. The recording of single neuron activity in the lateral hypothalamic area (LHA) of recording of single neuron activity in the lateral hypothalamic area (LHA) of these rats suggested that the neural plasticity occurred, specifically responding to deficient nutrient, Lys, centrally and during ingestion of AA. Also the release of possible neurotrophic factors, activin A ( $\beta_A$ - $\beta_A$ ) or inhibin ( $\alpha$ - $\beta_A$ ), in plasma of rat with or without deficiency both protein and Lys were determined respectively by Hydra Japonica assay. The present study determined the brain localization of activin A and inhibin using rabbit polyclonal antibody against several peptides of partial sequence both  $\alpha$ - and  $\beta_A$ -subunit. Sprague-Dawley strain male rats (N=3, each group), 6 weeks of age, fed a diet with or without protein or Lys deficiency for 4 days, then each brain, fixed by gluthalaldehyde, was serially sectioned 30  $\mu$ m in thick. The localization of immunochemically positive area for antibodies against  $\alpha$ -subunit in the brain were seen in the was serially sectioned 30  $\mu$ m in thick. The localization of immunochemically positive area for antibodies against  $\alpha$ -subunit in the brain were seen in the arcuate nucleus (AN), the ventromedial hypothalamus, CA1 layer of the hippocampus and the nucleus of tractus solitarius (NTS). In the case of antibodies against  $\beta_A$ -subunit, the AN, the amygdala and the NTS were also positive. The degrees of positive area were quite comparable to each other nutritional treatment. These results suggest that the neural plasticity is not merely happen in the lateral hypothalamic area induced by Lys deficiency, and that activin A and/or inhibin may be involved in the plasticity in brain to maintain AA homeostasis, coupling with changes of preference and appetite for AA.

## 257.8

FUNCTIONAL ADAPTATION TO CORTICOSPINAL TRACT DISRUPTION IN THE HUMAN BRAIN. JJM Kew. PN Leigh\*. RE Rassingham. RSJ Frackowiak. DJ Brooks. MRC Cyclotron Unit, Hammersmith Hospital, London, UK; Department of Neurology, Institute of Psychiatry, London, UK.

To determine the way the brain adapts to a corticospinal tract lesion, we studied cortical function in 12 patients with amyotrophic lateral sclerosis (ALS), a disease causing neuronal loss in the motor cortex and degeneration of the corticospinal tract. Six normal human volunteers were studied for comparison. Positron emission tomography (PET) was used to image regional cerebral blood flow (rCBF) in subjects at rest and during performance of paced, freely-selected movements of a joystick with the right hand.

Comparison of the increase in rCBF caused by the task between the two groups of subjects showed significantly (p<0.001) greater

activation in ALS patients in the lower third (face area) of the contralateral sensorimotor cortex, the contralateral anterior insula, and the ipsilateral cingulate cortex (dorso-caudal area 24). Accompanying facial movements were not observed in patients.

The ventral expansion of the upper limb output zone in ALS patients suggests that recruitment of neurons lying in the face output zone but projecting to upper limb target motoneurons may occur in response to a corticospinal tract lesion. Recruitment of insular and cingulate motor areas may represent further functional adaptation. (Supported by the Medical Research Council)

REGIONAL CORTICAL GYRAL VARIATIONS IN HUMAN MONOZYGOTIC TWINS. D. R. Weinberger, A. J. Bartley, D. W. Jones, J. R. Zigun. Clinical Brain Disorders Branch, National Institute of Mental Health, Washington, D.C. 20032

Early hypotheses about the role of physical forces in the development of human cortical gyri have yielded to the current view that gyral patterns are determined primarily by genetic factors and reflect underlying connectivity. The advent of high fidelity renderings of cortical surfaces from thin section (1.5 mm) MRI and a quantitative cross correlation method for comparing gyral patterns on such images (Bartley AJ, et al, Neuroscience Abs, 1992) have made it possible to test in living subjects hypotheses about human cortical development. We evaluated cortical gyral patterns on volume renderings of the cortical surface from MRI scans of five pairs of normal monozygotic (MZ) twins. Pattern concordance was greatest within twin pairs for cerebellar folia (mean  $\pm$  sem cross correlation value = .45  $\pm$  .02) and least for dorsolateral prefrontal cortex (.21  $\pm$  .02). Concordance in other cortical areas ranged from .25 to .33. No consistent lateralization effects were seen. In random pairings of unrelated twins, concordance values were considerably lower. This study demonstrates that while MZ twin pairs have greater cortical pattern similarity than pairs of unrelated individuals, even within MZ twins, there is considerable variability in cortical gyral patterns. Greatest variance is found in highly evolved, late maturing prefrontal cortex, suggesting that individual experiential factors play a role in the development of human cortical gyral variation.

SELECTIVE NEUROANATOMICAL PLASTICITY AND DIVISION OF LABOR IN THE HONEY BEE (APIS MELLIFERA). G.S. Withers', S.E. Fahrbach, & G.E. Robinson,

MELLIFERAL G.S. WILTIEST S.E. FAINDACH, & G.E. HODINSON.

Neuroscience Program & Dept. of Entomology, University of Illinois at

Urbana-Champaign, Urbana, IL 61801.

The division of labor in a honey bee colony is organized in part by
age of the worker bee. Younger bees typically work within the hive; older
bees forage for food. To determine whether neuroanatomical plasticity is
associated with this behavioral maturation, unbiased volume estimates of associated with this behavioral maturation, unbiased volume estimates of all major brain regions were made using Cavalien's Direct Estimator. Tissue was sampled from bees at three distinct stages: inexperienced 1-day old bees, nurse bees caring for brood (typically 7-10 days of age) and pollen foragers (21 days and older).

and pollen foragers (21 days and older).

While there was no overall change in the volume of the brain, our survey revealed two significant regional changes. Nurse bees had the greatest volume of olfactory glomenuli relative to both 1-day old bees and loragers. This may reflect the important role of chemosensory cues in regulating behavior within the dark hive. An entirely different pattern was seen in the mushroom bodies (corpora pedunculata). In this region, the volume of neuropii of was significantly increased in foragers, while the volume occupied by the intrinsic cell population was significantly decreased. As the mushroom bodies are important in both multimodal integration and learning, their function is likely to be critical in foraging behavior. This is the first evidence of substantial region-specific plasticity associated with the acquisition of complex behaviors in an

## 257.13

LONG-TERM ALTERATION OF SOMA MEMBRANE PROPERTIES IN PEDAL MOTOR NEURONS AND MUCUS MOTOR NEURON R2 OF *APLYSIA* FOLLOWING AXONAL INJURY. M. F. Dulin and E.T. Walters\*. Dept. of Physiology & Cell Biology, University of Texas Medical School at Houston, TX 77225. Crushing the axons of sensory neurons in *Aplysia* causes a delayed hyperexcitability of the soma that lasts for weeks (Walters et al. *Science* 253:797, 1991). We have now examined motor neurons using similar procedures. Relative to paired contralateral controls, pedal motor neurons with crushed axons displayed a significantly greater AHP (14.2 vs. 8.6 mV)(p=.03) and tendencies for a lower spike AHP (14.2 vs. 8.6 mV)(p=.03) and tendencies for a lower spike threshold (1.2 vs. 1.8 nA)(p=.09) and greater resting potential (-46.7 vs. -41.9 mV)(p=.2) 5 days after unilateral pedal nerve crush performed under strong anesthesia (n=6 animals with 4-6 cell pairs per animal, 2-tailed tests). In contrast to sensory neurons, pedal motor neurons did not display noticeable alterations in spike duration or accommodation (p>.3). Axons of mucus motor neuron R2 were injured by nearby crush of the right connective and branchial nerve (8 crushed and 10 control cells). Preliminary results indicate a tendency for spike accommodation to decrease (17.5 vs. 12 spikes/ tendency for spike accommodation to decrease (17.5 vs. 12 spikes) 1 s pulse, p=.08), resting potential to increase (-59.3 vs. -52.3 mV, p=.18), and AHP to decrease (5.6 vs. 8.6 mV, p=.23). These early results indicate that long-term, injury-induced plasticity of electrophysiological properties occurs in motor neurons as well as sensory neurons in Aplysia. Furthermore, the plastic changes differ between sensory and motor neurons, and may differ between different classes of motor neurons.

AGE RELATED PLASTICITY AND THE HIPPOCAMPAL MEMORY IMPAIR-MENT. E.J. Holmes, Lab. for Neuropsychology, Hampton University, Hampton, VA 23668.

Previous studies from this laboratory have demonstrated

that adult rats which received large bilateral lesions of that adult rats which received large bilateral lesions of the hippocampus in infancy were less impaired on an 8-choice radial arm maze task than animals which received analogous lesions during early adulthood. These studies also demonstrated that animals which were operated at approximately 3 weeks of age were the least impaired when tested as adults with the level of impairment increasing as the age at the time of surgery increased. Therefore, it appeared that the younger the animal was at the time of surgery, the greater the sparing of impairment should be when tested for spatial memory capacity during adulthood. To test this hypothesis, ten adult animals which were operated at approximately 2 weeks of age (i.e., 10-15 days old) were tested on the same radial arm maze task following a post-operative period equal to that given the other operated groups. Surprisingly, the results showed that the adults operated at at 2 weeks of age were markedly more impaired than the adults operated at 3 weeks (U=0, p < .05, Mann-Whitney U-test) and performed most like the subjects operated in early adulthood. These results are quite provoking and serve to help deflate the notion of "the earlier the brain damage, the better the recovery."
Clearly, the timing of the damage is critical and suggests significant ongoing changes in both neurochemical and neuroanatomical development during this period.

LONG-TERM INCREASE IN ACTION POTENTIAL AMPLITUDE AND SOMA EXCITABILITY IN APLYSIA SENSORY NEURONS FOLLOWING PERIAXONAL IMMUNE REACTION . A.L. Clatworthy\*, G.A. Castro, E.T. Walters. Dept. of Physiology & Cell Biology, Univ. Texas Medical School at Houston, TX 77225.

Implantation of cotton string around nerves containing axons of Implantation of cotton string around nerves containing axons of sensory neurons (SN) causes a foreign body reaction ("granuloma") associated with a long-term decrease in spike threshold and accommodation during 1 s depolarizing test pulses delivered to the SN soma (Alizadeh et al. Soc. Neurosci. Abstr. 16:597, 1990). Using similar methods we have found that additional properties of the soma are altered 6-9 days after ipsilateral implantation of string around pedal nerves, and that the soma alterations occur in the apparent absence of injury to the axons. For SNs on the implanted side vs. contralateral SNs, spike amplitude was greater (90 vs. 84 mV), spike duration was longer (3.8 vs. 3.3 ms), the AHP was smaller (3.4 vs. 3.8 mV), and input resistance was greater (40 vs. 28 smaller (3.4 vs. 3.8 mV), and input resistance was greater (40 vs. 28 M $\Omega$ ) (p<.05 in each case; n=14 animals with 4-8 SN pairs tested per animal). Replicating our previous findings, both spike threshold and accommodation were lower in these same animals (1.0 vs. 1.2 nA, and 3.2 vs 1.2 spikes/1 sec pulse)(p<.02). Stimulation of nerves distal to the granuloma always evoked a spike in the SN soma in cells that also responded with a spike to proximal nerve stimulation, indicating normal conduction through the implanted region. Furthermore, light microscopic examination of sections through the granuloma revealed no evidence of axonal injury. We are beginning to examine potential contributions from immunocytes, nerve stretch, and injury of the nerve sheath to this long-term SN plasticity.

OLFACTOMEDIN: A NOVEL EXTRACELLULAR GLYCOPROTEIN UNIQUELY EXPRESSED IN OLFACTORY NEUROEPITHELIUM. R. R. H. Anholt\*, Duke University Medical Center, Durham, NC 27710.

Olfactomedin is a 57 kD glycoprotein synthesized by

Bowman's glands and sustentacular cells and deposited in the extracellular matrix of the olfactory neuroepithelium where it remains confined to the viscous lower mucus The protein exists as a 120 kD homodimer formed via a disulfide bond. We purified olfactomedin from olfactory tissue of Rana catesbeiana by lectin affinity chromatography and determined its N-terminal sequence. We then used a 16-fold degenerate 47-mer oligonucleotide to screen a cDNA library and identify a clone with a 1.9 kb insert which encodes olfactomedin. Partial sequence analsis of this cDNA reveals a polyadenylation site near its 3'-end and an open reading frame at its 5'-end. It encodes a hydrophobic leader peptide followed by a highly hydrophilic domain which contains, as expected, several potential N-linked glycosylation sites along with cysteines, which may form intramolecular disulfides to stabilize the conformation of the polypeptide. The 250 amino acid sequence, thus far determined, does not display homologies to any known proteins. The abundance of this unique olfactory glycoprotein at the chemosensory surface suggests that it may be essential for the structural integrity. morphogenesis or chemosensory function of the olfactory membrane. Supported by NIH grant DC00394 and ARO grant DAAL03-89-K-0187.

EXPRESSION AND ANAYLSIS OF COMPONENTS OF THE OLFACTORY SIGNALING SYSTEM IN XENOPUS OOCYTES. Ionathan Bradley, Yasuhito Uezono, Norman Davidson, Henry Lester\*, and Kai Zinn. Division of Biology, California Institute of Technology, Pasadena, CA 91125

In order to identify and characterize olfactory receptors for specific odorant chemicals, we have developed a method for generating a electrophysiological signal in response to cAMP elevation in Xenopus ocytes. To do this, we expressed the cystic fibrosis transmembrane regulator (CFTR), a chloride channel that is controlled via phosphorylation by cAMP-dependent protein kinase A (see abstract by Y. Uezono et al.). When rat nasal epithelial polyA+RNA is injected into oocytes together with synthetic CFTR mRNA and a mixture of odorants applied to the oocytes, a large (up to 800 nA)chloride current is observed. We made an olfactory cDNA library, screened it at low stringency with a PCR probe recognizing the ofactory 7-helix receptor gene family recently identified by Buck and Axel (Cell 65, 175), and isolated a large number of hybridizing clones. Pools of synthetic mRNAs from these clones were injected into oocytes together with CFTR mRNA and tested with odorant mixtures. We now have preliminary data indicating that single clones can mediate odorant responses.

In other work, we have cloned cDNAs encoding a new cyclic nucleotide-gate cation channel expressed in rat nasal epithelium, and are characterizing this channel by heterologous expression. Support: NS28182, GM29836, CFF, Pew Foundation, McKight Foundation, Drown

PATTERNS OF ADRENERGIC AND PEPTIDERGIC INNERVATION OF HUMAN OLFACTORY MUCOSA. Y. Cheni, M.L. Getchell\*1.2, N.S. Rama Krishna3, Z.Y. Su³ and T.V. Getchell<sup>1,2,3</sup>. 1, Div. of Otolaryngol., Dept. of Surgery; 2, Sanders-Brown Center on Aging; 3, Dept. of Physiol. & Biophys., University of Kentucky College of Medicine, Lexington, KY. 40536.

Tyrosine hydroxylase (TH)- and dopamine-βhydroxylase (D\$H)-immunoreactive (ir) fibers innervate nydroxylase (DBH)-immunoreactive (IF) libers innervate blood vessels and Bowman's glands in the lamina propria of human olfactory mucosa. In this study, colocalization of neuropeptide Y (NPY) and DBH immunoreactivity and the relation of TH- and DBH-ir fibers to olfactory marker protein (OMP)-ir fibers were investigated using double staining immunofluorescence techniques. Sections were stained with antibodies to DBH and NPY, TH and OMP, or DBH and OMP simultaneously. Colocalized DBH- and NPY-ir as observed primarily in fibers around blood vessels in the deep vascular layer of lamina propria; few were found near Bowman's glands. TH- and DBH-ir fibers were present in the epineurium and perineurium of OMP positive nerve bundles; the adrenergic fibers appear to innervate vasa nervorum, blood vessels in the sheaths that supply enclosed olfactory nerve fibers. No fibers contained colocalized OMP- and TH-ir or OMP- and D $\beta$ H-ir. Thus vasomotor activity and secretion are regulated by adrenergic and peptidergic input, and sympathetic nerve fibers regulate blood flow to olfactory nerves. Supporte Supported by NSF BNS-88-21074 (MLG) and NIH DC-00159 (TVG).

PATTERNS OF EXPRESSION OF PUTATIVE OLFACTORY RECEPTORS A. M. Cunningham, N. S. Levy, D. K. Ryugo and R. R. Reed.\* Depts of Molecular Biology and Genetics, Neuroscience and Otolaryngology-HNS, Johns Hopkins Univ. School of Medicine, Baltimore, MD 21205.

Olfactory signal transduction has been shown biochemically to involve a GTP-dependent increase in cAMP levels in olfactory neuronal cilia. Subsequently, novel components of this G-protein coupled cascade have been identified; an olfactor specific G-protein, Golf, an adenylate cyclase and a cyclic nucleotide-gated ion channel specific G-protein, Goff, an adenylate cyclase and a cyclic nucleotide-gated ion channel. The receptors involved in odorant binding remained unknown until efforts to identify them by sequence similarity to other G-protein coupled receptors succeeded in defining a new large gene family (Buck & Axel, 1991). Work in our laboratory has added new members to this family and we are studying their genomic organization.

We have generated anti-peptide antibodies designed to recognize most members of this family. Immunohistochemical studies have confirmed expression of the receptor

proteins exclusively by neurons in the rat olfactory neuroepithelium, both in dendrites and sensory cilia. Current immunoEM studies of olfactory cilia will define the relationship of these receptors to other components of the transduction apparatus. Recently we have produced antibodies to a small subset of the receptors. These antibodies recognize only a subpopulation of the sensory neurons (approx. 10-20%) and the expressing cells are distributed uniformly in the neuroepithelium. Information about receptor distribution within neurons in the epithelium and the connections of these cells in the olfactory bulb will form the basis of our understanding of the mechanism of olfactory sensory coding at a molecular level. To further this, we are performing in situ hybridization studies with probes made to specific receptors.

It has been shown that some odorants can stimulate the phosphatidylinositol (Pl) pathway. As we have shown virtually all neurons in the epithelium express this receptor family, it may be that some of these receptors are capable of activating the Pl pathway. We have expressed receptors in a mammalian cell line in an attempt to study receptor-ligand relationships and second messenger generation. The combined results of these approaches will provide insight into the mechanism of olfactory receptor stimulation and how odorant information is conveyed to the higher centers.

BASAL CELLS MODULATE RECEPTOR CELL FUNCTION IN NECTURUS TASTE BUDS BY A SEROTONERGIC MECHANISM. Douglas A. Ewald\* & Stephen D. Roper Dept. of Anatomy and Neurobiology, Colorado State University, For Collins CO 80523 and the Rocky Mountain Taste and Smell Center, Denver CO 80262

Basal cells, which comprise only 10% of the total cell population of Necturus taste buds, are involved in the majority of morphologically identifiable synapses in the taste bud (Delay & Roper, J. Comp. Neurol. 277: 268, 1988). In slices of lingual epithelium, focal chemical stimulation (140 mM KCl) of the apical tips of taste receptor cells elicits receptor potentials in taste receptor cells and postsynaptic responses in basal cells (Ewald & Roper, J. Neurophysiol. 67: 1316, 1992). It is now known that Merkel-like basal cells in the Necturus taste bud contain serotonin (5-HT; Welton, Taylor, Delay & Roper, AChemS, Abstr. #48 & #194, 1992). We have bath applied 5-HT (100 µ M) to thin slices of lingual epithelium that contain taste buds while recording intracellular responses from taste cells. Under these conditions 5-HT increased the input resistance of receptor cells (mean ± S.E.: 54 ± 9%, N=14) and thereby decreased the electrotonic decay of receptor potentials from the apical to the basal ends of the receptor cells (139 ± 13% increase in amplitude in the same cells). During 5-HT application we also observed an increase in the postsynaptic potentials recorded in basal cells (140 ± 17%, N=9), presumably due to the increased amplitude of the presynaptic (receptor) potential. Next, direct electrical depolarization of basal cells (two or more 1-sec pulses to 20-50 mV above resting potential, applied through the intracellular recording electrode) was used in an attempt to stimulate the release of endogenous 5-HT. This procedure increased the amplitude of subsequent postsynaptic responses recorded in the same basal cell (42 ± 10%, N=8) and thus mimicked the effect of bath-applied 5-HT. These results are consistent with the view that 5-HT, re

EFFECTIVENESS OF HOMOLOGOUS SERIES OF NONREACTIVE AIRBORNE CHEMICALS IN EVOKING NASAL IRRITATION AND ODOR. J. E. Cometto-Muñiz and W. S. Cain\*. John B. Pierce Lab. and Yale Univ., New Haven, CT 06519.

By testing anosmic and normosmic subjects we assessed the relative sensitivity of the nasal trigeminal and olfactory nerves in the detection of nonreactive airborne chemicals. Anosmics, lacking a functional sense of smell, provided nasal irritation thresholds. Normosmics provided odor thresholds. The stimuli comprised homologous ketones and selected secondary and tertiary alcohols and acetates. Anosmics detected all compounds. albeit at much higher concentrations than normosmics. As seen before with homologous alcohols (Physiol, Behav, 48(5) 719-725, 1990) and acetates (Pharmacol, Biochem, Behav. 39(4) 983-989, 1991), both types of thresholds decreased with carbon chain length, odor declining more rapidly. Nasal irritation was evoked at a fairly constant percentage of vapor saturation (~32%) irrespective of molecular size or chemical functionality. Such a relationship does not hold for odor thresholds. The outcome suggests that nasal irritation from nonreactive substances relies heavily on a physical, rather than chemical, interaction with the nasal mucosa. Supported by NIH Grant DC00284. J.E.C.-M. is a member of the Carrera del Investigador Científico, Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), República Argentina.

NOVEL MICROVILLAR CELL IN THE OLFACTORY EPITHELIUM OF CARTILAGINOUS FISH. <u>S. Takami\*and</u>

P.P.C. Graziadei. Department of Biological Science, Florida State University, Tallahassee, FL 32306. It has been reported that the olfactory epithelium (OE) of cartilaginous fishes contains exclusively microvillar receptor cell but no ciliated receptor cells. We will report here that the OE of the clearnose skate (Raja cells. We will report here that the OE of the clearnose skate (Raja eglanteria) contains a novel type of microvillar cells. The OE of juvenille Raja of 2-4 months after hatching was observed by using transmission electron microscopy (TEM) and scanning (S) EM. By TEM, we have confirmed the microvillar receptor cells which have been reported in other fishes; these cells contained well developed lamellae of rough endoplasmic reticulum (rER) in the perikaryal region and their dendritic ending had some microvilli (thickness; about 100 nm) on the surface. We also found a second type of receptor cell-like perikarya which contains a well developed Golgi apparatus and many smooth vesicles around it, but rare rER. Apical processes (dendrites) of these cells contained some mitochondria, sparse microtuber and numerous smooth vesicles and projected a hemispherical ending from and numerous smooth vesicles, and projected a hemispherical ending from the luminal surface. This ending appeared to have a few thick microvilli (thickness; 250-300 nm) which were even thicker than cilia of sustentacular cells. Each microvillus was filled with a bundle of filaments and this bundle cells. Each microvillus was filled with a bundle of filaments and this bundle could be traced down to the dendrite as far as 7 µm. By SEM, hemispherical endings with a few short and thick processes were confirmed. The above observations strongly suggest the presence of two types of olfactory receptor cells in skates; one with "stiff" microvilli and the other with microvilli of more conventional structure. (The specimens were kindly provided by Dr. Carl A. Luer, Mote Marine Laboratory. Supported by NIH Grants NS20699 and DC01071-01.)

HYPERTHYROIDISM STIMULATES CELL GENESIS IN THE OLFACTORY EPITHELIUM OF PREMETAMORPHIC, XENOPUS LAEVIS LARVAE. G.D. Burd\*. Depts. of Anatomy and Molecular & Cellular

Biology, Life Sciences South, University of Arizona, Tucson, AZ 85721. In *Xenopus* larvae, thyroxine  $(T_4)$  pellets (10%) placed adjacent to the nasal capsule stimulate cell genesis in the olfactory epithelium and produce an increase in the number of olfactory axons (Burd. 1990. In: ISOT X, Døving, ed.). Blocking thyroid hormone synthesis with propylthiouracil (0.01%) reduces cell genesis in the olfactory epithelium (Burd and Thomas. 1990. Chem. Sen. 15:558) and the number of olfactory axons (Burd. 1992. J.Comp.Neur. 315:255). In the present study, I examined whether olfactory axon number and olfactory epithelium volume and cell genesis were increased in tadpoles treated for 6 days with 5 nM T<sub>4</sub> in rearing solution (a dose similar to blood levels of larvae entering metamorphic climax). Treatment began when larvae reached stage 48, well before normal synthesis of thyroid hormone begins. Six days stage 46, well before normal synthesis of thyroid normone begins. Six days after hormone treatment,  $T_4$ -treated larvae and sibling controls were injected (I.P.) with 1  $\mu$ Ci <sup>3</sup>H-thymidine. Twenty-four hours later, the animals were processed for electron microscopy and autoradiography. I found that this  $T_4$  treatment stimulates a 5-fold increase in the number of <sup>3</sup>H-thymidine labelled cells in the olfactory epithelium and a 2-fold increase in the volume of the sensory epithelium. The number of olfactory axons also increased, but not significantly. In summary, thyroid hormone, at levels equivalent to physiological values in larvae entering metamorphic climax, induces cell genesis and expansion of sensory epithelium in premetamorphic larvae. A significant increase in olfactory axon number is expected to occur at later time points. Supported by Whitehall Foundation and Arizona Disease Control Research Commission.

#### ACETYLCHOLINE: RECEPTORS

## 259 1

MOLECULAR CHARACTERIZATION OF CURARE BINDING SITE OF THE TORPEDO ACETYLCHOLINE RECEPTOR. M. E. O'Leary\* and M. M. White, Department of Physiology, Medical College of Pennsylvania, Philadelphia, PA 19129 Curare is a well-characterized antagonist of nicotinic

acetylcholine receptors. Despite its designation as a competitive antagonist, it is not clear if curare interacts with the same residues as does ACh, or rather binds to an adjacent, yet overlapping domain; both mechanisms are consistent with the competitive classification. We have recently described two conserved tyrosine residues ( $\alpha$ Y190,  $\alpha$ Y198) that are important components of the agonist binding site of the *Torpedo* AChR. We have further characterized these residues by examining the curare inhibition of mutant receptors expressed in *Xenopus* oocytes. In voltage clamp experiments, curare inhibits wild-type receptors by binding to a single class of high affinity sites (K<sub>1</sub>=40 nM). Phenylalanine substitution of  $\alpha$ Y198 ( $\alpha$ Y198F) causes a 10-fold increase in the curare affinity ( $K_i$ =3.1 nM), and measurement of the rate of recovery from inhibition by curare shows that the main effect of the  $\alpha$ Y198F mutation is to decrease the off-rate for curare by approximately 10-fold. Our data are consistent with the notion that this mutation stabilizes curare binding by increasing the hydrophobic interaction between curare and the binding site. In contrast, the  $\alpha$ Y190F mutation reduces the curare affinity 10-fold ( $K_1$ =400 nM), suggesting that this tyrosine residue is important for high-affinity binding, possibly through a cation- $\pi$  interaction with the quaternary or tertiary ammonium moieties of curare. Supported by NIH grants NS23885 and NS08880.

### 259.2

NICOTINIC RECEPTOR δ SUBUNIT D180 and E189 CONTRIBUTE TO THE BINDING OF ACETYLCHOLINE. C. Czajkowski\*, C. Kaufmann and A. Karlin. Center for Molecular Recognition, Columbia University, New York, NY 10032.
The negative subsite of the nicotinic receptor inter-

The negative subsite of the nicotinic receptor interacting with the quaternary ammonium group of ACh is about 1 nm from  $\alpha$ C192 and  $\alpha$ C193. Recently, we showed that Torpedo  $\delta$ 164-224 contains D or E residues about 1 nm from  $\alpha$ C 192/193 (J. Biol. Chem. <u>266</u>:22603, 1991). We have now mutated three D/E residues in this region of the mouse  $\delta$  subunit to N/Q and expressed the mutant  $\delta$  subunits, together with wild-type  $\alpha$  and  $\beta$  subunits, in Xenopus oocytes. Voltage-clamp data show that wild-type  $\alpha$ 8 $\delta$  recentors are half-maximally activated (Kan) by 3 which with the maximally activated (Kapp) by 3  $\mu$ M ACh. The mutations  $\delta$ D180 to N ( $\delta$ D180N),  $\delta$ E186Q, and  $\delta$ E189Q have Kapp of 227  $\mu$ M, 6  $\mu$ M, and 36  $\mu$ M, respectively. The affinity of ACh, measured by its inhibition of  $\alpha$ -bungarotoxin binding, changes comparably to Kapp.  $\delta$ D180 and  $\delta$ E189, which are conserved in all species of  $\delta$ ,  $\gamma$ , and  $\epsilon$ , but not  $\beta$ , are likely to be part of the negative subsite at both the  $\alpha$ - $\delta$  and  $\alpha$ - $\gamma$  ACh binding sites. NS07258 and by MDA. Supported by NIH grants NS07065 and

## 259.3

EXPRESSION OF A SYNTHETIC GENE FOR α-BUNGAROTOXIN IN E. coli. E. Hawrot\*, N.J. Messier, C.A. Vaslet, S.H. Hsu, L.N. Gentile. Section of Molecular and Biochemical Pharmacology, Division of Biology and Medicine, Brown University, Providence, RI 02912.

The snake venom-derived polypeptide, α-bungarotoxin (BGTX), has played a key role in the biochemical and molecular characterization of nicotinic acetylcholine receptors (nAChR) obtained from fish electric organs and from the neuromuscular junction of skeletal muscle. Although site-directed mutagenesis of the nAChR has been pursued effectively to study structure-function relationships in the nAChR a similar approach has not previously been applied to BGTX.

We have constructed a synthetic gene for BGTX based on the primary amino acid

sequence of this 74-amino acid protein and using the codon usage preferences of E. coli. The synthetic gene was assembled from six overlapping synthetic oligonucleotides and the final annealed, ligated product was amplified by PCR. The BGTX-gene was then fused to a gene encoding a highly soluble T7 coat protein. A protease site recognized by Factor Xa was engineered at the junction site to allow selective release of the recombinant BGTX. Crude extracts of transfectants containing the recombinant BGTX gene contained BGTX activity as determined by competition binding assays utilizing <sup>125</sup>I-labelled authentic BGTX and Torpedo competition binding assays utilizing "1-labelled authentic BGTX and Torpedo AChR-enriched membranes. The fusion protein, purified by ion-exchange chromatography, is active although its specific activity is reduced by approximately 100-fold compared to authentic BGTX. After Factor Xa cleavage, the major released product co-migrates with authentic BGTX on reverse-phase HPLC. These studies suggest that recombinant BGTX refolds correctly and that site-directed mutagenesis studies currently in progress will shed light on the mechanisms with the state of the progress of the state of the st

underlying receptor recognition and binding.

## 259.4

REGULATION OF NEURONAL NICOTINIC ACETYLCHOLINE RECEPTOR GENE **EXPRESSION** 

R.T. Boyd\*, Department of Pharmacology and The Neuroscience Program, The Ohio State University College of Medicine, Columbus, Ohio, 43210.

The neuronal nicotinic acetylcholine receptors (nAChR) are composed of ligand binding subunits ( $\alpha$ ) and structural subunits ( $\beta$ ). Different combinations of  $\alpha$  and  $\beta$  subunits produce nAChR subtypes with different pharmacological and ion conducting properties. Transcriptional regulation may be an important determinant of receptor subtype in a neuronal population and thus influence transmission through a ganglia or group of population and thus influence transmission through a ganglia or group or neurons by controlling the nAChR subtype(s) present. In order to understand the transcriptional regulation and promoter

structure of the rat neuronal nicotinic acetylcholine receptor alpha 3 gene, 2781 nucleotides of genomic DNA were sequenced upstream of the start of the coding region. Known transcriptional regulatory elements such as octamer site, AP-1 site, CCAAT box, and two TATA boxes were shown to be present. A series of fragments from this region were cloned upstream of a luciferase gene (Promega, pGL2-Basic) and the resulting series of constructs were transfected into PC12 cells. Sequences required for the expression of this gene were defined in this manner.

PC 12 cells were grown in the presence of agents that have been shown to modulate cholinergic receptors such as TPA, NGF and nicotine. The effects of these agents on the level of several nAChR subunit RNAs (  $\alpha$ 3,  $\beta$ 2,  $\beta4$ ,  $\alpha5$ ,  $\alpha7$ ) were determined. This work was supported in part by the AHA (Ohio Affiliate) and the Bremer Foundation.

(+)2-METHYLPIPERIDINE: AN ALLOSTERIC MODULATOR OF CENTRAL NEURONAL NICOTINIC RECEPTORS? S.P. Arneric\*. J.P. Sullivan, J. Raszkiewicz, M.L. Hughes, C. Briggs, M.J. Buckley, M.W. Decker, A.M. Hettinger and D.S. Garyey. Neuroscience, Pharmaceutical Discovery Division, Abbott Laboratories, Abbott Park, IL 60064-3500

Previous work suggested that (+)2-methylpiperidine [(+)2-MP] is a putative allosteric modulator of brain receptors labelled by [<sup>3</sup>H]nicotine (Sloan et al., *Life Sci.* 37:1367, 1985), since it increased the specific binding of [<sup>3</sup>H]nicotine. This study sought to determine: 1) Can this effect be replicated using the new nicotinic ligand [<sup>3</sup>H]cytisine? 2) Are there physiological correlates consistent with enhancement of nicotinic transmission?

using the new nicotinic ligand [<sup>3</sup>H|cytisine? 2) Are there physiological correlates consistent with enhancement of nicotinic transmission? Preincubation of rat whole brain synaptic membranes with 10-1000 pM (+)2-MP enhanced specific binding of [<sup>3</sup>H|cytisine up to 125 % of control; (-)2-MP was without effect. No effect of (+)2-MP was observed on the rate of association or dissociation of [<sup>3</sup>H|cytisine. (+)2-MP caused a dose-related (3-10 mg/kg, i.p.) enhancement of the habituation process normally seen in mice; an effect which can be dissociated from impairment of locomotor activity. (+)2-MP (0.1 mg/kg, i.p.) also made effective a subthreshold dose of (-)nicotine to diminish the avoidance response elicited by the elevated plus maze, but was without effect alone. Moreover, (+)2-MP, but not (-)2-MP, (0.1-1 mg/kg, i.v.) enhanced (up to 145 % of control) endogenous central nicotinic transmission assessed by increases in rat cortical blood flow elicited by basal forebrain activation. In contrast, (-)nicotine induced hypothermia and lethality were not potentiated in mouse by (+)2-MP (up to 100 mg/kg, i.p.). Nor were there significant effects to potentiate nicotinic synaptic transmission in the rat superior cervical ganglion. <u>CONCLUSIONS</u>: (+)2-MP may be a selective modulator of central neuronal nicotinic receptors. The allosteric nature of this interaction requires further study before drawing any analogy to the glycine/MDA modulatory site. Its pharmacologic profile appears to potentiate the beneficial, not detrimental, effects of nicotinic receptor activation.

### 259.7

THYMOPOIETIN INTERACTS IN A SIMILAR MANNER WITH  $\alpha$ -BUNGAROTOXIN RECEPTORS IN DIFFERENT RAT BRAIN REGIONS: QUANTITATIVE AUTORADIOGRAPHY. R. Afar', P.B.S. Clarke, G. Goldstein and M. Quik. Dept. Pharmacol., McGill U., Montréal, Canada & Immunobiol. Res. Inst., Annandale, NJ, U.S.A.

The  $\alpha$ -bungarotoxin ( $\alpha$ -BGT) binding site in nervous tissue has long been known to a possess nicotinic pharmacology. Recently, an α-BGT binding subunit ( $\alpha$ 7) has been cloned and expression studies have demonstrated activation by acetylcholine and inhibition by low concentrations of  $\alpha$ -BGT. As well, other subunits ( $\alpha$ 8,  $\alpha$ 5) that may represent  $\alpha$ -BGT binding proteins have been reported. Thymopoietin (TPO), a thymic polypeptide hormone, has been previously shown to inhibit 125I-\alpha-BGT binding to rat brain membranes and brain sections. The present experiments were done to quantitate the interaction of TPO with the  $\alpha$ -BGT receptor, in order to evaluate whether or not TPO might be interacting in a homogeneous manner with all  $\alpha$ -BGT binding sites. Quantitative image analysis of inhibition of 125I-α-BGT binding in the presence of increasing concentrations of TPO was performed on different brain areas. Formaldehyde fixed rat brain sections (20  $\mu$ m) were incubated with I nM  $^{12}$ I- $\alpha$ -BGT in the absence and presence of TPO (10 $^{11}$ - 10 $^{6}$  M). TPO (1  $\mu$ M) almost completely inhibited  $^{12}$ I- $\alpha$ -BGT binding in all brain areas visualized. Quantitation of displacement curves performed on different brain areas revealed that TPO affected these regions with similar potency. IC<sub>50</sub> values for TPO obtained over six regions ranged from 16.5  $\pm$  9.8 nM to 32.4  $\pm$  9.9 nM. The results suggest that TPO recognizes all high affinity (1 nM) α-BGT binding sites in rat brain. Supported by MRC (Canada) and FRSQ.

## 259.9

STUDIES WITH AN AFFINITY LIGAND, 4-BROMOACETAMIDOPROCAINE (BAP), ON AN ADRENAL CELL LINE TRANSFECTED WITH THE M1 MUSCARINIC CHOLINERGIC RECEPTOR (mCR) GENE. D. X. Wang, S-S. Sheu, and L. G. Abood\*. Department of Pharmacology, University of Rochester, School of Medicine and Dentistry, Rochester, NY 14642.

A mouse adrenal cortex tumor cell line (Y1) transfected with an M1 mCR gene M1/zem228 (obtained from Neil Nathanson) has been used to probe the site and mechanism of action of BAP, an affinity ligand for mCR recognition site. With  $^3\text{H-QNB}$  binding, the transfected Y1 cells had Kd values of 10 pM and 100 pM and Bmax value of 400 fmol/mg and 800 fmol/mg respectively. The apparent Ki of BAP for inhibition of  $^3\text{H-QNB}$  binding was about 0.1  $\mu\text{M}$ . At 1  $\mu\text{M}$  BAP there resulted complete irreversible inhibition of  $^3\text{H-QNB}$  binding and 50% inhibition of carbachol-stimulated phosphoinositide turnover. At 0.2  $\mu\text{M}$  BAP, the carbachol-stimulated calcium transient, as measured by fura-2 fluorescence with a photomultiplier detector, was irreversibly inhibited almost 50%. The study has extended findings of others that the transfected Y1 cell line is useful for examining the functional characteristics of the mCR and examining the site of interaction of BAP. Supported by DA 00464.

PHARMACOLOGICAL CHARACTERIZATION OF TRANSIENTLY EXPRESSED NEURONAL NICOTINIC SUBTYPES J.R. Forsayeth\* and B. A. Dodson Dept. of Anesthesia, Univ of Calif, San Francisco, San Francisco, CA 94143

CA 94143 Characterization of neuronal nicotinic acetylcholine receptor (neuronal nAChR) subtypes within the CNS has been formidable due to low receptor number and lack of specific subtype ligands. In this study we report on a transient expression system using COS cells that permits the rapid and reproducible expression and pharmacological characterization of neuronal nAChR subtypes. Briefly, cDNA plasmids for each subunit were subcloned into pCDLSRa296 as blunt fragments inserted between the Pst 1 and Eco R1 cloning sites. COS cells (a simian kidney cell line) were transfected by a DEAE-dextran/ DMSO technique (Gu Y, Neuron 5:147-157, 1990). Specific L3H-nicotine or  $^3$ H-ACh binding to expressed nAChR was determined by filtration (Dodson B, Ann NYAS 625:649-652, 1991) with non-specific binding defined as that occurring in the presence of excess (1mM) unlabeled L-nicotine or carbachol, respectively. No specific ligand binding was detected with cells transfected with c4 subunit alone or  $\alpha$ 4 in combination with  $\beta$ 3. The  $\alpha$ 492 combination resulted in low expression but high affinity binding (Bmax=6 fmol/mg protein, Kd=4.5nM) of both ligands, whereas  $\alpha$ 494 resulted in high expression but low affinity binding (Bmax=72 fmol/mg protein, Kd=30nM). The addition of  $\beta$ 3 to the  $\alpha$ 4924 mixture (i.e.,  $\alpha$ 4923 $\beta$ 44 resulted in >20-fold increase in high affinity binding such that high and low affinity binding to the  $\alpha$ 494 combinations, respectively. These results suggest the neuronal nAChR to be pentameric with the high affinity  $\alpha$ 492 and the  $\alpha$ 494 combinations, respectively. These results suggest the neuronal nAChR to be pentameric with the high affinity  $\alpha$ 492 and the  $\alpha$ 494 combinations, respectively. These results suggest the neuronal nAChR to be pentameric with the high affinity  $\alpha$ 492 and the muscle nAChR (Blount P, Neuron 3:349-357, 1989). [Supported for the muscle nAChR (Blount P, Neuron 3:349-357, 1989). [Supported by NIH Grant NS28062 (JRF) and UCTRD Grant RT352 (BAD)]

POLYMERASE CHAIN REACTION ANALYSIS OF MUSCARINIC RECEPTOR SUBTYPES IN THE MOUSE COCHLEA. <u>D.G. Drescher<sup>1</sup>\* S. Upadhyay<sup>1</sup>, E.R. Wilcox<sup>2</sup> and J. Fex<sup>2</sup>. <sup>1</sup>Lab. of Bio-otology, Wayne State Univ. Sch. of Med., Detroit, MI 48201; <sup>2</sup>Lab. of Molecular Biology, NIDCD, NIH, Bethesda, MD 20892.</u>

Cloning studies have indicated that there exist at least five genes for muscarinic acetylcholine receptors (mAChRs), termed m<sub>1</sub>-m<sub>5</sub>, which lack introns in their coding sequences (Bonner et al., Science 237: 527-532, 1987; Neuron 1: 403-410, 1988). Generally, the receptors corresponding to m<sub>1</sub>, m<sub>3</sub>, and m<sub>5</sub> couple to G proteins and stimulate phosphatidylinositol turnover, while those corresponding to m<sub>2</sub> and m<sub>4</sub> are linked to adenylyl cyclase inhibition via G<sub>1</sub> proteins. Biochemical and pharmacological investigations have suggested that mAChRs are present in the mammalian cochlea, consistent with evidence that efferent neurons to the auditory organ use acetylcholine as a neurotransmitter. In the present study, total RNA was extracted with guandiine thiocyanate from the cochleas of 16-day-old CBA<sub>2</sub> mice. Messenger RNA was purified from the total RNA using oligo dT cellulose, and the mRNA was treated with DNase to degrade genomic DNA. After reverse transcription, resulting cDNA was amplified by polymerase chain reaction (PCR), using primers specific for nucleotide sequences m<sub>1</sub>-m<sub>5</sub>. PCR products corresponding to subtypes m<sub>1</sub>, m<sub>3</sub>, and m<sub>5</sub>, but not to m<sub>2</sub> and m<sub>4</sub>, were amplified. These results suggest that muscarinic acetylcholine receptors of these odd-numbered subtypes are expressed in the mammalian cochlea, consistent with a coupling to cochlear phosphoinositide metabolism. FREE RADICALS GENERATED BY CALPHOSTIN INHIBIT PROTEIN KINASE C. S.S.-H.Wang and S.H.Thompson. Neurosciences Program and Hopkins Marine Station of Stanford University,

Pacific Grove, CA 93950.

Calphostin A and C are lipophilic, light-sensitive perylenequinones that generate singlet oxygen upon illumination. They also inhibit protein kinase C (PKC) with high potency ( $IC_{50}=250,\ 50\ nM$ ) and specificity, but only in the presence of light. We propose that calphostin acts by partitioning into the membrane and producing singlet oxygen, which then irreversibly modifies the diacylglycerol-

binding domain of PKC. Our assay is inhibition of muscarinic receptor-mediated calcium release in N1E-115 cells by the PKC activator phorbol 12-myristate 13-acetate

Inhibition by PMA is blocked by 100 nM calphostin A. This block is reduced in the presence of 1 mM of the antioxidant 2-mercaptoethanol and does not occur in the absence of light. At higher levels of illumination, calphostin causes progressive failure of calcium regulation, an effect not seen in cells injected with the pseudosubstrate inhibitor PKC(19-36). This leads us to conclude that calphostin can affect free radical-sensitive membrane constituents other than PKC. We speculate that free radicals can act as endogenous second messengers that inhibit PKC. (Supported by BNS 9021217 to S.H.T. and MH10088 to S.S.-H.W.)

DIFFERENT SENSITIVITY OF IP3-DEPENDENT INTRACELLULAR Ca++ STORES BY MULTIPLE PHOSPHOINOSITIDE LINKED RECEPTORS IN HUMAN NEUROBLASTOMA CELLS. A. Fatatis\*, A. Bassi, G.F. Di Renzo and L. Annunziato. Sect. of Pharmacology, Dept. Human Comm. Science, II Sch. of Med, Univ of Naples, Naples ITALY.

In LAN-1 human neuroblastoma cells, 1 minute pulses of CCh, Bk, ATP and ET were all able to elicit  $Ca^{++}$  release from IP3-dependent intracellular stores, monitored by fura-2 single-cell microfluorimetry. The dose-response curve of the 4 agonists showed that CCh elicited the highest increase of  $[Ca^{++}]_1$ . When ET, BK and ATP were superfused consecutively at 2 minute intervals in a random sequence and in absence of extracellular  $Ca^{++}$ , a condition which prevents the refilling of  $IP_3$ -dependent stores from extracellular Ca++ sources, the 2nd and the 3th agonist application still evoked a [Ca++]i increase, although progressively reduced, suggesting a partial refilling from the intracellular space. However, if CCh was added consecutively as a 4th stimulus, a sustained elevation of [Ca++] i reappeared. On the other hand, when CCh was applied as 1st stimulus, all the other phosphoinositide linked agonists, subsequently applied, were unable to elicit  $[Ca^{++}]_1$  elevation. The same phenomenon happened when CCh was applied as 2nd or 3th stimulus. All together these results demonstrated that when ET, BK and ATP have exhausted their Ca<sup>++</sup> releasing actions, CCh was still able to elicit an additional [Ca++]i increase from IP3-dependent internal stores.

SUSTAINED EFFECTS OF PILOCARPINE-INDUCED CONVULSIONS ON BRAIN INOSITOL LIPID SIGNALLING AND BRAIN MORPHOLOGY. K.M.Savolainen\*, M.-R.Hirvonen and <sup>1</sup>L. Paljärvi. Div. Env. Hlth, Natl. Publ. Hlth. Inst., and Dept. Pathol., Univ. Kuopio, Kuopio, Finland.

Sustained effects of pilocarpine-induced convulsions on brain phosphoinositide (PI) signalling, and histology, were studied in young (10 weeks) and old (24 months) male rats. Pilocarpine doses were 300 and 175 mg/kg for young and old rats, respectively. Diazepam was used to stop convulsions 2 h after their initiation. Rats were followed for 5 days, and then brain inositol, inositol-1 (Ins1P) and 4-monophosphate (Ins4P) were studied by gas chromatography, and histology by light microscopy. Brain inositol decreased, and Ins1P increased, similarly in young and old rats, except in thalamus where Ins1P remained stable in aged rats. Ins4P did not change in young rats, but in old rats it increased in the frontal cortex and caudate. Widespread brain damage, present in all exposed rats, was more prominent in the old ones. These results suggest that old rats are more sensitive than the young ones to pilocarpine-induced cholinergic convulsions and associated brain damage, possibly due to differences in PI metabolism, as suggested by the differences in Ins4P levels. Supported by the Research Council for Environmental Sciences of The Academy of Finland.

PROTEIN KINASE C INHIBITORS DO NOT COMPLETELY BLOCK

PROTEIN KINASE C INHIBITORS DO NOT COMPLETELY BLOCK THE REDUCTION OF I(AHP) BY PHORBOL ESTERS IN HIPPOCAMPAL CAI NEURONS. K. L. Engisch and B. E. Alger\*, Dept. of Physiol., Univ. MD Sch. of Med., Baltimore, MD 21201.

Activation of the slow afterhyperpolarization in CA1 hippocampal pyramidal neurons produces accommodation (the reduction of action potential firing in the presence of a maintained depolarization). Modulation of the Ca²-activated K² current underlying the slow afterhyperpolarization, I(AHP), can increase or decrease cell excitability. Phorbol esters inhibit I(AHP), suggesting that it can be regulated by PKC activation. To test this hypothesis, we examined whether inhibitors of PKC could prevent the action of phorbol esters on I(AHP). Using whole-cell voltage clamp to record I(AHP) in rat hippocampal CA1 neurons in the slice preparation, we found that inclusion of the peptide pseudosubstrate inhibitor PKCI(19-31) in the intracellular pipette solution at 70 µM had only a small effect on the inhibition of I(AHP) by 1 µM PDA (% inhibition of I(AHP), control, 34. 4 ± 4.3, N=19; PKCI(19-31), 20.1 ± 3.1, N=9; p < 0.05, t test). Cells were perfused with the peptide for at least 45 min prior to PDA application. We also bath-perfused 30 µM sphingosine for 45 min to 1½ hr before applying PDA and found a similar, small effect on PDA inhibition of the I(AHP) (% PDA inhibition in sphingosine, 22.9 ± 2.8, N=13).

Our results show that PKCs of cells in the slice preparation require doses for inhibition many times the published half-maximal doses of PKC inhibitors measured in cell-free assays. These findings have implications for the interpretation of studies which use PKC inhibitors to support the involvement of PKC. For example, because 10 µM sphingosine prevents LTP induction in the hippocampal slice (Malinow, et al., 1988), it has been suggested that PKC or CAMKII activation are required for LTP. We conclude that either sphingosine acts on LTP via CAMKII, or LTP induction involves PKC isozymes different from th

### 260.4

PHOSPHATIDYLINOSITOL HYDROLYSIS IS FACILITATED BY NMDA AND HARMALINE IN ADULT RAT CEREBELLUM: AN ACTION OF NITRIC OXIDE. <u>I.Li\* and S.S. Smith.</u> Anat. Dept, Neuro Ins, Hahnemann U., Phila. Harmaline evokes the synchronized discharge of the inferior olivary nucleus (Llinas and Muhlethaler, 1988), and is thus an effective tool for increasing climbing fiber discharge to the cerebellum. Previous studies from this lab have demonstrated that NMDA increases the hydrolysis of phosphatidylinositol (PI) in neonatal cerebellum in the presence of low level GABAB receptor stimulation (Smith and Li, 1991), an effect mediated by the gaseous second messenger nitric oxide (NO; Li and Smith, 1991). In the present study, PI turnover was determined using [ $H^3$ ]- inositol in 160  $\mu$ M crosschopped slices of cerebellar tissue from female rats at post- natal day 7, 14 or 20 and in the adult. 12 hs and 90 min prior to sacrifice, animals were injected with harmaline (120 µgs/kg) or vehicle. Following a 20 min incubation of cerebellar slices with NMDA (100 µM), chloroform extraction and anion exchange chromatography isolated total inositol phosphates. NMDA alone did not significantly alter PI turnover, as previously reported. However, harmaline treatment increased NMDA-stimulated PI turnover up to 70% above basal levels in the adult (P < 0.05), an effect dependent upon the full maturation of the climbing fiber system. The permissive effect of harmaline on NMDA-stimulated PI turnover was first observed after day 14 in the prepubertal rat (a 20-30% increase). In the adult, this effect was inhibited completely by the application of the NO synthase blocker L-N  $_{G^{-}}$  nitroarginine (100  $\mu M$  ), which suggests that the NO signalling system is involved in this permissive action of climbing fiber stimulation on excitatory amino acid-induced hydrolysis of PI. Climbing fiber activation is thought to release NO directly (Southam and Garthwaite, 1991). Products of PI hydrolysis evoked by this combined mechanism, Ca++ release and protein phosphorylation, may underlie changes in synaptic efficacy in the adult cerebellum. DISTRIBUTION OF G, AND G, PROTEINS CORRELATE WITH ADENYLYL CYCLASE ACTIVITY IN POSTMORTEM HUMAN BRAIN. J.J. Warsh\*, L.T. Young, P.P. Li, Siu K.P. and S.J. Kish. Clarke Institute of Psychiatry, Toronto, Ontario, Canada M5T 1R8

Abnormalities in receptor coupling to adenylyl cyclase and stimulatory (G<sub>s</sub>) and inhibitory (G<sub>i</sub>) G-proteins have been demonstrated in neuropsychiatric disorders, however, little is known about either the brain regional distribution of G-proteins or the actual relationship between brain G-protein levels and G-protein-linked functional responses in normal human brain. Postmortem brain was obtained from 7 subjects who were free of neurologic or psychiatric disorder with autopsy intervals to -80°C less than 24 hours. Using specific polyclonal antisera, G, and G<sub>i</sub> α immunoreactivities were determined by Western blotting in various brain regions. On the same tissue samples, basal and stimulated adenylyl cyclase activity was determined by radioimmunoassay. The highest levels of G, 52 kDa and G, \alpha subunits occurred in frontal cortex, and highest G, 45 kDa levels in caudate compared with other brain regions. Although basal adenylyl cyclase was similar in all regions, both GTPyS- and forskolin-stimulated adenylyl cyclase activity were highest in frontal cortex, caudate and cerebellum. Furthermore, forskolinstimulated cAMP formation correlated significantly with both G, 45 kDa and  $G_i$   $\alpha$  levels whereas only  $G_i$   $\alpha$  correlated with GTP $\gamma$ S-stimulated cAMP formation. These findings underscore the important regional relationship between these G-protein  $\alpha$  subunits and adenylyl cyclase activity in human brain.

DIFFERENTIAL LOCALIZATION AND pH DEPENDENCY OF THE INOSITIDE IP3, IP4 and IP6 BINDING SITES IN RAT BRAIN: AN AUTORADIOGRAPHIC ANALYSIS. A.R. Parent\* and R. Quirion. Douglas Hospital Res. Ctre and Dept. Psychiatry, McGill University, 6875 LaSalle Blvd., Verdun, Québec. H4H 1R3.

It is well established that the inositol lipids mediated signal transduction in several cellular populations. Many neurotransmitters, hormones and growth factors act at membrane receptors to induce hydrolysis of phosphatidylinositols generating various inositol phosphates (IP). The best known members of this family are the 1,4,5-IP3 and 1,3,4,5-IP4, which are associated with Ca²+ homeostasis. Recently, it was also proposed that IP6 could be related to Ca²+ uptake processes. As mean to study the possible roles of the IPs in neuronal tissues, we have localized and quantified specific binding sites for 1,4,5-IP3, 1,3,4,5-IP4 and IP6 under acidic and basic conditions and using their respective tritiated ligands. [³H]-1,3,4,5-IP4 binding densities are concentrated in the hilus and molecular layer of the hippocampal formation while an opposite pattern is seen with [³H]-1,4,5-IP3; the highest amounts being concentrated in the oriens and radiatum laminae. This contrasting profil of distribution is also observed in others brain areas. Morever, while highest binding of [³H]-IP3 is seen at pH 8.5, the opposite pattern is found for [³H]-IP4 with high binding levels at pH 5.0. For [³H]-IP6, labelling is more specifically localized to neuronal cell bodies (e.g. granular layer of the dentate gyrus > pyramidal cells of the hippocampus and olfactory bulb = piriform cortex = septohippocampal cells > hilus). Morever, [³H]-IP6 is most abundant at basic pH. The differential localization of specific receptor sites for these three IPs related to Ca²+ homeostasis suggests that each are mediators of a specific set of functions in enriched cellular population. Additionally pH's dependency of each IP binding sites can be correlated to intracellular pH events. Supported by MRCC, Alzheimer Society of Canada.

PROTEIN KINASE C CHARACTERIZATION IN FIBROBLASTS FROM ALZHEIMER'S DISEASE (AD) PATIENTS.

S. Bergamaschi, M. Trabucchi, F. Battaini<sup>1</sup>, V. Ladisa, G. Binetti<sup>2</sup>, A. Bianchetti<sup>2</sup> and, S. Govoni\*, Inst.Pharmacol.Sci., Univ. of Milano, <sup>1</sup>Dept. Exptl.Med.Biochem. Sci., Ilnd Univ. of Roma, <sup>2</sup>Alzheimer's Dept. of the Sacred Heart Hospital of Brescia, Italy.

Alterations at the level of PKC have been reported in brain and in skin

Alterations at the level of PKC have been reported in brain and in skin fibroblasts from patients with AD. In particular, the amount of PKC, as measured by immunoblotting techniques, is reduced in fibroblasts from patients with sporadic and familial AD. The reduced amount of the enzyme is not correlated with a reduced PKC activity using an exogenous substrate (Cole et al. Arch.Neurol. 46,1195,1989). In the present study biopsies of shoulder skin of patients with sporadic AD and controls were obtained after ethical committee approval at the Alzheimer's Dept. of the Sacred Heart Hospital in Brescia. 10 cell lines from sporadic AD and 6 cell lines from age-matched controls were obtained. PKC distribution between the soluble (S) and particulate (P) fraction was evaluated by means of [3H]-phorbol ester (PdBu) binding. A modified procedure from that described by Wehner (Brain Res. 523,181,1990) was used to prepare S and P fractions. In the S fraction the binding values of [3H]-PdBu were: Bmax: 7.8±1.5 pmol/mg prot.; Kd: 3.7±1 nM. Specific binding represented 70% of total binding. At least 20-30 µg of protein/sample were needed for optimal binding detection. The distribution of the binding between P and S indicated a preferential presence of PKC at cytosolic level. In order to determine the subtypes of PKC present in control and AD fibroblasts the same cell lines were used also for the extraction of mRNA for Northern blot analysis.

## 260.11

GENOMIC CLONING OF THE NEURON-SPECIFIC SPLICING REGION OF THE HUMAN INOSITOL (1,4,5)-TRISPHOSPHATE RECEPTOR (IP<sub>3</sub>R). Danoff, S.K.\* McInnis. McG. Kearns. W.. Snyder, S.H. and Ross. C.Departments of Psychiatry and Neuroscience, and Center for Medical Genetics. Johns Hopkins Univ. Sch. of Med., Baltimore, MD. 21205

The phosphatidyl inositol second messenger pathway is an important signalling system in neurons, as well as in other cells. We have previously shown that the IP<sub>3</sub>R messenger RNA in rat neuron differs from that in non-neuronal tissues by 120 nucleotides [Danoff, et al. PNAS, 88 2951-55 (1991)]. Using PCR amplification of first strand cDNA, we now demonstrate that these two alternative forms are also expressed in human RNA. We have cloned a portion of the human genomic DNA containing the region of the putative alternative splice site. Both messages are derived from a single gene, produced by an alternative splicing event involving three small exons. A cryptic splice acceptor site in the third alternative exon results in the variable expression of the codon for Gln 1716. We are currently pursuing the chromosomal localization of the human IP<sub>3</sub>R.

DIFFERENTIAL REGULATION OF PROTEIN KINASE C ISOZYMES IN AGING RAT BRAIN. F. Battaini\*. V. Ladisa^. S. Bergamaschi^. L. Lucchi ^ S. Govoni^ and M. Trabucchi, Chair of Toxicology, IInd Univ. of Roma. Alast Pharmacol Sci. Univ. Milano, Italy

Lucchi ^ S. Govoni^ and M. Trabucchi. Chair of Toxicology, IInd Univof Roma, ^Inst. Pharmacol. Sci., Univ. Milano, Italy.
Previous studies have demonstrated age-related modifications in protein kinase C (PKC) levels and activity in central and peripheral tissues. Selected PKC isoforms, in particular, seem to be implicated in a number of functions that are modified during aging such as neurotransmitter release and synaptic plasticity. In this study we have analyzed PKC activity and the various isozymes expression in aging Wistar rat brain areas. PKC activity (histone IIIS as substrate) does not show age-dependent changes across young (3 months), adult (8 months) and aged (28 months) animals in soluble and membrane fractions from various brain areas investigated (cortex, cerebellum and hippocampus). However the pharmacologically-induced (PMA 160 nM for 15') enzyme translocation from the soluble to the membrane fraction, assessed as kinase activity, is impaired in aged rats. Isozyme mRNA expression (investigated by in situ and Northern hybridization) indicate that, among the calcium-dependent isoforms the α and β type show age-dependent decrease in cortex. The γ isoform is barly detectable in this brain area. Hippocampal subfields and cerebellar α, β and γ isoform expression do not seem to be affected by age in this strain of rats.

or rats. These observations indicate that aging, although not modifying PKC activity assessed in vitro under optimal conditions, affects PKC translocation and thus its capability to respond to appropriate stimuli. This could be ascribed to age-related modifications in endogenous environment and/or availability of PKC activators. In light of the involvement of the various PKC isoforms in selected neuronal functions, the analysis of all PKC isozyme mRNA coupled to the immunodetection of the gene products will help to better define processes particularly sensitive to aging.

### 260.10

DUAL REGULATION OF ADENYLYL CYCLASE BY MUSCARINIC RECEPTORS IN RAT OLFACTORY BULB. Pierluigi Onali\* and Maria C. Olianas, Department of Neurosciences, University of Cagliari, Cagliari, Italy.

We have previously reported that in rat olfactory bulb stimulate basal adenylyl cyclase muscarinic agonists (a.c.) activity in a GTP-dependent and pertussis toxinsensitive manner. In the present study we show that carbachol (CCh) potentiates the Gs-mediated stimulation of a.c. by either CRH or VIP. The synergistic interaction occurs at free Ca++ below 100 nM, requires micromolar GTP and consists in an increase of the Vmax of the enzyme. On the other hand, the Ca++/calmodulin stimulated (type I) a.c. is inhibited by CCh. Cholinergic agonists also reduce the maximal enzyme stimulation by forskolin with potencies equal to those displayed in increasing basal a.c.. Moreover, the Ki values of pirenzepine, methoctramine and pFHHSiD in antagonizing the muscarinic stimulation and inhibition of a.c. are similar. These results indicate that in rat olfactory bulb a pharmacologically homogeneous receptor population can either up- or down-regulate cyclic AMP formation possibly by affecting the activity of different molecular forms (i.e. type I and type II) of a.c..

## 260.12

MOLECULAR CLONING OF A STRIATAL SPECIFIC ADENYLATE CYCLASE WHICH MAY BE INVOLVED IN DOPAMINE SIGNAL TRANSDUCTION. <u>C.E. GLATT\* and S.H. SNYDER</u>. Dept. of Neuroscience, Johns Hopkins University School of Medicine, Baltimore, MD 21205.

A comparison of forskolin autoradiography and in situ hybridization maps of all of the currently known adenylate cyclase isoforms demonstrated a marked discrepancy between adenylate cyclase protein and mRNA expression in the rat striatum. This suggested that a major member of the adenylate cyclase family had yet to be identified.

Screening of a cDNA library from rat striatum with full length probes from the types I, II, and III adenylate cyclases detected clones which hybridized at low but not high stringency. Sequencing of several clones demonstrated a novel cyclase with high homology to known adenylate cyclases.

Northern blot analysis showed a high level of expression of this form in the striatum but no other brain region or tissue examined. In situ hybridization analysis demonstrated expression in the caudate-putamen, nucleus accumbens and olfactory tubercle.

A full length clone has since been obtained identifying a predicted open reading frame of approximately 3.7 kilobases. A full length expression construct is being prepared to allow a functional assessment of the protein coded for by this gene.

The unique pattern of expression of this gene suggests that it is involved in dopaminergic signal transduction in the striatum.

CHARACTERISATION OF AvGp50 IN THE AVIAN NERVOUS SYSTEM. P.L. Jeffrey\*, A.M. Shepard and K.A. Hancox Children's Medical Research Institute, Camperdown N.S.W. Australia, 2050.

A size fractionated lentil lectin-positive fraction (40-100kDa) of one day old chick forebrain membranes was used to generate a monoclonal antibody, MabSA1.7, which recognises the nervous system specific glycoprotein AvGp50. Expression of AvGp50 is predominant within the molecular and granule cell layers in the cerebellum. AvGp50 is comprised of at least two isoforms and its pattern of expression is developmentally regulated. Removal of the carbohydrate side chains led to a loss of recognition by the MabSA1.7 of the 31kDa isoform and a reduction in recognition of the 34kDa isoform, suggesting that the monoclonal antibody recognises a carbohydrate rather than peptide epitope, confirmed by periodate oxidation /borohydride reduction studies which results in a complete loss of antigenicity AvGp50. We are screening an embryonic day 1 forebrain pUEX-1 expression library with the polyclonal antibody PCA.2 (raised against deglycosylated AvGp50) in order to identify possible cDNA clones of AvGp50. (Supported by the NH&MRC of Australia).

### 261.3

POSTNATAL EXPRESSION OF MYOSIN II ISOFORMS IN RAT CORTEX, HIPPOCAMPUS, AND CEREBELLUM. M. E. Miller\*, P. D. Chantler, and P. Levitt. Med. Coll. of Penn., Dept. of Anat. & Neurobiol., 3200 Henry Avenue, Phila., PA 19129.

Using an affinity-purified polyclonal antibody generated against murine neuroblastoma (Neuro-2A) myosin II (Miller et al., Neuron (1992) 8:25-44) and a commercially available polyclonal antibody directed against myosin II from human platelets, we are investigating the postnatal expression of myosin II isoforms in rat cortex, hippocampus, and cerebellum. Preliminary results from indirect ocytochemical studies of fixed, free-floating tissue sections indicate that within these anatomical areas the antibodies discriminate between at least two distinct myosin II isoforms which are expressed in a predominantly non-overlapping fashion.

Within cortex and hippocampus, anti- neuroblastoma myosin II strongly labels cortical and hippocampal neurons (cell bodies, apical/basal dendrites, dendritic spines) from P0 to P10, the labeling intensity decreasing to adult levels after P12. Cortical axons are labeled from P4 to P10, while axons in the hippocampus are labeled from P0 to P12. Anti- platelet myosin II labels cortical and hippocampal axons (PO to P4), a population of macrophages in the intermediate layers of cortex at the tips of the lateral ventricles (PO to P4), and many blood vessels and apparent microglial cells (P0 to adult).

In cerebellum, anti- neuroblastoma myosin II labels Purkinje cells (cell bodies/ dendritic arbors) from P0 to adult. Purkinje axons are also labeled from P7 to P12, as are dendritic spines from P7 to adult. Anti- platelet myosin II labels cells in the external (but not internal) granule cell layer (P0 to P12), Golgi epithelial cells and Bergmann glial fibers (P7 to adult), and many blood vessels and apparent microglial cells (P0 to adult). This work demonstrates that neuronal myosin isoforms display

a characteristic distribution during postnatal development. Supported by grant #AR32858 to PDC and #MH45507 to PL

CORTICAL REPAIR AND REORGANIZATION FOLLOWING TRAUMATIC MICROINJURY IN THE DEVELOPING RAT NEOCORTEX. J.T. Morgan and M. Marin-Padilla\*. Dartmouth Medical School, Hanover, NH USA 03755.

A single superficial microinjury of the developing right somatosensory neocortex was performed in four day-old rats, under hypothermic anesthesia, using a fine surgical needle. The undamaged left hemisphere was used as a control. The pial surface was damaged and secondarily repaired in all animals. At the puncture site, a focal leptomeningeal and/o marginal heterotopia developed. The progressive evolution of the lesion was then studied with H&E, Kluver-Barrera, and rapid Golgi procedures at 1, 8, 11, 21, 44, 56, 71, 173, 191, and 193 days following the trauma. Abnormal vascular patterns, focal cortical dysplasia, abnormal myelin patterns, and pockets of displaced neurons within layer I were found in the damaged area. In addition, the Golgi study showed abnormalities in the neuronal morphologies and in the local circutry in and around the lesioned area. These neuronofibrillary abnormalities are considered to be the result of the focal reoganization that occurs in the damaged area after the injury. The most striking finding, to be presented and discussed, was the number of neurons with abnormal morphologies encountered. These experimentally induced leptomeningeal heterotopias are similar in several aspects to those found in the brains of: a) prematurely born infants who have suffered neonatal asphyxia (Marín-Padilla, Soc. Neurosci. Abs.,17: 1991); b) some cases of developmental dyslexia (Galaburda et al., Ann. Neurol., 18: 1985); and c) patients with developmental epilepsy (Farrell et al., Acta Neuropathol., 83: 1992). We introduce this experimental model as a possible tool for the study of the development of these kinds of disorders in humans.

CELL TYPE AND DEVELOPMENTAL REGULATION OF THE RET PROTO-ONCOGENE DURING PERIPHERAL AND CENTRAL NERVOUS SYSTEM DEVELOPMENT. A.M. Gormley, R.J. Morris, R.V. Stirling \*1 and V. Pachnis\*, Lee Research Centre, Lab of Neurobiology, National Institute for Medical Research, The Ridgeway, London NW7 1AA, UK. <sup>1</sup>Dept Biol, Open University, Walton Hall, Milton Keynes MK7 6AA, UK; 2Lab of Gene Structure & Expression, NIMR, London NW7 1AA, UK.

Normal development of the nervous system depends on the proper communication between diverse cell types, mediated to a large extent by polypeptide differentiation and growth factors. A number of these factors bind to cell surface receptors that have intrinsic and ligand dependent tyrosine kinase activity. The ret proto-oncogene is a member of the family of tyrosine kinase receptors that was originally identified by its ability to transform NIH3T3 cells. We have previously shown that during the early stages of organogenesis of the mouse embryo, ret mRNA is predominantly localized in the precursors of the peripheral and central nervous system. Here we have used hybridization histochemistry with digoxigenin labelled probes to further define the pattern and cell type specificity of ret expression during later stages of CNS and PNS development. Our findings indicate that ret is expressed in specific subpopulations of neurons of the PNS and CNS, and suggest a role of the ret proto-oncogene in neuronal

LOCALIZATION AND **PHOSPHORYLATION** RETINOBLASTOMA PROTEIN IN ADULT AND DEVELOPING BRAIN. G.A. Oyler\*, K.A. Harris, and M.L.

DEVELOPING BRAIN. G.A. Oyler\*, K.A. Harris, and M.L. Billingsley. Dept. Pharmacology, Penn State University College of Medicine, Hershey, PA 17033

Phosphorylation of retinoblastoma protein (Rb) regulates progression through the cell cycle in a phosphorylation-dependent manner. The role of Rb, a growth suppressor protein, in maintenance of terminal neuronal differentiation is not known. Localization and phosphorylation of Rb were investigated in rat and human brain using monoclonal antibodies. Using immunocytochemistry, Rb was localized in neuronal nuclei throughout adult rat brain, and was enriched in hippocampal pyramidal neurons. Developmental studies in rat brain indicated that multiple forms (110-116 kDa) and rat brain indicated that multiple forms (110-116 kDa) and higher levels of Rb were present from E15-PND7. In adult human and rat brain, Rb was found as a single, 110 kDa human and rat brain, Rb was found as a single, 110 kDa unphosphorylated peptide. Phosphorylated forms of Rb were not observed following metrazole-induced seizures in adult rats. Treatment of adult rat hippocampal slices with the phosphatase inhibitor okadaic acid also failed to induce Rb phosphorylation. However, okadaic acid induced Rb phosphorylation in human SMS-KCNR neuroblastoma cells. These results suggest that neurons, unlike neuroblastoma cells, lose the ability to phosphorylate Rb protein during normal development. Thus, Rb expression and lack of phosphorylation in adult brain may be involved in the maintenance of neuronal differentiation.

DENDRITIC TOPOLOGY AND PASSIVE ELECTROTONIC PROPERTIES. J. van Pelt, M.A. Corner\*. Netherlands Institute for Brain Research, Meibergdreef 33, 1105 AZ Amsterdam, The Netherlands.

Dendrites have characteristic geometrical features both in metrical parameters and in their topology, i.e. the pattern in which the segments are connected to each other. A new topological measure, <u>tree asymmetry</u>, is used with values ranging from 0 (completely symmetrical trees) through 1 (maximally asymmetrical trees). The measure is through I (maximally asymmetrical trees). The measure is shown to be both efficient and discriminative, with expectations being almost independent of the size of the trees. The population spread in its values for three neuronal types indicates that only a small fraction of the possible topologies actually occurs. Using theoretical models for dendritic growth, the observed variance could be completely explained by assuming random choices for branching segments during growth.

choices for branching segments during growth.

Passive electrotonic properties of dendritic trees in relation to their topology have been studied using a vector implementation of the Laplace-transformed cable equation for branching structures. The structure of the conductance matrix in the current-voltage vector equation is a direct mapping of the topological structure of the dendrite. Topology appears to play a significant role in steady-state and transient spatial attenuation (centrifugal as well as centripetal from the point of activation) and equalization time constants. activation) and equalization time constants.

EARLY DEVELOPMENT OF AN IDENTIFIED SEROTONERGIC NEURON IN EMBRYOS OF THE GASTROPOD, HELISOMA TRIVOLVIS. J.I. Goldberg\* and T.J. Diefenbach. Department of Zoology, University of Alberta, Edmonton, Alberta, Canada T6G 2E9. One of the earliest events in the development of the Helisoma nervous

one of the earnest events in the development of the Helisoma nervous system is the differentiation of a single pair of serotonergic neurons, embryonic neurons C1 (ENC1s). Since ENC1s are identifiable and accessible in live embryos, in vivo experimental studies can now be implemented at the cellular level. To provide a foundation for experimental studies, we now describe the sequence of events underlying ENC1 differentiation. Immunofluorescence, 5,7-DHT fluorescence, Nomarski DIC and intracellular recording techniques were used ENC1 differentiation. DIC and intracellular recording techniques were used. ENC1 differentiation commenced around stage E15 (15% of embryogenesis) with the weak, granular expression of serotonin immunoreactivity. Neurite outgrowth was initiated soon after (stage E15-16), and was characterized by the rapid ventral extension of primary neurites around the buccal mass to the ciliated target cells in the primordial foot. In the posteroventral region of the foot, the primary neurites from left and right ENC1s turned medially, fasciculated with one another, and terminated in a posteromedial location. fasciculated with one another, and terminated in a posteromedial location. Putative guidepost cells were observed at specific points along the route of primary neurite extension. Around stage E18, the ENC1 soma migrated ventromedially beneath the epidermal placode, leaving behind a presumed sensory structure at the surface. Also occurring at this stage was expression of a serotonin uptake system and initiation of neurite branching in the region of the pedal ciliated epithelium. Preliminary electrophysiological experiments indicated that ENC1 is electrically excitable by stage E25, however the exact onset of excitability has yet to be staged. This description of ENC1 development provides a foundation for *in vivo* experiments on the regulatory factors controlling the development of an identified embryonic neuron. (Supported by NSERC of Canada).

INFLUENCES ON POSTEMBRYONIC DENDRITIC CHANGES IN AN IDENTIFIED LEG MOTOR NEURON. K. S. Kent\*, Dept. Biol. Structure & Function, Oregon Health Sci. Univ., Portland, OR 97201 During metamorphosis of the moth, Manduca sexta, thoracic leg motor neurons (MNs) persist from larva to adult but undergo dramatic dendritic changes including regression and growth. In order to identify the signals involved in shaping these changes, we have examined the dendritic morphology of an identified leg MN under conditions in which hormonal signals or cell-cell interactions were altered. Ligation / infusion experiments, in which the source of ecdysteroid hormone was removed or removed and replaced, confirmed that ecdysteroid hormone is required for both dendritic regression and growth in thoracic leg MNs. Similarly, manipulation of sensory inputs during the time of dendritic regression or growth confirmed that sensory inputs have little influence over the processes of dendritic regression and growth. Application of a juvenile hormone analogue (methoprene) to the larval legs was used to create mosaics in which larval legs were retained on a pupal insect. Despite retention of larval legs sensory neurons (SNs) and leg muscles, the MN underwent its normal course of dendritic regression. Injections of Mitomycin C into young pupae were used to prevent the generation of adult leg SNs. Despite the lack of adult leg SNs, the MN underwent extensive dendritic growth, in agreement with our previous findings that dendritic growth occurs in the total absence of the adult legs. Together, these results support the hypothesis that dendritic regression and growth in thoracic leg MNs are under hormonal control as has been reported for abdominal proleg MNs (Weeks and Truman, 1985; Weeks and Ernst-Utschneider, 1989; Jacobs and Weeks, 1990). However, alterations of specific aspects of MN dendritic morphology were apparent in the "deafferented" preparations suggesting that sensory inputs shape the growth of MN dendrites in specific regions of the dendritic

## 261.11

ABNORMAL SARCOMERES AND LOSS OF ATTACHMENTS TO BODY WALL IN <u>C. ELEGANS</u> MUSCLES DUE TO MUTATION OF  $\beta$ -INTEGRIN GENE <u>pat-3</u>. <u>D.H. Hall\* and E.M. Hedgecock</u>. Albert Einstein College of Medicine, Bronx, N.Y. 10461 and

Albert Einstein College of Medicine, Bronx, N. Y. 10461 and Johns Hopkins University, Baltimore, MD 21218.

The gene <u>pat-3</u> encodes a \(\theta\)1-like integrin subunit in the nematode <u>Caenorhabditis elegans</u> (S. Gettner, pers. comm.). Three mutant alleles have been isolated. The strongest allele, <u>pat-3</u> (rh54), is embryonic lethal, and affects development of most muscles, plus cell migrations and attachments in non-muscle tissues. <u>pat-3</u> (rh151) is viable but sterile, and does not appear to disrupt body muscle cells. The mildest allele, <u>pat-3</u> (rh96), is viable. Using genetic mosaics of rh54, and serial thin section reconstruction

of adult mosaics by EM, we compared mutant and non-mutant body muscles to determine the role(s) of  $\beta$ -integrin in muscle development. Normal body muscles adhere to the body wall cuticle via fibrous linkages to membrane densities along the inner surface of the muscle's plasma membrane. A normal cell contains several sarcomeres lying oblique to the body axis, also anchored to membrane densities. The rh54 mutant phenotype is cell autonomous. Affected cells are not contractile. They detach from the body wall, but remain in close contact with nearby wild type muscle cells, forming both gap junctions and adherens junctions with them and with each other. Mutant cells are longer and much thinner than normal. No sarcomeres are formed, but separate bundles of thick filaments, thin filaments, and dense aggregates are found in the cytoplasm. Some cells form branches which extend dorsoventrally to the opposite muscle quadrant. Interestingly, mutant cells still form "muscle arms" which extend in normal fashion to the nerves and nerve ring in order to receive synaptic inputs. The <u>lethal myospheroid</u>  $\beta$ -integrin mutant in <u>Drosophila</u> causes similar defects in muscle development (Volk et al., <u>Cell</u> 63:525-536, 1990).

EVIDENCE FOR AUTOREGULATION OF NEURITE BRANCH DEVELOPMENT IN IDENTIFIED SEROTONERGIC NEURONS FROM HELISOMA EMBRYOS. T. J. Diefenbach\* and J. I. Goldberg. Department of Zoology, University of Alberta, Edmonton, Alberta, Canada 76G 2E9

HELISOMA EMBRYOS. T. J. Diefenbach\* and J. I. Goldberg. Department of Zoology, University of Alberta, Edmonton, Alberta, Canada T6G 2E9 Embryonic neurons C1 (ENC1s) are cilioexcitatory motor neurons that may influence the development of other embryonic neurons through expression and release of serotonin. From stages E15 (15% of embryogenesis) to E40, ENC1s are the only serotonergic neurons present in the Helisoma nervous system. Furthermore, ENC1s elaborate a consistent pattern of neurite branching during this period. Given that neurite outgrowth of adult serotonergic neurons can be regulated by serotonin (McCobb et al., 1988; Murrain et al., 1991), we hypothesized that serotonin released by ENC1 regulates the branching pattern of ENC1 neurites by binding serotonin autoreceptors. To test if a reduction in serotonin synthesis would result in altered neurite outgrowth, stage E15 embryos were treated with the serotonin synthesis inhibitor p-chlorophenylalamine (PCPA) for 1 hour, and then allowed to develop in artificial pond water for 48 hours. Resultant changes in outgrowth were then visualized using serotonin immunofluorescence technique. ENC1s of embryos treated with PCPA displayed a marked, transient reduction in serotonin content per embryo (Control: 488 ± 122 fg/embryo; PCPA: 158 ± 42 fg/embryo). Examination of ENC1 morphology in PCPA-treated embryos revealed a significant increase in the total number of branch points (PCPA: 30.6 ± 2.6; Control: 21.5 ± 1.2). These results suggest that, during ENC1 development, neurite branching is limited by serotonin through an autoreceptor-mediated mechanism. Given preliminary evidence of serotonin uptake by ENC1 target cells, neurite branching may be regulated by the competition between target cell uptake systems and ENC1 autoreceptors for extracellular serotonin.

INNERVATION AFFECTS THE DEVELOPMENT OF ADULT-SPECIFIC MUSCLES IN MANDUCA SEXTA. R.I. Bayline\* and R. Booker. of Neurobiology and Behavior, Cornell Univ., Ithaca, NY 14853.

We are studying the respecification of abdominal muscles during metamorphosis in the moth, Manduca sexta, to determine the factors which regulate muscle development. From the onset of pupation (P+0) until four days later (P+4), the larval muscles dedifferentiate, resulting in the loss of myofibril structure as well as a 41% reduction in muscle size. From P+4 through P+12, the nuclei within the dedifferentiated fibers proliferate. The number of muscle fibers also increases dramatically at this time. For example, in the dorsal intersegmental muscle in the second abdominal segment (A2-DISM), fiber number increases from 15-20 at P+4 to several hundred in the adult. As the muscles grow, they alter their attachment points. By P+16, the muscles appear fully differentiated, with Z-bands, myofibrils, and adult attachment points. To determine the role of innervation in muscle respecification, we cut the nerve innervating the muscles during the larval stage and observed the effects in the adult. In the adult A2-DISM, only 5-10 fibers were present on the denervated side. The denervated fibers had the adult attachment points and contained myofibrils, although the fiber diameters were reduced by 33%. To determine the mechanism by which innervation regulates muscle development, we labeled S-phase nuclei with 5-bromo-deoxyuridine three days after cutting the nerve during the pupal stage. Substantially fewer muscle nuclei labeled on the denervated side than on the control side. These results demonstrate that innervation is necessary for the proliferation of muscle nuclei and muscle fibers during respecification. Dedifferentiation, alteration of attachment points, and muscle differentiation proceed normally even in the absence of innervation

ELECTRICAL ACTIVITY AND GAP-43 EXPRESSION P.X. Lin, R.D. Fields and P.G. Nelson\*, Lab. of Developmental

Neurobiology, NICHD, NIH, Bethesda, MD 20892. GAP-43 has been associated with growth cone motility, synaptic plasticity, and axon outgrowth during development and regeneration. We investigated effects of electrical stimulation on expression of GAP-43 in mouse DRG neurons in culture, using a multicompartment method of delivering electrical stimulation (Fields, et al., J. Neurosci. 10:2950-2964).

Trains of action potentials were delivered to neurons in culture at 10 Hz in 1/2 sec. bursts every 2 seconds for 3 days. No difference in amount of GAP-43 was detected in stimulated cultures compared to unstimulated controls, using ELISA or quantitative video fluorescence immunocytochemistry. Depolarization with 10, 20 or 30 mM K+ for 3 days in 1,2 or 3 week old cultures failed to alter GAP-43 levels. Consistent with protein measurements, the amount of mRNA encoding for GAP-43 was unchanged following potassium depolarization or electrical stimulation. GAP-43 was regulated by development, however. Levels of GAP-43 mRNA and protein were highest at 3 days in vitro, and declined to stable values between 1 and 3 weeks in culture.

The results suggest that GAP-43 expression is not regulated by electrical stimulation, even though growth cone motility, synaptic plasticity and axon sprouting are sensitive to changes in electrical activity. Therefore post-translation modification, such as phosphorylation, may be more important in regulating activity-dependent effects of GAP-43.

### 262.3

p59<sup>fyn</sup> Tyrosine Kinase in Growth Cones and Axonal Tracts of the Developing Rat Brain. <u>D.J. Bare .J.M. Lauder and P.F. Maness</u>. Department of Biochemistry and Biophysics and Department of Cell Biology and Anatomy. University of North Carolina School of Medicine, Chapel Hill, NC 27599.

The product of the proto-oncogene c-fyn (p59fyn) is a non-receptor tyrosine kinase. This src-related kinase is principally expressed in Tlymphocytes and neurons as two distinct forms, which differ in their kinase domains and are encoded by alternatively spliced mRNA. In the embryonic chick retina, p59<sup>fyn</sup> is localized in the soma of differentiating neurons and in the outgrowing neuronal processes of the developing plexiform layers, whereas in the mature retina it is found chiefly in cell soma. To investigate whether p59fyn in embryonic neurons is a component of the nerve growth cone, its expression was analyzed in fetal rat brain by immunoblotting and immunocytochemistry. p59fyn was found to be concentrated in the membranes of a growth cone-enriched subcellular fraction isolated from fetal (day 18) rat brain. A synaptic plasma membrane fraction from adult brain exhibited much lower levels of p59<sup>fyn</sup>. Interestingly, in the growth cones of regenerating sciatic nerve, p59<sup>fyn</sup> was not expressed at elevated levels characteristic of embryonic growth cones. Immunoperoxidase staining of E18 rat brain revealed that p59<sup>fyn</sup> was localized primarily in axons of developing tracts. Prominent staining was visualized in the lateral olfactory, optic and pyramidal tracts and cerebral peduncles, but not in the striatum and ventricular zone of the cerebral cortex. In the adult brain tracts, no staining was observed, however, immunoreactivity was seen in the olfactory bulb particularly in the glomeruli, mitral cell bodies and their dendrites. These results suggest that the neuronal form of p59fyn may play a principal role in neurite outgrowth of developing CNS neurons.

## 262.5

GAP-43 STIMULATION OF G<sub>0</sub> IS BLOCKED BY PALMITOYLATION. S.M.Srittmatter. Y. Sudo, D.Valenzuela, A.G. Beck-Sickinger, M.C.Fishman\*. Depts. of Neurology and Medicine, Massachusetts General Hospital, Boston, MA, USA, and Institute for Organic Chemistry, U. of Tubingen, Tubingen, Germany. GAP-43 is a neuronal protein bound to the growth cone membrane by

ĞAP-43 is a neuronal protein bound to the growth cone membrane by a short amino terminal stretch which contains two palmitoylated cysteine residues (J.Cell Biol. 108:613, Nature 341:345). The hydrophobicity of the palmitates is likely to contribute substantially to the membrane localization of GAP-43, as for other fatty acylated proteins. We have studied whether this modification affects GAP-43 function as well as localization. GAP-43 can stimulate G protein activity, and this may alter growth cone motility (Nature 344:836). The GAP-43 domain which stimulates Go is localized to the first ten amino acids of the protein where palmitolylation occurs. We have compared the ability of palmitoylated and non-palmitoylated GAP-43 N-terminal 1-25 peptides to stimulate Go. The palmitoylated species have essentially no activity compared to the non-palmitoylated molecules. Palmitoylated GAP-43 protein is also inactive in this assay. Depalmitoylation restores Go stimulation. The palmitoylated forms are inactive in both detergent solution and phospholipid vesicles. Modification of the GAP-43 cysteines with PCMPS also reversibly blocks Go stimulation. It is well known that protein palmitoylation is a dynamic modification with a rapid turnover time, so cycles of fatty acid acylation within growth cones may control a cycle of GAP-43 between an acetylated membrane-bound reservoir of inactive protein and a nonpalmitoylated, active pool. This work also demonstrates that palmitoylation can directly modify protein-protein interactions in addition to directing subcellular localization.

PROTEIN KINASES AND REGULATION OF GROWTH CONE STRUCTURE AND MOTILITY IN GOLDFISH RETINAL GANGLION CELLS. X. Jlan\* and J.T. Schmidt. Dept. of Biol. Sci., SUNY Albany NY 12222 Much evidence suggests that cytoplasmic Ca<sup>++</sup> levels regulate neurite

elongation and growth cone motility (Kater <u>et al.</u> 1988, TINS 11:315), and Ca<sup>++</sup> can activate several protein kinases. To test whether protein phosphorviation has effects on growth cone structure and motility, we have locally applied from a micropipette several different kinase inhibitors and activators and a phosphatase inhibitor to the growth cones growing on ependymin while observing with videomicroscopy. General kinase inhibitors sphingosine ( $50\mu M$  in pipette) and H7 ( $500\mu M$ ) caused growth cone swelling and collapse. The filopodia, however, remained attached to the substrate as the swelling moved back the retracting neurite. In contrast, neither stimulation of protein kinase A (PKA) by db-cAMP (20mM) or phosphodiesterase inhibitor IBMX (2mM) nor inhibition of PKA by Rp-cAMPS (2mM) caused any change in growth cone shape and behavior. Similarly, neither stimulation of protein kinase C (PKC) by TPA ( $1\mu$ M) or arachidonic acid+diacylglycerol ( $50\mu$ M each) nor inhibition of PKC by calphostin C ( $1\mu$ M) produced any obvious effects. The tyrosine kinase inhibitor Lavendustin A ( $1\mu$ M) was also without effect. ML-7 (5µM), the inhibitor of myosin light chain kinase (MLCK), however, caused growth cone swelling and retraction, as did the calmodulin antagonists calmidazolium (0.1 µM) and CGS 9343B (100 µM). Finally, the phosphatase inhibitor okadaic acid (50nM) caused growth cone swelling and collapse like that of sphingosine. These results indicate that both increasing and decreasing protein phosphorylation in retinal growth cones can lead to abnormal structural changes, Among the kinases, PKA, PKC and tyrosine kinases may not be critical, while calmodulin dependent kinases, such as MLCK and CamKII, may play an important role in regulating growth cone structure and motility. Supported by NIH grant EY-03736.

TRANSCRIPTIONAL REGULATION OF THE GAP-43 GENE IN CULTURED NEURAL, GLIAL AND NON-NEURAL CELL LINES. R.G. Start\*, B. Lu and H.J. Federoff. The Albert Einstein College of Medicine, Bronx, NY 10461.

The GAP-43 gene encodes a 24 kDa phosphoprotein whose

The GAP-43 gene encodes a 24 kDa phosphoprotein whose expression in vivo is restricted to neurons, predominantly those undergoing axonal growth. However, GAP-43 expression has also been demonstrated in astrocytes and in Schwann cells, arguing against strict neuron-specific expression. As an initial step towards understanding the mechanisms that specify the cell-type specific regulation of the gene, we have begun an analysis of the GAP-43 promoter by preparing promoter constructs that are linked to the reporter gene chloramphenicol acetyltransferase (CAT) and then stably transfecting them into neural (PC12), glial (C6) and nonneural cell lines (Rat 2). Analysis of pools of stable transfectants indicate that 230 bp of 5' flanking DNA sequence defines a GAP-43 minimal promoter that is active in both neural and glial cell lines, but not in non-neural fibroblast cell lines. Furthermore, additional sequence regions lying upstream of the first 1000 bp are required for high level expression in both neural and glial cell lines. Further characterization of the sequence regions that define cell type specific transcription is in progress. Supported by USPHS grant HD27226.

## 262.6

THE IMMUNOSUPPRESSANT FK-506 ENHANCES PHOSPHORYLATION OF GAP43: IMPLICATIONS FOR A ROLE IN MODULATION OF GROWTH CONE FUNCTION AND NEUROTRANSHITTER RELEASE. J.P. Steiner\* T.H. Dawson, M. Fotuhi, C. Glatt, A.M. Snowman, N. Cohen and S.H. Snyder. Johns Hopkins Univ. Sch. of Med., Depart. of Neurosci., Baltimore, MD 21205.

The immunophilins cyclophilin and FKBP are small predominantly soluble proteins that bind with high affinity the immunosuppressant drugs cyclosporin A (CsA) and FK-506, respectively, and which appear to mediate their pharmacologic actions. Interaction of FK-506-FKBP and CsA-cyclophilin with the Ca²+/CaM-dependent protein phosphatase calcineurin inhibits calcineurin activity, suggesting that calcineurin may mediate actions of these drugs. We report extraordinarily high levels of FKBP protein and mRNA in rat brain, with a unique regional localization that is essentially identical to that of calcineurin, indicating a physiologic link between calcineurin and the immunophilins. We also report that FK-506 and CsA, in low nanomolar concentrations, enhance the phosphorylation of endogenous protein substrates in brain tissue and in intact PC12 cells. The phosphorylation of GAP43, a prominent calcineurin substrate, is regulated by FK-506-FKBP and CsA-cyclophilin complexes. Since GAP43 appears to be involved in neurotransmitter release, as antibodies to GAP43 selectively inhibit neurotransmitter release, we have investigated a role for FK-506 and CsA in this process.

INCREASED EXPRESSION OF FK-506 BINDING PROTEIN DURING PERIPHERAL NERVE REGENERATION W.E. Lyons<sup>1\*</sup>, J. P. Steiner <sup>2</sup>, T.M. Dawson<sup>2</sup>, and S.H. Snyder<sup>2</sup>, <sup>1</sup>Depts. Toxicology & <sup>2</sup>Neurosci. Johns Hopkins Univ. Baltimore, MD 21205

Ligand binding studies from this laboratory using <sup>3</sup>H-FK-506 (see adjacent abstract: Steiner et al.) have demonstrated that the immunophilin FKBP is present at high levels in soluble and particulate fractions of rat brain. Previous studies have also shown that the FKtractions of rat orain. Previous studies have also shown that the FK-506/FKBP complex acts as an inhibitor of the protein phosphatase calcineurin, which is also enriched in the CNS. These data suggest that through its effects on calcineurin, FKBP may play an important role in brain function by regulating the phosphorylation state of neuronal proteins. One of the most prominent substrates of calcineurin is GAP43, a protein whose expression has been correlated with neurite outgrowth during development and regeneration. We therefore examined the expression of FKBP during regeneration of the facial nerve, a well characterized model of regeneration in which increases in GAP43 levels have been clearly demonstrated. Experimentally the nerve was crushed with forceps 2mm distal to its exit from the stylomastoid foramen, and expression of FKBP and its mRNA was examined in the facial nucleus at various times after the lesion. An examined in the facial nucleus at various times after the lesion. An increase in FKBP mRNA was observed beginning between 24 and 48 hours after crush using *in situ* hybridization. Elevated levels of mRNA were also observed at 7 days, suggesting that the increased expression may persist during the period of regeneration. Increases in the levels of FKBP were also observed using <sup>3</sup>H-FK-506 autoradiography. These data suggest a role for FKBP in nerve regeneration, possibly by regulating the observed that the observed the story of GAPA'. regulating the phosphorylation of GAP43.

## 262.9

REGULATION OF GAP-43 PHOSPHORYLATION DIRECTLY CORRELATED WITH GROWTH CONE BEHAVIOR IN CULTURE E.W.Dent and K.F. Meiri\* Dept. Pharmacology, SUNY Health Science Center, Syracuse, NY 13210. Phosphorylation of GAP-43 by kinase C in vivo and in tissue culture occurs after axonogenesis has been initiated and is confined to distal axons and growth cones. Within individual growth cones too, phosphorylation of GAP-43 is locally regulated and its distribution is restricted. Here we have used video enhanced microscopy of cultured DRG neurons together with immunocytochemistry with our specific monoclonal antibody to show that changes in the distribution of phosphorylated GAP-43 correlate with two aspects of growth cone behavior: In individual translocating growth cones phosphorylated GAP-43 is confined to the central region where organelles are concentrated, and accompanies the redistribution of the organelles within the body of the growth cone that occurs when the neurite elongates. Phosphorylated GAP-43 is very low in those highly motile distal lamellae where organelles are absent, and in lamellae or filopodia that are actively retracting, but levels of phosphorylated GAP-43 are increased in those areas when they become stabilized. However, whenever one growth cone touches another part of a cell, neuronal or non-neuronal, GAP-43 phosphorylation is rapidly stimulated throughout the whole growth cone overriding its previous restriction. These results suggest that kinase C phosphorylation of GAP-43 may be involved in discriminatory functions of the growth cone, possibly by stabilizing components of the growth cone membrane. Supported by NS 26091

## 262.11

DISTRIBUTION OF GAP-43 mRNA IN THE GOLDFISH BRAIN. L.M. Console-Bram.\*1 S.G. McElligott2 and J.G. McElligott1.

Dept of Pharmacology, Temple Univ. Sch. of Med., Philadelphia, PA 19140 and

2E.I. DuPont, Medical Products, Wilmington, DE 19810.

Expression of GAP-43 mRNA has been found in the central nervous system of both immature and mature animals. Within the developing brain, expression of the GAP-43 gene is most abundant and appears to correlate with periods of axonal outgrowth and synaptic organization. In the adult, GAP-43 mRNA is found at lower levels, and is localized to regions of the brain associated with neural plasticity and regeneration. Our study was designed to examine the histological distribution of GAP-43 mRNA in the brain of an adult teleost, Carassius auratus (goldfish), which corresponding to GAP-43 mRNA was synthesized from the known cDNA sequence of the goldfish GAP-43 gene. The oligonucleotide was radiolabelled and used to probe sections of goldfish brain according to in situ hybridization methodology. From these experiments, GAP-43 mRNA was found to be most abundant in the stratum periventriculare and stratum album centrale of the optic tectum, hypothalamic nuclei, the granule cell layer of the valvula, corpus and lateral cerebelli and the inferior olivary complex. Less intense hybridization was found in the stratum griseum centrale of the optic tectum, reticular nucleus, nucleus rotondus, area stratum griseum centrale of the optic tectum, reticular nucleus, nucleus rotondus, area pretectalis, glomeruli, vestibular and tegmental nuclei, as well as vagal and facial lobes. The goldfish diencephalon appears to be devoid of GAP-43 mRNA. Control studies were performed using a radiolabelled sense oligonucleotide. This probe did not hybridize with GAP-43 mRNA thereby demonstrating specificity of binding of the antisense oligonucleotide to the mRNA. To our knowledge this is the first study to examine the histological localization of GAP-43 mRNA in the goldfish. The presence of GAP-43 mRNA in many brain regions of the adult goldfish suggests that the high degree of plasticity associated with these animals could be related to the expression of GAP-43.

Expression of B-50(GAP43) via a defective Herpes Simplex virus vector in cultured non-neuronal cells. J. Verhaagen', W.H. Gispen', W. Hermens', S.D. Rabkin', D.W. Pfaff', M.G. Kaplitt'.

Rockefeller Univ., NY, NY, USA. 3. Memorial Sloan Kettering Cancer Inst., NY, NY USA

The expression of the neural phosphoprotein B-50 correlates closely with nerve fiber formation but its causal involvement in nerve fiber growth has not been established. Here we report B-50-gene transfer to cultured cells with a previously described Herpes Simplex virus (HSV) type I defective vector system (Kaplitt et al. Molec. Cell. Neurosci. 2:320-330,1991). Two defective HSV vectors expressing B-50 from the human cytomegalovirus (CMV) promoter were generated. Plasmid pSRa-ori-CMV-B-50 was created by introducing a CMV-B-50 fragment into pSRa-ori, a plasmid containing the HSV-1 cleavage/packaging signal and an HSV-2 origin of replication. A second plasmid, pHCL-CMV-B-50, contains the same sequences with the addition of a CMV-lacZ expression cassette allowing for the identification of infected cells by histochemical staining for ßgalactosidase (β-gal). Titers of viral stocks were determined by β-gal histochemistry and immunocytochemical staining for 8-gal and B-50. Similar results were obtained with both methods indicating that viral titers can reliably be determined by immunocytochemical means. Vero cells (African green monkey kidney cells) infected with defective HSV-B-50 viruses exhibited striking morphological changes including filopodial-like structures, ruffled membranes and long thin extensions reminiscent of neuronal processes. Similar processes did not appear in controls treated with vectors not expressing B-50. These results suggest a role for B-50 in the determination of cell shape. Our defective viral vectors will enable the study of B-50's role in regenerative sprouting in vivo.

MYELIN AND GAP-43 HAVE A PATTERN OF COMPLEMEN-TARY REGIONAL DISTRIBUTION IN CNS GRAY MATTER OF NORMAL ADULT RATS. Josef P. Kapfhammer\* and Martin E. Schwab. Brain Research Institute, University of Zurich, August-Forel-Str. 1, CH - 8029 Zurich, Switzerland.

In the CNS, myelin is present not only in white matter, but also in

gray matter areas in varying amounts. Some brain areas are fairly high in myelin, whereas others are only lightly myelinated. Oligodendrocytes and myelin contain proteins inhibitory to fiber growth *in vitro* and for fiber regeneration *in vivo*. In this study we investigate whether these neurite growth inhibitors could also restrict fiber growth and rearrangement of terminals in the normal adult CNS.

We have compared the pattern of myelination in gray matter areas (revealed by myelin staining and MBP immunohistochemistry) with the regional expression of a marker for fiber growth and terminal rearrangement, GAP-43 (revealed by immunohistochemistry), on adjacent CNS sections. In the majority of the CNS regions the myelin and cent CNS sections. In the majority of the CNS regions the myelin and GAP-43 pattern are exactly complementary. Highly myelinated areas like the inferior colliculus, the tegmentum and most brain stem nuclei are low in GAP-43, whereas only lightly myelinated areas as the striatum, the substantia nigra or the substantia gelatinosa of the spinal cord express relatively high amounts of GAP-43. In laminated structures such as the cerebral cortex, the cerebellar cortex or the superior colliculus laminate high in mysilic are law in GAP 43 and vice users. colliculus laminae high in myelin are low in GAP-43 and vice versa.

These results are consistent with a possible role of neurite growth inhibitors from oligodendrocytes in regulating terminal sprouting and rearrangement in the normal adult CNS. terminal We thank Dr. Karina Meiri for the generous gift of anti-GAP-43 antibodies.

NEURITE OUTGROWTH IN PC12 CLONES WITH VARIOUS AMOUNTS OF GROWTH-ASSOCIATED PROTEIN B-50 (GAP-43)

Rat pheochromocytoma (PC12) cells acquire a sympathetic, neuron-like phenotype with neuritic extensions upon NGF induction. This is accompanied by a translocation of the neural-specific phosphoprotein B-50 (= GAP-43, Fl or neuromodulin) to the plasma membrane and an enhanced expression of B-50 mRNA and protein. We selected a number of clonal PC12 cell lines with altered B-50 expression. Protein levels are 2-3 fold enhanced, or 10-20 fold reduced, as determined by ELISA and Western blot.

These clones were further characterized by Northern and Southern blotting. Low expression of B-50 did not markedly reduce the rate of NGF-induced neurite outgrowth, as was reported by Beatge and Hammang (Neuron 6, 1991), but remarkable changes in morphology of neurites and growth cones were observed. These changes could be visualised by immunofluorescence using antibodies against B-50 and cytoskeletal proteins. Transient overexpression of B-50 cDNA under control of the CMV promoter induced the enhanced formation of numerous small extensions, i.e. filopodia, as was found by Zuber et al. (Science 224, 1989) in COS cells. This indicates that B-50 is involved in formation of filopodia and normal growth cone development, but is not under all circumstances essential for neurite outgrowth in PCI2 cells. RNA-PROTEIN INTERACTIONS BETWEEN THE 3' UTR OF GAP-43 mRNA AND CYTOSOLIC PROTEINS FROM RAT BRAIN. Implications for the post-transcriptional regulation of the mRNA. D.T. Kohn\* and N.I. Petrone-Bizzozero. Destinance of Biosbanistics. Universities of New Maryles Albuquerum NM 471.

pearment of Biochemistry, University of New Mexico, Albuquerque, NM, 87131.

The growth-associated protein, GAP-43, is a nervous system specific phosphopotein that has been implicated in the development, regeneration, and memodeling organic organic to the memodeling organic to the memodeling organic to the memodeling organic to the memodeling of synaptic connections. Previous work from our laboratory indicated that GAP-43 expression in NGF induced-PC12 cells is controlled by protein kinase C-dependent subilization of the mRNA (Soc. Neurosci. Abstr.17: 1310). In order to investigate the mechanisms that influence GAP-43 mRNA stability, we performed in vitro RNA-protein binding reactions using labeled 3 UTR sequences from GAP-43 mRNA and \$100 extracts from adult and neonate rat brains. Complex formation was determined by RNAse T1 protection and gel retardation assays in non-denaturing polyacrylamide gels. The specificity of the interactions was confirmed by competition experiments using an excess of unlabeled homologous or non-homologous RNAs. A 20-100 fold excess of sense RNA fully displaced the labeled 3 UTR sequences from the complex, whereas antisense RNA or unrelated RNAs had no effect on complex formation. Following UV-crosslinking, RNA-protein complexes were analyzed by SDS-PAGE. This demonstrated the formation of three main complexes that migrate with apparent sizes of ~95kDa, ~70kDa, and ~45kDa. Analyses of the complexes by label-transfer experiments revealed that the major GAP-43 mRNA binding proteins have apparent sizes of ~85kDa, ~60kDa, and ~40kDa. Since the stabilization of GAP-43 mRNA was found to require the activation of PKC but was independent of de now protein synthesis, we examined whether RNA-protein complex formation was regulated by specific protein phosphorylation. Treatment of cytosolic extracts with alkaline phosphatase adoishes the formation of the intermediate size complex, suggesting that protein phosphorylation is required for this interaction. The possibility that this RNA-binding pr

## 262 17

GAP-43 IN DEGENERATING PERIPHERAL NERVE: AXONAL AND SCHWANN CELL ORIGIN. <u>L.M. Young, K.C. Harrington, W. Tetzlaff and M.A. Bisby\*</u>, Dept. of Physiology, Queen's Univ., Kingston, Ont., K7L 3N6, Canada and Dept. of Anatomy, University of Calgary, Calgary, Alta., Canada.

We used immunocytochemistry, in-situ hybridization and RT-PCR to investigate the appearance and sources of GAP-43 in rat sciatic nerve distal to axotomy. In normal and short-term transected nerves, GAP-43-IR was restricted to Remak fibres (Schwann cells enveloping unmyelinated axons), but in crushed nerves strong GAP-43-IR was also present both within regenerating axons and around the margins of Schwann cells (bands of Büngner) in the vicinity of the axons, as previously reported (Tetzlaff et al., J. Neurosci. 9:1303-1313). By 21d following resection, all Schwann cells forming bands of Büngner were uniformly GAP-43 immunoreactive, in contrast to the 21d crushed nerves where GAP-43-IR was seen in many regenerating axonal profiles and to a lesser degree with Schwann cells. At 3d and 7d, GAP-43 mRNA was increased in both crushed and resected distal nerve segments compared to the contralateral control nerves. No further mRNA increase was seen at later timepoints after crush, while a massive further increase in GAP-43 mRNA expression was seen in 14d to 50d resected nerves. Thus, GAP-43 mRNA increased in distal stumps after axotomy, and if regeneration was prevented there was a delayed further increase which was sustained for up to 50 days. The latter correlated with a strong R of all bands of Büngner, indicating that the Schwann cells synthesize significant amounts of GAP-43. The observation of GAP-43-IR around the margins of Bungner bands 3d and 7d after crush, but not 3d and 7d after resection, without differences in GAP-43 mRNA expression, suggest that GAP-43-IR may also be derived from degenerating axonal sprouts during the early stages of regeneration.

ARE B-50 / GAP-43 DECORATED ELECTRON-LUCENT VESICLES INVOLVED IN NEURONAL AXONAL TRANSPORT?
A.B. Oestreicher\*, M. Van Lookeren Campagne, A. Marquart, W.H. Gispen and C.G. Dotti<sup>1</sup>. Rudolf Magnus Inst., University of Utrecht, Utrecht, NL, and <sup>1</sup>Eur. Mol Biol. Lab., Heidelberg, FGR. (Spon: ENA)

By immuno electron microscopy we have shown that in developing and adult rat brain B-50 / GAP-43 is predominantly localized at the axonal plasma membrane. Using immuno gold labeling we studied how B-50 is intracellularly targeted to the plasma membrane of developing rat hippocampal neurons in vitro. B-50 was visualized on the cytoplasmic side of the membrane of electron-lucent vesicles (average diameter 100 nm) of the cytoplasm. These B-50 vesicles were present in trans regions of the Golgi apparatus, juxtaposed to microtubules in neurites and growth cones. They accumulated close to the plasma membrane. Interfering with axonal transport by nocodazole (Baas and Black, J. Cell Biol. 111, 495, 1990) altered the distribution of B-50 and these vesicles. Antikinesin antibodies were applied to identify axonal motor driven vesicles. We hypothesize that B-50 may be conveyed on membrane vesicles to the plasma membrane as part of the constitutive transport pathway.

### 262.16

MOTONEURON SPROUTING IS NOT ASSOCIATED WITH INCREASES IN GAP-43 MRNA. M.C. Brown'\*, C.M. Booth', M.A. Bisby², and W. Tetzlaff'. 'Lab. of Physiology, Oxford Univ., U.K., 'Dept. of Physiology, Queen's Univ., Kingston, Ont., Canada, and 'Dept. of Anatomy, Univ. of Calgary, Calgary, Alta., T2N 4N1, Canada.

High GAP-43 mRNA levels are associated with axon growth during development or following injury. Another type of axonal growth is collateral sprouting from uninjured neurons in response to partial denervation. We asked whether increased GAP-43 mRNA occurs during collateral sprouting of mouse gluteal motoneurons with axons in the superior gluteal nerve, in response to cutting the inferior nerve. When retrograde tracer (true blue) was applied to the cut inferior nerve and after one week, to allow sprouting to begin, spinal cord was processed for in-situ hybridization with a GAP-43 cDNA probe, only dye-labelled (axotomized) cells had high mRNA levels. When fluorogold was instead applied to the surface of the muscle, and so could be only taken up by the sprouting motoneurons with axons in the superior nerve, fluorescent cells had mRNA levels undistinguishable from those of motoneurons in other parts of the motor column: none containing high GAP-43 mRNA levels were fluorescent. Preliminary observations of sternomastoid motoneurons induced to sprout by marcaine applied to the muscle also reveal no increase in GAP43 mRNA. We conclude that collateral sprouting of motoneuron axons occurs without detectable increases in cell body GAP-43 mRNA expression. (MCB was a Visiting Scientist of the Alberta Heritage Foundation for Medical Research).

## 262.18

EXPRESSION OF GAP-43 IN PC12 CELLS CLONES IS INDEPENDENT OF NEURITE OUTGROWTH. <a href="https://richard.www.burry-2-Noral.Perrone-Bizzozero and 2Victor V. Cansino," Dapt. of Cell Biology, Neurobiology and Anatomy, The Ohio State University, Columbus, Oh, and 2Dept. of Biochemistry, University of New Mexico, Albuquerque, NM</a>

The expression of GAP-43, a growth associated protein, has been postulated to function in controlling neuritic outgrowth. We investigated this possibility in a series of PC12 cell clones which express different phenotypes in response to nerve growth factor (NGF) and second messenger stimulating drugs. One PC12 clone, PC12-N21, grew neurites in response to NGF or forskolin (FOR) and increased levels GAP-43 mRNA and protein in response to NGF or phorbol ester (PMA). These cells gave a typical PC12 cell response to NGF, PMA or FOR, A second clone, PC12-N09, did not grow neurites in response to NGF, but did increase GAP-43 levels in response to NGF or PMA. However, in sponse to FOR the PC12-N09 cells did grow neurites. When PMA and FOR were used together, PC12-N09 cells both initiated neuritic outgrowth and increased GAP-43 expression. These results show that PC12-N09 cells respond to NGF by increasing GAP-43 levels without concomitant neurite outgrowth, but these cells have the ability to express both phenotypes if treated with a combination of drugs that act on different second messenger systems. The behavior of these PC12 clones suggests that NGF stimulation activates at least two different pathways, one which initiates neurite outgrowth and the other which increases the expression GAP-43. MEASUREMENT OF RELATIVE AMOUNTS OF PHOSPHO- AND DEPHOSPHO-B-50(GAP-43) PEPTIDES BY FAST ATOM BOMBARDMENT-MASS SPECTROMETRY (FAB-MS) M. Di Luca. P.N.E De Graan, L. De Angelis, W.H. Gispen and F. Cattabeni\*, Institute of Pharmacological Sciences, University of Milano, 20133 Milano, Italy and Rudolf Magnus Institute of Pharmacology, University of Utrecht, 3521 GD Utrecht, The Netherland.

The biological role of phosphoproteins depends upon their degree of phosphorylation. Methods currently available to measure the actual in *vivo* phosphorylation state of a protein involve indirect procedures based on <sup>32</sup>P incorporation.

B-50(GAP-43) plays a crucial role in neuronal plasticity. The possibility of elucidating its physiological role requires the measurement of its degree of phosphorylation in vivo. We have explored this possibility by measuring relative amounts of phospho- and dephosphopossibility by measuring relative anionits of piospho- and dephospho-forms of the peptide corresponding to amino acid sequence 39-51 of B-50(GAP-43) by FAB-MS. The peptide was phosphorylated by purified Protein Kinase C and the reaction mixture was directly analyzed: the mass spectrum showed two molecular ions at m/z 1583.9 and 1663.9, corresponding respectively to the dephospho- and phospho-forms of the peptide. By changing their relative amounts, linear changes in the ratio of the intensities of the two ions was obtained. The lowest detectable amount of the peptide was 30 pmol, with a signal to noise ratio value of

This demonstrates the applicability of FAB-MS to quantitate realtive amounts of phospho- and dephospho- peptides derived from B-50(GAP-43) by proteolytic digestion, in the same sample and in the same experimental conditions.

ANTI-β1 INTEGRIN ANTIBODIES INHIBIT REGENERATING RETINAL GANGLION CELL AXON OUTGROWTH AS WELL AS GLIAL CELL ADHESION AND SPREADING. D.S. Sakaguchi\* and K. Radke. Dept. Zool. and Genetics, Neurosci Prog., Iowa State Univ., Ames, IA 50011.

The  $\beta 1$  family of integrin receptors have been shown to mediate embryonic axonal outgrowth onto extracellular matrix (ECM) substrates in a number of experimental systems. In the present study we have investigated a role for the \$\beta\$1 integrins during regeneration of retinal ganglion cell axons in *Xenopus laevis*. Late stage tadpole retinas, from eyes that received a conditioning optic nerve crush 2 weeks earlier, were cultured on laminin or ECL (entactin, collagen and laminin ECM preparation) substrates. These explanted retinas were allowed to attach to the substrates and polyclonal antibodies to the  $\beta$ 1 integrin subunit (from K. Yamada) added 24 hrs later. IgGs, as well as Fab fragments, inhibited axon outgrowth in a dose-dependent fashion, while control, preimmune rabbit antibodies had no effect.

We also investigated a role for the \$1 integrins in mediating glial cell adhesion and spreading. Culturing the Xenopus XR1 glial cell line on collagen substrates in the presence of the anti-β1 antibodies resulted in a dose-dependent inhibition of cell attachment. To examine cell spreading XR1 cells were allowed to attach to the substrate and control or anti-\$1 antibodies added 12 hours later. This analysis revealed that the anti-β1 antibodies inhibited the spreading of the XR1 cells and in addition, could lead to the retraction of the glial cell lammemapodia. Removal of the antibody containing medium and replacement with fresh medium resulted in the recovery of the XR1 glial cell morphology. B1 family integrins appear to play important functional roles during regeneration and also in glial cell adhesion and spreading *in vitro*, and may play similar roles *in vivo*.

## 263.3

EXPRESSION OF INTEGRIN SUBTYPES ON EMBRYONIC CHICKEN SENSORY NEURONS IN CULTURE -- FUNCTIONAL RELATIONSHIPS TO NEURITIC OUTGROWTH. AW. Lyckman\*. C.B. Herbert. R.C. Lewis. L. Suggs. S.P. Massia, G.D. Bittner and J.A. Hubbell. Depts. of Chem. Eng. and Zoology, Univ. of Texas, Austin, Texas 78712.

S.P. Massia. G.D. Bitmer and J.A. Hubbell. Depts. of Chem. Eng. and Zoology, Univof Texas, Austin, Texas 78712.

Neuronal survival and differentiation has a strong dependence on local environmental conditions. With regard to neuritic outgrowth, sensory neurons are differentially responsive to extracellular matrix (ECM) proteins. Many cells, including neurons, carry cell surface receptors for ECM proteins called integrins which may mediate cellular responses to the ECM. Integrins are a superfamily of heterodimeric  $(\alpha, \beta_h)$  proteins. Integrins with selective affinities for different ECM proteins derive from specific combinations of  $\alpha$ -subunits (at least 11) and  $\beta$ -subunits (at least 7). To better understand mechanisms underlying neuritic outgrowth on different ECM proteins, we used immunofluorescence to determine which integrin subtypes are expressed on embryonic chicken sensory neurons.

Our immunofluorescence studies utilized commercially available monoclonal and polyclonal antibodies to human integrin subtypes (Tellos, Chemicon). Cells from dissociated dorsal root ganglia (DRG) of embryonic day 7 chicken embryos were grown in serum-free F-12 medium on different ECM proteins adsorbed to glass. After 12-48h, cells were fixed for 15min with 4% paraformaldehyde and treated overnight at 4°C with antisera diluted with 0.1% Triton X-100 in PBS. Primary antibodies were stained with fluorescently labeled secondary monoclonals (Boehringer-Mannheim). DRG neurons were immunopositive for subunits ( $\alpha_4$ ,  $\alpha_5$ , and  $\alpha_7$ ); specific  $\beta$ -subunits ( $\beta_1$  and  $\beta_3$ ); and, specific  $\alpha$  subunits ( $\alpha_4$ ,  $\alpha_5$ , and  $\alpha_7$ ); specific  $\beta$ -subunits ( $\beta_1$  and  $\beta_3$ ); and, specific integrin subtypes ( $\alpha_6\beta_1$  and  $\alpha_7\beta_3$ ). DRG neurons were not immunopositive for antisera against  $\alpha_2$ . The staining pattern of positive immunofluorescence was usually punctate, and appeared on growth cones, neurites, and the soma. Staining for  $\alpha_4$  also appeared tubulovesicular. Integrin subtype vexpression was the same whether neurons were grown

### 263.2

β1 Integrin-Like Immunoreactivity in the Adult Rat Brain.

\$\begin{align\*} \text{Integrin-like Immunoreactivity in the Adult Rat Brair L.S.Jones\*, S.Grooms, L.Terracio, Dev. Bio. & Anat., U. South Carolina, Columbia, SC 29208. \$\beta\$1 integrin-like immunoreactivity was localized in adult rat brain using a rabbit-raised anti-rat liver \$\beta\$1 integrin antibody (\( \frac{1}{2}\) \text{Biol.chem.} \( \frac{264}{2} \)!12686, 1989). Standard immunohistochemical techniques were applied to Standard immunohistochemical techniques were applied to 10µm paraffin-embedded sections from paraformaldehyde perfusion-fixed brains. Specific staining of integrin-like immunoreactivity was found in vascular structures of the CNS, including microvessels, ventricular ependymal cells, and pla mater. Labelling of medium-sized vessels was particularly striking, as antibody labelled what appeared to be smooth muscle in a "slinky-like" pattern of circumferential organization. The pineal gland was the most densely stained CNS structure. Diffuse staining was present throughout the gray matter of the brain. This most densely stained CNS structure. Diffuse staining wa present throughout the gray matter of the brain. This staining took on a patterned appearance in certain regions, such as the apical dendritic field of CAl in hippocampus; in CAl the labelling appeared to parallel and outline the apically radiating dendrites of the pyramidal neurons, and bore a resemblance to the appearance of GFAP staining in the same region. Faint labelling of astrocytes was noted, and in occasional adjacent sections an astrocyte that appeared labelled both with GFAP and integrin-like immunoreactivity was identified. The localization of integrin-like immunoreactivity in the dendritic fields of hippocampus may indicate that these proteins play a structural role in indicate that these proteins play a structural role dendritic morphology. POTENTIATES LAMININ-INDUCED REURITE OUTGROWTH IN PC12 CELLS. A. Buriani\*
L. Facci, R. Dal Toso and S.D. Skaper. Fidi
Research Labs, Abano Terme, Italy.
NGF-differentiated PC12 cells grown on

polylysine surface regenerate few or no neurites in the absence of serum or certain adhesion molecules. Acute addition of laminin to sion molecules. Acute addition of laminin to such cultures produces long neurites within several hours. Pretreatment of PCl2 cells with the monosialoganglioside GMl led to significant increases in both the number of neurites and their rate of growth in the copresence of laminin. In effect, GMl rendered weakly active concentrations of laminin as effective as amounts 2-3 fold greater, thus appearing to shift the laminin dose-response relationship. This effect of GMl required the presence of an external source of Ca<sup>2+</sup> and was concentration-dependent, being optimal at 10-7M GMl in a serum-free environment. GMl has also been described to potentiate N-CAM and N-cadherin in a serum-free environment. GM1 has also been described to potentiate N-CAM and N-cadherin dependent neurite outgrowth in PC12 cells (Doherty et al., J. Cell Biol., in press) in a Ca<sup>2+</sup>-dependent fashion, suggesting a common signaling pathway in the interaction of GM1 with extracellular matrix and cell adhesion relaculates. molecules.

ULTRASTRUCTURAL ANALYSIS OF EMBRYONIC NEURAL CELL ADHESION MOLECULE (N-CAM) EXPRESSION IN RAT DENTATE GYRUS FOLLOWING ENTORHINAL CORTEX LESION. S.D. Styren\*. P.D. Miller, C.F. Lagenaur, S.T. DeKosky. Depts. of Psychiatry, Neurobiology, Anatomy & Cell Science, Neurosurgery, and Neurology, Univ. of Pittsburgh Sch. of Med. and Western Psychiatric Inst. & Clinic, Pittsburgh, PA 15213.

Re-expression of developmental proteins following CNS lesions or in degenerative diseases have been demonstrated in some neural systems. We examined changes in embryonic N-CAM expression in adult rat dentate gyrus during axon sprouting and synaptogenesis following ipsilateral entorhinal cortex (ERC) lesion. This lesion denervates the outer 2/3 of the dentate gyrus molecular layer (ML) by disconnecting the perforant pathway afferents, leaving the inner 1/3 unaffected. Light microscopic analysis of dentate gyrus utilizing a monoclonal antibody (recognizing highly polysialyated embryonic N-CAM) demonstrated weak to undetectable staining throughout the ML in normal rats; ultrastructural examination of this zone revealed sporadic weak staining limited to a few dendrites. Ten days post-lesion, intense embryonic N-CAM immunoreactivity was present in the deafferented outer ML. In these animals ultrastructural examination of the outer ML revealed intense immunoreactivity associated with dendrites. Embryonic N-CAM immunoreactivity was most often seen at contact sites between dendrites and axonal profiles, including terminals. Intense staining was localized to the cell surface membrane. In the inner ML embryonic N-CAM was unchanged compared to normal animals. The loss of synaptic contacts in the denervated zone appears to signal rexpression of embryonic N-CAM as a means to re-establish synaptic contacts.

### 263.7

EXPRESSION OF GM2 GANGLIOSIDE BY NEURONS ELABORATING

NEURITES IN FETAL RAT CEREBRAL CORTEX CULTURES.

K. Dobrenis and S.U. Walkley.\* Depts. of Neuroscience and Pathology,
Albert Einstein College of Medicine, Bronx, NY 10461.

Despite the fundamental importance of dendritic growth, little is known about the regulatory factors involved. Previous studies examining normal dendritogenesis during brain development and ectopic dendrite growth in neuronal storage diseases have suggested a correlation between the appearance of GM2 ganglioside (GM2) and dendritic sprouting (PNAS 88: 11330-34, 1991). To further test the importance of GM2, we are investigating whether a similar relationship is manifested in vitro.

investigating whether a similar relationship is manifested in vitro. Cell cultures were prepared from rat cerebral cortices of embryonic day 15-16, a time at which neurons are commencing neuritic growth. Mechanically dissociated cells were plated on polylysine coated substratum with chemically-defined or fetal bovine serum-containing medium. Cultures were processed by immunofluorescence with monoclonal antibodies to microtubule-associated proteins 2a+2b (MAP2), for unambiguous identification of differentiating neurons, and to GM2. A total of 3907 cells were examined. In serum-fed cultures, cells of neuronal measures (consider one with purpose processes) at the vitro vitro. appearance (rounded somas with narrow processes) at 1 day in vitro (DIV) primarily bore 1-2 short ( $<100\mu m$ ) unbranched neurites. At 14 DIV primarily bore 1-2 short (<100µm) unbranched neurites. At 14 DIV neurons had lengthy tapering dendritic-like processes and included bipolar-, pyramidal- and stellate-like cells. The percentage of neuron-like cells with MAP2 staining increased over time: 36, 74 and 93% at 1, 2 and 5 DIV, respectively. The percentage of MAP2\* neurons that were GM2\* also increased over these times: 23, 43 and 99%. This value appeared to decline subsequently to 94 and 86% at 8 and 14 DIV. GM2\*, MAP2\* neuron-like cells were rare (<4%). In early cultures GM2\* staining was mostly punctate in form and in the somatic domain; over time staining more frequently appeared as patches or rings and extended over dendritic-like profiles. Serum-free cultures show similar results. (NS18804)

LDL RECEPTOR EXPRESSION DURING SYNAPTIC REMODELLING IN THE HIPPOCAMPUS FOLLOWING ENTORHINAL CORTEX LESIONING. D. Dea A. Baccichet, P. Bertrand and I. Poirier. Douglas Hospital Research Centre, Department of Psychiatry and Centre for Studies in Aging, McGill University, Montreal, Quebec, Canada, H4H 1R3.

Apolipoprotein E (apo E) is synthesized and secreted by astrocytes in the hippocampus following lesions of the entorhinal cortex. It was proposed that apolipoprotein E, by analogy to its role in cholesterol transport in circulation, could regulate the salvage and reutilization of cholesterol released during terminal breakdown. This cholesterol could then be transported to neurons by apolipoprotein E-complexes and taken up via the apo E/apo B (LDL) receptor. As a test of this hypothesis, we have examined LDL receptor binding in brain sections of rats undergoing hippocampal reinnervation. The number of neuronal cells labelled by fluorescent Dil-LDL as well as the density of 125I-LDL binding sites in the dentate gyrus were found to increase in parallel with the extent of cholinergic reinnervation occurring in the deafferented hippocampus. Analysis of the mRNA prevalence for the LDL receptor indicates a profile of induction that parallels the ceptor binding sites alterations observed in the dentate gyrus area. Previous results showed that the cholesterol released during terminal breakdown is esterified and apparently transported to neurons undergoing reinnervation via the apo E transport system. The present findings indicate that the apo E-complex is taken-up preferentially by neurons though the LDL receptor pathway, where it is presumably used as precursor molecule for the synthesis of new synapses and terminals. Supported by the Medical Research Council of Canada and American Alzheimer's

NEURAL CELL ADHESION MOLECULE (N-CAM) EXPRESSION IN THE RAT DENTATE GYRUS FOLLOWING ENTORHINAL CORTEX LESION. P.D. Miller\*, S.D. Styren, C.F. Lagenaur, S.T. DeKosky. Depts. of Neurobiology, Anatomy & Cell Science, Neurosurgery, Psychiatry, and Neurology, University of Pittsburgh School of Medicine and Western Psychiatric Institute & Clinic, Pittsburgh, PA 15213.

We evaluated immunohistological changes in N-CAM expression in adult rat dentate gyrus during the period of axonal sprouting and synaptogenesis following ipsilateral entorhinal cortex (ERC) lesion. This lesion denervates rollowing ipsilateral enforminal cortex (ERC) lesson. Inis lesson denervates the outer 2/3 of dentate granule cell dendritic fields and induces compensatory sprouting from the subjacent inner 1/3 into the denervated zone, as well as reactive synaptogenesis in the denervated outer molecular layer. Antibodies to total N-CAM and the monoclonal antibody 12F11 (which cognizes N-CAM 140 and 180) intensely stained the inner molecular layer (ML) in controls, and after ERC lesion this intense staining exactly followed the known temporal sequence for the sprouting of axon collaterals into the denervated zone. The area of increased staining expanded to ultimately occupy the inner half of the ML. Monoclonal antibody 12F8 recognizes the highly polysialylated, embryonic form of N-CAM. Controls had very light, uniform ML staining. By 6 days post-lesion, robust staining of the outer 2/3 of the molecular layer developed. This area of intense staining, marking the entire outer ML, receded as axon collaterals from the inner 1/3 entered the denervated zone, so that by 30 days the intense 12F8 staining only occupied the outer half of the ML. This upregulation of embryonic N-CAM persisted at 60 days post-lesion, past the point when synaptic density has returned to normal levels in the denervated zone. Following injury, the hippocampus recapitulates developmental sequences of embryonic N-CAM expresssion. Unlike the developmental sequence, post-injury embryonic N-CAM persists.

### 263.8

NEURONAL CELLS IN PRIMARY CULTURE EXHIBIT LDL RECEPTOR-MEDIATED ENDOCYTOSIS OF LIPOPROTEINS: A ROLE IN CNS CHOLESTEROL METABOLISM. I. Poirier, P. Bertrand, R. Alonso, R. Ouirion and P. Boksa. Douglas Hospital Research Centre, Department of Psychiatry and Centre for Studies in Aging, McGill University, Montreal, Canada

Apolipoprotein E, a major plasma protein in humans and rats, is best known in peripheral lipoprotein transport to LDL receptors on liver and adrenal cells. While its role and that of its receptor in neural tissues are less known, the production of apo E during responses of hippocampus to deafferentation and reinnervation implies a role in lipid transport associated with terminal proliferation and synaptic remodelling. To test this postulate, we examined the expression of the LDL receptor in hippocampal neuronal cells in primary culture maintained in serum free conditions to prevent glial proliferation. LDL, which has been labelled with a fluorescent dye, was internalized by the neurites and growth cones at 37°C. The intracellular fluorescence appears to be mostly concentrated at the basis of axons. The extent of the internalization process was significantly reduced (>50%) by incubating cells for 48 hours with 0.1 uM of dexamethasone, a potent glucocorticoid analog. This observation is consistent with the known reduction of LDL receptors prevalence in hepatocytes treated with dexamethasone, and would be expected if the uptake of cholesterol-rich lipoproteins represent the major source of lipids in developing neurons. Supported by the Medical Research Council of Canada and American Alzheimer's disease Association.

INOSITOL PHOSPHATE BINDING SITES AND NEURONAL PLASTICITY FOLLOWING ENTORHINAL CORTEX LESIONS. S. Gauthier\*. A.R. Parent. D. Dea, R. Quirion and J. Poirier. Douglas Hospital Res. Ctre, Centre for Studies in Aging and Dept. Psychiatry, McGill University, 6875 LaSalle Blvd., Verdun, Québec. H4H 1R3.

Entorhinal cortex lesioning (ECL) produces a loss of more than 80% of the Enforhmal cortex lesioning (ECL) produces a loss of more than 80% of the synapses in the outer molecular layer of the hippocampus. However, the loss of synapses is transient. Beginning a few days after denervation, new synapses are formed, virtually replacing the lost inputs within two months. Synaptic remodelling induced by ECL is associated to specific modifications of neurotransmitters, hormones and growth factors. Many of these substances act at membrane receptors to induce hydrolysis of phosphatidylinositols generating various inositol phosphates (IP). The most important members of this family are the 1,4,5-IP<sub>3</sub> and 1,3,4,5-IP<sub>4</sub> which are associated with Ca<sup>2+</sup> homeostasis. To investigate the potential roles of the IPs in ECL, we characterized and quantified their exercise binding sites of 14.5-IPs, and 13.4.5-IP, which the respective respective their specific binding sites of 1,4,5-IP3 and 1,3,4,5-IP4, using their respective tritiated ligands, after different days post-lesion. [3H]-1,4,5-IP3 binding sites are maximally increased (30%) between 4 and 8 days post-lesion in hippocampal formation on both sides of the lesion. Interestingly in the cortex, [3H]-IP3 binding sites increased by up to 25% in the ipsilateral side and by 70% in the contralateral side. [<sup>3</sup>H]-1,3,4,5-IP<sub>4</sub> binding site changes are delayed and reduced (20%) in magnitude compared to [<sup>3</sup>H]-IP<sub>3</sub> alterations. The maximal peak is observed between 8 and 14 days after the lesion in the hippocampal formation and the cortex. These results suggest that IPs could be involved in the process of reinnervation following deafferentation observed in the ECL model. The bilateral changes observed in unilaterally lesioned animals suggest a general reorganization of neuronal circuitry that extend beyong the hippocampal formation. Supported by MRCC, Alzheimer Society of Canada and Alcan.

ABNORMAL NEURONAL OUTGROWTH AND GENE EXPRESSION IN DEVELOPING CEREBELLUM FOLLOWING PERINATAL HYPO- AND HYPERTHYROIDISM. B.C. Figueiredo\*: G. Almazan, Y. Ma, W. Tetzlaff, F.D. Miller and A.C. Cuello. Dept. of Pharm. and Ther., McGill Univ. Montreal; Dept. of Anat. and Cell Biol. Univ. of Alberta, Edmonton; Dept. of Anatomy, Univ. of Calgary, Calgary, Canada.

We examined the effects of perinatal hypo- and hyperthyroidism on the development of the rat cerebellum by studying the expression of genes that play a role in neuronal outgrowth [GAP-43, tubulin- $\alpha$ 1 (T $\alpha$ 1)], as well as those encoding the low-affinity neurotrophin receptor (LNGFR), a constitutive cytoskeletal protein (tubulin 26) and the principal myelin proteins MBP and PLP. One group of pups were made hypothyroid (ho) by feeding dams a 0.4 % propylthiouracil enriched diet (initiated on gestational day 19). The second, a hyperthyroid (Hr) group, were injected subcutaneously with thyroxine (0.3  $\mu g/gm$ , bwt) daily after birth. Immunostaining for LNGFR using 192-IgG revealed abnormalities in Purkinje cell (PC) axons of ho rats, such as twisting, proximal varicosities and dramatic differences in axonal caliber relative to control rats. The observed increase in LNGFR immunoreactivity (IR), which was greater than the relative increase noted in its mRNA suggests that thyroid hormone may regulate this receptor at a number of cellular levels. The levels of  $T\alpha 1$  and GAP-43 mRNAs were increased in ho cerebellum, thus correlating with the observed abnormal neuronal growth. By contrast, T26  $\alpha$ -tub. mRNA, which is expressed by both neurons and glial cells, was only slightly affected by thyroid hormone imbalance. Interestingly, levels of MBP and PLP mRNAs were altered in ho and Hr rats only during early cerebellar development. This contrast with the permanent changes in these two mRNAs which occur in vitro. Thus, hypothyroidism led to specific increases in  $T\alpha 1$ -tub. and GAP-43 mRNAs, and LNGFR (IR, mRNA), all changes that may play a role in the observed abnormal neuronal outgrowth. THE POSTNATAL DEVELOPMENT OF SEROTONERGIC HYPERINNERVATION IN THE CORTEX OF THE HEMIZYGOUS BRINDLED MOUSE. P.M. Martin\*, M. Ohno, R. Mailman, and Kinuko Suzuki. Brain and Development Research Center, and Departments. of Pathology, Psychiatry and Pharmacology, University of North Carolina, Chapel Hill, NC 27599.

Mottled brindled (MOb\*) is an X-linked mutation in the mouse, maintained in hybrids of the C3H and C57BL strains. Hemizygous males (MOb\*)y) have low copper concentrations in the brain, very low concentrations of norepinephrine, and neuronal degeneration of the cerebrum. They begin to lose weight on approximately postnatal day (P) 10, and die around P15. We have reported that the hemizygous males also have high concentrations of scrotonin (5-HT) in the brainstem, and high concentrations of 5-hydroxyindoleacetic acid in the hindbrain and all areas of the forebrain (Satoh et al., 1991). In this experiment, 5-HT immunoreactive fibers in the cerebral cortex and striatum were quantified and compared in hemizygous males and control littermates at P7, P10, P12 and P14 (n=3 pairs at each time point). Forty micrometer Vibratome sections were immunostanted with 5-HT antibody. Density of 5-HT immunoreactive fibers was measured using a digitized imaging system in control littermates at P7, P10, P12 and P14 (n=3 pairs at each time point). Forty micrometer Vibratome sections were immunostained with 5-HT antibody. Density of 5-HT immunoreactive fibers was measured using a digitized imaging system in conjunction with darkfield microscopy. Measurements of 5-HT innervation show an age-dependent increase in density of 5-HT immunoreactive fibers in all layers of the cerebral cortex. No differences in innervation were found on P7, but there was a steady increase from P10 to P14, when fiber density in brindled mice was approximately 70% above their matched controls. No significant increase in fiber density was found in the striatum. High performance liquid chromatography showed increasing concentrations of serotonin and 5-hydroxyindoleacetic acid, coupled with a very low concentration of norepinepherine in several brain regions. We have found that brindled mice also show an age-dependent change in 5-HT immunoreactive fibers in the subependymal layer of the lateral ventricles, with fibers becoming increasingly thick and darkly stained, and nodal points appearing very swollen. Preliminary data from mouse pups who were food deprived between P5 and P15 show similar changes in the 5-HT immunoreactive fibers in the subependymal layers. These data suggest that the alterations in 5-HT metabolism and innervation may be initiated, at least in part, to the weight deficits seen in the MO<sup>bt</sup> mice. SPROUTING OF SP OR 5HT CONTAINING TERMINALS IN LAMINA II OF RAT SPINAL CORD AFTER DORSAL RHIZOTOMY. B. Zhang\*, and M. Murray. Department of Neurobiology, Medi Anatomy and Neurobiology Pennsylvania, Philadelphia, Pa Medical College

Synaptic plasticity of Substance P (SP) and Serotonin (5HT) containing systems in lamina II of rat spinal cord has been studied using quantitative electron microscopic immunocytochemical techniques (EM-ICC). Dorsal roots were sectioned and dorsal root ganglia were removed from L1 to S2 in 18 rats. After 3, 10 or 60 days rats were perfused, and the L5 segments of the spinal cord removed and prepared for post-embedding immunocytochemistry. Quantitative EM-ICC study demonstrates that the number of SP containing terminals in lamina II decreased by 58% at 3 days postoperatively and recovered to normal numbers in the chronic group. The loss of SP terminals in the acute group is due to loss of SP containing dorsal root afferents, while the recovery in the chronic group suggests replacement of lost terminals by intrinsic SP systems. These results therefore indicate homotypic sprouting in response to dorsal root deafferentation. The number of 5HT containing terminals in lamina II of spinal cord increased by 55% on the deafferented side of the chronic group. The increase in 5HT containing terminals indicates that descending 5HT system shows heterotypic sprouting in response to complete dorsal root deafferentation.

ABERRANT DOPAMINE INNERVATIONS OF SUBSTANTIA NIGRA AND INTERPEDUNCULAR NUCLEUS FOLLOWING CEREBRO-VENTRICULAR ADMINISTRATION OF 6-OHDA IN NEWBORN RAT.

AND INTEREDUNCULAR NUCLEUS FOLLOWING CEREBROVENTRICULAR ADMINISTRATION OF 6-OHDA IN NEWBORN RAT.

E. G. Fernandes Xavier, G. Doucet, L. Descarries, T.A. Reader\* and
M. Geffard, CRSN (Dép. de pathol, t. Descarries, T.A. Reader\* and
M. Geffard, CRSN (Dép. de pathol, Univ. Bordeaux II, FRANCE.

In adult rats subjected to bilateral cerebroventricular administration of
6-OHDA neonatally (P3), a relatively dense network of dopamine (DA) axons
pervades the substantia nigra (SN), where this transmitter would be normally
contained and released by nerve cell bodies and dendrites. Considerable DA
axonal sprouting is also observed in the interpeduncular nucleus (IP), which
normally receives a very scant DA innervation. To examine the development
of these aberrant innervations and determine the critical period for their
induction, a first series of rats were lesioned at P3 and perfused with 3.5%
glutaraldehyde at P7, P10, P15 or P30; another series were lesioned at P6 or
P15, and perfused 30 d later. Brain sections were processed for immunocytochemistry with monoclonal antibodies against DA-glutaraldehyde
conjugates. All lesions practically eliminated DA cell bodies and dendrites
from the SN, but spared many DA neurons in the adjacent ventral tegmental
area and rostral midbrain raphe. Following P3 lesioning, some DA immunoreactive fibers were already observed in SN at P7. The density of this
neoinnervation increased sharply until P15, but only slightly further until P30,
at which time its intraregional distribution typically resembled that of the DA at which time its intraregional distribution typically resembled that of the DA cell bodies and dendrites in a normal adult. In IP, DA innervation was already cell bodies and dendrites in a normal adult. In IP, DA innervation was already much denser than normal at P10 and did not show further increase with longer survival. A similar DA innervation of SN was observed after lesioning at P6 and P15. Thus, the development of both aberrant DA innervations is rapid (2 weeks) and the critical period for their induction extends beyond P15. STIMULATION OF THE 5-HT1A RECEPTOR INHIBITS CORTICAL NEURAL GROWTH DURING THE LAST PRENATAL WEEK OF RAT DEVELOPMENT.

B. C. Swarzenski\* and R. D. Todd. Departments of Psychiatry and Genetics,
Washington University, St. Louis, MO 63110.

Serotonin has a variety of effects on pre- and postnatal neural development including neuronal differentiation, neurite outgrowth, and synapse formation. Previous studies from this laboratory demonstrated the presence of 5-HT1A receptors on cultured rat fetal frontal cortical neurons and showed that stimulation of the serotonin 5-HT1A receptor by the specific agonist 8-OH-DPAT inhibits neurite branching during late rat frontal cortical development (E17-E19: gestational age in days). The purpose of the present study was to determine whether the inhibitory effect of 5-HT1A receptor stimulation on frontal cortical neuron outgrowth was present over an extended time during rat embryogenesis. Frontal cortices from Sprague-Dawley rat fetuses ages E14 to E21 were mechanically dissociated to single cell suspensions. The cells were plated in 5% fetal bovine serum at a density cell suspensions. The cells were placed in 3 % letal bowing a cell at a cells of 50 cells/mm2 onto poly (D-lysine) coated culture dishes and after 12 hours in culture at 37° C under 5% CO<sub>2</sub> either 1 μM 8-OH-DPAT (experimental group) or serum medium (control group) was added every 12 hours. After an additional 48 hours in the presence of 8-OH-DPAT or medium 100 consecutive cells in each group were photographed (Nikon Diaphot) and quantitatively analyzed using a Bioquant image analysis system. The data show (i) that the growth inhibitory effects of 5-HT1A receptor stimulation by snow (i) that the growth inhibitory effects of 3-11 in receptor sufficiently as substantial part of rat ontogenesis (at least from E14 until birth), and (ii) that the inhibitory effects include a dramatic decrease in the number of neurite branch points and a less pronounced inhibition in the outgrowth of neurites. Our results suggest that the 5-HT1A receptor has a regulatory role in cortical neural morphogenesis during a substantial period of fetal mammalian development.

GUANETHIDINE SYMPATHECTOMY INCREASES SUBSTANCE P CONCENTRATION IN THE SYMPATHETIC GANGLIA OF ADULT RATS. P. J. Zollman, E. E. Benarroch, J. D. Schmelzer\*, D. K. Nelson and P. A. Low. Neurophysiology Laboratory, Department of Neurology, Mayo Clinic, Rochester, MN 55905.

Chronic sympathectomy produces increased expression of sensory neuropeptides in sympathetically innervated tissue (Aberdeen et al., We sought to determine whether chronic guanethidine sympathectomy in adult rats results in expression of substance P in the superior cervical ganglion (SCG). Adult rats received intraperitoneal injections of guanethidine or saline for 5 weeks. Six to eight weeks following completion of treatment, concentrations of substance P and neuropeptide Y (NPY) were measured by radioimmunoassay in the superior cervical ganglion (SCG) and thoracic spinal cord. The SCG was also immunostained for NPY and substance P. No differences were observed in thoracic spinal content of either NPY or substance P. We observed depletion of NPY immunoreactive neurons and NPY levels in the SCG (control 9615  $\pm$  2894 vs. guanethidine 236  $\pm$  39, p=0.005). In guanethidine-treated rats, there was a marked increase of substance P levels in the SCG (control 8.7 ± 0.9 vs. guanethidine 39.5 ± 9.19, P=0.005). Substance P was localized in fibers, but not cell bodies of the SCG of guanethidine-treated rats. Thus, sprouting of substance Pcontaining sensory fibers in the sympathetic ganglia occurs late following postganglionic sympathectomy in adult rats. (Reference: Aberdeen J, Milner P, Lincoln J, Burnstock G. Neuroscience 47:453-461, 1992)

EARLY DEVELOPMENT OF THE SEGMENTAL INNERVATION OF THE RAT HINDLIMB. K. Mirnics\*, R.H. Adolph, H.R. Koerber. Dept. of Neurobiol., Anat. and Cell Sci., University of Pittsburgh, Pittsburgh, PA 15261

Individual dorsal root ganglia (DRGs) and/or ventral horn (VH) segments were isolated in rat embryos fixed at different stages (E13-E16) and filled with one of three carbocyanide dyes Dil, DiA and DiO. Individual experimental preparations included labelling of: 1) single dorsal root ganglia; 2) multiple DRGs (L2-L6) with alternating DiO, DiI and DiA; 3) single ventral horn segments; 4) multiple isolated VH segments (L2-L6) with alternating dyes; 5) single isolated VH segments and the corresponding segmental DRGs with different dyes. After diffusion was determined to be complete, the tissue was sectioned by vibratome and observed under fluorescent microscopy. Results from these preparations reveal that by E13 the plexus is formed and the primordia of the femoral and the sciatic nerve trunks are established. At E14 individual muscle and cutaneous nerves can be identified. At this stage fibers are present in the epidermis of the proximal hindlimb and the nerve trunks extend into the shank. Fibers originating from L3-L5 (DRG and VH) reach the paw by E14.5. At E15 the individual digital nerves are visible and contact the skin of the proximal toes, while the epidermis of the more distal toes is innervated by E16. At all stages sensory and motor fibers are observed to grow in unison. Multiple DRG and VH labelling with different dyes revealed that fibers of different segmental origin are combined in the plexus and diverge in the developing peripheral nerve trunks with little or no mixing. This segmental topographic organization is true of both motor and sensory fibers and can be observed as early as E13. However, afferent and efferent fibers of the same segmental origin intermix extensively in the spinal nerves and form joint fascicles as they enter the plexus and give rise to peripheral nerve trunks. Supported by NS23725 (HRK).

### 264.3

SOMITE AND SPECIFICITY OF SYMPATHETIC PREGANGLIONIC PROJECTIONS. J. W. YIP. \*Dept. of Physiology, University of Pittsburgh, Sch. of Med., Pittsburgh, PA 15261.

of Med., Pittsburgh, PA 15261.

The pattern of preganglionic projections in the avian sympathetic system is segmentally specific. Preganglionic axons arising from the TI spinal cord segment, for example, project predominantly in the rostral direction, whereas T4 preganglionic axons project predominantly in the caudal direction. Individual ganglia, moreover, are innervated in a stereotyped pattern by preganglionic axons arising from several contiguous spinal cord segments. The formation of these patterns is target independent, is not determined by the neurons' segmental origin in the spinal cord, but is influenced by the local environment along which preganglionic axons project.

The somitic mesoderm has been shown to influence the segmentation of peripheral nerves and ganglia. Whether the somitic mesoderm also determines the perphera nerves and gangita. Whether the somitte mesoderm also determines used to pattern of preganglionic projections is not clear. In order to address this issue, I have examined: 1) whether the tissue immediately surrounding the sympathetic trunk is derived from the somitic mesoderm, 2) the patterns of preganglionic projections following somite removal, and 3) the direction of preganglionic projections subsequent to rostro-caudal somite transplantations. Quali-chick somite projections subsequent to restrict a cause a some transplantations. Qual-trait x somitine transplantations show that the tissue immediately surrounding the sympathetic trunk is derived entirely from the somite. Anterograde and retrograde HRP studies show that following somite removal, the specificity of preganglionic projections is disrupted. Thus for example, T1 preganglionic neurons, which normally project in the rostral direction, may now project caudally. Consistent with this finding, the segmental pattern of preganglionic neurons projecting to individual ganglia is also altered. Finally, when cervical somites are transplanted to the thoracic region, T1 preganglionic axons project caudally, in addition to the normal rostral directi

These results indicate that somites are important for the specificity of sympathetic preganglionic projections.

## 264.5

INHIBITION OF NEURITE GROWTH FROM EMBRYONIC RAT DORSAL ROOT GANGLIA (DRG) EXPLANTS BY VENTRAL, BUT NOT DORSAL, SPINAL CORD. GC Kwiat\*, J Meredith-Middleton, A Pini, and MFitzgerald. Dept. of Anat. and Dev. Biol., Univ. Coll., London WC1E 6BT.

We have studied, using in vitro organotypic culture methods, central factors which might influence development of the dorsoventral termination pattern of different types of primary afferent neurons in the spinal cord.

Lumbar DRG explants were co-cultured with either dorsal or ventral spinal cord explants in a collagen matrix gel covered with culture medium containing 5% calf serum and 50ng/ml nerve growth factor. DRG neurites were fluorescently labeled with dil by immersion of the DRG explant in a pension of dil crystals. After 24 hrs in culture the distribution and density of labeled neurites were analyzed using a confocal microscope and image analysis software. Neurite growth from DRG explants from E14-15 embryos typically exhibited a uniformly radial pattern when DRGs were cultured alone, or when co-cultured with dorsal cord explants from the same embryo. In contrast, when DRG explants at this age were co-cultured with ventral cord, DRG neurites were consistently found growing only in directions away from the cord explant. The effect was specific in that ventral cord did not inhibit outgrowth from dorsal cord explants. The inhibition of DRG neurite growth by ventral cord was absent, or greatly diminished, by E18. These results suggest that development of the dorsoventral termination pattern of primary afferent neurons in the spinal cord might involve a transient inhibition of afferent axon growth, and are consistent with in vivo results which show that the earliest arriving afferents arborize in intermediate cord regions at a time which overlaps the period of inhibition.

#### 264.2

PATHWAY SELECTION BY REGENERATING PERIPHERAL NERVE AXONS GROWING THROUGH A Y-SHAPED TUBE IS RELATED TO DISTAL STUMP SIZE D.F. Davey, C.S. Brown and A.D. Ansselin. Microsurgery Research Centre, Sydney and Department of Physiology, University of Sydney, NSW 2006, Australia.

We have confronted regenerating rat sciatic nerve axons with a binary choice at the branch in a Y-shaped tube. The sciatic nerve of young Wistar rats was severed under Halothane anaesthesia proximal and distal to the peroneal-tibial branch. The distal peroneal and tibial stumps were inserted into the ends of the Y branches, and only the peroneal or tibial proximal stump into the base of the Y, leaving a 10 mm gap between the proximal and distal stumps. The tubes were cast from silicone (Sylgard 184; internal diameter 1.2 mm) and allowed for a tight seal when the nerves were sutured in place (ensured by application of a small amount of Vaseline). 8 to 12 weeks later, animals were anaesthetised before perfusion for electron microscopy. The number of myelinated axons in the two branches, and the base of the Y were estimated with a random sampling method. In all cases where regeneration occurred (10 of 17 experiments), axons were found in both branches of the Y. The mean ratio of axons entering the peroneal branch to those entering the tibial branch was 2.3:1 (SD=0.6, n=7) when the peroneal nerve regenerated. For tibial nerve regeneration, the ratio was 2.1:1 (S.D.=1.33, n=3). This result confirms that of Seckel, Ryan, Gagne, Chiu & E. Watkins, (Plastic Reconstr. Surg. 78:793-798, 1986) who reported a mean ratio of 2:1 for peroneal regeneration but is in marked contrast to that of Politis (Brain Res. 328:271-276, 1985) who reported that peroneal axons were almost always 100% correct in selecting the peroneal stump.

### 264.4

SOMITE MANIPULATION IN THE CHICK EMBRYO ALTERS SYMPATHETIC PREGANGLIONIC AXONAL TRAJECTORY E.B. Ezerman\* and C.J. Forehand. Department of Anatomy and Neurobiology,

Univ. of Vermont, Sch. of Med., Burlington, VT 05405.

Sympathetic preganglionic axons exit the spinal cord in the ventral root to project into the spinal nerve at each thoracic segment. After entering the spinal nerve, preganglionic axons make two turns en route to their targets in the paravertebral chain of sympathetic ganglia. First, the axons turn ventromedially to form the ramus communicans, through which they reach the sympathetic ganglion at their segment of origin. Then, the axons turn to project either rostrally or caudally within the chain to innervate ganglion cells at several segmental levels. The cues preganglionic axons use to make these turns are unknown. We have examined whether information derived from an appropriate relationship to somitic tissue during axon outgrowth plays a role in guiding these axons in the chick embryo. At the 22-26 somite stage, midthoracic somites were removed unilaterally and replaced with somites consisting only of either anterior somitic tissue or posterior somitic tissue. Embryos were sacrificed at stages from embryonic day 5-12 (E5-12). Preganglionic projections were mapped in E10-12 embryos by retrogradely labeling preganglionic neurons from the sympathetic chain in vitro. Axon pathways in E5-9 embryos were examined by immunohistochemical detection of GAP-43. In both types transplants, normal segmentation of the ventral roots, spinal nerves, sensory ganglia and sympathetic ganglia was disrupted. Despite this disruption, normal appearing rami communicantes arose from each of the spinal nerves that did form. However, the pattern of rostrocaudal projections within the sympathetic chain was abnormal. Supported by NIH NS 01344 and AHA 881168.

## 264 6

CELLS OF THE PERIPHERAL NERVE TUBE RELEASE A NEUROTROPHIC FACTOR PROMOTING PROCESS ELONGATION BY CULTURED ADULT FROG DORSAL ROOT GANGLION NEURONS. D.P. Kuffler\*, O. Megwinoff, C. Santiago<sup>+</sup> and D. Balsolobre<sup>+</sup>. Inst. of Neurobiology & Dept. of Physiology and Biology Dept. of P.R., Old San Juan, P.R. 00901

Peripheral motor axons regenerate in vivo to precisely re-innervate their denervated targets (Letinsky et al., '76). This regeneration is directed by diffusible neurotropic factors released from pieces of peripheral nerve (the normal pathway of the axons) and denervated muscle fibers (the original targets) (Kuffler, '89). Our present experiments are aimed at isolating and characterizing the responsible longrange targeting neurotropic factors.

Techniques were developed to isolate pure populations of dorsal root ganglion (DRG) neurons from the adult frog, <u>Rana pipiens</u>. These DRG neurons survive in a defined medium without serum or growth factors in tissue culture for more than 4 weeks and extend processes

To test for the presence of neurotrophic and neurotropic factors released from denervated neuronal targets DRG neurons have been co-cultured with pieces peripheral nerve. The average total process outgrowth was measured for control neurons as well as neurons co-cultured with peripheral nerve. After 10 days in culture the processes of neurons in the co-cultures were ca. 9 times longer than those of control neurons. These results indicate the release a neurotrophic factor from cells of the peripheral nerve tube. Experiments are under way to isolate and characterize this neurotrophic factor and determine whether, in addition to its neurotrophic role, it also functions as a neurotropic factor.

MULTIPLE NAVIGATIONAL STRATEGIES IN INDIVIDUAL AXONS OF DEVELOPING MUSCLE NERVE. M.Morgan-Carr and M.Hollyday\*. Department of Biology, Bryn Mawr College, Bryn Mawr PA 19010.

Previous studies of developing motor nerves have led to the conclusion that axons grow directly to target muscles, apparently guided by both active and passive cues. We observed the morphology of single axons to learn more about navigational strategies and the location of guidance cues for a compartadout havigational strategies and the location to glutance cues for a compart-mentalized and topographically innervated muscle. Individual motor axons of the embryonic chick (stage 26 to 34) were anterogradely labeled by spinal cord injections of HRP. Over 300 axons within the pectoralis nerve were examined with DIC optics in serial 100 µm sagittal sections. Labeled axons could be traced for more than 1mm, often to their terminal endings. The region examined encompassed the origins of several primary branches

The region examined encompassed the origins of several primary branches to m. pectoralis, and nerves to at least two other muscles. In this region, labeled axons displayed various features suggestive of active exploration and response to local guidance cues. Over 20% of the axons showed abrupt changes in trajectory, including 180° reversals and 360° loops. These loops often gave rise to short, fine axonal buds tipped with growth cones; these were also seen along the main body of the axon and may be interstitial sprouts. Filopodial sprays and lamellopodial "ghosts" were also observed and are thought to be remnants of decision region growth cones, elaborated in search of, or in response to local cues. In addition, 15% of the axons were bifurcated: 60% of the axonal pairs took parallel routes, with the remaining pairs taking disparate routes, usually entering different primary nerve branches, but occasionally even entering different muscle nerves. These navigational features are prevalent in an area of multiple decision regions, where adjacent axons diverge from single points to take completely different routes. These observations suggest that guidance cues are extremely specific and localized observations suggest that guidance cues are extremely specific and localized in this region, and that axons use multiple navigational strategies to find and respond to them. Supported by NS-25340 to MH.

NEUROMUSCULAR SPECIFICITY DEPENDS UPON THE PHYSICAL STRUCTURES ENCOUNTERED BY
REGENERATING MOTOR AXONS. P.B. Farcl\* and M.L. Mecker.

Dept. of Physiol. Univ. N. Carolina Sch. Med., Chapel Hill, NC 27599.

Regenerating lumbar motoneuron axons can specifically reinnervate their hindlimb targets during the first third of larval (tadpole) life in the bullfrog, after which time regenerative specificity s lost. Ultrastructural appearance of the Schwann cell-derived basal lamina coincides with the loss of regenerative specificity; however, appearance of immunoreactivity to two major constituents of the basal lamina, laminin and heparan sulfate proteoglycan (HSPG, antibody provided by M.J. Anderson), does not. These data indicate that the molecular components of the basal lamina are present prior to their organization into a discrete structure and that their presence per se does not impede regenerative specificity.

We have extended these observations to regenerating axons to show that, following transection, regrowing axons at all developmental stages encounter non-neural elements expressing laminin and HSPG. However, regrowing axons are not found in association with basal lamina tubes at stages when regeneration is specific, whereas axons are always found within basal lamina tubes at stages after regenerative specificity is lost. These data are consistent with the hypothesis that it is development of the the physical constraints imposed by the basal lamina (rather than expression of its molecular constituents) that prevents axons from regenerating to their proper targets

### DEVELOPMENT OF NEUROTRANSMITTER SYSTEMS: AMINO ACIDS

### 265.1

STRYCHNINE SENSITIVITY OF GLYCINE RESPONSES OF EMBRYONIC RAT SPINAL CORD NEURONS IN CELL CULTURE. M.D. Withers, R.B. Levine and P.A. St. John. Program in Neuroscience, Div. of Neurobiology and Dept. of Anatomy, University of Arizona, Tucson, AZ 85721.

Cell-cell interactions have been shown to be important in the regulation of neurotransmitter receptors at the mammalian neuromuscular junction, but relatively little is known about regulation of receptors on neurons. We are examining the expression of glycine receptors by rat spinal cord neuron developing in culture. Previous work using binding assays with a radio-labelled form of the glycine antagonist, strychnine, indicated that embryonic rat spinal cord neurons did not express strychnine binding sites before 5-6 days in culture. Presently, we are using electrophysiological techniques to examine responses to glycine at earlier stages. Rat spinal cord cells were dissociated at embryonic day 14 and placed in culture. Using the whole-cell patch clamp configuration we examined the response of the neurons to the application of glycine and the sensitivity of this response to strychnine blockade. Initial results demonstrated the presence of glycine activated currents after 2-3 days in vitro; that is 2-3 days before strychnine binding sites were detected. The currents exhibited a reversal potential near the chloride equilibrium potential, suggesting that chloride ions are the charge carriers as with conventional glycine receptors. These glycine-activated currents were not blocked by strychnine at a concentration of 1  $\mu$ M. The observation of strychnine-insensitive responses to glycine is consistent with recent findings from Becker et al. (EMBO J. 7:3717, 1988), which suggest the existence of a strychnine-insensitive neonatal isoform of the glycine receptor. The present results suggest that expression of these neonatal receptors by developing spinal cord neurons in culture precedes expression of the adult isoform by at least 2-3 days. (Supported by NIH NS29657 and NSF 8808506 to PSJ and NS 24895 to RBL).

GABA, RESPONSES AND ASSOCIATED CALCIUM ELEVATIONS ARE PREFERENTIALLY ELIMINATED IN POSTNATAL RAT SPINAL CORD NEURONS BY SHORT TERM CULTURE. M.K. Walton, A.E. Schaffner, and J.L. Barker. Lab. of Neurophysiology, NINDS, NIH, Bethesda, MD 20892.

GABA<sub>A</sub> receptor activation has previously been shown to produce depolarizations in spinal cord neurons dissociated from rat embryos, and these depolarizations are associated with an increase in intracellular calcium. We have examined GABA, responses in spinal cord neurons dissociated from postnatal (PN) rat pups using fluorescent dyes for either membrane potential (MP) (oxonol) or calcium (fura-2). Responses by GABA, receptors were probed for by bath perfusate addition of muscimol (2µM) and non-NMDA glutamate receptors by kainate (40uM). Tetanus toxin staining was used to identify cells as neurons.

Acutely examined cells revealed the presence of both muscimol and kainate membrane potential responses on the cell bodies of the majority of cells, in similar percentages at embryonic day 17 (E17) and PN days 0, 7, 14. The responses to both muscimol and kainate were depolarizing in acutely examined cells. After 1 day in culture E17 cells continued to show depolarizing responses to both ligands. The PN cells cultured 1 day showed progressive elimination of GABA<sub>A</sub> responses in cells from successively older PN ages, declining to none in PN14 cells, while kainate responding percentage showed only a small decrease. Calcium responses to the muscimol depolarization showed a change with developmental age of the cells. PN cells showed a Ca2+ rise to a peak and decline towards baseline during the 2-3 min. exposure to muscimol, while embryonic derived neurons showed sustained Ca24 elevation. This was paralleled in the MP recordings by many PN neurons showing a transient depolarization to muscimol, more pronounced when Cl was changed to produce stronger depolarization. These results indicate that neurons from PN spinal cord eliminate the GABA<sub>A</sub> response as measured by oxonol or fura-2 preferentially over the kainate response when cells are held in culture for 1 day.

### 265.2

GLYCINE- AND GABA-ACTIVATED CURRENTS IN MOTONEURONS OF DEVELOPING RAT SPINAL CORD.

B-X. Gao\*, and L. Ziskind-Conhaim. Dept.

Physiol. and Ctr. Neurosci., Univ. of Wisconsin, Madison, WI 53706.

Motoneuron responses to both glycine and GABA decrease during embryonic development. However, at all ages GABA-induced membrane depolarization is significantly larger than that induced by glycine, although both amino acids generate a similar decrease in membrane resistance (Wu and Ziskind-Conhaim, Soc. Neurosci., 1991, 17:88). To further characterize these changes, and determine the ionic mechanisms underlying the potentials induced by glycine and GABA, whole-cell voltage-clamp recordings were done in thin slices of spinal cords of embryonic rats. In motoneurons of Day 19-21 embryos, both glycine (2 mM) and GABA (1 mM) produced large inward currents (0.6-2 nA), that desensitized in the presence of the amino acids. At the peak current, there was a significant increase in membrane conductance. Our preliminary results show that glycineactivated currents reversed at about -7 mV, close to the estimated equilibrium potential for Cl<sup>-</sup> (-5 mV). However, the average reversal potential for GABA-mediated currents was +5 mV. The changes in glycine- and GABA-induced currents during embryonic development will be discussed. Supported by RCDA (NS01314) and NS23808 to LZ-C.

## 265.4

EFFECT OF GABA TREATMENT ON RAT CEREBELLAR GRANULE CELL CULTURE. H.Y. Kim, D.W. Sapp, R.W. Olsen, and N.J.K. Tillakaratne\*, A.J. Tobin, Departments of Biology and Pharmacology, UCLA, Los Angeles, California

To study the molecular basis of the often reported trophic activity of GABA, we have analyzed the effects of GABA and the GABA agonist THIP on primary cultures of rat cerebellar granule cells using quantitative PCR. These immature cerebellar granule cells display only the high affinity GABA binding sites in vitro. Exposure of these cells to GABA or THIP induces an increase in the levels of mRNAs encoding specific GABAA- receptor polypeptides including alpha 1 and Our preliminary data suggest that this increase is accompanied by the formation of low affinity GABA binding sites. Furthermore, this induction is abolished by bicuculline treatment in a dose dependent manner. These results suggest that GABA regulates the expression of genes encoding its own receptors and that the effect is mediated by GABAA-receptors. GABA may thus have a regulatory role in the development and cytodifferentiation of the central nervous system. (supported by NS22256).

GABA¢BENZODIAZEPINE RECEPTOR ½ SUBUNIT GENE EXPRESSION IN DEVELOPING NORMAL AND IN MUTANT MOUSE CEREBELLUM. <u>V. Luntz-Leybman\*</u>. <u>A. Frostholm and A. Rotter</u>. Department of Pharmacology, The Ohio State University. Columbus. OH 43210.

Ohio State University, Columbus, OH 43210.

The expression GABA<sub>2</sub>/BZ receptor γ<sub>2</sub> subunit mRNA was studied during normal development and in adult reeler (rl/rl), weaver (wv/wv), staggerer (sg/sg), lurcher (lc/lc) and Purkinje cell degeneration (pcd/pcd) mutant mouse cerebellum. In situ hybridization with a [35S] cRNA specific probe revealed a diffuse signal, which was present at birth, in the deep cerebellar nuclei and over Purkinje cells in the molecular layer. At postnatal day (P)5-7, labeling became more punctate in appearance as Purkinje cells began to form a monolayer at the interface of the granule cell and molecular layers. Autoradiographic grains were absent in the external germinal layer. Weak labeling was detected over the forming internal granular layer at P5-7, and reached moderate adult levels by P20. Punctate labeling over basket and stellate cells in the molecular layer became visible at the end of postnatal week two. In pcd/pcd and lc/lc mutants, in which Purkinje cells have degenerated, the hybridization signal was absent from the interface of molecular and granule cell layers. In sg/sg mice, where synaptic contacts with granule cells are not formed, no punctate labeling characteristic of Purkinje cells was detected. However, in rl/rl mutants, where all classes of cells are malpositioned, and in wv/wv mutants, in which many granule cells have degenerated, a strong hybridization signal remained over Purkinje cells. Our results suggest that Purkinje cells express the γ2 subunit prior to receiving GABAergic inhibitory input, and that γ2 expression in mutant animals is not affected by the absence of afferents.

### 265.7

DIFFERENTIAL DEVELOPMENTAL EXPRESSION OF GABAA/BZ RECEPTOR SUBUNIT mRNAS IN THE MURINE INFERIOR OLIVARY NUCLEUS. A. Frostholm\*, D. Zdilar, V. Luntz-Leybman, V. Janapati and A. Rotter, Department of Pharmacology, The Ohio State University, Columbus, OH 43210

The developmental expression of the  $\alpha_1, \alpha_6, \beta_{1-3}, \gamma_2$  and  $\delta$  subunits of the GABA\_/benzodiazepine (GABA\_A/BZ) receptor was examined in the murine inferior olivary nucleus by in situ hybridization with antisense cRNA probes. The postnatal appearance and distribution of [ $^3$ H]funitrazepam and [ $^3$ H]muscimol binding sites,  $\alpha$  and  $\beta$  subunit-specific ligands respectively, were also studied autoradiographically. The  $\beta_3$  subunit was transiently expressed in each of the subnuclei of the inferior olive: The signal was strong at birth, increased throughout postnatal week one, and rapidly declined thereafter to low adult levels. A similar pattern of labeling was observed with [ $^3$ H]muscimol. Low to moderate levels of  $\alpha_1$  subunit mRNA hybridization signal and [ $^3$ H]flunitrazepam binding sites were also present in inferior olivary neurons at birth, decreasing slowly to adult levels thereafter. Olivary neurons expressed low to moderate levels of  $\beta_1$ ,  $\beta_2$ , and  $\gamma_2$  mRNA throughout postnatal development, while  $\alpha_6$  and  $\delta$  mRNAs were absent. Our results suggest that the subunit composition of the GABA\_A/BZ receptor in inferior olivary neurons may change during development, and that this process may be related to the elimination of multiple climbing fiber innervation of cerebellar Purkinje cells, which also occurs during the second postnatal week.

## 265.9

MANY EMBRYONIC RAT CENTRAL NEURONS EXHIBIT SPONTANEOUS CIT CONDUCTANCE WHICH MAY INVOLVE GABA A RECEPTORS.

A.Y.Valeyev.\* R.A.Cruciani. G.D.Lange. V.Smallwood. R.Serafini and J.L.Barker. Lab. of Neurophysiology, Instrumentation and Computer Section, NINDS, NIH, Bethesda, MD, 20892, U.S.A. Whole-cell voltage clamp recordings with Cl-filled pipettes were performed on embryonic central neurons either acutely

Whole-cell voltage clamp recordings with CI-filled pipettes were performed on embryonic central neurons either acutely isolated or cultured for 1-15 days. In the majority of these cells recorded in 1μM TTX and 10 mM MgCl<sub>2</sub> the baseline current signal fluctuated at all potentials except 0 mV, which corresponds to the reversal potential for CI<sup>-</sup> ions. Spectral analysis of the fluctuations consistently showed a multi-component Lorentzian fit, suggesting that they were derived from exponentially distributed openings of CI<sup>-</sup> ion channels. Close application of medium consistently and reversibly decreased the holding current and membrane current variance. Spectral analysis of the baseline during application of bathing medium showed a relatively simple 1/f relationship between power and frequency. Presumably, the medium removed diffusible substances accumulating at the cell surface. Both application of antagonists at GABA<sub>A</sub> receptors (bicuculline, picrotoxin) and the steroid 5β-Pregnane-3β-OL-20-ONE mimicked the effects of saline on current and varience, strongly implicating GABA<sub>A</sub> receptor-coupled CI<sup>-</sup> channels in the baseline.

#### 265.6

ONTOGENY OF GABAA/BENZODIAZEPINE RECEPTOR  $\alpha_6$  mRNA EXPRESSION IN MOUSE CEREBELLUM AND COCHLEAR NUCLEI. <u>A. Rotter\*, L. Varecka and A. Frostholm</u>, Department of Pharmacology, Ohio State University, Columbus, OH, 43210

Although it has been suggested that granule cells of the cerebellum and cochlear nucleus are derived from a common precursor pool, the GABAA/BZ receptor  $\alpha_6$  subunit mRNA has been reported to be associated only with the granule cells of the adult rodent cerebellum. We have examined the expression of the  $\alpha_6$  subunit mRNA in the cerebellum and cochlear nucleus during postnatal development. A cDNA fragment, encoding a portion of the M3-M4 intracellular loop of the  $\alpha_6$  subunit, was generated by polymerase chain reaction; a  $[^{35}\text{S}]$ riboprobe transcribed from the cDNA fragment was used for in situ hybridization studies. In the adult mouse brain, a strong hybridization signal was observed over the granule cell layers of the cerebellum and the cochlear nuclei. The hybridization signal in the cochlear granule cells appeared towards the end of the first postnatal week, between postnatal days 6 and 7, coinciding with the appearance of labeling in the cerebellar granule cells. The intensity of the hybridization signal increased gradually, reaching a plateau at approximately postnatal day 25. Our results demonstrate that, in the mouse,  $\alpha_6$  subunit mRNA is not constrained to the cerebellum, and support the suggestion that both cerebellar and cochlear granule cells share a common cellular precursor. These data further suggest that granule cell precursors may be intrinsically programmed to acquire a specific form of the GABAA/BZ receptor, irrespective of their final location in the hindbrain.

### 265.8

IMMUNOCYTOCHEMICAL ANALYSIS OF THE EFFECTS OF DIAZEPAM IN UTERO ON CORTICOTROPIN RELEASING FACTOR NEURONS AND NORADENERGIC INPUTS OF PARAVENTRICULAR NUCLEUS IN ADULT RATS. Inglefield, J.R. 1\*, Bitran, D. 2\*, Olschowka, J.A. 1, and Kellogg, C.K. 2 Depts. of Neurobiology and Anatomy 1 and Psychology 2\*, University of Rochester, New York, 14642

Earlier work shows that prenatal exposure to diazepam (DZ) modifies the development of hypothalamic noradrenergic (NE) terminals in the rat. Such exposure markedly decreases NE levels, NE turnover rate, and depolarization-induced NE release in the hypothalamus (HYP) of adult offspring. The DZ exposure does not impact NE terminals in hippocampus, cortex, or cerebellum, suggesting selectivity. HYP NE affects stress-induced corticosterone (CS) release by influencing paraventricular nucleus (PVN) corticotropin releasing factor (CRF) neurons. Indeed, there is a reduction in stress-induced CS levels in adults exposed in utero to DZ. In the present work, we have studied the effects of DZ exposure on two HYP systems, namely NE and CRF, to determine any associated anatomical changes. Using ICC in conjunction with image analysis, we observed a marked reduction of dopamine-Bhydroxylase (DBH)-immunoreactivity(-ir) (for (nor)adrenergic terminals) within the PVN in adult rats prenatally exposed to DZ. Interestingly, DBH-ir in the subcommisural portion of the bed nucleus stria terminalis was also reduced. However, DBH staining in supraoptic nucleus did not exhibit any change. Preliminary evidence suggests a reduction in PVN CRF-ir as well. Overall, this gives anatomic evidence for the earlier findings in the HYP of adults prenatally exposed to DZ, and confirms a developmental alteration in HYP NE and possibly CRF systems when GABA/benzodiazepine receptors are targeted.

## 265.10

GABAB MEDIATED RESPONSES IN THE IN VITRO DENTATE GYRUS OF THE DEVELOPING RAT. D. S. Garant\*, S. L. Moshé, and P. K. Stanton. Departments of Neurology and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

We utilized the paired-pulse paradigm in hippocampal slices in vitro to examine the developmental profile of facilitation and suppression of dentate granule cell responses to perforant path stimulation. Reproducing previous results from our laboratory, slices from 15- and 30-day old immature rats demonstrated profound early paired-pulse suppression (interstimulus intervals up to 25 ms) and facilitation (intervals from 50 ms to 250 ms), followed by modest late paired-pulse suppression (intervals from 500 ms to 5 s). Perfusing slices from immature rats in medium containing either of the selective GABAB receptor antagonists, 2-hydroxy-saclofen (25  $\mu$ M) or CGP-35348 (100  $\mu$ M), only slightly facilitated the profile of paired-pulse responses between 100 ms and 5 s. These results suggest that in the dentate gyrus of immature rats, the contribution of GABAB receptors to the granule cell response to perforant path stimulation is much less than in adults.

COMPARATIVE DEVELOPMENT OF GLUTAMATE AND GABA IMMUNOREACTIVE NEURONALPOPULATIONS IN THE CEREBRAL CORTEX OF RAT FERRET AND MONKEY. D.L. Meinecke\* and M. L. Schwartz. Section of Neurobiology, Yale Sch. Med New Haven, CT 06510

Our previous studies in primate show that during development GABA is expressed very early in neurons of the cerebral cortex, prior to the formation of synaptic circuits, suggesting a potential trophic role. In contrast to the information known about GABA, little is known about the expression and distribution of excitatory transmitters in the developing brain. We address this question here using an antibody to glutamate (Arnel) to determine when during embryogenesis cortical neurons become immunopositive for glutamate in the rat, ferret, and rhesus monkey. Material from each of these species was taken through times of neurogenesis, cell migration, and

synapse formation.

Double immunolabeling in adults of each of these species revealed that GABA and glutamate are present in separate populations of cortical neurons. In the developing cortex specific GABA labeling can be seen in cells throughout the telencephalic wall at all embryonic ages, including the germinal neuroepithelium, migrating neurons, and the earliest born layers of the cortical plate. In contrast, glutamate immunoreactivity was not present in cells of the germinal zone, or migrating cells. Within the cortical plate glutamate positive cells were not found until far later ages than the first appearing GABA labeled cells at comparable cortical depths. Generally, the first appearance of glutamate positive cortical cells coincided with the ingrowth of major fiber tracts in each of these species. These results support the hypothesis that GABA may have a unique developmental role unrelated to its transmitter role in adult, whereas glutamate seems to increase in cortical to its transmitter role in adult, whereas glutamate seems to increase in cortical neurons after they attain their adult positions and connections, possibly reflecting the emergence of glutamate transmitter pools. Supported by NS 22807-06.

### 265.13

EXPRESSION OF GENES ENCODING GLUTAMIC ACID DECARBOXYLASE IN PLURIPOTENT STEM CELL LINES. G. Bain, T.P. Ramkumar, J. Cheng and D. Gottlieb\*, Department of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO The inhibitory neurotransmitter y-amino butyric acid (GABA) is synthesized by the enzyme glutamic acid decarboxylase (GAD). This

enzyme is encoded by two genes in the mammalian genome. Since the expression of GAD in the central nervous system is restricted to GABAergic neurons, it provides an excellent marker with which to analyze the mechanisms which regulate cell-type-specific gene expression in the

the mechanisms which regulate cell-type-specific gene expression in the brain.

The availability of cell lines which express the GAD genes would provide a powerful in vitro system for the analysis of their regulation. The P19 murine embryonal carcinoma cell line is potentially very useful for the analysis of neural gene control. These cells can be induced to differentiate into neurons, glia and fibroblasts by culturing them as aggregates in the presence of retinoic acid. We have therefore examined these cells for GAD gene expression using an RNase protection assay. We have found that both GAD genes are expressed in P19 cells. Undifferentiated cells contain low but detectable levels of GAD mRNA. After neural differentiation is induced, there is a substantial increase in expression for both genes. The presence of normal transcripts from both GAD genes in differentiated P19 cells has been confirmed by RNA blot analysis.

The observation that undifferentiated P19 cells express the GAD genes was somewhat surprising. To determine if this expression is a peculiarity of P19 cells, we analyzed their expression in undifferentiated mouse embryonic stem cells. Both GAD genes are expressed in these cells, although at significantly different levels. This result raises the possibility that GAD may play a role in early embryonic development.

Our data demonstrate that P19 cells inducibly express both GAD genes. They should therefore provide a useful system with which to study the mechanisms which regulate the expression of these two genes.

mechanisms which regulate the expression of these two genes.

## 265.15

DEVELOPMENTAL INCREASES IN N-METHYL-D-ASPARTATE RECEPTOR-STIMULATED CATECHOLAMINE RELEASE IN RAT BRAIN CORTEX AND HIPPOCAMPUS. L.M. Brown\*, Dept. of Pharmacology, Northeastern Ohio Universities College of Medicine, Rootstown, Ohio 44272.

Rootstown, Ohio 44272.

N-methyl-D-Aspartate (NMDA) receptor binding has been shown to exhibit transient increases during postnatal development in rat brain (Tremblay et al., Brain Res. 461 (1988) 393-396). This study was performed to examine postnatal alterations in NMDA receptor-stimulated catecholamine release. The NMDA receptor-stimulated catecholamine release assay has been shown to be a good indicator of NMDA receptor-mediated functional activity (Gonzales and Woodward, PET. 253 (1990) 1138-1144).

Perio dicinc (360um) from the contract and hispocompus of male and formula

Brain slices (350µm) from the cortex and hippocampus of male and female Sprague-Dawley rat pups of varying ages (1, 7, 14, and 21 days) were used. The slices were washed and incubated in oxygenated Krebs-Ringers bicarbonate buffer and allowed to accumulate [3H]-Norepinephrine ([<sup>3</sup>H]NE). After uptake of the label, the slices were washed again and aliquots placed into baskets which were transferred through a series of vials containing varying concentrations of NMDA (10, 50, 100, 500 and 1000 hM). Percent [3H]NE overflow was calculated and logistic parameter curve fitting performed using ALLFIT (Delean et al., Am. J. Physiol. 235 (1978)

E97-E102).

In the cortex and hippocampus NMDA resulted in a concentration-dependent increase in [<sup>3</sup>H]NE overflow. The maximal response to NMDA increased with age (1, 7, 14 and 21 days). The cortical responses were (1.55±0.15, 3.67±0.22, 2.94±0.22 and 4.61±0.30) respectively. The hippocampal responses were (1.93±0.19, 2.97±0.12, 3.66±0.15 and 5.31±0.22) respectively. The EC<sub>50</sub> values also increased with age in both brain regions. These results indicate that significant developmental alterations in NMDA extinuited (3.1M) Exercisely see the state of the contractions. in NMDA-stimulated [3H]NE overflow are observed postnatally.

NEURONS DERIVED FROM P19 CELLS CONTAIN L-GLUTAMATE, GABA AND THEIR RECEPTORS. PA MacPherson 1, DSK Magnuson 2, DJ Morassutti 1, WA Staines 3\*, KC Marshall 2, and MW McBurney 1. 1Depts Med & Biol, 2Phys & Anat/Neurobiol, Univ. Ottawa, Ottawa, Ontario Canada K1H 8M5 P19 cells, a pluripotential embryonic line, can be induced to differentiate with retinoic acid (RA) into a mixed population of both neurons and glia. The neuronal cells obtained are immunoreactive for the NeuN antigen, a characteristic of neurons of the CNS. Immunofluorescence has also been used to identify a variety of neurotransmitters within these cultures, the majority being either L-glu, or GABA. Glutamate immunoreactivity appears within the first 10 days following RA treatment and is found regardless of whether L-glu is contained within the culture medium. When treated with RA, P19 cells both in culture and when grafted into the striata of young adult rats demonstrate an electrophysiological maturation of their membranes. In response to L-glu, intracellular recordings from grafted cells show depolarizations within 10-14 days post RA. These depolarizations are Mg<sup>2+</sup> sensitive, are reduced by AP5 and blocked by kynurenate, suggesting the presence of both NMDA and non-NMDA excitatory amino acid receptors. In addition, more mature grafts are often observed to develop rhythmical spontaneous synaptic activity with a pharmacological sensitivity to that of exogenous glutamate.

### 265.14

SIGNAL TRANSDUCTION MECHANISMS SUBSERVING ACTIVITY-DEPENDENT RELEASE OF GROWTH-PROMOTING PROTEOGLYCANS BY HIPPOCAMPAL NEURONS. M. Sugiura and K.E. Dow\*, Queen's University, Dept. of Pediatrics, Kingston, Ontario, Canada,

Excitatory amino acid (EAA) neurotransmitters are involved in activity-dependent neuronal growth during development and in enduring changes in synaptic efficacy in the hippocampus. Neurons produce and release proteoglycans (PGs) which are known to promote neuronal growth and cell adhesion. The present studies were designed to analyze the regulation of PG release by EAA receptor activation of neurons in vitro. Neuron-enriched cultures were established from dissociated hippocampus of 19 day fetal rats. [3H]leucine and [35SO<sub>4</sub>]-labelled PGs were extracted and isolated using ion-exchange chromatography. Exposure of neurons to the EAA agonist glutamate (100 µM) resulted in an increase in PG release during the 5 minute exposure period. The glutamate effect was partially inhibited by the N-methyl-Dexposure period. The glutamate effect was partially minimized by the N-illerity aspartate (NMDA) receptor antagonist D-2-amino-5-phosphonovaleric acid (AP5) and the metabotropic receptor antagonist 2-amino-3-phosphonopropionic acid (AP3). The effect was completely antagonized by the combination of AP5, AP3 and the non-NMDA receptor antagonist 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX). Glutamate-induced neuronal PG release was inhibited by sphingosine and the nitric oxide synthase inhibitor, N-nitro-L-arginine. EAA-stimulated activity-dependent responses of thase inhibitor, N-nitro-L-arginine. EAA-stimulated activity-dependent responses of neurons which may influence exquisite connectivity in development may be mediated by PGs in the extracellular milleu. By virtue of their binding interactions in the extraneuronal milieu, neuronal PGs with growth modulatory activity may be both necessary and sufficient for enduring changes in synaptic efficacy. The release of these PGs is regulated by both ionotropic (NMDA and non-NMDA) and metabotropic EAA receptor activation. The signal transduction mechanisms subserving EAA-stimulated PG release may involve protein kinase C and/or Ca<sup>2+</sup>-calmodulin type II kinase. Nitric oxide may be a diffusible messenger responsible for PG release

## 265.16

NEUROCHEMICAL ANALYSIS OF DIFFERENTIATION IN THE LA-N-5 HUMAN NEUROBLASTOMA CELL LINE. B. Anton\* C. Evans+ J. Hu. E. Innauer, N.T. Maidment+, J. Talvenheimo# and R.E. Weiss. Depts. of Physiology and Psychiatry<sup>+</sup>, BRI, UCLA, Los Angeles, CA 90024 and Amgen Inc<sup>#</sup>. Thousand Oaks, CA 91320.

The effects of the differentiating agents retinoic acid (RA) and nerve growth factor (NGF) on neurotransmitter content and release were studied on the LA-N-5 human neuroblastoma cell line. Cells were cultured in RPMI + 10% FCS medium and plated on different substrates. Both NGF and RA induced extensive neurite formation and a decrease in proliferation when cells were plated on collagen or laminin. Cells plated on plastic showed pronounced morphological changes in response only to RA. Amino acids and catecholamines were assayed by HPLC with fluorometric and electrochemical detection respectively. Cells were exposed entially to normal physiological saline (PS) and PS containing 50mM K+ for 1 sequentially to normal physiological saline (PS) and PS containing S0mM K\* for h. K\*-induced release of glutamate, glycine and taurine was upregulated after either RA or NOF treatment independent of the plating substrate. Total cell content of these transmitter amino acids was much larger than the apparent releasable pools. These results are compared to our findings on sodium channel density which show similar upregulation (~ 300 %) by both NOF and RA independent of the plating substrate of the cells. These data suggest that LA-N-5 cells may be useful in the study of the induction of neuronal differentiation in vitro.

CELL VOLUME CHANGES AND TAURINE RELEASE IN BRAIN SLICES INCUBATED IN MEDIA OF DIFFERENT IONIC COMPOSITIONS. S.S. Oja and P. Saransaari. Tampere Brain Res. Ctr, Dept. Biomed. Sci., Univ. Tampere, Finland.

In the mammalian brain taurine has been claimed to act as osmolyte which is released predominantly from astrocytes upon cell swelling. We endeavored to investigate the relation of cell volume changes to taurine release in mouse cerebral cortical slices superfused with media of different ionic compositions. The release of taurine was enhanced in hypoosmotic media and inhibited in hyperosmotic media. The release was also enhanced, however, by a partial or total omission of Na+ or Cl- and by high K+ concentrations. An enhancement of release was obtained in media in which Cl was replaced by a relatively permeant organic anion acetate and in which there occurred massively intracellular swelling in the slices. A marked stimulation was discernible also in media in which an impermeant anion gluconate was used as replacer and in which there occurred no or only negligible swelling of even intracellular shrinking. Most experimental conditions which enhanced the release simultaneously also inhibited the influx of taurine. In view of the low capacity of both low- and high-affinity transport systems of taurine, an inhibition of reuptake may not, however, constitute the sole explanation of the apparent stimulation of release under these conditions. Since a positive correlation between the release of taurine and changes in cell volumes obtains only under certain isolated experimental conditions, we infer that taurine is not released from slices only as a response to cell swelling and may not act as a major osmolyte in the mammalian brain. (Supported by the Emil Aaltonen Foundation, Finland).

### NERVE GROWTH FACTOR III

### 266.1

THE MECHANISM OF NERVE GROWTH FACTOR-INDUCED LONG-TERM HETERODOWN REGULATION OF THE EPIDERMAL GROWTH FACTOR RECEPTOR IN PC12 CELLS. M. Oshima, D. Shavit, D. Fink\*, P. Lazarovici, and G.Guroff Section on Growth Factors, NICHD, NIH, Bethesda, MD 20892 and Department of Pharmacology, Hebrew University, Jerusalem, Israel

Differentiation of PC12 cells with nerve growth factor (NGF) produces a sympathetic neuron-like phenotype, which is accompanied by a cessation of cell division. During the differentiation, the epidermal growth factor receptor (EGFR), measured by both binding and EGF-induced phosphorylation, on the cells decreased by 70-90%. Northern blotting indicated that neither of the two EGFR mRNAs (13 and 4.6 kb) were decreased. Western blotting showed that the EGFR protein (170 kD) decreased in proportion to the decreased binding of EGF. Labeling studies showed that NGF had no effect on the rate of degradation of the EGFR. Pulse-chase experiments revealed a series of biosynthetic intermediates leading to the complete EGFR, and, in NGF-treated cells, a failure of the 160 kD EGFR precursor to mature into the 170 kD EGFR protein. The data suggest that the NGFinduced down-regulation of the EGFR is due, at least in part, to an inhibition of some of the final post-translational modifications of the protein, probably at the level of glycosylation.

## 266.3

p210-ras Mediates Nerve Growth Factor Signal Transduction in Embryonic Sensory Neurons and PC12 Cells. N. F. L. Ng and E. M. Shooter. Department of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305.

During their development, sensory and sympathetic neurons acquire a dependence for nerve growth factor (NGF) in order to maintain their differentiated state. Little is known, however, about the mechanism by which NGF transduces its signal in these neurons, with much of the knowledge extrapolated from studies using the NGF-responsive pheochromocytoma PC12 cell line. We investigated the role of cellular p21c-ras in mediating the NGF signal in embryonic sensory neurons and PC12 cells. Changes in the levels of active p21c-ras in response to NGF were analysed, based on the ratio of the levels of active GTP-bound ras to inactive GDP-bound ras. Following treatment with NGF, 32P-labelled E9 chick dorsal root ganglion and PC12 cells were lysed and immunoprecipitated with anti-ras antibody (Y13-259), guanine nucleotides were eluted, and the GTP and GDP levels were separated and quantitated. In sensory neurons, NGF stimulated a 2-3 fold increase in the levels of ras-GTP within 5 min, with these levels remaining elevated, though at a lower activation state of 1.6-fold of control by 60 min. In PC12 cells, MGF stimulated a 3-4 fold increase in active ras-GTP within 1 min, with the activation remaining elevated at these levels for up to 60 min. In the neurons, a minimum concentration of 20 ng/ml NGF was required to obtain maximal ras activation within 5 min, while in PC12 cells, a minimum of 10 ng/ml NGF was required. At lower concentrations of NGF, ras activation in both sensory neurons and PC12 cells increased slowly with time, with an apparent plateau by 60 min. At this low concentration of NGF, neither sensory neurons nor PC12 cells attained the maximal activation seen with the high concentrations. Treatment of both sensory neurons and PC12 cells with the protein kinase inhibitor K252a inhibited activation of ras in response to NGF. These results demonstrate the involvement of p21c-ras in mediating NGF signal transduction in embryonic sensory neurons and

THE REGULATION OF NERVE GROWTH FACTOR-STIMULATED CALCIUM UPTAKE BY INTRACELLULAR CALCIUM LEVELS IN PC12 CELLS. B. Nikodijevic, D. Nikodijevic-Kedeva, A. Kozak, E. Yavin, and G. Guroff. Section on Growth Factors, NICHD, NIH, Bethesda, MD 20892 and Department of Neurobiology, The Weizmann Institute, Rehovot, Israel.

Nerve growth factor (NGF) stimulates the uptake of calcium and raises intracellular calcium levels in PC12 cells. The stimulation of uptake is maximal after 3-5 minutes of treatment with nerve growth factor and is usually on the order of 50%. The data suggests that the NGF-sensitive calcium channel is different than the L-type calcium channel and the other major calcium channels in PC12 cells. Introduction of phosphatases into permeabilized PC12 cells indicates that the activation of this NGF-sensitive channel is due to a phosphorylation of one of the channel proteins. When calcium levels were lowered by pre-incubation of the cells with nickel, the effect of NGF on calcium uptake was enhanced. Conversely, when intracellular calcium levels were raised by pre-incubation of the cells with high potassium, the effect of NGF on calcium uptake was decreased. Since intracellular calcium levels fluctuate with cell density and change when cells are placed in suspension, these data may indicate why previous reports in this area have been so inconsistent. In the light of recent studies on the enhanced survival of neurons when their intracellular calcium levels have been raised, the actions of NGF on calcium levels may be relevant to the ability of NGF to promote the survival of sympathetic and sensory neurons.

## 266.4

PTP-P1, A NOVEL PROTEIN TYROSINE PHOSPHATASE DOWN-REGULATED BY NGF. M.-G. Pan. T. Floric\*. C. Rim, P.J.S. Stork. Vollum Institute and Department of Cell Biology and Anatomy, Oregon Health Sciences University, Portland OR 97201.

Tyrosine phosphorylation of proteins in multicellular organisms is mainly associated with the response of cells to stimuli mediated by receptors for hormone and growth factors and plays an important role in signal transduction and cellular differentiation. Tyrosine phosphorylation is transient and is thought to depend on the activity of both protein tyrosine kinases and protein tyrosine phosphatases. NGF, a neurotrophic factor, can stimulate tyrosine phosphorylation and neurite outgrowth of the rat pheochromocytoma cell line PC-12 trough is receptor trk, a proto- oncogene with tyrosine kinase activity. We repot here the cloning and the characterization of a cDNA from PC-12 cells encoding a novel protein tyrosine phosphatase, PTP-P1. This phosphatase correspond to a 6.2kb transcript and is down-regulated upon NGF-induced differentation of PC-12 cells. The down-regulation of PTP-P1 may be required for the induction of neurite outgrowth by NGF.

MULTIPLE SIGNAL TRANSDUCTION PATHWAYS LEAD TO INDUCTION OF C-FOS EXPRESSION BY NGF IN PC12 CELLS. H. Oi\*, R. C. Armstrong and S. Halegoua. Dept. of Neurobiology and Behavior, SUNY at Stony Brook, Stony Brook, NY 11794

In PC12 cells the  $c_2$ -fos gene can be transcriptionally stimulated by nerve growth factor (NGF) or by agents which activate distinct second messenger pathways involving A-kinase, C-kinase and Ca<sup>2+</sup>/calmodulin kinase. Moreover, the A-kinase and C-kinase pathways have been implicated in the mechanims of NGF actions. Recently, the tyrosine kinase Src, the GTP-binding protein Ras and the serine/threonine kinase Raf have also been shown to play critical roles in mediating NGF signals with the order of Src -> Ras -> Raf. roles in mediating NGF signals with the order of Src -> Ras. -> Raf. To better understand the second messanger systems which regulate the c-fos gene in response to NGF in PC12 cells, we have developed a unique approach which uses a pathway-specific reinduction paradigm. Results using this experimental paradigm suggest that two thirds of the c-fos induction by NGF involve the C-kinase pathway. The remaining one third of the gene induction is mediated by a poyel pathway inducement of both A-kinase and Cmediated by a novel pathway independent of both A-kinase and C-kinase. The roles of Src and Ras in pathways mediating NGFinduced c-fos gene expression are being elucidated using PC12 induced *c-fos* gene expression are being efficiated using PC12 sublines transfected with *v-src* or activated *ras* cDNA or cDNA encoding a dominant negative *ras* mutant. The relative contributions of Src and Ras to the C-kinase pathway and the novel pathway will be presented. (Supported by NIH grant NS18218).

### 266.7

PHARMACOLOGICAL MANIPULATION OF NGF/PROTEIN KINASE C INTERACTIONS IN PC12 CELLS E. J. Martin\* and E. M. Meyer, Department of Pharmacology and Therapeutics, College of Medicine, Univ. of Florida, Gainesville, FL 32610

Protein kinase C (PKC) is a phospholipid-dependent, calcium- and diacylglycerol-activated kinase that preferentially phosphorylates serine and threonine residues. In the brain, PKC is involved in gene transcription, diacylglycerol-activated kinase that preferentially phosphorylates serine and threonine residues. In the brain, PKC is involved in gene transcription, neurotransmitter release, synaptic plasticity and receptor transduction.

Consequently, this enzyme has been implicated in the second messenger pathways underlying trophic events in the brain, including those triggered by NGF administration. However, to what extent PKC is involved in the events that take place secondary to NGF binding its receptor remains unclear. We therefore designed experiments to study the effects of NGF and phorbol ester applied at different concentrations and for different periods of time. PC12 cells are a commonly accepted model system for studying the complex biological transduction processes initiated by NGF. Cultures of PC12 cells were assayed for PKC activity by permeabilization with low concentrations of digitonin. By permeabilizing the cells, it is possible to introduce a specific substrate peptide and phosphate source [(32P) ATP] into the cells. These components interact with the intracellular environment in such a way that PKC-phosphorylated substrate can be collected on phosphocellulose filters and quantified. We demonstrated in preliminary studies that 10 nM phorbol 12-myristate 13-acetate (PMA) was able to stimulate PKC activity within 15 minutes. This stimulation was attenuated with PKC inhibitor peptide [PKC (19-36)]. NGF at a concentration of 100 ng/ml, but not 50 ng/ml, was also able to stimulate enzyme activity. NGF in combination with PMA produced a thirty percent increase in PKC activity over that of NGF alone. These studies are being extended by measuring the role of PKC activity in other indices associated with cell proliferation and differentiation. cell proliferation and differentiation.

NGF CORRECTS THE LOSS OF DA UPTAKE ACTIVITY IN EMBRYONIC MESENCEPHALIC CULTURES TREATED WITH

A.Dalia', N.H.Neff<sup>13</sup> and M.Hadjiconstantinou<sup>1,23</sup>
Depts of Pharmacology and of Psychiatry and the Neuroscience
Program<sup>3</sup>. The Ohio State University College of Medicine, Columbus, OH

Nerve growth factor (NGF) promotes the development and survival of sympathetic and sensory neurons in the periphery, however, it is believed that it is neurotrophic for cholinergic but not catecholaminergic neurons of brain. We found that NGF 7S or 2.5S partially restores the biochemistry, morphology and pharmacological responsiveness of striatal dopaminergic neurons in mice treated with MPTP. MPP<sup>+</sup>, the neurotoxic metabolite of MPTP, decreases dopamine (DA) uptake activity in embryonic mesencephalic cultures. We have used mbryonic (E 15) mesencephalic cultures to investigate the action of NGF on dopaminergic parameters. Cultures were treated with MPP<sup>+</sup>, 3μM, for 24 hr, then NGF 2.5S was added to the medium and DA uptake assayed 22 days later. NGF restored DA uptake activity in a dose-dependent manner, with about 500 ng/ml NGF 2.5S returning transport activity to "aear control values. Pretreatment or cotreatment with NGF did not prevent the MPP" induced neurotoxicity. Moreover, NGF partially restored the number and the morphology of TH-immunopositive cells in MPP treated cultures. NGF had no effect on the above parameters in control cultures. We postulate that injury induces dopaminergic neuron to become sensitive to NGF.

#### 266.6

RAPID MEASUREMENT OF RESPONSES BY PC12 CELLS TO NERVE GROWTH FACTOR (NGF) USING THE CYTOSENSORTM MICROPHYSIOMETER. S. Pitchford. B.S. Glaeser\* & K. De Moor, Molecular Devices Corp., Menlo Park, CA 94025.

Study of cellular responses to growth factors typically involves monitoring either signal transduction activation or changes in cell number or morphology in the continued presence of the growth factor of interest. Using the Cytosensor Microphysiometer System to measure alterations in cellular metabolic activity (by monitoring extracellular acidification of a low-buffered RPMI media bathing cells), we have demonstrated early responses of PC12 cells to NGF. The factor stimulated metabolic activity in an apparent dose-dependent fashion between 0.1 and 100ng/ml NGF. The cells were stimulated by only a brief (12 minute) exposure to NGF with extracellular acidification rates reaching a peak between 10 and 20 minutes after the initial introduction of NGF and then declining over the subsequent 2-3 hours. The response to NGF was abolished by pre-incubation of the cells with 25µg/ml genestein, a tyrosine kinase inhibitor, suggesting the involvement of this signal transduction pathway in the metabolic response of PC12 cells to NGF.

### 266.8

A PROTO-ONCOGENE SIGNALLING PATHWAY MEDIATES

A PROTO-ONCOGENE SIGNALLING PATHWAY MEDIATES NGF-INDUCED GENE EXPRESSION EVENTS IN PC12 CELLS. G. D'Arcangelo\* and S. Halegoua, Dept. of Neurobiology and Behavior, S.U.N.Y. at Stony Brook, Stony Brook, N.Y. 11794. The rat pheochromocytoma cell line, PC12, is a useful model system for studying the molecular basis of NGF actions. Treatment of these cells with NGF results in the elaboration of a sympathetic neuron-like phenotype, including the extension of neuritic processes and the expression of several genes, some of which encode specific neuronal markers. The signal transduction mechanisms that follow the neuronal markers. The signal transduction mechanisms that follow the binding of NGF to its receptor are still largely unknown, however a sequence of proto-oncogene activities including the NGF receptor trk, src tyrosine kinase, ras GTP-binding protein and raf serine/threonine kinase have been implicated in the induction of neurite outgrowth.

NGF induces an exquisite temporal pattern of gene expression events which provide a convenient assay for the different signal events which provide a convenient assay for the different signal transduction pathways emanating from the growth factor receptor. In this study, we have used PC12 sublines expressing activated, oncogenic forms of src, ras or raf and sublines expressing dominant inhibitory forms of these proteins to dissect the signal transduction pathways which induce changes in gene expression. Our results pannways which induce changes in gene expression. Our results describe four classes of gene induction events which identify branchpoints in the NGF signal transduction pathway to gene induction. These results indicate parallel processing from the protoncogene components of the NGF signal transduction machinery. (Supported by NIH grant NS18218 to SH and predoctoral fellowship from Hoffman La Roche to GD).

## 266.10

KAINATE RECEPTOR MEDIATED DIFFERENTIAL REGULATION OF BRAIN-DERIVED NEUROTROPHIC FACTOR mRNA AND PROTEIN

C Wetmore\*, AJ Bean, T Hökfelt, L Olson

Dept. of Histology & Neurobiology, Karolinska Institute, Stockholm, Sweden 10401

BDNF and NGF mRNA have been reported to be increased after seizures induced by electrolytic lesions as well as after injections of the glutamate agonist, kainic acid. However, the receptor subtype specificity of neurotrophin regulation and whether this upregulation results in a concomitant increase in trophic factor protein has yet been determined

In the present study we report specific regulation of BDNF mRNA and protein in vivo exclusively via the kainate and not the NMDA receptor. Systemic injection of kainic acid (12 mg/kg i.p.) resulted in a dramatic increase in BDNF as well as NGF mRNA throughout several hippocampal and cortical areas. No changes in BDNF mRNA or protein were detected after intracerebral injection of NMDA (1 nmol). The kainate-induced upregulation of BDNF was completely blocked by the kainate receptor antagonist DNQX and not affected by the the NMDA antagonist AP7. Interestingly, differential modulation of BDNF protein was detected

with BDNF peptide antibodies. Little change in BDNF immunoreactivity (BDNF-IR) was noted 6 hr post injection. At 8 hr postlesion, increased BDNF-IR was detected in hippocampal pyraminal and granule cells. At 12 and 24 hours postlesion, increased BDNF-IR was noted in CA1, CA2, and in piriform cortex. Significant cell death was noted in CA3, and reduced BDNF-IR noted in the dentate granule and hilar cells. No significant change was noted in cingulate, temporal and parietal cortices. These data indicate that while there appear to be changes in levels of BDNF protein after kainic acid perturbation, these changes are not as widespread nor do they show the same magnitude and temporal modulation as noted for BDNF mRNA.

CLONING OF CHICK BDNF: TECTAL FACTOR AND POTENTIAL ALTERNATE PRECURSORS . J. M. Voci and T.H. Large\*, Dept.

ALTERNATE PRECURSORS . J. M. Yoo; and T.H. Large\*. Dept.
Neuroscience, Case Western Reserve University, Cleveland, Ohio 44106-4975.
Retinal ganglion cell (RGC) survival is dependent on factor(s) from the optic tectum beginning at age E10-11. In vitro, BDNF has been shown to support RGC survival and stimulate process outgrowth, suggesting that BDNF may be a tectal-derived factor for developing RGCs. As a first step in examining in vivo the BDNF-dependence of RGCs, we have cloned the chick BDNF gene.

A PCR amplified fragment of chick BDNF was used to screen a chicken cosmid library under high stringency conditions. Two BDNF clones were identified, verified by PCR amplification and a cosmid fragment coding for the short BDNF precursor was subcloned and sequenced. Primary sequence analysis reveals that BDNF is extremely well conserved among mammalian, amphibian, and avian species. The mature chicken factor (119 aa) contains only 7 amino acid differences compared to mammalian BDNF. The precursor coding region is almost as well conserved; chick BDNF, like human BDNF, lacks a 2-5 aa insertion at position -72 that is seen in other mammalian species. For mouse NGF, alternate splicing of upstream exons containing start ATGs gives rise to short and long precursor proteins. Consistent with the possibility of long BDNF precursors, the chick gene possesses a splice acceptor site 21 bp upstream from the start ATG and the 7 upstream amino acids are identical to those in mammalian BDNF genes. A potential splice acceptor site 12 bp upstream in mammals is absent in chicken, in agreement with use of the first, but not second, splice site in mammalian BDNF cDNA clones.

Northern analysis reveals relatively low expression of BDNF in the embryonic geting but relatively high expression in the notice texture with the description.

Northern analysis reveals relatively low expression of BDNF in the embryonic retina but relatively high expression in the optic tectum, with levels reaching a maximum by E11-13. These results argue that BDNF is unlikely to be an "intrinsic" factor regulating early retinal development, but is expressed within the optic tectum at an appropriate time to regulate the target-dependent survival of RGCs. Expression of chicken BDNF in baculovirus will be used to generate the active factor and antibody reagents necessary for directly testing BDNF actions in vivo.

MITOMYCIN C DECREASES EXPRESSION OF NERVE GROWTH FACTOR AND ITS RECEPTOR IN SEAD CELLS. E.L. Imperato\*, J.T. Hansen, R. Loy^ and M.F.D. Notter. Department of Neurobiology and Anatomy, and ^Department of Neurology, University of Rochester School of Medicine and Dentistry, Rochester, NY 14642.

Rochester, NY 14642.

SEAD cells were developed by infecting primary rat Schwann cells using a retroviral vector containing the 128 E1A gene. SEAD cells expressed the characteristic Schwann cell markers S-100, nerve growth factor receptor (NGF-rec), and insulin-like growth factor-1 (IGF-1) as detected immunocytochemically. NGF protein also was observed in SEAD cell lysates by ELISA. Mitomycin C (M-C), an antimitotic agent, decreased NGF-rec immunoreactivity and NGF protein expression in SEAD cells; however, there was no effect on IGF-1 immunoreactivity. M-C arrested SEAD cell proliferation but this effect was completely M-C arrested SEAD cell proliferation but this effect was completely reversible following removal of M-C and a brief recovery period. Decreased mitosis with a decrease in NGF-rec immunoreactivity and NGF protein expression in SEAD cells mimics Schwann cells in vivo during later stages of peripheral nerve regeneration. However, Schwann cell proliferation and expression of NGF and its receptor may not be directly related. These are the first observations of a reversible M-C action. Supported by AG09231 (RL), EY06947 (MFDN), and NS25778 (JTH).

## RECOMBINANT HUMAN NGF SIGNIFICANTLY ENHANCES THE SURVIVAL OF CHROMAFFIN CELLS IN VITRO.

M.A. Tokiwa\*, L.C. Doering, J.W. Winslow<sup>8</sup> and L.E. Burton<sup>8</sup>. Division of Anatomy, McMaster University, Hamilton, Ontario, CANADA L8N 3Z5 and Genentech Inc., South San Francisco, CA 94080, U.S.A.

Based on the long term survival of transplanted chromaffin cells in peripheral nerve (Doering and Tokiwa, 1991; Brain Res. 551:267) we set out to systematically evaluate the role of the constituent peripheral nerve cells and selected trophic factors on chromaffin cell survival in vitro.

Enriched adrenal medulla (AM) cell cultures from 5-7 day old Wistar rat pups were established and grown in 24 well plates by the method of Unsicker et al., 1978; PNAS 75:3498. After 1 week in vitro, the AM cells were identified by tyrosine hydroxylase immunohistochemistry and counted.

Co-cultures of Schwann cells/fibroblasts plus chromaffin cells promoted AM cell survival (P < 0.001). Conditioned medium from 4 day-old Schwann cell/fibroblast cultures, when added to the AM cultures, also enhanced survival (P < 0.001) when compared to the controls.

Recombinant human (rh) factors including neurotrophins (NGF, BDNF) and basic fibroblast growth factor (bFGF) were added alone or in combinations to the enriched AM cell cultures at concentrations of 25, 50, 100 and 1000 ng/ml of medium. Only rhNGF at concentrations  $\geq$  50 ng/ml had a significant (P < 0.05) effect on the survival of the AM cells. No other rh trophic factor, alone or in combination exceeded the level of survival obtained with the rhNGF added alone.

At the present time, of the trophic factors tested, rhNGF appears to be the factor that is most critical to chromaffin cell survival in vitro.

ALPHA-2-MACROGLOBULIN, A CARRIER OF NEUROTRANSMITTERS, FORMS AN INHIBITORY COMPLEX INTERFERING WITH NGF-DEPENDENT NEURITE OUTGROWTH AND SURVIVAL OF CNS NEURONS. D.J. Liebl\* and

NEURITE OUTGROWTH AND SURVIVAL OF CNS NEURONS. <u>D.J. Liebl\* and P.H. Koo.</u> Northeastern Ohio Univ. College of Med., Rootstown, OH 44272. Alpha-2-macroglobulin ( $\alpha_z$ M) is a rather ubiquitous protein in extracellular fluids of mammals including CSF. We have recently demonstrated that methylamine-activated  $\alpha_z$ M can inhibit neurite outgrowth and damage embryonic sensory neurons (P.H. Koo and D.J. Liebl\* (1992) J. Neurosci. Res. 31:678-692). The objective of this study is to determine whether  $\alpha_z$ M can combine with monoamine-neurotransmitters to also produce reutific inhibitors, and evere demander of the methods and the methods in the complexes. neurite-inhibitory and neuron-damaging complexes, and the mechanism of action of serotonin-activated  $\alpha_2 M$ . Our results demonstrate that  $\alpha_2 M$  can form stable complexes with serotonin (5HT), histamine, and catechol-amines, and the resultant complexes produced all can inhibit NGF-promoted neurite outgrowth by embryonic chicken dorsal root ganglia.  $\alpha_2 M$  (1.4  $\mu$ M) can absorb about 55-65% of the total 5HT (4-8 nM) in solution. At much higher absorb about 9-5-65% of the total SHT (4-6 Init) in Solution. At flucth righer SHT concentrations,  $\alpha_{\rm s} M$  can combine maximally with 15.2  $\pm$  1.8 moles of SHT, in which 4.5  $\pm$  0.4 moles may be covalently bound. Serotonin-modified  $\alpha_{\rm s} M$  at concentrations greater than about 0.17  $\mu M$  exerts a dose-dependent inhibition on neurite outgrowth and can seriously damage sensory and CNS neurons. Normal  $\alpha_{\rm s} M$  and free SHT (up to 188  $\mu M$ ), under identical conditions, produce very little or no effect. The neurite-inhibitory and neurondamaging activities of SHT-activated  $\alpha_2 M$  can be blocked by higher concentrations of NGF. Similar effects can be partially induced in the cerebral cortical culture with anti-NGF IgG antibodies. We conclude that  $\alpha_2 M$  has natural affinity for all the monoamino-neurotransmitters and the amine-activated and appears to inhibit neurites and neuronal survival by interferring with the NGF action. (NIH NS-30698 and MEFCOM Foundation grant).

DIFFERENTIAL MODULATION OF NEUROACTIVE SUBSTANCES IN THE CHICK SYMPATHOADRENAL SYSTEM BY NERVE GROWTH FACTOR AND FIBROBLAST GROWTH FACTOR. R. Ramírez-Ordófiez\* and J.E. García-Arrarás, Biology Department, University of Puerto Rico, Río Piedras, P.R. 00931.

Environmental factors are known to influence the differentiation of the sympathoadrenal system. Cells in this system synthesize catecholamines (CA) as their main neurotransmitter together with various neuropeptides. Using indirect immunofluorescence and CA histofluorescence we have demonstrated that phenotypes similar to those found in vivo are expressed by cells in vitro. We have studied the effect of nerve growth factor (NGF) and fibroblast growth factor (FGF) on the expression of the CA, epinephrine (E), norepinephrine (NE) and of the neuropeptides, somatostatin (SS), neuropeptide Y (NPY), vasoactive intestinal peptide (VIP), and enkephalins (ENK) in adrenal glands and sympathetic neurons. Cells from 10 day chick embryos were exposed in vitro for 5-6 days to 50ng/ml of NGF or 75ng/ml of FGF. Their neuropeptide content was measured by radioimmunoanalysis and the amount of NE and E analyzed by high performance liquid chromatography. In sympathetic cultures NGF increased the levels of NPY, ENK and VIP increased without changing the level of SS, while FGF decreased slightly the levels of SS and NPY without changing the level of ENK and VIP. NGF had no effect on cultured adrenal cells, but FGF decreased the level of SS without changing the level of the sympathetic ganglion Environmental factors are known to influence the differentiation of the

NGF had no effect on cultured adrenal cells, but FGF decreased the level of SS without changing the level of the other neuropeptides. In sympathetic ganglion cultures neither NGF nor FGF had any effect on the quantity of NE.

These results demonstrate that, in contrast to the mammalian system, FGF does not mimic NGF effect in chick sympathoadrenal cells. In our system NGF and FGF are modulating differentially the expression of neuroactive substances, suggesting that both neurotrophic factors may have independent roles during the development of the avian sympathoadrenal system. [Supported by grants from NSF (BNS-8801538) and NIH-MBRS Program (RR-8102-18) and partial support of NIH-RCMI (RRO 3641-01).

## 266.16

A NOVEL FUNCTION FOR THE NGF AND NGF RECEPTORS EXPRESSED ON SCHWANN CELLS: A ROLE IN SCHWANN CELL MIGRATION. E. S. Anton\* and W. D. Matthew. Department of Neurobiology, Duke University Medical Center, Durham, NC 27710.

Schwann cell migration is an event critical to the normal development and successful regeneration of peripheral nerves. During the development and regeneration of peripheral nerves, migrating Schwann cells are known to express increased levels of NGF and low affinity NGF receptors (NGFr). Compared to a normal nerve, a denervated sciatic nerve contains 50 and 5 fold more NGFr and NGF, respectively (for review see Johnson et. al., 1988) and pre- treatment of a denervated sciatic nerve substrate with NGF results in a 'NGF- laden substratum'. In order to test whether Schwann cells use NGF and its receptors for migration, we studied Schwann cell migration on cryostat sections of normal and denervated sciatic nerves, pre-treated with or without 2.5S NGF. Dorsal root ganglia from 1 day old rats were explanted on to these substrates and the ganglionic Schwann cells that migrated on nerve substrates were visualized after 72 hours in culture with the vital dye, fluorescein di- acetate. Schwann cells migrated significantly farther on a denervated sciatic nerve substrate than on a normal sciatic nerve substrate. Pre- treatment of denervated substrates with NGF significantly enhanced Schwann cell migration on this substrate. The presence of anti-serum to NGF in culture medium abolished the NGF effect. Pre- treatment of normal sciatic nerve substrates with NGF has no detectable effect on Schwann cell migration.

Based on these results we propose that during development and regeneration of peripheral nerves, Schwann cells use their cell surface NGF receptors to migrate in their NGF rich environment in addition to using them to provide tropic and trophic support to NGF responsive neurons.

NORMAL CNS GLIAL CELLS EXPRESS NEUROTROPHIN RECEPTORS WHOSE LEVELS ARE MODULATED BY NEUROTROPHIN TREATMENT. Shalini Kumarl, Louis A. Peña² and Jean de Vellis¹\* (1) UCLA, Lab. of Biomedical and Environmental Sci., and Neuropsychiatric Institute, Los Angeles, CA 90024, (2) Cold Spring Harbor Lab., Beckman Neuroscience Ctr., Cold Spring Harbor, NY 11724.

We have previously examined the role of a neurotrophin, NGF, and its receptors in the C6 glioma cell line (Kumar et al., J Neurosci Res 27:408, 1990). We now extend these findings to primary cultures of pure, normal rat astrocytes and oligodendrocytes. Neurotrophins (NGF, BDNF, NT-3) bind to a common receptor subunit designated LNGFR and to more ligand-specific, tyrosine kinase-containing subunits designated TrkA, TrkB, and TrkC. Northern blot analysis and transcription assays confirmed a basal level expression of the LNGFR subunit in C6 and in oligodendrocytes and but an absence of basal levels in astrocytes. Following neurotrophin treatment, C6 and astrocytes dramatically upregulated LNGFR synthesis. TrkA mRNA was not detectable, however, multiple bands of TrkB transcripts were present at relatively high levels. TrkB was also upregulated by neurotrophin treatment in astrocytes but not in oligodendrocytes. The inductions occurred on a time scale of 4-6 hrs and could be similarly evoked by cycloheximide treatment -- results consistent with observations of receptor autoregulation by its ligand (e.g., EGF and TrkB but not TrkA, a finding which warrants further investigation. (Supported by DOE, NICHD, and Ford Foundation.)

### OTHER FACTORS AND TROPHIC AGENTS: CNTF

### 267.1

# CHARACTERISATION OF THE HIGH AND LOW AFFINITY RECEPTOR FOR CNTF

J. Huber, H. Thoenen and M. Sendtner\*

Department of Neurochemistry, Max-Planck-Institute for Psychiatry, 8033 Martinsried, FRG Ciliary neurotrophic factor (CNTF) supports the survival of a variety of embryonic chick neurons in culture at a half maximal concentration of 1-5 pM. We have characterized the binding of iodinated CNTF to E11 chick sympathetic neurons and human neuroblastoma SKN-SH cells. Both cell types express low and high affinity binding sites with Kns of 3 nM and 11 pM, respectively. There are about 200 high affinity receptors and 10 000 low affinity binding sites per cell. The specific binding of <sup>125</sup>I-CNTF to low and high affinity receptors could be blocked with a 50 times excess of unlabeled CNTF, whereas LIF at 200 fold higher concentrations did not impair binding to either sites. The off-rate of CNTF from high affinity receptors at 4 °C is very slow, such that no discernible change in binding could be detected after 3 hours. The off-rate from low affinity binding sites is comparatively fast ( $t_{1/2}$ = 15 min). In crosslinking experiments with <sup>125</sup>I-CNTF under low affinity conditions with high affinity binding blocked by cold CNTF, a single protein could be labelled with a molecular weight of approx. 75 kD. This protein might correspond to a recently cloned low affinity CNTF receptor (S. Davis et al. Science, Vol. 253, 59-63, 1991). Under high affinity binding conditions, a second protein of about 140 kD could be detected. Occasionally, crosslinked products greater than 200 kD could been seen, but the specificity of these labelled proteins is not yet clear. The identity of the cross-linking products is being determined.

LIF- AND CNTF-INDUCED CHANGES IN GENE EXPRESSION IN SYMPATHETIC NEURONS IN VITRO. S.E. LEWIS<sup>1\*</sup>, M.S. RAO<sup>2</sup>, W.T.DAUER<sup>1</sup>, A.J. SYMES<sup>1</sup>, S.C. LANDIS<sup>2</sup>, LS. FINK<sup>1</sup>, AND S.E. HYMAN<sup>1</sup>. <sup>1</sup> Molecular Neurobiology Laboratory, Massachusetts General Hospital and Program in Neuroscience, Harvard Medical School, Boston, MA. 02114 and <sup>2</sup> Dept. of Neuroscience, Case Westem University, Cleveland, OH. 44106. Plasticity of neuropransmitter (NT)/ neuropeptide (NP) phenotype in rat sympathetic neurons has been described in detail and shown to be target tissue

Plasticity of neurotransmitter (NT)/ neuropeptide (NP) phenotype in rat sympathetic neurons has been described in detail and shown to be target tissue dependent. A similar switch from noradrenergic to cholinergic phenotype can be induced in dissociated cultures of superior cervical ganglion (SCG) neurons by treatment with target tissue extracts or with non-neuronal cell conditioned medium. These treatments cause a decrease in catecholamines and neuropeptide Y (NPY) and a concomitant increase in acetylcholine and several peptides, including vasoactive intestinal peptide (VIP), substance P (SP) and somatostatin (SST). Recently, several cytokines have been shown to induce similar changes in NT/NP expression in vitro. We have used the in vitro SCG model to investigate changes in mRNA levels for NPs and neurotransmitter synthetic enzymes (NTSEs) induced by two othese cytokines, leukemia inhibitory factor (LLF) and ciliary neurotrophic factor (CNTF). For all of the genes examined, including ChAT, TH, VIP, SP, SST and NPY, the previously observed changes in NT/NP levels are mirrored by changes in he levels of NTSE or NP mRNAs. In addition, the reported inhibition of LIF-induced changes in NT/NP levels by elevated KCl also occurs at the level of mRNA accumulation. We found no significant difference in the time courses for alteration of NP/NTSE mRNAs by LIF vs. CNTF; changes were apparent by northern analysis at 3 to 6 hours of cytokine treatment. To further investigate the mechanism underlying these observed changes in gene expression, we examined the effect of protein synthesis inhibitors one LIF- and CNTF- induced alterations in mRNA accumulation. Both cyclohexamide and anisomycin block LIF- and CNTF- induced changes. Since the required newly synthesized protein may well be a transcription factor, we screened for changes in IEG expression after treatment with LIF or CNTF.

### 267.2

BINDING CHARACTERISTICS OF CILIARY NEUROTROPHIC FACTOR (CNTF) TO SYMPATHETIC NEURONS AND OTHER RESPONSIVE CELL LINES. <u>V. Wong\*</u>, <u>D. Pearsall</u>, <u>R. Arriaga</u>, <u>S. Davis</u>, <u>N. Stahl</u>, and <u>R.M. Lindsay</u>. Regeneron Pharmaceuticals Inc., Tarrytown, NY 10591

A receptor for CNTF which has a molecular mass of 72kD has been cloned (Davis et al., 1991). In this study, we have examined the binding characteristics of 125I-CNTF to its receptor by using a cell line (MG87) stably transfected with the cloned receptor, an Ewing sarcoma cell line (EW1), and cultured primary sympathetic neurons (superior cervical ganglion, SCG). Rat CNTF was iodinated by Bolton-Hunter reagent and the radiolabelled CNTF retained full activity in a ciliary ganglion neuron bioassay. Exposure to CNTF (1ng/ml) for 24 hours resulted in a decrease of 125I-CNTF binding in both SCG and EW1 cells, but not MG87/CNTFR cells. The binding of CNTF to SCG neurons and EW1 cells was saturable and consisted of both high (10-12M) and low (10-9M) affinity, as demonstrated by Scatchard analysis. Binding to MG87/CNTFR cells was only of low affinity (10-9M), suggesting that these responses require a high affinity component. Competition analysis showed a pharmacological rank order of potencies of rCNTF≈ CNTF-myc > hCNTF >> LIF, IL6, NGF, BDNF. Further studies are underway to elucidate the signal transduction pathway that mediates the effect of CNTF.

EFFECTS OF CILIARY NEUROTROPHIC FACTOR ON THE SURVIVAL AND NERVE GROWTH FACTOR-PROMOTED DEVELOPMENT OF CULTURED SYMPATHETIC NEURONS. P. Burnham\* J.-C. Louis, E. Magal and S. Varon. Biology Department, University of California, San Diego, La Jolla, CA 92093.

Ciliary neurotrophic factor (CNTF) has been found to have a wide spectrum of target cells and functions in the nervous system, supporting the emerging view that CNTF acts as a cytokine rather than as a classical neurotrophic factor. In this study we examined the supportive capability of CNTF for sympathetic neurons from the neonatal rat superior cervical ganglion (SCG), traditionally considered to require nerve growth factor (NGF) for long-term survival in culture. If CNTF was provided instead of NGF in low-density cultures depleted of nonneuronal cells, nearly as many neurons survived for 24 hrs as with NGF, and about one fifth the NGF-maintained number of neurons survived for 6 days. The CNTF-supported neurons were smaller than those supported by NGF, had very short processes and showed no immunostaining for the low-affinity NGF receptor (LNGFR), in contrast to the NGFsupported neurons, which developed intense staining for LNGFR over the 6 days in culture. If such cultures were supplemented with Schwann cells, CNTF supported the 6-day survival of nearly as many neurons as did NGF. However, if CNTF was given in combination with NGF in the non-supplemented cultures, the number of neurons surviving for 6 days was decreased by about one third compared to the number supported by NGF alone, and the neurons showed reduced neuritic development and a considerably lower level of LNGFR immunostaining. Supplementation with Schwann cells restored the number of surviving neurons. These results suggest that CNTF can provide trophic support, either directly or in conjunction with nonneuronal cells, to traditional NGF target neurons and can modulate the effects of NGF on its target neurons. Supported by NINDS grant NS-16349.

CNTF AND LIF REGULATE VIP GENE EXPRESSION BY SIMILAR MECHANISMS. A.J.Symes\*, S.E.Lewis, S.E.Hyman and J.S.Fink Molecular Neurobiology Laboratory, Massachusetts General Hospital and Departments of Neurology and Psychiatry, Harvard Medical School, Boston, MA 02114

Medical School, Boston, MA 02114

Neurotrophic molecules have been shown to influence neuronal phenotype, although little is known of the molecular mechanisms through which they act. One such molecule, ciliary neurotrophic factor (CNTF), promotes the differentiation of cultured sympathetic neurons towards the cholinergic phenotype, inducing choline acetyltransferase and neuropeptides including vasoactive intestinal polypeptide (VIP). We have previously identified a human neuroblastoma cell line (NBFL) in which CNTF activates VIP gene expression. In this study we have identified cis-acting genomic sequences important to the induction of the VIP gene by CNTF. VIP-luciferase reporter plasmids, containing portions of the 5 flanking sequences of the human VIP gene, were transfected into NBFL cells, treated with CNTF, and the luciferase activity measured. We find that a 50bp region of the VIP gene, distinct into NBFL cells, treated with CNTF, and the luciterase activity measured. We find that a 50bp region of the VIP gene, distinct from the previously defined cAMP responsive element, subserves transcriptional activation by CNTF. Leukemia inhibitory factor (LIF), another neurotrophic factor that can alter the phenotype of cury, another neurotrophic factor that can alter the prenotype of primary sympathetic neurons in a manner similar to that of CNTF, activates VIP gene expression through the same 50bp region in NBFL cells. These studies demonstrate that the neurotrophic molecules CNTF and LIF share common mechanisms of signal transduction.

RECOMBINANT HUMAN CILIARY NEUROTROPHIC FACTOR STIMULATES METABOLIC RATE INCREASES IN SH-SY5Y CELLS AS MEASURED BY A CYTOSENSOR MICROPHYSIOMETER. B. M. Johnson † P. A. McNeeley , B. S. Glaeser§ and S. Pitchford§, †Dept. of Neurosciences, Institute of Pharmacology, Syntex Discovery Research, Palo Alto, CA 94304 and §Molecular Devices Corp., Menlo Park, CA 94025

Information on the transmembrane signalling events and subsequent biochemical processes initiated by ciliary neurotrophic factor (CNTF) receptor activation in neurons is lacking. SH-Sy5y cells, a human neuroblastoma cell line expressing CNTF receptors, were used to study metabolic changes associated with functional ligand-receptor interactions. Real-time measurements of the acidification rate of the external medium bathing the cells after stimulation with recombinant human CNTF (rhCNTF) beaming the cens and summation with recombinant infinite form (interference) were continuously monitored by detecting small changes in extracellular phusing a silicon-based microphysiometer. Application of rhCNTF or nerve growth factor (NGF) to resting SH-SY5Y cells increased their metabolic rate in a concentration dependent manner (200 - 1000 ng/ml). Maximum metabolic rate increase was observed with 1  $\mu$ g/ml rhCNTF and NGF (basal rate in  $\mu$ Volts/sec = 67.6  $\pm$  1.1; rhCNTF, 104  $\pm$  0.5; NGF, 130.9  $\pm$ 1.0; mean  $\pm$  S.E.M., N = 6-19). Application of 1  $\mu$ g/ml basic fibroblast growth factor £5.E.M., N = 6-19). Application of 1, pg/fill basic individual growth factor. (bFGF) to the cells did not affect metabolic rate (68.8 ± 2.9 µVofts/sec, N=9). These results are consistent with reports demonstrating SH-SY5Y cells express functional CNTF and NGF but not bFGF receptors. The study provides evidence suggesting that the signal transduction mechanism used by the CNTF receptor in SH-SY5Y cells ultimately stimulates effector systems responsible for increasing a cellular metabolic response.

## 267.9

AXONAL RETROGRADE TRANSPORT OF CNTF; MODULATION BY PRIOR NERVE INJURY AND SOLUBLE CNTF RECEPTOR. R. Curtis\*, Y. Zhu, R.M. Lindsay and P.S. DiStefano. Regeneron Pharmaceuticals, Tarrytown, NY 10591.

Ciliary neurotrophic factor (CNTF) is known to promote

the survival and modulate phenotypic differentiation of several neuronal types, including sensory and motor neurons. We show that, like nerve growth factor and the other neurotrophins, <sup>125</sup>I-CNTF (rat) can be retrogradely transport and visualized in dorsal root ganglion neurons of the property payers of the payers payers of the payers payers of the payers of the payers payers of the payers of the payers payers of the payers of the payers of the payers of the payers of the payers of the payers of the payers of the payers of the payers of the payers of the payers of the payers of the payers of the payers of the payers of th and spinal cord motor neurons after injection into sciatic nerve. Moreover, the retrograde transport of CNTF is increased by a conditioning crush lesion (1 or 7 days previously) and by coinjection of soluble recombinant CNTF receptor. Depletion of endogenous CNTF from Schwann cells by axotomy did not affect <sup>125</sup>I-CNTF transport. Northern blot analysis showed that CNTF receptor mRNA was increased in DRG and ventral spinal cord 24 hr post sciatic nerve crush. This up-regulation of CNTF receptor may be the mechanism by which CNTF transport is enhanced. Retrograde transport of CNTF may represent a critical step in the response of sensory and motor neurons to injury.

REGULATION OF TYROSINE HYDROXYLASE EXPRESSION IN DOPAMINERGIC AND NORADRENERGIC NEURONS BY COOPERATIVE ACTIONS OF CNTF AND CATECHOLAMINES. E. Magal\*, P. Burnham, S. Varon and J.C. Louis. Dept. Biology, Univ. of California, San Diego, La Jolla, CA 92093.

While there is growing evidence for a role of ciliary neurotrophic factor (CNTF) on selected sets of CNS neurons, no effects of CNTF have been described so far on the catecholamine neurons. We report here that CNTF promotes the expression of tyrosine hydroxylase (TH) by cultured dopaminergic neurons from E16 rat substantia nigra (SN) and noradrenergic neurons from E18 locus cœruleus (LC). In SN as well as in LC cultures, TH-positive cells decrease progressively to about 30% of their original number determined after 3 hours in vitro. CNTF is able to i) maintain the number of TH-positive neurons in SN and LC cultures for 3 days when given at the time of seeding, and ii) restore the population of TH-positive neurons to its original level when given for 24 hours after a delay of 2 days (SN and LC) or even 5 days (LC). In both cases, however, CNTF is effective only when the neurons own neurotransmitter, e.g. dopamine (DA) for SN neurons and norepinephrine (NE) for LC neurons, was applied simultaneously. While NE alone does not affect TH expression in LC neurons, DA is able by itself to increase the number of TH-positive cells in SN cultures, albeit to a lesser degree than the CNTF/DA combination. Experiments with selective agonists and antagonists indicate that the effects of DA and NE are mediated through D2-DA receptors and α2-adrenoceptors, respectively. These results define a novel mode of neurotransmitter enzyme regulation in SN and LC neurons by CNTF and the neurons own neurotransmitter, acting in convergence and in an autocrine/paracrine fashion to replace the instructive influences to which the neurons are exposed in vivo. Supported by NINDS grant NS-16349.

CNTF PREVENTS CELL DEATH AND MAINTAINS CNTF PREVENTS CELL DEATH AND MAINTAINS p75NGFR BUT NOT CHAT IMMUNOREACTIVITY IN DEVELOPING SEPTAL CHOLINERGIC NEURONS FOLLOWING NGF WITHDRAWAL IN VITRO J.N.C. Kew, C.N. Svendsen\*, S.J. Stevens and M.V. Sofroniew. Department of Anatomy, University of Cambridge, U.K. Ciliary neurotrophic factor (CNTF) promotes the survival of various embryonic neurons in vitro and prevents the degeneration of certain neurons after injury in vivo. The effects of CNTF\* were examined on sental cholinergic neurons grown in sandwich tissue cultures. Septal

septal cholinergic neurons grown in sandwich tissue cultures. Septal cultures (E16 embryos) maintained in the presence of nerve growth factor (NGF) for 14 days from plating contain a population of neurons which stain intensely for p75NGFR, ChAT and AChE. Without added NGF, very few cultured septal neurons stain for these markers. At 14 days, removal of NGF and addition of NGF antibodies (NGF-Ab) days, removal of NGF and addition of NGF antibodies (NGF-Ab) causes the progressive loss of ChAT, AChE and p75NGFR staining. By four days after addition of NGF-Ab there is widespread degeneration and cell death with fewer than 20% of the cholinergic neurons remaining. Under identical conditions of NGF withdrawal, the addition of CNTF in the presence of NGF-Ab significantly prevents cell death and maintains p75NGFR immunoreactivity in about 90% of the cholinergic cells, while by 4 days ChAT and AchE staining are lost. In addition, CNTF added to septal cultures from plating, leads by 14 days to a similar number of p75NGFR, but not ChAT or AChE stained, neurons as seen with addition of NGF. These results suggest that CNTF can act as a survival factor for septal cholinergic neurons in vitro, and can maintain p75NGFR but not ChAT and AChE expression in these \*Recombinant CNTF kindly provided by Regeneron

## 267.10

AXONAL RETROGRADE TRANSPORT OF CNTF AND LEUKEMIA INHIBITORY FACTOR (LIF) SHARE A COMMON RECEPTOR MECHANISM. P. S. DiStefano\*, R. M. Lindsay and R. Curtis. Regeneron Pharmaceuticals, Tarrytown, NY 10591.

Ciliary neurotrophic factor (CNTF) and leukemia inhibitory factor (LIF) are ligands for a related family of cytokine receptors and may share common receptor components (N.Y. Ip, et al, Cell, in press). <sup>125</sup>I-CNTF and to a greater extent <sup>125</sup>I-LIF are retrogradely transported to dorsal root ganglion neurons and spinal cord motor neurons after injection into sciatic nerve. Cross-competition studies showed that LIF blocked 125I-CNTF transport but CNTF could not inhibit <sup>125</sup>I-LIF transport. Prior nerve injury and coinjection of soluble CNTF receptor (CNTF-R alpha) enhance both <sup>125</sup>I-CNTF and <sup>125</sup>I-LIF transport. The interleukin-6 (IL-6) binding-protein, gp130, has been suggested to be component of the CNTF/LIF receptor complex, but IL-6 was without effect on either <sup>125</sup>I-CNTF or <sup>125</sup>I-LIF transport. These results suggest that sensory and motor neurons respond, via retrograde transport, to both CNTF and LIF through overlapping receptor mechanisms, involving CNTF-R alpha.

Ciliary Neurotrophic Factor (CNTF) Delays Motor Impairments in the Mnd Mouse, a Genetic Model of Motor Neuron Disease. M. E. Helgren\*, B. Friedman, M. Kennedy, K. Mullholland, A. Messer, V. Wong.and R. M. Lindsay. Regeneron Pharmaceuticals, Inc. Tarrytown, NY 10591.

CNTF is a trophic factor which supports the survival of motor neurons and certain PNS neurons in vitro. In these studies we have tested the effects of CNTF on preventing or slowing the progression of motor dysfunction in the Mnd mouse, a mutant characterized by adultonset, progressive motor impairments. We have designed methods to quantify this motor impairment and demonstrated deterioration of locomotor patterns in Mnd mice as evidenced by shift from a reciprocal gait pattern to a synchronous hopping pattern during the progressive stages of the disease. Using this behavioral assay we compared the effects of an 8 week treatment with recombinant human (rh) CNTF (n=42) or a vehicle solution (n=42) in Mnd mice. Animals were tested weekly to evaluate the rate of change in locomotor patterns. Quantitative analysis of foot-fall patterns show that the magnitude and rate of decline in measurements of stride length and intra-step distance are significantly less in CNTF-treated mice as compared to vehicletreated Mnd mice. Experiments in progress aim to assess anatomical changes that may underlie these behavioral effects. The results indicate that rhCNTF can slow the progression of motor dysfunction in the Mnd mouse and is a useful model in testing therapeutic agents for the treatment of motor neuron diseases.

CILIARY NEUROTROPHIC FACTOR (CNTF) PREVENTS MOTONEURON DEATH IN THE DEVELOPING RAT SNB. N.G. Forger\*, S.L. Roberts, V. Wong¹ and S.M. Breedlove, Dept. Psychology, Univ. California, Berkeley, CA 94720 and <sup>1</sup>Regeneron Pharmaceuticals, Tarrytown, New York, 10591.

Many motoneurons die during the course of vertebrate development, although the molecular mechanisms determining survival remain unknown. CNTF, originally isolated from chick eye as a survival factor for ciliary neurons in vitro, also preserves embryonic rat and chick motoneurons in vitro and chick moto-We have exploited the perinatal period of neurons in ovo. motoneuron death in the rat spinal nucleus of the bulbocavernosus (SNB) to test the ability of CNTF to rescue developing rat motoneurons in vivo. Most motoneurons in the sexually dimorphic SNB of females normally degenerate between embryonic day 22 (E22) and postnatal day 10 (P10). Female Sprague-Dawley rat pups were, therefore, delivered by cesarean section on E22 and injected with CNTF (1 µg) or vehicle on E22, P1, P2, and P3. Animals were killed on P4 and the number of motoneurons and pyknotic cells determined in the SNB region. CNTF treatment markedly increased SNB motoneuron number (CNTF: 209 ± 14 vs Vehicle:  $122 \pm 10$ ; p < 0.001) and decreased the number of degenerating cells to less than 1/3 that seen in controls (p < 0.001). These results establish CNTF as the first protein shown to alter naturally occurring motoneuron death in mammals. Supported by NIH grant #NS28421.

CILIARY NEUROTROPHIC FACTOR PROMOTES THE RETENTION OF MULTIPLE INNERVATION OF DEVELOPING SKELETAL MUSCLE FIBERS. Arthur W. English\* and Gail Schwartz, Department of Anatomy & Cell Biology, Emory University, Atlanta, GA 30322

To examine whether developing neuromuscular synapses compete for neurotrophic molecules which are available in compete for neurotrophic molecules which are available in limited quantities, the effects of exogenous ciliary neurotrophic factor (CNTF) on postnatal neuromuscular synapse elimination were investigated. CNTF was injected daily for one week into the lateral gastrocnemius muscle beginning on postnatal day 2 (P2). The effect of these injections was evaluated using intracellular recording techniques at ages P6-P16. At doses >200 µg/kg, CNTFinjected muscles contained more polyneuronally innervated fibers and more synaptic inputs per cell, than either muscles from normal animals or from saline injected contralateral muscles. The amount of polyneuronal innervation remained fairly constant (at the amount expected at P9-P10) even one week after the cessation of injections. Lower doses of CNTF had no significant effect. Thus CNTF promotes the retention of multiple innervation of developing skeletal muscle fibers in a dose-dependent manner. Whether it exerts this effect directly or indirectly on the synapses is not known. Supported by NS20545 and Regeneron Pharmaceuticals Inc.

#### 267.12

INDUCTION OF MOTOR NEURON SPROUTING IN VIVO BY CILIARY NEUROTROPHIC FACTOR AND BASIC FIBROBLAST GROWTH FACTOR Mark Gurney\*, Hirotaka Yamamoto, and Young Kwon. Department of Cell, Molecular & Structural Biology, Northwestern University, 303 East Chicago Ave. Chicago, IL 60611.

Ciliary neurotrophic factor (CNTF) and basic fibroblast growth factor (bFGF) were tested for effects on sprouting by motor neurons

innervating the adult mouse gluteus muscle. Factors were delivered by subcutaneous injection directly over the surface of the superior gluteus muscle once daily for 7 days. Endplates and axons were visualized in a whole mount of the gluteus muscle by combined silver and cholinesterase staining. CNTF (500 ng daily) induced sprouting from both endplates and from the subset of nodes of Ranvier that are closest both endplates and from the subset of nodes of Ranvier that are closest to the endplate. CNTF increased the occurrence of endplates with sprouts approximately 30 fold to  $12.7 \pm 3.5\%$  (SEM) from  $0.4 \pm 0.2\%$  in muscles treated only with BSA. Combined treatment with CNTF and 2 ng bFGF daily potentiated the effect of CNTF approximately 2 fold to  $30.3 \pm 2.9\%$ , while bFGF alone had no discernable effect on the occurrence of sprouting from endplates. Sprouting from the node of Ranvier closest to the endplate increased from  $0.4\% \pm 2\%$  in muscles treated with BSA to  $1.9 \pm 0.6\%$  after treatment with CNTF, and to 4.6  $\pm$  0.6% in muscles treated with CNTF and bFGF, while treatment with bFGF only had no effect. The sprouting stimulus delivered by CNTF showed limited penetrance into the muscle. Beneath the site of injection, 27.9  $\pm$  6.1% of the endplates on the dorsal surface of the gluteus muscle developed sprouts, while only 7.5 ± 2.6% of the endplates on the ventral surface of the muscle had sprouts. Thus, CNTF is a candidate for a physiological mediator of sprouting *in vivo*.

### 267.14

LOCAL ADMINISTRATION OF CNTF ENHANCES PERIPHERAL NERVE REGENERATION IN VIVO. C.F. Da-Silva\*1. F. Langone², A. Negro² and R.S. Pires¹. ¹Dept. of Histology, University of Sao Paulo, Brazil and ²Fidia Research Laboratories, Italy. The aim of this study was to take advantage of the entubulation repair model to study the in vivo role of exogenously administered ciliary neuronotrophic factor (CNTF) during peripheral nerve regeneration. The left sciatic nerve of eight C57BL/6J adult male mice was transected and both the proximal and distal nerve stumps were secured by a single 10-0 suture into a 6-mm length of a polyethylene tube (0.76 mm ID) to give a final gap length of 4 mm. The animals were divided into 2 groups of 4 animals each. One group was implanted with tubes filled with a purified preparation of collagen (Vitrogen, 2.4 mg/ml). The second group was implanted with tubes filled with collagen plus CNTF (1:1, with 100 ng of CNTF in the tube). Recombinant human CNTF was produced and purified from E. coli (Negro et al, J. Neurosci. Res., 29:251, 1991). Following a survival time of 6 weeks, the tubes with the regenerating nerve cables were processed for Epon embedding. Myelinated nerve fibers were counted from the mid-portion of the cables with a computer-controlled system (Biographics). The results showed a significant difference in the number of myelinated axons between the collagen + CNTF group (3027±62, mean±5EM) and the collagen alone group (1813±135) (p<0.05, Neumana Reuls). No difference was observed between the CNTF group and a group (n=4) of non-operated mice (331±54). The data demonstrate that local application of exogenous CNTF causes a stimulation of axonal regeneration in adult animals. Studies with retrograde neuronal tracers (under way) should reveal a possible selective action of this factor on motor and/or sensory regenerating neurons.

## 267.16

SPATIAL AND TEMPORAL EXPRESSION OF CNTF FOLLOWING PERIPHERAL NERVE INJURY. E.D. Rabinovsky G.M. Smith, J. McManaman¹ and H.D. Shine. Dept. of Neurosurgery, Baylor College of Medicine, Houston, TX 77030; ¹Synergin, Boulder, CO, 80503.

Ciliary neurotrophic factor (CNTF) is highly expressed in normal

peripheral nerves and may be important in the survival of motoneurons and regeneration of injured motoneurons. Both CNTF mRNA and protein decrease in sciatic nerve within 7 days after a crush injury. The changes in CNTF expression are opposite from that of low-affinity NGF receptor (p75NGFR) expression, which increases after crush. To examine the regulation of CNTF expression, we characterized the spatial and temporal patterns of CNTF expression after injury. Rat sciatic nerves were crushed, then 1,3,5, and 7 days later removed and cut into 4mm sections (1 segment proximal to crush site and 5 distal). CNTF expression in the segments was measured by western blot and northern blot analysis. Longitudinally sectioned nerves were immunostained for CNTF at 1,3,5 and 7 days after injury. There was no significant change in CNTF mRNA 1 day after crush, but CNTF protein decreased adjacent to the crush site. Both the amounts of mRNA and protein were reduced on day 3 and continued to decrease on days 5 and 7. Immunohistochemical staining localized CNTF to Schwann cell cytoplasm. Injury reduced staining distal to the crush. The decrease in CNTF expression followed the general course of Wallerian degeneration and implies that its regulation is, in part, governed by Schwann cell-axon Supported by grants from the Kleberg Foundation and the U.S.Navy (N00014-89-J3003)

INTERACTIONS OF CHONDROITIN SULFATE PROTEOGLYCANS FROM BRAIN WITH NEURAL CELL ADHESION MOLECULES.

A. Flaccus, M. Grumet, and R.U. Margolis\*. Dept. of Pharmacology, New York University Medical Center, New York, NY 10016.

Ng-CAM is a cell adhesion molecule (CAM) that can bind homophilically as demonstrated by the ability of CAM-coated Covaspheres to

Ng-CAM is a cell adhesion molecule (CAM) that can bind homophilically as demonstrated by the ability of CAM-coated Covaspheres to self-aggregate. In the present study, we found that the aggregation of Covaspheres coated with Ng-CAM was strongly inhibited in the presence of two rat brain chondroitin sulfate proteoglycans (PGs), designated 1D1 and 3F8, at concentrations of <10 µg/ml; in contrast, much higher concentrations of a rat chondrosarcoma chondroitin sulfate PG had no effect on the aggregation. The chondroitin sulfate PGs from brain, but not from chondrosarcoma, also inhibited binding of neurons to Ng-CAM when mixtures of the proteins were adsorbed to polystyrene dishes. Neither of these effects are attributable to the chondroitin sulfate, inasmuch as similar results were observed with the core glycoproteins obtained by chondroitinase treatment of the PGs. To investigate whether cells could bind directly to the PGs, we have used an assay in which cell-substrate contact was initiated by centrifugation. Although no binding to the PGs was detected in gravity assays, neurons bound to the 1D1 and 3F8 PGs but not to chondrosarcoma PG in centrifugation assays. Different forms of the 1D1 PG have been identified in developing and adult brain. The early postnatal form was found to bind neurons more effectively, and neuronal binding to the 1D1 PGs was specifically inhibited by the 1D1 mAb. These results suggest that certain brain PGs can bind to neurons, and that Ng-CAM may be a heterophilic ligand for the 1D1 and 3F8 PGs. The abilities of these brain PGs to inhibit cell adhesion to CAMs may be one mechanism to modulate cell adhesion and migration in the nervous system.

### 268.3

THE DEVELOPMENTAL CHARACTERIZATION OF GLIAL HYALURONIC ACID BINDING PROTEIN (GHAP) IN RATS. M.A., Hosley<sup>1</sup> and A. Bignami<sup>1,2</sup>. Spinal Cord Injury Research<sup>1</sup>, V.A. Med. Ctr., West Roxbury MA and Harvard School of Medicine, Boston, MA.<sup>2</sup>

The developmental occurrence and localization of GHAP (glial hyaluronic acid binding protein) was studied in rats utilizing indirect immunofluorescence with the monoclonal antibody 12CS as the primary antibody. Animals were sacrificed from G12 (gestational day 12) through 90d p.p. (postpartum) with the brain and spinal cord removed, ten micrometer fresh-frozen sections mounted on slides and fixed in -20°C acetone for 10-20 minutes.

GHAP is first detected at G15 in the olfactory tracts and

GHAP is first detected at G15 in the olfactory tracts and periventricular regions of the brain and in the spinal cord as a diffuse, low level of staining in both the white and gray matter. In the brain, GHAP localizes to the corpus callosum and Purkinje-granule cell layers of the cerebellum by G19 at which time it is also beginning to localize in the ventral white matter tracts of the spinal cord, low levels, however, still remain in the spinal cord gray matter. At 3d p.p., there is focal GHAP staining in all major myelinated tracts in the brain, including the cerebellar fiber tracts. In addition, the olfactory fiber tracts remain GHAP positive and, by this age, the olfactory glomeruli are also GHAP positive. At this age, the spinal cord has its GHAP staining generally restricted to the white matter tracts with decreasing amounts of staining in the gray matter. From this point on, there is gradual refinement of the above patterns to assume the adult staining pattern of white matter tracts in the brain and spinal cord, the olfactory tracts and glomeruli, and with the ecrebellum containing moderate staining in the granular cell layer with intense staining in the fiber tracts.

Supported in part by NIH Grant NS 13034 and V.A. Gen. Res. Service Merrit 0002.

TENASCIN DISTRIBUTION DURING DEVELOPMENT OF TASTE ORGANS SUGGESTS ROLES IN REGULATING TASTE BUD MULTIPLICATION AND PAPILLA INNERVATION. C.M. Mistretta and L.F. Haus. School of Dentistry, Univ. of Michigan. Ann Arbor. MI 48109.

Tenascin is an extracellular matrix molecule with demonstrated roles in segregation, migration and aggregation of cells during tissue differentiation and morphogenesis. We used a rabbit anti-human polyclonal antibody to localize tenascin immunoreactivity in developing fungiform and circumvallate papillae and taste buds, in fetal, perinatal and postnatal sheep. Taste organs were studied from stages of initial papilla morphogenesis through advanced stages of papilla development and periods of taste bud differentiation and proliferation. The spatial pattern of tenascin immunoreactivity (IR) changes during papilla development in fetal sheep: from an initial intense localization in connective tissues beneath the early taste papillae; to diffuse localization within the core of papillae; to a very limited distribution in regions of the papillae core that are directly under epithelium in which taste bud multiplication is occurring. Tenascin IR is absent from the papilla core under nongustatory papilla epithelium. In postnatal animals, tenascin IR is intense and once again is diffuse, throughout the core of taste papillae. At all stages, tenascin IR outlines bundles of nerve fibers within the papillae. In summary, tenascin IR becomes progressively restricted to gustatory portions of taste papillae in fetal and perinatal animals. A role for tenascin in papilla morphogenesis and taste bud multiplication is suggested. Tenascin might modulate adhesion between taste bud and papilla cells and substrate by stimulating de-adhesion at certain areas. In addition, the pattern of IR suggests a role for tenascin in fasciculation of nerve fibers within taste pepiliae. (Supported by NIH Grant DC00456).

INCREASED NEURITE OUTGROWTH ON GLIAL SCARS FOLLOWING ENZYMATIC DIGESTION OF CHONDROITIN SULFATE PROTEOGLYCAN R.I. McKeon\* and lerry Silver. Dept. of Neurosciences, Case Western Reserve University, Cleveland, OH 44106

Recent evidence has demonstrated that an increased expression of

chondroitin sulfate proteoglycan (CSPG) is correlated with a limited ability of glial scars to support neurite outgrowth in vitro. In order to directly test whether this molecule can actively inhibit neurite outgrowth on glial scars, Millipore filters were, first, implanted into the gray matter of the cerebral cortex in both neonatal or adult rats. Animals were allowed to survive for either 10 days or 1 month. During this time, CSPG is reexpressed in the area of the implant in adult but not neonatal animals and is qualitatively greater after 30 days than at 10 days. Next, the implants were removed, placed in culture, and used as a substrate for dissociated E-6 chick retinal ganglion cells (RGC). RGC's were grown for 48 hrs. in media either with or without 0.5 U/ml chondroitinase ABC, which specifically cleaves chondroitin sulfate GAG sidechains from the core protein. Cultures were then fixed and stained for RGC specific TU-J1. Neurite lengths were measured and digitized blindly. Statistical analysis revealed a significant enhancement of neurite outgrowth on treated adult glial scars removed one month after implantation (p<0.001), as opposed to implants removed from adult animals after 10 days (p=0.1). Neurite lengths on implants removed after one month from animals implanted as neonates were virtually identical between the treated and untreated groups. These data are consistent with the hypothesis that CSPG is inhibitory to neurite outgrowth and plays a role in regenerative failure after injury to the adult CNS. Supported by a grant from the Paralysed Veterans of America Spinal Cord Research Foundation and NS 25713.

DEVELOPING TASTE PATHWAYS IN SHEEP BRAINSTEM DEMARCATED BY GLIAL AND GLYCOPROTEIN MARKERS. <u>C.T. King</u>, <u>L.F. Haus and C.M. Mistretta</u>. School of Dentistry, Univ. of Michigan, Ann Arbor, MI 48109.

During central nervous system development, glia and extracellular matrix molecules demarcate functional pathways and groups of neurons. In the gustatory system, afferent fibers from the VIIth and IXth nerves enter and fasciculate within the brainstem in a stereotyped pattern as demonstrated by Lucifer Yellow labeling. To examine whether glia and/or extracellular matrix boundaries are associated with organization of the solitary tract, we are studying immunocytochemical localization of the glial markers, vimentin (VIM) and glial fibrillary acidic protein (GFAP), and the glycoprotein, tenascin (TN), in the developing sheep brainstem. Horizontal sections of the brainstem from fetuses aged 80-130 days of gestation (term = 147 days) were cut for immunocytochemistry. In midterm sheep fetuses, VIM and GFAP immunoreactive processes are seen within the solitary tract and also provide an outline for the rostral solitary nucleus. Bundles of fibers within the tract are surrounded by a network of intense TN immunoreactivity, suggesting that tenascin promotes fasciculation of the fibers. These patterns are apparent during periods when taste fibers are assembling the solitary tract and neurons in the solitary nucleus are acquiring more complex dendritic arbors and an increasing number of spines. Later in gestation, patterns of GFAP and TN immunoreactivity are essentially unchanged but seem more distinct. Experiments are in progress to determine whether these markers are developmentally regulated and contribute to the initial organization of the solitary tract and nucleus. TENASCIN-LIKE MOLECULES IN A DEVELOPING INSECT OLFACTORY SYSTEM. C.E. Krull<sup>1</sup>\*, D.B. Morton<sup>1</sup>, L.P. Tolbert<sup>1</sup>, M. Schachner<sup>2</sup>, A. Faissner<sup>2</sup>, <sup>1</sup>ARL Div. of Neurobiology, Univ. of Arizona, Tucson, AZ, <sup>2</sup>Swiss Fed. Inst. of Technology, Zurich, Switz., and <sup>3</sup>Dept. of Neurobiology, Univ. of Heidelberg, Heidelberg, Germany.

Neurobiology, Univ. of Heidelberg, Heidelberg, Germany.

Glial cells form boundaries around developing olfactory glomeruli in the antennal lobe (AL) of the brain of the moth Manduca sexta, and appear to be necessary for the induction by olfactory axons of glomerular branching patterns in AL neurons. Previously (Krull et al., Soc. Neurosci. Abstr., 1991), we demonstrated that the glial cells in the developing AL are recognized by antibodies against human and mouse tenascin; the binding gradually decreases with maturation. We now have further characterized the proteins labeled by these antibodies at different stages of development using Western blot analysis and have begun tests of the effects of tenascin on neurite outgrowth in vitro. The major bands recognized by antibody at all stages of development are two high-molecular weight proteins of approximately 220 and 160 kD. The 220-kD band comigrates with purified mouse tenascin. Following extraction in 2M urea and centrifugation of AL material at 10,000 x g for 5 min, most of the 220- and 160-kD antigens appear in the supernatant, suggesting that they are not integral membrane proteins. Preabsorption of the antibody with mouse tenascin blocks staining of glia in sections). In tissue culture experiments, AL cells grown on a substrate of con A/laminin plus purified tenascin show decreased adhesion and process outgrowth compared with cells grown on con A/laminin alone. Thus, it appears that molecules of molecular weights and antigenicity similar to vertebrate tenascins are present in the developing AL and that tenascin may inhibit growth of the neurites of AL neurons across glomerular boundaries.

DO PIONEERING OLFACTORY AXONS INDUCE THE RAT OLFACTORY BULB? Q. Gong\*, M.S. Bailey and M.T. Shipley. Department of Anatomy & Cell Biology, University of Cincinnati College of Medicine, Cincinnati, OH 45267.

We are testing the hypothesis that the earliest olfactory axons induce the formation of the olfactory bulb from the telencephalic vesicle.

GAP43 labels olfactory axons as early as E12 but these axons do not reach the telencephalon. By E13, a few GAP43+ axons enter the rostromedial part of the telencephalic vesicle. These axons penetrate directly to the ependymal zone. At E14, there is no obvious "olfactory bulge", but large numbers of GAP43+ olfactory axons penetrate through the mantle layer and marginal zones to reach the ventricular zone in a highly restricted sector of the telencephalon. By E15, the olfactory bulge is visible as a evagination of the rostromedial part of the telencephalon. At this stage, most GAP43+ olfactory axons terminate in the intermediate zone of this bulge.

Immunostaining of CDA1, an antigen selectively expressed in growth cones, was in excellent agreement with the GAP43 observations. The tract tracer, "fast" was in caceticin agreement with the Carty's observations. The tract tracer, "fast" Dil, injected into the nasal cavity demonstrated that the GAP43+ axons originate from the olfactory epithelium. Dil labeled axons penetrate to the ventricular zone exactly as do the GAP43+ axons

These results demonstrate that the olfactory axons reach the mitotic zone of the telencephalon prior to the induction of the olfactory bulb. Pioneering olfactory axons, thus, may modulate the proliferation of the cells in this specific zone of the telencephalon to induce the formation of the olfactory bulb. We have developed a method to double label BrdU and GAP43. This will be used to compare proliferation in the zone innervated by pionerering olfactory axons with other parts of the telencephalon. LECTIN BINDING PATTERNS IN THE DEVELOPING RAT TRIGEMINAL SYSTEM. JJ Christensen\*, C Austin and TA Woolsey. Dept. Neurology and Neurological Surgery, Washington University, St. Louis, MO 63110

The plant lectin peanut agglutinin (PNA) conjugated to HRP was used to demonstrate patterns of extracellular matrix molecules in the whisker pathway of postnatal rats. Infraorbital nerve (IO) lesions at birth were used to disturb the development of the normal whisker related patterns in animals studied from birth (P0) to 20 days old. Details of processing and sectioning have been reported previously (see Steindler & Cooper '86, J. Comp. Neurol. 249:157; Christensen & Woolsey '88, Soc. Neurosci. Abstr. 14:1273). In normal rats, there is no whisker-like pattern in any of the trigeminal centers on P0. Patterns appear in the trigeminal spinal subnuclei interpolaris and caudalis - on P1. They emerge in the principal nucleus of V and VB thalamus on P2, and may be present in the cortex as early as P4. Patterns persist at all levels until P10 although the intensity of binding is reduced. The whisker patterns are absent at all levels by P20. IO lesions abolish the pattern all levels. In comparison to the timing of PNA binding patterns in postnatal mouse trigeminal system, the rat develops patterns about one postnatal day later but the patterns persist longer. Given other studies which suggest that the rat is farther along in pattern formation of this pathway at birth this is further evidence for a non-sdirective role of these

EFFECTS OF POSTNATAL BLOCKADE OF CORTICAL ACTIVITY UPON THE DEVELOPMENT AND PLASTICITY OF VIBRISSAE-RELATED PATTERNS IN THE SOMATOSENSORY CORTEX OF RAT AND HAMSTER. W.R. Bauer, N.L. Chiaia, S.E. Fish, B.A. Figley, M. Eck, C.A. Bennett-Clarke and R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699

Neuronal activity influences pattern formation in a number of neural systems. In this study, we determined whether or not this was also true in the somatosensory systems of rodents by silencing the primary somatosensory cortex of animals of hamsters and rats with either TTX or a combination of TTX and the NMDA receptor antagonist APV for the first 6-9 days of life. Tetrodotoxin-impregnated implants were also applied to the cortices of rats and hamsters that sustained removal of a single row of mystacial vibrissae follicles or transection of the entire infraorbital nerve (ION, the trigeminal branch which innervates the vibrissa pad) on the day of birth. Neither application of TTX alone nor TTX in combination with APV prevented the formation of the vibrissa-related pattern in the primary somatosensory cortex of either species as visualized with either anterograde tracing with the carbocyanine dye, Di-I, or immunocytochemistry for serotonin (5-HT). Furthermore, TTX implants had no appreciable influence upon the postnatal cortical reorganization observed after either destruction of a row of vibrissae follicles or transection of the ION. These data indicate that normal physiological activity that can be blocked with TTX and APV is not required for either qualitatively normal pattern formation or the postnatal development of lesion-induced abnormal patterns in the somatosensory cortex of either hamsters or rats. NS 28888, DE 08971, DE 07734

ROLE OF INHIBITORY ECM MOLECULES IN THE FORMATION OF OLFACTORY BULB GLOMERULL M. de L., Gonzalez\* and J. Silver. Dept. of Neuroscience, Case Western Reserve University, School of Medicine, Cleveland, OH 44106.

We have described the normal anatomy of the olfactory bulb (OB) throughout development, focusing on the role of purported barrier molecules, that are associated with astroglial cells, as potential guidance factors in glomeruli formation. Glomeruli are unusual structures within the OB formed by extremely tight bundles of afferents that fail to grow deeply into the brain. Our data suggests the hypothesis that Cytotactin/Tenascin (CT) and Chondroitin-6-sulfate proteoglycan (C-6s-PG), in the core of the early developing OB, together form a molecular wall that helps position the ingrowing olfactory axons within the olfactory nerve layer (ONL) at the outer edge of the astroglial territory. Using olfactory marker protein antibodies, we found that at E18 olfactory axons are in long strands at the outermost edge of the bulb. By E20-21 axons cluster and form small spheres and by PD1 they gather into distinct glomeruli. Prior to and during the transformation of olfactory afferents into glomeruli that form at the interface between ensheathing cells and astrocytes, there was an enhanced expression of both ECM molecules CT and C-6s-PG associated with VIMGFAP positive astroglial cell processes, deep to the glomeruli. As glomeruli continue to develop at later stages (PD3-PD9), the GFAP positive astroglial processes beneath them intensify their GFAP, maintain their expression of CT and C-6s-PG, and then migrate peripherally into the ONL to encapsulate and infiltrate the glomeruli. Thus, at later stages, axon/glia interactions occur which result in astroglial rearrangement and interaction with the glomeruli. We suggest that the astroglia and ensheathing cells play a fundamental role in directing the position at which formation of the synaptic glomeruli will occur. Since the olfactory axons continue to elongate during deve

NEW AND IMPROVED METHODS FOR ASSESSING DENDRITIC DEVELOPMENT RELATIVE TO SOMATOTOPIC PATCH BORDERS IN THE BARREL NEURAXIS, W.M. Panneton\*, J.J.A. Arends & M.F. Jacquin. Department of Anatomy and Neurobiology, St. Louis University School of Medicine, St. Louis, MO 63104.

Many developing granule cells in barrel cortex acquire polarized dendritic trees by selective pruning and reorientation relative to thalamocortical patch boundaries. Whether similar rules apply to the developing dendritic trees of trigeminal brainstem neurons is not clear, although we know that most of the cells in trigeminal nucleus principalis (PrV) in adult rats have polarized trees. In attempting to resolve this issue, a number of methods proved inadequate to the task. Golgi staining combined with pattern markers, such as cytochrome oxidase or transported fluorescent dyes, failed to provide sharp whisker patches, silver preservation and/or complete reconstructions. In vivo tracer injections into thalamus always made a lesion that had a confounding effect on PrV dendritic development. Lucifer yellow staining of PrV cells in the fixed slice, while producing complete fills, impeded cytochrome oxidase staining in regions exposed to Lucifer yellow. In our hands, the only successful method to date optimizes conditions for intracellular injection and utilizes postinjection immunohistochemical staining of both Lucifer yellow filled cells and matrix components preferentially present in the inter-patch septa, such as J1-tenascin. Preliminary data suggest that in newborn to 7 day old rats, most PrV dendrites are polarized and they do not cross tenascinstained, whisker-related, patch borders. Notable exceptions are dendrites from the minority of PrV cells that have large somata and are likely to be responsive to multiple whiskers

# EXPANSION OF THE BARRELFIELD AFTER NEONATAL ENUCLEATION IN MICE.

G. Bronchti, N. Schönenberger, E. Welker, and H. Van der Loos\* Institute of Anatomy, University of Lausanne, 1005 Lausanne, Switzerland.

We investigated the effect of neonatal eye removal on the tangential extent of the barrelfield in adult mice. Areas were measured in drawings made from tangentially cut NissI-stained sections of somatosensory cortex. We compared areas of 29 barrels-shown in figure - corresponding to 29 mystacial vibrissae, between 60 days old mice enucleated at birth (n=13) and their intact littermates (n=13). Multivariate ANOVA showed that the barrelfield was larger in enucleated mice (by 6%; p<0.0028). This expansion was almost entirely due to the areal increase of barrels corresponding to the dorsalmost row of vibrissae (row A), and of a set of barrels corresponding to

rostral vibrissae near the nose and mouth. These barrels are rendered black in the figure; numbers within barrels indicate the percentage of areal expansion in enucleated versus control mice; asterisks are placed beside barrels that showed significant areal increase (p<0.0017); other labels indicate nomencla ture for barrels in rows (letters) and arcs (numbers). Assessment of the follicular innervation density in enucleated mice will help

to better understand the substrate of this cross-modal phenomenon. Support: Swiss NSF - 31-30932, and the Geigy Jubiläums Stiftung.

RELATIONSHIP BETWEEN SUBCORTICAL AND CORTICAL REORGANIZATION AFTER FETAL CAUTERIZATION OF VIBRISSAE FOLLICLES IN RAT. R.W. Rhoades\*, N.L. Chiaia, C.A. Bennett-Clarke, G.J. Janas, M. Eck and C.M. Fisher. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699

Cauterization of vibrissae follicles in rats on embryonic day (E-) 15 through E-18 results in an increase in the brainstem areas devoted to the representation of the remaining follicles. Lesions at later ages (E-19 through the day of birth [P-0]) result in smaller and statistically non-significant increases in the brainstem representations of undamaged follicles. This study compared the changes in the areas devoted to the representation of a given follicle in trigeminal subnucleus interpolaris (SpI) and the primary somatosensory cortex (S-I) of rats that sustained vibrissae follicle lesions on E-15 through P-0 with the aim of determining: 1) the degree to which the brainstem changes are magnified or reduced in cortex, and 2) whether the sensitive period for expansion of the representation of intact follicles in SpI and S-I are the same or different. Follicle cauterizations on E-15 resulted in significant increases in the representations of the remaining follicles in both SpI and S-I and there was no significant difference in the magnitude of the changes in these two regions. Similar damage on E-16 through E-18 resulted in significant increases in both SpI and S-I with those in S-I exceeding those in Spl. Damage on E-19 and P-O resulted in non-significant changes in Spl and small, but significant, increases in S-I. These data show that the sensitive period for central reorganization after peripheral damage ends later in S-I than in SpI and that changes in the brainstem are generally magnified in cortex. ## 268.15

EARLY FETAL DEVELOPMENT AND MATURATION OF RAT VAGAL MOTOR NEURONS. L. Rinaman\* and P. Levitt Medical Coll. of Pennsylvania, Dept. Anat. & Neurobiol., Philadelphia, PA 19129.

The embryonic development and maturation of vagal motor neurons was

examined, with an emphasis on neurons innervating the proximal gut and their central relationship to gastric sensory afferents. Embryos (E12-E21) were fixed and crystals of dil were placed in the proximal gut or cervical vagus nerve. After 14-30 days, sections were examined to visualize vagal sory and motor neurons projecting to the dil placement site. At E12, the nodose ganglia contain gastric sensory neurons with central axons that enter superficial layers of the dorsal medulla (tr. solitarius) with little or no At E13, a few labeled motor neurons (presumably nucleus ambiguus; NA) are seen midway between the dorsal and ventral medullary surface. Some NA neurons appear to be migrating, trailing neurites that reach medially towards the 4th ventricle; others exhibit proximal dendritic arbors. Labeled NA motor axons exit laterally, separate from sensory afferents. At E14, sensory axons penetrate deeper in the dorsal medulla and have a more extensive rostrocaudal distribution, and a new group of labeled motor neurons (presumably dorsal motor nucleus of the vagus; DMV) are seen near the germinal zone of the 4th ventricle. They are completely separate from labeled sensory fibers, do not form a distinct nucleus, and have short trailing processes extending to the outermost cell layer of the ventricular zone. Their axons exit the ventral medulla along with the axons of scattered labeled NA neurons. By E18, the adult nuclear organization of the vagal complex is evident, with distinct NST, DMV and NA; furthermore, some DMV motor neuron dendrites enter the NST sensory terminal field. These data show a remarkable early onset of vagal sensory and motor interactions during embryonic development. Supported by MH45507 and NRSA 1F32NS08900.

DEVELOPMENT AND ORGANIZATION OF THE WHITE MATTER OF THE RAT SPINAL CORD. L. A. Gomez. A. Brusco\*, E. M. Lopez and J. Pecci Saavedra. Instituto de Biología Celular, Facultad de Medicina, Paraguay 2155, 1121 Buenos Aires, Argentina.

Argentina.

In a previous study we have demonstrated an organized glial pattern in the brainstem of the rat embryo (IBRO Abstr. 1991, pp 35). In order to investigate the possible participation of radial glia in the assembly of the developing spinal cord, vibratome sections (Embryos aged: E13 to E18) were immunostained for S-100 protein, vimentin or the phosphorylated 180 kDa neurofilament protein.

vinentin or the phosphorylated 160 KPa neurofilament protein.

Vinentin immunostaining revealed radial glial fibers (RGF) extending from the ventricle to the pial surface. In the peripheral zone the RGF became superimposed to form cephalocaudal plates (CP) that ensheathe developing axonal tracts (evidenced by neurofilament immunostaining). This pattern was first evidenced at E13 in a small area of the ventral portion; in correspondence with the increment of axonal tracts the CP became denser and extended ventrolaterally. This glial pattern was only found in the white matter. In the central zone RGF do not form CP; this pattern was found in the gray matter. Immunoreactivity to S-100 protein appeared at E17 in the midline and, at E18, overlapped to vimentin immunostaining. The pattern of glial plates is similar to the organization demonstrated in previous studies in the brainstem. Is is concluded that the glial pattern revealed in this study is the result of interactions between developing axonal tracts with radial glia, and that it could set the structural basis for an organized assembly of the developing spinal cord.

(Work performed with grants from CONICET, Argentina).

ANATOMICAL AND FUNCTIONAL CHANGES IN THE ORGANIZATION OF THE CUNEATE NUCLEUS OF ADULT RATS AFTER FETAL FORELIMB AMPUTATION. N.L. Chiaia\*, J.T. Wall, H.P. Killackey, C.A. Bennett-Clarke, and R.W. Rhoades. Dept. of Anatomy, Medical College of Ohio, Toledo, OH 43699

Fetal forelimb removal in rat increases the portion of the somatosensory cortex devoted to the hindlimb representation and it has been suggested that this may result from primary afferent reorganization in the dorsal column nuclei (H.P. Killackey and D.R. Dawson, Eur J. Neurosci., 1:210-221,1989). The present study used both anatomical and electrophysiological techniques to test this proposal. Rats sustained forelimb removals on embryonic day 16 and were used in terminal experiments as adults. The cuneate nucleus ipsilateral to the lesion decreased in volume by an average of 36.7% (N=7, p = < 0.001), but there was no corresponding increase in the volume of the gracile fasciculus and nucleus. Bilateral application of HRP to the sciatic nerves demonstrated that axons which innervate only the gracile nucleus on the intact side of the brainstem were present in the deafferented cuneate nucleus. Injection of HRP into the skin overlying the point of the amputation (the stump) indicated that axons innervating this region filled most of the dorsal one-half of the shrunken cuneate nucleus and overlapped with the sciatic nerve afferents on this side. Receptive field mapping demonstrated a zone in the deafferented cuneate nucleus devoted to the skin overlying the stump and adjacent shoulder. Only 9.1% of the unit clusters (N=328) in this region were also excited by hindlimb stimulation. Unit clusters with receptive fields including the skin overlying the stump and the hindlimb were located throughout the rostrocaudal extent of the cuneate nucleus. NS 28888, DE 07734, NS 21105, BNS 90-22168

#### 268.10

DEVELOPMENT OF AN INTERNEURONAL PATTERN WITHIN THE SPINAL CORD. A. Chen' and R.D. Heathcote. Department of Biological Sciences, University of Wisconsin, Box 413, Milwaukee, WI, 53201. Although the central nervous system has a high degree of functional

Although the central nervous system has a high degree of functional organization, it is not clear how much is due to the spatial arrangement of neurons. Recently, a population of interneurons was shown to extend the length of the spinal cord of the larval frog Xenopus laevis. The catecholaminergic cells were located in two longitudinal columns in the ventral spinal cord and established a uniformly spaced pattern along each column.

The formation of the unique catecholaminergic pattern was examined during embryonic and larval development. The first tyrosine hydroxylase immunoreactive neurons appeared at 1.4 days (stage 28) of embryonic development. The low numbers and irregular spacing of embryonic cells showed that the pattern emerged gradually during development. The first cells differentiated at random sites along the ventral midline of the spinal cord. Many cells were separated by long distances (> 100  $\mu$ m), and some formed groups of regularly spaced cells within a column. By one week of development (stage 48) the mean distance between cells had decreased to approximately 20  $\mu$ m, reflecting a sustained increase in the size of uniformly spaced groups of cells. Even though the spinal cord continued to increase in length, the spacing between cells remained constant, indicating that cells were added to new regions of the spinal cord. The domain of catecholaminergic neurons also gradually expanded anteriorly toward the posterior border of the hindbrain during postembryonic development. Thus the mechanisms directing pattern formation during embryogenesis persist into larval life. The establishment of the boundary and spacing of catecholaminergic intermeurons could show how at least portions of the central nervous system become partitioned into functional groups of cells.

TEMPORAL PATTERNS OF MUSCLE FORMATION IN THE AVIAN LIMB BUD. C. Lance-Jones\* and J. Van Swearingen. Dept. of Neurobiology, Anatomy and Cell Science, Univ. of Pittsburgh, Sch. of Med., Pittsburgh, PA 15261.

The muscle cells of the avian limb originate from the adjacent somites and migrate into lateral mesoderm as the limb bud is forming. What factors govern where somitic

The muscle cells of the avian limb originate from the adjacent somites and migrate into lateral mesoderm as the limb bud is forming. What factors govern where somitic cells will migrate to within the limb and what fiber types they will become? We have examined the relationship between the time that a muscle cell precursor leaves the somite and that cell's fate with respect to limb position and fiber type. At different stages during the migration period (stages 16-18) chick limb buds were removed to a host embryo's coelomic cavity to isolate the bud from further population by somitic cells. Examinations of stage 32-34 limb bud sections stained with H&E or antibodies to fast and slow isoforms of myosin heavy chain (kindly provided by Crow and Stockdale) suggest that early migrating muscle cell precursors contribute predominantly to muscles that normally contain a large number of slow fibers. Compatible results are obtained in quail-chick limb bud chimeras. We have begun to assess slow muscle fiber numbers in limbs that developed from transplantations of an early chick limb bud onto an older chick host. Preliminary results suggest a depletion of slow fibers, thus supporting the hypothesis that there are distinct slow and fast limb muscle cell lineages prior to migration into the limb. Supported by NIH HD25676.

I<sub>1</sub>-IMIDAZOLINE BINDING SITES IN PC12 CELLS ARE UP-REGULATED BY NERVE GROWTH FACTOR (NGF). P. Ernsberger\* Departments of Medicine & Neuroscience, Case Western Reserve University, Cleveland, OH 44106.

Imidazolines bind with high affinity not only to α-adrenergic receptors, but also to I-sites, which can be labeled by [1251]p-iodoclonidine ([1251]PIC; proposed I<sub>1</sub>) or by [3H]idazoxan (1<sub>2</sub>). 1<sub>1</sub>-Imidazoline sites have been found in adrenal chromaffin cells; in the present study the PC12 cell line was used. Washed P2 membranes were incubated 30 min at 25°C with 0.5 nM [1251]PIC; nonspecific binding was defined by 0.1 mM naphazoline. In PC12 membranes, specific [1251]PIC binding was not inhibited by the adrenergic agents epinephrine (0.1 mM), rauwolscine (10 μM) or SK&F86466 (1 μM) (binding as % of control was 127±6, 110±5, and 93±2, respectively). The imidazol(in)es cimetidine (1 mM) and cirazoline (3 μM) completely inhibited binding (as % of control, 1±5 and 2±3, respectively). Thus, PC12 express I<sub>1</sub> but not α<sub>2</sub> sites. [1251]PIC binding was inhibited by guanine nucleotides (GTPγS = Gpp(NH)p > GTP), implying that I<sub>1</sub> are G-protein coupled. Crude subcellular fractions were prepared and assayed for the density of I<sub>1</sub> and muscarinic sites. Both

receptor sites were enriched in plasma membranes relative to mitochondrial, P1 and P3 fractions. Daily treatment with 200 ng/ml NGF increased the density of  $l_1$  sites within 2d (Figure).  $l_1$  density reached a peak of 250±30% of control at 4d, and did not increase further by 6-7 d of treatment. Increased  $l_1$  density coincided with initial neurite outgrowth. The ligand specificity of  $l_1$  binding was not affected by NGF. PC12 cells express  $l_1$ -imidazoline sites which are (a) sensitive to guanine nucleotides, (b) neither mitochondrial nor nuclear, and (c) up-regulated by differentiation with NGF.  $l_1$  sites may be developmentally regulated neuronal receptors.

Quantification of the Transient Expression of  $\gamma$ -aminobutyric acid (GABA) in the Developing Rat Optic Nerve. J.Y. Lim¹-⁴, S. Qchi¹-⁴, M.J. During³. K. Sakatani¹-⁴, C.C. Duncan²-², & J.D. Kocsis¹-⁴, Dept. of Neurology¹, Dept. of Neurosurgery², & Sect. Neuroendocrinology³, Yale Medical School, New Haven, CT 06510; and VAMC⁴, West Haven, CT 06516.

Our electrophysiological studies on developing rat optic nerve indicate the transient presence of GABA, receptor and endogenous GABA during the first three postnatal weeks. Immuno-electron microscopic studies have localized the GABA in developing rat optic nerve to glia and premyelinated axons. Evidence also indicates endogenous release of GABA which leads to depolarization in the developing rat optic nerve. However, an accurate biochemical quantification of the transient expression of GABA has not yet been established.

To determine GABA content in intact rat optic nerve, high pressure liquid chromotography (HPLC) was employed at 3 postnatal time points:  $P3(N=3),\,P19-20(N=2),\,P>90(N=4).$  Optic nerves were rapidly removed, frozen in liquid nitrogen, and then assayed for GABA. These measurements, normalized to tissue protein (modified Bradford), displayed a peak of  $5.558\pm0.993$  ng GABA/µg protein (mean  $\pm$  standard deviation) at P3. The GABA presence then sharply declined to  $1.223\pm0.072$  ng GABA/µg protein at P19-20 and  $0.662\pm0.178$  ng GABA/µg protein at P>90. These results are consistent with the time course of GABA activity shown by electrophysiological and immunoelectroscopic studies and serve as an independent, biochemical confirmation of the transient expression of GABA during development of

Supported in part by the NIH and the Dept. of Veterans Affairs.

DAMAGE TO THE STRIATAL DOPAMINE SYSTEMS IN EARLY DEVELOPMENT SELECTIVELY SPARES THE MATRIX-DIRECTED DOPAMINE SYSTEM. P.A. Frohna\*, L. Rioux, B.S. Neal, and J.N. Joyce. Depts. Psychiatry and Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA, U.S.A.

Destruction of the nigrostriatal patch-directed and mesostriatal matrix-directed DA systems in the rat with 6-OHDA have been used as models for exploring regulation of DA receptors, DA-mediated behaviors, and DA biochemistry of the striatum. It is evident that lesions made in early development compared to adult lesions result in very different effects. Recent studies from this laboratory have begun to elucidate the neural mechanisms underlying these age-related differences. We have shown that during development, expression of DA receptors in adults is controlled by the integrity of DA afferents at the time when receptor proliferation occurs. 6-OHDA lesioning of the DA system innervating the patch compartment during early development spares the matrix innervation and causes a loss of D1 receptors from the patch compartment and a behavioral syndrome consisting of a selective D1 super-

The present study focuses on the consequences of intrastriatal 6-OHDA lesions made at postnatal day 1(P1) on surviving patch- and later developing matrix-oriented DA afferents of the SN-VTA complex. We performed: 1) In-situ hybridization histochemistry for tyrosine hydroxylase (TH) and D2-receptor mRNA, 2) TH-immunohistochemistry, and 3) Receptor autoradiography for DA uptake sites (3H-mazindol) and D2 receptors (1251-epidepride), in the SN-VTA complex of P1 6-OHDA lesioned and saline-injected animals at postnatal day 90. There is a significant reduction in the number of neurons expressing TH mRNA and TH immunoreactivity from the ventral tier of the SNpc and SNpr of 6-OHDA treated animals. [3H]mazindol and [1251]epidepride binding are almost absent from the SNpc of this group. The VTA is unchanged between groups in all measures, and may show slightly elevated levels of TH mRNA following 6-OHDA lesion. Thus, the late-developing matrix-directed DA system is spared by P1 6-OHDA lesions but may be biochemically altered in these animals. Funded by R29 MH 43852.

SPATIOTEMPORAL CHANGES IN EXPRESSION OF TWO FORMS OF A DELAYED RECTIFIER K+ CHANNEL PROTEIN IN NEURONS ARE SIMILAR IN VIVO AND IN VITRO.

N.J. Lenn\* & J. Trimmer. Dept. Neurol, Pediatr, Biochem, Cell Biol, SUNY, Stony Brook, NY 11794

Two major forms of the delayed rectifier K+ channel exist in rat brain neurons, a lower molecular weight polypeptide present from

Two major forms of the delayed rectifier Ktchannel exist in rat brain neurons, a lower molecular weight polypeptide present from embryonic to adult ages and a higher molecular weight form that increases postnatally. They can be distinguished by their immunoreactivity (IR) to two site-directed antibodies, pGEXdrk1 and KC. IR of these two antibodies with E18 dissociated, cultured rat hippocampal neurons (courtesy of G.Banker) were ranked by random, blinded observations of 20-30 cells per age per antibody on a 0/+/++ scale. pGEXdrk1-IR occurred at all times studied, 6-25 days in vitro (DIV), not changing with increasing DIV (p>0.23 for plasma membrane, cytoplasm and processes). KC-IR, present in the cytoplasm of cell body at all DIV (p>0.9), increased between 10-13 DIV in plasma membranes and between 13-17 DIV in processes (all p<0.0001). Changes in expression of these K+ channel isoforms may be intrinsic to neurons or relate to neuronal interaction, perhaps synaptogenesis.

EVIDENCE FOR AN UPSTREAM ELEMENT WHICH ENHANCES THE TRANSCRIPTION OF THE MOUSE TYROSINE HYDROXYLASE GENE. W. W. Morgan\*, M. Gamez and K. A. Rodriguez. Dept. Cellular and Structural Biology, Univ. Texas Hlth. Sci. Ctr. at San Antonio, TX 78284-7762.

Precise molecular genetic mechanisms limit the expression of the tyrosine hydroxylase (TH) gene to catecholaminergic neurons located within select nuclei of the brain, the sympathetic chain ganglia and paraganglia and adrenal medullary cells. To investigate these mechanisms, chimeric genes were constructed by linking 3.5, 1.1, 0.8 or 0.3 kb of the 5' flanking DNA of the mouse TH gene to a E. coli beta galactosidase reporter (Lac Z). Each of these constructs included the +1 initiation site for TH mRNA synthesis. The chimeric genes were introduced separately into PC 12 cells by lipofection. Stably transfected cell lines were established by co-transfection of RSV neo and subsequent G418 selection. Several clones, each originating from a single cell containing one of the above chimeric genes, were expanded for analysis. The enzymatic expression (picomoles/minute/µg protein) of the Lac Z reporter as well as the levels of transcript synthesized from the reporter were more that 50 fold greater in clones stably transfected with chimeric constructs containing 1.1 or 3.5 kb of TH 5' DNA as compared to those containing 0.3 or 0.8 kb of 5' DNA. The size of the transcript produced was the same across the different constructs and was consistent with initiation from the +1 site for TH mRNA synthesis. Analysis of southern blots provided no evidence for marked differences in the number of constructs incorporated into the genome of the PC 12 cells. Collectively, these results provide evidence for the presence of an element between 0.8 and 1.1 kb upstream which markedly enhances the expression of the TH promoter. Supported by DA00755 and GM43763 to www.

TIMING OF THE LESION IS A CRITICAL DETERMINANT OF THE LONG-TERM EFFECTS OF NEONATAL DOPAMINE (DA) DEPLETION IN THE RAT. B.S. Neal\*, S. Daly and J.N. Joyce. Depts. of Psychiatry and Pharmacology, Univ. Penn. Sch. of Med., Phila., PA 19104 and Dept. of Clin. Pharmacology, Royal College of Surgeons, Dublin, Ireland. The DA system undergoes a great deal of postnatal development, which occurs in three distinct stages (Devl. Br. Res. 60:161,1991). To explore how

The DA system undergoes a great deal of postnatal development, which occurs in three distinct stages (Devl. Br. Res. £0:161,1991). To explore how loss of DA during these stages disrupts the functional expression of DA receptors, neonatal rats received bilateral intrastriatal injections of 6-hydroxy-dopamine (6-OHDA) on day of birth/postnatal day 1 (P0/P1), P7 or P15. Controls received vehicle injections in lieu of 6-OHDA. On P90 (adulthood), half of the rats were killed and brains processed for neurochemical studies (See also, Frohna et al., this session). The remaining rats began behavioral testing. Rats were challenged with L-DOPA (DA precursor), and various DA agonists (3 doses per drug). P0/P1-lesioned rats exhibited an increased incidence of oral dyskinesias (vacuous chewing, jaw tremor, tongue protrusions) following a low dose of the mixed DA agonist apomorphine (APO; 0.1 mg/kg) and the partial D1 agonists SKF32933 and SKF77434, but not with the full D1 agonist SKF82958 (0.32-3.2 mg/kg). P7-lesioned rats did not exhibit oral dyskinesias; instead, they were hyperactive (i.e., increases in locomotor activity, rearing and jumping). They also engaged in more grooming behavior after APO (0.1-1.0 mg/kg), SKF38393 (1-10 mg/kg), and SKF77434 (0.1-1.0 mg/kg). The D2 agonist quinpirole also induced grooming in the P7 group, suggestive of altered interactions between D1 and D2 receptors SKF82958 did not induce grooming; rather, the rats were extremely hyperactive, aggressive and exhibited explosive jumping. The P15 group did not respond like the other groups. These findings support our hypothesis that the functional effects are dependent upon the timing of the DA loss. The neurochemical studies are underway to determine what types of receptor changes underlie these behavioral effects. Supported by a Tourette Syndrome Association grant and USPHS grant MH43852).

TUESDAY PM

THE EFFECT OF IN UTERO ADMINISTRATION OF BUTHIONINE SULFOXIMINE ON RAT

THE EFFECT OF IN UTERO ADMINISTRATION OF BUTHIONINE SULFOXIMINE ON RAT DEVELOPMENT. E. Reyes\*, S. Ott, B. Robinson and R. Contreras. Department of Pharmacology, Univ. of New Mexico Sch. of Med., Albuquerque, NM 87131. Glutathione (GSH) is a tripeptide that is thought to be an essential cell component playing an important role as a cellular antioxidant and scavenger of free radicals. GSH depletion has been shown to render cells more sensitive to various insults, whereas, an increase in GSH has a protective effect. GSH levels can be decreased by inhibition of its synthesis with buthionine sulfoximine (BSO) which inhibits y—glutamylcysteine synthetase. Several studies have shown that treatment with BSO enhances the toxicity of some drugs and radiation. A previous study indicated that the effects of BSO on the developing embryo were short lived and did not persist to birth. In the above mentioned study the mothers were treated with BSO on days 10 and 11 of gestation. The objective of the present study was to determine the effects of GSH depletion throughout pregnancy on the developing rat. Timed pregnant Sprague—Dawley rats were placed on a liquid BioServ diet containing BSO (2 to 8 mmole/Kg/24h) starting on day one of pregnancy. The mothers were maintained on the diet until gestation day 21 when they were anesthetized with sodium pentobarbital and the pups delivered by Cesarean Section. Various parameters relating to development were determined and GSH levels were measured in brain and liver. A dose response curve showed that a maximum depletion of GSH in the method is the property of BSO. And RSO decrease in liver. relating to development were determined and GSH levels were measured in brain and liver. A dose response curve showed that a maximum depletion of GSH in the mother's liver was produced by the 8 mmole dose of BSO. An 86% decrease in liver GSH was observed. However, no change was seen in brain GSH levels. GSH levels in brain and liver of the offspring were decreased by 60% and 66%, respectively. No significant effect of treatment with BSO was observed on growth related parameters, such as body weight or brain weight. A significant decrease in neuron specific enolase (NSE) activity in cerebellum and an increase in liver  $\gamma$ —glutamyl transpeptidase activity were observed in pups born to mothers treated with BSO. A decrease in NSE activity and an increase in  $\gamma$ —GTP activity are both consistent with delayed development. Therefore, we conclude that although a decrease in GSH may not produce teratogenic effects it may produce a delay in development and may have a permissive role in teratogenic effects produced by other drugs (Supported by NIH/MBRS RR 081399 and NIAAA AA 08072.

### 269.9

EXPRESSION OF COMPLEMENT C1qB mRNA DURING BRAIN DEVELOPMENT, SA Johnson\*, I Rosovsky, M Etchells and CE Finch. Neurogerontology Division, Andrus Gerontology Center and Dept of Biol. Sci., University of Southern California, Los Angeles, CA 90089-0191

We recently demonstrated the presence of several complement (C) component mRNAs in neurons and microglia of normal brain, and have found up-regulation of C mRNAs during Alzheimer's disease (AD) (Johnson, et al., submitted). Previous immunocytochemical studies localized C components to plaques and dystrophic neurites in AD brain. Considering the normal cytotoxic role of the C system, a humoral defense arm of the immune system, these data suggest C could play a role in AD pathology. C1qB and C4 mRNAs are also increased in afferent targets after acute deafferenting lesions (Pasinetti, et al., Exp. Neurol., in press), where a lack of neurodegeneration in the afferent target suggests C may be involved in synaptic reorganization. Because C1qB is present in normal human and rat brain, it is important to ascertain the expression of C mRNAs during brain development. Northern blot hybrization showed C1qB mRNA was present in brain from as early as E14. Initial in situ hybridization data at E16 shows cellular localization of C1qB mRNA, predominantly in meningeal zones, with scattered cells in thalamic, hypothalamic, striatal, cortical and hippocampal primordia. Cells of the ventricular zone and cortical plate lamina in the cerebral wall are generally negative, except for a few scattered positive cells. The data are consistant with C expression in blood-borne cells, but probably not neurons, at E16, which is prior to formation of the blood brain barrier. Later developmental stages are being examined. Supported by AG-07909 (CEF) and AG-10673 (SAJ).

EXPRESSION OF RB, CDC2, NSE, AND FOS BY NEURONAL PRECURSOR CELLS IN THE ADULT BRAIN. <u>H.J. OKANO\*</u>, <u>D.W. PFAFE</u>, AND <u>R.B. GIBBS</u>. Lab. of Neurobiol. & Behav., The Rockefeller Univ., NY, NY 10021.

Relatively little is known about cell-cycle regulation during neurogenesis. In the present study we examined the expression of cell-cycle regulatory proteins by neuronal precursor cells located in the hippocampal formation of adults. Male, Sprague-Dawley rats (180-250 g) were killed 2 hours - 4 weeks after receiving a single injection of 3H-thymidine (4µCi/g.b.w. i.p.). Adjacent, 30 µm sections were cut and processed for immunocytochemical detection of mammalian cdc2 (G6

cut and processed for immunocytochemical detection of mammalian cdc. (Go antiserum; Dr. D. Beach), RB (Pharmingen Pharm.), Fos and Fos-related antigens (Dr. M. ladarola), and neuron-specific enolase (NSE; Chemicon Pharm.). Sections were then dipped in NTB-3 emulsion and radiograms were developed 2-6 weeks later. 3H-Thymidine-labeled (3H-T) cells were detected in the subgranular region of the dentate gyrus (DG). Two hours post-injection (n=3), 79% of these 3H-T cells contained RB-like immunoreactivity (RB-I) and 33.8% contained cdc2-I. After 12 hours the number of 3H-T cells in the DG had doubled. At this time, the percentage of 3H-T cells double-labeled with RB-I decreased to 54.9% while the percentage double-labeled with cdc2-l increased to 42.7%. At later time-points, the percentage of 3H-T cells double-labeled with RB-I decreased to 41.5%, 1.4%, and 0.3% at 24 h, 1 3H-T cells double-labeled with RB-I decreased to 41.5%, 1.4%, and 0.3% at 24 h, 1 week, and 4 weeks respectively. Similarly, the percentage of 3H-T cells double labeled with cdc2-I was 43.5% at 24 h, and then decreased to 1.7% and 0% at 1 week and 4 weeks. Very few (0.1%) 3H-T cells in the DG were double-labeled for NSE-I -224 h post-injection. This percentage increased significantly to 13.9% and then to 80.6% at 1 week and 4 weeks, suggesting that the majority of these cells had differentiated into neurons. Very few (<1%) 3H-T cells were double-labeled with Fostal and time-point. However, seizure activity (induced by pentylene tetrazol) was able to induce Fos-I within 3H-T cells in the DG as early as 1 week post-injection, suggesting that these cells had formed functional connections. The data demonstrate that RB and cdc2 expression are regulated during neurogenesis in the adult suggesting that use certain the truth of the truth at the control of the state temporature that RB and cdc2 expression are regulated during neurogenesis in the adult hippocampal formation. A similar analysis of neurogenesis in the adult olfactory bulb is in progress and will be discussed. Supported by NIH grant #NS28896.

RETINOIC ACID RESPONSIVENESS AND DEVELOPMENTAL EXPRESSION OF THYMOSIN B10 FUSION GENE IN TRANSGENIC MICE. S.-C. Chen. R. J. Smeyne. C. Bocchiaro, J. G. Corbin. R. J. Wurzburger\* and J. I. Morgan, Roche Institute of Molecular Biology, Roche Research Center, Nutley, NJ 07110.

Thymosin B10 is an acidic polypeptide that is present in high

Thymosin B10 is an acidic polypeptide that is present in high concentration in the immature nervous system, but that is a minor component in the adult brain. In addition, the expression of this gene is up-regulated by the morphogen, retinoic acid (RA), in a variety of neuroblastoma cell lines eg., B104. The rat thymosin B10 gene has been isolated and used to identify its RA-responsive element(s). We now report that expression vectors encoding the human retinoic acid receptors can activate chloramphenicol acetyltransferase (CAT) expression from thymosin B10-CAT chimeric constructs in B104 cells. Through the use of deletion and mutation analyses the RA-responsive Through the use of deletion and mutation analyses, the RA-responsive element of the thymosin β10 gene has been identified on its 5' flanking

region.

Using lacZ as a reporter, we have constructed transgenic mice that carry a <u>\( \beta \) 10-lacZ</u> fusion gene and examined its expression during development. This fusion gene contains a 1.3 kb upstream region of the thymosin \$10 gene and its expression was first detected at embryonic day 8.5. High levels of expression of this construct was observed in the embryonic nervous system, especially sensory neurons. The expression of this fusion gene was found to be regulated developmentally. Several other constructs, with different lengths of the thymosin \$10 promoter, have also been used to dissect out the regulatory elements responsible for the developmental expression of the thymosin \$10 gene.

DEVELOPMENTAL REGULATION OF c-fos AND ITS RESPONSIVENESS IN SPINAL CORD CULTURES. C. G. Palkovits. D. E. Brenneman, S. C. Fitzgerald, R.W. Summers\* and D.V. Agoston, Laboratory of Developmental Neurobiology, NICHD, National Institutes of Health, Bethesda, MD 20892 fos and fos-related proteins are transcription factors that couple extracellular

stimuli to cellular responses by altering the expression pattern of their target genes. During the "critical period" of neuronal differentiation, the expression of genes is modulated by such extracellular factors. We have choosen fos-immuno histochemistry to assess neuronal responsiveness to various environmental stimul during different stages of neurodifferentiation in the embryonic spinal cord-dorsal root ganglia culture (SC-DRG). The earliest expression of fos-immunoreactivity was seen after 7 days in culture (DIC), restricted to neuronal nuclei. This expression was driven by the spontaneous electrical activity and could be blocked by tetrodotoxin (TTX). Changing the medium to fresh serum-rich medium caused upregulation of fos-immunopositivity in the nuclei of neuronal and background cells alike. In neurons but not in background cells, this effect decreased as a function of age and was blocked by TTX. BayK6844 and (+) 202791, agonists of the L-type voltage-sensitive calcium channel (VSCC), dramatically upregulated fos expression in neuronal nuclei but not in nuclei of background cells. BayK 6844 was most effective in 15 DIC cells whereas (+) 202791 showed maximum effect in 21 DIC neurons. The antagonists of L-type VSCC Nifedipine and (-) 202791 reduced constitutive fos expression an age-dependent way. Pretreatment with BayK 6844 or (+)202791 prevented TTX-induced downregulation of fos expression in a similar age-dependent manner. Increasing extracellular calcium levels alone did not increase constitutive expression or prevent TTX-caused downregulation of fos-protein. Veratridine depolarization increased fos-expression in 4 DIC neurons only, whereas exposure of cells to PMA caused a substantial increase of fos- expression in all but the youngest cultures; however mostly in non-neuronal cells. Our results indicate that the expression of fos as nuclear signalling molecule, can be used to assess the responsiveness of the developing nervous system to various extracellular stimuli.

## 269.12

EXPRESSION OF THE HLH PROTEINS ND-1, MASH-1, AND ID IN DEVELOPING MOUSE NERVOUS SYSTEM. M. P. Armanini, G. R. Laramee, J. W. Winslow, and H. S. Phillips. Dept. of Neuroscience, Genentech, Inc., S.S.F., CA 94080.

In situ hybridization was employed to examine the distribution of mRNA for the HLH proteins ND-1, MASH-1, and Id in the developing mause. A series of embryose from F. 7.5 to 17.5 types examined.

mouse. A series of embryos from E 7.5 to 17.5 was examined. Hybridization signals for ND-1 and Id were widely expressed in the earlier embryos. With increasing age, Id expression became quite restricted within the nervous system while ND-1 expression was restricted within the nervous system while ND-1 expression was maintained at high levels in several regions of the CNS. MASH-1 signal was transiently expressed in the developing sympathetic ganglia and enteric nervous system as well as in selected regions of the developing CNS. At embryonic days 9.5 to 11.5, mRNA for ND-1, MASH-1, and Id all display prominent expression in the ventricular zone of the neural tube. From E 11.5 to 17.5, Id is progressively eliminated from the ventricular zone and shows very limited expression in CNS. In marked contracts as development, proceedes, ND, In marked contracts as development, proceedes, ND, in CNS. In marked contrast, as development procedes, ND-1 expression remains prominent within the CNS. At all ages investigated, ND-1 expression is maintained at high levels throughout the germinal zone of the lateral ventricle and is prominent in numerous telencephalic structures. MASH-1 expression within the CNS, appeared to be largely restricted to germinal zones. The pattern of ND-1 and MASH-1 mRNA expression suggests some regions of neurogenesis in which ND-1 and MASH-1 might associate with one another, but indicates other regions in which these molecules might be expected to associate with other dimeric cohorts.

Regulation of c-myc RNA Expression in the Developing Nervous System. G. Weisinger and J.D. DeCristofaro, Dept. of Peds. and Neurobiol., SUNY, Stony Brook, N.Y.

The c-myc protooncogene has been implicated in the regulation of normal cellular growth and differentiation for all but two neuronal cell lines. Recently, Xu et al [MCB 11, 6007 (1991)] demonstrated that c-myc steady state RNA expression is elevated in whole brain total RNA preparations from neonatal mice. This c-myc RNA expression was turned off by 3 weeks of age. We wanted to determine whether c-myc steady state RNA was developmentally regulated in rat nervous system tissues, and if so, whether these tissues are linked to cellular proliferation or not. Total RNA was prepared from numerous nervous system structures from 1 day and 3 week old rat pups and studied by northern analysis. Our data indicates that c-myc RNA is not exclusively associated with cellular proliferation within the developing rat nervous system. In the olfactory bulb and adrenal medulla, there is a tight correlation with cellular proliferation, but in the cerebellum, cerebral cortex and hippocampus, this is clearly not the case. Hence, c-myc may have a nonmitogenic function. Interestingly, c-myc RNA levels in the neonatal cerebral cortex were much greater than that found in the adult rat thymus, a tissue expressing high levels of c-myc RNA. Using this data we want to determine at what transcriptional level these changes occur so that we can develop an understanding of what factors and mechanisms control c-myc, in vivo. Sponsored by NIH RR05736.

CHARACTERIZATION OF BC1 scrnp, A BRAIN-SPECIFIC CYTOPLASMIC RIBONUCLEOPROTEIN COMPLEX. J.G.Cheng\*,

CYTOPLASMIC RIBONUCLEOPROTEIN COMPLEX, J.G.Chengt. H.Tiedge and J. Brosius. Fishberg Center for Neurobiology and Depto fo Molecular Biology, Mt. Sinai Sch. of Med., New York, NY 10029

The brain specific small cytoplasmic RNA (BC1 RNA) in the rat contains many interesting features. It is the first known RNA polymerase III transcript with neuronal specificity. The expression of BC1 RNA in the CNS is regionally and developmentally regulated. Furthermore, it is one of the few RNAs which is actively transported into dendrites. From sequence comparison, BC1 RNA is conserved only in rodents. However, a small RNA that is an analog but not a homolog to BC1 RNA has been characterized in primates.

BC1 RNA has been characterized in primates.

Four pieces of evidence support the notion that BC1 RNA exists as a roun pieces of evidence support use induor that BCT NNA exists as a ribonucleoprotein complex in vivo; first, by running brain extract into CsCl or Cs2SO4 gradient the bouyont density of fractions containing BC1 RNA signal is 1.45 gm/ml and 1.25 gm/ml, respectively, which is consistent with the density of a protein-RNA complex; second, the BC1 particle has a larger S value (8.5S) than naked RNA (4.5S) in sucrose gradients; third, the BC1 RNA signal from brain extract migrates with retarded mobility in agarose electrophoresis; finally, specific portions of BC1 RNA are protected by certain proteins and become more RNase resistant. Compared with the signal recognition particle, integrity of BC1 RNP is not Mg++ dependent and is more heat resistant. By using conventional purification (chromatography and ultracentrifugation) as well as RNA binding assays performed on protein blots, there are at least one protein which appears to directly interact with BC1 RNA. Necessary amounts of BC1 RNP are being purified for characterization of binding proteins.

EXTRACELLULAR MATRIX MOLECULES IN THE RAT AND HUMAN OPTIC NERVE: CHANGES IN PATTERNS OF EXPRESSION AFTER

INJURY. W.P.Battisti\*, J.Wang, J.Kennerdell 1, and M. Murray, Med.Coll.

Pa., Phila., Pa. 19129 and Allegheny Gen'l. Hosp. <sup>1</sup>, Pittsburgh, Pa. The environment of the CNS is important in regulating regrowth following injury. We used immunocytochemistry to compare the distribution of tenascin, chondroitin sulfate proteoglycan (CSPG), HNK-1, and laminin, molecules implicated in facilitating or inhibiting regrowth, in the human and rat optic nerve, species in which regeneration does not normally occur. The human optic nerve is organized in large fasicles containing axons and their associated glid cells each delineated by beat larging. Ench of the molecules associated glial cells, each delineated by basal lamina. Each of the molecules examined shows a unique and constitutive expression in the normal optic examined shows a unique and constitutive expression in the normal optic nerve. Tenascin staining is ubiquitous and strong labeling is seen over the basal lamina, within axon fascicles, and also defining large interfascicular nonneuronal cells. CSPG and HNK-1 staining are limited to areas of axon fascicles but each with different patterns. Laminin stains external basal lamina. Injured human optic nerve, obtained subsequent to eye trauma or disease, shows a decrease in intensity and a change in the pattern of staining for tenascin, CSPG and HNK-1. Laminin is unchanged. These extracellular matrix molecules have similar staining patterns in the normal rat optic nerve. However, the pattern of expression and intensity is different after crush. In rat optic nerve sacrificed 2 weeks PO, tenascin, CSPG and HNK-1 staining appear normal proximal to the crush but their association with the nonneuronal cells that fill the area at the crush and distally is marked and the pattern of association is distinct. Laminin staining appears within the crush pattern of association is distinct. Laminin staining appears within the crush site, but the staining is weak. We are currently examining the population of nonneuronal cells that may contribute to this environment and the colocalization of these cells with the distribution of the ECM molecules. Supported by NS 16556 and ASRI 910161.

DIFFERENTIAL REGULATION OF CONNEXIN-43 AND -32 mRNA IN THE DEAFFERENTED STRIATUM AFTER A UNILATERAL CORTICAL LESION. H-W. Cheng \*and T.H. McNeill. Andrus Gerontology Center, University of Southern California, Los Angeles, CA 90089-0191.

During development, electrical coupling via gap junctions constitute and important mode of intercellular communication by allowing for direct cell to cell communication between both neurons and glia. However, little information exists regarding the formation of gap junctions between either neurons or glia following experimental brain lesions. To address this issue we examined changes tollowing experimental brain tesions. To address this issue we examined changes in the prevalence of mRNA for two gap junctional proteins, connexin-43 (Cnx-43) and -32 (Cnx-32), between 1 and 27 days postlesion in the deafferented striatum (ST), following a unilateral cortical lesion. Based on previous immunocytochemical studies, it is suggested that Cnx-43 is associated with the formation of gap junctions between glia; while Cnx-32 is part of the gap junctional complex formed primarily between neurons.

By northern blot and <u>in situ</u> hybridization analysis, we found an increase in the prevalence of mRNA for Cnx-43 but not Cnx-32 in the deafferented ST following the ipsilateral cortical lesion. In addition, the time course for changes in the prevalence of Cnx-43 mRNA was correlated with the temporal sequence of increased glial reactivity as measured by changes in protein and mRNA for GFAP at the lesion site. In the dorsal aspect of the deafferented ST, an increase in Cnx-43 mRNA prevalence was found at 3 days postlesion and reached a maximum at 10 days postlesion. By 27 days postlesion Cnx-43 mRNA was reduced but still elevated over intact controls. These data suggest that the formation of gap junctions between glia are involved in orchestrating the cellular response of reactive astrocytes in the ST following a cortical lesion. However, the precise role of electrically coupled astrocytes during reactive synaptogenesis remains unclear.

# 270.3

DIFFERENTIAL MODULATION OF GFAP and SGP-2 mRNA FOLLOWING TWO FORMS OF STRIATAL DEAFFERENTATION. P. Elyse Schauwecker H-W. Cheng 1. T.J. Collier 2. and T.H. McNeill 1. Andrus Gerontology Center, Univ. of Southern California, Los Angeles, CA 90089, <sup>2</sup>Dept. of Neurobiol. & Anat., Univ. of Rochester, Rochester, NY 14642.

Previous studies have reported that reactive astrocytes play an important role in both removing degenerative debris and the reinnnervation of target neurons following brain injury. However, few studies have correlated the time course of the astrocytic response with the time course of reactive synaptogenesis. In order to address this issue, we examined changes in two astrocytic proteins, GFAP and SGP-2, following a unilateral lesion of either the cortex or substantia nigra (SN), which differ with respect to total synaptic input, transmitter content and reinnervation response. Temporal changes in mRNA prevalence for GFAP and SGP-2 were measured at 3, 10, and 27 days postlesion in the ST following either a nigral lesion with 6-OHDA or unilateral cortical ablation.

Using northern blot and in situ hybridization analysis, we found an increase in GFAP mRNA in the ipsilateral ST following both the nigral and cortical lesions. However, the time course of the GFAP response differed betwen the two lesions. Following the nigral lesion, a transient increase in GFAP mRNA was found at 3 days postlesion which rapidly returned to control levels by 10 days postleison. No changes in SGP-2 mRNA were found. By comparison, both GFAP and SGP-2 mRNA remained significantly increased at all timepoints after a unilateral cortical lesion. These results support the notion that reactive astrocytes perform multiple time dependent functions during reactive synaptogenesis and that the time con of the astrocytic response corresponds to the cellular events that characterize the reorganization of synaptic circuits following a specific deafferentation lesion.

## 270.4

INCREASES IN GLIAL FIBRILLARY ACIDIC PROTEIN (GFAP)-LIKE IMMUNOREACTIVITY (IR) IN THE RAT SUPERIOR CERVICAL GANGLION (SCG) AFTER DECENTRALIZATION, AXOTOMY AND EXPLANTATION. U. Vaidyanathan, H. Hyatt-Sachs\* and R.E. Zigmond. Department of Neurosciences, Case Western Reserve University, School of Medicine, Cloydard, ONL 44108. Cleveland, OH 44106.

Cleveland, OH 44106.
Studies of the effects of decentralization, axotomy and explantation of the SCG have focused primarily on changes occuring in neurons in the ganglion. Evidence in the literature indicates, however, that some of these manipulations also affect ganglionic non-neuronal cells (e.g., Effvin et al., Cell Tissue Res. 250:79, 1987). We have examined the effects of all three manipulations on GFAP-IR in the SCG. GFAP staining in control ganglia was seen in satellite cells apposed to some principal neurons. In some instances, immunoreactive cells surrounded a principal neuron. Forty-eight hours after cutting the preganglionic cervical sympathetic trunk or the postganglionic internal and external carotid nerves or after placing ganglia in organ culture, there was a large increase in GFAP-IR in the SCG. Most principal neurons were surrounded by immunostained cells, and the perineuronal area of staining was considerably greater than that seen in control tissue. The magnitude of these changes was greatest after explantation and smallest after decentralization. When only one of the postganglionic trunks of the SCG was cut, the increase in GFAP-IR occurred primarily in that half of the ganglion known to contain the cell bodies of neurons projecting out that trunk.

POSTGANGLIONIC AXOTOMY AND 6-HYDROXYDOPAMINE (6-HDA) PRODUCE A BURST OF SATELLITE CELL PROLIFERATION IN ADULT RAT SUPERIOR CERVICAL GANGLION (SCG). M. Bachoo, A.K. Hall\*, C. Polosa, R. Zigmond, Case Western Reserve Univ. School of Medicine, Cleveland, OH; McGill Univ., Montreal, PQ.

The possibility that increased glial fibrillary acidic protein (GFAP) staining seen in SCG after axotomy (Vaidyanathan et al., this volume) is accompained by glial cell proliferation was tested by immunofluorescent detection of an incorporated thymidine analogue, bromodeoxyuridine (BrDU), using microscopic image analysis. number of labeled nuclei/unit area was compared between experimental and sham treated rat SCG sections (3-5 animals/ group). A dramatic increase in the number of BrDU labeled nuclei throughout the SCG was seen 48 hrs after internal and external carotid nerve section (16 fold) or 6-HDA administration (75 mg/kg two twice at 12 hr intervals; 11 fold). Double labelling showed BrDU labeled cells to express GFAP but lack fibronectin and laminin. Frequently, BrDU labeled cells were in close proximity and surrounding tyrosine hydroxylase-labeled neurons, suggesting that they were likely to be satellite glial cells.

The time course of cell proliferation following axotomy was determined by administering BrDU for a 24 hr period before sacrifice. Significant proliferation was detected after 1 day (4 fold), dramatically increased at 2 days (14 fold), moderately increased at 3 days (5 fold), and persisting at a low level (3 fold) at 1 and 2 weeks, relative to sham-treated SCG. These results suggest that lack of a retrograde target derived growth factor may produce a cell body response which stimulates satellite cell proliferation.

STIMULATION OF ASTROCYTE PROLIFERATION BY AN MPTP-INDUCED LESION IN THE MOUSE CAUDATOPUTAMEN. W.G. McAuliffe\* and R.S. Nowakowski, Dept. of Neuroscience and Cell Biology, Robert Wood Johnson Medical School/UMDNJ, Piscataway, NJ 08854.

MPTP is a dopaminergic neurotoxicant which causes a Parkinsonian syndrome in man, monkeys and mice. Previous work has shown that MPTP causes gliosis, as measured by biochemical detection or immunostaining of glial fibrillary acidic protein (GFAP), in the caudatoputamen (CP). This gliosis appears to be a reaction to the destruction of nigrostriatal dopaminergic nerve terminals. However, it is not clear whether this gliosis is due to the upregulation of GFAP in and hypertrophy of existing astrocytes or if DNA synthesis and cell division of astrocytes also occurs. To investigate this question male C57Bl/6J mice were given a single intraperitoneal dose of MPTP, 50 mg/kg. Forty-eight to 72 hours later these mice were given a single i.p. injection of the thymidine analogue bromodeoxyuridine (BUdR, 50 mg/kg) and sacrificed 30 minutes later. Paraformaldehyde-fixed, paraffin-embedded sections through various levels of the CP were stained with antibodies to GFAP (Dako) or BUdR (Becton-Dickinson) using a Vector ABC kit. The single MPTP injection was sufficient to produce marked increase in astrocytic GFAP staining in the CP by 48 hours. The CP also contained a significant number of BUdR-labeled nuclei reflecting an increased rate of cell proliferation compared to untreated mice. Labeled nuclei were found in various regions of the CP at 48, 54, 60 and 72 hours after MPTP. Mitotic figures were seen occasionally at 48 hours post-MPTP. The size and shape of the BUdR-labeled nuclei indicate that they are astrocytes. We conclude that MPTP causes both hypertrophy and hyperplasia of astrocytes in the caudatoputamen.

CHARACTERIZATION OF MACROPHAGES IN NORMAL AND TRANSECTED NERVES. C. Lobato and J.W. Griffin\*. Dept. of Neurology,

NERVES. <u>C. Lobato and J.W. Griffin</u>\*. Dept. of Neurology, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205
Resident macrophages, well-characterized in many tissues, have only rarely been described in the peripheral nervous system (PNS). In this study we characterized the numbers, distributions, and immunophenotypes of the resident macrophages of the PNS, and their responses to injury, using as a model system Wallerian degeneration (WD) of the rat sciatic nerve. By immunocytochemistry, the resident macrophages in normal nerve were thin, longitudinally oriented, had long branched processes, and many were Class II-positive, even in germ-free, isolatormany were Class II-positive, even in germ-free, isolator-reared rats. Over 9% of cell nuclei in normal rat sciatic nerves were associated with resident macrophages.

After nerve transection, the number of macrophages began to increase on day 2, and increased more as time post-transection advanced. Within short-term organ cultures of rat sciatic nerve, there was no increase in macrophage number, indicating that most of the macrophages seen during WD are derived from the circulation.

The prominence of these MHC Class II-positive cells in normal peripheral nerve and their localization near blood vessels makes them candidates for being the antigen-presenting cells of the PNS. During WD of the PNS, circulating macrophages are recruited.

REACTIVE ASTROCYTE FORMATION IN THE SPINAL DORSAL HORN IS REDUCED BY B-ADRENERGIC RECEPTOR BLOCKADE. J. Sutin\* and R. Griffith. Dept. of Anatomy and Cell Biology, Emory Univ. School of Medicine, Atlanta, GA 30322

Astrocytes in primary cultures express B-adrenergic receptors (B-ARs) and isoproterenol accelerates the transformation from an ovoid, epithelial-like appearance to a stellate, process bearing morphology (McCarthy et al., J. Neurochem. 10:723 1985). Since astrocytes isolated from several regions of the adult rat brain possess B-ARs (Shao and Sutin, Glia 6: 1992 in press), we examined the effect of the B-AR antagonist propranolol on the formation of reactive astrocytes in the rat spinal cord. The lectin Ricin communis (1.5  $\mu$ g) was injected into the sciatic nerve on one side to destroy dorsal root ganglion cells and motor neurons. Seven days later sections from the lumbar spinal cord were ocessed for GFAP immunocytochemistry and the optical density in Laminae I processed for GFAP immunocytochemistry and the optical density in Laminae I-III of the intact dorsal horn compared with the corresponding region on the side with primary afferent axon degeneration (N=12). A second group of Ricin treated animals received a continuous infusion of propranolol from subcutaneously implanted osmotic pumps (N=12). The pumps delivered 300  $\mu$ g/hr d,l-propranolol which, taking into account plasma protein binding and clearance half-life, is calculated to produce a steady state free plasma concentration of 4.4 nM l-propranolol. The  $\beta$ -AR antagonist treatment resulted in a 68% reduction in the increase of GFAP optical density (p < 0.001) in the dozed here of the receipheap larger injury, which we interpret to show a major dorsal horn after peripheral nerve injury, which we interpret to show a major reduction in glial scar formation. Supported by a grant from the American Paralysis Association.

## 270.8

REACTIVE ASTROGLIOSIS IS DELAYED IN THE OPTIC NERVES OF SLOW DEGENERATING C57BL/Ola MICE FOLLOWING RETINA REMOVAL A. Trimmer\*. Department of Neuroscience, University of Virginia School of Medicine, Charlottesville, VA 22908.

Following a lesion, there is a loss of propagated electrical activity

as well as other degenerative changes in the CNS. In wild type mice (C57BL/6, BL/6), it has not been possible to determine if reactive astrogliosis is triggered by the loss of electrical activity alone or by factors associated with CNS degeneration (ex. macrophage activity and degeneration of myelinated axons). This study capitalizes on the recent discovery of a novel strain of mice, C57BL/Ola (BL/Ola) that express prolonged axon viablity, delayed macrophage recruitment and delayed removal of degenerating debris following a lesion in the PNS (Lunn et al., 1989). BL/6 and BL/Ola mice were subjected to unilateral retina removal and processed for electron microscopy (EM) and immunocytochemistry at 2-28 days post-operation (DPO). At the EM level, degenerating myelinated axons and hyperfilamentous, reactive astrocytes were first detected in BL/6 mice at 7 DPO but similar changes were not detected in lesioned BL/Ola mice until 28 DPO. Increases in glial fibrillary acidic protein immunoreactivity were also delayed in the lesioned BL/Ola mouse optic nerve. The results of this study suggest that the loss of propagated electrical activity that occurs concurrent with retina removal is <u>not</u> a trigger for the formation of reactive astrocytes in the BL/Ola mouse optic nerve. Because reactive astrogliosis is delayed, the most likely source of factors that trigger reactive astrogliosis are the activated macrophages and degenerating myelinated axons whose expression is also delayed in the lesioned optic nerve of BL/Ola mice.

## 270.10

THE RESPONSE OF MACROPHAGES TO OPTIC NERVE INJURY IN GOLDFISH. J. Wang\*, W.P. Battisti, T.C. Eckenrode and M. Murray. Department of Anatomy and Neurobiology, Medical College of Pennsylvania, Philadelphia, PA 19129.

Macrophages may contribute to the role that the environment plays in successful axonal regeneration. The goldfish optic nerve regenerates readily after crush lesion and this system therefore permits the examination of the role of macrophages in regeneration in the CNS. The monoclonal antibody OX-42 recognizes complement type 3 receptors and its expression in unprescribed in activated macrophages. We monoclonal antibody OX-42 recognizes complement type 3 receptors and its expression is up-regulated in activated macrophages. We examined the expressions of OX-42 antigens on macrophages in the goldfish optic nerve at the light and EM level. Two types of macrophages are recognized in goldfish optic nerve, granule bearing interfascicular macrophages, and intrafascicular macrophages which resemble conventional macrophages and which phagocytose debris after injury. Neither type is strongly labeled in control optic nerve. Optic nerves were crushed and fish sacrificed 1 hour to 14 wks later. Some labeled interfascicular macrophages are seen by 1 hour and many are labeled by 3 hours PO, before regeneration commences. Labeled intrafascicular macrophages are seen later. The number of labeled macrophages increases to a maximum 4 wks PO, when regeneration is largely complete, and then declines. After 8 wks no labeled macrophages are detected. These results show that the macrophage response is closely related to axonal regeneration in the fish optic nerve, and suggest that the two types of macrophages may have different functions. Supported by ASRI 91-016-1 and NS 16556.

OXYTALAN FIBRILS ACCUMULATE IN RENAUT BODIES. J. Weis\*, M.E. Alexianu, G. Heide, J.M. Schroeder. Inst. of Neuropathol., Technical Univ., D-5100 Aachen, Germany.

Renaut bodies (RBs) are fusiform endoneurial structures found at sites of nerve entrapment, often occupying more than 30% of the cross sectional area of nerve fascicles. Their origin, composi-tion, and function, however, is still incompletely understood.

In this study, the causal relationship between the development of RBs and nerve entrapment was confirmed. RBs were absent in fetal median nerves at the level of the wrist and in adult median fetal median nerves at the level of the wrist and in adult median nerves above the wrist, but they were found in median nerves within carpal tunnels of 10 year-olds and adults. The number of RBs increased with age. The cells in RBs had long processes resembling fibroblasts. Like perineurial cells, these cells were immunoreactive with antibodies against epithelial membrane antigen (EMA) and were partially covered by a basal lamina reactive with antibodies against laminin and s-laminin. Focally accumulated microfibrils dispersed in an amorphous matrix and bundles of 30.40 nm collagen fibers were major extracellular. bundles of 30-40 nm collagen fibers were major extracellular components of RBs. The diameter of the microfibrils (8-12 nm) corresponded to the size of the microfibrillar component of elas-

tic fibers, the oxytalan fibrils. RBs were stained with antibodies against oxytalan fibrils, several types of collagen, and tenascin.

On the basis of these results, we propose that RBs are composed of fibroblast-like cells that often show perineurial differentiation. These cells produce an extracellular matrix highly entitled. riched in elastic fiber components. Thus, RBs might serve as pressure absorbing cushions for entraped nerves.

## 270.13

NEUROIMMUNE RESPONSE IN THE NEONATAL MOUSE HIPPOCAMPUS FOLLOWING PRENATAL LESIONS TO THE ENTORHINAL CORTEX. C.F. Ide\*, U. Chu, D.C. Snyder, B.W. Coltman, and J. Scripter. Dept. of Cell and Molecular Biology, Tulane University, New Orleans, LA 70118.

The nervous system and the immune system cross-regulate each others activities via a series of complex cellular and molecular interactions Development of specific aspects of this interacting system is of considerable interest, e.g., the ontogeny of reactivity of neuroimmune cells to trauma during late fetal development. To define the capabilities of neuroimmune cells to respond to local damage in the developing fetal cerebral cortex, we lesioned the fetal entorhinal cortex (EC) using exo utero surgical methods at embryonic day 15-16 (E15-16) in the mouse. At the time of birth (P0), we examined the hippocampal formation, a structure adjacent to the damaged examined the hippocampal formation, a structure adjacent to the damaged EC and which receives significant prenatal innervation from the EC. Lesioned animals showed increased numbers of GFAP-reactive cells, and increased numbers of cells with macrophage-like staining properties in the hippocampus as determined by immunocytochemistry. Additionally some large bipolar-like cells exhibited an endogenous peroxidase activity. These data indicate that the late fetal cerebral cortex is capable of responding to trauma with basic elements of a more mature neuroimmune response characteristic of older animals.

## 270.15

THE CHARACTERISTICS OF REACTIVE ASTROGLIOSIS CAN BE DIFFERENTIALLY MODULATED BY CYTOKINES. V.W.Yong\*, T.Tejada-Berges, E.Wright and V. Balasingam. Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada H3A 2B4.

Quebec, Canada H¾A 2B4.

There is emerging evidence that cytokines may mediate reactive astrogliosis post-injury. This study addresses whether particular changes of the reactive astrocyte are regulated by different cytokines. Postnatal day 3 mouse pups were subjected to a scalpel blade injury to the cortex, and 20 U (in 2 ul) of cytokines or vehicle applied to the stab cavity. Four days later, brain samples were analysed for GFAP immunoreactivity (IR) or GFAP content. Astrocytic proliferation was assayed in vitro using ³H-thymidine incorporation. GFAP IR was minimal in vehicle-treated pups, in correspondence with reports that gliosis occurs to a lesser extent, if at all, following injury to the in vehicle-treated pups, in correspondence with reports that gliosis occurs to a lesser extent, if at all, following injury to the neonatal brain. In contrast, all cytokines tested ( $\gamma$ -IFN, IL-1, IL-2, IL-3, IL-6, TNF- $\alpha$ , M-CSF) increased GFAP IR. The specificity of the cytokine effect was shown by the inability of human  $\gamma$ -IFN to evoke gliosis in mice, in accordance with reports that the interaction of  $\gamma$ -IFN with its receptor is speciesspecific. Content of GFAP is currently being determined. <sup>3</sup>H-thymidine measurements revealed that only  $\gamma$ -IFN and TNF- $\alpha$  could alter proliferation. These data suggest that the various parameters of reactive astrogliosis can be differentially regulated, and support the postulate that cytokines are mediators of gliosis post-injury to the CNS.

GLIAL PROLIFERATION IN ADULT RAT BRAIN FOLLOWING INJURY. H. Ishiguro, J. Amat, K. Nakamura, and W.T. Norton\*. Neurclogy Dept., Albert Einstein Coll. of Med., Bronx, NY 10461.

It is known that a few immature glia proliferate in the adult CNS, and we have shown that ganglioside GD3+ astrocyte precursors can be isolated from mature brain (Norton and Farooq, <u>J. Neurosci.</u> 9:769-775,1989). We have initiated a study brain (Notion and Parood, <u>J. Neurosci. 9</u>, 109-173,15-99). We have initiated a study of the fate of such glioblasts in the normal CNS, and whether they contribute to glial proliferation following injury. Adult (250g) rats were subjected to unilateral stab wounds. Proliferating cells were detected by <sup>3</sup>H-thymidine autoradiography and by PCNA immunostaining (a marker for S-phase). At 2, 3, 4, 7, 14 and 21 days postinjury (dpi) animals were perfused and sections triple-immunostained for various combinations of the antigens: PCNA, GD3, GFAP, carbonic anhydrase, π and μ isoforms of glutathione-S-transferase, ED-1, and ricin lectin (for microglia). Dividing cells increased dramatically at 2 dpi, reached maximum levels at 4 dpi and diminished considerably by 7 dpi. At 2 dpi these were 1/3rd GD3+/GFAP- and 2/3rds ricin+ (GD3-, GFAP-, ED-1-), but none were astrocytes. At 3 dpi reactive astrocytes proliferated, some of which were also GD3+. At 4 dpi four populations astrocytes promated, some to made the state and of dividing cells (ricin+, GD3+/GFAP-, GFAP+/GD3-, and GFAP+/CD3+) were present in the ratio of 43:24:27:6. Thus nearly half of the proliferating cells were microglia (macrophages at the edge of the wound are PCNA-), 33% were astrocytes, and 24% were immature GD3+ cells. GD3+/PCNA+ cells exhibit three different morphologies: small GFAP- cells having few processes and small nuclei, large GFAP+ cells with large round nuclei, and immature subventricular zone cells (also present in controls). As yet we have no evidence that the small GD3+ cells differentiate into either astrocytes or oligodendrocytes. We provisionally conclude that differentiated astrocytes enter the cell cycle at 3 dpi and divide once, and then acquire GD3. (Supported by USPHS grants NS02476 and NS23705)

## 270.14

CULTURED ASTROCYTES FROM ADULT RATS AFTER PERFORANT PATH TRANSECTION OR ELECTROLYTIC ENTORHINAL CORTEX LESIONS C. Peterson\*, N. Laping, J. Valverde and J. Day. Dept. Gerontology, University of Southern California, Los Angeles, CA 90089 Degenerative changes similar to those in Alzheimer's disease have been

observed in rats with entorhinal cortex lesions. Four days post-lesion there is a marked elevation in GFAP immunoreactivity and mRNA in the hippocampus in vivo on the side ipsilateral to the lesion. Following surgical or chemical lesions in vivo proliferating cultures of astrocytes can be obtained from adult rat brain in vitro. Unilateral knife-cut or electrolytic lesions were performed on adult male rats. Four days post-lesion the brains were separated into ipsilateral from contralateral and dissected into various regions (e.g., cortex, hippocampus and striatum). Following enzymatic digestion viable cells from similar regions were plated at identical densities into poly-lysine coated flasks and maintained in Ham's F12/DMEM medium with 10% fetal calf serum. Cells were counted at 1, 3, and 7 days after plating. One day after plating the number of cortical and hippocampal cells that attached was 2 times greater in the lesioned when compared to the non-lesioned side. By 3 and 7 days after plating, the differences had increased to 4 and 6 times greater, respectively. Phase contrast and immunofluorescent antibody identification revealed that all of the cells were astrocytes. Similar results were obtained whether knife cut or electrolytic lesions were used. The differences in the number of cells was not due to an increased proliferation of cells isolated from the lesioned side, because the percentage of nuclei labelled by tritiated thymidine after 24 hours was similar in lesioned and non-lesioned sides. Whether these in vitro astrocytes express some of the in vivo changes due to the lesion remains to be

Supported in part by AG07855.

## 270.16

AXOTOMY INDUCED MITOGENIC SIGNALS FOR GLIAL PROLIFERATION IN THE

AXOTOMY INDUCED MITOGENIC SIGNALS FOR GLIAL PROLIFERATION IN THE ADULT TRIGEMINAL GANGLIA DEPEND ON PROTEIN SYNTHESIS JYM. Wen'T. CM. Morshead and D. van der Kooy. Neurobiology Research Group, University of Toronto, Toronto, Ont., Canada MSS 1A8.

Axotomy of the trigeminal ganglion in adult rats induces a subpopulation of satellite glial cells to proliferate between 15 and 27 hr post-axotomy in explant cultures. In vivo studies support the idea that injured neurons produce signals inducing the glial proliferation. The present study asks whether protein synthesis is required to induce this satellite glial cell population to proliferate, and it so when it is necessary. We demonstrate that blocking neuronal protein synthesis with cycloheximide (1ug/ml) over the first 13.5 hr in culture prevented the glial proliferation seen at 27 hr as measured by scintillation counting after continuous 31-thymidine uptake. However, cultures exposed to cycloheximide over the last 13.5 hr showed the same amount of glial proliferation as control cultures. Experiments to pinopoint the critical time for rortein synthesis to cycloreximide over the fast 1.5 in shower the same amount of ging pointeration as control cultures. Experiments to pinpoint the critical time for protein synthesis inhibition revealed that cycloheximide exposure over the first 7 hr prevented the proliferation seen at 27 hr. Moreover, limiting cycloheximide exposure to the period from 3.5 to 7 hr in culture completely suppressed the glial proliferation assessed at 27 hr. It is important to note that this suppression of proliferation was not permanent, since glial cells in similar cultures did proliferate when culture times were extended to 3.4 hr. However, it is not clear if the proliferation seen at 34 hr in vitro represents a delayed division of the same population of cells normally assessed at 27 hr or rather a new population of glial cells activated only with longer culture times. Experiments designed to double label proliferating cells using independent markers of DNA synthesis at to double label prolineraling cells using independent interface of DNA synthesis at shorter versus longer culture times will help distinguish between these two possibilities. Surprisingly, limiting cycloheximide exposure to the period between 0 and 3.5 hr produced greater glial proliferation compared to 27 hr control cultures. This reflect the disruption of a constitutive glial inhibitory signal for glial proliferation from neurons or of a constitutive negative signal for profileration between glial cells. Blocking protein synthesis in the early period after neuronal injury reveals mechanisms that serve to dynamically control glial proliferation.

CULTURE FROM ALZHEIMER'S DISEASE CNS CELL AUTOPSIES. M.P. McKinley\*, J.A. Schaller, L.I. Sue, M.H. Sun Health Research Institute, Perry, P. Riely, and J. Rogers. Sun City, Arizona 85372.

Many attempts to elucidate pathophysiologic mechanisms of Alzheimer's disease (AD) have been limited to observations Alzheimer's disease (AD) have been limited to observations in postmortem human brain tissue, so that direct evidence of causality, specificity, and temporal sequencing of events has been difficult to obtain. We have begun to develop and characterize primary mixed cultures from human adult brain autopsies from AD and control aged brains. Optimal cell growth was found only if the post mortem interval does not exceed 3 hours before cell plating. Sterility of cultures requires a thorough sterile saline flush of exposed cerebral hemispheres immediately prior to excision of tissue for processing. Various tissue discustion techniques have been hemispheres immediately prior to excision or tissue for processing. Various tissue disruption techniques have been tried: a combination of mincing with razor blades, shearing in pipettes, digestion with collagenase and trypsin, and washing through a sieve mesh provides for the best cell growth. Growth of cells is optimal if flasks are pretreated with polyniciate and cells are immediately resustended in a medium lysine and cells are immediately resuspended in a medium containing M-199 and OPTIMUM (1:1) plus 10% fetal calf serum and 1% glutamate. Even under these conditions, cells did not become adherent to the flask for more than 24 hours. Numerous GFAP immunoreactive cells have been detected. Additionally, endothelial reactive cells have been identified.

Currently we are characterizing the cells in mixed cultures with the intent of developing primary cultures enriched for astrocytes and microglia.

#### 270 18

APOLIPOPROTEIN E EXPRESSION IN ALZHEIMER'S DISEASE AND AFTER HIPPOCAMPAL DEAFFERENTATION IN THE RAT. C. Zarow\* and C.E.Finch Andrus Center, Univ. of Southern California, Los Angeles, CA 90089-0191

Apolipoprotein E (ApoE) is a low-density lipoprotein receptor ligand, expressed by astrocytes in the CNS. It plays a role in the redistribution of cholesterol between cells, especially during injury and repair. ApoE mRNA is elevated after a bilateral electrolytic entorhinal cortex lesion (ERC lesion) in the rat [Poirier et al., Mol. Br. Res. (1991) 11:97]. Two days after a unilateral ERC lesion ApoE mRNA levels in the ipsilateral hippocampus dropped to half of the control level. These levels increased to control values by 6 days after injury and exceed control values 2-fold at 10 days after ERC lesion. Analysis of hippocampal sections following in <u>situ</u> hybridization revealed a shift in ApoE mRNA expression from astrocytes in the molecular layer to cells with astrocytic morphology in neuronal subfields. Optical density (O.D.) measures were taken over the CA1 neuronal layer and over the molecular layer of CA1 and expressed as a ratio (N:M). There is a shift in the N:M ratio from 0.73 for control to 1.72 at 14 days after lesion (ANOVA, p<.05). This analysis was also done for hippocampal sections from 8 Alzheimer and 9 non-Alzheimer brains. There is an increase in the N:M ratio in AD (1.58  $\pm$  .04) compared to non-AD (0.93  $\pm$  .03) (ANOVA, p<.0001). In AD, CA1 suffers the loss of ERC afferents and is subject to neuronal loss and neurofibrillary tangle formation. Our analysis cannot distinguish between neurons with and without tangles. However, we hypothesize that the astrocytes adjacent to these neurons would be recycling the lipids derived from degenerating neurons to those neurons surviving and undergoing dendritic remodelling and axonal sprouting in response to deafferentation. (Supported by AG-07909).

## REGENERATION II

Septo-hippocampal regeneration through biosynthetic bridges containing adult Schwann cells. D. Hoffman and P. Aebischer. Section for Artificial Organs, Biomaterials and Cellular Technology. Brown University. Providence, R.I. Schwann cells' production of neurotrophic and neurotropic molecules

Schwann cells production of neurotrophic and neurotropic molecules as well as their complex role in PNS regeneration suggest that they may facilitate regeneration of CNS neurons as well. While embryonic-derived Schwann cells have been shown to aid in CNS regeneration, the present studies utilized Schwann cells cultured from injured adult peripheral nerves. Because of their origin, these cells retain characteristics which may aid regenerating nerve fibers. The purpose of this study was to determine the extent to which a matrix containing purified dult Schwann cells could induce naturity contraining purified adult Schwann cells could induce neurite outgrowth from axotomized neurons of the septo-hippocampal system. Schwann cells isolated from adult Fisher rat sciatic nerves were suspended at a density of 80 x 10<sup>6</sup> cells/ml in an extracellular matrix-containing gel, and of 80 x 10° cells/ml in an extracellular matrix-containing get, and surrounded by a hollow permselective poly(acrylonitrile / vinyl chloride) polymer tube. Following a unilateral aspirative lesion of the fimbria-fornix, adult Fisher rats received cell-containing tubes in the lesion cavity, placed so as to abut the septum and the hippocampus. lesion cavity, placed so as to abut the septum and the hippocampus. After three weeks, cellular cables bridging the septum to the hippocampus were observed in the implanted tubes. Axons positive for acetylcholinesterase migrated along the longitudinal axis of the cable, throughout the length of the tube, closely associated with the Schwann cells. We surmise that the transplantation of an oriented polymer tube seeded with adult Schwann cells constitutes a favorable milieu for the regeneration of axotomized CNS neurons.

## 271.3

LONG TERM MAINTENANCE OF AXONAL REGENERATION IN PRIMATES FOLLOWING COLLAGEN NERVE GUIDE REPAIR OF 2CM MEDIAN NERVE DEFICIT. 1S.J. Archibald\*, 4C. Kranup, 1L. Wrage, A. Friedman, and 1,283 R.D. Madison, 1 Departments of Surgery (Neurosurgery) and <sup>2</sup>Neurobiology, Duke University Med. Ctr., Durham, N.C. 27710, <sup>3</sup>Research Service V.A. Hospital, Durham, N.C. 27710, and Department of Clinical Neurophysiology, Rigshospitalet, Copenhagen,

This study follows the course of motor and sensory physiological recovery resulting from the repair of a 2cm median nerve deficit in Macaca fasicularis. Adult male macaques received bi-lateral median nerve sections at the wrist and removal of a 2cm nerve segment, followed by either: A) Sural nerve cable graft repair (n=8 nerves), B) Entubulation repair with 2mm I.D. nerve guide conduits (n=8 nerves), and C) No repair performed (negative controls).

Evoked EMG studies of the abductor pollicis brevis (APB) and evoked sensory studies of the median nerve were performed bi-weekly for 154 days following surgery and at monthly intervals thereafter. These assessments of functional recovery have been completed over a period of 546 days to date.

The onset of the first evoked motor response in each group ranged between 98 to 182 days in entubulation repairs, 56 to 126 days in nerve grafts, and 84 to 350 days in negative controls. The onset of sensory recovery was more delayed and ranged between: 210 to 378 days for entubulation repairs, 154 to 266 days for nerve grafts, and 154 to 490 days in negative controls.

At 518 and 546 days the recovery of the compound motor unit action potentials of the APB compared to normal were: 73% for entubulations, 76% for grafts, and 49% for negative controls which had significantly lower emg amplitude compared to the other procedures (P= 0.01).

Supported by NS-22404-07 and Colla-Tec, Inc.

PERIPHERAL NERVE REGENERATION THROUGH RESORBABLE HYALURONIC ACID ESTER AND SILICONE NERVE GUIDES. G. Favaro, F. Langone<sup>§</sup>, A. Schiavinato, S. Spini, E. Lini, L. Cavicchioli\*. F. Dorigatti and E. Govoni. FIDIA Research Laboratories, 35031 Abano Terme (PD), Italy. §State University of Campinas, 13100 Campinas (SP),

Peripheral nerve regeneration successfully occurs through many mm-long gaps in nerve guides made of various resorbable or permanent materials. Here we assessed the efficacy of resorbable nerve guides made of a hyaluronic acid ester (HYAFF11p75) or silicone in promoting rat tibial nerve regeneration through an 8 mm-gap. An autologous nerve graft was used in another group of animals. Electrophysiologic evaluation 90 days after surgery demonstrated that regeneration through the HYAFF11p75 nerve guides was equivalent to that obtained with the silicone ones, and similar to that observed using the grafting technique. The nerve compound action potential amplitude was 0.083±0.037 mV (±S.E.M.) in the autograft group, 0.034±0.01 mV in the silicone group and 0.033±0.01 mV in the HYAFF11p75 group. An ultrastructural study 56 weeks after surgery showed nerves regenerated through silicone tubes with the axonal pathologic alterations described by Le Beau et al. (1988). In addition, the finding of many myofibroblasts in the epineurium-like structure strongly supports the hypothesis that compressive forces are the main factor inducing such alterations. The absence of myofibroblasts and the low percentage of altered axons in fascicles regenerated through the HYAFF11p75 nerve guides suggests that only resorbable materials can be suitably applied for short nerve gaps in severed human nerves. Grants FAPESP(90/4970-0) and FIDIA.

## 271.4

DELAYED REPAIR OF A GAP IN A PERIPHERAL NERVE UTILIZING A SCHWANN CELL CABLE FORMED IN A SILICONE CHAMBER. N. A. Azzam. \*A. A. Zalewski and L. R. Williams. Lab. of Neural Control NINDS, NIH, Bethesda, MD 20892 and CNS Diseases

N. A. Azzam.\*A. A. Zalewski and L. R. Williams. Lab. of Neural Control NINDS, NIH, Bethesda, MD 20892 and CNS Diseases Research (L.R.W.), The Upjohn Co., Kalamazoo, MI 49001.

A tissue cable containing Schwann cells can form at 4 weeks in a silicone chamber in the absence of regenerating axons. In the present study we investigated whether axons would regenerate through such a preformed cable. Transected stumps of sciatic nerves of adult rats were sutured into the ends of silicone chambers filled with dialyzed plasma, leaving a 10-mm interstump gap. The proximal sciatic nerve was further transected between two ligatures. The proximal nerve stump was reflected leaving a ligated, denervated nerve plug attached to the proximal end of the chamber. After 4 weeks, nerve ligatures were removed and the proximal sciatic nerve stump was anastomosed to the nerve plug-cable-distal nerve stump tissue complex. In some animals, the ligated nerve plug was left undisturbed in order to determine the fate of a chronically denervated Schwann cell cable. Four months later, the cables and segments of nerve proximal and distal to them were removed and examined by light and electron microscopy. All the anastomosed nerve plugs, cables and distal nerve stumps contained numerous myelinated and unmyelinated nerve fibers. Leg muscles were reinnervated and skin sensory function returned. It is interesting that almost all the Schwann cells disappeared from chronically denervated nerve plugs and cables, but not from distal nerve stumps. Since a cable formed by our surgical method promotes axonal regeneration, it has the potential to eliminate the need for a nerve graft to repair a gap in a nerve that requires delayed surgical intervention.

REGENERATION OF THE RAT OLFACTORY EPITHELIUM AFTER EXPOSURE TO METHYL BROMIDE: THE MICROVILLAR CELL. ML Miller, L Hastings, JE Evans and IA Michaelson\*. Department of Environmental Health, Univ. of Cincinnati, Cincinnati, OH, 45267.

Methyl bromide (MeBr) is a toxin which destroys olfactory epithelium while sparing respiratory epithelium. Microvillar cells are depleted from olfactory epithelium immediately after injury but reappear after several months in the late stages of repair.

Male hooded rats were exposed to 200 ppm MeBr 6hr/d for 10 days, and sacrificed 1, 4, 11, 22, 30, 39 and 73 days after exposure. Semi-thin plastic sections perpendicular to the septum were stained with toluidine blue. Microvillar and sustentacular cells were absent from the epithelium until 11 days after exposure.

During regeneration, the distance from the nuclei of these cells to the nasal lumen increased. The ratio of microvillar to sustentacular cells in controls was 1:30; at 39 days after exposure, 1:300. The appearance of the olfactory epithelium was nearly normal at day 39, but microvillar cells remained depressed. The microvillar cells do not degenerate after bulbectomy suggesting they are not sensory in nature (Carr et al., 1991). The presence of microvillar cells may indicate a fully reconstituted epithelium. Their function remains to be determined

Over-riding the outgrowth inhibitory effect of CNS myelin. M.K. Carpenter \* T. Hassinger, L.R. Whalen, S.B. Kater, Program for Neuronal Growth and Development, Dept. of Anatomy and Neurobiology, Colorado State Univ., For Collins, CO. 80523

Forn Collins, CO 80523.

In the adult mammalian brain and spinal cord, myelin is an inhibitory signal for neurite outgrowth. This phenomen has been investigated by culturing neurons on cryostat sections from adult rat brain or spinal cord (Crutcher, K.A., (1989) Exp. Neurol. 104: 39-54; Savio and Schwab, (1989) J. Neurosci. 9(4): 1126-1133). Using this type of culture system, it has been previously shown that neurons seldom adhere to or grow on white matter, but will attach and grow on gray matter.

The experimental conditions developed here allow neurons to attach and grow on white matter. Embryonic rat hippocampal neurons were grown on cryostat sections in the presence of glial co-cultures. Under these conditions, neurons will attach and grow on both gray and white matter. In conditioned medium, outgrowth on white matter is approximately 10-fold greater than outgrowth in defined medium, and approximately 3-fold better than outgrowth in serum supplemented medium. Glial cultures condition the media by producing many growth promoting factors (Banker, G. (1980) Science, 209: 809-810). To determine if these growth stimulating factors from the conditioned medium are acting by binding to the substrate, CNS cryostat sections were pre-incubated with a glial culture for 2 days. The conditioned medium and the glial cultures were then removed and neurons were plated on the pre-conditioned sections, in defined media. The outgrowth on the pre-conditioned sections was similar to or better than the outgrowth seen on cryostat sections that had neurons growing with glial co-cultures. Therefore, the outgrowth inhibitory signal of myelin is not absolute and, under appropriate conditions, it can be over-ridden.

A NERVE REPAIR METHOD THAT ENHANCES COLLAGEN FORMATION AND AXONAL REGENERATION. J.E. Swett\* and C.E. Ribak. Dept. of Anatomy and Neurobiology, University of California, Irvine, CA, 92717.

Traditional surgical repairs (epineurial suturing) of severed peripheral nerve (rat sciatic) seldom result in good functional recovery following nerve regeneration partly because only 1/2 to 1/3 of the normal number of neurons regenerate axons distally into the nerve's tributary branches. Experiments were carried out to test alternative methods of neurorrhraphy of the rat sciatic severed at mid-thigh level using fibrin glue to bind nerve ends together in a semipermeable matrix of biocompatible material. Light microscopic analysis led that the numbers of sensory and motor neurons, labeled retrogradely with HRP from the common peroneal nerve 10-15 mm distal to the repair site, were close to normal. While large numbers of myelinated axons were present many (25-40%) were from non-peroneal motoneurons. Distally and proximally to the repair the perineural sheath was intact, but, near the repair, it was thin or absent, being replaced by the matrix material. At light and electron microscopic levels large numbers of microfascicles were present within endoneurial spaces and in the outer matrix near the repaired zone along with clear evidence of misdirected axonal profiles. The lamellae of the microfascicles resembled in every respect perineurial cells. Some microfascicles were found in the matrix proximal to the repair site indicating axonal regeneration in inappropriate directions. Collagen formation was particularly enhanced in the endoneurial regions around newly established blood vessels and in the vicinity of the matrix. Circumferentially oriented rings of collagen were separated by longitudinal bands of collagen, their margins often delineated by thin processes of endoneurial fibroblasts. The unusually large accumulation of collagen appears to be induced by the presence of the matrix. The micro-environment thus created appears to favor abundant regeneration of axons into the distal parts of the nerve.

PERIPHERAL NERVE REGENERATION ACROSS LONG GAPS. A COMPARISON OF ARTIFICIAL NERVE GRAFT AND SUTURED AUTOGRAFT REPAIRS. Jose Padilla, Tanya Atagi, Robert Keeley, Khoi Nguyen, Paula Kadlcik, Eric Sabelman, Albert Yu\*, Lawrence Eng., and Joseph Rosen. Dept. of Functional Restoration, Stanford Univ. Sch. of Med., Stanford, CA, 94305.

A study was conducted to compare the regeneration of rat peroneal nerves across 14 mm gaps repaired with artificial nerve grafts (ANG) or sutured autografts (SAG). The ANG models are composed of a synthetic biodegradable conduit made of glycolide trimethylene carbonate (GTMC) filled with either a 1% collagen type I matrix (Coll-ANG) or 0.9% saline (PBS-ANG). Ten rats were implanted with SAGs and Coll-ANGs in contralateral limbs, 10 compared the SAG and PBS-ANG, and 10 compared the Coll-ANG and PBS-ANG. Functional recovery was evaluated by walking track analysis charted throughout the 9-month experiment. Nerves were further analyzed by electrophysiology and histology.

the 9-month experiment. Nerves were further analyzed by electrophysiology and histology.

Walking track analysis demonstrated the SAG and Coll-ANG to have equivalent recovery, while both the SAG and Coll-ANG were significantly better than the PBS-ANG (p<.05). Electrophysiological values for SAG, Coll-ANG, and PBS-ANG were 88.5±1.9%, 82.9±4.3%, and 81.8±3.1% respectively. The SAG value was significantly higher than the PBS-ANG value (p<.02). Myelinated axon counts and average diameters are pending. At biopsy ANGs were resorbed, and reaction to collagen was minimal. Comparison of ANG and SAG peripheral nerve gap repairs demonstrates that a 1% collagen matrix inside a resorbable conduit enhances functional recovery versus a saline matrix, and supports equivalent recovery to a SAG repair.

## 271.8

SHORTENING OF THE SPINAL COLUMN IN RAT: A METHOD OF STUDYING REGENERATION POSSIBILITIES IN LESIONED SPINAL CORD. K.Trok, L. Olson\*. Dept. of Histology & Neurobiology, Karolinska Institutet, Stockholm, Sweden

The mammalian spinal cord has a certain degree of tension under normal conditions. After a complete spinal cord transection, the spinal cord stumps are separated because of this tension, thereby limiting regenerative possibilities. One possible approach to reduce the tension on the spinal cord is to remove a vertebra. The method of removing half of two adjacent vertebrae (rather than an entire single vertebra) gives greater possibility for spinal column stability when the bone is restored. Three different operations were performed in rats: (1) Complete spondylectomy without cutting the spinal cord. The rostral half of T9 and caudal half of T8 were removed.

spinal cord. The rostral half of T9 and caudal half of T8 were removed.

(2) Complete spondylectomy (as above) with complete transection of the spinal cord. In both cases the remaining parts of T8 and T9 were brought into contact and stabilized with small rods placed on both sides of the column and fixed with non-absorbable thread.

(3) Laminectomy of T8 and complete transection of the spinal cord. Animals were sacrificed after 6 to 10 months. During this period the rats were repeatedly evaluated for motor and sensory deficits. Perfusion was made with PVP (polyvinylpyrrolidone). This method enables cryostat sectioning of undecalcified bone together with soft tissue for immunohistochemistry. After perfusion, the spinal column containing the spinal cord was removed, stored in PVP and then cryostat-sectioned and evaluated immunohistochemically. This method allows lesioned spinal cord stumps to be in physical contact, thereby increasing any possibility of regeneration or sprouting. Functional differences between these three groups can be detected.

## 271.10

AN ACTH 4-10 ANALOG, BIM 22015 DECREASES MOTONEURON DENSITY AFTER NERVE TRAUMA. T.S. Lee\*S.J. Lee and F.L. Strand. Department of Biology and Center for Neural Science, New York University, Washington Square, New York, New York 10003.

Previous studies have demonstrated that ACTH 4-10 and its various analogs possess neurotrophic and myotrophic properties<sup>1,2</sup>. This current study was undertaken to determine whether the ACTH 4-10 analog BIM 22015 has an effect on the ventral horn motor cells following peripheral nerve crush.

Male Sprague-Dawley rats (175-200g) were subjected to peroneal nerve crush under ketamine (80mg/kg) xylazine (5mg/kg) anesthesia. A #5 forceps was used for nerve crush, resulting in a 1mm wide lesion, leaving the neural sheath intact. Directly following surgery, the peptide BIM 22015 (40μg/kg/48hrs i.p.) or saline vehicle was administered for 7 days. Animals were perfused transcardiacally with 4% paraformaldehyde and the spinal cords were dissected out. The spinal cord was sectioned and regions L4 to S1 were stained with cresyl violet (Nissl) to observe nerve cell bodies. A decrease in motoneuron density, in the ipsi lateral side was observed with BIM 22015 treatment compared to the control(contra lateral side). We are currently investigating the effect of ACTH 4-10 in this model. This technique may serve to quantify the effects of axonal crush on the soma of the spinal motoneuron. This study was supported by Biomeasure, Inc.

THE EFFECTS OF AN ACTH 4-9 ANALOG, ORG 2766, ON 6-OHDA LESIONING OF THE SUBSTANTIA NIGRA. F.J. Antonawich\*, H.M. Akbari, E.C. Azmitia and F.L. Strand. Department of Biology and Center for Neuroscience, New York University, New York, N.Y. 10003

ACTH peptide fragments demonstrate potent neurotrophic effects on peripheral nerves in situ, central neurons in culture and have been implicated to affect central neuron in vivo. Neurotoxic lesioning of the nigostriatal system, which depletes the striatum of dopamine, provides a feasible model of central regeneration in which to test these peptides. Male Sprague Dawley rats were lesioned unilaterally with 6-hydroxydopamine (8µg/4µl), infused into the substantia nigra over a ten minute period, resulting in unilateral Parkinsonism. They were subsequently treated with 10 µg/kg i.p. of ORG 2766 (ACTH 4-9 analog) or saline every 24 hours starting immediately after the infusion. Since initial behavioral data indicated an effect of ACIH on the nigrostriatal system, a morphological and biochemical evaluation was undertaken. In order to determine the period of therapeutic administration, a time course experiment was performed with morphological analysis being done at various time periods during the experiment. High affinity uptake of the striatum is being performed as a quantitative measure of fiber density.

Evaluation of immunohistochemical staining for dopamine using an antityrosine hydroxylase antibody indicates an enhanced intensity of staining in the ORG 2766 treated tissue as compared to its saline counterpart. High affinity dopamine uptake studies are being conducted to support immunohistochemical findings. Higher dopamine uptake levels in ACTH treated animals would correlate to a high fiber density level in this group. Therefore, it appears that treatment with the ACTH 4-9 analog ORG 2766 (10µg/kg/ 24hrs.) could offer a protective effect from 6-OHDA lesions in the substantia nigra.

### 271.13

REGENERATION OF 5-HT PROJECTIONS TO NEOCORTEX: MAGNITUDE

REGENERATION OF 5-HT PROJECTIONS TO NEOCORTEX: MAGNITUDE OF p-CHLOROAMPHETAMINE-INDUCED DENERVATION INFLUENCES REINNERVATION. K.J. Axt\*, L.A. Mamounas, and M.E. Molliver. Dept. Neurosci., The Johns Hopkins University Schl. Med., Baltimore, MD 21205. p-Chloroamphetamine (pCA) causes a selective and profound loss of one morphologic type of 5-HT axons in rat forebrain. This neurotoxic effect on fine 5-HT axons is dose-related, and exhibits a rostro-caudal gradient at 2 weeks after drug administration. At all doses used, axon loss is greater caudally (occipital pole) than rostrally (frontal pole). After a low dose of 2.5 mg/kg pCA, decreased axon density is most apparent in occipital pole with substantial sparing of fine axons, particularly in frontal pole. At 5 mg/kg, axon loss is more robust, yet many fine axons survive; a notable decrease in fine axon density is observed in the middle layers of parietal cortex dorsal to anterior hippocampus. At 10 mg/kg pCA, the density of fine 5-HT axons in frontal pole is significantly reduced, while the thicker preterminal axons are spared. This dose also produces a marked decrease in the density of fine axons in mecortex, dorsal to striatum. In both 5 and 10 mg/kg-treated rats, the occipital pole is markedly (and comparably) denervated. The pattern of reinnervation of neocortex by 5-HT axons was studied at 4 and 8 mos. post-drug. At all doses, the frontal pole was reinnervated earlier and more completely than occipital pole. Four mos. after 2.5 mg/kg, 5-HT axons reach control density in frontal pole, whereas at 8 mos., the axon density in occipital pole remains less than control. After the higher doses, reinnervation of frontal pole is more gradual, and is dose-related. In occipital pole, there is little to no reinnervation at 4 mos., whereas at 8 mos some reinnervation is apparent at the 5 (but not 10) mg/kg dose. These data indicate [1] that the degree of reinnervation is inversely correlated with the magnitude of initial denervation, and [2] target areas closer to the dor

THE EFFECTS OF INTRASEPTAL BONF ON COGNITION IN RATS WITH

THE EFFECTS OF INTRASEPTAL BDNF ON COGNITION IN RATS WITH MS/DB LESIONS. Mary Ann Pelleymounter and Mary Jane Cullen. Amgen, Inc., Amgen Center, 1840 DeHavilland Dr., Thousand Oaks, CA 91320. Level of expression for BDNF mRNA is high in the granule cell layer of the hippocampus relative to other brain areas. The granule cell layer contains the nerve terminals of a major cholinergic projection from the medial septal nucleus (MS) and the nucleus of the diagonal band (DB). Lesions in the MS/DB generally produce a 40-60% depletion of hippocampal ChAT and disrupt certain cognitive functions, such as working memory. We have attempted to reverse both the loss of hippocampal ChAT and the decline in cognitive function that results from MS/DB lesions by chronic infusion of BDNF into the MS/DB area one month after the lesions were produced. Lesions were produced by passing DC current (1.2mA; 10 sec) through the tip of an insulated insect pin (000) that was placed stereotaxically into three sites within the MS/DB area. Sham lesions were produced by lowering the electrode without administering current. Following a three week recovery period, rats were tested on the 8 arm radial maze, which has traditionally been used to test working memory. Rats administering current. Following a three week recovery period, rats were tested on the 8 arm radial maze, which has traditionally been used to test working memory. Rats with lesions made significantly more errors than sham controls. After this lesion-induced memory deficit had been demonstrated, rats were implanted with osmotic minipumps that contained BDNF which was infused into the MS area via a 28 g cannula that had been placed stereotaxically. Rats received BDNF (8 ug/day) or PBS whicle at an infusion rate of 0.5 ul/hour for a period of two weeks, at which time the pumps were removed. Rats were then retested on the radial maze task. MS/DB rats that had received BDNF made significantly fewer errors than their MS/DB counterparts that had received the PBS vehicle. This same group of rats were also tested on tasks that required selective attention or spatial memory. MS/DB rats showed deficits in the selective attention task. MS/DB rats that received BDNF, however, could not be distinguished from their intact counterparts. MS/DB rats dot show deficits in spatial learning. Immnohistochemical studies are currently not show deficits in spatial learning. Immnohistochemical studies are currently underway to assess cholinergic/non-cholinergic sprouting or regeneration.

THE EFFECTS OF  $\alpha$ -MSH AND ITS ANALOGS ON NERVE AND MUSCLE REGENERATION FOLLOWING AN INDUCED NERVE CRUSH, K.A. Williams, & F.L. Strand.\* Department of Biology and Center for Neural Science, New York University, Washington Square, New York, New York 10003

This study was undertaken to compare various  $\alpha$ -MSH analogs with respect to their effects on nerve regeneration. Sprague-Dawley rats (200-275g) were subjected to crush denervation under ketamine (80mg/kg) and xylazine (5mg/kg) anesthesia. A 1 mm lesion was made on the deep peroneal nerve with #5 watchmaker forceps. Immediately after surgery and every 24h until day 8, the animals were injected i.p.  $(40\mu g/kg)$  with one of three  $\alpha$ -MSH analogs,  $\alpha$ -MSH (1-13), or physiological saline which served as a control. Footprints were collected from the animals by dipping their hind limbs in non-toxic ink and having them walk up an inclined plane lined with white paper. On day 9 the animals were subjected to electromechanical tests in which twitch response, motor units, tetanic tension at fusion frequency and fatigue at 400Hz of the

extensor digitorum longus (EDL) muscle were obtained.

Based on the footprint data the BIM 22029 analog significantly improved the parameters of print area and toespread. Also a trend towards improvement was noted for the the print length parameter using this analog. An improvement of tetanic prameters was seen following treatment with 2 of the analogs. However, it was not significantly different from saline controls. The  $\alpha\text{-MSH}$  (1-13) did not improve footprint parameters or the electrophysiological parameters. This may be due to the high dosage (40µg/kg) that was used in this study. Future studies will examine varying dosages of α-MSH and its analogs. Subsequent investigations are being undertaken to determine the effectiveness of these analogs as myotrophic agents via the histological examination of the peptide treated EDL muscle.

ARNORMAL MORPHOLOGY OF REGENERATED 5-HT AXONS IN RAT CEREBRAL CORTEX ONE YEAR AFTER ABLATION BY P-CHLORO-AMPHETAMINE (PCA): ACCELERATED AGING OF SEROTONERGIC

CREBRAL CORTEX ONE YEAR AFTER A BLATION BY p-CHLORO-AMPHETAMINE (PCA): ACCELERATED AGING OF SEROTONERGIC PROJECTIONS. L.A. Mamounas\*, K.J. Axt and M.E. Molliver. Dept. Neurosci., The Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205.

The neurotoxin PCA (10 mg/kg s.c. to 2-mo old rats) causes acute degeneration of fine 5-HT axons in forebrain followed by robust but gradual sprouting of normal-appearing 5-HT axons into denervated regions. However, six months after drug treatment, reinnervation by 5-HT axons remains incomplete, particularly in caudal areas of necorrex; at longer survival times (6-12 months), sprouting terminates, and the density of 5-HT axons in cortex gradually decreases. This delayed axon loss is accompanied by increasing numbers of structurally abnormal 5-HT axons which form thickened, tortuous tangles. In 14-mo old treated rats (1-year after PCA), the pathologic 5-HT axon tangles comprise a large proportion of the 5-HT axons in cortex: they are increased nearly 3-fold (2-9 ± 0.4 axon tangles/mm2 of cortex) relative to age-matched controls (1.0 ± 0.02), coupled with the markedly lower 5-HT axon density 1-year after PCA. Since 5-HT axon tangles of this type are commonly seen in aged, untreated rats (24-mo old: 4.6 ± 0.6) but rarely in young control rats (2-mo old), they are thought to be "degenerative" changes that result from the normal aging process. We further examined whether the emergence of 5-HT axon tangles after PCA treatment (i) constitutes a late phase of the sprouting process or (ii) may be an age-related property, characteristic of axonal sprouting in older (10-14 mo) as apposed to younger (2-6 mo) rats. We found that rats treated with PCA at 10-mo of age and allowed to survive 4 months (to 14-mo of age) exhibit robust sprouting of normal-appearing 5-HT axons, as seen in younger rats. These results suggest that the late degenerative changes seen one year after PCA are more dependent upon long survival-time than age; thus, the occurrence of tangles should not be attributed to advanc

BRAIN-DERIVED NEUROTROPHIC FACTOR (BDNF) RESCUES MESENCEPHALIC DOPAMINERGIC FROM 6-OH DOPA TOXICITY IN VITRO.

Toso\*1, A. Negro<sup>2</sup> and S.D.

1Fidia Research Labs and R. Dal Skaper<sup>1</sup>. 2Advanced

IFidia Research Labs and <sup>2</sup>Advanced Technology Division, Fidia S.p.A., Abano Terme, Italy.

BDNF supports the survival of sensory neurons as well as retinal ganglion cells, basal forebrain cholinergic neurons and mesencephalic dopaminergic (DA) neurons in culture. Here we examined the ability of recombinant rat BDNF to protect cultured DA neurons from the toxicity of 6-OH DDPA, a metabolite of the DA pathway hypothesized to participate in the pathology of Parkinson's disease. Cells prepared from E14-15 rat mesencephalon were mainpathology of Parkinson's disease. Cells prepared from E14-15 rat mesencephalon were maintained with 10-50ng/ml BDNF for 7 days prior to addition of 6-OH DOPA (10-30uM) for 24hr. BDNF prevented the death of virtually all tyrosine hydroxylase immunoreactive neurons, but the loss of only 25-30% of the overall cell population. Furthermore, the monosialoganglioside GM1 (10uM) acted synergistically with subthreshold amounts of BDNF to rescue DA neurons against 6-OH DOPA toxicity. These results propose that BDNF and gangliosides may provide a new pharmacological approach in the treatment of Parkinson's disease.

TESTOSTERONE EFFECTS ON SYNAPTIC BOUTON CHANGES AFTER FACIAL NERVE INJURY IN THE HAMSTER. S.K. Jacob<sup>1</sup>, T. E. Durica<sup>2\*</sup>, K.J. Jones<sup>3</sup>. Department of Anatomy<sup>1,2</sup>, Rush Medical College, Chicago, IL 60612 and Department of Physical Therapy<sup>3</sup>, University of Illinois at Chicago, Chicago, IL 60612.

Gonadal steroids regulate axosomatic synapses in the normal adult mammalian nervous system. We have previously shown that testosterone propionate (TP) significantly enhances the nerve cell body response to facial nerve injury in hamsters. In this study, we tested the hypothesis that TP achieves this effect by attenuating the synaptic bouton stripping that has been shown to occur after axotomy. Adult intact male hamsters were subjected to right facial nerve axotomies, with one-half of the axotomized animals immediately implanted subcutaneously with 2 TP capsules. At 5 days postoperative (dpo), the animals were sacrificed, and processed for routine ultrastructural examination. The Bioquant System IV was used to assay the percent coverage of somal profiles by synaptic boutons on normal and axotomized neurons from hormone-treated and nonhormone-treated animals, as well as synaptic length. After axotomy alone, there was an 81% decrease in synaptic bouton coverage and a 26% decrease in average synaptic length. Exposure to TP at the time of injury resulted in a 48% decrease in synaptic bouton coverage and a 16% decrease in average synaptic length. Thus, it appears that regulation of synaptic input by TP may play an important role in the accelerative effects of the steroid on facial nerve regeneration.

THROMBOSPONDIN PROMOTES SCIATIC NERVE REGENERATION IN POLYETHYLENE TUBE GRAFTS. J.R. Hoffman\*, V.M. Dixit, and K.S. O'Shea University of Michigan, Ann Arbor, MI 48109

Thrombospondin (TSP) is an extracellular matrix molecule associated with regeneration in both the peripheral (Soc. Neurosci. Abst. 16:338) and central nervous systems (Soc. Neurosci. Abst. 17:48). The ability of TSP to promote nerve regeneration was evaluated *in vivo*. Four mm polyethylene tubes were filled with either 10 ug/ml purified platelet TSP, 20 ug/ml laminin (LN), 100 ug/ml anti-TSP polyclonal antibodies or PBS, and implanted into mouse sciatic nerves leaving a 3 mm gap. When functional recovery was assessed using a sciatic function test, after 23 days, TSP grafts showed improved functional recovery over LN, PBS, and anti-TSP grafts. After 29 days, grafts were removed and analyzed visually and histologically for regenerates through TSP and LN grafts had a larger cross-sectional area than PBS grafts. Nerves in anti-TSP grafts had significantly smaller diameter than other groups. Consistant with its role in supporting neurite outgrowth *in vitro*, TSP appears to support nerve regeneration *in vivo*.

ACTION POTENTIALS PASS SEVERED INVERTEBRATE AXON SEGMENTS RECONNECTED BY ELECTRIC-FIELD PULSES. G. Rodziewicz\*, P. Qi. A.T. Todorov, I. Fendler, N. Todorova. Neurosurgery Dept (SUNY Med. Sch.) & Chemistry Dept. (Syracuse U.), Syracuse, NY, 13210, USA.

We have previously shown anatomical evidence of successful axon reconnection in the earthworm. (I multiples targetric) medial giant.

We have previously shown anatomical evidence of successful axon reconnection in the earthworm (Lumbricus terrestris) medial giant axon (MGA) in vitro system by the application of 100 µsec, 700-800 V electric field pulses (Todorov, A.T., et al: Electric-field-induced reconnection of severed axons, Brain Res., in press). We now report initial results of attempts to pass action potentials (AP's) across the reconnected axon segments.

reconnected axon segments.

AP's were generated by stimulating the axon with an extracellular silver-wire electrode pair before and after severing. AP's were recorded with intracellular 3M KCl-filled glass electrodes both proximal and distal to the severed segment. Anatomical reconnection was shown by light microscopy of serial 1-2 µm longitudinal sections.

Of 150 total attempts to record AP passage after reconnection, 11

Of 150 total attempts to record AP passage after reconnection, 11 (7.3%) were successful. Illustrative cases are shown, with evidence of AP passage together with anatomical documentation of reconnection. Control preparations are presented.

Recovery of function in systems such as severed spinal cord and peripheral nerve requires the integrity of the axons transmitting information across the injured segment. Axon reconnection promises the rapid return of axon integrity, a necessary condition for the functional recovery of these systems.

#### 271.18

ANDROGEN EFFECTS ON FUNCTIONAL RECOVERY FROM FACIAL PARALYSIS AFTER FACIAL NERVE CRUSH IN FEMALE HAMSTERS. A.M. Puccil and K.J. Jones 1.2\* Departments of Anatomy and Cell Biology<sup>1</sup>, and Physical Therapy<sup>2</sup>, University of Illinois at Chicago, Chicago, IL 60612.

In adult male hamsters, androgens accelerate functional recovery from facial paralysis after facial nerve crush through an effect on the rate of regeneration. In females, androgens also increase the rate of regeneration, albeit to a lesser degree (30% increase vs. 10%, respectively. In this study, the effects of dihydrotestosterone (DHT), a nonaromatizable form of the steroid, on recovery from facial paralysis following crush axotomy of the facial nerve in female hamsters were examined. Hamsters were subjected to right facial nerve crush axotomies at the level of the stylomastoid foramen, with the left side serving as internal control, and either implanted subcutaneously with 2 or 4 DHT capsules or blanks. The 3 experimental groups were then coded. Signs of recovery from facial paralysis, which included the occurrence of a semi-blink, return of the eye blink reflex and full vibrissae movement, and vibrissae orientation, were then monitored daily. A replicate experiment was also accomplished. In contrast to the males, DHT did not appreciably alter functional recovery from facial paralysis in the females. This may be due, in part, to the reduced effects of androgens on the regeneration rate in females as compared to males. Supported by NIH grant NS28238 (KJJ).

GM-1 GANGLIOSIDE ENHANCES MOTOR SCORES IN INCOMPLETE HUMAN CHRONIC SPINAL CORD INJURY: RESULTS OF A DOUBLE BLIND CROSSOVER TRIAL.

J.B. Walker, M.D., Ph. D.\*, H. Gu, Ph. D.
M. Harris, PT., Walker Institute, 881 Alma Real
Dr., Pacific Palisades, CA 90272.
In a randomized double-blind crossover study, human subjects with chronic spinal cord injury

In a randomized double-blind crossover study human subjects with chronic spinal cord injury received GM-l or placebo for 2 months. Sygen (GM-l) administered intravenously at a dose of 100 mg, six days a week, resulted in an improvement of motor scores (p  $\leq$  .05) whether given before or after two months of placebo. There was no placebo effect on motor scores, but subjects who received GM-l before placebo maintained their improvement during the placebo phase (i.e. there was no "washout")

maintained their improvement during the placebo phase (i.e., there was no "washout").

S's who were able to ambulate at speeds greater than 0.5 mph also demonstrated sigificant improvement in efficiency of gait as a result of GM-l and not of placebo.

These results constitute the first finding

These results constitute the first finding that any chemical substance improves function in chronic spinal cord in jury.

## 271.22

VIABILITY OF THE OPTIC NERVE FOLLOWING DAMAGE AND SUBSEQUENT CHRONIC TREATMENT WITH D.C. ELECTRIC FIELDS. M.F. Zanakis\*, A. Bozack, R.M. Cebelenski, P. Jacovina, L. Guarino, B.H. Hallas. N.Y. College of Osteopathic Medicine, Old Westbury, N.Y. and American BioInterface Corp., New York, N.Y.

Several Previous studies have demonstrated that chronic D.C. stimulation of damaged CNS tissue results in what appears to be either regenerated CNS axons or a "rescuing" of these fibers. Which ever mechanism may be operating, the present study was aimed at further characterizing the extent and degree of viability of these axons in the damaged rodent outic nerve model. Adult rat optic nerves were crushed and a 1.5uA constant current D.C. stimulator (Traxon) was amplied so that the cathode was oriented distal to the lesion. Control animals received sham (no current) stimulators. After 5 weeks, animals were intraocularly injected with a 20% solution of HRP and sacrificed 48 hours later. TMB processing of the injected eye, optic nerve and brain followed by histological analysis of the visual system revealed that HRP was transported to the brain in "active" stimulator animals, but not in "inactive" stimulator animals. HRP transport could be demonstrated in virtually all animals that were treated, and in none of the animals that were not. These studies lend further support to D.C. therapy of damaged CNS tissues. Additional studies are aimed at analyzing the underlying mechanisms.

TIME-DEPENDENT CHANGES IN DNA SYNTHESIS IN NERVE AND DORSAL ROOT GANGLIA (DRG) AFTER CRUSH LESION OF SCIAT-IC NERVE: THE EFFECTS OF ELECTROMAGNETIC FIELDS. BE Sisken\*, J Walker, H Traurig and R Stach. Center Biomed Engr & Dept Anat & Neurobiol; Div Orthop Surg, Univ of Kentucky, Lexington, KY 40506; Dir Res, Univ Mich-Flint, Flint, MI 48502

We have reported that low levels of pulsed electromagnetic fields (PEMF, amplitude 3 gauss, rep rate 2 Hz) increase the rate of sciatic nerve regeneration after a crush lesion (Br Res 485:1989). To understand the mechanisms underlying this stimulation, we are investigating the influence of PEMF on non-neuronal cell proliferation. Four days and 17 days following crush lesion, DRG and sciatic nerve from untreated and PEMF-treated rats were incubated with 25 uCi/ml <sup>3</sup>H- thymidine, fixed and processed for autoradiography. Labeled non-neuronal cells in DRG and different areas of the sciatic nerve were counted on autoradiographs. Four days post-lesion, significant (p<0.001) increases in numbers of labeled cells in DRG ipsilateral to the injury occurred relative to the unoperated side; PEMF had no significant effect on this response. There was an increase in labeled cells in lesioned nerve and PEMF significantly increased (p<0.05) the percentage of cells incorporating label at the crush site. At 17 days post-lesion satellite cells of DRG from PEMF-treated rats maintained a higher rate of proliferation compared to controls. In contrast PEMF did not affect Schwann cell proliferation in sciatic nerve. The PEMF-induced increases in labeled Schwann cells at the crush site at four days and in the satellite cells of DRG at 17 days post-lesion may play a role in the mechanism of PEMF stimulation of nerve regeneration. LOW-INTENSITY ELECTRIC FIELD EFFECTS ON INJURY CURRENT FLOW IN A MODEL OF MAMMALIAN MYELINATED NERVE. K. Mosallaie and J.D. Sweeney\*. The Bioengineering Program, Arizona State University, Tempe, AZ 85287-6006.

It has been reported that steady low-intensity electric fields (LIEFs) can in certain circumstances be used to induce, accelerate and/or guide nerve regeneration. One possible proposed mechanism for this effect is suppression of the axonal 'injury' currents that flow in the early stages of damage and regeneration. Such currents may contribute to axonal 'dieback' [see R.B. Borgens, Adv. Neurol. 47:51-66, 1988]. Our objectives have been (i) to create a computer-based mathematical model of injury current flow in transected mammalian myelinated nerve, and (ii) to simulate the effects of imposed steady LIEFs on injury current suppression. The model is based on iterative solution of a set of coupled finite-difference equations describing intracellular electroneutrality and conservation of ionic current. Nerve fiber nodal and internodal parameters in our compartmental-cable model are based on known or estimated mammalian myelinated nerve values. Ionic conductances of variable type (Ca<sup>2+</sup>, Na+, K+, non-specific) and magnitude are included at the transection site that allow simulation of injury current flow in the early stages following damage. Our results indicate that cathode-distal steady electric fields of low-intensity can be used to suppress injury current entry of calcium and sodium ions at nerve transection sites.

NOVEL ISOFORMS OF MOUSE MYELIN BASIC PROTEIN PREDOMINANT-LY EXPRESSED IN EMBRYONIC STAGE. K. Nakajima¹. K. Jkana-ka¹. T. Kagawa¹. J. Aruga². J. Nakao¹. K. Nakajira¹. C. Shlota¹. S. U. Kim² and K. Mikoshiba.²\* ¹Div. of Regulation of Macromolecular Function. Inst. for Protein Research, Osaka Univ., 3-2 Yamadaoka, Suita 585. ²Dept. of Nolecular Neurobiology, The Inst. of Med. Sci..The Univ. of Tokyo, 4-6-1 Shirokanedai, Minato-ku, Tokyo 108, Japan. ³Div. of Neurology, Dept. of Med., Univ. of British Columbia, Vancouver, B. C. V6T 1W5, Canada.

Myelin basic protein (MBP) is one of the major pro-

Myelin basic protein (MBP) is one of the major proteins of myelin and thought to play an important role in myelin formation. Since myelination occurs postnatally in mice, the expression of MBP has been studied mainly in the postnatal stage. We report here that the MBP gene is expressed in mouse brain from 12th embryonic day (E12), before major gliogenesis occur, and that most of the predominant isoforms expressed in the embryonic stage are not those reported to date. They do not contain the se quence encoded by exon 5, probably due to specific alternative splicing. These isoforms without exon 5 show similar developmental profile with respect to each other, that is, they all peak at the embryonic stage and decrease thereafter. In the dysmyelinating mutant, jimpy, the level of these isoforms remain high even in the older ages. These results suggest that MBP has some unknown functions before myelinating stage other than that dedicated for myelination.

OLIGODENDROCYTE SURVIVAL AND MYELIN GENE EXPRESSION IN THE OLDER STRAIN OF THE MYELIN DEFICIENT RAT. N. L. Nadon\*. I. D. Duncan\*. D. Archer\*, K. Hoffman\*. C. Czisa# and M. Wells∞. University of Tulsa, Tulsa OK 74104, \*University of Wisconsin, Madison WI 53706, #New York State Department of Health, Albany NY 12208, and ∞VA Medical Center, Northport NY 11768.

A strain of the myelin deficient (md) rat has been found that lives for up to 70-80 days, three to four times the lifespan of the normal md rat. These animals provide a model for studying the effect of the mutation in the proteolipid protein (PLP) gene on long-term oligodendrocyte (OL) survival. Quantitative Northern blot analysis indicated that in both brain and spinal cord, PLP mRNA levels remain relatively constant from 22 to 70 days of age, as do myelin basic protein (MBP) mRNA levels. The level of GFAP mRNA ranged from 50-180% of control levels, perhaps indicating extreme variability in the response of individual rats to long-term survival in the absence of myelination. EM analysis showed that cells typical of OLs are still present at 80 days of age In vitro studies likewise show evidence of mature OLs, as identified by the cell specific antibody 01. In sum, these results demonstrate that OLs survive up to 80 days despite the PLP mutation, and that the expression of the myelin genes does not change significantly with age. ### 272.2

A NEW X-LINKED MYELIN MUTANT MOUSE. S. Billings-Gagliardi, D. Kirschner<sup>1</sup>, P. Lane<sup>2</sup>, N. Nadon<sup>3</sup>, C. Stanhope and M. K. Wolf\*, Dept. of Cell Biol., Univ. of Mass. Med. School, Worcester, MA 01655. <sup>1</sup>Children's Hosp. Med. Center, Boston, MA, <sup>2</sup>The Jackson Laboratory, Bar Harbor, ME and <sup>3</sup>Univ. of Oklahoma, Tulsa, OK.

A new mutation resembling jp, designated jp<sup>4,1</sup>, occurred in 1990 in Jackson C3H/HeJ mice. Lithkage with Ta supports allelism with jp. The tremor of affected jp<sup>4,1</sup> males is not as marked as in jp but death comes 4-5 days earlier, about P-20. CNS has the least myelin of any known mouse with a single mutation. In 5 mice examined at P-16 to 20, optic nerves, dorsal cervical spinal cord and dorsal brainstem are devoid of myelin with few normal oligodendrocyte-like cells and rare foamy cells. Ventral cervical spinal cord and brainstem have cells. Wentral cervical spinal cord and brainstem have the most 12-15 myelin profiles in 2-3 clusters per total cross-section. Most of that myelin consists of thin sheaths with poorly compacted lamellae. PNS appears unaffected. Immunoblot analyses (4 mice) show no detectable PLP in brain, but perhaps trace amounts in spinal cord. MBP is also significantly decreased but is more abundant than PLP, as in jp. Direct comparisons with jp (restriction enzyme analysis of PCR-amplified fragments) and jpmsd (single-strand conformation polymorphism assay) demonstrate that the PLP gene of jp<sup>4,1</sup> differs from both. DISTINCT NEUROLOGICAL PHENOTYPES IN MBP-SV40 LARGE-T TRANSGENIC MICE: MYELIN GENE EXPRESSION IN A CLONAL CELL LINE. N.A. Jensen¹, G.M. Smith², J.S. Garvey¹, L. Hood¹ and H.D. Shine², ¹Div. of Biology, Caltech, Pasadena, CA 91125² Dept. of Neurosurgery, Baylor College of Medicine, Houston, TX 77030.

We have targeted the expression of the SV40 large-T antigen to oligodendrocytes and Schwann cells in transgenic mice using the Myelin Basic Protein (MBP) promoter. Two neurological phenotypes, type-A and type-B, appeared in several founders and their offspring. Type-A mice developed action tremors that progressed to convulsions, an early death and had a hypomyelinated CNS. B-type mice exhibited progressive hindlimb ataxia and had either a hypomyelinated PNS or both hypomyelinated CNS and PNS. Immunohistochemical analysis of the CNS of type-A mice revealed T-antigen expression coincident with MBP and O4 positive cells; evidence that oligodendrocytes expressed the T-antigen. Several immortalized cells lines were established from type-A and -B mice. Cells from one cell line, 6E12, established from type-A CNS, were negative for the A2B5 antigen and only a portion were O4<sup>+</sup> and GalC<sup>+</sup>. Treatment with dibutyryl cAMP (DBC) increased the number of O4<sup>+</sup> and GalC<sup>+</sup> cells. High amounts of MBP mRNA and low amounts of Proteolipid Protein (PLP) were present in cells not treated with DBC. DBC treatment reduced MBP mRNA and increased PLP mRNA. No MBP translation products were detected in the 6E12 despite the high levels of MBP mRNA. Supported by grants from NIH (PO1 AG07687), the Kleberg Foundation,

the Retinal Research Foundation, and the Alfred Benzon Foundation.

OLIGODENDROCYTE-SPECIFIC EXPRESSION OF BACTERIAL BETA-GALACTOSIDASE IN TRANSGENIC MICE.  $\underline{V.L.}$ Friedrich. Jr. \* A. Gow and R.A. Lazzarini. Brookdale Center for Molecular Biology, The Mount Sinai Medical Center, New York, New York 10029

The mechanisms which restrict expression of the

MBP gene to oligodendrocytes and Schwann cells are unknown. To approach this problem we created transgenic mice bearing a chimeric gene (designated M $\beta$ P) consisting of the *E.coli lacZ* gene flanked upstream by MBP gene fragment –1907 to +36 and downstream by a fragment of the PLP gene containing splice and polyadenylation signals.

Enzyme histochemistry and immunofluorescence of cryostat and vibratome sections showed strong and specific expression of MBP in oligodendrocytes of adult mice and during development. Nuclear run-on assays showed transcription rates approaching 1/3 the native MBP gene. Remarkably, the M $\beta$ P transgene was not expressed in Schwann cells, which do make MBP. MBP gene. expressed in Schwann cells, which do make MBP. These results suggest that the MBP promoter/enhancer sequences are at least tripartite: a core promoter, the oligodendrocyte-specific enhancer elements, and a third component that either modifies the action of oligodendrocyte-specific enhancer elements to include Schwann cells or acts independently of it and specifically stimulates transcription in Schwann cells.

## 272.7

CNP LABELING OF OLIGODENDROCYTES AND MYELIN IN DEVELOPING RAT BRAIN. N. Nousek-Goebl\* and D. S. Grega<sup>+</sup>. R&D Division, Boehringer Mannheim Corp. and <sup>+</sup>Indiana Univ. School of Medicine, Program in Medical Neurobiology, Indianapolis, IN 46250.

CNP (2',3'-cyclic nucleotide 3'-phosphodiesterase) is found in high levels in the brain, especially in oligodendrocytes (oligos) and areas rich in myelin. Most in vivo studies have been biochemical in their characterization of CNP distribution, while the most convincing immunohistochemical localization has been reported with cultured cells. We have been interested in the expression of CNP as an oligo marker in the developing rat brain and report a method for the immunohistochemical localization of CNP in rat brain sections using the monoclonal antibody, anti-CNP with an immunoperoxidase method. Brain sections from postnatal day 10, 18 and >4 months (adult) were used as they represent ages of early, peak and mature myelination. Anti-GFAP labeling of astrocytes was performed for comparative purposes. Anti-CNP labeled oligo soma and processes at all ages. Unmyelinated regions first exhibited CNP labeling of highly stellate cells. As myelination progressed, cells displayed fewer labeled processes. There was a shift in the frequency and morphology of labeled cells with age with a peak of the highly stellate cells at PN18. Labeling of myelin increased with age, peaking in the adult, concomitant with a marked decrease in labeled stellate cells. Anti-CNP and anti-GFAP label distinctly different populations of cells. Anti-CNP is an excellent marker for oligos and myelin.

# 272.9

MYELIN BASIC PROTEIN mRNA IS ASSOCIATED WITH THE OLIGODENDROCYTE CYTOSKELETON. S.J. Hill\* and E. Barbarese, Dept. Neurology, U. Conn. Health Center, Farmington, CT

Oligodendrocytes synthesize myelin basic protein (MBP), a major component of CNS myelin. In monolayer cultures of oligodendrocytes, MBP is associated with the cell plasma membrane and is localized to the cell body, the processes and their membranous expansions. Extraction of the soluble their membranous expansions. Extraction of the soluble components of the oligodendrocytes using the protocol of Biegel and Pachter (1991), resulted in an insoluble fraction termed CSK composed mainly of cytoskeletal elements as demonstrated by immunocytochemistry and SDS gel analysis of the proteins. MBP polypeptide and other myelin components such as galactosylcerebroside and cyclic nucleotide phosphohydrolase partitioned with the soluble fraction, in contrast with the results of Wilson and Brophy (1989). Fluorescent in situ hybridization (FISH) was used to The majority of the MBP mRNA remained associated with the CSK of the oligodendrocyte. Combined immunocytochemistry and FISH also indicated that tRNA synthetase and elongation and rish also indicated that the NA synthetase and clongation factor I are found with the CSK of the oligodendrocytes and in close proximity to the MBP mRNA. These results support the notion that MBP is translated in the oligodendrocyte processes in association with the cytoskeleton.

OLIGODENDROGLIAL HETEROGENEITY IN SITU AND IN VITRO.

C. Bjartmar\*, and C. Hildebrand. Dept of Cell Biology, Faculty of Health Sciences, S-581 85 Linköping, Sweden. The morphology of myelinating rat oligodendrocytes was examined by light and electron microscopy, using in situ and in vitro preparations of spinal and telencephalic tissue. Light microscopic examination of galactocerebroside (GC) immunoreactive early oligodendrocytes in frozen sections from the initially myelinating cervical spinal cord (neonatal) and the corpus callosum (17 days postnatal) showed that the spinal cells present a generally bipolar morphology, whereas the callosal cells tend to be multimorphology. polar. These data were supplemented by serial section electron microscopy, showing that the spinal cells exhibit a few relatively short velate extensions, which provide 2-3 axons with myelin sheaths. The callosal cells reconstructed so far myelinate 6-10 axons through slender processes with varying lenghts. Examination of cultured GC-immunoreactive glial cells prepared from suspensions of neonatal spinal and telencephalic tissue showed that most of the spinal cells develop a fusiform shape, while the telencephalic cells achieve a stellate outline in vitro, in the absence of neurons. The picture is principally similar in oligodendroglial-enriched cultures. The results support the view that oligodendrocytes constitute a structurally heterogeneous population, and that this heterogeneity may be a primary property intrinsic to these cells.

### 272.8

ISOLATION OF CDNA CLONES FROM RAT OLIGODENDROCYTES CODING FOR ZINC FINGER PROTEINS. <u>U. Pott, N. Schaeren-Wiemers\*, M.E. Schwab</u>. Brain Research Institute, University of Zurich, August-Forel-Str. 1, CH-8029 Zurich, Switzerland

The function of the vertebrate nervous system is dependent on the appropriate myelination of its fiber tracts. In the CNS, the myelin sheath around the axons is produced by oligodendrocytes. In order to understand oligodendrocyte differentiation in more detail, we aimed at the cloning of putative transcription factors expressed in this particular glial cell type

A cDNA library was constructed from highly enriched differentiated rat oligodendrocytes and screened with an oligonucleotide deduced from a conserved region of the Krüppel family of zinc finger proteins (the H/C link). Eleven different cDNAs were obtained, four of which were selected for further analysis. So far, complete sequencing of two clones revealed that they comprise the coding capacity for two new members of the zinc finger gene family; the deduced proteins contain 458 amino acids (with 12 finger repeats) and 503 amino acids (with 13 finger repeats), respectively. While one of the proteins is not complete at its amino terminus the other one seems to be full length. Northern blot analysis was done to investigate tissue specific expression of the corresponding mRNAs. As expected, all four genes are expressed in the spinal cord, the expression of three clones being higher in the CNS than in all peripheral tissues tested (with the exception of testis). Two of the cDNAs recognize RNAs of considerably different sizes, the relative abundances of which vary in different tissues. The expression pattern of all four clones clearly shows that the mRNAs also occur in other cell types in addition to oligodendrocytes.

GLUTAMATE IS TOXIC TO OLIGODENDROGLIA BY AN UPTAKE DEPENDENT MECHANISM. A. Oka\*, M.J. Belliveau. P.A. Rosenberg and J.J. Volpe. Children's Hospital and Harvard Medical School, Boston, MA, 02115.

We investigated the potential role of excitatory amino acids in white matter injury, using oligodendroglial (oligo) cultures separated from mixed glial primary cultures of dissociated rat cerebral hemispheres. Oligos were highly vulnerable to L-glutamate (GLU) (EC<sub>50</sub> for 24 hr exposure: 260 µM); no toxicity was observed in astrocytes with 20-fold higher concentrations. Uptake studies and autoradiography with L-[3H]-GLU showed the presence of GLU uptake into oligos. D.L-threo-B-hydroxyaspartate, which inhibited the uptake of L-[3H]-GLU, protected oligodendroglia against GLU. Antagonists for NMDA (MK-801) and non-NMDA (CNQX) GLU ionotropic receptors, respectively, did not prevent toxicity, indicating that cell death is due to GLU transport rather than receptor-mediated mechanisms. Both Natdependent and Na+-independent uptake was present. A role for cell swelling in the GLU-induced cell death was shown by protection in the presence of hypertonic solutions (100 mM sucrose, raffinose or 50 mM

These findings indicate oligos are killed by micromolar concentrations of GLU and that the mechanism of this cytotoxicity involves GLU uptake and cell swelling. Supported by NIH R01-HD-07464 (J.J.V.)

OXIDATIVE STRESS MEDIATES GLUTAMATE TOXICITY IN RAT OLIGODENDROGLIA. M.J. Belliveau, A. Oka, J.W. Lin, P.A. Rosenberg and J.J. Volpe\*. School, Boston, MA, 02115. Children's Hospital and Harvard Medical

We demonstrated that L-glutamate (GLU) induces cytotoxicity in cultured oligodendroglia (oligos) and that GLU transport into the cell is critical for the toxicity (see abstract of Oka et al.). Toxicity was completely prevented by the addition of cystine (CYS; 200 µM). Because glutathione (GSH) is a crucial product of intracellular CYS and an important protective agent against oxidative stress, we measured intracellular GSH levels after exposure to GLU. GSH levels decreased rapidly (60% reduction in 9 hours with 2 mM GLU) prior to the decrease in cell viability, and there was nearly total prevention of GSH depletion at a concentration of CYS that prevented GLU-induced oligo death. Moreover, two free radical scavengers, vitamin E (30 µM) and idebenone (1 µM), protected oligos from the toxicity of 2 mM GLU. Vitamin E did not inhibit uptake of L-[3H]-GLU, and depletion of intracellular GSH occurred in the presence of vitamin E. Protection from GLU-induced cell death by CYS and antioxidants has also been observed with immature neurons by Coyle and co-workers (Murphy et al. (1990) FASEB J. 4:1624-1633).

Taken together with the results of our previous abstract (Oka et al.), our findings indicate that GLU causes oligo death by uptake into the cell, cell swelling, induction of GSH depletion, and lethal accumulation of oxygen radicals. Supported by NIH R01-HD-07464 (J.J.V.)

CARBACHOL INCREASES CYTOSOLIC FREE CALCIUM IN CULTURED RAT MICROGLIA. E.R. Whittemore\*, A.R. Korotzer, A. Etebari, and C.W. Cotman, Department of Psychobiology, University of California, Irvine, CA 92717

Microglia are resident macrophages in the CNS and may serve as the principle scavenger cells of the brain. In addition, microglia are known to release polypeptide growth factors that can influence neuronal and glial survival and growth. However, the possible signals from neurons to microglia are not well understood. It is possible that select neurotransmitters may signal microglia. Thus, we measured intracellular calcium responses to carbachol in cultured rat microglia using the calcium-sensitive dye Fura-2.

Purified cultures of microglia were prepared from the cerebral cortex of 1-4 day old rat pups, and were plated onto glass coverslips for observation using digital fluorescence imaging microscopy. Microglia were identified by morphological criterion and by using the microglia-specific label, acetylated low density lipoprotein. Cells were loaded with Fura-2/AM, and placed in a flow-through chamber on the stage of a Nikon Diaphot microscope. In these experiments, microglia were found to respond to carbachol  $(1-100 \,\mu\text{M})$  with an increase in intracellular free calcium that was oscillatory in nature. Some cells responded with robust increases in free calcium, while others showed weaker signals. Generally a second application of carbachol gave a weaker response than the first, or none at all. Carbachol also induced increases in intracellular free calcium in nominally calcium-free medium, suggesting that this response was due to the release of calcium from intracellular stores. The response to 10 µM carbachol was inhibited by 10 µM atropine, consistent with an action of carbachol at muscarinic receptors. These data suggest the possibility that microglia can respond to neurotransmitters, and therefore that there may exist a signaling loop between these two cell types.

# 272.15

BIOLOGY OF ADULT HUMAN MICROGLIA IN VITRO UNDER BASAL AND ACTIVATED CONDITIONS. K. Williams, N.P. Dooley, G.C. Trudel\*, V.W. Yong, and J.P. Antel. Dept. of Neurology and Neurosurgery, Montreal Neurological Institute, McGill University, Montreal. P.O. H3G 2B4.

Microglia participate in multiple types of pathologic reactions occurring in the CNS. We have established highly purified cultures (> 95%) of brain microglia from young adult humans. Microglia under basal culture conditions express Fc receptors I-III, MHC class I and II antigens, and are Leu-M5 and EBM11 immunoreative. In contrast to peripheral blood monoctyes, microglia do not stain with Leu-M3 or anti CD4 antibody and are negative for non-specific esterase. After stimulation with interferon gamma (IFN) (100 U/ml) microglia show increased staining intensity for Fc receptor I and MHC class II antigen, and enhanced ability to present recall antigens (tetanus, candida albicans) to autologous T-cells. Using reverse transcriptase polymerase chain reaction (RT-PCR), levels of IL-1 alpha and IL-6 mRNA expression by microglia were compared with glyceraldehyde-3phosphate dehydrogenase (GADPH), a house keeping gene. Results show that human microglia express IL-1 alpha and IL-6 mRNA and that the levels of expression are increased after the cells are exposed to IFN. These results indicate that human adult microglial cells can interact with endogenous and exogenous CNS cells via both cell-cell and soluble factor (cytokine) mediated mechanisms.

RESPONSES OF OLIGODENDROCYTES ISOLATED FROM THE SPINAL CORD OF EARLY POSTNATAL DOG TO bFGF, NGF, AND SERUM IN A DEFINED MEDIUM K.L. Hoffman, D.R. Archer, and I.D. Duncan\*. School of Veterinary Medicine, University of Wisconsin-Madison, 53706

The growth factors bFGF, and more recently, NGF have been implicated in regulating the mitotic cycle and process outgrowth of oligodendrocytes from neonatal rats and adult pigs. We investigated the effects of these growth factors and low concentrations of several kinds serum on the process outgrowth of early postnatal canine oligodendrocytes in a defined medium. Highly enriched oligodendrocytes (95-100% immunoreactive for the O1 anti-galactocerebroside antibody) were obtained from enzymatically and mechanically dissociated spinal cords of early postnatal dogs, using antibody coated dishes to isolate cells immunoreactive for the O1 antibody. The responses of these cells to various environmental conditions were determined in the virtual absence of other cell types. We have found that, although these cells are able to adhere to and extend processes onto a poly-L-lysine coated glass surface within 1-2 days of plating, a very low concentration of serum (0.5%) is necessary for the longer term (7+ days) maintenance of processes. To test the possibility that a component of serum that had adsorbed onto the culture surface was responsible for the maintenance of processes, cells were cultured on poly-Lysine coated coverslips exposed to FBS for 4 hours, and then rinsed. This modified substrate was not effective at maintaining processes. 2.5S NGF and bFGF were added to serum free medium to determine their effects on the morphology of these cells. Cells exposed to bFGF at 5 and 50ng/ml for 4 days had few processes compared to control and tended to have an elongated, bipolar morphology, whereas NGF slightly enhanced the outgrowth of processes. (Supported by NIH grant NS23124, The Myelin Project, and The Elizabeth Elser Doolittle Charitable Trust.)

EXTRACELLULAR ATPOPENS CATION CHANNELS IN CULTURED MICROGLIAL CELLS. W. Walz\*, R. Banati

IN CULTURED MICROGLIAL CELLS. Walz\* R. Banati and H. Kettenmann. Institut f. Neurobiologie, Universität Heidelberg, Im Neuenheimer Feld 345, W-6900 Heidelberg, Germany.

Extracellular ATP is now a well established modulator which is released by neurons, endothelial cells, as well as damaged cells. We studied the effect of ATP on mouse microglial cells in primary cultures using the whole-cell patch clamp technique. If the cells were clamped at their resting potential (-70mV), application of 100µM ATP evoked an inward current of about 100pA, which desensitized rapidly. Application of extracellular ADP, AMP and adenosine did not evoke any responses under these conditions. If during such an ATP response the potential of the cells was clamped stepwise at various voltages between -105 and +35mV, the conductance change evoked by ATP was 2.2nS and the reversal potential of the response was -11mV. Removing extracellular Ca²² and Cl¹ did not change the conductance nor the reversal potential of the response was -11mV. Removing extracellular Ca<sup>2+</sup> and Cl<sup>-</sup> did not change the conductance nor the reversal potential of the ATP response. Removing extracellular Na<sup>+</sup> by choline shifted the reversal potential of the ATP response to -43mV and reduced the conductance by 88%. Replacement of extracellular Na<sup>+</sup> by K<sup>+</sup> changed the reversal potential from -10 to +9mV and reduced the conductance by 82%. The results are all comparible with extracellular ATP extract through a P are all compatible with extracellular ATP acting through a P<sub>2</sub>-purinoceptor and opening up a cation conductance. The resulting response could well act as an activation signal for microglia.

# 272.16

INDUCTION OF NITRIC OXIDE SYNTHASE IN RAT BRAIN MICROGLIA. L. J. CHANDLER\*, N. GUZMAN, F. CREWS AND C. SUMNERS. University of Florida College of Medicine, Box 100267, Gainesville, FL 32610 USA.

Nitric oxide (NO) is formed in a variety of tissues where it appears to play an important role in a number of physiological and pathological processes. NO is synthesized from L-arginine by nitric oxide synthase (NOS) with formation of citrulline as a end-product of the reaction. Brain neurons possess a constitutive calcium/calmodulin dependent form of NOS, whereas many non-neuronal tissues possess an inducible form of NOS that is calcium/calmodulin independent and can be induced by lipopolysaccharide and cytokines. In the present study, we investigated the possibility that brain may possess both types of NOS. NOS activity was determined by measuring the formation of [<sup>3</sup>H]citrulline from [<sup>3</sup>H]arginine in rat primary neuronal cortical, astroglial and microglial cultures. Neurons were observed to possess the constitutive form of NOS that was activated by NMDA, kainate and ionomycin, whereas neither astroglial or microglial cultures exhibited constitutive NOS activity. Exposure of microglial cultures to lipopolysaccharide resulted in a 3-4 fold increase in NOS activity. Induction of NOS by lipopolysaccharide was both dose (maximum at 1  $\mu$ g/ml) and time (maximum at 24 hrs) dependent and was inhibited by dexamethasone (1 µM), cycloheximide (40 µM) and actinomycin (4  $\mu$ M). NOS was also induced by the cytokine interferon- $\gamma$  (100 U/ml), but not interleukin-1β (3 nM) or tumor necrosis factor (200 ng/ml). These studies demonstrate that in addition to possessing a constitutive form of NOS, the brain also contains an inducible form of NOS. Induction of NOS in brain microglia may have important implications in terms of the possible involvement of microglia in many neurodegenerative processes (Supported by NIAAA grants AA10027 and AA06069 and PHS grant NS-19441).

QUANTAL SECRETION FROM VISUALIZED VARICOSITIES OF SYMPATH-ETIC NERVE TERMINALS. M.R.Bennett\*, W.Gibson, N.A.Lavidis and R.Poznanski of Neurobiology Laboratory, Department of Physiology, University of Sydney, NSW 2006, Australia.

The probability of quantal secretion from sets of one to six varicosities of individual sympathetic nerve terminals on the surface of the mouse vas deferens has been determined. Varicose preterminal axons are observed giving rise to single axons on the surface of the vas deferens using either the FAGLU stain for catecholamines or confocal microscopy following neurofilament antibody staining. Electronmicroscopy shows that the varicosities of these single axons are found up to 4 µm apart and sometimes form close contacts with the smooth muscles. The distribution of current in the three-dimensional bidomain of the smooth muscle syncytium following the secretion of a quantum from a varicosity has been determined using a finite-element model. It is shown that an extracellular electrode of about 4 µm diameter can be used to analyze quantal secretion from single varicosities. In high Ca<sup>2+</sup> only one quantum per varicosity has been observed using this technique, indicating that a release site is probably only able to secrete at most one quantum on arrival of the nerve impulse.

ANTIBODIES AGAINST B-50/GAP-43 AND CALCINEURIN INHIBIT Ca2+-INDUCED CATECHOLAMINE RELEASE. P.N.E. De Graan\*, J.J.H. Hens, A.B. Oestreicher and W.H. Gispen. Rudolf Magnus Inst. and Inst. Mol. Biol., Padualaan 8, 3584 CH Utrecht, NL.

Protein B-50 (also known as GAP-43, F1 and neuromodulin) is a nervous tissue specific protein, which is associated with the presynaptic membrane. B-50 is a wellcharacterized substrate of protein kinase C (PKC) with a single PKC phosphorylation site at ser41. B-50 dephosphorylation (at least in vitro) can be mediated by a number of phosphatases, including the Ca<sup>27</sup>(calmodulin-dependent phosphatase calcineurin. B-50 is an atypical calmodulin-binding protein. Under resting Ca<sup>2\*</sup> conditions (10\*-10\*) M) calmodulin is bound, whereas at Ca2+ concentrations from 10-6 M and higher (concentrations occurring locally during depolarization in the submembrane region) calmodulin progressively dissociates from B-50. The calmodulin-binding domain in B-50 (residues 39-51) includes the PKC phosphorylation site. Phosphorylation of this site prohibits calmodulin binding. Using streptolysin-O-permeated synaptosomes we have shown that polyclonal IgGs against B-50, which interfere with B-50 phosphorylation, inhibit Ca2+-induced noradrenaline (NA) release (Dekker et al., Nature 342: 74, 1989). In this study we introduced monoclonal IgGs directed against N- or C-terminal B-50 epitopes and polyclonal IgGs against calcineurin into permeated synaptosomes to study their effects on Ca2+-induced NA release. We show that only anti-B-50 IgGs inhibiting B-50 phosphorylation, dephosphorylation and calmodulin binding, interfere with Ca2+-induced endogenous and 3H-labeled NA release. These data confirm that B-50 is involved in the molecular mechanism of catecholamine release after the Ca2+ trigger. Since Ca2+-induced NA release cannot be inhibited by PKC inhibitors (PKC<sub>19-36</sub> and H-7), but is almost completely blocked by anticalcineurin IgGs, we propose that dephosphorylation (possibly of B-50) by calcineurin, which is stimulated by a depolarization-induced local increase in Ca<sup>2+</sup> and calmodulin levels, is an important event in the regulation of NA release.

VX ENHANCES TRANSMITTER RELEASE IN CULTURED HIPPOCAMPAL NEURONS. E.S. Rocha\*, Y. Aracava & E.X. Albuquerque. Dept. Pharmacal. Exp. Ther., Univ. Maryland Sch. Med., Baltimore, MD 21201; Lab. Mol. Pharmacal., UFRJ, 21944, Rio de Janeiro, Brazil.

VX and (-)physostigmine (Phy), organophosphate and carbamate acetylcholinesterase inhibitors, respectively, have been reported to elicit excitatory postsynaptic potentials and action potentials at the locust neuromuscular junctions (JPET 239: 270, 1986). This activity, resulting from an intense neurotransmitter release, was abolished by tetrodotoxin (TTX). To examine whether these compound also affect the transmitter release at mammalian brain synapses, we used the wholecell technique to record miniature excitatory postsynaptic currents (mEPSCs) from rat fetal (18- to 20-day-gestation) hippocampal neurons kept in culture for 10-30 days. In the absence of TTX, the spontaneous mEPSC activation was characterized by high frequency bursts of events followed by silent periods. For the VX study, neurons with spontaneous synaptic activity markedly suppressed by TTX  $(0.3 \,\mu\text{M})$  were used. Addition of VX  $(10\text{-}500 \,\text{nM})$  caused a significant increase in the frequency of mEPSCs. In contrast to the TTX-sensitive currents, the VX-induced mEPSCs appeared randomly. The mean amplitude of these currents was dependent on the transmembrane voltage. Antagonists of the N-methyl-D-aspartate, nicotinic acetylcholine and GABA receptors were tested, separately, by bath application. All antagonists decreased the number of mEPSCs, the proportion depending upon the contribution of the synapses present on the cell. This indicates a nonspecific action of VX. However, most of spontaneous mEPSCs were blocked by the GABA inhibitor bicuculline. Phy (100 nM-100 µM) had no effect on the mEPSCs, either in the presence or absence of TTX. The present results showed a massive non-specific transmitter release in the presence of VX through a mechanism independent of TTX-sensitive Na+ channels. Support: US Army Med. Res. Dev. Comm. Contr. NEUROTRANSMITTER RELEASE FROM SYNAPTOTAGMIN-DEFICIENT CLONAL PC12 VARIANTS Y. Shoji-Kasai, A. Yoshida, K. Sato, T. Hoshino, A. Ogura, S. Kondo, M. Takahashi\*, Mitsubishi Kasei Institute of Life Sciences. Machida, Tokyo, JAPAN

Synaptotagmin (p65) is an abundant synaptic vesicle protein of neurons and contains regions similar to the regulatory domain of protein kinase C. In PC12 cells synaptotagmin is expressed and located in large dense-core vesicles, containing catecholamines. To assess the functional role of synaptotagmin, we attempted to isolate clonal variants of PC12 cells which are deficient in synaptotagmin. First we elimi nated most of the cells expressing synaptotagmin by selectively killing those cells that reacted with an antibody recognizing synaptotagmin located on the cell surface with the complement. After repeating the selection procedure, we selected three synaptotagmin-deficient clones. No synaptotagmin was detected in the variant cells by immunoblotting with three antibodies of different specificity. Synaptotagmin mRNA was not detected in Northern blotting experiments. Like normal PC12 cells, all of the variants released catecholamine and ATP when treated with medium containing a high concentration of K+, (60 mM). We conclude that synaptotagmin is not essential for the exocytosis of the large dense-core vesicles of PC12 cells. We are further studying the neurotransmitter release from the variant cells differentiated to neurons by NGF.

SPACE AND TIME CHARACTERISTICS OF ACETYLCHOLINE RELEASE IN THE TORPEDO ELECTRIC ORGAN. R. Girod, P.Correges, J. Jacquet, M. Schorderet\* and Y. Dunant. Departement de Pharmacologie, C.M.U., 1211 Geneve 4, Switzerland.

Spontaneous miniature electroplaque potentials (MEPPs) and evoked electroplaque current (EPCs) were recorded focally with an extracellular electrode in untreated Torpedo electric organ. 75 % of MEPPs (fast-MEPPs) had a homogenous and rapid time course. Their amplitude distribution revealed a main bell-shaped population, and a population skewed towards the noise. Both the time-to-peak and the half-decay time of fast-MEPPs showed a positive correlation with the amplitude. 25 % of MEPPs had a much slower time-course. Slow-rising MEPPs with rapid decay were analysed in details. They showed a wide variety of shapes and were in average smaller than the fast-MEPPs. These characterisitics were compared with a bidimensional computer model of synaptic transmission designed to deliver various amounts of acetylcholine (ACh) molecules at the same or at different sites of the synapse, either synchronously or with various temporal patterns. The electric organ MEPPs were found consistent with a model in which a quantum of transmitter is composed of a preferential number of 10 subunits of ACh; the subunits are produced either from a single point or from sites situated at less than 300 nm from each other, so that they act on overlapping receptor fields. The subunits are released in a single synchronous discharge for the majority of events (fast-MEPPs), but with desynchronized shots for a certain percentage of MEPPs (slow-rising MEPPs).

Multiquantal EPCs were elicited by activation of nerve terminals. Their tim to-peak was independent of amplitude but their decaying phase showed a positive correlation with amplitude. Comparison with the computer model suggested that in the electric organ evoked quanta are released from sites separated from each other by 600-1,000 nm.

## 273.6

CALCIUM AND NICOTINE INDUCED DESENSITIZATION OF ENDOGENOUS ACETYLCHOLINE RELEASE FROM MAMMALIAN BRAIN CHOLINERGIC NERVE ENDINGS. Tarun Tandon and Enrique L.M. Ochoa \* Dept. of Pediatrics, University of California at Davis, Davis CA 95616.

Quantal release of transmitter from presynaptic terminals can be desensitized by calcium injection, reduction of intracellular calcium sequestration, or repetitive electrical stimulation (Miledi, 1966; Katz and Miledi, 1969; Adams et al., 1985; Israel and Lesbass, 1987). Nicotine evokes transmitter release from pharmacologically distinct neurons, but its capacity to induce desensitization has not yet been demonstrated at central mammalian cholinergic synapses. Endogenous acetylcholine release from hippocampal synaptosomes was monitored by a novel continuous fluorometric technique with nanomolar sensitivity using 2-7-dichlorofluorescein. Concurrent depolarization of the synaptosomal membrane by (-) nicotine was assessed using the transmembrane equilibrium distribution of tetraphenylphosphonium ion. Nicotine and veratridine depolarizated synaptosomes in a terrodotoxin insensitive and sensitive manner respectively, and κ-bungarotoxin blocked the effects of (-) nicotine. Calcium-dependent acetylcholine release was induced by 30 mM KCl., 30 μM veratridine and 0.001 - 300 μM (-) nicotine. Calcium influxinduced transmitter release in calcium-free media was demonstrated in the presence of gramicidin D (0.1 μM) and the calcium ionophore ionomycin (0.5 μM). A concentration-response curve was constructed for ionomycin-mediated calcium influx (0.05 - 10 mM) showing inactivation of release starting at 3.5 mM. Preincubation with femtomolar concentrations of the Ca-ATPase blocker thaspiagnin in the presence of external calcium, reduced the amount of acetylcholine release stimulated by 30 μM veratridine. This suggests that the phenomenon is mediated by an elevation of intracellular calcium. Nicotine-induced acetylcholine release (ECS0 3 μM) was calcium and κ-bungarotoxin sensitiitive (0.1 μ

#### 973 7

STRONTIUM IONS HAVE A LESSER EFFECT THAN CALCIUM IONS TO MOBILIZE QUANTA BUT A GREATER ABILITY TO INCREASE PROBABILITY OF TRANSMITTER RELEASE. Provan\* and M.D. Miyamoto, Dept. of Pharmacol., East Tenn. State Univ. Col. of Med., Johnson City, TN 37614-0577.

Extracellular [Sr2+] is less effective than equimolar [Ca2+] in supporting synchronous transmitter release from nerve terminals. We tested whether this was due to a lower efficacy at transmitter release sites by using miniature endplate potentials and sustained 10 mM K+ stimulation to obtain unbiased estimates of n (no. of functional release sites), p (probability of release), and var p (spatial variance in p). Data were obtained from single endplates of frogs during 3 changes each in [Sr2+] and [Ca2+], and linear regressions computed for each relationship. The intersection of the 2 lines for m represented the point at which Sr2+ and Ca2+ were equi-effective in supporting quantal release at a particular junction. Since m = np, this could be due to equal n and p, larger n and smaller p, or any combination thereof. For equivalent m's,  $n_{Ca} = 14.95 \pm 2.66$  quanta and  $p_{Ca} = 0.233$ , whereas  $n_{\rm Sr} = 10.13 \pm 1.09$  quanta and  $p_{\rm Sr} = 0.332$  (8 experiments). If p represents activation of release sites by  $Ca^{2+}$  (or surrogate) and n the no. of occupied release sites, this indicates that Sr2+ is more effective in activating the release sites and less effective in mobilizing vesicles to these sites. This may be due to the different ionic potentials of Sr2+ and Ca2+ (Silinsky, Pharmacol. Rev. 37: 81, 1985). (NIH NS22457.)

## 273.9

EFFECT OF CALCIUM CHANNEL BLOCKERS ON PREJUNCTIONAL D2 DOPAMINE RECEPTOR MEDIATED INHIBITION OF NOREPINEPHRINE RELEASE. D.J. Friedman\* and S.P. Duckles, Dept. of Pharmacology,

University of California, Irvine, CA 92717

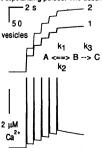

Activation of prejunctional D<sub>2</sub> dopamine receptors mediates an inhibition of norepinephrine release from perivascular nerves of the rat tail artery, an effect which is inversely correlated to stimulation intensity and external calcium concentration. Therefore, the role of calcium channels in the  $D_2$ calcium concentration. Therefore, the role of calcium channels in the D<sub>2</sub> receptor-mediated inhibition of norepinephrine release was investigated in perfused rat tail arteries preloaded with <sup>[3</sup>H]norepinephrine. Nifedipine (10<sup>-7</sup> M) and ω-conotoxin (10<sup>-8</sup> M) were used to block L-type or N- and L-type calcium channels, respectively. Tritium efflux in response to low intensity (1 Hz/50 pulses) or high intensity (4 Hz/100 pulses) stimulation was measured. At 4 Hz/100 pulses nifedipine alone reduced tritium efflux by 22 ± 6%, while no decrease was observed at 1 Hz/50 pulses indicating that L-type calcium channels contribute more to calcium influx at high levels of nerve stimulation. Together nifedipine and ω-conotoxin reduced stimulation-evoked fritium efflux by 7.3 + 8%, and 80 + 3%, at 100 + 33% at 100 and high levels of stimulation. tritium efflux by 73  $\pm$  8% and 80  $\pm$  3% at low and high levels of stimulation, respectively. The D<sub>2</sub> dopamine agonist N-0923 (10<sup>-8</sup> M) inhibited stimulation-evoked tritium efflux by 60  $\pm$  9% at 1 Hz/50 pulses and 38  $\pm$  8% at 4 Hz/100 pulses. In the presence of calcium channel blockers the inhibition produced by N-0923 was 73 ± 11% at 1 Hz/50 pulses and 9 ± 15% at 4 Hz/100 pulses. Thus, the effects of D<sub>2</sub> receptor activation appear to be more sensitive to calcium channel blockers at high levels of stimulation.

A TWO-STEP MODEL FOR SECRETORY CONTROL IN NEUROENDOCRINE

CELLS. Ch. Heinemann. L. v. Rüden. R. H. Chow. and E. Neher. Max-Planck-Institut für biophysikalische Chemie. Göttingen, Germany Recent evidence indicates hat neurosecretory cells have at least two functionally distinguishable pools of vesicles -- a small one that is "readily released" ("B", below), and a larger "reserve" pool ("A", below). We examined a model in which these two pools lead sequentially to a "secreted" pool ("C", below). Rates k1 and k3 are calcium dependent, and were estimated from membrane capacitance measurements in bovine chromaffin cells: at high fixed Ca step A --> B becomes rate-limiting (after pool B is partially depleted), and k1 can be obtained (Augustine and Neher, J. Physiol. 450, 247-271, 1992); calcium transients induced by caffeine were used to estimate kg. As illustrated below, calcium transients were simulated for trains of 5 depolarizing pulses. The accummulation of released vesicles (pool C) elicited by

two such trains occurring 90 sec apar superimposed and numbered 1 and 2. Decreasing steps in pool C size within each train are due to rapid depletion of vesicles in pool B. The increased overall response in the second train is due to a larger initial pool B size, as the moderately elevated inter-train calcium leads to faster supply (k1) than consumption (k3) of pool B vesicles. Thus the model simulates secretory depression and augmentation at appropriate time scales. For the simulations illustrated, rate constants were

 $k_1 = 0.009s^{-1}$  [Ca]/(1.2 $\mu$ M+[Ca]),  $k_2 = 0.0055s^{-1}$ ,  $k_3=0.023\mu M^{-3}s^{-1}[Ca]^3$ , and the total number of vesicles in all pools together was 2200.

LINOPIRDINE (DuP 996)-A DRUG POTENTIALLY USEFUL FOR ALZHEIMER'S DISEASE—ACTS AT AN EXTRACELLULAR SITE TO INCREASE THE QUANTAL RELEASE OF CHOLINERGIC TRANS-MITTER. M.D. Miyamoto\* and S.D. Provan, Dept. of Pharmacol., East Tenn. State Univ. Col. of Med., Johnson City, TN 37614-0577.

The actions of linopirdine (3,3-bis(4-pyrindinylmethyl)-1-phenylindolin-2-one) at the frog neuromuscular junction were examined by using miniature endplate potentials (MEPPs) and sustained 10 mM K+ stimulation to obtain unbiased estimates of n (no. of functional release sites), p (probability of release), and  $var_{p}$  (spatial variance in p). Linopirdine produced an increase in m (no. of quanta released) which was due to an increase in n and p. The increase was dose-dependent between 0.1-100  $\mu$ M and completely reversible after 15-20 min of wash. At > 10  $\mu$ M, there was a saturation in the increase in p, but not in m or n. There was no change in  $var_{p}$  (believed to reflect  $Ca^{2+}$ release from intraterminal stores). Block of presynaptic Na and Ca channels with tetrodotoxin (3  $\mu$ M) and Co<sup>2+</sup> (1.8 mM) produced a reversible inhibition in the MEPP frequency increase to linopirdine. MEPP amplitude and time course were not affected, indicating that the drug had little or no anticholinesterase activity. Linopirdine thus enhances cholinergic transmission by a pre- and not a postsynaptic mechanism. This appears to involve an extracellular action to increase  $Na^+$  and/or  $Ca^{2+}$  influx at the terminal and not an intracellular action to release Ca2+ from cytoplasmic stores. (Supported by NIH NS22457.)

### 273.10

ANALYSIS OF THE AUTOINHIBITORY MECHANISM OF NOR-ADRENALINE RELEASE IN CHICK SYMPATHETIC NEURONS. S. Huck\*, S. Boehm, H. Drobay, E. A. Singer. Depts. of Neuropharmacology and Pharmacology, Univ. of Vienna, Waehringerstrasse 13a, A-1090 Vienna, Austria. Signal transduction mechanisms underlying the α2-adrenergic modulation of noradrenaline (NA) release from cultured chick sympathetic neurons were studied with patch-clamp techniques and by measuring electrically evoked <sup>3</sup>H-NA release. After 1 day in vitro, whole-cell Ca²+² currents were recorded with 115mM N-methyl-D-glucamine and 120mM choline chloride as bulk ions of the pipette and the bathing solution, respectively. For release studies, cells were loaded with <sup>3</sup>H-NA after 5 days in vitro and superfused. <sup>3</sup>H-overflow was elicited by 36 monophasic pulses (0.5ms, 3Hz, 40V/cm, 60mA) 76 (S₁) and 96min (S₂) after onset of the superfusion. Test drugs were added to the buffer 16min before S₂, and drug effects were evaluated by calculating S₂/S₁ ratios.

NA (in presence of the reuptake inhibitor cocaine) and the selective α2-adrenoceptor agonists UK 14304 (UK) and clonidine induced a concentration-dependent, yohimbine-sensitive inhibition of Ca²+ currents and of the electrically evoked <sup>3</sup>H-overflow. Yohimbine alone affected neither Ca²+ currents nor <sup>3</sup>H-overflow. Δ-Conotoxin greatly reduced Ca²+ currents and diminished stimulation-induced <sup>3</sup>H-overflow by 95%. The proteinkinase C inhibitor polymyxin B reduced the electrically induced overflow and antagonized the facilitatory action of 48-phorbol-12,13-dibutyrate (48-PDB). Neither polymyxin B nor a 24h treatment with 48-PDB (aming at down-PDB). 95%. The proteinkinase C inhibitor polymyxin B reduced the electrically induced overflow and antagonized the facilitatory action of 4β-phorbol-12,13-dibutyrate (4β-PDB). Neither polymyxin B nor a 24h treatment with 4β-PDB (aiming at down-regulating proteinkinase C) impaired the inhibitory effect of UK. Adenylate cyclase stimulation by forskolin enhanced the evoked release but left the inhibitory action of UK unaltered. Neither the Ca<sup>2+</sup> current itself nor its inhibition by UK were affected by either 4β-PDB or forskolin.

attected by either 4B-PDB or forskolin. Thus, a G-Protein mediated inhibition of  $\omega$ -Conotoxin-sensitive Ca<sup>2+</sup> currents underlies the autoinhibitory modulation of NA release in chick sympathetic neurons. Adenylate cyclase and proteinkinase C both control the neurotransmitter release, but are not involved in the  $\alpha_2$ -adrenoceptor-mediated autoregulation.

## 273.12

PHOSPHATASE INHIBITORS INTERACT WITH PROTEIN KINASES TO REGULATE NEUROTRANSMITTER RELEASE, BUT DO NOT AFFECT CA++ HOMEOSTASIS. J.E.Swain\*, R. Robitaille, M.P. Charlton. Department of Physiology, University of Toronto, Toronto, Ontario, M5S-1A8.

The purpose of this study is to investigate how protein phosphorylation modulates the synaptic transmission. The phosphatase inhibitor, okadaic acid (OA), causes a reversible, dose- and temperature-dependent increase in neurotransmitter release (NTR) from presynaptic terminals in crayfish and frog neuromuscular junctions (P.N.A.S. 88:1803-1807, J. Neurobiol. 22(8):855-864). Excitatory postsynaptic potentials evoked by electrical nerve stimulation were recorded to monitor NTR at neuromuscular synapses. In addition to OA, we have found that another membrane permeant phosphatase inhibitor, calyculin-A, also enhances NTR.

Since NTR is a function of Ca<sup>++</sup> entry into the presynaptic terminal, we wondered whether OA affects Ca<sup>++</sup> homeostasis. Intracellular Ca<sup>++</sup> was monitored with a confocal microscope and the fluorescent indicator fluo-3. Neither resting nor stimulated Ca<sup>++</sup> levels were affected by OA. Thus, OA action does not involve altering intracellular Ca\*\* homeostasis. To determine the kinases, whose substrates involved in NTR are dephosphorylated by phosphatases sensitive to OA, kinase inhibitors were used. The general kinase inhibitor staurosporine prevented OA from increasing NTR. Calphostin, a PKC inhibitor, does not affect OA action. We also studied the interaction of kinase stimulators and phosphatase inhibitors in NTR. Serotonin facilitation (involving both PKC and PKA stimulation) was enhanced by OA. The increase in NTR caused by SP-cAMP (a specific PKA stimulator) was larger in the presence of OA and calyculin-A. substrates of PKA may be hyperphosphorylated in the presence of OA and cal-A, and increase NTR without affecting Ca<sup>++</sup> homeostasis. Thus, calcium channels, pumps and endogenous buffers are unlikely to be targets of the inhibited phosphatases.

THE ROLE OF PROTEIN KINASE C IN THE REGULATION OF GLUTAMATE RELEASE FROM ISOLATED NERVE TERMINALS. E.T. Coffey, T.S. Sihra and D.G. Nicholls\* 2+Dept. of Biochemistry, University of Dundee, Dundee DD1 4HN, Scotland, UK,

Previous work from this laboratory has indicated that the phorbol ester potentiation of glutamate exocytosis from cerebrocortical synaptosomes can be ascribed to a PKC-mediated inhibition of a presynaptic K\* channel (Barrie et al., 1991, J. Neurochem. 57, 1398-1404). This would regulate action potential intensity or duration and hence control Ca2+ entry through the non-inactivating Ca<sup>2+</sup> channels closely coupled to glutamate exocytosis (McMahon & Nicholls, 1991, J. Neurochem., 56, 86-94). In this study we further examine the nechanism of this regulation in rat cortical synaptosomes by exploiting the specific inhibitor of PKC, Ro-31-8220. PKC in synaptosomes is partially activated in the absence of depolarization or added agonist since phosphorylation of the PKC-specific substrate 87k is decreased by 10µM Ro-31-8220. The inhibitor also causes a hyperpolarization, a decrease in spontaneous Ca2+-independent glutamate release from the cytoplasm, and decreases in both the 4-aminopyridine (4AP)-evoked increase in cytoplasmic free Ca<sup>2+</sup> and the 4APevoked Ca<sup>2+</sup>-dependent glutamate exocytosis. Each of these is consistent with a reversal of a tonic PKC-dependent K\*-channel inhibition. Thus little effect is seen on KCI-evoked Ca<sup>2+</sup> elevation or glutamate release. The effects of Ro-30-8220 are therefore diametrically opposite to those of added phorbol ester. Additionally the inhibitor reverses each of the effects of added phorbol ester The delayed rectifier inhibitor colfilium mimics the phorbol ester potentiation of 4AP-evoked depolarization. The results are consistent with a major role of PKCregulated K\*-channels in the presynaptic regulation of glutamate release.

N-(n-PROPYL)-N-(3-FLUORO-4-PYRIDINYL)-1H-3-METHYL N-(n-PROPYL)-N-(3-FLUORO-4-PYRIDINYL)-IH-3-METHYL
INDOL-1-AMINE HYDROCHLORIDE (HP 184): EFFECTS
ON THE SPONTANEOUS RELEASE OF ACh AND NE.
C.P. Smith\*, L.R. Brougham, F.P. Huger, R.C. Effland, and L. Davis.
Neuroscience Strategic Business Unit, Hoechst-Roussel
Pharmaceuticals, Inc., Route 206, Somerville, NJ 08876.

This report describes the *in vitro* acetylcholine (ACh) and
norepinephrine (NE) release properties of HP 184 studied in perfused

norepinephrine (NE) release properties of HP 184 studied in pertused rat brain slices. HP 184 selectively enhanced the spontaneous release of these neurotransmitters but did not affect electrically-stimulated release. HP 184 caused [<sup>3</sup>H] release from striatal slices loaded with [<sup>3</sup>H]choline and was unaffected by the absence of extracellular calcium or the presence of vesamicol, suggestive of either a cytoplasmic or vesamicol-insensitive vesicular source of ACh. Chromatographic analysis showed that the spontaneous release of [3H] correlates with increased release of endogenous ACh and not choline efflux. Similarly, HP 184 enhanced the spontaneous release of [3H]NE from cortical slices in a calcium and sodium channel independent fashion (not blocked by 1 mM EGTA or 5 µM TTX), and independent fashion (not blocked by 1 mM EGTA or 5 µM TTX), and was not carrier mediated (occurred in the presence of 10 µM nomifensine). Reserpine treatment prior to [<sup>3</sup>H]NE loading prevented HP 184-induced release, suggesting that in contrast to its ACh release profile, HP 184 seemed to require intact vesicles to maintain spontaneous [<sup>3</sup>H]NE release. In summary, the release properties of HP 184 in rat brain slices were found to be novel and of unresolved mechanism. In vivo release studies will be necessary to determine if these results are predictive of in vivo effects. these results are predictive of in vivo effects.

MODULATION OF SYNAPTOSOMAL GLUTAMATE RELEASE, CALCIUM HOMEOSTASIS AND MEMBRANE POTENTIAL BY ADENOSINE ANALOGS AND IDEBENONE. F. Dagani, F. Cattabeni, R. Ferrari, L. Canevari and M.P. Abbracchio\* Inst. of Pharmacology, Univ of Pavia, 27100 Pavia (ITALY); Inst. of Pharmacological Sciences, Univ of Milan 20100 Milano (ITALY).

In this study we investigated the effect of two class of drugs adenosing

In this study we investigated the effect of two class of drugs, adenosine analogs and idebenone on the modulation of glutamatergic neurotransmission and the related biochemical mechanisms such as energy metabolism, membrane potential and free calcium levels ([Ca<sup>2+</sup>]i) in synaptosomes isolated from cerebral cortex, hippocampus and striatum of rat brain . Glutamate release was measured by HPLC-ECD or flurometric technique in continuous; [Ca<sup>2+</sup>]i was measured by Fura-2 and membrane potential by CC5 fluorescence, oxygen uptake (QO<sub>2</sub>) and ATP/ADP were also measured by polarographic and luminometric methods. Synaptosomal metabolism and neurotransmitter release were stimulated by addition of both 30-40 mM KCl or 30-40 µM veratridine. Utilizing the binding of A<sub>1</sub>-specific agonist [3H]-CHA and by A<sub>2</sub>-selective ligand [3H]-CGS 21680, no detectable specific A<sub>2</sub> binding sites was found whereas  $A_1$  binding sites are present: in order of density in the hippocampus-striatum>cerebral cortex. Only in the hippocampus the  $A_1$  specific agonist CPA, in the range of concentrations of  $0.01\text{-}100 \mu\text{M}$ , significantly counteracted the KCl-evoked release of glutamate. The same trend was detectable if veratridine was utilysed as depolarizing agent. CPA  $10^{-4}$ M also reduced by 30% the KCl-stimulated increase of  $[Ca^{2+}]i$ . Idebenone (in vitro addition at  $1-10 \mu$ M) was able to inhibit by 30% the eratridine stimulated (QO2) but no effect was found on ATP levels both in basal conditions and after stimulation with veratridine.

TWO METHODS TRADITIONALLY USED TO PREVENT MUSCLE CONTRACTION AFFECT STIMULATION-INDUCED CHANGES IN NEUROTRANSMITTER RELEASE AT THE FROG NEURO-MUSCULAR JUNCTION. M.A. Sosa\* & J.E. Zenrel. Depts Neurosci/Neurosurg., Univ. of Fl. Coll. of Med. & Dept. Vet. Affairs Medical Center, Gainesville, FL 32610.

Medical Center, Gainesville, FL 32610.

At the frog neuromuscular junction, repetitive stimulation of the presynaptic nerve can lead to an increase and/or a depression in the amount of transmitter released, depending on the levels of quantal release. To study these stimulation-induced changes in release under normal or high quantal conditions, muscle contraction must be prevented. This has traditionally been done by pretreating the muscle with a glycerol solution or by adding curare. We thought it was important to determine whether these treatments could also affect the release process itself.

End-plate potentials were recorded from frog sartorius muscle under conditions of low (0.6mM Ca<sup>2+</sup>/5mM Mg<sup>2+</sup>), normal (1.8mM Ca<sup>2+</sup>) and high (3.6mM Ca<sup>2+</sup>) levels of release. Curare (3-5 µg/ml) was added

high (3.6mM Ca<sup>2+</sup>) levels of release. Curare (3-5 ug/ml) was added when levels of release were normal or high. Nerves were conditioned with trains of 10 to 200 impulses (20 impulses/sec).

We found that after return to a Ca<sup>2+</sup> Ringer solution following a one hour exposure to glycerol (0.5-1M), the level of stimulation-induced increases in release was higher than that observed before glycerol. This effect was observed within 30 min after removal of glycerol and continued to increase for up to 3 hr. In experiments done under low quantal conditions, addition of curare (1-2 ug/ml) also resulted in a higher level of stimulation-induced increases in release. Under conditions of normal or high levels of release, increasing the concentration of curare also increased the level of depression of release.

These results indicate that both of these methods of preventing

These results indicate that both of these methods of preventing muscle contraction can also affect the process of transmitter release.

ADENOSINE INHIBITS THE CALCIUM-DEPENDENT ACETYLCHOLINE SECRETION INDUCED BY IONOMYCIN. J.M. Hunt, H.M. Wilfehrt, and E.M. Silinsky.

Dept. of Pharmacology, Northwestern Univ.
Medical School Chicago, IL 60611.
The calcium ionophore, ionomycin, was used to stimulate secretion of acetylcholine (Ach) quanta stimulate secretion of acetylcholine (Ach) quanta from frog motor nerve terminals. In the presence of extracellular  ${\rm Ca}^{2+}$ , bath application of 5-15  $\mu{\rm M}$  ionomycin, or local application 1-20  $\mu{\rm M}$  ionomycin via an extracellular pipette (dia  $\approx 300~\mu{\rm m}$ ) positioned adjacent to the nerve terminal produced a rapid, profound increase in the rate of asynchronous Ach secretion. The amount of ionomycin-stimulated secretion depended upon both asynchronous Ach secretion. The amount of lonomy-cin-stimulated secretion depended upon both ionomycin and external Ca<sup>2+</sup> in a dose-dependent manner. Quantal content of end plate potentials was also augmented by ionomycin. These results suggest that ionomycin transports Ca<sup>2+</sup> across the plasma membrane to stimulate secretion of Ach

Adenosine and 2-Chloroadenosine ionomycin-induced Ach secretion with a similar efficacy to that observed against physiological Ach secretion. These results suggest that adenosine receptor activation inhibits Ach secretion by reducing the ability of Ca<sup>2+</sup> to promote exocytosis.

DUAL ACTION OF D-TUBOCURARINE AND HEXAMETHONIUM ON TRANSMITTER RELEASE AT THE NEUROMUSCULAR JUNCTION OF THE RAT. D. F. Wilson and A.E. West Zoology Dept.

Miami Univ., Oxford, OH, USA 45056.

Previously we reported that d-tubocurarine hexamethonium enhance transmitter release and we concluded that this was due to blocking the presynaptic nicotinic receptors. In this study we report the effects of d-tubocurarine (0.075 µM) and hexamethonium (400 µM) on transmitter release from the rat diaphragmphrenic nerve preparation with the calcium level in the bathing medium reduced from 2.0 mM to 0.5 mM. The intent of this study was to reduce the negative feedback action of the transmitter on the autoreceptors feedback action of the transmitter on the autoreceptors and determine if a second action of these nicotinic antagonists could be demonstrated. Intracellular recording techniques were used to monitor end-plate potentials (EPPs) and miniature end-plate potentials (MEPPs) in the isolated cut-muscle preparation. Quantal release in the presence and absence of the antagonists were examined. In the presence of each of these antagonists a significant decrease in quantal release was observed. These results suggest that both hexamethonium and d-tubocurarine have a dual action on transmitter release. It is proposed that the inhibitory effect is unrelated to blockage of autoreceptors and inhibition may dominate at higher concentrations. This may help to explain the divergence in views concerning the role of the autoreceptors. (Supported by NIH grant NS-27260).

Arachidonic acid potentiates vasopressin release from isolated neurohypophysial nerve endings. E.L. Stuenkel, G. Dayanithi<sup>#</sup>, J. J. Nordmann<sup>#</sup>. Dept. of Physiology, Univ. of Michigan, Ann Arbor MI, and Centre de Neurochimie du CNRS, 67084 Strasbourg Cedex, France.

Arachidonic acid (AA) and a number of AA metabolites are generated in response to various physiological stimuli. It has been postulated that AA may be important in modulating calcium signaling and neurotransmitter/neurohormone release from nerve endings. Thus, we have evaluated the effects of AA on intracellular calcium ([Ca $^2$ +];) and vasopressin (AAVP) release in a preparation of rat isolated neurohypophysial nerve endings. AA was found to increase basal AVP release and potentiate elevated K $^+$ -evoked release in a concentration-dependent manner (minimal effective dose = 25  $\mu$ M). Sequential AA pulses gave sequential secretory responses. AA was found to dose-dependently (10 - 100  $\mu$ M) increase [Ca $^2$ +]; as monitored by Fura-2 at the level of single nerve endings. Application of inhibitors of AA effects on AVP release or [Ca $^2$ +]; Moreover, application of a mixture of HETEs was ineffective at inducing a secretory response. AA could still induce AVP release and evoke, although reduced from control, an increase in [Ca $^2$ +]; in nerve endings bathed in EGTA-containing Ca $^2$ +-free medium. A series of experiments also found that AA could evoke a secretory response in streptolysin-O permeabilized nerve endings in the presence of 2 mM EGTA. The data suggest, therefore, that AA can directly increase basal and potentiate evoked AVP release from nerve endings. Furthermore, although AA has strong effects on Ca $^2$ + signaling the results on permeabilized nerve endings suggest that AA can induce secretion in a Ca $^2$ +-independent manner.

PURIFICATION AND ANALYSIS OF THE EFFECTS OF SUBSTANCE B ON ACETYLCHOLINE RELEASE. L. B. Pearce\*. A. F. Gaillunas and R. MacCallum. Dept. Pharmacology, Boston University Sch. of Med. Boston, MA 02118

Substance B (SB) is a neuromodulator found in both brain and heart that has been proposed to reverse inhibitory presynaptic receptor function by a mechanism that does not involve direct stimulation of acetylcholine (ACh) release (Pearce et al. PNAS 83:7979,1986). The purpose of this study was to critically examine whether or not the effects of SB can be accounted for by direct effects of this modulator on basal or evoked release of ACh. The effects of purified bovine brain SB on basal and evoked release of ACh were studied in three different preparations. Substance B was purified from an aqueous extract of whole bovine brain by tangential flow filtration, BioGel P2 gel filtration chromatography, methanol extraction, and two step chromatography by HPLC on a silica column using both methanol and H<sub>2</sub>O elution. Purification of SB by this procedure resulted in a 3% yield of activity. Superfusion of rat right atria in the presence of HPLC-purified SB did not produce a direct effect on basal or stimulated release of 13H]ACh. However, addition of supernormal amounts (>7 units) of HPLC-purified SB potentiated potassium-evoked release from superfused rat right atria and produced small increases in electrically-evoked contractions without increased baseline tension in guinea pig lieum longitudinal muscle strip preparations. Analysis of the effect of SB (8 units/10 ml superfusate) on brain synaptosomes, indicated that this neuromodulator did not significantly increase basal nor potassium-evoked (50 mM KCl) release of [3H]ACh. The results of these studies describe a procedure for the preparation of highly purified SB. In addition, the actions of SB on basal and evoked release are not inconsistent with the original hypothesis however, high levels of this modulator potentiate evoked release in two of the three systems studied.

## LONG-TERM POTENTIATION II

Ca<sup>2+</sup>-INDUCED PROTEOLYTIC ACTIVATION OF PKC IN HIPPOCAMPAL HOMOGENATES. J. S. Sessoms, D.M. Chelkovich, J. D. Sweatt \*, and E. Klann, Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030

Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030 Previous studies by our laboratory demonstrate a persistently activated form of PKC in association with the maintenance phase of LTP in area CA1. Ca<sup>2+</sup> influx through NMDA receptors contributes to the induction of LTP at these synapses. To investigate potential mechanisms for the LTP-associated persistent PKC activation, we used a model system in vitro: Ca<sup>2+</sup> addition to hippocampal homogenates. Ca<sup>2+</sup> (ImM excess over EGTA) was added to homogenates and the mixture incubated at 37°C for two min. The incubation was stopped by addition of EGTA (excess over Ca<sup>2+</sup>). Kinase activity was then measured using a synthetic peptide fragment of ribosomal S6 protein or the selective peptide substrate for PKC, neurogranin(28.43) (NG(28-43)). Ca<sup>2+</sup> pretreatent caused increased phosphorylation of S6 peptide (ctrl = 2.0±0.49 pmol/min/µg, Ca<sup>2+</sup> pretreated = 4.56±0.76, n=9) and NG(28-43) (cut = 7.5±1.5 fmol/min/µg, Ca<sup>2+</sup> pretreated = 29.5±4.6, n=4). The increased activity was expressed in EGTA, indicating an increase in Ca<sup>2+</sup>-independent (basal) PKC activity. In fractionation experiments the increased PKC activity was localized to the soluble fraction (for NG(28-43) ctrl = 0.42±0.21 pmol/min/µg protein, Ca<sup>2+</sup> pretreatment = 5.22±0.56, n=3). Expression of the increased activity could be blocked by the selective PKC inhibitor peptide PKC(19-36). Leupeptin (50 µg/ml) or an inhibitor of Ca<sup>2+</sup>-activated neutral proteases (0.78 U/ml, Sigma) blocked induction of the increase in basal PKC activity. The persistently activated form of the kinase appeared as a novel peak of activity eluting with 0.4 M NaCl from DEAE columns, as has been previously reported for proteolytically activated PKC. In addition, the persistently activated kinase cluted as a species of lower molecular weight than the native enzyme on HPLC gel filtration columns. Taken together, these results demonstrate robust proteolytic activation of PKC in hippocampal homogenates. Thus, it is reasonab

## 274.3

RAPID INCREASE IN CYTOSOLIC PROTEIN KINASE C ACTIVITY AFTER LONG-TERM POTENTIATION, BUT NOT SHORT-TERM POTENTIATION

Otani S., Barbin G.\* & Roisin-Lallemand M.-P.
INSERM U29, Hôpital de Port-Royal, Paris, FRANCE

We have reported that coupling a short-term potentiation (STP)-inducing weak tetanus with metabotropic  $(Q_P)$  receptor stimulation with trans-(±)-1-amino-1,3-cyclopentanedicarboxylic acid (ACPD, 50  $\mu$ M) induces long-term potentiation (LTP) in rat CA1 slices. We adopted this method to test whether the conversion of STP to LTP involves protein kinase C (PKC) activation. PKC activity was measured in the presence or absence of Ca2+, phosphatidylserine and phorbol ester using the synthetic substrate peptide. Two minutes, but not 30 min, after the coupling, there was a significant increase (>70%) in the cytosolic activator-dependent PKC activity. Either STP alone or ACPD alone was ineffective. There was no change in membrane-associated PKC. When STP was induced by agonist-coactivation of  $Q_P$  and ionotropic receptors, there was no change in PKC.

LTP was also induced by strong tetanic stimulation. There was a similar cytosolic PKC increase 2 min, but not 5, 15, 60, 180 min, after tetanus, which was not seen when LTP was reduced by APV. No change in the activator-independent cytosolic PKC was detected, nor was there any change in the membrane-associated PKC during the 3 h.

Qp receptor involvement in tetanic LTP has been suggested. Our results indicate that Qp receptor activation may play a part in LTP induction by conjointly activating cytosolic PKC.

LTP IS ASSOCIATED WITH REGIONAL AND CELLULAR SPECIFIC ALTERATIONS OF PROTEIN KINASE C ISOFORMS α AND βΙ. <u>K.Horsburgh\*</u>. <u>U. Slaubli, E. Masliah, T. Saitoh</u>, Department of Neurosciences, UCSD, La Jolla, CA 92093.

Each of the eight protein kinase C (PKC) isoforms may be differentially involved in modulating synaptic plasticity. We have previously reported biochemical data indicating the involvement of PKC isoforms α, βI and βII in LTP (as a model of synaptic plasticity) using Western blot techniques (Soc. Neurocience Vol.17 S160.16). In order to further characterize these PKC alterations, quantitative immunohistochemistry was applied to localize PKC isoforms α, βI, βII and γ in discrete rat hippocampal areas following LTP.

isoforms α, βι, βil and γ in discrete rat hippocampal areas following LTP.

To induce LTP, five animals received 10 trains of 400Hz pulses to the perforant path. Another group of six animals received the LTP stimulation at 0, 3, 24 and 27 hours (asymptotic LTP). Low frequency stimulation (100 pulses, 1 per 40sec) was given to a control group of five animals. One hour after the last stimulation the animals were sacrificed, the brains removed and processed for immunohistochemistry using affinity purified polyclonal antibodies against peptides specific for each PKC isoform.

PKC(α) was found to be significantly reduced in the granule cell layer of the dentate gyrus from the LTP induced animals by 78% compared to the group of animals receiving low frequency stimulation. However, this dramatic reduction in PKC(α) was not found in the hippocampus of animals in which asymptotic LTP was established. PKC(βI) was unaltered in animals receiving one LTP stimulus but following asymptotic LTP was markedly reduced (30%) in the pyramidal cells of CA3 compared to controls. PKC isoforms βII and  $\gamma$  were not significantly altered in any of the hippocampal regions examined in the LTP groups.

Well of Significancy — in the LTP groups. These data would indicate that LTP is associated with specific regional and cellular alterations in PKC isoforms  $\alpha$  and  $\beta$ I. Furthermore, these isoforms may be differentially involved in the induction and maintenance of LTP.

## 274.4

ALTERED STRUCTURAL GENE EXPRESSION AFTER LTE/LTP OF THE SAME PROTEINS (PKC AND F1/GAP-43) WHICH HAVE PHOSPHORYLATION ACTIVITY ALTERED BY LTE/LTP. P\_J\_Mcherg\*1, C\_A.Barnes<sup>2</sup>, B.L. McNaughton<sup>2</sup> and A.Routtenberg\*1. 1. Cresap Neurosci. Lab., Northwestern Univ. Evanston, II. 60208. 2. Div. Neural Systems, Memory and Aging, Univ. Arizona, Tucson, AZ 85724

Protein kinase C (PKC) activation is critical for the persistence of long-term synaptic enhancement (LTE or LTP). LTE-induced increase in phosphorylation of F1/GAP-43, a PKC substrate, is directly related to LTE persistence. We used quantitative *in situ* hybridization to determine if F1/GAP-43 or PKC gene expression is altered three days after LTE induction in chronically-prepared, conscious rats. Field potentials were recorded from the hilar/CA3 region of the hippocampus following perforant-path stimulation. One hemisphere received high-frequency stimulation (HFS), the other low-frequency (LFS). Results are reported as the difference in labeling between the two sides. In the CA3 subfield a negative correlation was observed between LTE and HFS-LFS hybridization differences for F1/GAP-43 (r = -0.801, p < 0.01), γ-PKC (r = -0.781, p < 0.01), and β-PKC (r = -0.692, p = 0.057), but not for α-PKC (r = +0.154, p > 0.75). Animals with an increase in EPSP magnitude of greater than 20% (n=6) had less F1/GAP-43 (p < 0.05) and γ-PKC (p < 0.01) hybridization in CA3 than those with less than a 20% increase (n=6). The decreased F1/GAP-43 mRNA may signify a reduced potential for synaptic plasticity and therefore greater synaptic stability. F1/GAP-43 HFS-LFS hybridization differences were highly correlated with γ-PKC in CA3 (r = +0.928, p < 0.001), suggesting coordinate regulation. No correlation was observed in any cell field between LTE and hybridization of post-synaptic proteins MAP-2, neurogranin, or the B-flip form of the glutamate receptor. Enduring changes in synaptic efficacy or memory formation may involve phosphorylation of proteins initially, followed by changes in gene expression of the same proteins that participate in the phosphorylation reaction. QUANTITATIVE ANALYSIS OF PROTEIN KINASE C AND PHOSPHORY-LATION OF GAP-43 SUBSTRATE FOLLOWING LTP IN HIPPOCAMPAL SLICES. Y. LUO, J. C. LEAHY, C. S. KENT, K. F. MEIRI AND M. L. VALLANO\*. Dept. of Pharmacology, SUNY Health Science Center at Syracuse, Syracuse, NY 13210.

Quantal analysis studies suggest that enhanced neurotransmitter release from presynantic terminals is involved in the maintenance of long-term potentiation (LTP). A majority of the  $\alpha$  isoform of protein kinase C (PKC) and some  $\beta$  isoforms are presynaptic, whereas PKC  $\gamma$  is exclusively postsynaptic. Furthermore, phosphorylation of the presynaptic PKC substrate, GAP-43, correlates with neurotransmitter release. Hippocampal slices were used to study the role of neutoransmitter release. Hippocampia sities were used to study the role of presynaptic PKC in the early maintenance phase of LTP in area CA1. The redistribution of PKC isoforms and the state of GAP-43 phosphorylation were examined for up to 1 hour after LTP induction. PKC activation was assessed by quantitative immunoblotting of cytosolic and membrane fractions with monoclonal antibodies recognizing, both the  $\alpha$  and  $\beta$  isoforms, the  $\alpha$  isoform only, or the single PKC phosphorylation site in GAP-43. Results indicate that tetanization of the Schaffer collateral-CA1 synapse, which induced LTP, causes significant increases in both the translocation of presynaptic PKC isoforms and the PKC-specific phosphorylation of GAP-43. The observed changes were time and frequency dependent, and inhibited by APV, a NMDA receptor antagonist. Bath application of arachidonic acid, one of the putative retrograde messengers for maintenance of LTP, enhanced PKC redistribution to the membrane in hippocampal slices with high potassium depolarization. This redistribution was accompanied by concomitant enhancement of GAP-43 phosphorylation. Preliminary data using hippocampal synaptosomes show similar results. These observations support the hypothesis that presynaptic mechanisms, involving release of retrograde messenger postsynaptically, activation of presynaptic PKC and PKC-specific phosphorylation of GAP-43, contribute to the early maintenance of LTP. ## 274.7

INHIBITION OF PROTEIN KINASE ACTIVITY FACILITATES LONG-TERM POTENTIATION OF IPSPs IN HIPPOCAMPAL CA1 NEURONS. B. R. Sastry\* and Z. Xie, Neuros Pharmacology & Therapeutics, Neuroscience Research Laboratory, Dept. of apeutics, The University of British Columbia. Vancouver, B. C., Canada, V6T 1Z3.

The activation of protein kinase C (PKC) has been implicated in long-term potentiation (LTP) of excitatory postsynaptic potentials (EPSPs) in the hippocampus. In the present study on guinea pig hippocampal slices, the actions of intracellularly injected K-252b, an inhibitor of protein kinase C (PKC), were examined to determine the involvement of postsynaptic PKC in LTP of gamma-aminobutyric acid (GABA) receptor-mediated fast (GABA<sub>A</sub>) and slow (GABA<sub>B</sub>) inhibitory postsynaptic potentials (IPSPs). In control neurons, the IPSPs were recorded with electrodes containing K acetate. A tetanic stimulation (400 Hz, 1 s) of the stratum radiatum induced LTPs of the EPSP and the fast IPSP, but not of the slow IPSP (n=8). If the recording electrode contained K acetate and K-252b (5 μM), a tetanic stimulation of the stratum radiatum did not induced LTP of the EPSP, but LTPs of the fast IPSP and the slow IPSP (n=16) were observed. In some CA1 neurons injected with K-252b, during LTP of the IPSPs a decrease in the height and the duration of the EPSP was observed. This distortion of the EPSP was

greatly reduced when the IPSPs were pharmacologically blocked (n=8).

These results suggest that the activation of the PKC is necessary not only for LTP of the EPSP but also to minimize LTP of the IPSPs so that the EPSP

GLUTAMATE-INDUCED PHOSPHORYLATION OF SYNAPSIN I AND MAP2 IN CULTURED HIPPOCAMPAL NEURONS. 

1K. Fukunaga\*, 2T.R. Soderling and 1E. Miyamoto. 1Dept. of Pharmacol., Kumamoto Univ. Sch. of Medicine, Kumamoto 860, Japan, 30 Julius 10 Julius Vollum Institute, Oregon Health Sciences Univ., Portland, Oregon

The role of Ca2+/calmodulin-dependent protein kinase II (CaM kinase II) and protein kinase C has been implicated in the induction of long-term potentiation (LTP) in the hippocampus. However, little is known about how the activation of the protein kinases results in long-lasting change of the synaptic efficiency in LTP. In the present study, we have focused on the target proteins for CaM kinase II in the signaling pathway induced with glutamate in the cultured hippocampal neurons. In the experiments with  $^{32}$ P-labeled cells, the phosphorylation of MAP2 and synapsin I as well as autophosphorylation of CaM kinase II were stimulated by the exposure to  $10~\mu$ M glutamate. The phosphorylation of MAP2 and synapsin I significantly increased by  $128~\pm~11$  and  $126~\pm~00$  m. %, respectively, at 1 min and was maintained until at least 15 min in 9 %, respectively, at 1 min and was maintained until at least 15 min in the continued presence of glutamate. The increase in MAP2 phosphorylation and autophosphorylation of CaM kinase II were completely inhibited by the pretreatment with AP5, an antagonist of the NMDA receptor. However, the increase in synapsin I phosphorylation was only partially inhibited with AP5. These results suggest that the activation of CaM kinase II through the NMDA receptor increases the phosphorylation of MAP2 and synapsin I and in turn induces neuronal functions. functions

TOWARD A FUNCTION FOR THE RC3 PROTEIN; A CALMODULIN

TUESDAY PM

BINDING, PROTEIN KINASE C SUBSTRATE LOCATED IN DENDRITIC SPINES. D.D. Gerendasy, K. Wong, J.G. Sutcliffe. Dept. Molecular Biology, Research Institute of Scripps Clinic, La Jolla, CA 92037. RC3 is a 78 AA substrate for Protein kinase C which binds calmodulin in the absence of Ca<sup>2+</sup>. It exhibits a postnatal onset and is significantly enriched in the cerebral cortex, striatum and hippocampus where it is primarily localized to dendritic spines and can often be found associated with post-synaptic densities. These qualities suggest the hypothesis that it plays a postsynaptic role with respect to memory, associative learning and possibly, long term potentiation.

We have cloned, bacterially expressed and purified RC3 to homogeneity. The recombinant protein binds to calmodulin, in the absence of Ca2+ and is able to serve as a substrate for protein Kinase C in vitro. This preparation is suitable for structural studies (NMR and X-ray preparation is suitable for structural studies (finith and A-lay crystallography), as well as electro-physiological studies (microinjection into hippocampal brain slice neurons).

We have also constructed and bacterially expressed two mutant forms of RC3. One mutant (Ser36 to Ala) fails to act as a substrate for PKC,

RC3. One mutant (Ser36 to Ala) fails to act as a substrate for PKC, indicating that in vitro phosphorylation of recombinant RC3 is specific (Ser36 is the residue which is normally phosphorylated). This mutant retains the ability to bind calmodulin in a Ca<sup>2+</sup> manner and can, therefore, be purified in the same manner as the wildtype. The other mutant (Ser36 to Asp) fails to bind calmodulin, indicating that a negative charge at position 36 is sufficient to prevent binding to calmodulin. This is consistent with the fact that the phosphorylated form of RC3 does not bind calmodulin. calmodulin.

Additional mutants have been created and we are investigating the effects of over-expression of RC3 and mutants in transgenic mice and cultured cells. Structural and biochemical studies utilizing purified recombinant RC3 are also in progress.

PROTEIN KINASE INHIBITORS REVEAL TEMPORALLY DISTINCT PHASES OF LTP. K.M. Huber\*. M.D. Mauk and P.T. Kelly. Dept. of Neurobiology and Anatomy, Univ. of Texas Medical School, Houston, TX 77225.

Previous studies have demonstrated the importance of protein kinases in the LTP induction, however, the role of protein kinases in the persistent expression of LTP is unclear, if not controversial. Our studies have systematically examined the temporal requirements for protein kinase activities during LTP induction and expression have utilized the broad range and potent protein kinase inhibitor K-252a (Kase, H. et al., J. Antibiotics 39: 1059-1065, 1986) to study protein kinase dependent processes at different times during LTP induction and expression in area CA1 of the rat hippocampal slice. K-252a (0.2-0.6 µM) applied 20 minutes before and after a high frequency tetanus (100 Hz for 1 sec) blocked LTP induction; following post-tetanic potentiation EPSP slopes decayed at a rate of 28.5  $\pm$  6 % per hour. When K-252a (0.4 - 2  $\mu M$ ) was applied for 20 minutes immediately after tetanus, potentiation decayed at a rate of 18 ± 2 % per hour, indicating that decremental LTP occurred under these conditions. When K-252a was applied 20 minutes before and washed out immediately after the tetanus, potentiation decayed at rates (9.6  $\pm$  1 %) that were similar to control slices (7.8  $\pm$  6 %). K-252a (0.2-2  $\mu$ M) had no effect on basal synaptic transmission, unlike H-7 (400 μM) which attent ates synaptic tran at the same concentration that it blocks LTP induction (Muller, D. et al., PNAS 87: at the same concentration and it offices for induction (white). Let al., 1983 87. 4073-4077, 1990). Our results implicate a role of protein kinases during, as well as, minutes after tetanic stimulation. This period of kinase involvement is qualitatively similar to consolidation processes believed to occur during memory formation. Our results suggest that protein kinase activation is required during LTP induction (e.g., NMDA receptor activation) and may be involved in processes during the period after the tetanus (e.g., the production of retrograde messengers and/or presynaptic mechanisms), suggesting a role for protein phosphorylation in the consolidation of the expression of LTP.

## 274.10

GENETIC ANALYSIS REVEALS THAT THE FYN TYROSINE KINASE GENE IS NECESSARY FOR LTP AND LEARNING IN MICE. S.G.N. Grant, T.J. O'Dell\*, K. Karl, P. Stein, P. Soriano, and E.R. Kandel. HHMI, Ctr. Neurobiol. & Behav. Columbia P&S, NY, NY 10032; HHMI, Baylor Coll. Med., Houston, TX 77030. Tyrosine kinase inhibitors block long-term potentiation (LTP) in the CA1

region of the hippocampus (O'Dell et al., 1991). To identify specific tyrosine kinases involved in LTP, we have screened mice with mutations engineered in either of four cytoplasmic tyrosine kinase genes: src, abl, yes, and fyn. Although these four kinases are coexpressed in the hippocampus, only the fyn mutant mice failed to show normal LTP. With low intensity (25% of max. EPSP) tetanic stimulation (100 Hz/1-sec. x 2) responses one hour posttetanus were only 108.1  $\pm$  7.6% of control (mean  $\pm$  sem, n = 3) in slices from fyn mutant mice. A modest amount of LTP could be induced using higher intensity (75% of the max. EPSP) tetanic stimulation (133.2  $\pm$  9.3% of control, n = 3), but this potentiation was smaller than that observed in slices from control animals (168.5  $\pm$  11.6% of control, n = 4). Synaptic transmission appeared normal in slices from fyn mutant mice and pairedpulse facilitation was not different from that observed in control animals

The impairment of LTP appears to correlate with impaired spatial learning in the Morris water maze, suggesting a functional link between LTP and spatial memory. In addition to its importance in LTP the fyn gene is also necessary for the normal development of the pyramidal cell layer of the hippocampus, since in the CA3 region the cell layer shows structural abnormalities. Together, these data suggest that the fyn tyrosine kinase is important for the induction of LTP and implicates a new biochemical pathway contributing to synaptic plasticity

NITRIC OXIDE PRODUCES LONG-TERM ENHANCEMENT OF SYNAPTIC TRANSMISSION IN THE CA1 REGION OF HIPPOCAMPUS BY AN ACTIVITYDEPENDENT MECHANISM. S.A. Small\*, T.J. O'Dell, E. R. Kandel, and R.D.
Hawkins. Ctr. Neuro. & Behav., Columbia Univ., HHMI, NY, NY 10032.

here is evidence that the membrane-permeant molecule nitric oxide may act as a retrograde message during long-term potentiation (LTP) in hippocampus. A difficulty with the retrograde message idea, however, has been that lateral spread of a diffusible message could lead to potentiation of transmission at inactive presynaptic terminals, which would violate the observed pathway specificity of LTP. A possible solution to this problem would be for the effects of the message to be restricted to recently active presynaptic fibers. We tested this possibility by applying nitric oxide to hippocampal slices either alone or coincident with weak presynaptic stimulation (50 Hz for 0.5 sec). 100 nM nitric oxide alone, presynaptic stimulation alone, or nitric oxide 5 min after presynaptic stimulation ("unpaired" training) produced no significant long-term effects on the field EPSP recorded in the CA1 region. However, when nitric oxide was applied at the same time as the presynaptic stimulation ("paired" training), the synaptic potential was immediately enhanced and remained enhanced for at least one hour ( $\bar{x} = 184\%$  of Pre, p < .05). Paired training still produced significant long-term enhancement of the PSP in the presence of APV, which blocks postsynaptic NMDA receptors and thus blocks the induction of LTP by tetanic stimulation ( $\bar{x} = 158\%$  of Pre, p < .05). Paired training also produced enhancement in the presence of APV plus picrotoxin ( $\bar{x} = 147\%$  of Pre, p < .05). These results are consistent with the hypothesis that nitric oxide acts as a retrograde message with activity-dependent presynaptic effects during LTP. This mechanism would be formally similar to activity-dependent presynaptic facilitation in Aplysia and activitydependent neuromodulation more generally

NEURONS CONTAINING NITRIC OXIDE SYNTHASE IN RAT HIPPOCAMPUS

HIPPOCAMPUS

1.G. Valtschanoff\*, V.N. Kharazia and R.J. Weinberg

Dept. of Cell Biology & Anatomy, and Dept. of Physiology,

University of North Carolina, Chapel Hill, NC 27599.

Histochemistry for NADPH diaphorase was used to study the

distribution of nitric oxide synthase (NOS) in the rat hippocampal

formation. Animals were perfused with mixed aldehydes; 10-100 µm

thick Vibratome sections were stained for NADPH diaphorase and

counterstained with neutral red. The distribution of NOS-stained cells

was plotted; camera lucida drawings were made to show their

memphology. Most of the stained neurons were in the pyramidal layer. hology. Most of the stained neurons were in the pyramidal layer of the subiculum, stratum radiatum of Ammon's horn, and the subgranular zone of the dentate gyrus. Neurons were also conspicuous in the molecular layer of the dentate gyrus and in the pyramidal layer at CA3. Stained neurons were sparse in the pyramidal layer of CA2 and CA1, and almost absent from presubiculum and parasubiculum. Numerous stained fibers were seen, especially in stratum radiatum and lacunosum-moleculare of Ammon's horn.

Based on their shape and location, the large majority of NOSpositive cells in the hippocampus were probably local circuit neurons. Preembedding and postembedding immunocytochemistry in combination with NADPH diaphorase histochemistry demonstrated that a large fraction of NOS-positive somata also contained GABA. These data suggest that nitric oxide in CA1 may function as a paracrine agent, rather than a spatially-precise retrograde messenger, in long-term potentiation.

Evidence for Nitric Oxide Synthase Inhibitor-Sensitive and Insensitive Hippocampal Long-Term Potentiation in vitro. IT.Lum-Ragan\* and V.K. Gribkoff, Neuropharmacology, Bristol-Myers Squibb Pharmaceutical Research Institute, 5 Research Parkway, Wallingford, CT. 06492, USA

Nitric oxide (NO) has been implicated as a possible retrograde messenger in the initiation of hippocampal long-term potentiation (LTP; O'Dell et al., Proc. Natl. Acad. Sci. 88: 11285-11289, 1991). To examine this hypothesis, we have inhibited NO synthase (NOS) to determine if LTP produced by different conditioning stimulus models was differentially affected by reduced NO levels. The models were: 1.) a single 100Hz, 1s conditioning train delivered at half-maximal stimulus intensity; or 2.) two 100Hz, Is conditioning trains, separated by 60s, delivered at maximal stimulus intensity. The NOS inhibitors  $N^G$ -nitro-L-arginine (NOARG; 0.1-200 $\mu$ m) and  $N^G$ -monomethyl-L-arginine (NMMA; 100µm) produced no direct effects on synaptic responses, and in the 1-train model, neither inhibitor was effective in reducing or blocking LTP. In the 2-train model, both NOARG (50 and 100µm) and NMMA (100µm) greatly reduced LTP. Application of the specific N-methyl-D-aspartate (NMDA) excitatory amino acid AP5 (50µm) significantly reduced LTP in both model. These results support the role of NO in the expression of LTP in the hippocampus, but also suggest that NO is not required for the production of LTP in vitro under all conditions.

PROTEIN KINASE A INDUCES A PROTEIN SYNTHESIS-DEPENDENT LATE STAGE OF LTP IN HIPPOCAMPAL CA1 NEURONS. <u>U. Frey\* and E. R. Kandel.</u> Ctr. Neurobiol. & Behav., Columbia P&S, HHMI, NY, NY 10032; Inst. Neurobiol., PG Biotech., Magdeburg, Germany

Because of its long time course, hippocampal long-term potentiation (LTP) is thought to be an elementary mechanism for certain forms of memory. By using three repeated high-frequency trains separated by ten minutes, it has been possible to generate LTP in hippocampal slices that persists for more than ten hours. In these slices it has been possible to show persists for more train terminates makes sinces trained and the solution that LTP has stages similar to those of behavioral memory. A short-lasting early potentiation, which we call E-LTP, lasts 1-3 hours and is independent of protein synthesis. This is followed by a later, longer-lasting, stage, which we call L-LTP, and which requires protein synthesis. Here we report that inhibitors of cyclic AMP-dependent protein kinase (PKA) can specifically block L-LTP without dramatically effecting E-LTP and that analogues of cAMP can induce the protein synthesis-dependent late phase of LTP (L-LTP). The late phase can also be induced by repeated application of dopamine or by the joint activation of the N-methyl-D-aspartate and the dopaminergic D1 receptor in the hippocampal CA1 region in vitro.

INHIBITION OF LONG-TERM POTENTIATION BY NMDA-MEDIATED NITRIC OXIDE RELEASE Y. Izumi\*, D.B. Clifford & C.F. Zorumski
Depts of Psychiatry and Neurology, Washington Univ. School of Medicine St. Louis, MO 63110

Recent studies indicate that activation of N-methyl-D-aspartate (NMDA) receptors prior to tetanic stimulation blocks long-term potentiation in the receptors prior to tetanic stimulation blocks long-term potentiation in the CA1 hippocampal region. In control slices,  $38.6\pm8.1\%$  (mean  $\pm$  SE, N=7) increase in EPSP slope was detected 60 min after tetanic stimulation. When  $1\mu M$  NMDA was administered to slices for 5 min prior to the tetanus LTP was inhibited (-4.5  $\pm$  6.9%, N=7).

We have found that NMDA-mediated LTP inhibition can be reversed by coadministration of the nitric oxide inhibitors, L-N°-monomethylarginine (100 $\mu$ M, 36.8 ± 7.1% N = 5) or hemoglobin(0.1 $\mu$ M, 42.5 ± 6.2% N = 5). When applied alone for 10 min prior to the tetanus, 100 $\mu$ M L-NMMA did not inhibit LTP (30.8 ± 13.3% N = 5). Application of 1mM L-arginine with 100 $\mu$ M L-NMMA and 1 $\mu$ M MMDA blocked the development of LTP (1.0 ± 3.8%, N=6). However, 1mM D-arginine did not overcome the effect of 100 $\mu$ M L-NMMA (33.8 ± 11.4 % N=6). Sodium nitroprusside (10 $\mu$ M) mimicked NMDA-mediated LTP inhibition (-5.8  $\pm$  6.9%, N = 5). Furthermore, the inhibitory effect of 10 $\mu$ M SNP on LTP could be overcome by 1 $\mu$ M hemoglobin allowing LTP development (47.0  $\pm$  16.5%, N=5). 10µM SNP failed to alter the NMDA component of synaptic potentials (N = 2).

These results indicate that the timing of NO release relative to high frequency activation of CA1 synapses may be an important determinant of LTP generation and coupled with earlier studies suggest that NO may play a positive or negative modulatory role in LTP depending on events occurring prior to tetanization.

ACETYL-L-CARNITINE AFFECTS SYNAPTIC TRANS-MISSION IN AGED RATS. V. Tancredi\*1, P. Lo Giudice<sup>2</sup>, G. D'Arcangelo<sup>1</sup>, A. Siniscalchi<sup>1</sup>, L. Pacifici<sup>2</sup>, M.T. Ramacci<sup>2</sup>. <sup>1</sup>Dept. Medicina Sperimentale, Tor Vergata II Univ. of Rome, Italy. <sup>2</sup>Institute for Research on Senescence, Sigma Tau, Pomezia, Rome. Acetyl-L-Camitine (ALCAR) an endograpus substance process:

Acetyl-L-Carnitine (ALCAR), an endogenous substance present in CNS, has been shown to increase spontaneous and evoked CNS, has been shown to increase spontaneous and evoked electrocortical activity and to improve learning and memory when administered in the aged rat. The aim of the present study was to verify the effect of ALCAR on long-term potentiation (LTP). LTP was examined in the Shaffer collateral/commissural CA1 pathway in hippocampal slices (400 mm thick) of aged (24-26 months) Fischer rats. Recordings of the population extracellular postsynaptic potentials were made in the stratum radiatum of the CA1 subfield, by means of electroches felled with 2M NeCl. Orthodomic stimuli (10 glass microelectrodes filled with 2M NaCl. Orthodromic stimuli (10-500 mA, 20-90 ms, 0.1 Hz) were delivered through an electrode placed in the stratum radiatum. After stable signals were recorded, a short high frequency train (100 Hz, 1s) was delivered at the same stimulus intensity used for the baseline responses. The addition of ALCAR (at doses ranging from  $10^{-3}$  to  $10^{-5}$  M) 30 min before tetanic stimulation enhanced basal synaptic transmission by some 20% and augmented LTP by some 150%, the increase of the latter being only about 125% in controls. These data suggest that ALCAR increases the efficency of excitatory neurotransmission in aged rats.

### IMPAIRMENT OF SPATIAL AND OLFACTORY MEMORY

BY L-NITRO-ARGININE. G.A. Böhme, C. Bon, J.M. Stutzmann, A. Uzan\*, A. Doble, M. Reibaud, M. Lemaire & J.C. Blanchard, Rhône-Poulenc Rorer, Centre de Recherches de Vitry-Alfortville, 94403 Vitry/seine, France.

We (Bon et al., Eur. J. Neurosci., 4: 420) and others recently confirmed our initial observation that nitric oxide (NO) plays a role in LTP. Our aim here was to determine whether blocking NO production also impairs memory formation in hippocampaldependent learning tasks. LTP of Schaffer collaterals/CA1 pyramidal cell synapses was dose-dependently blocked in hippocampal slices prepared from rats pretreated for 4 days with the NO-synthase inhibitor L-nitro-arginine (L-NOARG, 25-100 mg/kg i.p., b.i.d.). The same subchronic treatment with 100 mg/kg L-NOARG significantly increased the number of exploration errors made by rats trained to find bait in a radial 8arm maze having food or water as the reinforcing stimuli. Similarly, L-NOARG at this dose also impaired social recognition of a juvenile by an adult male rat following two consecutive encounters at short (30 min) intervals. These results demonstrate that inhibiting endogenous NO production impairs learning. They also support the hypothesis that LTP may be a cellular substrate of spatial and olfactory memory.

PLATELET-ACTIVATING FACTOR AS A POTENTIAL MESSENGER IN LONG-TERM POTENTIATION K. Kato<sup>1</sup>, G.D. Clark<sup>2</sup>, N.G. Bazan<sup>2</sup>, D.B. Clifford<sup>3</sup> & C.F. Zorumski<sup>1</sup> 'Depts. of Psychiatry and <sup>3</sup>Neurology, Washington Univ. Med. Sch, St. Louis MO 63110; <sup>2</sup>Dept. of Neuroscience, Louisian State Univ. Med. Sch., New Orleans LA 70112

Previously we have shown that platelet-activating factor (PAF) selectively augments EPSCs in cultured hippocampal neurons by a presynaptic mechanism, suggesting that this agent could be involved in hippocampal long-term potentiation (LTP). We have examined the possible involvement of PAF in LTP in the CA1 region of rat hippocampal slices using the hydrolysis-resistant analog, methyl-carbamyl-PAF (MC-PAF), and PAF receptor antagonists. When applied for 30 min prior to the tetanus, 2µM BN-52021, a synaptosomal PAF antagonist, inhibits LTP (N=7) whereas 5μM BN-50730, a microsomal PAF antagonist, has no effect (N=5). A 20 min application of 1 µM MC-PAF in the absence of tetanic stimulation produces a slowly developing potentiation of extracellularly recorded EPSPs which persists for > 2h (N=5). In neurons whole-cell voltage clamped at -80mV, MC-PAF produces a small enhancement of EPSCs. However, if MC-PAF is administered immediately following tetanic stimulation, LTP occurs. In the absence of MC-PAF, LTP cannot be produced by tetanic stimulation in neurons clamped at -80mV. This MC-PAF-induced LTP is blocked by  $2\mu M$  BN-52021 but not  $2\mu M$  BN-50730 or  $50\mu M$  APV. Extraor intracellular administration of MC-PAF also appears to slow the washout of LTP-generating ability which occurs during whole-cell recording, making it possible to induce LTP for as long as 60 min after cell penetration. These data suggest that PAF or PAF-activated processes are important in LTP.

MODULATION OF SYNAPTIC PLASTICITY BY ENDOGENOUS ADENOSINE: ADENOSINE ANTAGONISTS BLOCK INDUCTION OF LONG-TERM POTENTIATION AND DEPRESSION IN THE CA1 REGION OF THE HIPPOCAMPAL SLICES. Y. Sekino\*, Department of Molecular and Cellular Neurobiology, Tokyo Metropolitan Institute for Neuroscience Euchucity Tokyo 133 Janae

REGION OF THE HIPPOCAMPAL SLICES. Y. Sekino\*. Department of Molecular and Cellular Neurobiology, Tokyo Metropolitan Institute for Neuroscience, Fuchu-city, Tokyo 183, Japan.

ATP and adenosine derivatives (ADs) are released and accumulated in reveal the roles of the ADs in synaptic plasticity, we have examined the effects of blockers of adenosine receptors (A1 and A2) on synaptic plasticity induced by brief repetitive stimulation in CA1 region of the hippocampal slices.

An A2 receptor antagonist (CP-66713) Inhibits induction of long-term potentiation by high-frequency stimulation (100 Hz 1s) of excitatory postsynaptic potentials (EPSPs) but not of the population spike (PS) (Y.Sekino et al.; B.B.R.C.; 181, 1010-1014,1991). Low-frequency stimulation (5Hz 20s) to the Schaffer collaterals caused homosynaptic depression in the PS and field EPSPs evoked by single test stimulation of the tetanized pathway (the Schaffer collaterals) and heterosynaptic depression in the PS and field EPSPs evoked by the non-tetanized pathway (the stratum oriens). The levels of both types of depression were maximal soon after tetanic stimulation and returned to nearly the control level within 5-7 min. Application of an A1 antagonist (8-cyclopentyltheophylline) blocked the induction of homosynaptic depression but not of heterosynaptic depression. This reduction of the synaptic activity only in the tetanized pathway indicates that ADs at the tetanized synapses induce homosynaptic depression through A1 receptors. These results suggest that ADs released from presynaptic terminals during tetanic stimulation and depression, which originate from different frequencies tetanic stimulation, through different types of adenosine receptors.

BY PLATELET-ACTIVATING FACTOR (PAF) A. Wieraszko\*, G. I. E. Komecki¹ and Y.H. Ehrlich, CSI/IBR Ctr. Dev. Neurosci. and Dev. Disab., CUNY, Staten Island, NY 10301 and ¹ Dept. Cell Biol. Anat. SUNY, Brooklyn Platelet-Activating Factor (PAF) is an alkyl-ether phospholipid which has neuroregulatory actions (Kornecki and Ehrlich, Science, 240; 1792,1988). The abilities of PAF to cause increase in intrasynaptosomal calcium levels and to induce vesicular release have suggested that PAF may modulate synaptic efficiency (Kornecki and Ehrlich, Lipids, 26: 1243, 1991). Inhibition of long-term potentiation (LTP) by a PAF antagonist has been reported (Del Cerro, Arai and Lynch, Behav.Neural.Biol. 54:213, 1990) but direct effects of PAF on LTP have not yet been demonstrated. Here we examined the direct effect of PAF on synaptic excitability in hippocampal slices maintained in an interface chamber at 33°C. Stimulating electrode was localized in the Schaffer collateral fibers. Population spike and field EPSP were recorded with two electrodes positioned on the pyramidal cell body layer and on stratum radiatum, respectively. PAF produced an increase in the magnitude of the population spike and of EPSP slope in a concentration-dependent manner (5nM to10µM). The increase in the amplitude of population spike became visible 20-30 min following PAF application and reached maximum within 40-60 min (47% increase with 5nM PAF and over 700% above control levels with 10µM PAF). The potential remained elevated for up to 90 min and then gradually declined to control levels. The potentiating effects of 100nM PAF could be blocked by application of either of two structurally different PAF receptor antagonists, WEB2086 (2µM) or BN52021 (2µM), added 30 min before PAF. These results suggest that PAF may play a role in the modulation of synaptic plasticity. Supported by NIH NS 27866.

SYNAPTIC POTENTIATION IN THE HIPPOCAMPUS INDUCED

A bee venom, MCD peptide, which induces long-term

A bee venom, MCD peptide, which induces long-term potentiation (LTP) in hippocampal slices, was found to voltage-dependent K-channel in brain membranes, [2] interaction with a lipid bilayer to form voltage-dependent and cation-selective channels by itself, and [3] activation of a pertussis toxin (Ptx)-sensitive GTP-binding proteins. In this study, we prepared several derivatives and analogues of MCD and investigated which function is more closely related to the inducibility of LTP. Another bee venom, apamin, formed ion channels in a lipid bilayers. D-MCD, an optical isomer of MCD, activated a Ptx-sensitive G-protein. However, these peptides did not induce LTP in the hippocampal slices. A snake venom, dendrotoxin-1 (DTX-1), bound to the same K<sup>+</sup>-channels as MCD and did induce LTP. These results suggest that the most potent aspect of MCD involved in LTP inducibility is its interaction with the voltage-dependent K<sup>+</sup>-channel.

EXCITATORY POSTSYNAPTIC CURRENTS EVOKED IN CA1 HIPPOCAM-PAL PYRAMIDAL NEURONS ARE ENHANCED BY DIRECT ACTIVATION OF ADENYLATE CYCLASE. L. E. Chavez-Noriega \* and C. F. Stevens. The Salk Institute, Howard Hughes Medical Institute, La Jolla, CA 92037.

We have recently shown that synaptic efficacy of Schaffer/commissural afferents to field CA1 of the rat hippocampus is potentiated by forskolin, a direct activator of adenylate cyclase (Chavez-Norlega and Stevens, 1992, Brain Res, 574: 85-92). Using the whole-cell patch clamp technique, we have now investigated the effect of forskolin on the excitatory postsynaptic current (EPSC) evoked by Schaffer/commissural activation in CA1 pyramidal neurons of rat hippocampal slices. Transverse hippocampal slices from 2-3 week old rats were prepared using standard procedures. All recordings were carried out in the presence of 10-25 uM bicuculline.

The EPSC peak amplitude was enhanced by forskolin (50 uM) in 5 out of 10 cells by 62  $\pm$  13 % (mean  $\pm$  SEM). Since the increase produced on the field EPSP slope by forskolin is potentiated in the presence of the phosphodiesterase inhibitor and adenosine receptor antagonist IBMX (Chavez-Norlega and Stevens, 1992), we tested its effect on the EPSC amplitude. We found that in the presence of IBMX (50 uM) the effect of forskolin is enhanced: 7 out of 8 cells manifested an increase in EPSC amplitude of 86  $\pm$  26%. IBMX itself enhanced the EPSC amplitude in 9 out of 10 cells by 76  $\pm$  13%. Changes in the coefficient of variation squared  $(c^2=V/m^2, V=$  variance, m= mean peak EPSC), suggest that presynaptic mechanisms significantly contribute to the enhancement produced by IBMX and forskolin in the presence of IBMX. Further studies will be carried out to confirm and extend these observations. Altogether, our data indicate that the CAMP cascade is an important

Altogether, our data indicate that the cAMP cascade is an important modulator of glutamatergic neurotransmission in field CA1 of the mammalian hippocampus.

ROLE FOR CYCLIC AMP IN LONG-TERM POTENTIATION (LTP)

IR Slack\* S Pockett & S Peacock. Department of Physiology University of Auckland Medical School, Private Bag, Auckland, New Zealand.

Brief application of cAMP analogues or the adenylate cyclase activator forskolin to rat hippocampal slices produces long lasting potentiation of the CA1 population spike. potentiation is due to increased pyramidal neuron excitability, since the field EPSP is not potentiated. Evidence that a cAMP dependent mechanism underlies the excitability component of activity-induced LTP is provided by occlusion experiments using high frequency stimulation (HFS) of the Schaffer collateral/commissural pathway in combination with a 15 minute bath application of 200µM dibutyryl-cAMP (dbcAMP). Application of dbcAMP after induction of maximal LTP by HFS does not result in any further potentiation of the CA1 population spike. Conversely, HFS applied after dbcAMP induced potentiation does cause further potentiation, but only to the level produced by HFS alone. These results support the the hypothesis that the brief increase in cAMP which can be measured after HFS is the cause of the excitability component (E-S potentiation) of LTP.

## 274.25

DIFFERENTIAL EFFECTS OF INTRASEPTAL OXOTREMORINE ON non-NMDA AND NMDA DEPENDENT LTP. K. Pang\*, M.J. Williams, P. Hinkle and D.S. Olton, Department of Psychology, Johns Hopkins University, Baltimore, MD 21218.

Long-term potentiation (LTP) in the hippocampus may be utilized in memory formation. LTP of the medial entorhinal to dentate gyrus synapse (MEC-DG) depends on activation of NMDA receptors, whereas LTP of the lateral entorhinal to dentate gyrus synapse (LEC-DG) does not. Oxotremorine (OXO), a muscarinic agonist, infused into the medial septal area (MSA) improved memory and enhanced LTP of the MEC-DG in aged rats. The present study examines the effect of intraseptal OXO on NMDA and non-NMDA dependent LTP in aged F-344 rats. Each rat received five treatments in a pseudo-random order: OXO (2  $\mu$ g) alone, saline followed by high frequency stimulation (HFS) of the LEC-DG, OXO followed by HFS of the LEC-DG, saline followed by HFS of the MEC-DG, and OXO followed by HFS of the MEC-DG. As in previous studies, preliminary results indicate that LTP of the MEC-DG is enhanced by OXO. In contrast, LTP of the LEC-DG was not enhanced by OXO. High frequency stimulation of the LEC-DG also produced long-term depression of the MEC-DG, which was not altered by OXO. The results suggest that OXO may improve memory by selectively enhancing the NMDA-dependent LTP in the hippocampus.

## 274.27

SEROTONIN FACILITATES LONG-TERM POTENTIATION IN AREA CA1 OF RAT HIPPOCAMPUS VIA A 5-HT4 RECEPTOR. S.M.Roychowdhury and E.G.Anderson\*. Dept. of Pharmacology, University of Illinois at Chicago., Chicago,

Serotonin produces a dual effect on the evoked population spike in the CA1 area, namely a decrease, followed by a long-lasting increase in its amplitude upon washout. The increase in amplitude, which is mirrored in intracellular recordings as a long-lasting depolarization, and in extracellular single unit recordings as an increase in spontaneous firing, is mediated, in part, by 5-HT<sub>4</sub> receptors. We show here that 5-HT, acting via the 5-HT<sub>4</sub> receptor, can facilitate long term potentiation

In the presence of the 5-HT<sub>1A/2</sub> antagonist spiperone, 10 min. applications of 5-HT increased the pop. spike amplitude often lasting an hour. LTP was induced by delivering a train of pulses at 100Hz for 1 second. Tetanic stimulation applied during the response to 5-HT resulted in an elevated level of LTP at 40 minutes (78±13% vs 44.2±8% increase for controls). In the absence of spiperone, 5-HT induced stimulation upon drug washout. Application of a tetanus after washout also resulted in an increase in LTP (123±10% vs 48±6%). This increase was blocked by 10uM ICS 205-930, but not by 10nM, suggesting the involvement of 5-HT4, but not 5-HT3 receptors. Cisapride, a 5-HT4 agonist, also increased the LTP (110±15% vs 36.5±7%)

Therefore, we conclude that serotonin acting on 5-HT<sub>4</sub> receptors can augment LTP, probably by increasing the degree of postsynaptic depolarization. Since the stimulatory response outlasts the presence of the transmitter, this may be an important modulatory mechanism to incoming synaptic traffic.

CHOLINERGIC AGONISTS ALLOW OTHERWISE INEFFECTIVE SYNAPTIC STIMULATION TO INDUCE LONG-TERM ENHANCEMENT OF SYNAPTIC EFFICACY. P.T. Huerta and J.E. Lisman\*. Dept. of Biology, Brandeis Univ., Waltham, MA 02254.

Central cholinergic systems play a critical role in learning and memory, but the underlying mechanisms are unclear. Here we report that carbachol (CCh), a mixed muscarinic-nicotinic agonist, strongly affects the strength of stimulation required to produce synaptic plasticity at the glutamatergic synapses of CA1 neurons of the rat hippocampus. We used the in vitro slice preparation for extracellularly recording evoked responses to low frequency (0.1 hz) stimulation of Schaffer-collateral inputs. This weak stimulation normally produces no change in synaptic efficacy. However, when given during brief (5 min) bath superfusion of CCh (50  $\mu$ M), both the population spike (PS) amplitude and the field-EPSP slope were enhanced following removal of CCh and remained persistently potentiated (1-2 hr) (PS:  $219\pm14\%$ , n=18; EPSP:  $197\pm13\%$ , n=15 at 1 hr post-CCh). The field-EPSP enhancement was shown to be synapse-specific, e.g. only synapses which were active during CCh superfusion became potentiated while unstimulated synapses stayed unchanged (n=5). This is the first cellular model demonstrating a permissive role for acetylcholine in long-term synaptic plasticity

Another effect of CCh superfusion was the appearance of rhythmic (4-10 hz) oscillations similar to theta rhythm recorded in vivo. The possible connection of these oscillations with the synaptic enhancement is under investigation.

### 274.26

EIPRESSION OF LONG-TERM POTENTIATION (LTP) IN HIPPOCAMPAL CAI IS CONTINGENT UPON SUPPRESSION OF GABRA RECEPTOR FUNCTION A. Stelzer\* and G. Simon. Dep. of Pharmacology, SUNY Brooklyn, Brooklyn, NY 11203.

A number of studies have demonstrated that during LTP orthodromically evoked IPSPs are generally unchanged or increased (cf. Abraham et al., 1987., J. Physiol.) and suppression of GABRA-receptor function has been ruled out as a factor in the maintenance of LTP. In the guinea-pig hippocampal slice bath application of GABRA antagonists bicuculline (bic) or picrotoxin (PTX) at low concentrations results in a potentiation of all orthodromic synaptic potentials in CAI pyramidal cells similar to changes following tetanization of the Schaffer collaterals. Most notably, partial suppression of GABRA receptors leads also to a potentiation of the orthodromic early (GABRA—mediated) IPSP. In addition, following tetanization of the Schaffer collateral pathway increased orthodromic IPSPs are found in cells which exhibit a pronounced reduction of the response to iontophoretic GABRA (35/39 cells). Bath application of the NMDA-receptor antagonist D-APV (10 µM) prevents both, tetanization-induced increase of orthodromic synaptic potentials and reduction of GABRA sensitivity. In the presence of 100 µM PTX, GABRA, mediated IPSPs are not observed, but a remainder of a GABRA, mediated IPSPs are not observed, but a remainder of a GABRA, mediated IPSPs are not observed, but a remainder of a GABRA, mediated IPSPs are not observed, but a remainder of a GABRA, mediated IPSPs are not open of GABRA, antagonists to block all GABRA responses (>100 µM PTX. In the presence of sufficient concentrations of GABRA, antagonists to block all GABRA responses (>100 µM DIC. >300 µM PTX. resp.) potentiated synaptic potentials following tetanization recover to control values between 20 to 30 min after the tetanus. These data demonstrate that during LTP the general increase of synaptic efficacy and the activation of the inhibitory circuit are contingent up

INTERACTION OF CHOLECYSTOKININ AND AFFERENT TETANIZATION IN THE INDUCTION OF SYNAPTIC MODIFICATIONS IN FIELD CA1 OF THE RAT HIPPOCAMPAL SLICE D. Dahl\*, E. Rich-Bennett, and B.B. LeCompte III. The Univ. of Texas at Dallas, Richardson, TX 75083

In the cortex, the ubiquitous neuropeptide cholecystokinin (CCK) is colocalized with GABA, or other neurotransmitters. Little is known of the function of this colocalization, but inference from models of CCK-dopamine colocalization would indicate a modulation of GABA release.

In field CA1, the temporo-ammonic pathway was stimulated, and EPSP and

population spike recordings were taken in lacunosum moleculare and stratum pyramidalis, respectively. The sulfated octapeptide of CCK (CCK-8S) was applied by perfusion in doses of ca. 500 nM, 750 nM, 900 nM, or > 1  $\mu$ M. Tetanization (4 trains, 10 pulses, 100 Hz) in the presence of 500 nM CCK-8S was associated with a modest (12-15%) depression of EPSPs and population spikes, whereas tetanization in the presence of 900 nM to 1 μM CCK-8S was associated with a modest (15-20%) potentiation of responses. Both potentiation and depression persisted for at least 30 min in drug-free ACSF. The 750 nM dosage was not associated with any tetany-induced depression or potentiation. At dosages  $< 1~\mu\text{M}$ , CCK-8S perfusion had no apparent effect on field potential responses. However, at dosages  $> 1~\mu\text{M}$ , CCK-8S sometimes induced a complete suppression of responses that was probably based on a depolarization block, and was reversible upon washout with drug-free ACSF.

In visual cortex, depression or potentiation of synaptic transmission may be ssociated with specific levels of postsynaptic depolarization. If CCK modulates GABA release, then a parametric application might affect postsynaptic voltage via a disinhibition and underlie depression or potentiation. The results of this work support such an hypothesis. (Supported by the Whitehall Foundation.)

HIGH CONCENTRATIONS OF GLYCINE PRODUCE A LONG LASTING INCREASE IN SYNAPTIC EFFICACY IN HIPPOCAMPAL SLICES. K. Shahi\*, J. C. Marvizon and M. Baudry, Neuroscience Program, USC, Los Angeles, CA. Glycine has been shown to be a co-agonist of the NMDA receptor. Ligand binding studies have indicated the existence of a high affinity strychnine insensitive binding site with a Kd of about 100 nM. Physiological studies have also shown that this site needs to be occupied for NMDA receptor activation. However, the physiological significance of this site has been questioned as this site is likely to be always saturated under normal conditions. We report here that high concentrations of glycine produce a long lasting increase in synaptic efficacy in hippocampal slices, possibly by acting on the NMDA receptors. Perfusion of hippocampal slices with high concentrations of glycine (5-10 mM) for 10 min was followed by a slow increase in the slope and amplitude of EPSPs evoked in CA1 by stimulation of the Schaffer-commissural pathway. The effect reached a plateau within 30 - 45 min after glycine application and represented a 2-3 fold increase in slope and amplitude. Two lines of evidence suggest that the effect may be due to the activation of the NMDA receptors. The repetitive bursting activity recorded in slices incubated in low Mg++ containing medium was potentiated by glycine (5 - 10 mM) and blocked by Mg<sup>++</sup> and ketamine. High concentrations of glycine were shown to increase 3H-MK-801 binding to extensively washed synaptic membranes. These results suggest that high concentrations of glycine might activate NMDA receptors and produce long lasting changes in synapotic efficacy. (Supported by Grant BNS 96284 from NSF and N00014-91-J-1796 from ONR).

CO-ACTIVATION OF A METABOTROPIC AND N-METHYL-D-ASPARTATE (NMDA) RECEPTORS PRODUCES SUSTAINED HIPPOCAMPAL SYNAPTIC POTENTIATION. M. A. Musgrave and J. W. Goh. Department of Pharmacology & Toxicology, Queen's University, Kingston, Canada K7L 3N6.

Induction of long-term potentiation (LTP) in the hippocampal CA, region is blocked by NMDA antagonists. However, some reports indicate that exogenously applied NMDA to the hippocampus produces only a transient exogenously applied NMDA to the injopocampus produces only a transient synaptic potentiation. This suggests that NMDA receptor activation is necessary but not sufficient for successful induction of LTP. We report that maintained synaptic potentiation can be elicited by co-application of NMDA and 1-aminocyclopentane-trans-1,3-dicarboxylic acid (t-ACPD), a selective agonist for a metabotropic glutamate receptor (mGluR). Stratum radiatumagonist for a metabotropic guitamate receptor (inclusiv). Statum raviation evoked CA<sub>1</sub> dendritic EPSPs of rat hippocampal slices showed no change in slope 30 min after bath perfusion (2 min) of either 200  $\mu$ M r-ACPD (93  $\pm$  8% [SEM] of control, n = 11) or 50  $\mu$ M NMDA (97  $\pm$  5%, n = 11) alone. In contrast, a potentiation at 30 min was elicited by co-application of both drugs (133  $\pm$  9%, n = 11). L-2-Amino-3-phosphonopropionic acid (L-AP3; 500  $\mu$ M) and Lerine-O-phosphate (SOP; 1 mM), agents which reportedly block mGluRinduced phosphoinositide (PI) metabolism, failed to block tetanus-induced LTP (148  $\pm$  18%, n = 7; 153  $\pm$  20%, n = 8; respectively). Preincubation of slices with Li $^+$  (20 mM for at least 60 min), which blocks PI turnover as well as function of GTP-binding proteins, resulted in blockade of tetanus-induced LTP (103  $\pm$  5%, n = 13) but not post-tetanic potentiation (PTP) (148  $\pm$  11%, n = 13) measured at 30 and 1 min post-tetanus, respectively. Control slices showed both LTP (136  $\pm$  10%, n = 10) and PTP (159  $\pm$  17%, n = 10). The results suggest that co-activation of mGluR as well as NMDA receptor is required for LTP induction. The subtype of mGluR stimulated by t-ACPD may be coupled to a GTP-binding protein and/or PI metabolism that is not antagonizable by L-AP3 and SOP. (Supported by MRC of Canada.)

AGE- AND LTP-DEPENDENT CHANGES IN ARACHIDONIC ACID CONTENT OF MEMBRANES FROM DENTATE GYRUS. M.A. Lynch\*, K.L. Voss and T.V.P. Bliss, National Institute for Medical Research, Mill Hill, London NW7 1AA, U.K. (Spon: BRA)

We have measured the concentration of free arachidonic acid in membranes from the dentate gyrus of old and young PVG hooded rats following unilateral tetanization of the perforant path under urethane anaesthesia. The contralateral dentate gyrus received the same number of stimuli but no tetanus. LTP was induced in 6/6 animals in the 4 month-old group, and in 9/16 animals in the 22 month-old group. Forty-five min after the tetanus, the dentate gyri were dissected on ice and lipids extracted for analysis of fatty acids by HPLC. In the 4 month old group, membrane concentrations of arachidonic acid were significantly higher in the potentiated side than in the control side (0.52  $\pm$  0.05 and 0.43  $\pm$  0.03 nmol/µg respectively; mean  $\pm$  sem n=6; p < 0.05, paired t-test). The arachidonic acid content in the dentate gyrus of aged animals was also increased following the tetanus but only in the group which sustained LTP (0.34  $\pm$  0.05 and 0.24  $\pm$  0.01 nmol/µg for potentiated and control sides respectively; n=9, p<0.05, paired t-test); there was no significant change in old animals in which LTP was not induced  $(0.22 \pm 0.03 \text{ nmol/}\mu\text{g})$  and  $0.19 \pm 0.01 \text{ nmol/}\mu\text{g}$  for tetanized and control sides respectively; n=7, p>0.05, paired t-test). There was a significant reduction in the arachidonic acid content of aged compared to young animals  $(0.43 \pm 0.03 \text{ (n=6)})$  and  $0.22 \pm 0.01$ (n=16) nmol/µg respectively, p<0.01, unpaired t-test). The age-related decrease in membrane arachidonic acid may be a consequence of parallel decreases in the activities of phospholipases A1, A2 and C.

CALCIUM RELEASE FROM INTERNAL STORES IS REQUIRED FOR THE INDUCTION OF METABOTROPIC GLUTAMATE RECEPTOR-DEPENDENT LONG-TERM POTENTIATION (LTP) IN DORSOLATERAL SEPTAL NUCLEUS

LONG-TERM POTENTIATION (LTP) IN DORSOLATERAL SEPTAL NUCLEUS (DLSN) NEURONS /W VITRO.

F. Zheng\* and J.P. Gallagher. Dept. of Pharmacol. and Toxicol., Univ. of Texas Medical Branch, Galveston, TX 77550.

We have previously demonstrated that induction of LTP in the DLSN was not blocked by the selective NMDA receptor antagonist, D-2-amino-5-phosphonovaleric acid (100µM), but is blocked by a putative metabotropic glutamate receptor (met-GluR) antagonist1-2-amino-4-phosphonobutyrate.

phosphonovaleric acid (100/M), but is blocked by a putative metabotropic glutamate receptor (met-GluR) antagonist L-2-amino-4-phosphonobutyrate. Superfusion of (1s, 3n)-1-aminocyclopentane-1,3-dicarboxylic acid (1s, 3n-ACPD), a selective met-GluR agonist, resulted in a long-lasting potentiation of synaptic transmission similar to that induced by tetanic stimuli (TS) (Zheng & Gallagher, Soc. Neurosci. Abstr. 16,653; 17,950).

In the present study, we demonstrated that another putative met-GluR antagonist L-2-amino-3-phosphonopropionic acid (L-AP3, 50/M) blocked the induction of LTP when it was applied before TS. Superfusion of the same concentration of L-AP3 after TS did not block, but slightly enhanced LTP induced by TS. These data suggest that the induction, not the maintainance, of LTP is blocked by the metabotropic glutamate receptor antagonist. L-AP3 (50/M) also blocked the LTP induced by 1s,3-ACPD. Intracellular injection of GTPyS, a non-hydrolysable analogue of GTP blocked both TS-induced and 1s,3n-ACPD-induced potentiation, suggesting the involvement of a GTP-binding protein in the induction of LTP at the DLSN. Intracellular injection of BAPTA, a calcium chelator, also blocked the induction of LTP, suggesting that the induction of the met-GluR-dependent LTP also required an increase of free calcium concentration during TS in the postsynaptic neurons. The induction of LTP was also blocked by pretreatment with thapsigargin (5/M), which depletes internal calcium stores via inhibition of a Ca<sup>2+</sup>-dependent ATPase. These data suggest that calcium release from internal stores is required for the induction of LTP at rat DLSN. (Supported by NIMH Grant MH-39163)

PHOSPHATIDYLSERINE INCREASES HIPPOCAMPAL SYNAPTIC EFFICACY. O. A. Ramirez<sup>1</sup>, C. M. Borghese<sup>1</sup>, R. F. Thompson<sup>2</sup>\*. <sup>1</sup>Dept. Pharmacology, Fac. de <sup>1</sup>Dept. Pharmacology, Fac. de Ciencias UNC, Quimicas Cordoba Argentina. <sup>2</sup>Neurosciences Program, USC, LA, CA 90089-2520.

In the present study, the effects of phosphatidylserine on hippocampal synaptic transmission were evaluated. The potential evoked by subthreshold stimulation (0.2 Hz) on perforant path (PP) was recorded from the granulle cell body layer of dentate gyrus in 400 um hippocampal slices perfused with either BC-PS alone (10 µM) or BC-PS in combination with DL-2-amino-5phosphonovaleric acid (APV, 20 µM) or after previous perfusion with dizocilpine (MK-801, 10  $\mu M$ ) . The evokedresponses potentiation observed after perfusion with BC-PS (173  $\pm$  87 %) was bloked in presence of MK-801 (10  $\mu M$  but not by APV (20  $\mu M$ ). The increased hippocampal synaptic efficacy produced by BC-PS is discussed in terms of N-methyl-D-aspartate receptors (NMDA) and the associated channels.

REGULATION OF HIPPOCAMPAL LONG-TERM POTENTIATION BY GLUCOSE: role of glutamate synthesis and energy metabolism. M. W. Fleck\*. A. M. Palmer, & G. Barrionuevo, Departments of Behavioral Neuroscience, Psychiatry, & Pharmacology, University of Pittsburgh, Pittsburgh, PA 15260.

We examined the effects of extracellular glucose concentration on the industry of the concentration of the industry of the concentration of the concentrat

the induction, expression, and maintenance of long-term potentiation (LTP) in area CA1 of rat hippocampal slices. Tetanization of the Schaffer collateral-commissural afferents in normal glucose (10 mM) medium produced LTP of field excitatory postsynaptic potentials (fEPSPs). LTP was not observed after tetanization in glucose-deficient (1 mM) medium. When these slices were returned to normal glucose, LTP appeared, suggesting that LTP expression, but not induction, was prevented by low glucose. To confirm this, slices were tetanized prior to reducing glucose concentration. Glucose-deficient medium had no effect on IEPSPs in control slices but suppressed LTP expression in tetanized slices. Subsequent return to normal glucose restored LTP expression in these slices. These results demonstrate that LTP expression, but not induction or maintenance, is regulated by glucose availability. While fiber volleys and antidromic population spikes were unaffected, potassium-evoked glutamate release was significantly attenuated by low glucose. Addition of 1.0 mM L-glutamine as an alternate metabolic source failed to maintain either LTP expression or glutamate release in glucose-deficient medium. Therefore, glucose regulation of LTP is most likely indicative of enhanced glutamate synthesis not increased energy demand in potentiated Schaffer collateral-commissural synapses. Supported by NS01196, NS24288, AG0897401, and an NIMH Predoctoral fellowship.

VOLUME-SENSITIVE CHLORIDE CONDUCTANCE IN RETINAL PIGMENT EPITHELIAL CELLS. Lev Botchkin and Gary Matthews\*. Dept. of Neurobiology & Behavior, SUNY, Stony Brook, NY 11794-5230.

Whole-cell patch-clamp recordings were made from single retinal pigwhole-ten pater-teamp recordings were made non-single remaining ment epithelial cells isolated from neonatal rats (6-10 days); outward K current was blocked with internal Cs and TEA. As shown in the Fig., the resting conductance was small under these conditions. When cells were briefly exposed to hypotonic solution (osmolarity 50-70% of normal), cell volume reversibly increased, accompanied by an increase in conductance (see Fig.). The conductance could also be activated when cell volume was increased by applying positive pressure to the patch pipette, and sometimes developed spontaneously during prolonged recordings. The swelling-activated current reversed at  $-43 \pm 1$  mV (mean  $\pm$  s.e.m.; n=10) with low [CI]<sub>i</sub> and high [CI]<sub>b</sub> and at  $-2 \pm 3$  mV (n=9) with symmetrical [CI]. The current was reversibly reduced by the CI-channel blockers DIDS (see Fig.) and SITS, but not by the K-channel blocker tolbutamide. This suggests that swelling activates a CI conductance, which may be involved in regulatory volume changes. Supported by NIH grant EY08673. Fig. Current-voltage relations in response to voltage ramp (100 mV/sec); no leak subtraction. Internal solution (mM): Cs. gluconate (130), TEA-Cl. (10), EGTA (10), HEFES (5), ATP (2), GTP (0.3). All traces were obtained in normal Ringer's solution (2.6 mM 400 r pA K), either in resting condi-

tions ('normal') or after swelling was induced by brief exposure to 50% osmolarity solution ('hypotonic' & 'DIDS'). DIDS concentration: 100 uM.

PRESSURE CLAMP: A METHOD FOR RAPID ACTIVATION OF MECHANOSENSITIVE CHANNELS IN PATCHES AND WHOLE CELLS. D.W. McBride. Jr. and O.P. Hamill. Section of Neurobiology and Behavior, Cornell University, Ithaca, NY 14853.

A pressure clamp technique has been developed which enables the

application of rapid step changes in suction or pressure to membrane patches or whole cells. The technique is based on a strategy that involves a balance between negative (suction) and positive pressures under feedback control to achieve the desired pressure or suction. This strategy has the advantage of being able to apply both positive and nastive pressures. Furthermore, because it involves active processes, fast step changes (-10 ms) in pressure/suction can be achieved. Details of the construction and feedback circuitry of the technique will be presented. Under computer control complex pressure waveforms can be constructed to study the time, pressure and voltage dependence of the dynamic properties of mechanosensitive (MS) channels. Using this technique we have characterized MS channels in a number of different reparations including *Xenopus* oocytes and skeletal muscle cells. In both preparations MS channels display voltage dependent adaptation in response to step changes in suction or pressure. The application of this technique to nonsensory and sensory cells should provide new insights into the molecular mechanisms of MS channels.

INCORPORATION OF ION CHANNELS FROM THE NEMATODE WORM, CAENORHABDITIS ELEGANS, INTO GIANT LIPOSOMES SUITABLE FOR PATCH CLAMP RECORDING. C.A.Leech. J.M.Skeer. C.Tornøe and D.B.Sattelle (SPON: Brain Research Association) AFRC Laboratory of Molecular Signalling, Department of Zoology, Downing Street, Cambridge, CB2 3EJ, U.K.
The nervous system of the nematode worm,

Caenorhabditis elegans, has been extensively studied and each cell identified and mapped. C. elegans provides access to the only known viable mutants of certain ligand gated ion channels, notably nicotinic acetylcholine receptors. The small size of *C. elegans* neurones has limited physiological investigation of such channels in both normal and mutant phenotypes, in vivo. Injection of RNA extracted from C. elegans into Xenopus oocytes results in expression of nicotinic acetylcholine receptor/channels at which levamisole is a potent agonist. With the aim of providing complementary data on native ion channels, we have fused native membrane preparations with exogenous lipids by dehydration and rehydration (Criado and Keller, 1987) to form giant liposomes. These liposomes are suitable for study using conventional patch clamp techniques. Employing this technique, we have obtained single channel recordings from ion channels of C.

Criado, M. and Keller, B.U. (1987). FEBS Lett. 224, 172-176.

CHLORIDE CHANNELS OF MAMMALIAN AND AMPHIBIAN SKELETAL MUSCLES DIFFER IN THEIR PHYSIOLOGICAL AND PHARMACOLOGICAL CHARACTERISTICS. <u>D.Tricarico\*</u>, R. Wagner°, S.H. Bryanto, V. Tortorellan and D. Conte Camerino, Dept. of Pharmacobiology and ^Pharmacochemistry, Fac. of Pharmacy, Univ. of Bari, Italy and °Dept.of Pharmacol. and Cell Biophysics, Univ. of Cincinnati, USA.

The major component of the resting conductance of mammalian and amphibian skeletal muscle is due to chloride permeability, although the absolute magnitude of the resting chloride conductance (GCl) in mammalian muscle is considerable larger than that detectable in frog muscle(Bretag, Physiol. Rev. 67:618, 1987). Recently it has been demonstrated that in mouse fiber the Cl- channels responsible for the resting GCl are almost exclusively relegated in the T-system(Chua and Betz, Biophys J. 59:1251, 1991); in contrast, in frog fiber the Cl<sup>-</sup> channels are mainly distributed on the surface membrane. It has been shown that CI- cha mammalian muscle are modulated by protein kinase C(Tricarico et al., Pflugers Arch. 418:500, 1991), indeed application of 4ß-phorbol 12,13 dibutyrate (4ß-PDB) decreases GCl with an EC50 of 23nM. Moreover the application of highly specific C1- channels blockers such as anthracene 9-carboxilic acid and S(-) 2(p-chlorophenoxy)propionic acid (S(-) CPIB) produces a drammatic and streospecific block of GCI (De Luca et al., JPET 260;364, 1992). In the present experiments we block of GCI (De Luca et al., JPET 260:364, 1992). In the present experiments we tested the effects of 48-PDB and S(-) CPIB on the component conductances of frog semitendinosus muscle fibers at 25°C by standard two microelectrodes computerized cable technique (Bryant and Conte Camerino, Pflugers Arch., 417:605, 1991). Althought the 48-PDB did reduce GCI, even at 30µM it never produced an inhibition greater than 23%, suggesting a saturation for this responce. This effect was prevented by 1µM of staurosporine. Moreover S(-) CPIB at a concentration of ImM which would block more than 95% of GCI in the rat, did not block GCI in the frog. These results suggest that the frog Cl- channels are qualitatively distinct from the mammalian Cl<sup>-</sup> channels for physiological as well as biochemical and pharmacological aspects.(Telethon-Italy, 1991).

CALCIUM INDEPENDENCE OF RAPID ADAPTATION OF MECHANOSENSITIVE CHANNELS IN XENOPUS OOCYTES. Q.P. Hamill\* and D.W. McBride. Ir. Section of Neurobiology and Behavior, Comell University, Ithaca, NY 14853.

The Xenopus oocyte expresses a mechanosensitive (MS) channel which displays rapid adaptation in response to step changes in suction or pressure. This adaptation is voltage sensitive but does not require extracellular or intracellular Ca<sup>++</sup> (Fig. 1). Inclusion of 10 mM ECTA (or BAPTA) in the pipette solution does not eliminate adaptation. Furthermore, adaptation is still present in oocytes preincubated with the membrane permeable form of BAPTA (25 µM) which is sufficient to prevent Ca<sup>++</sup> activation of C1 currents in oocytes C2<sup>++</sup> permeabilized with A23187. Our observation of C3<sup>++</sup> independence of adaptation contrasts with the current hypotheses concerning the role of Ca<sup>++</sup> in MS channel adaptation in hair cells in which voltage dependent Ca<sup>++</sup> influx through the MS channel causes adaptation.

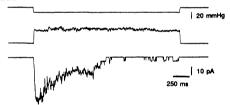

Figure 1. Voltage dependent MS channel adaptation with  $[Ca^{++}]_0 \pm [Ca^{++}]_i \pm 0$ . Pipette solution (in mM): 100 KCl, 10 Hepes, 10 K-EGTA. Bath solution (in mM]: 115 NaCl, 1.5 KCl, 10 Hepes, 25  $\mu$ M BAPTA AM. (Top trace) Suction waveform, MS current at 100 mV (middle trace), at -100 mV (toutom trace).

## 275.6

EFFECTS OF AMITRIPTYLINE ON GABA STIMULATED 36CI-UPTAKE IN BRAIN MEMBRANE VESICLES OF DOMINANT AND SUBMISSIVE RATS. Irene A. De Leon, Ewa Malatynska\*, Doug C. Allen, and Henry I. Yamamura, Dept. of Pharmacology, College of Medicine, University of Arizona, Tucson, AZ

The *in vitro* effect of amitriptyline (AMI) on GABA-stimulated  $^{36}\text{Cl}^-$  uptake by cortical membrane vesicles of two behaviorally distinct groups of rats, dominant and submissive, was investigated. Behavioral changes in the dominant-submissive relationship between rats competing for food, as well as the modification of *in vitro* AMI effects on chloride uptake in these two groups after chronic treatment with AMI were also studied.

In vitro 36Cl- uptake assays reveal a dual effect of AMI at the GABAA receptor chloride ionophore complex for dominant rats; AMI enhances GABA-stimulated chloride uptake at concentrations between 10 nM and 1 µM while inhibiting this

comorned uptake at concentrations between 10 mM and 1  $\mu$ M white inhibiting this effect at 100  $\mu$ M. AMI shows only one effect in submissive rats. This is inhibition of GABA-stimulated  $^{36}$ Cl<sup>-</sup> uptake by 10  $\mu$ M and 100  $\mu$ M AMI. The opposite was true for the rats treated *in vivo* (i.p. injections for 21 days) with AMI. The dominant rats show only inhibition of GABA stimulated chloride uptake by 10  $\mu$ M and 100  $\mu$ M AMI. The dual effect of AMI was observed in submissive rats; GABA stimulated  $^{36}$ Cl<sup>-</sup> uptake was elevated at low concentrations (10 nM to 1) and 100  $\mu$ M and 10  $\mu$ M) and inhibited at 10  $\mu$ M and 100  $\mu$ M concentrations

Both dominant and submissive rats exhibited significant submissive behavior after chronic treatment with AMI. Although in vitro studies yielded distinct responses of dominant and submissive rats regarding the stimulation of <sup>36</sup>Cl<sup>-</sup>
uptake by AMI, the two groups of rats showed no obvious correlation between this
effect of the antidepressant and the behavioral response to AMI in vivo. This may
be due to the strong inhibitory effect of high AMI concentrations on the GABAstimulated chloride uptake which is similar for all treatment groups.

PANNING FOR SELECTION OF TRANSFECTED CELLS IN ELECTROPHYSIOLOGICAL STUDIES. R. F. Margolskee. B. McHendry-Rinde and R. Horn\*. Neurosci. Dept., Roche Instit. Molec. Biol., Nutley, NJ 07110.

Panning was used to select transfected cells expressing plasmid-encoded ion channels. Adherent cells cotransfected, using standard CaPO4 methods, both with the plasmid of choice and with a separate plasmid encoding CD8, a membrane protein. After 1-3 days the cells were suspended, treated with a biotinylated CD8-specific antibody, and placed into streptavidin-coated bacterial petri dishes. After 2 hr these dishes were washed with a saline solution to remove non-adherent cells. Histological assays used a plasmid encoding bacterial B-galactosidase detected by X-Gal. We also expressed either sodium channels or CFTR chloride channels, and assayed for them using whole-cell, perforated-patch, and single-channel recording. The method was tested on TSA-201 and NIH3T3  $\,$ cells, the latter of which transfected very poorly (usually <4% efficiency) with our standard protocols. By using ratios of ≥8:1 (by molecular weight) of the 'plasmid of interest'-to-the CD8 plasmid, the adherent cells were >50% positive for expression of the co-selected gene. Panning may increase the percentage of positively transfected cells by more than 20-fold

ALTERATION OF ELECTRICAL PROPERTIES AND EXCITATION-CONTRACTION COUPLING IN TAURINE DEPLETED RAT SKELETAL MUSCLE. D. Conte Camerino\*. A. De Luca. S. Pierno and R. J. Huxtable¹. Unit of Pharmacology, Dept. of Pharmacobiology, Fac. of Pharmacy, Univ. of Bari, Italy and 'Dept of Pharmacology, Coll. of Med., Univ. of Arizona, Tuscon, Arizona, USA. Taurine, largely present in mammalian skeletal muscle, has membrane stabilizing effects by increasing membrane chloride conductance (GCI) (Conte Camerino et al. Pharmacol. Pac. Comm. 19: 685-1987). To get incipht just observed the role of taurine in the

Taurine, largely present in mammalian skeletal muscle, has membrane stabilizing effects by increasing membrane chloride conductance (GCI) (Conte Camerino et al. Pharmacol. Res. Comm., 19: 685,1987). To get insight into the role of taurine in the control of membrane properties we tested the effect of taurine depletion in rat skeletal muscle by chronic oral administration of guanidinoethane sulfonate (GES; 1% in drinking water) (Huxtable et al., 1PET, 211-465, 1979). The effects of 4 weeks treatment were evaluated in vitro on ionic conductances and membrane excitability of extensor digitorum longus (EDL) muscle with computerized two intracellular microelectrodes technique (Conte Camerino & Bryant, Pfiltgers Arch, 417: 605,1991). The chronic GES treatment decreased GCI from a control value of 2917±97µS/cm² (n=15) down to 1973±94µS/cm² (n=38) and significantly increased by 80% potassium conductance (GK). Accordingly, the treated EDL had increased membrane excitability. In vitro application of 60mM taurine on depleted muscles complitely restored membrane conductance. The voltage threshold for mechanical activation (MT) of treated and control muscles was evaluated by means of two microelectrodes "point" voltage clamp (holding potential=-90mV), measuring the rheobase voltage at long test pulse durations (200-500ms). The GES treated fibers contracted at significantly more negative potentials (-71.1±2.3mV; n=11) with respect to the normal control (-61.4±2.2mV; n=22). Again, in vitro application of 60mM taurine on depleted muscle brought rheobase voltage to -64.8±2.9 mV (n=10). In vitro application of 60mM of either GES or taurine on untreated EDL did not produce significant changes of MT. Our data corroborate the membrane stabilizing role of taurine via direct control of muscle chloride channels. The GES effects on GK and on mechanical threshold may be related to the ability of taurine to increase Ca²+ uptake by sarcoplasmic reticulum (Lake et al., Biophys.J., 59: 64a, 1991) and therefore to modulate cytosolic Ca²+ conc

#### 275.8

CONVULSANT POTENCY OF LAUDANOSINE. R. Thies, F. Dreyer<sup>1</sup>, and H. Bigalke\*, Med. School of Hannover, Inst. of Toxicology, 3000 Hannover 61, Germany. <sup>1</sup>Univ. of Giessen, Rudolf-Buchheim-Institute, 6300 Giessen, Germany.

Laudanosine (N-methyltetrahydropapaverine), an alcaloid from Papaver somniferum and also a metabolite of the peripheral muscle relaxant, atracurium, elicits convulsant activity in several animal models. Here we report that laudanosine also induced paroxysmal depolarizing events (PDs) in cultured spinal cord neurons while papaverin and atracurium were ineffective. - Electrophysiological experiments were performed in the whole-cell mode. Spontaneous synaptic activity recorded in current clamp consisted of randomly evoked inhibitory and excitatory potentials. The neurons developed PDs when laudanosine was applied. Depending on the concentration, these events became more and more organized. - To elucidate the underlying mechanism the interaction of laudanosine with chemosensitive and voltage-dependent membrane currents was investigated using voltage clamp recording. Glycine and GABA, resp., were applied to single neurons by pressure ejection which caused a strychnine- or bicuculline-sensitive current. Only the glycine-evoked current was dose-dependently reduced by laudanosine (EC50: 34.7 µM). The GABA-evoked current and the voltage-dependent sodium inward current were, if at all, only minimally affected. The appearance of the PDs and the suppression of the Cl- current were fully reversible after withdrawal of laudanosine. We postulate that an interaction of laudanosine with the glycine-operated Cl channel is responsible for its convulsant effects. - This examination also confirms the usefulness of neuronal cells in culture to investigate convulsant and anticonvulsant activity.

GAP JUNCTION HEMICHANNELS OF CX32 AND CX26 HAVE SLOW VOLTAGE DEPENDENCE OF OPPOSITE SIGN AND FORM JUNCTIONS WITH SOME PROPERTIES OF RECTIFYING SYNAPSES. V.K. Verselis, J.R. Rubin, C. Ginter, M.V.L. Bennett\* and T.A. Bargiello. Dept. of Neuroscience, Albert Einstein Coll. of Med., Bronx, N.Y. 10461.

Voltage dependence of homotypic junctions is generally characterized by a slow, symmetric reduction in junctional conductance, g<sub>1</sub>, about V<sub>1</sub>=0. These symmetric changes in g<sub>1</sub> have been shown to result from the pairing of two identical hemichannels in opposite orientation such that each closes for opposite polarities of V<sub>2</sub>. A perplexing loss of sensitivity to one polarity of V<sub>3</sub> and the appearance of a novel fast V<sub>4</sub> dependent rectification were reported in heterotypic junctions formed by two V<sub>4</sub>-dependent connexins, Cx32 and Cx26 (Barrio et al., PNAS 88:8410, 1991). Domain exchanges of the extracellular loops (E1 and E2) suggested that the altered gating properties were due to interactions of E1 (Rubin et al., Biophys J 62:197, 1992). We now report that the loss of slow V<sub>4</sub> dependence of one polarity is due to pairing connexins possessing opposite polarities of slow V<sub>4</sub> dependence. Site directed mutagenesis of the first two amino acids of E1 produced a characteristic change in slow V<sub>4</sub> dependence in homotypic junctions which could be recognized in heterotypic junctions. Thus we could show that Cx32 and Cx26 hemichannels close when V<sub>5</sub> on their side is made relatively negative and positive, respectively. All junctions in which the hemichannel polarities were of opposite sign showed one-sided slow V<sub>1</sub>-dependence, as well as a marked fast V<sub>1</sub>-dependent rectification. All junctions in which hemichannel polarity was of the same sign showed slow changes in g<sub>5</sub> for both polarities of V<sub>5</sub>, and in some cases a weak fast rectification. These studies suggest that pairing of hemichannels with opposite polarities may underlie the rectification observed at electrical synapses.

Vulnerability of neurons overexpressing Cu,Zn-Superoxide dismutase (SOD-1) to oxidative stress. Paul J. Schwartz\* Yoram Groner¹ and Joseph T. Coyle. Neuroscience Dept., The Johns Hopkins Medical School, Baltimore MD; Psychiatry Dept., Harvard Medical School, Boston MA; and ¹Molecular Genetics Dept. The Weizmann Institute. Rehovot. Isreal

<sup>1</sup>Molecular Genetics Dept., The Weizmann Institute, Rehovot, Isreal The homology between the 16th mouse and 21st human chromosomes has led to the use of mice trisomic for chromosome 16 (Ts16) as a model of human trisomy 21 (Down syndrome, DS). A consequence of DS is the appearance of pathological and behavioral changes associated with Alzheimer's disease. There are indications that a common pathway for many neurodegenerative disorders is the failure to regulate reactive oxygen species such as the superoxide anion and hydrogen peroxide. The antioxidant enzyme Cu, Zn-superoxide dismutase (SOD-1) is located in the triplicated region of human chromosome 21 requisite for the phenotypic expression of DS. It is unclear whether overexpression of SOD-1 should lead to increased or decreased oxidative stress in the form of highly reactive oxygen radicals. Since both the murine 16th and the human 21st chromosomes contain the gene for SOD-1, we have investigated differences in the vulnerability of neurons derived from Ts16 and euploid embryos to potential oxidative stressors. We use primary cortical cultures from mice trisomic for the 16th chromosome (which encompasses the DS region noted above) and transgenic for human SOD-1 to address questions of the state of antioxidant defense mechanisms in neurons which overexpress SOD-1. We have found that neurons overexpressing SOD-1 are less vulnerable to glutamate analogue-mediated glutathione depletion and cell death (presumably due to blockade of the glutamate-cystine antiporter) than non-overexpressing controls.

PROTECTION AGAINST FREE RADICAL DAMAGE IN CEREBELLAR GRANULE CELL CULTURES.

Puttfarcken. and J.T. Coyle\* Dept of Psychiatry, Harvard Sch. of Medicine /MGH, Boston, MA.

Previous studies implicate the generation of free radicals in the progression of excitatory amino acid-induced neuronal death. Both in vitro and in vivo studies from our laboratory, demonstrated that treatment with lipophilic antioxidants provides protection against the neurotoxic effects of kainic acid (KA). As a result of these observations, we have compared the generation of lipid peroxidation products in cerebellar granule cell cultures (CGC) exposed to 3 different free radical generating systems (FRG); 200 µM ferrous ammonium sulfate (FAS), 20 µM copper (Cu) and 0.01U/ml xanthine oxidase/2.3 mM purine/2.4 µM transferrin (XO), to that observed following exposure to KA (see Puttfarcken, 1992). The effectiveness of the antioxidant, BHT and the lipid peroxidation inhibitor, U78517F, in attenuating these changes was also evaluated. Studies demonstrated a difference in the time course of neuronal death following a 30 minute exposure to each FRG: FAS (90 min), XO (180 min), and Cu (270 min). Despite these time differences, a similar 2-3 fold increase in both lipid hydroperoxide (HP) and conjugated diene (CD) generation was observed. The addition of 100µM BHT significantly attenuated FAS-Cu- and XO-induced HP and CD formation. BHT reduced the formation of lipid peroxidation products by approximately 60-70%. Unlike BHT, the potency of U78517F depended upon the system utilized to induce lipid peroxidation. Although the protection provided by U78517F appeared to be approximately 50-60%, it was most potent in attenuating FAS-induced HP and CD formation (100 nM), followed by Cu (750 nM), and lastly by XO (>2µM).

KAINIC ACID INDUCED LIPID PEROXIDATION: PROTECTION WITH LIPOPHILIC ANTIOXIDANTS IN CEREBELLAR GRANULE CELL CULTURES. P.S. Puttfarcken\*. R.L. Getz. and J.T. Coyle. Dept. of Psychiatry, Harvard Sch. of Medicine/ MGH, Boston, MA. Previous studies from our laboratory have demonstrated that treatment of cerebellar granule cell cultures (CGC) with lipophilic antioxidants

of cerebellar granule cell cultures (CGC) with hipophilic antioxidants significantly attenuated the neurotoxic effects of kainic acid (KA). In light of these observations, we have investigated the relationship between KA-induced neuronal toxicity and the appearance of lipid peroxidation products. Additionally, to assess the ability of KA to induce membrane damage, we have measured the products of lipid peroxidation following treatment with free radical generating systems (FRG) in the CGC (see Getz, 1992). Under conditions designed to examine delayed toxicity, we have demonstrated a dose-dependent increase in KA-mediated conjugated diene (CD) and lipid hydroperoxide (HP) formation which correlates with an increase in LDH release. Maximal doses of KA (500 nM to  $1\mu M$ ), an increase in LDH release. Maximal doses of KA (500 nM to 1µM), induced both CD and HP formation by approximately 2-4-fold above control. Moreover, the treatment of cells with various antioxidants significantly attenuated KA-induced lipid peroxidation. Treatment with nM concentrations of U78517F, a lipid peroxidation inhibitor, decreased 500 µM KA induced CD formation by approximately 30-40%. The protection provided by U78517F was assessed by examining LDH release. Although U78517F did not alter the release of LDH induced by low concentrations of KA (50-300nM), there was a 30% decrease in the release elicited by maximal doses (350nM to 1  $\mu$ M) of KA. These data provide further evidence that the generation of free radicals, subsequently leading to membrane disruption, is most likely involved in the process of KA-elicited neuronal death in CGC.

NEUROTOXIC EFFECTS OF SODIUM NITROPRUSSIDE IN RAT HIPPOCAMPAL SLICES A. M. Benz, Y. Izumi, D. B. Clifford', C. F. Zorumski and J. W. Olney Depts. of Psychiatry and Neurology, Washington Univ., School of Med., St. Louis, MO 63110.

To investigate the involvement of nitric oxide (NO) in the pathogenesis of N-methyl-D-aspartate(NMDA)-induced toxicity we examined the effects of sodium nitroprusside (SNP) using rat hippocampal slices. Incubation of slices with 3mM SNP for up to 2 hours generated a novel pattern of morphological change characterized by nuclear swelling in CA3 and CA1 pyramidal neurons and interneurons, with relative sparing of dendritic fields. The nuclear ballooning was not blocked by lowering the external calcium concentration or co-incubation with MK-801 and/or 6,7-dintro-quinoxaline-3,4-dione (DNQX). Several observations indicate that the SNP neurotoxicity is not mediated by NO. Inactivation of SNP by UV light did not prevent the characteristic nuclear ballooning, and it was not attenuated by coadministration of hemoglobin. Additionally, KCN (0.3-15mM) failed to mimic the nuclear swelling.

Electrophysiologically, 100µM SNP diminished the CA1 population spike amplitude and subsequently inhibited the field EPSP irreversibly. The NMDA component of the field EPSP slope was inhibited by 10 $\mu$ M light inactivated SNP (-52  $\pm$  17%, N=6) but not by active SNP 10 $\mu$ M (6  $\pm$ 7%, N = 6). Consistent with this, the excitotoxicity produced by  $100\mu M$ NMDA is also blocked by inactivated SNP but not by the active compound.

These results suggest that active SNP and light inactivated SNP have different effects on hippocampal neurons and that SNP induces a characteristic toxicity which differs from that of cyanide or NMDA.

## 276.7

THE EFFECTS OF NO SYNTHASE INHIBITOR ON BRAIN NESCHEMIA IN VIVO. S. Shapira\*, R. Brandeis, B-A Weissman and T. Kadar. Dept. Pharmacol., Israel Inst. Biol. Res., Ness-Ziona IL-70450, Israel.

There is vast amount of in vitro data to indicate that NMDA-induced brain damage is mediated by NVO activities and the tiphibition of NO.

There is vast amount of in vitro data to indicate that NMDA-induced brain damage is mediated by NO activity, and that inhibition of NO synthesis is beneficial to ischemic brain tissue. The purpose of the present study was to investigate the effects of NO on ischemic brain in vivo. Male mongolian gerbils were exposed to 5 min ischemia, 4 hr after administration of nitro-L-arginine (NARG). At 1, 2 and 6 days, spont-aneous activity was evaluated, and at 6 days the gerbils were sacrificed and their brain removed for histological assessment. Two days after ischemia, significant increase in spontaneous activity was observed only in NARG pretreated ischemic gerbils, as compared to sham operated NARG pretreated, and to gerbils exposed to ischemia without pretreatment. The usual neuropathology confined to vulnerable areas was observed in animals exposed to 5 min ischemia. NARG pretreated ischemic gerbils displayed neuropathology which extended beyond the vulnerable areas, and was significantly worse on quantitative analysis. It is suggested that through mechanisms yet unknown, NO might be beneficial in cases of massive brain ischemia.

NITRIC OXIDE SYNTHASE ACTIVATION, OR CYSTINE DEPLETION, MAY NOT BE CRITICAL TO NMDA RECEPTOR-MEDIATED INJURY IN MURINE CORTICAL CULTURES. K. Rose\*, D. Liu, and D.W. Choi Dept. of Neurology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

Oxygen free radicals may mediate some of the neuronal damage oxygen free radicals may mediate some of the neutronal damage induced by overstimulation of glutamate receptors. Several specific mechanisms might link such overstimulation to the overproduction of free radicals, for example, Ca<sup>2+</sup> activation of phospholipase leading to increased metabolism of arachidonic acid by lipoxygenase pathways (Soc. Neurosci. Abst. 17:784, 1991). Two other possible mechanisms are Ca<sup>2+</sup> activation of nitric oxide (NO) synthase, promoting NO and peroxynitrite formation (Dawson et al., PNAS

promoting NO and peroxynitrite formation (Dawson et al., PNAS 88: 6368, 1991), or glutamate inhibition of cystine uptake, lowering protective glutathione levels (Murphy et al., Neuron 2: 1547, 1989). Cultured murine cortical cells exposed to 75 µM NMDA for 5 min developed an intermediate level of neuronal death by the next day. Addition of 100 µM-300 µM NG-nitro-L-arginine, or 300 µM-1 mM NG-monomethyl-L-arginine to the exposure solution did not alter resultant neuronal death, even if the cultures were exposed to arginine-free medium for 24 hr prior to NMDA exposure. 24-48 hr exposure to cystine-free medium did not induce cell death. While neuronal NO production or cystine depletion may be critical to glutamate neurotoxicity in some systems, the role of these two mechanisms is not readily apparent in our system. perhaps because

mechanisms is not readily apparent in our system, perhaps because of masking by other, more powerful injury pathways.

HYDROXYL RADICAL SCAVENGER, DIMETHYLTHIOUREA, PARTIALLY ATTENUATES NMDA RECEPTOR MEDIATED TOXICITY. D. E. Supko\* and M.V. Johnston. Kennedy Krieger Institute and Johns Hopkins University School of Medicine, Baltimore,

The formation of free radicals and subsequent lipid peroxidation may be factors contributing to glutamate neurotoxicity. To explore this possibility, the effect of a free radical scavenger, dimethylthiourea possibility, the effect of a free radical scavenger, dimethylthiourea (DMTU) on glutamate receptor-mediated neurotoxicity was investigated in the rat. Unilateral intrastriatal injections of the glutamate receptor agonist NMDA, were made with or without prior administration of DMTU (500 mg/kg, ip) to post-natal day 7 rats. Damage was assessed one week later by measurement of the change in cytochrome oxidase (CO) activity between the lesioned and control sides of the brain determined practically by (CO) activity between the lesioned and control sides of the brain (determined spectrophotometrically by measurement of the rate of oxidation of cytochrome C). NMDA produced a dose-dependent inhibition of CO activity with 5, 10 and 20 nmols resulting in 10.7%, 24.1% and 38.3% inhibition, respectively. Pretreatment with DMTU 1 hour prior to NMDA injection significantly attenuated damage only from 20 nmol NMDA: 19.5% inhibition of CO activity (48.2% protection, p<0.025). Intrastriatal injection of AMPA produced a similar decrease in CO activity which was not attenuated by DMTU. The results indicate that treatment with the free radical scavenger. DMTU affords partial that treatment with the free radical scavenger, DMTU affords partial protection against NMDA receptor-mediated damage.

NITRIC OXIDE AND FREE RADICALS MEDIATE NMDA-INDUCED NEURODEGENERATION. M. Li, A.M. Szczepanik\*, K.M. Brooks and C.A. Wilmot. Dept. Biological RESEARCH, Neuroscience Strategic Business Unit, Hoechst-Roussel Pharmaceuticals, Inc., Somerville, NJ 08876-1258.

Excessive NMDA receptor activation and subsequent Ca<sup>2+</sup> entry

Excessive NMDA receptor activation and subsequent Ca<sup>2+</sup> entry produce neurodegeneration in many experimental models. The generation of the free radicals nitric oxide (NO•) and superoxide (O2•) may contribute to this process by forming the peroxynitrite anion (ONOO·), which decomposes to the highly damaging hydroxyl (OH•) and nitrogen dioxide (NO2•) radicals. The NO• synthase (NOS) inhibitor N-mono-methyl-L-arginine (NMMA) and the free radical scavenger N-tert-butyl- α-phenylnitrone (PBN) were tested for protective effects *in vivo* against NMDA-induced lesions of the striatum in rats. NMDA (150 nmol) or an equiosmolar solution of NaCl was infused into the left or right striatum, respectively. Rats were sacrificed seven days later. Using the respectively. Rats were sacrificed seven days later. Using the contralateral striatum as a control, NMDA-induced deficits of the enzyme markers choline acetyltransferase (ChAT) and glutamic acid decarboxylase (GAD) were determined. When coadministered with NMDA directly to the striatum, NMMA at 1875 and 3750 nmol produced a partial protection. PBN at 100 mg/kg, ip, 30' pretreatment, showed nearly complete protection against NMDA-induced deficits of ChAT and GAD, and was also effective as a 30' posttreatment. These findings support the hypothesis of an involvement of free radicals in NMDA-induced neuronal damage.

EAA AGONISTS STIMULATE THE FORMATION OF FREE RADICAL SPECIES IN SYNAPTO-NEUROSOMES S.C. Bondy, and R.J. Bridges\*. Depts. of Community and Environ. Med. and Neurology, University of California, Irvine, CA 92717. Excitatory amino acid (EAA) agonists are well recognized for their

ability to induce excitotoxic-mediated neuronal damage. Although considerable progress has been made in elucidating the early roles of receptor activation and ion influx in the excitotoxic mechanism, much less is known about later steps in the pathological process. In the present study we have examined the ability of EAA agonists to promote the formation of reactive oxygen species (ROS), key intermediates in the process of free radical-mediated oxidative injury. intermediates in the process of free radical-mediated oxidative injury. The generation of ROS in the synaptoneurosomes was followed with 2,7-dichlorofluorescin diacetate which, after its intracellular conversion to 2,7-dichlorofluorescin, reacts with ROS to form a fluorescent species (excitation: 488 nm, emission: 525 nm). Kainate (KA), \( \alpha \)-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA), and N-methyl-D-aspartate (NMDA) each stimulated the formation of ROS in a time- and concentration-dependent manner. Of these three agonists, KA proved to be the most potent, with a 60 min exposure to 1 mM KA increasing ROS formation to about 200% of the basal level. Exposure to a similar level of L-glutamate also stimulated ROS formation, but only to about 130% of the basal level. The effectiveness of the L-glutamate may, however, have been limited by its rapid removal by high affinity transport, similar to what has been observed in electrophysiological studies. These findings add further support to the hypothesis that free radical-mediated oxidative injury contributes to the process of excitotoxic neuronal pathology.

## 276.11

IMMUNOLOGIC ACTIVATION OF ASTROCYTES: DISSOCIATION OF NITRIC OXIDE PRODUCTION AND NMDA MEDIATED NEURONOCYTOTOXICITY. E. Bernton, M. DeCoster, J. Dave, L. Robles\* and F. Tortella. Walter Reed Army Inst. Res., Washington, DC 20307.
Addition of bacterial endotoxin, fixed staphylococci, or Mycoplasma hominis to 14 day

cultures of fetal rat cortex is cytopathic for neurons. These neuronocytopathic effects resemble those observed following addition of toxic concentrations of glutamate, and are blocked by μM MK-801, an NMDA-receptor antagonist. Following such immunologic stimuli, nitrite accumulation in cortical culture supernatants, reflecting nitric oxide (NO) production, increased from  $<0.2~\mu\text{M}/72~\text{h}$  to 1-4  $\mu\text{M}/72~\text{h}$ . Nitrite accumulation and neuronocytopathic effects occurred in the absence of microglia, but not in the absence of astrocytes and microglia. Addition of N-methyl-1-arginine (0.5mM) prevented NO or N-methyl-l-arginine (0.5mM) prevented NO production, but not the neuronocytopathic changes. Critically, MK-801, which is neuroprotective, did not prevent NO production. In conclusion, the astrocyte response to immunologic stimuli, which includes IL-1 and TNF release, included NO release (albeit at low levels). However, the associated MK-801-antagonized representation offsets neuronocytopathic MK-801-antagonized appeared to be independent of NO release.

## 276 13

BUTHIONINE SULFOXAMINE-MEDIATED GLUTATHIONE DEPLE-TION EXACERBATES EXCITOTOXIC BRAIN INJURY IN THE NEONATAL RAT. C. J. Hudson, J. S. Althaus\*, P. F. VonVoigtlander.
The Upjohn Company, Kalamazoo, MI 49001.
L-Buthionine-(S,R)-sulfoxamine (BSO) selectively blocks glutathione

(GSH) synthesis when administered to neonatal rats. This results in the depletion of GSH and, thus, the formation of reactive oxygen We tested the effects of BSO species are largely unopposed. administration in a model of NMDA-induced brain injury in the neonatal rat. A number of different BSO dosing paradigms were employed (3 mmol/kg/dose). In pups dosed 5 times over 72 hours and in pups dosed 6 times over 96 hours, a significant exacerbation in hemisphere weight reduction produced by intracerebral injections of NMDA was found. However, in pups dosed only 4 times over 96 hours, no change in injury was observed. In separate experiments, with pups dosed 3 times over 72 hours, GSH was depleted by 93%, and in pups dosed 5 times over 72 hours, GSH was depleted 95%. In a less than optimal dosing paradigm in terms of excitotoxicity potentiation, BSO failed to deplete brain vitamin E. There may be a minimum concentration of GSH (e.g. >5% of normal) above which significant protection from radical enhanced excitotoxicity occurs.

NITRIC OXIDE IS RESPONSIBLE FOR CONTINUED SYNAPTIC TRANSDUCTION FOLLOWING EXCITOTOXIC EVENT T. Akira, R.A. Baldwin and C.G. Wasterlain'. Dept. of Neurology, UCLA School of Medicine, Brain Research Institute UCLA Los Angeles, CA.90024 and Epilepsy Research Lab. VAMC, Sepulveda, CA.91343

UCLA Los Angeles, CA.90024 and Epilepsy Research Lab. VAMC, Sepulveda, CA.91343
Nitric oxide (NO), a candidate for retrograde messenger, probably plays a role in cell to cell signaling including Ca<sup>2+</sup> influx through NMDA receptorgated ion channels (NMDARC). In addition, NO may mediate glutamate-induced neurotoxicity. Varied actions of NO in the central nervous system are expected under both physiological and pathological conditions.

We have already shown, utilizing a <sup>3</sup>H-MK-801 binding technique that NMDARC remains open after ischemic, hypoxic or excitotoxic events in both in vivo and in vitro systems. In the present study, we examined in rat hippocampal slices (475 μm-thick) the mechanism(s) underlying such a sustained activation of NMDARC. This process must be important to bridge the time gap between initially increased release of excitatory amino acids and delayed cell death dependent on intracellularly accumulated Ca<sup>2+</sup>. This sustained activation of NMDARC was significantly blocked by 100μM N\*-nitro-Larginine (NLA), a nitric oxide synthase inhibitor, or by pretreatment of 100μM hemoglobin, which would capture extracellular NO directly. The inhibitory effect of NLA was reversed by 1 mM L-arginine (LA), a substrate for NO-formation. Sodium nitroprusside (SNP) and LA potentiated the activation of NMDARC by glutamate/glycine, although SNP alone dramatically decreased <sup>3</sup>H-MK-801 binding. Interestingly, the continued opening of the cationic channels was TTX-sensitive, Ca<sup>2+</sup>-dependent, but cGMP-independent. Furthermore, this sustained opening of NMDARC was associated with increase release of glutamate and aspartate. Accordingly, NO seems to persistently open the cationic channels linked to NMDA receptors and to increase release of excitatory amino acids.

These findings may account for the participation of NO in excitotoxic neuronal injury and in continued synaptic transduction in LTP.

## 276.12

NMDA RECEPTOR ACTIVATION RESULTS IN HYDROXYL RADICAL PRODUCTION IN PRIMARY MURINE CORTICAL CULTURES R.G. Giffard\*, V.M.G. Bruno, S.M. Amagasu, D.W. Choi and L.L. Dugan. Dept. of Anesthesia, Stanford Univ. Sch.of Med., Stanford, CA 94305; Dept. of Neurology, Wash. Univ. Sch. of Med., St. Louis, Mo. 63110.

Free radical damage has long been thought to play a role in ischemic neuronal injury. The hydroxyl radical is one of the more reactive species that may be generated during ischemia and may be one of the species responsible for free radical damage in this setting. Neuronal death can result from excessive N-methyl-D-Aspartate (NMDA) receptor activation. As NMDA receptor activation is an important component of ischemic injury and we have previously shown that antioxidants can diminish NMDA neurotoxicity we attempted to detect the production of hydroxyl radicals in response to NMDA receptor activation. The hydroxyl radical specific metabolite of salicylate, 2,3-dihydroxybenzoate, was measured using an HPLC method (Ingelman-Sundberg et.al. Biochem.J.276:753). We demonstrated an increase in hydroxyl radical production of 15-30% over baseline following 10 min exposure to 500 µM NMDA in murine cortical cultures (n=4-8 each condition, three repetitions). This increase was blocked by the NMDA antagonist MK801. Hydroxyl free radical production is detectable in response to toxic exposure to NMDA and may contribute to neuronal damage in the setting of ischemia.

Sponsored in part by NS01425.

# 276.14

NITRIC OXIDE IS NOT INVOLVED IN NMDA-INDUCED NEUROTOXICITY IN RAT CORTICAL CULTURES. W. C. Zinkand\*, R. J. Stumpo, C. Thompson, H. M. Hargrove, L. M. Pullan and J. Patel. ICI Americas Inc., Wilmington, DE 19897.

The excitatory amino acid N-methyl-D-aspartate (NMDA) is capable of producing extensive neurotoxicity in cultures of the rat cerebral cortex. NMDA has also been shown to generate the second messenger nitric oxide (NO) from arginine by activation of the calcium-calmodulin-dependent enzyme nitric oxide synthase. The primary role of NO in the cell seems to be activation of the enzyme guanylate cyclase and resultant production of cyclic guanin monophosphate (cGMP). We have therefore investigated the role of nitric oxide in NMDA-induced neurotoxicity.

Neuronal cell death of 30-60% was observed following the 5 min. NMDA exposure. Sister cultures showed a 2.5 to 3-fold increase of cGMP over control. The substituted arginine N-nitroarginine (NNA) has been shown to be a membrane permeant inhibitor of NO synthase. NNA pre and co-incubated at 100uM with NMDA blocked the induction of cGMP, however neurotoxicity was not blocked at any dose of NNA.

Sodium nitroprusside (SNP) generates NO by spontaneous hydrolysis. When added to the culture media for 5 min. SNP induces an 8 to 20-fold increase in cGMP levels and nearly 100% neuronal cell loss. Hemoglobin, which is capable of scavenging the NO radical completely abolishes the SNP-duced increase in cGMP but does not significantly block SNP neurotoxicity.

These observations lead us to postulate that release of NO and subsequent production of cGMP by NMDA represents a metabolic pathway not involved in the excitotoxic chain of events. Further evidence is provided by the observation that 8-bromo-cGMP, which is a membrane permeant and functional analog of cGMP in not neurotoxic to cortical cells.

#### 276 15

EXCITOTOXICITY OF TOPA QUINONE IN VITRO AND IN VIVO. E Aizenman\*, FA Boeckman, C Stafstrom & PA Rosenberg. Dept of Physiol, Univ of Pittsburgh Sch Med, Pittsburgh, PA 15261, and Dept of Neurol, Children's Hosp and Harvard Med Sch, Boston, MA 02115.

We studied whether reduction of the non-NMDA excitotoxin 2,4,5trihydroxyphenylalanine quinone (TOPA quinone) to its catechol precursor is sufficient to abolish its agonist properties and prevent its neurotoxicity in rat cortical neurons in culture. Also, we examined whether systemic administration of TOPA quinone can produce neurological abnormalities in rats. We first monitored the formation of TOPA quinone from TOPA (30-500  $\mu$ M) at pH 7.2 spectrophotometrically (O.D. 480). Utilizing glutathione (GSH; 0.05-3 mM) as the reducing agent, we found that the optimal [GSH]:[TOPA] ratio which significantly retards topa quinone formation was 10:1. Thus, 3 mM GSH prevented whole-cell currents induced by a solution of 300 µM TOPA but did not affect currents elicited by 300 µM kainate. In addition, 2 mM GSH protected neurons from the toxic effects of 200 µM TOPA, but was not effective against 200 µM NMDA. In whole animal experiments, i.p. injections of TOPA (50 mg/kg) in 1 mM ascorbate in PBS produced epileptic-like behavior with and EEG correlate in P11-12 rats. These studies suggest that: 1) the presence of endogenous reductants may limit the toxicity of TOPA, and 2) peripheral sources of TOPA may have CNS toxicity.

### 276.16

PERSISTENT INHIBITION OF GLUTAMATE UPTAKE BY OXYGEN FREE RADICALS: SELECTIVE PROTECTION BY DISULFIDE-REDUCING AGENTS A. Volterra, D. Trotti, S. Floridi and G. Racagni Ctr. Neuropharmacology & Inst. Pharmacol. Sci., University of Milan, Milan, Italy.

Oxygen free radicals play a role in ischemic brain damage. However, the details of their mode of action are still largely undefined. Here we report that oxygen radicals inhibit high-affinity Na<sup>+</sup>\K<sup>+</sup>-dependent glutamate reuptake in primary cultures of astrocytes from neonatal rat cerebral cortex. Thus, 10 min incubation with either xanthine (500 μM) + xanthine oxydase (10-50 mU\ml) (XA\XOD) or H<sub>2</sub>O<sub>2</sub> (SOO AM), but not XA or XOD alone, results in a 20-40% reduced uptake. The effect of XA\XOD is prevented by > 80% in the presence of scavenger enzymes superoxide dismutase (SOD, 90 U\ml) + catalase (CAT, 3000 U\ml). Similarly, H<sub>2</sub>O<sub>2</sub> inhibition is prevented by CAT. Longer incubations with XA\XOD result in a progressive increase of inhibition. Upon removal of radicals such increase is blocked, but inhibition remains at a steady level for at least 1 h. Reduced glutamate uptake does not correlate with cell damage, since no extracellular lactate dehydrogenase (LDH) activity was detected following 10 min incubation with XA\XOD, while a slight enhancement was observed at 30 min. We tested the possible protective effect of various antioxidants by adding them 10 min prior to exposure to XA\XOD 50 mU\ml: lipophilic Vit. E (20-200  $\mu$ M) and methylprednisolone (100  $\mu$ M) and hydrophilic Vit. C (1 mM) did not affect inhibition, while disulfide-reducing agents glutathione (GSH, 4 mM) and dithiothreitol (DTT, 2 mM) both prevented XA\XOD inhibition by 60-80%. This data suggests that radicals likely act by oxidizing functionally relevant SH groups on the glutamate transporter or on a related protein. In summary, oxygen free radicals persistently inhibit glutamate uptake in astrocytes without appreciable cell damage. Such inhibition may be an important early step in the ischemia-induced sequence of events leading to neuronal damage, since it may contribute to elevate extracellular glutamate up to neurotoxic levels

IN VIVO ACTIVATION OF METABOTROPIC GLUTAMATE RECEPTORS BY tACPD POTENTIATES AGONIST EFFECTS AT IONOTROPIC GLUTAMATE RECEPTORS. H. Klitgaard and P. Laudrup. Novo Nordisk A/S, Novo Nordisk Park, DK-2760 Maaloev, Denmark.

Subtypes of glutamate receptors can be differentiated by their coupling to either ion channels (NMDA, kainate, AMPA receptors) or G-proteins (metabotropic receptors). The present study compares the effect of separate or combined in vivo activation of both ionophoretic and G-protein-coupled glutamate receptors using selective glutamate agonists. Male NMRI mice (25+2 g) were infused i.c.v. with different doses of L-glutamate, NMDA, kainate, quisqualate, AMPA or (1S,3R)-tACPD. In another set of experiments the ionophoretic glutamate agonists were coinfused i.c.v. with a fixed dose of tACPD. I.c.v. infusion of Lglutamate, NMDA, kainate, quisqualate and AMPA dosedependently induced clonic convulsions. In contrast, tACPD elicted dose-dependent grooming and scratching, but was not convulsant. I.c.v. co-infusion of either L-glutamate, NMDA, kainate, quisqualate or AMPA with tACPD markedly reduced the time to onset of convulsions. In conclusion, ionophoretic and Gprotein-coupled glutamate receptors induce different behavioral effects. However, the convulsant effects of ionophoretic receptor agonists are markedly potentiated by simultaneous activation of the G-protein-coupled metabotropic receptors.

## 277.3

SELECTIVE EFFECTS OF PROLINE ON GLUTAMATE UPTAKE M.L. Cordero, J.G. Ortiz\*, G. Santiago and O. Torres. Department of Pharmacology, University of Puerto Rico, School of Medicine, San Juan, Puerto Rico, 00936-5067

Puerto Rico, 00936-5067

Proline (PRO) has been suggested as a possible neuromodulator of glutamate (GLU) transmission (Cordero et al., 1991, Helm et al., 1990, Nadler et al., 1989, Ault et al., 1987). PRO does not affect [ H]GLU uptake in whole brain crude synaptosomal preparation (P<sub>2</sub>) from normal (SPS/SPS) mice, but increases GLU Umax in 15 day-old mice. In audiogenic seizure-susceptible (SPS/SPS) mice, Pro decreases the apparent K<sub>m</sub> (56.3 ± 13.08 µM vs. 15.3 ± 1.47 µM, p<0.0001) and the Umax (4.46 ± 0.44 vs. 1.5 ± 1.93 ± 0.103 nmoles/mg protein, p<0.0001) of GLU uptake while in astrocyte-enriched cultures PRO increases both the K<sub>m</sub> (177.9 ± 16.8 µM vs. 27.3 ± 3.01 µM) and the Umax values (12.66 ± 0.976 vs. 3.09 ± 0.193 nmoles/mg protein). Dihydrokainate (DHK), an inhibitor of GLU uptake, produces similar effects in the astrocytes and normal mice synaptosomes. These results point to the possible use of PRO as a pharmacological tool for examining GLU uptake system(s)in normal and diseased states, such as epilepsy. (Supported by the Institutional MBRS and RCMI Programs and the Animal Resource Center)

BRADYKININ SELECTIVELY RELEASES EXCITATORY AMINO ACIDS FROM CULTURED GLIA IN A CALCIUM-DEPENDENT MANNER.

F. Liu\*. K. Jeffinija. and S. Jeffinija. Department of Vet. Anatomy and

Neuroscience Program, Iowa State University, Ames, IA 50011, USA.

Bradykinin (BK) is a nonapeptide that plays a central role in the production of pain and inflammation. It has been shown that BK induces changes in interestillate at lating the production of the control of the production of the control of the production of the control of the production of the control of the production of the control of the production of the

Bradykinin (BK) is a nonapeptide that plays a central role in the production of pain and inflammation. It has been shown that BK induces changes in intracellular calcium in neurons and glia but no data are available regarding the capacity of BK to release excitatory amino acids (EAA) from glia. The specific objective of this study was to study the mechanism by which BK releases EAA from cultured peripheral glia. DRG or sciatic nerve from 1 to 8-day-old rats were dissected and cultured on chicken plasma-coated slides for 6 to 8 days. Cultures were mounted in a perfusion chamber and perfused at a rate of 200µ/min, with aerated Ringer solution at 36£19°C. Quantification of amino acids was performed by high performance liquid chromatography utilizing fluorescence detection and pre-column OPA-derivatization. Following a period of culture equilibration, 1min, 200µ samples were collected. Baseline concentrations of Asp and Glu in glia cultures were 6.7±0.6M (mean±5EM) and 23.6±2.1nM, respectively. Perfusion application of 10nM BK for 1min resulted in an 365±27% increase of Asp and 1038±183% increase of Glu release from cultured glia. A second applications of BK 10 min after first application resulted in an increase in the release of both EAAs that was at the level of 42% of that from the first application. This release of EAA evoked by BK was not abolished in low Ca -EGTA solution, but a second application of BK was without effect. Pretreatment of the glia cultures (30 min) with 50µM BAPTA-AM abolished the effect of BK. Pretreatment of the glia cultures with low Ca-EGTA solution with added ryanodine (10µM) failed to produce depression of BK-evoked release of EAAs. When thapsigargin (1µM) was added to low Ca-EGTA solution for 30 min, BK-evoked release of EAA was abolished. Capsaicin and high potassium were not able to produce any effect on release of EAA from cultured glia. Our results show that BK selectively evokes the release of EAAs from cultured glia in a Ca-dependent manner.

1S,3R-ACPD IS AN AGONIST AT L-AP4 RECEPTORS. W. B. Thoreson' and R. F. Miller. Department of Physiology, University of Minnesota, Minneapolis. MN 55455.

There are two classes of G-protein coupled excitatory amino acid (EAA) receptors: 1-aminocyclopentane-1,3-dicarboxylic acid (ACPD) and L-2-amino-4-phosphonobuyric acid (L-AP4) receptors. L-AP4 receptors can be distinguished from ACPD receptors by their sensitivity to micromolar L-AP4. However, the sensitivity of L-AP4 receptors to ACPD is not known. Using whole cell patch clamp recording techniques, we examined the effects of ACPD on ON bipolar cells in a mudpuppy retinal slice.

effects of ACPD on ON bipolar cells in a mudpuppy retinal slice. Like L-AP4 (5  $\mu$ M), 1S,3R-ACPD (160  $\mu$ M) and racemic 1S,3R/1R,3S-ACPD (100  $\mu$ M; commonly called "trans-ACPD") evoked outward currents accompanied by an increased input resistance and reduced membrane noise. 1R,3S-ACPD (1 mM) had no effect. The response to 1S,3R/1R,3S-ACPD was suppressed by prior activation of the L-AP4 receptor, but unaffected by the ACPD receptor antagonist L-AP3 (1 mM). The inclusion of neomycin (100  $\mu$ M) in the patch pipette, which should suppress ACPD receptor-stimulated phosphoinositide hydrolysis, also had no effect on the responses to L-AP4 or 1S,3R/1R,3S-ACPD. These results indicate that 1S,3R-ACPD is an agonist at the L-AP4 receptor.

L-AP4 receptors are the only EAA receptors in mudpuppy ON bipolar cells. Using the b-wave of the electroretinogram as an assay for ON bipolar cell responses, we could thus obtain dose/response curves for ACPD enantiomers acting at L-AP4 receptors uncontaminated by effects at other EAA receptors. The rank order potency and  $IC_{50}$ 's are L-AP4 (1.1  $\mu$ M) >> 1S,3R-ACPD (89  $\mu$ M) > 1S,3S-ACPD (417  $\mu$ M) >> 1R,3S-ACPD (117,3R-ACPD (55  $\mu$ M). Supported by NIH grants EY03014 and EY06213.

PHARMACOLOGY OF METABOTROPIC GLUTAMATE RECEPTORS NEGATIVELY COUPLED TO cAMP FORMATION IN THE RAT HIPPOCAMPAL SLICE. B.G. Johnson' and D.D. Schoepp. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, Indiana 46285
Metabotropic glutamate receptors (mGiuRs) are G-protein coupled to transduction enzymes that produce increased phosphoinositide (PI) hydrolysis and decreased cAMP formation. The pharmacology of Pl-linked mGiuRs have been well characterized in a variety of CNS tissues (see TiPS 11: 509, 1992). Recently, mGluR(s) negatively coupled to cAMP formation have been cloned (Tanabe et al. Neuron 8: 169, 1992). In this study the pharmacology of cAMP-linked mGluRs were examined in cross chopped slices of the adult rat hippocampus. Various excitatory amino acid agonists and antagonists were examined for effects on forskolin (30 µM)-stimulated cAMP formation. The selective metabotropic agonist (15,3R)-1-aminocyclopentane-1,3-dicarboxylic acid (15,3R-ACPD) was highly potent at inhibiting forskolin-stimulation, producing a maximal effect of 55% inhibition at 30 µM. 18,3S-ACPD was much less potent, but produced full inhibition at higher concentrations (90% inhibition at 1000 µM). The ionotropic agonists the MDA, AMPA, and kainate did not after cAMP at up to 500 µM. Non-selective ionotropic/metabotropic agonists that inhibited forskolin-stimulated cAMP included quisqualate (92% at 500 µM), ibbotenate (44% at 500 µM), and L-glutamate (41% at 1000 µM). Inhibition of cAMP formation induced by 15,3R-ACPD (100 µM) was not affected by the ionotropic antagonists MK801 (10 µM), CNOX (100 µM), AP5 (500 µM), or AP7 (500 µM). LAP3 and L-AP4 have been shown to inhibit the effect of 1S,3R-ACPD inhibition of forskolin-stimulation, respectively. These studies show that mGluRs negatively coupled to cAMP formation can be readily demonstrated in the brain slice preparation. This class of metabotropic glutamate receptors has a pharmacology that is distinct from the ionotropic and Pl-linked glutamate receptors.

PERTUSSIS TOXIN DIFFERENTIATES BETWEEN THE ADENYLATE CYCLASE- AND PHOSPHOINOSITIDE (PI)-LINKED METABOTROPIC GLUTAMATE RECEPTORS IN VIVO. A.I. Sacaan and D.D. Schoepp. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis,

There is evidence for heterogeneity of metabotropic (G-protein linked) glutamate receptors. One type is associated with the stimulation of PI hydrolysis, while the other is negatively coupled to stimulation of PI hydrolysis, while the other is negatively coupled to adenylate cyclase. In this study, pertussis toxin was utilized to distinguish between these two types of metabotropic glutamate receptors in vivo. Male Sprague-Dawley rats were anesthetized and placed in small animal stereotaxic instrument. Pertussis toxin (4 µg / 4 µl) or its vehicle (4 µl) was injected into the dorsal hippocampus. At 48 hours after injection, stimulation of PI hydrolysis and inhibition of forskolin-stimulated cyclic AMP formation by 1S,3R-ACPD was assessed in cross-chopped hippocampal slices. In vehicle injected rats, 100 µM 1S,3R-ACPD produced 60.8 ± 4.7% inhibition of forskolin-stimulated cyclic AMP levels. Following pertussis toxin, the inhibitory effect of 1S,3R-ACPD (100 µM) on forskolin-stimulated cyclic AMP levels was completely prevented (4.7 ± 20.0% inhibition). In contrast, there was no significant difference between 1S,3R-ACPD stimulations of PI hydrolysis in vehicle injected (486 ± 58% of basal hydrolysis) hippocampal tissues. Thus, pertussis toxin can be utilized in vivo as a pharmacological tool to selectively uncouple adenylate in vivo as a pharmacological tool to selectively uncouple adenylate cyclase-linked, but not Pl-linked, metabotropic glutamate receptors. This may provide an approach to identify which subtypes of metabotropic glutamate receptors are involved in different physiological and pathological events.

## 277.9

A PHARMACOLOGICAL CHARACTERIZATION OF THE mGlu\_gR-1 $\alpha$  AND THE mGlu\_gR-1 $\beta$  SUBTYPE OF THE METABOTROPIC GLUTAMATE RECEPTOR EXPRESSED IN A MAMMALIAN CELL LINE. C. Thomsen, E. Mulvihill, B. Haldeman and P.D. Suzdak. Novo Nordisk A/S, CNS Division, DK-2760 Maaloev, Denmark, and ZymoGenetics, Seattle.

Excitatory amino acid receptor subtypes have been classified into two categories based on the signal transduction mechanisms to which they are associated. The "ionotropic" glutamate receptors are directly coupled to ion channels, whereas the "metabotropic" glutamate receptors (mGlu<sub>G</sub>R) are linked to their effectors via a G-protein-dependent mechanism. The mGlugR-1a and the mGlu<sub>c</sub>R-1β cDNA's were subcloned into mammalian expression vectors and transfected into a baby hamster kidney cell line. Two subclones, stably expressing the mGlu<sub>G</sub>R-1 $\alpha$ - and 1 $\beta$ -subunit, respectively, were selected. Both subtypes were coupled to phosphoinositide hydrolysis in this cell line. The relative order of potency was: quisqualate > glutamate > ibotenate ≥ (1S,3R)-t-ACPD for subtype mGlu<sub>G</sub>R-1 $\alpha$  and for subtype mGlu<sub>G</sub>R-1 $\beta$ : quisqualate> ibotenate  $\geq$  glutamate> (1S, 3R)-t-ACPD. The time course for, and possible mechanism of, desensitization of the mGluR<sub>g</sub>-1 receptor subtypes following exposure to glutamate was characterized. Regulation of the mGlu<sub>G</sub>R-1 subtypes by other endogenous modulators was investigated.

(1S,3R)-1-AMINOCYCLOPENTANE-1,3-DICARBOXYLIC ACID (1S,3R-ACPD)-SENSITIVE L-3H-GLUTAMATE BINDING TO METABOTROPIC RECEPTORS IN RAT BRAIN R.A. True\* and D.D. Schoepp. Lilly Research Laboratories, Eli Lilly

RAT BRAIN R.A. True\* and D.D. Schoepp. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, Indiana 46285.

We studied L.3H-glutamate (10 nM) binding to rat forebrain membranes in the presence of saturating concentrations (100 LM) of ionotropic glutamate receptor agonists, NMDA, AMPA, kainate and the uptake inhibitor 4-acetamido-4-isothicoyano-stilbene-2,2'-disulfonic acid (SITS). Nonspecific binding (~50%) was defined with 1 mM of the highly selective metabotropic agonist, 18,3R-ACPD. Samples were incubated on ice 45 minutes, centritued @ 50,000 x g for 5 minutes and pellets rapidly washed with ice-cold buffer.

18,3R-ACPD-sensitive binding was saturable (B<sub>max</sub> = 2.50 ± 0.27 pmole/mg rotatin). Ci-depondrat temperature-independent reversible and of relatively.

protein), Cl'-dependent, temperature-independent, reversible and of relatively high affinity, ( $K_d = 187 \pm 60$  nM). This binding was differentially distributed in brain regions with the highest levels in hippocampus, striatum and cortex. Like 1S,3R-ACPD, other metabotropic EAA compounds displaced this binding with a pharmacology consistent with known functional metabotropic data.

| Compound    | Ki (μM)       | Hill Coefficient  |
|-------------|---------------|-------------------|
| L-Glutamate | 0.092 ± 0.050 | 1.109 ± 0.049     |
| 1S,3R-ACPD  | 10.3 ± 2.06   | $0.848 \pm 0.064$ |
| Ibotenate   | 36.2 ± 5.40   | 1.184 ± 0.217     |
| L-AP3       | 138 ± 23.8    | 0.866 ± 0.156     |
| 1R,3S-ACPD  | 434 ± 150     | $0.794 \pm 0.049$ |

The glutamate uptake inhibitors, L-cystine and L-AP4, did not significantly affect the specific binding ( $K_i$ >300  $\mu$ M). Quisqualate (QUIS) produced a biphasic inhibition curve ( $K_{i1}$  = 0.0087  $\pm$  0.0058  $\mu$ M;  $K_{i2}$  = 59.4  $\pm$  14.3  $\mu$ M). Low affinity QUIS sites (78% of binding) may represent cAMP-linked metabotropic receptors. The remaining 22% (high-affinity QUIS binding), may reflect binding to phosphoinositide hydrolysis-linked metabotropic receptors.

ACTIONS OF PHENYLGLYCINE DERIVATIVES ON METABOLIC AND EXCITATORY EFFECTS OF (18, 3R)-1-AMINOCYCLO-PENTANE-1,3-DICARBOXYLATE. P.J. Roberts<sup>1</sup>, E.F. Birse, S.A. Eaton<sup>2</sup>, P.L.St.J. Jones, P.C-K. Pook, R.H.P. Porter<sup>1</sup>, P.M. Udvarhelyi, B. Wharton, T.E. Salt<sup>2</sup> & J.C. Watkins\*, Dept of Pharmacol, The Medical School, Bristol BS8 1TD UK; <sup>1</sup> Dept of Physiol. & Pharmacol, Univ. of Southampton, SO9 3TU UK; <sup>2</sup> Dept of Visual Science, Inst. of Ophthalmology, London WC1H 9QS UK.

(1S,3R)-1-Aminocyclopentane-1,3-dicarboxylate (ACPD) is an agonist at metabotropic excitatory amino acid (EAA) receptors linked to phosphoinositide (PI) hydrolysis and also has excitatory effects on central neurons. We report here that members of a series of phenylglycine (PG) derivatives have differential actions on the metabolic and excitatory effects of ACPD. On chopped cerebral cortex tissue from neonatal rats, (S)-4-carboxy-3hydroxy-PG and (S)-3-hydroxy-PG stimulated PI hydrolysis in a dosehydroxy-PG and (S)-5-hydroxy-PG stimulated PI hydrolysis in a dosedependent manner, giving increases of 370% and 507%, respectively, over basal at the highest dose tested (1 mM). These two PGs also potentiated the stimulation of PI hydrolysis produced by submaximal doses of ACPD, but had no effect on the maximal ACPD response (approx 800% stimulation at  $100 \, \mu \text{M}$ ). (R)-4-Carboxy-PG had little or no effect on basal PI hydrolysis but competitively antagonized ACPD (1  $\mu \text{M} - 1 \text{ mM}$ )-stimulated PI hydrolysis with a  $K_{\text{B}}$  of approx 0.6 mM. All three compounds selectively antagonized ACPD- (relative to NMDA and/or AMPA-) induced motoneuronal depolarizations in the neonatal rat spinal cord in vitro (bath motoneuronal depolarizations in the neonatal rat spinal cord in vitro (bath application) and ACPD-evoked excitatory responses of rat thalamic neurons vivo (iontophoretic application). In motoneurons, the antagonist action of (R)-4-carboxy-PG was competitive, while that of the other two PGs was non-competitive. (S)-3-Hydroxy-PG also showed weak excitatory actions in both types of neuron. Supported by M.R.C. (UK) and US PHS NS 26540.

D-ASPARTATE (D-Asp) MAY STIMULATE A NOVEL EXCITATORY AMINO ACID (EAA) RECEPTOR COUPLED TO PHOSPHOINOSITIDE (PI) HYDROLYSIS. L. Littman\*. B.S. Glatt. and M. B. Robinson. Children's Seashore House; Depts. of Pediatr. & Pharmacol., U. of Penn; Phila, PA 19104 Molecular biological (Tanabe, Neuron 8:169, 1992) and pharmacological studies suggest that there are several subtypes of EAA receptors coupled to the hydrolysis of PI. The effects of quisqualate (Ouis), ibotenate, or (±)-1-aminocyclopentane-trans-1,3-dicarboxylate (tACPD) can be non-competitively inhibited by L-aspartate-8-hydroxamate (L-ABHA) or DL-2-amino-3-phosphonopropionate (DL-AP3) (Littman et al., Neurosci. Abs., 1991). In the current studies, we attempted to identify compounds that are selective for subtypes of metabotropic EAA receptors. D-Asp stimulated PI hydrolysis in hippocampal cross-sections prepared from neonatal (7-12 day old) rats (EC5g = 530 ±80 µM; max. effect = 24,500 ±3,500 DPM/100,000 DPM incorporated; n=10; mean ± SEM). L-ABHA (100 µM) and DL-AP3 (1000 µM) were much less potent as inhibitors of 0-Asp than as inhibitors of 1ACPD (L-ABHA, 14 ± 7% versus 49 ± 6%; DL-AP3, 13 ± 6% versus 46 ± 4%; n=11, p=0.01), suggesting that D-Asp may activate a subtype of metabotropic EAA receptors. Several approaches were used to further investigate the mechanism of action of D-Asp. Although D-Asp is a substrate for glutamate uptake, the high-affinity uptake inhibitor L-trans-pyrrolidine-2,4-dicarboxylate (100 µM), all on block PI hydrolysis stimulated by D-Asp (9 ± 18%, n=3). D-2-amino-5-phosphonopentanate (100 µM), an NMDA receptor antagonist, airopine (100 µM), a muscarinic receptor antagonist, pirenzepine (100 µM), an adrenergic receptor antagonist, and mianserin (100 µM), a serotonergic receptor antagonist, inhibited both hydrolysis stimulated by Ouis. Water-soluble forskolin (100 µM), alloguesting that the intracellular transduction pathways for these two agonists are similar. In neonates, the maximal responses of D-Asp and tACPD were similar. In

GLUTAMATE TRANSPORT INHIBITORS: EFFECT OF DISTAL ACIDIC GROUP SUBSTITUTIONS ON ACTIVITY R.J. Bridges. W. Daily. F. Lovering. T. Blakely. H. Koch. S. Ho. and A.R. Chamberlin\*. Depts. of Chemistry and Neurology, University of California, Irvine, CA 92717.

High-affinity transport of L-glutamate is a key step in the process of excitatory transmission, contributing to signal termination, the recycling of the transmitter, and the regulation of extracellular levels of glutamate below those which will induce excitotoxic pathology. In previous studies we identified L-trans-2,4-pyrrolidine dicarboxylate (L-trans-2,4-PDC) as a potent and selective inhibitor of sodium-dependent glutamate transport in rat brain synaptosomes. of sodium-dependent glutamate transport in rat brain synaptosomes. To investigate the structure/function relationships of this transporter in greater detail, we have now prepared several novel derivatives of L-trans-2,4-PDC in which the 4-carboxylate group has been replaced with phosphonate and sulfinate groups. In contrast to the activity of L-trans-2,4-PDC, L-trans-4-phosphonopytrolidim-2-carboxylate (L-trans-2,4-PPC), exhibited little or no ability to inhibit the synaptosomal uptake of <sup>3</sup>H-D-aspartate. The structurally analogous 4-sulfinic acid, however, potently inhibited transport. analogous 4-suitinic acid, nowever, potentily infibited transport. This specificity conferred by the terminal acidic group is also consistent with previous studies using acyclic  $\alpha$ -amino diacids. Thus, while serine-O-phosphate does not inhibit uptake, serine-O-sulfate is an effective transport blocker. This narrow tolerance for changes in the distal acidic group provides insight into molecular interactions responsible for binding to the transport protein.

# 277.13

MODULATION OF SYNAPTIC ACTIVATION OF NEOCORTICAL NEURONS BY GLUTAMATE METABOTROPIC RECEPTORS. J.P. Burke\* and J.J. Hablitz. Neurobiology Research Center, University

of Alabama at Birmingham, Birmingham, AL 35294.

Cerebral cortex contains high levels of mRNA for metabotropic glutamate receptors (Neuron, 8: 169-179, 1992). Although their function is not yet known in the neocortex, this class of receptors modulates excitability of neurons in hippocampus, septum and thalamus. We studied the actions of <u>trans-ACPD</u>, a potent and selective metabotropic glutamate receptor agonist, on evoked synaptic activity in adult rat

Conventional intracellular recordings were obtained from layer II-III neurons. Post-synaptic potentials (PSPs) were evoked via bipolar tungsten electrodes before and after bath application of 20-100  $\mu\rm M$  transbefore and after bath application of 20-100 µM transACPD. EPSPs evoked by weak stimulation were reduced by
39% (n=12). Strong stimulation evoked EPSP-IPSP
complexes. The EPSP component was reduced by 35%, and
the IPSP by 41%. Trans-ACPD caused a membrane
depolarization in 7 of 12 cells; input resistance,
tested at the original membrane potential, was not
altered. All effects were reversible upon washing.

These results show that trans-ACPD has significant
effects on synaptic transmission in the adult neocortex
and suggest that metabotronic recentors also inverses.

and suggest that metabotropic receptors play important modulatory roles in this brain region. (NS18145, MH10150).

GLUTAMATE DEHYDROGENASE MODIFIED CARBON-FIBER MICROELECTRODES WITH MILLISECOND RESPONSE TIMES.

Werner G. Kuhr\*, Paul Pantano and Michelle R. Gagnon.

Department of Chemistry, University of California, Riverside, CA 92521

The fast scan cyclic voltammetry (FSCV) experiment performed with ultramicroelectrodes has been well established for the measurement of the release and uptake
of the easily oxidized neurotransmitters (i.e. dopamine). However, most other neurotransmitters and metabolic intermediates are not oxidized at analytically useful potentials. While many strategies have been developed to immobilize enzymes onto electrodes to improve the selectivity of the electrochemical measurement, few have been constructed that afford both a small probe size and the temporal response required to follow physiologically relevant events. Recently we have developed two such enzym immobilization techniques for 10µm carbon-fiber microelectrodes that meet these requirements. Dehydrogenases are used in both cases to enzymatically oxidize the non-electroactive species (i.e. glutamate). The concurrent reduction of the enzyme cofactor, NAD+, produces the electroactive species NADH. It is this enzymatically-generated NADH which diffuses back to the carbon surface where the faradaic current generated by its oxidation during the FSCV experiment (100Vs) is proportional to the relative concentration of glutamate. Response times for the indirect detection of glutamate have been observed in the range of milliseconds to seconds, and selectivity has been demonstrated by the lack of signal generated following the introduction of aspartate. demonstrated by the lack of signal generated following the introduction of aspartate. The first technique involves the covalent attachment of the enzyme onto the carbon-fiber via a hydrophilic tether using biotin-avidin technology as the coupling technique. The second technique utilizes a micro-dialysis membrane (9,000 MW cut-off, 150µm i.d.) to entrap the dehydrogenase close to the carbon-fiber microelectrode while permitting small molecular weight analytes to diffuse through for enzymatic reaction and subsequent indirect detection. Both approaches have the advantage of having the selectivity of the electrochemical measurement easily changed simply by changing the dehydrogenase used. Work is now in progress to apply these dehydrogenase-modified carbon-fiber microelectrodes to the measurement of glutamate release and uptake in the mammalian brain. mammalian brain.

QUISQUALATE RESOLVES TWO DISTINCT [3H]GLUTAMATE METABOTROPIC BINDING SITES. M.V. Catania\*. Z. Hollingsworth, J.B. Penney and A.B. Young. Neurology Service, Massachusetts General Hospital, Boston, MA 02114.

Subtypes of metabotropic excitatory amino acid receptors have been

proposed on pharmacologic, signal transduction, and DNA bases. We assessed potential metabotropic binding site subtypes with in vitro assessed potential inclassification in the presence of saturating concentrations of N-methyl-D-aspartate (NMDA) (100 mM) and α-amino-3-hydroxy-5-methyl-4-isoxazolepropionate (AMPA) (10 mM). Under these conditions, quisqualate(QUIS), a potent agonist, and trans-1-amino-1,3-cyclopentanedicarboxylic acid (t-ACPD), a very specific agonist, were tested as competitors of [3H]glutamate binding to metabotropic receptors. QUIS (1 nM to 1 mM) resolved two distinct binding sites with apparent Ki values of 13±5 nM and 125±35 mM. The two sites were unevenly distributed. The ratio between high and low affinity sites was 3:1 in cerebellar molecular layer, 1:2 in outer cortex, 1:1 in striatum and stratum radiatum of CA1. t-ACPD (2.5 nM to 2.5 mM) stratum and stratum radiatum of CA1. t-ACPD (2.5 nM to 2.5 mM) competition curves were monophasic with apparent Ki values varying from 33 µM to 110 µM. t-ACPD displaces [<sup>3</sup>H]glutamate binding in the presence of 2.5 µM QUIS and there is no additivity between maximal concentrations of QUIS and t-ACPD. These results indicate that two metabotropic binding sites with different regional distributions can be detected in adult rat brain on the basis of their different affinities for QUIS and strongly support the existence of distinct and differentially distributed metabotropic receptors in brain.

EFFECT OF THE KAPPA AGONISTS PD117302 AND CI-977 ON POTASSIUM-STIMULATED GLUTAMATE RELEASE FROM NEURONAL CULTURES. M. A. OLESHANSKY\*, R. A. Med. Neurosci., Walter Reed Army Inst. Res., Washington, D.C. 20307-5100.

We have previously reported the effects of the kappa opioid agonists PD117302 (PD) and CIthe Kappa opioid agonists PDII 7302 (PD) and CI-977 (CI) to protect cell cultures from glutamate neurotoxicity. CI has also been shown to inhibit potassium chloride (KCI)-stimulated glutamate release from slices of rat parietal cortex. Here we evaluated the effect of CI and PD on KCI-stimulated glutamate release from primary rat cortical cultures. Two-week old primary rat cortical cultures. Two-week old neuronal cultures were stimulated with 50 mM KCl and glutamate release was determined using fluorometric detection via HPLC analysis. fluorometric detection via HPLC analysis. KCl-stimulated glutamate release was 213, 152, and 126% of basal release at 5, 10 and 15 minutes after stimulation, respectively. In cultures stimulated 10 minutes with 50 mM KCl, the presence of 50 nM CI or PD inhibited glutamate release by 27 and 37%, respectively. The ability of these novel kappa opioids to prevent EAA release in culture supports a possible presynaptic mechanism of action mediating their neuroprotective activity.

SYNTHESIS OF QUISQUALIC ACID ANALOGUES AS POSSIBLE SELECTIVE LIGANDS AT QUISQUALIC ACID RECEPTORS. R.J. Roon\*, M.K. Schulte, J.F. Koerner, N.L. Subasinghe and R.L. Johnson,
Departments of Medicinal Chemistry and Biochemistry, University of Minnesota, Minneapolis, MN 55455

Quisqualic acid (1,L-QUIS) is a potent agonist at multiple excitatory amino acid receptor subtypes in the CNS. In addition to a high affinity for kainate, AMPA, and metabotropic receptors, L-QUIS also inhibits the Ca2+/Cl- dependent glutamic acid uptake system in brain synaptic plasma membrane preparations and an N-acetyl αlinked acidic dipeptidase which hydrolyzes the brain dipeptide N-acetyl-L-aspartyl-L-glutamic acid. We have previously demonstrated that exposure of slices to L-OUIS also produces a 30-100 fold sensitization of neurons to depolarization by D- or L-2amino-4-phosphonobutanoic acid (AP4) and related phosphonates (QUIS-effect). At least two binding sites are involved in this effect; a L-QUIS "induction site" and a QUIS-sensitive-AP4 site These are novel sites of action for L-QUIS which are different from the classical AMPA and AP4 receptors. In order to gain additional information regarding the structural requirements of these sites, the quisqualic acid analogues 2-8 have been synthesized and their effects on the various components that make up the QUIS-effect investigated. While none of these compounds induced the QUIS-effect, neurons were sensitized to depolarization by 4,5 and 6 after exposure to L-QUIS. Compound 2 was a potent depolarizer of neurons, but little enhancement of potency was observed after exposure to L-QUIS.

ATYPICAL NEUROLEPTICS PREFERENTIALLY ALTER GLUTAMATE CONCENTRATIONS IN THE RAT NUCLEUS ACCUMBENS. J. G. Csernansky\*, C. T. Wrona, M. E. Bardgett, Psychiatry Dept., Wash. Univ. Sch of Med., St. Louis, MO 63110.

Previous reports have suggested that atypical neuroleptics exert mesolimbic-specific neurochemical changes in comparison to typical neuroleptics. In the present study, the effects of three atypical neuroleptics on glutamate levels in the rat nucleus accumbens (NA) and corpus striatum (CS) were compared to the effects of the typical neuroleptic, haloperidol, after acute and subchronic treatment. Animals received s.c. injections of either saline vehicle, haloperidol Animals received s.c. injections of either sainte venicle, natoperator (0.18 mg/kg), clozapine (19.4 mg/kg), sulpiride (0.95 mg/kg), or (-)-3-(3-hydroxyphenyl)-N-n-propyl-piperidine (PPP)(65.1 mg/kg) for 1 or 28 days. Relative drug doses were determined by *in vivo* competition for [<sup>3</sup>H]spiperone binding sites in the NA and CS. All three atypical drugs, but not haloperidol, significantly reduced three atypical drugs, but not haloperidol, significantly reduced glutamate concentrations in the NA after acute treatment. Glutamate levels were modestly elevated in the CS after acute haloperidol treatment. Chronic PPP and clozapine treatment were found to slightly increase NA and CS glutamate, respectively, in the left side of the brain only. The results indicate that atypical neuroleptics exert a preferential effect on glutamatergic terminals in the NA.

PHYSICAL DEVELOPMENT AND NEUROCHEMICAL CHANGES FOLLOWING NEONATAL EXPOSURE TO 1-AMINOCYCLOPENTANE-TRANS-1,3-DICARBOXYLIC ACID (TRANS-ACPD) OR D,L-2-AMINO-3-PHOSPHONOPROPIONIC ACID (D,L-AP3) IN ADULT RATS. J. P. Tizzano\*K. I. Griffey and J. A. Johnson. Lilly Research Laboratories, Eli Lilly and Company, Greenfield, IN 46140

The metabotropic (met) receptor is a recently discovered receptor of the excitatory amino acid (EAA) class. This receptor is G-protein linked to the hydrolysis of cellular phosphoinositides and is pharmacologically distinguished from inontropic EAA receptors (NMDA, AMPA or kainate). Met distinguished from biotrotopic EAA fedeptors (NMDA, AMPFA of Kallate). MEAA receptor coupling is greatly enhanced during the early period of neonatal development in the rat, suggesting that these receptors play a role in brain development. This study evaluated the postnatal treatment effects of trans-ACPD (met agonist) or D,L-AP3 (met antagonist) on physical development, glutamic acid decarboxylase (GAD) and choline acetyltransferase (ChAT) enzyme activities in various regions in the brain of during the control of the control acetyltransterase (ChAT) enzyme activities in various regions in the brain of adult rats. Six litters of CD rats were dosed i.p. (1 pup/sex/litter) on postnatal days (PND) 3-10 with saline, 25 mg/kg/day trans-ACPD, or 400 mg/kg/day D,L-AP3. Body weights were reduced in animals dosed with D,L-AP3 on PND 7-21 and at necropsy (PND 84), while relative brain weights were increased. Retinal dysplasia was found in the D,L-AP3 dosed animals, with severe atrophy of the optic nerve and chiasm. For trans-ACPD treated animals no differences were observed in body weight or gross pathology of the brain and visual system compared to control animals. GAD and ChAT activities were increased in the olfactory region of the brain in animals treated with D,L-AP3, whereas GAD activity was decreased in the striatum and cortex of animals treated with either drug. This study showed that postnatal exposure to met agents can result in persistent neurochemical alterations in the brain and profound degeneration of the visual system that are agonist/antagonist specific. agonist/antagonist specific

A NOVEL METABOTROPIC GLUTAMATE RECEPTOR AGONIST: DEPRESSION OF MONOSYNAPTIC EXCITATION OF MOTONEURONS IN THE NEWBORN RAT SPINAL CORD. M. Ishida\*, T. Saito and H. Shinozaki. The Tokyo Metro. Inst. of Med. Sci. Tokyo 113, Japan.

2S,3S,4S-2-(Carboxycyclopropyl)glycine (L-CCG-I) is a potent 25,35,45-2-(Carboxycyclopropyl)glycine (L-CCG-I) is a potent metabotropic glutamate receptor agonist. From various CCGs, we recently looked for novel agonists which were more potent than L-CCG-I or 1S,3R-ACPD. DCG-IV, (25,3R,4R,6R)-2-(4,6-dicarb-oxycyclopropyl)glycine, is so far the most potent metabotropic agonist. DCG-IV contains the moieties of L-CCG-I and (2S,3R, 4S)-CCG (L-CCG-IV), which is an NMDA agonist more potent than NMDA. In high concentrations, DCG-IV caused NMDA-like depolarities but was considerably less potent than L-CCG-IV. depolarization, but was considerably less potent than L-CCG-IV. Like L-CCG-I, DCG-IV depressed spinal reflexes evoked by stimulation of dorsal roots, in particular, attenuated monosynaptic reflexes without causing postsynaptic depolarization at significantly low concentrations. The threshold concentration of DCG-IV to depress monosynaptic reflexes was lower than 0.1 \(^{\mu}M that was markedly lower than that of L-CCG-I. It seems likely that DCG-IV and L-CCG-I act on presynaptic terminal to control transmitter release, and the mode of action of DCG-IV seems different from that of 15,3R-ACPD, L-AP4 and L-CCG-I. DCG-IV was more potent than baclofen, which is so far the most potent blocker of monosynaptic reflexes in the newborn rat spinal cord. The action nonosynapure retrexes in the newborn rai spinal cord. The action of DCG-IV was slow onset and slowly recovered, and was not blocked by any known pharmacological agents including GABA antagonists. DCG-IV did not depress the depolarizing effect of other excitatory amino acids in the newborn rat spinal motoneuron.

GLUTAMATE RECEPTOR MEDIATED PHOSPHOINOSITIDE TURNOVER IN PRIMARY CEREBROCORTICAL NEURONAL CULTURES. G. J. Birrell and F.W. Marcoux. Parke-Davis Pharmaceutical Research Division, Warner-Lambert Company, 2800 Plymouth Road, Ann Arbor, MI 48106.

Characterization of glutamate receptor stimulated phosphoinositide turnover was performed in cerebrocortical cultures in vitro. <sup>3</sup>H phosphoinositide hydrolysis was measured in cultures pre-incubated with HBSS containing 10 mM LiCl. Test

incubations (20 mins) were terminated by addition of 5% TCA.

Quisqualate, 1s, 3r-ACPD, glutamate and ibotenate evoked dose-dependent inositol phosphate formation (see table below).

### Maximal Effect

| . E         | C50 (µM) | (% of basal) | n  |
|-------------|----------|--------------|----|
| Quisqualate | 0.34     | 192          | 28 |
| 1s, 3r-ACPD | 3.1      | 224          | 24 |
| Glutamate   | 17.3     | 170          | 16 |
| Ibotenate   | 17.8     | 240          | 4  |

Dose-response curves for quisqualate and glutamate were bell-shaped and maximum responses were lower than those for 1s. 3r-ACPD or ibotenate. The selective inotropic receptor antagonists CPP (100 µM) or NBQX (1-100 µM) enhanced the effects of quisqualate and glutamate, causing a left-wards shift in the dose-response curves for these two agonists. These results suggest the occurrence of interaction between inotropic and metabotropic glutamate receptor mediated events

# EXCITATORY AMINO ACIDS: RECEPTORS IV

COMBINATORIAL RNA SPLICING ALTERS THE SURFACE CHARGE ON THE NMDA RECEPTOR. V. Anantharam\*, R.G. Panchal², A. Wilson¹, V.V. Koltchin¹, S. Cheley², S.N. Treistman¹ and H. Bayley². Topt. of Pharmacology, Univ. of Mass. Medical School, Worcester, MA 01655 and ²Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545.

Recently, a cDNA encoding a 105.5 kD, a subunit of the rat brain NMDA receptor, was isolated by expression cloning (Moriyoshi et al., Nature 354:31, 1991). Using RT-PCR, we now demonstrate alternatively spliced transcripts encoding four related NMDAR1 subunits. NMDAR1-LL contains both the 21 amino acid cassette 1 (positions 191-211) and the 37 amino acid cassette 2 (positions 885-821), while NMDAR1-SL lacks cassette 2 and NMDAR1-SL lacks cassette 2 and NMDAR1-SL lacks cassette 2 and NMDAR1 transcripts are present in rat brain RNA at ratios of LL:SL:LS:SS of about 3:12:2:8. When injected into Xenopus oocytes, RNA transcripts derived from cDNAs encoding the splice forms each direct the synthesis of glutamate-activated channels with NMDA receptor pharmacology. The currents elicited by NMDA were dramatically reduced by physiologically relevant concentrations of tethanol suggesting that the NMDAR1 subunits are targets of this drug (see S.N. Treistman et al. abstract this meeting). If a commonly used folding model is accepted, the two amino acid cassettes found in the splice variants together increase the extracellular surface charge by +11 units (+55 for a functional pentamer by analogy with the acetylcholine receptor). Hence, the presence or absence of the Cassettes may modulate functional properties of the NMDA receptor such as conductance, ion selectivity, the affinity and effects of charged ligands, and voltage-dependent block by MDAMHA (S.N.T.).

CALCIUM-INDUCED ACTIN DEPOLYMERIZATION REDUCES NMDA CHANNEL ACTIVITY. C.Rosenmund\* † and G.L.Westbrook\*. Vollum Institute, and Departments of †Physiology and \*Neurology, Oregon Health Sciences University, Portland, OR 97201.

University, Portland, OR 97201.

Calcium transients in the postsynaptic spine following activation of NMDA channels are important for the modification of synaptic transmission. However, the calcium-dependent effector site(s) have yet not been identified. The activity of NMDA channels in cultured hippocampal neurons is reduced by [Ca]i, and ATP is required for the maintenance of channel activity in the presence of extracellular calcium. This suggests that the effects of Ca and ATP are interrelated. However, in our experiments

the maintenance of channel activity in the presence of extracellular calcium. This suggests that the effects of Ca and ATP are interrelated. However, in our experiments this did not appear to be due to kinase or phosphatase activity. We therefore examined alternative Ca- and ATP-dependent processes. One possibility is actin filaments which are highly concentrated in the postsynaptic density and depolymerized by micromolar calcium; reassembly requires ATP, low [Ca]i and other factors.

Whole-cell recordings were made on cultured rat hippocampal neurons. The cell interior was dialyzed with standard intracellular solution buffered to 20 nM [Ca]i, and the NMDA channel activity was measured with pulsed application of 10 µM NMDA/2 mM [Ca]o (see Soc.Neurosci.Abstr. 383.5, 1991). Intracellular dialysis with cytochalasins B, B-dihydro or D (each 1 µM), thought to destabilize actin filaments by enhanced ATP-actin hydrolysis, antagonized the effect of ATP on NMDA currents. Similar effects were observed following 18-30 hr. pretreament with botulinum toxin C (250 ng/ml) which promotes disassembly of actin filaments via ADP ribosylation. Phalloidin (1 µM), which stabilizes polymerized actin, resulted in well maintained NMDA currents veen in absence of ATP, but phalloidin was without effect on kainate currents. Reagents which disrupt (colchicine) or stabilize (taxol) microtubules as well as protease inhibitors (leupeptin and Calpain inhibitor type 1) were also without effect. This suggests that the state of cortical actin filaments has an important influence in the activity of NMDA channel. This could be due to a direct interaction, but perhaps more likely involves another regulatory protein. Supported by USPHS grant MH46613.

SODIUM NITROPRUSSIDE INHIBITION OF THE NMDA CURRENT IN mRNA-INJECTED XENOPUS OOCYTES A. Omerovic\*, and S.R. Kelso. Department of

Biological Sciences, University of Illinois at Chicago, Chicago, Il 60680

The effect of sodium nitroprusside (SNP), a compound which spontaneously releases nitric oxide (NO), was tested in Xenopus oocytes injected with total rat brain mRNA. Using two microelectrode voltage clamp technique, NMDA-induced currents were recorded before and after perfusion of the oocytes in SNP (1uM-1mM) for 3-5 minutes. SNP induced a dose-dependent inhibition (EC50 about 3uM) of the NMDA current, with 10uM causing a reduction to 22.9±5.7% of control (9 cells). Currents gradually returned to control level 10-15 minutes after SNP wash out. The effect was specific for NMDA currents: kainate-induced currents remained unchanged after perfusion in 100 uM (5 cells) and 1 mM SNP (5 cells).

Hemoglobin, 10 and 100 uM, coapplied with SNP reduced the SNP-induced effect to  $55.8 \pm 15.8$  % (n=5) and  $108.8 \pm 15.3$  % (n=6) of control. Since hemoglobin is a scavenger for NO, this experiment suggests that SNP effect on NMDA currents involved the NO action.

To test the hypothesis that NO may act at the redox modulatory site of the NMDA receptor, SNP was applied after a strong oxidant (DTNB, 500 uM). SNP produced additional inhibition after DTNB-induced reduction of NMDA current, NEM, an alkylating agent commonly used to irreversibly change SH groups of proteins, also failed to block the SNP effect. The dose-response curve for NMDA in the presence of SNP demonstrated non-competitive inhibition. The presence of either the agonist (NMDA) or antagonist (APV) during SNP perfusion did not prevent receptor inhibition. In conclusion, SNP-induced inhibition of NMDA current is most likely a result of interaction of NO, spontaneously released by SNP, with the NMDA receptor. In this oocyte preparation it appears that NO does not act at the redox modulatory site or the agonist binding site

Augmentation of NMDA Currents by Cyclic AMP and Forskolin

Augmentation of NMDA Currents by Cyclic AMP and Forskolin

W.B. McVaugh\* and M.N. Waxham Dept. Neurobiology & Anatomy, Univ. of

Texas Med. School at Houston, Houston Texas 77025

The NMDA receptor's role in plasticity and pathology has led to

questions regarding its regulation. There is evidence to suggest that protein

kinases-specifically protein kinases A and C, may modulate NMDA receptor
mediated currents. This study examines the effect of cAMP and forskolin,

both of which lead to activation of PKA, on NMDA and kainlic acid (KA)

currents expressed in Xenonus covers injected with rat brain RNA Currents heolated currents. This study examines the effect of DAMP and to institute both of which lead to activation of PKA, on NMDA and kainic acid (KA) currents expressed in Xenopus occytes injected with rat brain RNA. Currents were examined using the two electrode voltage clamp technique. Occytes were voltage clamped at -30mV, which is about the reversal potential for chloride, to eliminate contamination of the NMDA response by the endogeneous Ca<sup>2+</sup> activated Cf current of the occyte. Experiments were conducted in frog ringer with 5mM Ba<sup>2+</sup>. Responses to 200 M NMDA or 100 M KA were recorded before and up to 90 min. after incubation with either 5mM 8Br-cAMP (15 min), 50 M forskolin (30 min), 5mM 8Br-AMP (control, 15 min) 50 M 1,9, dideoxy forskolin (control 30 min), 8 Br-cAMP augmented NMDA but not KA currents. The 8Br cAMP-induced increase in NMDA responses persisted for 45 to 60 minutes after washoff of the 8Br-cAMP (n=6). The mean increase in current amplitude was 20% at 45 minutes. Forskolin had similar effects producing an increase in steady-state amplitude in NMDA currents that was shorter lived with the current amplitude relating to baseline levels within 15 to 30 minutes (n=7). 8 BrAMP and 1,9 dideoxyforskolin had no effects on NMDA currents. These data suggest that cAMP-dependent processes, most likely activation of PKA regulates the NMDA receptor-channel complex.

## 278.7

PHOSPHORYLATION BY MULTIFUNCTIONAL PROTEIN KINASES OF THE GLUTAMATE 1 RECEPTOR EXPRESSED IN THE BACULOVIRUS/Sf9 CELL SYSTEM.

H. Yamamoto\*, D.A. Brickey and T.R. Soderling. Vollum Institute, Oregon Health Sciences Univ. Portland, OR

The cDNA for the kainate/AMPA glutamate-1 receptor (GluR1) (Hollmann et al., Nature 342: 643-648, 1989) was expressed in the baculovirus/Sf9 cell system. Western immunoblot analysis two forms of GluR1 were detected: a 102 kDa protein, which comigrated with GluR from rat brain hippocampal membranes, and a nonglycosylated 91 kDa protein. Immunostaining of the Sf9 cells with GluR1 antibody, generated against the extracellular COOH-terminal 13 residues of the receptor, indicated that some of the GluR1 was properly inserted in the Sf9 cell membrane. GluR1 phosphorylation was studied in vitro in an immunoprecipitate using exogenously added protein kinases. CaM-kinase II (10-100 nM) and protein kinase C (100 nM), but not cAMP-dependent protein kinase (cAMP-kinase), catalyzed rapid phosphorylation, predominantly on serine. These studies indicate that GluR1 is an <u>in vitro</u> substrate for phosphorylation by CaM-kinase II and protein kinase C, but not by cAMP-kinase.

CLONING OF A NMDA RECEPTOR CDNA VARIANT WITH ENHANCED SENSITIVITY TO PROTEIN KINASE C. Durand\*, P. Gregor', M.V.L. Bennett, R.S. Zukin, and G.R. Uhl'. Dept. Neurosci., Albert Einstein Coll. Med., Bronx, NY 10461 and ARC/NIDA and Depts. Neurol. and N.S.C.I., J.H.U.S.M., Baltimore,

We used PCR and the published sequence of NMDAR1 to isolate a 3.5 kb cDNA encoding an NMDA receptor (NMDAR1b) from a rat ventral midbrain library. Partial sequencing revealed nearly 100% sequence identity to NMDAR1 at the 5' and 3' ends, but restriction analysis suggested differences from NMDAR1, consistent with the possibility of alternate splicing. NMDAR1b RNA injected into Xenopus oocytes directed the translation of functional NMDA channels with electrophysiological properties distinct from those of NMDAR1. NMDAR1b homomeric channels exhibited ~4-fold lower affinity for NMDA (EC<sub>so</sub>=74±4µM) than did NMDAR1 channels (EC<sub>50</sub>=20±1μM). Co-expression of the receptor variants generated channels with an intermediate affinity for NMDA (EC<sub>50</sub> =  $36 \pm 1 \mu M$ ). NMDAR1b and NMDAR1 showed identical affinities for glycine and APV. As for NMDAR1, no response was elicited at NMDAR1b receptors by kainate or quisqualate. Pre-application of the protein kinase C activator phorbol 12-myristate 13-acetate potentiated NMDAR1b responses by ~20-fold; potentiation of NMDAR1 responses was 4.5-fold, comparable to the 5-fold enhancement noted for rat brain message. These findings suggest a role for receptor variants in determining NMDA channel properties.

### 278.6

PROPERTIES OF NMDA-ACTIVATED CHANNELS IN CELL-ATTACHED PATCHES FROM HIPPOCAMPAL CULTURES K.Z. Haas\*, R.C. Araneda & M.V.L. Bennett. Dept. Neuroscience, Albert Einstein Coll. Med., Bronx, NY 10461.

NMDA receptors play an important role in plasticity and excitotoxicity. Regulation of NMDA receptors by second messenger systems may be involved in these processes. We are studying NMDA-activated channels in cell-attached patches on central neurons to examine possible regulation of the receptors by second messenger systems.

Activity from cell-attached patches was recorded with electrodes containing NMDA (30  $\mu$ M) and glycine (1  $\mu$ M) in rat hippocampal cultures (1 to 2 weeks old). NMDA-activated channels had a conductance of 57+6 pS as determined from the slope of I-V relationships. Open time distributions were fit well with a single exponential which gave a mean open time of 4.4+0.74 ms. at -60 mV. At hyperpolarized potentials there was a decrease in the mean open time of the channel (30 % at -130 mV), but opening rate was unaffected. In control experiments when PCP (1 µM) was included in the pipette, NMDA channels were blocked near the resting potential, but depolarization relieved the block. In preliminary experiments we found that serotonin (0.1 - 3 µM) increased the open probability but not the mean open time. However, the PKC activator phorbol 12-myristate 13-acetate (100 -300 nM) produced no change in the NMDA-channel properties.

PROTEIN KINASE A MODULATES A HIGH AFFINITY KAINATE RECEPTOR EXPRESSED IN HUMAN EMBRYONIC KIDNEY CELLS. F.A. Taverna, L.-Y. Wang, X.-P. Huang, J.F., MacDonald, and D.R. Hampson\*. Faculty of Pharmacy and Dept. of Physiology, University of Toronto, Toronto,

Canada.

Recent cloning studies have revealed a large diversity of non-NMDA receptors (GluR1-GluR7). We and others (L.-Y. Wang et al. (1991) Science 253,1132, P. Greengard, J. et al. (1991) Science 253,1135) previously reported that non-NMDA receptors in neurons are subject to neuromodulation by PKA. Among the cloned receptors, GluR6 possess a potential consensus site for PKA phosphorylation on the loop between third and fourth transmembrane domain. We therefore examined PKA regulation of GluR6 expressed in HEK 293 cells. Membranes from human embryonic kidney (HEK) cells transiently expressing GluR6 showed a high level of <sup>3</sup>H-kainic acid binding. Membranes from cells expressing GluR6 were solubilized with Triton X-100 and immunoprecipitated using an antibody raised against a peptide corresponding to the C-terminus of GluR6. A major immunuoreactive band was observed at about M<sub>T</sub>=109 kDa. The immunoprecipitated receptor was incubated with the catalytic subunit of PKA and P3<sup>2</sup>-ATP; autoradiography of the sample after electrophoresis and transfer to nitrocellulose revealed a P<sup>32</sup>-labelled protein corresponding to GluR6.

Application of kainate to GluR6 transfected HEK 293 cells induced inward

protein corresponding to GluR6.

Application of kainate to GluR6 transfected HEK 293 cells induced inward currents which displayed a dramatic desensitization. This desensitization was blocked by treatment with the lectins WGA or Con A. Direct injection of the catalytic subunits of PKA into Con A pretreated HEK cells significantly potentiated kainate evoked currents with no effect on reversal potential. This potentiation was reversed by subsequent injection of the specific PKA inhibitory peptide. Comparisons of kainate dose-response curves before and after PKA injection showed a marked increase in maximal current amplitude with less change in apparent K<sub>D</sub>. These results further suggest that PKA plays an important role in modulating EAA receptors and may potentially contribute to synaptic plasticity. We thank Drs. Egebjerg, Heinemann, and Wenthold for cDNAs and antibodies.

SUSTAINED ENHANCEMENT OF NMDA RECEPTOR-MEDIATED SYNAPTIC POTENTIAL BY ISOPROTERENOL IN RAT AMYGDALAR SLICES. P.W. Gean<sup>\*</sup>, C.C. Huang and J.H. Lin. Dept. of Pharmacol, Coll. of Med., National Cheng-Kung Uni., Tainan, Taiwan, R.O.C. Norepinephrine (NE) and isoproterenol (Iso) acting on

the beta-adrenergic receptors have been shown to exert long-term regulation of excitatory neurotransmission. One notable example is norepinephrine-induced long-lasting potentiation (NELLP) of perforant path evoked potentials in the hippocampal dentate gyrus. In view of NE induced plasticity requires the activation of NMDA receptors, it became of interest to test the possible effects of Iso on the synaptic potential mediated by NMDA receptors (EPSP<sub>NMDA</sub>).

EPSPNMDA was isolated pharmacologically by application of a solution containing CNQX (10  $\,\mu$ M) and bicuculline (20  $\,\mu\,\text{M})$  in the rat basolateral amygdala (BAL) neurons using intracellular recording techniques. Superfusion of Iso (15  $\mu$  M) produced a long-lasting enhancement of EPSP<sub>NMDA</sub> (165±11%, n=14). Pretreatment the slices with propranolol (10  $\mu$ M) completely prevented the effect of Iso (97±4%, n=6) confirming the mediation by betaadvenergic receptors. Furthermore, the persistent increse in EPSP<sub>NMDA</sub> induced by Iso was mimicked by forskolin (50  $\mu$ M) suggesting the possible mediation by c-AMP. These results provide the direct evidence for adrenergic modulation of excitatory amino acid neurotransmission in the vertebrate central nervous system.

DIFFERENTIAL BLOCK BY INTRACELLULAR MG2+ OF THE NMDA RESPONSE IN WHOLE-CELL AND OUTSIDE-OUT PATCH RECORDINGS. Y .- Y. Li\* and J. W. Johnson. Department of Behavioral Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

The NMDA receptor is regulated physiologically by many mechanisms. Intracellular Mg<sup>2\*</sup> has been shown to block the single-channel current of the NMDA receptor at positive potentials. However, it is unclear how intracellular Mg<sup>2\*</sup> affects the NMDA current at the whole-cell level nor by what mechanism(s). The effects of intracellular Mg2+ on the NMDA response in both whole-cell and outside-out patch recordings have been studied.

The whole-cell and outside-out patch responses to 30 µM NMDA plus 10 µM glycine were recorded from cultured neurons of embryonic rat brain cortex at holding potentials from -60 to 60 mV. The current was measured in the absence and presence of various concentrations of MgCl in the pipette solution. The results of the whole-cell recordings show that the I-V relationships with 1, 10 or 30 mM Mg<sup>2</sup> significantly different from that of control, indicating that intracellular Mg2+ seems to have little if any effect on whole-cell NMDA current at these concentrations. In contrast, Mg<sup>2+</sup> significantly reduces the total charge flowing through NMDA receptors in outside-out patches at positive potentials, as well as reducing the single-channel current. The block is dose-dependent. At a holding potential of +60 mV and with 1, 3 or 10 mM Mg<sup>2+</sup> in the pipette, the single-channel current is reduced to 64, 34 and 19% and the total charge to 82, 50 and 31% of the control values, respectively. Neither the mean open time nor the burst length was increased by Mg2+, suggesting that the data are not consistent with the traditional open channel block model. It is not clear why the reduction in the whole-cell current is inconsistent with the reduction in the total charge flow of patches. One possibility is that the concentration of  $Mg^{2^{\star}}$  in the cell was not well controlled. Further studies will address this apparent inconsistency. Supported by NIMH grant R29-MH45817.

## 278.13

CHARACTERIZATION OF GLUR6(R) GLUTAMATE RECEPTOR CHANNELS EXPRESSED IN HEK-293 CELLS. L.A. Raymond\*. C.D. Blackstone and R.L. Huganir, Depts. of Neurology and Neuroscience, Howard Hughes Med. Inst., Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205

GluR6 is one of a family of recently cloned non-NMDA glutamate receptor subunits with high affinity for kainate, and it contains a consensus site for phosphorylation by cAMP-dependent protein kinase (PKA) in the proposed major intracelluar loop region. Unlike GluR1-4 (A-D), the recombinant GluR6 subunit exhibits desensitizing current responses to kainate when expressed in <u>Xenopus</u> oocytes (Nature 1991;351:745). Using a mammalian expression system, we have further characterized the ion channel properties of the recombinant GluR6(R) subunit. Current responses to glutamate and kainate were recorded using the whole-cell patch clamp technique. After lifting the cell, agonists were applied by a rapid perfusion system; solution exchange was complete within 2 ms. High concentrations of both glutamate and kainate elicited currents which desensitized completely, following a single exponential time course. The time constant for desensitization was 9-11 ms for 4 mM kainate. The desensitization time constant for glutamate-evoked current was dependent on agonist concentration, with values of 7-11 ms for high concentrations (>300 uM) and 80-120 ms for low concentrations (10 uM). The I-V relation for both glutamate (1 mM) and kainate (4 mM) exhibited slight outward rectification. The dose response curve for glutamate-activated peak currents revealed an EC50 of 200-300 uM. Using the HEK-293 expression system, we are now examining the functional effects of PKA phosphorylation of the GluR6(R) subunit. Supported by the NIH and HHMI.

#### 278.10

EFFECT OF TRANSMEMBRANE VOLTAGE ON THE NMDA RECEPTOR REDUCTION AND OXIDATION PROCESSES LH Tang\* and E Aizenman, Dept. of Physiology, Univ. of Pittsburgh School of Medicine, Pittsburgh, PA 15261.

We have examined the effects of the reducing agent DTT and the oxidizing agent DTNB on the NMDA receptor redox modulatory site (Aizenman et al., Neuron, 2:1257; 1989) under different transmembrane voltages. In cultured rat cortical neurons using the whole-cell patch-clamp technique, DTT (4 mM, 2 min) produced a similar level of potentiation of NMDA (30  $\mu M$ )-induced responses at either -60 mV or +30 mV holding potential (1.8±0.1 fold increase at -60 mV, n=8;  $1.8\pm0.1$  fold increase at +30 mV, n=8). In contrast, DTNB (500 µM, 2 min) was a more effective oxidizing agent at -60 mV than at +30 mV: Compared to the DTT-potentiated response, DTNB decreased NMDA responses by 62±3% when the oxidation took place at -60 mV (n = 13), while it only decreased these responses by  $39\pm2\%$  at +30 mV (n = 13). Interestingly, the NMDA response peak current to voltage relationship became substantially outwardly rectifying when the oxidation took place at a positive holding Furthermore, this rectification was not reversed after holding the cell under study at -60 mV for >5 minutes. The -60/+30 mV response amplitude ratios were: 2.0+0.1 (control, n=13), 1.8+0.2(oxidation at -60 mV, n=11),  $1.4\pm0.1$  (oxidation at +30 mV, n=13). Supported by NIH grant NS29365.

### 278.12

L- AN D-HOMOCYSTEATE ACTIVATE CURRENTS OF NMDA TYPE IN CEREBELLAR GRANULE CELLS IN CULTURE. M. Sciancalepore\*, G. Kilic, and E. Cherubini. Biophysics Laboratory. International School for Advanced Studies, Trieste, Italy 34014.

The patch clamp technique (whole-cell and outside-out configuration) was used to study whole-cell and single channel currents activated by L- and D-homocysteate (Land D-HC) in cerebellar granule cells in culture. Both Land D-HC (15-50  $\mu M)$  at holding potential of -50 mV, induced inward currents (in the range of 20-50 pA) which after an initial peak slowly declined to a plateau. These currents were reversibly blocked by AP-5 (20µM). AMPA (100µM) and kainate (50uM) induced inward currents which were unaffected by AP-5 (20 $\mu M$ ) but were blocked by CNQX (10 $\mu M$ ).

In the outside-out configuration L- and D-HC elicited single-channel events the same conductance mean open time and reversal potential of the NMDA-activated single channel currents. In the presence of  ${\rm Mg}^{2+}({\rm 2mM})$  L- and D-HC-activated single channel events became voltagedependent. It is concluded that in cerebellar granule cells in culture, both L- and D-HC activate the same NMDAreceptor channel complex.

## 278.14

RAT BRAIN GLUTAMATE (AMPA) RECEPTORS RECONSTITUTED IN LIPID BILAYERS EXHIBIT LOW AND HIGH CONDUCTANCE STATES. V. Vodyanoy<sup>1</sup>. BA. Bahr<sup>2</sup>. V. Suppiramaniam<sup>1</sup>. R.A. Hall<sup>2</sup>. M. Kessler<sup>2</sup>. M. Baudry<sup>2</sup>. and G. Lynch<sup>2</sup>. Institute for Biological Detection Systems, Dept. of Physio. and Pharm., Auburn Univ., Auburn, Al. 36849; <sup>2</sup>Center for the Neurobiology of Learning and Memory, Univ. of Calif., I rivine, CA 92717; <sup>3</sup>Dept. of Biological Sciences, Univ. of Southern Calif., Los Angeles, CA 90089.

AMPA (or-amino-3-hydroxy-5-methylisoxazole-4-propionic acid) activates a specific subclass of glutamate receptors (AMPA receptors) that mediate most of the excitatory synaptic transmission in the brain. In order to study their channel properties, AMPA receptors were solubilized from adult rat forebrain with n-oxly glucoside, partially purified 30 to 60-fold, and incorporated into planar bimolecular lipid membranes (BLMs). The channel conductance of the reconstituted receptors was activated by kainate with an EC<sub>50</sub> of 600 nM and a Hill coefficient of 2.77 ± 0.35, and by AMPA with an EC<sub>50</sub> of 174 nM and a Hill coefficient of 2.77 ± 0.54. This suggests that cooperative binding of three agonist molecules is required to induce channel opening. Conductance through the reconstituted AMPA receptors was blocked by the specific antagonist DNOX (dinitroquinoxaline-23-dione, 2.5 µM). Conversely, the nootropic compound aniracetam (1-anisoyl-2-pyrrolidinone) significantly increased the conductance activated by AMPA. When the partially purified AMPA receptors were reconstituted by the tip-dipping method in asymmetric saline conditions ('outside-out configuration'), the addition of 300 nM AMPA to the pseudocatracellular solution elicited single ion channel fluctuations. The current activity mediated by AMPA was completely inhibited by 1 µM DNOX. Analysis of currents revealed that AMPA receptors have two distinct conductance levels of 60 ± 16 and 11.7 ± 1.6 p. (mean ± S.D.) and a reversal potential of 6 ± 5 mV. These results suggest t

VOLTAGE-DEPENDENT KINETICS OF CURRENTS ACTIVATED BY GLUTAMATE OR KAINATE. I.M. Raman' & L.O. Trussell Neuroscience Tra Program & Dept. of Neurophysiology. U. Wisconsin - Madison, 53706.

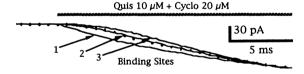

The response of neurons to agonists of the AMPA-kainate receptor shows a variable degree of voltage dependence (e.g., Mayer & Westbrook, 1984, J.Physiol 354:29). We have examined this effect in isolated, voltage-clamped neurons and outsideout membrane patches from the avian nucleus magnocellularis. Under conditions in which the NMDA receptor is inactive, peak and steady-state responses to glutamate and kainate showed a non-linear I-V (current-voltage) relation. With high agonist concentrations, the chord conductance between +60 and +80 mV was 2-3 times higher than the conductance between -60 and -80mV. Five lines of evidence suggest that the apparent voltage dependence in the conductance change induced by glutamate and kainate is due to a voltage dependence in the kinetics of channel gating.

- 1) The increase in conductance at positive potentials was associated with an increase in the time constant of desensitization to glutamate
- 2) The time course of current decay following removal of kainate lengthened with depolarization, and exactly matched the glutamate desensitization time course at any
- 3) In the presence of kainate, voltage jumps to positive potentials resulted in a gradual increase in outward current over several milliseconds.
- 4) Rectification in the I-V relation was much more pronounced with lower agonist
- 5) Non-linearity in the I-V relation persisted in nominally Ca/Mg-free bath solutions.

Mechanisms for voltage dependence which invoke voltage-dependent single channel conductance or channel block either by divalents or by agonist are not sufficient to explain these data. Rather, in the AMPA/kainate receptor, the kinetics of channel gating are sensitive to membrane potential. Supported by NS28901 and the Klingenstein

NUMBER OF AGONIST BINDING SITES ON AMPA/KAINATE CHANNELS. I.D. Clements, Y. Sahara\* & G. L. Westbrook. Vollum Institute, Oregon Health Sciences Univ., Portland, OR. 97201.

The number of agonist binding sites on AMPA or kainate channels, and the binding rate of glutamate to these receptors is not known. These parameters are useful in predicting the number of subunits which form the channel, and in estimating the occupancy (saturation) of the postsynaptic receptors following evoked glutamate release. The number of binding sites was estimated by analysing activation kinetics of ensemble currents following rapid application of quisqualate (Quis) to outside-out patches from cultured hippocampal neurons. Cyclothiazide (Cyclo, 20 µM) was used to reduce desensitization of the Quis response. Responses to high concentration of Quis (200  $\mu$ M + Cyclo) peaked in within 1 ms and desensitized to 70% of peak ( $\tau$ =16 ms). At lower concentrations (10  $\mu$ M) agonist binding was rate limiting and the activation timecourse was sigmoidal. Fits of the activation timecourse suggests that two molecules of Quis are required to open AMPA/kainate channels in the presence of cyclothiazide. However preliminary analysis of domoate responses suggest that >2 molecules of domoate are required for channel opening. Supported by NS26494 and MH46613.

## 278.19

PENTOBARBITAL INTERACTION WITH SINGLE KAINATE CHANNELS IN MOUSE CORTICAL NEURONS. L.L. Stockbridge\* and F.F. Weight.

Laboratory of Molecular and Cellular Neurobiology, National Institute on Alcohol Abuse and Alcoholism, Rockville, MD 20852.

Previous whole-cell patch clamp studies in this laboratory have indicated that pentobarbital (PTB) inhibits kainate currents in a concentrationdependent manner (1). We are currently investigating the actions of PTB on single kalnate channels in order to elucidate the mechanism of this inhibition

Cortical neurons from day 15-17 fetal mice are plated on collagen/polylysine-coated plates and cultured for 1-4 weeks in an enriched MEM medium prior to use. Single kainate channels are recorded in excised outside-out patches. Data is analyzed with commercial software designed for ligand-gated channels (RC Electronics). This allows observations of for ligand-gated channels (RC Electronics). This allows observations of changes in charge per unit time as well as changes in amplitude distributions and channel kinetics. Patch pipettes contain (mM): CsCl 155, MgCl<sub>2</sub> 2, EGTA 5, HEPES 10 (pH 7.4). The bath solution (HBS) contains (mM): NsCl 150, KCl 5, CaCl<sub>2</sub> 2, MgCl<sub>2</sub> 1, HEPES 10, TTX 0.0002. An exchange solution of HBS plus kalnate (50  $\mu$ M) and 2-amino-5-phosphonovaleric acid (100  $\mu$ M) is applied to initiate kalnate channel response while blocking NMDA channels. Under these conditions, at least two types of kainate channels have been distinguished with similar conductance and behavior to those already described for cerebellar granule cells (2). The addition of 100  $\mu$ M PTB appears to inhibit all kainate channel activity. Concentration-dependency and the mechanism of single-channel current inhibition are being explored.

PROTEIN KINASE C MODULATES GLUTAMATE RECEPTORS (KAINATE/AMPA) AND SYNAPTIC TRANSMISSION IN CULTURED HIPPOCAMPAL NEURONS. L.-Y. Wang, E. M. Dudek, M. Browning, and J.F. MacDonald\*. Dept. Physiol., University of Toronto, Toronto, Canada and Dept. Pharmacol. University of Colorado, Denver, Co. 80262,

Recent evidence strongly suggests that Protein Kinase C (PKC) plays a key role in modulating excitatory amino acid transmission in the CNS (D. Muller et al. P.N.A.S. 85:6997, 1988, G.-Y. Hu et al. Nature 328:426, 1987). Excitatory amino acid channels are themselves a potential target for functional regulation and phosphorylation by PKC. For example, the non-NMDA receptor clones (GluR1-7) possess a number of potential sites of phosphorylation by this kinase. We therefore investigated the effects of PKC on kainate and AMPA currents and on minature excitatory synaptic currents (mEPSC) recorded from cultured hippocampal neurons The intracellular injection of the catalytically active fragment of PKC (PKCM) potentiated kainate and AMPA currents and/or reversed the ongoing decline in amplitude following rupture of the patch. Reversal potentials were not altered by PKCM. Furthermore, application of the PKC activator phorbol ester, PMA (100 nM), significantly increased the open probability of kainate (20 μM) channels recorded in the cell-attached configuration. In order to examine synaptic receptors, we evoked mEPSCs from the cell soma by making brief, localized applications of sucrose (0.25 M) in the presence of TTX (500 nM), MgCl<sub>2</sub> (1 mM), AP5 (20  $\mu$ M) and bicuculline (10 µM). These mEPSCs demonstrated a rapid rise time to peak followed by a mono-exponential decay (time constant of about 2 ms). In individual neurons comparisons of mEPSCs were made before and after the injection of PKCM. PKCM significantly increased the amplitude and/or the time constant of decay of the mEPSCs. These data suggest that postsynaptic glutamate (non-NMDA) receptors are under the modulation of protein kinase C in hippocampal neurons and may potentially contribute to synaptic plasticity. Supported By The MRC.

MODIFICATION OF THE IONIC PERMEABILITY OF AMPA RECEPTORS BY

MODIFICATION OF THE IONIC PERMEABILITY OF AMPA RECEPTORS BY IN VITRO MUTAGENESIS. Bochet P., Curutchet P., Dutriaux A., Lambolez B., Prado de Carvalho L., Nalivalko E., Stinnakre J.\* and Rossler J. Institut Alfred Fessard and L. MBCM\*, CNRS, 91198, Glf sur Yvette, Cedex, France. The sequences of several, very analogous AMPA receptor subunits have been determined. These subunits form receptors with different electrophysiological properties. In Xenopus ocytes GluR1 forms an homomeric receptor permeable to Ca<sup>2+</sup> lons and displaying a strong inward rectification. GluR2 does not seem to form functional receptors in the ocyte. But the association of GluR1 and GluR2 forms a non rectifying heteromeric receptor impermeable to Ca<sup>2+</sup>. Through the construction of chimeras and point mutants, structural determinants of ion flow have been determined. It is now established for instance that a single residue (Glutamine in GluR1 versus Arginine in GluR2) in the putative second transmembrane domain accounts for the different properties of GluR1 and GluR2. Substitution of this Glutamine in GluR1 by an Histidine at the same position results in a mutant subunit with properties which differ from both GluR1 and GluR2.

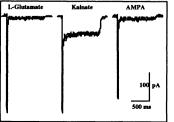

|  | rectification | Calcium permeability |
|--|---------------|----------------------|
| GluR1  | +             | +                    |
| GluR2  | no response   |                      |
| GluR1 + GluR2  | _             | -                    |
| $\text{GluR1} + \text{GluR1}(\text{Q} \rightarrow \text{R})$ | -             | _                    |
| $GluR1(Q \rightarrow H)$                                     | _             | +                    |

In conclusion the nature of the residue in the Glu/Arg position accounts for both the  ${\rm Ca^{2+}}$  permeability and the rectification properties but different mechanisms are implicated since both properties can be dissociated.

EXPRESSION OF UNIQUE AMPA/KAINATE RECEPTOR CHANNELS IN

EXPRESSION OF UNIQUE AMPA/KAINATE RECEPTOR CHANNELS IN GLIAL PRECURSOR CELLS. V. Gallo<sup>2</sup>. D. K. Patneau, and M. L. Mayer. Lab. of Cellular and Molecular Neurophysiology, NICHD, NIH. Bethesda, MD 20892. We have studied glutamate receptor channels in a permanent cell line (CG-4) of rat glial cell precursors established from primary cultures of bipotential oligodendrocyte-type 2 astrocyte progenitors (Louis et al., 1992). In voltage-clamp recordings from proliferating progenitor cells, characterized by bipolar morphology, concentration-jump application of L-glutamate, kainate and AMPA evoked large inward currents which rapidly desensitized (see figure); there was no response to NMDA. The kinetics of the onset of desensitization were similar for all three agonists, with time constants of 8.9±2.1, and 9.2±2.4 ms for L-glutamate, kainate and AMPA, respectively. However, the steady-state response to kainate was on average 6 times larger than to L-glutamate. Responses to kainate exhibited less desensitization in cells with multipolar morphology, as well as in exhibited less desensitization in cells with multipolar morphology, as well as in oligodendrocytes or type 2 astrocytes derived from CG-4 progenitor cells, suggesting the existence of a developmental switch for AMPA/kainate receptor expression AMPA/kainate receptors on CG-4 glial cell progenitors exhibit different

functional properties than any of the previously characterized glutamate receptors expressed in neurons. The kinetics of kainate responses are similar to recombinant heteromeric GluR5(Q)/KA-2 receptors GIUNN(Q)/KA-2 receptors (Herb et al., 1992), but the sensitivity to AMPA suggests that additional or different subunits may be expressed in CG-4 progenitor cells

GABAA RECEPTORS: EFFECT OF A POINT MUTATION phe-64-->leu IN THE α-SUBUNIT AFFECTING AGONIST-DEPENDENT GATING OF THE RECEPTOR CHANNEL AND CELLULAR EXPRESSION OF RECEPTOR SUBUNIT MRNAS IN HUMAN BRAIN AND SPINAL CORD. P. Malherbe\*, E. Sigel#, R. Baur#, S. Kellenberger<sup>#</sup>, E. Persohn, A. Müller, P. Seeburg<sup>±</sup> and J.G. Richards. Pharma Division, Preclinical Research, F.Hoffmann-La Roche Ltd. CH-4002 Basel, #Institute of Pharmacology, University of Bern, Switerzland, +Laboratory of Neuroendocrinology, Heidelberg, FRG.

GABAA receptors are ligand-gated chloride channels and the targets for a variety of psychoactive drugs. The precise location of binding sites for GABA and competitive antagonists in the primary structure of the receptor is not known. Using in vitro mutagenesis, we have found that a single mutation of the phe-64->leu in the  $\alpha$ -subunit but not homologous mutation in the B2- and  $\gamma 2$ -subunits- strongly decreases the apparent affinity of GABA-dependent channel gating from 6  $\mu$ M to 1260  $\mu$ M for the  $\alpha$ 182 $\gamma$ 2 channel expressed in *Xenopus* oocytes. Furthermore, the apparent affinities of the competitive antagonists bicuculline methiodide and SR 95531 were decreased 60 to 200-fold. Our results suggest a close functional and structural association of  $\alpha\textsubunits$  with the agonist-antagonist binding site.

The cellular expression of mRNAs encoding different human GABAA receptor subunits ( $\alpha$ 1-3,  $\beta$ 1,  $\gamma$ 1,2 and  $\delta$ ) in human brain and spinal cord was investigated by *in situ* hybridization histochemistry. Pronounced differences in hybridization signals in various regions of the CNS –hippocampus, dentate gyrus, visual cortex, substantia nigra and lumbar spinal cord- were obtained with the isoform-selective probes.

Molecular and Electrophysiological Characterization of an Allelic Variant of the Rat α6 GABA<sub>A</sub> Receptor Subunit. <u>F. Tan+, T.P.</u> Angelotti∇, K.Kelly\*+, and R.L. Macdonald+#. Depts. of Neurology+, Pharmacology⊽, and Physiology#, Univ. of Mich., Ann Arbor, MI 48104.

A 1.45 kb DNA sequence encoding the rat α6 GABAA receptor subunit (nucleotides #33-1483) was cloned from a Sprague-Dawley rat brain cDNA library by PCR amplification. Dideoxy sequencing of two individual clones revealed that the nucleotide sequence differed at only one basepair (T $^{480}$  ---> G) from that published previously. This difference altered the deduced amino acid sequence, producing a conservative amino acid substitution (His 121 ---> Gln). A Gln residue is present at the same location in the bovine  $\alpha 6$  subunit. Restriction endonuclease analysis of the total PCR product verified the authenticity of the base pair change and demonstrated that this variant of the rat  $\alpha$ 6 subunit is the only allele found in this particular rat brain library; the original allele was not present. The  $\alpha$ 6 subunit with the  $\beta$ 1 and  $\gamma$ 2S subunits were transiently expressed in L929 cells. Whole-cell recordings obtained from the cells demonstrated that GABAA receptors with the expected GABA and benzodiazepine pharmacology were produced. Excised outside out single channel recordings from the same cells revealed that GABA elicited brief duration openings to a 33 pS main conductance level and to at least one smaller (approximately 21 pS) subconductance level. Thus this allelic variant of rat  $\alpha 6$  subunit could assemble with other subunits to form a functional GABAA receptor with similar properties to the original allelic form.

GABAA-RECEPTOR HETEROGENEITY: IMMUNOPURIFICATION OF RECEPTOR SUBTYPES FROM THE BRAIN AND ANALYSIS OF RECOMBINANT RECEPTORS. D. Benke, S. Merlens, F. Knoflach, J.A. Benson\* and H. Mohler. Institut of Pharmacology, University of Zürich, CH-8006 Zürich, Switzerland.

Supported by a grant from the Lucille P. Markey Charitable Trust Fund

The structure of GABAA-receptors is characterized by an extended heterogeneity of constituent subunits classified into five groups ( $\alpha_{1-6}$ ,  $\beta_{1-4}$ ,  $\gamma_{1-3}$ ,  $\delta$ ,  $\rho$ ). To characterize various GABA<sub>A</sub>-receptor subtypes we  $p_1$ -4, n-3, o, p). To chalacterize various GABA<sub>R</sub>-receptor subtypes we developed subunit-specific antisera for their immunoisolation and analyzed their drug binding properties and subunit associations. Four receptor populations with distinct pharmacological properties were identified by immunoisolation with o<sub>1</sub>-o<sub>2</sub>, o<sub>3</sub>-o<sub>4</sub> and o<sub>5</sub>-subunit-specific antibodies. The receptor population containing the o<sub>1</sub>-subunit displayed

antibodies. The receptor population containing the  $\alpha_1$ -subunit displayed benzodiazepine receptor (BZR) type I pharmacology whereas receptors containing the  $\alpha_3$ -subunit corresponded to type II BZRs. Receptors containing the  $\alpha_5$ - or  $\delta$ -subunit displayed novel drug binding profiles and thus, appear to contain novel types of BZR binding sites. The role of receptor heterogeneity with regard to the efficacy of BZR ligands was tested electrophysiologically on recombinant receptors. Two subunit combinations differing in their  $\alpha$ -subunits were analyzed ( $\alpha_3\beta_2\gamma_2$ ,  $\alpha_5\beta_2\gamma_2$ ). While bretazenil and divaplon acted as partial agonists on both receptor types, abecarnil displayed differential efficacies acting as full agonist on  $\alpha_3\beta_2\gamma_2$  and as partial agonist on  $\alpha_5\beta_2\gamma_2$ . Thus, subtyoe-specific variations in the intrinsic activity of BZR  $\alpha$ 5 $\beta$ 2 $\gamma$ 2. Thus, subtype-specific variations in the intrinsic activity of BZR ligands may contribute to novel therapeutic profiles.

## 279.4

Assembly of α1β1 and α1β1γ2S GABAA Receptor Subunits Produce Unique Ion Channels with Dissimilar Single-Channel Properties. I Ryan-Jastrow\*+, T.P. AngelottiV, R.L. Macdonald+#. Neurology<sup>+</sup>, Pharmacology<sup>∇</sup>, and Physiology<sup>#</sup>, Univ. of Michigan, Ann Arbor, MI 48109

Various dimeric and trimeric combinations of GABAA receptor (GABAR) subunits were transiently expressed in mouse L929 cells. Whole-cell (W-C) and single-channel (S-C) electrophysiological techniques were utilized to determine if the subunits assembled into a random heterogenous mixture of receptor configurations or if a preferred form of the receptor existed. Expression of  $\alpha1\gamma2S$  and  $\beta1\gamma2S$  subunits produced no functional ion channels, whereas  $\alpha 1\beta 1$  and  $\alpha 1\beta 1\gamma 2S$  subunits produced GABARs with dissimilar W-C and pharmacological properties. analysis of  $\alpha 1\beta 1$  and  $\alpha 1\beta 1\gamma 2S$  receptors demonstrated that for each, GABA elicited openings to both a main (15 and 29 pS respectively) and a subconductance level (10 and 21 pS respectively). Open, closed, and burst duration histograms for both recepters were best fit with similar exponential time constants, but the relative proportions of each component differed. The lack of heterogeneity in the S-C properties among different single-channel patches suggest that there most likely exists configuration for each of the two assembled ion channels, and furthermore, the lack of  $\alpha 1\beta 1$  dimeric receptors upon co-expression with the  $\gamma 2S$  subunit demonstrates that the \(\alpha 1\beta 1\gamma 2S\) receptor is the preferred final form of the GABAA receptor.

Supported by a grant from the Lucille P. Markey Charitable Trust Fund

## 279.6

CHANNEL PROPERTIES OF A PICROTOXIN-RESISTANT GABA RECEPTOR. H.-G. Zhang, R.H. ffrench-Constant, & M.B. Jackson\*, Depts. of Physiology and Entomology, University of Wisconsin, Madison, WI 53706.

A picrotoxin-resistant mutant of Drosophila was previously identified on the basis of insecticide resistance, and cloning showed that the resistance gene codes for a GABAA receptor (ffrench-Constant et al., P.N.A.S. 88, 7209, 1991). In order to establish the nature of this mutation at the cellular and channel level, we have used patch clamp techniques to study the GABA responses of dissociated cultured fly larvae neurons from the resistant and sensitive strain. Pressure application of 50 µM GABA to fly neurons elicited chloride currents. In neurons from wild-type flies these responses were very sensitive to picrotoxin, with 50% blockade at approximately 0.1 µM. In contrast, the resistant mutant had GABA responses that were 50% blocked by approximately 150 µM. These experiments confirmed the nature of the mutation with a direct physiological assay of the receptor. GABA application to excised outside-out patches elicited single channel currents in neurons from both wild-type and resistant flies. The single channel conductances were  $24.6\pm.4$  (n=4) and  $27.5\pm.3$  (n=3) for neurons from wild-type and resistant flies, respectively. Thus, a mutation can alter the way in which the channel is blocked, while only slightly altering the channel's permeation properties.

279.7

ACTIVATION OF PKC ENHANCES BENZODIAZEPINE POTENTIATION OF RECOMBINANT GABA, RECEPTORS. N.J. Leidenheimer\*, P.J. Whiting, R.A. Harris. Dept. of Pharmacol., Univ. of Colorado and Denver VANC, Denver, Co 80262 and Merck, Sharp and Dohme Res. Lab., Essex, U.K.

The GABA, receptor is a heteromeric ligand gated-ion channel which is the site of action of benzodiazepines (82s). Recently, this receptor has been shown to be regulated by protein phosphorylation (Leidenheimer, et al. 1991). The present experiments determine if phosphorylation alters the ability of BZs to potentiate GABA, receptor function. Human cDNAs for α<sub>1</sub>β<sub>1</sub>γ<sub>21</sub> GABA<sub>A</sub> receptor subunits were coexpressed in Xenopus cocytes and GABA responses were measured by two-electrode voltage clamp (-70 mV). GABA (10 μM) responses averaged 326±56 nA (n=10, ±SEM) and were potentiated by 300 nM diazepam (181±42% potentiation, n=8, ±SEM). Following bath application of the PKC activator PMA (5-25 nM) GABA responses were decreased to 106±53 nA (n=10, ±SEM), significantly different from control, ps0.005) and diazepam potentiation was increased to 387±82% (ps0.05, n=8). The ability of PMA to inhibit GABA responses was significantly correlated with the enhancement of diazepam potentiation (r=0.7, ps0.05, n=9). The inactive phorbol ester PMM (25 nM) did not significantly alter either GABA responses (control=438±90 nA; PMM=513±158, ±SEM, n=4) or diazepam potentiation (control=169±29%; PMM=169±27%, ± SEM, n=4). Furthermore, lowering the clamping voltage toward the chloride equilibrium potential resulted in decreased GABA responses but did not alter diazepam action. Therefore, it appears that PKC-dependent phosphorylation increases the ability of BZs to enhance GABA<sub>A</sub> receptor function. We are currently examining the effect of PMA on BZ potentiation on other recombinant receptors.

## 279.9

POSTNATAL DEVELOPMENT OF GABA, RECEPTORS IN RAT SYMPATHETIC NEURONS. Luis G. Aguayo\*, Inan M. Alarcón and Floria C. Pancetti. Neuropharmacology Laboratory, Institute of Chemistry, Catholic University at Valparaíso, Valparaíso, Chile.

It was previously suggested that some physiological and pharmacological properties of GABA<sub>A</sub> receptors changed during neuronal development (Smart and Constanti, 1990; Cherubini, et al., 1991). We have examined the effects of several Constant, 1990; Cherubint, et al., 1991). We have examined the effects of several modulators of the GABA<sub>A</sub> receptor including Zn<sup>2+</sup>, benzodiazepines, barbiturates and ethanol on acutely isolated rat (1 day to 4 months) superior cervical ganglion neurons using patch-clamp recordings. Within 12 hours after birth the neurons were sensitive to GABA (1-200  $\mu$ M). The relationship between the amplitude of the current ( $I_{GABA}$ ) and the concentration of GABA (EC<sub>50</sub> = 24  $\mu$ M; n = 14) in newborn neurons was fitted with a slope (Hill coefficient) close to 1.0. Adult neurons had a similar EC50 to that of newborn neurons, but the slope was steeper and better fitted with a Hill coefficient close to 1.5 (n=13, p<0.05).

The concentration of Zn²- that reduced  $l_{caba}$  by 50% ((Cs<sub>0</sub>) was 37±16  $\mu$ M in newborns (n=8) and 43±15  $\mu$ M in adults (n=12). Consistent with the evidence indicating that GABA<sub>A</sub> receptors blocked by Zn<sup>2+</sup> lack the γ2 subunit (Draguhn et al., 1990), we found that benzodiazepines (flurazepam [10 µM] and diazepam [1-1000 nM]) had minimal effects on IGABA activated in newborn and adult neurons (n= 18). Ethanol (40 mM) reduced the amplitude of  $I_{GABA}$  to  $87\pm8\%$  in adult neurons (n=6) and  $74\pm10\%$  of control (n=5) in newborn neurons (<7 days).

In conclusion, we found that the sensitivity of the GABA receptor to GABA and Zn<sup>22</sup> did not change during in situ neuronal development. However, only in newborn neurons the relationship between the amplitude of the response and the concentration of GABA was better described by a single binding site. In addition, the GABAA receptor was more sensitive to ethanol in newborn than in adult neurons. (Supported by a Grant from NIAAA).

QUANTITATIVE AUTORADIOGRAPHY OF [3H]TBOB BINDING TO GABAA RECEPTORS. S.Y. Sakurai\*, D.E. Burdette and R.L. Albin. Dept. of Neurology, U. of MI., Ann Arbor, MI

We have characterized in vitro quantitative [3H]TBOB We have characterized in vitro quantitative [3H]TBOB autoradiography in rat brain. Tissue sections were prewashed in buffer containing 1 mM EDTA. Kinetic and pharmacology experiments were performed at room temperature on 20 μm sections of adult rat brain in 20 nM [3H]TBOB. Binding to the GABAA agonist site and benzodiazepine site (BZ) was also assessed using [3H]muscimol and [3H]flunitrazepam ([3H]Flu), respectively, in resielly discent rections

[3H]muscimoi and [3H]fluntrazepam ([3H]flu), respectively, in serially adjacent sections.
[3H]TBOB binding reached equilibrium at 60 minutes. Under these conditions specific binding was greater than 80-90% of total binding. Isoguvacine, a GABAA agonist, inhibited [3H]TBOB binding in a dose-dependent manner. [3H]TBOB binding was inhibited by picrotoxin, a cage convulsant. Bicuculline, a GABAA antagonist, enhanced [3H]TBOB binding in cerebellar granule cell layer but had no effect on binding in forebrain structures. Clonazepam, a benzodiazepine, enhanced [3H]TBOB binding throughout brain.

The relative distribution of [3H]TBOB binding sites was subiculum

The relative distribution of [3H]TBOB binding sites was subiculum medial cortex > nucleus accumbens > lateral cortex > stratum moleculare of dentate gyrus = cerebellar molecular layer > stratum oriens of CA3 > globus pallidus > striatum > cerebellar granule cell layer. The distribution of [3H]TBOB, [3H]Flu and [3H]muscimol binding in adjacent sections was not closely correlated. Supported by USPHS NS19613, NS01300, NS15655 and NS07222.

HETEROGENEITY OF GABAA RECEPTOR IN THE RAT BRAIN, T. Araki\* H.Kiyama and M. Tohyama. Dept.of Anatomy and Neuroscience,

Osaka Univ, Med. Sch., Osaka, JAPAN
The GABAA receptor, which is a member of the ligand-gated ion channel family of receptors, has been shown to be comprised of a number of subunits and variants. Using in situ hybridization histochemistry, we investigated the distri-bution of neurons expressing various GABAA receptor subunits in the mature rat central nervous system and the developmental changes of the expression in the fetal rat brain.

In the fetal brain, no  $\alpha_1$  subunits were detected. Among other subunits,  $\alpha_4$  and  $\beta_1$  subunits were seen in both the developing neuronal layers and undifferentiated neuroepithelium, while  $\alpha_3,~\beta_2,_3$  and  $\gamma_2$  subunits were seen only in the developing layers.

In the mature brain, differences were found in the distribution of the subunits. Among various subunits,  $\gamma$  subunits showed unique patterns. The distribution of the  $\gamma_2$  subunit often overlapped with that of neurons expressing glutamic acid decarboxylase, an enzyme synthesizing GABA. On the other hand, the  $\gamma_1$  subunit was observed in relatively restricted areas, most of which only weakly expressed the

Our results indicate that regulation of expression of GARAA receptor subunits is both region-specific and devel-opmental stage specific, and that some subunits are likely to be involved in neuronal development.

PHENOTYPIC VARIATIONS IN GABA, RECEPTOR FUNCTION K.M. Garrett\*, I. Niekrasz and T.W. Seale, Depts. of Physiology and Pediatrics, University of Oklahoma HSC, Oklahoma City, OK 73190

The GABA, receptor contains pharmacologically and structurally discrete binding sites for GABA, benzodiazepines, barbiturates and convulsants acting at the chloride ionophore. Previous behavioral studies have shown that C57BL/6J and DBA/2J inbred mice vary in their responses to drugs which modulate GABAergic transmission. The present study extends the behavioral phenotypic characterization of these two inbred strains to additional drugs acting on the GABA, receptor. C57BL/6J mice were significantly less sensitive than DBA/2J to tonic convulsions produced by DMCM and picrotoxinin; however, no significant differences were observed in their sensitivity to tonic seizures elicited by bicuculline or NMDA. Diazepam had a significantly larger anxiolytic-like effect in C57BL/6J than in DBA/2J mice a significantly more efficacious in C57BL/6J than in DBA/2J mice. There was significantly more efficacious in C57BL/6J than in DBA/2J mice. There was no difference in the effects of buspirone in the mirrored-chamber apparatus between these two strains of mice. Anxiogenic-like behaviors were measured by a modification of the mirrored-chamber paradigm. DBA/2J mice were more sensitive than C57BL/6J mice to the anxiogenic-like effects of DMCM. DBA/2J mice were also significantly more sensitive than C57BL/6J mice to decreases in motor activity produced by diazepam. These results suggest that inherent differences occur in specific behavioral responses to drugs that modulate GABA, receptor function in C57BL/6J and DBA/2J mice, and these differences may be due to polymorphisms that quantitatively or qualitatively alter the subunits of GABA, receptors.

## 279.12

CHARACTERIZATION OF THE GABA-A RECEPTOR COMPLEX IN THE BRAIN OF THE SHARK. M.G. Corda\*, M. Orlandi, M.G. Pibiri, M.R. Murqia, D. Lecca, S. Salvadori (I), A.M. Deiana (I) and O. Giorqi. Dept. of Exp. Biology, Section of Neurosci. and (I) Dept. of Animal Biology and Ecology, Univ. of Cagliari, Italy.

(1) Dept. of Animal Biology and Ecology, Univ. of Cagliari, Italy.

The present study was designed to investigate the phylogenesis of the functional interactions between the different components of the GABA-A receptor complex in primitive vertebrate species. To this aim, we examined the modulatory effects of GABA and benzodiazepine (BZ) receptor ligands on the binding of 35S-T-butylbicyclophosphorothionate (35S-TBPS) in the brain of the shark (Scyliorhinus canicula) and in the rat brain. GABA inhibited 35S-TBPS binding in a concentration-dependent manner both in the shark brain (IC50: 0.5 µM) and in the rat brain (IC50: 0.5 µM) and in the rat brain (IC50: 0.5 µM) and in the rat brain (IC50: 0.5 µM) and in the rat brain. The convulsant B-carboline derivative methyl 6,7-dimethoxy-4-ethyl-beta-carboline-3-carboxylate (DMCM) increased 35S-TBPS binding in the rat brain (Emax: +35 % at 0.1µM) but had no effect in the shark brain (up to 1 µM). In line with the above results, DMCM failed to induce convulsions in sharks in doses up to 40 mg/kg, i.v. was unable to induce sedation and to antagonize the convulsions elicited by pentylenetetrazol (150 mg/kg, i.v.) was unable to induce sedation and to antagonize the convulsions elicited by pentylenetetrazol (150 mg/kg, i.v.) and bicuculline (1 mg/kg, i.v.) in sharks. Our results reflect significant differences in the allosteric interactions between the components of the GABA-A receptor complex in the CNS of mammals and lower vertebrates.

REPEATED SWIM-STRESS REDUCES GABAA RECEPTOR α1 SUBUNIT mRNAS IN MOUSE HIPPOCAMPUS. P.Montpied\* A. Weizman, R. Weizman, K. A. Kook, A.L. Morrow, and S.M. Paul. CNB NIMH Bethesda, MD 20892.

We have recently demonstrated (J.P.E.T. 249: 701,1989) that repeated swim-stress in mice reduces the density and/or functional properties of the GABA A/ benzodiazepine-chloride ionophore receptor complex (GABA/BZD). Using [3H] Ro 15-1788 to label GABA /BZD receptors in vivo, we have observed a reduction in the apparent number (Bmax) of GABA /BZD receptors measured 24 hrs after the last session of repeated swim-stress (7 or 14 days). The most robust reduction in GABA/BZD receptors was observed in hippocampus, an area with both a high density of GABA/BZD receptors and glucocorticoid receptors. Moreover, adrenalectomy prevented the stress-induced reduction in GABA/BZD receptors (Brain Res. 519:341,1990). We hypothesized that stress may induce an alteration of GABA, receptor expression (perhaps at the level of the transcription) and investigated the effects of repeated stress on GABAA a subunit mRNA levels in hippocampus. Following 7 daily sessions of swim-stress, there was a trend (non significant) toward a reduced level of  $\alpha$ 1 subunit mRNAs in the hippocampus. At 14 days, the 4.8 Kb and 4.4 Kb  $\alpha$ 1 subunit mRNAs were reduced by 47.3% +/-6.5 (n=16; p < 0.05) and 39.8 % +/-7.6 (n=16; p < 0.05) respectively. In contrast, no significant alteration in the levels of GAD (glutamic acid decarboxylase) or Bactin mRNAs were observed suggesting that stress alters the GABA<sub>A</sub> α1 subunit mRNAs without affecting mRNAlevels in general. The stress induced reduction GABAA receptor all subunit mRNA may underlie the reduction in GABA/BZD receptor number observed following repeated stress. The possible role of stress hormones such as the glucocorticoids in mediating the stress-induced reduction in GABA/BZD receptors is currently being studied.

## 279.15

ONTOGENY OF GABAB BINDING IN RAT BRAIN. S.M. Turgeon\* and R.L. Albin. Neuroscience Program and Dept. of Neurology, University of Michigan, Ann Arbor, Michigan 48109.

Quantitative receptor autoradiography using [3H]GABA under selective conditions was used to characterize the ontogeny of GABAB selective conditions was used to characterize the ontogeny of GABAB binding in rat brain. GABAB binding was assessed at P1, P3, P7, P14, P21, and P28. GABAB binding peaked at P3 in the globus pallidus, substantia nigra, and CA3 region of the hippocampus. At P7, GABAB binding peaked in the deep cerebellar nuclei, striatum, nucleus accumbens, and CA1 region of the hippocampus. GABAB binding peaked at P14 in the superior colliculus, neocortex, and at P21 in the medial geniculate. At P28, GABAB binding peaked in the molecular layer of the cerebellum and the binding peaked in the molecular layer of the cerebental and the regional distribution of GABAB binding was identical to that seen in adults (Chu et al., Neurosci., 34:341, 1990). Following these regionally specific peaks during the first four weeks of life, binding decreased globally from P28 to adult (P42). The regionally specific ontogenic regulation of GABAB binding suggests a role for GABAB binding sites in neuronal development. A developmental function for GABA<sub>B</sub> receptors is supported by evidence that GABA<sub>B</sub> receptor agonists and antagonists can modulate neurite outgrowth in vitro (Michler L Development) 8.463, 1900). (Michler, J. Devl. Neurosci., 8:463, 1990). Comparative pharmacology of early postnatal and adult GABAB binding will be discussed

Supported by NS01300, NS 19613, and NS07222.

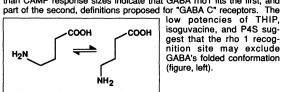

## 279.17

GABA RHO 1 EXPRESSION. T. Kusama, C.E. Spivak\*, V. Dawson and G. Uhl, Lab. Mol. Neurobiol., ARC/NIDA & Depts. Neurol. & Nsci., JHUSM, Box 5180, Baltimore, MD. 21224.

The GABA rho 1 receptor, highly expressed in retina, readily forms a homooligomeric GABA-gated chloride channel that displays the insensitivity to baclofen and bicuculline that provided the first definition proposed for GABA C receptors by Johnston. GABA rho activities of agonists including CACA and CAMP, whose selective potency defines GABA C receptors in a second fashion, the less specific trans isomers TACA and TAMP, and other rigid GABA analogs were assessed to

further characterize the rho 1 site.

Xenopus oocytes expressing GABA rho1 after intranuclear injection of pcDNA1RHO1 were tested under two electrode voltage clamp; COS cells transfected by electroporation were tested by patch clamp. The rank order of agonist potencies was TACA> GABA> muscimol> TAMP> CAMP> CACA> isoguvacine>> piperidine-4-sulfonate(P4S)≥ THIP. Hill coefficients were > 1.5. The predominant channel conductance was 28 pS. Higher TACA than CACA but lower TAMP than CAMP response sizes indicate that GABA rho1 fits the first, and

nition site may exclude GABA's folded conformation (figure, left).

IMPORTANCE OF INHIBITORY GABAB AUTORECEPTORS IN MOD-ULATING ENDOGENOUS GABA RELEASE FROM RAT STRIATAL SLICES. R.D. Mayfield\* and N.R. Zahniser. Dept. Pharmacol., Univ. of Colorado Hlth. Sci. Ctr., Denver, CO 80262.

Endogenous GABA efflux evoked by multiple periods of electrical field stimulation was examined in rat striatal slices. The GABA uptake inhibitor NO-328 (tiagabine; 10 nM - 50 µM) increased basal outflow (spontaneous release) of GABA from marginally detectable levels to 0.25-0.35 ng/mg/ml at higher concentrations. Electrically-evoked GABA overflow (stimulated release) also increased as a function of NO-328 concentration (EC<sub>50</sub>=2.0 μM) and was completely Ca<sup>2+</sup>-dependent. An invariant observation in these experiments was that basal GABA outflow continuously decreased as a function of superfusion time and that stimulation-evoked GABA overflow decreased 25-30% in response to the second of two periods of stimulation (S2/S1 ratios=0.70-0.75). The observed decreases in GABA efflux could not be explained by the amount of GABA lost to the superfusion buffer (percent fractional release), direct depletion of releasable pools of GABA, or slice viability. However, the GABAB receptor antagonist 2-hydroxy-saclofen (SAC, 316 µM) not only enhanced stimulated GABA release but also resulted in S2/S1 ratios of unity when superfused throughout both periods of stimulation. When SAC was superfused throughout the second stimulation period only, evoked GABA overflow was almost 2-fold greater stimulation period only, evoked GABA overflow was armost 2-fold greater than that evoked by the corresponding initial period of stimulation (SAC-free) and was approximately 30% greater than S1 responses that were observed in the presence of SAC. These results suggest that GABAB autoreceptors provide an important negative feedback control of endogenous GABA release from striatal slices. Experiments are currently underway to determine whether similar GABAB modulation occurs pallidal slices. (Supported by DA 04216 and AA 07464)

### 279.16

DOES GABA MODULATE THE EXPRESSION OF IMMEDIATE EARLY GENES IN RAT HIPPOCAMPAL SLICES DURING DEVELOPMENT? T. Massamiri\*, K. Bugra, M. Khrestchatisky and Y. Ben-Ari, INSERM Unit 29, 123 Bd. de Port-Royal, Paris, 75014, France

Induction of immediate early gene (IEG) expression occurs following a variety of stimuli and is characterized by a rapid onset and a transient effect. Induced transcription factors are thought to subsequently alter the expression of effector genes leading to long term changes. Since the neurotransmitter GABA has an excitatory action in the developing hippocampus (Cherubini et al., TINS, 1991 12: 515-519), as opposed to an inhibitory effect in the adult brain, we examined, in a comparative study, ssion of mRNAs for c-fos, c-jun and zif/268 during development.

Using an in-vitro slice model preparation, pooled hippocampal slices were treated with either kainate (200nM), GABA (0.3-3mM) or bicuculline (15µM), prior to RNA extraction. Relative estimations of specific mRNA were determined by a reverse transcriptase coupled

polymerase chain reaction followed by southern blots.

In the adult hippocampal slice model, kainate induces the expression of mRNA for c-fos but not c-jun, or zif/268, within 30 minutes of treatment

Activation and inhibition of the GABAergic system by GABA or bicuculline, respectively, has no effect on the basal expression of mRNA for zif/268 at the three different ages studied: P0, P4, and P37. Further studies are now in progress to look at the expression of other IEGs upon modulation of the GABAergic system during development.

## 279.18

CHRONIC ETHANOL ADMINISTRATION INDUCES DOWNREGULATION OF GABA, RECEPTOR α SUBUNIT POLYPEPTIDE EXPRESSION IN RAT CEREBRAL CORTEX. M.C. Mhatre and M.K. Ticku\*. Univ. TX Hlth. Sci. Ctr., Dept. of Pharmacology, San Antonio TX 78284-7764

Chronic ethanol administration results in the development of tolerance and dependence. The repeated ethanol administration results in a reduction in GABA, receptor—mediated <sup>36</sup>Cl uptake in cortical synaptoneuro somes and primary cultured neurons. We and others have shown that it also results in a 40–50% reduction in GABA, receptor  $\alpha$  subunit mRNA levels in the rat cerebral GABA, receptor  $\alpha$  subunit mRNA levels in the rat cerebral cortex. In the present study, we investigated the expression of  $\alpha_1$ ,  $\alpha_2$  and  $\alpha_3$  subunits of GABA, receptor by immunoblotting using polyclonal antibodies raised against  $\alpha_1$ ,  $\alpha_2$  and  $\alpha_3$  subunit polypeptides (Zezula et al. Brain Res. 563:325, 1991). Comparison between the control and ethanol treated rats revealed 47% reduction in the  $\alpha_1$  subunit (51 KDa), 37% reduction in the  $\alpha_2$  subunit (53 KDa) and 29% reduction in  $\alpha_3$  subunit polypeptide (59 KDa) and 58% reduction in the lower band (53 KDa) of  $\alpha_3$  subunit. In summary, these data indicate KDa) of  $\alpha_3$  subunit. In summary, these data indicate that chronic ethanol treatment results in a decrease in the expression of GABA, receptor subunits which may underlie alterations in GABA, receptor function, and could be related to cellular adaptation to the function. al disturbance caused by ethanol. Supported by NIAAA grant #AA04090.

TUESDAY PM

CHANGES IN GABA-A RECEPTOR BINDING AND EXPRESSION FOLLOWING CHRONIC INTERMITTENT ETHANOL IN RATS. D.W. SAPP, R. TYNDALE, N. KOKKA, A.J. TOBIN AND R.W. OLSEN. Dept. Pharmacology, Brain Research Institute, UCLA, CA 90024.

As we reported before, there is a decrease in PTZ-induced seizure threshold in rats given chronic intermittent ethanol (CIE) compared to control animals. This decrease persists for at least a month following discontinuation of alcohol administration. A change in PTZ-induced seizure sensitivity suggests that the GABA-A receptor complex is involved in the differences observed between CIE and control animals. In cerebellum the binding of the partial inverse agonist Ro15-4513 to diazepam-insensitive (DZ-IS) sites is decreased in CIE. This change appears to be a lowered affinity and not a change in Bmax. A possible explanation for the change in binding is altered subunit composition. Analysis of mRNA from the cerebellum of CIE and control rats does not show any change in the expression of the a6 subunit which is reported to be responsible for DZ-IS binding. If  $\alpha$ 6 expression remains unchanged, then some other mechanism must be involved in altering DZ-IS binding in CIE rats. Similar studies on receptors in other brain regions are in progress to attempt to explain increased seizure susceptibility. Supported by AA07680.

OPIOIDS: BEHAVIOR

## 280.1

CHRONICALLY ADMINISTERED NALTREXONE DUPLICATES THE MAJOR BEHAVIORAL EFFECTS OF ACUTELY ADMINISTERED DRUG IN AUTISTIC CHILDREN. B.H. Herman\*, I.F. Borghese, G.S. Asleson, E. Lukens, M.B. Benoit, I. Chatoor, P. Papero, L. Anselmi, & C. Fitzgerald, Brain Res Cen & Depts Psychiat, Children's National Med Cen & Depts Psychiat & Behav Sci & Peds, GWUSM, Washington, D.C. 20010

There are several lines of evidence implicating a role of opioid peptides in autism (for review see Herman, In J.J. Ratey (ed.), Mental Retardation. Developing Pharmacotherapies, 1991). In a preliminary study of 13 autistic children (3 to 12 y.o.), single doses of naltrexone (0.5 to 2.0 mg/kg, once per week), were found to induce dose-dependent decreases in the severity of autistic symptoms as measured by the Childhood Autism Rating Scales (CARS) and four additional measures of hyperactivity including the Conner's Parent Teacher Rating Scales (CPTRS) (Herman et al., AACAP 7: 52 (1991). Here we show that naltrexone produce similar effects when chronically administered.

Subjects were 15 autistic children (3 to 13 y.o.). Drug included surrounding placebo (P) trials (P1, P2) and four naltrexone doses (0.5, 1.0, 1.5, and 2.0 mg/kg). Each drug dose was administered three days a week, every other day. Results indicated that chronically administered naltrexone significantly decreased CARS scores (p < 0.005) and CPTRS scores (p < 0.05). For CPTRS,no significant differences were obtained among the 3 drug days. A subgroup of autistics (N =11/15) also showed evidence of reduced extraneous motor behavior scores under naltrexone. Therefore, these data indicate that chronically administered naltrexone significantly decreases the severity of autistic symptoms and the hyperactivity associated with autism, and that repeated administration does not result in an attenuation of these effects. Sponsored by NICHD, FDA and DuPont Pharmaceuticals.

## 280.3

Differential sensitization and tolerance to the discriminative stimulus properties of *mu*-opioids. <u>C.A. Paronis\* and S.G. Holtzman</u>, Dept. of Pharmacology, Emory Univ. Sch. of Med., Atlanta, GA 30322.

Analgesic potency of  $\mu$ -opioids is increased by continuous exposure to naloxone (NX) and decreased by continuous exposure to morphine (MOR) or other  $\mu$ -agonists. We examined whether similar changes in potency are seen in the discriminative stimulus (S^D) properties of  $\mu$ -agonists. Male Sprague-Dawley rats, trained to discriminate 3.0 mg/kg MOR from saline in a discrete trial avoidance/escape procedure, were tested for generalization to MOR or fentanyl (FEN) before and 24 hr after 7-day se infusions of 0.3 mg/kg/hr NX, 0.75 mg/kg/hr MOR, or 0.01 mg/kg/hr FEN. Both MOR and FEN infusions produced tolerance, the magnitude of which varied with both the infused drug and the test drug. The MOR generalization curve was shifted to the right after either a MOR infusion or, to a lesser extent, a FEN infusion; the MOR ED50 for generalization increased from 1.43 to 2.23 mg/kg and from 1.39 to 1.73 mg/kg, respectively. The FEN generalization curve, however, was shifted roughly 3-fold to the right following either MOR or FEN, the FEN ED50 for generalization increasing from 0.011 to 0.39 mg/kg and from 0.014 to 0.042 mg/kg, respectively. Following NX infusion, a sensitization to the SD properties of opioids was seen and, as with tolerance, the magnitude of the sensitization varied between the test drugs. Our results show that while both tolerance and sensitization to the SD properties of  $\mu$ -opioids develop, a) the decreases and increases in potency are not necessarily proportional for a given drug, and b) the magnitude of potency changes varies between drugs. (Supported by Grants DA00541, K05 DA00008 and Fellowship F31 DA05484.)

## 280.2

INHIBITION OF MORPHINE TOLERANCE BY NITRIC OXIDE SYNTHESIS INHIBITOR NG-nitro-L-arginine. Y.A. Kolesnikov, C.G. Pick and G.W. Pasternak\*. The Cotzias Laboratory of Neuro-Oncology, Memorial Sloan-Kettering Cancer Center and Departments of Neurology & Neuroscience and Pharmacology, Cornell U. Medical College, New York, NY 10021

The NMDA antagonist MK801 reportedly blocks the development of morphine tolerance in rodents. Nitric oxide (NO) is an important messenger molecule in various physiological functions in the central nervous system and in the periphery which is produced by the enzyme NO synthetase. Activation of MNDA receptors increases the release of NO. In the current study, we examined the effect of the NO synthesis inhibitor NG-nitro-L-arginine (I-NOARG) on tolerance to morphine analgesia in mice using the tailflick assay. After daily injections of morphine (5 mg/kg, s.c.) for 5 days no mice were analgesic compared to 60% after a single dose. In contrast, 40% of mice receiving combined doses of I-NOARG (2 mg/kg, i.p.) along with the morphine were analgesic after 5 days (p < 0.05). I-NOARG did not affect the response to single morphine doses and after 5 days of repeated dosing with I-NOARG a single morphine dose still elicited analgesia in 50% of mice. These results suggest that NO may have an important role in the development of morphine tolerance which may involve an NMDA/NO pathway.

## 280.4

NALTRINDOLE (NTI) IS LESS EFFECTIVE THAN ITS BENZOFURAN ANALOG (NTB) IN ATTENUATING MORPHINE'S DISCRIMINATIVE STIMULUS, STRAUB TAIL AND DEPENDENCE EFFECTS. P. M. Beardsley. O. T. Lopez and J. L. Bloss\*. Neurological Diseases Research Dept., G.D. Searle & Co., 4901 Searle Parkway, Skokie, IL 60077.

It has been reported that i.c.v. administration of the delta opioid receptor antagonists, naltrindole (NTI), and its non-equilibrium analog, naltrindole 5'-isothiocyanate, could prevent the development of morphine tolerance and dependence (Abdelhamid, 1991). In order to further explore the range of interactions between delta opiate receptor antagonists and the pharmacology of morphine, NTI, and its benzofuran analog, NTB, were examined following s.c. administration for their ability to affect naloxone-precipitated jumping in morphinized mice, morphine's Straub-tail effects in mice, and morphine's discriminative stimulus effects in rats. NTB dose-dependently (0.5–3.0 mg/kg) reduced naloxone-precipitated jumping, and (0.1–2.0 mg/kg) morphine's discriminative stimulus effects, although NTI had little effect on either response up to 90 mg/kg. Both NTB (0.5–3.0 mg/kg) and NTI (15–90 mg/kg) were able to attenuate morphine-induced Straub-tail, but only NTB was able to completely abolish it.

OPPOSITE EFFECTS OF  $\mu$  AND K OPIOID RECEPTOR AGONISTS ON ABSENCE EPILEPSY IN WAG/RIJ RATS. W. Lason\*, B. Przewlocka, E.L.J.M. van Luijtelaar, A.M.L. Coenen and R. Przewlocki. Institute of Pharmacology, Polish Academy of Sciences, Cracow, Poland and Department of Psychology, University of Nijmegen, Nijmegen, The Netherlands.

Involvement of endogenous opioids and their receptors in the mechanisms of absence epilepsy has previously been postulated (Snead, '82; Lason et al. '92). In the present study we investigated the effects of opioid receptor agonists on spike-wave discharges (SWD's) in WAG/Rij opioti receptor agoinist on spike-wave discharges (SWDS) in WAO/RIJ rats, which are regarded as a genetic model of absence epilepsy. The selective  $\mu$  opioid receptor agonist DAMGO (0.2-0.7  $\mu$ g/5 $\mu$ l, icv) increased in a dose-dependent manner the number as well as the total duration of SWD's, and this effect was significantly attenuated by the irreversible  $\mu$  receptor antagonist  $\beta$ -FNA (10  $\mu$ g/5 $\mu$ l, icv) which was not effective in itself. On the other hand, the  $\kappa$  receptor agonists U50,488H, 150 50 3 and PDI-17302 (50 150  $\mu$ g/5 $\mu$ l, icv) and expendently 109,593 and PD117302 (50-150  $\mu$ g/5 $\mu$ l, icv) all dose-dependently decreased the number of SWD's and in a higher dose they decreased also the mean duration of the SWD's. The order of the potency of these  $\kappa$  agonists in suppressing SWD's was as follows: U69,593, U50,488H and PD117302

and PD117302. It can be concluded that the  $\mu$  and  $\kappa$  receptor activation modulates the number and mean duration of the SWD's in WAG/Rij rats in an opposite manner. Furthermore, the obtained data may point to putative antiepileptic properties of  $\kappa$  opioid receptor agonists in absence epilepsy. This research was supported by TNO CLEO grant A 83 of the Research Committee on Epilepsy of the Division for Health Research

and to grant KBN 4 1626.

### 280.7

Tyr-MIF-1 ANTAGONIZES KAINIC-INDUCED, FOCAL SEIZURES AND WET DOG SHAKES. J.Thomas, W.L. Nores, V.A. Kenigs, R.D.Olson, A.J.Kastin, and G.A.Olson. Dept. of Psychology, University of New Orleans, New Orleans, LA 70148.

The effects of the endocessor

New Orleans, New Orleans, LA 70148.

The effects of the endogenous opiate antagonist, Tyr-MIF-1, on kainic acid-induced focal seizures and wet dog shakes (WDS) were investigated. Male rats were injected IP with Tyr-MIF-1 (1 mg/kg) or saline 15 min prior to testing with kainic acid (KA) (10 mg/kg, IP). The latencies to focal seizures and WDS, the total number of focal seizure episodes, and the number of WDS in each of three 30-min periods following injection were scored for 90 min after KA injection. Pretreatment with Tyr-MIF-1 increased the latency to the first focal seizure. The mean number of focal seizure episodes over the test session was also lower in episodes over the test session was also lower in animals pretreated with Tyr-MIF-1. The time course of the appearance of WDS was delayed by pretreatment with Tyr-MIF-1, with the largest number of WDS occurring during the third, 30-min interval in Tyr-MIF-1-treated rats, but during the second 30-min period in saline pretreated rats. The results suggest that Tyr-MIF-1 plays a role in the modulation of focal seizures and shaking behavior and should be investigated further.

## 280.9

THE NEUROPHARMACOLOGY OF OPIATE-INDUCED MUSCLE RIGIDITY IN THE RAT. M. B. Weinger', T. Lin. C. Lau, G. F. Koob. Dept. of Anesthesiology, UC San Diego & Dept of Neuropharmacology, Scripps Clinic, San Diego, CA 92093. Large doses of opiates produce muscle rigidity. While previous studies have

identified discrete sites which may mediate this rigidity [Brain Res 544: 181, 1991] and several putative neurochemical mediators of rigidity have been proposed [Anesthesio] 71: 249,1989], the neuropharmacology of this effect remains to be elucidated. After Animal Care Committee approval, anesthetized male Wistar rats were implanted with icv cannulae. The  $\alpha$ -2 agonists dexmedetomidine (DEX; 0-10 $\mu$ g) and ST91 (0-100 $\mu$ g), the  $\alpha$ -1 antagonist prazosin (PRZ; 0-30 $\mu$ g), the 5HT2 antagonist ketanserin (KET; 0-100 $\mu$ g), or the opiate antagonist methylnaloxonium (MN; 0-4 $\mu$ g) were injected icv in 10  $\mu$ l by a blinded observer. Left hindlimb electrodes were used to record EMG activity. After a 15 min baseline, ALF (500µg/kg sc) was given, and EMG activity was recorded for 60 min. Time-course data were analyzed using 2way ANOVA. Log dose data were then corrected to reflect % of baseline rigidity (based on the zero dose for each group) and the lines-of-best-fit were calculated. MN, DEX, and ST91 dose-dependently antagonized ALF rigidity. The slopes of these 3 dose-effect curves were virtually identical; MN and DEX showed similar potency, while ST91 was less. The fact that the slopes of  $\alpha$ -2 agonists' dose-effect curves were almost identical to that of MN suggests possible similarity in either site of action or second messengers involved. In contrast, neither KET nor PRZ significantly affected rigidity. The lack of effect of icv KET suggests a peripheral site of action after systemic dosing. PRZ's inactivity contrasts with previous work [Neuropharmacol 28:1163, 1989]; thus the role of α-1 receptors in opiate rigidity remains unclear.

EFFECTS OF NALOXONE ON SEIZURE SUSCEPTIBILITY IN RATS CHRONICALLY TREATED WITH PICROTOXIN. V.A. Kenigs, W.L. Nores, J. Thomas, R.D. Olson, A.J. Kastin, G.A. Olson, and J.H. Mclean.\* Department of Psychology, University of New Orleans, New Orleans, LA 70148.

From previous formal and pilot investigations conducted in our laboratory, there was reason to hypothesize that in a repeated injection conducted in our laboratory, there was reason to hypothesize that in a repeated injection paradigm, naloxone (NAL) might have effect on the period of akinesis which follows picrotoxininduced focal seizures. Male rats received IP injections of saline or NAL 20 min prior to SC injections of picrotoxin (3 mg/kg). Rats were observed for 45 min on 3 test days at 5-day intervals for behavioral signs of seizures. Latencies, incidences, durations, and numbers of Latencies, incidences, durations, and numbers of episodes were scored for selected categories of seizures. Repeated injection of picrotoxin made NAL pretreated animals more susceptible to generalized tonic-clonic (GTC) and generalized clonic (GC) seizures on the third day of testing, but had no effect on akinetic seizures. The latencies to none of the seizure categories studied were significant. The effects of NAL on GTC and GC seizures suggest NAL has pro-convulsant actions on some types of seizures as well as anti-convulsant effects on focal seizures.

NALOXONE CANCELS COMPULSORY APPROACHING SYNDROME IN CATS WITHOUT THE CAUDATE NUCLEI, J.R.Villablanca\*, Ch.E. Olmstead and I. de Andrés. Depts. Psychiatry and Anatomy, Mental Retard. Res. Center, UCLA Sch. of Med., LA, CA 90024.

Cats with ablation of the caudate nuclei show a profound behavioral change called compulsory approaching syndrome (CAs; Exper. Neurol. 52:389,76) as well as a changed behavioral response to morphine (Brain Res. 248:159,82). Here we report the effects of naloxone (Nx) upon the behavior of acaudate cats. We used 5 male cats with over 80% bilateral ablation of the caudate nuclei caspiration, midline approach). The animals received 1.0 to 3.0 mg/kg Nx, either i.m. or through remote i.v. injection. As controls, intact cats received Nx and acaudate cats received saline injections. Prior to Nx, acaudate cats exhibited a full blown CAs: jumped out of a box and approached the investigator; stuck to (the stationary) and followed (the walking) investigator or moving object; came back repeatedly after being pushed away; showed persistant visual tracking as well as tactile and auditory approach; showed "female" lordosis behavior, persistent rooting, purring, paw treading, stereotyped friendliness and hyperactivity. Before and after injection, cats were scored for the above components of the CAs (0-5 point scale; max=49). CAs was no longer present after NX (mean scores, before =32,5; after= 5.3; Wilcoxon P < 0.001) but components slowly reappeared after about 60 min and reached preinjection levels after 4-5hr. In addition, signs of precipitated withdrawal were observed in 3 cats (head and tail shakes, salivation, plaintive vocalization, pyloerection, shivering and panting). Results suggests an inbalance of endogenous opiates in acaudate cats (opiate "high"?). Neostriatal dysfunction has been suggested for obsessive-compulsive and Tourette's disorders with Nx having ameliorative effects. Grants. RO1 DA 02518;HD 04612.

## 280.10

INDUCTION OF CONDITIONED PLACE PREFERENCE BY ELECTRICAL KINDLING. Raúl G. Paredes, Verónica Romero and Anders Agmo. Escuela de Psicología, Universidad Anáhuac. México.DF.

Several lines of evidence suggest that opioid peptides are involved in the mechanisms of reinforcement. Intracerebral infusion or systemic administration of opioids have been shown to induce conditioned place preference. Several brain sites including the medial preoptic area (MPOA), are able to sustain opioid reward. Kindling is a model in which repeated subconvulsive electrical stimulation of different brain areas eventually produces generalized mo-tor seizures. A kindling seizure is associated with release of opioid peptides. It could be argued then that the generalized release of opioids could induce a reward state. In the present study this possibility was evaluated. Male wistar rats were implanted with a bipolar electrode in tha right MPOA or right AMG.Once kindling was fully established the animals were tested for place preference. The compartment where the subject spent more time was  $\cos$ sidered as the preferred compartment. The place preference conditioning was performed with a kindled stimulus as the reinforcing event. At the end of conditioning the animals were tested again for preference. Animals kindled in the MPOA or the AMG showed place preference after conditioning suggesting that the release of opioids produced by a kindled seizure may have reinforcing properties.

EFFECTS OF MORPHICEPTIN ON SEVERAL PARAMETERS OF MALE COPULATORY BEHAVIOR.

L. Matuszewich\* & E. M. Hull. Department of Psychology,
SUNY at Buffalo, Buffalo, New York 14260.

As previously reported by Matuszewich & Dornan (1990), morphiceptin, a selective mu opioid receptor agonist, injected into the medial preoptic area (MPOA), delayed the onset of copulation in male rats. Recent experiments tested the site specificity of this effect and whether decreased locomotion,

sexual motivation, or genital reflexes contributed to the delay.

Male copulatory behavior was recorded following unilateral injections of morphiceptin into the MPOA or the ventromedial hypothalamus (VMH). Both doses of morphiceptin (100 or 1000 ny) significantly increased mount and intromission latencies following injection into the MPOA, but not into the VMH. After injection of morphiceptin into the MPOA, sexual motivation and locomotion were measured in an X-maze. Morphiceptin did not affect choice of the female or running time to the goal boxes, but did increase the number of trials in which the male did not choose a goal box. In an open field test, morphiceptin did not affect either the number of rears or the number of lines crossed. MPOA injections of morphiceptin had no significant effect on genital reflexes in restrained supine male rats.

These experiments showed: site specificity of the delay in copulation; neither sexual motivation nor genital reflexes were affected by morphiceptin in the MPOA; and there was an impairment of one measure of locomotion.

OPIOIDS IN THE VENTRAL TEGMENTAL AREA FACILITATE THE ONSET OF MATERNAL BEHAVIOR IN THE RAT. Alexis C. Thompson\* and Mark B. Kristal, Dept. of Anatomy & Cell Biology, Emory Univ. Sch. of Med., Atlanta, 6A 30322, and Dept. of Psychology, SUNY at Buffalo, Buffalo, NY 14260.

The influence of opioids in the ventral tegmental area (VTA) on the onset of maternal behavior was investigated. In Exp. 1, maternal sensitization latencies were determined in virgin rats given unilateral intra-VTA injections of 1 of 5 doses of morphine sulfate (MS) (0.0, 0.01, 0.03, 0.1, or 0.3 μg) or were given no treatment, on the first 3 days of pup exposure. A dose-dependent decrease in sensitization latencies was found. Rats treated with 0.0 μg, 0.1 μg, or receiving no treatment (Med ≥ 10 days). Latencies in rats receiving 0.1 μg MS or 0.3 μg MS were intermediate and did not differ significantly from any group. In a follow-up study, we confirmed that the facilitating effect of 0.03 μg MS in the VTA on the onset of maternal behavior was mediated through the opioid receptor (blocked by 1 mg/kg naltrexone hydrochloride, 1.P.) and was specific to the VTA (placements dorsal to the VTA were ineffective).

In Exp. 2, parturitional rats were used, and the effect of blocking opioid activity in the VTA on the onset of maternal behavior was tested. To minimize disruptive effects of drug treatment on labor and delivery, mother rats were unmanipulated until after delivery of the last pup. To minimize maternal behavior during parturition, pup contact was limited by having mothers delivery on a grid floor, and removing each pup from beneath the grid as it was born. Forty min after delivery of the last pup, mothers were given bilateral intar-VTA injections of either the opioid antagonist naltrexone methobromide (quaternary naltrexone, QN, 1 μg), its vehicle, a sham injection, or left untreated. Thirty min after drug treatment, foster pups were introduced and sensitization latencies were determined. Mother rats treated with QN showed significantly long

parturition.

MK-801 BLOCKS MORPHINE-INDUCED ANALGESIA AND

MK-801 BLOCKS MORPHINE-INDUCED ANALGESIA AND TOLERANCE IN MICE. K. Lutfy\* and E. Weber, Dept. of Pharmacology, UC Irvine, Irvine, CA 92717.

The present study was aimed to examine the effect of the non-competitive N-methyl-D-aspartate (NMDA) receptor antagonist, MK-801 (dizocilpine) on morphine-induced analgesia and tolerance in Swiss Webster mice. Mice were injected with either MK-801 (0.1 mg/kg, i.p.) or saline. Thirty min later, mice were injected with morphine (2.5-10.0 mg/kg, s.c.) and tested for analgesia (tail flick assay, (TFA)) 45 min following morphine administration. Pretreatment with MK-801 Pretreatment with MK-801 a. In tolerance studies, following morphine administration. P blocked morphine-induced analgesia. mice were injected with either saline or MK-801 (0.1 mice were injected with either saltne or MK-801 (0.1 mg/kg, i.p.). Thirty min later, mice were injected with either saline or morphine (10, 20, and 50 mg/kg, s.c. for three consecutive days on day 1, 2, and 3, respectively) and tested for analgesia on day 4. On day 4, a test dose of morphine (2.0 mg/kg, s.c.) was injected and analgesia (TFA) was measured 45 min later. Pretreatment with MK-801 attenuated the development of chronic tolerance to morphine. MK-801 displayed poor affinity for the (34) relayone brighting site in mouse whole brain for the [3H]naloxone binding site in mouse whole brain homogenates. These data together suggest that the MK-801-sensitive component of morphine-induced analgesia might be sensitive component of morphine-induced analgesia might be responsible for the development of tolerance. Furthermore, these data support the possibility that MK-801 does not act directly via the opioid binding sites but inhibits morphine-induced analgesia and tolerance by some other mechanism. (Supported by NIDA Grant DA 06356)

EFFECTS OF OPIATE ANTAGONISTS ON QUINPIROLE-INDUCED PENILE ERECTION AND YAWNING IN THE MALE RAT. P.C. Doherty\* and P.A. Wisler The Lilly Research Laboratories, A Division of Eli Lilly and

Company, Indianapolis, IN 46285.

Administration of the opiate antagonists naloxone and nattrexone induces erections in men and monkeys, and increases the number of erections Administration of the opiate antagonists naloxone and natrexone induces erections in men and monkeys, and increases the number of erections observed in rats during the penile erection/stretch-yawn syndrome (PE/SYS) induced by dopamine (DA) agonists. In the present experiments we have compared the efficacy of several phenylpiperidine opiate antagonists with naloxone for their ability to enhance the display of PE/SYS after treatment with the D2 DA agonist quinpirole. Adult male Sprague-Dawley rats, (400-500 mg) were injected s.c. with the antagonists. One half hour later each animal was given an additional injection of saline, 25 or 50 µg/kg of quinpirole. Immediately thereafter, the animals were placed in clear plastic cages and observed over the next thirty minutes for the display of the penile erections and yawns. Naloxone (1-10 mg/kg) induced dose dependent increases in the number of erections induced by both 25 and 50 µg/kg of quinpirole. In contrast, the high level of yawning observed after treatment with quinpirole was inhibited by the opiate antagonists. Two phenylpiperidine opiate antagonists, LY243670, a racemic mixture of four trans isomers, and LY255582. Its most active diastereomer at the µ and k receptor subtypes, also showed significant dose dependent enhancement of quinpirole induced erections in doses from 0.03 to 1.0 mg/kg. Quinpirole induced yawning was enhanced by the lower doses and inhibited by the higher doses of LY255582. The peripheralty selective opiate antagonists LY280927 had no effect on the occurrence of erections, but significantly enhanced yawning. These findings demonstrate that opiate antagonists can increase the display of quinpirole induced erections in the rat and that this, unlike yawning, occurs through an interaction with opiate receptors sequestered by the blood brain barrier. These findings also support the potential utility of opiate antagonists in the reatment of erectile dysfunction.

U50,488 AND PENTYLENETETRAZOL, BUT NOT NALTREXONE, ELICIT ULTRASONIC VOCALIZATIONS FROM RAT PUPS IN THE HOMECAGE. S.E. Carden\*, A.T. Bortot, & M.A. Hofer. Columbia Univ. & N.Y.S. Psychiatric Inst., New York, NY 10032

Rat pups isolated in an unfamiliar setting Rat pups isolated in an uniamiliar setting emit ultrasonic vocalizations. In the homecage with litter intact, such calls are infrequent. Benzodiazepine and opiate drugs, among others, decrease isolation calls. We now find that U50,488, a highly selective kappa opioid agonist, and pentylenetetrazol (PTZ), an anxiogenic drug that binds at the (PTZ), an anxiogenic drug that binds at the GABA-benzodiazepine receptor complex, both elicit ultrasonic vocalizations in the homecage. Ten-day old Wistar pups were injected with saline or PTZ (5 - 45 mg/kg) or U50,488 (1 - 30 mg/kg) then returned to their littermates in the homecage. Pre- and post-drug periods were virtually free of vocalization, compared to describe the interescent when periods were virtually free of vocalization compared to dose-related increases when animals were given PTZ or U50,488. There were also drug related changes in level of activity and time spent in physical contact with littermates. The opiate receptor blocker naltrexone, at doses up to 5 mg/kg, did not alter rates of vocalization.

INDEPENDENT GENETIC CONTROL OF TWO PHARMACOLOGICALLY DISTINICT BRAINSTEM MU
ANALGESIC SYSTEMS. C.G. Pick\* and G.W. Pasternak. The
Cotzias Laboratory of Neuro-Oncology, Memorial Sloan-Kettering
Cancer Center and Departments of Neurology & Neuroscience and
Pharmacology, Cornell U. Medical College, New York, NY 10021

Morphine injected in a plaint angle in class or practical sides.

Morphine injected i.c.v. elicits analgesia alone or synergistically with spinal systems. We now show that the brainstem mu receptors with spinal systems. We now show that the brainstem mu receptors mediating this synergy are genetically and pharmacologically distinct from those responsible for analgesia following only i.c.v. morphine. Mu<sub>1</sub> receptors mediate morphine analgesia supraspinally while mu<sub>2</sub> receptors act spinally. In CXBK mice, a strain deficient in mu<sub>1</sub> receptors, i.c.v. morphine given alone elicits only 20% analgesia at a dose 20-fold greater than the ED<sub>50</sub> in CD-1 mice. However, the CXBK and CD-1 strains are equally sensitive to i.t. morphine, a mu<sub>2</sub> action. Despite its inactivity given alone, morphine administered i.c.v. potentiates i.t. morphine as effectively in CXBK mice as in CD-1 mice. Additional studies using selective mu antagonists differentiated these two analgesic responses pharmacologically. β-Funaltrexamine, a mu<sub>1</sub> and mu<sub>2</sub> antagonist. that antagonists differentiated these two antageste responses pharmacologically.  $\beta$ -Funaltrexamine, a  $mu_1$  and  $mu_2$  antagonist, given i.c.v. blocks the analgesia following i.c.v. morphine alone as effectively as its potentiation of i.t. morphine, confirming a role for mu receptors in both actions. In contrast, the  $mu_1$ -selective antagonist naloxonazine antagonizes the analgesia following i.c.v. morphine alone 6-fold more potently than the potentiation of i.t. morphine. Together our results indicate the presence of two genetically and pharmacologically distinct populations of mu receptors within the brainstem involved with morphine analgesia.

L-TRYPTOPHAN POTENTIATION OF MORPHINE-INDUCED ANALGESIA IN MICE. K.M. Hull\*, D.E. Tolland and T.J. Maher. Dept. of Pharmacol., Mass. College of Pharmacy, Boston, MA 02115.

Opioid administration has been shown to in-

Opioid administration has been shown to increase the serotonin (5HT) turnover in regions of the CNS. Moreover, drugs that enhance 5HT are known to augment several morphine-induced actions (e.g., analgesia) while pharmacological manipulations which impair 5HT function (e.g., p-chloro-phenylalanine) attenuate the morphine-induced response. We examined the ability of the immediate amino acid precursor for 5HT, L-tryptophan (L-TRP), to potentiate morphine-induced analgesia as measured by a hot plate (52 C) test. L-TRP (200 mg/kg) significantly potentiated the analgesic activity of morphine sulfate (2.5, 5, and 10 mg/kg, by 104, 169, and 149%, respectively). L-TRP was without effect when administered alone. The L-amino acids alanine, histidine and lysine, when administered in equimolar amounts, failed to significantly alter the morphine-induced analgesia, nor did they have an effect when administered alone. The pharmacologic use of L-TRP to potentiate morphine-induced analgesia may constitute a rational strategy to reduce the exposure of patients to the opioids if the undesirable effects (e.g., respiratory depression, tolerance development) are not similarly potentiated.

#### 280 18

ROLE OF THE NUCLEUS ACCUMBENS IN THE EFFECTS OF MORPHINE ON SEPARATION INDUCED CRYING IN INFANT RATS. G. A. Barr, M.A. Hofer\* and S. Wang. Dept. Psychology, Hunter College New York, NY 10021 and Dept. Develop. Psychobiol., New York State Psychiatric Institute, New York, NY 10032.

Crying following separation from the mother and siblings is a

characteristic response of the young of a number of species and is thought to reflect the internal affective state of the infant. In the rat pup, crying is in the ultrasonic range. Opiates modulate this response;  $\mu$  and  $\delta$ -agonists quiet the infant and antagonists block the effects of the agonists. Furthermore, following precipitated withdrawal from chronic treatment with morphine, infant rats cry at higher rates than do controls. Little is known of the neural substrates that mediate this fundamental response of the infant. In this experiment, 6 day old pups were implanted with chronic indwelling cannulas aimed at the nucleus accumbens. Sixteen hours later, pups were injected with morphine (3.0 mg/kg i.p.) or saline followed by intracerebral injection of naltrexone  $(0,0.3,1.0,3.0~\mu g)$  or vehicle into the nucleus accumbens. Pups were then tested alone for ultrasonic vocalizations in a six minute test. The peripheral injection of morphine drastically suppressed crying. Intraaccumbens injection of naltrexone reversed the suppression in a dosedependent manner and had minimal effect on saline injected pups. These results indicate that at least one site of morphine's quieting action is the nucleus accumbens. If crying by the infant rat is a reliable concomitant of its internal state, then the nucleus accumbens is likely involved in the modulation of affect in the infant as it is hypothesized to be in the adult. (Supported in part by DA-06600)

## CATECHOLAMINE RECEPTORS: DOPAMINE II

### 281.1

FUNCTIONAL ANALYSIS OF THE PROMOTER OF THE RAT D-2 DOPAMINE RECEPTOR GENE. T. Minowa, M. T. Minowa and M. M. Mouradian\*. Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892.

The D-2 dopamine receptor is classically recognized to be the primary mediator of the motor, endocrine and behavioral effects of central dopaminergic transmission. To investigate the molecular events leading to the transcriptional regulation of the rat D-2 gene, we have cloned and sequenced the 5' flanking region of this gene. Although multiple transcription initiation sites were identified, strong preference to three consecutive nucleotides were noted. The promoter lacks TATA and CAAT boxes. Transfection of D-2 expressing cells with chimeras of the D-2 promoter deletion mutants / CAT gene indicated a cis-acting enhancer region between nucleotides -75 and -29 relative to the main transcription start site, and a silencer between -217 and -76. DNaseI footprinting revealed Sp1 binding to its consensus sequence at -48 to be crucial for promoter activity of this gene. Lack of Sp1 binding to its consensus sequence at -86 may relate to the negative regulation of this gene. The initiator-like sequence around transcription start site is also discussed. We conclude that the rat D-2 promoter shares with the human D-1A promoter some "housekeeping"-like features, but the D-2 gene has a strong preference for transcription initiation with Sp1 playing a critical role.

## 281.3

RETINOIC ACID MEDIATED INDUCTION OF DOPAMINE D2 RECEPTOR IN HUMAN SHSY-5Y NEUROBLASTOMA CELLS. S. M. Farooqui and C. Prasad\*. Laboratory of Neurosciences, Pennington

Biomedical Research Center, Baton Rouge, Louisian and Department of Medicine LSUMC, New Orleans, Louisiana.

Differentiation of human SHSY-5Y nueroblastoma cells by retinoic acid (RA) is accompanied by the growth of axonal processes, increased electrical activity, induction of many neurotransmitter synthesizing enzymes and catecholeamine transporters and loss of tumorigenicity. The status of dopamine D2 receptor (DR) during differentiation of these cells, however, has not yet been examined. To this end SHSY-5Y cells were treated with increasing concentrations of RA for 15 min-72 hours; RA treatment resulted in to a dose and time dependent increase (4-fold) in the specific binding of [3H]YM09151-2, a DR selective antagonist, to the partially purified cell membranes The level of DR protein (120 kDa), detected by Western blot analysis using a monoclonal antibody to DR peptide, was induced within 30 min of RA treatment. This monoclonal antibody has been characterized in detail elsewhere (Biochem. Biophys. Res. Comm. 1992). The maximal induction of 120 kDa protein was observed after 2 hours of RA treatment and the elevated levels of DR protein was maintained up to 72 hours. The increase in the [3H]YM09151-2 binding, however, appeared several hours after the DR protein induction. In contrast, significant morphological changes in RA treated cells were visible only after 12 hours. Therefore, we conclude that the induction of DR may be one of the early steps in RA-mediated differentiation of SH-SY5Y cells. Supported by US Army grant #DAMD 17-88-Z-8023.

### 281.2

DOPAMINE D2 RECEPTOR GENE EXPRESSION IN MMQ CELLS AND RELATED TRANSDUCING MECHANISMS Carmelo Ventra\* Tullio Florio, Maurizio Grimaldi, Saverio Talia and Gennaro Schettini Dip. di Farmacologia, II Facolta' di Medicina, Universita'degli Studi di Napoli, Italy.

The MMQ cell line, recently isolated from the 7315a transplantable rat pituitary tumor, secretes prolactin and expresses a native and functional dopamine (DA) D2 receptor. These properties make this cell line an useful model to study the D2 receptor, acting via its native "coupling environment". We evaluated a possible functional diversity between this receptor, that expressed in anterior pituitary lactotrophes and that transfected in GH4C1 cells (GH4C1Z-R7). In membranes derived from these cells, we extensively analyzed the transducing mechanisms mediating the effect of DA on basal and stimulated adenylate cyclase activity, focusing on the interaction between this receptor and G-protein/s, using GTP and its non-hydrolyzable analogues. The modulation of DA D2 receptor-gene expression by various stimuli acting via different second messenger-activated pathways is currently under evaluation. (CNR grant n° 9003204 to G.S.)

## 281.4

DISTRIBUTION OF DOPAMINE D2 RECEPTORS IN SUBPOPULATIONS OF PRIMATE MIDBRAIN DOPAMINERGIC NEURONS. K. Nagamoto.\* W.X. Lu. and S.N. Haber. Dept. of Neurobiology and Anatomy, School of Medicine and Dentistry, Univ. of Rochester, Rochester, NY 14642.

The mesencephalic dopamine neurons can be divided into two subpopulations of cells based on their anatomical connections, biochemical compositions, and vulnerability to degeneration under pathological conditions. The ventral tier of dopaminergic cells projects primarily to the dorsolateral striatum, and these cells contain higher levels of tyrosine hydroxylase (TH) mRNA than the dorsal tier (Weiss) Wunder & Chesselet, J. Comp. Neurol., 303: 478-488, 91). In contrast, dopaminergic cells in the dorsal tier including the ventral tegmental area (VTA) receive projections from ventral striatum, and co-contain echolecystokinin (CCK) and calbindin (Lavoie & Parent, Neuroreport, 2: 1601-1604, 91). In order to further characterize the mesencephalic dopamine neurons, we examined distribution of the D2 receptor (D2R) in the midbrain of the monkey. We combined in situ hybridization histochemistry and immunocytochemistry on the same sections for localization of D2R and identification of TH-immunoreactive dopaminergic cells, respectively. Our preliminary results show that the dopaminergic neurons in the dorsal tier contain relatively lower levels of D2R mRNA than those in the ventral tier. These results further characterize the mesencephalic dopamine neurons biochemically, suggesting that the D2R is differentially regulated in the two subpopulations of the dopaminergic cells in primates. Supported by NIMH MH 45573 7NIH NS22511.

THE DISTRIBUTION OF DOPAMINE D2 RECEPTOR HETERONUCLEAR RNA (hnrna) BY INTRONIC IN SITU HYBRIDIZATION OF THE RAT BRAIN. C.A. Fox\*, R. C. Thompson. J. Bunzow. O. Civelli and S.J. Watson. Mental Health Research Institute, University of Michigan. Ann Arbor. MI 48109–0720 and Vollum Institute, Oregon Health Sciences University, Portland OR 97201.

Studies evaluating acute changes in brain dopamine D2 receptor mRNA in response to a variety of stimuli indicate that D2 mRNA levels are resistant to change. To more carefully investigate transcription of the D2 receptor gene, we have subcloned a 425 bp Eco RI/Ava II fragment of intron 7 (O'Malley et al., 1990) of the rat D2 gene into pGEM4. This construct was then used as a template to generate a riboprobe for intronic in situ hybridization. Since intronic sequences are only included in the short lived heteronuclear RNA (hnRNA). hybridizing to introns reveals the amount of hnRNA in the cell, allowing a more sensitive method for evaluating transcription. The anatomical distribution of the D2 hnRNA is virtually identical to the distribution of D2 mRNA in the rat brain. Signal from the D2 intronic probe is found in the caudate putamen, nucleus accumbens, olfactory tubercle, substantia nigra, ventral tegmental area, and zona incerta. Other regions that contain D2 mRNA, but do not contain D2 hnRNA, include the globus pallidus, prefrontal, cingulate, entorhinal, and piriform cortex, septum, and amygdala. However, these areas have low amounts of D2 mRNA (Meador-Woodruff et al., 1989) and may contain levels of D2 hnRNA that are below detection. This study indicates that D2 intronic in situ hybridization may prove to be a useful tool for evaluation of the D2 gene's transcription. Studies are underway to evaluate the ability of specific drugs to alter the activity of the dopamine D2 receptor gene. Supported by NIMH grant PO1 MH42251 and a PMA Foundation Award to C.A.F.

## 281.7

PLASTICITY AND ONTOGENY OF MELANOTROPE D7A DOPAMINE RECEPTOR mRNA AND ISOFORM PROTEIN EXPRESSION. B.M. Chronwall", D.S. Dickerson

and K.A. Gary. Biological Sciences, Univ. of Missouri, Kansas City, MO 64108. Peptide secretion from the rat pituitary intermediate lobe is regulated by  $D_{2A}$  dopamine receptors. Chronic antagonist treatment increased  $D_{2A}$  receptor binding,  $B_{max}$ , but not  $K_d$ ; chronic agonist treatment did not change either  $B_{max}$  or  $K_d$ . In situ hybridization histochemistry showed a 50% increase of  $D_{2A}$  receptor mRNA following chronic antagonist and a 40% decrease following chronic agonist treatment.  $D_{2A}$  receptor mRNA levels differed among individual melanotropes

A short isoform  $(D_{2A,3})$  and a long isoform  $(D_{2A,1})$  of the  $D_{2A}$  receptor have been distinguished by biochemical characteristics. Antisera have been generated against  $D_{2A,1}$ and the total population of the  $D_{2A}$  receptor protein  $(D_{2A-S+1})$  (Dr. D. Sibley, NIH, Bethesda MD) which were used for immunohistochemical localization.

In control pituitaries stained with antibodies to the D<sub>2A-S+L</sub> receptor protein, brightly labeled melanotropes were randomly distributed throughout the lobe; all other melanotropes showed differing degrees of lesser staining intensity. The  $D_{2A,L}$  receptor isoform staining pattern differed substantially from the  $D_{2A,S+L}$  receptor staining, showing a few randomly distributed, brightly labeled melanotropes. Antagonist treatment led to an increase in the number and staining intensity of melanotropes positive for the D<sub>2A-L</sub> receptor antiserum. A concurrent increase in staining intensity of all melanotropes was observed with the D<sub>2A-S+L</sub> receptor antiserum. Conversely, agonist treatment led to no

change in either D<sub>2A-S+L</sub> or D<sub>2A-L</sub> receptor immunoreactivity (IR).

Ontogenic studies indicated that prior to postnatal day (PN) 4, D<sub>2A-L</sub> is the only isoform detected; the numbers of D<sub>2A-L</sub>-IR cells increased relative to non-labeled cells from PN1 to PN4. After PN6, D<sub>2A-L</sub>-IR is associated with the axons innervating melanotropes as well as the melanotropes themselves. D<sub>2A-S+L</sub>-IR appeared after PN4 and then gradually increased to attain a pattern characteristic of the adult around PN14. No axon staining was apparent with the  $D_{2A,S+L}$  antiserum. In general,  $D_{2A,S+L}$ -IR seems to lag behind the onset of doparminergic innervation.

## 281.9

IN VIVO SPECIFICITY OF N-(2'-[F-18]FLUOROETHYL)BENPERIDOL FOR PET INVESTIGATION OF DOPAMINERGIC D-2 RECEPTOR BINDING. S.M. Moerlein\*, J.S. Perimutter and D. Parkinson. Mallinckroot Institute of Radiology, Department of Neurology and Neurological Surgery, and Department of Cell Biology and Physiology, Washington University School of Medicine, St. Louis, MO 63110.

Benneridol is a butyrophenone that binds to dopaminergic D-2 receptors with high affinity and high selectivity. We have evaluated an analogue of enperidol, N-(2'-fluoroethyl)benperidol (FEB), in which the positron-emitting fluorine-18 (t<sub>1/2</sub> = 110 min) was attached to the ligand for use as a PET tracer. [F-18]FEB was synthesized in 25-30% radiochemical yield and specific activity exceeding 1000 Ci/mmol within 90 min. Receptor-binding studies in vitro using primate brain tissues show that FEB has high affinity for D-2 receptors  $(K_i = 5.2 \text{ nM})$  and relatively low affinity for serotonergic S-2 receptors  $(K_i = 31 \text{ nM})$ . PET imaging of baboons indicated that the radioligand localized in vivo preferentially within D-2 receptor-dense tissues. The free fraction of [F-18]FEB was 2.5 ± 1.3%, and almost all peripherally-generated radiolabeled metabolites were polar. To evaluate the receptor-specificity of radioligand accumulation *in vivo*, receptor-saturating doses of eticlopride (4 mg/kg, i.v.), ketanserin (0.54 mg/kg, i.v.), SCH 23390 (1.1 mg/kg, i.v.) were injected prior to administration of [F-18]FEB. The regional tissue-activity curves after injection of unlabeled S-2 ligand ketanserin or D-1 ligand SCH 23390 were identical to those in the control study. In contrast, pretreatment of the animal with unlabeled D-2 ligand eticlopride resulted in identical striatum and cerebellum tissue-activity curves. For all interventional PET studies, CBF and CBV did not change, neither were the free fraction nor the peripheral metabolism of [F-18]FEB altered. These results indicate that [F-18]FEB is a specific ligand for PET investigation of D-2 receptor binding in vivo

D2 DOPAMINE RECEPTOR EXPRESSION ON STRIATONIGRAL D2 DUPAMINE RECEPTOR EARNESSION ON THE STORY OF THE STORY

We have developed specific polyclonal antibodies directed against synthetic peptide sequences unique to the rat D<sub>2</sub> dopamine receptor, enabling detection of the cellular location of this neurotransmitter receptor. The antisera were generated against extracellular and intracellular epitopes, and recognize the native receptor protein, as judged from immunofluorescent expression in stably transfected fibroblasts or Chinese Hamster Ovary cells (BBRC 179: 824, 1991; Proc. Nat. Acad. Sci. USA 88: 1441, 1991). The rat substantia nigra was stereotaxically infused with 1 µl of fluorescent labeled latex microspheres. Following a one week survival period allowing for retrograde transport of the label to the striatum in order to mark the striatonigral projection system, the animals were sacrificed and the brain extracted and rapidly frozen. antisera were applied to 10 μm thick coronal forebrain sections, using antibody dilutions of 1:8000 to 1:20,000 in phosphate-buffered saline (pH 7.2). The fluorescent staining was robust within the neuropil and circumscribing the soma of medium-sized neurons of the striatum. Combining retrograde labeling and immunofluorescence techniques with localization by the various anti-peptide antisera, the D<sub>2</sub> dopamine receptor subtype could be distinguished on as many as 60% of the neurons comprising the striatonigral efferent system. However, some 65% of all  $D_2$  receptor positive cells are represented by other intrinsic neurons in this basal ganglia nucleus, such as the striatopallidal outflow or the aspiny interneuron populations. This work was supported in part by USPHS NS 23079 to MAA.

NON-SPECIFIC BINDING CORRECTION IN HUMAN IN VIVO 123I-BZM SPECT STUDIES BY MEANS OF ACTIVE AND INACTIVE ENANTIOMERS R.H., Sexton\*, D.W., Jones, A., Braun, K.S., Lee, J.R., Zigun, D.R. Weinberger, CBDB, IRP, NIMH, Washington, DC 20032.

In vivo CNS radioligand-receptor binding studies require correction for non-specific binding. The usual approach is to subtract radioactivity counts in an area of low specific binding (e.g., cerebellum) from counts in an area of high specific binding, An alternative approach is to use an enantiomeric pair of radioligands with one isomer actively binding to a specific receptor type and the other Isomer exhibiting no specific binding. We have applied this approach to human SPECT studies with (S)-123I-BZM, a potent D-2 dopamine receptor antagonist, and (R)-123I-BZM, the corresponding inactive isomer. Subjects were injected with 5mCi of (S)-123I-BZM and kinetic SPECT scans were acquired for 3hrs. Acquisition times varied from 20sec/scan initially when rapid changes occur in the uptake kinetics to 30min/scan at lajer times. We performed a second identical study sequence with (R)-123I-BZM within several days of the active study. Sufficient time was allowed between studies for essentially complete decay of previously injected radioactivity. ROI analyses were performed to generate time-activity curves of the striatum and of frontal, temporal, and occipital cortices. The inactive isomer kinetics for all ROI's are nearly identical as expected for non-specific binding; the active isomer curves display similar behavior for the cortical regions but substantially more accumulation in the striatum. This excess uptake of active isomer in the striatum may be attributed to specific binding to D-2 receptors that are relatively dense in this area of the brain. We have developed a normalization method that allows comparison of active and inactive studies on the same scale. This makes it possible to subtract the non-specific binding, revealed by the inactive isomer study, from the active lsomer data t

## 281.10

CHARACTERIZATION OF A DOPAMINE/ANGIOTENSIN II CHIMERIC RECEPTOR: THE ROLE OF THE THIRD CYTOPLASMIC LOOP IN DISTINGUISHING THE AGONIST AND ANTAGONIST BINDING SITES. H. Chen, Y.-H. Hsih, L.-H. Wu, D. A. Downs, D. L. Oxender and F.-Z. Chung\*. Parke-Davis Pharmaceutical Research Division, Warner Lambert Company, Ann Arbor, MI 48106-1047.

It has been documented that the third cytoplasmic loop (3 CL) of Gprotein coupled receptors played an important role in determining the specificity of receptor G-protein interaction. To determine the importance of the 3 CL of dopamine D2 receptor in affecting receptor binding and in conferring G-protein coupling specificity, the entire loop was replaced by the counter part of the angiotensin II receptor. Angiotensin II receptor (AT1a) has one of the shortest third cytoplasmic loop among all G-protein receptor coupled to phophotidyl inositol (PI) turnover with only twenty four amino acid idues in the loop region. The chimeric receptor gene was transfected into CHO-K1 cells and a cell line producing high levels of the chimeric receptor was isolated and analyzed for receptor binding. Using 3H-labelled spiperone in displacement binding studies, the IC50 values for the two dopamine D2 antagonists spiperone and (+)-butaclamol are 20 nM and 250 nM, respectively. Interestingly, 10 uM concentration of dopamine or (-)-quinpirole displaced only 50% of 3H-labelled spiperone binding, and up to 100 uM concentrations of the two agonists could not displace any of the remaining spiperone binding sites. Our results indicated that in the chimeric receptor, the binding sites for spiperone and (+)-butaclamol are quite different from the binding sites for dopamine and (-)-quinpirole.

A MOLECULAR MODEL OF THE DOPAMINE D2 RECEPTOR L.P. Taylor\*, A. Mansour, K. De Young, M. Hoversten & H. Akil Mental Health Research Institute, University of Michigan 481100

A framework molecular model of the seven transmembrane domains of the dopamine D2 receptor has been assembled. This coupled with computer simulation using SYBYL software provides a qualitative tool for the analysis of dopamine-ligand interactions. The model was assembled with the following assumptions: invariant amino acid residues within the seven transmembrane family of adrenergic/dopaminergic receptors are critical for receptor function, the transmembrane domains are alpha-helical, the "bends" produced by the Pro residues are essential for defining an interlocked structure of the transmembrane domains, the primary catechol binding sites (based on analogy to the adrenergic receptor) are Asp-114, Ser-194, and Ser-197, and the binding of an agonist must reversibly alter the receptor conformation for signal transduction to occur.

The model was used to examine the putative binding cavity of

The model was used to examine the putative binding cavity of the receptor with respect to potential interaction with the D4 selective ligand clozapine. Differences in potential steric interactions between clozapine and the D2 or D4 receptor were noted. In order to reduce these potential steric problems, specific amino acids in the D2 receptor were mutated. Mutant D2 receptors were subcloned in a CMV expression vector and expressed in COS-1 cells. Dopamine agonist and antagonist binding to these mutant receptors will be evaluated.

### 281.13

THE ROLE OF KEY PHENYLALANINE RESIDUES IN G-PROTEIN COUPLING OF THE D<sub>2</sub> RECEPTOR. A. Mansour, K. DeYoung, L.P. Taylor, F. Meng and H. Akil, Mental Health Research Institute, University of Michigan, Ann Arbor MI 48109.

The dopamine receptors are members of a larger family of G-protein coupled receptors that include the adrenergic, muscarinic, and peptidergic receptors. These receptors share a structural motif with rhodopsin which spans the plasma membrane seven times, with the transmembrane domains forming a binding pocket. Site-directed mutagenesis studies suggest that the amino group of dopamine interacts with aspartate 114 of the D2 receptor, while the meta-hydroxyl of the catechol moiety likely forms a hydrogen bond with serine 197 (submitted). Beyond the anchoring at aspartate 114, it is unclear which amino acid residues are critical in triggering the cascade of events necessary for coupling to G-protein. Computer modeling of the D2 receptor suggests that there may be a series of phenylalanines (198, 389, 390, 411) that are important in conformationally altering the receptor resulting in an enhanced G-protein coupling. To test this hypothesis, the above phenylalanines were selectively mutated to alanine using site-directed mutagenesis. Mutant D2 receptors were subcloned in a CMV expression vector and expressed in COS-1 cells where agonist and antagonist binding will be evaluated in conjunction to G-protein coupling.

## 281.15

SYNTHESIS AND CHARACTERIZATION OF MODEL PEPTIDES CORRESPONDING TO TRANSMEMBRANE DOMAINS OF THE DOPAMINE Description of the Dopamine of the Dop

Site-selective mutagenesis studies have demonstrated that the ligand binding site of the dopamine D2 receptor is contained within the transmembrane domains, in particular TM III, V, and VII. A substantial degee of homology is observed across these domains which are constitituted of highly hydrophobic amino acid residues. We have designed and prepared a consensus peptide which is based upon the sequences in these domains. The sequence is NH<sub>2</sub>-D-Y-A-I-F-V-L-Y-A-S-A-W-L-S-F-L-N-C-P-F-I-V-T-L-N-I-K-COOH. Novel HPLC methodology was developed in order to purify this highly hydrophobic sequence. The secondary conformation was examined in organic solvents and lipid vesicles. Interestingly, this peptide was not found to be substantially  $\alpha$ -helical as has been the common assumption, but is relatively extended in structure. Fluorescence studies in lipid vesicles demonstrate that the peptide inserts into the membrane. These experiments suggest that the consensus peptide can be used as a biophysical model for the dopamine D2 receptor system. (Supported by NSF and New York University)

STRUCTURE-FUNCTION RELATIONSHIP OF DOPAMINE RECEPTORS: A CHMERIC STUDY. F. Meng\*, A. Mansour, M. Hoversten, L.P. Taylor, and H. Akil. Mental Health Research Institute, University of Michigan, Ann Arbor MI 48109

The molecular basis of selective ligand binding to D1 and D2 receptors was studied by construction of D1/D2 chimeras. Three pairs of reciprocal constructs were made by ligating transmembrane(TM) domains of the D1 and D2 receptors together using oligo adaptors. These constructs were expressed in COS-1 cells and studied with the selective D1 and D2 ligands (5 nM) listed below.

(-) indicates no specific binding was detected

These preliminary results suggest that in the wild type receptors, all TM regions may work synergically with each other to produce selective binding and ligands may differentially interact with transmembrane domains to achieve selectivity. Complete Scatchard analysis and competition studies will follow to better characterize these results.

## 281.14

CO-TRANSFECTION OF THE DOPAMINE D2 RECEPTOR WITH G PROTEIN α-SUBUNITS ALTERS D2 BINDING. William Cho\*, Alfred Mansour and Huda Akil, Ph.D. Dept. of Psychiatry, University of Michigan, Ann Arbor, MI 48109.

The specific interactions between dopamine receptors and guanine nucleotide regulatory proteins (G proteins) are not well characterized. The D2 dopamine receptor subtype is negatively coupled to adenylyl cyclase, presumably through variants of the inhibititory G-protein, Gi, and may also be linked to K\* channel activity and PI turnover through other G proteins. COS-1 cells were transiently transfected with the long variant of the D2 receptor ( $10\mu g$ ) along with either the  $\alpha$ -subunit of  $G_i$   $(G_{i\alpha 2}$  or  $G_{i\alpha 3})$  or  $G_0$   $(G_{0\alpha})$   $(20\mu g)$ . Cells were also simultaneously transfected with a  $\beta$ -galactosidase construct (5 $\mu g$ ) for transfection efficiency corrections. Cells were harvested 48h after transfection and assayed for D2 agonist ([3H]N-0437) and antagonist ([3H]raclopride) binding. In preliminary studies, co-transfection of D2 with G<sub>iα3</sub> caused a complete loss of high affinity agonist binding and a marked reduction in low-affinity agonist binding capacity (Bmax=4.1 without  $G_{i\alpha 3}$  vs. 0.76 fmol/10<sup>5</sup> cells with  $G_{i\alpha 3}$ ). Similarly, antagonist binding capacity was reduced in the presence of  $G_{i\alpha,3}$  (Bmax=2.9 vs. 0.97 fmol/10<sup>5</sup> cells). β-gal activity did not significantly change between transfections. This phenomenon was relatively specific to  $G_{ia3}$  in that transfection of D2 with  $G_{0\alpha}$  exhibited a much less dramatic reduction in Bmax, and co-transfection with  $G_{i\alpha 2}$  produced no change in D2 binding. Control transfections with D1 and  $G_{i\alpha 3}$  failed to show reductions in D1 antagonist ([3H]SCH23390) Bmax.

## 281.16

PHARMACOLOGICAL CHARACTERIZATION OF A MODEL PEPTIDE CORRESPONDING TO TRANSMEMBRANE DOMAINS OF THE DOPAMINE D<sub>2</sub> RECEPTOR. <u>Randall B. Murphy</u>, <u>Valerie L. Williams</u>, <u>and David I. Schuster</u>, Department of Chemistry and Center for Neural Sciences, New York, University, New York, NY 10003

In the dopamine  $\mathrm{D}_{\mathrm{2}}$  receptor, the transmembrane domains have been implicated in functional association with ligands. Preliminary work in our laboratory has demonstrated that the type hydrophobic peptides which constitute the highly transmembrane domains can be synthesized and purified. (see Williams, V.L. et al, This Meeting) We hypothesize that the functional D<sub>2</sub> binding site consists of a multimeric assembly of these transmembrane domains within the lipid bilayer. In order to examine this hypothesis, we have carried out radioligand binding assays to determine if a consensus peptide derived from the transmembrane domains will form a functional binding site in lipid (DMPC) bimolecular vesicles. We observed high-affinity binding with [3H]-spiperidol. The number of binding sites determined indicates that a small percentage of the total peptide which is present forms a functional binding site. These results suggest that molecular engineering of multiple consensus sequences can in principle be used as a model for the dopamine D2 receptor ligand binding site. (Supported by NSF and New York University)

REGULATION OF THE D $_{2L}$  DOPAMINE RECEPTOR IN STABLY TRANSFECTED CHO CELLS. L.-J. Zhang\*, E.M. Smyk-Randall , F.J. Monsma, Jr. & D.R. Sibley, Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892

To investigate the regulatory properties of the rat D<sub>2L</sub> dopamine (DA) receptor, we have stably expressed its cDNA in Chinese Hamster Ovary (CHO) cells. One cell line was characterized using the D<sub>2</sub>-selective radioligands [3H]methylspiperone ([3H]MSP) and [3H]YM091512 ([3H]YM). Both radioligands exhibited K<sub>d</sub> and B<sub>max</sub> values of about 50 pM and 2 pmol/mg protein, respectively. DA produced a dose-dependent and pharmacologically-best fits in the court of the collection of t specific inhibition of adenylyl cyclase activity in both intact cell and membrane preparations. DA's EC<sub>50</sub> for inhibiting forskolin-stimulated cAMP accumulation was about 50 nM with a maximal response at 10  $\mu$ M which represented a 60-70% inhibition. Pretreatment of the cells with 500  $\mu$ M DA produced a ~5-fold shift (lower affinity) in the EC<sub>50</sub> for DA inhibition of cAMP accumulation but no change in the maximum response. Surprisingly, the DA pretreatment resulted creating in the maximum response. Surprisingly, the DA pretreatment resulted in a ~3 fold increase in the maximum binding capacity for both [ $^3$ H]MSP and  $^3$ H]YM with no change in their K<sub>0</sub> values. This effect was time-dependent reaching maximal levels after 24 hr with a  $t_{1/2} \geq 5$  hr. In a preliminary experiment, prior treatment of the cells with 1  $\mu$ g/ml of pertussis toxin for 24 hr did not block the DA incread in the cells with 1  $\mu$ g/ml of pertussis toxin for 24 hr did not block the DA-induced increase in radioligand binding. Treatment of the cells with various intracellular activators of protein kinases resulted in a general blunting of the D $_{2L}$  receptor responses. Exposure to 1  $\mu$ M PMA for 24-48 hr resulted in a  $^{\sim}3$  fold reduction in the potency of DA to inhibit cAMP accumulation with no change in the maximum response along with a ~25% decrease in receptor  $B_{\text{max}}$  values. Similarly, treatment with 0.4 mM Sp-cAMPS for 24 hr resulted in a 25-50% reduction in the maximum DA cAMP response with no change in potency along with a 25-50% reduction in  $B_{\text{max}}$  values. Similar experiments involving the  $D_{2S}$  isoform are currently being performed.

## 281.19

otentiation of ATP Stimulated <sup>3</sup>H-Arachidonic Acid Release in CHO-D2i Cells as a Measure of Intrinsic Activity. D.L.Evans\* and R.A.Lahti. CNS Diseases Research, Upjohn Laboratories, Kalamazoo, MI

G protein-coupled receptors have been shown to be linked to numerous signal transduction pathways such as adenylate cyclase, phospholipase A<sub>2</sub>, and phospholipase C. Felder, et al. (Proc. Natl. Acad. Sci. 88:6477, 1991) found that dopamine D2 receptors which inhibit adenylate cyclase can also amplify ATP stimulated arachidonic acid release. This procedure may provide a reliable means of determining the intrinsic activity of dopamine agonists.

CHO-D2i cells are preloaded with 3H-arachidonic acid by incubating with the radiolabel, rinsed to remove surface radioactivity, and incubated with differing concentrations of dopaminergic compounds in the presence of ATP for 30 minutes. The compound's effect on 3H-arachidonic acid release is measured by counting an aliquot of the media using standard scintillation techniques. The dose dependent <sup>3</sup>H-arachidonic acid release is then plotted as a percent response and the maximum response is taken as the compound's intrinsic activity. This procedure provides a quick and simple method for measuring a compound's intrinsic activity via a second messenger system.

Different maximum levels of ATP stimulated arachidonic acid release were found with the full agonist quinpirole (100%), as compared to that of the partial agonists (-)3PPP (72%), terguride (60%), and SDZ-208-912 (22%). These values correlate well with other measures of intrinsic activity such as binding (r=0.85) and electrophysiology (r=0.97) and thus provide a reliable means of determining a drug's intrinsic activity.

COUPLING OF THE RAT DOPAMINE D2L AND D2S RECEPTORS TO VOLTAGE SENSITIVE CALCIUM CHANNELS IN ATT20 CELLS LA Snyder\*1.3 M. Tsutsumi¹ and S.C. Sealfon¹.2.

IN ATT20 CELLS LA Snyder\*1.3 M. Tsutsumi¹ and S.C. Scalfon¹². Fishberg Center for Research in Neurobiology and ²Department of Neurology, The Mount Sinai School of Medicine, NY 10029; ³The Graduate School of the City University of New York, 33 W. 42 St., NY, NY 10036-8099
Alternative splicing of the dopamine D2 receptor gene leads to two D2 receptor soforms, the D2L and D2S. The receptors differ in the third cytoplasmic loop, a domain implicated in G-protein coupling. Activation of the lactotroph D2 receptor has been shown to inhibit calcium influx through voltage sensitive channels. We have investigated the coupling of each D2 isoform in stably transfected cell lines. Rat D2S and D2L constructs (McChesney et al., Mol Cell Endo 79:R1-R7, 1991) were introduced into AfT20 cells via lipofectim mediated transfection. Cell lines prepared containing roughly equivalent levels of receptor. transfection. Cell lines generated containing roughly equivalent levels of receptor expression were selected for study. Cells were loaded with the calcium sensitive dye Fluo-3. Cell suspensions in cuvets were monitored using a spectrofluorimeter equipped with a micro stirrer. 1 uM Bay K 8644, an L-type spectrolitorimeter equipped with a mirco stirrer. I will Bay K 2044, an L-type calcium channel agonist, led to an ~50% increase in intracellular calcium concentration above baseline in transfected and untransfected AtT20 cells. In AtT20 cells expressing either D2L or D2S which were first exposed to Bay K 6644, the addition of 1 uM dopamine or quinpirole (a D2 receptor agonist), rapidly decreased intracellular calcium levels to baseline. When introduced just before Bay K 8644, quinpirole was able to block the increase in intracellular calcium levels. Quinpirole was able to block the increase in intracetiniar carcium levels. Quinpirole had no effect on calcium influx in the presence of the D2 antagonist (+)butaclamol, or in untransfected ArT20 cells. These results indicate that both D2L and D2S stimulation inhibit L-type voltage sensitive calcium channel activation in ArT20 cells. The coupling of each isoform will be further characterized in ArT20 and other cell lines. Supported by NIH grant MH45212

## 281.20

G-protein Coupling and Regulation of Dopamine Release by D2-like Receptors in the Central Amygdaloid Nucleus. J. E. Lachowicz\* and C. D. Kilts, Experimental Therapeutics Branch, NINDS, NIH, Bethesda, MD 20892 and Department of Psychiatry, Duke University, Durham, NC 27710.

We have previously demonstrated that D<sub>2</sub> receptor activation in the central amygdaloid nucleus (CAN) does not stimulate or inhibit adenylate cyclase activity. To determine whether these D<sub>2</sub>-like adentifie Cyclase activity. To determine whether these D<sub>2</sub>-Tike receptors are coupled to guanine nucleotide binding (G) proteins, the effect of GppNHp on dopamine competition for D<sub>2</sub> radioligand binding was examined. [125]Iodosulpiride binding in the CAN was assayed by quantitative autoradiography on serial coronal rat brain sections. In the absence of GppNHp, CAN dopamine competition for [125I] iodosulpiride binding conforms to a two site model with a high (IC<sub>50</sub>=0.14  $\mu$ M) and low (IC<sub>50</sub>=4.99  $\mu$ M) affinity site. GppNHp (10 μM) converts dopamine competition to the low affinity opphrip (10 µM) converts dopamine competition to the low arimustic (IC<sub>50</sub>=4.60 µM), indicating that these D<sub>2</sub>-like receptors exhibit a negative allosteric interaction with a G-protein. D<sub>2</sub> receptor regulation of *in vivo* dopamine release in the CAN was investigated by superfusion of the microdissected CAN with the D<sub>2</sub> receptor antagonist eticlopride to inhibit endogenous dopamine activation of D<sub>2</sub> autoreceptors. Eticlopride produced a 3-fold increase in dopamine release quantified by HPLC and electrochemical detection. These data how that the new advantage coupled D<sub>2</sub> like recentors in the show that the non-adenylate cyclase coupled  $D_2$ -like receptors in the CAN are coupled to inhibition of dopamine release, possibly via G-protein coupling. (Supported by MH 39967)

## CATECHOLAMINES: DOPAMINE I

## 282 1

HUMAN DOPAMINE TRANSPORTER cDNAs: STRUCTURE AND EXPRESSION. D.J. Vandenbergh\*, A.M. Persico, A.M. Gonzalez and G.R. Uhl, Lab. Mol. Neurobiol., ARC/NIDA, & Depts. Neurol. & Nsci., JHUSM, Box 5180, Baltimore, MD. 21224.

The dopamine transporter (DAT) removes dopamine from the synaptic cleft to help terminate dopaminergic neurotransmission and may participate in Parkinson's disease pathogenesis, Tourettes syndrome and/or drug addictions. We have isolated human DAT cDNAs that encode a reconstructed 3.9 kb human cDNA with short 5' and long 3' untranslated regions, an open reading frame of 620 amino acids 94% identical to the rat, 3 N-glycosylation sites in the second putative extracellular domain, and 10 copies of a unique 40 bp tandem repeat in the 3' untranslated region. In situ hybridization using oligonucleotides complementary to this sequence reveals high levels of expression in neurons of the human substantia nigra compacta and paranigralis nuclei. This cDNA identifies VNTR and RFLP genetic polymorphic markers; Taq I RFLPs show race-specific differences in allelic frequencies.

## 282.2

COCAINE INHIBITS DOPAMINE STIMULATED INTRACELLULAR ACCUMULATION OF SODIUM ION IN STRIATAL SUSPENSIONS OF THE RAT. S. M. Meiergerd and J. O. Schenk\*, Dept. of Chemistry, Dept. of Biochemistry and Biophysics, and Prgm. in Pharmacology/Toxicology, Washington State University, Pullman, WA 99164-4630.

Recently, we proposed a multisubstrate transport mechanism, involving  ${\rm Na}^+$  and  ${\rm Cl}^-$  as cosubstrates in the uptake of dopamine (DA) into striatal suspensions (see McElvain and Schenk, Biochem. Pharmacol., <u>in press</u>) Briefly, it was found that DA and Na<sup>+</sup> bind to the transporter first in random order followed by Cl binding last prior to the transport of DA. Cocaine inhibited DA transport uncompetitively by competing with Na $^{\dagger}$  for its binding site. The reaction sequence and implication of co-transport of DA with Na $^{\dagger}$  and Cl $^{-}$  was obtained by kinetic studies of the effect of the ions on DA transport and their reaction orders. Thus, co-transport is implied by our findings, but is not proven. The results of the work to be described show that DA stimulates accumulation of Na<sup>+</sup> into the intracellular compartment of striatal tissue as measured by ion selective electrodes. Na+ accumulation was inhibited ca. 50% by 1.0 uM cocaine, the  ${\tt K}_{1}$  for inhibition of DA uptake, suggesting that the kinetic implications of the kinetic transport model are valid with regard to  ${\tt Na}^{+}$ . Supported by the WA Alcohol and Drug Abuse Program (Legislative Initiative 171) and NIDA grant, DA07384.

DIFFERENTIAL REGULATION OF EXTRACELLULAR DOPAMINE DYNAM-ICS IN THE BRAIN. P.A.Garris\* and R.M.Wightman. Depart ment of Chemistry and Curriculum in Neurobiology, University of North Carolina, Chapel Hill, NC 27599-3290.

Synaptic dopamine (DA) overflow in the medial prefrontal cortex (MPFC), basolateral amygdala (BAN), caudate putamen (CP) and nucleus accumbens (NAc) during transient electrical stimulation of the medial forebrain bundle was monitored using fast-scan cyclic voltammetry in anesthetized rats. Signals were assigned to DA based on electrochemical, pharmacological and anatomical evidence. Despite a 90-fold disparity in terminal density, stimulation in a physiological range of 10 and 20 Hz elicited comparable DA levels in all regions. In contrast, pronounced differences were observed in the dynamics, frequency-dependence and clearance rates of overflow. Rates of DA release and uptake were similar in the MPFC and BAN but approximately 8- and 50-less, respectively, than that in the CP and NAc. When normalized to DA terminal density, relative release was 10-times greater in the MPFC and relative uptake was 10-less in the BAN. In conclusion, sparse mesoprefrontal and mesoamygdaloid DA projections have evolved unique mechanisms to evoke and maintain high concentrations of extracellular DA. The results further define the functional characteristics of mesotelencephalic DA neurons and raise the possibility of the regiospecific nature of DA neural transmission in the brain.

Single DA neurons recorded in the substantia nigra zona compacta

(SNC) undergo time-dependent changes in their sensitivity to intravenous apomorphine during withdrawal from continuous cocaine infusion (subsensitivity on day 1 followed by supersensitivity on day 7). We have observed in the present study that only supersensitivity on day 7 is observed when firing rate inhibition by bath-applied DA is tested in vitro; single DA neurons are normosensitive on day 1. This lack of subsensitivity on day 1 is consistent with a previous in vivo report that an intact striatonigral feedback is necessary for expression of the decreased sensitivity immediately following daily injections of another stimulant, d-amphetamine. soma/dendritic DA autoreceptors in the SNC are probably not subsensitive immediately following cocaine withdrawal. In contrast, the preservation of the supersensitivity in <u>vitro</u> suggest that DA autoreceptors indeed become supersensitive as the withdrawal phase is prolonged. To further examine the time-dependent sensitivity changes, we are currently examining the in vivo sensitivity of antidromically-identified nigrostriatal DA neurons to locally applied D, agonists, quinpirole. We will compare and contrast our <u>in vivo</u> and <u>in vitro</u> data. It is hypothesized that DA neurons will be normosensitive to DA on day 1 but supersensitive on day 7, confirming that the supersensitivity is due to a local change within the SNC, probably supersensitive DA soma/dendritic autoreceptors.

ISOFLUROPHATE ENHANCES THE NEUROTOXICITY OF MPTP N.H.Neff', T.Wemlinger' and M.Hadjiconstantinou<sup>12</sup>,
Depts of Pharmacology' and of Psychiatry<sup>2</sup> and the Neuroscience
Program, The Ohio State University College of Medicine, Columbus, OH

The irreversible cholinesterase inhibitor isoflurophate (diiso propylfluorophosphate, DFP) is often administered to exaggerate brain cholinergic activity. One consequence is enhanced turnover of dopamine (DA) in the striatum probable because of activation of nigrostriatal feedback loops and intrinsic striatal mechanisms to compensate for enhanced cholinergic tone. MPTP selectively destroys nigrostriatal dopaminergic neurons. To test the hypothesis that active nigrostriatal dopaminergic neurons are more vulnerable to neurotoxins, we administered DFP to enhance DA turnover and then administered MPTP. After a single injection of DFP there was a rise of acetylcholine (ACh) and a concomitant fall of DA and DOPAC. With 7 days of treatment with DFP, however, tolerance developed and DA and ACh content were essentially normal while DOPAC increased suggesting enhanced DA turnover. If MPTP, 30 mg/kg ip, was administered 2 hr after DFP, 1.5 mg/kg sc, for 7 consecutive days there was a dramatically enhanced loss of DA, DOPAC and tyrosine hydroxylase activity from the striatum compared with MPTP treatment alone. The enhanced loss of dopaminergic parameters did not appear to be related to altered MPTP metabolism in the two groups. We postulate that metabolically active dopaminergic neurons are more vulnerable to MPTP.

REGIONAL CHANGES IN EXTRACELLULAR NOREPINEPHRINE FOLLOWING FOCAL AND SYSTEMIC COCAINE. D.N. Thomas\*, R.M. Post Biological Psychiatry Branch, NIMH, Bld. 10, Rm. 3N212. and A.Pert. Bethesda, MD. 20892

Cocaine prevents the neuronal reuptake of brain catecholamines and indoleamines. Alterations in dopaminergic function have been studied extensively and presumably underlie the majority of the behavioural effects of this psychomotor stimulant. However, considerably less is known about the actions of cocaine on the norepinephrine (NE) system. In the present study using <u>in vivo</u> microdialysis we have characterised the effects of focal and systemic cocaine on extracellular NE in two noradrenergic terminal regions, the systemic cocaine on extraccular NE in two noradrenergic terminal regions, line hippocampus (HI) and frontal cortex (FC). Male Sprague Dawley rats were anaesthetised with chloral hydrate and dialysis probes were stereotaxically implanted into either the HI or FC. Basal NE concentrations in the HI and FC were 5.8 ± 0.21 pg/sample (mean ± SEM, n=4) and 4.2 ± 0.3 pg/sample (n=4) respectively. Following stabilisation of basal NE, cocaine was applied from the respectively. (n=4) respectively. Following stabilisation of basal NE, cocaine was applied focally via the dialysis probe at concentrations of 1, 10 and  $100\mu$ M for 15mins. Sampling was then continued for a further 4 samples prior to application of the successive concentration of cocaine in the III. the successive concentration of cocaine. In the HI cocaine (1 -  $100\mu$ M) produced a concentration dependent increase in the extracellular NE of 20%, produced a concentration dependent increase in the extracellular NE of 20%, 52% and 142% respectively. However, in the FC only the highest concentration of cocaine (100µM) produced an increase in the extracellular NE (63%). Systemic administration of cocaine (20mg/kg, i.p.) produced no effect on the extracellular NE in either the HI or the FC. These data are consistent with a previous report in which we have shown that desmethylimipramine administered focally into the two regions produces increases in extracellular NE (Thomas et al., 1991 Br.J.Pharmacol. 102), yet systemic administration is unable to alter extracellular NE in either region. The differential effects of cocaine in the two regions may suggest differences in the affinity of cocaine for the NE uptake site.

## 282.6

MODULATION OF DOPA DECARBOXYLASE IN THE STRIATUM OF A MOUSE MODEL OF PARKINSON'S DISEASE M.Hadjiconstantinou12, T.Wemlinger1, J.P.Hubble1, C.P.Silvia1

Depts of Pharmacology<sup>1</sup> and of Psychiatry<sup>2</sup> and the Neuroscience Program, The Ohio State University College of Medicine, Columbus, OH

DOPA decarboxylase (aromatic L-amino acid decarboxylase AAAD) is the rate-limiting enzyme for the production of dopamine (DA) in Parkinsonians undergoing L-DOPA therapy. A change of enzyme activity could have major clinical consequences. Based on our published studies for retina, we found that subchronic treatment (two treatments daily for 7 days) with DA receptor antagonists (SCH 23390, sulpiride & haloperidol) enhanced AAAD activity in the striatum while agonists (L-DOPA, bromocriptine & SKF 38393) depressed activity. Treatment with reserpine also enhanced AAAD activity. Using the mouse MPTP model, we found that AAAD activity could be significantly enhanced to near normal values by treatment with antagonists. From dose-response studies, the MPTP-treated mice were more responsive to the antagonists than normal mice, both by responding sooner after treatment and at lower doses. There was an apparent increase of the Vmax with no apparent change of the Km for L-DOPA or B6. We conclude that AAAD activity is modulated by either DA D1 or D2 receptors and that MPTP mice are more sensitive to modulating drugs. We postulate that L-DOPA, for treating Parkinson's disease, may in the long run actually impede its own conversion to DA by activating receptors that modulate AAAD activity.

## 282.8

PHENYTOIN PREVENTS METHAMPHETAMINE-INDUCED DOPAMINERGIC NEUROTOXICITY IN MICE. L. Manzino and P.K. Sonsalla. Neurology Dept., UMDNJ-RWJ Med.Sch., Piscataway, N.J. 08854.

Excitotoxicity mediated through stimulation of N-methyl-Daspartate (NMDA) receptors is an essential component of (METH)-induced methamphetamine dopaminergic neurotoxicity. Excitotoxicity is also thought to be responsible for neurodegeneration in epilepsy. Anticonvulsants have been reported to attenuate excitotoxin-induced neuropathology in This study was undertaken to determine if anticonvulsants would prevent METH-induced dopaminergic neurotoxicity in mice. Neostriatal tyrosine hydroxylase activity and dopamine content were decreased by 67% and 80%, respectively, 7 days after METH treatment (3 i.p. injections, 10 mg/kg, 2-h intervals). Phenytoin (10-50 mg/kg) prevented these METH-induced changes in a dose-related manner although it did not prevent dopaminergic neurotoxicity produced by 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP). METH-induced neuropathology was not prevented by two other anticonvulsants (valproic acid or diazepam) under the treatment conditions used. These results suggest a novel form of protection against METH-induced neurotoxicity by phenytoin.

CORRELATION OF POSTMORTEM STRIATAL DOPAMINE LEVELS WITH NIGRAL CELL COUNTS AND UPTAKE OF 18F-FLUORODOPA IN PREMORTEM PET SCANS. E.G. McGeer, D. Calne. B. Snow. I. Tooyama. H. Takahashi and T. Yamada. Kinsmen Lab. for Neurological Research and the Neurological Disorders Centre, U. B. C., Vancouver, B.C., Canada V6T1Z3

Brains of 1 Parkinson (PD), 1 Alzheimer with some PD pathology, 1 ALS and 3 PSP cases PET scanned during life with [18F]-6-fluorodopa (FD) have come to autopsy. Dopamine (DA), serotonin (5HT) and their metabolites were determined by HPLC on samples of the left midcaudate and midputamen and averaged to get a mean for the striatum (CP). In this small group, only the postmortem DA levels were significantly correlated with FD uptakes (R = 0.96). Correlations between FD uptake data and levels of individual DA metabolites, or with 5HT and its metabolite (5HIAA), were positive but insignificant with very low Rs. In another series of 5 PD and 5 age-matched controls, the number of pigmented neurons counted at the level of the oculomotor nerve correlated significantly with the mean striatal DA level (R = 0.86). The postmortem DA levels probably reflect DA bound in vesicles within endings. These data are consistent therefore with the hypothesis that the FD uptake measured by PET is an index of the number of surviving DA terminals in the CP, and probably reflects in most cases the number of surviving DA neurons. (Supported by the MRC).

## 282.11

CHANGES IN THE CENTRAL DOPAMINERGIC SYSTEMS IN THE STREPTOZOTOCIN-INDUCED DIABETIC RATS, <u>D.K. LIM\*1, B. HOSKINS2 AND I.K. HO.2</u> School of Pharmacy<sup>1</sup>, Chonnam Natl. Univ., Kwang Ju, 500-757 Korea and Dept. Pharmacol, & Toxicol, <sup>2</sup>, Univ. MS Med, Ctr., Jackson, MS 39216

Dopamine metabolism and characteristics of D-1 and D-2 receptors after chemically inducing the diabetic state were studied in rat striatum. Streptozotocin (STZ) was administered on three consecutive days (40 mg/kg, ip) to induce diabetes. Twenty-four hours after the last administration of STZ, the occurrence of catalepsy produced by an injection of SCH-23390 (0.05 mg/kg, sc) were monitered. After some rats were sacrificed 24 hr after the last treatment with STZ, changes in dopamine metabolism and in D-1 and D-2 receptors were determined using HPLC-ECD and radioligand binding ([3H]SCH-23390 and [3H]Sulpiride) assays, respectively.

The latency to onset of and the duration of SCH 23390-induced catalepsy were significantly increased (2 times) and decreased (0.4 times), respectively, in the diabetic rats. Striatal concentrations of DOPAC and HVA and their ratios to DA were significantly decreased (0.65 - 0.72 times) in the diabetic rats. Also the affinities of striatal D-1 receptors were significantly increased (18 %) without changes in the densities, while the densities of D-2 receptors were significantly increased (11 %) without affecting affinities. These data indicate an upregulation of dopamine receptors that may be due to decreased dopamine metabolisms. Furthermore, the results suggest that central dopaminergic activities is altered in the diabetic states,

## 282.13

KINETICS OF ASCORBATE'S EFFECTS ON DOPAMINERGIC AGONIST BINDING. L.C. Tolbent\*, S.C. Ashe, and I.J. Spollen. Dept. of Psychiatry and Behavioral Neurobiology, Univ. of Alabama, Birmingham, AL 35294.

Experiments conducted over the last decade or so using a variety of approaches ranging from in vitro and in vivo animal work to clinical trials in subjects with schizophrenia or autism have produced results consistent with the hypothesis that one of the roles of this vitamin in the CNS might be that of a dopamine neuromodulator. One of the approaches this lab has been exploring to investigate this hypothesis is that of in vitro ligand binding studies. Our previous results indicated that ascorbate inhibited dopaminergic agonist binding whether [3H] dopamine or the more selective and stable, D<sub>1</sub> or D<sub>2</sub> receptor specific ligands, [3H] SKF 38393 or [3H] N-0437 were used. Further, this inhibition was not explained by a simple "redox" effect on either ligand stability or at the level of the receptor(s) because the effect of ascorbate was not mimicked by structural analogues with essentially identical redox properties. The purpose of the present experiments was to explore possible mechanisms of this inhibition of dopaminergic agonist binding by ascorbate.

ascorbate. The inclusion of the non-hydrolyzable GTP analogue, Gpp(NH)p, to shift the affinity state of the receptors "right shifted" the  $IC_{50}$  for ascorbate inhibition of both  $D_1$  and  $D_2$  agonist binding. Kinetic experiments of both  $D_1$  and  $D_2$  agonist binding in the presence and absence of ascorbate failed to demonstrate any effect of ascorbate on the association rate. Conversely, the dissociation rate constants for both the  $D_1$  agonist,  $I^3H$  N-O437, were effected by the inclusion/exclusion of ascorbate at physiologically relevant concentrations.

the D<sub>2</sub> agonist, [<sup>3</sup>H] N-0437, were effected by the inclusion/exclusion of ascorbate at physiologically relevant concentrations.

These results are consistent with the hypothesized dopamine neuromodulator role for ascorbate and the relationship to an allostearic mechanism will be discussed.

IN VIVO STRIATAL DOPAMINE TURNOVER IS INCREASED IN RATS WITH HALOPERIDOL-INDUCED ORAL DYSKINESIA. Ronald E. See\* and Cathy E. Murray, Department of Psychology, Washington State University, Pullman, WA. 99164-4820.

We have previously found that chronic haloperidol (HAL) administration in rats produces unique changes in oral movement patterns that are not seen after short-term treatment. The present study examined changes in oral movements and dopamine (DA) activity in rats treated with chronic HAL. Female, SD rats were administered HAL or no drug via subcutaneous implants for 32 weeks. Oral movements were recorded with a video analysis system and analyzed for total number and form of movements. After 24 weeks, HAL-treated rats began to show persisting, significant increases in oral activity at 1-3 Hz and decreases at 5-7 Hz when compared to control animals. DA release and metabolism were assessed at the end of the chronic HAL administration period using in vivo microdialysis. Bilateral guide cannulae were implanted into the striatum (A +0.2, L +3.4, V -5.0). Following one week of recovery, during continuous HAL treatment, dialysis probes were unilaterally inserted and perfusion initiated. The same procedure was conducted 3 days after drug withdrawal on the contralateral side. Perfusates were injected into an HPLC-EC system and analyzed for DA, DOPAC, and HVA. Basal extracellular levels of DOPAC were significantly increased in the HAL-treated rats during continuous administration, while HVA and DA showed non-significant increases. Following withdrawal, there were no differences between groups in basal levels of any of the analytes. Increased DA turnover, manifested during continuous HAL administration, may be related to the development, but not the maintenance of orofacial dyskinesia. Supported by National Institutes of Health Grant DE09678.

BORNA DISEASE VIRUS CAUSES DOPAMINE DISTURBANCES IN RATS. Marylou V. Solbrig, George F. Koob, Sandra Loughlin, William Tsai and W. Ian Lipkin\*

\*University of California, Irvine, CA 92651 and The Scripps Research Institute, La Jolla, CA 92037  $\,$ 

Borna disease virus (BDV) causes neurologic dysfunction in a wide variety of animal species. To define motor and behavioral features of Borna disease, infected adult rats were studied using video, activity cage monitors and EEG. Rats showed a syndrome characterized by myoclonus, athetosis, dystonias, dyskinesias, autostimulation, self-mutilation, cannibalism and seizures (automatisms or behavior arrest). The pharmacology of these behaviors was analyzed using direct-and indirect-dopamine (DA) agonists, D1 and D2 receptor antagonists and a DA synthesis blocker. Amphetamine increased stereotypy and locomotion. SCH23390 decreased self-mutilation and, at higher dosage, suppressed all movement. Low dose apomorphine had a presynaptic autoreceptor effect rendering rats akinetic. BDV causes a syndrome of apparent DA excess with behavioral supersensitivity to amphetamine and apomorphine.

## 282.14

REPEATED HALOPERIDOL AND ASCORBATE TREATMENTS INCREASE BASAL ASCORBATE BUT NOT BASAL DOPAC IN RAT NEOSTRIATUM. R. C. Pierce\*, L.A. Shapiro, A.J. Clemens and G.V. Rebec, Prog. Neural Science, Dept. Psychology, Indiana Univ., Bloomington, IN 47405.

Growing evidence suggests a neuroleptic-like action of neostriatal ascorbate (Pierce et al., Neuroscience, 1991, 45: 373-378; Rebec et al. Science, 1985, 227: 438-440). Because neuroleptics exert maximal therapeutic effects with chronic treatment, we monitored extracellular ascorbate and DOPAC levels voltammetrically (via electrochemically-modified carbon-fiber electrodes) in the neostriatum of freely moving rats 24 hrs after the last of 21 daily treatments (s.c.) of 0.5 mg/kg haloperidol. Our results revealed that repeated haloperidol treatments increased basal neostriatal ascorbate to 350  $\mu$ M (relative to the control value of 200  $\mu$ M). Similarly, repeated daily administrations of ascorbate (500 mg/kg for 21 days, i.p.) significantly increased the extracellular concentration of neostriatal ascorbate (100  $\mu\text{M}$  above control). Neither chronic haloperidol nor chronic ascorbate treatment altered basal neostriatal DOPAC. Taken together, these results suggest that increased basal neostriatal ascorbate may contribute to the antipsychotic effect of chronic haloperidol treatment.

Supported by NSF grant BNS 91-12055.

#### 282.15

OPPOSING EFFECTS OF d-CPPene AND HALOPERIDOL ON ASCORBATE AND DOPAC LEVELS IN THE NEOSTRIATUM AFTER LONG-TERM AMPHETAMINE TREATMENT. M.E. Taylor\*, C.T. Carter, and G.V. Rebec. Prog. Neural Science, Dept. Psychology, Indiana University, Bloomington, IN 47405.

Glutamate appears to regulate the amphetamine (AMPH)-induced release of ascorbate (AA) in the neostriatum (Basse-Tomusk and Rebec, Pharmacol. Biochem. Behav., 35:55, 1990). To assess the mechanisms underlying this process, we examined the effects of d-CPPene (SDZ-EAA-494), a competitive NMDA antagonist, on extracellular levels of AA and DOPAC in the neostriatum after acute or long-term AMPH treatment. Rats were prepared for freely moving voltammetry and received 7 days of either 2.5 mg/kg d-AMPH or saline treatment. On the following day, electrochemically modified carbon-fiber electrodes were lowered into the neostriatum, and the rats received either d-CPPene (2.0 or 5.0 mg/kg), 0.5 mg/kg haloperidol, or saline. After 20 min all animals then received 2.5 mg/kg d-AMPH. Our results indicate that whereas acute and long-term AMPH treatment induced comparable increases in AA, CPPene potentiated this effect but haloperidol reversed it. In contrast, DOPAC was decreased in both the saline and CPPene treatments, but increased by the haloperidol treatment. Amphetamine-induced behaviors were reversed by haloperidol, and in CPPene animals, accompanied by ataxia. Collectively, this evidence suggests that AMPH-related changes in extracellular AA, which are reversed by haloperidol, are enhanced by competitive blockade of NMDA receptors. Supported by NSF grant BNS 91-12055.

## 282.17

ASCORBATE AND GLUTATHIONE ACT SYNERGISTICALLY TO MAINTAIN BRAIN SLICE ASCORBATE LEVELS AND TO PROTECT TISSUE FROM OXIDATIVE DAMAGE. M.E. Rice\*, E. Lee & M.A. Pérez-Pinzón, Dept. Physiology & Biophysics, New York University Medical Center, New York, NY 10016.

Ascorbate, like glutathione, is an endogenous, water soluble antioxidant and free-radical scavenger. Ascorbate is rapidly lost from mammalian brain slices incubated in ascorbate-free media (Schenk et al. Brain Res. 253: 353, 1982). This loss leaves the tissue vulnerable to damage from reactive oxygen species in the hyper-oxygenated *in vitro* environment generated by equilibration with 95% O<sub>2</sub> / 5% CO<sub>2</sub>. Here we describe incubation conditions necessary to maintain tissue ascorbate content, determined by HPLC-ED, in slices of rat cerebral cortex. Vibratome cut slices (400 µm) were incubated at room temperature for 6 hours in physiological saline with 0, 200 or 400 μM ascorbate (normal extracellular ascorbate concentration is 200-400 µM), with an equivalent level of thiourea, sodium bisulfite or glutathione. Intact cortex had an ascorbate content of  $2.34 \pm 0.07 \mu mol/g$  tissue wet weight (S.E.M., N = 26). With incubation in ascorbate-free media, ascorbate content fell to 23% of the intact value. This loss was inhibited by including ascorbate in the incubation medium, which maintained a 50% ascorbate level. The addition of a second antioxidant did not alter these levels, with one exception. Ascorbate content was maintained at nearly 100% of intact values when 400  $\mu$ M glutathione was included with 400  $\mu$ M ascorbate. Preliminary histological data suggested that maintenance of ascorbate content helped protect tissue from oxidative and glutamate-induced damage in vitro. demonstrate a synergism between ascorbate and glutathione and the benefit of their inclusion in in vitro media.

This study was supported by NIH Grant NS-28480.

SEROTONIN INTERACTIONS WITH ASCORBATE INDUCED LIPID PEROXIDATION IN POSTMORTEM HUMAN BRAIN. A. C. Andorn\* and R. Strong. Depts. of Psychiatry and Pharmacology, St. Louis Univ. Schl. of Med. and St. Louis VAMC.

Ascorbate (0.1 mM) induces lipid peroxidation (LP) as measured by the production of thiobarbituric acid positive reactants (TBAR) in particulate membrane fragments (PMF) derived from postmortem human brain. Using a standard photometric assay for TBAR with malondialdehyde as the standard, incubation of PM from prefrontal cortex (PFC) at 0.2 mg protein with Na-Hepes (34.4 mM) and 0.1 mM ascorbate for 120 min at 37°C produces  $19.4 \pm 4.0$ nmoles MDA per mg protein in young (< age 45) specimens (N = 12). Adding increasing concentrations of serotonin (5HT) to the incubation medium reduces the amount of MDA produced in the presence of ascorbate. No dose of 5HT enhances ascorbate stimulated LP in PFC. The logIC50 for 5HT inhibition of ascorbate stimulated MDA production is  $-5.14 \pm \text{an SEM of } 0.07 \text{ (N = 3) for an }$ IC50 of  $7.1 \times 10^{-6} M$ . In caudate and cerebellum, however, the dose response relationship of 5HT and ascorbate induced LP is changed. Nanomolar doses of 5HT actually enhance ascorbate stimulated LP, even though the IC50 for the inhibition of ascorbate induced LP remains nearly the same in both caudate (2.7x10 - 6M) and cerebellum (7.4x10 -6M). The PFC is an area rich in 5HT1 and 5HT2 receptors, while the caudate has a paucity of 5HT2 and the cerebellum, a virtual absence of both of these types of 5HT receptor. We hypothesize that there may be an interaction between 5HT receptors and LP in human brain.

## HYPOTHALAMIC-PITUITARY-ADRENAL REGULATION: CRF

## 283.1

PREFERENTIAL INDUCTION OF THE INTERMEDIATE-EARLY GENE, NGFI-B, IN HYPOTHALAMIC NEUROSECRETORY NEURONS IN RESPONSE TO STRESSES OR CORTICOSTEROID WITHDRAWAL. E.R. Frown\* R.K.W. Chan, K. Kovacs and P.E. Sawchenko, The Salk Institute, P.O. Box 85800, La Jolla, CA 92037.

The promoter regions of the rat CRF, oxytocin (OT) and vasopressin (AVP) genes contain sequences similar to the response element identified for NGFI-B, an intermediate-early gene structurally related to the steroid receptor superfamily. Combined immuno and hybridization histochemical approaches were used to determine whether challenges that target CRF, OT and/or AVP secretion and expression result in alterations in expression in neurosecretory neurons of NGFI-B, and another intermediate early gene, c-fos, which is widely used in the neuroendocrine and other systems as a marker for functionally activated neurons. Unlike c-fos, NGFI-B mRNA was found to be expressed at constituitively high levels in the telencephalon, but not in the endocrine hypothalamus, of unperturbed controls. NGFI-B and c-fos mRNAs and Fos protein were induced with a similar time course and in similar cell types in response to acute hypotensive hemorrhage (15% blood volume), salt loading (7 days on 2% saline) and adrenalectomy (at 6, 12, 24, but surprisingly not at 48 h or longer). Fos mRNA and protein were readily demonstrable in afferent pathways we have implicated as mediating the neuroendocrine responses in the two stress paradigms; these include medullary catecholaminergic cell groups in response to paraugms; these include medulary catecholaminergic cell groups in response to hemorrhage, and cell groups lining the lamina terminalis in response to salt loading. By contrast, NGFI-B mRNA was expressed at much lower levels, if at all, in these relevant afferents. Unlike c-fos, NGFI-B appears to be a preferential marker for synaptic and/or transcriptional activation in aspects of the magno- and parvocellular neurosecretory systems.

## 283.2

EFFECTS OF ANDROGEN ON HYPOTHALAMIC CORTICOTROPIC-RELEASING HORMONE (CRH) AND CRH mRNA. E.W. Bingaman\*, R.J. Handa. Dept. of Cell Biology, Neurobiology, and Anatomy, Loyola University, Chicago. Maywood, IL

The plasma corticosterone and ACTH response to novelty or foot shock stress is greater following long term gonadectomy of male rats. To further characterize the role of androgens in the regulation of the hypothalamo-pituitary-adrenal (HPA) axis we gonadectomized (gx'd) male Fischer 344 rats and treated them with dihydrotestosterone (DHT). Control animals were either gx'd and sham treated or left intact. After 3 weeks of treatment animals were sacrificed immediately following removal from their home cage. Radioimmunoassay of CRH in the hypothalamus showed a significant increase (p < .05) in CRH concentration in gx'd, sham-treated rats compared to intact animals (529.3±42.3 and 217.0±23.7 pg/mg protein, respectively). DHTtreatment of gx'd rats prevented this increase (220.5±58.0 pg/mg protein). CRH mRNA was examined by in situ hybridization histochemistry (ISHH) using an 35S-labelled oligonucleotide probe complemented to nucleotides 496-543 of rat CRH mRNA. Image analysis of hybridization density in the paraventricular nucleus (PVN) showed no significant differences between the treatment groups. These data suggest the influence of androgens on the HPA axis occurs, at least in part, at the level of the hypothalamus, and changes in CRH content en after 3 weeks of castration cannot be explained by concurrent changes in CRH mRNA in the PVN. Supported by NSF BNS9109226.

NEUROTENSIN AND IT'S ANALOGUE NT 8-13 ACTIVATES THE HYPOTHALAMIC-PITUITARY-ADRENAL AXIS: A ROLE FOR THE PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS.

PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS.

W. Rowe\*, M.J. Meaney, R. Ouirion, Douglas Hospital Research Center, Dept. of Psychiatry, McGill University, Montreal, H4H 1R3, Canada.

Central administration of neurotensin (NT) has been shown to activate the hypothalamic-pituitary-adrenal (HPA) axis in rat sa evidenced by increases in circulating ACTH and corticosterone (B). We investigated the effects of NT analogues (NT 1-8, and NT 8-13) on HPA activity as well as the possible site of action of NT. Intraventicular (icv) injection of the biologically active NT 8-13 into freely moving adult male rats caused significant increases in plasma ACTH and B compared to NT 1-8 and saline-treated controls. The temporal profile revealed peak activation of ACTH and B for NT 8-13 at 60 min following icv revealed peak activation of ACTH and B for NT 8-13 at 60 min following icv administration. This time point coincides with that previously reported for the parent compound NT 1-13 (Rowe et al. Annals NYAS. in press). Since NT 8-13 is capable of causing the same activation of ACTH and B as NT 1-13, this suggests that it is acting via the well known pharmacologically characterized NT receptor. We found that irCRF content to be higher in NT-treated animals 60 min following injection. However, there was no change in irAVP. Taken together these findings suggests that NTF stimulatory effects on HPA activity occur, in part at the level of the paraventricular nucleus (PVN) of the hypothalamus to regulate the synthesis/release of CRF.

Eight days following electrolytic bilateral lesions of the PVN, NT (6 ng/µl)

right days following electrolytic bilaterial tesions of the PVN, NT (6  $gg/\mu$ ) was administered iev to freely moving animals. PVN lesioning significantly attenuated (p< 0.05) the NT induced activation of ACTH and B compared to sham lesioned controls up to 4 hrs following injection: ACTH; 96.7  $\pm$ 5.1 vs 143.1  $\pm$ 19.6 pg/ml/min, respectively, B; 5.7  $\pm$  1.3 vs 13.2  $\pm$ 2.9  $\mu g/ml/mi$ n. This suggests that the PVN is required for the stimulatory action of NT on HPA

#### 283.5

COORDINATE REGULATION BY THE VENTRAL LAMINA TERMINALIS OF OSMOTIC INFLUENCES ON CRF EXPRESSION IN MAGNO- AND PARVOCELLULAR NEUROSECRETORY NEURONS. K. Kovács and P.E. Sawchenko\*, The Salk Institute, La Jolla, CA 92037.

Chronic hyperosmolality results in a marked down-regulation of corticotropinreleasing factor (CRF) expression in parvocellular neurosecretory neurons and an up-regulation in magnocellular oxytocin (OT) neurons, such that after as few as 3 days of maintenance on 2% saline as a sole source of fluids, the pattern of CRF expression is virtually indistinguishable from that of OT. A variety of in situ approaches were used to identify the afferent pathways that mediate these effects. Five days of salt-loading resulted in prominent Fos protein induction in cell groups associated with the lamina terminalis, including the subfornical organ (SFO), the median preoptic nucleus (MePO) and the vascular organ of the lamina terminalis (OVLT). Unilateral knife cuts in the coronal plane, just caudal the OVLT and extending 2 mm laterally from the midline and 2 mm dorsally from the base of the brain, abolished the effects of 5 days of salt loading on CRF mRNA in both neurosecretory cell types on the ipsilateral side. Cuts in the horizontal plane that sever projections from the SFO and/or MePO to the hypothalamus did not alter the effects of salt loading on hypothalamic CRF mRNA. Finally, ibotentic acid lesions of the OVLT and immediately adjoining aspects of MePO abolished the effects of salt loading on CRF mRNA levels in the magno- and parvocellular neurosecretory systems. The ventral lamina terminalis is either the seat of, or an obligate relay for, osmosensitive neurons that appear capable of coordinately influencing CRF expression in two neurosecretory cell types.

REPEATED ECS PRODUCES A LONG-LASTING INCREASE IN CRH mRNA EXPRESSION IN RAT HYPOTHALAMUS. Linda S. Brady\*, Allison B. Lynn, John R. Glowa, Dung O. Le, and Miles Herkenham. Section on Functional Neuroanatomy, Clinical Neuroendocrinology Branch, NIMH, Bethesda, MD 20892.

Electroconvulsive shock (ECS) therapy is effective in treating depressed patients that do not respond to antidepressant drugs. We used in situ hybridization histochemistry to examine the we used in situ hybridization histochemistry to examine the effects of repeated ECS in rats on the mRNA expression of CNS genes thought to be dysregulated in major depression. Treated rats received ECS (80 mA, 0.5 s) via ear-clips daily for 1, 3, 7, or 14 days. Control animals were treated similarly but received 0 mA. Rats were sacrificed 24 h after the last treatment. A single ECS treatment increased tyrosine hydroxylase (TH) mRNA levels in the locus coeruleus (LC) (200% of control), but did not alter corticotropin-releasing hormone (CRH) mRNA levels in the hypothalamic paraventricular nucleus (PVN). Repeated ECS (3, 7, or 14 daily treatments) increased TH mRNA levels further, with a peak effect at 7 treatments (367% of control). CRH mRNA levels in the PVN rose to their peak at 3 days (210% of control) and plateaued. Unlike TH mRNA which dropped, this elevation persisted at 4 weeks after discontinuation of ECS. The data persisted at 4 weeks after discontinuation of ECS. The data suggest that alterations in activity of the hypothalamic CRH and LC-norepinephrine systems may be responsible for the therapeutic efficacy of ECS in the treatment of human depression.

CALCIUM DEPENDENCY OF *IN VIVO* RELEASE OF CORTICOTROPIN RELEASING FACTOR FROM RAT MEDIAN EMINENCE. R. W. Gabr<sup>in</sup>, D. L. RELEASING TO A TOWN AT MEDIAN EMIRENCE. W. Gabi D. E. Birkle' and A. J. Azzaro<sup>th</sup>, 'Departments of Pharmacology and Toxicology' Neurology/Behavioral Medicine/Psychiatry, WVU, Morgantown, WV 26506.

Corticotropin releasing factor (CRF) has been characterized as a major neurotransmitter in many autonomic, neuroendocrine, and behavioral responses to stress (Nemeroff, 1991). The characteristics of endogenous CRF release from the nence/arcuate nucleus were investigated using the technique of in vivo microdialysis. Male Sprague-Dawley rats (250-300 g) were acutely implanted with microdialysis probes in the anterolateral median eminence under chloral hydrate anesthesia (David Kopf stereotaxic coordinates: +6.1 anterior to interaural line, +.3 lateral to saggital sinus, and -9.8 from dura). A solution of artificial CSF containing 0.5% BSA was perfused through the probe at a flow rate of 1  $\mu$ L per minute. Inclusion of ascorbate (200  $\mu$ M) and aprotinin (25  $\mu$ g/mL) in the perfusion media optimized recovery of CRF for analysis. Standards spiked into a pertison means application of the problem of the pr quantified by RIA with a detection limit of 2.5 pg per sample. Basal levels of CRF at 2 hours post-implantation averaged 12.1 pg/20  $\mu$ L/20 min (n=9). Addition of 100 mM KCl to the perfusate caused a 3.5 - fold increase in CRF release. Because levels mm KU to the perfusate caused a 3.5 - fold increase in CRF release. Because levels of CRF tended fluctuate following K\*-depolarization, a period of two hours between stimuli was necessary for basal levels to stabilize. K\*-evoked release was found to be inhibited by the L-type Ca++-channel blocker verapamil (100 µM). In addition, a be infinited by the L-type Ca Chainer Olocket Verapauli (AS  $\mu$ ). Large perfusate containing 100  $\mu$ M of the calcium ionophore A23187 caused a significant increase in CRF release over basal levels. This demonstration of  $\mu$  vivo calcium dependency of evoked CRF release supports the findings of in vitro (Smith, 1986) and in vivo (Merlo Pich, 1991) experiments performed in other laboratories

## 283.6

EFFECT OF A GLUCOCORTICOID RECEPTOR ANTAGONIST (RU-38486) ON CORTICOTROPIN RELEASING HORMONE GENE EXPRESSION IN THE NEONATAL HYPOTHALAMUS. T.Z. Baram\*, S.-J. Yi, J.N. Masters. Div. of Neurology, Childrens Hospital Los Angeles, Los Angeles, CA 90027 (S.-J.Y., T.Z.B.), Biotechnology Center, Ohio State Univ., Columbus, OH 43210 (J.N.M.)

Mechanisms controlling the synthesis of corticotropin releasing hormone (CRH) in neonatal rat hypothalamus and the ontogeny of glucocorticoid (GC) feedback control of hypothalamic CRH have not been defined. Stress-induced up-regulation of CRH gene expression during the first postnatal week may be impaired, and GC feedback role at the hypothalamic level in the stress-hyporesponsive period is unclear.

We studied the ontogeny of the negative feedback regulation of CRH gene expression by GC in the paraventricular nucleus (PVN). We gene expression by GC in the paraventricular nucleus (PVN). We implanted chronic cannulae containing a GC-receptor antagonist, RU 38486, in neonatal rats on postnatal days 3, 4, 5, 7, 9, 10, 12 and 15. Three days later, animals were sacrificed, and brains were analyzed for CRH-messenger RNA (CRH-mRNA), using semi-quantitative in situ hybridization. Animals implanted with cholesterol-containing cannulae served to evaluate the stressful effect of implantation on CRH-mRNA abundance. The presence of GC receptor messenger RNA (GR-mRNA) in the PVN of neonatal rats was also determined.

BU 38486 did not increase CRH-mRNA abundance during the first

RU 38486 did not increase CRH-mRNA abundance during the first postnatal week, despite the presence of GR-mRNA in the PVN. Chronic-implantation stress also failed to increase CRH synthesis during this period. CRH gene expression in the PVN was enhanced in infant rats implanted with either RU-38486 or cholesterol on postnatal day 9 or later. CRH-mRNA is enhanced by chronic blockade of GC receptors, compared to cholesterol, only subsequent to the eighth postnatal day. Furthermore, such blockade does not affect the response of CRHmRNA to chronic stress in the neonatal rat.

## 283.8

IN SITU HYBRIDIZATION STUDIES OF AVT, IST AND CRF mRNAs IN THE GOLDFISH NEUROHYPOPHYSEAL SYSTEM J.N. Fryer\* and Y. Okawara. Department of Anatomy, University of Ottawa, 451 Smyth Road, Ottawa, Ontario, Canada K1H 8M5.

In goldfish, secretion of adrenocorticotropic hormone is stimulated by corticotropin releasing factor (CRF), as well as by arginine vasotocin (AVT) and isotocin (IST). Immunocytochemical studies of the goldfish hypothalamus have revealed that CRF and AVT are co-localized in perikarya of the nucleus preopticus (NPO).

We have established techniques to examine the regulation of CRF, AVT and IST gene expression in the goldfish hypothalamus by the localization of the messenger RNAs (mRNAs) for each of these peptides with in situ hybridization histochemistry. The structure of the goldfish genes and of the mRNAs encoding CRF, AVT and IST have not, as yet, been characterized. As hybridization probes, so-called guessmen oligonucleotide sequences were synthesized, based upon sequences deduced from precursor cDNA sequences determined for another Cypriniform fish, Catostomus ersoni. The oligonucleotide probes were non-radioactively labelled at the 3'-end with digoxigenin-11-dUTP using terminal deoxinucleotidyl transferase and the probe-mRNA hybrids visualized enzymatically with alkaline phosphatase conjugated to a digoxigenin antibody.

AVT mRNA was localized in some parvocellular (pc) and many magnocellular (mc) perikarya of the NPO with intermediate staining intensity. IST mRNA was distributed ubiquitously in pc and mc cell bodies with high staining intensity. AVT and IST mRNAs were co-localized in some mc perikarya. CRF mRNA was localized in scattered pc and mc perikarya with low staining intensity, and was co-localized with AVT or IST mRNA in some mc perikarya.

The present investigations lay the foundations for investigation of gene expression

for hypothalamic neuropeptides regulating pituitary-adrenocortical function in the goldfish, a well established teleost endocrine model. (Supported by the M.R.C.)

PRIMARY CULTURES OF FETAL RAT AMYGDALA CONTAIN CORTICOTROPIN-RELEASING FACTOR (CRF) THAT IS RELEASED BY DEPOLARIZATION. M.S. Cratty, D.L. Birkle. Dept. of Pharmacology and Toxicology, West Virginia University, Morgantown, WV 26506.

CRF is a 41 amino acid peptide found in many brain regions. This peptide appears to play a pivotal role in stress, anxiety and depression. A limbic brain region that is of particular interest is the amygdala, which has high concentrations of CRF and is important in emotional and autonomic responses to stress. Few studies have examined the release of CRF from the amygdala. We used primary neuronal cultures prepared from amygdala/piriform cortex from embryonic (E18-20) rat brains to study the regulation of CRF release. Amygdala neurons were dissociated and plated in 35 mm wells. In these cultures, the presence of CRF-containing neurons was confirmed using indirect immunocytochemistry. CRF-like immunoreactivity was distributed in a bead-like fashion in about 1% of the neurons. After 15-20 days in culture, CRF release experiments were done by collecting samples of incubation media at various times. CRF was measured by radioimmuno-assay. Basal CRF release was undetectable. Time dependent CRF release in response to 56 mM K' was detectable at one minute and reached a plateau at ten minutes. These data suggest that primary cultures are an effective model system to study the regulation of CRF release in the amygdala.

ELECTROPHYSIOLOGICAL ACTIONS OF CORTICOTROPHIN-RELEASING HORMONE (CRH) ON NEURONES OF THE PARAVENTRICULAR NUCLEUS (PVN) OF THE RAT IN VITRO. D.W.F. Porter\* & O.I. Pittman. Dept. Med. Physiol. & Neurosci. Res. Group, Univ. of Calgary, Alberta, Canada. The PVN, pivotal to the neuroendocrine regulation of the HPA axis.

contains both magno- and parvocellular neurones immunoreactive for CRH and/or AVP. These two neuropeptides act synergistically on pituitary corticotrophs to encode ACTH secretion in response to specific stress-related stimuli. Anatomical and functional studies suggest there is also an interaction of the two neuropeptides within the PVN itself. We therefore investigated the electrophysiological actions of CRH on PVN neurones in the in-vitro hypothalamic slice. Male Sprague-Dawley rats (80-100 g) were perfused intracardially under pento-barbital anaesthesia with oxygenated ice-cold high-sucrose, high-Mg<sup>2+</sup> aCSF. The hypothalamus was excised and coronal slices (400  $\mu$ m) containing the PVN were cut. Electrophysiological recordings were made from submerged slices perfused with aCSF (2-2.5 ml/min). Intracellular electrodes (~100-200 MQ; 2 M K<sup>+</sup> acetate, containing 2% Neuro biotin) were directed visually to the PVN. Recordings of cells characterized as type-I (magnocellular, Tasker & Dudek, '91) on the basis of electrophysiological and immunocytochemical evidence showed that bath-application of CRH (10-6 M; 5 min) resulted in a long-lasting, but reversible, depolarization (10-25 mV), accompanied by an increased membrane resistance and firing of action potentials. CRH appeared to act directly on the resorted cells as the depolarization persisted in the presence of TTX (1 µg/ml). In a second group of cells, identified as type-II (parvocellular) cells, application of CRH resulted in a long-lasting hyperpolarization (~10-15 mV) with increased membrane resistance. Thus, CRH has contrasting actions on putative magnoand parvocellular neurones within the PVN.

### HYPOTHALAMIC-PITUITARY-ADRENAL REGULATION: POMC, ACTH, OTHER FACTORS

ENHANCEMENT OF TRANSIENT OUTWARD (A) CURRENT BY DEXAMETHASONE IN MOUSE CORTICOTROPE TUMOR (AIT-20) CELLS: CORRELATION WITH HORMONE RELEASE. A. J. Pennington. M. D. Woods. J. S. Kelly and F. A. Antoni (*SPON: Brain Research Association*) Department of Pharmacology and MRC Brain Metabolism Unit, Univ. of Edinburgh, Edinburgh, EH8 9JZ, U.K.

Edinburgh, Edinburgh, EH8 9JZ, U.K.

Glucocorticoids suppress stimulated corticotropin (ACTH) release in AtT-20 cells by inducing new protein(s). The aim of the present study was to investigate whether glucocorticoid-mediated inhibition is brought about by changes in membrane currents. The nystatin-perforated whole-cell patch configuration was used to record K+ currents from AtT-20 D16:16 cells at room temperature. In separate studies, hormone secretion at 37°C was measured by radioimmunoassay. Four types of K+-current could be discerned: 1)A transient outward (A-type) current that was fully blocked by 1mM 4-aminopyridine (4-AP) and partly suppressed by 30 mM tetraethylammonium (TEA); 2) a delayed rectifying component sensitive to TEA, 3) a delayed rectifying component not blocked by apamin and 4) a residual delayed rectifying component not blocked by the combination of 30mM TEA and 100nM apamin. Treatment with 100 nM dexamethasone (DEX) for 2h markedly increased the proportion of cells with A-current (Contr. 10/33 cells; DEX:13/19 cells, P< 0.005, chi² test), moreover, the size of A-current evoked by a -60mV to +50 voltage step was enhanced (Contr.; 30.7±4.5 n=8; DEX; 44±4 pA/pF, n=12 meant:5E, P<0.05, t-lest), in secretion studies, ACTH release induced by corticotropin releasing-factor (CRF) was strongly inhibited by DEX (EC5g) 3 nM, 70-100 % inhibition at 100 nM). Hormone release was also stimulated by TEA (5-25 mM). DEX inhibition at 100 nM). Hormone release induced by 50mM kCl or by the combination of TEA and 4-AP was largely resistant to inhibition by dexamethasone. These data suggest that treatment with dexamethasone enhances potasssium currents in AT-20 cells, and that these changes are instrumental to the inhibition of hormone secretion.

## 284.3

MICROINJECTIONS OF GALANIN ALONG THE LATERAL BORDER OF THE LOCUS COERULEUS INHIBIT PLASMA ADRENOCORTICOTROPIN IN CATS. D. E. Carlson and D. S. Gann. Departments of Surgery and Physiology, University of Maryland School of Medicine, Baltimore, MD 21201.

The locus coeruleus (LC) has been implicated in the control of adrenocorticotropin (ACTH) release in cats. In the rat, galanin-containing processes that originate from the dorsal medulla have been identified in the LC and the laterally adjacent parabracheal nucleus (PBN). To determine if galanin-like activity is present in these areas in the cat, immunocytochemistry was employed. Several areas of the PBN had dense distributions of reactive processes. In contrast, a less dense had dense distributions of reactive processes. In contrast, a less dense distribution of such processes was found to extend medially into the lateral locus coeruleus. Eleven acutely prepared, chloralose-anesthetized cats were then tested with microinjections of galanin (10  $\mu$ M, 100 nl/min, cats were then tested with microinjections of galanin (10 µM, 100 nl/min, 2 min) into these nuclei. Injections at five sites along the lateral border of the LC elicited significant inhibition of plasma ACTH (P<0.01, ANOVA) at 2 (-17.8±4.6 pg/ml), 4 (19.0±7.0 pg/ml), and 6 min (-19.6±6.8 pg/ml) after the onset of injection. This response differed significantly from that to vehicle at the same 5 sites (P<0.05) and from that to galanin at 10 sites that were remote to the lateral LC (P<0.01). Furthermore, mean arterial pressure did not change during the injection of galaning along the lateral LC. The results suggest that the galania containing along the lateral LC. The results suggest that the galanin-containing processes in the lateral LC drive an ascending pathway to the hypothalamus that modulates the release ACTH. Supported in part by DK-26831.

EARLY GLUCOCORTICOID INHIBITION IN MOUSE CORTICOTROPE TUMOR EARLY GLUCCORT ICOID INHIBITION IN MOUSE CORTICOTHOPE TOMOR (Att-20) CELLS: INDUCTION OF CALMODULIN BUT NO CHANGE IN LIPOCORTIN (ANNEXIN) I MRNA OR PROTEIN. M.J. Shipston. E.L. Mullens. S.L. Lightman. M.D. Woods. and F.A. Antoni. MRC Brain Metabolism Unit, Department of Pharmacology, University of Edinburgh, Edinburgh, U.K. and Neuroendocrinology Unit, Charing Cross and Westminster Medical School, London, U.K.,

Early inhibition (<2h) of secretagogue-stimulated adrenocorticotropin (ACTH) release by glucocorticoids involves the induction of new mRNA and protein. In the present study we have investigated whether calmodulin and the purported "second messenger" protein of glucocorticoid action, lipocortin I, may be involved in this process. AtT-20 D16:16 cells (passage 15-35) were used in all experiments, ACTH was measured by radioimmunoassay. Corticotropin releasing factor (CRF, 10 nM) stimulated ACTH release to 2-3-fold above basal releasing factor (CRF, 10 nM) stimulated ACTH release to 2-3-fold above basal. Preincubation with devamethasone dose-dependently inhibited CRF-induced ACTH release (EC50 ca.3nM) within 45 min, maximal effect was evident at 120 min. The inhibitory action of dexamethasone was prevented by blockers of mRNA and protein synthesis. Using a <sup>32</sup>P-labeled 0.4 kbp fragment of mouse calmodulin (pCAM2) Northern blots of total RNA revealed that treatment with dexamethasone increased the level of a ca. 1.6kb mRNA to about 5-fold within 45 min. No change in the level of lipocortin I mRNA was observed using a <sup>32</sup>P- labeled 1.37 kbp human lipocortin I cDNA probe. Immunoblotting for lipocortin with a monoclonal antibody showed no aversasion of this protein before or I with a monoclonal antibody showed no expression of this protein before or after treatment with dexamethasone in D16:16 cells. In contrast, both arrer treatment with dexamethasone in D16:16 cells. In contrast, both ilipocorful protein and mRNA could be readily detected by these methods in At7-20 D1 cells, but no induction by dexamethasone could be found. In summary, lipocorful I mRNA or protein were undetectable in At7-20 D16:16 cells at a time when glucocorticoid mediated inhibition was maximal. In contrast, a marked induction of calmodulin mRNA occurred, the significance of which requires further study.

## 284.4

ELEVATED ANTERIOR PITUITARY PROOPIOMELANOCORTIN (POMC) GENE EXPRESSION AT LIGHTS OFF IN AGED RATS WITH SPATIAL MEMORY IMPAIRMENT. N. Levin\*, N. Bengani, W. Rowe, M.J. Meaney, J.L. Roberts. Fishberg Res Ctr Neurobiol, Mount Sinai Sch Med, NY, NY 10029 USA & Douglas Hosp Res Ctr. Montreal, Quebec, Canada.

Ctr, Montreal, Quebec, Canada.

Several studies have reported elevations in basal or stress-induced plasma corticosterone (Cort) levels in aged rats. The present studies were undertaken to determine the effects of age-related elevations in plasma Cort on anterior pituitary (AP) POMC gene expression. A population of 24-26 month-old Long-Evans rats was subdivided into aged-impaired (Al) or aged-unimpaired (Al) groups based on behavioral screening using a test for spatial memory. See Sarrieau et al, abstract submitted to the 1992 Neuroscience Meeting, for a complete description of this paradigm and the hormonal status of these animals. Au, Al and young (Y) rats were decapitated under basal conditions at the nadir (AM) or peak (PM) of the circadian rhythm in HPA axis activity. Steady state levels of AP POMC nuclear RNA primary transcript and cytoplasmic mRNA were determined by solution hybridization/nuclease protection analyses.

[POMC corriant transcript | POMC corticolasmic mRNA |

|                 | POMC primary transcript | POMC cytoplasmic mRNA |
|-----------------|-------------------------|-----------------------|
| Group, time (n) | pg/0.5 AP (±SEM)        | pg/μg RNA (±SEM)      |
| Y, AM (11)      | 67.7±5.8                | 318.1±89.2            |
| Y, PM (2)       | 62.2±3.2                | 105.8±39.5            |
| AU, AM (7)      | 68.0±3.4                | 267.1±62.1            |
| AU, PM (2)      | 70.4±4.8                | 110.3±11.7            |
| Al, AM (7)      | 71.1±10.5               | 311.6±67.5            |
| Al. PM (5)      | 117.8±22.6**            | 196.5±24.7            |

Al, PM (5) 117.8±22.6\*\* 196.5±24.7

There was a significant increase in AP POMC gene expression in the PM in AI rats (\*\*pc.0.05 versus AU, PM and Y, PM), consistent with an increase in ACTH secretion in the PM in AI rats, with respect to AU or Y rats (see Sarrieau et al). From these initial data it appears that the decrease in cytoplasmic mRNA levels in the PM in Y and AU rats is not achieved in AI rats, despite elevated PM plasma Cort levels in AI rats (see Sarrieau et al). These data suggest that there is a greater than normal increase in POMC gene expression in the PM in AI rats, possibly due to a decreased sensitivity of the HPA axis to Cort feedback inhibition in AI rats.

HYPOTHAL AMIC-PITLITARY-ADRENAL ACTIVITY AND CORTICOSTEROID RECEPTOR EXPRESSION IN AGED, COGNITIVELY-IMPAIRED AND COGNITIVELY-UNIMPAIRED RATS. A. Sarrieau<sup>1</sup>, W Rowel, D. O'Donnelll, S. LaRocquel, N.P.V. Nair\*1, N. Levin2, J.R. Seckl3, and M.J. Meaney<sup>1</sup>. <sup>1</sup>Douglas Hosp. Res. Ctr., Depts. of Psychiatry, and Neurology and Neurosurgery, McGill Univ., Montreal, Canada H4H 1R3. <sup>2</sup>Dept. of Neurobiology, Mount Sinai Medical Ctr., New York, NY 10029. 3 Dept. of Medicine, Western Gen. Hosp., Univ. of Edinburgh, Edinburgh EH4 2XU. Scotland.

Increased glucocorticoid levels have been associated with hippocampal neuron loss and cognitive impairments in rats. Among 24-26 month old rats increased hypothalamic-pituitary-adrenal (HPA) activity is selectively associated with hippocampal dysfunction. Aged, cognitively-impaired (Al) rats show increased glucocorticoid secretion, while aged, cognitively-unimpaired (AU) rats do not differ from young animals. In the present study we found that AI animals show elevated plasma levels of both ACTH and B-endorphin compared with both AU and young animals, but only in the dark phase of the cycle. In addition, AI animals show increased median eminence levels of both CRF and, to a greater extent, AVP; again increased median eminence levels of both CRF and, to a greater extent, AVF; again only in the dark phase of the cycle. Previous studies (Sapolsy et al. Neuroendo, 1990; Herman et al., J. Neurosci., 1989) have shown that glucocorticoids (via both mineralocorticoid and glucocorticoid receptors) feedback at the level of the hypothalamus and hippocampus to regulate CRF and AVP synthesis. Interestingly, Al animals show decreased hippocampal mineralocorticoid and glucocorticoid receptor density; receptor mRNA levels are currently being analyzed from in situ hybridization studies. These studies suggest that the loss of hippocampal neurons and the decreased sensitivity to circulating corticosterone sult in increased synthesis of ACTH secretagogues and elevated pituitary-adrenal activity in AI animals

THE ROLE OF TYPE LAND TYPE II ADRENAL STEROID RECEPTORS IN MAINTENANCE OF BASAL ACTH LEVELS. R.L. Spencer\*, A.H. Miller, H. Moday, M. Stein and B.S. McEwen. Lab. of Neuroendo., Rockefeller Univ., and Dept. Psychiatry, Mt. Sinai School of Med., New York, NY.

Adrenalectomy of rats results in an increase in basal ACTH levels, which can be normalized by glucorticoid treatment. The subtype and location of the adrenal steroid receptors responsible for maintaining location of the adrenal steroid receptors responsible for maintaining normal ACTH levels have not yet been fully determined. We have treated adrenalectomized (ADX) male Sprague-Dawley rats (250-300 g) with the selective Type I receptor agonist, aldosterone (ALDO), or the selective Type II receptor agonist, RU28362, (1, 4, or 10  $\mu$ g steroid/h, s.c., Alzet miniosmotic pump, n = 5). After 7 days of steroid replacement, ADX rats and sham ADX rats were sacrificed 2 h into their light period. Thus blood was collected for RIM determination of ACTH light period. Trunk blood was collected for RIA determination of ACTH levels, and the hippocampus, hypothalamus, and pituitary were removed for measurement of available cytosolic Type I and Type II ratio measurement of available cycosine Type I and Type II addrenal stereoid receptor binding. Plasma ACTH levels of 7 day ADX rats were 438±92 pg/ml compared to 55±7 pg/ml in sham ADX rats. RU28362 normalized ACTH levels, whereas none of the doses of ALDO (high dose plasma ALDO = 3.2±0.7  $\mu$ g/dl) reduced ACTH from ADX levels. The high dose of ALDO occupied/activated more than 90% of the Number Compared and the pituiting. Type I receptors in the hippocampus and the pituitary. RU28362 occupied/activated Type II receptors in a dose-related manner while having no effect on Type I binding. These data suggest that activation of the Type II receptor is sufficient to maintain normal basal ACTH levels. The prospect that Type I receptor activation by corticosterone may have effects on basal ACTH secretion that were not apparent with Type I activation by ALDO is under investigation. INDUCTION OF c-FOS PROTEIN BY NICOTINE IN THE RAT BRAIN. S.G.

INDUCTION OF c-FOS PROTEIN BY NICOTINE IN THE RAT BRAIN. S.G. Matta\* and B.M. Sharp, Endocrine-Neuroscience Lab and Depts. of Medicine, Hennepin County Medical Center and University of Minnesota, Mpls, MN 55404. Nicotine is a potent secretagogue for ACTH and this response appears to be mediated by central catecholamine secretion. We have previously shown that fourth ventricular (IV) administration of nicotine rapidly elevated plasma ACTH levels and that a nicotinic cholinergic antagonist, instilled into the IV, inhibited the ACTH response to i.v. nicotine. The present investigations sought to identify brain sites which were responsive to nicotine as evidenced by the induction of c-Fos protein. Rats received nicotine sulfate [2.0 mg/kg bw i.p., 0.05 or 0.10 mg/kg bw i.v. (via indwelling jugular cannulae)] or saline, 60 min prior to cardiac perfusion with 2.5% acrolein + 4% paraformaldehyde in phosphate buffer, blt 7.2. mg/kg bw i.v. (via indwelling jugular cannulae)] or saline, 60 min prior to cardiac perfusion with 2.5% acrolein + 4% paraformaldehyde in phosphate buffer, pH 7.2. Free-floating, frozen sections (20µ) were incubated for 48h with c-Fos antiserum (Oncogene Science; 1:2500) and stained by the ABC method. The c-Fos response showed regional specificity and varied with dose. In the hypothalamus, paraventricular nucleus (predominantly parvocellular) and supraoptic nucleus were positive compared to saline. In brainstem, locus coeruleus and nucleus of the solitary tract (NTS) were positive, whereas A1 and C1 regions were negative. The greatest staining in the brain, in response to i.v. nicotine, was evident in the dentate gyrus, followed by CA3 region of the hippocampus. In cortex, cingulate gyrus was positive after i.v. and i.p. nicotine, whereas piriform cortex only stained in response to i.p. nicotine. These findings suggest that locus coeruleus and NTS may be directly activated by systemic nicotine, leading to stimulation of cells may be directly activated by systemic nicotine, leading to stimulation of cells within the paraventricular nucleus which depend on ascending catecholaminergic afferents from these brainstem regions. (Supported by DA 03977)

A COMPARISON OF HYPOTHALAMIC ACTH SECRETAGOG CONTENT IN THE MEDIAN EMINENCE AFTER COLCHICINE BLOCKADE TO PORTAL SECRETAGOG RELEASE. L. Michael Romero. \*1 Paul M. Plotsky. 2 Steven W. Sutton, 2 and Robert M. Sapolsky 1 Depart. of Biological Sciences, Stanford Univ., Stanford CA 94305; <sup>2</sup>Peptide Biology Lab, Salk Institute, La Jolla, CA 92037.

Stanford CA 94305; "Prepluce Biology Lao, Saik Institute, La John, CA 92037.

Hypothalamic portal cannulation studies indicate that release of ACTH from the anterior pituitary is controlled by several secretagogs, primarily corticotropin releasing factor (CRF), arginine vasopressin (AVP), and oxytocin (OT). The precise patterning of each of these secretagogs appears to be determined by the stressor applied, indicating that various stress afferents are integrated at the median eminence (ME) to produce a coordinated ACTH response to variety of different stressors. Unfortunately, the invasiveness of portal vessels cannulation precludes measuring secretagog patterns in an awake animal undergoing psychological stressors. To circumvent this, we modified the technique of Berkenbosch and Tilders (Brain Research 442:312, 1988). We injected colchicine into the lateral ventrielse of feesly behavior are the property of the property of the colchicine into the lateral ventrielse of feesly behavior are the property of colchicine into the lateral ventricles of freely-behaving rats to disrupt secretagog resupply to the ME and compared decreases in the ME content of CRF, AVP, and OT resupply to the ME and compared decreases in the ME content of CRF, AVP, and OT to various stressors. In first comparing this technique to published portal data we discovered that awake rats show a different secretagog output to insulin-induced hypoglycemia than that seen with portal cannulation. In agreement with Berkenbosch et al. (Endocrinology 125:28, 1989), we found that both CRF and AVP content declined in the ME during hypoglycemic stress. In a novel observation, we see no changes in OT content. This contrasts with our prior findings using the portal cannulation technique (Plotsky et al. Endocrinology 117:323, 1985) showing that only AVP is released into the portal vasculature in response to insulin-induced hypoglycemia. Although it would seem a priori that measuring actual secretagog output into the portal vasculature would be preferable to measuring changes in ME content, the invasiveness of portal cannulation surgery makes results difficult to interpret. It is unclear, therefore, which technique produces the more physiological results. It is, however, impossible to assess ME integration of a psychological stress response with a portal preparation. Preliminary data of ME secretagog content indicate that the psychological stressor of restraint has a distinct pattern of secretagog output.

MICROINJECTION OF NICOTINE INTO BRAINSTEM REGIONS ELEVATES PLASMA ACTH. B.M. Sharp, F., Wilson\* and S.G. Matta. Endocrine-Neuroscience Lab and Depts. of Med., Hennepin County Med Center and Univ of Minn, Mpls, MN 55404 and UMDNJ-RWJohnson Med. Sch., Piscataway, NJ 08854.

Nicotine is a potent secretagogue for ACTH; this response appears to be mediated by central catecholamine secretion. We have previously shown that fourth ventricular administration of nicotine rapidly elevated plasma ACTH levels and that a nicotinic cholinergic antagonist, mecamylamine (MEC), instilled into the fourth ventricle, inhibited the ACTH response to i.v. nicotine. Thus, the present investigations sought to identify nicotine-responsive regions in the brainstem which result in ACTH secretion and give rise to the ascending catecholaminergic afferents. Chronic brain and jugular cannulae were implanted and nicotine (50 nl over 30s) was infused into the locus coeruleus (LC), nucleus of the solitary tract (NTS),  $C_1$ , into the locus coeruleus (LC), nucleus of the solitary tract (NTS),  $C_1$ , or  $A_1$  cell regions of freely moving adult male rats. Injection of nicotine (free base;  $0.1-10\,\mu\mathrm{g}$ ) into NTS resulted in a dose-dependent increase in plasma ACTH. Injection into  $A_1$  or  $C_1$  cell groups only showed responses to the highest dose of nicotine in  $C_1$ . In LC, nicotine induced a dose-dependent elevation of plasma ACTH in response to 2.5, 5.0 and 10.0  $\mu\mathrm{g}$ . MEC (0.1 mg/kg bw, i.v.), administered 2 min prior to nicotine (10  $\mu\mathrm{g}$  into LC), inhibited the 7 min peak ACTH response (60% inhibition of the net response). Taken together with our previous reports, both the LC and NTS appear to mediate the ACTH response to systemic or fourth ventricular nicotine. (Supported by DA 03977)

PERIPHERAL AND CENTRAL SEROTONIN, RECEPTOR ACTIVATION DIFFERENTIALLY REGULATES ADRENOCORTICAL SECRETION. Jon E. Welch and David Saphier\*, Dept. of Pharmacology, LSU Medical Center, P.O. Box 33932, Shreveport, LA 71130.

Serotonin (5-HT) is generally considered to exert a facilitatory effect in the regulation of adrenocortical secretion in the rat, with several studies indicating that central 5-HT<sub>2\1C</sub> receptor activation mediates such responses because agonists increase plasma corticosterone (CS) concentrations. 20 min following either intraperitoneal (ip) or intracerebroventricular (icv) injection of selective 5-HT<sub>2/I/C</sub> receptor agonists or antagonists, blood was collected for measurement of plasma CS concentrations. IP administration of the 5-HT2 agonist (±)DOI increased plasma CS concentrations, as did icy administration at the higher doses tested. ICV administration of m-CPP, an agonist with greater selectivity for 5-HT<sub>1C</sub> receptors, failed to alter adrenocortical secretion. ICV administration of the 5-HT<sub>2</sub> antagonis ketanserin dose-dependently increased adrenocortical secretion, suggesting that 5-HT tonically inhibits adrenocortical secretion through 5-HT, receptors. Central administration of ketanserin did not block the plasma CS increases observed after ip (±)DOI, suggesting that the adrenocortical increases were not due to central 5-HT<sub>2</sub> receptor activation. In sodium pentobarbital anesthetized rats, icv (±)DOI decreased adrenocortical secretion at all doses tested, whereas, ip administration continued to increase adrenocortical secretion. ICV ketanserin again did not block the plasma CS responses to ip  $(\pm)$ DOI in anesthetized rats. 6-OHDA-induced lesions of the ventral noradrenergic ascending bundle abolished the ip response to  $(\pm)$ DOI suggesting that  $(\pm)$ DOI interacts with central noradrenergic systems to increase adrenocortical secretion. These results suggest that central and peripheral 5-HT<sub>2</sub> receptors differentially regulate adrenocortical secretion, the central component being sensitive to pentobarbital anesthesia and the peripheral component dependent upon central noradrenergic systems.

EFFECTS OF COCAINE ON ACTH SECRETION, STRIATAL C-FOS EXPRESSION, AND LOCOMOTOR SENSITIZATION IN AWAKE AND ANAESTHETIZED RATS. German Torres.\* Catherine Rivier. and Friedbert Weiss. The Salk Institute, The Clayton Foundation Laboratories for Peptide Biology, and 'The Scripps Research Institute, Department of Neuropharmacology, San Diego, CA 92186. The response of ACTH secretion, striatal immunoreactive c-fos

expression and locomotor activity to cocaine exposure was studied in awake rats and in animals anaesthetized with a combination of ketamine hydrochloride, acepromazine, and xylasine. In the absence of anaesthesia, acute cocaine exposure significantly increased plasma ACTH secretion and the expression of c-fos within neurons of the caudate putamen. In contrast, the aforementioned neurochemical or neuroanatomical effects were not observed in rats anaesthetized with ketamine. Daily injections of cocaine administered to awake rats for 5 days caused the well documented locomotor sensitization. However, when the rats were anaesthetized before each daily cocaine injection, the behavioral effects normally before each daily occarine injection, the benavioral effects hormally associated with the progressive and potent enhancement of locomotor behavior was absent. By itself, ketamine did not measurably alter pituitary or striatal metabolic function as reflected by the integrity of responsiveness of these loci to subsequent pharmacological challenges. These observations suggest that the effects of cocaine in the rat brain may depend at least in part on sensorimotor mechanisms, and on the participation of common excitatory neurochemical systems in both hypothalamic and striatal systems. # 284.13

THE ROLE OF c-fos IN THE CELLULAR REGULATION OF POMC.

B.B. Ruzicka\* and H. Akil. Mental Health Research Institute, University of Michigan, Ann Arbor, Michigan, 48109-0720. While the integrative function of the hypothalamic-pituitary-adrenal (HPA) axis during stress is fairly well understood, less clear is how the pituitary corticotroph integrates the signals it receives during stress to coordinate the secretion and biosynthesis of relevant peptides. The objective of this work was to study the role of the proto-oncogene, c-fos, in the cellular regulation of pro-opiomelanocortin (POMC). Mouse anterior pituitary tumor (AtT-20) cells were plated (10<sup>6</sup> cells/100 mm plate) in Mouse antenor pitulary tumor (At1-20) cells were plated (10º cells/10) mm plate) in DMEM (+2.5% FCS) and grown until 70% confluent. The cells were then exposed to corticotropin releasing factor (CRF) (10nM) for various times (5min-48h) and analyzed for levels of B-endorphin (BE) and B-lipotropin (BLPH) secretion, content and POMC and c-fos mRNA. CRF increased BE release at all time points when compared to cells not exposed to CRF. The maximal response, representing a 4-fold increase in BE release, occurred after 0.5h of CRF stimulation. Generally, CRF evoked only BE release, occurred after 0.5h of CRF stimulation. Generally, CRF evoked only small, if any, increases in BLPH release, with the maximal response (2-fold increase) occurring at 1h. However, CRF produced biphasic and parallel changes in the contents of BE and BLPH: these changes, which were more pronounced with BE, reflected an initial (at 5-15 min) decrease (~50%) in peptide content followed by an increase towards control levels at 0.5-1h of CRF exposure. A second decline in peptide content, observed at 2-4h, was followed by a gradual increase to beyond control levels (1.5-2-fold) by 12h. Thereafter, peptide levels returned to control levels. c-fos mRNA was elevated as early as 5min after CRF treatment, was maximally induced (3-fold) at 1-2h and returned to control levels by 12h. The temporal relationship between CRF-induced changes in c-fos and POMC mRNA are currently under investigation. The present data show that CRF alters the secretion and content of POMC-derived peptides and c-fos gene expression. Experiments conducted in the presence of anti-sense c-fos and c-for gene expression. Experiments conducted in the presence of anti-sense c-for RNA should provide more conclusive data regarding the role c-for may play in the cellular regulation of POMC. Supported by NIMH grant PO1MH42251. B.B.R. is the recipient of a Medical Research Council of Canada post-doctoral fellowship.

EFFECTS OF CORTICOSTERONE ON HIPPOCAMPAL 5HT AND SPATIAL MEMORY. V. Luine\*, R.L. Spencer and B.S. McEwen. Dept. of Psychology, Hunter College, and Lab. of Neuroendocrinology, Rockefeller University, NY, NY 10021.

The effects of chronic corticosterone (CORT) treatment on spatial

memory performance and serotonergic function in the hippocampus were investigated in ten month old, male Fisher 344 rats. Rats initially received 20 training trials on the 8-arm radial maze and then were split into a control group and a group that received CORT in their drinking water (400  $\mu$ g/ml) for 8 weeks. Serum CORT levels were 25±6  $\mu$ g% midway through lights off. Two weeks following treatment, another 20 trials of maze testing were given, and then 5HT and its metabolite, 5HIAA, and NE were measured by HPLC in CA1, CA3 and dentate gyrus (DG) of the hippocampus, frontal cortex (FCtx) and n. basalis. Post treatment maze testing showed no overall effect of CORT on trials to criterion or choice accuracy measures. However, performance in the CORT group was heterogeneous and several rats were impaired relative to all subjects. These impaired rats had consumed the most CORT during treatment. CORT treatment increased SHT (44%) in the DG and decreased SHT and NE in the FCtx (50%). In addition, levels of SHT AND SHIAA in some hippocampal areas was correlated with performance. Performance of both groups combined was negatively correlated with 5HT levels in CA1 (p<0.05), and in the DG, higher SHIAA levels in the CORT group were correlated with lower correct choice scores and earlier mistakes (p<0.01). Thus, prolonged ORT ingestion is associated with altered forebrain and hippocampal SHT, and some of these changes correlate with impaired spatial memory performance. INTERLEUKIN 1 INDUCES POMC VIA c-FOS AND c-JUN

+Mirela O. Fagarasan.++ Francesca Aiello.++ Katherin Muegge. ++ S.KDurum. J.Axelrod\* + Dept. of Pharmacology, Georgetown University, Washington D.C. 20007, ++ National Cancer Institute, \*National Institute of Mental Health, Bethesda, MD,

We have demonstrated that IL-1 after a long period of treatment stimulates B-endorphin release and potentiates the effects of other secretagogues in AtT-20 cells, a mouse anterior pituitary cell line. The mechanism of transduction of this effect was examined. IL-1 markdly increases the precursor of  $\beta\text{-endorphin},\ proopiomelanocortin\ (POMC),\ over$ a period of 24 hours. The role of intermediate early genes c-fos and c-jun on the ability of IL-1 to induce POMC was determined. We found that an early signal triggered by IL-1 in AtT-20 cells involves the enhancement of c-fos and c-jun mRNA expression. The treatment of the cells with antisense oligonucleotides to c-fos and c-jun had no effect on the ability or IL-1 to induce POMC synthesis. However when antisense to c-fos and c-jun were added together to AtT-20 cells, IL-1 no longer induced POMC. Nifedipine, a calcium channel blocker abolished the ability of IL-1 to increase POMC. These findings show that the effect of IL-1 on c-fos and c-jun is a necessary step in IL-1 inducing POMC mRNA.

## 284.16

SEPTAL LESIONS INCREASE SUBMISSIVE BEHAVIOR AND HPA ACTIVITY IN HAMSTERS. B.N. Bunnell\*, M.H. Hebert, B.R. Metcalf, E.H. Mougey¹, and J.L. Meyerhoff¹. Dept. of Psychology, U. of Georgia, Athens, GA 30602 and <sup>1</sup>Walter Reed Army Inst. Research, Washington, DC 20307. Submissive hamsters have elevated levels of POMC-

derived hormones. Septal lesions increase submission by increasing approach behaviors toward aggressive opponents. To see if lesion-induced increases in submissive behavior would result in increased HPA activity, 12 male hamsters received septal lesions and 8 served as operated or normal controls. After 14 days recovery, jugular catheters were placed in all males. 48 hours later they began five days of social tests against ovariectomized female opponents. Each test lasted 15 min. and blood samples were obtained immediately after the tests on days 1, 3, and 5. Plasma was assayed for cortisol and ACTH. Social behavior was scored by two observers, using a 30 category inventory. Each male faced 1 of 2 females on different days. All males became submissive to their female opponents. Those with lesions of the medial septal nuclei made significantly more submissive responses per aggressive act by their opponents and had significantly elevated cortisol and ACTH compared to controls. The and ACH compared to controls. The magnitude of the hormone changes reflected the increases in frequency of submissive behaviors. There was no indication that the lesions themselves alter normal HPA activity in stressful situations.

REGULATION OF BRAIN VASOPRESSIN RECEPTORS BY GLUCOCORTICOIDS. V.K. Patchev<sup>1</sup>, O.F.X. Almeida<sup>2</sup> and G.P. Chrousos<sup>1\*</sup>. <sup>1</sup>SPE, DEB, NICHD, Bethesda, MD 20892 and <sup>2</sup>Max Planck Institute of Psychiatry, Munich, Germany.

Arginine-vasopressin (AVP) plays significant roles in neuroendocrine regulation and cognitive information processing. AVP, along with CRH, is a major regulator of ACTH and glucocorticoid secretion. Hippocampus (HIPP) and hypothalamus (HT) are principal target sites of glucocorticoid neuroregulatory effects and contain significant concentrations of AVP receptors. We investigated the effects of bilateral adrenalectomy (ADX) and subsequent replacement with supraphysiological doses of corticosterone or dexamethasone on the binding characteristics of AVP receptors in HIPP and HT of male rats. ADX significantly decreased AVP receptor concentrations in both structures. Interestingly, chronic glucocorticoid treatment was associated with further suppression of receptor concentrations in HIPP, but had no effect on the receptors in HT. Thus, AVP receptors in the brain are regulated by glucocorticoids, however, HIPP and HT receptors differ in their responsiveness to chronic glucocorticoid administration.

EFFECT OF DEXAMETHASONE ON THE CONDITIONED ENHANCEMENT OF NATURAL KILLER CELL ACTIVITY. C. Hsueh. R. Hiramoto. S. Christian\*, and Y. Ghanta. Departments of Biology, Microbiology, and Psychiatry, Univ. of Alabama at Birmingham, Birmingham, AL 35294.

The involvement of hypothalamic-pituitary-adrenocortical (HPA) axis in conditioned enhancement of natural killer (NK) cell response was examined. Dexamethasone (Dex, at 100 μg/kg) was injected intraperitoneally into conditioned animals prior to the conditioned stimulus/uncoditioned stimulus (CS/US) association or before reexposure to the CS. Conditioned enhancement of NK cell response was blocked by Dex given at recall (test) but not at the association. The results indicated that activation of the HPA activity was required to elicit the conditioned NK cell response at recall but not at the association level. However, the central stimulatory effect of methionine-enkephalin (Met-Enk) on NK cell activity was not blocked by prior injection of Dex. Methionine-enkephalin either exerts its effect independently of the HPA axis or it acts through the HPA axis by overriding the inhibitory effect of Dex on the HPA

# CALCIUM-MEDIATED METABOLIC STIMULATION OF NEUROENDOCRINE STRUCTURES BY CENTRAL ENDOTHELIN-1 IN RATS.

D.S. Wainman, D.F. Weaver, F.J. Espinosa and P.M. Gross\*, Departments of Surgery, Chemistry & Physiology, Queen's University & Kingston General Hospital, Kingston, Canada K7L 3N6 Although the cerebral distribution of binding sites for the endothelium and brain-derived peptide, endothelin-1 (ET), is known (Kohzuki et al., Neuroscience 42:245, 1991), functional responses in the nervous system to systemic or central ET have not been well characterized. We reasoned that the effects of ET would be particularly distinct in neuroendocrine structures of the hypothalamohypophysial system in which ET appears to be a native molecule (Yoshizawa et al., Science 247:462, 1990). We applied the quantitative autoradiographic ['4C]deoxyglucose method to assay focal rates of cerebral and pituitary glucose metabolism (GM) in conscious male Sprague-Dawley rats given saline or ET either intravenously (14 nmol/min, iv) or centrally (9 pmol in 3  $\mu$ l, icv) via a lateral cerebral ventricular cannula. Compared to values for saline-infused rats, iv ET produced no significant alterations in GM among forebrain neuroendocrine structures, except for substantial increases (106-219%) in the pituitary anterior and intermediate lobes (Endocrinology 129:1110, 1991). Compared to saline effects, icv injection of ET evoked diverse neuroendocrine stimulation, including the subformical organ, median eminence, paraventricular n., supraoptic n., periventricular n., ventromedial n., and all lobes of the pituitary gland (range of GM increases was +30-109%). These stimulatory effects of ET were inhibited by central pretreatment with the Ca<sup>2+</sup> L-channel antagonist, nimodipine (72 nmol in 1 µl, icv). The results identify that central, but not peripheral, ET produces a Ca<sup>2\*</sup>-mediated hypermetabolism of several forebrain neuroendocrine structures. ET, therefore, is a neuroendocrine stimulant centrally, whereas its functional effects as a circulating hormone acting on neuroendocrine activity may be important only in the intermediate and anterior lobes of the pituitary gland.

## HYPOTHALAMIC-PITUITARY-GONADAL REGULATION: LHRH AND LH II

## 285.1

RAPID SUPPRESSION OF GLUCOSE AVAILABILITY REDUCES FOS EXPRESSION IN GRRH NEURONS IN SYRIAN HAMSTERS. S.J. Berriman\* and G.N. Wade. University of Massachusetts, Dept. of Psychology, Neuroscience and Behavior Program, Amherst, MA 01003

The availability of metabolic fuels controls Syrian hamster ovulatory

cycles. Food deprivation during days 1 and 2 of the estrous cycle prevents the next expected estrus and ovulation. In rats, sheep, and other species, food deprivation results in cessation of pulsatile luteinizing hormone (LH) secretion. Treatment with drugs such as 2-deoxy-D-glucose (2DG) and insulin which rapidly reduce availability of glucose, inhibit ovulatory cycles in hamsters and pulsatile LH secretion in lambs (Hilleman, et al. Biol. Reprod. 44 (Suppl. 1):138, 1991). We have shown previously that food deprivation blocks the Fos expression normally seen on day 2 in caudal preoptic (POA) GnRH neurons. To determine whether inhibition of glucose availability affects the same subset of GnRH neurons, hamsters were injected with 10 U Lente insulin (n = 3), 2DG (2000 mg/kg body weight) (n = 3), or saline (n = 3) on day 1 of the cycle and killed 6 h later. A double-label immunoperoxidase technique was used to localize Fos and GnRH in hamster brains. The percent of Fos/GnRH colcalization was determined in the diagonal bands, medial septum, and rostral and caudal POA. Inhibition of glucose availability significantly reduced Fos expression in caudal POA GnRH cells; 6% of the GnRH neurons expressed Fos in the insulin- and 2DG-treated groups compared to 43% in the saline group. These results support the idea that glucose availability affects a site-specific population of GnRH neurons in the caudal POA. Since caudal POA GnRH neurons are the only GnRH neurons that express Fos on the days of the estrous cycle when LH is secreted in a pulsatile pattern, it is possible that glucose availability controls those GnRH neurons responsible for pulsatile LH secretion.

## 285.2

GnRH GENE EXPRESSION IS DECREASED WITH FASTING IN THE MALE RAT BRAIN. D.A. Gruenewald and A.M. Matsumoto\*, Univ. of Washington Sch. of Med. and VA Med. Ctr., GRECC, Seattle, WA 98108

Fasting causes a decrease in serum gonadotropin and testosterone (T) levels in the male rat. However, the mechanism underlying this decrease is unclear. We hypothesized that the fasting-induced decrease decrease is unclear. We hypothesized that the tasting-induced decrease in serum gonadotropins is due to decreased GnRH gene expression. Prepro (pp-) GnRH mRNA and serum gonadotropin and T levels were compared in 90 day old male Wistar rats fed ad lib or fasted for 60 hours (n=8/group). pp-GnRH mRNA was quantitated by in situ hybridization and computerized image analysis in 18 anatomically matched 20 µm coronal sections from the medial preoptic area (MPOA) and diagonal band of Broca (DBB), using a 35S-labeled 48 base oligodeoxynucleotide probe complementary to rat pp-GnRH mRNA. Trunk blood was assayed for LH, FSH and T by RIA. LH, FSH and T levels were lower in fasted vs. fed rats (LH:  $0.17 \pm 0.03$  vs.  $0.36 \pm 0.06$  ng/ml, p<0.01; FSH:  $6.7 \pm 0.5$  vs.  $8.7 \pm 0.6$  ng/ml, p<0.05; T:  $1.34 \pm 0.36$  vs.  $2.21 \pm 0.30$  ng/ml, p=NS [0.08]). In both the MPOA and DBB, the number of neurons expressing GnRH was lower in fasted vs. fed rats  $(6.6 \pm 0.7 \text{ vs. } 11.1 \pm 1.4 \text{ cells/section, p=0.01})$ , while cellular GnRH mRNA content was unchanged with fasting (83 ±  $80 \pm 2$  grains/cell). These data support the hypothesis that in the Wistar rat, fasting-related decreases in gonadotropin secretion are due, at least in part, to a decrease in GnRH gene expression, which is manifested by a decrease in the number of neurons expressing the GnRH gene.

LONG-TERM FOOD RESTRICTION DOES NOT ALTER LUTEINIZING HORMONE-RELEASING HORMONE (LHRH) GENE EXPRESSION IN SHEEP HYPOTHALAMI T. McShane \*, S.L. Petersen, S. McCrone, and D.H. Keisler. University of Missouri, Columbia, MO.

Long-term food restriction decreases secretion of LH, presumably as a result of central inhibitory influences on secretion of LHRH. We tested the hypothesis that long-term food restriction results in decreased biosynthesis of LHRH. Ten female lambs were ovariectomized at 18 wks of age, and received 100% nutritional requirements for metabolizable energy and crude protein (FED; n=5) or 30% requirements (R; n=5), fed between 18 and 25 wks of age. At 25 wks of age, blood samples were taken every 10 min for 6 h, and serum assayed for LH. Fewer than 2 pulses in 6 h were detected in 3/5 R lambs, and FED lambs averaged 6.2 ± 0.6 pulses/6 h. Four days following blood sampling, brains were collected and hypothalami dissected and stored at -80°C prior to sectioning. Coronal sections (12  $\mu$ m) were taken through the hypothalamic preoptic region. Using in situ hybridization histochemical techniques relative levels of mRNA encoding LHRH were determined. Mean levels of LHRH mRNA per neuron were not different between R and FED lambs. Individual mean concentrations of LH did not correlate with mean cellular levels of LHRH mRNA. These results provide evidence that the inhibitory effects of long-term food restriction on secretion of LH probably do not involve changes in LHRH biosynthesis.

A HYPOTHALAMIC SITE OF ACTION FOR SYSTEMICALLY ADMINISTERED EXCITATORY AMINO ACIDS. M.M. Fahy\* and H.F. Urbanski. Division of Neuroscience, Oregon Regional Primate Research Center, Beaverton, OR 97006.

Excitatory amino acids (EAAs), such as N-methyl-D-aspartate (NMDA), can stimulate the secretion of LH through a suprapituitary pathway involving LHRH. The aim of the present study was to determine whether specific EAA receptors exist in the vicinity of LHRH neurons, within the mediobasal hypothalamus, and whether they are accessible to systemically administered EAAs. was to determine whether specific EAA receptors exist in the vicinity of LHRH neurons, within the mediobasal hypothalamus, and whether they are accessible to systemically administered EAAs. Brains from adult rats were perfused with 4% paraformaldehyde and sectioned coronally using a cryostat (10  $\mu$ m). They were then hybridized with a <sup>35</sup>S-labeled NMDA receptor cRNA probe (NMDAR1; Moriyoshi et al., 1991). Intense hybridization was observed in the cerebral cortex and hippocampus, a finding that is in harmony with previous radio-ligand autoradiographic studies. Interestingly, intense hybdridization was also found within the hypothalamus, especially in the arcuate nucleus and ventromedial region. In a parallel study, involving the systemic administration of [ <sup>3</sup>H]-glutamate (200  $\mu$ Ci/kg BW), autoradiography revealed the accumulation of glutamate in the mediobasal hypothalamus, but not in other brain regions. These results demonstrate that EAA receptor mRNA is expressed in a brain area that is associated with the neuroendocrine control of the reproductive axis. Moreover, since this area appears to lie outside of the blood-brain barrier the findings raise the possibility that exogenous EAAs (e.g., of dietary origin) are capable of influencing the secretion of LHRH. (Supported by NIH Grants HD-24312 and RR-00163)

## 285.7

EFFECTS OF NMDA ON LH RELEASE AND LHRH MRNA LEVELS IN ESTROGEN-TREATED OVARIECTOMIZED NORMAL AND ANDROGEN-STERILIZED RATS (ASR). C.A.Barraclough\* and J-J Liaw, Dept. of Physiol., Sch. Med., Univ. Maryland, Baltimore, MD 21201.

The present studies examined the temporal changes which occur in plasma LH and LHRH mRNA levels following the iv injection of NMDA (30 mg/kg b.wt.) to control and ASR. In both groups, plasma LH increased significantly within 10 min, peaked between 20-30 min and declined thereafter. However, all LH values were significantly less in ASR. No differences in LHRH mRNA levels were detected in OVLT versus rostral (r), medial (m) or caudal (c) preoptic area (POA) neurons of controls nor were these levels different in LHRH neurons of controls versus ASR. 1 h after NMDA treatment of controls, LHRH mRNA levels were significantly elevated but only in rPOA and OVLT and they remained high to 4 h. In contrast, LHRH mRNA levels in these same brain regions of NMDA-treated ASR did not differ from untreated control or ASR values in any of the brain regions analyzed. Thus, although NMDA induces LHRH release it doesn't increase transcription of LHRH mRNA in ASR. We conclude that if NMDA acts directly on LHRH neurons to evoke LH release, then the intracellular mechanisms responsible for increasing transcription of LHRH mRNA have been damaged by neonatal androgen treatment. Supported by HD-02138.

FASTING REDUCES SERUM LH AND MODULATES LHRH RELEASE IN THE RAT. J.A. Farr, P.G. Harms, and N.H. McArthur\*, Depts of Animal Science and Vet Anat and Public Health, Texas A&M Univ, College Station, TX 77843.

To evaluate the influence of fasting on serum LH and hypothalamic

(HYP) LHRH, intact or castrate adult male rats were allowed at libitum access to food (CONT) or fasted for 96 hours (FAST). Serum LH and HYP LHRH release was measured by RIA. Serum LH (ng/ml) was reduced (p<0.05) in the intact FAST animals (CONT=1.66±0.10, FAST=1.16±0.15). Preopticohypothalamic (POA-HYP) explants were placed in culture tubes containing 0.6 ml of Krebs-Ringer bicarbonate medium (4.7mM potassium, K+, 10mM glucose, 0.1% BSA). The explants were incubated for 3 hours at 37°C in a BSA). The explants were incubated for 3 hours at 37°C in a 95%O<sub>2</sub>:5%CO<sub>2</sub> atmosphere using a vortex mixer. At 30 min intervals, 0.5 ml of incubate was removed from each tube and replaced with fresh media. All explants were challenged, after the fourth 30 min sampling period, with 60mM K+ in KRB to quantitate (mean difference ± SE between fourth and fifth samples) depolarization induced LHRH release. Explants from FAST rats released more (p<0.05) LHRH than CONT when K+ challenged (CONT=90.61 ±16.8, FAST=267.13±37.4). When POA-HYP explants from similarly reased intact rats were acid extracted, there was no difference (p>0.1) treated intact rats were acid extracted, there was no difference (p>0.1) (CONT= 6.71±0.69, FAST= 6.80±0.43) in total POA-HYP LHRH content (ng/ml extract); however, POA HYP explants from FAST castrate rats had a greater (pc-0.05) content of LHRH than the castrate controls (CONT=2.09±0.10, FAST=2.64±0.13). These data demonstrate that fasting reduces serum LH and suggest that LHRH release is modified in intact and castrate male rats.

## 285.6

NMDA-INDUCED PUBERTY AND ACTIVATION OF GRRH NEURONS IN THE MALE DJUNGARIAN HAMSTER. S.M. Yellon. Div Perinatal Biol, Depts Physiol, Peds and Anat, Loma Linda Univ Sch of Med, Loma Linda, CA 92350

The excitatory amino acid NMDA (N-methyl D-aspartate) induces precocious puberty, presumably by the activation of GnRH neurons that control gonadotropin secretion. Following NMDA treatment, GnRH cells express the proto-oncogene FOS (Dev Br Res 56: #294, 1990), an indication of increased transcriptional, hence neuronal activity (Soc Neurosci Abstr 17: #361.10, 1991). In the Djungarian hamster at the onset of puberty, an increase in the number of unipolar, but not bipolar GnRH-immunoreactive neurons in the medial preoptic area (MPOA) and diagonal band of Broca (DBB) is associated with increased gonadotropin secretion and rapid testes growth. Since GnRH cell subtypes may be differentially regulated, the present study tested the hypothesis that NMDA activates the unipolar subpopulation of GnRH neurons to induce puberty. Males were shifted from long (16L:8D) to short days (10L:14D) at 18 d of age and injected each morning with NMDA (1.6 mg ip; n=4) or saline (n=4). At 25 d, brains were obtained following intracardiac perfusion with Zamboni's fixative 1 h after treatment. Brain sections (60 μm) from the MPOA and DBB were stained by immunocytochemistry for FOS (Iaderola antiserum) and GnRH (Benoit LR1 antiserum). Testicular development was induced by daily NMDA treatment but blocked in saline-treated males; mean testes weights (±SE) were 245±16 and 43±11 mg, respectively. The mates; mean testes weights (±5E) were 245±16 and 43±11 mg, respectively. Ine number of GnRH-stained cells (both subtypes) was significantly increased in NMDA-treated males compared to that in saline controls (152±21 vs 73±7; p<0.05, ANOVA). Although both unipolar and bipolar GnRH cells expressed FOS, less than 14% of each subtype, irrespective of treatment, were FOS-labelled. In this experimental paradigm, the data suggest that NMDA-induced puberty coincides with increased numbers of both unipolar and bipolar GnRH perikarya but reproductive development is not necessarily associated with activation of a specific subpopulation of GnRH neurons. ACUTE EFFECT OF NMDA ON GONADOTROPIN SECRETION IN MALE SYRIAN HAMSTERS. H.F. Urbanski\* and M.M. Fahy. Division of Neuroscience, Oregon Regional Primate Research Center, Beaverton, OR 97006.

The inhibitory effects of short days on the reproductive axis of Syrian hamsters can be overcome by daily administration of N-methyl-D-aspartate (NMDA), an excitatory amino acid analogue. In the present study, the acute effect of NMDA (15-20 mg/kg BW, i.v.) on gonadotropin secretion was determined both in intact and orchidectomized hamsters of the LSH/Ss Lak strain, maintained orchidectomized namsters of the LSH/SS Lak strain, maintained under either long or short days. Although the intact animals showed a significant increase (P<0.05) in plasma LH levels within 10 min of NMDA injection, under both photoperiods, the orchidectomized animals showed a significant increase (P<0.01) only under short days. On the other hand, NMDA had no acute effect on FSH secretion in any of the treatment groups, a surprising finding in view of previous reports that chronic NMDA treatment of short days have the strain of short days have the strain that the property described in the strain of the short day have the strain of the short days have the strain of the short days are strained by increased plasma FSH levels. of short-day hamsters dramatically increased plasma FSH levels. Therefore, in contrast to the immediate stimulatory effect of NMDA on LH secretion, this long-term enhancement of plasma FSH levels might result from NMDA-induced suppression of rest levels might result from NMDA-induced suppression of melatonin release; in turn, this would cause a more sustained alteration in the pattern of LHRH secretion. To investigate this possibility, short-day hamsters were given a single injection of NMDA (25 mg/kg BW, s.c.) and the effect on plasma melatonin levels was determined by RIA. The nocturnal peak of melatonin release, however, remained unperturbed by the NMDA treatment. (Supported by NIH Grants HD-24312 and RR-00163)

81ZE AND AGE-RELATED CHANGES IN GNRH-CONTAINING NEURONS OF THE TERMINAL NERVE AND PREOPTIC AREA IN JUVENILE HAPLOCHROMIS BURTONI. R.C. Francis\*, H. Lee and R.D. Fernald. Neuroscience Program, Stanford University, Stanford, CA 94305. Soma size of irGnRH neurons in the preoptic area (POA) of the teleost fish, H. burtoni, varies according to social status and reproductive condition. GnRH neurons in the terminal nerve (TN), however, show no such plasticity. We monitored changes in the number and size of irGnRH neurons in the TN and POA in juvenile (sexually immature) fish in order to determine whether these two irGnRH populations exhibit different developmental trajectories. We sampled from two broods that exhibited markedly different growth rates. Two to four subjects were removed from each group at weekly intervals, and processed for ICC with an antibody to salmon GnRH. In both the TN and POA, irGnRH neurons first appear at age 2-4 weeks when the size of the fish reaches approximately 1 cm. Thereafter, cell number remains constant in the TN but continues to increase in the POA throughout the juvenile phase. Both number and size Thereafter, cell number remains constant in the TN but continues to increase in the POA throughout the juvenile phase. Both number and size of irGnRH neurons were more highly correlated with body size than with age. However, comparisons of individuals of the same size from the slowand fast-growing broods revealed that size rank within broods, not absolute size, accounts for most of the variance in soma size of POA irGnRH neurons. The TN population of irGnRH neurons shows no such effect of relative body size. Relative size is an important determinant of social rank. Hence, size of the POA neurons, but not the TN neurons, may be socially modulated. These results provide further evidence for the functional independence of the irGnRH neurons in the TN and POA. Supported by NIH HD23799 and MH09485.

### 285.11

GONADOTROPIN-RELEASING HORMONE (GNRH)-CONTAINING NEURONS CHANGE SIZE WITH REPRODUCTIVE STATE IN FEMALE FISH. SA.WHITE\* & R.D.FERNALD. Neuroscience Program, Stanford University. GnRH plays a vital role in regulating reproduction. In mammals, hypothalamic release of GnRH into the portal vasculature causes secretion of pituitary gonadotropins which stimulate gonadal production of sex steroids. In the teleost fish, Haplochromis burtoni, GnRH-containing neurons in the preoptico-hypothalamic area (POA) send direct projections to the pituitary. Here we show that in female H. burtoni, GnRH-soma size depends critically on reproductive state. We selected animals prior to, during, and after the reproductive portion of their life history, in both brooding and spawning states. Immunocytochemical staining of brain sections showed that the two-dimensional areas of POA GnRH neurons are up to twice as large in spawning females than in females carrying broods, a transformation which occurs within two weeks. At a younger age, GnRH neurons are larger in females which have never spawned than in brooding age-mates. Older, post-reproductive females have the largest GnRH neurons and little to no ovarian tissue. Enlargement of GnRH cells in these fish may be due to a lack of negative feedback of sex steroids, comparable to that reported for castrated tissue. Enlargement of GnRH cells in these fish may be due to a lack of negative feedback of sex steroids, comparable to that reported for castrated male conspecifics (Francis et al., 1992). In intact male H. burtoni, social stimuli regulate changes in GnRH soma size (Francis & Fernald, 1992). Since reproducing females have no social hierarchy and are exposed to similar external stimuli, the primary factor(s) controlling GnRH neuron size appears to be internal reproductive state. Thus, while GnRH neuronal size is plastic in both males and females, its regulation is dramatically different in each. Cyclical changes have been described for neurons in female rat hypothalamic nuclei (cf. Naffolin et al., 1990; McEwen, 1991). The present finding of soma size change in a non-mammalian vertebrate reveals a novel way in which neuronal plasticity underlies dynamic regulatory processes in adult brain. MAST CELLS WITH GRRH- IMMUNOREACTIVITY occur in the Brain After Courtship. R. Silver<sup>1</sup> and A.J. Silverman\*<sup>2</sup>, Barnard College of Columbia University<sup>1</sup>, N.Y., N.Y. 10027 and Department of Anatomy and Cell Biology<sup>2</sup>, Columbia College of Physicians and Surgeons, N.Y. 10032.

interest has recently been focused on interactions between the nervous and immune systems. We report here a new relationship between environmental stimuli that activate the reproductive axis and cellular elements of the immune network. We have previously and centural elements of the limitude network. We have previous described the migration of non-neuronal, GnRH immunoreactive cells into the brain of the ring dove following a brief period of courtship. Ultrastructurally the cells contain large vacuoles, a highly condensed nucleus and numerous filamentous processes. highly condensed nucleus and numerous filamentous processes. These characteristics suggested either a monocyte or mast cell lineage. The current experiments were destined to distinguish between these two classes. Two markers for macrophages, the OX42 antibody and the lectin, Bandetraea simplifolia B4 isolectin, did not label these cells. When markers for endocytotic activity (fluorogold and I125 GnRH) were either ICV or IP prior to courtship initiation, the cells did not capture any label. We conclude that the cells are not of the monocyte lineage. On the other hand, the habenula cells were metachromatic with acidic thionin and immunoreactive for histamine. Double label experiments indicated that all habenular GnRH nositive cells of this morphology contained histamine. Future instaintie. Dotto label experiments indicated that an naperitual finRH positive cells of this morphology contained histamine. Future studies will explore the nature of the signal that elicits the movement of mast cells into the brain and the role that the mast cells might play in altering nervous system function. ABSENCE OF FOS EXPRESSION IN GNRH NEURONS IN POA-GRAFTED HYPOGONADAL MICE (HPG). T.J. Wu\* G.M. Miller, M.J. Gibson and A.-J. Silverman, Dept. of Anat. Cell Biol., Columbia Univ., New York, NY 10032 and Dept. of Medicine, Mt. Sinai Sch. of Med., New York, NY 10029.

Fos oncoprotein expression is widely accepted as a marker for neuronal activation. We have shown that in normal steroid-primed ovariectomized mice paired with an ejaculating male, Fos expression occurs in greater than 40% of GnRH neurons and is maintained at this level for a longer time than similarly treated females paired with an unsuccesful male. HPG's lack a functional GnRH gene; females can enter persistent estrus when a preoptic area (POA) graft is placed in the third ventricle. The expression of Fos in these grafted GnRH neuron was determined in HPG/POA introduced to experienced males at 1400 h and sacrificed 50-60 min postejaculation. All mice were anesthetized and prepared for combined Fos and GnRH immunocytochemistry. Increased Fos expression in response to sexual behavior occurred in neurons widely distributed in the brain of HPG/POA. However, under these conditions, only 1 GnRH neuron (1.5% of 26-41 neurons/ animal) contained Fos. Experiments are in the determinents are increased to determine the contained Fos. progress to determine the overall capacity of grafted GnRH cells to synthesize this oncoprotein. BEHAVIOR-RELATED ALTERATIONS IN DISTRIBUTION OF BRAIN GNRH-IR MAST CELLS. X

Zhuang and R. Silver\*, Columbia University and Barnard College, New York, N.Y. 10027.

We have previously described the appearance of GnRH immunoreactive (ir) mast cells in doves that had been courting for 2 hrs (Silver and Silverman, Soc Neurosc Abstr 1992; Silver et al. J Neuroendocrinol. 1992). The present study describes the overall distribution of mast cells in the dove brain, and examines the effects of behavioral cues on the distribution of brain mast cells. GnRH-imast cells were observed in or around circumventricular organs mast cells were observed in or around circumventricular organs mast cens were observed in or around circumstitution organs (OVLT and SSO), the pla mater, blood vessels, and in the parenchymal tissue of the habenula. Four groups of adult male birds were studied. In the courtship group, males were paired with sexually active females and were permitted to court for 2 hours. In the aggression fried courising group, males were parted with sexually active females and were permitted to court for 2 hours. In the aggression group, males were paired with a squab for 2 hours, during which time they displayed aggressive behavior towards the squab. The third group were visually isolated from other birds for at least 3 weeks. The fourth group were long term castrates housed communally. In the first three groups, GnRH-ir mast cells were observed in all the areas described above, with differences among groups in numbers of habenular mast cells. As previously reported, there were significantly fewer mast cells in the habenula of isolated animals than in courted animals. Animals displaying aggressive behavior were intermediate between these two groups. The most dramatic effect was seen in castrated animals where virtually no mast cells were seen in the habenula and few in the pla mater. These results suggest a mechanism for interactions among the nervous, endocrine, and immune system in the brain during specific behavioral activities. Supported by NIMH grant 29380 (to RS).

## 285.14

EXPRESSION OF THE INTERMEDIATE FILAMENT PROTEINS PERIPHERIN AND VIMENTIN IN GONADOTROPIN
RELEASING HORMONE PRODUCING NEURONS. L. Jenn
Dept. Anatomy & Neurobiology, University of
Kentucky, College of Medicine, Lexington, KY 40536.

Immunofluorescent double stainings for gonadotropin releasing hormone (GnRH) and peripherin, vimentin or neurofilament-70 were used to determine the identity of the intermediate filaments in GnRH neurons of the adult rat. The results show that GnRH cells are unique neurons in the septum-diagonal bandrostral hypothalamus in that they express peripherin and vimentin but not neurofilament-70. Both peripherin and vimentin form dense perinuclear networks from which peripherin extends only into the proximal neurites while vimentin can be seen in certain GnRH terminals in the median eminence. The presence of peripherin and vimentin and the absence of neurofilament-70 in GnRH neurons as well as in olfactory receptor neurons suggests close embryological ties between these cell types and supports the view that both cell types arise from a common ancestor. DIFFERENTIAL EFFECTS OF UNILATERAL LESION IN THE PREOPTIC AREA (POA) ON COMPENSATORY OWLATION (CO) AND COMPENSATORY OWARIAN HYPERTROPHY (COH) IN ADULT HEMISPAYED RATS. J.L. Morán , M.E. Cruz , R. Salceda\*and R. Domínguez . ENEP-Zaragoza and Instituto de Fisiología Celu-

There are several indications that POA exerts an asymmetrical control on the regulation of ovulation and ovarian weight. Our interest was to analyze in unilateral lesions in POA affects CO and COH in the same way. Animals with unilateral lesions of POA in the day of estrus (E), after three consecutive 4-day cycles were hemispayed on the day of E, after three consecutive 4-day cycles were hemispayed on the day of E, right of left ovary extinpated. In another experiment rats hemispayed on E received a unilateral lesion in POA 12 days later. All the animals were autopsied on E. No differences in ovulation rate, CO and COH in right or left hemispayed rats were observed. Only 7/19 rats with lesion in the right side of POA ovulated, while 16/22 with left side lesion did (p<0.05). The left ovary did not show CO when the animals had a lesion in either side of POA (O and 33% vs. 107%, p<0.05). The COH of the night current was the property of the pro the right ovary was lower in rats with a ipsilateral lesion of POA (17 and 2% vs. 58%, p<0.05).

Data present herein support the existence of asymmetry in the

regulation of ovulation by POA. In both, hemispayed and intact animals, the lesion of the right side of POA partially blocks ovulation while it does not occur when the left side was lesioned.

ENDOCRINE DEREGULATION AND FERTILITY OF SPINAL CORD INJURED MEN. N.L. Brackett\*, C.M. Lynne, M.J. Amador and W.E. Bloch. The Miami Project and Dept. of Urology, Univ of Miami School of Medicine, Miami, FL 33136

Miami, FL 33130 Following spinal cord injury (SCI), most men are infertile because of poor semen quality, most notably, poor sperm motility. The etiology of impaired semen quality in SCI men is poorly understood. Several mechanisms have been hypothesized, including deregulation of the hypothalamic-pituitary-gonadal axis, but little is known about this possibility. The objectives of the present study were 2to determine the prevalence and severity of endocrine deregulation in SCI men, and to determine the providence and severity of endocrine deregulation in SCI men. and to determine if endocrine deregulation in SCI men is related to impairments

in their semen quality.

Serum levels of testosterone (T), follicle-stimulating-hormone (FSH), uteinizing hormone (LH) and prolactin (PRL) were measured in fifty SCI adult male volunteers. Within two weeks after hormone determination, semen was

mate volunteers. Within two weeks after hormone determination, semen was obtained either by masturbation, vibratory stimulation, or electroejaculation. More than half of the subjects (Ss) (26 out of 50) had abnormal hormone profiles. The remainder had a high prevalence of hormones in the low-normal range. The most common alteration occurred in levels of FSH, which were below normal in 13 subjects and above normal in 5 subjects. T, LH, and PRL were below normal in 5, 8 and 0 Ss and above normal in 0, 3 and 3 Ss, respectively. 12 of the above Ss had more than one abnormal hormone level. The incidence of hormonal abnormality was significantly higher at levels T8-12 compared to levels T3-4, which had the lowest incidence of abnormality. 5 out of 6 Ss with a levels T3-4, which had the lowest incidence of abnormality. 5 out of 6 Ss with a C5 injury had abnormal FSH levels. Semen quality was impaired in all Ss, but the impairments did not relate to any specific hormone abnormality. For example, of 5 Ss who were azoospermic, three had high FSH, and two had normal FSH. Sperm motility and viability were low in all Ss, and did not relate to a particular endocrine profile. We conclude that endocrine deregulation is a likely consequence of SCI in men, but is not the sole mechanism contributing to impairments in their semen quality.

COMPARISON OF PULSATILE AND CONSTANT TESTOSTERONE INFUSION ON LUTEINIZING HORMONE SECRETION IN THE RAM. T.J. Rhim, D.J. Schaeffer, D. Kuehl, L. Lubbers, G.L. Jackson\*. Department of Veterinary Biosciences, University of Illinois, Urbana, IL 61801.

Although testosterone (T) is secreted in an episodic pattern in males, previous studies have used constant T administration to study the effect of T on luteinizing hormone (LH) and/or LH-releasing hormone secretion. Thus, the objective of the present study was to compare the effectiveness of a pulsatile versus a constant pattern of T to suppress LH secretion in the ram. The study was conducted as a cross over experiment in a 4 x 4 Latin square design. Adult castrated rams (n = 8) were subjected to each of four different i.v. infusion regimens for 3 days: (1) constant diluent; (2) constant T; (3) pulsatile diluent (one pulse every 4 h); (4) pulsatile T. Equal amounts of T (768 ug/kg/24 h) were delivered by the pulsatile and constant regimens. Blood samples taken at 10-min intervals for 4 h prior to infusion (Day 0) and during the last 4 h of the infusion (Day 3) were analyzed for T and LH. Neither mean, pulse amplitude, nor inter-pulse interval of LH differed (p>0.1) among treatment groups at Day 0. Compared to diluent, T-treatment decreased (p<0.001) mean LH and increased (p<0.001) LH inter-pulse interval. LH inter-pulse interval was increased more (p<0.005) by constant T than by pulsatile T. Mean LH was slightly more suppressed (p = 0.052) by constant T than by pulsatile T. None of the treatments affected LH pulse amplitude. These results indicate that constant T is more effective than pulsatile T in suppressing LH secretion in the ram. (Supported by USPH Grant 1R01 HD 27453)

LOCALIZATION OF NEURONS CONTAINING LUTEINIZING HORMONE-RELEASING HORMONE (LHRH) mRNA IN THE HUMAN HYPOTHALAMUS AND BASAL FOREBRAIN. N.E. Rance', W. S. Young, III, B.O. Parks, N.T. McMullen. Depts. of Pathology and Anatomy, Univ. of Arizona Col. Med., Tucson, AZ 85724 and Lab. Cell Biol., NIMH, Bethesda, MD, 20892.

In the present study we used  $\underline{\text{in situ}}$  hybridization and computer-assisted microscopy to map the distribution of neurons expressing LHRH gene transcripts in the human hypothalamus. Every 20th section from the hypothalami of five adult males was incubated with an [35S]-labeled cDNA probe complementary to LHRH mRNA. Specificity was confirmed by hybridization of adjacent sections with a probe targeted to the gonadotropin-associated protein region of the LHRH mRNA. Maps were manually digitized with the aid of an image-combining computer microscope. We report a much greater number of LHRH neurons than previously described in the human brain. Three morphologic subtypes were observed 1) Small, oval and sparsely labeled neurons which were numerous in the septal-preoptic region (20 to 40 neurons/section) and also scattered from the bed nucleus to amygdala ("extended amygdala"); 2) Heavily labeled oval or elongated cells located in the base of the infundibular nucleus, the infundibular stalk, lateral hypothalamus immediately dorsal to the supraoptic nucleus, and rostral periventricular hypothalamus (6 to 12/section); and 3) Large neurons (> 500  $\mu$ m<sup>2</sup> cross-sectional area), intermediate in labeling density which were distributed in the extended amygdala, substantia innominata, ventral pallidum, putamen and nucleus basalis of Meynert (20 The pronounced differences in staining intensity, morphology and location of these three subtypes suggest distinct functional subgroups of LHRH neurons in the human brain. (Supported by NIH Ag-09214 and the Arizona Disease Control Research Commission)

#### OSMOTIC REGULATION I NEUROENDOCRINE REGULATION:

ENDOCRINE FACTORS DIFFERENTIALLY MODULATE PERIPHERAL

ENDUCKINE FACTORS DIFFERENTIALLY MODULATE PERIPHERAL
BENZODIAZEPINE RECEPTORS IN MALE AND FEMALE RATS. R.C.
Drugan\* and P.V. Holmes. Schrier Research Lab, Dept. of
Psychology, Brown Univ., Providence, R.I. 02912
The peripheral benzodiazepine receptor (PBR) has been
shown to be under tonic hormonal control. Rapid alterations
in renal PBR have also been reported in response to acute
hormone administration and stress. Thus, the renal PBR is regulated both tonically and phasically. We reported a sexual dimorphism in the stress-induced reduction in renal PBR. Ovariectomy and castration had no effect on this PBR. Ovariectomy and castration had no effect on this response. We recently discovered a rapid hormonal regulation of renal PBR by Angiotensin II (ANG II, see Holmes and Drugan. this volume). We examined the impact of ANG II and Atrial Natriuretic Peptide (ANP) as possible mediators of this gender effect. Both male and female rats received either a 25 ug injection of ANG II and were sacrificed 5 min. later or 3 X 25 ug injections of ANG II at 0, 30 and 60 min. and were sacrificed at 80 min. Male rats showed a significant reduction (25%) in renal PBR binding at both time points while female rats exhibited a significant reduction only after 80 min. Preliminary data also indicate gender differences 5 min. following a single, 30 ug injection of ANP. Females show an increase single, 30 ug injection of ANP. Females show an increase in renal PBR, while males show no effect at this dose. A sexual dimorphic response to both ANG II and ANP may be important causal factors in the gender differences in renal PBR stress reactivity. Supported by a Sloan Research Fellowship (R.C.D)

ANGIOTENSIN II REGULATES THE PERIPHERAL BENZODIAZEPINE RECEPTOR IN RATS. P.V. Holmes\* and R.C. Drugan. Schrier Research Lab., Dept. of Psychology, Brown Univ., Providence, RI 02912

The peripheral benzodiazepine receptor (PBR) is an outer mitochondrial membrane receptor found in both peripheral and CNS tissues. Recent evidence links the PBR to steroidogenesis in adrenal, gonads, and glia. The PBR is rapidly regulated during stress. Mild or brief stressors are generally reported to cause increases in PBR densities in several tissues whereas intense or prolonged stressors cause decreases. This biphasic response suggests that PBR alterations during stress reflect an endocrine feedback regulatory mechanism. Previous research has suggested that the renal PBR response to stress occurs independently of the hypothalamo-pituitary-adrenal axis or sympathetic nervous system. The roles of angiotensin II (ANG II) and atrial natriuretic factor (ANF) in the PBR stress response were examined. The stress-induced decrease in [3H]Ro5-4864 binding to renal PBR was attenuated by captopril pretreatment, and acute ANG II administration (25-125 µg s.c.) alone rapidly modulated the PBR in a fashion similar to stress. Decreases in PBR binding in kidney, heart, and cortex occurred within 5 minutes following a single 25 µg dose of ANG II, and the decrease observed in these tissues persisted for two hours following the final 25 µg injection of a 125 µg cumulative dose. Scatchard analysis revealed that the ANG II-induced decrease in renal PBR binding was due to a reduction in Bmax. Possible interactions between ANG II and ANF decreases. This biphasic response suggests that PBR alterations during to a reduction in Bmax. Possible interactions between ANG II and ANF are being explored. These experiments suggest that ANG II may act as the extracellular signal to regulate PBR activity in several tissues during stress. Supported by Alfred P. Sloan Fellowship #Br 2852 to R.C.D.

E NATRIURETIC PEPTIDE (CNP) AFFECTS VASOACTIVE PINAL PEPTIDE (VIP)-PEPTIDE HISTIDINE ISOLEUCINE NEURONS IN THE RAT HYPOTHALAMO-NEUROHYPOPHYSIAL XYSTEM. N. Minamitani, A.Kawaquchi, I.Naqai, K.Chihara, K.Sakai\*. Med. Ctr. for Students, Third Div. Dept. Med., Dept. Psy. Kobe Univ. Sch. Med., Kobe Merc. Ma. Univ., Kobe 650 Japan.

Recently identified CNP has been demonstrated to

Univ., Kobe 650 Japan.

Recently identified CNP has been demonstrated to possess pharmacological spectrums and amino-acid structure very similar to those of atrial NP and brain NP. It, however, remains to be clarified whether CNP affects VIP-PHI neurons in the hypothalamus (HT) and neurohypophysis (NL). Using the perifiusion study, as previously reported we investigated the effect of CNP on basal levels and osmotic-stimulated VIP and PHI releases from isolated NL and two different hypothalamic slices of adult male rats; one, frontal section (HT) without median eminence (ME), including paraventricular nucleus and suprachiasmatic nucleus, the other, horizontal section (ME). CNP induced a significant increase of VIP and PHI releases in 20 minperifusates from HT, ME and NL in the range of doses from 10<sup>-12</sup> to 10<sup>-7</sup>M. The rises by osmotic pressure (310 mOsm/kg) of VIP and PHI release from these tissues were significantly suppressed by the addition of CNP with the range of 10<sup>-12</sup> to 10<sup>-7</sup>M.

These results suggest that CNP acts on the VIP-PHI neurons in the NL as well as in the hypothalamus to stimulate the basal secretion and to attenuate the osmotic-stimulated releases of VIP and PHI. possess pharmacological structure very similar

### 286.5

HYPOPHYSIAL-PORTAL PLASMA LEVELS OF VASOPRESSIN AND OXYTOCIN INCREASE AFTER COMPRESSION OF THE PITUITARY STALK. G.B. Makara. S. Sutton. S. Otto. and P.M. Plotsky\*. Institute of Experimental Medicine, Budapest, Hungary and The Clayton Foundation Laboratories for Peptide Biology, The Salk Institute, La Jolla, CA 92037.

Compression of the pituitary stalk has been used to induce posterior pituitary gland denervation (PPD) in the rat and to study the role of the magnocellular neurosecretory system in regulation of the anterior pituitary gland (AP). Earlier studies demonstrated that PPD resulted in a loss of arginine vasopressin (AVP) from the neural lobe and an accumulation of immunoreactive AVP and oxytocin (OT) in fibers of the stalk median eminence (SME). In the present experiments, we studied the time-course of alterations in hypothalamic-pituitary peptide from the neural lobe and an accumulation of immunoreactive AVP and oxylocin (OT) in fibers of the stalk median eminence (SME). In the present experiments, we studied the time-course of alterations in hypothalamic-pituitary peptide systems from one to four weeks following PPD. SME content of AVP and OT increased sharply while CRF content was unchanged one week after PPD. Assay of peptide levels in hypophysial-portal blood collected from anesthetized (urethane, 1.1 g/kgBW, ip) rats via a ventral transpharyngeal approach revealed an incremental 4- to 11-fold elevation of portal AVP levels above controls from one to four weeks following PPD; portal OT levels were increased 8- to 14-fold over the same time period. In contrast, hypophysial-portal plasma levels of corticotropin-releasing factor (CRF) were decreased following PPD. Evaluation of AP sensitivity to CRF and AVP was performed one week post-PPD by measuring in vitro release of ACTH from incubated AP fragments exposed to various secretagogue concentrations. CRF-induced (0.1, 1, 10 nmol/l) ACTH release was similar in sham and PPD animals, while ACTH release elicited by AVP (0.5, 5, 50 nmol/l) was markedly reduced in PPD rats as compared to shams. The large and prolonged elevation of AVP and OT content in hypophysial-portal plasma and in the SME was probably due to peptide secretion from sprouting fibers of the magnocellular system in the SME above the level of the compression. The sustained elevation of portal AVP concentration following PPD was associated with desensitization of corticotropes to the actions of AVP on ACTH secretion. This model may be useful for studying the consequences of chronic hypersecretion of AVP and OT into the hypophysial-portal system.

PASSIVE REGULATION OF POSTERIOR PITUITARY VASOPRESSIN CONTENT. M.D. Fitzsimmons\*, M.M. Roberts, and A.G. Robinson. Department of

Medicine, Division of Endocrinology Univ. of Pittsburgh PA 15261.

In these experiments, we sought to determine whether the increasing pituitary vasopressin (AVP) content in the young adult male rat is actively regulated. Both hypo- and hypernatremia decrease AVP content relative to age-matched controls: hyponatremia by decreasing AVP synthesis and hypernatremia by increasing release faster than synthetic mechanisms can compensate. We postulated that the patterns of recovery from these conditions would indicate how pituitary AVP

| age(week | s) Control | Hyponatremia | Hypernatremia | content is controlled; if pituitary content is actively |

at 1 and 3 weeks after 1 week of hyponatremia or hypernatremia (2% NaCl for 21 hours/day) beginning at age 7 weeks. Six male Fischer 344 rats were sacrificed at each time and assayed for pituitary AVP. Whole pituitary AVP content (ng  $\pm$  SE)

Diminished AVP content in the hyponatremic animals is not the result of weight maintenance because, in another study, hyponatremia with weight gain still blocked age-related increase in pituitary AVP content. Both hyper- and blocket age-related interess in pluntary AVF content. Soot in yet-approximately objective the hyponatremia reduced pituitary content (versus age-matched control) but pituitary AVP during recovery caught up to controls only in the hypernatremic animals. These results support our hypothesis that AVP mRNA transcription (which increases during hyper-but decreases during hyponatremia) controls AVP synthesis and that posterior pituitary content passively reflects the balance between synthesis

ROLE OF NATRIURETIC PEPTIDES IN THE REGULATION OF MAGNOCELLULAR NEUROENDOCRINE NEURONS. K.M. Hurley

MAGNOCELLULAR NEUROENDOCRINE NEURONS. K.M. Hurley\*
and C.B. Saper. Depts. of Pharm. & Physiol. Sci. and Neurology, Univ.
of Chicago, Chicago, IL 60637

Natriuretic peptides oppose the effects of vasopressin systemically,
and may play a role in regulating vasopressin secretion as neuromodulators in the brain. To explore the basis for this interaction, we
examined the origin of atrial natriuretic peptide- (ANP-) and brain
natriuretic peptide- (BNP-) like-immunoreactive (-ir) fibers innervating magnocellular neurons in the supraoptic nucleus (SON) in the rat using retrograde tracing in combination with immunocytochemistry,

using retrograde tracing in combination with immunocytochemistry. Most ANPir neurons that innervate the SON were found in the anteroventral periventricular nucleus, whereas most BNPir neurons projecting to this target were found in the tuberomammillary nucleus. In order to determine the functional significance of this projection, we recorded intracellularly from magnocellular neurons in the *in vitro* hypothalamic slice during the application of ANP ( $10^{-7}$  to  $10^{-10}$  M). Bursting neurons responded with a hyperpolarization of the membrane potential, associated with an increased conductance and enhancement potential, associated with an increased conductance and enhancement of the afterhyperpolarizing potential, consistent with potentiation of the IK<sup>+</sup><sub>Ca++</sub>. This effect was abolished in the presence of low Ca<sup>++</sup> and high Mg<sup>++</sup> medium. Non-bursting neurons showed more heterogeneous responses: Among irregularly firing neurons, 83% showed a hyperpolarization (63% with membrane conductance increased, 33% decreased) and 16% demonstrated a depolarization associated with increased conductance. Among continuously firing neurons, 43% were hyperpolarized, 14% depolarized and 43% did not respond. Silent neurons generally did not respond (67%), although 33% were depolarized. The effects of natriuretic peptides on ion currents in Assopressin cells may sculpt their characteristic bursting activity. vasopressin cells may sculpt their characteristic bursting activity, thereby reducing the secretion of hormone.

BAROREFLEX CONTROL OF VASOPRESSIN SECRETION DURING PREGNANCY IN CONSCIOUS DOGS. V.L. Brooks\* and L.C. Keil, Oregon Health Sciences University, Portland, OR 97201 and NASA-Ames Research Center, Moffett Field, CA 94035.

To test the hypothesis that baroreflex regulation of vasopressin (VP) secretion is altered during pregnancy, pregnant (P) dogs (n=8) were surgically prepared with femoral (arterial and venous) and atrial (right and left) catheters. On different days, one of 3 doses of nitroprusside (NP; 1,2 or 4 µg•kg-1•min-1) was infused for 30 min in P dogs, and the NP series was repeated >1 month after delivery (non-P dogs). Compared to non-P dogs, P dogs had lower basal arterial pressure (BP;  $102\pm3$  vs  $112\pm2$  mmHg; p<0.01), higher heart rate (113±9 vs  $74\pm3$ b/min; p<0.01), lower left atrial pressure (LAP; 7±0.9 vs 10.2±1.1 cm H<sub>2</sub>0), lower right atrial pressure (RAP; 2.5±1.0 vs 5.5±1.0 cm  $H_20$ ; p < 0.01), but similar VP (2.2±0.4 vs 2.3±0.2 pg/ml). In non-P dogs, the highest NP dose decreased BP by 21±2 mm Hg, LAP by 6.3±1.3 cm H<sub>2</sub>0 and RAP by 5.7±0.7 cm H<sub>2</sub>0, and increased VP by 19.1±2.8 pg/ml. In P dogs, NP produced similar decreases in BP (23±3 mmHg) and LAP (3.3±0.9 cm H<sub>2</sub>0), but smaller decreases in RAP (2.6±0.9 cm  $H_20$ ; p<0.05). The increase in VP was less  $(9.7\pm4.9 \text{ pg/ml}; p < 0.05)$ . As a result, the relationship between BP and VP was shifted downward (p < 0.05) in P dogs compared to non-P dogs. These results indicate that the cardiovascular system is altered during pregnancy in dogs as in other species, and suggest that reflex increases in VP may be blunted. Supported by NIH HL 39923.

A SEXUAL DIFFERENCE IN VASOPRESSIN-IMMUNOREACTIVE NEURONS WITHIN THE NEUROENDOCRINE SYSTEM OF GOLDEN HAMSTERS. C.F. Ferris' and Y. Delville. Physiol. Dept., Univ. of Mass. Med. Ctr., Worcester, MA 01655.

In mammals, large neurosecretory neurons localized within the hypothalamus, particularly the supraoptic (SON) and the paraventricular (PVN) nuclei are the source of vasopressin (AVP) released in the neurohypophysis. Although this system appears to be insensitive to gonadal hormones in rats, we now report the existence of a sexual difference in golden hamsters. In males, a larger number of AVP-immunoreactive perikarya was counted in all hypothalamic neurosecretory cell groups than in females. The difference was largest (50%) within the SON. In addition, the concentrations of AVP extracted from the hypothalamus were twice as high in males than in females. It is unclear whether these differences are related to any sexual difference in endocrine function. However, a relation with sexual differences in brain function is also possible, as a large number of magnocellular AVP-immunoreactive neurons do not project to the neurohypophysis.

VASOPRESSIN IS PRESENT IN THE ENDOCRINE PANCREAS OF THE RAT: IMMUNOHISTOCHEMICAL LOCALIZATION C.L. Cream, A.S. Friedmann, V.A. Memoli, W.G. North\* Depts of Physiology and Pathology, Dartmouth Medical School, Lebanon, NH 03756 USA

Earlier work by others demonstrated immunoreactive vasopressin (irVP) in human and rat pancreatic extracts. Subsequent studies revealed that VP can stimulate insulin release from pancreatic beta cells. In the present study, irVP was localized to cells of the rat pancreas using immunohistochemistry and our rabbit polyclonal antibodies (Gonzo3) specific for vasopressin. Pancreas from Long Evans rats were removed, fixed in Bouin's solution, embedded in paraffin, and sections of 2 microns prepared for use in immunohistochemistry. Vasopressin immunoreactivity was demonstrated in small cells throughout the endocrine pancreas. These cells were located at the periphery of the islets and contained dendritic-like processes. VP and insulin immunoreactivity failed to colocalize in serial sections. This demonstration of irVP in cells of the endocrine pancreas, raises the possibility of a paracrine role for this peptide in the regulation of insulin release. Future studies aimed at determining the characteristics of the irVP-containing cells should lend further insight into the role this peptide plays in the endocrine pancreas.

C-TYPE NATRIURETIC PEPTIDE (CNP) ATTENUATES OSMOTIC STIMULATED SOMATOSTATIN (SRIF) RELEASE FROM RAT HYPOTHALAMIC SLICES AND NEUROHYPOPHYSES PERIFUSED IN VITRO. A. Kawaquchi, N.Minamitani, I.Naqai, K.Chihara. H.Kaneda\*. Kobe Merc.Ma.Univ.,Med.Ctr.for Students, Third Div.Dept.Med.Dept.Psy.Kobe Univ. Sch

Chihara. H.Kaneda\*. Kobe Merc.Ma.Univ., ned.cur.Lo. Students, Third Div.Dept.Med.Dept.Psy.Kobe Univ. Sch Med., Kobe 650 Japan.

CNP has been identified from the porcine brain with its structure similar to atrial NP and brain NP. It remains to be settled whether CNP affects hypothalamo-neurohypophysial SRIF neuron system. Using the perifusion system, as previously described, we sought to find the site of action and the effect of CNP on basal levels of and osmotic-stimulated SRIF releases from isolated neurohypophyses (NL) and two different hypothalamic slices of adult male rats; one, frontal section (HT) without median eminence (ME), including periventricular nucleus, the other, horizontal section (ME). A significant rise of SRIF from basal levels in 20 min-perifusates from HT, ME and NL was induced by addition of CNP to artificial cerebrospinal fluid used for perifusates in the range of dose from 10-12 to 10-7M. The increase by osmotic pressure (310 mOsm/kg) of SRIF release from these tissues were significantly inhibited by CNP with the range of 10-12 to 10-7M in a dose dependent manner.

These results suggest that CNP acts on the SRIF neurons in the NL as well as in the hypothalamus to stimulate the basal secretion and to suppress the osmotic-stimulated releases of SRIF.

NMDA AND NON-NMDA RECEPTORS MEDIATE SYNAPTIC ACTIVATION OF SUPRAOPTIC VASOPRESSIN NEURONS FOLLOWING ORGANUM VASCULOSUM LAMINA TERMINALIS (OVLT) STIMULATION IN VITRO.

C.R. YANG\*, V.V. SENATOROV AND L.P. RENAUD. Neuroscience Research, Loeb Research Institute, Ottawa Civic Hospital, Canada, K1Y 4E9.

The OVLT is a circumventricular organ that projects to the supraoptic nucleus (SON). Neurones from both of these areas are osmosensitive and functionally involved in body fluid homeostasis. We previously reported that electrical stimulation of the OVLT evokes GABAergic inhibitory and glutamatergic excitatory post-synaptic tentials in SON neurones in rat superfused hypothalamic explants (Ya SN Abst. 1991). The present study further evaluates the role of NMDA and non-NMDA receptors in mediating this excitatory response.

In media containing bicuculline (10-20 µM) to abolish all IPSPs, low intensity repetitive stimulation of the OVLT ( $_{80}$   $_{\mu A,10}$  Hz,1 sec) evokes a voltage-dependent 3-7 mV slow depolarization (duration, 1.5-3 sec) upon which are superimposed fast EPSPs and burst firing. This slow depolarization is markedly enhanced in media containing 0-Mg2+ and is reversibly blocked by an NMDA antagonist (-)APV (10-20  $\mu$ M). The fast EPSPs are reversibly blocked by a non-NMDA antagonist CNQX (10-30  $\mu$ M). The SON cells activated by OVLT stimulation fired phasically and demonstrated VP-immunoreactivity. These data suggest that a glutamatergic input from the OVLT activates both NMDA and non-NMDA receptors on SON cells. The latter may depolarize the VP cells sufficiently to remove the voltage-dependent Mg<sup>2</sup> block of the NMDA receptor-channel complex and thus permit the NMDA receptormediated slow depolarization. A possible role of this OVLT input to SON VP cell in response to osmotic stimulation remains to be defined. (Supported by MRC)

DUAL ACTION OF C-TYPE NATRIURETIC PEPTIDE (CNP) ON ARG-VASOPRESSIN (AVP) RELEASES FROM RAT HYPOTHALAMIC SLICES AND NEUROHYPOPHYSES PERIFUSED IN VITRO. I. Nagai, N.Minamitani, A.Kawaquchi, K.Chihara, K.Maeday. Med. Ctr. for Students, Third Div. Dept.Med. Dept. Psy. Kobe Univ. Sch. Med., Kobe Merc.Ma.Univ., Kobe 650 Japan.

Pay. Kobe Univ. Sch. Med., Kobe Merc.Ma.Univ., Kobe 650 Japan.

Very recently, CNP was found to be the third member of the mammarian NP family identified from porcine brain following atrial NP and brain NP. CNP mRNA was also detected mainly in the brain. Its physiological function in the brain remains to be elucidated. In order to clarify both the site of action and the effect of CNP on basal levels of and osmotic- stimulated AVP releases, the perifusion studies were performed in such a way as previously reported, using isolated neurohypophyses (NL) and two different hypothalamic slices of adult male rats; one, frontal section (HT) without median eminence (ME), including paraventricular nucleus and supraoptic nucleus, the other, horizontal section (ME) containing ME. The addition of CNP to artificial cerebrospinal fluid for perifusates, ranging in doses from 10<sup>-12</sup> to 10<sup>-7</sup>M caused a significant increase of AVP release from basal levels in 20 min-perifusates from HT, ME and NL. CNP, however, significantly blunted osmotic- stimulated AVP release from these tissues with the range of 10<sup>-12</sup> to 10<sup>-7</sup>M.

These results indicate that CNP has a dual action on AVP release in the NL as well as in the hypothalamus; stimulatory on its basal release, and inhibitory on its rise by the osmotic stimulation.

PHASIC FIRING ACTIVITY IN RAT SUPRAOPTIC VASOPRESSIN NEURONS IS BLOCKED BY THE NMDA RECEPTOR ANTAGONIST KETAMINE. R. Nissen', B. Hu, L.P. Renaud. Loeb Research Institute, Ottawa Civic Hospital, Ottawa, Ontario, Canada. K1Y 4E9

A potent NMDA receptor system has recently been characterized in rat supraoptic vasopressin (VP) and oxytocin (OT) neurons in vitro. The physiological function of the NMDA receptor complex expressed in these neuroendocrine cells remains unknown. In this study we used ketamine, a non-competitive NMDA open channel blocker, to examine whether NMDA receptor blockade can affect the patterned spontaneous activities observed in VP/OT neurons <u>in vivo</u>. Extracellular recording of phasic activity or irregular continuous discharges was obtained from identified VP or OT neurons, respectively, in pentobarbital anesthetized Long-Evans rats. In 13/15 VP cells, respectively, in peritobarotial ariestinetized Long-Evairs fats. Int 13/15 vP ceins, systemic administration of ketamine (<1.5 mg/kg) caused a complete cessation of spontaneous phasic discharge. This blocking effect was dose-dependent and fully reversible, but did not affect the threshold of antidromic activation of the same cells. Most (5/6) continuously firing OT neurons recorded from the same preparation remained unaffected by ketamine. We further tested ketamine applied directly to an additional 8 VP cells using multibarrelled electrodes. In these neurons, locally applied ketamine (1mM intrabarrel concentration) consistently blocked ongoing phasic activity in a similar manner and repetitive application caused complete suppression of phasic discharges. The same concentration of ketamine was also effective in blocking the responses evoked by local application of NMDA. Our data suggest that NMDA receptors play a critical role in controlling the physiological activity in VP neurons in this species. (Supported by MRC).

CIRCANNUAL RHYTHM IN THE EFFECTS OF FOOTSHOCK ON HUMORAL IMMUNE RESPONSE IN RAT. J. Amat, A. Torres and H. Vanegas\*. Lab. Neurofisiología, Inst. Med. Exp., Univ. Central de Venezuela, Apartado 50587, Caracas, Venezuela.

nezuela, Apartado 50587, Caracas, Venezuela.

Many immunological mechanisms are subjected to large seseasonal fluctuations. Such phenomenon result from the circannual rhythm of neurotransmitter systems modulating hypothalamic function. Our study tested the possibility that stress might affect the circannual rhythm of immunity. Adult female sprague Dawley rats were kept in doors, under natural cycles of light and temperature. Twenty min of intermitent footshocks were delivery though the floor of a plexiglass box, the mornings of 4 consecutive days. After the last stress session, stressed and control animals were injected 10' sheep red blood cells ip. Afterwards, blood was drawn from the tail every 3 days, and the sera titrated by microhemagglutination. This was repeated once a month between July 1990 and March 1992. Stressed animals showed higher antibody titers than controls the two Jul-Aug periods studied, and lower ones both Sept-Feb periods. This opposite effect of stress is in phase with the annual rythm shown for humoral immunity in "unstressed" animals (1). Therefore, we suggest that the circannual rythm reported for immune mechanisms results from an interaction between the central effects of the minimal stress to which both animals and humans are normally exposed, and the hypothalamic effects of internal clocks with a circannual period.

SOCIAL STRESS DURING IMMUNE DEVELOPMENT: AN AVIAN MODEL. J. E. Cunnick\*, L. Kojic, and R. A. Hughes. Dept of Microbiology, Immunology, and Preventive Medicine and Dept. of Psychology, Iowa State University, Ames, IA 50011.

Young domestic fowl present a useful model to examine the effects of stress on a developing immune system. They express signs of distress during social isolation. Those indicators of stress include increased vocalization and increased body temperature.

We used social isolation paradigm to induce stress in 12 day old birds. We then measured functional immune parameters in the spleen, blood, and thymus after 0, 15, 30, 60, and 90 min of isolation. The immune parameters examined included mitogen responses to Concanavalin A (ConA) and Poke Weed mitogen (PWM). There was a time dependent change in blastogenesis with the greatest change occurring at 60-90 min. In particular, the thymus and peripheral blood showed the most significant suppression of blastogenesis.

Thus, this research demonstrates that stress can alter immune function in developing young birds. Moreover, this paradigm will prove very useful for an examination of acute and long term effects of stress on a developing immune system.

## 287.5

ENHANCED HUMORAL AND CELL-MEDIATED IMMUNITY INDUCED BY ELECTRIC FOOT-SHOCK STRESS IN RATS.

Paul Wood, Alex Kusnecov, Larry Weechslef, Bruce S, Rabin. Brain, Behavior, and Immunity Center, University of Pittsburgh, Pittsburgh, PA. USA

Rats were given electric foot-shocks at either day -1, 0, +1, or +3 in relation to a SOL g I.P. injection of Keyhole Limpet Hemocyanin (KLH). Fourteen days later the rats received an intradermal challenge with antigen and 72 hours later the rats were sacrificed and the response of spleen lymphocytes to stimulation with KLH and the IgG and IgM antibody levels determined. The mean diameters of the delayed hypersensitivity skin test reactions were measured and histology of the skin test reactions was determined. Although the mean diameters of the skin test reactions did not differ between groups the animals stressed on day 0 or day +1 had a large lymphocytic infiltrate in the dermis whereas the non-stressed rats had a minimal infiltrate and the day -1 or +3 stressed rats had an intermediate amount of infiltrate. The largest lymphocyte mitogenic response to KLH was present in spleen lymphocytes from the day 0 or day +1 rats (peak response of 40,000 CPM in comparison to 10,000 CPM in the non-stressed rats). Rats stressed on day -1 or +3 had elevated mitogenic responses in comparison to the non-stressed rats, but lower than the rats stressed on days 0 or +1. The response of the spleen lymphocytes to non-specific mitogen did not differ between groups. The highest IgM antibody responses were in the rats stressed on days 0 and +1. Thus, immunologic augmentation can be produced in rats to specific antigen challenge and several functional aspects of the immune system are each found to be affected. As KLH is a T-dependent antigen, it is possible that all immune parameters found to be enhanced are related to T-helper cell

#### 207 2

CLASSICAL CONDITIONING AFFECTS CHEMICALLY-INDUCED TUMORIGENESIS. <u>Joan M.C. Blom, Lawrence Tamarkin and Randy J, Nelson</u>. Dept. of Psychology, Johns Hopkins University, Baltimore, MD 21218 and Assay Research Inc., College Park, MD 20742.

Traditionally, the immune system has been regarded as an autonomous physiological entity responsible for host defense. Nonetheless, complex interactions exist between the central nervous system (CNS) and the immune system. Classical conditioning, which requires the CNS, of immune function has been demonstrated in several studies. Furthermore, classical conditioning effectively modifies host resistance to the growth and development of transplantable tumors. Suppressed immune function has been associated with increased risk of cancer in humans and non-human animals. Based on the hypothesis that certain aspects of the CNS and immune system interact and that altered immune function affects carcinogenesis, we examined the effects of learned immunosuppression on the development of chemically-induced tumors in mice. Cyclophosphamide (CY) (100 mg/kg ip), an immunosuppressive agent, was paired with saccharin in the drinking water (0.1 %) of adult female mice (CF-1). Conditioned mice were exposed to saccharin twice in the absence of CY, on days 4 and 7 after the first exposure (day 1). All mice were injected with the chemical carcinogen 9,10 dimethyl- benzanthracene (DMBA, 50 mg/kg sc) on day 4 of conditioning. Two subsequent exposures to saccharin substantially increased the risk of developing DMBA-induced tumors (91%), as compared to control animals (36%) that had not received this pairing. Mice that received all agents (i.e., CY, DMBA, and saccharin) in a slightly different order did not display elevated tumor incidence (36-44%). Three separate exposures to CY also significantly increased the number of animals developing tumors in response to the carcinogen (75%). These results indicate that suppression of the immune system enhances susceptibility to chemically-induced tumors, and that learned immunosuppression can increase the risk of developing cancer if coincident with a carcinogenic event.

IN VITRO ADRENOCEPTOR LIGANDS APPROXIMATE STRESS-INDUCED MITOGENIC SUPPRESSION OF HUMAN BLOOD LYMPHOCYTES. J.C. Cochran\*, E. Bachen, and B.S. Rabin. Brain, Behavior, and Immunity Center, Univ. Pittsburgh, Pittsburgh, PA 15213.

It is well known that stress can cause the lymphoid system to undergo

It is well known that stress can cause the lymphoid system to undergo functional alterations resulting in a decreased response to stimulation by nonspecific mitogens. The mechanism of this suppression in humans is thought to involve the sympathetic nervous system. We have found in high reactor subjects that the stress generated during performance of the Stroop Test reduced lymphocyte mitogenesis to phytohemagglutinin (0.5-5.0 ug/ml) in whole blood assay by an average of 10.5%, while mean catecholamines increased from 1.32 x 10<sup>-10</sup> to 2.64 x 10<sup>-10</sup> M for repinephrine, and from 7.35 x 10<sup>-10</sup> to 8.40 x 10<sup>-10</sup> M for norepinephrine. We now confirm the role of catecholamines in mediation of the altered functional response. Human blood lymphocytes were cultured, in whole blood or isolated lymphocyte assays, with 0.5, 1, or 5 ug/ml phytohemagglutinin. Norepinephrine, epinephrine, or the adrenoceptor agonist, isoproterenol, were added to these in vitro cultures at 10<sup>-10</sup> 10<sup>-10</sup>, or 10<sup>-6</sup> M concentrations. Separate analyses of variance with epsilon correction (p ≤ .01) were performed on the data of the two assays. In the whole blood assay, the suppressive effect was significant at all concentrations (9.8%, 10.5%, and 14.9% at 10<sup>-10</sup>, 10<sup>-6</sup>, or 10<sup>-6</sup> M, respectively), whereas in the isolated lymphocyte assay suppression was significant only at the highest concentration, suggesting the involvement of accessory cells in the whole blood assay. Thus, with in vitro addition of concentrations of catecholamines comparable to the increases measured in the in vivo stress paradigm, the whole blood dosony produced comparable suppression. These data indicate that in vitro addition of physiologic levels of catecholamines or agonist can approximate stress-induced immunosuppressive effects and point to future studies to examine the possible participation of other mediators of the mitogenic suppression.

## 287.6

OPIOID SYSTEM REGULATION OF STRESS INDUCED IMMUNE ALTERATION.

M.R. Shurin, A.W. Kusnecov, B.S. Rabin\*. Brain, Behavior, and Immunity Center, University of Pittsburgh, Pittsburgh, PA 15213.

The opioid system is believed to participate in the stressor induced modulation of immune system function. The aim of this study was to (1) evaluate the role of delta opioid receptors in stressor induced suppression of cellular immunity, and, (2) quantitate the changes of endogenous opioids in lymphoid organs after a stressor. The study was performed in male Lewis rats and the stressor used was 16-5 second electric foot shocks over 64 minutes. When the shock was preceded by the L.P. injection of 10ug/kg of the delta opioid agonist Leu-Enk (D-Ala', Arg'), there was an amelioration of the suppression of spleen lymphocyte proliferation to the non-specific mitogens PHA and Con-A. The PHA response was ameliorated by 98% and the Con-A by 80%. The amelioration was blocked by pretreating the rats with the delta opioid antagonist Naltrindole (50ug/kg I.P.). This suggests that agonists of the delta opioid receptor can inhibit the stressor induced suppression of lymphocyte responsiveness to non-specific mitogen. Following stress the activity of opioids was measured by displacement using a radioreceptor assay and acetic acid extracts of rat tissue. The opioid activity increased approximately 30% in the spleen and decreased approximately 15% in the thymus, 60% in the pituitary, and 70% in the adrenal. The composition of the opioid subtypes have not yet been determined. These studies support the hypothesis that opioid metabolism is changed in lymphoid tissue in association with a stressor and that the delta opioid receptor can antagonize stressor induced immune suppression.

EFFECTS OF FOOTSHOCK STRESS UPON SPLEEN AND PERIPHERAL BLOOD LYMPHOCYTE MITOGENIC RESPONSES IN PARAVENTRICULAR NUCLEUS (PVN) LESIONED RATS. M.A. Pezzone\*, J. Dohanics, J.G. Verbalis, and B.S. Rabin. Departments of Pathology and Medicine, University of Pittsburgh, School of Medicine, Pittsburgh, PA 15261.

Physically-aversive stressors such as mild electric footshock suppress the mitogenic responsiveness of peripheral blood and splenic lymphocytes as the mitogenic responsiveness of peripheral blood and splenic lymphocytes as well as other measures of immune function. Although, the pathways mediating these responses have not been fully characterized, neuroendocrine and autonomic components have both been implicated. Using c-Fos as a marker of stimulated neuronal activity, we have previously reported that cells of the hypothalamic PVN (some of which contain corticotropin-releasing hormone, CRH) where strongly activated following an immune-modulating, footshock stimulus. Because neuronal projections from the PVN can influence both the neuroendocrine axis and the autonomic nervous system, the PVN may thus be responsible for mediating many of the effects of stress. To further assess the immunomodulatory role of the PVN, the following study was performed. Male Lewis rats were subjected to either sham or bilateral PVN lesions using a triangle-shaped rotating knife. Six days following surgery, lesioned and sham a triangle-shaped rotating knife. Six days following surgery, lesioned and sham a triangle-shaped rotating finite. Six days following surgery, testoned and sham animals were subjected to either a one hour session of footshock stress or home cage conditions. Subsequently, spleen and peripheral blood samples were collected, and lymphocyte responses to the T-cell mitogens, Concanavalin-A (Con-A) and Phytohemagglutinin (PHA), were measured with the following results. In the peripheral blood, footshock induced a marked suppression of lymphocyte mitogenic reactivity to both PHA and Conmarked suppression of lymphocyte mitogenic reactivity to both PHA and Con-A that was significantly attenuated by the PVN lesions. In the spleen, however, the footshock-induced suppression of lymphocyte mitogenic reactivity to both PHA and Con-A was further suppressed in the PVN lesioned animals. Thus, the PVN has different roles in mediating stressor-induced immune alterations in the spleen and peripheral blood.

### 287.9

EFFECTS OF STRESS ON PULMONARY NATURAL KILLER (NK) CELL ACTIVITY IN THE RAT N. Quan\*, S.K. Sundar, K.M. Boericke & J.M. Welss. Department of Psychiatry, Duke University Medical Center, Durham, NC 27710.

NK cells in the lung are potentially important for destroying tumor cells, pathogenic microbes, and virus-infected cells at this privileged site. This study investigates the effects of acute stress on pulmonary natural killer (NK) cell activity in Charles-River CD-VAF and Fisher 344 rats. Rats were sacrificed either from their home cage (control) or immediately after an 8 hr session of intermittent tail shock (one per minute, 20 seconds' duration, 1.2 mA intensity). Pulmonary cells, free of blood cell contamination, were collected by the method of Thivierge and Rola-Pleszyczynski (Am. Rev. Respir Dis. 1991; 144: 272-277), and then purified. Lymphocytes from blood and spleen were also extracted. NK activity in these various compartments was measured by assaying the ability of their lymphocytes to lyse YAC ATCC cells. In control rats, NK activity of lymphocytes from the lung and spleen were not different in both CD-VAF and Fisher 344 rats. In CD-VAF rats, the NK activity in the lung, blood, and spleen cells was depressed by the stress to a similar extent (30-45% decrease as compared with the corresponding controls). In Fisher 344 rats, NK activity in the lung, spleen, and blood immediately after the stress was depressed by 50%, 20%, and 13%, respectively; these decreases had not completely recovered 24 hrs after the stress session. These results, therefore, indicate that the activity of resident pulmonary NK cells are also depressed by this form of stress as is NK activity of blood and splenic lymphocytes.

## 287.11

EFFECTS OF STRESS ON THE IMMUNE RESPONSE OF SPLEEN CELLS ARE MEDIATED BY THE SPLENIC NERVE. D.M. Nance\*, W. Wan, C.Y.

Vriend, L. Wetmore, J.G. Gartner and A.H. Greenberg. Depts. of Path. and Physiol. and Inst. of Cell Biol., Univ. of Manitoba, Winnipeg, MB., R3E 0W3, Canada Intermittent footshock (FS) suppresses immune function of spleen cells. To determine if the autonomic nervous system mediates this immunosuppression in splenic cells, we tested whether cutting the splenic nerve, which depletes splenic nore-pinephrine and eliminates catecholamine fibers, blocks the effects of stress. Splenic nerve sections, sham operation or no surgery was performed on male S/D rats. Ten days later, rats were injected with sheep red blood cells (SRBC). Three days later, rats days atter, ratis were injected with steep red of the other caps later, as were placed in a chamber equipped with a shock grid, FS (1.6 mA) was administered for 5 sec on a VI 3.5 min schedule for 60 min. Each FS was preceded by a 15 sec warning tone. Controls were treated identically except for the FS. The next day spleen cells were harvested and the number IgM plaque forming cells (PFC's) calculated. For the sham and unoperated control animals, the number of PFC's was reduced for the stressed animals, relative to the nonstressed controls and there was no reduced for the starm surgeries. In contrast, there was no difference between the stressed and nonstressed groups in which the splenic nerve had been sectioned and their PFC response was comparable to the controls. Next we compared the effects of FS on the proliferative response to mitogens (PHA and ConA) following splenic nerve sections or sham operations. One week following surgery, animals were given a 60 min session of FS or exposed to the chamber/tone without FS. Rats were then killed, spleens harvested and the proliferative response to mitogens determined. FS suppressed the response to mitogens in the sham rats, relative to the sham operated animals not exposed to FS. In contrast, there was no difference between the stressed and nonstressed groups in which the splenic nerve had been cut and their proliferative responses were comparable to the nonstressed-sham animals. Thus, the effects of stress on the PFC response and the proliferative response of spleen cells is mediated via the splenic nerve. These results indicate that the sympathetic nervous system is a fundamental and significant mediator of brain-immune interactions. Supported by MRC, MHRC and HSCRF.

MAJOR DEPRESSIVE DISORDER AND IMMUNE FUNCTIONING IN INNER-CITY ADOLESCENTS: BLOCKADE OF LYMPHOCYTE PROLIFERATION AT G<sub>2</sub>.

M.K. Demetrikopoulos, S.J. Schleifer, J.A. Bartlett,

and S.E. Keller Departments of Neurosciences and Psychiatry, University of Medicine and Dentistry of New Jersey, Newark, NJ, 07103 Our previous work has demonstrated decreased mitogen induced lymphocyte proliferation in healthy adolescents who met criteria for Major Depressive Disorder (MDD) compared to matched controls without MDD. The rate of who met criteria for Major Depressive Disorder (MDD) compared to matched controls without MDD. The rate of entry of stimulated lymphocytes into the various stages (G<sub>1</sub>, S, G<sub>2</sub>) of the cell cycle is an important determining factor in the proliferation response. We investigated the percent of cells in G<sub>1</sub>, S, and G<sub>2</sub> at 24, 48, and 72 hours post-stimulation for both PHA stimulated and media only samples. Ten sets of MDD and control subjects were analyzed and analyses revealed a trend for a G<sub>2</sub> block in the MDD subjects; MDD subjects had a higher percent of cells in G<sub>2</sub> than controls at 48 hours for both PHA stimulated (F=3.4, pc0.09) and non-stimulated samples (F=7.1, pc0.02) and at 72 hours for the non-stimulated samples (F=4.0, pc0.06). This suggests that decreased response to mitogen in adolescents with MDD may be due to cells remaining in the G<sub>2</sub> stage of the cell cycle. Future research to confirm these findings and explore mechanisms of G<sub>2</sub> block, such as blockage of the signal to begin anaphase, is warranted.

VOLUNTARY EXERCISE EFFECTS ON IMMUNITY IN RATS. K. J. Coleman, D. R. Rager and C. J. Karwoski\*. Dept. of Psychology, University of Georgia, Athens, GA 30602.

Most studies of effects of exercise on immune function in rodents have employed forced exercise paradigms which may be confounded by stress associated with either involuntary activity or the aversive methods used to induce exercise. To avoid these potentially confounding variables, we examined effects of voluntary wheel running on immune function in male Long-Evans rats. Exercised rats were allowed access to running wheels during the dark period of a 12:12 hr light/dark cycle daily for eight weeks. Five weeks into the study, exercised animals and non-exercised control rats were immunized with Keyhole Limpet Hemocyanin (KLH), and antibody responses to KLH were monitored during the subsequent three-week period. At the end of the study, rats were sacrificed, and spleens and whole blood were assayed for proliferation in response to Concanavalin A. In exercised rats splenic lymphocytes showed enhanced proliferation, and whole blood proliferation was suppressed, while antibody response did not differ from controls.

## 287.12

STRESS-INDUCED REDUCTION IN MLR IS DEPENDENT ON MACROPHAGES BUT NOT ON CHANGES IN PHENOTYPES. M. Fleshner\*. L. R. Watkins. M. L. Laudenslager. and S. F. Maier. Dept. of Psychology, University of Colorado, Boulder, CO 80309.

Exposure to inescapable shock (IS) has been shown to alter many aspects of immune function. We have previously reported that one possible mechanism of stress-induced decreases in anti-KLH antibodies is a shift in CD4/CD8 ratio. The following experiments examined whether 1) exposure to IS would result in changes in another measure of immune function, mixed lymphocyte reaction (MLR), 2) whether this change was associated with changes in phenotype, and 3) whether macrophage depletion would effect any stress-induced changes in MLR. Rats were exposed to either 100 1.6 mA inescapable tail shocks or remained in their home cage (HCC). Spleen (SPL), cervical nodes (CN), and mesenteric nodes (MS) were removed and weighed immediately after IS termination. CN, MS and nylon wool macrophage depleted lymphocytes were tested in an MLR. CD5, CD4, and CD8 positive cells were labeled and assessed using flow cytometry. IS was associated with a decrease in spleen weight (p<.05), a decrease in MLR in both CN and MS (p<.05), an increase in the % CD4+ cells (p<.05) only in MS, and an increase in the CD4/CD8 ratio (p<.05) only in MS. Depletion of macrophages eliminated the stress-induced reduction in MLR. These results suggest that IS induces a reduction in MLR and that this reduction is not associated with changes in phenotype as seen with in vivo antibody production, but is instead associated with alterations in macrophage function. The specific role of macrophages in the stress-induced reduction of MLR is currently being examined

ONTOGENY OF CORTOCOTROPIN-RELEASING FACTOR GENE EXPRESSION IN THE HYPOTHALAMUS, SPLEEN AND THYMUS OF IMMATURE RATS. F. Aird\* and E. Redei. Psychiatry Department, University of Pennsylvania, Philadelphia, PA 19104.

Corticotropin-releasing factor (CRF) initiates stress-induced immunosuppression via the hypothalamic-pituitary-adrenal axis and is known to have direct effects on immune cells. We have previously demonstrated the presence of CRF mRNA and bioactive peptide in rat spleen and thymus. In this study we analysed CRF mRNA expression in the rat hypothalamus, spleen and thymus at 7, 14, and 21 days of age. CRF mRNA levels were measured by the semi-quantitative reverse transcription-polymerase chain reaction. In the hypothalamus, the CRF transcript increased at day 14 and decreased at day 21. CRF mRNA levels in the spleen remained constant from day 7 to 21, and in the thymus decreased from day 7 to 21. The role of maternal glucocorticoids in regulation of CRF gene expression was also investigated. Our results suggest that the ontogeny and regulation of "immune" CRF are different from hypothalamic CRF. We propose that the effects of stress on immune function may be mediated through changes in expression of splenic and thymic CRF acting as an immunomodulator. Supported by ADAMHA grant AAO7389.

EVIDENCE FOR THE CONDITIONING OF IMMUNE REACTIONS TO A CHOLERA TOXIN.

B.J. Kucinski\*, L.E. Nelson, A.W. Kusnecov, Dept. of Psychology and Pathology, Univ. of Pittsburgh, Pittsburgh, PA 15260.

We previously demonstrated that a conditioned stimulus (CS) for a foot-shock unconditioned stimulus (US) suppresses the proliferation of splenic and whole-blood lymphocytes to T-cell mitogens. To investigate whether this conditioned effect would also interfere with immunologic reactions to a specific antigen, we first gave rats Pavlovian conditioning involving a clicker CS and a foot-shock US. Then, after an 11-day recovery in their home cages, the rats were given daily exposures to the conditioning chamber for 13 days and were sacrificed on the next. During this phase, all rats were immunized with a cholera toxin (CT) immediately after the 7th session. In addition, three experimental groups received CS presentations during every other session, starting with the day before, the day of, or the day after immunization. A control group was exposed to just the training context. To our surprise, the results of both a CT-stimulation assay of splenocyte proliferation and an ELISA of IgM and IgG responses indicated significantly enhanced reactions for the group that first experienced the CS on the day of immunization. That suggests that the CS induced an interoceptive effect which functioned as a conditioned stimulus for the unconditioned antibody response induced by the antigen, and that subsequent presentations of the CS during the incubation phase elicited conditioned antibody responses.

#### 287.14

SUPPRESSION AND ENHANCEMENT OF THE IMMUNE RESPONSE TO CHOLERA TOXIN.

Alex W. Kusnecov, Harry Fowler\* and Bruce S. Rabin. Brain, Behavior and Immunity Center, University of Pittsburgh, Pittsburgh, PA. USA

Studies were initiated to investigate the influence of a footshock stressor on antigen-specific immune responses in rats. Experiment 1: Male Lewis rats (n=5) were immunized ip with \$\mu\_g\$ cholera toxin (CT) and 7 days later exposed to footshock stress. Spleen cells were assayed immediately for PHA-and CT-stimulated proliferation. Home cage (HC) rats served as controls (n=5). Whereas PHA-induced proliferation was significantly suppressed by greater than 50% in shocked animals, the response to CT was significantly enhanced. Experiment 2: Rats were allocated into 4 groups (n=5/gp) prior to immunization with CT as above. Group D0 received a single session of shock immediately before immunization; Group D5-7 received 3 daily shock sessions on Days 5, 6, and 7 after immunization; Group D7 was shocked on Day 7 as in Expt 1; Group HC was immunized but never shocked. All rats were sacrificed on Day 7, with Groups D5-7 and D7 being sacrificed immediately after footshock exposure. Spleen cells were cultured with CT, and serum was assayed for anti-CT IgM and IgG by ELISA. The results replicated those of Expt 1 in that the D7 group, but not the D5-7 group, had significantly higher CT-stimulated proliferation. The proliferative response of the D0 group was significantly depressed, as were the serum IgM and IgG responses. Similarly, the D5-7 group showed a depressed IgG response, with the IgM response showing a relatively modest reduction. These results suggest a complex interaction between the timing of stressor exposure, immunization, and assessment for antigen-specific cellular and humoral immune function.

## NEURAL CONTROL OF IMMUNE FUNCTIONS

## 288.1

SEX HORMONES AND AGE: EFFECTS ON NATURAL KILLER CELL ACTIVITY S. BEN-ELIYAHU.\* G.G. PAGE, S.A. BOUN, J. Hasiang, J.C. LIEBESKIND & A.N. Taylor Brain Research Institute, and dept. of Psychology UCLA; and West LA VAMC, Los Angeles, CA 90024.

It has been suggested that sex hormones and estrous cycle can affect immune function. We undertook a longitudinal study comparing NK activity between males and females at pre- and postpubescence (36 and 63 d, respectively), and studied the relationships between estrous phase and NK activity in the Fischer 344 rat. A group of 70 d old males was used in each assay as an interassay reference for agerelated changes. NK cytotoxicity was assessed using a whole blood 4 h 51Cr release assay. Estrous phase was established using vaginal cellularity smears for 10 consecutive days. At 36 d (prepubescent), females exhibited higher NK activity than the age-matched males, and both exhibited less NK activity than the reference group. At postpubescence (63 d), however, males exhibited higher NK activity than females, nearly reaching the reference group level. Females in metestrus exhibited high NK activity, only slightly lower than agematched males, whereas females in proestrus, estrus, and diestrus, exhibited low NK activity, similar to their pre-pubescent level. The increase in NK activity from pre- to postpubescence in males may be related to increased circulating androgens or to other age related changes, while the similar increase evident in females, only during metestrus, seems to reflect estrous cyclicity. Supported by NIH-HD07228, NIH/NS 07628, VA Medical Research Service (ANT), and the UCLA Psychoneuroimmunology Task Force.

## 288.2

ETHANOL INCREASES METASTATIC COLONIZATION AND DECREASES LUNG CLEARANCE BY SUPPRESSING NK ACTIVITY IN VIVO G.G. Page\*S. Ben-Ellyahu, R. Yirmiya, J. C. Liebeskind and A. N. Taylor Depts of Anat. & Cell Biol. UCLA; and West LA VAMC, Los Angeles, CA 90024.

We have previously shown that ethanol increases metastasis in the Fischer 344 rat. We now provide direct evidence that suppression of natural killer (NK) cell activity mediates this ethanol effect. Male rats were injected i.p. with either 2.5 g/kg ethanol or saline. Whole blood cytotoxicity was assessed 2 h later using a 4 h 51Cr release assay in which serum was or was not replaced by RPMI 1640 medium (media). Additionally, we used in vivo methods shown to sensitively reflect NK activity: Lung clearance and metastatic colonization of the MADB106 tumor cell line. To assess the role of NK cells in mediating ethanol effect on lung clearance, a group of rats was selectively depleted of LGL/NK cells using the mAb 3.2.3. NK cytotoxicity per ml blood was significantly suppressed when serum was replaced by media: an even greater suppression was evident when serum was not replaced by media. Lung clearance was suppressed by ethanol in normal rats but not in LGL/NK depleted rats, demonstrating that this effect of ethanol is mediated by its effect on LGL/NK cells. Metastatic colonization was enhanced only at times in which the MADB106 is known to be sensitive to NK activity and blood ethanol levels were elevated. These findings demonstrate that by suppressing NK activity in vivo, ethanol increases the metastatic process. Supported by VA Medical Research Service (ANT), NIH/NS 07628, and the UCLA Psychoneuroimmunology Task Force.

ALCOHOL IMMUNOTOXICITY F. CHIAPPELLI', L. HANSON and T. WYLLE Psychiatry, Harbor-UCLA Med. Ctr., Torrance, CA 90509; BRI, Psychoneuroimmunol, Public Health, UCLA: West Los Angeles VAMC.

Alcohol is immunotoxic. The mechanisms of alcohol-mediated immunotoxicity remain to be described. Because of the crucial role of T lymphocytes in the initiation, propagation and regulation of antigen-driven immune competence, we study the mechanisms of alcohol toxicity upon T cells early during lymphocyte activation. We use established human T cell lines (HUT-78) or peripheral blood T lymphocytes from normal healthy donors. The cells are stimulated with anti-CD3 antibody or in a mixed leukocyte culture. Alcohol alters the growth patterns of HUT-78 cells plated in AIM-V medium: Day 4 (control: 7±5% X10 $^{\circ}$  cells; 0.1% alcohol: 11±4% X10 $^{\circ}$  cells, p<0.05); Day 6 (control: 14±4% X10 $^{\circ}$  cells. 0.1% alcohol: 11±4% X10 $^{\circ}$  cells, p<0.05). These preliminary data suggest that alcohol favors an initial burst in cell metabolism and growth, that is transient and reversed by prolongued incubation. Alcohol (0.1%) also impairs the expression of membrane activation markers (CD25, CD71) following activation. Experiments now test the effects of alcohol upon the PKC, PKA and phosphatase transmembrane pathways in the presence or the absence of glucocorticoids because alcohol consumption leads to an activation of the HPA axis and elevated cortisol levels. EFFECTS OF CGRP AND TACHYKININS ON RAT LYMPHOCYTE PROLIFERATION. <u>I.G. Hamra\*, X.-Y. Hua and T.L Yaksh</u>. Dept. of Anesthesiology, Univ. of California San Diego, La Jolla, CA 92093.

Sensory nerve fibers containing immunoreactive calcitonin gene-related peptide (CGRP), substance P (sP), and other neuropeptides have been demonstrated in both primary and secondary lymphoid organs. A number of studies have shown that CGRP and peptides of the tachykinin family have potent effects on immune responses. However, the effect of these peptides appears to vary with species and cell type. In this study, we evaluated the effect of CGRP and selective NK receptor agonists on rat lymphocyte proliferative responses. Rat spleens were removed and lymphocytes isolated by density gradient centrifugation. The lymphocytes were incubated with a combination of mitogens, Concanavalin A (ConA) and pokeweed mitogen (PWM), and peptides. CGRP enhanced lymphocyte proliferation in the absence of mitogens (10<sup>-8</sup>M, P<0.001) as well as in PWM stimulated cells (10<sup>-6</sup>M, P<0.01). Substance P and [Sar<sup>9</sup>, Met(O<sub>2</sub>)<sup>11</sup>]sP, a selective NK1 receptor agonist, had no effect on proliferative responses. Senktide, a NK3 receptor agonist, also had no effect. Neurokinin A (NKA) enhanced proliferative responses to suboptimal concentrations of PWM (10-<sup>6</sup>M, P=0.05). However, [Nle<sup>10</sup>]Neurokinin A<sub>4-10</sub>, a highly specific NK2 agonist, suppressed both ConA and PWM stimulated proliferation as well as roliferation in the absence of mitogens (10-6M, P<0.001). As sP, CGRP and NKA are costored in and coreleased from the peripheral terminals of sensory afferents, these results suggest a direct immunodulatory effect mediated by antidromic afferent activity, possibly through a NK2 site. These results also suggest that the cell population involved (i.e., T or B lymphocytes) may determine the net effect on proliferative responses. (Supported by NIH NS07329 - JGH, TRDRP 1KT-19 - XYH).

## 288.7

ACUTE AND CHRONIC EFFECTS OF N-METHYL-D, L, ASPARTIC ACID (NMA) INJECTION INTO THE ANTERIOR HYPOTHALAMIC AREA (AHA) ON THYMUS GLAND AND PERIPHERAL CORTICOSTERONE (CORT), PROLACTIN (PRL) AND LYMPHOCYTE SUBTYPES. C.P. Phelps\*, L.T. Chen, L.L. Poole, J.E. Miley, J.M. Oliver, B. Muffly and R.A. Menzies. Depts. of Anatomy and Psychiatry and Behavioral Medicine, Coll. of Med., Univ. South Florida, Tampa, FL 33612

We have studied the acute (firs) and longer (wks) term effects of NMA on endocrine and immune functions after bilateral NMA injections (0.6M in 0.1µ and 0.15µ laCSF) into the AHA of male rats (350-400g). Animals received atrial cannulas 5-7d before (0 day, AM, PM), over 2 hrs and at 3 and 4d intervals 3-28d after NMA. Plasma Cort and Prl were assayed by RIA and peripheral thymusorigin lymphocytes (T cell) were separated into %CD4+ (helper) and %CD8+ (cytotoxic/suppressor) using fluorescent antibody cell sorting antibodies (facs). Brains and thymus glands were removed and studied histologically. NMA produced 4 small (0.1mm²) conical-shaped cellular lesions, with aCSF damage restricted to needle tracks. Plasma Prl showed very little change during the first 2 hr after either aCSF or NMA. Plasma Cort was elevated 5X from Od(50-70 ng/ml) by pentobarbital (PB) and 8X from Od by PB plus stereotaxic surgery. Although NMA resulted in no additional acute Cort changes, there were subsequent chronic 2X elevations during the first few wks after NMA. Associated Prl levels were one-half basal levels (6-8 ng/ml). Thymus glands after NMA were reduced in size by approximately 50% when compared to glands from control rast at all intervals (8-10d, 14-18d, 20d and 28d) studied. The percentage of circulating CD8+ T cells in peripheral blood also fluctuated after NMA, whereas CD4+ T cells remained relatively constant. In summary, Cort and Prl changes after NMA injection into the AHA were associated with smaller thymus glands and a shift in CD8+ T cells. Supported by MH46808.

#### 288.4

MITOGEN-STIMULATED LYMPHOCYTE PROLIFERATION ACROSS THE ESTROUS CYCLE OF THE RAT. D.R. Rager\*, K.J. Coleman, T.E. Parsons, and J.D. Newbern. Dept. of Psychology, Univ. of GA, Athens, GA 30602.

Although a number of studies have shown that gonadal hormones can affect immune function, few have investigated whether immune responses vary as a function of estrous stage in intact cycling females. This experiment explored whether a standard in vitro measure of immune function (i.e., mitogen-stimulated lymphocyte proliferation) varies across the estrous cycle in the adult female Long-Evans rat. Estrous cycles were monitored by daily vaginal lavage, and peripheral blood samples were obtained from tail veins of normally cycling rats during either proestrus/estrus or metestrus/diestrus. Proliferation of peripheral blood lymphocytes (PBLs) in response to concanavalin A was determined using a radiolabeled thymidine incorporation assay. PBLs derived from females during proestrus/estrus exhibited lower proliferative responses as compared to PBLs derived from females during metestrus/diestrus. These data are discussed with regard to hormonal changes that may mediate estrous stage differences in immune responses.

### 288.6

CALCITONIN GENE-RELATED PEPTIDE (CGRP) INHIBITS EARLY B
CELL DIFFERENTIATION BY A RECEPTOR MEDIATED MECHANISM
J.P. McGillis\*, V. Rangnekar, and J. Ciallela. MicroImmunol., Univ. Kentucky, Lexington, KY 40536-0084
CGRP receptors and the effect of CGRP on 70z

CGRP receptors and the effect of CGRP on 70Z lymphocytes was examined. 70Z cells are pre B cells which have rearranged heavy  $(\mu)$  and light (H) immunoglobulin (Ig) genes. Following LPS treatment 70Z cells differentiate into immature B cells which express Ig on the cell surface. Binding studies with  $^{125}\text{T-CGRP}$  found that both differentiated and undifferentiated 70Z cells express high affinity CGRP receptors.  $^{125}\text{I-CGRP}$  binding was specific in that it could only be displaced by CGRP and CGRP analogs. The 70Z CGRP receptor protein was affinity labelled by crosslinking  $^{125}\text{I-CGRP}$  to the receptor with DSS. SDS-PAGE analysis of the affinity labelled 70Z CGRP receptor revealed that it is a single protein of 103,000 mw. CGRP also stimulated cAMP in a dose dependent manner. The effect of CGRP on LPS induced differentiation was examined by FACS analysis of surface Ig expression and northern blot analysis of  $\mu$  and K mRNA. LPS treatment increased the % of cells expressing surface Ig from less than 5% to greater than 90%. CGRP reduced the level of LPS induced surface Ig expression by about 30%. This was due to a decrease in the levels of both  $\mu$  and K mRNA. These studies suggest that CGRP inhibits early B cell differentiation by binding to an adenylate p cyclase linked receptor.

## 288.8

IN VIVO EFFECTS OF ACUTE AND CHRONIC NICOTINE ON THE IMMUNE SYSTEM OF RATS S. Knopf, A.R. Caggiula\*, C.G. McAllister, L.H. Epstein, S.M. Antelman, K.A. Perkins, A.L. Miller, S. Saylor Depts. of Psychology and Psychiatry, University of Pittsburgh, and Pittsburgh Cancer Institute, Pittsburgh, PA. 15260

Cigarette smoke alters several measures of immune function. However, since cigarette smoke contains at least 3800 products, its immunologic effects cannot necessarily be attributed to the actions of nicotine per se. We recently reported a dosedependent decrease in the proliferative response of blood T lymphocytes to Con A in male rats 1 hr after s.c. nicotine (Caggiula et al, 1992). In the present study, an ACUTE injection of nicotine bitartrate (1.32 mg/kg, free base) suppressed the blood lymphocyte response to Con A and PHA but had no effect on spleen lymphocytes. After CHRONIC (10 daily) injections of nicotine, tolerance developed to the suppressive effects in blood whereas the response of spleen lymphocytes actually increased above controls. The relative proportions of major cell types did not change after any of these treatments, so the differences between spleen and blood cannot be attributed to a change in the trafficking of the major cell types. In summary, nicotine can significantly alter functional measures of the immune system in rats. The effects are complex, depending on the duration of exposure and compartment sampled.

ANESTHESIA-INDUCED IMMUNOMODULATION OF IN VIVO ANTIBODY PRODUCTION. L.L. Lockwood\*, L.H. Silbert, L.R. Watkins, ^M.L. Laudenslager, and S. F. Maier. Department of Psychology, University of Colorado, Boulder, CO 80309. ^Dept. of Psychiatry, Univ. of CO-HSC, Denver, CO 80204.

Surgery and anesthesia alter immune function. These changes in immune function may have implications for the potential development of disease after surgery and complicate the study of the neural control of immune function. Further elucidation of anesthesia-induced changes in immune function is important to our understanding of the interplay between surgical stress, anesthesia, and the immune system. Previous research has demonstrated that anesthesia alone can alter lymphocyte proliferation and recirculation, reduce phagocytosis and accelerate metastasis of tumors. These were all measured soon after anesthesia administration. We sought to determine if various anesthetics would have long term immunomodulatory effects on an *in vivo* measure of antibody production. In a series of experiments, Sprague Dawley rats were injected intraperitoneally with 100 ug of antigen, Keyhole Limpet Hemocyanin (KLH), three weeks after exposure to surgical doses of pentobarbital, methoxyflurane, halothane, ketamine/xylazine, or chloral hydrate. Serum samples to measure anti-KLH IgG antibody production were taken 7, 9, and 14 days after antigen injection. When antigen was introduced three weeks after anesthesia exposure, animals that had been anesthetized with chloral hydrate or pentobarbital showed significant suppression of antibody production as compared to home cage controls. No significant differences were observed for halothane, ketamine/xylazine or methoxyflurane. Further studies are being done to investigate the range of effects of these anesthetics and potential interactions between surgery, anesthesia and immune function.

HYPOTHALAMIC CONTROL OF PERIPHERAL IMMUNE FUNCTIONS MEDIATED BY THE SYMPATHETIC NERVOUS SYSTEM IN RATS. T. Katafuchi\*, S. Take, T. Ichijo and T. Hori. Dept. of Physiology, Kyushu Univ., Fac. of Med., Fukuoka 812 Japan. ICV injection of recombinat human interferon α (IFNα) in rats

ICV injection of recombinat human interferon  $\alpha$  (IFN $\alpha$ ) in rats suppressed the cytotoxic activity of splenic natural killer (NK) cells, depending on central opioid receptors and intact splenic innervation. ICV IFN $\alpha$  (1500-6000U/rat) produced a dose-dependent and long-lasting (more than 1 hr) excitation of the electrical activity of the splenic sympathetic nerve, which was transiently suppressed by naloxone (iv). Since an electrical stimulation of the nerve suppressed the NK activity in the splene, the IFN $\alpha$ -induced suppression of NK activity is brought about by an opioid receptor-mediated activation of the splenic sympathetic nerve.

In the present study, we investigated the central mechanisms of the immunosuppression mediated by the splenic sympathetic nerve. In ure-thane-αchloralose anesthetized rats, lesion of the prooptic/anterior hypothalamus (POA) but not the thalamus induced a significant suppression of NK cytotoxicity, which was completely blocked by the splenic denervation. Ablation of the POA enhanced the splenic nerve activity, while electrical and glutamate stimulations of the POA suppressed it. Glutamate infusion into the PVN increased the activity. Furthermore, microinjection of IFNα (200U/rat) into the POA produced an excitation of the nerve activity, while an injection into the PVN had no effect. We have previously demonstrated that IFNα inhibited the POA neuronal activity in tissue slices. The present findings, taken together, suggest that the POA may play an important role in the INFα-induced suppression of splenic cellular immunity mediated by the splenic sympathetic nerve.

## 288.13

INTERFERON-INDUCED EFFECTS ON CA3 PYRAMIDAL CELLS IN RAT HIPPOCAMPAL SLICE CULTURES: MEDIATED BY HYDROGEN PEROXIDE? Michael Müller\*, Adriano Fontana, Gerhard Zbinden and Beat H. Gähwiler. Brain Research Institute, University of Zürich, 8029 Zürich, Switzerland.

Neuronal dysfunction observed in viral infection may be due to lytic effects of the virus and/or the antiviral host response including production of cytokines such as interferons (IFNs). We have therefore studied the effects of recombinant murine IFN- $\gamma$  and IFN- $\alpha/\beta$  on functional properties of pyramidal cells in hippocampal slice cultures. Bath application of IFNs induced an excitatory effect on CA3 pyramidal cells, and a decrease in IPSP amplitude eventually leading to epileptiform bursting. These effects were slow in onset (several minutes), suggesting an indirect mechanism of action. The release of hydrogen peroxide (H2O2) from non-neuronal cells may be in part responsible since IFN effects were found to be blocked by the free radical scavengers catalase and superoxide dismutase, and H2O2 mimicked the effects of IFN on pyramidal cells: it reduced evoked inhibitory synaptic transmission, leading to epileptiform bursting, and induced a hyperpolarizing K+-current. These data indicate that production of IFNs in the CNS may contribute to neurologic disease in virus infection.

IMMUNE AXIS ACTIVATION UP- AND DOWN-MODULATES BETA-ADRENERGIC RECEPTOR MESSENGER RIBONUCLEIC ACID LEVELS IN THE RAT THYMUS. M.C. Morale\*, F. Gallo, N. Batticane and B. Marchetti, OASI Inst. Mental Retard. and Brain Aging, Troina (EN) and Dept. Pharmacology, Medical School, University of Catania, 95125 Catania, Italy.

Important alterations of noradrenergic actitivity are known to occur in specific brain regions and in different lymphoid tissues during the course of an immune response (IR). Lymphokines and other soluble substances produced by the activated immune system in addition to changes in corticosterone production have been suggested as possible mediators in this crosstalk between the neuroendocrine and immune cells. The aim of the present study was to assess whether products of activated lymphocytes interact with the thymic beta-adrenergic receptor (BAR) signaling system. Thymic BAR gene expression was measured using a human BAR cDNA as a probe, at different time intervals after immunization. Northern blot analysis of thymic RNA and iodocyanopindolol binding measurements revealed almost 70% decreases of mRNA concentration and BAR numbers 3 days after immunogenic challenge. This effect was accompanied by a significant decrease in the ability of isoproterenol to stimulate adenylate cyclase activity in membranes preparations of thymic tissue. On the other hand, 15 days following immunogen administration, a marked increase of BAR mRNA content and BAR numbers, with a parallel stimulation of adenylyl cyclase activity, was observed. The up- and downmodulation of BAR gene expression coupled to the alteration of adenylyl cyclase-cAMP signaling pathway may represent feedback mechanisms to down regulate the immune response.

HYPOTHALAMIC INTERFERONα (IFNα) REDUCES SPLENIC NK CYTOTOXICITY. S.Take, T.Katafuchi, T.Ando, D.Uchimura, Y.Kanemitsu, T.Ichijo, N.Shimizu, T.Hori and T.Kosakā\*. Dept. Physiol. & Anat', Kyushu Univ., Fac. Med., Fukuoka 812, Japan The brain produces high levels of IFNα during viral infections. We

The brain produces high levels of IFN $\alpha$  during viral infections. We showed that ICV injection of rhIFN $\alpha$  (>1000U) reduced the cytotoxicity of splenic natural killer (NK) cells through brain opioid receptors. This immunosuppression was abolished by splenic denervation, but not by adrenalectomy. ICV rhIFN $\alpha$  increased the activity of the splenic sympathetic nerve. Thus, brain IFN $\alpha$  seems to stimulate opioid receptors and thereby reduces the NK activity through sympathetic innervation.

To determine the site of action of rhIFN $\alpha$  to reduce the NK activity,

To determine the site of action of rhIFN $\alpha$  to reduce the NK activity, rhIFN $\alpha$  was injected through an implanted cannula into different brain sites of male Wistar rats (150-200g). After 30 minutes, the spleen was extracted and the NK activity was measured by a standard chromium release assay. An injection of rhIFN $\alpha$  of 200U into the preoptic area (POA) induced a decrease of NK activity by about 60% which was of the same degree to that observed after ICV rhIFN $\alpha$  of 2000U. The other hypothalamic sites (PVN, the posterior hypothalamus) appear to be less sensitive to microinjected rhIFN $\alpha$  in affecting the NK activity. The injection into thalamus had no effect. Pretreatment with  $\alpha$ -helical CRF (25µg, ICV) completely abolished the IFN $\alpha$ -induced suppression of NK activity, while CRF (1-2.5µg, ICV) resulted in an increase of splenic nerve activity and noradrenaline release as determined by an in vivo microdialysis which accompanied by reduced NK activity. The results suggest that brain IFN $\alpha$  reduced the NK activit through activation of the CRF system and that the POA seems to be one of the sites of action of IFN $\alpha$ .

DEGRADATION OF MET-ENKEPHALIN BY HUMAN GRANULOCYTE MEMBRANE PEPTIDASES. M.K. Leung\*, R. Flowers, S. Houston and G.B. Stefano. Departments of Chemistry and Biological Sciences, SUNY/Old Westbury, Old Westbury, NY 11568-0210.

Met-enkephalin, (ME; YGGFM), as a immunoregulator, is capable of inducing changes in adhesion and morphology of human granulocyte. These changes are potentiated by peptidase inhibitors suggesting the inactivation of ME is mediated by membrane-bound peptidases. To identify these peptidases, human granulocyte membrane was washed free of all soluble peptidases and dissolved in PBS with 2% Triton X-100. ME (50 uM) was incubated with the solublized membrane preparation in the presence or absence of peptidase inhibitors at 37°C. The incubation mixtures were inactivated by the addition of an equal volume of 20% CH<sub>3</sub>CN in 0.2% trifluoroacetic acid at the end of the incubation periods and analyzed by HPLC. Time-course study, showed half of the ME was degraded by membrane peptidases in 10 min and this was accompanied by an increase in the degradation fragments, GGFM, FM and F. The formation of GGFM was inhibited by bestatin while FM, by phosphoramidon indicating the presence of aminopeptidase and neutral endopeptidase 24.11. The formation of F was inhibited by both bestatin and phosphoramidon suggesting F was formed by the action of aminopeptidase on the degradation product, FM. The role of these peptidases in the inactivation ME is currently under investigation

RIDIRECTIONAL SIGNALS RETWEEN TRYPANOSOMA BRUCET BRUCET

BIDIRECTIONAL SIGNALS BETWEEN TRYPANOSOMA BRUCEI BRUCEI AND DORSAL ROOT GANGLIA NEURONS. K.Kristensson. A. Eneroth\*, M. Bakhiet and T. Olsson. Clinical Research Center and Department of Neurology, Karolinska Institutet, Huddinge Hospital, S-141 86 Huddinge, Sweden.

The extracellular haemoflagellate Trypanosoma brucei brucei (T.b.b.) releases a factor (TLTF), which can trigger CD8+ T-cells to interferon-y (IFN-y) production, and IFN-y derived from these cells promotes proliferation of the T.b.b. We now report that T.b.b. can interact with of the I.b.b. We now report that I.b.b. can interact with small neurons in rat dorsal root ganglia (DRG) cultures, which contain a IFN-y-like immunoreactive (IR) molecule. Cultures of DRG could promote both the proliferation and survival of T.b.b. and this growth promoting effect by the cultures was completely blocked by monoclonal antibodies against TLTF, IFN-y and CD8+ and their Fab-fragments. Living T.b.b. and TLTF induced an increase in major histocompatibility complex (MHC) class I antigens major histocompatibility complex (MRC) class I antigens expression and a decrease in the levels of IFN-γ IR in the cultures. The MHC induction was blocked by Fab fragments of the IFN-γ antibody, indicating that it is mediated by release of the neuronal IFN-γ like IR molecule. These data strongly suggest, that the IFN-γ like IR molecule in small DRG neurons mimicks certain physiological effects of lymphocyte derived IFN-γ. Furthermore, T.b.b. and small sensory neurons seems to interact bidirectionally by the TLTF and the IFN-γ like molecule, whereby perhaps neuronal disturbances may be elicited.

THE NUIDE MOUSE AS MODEL TO STUDY THE IMMUNO-MODULATORY EFFECT OF LUTEINIZING HORMONE-RELEASING HORMONE (LHRH)

N.Batticane, M.C. Morale, F. Gallo, C. Tirolo, N. Testa, C. Romeo, Z. Farinella and B. Marchetti\*. OASI Inst. Ment. Retard. and Brain Aging and Dept. Pharmacology, Medical School, University of Catania, 95125 Catania, Italy.

Nude mice contain many T cells but cannot generate pathogenspecific T-cell responses because they have only a thymic rudiment. While there are many T cell marker positive cells in peripheral lymphatic tissues of nude mice and they contain alloreactive cytotoxic T-cell precursors as well as T-helper cell activity for antibody production, they do not generate protective MHC restricted pathogenspecific T cells. Thus, the question of how nude mice can select and propagate precursor T cells remains unknown, and the specific components of the thymic microenvironment involved in T cell development have not been well characterized. Since our recent studies have postulated a major role for the hypothalamic neuropeptide LHRH in thymus physiology, the purpose of this work was to investigate the ability of LHRH and one of its potent agonistic analog, D-Tryp<sup>6</sup>LHRH, to influence thymus-dependent immune functions in this model. Using flow cytometry as a tool to analyze intrathymic differentiation pathways, this study shows that pulsatile administration of the neuropeptide markedly stimulates thymocyte differentiation and maturation, suggesting that LHRH via an interaction with the thymic microenvironment may promote thymocyte development.

## PAIN MODULATION: BRAINSTEM AND THALAMUS

### 289.1

BEHAVIORAL CHARACTERIZATION OF THE INTERACTION BETWEEN THE NUCLEUS RAPHE MAGNUS AND THE LATERAL RETICULAR NUCLEUS: ROLE OF NORADRENALINE. A.Z. Murphy and M.M. Behbehani. Dept. of Physiology, Univ. of Murphy and M.M. Behbehani. Dept. of Physiol Cincinnati College of Medicine, Cinti., OH 45267-0576.

Using electrophysiological techniques we have recently shown that lateral reticular nucleus (LRN) receives a major input from the nucleus raphe magnus (NRM). In order to determine the role of this pathway in the descending analgesia system, we examined the effect of blocking noradrenergic activity within the LRN on NRM stimulation produced analgesia. Male Zivic-Miller rats were anesthetized and 25 gauge guide cannulas were stereotaxically placed within the NRM, and bilaterally within the LRN. Following a 7 day recovery period, the effect of bilateral yohimbine (YOH) administration into the LRN on the analgesic response produced by d,1-homocysteic acid (DLH) administration into the NRM was determined using the tail-flick (TF) test. Microinjection of DLH (2mM; 0.5 ul) into the NRM increased TFL's 140% of baseline at 20 min post-injection and remained stable for up to 2 hrs. Pretreatment with YOH (3ug/.5ul), bilaterally within the LRN, consistently potentiated the effects of DLH alone at all time periods tested, with an average increase in basal TFL of 160%. This effect was most notable within the first 10 mins following DLH administration into the NRM in which YOH pretreatment produced a 30% increase in TFL in comparison to DLH treatment alone. Administration of YOH alone (YOH + saline) had no effect on baseline TFL. These results concur with our previous studies and further show that this region is an important relay in the NRM-spinal cord descending system. Supported by PHS grant NS20643.

## 289.2

THE OPPOSITE EFFECTS OF CHOLECYSTOKININ (CCK) AND MET-ENKEPHALIN (ENK) ON PERIAQUEDUCTAL GRAY (PAG)
NEURONS MEASURED BY CONVENTIONAL AND PATCH
CLAMP METHODS. M.M. Behbehani\*, H. Liu, S.D.Chandler and
M.T. Shipley. Dept. of Physiol and Anatomy U. of Cincinnati,
Cincinnati, OH, 45267-0576

To determine the cellular basis by which CCK antagonists potentiate morphine's anagesic effect, in intact rats the effects of both CCK and ENK on the same PAG neuron was examined. ENK inhibited 84% (12/14) of cells that were excited by CCK. To further analyze these actions, extracellular procedures were used to measure the effects CCK and ENK on PAG neurons maintained in vitro. CCK excited 40/56, inhibited 7/56 and had no effect on 9/56 cells. The excitatory response to CCK was blocked by CR1409 in 32/36 cells and by proglumide in 25/27 cells. Conventional intracellular recording were made from 16 cells. In 13 cells CCK produced a 5-14 mv membrane depolarization and increased the firing rate by as much as 72%. An inhibitory response to CCK was noted in 2 cells and CCK had no effect on one cell. The response to both CCK and ENK was compared in 25 cells. CCK excited 15/25 and inhibited 5/25 cells. ENK inhibited 15/25 and inhibited 4/25 cells. In the whole cell patch clamp studies, the effects of CCK on 10 cells were examined. In these cells CCK produced a decrease in resting membrane conductance and shifted the IV curve to a more depolarizing potential. It is concluded that 1) The excitatory effect of CCK is due to depolarization of the membrane more likely due to increased Na conductance 2) The majority of cells that are inhibited by ENK are excited by CCK. Supported by PHS NS20643.

## 289.3

EFFERENT PROJECTIONS TO RAT PERIAQUEDUCTAL GRAY MATTER AND PARABRACHIAL NUCLEI FROM TRIGEMINAL NUCLEUS ORALIS. L. A. Smith\* and W. M. Falls. Dept. Anatomy, Michigan State University, East Lansing, MI 48824. Trigeminal nucleus oralis (Vo) is involved in the

reception and central processing of non-noxious orofacial sensory information and plays a significant role in the reception and central processing of nociceptive sensory information from oral and dental structures and cranial vasculature. Electrical stimulation of the midbrain periaqueductal gray (PAG) inhibits cutaneous nociceptive responses of brainstem trigeminal neurons. This study examines the overall course, distribution, organization and morphology of efferent axons and their terminal arborizations originating from neurons in dorsomedial (DM), ventrolateral (VL) and border zone (BZ) subdivisions of rat Vo and innervating brainstem structures contributing to the intrinsic analgesia system, i.e., PAC, nucleus parabrachialis (PB). Unilateral deposits of the anterograde tracer PHA-L were made iontophoretically into each Vo subdivision. Axons of Vo projection neurons form terminal arborizations of a single type in PAG and more than one type in medial and lateral PB. The greatest density of Vo efferents originate from DM neurons followed by BZ and VL cells. Vo efferent projections to PAG may play a role in relaying noxious information to initiate inhibitory feedback interactions through PAG innervation of nucleus raphe magnus which directly inhibits nociceptive trigeminal neurons. Supported by NIH/BRSG to C.O.M.

## 289.4

CHRONIC NOCICEPTION CAUSES AN INCREASE IN BASAL EN-KEPHALIN IN THE PERIAQUEDUCTAL GRAY: A MICRODIALYSIS STUDY. F. G. Williams\*, W. M. Renno, and A. J. Beitz. Department of Pathobiology, University of Minnesota, 1988 Fitch Ave., St. Paul, MN 55108

Opiate-induced antinociception has been postulated to involve GABAergio interneurons in the periaqueductal gray matter (PAG). In an animal model for chronic nociception, we have examined the functional, dynamic release of enkephalin in the ventral-lateral PAG. Extracellular enkephalin levels were determined using microdialysis followed by radioimmunoassay. Complete Freund's adjuvant (CFA) or mineral oil (120 ul) was injected into one hindpaw, and the ventrolateral PAG on the contralateral side was dialysed either 24 hours or 7 days later. Twenty-four hours following hindpaw injection, enkephalin recovery in the dialysate of animals receiving CFA was increased nearly five-fold over those that received oil: from 1.29 to 6.25 pg/ 12 minute fraction (p < .01). The increase was attenuated 7 days following CFA or oil injection: basal enkephalin levels in the dialysate dropped to approx. two-fold higher in animals that received CFA. Veratridine (75uM) induced the release of additional enkephalin from the PAG of all experimental groups. Veratridine-induced release was greater in oil-injected control rats than in CFA-injected experimentals. These release data correlate with behavioral data (paw withdrawal latencies) and increased enkephalin biosynbehavioral data (paw withdrawa) rateriores) and increased enkephalin biosynihetic capacity (determined using quantitative hybridization histochemistry for pro-enkephalin A mRNA) to suggest that the enkephaliergic system in the PAG is activated by nociception. The inverse relationship between GABA and enkephalin levels in PAG dialysates supports the hypothesis that endogenous enkephalin inhibits GABA release in the PAG. Supported by NIH grants NS28016, DA06687, and DE06682.

GABAERGIC INPUTS TO TWO TYPES OF PAIN MODULATORY NEURONS OF THE NUCLEUS RAPHE MAGNUS OF THE ADULT CAT SHOWN BY ELECTRON MICROSCOPIC IMMUNOCYTOCHEMISTRY.

K. Skinner\* 1, P. Mason 1, Al. Basbaum<sup>2,3</sup> and H.L. Fields 1,2. Depts of Neurology 1, Physiology<sup>2</sup> and Anatomy<sup>3</sup>, University of California, San Francisco, CA, 94143

The regulation of a GABAergic input to on and off cells of NRM has been

The regulation of a GABAergic input to on and off cells of NRM has been implicated in opioid analgesia (see Fields et al, Ann. Rev. Neurosci. 14:219, 1991). In this study we used postembedding immunocytochemistry to reveal the distribution and characteristics of direct GABA-immunoreactive (ir) inputs to two NRM neurons. Electrophysiologically characterized NRM cells were intracellularly labelled with horseradish peroxidase. After reconstruction of the cells, selected regions were processed with an immunogold procedure using antisera directed against gluaraldehyde-conjugated GABA.

GABA-ir boutons contacted the soma, proximal and distal dendrites of both on and off cells, however the distribution over the two cell types differed. Immunoreactive boutons were distributed uniformly over the entire on cell soma and dendrites, but we found no GABA-ir boutons on the proximal 50µm of the off cell dendrites sampled and only two boutons were found on the off cell soma. Bouton density on the off cell progressively increased over distal dendrites. GABA-ir terminals covered 15.6% and 8.9% of the total synaptic membrane of on and off cells respectively. Furthermore, GABA-ir boutons constituted 16.9% of the total number of boutons apposed to the on cell and 10.5% of the boutons apposed to the off cell.

This study provides anatomical confirmation that there is a GABAergic regulation of both on and off cells in the cat NRM. The more uniform input to the on cell may provide the anatomical basis for a tonic inhibition. The regionally distributed input to the off cell may subserve a selective inhibition. Supported by NS21445 and NS14627.

Interconnections between rostral ventral medullary nuclei in the rat: an anterograde tract tracing study <u>A. Zagon</u>\* University Dept. of Pharmacology, Oxford, U.K. and Dept. of Physiology, University of California, San Francisco CA 94143

The rostral ventral medulla oblongata is involved in both blood pressure control and the central modulation of nociception. Physiological and pharmacological data show that the area might be an important site where integration between these functions occur. Our aim was to reveal the anatomical connections among various nuclei of the rostral ventral medulla that could provide a basis for such functional interactions. Discrete injections of Phaseolus vulgaris leucoagglutinin (PHA-L) were placed into the rostral ventrolateral reticular (RVL), the lateral paragigantocellular (LPGi), the raphe magnus (RMg) and/or pallidus (RPa), obscurus (ROb) and gigantocellular pars alpha nuclei (GiA). After 12-14 days, the tracer content of the medulla oblongata was visualized immunohistochemically. The distribution of labelled terminals was mapped contralateral to the injection centre.

Following PHA-L injections into the RVL, labelled terminals were most abundant in the RMg, ROb, RPa, GiA and RVL. Projections from the LPGi targeted the RMg, ROb, RPa, GiA, ventral gigantocellular nucleus (GiV) and LPGi. Terminals from the GiA and rostral RMg-RPa areas were focused in the medial aspects of the ventral medulla oblongata, in the GiA, GiV, LPGi and GiA, ROb, LPGi respectively. A dense, widespread projection to all parts of the ventral medulla originated from the ROb, while only a small number of labelled efferents could be observed following injections of the RPa.

The observed widespread projections of the ROb suggest a coordinative role of this nucleus in the rostral ventral medulla. As inputs from the majority of the ventral medullary nuclei reached the LPGi and GiA, the data point to the LPGi and GiA as major sites of local information integration.

## 289.9

INFLUENCE OF MIDAZOLAM AND PROPOFOL ON ACTIVITY OF THALAMIC NEURONS IN RAT. <u>V.M. Tronnier\*, N.M. Pham, M. Lis-Planells and P.C. Rinaldi</u>, Dept. of Neurosurgery, University of California, Irvine, CA 92717

Functional stereotactic procedures performed in patients for relief of chronic pain are often accompanied by neurophysiological recordings from neurons to map appropriate thalamic targets. Recent recordings of neuronal hyperactivity and bursting in medial and lateral somatosensory thalamic nuclei may relate to chronic pain mechanisms. During fixation of the stereotactic frame and craniectomy, local anesthetic and sedation is often employed. Drugs include the short-acting benzodiazepine, midazolam, and the hypnotic, propofol. Both agents modulate cortical EEG, however little is known about their effects on subcortical areas. Of particular concern for our studies of thalamic neurons and chronic pain is the possibility that these drugs might be responsible for the bursting of neurons recorded during surgery in these patients. To study this hypothesis naive rats were sedated and neurons stereotactically localized and conventionally recorded from medial (MD,CL,Re,PC) or lateral (VPL,VPM) nuclei for computer analysis. Preand post-IV midazolam (0.014mg/Kg) or propofol (2.5mg/Kg) multiple and isolated single unit activity were compared. Custom interval histogram and burst analyses revealed varied degrees of suppression of neuronal activity following the administration of either drug. Midazolam (n=9) produced a depression of activity (49%) in all rats with a mean depression of 27% and 66% in intervals of lateral and medial thalamic multiple units respectively. Propofol (n=6) produced a similar depression of activity (47%) in all rats with a mean of 69% and 26% in lateral and medial multiple units respectively. Analysis of single units (n=9) showed depression of non-bursting (n = 8) and bursting (n = 1) activity. This study does not support the notion that these drugs would produce enhancement of either periodic activity or bursting in cells recorded from medial or lateral somatosensory thalamic nuclei of naive rats; it is thus unlikely that they can account for this activity in recordings from thalamic neurons of chronic pain patients.

#### 289.6

SEROTONIN IMMUNOCYTOCHEMISTRY OF PHYSIOLOGICALLY IDENTIFIED NEURONS IN THE RAT ROSTRAL VENTROMEDIAL MEDULLA. <u>S. Potrebic\*H.L. Fields. and P. Mason</u>. Dept of Neurology, UCSF, San Francisco, CA 94143.

The rostral ventromedial medulla (RVM) is the major source of serotonin (5-HT) in the dorsal horn. A large body of evidence suggests that RVM serotonergic neurons inhibit nociceptive transmission and mediate the antinociceptive effects of supraspinal opioids. Three physiological cell classes in RVM, off-, on- and neutral cells, putatively have different effects on nociceptive transmission. The aim of this experiment was to determine which RVM cell class contains 5-HT

RVM cells were characterized by their responses during a nociceptive withdrawal reflex in the lightly anesthetized rat. Cells were intracellularly labeled and then processed for 5-HT immunocytochemistry. Labeled cells were examined with epifluorescence and imaged using a confocal microscope.

A total of 24 RVM neurons were intracellularly labeled. Only neutral cells (4/8) contained 5-HT immunoreactivity. No off-(N=9) or on- (N=7) cells were immunoreactive for 5-HT.

Since opioids alter the firing of on- and off-, but not neutral cells in RVM, these studies indicate that opioid anti-nociception does not require a change in serotonergic RVM cell activity.

## 289.8

THE DISTRIBUTION OF BRAINSTEM AND SPINAL CORD NUCLEI ASSOCIATED WITH DIFFERENT FREQUENCIES OF ELECTROACUPUNCTURE ANALGESIA. J. H. Lee\*and A. J. Beitz. Dept. of Vet. PathoBiology, Univ. of Minnesota, St. Paul, MN55108.

Immunocytochemical localization of the c-fos primary gene protein, Fos, was utilized to identify spinal cord and brainstem sites activated by either 4Hz or 100Hz electroacupuncture(EA) applied to the Zusanli acupuncture points of both hindlimbs in lightly anesthetized rats. The number and distribution of Fos immunoreactive neurons in the brainstem and spinal cord of 4Hz and 100Hz EA treated rats were compared with those in anesthesia and room control rats Compared to nonstimulated control rats, both 4Hz and 100Hz EA treated groups exhibited a significantly greater number of Fos labeled neurons in the dorsal horn of the L2 spinal cord seqment, lateral parabrachial nucleus, substantia nigra, raphe pallidus, dorsal raphe nucleus, locus coeruleus, posterior pretectal nucleus and the ventrolateral periaqueductal gray. In the 4Hz treated group, significant increases in Fos labeling were also observed in the cuneiform nucleus. dorsal and dorsolateral subdivisions of the periaqueductal gray, habenular nucleus, arcuate nucleus, and the ventrolateral and lateral hypothalamic nuclei as compared to nonstimulated controls. The only brainstem nucleus that exhibited significantly increased Fos immunoreactive neurons in 100Hz but not 4Hz EA was the rostroventrolateral nucleus of the medulla. These results indicate that many brainstem regions are activated by both 4Hz and 100Hz EA but additional brain stem regions are selectively activated by 4Hz EA which may relate to the opiate sensitivity of 4Hz EA. In sum, these data identify several distinct brainstem nuclei that may play a role in acupuncture mediated analoesia. Supported by NIDA grant DA 06687 and NIH grants DE 06682 and NS 28016.

## 289.10

MORPHINE ANALGESIA IN THE FORMALIN TEST IN THALAMIC AND DECORTICATE RATS. <u>B.K. Matthies\*</u> and <u>K.B.J. Franklin</u>, Dept. Psychol., McGill University, Montreal, PQ, Canada H3A 1B1.

Rats with partial decortication or

Rats with partial decortication or transection of the brain just rostral to the thalamus, were tested for their response to nociceptive stimulation in the formalin (FN) and tail flick (TF) tests, and for the effect of morphine on these responses and motor activity. Undrugged rats showed vigorous responses to nociceptive stimulation in both tests. All thalamic, and some decorticate rats, exhibited continuous pain over 60 min in the FN test, rather than the typical biphasic response. In thalamic rats, doses of morphine (4 & 8 mg/kg) that were analgesic in sham operates produced catalepsy, and analgesia in the TF test, but not in the FN test. After morphine, rats with most of the neocortex removed were cataleptic and analgesic in both tests. Rats with lesions ventral to the rhinal fissure, extending into the piriform cortex and underlying structures showed analgesia in the TF but not in the FN test, and no catalepsy. On the basis of this and other evidence the amygdala may be critical for opioid analgesia in the FN test, and may play a role in the cataleptic effect of opioids.

HABENULA LESIONS ATTENUATE LATERAL HYPOTHALAMIC STIMULA-TION-PRODUCED ANALGESIA IN THE FORMALIN TEST. P.N. Fuchs and V.C. Cox\*. Dept. of Psychology, University of Texas at Arlington, Arlington, TX 76019.

The purpose of the experiment was to determine whether

the integrity of the habenula (Hb) complex was necessary for analgesia resulting from lateral hypothalamic (LH) stimulation for tonic pain. Female albino rats were divided equally into three groups (n=8). The LH group received electrical brain stimulation of the LH during formalin induced pain. The LH-Hb group received bilateral electrolytic lesions of the Hb complex. The LH-Caudate (LH-C) group received asymmetrical bilateral electrolytic lesions within the area of the caudate nucleus. Both LH-Hb and LH-C groups received LH stimulation during formalin induced pain. The results demonstrate that lesions of the Hb had no effect on nociceptive baseline response, but Hb lesions attenuated LH stimulation-produced analgesia in the formalin test. The modification of the analgesic effect of LH stimulation in the formalin test following Hb complex damage cannot be attributed to a non-specific brain damage effect since bilateral caudate nucleus lesions of similar extent as Hb complex damage failed to modify the analgesic effect of LH stimulation. It appears that the Hb is necessary for LH stimulation-produced analgesia for tonic pain. The critical damage was probably the lateral habenula nucleus since it receives a major input from the LH.

### 290.3

PARABRACHIAL AREA (PBA) AND NUCLEUS RAPHE MAGNUS (NRM)-INDUCED INHIBITORY EFFECTS ON THE ACTIVITY OF NOCICEPTIVE AND NON-NOCICEPTIVE TRIGEMINAL SUBNUCLEUS CAUDALIS (Vc) NEURONS ACTIVATED BY CUTANEOUS OR DEEP INPUTS. C.Y.Chiang\*, J.W.Hu and B.J.Sessle. Fac. of Dentistry, Univ. of Toronto, Toronto, Ontario M5G 1G6, Canada.

Both PBA and NRM have been implicated in central nociceptive mechanisms, and the present study tested for and compared modulatory influences from PBA and NRM on nociceptive cutaneous and deep inputs to single Vc neurons. Extracellular recordings were made in Vc of adult rats an esthetized with urethane/ac-chloralose, and conditioning stimulation (CS) applied to NRM and PBA (10 s repetitive stimuli, 0.2 ms, 400 Hz, 5-20  $\mu$ A). Neurons were classified as low-threshold mechanosensitive rapidly adapting Neurons were classified as low-threshold mechanosensitive rapidly adapting (RA, n=10) or slowly adapting (SA, n=6), wide dynamic range (WDR, n=16), nociceptive-specific (NS, n=5) or deep only (D, n=7). Spontaneous and mechanically evoked activity in WDR, NS, D and SA neurons was markedly inhibited by both NRM (15/15, 5/5, 7/7, 5/6) and PBA (15/16, 3/3, 6/7, 4/5), but fewer RA neurons were inhibited by PBA (1/8) than by NRM (5/9). PBA and NRM were equally effective in inducing potent inhibition (>50%) of cutaneous nociceptive inputs to WDR and NS neurons (PBA 17/19; NRM 19/20), although PBA may be less effective than NRM in inducing potent inhibition of deep nociceptive inputs to these neurons (2/4; 4/4) and to D neurons (3/7; 7/7). Both PBA and NRM-induced inhibition outlasted CS only in a few cases and its magnitude increased with increases in CS frequency (5-400 Hz). Glutamate (0.2M, 0.1-3  $\mu$ l) injected into PBA however produced a long-lasting, potent inhibition in 6 of 7 neurons tested. Thus, PBA as well as NRM can powerfully inhibit both deep and cutaneous inputs to Vc neurons. Supported by Canadian MRC and NIH (grant DE09559).

## 290.5

DIFFERENCES IN THE PROJECTIONS FROM THE NUCLEUS RAPHE MAGNUS (RMg) TO THE NUCLEUS LOCUS COERULEUS (LC) IN DIFFERENT SUBSTRAINS OF SPRAGUE-DAWLEY RATS: IMPLICATIONS FOR THE MODULATION OF NOCICEPTION. W.L. West and H.K. Proudfit.\*

Dept. of Pharmacology, Univ. of Illinois at Chicago, Chicago, IL 60612. We have recently provided anatomical evidence that LC neurons in Sprague-Dawley rats obtained from Harlan Sprague Dawley, Inc. innervate the spinal cord dorsal horn, but LC neurons in rats from Sasco, Inc. innervate the ventral horn. In addition, LC neurons modulate nociception in Harlan rats, but not in Sasco rats. We have also demonstrated that efferent projections from the RMg innervate the A5 and A7 catecholamine cell groups, but not the LC in Sprague-Dawley rats obtained from Sasco, Inc. We designed experiments to determine if the afferent projections from the RMg to the LC and other pontine catecholamine cell groups were the same or different in Sprague-Dawley rats obtained from Harlan, Inc. Fluoro-Ruby, an anterograde and retrograde tracer was injected iontophoretically into the RMg of animals from both vendors and brainstem sections were processed for tyrosine hydroxylase-immunoreactivity. In Sasco rats, there were moderate projections to the A5 and A7 cell groups, but only sparse projections to the LC. In contrast, Harlan rats had moderate projections to the LC, but only minor projections to the A5 and A7 catecholaminergic cell groups. These results provide evidence for a nociceptive modulatory thway from RMg to LC to spinal cord dorsal horn in Harlan rats and from RMg to the A7 cell group to the dorsal horn in Sasco rats. This work was supported by USPHS Grant DA03980 from the National Institute on Drug Abuse.

#### 290.2

THE ANTINOCICEPTION PRODUCED BY STIMULATION OF THE DORSO-LATERAL PONTINE TEGMENTUM IS MEDIATED IN PART BY NEURONS IN THE VENTROMEDIAL MEDULLA. J.A. Paice\* and H.K. Proudfit. Department of Pharmacology, University of Illinois at Chicago, Chicago,

We have demonstrated that electrical stimulation of neurons near the A7 catecholamine cell group in the dorsolateral pontine tegmentum (DLPT) produces antinociception that is blocked by intrathecal injection of serotonergic antagonists. In addition, we have shown that neurons in this area of the pons project to the area of the ventromedial medulla (VMM) that contains spinally-projecting serotonin neurons. The present studies were designed to determine whether activation of these DLPT neurons by microinjection of glutamic acid could produce antinociception that is blocked by microinjection of the local anesthetic tetracaine into the VMM. The excitatory amino acid glutamate was microiniected into the DLPT, near the A7 cell group, of partially anesthetized female Sprague Dawley (Sasco, Inc.) rats and the latency to a paw-withdrawal response to noxious heat was determined before and after glutamate microinjection. Glutamate microinjection elevated response latencies for an average of 2.5 minutes (SEM=0.58). Forty minutes later, tetracaine was microinjected into the VMM and glutamate microinjection into the DLPT was repeated. The antinociception produced by glutamate microinjection was blocked by the microinjection of tetracaine into the VMM. These findings provide evidence that neurons in the DLPT project to the VMM, and are involved in modulating nociception. EFFECTS OF ELECTRICAL AND CHEMICAL STIMULATION OF LATERAL RETICULAR NUCLEUS (LRN) ON DORSAL HORN NEURONS (DHN) IN THE CAT. <u>U.T. Oh</u>, <u>T.S. Moon, Y.K. Cho, J.Y. Kwak, K.H. Ko and H.C. Shin.</u> Lab. of Physiology, College of Pharmacy, Seoul National University, Seoul,

Electrical stimulation of LRN prolongs latency of tail-flick reflex, and electrical stimulation of LRN and adjacent areas inhibits dorsal horn neurons. Since many ascending and descending axons are located close to the area, it is necessary to inject chemicals such as L-glutamate (L-glu) to LRN to see whether inhibition of DHNs is caused by stimulation of LRN or axons of passage. Thus, the purpose of the present study was to determine if L-glu injection to LRN inhibits DHNs in the cat. Along with this, neural responses of DHNs to electrical stimulation of LRN were also characterized. Sixteen cats were anesthetized with alpha-chloralose (60mg/kg).

Recordings were made from 65 DHNs located in the L3 to S1 segments of the spinal cord. Sixty-two DHNs were tested for responses to peripheral stimulation; 32 cells were WDR cells, 17 were HT, and 6 and 7 cells were Deep and LT cells, respectively. Responses of DHNs to electrical stimulation (100uA, 100Hz, 100us) of LRN and adjacent area were tested for 55 DHNs: 38 DHNs were inhibited, 15 failed to show any response and 2 were excited. The electrical stimulation inhibited not only spontaneous activities but responses of DHNs to noxious peripheral stimulation. Effect of L-glu injection (500nl, 100nmole) to LRN was tested to 7 DHNs. Among these cells, 3 were inhibited, 3 were unaffected, and one cell was initially excited and then inhibited by the injection. Five more injections were made to areas distant to LRN, and none of these injections inhibited DHNs, suggesting that inhibition resulting from L-glu injection was localized to LRN. In summary, electrical and chemical stimulation of LRN inhibited DHNs, and the inhibition was due to activation of neurons in LRN. Supported by RCNDD grant of

THE PROJECTION OF NORADRENERGIC NEURONS IN THE A5 CELL GROUP TO THE SPINAL CORD IN THE RAT **USING ANTEROGRADE TRACING: EVIDENCE FOR A ROLE** OF A5 NEURONS IN MODULATING NOCICEPTION

F.M. Clark\* and H.K. Proudfit, Dept. of Pharmacology, Univ. of Illinois at Chicago, Chicago, IL 60680.

Noradrenergic neurons located in the A7 catecholamine cell group have been shown to innervate the spinal cord dorsal horn and stimulation of these neurons produces antinociception. Stimulation of noradrenergic neurons in the A5 cell group also produces antinociception, but the areas of the lumbar spinal cord innervated by these neurons have not been described. Experiments were designed to trace the projections from the A5 cell group to the spinal cord, using the anterograde tracer phaseolus vulgaris leucoagglutinin and immuno cytochemistry. The results of these experiments indicated that A5 noradrenergic neurons project ipsilaterally through the dorsolateral funiculus and terminate primarily in the ipsilateral deep dorsal horn and intermediate zone (laminae IV-VI) in lumbar and cervical segments, and the thoracic intermediolateral cell column. These results provide anatomical support for a role of A5 neurons in modulating nociception. Supported by USPHS Grant DA03980 from the National Institute on Drug Abuse.

QUANTITATIVE BEHAVIORAL ANALYSIS OF RAT FLEXION HINDLIMB WITH-DRAWALS TO GRADED NOXIOUS SKIN HEATING AND THEIR SUPPRESSION BY STIMULATION IN MIDBRAIN PERIAQUEDUÇTAL GRAY (PAG) AND LATERAL RETICULAR FORMATION (LRF). R.L. Kitchell and E. Carstens. Dept. of Animal Physiology, Univ. of Calif., Davis, CA 95616.

Most animal pain tests measure the latency of a nocifensive response, but provide no information on how suprathreshold responses are altered by analgesics. We therefore developed a method to measure the magnitude of rat hindlimb withdrawals to graded noxious heating of the paw, and have presently investigated effects of stimulation in midbrain analgesia areas.

presently investigated effects of stimulation in midbrain analgesia areas. One week following implantation of bipolar stimulating electrodes in PAG and LRF, rats were behaviorally tested. The rat rested comfortably in a restrainer with the protruding left hindpaw attached to a Peltier thermode. EMGs were recorded in biceps femoris during attempted limb withdrawals evoked by graded noxious heat stimuli (40-52° C, 5 s duration, 2 min intervals). Responses were quantified as area beneath the integrated EMG. Effects of PAG or LRF stimulation were tested by delivering electrical stimuli (100 ms, 100 Hz trains, 3/s, 10-800 uA) during the heat stimulus.

3/s, 10-800 uA) during the heat stimulus. PAG and LRF stimulation suppressed withdrawals in an intensity-dependent manner. Thresholds (range: 10-400 uA) were lower, and recruitment of reflex suppression greater, for LRF vs. PAG stimulation. Withdrawal magnitude increased linearly from 40-52° C. PAG stimulation produced a significant reduction in mean slope of the stimulus-response function with no change in threshold, while LRF stimulation produced a parallel rightward shift with a significant increase (4° C) in mean threshold (N=11 to date).

Medial or lateral midbrain stimulation thus exerts parametrically distinct suppressive effects on limb withdrawals, identical to the effects observed previously on stimulus encoding by lumbar dorsal horn neurons.

RESPONSES OF SPINAL DORSAL HORN NEURONS TO NOXIOUS HEATING OF THE RAT'S TAIL: STIMULUS CODING, INHIBITION BY MIDBRAIN STIMULATION, AND BEHAVIORAL CORRELATES. D.K. Douglass and E. Carstens. Dept. of Animal Physiology, Univ. of Calif., Davis, CA 95616.

Despite widespread use of the tail flick reflex as a pain assay, little is known about spinal interneurons in the reflex arc. We therefore investigated (a) whether spinal neurons respond to noxious tail heating, (b) if they are inhibited by midbrain stimulation, and (c) if the neuronal results correspond with behavioral data obtained from the same rats.

The same rats used in the preceeding behavioral study (Carstens, 1992) were anesthetized with sodium pentobarbital. The sacral-coccygeal spinal cord was exposed by laminectomy for single-unit recording from neurons with cutaneous tail input. Unit responses to the identical noxious radiant heat stimuli used in the preceeding study were quantified as the number of action potentials/10 s period beginning 2 s after heat onset.

In 10 rats to date, 29 units responded to noxious tail heating. Receptive fields ranged from unilateral areas of a few sq. mm to the entire tail. Mean responses to noxious heat increased linearly from a threshold near 38° C to 50° C and then levelled off. In 9/10 rats, neuronal responses were inhibited by stimulation in midbrain periaqueductal gray (PAG) or lateral reticular formation (LRF) at the same or slightly higher current intensities that had previously suppressed the tail flick. Neuronal responses were suppressed by PAG stimulation such that the slope of the mean stimulus-response function was significantly reduced with no threshold change. LRF stimulation produced a parallel rightward shift of the mean stimulus-response function with a significant increase in threshold. There was thus excellent correspondence between neuronal stimulus encoding and behavioral measures of tail flick magnitude, and their modulation.

## 290.11

DUAL LIDOCAINE INJECTIONS INTO VB THALAMUS ARE NOT ANALGESIC IN THE FORMALIN TEST.

J.E.McKenna\* and R.Melzack. Dept. of Psychology, McGill University, 1205 Dr. Penfield Ave. Montreal, Que. Canada H3A 1B1

The ventrobasal thalamus (VB) has long been proposed as a critical nociceptive sensory relay. Previous studies have indicated, however, that injection of the local anesthetic lidocaine into VB caused no observable changes in pain behavior expressed after peripheral formalin injection, while similar treatment of centromedial/posterior thalamus significantly reduced/enhanced pain behaviors. experiment was undertaken to determine if pain behaviors would be affected by lidocaine treatment of a larger part of VB. Long-Evans rats received 2 x 1.0 µl unilateral intracranial infusions of 2% lidocaine or saline, before or after a 60 ul injection of 2.5% formalin acetate into the contralateral hindpaw. Dual lidocaine infusion into VB did not cause a reduction in pain behaviors, regardless of the time of central administration relative to the peripheral stimulus. These results indicate that VB may not be critically involved in formalin-induced nociception. Supported by NSERC grant A7896.

#### 290.8

QUANTITATIVE BEHAVIORAL ANALYSIS OF THE RAT TAIL FLICK REFLEX AND ITS SUPPRESSION BY STIMULATION IN MIDBRAIN PERIAQUEDUCTAL GRAY (PAG) OR LATERAL RETICULAR FORMATION (LRF). E. Carstens\* Dept. of Animal Physiology, Univ. Calif. Davis, CA 95616.

The widely-used tail flick assay is a latency measure that gives an indication of pain threshold, but provides no information on suprathreshold responses or their modulation by analgesics. We therefore developed a method to measure the magnitude of tail flicks, and have investigated their modulation by stimulation in midbrain analgesia areas.

The same rats from the preceeding study (Kitchell & Carstens, 1992) were used. The rat rested comfortably in a restrainer, and the extended tail was attached to a radial array of force transducers to measure rostral, dorsal and horizontal isometric forces during attempted tail flicks elicited by graded noxious radiant heat pulses (38-58° C, 5 s duration, 2 min intervals) delivered unilaterally to the tail. Areas beneath force traces were measured to calculate integrated force vectors (N-sec). Brain stimulation was as described in the preceeding abstract.

Tail flicks were suppressed in an intensity-dependent manner, with LRF more effective than PAG stimulation. Hindlimb and tail flick reflexes were usually suppressed equally; in 4 rats tail flicks were suppressed at lower intensities compared to limb withdrawals. Tail flick magnitude increased linearly from threshold (40° C) to 50° C and then leveled off. PAG stimulation (N=12 rats to date) produced a mean stimulus-response function that was linear from 40-58° C, and whose slope was significantly lower (with no threshold change). LRF stimulation (N=11) produced a parallel rightward shift in the stimulus-response function with a significant increase (4° C) in threshold. Thus, the tail flick reflex is under the same two descending influences that operate on limb withdrawal reflexes and dorsal horn neurons.

## 290.10

ALTERED DESCENDING MODULATION FROM THE ROSTROVENTRAL MEDULLA IN CAPSAICIN-TREATED RATS.

M. Zhuo\* and G.F. Gebhart. Department of Pharmacology, College of Medicine, The University of Iowa, Iowa City, Iowa 52242

Descending biphasic modulation from the rostroventral medulla (RVM) on the spinal nociceptive tail-flick (TF) reflex and on lumbar spinal dorsal horn neuron responses to noxious cutaneous stimuli were studied in adult rats treated as neonates with capsaicin or vehicle. In vehicle-treated rats, descending facilitatory and inhibitory effects on the TF reflex were produced from the RVM. Electrical stimulation in the RVM produced biphasic (n=11), only inhibitory (n=13) or only facilitatory (n=1) effects on the TF reflex. In capsaicin-treated rats, the proportion of sites where electrical stimulation only inhibited the TF reflex was significantly less and the number of sites in RVM where electrical stimulation only facilitated the TF reflex was significantly greater than in vehicle-treated rats. In electrophysiological experiments, the number of sites where electrical stimulation produced only facilitatory effects on responses of spinal dorsal horn neurons to noxious stimulation (thermal or mechanical) of the skin were increased from 13.3% of the total sites in vehicle-treated rats to 40.0% in capsaicin-treated rats. The number of sites where stimulation only produced inhibitory effects on responses of spinal dorsal horn neurons to noxious stimulation was decreased from 46.7% of the total sites in vehicle-treated rats to 35% in capsaicin-treated rats. The present study suggests that neonatal capsaicin treatment has significant effects on bulbospinal systems important to the modulation of spinal nociceptive transmission.

NON-PEPTIDE NEUROKININ ANTAGONIST PREVENTS CAPSAICIN-INDUCED BLOOD PRESSURE REFLEXES IN RABBIT AND RAT. R. Amann', M. Eder and J. Donnerer. Dept. Exp. & Clin. Pharmacology, Graz Univ., A-8010 Graz, Austria.

RP 67580 has been shown to be a potent neurokinin (NK)-1 receptor antagonist which exhibits analgesic properties (Garret et al., 1991). We have compared the effect of RP 67580 and that of the NK-1 antagonist CP-96345 (Snider et al., 1991) in anesthetized rats and rabbits on blood pressure, and on the reflex blood pressure fall produced by close injection of capsaicin into the rat femoral artery and the rabbit central ear artery, respectively.

In both species, RP 67580 (up to 7 µmol/kg i.v.) had no effect on blood pressure but attenuated the capsaicin induced depressor reflex which recovered 50-80 min later. Inhibition could be overcome by increasing the dose of capsaicin. CP-96345 (0.7-7.0 µmol/kg i.v.) produced a long-lasting hypotension which prevented evaluation of a possible influence on the depressor reflex. CP-96344, the inactive enantiomer with no NK antagonistic properties, produced similar hypotension as CP-96345.

In rabbits, intracisternal injection of RP 67580 (100 nmol) as well of CP-96345 (30 nmol) had no effect on blood pressure but caused reversible inhibition (61% and 46%, respectively) of the capsaicin-induced depressor reflex. The results suggest an analgesic effect of NK antagonists, which, in the case of CP-96345 seems to be masked by side-effects which are not related to NK receptor antagonism.

### 291.3

TEST-DEPENDENT ANALGESIC EFFECT OF THE SELECTIVE NON-PEPTIDE NK-1 RECEPTOR ANTAGONIST CP96,345 O.-G. Berge\* and M. Ståhlberg. Astra Pain Control, Preclinical Research, S-151 85 Södertälje, Sweden.

The non-peptide NK-1 receptor antagonist CP96,345 provides advantages over the previously available peptidergic substance P antagonists with regard to selectivity and penetration of the bloodbrain barrier. We have investigated the effects of intraperitoneally administered (±)-CP96,345 in four tests of nociception in mice.

(±)-CP96,345 (8 - 73 μmol/kg) had no effect when tested 15, 30, 45 and 60 min after injection in the radiant heat tail-flick test, the constant temperature hot plate test (58 OC) or the increasing temperature hot plate test (42 - 50 °C, rate 3 °C/min).

Doses from 2.4 to 73 µmol/kg reduced the response in the late, inflammation-related phase of the formalin test (licking induced by 20 µl, 1% formaldehyde in saline injected subcutaneously into one hind paw). Only 73 µmol/kg affected the early phase.

At 73 µmol/kg, some sedation was evident, possibly interfering with the response in the formalin test. Increasing the dose to 109 µmol/kg in two animals produced profound stupor, precluding any behavioral testing

The data suggest that substance P plays a role in some but not all kinds of pain.

## 291.5

A GENETIC ANALYSIS OF SWIM STRESS-INDUCED ANALGESIA IN SELECTIVELY BRED MICE. J.S. Mogil'. P. Marek. W.F. Sternberg. M.A. Spence and J.C. Liebeskind. Dept. of Psychology and Brain

Research Institute, UCLA, Los Angeles, CA 90024.

We have previously demonstrated that 3 min forced swims in 32°C, 15°C and 20°C water produce swim stress-induced analgesia (SSIA) that is mediated by opioid, non-opioid, and mixed opioid/non-opioid mechanisms, respectively. The present study sought to opioid mechanisms, respectively. The present study sought to examine the patterns of inheritance of these SSIA paradigms, and also of morphine analgesia, in mice selectively bred in Poland towards high (HA) and low (LA) 20°C SSIA for more than 20 generations. To this end, Mendelian test-cross populations were bred from 21st generation HA and LA parents, including: F<sub>1</sub> hybrids (HAxLA), backcrosses to both parents ( $F_1xLA$ ,  $F_1xHA$ ), and  $F_2$  hybrids ( $F_1xF_1$ ). All populations were tested on the hot plate (56°C) immediately prior to and 2 min after a 3 min forced swim in 15°C, 20°C or 32°C water, and also immediately prior to and 25 min following a systemic injection of 10 mg/kg morphine. Results indicate that the LA genotype is partially dominant over the HA genotype with respect to the SSIA paradigms, but the reverse is true with respect to morphine analgesia. As well, a non-parametric statistical analysis comparing observed phenotypic values with those predicted by Mendelian ratios indicates that a single-locus hypothesis for 32°C SSIA and morphine analgesia cannot be ruled out. This suggests that the magnitude of opioid SSIA and morphine analgesia in selectively bred mice may be determined by a single major gene. Supported by NIH Grant NS07628 and an Unrestricted Pain Research Grant from the Bristol-Myers Squibb Company.

TEMPERATURE AND PAIN THRESHOLDS ARE INFLUENCED BY DIFFERENT GLUCOCORTICOIDS IN MAN. G. Fehm-Wolfsdorf\*, C. Körbächer, C. Maier, R. Arndt, Inst. of Psychology & Dept. of Anaesthesiology, University of Kiel, D-2300 Kiel, Germany.

Dexamethasone as compared to hydrocortisone differentially influence sensory thresholds of several modalities. The present study aimed to look for comparable effects on temperature and pain thresholds in male nonsmoking volunteers. 26 subjects participated in three medication sessions, each, and were pretreated with either 30 mg hydrocortisone, 1 mg dexamethasone or the respective placebo pills according to a double-blind crossover Latin-square design. Temperature and pain thresholds were obtained by a Path-Tester MPI 100 with a standard procedure starting at 32°C or 40°C, respectively. Temperature applied to the ball of the non-dominant thumb rose 0.7°C/ sec. Pain thresholds considerably vary between subjects: thus, in an additional untreated baseline session we studied the relationship between individual thresholds, cortisol response to the pain stimulation, and personality factors (anxiety and repression-sensitization). Salivary cortisol was determined at the start, middle and end of all sessions. As expected hydrocortisone treatment led to elevated temperature thresholds, but not pain thresholds. Dexamethasone had no effect other than placebo. High tendency to "situational control" in the repression-sensitization-questionnaire was positively correlated to high cortisol response within the untreated sessions, and negatively correlated to pain thresholds. Thus a combination of endocrine reactions to pain with personality variables may reliably predict interindividual differences in pain perception.

Research was supported by the Deutsche Forschungsgemeinschaft (DFG).

## 291.4

INFLUENCE OF SHOCK SEVERITY ON THE ACTIVATION OF ANALGESIC SYSTEMS IN PENTOBARBITAL TREATED RATS. J.W. Grau\*, P.A. Illich, K.D. Burks and M.W. Meagher, Dept. of Psychology, Texas A&M Univ., College Station, TX 77843. Terman et al. (Science, 226, 1270) showed that exposure to severe shock can elicit "analgesia" on the tail-flick test in pentobaribital anesthetized rats. Their least severe shock parameters

generated a naltrexone reversible ("opioid") analgesia and the most evere elicited a naltrexone-insensitive ("nonopioid") analgesia They proposed that a coulometric relation (shock intensity x duration) predicts whether the opioid or nonopioid system is engaged. The present experiments tested this hypothesis.

Experiment 1 looked at the minimum shock intensity and

duration that generates analgesia on the tail-flick test in pentobarbital (40 mg/kg) anesthetized rats. After baseline testing, subjects were exposed to three tailshocks and pain reactivity was tested 5 more times. We found 1.5-s/1.0mA, 25-s/1.0mA, & 25-s/0.5mA shocks elicited analgesia, and 1.5-s/0.5mA, 3.0-s/0.5mA, & 25-s/0.5mA did not. The results fail to support the

3.0-\$/0.5mA, & 25-\$/0.5mA did not. The results hall to support the coulometric relation but can be accommodated by a relation derived from Steven's power law: shock duration x intensity\*\*3.5.

Experiment 2 tested the impact of naltrexone (14 mg/kg) on the analgesia observed in pentobarbital anesthetized rats. In contrast to Terman et al., naltrexone did not attenuate the analgesia observed after the least severe shock schedules (e.g., 1.5-\$/1.0 mA). & 25-s/0.5 mA), but did attenuate the analgesia observed after more severe shocks (e.g., 2-s/3.0mA & 25-s/1.5mA). Very severe shocks (75-s/3.0mA) elicited a naltrexone-insensitive analgesia.

## 291.6

NON-COMPETITIVE NMDA ANTAGONIST, MK-801, AND GLYCINE ANTAGONIST, ACEA-1011, PREVENT THE DEVELOPMENT OF TONIC PAIN FOLLOWING SUBCUTANEOUS FORMALIN. Anthony L. Vaccarino!, Przemyslaw Marek<sup>2</sup>, Benjamin Kesi<sup>2</sup>, Eckhard Weber<sup>3</sup> and John C. Liebeskind<sup>2</sup>, <sup>1</sup>Department of Psychology, University of New Orleans, Lakefront, New Orleans, LA 70148, <sup>2</sup>Department of Psychology, University of California, Los Angeles, CA 90024 and <sup>3</sup>Department of Pharmacology, University of California Col. Med., Irvine, CA 92717. Several lines of evidence indicate a critical role of N-methyl-D-processic in the deval-among the formula of the color of

aspartic acid (NMDA) receptor in the development of persistent pain following injury. Subcutaneous injection of formalin produces a biphasic pain response: an early, transient phase followed by a late tonic phase. It has recently been demonstrated that the late phase of the formalin test is a partial result of long-term changes in central nervous system function produced by neural activity generated during the early phase. The present study examined the involvement of the NMDA receptor in the development of the late pain produced following subcutaneous injection of formalin into the hind paw in mice. Blockade of the NMDA receptor by the ion channel blocker, MK-801, prior to formalin injection, but not after, reduced pain during the late phase. Similarily, the blockade of the NMDA allosteric site by the novel glycine site antagonist, ACEA-1011, also reduced the pain response in the late phase. Supported by NIH Grant NSO7628 and an Unresricted Pain Research Grant from Bristol-Myers Squibb Company.

SEX DIFFERENCES IN THE ANTAGONISM OF NON-OPIOID STRESS-INDUCED ANALGESIA: EFFECTS OF GONADECTOMY AND ESTROGEN REPLACEMENT. W.F. Stemberg\* I.S. Mogil. P. Marek. B. Kest. and J.C. Liebeskind. Department of Psychology, University of California, Los Angeles, CA 90024.

Sex differences in the neurochemical mediation of non-opioid swim stress-induced analgesia (SSIA) were examined in Swiss-Webster mice. Intact and gonadectomized mice of both sexes were tested for their analgesic response (hot-plate test; 56°C) to 3 min forced swimming in 15°C water. SSIA resulting from 15°C swim was previously shown to be naloxone-insensitive (i.e., non-opioid). Our laboratory has demonstrated that this form of non-opioid analgesia is attenuated by the N-methyl-D-aspartate (NMDA) receptor antagonist dizocilpine (MK-801). We now report that this finding is specific to male mice. In female mice, neither naloxone (10 mg/kg; IP) nor dizocilpine (0.075 mg/kg; IP) significantly attenuated analgesia following 15°C swim. Thus, SSIA in intact females was neither opioid, nor NMDA- mediated, yet it was of similar magnitude to the SSIA displayed by intact males. After ovariectomy, females displayed a pattern of antagonism similar to males such that dizocilpine attenuated non-opioid SSIA. In a separate experiment, estrogen replacement (estrogen benzoate; 5.01g/d) administered to ovariectomized mice over a 6-8 d period reinstated the dizocilpine-insensitivity of 15°C SSIA characteristic of intact female mice. These findings suggest the existence of a novel, female specific, estrogen dependent mechanism of SSIA.

Nattrexone - Insensitive antinociception follows carbon dioxide aneathesia: a role for brain histamine H<sub>2</sub> receptors? S.A. Mischler, L.B. Hough, A.H. Battles and J.A. Raucci Jr., Dept. Pharmacology & Toxicology, and Animal Resources Facility, Albany Medical College, Albany, NY 12208.

Presently we have discovered and pharmacologically characterized the effects of CO<sub>2</sub> exposure on hot plate (52°) antinociception (ANC) in rats. Exposure (30 sec) to 100% CO<sub>2</sub> induced anesthesia with a duration of 2 - 4 min, followed by complete clinical recovery. This treatment resulted in significant ANC (25 - 30% of maximal effect) detected from 25 to 60 min later. Control animals, placed in the same chamber filled with room air, showed no such response. Carbon dioxide ANC was also additive with morphine ANC (5 mg/kg, s.c.). Pretreatment with a large dose of the opiate antagonist nattrexone (5 mg/kg, i.p., 7.5 min before exposure) did not significantly change CO<sub>2</sub> ANC, implying a non - obligatory role for endogenous opiates. In contrast, pretreatment with the brain - penetrating histamine H<sub>2</sub> antagonist zolantidine (5 mg/kg, s.c., 7.5 min, a treatment previously shown to inhibit naloxone - insensitive, footshock - induced analgesia) significantly attenuated the CO<sub>2</sub> - induced antinociceptive response. In the absence of CO<sub>2</sub> exposure, neither antagonist altered hot plate latencies. These findings suggest that: 1) brief exposure to anesthestic concentrations of CO<sub>2</sub> induces a long - lasting ANC that may represent a novel form of stress - induced analgesia, and 2) brain histamine may function as a mediator of this response (Supported by DA-03816).

## 291.11

SWEET TASTE AND MORPHINE ANALGESIA DURATION: EFFECTS OF DRINKING SCHEDULE ON PAW LICK AND TAIL FLICK TESTS. K.F. Green<sup>1</sup>, K.Y. Hiyoshida<sup>1</sup>, J. S. Jones<sup>1</sup>, and J. J. Kim<sup>2</sup>. <sup>1</sup>Psych. Dept., Cal. State Univ., Long Beach, CA 90840-0901 and <sup>2</sup>NSF Young Scholar, Bellflower High School, Bellflower, CA.

Reduced morphine analgesia after flavor experience (RMAFE) has been found in adult rats given low doses of morphine after flavor exposures lasting one day to 5 weeks (e.g., Bergmann et al., <u>Behav. Neural</u> <u>Biol.44.</u> 347-353, 1985). Our laboratory has had inconsistent success in finding RMAFE, indicating a need to identify controlling variables. The present experiment used 4 groups of 8 rats each. It compared 3-h drinking periods that were continuous vs intermittent (nine 5-min periods equally spaced over the 3 h) in which rats were given a saccharin-dextrose solution or water. Analgesic responses to 4 mg/kg morphine (sc) were assessed with hind paw lick (51.5° C hot plate) and tail flick (4 sec baseline) tests. Analgesia was marked in paw lick and tail flick tests 30 min -- but not 60, 90, and 120 min -after injection. At 30 min, intermittent flavor attenuated tail flick latencies but not paw lick latencies relative to intermittent water; continuous flavor vs water did not differ on either measure. However, the continuous flavor group showed strong negative correlations between amount consumed and paw lick (r = -0.85) and tail flick (r = -.80) latencies. Intermittent drinking thus provided experimental control over RMAFE in the tail flick test while continuous drinking provided statistical control in both tests.

#### 291.8

TYROSYL DIAMIDES AS POTENT MU AND DELTA OPIOID RECEPTOR LIGANDS. D.W. Hansen Jr.\*, N.S. Chandrakumar, R.K. Husa, K.B. Peterson, S.Tsymbalov, A.Stapelfeld, L.N. Williamson, M. Reichman, and P.M. Beardsley Depts. of Chemistry and Neurological Diseases, G.D. Searle & Co., 4901 Searle Parkway, Skokie, IL 60077.

In our effort to discover and develop  $\delta$  opioid-selective agonists that possess potent analgesic properties without the negative side effects associated with  $\mu$  opioid agonists, we evaluated a new class of antinociceptive amino acid diamides which are marginally selective for  $\delta$  opioid receptors. A limited series of novel  $\mu$  opioid-selective agents were recently disclosed by L.M. Sayre et al which consisted of a tyrosine and a variety of phenylalanine derivatives linked at their carboxyls by various diamine spacers. The tyrosine of the most potent analog was replaced by 2,6-dimethyllyrosine (DMT) to generate SC-50406. In contrast to its Tyr relative, this material not only had a preference for the  $\delta$  opioid receptor but was significantly more potent in a variety of rodent analgesic assays by a number of routes of administration. In this paper we describe the design, synthesis, and biological properties of the structurally varied DMT diamides which we prepared to exploit this newly discovered lead.

#### 291.10

THE EFFECTS OF SEROTONIN ANTAGONISTS ON STRESS INDUCED ANALGESIA FOR ACUTE AND CHRONIC NOCICEPTION. J. R. Prather, M. Shuck, E. Quinton Psychobiology Lab., Univ. of Lcuisville, Louisville Ky. 40292.

Stress induced analgesia (SIA) is mediated

Stress induced analgesia (SIA) is mediated through opiod (O) and non-opiod (NO) systems. This study investigated whether the two types of SIA were equally effective on acute and chronic nociceptive models, and whether 5HT2 and/or 5HT3 are involved. O-SIA was induced with a warm water swim (36°, 2.5 min.) and NO-SIA was induced with a cold water swim (2°; 1 min.) in C57/BI6j mice. Serotonin receptor antagonists (methysergide or metocloprimide) were administered one minute after stress and four minutes later the animals were tested on either the acute (hot-plate) or chronic (10µl, 10% formalin into rear paw; 60 min. observation) nociceptive test. Both SIA's produced analgesia on the acute test, but the NO-SIA was greater. Both SIA's were also effective in the chronic test, but the O-SIA was more effective in the early phase and the NO-SIA more effective in the late phase. The 5HT antagonists had inconsistent effects at the doses tested.

## 291.12

VERAPAMIL POTENTIATES MORPHINE ANALGESIA AND REDUCES EUPHORIA IN HUMANS. <u>D.B. Vaupel\*</u>, <u>W.R. Lange and E.D. London.</u> Neuropharmacology Laboratory, NIDA Addiction Research Center, Baltimore, MD 21224.

Verapamil (V) is one of several Ca<sup>2+</sup> channel blockers which enhances morphine (M)-induced analgesia in rodents (G. Benedek and M. Szikszay, Pharmacol. Res. Comm. 16:1009, 1984). As this effect may have therapeutic utility, we assessed M-V interactions in human volunteers. The ability of V to potentiate M-induced analgesia and to modulate the subjective effects of M was evaluated in 12 experienced male heroin users. Five treatments were tested: saline (S)+S; S+M (10 mg); V (10 mg) + S; V (2.5 or 10 mg)+ M (10 mg). The first drug listed was infused i.v. over 2 min; i.v. infusion of the second drug was over 10 sec and was initiated half-way through the 2-min infusion. Analgesia was measured using a finger pressure test and hand immersion in ice water. The Addiction Research Center Inventory (ARCI) questionnaire was used to measure the positive subjective effects of M on mood.

Pain threshold, as determined with the finger pressure stimulus, was increased marginally by M (p < .1), but V was inactive. However V+M combinations, (V 2.5 mg + M 10 mg and V 10 mg + M 10 mg) significantly elevated pain threshold to produce analgesia. Similar nonsignificant trends were observed in the effect on pain threshold determined using the cold water stimulus. M produced euphorigenic effects based on the elevated scores (p < .01) of the MBG scale of the ARCI. V itself produced no subjective effects, but 10 mg of V antagonized elevation of MBG scores produced by M 1 h after treatment (p < .01). We concluded that the abilities of V to antagonize the euphorigenic effects of M and to enhance opiate analgesia are therapeutically useful.

ANTINOCICEPTIVE ACTION OF SANDOSTATIN®: IN VIVO AND IN VITRO STUDIES. A. Dray\*, S. Bevan, R. Docherty, E. A. Campbell, L. F. James, M. Perkins, L. Urban and J. Wood, Sandoz Institute for Medical Research, 5 Gower Place, London WC1E 6 BN, UK.

The distribution and actions of somatostatin in mammalian sensory systems suggests a functional role in nociception. Supporting this are clinical observations that the long acting analogue, Sandostatin (octreotide) has analgesic activity (eg Pascal et al. 1991 Pain 47, 341). We have further investigated the analgesic activity of Sandostatin in various animal models and studied its effects on sensory neurons

Sandostatin (up to 1mg/kg) showed little activity against an acute pain stimulus (heat, pressure, chemical) but was effective (10ng-100µg/kg, s.c.) against the inflammatory hyperalgesia induced by uric acid or Freunds adjuvant injection into the rat knee joint. In an in vitro spinal cord-tail preparation, spinal administration of Sandostatin (EC<sub>50</sub>=50nM) attenuated heat and capsaicin-evoked responses. In cultured sensory neurons, Sandostatin (100nM) consistently inhibited voltage activated calcium currents but did not significantly affect K+ efflux or calcium accumulation. Finally ndostatin (1µM) inhibited K+-evoked substance P release from afferent fibres in slices of guinea pig heart.

Systemically administered Sandostatin was antinociceptive only against inflammatory hyperalgesia or when administered directly to the spinal cord. Depression of calcium currents and inhibition of sensory neuropeptide release may account for these actions.

PENTOBARBITAL ENHANCES ANTINOCICEPTION FROM 8-ENDORPHIN WHILE SUPPRESSING THE ACTION OF MORPHINE. <u>D.J. Smith\*, B. Robertson and P.J. Monroe</u>. Dept. of Anesth., WVU-HSC, Morgantown, WV 26506

Anesthesia modifies the antinociceptive potency of morphine (Banks et al., Pharm. Biochem. Behav. 31: 397, 88; Ding et al., Pain 43: 371, 90; Rosland and Hole, Anesth. Analg. 71: 242, 90). In the current study, the ability of pentobarbital to after the action of B-endorphin or morphine on the tail-flick reflex was studied following administration of the opioids into the periaqueductal gray (PAG) of the rat brain. Anesthesia initiated with 35 mg/kg of pentobarbital (i.p.) was maintained using 20 % of the initial dose when animals exhibited a lid reflex. The anesthetic itself did not after tail flick latency (TFL)  $(3.4 \pm 0.13,$ prior to anesthesia; 3.25 ± 0.25, 40 min post anesthesia). Compared to values obtained awake rats, pentobarbital caused a significant reduction in responses to morphine (3-30 nmol), while significantly elevating the responses to 8-endorphin (0.1-10 nmol). There was a marked leftward shift (10 fold) of the 8-endorphin dose-response curve with a 3 nmol dose yielding about 200 AUC units (area under the curve of the TF response for 60 min) in anesthetized, and 30 units in awake rats. Responses to morphine were absent at all but the highest dose where the average response was about 40 AUC units compared to 280 in awake animals. As they awakened, the anesthetized rats that had received morphine (10-30 nmol) exhibited rigidity in their limbs and tail ("catalepsy"), and the TFL rose to values expected in non-anesthetized, morphine treated rats. Rigidity was not observed in morphine-animals unless they were exposed to anesthesia, and was never seen in rats given  $\beta$ -endorphin. Since it appears that the actions of  $\beta$ -endorphin and morphine in the PAG may be mediated through separate neuronal pathways (Tseng and Tang, J.Pharm. Exp. Ther. 252: 546, 1990), these data would suggest that pentobarbital may differentially modify these systems.

## 291.17

OPIOID ANALGESIA AFTER SYSTEMIC ADMINISTRATION OF EIGHT OPIOID AGENTS IN AMPHIBIANS. C. W. Stevens\* and Alan J. Klopp, Dept. of Pharmacology and Physiology, Oklahoma State University, College of Osteopathic Medicine, Tulsa OK 74107.

The relative analgesic potency of fentanyl, levorphanol, methadone, morphine, buprenorphine, meperidine, codeine, and nalorphine after systemic administration in Northern grass frogs, Rana pipiens, was done to compare opioid action in nonmammalian vertebrates to that observed in mammalian species. Opioid agents were diluted in saline to 4-6 log-spaced doses and administered subcutaneously into the

| Agent         | ED50  | Rel. Pot. |
|---------------|-------|-----------|
| Fentanyl      | 1.4   | 61.6      |
| Levorphanol   | 7.5   | 11.5      |
| Methadone     | 19.9  | 4.3       |
| Morphine      | 86.3  | 1.0       |
| Buprenorphine | 99.1  | 0.87      |
| Meperidine    | 128.1 | 0.67      |
| Codeine       | 140.3 | 0.62      |
| Nalorphine    | 320.9 | 0.27      |

dorsal lymph sac. acetic acid test, nociceptive threshold (NT) was measured before (baseline) and at 60, 150, and 240 min after drug administration. Raw NT values were converted to maximum percent effect (MPE) values and doseresponse curves generated by taking the maximal effect over the time course curve for each drug

and dose. The ED50s (in nmol/g) and 95% confidence intervals (not shown here) were obtained by the PCS computer program. As shown in the Table, fentanyl was the most potent opioid and nalorphine the least potent, with morphine giving an ED50 of 86.3 nmol/g (=32.7 mg/kg). These data support the working hypothesis that the rank order of analgesic potency of systemic opioids in amphibians parallel that observed in mammalian models, with the caveat that greater doses may be needed due to the apparently tighter blood-brain barrier in amphibians. This research supported in part by OSU-COM and the Whitehall Foundation (A91-01).

COMPARISON OF THE ANALGESIC POTENCY OF LOCAL VERSUS SYSTEMIC ADMINISTRATION OF MORPHINE IN A RAT MODEL OF TONIC FACIAL PAIN. E.Eisenberg. B.P.Vos\* and A.M. Strassman, Pain Physiology Lab, Dept. of Neurology, Massachusetts

General Hospital, Charlestown, MA 02129.
Local administration of low doses of morphine can result in the blockade of mechanical or thermal hyperalgesia in inflamed tissue, presumably via activation of peripheral opioid receptors. The present study investigated the analgesic effect of local *versus* systemic morphine administration on tonic pain, using a model of formalin-induced facial pain in the

Formalin (5%, 50µl) was injected subcutaneously into the vibrissal pad of adult rats (250-300g). Morphine sulphate at doses of 100, 250, 500 and 1000µg was subcutaneously injected either locally (same area) or systemically (in the neck), 30 min prior to or simultaneously with the formalin. Control animals received saline injections. The number of seconds of formalin-induced face grooming during a 42 min post-injection observation period was determined using computer-assisted video analysis.

Control animals displayed biphasic increases in lace grooming directed to the vibrissal pad ipsilateral to the injection, consisting of an early "phasic" phase (0-6 min) and a delayed and prolonged "tonic" phase (12-42 min). Both local and systemic morphine administration produced a dose-dependent, naloxone-reversible decrease of both phases of formalin-induced face grooming. However, the suppression of face grooming was significantly greater when morphine was applied locally than systemically. Depending on the dosage, the time of injection and the response phase considered, local morphine administration produced 15%-58% more suppression of formalin-induced face grooming administratory produced 13 6-36 kinds suppression to inflamination and the systemic morphine. Local micro-injection of natioxone (10µg) completely reversed the analgesic effect of 1000µg local morphine (108%±22%), whereas the same dose of natioxone, applied systemically (i.p.), produced only a partial reversal (39%±4%). These data indicate that locally administered morphine can exert an analgesic effect on

tonic pain through an activation of peripheral opiate receptors.

THE SPECIFIC N-METHYL-D-ASPARTATE (NMDA) RECEPTOR ANTAGONIST MK-801 BLOCKS U-50,488, BUT NOT MORPHINE ANALGESIA. B. Kest\*, P. Marek, and J. C. Liebeskind. Department of Psychology, University of California, Los Angeles,

The present study compared the effects of the specific NMDA receptor antagonist MK-801 (0.05 and 0.1 mg/kg, IP) on analgesia produced by the specific kappa opiate receptor agonist U-50,488 (7.5, 15 and 30 mg/kg, IP) and morphine (1 and 5 orsolves (7.5, 15 and 30 highes), 17 and highline (1 and 3 highes) all three doses of U-50,488 was completely blocked by the higher dose of MK-801, and was partially antagonized by the lower dose. In contrast, both doses of MK-801 significantly lower dose. In contrast, both doses of mr-801 significantly potentiated the analgesia produced by the low dose of morphine. MK-801 had no effect on analgesia following the higher morphine dose. Naloxone (1 mg/kg, IP) completely blocked analgesia following U-50,488 (7.5 mg/kg, IP), thereby confirming its opiate character. Since U-50,488 is a specific kappa receptor opiate, and morphine exerts its analgesic effect primarily through the mu opiate receptor subtype, the present results suggest a critical role for the NMDA receptor in analgesia involving the kappa, but not mu, opiate receptor and support more generally a distinction between the mechanisms by which the different opiate receptor subtypes mediate analgesia. (Supported by NIMH training grant 5T32MH17140 (BK) and by NIH grant NS07628 (JCL)).

THE RELATIONSHIP BETWEEN THE APPEARANCE OF NEW ION CHANNELS AND ECTOPIC DISCHARGES FROM A REGION OF NERVE INJURY. Xie Y.K., Xiao W.H; Li H-Q and LaMotte R.H.\* Dept. of Physiology, Institute of Basic Medical Sciences, Chinese Academy of Medical Sciences, Beijing 100005 CHINA

Peripheral nerve injury can produce abnormal sensory states such as pain, hyperalgesia and paresthesias. In the present study, we recorded electrophysiological discharges, from single A- and C-fiber afferent nerve fibers, that originated from a nerve injury produced by a chronic nerve constriction.

Four loose ligatures were tied around the sciatic nerve at the mid thigh region in 80 rats. In 24 of these rats, a sham operation was performed on the contralateral nerve. Eighty percent of the rats exhibited hyperalgesia on the nerve-injured foot, as tested by the method of Bennett and Xie (Pain 33:87,1989). Channel blocking agents were applied to the nerve at the site of prior surgery and discharges in single sciatic nerve fibers recorded proximally. For 40 A-beta fibers tested, Tetraethylamonium (TEA), a potassium channel For 40 A-beta notes tested, retractnyamonium (LA), a potassium channel blocker, greatly facilitated spontaneous ectopic discharges or evoked ectopic firing in previously silent axons. These discharges were inhibited by the calcium channel blockers Verapamil, La<sup>3+</sup> and Mn<sup>2+</sup>. Ectopic discharges were facilitated by high concentrations of K<sup>+</sup> (6 A-beta fibers) or noradrenalin (1 A-delta-, 3 C-fibers) and blocked by La<sup>3+</sup> and Mn<sup>2+</sup>. The tested agents had no effect on the evoked or spontaneous activities of normal axons. These results suggest that following nerve injury, the action potential generating part of the membrane expressed ion channels, in particular Ca<sup>2+</sup> channels, that are not present in this region of normal sciatic nerves and that these channels are responsible for the generation of ectopic discharges. ELECTROPHYSIOLOGICAL EVIDENCE THAT PERIPHERAL NK-1 RECEPTORS MEDIATE HYPERALGESIA IN AN ACUTELY INFLAMED JOINT MODEL OF ARTHRITIS. D.E. Kellstein and M.M. Proffitt. Arthritis and Inflammation Section, Health Care Technology Division, Miami Valley Laboratories, The Procter and Gamble Company, Cincinnati, OH 45239.

Previous studies have implicated the release of substance P (SP) from peripheral C-fiber terminals in neurogenic inflammation, adjuvant-induced arthritis, and inflammation caused by intradermal or intra-articular injection of carrageenan. The present study used CP-96,345, a selective antagonist of SP at NK-1 receptors, to determine if peripheral NK-1 sites may be involved in inflammation-induced enhancement of the neuronal nociceptive response to ankle compression. Male Sprague-Dawley rats (400-550g) were anesthetized with urethane (1.5 g/kg). A laminectomy was performed from spinal segments L1-L4, and the dural membrane was retracted. Single unit extracellular recordings were made from wide dynamic range and nociceptive specific neurons of the spinal cord dorsal horn (laminae 2 to 7) during lateral ankle compression. Discretely graded stimuli (150-450 mmHg) were delivered for 10 sec at 2 min intervals with a pneumatic pressure controller, and the number of spikes during each stimulus was counted. For statistical comparisons, the total stimulus-response for each unit was converted to area under the curve; each neuron served as its own control. Compared to pretreatment values, injection of 4% kaolin (0.1 ml) and carrageenan (0.08 ml) (K+C) into the ankle joint significantly (P<0.05; N=6-10) increased compression-evoked firing (i.e., induced "hyperalgesia") 30, 60, and 90 min after injection. In a separate group of animals, intra-articular injection of CP-96,345 (50 nmol) significantly reduced firing compared to pretreatment controls; administration of drug before K+C also pre vented the enhancement of neuronal activity normally induced by K+C at 30, 60, and 90 min. These findings suggest that activation of peripheral NK-1 receptors, presumably by SP, may mediate hyperalgesia in this acute model of inflammation.

## 292.5

THE RELATIONSHIP BETWEEN DORSAL ROOT CONDUCTION VELOCITY AND SUSCEPTIBILITY TO A LOCAL ANESTHETIC. R. A. Jaffe\* and M. A. Rowe. Department of Anesthesia, Stanford University School of Medicine, Stanford, CA 94305-5123 Persistant differential nerve block is difficult to explain. Supported by clinical observations, susceptibility to local anesthetics was believed to be inversely related to axon diameter. Recent studies on myelinated axons do not support this "size principle." We have examined the sensitivity of single unmyelinated (UM) and myelinated (M) DR axons to lidocaine. Adult male rats were anesthetized with enflurane and lumbar dorsal roots were excised. The isolated roots were perfused at 37°C with artificial CSF. We studied 77 axons (CV = 0.53-25.3 m/s) using single-fiber techniques. After control measurements, each root was exposed to lidocaine HCl initially at 0.15 mM or 0.26 mM and subsequently advanced to a higher concentration (0.26 mM or 0.52 mM) if block failed to develop at the lower concentration. Estimated lidocaine ED<sub>50</sub> block concentrations were similar for M (0.24 mM) and UM (0.22 mM) axons. At subblocking concentrations, the occlusion of Na channels by lidocaine resulted in a proportional slowing of CV measured as an increasing latency. CV slowing at both 0.15 mM or 0.26 mM lidocaine was significantly greater for M (37%, 62%) than for UM (24%, 32%) axons. Regression analysis suggests a significant direct relationship between CV (axon diameter) and sensitivity to lidocaine.

C-FIBERS STIMULATE KATNATE RECEPTORS ON NOCICEPTIVE REFLEXES. B. Ault and L. Hildebrand, Dept. Neurosciences, Sterling Winthrop Pharmaceuticals Research Division, Rensselaer, NY

C-fibers in dorsal roots, and small diameter DRG neurons, are depolarized by kainate (KA). The physiological role of C-fiber KA receptors is not known. Using the isolated spinal cord-tail preparation of the neonatal rat, the ability of peripherally-applied excitatory amino acids to stimulate nociceptive reflexes has been examined. Capsaicin (3 uM) superfused over exposed skin of the rat tail for 3 s evoked depolarization and spiking activity that was recorded in ventral roots. Domoate (0.1-10 uM) or kainate (10-300 uM) evoked nociceptive responses comparable to those evoked nociceptive responses comparable to those evoked by capsaicin. L-glutamate (0.01-10 mM), quisqualate (0.1-1 mM) and AMPA (0.1-1 mM) were of reduced potency. L-aspartate (10 mM) and NMDA (1 mM) were inactive. KA responses were blocked by spinal application of 0.1 uM morphine, and were competitively antagonized by DNQX applied to the tail. The ability of KA receptors to stimulate nociceptive activity suggests that peripherally released glutamate may be involved in nociception. in nociception.

CAPSAICIN STIMULATES CGMP VIA NITRIC OXIDE IN DORSAL ROOT GANGLION CELL CULTURES. M.B. Bauer\*. S. Murphy and G.F. Gebhart. Dept. of Pharmacology, S. Murphy and G.F. Gebhart. Dept. of Pharmacology, University of Iowa, Iowa City, IA 52242. Dorsal root ganglia (DRG) harvested from embryonic 15-

16 day old Sprague-Dawley rats were dispersed and grown 16 day old Sprague-Dawley rats were dispersed and grown in the presence of mitotic inhibitors to produce predominantly neuronal cell cultures. Such cultures are useful for investigating messengers involved in the transmission of peripheral stimulation, such as that produced by the putative algesic agents bradykinin (BK) and capsaicin. Previously we demonstrated that BK stimulates production of cGMP via nitric oxide (NO) in DRG neuronal cell cultures. Capsaicin  $(0.5~\mu\text{M})$  stimulated cGMP-production in DRG neuronal cell cultures but not in nonneuronal cells. This effect was inhibited by methylene blue  $(10~\mu\text{M})$ , an inhibitor of soluble quanivlate cyclase, and nonneuronal cells. Ihis effect was inhibited by methylene blue (10  $\mu$ M), an inhibitor of soluble guanlylate cyclase, and N-monomethyl arginine (10  $\mu$ M), an inhibitor of NO synthase, suggesting the involvement of a nitrosyl compound. Atriopeptin II (1  $\mu$ M), which activates particulate guanylate cyclase, also stimulated cGMP production in DRG neuronal cultures, but this was unaffected by methylene blue (10  $\mu$ M). These results indicate that cGMP formed upon the release of NO may be involved in the excitation of first order neurons by nociceptive chemical stimuli.

## 292.6

EVALUATION OF ICGRP SECRETION FROM DENTAL PULP IN RESPONSE TO INFLAMMATORY MEDIATORS. D. Jackson\*, M. Garry, M. Engelstad, H. Geier, K. Hargreaves, Dept of Restorative Sciences, Univ. of Minnesota School of Dentistry, Minneapolis,

Sciences, Univ. of Minnesota School of Dentistry, Minneapolis, MN.

Although calcitonin gene-related peptide (CGRP) may participate in the development of neurogenically mediated inflammation, relatively little is known about the regulation and secretion of this neuropeptide from peripheral tissue. This study uses a previously validated dental pulp superfusion model (J. Dent. Res. 71:178.1992) to evaluate immunoreactive CGRP (iCGRP) secretion following exposure to prototypic inflammatory mediators. Bovine dental pulp tissue, collected shortly after slaughter, was sectioned into 200 µm cubes. The pulp was superfused with oxygenated Krebs buffer (300 µL/min @ pH 7.4 and 37°C). After baseline collections, prostaglandin E2, serotonin, bradykinin, and histamine (all at 1.0 µM) were added to the Krebs buffer for the remainder of the experiment. The collected superfusate fractions (2.1 ml) were assayed by validated radioimmunoassay. Data was analyzed using Student's-t tests and ANOVA and is expressed as mean ± s.e.m. Initial iCGRP secretion from pulp tissue following exposure to the buffer containing the inflammatory mediators was approximately four times greater than the basal release from untreated tissue (59.5 ± 10.3 fmol/G/7 min vs. 15.2 ± 2.6 fmol/G/7 min). The increase in iCGRP release was sustained under steady state exposure to the inflammatory mediators for more than 60 minutes (release at 60 min: 34.4 ± 6.0 fmol/G/7 min). Collectively, these results support the hypothesis that inflammatory mediators produced in response to tissue injury can elicit and maintain sustained release of iCGRP from a select population of primary afferent fibers.

## PROSTAGLANDIN E2 IMMUNOREACTIVITY IS RELEASED DURING INFLAMMATION OF THE RABBIT TMJ. MT Roszkowski\*.

DURING INFLAMMATION OF THE RABBIT TMJ. MT ROSZKOWSKI\*.

10 Swift, T Alton, and KM Hargreaves, Depts. of Restorative Sci, Oral
Surgery, and Pharmacology, University of Minnesota, Minneapolis, MN
Selection of successful treatment modalities for management of the inflamed temporomandibular joint (TMJ) has been based largely on empirical findings. We have addressed this issue by using microdialysis probes implanted into the superior compartment of the TMJ of the anesthetized rabbit. Five male New Zealand rabbits compartment of the TMJ of the anesthetized rabbit. Five male New Zealand rabbits (2-2.5 kg) were anesthetized with ketamine/xylazine and maintained with supplemental injection. A semilunar flap overlying both the left and right TMJ was elevated. The superior compartment of the TMJ was identified by palpation and confirmed by aspiration. Microdialysis probes (10,000 dalton cutoff) contained in a 27g needle were implanted into both right and left joint compartments and fixed by ligatures. Sterile Locke-Ringers buffer was pumped through the probes (8 µL/min) and 30 min fractions were collected. Carageenan (4mg) or an equal volume of saline (0,1cc) were injected into the right and left TMJs 60 min after placement of the probes. The dialysate samples were measured for iPGE2 by a previously validated ELISA method. Data were analyzed by repeated measures ANOVA followed by Dundan's Test. followed by Dundan's Test

The results indicate that carrageenan injection produces a 10-fold increase in synovial levels of iPGE2 by 270 min after carrageenan injection (9.243.3 pg at baseline vs 104.440.1 pg at 270 minutes; p<0.005). The inflamed rabbit TMJ may prove to be an appropriate animal model to evaluate therapeutic interventions for the management of the inflamed TMJ in patients.

## 292.9

PROSTAGLANDIN E2 AND ELEVATION OF INTRACELLULAR CYCLIC AMP ENHANCE BRADYKININ-STIMULATED RELEASE OF PEPTIDES FROM RAT SENSORY NEURONS IN CULTURE. K. J. Waite and M. R. Vasko\*, Dept. of Pharmacology and Toxicology, Indiana U. School of

Medicine, Indianapolis, IN 46202.

Prostaglandins (PGs) increase the inflammatory and algesic actions of bradykinin (BK). One possible mechanism to explain this effect is that PGs increase the formation of intracellular cyclic AMP and this enhances the BKinduced release of transmitters from sensory neurons. To test this hypothesis, we studied the effects of both PGs and alteration of intracellular cAMP on resting and BK-evoked release of substance P (SP) and calcitonin gene-

related peptide (CGRP) from rat sensory neurons grown in culture.

Neurons were dissociated from dorsal root ganglia of 16-18 day old rat embryos and grown in culture for 8-14 days. Release studies were performed by exposing neuronal cultures to HEPES buffer containing 3.5 mM KCl (basal release) or buffer containing PGE2 and/or bradykinin (stimulated release).

Buffer was then assayed for SP and CGRP using radioimmunoassay.

Exposure of cells to 1μM PGE2 did not alter the release of either SP or CGRP.

However, pretreatment of sensory neurons for 20 min with 1µM PGE2 increased the release evoked by 10nM BK by 2-3 fold for both peptides. In a similar manner, pretreating sensory neurons with 100 $\mu$ M 8-bromo cyclic AMP, 1.5  $\mu$ g cholera toxin, or 10  $\mu$ M forskolin, significantly enhanced the BKstimulated release of both SP and CGRP.

These results demonstrate that PGE2 enhances the release of neurotransmitter from rat sensory neurons and suggest that this effect may contribute to PG-induced sensitization. Furthermore, one possible mechanism to explain the actions of PGE2 on sensory neurons is an elevation of intracellular cyclic AMP. (Supported by PHS AR20582 and DA07176).

## 292.11

OPIOID AGONISTS ENHANCE AND INHIBIT RELEASE OF PEPTIDES FROM RAT SENSORY NEURONS J. Dymshitz\*, I. J. Chen, M.R.Vasko. Dept. Pharmacol. & Tox, Indiana U. Sch of Med, Indianapolis, IN 46202.

There is increasing evidence that different opioid agonists exert either inhibitory or facilitatory effects on primary afferent neurons; depending on the agonist concentration and receptor selectivity. To further study the actions of opioids on sensory neurons, we investigated the effects of the mu and delta selective opioids, (DAGO, and DPDPE, respectively) on the release of substance P (SP ) and calcitonin gene-related peptide (CGRP) from cultures of rat dorsal root ganglia (DRG) and from rat spinal cord slices.

Neurons were dissociated from fetal DRG (E15-E17) and grown in culture for 9-12 days. After 10 min preincubation with opioids in a HEPES buffer, cells were exposed for 10 min to either 30 mM KCl or 100 nM capsaicin. Slices of spinal cord, obtained from adult rats, were superfused with Kreb's buffer with or without opioid agonists, and 250 nM capsaicin was used to stimulate peptide release. The levels of SP and CGRP in buffer were measured by RIA.

In DRG cell cultures, DAGO (10 nM-5 µM) inhibited KCl-induced release of SP and CGRP in a dose-dependent manner, with a maximal inhibition of 30-40% below control levels. In contrast, when cells were exposed to 100 nM capsaicin in the presence of the same concentrations of DAGO, a dosedependent potentiation of the release of both peptides was observed. Application of DPDPE in the same concentration range did not significantly alter KCl-evoked release. In the slice preparation, DAGO (1  $\mu$ M) had an inhibitory effect on SP and CGRP release elicited by capsaicin.

These results indicate that DAGO can either enhance or diminish the evoked release of SP and CGRP from sensory neurons. The opioid-induced potentiation or inhibition is dependent on the agent used to stimulate peptide release and on the neuronal preparation studied. (Supported by DA07176).

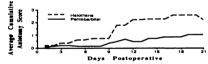

ADRENERGIC INHIBITION OF ICGRP RELEASE FROM CAPSAICIN-SENSITIVE FIBERS IN DENTAL PULP. M. Engelstad. M. Garry. D. Jackson. H. Geier. K. Hargreaves'.

University of Minnesota School of Dentistry. Minneapolis, MN 55455. Several studies have suggested that the sympathetic nervous system modulates pain and inflammation, possibly through activation of adrenergic receptors located on peripheral nociceptive nerve terminals. Accordingly, modulates pain and initialimation, possibly inflough activation of adrenergic receptors located on peripheral nociceptive nerve terminals. Accordingly, bovine dental pulp was evaluated for modulation of the evoked release of the inflammatory neuropeptide, calcitonin gene-related peptide (CGRP), by pretreatment with norepinephrine. Pulp tissue from bovine mandibular incisors was extracted, chopped into 300 µm cubes, and placed in 2c chambers for *in vitro* superfusion. Following a baseline recovery period, oxygenated Krebs buffer (pH 7.4 @ 37°C) containing norepinephrine (1mM) was superfused through the tissue before and after a stimulating pulse of capsaicin (10µM), a neurotoxin that selectively stimulates certain primary afferent neurons. Levels of immunoreactive CGRP (iCGRP) were analyzed by a validated radioimmunoassay. Data were analyzed by ANOVA and Duncan's test. Basal levels of iCGRP release were 68.4 ±8.2 fmolg tissue? min superfusion. Following capsaicin stimulation, release of iCGRP doubled in control chambers that did not receive norepinephrine (132.0 ±16.1 fmol/g/9 min; p-0.001). In contrast, there was a near complete inhibition of iCGRP release in chambers that did receive norepinephrine (66.7 ±3.5 fmol/g/9 min; p-0.001). Similar results were obtained by pretreatment with the alpha agonist clonidine and the beta agonist salbutamol. Collectively, these results indicate that adrenergic agonists could inhibit the release of iCGRP from capsaicin sensitive pain fibers located in dental pulp.

EFFECTS OF TWO DIFFERENT SURGICAL ANESTHETICS, SODIUM PENTOBARBITAL AND HALOTHANE, ON AUTOTOMY IN A RAT MODEL OF NEUROPATHIC PAIN. C. Fromm. J. A. DeLeo\*. R. W. Colbum. D. W. Coombs. Anesthesia Research Lab, Dartmouth-Hitchcock Medical Center, Lebanon, NH 3756.

Autotomy (self-mutilation) following peripheral somatic nerve damage is thought to be a behavioral marker for chronic neuropathic pain. The effects of 2 different surgical anesthetics on autotomy were studied in a rat model of sciatic cryoneurolysis (SCN). Under sodium pentobarbital (PB) anesthesia (40 mg/kg, i.p.), rats (n=21) underwent unilateral sciatic cryolesion with the contralateral side serving as an internal sham-operated control. The sciatic nerve was exposed by blunt dissection close to its emergence from the sciatic foramen and frozen with a cryoprobe (2 mm tip diameter, cooled to -60°C with NO<sub>2</sub> refrigerant) for a 30-5-30 sec freeze-thaw-freeze cycle. Under cooled to -60°C with NO2 retrigerant) for a 30-3-30 Sec freeze-tnaw-freeze cycle. Under halothane (HAL) inhalation anesthesia (2% maintainence), a second group of rats (n=12) underwent identical surgery. Rats were observed every other day for about 5 weeks postoperatively, and the severity of autotomy was assessed using Wall's scale (1 point for bloody nail(s), 1 point for each distal or proximal phalange removed; max score = 11). Rats anesthetized with PB showed a decrease in severity of autotomy, or average cumulative Wall score, as compared with rats anesthetized with HAL.

These data suggest that use of a specific anesthetic during surgical procedures such as amputations may decrease the incidence of phantom-limb pain and other neuropathic pain syndromes. In addition, these results strongly support the use of autotomy and SCN as a behavioral marker and animal model for neuropathic pain.

PROSTAGLANDIN E, ENHANCES THE SENSITIVITY TO BRADYKININ IN RAT SENSORY NEURONS GROWN IN CULTURE. G.D. Nicol' and M. Cui. Dept. of Pharmacology and Toxicology, Indiana Univ. School of Medicine, Indianapolis, IN 46202.

Prostaglandins increase the sensitivity of sensory neurons to bradykinin (BK) presumably by lowering the response threshold to this pain producing agent. We sought to investigate the physiological mechanisms that produce this prostaglandin-induced hypersensitivity. Sensory neurons were dissociated from the dorsal root ganglions (DRG) of 15-17 day-old rat embryos, plated on small plastic cover slips coated with collagen, and grown for 5 to 7 days. The effects of prostaglandin E, (PGE) and BK were examined by utilizing the whole-cell patch clamp technique. PGE, (10 uM) had no direct effect on either the membrane potential or the action potential (AP) threshold as measured in current-clamp recordings from 6 of 8 neurons. Two of these neurons responded directly to the PGE, as indicated by an increase in the firing frequency of spontaneous APs. Exposure of the neurons to PGE, produced a small enhancement of the calcium current in voltage-clamp recordings. Application of 1 uM PGE, did not produce a significant increase above the control values. Both 10 and 30 uM PGE, caused increases of only 1.32- and 1.29-fold, respectively. However, a 10 min pre-treatment of the sensory neurons with 1 uM PGE, greatly enhanced the neurons to control value of the produced in the level. caused increases of only 1.32- and 1.29-fold, respectively. However, a 10 min pre-treatment of the sensory neurons with 1 uM PGE, greatly enhanced the neuronal response to 100 nM BK. Under control conditions, the local application of 100 nM BK produced a small and slow increase in the inward current with relatively few large transient spikes of inward current. After exposure to PGE<sub>2</sub>, BK again elicited a small and slow increase in inward current but the frequency of the transient inward currents was increased greatly. Similar results were obtained in current-clamp recordings wherein the frequency of BK-induced AP firing was enhanced by prior treatment with PGE<sub>2</sub>. These findings suggest that PGE<sub>2</sub> does not have a direct excitatory action on the sensory neuron but rather a role in modulating the sensitivity to other stimulatory agents.

CARBA PROSTACYCLIN POTENTIATES CAPSAICIN-STIMULATED RELEASE OF NEUROPEPTIDES FROM RAT SENSORY NEURONS IN CULTURE. <u>C.M. Hingtgen\*, M.R. Vasko.</u> Dept. of Pharmacology and Toxicology, Indiana U. School of Medicine, Indianapolis., IN 46202. Because prostaglandin 12 (PGI2) injection into peripheral tissues produces

Because prostaglandin 12 (PGI<sub>2</sub>) injection into peripheral tissues produces an inflammatory response and sensitizes sensory neurons to noxious stimulation, it is possible that this prostanoid increases the release of transmitters from sensory neurons. We investigated whether the PGI<sub>2</sub> analog, carba prostacyclin (CPGI<sub>2</sub>), enhances resting or capsaicin-induced release of substance P (SP) and calcitonin gene-related peptide (CGRP) from rat sensory neurons grown in culture.

Release experiments were performed by incubating sensory neurons grown in culture with a HEPES buffer containing 3.5 mM KCl (basal release) or buffer containing various concentrations of CPGI<sub>2</sub>, capsaicin, or KCl. Buffer was assayed for SP and CGRP using radioimmunoassay.

Exposure of neurons to 1  $\mu$ M CPGI2 caused a 2 fold increase in the release of both SP and CGRP, compared to a 4-6 fold increase caused by either 30 mM KCl of 100 nM capsaicin. Pretreatment with 1  $\mu$ M CPGI2 potentiated the effects of 10 nM capsaicin (a nonstimulating concentration of capsaicin) on both SP and CGRP release. The release of SP increased significantly from a mean  $\pm$  S.E.M. of  $14\pm3$  fmol/well/10 min to  $46\pm4$  fmol/well/10 min, whereas, the release of CGRP increased significantly from  $47\pm5$  fmol/well/10 min to  $198\pm10$  fmol/well/10 min.

These results demonstrate that CPGI<sub>2</sub> can sensitize sensory neurons to increase the release of transmitter. This sensitization may explain some of the inflammatory and hyperalgesic effects of PGI<sub>2</sub>. (Supported by PHS AR20582).

INTERLEUKIN FACILITATES Ca++ RELEASE IN ACUTELY DISSOCIATED DORSAL ROOT GANGLION (DRG) CELLS OF THE RAT. M. Kawatani\* and L. Birder. Showa University, Dept. Physiology Tokyo Japan, 142.

It has been suggested that interleukin (IL) plays a key role in the inflammatory process. Using the Ca++ indicator FuraII-AM, we have visualized Ca++ transients in order to elucidate the mechanism of action of ILI and ILI . Addition of ILI (0.1 - 1 ug) and ILI (2 ug) in DMEM media resulted in an immediate, dose dependent increase in fluorescence due to increased Ca++ in acutely dissociated drg cells obtained from urethane anesthetized adult wistar rats (200-300 g). Blockade of Ca++ channels via addition of nifedipine (100-300 ug), or block of Ca++ activated K+ channels via use of iberiotoxin (0.5-5ug) was ineffective in reducing the effect of ILI . Indomethacin (100-300 ug), via prostaglandin blockade, inhibited the Ca++ increased by ILI . These data may suggest that elevated Ca++ transients via ILI may be due to release from intracellular storage sites mediated by increased prostaglandin levels.

Gd<sup>3+</sup> AS A PROBE FOR STRETCH ACTIVATED CHANNELS IN MAMMALIAN MECHANOSENSITIVE FREE NERVE ENDINGS.

M.B. MacIver\* and D.L. Tanelian. Pain Research Laboratory, Department of Anesthesia, Stanford University School of Medicine, Stanford, California 94305.

, at 20 to 100 µM, has been shown to block stretch activated channels in membrane patches from yeast, paramecium and invertebrate growth cones. It is possible that similar stretch activated channels could underlie mechanosensitivity in mammalian sensory neurons. The present study investigated this possibility using an in vitro preparation of mechanoreceptors innervating rabbit corneal epithelium. Extracellular recording electrodes were used to monitor multiple and single unit discharge from corneal nerves; response thresholds, discharge characteristics and receptive fields for mechanosensitive fibers were mapped. Corneal tissue was perfused with a PO<sub>4</sub> and CO<sub>3</sub> free HEPES buffer, since Gd<sup>3+</sup> forms a precipitate with these anions. The HEPES buffer did not alter mechanoreceptor responses. Gadolinium chloride 10 to 250 µM in HEPES buffer did not alter mechanoreceptor responses following a 2 hr exposure time. Further studies will investigate longer exposure times (10 hr), higher concentrations (500 µM), and the membrane permeant compound gadopentetate dimeglumine to rule out the involvement of Gd<sup>3+</sup>-sensitive stretch activated channels in mammalian mechanoreceptor sensory nerve endings. Supported by NIH grant NS28646-01 A1.

PERSISTENT THERMAL AND MECHANICAL HYPERALGESIA INDUCED BY ULTRA-VIOLET RADIATION IN THE RAT. M.N.Perkins\*, B.A.Campbell, D.Kelly, S.Patel, B.Sandells, L. Urban, and A.Dray.

Sandoz Institute for Medical Research, Gower Place, London WC1E 6BN, UK.

Animal models of hyperalgesia and neuropathic pain are important for understanding chronic pain in man and for the evaluation of novel analgesic drugs. We describe here a model of thermal and mechanical hyperalgesia in the rat, lasting for up to 12 days, induced by ultra-violet (UV) radiation.

Remale Sprague Dawley rats (100g) were exposed on one hindpaw to UVA light (intensity maximum 365 nm, 69mWatts/cm<sup>2</sup>) for 90s and this was repeated 18hrs later. On each day following this the withdrawal threshold to a focussed beam of beat to the underside of both hind paws was measured. Mechanical hyperalgesia was assessed by a modified Randall-Selitto test. Drugs were given on various days following UV exposure.

On the first day after UV exposure (day 1) there was a 70% reduction in the latency of response to noxious heat. This was maintained for 7-8 days with recovery to control latencies occurring by day 12-13. The contralateral paw also exhibited thermal hyperalgesia reaching a maximum by day 5 but recovered by day 7. Mechanical hyperalgesia was maximal on day 5 with approximately 40% reduction in threshold returning to control levels by day 7. The thermal hyperalgesia was reversed by morphine on days 1 and 5 and this was naloxone sensitive. Ibuprofen, indomethacin and aspirin (10-500mg/kg, sc) were weakly active or non-effective when given at day 6. However, ibuprofen (200mg/kg, sc) reversed the hyperalgesia when given on day ħ. In this model of prolonged thermal and mechanical hyperalgesia there is an early

In this model of prolonged thermal and mechanical hyperalgesia there is an early inflammatory component and a later NSAID-resistant hyperalgesia. The contralateral hyperalgesia suggests the involvement of central mechanisms.

POTENTIATION BY CAPSAICIN OF LIDOCAINE'S TONIC AND PHASIC IMPULSE BLOCK IN ISOLATED RAT SCIATIC NERVE. H.-C. Shin\*, S.A. Raymond, U.T. Oh\* and G.R. Strichartz. Anesthesia Research Labs. Brigham & Women's Hospital, Harvard Medical School, Boston MA, 02115, \*College of Pharmacy, Seoul National University, Seoul 151-742, Korea.

Compound action potentials (CAPs) of A- and C-fibers were recorded from isolated sciatic nerves of the rat to determine whether tonic and phasic block of impulse conduction induced by lidocaine was affected by low doses of capsaicin. Capsaicin alone (50 uM) did not change the CAPs of either A- or C-fibers. At a low frequency of stimulation (0.5 Hz), lidocaine (100 uM) for 30 min tonically reduced the amplitudes of A-fiber CAPs (by 20.6%,  $\,$ n = 19) and C-fiber CAPs (by 28.4%,  $\,$ n = 20). At higher stimulation frequencies (100 Hz for A-fibers, 20 Hz for C-fibers, 64 pulses), lidocaine (100 uM) phasically reduced both the A-fiber CAP (to a total steady state inhibition of 38.4%, n=7) and the C-fiber CAP (42.5%, n = 7). Lidocaine's effects were 95-98% removed by 30 min wash. Although low concentrations of capsaicin (5-30 uM) caused no change of the tonic blocking action of lidocaine, 30 min of 50 uM capsaicin administration did induce a significant potentiation of tonic block (A-CAP: 35.7%, n=14; C-CAP: 38.2%, n=16). Lidocaine's phasic impulse block was similarly potentiated after 30 min of subsequent capsaicin administration (A-CAP: total inhibition = 64%, n=7; C-CAP: 57.8%, n = 7). Capsaicin's tonic and phasic potentiating effects were not reversed completely after 30 min of wash. These results suggest that capsaicin may be a useful agent for the reversible potentiation of impulse blockade by lidocaine, although the hoped for selective potentiation of C-fiber blockade was not observed in these rat peripheral nerves.

## 292.18

DILTIAZEM PRODUCES NON-Ca-DEPENDENT DEPRESSION OF CORNEAL C FIBERS. H. Lukatch\*, M.B. MacIver and D.L. Tanelian.
Pain Research Laboratory, Department of Anesthesia, Stanford University School of Medicine, Stanford, California 94305.

The calcium channel blocker diltiazem has been reported to specifically block corneal C fiber nociceptive responses, in vivo, although high concentrations were required (3 mM, 30 s, applied topically). The present study investigated concentration-dependent effects of diltiazem (10 to 250 µM) using an *in vitro* preparation of C fibers innervating rabbit corneal epithelium. Extracellular recording electrodes were used to monitor multiple and single unit discharge from corneal nerves. Low concentrations of diltiazem (10 µM) reduced C fiber tonic discharge frequencies to 83.6 +/- 9 (mean +/- SD; n=5) % of control, higher concentrations produced greater depression (100 µM - 71.5 +/- 27.3, n=6; 200  $\mu$ M - 44.5 +/- 34, n=6) and total depression of tonic discharge occurred at 250  $\mu$ M. The broad spectrum calcium channel blockers Ni<sup>2+</sup> (200  $\mu$ M) and Cd<sup>2+</sup> (200  $\mu$ M), in phosphate free solution, did not alter tonic discharge activity; however, lidocaine (20 to 80  $\mu$ M) produced the same effect as diltiazem. Concentrations of diltiazem up to 250 µM did not alter A8 fiber mechanoreceptors. These results suggest that the depressant effects of diltiazem on corneal C fiber discharge are not due to  $Ca^{2+}$  channel block, but may be due to sodium channel block.

INHIBITION OF NEUROGENIC PLASMA EXTRAVASATION IN RATS BY A NON-PEPTIDE NK-1 ANTAGONIST RP67580. S.L. Shepheard, D.A. Cook, D.J. Williamson, R.G. Hill.\* & R.J. Hargreaves, M.S. D.Research laboratories, Neuroscience Research Centre, Terlings Park, Harlow, Essex, U.K.

Plasma extravasation occurs within the dura and other receptive fields (lip, eyelid, conjunctiva) of trigeminal sensory afferent nerves upon electrical stimulation of the trigeminal ganglia. The non-peptide, NK-1 antagonist RP67580 is selective for rodent NK-1 receptors whilst its enantiomer RP68651 is inactive. Using these enantiomers (synthesized in our labs) we investigated the role of NK-1 receptors in mediating neurogenic plasma extravasation in the dura and extracranial tissues of rats.

Male S-D rats were anaesthetised with pentobarbitone sodium (60 mg,kg<sup>-1</sup>, i.p.) and

Male S-D rats were anaesthetised with pentobarbitone sodium (60 mg.kg<sup>-1</sup>, i.p.) and 10 min after i.v. injection of RP67580 (1-1000 µg.kg<sup>-1</sup>), RP68651 (300 µg.kg<sup>-1</sup>) or vehicle the right trigeminal ganglion or saphenous nerve was stimulated (5 Hz, 2 ms, 25 V, for 5 or 2 min). The left sides were prepared as sham controls. <sup>125</sup>I bovine serum albumin (70 µCi.kg<sup>-1</sup>, i.v.) was used to measure plasma extravasation. Dura, lip, eyelid or skin from the dorsal surface of the hindpaw was removed 5 min after stimulation, washed, weighed and counted for radioactivity. Results were calculated for each tissue as the ratio of extravasation in the stimulated/unstimulated sides. Data are given as the  $1D_{50}$  i.e. the dose producing half maximal inhibition of extravasation.

Following trigeminal ganglion stimulation RP67580 blocked dose-dependently plasma extravasation in all tissues. The  $ID_{50}$ 's in the facial tissues (lip and eyelid) were between 10 and  $100~\mu g_{\nu} K g^{-1}$ , whereas the  $ID_{50}$  in the dura was lower. RP67580 also reduced stimulation-evoked plasma extravasation in the hindlimb with an  $ID_{50}$  of  $100~\mu g_{\nu} k g^{-1}$ . RP68651 (inactive) given at a dose equivalent to the  $ID_{80}$  in the extracranial tissues ( $300~\mu g_{\nu} k g^{-1}$ ) had no effect on extravasation in any tissue.

The enantiomeric selectivity found in the present studies indicates that, in the rat, the plasma extravasation resulting from endogenous peptide release in a variety of tissues after electrical stimulation of cranial and extracranial sensory afferent nerve fibres is predominantly caused by activation of the NK-, receptor.

NEURONAL AND BEHAVIORAL CORRELATES OF INTRASTRIATAL INFUSIONS OF AMPHETAMINE IN FREELY MOVING RATS. Z. R. Wangtand G. V. Rebec, Prog. Neural Science, Dept. Psychology, Indiana University, Bloomington, IN 47405.

Systemic amphetamine selectively increases and decreases the firing rate of motor- and nonmotor-related neurons, respectively, in the striatum of freely moving rats (Haracz et al., Brain Res., 489:365, 1989). To assess the role of striatal mechanisms in these differential neuronal responses, amphetamine (15-30 µg/µl) was infused (10 µl/hr) directly into the striatum of awake, behaving rats and single-unit activity was recorded simultaneously at the infusion site. Intrastriatal amphetamine typically activated motor-related. but suppressed nonmotor-related, neurons shortly after infusion onset. These changes in firing rate routinely preceded overt behavioral changes, supporting evidence that amphetamine-induced changes in striatal activity reflect a drug effect rather than behavioral feedback. Moreover, neurons in ventromedial and central striatum appeared more sensitive to amphetamine than other striatal neurons. Intrastriatal infusions of saline or extrastriatal infusion of amphetamine had no consistent effect. Our results indicate a direct role for both motor- and nonmotor-related striatal neurons in the behavioral effects of amphetamine and suggest regional differences in the sensitivity of striatal neurons to this drug.

MICROEXCITABLE ZONES IN THE THALAMUS ARE SEPARATE FROM PALLIDAL-RECEIVING NEURONS. <u>I.A. Buford\*</u>, <u>M. Inase and M.E. Anderson</u>. Depts. of Physiology and Biophysics and Rehabilitation Medicine and the Regional Primate Research Center, University of Washington, Seattle, WA 98185.

In the thalamus, most pallidal-receiving (PR) thalamic neurons are rostral to cerebellar-receiving (CR neurons). Ashe et al. (Soc. Neurosci., 1989) reported that movements were not elicited by microstimulation in rostral portions of the primate thalamus, whereas more caudal portions were microexcitable. He hypothesized that movements were elicited by microstimulation of CR, not PR, neurons.

We tested this hypothesis by comparing, in awake monkeys, the thalamic loci where pulse-train microstimulation produced muscle contraction (microexcitable zones) to the loci of thalamic cells (PR neurons) that exhibited fixed latency inhibition after single-pulse microstimulation in the internal globus pallidus (GPi). The GPi stimuli were delivered at locations where arm-related activity had been recorded.

Muscle contraction was elicited by stimulation at many thalamic locations. Microexcitable zones, however, were usually caudal and ventral to identified PR neurons. Our data support the hypothesis of Ashe et al. and emphasize the probability that excitation of PR thalamic neurons does not elicit movement. Supported by NIH NS15017 and RR00166.

BEHAVIORAL AND NEUROPHYSIOLOGICAL CONSEQUENCES OF LARGE PUTAMEN LESIONS IN THE MONKEY. S.J. Mitchell\*. VA Med. Ctr., Syracuse, NY 13210.

To understand the functional neural circuitry of the basal ganglia, we made unilateral excitotoxic lesions in the putamen of monkeys trained to perform a simple reaction-time reaching task, a finger coordination task, and a bimanual hand coordination task. The lesion aimed to damage the arm areas of putamen from 1 mm anterior to the anterior commissure through its caudalmost extent. Prior to the lesion, single cell studies were carried out during the reaction-time task to localize the arm areas of the putamen, and collect control data from arm-related cells in the globus pallidus. Ibotenic acid was injected at 12 sites in putamen, 6 sites per day, with one day intervening between the lesion days. For a period beginning with the first lesion day and lasting several days after the second lesion, animals were slow to react and move in the reaction-time task, were clumsy in the finger coordination task, and were impaired on the bimanual task. Deficits in the reactiontime task were bilateral although mild for the arm ipsilateral to the lesion. The contralateral arm was hypotonic. Long term behavioral impairments were variable and depended on the location and size of the lesion. Tonic discharge rates of neurons in both pallidal segments were not significantly altered by the lesions when damage was restricted to the putamen.

## 293.4

CHANGES IN THALAMIC CELL DISCHARGE AFTER INJECTION OF MUSCIMOL INTO THE GLOBUS PALLIDUS. M. Inase, J.A. Buford, and M.E. Anderson\*. Depts. of Physiology and Biophysics and Rehabilitation Medicine and the Regional Primate Research Center, University of Washington, Seattle, WA 98185.

Muscimol injected into the internal globus pallidus (GPi) causes flexor drift and slowed movement in the arm (Inase and Anderson, Soc. Neurosci. 1991). We tested whether this GABAA agonist disinhibited thalamic target neurons, presumably by inhibiting pallidal output.

The monkey held his hand at a central light (hold period) until a go-tone instructed him to move to a target light. In the visible condition, the target was continuously lit after the go-tone. In the pre-cue condition, the target was briefly lit 800 ms into the hold period and the monkey moved to the remembered target location. Thalamic neurons were studied before and after muscimol and were identified as pallidal-receiving (PR) if single-pulse stimuli at arm-related GPi loci produced fixed-latency inhibition of thalamic discharge.

After muscimol, the distribution of hold-period firing rates for PR cells included rates higher than those recorded before injection. A similar change in the distribution was noted in thalamic cells recorded near the PR cells. For PR cells recorded before and after injection, muscimol increased hold-period firing by about 50%. Movement-related PR-cell discharge increased by about 25% after muscimol. Because of the higher hold-period firing rates, the change in firing caused by movement (100\*[MovementAverage - HoldAverage] / HoldAverage) was reduced by about one third after muscimol. The post-injection emergence of increased firing rates coincided with the appearance of flexor drift and decreased velocity. Supported by NIH NS15017 and RR00166.

ALTERATIONS IN THE PHYSIOLOGY OF INTRALAMINAR AND MOTOR THALAMIC NEURONS IN CATS WITH MPTP-INDUCED PARKINSONISM. D.S. Rothblat\* and J.S. Schneider, Department. of Neurology, Hahnemann

University, Philadelphia, PA. 19102.
Previously, we have shown that striatal sensory responsiveness and information processing is severely impaired in cats with MPTP-induced parkinsonism and profound striatal dopamine (DA) depletion. Following such extensive striatal DA depletion, the spontaneous activity of striatal and entopeduncular nucleus (ENTO) neurons increases while activity of globus pallidus neurons decreases. This data supports the hypothesis that thalamic neurons which receive inputs from the ENTO may be under abnormal inhibitory influences in the Parkinsonian condition. The present study examined the physiology of thalamic neurons which are afferent to the striatum (centromedianum (CM) and centralis lateralis (CL)) in effort to examine whether the loss of sensory responsiveness in the Parkinsonian striatum can at least in part be explained by a loss of sensory responsiveness in striatum can at least in part be explained by a loss of sensory responsiveness in thalamic afferent structures. Spontaneous activity and responses to tactile stimuli were assessed in the CM and CL in awake, alert cats. Parkinson-like sensorimotor deficits were then produced by administering MPTP (7.5 mg/kg, i.p.) for 7-10 days. Spontaneous activity of CM and CL neurons decreased by approximately 54% in cats with severe Parkinsonian motor deficits. Responsiveness to tactile stimuli also significantly decreased by approximately 85% when animals were Parkinsonian. Preliminary results obtained from the ventral anterior/ventral lateral (VA/VL) nuclei show similar trends. These results suggest that the previously observed increase in ENTO activity leads to decreased spontaneous activity and sensory responsiveness in intralamirar (IL) and motor thalamic regions. These changes in thalamic physiology, and particularly in the IL region, may contribute to the parkinsonian sensorimotor deficits observed in MPTP-treated cats at least in part by limiting the access of sensory information to the striatum and cortex. part by limiting the access of sensory information to the striatum and cortex. Supported by NIH grant NS23980.

#### 293.7

INACTIVATION OF THE SENSORIMOTOR TERRITORY IN THE INTERNAL PALLIDUM REVERSES PARKINSONIAN SIGNS IN MPTP-TREATED MONKEYS. M.S. Baron, T. Wichmann and M.R. DeLong. Dept. of Neurology, Emory Univ. Sch. of Med., Atlanta, GA 30322

Recent studies suggest that increased neuronal activity in the internal pallidal segment (GPi) is a key element in the development of parkinsonian motor signs. This has led to renewed interest in neurosurgical lesions of GPi as treatment for Parkinson's disease. The goal of this study was to define the optimal target site for such lesions in parkinsonian monkeys.

A Rhesus monkey received bilateral intracarotid injections of MPTP (0.4 mg/kg/side), leading to stable parkinsonian motor signs (akinesia, bradykinesia, rigidity, flexed posture). In order to transiently inactivate small regions of GPi, injections of the GABA receptor agonist muscimol (1 µg/1µl) were carried out in a 2 mm grid throughout the nucleus under electrophysiological guidance. The unrestrained animal was observed for 20 minute periods before and after the injection (20-40 min and 60-80 min post injection).

Injections in a small central area of GPi that contained neurons responsive to

somatosensory stimulation led to marked contralateral improvement of akinesia, bradykinesia and posture, typically after 15 - 20 minutes and lasting several hours. Injections in other areas of the nucleus were less effective, and often induced atypical behavior (e.g. circling). Normal saline injections had no effect. Injections of muscimol into the external pallidal segment (GPe) failed to reverse parkinsonian

These results indicate that lesions restricted to the "sensorimotor" portion of GPi can be an effective treatment for parkinsonian motor signs. Electrophysiological methods should help to localize the optimal target for lesioning in GPi and minimize the incidence of side effects.

SUBTHALAMOTOMY PRIOR TO MPTP ADMINISTRATION REDUCES SEVERITY OF PARKINSONISM IN MONKEYS. J. Guridi, MR Luquin, MT, Herrero, J. Laguna, J. Guillen, JA Obesot Movement Disorders Unit. Department of Neurology. Clinica Universitaria. Apdo. 192-31080 Pamplona-Spain.

A subthalamic lesion was made by Kainic acid injection into STN in two groups of macaques: 1). In 2 previously normal monkeys macaques: 1. In 2 previously normal monkeys hemiballism become well established. MPTP (1mg/Kg, i.v.) was given up to 10 consecutive weekly doses. Animals showed a mild reduction in spontaneous activity, flexor posture and focal hypomimia but hemiballism persisted. This contrasted with the very severe and permanent parkinsonism induced in similar monkeys (n= 12) after a less agressive pattern of MPTP less agressive pattern of MPTP administration (0.5 mg/kg, 10 wks). 2) In 2 administration (0.5 mg/kg, 10 wks). 2) in 2 previously parkinsonian monkeys hemiballism developed in the contralateral limbs without clear cut motor improvement. These results support a pivotal role of the STN in parkinsonism but dyskinesias can coexist with parkinsonian sign following STN lesion.

CONTRIBUTIONS OF REUPTAKE INHIBITION AND DOPAMINE DENERVATION TO VOLUME TRANSMISSION OF DOPAMINE IN THE STRIATUM IN NORMAL AND MPTP-TREATED CATS. 1.S. Schneider\* D.S. Rothblat and L. DiStefano. Dept. of Neurol., Hahnemann Univ., Phila., PA 19102.

Rothblat and L. DiStefano, Dept. of Neurol., Hahnemann Univ., Phila., PA 19102. Cats become parkinsonian after MPTP administration but typically recover motor function within 4-6 wks. Tissue dopamine (DA) levels in the dorsal lateral (i.e., sensorimotor) caudate nucleus (DL CD) do not differ between symptomatic and recovered MPTP-treated cats, but there is significant recovery of ventromedial caudate/nucleus accumbens (VM CD) DA levels in recovered cats. Despite the lack of tissue DA recovery in the DL CD, in vivo microdialysis shows an approx. 50% recovery of extracellular fluid (BCF) DA in this region. The present study was to determine the source of this ECF DA in the DL. CD of previously parkinsonian cats. Cats were implanted with cannulae overlying the VM and DL CD on each side of the brain through which microdialysis probes (3-4 mm membrane) could be inserted. ECF DA levels were examined when cats were normal and after functional recovery from MPTP-induced parkinsonism. After basal levels of DA were measured in both striatal regions, KCl (60mM) was infused through one probe and the DA level was measured at both probes. In normal cats, KCl infusion stimulated the DA level was measured at both probes. In normal cats, KCl infusion stimulated a local 3-5 fold increase in ECF DA and no detectable increase in DA at the distant probe, approx. 5mm away. In normal cats treated with nomifensine (20mg/kg, i.p.), a DA reuptake inhibitor, DA released from KCl stimulation in one region was i.p.), a DA reuptake inhibitor, DA released from KCl stimulation in one region was detected in the distant region by the second dialysis sample after infusion, suggesting enhanced diffusion after reuptake inhibition. DA released by KCl stimulation of the VM CD was, by the second sample after infusion, detected in the DL CD in cats functionally recovered from MPTP-induced parkinsonism. In these cats, DL CD DA increased more from diffusion than from local stimulated release. These results suggest that DA may exert its effects after extensive (but heterogenous) striatal presynaptic denervation significantly through volume transmission. We suggest that functional recovery following DA-depleting lesions may depend on the extent to which DA diffusion occurs and the tissue volume through which DA must diffuse. Supported by NIH grant NS-23980.

BASAL GANGLIA MODULATION OF MOTOR CORTEX EXCITABILITY. Lawrence J. Ryan and David J. Sanders. Department of Psychology, Oregon State University, Corvallis, OR 97331-5303.

The basal ganglia are currently conceived to be part of parallel major and

The basal ganglia are currently conceived to be part of parallel major and minor positive feedback loops originating in the cortex, traversing the basal ganglia and thalamus and returning to cortex. We test whether changes in basal ganglia function can directly alter motor cortex excitability via this loop. Thresholds for evoking movements by electrical stimulation (50 ms trains, 333 Hz, 10-80uA, Pt-Ir electrodes) of primary motor cortex were determined in ketamine (100mg/kg, ip) anesthetized rats. Drugs were infused into the head of the neostriatum (0.4 uL over 90 seconds) and the motor cortex threshold was monitored for the next 60 minutes. The glutamate agonist kainic acid increased movement-eliciting thresholds to stimulation of the ipsilateral but not contralateral cortex. Thresholds returned near baseline by 60 minutes. In contrast GABA decreased thresholds of the ipsilateral motor cortex. These changes in excitability are likely due to modulation of the cortex rather than to direct competing descending influences on the muscles since cutting the loop changes in excitability are likely due to modulation of the cortex rather than to direct competing descending influences on the muscles since cutting the loop with biotenic acid lesions (7 days prior to testing) of the VL thalamus (n=6), but not the VM thalamus (n=5), eliminate the effect of kainic acid infusion.

Change in Motor Cortex Thresholds During First 10 Minutes After Infusion.

N Infusions lpsilateral +6.1% Contralateral 0.25 ug/ul Kainic acid 0.75 ug/ul Kainic Acid 10<sup>-3</sup>M GABA -24 6% +185.5% -11.1% -18.7% -6.4% 0.75 KA - VL Lesion 0.75 KA - VM Lesion -5.9% -16.0% + 183 2%

Thus, the basal ganglia can directly modulate motor cortical excitability These preliminary results suggests that increasing neostriatal activity inhibits the cortex, whereas decreasing neostriatal activity facilitates the cortex. ## 293.10

EFFECTS OF DOPAMINERGIC AGENTS ON THE TONICALLY ACTIVE NEURONS OF THE STRIATUM IN HEMI-PARKINSONIAN MONKEYS. T. Aosaki, A. Ishida, K. Watanabe, H. Imai, A.M. Graybiel and M. Kimura\* Dept. of Physiology, Jichi Medical School, Tochigi 329-04, Japan, and Dept. of Brain and Cognitive Sciences, M.I.T., Cambridge, MA 02139.

Tonically active (type I) neurons in the striatum respond with inhibition to

sensory stimuli that serve as cues for initiation of learned movements. In this study, we investigated the modulation of type I cell activity by the nigrostriatal dopamine system. After monkeys (2 Macaca fuscata) were well trained to lick a liquid reward after a click sound, the activity of type I cells was recorded during this learned behavior. About 70% of the type I cells (317/453 cells) showed significant inhibitory responses to the click stimuli. Then, the monkeys were rendered hemi-parkinsonian by local infusion of 1-methyl-4phenyl-1,2,3,6-tetrahydropyridine (MPTP, 4 mg) into the striatum by an osmotic minipump. The proportion of type I cells responsive to the click was dramatically decreased to about 15% (32/211 cells) in the depleted striatum, whereas the majority of Type I cells on the intact side (122/150 cells) remained responsive. When apomorphine (0.I-0.3 mg/kg) was injected systemically, 6 out of 9 non-responsive cells on the dopamine-depleted side acquired inhibitory responses to the click. After local application of 10  $\mu$ M haloperidol on the intact side, using a concentric drug-applying recording electrode, responses to the click stimulus decreased significantly in 3 cells examined. Local application of dopamine (10  $\mu$ M) immediately suppressed all firing of 14 type I cells examined. These results suggest that the behaviorally contingent activity of tonically active neurons in the striatum is strongly influenced by nigrostriatal dopaminergic inputs, and that these influences may be inhibitory. LOCALIZATION OF FUNCTIONAL ACTIVITY IN RAT NEO-STRIATUM DURING TRAINED FORELIMB MOVEMENTS. L. L. Brown\*, M. F. Gonzalez† and F. R. Sharp†. \*Department of Neurology, Albert Einstein College of Medicine, Bronx, NY 10461 and †UCSF, Department of Neurology, Veteran's Administration Hospital, San Francisco, CA 94121.

We have reported previously that electrical stimulation of forelimb motor cortex that induces movement in rats also causes activation in the ventral part of dorsolateral striatum. We here report that the same region is activated when a forelimb movement is made voluntarily. Rats were trained to reach through a hole and press a lever to receive pellets on a fixed ratio schedule of 16:1 or 32:1. Radiolabelled deoxyglucose was injected iv at the beginning of the final session; after 45 min the animals were killed with an overdose of pentobarbital and their brains were prepared for autoradiography. Experimental rats pressed the bar up to 5056 times during the deoxyglucose session and ate up to 158 pellets. After training, controls had been given pellets without a bar press for several weeks so that they would eat the same number of pellets as experimentals during the deoxyglucose session, but would not press the bar. The striatum was analyzed from 2.0 mm anterior to bregma to 1.0 mm posterior. Activation in the bar-pressing animals was different from controls in anterior striatum. Bar-pressing animals showed maximal activation in the region activated by forelimb motor cortex stimulation, while controls showed activation in the region activated by vibrissae motor cortex stimulation. The area of maximal activation was, however, smaller than in the motor cortex stimulation animals. The results confirm localization of forelimb motor neural activity in rat, during a natural movement, that is consistent with a topographic organization of activity in rat neostriatum.

DIFFERENTIAL ROLES OF THE CAUDATE AND PUTAMEN: BEHAVIORAL AND ELECTROPHYSIOLOGICAL ANALYSIS. K. Fujimoto\*, M. Yoshida, H. Yamada, E. Nakamura, Dept. of Neurology, Jichi Medical School, Minamikawachi-machi, Tochigi, 329-04, JAPAN

In order to reveal a functional difference between the caudate (Cd) and the putamen (Put), we studied the effects of local injection of bicuculline (BlC) into these nuclei on the motor behavior in the cat. BlC is a reversible GABA antagonist and is assumed to activate efferent neurons of the Cd and the Put by removing the action of GABA-ergic inhibitory synapses on them. Two weeks before the experiments, stainless-steel tubes for injections were

Two weeks before the experiments, stainless-steel tubes for injections were inserted stereotaxically under the anesthesia with pentobarbital sodium. Recording electrodes made of insect pins were also inserted into the Cd, Put, entopeduncular nucleu (Ent), external pallidum (GP), subthalamic nucleus (STH), and substantia nigra (SN). Silver-ball electrodes were fixed on the motor cortex (Cx). In the experiments, BIC (3µg/1.5µl) was injected into the Cd and the Put respectively with the interval of at least 1 day, and the field potentials were recorded from the fixed electrodes. Behavior of the cat was recorded with a video camera and the movement of the neck was analysed with a X-Y recorder.

Shortly after the unilateral injection of BIC to the Cd, spikes were seen in the Cd and locomotor hyperactivity without any postural asymmetry or circling tendency was observed. Then, the spikes spread to the Cx, Put, GP, Ent, STH, and SN and these generalized spikes triggered the jerky movements of the neck toward the contralateral side. Shortly after the unilateral injection of BIC to the Put, spikes were seen in the Put and the jerky movements towered the contralateral side were observed. Next, the bursts of generalized spikes developed and the neck turned to the contralateral side dystonically. The dystonic posture lasted while the burst of spikes continued.

These results demonstrate that the Cd and the Put are differentially associated

These results demonstrate that the Cd and the Put are differentially associated with locomotor and postural functions.

DOPAMINERGIC INPUT TO THE SUBTHALAMIC NUCLEUS REGULATES THE MUSCULAR TONE IN THE RAT. G. Flores, J. Valencia, A. Sierra, M. Rosales, J. Hernández\* and J. Aceves. Dept. of Physiology. CINVESTAV-IPN. Mexico.

The subthalamic nucleus (STN) plays a crucial role in the control of motor functions. The STN receives a dopaminergic input from substantia nigra compacta (SNc). However, the effect of dopamine (DA) on subthalamic neurons is not clear. Here we studied the role of the DA innervation of the STN on muscular tone of extensor muscles (gastrocnemius-soleus). 6-hydroxydopamine (6-OHDA) was unilaterally injected into the STN. Shams received ascorbate in saline. Muscular tone was measured by electromyography. DA content was measured in STN, striatum (str) and accumbens (acc). The 6-OHDA lesion provoked an ipsilateral increase in muscular tone, DA levels were significantly decreased only in the lesioned STN. No change in either DA content or on muscular tone was observed in sham animals. These results suggest that the dopaminergic input to STN is inhibitory. The loss of this input, would disinhibit the subthalamic neurons, which would, in some way, cause the increased muscular tone. (Supported by grant 0586N from CONACYT)

GLUTAMATERGIC MEDIATION OF ORAL MOTOR CONTROL IN THE RAT'S STRIATUM: INTERACTIONS WITH DOPAMINERGIC AND CHOLINERGIC SYSTEMS. M. Pisa\* D. Bosiljevac and D. Brain. Dept. Biomed. Sci., McMaster Univ., Hamilton, Ont., Canada, L8N 3Z5.

We previously showed that, in rats, bilateral injections of the wide-spectrum glutamate receptor antagonist kynurenic acid (12-72 nmol) in the lateral striatum induce an increase of nondirected (in vacuo) oral movements, suggesting a role of corticostriatal glutamatergic transmission in oral motor control. In the present study, we examined the hypothesis that this effect is mediated by increased activity of local dopaminergic and cholinergic systems. The oral hyperkinetic effect of kynurenate injections (36 nmoles in .4 ul) in the lateral striatum was confirmed. Co-injections of either SCH23390, sulpiride or cis-flupenthixol, which block D1 receptors, D2 receptors, and both D1 and D2 receptors, respectively, failed to reduce the kynurenate effect at doses known to abolish the oral stereotypies induced by the dopamine receptor agonist apomorphine. It appears, therefore, that the oral hyperkinesia induced by blockade of glutamatergic transmission in the lateral striatum is not mediated by a local increase of dopaminergic hyperactivity. The role of cholinergic mechanisms is being investigated and will be reported at the meeting. (Supported by the Scottish Rite Schizophrenia Research Program. M. Pisa is a Research Associate of the Ontario Mental Health Foundation).

EFFECT OF DOPAMINE AGONISTS ON TURNING BEHAVIOR AND LOCOMOTOR ACTIVITY IN RATS WITH KAINIC ACID-INDUCED LESIONS OF THE SUBTHALAMIC NUCLEUS. J.C. Pineda\*, G. Flores, M. Rosales, J. Flores-Hernandez, A. Sierra, V. Martínez and J. Aceves. Dept. of Physiology. CINVESTAV-IPN. Mexico.

Here we have explored the role of subthalamic nucleus (STN) on turning behavior and locomotory activity (LA) induced by dopamine (DA) activation. Kainic acid was injected either unilaterally or bilaterally into the rat STN. Shams animals received ascorbate in saline. Glutamic acid, glutamine and GABA contents were measured in substantia nigra reticulata (SNr) and entopeduncular nucleus (EPN). Unilaterally lesioned animals exhibited spontaneous contralateral turning, lasting 12 days. Systemic apomorphine (1 mg/Kg sc) or methamphetamine (4 mg/Kg sc) induced ipsilateral turning in these animals. In bilaterally lesioned animals, SKF 39383 (1 and 5 mg/Kg sc) increased, while quinpirole (0.5 and 2 mg/Kg sc) decreased LA when compared with controls. Glutamic acid levels were significantly decreased in the SNr and EPN of the experimental animals, but no decrease was observed in glutamine or GABA contents. This results show the relevance of the STN in the LA induced by activation of DA receptors.

## 293 16

REPEATED APOMORPHINE-INDUCED ROTATIONS POSSESS A LEARNING COMPONENT. C.S. Fong, S.J. Boyson\*, B.J. Hoffer, J.L. Hudson, Dept. of Pharmacology and Neuroscience Training Program, Univ. of CO HSC, Denver CO 80262.

Apomorphine-induced turning has been used, by many laboratories, to evaluate the extent of unilateral nigrostriatal denervation and functional striatal reinnervation catecholaminergic grafts after 6-hydroxydopamine (6-OHDA) lesions. It has been noted that the pre-graft rotational pattern is usually double-peaked and that fetal ventral mesencephalic grafts, or dopaminergic drugs, will alter the second peak but leave the first relatively intact. We hypothesized that the first peak may possess a learning component and will therefore be unperturbed by the above treatments. We investigated this by injecting 6-OHDA, unilaterally, into the nigrostriatal pathway of several groups of Fischer 344 rats. One experimental group was repeatedly tested with 0.05 mg/kg apomorphine. A second group received similar injections but were prevented from rotating. Vehicle control animals were also studied for both of the above experimental groups. Our results support the "learning" hypothesis in that the above experimental groups. Our results support the "learning" hypothesis in that the above experimental groups. Our results support the "learning hypothesis in that the above experimental groups. Our results support the bearing hypothesis in that the above experimental groups. Our results support the "learning hypothesis in that the above experimental groups. Our results support the bearing hypothesis in that the however, do show a first peak. We therefore conclude that learned rotations are a significant component of the first peak of apomorphine-induced turning. These rotations are unlikely to be related to the cellular changes induced by 6-OHDA learners.

TARGET SPECIFICITY AND NEUROTRANSMITTER TYPE OF FETAL C.N.S. TRANSPLANTS ARE IMPORTANT FOR FUNCTIONAL REINNERVATION OF 6-HYDROXYDOPAMINE TREATED RATS. J.L. Hudson, P. Bickford, B.J. Hoffer\*, I. Strömberg. Departments of Pharmacology and Psychiatry, Univ. of Colorado Health Sci. Ctr., Denver, CO 80262 and Department of Histology and Neurobiology, Karolinska Institutet, Stockholm, Sweden.

The ability of grafts of fetal ventral mesencephalic dopaminergic (DA) neuroblasts to reinnervate the unilaterally DA-denervated rat striatum and improve motoric asymmetry has been well documented in several laboratories. The importance of host target specificity, and catecholamine (CA) neurotransmitter species, in the ability of grafts to ameliorate rotational responses to apomorphine and to affect electrophysiological characteristics of striatal neurons has not been systematically studied. We unilaterally lesioned male Sprague-Dawley rats with 6-hydroxydopamine and verified the lesions using 0.05mg/kg apomorphine s.c.. Some of the animals subsequently received, intrastriatally, either DA neuroblasts from ventral mesencephalon that normally innervate the striatum, or from arcuate nucleus that do not. Additionally, two control groups were included that received either a catecholaminergic graft from locus coeruleus or a graft of cerebral cortex. Only the fetal ventral mesencephalic grafts were able to reduce apomorphine-induced rotations and normalize striatal-cell firing rates; firing rates with substantia nigra grafts were 1.5 Hz  $\pm$  0.25, with arcuate nucleus grafts were 5.6  $\pm$  0.8, with locus coeruleus grafts were 5.1  $\pm$  1.1, and with cerebral cortex grafts were 4.4  $\pm$  0.5. Moreover, only the ventral mesencephalic grafts produced a histochemically demonstrable CA reinnervation of striatum. We thus conclude that target specificity and neurotransmitter type are critically important in the ability of a graft to functionally reinnervate the 6-hydroxydopamine denervated striatum.

## 293.19

NEURONAL ACTIVITY IN RAT STRIATUM DURING A SIGNALED AVOIDANCE TASK: REGIONAL DIFFERENCES IN INFORMATION PROCESSING. <u>I.M. White\* L.M. Bartolo. and G.V. Rebec</u>, Prog. Neural Science, Dept. Psychology, Indiana University, Bloomington, IN 47405

The striatum, which receives substantial dopaminergic input, is known to play a critical role in active avoidance learning (Koob et al., Brain Res., 303:319, 1984). To begin to assess the neuronal mechanisms underlying this role, we recorded neuronal activity in the striatum during the performance of a signaled avoidance task in which rats were required to release a lever within 500 msec of the onset of an auditory signal to avoid footshock (White et al., Pharmacol. Biochem. Behav., 41:29, 1992). All animals were trained until performance reached or exceeded a 90%-avoidance rate for 5 consecutive sessions. Then they were surgically prepared for unit recording. Following a one week recovery, rats resumed training until performance was the same as before surgery. Striatal activity then was recorded during one or more sessions of 10-trials each. Data were obtained from more than 200 neurons, the majority of which responded in close temporal association with either the auditory signal or the lever-release response. Less than 20% of the cells responded to neither. Signal-responsive neurons tended to cluster in medial striatum, whereas response-specific neurons were found primarily in dorsolateral areas. Treatment with haloperidol (0.1 mg/kg, SC), a dopamine antagonist, 20 min before testing blocked performance as well as both signaland response-related neuronal activity. Taken together, out results indicate a functional differentiation between medial and dorsolateral striatum in processing the signal that triggers a learned movement and the movement itself. Haloperidol, however, appears to exert uniform effects on both processing functions.

Supported by USPH Grant DA 02451.

#### 293 18

PERSISTENT ROTATIONAL ASYMMETRY IN RATS. <u>CW Shulls\*d\* RI Matthews A and PJ Langlais.</u>+d\* ADept. of Neurosci., UCSD; +Psychol. Dept., SDSU, †Neurology Ser., VA Medical Ctr., San Diego, CA 92161 Brain-derived neurotrophic factor (BDNF) promotes survival of mesencephalic, dopaminergic neurons in vitro, and message for BDNF is transiently expressed in nigral neurons in rat pups and reexpressed in adult rats treated with intraventricular colchicine. To evaluate the effects of BDNF on the mesostriatal, dopaminergic system of the adult rat, w examined the effects of unilateral injection of BDNF into the mesencephalon. Rats were tested for amphetamine-induced (1 mg/kg) rotation before and at various times (2 d to 2 1/2 mon) after a single, unilateral injection of BDNF (1, 2, or 3 µg) or vehicle into the mesencephalon. Injections were made at the junction of the substantia nigra pars compacta and the ventral tegmental area. In a series of fou experiments, we noted that after a single, unilateral injection of BDNF (2 or 3 µg) but not vehicle, animals exhibited a statistically significant increase in amphetamine-induced rotation contralateral to the side of injection. The pattern of rotation is consistent with increased activity of the mesostriatal dopaminergic system on the side of injection. The increase in amphetamine-induced rotation was greater at 10 days than at 2 days after injection of BDNF and persisted for up to 2 1/2 mon (the longest period studied). Levels of catecholamines and indolamines in the striatum and immunohistochemical studies of tyrosine hydroxylase-immunoreactive neurons in the mesencephalon will be presented. Our studies indicate that a single injection of BDNF into the mesencephalon can induce a persistent behavioral change in rats. Supported by United Parkinson Fndn. and VA Merit Review Program.

NEUROTOXIC LESIONS OF THE NUCLEUS ACCUMBENS, BUT NOT NEOSTRIATUM, IMPAIRS PERFORMANCE ON A SIGNALED AVOIDANCE TASK IN RATS. G.V. Rebec\*. M.P. Hrebin. H.M. Karsch, and I.M. White, Prog. Neural Science, Dept. Psychology, Indiana University, Bloomington, IN 47405.

Antipsychotic drugs block performance on a signaled avoidance response task in which rats are trained to release a lever within 500 msec of the onset of an auditory signal to avoid a footshock (White et al., Pharmacol. Biochem. Behav., 41:29, 1992). Although the mesotelencephalic dopaminergic projection is known to paly a key role in active avoidance learning (Koob et al., Brain Res., 303:319, 1984), relatively little is known about the involvement of specific target sites. To address this issue, rats were trained on our signaled avoidance task, and the nucleus accumbens or specific subregions of the neostriatum (dorsolateral, medial, or ventral) were damaged with ibotenic acid. One week after surgery, rats were run on the same task. To assess lesion effects, the average number of avoidances and the average avoidance latency were compared before and after lesion. Bilateral, not unilateral, damage to the nucleus accumbens significantly decreased the number of successful avoidances without disrupting the latency of either the avoidance or escape responses. In contrast, neither sham nor any of the neostriatal lesions altered performance on this task Thus, the nucleus accumbens is a critical postsynaptic target of the ascending dopaminergic system involved in active avoidance learning Supported by USPHS Grant DA 02451.

SEROTONERGIC MODULATION OF NIGROSTRIATAL TERMINAL EXCITABILITY. L.D. Manley\*, S.J. Young, M.S. Manley and P.M. Groves. Dept. of Psychiatry, University of California, San Diego, La Jolla, CA 92093-0603.

Studies suggest that striatal dopamine (DA) levels are affected by local application of serotonergic (5HT) agents. These effects may be due to the activation of presynaptic receptors on nigrostriatal DA terminals. Previous studies have also shown that changes in the activation of receptors on DA terminals are associated with systematic alterations in the electrical excitability of the axonal terminal field. We investigated whether local striatal application of 5HT drugs similarly altered DA terminal excitability. Antidromic responses elicited by stimulation of ventral striatum were recorded extracellularly from DA neurons of the substantia nigra pars compacta in urethane-anesthetized rats. Drugs were delivered (300 nl over 3-5min) to the stimulating site with an infusion cannula. Excitability changes were assessed by determining the threshold current required for antidromic activation before and after drug infusion. Administration of the 5HT2 agonist, DOI, produced a dose-dependent decrease in excitability (10 µM: -63.742.6%; 5 µM: -22.243.3%; 1 µM: -17.141.6%; 0.1µM: -7.440.4%, n=4/dose). Prior infusion of the 5HT2 antagonist, ketanserin (0.1 to 10µM, n=4), produced a decrease in excitability (3/4 rats) and, in all cases, completely blocked the action of a subsequent infusion of DOI (1 or 5µM). Studies are underway to determine whether these effects are dependent on dopamine or on the action of postsynaptic neurons. Additional experiments are being performed to investigate the actions of other 5HT receptor subtypes. This work is supported by DA 02854 and PHS 5T32 GM07752.

## 294.2

ELECTROCHEMICAL EXAMINATION OF THE CONNECTIONS BETWEEN THE PEDUNCULOPONTINE TEGMENTUM, SUBSTANTIA NIGRA AND CAUDATE-PUTAMEN IN THE RAT. C.D. Blaha and P. Winn\* Depts. Psychol. & Psychiat., Univ. British Columbia, Vancouver B.C., V6T 1Z4, Canada (C.D.B.) and Dept. Psychol., Univ. St Andrews, Fife, Scotland KY16 9JU (P.W.)

The effects of cholinergic stimulation of substantia nigra pars compacta (SNPC) on DA efflux in the caudate-putamen (C-P) (measured by in vivo chronoamperometry: Blaha and Jung, 1991, J. Electroanal. Chem. 310: 317-334) was investigated in intact and pedunculopontine tegmental nucleus (PPTg) lesioned rats under urethane anesthesia. Using stearate-modified electrodes, dependent increase in oxidation current in the C-P corresponding to DA efflux was found following microinjection into the SNPC of nicotine (0.5 mM, 155+12%) maximal increase as percentage of baseline; 5.0mM, 512±55%) or carbachol (0.5mM, 132+4%; 5.0mM, 331+18%). Increasing extracellular concentrations of ACh in the SNPC by infusion of the anticholinesterase neostigmine also increased C-P DA efflux (0.25mM, 144+10%; 0.5mM, 227+6%). The stimulatory effects of neostigmine on C-P DA efflux were confirmed using in vivo microdialysis (0.5mM, 159+11%). Compared to sham-operated controls, rats with quinolinic acid lesions of PPTg showed an attenuation (p < 0.01) of the stimulatory effects on C-P DA of intranigral neostigmine (0.25mM, 120 $\pm$ 4%), but PPTg lesions enhanced (p<0.01) C-P DA efflux in response to SNPC injection of the receptor agonist nicotine (0.5mM, 188 ± 7%), suggesting that postsynaptic receptor supersensitivity had developed. Altogether, these data suggest (i) that there is a cholinergic innervation of the SNPC from the PPTg and (ii) that cholinergic is in the PPTg are indirectly involved in regulating the activity of the C-P by modulating the activity of DA-containing neurons in the SNPC.

AMPHETAMINE AND APOMORPHINE INDUCED LOCOMOTION AND ORAL STEREOTYPY IN PEDUNCULOPONTINE TEGMENTAL NUCLEUS LESIONED RATS. W.L. Inglis\*, L.F. Allen, R.B. Whitelaw, M. Latimer, H. Brace and P. Winn Dept. Psychol., Univ. St Andrews, Fife, Scotland KY16 9JU

The effects of ibotenate lesions of the pedunculopontine tegmental nucleus (PPTg) on responses to systemic injection of d-amphetamine and apomorphine were examined in rats. The following groups were tested: bilateral IBO lesions of PPTg (0.12M: 2 X 0.2ul injections/hemisphere; n=7), bilateral IBO lesions of deep mesencephalic nucleus (DpMe) (0.12M, 0.4ul; n=8), sham lesions (phosphate buffer vehicle) of PPTg (n=6) and DpMe (n=5). For PPTg, 24h separated lesions in right and left hemispheres. All rats recovered from surgery: food and water intake was normal within 14 days of surgery (though DpMe lesioned rats increased water intake [never >5ml] compared to sham lesioned rats). All rats were then given injections of 1.5, 3.0 and 5.0 mg/kg AMPH (ip), and saline control injections, in a randomized order. Locomotion to 1.5 mg/kg was increased after AMPH in all groups compared to saline injections. At 3.0 and 5.0 mg/kg sham and DpMe lesioned rats showed normal AMPH stereotypies: rearing, sniffing and locomotion (3-4, Creese-Iversen). PPTg lesioned rats showed compulsive biting predominantly directed at their forepaws. Injections of 0.1, 1.0 and 3.0 mg/kg APO (sc; ascorbate-saline vehicle) showed similar effects: locomotion at 0.1 mg/kg but a significantly increased incidence of biting and gnawing at higher doses by PPTg lesioned rats. In this case biting was directed at cage bars rather than forepaws. Histological analysis (cresyl violet, NADPH-diaphorase) showed that lesions had been effective. These data demonstrate that (i) lesions in this area of the pons have discriminably different effects; (ii) locomotion stimulated by DA agonists is not affected by PPTg or DpMe lesions; (iii) the PPTg may play an important role in mediating dorsal striatal outflow.

## 294.5

A TRANSIENT EXPRESSION OF SUBSTANCE P-LIKE NEURONS IN RAT SUBSTANTIA NIGRA (SN) AND VENTROTEGMENTAL AREA (VTA) PARTICIPATES IN DEVELOPMENT OF STRIATONIGRAL PROJECTION. N. Seno, T. Kono, Y. Kuga, S.T. Kitai, and E.J. Johnson\*, Dept. of Anatomy and Neurobiology, University of Tennessee, Memohis. Memohis. TN.

Early appearance of monoamine and peptidergic neurotransmitters has been interpreted to be an indication of their role in development of the CNS. We have studied the development of SP like immunoreactive (SP-LIR) neurons in SN and VTA during embryonic (E14-E21) and postnatal periods (P0-P14). Immunohistochemical analysis were used to identify SP-LIR and tyrosine hydroxylase like immunoreactive (TH-LIR) neurons. Bromodeoxyuridine (BrdU) was used as a marker of cell birth date. In some cases, a retrograde tracer fluorogold (FG) was injected in the neostriatum to identify nigrostriatal neurons.

No SP-LIR immunoreactive SN and VTA neurons were seen at E16 while many neurons were already TH-LIR positive. At E17, SP-LIR or SP-TH-LIR double (d) labeled neurons and at E18 striatonigral projections identified by GABA/SP-LIR terminals were observed for the first time. The number of single or d-labeled SP-LIR neurons increased as striatonigral terminals density increased and was maximum at the postnatal day 0 (at birth). From P2, SP-LIR neurons decreased gradually in both nuclei, until their total disappearance at P14. At E18 and E19 more than 95% of SP-LIR neurons were d-labeled with TH-LIR. D-labeled neurons declined to about 10% to 20% by P6 and P7. BrdU immunocytochemistry demonstrated that most of SP-LIR positive neurons were labeled with BrdU injected at E12 and E13. FG study at E20 and P0 demonstrated that many SP-LIR neurons were nigrostriatal projection neurons. These observations indicate that a transient expression of SP-LIR in SN and VTA dopaminergic projection neurons may participate in promoting proper development of striatonigral (GABA/SP-LIR) connections with their target neurons in SN and VTA. Supported by USPHS grant NS20702 and the Human Frontiers Propram

## 294.7

COUPLING BETWEEN DOPAMINE AND NON-DOPAMINE NEURONS IN RAT SUBSTANTIA NIGRA COMPACTA. <u>S.T. Kitai\*, T. Kono, and Y.Kang.</u> Dept. of Anatomy and Neurobiology, The University of Tennessee, Memphis, TN.

Anatomical and electrophysiological studies have indicated a coupling between substantia nigra compacta (SNc) neurons. We have further investigated a possible coupling among SNc dopamine (DA) neurons using intracellular recording and immunocytochemical techniques in in vitro slice preparation in the rat.

An atoxic binding fragment of tetanus toxin, Fragment C(TTC: 0.1-0.5% solution) with biocytin (2-3% in 0.05M Tris buffer and 0.5M KCl, pH 7.4) were intracellularly injected (300 msec duration, 1Hz, 15 to 30 min) to label the recorded and the coupled neurons. SNc neurons were identified as putative DA and non-DA cell on the basis of their electrophysiological characteristics (e.g., firing rate and action potential shape, etc.). Postinjection survival time varied from 5 to 120 min. Tyrosine hydroxylase (TH) immunocytochemistry was also used to identify the transmitter phenotype of the recorded and the coupled neurons. Serial sections (30 µm thick) were made through the slice (500 µm thick) for immunocytochemical analysis for Biocytin, TTC, and TH antibodies.

Intracellular analysis revealed that, in addition to typical SNc DA cell action potentials, small action potentials (SAP) (3-5 mV) followed by hyperpolarizing potential (3-5 mV in amplitude and 100-200 msec in duration) can be recorded. SAPs were abolished with TTX and their firing frequency could be manipulated by depolarizing and hyperpolarizing current injection. Rhythmic firing of DA neurons appeared to be modified by SAPs. Anatomical data demonstrated 2-3 TTC/ Biocytin labeled neurons with apparent contacts at varying distance among them. Immunocytochemical analysis indicated that a majority of coupling was between the DA neurons and TH immuno-negative neurons. These data indicate an existence of internuclear control of DA cell firing by non-DA neurons in SNc. Supported by USPHS grant NS20702 and the Human Frontiers Program.

CHOLINERGIC STIMULATION OF RAT SUBSTANTIA NIGRA: INTERACTIONS OF NICOTINIC AND MUSCARINIC RECEPTOR ACTIVATION ON BEHAVIOR. G.C. Parker\* and P. Winn Dept. Psychol., Univ. St Andrews. Fife. Scotland KY16 91U

Convergent lines of research show there is an excitatory cholinergic input to the substantia nigra pars compacta (SNPC) from the pedunculopontine tegmental nucleus (PPTg). Microinjection of muscarinic or nicotinic receptor agonists, or anticholinesterases, into SNPC increase DA efflux in the caudate-putamen and stimulate behavior for which there is a positive predisposition and a low baseline rate. We have now investigated the interaction between muscarinic and nicotinic receptor agonists in the SNPC. 55 rats were implanted with unilateral cannulae aimed at the SNPC and assigned to one of four drug groups: carbachol (CARB: 0, 0.039, 0.1, 0.257 ug), nicotine (NIC: 0, 0.055, 0.1, 0.25 ug), 0.055ug NIC + each dose of CARB, 0.1ug CARB + each dose of NIC. During each test rats received a 0.5ul/60sec microinjection through a stainless steel cannula into SNPC; doses were administered in an individually randomized order and successive injections were separated by 48h. Rats were placed in individual cages for 60min prior to microinjection and for 60min following and had free access to weighed amounts of tap water, lab chow, dry macaroni (1470 Kj/100g, 13.0g protein/100g) and polystyrene packing chips. NIC and CARB both stimulated significantly more feeding than SAL. Addition of a behaviourally activating dose of CARB to each dose of NIC caused a significant increase in feeding compared to NIC alone However, addition of a behaviourally activating dose of NIC to each dose of CARB caused no significantly increased feeding compared to CARB alone. This suggests that cholinergic stimulation of SNPC can have behaviourally similar effects when acting through either muscarinic or nicotinic receptors but that the levels of stimulation at these receptors have different characteristics.

MUSCARINIC MODULATION OF RHYTHMIC FIRING IN DOPAMINERGIC (DA) NEURONS OF RAT SUBSTANTIA NIGRA PARS COMPACTA (SNc) IN IN VITRO SILCE PREPARATION. Y. Kang\*. T. Kono. Y. Kuga. and S.T. Kitai. Dept. of Anatomy and Neurobiology, The University of Tennessee, Memphis, Memphis, TN 38163.

Using a whole cell recording method, we have analyzed cholinergic modulation of rhythmic firing of DA neurons. Slices containing SNc were obtained from the brain of 10-21 day old rats and sectioned in 120-150 µm thickness. Biocytin was intracellularly injected into the recorded neurons and processed for tyrosine hydroxylase (TH) immunohistochemistry to identify their transmitter phenotype. During rhythmic firing in SNc DA neurons, a pacemaker like slow depolarization preceded each spike followed by a prominent afterhyperpolarization (M-AHP). A bath application of carbachol (1-100 µM) or muscarine (1-100 µM) increased the frequency of rhythmic firing with a decrease in the amplitude of M-AHP. The membrane potential was also depolarized. These phenomena were considered due to the blockade of K+ currents. SNc DA neurons are also known to display membrane potential oscillation in the presence of TTX and TEA. With an increase in d.c. depolarization, the oscillation frequency increases while its amplitude decreases. A bath application of carbachol or muscarine in the presence of TTX and TEA suppressed spontaneous rhythmic membrane potential and current oscillation in a dose dependent manner. Atropine (20-50 µM) application in the media antagonized the carbachol and muscarine effects. These data indicate that rhythmic firing of SNc DA neurons could be modulated by extrinsic cholinergic inputs through activation of muscarinic receptors. Supported by NIII grant NS 20702 and Human Frontiers Program.

## 294.8

DEVELOPMENT OF NEUROTRANSMITTER PHENOTYPES IN THE NEOSTRIATUM AND THE SUBSTANTIA NIGRA AND THEIR EFFERENT PROJECTIONS STUDIED BY A COMBINED DOUBLE IMMUNOCYTOCHEMICAL TECHNIQUE WITH A RETROGRADE TRACING METHOD. T.Kono\*. M. Takada. and S.T. Kitai. Dept. of Anatomy and Neurobiology, College of Medicine, The University of Tennessee, Memphis, Memphis, TN 38163

Using a double immunofluorescence histochemistry for the neurotransmitter or neurotransmitter-synthesizing enzyme, or the neuropeptide and bromodeoxyuridine (BrdU) thymidine analogue, as a cell birthday marker, we studied the birth date and neurotransmitter phenotypes and neuropeptide expression date of cells in the neostriatum (ST) and substantianigra (SN). BrdU was injected intraperitoneally (50mg/kg b.w.) to pregnant Wistar rats with gestation days of 11 through 20 (N=13 for each day). Litters were sacrificed on the various embryonic ages (E12 through E21, postnatal day 0 (date of birth), P1,P3,P4,P7 and P14) under a deep anesthesia and perfused with 20% formalin in 0.1M phosphate buffer (PB) (pH 7.4) or 4% paraformaldehyde in 0.1M PB(pH 7.4). The brain was removed and coronal or sagittal sections (30µm thick) were made through the ST and the SN for immunocytochemical procedures for glutamic acid decarboxylase, GABA, enkephalin substance P, acetylcholine transferase, somatostatin, tyrosine hydroxylase and BrdU antibodies. In addition, fluorogold (0.02µl) was injected in the ST of the embryo at E14 and E15 and in the SN at E18, E19 and E20 in order to study the time of the establishment of efferent connections. The results indicate there is a difference in 1) the birth dates and the death dates of various neurotransmitter phenotypes, 2) the time of expression of various neurotransmitters, and 3) the time of the establishment of efferent projections for ST and SN neurons. Supported by USPHS grant NS20702 and Human Frontiers Program.

ELECTROPHYSIOLOGAL PROPERTIES OF ACCUMBENS CORE AND SHELL NEURONS. P. O'Donnell\*and A. A. Grace. Dept. Behavioral Neuroscience and Psychiatry, Center for Neuroscience, University of Pittsburgh, Pittsburgh, PA 15260.

The electrophysiological properties of neurons in the core and shell

The electrophysiological properties of neurons in the core and shell regions of the nucleus accumbens were studied using intracellular recording techniques in rat brain slices maintained in vitro. The passive membrane properties of the 49 core cells and the 20 shell neurons studied were overall quite similar, although several significant differences were found. The time constant was faster in shell (6.8±1.5 msec; n=4) than in core neurons (11.2±3.1 msec; n=12). In most accumbens neurons the action potentials evoked by membrane depolarization showed firing-frequency accommodation, and were preceded by a slow Ca\*\*-dependent depolarization that was observed more commonly in core than in shell neurons. Following TTX administration, all-or-none spike-like events resembling high-threshold calcium spikes were observed in both regions, although TTX-insensitive events resembling low-threshold spikes were oberved in core, but not in shell neurons. In addition, synaptic responses (EPSPs) observed following amygdaloid or cortical afferent stimulation in shell neurons were smaller in amplitude (5.3±2.1; n=4 vs. 8.6±3.3 mV; n=12) and exhibited a lower probability of evoking spikes (1/13 vs. 11/28) in comparison to the responses of core neurons to cortical afferent stimulation.

In summary, many of the basic physiological properties of core and shell neurons are similar. However, in each case where differences were noted, such as the differences in time constant, low-threshold spikes, and synaptic responses, the results suggest that the shell neurons may be less excitable in nature. Supported by USPHS MH 45156, MH 42217, and NS 19608.

EFFECTS OF DOPAMINE AGONISTS ON GABA-ACTIVATED INWARD CURRENTS IN MEDIUM SPINY NEURONS OF RAT STRIATUM: A WHOLE CELL VOLTAGE-CLAMP STUDY. J.Y. Chang\*, M.F. Pacheco¹ and D.J. Woodward, Department of Physiology & Pharmacology, Bowman Gray School of Medicine, Winston-Salem, NC 27157; and ¹ CUIB-Univ. de Colima, Colima, Col 28045 Mexico.

The neuronal circuitry in neostriatum includes complex interactions between several neurotransmitters. GABAergic medium spiny neurons (MSN) send an output to other basal ganglia structures to regulate locomotor activities, and has collateral inhibitory connections to other MSNs. This neuron type also receives dense dopaminergic input from the substantia nigra pars compacta. The aim of the present study was to explore possible interactions between dopamine and GABA on MSNs using whole cell voltage-clamp methods. Acutely dissociated MSNs were obtained from the striatum of newborn rats (1-10 days old) after papain treatment (1 mg/ml, 1-2 hrs at 32°C) of the tissue. GABA-activated whole cell currents ( $I_{GABA}$ ) were recorded in MSNs by means of an EPC-9 system under isomolar chloride concentration in the bath and pipette solutions, with  $V_x$ =-55mV. Drugs were applied by pressure ejection from independent pipettes (2 µm tip diameter) positioned 30-60 µm from the neuron being recorded. Brief application (4-5 sec, 1-3 psi, 0.1-1 mM in the pipette) of the dopamine D<sub>1</sub> agonist SKF-38393 inhibited  $I_{GABA}$  (20% suppression or more). The D<sub>1</sub> effect on  $I_{GABA}$  was attenuated by the D<sub>1</sub> antagonist SCH-23390 (1-10 µM) and by the protein kinase inhibitor H-7 (1-3 µM) in the bath solution (higher concentrations of H-7 inhibited both  $I_{GABA}$  and the D<sub>1</sub> agonist effect), and was mimicked by forskoline (3 mM in pipette). The dopamine D<sub>2</sub> agonist quinpirole inhibited  $I_{GABA}$  in the isolated MSN preparation and suggests that modulation of ligand-gated inhibition by GABA may be one action of dopamine. Supported by DA02338 and MH44339 (DJW): DGICSA-SEP and CONACYT (MFP).

A CADMIUM-SENSITIVE VOLTAGE-DEPENDENT CONDUCTANCE IS TRANSIENTLY EXPRESSED DURING DEVELOPMENT IN RAT NEOSTRIATAL NEURONS. F. Trent 1, Z.C. Xu<sup>2</sup>, C.I. Wilson<sup>2</sup>, and J.M. Tepper 1. Aidekman Research Center, Center for Molecular and Behavioral Neuroscience, Rutgers The State University of New Jersey, Newark, NJ, USA 07102 and Department of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, Memphis, TN, USA, 38163<sup>2</sup>.

Intracellular recordings from neostriatal (NS) neurons were obtained in vivo from urethane-anesthetized Sprague-Dawley rat pups from birth (P1) to P40 and in adult males, and in vitro from neonatal brain slices. NS neurons in neonates \$P15 both in vivo and in vitro displayed a transient voltage-sensitive depolarizing response (TDR) evoked by intracellularly applied depolarizing current pulses. The TDR appeared as a positive hump that arose near the onset of applied depolarizing transients. In vivo the TDR activated at potentials more negative than -37.2±1.6 mV (mean ± SEM; n=42). The mean maximal amplitude was 18.1±1.6 mV (n=40) and mean duration was 23±1 ms (n=44). The TDR was observed in 56% of NS neurons in P6-10 neonates (n=73), 47% at P11-15 (n=68), 6.1% at P16-29 (n=49) and was never seen in older animals. In >50% of neurons exhibiting the response, the TDR could be activated by depolarization from rest (-49.1±2 mV; n=45) although conditioning hyperpolarizing pulses (260 ms) increased both its frequency of occurrence and maximum amplitude. Inactivation of the TDR could be achieved by depolarizing prepulses that brought the cell to -40 mV or above. In vitro, the TDR was largely unaffected by TTX (1 µM) and almost completely abolished by cadmium (500 µM) suggesting that it is composed of an inward calcium current. In vivo, 59% of the neurons from P6-15 pups that displayed the TDR also exhibited a prominent T-current-like depolarizing response following the offset of hyperpolarizing current pulses that was never seen in older animals. Supported by MH45286 and NS26473.

INFLUENCE OF VENTRAL PALLIDUM ON RAT DORSAL THALAMIC NUCLEUS NEURONS. A. Lavin\* & A.A. Grace. Depts. Behavioral Neuroscience & Psychiatry, Univ. Pittsburgh, Pittsburgh, PA 15260.

The basal ganglia is thought to regulate motor behavior and affective states by its projections to the thalamus. In these experiments we used in vivo intracellular recording in rats to analyze the spontaneous activity and the response of dorsal thalamic nucleus neurons to electrical stimulation of the ventral pallidum (VP). A total of 20 neurons were recorded in the ventromedial (VM) and ventro-posterior medial (VPM) nuclei of the thalamus. Most of the neurons recorded (11/20) exhibited a spontaneous oscillatory burst firing pattern, with the oscillations ocurring at frequency of 6.2±0.6 Hz. Furthermore, four of the cells exhibited slow hyperpolarizing waves (0.9-1.5 Hz, 440-640 msec in duration) resembling spindle activity. In addition, 8 neurons had spontaneously ocurring ipsps which occured at 4-6 Hz and consisted of fast and slow components. In recordings made with KCl-filled electrodes, only the first component of the ipsp was reversed to a depolarization. VP stimulation evoked 3 responses in thalamic neurons: 1) 55% of the neurons (11/20) responded with an ipsp (latency  $6.0\pm3.0$  msec; amplitude  $9.5\pm6.1$  mV); 2) 25% (5/20) responded with an epsp (6.5 $\pm3.7$  msec, amplitude  $4.0\pm1.2$  mV); and 3) 15% (3/20) showed no response. Furthermore, in 4/5 cells that respond to VP stimulation with epsps, continued stimulation caused the response to slowly change from an epsp to an ipsp (ipsp latency 8.3±2.1 msec; amplitude 5.6±1.1 mV). In addition, in 3 neurons located in the laterodorsal thalamic nucleus (LDVL), VP stimulation had no discernable effect. Given the anatomy of this system a likely source for the spontaneous and evoked potentials could be the reticular nucleus of the thalamus

CHRONIC ENSEMBLE NEURON RECORDINGS IN RAT NEOSTRIATUM AFTER 6-OHDA: NETWORK PROPERTIES. <u>S.F. Sawyer\*, A.B. Kirillov, C.D. Myre and D.J. Woodward.</u> Department of Physiology and Pharmacology, Bowman Gray School of Medicine, Winston-Salem, NC 27157

The aim of this work was to employ extracellular recordings of multiple

The aim of this work was to employ extracellular recordings of multiple single neurons in the neostriatum to examine altered local activity and network interactions in normal rats and after unilateral destruction of the dopaminergic nigrostriatal projection from intracerebral injections of 6-OHDA. We report here indications of inhibitory, reciprocal synaptic interactions between neostriatal neurons in awake, behaving rats. As many as 24 neostriatal neurons were recorded concurrently from chronically implanted arrays of microwires (200-300 µm separation between adjacent microwires). Functional interactions between neurons were assessed with cross-correlation and ensemble analysis. Correlated spike activity of neuronal subpopulations were evaluated with graphical computer animations over short (seconds) and long (minutes) time scales. The spatial domain of cross-correlation interactions was restricted to neighboring microwires (200-500 µm range), and were most common between neurons recorded from the same microwire. These interactions were typically inhibitory and constant across experimental sessions. Administration of dopaminergic drugs to 6-OHDA-treated animals alterated spike activity that coincided with the time course of circling behaviors, and increased the number of cross-correlated neurons. Dopaminergic agonists often biased interactions such that one neuron in a pair of functionally connected neurons increased its spike activity whereas the other neuron was inhibited, the latter presumably due in part to increased inhibitory drive from recurrent inhibitory collateral connections from the active neuron. We interpret these reciprocal inhibitory events as due to the local circuit switching phenomena predicted by computer simulations of working memory properties of neostriatal circuits. Supported by NIDA 2338 and NIMH 44337.

## 294.14

POSTNATAL CHANGES IN NEOSTRIATAL SYNAPTIC INPUT. N.A. Sharpe. F. Trent, and I.M. Tepper. Aidekman Research Center, Center for Molecular and Behavioral Neuroscience, Rutgers, The State University of New Jersey, Newark, NJ, USA 07102.

Anterograde labeling of corticostriatal fibers with biocytin was used to characterize corticostriatal afferents in adult and neonatal rats. In adult rats (>8 weeks old) the majority of corticostriatal boutons terminated on the heads of dendritic spines (88%). The remaining corticostriatal synapses were either axodendritic or axosomatic. Virtually all labeled boutons that formed axospinous synapses contained small (40 nm) round vesicles and formed axymmetric synapses. The mean synaptic cleft width was 224±25 nm (mean±S.D.).

In neonatal (P14) rats, many vesicle-containing labeled profiles were observed, but relatively few labeled synapses were found. These profiles appeared significantly less densely packed with vesicles than in adults. In addition, the total synaptic density of the neostriatum was less at P14, (4.4±1.5 synapses/100  $\mu m^2$ ) than in adults (9.7±2.9 synapses/100  $\mu m^2$ ), t=4.97, p<0.001. Although most of the labeled asymmetric synapses observed in adults terminated on dendritic spines, in the neonates only 21% of all asymmetric synapses ended on spines while 72% terminated on dendritic shafts. The absolute density of axodendritic synapses did not differ between neonates (3.2 synapses/100  $\mu m^2$ ) and adults (3.0 synapses/100  $\mu m^2$ ). These data indicate that by P14, the synaptic neuropil of neostriatum is not yet fully mature, consistent with previous electrophysiological studies.

Supported by MH 45286.

MUSCARINIC MODULATION OF CALCIUM CURRENTS IN ACUTELY DISSOCIATED RAT NEOSTRIATAL NEURONS. A. Howe\* and D.J. Surmeier, Dept. of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, Memphis, TN 38163.

Although important clinically, the role of the cholinergic interneuron in regulating the excitability of other neurons in the neostriatum is unclear. Previous studies in other tissues have indicated that calcium currents are modulated by cholinergic agonists acting at muscarinic receptors. Using the whole-cell voltage-clamp recording technique we have shown that calcium currents in neostriatal neurons are modulated by muscarinic agonists.

Neurons from the neostriatum of young adult rats (3-5 wks postnatal) were dissociated using techniques previously described by our group. In brief, striata were dissected from 400 µm slices. Striata were then incubated in oxygenated saline containing pronase E (1.5 mg/ml) at 32 degrees C. After a 30 minute incubation, tissue was washed and mechanically dissociated in low calcium. (200 µM) Whole-cell recordings employed conventional techniques at room temperature.

Muscarine (500 nM) and/or carbachol (50 μM) application produced a significant inhibition (>20%) of calcium current in most neostriatal neurons studied (>95%, n>100). The modulation was antagonized by atropine (1 μM) as well as by pirenzipine (1 μM). Application of carbachol in the presence of GTPγS resulted in irreversible modulation while preincubation with pertussis toxin (PTX) blocked the modulation indicating the involvement of a PTX sensitive G-protein. The modulated component could be blocked with either dihydropyridines or ω-conotoxin. This work was supported by USPHS grant NS 28889.

### 294.17

VOLTAGE-CLAMP ANALYSIS OF BURST FIRING INDUCED BY N-METHYL-D-ASPARTATE IN RAT MESENCEPHALIC DOPAMINE NEURONS IN VITRO Vincent Seutin, Steven W. Johnson and R. Alan North\*. Vollum Institute, Oregon Health Sciences University, Portland, OR 97201.

Intracellular recordings from dopamine neurons in vitro showed that N-methyl-D-aspartate (NMDA) induces bursts of action potentials separated by large hyperpolarizations (Johnson et al., Soc. Neurosci. Abstr. 1992). Single-electrode voltage-clamp experiments showed that NMDA (20 µM) caused an inward current (200-300 pA) at -60 mV. In NMDA, voltage steps from -60 to -40 mV for 1 s were followed by an outward tail current (100-300 pA) that declined over 1 - 3 s. This was blocked by APV (50 μM). The tail current was unaffected by K+ channel blockers and was not blocked in Ca2+-free solutions. It was blocked in solutions with no added  $Mg^{2+}$  and much reduced in a low (20% of normal) Na+ concentration. The tail current was increased by a high K+ concentration (10.5 mM) and blocked by a low K+ concentration (0.5 mM). It was also blocked by ouabain (2  $\mu$ M), DNP (0.1 mM) and glucose-free solutions. We suggest that this outward current corresponds to the hyperpolarization between bursts of action potentials, and that it is due to activation of an electrogenic sodium pump.

#### 294.16

DOPAMINE RECEPTOR AGONISTS ALTER RESPONSES EVOKED BY EXCITATORY AMINO ACIDS IN NEOSTRIATUM AND NEOCORTEX.

C. Cepeda, Z. Radisavljevic, N.A. Buchwald and M.S. Levine. Mental Retardation Research Center, UCLA, Los Angeles, CA 90024

Our laboratory has demonstrated that dopamine (DA) potentiates responses evoked by N-methyl-D-aspartate (NMDA) but attenuates responses evoked by glutamate or Alpha-amino-3-hydroxy-5-methyl-4-isoxazolpropionicacid (AMPA) in neostriatum or neocortex. The present study was designed to assess the contribution of specific DA receptor subtypes (D<sub>1</sub> and D<sub>2</sub>) to this differential modulation. In slices of rat neostriatum or neocortex, excitatory responses were evoked by iontophoretic application of NMDA (0.1M, pH 8) or AMPA (0.1M, pH 8) within 100-200 µm of the intracellularly recorded neuron. Selective DA receptor agonists SKF-38393 (D<sub>1</sub>) or quinpirole (D<sub>2</sub>) were bath (SKF-38393, 2-25  $\mu$ M; quinpirole, 1-25  $\mu$ M) or iontophoretically applied. SKF-38393 consistently potentiated excitatory responses induced by NMDA in neostriatum or neocortex in a dose dependent manner (11/11 cells). The amplitude of the NMDA-induced depolarization was larger, the frequency of occurrence of action potentials increased and the response had a longer duration. Excitatory responses induced by AMPA were also potentiated by the D<sub>1</sub> agonist (5/7 cells, 2 did not respond). The effective threshold concentration of the D<sub>1</sub> agonist was 5  $\mu$ M. In contrast, quinpirole attenuated NMDA-induced responses in a dose-dependent manner (6/8 cells, 2 did not respond). The amplitude of the depolarization was reduced and the frequency of occurrence of action potentials decreased. The effective threshold concentration of the  $D_2$  agonist was 1  $\mu M$ . These findings indicate that activation of  $D_1$  or  $D_2$  receptors has opposing effects on responses evoked by excitatory amino acid receptor agonists. They indicate further that effects of DA release may depend upon relative proportions of  $D_1$  and  $D_2$  receptors activated. (Supported by USPHS HD 05958 and AG 7462).

## 294.18

BURST FIRING INDUCED BY N-METHYL-D-ASPARTATE REQUIRES ACTIVATION OF AN ELECTROGENIC ION PUMP IN RAT DOPAMINE NEURONS. S.W. Johnson', V. Seutin and R. Alan North. Vollum Institute, Oregon Health Sciences University, Portland OR 97201.

Dopamine cells fire in bursts in vivo, but with single regularlyspaced action potentials in vitro. Using intracellular recording from midbrain slice, N-methyl-D-aspartate (NMDA; 10 - 30 μM) converted single-spike firing to burst firing in about 90% of neurons. Burst firing consisted of 3 - 20 spikes followed by an inter-burst hyperpolarization of 5 - 30 mV. Tetrodotoxin blocked action potentials but did not block rhythmic hyperpolarizations which underlie burst firing. NMDA receptor activation was required because burst firing produced by NMDA, aspartate (500 µM), or focal electrical stimulation was blocked by APV (50  $\mu$ M) but not by CNQX (10  $\mu$ M), and because kainate (1 - 10  $\mu$ M) and quisqualate  $(1-10~\mu M)$  did not cause bursts. Burst firing was blocked by solutions containing no-added Mg<sup>2+</sup>, low Na<sup>+</sup> (20 mM Na+, 126 mM choline substitution), 0.5 mM K+, no-added glucose, ouabain (2 - 3  $\mu$ M), or dinitrophenol (100  $\mu$ M). It was not blocked by intracellular BAPTA or by solutions containing no-added Ca<sup>2+</sup>. Apamin (0.1 - 1  $\mu$ M) potentiated burst firing. It is concluded that NMDA-induced burst firing requires activation of an electrogenic energy-dependent Na+/K+ ion pump.

## OCULOMOTOR SYSTEM: SACCADES

## 295.1

A MODEL FOR 3-DIMENSIONAL EYE-HEAD SACCADES. <u>D Tweed\*</u>, <u>B Glenn</u>, <u>T Vilis</u>. Depts of Physiology and Ophthalmology, Univ of Western Ontario, London, Canada, N6A 5C1.

Eye and head together rotate with 6 degrees of freedom, while gaze direction has just 2. Thus there is a (6 - 2 =) 4-D set of eye-head configurations compatible with any given gaze direction. We present flow diagrams, and supporting data from 6 human subjects, for a feedback model of eye-head saccades with the following features: 1. Eye and head are not driven toward the nearest configuration compatible with the desired gaze direction, but to particular positions fitting additional constraints -- Donders' laws of eye in head and head in space - i.e. eye and head are each restricted to 2 degrees of freedom. 2. There is in general no Donders' law of eye in space, but the eye and head adopt configurations that approximate such a constraint for most gaze shifts. 3. The head is driven not by gaze error but by head position error alone, with no contribution from eye position signals.

4. The eye is driven toward a desired orientation in space, not in the head. 5. However, the eye position error signal saturates so as not to drive the eye to its mechanical limits in the orbit. In 1-D, saturation simply involves clipping any oversized signals, but 3-D saturation can take many forms. A saturation mechanism that allows eye in space to approach its target value as closely as possible while keeping eye in head within limits predicts transient departures from Donders' law of eye in head and 2 distinct patterns of curvature that are observed in 3-D eye in space trajectories. 6. The VOR is shut off in the direction of current eye in space error; we show that this feature would allow even misguided head movements to carry the gaze line toward the target.

## 295.2

EFFECTS OF TEMPORAL CONTEXT (CONDITIONAL PROBABILITY)
ON SACCADE LATENCY IN MACAQUE. D. Hans, F. Tu and J. Schall.

Department of Psychology, Vanderbilt University, Nashville, TN 37240
The influence of temporal predictability on saccade latency (SL) was investigated in a visual tracking task in Macaca mulatta. Fixation of a yellow spot was followed by target presentation (4 positions, 10° ecc.). Following a foreperiod (FP), a trigger signal (TS) was given by a change in the color of the fixspot: green for go (87% of trials), red for nogo. The temporal predictability of the TS was manipulated. Blocks of trials were run with constant FPs (cFP condition, 0 to 1000 ms in 50 ms steps), with FPs sampled equally from a range (rectangular distribution, FPP condition, 0-500 or 0-1000 ms) or with decreasing likelihood of longer times (exponential distribution eFP condition).

Variation of SL could be accounted for by the conditional probability of TS. With the most predictable TS (cFP condition) many anticipatory saccades (SL < 100 ms) were observed; however, mean SL of nonanticipatory saccades was constant across FPs. With a less predictable TS (rFP condition) numerous anticipatory saccades were observed near the end of the FP. Mean SL of nonanticipatory saccades was greater than that observed in the cFP condition, but mean SL decreased with FP. The relation of SL to FP in the rFP condition scaled according to the range of FPs used. With the least predictable TS (cFP condition) the incidence of anticipatory saccades was lowest. Mean SL following short FPs was equal to that observed in the cFP condition, and following an initial rapid decline in SL, there was no further reduction in SL with FP.

SL following a particular FP depends on the context within which that FP occurs. Using this manipulation, neurons responsible for regulating saccade initiation can be identified by their sensitivity to the conditional probability of events. (EY08890, McDonnell-Pew and Sloan Foundation)

TWO CLASSES OF CELLS WITH SACCADE-RELATED ACTIVITY IN THE MONKEY SUPERIOR COLLICULUS. D. P. Munoz<sup>41,2</sup> and R. H. Wurtz<sup>1</sup>. (1) Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD, USA 20892; (2) MRC Group in Sensory-Motor Physiology, Queen's University, Kingston, Ontario, Canada K7L 3N6.

We studied saccade-related cells in the deeper layers of the alert rhesus monkey superior colliculus (SC) to see if we could identify a "moving hill" of activity as reported in the cat (Munoz et al. J. Neurophysiol. 66: 1642). We identified two populations of saccade-related cells. Burst cells, located 1.2 - 2.0 mm below the dorsal surface of the SC, discharged high frequency bursts of action potentials immediately prior to the initiation of saccades of a specific amplitude and direction that defined a movement field and had almost no preparatory or long-lead activity before the saccade. Preparatory cells, found 1.5 - 2.5 mm below the dorsal surface of the SC, had anticipatory discharges in addition to saccade-related bursts. Preparatory cells had movement fields with no distal border; they were active for all saccades greater than their optimal amplitude. In the preparatory cell layer, prior to saccade initiation, activity built up at a specific locus on the motor map coding the amplitude and direction of the impending movement. Once the saccade began, there was a continuous change in the spatial distribution of activity in this population across the motor map. Preparatory cells located progressively more rostral to the initially active zone were activated sequentially until fixation cells, located in the rostral pole, were activated and the saccade terminated. In the burst cell population, activity also built up at a specific secare terminate. In the outside population, activity associated as a specific locus on the SC motor map immediately prior to saccade initiation and then diminished as the saccade was executed; there was no change in the spatial distribution of activity. In summary, of the two classes of saccade cells in the monkey SC, the preparatory cells have activity most similar to the "moving hill" cells seen in the cat SC while the burst cells show no such activity.

INITIAL EYE POSITION DEPENDENCE OF SACCADES ELICITED BY MICROSTIMULATION IN CAUDAL NUCLEUS RETICULARIS TEGMENTI PONTIS. T. Yamada, D.A. Suzuki\*, K.F. Betelak, and R.D. Yee. Dept. of Ophthalmology, Indiana Univ. School of Medicine, Indianapolis, IN.

Indianapolis, IN.

Microstimulation and lidocaine "lesion" results complement single unit recording in implicating a role for caudal nucleus reticularis tegmenti pontis (cNRTP) in regulating saccadic eye movements. µstimulation was delivered, via the recording µelectrode, where saccade-related unit activity identified cNRTP. Visually guided saccades were elicited with a backprojected, 0.25° target jumped to various eccentric positions. Biphasic µstimulation pulses: 0.3 msec; 100-800 Hz. Train durations were 15-2000 msec and current intensities ranged from 10-60 µA.

The elicited eye movements (EMs) were ipsilateral and similar to spontaneous saccades with respect to the relationship between peak eye

spontaneous saccades with respect to the relationship between peak eye velocity and amplitude. Both the latencies and amplitudes of evoked velocity and amplitude. Both the latencies and amplitudes of evoked EMs decreased with increases in µstimulus frequency. The amplitude of elicited EMs decreased for more ipsilateral, initial eye positions. These saccades were not, however, goal directed. For some NRTP sites, saccades to remembered target locations were not compensatory when preceded by evoked EMs. Injection of 1 µl, 4% lidocaine into the cNRTP resulted in hypometric ipsilateral, visually-guided saccades. Our results resemble those obtained from cMRF more than SC.

Initial eye position dependence of evoked "pursuit-like" EMs has been observed with ustimulation in rostral NRTP (1991). Similar dependence of saccades evoked with µstimulation in cNRTP would implicate initial eye position dependence as a basic function of NRTP in regulating EMs. Support: RPB & NIH (EY09082) grants; Grayson Fellowship.

TECTO-RETICULO-SPINAL NEURONS CONTRIBUTE TO THE GENERATION OF SLOW POST-SACCADIC EYE MOVEMENTS IN THE CAT. E. Olivier \*. A. Grantvn, M. Chat and A. Berthoz, Laboratoire de Physiologie Neurosensorielle, C.N.R.S., Paris, France.

Motor correlates of post-saccadic activity of identified tecto-reticulospinal neurons (TRSN) were studied in alert, head-fixed cats. Recordings were made from tectal axons in the pons. Some axons were injected with HRP to reveal terminal patterns in the periabducens region.

We have observed that visually triggered saccades are often followed by slow eye movements (post-saccadic drifts, PSD) approximately in the direction of preceding saccades. PSD have average mean velocity of 15 ± 4.3 deg/s and mean duration of 104 ± 50 ms. Their amplitude (mean 1.2 ± 0.6 deg) can reach 4-8 deg and contribute substantially to the total gaze shift. The duration of PSD is positively correlated (r=.72-.99) with the duration of phasic neck EMG increments reflecting an intended head movement. When saccades are followed by PSD, especially in combination with neck muscle contractions, TRSN bursts have longer durations. This is due to a slower decay of the firing rate after the saccade-related part of the burst. In such cases, a low frequency discharge may persist even beyond the termination of PSD. TRSN bursts have longer durations. This remination densities in reticular regions containing EBN, IBN, "neck bursters" and phasic-sustained "eye-neck" reticulo-spinal neurons (EN-RSN). In the abducens nucleus, densities of terminations given by TRSN collaterals correspond to only 60% of those reported for EN-RSN.

We suggest that prolonged TRSN discharges are at the origin of slow orienting eye movements of the cat. Most likely, net modulation of coular motoneurons is induced by a cascade connection "TRSN - EN-RSN" to the abducens nucleus. This connection ensures also synergic activation of neck motoneurons, and apparently does not depend on the "pulse" signal

the abducens nucleus. This connection ensures also synergic activation of neck motoneurons, and apparently does not depend on the "pulse" signal of the saccadic generator

IMPENDING SACCADES SHIFT VISUAL RECEPTIVE FIELDS IN SELECTED INTERMEDIATE SUPERIOR COLLICULAR NEURONS. M. F. Walker† and M. E. Goldberg\*. Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892. †HHMI-NIH Research Scholar. Visual neurons in the lateral intraparietal area (LIP) of the rhesus monkey use information about an impending saccade to shift transiently their retinal receptive fields to compensate for anticipated changes in the visual scene. When a saccade will bring a visual stimulus into their receptive fields, some LIP neurons begin to fire before the saccade is executed, while the stimulus still lies outside the receptive field. By this mechanism the parietal cortex updates its representation of visual space at the time of an eye movement, allowing spatially accurate processing of visual information without waiting for new retinal input. LIP projects strongly to the intermediate layers of the superior colliculus; therefore, we have sought to identify and characterize saccade-related receptive field shifts in visually responsive collicular cells.

We recorded from neurons in the superficial and intermediate layers of the superior colliculus; therefore, we have sought to identify and characterize saccade-related receptive field shifts in visually responsive collicular cells.

We recorded from neurons in the superficial and intermediate layers of the superior colliculus; therefore we have superior colliculus; therefore we have superior colliculus; therefore we have superior colliculus; therefore we have superior colliculus; therefore we have superior colliculus; therefore we have superior colliculus are ceptive fields at the time of a saccade. This was observed even when the stimulus was in the receptive field in the fire parameter of a subsequent saccade. The response of most cells began only after the saccade had been completed, when the stimulus was in the receptive field in LIP almost all cells have such memory trace responses. Cells with predictive shifts tended to be locate

SACCADIC EYE MOVEMENTS TO BRIEFLY

SACCADIC EYE MOVEMENTS TO BRIFTLY FLASHED TARGETS. C. S. Barnes and P.E.Hallett\*. Dept. of Physiology, Medical Sciences Building, University of Toronto, Toronto, Ontario, Canada M5S 1A8.

An interesting feature of the study of Hallett & Lightstone (1976a) was the occurrence of normal latency, normal accuracy saccades to small targets that were briefly flashed in darkness. We have sought to replicate their findings and targets that were briefly flashed in darkness. We have sought to replicate their findings, and those of Doma & Hallett (1988) who developed a model for the latency of saccades to variably intense continuously exposed targets. Our experiments have used yellow-green LED targets at 16 horizontal positions, in the range 2.0-5.5 deg to left and right of centre, in darkness. Up to 5 subjects and 5 luminous intensities have been examined for exposure durations mainly in the examined for exposure durations mainly in the range 1 to 200 msec. Pupils have been fixed in control experiments. If the duration is made sufficiently brief, latency increases, accuracy decreases, or the saccade may fail to occur. This "critical duration" increases as the luminous intensity of the target is reduced towards the cone threshold. We discuss the plausibility of modelling saccadic latency in terms of a "waiting time for a threshold number of photons" and a

PET ACTIVATIONS FOR VISUAL AND MEMORY SACCADES. F.M. Miezirf, M.Corbetta, G.L.Webb, M.E.Raichle and S.E.Petersen. Dept.Neurol. & Neurol.Surg., McDonnell Ctr. for Studies of Higher Brain Function, Wash. Univ. Sch. of Med., St.Louis, MO 63110.

Normal volunteers were scanned with PET activation methodology during the execution of visually or memory-guided saccadic eye movements. In the visually-guided task (VG), a saccade was triggered on each trial by the onset of a briefly flashed LED located 15° peripherally at six random locations. In the memory-guided tasks, saccaues were triggered by the offset of a fixation point LED, and directed toward targets which had been presented 5 sec (long memory delay, LMD) or 500 ms (short memory delay, SMD) before. Two control tasks were also run in which fixation was maintained on the central LED with or without simultaneous peripheral stimulation. The VG task activated: 1. bilateral parietal-occipital cortex, including cuneus, precuneus, lateral posterior parietal; 2. bilateral FEF; 3. SEF & anterior cingulate; 4. bilateral thalamus. Also, an enhancement was observed in primary visual cortex and/or lingual-fusiform gyrus. The same regions were similarly activated by both memory tasks. When the memory component was isolated by subtracting the SMD from the LMD condition, significant responses were observed in: 1. left putamen/caudatus; 2. ventral anterior cingulate/caudatus; 3. left frontal cortex, near precentral sulcus. These findings are consistent with single unit recording in monkey in posterior parietal and frontal cortex related to saccade generation, and in frontal cortex and basal ganglia related to spatial delayed activity. However, the superior parietal localization for eye-movement and spatial attention (Miezin et al., ARVO 1991) suggest differences in the specific organization of the posterior parietal cortex between humans and monkeys.

A COMPUTATIONAL MODEL FOR MODIFIED SACCADE TRAJECTORIES.

A COMPUTATIONAL MODEL FOR MODIFIED SACCADE TRAJECTORIES.

E.A. Henis<sup>1</sup>, T.R. Stanford<sup>1</sup>, and D.L. Sparks<sup>2</sup>. 1. Inst. for Research in Cognitive Science/CIS, 2. Dept. of Psych., U. of Pennsylvania, Phila. PA 19104.

An earlier study examined the effects of available processing time on the metrics of saccades to a visual goal (Stanford et al., Soc. Neurosci. Abstr. 16:901, 1990). Briefly, subjects synchronized saccade onset to the fourth of a series of equally spaced tones. Targets were presented randomly at one of two equally probable locations, and the processing time was controlled by presenting the target at various times prior to movement onset. When the interval between target presentation and saccade onset was > 175 ms, the resulting saccades were directed toward the target. For shorter time intervals, saccades were typically directed to a point between the two possible locations, followed by a separate correction. Occasionally, however, saccade direction changed in mid-flight resulting in a continuous trajectory that curved toward possible locations, followed by a separate correction. Occasionally, however, saccade direction changed in mid-flight, resulting in a continuous trajectory that curved toward the target. In this study, an explicit model to account for these curved trajectories was quantitatively tested. The horizontal and vertical components of the curved trajectories were each simulated by the addition of the corresponding components of two time-shifted elemental trajectories: one from the initial eye position to an intermediate location, and a second one from that location to the final eye position. The components were then combined to simulate the entire modified trajectory. The

The components were then combined to simulate the entire modified trajectory. In kinematic details (paths and velocity profiles) of predicted motions were in good agreement with the measured ones for a broad spectrum of curved saccades. The possibility that curved saccades are generated via the superposition of two simpler saccades has been previously proposed (Evinger & Fuchs, J. Physiology 285:209-229, 1978). Our results provide quantitative support for this hypothesis. Using this scheme the oculomotor system might generate prompt responses to novel stimuli. According to this scheme, each elemental movement is independently stimuli. According to this scheme, each elemental movement is independently generated in a similar manner as a simple saccade to a single goal. An analogous mechanism has been shown to account for curved hand trajectories (Henis & Flash, In: Neural Information Processing Systems 4, Morgann-Kaufman, 1992). Thus, our results suggest similarities in the mechanisms underlying the generation of eye and hand motions. (Support: NIH EY01189 & F32-EY06320).

SACCADIC BURSTS OF ABDUCENS NEURONS DO NOT FULLY COMPENSATE FOR ORBITAL NONLINEARITIES. C. Siebold, L. Ling, and A. F. Fuchs\*, Regional Primate Research Center, and Departments of Psychology and Physiology and Biophysics, University of Washington, Seattle, WA 98195

Within the oculomotor range, the metrics of saccades less than twenty deg generally do not depend on where in the orbit the movement is initiated. Therefore, the burst of ocular motoneurons during saccades may be adjusted to compensate for orbital non-linearities. We examined this issue by recording from abducens neurons during saccades of constant amplitude initiated from different eye positions. We recorded from over 40 neurons in the abducens nucleus of 3 monkeys. At

orbital positions below the position threshold the peak firing frequency usually increased with initial position. For saccades beyond threshold the peak firing rate often saturated. The saccadic amplitude for which peak burst frequency saturated varied for different cells, but there was usually no saturation for saccades less than 5°. Even for saccades < 5° the slope of the relation between peak firing rate and eye starting position never exceded the slope of the relation between steady firing rate and eye position during fixation. Therefore, the size of the motoneuron burst does not correct for orbital non-linearities.

For saccades of the same amplitude, the number of spikes in the burst increased with initial position even if peak burst rate was saturated. Similarly burst duration increased although saccade duration did not. The longer burst durations occurred because burst lead time increased as saccades were initiated more in the unit's ondirection even if the unit's threshold lay outside the oculomotor range.

For saccades with different amplitudes, the peak burst frequency is determined by

the saccadic end position. Thus the burst is constant for all saccades reaching the same position in the orbit. This result is consistent with Collins' measurements of

tension in the extra-ocular muscles during saccades.

DYNAMICS OF SUPERIOR COLLICULUS BURSTERS OBSERVED WITH THE USE OF A SHORT-LATENCY AVERAGING SACCADE PARADIGM J.A.Edelman, E.L.Keller\*, and K.Arai. Smith-Kettlewell Eye Research Institute, San Francisco, CA 94115 and University of California, Berkeley, CA 94720 and Mitsubishi Kasei Corp, Yokohama 227, Japan

Van Opstal and Van Gisbergen (Exp. Brain Res., 1990) demonstrated that the superior colliculus (SC) participates in generating averaging saccades in monkey, but could not determine if the discharge of collicular burst cells unambiguously coded the metrics of these saccades. We wished to quantify how the SC codes averaging saccades in a short-reaction-time task that did not require target selection. In 1/3 of our trials, two targets separated by 45 deg were presented at locations neighboring the center of the cell's motor field. Single targets were presented in 2/3of the trials to discourage formation of a strategy. Monkeys were rewarded for a short-latency saccade to a window surrounding the target configuration. All SC cells studied burst before and during both one-target and averaging saccades to the same location, corroborating the previous report. However, numerous spatio-temporal differences were apparent. Almost all cells fired less for averaging saccades in a 30ms prelude to the main burst. In approximately half the cells peak firing rate was also smaller. Some cells showed a late burst following the main burst at a time when discharge during normal saccades was rapidly declining. These temporal differences could not be accounted for by averaging saccade velocity, which was similar to that of one-target saccades. Distributions of 1-target and averaging saccade activity within the motor field were fit separately by a neural network multivariate technique. Distributions computed for the averaging saccades were generally more flat with a smaller peak. These data suggest that programming of saccadic eye movements, as reflected in collicular discharge, is not complete before the SC motor burst, and that SC motor-related activity is dependent on target configuration.

SACCADE-RELATED BURST CELLS OF THE CENTRAL MESENCEPHALIC RETICULAR FORMATION (cMRF) ASSOCIATED WITH DYNAMIC MOTOR ERROR. D. M. Waitzman\* University of Connecticut, 263 Farmington Ave, Farmington, CT, 06030, USA.

Recent experiments have shown a linear correlation between the decline in burst discharge and dynamic motor error in a subpopulation of saccade related burst neurons (SRBNs) in the superior colliculus (SC) (Waitzman et al., J. Neurophysiol., 66:1716-37, 1991). Since reticulotectal neurons (Moschovakis et. al., J. Neurophysiol., 60:263-302) in the cMRF represent a significant input into the SC, we have now examined the discharge properties of 17 SRBNs in the cMRF of one monkey during visually guided saccades. At least two groups are noted: one whose discharge is cut-off with the end of contralaterally directed visually guided saccades (clipped cells N=11) and another whose discharge continues for up to 50 msec following the end of the eye movement (partially clipped, N=6). Many neurons in the cMRF have a high spontaneous level of activity while the monkey is actively fixating. This discharge level is inhibited during saccades to the ipsilateral side and some of these neurons return to their background rate of activity prior to the end of the eye movement. Since cMRF neurons project to both ipsi- and contralateral SC, the difference burst was calculated by subtracting the discharge during ipsilateral movements from that generated during contralateral saccades. difference burst is closely correlated with dynamic motor error for both clipped and partially clipped cells. These results are consistent with the hypothesis that the SRBNs of the SC receive a differential input from cells in the cMRF and this discharge encodes dynamic motor error.

AUDITORY HEAD SACCADIC GAIN. <u>James H. Fuller</u>

Dept. Oral Anatomy, Univ. of <u>Illinois</u>, <u>Chicago</u> IL 60612

Nine young adult humans executed auditory-evoked

eye-head gaze shifts in a task identical that previously reported for visual stimuli (Soc Neurosci.: 861, 1991); the two tasks were interleaved. The non-aligned mode was a standard single-step gaze shift between fixation and target speakers; in the head-aligned mode the jump started with the head and fixation speaker aligned. Fixation/target speakers varied in position relative to the midline; amplitudes were 40, 60, and 80 deg.

The head velocity profiles, target/gain patterns, etc., showed gaze shifts were similarly executed in both tasks. Non-aligned gains in all subjects were elevated (vis, 0.27; aud, 0.42); like eye velocity, peak head velocity was slower. The head-aligned gains were lower in head-movers and higher in non-movers. Several instances of group reversal (head-mover exhibits non-mover traits, and vice-versa), and group trends showed a homogenization of head movement propensity; head-movers develop more midline attraction and non-movers more spatial head aiming. It is proposed that there is a wide continuum in head movement control: ideal head-movers use extrinsic (earth-fixed), and non-movers use intrinsic (e.g., body/head-oriented) coordinate reference frames; head-based auditory sensory acquisition and/or central mechanisms reduce the continuum.

## 295 14

IS THERE AN INFLUENCE OF SLEEP DEPRIVATION ON SACCADIC EYE MOVEMENTS?

B. Guldin, A. Lupp, D. Gross and T. Duka (SPON.: European Neuroscience Association)

CN Humanpharmacology, Schering AG, Müllerstr. 170-178, W-1000 Berlin 65, Germany

Sedating as well as stimulating drugs influence the peak velocity and duration of saccadic eye movements of a given amplitude, i. e. change the rise of the main sequence. In order to investigate the specificity of these findings the influence of sleep deprivation representing a rather unspecific precondition was examined.

Eye movements were measured in twelve healthy male volunteers using infrared reflection technique. Horizontal saccades from 5 to 20 degs. were elicited using a 0.3 deg. laser spot. Direction, frequency and amplitude changes occurred in pseudorandom order. Eye movements were registered every two hours between 8 am and 8 pm after a night of sleep deprivation as well as after a night's sleep.

Preliminary results reveal a substantial decrease in the slope of the main sequence after sleep deprivation. Thus, the reduced peak velocity of saccades after application of sedating drugs may be rather due to the reduced vigilance than to specific actions on the paramedian pontine reticular formation.

INCREASED VERGENCE SPEED DURING COMBINED SACCADIC AND VERGENCE EYE MOVEMENTS IN MONKEYS IS CENTRALLY PROGRAMMED. W. M. King\*, University of Rochester Medical Center and Center for Visual Science, Rochester NY 14642

Previous reports have established that the speed of vergence eye movements ans and monkeys is augmented when vergence and saccades occur in combination. To determine if the increase in vergence speed during saccades is centrally programmed, single unit activity from medial rectus motoneurons and premotor vergence cells was recorded in alert monkeys. Eye movements were measured binocularly using search coils. Monkeys were trained to make eye movements between near and far targets (2-18 deg vergence) that were offset horizontally or vertically (up to  $\pm 20$  deg) from each other. Peak divergence or convergence speed was always greater during gaze shifts that included saccades (in any direction) compared to those that did not include saccades. Vergence eye movements with saccades appeared to be a combination of a fast component superimposed on a slow component with the temporal characteristics of classically described vergence. The fast component was always associated with saccades, and peak vergence speed occurred in synchrony with peak saccade speed.

Motoneurons and vergence neurons exhibited changes in discharge that correlated with saccade-related increases in vergence speed. Changes in vergence cell discharge led changes in vergence speed by at least 30 msec. Some vergence cells exhibited high sensitivity for vergence speed but not position. discharged weakly with slow vergence changes in the absence of saccades but vigorously for fast vergence changes that were coupled with saccades. These data suggest that the augmented vergence speeds associated with gaze shifts that include saccades are centrally programmed in the brainstem.

The Responses of Quasi-Visual (QV) Cells of the Superior Colliclus (SC) During Target Presentation, Movement Specification and Movement Initiation. P. W. Glimcher' and D. L. Sparks, Department of Psychology, University of Pennsylvania, Philadelphia, PA 19104.

The responses of collicular QV cells (Mays & Sparks). Neurophysiol. 45: 207) were examined in movement selection tasks which spatially and temporally segregate movement selection from movement initiation and visual target presentation. Rhesus monkeys were trained to fixate a central yellow LED. While fixation was maintained, two eccentric yellow LEDs were extinguished. Four hundred to 600 msec tater the fixation LED served as insulated QV cell. After 1000 to 1500 msec the two eccentric LEDs were extinguished. Four hundred to 600 msec later the fixation LED changed color to either red or green. Red signaled that the remembered location of the upper eccentric LED served as the target for a saccade and that the lower LED served as an unreinforced distractor. Green identified the lower LED location as the target. The fixation target was extinguished after a further 750 msec and animals were rewarded for making a saccade to the remembered location of the rewarded target. Variants of this task have been used to study the prelude bursters of the SC which encode the metrics of an impending saccade, after selection but before movement initiation (Glimcher & Sparks Nature, 355: 542).

QV cells responded vigorously after the onset of an LED within their response field. The frequency of this discharge was reduced after 200 to 500 msec in most QV cells. Target offset did not abolish his responding. Finally, units maintained a more vigorous discharge if the LED location they responded to served as the target than if it served as the distractor. QV cells studied typically showed a lower target/distractor selectivity than has been measured in prelude bursters.

Converging lines of evidence suggest a role for the SC in the movement selection/specification process. Electri

DISCHARGE CHARACTERISTICS OF PUTATIVE INHIBITORY BURST NEURONS IN THE HEAD-FIXED AND HEAD-FREE CAT.

BURS1 NEURONS IN THE HEAD-FIXED AND HEAD-FREE CAT.

K.E.Cullen\*, D. Guitton, W. Jiang, M. Paré, Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada, H3A-2B4.

In prior studies in the cat we have shown that brainstem omnipause neurons and collicular output neurons have discharges that are best correlated to the trajectory of gaze during an orienting gaze shift that is generated when the head is unrestrained. We now report on gaze-related activity of inhibitory burst neurons (IBNs). IBNs are located in a discrete area of the brainstem just caudal to the adducent puckers. They burst

activity of inhibitory burst neurons (IBNs). IBNs are located in a discrete area of the brainstem, just caudal to the abducens nucleus. They burst during ipsilateral saccadic eye movements and project to the contralateral abducens motor neurons, thereby suppressing the activity of the antagonist lateral rectus muscle during saccades.

We have recorded from putative IBNs in the cat during four experimental conditions: 1) spontaneous saccades made head-fixed; 2) vestibularly driven quick phases generated by whole body rotation; 3) passive movements of the head on the body; and 4) active orienting gaze shifts made head-free. IBN discharges were best correlated with the metrics of gaze motion in both the head-fixed and head-free conditions; in the following relationships. 1) Burst duration was proportional to gaze duration. 2) Peak firing frequency was proportional to peak gaze velocity. Also the trajectories of neuronal firing frequency and gaze velocity profiles were similar. 3) Total number of spikes (NOS) was proportional to gaze amplitude (Ga). The slope of NOS vs Ga was greater for saccades made head-fixed than for gaze shifts made head-free. This would be made head fixed than for gaze shifts made head-free. This would be expected if IBN discharge reflected the burst generator signal, and if the eye and the head shared a burst generator: a given burst in the head-free condition is linked to the summed movement of eye and head, and therefore would produce a larger gaze shift than would be seen in the head-fixed condidition.

CHARACTERISTICS OF SACCADES TO SOMATOSENSORY TARGETS. J.M. Groh' and D. L. Sparks. Inst. of Neurological Sciences and Dept. of Psychology, Univ. of Pennsylvania, Philadelphia, PA 19104. Previous physiological studies have demonstrated that cells in an important oculomotor structure, the superior colliculus (SC), respond to visual, auditory and somatosensory stimuli in the anesthetized animal (Drager and Hubel, Nature 253:203, Stein et al., Science 189:224). Behavioral studies have compared saccades to auditory targets with those to visual targets (Jay and Sparks, Comparative Perception Vol I.ed. Stebbins and Berkeley, 1990), but little attention has been given to the characteristics of saccades to somatosensory stimuli. Before the functional significance of the SC somatosensory neurons can be understood, the role of somatosensory stimuli in guiding saccadic eye movements must be examined. The purpose of this study was to compare saccades to visual and somatosensory targets in rhesus monkeys.

Monkeys were trained to perform saccades to the locations of visual and somatosensory targets. The animal simultaneously grasped two levers mounted out of view beneath a visual display. Vibration of either of the levers served as a silent somatosensory stimplus. Monkeys performed a variety of tasks requiring fixation of a visual target followed by a saccade to a visual, somatosensory, or combined target. On simple trials, the onset of the target was simultaneous with the offset of the fixation light. The monkey was rewarded for making a saccade to the target work of the fixation light arget onset preceded fixation light offset by 600-800 ms. The offset of the fixation light served as the cue to initiate a saccade to the target within 500 ms.

The offset of the fixation light served as the cue to initiate a saccade to the target within 500 ms.

For both simple and delayed trial types, saccades to somatosensory targets were of lower velocity and longer duration than equivalent amplitude saccades to visual targets. The latency from target onset (simple type) or fixation light offset (delayed type) to movement onset was longer for somatosensory than for visual saccades. Somatosensory saccades were significantly less accurate than saccades to briefly illuminated visual targets.

SACCADES TO REMEMBERED TARGETS EXHIBIT ENHANCED ORBITAL POSITION EFFECTS IN MACAQUES.

E.J. Barton and D.L. Sparks\*. Inst. of Neurological Sciences and Dept. of Psychology, Univ of Pennsylvania, Philadelphia PA. 19104

The amplitude and direction of visually guided saccades in the light is relatively independent of the initial orbital position within the range of +/-20 deg. Saccades to remembered targets have been characterized as being less accurate and exhibiting an upward bias (Gnadt et al., Vis. Res. 31:693.1991). Contrary to visually guided saccades, remembered saccades are markedly influenced by the initial orbital position. The effect of orbital position was examined in rhesus monkeys trained to perform both visually guided and remembered saccades from different starting positions. For remembered trails, the monkeys waited 500 ms after the target was extinguished to look to the remembered location.

The amplitude and direction of saccades to remembered targets were modulated by the orbital position of the eye, with all orbital dependencies being exaggerated as the background illumination diminished. For horizontal targets, centrifugal saccades, especially those with an eccentric origin, have a smaller horizontal component than centripetal movements. For example, the amplitudes of saccades to the remembered locations of target displacements of 25 deg. could differ by as much as 10 deg. when initiated from orbital positions differing by 30 deg. The upward bias was also influenced by the initial orbital position, increasing monotonically with downward deviations (decreasing with upward). Vertical saccades to remembered targets exhibited a significant horizontal bias, which was greater for downward than upward saccades. There was a null point on the horizontal meridian at which this bias disappeared. As the starting position deviated from this null point, the direction of the saccades were altered in such a null point. The greater the horizontal bias.

The null point of the horizontal bias and the vertical o

hall point the greater to the bias.

The null point of the horizontal bias and the vertical offset were modulated by

patching one eye.

SACCADE-RELATED NEURONS IN THE MACAQUE'S ZONA INCERTA HAVE OMNIVECTORAL PAUSES. T. P. Ma\* and N. K. Hunt. Department of Anatomy, University of Mississippi Medical Center, Jackson, MS 39216.

We have made extracellular recordings of single cells in the ventral thalamus of a rhesus monkey (Macaca mulatta) while it executed spontaneous (made in the light and dark without presented stimuli), visually-guided (made in the dark to a target on a tangent screen), and memory-guided (made in the dark to the location where a target was presented) saccades. Electrolytic microlesions (10 µamp negative current, 25 sec) were placed where cells were recorded before the electrode was advanced farther. Electrode tracks were reconstructed in cytochrome oxidase-reacted and Nissl-counterstained sections and the locations of microlesions were identified. Microlesions marking the location of 8 cells were in the zona incerta (2l). These cells have moderate rates of activity (25-40 Hz) except during saccades. We were not able to elicit visual responses in these cells. When the monkey made a saccade, the activity rapidly declined at the beginning of the saccade and remained below background levels until after the end of the eye movement. The beginning of this pause in activity occurs near the start of the saccade. The neuron returned to its background level of activity at some point after the end of the saccade. Neither the duration of the pause nor the end of the pause could be related to the saccade. The pause in activity is present for saccades in every direction and amplitude, and for every behavioral paradigm tested. In light of the strong GABAergic projection from ZI to the deeper layers of the superior colliculus (SC), and the timing of the omnivectoral pause in incertal activity related to the beginning of saccades, we hypothesize that ZI functions within a feedback loop that controls the initiation of saccades by the ventral superior colliculus. Supported in part by a Grant-in-Aid from Fight for Sight (TPM), NIH grant RR05386 (TPM), and a Dean's Research Fellowship (NKH).

MORPHOLOGY OF INCERTOTECTAL AND INCERTOPRETECTAL NEURONS IN MACAQUES. J. C. Johnson\*, G. A. Hoskins, G. A. Mihailoff, P. J. May, and T. P. Ma. Departments of Anatomy and Ophthalmology, University of Mississippi Medical Center, Jackson, MS 39216.

We injected WGA-HRP into the superior colliculus (SC) and/or pretectum of six cynomolgus monkeys (Macaca fascicularis) and examined the morphology of labeled neurons in the zona incerta (ZI). Incertotectal cells are primarily located in the ventral lamina whereas incertopretectal cells are primarily located in the dorsal lamina. Similarly, tectoincertal terminals are usually found in the ventral lamina and pretectoincertal terminals are usually found in the dorsal lamina. Both populations of labeled cells have somatic and dendritic morphologies similar to principal cells in Golgi-impregnated preparations (Ma et al., J. Comp. Neurol. 320:273, 1992). Moreover, measurements of the long axes of cells retrogradely labeled by either injection (15 to 44 µm) are comparable to those obtained from Nissl and Golgi preparations. All labeled cells examined with the electron microscope have similar morphologies and could not be distinguished from unlabeled neurons in the same section on the basis of organelle content or relationships with nearby structures. In addition, there was no difference between the size range and proportion of various terminal types that contacted dendrites labeled after injections into the SC or pretectum, nor were there any differences between labeled and unlabeled dendrites in the same section. We conclude that the LM and EM morphology of incertal neurons is relatively homogeneous supporting the hypothesis that the zona incerta functions by integrating multiple inputs into a single common efferent signal. Thus, ZI possesses the morphological substrate to subserve feedback control of saccadic eye movements in the primate. Supported in part by a Grant from Fight for Sight (TPM) and NIH grants RR05386 (TPM), NS12644 (GAM), EY07166 (PJM).

TWO DIMENSIONAL SPATIOTOPIC MAPS OF PHORIA ADAPTATION. J.S. Maxwell\* and C.S. Schor . University of California at Berkeley, Berkeley, CA 94720

If presented with diplopia (and the disparity is not too large), the visual axis of the eyes soon begin to realign in order to bring the two ocular images into registration with corresponding retinal points and eliminate the double image. Aftereffects of this change in alignment are present even in the absence of binocular visual feedback. The adaptation of phoria (the open loop difference in the position of the two eyes) to a stimulus presented in one location in space (ONE POINT paradigm) spreads to eye positions not specifically adapted. Some previous studies suggest that the adaptive response is largest at the site where the disparity was presented and falls off at more distant locations. Studies of Schor et. al, however, suggest that adaptation spreads uniformly across the field. Schor et. al also demonstrated differential phoria adaptation to two disparities of opposite sign, presented simultaneously at two different locations in the field (TWO POINT paradigm). Adaptation occurred whether the stimuli were separated vertically or horizontally, as long as the disparities were neither too large If presented with diplopia (and the disparity is not too large), the visual axis POINT paradigm). Adaptation occurred whether the stimuli were separated vertically or horizontally, as long as the disparities were neither too large nor the two adaptation sites too close together. We have re-examined the spread of phoria adaptation to locations in the field not specifically adapted by measuring the change in phoria across a two dimensional surface using both one and two adapting sites. We found that the change in phoria was uniform across the field unless there was an opposing stimulus as in the TWO POINT paradigm, in which case, the phoria varied along the meridian in which the two disparities were given but constant along any particular orthogonal meridian. The time course of TWO POINT adaptation suggests that two mechanisms are involved in the early stages of phoria adaptation, one which immediately shifts the phoria uniformly across the field and one which immediately shifts the phoria uniformly across the field and another which then selectively adjusts the phoria to the demands of the stimulus. ASYMMETRICAL CYCLOFUSIONAL RESPONSES. Li Sun, I.P. Howard and P.K. Kaiser\*. The York Vision Group, York University, Toronto, Ontario, M3J 1P3, Canada

While investigating the dynamic properties of human cyclovergence, we noticed that several subjects had a severely asymmetrical response to sinusoidal cyclorotation of a dichoptic textured display. We used scleral search coils to record cyclovergence evoked by dichoptic textured patterns cyclorotating in antiphase through 6 deg at frequencies between 0 and 0.05 Hz. Cyclovergence was also measured by a psychophysical procedure in which subjects nulled the apparent misalignment of radial nonius lines superimposed on a small black disc at the centre of the cyclorotating textured pattern. A nonius procedure was also used to measure cyclophoria. We found that intorsional responses to topinward stimulus rotation were much larger than extorsional responses to top-outward stimulus rotation. For 5 out of 6 subjects, the amplitude of intortional responses was in the range of 5--9 degs, while the amplitude of extorsional responses was in the range of 0.3--3 degs. Similar results were also obtained from the psychophysical nonius procedure. Cyclovergence is an involuntary response presumably designed to keep the eyes in orientational alignment and, in particular, to correct for misalignment due to cyclophoria. We hypothesized that people with a strong cyclophoria would show a corresponding asymmetry in cyclovergence. However, we found that the direction and magnitude of asymmetrical cyclovergence was not related to the direction and magnitude of a subjects' cyclophoria. A similar dissociation is known to exist between horizontal fixation disparity and horizontal phoria and between convergence/divergence asymmetries and phoria.

CORRESPONDENCE BETWEEN PERCEIVED TARGET VELOCITY AND SMOOTH PURSUIT GAIN. H.R. Piroozi and L.A. Abel\*, Dep'ts of Ophthalmol. and Elect. Engr., IU Sch. of Med. and IUPUI, Indianapolis, IN

Visual tracking of moving objects and predicting their future position is a commonplace activity. We have studied the relationship between tracking performance and the perception of target velocity in 5 young normal subje Subjects pursued triangle wave targets for 2 or 3 half-cycles at 10, 20, 40 and 60°/s, with velocity, initial direction and stimulus duration randomized. Perceived velocity was estimated using the time between target disappearance and its predicted arrival at a prespecified position, as indicated by a button press. Simple reaction time (SRT) to the disappearance of the target was also obtained for the same stimuli. Eye velocity was calculated for the final halfcycle of tracking. Perceived target velocity was calculated both directly from the estimated target arrival time and after first subtracting SRT

Pursuit gain was < 1 only at 60°/s for most subjects. SRT declined at the higher target velocities for all subjects. Perceptual gain (estimated/actual target velocity) was ≈ 1 for both methods at the 2 lower speeds. For the 2 higher speeds, subtracting SRT gave better perceived estimates of target velocity. Eye velocity paralleled the subtraction-based estimate in 3 subjects and the estimate which used the total time in the other 2. The correspon declines in both perceptual and pursuit gain at 60°/s suggest that in normal subjects this limit on pursuit performance may derive from input processing rather than from any limit on motor command generation. Further determination of the relationship between SRT and estimate velocity is required, but this technique may serve as a means to evaluate both efferent and afferent processing in the pursuit system.

## 296.4

PRIMED TO FAIL. SELF INHIBITION OF THE BLINK. C. Evinger\*1,2, J.J. Pellegrini<sup>1</sup> and P.A. Sibony<sup>2</sup>, Depts. <sup>1</sup>Neurobiology & Behavior and <sup>2</sup>Ophthalmology, SUNY Stony Brook, Stony Brook, NY 11794

A unique aspect of the blink is that the occurrence of a blink produces the

stimuli to elicit a reflex blink. Rapidly closing the eyelid generates sensory stimuli that activate primary trigeminal afferents of the supraorbital branch of the trigeminal nerve (SO). Imposing these stimuli externally would elicit a blink. Thus, a blink should evoke a reflex blink. Paired electrical stimuli to the SO, however, demonstrate that the first reflex blink suppresses ensuing reflex blinks for 1-3 sec. Similarly, a voluntary blink suppresses subsequent SO evoked blinks for 400 msec. Thus, blinking initiates an inhibition of brainstem, trigeminal reflex blink circuits that decreases the probability of a blink launching a reflex blink. The present studies investigated the generality of blink self inhibition and tested whether reflex blinks modified the initiation of subsequent voluntary blinks.

We determined if the blinks evoked by saccadic eye and head movements suppressed subsequent SO evoked blinks. Measuring the orbicularis oculi EMG response to SO stimulation in normal humans revealed a clear reduction of SO evoked blink amplitude for at least 400 ms following a saccadic gaze shift. More importantly, we found that SO evoked blinks dramatically delayed the initiation of subsequent voluntary blinks. This result suggests that either inhibitory processes affect higher brain regions involved in the initiation of voluntary blinks or that the signal to make a voluntary blink remains active in the brainstem until the inhibitory processes subside.

Thus, the occurrence of a blink transiently prevents initiation of a reflex blink from the sensory stimuli produced by lid closure. The fact that this inhibitory process is reduced in patients with lid spasms suggests that disruption of this mechanism is a major cause of these spastic disorders. Supported by EY07391 (CE).

STIMULATION OF THE SUPERIOR COLLICULUS (SC) SHIFTS THE FOCUS OF ATTENTION IN THE MACAQUE. R. Gattass\* and R. Desimone. Lab. Neuropsychology, NIMH, Bethesda, MD

In a previous study of SC cells in animals performing a "spatial-attention" version of a matching to sample task with distractors, we reported that many SC cells respond better to an attended stimulus than to an irrelevant distractor. We have now examined the behavioral effects of electrically stimulating the SC in the same behavioral task, in one rhesus monkey. A sample stimulus was briefly presented at one location, followed, after a short delay, by a brief test stimulus at that (relevant) location. On some trials, a distractor was presented at another (irrelevant) location. location. The monkey, which maintained fixation throughout the trial, indicated whether the sample and test stimulus matched, ignoring the distractor. Electrical stimulation (200 Hz, 30-40  $\mu$ A) was applied in the superficial layers of the SC, at the same topographic site as either the relevant or irrelevant stimuli. The animal was impaired when we stimulated at the site of the distractor stimulus, but not when we stimulated at the same site in the absence of the distractor, or when we stimulated at the site of the attended stimuli. These results are consistent with a model of attentional control based on target competition within the visual field.

## 296.7

COMPARISON OF SHIFTS OF ATTENTION IN PATIENTS WITH HUNTINGTON DISEASE (HD) AND NORMALS. T.Tsai, A.G. Lasker, D.S. Zee, S.E. Folstein, and C. Peyser\*, The Johns Hopkins Hospital, Baltimore, MD 21205

We compared the ability of HD patients (n=25) and normals (n=22) to direct covery disual attention, using a thumb press reaction time task (TP) and a saccadic latency task (SL). For testing covert shifts of attention, the target appeared right or left 10°, 50-600ms after a central arrow cue that was valid (points in same direction), invalid (points in opposite direction), or neutral (points in both directions). There were 80 valid, 20 invalid and 50 neutral cues for each delay in TP task, and 80 valid, 20 invalid and 20 neutral cues for each delay in SL task.

HD patients showed abnormal eye movements; an inability to suppress reflexive saccades to a visual target (74-87% errors in HD vs < 25% errors in normals). In the TP task, the mean thumb reaction time (RT) for HD patients was  $507\pm97ms$  and for normals  $327\pm43ms$ , indicating a delay in motor response (p<.0001). In the St task, the mean eye latency for HD patients was  $301\pm69ms$  and for normals,  $283\pm41ms$  (ns). For both experiments, the influence of attention (the difference between RT for invalid and valid cues) was the same in patients and normals. For a delay of 600ms, for the TP task, the difference in RT was 50± 75ms in HD and 39± 28ms in normals. For the SL task, the difference in saccade latency was 48± 40ms in HD and 40±

We conclude that HD patients are able to use cues to facilitate covert shifts of visual attention as well as normals, in spite of the delayed manual responses and the difficulty suppressing reflexive saccades. These results are compatible with the hypothesis that in HD, frontal-basal ganglia circuits are more affected (accounting for the eye abnormalites) than the parietal lobes (accounting for the sparing of attentional mechanisms).

## 296.9

TORSIONAL AND VERTICAL EYE MOVEMENTS ELICITED BY ELECTRICAL MICROSTIMULATION OF THE ROSTRAL INTERSTITIAL NUCLEUS OF THE MLF. D. Straumann\*, Suzuki, V. Henn, B.J.M. Hess. Neurology Department, University Hospital, CH-8091 Zürich, Switzerland.

The riMLF contains premotor burst neurons with vertical-torsional ondirections for rapid eye movements. In the rhesus monkey, we have electrically stimulated this area and measured evoked eye rotations in three dimensions (search coil technique). The stimulation sites were selected by single unit recordings (short-lead burst neurons with verticaltorsional on-directions). Typical threshold currents to elicit eye movements were 40  $\mu A$  (train duration 70 ms, pulse frequency 330 Hz). On/off-latencies ranged between 10 and 20 ms. Movements were always binocular with extorsion of the ipsilateral eye with or without a verticalup or vertical-down component that was linked to the stimulation site. Movement directions deviated up to 35 deg from pure torsional. Amplitudes of eye rotations correlated linearly with the pulse interval and increased with current strength and train duration. Depending on stimulation parameters, mean eye velocities reached values up to 200 deg/s. After stimulation, the new torsional eye position was kept until the next spontaneous saccade reset the eye to zero torsion, i.e. into Listing's plane. Constant low level electrical stimulation produced nystagmus in the intorsional direction. These results complement findings from single neuron and lesion studies in the riMLF

SINGLE-UNIT ACTIVITY IN THE NUCLEUS RETICULARIS TEGMENTI PONTIS (NRTP) RELATED TO VERGENCE AND ACCOMMODATION. P.D.R. Gamlin\* and R. J. Clarke. Dept. of Physiological Optics, School of Optometry, UAB, Birmingham, AL 35294.

Our recent physiological and anatomical studies indicate that the cerebellum

is involved in the control of vergence and accommodation. Therefore single-unit activity in the NRTP, a precerebellar nucleus, has been investigated during these

Cells in the NRTP of alert, behaving rhesus monkeys were encountered that exhibited large, transient increases in their firing-rate during near-to-far viewing. Many of these cells displayed some tonic activity with far viewing. This activity declined to zero with effective viewing distances of 30-100 cm. Cells were also encountered that showed a burst of activity during far-to-near viewing. Many of these cells had a tonic firing-rate that increased as a function of increases in convergence and accommodation. A few cells were encountered that had predominantly tonic firing-rates related to vergence and accommodation. Recorded cells were often close to neurons displaying saccade-related activity. Marking lesions confirmed that the recording sites were in the medial NRTP in the same area as that reported for saccade-related neurons

The activity of some cells was tested during normal viewing, disparity vergence (blur open-loop), and accommodative vergence (disparity open-loop). In all cases, the firing-rate was modulated under all viewing conditions. Therefore, these cells would be expected to be located after the cross-links that couple the blur and

disparity controllers to vergence and accommodation.

The NRTP is known to receive cortical afferents and to have reciprocal connections with the cerebellum. Therefore, this study suggests that some cells in the medial NRTP form part of a cerebro-cerebellar pathway modulating or controlling vergence and accommodation. 3-DIMENSIONAL POSITION CODING OF EXTRA-OCULAR MOTONEURONS IN THE RHESUS MONKEY. Y. Suzuki, D. Straumann, V. Henn\*. Neurology Department, University Hospital, CH-8091 Zürich, Switzerland.

We have investigated the relation between motoneuron activity and 3-dimensional eye position. Rhesus monkeys were chronically prepared for single unit recordings from the oculomotor, trochlear, and abducens nerve. 3-dimensional eye position was measured with the dual magnetic search coil technique. After recording spontaneous eye movements with the head upright, the monkey was put in a 20 and 40 deg right or left ear down position to induce counterrolling which increased the range of torsional positions by up to +/- 7

Data were sorted in bins of firing frequencies, and correlated to eye positions plotted in 3-dimensional space, i.e. with respect to the horizontal, vertical, and torsional components. Data points could be approximated by second order surfaces. This analysis extends the previously described iso-frequency curves to iso-frequency surfaces. Oblique and vertical recti motoneurons showed characteristic configurations of these surfaces with vertical and torsional components as deduced from geometrical analysis of muscle insertions on the

EFFECTS OF FRONTAL EYE FIELD STIMULATION UPON OMNIPAUSE AND BURST NEURONS IN THE MONKEY PARAMEDIAN PONTINE RETICULAR FORMATION. M. A. Segrayes\*. Dept. of Neurobiology
and Physiology, Northwestern Univ., Evanston, II. 60208.
Frontal eye field (FEF) input to the monkey's paramedian pontine reticular
formation (PPRF) conveys the amplitude and direction of an impending saccadic eye movement as well as the time to initiate that saccade (Segraves,
1991). The effects of this input upon omnipause neurons and burst neurons in
the PPRF was examined in 1 rhesus monkey by electrically stimulating FEF
sites where neurons could be antidromically excited from the pons.
High-intensity, short-duration stimuli silenced omnipause neurons with latencies of 5 ms or less. The omnipause neurons remained quiet for a time pro-

tencies of 5 ms or less. The omnipause neurons remained quiet for a time proportional to stimulus intensity and lasting up to 30 ms after a 6 ms train of 3 0.2 ms biphasic pulses at 330 Hz with a maximum intensity of  $1000 \, \mu A$ . These stimuli sometimes evoked a saccade near the end of the break in pause neuron stimuli sometimes evoked a saccade near the end of the break in pause neuron activity whose amplitude appeared to be curtailed by the resumption in firing of the neuron. Low-intensity, long-duration stimuli (75 µA, 70 ms train of 24 0.2 ms pulses at 330 Hz), traditionally used to evoke saccades from the FEF, also were followed by a cessation in omnipause neuron firing, but only after a delay of about 30 ms. For these stimuli, the neuron resumed firing when the stimulus was turned off. Presumably, FEF input to omnipause neurons is mediated by inhibitory neurons within the PPRF. High-intensity, short-duration stimuli excited burst neurons with latencies of 4.2 - 9.8 ms, suggesting that the circuit from FEF neuron to PPRF burst neuron is, at least, disynaptic.

FEF input to the PPRF is likely to play a role in triggering saccades by si-

FEF input to the PPRF is likely to play a role in triggering saccades by simultaneously inhibiting omnipause neurons and exciting burst neurons. In addition, this input could provide the PPRF with targeting information for the

A NEURAL NETWORK MODEL FOR AUDITORY-EVOKED ORI-ENTING IN PRIMATES. A.J. VAN OPSTAL, M.A. FRENS, R.F. VAN DER WILLIGEN AND C.C.A.M. GIELEN\*. Dept. of Med. Physics and Biophysics, P.o. Box 6101, 6500 HB Nijmegen, The Netherlands.

In order to make an accurate eye-head orienting response towards an auditory target, an important localization cue for the auditory system is provided by Interaural Intensity Differences (IIDs). Because these differences are not available at the level of the cochlear nuclei, the brain has to reconstruct IIDs through neural computation. Monkey's are capable of making large excentric eye gaze shifts, which poses an interesting additional problem, since the auditory and visual sensory organs are generally not aligned. It has been found, that in monkey superior colliculus the auditory and visual representations take current eye position into account, in such a way that the neural map represents eye motor error. We present a simple neural network model that tries to account for these findings. A sound stimulus (random spectrum, azimuth and intensity) is transformed into intensity-related firing patterns in the tonotopic cochlear nuclei, taking relevant properties of head and pinnae into account. In the binaural stage, these cochlear patterns are combined. Eye position signals are added to the binaural output and transmitted to a topographic motor error map. The network is trained by error back-propagation. Two types of binaural units emerge, one that measures IIDs, the other relates to toto binding a mine sniege, one that measures IIDS, the other relates to total sound energy. These units resemble broadly tuned EI- and EE-cells, respectively, amply demonstrated in the auditory system. We conjecture that both types are needed for coding the azimuthal position of sound relative to the head.

## 296.13

APPLICATION OF THE EQUAL INNERVATION PRINCIPLE TO THE ANALYSIS OF BINOCULAR EYE MOVEMENTS IN THREE DIMENSIONS A.W.H. MINKEN, J.M.A. LOKATE and J.A.M. VAN GISBERGEN\* Department of Medical Physics and Biophysics, University of Nijmegen, Geert Grooteplein N21, 6521 EZ Nijmegen, The Netherlands.

The equal innervation principle (Hering) states that binocular eye positions can be decomposed into conjugate (CON) and disjunct (DIS) contributions. The CON signal denotes a common rotation (equal size and sign) in the two eyes while the DIS signal describes a rotation of equal size and opposite sign.

Binocular eye positions, represented as pairs of 3D rotation vectors, were measured with the 3D scleral search coil technique in four subjects. LED targets in

two depth planes elicited a variety of gaze shifts in direction or in depth, or both.

The CON component, interpretable as the rotation of the cyclopean eye from a reference position, was always confined to a flat plane, close to the Listing planes of the two eyes measured in far vision. This was even the case in near vision, when the eyes showed clear deviations from the far vision Listing planes (Mok et al., 1992). Remarkably, we found that the DIS signal, present in near vision, had horizontal and torsional components with similar time courses. The torsional DIS component showed clear modulation by the elevation of the eyes (vertical CON component), by shifting from intorsion in up gaze towards extorsion in down gaze.

Based upon these data, we propose that the conjugate system operates independently from the disjunct system, but not vice versa. While their interaction causes cyclorotations in near fixations (violations of Listing's law), the combined operation of the two systems works in the right direction to maintain a binocular version of Donders' law and to prevent cumulation of torsion in the two eyes

## 296.15

ORGANOTYPIC NERVE/MUSCLE CO-CULTURE AS A POTENTIAL MEANS OF ANALYSIS OF DEVELOPMENTAL REGULATORY MECHANISMS FOR EXTRAOCULAR MUSCLE. J.D. Porter \*, P.H. Bonner, and K.F. Hauser. Depts. of Anatomy/Neurobiology and Ophthalmology and Sch. of Biological Sciences, Univ. of Kentucky, Lexington, KY 40536.

The diversity and plasticity that is inherent in eye movement control systems is reflected in the unusual structure/function characteristics of extraocular muscle (EOM). Ontogenetic mechanisms that specify EOM fiber types are undetermined, although their unique myosin gene expression and morphology appear postnatally in the rat. We have used an organotypic explant culture system for the first time to test whether EOM primordia and motoneuron pools can be independently manipulated to assess myogenic versus neurogenic regulation of development of this system. Organotypic explants from 1-4 dayold rat pup EOMs were cultured with embryonic day 15 lumbar spinal cord for 10-17 days. Explant culture faithfully reproduces most of the features of in vivo development, while allowing daily visualization with Hoffman modulation and phase contrast microscopy. Muscle precursor cells migrated out of explants and subsequently fused to generate myotubes. Explants then supply progenitor cells; phase contrast microscopy. Muscle precursor cells migrated out of explants and subsequently fused to generate myotubes. Explants then supply progenitor cells; pre-existing fibers in explants degenerate. Spinal cord explants survive with cytoarchitectonic relationships essentially intact. Neurites made putative neuromuscular contacts with developing myofibers. Establishment of functional neuromuscular contacts was supported by observations of synchronous twitch activity after 8 days in viro. Myosin heavy chain immunocytochemistry (monoclonals SS8, FS9, and MF20) was used to examine terminal differentiation of fiber types in explant cultures and indicated the presence of fibers containing routine fast and slow myosin isoforms. Electron microscopy documented myoblast fusion and formation of stereotypical contractile filament organization within developing myofibers. These studies demonstrate that precursor cells from EOM primordia can develop into functioning myotubes independent from their normal innervation from oculomotor motoneurons. Organotypic culture may prove useful in examining the mechanisms that regulate the development and maintenance of the unusual properties of EOM.

#### 296 12

EFFECTS OF PREDICTABILITY OF TARGET MOTION ON SMOOTH PURSUIT. R.S. Gellman\* and W.A. Fletcher. Dept Clinical Neurosciences, Univ of Calgary, Calgary, AB, Canada T2N 4N1

When humans track simple ramp motions of unpredictable direction (left vs right) and speed, they initially produce a low acceleration smooth pursuit that is largely independent of target speed between 5-40°/s (Carl & Gellman J. Neurophysiol 57). We now report that making direction and speed predictable alters the acceleration, but not the latency, of the smooth pursuit response.

Eye movements of healthy volunteers were recorded with the search coil. The target appeared in the centre of the screen and, after an unpredictable delay, started moving. There were 3 conditions: (i) unpredictable direction and speed, (ii) predictable direction and unpredictable speed, and (iii) predictable direction and speed.

The stimulus-driven response started \$130 ms after onset of target movement. This was true for all conditions, including those that tended to evoke anticipatory drifts: foreknowledge of motion did not modify response latency. The initial acceleration, in contrast, depended strongly on predictability: acceleration increased if the subject knew the direction in advance, and increased further if the subject knew the target speed. Acceleration became strongly dependent on target speed under both conditions. These findings show that (i) the initial component of pursuit, even when time-locked to the stimulus, is not invariant and cannot be described purely by parameters of image motion; and (ii) predictability of target motion allows the CNS to prepare a scaled response 50-100 ms earlier than usual, as shown for limb movements (Van Donkelaar et al., Soc Neuro Abs 17).

### 296.14

INTRAOCULAR PRESSURE CHANGES DURING EDINGER-WESTPHAL STIMULATED ACCOMMODATION IN CHICKS. A. Glasser, D. Troilo. & H.C. Howland. Neurobiol. & Behav., Cornell Univ., Ithaca, NY 14853

The role of intraocular pressure (IOP) in accommodation is controversial. An IOP mediated mechanism of accommodation has been suggested in mammalian (Coleman, 1970) and chicken eyes (Suburo & Marcentoni, 1983). We investigated IOP changes during accommodation in chicken eyes and their possible role in corneal and lenticular changes

Accommodation was induced through stimulation of the Edinger-Westphal nucleus of 4 week old white leghorn Cornell-K strain chicks. We find a mean maximum total refractive change of 25.75 D (±.75 D SEM) as measured using infrared photoretinoscopy. A maximum change in corneal refracting power of 8.28 D (±1.01 D) was measured using keratometry. Significant changes in the axial dimensions of the eye were found during accommodation: lens thickness increased (0.20±0.01 mm) and there were decreases in anterior chamber (AC) depth (0.11±0.02 mm), vitreous chamber (VC) depth (0.13±0.02 mm), and axial length (AL) (0.05±0.02 mm). The

(VC) depth (0.13±0.02 mm), and axial length (AL) (0.05±0.02 mm). The anterior and vitreous chambers of the eye were cannulated and increases in pressure of ~2 mmHg were found in both chambers during accommodation. An increase in AC pressure in chicken eyes is contrary to the results from mammalian studies and may be due to the corneal component of accommodation seen in chicks. The magnitude and direction of pressure changes in the AC are not only insufficient but also in the wrong direction to account for a steepening of the cornea based on in vitro studies (Glasser & Howland, 1991). While the causal effects of the modest vitreous pressure changes observed remain unclear, the pressure changes in the AC appear to be a consequence and not a cause of corneal accommodation.

## 296.16

BLINK METRICS IN THE CHRONIC ALERT MONKEY: NORMATIVE DATA AND THE EFFECT OF BOTULINUM TOXIN. R.S. Baker and J.D. Ports. Depts. of Ophthalmology and Anatomy/Neurobiology, Univ. of Kentucky Medical Center, Lexington, KY 40536-0084.

Blink movement metrics were studied in three alert cynomolgous monkeys using electromagnetic search coils attached to the eyelids bilaterally. Monkey blinks were stereotypical, averaging approximately 20<sup>5</sup> in amplitude, with downphase peak velocities approximately twice those of the corresponding up phases. Monkey blinks exhibited higher peak velocities and shorter durations than previously described for similar amplitude movements in man. Blink main requence (amplitude-velocity) plots were linear and non-saturating within a 40<sup>6</sup> range for both up and down phases. Amplitude-duration behavior could be best described by a second-order polynomial.

Botulinum toxin is used in treatment of focal eyelid dystonia (blepharospasm). The toxin provides transient relief of continuous blinking through action as a presynaptic cholinergic blocker. Unilateral injection of botulinum toxin type A altered lid movement metrics in parallel with the morphologic changes that we have described previously (Arch. Ophthalmol. 109:396, '91). Blink gain (treated eye/untreated eye amplitude) decreased to <0.1 within 1-3 days and exhibited slow recovery starting 30-40 days post-injection. Initial overshoots in treated eye up phases were compensated for within 2 weeks. Recovery from toxin injection presumably is via preterminal sprouting of motoneuron axons that re-establishes functional neuromuscular junctions. During the recovery phase, while muscle fiber cross-sectional area was dramatically reduced, blink amplitudes were truncated, but their amplitude-velocity relationship still fell along the low end of the normal main sequence. Blink down-phase durations in the recovering eye exceeded those of normal blinks of the same amplitude. Downward lid saccades were not affected by toxin injections, thereby supporting were not affected by toxin injections, thereby supporting observations by others that these movements are not mediated by the orbicularis oculi. Taken together, these data provide a quantitative data base for normal and toxin-compromised blinks that can be used to assess putative improvements in the treatment of focal dystonia of lid musculature.

DISCHARGE CHARACTERISTICS OF BRAINSTEM OMNIPAUSE NEURONS IN THE ALERT CAT. M. Paré\* and D. Guitton, Montreal Neurological Institute and McGill Univ., Montreal H3A 2B4, Canada.

Omnipause neurons (OPNs), which cease firing for all saccades, have been implicated in controlling the duration of saccades by enabling or disabling the emotor burst generators. These neurons are regarded as one neuronal element linking the higher saccadic centers, which specify the movement metrics, to premotor neurons. In order to investigate the role of OPNs in saccade control the firing characteristics of these neurons, including the temporal relationships of the neuronal discharge relative to saccade parameters, were quantitatively analysed.

OPNs displayed a tonic activity during fixation periods. However, the regularity and the rate of that tonic activity varied amongst the units. OPN discharge was either regular or irregular. The average firing rate ranged from 55 to 150spikes/sec. Occasionally, OPNs had phasic excitatory visual responses. As shown by others, the duration of the cessation of OPNs firing was well correlated with the total duration of the concomitant saccade executed in head-restrained condition (mean r=0.93, mean slope=0.94). On average, OPNs ceased firing 20msec before the onset of a saccade and resumed their discharge closer to the saccade offset (10-15msec). Interestingly, the pause did not end at a fixed position error. Both the position error and the intantaneous velocity of the movement determined the time of the reactivation; for faster saccades, a larger error remained at the time of the pause ending. Similar results were obtained for gaze saccades executed in head-unrestrained condition.

The perisaccadic firing of OPNs varied considerably. Prior to the pause, the firing rate either abruptly dropped or declined slowly. Similarly, the resuming firing rate that followed the pause either rapidly reached its baseline or increased gradually. Moreover, OPNs were usually firing at a reduced rate during post-saccadic glissade suggesting that the gating action of OPNs is not an all or none process.

A BILATERAL MODEL FOR COORDINATED CONJUGATE AND VERGENCE EYE MOVEMENTS. A. C. Cova and H. L. Galiana\* Department of Biomedical Engineering, Faculty of Medicine, McGill University, Montreal, Ouebec, H3A - 2B4, Canada,

Traditionally, the Oculomotor Control System (OCS) has been considered as composed of several independent subsystems acting in parallel, where each dedicated subsystem controls a particular type of conjugate or disjunctive eye movement. Mathematical models built upon this assumption have mainly focused on input-output relationships, being difficult to relate to anatomy. This fact may limit the application of such models in the clinical environment. A new integrated approach for the modelling of the OCS is proposed, compatible with both known anatomy and physiology. This paper presents a single, bilateral model capable of predicting the general characteristics (dynamics) of vergence and the vestibulo-ocular reflex (VOR) during slow phase eye movements. It is motivated by growing evidence of interactions between conjugate and vergence premotor

The model relies on the sharing of neural signals among several premotor structures located on both sides of the brainstem. A new possible role for the superior colliculi in the control of slow phase and vergence eye movements is suggested. The proposed model incorporates the presence of near response cells located in the midbrain [Mays et al. JNP'84; Judge and Cumming JNP'86; Mays et al. JNP'86] including modulation of their discharge rate with vergence angle. The model reproduces the reported activity pattern of abducens interneurons during vergence responses [Gamlin et al. JNP'89] and can provide tentative explanations for changes in VN modulation during VOR responses at different vergence levels. Additional extensions of the model can easily include burst cell populations for the simulation of fast vergence responses, and their interaction with conjugate saccades or vestibular quick phases. [Mays and Zee pers. comm.]

COMPARISON OF NEURAL NETWORK SIMULATIONS OF BEHAVIOR

Delay\*, D.Q. Nquyen, & N.J. Matsushima, Dept. of Psychology, Regis University, Denver, CO 80221.

To simulate postoperative relearning of a brightness discrimination, Delay et al. (Neurosci. Abst., 17: 484, 1991) modified Kehoe's layered network model of general transfer (Psychol. Rev., 95: 411-433, 1988) to treat hidden units as functional CNS structures. This study extended the model to relearning of an auditory intensity discrimination after auditory cortex lesions. While relearning of the visual discrimination by normal and visual decorticate rats was successfully simulated with two associative units and a response unit, three associative units were required to model discrimination behavior of intact and auditory decorticate rats. In each case, the unit representing the respective sensory cortex had the greatest impact on simulations of preoperative learning but showed little change in unit connection weights after cortical injury. However, the units representing intact neurological systems exhibited characteristics which compensated for the disruption of the network by lesions. This compensation was enhanced by general transfer effects of cross-modal training prior to relearning. The accurate simulation of postoperative relearning suggests this simplified model may be a useful tool for studying recovery of function. (Supported by NSF Grant BNS-8909803)

NEURONS IN THE PREFRONTAL CORTEX OF THE MACAQUE SELECTIVE FOR FACES. J.P Skelly\*, F.A.W. Wilson, and P. S. Goldman-Rakic. Section of Neurobiology, Yale University School of Medicine, New Haven, CT, 06510.

It has been well established in other laboratories that a population of cells in inferior temporal cortex (IT) respond selectively to the presentation of pictures of faces. We have discovered that a similar population of neurons exist in a region of preference preference (PFC) which receives a direct projection from IT. We examined the responses of cells in PFC to the presentation of pictures of faces as well as to a variety of other stimuli. Using the scleral search coil technique animals were required to fixate a central fixation point for 0.5 sec which was then followed by presentation of a visual stimulus for 1.0 sec in the center of a video monitor.

We have found 9 out of 130 cells that responded selectively to visual stimuli responded specifically to the presentation of a subset of the face stimuli and showed little or no response to light spots, oriented bars, colored pattern stimuli, or a large variety of pictures of junk objects. The ratio of response magnitude to the best face vs. the best nonface ranged between 2.3 and 4.8 (mean = 3.7). Face selective cells were not randomly distributed throughout PFC, but were clustered on certain penetrations. On the basis both of sulcal patterns encountered on electrode penetrations compared with a stereotaxic atlas and comparison of X-rays of the ectrodes with bony landmarks these face selective neurons appear to be within the IT recipient zone of PFC

Given the lack of evidence for sensory or perceptual deficits in vision after prefrontal cortex damage it is unlikely that the face selective cells in PFC are involved in discriminating between faces. Rather, it seems probable that face discrimination is mediated by IT and that this information is accessed by PFC to enable cognitive processes such as working memory for faces. Preliminary results using faces as memoranda indicate that some PFC cells show face specific memory activity. (Supported by MH44866 and MH38546)

### 297.2

AREAL AND CELLULAR SEGREGATION OF SPATIAL AND OF FEATURE PROCESSING BY PREFRONTAL NEURONS
F.A.W. Wilson\*, J.P. Skelly and P.S. Goldman-Rakic, Section of Neurobiology, Yale University School of Medicine.

Neurons in prefrontal cortex are known to be visually responsive. The question addressed in the present study is whether spatial and feature processing are segregated at the areal and/or cellular level. The sensory, mnemonic and motor activity of prefrontal neurons was examined in monkeys performing an oculomotor delayed response task with interleaved spatial (SDR) and pattern (PDR) stimuli. Fixation of a central point was followed sequentially by a cue (0.5 s), a delay (2.5 s) and a left or right saccadic eye movement. On SDR trials, spatial cues were presented 13 degs to the left or right; on PDR trials, pattern cues were presented behind the fixation point, each pattern associated with a left or right saccade. bening the fixation point, each pattern associated with a lett or right sacctate. Electrode penetrations covering parts of the dorsolateral and inferior convexity cortex were regularly verified by x-ray. Regional differences were apparent. (1) Periarcuate neurons responded on both SDR+PDR trials generally with corresponding directional delay period activity. More rostrally, however, certain neurons responded specifically on SDR or PDR trials. (2) Cellular responses were also dissociable. Visual neurons located 15-20 mm lateral to the midline responded also dissociable. Visual neurons located 15-20 mm lateral to the midline responded differentially to the two pattern cues. When this occurred, they were further tested on a picture task in which objects and other stimuli were presented for 1 s each. Stimulus-selective neurons responded in a graded fashion to the different stimuli; for 60 neurons, the ratio of responses to the most and least effective stimuli averaged 5.5. The most selective neurons responded exclusively to the pictures of faces. Neuronal activity sometimes continued after stimulus offset. No neurons responded on the basis of novelty or familiarity, indicating that stimulus selectivity in these cells was not related to visual recognition processes. These results suggest that neurons in the inferior convexity cortex process attributes of stimuli rather than their location in contradistinction to neurons situated more dorsally. ## 297.4

MOKKEY ERPS DURING PASSIVE AND ACTIVE PROCESSING OF FACES. C. Nava, D. Swickand J. A. Pineda. Department of Cognitive Science, University of California,
San Diego, La Jolla, CA 92093.

Results from human studies indicate that a familiar face can activate
"semantic" associations in terms of N400-like potentials elicited upon
presentation of a face that is incompatible with a previously presented one.
Face recognition plays a role in the ability of non-human primates to derive
meaning from social communication and thus should result in N400-like
potentials. To test this hypothesis, epidural ERPs were recorded in a
priming paradigm in 1 juvenile and 2 adult macaque monkeys (Macaca
fascicularis). Subjects viewed pairs of faces tachistoscopically-presented
in four categories: human-human, monkey-monkey, monkey-human, human-monkey.
One adult subject was trained to associate the occurrence of a monkey-monkey
pair with a reward. In the passive condition, adult monkey ERPs exhibited a
P1-N1a-N1b-P2 complex during the initial 400 ms poststimulus interval, and a
long-duration negativity (LDN) during the last 400 ms of the 1400 ms epoch.
Between these components, a prominent negativity occurred in response to
monkey faces. This N400-like negativity was earlier in latency, larger in
amplitude, and larger over left hemisphere sites to monkey than to human
faces. It was also sensitive to the priming stimulus, exhibiting larger
amplitudes when the prime category (S1) matched the target (S2) than when it
did not. Thus, monkey-monkey responses exhibited larger amplitude potentials
compared to human-monkey responses. Juvenile ERPs differed from adults in
having no N1a peak while N400-like peaks were not as broadly distributed.
Juvenile N400-like potentials were similar to the adult responses in their
sensitivity to monkey faces and in their lateralization to left hemisphere
sites. Active monkey ERPs differed primarily in the occurrence of an N2-P3
complex. P3 was larger in both amplitude and area, delayed in latency, and
slight

### 297.7

UNIT DISCHARGE IN MONKEY'S PARIETAL CORTEX DURING PERCEPTION AND MNEMONIC RETENTION OF TACTILE FEATURES. Yong-Di Zhou and Joaquín M. Fuster\*. Department of Psychiatry and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.

Parietal unit activity is recorded from monkeys trained to perform a haptic delayed matching-to-sample task with objects (rods) of identical dimensions but different surface features (direction of parallel ridges or texture). The task is performed in a fully automated apparatus, with all events electronically recorded, including hand contact with objects; the performing hand rests on a fixed pedal between trials. A trial consists of: (1) click signalling that the sample object, a vertical rod (diameter 19 mm), is in position for touch; (2) reaching and grasping the rod to feel its surface; (3) hand return to pedal; (4) delay of 14-20 sec (memorization period); (5) second sound signalling accessibility of two rods side by side (relative position changing randomly between trials); (6) choice (pull) of the rod matching the sample; and (7) fluid reward if match is correct. Data reported here are from 871 units in one monkey, about 1/3 of them in hand areas and adjacent associative cortex (area 5a). Almost all units showed changes of discharge in relation to some aspect of the task. A number of cells reacted to the click with short latency (in some cases <20 ms). Most click-activated cells were also activated by other task some cases <20 ms). Most click-activated cells were also activated by other task events (e.g., arm projection, sample touch). Cells activated by sample touch were common in hand areas; many had large receptive fields covering parts of more than one finger. Some cells differentiated sample rods by their features. Twenty-two per cent of all units showed sustained activation during retention (delay), while 14% showed sustained inhibition. In that period, 27 units, most of them in hand areas, fired differentially depending on the feature in active memory. The findings indicate participation of parietal neurons in haptic perception and temporary retention of tactile features. Hand areas are apparently not only involved in tactile discrimination but in active short-term tactile memory. Cells responding to task events of different modality may belong to distributed cortical networks accessible to the various associated inputs that the animal uses for integration of behavior.

## 297.9

WHOLE-BODY MOTION CELLS IN THE PRIMATE HIPPOCAMPUS

WHOLE-BODY MOTION CELLS IN THE PRIMATE HIPPOCAMPUS S.M.O'Mara', E.T.Rolls, A.Berthoz and V.Walsh Univ. Oxford, Dept. Exptl. Psychol., Oxford OX1 3UD, England.

In previous work on the role of the primate hippocampus in spatial processing and memory we have shown that some single hippocampal and parahippocampal gyrus neurons respond to views of the environment while a monkey is moved on a remote controlled robot-mounted platform in a cuecontrolled test chamber (2m x 2m x 2m). Their activity did not occur in relation to the place where the monkey was located, but according to the place where the monkey looked (Rolls and O'Mara, 1992, Neurophysiological and theoretical analysis of how the hippocampus functions in memory. In Brain Mechanisms of Perception: From Neuron to Behavior, eds. T.Ono et al. Oxford University Press: New York). We describe here other hippocampal cells that respond to whole-body motion. Some of these cells responded to linear motion (n=9), and others to axial rotation (n=7). Some of these cells responded when the same motion occurred without a view of the visual field. These cells appeared to be driven by vestibular inputs. Other cells required a view of the visual field for their response. These cells appeared to be driven by optic flow. Further evidence that these latter cells were driven by optic flow is that some of them responded to rotation and linear motion of the test chamber while the monkey remained stationary.

These findings show that information about where the animal is looking, and about whole-body motion, is represented in the primate hippocampus. It is likely that this information is important in spatial memory and thus in spatial navigation (Rolls and O'Mara, 1992).

VISUAL AND MNEMONIC RESPONSES OF TE UNITS STIMULATED VIA TRANSCOMMISSURAL, FEEDBACK AND DIRECT PATHWAYS. S Sobotka\* & JL Ringo, Physiol, U Rochester.

We recorded single units in inferotemporal cortex of monkeys working on a visual memory task. The optic chiasm and corpus callosum were cut, limiting interhemispheric (and interocular) information flow to the anterior commissure (AC). By recording in posterior IT (12 mm caudal to the anterior commissure) and by limiting input to the contralateral eye, stimulus driven activity was funneled across the AC and then caudally through a feedback step. By recording in anterior IT (in the regions innervated by the AC) activity was funneled across the AC, without a subsequent, requisite feedback. These responses were compared to those recorded when input was limited to the ipsilateral eye (direct input). For those units which were well driven through feedback and direct pathways (n=103), responses to various stimuli presented through the two pathways show significant correlation. Similarly, good correlation was found between responses from transcommissural (only) and direct pathways.

A trend toward a decrement-with-repetition (habituation) effect with repeated stimuli was seen in 71% of cells. Interestingly, when the eye of presentation (hence the pathway for the activity) was switched following initial presentations, much of the habituation disappeared. The responses recovered (on average) 54% of the reduction from the previous habituation.

#### 297.8

ASSOCIATIVE CODING OF PLACE RELATED NEURONS IN MONKEY HIPPOCAMPAL FORMATION.

T. Ono\*, S. Eifuku, H. Nishijo, K. Nakamura, and E. Tabuchi Dept. Physiol., Fac. Med., Toyama Med. & Pharmaceu. Univ., Toyama 930-01, Japan.

We have previously recorded the place-related single unit activities from monkey hippocampal formation (HF) during the spatial moving task which increased firing specifically when the animals were in a specific place. In this study, we analyzed further the relation between placerelated and task-related activities during the tasks. Of 238 HF neurons we recorded, 110 neurons had task-related activities and 79 had place-related, including 33 placerelated neurons with task-related activity and 46 placerelated neurons without task-related activity. Subsequently fourteen place-related neurons were also recorded in the condition the experimenter control the moving cab without imposing any operant task on the monkey. The placerelated activities of 12 HF neurons turn to lose specificity to the place. These findings suggest associative coding in HF neurons between the specific behavior and the location of the animal.

## 297.10

SPATIAL REFERENÇE FRAMES OF HIPPOCAMPAL PLACE CELLS IN RATS. S.I. Wiener\*, R. Garcia and A. Berthoz. CNRS UPR 2, 75270 Paris & CNRS URA 339, Univ. Bordeaux I, Talence, FRANCE.

Hippocampal CA1 and CA3 pyramidal cells of the rat discharge when the rat occupies a small region (the "firing field") within a maze or an open field. Experimental displacements of salient environmental cues prod corresponding shifts in the location of the firing field. This supports the view that the spatially selective firing, and presumably the rat's knowledge of his position, is determined by the relations between an ensemble of distal cues or alternatively by the "local views" available at any given location. In contrast, internally generated information from the vestibular or kinesthetic sensory systems would not be useful in these formulations.

To test for the contributions of self-generated (and thus egocentrically referred) information on firing fields, hippocampal units were recorded extracellularly with fine-wire electrodes in 4 Long-Evans rats in a darkened open field (a 60 cm sided box). Each of the 4 corners and the center of the arena were alternately baited with water. One corner was distinguished as being the first corner to contain a reward and by having a cue card that was lit there during the remaining 3 corner visits. Periodically, the arena was rotated with the rat inside. However, the corner associated with the first reward and the lit cue card remained in its original position in the external (geomagnetic) reference frame

In 19/19 analysed units, the firing field and, when present, directional selectivity rotated along with arena after at least one rotation. However 11/19 of these units also had changes in the reliability of spatial selective firing following other rotations. No firing fields maintained a constant position relative to the cue card; thus the external reference frame was not of principal importance. These results show that the hippocampus receives information regarding both egocentric and allocentric reference frames.

HIPPOCAMPAL COMPLEX SPIKE CELLS SYSTEMATICALLY SHIFT PHASE RELATIVE TO THE EEG THETA AS THE RAT RUNS THROUGH THE PLACE FIELD. J.O'Keefe\* and M.Recce. Dept of Anatomy and Developmental Biology, University College London, Gower Street, London WC1E 6BT, England.

Complex spike cells in the hippocampus of the freely-moving rat signal the animal's location in an environment. We report the results of experiments on the phase relation-ship between place cells and the hippocampal theta waves as the rat ran in a straight line through the place field. Rats were trained to run back and forth on linear tracks for food rewards at each end or to run to the goal in a maze. Each cell fires in a series of bursts in the place field. Typically the firing starts with one spike at the edge of the field, builds to a burst of several spikes in the middle, and tapers off during the exit. The first spike almost invariably occurs at the same fixed point in the theta cycle (e.g. the + peak of the CA1 theta for CA1 cells). On each successive cycle the phase correlate systematically shifts forward in time, the amount of precession varying from one cell to another but never exceeding 360° (or one full theta cycle). The phase correlate improves the spatial resolution of the place cells and suggests major roles for wave interference patterns and phase coding in the spatial functions of the hippocampus.

INACTIVATIONS OF ONE HIPPOCAMPUS (HPC) WITH TTX OR LIDO-CAINE: LATERALIZATION AND INTERHEMISPHERIC TRANSFER (IHT) OF FLACE LEARNING IN RATS. A. Fenton and J. Bures. (SPON: ENA). Inst. Physiol., Czechoslovak Ac. Sci., Prague 14220 Functional hemidecortication has been used to study IHT

of visual discriminations. To use this approach in spatial memory studies, blockade of one HPC was produced by injecting 5 ng TTX into one dorsal HPC of chronically cannulated rats (n=20) before binocular training in the Morris water maze. Retrieval of the same task was then tested during block of either the ipsi- (I) or contralattested during block of either the ipsi- (I) or contralateral (C) HPC. Based on escape latencies (s) at the end of acquisition (A), and in I or C retrieval, lateralization absent after the first 4-trial block (A=49, I=40, C=44), and marginal after limited training (9 blocks) leading to an efficient search strategy (A=6, I=9, C=14) was complete in rats overtrained (15 blocks) to asymptotic target oriented navigation (A=4, I=4, C=12). Poor lateralization for lateral contracts their alization of place learning's early stages suggests their extrahippocampal basis. Shorter-acting lidocaine (1 ul, 4%) was similarly applied to investigate IHT of the place engram. 24 pretrained rats monocularly learned a new task during simultaneous lidocaine block of the HPC and visual ortex opposite the closed eye. Intact untrained eye retrieval, poor (30) on trial 1, improved to the trained eye performance (7) by trial 4. It is concluded that IHT is mediated by readout of the primary trace or by formation of the primary trace or by formations. tion of the secondary engram in the untrained hemisphere.

EFFECTS OF IBOTENATE ENTORHINAL CORTEX LESIONS ON A DELAYED NON-MATCHING TO PLACE TASK IN MICE. Y. H. Cho and R. Jaffard\*. Laboratoire de Neurosciences Comportementales et Cognitives, CNRS URA n° 339, Univ. Bordeaux I, Avenues des Facultés, 33405 Talence, France

The present study examined the effects of ibotenate lesions of the entorhinal cortex (EC) in mice on a delayed non-matching to place task (DNMTP), varying in the level of difficulty according to the number of interpolated arm visits between sample place presentation and subsequent recognition in a radial maze. Preoperatively non-trained mice were trained on the non-matching rule (P1: 1 interpolating visit: IV) until attaining the criterion of 85% correct responses. They were then submitted to memory testing at first, in a progressive manner; P3 (3 IV) and then P5 (5 IV) including interspersed rule trials within each daily

memory testing session, and then in a randomly mixed fashion.

Behavioral results indicated that naïve EC-lesioned mice require three times as many sessions as sham-operated controls to learn the rule. Subsequently, these experimental subjects performed significantly worse than controls in difficult (P3 and P5), but not simple significantly worse than controls in difficult (17s and 17s), but not simple rule problems during both the progressive and mixed procedures. Furthermore, when re-tested 1 month later using the mixed procedure, EC-lesioned animals did not exibit any signs of functional recovery.

These results demonstrated that EC-lesions not only impair the

acquisition of the DNMTP task, but also induce difficulty (occupied delay)-dependent memory deficits (accelerated rate of forgetting). This data will be compared to results obtained by subjects trained on the task prior to EC-lesions. Supported by CNRS URA 339.

AFTERDISCHARGE, BUT NOT BILATERAL PERFORANT PATH LTP OR KINDLING, DISRUPTS ACQUISITION OF THE WATER MAZE TASK.

D.P. Cain\*, E.L. Hargreaves, F. Boon, and Z. Dennison.

Dept. Psychology, Univ. Western Ontario, London, N6A 5C2, CANADA.

To evaluate the effect of hippocampal LTP on acquisition of the water maze task, we induced LTP saturation by applying trains of high frequency pulses bilaterally through perforant path (PP) electrodes in rats (n=14) for 14 days. We bilaterally kindled Stage 5 seizures from the through perforant path (PP) electrodes in rats (n=14) for 14 days. We bilaterally kindled Stage 5 seizures from the PP in other rats (n=5). Other rats (n=5) experienced a single PP-evoked afterdischarge (AD). Other rats (n=5) served as stimulated (1 Hz for 60 sec) or unstimulated (n=8) controls. All water maze training (12 1-min trials in 6 blocks of 2 trials each) began within 10 min the last treatment. The bilateral LTP group acquired the task as quickly as both control groups. The kindled and single-AD groups were equally impaired on acquisition over the 12 trials. However, a second day of training in the maze in the absence of any treatments showed normal performance by all groups, indicating that it was the maze in the absence or any treatments showed normal performance by all groups, indicating that it was the effect of the AD and not kindling per se that caused the impairment on Day 1. The severity of the behavioral impairment was related to the severity and duration of the but performance of the LTP rats was not related to the amount of LTP induced (regression coef.=+.91).

## 297.14

THE EFFECTS OF HIPPOCAMPAL, GLOBUS PALLIDAL, AND BASAL NUCLEUS OF MEYNERT LESIONS ON SPATIAL MEMORY. K.E. Armstrong\* and L.H. Hicks. Psychology Department.
 Howard University, Washington, D.C. 20059
 An animal model was designed to compare the roles of

the hippocampus (HP), globus pallidus (GP), and basal nucleus of Meynert (BNM) in spatial memory. The specific aim was to determine whether deficits due to HP, GP, or BNM lesions were dependent on the interaction between lesion location and task complexity. One-hundred and twenty male Sprague Dawley rats were selected for retention testing. First, they were randomly assigned to either sham operated control groups or one of three experimental groups (HP, GP, or BNM) and then tested on one of the following maze task: T-Maze task (TM), Complex Maze task (CM), or Both T-Maze and Complex Maze task (BTCM). The results showed that the ability to remember was dependent on the location of the lesion as well as the complexity of the task. The TM task was too simple to distinguish the groups. The CM task showed that the GP and BNM groups were more impaired than was the HP group. However, on the BTCM task, the HP group showed transient deficits in recall; whereas, both the GP and BNM groups showed persistent deficits in recall.

SPATIAL, MOVEMENT- AND REWARD-SENSITIVE DISCHARGE BY

SPATIAL, MOVEMENT- AND REWARD-SENSITIVE DISCHARGE BY MEDIAL NUCLEUS ACCUMBENS. A.M. Lavole\* & S.J.Y. Mizumori. Dept. of Psychology, Univ. of Utah, Salt Lake City, Utah 84112

It has been suggested that the nucleus accumbens (ACC) contributes to the integration of motivational aspects of a situation (i.e. reward) with appropriate motor outputs (Br. Res. Bull. 27:463-468, 1991). Given that the ACC receives both hippocampal sublicular and VTA afferents, we hypothesized that the ACC uses information from the hippocampus to direct future behavior. Specifically, ACC neurons may code information relevant to learned reward magnitude and/or motor responses as they relate to spatial/temporal aspects of behavior. This hypothesis was evaluated by recording single unit activity of rats (n=5) as they performed 8 trials daily on an 8 arm radial maze; alternate arms were batted with small or large reward. Of the 36 cells recorded, 44% demonstrated firing which varied as a function of specific maze related behaviors and/or the location of the animal on the maze. Many cells fired in response to particular motor behaviors such as stopping, turning or directional locomotion. 30% of these cells were also modulated at the theta frequency (7-10 Hz). All of the spatial firing biases consisted of directional firing in

Hz). All of the spatial firing biases consisted of directional firing one to three maze locations; these cells were usually quiescent if the animal remained still within the field.

Other behavioral correlates were associated with reinforcement.

14% of the cells fired in relation to reward encounter; two cells fired in anticipation of reward. Additionally, 8% of the cells fired at higher rates while approaching small versus large rewards.

Thus far, these data suggest that the accumbens is a candidate structure for integrating spatial information and reward significance with meter output.

with motor output. |Supported by NIH Grant AG09299 & the Neuroscience Program.|

INTERDEPENDENCE OF HIPPOCAMPAL AND LATERAL DORSAL THALAMIC REPRESENTATIONS OF SPACE. S. J. Y. Mizumori\* and J. D. Williams, Dept. Psychology, Univ. Utah, Salt Lake City, UT 84112

The lateral dorsal nucleus of the thalamus (LDN) may facilitate visuospatial learning by providing limbic cortex with information regarding the animal's current view (Mizumori & Williams, Soc. Neurosci. Abstr. 1991). The relationship between LDN and limbic cortex was evaluated by 1) comparing the dynamic properties of neural representations for place or head-direction in hippocampus or LDN respectively, and 2) observing the effects of LDN inactivation on hippocampal function

Single unit activity was recorded in Exp. 1 as rats performed 15 spatial memory trials on a radial maze. LDN head-direction cells required at least 1 min of exposure to a lit room before stable directional firing was observed. In contrast, about 47% of hippocampal cells exhibited stable place field after only 30 sec of such exposure. On other days, rats first performed trials 1-5 under lighted conditions. During trials 6-10 (performed in darkness), hippocampal place fields remained intact for about 5.5 min while LDN inspocaripal place fields remained intent of about 5.5 min while LDN directional firing became disrupted after 3.5 min. In Exp. 2 (n=3 rats), tetracaine-induced LDN inactivation impaired spatial maze performance and disrupted hippocampal place field activity. This result is consistent with a previous finding that the specificity of LDN directional firing is correlated with improved choice accuracy. Together, these data suggest that hippocampal place cells depend on LDN head direction information for normal function. Specifically, it is hypothesized that feedback from hippocampus modulates visual information processing such that LDN directional representations are more highly resolved. This, in turn, could result in more precise spatial representations by hippocampus and improved spatial performance. [Supported by NSF Grant 9120784]

## 297.19

# QUANTITATIVE ANALYSIS OF HEAD-DIRECTION CELLS

QUANTITATIVE ANALYSIS OF HEAD-DIRECTION CELLS RECORDED IN THE RAT ANTERIOR THALAMUS.

J.S. Taube\*. Dept. of Psychology, Dartmouth College, Hanover, NH 03755. Previous studies have identified neurons in the subicular complex which discharge as a function of the animal's head direction, independent of its behavior and location in the environment. This study was designed to determine how the head directions signal gets processed. Neurons in the subicular complex have reciprocal connections with the anterior thalamus. Although several studies have determined the behavioral correlates of neurons in the anterior thalamus, sittle is house about the precible agrided or products of these neurons in the freely. little is known about the possible spatial correlates of these neurons in the freely moving animal.

Long-Evans rats were trained to retrieve food pellets thrown randomly into a cylindrical apparatus containing a single orientation cue. Animals were then implanted with recording electrodes directed toward the anterior thalamus. Single cell recordings showed that 15 out of 35 cells discharged in relation to the animal's head direction in the horizontal plane, independent of the animal's behavior, trunk position, or location. For each head direction cell, there was only one head direction at which the cell discharged maximally. The preferred only one head direction at which the cell discharged maximally. The preferred firing directions for these 15 cells were distributed equally over a 360° range. For 5 head direction cells, an automated video-computer system tracked the animal's head direction while simultaneously monitoring the neuron's firing rate. Quantitative analysis of these 5 cells showed that the mean peak firing rate was 42 spikes/sec (range: 15-118) and the mean directional firing range was 112° (range: 106-118°). These results indicate that the discharge properties of head direction cells in the thalamus are similar to the properties of postsubicular head direction cells head direction cells.

## 297.21

EFFECT OF DIABETES ON SPATIAL LEARNING AND MEMORY IN MICE. P.J. Riley\* and N.E.Rowland. Psychology, Univ of Florida, Gainesville, FL 32611.

Diabetes mellitus induces structural and functional changes in the central nervous system that may cause dysfunction in complex cognitive tasks. Simple shock-avoidance tasks have failed to show large impairments in either learning or retention in diabetic rodents. In the present study, we employ the harder task of spatial navigation to screen for impairments in diabetic mice

Diabetes was induced by injection of streptozotocin in male CD-1 mice; controls received injection of vehicle. They were tested in a Morris water maze (with invisible underwater platform, requiring use of extra-maze cues) 6 and 14 weeks later. At each time, mice were given 10 trials per day for six consecutive days and videotaped measures of platform (escape) latency, distance swam, and time in the platform quadrant were determined. At 6 weeks, diabetic mice (mean blood glucose >4.0 g/l) showed no difference from nondiabetic controls in any of the measures of acquisition and retention of the task. At 14 weeks, the diabetic mice showed a slower escape latency, but no changes in either distance or quadrant time measures. Maze retention on week 14 was similar in the two groups. Diabetic mice are impaired only on time-dependent measures of neuropsychologic function.

HEAD-DIRECTION CELL ACTIVITY MONITORED IN A NOVEL ENVIRONMENT AND CONFLICT SITUATION. H.L. Burton\* and J.S. Taube. Dept. of Psychology, Dartmouth College, Hanover, NH 03755. Neurons have been identified in the rat brain which discharge as a function of

the animal's head direction. The nature of this spatial signal would suggest that the head direction cells are ideally suited for serving as part of an animal's ne nead unection cens are locary suried to serving as part of a failine in avigational system. Two distinct navigational systems are known to be used by mammals: taking-a-positional fix and dead-reckoning. This study was designed to determine how animals use head direction cells for navigation. Head direction cell activity was monitored as an animal entered either 1) a novel environment or 2) an environment in which a conflict situation was set-up in relation to the established orientation cues.

Head direction cells were recorded in the postsubiculum and anterior thalamus of Long-Evans rats in a cylinder containing a single orientation cue. Following of Long-Evans rats in a cylinder containing a single orientation cue. Following an 8 min session in the cylinder, a door was opened and the rat entered a U-shaped alleyway leading to a similarly cued rectangle. For most cells, the preferred firing direction remained constant between the cylinder and rectangle. In one case the preferred direction shifted throughout the experiment even when the alleyway, and remained shifted throughout the experiment, even when the animal returned to the cylinder. In the next session, with the animal out of view, the orientation cue in the cylinder was rotated 90° and the animal reintroduced The rat was then permitted to walk back via the alleyway, into the now-familiar rectangle. Immediately upon entering the alleyway, the preferred direction shifted back to its original orientation and remained the same in the rectangle. There did not appear to be any change in the cell's peak firing rate. When the rat was allowed to walk back and forth between the two environments, the cell's preferred firing direction was linked with the orientation of the cue for the corresponding environment. These results suggest that head direction cells may be involved in both the dead-reckoning and the taking-a-positional fix systems.

PHOTOPERIODIC REGULATION OF TESTIS SIZE AND SPATIAL MEMORY FUNCTION IN THE ALBINO RAT: ORGANIZATIONAL AND ACTIVATIONAL EFFECTS.

L. Davachi<sup>1</sup>, C.L. Williams<sup>1</sup>, S.C. Hinton<sup>2</sup> & W.H. Meck<sup>2</sup>. Depts. of Psych., Barnard College <sup>1</sup> & Columbia Univ. <sup>2</sup>, New York, NY 10027.

Male and female Sprague-Dawley rats were raised from conception in either short daylengths (SD = 8 h of light per day, 8L:16D) or long daylengths (LD = 16 h of light per day, 16L:8D). At 90 days all rats were gonadectomized and 2 weeks later training on a 12-arm radial maze with 8 baited and 4 unbaited arms began. During acquisition (Days 1-15) LD rats made significantly fewer working and reference memory errors than SD rats. Although significant differences in choice accuracy were not observed during steady-state performance (Days 16-30), LD and SD rats still differed in the response strategies used to solve the task. For example, during the last 15 days of training both sex and photoperiod influenced the magnitude and direction of rats' turning biases. LD rats were significantly more lateralized than SD rats, with LD females preferring to turn right and LD males preferring to turn left on exiting from a maze arm. Choice latency did not differ between LD and SD rats although it was predictive of choice accuracy for LD rats. and SD rats annough it was predictive of choice accuracy for LD rats. Interestingly, for SD males testes size and body weight showed a significant positive correlation and both of these measures were negatively correlated with choice accuracy. In contrast, the correlation between testes size and body weight was non-significant for LD males, while testes size, but not body weight, was significantly correlated with choice accuracy. These data suggest that both spatial memory and reproductive function are subject to combined organizational and activational effects of seasonal fluctuations in daylength.

Effects of excitotoxic lesions in ventral tegmental area, accumbens, ventral pallidum circuit on rewarding brain stimulation of the lateral hypothalamus in rats. P. Johnson\*, P. Tehrany, and J.R. Stellar. Dept of Psychology, Northeastern University, Boston, MA 02115.

The ventral tegmental area [VTA], accumbens [Acc], and ventral pallidum [VP] form a circuit that is critical for the expression of dopamine associated behavioral activation and cocaine self-administration. Using the rate-frequency curveshift method and testing at multiple currents, the reward threshold and motor/performance capacity following ipsilateral VTA and bilateral VP excitotoxin lesions were assessed. Surprisingly small reward degrading effects were observed two weeks post lesion when the region of cell death was restricted to VTA. Hypothalamic stimulation reward was diminished, however, in a few cases where the VTA lesion spread into the Substantia Nigra pars compacta. The bilateral VP excitotoxin lesions were also unsuccessful in producing large reward impairments, but did produce severe reductions in motor/performance capacity. Results are discussed in terms of a mediating vs. modulating role for dopamine in the expression of reward effects originating from sources outside the dopamine system.

#### 298.3

THRESHOLD FOR REWARDING VTA STIMULATION IS LOWERED TWENTY-FOUR HOURS AFTER INTRA-PREFRONTAL CORTEX MICROINJECTIONS OF THE D-1 ANTAGONIST SCH 23390. C.L. Duvauchelle\* and C. Kornetsky. Boston Univ. School of Med., Boston, MA 02118.

A number of studies have shown that manipulation of dopamine systems in the medial prefrontal cortex (mPFC) can result in changes in the activity or function of subcortical dopamine neurons. In the present study, a rate-free method of determining threshold for rewarding brain stimulation was utilized to test for effects of an mPFC-applied D-1 antagonist. Animals were given bilateral microinjections of SCH 23390 (0.0, 0.125, 0.25, 0.375 and 0.5 ug/.5 ul) into the mPFC and brain stimulation thresholds were then tested immediately and 24 hours Although there was no effect on reward threshold immediately following the D1 antagonist, animals receiving SCH 23390 (.125 ug/.5 ul) 24 hours prior to testing demonstrated significantly lower thresholds. Since no trace of the DA antagonist is seen 3 hours after brain injection (Vezina et al, Soc. Neurosci. Mtg, 1990), this increase in the animal's sensitivity suggests the SCH 23390 treatment causes a change in the reward system that persists even when the drug is no longer present in the brain. (Supported in part by NIDA grant DA02326 and Research Scientist Award DA00099 to CK).

## 298.5

BRAIN STIMULATION REWARD IN THE VENTRAL TEGMENTAL AREA INCREASES FOS EXPRESSION IN THE RAT BRAIN. D.F. Fiorino <sup>1</sup>, G.S. Robertson <sup>2</sup>, A.G. Phillips <sup>1</sup>, H.C. Fibiger <sup>2</sup>, and N. Swindale <sup>3\*</sup>. <sup>1</sup>Dept. of Psychology, <sup>2</sup>Div. of Neurological Sciences, Dept. of Psychiatry, and <sup>3</sup>Dept. of Anatomy, University of British Columbia, Vancouver, BC, Canada, V6T 1Z4.

Fos immunohistochemistry was used to map brain loci activated by rewarding electrical stimulation of the ventral tegmental area (VTA). Long Evans rats implanted with bipolar stimulating electrodes aimed at the VTA were tested for self-stimulation until stable rate-intensity curves were obtained. Rats displaying robust self-stimulation behavior were divided into three groups: 1) self-stimulators (SS), 2) yoked stimulators (YOKED), and 3) unstimulated controls. SS and YOKED animals received electrical stimulation (22uA, 60 Hz sine wave) for 30 minutes and were sacrificed 90 minutes later. Fos immunohistochemical procedures were conducted on fixed brain

Electrical stimulation of the VTA increased Fos immunoreactivity in many areas which included the nucleus accumbens, cingulate cortex, portions of the amygdala, olfactory tubercle, lateral habenula, mediodorsal thalamus, and the VTA. The positive results in the YOKED group suggest that the pattern of activation observed here may be due in large part to activation of neural circuits underlying brain stimulation reward rather than motor systems mediating vigorous operant responding. This hypothesis will be tested further in experiments where the mesocorticolimbic reward pathway is lesioned.

#### 298 2

COACTIVATION OF THE LATERAL HYPOTHALAMUS AND VENTRAL TEGMENTAL AREA YIELDS GREATER REWARD SUMMATION THAN COACTIVATION OF THE LATERAL HYPOTHALAMUS AND MEDIAL PRE-FRONTAL CORTEX. K.L. Conover® P. Shizgal. CSBN, Dept. Psychol., Concordia U., Montreal, Quebec, Canada H3G 1M8.

Rats were offered a choice between a train of rewarding brain stimulation that was held constant within test sessions (the "standard") and a train that varied in current or frequency from trial to trial. The currents delivered through electrodes in the ventral tegmental area (VTA) and medial prefrontal cortex (MPFC) were varied to obtain trains that were equally preferred to a standard lateral hypothalamic (LH) train when all sites were stimulated at the same frequency. Summation of rewarding effects was measured by determining the frequency of LH stimulation that was equally preferred to a standard train consisting of concurrent (paired pulse) stimulation of either the VTA and LH or the MPFC and LH. Although paired pulse stimulation of either the VTA and LH or the MPFC and LH was more rewarding than stimulation of the LH alone, the rewarding effects of stimulating the VTA and LH summated more effectively than the rewarding effects of stimulating the MPFC and LH. This finding is consistent with the notion that the substrates for selfstimulation of the medial forebrain bundle and the MPFC are neither identical nor independent.

### 298.4

REWARD-RELEVANT NEURONS DIRECTLY LINK SELF-STIMULATION SITES IN THE ANTERIOR LATERAL HYPOTHALAMUS AND VENTRAL TEGMENTAL AREA. B. Murray\* and P. Shizgal. CSBN, Dept. Psychol., Concordia U., Montreal, Quebec, Canada H3G 1M8.

Previous studies employing a behavioural version of the collision technique suggest that reward-relevant neurons directly link selfstimulation sites in the lateral hypothalamus (LH) and ventral tegmental area (VTA). In the present study, we asked whether this direct link extends into more anterior LH sites where electrolytic lesions degrade the rewarding effect of posterior LH and VTA stimulation. Six rats with electrodes in the anterior LH (ALH) and VTA served as subjects. Stimulation consisted of trains of paired conditioning (C) and test (T) pulses, with each electrode receiving one pulse from each pair. Collision was inferred when the rewarding effectiveness of the stimulation increased with C-T interval, and did so in the same manner regardless of whether the LH or VTA electrode delivered the C-pulses. In 4 of the 6 subjects, we found that rewarding effectiveness was lower at short C-T intervals (.4 msec) than at longer C-T intervals (6.4 or 12.8 msec), supporting the notion that some reward-relevant neurons directly link the ALH and VTA. The increase in rewarding effectiveness with C-T interval was smaller and more gradual than previously reported for more posterior LH and VTA self-stimulation sites.

## 298.6

REWARDING BRAIN STIMULATION INDUCTION OF FOS: PARALLEL BRAIN REGIONS ACTIVATED BY COCAINE. <u>J. Buggy \*, Z. Ying, A. Singha, and J. Valentine.</u> Depts. of Physiology and Psychology, University of South Carolina, Columbia, SC 29208.

The c-fos immediate early gene is acutely induced in many brain regions by relevant physiological or pharmacological stimuli. Whereas the phosphoprotein Fos acts in the cell nucleus to regulate gene transcription, Fos immunoreactivity (Fos-IR) presents a useful mapping technique to identify activated neuronal systems. Fos-IR was determined in rats after rewarding brain stimulation self-administered to the ventral tegmentum area, origin of the dopaminergic mesolimbocortical neurons. After a 1 hr brain stimulation session, Fos-IR was observed in the ventral tegmental area and, as observed after cocaine administration, in numerous terminal fields of the mesolimbocortical dopaminergic system. Fos-IR was particularly dense in the medial prefrontal and cingulate cortex, olfactory tubercle, nucleus accumbens, lateral septum, bed nucleus of the stria terminalis, striatum, habenula, and amygdala. Fos-IR was usually present bilaterally although the number of labeled neurons was typically greater ipsilateral to the stimulation, especially in the prefrontal cortex, nucleus accumbens, striatum, and amygdala. Similar to reduced Fos-IR with repeated administration of cocaine, there was a reduction in Fos-IR in animals with rewarding brain stimulation sessions repeated daily for one week or longer.

DOPAMINE IN VENTROLATERAL STRIATUM MODULATES THE REWARD VALUE OF HYPOTHALAMIC STIMULATION. S. E. Romer and D. B. Neill\*. Dept. of Psychology, Emory University, Atlanta, GA 30322

It has often been observed that rats performing intracranial self stimulation (ICSS) of the lateral hypothalamus engage in oral behaviors such as intense licking and gnawing. The stimulation may be rewarding because it activates motor programs for feeding and other consummatory behaviors. We hypothesized that the ventrolateral striatum, which has been implicated in feeding, modulates these motor programs and thus modulates the reward of lateral hypothalamic stimulation.

We tested this hypothesis by manipulating dopaminergic transmission in ventrolateral striatum via intrastriatal microinjections of amphetamine or flupenthixol. The behavioral measure was 2-lever autotitration ICSS. The results were that amphetamine evoked resetting at lower current intensities (enhanced reward) and flupenthixol evoked resetting at higher intensities (reduced reward).

These results supported our hypothesis that dopaminergic synapses in ventrolateral striatum modulate the reward of hypothalamic stimulation.

### 298.9

EFFECTS OF AVERSIVE PAC STIMULATION ON SELF-STIMULATION AND SELF-ADMINISTRATION OF BRAIN STIMULATION.

M. Lepore\* and K.B.J. Franklin. Dept. Psychology, McGill University, Montreal, PQ, Canada H3A 1B1.

Brain stimulation and drugs have both rewarding and aversive effects which may be simultaneous or sequential. Aversive effects are believed to limit the rate of responding and influence the rate of acquisition and extinction of responding reinforced by brain stimulation or drugs. We have used a computer to independently modulate the pulse frequency of brain stimulation delivered separately or simultaneously to a primarily rewarding site (MFB) and a primarily aversive site (PAG). By varying the parameters governing the increase and decrease of pulse frequency at the two sites, we explored the contributions of reward and aversion to the control of responding. It was found that rats subjected to continuous PAG stimulation would respond to self-administer reductions in stimulation pulse frequency, and their performance was similar to when they respond to increase the frequency of stimulation at a rewarding site. When aversive and rewarding stimulation were administered together, the rate of responding for rewarding stimulation was reduced as the pulse frequency of the aversive stimulation train increased. The properties of rewarding and aversive brain stimulation appear to be similar, except for sign.

## 298.11

INJECTION OF SELECTIVE DOPAMINE ANTAGONISTS INTO THE MEDIAL FOREBRAIN AND BASAL MIDBRAIN SITES OF RATS DURING SELF-STIMULATION. S. Nakajima\*, E. A. Rooney, and G. Tsouluhas. Department of Psychology, Dalhousie University, Halifax, Nova Scotia, Canada.

D1 and D2 dopamine agonists interact with each other in a synergistic manner to facilitate the reinforcing effect of hypothalamic stimulation (Nakajima & O'Regan, 1991). To locate the active sites of the D1 and D2 receptors involved in this function, selective antagonists were injected into the brain while rats were engaged in self-stimulation at a steady rate. SCH 23390, a D1 antagonist, suppressed self-stimulation when injected into the nucleus accumbens, the ventral tegmental area, or the substantia nigra. Raclopride, a D2 antagonist, suppressed responding when injected into the nucleus accumbens and its vicinity, but not all of the accumbens sites were affected by both antagonists. Injection of raclopride into the tegmental and nigral sites did not suppress responding except at the highest dosage tested, and no sign of facilitation was observed at lower dosage levels. Injection into the sites contralateral to the hypothalamic electrode had no effect. These results suggest that the synergistic interaction may take place between D1 and D2 receptors located some distance apart.

#### 298 8

PARABRACHIAL LESIONS HAVE LITTLE EFFECT ON MFB SELF-STIMULATION. M. Waraczynski\* and P. Shizgal. CSBN, Dept. Psychol., Concordia Univ., Montreal, Quebec H3G 1M8

The notion that parabrachial (PB) neurons may play a role in self-stimulation of the medial forebrain bundle (MFB) is consistent with the fact that the PB region supports self-stimulation and the fact that this region receives projections from and sends projections through the MFB. To test this hypothesis, a PB lesioning electrode and ipsilateral stimulation electrodes aimed at the LH and the ventral tegmental area (VTA) were implanted in male rats. At each stimulation site, rate-frequency curves were collected at each of 2-3 currents. In four rats, substantial damage to the PB region produced little or no increase in the frequency required to maintain half-maximal responding. The observed increases were similar in size to those seen following nearby lesions that spared the PB nucleus. In a fifth rat, a small lesion made through a PB electrode supporting self-stimulation also had minimal effects on selfstimulation of the LH and VTA. These results fail to implicate PB neurons in the rewarding effects of stimulating the LH and VTA.

### 298.10

Ch5 CHOLINERGIC NEURONS MEDIATE HYPOTHALAMIC REWARDING BRAIN STIMULATION VIA CONNECTIONS WITH A10 DOPAMINE CELLS. A. Mathur\*, M.K. Tampakeras and J.S. Yeomans, Dept. of Psychology, Univ. Toronto, Canada M5S 1A1.

Microinjections of muscarinic blockers near A10 dopamine cells increase frequency thresholds for lateral hypothalamic rewarding brain stimulation (Kofman & Yeomans, 1989). Ch5 cholinergic neurons of the pedunculopontine nucleus (PPT) are believed to monosynaptically excite these dopamine cells (Bolam et al., 1991; Lacey et al., 1991). Since Ch5 cells are inhibited by muscarinic agonists (Leonard & Llinas, 1988), carbachol was injected unilaterally near medial PPT, where lesions block opiate place preference (Bechara & Van der Kooy, 1990). Carbachol (1-4 ug) raised frequency thresholds by over 400% bilaterally, similar to the effects of muscarinic blockers near A10 dopamine cells. In these same Ch5 sites, scopolamine (100 ug), a muscarinic antagonist, reduced thresholds by 20-80%. Preinjection of scopolamine blocked the carbacholinduced attenuation of reward, and preinjection of carbachol blocked scopolamine-induced hypersensitivity to reward, suggesting common receptors. Gallamine (20 ug) M2 antagonist, reduced thresholds by 40%. Atropine (60 ug) injections near AlO dopamine cells blocked the facilitation of reward produced by scopolamine in medial PPT. Therefore, Ch5 neurons, via their linkage to AlO dopamine cells are critical for hypothalamic rewarding brain stimulation. (Supported by NSERCC grant to J.Y.)

## 298.12

INJECTING THE K-AGONIST U-50,488H INTO THE VENTRAL TEGMENTAL AREA, NUCLEUS ACCUMBENS OR MEDIAL PREOPTIC AREA DECREASES LOCOMOTOR ACTIVITY. M. Leyton\* and J. Stewart. Center for Studies in Behavioral Neurobiology, Psychology, Concordia University, Montréal, Qc., Canada H3G 1M8. Injections of kappa (k) agonists into either the cell body or terminal regions of dopamine neurons induce conditioned place aversions (Bals-Kubik et al., 1990 INRC: 11) and decrease male sexual behavior (Leyton & Stewart, 1991 Soc Neurosci Abs 17: 1539). To test whether stimulated central k receptors would decrease locomotor activity we injected the k agonist U-50,488H through bilateral cannulae aimed at the ventral tegmental area (VTA) (n=5), nucleus accumbens septi (NAS) (n=6) or medial preoptic area (mPOA) (n=5). During 60-min tests, given in counterbalanced order, U-50,488H (0.0, 0.0005, 0.05, 0.5, 5.0 nmol/0.5 µl/side) was co-administered with systemic injections of naloxone (0.0, 2.0 mg/kg, i.p.). At all three injection sites the highest dose of U-50,488H significantly decreased locomotor activity [p<.05]; differences between groups were not observed [p=.8254]. When the three groups were collapsed together, the two highest doses significantly decreased locomotion [p<.01]. In contrast, we previously observed that intracranial injections of a selective k antagonist, nor-binaltorphimine, blocks systemic U-50,488H-induced decreases in locomotor activity (Leyton & Stewart, submitted). These findings suggest that stimulating k receptors in the VTA, NAS or mPOA decreases locomotor activity, possibly related to a decreased interest in environmental stimuli.

REWARD AND REINFORCEMENT DIFFERENTIATED. Estela Marroquin , and Anders Agmo. Dept. of Psychology, Universidad Anahuac, Mexico City.

It has been proposed that reward (an affective state) and reinforcement (learning) may be experimentally distinguished. Saccharine may be rewarding but not reinforcing, guismed. Saccharine may be read along as the second with the sucrose is known to have both of these properties. The two sweeteners produce release of dopamine in the nucleus accumbens. It is belived that release of dopamine nne two sweeteners produce release of dopamine in the nucleus accumbens. It is belived that release of dopamine is associated with reinforcement. If this would be the case, then saccharine and sucrose should be about equally reinforcing. The present studies evaluated this hypothereinforcing. The present studies evaluated this hypothesis. Conditioned place preference: A biased procedure is used (reinforcement in the non prefered compartment). The subjets (male rats) were allowed to drink a 0.1% saccharin solution or 18% sucrose for 15 min, and then transferred to the place preference box. No deprivation was used. Both sweeteners were consumed in similar amounts. Sucrose produced a reliable place preference whereas saccharine was ineffective. Discrimination learning: A straight runway ending in a chotee box with two discriminative openings was used. 0.5 ml of the respective solution or plain water were available in the goal box. Ten sessions of five trials each were preformed. Sucrose produced reinforcement (learning) while saccharine was ineffective. These data suggest that reward and reinforcement are distinguishable and that the latter process does not depend exclusively in dopamine release.

**EXAMINING MFB REWARD ANATOMY FROM ICSS PSYCHOPHYSICAL CHANGES IN MULTIPLE ELECTRODES** AFTER ELECTROLYTIC LESIONS. D. Garity\*, H. Albert. Jaehn, J. Nunnally, and J.R. Stellar, Dept. of Psychology,

Northeastern University, Boston, MA, 02115.
Building on Gallistel's (<u>JCCP</u>, 92:997-98,1978) observation of the reciprocal relationship between intracranial selfstimulation (ICSS) current and rate-frequency half-maximal thresholds in a single electrode, Shizgal's laboratory (Forgie & Shizgal, in press) has developed a sophisticated technique for revealing the functional anatomy of normal rewardrelevant medial forebrain bundle (MFB) fibers with a movable electrode. We extend this technique by using a fixed array of closely spaced electrodes to determine frequency-current (Hz-C) trade-offs before and after small electrolytic MFB lesions. Particular changes in the Hz-C curves after adjacent MFB lesions reveal aspects of alignment between lesion and electrode that may be efficacious in tracing brain stimulation reward-relevant MFB fibers. Also, a technique of implanting an IC-size rotary switch is presented to allow rapid movement between fixed electrodes with simple stimulation equipment. (Supported by Whitehall Foundation)

## 298.17

DISSOCIATION OF REWARD AND PERFORMANCE CHANGES FOLLOWING CHRONIC TREATMENT WITH HALOPERIDOL.

S.M.Boye & P.-P. Rompré. Département de psychiatrie, Université de

Montréal, Montréal, Québec, H4J 1C5.

Previous studies have reported that chronic administration of the typical neuroleptic, haloperidol, increases rates of responding for rewarding electrical brain stimulation and this effect has been hypothesized to reflect an increase in sensitivity of the reward-relevant neural substrate(s). However, it is not clear whether the facilitation of responding is linked to an increase in the rewarding value of the stimulation and/or to a potentiation of performance follochronic drug treatment. In this experiment, we studied the effects of chronic halopendol treatment on dorsal raphe self-stimulation using the curve-shift paradigm. Male rats were implanted with a stimulating electrode aimed at the paradigm. Male fats were imparated with a stitution in electrone animal at the dorsal raphe and trained to lever press for the delivery of 200 misec trains of 0.1 misec pulses of fixed intensity and variable frequency. Once reward thresholds were stable, rats received 20 daily injections of haloperidol (0.5 mg/kg, s.c.) or its vehicle. On day 21, all rats received a similar dose of haloperidol and were its vehicle. On day 21, all rats received a similar dose of haloperidol and were tested every day for 28 days, beginning 24 hrs after the last injection. Asymptotic rates of responding and reward thresholds were differentially affected by chronic drug treatment. Asymptotic rates of responding were increased by 30%, an effect that persisted for three weeks before returning to pre-treatment levels. Reward thresholds were elevated for both groups (23%) on the first day of drug withdrawal and returned to pre-treatment levels on day four. The magnitude and time-course of elevation in reward thresholds were the same for acutely- and chronically-treated rats, suggesting that the chronic treatment did not change the sensitivity of the reward-relevant neural substrate(s). These results show that performance only is potentiated substrate(s). These results show that performance only is potentiated following chronic haloperidol treatment, a phenomenon that could explain the increase in rates of responding for brain stimulation reward reported in previous

Supported by a grant (P.P.R.) and a fellowship (S.M.B.) from MRC.

EXAMINATION OF RELATIONS BETWEEN SELF-STIMULATION AND SNIFFING PATHWAYS. S. Ikemoto\* and J. Panksepp. Dept. of Psychology, Bowling Green State Univ., Bowling Green, OH 43403.

Sniffing behavior appears to be a good indicator of exploratory and appetitive motivational states in rats. Since electrical self-stimulation of the brain (ESSB) may reflect the activation of such intrinsic processes, the relationship between ESSB and sniffing was examined. In order to identify neural sites involved in sniffing, Experiment 1 examined sites at which electrical stimulation can induce sniffing in the anterior telencephalic area (ATA) and the midbrain-pons [hence, the lower brain sten (LBS)] using anesthetized rats. Sniffing was elicited in many ATA and LBS sites. These sites appear to correspond to reported ESSB sites, but in the LBS, sniffing sites also included non-ESSB sites. Experiment 2 evaluated the relationships of ESSB and sniffing in the medial prefrontal cortex (MPC) and LBS of awake animals. All ESSB sites induced sniffing in MPC and LH-MFB sites. In the LBS, this was usually the case, but there were exceptions (one subject exhibited sniffing but no ESSB, and another exhibited ESSB and jaw movements without snffing). The third experiment examined the effects of lesions in the MPC or LBS on LH-MFB ESSB and sniffing. MPC lesions had no reliable effects on sniffing and ESSB from the LH-MFB. LBS lesions had no apparent effects on sniffing but disrupted ESSB (increasing thresholds and decreasing response rates). In summary, anatomical organizations of ESSB and stimulation-induced sniffing are very similar in the higher areas of the brain, but they can be particularly dissociated in the LBS. In general, sniffing substrates in brain appear to be more widely distributed than ESSB substrates.

### 298.16

EVIDENCE OF INHIBITORY G PROTEIN-MEDIATION OF STIMULANT AND OPIOID REINFORCEMENT. D.W. Self', R.T. Mai and L. Stein. Dept. of Pharmacology, College of Medicine, Univ. of California, Irvine, CA 92717.

A substantial literature suggests that stimulant and opioid drugs exert their addictive or reinforcing actions in large part at dopamine D2, and μ and δ opioid receptors. These receptors utilize pertussis toxin (PTX)sensitive inhibitory G proteins for signal transduction. We tested whether PTX, injected into a reinforcement-relevant brain region (nucleus accumbens), could antagonize stimulant and opioid (nucleus accumeens), could antagonize simulant and option reinforcement using the self-administration paradigm. In control rats, bilateral intra-accumbens injections of heat-inactivated PTX (0.1 µg/ul/side) failed to alter the rate or pattern of cocaine (0.75 mg/kg/injection)and heroin (0.3 mg/kg/injection)self-administration. However, the same dose of active PTX produced significant compensatory increases in the self-administration rates of both drugs. The onset of the PTX-induced increases was delayed 5-6 days, consistent with the slow rate of G protein ribosylation and other in vivo measures of PTX effects. Increased self-administration in PTX-treated animals was initially characterized by highly regular, yet shortened interinjection intervals (mostly evident with cocaine), but progressed to burst-like responding over the next several days. Recovery of baseline performance was not observed even after three weeks. Compensatory increases in self-administration suggest that PTX antagonizes both cocaine and heroin reinforcement. Thus, these results support the hypothesis that inhibitory G proteins mediate both stimulant and opioid reinforcement (Self & Stein, Pharmacol. Toxicol. 70:87-94, 1992). (Supported by DA 05107, DA 05379 and AFOSR 89-0213)

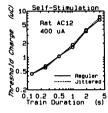

CHANGE IN ADENYLATE CYCLASE ACTIVITY FOLLOWING CHRONIC REWARDING BRAIN STIMULATION IN THE RAT. E.M. Bedwell\*. C.J. Hillard, and E.A. Stein, Departments of Pharmacology and Psychiatry, Medical College of Wisconsin, Milwaukee, WI 53226. Recent reports of regional brain adenylate cyclase (AC) upregulation in response to chronic cocaine and morphine raise the

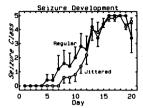

question of the role of this system in brain reward mechanisms. While dopamine (DA) is generally accepted as the principal transmitter involved in reinforcement, changes in second messenger systems involved in DA receptor activation are not well-understood. In this study, we report preliminary results of our investigation of the effects of chronic rewarding brain stimulation (RBS) on AC activity in the mesolimbic DA pathway. Rats were trained to respond for RBS from chronic ventral tegmental electrodes at a current set to that producing 80% maximal responding, and were allowed to respond twice/day in 45 min RBS sessions for 10 days. Rats were divided into 3 groups: active responders, yoked stimulation, and sedentary controls. Immediately following the 20th RBS session, rats were sacrificed and ipsilateral punches from 8 brain regions were isolated. Forskolin-stimulated (10μM) AC activity was determined in membrane preparations and was corrected for basal activity (ATP only). Results point towards an increase in forskolin-stimulated AC activity in yoked animals compared to controls in membranes from the nucleus accumbens and the ventral tegmentum. These results suggest that, in a manner similar to that seen in response to chronic cocaine and morphine, repeated exposure to RBS results in an increase in AC activity in some brain regions within the mesolimbic pathway. Supported in part by NIDA grant DA 06485 to EAS.

PULSE JITTER RETARDS THE DEVELOPMENT OF SEIZURES WITHOUT AFFECTING INTRACRANIAL SELF-STIMULATION CHARGE-DURATION FUNCTIONS.

G. Fouriezos\* and J. Th. Rick. Sch. of Psychol., U of Ottawa, Ottawa Ontario, Canada K1N 6N5

Behaviourally derived charge-duration functions collected from three self-stimulating rats with lateral hypothalamic electrodes were not affected by a controlled, 50% jitter to the interpulse interval of rewarding trains. In a second experiment, we kindled two groups of 6 rats with once-daily, 1.0 s bursts of either regularly timed or jittered pulses to the amygdala until full motor seizures developed. Although both groups eventually attained Class 5 convulsions, the time to first seizure was about two days longer with jittered pulses. Thus, while the circuitry that accumulates input from self-stimulation is not affected by the irregularity of asynchronous pulses, the jitter does seem to retard the development of seizures.

CONTRIBUTION OF PERSISTENT PROTEIN KINASE A TO SEROTONIN-INDUCED LONG-TERM FACILITATION OF APLYSIA SENSORY-MOTOR SYNAPSES IN CULTURE. P.G. Montarolo, M. Ghirardi, and E. R. Kandel\*. Ctr. Neurobiol. & Behav., Columbia P&S, HHMI, NY, NY 10032; Dip. Anat. & Fisiol. Umana,

Univ. Torino, 10125 Italy.

The serotonin (5-HT)-induced long-term facilitation of Aplysia sensory. motor synapses leads to two protein synthesis-dependent sets of changes:
(1) persistent activation of the cAMP-dependent protein kinase (kinase A) leading to persistent phosphorylation of the substrates phosphorylated during short-term facilitation (Bergold et al., 1990); and (2) growth of new presynaptic contacts. To determine the relative contribution of the persistently active PKA to the facilitation present throughout the first 24 hours of long-term facilitation, we used Rp-cAMPS (500 µM), a specific PKA inhibitor, to intercept the active kinase at various time points. In culture, five (5-min) pulses of 10  $\mu$ M 5-HT induced an increase in EPSP amplitude of about +156.32% ( $\pm$  18.09, n = 11) when tested immediately after the end of the application of the five pulses of 5-HT. The amount of EPSP facilitation decreased progressively to +126.21% ( $\pm$ 17.71, n = 7) at 12 h and to +62.2% ( $\pm$ 7.2, n = 25) when tested at 24 h. Rp-cAMPS applied for 30 min at the end of the of the 5-HT application (1.5 h) or at 12 h after 5-HT dramatically reduced the synaptic facilitation to + 11.75% ( $\pm$  7.17 n = 12) and + 33.5% ( $\pm$  13.04, n = 11), respectively. By contrast, Rp-cAMPS applied at 24 h after the end of 5-HT training produced no statistically significant effect ( $\pm 42.83\% \pm 12.29$ , n = 9). These results suggest that persistent PKA activity is particularly important during the first 12 hours after the induction of long-term facilitation by 5-HT, and that other mechanisms, perhaps the newly emerging morphological changes, carry the facilitation at later stages.

THE MAJORITY OF THE NEURONS IN THE APLYSIA ABDOMINAL GANGLION HAVE UNRELIABLE RESPONSES TO SIPHON STIMULATION. A.C. Tang, C.X. Falk, L.B. Cohen, J.Y. Wu. Dept. of Physiology, Yale Univ. Sch. of Med., New Haven, CT 06510

Optical recording with a voltage sensitive dye was used to study the response of the neuronal population in the Aplysia abdominal ganglion. In the absence of learning, an identical stimulus (suction electrode;intensity=6v; duration=5ms; ISI=10-15min) was repetitively delivered to the siphon skin. We assessed the reliability of the neuronal population in responding to a constant stimulation, where the reliability is defined as the percentage of times a neuron responded. A neuron is considered to have responded when the chance of a background spike count being as large as the observed post-stimulus spike count is less than 5%. Our results show that (1) Stimulus response was widely distributed within the ganglion (about 75% of all recorded neurons responded to the siphon stimulation); (2) The reliabilities of these neurons had a broad spectrum, indicating that the neuronal population is made up of neurons with greatly varied response reliability; (3) The majority of neurons had unreliabe responses; (4) As a result, the response patterns across the neuronal pool triggered by an identical stimulus varied considerably. Studies from visual and computer sciences show that our visual system is built upon neurons of low reliability, and suggest that a reliable response can be synthesized from unreliable components. Given the existence of a majority of unreliable neurons in response to a siphon stimulation, their possible role in the production and plasticity of behavior requires future study.

A POSSIBLE ROLE FOR A C/EBP FAMILY MEMBER IN APLYSIA LONG-TERM FACILITATION. C. Alberini, M. Ghirardi, R. Metz, A. Barzilai\*, and E. R. Kandel. Ctr. Neurobiol. & Behav., Columbia P&S, HHMI, NY, NY 10032.

Long-term memory for sensitization in Aplysia, as well as for many forms of learning in vertebrates, requires RNA and protein synthesis. In Aplysia aspects of the transition from the short- to the long-term form can be studied on the cellular level in the synaptic connections between the sensory and motor neurons. In the sensory neurons injection of cAMP can induce both short-term and long-term changes. However, only the longterm form requires transcription. Thus, injection of the oligonucleotide encoding the cAMP recognition element (CRE) characteristic of the cAMP-inducible gene selectively blocks long-term facilitation, suggesting that one or more CREB-like proteins are involved. To explore the role of related transcription factors we are attempting to clone CREB related proteins. As a first step we have cloned the Aplysia homologue of NF-IL6, a transcription factor activated via a cAMP-dependent pathway in mammalian cells. Like its mammalian homologues, Aplysia NF-IL6 has a conserved b-zip domain. The remaining sequence, including the putative activation domain, appears to diverge. In vitro translation of the cDNA resulted in phosphorylated products of 38-42 kd that specifically bound to an oligonucleotide containing the NF-IL6 binding motiv (oligo NF-IL6), and also the C/EBP binding site of Rous Sarcoma Virus LTR (RSV-LTR). Injection of oligo NF-IL6 into the sensory neurons, but not of the two bases-mutated oligo NF-IL6, selectively blocked the 5-HT-induced long-term facilitation similar to the block produced by CRE. This suggests that NF-IL6 is involved in one of the activation steps of long-term facilitation. We are now studying transcription activation via NF-IL6 as well as its interactions with other cAMP-responsive transcription factors like CREB.

OPTICAL RECORDING AND ANALYSIS OF APLYSIA LEARNING NETWORK IN ABDOMINAL GANGLIA. M. Nakashima\*, S. Yamada, S. Shiono and K. Matsumoto\* Central Research Laboratory, Mitsubishis Electric Corp., Amagasaki 661, Japan and \*Department of Pharmacology, Hokkaido University, Sapporo 060, Japan. We have been studying the neural network mechanism of the Aplysia gill-withdrawal reflex, using an optical apparatus with 448 detector elements (Nakashima et al, IEEE Trans. BME, 39, 26, 1992). Intracellular recordings were used simultaneously with the optical recording, to identify optically detected neurons as well as to detect neural signals from smaller cells which our optical apparatus could not detect. Siphon nerve was stimulated with a pulse train of electric shocks. The stimulation could elicit gill contraction in a similar manner to that caused by mechanical touch to the siphon. Repetitive touch to the siphon caused habituation, whereas 20 µM serotonin apparently enhanced the gill contraction when bath-applied to the abdominal ganglion (sensitization).

The spike trains of optically detected neurons were statistically analyzed by the technique based on the informational theory, calculating the quantity called "channel capacity" from one neuron to another (Yamada et al, submitted to Biol. Cybern., 1992). The calculation of channel capacity was useful to estimate neural connectivities.

The information theoretic analysis was applied to the

channel capacity new tries.

The information theoretic analysis was applied to the spike trains detected in the sensitization and habituation experiments. The analysis technique was useful for detecting changes in the neural connectivities caused by the sensitization and habituation.

STRESS-EVOKED CHANGES OF CIRCULATING AMINO ACIDS IN APLYSIA CALIFORNICA. J. K. Krontiris-Litowitz\*, E. T. Walters, and D. J. McAdoo. Dept. Biol. Sci., Youngstown State Univ., Youngstown, OH 44555, Dept. Physiol., U. Texas Med. Sch. at Houston, Houston, TX 77225, U. Texas Med. Branch, Galveston, TX 77550.

Previous studies have demonstrated that local mechanical and electrical stimuli can cause the release of amino acids from <u>Aplysia</u> body wall. In this study we investigate whether mechanical trauma can alter circulating amino acids levels sampled at a site distant from the Animals were stressed by cutting the right parapodium and pinching the tail for 1 minute. Glutamate and alanine levels were significantly increased at 15 minutes (+714%, +208% p < 05) and remained elevated for at least 6 Conversely, asparagine and glutamine levels were significantly decreased at 60 minutes (35%, 40% p.05) and remained reduced for at least 6 hours. These results suggest that selective alteration of amino acid content of hemolymph may reflect metabolic or physiological responses associated with stress.

NEURAL MECHANISMS OF RESPONSE SPECIFICITY. II. CUTANEOUS TAIL AND MANTLE SHOCK PRODUCE DIFFERENTIAL EFFECTS ON THE SIPHON-WITHDRAWAL NEURONAL CIRCUIT IN APLYSIA. X. Fang\* and G. A. Clark. Psychology Department, Program in Neuroscience, Princeton University, Princeton, NJ 08544.

Both sensitization and classical conditioning of the siphon-withdrawal response in Aplysia exhibit response specificity. To extend our previous physiological investigations using nerve stimulation, we have examined the effects of cutaneous shocks to the tail and mantle on behavioral and neuronal responses. We utilized a semi-intact preparation with the intact mantle organs, tail, and abdominal and ring ganglia. Cutaneous shocks were delivered to the tail or mantle through implanted silver wire electrodes, with shock intensity set at 400% of threshold for siphon movement. Behaviorally, tail shock and mantle shock elicited different reflexive siphon withdrawals (flaring and backward bending vs. constriction and forward bending, respectively); training with these two stimuli also differentially modified the response to a siphon tap presented subsequently. Physiologically, we found that LFS-B siphon motor neurons (which produce flaring and backward bending of the siphon) responded more vigorously to tail shock than did LFS-A siphon motor neurons (which produce constriction and forward bending of the siphon). In addition, LFS-B cells responded more strongly to tail shock than to mantle shock. In contrast, LBS siphon motor neurons fired more to mantle shock than to tail shock. These and related findings (Fang & Clark, Soc. Neurosci. Abstr., 1990; Hickie & Walters, Soc. Neurosci. Abstr., 1990, 1991) help identify the neuronal elements mediating the different forms of reflexive and learning-dependent siphon movements produced by tail and mantle shock.

## 299.9

A SIMULATION APPROACH TO EVALUATING RELATIVE CONTRIBUTIONS OF MULTIPLE 5-HT-MODULATED K+ CURRENTS TO SPIKE BROADENING IN APLYSIA SENSORY NEURONS. K.J. Belkin\*, M.J. Goldstein, B.A. Goldsmith and T.W. Abrams Dept. of Biol. & Inst. of Neurological Sci., Univ. of Pennsylvania, Phila., PA 19104.

Prolongation of action potentials in Aplysia SNs contributes to facilitation of transmitter release during behavioral modulation of withdrawal responses. Spike broadening is due to a reduction in K+ current produced by facilitatory transmitters, including 5-HT. Because 5-HT modulates multiple K+ currents that are not pharmacologically dissociable, it is difficult to determine experimentally the contribution of each to broadening. To examine their contributions, we simulated a SN using the Nodus program (De Schutter, 1989). Data on voltage sensitivity and kinetics of activation and inactivation from published studies and our measurements were used in simulating K+ currents. We simulated four K+ currents that are modulated by 5-HT corresponding to: rapidly activating, V-insensitive and V-sensitive IK-S channels (Schuster et al., 1991); the slowly activating, V-sensitive macroscopic  $I_{K-S}$  (Klein et al., 1982); and the rapidly activating, highly V-sensitive  $I_{K-V,early}$  (Baxter and Byrne, 1989). 5-HT-like alteration in the properties of these currents resulted in both anti-accommodation and spike broadening. Modulation of the rapidly activating  $I_{K-S}$  substantially increased excitability, but had a minor contribution to broadening. Modulation of the slowly activating  $I_{K-S}$  decreased the SN's accommodation. Modulation of  $I_{K-V,early}$ resulted in substantial spike broadening.

FREQUENCY-DEPENDENT PLASTICITY OF LFS<sub>B</sub> SIPHON MOTOR NEURON ACTIONS IN *APLYSIA*. C. Hickie\* and E.T. Walters. Dept. of Physiology & Cell Biology, University of Texas Medical School at Houston, TX 77225.

The 4 LFS<sub>B</sub> siphon motor neurons appear to account for flaring,

tailward movements of the siphon in response to stimulation of the rear of the animal (Hickie & Walters, Soc. Neurosci. Abstr. 16:19, 1990). At least some of these motor neurons show frequency-1990). At least some of these motor neurons show frequency-dependent enhancement of the movements they produce, which may contribute to response-specific learning (*ibid*. 17:548, 1991). We have used detailed video analysis to further characterize peripheral plasticity and potential peripheral interactions of these motor neurons. Test stimuli were 1 s, 15-25 Hz trains of intracellular pulses just suprathreshold for producing a siphon movement. All 4 LFS<sub>B</sub> neurons reliably showed enhancement of test responses by tonic background firing at 0.5-2Hz (n>15 cells)(see also Frost et al. *J. Neurobiol.* 19:297, 1988). This enhancement lasted <2 min after the offset of background firing. Brief, high frequency activation produced much longer-lasting, but more variable effects. A 2 s, 40Hz burst enhanced test responses for <2 to >35 min, with the average enhancement lasting >10 min (n=12 cells). Firing a burst in 1 LFS<sub>B</sub> neuron had no effect on subsequent test responses of other LFSB neurons. Similarly, tonic background activity in 1 LFS<sub>B</sub> neuron did not affect the others. We are now using summation tests as an indication of convergence of different LFS $_{\rm B}$  neurons onto the same muscles. Convergent actions coupled with a lack of crosstalk of plasticity would imply a presynaptic locus of long-lasting, frequency-dependent facilitation in the periphery.

## 299.8

A NEURAL NETWORK MODEL OF USE-DEPENDENT GAIN

A NEURAL NETWORK MODEL OF USE-DEPENDENT GAIN CONTROL IN THE SIPHON WITHDRAWAL REFLEX OF APLYSIA. D.E.J. Blazis\*. T. M. Fischer. and T.J. Carew. Depts of Psychology and Biology, Yale University, New Haven, CT 06520. In the siphon withdrawal reflex (SWR) of Aplysia, intracellular activation of a single member of a class of excitatory interneurons (the L29s) results in significant transient inhibition of reflex input to siphon motor neurons (MNs) [Fischer and Carew, 1991]. The mechanism underlying this inhibition involves L29 recruiting inhibition onto itself from inhibitory interneuron L30, which produces an IPSP in L29 that exhibits marked activity-dependent facilitation. Thus the 1.291.30 interaction provides for use-dependent gain control in the

produces an IPSP in L29 that exhibits marked activity-dependent facilitation. Thus the L291.30 interaction provides for use-dependent gain control in the SWR [Fischer and Carew, 1991].

We previously described a neural network model with a single L29 and a single L30 that generated important aspects of the interactions of these cells, as well as L29-induced inhibition of reflex input to MNs [Blazis et al, 1991]. In the SWR network there are at least 5 L29s and 2 L30s. Thus, our current the SWR network there are at least 5 L29s and 2 L30s. Thus, our current simulations examined the effects of incorporating additional L29s and L30s into the model neural network. Our model was implemented using the network simulator GENESIS and consisted of single compartment cells. Biophysical and synaptic parameters were empirically derived or estimated from cellular studies. Initial results indicate that the expanded model shows improved descriptions of the firing patterns of L29 and of the magnitude of L29-induced inhibition of reflex input to MNs.

Since the behavioral implications of L29-induced reflex inhibition are

Since the behavioral implications of L29-induced reflex inhibition are unknown, we are currently using the model to examine the role of L29/L30 interactions in various forms of plasticity in the SWR, such as habituation, which is known to involve reduction in MN output with repeated sensory stimulation. Initial results show that diminution of reflex output occurs depending on stimulus duration and interstimulus interval. These results suggest that the inhibition created by L29/L30 interactions could augment other mechanisms, such as homosynaptic depression, thought to subserve habituation.

SPONTANEOUS BEHAVIOR OF THE NUDIBRANCH MOLLUSC MELIBE LEONINA IS A MARKOV PROCESS. A.E.Schivell', S.S.-H.Wang. and S.H.Thompson. Hopkins Marine Station of Stanford University, Pacific Grove, CA 93950.

We observed the spontaneous behavior of 20 individual Melibe leonina in the absence of overt stimulation and identified six canonical behavioral states: feeding (F). open hood (OH), roaming/open hood (R/OH), alert posture (AL), roaming/alert (R/AL), and resting (RST). We recorded behavioral states at 15-minute intervals in four six-hour sessions and calculated one- and two-step transition frequencies. The frequencies of one-step transitions quantitatively predicted the observed frequencies of two-step transitions through the Markovian relationship P(A->B->C) = P(A)P(A->B)P(B->C).

The six behaviors fall into two behavior loops, feeding (F, OH, R/OH) and resting (AL, R/AL, RST), with 92% of one-step transitions occurring betweeen behaviors within the same loop. Total time spent by an individual animal in the feeding loop increases with body volume (r = 0.87). This tendency to remain in one behavior loop, in conjunction with the Markov model governing transitions, may be useful for putting whole-animal electrophysiological recordings in context. (Supported by BNS 9021217)

CHAOTIC DYNAMICS IN A MODEL NEURON SERVE AS PUTATIVE MEMORY MECHANISMS. C. C. Canavier\*, D. A. Baxter, J. W. Clark, and MEMORY MECHANISMS. C. C. Canavier\*, D. A. Baxter, J. W. Clark, and J. H. Byrne. Dept. of Neurobiology and Anatomy, The University of Texas Medical School, Houston, TX 77225 and Dept. of Electrical and Computer Engineering, Rice University, Houston, TX 77251.

We have extended our previous analysis of the bursting neuron R15 in Aphysia (Canavier et al., J. Neurophysiol. 1991) by examining the interaction of transient synaptic inputs with the nonlinear chaotic dynamics of the model.

in the absence of synaptic input, multiple modes of activity are associated with stable nested attractors that coexist in the eleven-variable phase space of the model.

In the absence of synaptic input, multiple modes of activity are associated with stable nested attractors that coexist in the eleven-variable phase space of the model at fixed parameter settings. The outermost attractor is associated with a periodic bursting mode. Inside that stable limit cycle is an attractor associated with a periodic bursting mode (Type I). Nested within this chaotic attractor is yet another attractor associated with a distinct chaotic bursting mode (Type II). At the core of the nested attractors is found a limit cycle associated with a beating mode. Thus, we have found chaos to be transitional between bursting and beating in phase space, as well as in parameter space as reported previously (Canavier et al., Biophys. J. 1990).

A brief (one sec) train of synaptic input can switch the activity of the model from one mode to another "adjacent" mode. Moreover, the ability of the synaptic input to induce shifts between modes exhibits temporal specificity. For example, a depolarizing input just prior to a burst can shift the activity from Type I chaotic bursting to periodic bursting, whereas a similar input just after a burst can shift it in the opposite direction, to Type II chaotic bursting. No parameter changes are required for these shifts. Rather, these shifts occur because the state of the system is perturbed into the basin of another attractor. Thus, a transient input can dramatically alter the long-term activity of the system. These results suggest a role for chaotic dynamics in information processing and storage at the level of a single neuron. Specifically, brief "teaching" signals could induce persistent shifts in the long-term activity, which could contribute to the expression and maintenance of persistent cellular alterations of a type necessary for learning and memory. Supported by a grant from the ONR.

QUANTITATIVE ANALYSIS OF THE MODULATION BY SEROTONIN OF THE VOLTAGE-DEPENDENT POTASSIUM CURRENT IN PLEURAL SENSORY NEURONS OF APLYSIA J.A. White\* D.A. Baxter, and J.H. Byrne Dept. of Neurobiol. and Anat., Univ. of Texas Med. Sch. Houston, TX 77030 Baxter and Byrne (1989) found that serotonin (5-HT) modulates a TEAsensitive, voltage-dependent potassium current (Ik.v) in pleural sensory neurons of Aplysia. The precise nature of the serotonergic modulation of Ik.y was not analyzed, however. We isolated Ik.y using TEA difference currents and examined this kinetics of activation and in net visition in country conditions and in the researce its kinetics of activation and inactivation in control conditions and in the presence of 5-HT. The data were fit using a Hodgkin-Huxley type model. The kinetics and steady-state properties of this potassium current were sharply dependent on membrane potential for potentials above 0 mV and otherwise consistent with the membrane potential for potentials above 0 mV and otherwise consistent with the criteria established by Rudy (1988) for delayed potassium currents. The effects of 5-HT on Ixv were complex. 5-HT significantly decreased the steady-state magnitude of Ixv (Iss). Iss in response to a voltage-clamp pulse from -50 mV to +20 mV was decreased by 50%. In addition, 5-HT significantly slowed both activation kinetics (the time constant of activation was increased by 29% at +20 mV) and inactivation kinetics (the time constant of inactivation was increased by 120 mV). No significant effect of 5-HT on steady-state values of inactivation was noted. Our mathematical descriptions of Ixv in control conditions and in the presence of 5-HT were used to estimate the contribution of serotonergic modulation of Ixv to the total 5-HT difference current. Effects of 5-HT on Ixv account for almost all of the 5-HT-induced reduction in outward current during the first 20 ms of a voltage-clamp pulse to +20 mV. This result implies that 5-HT may exert many of its effects on spike width in sensory neurons via modulation of Ixv. exert many of its effects on spike width in sensory neurons via modulation of lky. Effects of 5-HT on lky are consistent with a model in which the maximal conductance underlying the current is decreased by 50% and the rate constants between open and closed states of both the activation and inactivation processes are diminished in magnitude across all membrane potentials. Supported by AFOSR Grant 91-0027 and NIMH Fellowship MH10215.

DIFFERENTIAL PHOSPHORYLATION WITH TREATMENTS THAT INDUCE SHORT-AND LONG-TERM FACILITATION IN APLYSIA. R. Homayouni \*.1.H. Byrne. A. Eskin, Dept. Biochem., Univ. of Houston, Houston, TX 77204. Dept. Neurobiol. & Anat., Univ. of Texas Med. School, Houston, TX 77205.

Application of serotonin (5-HT) for 2 min produces short-term facilitation of tail sensory neurons (SNs) that lasts a few minutes, whereas repeated application of 5-HT for 1.5 hr produces long-term facilitation of SNs that lasts 24 hr. Both short- and long-term facilitation appear to be mediated at least in part by cAMP-dependent protein kinase. Activation of protein kinase C (PKC) may also play a role in mediating short-term facilitation appear to be mediated at least in part by cAMP-dependent protein kinase. Activation of protein kinase C (PKC) may also play a role in mediating short-term facilitation produced by 5-HT (Homayouni et al., 1991). To investigate further the difference in events that may be responsible for inducing short-term and long-term facilitation we addressed two questions. Does the activation of PKC by phorbol diacetate (PDAc) alter the phosphorylation of the same proteins whose phosphorylation was affected by 5-HT? Are the same proteins whose phosphorylation was affected by 5-HT? Are the same proteins whose phosphorylation was affected by 5-HT? for a ganglia and their matched controls were incubated in 32P for 20.5 hr. After 19 hr of labeling, experimental ganglia were treated with either PDAC for 1.5 hr or with 5-HT for 2 min or 1.5 hr. Clusters of sensory neurons were removed and the incorporation of 32P into proteins was examined using 2D-PAGE. The application of PDAc for 1.5 hr increased the phosphorylation of 11 proteins and decreased the phosphorylation of 2 proteins. Four of these proteins were altered similarly immediately after 2 min 5-HT. The proteins whose phosphorylation was altered by 2 min 5-HT and PDAc are good candidates for proteins involved in mediating some of the aspects of short-term sensitization.

The phos

SEROTONIN INHIBITS INHIBITORY INTERNEURONS IN THE NEURAL CIRCUITRY FOR THE TAIL-WITHDRAWAL REFLEX OF APLYSIA. Y. Xu-1. P. Pieroni. L. J. Cleary and J. H. Byrne. Department of Neurobiology and Anatomy. University of Texas Medical School, Houston, TX 77225.

Sensory neurons (SNs) in the pleural ganglion are hyperpolarized by mechanical stimulation of the tail outside their receptive fields. Previously, we identified two types of inhibitory interneurons (iINs) in the right pleural ganglion of Aplysia that may mediate this hyperpolarization (Xu et al., 1991). These iINs are differentiated by the time course of the hyperpolarization that they evoke in SNs, and by the presence or absence of immunoreactivity to the inhibitory peptide FMRFamide. We also found that non-FMRFamide immunoreactive (NF-) IINs were distinctive in that they also hyperpolarized tail motor neurons (MNs) in the pedal ganglion.

The neuromodulator serotonin (5-HT) has well-established facilitatory actions on the connections between SNs and MNs, but little is known about its effects on other elements (e.g., interneurons) in the neuronal circuitry underlying the tail-withdrawal reflex of Aphysia. We examined the effects of 5-HT on NF-iINs themselves, and on the associated hyperpolarization of SNs and MNs produced by NF-iINs. Identified NF-iINs were stimulated by 2-sec depolarizing current pulses at 5-min intervals. These successive test stimulations produced at least two effects: bursts of action potentials in the NF-iINs (with a consistent number of spikes in each test) and pronounced hyperpolarization of SNs. Application of 5-HT (25 µM) after the second test stimulation hyperpolarization of monitored MNs (and usually a small hyperpolarization of monitored SNs). Application of 5-HT (25 µM) after the second test stimulation hyperpolarization of the MNs and SNs was either decreased or absent after application of 5-HT, even in cases in which the number of spikes elicited by the stimulation is modulated by 5-HT. Thus, the sensitizing effect of 5-HT on

ACTIVATION OF PROTEIN KINASE C MIMICS SEROTONIN-INDUCED MODULATION OF A VOLTAGE-DEPENDENT POTASSIUM CURRENT IN PLEURAL SENSORY NEURONS OF APLYSIA. S. Sugita\*. D.A. Baxter and J.H. Byrne, Dept. of Neurobiology and Anatomy, University of Texas Medical School, Houston, TX 77225.

Byrne, Dept. of Neurobiology and Anatomy, University of Texas Medical School, Houston, TX 77225.

Modulation of a voltage-dependent K<sup>+</sup> current (lk,v) appears to play a major role in serotonin (5-HT) -induced spike broadening, which develops slowly in pleural sensory neurons (Baxter and Byrne, 1989, 1990). Little is known regarding which protein kinase mediates this modulation, however. Since activation of protein kinase C (PKC) by phorbol esters mimics a component of 5-HT-induced broadening (Sugita et al., 1991, 1992), we examined the effects of phorbol esters on Ix.v. Two-electrode voltage-clamp techniques were used to measure current responses to 200 ms pulses from -70 mV to -30, -20, 0, +20 mV in isolated clusters of pleural sensory neurons maintained at 15 ± 1 °C. Phorbol esters, phorbol-12,13-diacetate (3 μM) or 12-deoxyphorbol, 13-isobutyrate (2 μM), had little effect on membrane current at -30 and -20 mV. At more depolarized potentials, e.g. +20 mV, where Ix.v predominates, phorbol esters produced complex modulation of the membrane current. Phorbol esters appeared to slow the kinetics of the current responses. This resulted in a decrease in outward current at the end of pulse. This modulation is similar to 5-HT-induced modulation of Ix.v (Baxter and Byrne, 1989; White et al., this volume). In addition, application of 5-HT after phorbol esters had little additional effect on membrane current. Inactive phorbols did not produce changes in membrane current and symp, phorbol esters had little additional effect on membrane current inactive phorbols did not produce changes in membrane (Ix.c.), blocked a portion of the phorbol ester-induced modulation of Ix.v. Low concentration of TEA (2 mM), which blocked a Ca<sup>2+</sup>-activated potassium current (Ix.c.), blocked a portion of the phorbol ester-induced modulation at the end of voltage-clamp pulse, suggesting that an increase in outward current at the end of voltage-clamp pulse, suggesting that an increase in outward current at the end of voltage-clamp pulse, sugge

PHOSPHORYLATION AND SYNTHESIS OF INTERMEDIATE FILAMENT PROTEINS ARE AFFECTED BY TREATMENTS MIMICKING SENSITIZATION IN APLYSIA. F. Noci\* R. Homayouni. M. Nuñez-Requeino J.H. Byrne. A. Eskin. Dept. of Neurobiol. & Anat., Univ. of Texas Med. Sch., Houston, TX 77225 & Dept. of Biochem. & Biophys. Sciences, Univ. of Houston, TX 77225.

Houston, TX 77224 & Dept. of Biochem. & Biophys. Sciences, Univ. of Houston, TX 77204.

To investigate the involvement of individual proteins in learning and memory, we examined the effects of analogues of sensitization training on the synthesis and phosphorylation of proteins in pleural sensory neurons (SNs) of Aplysia. In one series of experiments we searched for proteins whose synthesis was altered by electrical stimulation of peripheral nerves of pleural-pedal ganglia over a 1.5 hr period. Incorporation of labeled amino acid was examined immediately after and 24 hr after electrical stimulation. In another series of experiments changes of phosphorylation of proteins were examined after a 2 min or 1.5 hr application of serotonin (5-HT). These studies focused our attention on two relatively abundant proteins. The incorporation of labeled amino acid into protein 17 (MW: 50; pl: 5.2) was increased 24 hr after electrical stimulation but was not affected immediately after stimulation. Although label incorporation into protein 6 (MW: 57; pl: 5.25) did not appear affected by electrical stimulation, its phosphorylation was increased after 1.5 hr application of 5-HT. Phosphorylation of protein 17 was increased after 1.5 hr application of 5-HT. Phosphorylation of protein 17 was increased after 1.5 hr application of 5-HT. Phosphorylation of protein 17 and fem protein of these proteins and their roles in learning and memory, amino acid sequences of peptides derived from the proteins by V8 protease digestion were obtained. Three partial sequences from protein 17 and 5 mere determined. The partial sequences from protein 17 mere 83 %, 96 % and 94 % identical to Aphysia IFP. The peptides from protein 17 were 83 %, 96 % and 94 % identical to Aphysia IFP. The peptides from protein 17 here 10 protein 17 and 5 mere 100 %, 80 %, 100 % and 100 % identical to Aphysia IFP.

DELAYED APPLICATION OF ANISOMYCIN BLOCKS LONG-TERM (24 HR) CAMP-INDUCED MORPHOLOGICAL CHANGES IN PLEURAL SENSORY NEURONS OF APLYSIA. F.A. NAZIF\* J.H. BYRNE and L.J. CLEARY. Dept. Neurobiology and Anatomy, Univ. Texas Med. Sch., Houston, TX 77225 Intracellular injection of cAMP into sensory neurons elicits changes in morphology similar to those seen with long-term sensitization (Nazif et al, 1991a). The induction of these changes is dependent on protein synthesis during the injection period (Nazif et al, 1991b). Long-term facilitation of synaptic transmission by 5-HT is blocked by anisomycin applied concurrently with 5-HT, but not when application of anisomycin is delayed by 0.5 to 4 hr (Montarolo et al, 1986). Therefore, we examined the effects of delayed application of anisomycin on cAMP-induced morphological changes. morphological changes

morphological changes.

cAMP (200 µM) was iontophoresed into sensory neurons of paired pleural ganglia. Four hr later, one ganglion from each pair was incubated in culture medium containing anisomycin (10 µM), while the other was incubated in culture medium containing the inactive derivative deacetylanisomycin (10 µM). Three hours later, the ganglia were perfused with fresh culture medium. About 22 hr after nucleotide injection, the same neurons were pressure injected with HRP, incubated for another 2 hr, and processed. The number of varicosities was greater in neurons whose ganglia were bathed in deacetylanisomycin than in neurons from contralateral ganglia bathed in anisomycin (52 ± 13 SEM vs 17 ± 4 SEM; P<0.02; n=6). In control experiments, a 3 hr application of anisomycin alone had no significant effects on varicosity number 22 hr after application (31 ± 11 SEM vs 33 ± 10 SEM; P=0.18; n=9).

These data indicate that the morphological changes induced by cAMP are

These data indicate that the morphological changes induced by cAMP are dependent on de novo protein synthesis not only during the injection period but also at least 4 to 7 hr afterwards. Although the time course of sensitivity to anisomycin is not identical to that for long-term facilitation, it is consistent with the time course for development of long-term morphological changes (Bailey and Chen, 1989). Moreover, changes in the synthesis of proteins have been observed as long as 24 hr after long-term training (Castellucci et al. 1988; Barzilai et al. 1989; Noel et al. 1990). These data suggest that structural changes and transmitter release are 1990). These data regulated separately.

ARGININE VASOPRESSIN POTENTIATES THE EFFECTS OF OF CORTICOTROPIN RELEASING FACTOR ON BEHAVIOR IN RATS. M.K. Salander, S.T. Ahlers, and P.A. Shea\* Naval Medical Research Institute, Bethesda, MD 20889-5055

Research suggests that corticotropin releasing factor (CRF) and vasopressin interact in modulating the release of glucocorticoids in The present study examined whether the response to stress. facilitative effects of vasopressin on CRF would extend to a behavioral baseline which has been shown to be sensitive to CRF. Rats were administered intracerebroventricular (i.c.v.) CRF (0.1-1.0 µg) or saline 60 minutes prior to performing on a multiple fixed interval (FI) 60 sec/fixed ratio (FR) 20 schedule for food reinforcement. A session consisted of 10 components of each schedule which alternated, starting with the FI component. Thirty minutes prior to the test session rats were administered either 1.0µg arginine vasopressin (AVP) or saline (sub-Q) in the nape of the neck. All injections were given in a mixed sequence. Compared to saline control performance, administration of AVP slightly decreased the rate of responding in the FI component but did not effect FR responding. Administration of CRF produced dosedependent suppression of FI and FR responding. Co-administration of AVP and CRF shifted the CRF dose-response curve to the left indicating that AVP potentiated the effects of CRF on behavior.

## 300.3

BEHAVIOR AND TELEMETERED AUTONOMIC RESPONSES TO ALCOHOL AND SOCIAL STRESS W. Tomatzky and K.A. Miczek, Dept. Psychology, Tufts University, Medford, MA 02155.

Animals react to social stress with defensive and submissive

behavior as well as with increased cardiovascular activity and core temperature. To evaluate the involvement of alcohol and anxiolytics on telemetered heart-rate, core temperature and on behavioral reaction of a rat that is exposed for 1 hour to threats by an opponent, ethanol (0.1-3.0 g/kg, p.o.) and diazepam (1.0-10.0 mg/kg, ip.) were administered. The acute social stress situation consisted of brief physical agonistic interactions until the experimental rat was forced into a prolonged submissive supine posture, emitted ultrasounds and, subsequently, exposure to the opponent's threats, while being shielded from physical contact. Alcohol attenuates the stress induced hyperthermia, induces a dose-dependent decline in upright postures and a disruption of high-frequency ultrasonic calls. The protocol includes a time period prior to the physical interaction, where the defeat experienced intruder is confronted only with the olfactory cues of the resident homecage. In this period of conditioned anticipation of an upcoming defeat, alcohol in contrast to diazepam, decreases vocalization, defensive behavior and increases exploratory behavior. Components of the autonomic and behavioral responses to different grades of social stress can be pharmacologically

## 300.2

INDIVIDUAL CHARACTERISTICS AND BEHAVIORAL AND HORMONAL RESPONSES TO ACUTE STRESS IN RATS. V.M. Wiegant\*, M. Broekhoven, A. Frankhuyzen-Sierevogel, M. Nijsen, I. Raats and G. Croiset. Rudolf Magnus Institute, Dept. Medical Pharmacology, University of Utrecht, The Netherlands. Rats respond to a stressor with coordinated behavioral and neuro-endocrine reactions. It is thought that such reactions depend not only on quality and intensity

of the stressor, but also on individual characteristics (innate and acquired) of the animal. The aim of the present study was to investigate the relationships between such characteristics, determined in water competition (ranking) and open field

animal. The aim of the present study was to investigate the relationships between such characteristics, determined in water competition (ranking) and open field (innate activity) tests, and responses to acute stress in a shock-prod burying test. For the water competition test, rais were housed five per cage with ad libitum food and water for at least two weeks. On four consecutive test days, water was withheld for five hours. Then drinking behavior was monitored for ten minutes, and rank numbers were assigned based on sequence and duration of access to the drinking nipple. Activity tests were performed on four consecutive days. Rats were placed in an open field for 10 min and total locomotor activity (travelled distance) was determined. Following assessment of the individual characteristics in these paradigms, the animals were surgically fitted with a jugular vein cannula for repeated blood sampling, and housed single-caged. After a one-week recovery period, they were confronted with an electrified prod that was inserted into the home cage. The behavioral response of each rat was analysed for time spend approaching and burying the prod. Blood samples for plasma corticosterone assay were collected 5 min prior, and 0, 5, 15 and 45 min after prod insertion.

High active rats (open field) displayed more burying behavior than low active rats, whereas low active rats spent more time approaching the prod. Both types of animals showed an increase in plasma corticosterone. High ranked animals (water competition test) spent significantly more time burying than low ranked rats, and showed more approaching behavior. In contrast to low ranked animals (water competition test) spent significantly more time burying than low ranked rats, and showed more approaching behavior. In contrast to low ranked animals two did not show an increase in plasma corticosterone. High ranked animals (water competition test) spent significantly more time burying than low ranked rats, and showed more approaching behavior. In contrast to low ranked

The results suggest that differences in behavioral and neuro-endocrine responses to a given stressor are determined by preexisting individual characteristics

## 300.4

TYROSINE REDUCES THE ADVERSE EFFECT OF HYPOBARIC HYPOXIA ON SPATIAL WORKING MEMORY OF THE RAT. H.R. Lieberman, B. Shukitt-Hale<sup>1</sup>, S. Luo, J.A. Devine and J.F. Glenn\*, Military Performance and Neuroscience Division, U.S.Army Research Institute of Environmental Medicine, Natick, MA 01760 and GEO-CENTERS, INC., Newton Centre, MA 02159.

Exposure to hypobaric hypoxia rapidly produces profound decrements in various cognitive functions including learning and memory. neurotransmitter precursor tyrosine has been reported to have beneficial behavioral effects when it is administered to experimental animals and humans who are exposed to various acute stressors. To determine whether tyrosine would protect animals from the adverse effects of hypobaric hypoxia on spatial memory, it was administered, in a divided dose, at 1.5 hours (400 mg/kg, i.p.) and again at 5.5 hours (400 mg/kg, i.p), after ascent to a simulated altitude of 5950 m (19,500 ft). Nine rats were treated with tyrosine and nine received vehicle. Working and reference memory were ssed using the Morris Water Maze task. Tyrosine treatment significantly reduced working memory escape time when compared to vehicle (53.4 sec  $\pm$  10.1 vs. 90.7  $\pm$  7.3; mean  $\pm$  SEM) (p < .04) but did not affect reference memory. There were no treatment related differences in performance when animals were tested the next day at sea level. The beneficial effects of tyrosine on working memory may be due to a direct effect of tyrosine on memory function or to other central or peripheral effects of this dietary catecholamine precursor. The absence of carry-over effects when animals were tested the next day supports the latter hypothesis.

EXPOSURE TO HEAT STRESS DISRUPTS THE ACQUISITION AND PERFORMANCE OF RESPONSE CHAINS IN RATS. J. Schrot\* and J.R. Thomas. Naval Medical Research Institute, Bethesda, MD 20889-5055.

Performance of well-learned behavior is disrupted by exposure to heat. The extent to which heat interferes with the acquisition (learning) of behavior is less well understood. This study examined the effect of acute heat stress on both the acquisition and performance of four-member response sequences in rats. Four animals were trained on a four lever, four member repeated acquisition procedure in which each day of the week was associated with a different required sequence of responses. Each correct response advanced the sequence to the next member and the fourth correct response resulted in the delivery of a food pellet. Incorrect responses resulted in a three second period of timeout. This procedure generates a daily acquisition or learning curve. During the performance condition the sequence remained the same from day to day. The animals were exposed to a control air temperature of 22°C, or experimental temperatures of 31°C, 35°C, or 38°C for 30 minutes prior to the start of and during sessions. The results indicate that exposure to the two highest temperatures disrupted accuracy of responding during both the acquisition and performance of sequences. At the highest temperatures animals frequently did not complete sessions. With comparable temperatures, the animals tended to complete fewer sequences per session during the acquisition condition, indicating that acquisition was more sensitive to heat stress than was performance.

AGED RATS: PLASMA CATECHOLAMINE RESPONSES TO ACUTE COLD STRESS. T. R. Mabry, H. Tong, R. McCarty, and P. E. Gold\*. Department of Psychology, University of Virginia, Charlottesville, VA 22903.

One consequence of normal aging appears to be a diminished capacity to adapt to stressful stimulation. Specifically, aged animals and humans exhibit altered patterns of sympathetic-adrenal medullary activation when exposed to a variety of homeostatic challenges. In the present series of experiments, Fischer 344 male rats (3 and 22 months of age) were prepared with chronic tail artery catheters three days prior to exposure to acute stress (immersion in water at 20°, 25°, 30° or 35° C) for 15 minutes. Blood samples were collected under basal conditions and at 0, 15, 30 and 45 minutes post-immersion. Plasma samples were later assayed for content of norepinephrine (NE, pg/ml) and epinephrine (EPI, pg/ml) as a measure of sympathetic-adrenal medullary activity. Our findings indicate that aged rats have significantly greater plasma NE and EPI responses to immersion at 20° and 25° C and their return to baseline is more prolonged. In contrast, the plasma NE and EPI responses of aged rats more closely resembled those of young adult controls following immersion in 30° or 35° C water. These data are consistent with the view that aged rats display exaggerated plasma catecholamine responses to intensely stressful stimulation. These exaggerated physiological responses may underlie in part the inability of aged animals to adapt to or, in some cases, to survive significant environmental challenges.

## 300.9

THE EFFECTS OF STRESS ON SPATIAL LEARNING CAN BE ATTENUATED BY BLOCKING NMDA RECEPTORS (AND LTP). T. J. Shors\* Department of Psychology, Princeton University, Princeton, NJ 08540.

A number of correlations between stress and LTP have led me to hypothesize that stress is inducing a form of synaptic potentiation similar to, if not the same as, LTP. For example, both stress and LTP increase classical conditioning (Shors et al., 1992; Berger, Science 224, 1984). If such a hypothesis were true, then stress should impair spatial learning, just as LTP does (McNaughton et al., J. Neurosci. 6, 1986).

Sprague-Dawley rats (n=16) were habituated to an 8-arm radial maze and half were restrained and exposed to 90, 1s, 1 mA tailshocks. 24 hours later, they were exposed to 5 booster shocks and tested 2 trials per day for 6 days. Relative to unstressed controls, stressed rats were impaired in acquisition of the maze [F(5,70)=6.86; p<0.001].

If stress impairs maze learning by inducing LTP, blocking NMDA receptors (and LTP) during the stressor should eliminate the impairment. 12 rats were injected with CGP (30 mg/kg), a reversible and competition NMDA antagonist, and half were exposed to the stressor. Rats with CGP during the stressor were not impaired relative to stressed controls  $[F(5,120)=3.08;\ p<0.01]$ . Although CGP induced a notable motor impairment, rats with CGP alone learned as well as unstressed controls and CGP/stressed rats (p>0.05). These results suggest that the effects of stress on spatial learning are mediated through glutamate receptor activation and, potentially, LTP.

FURTHER EVIDENCE TYROSINE REVERSES BEHAVIORAL DEFICITS CAUSED BY COLD EXPOSURE. S. Luo, L. Villamil, C.J. Watkins\* and H.R. Lieberman. Military Performance and Neuroscience Division, U.S. Army Research Institute of Environmental Medicine, Natick, MA 01760.

Neurotransmitter-related behavioral deficits may occur when animals are under acute stress. The neurochemical alteration most consistently observed has been a reduction of brain norepinephrine (NE) levels. The objective of this crossover study was to determine if the NE precursor tyrosine could prevent or alleviate stress-induced adverse behavioral changes in male Fischer rats. On two separate trials nine animals were restrained and immersed in a water bath (17°C) for about 20 min. until a core body temperature (T<sub>c</sub>) of 30°C was obtained. On one trial tyrosine (400 mg/kg, ip) was administered 30 min prior to hypothermia and on another saline was given. On a third trial animals were restrained and immersed in a 36°C water bath for 20 min, which did not alter normal T<sub>c</sub>. Immediately following these treatments the animals were placed in a narrow cylinder filled with water maintained at 18°C and duration of immobility was assessed over a six minute period. A repeated measures ANOVA revealed a significant treatment effect (p<0.0001). Post hoc Duncan's comparisons showed that mean ( $\pm$ SEM) immobility following immersion in cold water was significantly greater than immersion in 36°C water ( $104\pm15.0$  vs.  $31\pm5.7$  s. respectively, p<.01). In addition, when rats were treated with tyrosine mean immobility was  $40\pm5.1$  s., a significant reduction compared to placebo treatment (p<.01) but not different from immersion in 36°C water. This study confirms that hypothermia was highly effective in producing behavioral depression which was reversed by tyrosine treatment.

#### 300.8

EFFECT OF STRESS ON THE DOMINANT/SUBMISSIVE RELATIONSHIP BETWEEN MALE RATS. A.B. Lucion and W.H. Yogel\*, Dpt. of Pharmacology, Jefferson Medical College, Philadelphia, PA 19107 and Dpt. of Physiology, Federal University Rio Grande Sul, Porto Alegre, 90049, Brazil.

A dominant/submissive relationship between 2 rats based on frequency, total and mean duration of competitive water consumption was formed quickly and remained stable during all the experiment (control group). Nine dominant rats were exposed to a mild (2 hr restraint) and another group of 9 dominant rats to a severe (18 hr restraint) stressor. Restraint was repeated 3 times and the animals were always released 2 hr before the water competition test. During mild stress, there was a significant decrease of water intake by the stressed rats without an increase by the unstressed. After termination of the restraint, the dominant rats quickly regained their former positions. The severe stress caused a more profound decrease in water intake by the dominant rats with a concomitant increase by the submissive ones or an actual reversal of the dominant/submissive relationship. After termination of restraint, the dominant rats regained their former positions more slowly. Thus, acute stress of a dominant animal decreases aggression in the water competition test leading to a loss of social dominance. Cessation of stress restores the original social relationship. ADENOSINE ANALOGS MIMIC, METHYLXANTHINES REVERSE, AND GLUCOSE MITIGATES STRESS-INDUCED DEPRESSION IN RATS. Thomas R. Minor\*, Wei-Chao Chang, & Jeff L. Winslow. Dept. of Psychology, UCLA, Los Angeles, CA 90024-1563.

The possibility was examined that the behavioral depression and escape deficits observed in rats exposed to inescapable electric shock (IS) 24 hr earlier result from compromised energy metabolism and a consequent increase in adenosine (ADO) mediated inhibition in the CNS. Caffeine (Caf: 1,7,14,30 mg/kg) and theophylline (3,10,17 mg/kg), ADO receptor antagonists, reversed (but did not prevent) escape deficits in IS rats in a dose-dependent manner. Amphetamine (AMP), another psychomotor stimulant, failed to improve the escape performance of IS rats and produced a progress deterioration of escape in restrained (noshock) controls. The AMP-induced deficit was reversed by Caf. ADO analogs administered 24 hr after simple restraint (i.p. injection: .01-10 µmol/kg) mimicked the effect of earlier inescapable shock on test performance (NECA>R(-)PIA>S(+)PIA). A submaximal dose of NECA summated with earlier exposure to a submaximal number of inescapable shocks to maximize the test escape deficit. Finally, access to a 40% glucose solution over the 24 hr between inescapable shock pretreatment and escape testing markedly improved test performance. These data strongly implicate metabolic and purine-regulatory processes in behavioral depression following acute, traumatic stress. (Supported by R01 MH41170-03).

"NONOPIATE" COLD WATER SWIM-INDUCED ANALGESIA ATTENUATES MORPHINE ANALGESIA.

J.E. Grisel\*. R.E. Grahn. L. Sutton. L.R. Watkins & S.F. Maier.

Department of Psychology, University of Colorado, Boulder CO 80309

Department of Psychology, University of Colorado, Boulder CO 80309

These experiments investigate the relationship between a "nonopiate" stress-induced analgesia (SIA) and the opiate analgesia produced by systemic morphine. Rats who were given morphine (1.5 mg/kg sc) prior to cold water swim (CWS; 4 min at 14°C) demonstrated less analgesia than those who received either morphine or CWS alone. These results are interpreted as evidence for a model of collateral inhibition (Kirschgessner et al., 1982) in which opiate and nonopiate systems can be mutually inhibitory. Since the specific mechanism(s) involved in this interaction are not yet understood, additional experiments manipulated variables known to differentially effect opiate and nonopiate analgesias. Rats given prior experience with escapable shock known to attenuate opioid analgesia (100, 1 mA, 5 sec tailshocks) did not show the attenuated levels of analgesia resulting from CWS + morphine. Inescapably shocked, restrained and home cage control rats did not differ from each other, and all showed decreased levels of analgesia in response to the dual manipulation. Further, adrenalectomy was shown to block the ability of CWS to attenuate morphine analgesia in inescapably shocked rats, but this effect was reinstated when rats were supplemented with corticosterone in their water.

#### 300.13

MODULATION OF IMMUNE RESPONSES IN NEONATALLY STRESSED RATS BY THE MATERNAL PRESENCE. S.K.Sobrian\*, M. Lazarevic, B.M. Markovic, V.J. Djuric and B.D. Jankovic. Dept. Pharmacology, Howard Univ. Col. of Med., Washington, DC 20059 and Immunology Research Institute, Belgrade, Yugoslavia.

Early experience can influence adult immune responses. Increases, decreases and no changes in tumor growth, disease incidence and survival time have been reported following neonatal manipulations. These discrepancies may reflect inadvertent stressing of control pups by maternal separation. To test this hypothesis, Wistar rat pups were sound stressed on postnatal days (PND) 15.18 and 21. Stress consisted of exposure to a 90 dB fire alarm bell that was programmed, on a variable interval schedule, to ring 60 times in 1 hr. Pups were stressed in groups of 3-4, either with (SPM), or without (SP) the dam present. Non-stressed controls were either isolated from (CP) or left with the dam (CPM) for the 1 hr period. All maternally isolated pups were maintained in an 80-85° F environment. At PND 46-49, rats were immunized with bovine serum albumin (BSA) in complete Freund's adjuvant; 14 days later, antibody production to BSA, and Arthus and delayed skin reactions to BSA and old tuberculin (OT) were measured. The severity of adjuvant-induced inflammation of the injected foot was also assessed. SP rats showed a decrease in the Arthus reaction to BSA in comparison to CP and CPM groups, which did not occur in SPM animals. The delayed reaction to OT was decreased in both SP and CP males; the response of SPM animals was unaltered. The inflammatory response was attenuated in both stressed groups. Antibody titers were reduced in CP, SPM and SP males. Therefore, the presence of the dam during neonatal stress can attenuate the stress-induced suppression of some *in vivo* humoral and cellular immune responses. The fact that some humoral responses were sensitive to maternal separation alone supports our hypothesis that maternally isolated nonstressed pups may not be adequate controls. (Supported by CIES and Republic of Serbia Research Fund).

## 300.15

PSYCHOBIOLOGIC CONSEQUENCES OF POSTNATAL REARING ON MEASURES OF SHOCK-INDUCED STRESS IN YOUNG RATS.

I. Goodman\*, K. Vrana, S. Vrana, L. Beeler & A. Azzaro.
Dept. of Behav. Med. & Psychiatry, Biochemistry,
Neurology and Psychology, West Va Univ. Morgantown, WV 26506.

This study attempted to measure combined effects of weaning time (15 vs 30 day) and housing (single vs mult. caged) on future shock-induced (4 15-min sess. of brief footshock, .8 ma) stress in 45-d old male rats, using a factorial design. 8 treatment combinations were used. Fear assessment included locomotion in a novel open field, defecation, and plasma corticosterone (pCORT).

Among groups, 30d wean/single cage/shock rats, relative to their nonshock controls, showed most marked fear in tests initiated 48 hr after shock. They had elevated fecal bolus and pCORT and lower exploratory habituation (EH) mean scores. When 2 added groups of 30d wean/single cage/shock rats were given a single inj. of saline (SAL) or centrally-acting anxiolytic chlordiazepoxide (CDP, 5 mg/kg) prior to exploratory locomotion testing, SAL rats showed an EH score lower than CDP rats, a pattern like that found in shocked vs nonshocked rats in the prior expt. EH as a useful behavioral index of fear (Johnson et at, 1991) is supported. The findings raise questions regarding the role of time in relation to multiple life stressors and fear outcomes.

#### 300.12

IMMUNE STATUS ASSOCIATED WITH DYSTHYMIA, MAJOR DEPRESSION AND STRESSFUL LIFE EVENTS. J. Griffiths\*, A. Ravindran, C. Waddell and H. Anisman. Royal Ottawa Hospital and Carleton University. Ottawa, Ontario, Canada.

Depression and stressful life events have been associated with alterations of immune functioning. The present investigation sought to establish whether the ability to cope with major and minor stressors (daily hassles) would influence immune status in individuals suffering from either major depression or dysthymia (chronic mild depression). Circulating T cell subpopulations (activated T cells, CD4 helper, CD8 suppressor/cyctotoxic), B cells or NK cells were found not to differ among these patients relative to nondepressed controls. The depressed and dysthymic patients reported increased frequency of life event changes during the preceding 12 months, as well as the hassles encountered during the preceding month. The frequency and severity of these stressors were correlated with several immune measures. Moreover, immune status also varied as a function of the coping styles that patients had employed. The data are related to the notion that affective state per se may not be related to immune alterations; however, in depressed patients perceived stressors and coping styles are associated with immune status.

### 300.14

STRESSOR EFFECTS ON IMMUNE AND CENTRAL NEUROTRANSMITTER ACTIVITY: STRAIN DIFFERENCES IN MICE. <u>L. Kerr. D. Francis & H. Anisman\*</u>. Dept. Psychology, Carleton Univ., Ottawa, Ontario K1S 5B6, Canada.

Stressors influence the splenic plaque forming cell (PFC) titers following antibody response and plasma administration of sheep red blood cells (SRBC). However, in CD-1 mice, this effect was dependent on the timing of the stressor relative to antigen treatment. A critical period existed, such that a stressor applied 72 hr after SRBC inoculation suppressed the peak immune response, but was without effect at other intervals. In the present report we demonstrate that the magnitude and time of the peak immune response to SRBC (106) varied across strains of mice (CD-1, C57BL/6ByJ, BALB/cByJ, DBA/2J). Moreover, a stressor (360 shocks, 2 sec, 300 uA) provoked strain-specific alterations of the immune response. Indeed, in some instances footshock elicited an immunoenhancement, rather than a suppression. Additionally, systemic SRBC administration provoked strain-dependent alterations of central norepinephrine and dopamine, but did not influence either plasma corticosterone or ACTH accumulation. The data are related to bidirectional communication between the immune and CNS.

## 300.16

CORTICOSTEROID INDUCTION OF THREAT-INDUCED BEHAVIORAL INHIBITION IN THE PREWEANLING RAT. <u>L. K. Takahashi\* and W. W. Rubin.</u> Dept. of Psychiatry, Univ. of Wisconsin Med. Sch., Madison, WI 53792 and Middleton Veterans Hospital, Madison, WI 53705.

In rats, basal plasma corticosterone (CORT) increases after the first postnatal week and the hypothalamic-pituitary-adrenal system becomes responsive to stressors by the end of the second week. In addition, 14-day-old rats, but not 7-day-old pups, inhibit their emission of ultrasounds and freeze when socially isolated and exposed to an unfamiliar adult male rat, a naturalistic threat. This study examined whether CORT plays a major role in the developmental emergence of threat-induced behavioral inhibition.

Ten-day-old rats were adrenalectomized (ADX) and exposed to an adult male rat at 14 days of age. ADX rats emitted more ultrasounds (p < .05) and exhibited less freezing (p < .01) than intact rats. This noninhibited occurrence in vocalizations by ADX rats was not due to a potentiated increase in ultrasound production because when tested in social isolation without the adult male rat, vocal production did not differ significantly between groups. ADX rats treated daily with CORT (3mg/kg) from 10 to 13 days of age displayed significantly more freezing (p < .05) when threatened at 14 days of age than ADX rats treated with lower doses of CORT (0-0.3 mg/kg). Results indicate that during development one important action of CORT is to induce in rat pups the capability to adaptively inhibit behavioral activity when threatened. Supported by grant MH-43986.

CORTICOSTERONE MODULATES EXPLORATION VIA CENTRAL MINERALOCORTICOID RECEPTORS. M.S. Oitzl\* and E.R. de Kloet. CBPS, Div. Med. Pharmacol., University of Leiden, NL-2300 RA Leiden, The Netherlands.

Corticosterone (B) exerts its central effects via mineralocorticoid (MRs) and glucocorticoid receptors (GRs). MRs display a high affinity for B and are occupied at low, basal levels of B: GRs are mainly occupied at stress levels of B. MRs are thought to be involved in the regulation of the threshold of the stress response, GRs in processes of information storage. To elucidate the role of MRs in the behavioral stress response we analyzed the exploration pattern of Wistar rats in a large open field with an object in its center. First, we demonstrated that B plays a role in this task: One day after adrenalectomy (ADX) rats explored significantly more the center area and its object compared to sham-ADX or intact rats. Treatment of ADX rats with a low dose of B (50  $\mu$ g/kg sc; basal condition, and preferential occupation of MRs) normalized the exploration pattern. ADX and intact rats treated with a high dose of B (1000  $\mu$ g/kg sc; stress condition) showed more exploration of the center. Blockade of central MRs by a selective MR antagonist (RU28318; 100 ng/µl icv) in intact rats prevented the Binduced increase in exploring the center area. - Occupation of MRs is necessary for the exploration, not only in basal but also during stress

AMPEROZIDE REDUCES PSYCHOSTIMULANT-INDUCED
HYPERLOCOMOTION BUT NOT DOPAMINE RELEASE IN
NUCLEUS ACCUMBENS.

T.H.SVENSSON. Dept. of Pharmacology, Karolinska
Institute, Box 60400, S-10401, Stockholm, Sweden.

Institute, Box 60400, S-10401, Stockholm, Sweden.

Amperozide (APZ) is a novel atypical neuroleptic that appears to selectively act on the
limbic system. The present study investigated
behavioral and biochemical effects of APZ on
either d-amphetamine (AMPH) or cocaine (COC)
treated rats. Behavior was assessed by locomotor
activity measurements. Compared to saline controls, APZ (5 and lOmg/kg,SC) decreased locomotion. Hyperlocomotion induced by AMPH (Img/kg,
SC) or COC (10mg/kg,IP) was greatly reduced by
APZ administered 20min earlier. Biochemical data
was obtained by in vivo microdialysis in freely
moving animals. APZ dose-dependently increased
interstitial concentrations of dopamine (DA,
+30%) in the nucleus accumbens (NAC). While AMPH
or COC alone increased DA levels (450% and 270%,
respectively), APZ had no effect on this
increase. In contrast, APZ pretreatment dosedependently attenuated the reduction of DA
metabolites induced by AMPH and COC. These
results indicate that APZ blocked hyperlocomotion induced by psychostimulants, without
correlative changes in DA concentrations in NAC.

## 301.3

INVOLVEMENT OF NUCLEUS ACCUMBENS DOPAMINE IN AVERSIVE MOTIVATION: A MICRODIALYSIS AND BEHAVIORAL INVESTIGATION. L.D. McCullough\*, J. D. Sokolowski, M. Cousins and J. D. Salamone. Dept. of Psychology, Univ. of Connecticut, Storrs, CT 06269-1020.

Four experiments were conducted to investigate the

Four experiments were conducted to investigate the role of nucleus accumbens dopamine (DA) in aversive motivation. In the first experiment groups of rats were trained on a lever press avoidance procedure, in which 0.5 mA shock was presented for 5 sec every 30 sec, but the rat could escape shock or avoid shock for 30 sec by pressing a lever. Accumbens DA depletion produced by 6-hydroxydopamine injection led to a substantial decrease in lever pressing to avoid or escape shock. In the second experiment, dialysis probes were implanted into the nucleus accumbens. Compared to control rats and rats exposed to periodic shock, rats performing the avoidance task showed significant increases in extracellular DA, DOPAC and HVA. In the last two experiments, in vivo dialysis methods demonstrated that the anxiogenic drugs beta-CCE (1.25-2.5 mg/kg) and FG 7142 (10.0-30.0 mg/kg) both increased accumbens DA release. These results indicate that DA in nucleus accumbens is important for avoidance responding, and that the involvement of accumbens DA in motivation is not unique to positive reinforcement or drugs of abuse.

## 301.2

INVOLVEMENT OF NUCLEUS ACCUMBENS DOPAMINE IN INSTRUMENTAL RESPONDING FOR FOOD: A MICRO-DIALYSIS AND BEHAVIORAL INVESTIGATION. J.D. Salamone\*, J.D. Sokolowski, P. Kurth and L.D. McCullough. Dept. of Psychology, Univ. of Connecticut, Storrs, CT 06269-1020. Three experiments were conducted to investigate the role of nucleus accumbens dopamine (DA) in lever pressing for food on a continuous reinforcement schedule (CRF). In the first experiment, dialysis probes were implanted into the nucelus accumbens. Compared to food-deprived control rats, rats performing on a CRF schedule showed significant increases in extra-cellular DA, which were highly correlated (r=0.90) with the number of lever press responses. In the second experiment, rats were trained to press a lever on a CRF schedule, and a computer program recorded the interresponse time (IRT) for each response, which is an index of response latency. Accumbens DA depletion produced by 6-hydroxydopamine injection led to a minor and transient suppression of total number of lever pressing responses. depleted rats showed a persistent slowing of responses as measured by their IRT distribution. The third experiment showed that, in contrast to the effects of accumbens DA depletion, extinction decreased the number of responses but increased the speed of responding. These results suggest that increased release of accumbens DA during operant performance may be acting to modulate the rate of responding.

## 301.4

BEHAVIORAL RESPONSE TO SKF 38393 IN NUCLEUS ACCUMBENS SHOWS BOTH HEMISPHERIC ASYMMETRY AND REGIONAL NON-UNIFORMITY. N. A. Dimakhova, C.H. Woodworth and R.G. Robinson.\*
Dept. Psychiatry, Univ. of Iowa Coll. of Med., Iowa City, IA 52242.

Previous studies in our laboratory have shown that injections of the selective D1 agonist SKF 38393 into right nucleus accumbens (NA) in rat produced significantly more spontaneous activity in 1 hours than identical injections into left Na, suggested possible hemispheric asymmetry in the distribution of D1 receptors. The present study investigates whether this asymmetry is exhibited uniformly in both frontal and caudal regions of NA. Fifteen male SD rats were implanted with cannulae chronically and laterally in both frontal and caudal regions of the NA. Every other day animals were injected with either saline or 0.25, 0.5, or 1.0 ug SKF 38393 in 0.5 ul distilled water and monitored for two hours in Omnitech cages.

Results indicated that horizontal and vertical activity were significantly increased, but that circling and sterotypy were unchanged. For total horizontal distance, four-way ANOVA revealed significant effects for side of injection (right side advantage, F(1,14) = 5.09, p < 0.05), dose (F(3,12) = 12.55, p < 0.001) and time (F(5,10) = 42.35, p < 0.001). Although the effect of cannula position did not reach significance, post-hot t-tests revealed that horizontal activity was greater after caudal injections, and right vs. left asymmetry was more pronounced after frontal injections. For vertical time, significant effects were found for cannula position (caudal advantage, F(1,14) = 6.0, p < 0.03), time (F(5,10) = 25.68, p < 0.001) and position-dose interaction (F(3,12) = 4.67, p < 0.03), but not for laterality. These data support the conclusion that the D1 system of the NA differs not only between hemispheres, but also between frontal and caudal regions within the NA, and that the mechanisms involved in horizontal and vertical movement are different.

BASAL EXTRACELLULAR DOPAMINE IN THE NUCLEUS ACCUMBENS DURING AMPHETAMINE WITHDRAWAL. Donita L. Robinson\*. Dianne M. Camp and Terry E. Robinson. Dept. of Psychology, University of Michigan, Ann Arbor, MI, 48109. The amphetamine (AMP) withdrawal syndrome is associated with

changes in dopamine (DA) activity; and in rats, it is also associated with a transient depression in spontaneous nocturnal locomotor activity. The present experiment was designed to determine the relationship between behavioral depression and changes in DA neurotransmission by use of *in vivo* microdialysis. Although microdialysis is used extensively to sample DA in the extracellular fluid, conventional techniques do not allow strong inferences about the actual extracellular concentration of DA; however, recently the actual extracellular concentration of DA; however, recently developed quantitative dialysis techniques do. One such method is 'no net flux microdialysis,' in which perfusion solutions containing varying concentrations of DA are perfused through a dialysis probe implanted into the brain. The difference between the DA concentration in the perfusate entering the probe and the concentration in the perfusate exiting the probe is measured. The point at which this difference is zero, the point of 'no net flux,' provides a direct estimate of the extracellular concentration of DA. In the present experiment this method was used to assess the temporal the present experiment this method was used to assess the temporal relationship between the basal concentration of DA in the nucleus accumbens and behavior during AMP withdrawal. Rats were pretreated with escalating doses of AMP or saline and underwent 'no net flux microdialysis' 3, 7 or 28 days following the discontinuation of drug treatment. Spontaneous nocturnal locomotor activity was also monitored. Results will be reported at the meeting.

### 301.7

THE ACUTE EFFECTS OF AMPHETAMINE AND COCAINE ON BEHAVIOR AND EXTRACELLULAR DOPAMINE IN THE NUCLEUS ACCUMBENS IN LEWIS AND FISCHER 344 RATS. Dianne M. Camp\*, Erin K. Wolfe and Terry E. Robinson.
Dept. of Psychology, University of Michigan, Ann Arbor, MI 48109.

Lewis (LEW) and Fischer (F344) rats, two inbred strains, differ in a variety of behaviors, including cocaine-induced locomotion and the propensity to self-administer several drugs of abuse. For example, LEW rats show greater self-administration of opiates, cocaine and alcohol than F344 rats. The mesolimbic dopamine (DA) system is thought to mediate the reinforcing effects of drugs of abuse, and therefore, strain differences in the mesolimbic DA system may underlie the strain differences in self-administration behavior. However, no strain differences have been reported in D1, D2 and mazindol binding. Therefore, the purpose of this experiment was to determine whether there are strain differences in the ability of amphetamine (AMP) or cocaine (COC) to elevate the extracellular concentration of DA in the received to devate the extracential concentration of DA in the nucleus accumbens. This was done by use of in vivo microdialysis in freely moving LEW and F344 rats. Animals received two dialysis tests with a single removeable microdialysis probe lowered into the right or left accumbens during one test and into the opposite hemisphere during a second test given one week later. Each rat received saline (i.p.) plus one of 4 doses of AMP (0.5, 1, 2, or 4 mg/kg, i.p.) or COC (5, 10, 20 or 40 mg/kg, i.p.) during each test, and the effect of the drug on both extracellular DA and behavior was quantified. Dose-response curves will be presented at the meeting. Supported by NIDA grant #04294.

## 301.9

A MICRODIALYSIS STUDY OF EXTRACELLULAR ACCUMBENS DOPAMINE AND SEXUAL BEHAVIOR IN FEMALE SYRIAN HAMSTERS. RL. Meisel\* and T.E. Robinson. Dept. of Psychological Sciences, Purdue University, West Lafayette, IN 47907 and Neuroscience Lab Bldg., University of Michigan, Ann Arbor, MI 48109.

Release of dopamine in the nucleus accumbens has been associated both with

response to incentive motivational stimuli and increased motor activity. Taking advantage of the immobility accompanying lordosis in female Syrian hamsters we sought to examine dopamine release in the nucleus accumbens using a motivated behavior unconfounded by high levels of motor activation.

Female Syrian hamsters were injected on consecutive days with either 10 µg estradiol benzoate or the oil vehicle. After the second injection, a removable dialysis probe was lowered into the nucleus accumbens, and the animal was left over night. The next day, four 15 min basal samples were taken after which estradiol-treated animals were injected with 500 µg progesterone and the remaining animals injected again with oil. Four additional samples were taken starting 3 hr after progesterone injection. Male hamsters were then placed in the cages with the females for 1 hr, with samples collected during that period. Preliminary results indicate that introduction of the male was followed by a significant increase in dopamine only in females pretreated with estradiol and progesterone. For these females, dopamine was elevated primarily in the first 15 min following introduction of the male, despite observations of high levels of lordosis throughout the 1 hr test session. These results indicate that release of dopamine in the nucleus accumbens is triggered by incentive stimuli involved in the initiation, but not necessarily the maintenance, of sexual behavior

THE RELATIONSHIP BETWEEN MOTOR ACTIVITY AND DOPAMINE NEUROTRANSMISSION IN THE DORSAL AND VENTRAL STRIATUM ACROSS THE DAY-NIGHT CYCLE Pamela E. Paulson\* and Terry E. Robinson. Department of Psychology, The University of Michigan, Ann Arbor, MI 48109

Although the effects of drugs on dopamine (DA) systems and behavior have been studied extensively, the relationship between DA neurotransmission and *spontaneous* changes in motor activity have received little attention. The present experiment was designed to do this by use of a fully automated in vivo microdialysis technique. Dialysate was sampled continuously across the day-night cycle (20 hrs) in both the dorsal and ventral striatum. Motor activity and feeding were also the dorsal and ventral striatum. Motor activity and teeding were also quantified over the same period of time. The results revealed both interesting relations, and lack of relations, between DA neurotransmission and behavior. For example, DA metabolites varied significantly across the day-night cycle, in both structures (night > day). However, there was no significant change in accumbens DA between day and night, despite a marked increase in nocturnal motor activity. Extensive correlational analyses on hundreds of data points did reveal a small, but statistically significant relationship between DA and behavior, but this accounted for only a tiny fraction of the total variance. For example, changes in DA neurotransmission in the dorsal striatum accounted for only 14.4% of the total variance in motor activity, and in the ventral striatum only 4.0%. These findings suggest that DA release plays only a minor role in regulating the large changes in motor activity that occur across the day-night cycle.

TIME COURSE OF CHANGES IN STRIATAL DOPAMINE NEUROTRANSMISSION AND BEHAVIOR FOLLOWING A UNILATERAL 6-OHDA LESION. Z. Mocsary, E. Chan. M. Noordhoorn, D. M. Camp, I. Q. Whishaw & T. E. Robinson\*. Dept. of Psychology, Univ. of Michigan, Ann Arbor, MI 48109.

The purpose of experiments reported here was to characterize timedependent changes in DA neurotransmission following a unilateral 6-OHDA lesion of the substantia nigra in rats, using in vivo microdialysis. In the first experiment we examined very early changes in DA neurotransmission, because amphetamine (AMP)changes in DA neurotransmission, because amphetamine (AMP)-induced rotation completely reverses direction between 4 and 8 days after a large (>95%) 6-OHDA lesion. All animals turn contraversive at 4 days and ipsiversive at 8 days. This change in the direction of rotational behavior is accompanied by changes in AMP-induced DA release on the lesion side. At 4 days the lesion side shows considerable DA release in response to AMP, but by 8 days the lesion side no longer responds to AMP. In a second experiment we responsible no longer responds to AMP. In a second experiment we examined changes in extracellular DA between 4 and 30 days following DA depletion of varying severity (20-99%). Preliminary data suggest that there is a gradual normalization of basal extracellular DA in the striatum between 4 and 30 days following a strategic (20-60). This is the striatum between 4 and 30 days following a partial lesion (<95%). This is in contrast to reports of very rapid presynaptic neuroadaptations, based on postmortem tissue measures of DA synthesis and metabolism, and suggests that the normalization of extracellular DA may better account for the time course of recovery of function.

MICRODIALYSIS DETERMINATION OF DOPAMINE IN FEMALE

RECHODIALTSIS DETERMINATION OF DOPAMINE IN FEMALE RAT STRIATUM AND ACCUMBENS DURING SEXUAL BEHAVIOR. P. G. Mermelstein\* and J. B. Becker.

Neuroscience Program, University of Michigan, Ann Arbor, MI 48104 Extracellular dopamine increases in the nucleus accumbens and striatum of male rats during copulation (Damsma et al., Behav, Neurosci., 106:181, 1992.). This present experiment examines the possible role of these brain recipris in the templa et al. with and without the proportion for the templa to regions in the female rat, with and without the opportunity for the female to pace the rate of the sexual encounter.

pace the rate of the sexual encounter.

Ovariectomized rats with guide cannulae aimed at the left and right striatum and accumbens were hormonally primed with estradiol benzoate and progesterone. One group of subjects was acclimated to a testing arena containing a passable barrier for the females (adapted from Erskine and Baum, <a href="Pharm.Bio.Behav.">Pharm.Bio.Behav.</a>, 17:857, 1982.) to allow them to pace the rate of the sexual encounter. A second group was placed in the same arena, but without the divider, so they could not escape the male rat. A third group of animals were controls, injected with hormones but no male was introduced. The testing period was approximately one hour. After two practice sessions, animals underwent in vivo microdialysis. Concentrations of donamine and its metabolities within the striatum and accumbons were of dopamine and its metabolites within the striatum and accumbens were measured before, during and after the sexual encounter or control interval. Following testing, animals were killed and their brains sectioned to verify probe placement.

Preliminary results indicate increased extracellular dopamine in both the accumbens and striatum during the first interval after the male was placed in the chamber, and again upon the removal of the male. Moreover, the dopamine metabolites DOPAC and HVA are elevated throughout the sexual encounter, suggesting these regions play a role in behavior involved in sexual activity.

SEX DIFFERENCES IN DOPAMINE RECEPTOR BINDING IN STRIATUM AND ACCUMBENS: REGIONAL VARIATION AND RESPONSE TO ESTROGEN. J.B. Becker\*, T.J. Bazzett, M.D. Rice & S.H. Rybak Psychology Dept, Neuroscience Prgm, & Reproductive Sciences Prgm Univ Michigan Ann Arbor M 143104-1587

RICE & S.H. Rybak Psychology Dept, Neuroscience Prgm, & Reproductive Sciences Prgm, Univ. Michigan, Ann Arbor, MI 48104-1687.

Estrogen modulates striatal doparnine (DA) release, striatal DA receptor binding, and DA-mediated behaviors in rats. Last year we reported that estrogen treatment induces a rapid down-regulation in DA receptor binding in the striatum of females but not in males. This experiment was conducted to further investigate sex differences and estrogen effects on DA receptor binding in rat striatum and accumbens.

binding in rat striatum and accumbens.

Castrated (CAST) or ovariectomized (OVX) adult male and female rats received s.c. injections of oil or 2 µg estradiol benzoate (EB)/100 g. In Exp. 1, animals received 4 injections of EB or oil at 24 hour intervals and were killed 4 hr, 24 hr, or 4 days after the last injection. In Exp. 2, animals received 1 injection of EB or oil and were killed 30 min or 4 hours later. Specific binding in striatum and accumbens to [3H]SCH23390 and [3H]spiperone were determined from fresh frozen coronal sections using turn thicking automatic autom

Specific binding in striatum and accumbens to [3H]SCH23390 and [3H]spiperone were determined from fresh frozen coronal sections using quantitative autoracilography for D1 and D2 DA receptors.

Exp 1. Striatal D1 DA receptor binding was decreased by 23% 4 hr after repeated EB in striatum of OVX (p<0.001), but not in CAST rats. Interestingly, D2 DA receptor binding in rostral striatum and accumbens of oil treated OVX rats was significantly greater than that of oil treated CAST. Furthermore, 4 hours after EB treatment, D2 DA receptor binding was decreased in striatum of OVX, the same trend was seen for CAST. There was regional variation in the sex difference and in the effect of EB. In Exp. 2, one dose of EB in OVX produced a rapid down-regulation of striatal D1 and D2 DA receptors. We conclude that for striatal D1 and D2 DA receptor binding: 1) there are sex differences; 2) physiological doses of EB modulate binding; and 3) there is regional variation in these effects. DIFFERENTIAL INFLUENCE OF THE NUCLEUS ACCUMBENS ON PATTERNS OF RAT MOTOR ACTIVITY. M.P. Paulus C.W. Callaway, and M.A. Geyer. UCSD Dept Psychiatry, La Jolla, CA 92093.

Dopaminergic modulation in the nucleus accumbens (ACC) has been asso-

Dopaminergic modulation in the nucleus accumbens (ACC) has been associated with varied locomotion as opposed to stereotypy elicited by dopaminergic stimulation in the caudate-putamen. The experiments were designed to test whether DA modulation exerts differential effects on the geometrical structure and the dynamical characteristics of rat movement sequences. Specifically, 32 animals were divided into two groups, 16 animals were lesioned by injections of 6-OHDA into the ACC, 16 animals received saline injections. 48 hr and 2 weeks after lesioning, the rats were tested for 2 hr in the Behavioral Pattern Monitor (BPM). 8 animals of each group were injected with saline or 5.0 mg/kg nomifensine, respectively. The following measures of rat motor behavior were obtained: amount of motor activity (counts, the temporal scaling exponent  $\alpha$ ), the average spatial scaling exponent  $\alpha$ , the fluctuation spectrum of local spatial scaling exponents ( $f(\alpha)$ ), the average dynamical entropy (h). 6-OHDA ACC lesions reduced the amount of activity in saline treated animals which was accompanied by a slight but non-significant increase in the average scaling exponent, d. Nomifensine reverted the reduced activity levels but increased strongly the average spatial scaling exponent, d. The fluctuation spectrum indicated that a reduced contribution of straight local movements and an increased contribution of local movements accounted for the shift of the average scaling exponent. The contribution of straight movements for 6-OHDA-lesioned animals was significantly reduced compared to the sham-lesioned animals movements in sham-lesioned relative to 6-OHDA-lesioned rats. These results suggest that the contribution of straight and directed movement sequences is modulated sensitively in the ACC which might correspond to the initiation of goal directed motor behavior.

## 301.15

PRIOR EXPOSURE TO INTRA-VTA AMPHETAMINE SENSITIZES THE NUCLEUS ACCUMBENS DOPAMINERGIC RESPONSE TO SYSTEMIC AMPHETAMINE AS MEASURED BY IN VIVO MICRODIALYSIS.

P. Vezina\* and B. Zurakowski. Neurosciences, Loeb Medical Research Institute, Ottawa Civic Hospital, Ottawa, Ontario K1Y 4E9 Canada.

Injections of amphetamine into the ventral tegmental area (VTA), but not the nucleus accumbens (N.Acc.), have been shown to sensitize rats to the locomotor activating effects of amphetamine, cocaine and morphine. These findings, together with others showing that this type of behavioral sensitization is paralleled by enhanced reactivity in mesolimbic dopamine (DA) neurons, suggest that the induction of sensitization in these neurons occurs in their somatodendritic region. The present experiment investigated this possibility. Rats received three injections of either d-amphetamine sulfate (2.5 ug/0.5 ul/side) or saline into the VTA, one injection every third day. Two weeks following the last injection, DA neurotransmission in the N.Acc. was assessed with in vivo microdialysis before and after a challenge with systemic amphetamine (1.0 mg/kg, i.p.). Prior to challenge, basal extracellular concentrations of DA in the N.Acc. did not differ in VTA amphetamine and saline preexposed animals. Following challenge, however, both groups showed an increase in N.Acc. DA but this was significantly greater (two fold) in VTA amphetamine preexposed animals. These latter animals also showed significantly higher extracellular concentrations of DOPAC and HVA in the N.Acc. before and after challenge. These findings demonstrate that amphetamine applied to the somatodendritic region of mesolimbic DA neurons sensitizes these neurons as evidenced by their enhanced N.Acc. DA response to a systemic amphetamine challenge.

SCHEDULE-INDUCED POLYDIPSIA AND THE NUCLEUS ACCUMBENS: MEASUREMENT OF DA EFFLUX AND EFFECTS OF NMDA LESIONS. <u>R. Weissenborn\*, C.D. Blaha, P. Winn and A.G. Phillips</u> Dept. Psych., Univ. Andrews, Fife, Scotland KY16 9JU (RW, PW); Dept. Psych. (AGP) and Psych. & Psychiat. (CDB), Univ. Brit. Columbia, Vancouver B.C., V6T 1Z4, Canada

The role of the nucleus accumbens (NAS) in the production of schedule-induced polydipsia in rats was investigated. In Expt. 1 the effects of acquisition of SIP on DA efflux in the NAS were measured using in viw rapid-scan voltammetry (Blaha and Jung, J. Electroanal. Chem. 1991, 310:317-334). Recordings from chronically implanted stearate-modified electrodes (n=5) on 3 days preceding and 3 days following SIP acquisition showed that while DA efflux increased significantly within individual 60min sessions (24±3%, p<0.001), absolute DA oxidation peak heights across days did not change. Thus, increased DA efflux in the NAS was not related to the acquisition of SIP. In Expt. 2 the effects of bilateral NMDA lesions of the NAS on acquisition of SIP were measured in rats. Lesions were made by 1.0ul 0.06M NMDA infused into medial NAS (n=10); sham-lesions were made by 1.0ul phosphate buffer (n=8). Although NMDA-lesioned rats had lower post-operative body weights than controls, recovery was not affected as food and water intake increased at the same rate. After exposure to 26 daily 60min SIP sessions, 7 out of 10 NMDA- and 4 out of 8 sham-lesioned rats had become polydipsic and were included in the statistical analysis. NMDA rats were found to drink 4.8±0.3ml water, compared to 8.7±0.7 by controls (p<0.01). The number of food hopper panel pushes was unaffected by NMDA lesions. NMDA lesions of the NAS therefore did not interfere with SIP acquisition but significantly attenuated water intake in polydipsic rats. Altogether, these data suggest involvement of other, non-DA components of the NAS or its projection sites in the acquisition of SIP.

### 301.14

DISSOCIATION OF THE EFFECTS OF MK-801 ON BASELINE AND AMPHETAMINE STIMULATED LOCOMOTOR ACTIVITY AND DOPAMINE OVERFLOW IN THE NUCLEUS ACCUMBENS. J.P. Druhan\*. H. Rajabi and J. Stewart. Center for Studies in Behavioral Neurobiology, Psychology Department, Concordia University, Montréal, Que, Canada, H3G 1M8.

We examined the effects of the NMDA antagonist, MK-801 on locomotor activity and on extracellular dopamine (DA) levels in the nucleus accumbens (NAS) both when given alone and when co-injected with d-amphetamine HCI (1.5 mg/kg, IP). Microdialysis probes (removable, concentric design) were inserted into the NAS through stationary unilateral guide cannulae 18 - 24 h before testing. On the morning of the test session the flow rate of the modified ringer solution was set at 1.75 µl/min and baseline samples were collected every 20 min for 2 to 3 hrs, with locomotor activity monitored continuously by photocells stationed in the test chambers. After this baseline period, rats in the first experiment were injected with MK-801 (0.125, 0.25 or 0.50 mg/kg, IP) or saline, and activity and DA overflow were measured for 160 min post-injection. In the second experiment, rats were given an injection of d-amphetamine 40 min after receiving these same doses of MK-801 and testing was continued for 120 min. The two highest doses of MK-801 and testing was continued for 120 min. The two highest doses of MK-801 and testing was continued for 120 min. The two highest doses of MK-801 and testing was continued for 120 min. The two highest doses of MK-801 and testing was continued for 120 min. The two highest doses of MK-801 failed to increase DA overflow when given alone and it non-significantly elevated d-amphetamine stimulated DA overflow only at the highest dose (0.50 mg/kg). These results suggest that the locomotor activating effects of MK-801 are not due to actions of this drug on dopaminergic projections to the NAS.

## 301.10

STRESS-INDUCED SENSITIZATION OF DOPAMINE AND NOREPINEPHRINE RELEASE IN MEDIAL PREFRONTAL CORTEX. Paul J. Gresch\*, Janet M. Finlay, Michael J. Zigmond and Alan F. Sved. Dept. of Cellular & Behavioral Neuroscience, Center for Neuroscience, University of Pittsburgh, Pgh, P4 15260

Prior exposure to chronic cold (5°C, 2-3 weeks) results in enhanced release of norepinephrine (NE) in hippocampus and medial prefrontal cortex (mPFC) in response to 30 min of low intensity intermittent tail-shock or tail-pressure (Nisenbaum et al., *J Neurosci*, 1991, Finlay et al., *Soc Neurosci*, 4bs, 1991). Whereas acute stress elicits an increase in dopamine (DA) release in mPFC, nucleus accumbens (NAS) and striatum (STR) (Abercrombie et al., *J Neurochem*, 1989), at present, it is unknown whether DA neurons also exhibit this sensitization following chronic cold. Therefore, we examined the effect of prior exposure to chronic cold on extracellular DA and NE in the mPFC and DA in the NAS and STR in response to tail shock using *in vivo* microdialysis. Basal DA and NE values did not differ between chronically cold-stressed and naive rats in any of the brain regions. In the mPFC, tail shock elicited a greater increase in DA and NE release in chronically cold-stressed than naive rats. However, the stress-induced release of DA in NAS or STR did not differ between cold-stressed and naive rats.

|  | mPFC-NE |     | mPFC-DA |     | NAS-DA |     | STR-DA |      |
|--|---------|-----|---------|-----|--------|-----|--------|------|
| Chronic cold   | 128%*   | (5) | 238%*   | (5) | 46%    | (3) | 41%    | (7)  |
| Naive  | 56%     | (5) | 78%     | (5) | 32%    | (4) | 41%    | (11) |
| Decite on a count because to a state the collection of the state of th |         |     |         |     |        |     |        |      |

Results are percent increase from baseline; (n) = # of animals, \* significantly different than naive, p < 0.05.

These data suggest that like cortical NE projections, cortically projecting DA neurons exhibit sensitization after chronic exposure to stress, whereas subcortical DA projections do not. Supported in part by a MRC fellowship (JMF) and USPHS grants MH43947 and MH45156.

EFFECTS OF REPEATED EXPOSURE TO STRESS ON EXTRACELLULAR

DOPAMINE LEVELS IN PREFRONTAL CORTEX OF RAT. M.D. Dohenty\* and A. Gratton. Douglas Hosp. Res. Ctr, McGill Univ., Montréal, Canada, H4H 1R3. We have recently reported that, with repeated daily exposure, increases in dopamine (DA)-related electrochemical signals recorded in nucleus accumbens (NAcc) during restraint stress become progressively larger (Doherty & Gratton, 1992). In this experiment, we examined the effects of five, once daily exposures to restraint (15 min) experiment, we examined the effects of the top, once daily exposures to restraint (13 min) or tail pinch (10 min) stress on extracellular DA levels in prefrontal cortex (PFC) using high-speed chronoamperometry. Restraint caused a pronounced increase of the electrochemical signal in PFC that out-lasted the period of restraint but the magnitude of which did not change across test days. However, as previously reported with microdialysis (Imperato et al., 1991), releasing the animal from the restrainer further increased the signal. Interestingly, this second increase became progressively larger increased the signial. Interestingly, this second increase became progressively target with repeated testing. In contrast to restraint, the amplitude of the electrochemical signal recorded during tail pinch increased with each daily test and no further increase in the signal occured upon termination of stress. These results and those of our previous studies suggest that differences between the stress responses of the meso-PFC and meso-NAcc DA pathways depend on the type of stress and the number of exposures to stress. Whereas a single exposure to restraint caused a pronounced exposures to stress. Whereas a single exposure to restraint caused a pronounced increase in extracellular PFC DA levels, similar effects of restraint were observed in NAcc only after several daily exposures and while the effects of tail pinch on PFC DA levels increased with repeated testing, those of restraint did not; opposite to what was observed in NAcc. Unlike meso-NAcc DA neurons, meso-PFC DA neurons appear to respond to the cessation of a stressful event in addition to stress per se. Finally, pretreatment with apomorphine, at a dose (50µg/kg, s.c.) that inhibited restraint-elicited increases in NAcc, did not affect the electrochemical signal elicited by restraint in PFC. The differential effect of apomorphine could be due to the reported paucity of impulse-regulating receptors on meso-PFC DA neurons. Alternatively, it may suggest that stress-elicited electrochemical signals in PFC also reflect increased extracellular levels of an electroactive species other than DA. Supported by FCAR and MRC.

NUCLEUS ACCUMBENS DOPAMINE DEPLETIONS: PROXIMATE STRIATAL AND BEHAVIORAL CHANGES. L.T.L <u>Tran\* and E. Castañeda</u>. Dep't. of Psychology, Arizona State University, Tempe, AZ 85284.

It has been suggested that some initial behavioral depression following brain damage might be due to secondary changes in other brain areas. To test this, rats were given bilateral 6 hydroxydopamine lesions of the nucleus accumbens and then tested for changes in extracellular levels of striatal monoamines using in vivo microdialysis. Rats were tested on days 2 and 3 post-lesion (Acute LX) or, after a recovery period, on days 14 and 15 (Chronic LX). Dopamine (DA), its metabolites DOPAC and HVA, and 5-HIAA were assayed by HPLC-EC from 20-min samples. After baseline measurés, a Ringer's solution containing 60 mM potassium was infused through the microdialysis probe for 20 min to evoke depolarization-induced overflow. The next day after additional baseline measures, animals received d-amphetamine (1.5 mg/kg, s.c.). Extracellular levels of DOPAC, HVA and 5-HIAA were generally enhanced in the Acute LX group compared to Chronic LX and control animals. Also, the Acute LX group displayed an enhancement in amphetamine-stimulated DA release that was not observed after 2 weeks recovery (Chronic LX). Finally, these early changes in striatal DA release were related to a potentiation in AMPH-induced stereotypy. Results will be discussed in terms of how these changes may relate to recovery of function.

INVOLVEMENT OF PREFRONTAL CORTEX IN AMPHETAMINE-INDUCED SENSITIZATION OF MESOLIMBIC DOPAMINE NEURONS. K. E. Banks\* and A. Gratton. Douglas Hosp. Res. Ctr, McGill Univ., Montréal, Canada, H4H 1R3.

The stimulant effect of d-amphetamine (d-AMP) on locomotor activity and on mesolimbic dopamine (DA) neurotransmission is potentiated—or sensitized—for some time following repeated, daily administration of this and other psychostimulants. We have previously reported that, with repeated daily presentation, increases in DA levels in nucleus accumbens (NAcc) elicited by a sex-related stimulus become progressively larger and more recently, we reported that this effect was potentiated in animals with 6-OHDA-induced lesions of DA terminals in prefrontal cortex (PFC). In the present study, we examined the role played by meso-PFC DA neurons in sensitization to the stimulant effects of d-AMP. Six weeks prior to testing, male rats received bilateral microinfusions of 6-OHDA or of vehicle (sham) into PFC. Following 3 days of habituation to the test chamber, the locomotor response of each animal to a test dose habituation to the test chamber, the locomotor response of each animal to a test dose of d-AMP (0.5 mg/kg ip) was monitored. On each of the five following days, of d-AMP (0.5 mg/kg ip) was monitored. On each of the five following days, animals from both groups received either d-AMP (1.0 mg/kg ip) or vehicle. Five and then thirteen days later, the locomotor response of each animal to the test dose of d-AMP was again measured. Selective destruction of DA terminals in PFC was found to significantly facilitate development of sensitization to the locomotor stimulant effect of d-AMP. That is, while lesioned and sham-lesioned animals responded similarly to the first d-AMP test dose, repeated daily d-AMP injections sensitized lesioned animals to the effects of the two subsequent d-AMP test doses to a greater extent than sham-lesioned animals. Consistent with these results, d-AMP caused a 3extent than snam-lestoned animals. Consistent with these results, d-AMP caused a 3-fold greater increase of DA-dependent electrochemical signals recorded in NAcc of lesioned than in NAcc of sham-lesioned animals. The results of this study are consistent with those of others indicating that the DA input to PFC exerts an indirect, inhibitory influence on mesolimbic DA neurotransmission. The present experiment also suggests that the long-lasting enhancement of mesolimbic DA neurotransmission that occurs with repeated exposure to a stimulus may reflect changes to a DA-sensitive mechanism in PFC. Supported by FCAR, MRC and NSERC.

# DRUGS OF ABUSE: PHARMACOLOGY OF COCAINE

## 302.1

COMPARISON OF THE REINFORCING EFFECTS OF THE NOVEL TROPANE ANALOG (PTT) WITH COCAINE. S.I. Dworkin, H. Davies, E. Saikali, S.Childers and J.E. Smith. Center for the Neurobiology of Drug Abuse, Dept. of Phys/Pharm., Bowman Gray Sch of Med., Dept. Chemistry, Wake Forest Univ., Winston-Salem, NC, 27157.

Novel cocaine derivatives have been synthesized in a concerted effort to

develop pharmacotherapies for the treatment of cocaine abuse. reinforcing effects of one of these compounds  $2(\beta)$ -propanoyl- $3(\beta)$ -(p-tolyl)tropane (PTT) have been assessed in rats trained to self-administer cocaine under an FR 10 schedule and in drug naive subjects. Doses of PTT (1.0-90  $\mu$ g/inj) were substituted for cocaine (0.33 mg/inj) during 3 and 6 hour self-administration sessions. All doses of PTT substituted for cocaine and resulted in an inverted "U" shaped function for injections selfadministered. The pattern of self-administration consisted of alternating periods of long interinjection intervals (>20 min) followed by sustained periods of very rapid responding resulting in several very short interinjection intervals (<60 sec). This pattern was dose related repeated throughout the 3 or 6 hour sessions, and was different from those maintained by either saline or the DA uptake inhibitor buproprion. PTT ( $10\mu g/inj$ ) did not engender or maintain responding in drug naive rats, however, these subjects did self-administer cocaine following exposure to PTT. The novel cocaine derivative PTT maintains responding when acutely substituted for cocaine but does not appear to be reinforcing in drug naive subjects. Further evaluations of the pharmacologic neurobiologic and behavioral actions of this compound should increase our understanding of the effects of cocaine and provide useful information for the development of pharmacotherapies for the treatment of cocaine abuse (Research Supported by NIDA P50- DA06634)

EFFECTS OF THE NOVEL COCAINE ANALOG, PTT, ON EXTRACELLULAR DOPAMINE LEVELS IN THE NUCLEUS ACCUMBENS AND LOCOMOTOR DUPAMINE LEVELS IN THE NOCLEUS ACCUMBENS AND LOCOMOTOR ACTIVITY IN THE RAT. L.L. Devaud\*, L.J. Porrino, S.R. Childers, H.W. Davies, E. Saikali, S.R. Dworkin and J.E. Smith, Dept. of Physiology & Pharmacology, Bowman Gray School of Medicine; Dept. of Chemistry, Wake Forest University, Winston-Salem, NC.

A series of novel cocaine analogs has recently been synthesized. The present experiments examined the effects of one of these, 2(B)-propanoyl-3(B)-(p-tolyl) tropane (PTT), on extracellular dopamine (DA) levels in the nucleus accumbens and on locomotor activity in the rat. These effects were compared to those of cocaine. PTT or cocaine was given iv to freelymoving rats and extracellular DA levels were measured by *in vivo* microdialysis. Extracellular DA levels were increased dose-dependently within 15 min of PTT treatment and remained elevated for up to 3 hrs. After cocaine DA levels returned to baseline within 1 hr of treatment. PTT, administered iv, also produced significant dose-dependent increases in locomotor activity as measured by photocell interruption. These increases persisted for 2.5 hrs after low doses and up to 4 hrs at the highest dose tested (2 mg/kg). Rearing and sniffing similar to that seen following cocaine were observed at lower doses (0.1-0.5 mg/kg) whereas intense stereotypic head bobbing was evident at higher doses (1-2 mg/kg). These data indicate that PTT is a potent cocaine analog with stimulant properties, but is different from cocaine in its duration of action and the form and intensity of its behavioral activating properties. Supported by P50DA06634.

BINDING AND TRANSPORT PROPERTIES OF NOVEL 2-SUBSTITUTED TROPANE ANALOGS OF COCAINE. S.R.Childers\*, T. Sexton. B. Bennett, C. Hyde, E. Saikali and H. Davies, Dept. Physiol/Pharmacol, Bowman Gray Sch. Med. and Dept. Chemistry, Wake Forest Univ., Winston-Salem, NC 27157.

A novel scheme utilizing vinylcarbenoid precursors has been developed for the synthesis of novel tropane analogs of cocaine. Using this method, 19 analogs have been tested for activity in binding to dopamine transporters in rat striatal membranes using [1251]RTI-55, and inhibition of dopamine transport into dissociated striatal neurons from fetal rat brain. In all the analogs, the aryl group at the 3 position was directly bound to the tropane ring (as in WIN-35,428), and methyl or ethyl ketone moieties were present at the 2 position instead of the typical ester group. In general, all analogs displayed significant correlation (R=0.95) of IC50 values in displacing [ $^{125}$ I]RTI-55 binding and inhibiting dopamine uptake. Methyl and ethyl ketone groups in the 2 position did not affect potency compared to ester groups in the same position, but substituents on the benzene ring greatly affected potencies. Analogs which contained the 2-ketone in the  $\beta$  position were 10-80 times more potent than their  $\alpha$  isomers. The two most potent analogs were the naphthyl and toluyl derivatives (IC<sub>50</sub> values were 5-10 nM, vs. 170 nM for cocaine), while replacement of the aryl with either ethyl or cyclohexyl drastically reduced potency (to >100  $\mu$ M and 5  $\mu$ M, respectively). These novel compounds provide new understanding of SAR of cocaine analogs at dopamine transport sites.

Supported by PHS grant DA-06634 from NIDA.

### 302.5

DIFFERENTIAL EFFECTS OF ISOTHIOCYANO-BTCP DERIVATIVES ON THE BINDING OF RADIOLABELED LIGANDS TO AND ON DOPAMINE UPTAKE IN RAT STRIATUM. <u>L.P. RAYMON\*, B. DE COSTA\*, C. DOMINGUEZ\*, M.E. ELDEFRAWI</u>. Dept. Pharmacol. and Exp. Therap., UMAB, Sch. Med., Baltimore, MD 21201 and <sup>1</sup> Lab.Medicinal.Chem., NIH.

The potency of several isothiocyanate (NCS) derivatives of N-[1-(2-benzo(b)thienyl)cyclohexyl]piperidine (BTCP), differing in the position of the NCS group, on [4H]BTCP, [4H]cocaine binding, and [3H]dopamine uptake in rat striatal membranes was studied in vitro. BTCP is a potent inhibitor of dopamine uptake, and [4H]BTCP binds to high and low affinity sites. High affinity [4H]BTCP and [4H]cocaine binding have similar drug profiles. The isothiocyanate derivative in meta position to the sulphur of the thiophenyl was a poor inhibitor of [4H]BTCP and [4H]cocaine binding, as well as of [4H]dopamine uptake. Preincubation with it, preferentially inhibited the low affinity [4H]BTCP binding site. Furthermore, various isothiocyanate derivatives discriminated between cocaine and dopamine binding sites. When the isothiocyanate group was para to the sulphur of the thienyl moiety, the compound was as potent as BTCP or cocaine in inhibiting dopamine uptake but displaced cocaine binding very poorly.

These findings suggest that [3H]BTCP and its NCS derivatives may be useful probes to investigate the dopamine transporters and in particular the cogains recentor site.

(supported in part by a NIDA grant #DA03680,MEE)

## 302.7

INTRAVENTRICULAR PROCAINE ACTION ON RESPIRATORY PATTERNING. C.A. Richard\*, R.K. Harper and R.M. Harper. Brain Research Institute and the Dept. of Anatomy & Cell Biology, UCLA School of Medicine, Los Angeles, CA 90024.

Intravenous or cerebral ventricular administration of cocaine results in a short-latency, substantial, and prolonged increase in respiratory rate, which is usually accompanied by a reduction in breath-to-breath variability. Cocaine has the potential to exert respiratory effects through anesthetic action, as well as through its traditional modes. We partitioned local anesthetic actions on respiratory patterning by recording diaphragmatic EMG responses to intraventricular cocaine and procaine administration and measuring total cycle time (Ttot), as well as the inspiratory and expiratory phase durations (Ti and Te, respectively). Adult cats were anesthetized and instrumented with EMG leads in the costal diaphragm and with ventricular cannulae. After 1 wk of recovery, baseline recordings were performed for 30-60 min in unanesthetized, unrestrained animals, following which an injection (0.625, 1.25, 2.5mg) of procaine or cocaine was delivered intraventricularly. Procaine significantly reduced Ttot at 10 min post-injection, with values rapidly returning to baseline after this time. Cocaine-induced respiratory effects persisted for 2-3 hr post-administration. No significant differences occurred between Ttot values for cocaine and procaine at 10 min. Breath-to-breath variability was reduced following some, but not all, procaine injections; such reductions occurred only at 10 min. We conclude that at least part of the early tachypnea that results from cocaine intoxication results from anesthetic effects. (Supported by DAO4913)

#### 302.4

POTENT PHENYLTROPANE COCAINE ANALOGS INHIBIT SEROTONIN (5-HT) DORSAL RAPHE CELL FIRING.

J.M. Lakoski\*, H. Zheng, J.W. Boja¹, F.I.Carroll¹ and M.J. Kuhar¹. Dept. Pharmacol. & Tox., Univ. Texas Med. Br., Galveston, TX 77555 and ¹Addiction Research Center, NIDA, Baltimore, MD 21224.

Potent substituted-3 $\beta$ -phenyltropane analogs of cocaine have been developed with high affinity for cocaine and dopamine uptake sites in the striatum (Boja et. al., Eur.J. Pharm. 184:329-332, 1990). We have addressed whether 3 $\beta$ -(4-chlorophenyl)-(RTI-COC-31) and 3 $\beta$ -(4-methylphenyl)-tropane-2-carboxylic acid methylesters (RTI-COC-32) interact with serotonergic function utilizing both in vivo and in vitro recording preparations of the dorsal raphe nucleus (DRN).

Electrophysiologic recordings were conducted in chloral hydrate anesthetized adult male Sprague-Dawley rats or in 400 $\mu$ m thick slices containing the DRN. Intravenous administration of RTI-COC-32 and RTI-COC-31 completely inhibited spontaneous cell firing with a 5X and 10X increased potency, respectively, as compared with cocaine (ID<sub>60</sub> = 0.125 and 0.07 mg/kg versus 0.6 mg/kg). A 2X enhanced potency of RTI-COC-32 (ID<sub>60</sub> = 4.2 $\mu$ m) in comparison to cocaine was evident in vitro. Indicative of a 5-HT reuptake inhibitor, maximal inhibition of cell firing produced by RTI-COC-32 was delayed beyond the period of drug perfusion and potentiated with addition of 10 $\mu$ m 5-HT. The data demonstrate a potent interaction of novel cocaine analogs with serotonergic neuronal systems. Supported by PHS AGO0450 (JML).

### 302.6

THE DOPAMINE TRANSPORTER: SELECTIVE INHIBITION BY NOVEL COCAINE ANALOGS. T.A. Kopajtic\*, J.W. Boja, M. Milberger, F.I. Carroll, A.H. Lewin, P. Abraham, K. Parham and M.J. Kuhar. NDA Addiction Research Center, P.O. Box 5180, Baltimore, MD 21224 and Research Triangle Institute, Research Triangle Park, NC 27709.

Previous work by our laboratories has determined that modifications of the cocaine molecule at the C-2 position resulted in increased selectivity for the dopamine transporter compared to the NE and 5-HT transporters. Modification of the highly potent cocaine analogs RTI-31 (3β-[4-chlorophenyl]tropane carboxylic acid methyl ester) and RTI-55 (3β-[4-iodophenyl]tropane-2β-carboxylic acid methyl ester) at the C-2 position also resulted in selective potency changes at the DA, NE and 5-HT transporters. Elimination of the methyl ester from the C-2 position decreased DA, NE and 5-HT potency 400-500 fold. Substitution of the 2 methyl ester with a carboxamide decreased DA potency 10 fold; however, NE and 5-HT potencies were reduced 50 and 75 fold respectively. Substitution of an isopropyl ester or a phenyl ester at the C-2 position had no or little effect upon DA potency, but NE and 5-HT potencies were reduced greater than 50 fold. This increase in selectivety for the DA transporter was reduced with halogen addition to the phenyl ring. The use of these cocaine analogs will allow for the selective study of the dopamine transporter.

## 302.8

COCAINE AND COCAETHYLENE: ACUTE AND SUBACUTE MOTILITY EFFECTS. Y. Wang and W.M. Davis, Dept. of Pharmacology and Research Institute of Pharmaceutical Sciences, School of Pharmacy, University of Mississippi, University, MS 38677.

Concurrent use of cocaine (C) and ethanol (E)

Concurrent use of cocaine (C) and ethanol (E) is a popular polydrug abuse pattern. A metabolite of C, cocaethylene (CE), is formed only in the presence of E. Motor activity after C, CE and a 50/50 combination (COM) was tested in CD-1 mice at doses equimolar to 0.3, 1, 3, 10 & 30 mg/kg of C. Both C and CE increased motor activity at the 2 highest doses, but not at lower ones. Motility after COM increased only at the highest dose. When mice received a 2nd exposure 1 wk. later to the same doses, the motor response to CE was elevated over the 1st exposure at the 2 highest doses, and to C at 30 mg/kg only. Daily dosing was then conducted in the 3 highest dose groups of each drug, and activity was tested on the 6th & 12th days of subacute dosing. Motility after the highest CE dose was lower on the 6th day than at the 2nd acute dose. Motility after doses of COM equimolar to 3 and 10 mg/kg of C increased so that 12th day activity was significantly greater than on 1st and 2nd acute exposures. Thus, the data are suggestive of both sensitization and tolerance development. (CE supplied by NIDA)

#### 302 9

COCAINE DIFFERENTIALLY DECREASES SYMPATHETIC NERVE ACTIVITY IN ANESTHETIZED RATS. K.J. Varner\*, T.P. Abrahams and M.C. Cuntapay. Dept. Pharmacology & Alcohol and Drug Abuse Center, LSUMC, New Orleans, LA 70112.

It is widely believed that an increase in sympathetic outflow is responsible

for the increases in arterial pressure (AP), heart rate (HR) and circulating catecholamines after administration of cocaine. However, recent evidence suggests that cocaine decreases sympathetic nerve activity (SNA) in dogs and cats. The present study was performed to examine the sympathetic nerve responses elicited by the intravenous administration of cocaine in pentobarbital anesthetized rats. Platinum bipolar electrodes were used to record renal (RSNA, n=7), splanchnic (SSNA, n=6) or lumbar (LSNA, n=7) symathetic nerve activity. Cocaine (0.005-5 mg/kg) elicited dose-dependent increases in mean AP (MAP) (max. 18±2 mmHg) and decreases in SNA on the 3 nerve types. The duration of the pressor responses (0.5-2.5 min.) was markedly shorter than the duration of the sympathoinhibitory responses (2-60 min.), indicating that the sympathoinhibitory responses were not baroreceptor reflex-mediated. The magnitude of the cocaine-mediated decreases in SNA between the 3 nerves was not uniform. For example, the maximum dose of cocaine (5 mg/kg) decreased SSNA 97±2%, RSNA 82±4% and LSNA 55±6%. For all doses, the rank order of sensitivity (most to least) to the inhibitory actions of cocaine was SSNA > RSNA > LSNA. As the dose response curves of MAP for the three experimental groups were virtually identical, the differential nerve responses were not due to differences in pressor-mediated baroreceptor reflex activity. We conclude that, in anesthetized rats, cocaine: 1) produces sympathoinhibition rather than sympathoexcitation, and 2) differentially inhibits activity in sympathetic nerves innervating different target organs.

## 302.11

ACUTE COCAINE TOXICITY: THE EFFECT OF AGENTS IN NON-SEIZURE INDUCED DEATH. RW Derlet\*, J Tseng, and TE Albertson. Emergency Dept., UC Davis, Davis, CA 95616
Death from cocaine intoxication results from one of multiple mechanisms including seizures, cardiovascular collapse or apnea. In the free-moving rat model, continuous seizures are the primary means of death. In order to study mechanisms of death unrelated to seizures, we supressed lethal seizures with diazepam and investigated the effect of several pharmacologic agents. METHODS: Male S.D. rats were pre-treated with vehicle, diazepam 5 mg/kg alone (Dzp) or in combination with and test agents; nifedipine 1 mg/kg (Nifed), propranolol 5 mg/kg (Prop) or prazocin 5 mg/kg (Praz). Five minutes after pre-treatment animals received cocaine 100 mg/kg. Each test group consisted of 15 animals and all agents were given i.p. Two animals in each group had cortical electrodes implanted and EEG's monitored. RESULTS: In Group 1, animals received vehicle followed by cocaine. The incidence of seizures was 100% and death 100%. Group 2 received Dzp in combination with Prop, Praz or Nifed resulting in no seizures and no deaths. Group 3 received Dzp followed by cocaine resulting in no seizures and 53% death. Group 4 received Dzp and Nifed followed by cocaine resulting in 10% seizures and 87% death. Group 5 received Dzp and Prop followed by cocaine resulting in 10% seizures and 13% death (pc0.02). EEG recordings showed electrical spikes in all animals observed to have seizures and an absence in non-seizuring animals. CONCLUSION: Animals protected from seizures with Dzp have non-seizure deaths after high dose cocaine. Death in these animals is potentiated with Nifed and Prop, but protected with prazocin.

## 302.13

EFFECT OF REPEATED COCAINE ADMINISTRATION ON [ $^3$ H]WIN 35,428 BINDING *IN VIVO* IN DORSAL AND VENTRAL STRIATUM AND MIDBRAIN; REGIONAL DISSECTION AND QUANTITATIVE AUTORADIOGRAPHY Elizabeth J. Cline\*, Nancy S. Pilotte, Wm. Mark Mitchell, Ursula Scheffel, and Michael J. Kuhar NIDA Addiction Research Center, P. O. Box 5180, Baltimore, MD 21224, and The Johns Hopkins Medical Institutions, Baltimore, MD 21205

Studies examining neurochemical correlates of cocaine abuse have demonstrated regional differences in the distribution of DA uptake sites in mesolimbic and nigrostriatal pathways implicated in the behavioral effects of cocaine. Repeated cocaine administration can produce changes i stimulated DA release, DA uptake, and binding of various ligands to DA transporter sites in these pathways in rats. These effects are influenced by dose, dosing regimen, and route of administration

In these experiments, we examined the regulation of cocaine binding sites in rats given cocaine or saline for 10 days. Cocaine was given by either i.p. injection (10mg/kg) or i.v. infusion (total 10mg/kg in a 2 hr session). One or 10 days after the last cocaine exposure, *in vivo* binding of [<sup>3</sup>H]WIN 35,428 was measured 1 hr after i.v. injection of either 10 or 20 μCi. Potential changes in in vivo binding as a result of cocaine administration were measured by dissolving and counting dissected tissue or by quantitative autoradiography. Preliminary results show the i.p. regimen did not change [3H]WIN 35,428 binding in cocaine injected animals as compared to controls at either 1 or 10 days after the last injection. The results of these studies will provide further information as to the influence of regimen, route of dministration, and time since cocaine exposure on regulation of transporter binding sites in vivo.

#### 302.10

CARDIOVASCULAR RESPONSES ELICITED BY COCAETHYLENE AND COCAINE IN INTACT AND ADRENAL DEMEDULLATED RATS. T.P. Abrahams\*, W.L. Reed, Z. Zhang and K.J. Varner. Dept. Pharmacology & Alcohol and Drug Abuse Center, LSUMC, New Orleans,

Cocaethylene (benzoylecgonine ethyl ester, CE) has been implicated in the cardiovascular toxicity associated with concurrent use of cocaine (C) and ethanol. In the present study we compared the changes in arterial pressure (AP), heart rate (HR) and myocardial oxygen consumption (MOC) elicited by intravenous CE or C in conscious unrestrained rats. The involvement of adrenal catecholamine release in mediating these cardiovascular responses ssed by administering CE or C 1 week after bilateral adrenal demedullation. In sham operated rats CE (n=6) and C (n=9) (0.005-5 mg/kg, iv) elicited similar dose-dependent increases in mean AP (MAP) up mg/kg) and C (0.005-0.5 mg/kg) elicited tachycardia (max.  $37\pm6$  and  $20\pm6$ bpm, respectively). The larger doses (CE=3.5 mg/kg; C=1.5 mg/kg) produced bradycardia (max. -38±3 and -34±22 bpm, respectively). Druginduced changes in rate-pressure product (R-PP; HR x systolic AP) were used as an index of MOC. Doses of CE and C which elicited tachycardia also produced dose-dependent increases in R-PP (max, CE=27%; C=40%), while doses which produced bradycardia produced smaller increases in R-PP. Bilateral adrenal demedullation did not significantly change the magnitude or pattern of the MAP, HR or R-PP dose response relationships. We conclude: 1) CE and C produce a similar pattern of MAP and HR responses in conscious unrestrained rats, 2) CE, like C, increases MOC in conscious rats, 3) the pattern of cardiovascular responses elicited by CE and C does appear to be dependent on adrenal catecholamine release.

### 302.12

TIME COURSE OF COCAINE'S CNS ACTIVATION: AN AUTO-RADIOGRAPHIC BLOOD FLOW STUDY. E.A. Stein\* and S.A. Fuller. Dept. of Psychiatry, Medical College of Wisconsin, Milwaukee, WI 53226.

Among the notable effects cocaine exerts upon the mammalian CNS

is its potent reinforcing property. This action is extremely short lived and is thought to reflect cocaine's short plasma half life of 15-20 min. However, plasma levels alone apparently cannot predict these actions as, following a loading dose, rats self-administer additional cocaine prior to decreases in plasma levels. It thus appears that temporal alterations in regional brain activity may be critical in understanding cocaine's reinforcing ontogeny. With its 30 sec measurement window, the autoradiographic regional cerebral blood flow (rCBF) method of Sakurada et al permits a study of the time course of cocaine action simultaneously in large numbers of brain regions. As such, rats were simultaneously in large numbers of brain regions. As such, rats were prepared with acute femoral arterial and venous catheters. Four to five hours after surgery, rCBF was determined 1, 5, 15 and 45 min after a single 1.0 mg/kg IV cocaine injection. A heterogenous pattern of cerebral activation was seen. Of those regions which responded to cocaine, all did so with a time threshold of 1 min. Several groups of structures were evident: 1) those regions whose rCBF returned to baseline prior to the 5 min measurement group (including the claustrocortex, lateral and basomedial amygdala); 2) those returning to baseline between the 15 and 45 min measures (including the VTA, nedial septum, ventral pallidum and cingulate); and 3) those demonstrating persistent rCBF alterations at least through the 45 min group (including accumbens, olfactory tubercle, hippocampus, lateral septum and caudate). It thus appears that cocaine's duration of action varies heterogenously across both time and brain structure. Supported in part by NIDA grant DA 05012 to EAS.

## 302.14

PRAZOCIN AND ICS 205-930 HAVE DIFFERENTIAL EFFECTS ON HIGH AND LOW RATES OF COCAINE- AND AMPHETAMINE INDUCED RESPONDING. B. J. Van Groll, R. B. Saunders and J. B. Appel. Behavioral Pharmacology Laboratory, Department of Psychology, University of South Carolina, Columbia, S. C. 29208.

Rats (n=8/group) were trained to press a lever for water under a schedule of continuous reinforcement and were treated with either cocaine or d-amphetamine (AMP), the a<sub>1</sub> antagonist prazocin (PRAZ) and the 5 HT<sub>3</sub> antagonist ICS 205-930 (ICS). When given alone, 1 and 3 mg/kg of cocaine had no reliable effects on response rates; 10 mg/kg decreased high rates. AMP had no effect on low and decreased high rates at a dose of 0.03 mg/kg, increased low and decreased high rates at 0.56 mg/kg, and had no effect on either rate at 3.0 mg/kg. When given alone, PRAZ (1 mg/kg) increased both low and high rates in animals previously treated with cocaine but not with AMP; ICS (10 mg/kg) decreased both low and high rates in animals previously treated with cocaine but not with AMP. When given in combination with cocaine (1 mg/kg), PRAZ (1 mg/kg) increased low and decreased high rates while ICS (10 mg/kg) increased both low and high rates. When given in combination with AMP, PRAZ (1 mg/kg) had no effects on low or high rates while ICS had no effect on low and decreased high rates. Combinations of cocaine (1 mg/kg), PRAZ (1 mg/kg) and ICS (10 mg/kg) lowered the rate-increasing effects and potentiated the rate-decreasing effects of the combination of cocaine and ICS. Combinations of AMP (0.03 mg/kg), PRAZ (1 mg/kg) and ICS (10 mg/kg) decreased low rates but did not affect high rates. These data point to the significance of drug history in determining rate dependencies and suggest that NE and 5-HT systems may be involved to a different extent in the actions of cocaine

Supported by USPHS Research Grant R01 DA02543, from NIDA

EFFECTS OF TRAZODONE ON INTRAVENOUS COCAINE SELF-ADMINISTRATION IN RATS. G.F. Guerin\*, C. Crow, K.A. Cunningham and N.E. Goeders. Departments of Pharmacology and Psychiatry, LSU Med. Center, Shreveport, LA 71130-3932

Although dopamine is involved in the stimulus effects and reinforcing properties of cocaine, recent data also suggest a role for serotonin in the mediation of these effects. Since anxiety and depression are often observed during cocaine withdrawal in humans, the following experiment was designed to investigate the effects of the serotonergic antidepressant drug, trazodone, on intravenous cocaine self-administration in rats. Adult male Wistar rats were trained to self-administer cocaine (0.25 mg/kg per 0.2 ml infusion delivered over 5.6 sec) on a fixed-ratio 4 schedule of When stable baselines of drug-intake were obtained, the rats were pretreated with trazodone (2.5 to 20 mg/kg, ip) 45 min before the start of the behavioral session. Acute pretreatment with relatively low doses of trazodone (e.g., 5 or 10 mg/kg, ip) completely blocked cocaine selfadministration, suggesting a role for serotonin in the reinforcing effects of cocaine. Experiments are currently in progress to determine the effectiveness of chronic trazodone administration. This research was supported by USPHS grant DA06013.

### 302.17

COCAINE-SENSITIVE AND -INSENSITIVE DOPAMINE UPTAKE IN PREFRONTAL CORTEX, NUCLEUS ACCUMBENS AND STRIATUM. J.R. Taylor\* J.D. Elsworth and R.H. Roth. Depts of Pharmacology and Psychiatry, Yale Univ. Sch. of Medicine, New Haven, CT 06510

The reinforcing effects of cocaine are believed to be dependent on inhibition of dopamine (DA) uptake in nucleus accumbens and prefrontal cortex. As previous studies have suggested that DA uptake in nucleus accumbens, prefrontal cortex and striatum may differ, we have further characterized DA uptake in these regions.

A selective lesion of the prefrontal cortex DA terminals induced by simultaneous infusion of desipramine and 6-hydroxydopamine produced a corresponding decrease in DA concentration and in vitro [3H]DA uptake. [3H]DA uptake was resolved into two processes. One was very sensitive to cocaine, GBR 12909 or ouabain and was dependent on temperature and sodium ion concentration; this was responsible for most of the observed uptake in tissue from striatum and nucleus accumbens, but not from prefrontal cortex. There was no regional difference in the susceptibility of cocaine-sensitive [3H]DA uptake to either cocaine or GBR 12909. The other type of [3H]DA uptake, which represented a significant proportion of the total uptake in prefrontal cortex was relatively insensitive to cocaine, GBR 12909 and ouabain and was dependent on temperature, but not sodium ion concentration. Cocaine-insensitive [3H]DA uptake was saturable and distinguished DA from 5HT, but not DA from norepinephrine. Cocaine-insensitive [3H]DA uptake may be associated with glia and play an important role in regulating extracellular DA concentration when synaptic levels are elevated.

These results may account for some of the reported regional differences in sensitivity of DA uptake to inhibition by cocaine. Supported by NIDA P50DA-04060 and DA-05119.

## 302.19

IN VIVO CONCENTRATIONS OF COCAINE ARE ENHANCED FOLLOWING A SINGLE PREEXPOSURE TO COCAINE, H.O. Pettit\* and A.J. Eckstrom; Pett of Neuroscience, SQL International, Menia Park California, 94025.

A SINGLE PREEXPOSURE TO COCAINE. H.O. Pettit\* and A.J. Eckstron; Dept. of Neuroscience; SRI International; Menlo Park, California, 94025.

Previous in vivo microdialysis work has revealed that cocaine concentrations in the blood and brain can be enhanced in animals that receive daily cocaine injections over a 10 day period (Pettit, et al., J. Neurochem. 55: 798-804, 1990). Microdialysis studies to be presented reveal that cocaine concentrations are also enhanced in the blood and brain of rats that have been given one injection of cocaine (20 mg/kg, s.c.) on the day before a challenge injection is given (30 mg/kg, i.p.). Effects of pretreatment on cocaine metabolism may explain how cocaine concentrations are increased. However, levels of the cocaine metabolism reconcentrations are increased. However, levels of the cocaine metabolism rate) were not significantly different between groups. Measures of cocaine levels in the peritoneal cavity following an i.p. injection revealed no significant differences between cocaine naive and experienced groups. Likewise, significant differences were not observed in the transfer rate of cocaine into the blood (i.v./l.p. cocaine concentration ratio). The results indicate that neither the rate of transfer of cocaine into the blood (i.v./l.p. cocaine concentration ratio). The results do not, however, discount possible effects of repeated administration. The results do not, however, discount possible effects of repeated administration on the metabolism of cocaine into benzoylegonine, another major cocaine metabolite. Although enhanced cocaine incocentrations can be observed following an i.p. challenge, when the challenge injection of cocaine is blood and brain cocaine levels occur between cocaine naive and experienced animals. Thus, the effects of repeated docaine into the blood stream. Present results indicate that a single preexposure to cocaine can produce effects that increase the concentration of cocaine in the blood and brain. These effects will play a major tole in the develo

COCAETHYLENE AND OTHER COCAINE ANALOGS: DIFFERENTIAL EFFECTS ON MONOAMINE UPTAKE AND BEHAVIOR. LD. Elsworth\*, LR. Taylor, M.A. Medynski, P. Jatlow and R.H. Roth. Departments of Pharmacology, Psychiatry and Laboratory Medicine, Yale University School of Medicine, New Haven, CT 06510.

The ethyl ester of cocaine (cocaethylene, CE) resembles cocaine in its affinity for the dopamine (DA) uptake site and in certain behavioral tests. The *in vivo* formation of CB following concurrent ingestion of cocaine and ethanol may explain the preference of cocaine abusers for this combination of drugs to cocaine alone. However, CE has been reported to be more toxic than cocaine. We tested the hypothesis that alteration of the ester group has a significant effect on potency and selectivity of cocaine as a monoamine uptake inhibitor and on its behavioral profile.

There was a 2-fold difference among ester analogs of cocaine in their Ki value for [3H]DA uptake and [3H]WIN 35428 binding; iso-propylcocaine and n-butylcocaine being the least potent and cocaine and CE the most potent. A more striking difference (25-fold) was observed in the Ki values for [3H]SHT uptake and [3H]paroxetine binding; CE and iso-propylcocaine being least potent and cocaine and n-butylcocaine the most potent. The analogs that were most selective for DA, compared to 5HT, were CE and iso-propylcocaine.

After injection of high doses (20 mg/kg i.p.) to rats, cocaine at first produced more motor activation than CE, but this initial difference between the drugs did not persist. A different modification of the cocaine structure produces  $\beta$ -CIT (2 $\beta$ -carbomethoxy-3 $\beta$ -(4-iodopheny)-tropane) which has been used in SPECT imaging studies.  $\beta$ -CIT showed no selectivity for the DA uptake site, yet was approximately 100 times more potent than cocaine at inhibiting [3H]DA or [3H]5HT uptake. Thus, a derivative of  $\beta$ -CIT with an altered ester group may be a high affinity ligand suitable for labelling the DA transporter selectively.

ETHANOL ENHANCES THE BEHAVIORAL EFFECTS OF CO-CAINE AT VERY LOW DOSES. <u>J. Peris\*</u>, <u>J. Burry</u>, <u>S. Iyer & J. Scott</u>. Dept. Pharmacodynamics, Univ. Florida, Gainesville FL 32610.

The stimulatory effects of cocaine are enhanced in rats consuming 8 g/kg ethanol daily (Pecins-Thompson & Peris, Psychopharmacol., in press) however ethanol drinking may not have occurred coincident with cocaine injection. In the present study, male rats were divided into 4 groups based on body weight and sucrose consumption in a 30-min period. For 14 consecutive days, rats received 30-min access to either sucrose (Groups S and C) or 10% ethanol in sucrose (Groups E and CE) followed immediately by a saline (Groups S and E) or cocaine (10 mg/kg, i.p.) injection (Groups C and CE). Locomotor activation and stereotypy were measured immediately after the first and fourteenth injection. On the first day, ethanol enhanced the stimulatory effect of cocaine (U(12) = 27.5; p < 0.05) but did not have an effect alone. After the fourteenth injection, both Groups C and CE exhibited cocaine sensitization but behavior of Group CE was still greatest (U(12) = 23.5; p < 0.05). Rats consumed an average of 0.8±0.2 (Group E) and 0.9±0.2 g/kg (Group CE) ethanol prior to the first injection but consumption decreased over days in Group CE (F(13,224) = 3.5; p < 0.001). Sugar consumption was similarly decreased over days in Group C (F(13,546) = 3.1; p < 0.001) indicating that a taste aversion to sucrose was formed in all cocaine-induced decrease in ethanol consumption confounded interpretation of the behavioral data, very low ethanol consumption still increased the sensitized response to cocaine. Thus, even when ethanol consumption is too low to affect locomotion alone, it enhances both the initial and sensitized response to simultaneous cocaine. This work was supported by PHS grants AA08262 and AA00135.

DOSE EFFECTS OF ACUTE COCAINE ADMINISTRATION ON EEG AND AUDITORY EVENT-RELATED POTENTIALS IN RATS. W.M. Kaneko,\*P. Robledo, and C.L. Ehlers. The Scripps Research Institute, La Jolla, CA 92037.

Cocaine administration appears to affect several CNS sites in the limbic forebrain. The nucleus accumbens has been implicated as an important site for the reinforcing aspects of the drug, whereas, the amygdala and hippocampus may be more sensitive to cocaine's "pre-kindling" actions. In the present study, EEG and auditory event related potentials (ERPs) were utilized to explore the actions of cocaine on several limbic sites. Eleven adult male Wistar rats were stereotaxically implanted with electrodes aimed at the dentate gyrus, dorsal hippocampus (CA1-CA2), amygdala, and nucleus accumbens. The rats received intraperitoneal injections of either saline, 2.5 mg/kg, 5.0 mg/kg, 10.0 mg/kg, or 20 mg/kg, in a latin square design. The ERPs were recorded in response to an auditory "oddball" paradigm consisting of frequent and infrequently presented tones. Cocaine was found to produce a significant dosedependent main effect on both EEG and ERPs. This effect was to reduce the variance in the amplitude of several ERP components as well as the variance in power in several spectral bands. ERP effects of cocaine were most prominent following the frequent tone at the highest dose in the dentate, amygdala and nucleus accumbens, whereas lower dose effects were observed in the nucleus accumbens and dentate. EEG effects of cocaine were prominent at all doses primarily in the CA fields of dorsal hippocampus, although high dose effects were observed in the amygdala. The studies suggest that the sensory/cognitive effects of cocaine as quantified by ERPs may involve amygdala, nucleus accumbens as well as dentate gyrus. Whereas, state effects of cocaine which were quantified by EEG measures appear to be mediated through hippocampus CA fields. This reduction of variance of the EEG and ERPs suggests an increase in signal to noise ratio of these measures which may be related to a focussing of the animals attention and/or behavioral state, an effect previously ascribed to noradrenergic systems.

EFFECT OF CHRONIC LITHIUM TREATMENT ON PHOSPHO-INOSITIDE-LINKED SIGNAL TRANSDUCTION PATHWAY IN RAT CORTEX. P.P. Li\*, D. Sibony, M. Green and J.J. Warsh. Clarke Institute of Psychiatry, Toronto, Ontario, Canada, M5T 1R8.

Recent work indicates that the therapeutic action of lithium may be mediated through pertubation of postreceptor second messenger systems. To further elucidate the cellular mechanism of lithium, the effect of chronic lithium treatment on various components of the receptor-activated phosphoinositide (PPI) pathway was investigated. We found that chronic administration of lithium (0.2% LiCl, 21 days) to adult male rats did not significantly affect PPI hydrolysis in cerebral cortical slices induced by carbachol (1 mM) or NaF (10 mM). Neither did the same treatment alter the carbachol (1 mM)-potentiation of GTPγS (1-30 μM) stimulation of PPI hydrolysis (an index of receptor/G protein coupling) in cortical membranes Immunoblotting studies revealed no changes in the levels of G<sub>q/11</sub> immunoreactivity in the cortex after chronic lithium. In contrast, the specific binding of [3H]phorbol dibutyrate (PDBu) was significantly reduced in cytosol (-20%) and increased (27%) in the particulate fraction of rat cortex after chronic lithium, although the  $K_d$  of [ $^3$ H]PDBu binding remained relatively constant. A small and insignificant decrease (-13%) in the density of [3H]InsP binding was also found in the cortex. The above data suggest that chronic lithium treatment affects neither the muscarinic cholinergiclinked PPI turnover, nor the putative G protein (Go(11) responsible for phospholipase C activation. However, a possible translocation and activation of protein kinase C activity may be significant in the therapeutic effect of this mood stabilizing agent. Supported by the OMHF.

EFFECTS OF SEROTONERGIC ANXIOLYTICS ON BEHAVIOR MAINTAINED BY TIMEOUT FROM AVOIDANCE. M. Galizio\*, K. L. Hale, M. Liborio, and M. Miller. Department of Psychology, University of North Carolina at Wilmington, NC 28403.

The effects of 5-HTla ligands buspirone (.3-2.0 mg/kg), gepirone (3-20 mg/kg), and 8-hydroxy-2-(di-n-propyl-amino)tetralin (8-0H-DPAT) (.1-3.0 mg/kg) were studied, along with the benzodiazepine chlordiazepoxide (CDZ) (2.5-20 mg/kg), on rat behavior maintained by negative reinforcement. Concurrent performances were studied under conditions where responses on one lever postponed shock on a Sidman avoidance schedule and responses on a second lever produced brief periods of signaled timeout from avoidance. As in previous studies, CDZ increased responding on the timeout lever at doses that decreased avoidance. In contrast buspirone and gepirone decreased responding on both levers at all effective doses. Initially 8-OH-DPAT produced disruption of responding similar to buspirone and gepirone, but after repeated administrations, 8-OH-DPAT increased responding on both levers at he differences in the behavioral effects of these drugs were not expected on the basis of their known neuropharmacological or their anxiolytic properties. anxiolytic properties.

## 303.5

SEDATIVE AND AMNESIC EFFECTS OF TRIAZOLAM AND ITS METABOLITES IN MICE, A.H.Tang\* and C.S.Himes, The Upjohn Company, Kalamazoo, MI 49001.

The sedative and amnesic effects of triazolam and its metabolites

were studied in mice using exploratory locomotor activity and the one-trial passive avoidance response, respectively. Drugs were administered on the first day, before measuring locomotor inhibition and training for passive avoidance. Memory recall was tested 24 hrs later with no further drug treatment. Triazolam administered either i.p. or p.o. 30 min before training had an amnesic effect at doses that also produced marked sedation. The same doses of triazolam given p.o. 4 hrs before training produced neither sedation nor amnesia. Pentobarbital sodium and ethanol at sedative doses also produced amnesia in mice. Both the sedative and amnesic effects of triazolam were antagonized by a simultaneous administration of the specific benzodiazepine antagonist, flumaze nil. Five metabolites of triazolam identified in human urine were tested in the above paradigms using i.p. administrations. The major metabolite, α-hydroxy triazolam, was comparable in potency to triazolam for both sedative and amnesic effects. The other metabolites were all inactive in either measure. The results indicated that triazolam is similar to other benzodiazepines in producing anterograde amnesia at grossly sedative doses. The effects are mediated through the flumazenil-sensitive receptors and the metabolites of triazolam are either pharmacologically inactive, or have an identical sedative/amnesic effects as triazolam itself.

LITHIUM AND PILOCARPINE INDUCE IMMEDIATE EARLY GENE TRANSCRIPTION IN RAT BRAIN. M.B. Williams\* and R.S. Jope. Dept. of Psychiatry and Behavioral Neurobiology, Univ. of Alabama, Birmingham, AL 35294.

Although lithium is used to treat bipolar affective disorder, its mechanism of action is unknown. Lithium generally inhibits second messenger production but in vivo lithium enhances cholinergic activity. For example, in rats administration of lithium (3 mmol/kg) or pilocarpine (30 mg/kg) alone has no effect on EEG recordings, but the combination causes generalized convulsive status

epilepticus. In rat brain lithium potentiates pilocarpine-induced c-fos expression (Weiner et al. Br. Res. <u>553</u>; 117, 1991).

We extended this finding in rat brain by measuring c-jun, jun B and jun D, as well as c-fos, mRNA and the drug dose and time-dependency of the increases. Pilocarpine (30 mg/kg) alone induced small increases in these mRNA levels and with lithium pretreatment large increases occurred concomitant with seizures. Lithium followed by a nonconvulsive dose of pilocarpine (5 mg/kg) also increased these mRNA levels more than pilocarpine alone. Work is in progress to determine the extent of the modulatory effect of lithium on the expression of each of these genes.

## 303.4

PHARMACOLOGY OF CL 284,846, A NON-BENZODIAZEPINE SEDATIVE WITH REDUCED AMNESTIC LIABILITY. Ivana P. Day, Donald E. Clody, Michael M. Monaghan, Marc S. Abel‡, John P. Dusza and Bernard Beer\*. American Cyanamid Company, Medical Research Division, Lederle Laboratories, Pearl River, NY 10965 and ‡The Chicago Medical School, Dept. of Cell Biology and Anatomy, North Chicago, IL 60064

The profile of effects for CL 284,846, N-[3-(-cyanopyrazolo[1,5-a]pyrimidin-7-yl)]-n-ethylacetamid, identifies this compound as a potential drug for the treatment of insomnia. It is orally active in rodents and primates and is pharmacologicaly similar to sedative benzodiazepine agents produces significant and dose-related anxiolytic-like effects on conflict procedures in rats and squirrel monkeys. In rats, this compound decreases motor activity, induces muscle relaxation, impairs coordinated movement, and promotes EEG sleep. In squirrel monkeys, it has a sedative-hypnotic profile of effects on vigilance behavior. CL 284,846 has anticonvulsant activity in rats similar to the benzodiazepine sedative-hypnotic drugs.

Similar to other sedative-hypnotic agents, CL 284,846 binds to brain benzodiazepine receptor sites (much more avidly to type I receptors), produces a significant enhancement of TBPS binding and has pharmacological effects that are antagonized by the benzodiazepine receptor antagonist Ro 15-1788.

In general, the potency of sedative-hypnotic effects appears to be slightly less than that of triazolam and greater than that of flurazepam. CL 284,846, at efficacious doses, has fewer side effects than standard BDZ sedativehypnotics. It shows reduced tolerance, a lessened tendency to potentiate ethanol neurotoxicity, is devoid of next-day hangover effects and has a reduced amnestic liability.

## 303.6

INITIAL SUB-SENSITIVITY TO BENZODIAZEPINE TREATMENT ON CONFLICT BEHAVIOR IN RATS: PARAMETRIC STUDIES ACROSS DRUG CLASSES. R. Kleinsorge\* and R. Commissaris. Dept. of Pharmacy and Allied Health, Wayne State Univ., Detroit, MI 48202

In rodent conflict paradigms, benzodiazepines (BZs) often exhibit sub-maximal anti-conflict (i. e. anxiolytic-like) effects initially, with maximal effects being observed only after 3-4 BZ exposures (Anxiolytic Initial Sub-sensitivity; AIS). The present experiments examined (1) whether AIS occurs with non-BZs and (2) whether prior exposure to non-BZs prevents the BZ-AIS. Female Sprague-Dawley rats were trained to stable responding levels on a repeated ip, 15 min. pretreatment) were determined in 3 groups (n=8 per group) of drug-naive rats using a 2 day balanced cross-over design, group) of drug-naive rats using a 2 day balanced cross-over design, with each group receiving all doses of a single drug. Redetermination of the dose-response curves showed an AIS for the anti-conflict effects of CDP, but not for the effects of PB; the effects of CBZ were weak for both determinations. In Experiment-2, the rats from Experiment-1 were administered CDP (10 mg/kg, 30 min. pretreatment, ip) using a similar cross-over design. Compared to CDP-experienced rats, subjects with a history of repeated PB or CBZ treatments exhibited anti-conflict responses that were smaller in magnitude. These data suggest that (1) the AIS does not occur with non-BZ anxiolytics and (2) the BZ-AIS cannot be prevented by exposure to non-BZs. (Supported in part by USPHS MH#47181)

EFFECTS OF CHRONIC STIMULANT TREATMENT ON CEREBRAL METABOLISM IN ADULTS WITH HYPERACTIVITY. J. A. Matochik\*, A. J. Zametkin, L. L. Liebenauer and R. Cohen. NIMH, Section on Clinical Brain Imaging, B 10/4N317, Bethesda, MD 20892.

The neural mechanisms of action of dextroamphetamine (DEX) and methylphenidate (MPH) in the treatment of Attention Deficit Hyperactivity Disorder (ADHD) are unknown. To measure cerebral glucose utilization, 34 adults diagnosed with ADHD received 4-5 mCi of 18-fluoro-2-deoxyglucose while performing an auditory attention task. Images were obtained with a Positron Emission Tomograph (PET) with 5-6 mm in plane resolution. Whole brain and 60 regional measures of glucose metabolic rate were extracted. Following the baseline PET scan, 16 patients received a daily dose of DEX individually titrated to achieve clinical effect and the remaining 18 patients received MPH. The 2nd PET scan was performed 6-8 weeks after the begining of drug treatment. Despite significant improvement in behavior (Connor's Rating Scale) and detectable blood levels for both stimulants, neither drug changed global or whole brain metabolism. Metabolism (normalized values) was significantly decreased in the right posterior frontal cortex (4% change) and right anterior putamen posterior frontal cortex (4.% change) and figure DEX increased metabolism in the left anterior putamen (9%). Performance on the attention task was unaffected. Analysis of the responders versus nonresponders within each chronic drug treatment may reveal different cerebral metabolic patterns.

## 303.9

AN ANATOMICAL METHOD FOR ANALYZING PET DATA: VOLUMETRIC RECONSTRUCTION WITH MRI SURFACE SAMPLING VS TRADITIONAL SLICE ROI SAMPLING. E.A.Gastineau<sup>1</sup>, H.L. Loats<sup>2</sup> C.A. Tamminga<sup>1</sup>, H.H. Holcomb<sup>1,3</sup>, T. Rippeon<sup>2</sup>, D. Francis<sup>2</sup>, M. McIver<sup>2</sup>, D.Ross\*1. 1Maryland Psychiatric Research Center, Baltimore, MD 21247. <sup>2</sup>Loats Assoc.Inc, Westminster,MD. <sup>3</sup>Johns Hopkins Hospital,Balto.,MD.

Traditional Region of Interest (ROI) sampling of functional images such as FDG-PET have been on acquired axial slices. Reconstructing these slices into volume allows for dynamic interaction with the data to render slice through any plane and generate surfaces. Here, an MRI and 3 FDG-PET scans were acquired from 8 patients enrolled in an on-off-off drug paradigm using Haloperidol. PET and MRI images were registered by overlaying the three orthogonal midplanes and adjusting the PET for X, Y, Z, translation and roll pitch and yawl, matching the functional image to the anatomy of the MRI. Once registered corresponding slices were constructed for all data sets and surfaces rendered. Surfaces were created using the MRI to describe a volumetric template. This template was then used to reconstruct surface views for the MRI and PET data sets. Atlases were described for the surfaces views for the MKI and PET data sets. Attases were described for the surface and midbrain area using the anatomy of the reconstructed MRI and applied directly to the associated PET studies. Measurements from the atlases were correlated with traditional slice ROI measurements and validation and reliability data is reported. Validation of both inter and intra-rater methods are also reported. Anatomical sampling based on reconstructed volumetric MRI data provides precise location for functional image sampling and shows the variability of activity within a perscribed area. Heretofore, this area was measured by a single ROI that was assumed to be representative. With the method described, volumetric as well as spatial relationships may be much more accurately reported.

## 303.11

DISCRIMINATIVE STIMULUS PROPERTIES OF THE COMBINED 5-HT1A PARTIAL AGONIST/5-HT2 ANTAGONIST WY-50324 IN RATS. K.L. Marquis. A.T. Shropshire. M.I. Piesla and J.A. Moyer\*. Wyeth-Ayerst Research, CN 8000, Princeton, NJ 08543.

and J.A. Moyer\*. Wyeth-Ayerst Research, CN 8000, Princeton, NJ 08543. WY-50324, a combined 5-HT1A partial agonisty5-HT2 antagonist, is under development as an anxiolytic and antidepressant (Abou-Gharbia and Moyer, Drugs of the Future 15:1093-4, 1990; Barrett and Zhang, Drug Dev. Res. 24:179-188, 1991). The current experiment assesses the role of both mechanisms in the discriminative stimulus properties of WY-50324. Fifteen male Sprague-Dawley rats were trained to discriminate 2.5 mg/kg of WY-50324 from saline when administered i.p. 15 min prior to daily 10-minute two-lever food-reinforced operant sessions. Discriminative control was obtained in an average (± SD) of 17.5 ± 8.7 sessions after double alternation between drug and saline injection was initiated. Generalization of a range of doses of WY-50324 to the training dose occurred at an ED50 of 1.08 mg/kg ip. The full 5-HT1A agonist 8-OH-DPAT, given 15 minutes prior to test sessions, generalized to WY-50324 at an ED50 of 0.1 mg/kg minutes prior to test sessions, generalized to WY-50324 at an ED50 of 0.1 mg/kg i.p. The selective 5-HT2 antagonist ritanserin, when given at 1, 3 and 10 mg/kg i.p. The selective 5-HT2 antagonist ritanserin, when given at 1, 3 and 10 mg/kg i.p. 1 hyprotrope to test session, did not generalize to WY-50324. In addition, WY-50324 generalized to 8-OH-DPAT at an ED50 of 0.8 mg/kg ji in a separate group of rats trained to discriminate 8-OH-DPAT (0.4 mg/kg i.p.) from saline. Combinations of 3 mg/kg of ritanserin with various doses of 8-OH-DPAT did not significantly change the generalization of 8-OH-DPAT in WY-50324. These data indicate that the stimulus properties of WY-50324 are related to its agonist effects at 5-HT1A receptors at the training dose used. In addition, 5-HT2 antagonism does not block the 5-HT1A agonist effects of WY-50324. Given that ritanserin, by itself, does not function as a discriminative stimulus (Meert and Janssen, Drug Dev. Res. 18:119-44, 1989), the contribution of 5-HT2 antagonism to the discriminative stimulus effects of WY-50324 will need to be determined in antagonism experiments. antagonism experiments.

THE SEX AND AGE RELATED DIFFERENCES IN THE OPTIMAL DOSE OF L-DEPRENYL FOR INCREASING SOD AND CATALASE ACTIVITIES IN RAT STRIATUM. G.O. Ivyl<sup>1\*</sup>, M.-C. Carrillo<sup>2</sup>, W. Switzer<sup>3</sup>, N.W. Milgram<sup>1</sup> and K. Kitani<sup>2</sup>. <sup>1</sup>Dept.Anatomy and Cell Biology, Univ. Toronto, Scarborough, ON M1C 1A4, <sup>2</sup>Tokyo Met.Inst.Gerontology, Japan and <sup>3</sup>Neurosci.Assoc., Knoxville, TN 37922.

We have shown that administration of the anti-Parkinsonian drug, l-deprenyl, increases activities of superoxide dismutase (SOD) and catalase (CAT) in striatum (ST) of young male (YM) rats. We now clarify sex and age related differences in the optimal dose of deprenyl for increasing SOD and CAT activities and demonstrate brain region selectivity. YM and Y and old (O) female (F) rats were infused s.c. with various doses of deprenyl or saline for 3 wks via osmotic mini-pump or by daily s.c. injection. YF rats required a 5-10-fold lower drug dose to optimally elevate SOD and CAT levels in ST than did YM rats while OF rats required intermediate doses. SOD and CAT levels were not increased in hippocampus (H) in any rats and glutathione peroxidase levels were not increased under any conditions. A study in YM rats showed that SOD and CAT activities increased in ST and substantia nigra (SN) but not in H, cerebellum or liver. Rat body weight, H and ST weights were unaltered by treatment, with the notable exception that ST weight was significantly lower in deprenyl treated Fs. We thus investigated possible ST degeneration in treated Fs and Ms using a variety of methods including the cupric-silver degeneration strain. No pathology was seen. Thus, I-deprenyl significantly increases activities of free-radical scavengers in ST of both M and F rats and in SN of M rats, but doses vary with sex and age. Further, no pathology was present in any brain region even with relatively high drug doses. Supported by Deprenyl Animal Health.

MAGNETIC RESONANCE IMAGING REVEALS THAT BMS 181100 REDUCES EDEMA AFTER BILATERAL CAROTID OCCLUSION IN THE GERBIL. E. A. Marshall<sup>1</sup>, S. L. Moon<sup>2\*</sup>, K. E. Timko<sup>2</sup>, M.A. Kapin<sup>2</sup>, I.E. Rosenberg<sup>1</sup>, and B.S. Krishnan<sup>1</sup>

Depts. of Analytical Research & Development. 1 and CNS Neuro-

pharmacology<sup>2</sup>, Bristol-Myers Squibb Co., Wallingford, CT 06492. We have reported that BMS 181100 (Bristol-Myers Squibb, formerly coded BMY 14802) attenuated hippocampal histopathology and improved behavioral impairment resulting from 15-min bilateral carotid occlusion (BCO) followed by a 96 hr reperfusion/survival period in the Mongolian gerbil. We now report that proton NMR imaging after BCO shows that BMS 181100 decreased sized intensities in Toward sheet directors of the BMS 181100 decreased signal intensities in T2-weighted images of the striatum relative to vehicle-treated controls. Standard Nissl stain confirmed the striatum as a site of severe damage in this model.

Gerbils received BMS 181100 (50 mg/kg) or vehicle 1 hr postsurgery, then once/day for 3 days. Once every 24 hrs after BCO, they were

anesthetized and positioned in the imaging probe of a Bruker WM 360 NMR spectrometer fitted with a micro-imaging accessory. The radio-frequency coil was tuned to the proton Larmor frequency of 360.13 MHz. Sham-operated, vehicle and drug treated animals were imaged. At the end of the study, brains were fixed and stained with cresyl violet.

A consistent increase in signal intensity was noted in the striatum of

occluded animals compared to that of sham controls. Evident from the first day of imaging, the striatal signal intensity in the BMS 181100-treated animals was smaller compared to the vehicle-treated animals. At 24 and 72 hrs, this signal attenuation was significant. Nissl stain indicated that the hippocampus showed cell death that is typical of this model, but also the striatum showed extreme cell loss.

## 303.12

ACUTE EFFECTS OF ANTIDEPRESSANTS ON LOCUS COERULEUS (LC) DISCHARGE OF ANESTHETIZED AND UNANESTHETIZED RATS.  $\underline{A.L.}$ Curtis\* and R.J. Valentino, Dept. Mental Health Sci., Hahnemann University, Philadelphia, PA 19102, U.S.A.

Philadelphia, PA 19102, U.S.A.
Antidepressants are thought to produce their clinical effects by actions on central biogenic amine systems. This study characterized the acute effects of 4 antidepressants on discharge activity of the noradrenergic nucleus, LC. Because LC discharge is state dependent, antidepressant effects were compared in anesthetized and unanesthetized rats. In halothaneanesthetized rats desmethylimipramine (DMI) and phenelzine (PHE) decreased LC spontaneous discharge rate in a dose-dependent manner. In contrast, the atypical antidepressant, mianserin (MIA) increased LC spontaneous discharge rate, and the selective serotonin reuptake inhibitor, sertraline (SER) had no effect. In unanesthetized rats DMI had qualitatively similar effects but was 1/10th as potent. MIA and SER did not alter LC spontaneous discharge rates of unanesthetized rats. LC discharge was evoked by sciatic nerve stimulation in anesthetized rats and by auditory. spontaneous discharge rates of unanesthetized rats. LC discharge was evoked by sciatic nerve stimulation in anesthetized rats and by auditory stimulation in unanesthetized rats. DMI decreased LC discharge evoked by sciatic nerve stimulation at doses greater than those that decreased spontaneous discharge. MIA and SER also decreased LC discharge evoked by sciatic nerve stimulation. In unanesthetized rats only DMI and MIA decreased auditory-evoked LC discharge and these drugs were 30-3000 times less potent in unanesthetized rats, respectively. These findings suggest that antidepressants have qualitatively similar effects on LC spontaneous discharge but are less potent in unanesthetized vanidepressants to suppress LC discharge. Potency and efficacy differences between antidepressants on auditory vs. sciatic nerve -evoked LC discharge may be due to the different neuronal circuitry underlying LC activation by these stimuli. Supported by MH42796, MH 40008 and MH00840.

BEHAVIORAL EFFECTS OF FLUVOXAMINE ON SEVERAL PARADIGMS IN RODENTS.

Imanishi and A. Sawa Pharmaceutical Research and A. Sawa. Pha Meiji Seika Kaisha Yokohama 222. Ltd.,

Fluvoxamine(FLV) is a serotonin(5-HT) inhibitor, which is marketed as an effective anti-depressant in many countries throughout the world. registration dossier for obsessive complusive A registration dossier for obsessive complusive disorder(OCD) has been submitted to the U.S. Food and Drug Administration. It is recently and widely accepted that 5-HT mediates various functions of the central nervous system, i.e., anxiety, mood, schizophrenia and memory, etc. In these experiments, the effects of FLV were investigated in several rodent depression and anxiety models. The antidepressant effects of FLV were tested in a male ICR mouse forced swim model. These data revealed the significant but weaker effect of FLV revealed the significant but weaker effect of FLV than that of desipramine. The anti-OCD effect of FLV was investigated in the following paradigms. The anxiolytic effect of FLV was not detected in Vogel-type conflict and elevated plus maze paradigms in male Fisher 344 rats. However, the anxiolytic effect of FLV via 5HT1A receptor was detected in the marble burying paradigm which is recently considered as a model of OCD. From these results, it is suggested that FLV has both anti-depressant and anti-OCD effects.

## 303.15

THE MECHANISM OF ANTIDEPRESSANT ACTION IN DEPRESSION. P.L. Delgado\*, H.L. Miller, R.M. Salomon, J. Llcinio, L.H. Price, G.R. Heninger, D.S. Charney, West Haven VAMC and Dept. of Psychiatry, Yale University School of Medicine, 950 Cambell, West Haven, CT 06516
Brain serotonin (5-HT) is reduced by depleting plasma tryptophan (TRP). Brain catecholamines are reduced by inhibiting their synthesis with the tyrosine hydroxylase inhibitor alpha-methyl-para-tyrosine (AMPT). If antidepressant drugs relieve depression by changing 5-HT or norepinephrine (NA), then reducing 5-HT or NA should alter mood in depressed patients having had therapeutic antidepressant responses to designamine (DMI) or fluoxetine (FLU). METHOD: Thirty depressed (DSM-III-R) patients (5 AMPT, 25 TRP Depletion) having had therapeutic responses to DMI or FLU participated in 2 tests one week apart. Antidepressants are continued throughout testing. TRP depletion and AMPT tests were conducted in a double-blind, placebo-controlled, randomized crossover fashion. TRP depletion was as in our previous studies (Delgado et al., 1990). Tashion. TRP depletion was as in our previous studies (Delgado et al., 1990).

AMPT testing includes a baseline day, two days with AMPT 1 gm TID or diphenhydramine 50 mg TID and a follow-up day. Ratings (Hamilton Depression Scale (HDRS)) and plasma and urine (for TRP or MHPG and HVA levels) were obtained prior to, during and after testing. Depressive relapse was defined as a 50% increase in HDRS with total ≥20. RESULTS: 6/12 was defined as a 50% increase in FIDH'S with total 220. REQUELS: 612
FLU responders but only 1/13 DMI responder relapsed with TRP depletion.
Preliminary results show that 3/3 DMI-responders but 0/2 FLU-responders relapsed during AMPT testing. No patient relapsed during control (placebo) testing. IMPLICATIONS: Rapid depletion of plasma TRP transiently reverses antidepressant responses to FLU but not DMI. These results along with preliminary results from AMPT testing suggest that antidepressants may mediate their therapeutic effects through different mechanisms and highlight the importance of NA and 5-HT in antidepressant action.

## 303.17

EFFECT OF ANTIDEPRESSANTS ON 5-HT UPTAKE SITES AND 5HT1A RECEPTORS: HOMOGENATE BINDING AND AUTORADIOGRAPHIC STUDIES. E.K. Nénonéné<sup>1</sup>\*, F. Radja<sup>2</sup>, M. Ohayon<sup>2</sup>, and T.A. Reader<sup>2,3</sup>, Centre de recherche en sciences neurologiques and Centre de recherche psychiatrique Fernand-Séguin (Départements de physiologie et de psychiatrie), Université de Montréal (Québec) CANADA.

The mechanism(s) of action of antidepressants has not yet been fully clarified, but all available evidence indicates that they affect monoamines, in particular serotonin (5-HT) nerve terminals and/or receptors. We compared in vitro the effects of the novel antidepressant Reboxetine (REB) with Imipramine (IMI), Trimipramine (TRI), Fluoxetine (FLU) and Buspirone (BUS). The ligands [3H]citalopram and [3H]paroxetine were used to examine 5-HT uptake sites, while [3H]8-OH-DPAT was employed for 5-HT1A receptors. In homogenate studies, REB inhibited ( $^{1}$ H)paroxetine binding with an IC50 of 15.4  $\pm$  5.8  $\mu$ M; the rank order of potency was FLU > IMI > REB > TRI. For 5-HT1A receptors, competition of [3H]8-OH-DPAT binding had the following orders of potency: BUS > TRI > IMI > REB > FLU for cortex, and BUS > TRI > FLU > IMI > REB for hippocampus. This survey thus shows that antidepressant drugs can compete with 5-HT1A receptors in the micromolar range. Quantitative autoradiography of 5-HT uptake sites showed that REB inhibited [3H]citalopram binding with IC50 values of 4.1  $\pm$ 1.3, 0.79  $\pm$  0.2 and 2.5  $\pm$  1.5  $\mu$ M for dorsal Raphe nuclei, Substantia nigra and neostriatum, respectively. The main conclusions that can be drawn from these studies are that 1] REB has micromolar affinities for 5-HT uptake sites and 5-HT1A receptors, and 2] it exhibits a regional heterogeneity to compete with markers of 5-HT uptake sites. (Supported by the 1 Savoy Foundation, the 2 FRSQ and 3 MRC Grant MT6967).

ACUTE AND CHRONIC DESIPRAMINE INCREASES NOREPINEPHRINE ACUTE AND CHRONIC DESIFYAMINE INCREASES NOREPINEPHRINE CARRIER MRNA IN THE LOCUS COERULEUS. R. Veith, P. Szot. A. Ashleigh, E. Petrie and D.M. Dorsa. GRECC, Seattle VAMC, WA 98108 and Dept. of Pharmacology, Univ. Washington, Seattle, WA 98195. Designamine (DMI), a tricyclic antidepressant, is known to have pronounce effects upon the postsynaptic and presynaptic noradrenergic (Nepi) system.

effects upon the postsynaptic and presynaptic noradrenergic (Nepi) system. Presynaptic effects include down regulation of \( \alpha \)-adrenergic receptors, blockade of the transport protein responsible for the reuptake of Nepi after its release, and a decrease in tyrosine hydroxylase (the rate limiting enzyme responsible for synthesis of Nepi) mRNA in the locus coeruleus (LC). This study was performed to observe the effects of DMI on levels of the mRNA encoding the Nepi carrier protein in LC cells. In situ hybridization for the Nepi encoding the Nepi carrier protein in LC cells. In situ hybridization for the Nepi carrier mRNA was performed in animals receiving short term and chronic treatment with DMI. Three end-labeled oligonucleotides (108-150, 186-197 and 579-591) were used. Animals received either (a) 2 intraperitoneal injections of DMI (10mg/kg) or saline 24 hours apart (acute) or (b) 4 weeks of daily intraperitoneal injections of DMI (10mg/kg) or saline (chronic). Following the acute DMI treatment there was a tendency to increase (p<0.10) the Nepi carrier mRNA in the LC (OD control = 0.108±0.01 (n=3) compared to OD DMI = 0.276±0.07 (n=4)). However, chronic DMI treatment (4 weeks) resulted in a significant elevation (OD control = 0.207±0.01 (n=4) compared to OD DMI =  $0.316\pm0.03$  (n=4)) of Nepi carrier mRNA (p<0.05). This indicates that prolonged DMI treatment may increase the expression of the gene encoding the Nepi carrier. The mechanism of this increase in carrier protein mRNA or its involvement in the therapeutic effects of tricyclic antidepressants remains to be determined. (Supported by NS 20311 and the VA)

### 303.16

CHRONIC TREATMENT WITH IMIPRAMINE AND CLOMIPRAMINE BUT NOT CLORGYLINE INCREASES m-CPP LEVELS IN THE BRAIN BUT NOT IN PLASMA. <u>Teresa Tolliver, Charanjit S. Aulakh, James L.</u> Hill, James M. Tolliver\*, and Dennis L. Murphy. Lab. of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892.

We investigated the effects of chronic (21 days) imipramine (5 mg/kg/day), clomipramine (5 mg/kg/day), clorgyline (1 mg/kg/day) or saline treatment on m-chlorophenylpiperazine (m-CPP, a 5-HT<sub>1</sub> agonist) levels in the brain and plasma as well as hypothalamic levels of various neurotransmitters following intraperitoneal administration of 1.25, 2.5 and 5.0 mg/kg doses of m-CPP in male Wistar rats.

Chronic treatment with imipramine and clomipramine significantly

enhanced m-CPP levels in brain but not in plasma by 74% and 33%, respectively, relative to saline treatment. Neither brain nor plasma levels of m-CPP were significantly affected by chronic clorgyline treatment. On the other hand, chronic imipramine and clomipramine treatment did not have any significant effect on hypothalamic levels of treatment du for have any significant effect on hypothalantic levels on norepinephrine (NE), dopamine (DA), serotonin (5-HT) and 5-hydroxyindoleacetic acid (5-HIAA) while chronic clorgyline treatment produced significant increases in NE, DA and 5-HT levels and a significant decrease in 5-HIAA levels. These findings suggest that pharmacokinetic factors might partially contribute to modification of m-CPP's effects following chronic treatment with imipramine and clomipramine but not clorgyline.

## 303.18

EFFECTS OF CHRONIC ANTIDEPRESSANT TREATMENT ON CORTICAL [3H]PAROXETINE BINDING AND SEROTONIN CONTENT. K.M. Dewar\*1 M. Ohayon<sup>1</sup>, E. Nénonéné<sup>3</sup> and T.A. Reader<sup>1,4</sup>. Centre de recherche psychiatrique Fernand-Séguin and Centre de recherche en sciences neurologiques (Départements de physiologie et de psychiatrie), Université de Montréal (Québec) CANADA.

Serotonin (5-HT) appears to play a pivotal role in many central nervous system (CNS) functions such as sleep, feeding and motivation; many antidepressant drugs that influence these functions act via blockade of the 5-HT transporter. Serotonin uptake sites were quantified using high affinity binding of [3H]paroxetine to cortical membranes of neonatal (7 days of age) or adult rats treated chronically (21 days) with tricyclic (Imipramine, Trimipramine) and monocyclic (Fluoxetine) antidepressants. The tissue concentrations of 5-HT and its metabolite 5-hydroxyindole-3-acetic acid (5-HIAA) were determined by HPLC with electrochemical detection, in the cingulate cortex, neostriatum, hippocampus and Raphe nuclei. Following treatment with the antidepressants, neither the maximum binding capacity (BMAX; receptor number) nor the equilibrium dissociation constant (KD) of [<sup>3</sup>H]paroxetine differed from control values in neonatal or adult treated animals. Furthermore, the concentration of both 5-HT and 5-HIAA were unchanged in the various brain regions examined. These data indicate that neither [<sup>3</sup>H]paroxetine binding nor endogenous 5-HT content are altered by chronic treatment with drugs that block the 5-HT uptake site; suggesting that [3H]paroxetine provides a reliable marker of 5-HT innervation density within the mammalian CNS, even following antidepressant drug treatments. (Supported by the <sup>1</sup>FRSQ, the <sup>2</sup>Banting Research Foundation, the 3 Savoy Foundation and 4 MRC Grant MT-6967).

JUVENILE DESMETHYLIMIPRAMINE TREATMENT REDUCES SENSITIVITY TO ADULT IMIPRAMINE ADMINISTRATION IN FORCED SWIMMING AND OPEN FIELD TESTS.

SENSITIVITY TO ADULT IMIPRAMINE ADMINISTRATION IN FORCED SWIMMING AND OPEN FIELD TESTS.

K.D.Dwyer\* and E.J.Roy. Neuroscience Program, University of Illinois, Champaign, IL 61820.

Juvenile administration of antidepressants to rats has been proposed as an animal model of depression. In the present study we compared the effect of adult imipramine in female rats administered desmethylimipramine as juveniles (JDMI) with rats administered saline as juveniles (Jsal) and with rats that were untreated as juveniles (Junt).

Treated rats were injected with saline or 5mg/kg DMI daily between 1 and 3 wks old.

Animals were tested in the swimming test at 10-12 wks and in the open field at 12-14 wks. In the swimming test imipramine increased activity among all juvenile groups when administered short-term after a pretest or when administered long-term prior to an initial exposure to the test. When administered with no prior pretest, short-term imipramine had different effects on Junt and Jsal rats and no effect on JDMI rats. In the open field short-term imipramine influenced all 3 juvenile groups, but long-term imipramine had no effect on JDMI rats. The results of this study indicate that JDMI treatment may have long-term effects on the mechanism underlying imipramine effects on the mechanism underlying imipramine treatment may have long-term effects on the mechanism underlying imipramine action.

NEUROANATOMICALLY-SPECIFIC TRANSGENE EXPRESSION OF A NEURON-SPECIFIC HERPES VIRUS VECTOR
STEREOTACTICALLY DELIVERED INTO THE RAT STRIATUM. J.K. Andersen\*, D.M. Frim, O. Isacson, and X.O. Breakefield. Neuroscience Center, Massachusetts General Hospital East, Charlestown, MA 02129 and Neuroregeneration Laboratory, McLean Hospital, Belmont, MA 02178.

Herpes virus infection with genetically engineered vectors is an effective way to deliver foreign genes to various cell populations in culture and in vivo. Selective delivery to neurons in the brain has been achieved using a replication-defective (TK-), recombinant herpes virus vector containing the bacterial lac Z gene under control of the rat neuron-specific enolase promoter. Direct stereotactic injection of 10<sup>6</sup> plaque forming units of this virus vector into the adult rat striatum resulted in transfer and stable expression of the transgene in a small number of neurons in the striatum, and in neurons ipsilateral to the injection site in the frontal cortex, substantia nigra, and lateral thalamus, as visualized by PCR, in situ histohybridization, and immunocytochemical and histochemical analyses. Neurons at these anatomical locations contain axons that project directly to the striatum. No other neurons within the brains of animals injected with the recombinant virus were found to express the transgene. As herpes virus can be transported in a retrograde fashion in neurons, these results indicate that gene transfer with this vector is constrained not only by the promoter used to drive gene expression and the type of cell that can harbor HSV in latency, but also by placement of viral particles at a specific anatomical location. This finding will help in designing strategies for gene replacement therapy for specific populations of neurons.

## 304.3

FOCAL ASTROCYTOSIS IN S100\$ TRANSGENIC MOUSE. P.J. Yarowsky B. B.K. Krueger", S. Buck", T. Michal", J.D.Gearhart', R.H. Reeves', and D.C. Hilt". Depts. of Pharmacology & Exp. Therap. Physiology, and Neurology, Univ of Maryland Sch. of Med., Baltimore, MD 21201 and Dept. of Physiology, Johns Hopkins University Sch. of Med., Baltimore, MD 21205.

Recent evidence suggests that astrocytes produce S100β, a Ca<sup>2+</sup>binding protein, glial mitogen and neurite extension factor. Levels of S100 $\beta$  have been found to be substantially elevated in Alzheimer's disease and in adults with Down Syndrome. Since S100\$\beta\$ has been shown to act as a glial mitogen in vitro, it was of interest to examine the density and distribution of astrocytes in transgenic S100 $\beta$  mouse brain.  $S100\beta$  transgenic mice have been produced which overexpress mouse S100 $\beta$  mRNA (by 2.2 fold to 6.6 fold) in a tissue-appropriate manner as determined by northern blotting. Immunocytochemical staining of adult animals with an antibody against \$100\beta demonstrates that there is overexpression of S100 $\beta$  in all brain regions of the transgenic. Immunostaining with antibody to the astrocyte specific protein, GFAP revealed focal astrocytosis in the olfactory bulb, hippocampus and cerebellum in S100β transgenic animals. This astrocytosis shows a dose-dependent relationship based upon the level of S100 $\beta$  expressed. These results suggest that S100 $\beta$  functions as a regulator of astrocyte proliferation in the CNS in vivo in a regionallyspecific fashion. Supported by NIH and NSF.

## 304.2

ALTERING CENTRAL NERVOUS SYSTEM PHYSIOLOGY WITH A DEFECTIVE HERPES SIMPLEX VIRUS VECTOR EXPRESSING THE GLUCOSE TRANSPORTER GENE. D. Y. Ho<sup>1</sup>, E. S. Mocarski<sup>2</sup> and R. Sapolsky\*<sup>1</sup>. <sup>1</sup>Dept. of Biological Sciences, <sup>2</sup>Dept. of Microbiology and Immunology, Stanford Univ. Stanford, CA94305.

Because of their postmitotic nature, neurons are difficult subjects for gene therapy. To circumvent this, we have used a defective herpes simplex virus (HSV) vector to overexpress the rat brain glucose transporter gene under the control of the human cytomegalovirus iel transporter gene under the control of the human cytomegalovirus is promoter. This vector, designated as vIEIGT, was propagated using an HSV-1 temperature sensitive mutant 1s756. Glucose transporter expressed from vIEIGT was readily immunoprecipitated from membrane fractions of vIEIGT-infected Vero cells. Using indirect double immunofluorescence techniques, vIE1GT was shown to be capable of enhancing expression of the glucose transporter in both cultured hippocampal neurons and glia. Glucose transport in such vIE1GTinfected cultures was increased approximately two-fold, and the increase was resistant to the effects of glucocorticoid treatment, which had been shown previously (Horner, et al., 1990) to inhibit glucose transport. The efficacy of this system in vivo was then tested by microinjection of vIE1GT into adult rat hippocampus and measurement with [14C]2-deoxyglucose uptake autoradiography. significantly enhanced glucose transport in regions near the site of injection without causing adverse cytopathology; in particular, an approximately 10% increase was observed in a small sphere of tissue surrounding the injection site. Thus, this approach can be used to alter central nervous system physiology both in vitro and in vivo.

- CHARACTERIZATION OF AN INHIBITORY FACTOR OF PEIDERNAL GROWTH FACTOR RECEPTOR PHOSPHORYLATION (EGF-R) IN CYST FLUIDS ASSOCIATED WITH GLIOMAS. • A.L. Benabid\*, F. Berger, M. Lainé, G. Amalfitano, J.F. M Brunet, L. Molin, T. Bachelot, T. Gustin, M.F Nissou, J.M. Verna, INSERM U 318. CHU BP 217 X 38043 Grenoble Cedex FRANCE.
- 24 to 55% of gliomas have a cyst fluid (CF) component. Du to their closed contact with tumor cells they represent a good approach to study the biology of gliomas and to test the autocrine hypothesis. As EGF-R is the most frequently involved proto-oncogene in gliomas we searched for "EGF-like" factors in CFs.

We studied the effect of 30 different CFs on the EGF-R phosphorylation in A 431 cells membranes. CF effect was also analyzed in cell culture on

A 431 and 3 human established glioma cell lines.
Unexpectedly, CFs, on the contrary of EGF, induced an inhibitory effect on EGF-R phosphorylation. Biochemical analysis suggested that it was an anti-tyrosine kinase effect. It persisted at high dilution and on cells in culture where an antitrophic effect was also observed for cell lines expressing EGF-R. This inhibitory effect was present in the 20-30 kDa fraction after HPLC superose 12 separation.

We conclude that an anti-tyrosine factor of 20-30 kDa is present in CFs from gliomas. Effect at high dilution and in vitro on whole cells suggest that this factors may play an anti-oncogenic role in the tumoral progression of gliomas. The recent report of EGF-responsive stem cells in the adult mice thalamus suggests that such factor may be important at the physiological level. Further purification and microsequencing are in process to clarify these issues.

SELECTIVE INDUCIBLE ABLATION OF HIV-TAT EXPRESSING GLIOMA CELLS BY RETROVIRUS GENE TRANSFER. D. Platika\* and H. Rubinson. Depts. of Neurology and

Neuroscience, Albert Einstein Coll. of Medicine, Bronx, NY 10461
We have previously demonstrated the killing of glioma cells in vitro and in vivo by retrovirus vector transfer of the herpes simplex thymidine kinase gene (TK) (Ezzeddine, et al. 1991). Unlike genes such as diphtheria toxin whose product is toxic to mammalian cells, TK is non-toxic except in the presence of specific nucleoside analogues such as acyclovir and ganciclovir. The report utilized a retrovirus based vector containing TK under the transcriptional control of the Moloney murine leukemia virus long terminal repeat. Selectivity was based on the fact that gliomas represent rapidly dividing cells in a setting of essentially nondividing cells.

Selectivity and specificity can be further enhanced by utilizing

tissue specific promoters or promoters that are induced in the cells targeted for ablation. We have designed a series of replication-deficient retrovirus vectors in which TK is under the transcriptional control of human immunodeficiency virus (HIV) promoter sequences. HIV demonstrates neurotropism and has been identified as the etiological agent in AIDS. AIDS has been associated with primary neoplasms at various sites including the CNS.

The vectors have been used to transduce C6 rat glioma-derived

cells. Northern analysis revealed that the presence of HIV transactivator protein (tat) increases TK expression. Both in vitro and in vivo studies showed that in the presence of tat, these cells can be selectively killed with the use of acyclovir or ganciclovir.

# 304.7

STUDIES OF CHROMOSOME DYNAMICS IN ALZHEIMER'S DISEASE CELLS: EVIDENCE FOR A DIFFERENTIAL RESPONSE TO MITOTIC ARREST AND THE OCCURRENCE OF LOW FREQUENCY CHROMOSOME 21 TRISOMIES. Lisa N. Geller'. Mark B. Benjamin and Huntington Potter. Dept. of Neurobiology, Harvard Medical School, Boston, MA 02115.

Huntington Patter. Dept. of Neurobiology, Harvard Medical School, Boston, MA 02115.

The overexpression of a gene or genes on chromosome 21 has been proposed as an explanation for the link between Down syndrome and Alzheimer's Disease (AD), since Down patients living into their 30s and 40s develop neuropathology essentially indistinguishable from classic AD. The amyloid precursor protein is now known to be encoded by a gene residing on chromosome have been seen in some AD families. These mutations of not, however explain the vast majority of AD cases. We have been pursuing the hypothesis that the formation of trisomy 21 cell clones in the developing brain might explain sporadic and some familial cases of AD. We have examined AD cells growing in culture for the occurrence of spontaneous trisomy 21. Two methods are employed: chromosomal in situ hybridization to interphase cells using a chromosome 21-specific probe, and flow cytometry employing antibodies directed against the α2-interferon receptor which is expressed on lymphoblasts in proportion to the number of chromosomes 21 they possess. Secondly we have exposed lymphoblasts in culture to the antimicrotubule agent colchicine to examine the short-term effects such exposures have on chromosome dynamics. In situ hybridization has shown evidence for low but significant frequency spontaneous trisomy 21 in one AD cell line. Preliminary data from colchicine exposures, measured by premature centromere division, show that chromosomes in AD lymphoblasts are much more sensitive to colchicine exposure than control lines from similarly aged individuals. These data, taken together, suggest that chromosomes in AD cells respond differently to those in non-AD cells and may be more likely to undergo non-disjunction in response to transient microtubule disruption.

REDUCED EXPRESSION OF NEURONAL PROTEINS IN PC12 CELLS TRANSFECTED WITH THE A4-C-TERMINAL PORTION OF AMYLOID PRECURSOR PROTEIN (APP)

CELLS TRANSFECTED WITH THE AA-C-TERMINAL PORTION OF AMYLOID PRECURSOR PROTEIN (APP)

R.E. Majocha\*, E. Lai and C.A. Marotta

Harvard College, Harvard Med. School, Mass. Gen. Hosp., Boston, MA. 02114

We previously reportd that PC12 cells transfected with A4-C-terminal APP DNA undergo morphological transformations, have incrased levels of immunologically detectable A4 in membranes, display reduced response to NGF, and secrete stimulatory factors which cause non-transfected cells to increae in size and extend neurites (Majocha, et al, J. Molec. Chem. Neuropathol., in press). Normal control PC12 cells contain immunocytochemically detectable levels of tyrosine hydroxylase, synaptophysin, and the 145 kD neurofilament protein (NFP). However transfectants that overexpress the A4 antigen do not appear to accumulate the proteins or do so at lower levels. AD brain also contains reduced levels of synaptophysin and tyrosine hydroxylase, in addition to modified NFPs. Ongoing studies are aimed at determinig the mechanistic relationship between A4 overexpression and reductions in neuronal marker proteins. Supported by NIA PO1 AGO2126 and an overexpression and reductions in neuronal marker proteins. Supported by NIA P01 AG02126 and an award from the Metropolitan Life Foundation.

DISTRIBUTION OF HUMAN LIGHT NEUROFILAMENT PROTEIN IN THE BRAIN OF TRANSGENIC MICE: AN IMMUNOCYTOCHEMICAL STUDY. J.F. Mathieu, G. Doucet\*, A. Vallée, L. Descarries and J.P. Julien. Centre de recherche en sciences neurologiques (Département de pathologie), University de Montréal, and Montreal General Hospital Research Institute, McGill University, Montreal, Québec, Canada.

The distribution of human light neurofilament protein (hNF-L) immunoreactivity was studied in the brain of adult transgenic mice and compared to that of mouse NF-L in normal mice, using two monoclonal antibodies against NF-L, specific or not for the human protein (clones Bio/Can DP5-1-12 and Sigma NR4, respectively). In transgenic mice, numerous nerve cell bodies were labeled with both antibodies in several brain regions, such as cerebral cortex (laminae II/III and V), thalamus, amygdala, septum, substantia nigra and many brain stem nuclei, in addition to major fiber bundles. Other regions such as the striatum showed no cell body immunoreactivity whatsoever. The labeled cells in cerebral cortex were of the pyramidal type and unevenly distributed in large columns. Nerve cell body labeling was particularly striking in specific thalamic nuclei, where darkly stained, enlarged perikarya also displayed excentric and fragmented nuclei. At the electron microscopic level, these perikarya were mostly filled with disarrayed filaments to the extent that other organelles were repelled to a narrow rim underneath the plasma membrane. organelles were repelled to a narrow rim underneath the plasma membrane. However, there were marked interindividual variations in the relative intensity However, there were marked interindividual variations in the relative intensity of the cortical versus thalamic immunostaining. In normal mice, weaker immunoreactivity was present only after using clone NR4 antibodies, and confined to the major fiber bundles and pyramidal neurons of the cortex. These observations suggest that hNF-L expression and processing are regulated differentially in different regions of transgenic mouse brain, where these processes may even escape the regulatory capacities of some neurons, resulting in obvious neuropathological alterations. (Supported by FRSQ and MRC grants MT-10982, MA-9865 and MT-3544).

REDUCTION IN ANTIOXIDANT LEVELS IN TRISOMY 16 MOUSE BRAIN

REDUCTION IN ANTIOXIDANT LEVELS IN TRISOMY 16 MOUSE BRAIN S.F.Chen\*. J. Gafni. L.Reola. E. Carlson. C.J. Epstein and P.H.Chan. Depts of Neurology, Neurosurgery, Pediatrics, UCSF, San Francisco, CA 94143 Mouse trisomy 16 (Ts16), a model for human trisomy 21(Down syndrome), has been used as a tool to study the neurodegeneration involved in mental retardation and Alzheimer disease. Copper/zinc-superoxide dismutase (CuZn-SOD) is one of the genes mapped to the homologous regions of mouse chromosome 16 and human chromosome 21. Since Ts16 mice has one and a half times the regular gene dosage of CuZn-SOD, we studied the oxidative status of the Ts16 brain by measuring the oxygen radical scavenging system. Brains from Ts16 and euploid littermates at sixteen days of gestation were assayed for the activities of antioxidative enzymes [CuZn-SOD, glutathione peroxidase(GSH-Px), manganese-SOD(Mn-SOD), catalase(CAT)] and antioxidant levels [reduced glutathione(GSH), oxidized glutathione(GSSG) and ascorbate(AH2)]. In Ts16 brain, CuZn-SOD activity is significantly increased over normal (3.14 vs 1.79 U/mg protein, p<0.0001), whereas glutathione(GSSG) and ascorbate(AH2)]. In Ts16 brain, CuZn-SOD activity is significantly increased over normal (3.14 vs 1.79 U/mg protein, p<0.0001), whereas activities of other antioxidative enzymes are not altered significantly [Mn-SOD (Ts/N:0.79/0.88U/mg protein), CAT (Ts/N:0.48/0.51 U/mg protein), GSH-Px (Ts/N:11.04/10.80 U/mg protein), CAT (Ts/N:0.48/0.51 U/mg protein), GSH-Px (Ts/N:11.04/10.80 U/mg protein), Incover, both GSH and AH2 levels are dramatically decreased in Ts16 brains (GSH,Ts/N: 20.2/9.1 nmol/mg protein, p<0.001; AH2,Ts/N: 2.50/1.81 nmol/mg protein, p<0.05). Cell-specific changes were studied in cortical astrocyte and neuronal cultures prepared from fetal day 16 Ts16 and euploid brains. GSH levels are significantly decreased in both Ts16 astrocytes (Ts/N:42.68/77.06, p<0.001) and in neurons (Ts/N:10.30/14.30, p<0.05), whereas GSSG levels show a slight increase in Ts16 cultures. Furthermore, the uptake of glutamate is significantly reduced in Ts16 astrocytes. These observations suggest that, despite the overexpression of CuZn-SOD, there is a reduction in GSH and AH2 levels in the Ts16 brains as compared to the normal ones. Whether these decreases in Ts16 mouse neurons and astrocytes contribute to neuropathological decreases in Ts16 mouse neurons and astrocytes contribute to neuropathological changes that are associated with oxidative stress needs further elucidation. Supported by AG-08938, NS-14543, and NS-25372.

# 304.10

IN VITRO AND IN VIVO MODEL SYSTEMS FOR THE STUDY OF β-AMYLOIDOSIS. K. Fukuchi, S. S. Deeb<sup>1</sup>, K. Kamino, C. E. Ogburn, A. C. Smith, D. Nochlin, S. M. Sumi, C. Furlong<sup>1</sup>, P. A. Schwartzkroin<sup>2</sup>, D. D. Kunkel, and G. M. Martin<sup>3</sup>. Depts. of Pathology, <sup>1</sup>Medicine (Div. of Medical Genetics), and <sup>2</sup>Neurosurgery, Univ. of Washington, Seattle, WA 98195.

We have previously demonstrated that overexpression of a C-terminal fragment of amyloid protein precursor (APP) brings about altered cleavage of APP and the lateral electrons of the protein formatter (Esturble 18 PBP of

regiment or amyloid protein precursor (APP) brings about alreved cleavage or APP, resulting in amyloidogenic and cytotoxic fragments (Fukuchi et al., BBRC 182:165). In further analyses, overexpression of the DNA construct in COS cells resulted in at least 6 C-terminal fragments (10-16.5 kDa by Tris-tricine SDS-PAGE) and their aggregates (23->200 kDa), suggesting the involvement of the C-terminal fragments in the intracellular formation of amyloid protein aggregates. P19 (embryonal carcinoma cell) transformants overexpressing the DNA construct degenerated to various extents corresponding to the degree of expression of the C-terminal fragments when the transformants were treated with retinoic acid for differentiation into neural cells. Transformants differentiated into muscle cells (DMSO treatment) survived as well as nontransformed P19 cells. When the DNA construct was introduced into SK-N-SH (a heterogeneous culture of neural and non-neural cells), the surviving cells overexpressing the C-terminal fragments lacked neuronal morphology. These results suggest selective neurotoxicity of the C-terminal APP fragments. Neuronally differentiating P19 transformants were transplanted into the hippocampus of C3H mice. APP immunoreactivity identified the transplanted P19 campus or C3H mice. APP immunoreactivity locatined the transplanted P19 cells; adjacent cerebral vessels were also heavily stained. The construct was also used to develop transgenic mice. Strong expression of the transgene was confirmed in vitrually all tissues by both Northern and Western blot analysis. Western blot analysis of the animals revealed tissue-specific processing of APP in the brain. Moreover, in contrast to the *in vitro* experiments, no ficant neurotoxicity has so far been observed in the in vivo models. Both models, therefore, offer an opportunity to study suppressor mechanisms.
