Stimulus-evoked monosynaptic GABA_A or GABA_B currents were comparable in control and epileptic preparations, but presynaptic inhibition of GABA release was significantly decreased after kindling. Thus, GABAergic inhibition of DG GCs is not impaired in kindling-induced epilepsy; on the contrary, a "compensation" for the hyperexcitability appears to be accomplished in the following ways: (1) by increasing excitatory input onto GABAergic neurons, (2) by increasing the IPSC quantal size, and (3) by reducing presynaptic autoinhibition of GABA release.

SUITABILITY OF α -CHLORALOSE ANESTHESIA PLUS HALOTHANE INDUCTION FOR CEREBROVASCULAR RESEARCH. G. Bonvento, P. Lacombe, R. Charbonné, J. Benavides*[§] and J. Seylaz. CNRS UA641, Université Paris VII, 75010 Paris, France; [§]Department of Biology, Synthelabo Recherche, 92220 Bagneux, France.

Alpha-chloralose is a widely used anesthetic in neurophysiological studies including the cerebrovascular field since it both maintains cardiovascular reflexes and potentiates the generation of evoked responses. However, the use of α -chloralose has been ethically questioned mainly because it induces an EEG that cannot readily be interpreted (J. Physiol., 445, pp. v-xvi, 1992) and a cataleptic behavior, two facts that preclude a proper assessment of the adequacy of anesthesia. In this study, we sought to determine whether α -chloralose when associated with halothane (for the initial surgical step) could be a suitable anesthetic regimen. Using laser-Doppler flowmetry to measure cortical blood flow in either chronically instrumented rats (n=5) or in an acute preparation (n=7), we have shown that halothane (1.5%) given during the first 30-45 min of α -chloralose anesthesia (40mg/kg s.c.) without curare leads to stable cardiovascular parameters and immobility of ventilated rats placed in ear bars for at least 3h without any sign of discomfort, and that halothane delays the appearance of desynchronized EEG activity (stage I). With regards to the cerebrovascular reactivity, a nearly total inhibition of the vascular response to CO₂ is observed (-85%, p<0.01), but this inhibition is reversible since a CO₂ reactivity similar to that observed in the awake rat is restored 2.5-3h after α -chloralose injection and before the appearance of desynchronized activity. Interestingly, halothane (1.5%) given alone continuously induces a marked and sustained decrease in the CO₂ reactivity (-75%, p<0.01) and a consistent hypotension. These results provide evidence that α -chloralose used in conjunction with a short initial period of halothane prevents any discomfort for the animals and that this ethical anesthetic regimen displays a temporal window of normal cerebrovascular reactivity.

THE ROLE OF L-ARGININE-NITRIC OXIDE SYSTEM IN THE MEDIATION OF REGIONAL CEREBROVASCULAR CO₂ RESPONSIVENESS OF THE CAT. P. Sandor, K. Komjati, M. Reivich*, I. Nyary. Cerebrovascular Res. Ctr., Univ. of Pennsylvania, Philadelphia, PA 19104 USA and Semmelweis Univ. Med. Sch., Budapest, 1082 Hungary

The role of nitric oxide (NO) in the mediation of cerebrovascular CO₂-responsiveness was studied in ten distinct brain and spinal cord regions of anesthetized, ventilated, temperature controlled normoxic cats. Regional cerebral blood flow was measured with 15 μ m radiolabeled microspheres in hypocapnic, normocapnic and hypercapnic conditions. CO₂-responsiveness of each region was determined from the equation of the best fit regression lines to the obtained flow values. The effect of decreased endothelial and/or neuronal NO synthesis on CO₂-responsiveness was studied following either selective blockade of the NO-synthase enzyme by L-Name (N^ω-nitro-L-arginine methyl ester, 3 or 30 mg/kg i.v.) or following combined administration of 3 mg/kg L-Name and a large dose of the NO-precursor L-Arginine (30 mg/kg, i.v.). Blockade of NO synthesis by 30 mg/kg L-Name resulted in a significant reduction of the steady state regional blood flow values, and in an almost complete abolition of the CO₂-sensitivity in each region studied. Changes of the basal flow values as well as the reduction of the regional CO₂-sensitivity were dose dependent. Hypothalamic, sensory motor cortical and cerebellar regions were the areas most sensitive to the NO blockade. Impaired CO₂-responsiveness following NO-synthase inhibition, however, was reversed in these these regions by simultaneous administration of a large dose of i.v. injected L-Arginine. These findings suggest a major role of nitric oxide in the mediation of regional cerebrovascular CO₂-responsiveness in cats. (Supported by NIH NS 10939, OTKA-1371 and ETT 4-280 Grants)

NITRIC OXIDE MEDIATES NMDA-INDUCED INCREASES IN CEREBRAL BLOOD FLOW IN NEWBORN LAMBS. F.J. Northington, J.R. Tobin*, R.C. Koehler, R.J. Traystman. Depts. of Pediatrics and Anesthesiology/CCM, Johns Hopkins Medical Institutions, Baltimore, MD 21287

Several studies suggest that increases in cortical activity are coupled to increases in local cerebral blood flow (CBF) via a nitric oxide(NO)-dependent mechanism. We adapted the ¹⁴C-arginine to ¹⁴C-citrulline conversion assay, developed for *in vitro* NO measurement, for use with microdialysis to measure *in vivo* NO production in brain. This study examines the effect of NMDA on local CBF and assesses the contribution of NO to CBF changes. Newborn lambs were anesthetized with halothane and bilateral superficial parietal cortex microdialysis cannulas implanted. Cannulas were perfused at 1 μ l/min with either: mock CSF(n=10), CSF with 1mM NMDA(n=10), or 1mM NMDA + 1mM L-nitroarginine methyl ester (L-NAME) (n=5). Infusions also contained 3 μ M ¹⁴C-arginine. Microdialysis effluent was collected at hourly intervals for 4 hours, and CBF measured by H₂ clearance. CBF was unchanged throughout the 4 hr period in the mock CSF group (53 \pm 6.9, 55.6 \pm 6, 46 \pm 2.9 and 48 \pm 3.6 ml/min/100g) and NO production was unchanged until 4 hours of perfusion (6.7 \pm 0.7, 18.9 \pm 3.6, 33.5 \pm 9.5, 55.2 \pm 10.1* fm/min). NMDA caused significant increases in CBF (88 \pm 7.5*, 99.8 \pm 7.9*, 114 \pm 9.5*, and 116 \pm 10.5* ml/min/100g) at all times, and NO production (36.9 \pm 11.9, 75.5 \pm 17.2*, 103.4 \pm 18.1*, and 141.9 \pm 20.3* fm/min) at 2, 3, and 4 hours compared to control. When 1mM L-NAME was added to NMDA, neither CBF nor NO production was different than control (37.5 \pm 2.6, 53 \pm 7.6, 45.5 \pm 4.3, 43.3 \pm 4.4ml/min/100g) and (6.1 \pm 3.1, 12.0 \pm 4.9, 21.9 \pm 3.8, 59.3 \pm 14.0 fm/min). These results demonstrate that NMDA-induced changes in CBF are correlated with NO production, and that inhibition of NO synthesis completely inhibits NMDA-induced increases in CBF. Microdialysis is capable of measuring *in vivo* NO production. Supported by NIH Grant: NS20020.

NITRIC OXIDE-DEPENDENT AND INDEPENDENT COMPONENTS OF CEREBROVASCULAR DILATION ELICITED BY HYPERCAPNIA. C. Jadedcola*, F. Zhang, and J. Li. Dept. of Neurology, Univ. of Minnesota, Minneapolis, MN 55455.

Inhibitors of nitric oxide (NO) synthase (NOS) attenuate, but do not abolish, the increase in cerebral blood flow (CBF) elicited by hypercapnia (PNAS 89:3913, 1992), suggesting that part of the vasodilation is independent of NO synthesis. Whether this NO-independent component of the response is more pronounced at higher levels of hypercapnia remains to be established. We, therefore, studied the effect of nitro-L-arginine methyl ester (L-NAME), a NOS inhibitor, on the increases in CBF elicited by graded elevations in arterial pCO₂ up to 140 mmHg. Rats were anesthetized with halothane and ventilated. CBF was monitored over the parietal cortex using a laser-Doppler flowmeter. Increasing levels of hypercapnia elicited graded increases in CBF that reached a plateau at pCO₂=82 \pm 1 (CBF:+215 \pm 25%). L-NAME (40 mg/kg, i.v.; n=8), but not D-NAME (n=8), reduced resting CBF by 42 \pm 4% (p<0.05) and attenuated the increase in CBF elicited by hypercapnia. The attenuation occurred only at pCO₂ 40-80 (e.g., pCO₂:54-55, before:+134 \pm 21%; after L-NAME:+33 \pm 10%; p<0.001) and not at pCO₂ 130-140 (before:+233 \pm 19%; after:+271 \pm 35%; p>0.05). To determine whether the effect of L-NAME was due to the vasoconstriction induced by this agent, the CO₂ response was tested before and after reducing resting CBF with the anesthetic chloralose. In halothane-anesthetized rats, chloralose administration (20-30 mg/kg i.v.; n=5) reduced resting CBF (-31 \pm 9%; p>0.05 from L-NAME) but did not affect the CBF response to CO₂ (pCO₂:43-137 mmHg; p>0.05). We conclude that L-NAME does not attenuate the CBF response to CO₂ uniformly at all levels of hypercapnia. Rather, significant attenuation occurs only at pCO₂ 40-80. Thus, the cerebrovascular response to CO₂ may have NO-dependent and NO-independent components: During moderate hypercapnia NO mediates most of the vasodilation, whereas in extreme hypercapnia other vasodilating agents are responsible for the CBF increase. (Supported by the L. Sklarow fund and the American Heart Association)

SOURCES OF NITRIC OXIDE OF IMPORTANCE FOR HYPERCAPNIC RISE OF CEREBRAL BLOOD FLOW. M. Lauritzen* & M. Fabricius. Depts. of Medical Physiology & Clinical Neurophysiology, Univ. of Copenhagen, DK-2200 Copenhagen, Denmark.

We examined sources of nitric oxide (NO) modulating the hypercapnic rise of cerebral blood flow (CBF) by laser-Doppler flowmetry in halothane anesthetized rats. NOS inhibition was achieved by i.v. (30 mg/kg) and/or topical application (1 mM) of N^G-nitro-L-arginine (NOLAG). Activity in cortical perivascular nerves was inhibited by topical application of TTX (20 μM). Parietal CBF changed by 2.89% ± 0.18% and cerebellar CBF by 3.41±0.17%/mmHg change of PaCO₂ during control conditions. I.v. NOLAG decreased basal CBF by 8±4% and inhibited the hypercapnic rise of CBF already at 10 minutes after infusion to 0.72±0.17% in parietal cortex and 1.19±0.09% in cerebellum. When NOLAG was infused after 10 min of sustained hypercapnia, CBF rapidly decreased. L-arginine partially prevented the effect of NOLAG. Topical NOLAG (1 mM) reduced the CO₂ reactivity to 2.04±0.17% in parietal cortex, and 2.21±0.15% in cerebellum within 45 min. When NOLAG was applied after 10 min of sustained hypercapnia CBF remained constant. TTX decreased basal CBF by 23±3% in parietal cortex and by 9±3% in cerebellum, while CO₂ reactivity increased to 3.21±0.20% and 4.74±0.66% respectively. Blood-borne NOLAG was far more effective as blocker of the CO₂ response than topical NOLAG. Endothelial cells, not neurons or perivascular nerves, appear to be the source of NO regulating hypercapnic CBF.

THE EFFECTS OF (+)SK&F 10047 AND MK-801 ON CORTICAL SPREADING DEPRESSION. R.N. Willette*, P.G. Lycko and C.F. Sauermeich. Division of Pharmacology, SmithKline Beecham Pharmaceuticals, King of Prussia, PA 19406.

NMDA-receptor mediated neurotransmission is essential for the initiation and/or propagation of cortical spreading depression (CSD). The demonstration of CSD in migraine patients has led to the suggestion that antagonism of NMDA-receptor mediated mechanisms may represent a novel therapeutic approach to the treatment of migraine. In the present study, the effects of (+)SK&F 10047 (N-allylnormetazocine) and MK-801 on CSD (evoked with KCl) were compared. MK-801 is an effective NMDA-receptor channel blocker which binds with high affinity (K_d = 6 nM) in a use/voltage dependent manner. (+)SK&F 10047 is an equieffective inhibitor of the NMDA-receptor channel, but it binds with much lower affinity (K_d = 475 nM) to the MK-801 site. MK-801 and (+)SK&F 10047 caused a dose-related inhibition of the EEG suppression and cortical hyperemia associated with CSD and reduced the CSD propagation rate; ED₅₀ = 1 mg/kg, iv and 20 mg/kg, iv, respectively. MK-801 had a delayed onset of action (inversely related to dose) and a prolonged duration of action at all doses (>2h). In contrast, (+)SK&F 10047 had a rapid onset of action (< 30 min) and a predictable dose-related duration of action. These results suggest that an efficacious compound acting with low affinity at the NMDA-receptor channel, eg (+)SK&F 10047, may possess a time-course and toxicity profile which is more suitable than agents interacting with high affinity.

MEASUREMENT OF THE PENTOSE PHOSPHATE PATHWAY (PPP) IN BRAIN AND GLIOMA *IN VIVO* BY MICRODIALYSIS. B.D. Ross*, O. Ben-Yoseph, D.M. Camp† and T.E. Robinson‡. University of Michigan, Departments of Radiology, Biological Chemistry and †Psychology, Ann Arbor, MI 48109.

The activity of the PPP has traditionally been assayed *in vitro* by comparing the relative rates of ¹⁴CO₂ production from [¹⁴C]glucose and [6-¹⁴C]glucose. Here, we report the use of a novel isotope, (1,6-¹³C₂,6,6-²H₂)glucose (1), in combination with intracerebral microdialysis and gas chromatography/mass spectrometry (GC/MS) for measuring the relative activities of the PPP and glycolysis in the forebrain and intracerebral 9L glioma in the conscious rat. Metabolism of (1,6-¹³C₂,6,6-²H₂)glucose through glycolysis produces (3-¹³C)lactate (m + 1) and (3-¹³C,3,3-²H₂)lactate (m + 3), whereas metabolism through the PPP produces (3-¹³C,3,3-²H₂)lactate (m + 3). GC/MS analysis of extracellular lactate, collected in dialysate over 50 minute intervals, revealed a basal PPP activity of 3.5 ± 0.4% and 6.4 ± 0.5% (n=4) of glucose metabolized to lactate in rat brain and glioma, respectively. Addition of 50μM phenazine methosulfate (PMS) to the perfusate in brain and glioma resulted in an increased PPP activity to 18.7 ± 1.9% and 8.4 ± 1.1%, respectively, followed by a rapid return to basal levels upon removal of PMS. The higher basal PPP activity in glioma compared to brain may be due to the increased NADPH and ribose 5-phosphate requirements for lipid and DNA synthesis of proliferating cells. This technique provides a unique opportunity to measure the PPP in localized regions of the brain (and glioma) in a conscious rat. Sample collection using microdialysis together with high GC/MS sensitivity allow for dynamic changes in PPP activity to be followed in a single animal with a time resolution of 5 min or less. Measurements of PPP activity have also proven successful in tissue cultures. As the PPP is coupled to the glutathione pathway, this technique will provide the ability to monitor oxidative stress known to be associated with various neuropathological conditions.

A HIGH RESOLUTION TIME-OF-FLIGHT POSITRON EMISSION DETECTION PROBE SYSTEM: PHYSICAL CHARACTERIZATION AND HUMAN STUDIES. K.J. Jeffries*, C.A. Tamminga, H.L. Loats, R.R. Conley, and A.C. Lahti. Maryland Psychiatric Research Center, P.O. Box 21247, Baltimore, MD 21228.

A high resolution time-of-flight positron emission detection probe system has been developed and applied to the study of drug pharmacokinetics in the human brain. The probe system in its simplest form consists of a pair of barium fluoride (BaF₂) radiation detectors which are placed on opposite sides of the head. Time-of-flight detection circuitry has been developed which provides spatial resolution between the detectors of at least 6 mm. For circular detectors, the probe provides resolution elements in the form of disks with diameter roughly equal to 1/2 that of the detectors and width of no more than 6 mm. The probe system provides high count efficiency relative to PET allowing for lower radiation dose. This provides the ability to perform significantly more studies in a single subject (i.e., 20 - 40 studies per year). Further phantom studies demonstrating the spatial resolution and count efficiency of the system will be presented. Results with human studies using multiple time points after neuroleptic drug administration to show occupancy kinetics with ¹¹C-N-methyl-spiperone will also be presented. The time-of-flight positron emission detection probe system represents a new technology for the study of *in-vivo* brain chemistry. The system provides the ability to measure the distribution of positron-emitting radionuclide labeled compounds with both high spatial (i.e., 6 mm) and temporal (i.e., 5 studies per day) resolution.

COMPARISON OF THERMAL AND AUTORADIOGRAPHIC MEASUREMENTS OF CBF. Datong Wei, Gerald M. Sidel, Alejandro D. Perez-Trepichio, Carol R. Radinsky and Stephen C. Jones*. Cerebrovascular Research Lab., Cleveland Clinic Foundation, Cleveland, OH 44195 and Dept. of Biomed. Eng., Case Western Reserve Univ., Cleveland, OH 44106.

A thermal system was developed to quantify cerebral blood flow (CBF) in absolute units (mL/100g-min) as well as continuous CBF changes. From the dynamic heat transfer model, CBF and other parameters in the model can be obtained by non-linear least-squares estimation. The thermal CBF estimates were compared to the measurements from the autoradiographic technique.

Thirteen Sprague-Dawley rats were anesthetized with halothane and artificially ventilated. Changes in blood flow were produced by modifying inspired CO₂ or respiration rate (PaCO₂ 15-85 mm Hg). Two cranial windows (7 mm diameter) were created for thermistors (0.65 mm diameter) encased in styrofoam cylinders. The flow probe was a self-heated thermistor placed on the tissue surface. Thermal CBF (CBF_T) was averaged from twelve flow estimates obtained from corresponding transient temperature responses to step heating power changes. Tissue equilibration or indicator fractionation of ¹⁴C-IAP and autoradiography were used to determine the mean autoradiographic CBF (CBF_A) in the areas under the thermal flow probe. Linear regression showed that CBF_T = 56 + 0.7 • CBF_A, with r = 0.75. The slope and intercept were significantly different from zero (t-test, p<0.01). The coefficient (mean ± SD) between CBF and temperature changes linearized at steady-state perfusion levels was 0.8 ± 0.2 mL/100g-min-m°C.

By statistical analysis, the mean thermal CBF was found to be linearly related to the mean autoradiographic CBF. The advantage of the thermal method is that it can follow and quantify continuous changes in CBF.

NONLINEAR ENHANCEMENT OF CAROTID ARTERIAL OCCLUSION EFFICIENCY IN THE RAT BY ROSE BENGAL-MEDIATED PHOTOTHROMBOSIS CONDUCTED AT 562 NM. B.D. Watson*, R. Prado, W.D. Dietrich, CVD Research Center and Dept. of Neurology, Univ. of Miami Sch. of Med., Miami, FL 33101.

Occlusion of cerebral arteries by an intravascular photochemical interaction sensitized by an appropriate laser has been used to induce experimental stroke, and been proposed for occlusion of arteriovenous malformations. With rose bengal (RB) as photosensitizer, we measured occlusion time (OT) for the rat common carotid artery (CCA) with 1 W laser irradiation at 514.5 nm (standard argon line) and at 562 nm (tunable argon/dye laser) - the RB absorbance (A) maximum in tissue. The right CCA of male Wistar rats (300-390 g) was exposed and covered with saline with rats supine. After 40 mg/kg RB injection the CCA was irradiated at an intensity of ca. 150 W/cm² until occlusion. OT at 562 nm was 23 ± 17 sec (S.D., n=4), but OT at 514.5 nm was 287 ± 87 sec (n=3). Since the number of photons (T) generating occlusion is proportional to OT•A, and $A_{562}/A_{514.5} = 2.6$, the relative occlusion efficiency is $T_{514.5}^{514.5}/T_{562}^{562} = 20\%$. The reaction lacks reciprocity and is thus nonlinear. Further, 562 nm-induced thrombi consist only of agglutinated platelets; those at 514.5 nm are mixtures of platelets, RBCs and coagulum (J Neurosurg 66:748-754, 1987). Irradiation at 562 nm therefore accentuates the intrinsic nonlinear platelet response, and greatly enhances photothrombotic occlusion efficiency.

524.11

PREOPERATIVE CORTICAL FUNCTIONAL MAPPING FOR PATIENTS WITH INTRACEREBRAL GLIOMA. T. Nariai^{1,2}, M. Senda¹, K. Ishii¹, T. Machara², K. Ishiwata¹, H. Toyama¹, K. Oda¹, T. Murakoshi², K. Hirakawa². Tokyo Metropolitan Inst. of Gerontology¹, Tokyo Med. & Dent. Univ.², Tokyo, Japan.

In order to remove the intracerebral glioma in the maximum extent without damaging the cortical function, we have developed a protocol to visualize the spatial relationship between the tumor and the eloquent cerebral cortex using 3D registration of PET and MRI. The results were compared to the intraoperative cortical mapping. Informed consent was obtained from each patient. Four patients bearing glioma adjacent to the motor or language cortex underwent the MRI scan of 3 mm thickness and PET scans using ¹¹C-methionine to visualize active tumor area and H₂¹⁵O activation technique to locate eloquent cortex. The hand and oral movement task and the words repetition task was used to map the motor and the language cortex respectively. The PET images were re-sliced at the MRI image planes using 3D registration program on the workstation Stellar GS2000. The area with high ¹¹C-methionine uptake and the area activated by the task was mapped on the MRI images. The registered ¹¹C-methionine image was superior to Gd-enhanced MRI in locating cortical gyri with tumor infiltration. Intraoperative localization of the somatosensory cortex (by the cortical recording of SEP) and the language cortex (by the electrical stimulation of cortex under local anesthesia) confirmed the accuracy of our 3D registration technique in locating the eloquent gyrus, although the mass effect of tumor shifted the cortical structures. Using this protocol, successful resection of tumor was performed without damaging the remaining cortical function.

524.12

MAPPING OF CEREBRAL CORTEX METABOLISM IN SOMAN INDUCED SEIZURES. O.U. Scremin*, T.-M. Shih and M.G. Li., West LA VAMC/UCLA, Los Angeles, CA 90073 and USAMRICD, APG, MD 21010.

This investigation was undertaken to map in detail the pattern of metabolic activation of the cerebral cortex during seizures induced by soman, a highly toxic cholinesterase inhibitor. Twelve rats were injected with 100 µg/kg soman, s.c., after pretreatment with 26 µg/kg pyridostigmine, i.m., to decrease lethality. Seven animals developed seizures (S), and 5 did not (NS). Five additional rats were injected with saline (C). Glucose utilization (CGU) of cortical regions and brain stem was determined with the quantitative, autoradiographic technique. Values of CGU cortex/CGU brain stem (nCGU) (Mean ± SE, p vs C) were calculated for 96 regions in 9 coronal slices between 1.7 mm rostral and 8.3 mm caudal to bregma. Group S showed statistically significant increases with regard to C in 33 regions, 27 of which were in a single cluster, with the piriform cortex (C=1.08±0.06; S=2.53±0.37, P<0.01) at its center. Perirhinal cortex of bregma planes -1.8 to -5.3, piriform cortex of bregma planes -0.8 to -5.3 and insular cortex of planes 1.7 to -1.3, showed also significantly higher nCGU in S than in C. Other foci of elevated nCGU were found in the frontal (C=1.37±0.06; S=2.07±0.25, P<0.05) and parietal (C=1.36±0.08; S=2.20±0.29, P<0.05) regions at bregma -3.3. In the non-seizing animals, the only region with a significantly higher nCGU than controls was piriform cortex at bregma -3.3 (C=1.08±0.06; NS=1.31±0.06, P<0.05). In conclusion, the presence of seizures and not soman determined the pattern of nCGU cortical activation. The piriform cortex showed nCGU increase prior to seizures and became the center of the most important focus of activation during seizures.

NEUROTENSIN INHIBITS GROWTH AND STIMULATES INTRACELLULAR CALCIUM RELEASE IN THE HUMAN PROSTATIC CARCINOMA CELL LINE LNCaP. C.A. Mayr*, G. Powis and T.P. Davis. Dept. of Pharmacology and Toxicology, University of Arizona College of Medicine, Tucson, AZ 85724 USA.

Neurotensin (NT) has been postulated to act as a modulatory agent in the central nervous system. Besides its presence in brain, a NT-like immunoreactivity is produced and secreted in the prostate cancer cell line LNCaP. High affinity binding of NT in these cells has also been previously shown, leading to the suggestion that NT may function as a regulatory peptide in prostate cancer, acting in an autocrine fashion. Using a soft agar *in vitro* growth assay, we report that exogenous NT (0.1nM to 1.0 µM) significantly (p<0.01) decreased colony formation of LNCaP cells. Exposure of the LNCaP cells to NT (3.3nM to 3.3µM) in an aquorin protein intracellular calcium assay, increased intracellular calcium content. The increase in intracellular calcium is evidence that the LNCaP cell line expresses the NT receptor, and that the inhibition of growth may be via interactions at the NT receptor. In conclusion, NT causes decreased growth by a mechanism which may involve NT acting at receptors leading to the activation of a second messenger system and subsequent intracellular calcium release.

GHRP-6 RAISES INTRACELLULAR CALCIUM IN RAT PITUITARY CELLS BY TWO DIFFERENT MECHANISMS. J. Herrington, A. Naumov, M.E. Freeman* and B. Hille. Dept. of Physiology and Biophysics, Univ. of Washington, Seattle, WA 98195.

Cellular mechanisms mediating stimulation of growth hormone release by the enkephalin-derived synthetic hexapeptide, GHRP-6, are not known. We have studied the changes in intracellular calcium concentration ([Ca²⁺]_i) produced by GHRP-6 in single pituitary cells isolated from 100-150 g male rats. [Ca²⁺]_i was monitored by measuring fluorescence intensity of indo-1 (loaded into cells as the acetoxymethyl ester) at two wavelengths, 405 nm and 500 nm. Increases in the 405/500 emission intensity ratio (R) reflect increases in [Ca²⁺]_i.

Presumptive somatotropes were chosen based on cell size, presence of spontaneous transients in [Ca²⁺]_i and ability of 100 nM somatostatin (SOM) to inhibit the transients. Application of 500 nM GHRP-6 increased [Ca²⁺]_i in 32 out of 56 cells studied; in 17 cells R increased from 0.66 (±0.09 SD) to 1.03 (±0.12). Long duration applications (100 sec) produced a relatively sustained elevation in [Ca²⁺]_i that was blocked 79% (±3; n=4) by lowering extracellular Ca²⁺ to 50 nM, 91% (±4; n=3) by removal of extracellular Na⁺ and 84% (±6; n=5) by 100 nM SOM. Application of GHRP-6 for 20-25 sec following preexposure of cells to low Ca²⁺, 0 Na⁺, SOM or 1 µM nitrendipine resulted in only a transient elevation in [Ca²⁺]_i that decayed to preagonist levels with a τ = 13.8 sec (±9.7; n=22) (resting R= 0.61 ±0.06; peak R= 0.96 ± 0.18; n= 4 each for 0 Ca²⁺, 0 Na⁺, NIT and n=10 for SOM). Long (50-80 sec) applications under these conditions did not produce further rises in [Ca²⁺]_i (n=6). These results suggest that GHRP-6 elevates [Ca²⁺]_i in somatotropes by at least two mechanisms, a rapid release of Ca²⁺ from intracellular stores followed by enhanced influx of Ca²⁺ through Ca²⁺ channels probably requiring action potentials. INSULIN ELEVATES INTRACELLULAR CALCIUM AND CAUSES OSCILLATIONS IN CALCIUM LEVELS IN THE BAG CELL NEURONS OF APLYSIA. E. A. Jonas*, R. J. Knox, J. A. Connor, L. K. Kaczmarek. Dept. Pharmacology, Yale Univ. Sch. Med., New Haven, CT 06510, and Dept. Neurosciences, Roche Institute of Molec. Biol., Nutley, NJ 07110.

Insulin may produce changes in the properties of cells by activating signalling pathways linked to tyrosine kinases. Previous work by Solomon et al., Jonas et al., (Soc. Neurosci. Abstr., 1992) has shown that the bag cell neurons of *Aplysia* express insulin receptors and that insulin produces enhancement of calcium action potentials and voltage dependent calcium current. We have now used imaging techniques to study the actions of insulin on intracellular calcium levels in isolated bag cell neurons. Cells were injected with the calcium indicator fura-2, or with dextran-conjugated fura-2, a large molecule less subject to transport into intracellular compartments. Control cells demonstrated stable Ca²⁺ concentrations of 200-300nM. After addition of insulin to the bathing medium, Ca²⁺ levels were found to increase in the somata over a period of at least one hour. Levels in the neurites remained relatively unchanged. In 4 cells, Ca²⁺ levels were seen to oscillate with periods of 5-10 seconds. In cells injected with fura-2, but not in cells injected with dextran fura-2, insulin induced "hot spots" of elevated Ca²⁺ levels in the somata, suggesting that insulin may also induce changes in Ca²⁺ levels within certain intracellular organelles. Elevations of Ca²⁺ levels by insulin did not occur in cells placed in media lacking Ca²⁺. In insulin-treated cells, injection of heparin did not reverse the effects of insulin. Our studies suggest that a change in intracellular Ca²⁺ homeostasis may be one component of long-term changes in the excitability of bag cell neurons induced by insulin.

REGULATION OF DARPP-32 PHOSPHORYLATION BY CHOLECYSTOKININ OCTAPEPTIDE (CCK-8S) IN STRIATAL SLICES.

G.L. Snyder*, G. Fisone, P. Morino¹, V. Gunderson², O.-P. Ottersen², T. Hökfelt¹, and P. Greengard. Lab. of Molec. & Cell. Neurosci., The Rockefeller University, NY, NY 10021; ¹ Dept. of Histology & Neurobiology, Karolinska Institute, S-10401 Stockholm, Sweden, and ² Dept. of Anatomy, University of Oslo, Blindern, N-0317 Oslo, Norway.

DARPP-32, a dopamine and cAMP-regulated phosphoprotein, Mr 32,000, that is highly enriched in medium-sized spiny neurons comprising the striatonigral pathway, is converted to a potent inhibitor of protein phosphatase-1 upon phosphorylation on threonine³⁴, *in vitro*. In the present study, COOH-terminal sulfated octapeptide of cholecystokinin, CCK-8S, inhibited the forskolin-induced phosphorylation of DARPP-32 by one-half in striatal slices. The inhibition of DARPP-32 phosphorylation by CCK-8S was probably mediated through activation of a CCK-B receptor, since the effect was prevented by pretreatment of slices with CI-988, a potent and selective antagonist of this receptor. NMDA-type glutamate receptors also were apparently involved, since the inhibition of DARPP-32 phosphorylation by CCK-8S was blocked by MK-801, an NMDA antagonist and since the inhibitory effects of NMDA and CCK-8S on DARPP-32 phosphorylation were not additive. Immunohistochemical analysis revealed the presence of CCK- and glutamate-immunoreactive nerve endings in the striatum, presumably with a cortical origin and aspartate-containing interneurons as possible sites for the action of CCK-8S. These data provide further evidence for the hypothesis that DARPP-32 is a final common pathway which integrates the actions of numerous first and second messengers released from nigro-striatal and cortico-striatal neurons, and perhaps interneurons, on the activity of striatonigral neurons. MEDULLARY SITES OF CENTRAL ACTION OF TRH TO INDUCE VAGAL MEDIATED GASTRIC CYTOPROTECTION IN URETHANE ANESTHETIZED RATS. K. Kato, H. Yang, I. Murai* and Y. Taché. CURE/VA Wadsworth Medical Center and Dept. of Medicine and Brain Research Institute, UCLA, Los Angeles, CA 90073 and Dept. of Biochemistry, Nihon University School of Medicine, Tokyo, JAPAN*.

The vagus nerve plays an important role in gastric cytoprotection as well as gastric lesion formation. Our previous report (Gastroenterology 102:1568, 1992) indicates that intracerebral injection of TRH at low doses is cytoprotective against ethanol lesions in conscious rats. The role of the dorsal motor nucleus of the vagus (DMN) in providing gastric cytoprotection was further investigated.

Method: Under urethane anesthesia (1.25 g/kg, ip), fasted rats were microinjected with saline (50 nl) or TRH analog RX 77368 (1.5, 3.0, 5.0, 10, 15, 30 ng/50 nl) into the DMN 30 min before intragastric administration of 60% ethanol (5 ml/kg). Percentage of corpus mucosa containing lesions was determined by computerized image analyzer one hour after ethanol. Atropine sulfate (2 mg/kg, sc, -30 min) and indomethacin (5 mg/kg, ip, -60 min) was given before microinjection of RX 77368 (3 ng).

Results: RX 77368 (3, 5, 10 ng, into DMN) significantly decreased gastric damage (lesions: 3 ng: 2.5 ± 0.6%, 5 ng: 3.8 ± 0.4%, 10 ng: 4.6 ± 0.6%, compared with saline: 10.2 ± 1.4%, P<0.01). The other doses had no cytoprotective effect as well as peptide injection (3 - 10 ng) into the hypoglossal nucleus, or medullary reticular field. The cytoprotective effect of RX 77368 (3ng, into DMN) was completely blocked by atropine and significantly inhibited by indomethacin.

Conclusion: These results suggest a possible role of TRH in the DMN in the control of gastric mucosal integrity through vagal cholinergic and prostaglandin dependent pathways.

BIOLOGICAL ACTIVITY OF A POTENT BOMBESIN RECEPTOR ANTAGONIST. M. Knight, K. Takahashi, B. Chandrasekhar, R.T. Jensen, D.B. Strader and T.W. Moody. Peptide Technologies Corp., 8401 Helgerman Court, Gaithersburg MD 20877, National Institutes of Health, Bethesda MD 20892 and George Washington University, Washington DC 20037.

Structural modifications of the known inhibitory heptapeptide sequence of the tetradecapeptide bombesin (BBN), a neuropeptide, has produced a potent inhibitor. [N-chlorambucil, D-Ala¹] BBN(7-13)ethyl ester, (PTC 821) inhibits the effect of BBN to raise cytosolic Ca²⁺ levels in small cell lung carcinoma cells (SCLC), a neuroendocrine tumor. The peptide displays specific binding to SCLC BBN receptors with an I.C.₅₀ of 8 nM. The peptide with one more amino acid in its sequence was found to prevent colony formation of gastrin releasing peptide-containing human tumor cell lines. PTC 821 has also been studied for its effects on pancreatic acinar cells which also have BBN receptors and are stimulated by BBN to secrete the digestive enzymes. The peptide is a specific BBN antagonist with an I.C.₅₀ of 4.9 nM. The chlorambucil is a large aromatic structure with N-alkyl chlorides that can alkylate certain reactive groups in the receptor protein. Complete irreversible inhibition was not observed, but the biologic inhibition remained potent and long lasting in washing experiments on the cells without any toxic effects. Whether the potency of this modification is due, not only to the aromaticity of the derivative but also to the alkyl halide groups, remains to be studied. Nevertheless, this is a useful structure for further development of a chemotherapeutic for neuroendocrine tumors. (Supported by SBIR NIH grant no. CA55468)

525.9

A NEW GALANIN RECEPTOR SUBTYPE IS INVOLVED IN THE REGULATION OF 5-HT_{1A} RECEPTORS IN THE RAT BRAIN.

P. B. Hedlund*, N. Yanaihara¹ and K. Fuxe. Dept. of Histology and Neurobiology, Karolinska Institutet, Box 60400, S-10401 Stockholm, Sweden and ¹School of Pharmaceutical Sciences, University of Shizuoka, 395 Yada, Shizuoka, Japan.

Galanin is a peptide with 29 amino acid residues widely distributed in the brain and associated with several biological effects. The N-terminal part of the molecule has been shown to be critical for the retention of biological activity. Recently the existence of specific binding sites for [¹²⁵I]galanin-(1-15) with a unique distribution in the brain was demonstrated. In line with the previously demonstrated reciprocal interactions between galanin and 5-hydroxytryptamine_{1A} (5-HT_{1A}) receptors we have in the present study evaluated whether galanin-(1-29) and galanin-(1-15) can modulate the 5-HT_{1A} receptors using [³H]8-OH-2-(di-n-propylamino)-teralin ([³H]8-OH-DPAT) as a radioligand in membrane preparations from the ventral limbic cortex, an area having both porcine [¹²⁵I]galanin-(1-29) and [¹²⁵I]galanin-(1-15) binding sites, and from the dorsal hippocampus, an area having only the [¹²⁵I]galanin-(1-15) fragment binding sites. In the dorsal hippocampus galanin-(1-15) produced a concentration dependent increase in the K_D value of [³H]8-OH-DPAT with a maximal effect of approximately 65% at 3 nM of galanin-(1-15), whereas galanin-(1-29) had no effect. In the ventral limbic cortex galanin-(1-15) also produced a concentration dependent increase in the K_D value of [³H]8-OH-DPAT. The effect of galanin-(1-15) (3 nM) on the K_D value of [³H]8-OH-DPAT binding in the dorsal hippocampus could be completely counteracted by the putative galanin antagonist M35 (1 nM). The B_{max} values were not affected in any experiment. These results give further evidence for the existence of a galanin receptor subtype mainly recognizing N-terminal galanin fragments and for the first time provide evidence that also this putative galanin fragment receptor can reduce the affinity of 5-HT_{1A} receptors.

525.6

DIFFERENTIAL REGULATION OF GALANIN ANTAGONISTS M15 AND M35 ON ACETYLCHOLINE RELEASE IN THE RAT STRIATUM. A. Pramanik*, S.O. Ögren†, T. Landt and Ü. Langelt. †Dept. of Histology and Neurobiology, Karolinska Institute, Box 60 400, S-104 01 Stockholm, Sweden; *Dept. of Neurochemistry and Neurotoxicology, Arrhenius Laboratories, Stockholm University, S-106 91 Stockholm, Sweden.

Galanin (GAL), a 29-amino acid peptide with numerous biological functions (Rökæus (1987), Trends Neurosci. 10, 158-164), has a widespread distribution in the CNS and the PNS. In view of the multiple actions of exogenous GAL it is of interest to develop GAL agonists or antagonists in order to characterize the functional role of endogenous GAL. Recently, the putative GAL antagonists M15 [(GAL-(1-12)-Pro-substance P-(5-11)-amide] and M35 [GAL-(1-12)-Pro-bradykinin-(2-9)-amide] have been developed (Bartfai et al. (1992), Trends Pharmacol. Sci. 131, 312-317).

The effects of M15 and M35 on the basal and the GAL-evoked release of acetylcholine (ACh) in the striatum were studied in male Sprague-Dawley enflurane-anesthetized rats (body wt. 270-300 g) using *in vivo* microdialysis and HPLC techniques. M15 and M35 were able to produce differential effects on both the basal and the GAL-evoked ACh release *in vivo* in the striatum. Thus, the GAL-evoked ACh release was completely blocked by M15 but partially by M35 when they were coinfused with GAL (300 μM or 3 nmol/10 μl, intrastriatal infusion). Moreover, M35 elevated the basal ACh release whereas M15 failed to do so. These results suggest that M15 is a full antagonist of the striatal GAL receptor modulating ACh release while M35 behaves as a mixed agonist-antagonist. In addition, M15 and M35 recognized two types of galanin binding sites in striatal membranes of the rat with equal affinities but with different relative occupancies (Ögren et al. (1993), Eur. J. Pharmacol., submitted). Thus, different relative receptor occupancies may be one of the possible explanations for the difference between M15 and M35. These findings may be of significance for the analysis of multiple GAL receptors in the central nervous system.

525.8

BOMBESIN BINDING SITES IN THE NUCLEUS OF THE SOLITARY TRACT ARE NOT OF VAGAL ORIGIN. E.F. Ladenheim*, R.T. Jensen, S.A. Mantey, K.A. Moore and T.H. Moran. Dept. Psychiatry, Johns Hopkins Univ. Sch. Med., Baltimore, MD 21205 and NIDDK, NIH, Bethesda, MD 20892.

High affinity binding sites for bombesin (BN)-related peptides have been identified in the nucleus of the solitary tract (NTS), the primary site of termination for vagal afferent fibers. We evaluated the possibility that BN binding sites in this region are of vagal origin in two ways. In the first experiment, rats were pretreated intraperitoneally with either 145 mg/kg of capsaicin, a neurotoxin that destroys small diameter vagal sensory neurons, or the injection vehicle. Binding of [¹²⁵I]-Tyr⁴BN was examined in the medial NTS by *in vitro* receptor autoradiography. In the second experiment, peripheral transport of BN binding sites was evaluated in rats receiving unilateral ligation of the left cervical vagus nerve distal to the nodose ganglia. Accumulation of BN binding sites in the ligated nerve segment was examined 24 h after ligation by receptor autoradiography. Our results indicate that capsaicin treatment had no effect on [¹²⁵I]-Tyr⁴BN binding in the NTS compared with controls. Additionally, there was no accumulation of BN binding sites in the vagus nerve proximal to the ligation. Together, these results suggest that BN binding sites in the NTS are not of vagal origin but are most likely postsynaptic to vagal afferent input.

BW-2258: A NEW GASTRIN RELEASING PEPTIDE RECEPTOR ANTAGONIST

T.W. Moody*, F. Zia, J.J. Leban, J.D. McDermid and M. Fagarason. Dept. Biochemistry and Molecular Biology, The George Washington University Med. Sch., Washington, D.C. 20037, Organic Chemistry Div., Burroughs Wellcome Co., Research Triangle Park, NC 27709

Bombesin/Gastrin releasing peptide (BN/GRP) may function as a growth factor in certain tumor cells. Previously, GRP receptors were identified on human glioblastoma (U-138) and neuroendocrine small cell lung cancer (NCI-H345) cells. Here the effects of synthetic antagonists which have a reduced peptide bond between the 26 and 27 position of GRP were investigated.

Specific [¹²⁵I]-Tyr⁴BN to U-138 or H345 cells was inhibited with high affinity (IC₅₀ = 5-10 nM) using BW462, 1023 or 2123. Also, [¹²⁵I]-BW1023 bound with high affinity (K_d = 5 nM) to a single class of sites (B_{max} = 20,000/cell). Specific [¹²⁵I]-Tyr⁴BN but not [¹²⁵I]-BW1023 binding was internalized at 37°C. BN (10 nM) elevated the cytosolic Ca²⁺. In contrast, BW462, 1023 or 2123 had no effect on the cytosolic Ca²⁺ but inhibited the increase caused by 10 nM BN. Also, BN caused a transient increase in c-fos mRNA and the increase in c-fos mRNA was reversed by 10 μM BW2258. BN (10 nM) stimulated colony formation and BW2258 inhibited proliferation. These data suggest that BW2258 may be a useful peptide to antagonize GRP receptors. Supported in part by NCI-grant CA-53477.

Alterations in hypothalamic-brain stem angiotensin II (AII) receptor binding in captopril (CAP) treated spontaneously hypertensive rats (SHR)

Kathleen H. Berecek* and Jian -Nan Wu

Hypertension Program, University of Alabama at Birmingham, Birmingham AL 35294

The purpose of this study was to determine the effects of the angiotensin converting enzyme inhibitor CAP on hypothalamic AII receptor binding. We performed radioligand binding studies (125 I - [Sar¹, Ile⁸] AII) with hypothalamic-brain stem membranes from control (CON) and CAP treated Wistar Kyoto rats (WKY) and SHR at 1, 8 and 120 days post birth. We also estimated the percentage (%) of AII receptors subtypes (AT₁ and AT₂) by generating competition curves using losartan and CGP42112 to block AT₁ vs AT₂ receptors, respectively. SHRCO at one days of age showed a greater number of AII receptors (Bmax) 43.1±2.8 fmol/mg protein than the other rat groups. CAP treatment of SHR but not WKY lowered the number of AII receptors (34.6±2) to levels not different from WKYCON (31.7±4) and WKYCAP (33.3±0.6). The same pattern occurred at 120 days of age although all rats showed a decrease in the number of AII receptors. At 1 day of age 30% of the AII receptors were AT₁; whereas at later ages the % of AT₁ fell to 20%. The proportion of subtypes was not different between CON and CAP treated SHR and WKY. Our data suggest that part of the antihypertensive action of CAP may be due to a decrease in AII binding in central cardiovascular areas.

EFFECTS OF DESOXYCORTICOSTERONE ACETATE ADMINISTRATION ON PREPROTACHYKININ-A GENE EXPRESSION IN DISCRETE RAT BRAIN REGIONS: AN *IN SITU* HYBRIDIZATION ANALYSIS.

P. Pompei, F. Riffina* and B. McEwen, Lab. of Neuroendocrinology, the Rockefeller University, New York, NY 10021.

It is well-known that doses of the mineralocorticoid desoxycorticosterone acetate (DOCA) in excess of about 1mg/kg/day exhibit sharp increases in salt intake. Male Sprague-Dawley rats (n=6) received subcutaneous (sc) daily DOCA injection (5mg/kg/day), whereas control (CON) animals were injected sc with isotonic saline solution. On day 8 they were given access to 2% saline to drink for 2 hr and on day 11 were sacrificed by decapitation. This study describes the presence and abundance of Preprotachykinin-A gene (PPT-A) mRNA transcripts in the bed nucleus of the stria terminalis (BNST), in the caudate-putamen (CP) and in the medial preoptic area (mPOA) of DOCA treated and CON animals. *In situ* hybridization with synthetic oligodeoxyribonucleotide probes specific for PPT-A gene was performed. Quantitative analysis revealed a sharp decrease by 50% in the level of PPT-A mRNAs in BNST and CP of DOCA treated when compared to CON rats. The intensity of silver grains in the ventral CP was greater than in the dorsal CP. Moreover, the expression of PPT-A mRNAs in the mPOA of DOCA treated rats was decreased by 25% when compared to CON animals.

These findings show changes in the PPT-A gene expression under DOCA administration, further suggesting a possible interaction between tachykinins and mineralocorticoids in the regulation of sodium appetite. (Supported by MH 43487).

FORMATION AND SPECIFICITY OF SYNAPSES

526.1

IMAGING TRANSFECTED MUSCLE FIBERS AND THEIR SYNAPSES OVER TIME IN LIVING MICE. P. van Mier*, M.J. Donoghue, J.R. Sanes, and J.W. Lichtman. Dept. Anatomy & Neurobiol., Washington University Sch. Med., St. Louis, MO 63110

In order to better understand the regulation of synapse formation and maintenance we have begun to study transfected muscle fibers in the sternomastoid muscle of living mice. Muscle fibers were transfected *in situ* (see Wolff et al., 1990, Science 247:1465-68) by placing pellets of DNA on the muscle surface near the endplate band and gently pressing the DNA into the muscle with a needle. The DNA encoded bacterial β -galactosidase (*lacZ*) driven by RSV (viral) regulatory elements; subsequent staining for the presence of *lacZ* in fixed muscle revealed 5-10 transfected muscle fibers per sternomastoid, of which an average of about 1/4 was found on the surface of the muscle. Transfected muscle fibers were observed as early as 2 days, and for at least 2 months after DNA application. In living mice, single transfected muscle fibers were located using FDG (Molecular Probes, Eugene, OR), a caged fluorescein that is released in the presence of *lacZ*. Fluorescent muscle fibers and their rhodamine-bungarotoxin labeled acetylcholine receptors were imaged using standard epifluorescence optics in conjunction with a SIT camera connected to a digital imaging system. Once located with FDG staining, transfected muscle fibers could be restained on multiple occasions and some were followed for up to 4 weeks. In later views transfected muscle fibers and their neuromuscular junctions appeared unchanged suggesting that transfection with a reporter gene and repeated staining did not affect the muscle fibers. We have also used a recombinant adenovirus vector to deliver *lacZ* to sternomastoid muscle fibers. Currently we are trying to transfect or infect with vectors that encode both *lacZ* and synaptically relevant protein molecules that affect synaptic interactions.

526.3

WEAKENING OF SYNAPTIC INPUTS DUE TO LOW QUANTAL CONTENT AND EFFICACY AT DEVELOPING NEUROMUSCULAR JUNCTIONS

H. Colman* and J.W. Lichtman, Dept. of Anatomy & Neurobiology, Washington University School of Medicine, St. Louis, MO 63110

During the process of synapse elimination at developing neuromuscular junctions, all but one of the axons initially innervating each junction are eliminated. The mechanism underlying this synaptic loss is not well understood. Changes in synaptic efficacy are associated with synapse elimination (*Soc. Neurosci. Abst.* 15:165, 1989), indicating that the synaptic strengths of the competing axons are altered during the process. To determine what causes this alteration in synaptic strength, we recorded intracellularly from mouse trapezius muscle fibers and separately stimulated each axon converging on multiply innervated fibers. By bathing the muscle in a high magnesium Ringer's solution, we could simultaneously assay the quantal content (the number of vesicles released in response to stimulation) and quantal efficacy (the postsynaptic response to the release of a single vesicle of ACh) for each axon innervating a junction.

Measurement of relative quantal contents of inputs to the same muscle fiber demonstrated that the synaptic strengths of the competing inputs becomes increasingly different over the first two postnatal weeks. At early ages, the quantal contents of the axons innervating a single muscle fiber were usually similar, while at later ages, one axon was likely to have a substantially larger quantal content than its competitor.

Analysis of the amplitudes of single quanta evoked from each innervating axon indicated that changes in quantal efficacy also occur during synapse elimination. We found many cases in which the postsynaptic responses from one axon contained a subset of unusually small events. These were a discrete population of quantal events that were smaller than other single quantal events recorded from either axon. In one extreme case in which we recorded 3000 responses to stimuli of each axon, approximately 70% of the quantal responses from one axon were small. Observation of small quantal responses was correlated with multiple innervation; singly innervated junctions at the same ages rarely showed small quanta. This evidence suggests that a physiological correlate of imminent synapse elimination is the appearance of small quantal events. Because the weaker axon often had both a low quantal content and small evoked quantal events, these phenomena may be two features of synapses at risk for elimination.

526.2

LOCAL CONTROL OF ACh RECEPTOR STABILITY AND LOCATION WITHIN NEUROMUSCULAR JUNCTIONS. R.J. Balice-Gordon*, C. Garriga, and J.W. Lichtman Dept. Anatomy & Neurobiology, Washington Univ. School Medicine, St. Louis, MO 63110.

After motor nerve terminals are paralyzed by exposure to botulinum toxin, functional recovery is accompanied by loss of some original synaptic sites and the concurrent formation of new ones. We studied how the distribution of postsynaptic AChRs changed as activity resumed in botulinum toxin poisoned junctions in the mouse sternomastoid muscle using *in vivo* imaging as previously described. Fluorescently tagged α BTX was used to label the original distribution of AChRs at the first view; at intervals of 1-2 weeks, the distribution of remaining originally labeled AChRs and the location of newly inserted AChRs was determined by comparing the location of AChRs before and after restaining.

There were striking differences in the distribution of AChRs 3-4 weeks after botulinum poisoning compared to that present at the first view. After restaining at the second view, some areas in the AChR distribution that were present at the first view had disappeared entirely. The remaining areas were patchy in that the density of AChRs varied widely from one small area to another. These differences suggested highly localized control of AChR stability within recovering junctions. The local variability in AChR density could be due either to local differences in AChR turnover or to a redistribution of AChRs within the junction. Consistent with the latter possibility, we found at the second view (before restaining) that some of the AChRs which were labeled with α BTX at the first view had been relocated to new synaptic sites which were not present at the first view. Thus AChRs may migrate away from postsynaptic areas underlying inactive motor nerve terminals still paralyzed by botulinum toxin and cluster beneath new, active terminal sprouts. The local differences in AChR stability we observed may be one consequence of 'competition' between motor nerve terminal branches that resume activity at different times.

526.4

MUTATIONAL ANALYSIS OF THE CELL ADHESION MOLECULE FASCICLIN I IN THE DEVELOPMENT OF SYNAPTIC FUNCTION IN *DROSOPHILA*. Y. Zhong*, Neuroscience Center Cold Spring Harbor Lab, P.O. Box 100, Cold Spring Harbor, NY 11724.

5-HT stimulated down regulation of *Aplysia* cell adhesion molecules has been suggested as a mechanism of learning-related synapse formation (Bailey et al., Science 256: 654). In this study, I examined mutations of the *Drosophila fasciclin I* (*fas I*) gene, which encodes a membrane-associated glycoprotein capable of homophilic cell adhesion (Elkins et al., 1990, Cell 60:565), for their effects on nerve terminal arborization and synaptic transmission during development of larval neuromuscular junctions. As compared to normal larvae by anti-HRP staining, the numbers of nerve terminal branches and varicosities were increased in the *fas I^{TE}* mutant which lacks the *fas I* protein. However, evoked excitatory junctional currents (ejcs) were significantly smaller in *fas I^{TE}* recorded by voltage clamp at 0.1 to 0.4 mM external Ca²⁺ concentrations. Conversely, duplication of the *fas I⁺* gene in *Dp(fas I⁺)* or additional *fas I⁺* introduced by a P element insertion in *P(fas I⁺)* reduced the numbers of branches and varicosities, but enhanced transmitter release. Such an inverse relation of less varicosities or synapses with stronger synaptic transmission led me to further examine the electrophysiological properties of these neuromuscular junctions. After a 10 to 30 second tetanic stimulation (10 Hz), spontaneous discharges or multiple discharges in response to a single stimulus could be induced in *Dp(fas I⁺)* and *P(fas I⁺)*, a phenomenon which was not observed in normal or *fas I^{TE}* larvae. It suggests that the membrane excitability is enhanced in nerve terminals with more *fas I* proteins, which may account for the larger ejcs observed. In addition, the duration of post-tetanic potentiation induced by 5 or 8 Hz stimulation is much shorter or even missing in both *fas I^{TE}* and *Dp(fas I⁺)* or *P(fas I⁺)*. This result demonstrates for the first time *in vivo* that changes in the number of a cell adhesion molecule can influence not only the number of synapses formed, but also the strength of synaptic transmission and capability of synaptic plasticity.

526.5

Development of CNS structure and connections in the NMDA receptor deficient mouse. Yuqing Li¹, Elizabeth Messersmith², Carla Shatz^{2*}, Susumu Tonegawa¹. ¹Center for Cancer Research, Massachusetts Institute of Technology, Cambridge, MA 02193, ²Department of Molecular & Cell Biology, University of California, Berkeley, CA 94720

Development of precise neural connections in the vertebrate central nervous system (CNS) occurs by two distinct phases; one that occurs early and acts via molecular cues, and one that subsequently requires neuronal activity. Recently, evidence has suggested that precise connections in the visual system are achieved via neural activity acting through NMDA receptors. To study the role of NMDA receptors during formation of CNS connections, we have created, using the embryonic stem cell technology, knockout mice lacking the NMDAR1 subunit, which renders the NMDA receptor nonfunctional. We have examined the brains of newborn NMDA receptor deficient mice for abnormalities in gross anatomy, neurogenesis, cell migration, and formation of neuronal pathways. We find that the brains of newborn NMDA receptor deficient mice do not differ in gross morphological appearance in comparison to normal mice. Birthdating studies with 3H-thymidine indicate that there is no difference in neurogenesis. Dil labeling of retinal ganglion cells (RGC) projections indicate that RGC axons do not grow to alternative target sites in the absence of NMDA receptor activity, but that they grow to their appropriate target within the thalamus. These observations support the hypothesis that initial pathfinding and target selection by growing axons is not dependent upon NMDA receptors and leaves open the possibility that later fine tuning to the precise adult pattern does require activation of NMDA receptors. Funded by Howard Hughes Medical Institute (ST) and NSF IBN 92-12640, March of Dimes (CJS).

526.7

THE ROLE OF HEPARIN-BINDING GROWTH-ASSOCIATED MOLECULE (HB-GAM) IN POSTSYNAPTIC INDUCTION IN CULTURED MUSCLE CELLS. H. Benjamin Peng[†], Zhengshan Dai[‡], Erkki Raulo[‡] and Heikki Rauvala[‡]. [†]Dept. of Cell Biol. and Anatomy and Curr. in Neurobiology, Univ. of North Carolina, Chapel Hill, NC, USA and [‡]Inst. of Biotechnology, Univ. of Helsinki, Helsinki, Finland.

HB-GAM (pleiotrophin, p18) is a novel heparin-binding growth factor (HBGF). Unlike several other HBGFs, its transcript possesses a signal sequence and its secretion has been shown. It is widely expressed in the brain and spinal cord and its transcripts have also been detected in skeletal muscle. We examined the function of HB-GAM in inducing the formation of acetylcholine receptor (AChR) clusters in cultured muscle cells. Using an antibody against recombinant rat brain HB-GAM, we found that this protein is present prominently on the surface of cultured *Xenopus* myotomal muscle cells by immunocytochemistry. It is associated with heparan-sulfate proteoglycans because heparin and heparinase treatment greatly diminished the antibody labeling. HB-GAM is concentrated at a fraction of the spontaneously formed AChR clusters (hot spots). To assess its function in synaptic induction, we applied recombinant HB-GAM-coated beads to cultured muscle cells to effect focal presentation. Over 70% of the beads induced the formation of AChR clustering as shown by fluorescent α -bungarotoxin labeling. This induction can be blocked by the polyanion suramin (100 μ M), suggesting the stimulation of a cell surface receptor. It is also blocked by a tyrosine kinase inhibitor (tyrphostin RG-50864) with a half maximum inhibitory dosage of 50 μ M, suggesting the role of tyrosine phosphorylation in this induction. This work indicates that HB-GAM is an endogenous muscle-derived factor that may play an important role in postsynaptic induction. (Supported by NIH and MDA)

PRODUCTION OF MONOCLONAL ANTIBODIES TO THE AGRIN RECEPTOR. M.A. Bowe*, K.A. Deyst and J.R. Fallon. Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545.

Agrin is a synapse organizing molecule crucial for the formation and regeneration of the neuromuscular junction. Agrin induces the clustering of acetylcholine receptors in the postsynaptic muscle cell membrane. The cell surface receptor for agrin has not been identified. However, our laboratory has previously characterized a putative agrin receptor, based on both cell biological and biochemical criteria (Nastuk et al., 1991 Neuron 7:807).

Here, we have used immunological methods to further our studies of the agrin receptor. We developed a screen to detect the immunoprecipitation of agrin binding proteins from solubilized membrane preparations. Mice were immunized with postsynaptic-enriched membranes from the electric organ of *Torpedo*, and hybridomas were produced. Hybridomas secreting antibodies that immunoprecipitate the agrin receptor were cloned. We have characterized one MAB in detail and found that it binds an integral membrane glycoprotein in postsynaptic membranes. This MAB immunoprecipitates the agrin receptor but not the acetylcholine receptor. We are currently using this antibody to identify and purify the agrin receptor.

Passover in *Drosophila* and *unc-7* in *Caenorhabditis* both disrupt neural connectivity and code for proteins that are homologous. R.J. Wyman, G.P. Swain, E. Frei, Y.A. Sun* and S.N. Krishnan. Department of Biology, Yale University, New Haven, CT 06511.

Mutations at the *Passover* locus disrupt transmission through the Giant Fiber pathway which commands the light-off escape jump in *Drosophila*. The block is at the output from the Giant Fiber to its postsynaptic targets, the Peripherally Synapsing Interneuron and/or the Tergotrochanteral motoneuron which drive the middle leg jump muscle. The synapses from the GF to these cells are dual electrical/chemical. The fast electrical pathway is the effective one in the startle response.

Mutations of the *C. elegans* gene *unc-7* (Starich et al., Genetics 133:527-541, 1993) cause miswiring. Instead of moving in a sinuous pattern during forward locomotion, the body 'kinks'. Electron micrographic reconstruction of a mutant nerve cord shows that the AVA interneuron, which normally forms synapses only with motoneurons for backward locomotion, now makes gap junctions with motoneurons for forward locomotion. If the interneuron elicited forward and backward locomotion at the same time, the opposite running sinusoids would interfere, causing kinks. The neurons observed to connect abnormally in *unc-7* form gap junctions as do those disrupted by *Pas*. *Pas* and *unc-7* amino acids are 33% identical + 15% conserved (over 293 aa). Both are transmembrane with similar genomic and protein structure. Since nematodes are evolutionarily quite distant from insects, it is likely that homologous molecules exist in other animals, perhaps defining a molecular family involved in connectivity of the nervous system.

AGRIN ISOFORMS IN DEVELOPING CHICK MOTOR NEURONS. L. S. Honig*, D. Stone#, K. Nikolic#, and U. J. McMahan. Dept. of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305; and #Genentech, Inc., S.S.F., CA 94080.

Agrin is thought to mediate the motor neuron-induced aggregation of AChRs in muscle fibers at their neuromuscular junctions. The nervous system expresses several alternatively spliced isoforms of agrin; isoforms active in inducing aggregation of AChRs in cultured chick myotubes must have sequence inserts at two C-terminal sites called A (4 amino acids) and B (8, 11, or 19 (8+11) amino acids). We have examined the expression of agrin isoforms in the chick lumbar spinal cord using *in situ* hybridization with oligonucleotides complementary to the specific isoforms. We find that at embryonic days 4-10 when motor neurons begin to form neuromuscular junctions, B0 mRNA is concentrated in the mitotic ventricular zone (VZ). In contrast, B11 and B19 mRNA are concentrated in the postmitotic mantle, including the motor neuron column. B19 mRNA is far more abundant in motor neurons than other cells. In later embryos ($\geq 10d$), B8 mRNA appears in motor neurons; B8 persists postnatally (0-2wk) while the amounts of B11 and B19 mRNA decrease below detectability. At early stages, A0 mRNA predominates in the VZ, while A4 mRNA is concentrated in the postmitotic mantle. A4 persists in motor neurons to maturity. We conclude that motor neuron progenitor cells express A0/B0 agrin, but by the time differentiated motor neurons are positioned in the ventral horn they express isoforms having both A and B inserts. Developing motor neurons express isoforms having each of the B inserts, but during neuromuscular junction formation, isoforms having the B19, and later the B8, insert are most abundant.

NEURONAL SPECIFICITY IN THE EXTERNALIZATION OF AGRIN. M.W. Cohen* and E.W. Godfrey. Dept. of Physiol., McGill Univ., Montreal, Que. and Dept. of Cellular Biol. & Anat., Medical College of Wisconsin, Milwaukee, WI.

Agrin mRNA transcripts are present in the ventrolateral spinal cord (SC) as well as in dorsal root ganglia (DRG) of rat and chick. Previously we found that a subpopulation of *Xenopus* SC neurons externalize agrin along their neuritic outgrowth in culture. In this study we examined whether *Xenopus* DRG neurons also externalize agrin. Agrin immunofluorescence was rarely detected in the DRG cultures, and the few positive examples were faint and limited to regions of DRG somata. In addition the DRG neuritic pathways, unlike SC neuritic pathways, failed to cause acetylcholine receptors (AChRs) on test muscle cells to accumulate at sites where they contacted the pathways. The DRG neurons may have failed to synthesize significant amounts of agrin, the factors regulating externalization of agrin may differ in SC and DRG neurons, or the binding properties of SC agrin and DRG agrin may be different. The correlation that SC and DRG neurites differ not only in their deposition of agrin but also in their capacity to influence AChR distribution on muscle cells supports the conclusion that agrin is the primary neural agent responsible for the accumulation of AChRs at newly forming nerve-muscle synapses. EXPRESSION OF THE POSTSYNAPTIC 43K PROTEIN IN *XENOPUS* EMBRYONIC CELLS AND ITS ASSOCIATION WITH PHOSPHOTYROSINE. Zhengshan Dai[†], Paula B. Scotland[‡], Stanley C. Froehner^{†*} and H. Benjamin Peng[‡], Departments of [†]Cell Biology and Anatomy and [‡]Physiology, and ^{††}the Curriculum in Neurobiology, University of North Carolina, Chapel Hill, NC 27599.

The postsynaptic membrane of cholinergic synapses in skeletal muscle and electric organ is enriched in 43K protein. Expression of this protein alone in *Xenopus* oocytes or in fibroblasts results in the formation of membrane-associated 43K micropatches and coexpression with AChRs results in the microclustering of the receptors. In this study, we expressed the 43K protein with or without AChRs in *Xenopus* embryos by mRNA injection. Blastomeres at 8-cell stage were injected with mRNAs and the animal caps were dissected out prior to gastrulation, dissociated and cultured. When AChR and 43K were coexpressed, AChR and 43K clusters were observed. When the 43K was expressed alone, 43K microclusters with a diameter of 0.5 to 3µm were observed in both cultured cells and whole-mount animal caps. Most of the clusters were associated with the substratum-facing membrane in cultured cells and with cell-cell contacts in whole mounts. No clusters were observed in cells that expressed AChRs alone. In 43K-expressing cells, double-labeling with a polyclonal 43K antibody and a monoclonal phosphotyrosine (PY) antibody revealed a colocalization of PY-containing proteins with the 43K clusters in the absence of AChRs. Although they were colocalized, the 43K and PY patches were often not exactly congruent. Since there is no evidence that the 43K protein is a substrate for tyrosine kinase, these data suggest other PY-containing proteins are co-clustered with 43K in these cells. This embryonic cell culture should offer a convenient system for understanding the function of postsynaptic proteins in synaptogenesis. (Supported by NIH and MDA)

DEVELOPMENTAL EXPRESSION OF ARIA mRNA IN THE CHICK: AN *IN SITU* HYBRIDIZATION STUDY. G. Corfas^{*}, K.M. Rosen, H. Aratake and G.D. Fischbach. Dept. of Neurobiology, Harvard Medical School, Boston, MA 02115 and Asahi Chemical Co., Shizuoka, Japan.

ARIA is a protein purified from chick brain that promotes an increase in synthesis of acetylcholine receptors. It may play a role in the formation and maturation of the neuromuscular junction. ARIA has been recently cloned and its sequence shown to be homologous to Heregulin and NDF, two putative ligands for the receptor tyrosine kinase HER2/neu, and to glial growth factor. In order to study the role of ARIA in the development of the nervous system we have studied the expression of ARIA mRNA in the chick by *in situ* hybridization. ³⁵S-labelled riboprobe coding for the 5' most 337 bp of the pro-ARIA1 clone was used.

A clear signal above background is evident in the neural tube at embryonic day 4 (E4), the earliest time examined. On E5, grains are concentrated over spinal cord motoneurons. This distribution is maintained throughout embryonic development and on post-hatched day 1 (P1).

ARIA mRNA is not uniformly distributed in the P1 brain. Rather, the label is concentrated in brain stem motor nuclei, the isthmo-optic nucleus, the optic tectum, in cerebellar granule cells and the hippocampus. At earlier times the label is somewhat more widely distributed.

The gene is also expressed outside the nervous system. Significantly the message can be detected with the same probe in skeletal muscle. The probe used here is directed to regions of ARIA that are expected to be present in many different spliced forms of the molecule. Different isoforms may exert different biological actions, and their expression may be developmentally regulated. This could be analyzed using isoform-specific probes.

TRANSMITTERS IN INVERTEBRATES

PHARMACOLOGICAL PROPERTIES OF A SEROTONIN-ACTIVATED SODIUM CURRENT IN AN IDENTIFIED NEURON FROM *HELISOMA TRIVOLVIS*. C. J. Price^{*} and J. J. Goldberg. Dept. of Zoology, Univ. of Alberta, Edmonton, Alberta, Canada T6G 2E9.

Serotonin (5-HT) activates a cyclic AMP-dependent sodium current in neuron B19 from *Helisoma trivolvis*. To determine the pharmacological characteristics of the receptor mediating this response, tight-seal whole cell recordings were obtained from isolated neuron B19s and the agonist and antagonist activities of various compounds were tested. Dose-response experiments indicated a relatively high affinity for 5-HT, with an EC50 in the range of 10 to 100 nM. To obtain a pharmacological profile of the response, the abilities of various indoles to mimic 5-HT's action were examined. 5-carboxyamidotryptamine and tryptamine both activated the response with an EC50 around 1 µM, while 5-methoxytryptamine and α-methyl serotonin had EC50s close to 10 µM. Methysergide displayed weak agonist activity with relatively high affinity (EC50 between 10 and 100 nM). Several compounds were tested for specific antagonist activity. Two compounds, mianserin and cyproheptadine, showed apparent antagonistic actions. However, at the high concentrations (>1 µM) needed for antagonism, these drugs also reversibly blocked voltage-gated sodium and potassium currents. Therefore, it remains possible that the apparent antagonism of the B19 5-HT receptor was actually due to nonspecific blockade of the ion channels mediating the 5-HT-activated sodium current.

DIFFERENT PATTERNS OF APPEARANCE OF OCTOPAMINE- AND SEROTONIN-IMMUNOREACTIVE NEURONS IN THE DEVELOPING LOBSTER CNS. H. Schneider^{1*}, E. Peckol², P. Budhiraja¹, B.S. Beliz², & E.A. Kravitz¹. ¹Neurobiology Dept., Harvard Medical School, Boston, MA 02115, and ²Biology Dept., Wellesley College, Wellesley, MA 02181.

In the lobster (*Homarus americanus*), octopamine and serotonin have opposing effects on postural regulation. Amine neurons likely to be involved in that regulation have been identified by immunocytochemical and biochemical methods. In the present study we describe cell-type specific patterns of appearance of octopamine-immunoreactive neurons throughout embryonic and early larval life. At E43% octopamine-immunoreactivity is seen in brain neurons and in descending interneurons in the subesophageal ganglion (SEG). Later, neurosecretory cells in the SEG and the second thoracic ganglion show staining (E69%). The last group of cells to stain are ascending interneurons in the SEG (E82%). The adult complement of cells is not fully stained until early larval life. By contrast, serotonin-immunoreactive cells appear early in embryonic development with the adult complement labeled by midembryonic life. The observed differences suggest that regulation of the onset of octopamine and serotonin synthesis in each neuron type is distinct. Behavioral or other factors involved in that regulation are under investigation. Supported by NIH and DFG.

SEROTONERGIC SELF-RE-EXCITATION IN THE LOCOMOTORY PEDAL NEURONS VIA CYCLIC AMP-GATED Na⁺ CURRENT IN *Pleurobranchaea californica*. L.C. Sudlow^{*} & R. Gillette. Dept. of Physiology and Biophysics, U. of Ill., Urbana Il 61801.

Serotonin (5-HT) induces a cAMP-gated Na⁺ current (I_(Na,cAMP)) in 5-HT immunoreactive pedal neurons (G neurons) involved in locomotion. Using two different measures we have characterized the interactions of the I_(Na,cAMP) and 5-HT in these neurons. Two-electrode voltage clamp experiments (one electrode for voltage sensing, one double barrel electrode for both current injections and cAMP iontophoresis) were used to measure responses to cAMP injections. Occlusion of the cAMP response during 5-HT treatment or steady-state cAMP injections was indicative of saturation of the cAMP cascade. Depolarization-dependent inactivation of 5-HT-induced current was similar to I_(Na,cAMP) inactivation. Measures of phosphodiesterase (PDE) rate constants indicated that 5-HT application caused no changes in the activity of PDE. 5-HT applied to the G neurons of the pedal ganglion activated the cAMP cascade resulting in an increase in I_(Na,cAMP) and the net excitation of these neurons. Self-excitation induced by release of 5-HT in the neuropil by the G neurons may be used to establish motor patterns in this population of motoneurons that innervate the foot musculature. This research was supported by NIH RO1 NS26838 to RG.

MOLECULAR CHARACTERIZATION OF THE DROSOPHILA HISTIDINE DECARBOXYLASE GENE REQUIRED FOR PHOTORECEPTOR SYNAPTIC TRANSMISSION. M.G. Burg^{*}, J. Liu^{*}, and W.L. Pak, Dept. of Biol. Sci., Purdue Univ., West Lafayette, IN and ^{*}Dept. of Biology, Univ. of Science and Technology, Hefei, China.

We have previously identified and characterized the *Drosophila* cDNA which encodes histidine decarboxylase (HDC) involved in the synthesis of histamine, used as transmitter in photoreceptors and a subset of neurons in the brain (*EMBO J* 12:911, 1993). Immunocytochemical analysis of mutants isolated in this gene (*hdc*) suggests that *hdc* expression may be differentially regulated between photoreceptors and neurons in the brain. To study the transcriptional regulation of this gene, we isolated 12 overlapping genomic clones, covering ~30 kb, by high stringency screening of a *Drosophila* genomic library. The *hdc* transcription unit was identified within the cloned genomic region by restriction analysis and Southern blotting of the genomic clones. A 9.4 kb XbaI fragment, containing the transcriptional unit and a 4.4 kb upstream sequence was used to rescue an *hdc* mutant by P-element mediated germline transformation. Deletion analysis of the 5' noncoding region is in progress with a view toward identifying the regulatory regions required for normal *hdc* expression and the regions responsible for differential expression between photoreceptors and brain neurons. These results will also be useful in the molecular analysis of *hdc* mutants that are presently available for study. Supported by EY06214 and EY00033.

GABA IS AN EXCITATORY AMINO ACID ACTING ON SPECIFIC IDENTIFIED FEEDING MOTONEURONS IN THE SNAIL, *HELISOMA*. A.D. Murphy. Dept. Biol. Sci., University of Illinois at Chicago, Chicago, IL 60607.

The neural pattern underlying feeding in *Helisoma* is triphasic, with each of 3 sets of interneurons driving a corresponding set of motoneurons. We previously showed that the primary neurotransmitter of phase 2 interneurons is glutamate, which has both excitatory and inhibitory effects on subsets of motoneurons. GABA, like glutamate, has both inhibitory and excitatory effects in *Helisoma*. GABA inhibits some motoneurons via a GABA_A mechanism. However, GABA excites identified phase 1 motoneurons, apparently also via a GABA_A-like mechanism. These cells are depolarized by GABA or muscimol and the depolarization is picrotoxin sensitive. The excitatory effects are seen in the presence of 10mM CoCl₂, and thus appear to be direct and not due to disinhibition. These data suggests that phase 1 motoneurons may have a "reversed" chloride gradient leading to GABA_A excitation. Finally, immunocytochemistry suggests that some phase 1 interneurons are GABAergic. (Supported by NSF IBN-9121374).

ISOLATION AND SEQUENCING OF TWO NEW MEMBERS OF THE *MANDUCA SEXTA* FLRFAMIDE FAMILY OF PEPTIDES. J.L. Witten^{*1}, T. Kingan², J. Shabonowitz³ and D.F. Hunt³. ¹Dept. Biol. Sci., UW-Milwaukee, ²ARS, USDA, Beltsville, MD and ³Dept. Chem., U. Virginia.

FMRFamide-like immunoreactivity (FLI) is present in the nervous and neuroendocrine systems of the tobacco hornworm, *Manduca sexta*. The FLI in motoneurons, however, is developmentally regulated and is found only in larvae (Witten and Truman, 1990, Soc. Neuro. Abstr.). As a first step towards understanding the physiological significance of this developmental plasticity, we isolated and sequenced the immunoreactive material in the larval thoracic and abdominal ganglia.

The rising ecdysteroid titers at the onset of metamorphosis regulate the decline in FLI in the motoneurons (Witten and Truman, 1990). Thus, by manipulating the ecdysteroid levels to prolong the larval stage, we obtained a ten-fold increase in FLI which facilitated the sequencing. Using a two-step HPLC purification combined with a competitive ELISA, two immunoreactive fractions were detected. Tandem mass spectroscopic analysis yielded the following amino acid sequences: DPSFXRF-NH₂ and GNSFXRF-NH₂ with X being either a L/I. These heptapeptides are structurally related to the larger, myoactive FLRF peptide, pEDVVHSLRF-NH₂, isolated from the neuroendocrine system of adults (Kingan et al., 1990, Peptides 11: 849-856). They differ, however, in one striking aspect. Only the larger, neuroendocrine derived peptide is protected from degradation at both termini consistent with its proposed role as a circulating factor. This suggests that the structural differences may reflect distinct functional roles for the members of this peptide family. Preliminary results showing a differential tissue distribution of the FLRFamide peptides supports this hypothesis.

527.9

EXPRESSION OF THE NEUROPEPTIDE GENE FMRFamide AND MYOMODULIN IN *LYMNAEA*. J.F. Burke*, N. Santama, E. Kellelt, S. Saunders, M. Yeoman and P.R. Benjamin. Sussex Centre for Neuroscience, Biological Sciences, University of Sussex, Brighton, E Sussex BN1 9QG (UK)

The FMRFamide gene in *Lymnaea* consists of at least six exons. These are alternatively spliced to produce two major transcripts whose expression is mutually exclusive (Saunders et al. (1992) J Neurosci). The FMRFamide peptide is produced in 250 cells including the heart motor neurons, whereas the GDP/SDPFLRFamide peptides are produced in fewer cells, including a major interneuron (Bright et al. (1993) J Neurosci; Skingsley et al. (1993) J Neurophys). A novel peptide (abbreviated to SEEPLY) encoded by the FMRFamide precursor protein has been identified on the basis of immunocytochemistry and protein sequencing (Santama et al. (1993) Eur J Neurosci). This peptide exhibits physiological activity in association with FMRFamide. The myomodulin peptides from *Lymnaea* are encoded in a similar manner to those of *Aplysia*. By *in situ* hybridization it appears that this gene is expressed in approximately 200 neurons. Some of these cells appear to be associated with a previously described neural network regulating feeding behaviour (Elliott and Benjamin (1985) J Neurophys).

527.6

INHIBITION OF THE CRAYFISH SWIMMERET RHYTHM BY GABA AND GLUTAMATE. C.M. Sherff* and B. Mulloney. Zoology, University of California, Davis, CA 95616.

While swimming, the crayfish beats its swimmerets with alternating power-strokes and return-strokes. This pattern is generated in the CNS and transmitted to the swimmeret muscles by excitatory and inhibitory motor axons. At neuromuscular junctions, the exciters release glutamate, while the inhibitors release GABA. The motor neurons in the swimmeret system also make inhibitory chemical synapses in the CNS (Heitler, 1978). The difference in peripheral and central responses to neurotransmitter, especially in the case of glutamate, which excites muscle cells but inhibits swimmeret neurons, suggests that either these central synapses are not monosynaptic or that different postsynaptic mechanisms are used at the muscle and in the CNS. We studied the effects of these neurotransmitters on the swimmeret system by pressure-injecting GABA and glutamate from a multibarreled micropipet into the lateral neuropil, while recording the swimmeret motor pattern from peripheral nerves and the responses of individual swimmeret neurons with microelectrodes.

GABA and glutamate (0.1-1.0 mM) independently inhibited the production of the swimmeret motor pattern in the hemiganglion in which they were applied, but did not alter the ongoing rhythm in the contralateral hemiganglion or in other ganglia. Activity in swimmeret interneurons and motor neurons was also inhibited by GABA and glutamate. The cellular responses consisted of a decrease in input resistance and, usually, a hyperpolarization of the membrane potential. These neurotransmitter effects on the swimmeret neurons were direct since they can be elicited when the nerve cord is perfused with saline containing elevated Mg²⁺ and reduced Ca²⁺ concentrations. These results suggest that the motor neuron transmitters, GABA and glutamate, have different functions in peripheral and central synapses, and that these different functions are mediated by the different postsynaptic receptors located at the muscles and in the CNS.

LOCUST VPLI NEURONS CONTAIN THREE VASOPRESSIN-RELATED PEPTIDES; VPLI ACTIVITY REDUCES CYCLIC AMP LEVELS IN THE CNS. K.S.J. Thompson, R.A. Baines, R.C. Rayne, J.R. Thorpe, A. Alef and J.P. Bacon*

Sussex Centre for Neuroscience, Sussex University, Brighton BN1 9QG, UK.

The pair of vasopressin-like immunoreactive (VPLI) neurons of locusts have remarkable arborisations which extend to every ganglion of the CNS. Their immunoreactivity was reportedly due to expression of a vasopressin-related peptide and its antiparallel dimer. We have used HPLC separation and radioimmunoassay to detect vasopressin-like peptides in an extract of 200 electrophysiologically identified VPLI neurons. Three vasopressin-related peptides were found: the nonamer CLITNCPRGamide (1.2 pg/cell), and its antiparallel (1.5 pg/cell) and parallel (1.6 pg/cell) dimers. None of these peptides has any diuretic effect on locust Malpighian tubules¹, despite published reports to the contrary.

In a survey of 17 grasshopper species, we found two forms of VPLI morphology: that typified by *Locusta migratoria* has processes in peripheral nerves; the other, typified by *Schistocerca gregaria*, has no such processes². Using immunogold labelling in *Locusta*, we find that most peripheral VPLI processes lie deep within the nerve, unlike superficial neurohaemal endings. This suggests VPLI peptides are released centrally. We have searched for a central effect by measuring second messenger levels in the CNS. Stimulation of a VPLI neuron causes a significant cyclic AMP reduction (38.9 ± 16 pmol/mg protein, n=25; approximately 12% of control) compared with the inactive contralateral side. This is an unusual, possibly unique, example of a neurotransmitter reducing cyclic AMP levels in an invertebrate. (Supported by SERC grant GR/G52524)

527.10

LOCALIZATION OF TRANSCRIPTS ENCODING FMRFamide-LIKE PEPTIDES IN *C. ELEGANS* AND COMPARISON OF TWO *CAENORHABDITIS* GENES ENCODING FMRFamide-LIKE PEPTIDES.

K. Schinkmann and C. Li*. Dept. of Biology, Boston University, Boston, Ma 02215.

To examine the cellular and molecular mechanisms of transmitter expression, we are studying the regulation of the family of FMRFamide(Phe-Met-Arg-Phe-NH₂)-like neuropeptides in *C. elegans*. We have shown previously that one of the functions of FMRFamide-like peptides in *C. elegans* is to potentiate the actions of serotonin in egg-laying.

A gene, *flip-1*, produces two transcripts encoding FMRFamide-like peptides in *C. elegans*. *In situ* hybridization experiments on whole mount animals suggest that most of the FMRFamide-like immunoreactivity can be accounted for by *flip-1* expression and indicate differential expression of the two transcripts.

To identify possible regulatory elements in the *flip-1* gene, we cloned and characterized a FMRFamide-like gene, *cvlfp-1*, from the closely related nematode *C. vulgarensis*. Genomic Southern blotting experiments indicate the presence of one FMRFamide-like gene in *C. elegans*, but possibly more than one related gene in *C. vulgarensis*. The genomic organization of the *flip-1* and the *cvlfp-1* genes is very similar. Comparison of the regions upstream of the start site of transcription revealed several areas of homology, the functional significance of which remains to be elucidated by promoter deletion studies.

527.11

STORAGE AND RELEASE OF PEPTIDE COTRANSMITTERS FROM B16 NEUROMUSCULAR JUNCTIONS OF *APLYSIA*. E.S. Vilim¹, E.C. Cropper², D.A. Price³, I. Kupfermann¹, and K.R. Weiss². ¹Centr. Neurobiol. & Behav., Columbia Univ., NYS Psych Inst., NY, NY, ²Dept. Physiol. & Biophys., Fishberg Res. Ctr. in Neurobiol., Mt. Sinai School of Med., NY, NY, and ³Whitney Labs St Aug. FL.

The accessory radula closer muscle (ARC) and its innervation provide a model system for studying the behavioral role of neuromodulation and cotransmission. The ARC is innervated by two cholinergic motoneurons, B15 and B16, and a serotonergic modulatory neuron, the MCC. The motoneurons also contain modulatory peptide co-transmitters falling into 3 families. B15 contains the SCPs and buccalins (BUCs), and B16 contains the BUCs and myomodulins (MMs). The SCPs and MMs act postsynaptically to increase contraction amplitude and relaxation rate. The BUCs act presynaptically to decrease contraction amplitude by decreasing ACh release. We have developed a method using RIA to directly measure release of these peptide cotransmitters in the ARC following intracellular stimulation of a single motoneuron. We previously showed that SCPs and BUCs are co-stored in the same dense core vesicles (DCV's), and are co-released in response to physiologically relevant patterns of B15 stimulation. Here, we report that the BUCs and MMs are co-stored in the same DCV's, and they are co-released in response to physiologically relevant patterns of B16 stimulation. Ultrastructural immunogold double labeling was used to demonstrate that the two peptide families were co-stored in DCV's of B16 motor terminals in the ARC. The kinetics of the release of MMs and BUCs in the ARC were identical, consistent with co-storage and co-release from the same DCV's. BUC and MM release was dependent on extracellular calcium and independent of the contraction of the muscle indicating that release of these peptide cotransmitters was not an artifact of stimulation or contraction of the muscle. These results provide evidence that these peptides are co-released *in vivo*, and suggest that they play a role in feeding behavior.

527.12

CHARACTERIZATION AND MODULATION OF THE ACCESSORY RADULA OPENER NEUROMUSCULAR SYSTEM OF *APLYSIA*. C.G. Evans*, O. Harish, E.S. Vilim, E.C. Cropper, I. Kupfermann and K.R. Weiss. Mt. Sinai Sch. Med., N.Y., N.Y., 10029.

Feeding behavior in *Aplysia* requires that the radula opens and closes. Based on extensive studies of the neuromuscular system that produces radula closing it has been suggested that when animals feed quickly, neuromodulators decrease the duration of closer contractions, preventing coactivation with the opener muscles. In order to test this hypothesis opener muscles must be characterized. Towards this end we are now describing a set of muscles which when stimulated electrically in a dissected prep, will open the radula. Recordings from these muscles during feeding suggest that their contractions contribute to radula opening. The muscles are innervated by a cholinergic buccal motoneuron which preliminary HPLC data indicates contains myomodulin and FMRFamide. Additionally, the muscles show 5HT and FRF-like immunoreactivity. Action potentials in the motoneuron are 1:1 with hexamethonium sensitive EJPs in the fibers, and summation of EJPs can lead to a spike. A denervated muscle will contract rhythmically when subjected to a constant stretch. Contractions are accompanied by spikes in the fibers. These spikes are not blocked by hexamethonium. Both motoneuron and stretch-induced contractions are modulated by MMA, MMB, 5HT and FMRFamide. MM, 5HT, and physiological motor neuron stimulation increases cAMP levels in the muscles. These effects are mimicked by forskolin. Thus, it appears that contractions of the radula opener can be induced (a) by the radula opener motor neuron, and (b) by stretch produced by contraction of the radula closer muscle. Muscle contractions elicited in either manner are modulated. Comparisons of the modulation of these two forms of contraction as well as comparisons of the modulation of the opener muscle with the nonspiking ARC muscle may provide new insights into the behavioral role of neuromodulation.

DEGENERATIVE DISEASE: ALZHEIMER'S— β -AMYLOID X

NEUROTOXICITY OF AMYLOID β PROTEIN IN CULTURED CORTICAL AND CEREBELLAR GRANULE CELLS: IMPORTANCE OF NEURON/GLIA INTERACTIONS. M. D. Ikonovic*, M. Grekova, S. Pshenichkin, A. Berkovich, B. C. Wise, and D. M. Armstrong. Fidia-Georgetown Institute for the Neurosciences, Georgetown Univ Med Sch, Washington, DC 20007.

At present the effect of amyloid-beta protein ($A\beta$) on neurons grown in culture remains controversial. These controversies may in part reflect certain technical aspects such as the peptide employed including its aggregation state as well as the culture system and/or the culture conditions under study. In our investigations neonatal cortical neurons exhibited a significant decrease in viability when exposed to $A\beta$ 1-40 22 μ M or 25-35 90 μ M. Importantly, the neurotoxic effect of $A\beta$ in cortical neuronal cultures was inhibited when cultures were treated with an allosteric antagonist of the NMDA-selective glutamate receptor (eg. MK-801) thus reinforcing the notion that glutamate participates in the $A\beta$ -mediated neurotoxicity. In contrast to the above findings, cultured cerebellar granule cells failed to exhibit any neurotoxicity when exposed to $A\beta$ 1-40 or 25-35 although they do exhibit a clear dose-dependent excitotoxicity to glutamate in the absence of $A\beta$. Importantly, a fundamental difference between the two culture systems is the presence of numerous glial cells in the cortical culture, whereas cerebellar granule cultures are relatively free of glia. However, when cerebellar granule cells are grown under culture conditions which promote glial cell proliferation the neurons exhibit a significant $A\beta$ -mediated neurotoxicity similar to cortical neurons. These data suggest that the interactions between neurons and glia may be an important factor in determining $A\beta$ -mediated neurotoxicity. In addition, studies using pure glial cultures demonstrated a mitogenic effect of $A\beta$ upon these cells.

Ca^{2+} ELEVATIONS INDUCED BY β -AMYLOID PEPTIDE 25-35 IN CULTURED NEURONS DEPEND ON GLUTAMATERGIC SYNAPTIC ACTIVITY. J.R. Brorson*, J.C. Chisholm³, C.J. Marcuccilli², V.P. Bindokas², and R.J. Miller². Departments of ¹Neurology, ²Pharmacological and Physiological Sciences, University of Chicago, Chicago IL 60637, and ³Miles Inc., West Haven, CT, 06516-4175.

The β -amyloid peptide fragment 25-35 (β AP25-35) has been found to enhance the toxicity of glutamate in neuronal cultures over prolonged exposures. The mechanism is unknown. We examined the effects of β AP25-35 (10-60 μ M) on cultured rat hippocampal neurons by microfluorimetric measurements of the free intracellular Ca^{2+} concentration ($[Ca^{2+}]_i$) and with whole-cell patch clamp recordings. In whole-cell current clamp recordings β AP25-35 produced reversible increases in excitatory activity, with bursts of action potentials or EPSPs, in a fraction of neurons. In keeping with the electrophysiological findings, fura-2 microfluorimetry revealed elevations in the $[Ca^{2+}]_i$ during β AP25-35 exposure in 61 of 98 cells examined. These responses were enhanced in Mg^{2+} -free medium but were blocked completely by tetrodotoxin (0.5 μ M) or by CNQX (10 μ M), and incompletely by D-AP5 (25-50 μ M). Fluorescence imaging revealed concurrent $[Ca^{2+}]_i$ spikes among synaptically connected neurons. Neither the β AP1-11 fragment nor solvent alone duplicated these effects. Responses were not observed in cultures of cerebellar neurons, in which >80% of the neurons are inhibitory. These results suggest an effect of β AP25-35 which depends on endogenous excitatory synaptic activity in networks of cultured neurons which is mediated by glutamatergic synapses. This may relate to the *in vitro* toxicity of β AP25-35.

INDUCTION OF β -APP RESULTS IN INCREASED SECRETION OF SOLUBLE β -APP INTO CSF OF SUBCORTICALLY LESIONED RATS. V. Haroutunian*, I. Lieberburg, K.L. Davis, E. Fiber, R. Gluck, and W.C. Wallace Lab. Biochem. Genetics, NIMH, Washington D.C. Dept. Psychiatry, Mount Sinai School of Medicine, NY, NY, and Athena Neurosciences, South San Francisco, CA.

Lesions of various subcortical inputs to the rat cortex result in a rapid (within 1hr) and persistent (at least 6 wks) induction of β -APP in the cortical projection areas. The induction was observed as both elevated β -APP mRNA (northern blots) and increased synthesis of β -APP (polysome run-off assays). This induction occurred in response to neurotransmitter deficits and was independent of physical injury. We examined cortical homogenates by immunoblots using various antibodies directed at β -APP and observed that the levels of mature β -APP in the transmitter deficient cortical tissues did not exhibit any increase from 1 hour to 6 weeks post subcortical lesioning. The elevated synthesis of β -APP in the absence of accumulation is consistent with an increased turnover of β -APP in the transmitter deficient cortex. To test this possibility we examined CSF of lesioned and naive rats. CSF from one week post lesion animals exhibited significantly elevated levels of β -APP (2.3-fold $n=6$ /group). This β -APP species reacted with $\alpha 5$ antibody (directed to an extra cellular domain), but not $\alpha 6$ (directed to an intracellular C-terminal domain) indicating that the species was the secreted form of β -APP. No such elevation was found 1 hour post lesion. These results indicate that upon loss of subcortical innervation the cortex responds with induction of β -APP and increased secretion of the soluble form β -APP. These results taken together with evidence for secreted β -protein in the CSF of humans indicate that the subcortically lesioned rat represents a relevant *in situ* model for studying the physiological roles of β -APP and the factors which lead to the deposition of β -amyloid protein.

β -Amyloid and its Precursor (APP) in AD Fibroblasts. G. M. Cole¹, K. Mak¹, J. Wu¹ and S.A. Frautschy² Neurosciences¹, UCSD, La Jolla, Ca. 92093 and Dept. of Cellular and Molecular Biology², Whittier Institute, 9894 Genesee, La Jolla, Ca. 92037 β -flanking APP mutations have been linked to <1% of familial Alzheimer's disease (AD); one results in ~6 fold more secreted β -protein per mole APP in non-neuronal cells. If increased β production accelerates amyloidosis and AD to the fifth decade, then other, earlier, onset familial AD cases could also have greatly increased APP and β -protein or β as a % of APP in non-neuronal cells. Accordingly, we studied levels of APP and β -protein in fibroblasts from 3 families with AD linked to chromosome 14 using 12 confirmed AD and 10 probable escapees. Detergent lysates and media from duplicate, 16 hour labeled, confluent 75 cm² flasks were examined by immunoprecipitation. No significant differences in C-terminal APP in lysates or APP or β -protein in conditioned media could be found. Because heat shock (HS) elements and AP-1 sites are found in the APP promoter, HSP70 and c-fos genes near linkage markers on chromosome 14 are candidate AD genes. We tested effects of heat shock and serum stimulation of c-fos, but again found no differential effect on APP production. Studies of β -protein and APP in AD and control CSF also indicate no increase in β or APP in AD. Therefore, we propose that other factors accelerate β -amyloidosis in the majority of AD cases and we will present experimental evidence for a novel example of one of them. (Supported by Calif. Dept. Health Service, (GMC), AG09009, (GMC) and AG10685 (S.A.F.))

β -AMYLOID PRECURSOR PROTEIN IN AXOLEMMA AND PERIAXOLEMMAL-MYELIN. V. Sapirstein, M.L. Berg, R. Durrie & N. Marks* Div. of Neurobiology, N.S. Kline Inst. Orangeburg NY 10962.

The β amyloid precursor protein (BAPP) is widely distributed within the CNS. BAPP is transported down the axon and has been found in synaptic endings. We have utilized techniques to isolate axolemma (AX) and periaxolemmal-myelin (PAM) and have found BAPPs, Mr 100-110Kd, to be major constituents of these membrane. Isolation of AX and PAM and compact myelin show that BAPP represents 1% AX and 0.6% PAM protein but is absent from compact myelin. These results indicate that BAPP transported down the axon is deposited at sites in the axolemma as well as at the synapse and that within the oligodendrocyte BAPP, is targeted to the periaxolemmal domain. These results were replicated in membranes isolated from bovine brain. Bovine studies were extended to analysis of white matter clathrin coated vesicles; these data show that coated vesicles isolated from white matter under conditions that yield largely endocytic vesicles, contain levels of BAPP comparable to that found in AX and PAM. Studies carried out on human autopsy material, frozen 2 hours post-mortem, showed nearly identical results. In addition, both rat and human axolemma contained a C terminal 10.5Kd BAPP peptide suggesting this membrane is a site for endopeptidase cleavage of BAPP. Incubation of axolemma with metallo-endopeptidase did not detectably degrade BAPP. However, incubation of axolemma with cathepsin B at pH 6.0 caused a rapid loss of BAPP when analyzed with antibodies to BAPP 672-695 but not when analyzed with antibodies reacting with sites more distal to the C terminus. Thus, cathepsin B selectively cleaves membrane bound BAPP at a site close to the C terminus and may be a valuable tool for altering C terminal BAPP function. Supported by NYS-OMH.

AMYLOID β -PROTEIN ($A\beta$) IS PRODUCED BY I-CELLS EXPRESSING SEVERE LYSOSOMAL DEFICIENCY. M. Podlisny*, C. Haass, C. Miller, T. Oltersdorf, I. Lieberburg, and D. Selkoe. Harvard Med. Sch., Boston & Athena Neurosciences, South San Fran.

Insoluble cerebral aggregates of $A\beta$ are deposited in AD and to a lesser extent during aging. Soluble $A\beta$ is released from cells into the media during normal metabolism *in vitro*. It has previously been postulated that $A\beta$ could be generated from larger (~10-22 kD) C-terminal fragments of β APP that are found in lysosomes. These potentially "amyloidogenic" fragments are enhanced in amount by inhibition of certain lysosomal proteases by leupeptin. To investigate whether lysosomal processing of β APP is necessary for $A\beta$ production, we examined β APP processing in skin fibroblasts from normals and in I-cell fibroblasts derived from patients with mucopolipidosis II, a fatal disease caused by severe deficiency of lysosomal enzymes due to failure of mannose-6-phosphate addition. Immunoprecipitation of cell lysates revealed markedly enhanced levels of ~10-22 kD C-terminal β APP fragments in I-cells compared to normal fibroblasts treated with or without leupeptin. Immunofluorescent labeling of I-cells localized these C-terminal fragments to endosomes and lysosomes. Precipitation of conditioned media with R1280 (to $A\beta_{1-40}$) revealed $A\beta$ production by both normal and I-cell fibroblasts. These data support the notion that the proteolytic cleavages generating both $A\beta$ and C-terminal fragments largely occur in vesicles prior to lysosomes. Similar techniques for studying β APP processing and $A\beta$ production are being applied to skin fibroblasts derived from FAD patients and (in collaboration with V. Askanas) to cultured myoblasts containing intracellular $A\beta$ from patients with inclusion body myositis.

REGULATION OF β -AMYLOID PRECURSOR PROTEIN PROCESSING INTO NON-AMYLOIDOGENIC AND AMYLOIDOGENIC DERIVATIVES BY PROTEIN KINASE C. Albert Y. Hung, T.L. Munsat* and Dennis J. Selkoe. Center for Neurologic Diseases, Harvard Medical School and Brigham and Women's Hospital, and *Tufts N.E., Medical Center, Boston, MA.

The 4 kDa amyloid β -protein ($A\beta$), the major component of cerebral and cerebrovascular plaques in Alzheimer's disease, is derived from proteolytic cleavage of a larger membrane-bound precursor, the β -amyloid precursor protein (β APP). In addition to $A\beta$, processing of β APP gives rise to a large, secreted molecule (APP_s) whose generation precludes the formation and deposition of amyloid. The cellular mechanisms which regulate β APP metabolism are largely unknown. However, protein phosphorylation has been proposed to play a role. Addition of the protein kinase C (PKC) activator phorbol 12,13-dibutyrate (PDBu) to cells expressing β APP resulted in a dramatic inhibition of $A\beta$ release, in parallel with an increase in APP_s secretion. This effect was enhanced by the protein phosphatase inhibitor okadaic acid and blocked by staurosporine, a kinase inhibitor. To determine if this regulation involves direct precursor phosphorylation, we examined the phosphorylation state of β APP in β APP-transfected 293 cells. β APP is phosphorylated only on serine residues. Surprisingly, phosphoserine was detected only within the ectodomain, resulting in the secretion of phosphorylated APP_s . Addition of PDBu did not enhance the phosphorylation of β APP. Furthermore, mutation of the two cytoplasmic serine residues did not abolish the increase in APP_s release and the decrease in $A\beta$ production observed upon PKC activation. Truncation of the β APP cytoplasmic domain similarly did not abolish the effect of PDBu on APP_s upregulation and $A\beta$ inhibition. These results indicate that PKC plays a critical role in the control of β APP processing into non-amyloidogenic and amyloidogenic derivatives. However, in contrast to current postulates, this regulation appears to be independent of direct precursor phosphorylation and is thus likely to involve an additional kinase substrate, perhaps APP_s secretase.

528.6

EXPRESSION OF AMYLOID PRECURSOR PROTEIN IN THE ISCHEMIC RAT HIPPOCAMPAL SLICE PREPARATION

R.N. Kalaria* and A.B. Pax. Departments of Neurology & Neurosciences, CWRU Sch. of Medicine, Cleveland, OH 44106.

It is now established that the amyloid precursor protein (APP) of Alzheimer's disease (AD) is rapidly induced during brain tissue injury. We recently described the expression of APP in experimental ischemic brain injury and chronic hypoperfusion (*Neuroreport* 4, 211-214, 1993). Here, we studied the regulation of APP after experimental manipulations in *in vitro* hippocampal slice preparations from rat brain. Tissue slices were incubated and maintained in oxygenated culture medium containing radiolabelled 35 S-methionine for incorporation into newly synthesized proteins and the effects of ischemic/anoxic insults were examined. We observed that brief periods (20-40 mins) of anoxia affected the incorporation of 35 S-methionine in the tissue proteins including APP. Cell extracts of slices assessed for APP showed that antibodies to C-terminal domains of APP and A4/B protein immunoprecipitated full-length APP forms and smaller amyloidogenic fragments. Our findings emphasize that ischemic or oligemic events, which presumably trigger release of cytokines or related factors and heat shock proteins, may mediate APP accumulation and metabolism that is germane to β /A4 amyloid deposition in Alzheimer's disease.

AMYLOID PRECURSOR PROTEIN-ENRICHED MEDIUM STIMULATES MAP KINASE AND PHOSPHORYLATION OF TAU. S.M. Greenberg, E.H. Koo, W.O. Qiu, A.W. Sandrock*, K.S. Kosik. Center for Neurologic Diseases, Brigham and Women's Hospital and Harvard Medical School, Boston, MA, 02115.

The microtubule-associated protein tau is a major constituent of paired helical filaments (PHF) in Alzheimer's disease (AD). PHF tau is abnormally phosphorylated at multiple sites, many of which are phosphorylated *in vitro* by the mitogen-activated protein (MAP) kinases. The stimulus for abnormal phosphorylation of tau in AD is unknown. Potential candidates include amyloid β -peptide ($A\beta$) and its progenitor the β -amyloid precursor protein (β -APP).

We report that medium from CHO cells stably transfected with β -APP activates MAP kinase in PC-12 cells. The 44 kD form of MAP kinase was stimulated approximately 25-fold by 10 min exposure to medium from cells transfected with β -APP₉₆₅ and to a comparable extent with cells expressing β -APP₇₇₀. This activity was largely blocked by prior immunoprecipitation of conditioned medium with the antibody anti-B5, which recognizes sequence in APP outside the $A\beta$ region. Purified $A\beta$ had no effect. Induction of an inhibitory form of the ras protein blocked the activation of MAP kinase, suggesting that the β -APP-enriched medium stimulates a ras-mediated pathway. Following incubation in [32 P] phosphate, 15 min exposure to conditioned medium increased intracellular phosphorylation of tau by approximately 2-fold. These findings suggest a potential mechanism by which β -APP may stimulate phosphorylation of tau.

INHIBITION OF BETA AMYLOID PRODUCTION BY ACTIVATION OF PROTEIN KINASE C. J. Busciglio*, D. Gabuzda and B.A. Yankner. Dept. of Neurology, Harvard Medical School, Children's Hospital and Dana Farber Cancer Institute, Boston, MA 02115.

The β amyloid protein is secreted by many different cell types in culture. Protein kinase C (PKC) has previously been shown to increase constitutive secretion of the amyloid precursor protein (APP). We examined the effect of PKC activation and inhibition on the secretion of β amyloid in transfected COS cells and a non-transfected human glioma cell line. Activation of PKC by the phorbol ester PMA inhibited secretion of the 4 kD β amyloid peptide by 60-90%. The inactive phorbol ester analog 4 α -PDD was ineffective suggesting that the inhibitory effect of PMA is due to activation of PKC. PMA increased secretion of the 3 kD truncated derivative of β amyloid and secretion of APP_s . Immunoprecipitation of cellular and secreted APP from 32 P-labeled cells showed that both APP and APP_s were phosphorylated on serine residues. The 4 kD β amyloid protein was not phosphorylated. PMA did not increase 32 P incorporation into APP or APP_s , suggesting that PKC does not directly phosphorylate APP. These results suggest that PKC modulates the proteolytic processing of APP indirectly by phosphorylation of another protein. The level of β amyloid secretion may be regulated by neurotransmitters and growth factors that act through the PKC signal transduction system.

β -AMYLOID REGULATES S100 β GENE EXPRESSION IN C6 GLIOMA CELLS AND PRIMARY ASTROCYTE CULTURES.

L.A. Peña*, C.W. Brecher, and D.R. Marshak. Cold Spring Harbor Laboratory, Cold Spring Harbor, New York 11724-2220.

S100 β , a calcium-binding protein expressed by CNS astrocytes, has trophic effects *in vitro* (neurite extension and glial proliferation). In Alzheimer's disease and Down's syndrome, severely afflicted brain regions exhibit up to 20-fold higher levels of S100 β protein, and astrocytes surrounding neuritic plaques exhibit highly elevated levels of S100 β immunostaining. A major constituent of plaques, β -amyloid, has been reported to have neurotoxic and neurotrophic effects *in vitro*.

In our study we examined the responses of CNS glia to β -amyloid. C6 glioma cells and primary rat astrocyte cultures were synchronized and treated with β A(1-40) peptide at doses up to 1 μ M. Weak mitogenic activity, measured by [³H]-thymidine incorporation, was observed. Northern blot analysis revealed increases of S100 β mRNA within 24 hours in a dose-dependent manner. Nuclear run-off transcription assays showed that β A(1-40) specifically induced new synthesis of S100 β mRNA in cells maintained in serum, but under serum-free conditions, there was a general elevation of several mRNA species. Corresponding increases of S100 β protein synthesis were observed by immunoprecipitation of [³⁵S]-labeled cellular proteins. The hypotheses that β -amyloid activity is mediated via neurokinin receptors or by calcium fluxes were evaluated. These data suggest that in neuropathological conditions, β -amyloid itself is an agent which may provoke gliosis and the production of trophic substances by astrocytes.

β -AMYLOID (A β 1-40) MODULATES NIGROSTRIATAL (A9) DOPAMINERGIC NEURONS IN VIVO: NEUROCHEMICAL EVIDENCE FOR A FUNCTIONAL NEUROMODULATORY ROLE IN THE NORMAL ADULT RAT BRAIN. S. Iyengar*, B. M. Simmons and D. Li. CNS Research, Eli Lilly and Company, Indianapolis, In 46285.

Aberrant processing of the Amyloid Precursor Protein, APP, leading to the generation of β amyloid (A β), has been implicated in the pathology of Alzheimer's disease. Recent findings suggest that APP and some of its product peptides may interact with Ca⁺⁺ mediated neuronal mechanisms (Mattson et al., 1990, J. Neuroscience, 12:376; Nitsch et al., 1992, Science, 258:304). Although neuronal degeneration in the Alzheimer's brain appears in specific forebrain pathways, APP appears to be present in brain regions other than forebrain structures as well. These observations raise the possibility that APP or its product peptides may have a functional role in normal brain. The current study was initiated to evaluate A β (1-40) in defined brain regions for potential neurochemical effects in normal adult rat brain. A β (1-40) (Bachem, California, lot WJ 209) was injected intracerebroventricularly (i.c.v.) at various doses, into awake, freely-moving rats (Sprague Dawley, Charles River, 225-250 g) that had been implanted with PE20 cannulas 7 days prior to the experiment. A β caused dose dependent increases in striatal dopamine metabolism and release 60 minutes after injection, as was evident from the levels of dopamine and its metabolites, DOPAC, HVA and 3-MT, which were measured by GC/MS. This neurochemical observation appears to be the first evidence for the ability of A β (or other APP products) to modulate neuronal function in a defined neuronal circuit (A9 nigrostriatal dopaminergic pathway), *in vivo*, in the normal rat brain. This data further raises the possibility that APP and its product peptides may modulate neuronal function.

528.12

THE β -AMYLOID PRECURSOR PROTEIN REGULATES CYTOKINE PRODUCTION IN VITRO. Russell E. Rydel*, Alan R. Culwell, Elizabeth F. Brigham, and Ivan Lieberburg. Athena Neurosciences, Inc., South San Francisco, CA 94080.

Alzheimer's disease (AD) is a neurodegenerative disorder characterized by the extracellular accumulation of senile plaques in the brains of affected individuals. Senile plaques are primarily composed of a 40-42 amino acid amyloid- β peptide that is derived from a much larger (largely extracellular) membrane-spanning β -amyloid precursor protein (β APP). Recent studies have demonstrated that several mediators of inflammation are also associated with senile plaques. These include cytokines (eg., IL-1, IL-6, TNF α), acute phase proteins (eg., α 1-antichymotrypsin), brain macrophages (ie., activated microglia), and classical pathway complement proteins. We have found that secreted forms of β APP (APP^S, nM) and the amyloid- β peptide (A β , μ M) are potent inducers of cytokine release in human cortical mixed brain cultures. These activities are not due to endotoxin contamination, are dose-dependent, and occur in forms of APP^S that both contain (APP^S₇₅₁) and lack (APP^S₆₉₅) the Kunitz-type protease inhibitor domain. These results extend the known activities of β APP to include the regulation of cytokines, and suggest that alternative processing of β APP allows for differential regulation of cytokines by APP^S and A β . These studies further suggest the β APP may play a primary role in the inflammatory responses shown to occur in the brains of patients with Alzheimer's disease.

CEREBELLUM IV

529.1

CEREBELLAR AGENESIS. M. Glickstein*. Department of Anatomy and Developmental Biology, University College London, Gower Street, London WC1 England

The importance of the cerebellum for motor control has sometimes been questioned because of an alleged absence of obvious motor deficits in people born with partial or complete agenesis of the cerebellum. A few such cases have been described in the literature as having been discovered only at autopsy. Some reviewers have concluded that other brain structures therefore must compensate for the absence of the cerebellum. The original case reports, however, point to quite a different conclusion. The myth of normal functioning in cases of agenesis tends to reinforce itself. I report here on one such case. A brain in the Department of Anatomy at Cambridge University has been on display for about forty years with the label "The man without a cerebellum". Verbal reports suggested that in life, the man was either a skilled carpenter or a high scaffolding worker. The evidence is, however, that the story was elaborated over time by oral tradition. The brain was in fact from an unclaimed body, with the designation of "building worker" on the death certificate. Moreover, a sagittal MRI scan of this brain revealed that agenesis was not complete. A very small cerebellum was present, rather than complete agenesis. Combined with a sceptical review of the literature, this case re-affirms the major importance of the cerebellum for normal motor control.

529.2

A PET COMPARISON OF CEREBRAL ACTIVATION ASSOCIATED WITH ESSENTIAL AND WRITING TREMOR. A.J.Wills, I.H.Jenkins, P.D.Thompson, L.J.Findley and D.J.Brooks*. MRC Cyclotron Unit, Hammersmith Hospital, Du Cane Road, London W12 and Institute of Neurology, Queen Square, London WC1, UK.

There has been debate about whether writing tremor (WT) is a variant of essential tremor (ET) or a separate entity (dystonia). The aim of our study was to compare the abnormal patterns of cerebral activation associated with these two conditions. Six ET patients had rCBF measured with H₂¹⁵O PET during postural tremor of the right arm and at rest. The field of view ranged from medulla to thalamus. Abnormal bilateral cerebellar, red nuclear and contralateral pontine activation was seen. Six WT patients had rCBF measured during writing tremor and again whilst holding a pen in the same hand but without tremor. Bilateral cerebellar overactivity was also demonstrated. No olivary activity was apparent in either condition.

We have previously demonstrated similar findings in patients with "rubral" and neuropathic tremors. This suggests a common abnormality of cerebellar networks in all these tremulous disorders.

529.3

CEREBELLAR ACTIVATION DURING WRIST FLEXION AND EXTENSION MOVEMENTS INVESTIGATED USING MAGNETIC RESONANCE IMAGING. D. Flament*, J. Ellermann, S.G. Kim, Q.-G. Fu, H. Merkle, K. Ugurbil and T.J. Ebner. Depts. of Neurosurgery and Radiology, University of Minnesota, Minneapolis, MN 55455.

Using multi-slice functional imaging at high field strength (4T Seimens/SISCO whole body system) we studied cerebellar activation in 8 subjects making a series of wrist flexions against constant inertial loads and in 6 subjects also making alternating wrist flexions/extensions in a finger-to-nose pointing task. Typically, 10 control, 10-20 task and 10 recovery T_2^* weighted images of each slice were obtained.

Cerebellar activation was predominantly bilateral, but stronger ipsilateral to the moving limb. The pattern of activation varied considerably, ranging from highly localized, discrete parasagittal strips in the intermediate zone to a general mosaic-like activation of the entire hemisphere. Some subjects had activity localized in a medio-lateral band that extended from the midline to the lateral aspect of the cerebellum, following the contour of individual folia.

Time-course plots of T_2^* measurements confirmed that activation began after the onset of a series of movements and persisted throughout the series. Activation intensity ranged from 2.6% to 11.5% above baseline. The finger-to-nose pointing task was also an effective activator but produced slightly lower activation of the cerebellum than the inertial load task. Our results show that in humans cerebellar activation is strongest ipsilateral to the moving limb, but that bilateral activation is the norm.

Supported in part by NIH grant RO1-NS-18338.

EFFECTS OF RED NUCLEUS STIMULATION ON FORELIMB EMG ACTIVITY DURING REACHING IN THE CAT. K. M. Horn*, P. L. E. Van Kan, and A. R. Gibson. Barrow Neurological Institute, Phoenix, AZ., 85013.

The magnocellular red nucleus (RNm) receives input from the cerebellar interpositus nucleus and projects to interneurons of laminae V - VII throughout the spinal cord. RNm neurons terminate directly on motoneurons that innervate distal forelimb muscles, suggesting that the RNm preferentially controls movements of the hand and fingers. This hypothesis was tested in cats trained to reach to grasp a lever, a task that involves the entire forelimb.

We stimulated (monopolar pulses, 0.2 msec, 10 Hz) at 15 sites within the RNm of 2 cats and constructed stimulus triggered averages of rectified EMG activity of 4 distal and 3 proximal forelimb muscles. For each muscle, EMG activity was averaged during phases of the reach to grasp in which the muscle was active.

RNm stimulation resulted in post stimulus facilitation at latencies that ranged from 5 to 8 msec. Although both distal and proximal muscles showed facilitation, at threshold stimulus strength (average threshold: 12 uA) 12 of the 15 sites produced facilitation of digit or wrist muscles and not elbow or shoulder muscles. These results support further a preferential involvement of RNm in the control of the distal forelimb during reaching to grasp.

529.7

THE LAMELLAR BODY: A NEW NEURONAL ORGANELLE ASSOCIATED WITH DENDRODENDRITIC GAP JUNCTIONS. C.I. De Zeeuw*, E. Hertzberg, and E. Mugnaini. Dept. of Anat., Erasmus University Rotterdam, 3000 DR, Rotterdam, The Netherlands.

Gap junctions, the site of electrotonic coupling, occur between certain types of neurons and are ubiquitous between glial cells. Recently, sequence-specific antibodies to various regions of gap junction proteins, termed connexins (Cx), have been used to map the distribution of these gap junctions in the brain. No antibodies yet developed, however, bind specifically to neuronal gap junctions. We have found that an antibody, designated $\alpha 12$, to the first extracellular loop of rat Cx43 (amino acids 49-60, highly conserved among known Cxs) provides punctate labeling in a very restricted number of brain regions in the rat. The highest density of labeling occurs in the inferior olive (IO) where the puncta are ubiquitously distributed in its subnuclei. Robust immunoreactivity was also observed in areas CA1 and CA3 of the hippocampus, the dentate gyrus, the olfactory bulb, and the pyriform cortex. Ultrastructural analysis demonstrates that in all these areas dendrodendritic gap junctions do exist, yet the immunoreactive puncta do not directly indicate neuronal gap junctions. Rather, they correspond to a special lamellar organelle that is exclusively located in dendritic appendages. Another antibody against Cx43, which stains astrocytic gap junctions did not label any neuronal structures, suggesting that another member of the Cx family may be responsible for forming dendrodendritic gap junctions. In the adult IO, the density of puncta is highest in the rostral medial accessory olive, the subnucleus where electrotonic coupling is most prominent. Preliminary data indicate that immunoreactivity in the IO appears between P9 and P15, which coincides with the appearance of gap junctions in this nucleus. The present study shows that antiserum $\alpha 12B$ specifically detects a new neuronal organelle that may be related to dendrodendritic gap junctions. In addition, it suggests that dendrodendritic coupling in the IO is more prominent than in other brain regions. Supported by PHS grant GM 30667 and PHS grant NS 09904.

DIFFERENTIAL EFFECTS OF LOCALIZED INACTIVATION OF DEEP CEREBELLAR NUCLEI ON REACHING IN THE CAT. S.E. Cooper*, J.H. Martin, C. Ghez. Columbia U., Ctr for Neurobio. and Behav., NY, NY 10032

In this study, we have explored the deep cerebellar nuclei with small muscimol injections in cats trained to reach into a baited food well. We analyzed changes produced by inactivation in the animal's ability to aim movements and adapt them to variations in the vertical and horizontal target position and to obstacles in the movement path.

Normal animals reach for targets at different heights by scaling the amplitude and velocity of elbow flexion. Motions at other joints are coordinated with the elbow to control paw path. Movements are adapted to horizontal position of the target and to obstacles by changes in movements of shoulder and wrist, rather than elbow. Elbow muscles acted in a simple way to accelerate or decelerate the elbow. In addition to such simple actions, shoulder and wrist muscles interacted in a more complex ways with torques due to motion of other joints (e.g., elbow).

Neither accuracy nor adaptation were substantially altered by inactivation within dentate, or fastigial nuclei although the fastigial injections produced severe postural defects. *Posterior interpositus* injections produced overshoot reaching (Milak et al., 1992) and 'goose-stepping' gait.

Inactivation of *anterior interpositus* (AIP) severely degraded accuracy as well as adaptation to changes in horizontal target position and to obstacles. Errors consisted of systematic biases in which the paw reached below the target ('undershoot'). Scaling of elbow flexion with variations in target height was unimpaired. However, shoulder flexion and wrist dorsiflexion occurred prematurely; moreover, movements of these joints no longer varied with the relevant task parameters. We propose that the AIP is essential for coordinating the action of muscles acting at a given joint with the motion of other joints that produce interaction torques. Supported by NS31391.

PROGRESSIVE CHANGES IN THE MODULATION OF CEREBELLAR NUCLEAR NEURONS DURING THE LEARNING OF A COMPLEX FORELIMB MOVEMENT. J.R. Bloedel*, V. Bracha, M.S. Milak. Barrow Neurological Institute, Phoenix, AZ 85013.

Experiments were performed using a chronic multiple single unit recording technique to examine the changes in the modulation of cerebellar nuclear neurons during the acquisition of a complex, sequential forelimb movement in cats. On cue each animal was required to reach for a vertical bar and to move it to a target zone through a template by learning the orientation of 2-3 straight segments. A 24 microwire, adjustable electrode system was used to record activity in each cerebellar nucleus as the animal learned and practiced the task. The kinematics of the ipsilateral forelimb movements and the EMG of specific ipsilateral and contralateral forelimb muscles also were recorded. After sorting trials into groups based on specific stages of task acquisition, the amplitude of event-related responses in each group's perievent histogram was plotted as a function of task acquisition. Ninety-two percent of the measured responses changed in a strikingly similar manner during learning: their modulation was maximal during the first successful, smoothly executed trials and then decreased progressively as the task was practiced and performance improved. These observations are consistent with the notion that the cerebellum participates in the synthesis of movements required to learn new motor skills, possibly by contributing to the specification of the optimal strategy with which a new goal-directed movement is executed.

TEMPORAL RELATIONS OF THE ACTIVITY OF PURKINJE CELL PAIRS IN THE RABBIT NODULUS. D.R. Wylie*, C.I. De Zeeuw, D. Wang and J.I. Simpson. Physiology & Biophysics, NYU Medical Center, New York NY, 10016.

Gap junctions between neurons in the inferior olive (IO) are thought to be important for synchronization of the complex spike (CS) activity of cerebellar Purkinje cells (P-cells) within the same parasagittal zone (e.g. Llinás and Sasaki, 1989). The ventral nodulus can be divided into at least four parasagittal zones, based on CS responses to optokinetic stimulation (OKS) as well as the differential inputs from the IO to each zone. In the most medial zone cells are non-responsive (NR) and receive climbing fibre (CF) input from the beta-subnucleus of the IO. Most P-cells in the adjacent zone and the most lateral zone respond best to OKS about the vertical axis (VA). Between these two VA zones are P-cells that respond best to OKS about an horizontal axis perpendicular to the ipsilateral anterior canal. The three visual zones receive CF input from specific regions of the dorsal cap and ventrolateral outgrowth. To estimate the degree of synchrony we recorded CS activity of P-cell pairs in the ventral nodulus of ketamine-anesthetized pigmented rabbits. The two electrodes were independently manipulable, and spaced 200-600 μ m apart rostrocaudally and <250 μ m mediolaterally. Recordings were obtained from 37 pairs of the same functional type (like-pairs, e.g. VA/VA), and 13 unlike-pairs (e.g. VA/NR). CS activity occurring spontaneously and during OKS produced by a rotating planetarium projector was obtained. We found that the CS activity of 14 like-pairs was synchronous as determined from peaks in the cross-correlograms binned at 1 msec intervals (cross-correlation coefficients ≥ 0.01 , as high as 0.25). The degree of synchrony was unaffected by OKS. For unlike-pairs, synchronous firing within 1 msec was rare, and cross-correlation coefficients did not exceed 0.007. These data demonstrate that synchronous firing is most prominent between cells of the same functional type, and that the degree of CS synchrony is not influenced by optokinetic stimulation that modulates their firing rates.

THE MICROSTRUCTURE OF COHERENCE IN THE OLIVOCEREBELLAR SYSTEM DURING RHYTHMIC MOVEMENT IN NORMAL AND DEAFFERENTED RATS. J.P. Welsh*, E.J. Lang, and R. Llinás, Dept. of Physiology & Biophysics, NYU Medical Center, NY, NY 10016.

We have demonstrated strong temporal relationships between coherent activity within the olivocerebellar system and rhythmic oro-facial movements. We sought to determine a) whether these rhythmic and coherent olivocerebellar activities are causally related to movement; b) whether they are driven by sensory consequences of the movement; and c) the spatial distribution of coherent activity across the cerebellar cortex during movement. Ten rats were trained to perform large and repetitive 7-Hz protrusions of the tongue in response to a tone before glass microelectrodes were implanted into 2-mm² of Crus IIa to record the complex spike (CS) activity of 18-33 Purkinje cells (PCs). Prior to recording, the faces of 6 rats were deafferented by bilateral resection of the supralabial and mental branches of the V nerve alone or in combination with bilateral resection of the external nasal branches of the V nerve. Deafferentation did not alter the tone's ability to reset olivary rhythmicity and entrain rhythmic (5-11 Hz) CS firing of individual PCs or impair the rhythm of the movement. However, deafferentation impaired movement initiation and thereby degraded the temporal relation between rhythmic CS activity and movement. In normal and deafferented rats, groups of 3-7 PCs fired CSs coherently (within 1 ms) during movement. These groups exhibited diverse spatial organizations that included distinct parasagittal, oblique, and fractured architectures. We conclude that rhythmic olivocerebellar activity is not in itself sufficient to generate rhythmic tongue protrusions, but neither is it driven by the sensory consequences of the movement. Yet, olivary neurons, uncoupled during states of quiescence, become coupled during movement to induce complex patterns of coherent activity in the cerebellar cortex. Support by NS31224 and NS13742.

HIGH-RESOLUTION IMAGING OF CLIMBING FIBER RESPONSES IN THIN RAT CEREBELLAR SLICES USING A VOLTAGE-SENSITIVE DYE

M. Ichikawa, I Vranesic, T. Knöpfel, G. Matsumoto* and T. Iijima
Electrotechnical Laboratory, 1-1-4 Umezono, Tsukuba, Ibaraki 305, Japan and Pharmaceuticals Division, R&D, ciba, CH-4002 Basel, Switzerland

Until recently, the applicability of voltage-sensitive dyes for imaging the propagation of electrical signals along the membranes of single cells or within neuronal circuits was limited mainly due to the lack of photodetector system for accurate measurements of optical signals with both high spatial and temporal resolution. We report here the application of a novel low-noise imaging system (frame rate 1.7kHz, 64 x 64 pixels) to recordings of the spatio-temporal properties of climbing fiber responses in thin slices of rat cerebellum.

Thin rat cerebellar slices from the vermis were stained with the voltage-sensitive absorption dye RH-155. Electrical stimulation in the granule cell layer induced all-or-nothing climbing fiber responses in the adjacent Purkinje cells. These climbing fiber responses first emerged at a level close to the Purkinje cell bodies and subsequently, at the level of distal dendrites. Lowering the external calcium concentration from 2 to 0.2 mM abolished the long-lasting plateau component, but left an initial fast rising spike.

3D VISUALIZATION OF CEREBELLAR GROSS ANATOMY IN THE RAT

E.M. Santori* and A.W. Toga

Laboratory of Neuro Imaging, Dept of Neurology, UCLA Los Angeles, CA 90024

Radial organization of lobules in the cerebellum makes comprehension of its gross anatomy difficult. Through the application of three-dimensional (3D) digital reconstruction techniques we have sought a better representation of this anatomic division in the rat brain.

Representations were developed from a 3D stereotaxic map of the rat brain. This map is a digital volume made up of cryosectional images from a single subject which based on anatomic correspondence is representative of a cohort of six specimens.

Closely spaced coronal, sagittal, and horizontal serial images reconstructed from the map reveal the evolution of structural features across the cerebellum. Furthermore, as these orthogonal images are from the same subject, their shared spatial framework facilitates the localization of structural features in 3-space.

Surface-based models of lobules and nuclei were created. Rendered displays of these models effectively convey the shape and structural divisions of the cerebellum. Interactive display of these models is especially helpful in illustrating the relationships of folia in the vermis and hemispheres.

These digital representations provide more information about the configuration of cerebellar lobules than has previously been possible. Resampled cutplanes provide an almost seamless view of the neuroanatomy and 3D rendering of surface models provide a powerful means for understanding spatial relationships in the cerebellum.

SPATIO-TEMPORAL STRUCTURE IN ARRAY RECORDING OF THE BEHAVING RAT INFERIOR OLIVE.

A. Sivaramakrishnan*, J. P. Welsh, E. J. Lang & R. Llinás, Department of Physiology and Biophysics, New York University Medical Center, 550 First Avenue, New York NY 10016

We apply recently developed statistical techniques to microelectrode array recordings of Purkinje cell complex spikes from the surface of the conditioned rat cerebellar cortex while it responds to stimuli. The stimuli and trained responses were continuously monitored during the experiment. Such data are known to show 5-11Hz oscillations and various spatial patterns including rostro-caudal banding of Purkinje cell climbing fiber activation. These patterns are indicative of the intrinsic neuronal organization of the inferior olivary nucleus, the site of origin of the climbing fibers. We investigate the patterns of coherent activity on the cortical surface on timescales of tenths of a second to a second during stimulus and response in order to determine the degree of spatial organization of inferior olivary firing - known to reflect electrical coupling - and the relation of such patterns to movement. Signals indicating the presence of trains of complex spikes with interspike intervals between 80 to 200ms are cross-correlated. A significant increase in correlated activity is found both following stimulus-evoked movement as well as when the animal initiates movement spontaneously. Protracted movement is accompanied by a decrease in correlated activity in the olive when compared with the initiation of the movement. (ONR N00014-93-0225)

CONVERGENCE ON SINGLE CEREBELLAR FOLIA OF NEURONS LOCATED IN LAMELLA-SHAPED SUBSPACES OF THE BASILAR PONTINE GREY

J.G. Bjaalie, A.M. Nikundiwe and P. Brodal Dept. Anatomy, Oslo University, P.O. Box 1105 Blindern, N-0317 Oslo, Norway

The aim of the study was to search for general rules determining the mutual arrangement of pontocerebellar neurons according to cerebellar target region. The paraflocculus of the cat was chosen as a model. Individual folia, adjacent or separated, were injected with either of the fluorescent tracers Rhodamine-B-isothiocyanate, Fluoro-Gold, or Fast Blue. Three-dimensional computer reconstructions of the distributions of the retrogradely labeled pontine neurons were made. At a large scale, we found that the majority of the cells of each labeled population was confined to a lamella-shaped tissue volume. Each lamella extended from medial to lateral, and accordingly, followed the curving of the pontine grey around the corticospinal and corticobulbar fiber tracts. At a smaller scale, i.e., within each lamellar subspace, the neurons belonging to one labeled population were distributed in aggregates of various shapes. To enable further analysis of the shapes of the intralaminar aggregates, we developed a computer program for unfolding of the lamellae, based on cubic B-spline approximation. The flattened reconstructions were three-dimensional polygonal windows, circumscribing the large majority of the labeled cell swarm (usually 70-80% of the total number of labeled cells in one population).

The present findings, taken together with previous data on a gradual, rather than disjunctive, shift of pontocerebellar neuronal position in relation to a gradual shift of target region (Bjaalie et al., Anat. Rec. 231:510-523, 1991), suggest that the cerebro-ponto-cerebellar system may be organized according to a set of fairly simple, topographic rules.

TRANSGENIC RATS AS MODEL SYSTEMS TO STUDY VASOPRESSIN GENE EXPRESSION

O. Zeng, J. Funkhouser, D. A. Carter, D. Murphy*, Neuropeptide Laboratory, Institute of Molecular and Biology, National University of Singapore, Singapore 0511, Republic of Singapore.

We are studying the molecular mechanism of the vasopressin (VP) gene expression in specific groups of neurons in rat hypothalamus and its regulation by physiological stimuli, including dehydration. By observing normal rats, we have shown that there is an increase in VP gene transcription and a dramatic increase in the poly(A) tail length of the VP transcript in the supraoptic nucleus in response to the physiological stimulus of water deprivation. In order to define the cis-acting elements responsible for these effects, we have generated transgenic rats bearing rat VP-CAT (chloramphenicol acetyl transferase) constructs. The transgenic rats are successfully expressing the transgene appropriately in the hypothalamus. The transgenes are regulated by physiological stimuli in parallel with the endogenous rat VP gene. Indeed, the magnitude of the increase in transgene transcripts is 5-10 fold greater than the increase in the level of the endogenous VP mRNA. These transgenic rats will provide us with more information about how VP gene expression is confined to the hypothalamus and how the VP gene in the hypothalamus responds transcriptionally and posttranscriptionally to physiological stimuli.

C-FOS AND C-JUN EXPRESSION IN HYPOTHALAMIC MAGNOCELLULAR NEURONS AFTER PITUITARY STALK INJURY. **J. Dohanics*, G.E. Hoffman and J.G. Verbalis.** Univ. of Pittsburgh, Pittsburgh, PA 15261

Compression of the pituitary stalk (SC) in rats causes disappearance of vasopressinergic (AVP) and oxytocinergic (OT) axons from the posterior pituitary, but hypothalamic AVP neurons are much more susceptible than OT neurons to retrograde degeneration following this injury. In view of this finding, we evaluated the effect of SC on basal and stimulated expression of the proto-oncogene products c-Fos and c-Jun by magnocellular AVP and OT neurons. Adult male rats were perfused 21 d after either SC or sham surgery. Rats were given 2 ml of either 150 mM NaCl (NS) or 2M NaCl (HS) iv 75 min before perfusion. Serial hypothalamic sections were immunocytochemically stained for c-Fos or c-Jun protein and AVP or OT immunoreactivities. In both SC and sham rats neither AVP nor OT neurons expressed c-Fos following NS treatment, but both expressed abundant c-Fos in response to HS treatment. Only faint c-Jun staining was present in normoosmotic sham rats, and was predominantly localized in OT rather than AVP neurons. In normoosmotic SC rats c-Jun expression was very significantly increased, but predominantly in OT neurons. Osmotic stimulation also increased c-Jun expression in both SC and sham rats, but again more prominently and consistently in OT neurons. These results indicate that: 1) the activity of AVP and OT neurons as reflected by c-Fos expression is not basally elevated after SC; 2) magnocellular responsiveness to osmotic stimulation is not impaired by SC; and 3) magnocellular injury causes a prolonged expression of c-Jun that is much more marked in OT neurons. The last finding supports the possibility that c-Jun may play an important role in regenerative and reparative responses following axonal injury, and if so this might account for the much greater resistance of OT neurons to cell death following axonal injury.

FOS PRODUCTION IN RETROGRADELY - LABELED NEURONS OF THE LAMINA TERMINALIS FOLLOWING INTRAVENOUS INFUSION OF EITHER HYPERTONIC SALINE OR ANGIOTENSIN II. **B.J. Oldfield*, D.K. Hards, M.J. McKinley.** Howard Florey Institute of Experimental Physiology and Medicine, University of Melbourne, Parkville, Victoria, 3052, Australia.

Neurons in the lamina terminalis (LT) have been shown previously to be activated by intravenous infusions of hypertonic solutions or angiotensin II (ANG II). The present studies have been designed to determine the extent to which there is differential activation of those neurons within the LT which project to the supraoptic nucleus (SON). Cholera toxin-gold (CTB-Au) was injected bilaterally into the SON of rats anaesthetised with sodium amobarbital. After at least 1 week intravenous infusions of hypertonic saline, n = 4 (1.5 ml of 1.5M NaCl) or ANG II, n = 4 (1mg/ml/hr) were made and after 90-120 mins. rats were perfusion fixed. Antibodies raised against Fos were applied to brain sections and located using avidin-biotin-peroxidase procedures. In four cases, HRP was injected intravenously 3 mins prior to killing rats in order to delimit the boundaries of structures in the LT which lack a blood brain barrier. This material was prepared for EM examination. Neurons within the component regions of the LT which contained both retrogradely-transported CT B-Au and Fos-positive nuclei were counted. The mean percentage of double-labeled neurons following iv hypertonic saline was by far the highest in the organum vasculosum lamina terminalis (OVLT) and decreased in the median preoptic nucleus (MnPO) and subfornical organ (SFO). Conversely neurons in the subfornical organ projecting to the SON were more often activated following ANG II infusion. The results show firstly, that different populations of neurons in the LT are activated following the two stimuli, and secondly, that osmotically activated neurons, which project directly to the SON, are concentrated in the dorsal aspect of the OVLT.

REGULATION OF VASOPRESSIN (AVP) GENE EXPRESSION IN THE HYPOTHALAMUS OF THE OSMOTICALLY-CHALLENGED RAT BY TESTOSTERONE AND ITS METABOLITES. **J.A. O'Keefe*, R.S. Crowley, N.B. Kim, J.A. Amico.** University of Pittsburgh School of Medicine and VA Medical Center, Pittsburgh, PA 15261

Chronic osmotic stimulation enhances AVP expression in the hypothalamus of the intact rat. We reported (Soc. N.S. Abs. 392.12: 930, 1992) that gonadectomy (GDX) prior to osmotic challenge prevented enhanced accumulation of AVP mRNA in the hypothalamus of male and female rats. The present study was done to determine the contribution of testosterone (T) or its metabolites, dihydrotestosterone (DHT) or estradiol (E₂), upon the AVP gene in the hypothalamus of the osmotically-stimulated male rat. To determine the effect of T, one-week (wk) GDX, sham GDX (intact), and GDX-T-implanted male rats received 2% NaCl solution x 5 days and matched cohorts received tap H₂O x 5 days. All NaCl groups lost comparable amounts of weight, developed hypernatremia, and had significantly lower pituitary stores of AVP compared to tap H₂O controls (p < .05, Scheffé F-test). Intact and GDX-T-replaced rats, but not GDX rats, receiving 2% NaCl increased hypothalamic AVP mRNA accumulation compared to respective tap H₂O controls (p < .05, Scheffé F-test). To determine the contributions of T metabolites, one-wk GDX osmotically-challenged male rats received T, DHT, E₂, DHT + E₂, or sham implants at GDX. NaCl groups developed comparable hypernatremia and depletion of pituitary AVP stores. GDX osmotically-stimulated animals with T, DHT, or DHT + E₂, but not E₂ or sham implants increased AVP mRNA accumulation compared to GDX males receiving tap H₂O. The data suggest that induction of AVP mRNA by T is the result of the action of DHT in the hypothalamus of the osmotically-challenged rat.

CHOLECYSTOKININ ACTIVATES HYPOTHALAMIC C-FOS EXPRESSION IN A SPECIES-SPECIFIC PATTERN. **J.G. Verbalis*, D.A. Schreihoffer, J.L. Cameron, W.H. Kaye, E.M. Stricker and G.E.Hoffman.** University of Pittsburgh, Pittsburgh, PA 15261.

Previous studies from our laboratories have shown a marked species variability in cholecystokinin (CCK)-stimulated neurohypophysial secretion. In rats systemic administration of CCK causes a dose-related increase in plasma oxytocin (OT) levels but no increase in plasma vasopressin (AVP) levels, whereas in both monkeys and humans CCK stimulates pituitary AVP but not OT secretion. Using c-Fos as a marker of neuronal activation, we have shown that in rats CCK activates magnocellular OT, but not AVP, neurons projecting to the pituitary and also parvocellular OT neurons projecting centrally within the brain. To determine whether CCK activates hypothalamic AVP and/or OT neurons in primates, we analyzed c-Fos expression in the hypothalamus of adult male rhesus monkeys treated with CCK 15 µg/kg iv 75 min before perfusion. Serial brain sections were stained immunocytochemically for c-Fos protein (Oncogene Science) and either AVP or OT. In the supraoptic nucleus (SON) the pattern of c-Fos expression paralleled pituitary secretion: there was abundant c-Fos expression in virtually all AVP neurons but in very few (<1%) OT neurons. In the paraventricular nucleus (PVN) similar results were found for AVP, but in addition many OT neurons in the caudal and medial regions of the PVN also expressed c-Fos. These results show that c-Fos expression in magnocellular neurons accurately reflects the differential pituitary hormone secretion found in monkeys and rats, but despite a reversed pattern of pituitary peptide secretion, CCK activates parvocellular OT neurons in both species. Thus, CCK activation of central OT neurons appears to be conserved across species, which suggests that brain OT secretion likely contributes to central effects produced by CCK in primates as well as in rats.

FOS-LIKE IMMUNOREACTIVITY IN ARCuate NUCLEUS AFTER INTRACEREBROVENTRICULAR HYPERTONIC NaCl. **L.P. Solano-Flores*, M.P. Rosas-Arellano and J. Ciriello.** Department of Physiology, University of Western Ontario, London, Canada N6A 5C1.

Intracerebroventricular infusions of hypertonic NaCl solutions have been shown to elicit drinking behaviour, natriuresis and cardiovascular responses. The arcuate nucleus of the hypothalamus (Arc), a paraventricular structure, has been suggested to be a possible site of action of the hypertonic stimulus. However, direct evidence in support of this suggestion is not available. This study was done to investigate whether neurons in Arc alter their activity to infusions of NaCl solutions into the rostral part of the third ventricle in the awake rat. The immunohistochemical detection of c-fos was used as an indicator of neuronal activation. Infusions of either isotonic (143 mM) or slightly hypertonic (172 mM) NaCl solutions resulted in the c-fos labelling of very few Arc neurons. On the other hand, infusions of hypertonic (339 mM) NaCl solution resulted in a large number of c-fos labelled neurons within Arc. In particular, the very rostral pole of Arc contained a conspicuous cluster of c-fos labelled cells. These data demonstrate that changes in the environment of the intraventricular fluid after infusion of hypertonic NaCl activates Arc cells and support the suggestion that Arc functions as a component of central neural and humoral mechanisms in the control of body fluid and circulatory homeostasis (Supported by MRC of Canada and HSFO; LPSF and MPRA are fellows from UNAM México).

EFFECT OF ARCuate NUCLEUS STIMULATION ON THE RESPONSE OF SUBFORNICAL ORGAN NEURONS TO SYSTEMIC CHANGES IN ANGIOTENSIN II OR PLASMA OSMOLALITY. M.P. Rosas-Arellano, L.P. Solano-Flores and J. Ciriello. Department of Physiology, University of Western Ontario, London, Canada, N6A 5C1.

We have previously shown the existence of a pathway from the arcuate nucleus of the hypothalamus (Arc) to the subfornical organ (SFO) in the rat. In addition, we have shown that the discharge rate of SFO neurons is altered during Arc stimulation. This study was done to investigate the effect of Arc activation on the discharge rate of SFO neurons during systemic changes in Angiotensin II (Ang II) or plasma osmolality in the urethane anesthetized rat. Extracellular recordings were made from 44 SFO neurons. Of these, 24 neurons responded to stimulation of Arc. Ten of these neurons were also excited by intracarotid infusion of hypertonic saline (0.5 M in 0.1 ml) and 5 were also excited by intracarotid infusion of Ang II (0.5 µg in 0.1 ml). Of the 10 units excited by hypertonic saline or Arc stimulation, the response of 9 of the neurons to hypertonic saline was potentiated after Arc stimulation. Similarly, in two units excited by Ang II or Arc stimulation, the response of the units to Ang II was potentiated after Arc stimulation. In the three units excited by Ang II or inhibited by Arc stimulation, the excitatory response to Ang II injection was attenuated in two units and not altered in one unit after Arc stimulation. These data suggest that Arc functions to modulate the response of SFO neurons to systemic changes in circulatory levels of Ang II and to hypernatremia. (Supported by MRC of Canada and HSFO; MPRA and LPSF are fellows from UNAM México).

530.9

BRAINSTEM VASOPRESSIN (VP) RECEPTORS MEDIATE THE PRESSOR RESPONSE TO OSMOTIC STIMULATION OF THE SUPRAOPTIC NUCLEUS (SON). M.F. Callahan*, M. Ludwig, L.J. Sim, K.P. Tsai and M. Morris. Dept. of Phys. and Pharm., Wake Forest Univ. Medical Center, Winston Salem, NC 27157 and Dept. Biosci., Univ. Leipzig, Leipzig, Germany.

Osmotic stimulation of the SON results in an increase in arterial pressure and heart rate. We have shown that blockade of vascular VP receptors has little effect on this response. Blockade of brainstem VP receptors blocks the pressor response to Angiotensin II or hypertonic saline (HS) administered intracerebroventricular (ICV). We examined whether this blockade would affect pressor responses to direct osmotic stimulation of the SON.

Male S-D rats received an arterial catheter, fourth ventricular cannula and bilateral microdialysis probes directed at the SON. HS was administered via the microdialysis probe (90 µl/30min), followed by administration of either artificial CSF or d(CH₂)₁Tyr(Me)AVP (9 µg/30 µl/30 min). The HS was then readministered. ICV artificial CSF had little effect on the peak pressor response to hypertonic saline (1M) delivered by microdialysis probe (20.5 ± 2 mmHg before -v- 17 ± 8). ICV VP antagonist inhibited the pressor response (20 ± 5 before -v- 3.5 ± 0.5 after the antagonist).

The results of this study suggest that there may be an important cardiovascular pathway from the SON to brainstem regulatory centers. Alternatively, this may indicate that direct osmotic stimulation of the SON causes activation of previously demonstrated pathways from the PVN to brainstem. (Supported by HL 43178).

A NEW DIRECT AFFERENT TO THE HYPOTHALAMUS: THE VOMERONASAL ORGAN. J. Larriva-Sahd, H. Orozco, R. Aguilar-Roblero*, A. Rondán and M.R. Sánchez-Robles. Laboratory of Experimental Pathology, Instituto Nacional de la Nutrición, México City, Tlalpan 14,000. México City, MEXICO.

In terrestrial mammals, the vomeronasal organ (VO) allows the recognition of conspecifics in terms of specie. In rodents, pheromones contained by urine, are uptaken by the VO, influencing neuroendocrine responses, particularly LH secretion. It has been established that the VO neuroepithelium projects to the accessory olfactory bulb, from which afferent fibers reach the vomeronasal amygdala (VNA). More centrally, fibers from the later proceed to the bed nucleus of the stria terminalis (BNST). The VNA also projects to the BNST and medial preoptic (MP) area via the ventral amygdaloid path. Both fiber systems project to the ventral medial hypothalamic nucleus (VMHN). In this study the vomeronasal nerves (VN) (but not terminal nerves) of six young albino rats from each sex were cut by stereotaxical surgery through the palate. Six animals (three from each sex) were sham lesioned. 72 h.s. later animals were killed by transcardial perfusion with Karnovsky's fixative and their brains processed for electron microscopy. Only in VN lesioned animals, orthograde degeneration was found in dendrites and neuronal somata of (in order of frequency): the MP nucleus (MPN), VMHN, BNST, and arcuate. It is concluded that 1. neurosensory VO cells provide a direct innervation to the MPN and hypothalamus; 2. neurosensory cells of the VO may exert direct, perhaps faster, hypothalamic control on sex behavior and LHRH secretion via this neural path.

Supported by a grant from CONACYT.

ALTERATIONS IN PLASMA OSMOLALITY ELICITS INCREASES IN NEURONAL DISCHARGE OF NUCLEUS TRACTUS SOLITARIUS NEURONS. S. L. Hochstenbach* and J. Ciriello. Department of Physiology, University of Western Ontario, London, Ontario, N6A 5C1.

Recently, we have demonstrated that increases in plasma osmolality results in c-fos expression in neurons of nucleus tractus solitarius (NTS) in the rat. In addition, microinjections of hypertonic saline into NTS elicits depressor and bradycardic responses. This study was done to investigate the effect of changes in plasma osmolality and baroreceptor activation on the discharge rate of NTS neurons. NTS was systematically explored for spontaneously active single units that altered their discharge rate to intracarotid infusions of hypertonic saline (0.5 M; 0.1-0.2 ml) in the chloralose-anesthetized, paralyzed and artificially ventilated rat. Responsive units were then assessed for their response to reflex activation of baroreceptors following pressor doses of phenylephrine (2-10 µg/kg, i.v.). Of 70 spontaneously active cells recorded extracellularly in NTS, 21 (30%) responded to plasma hypernatremia with an increase in firing frequency. Sixteen of these cells were also tested for baroreceptor input: 5 cells (31%) were excited, 3 cells (19%) were inhibited and 8 (50%) did not respond. These data suggest that within NTS there exists a pool of neurons that are sensitive to plasma osmolality changes and that these neurons may also function in cardiovascular regulation. (Supported by HSFO and MRC of Canada.)

GABA-ERGIC GRANULE CELLS ARE THE POST-SYNAPTIC TARGETS OF THE CCK-ERGIC INTRABULBAR ASSOCIATION SYSTEM IN THE RAT OLFACTORY BULB

W.L. Liu* and M.T. Shipley

Dept. Anat. & Cell Biology, University of Cincinnati Col. of Med., Cincinnati, OH 45267

The intrabulbar association system (IAS) interconnects opposite sides of the olfactory bulb. Using combined retrograde tracing (WGAoHRP-Au) and CCK immunocytochemistry we have demonstrated that this system is composed exclusively of CCK-containing axons that originate from the superficial middle and external tufted cells. Using biocytin anterograde tracing and CCK immunocytochemistry we further show that the IAS terminates densely and locally in the internal plexiform layer (IPL) on the opposite side of the olfactory bulb. The strict location of IAS terminals to the IPL suggests that this system synaptically targets neural elements present in the IPL. We hypothesized that the most likely post-synaptic targets of the terminals of this system are the dendrites of the granule cells coursing through the IPL to the EPL.

To test this hypothesis, biocytin was injected into the superficial part of the EPL of the olfactory bulb; 60 µm thick sections were cut on a vibratome and reacted by avidin-biotin complex (ABC)-DAB. Sections containing biocytin labeled axons in the IPL were processed for EM immunocytochemistry using post-embedding immunogold staining for GABA. Biocytin labeled axons and terminals in the IPL were easily observed as dark profiles at the EM level. The biocytin-labeled terminals were apposed to dendritic profiles. Biocytin labeled boutons made synaptic contacts with dendrites that had a high density of immunogold particles for GABA. As the granule cells are GABAergic and their apical dendrites comprise the majority of dendrites in the IPL, we conclude that the post-synaptic targets of the terminals of the IAS are the GABAergic granule cells.

In other neural systems, CCK consistently produces postsynaptic depolarizing responses. If CCK has a similar action in the IAS, then it is reasonable to hypothesize that IAS functions to depolarize granule cell dendrites. This could increase GABA release from granule cell synapses thus inhibiting a discrete population of mitral/tufted cells on the same and opposite sides of the bulb. Alternatively, CCK could shunt conduction in the granule cell dendrites causing a decrease in GABA release, thus exciting discrete populations of mitral/tufted cells. Supported by NIH DC00347, NS29218 and US Army DAMD 17-91-C1071.

PERFORMANCE DEFICITS IN CONDITIONED TASTE AVERSION AND SALT DISCRIMINATION CAUSED BY LESIONS IN THE PARABRACHIAL NUCLEI. A.C. Spector and S.J. St. John. Dept. of Psychology, Univ. of Florida, Gainesville, FL 32611.

Rats with lesions in the gustatory zone of the parabrachial nuclei (PBN) are severely impaired in their ability to form conditioned taste aversions (CTA). Accordingly, we used this behavioral paradigm as a functional assay of the PBN lesion and then tested rats for their ability to discriminate NaCl from KCl in a conditioned shock avoidance task. Rats with electrophysiologically-guided lesions (ibotenic acid, 4 µg/0.2 µl, pH = 7.4) centered in the gustatory zone of the PBN (PBNX; n = 12) and vehicle-treated controls (CON; n = 7) received 15 min presentations of 0.1 M sucrose immediately followed by LiCl injection (2.0 mEq/kg, ip) on 3 separate occasions. On the fourth presentation all control rats ingested virtually no sucrose, whereas PBNX rats drank between 10.0 and 33.0 ml. In a specially-designed gustometer, half the rats were then trained to suppress spout licking in response to various concentrations (0.05 - 0.2 M) of NaCl and to maintain licking to the same concentrations of KCl in brief access trials. The other half were trained in the opposite manner. Six PBNX rats learned to discriminate NaCl from KCl and final performance was not substantially different from CON rats. Five PBNX rats showed no sign of competence in the NaCl vs. KCl discrimination and one rat was partially impaired. Rats with the most complete lesions were the most impaired on both behavioral tasks, although partial lesions appeared to have a greater effect on CTA than on conditioned salt discrimination performance. This suggests that the pre-PBN circuitry is not capable of supporting performance on either behavioral task.

CLASSIFICATION OF TASTE RESPONSES IN BRAIN STEM: MEMBERSHIP IN MULTIPLE GROUPS. Robert P. Erickson,* Patricia M. Di Lorenzo and Max A. Woodbury. Department of Psychology, Duke University, Durham, N.C. 27706.

Classification schemes for gustatory neurons have taken several forms. For example, neurons have been grouped according to the stimuli to which they are most responsive, by their proximities in multidimensional spaces, and by their temporal patterns of response. With each of these methods, the neurons encompassed by a group are quite heterogeneous in their response characteristics. An alternative method is presented which allows "grades of membership" for each neuron in several categories. This method also provides classification of stimuli. A neuron is given ratings which represent membership in several categories, and each stimulus is also rated in these same categories; i.e. instead of being in one category each, each neuron and stimulus belongs in various degrees to several categories. These few categories might be related to real physiological variables, such as receptor and/or other mechanisms. With three stimulus/neuron categories, a good fit is found to the responses of neurons in the rat nucleus of the solitary tract and pontine taste area. The idiosyncratic temporal pattern of response of each neuron to each stimulus is also accounted for by a few subdivisions of the stimulus part of the three stimulus/neuron categories. ASCENDING AND DESCENDING EFFERENT NEURONS IN THE NUCLEUS OF THE SOLITARY TRACT COMPRISE TWO DISTINCT POPULATIONS. C.B. Halsell*, S.P. Travers and J.B. Travers, Dept. of Oral Biology, The Ohio State Univ., Columbus, OH 43210.

The rostral division of the nucleus of the solitary tract (rNST) is the site of the first central synapse for primary taste afferents. In rodents, rNST efferent neurons send ascending projections to specific areas of the parabrachial nucleus and descending projections to local medullary regions, including the parvocellular and intermediate reticular nuclei (RF) and specific subdivisions of the caudal division of the NST. The descending pathway is not as well studied as the ascending pathway and the relationship between rNST neurons comprising these two pathways is unknown. The present study directly compared the distribution and morphological characteristics of the rNST neurons contributing to these two efferent pathways, using dual injections of different fluorescent retrograde tracers. The tissue was processed in the conventional manner. The majority of ascending and descending efferent neurons were separate. Ascending efferents were located in the medial half of the rostral-central NST as a tight cluster that contained few neurons with descending connections. Descending efferents, on the other hand, were scattered throughout the rostral-lateral and ventral NST, and subjacent RF. Although some ascending efferent neurons were intermingled with the descending efferents ventrally, the proportion of double-labelled cells was small. Most efferent neurons with connections to the RF terminated in close proximity to the NST, with fewer projections to caudal and deep ventral RF levels. In contrast, more neurons with intra-NST connections had longer projections, extending to caudal levels of the NST. These findings support a segregation of direct projection neurons ascending to higher brain regions and descending to orofacial pre-motor regions.

VISUAL CORTEX: EXTRASTRIATE—MOTION PROCESSING

531.1

INTEGRATION OF LOCAL MOTION SIGNALS IN AREA MT. M.N. Shadlen*, W.T. Newsome, E. Zohary, & K.H. Britten. Depts. of Neurobiology and Neurology, Stanford Univ., Stanford, CA 94305

MT neurons receive direction selective afferents from V1 and other extrastriate areas. In principle, this input can account for direction selective responses within small subregions of the MT receptive field, but not for broader interactions. We wish to assess the relative contribution of local and broad range spatiotemporal interactions to MT direction selectivity. Therefore we devised an apparent motion (AM) stimulus that permits independent manipulation of local and broad range motion signals. The stimulus consists of a brief localized motion which is sequentially repeated at one deg displacements across the receptive field. It may be approximated as a strobe-sampled AM display, convolved with the impulse response of a linear motion filter. Mechanisms that confer sensitivity to local motion signals should be unaffected by the direction of AM, while broad range interactions should be reflected by a difference in response to opposing directions of AM despite identical local motion cues. We have recently reported that MT neurons characteristically respond to the local motion in these displays (ARVO, 1993). We found no evidence for direction selective mechanisms operating over spatial displacements exceeding one deg for speeds of 7-8 deg/sec. One possibility is that such interactions only occur at faster speeds and shorter temporal intervals. We therefore examined the direction selectivity of MT neurons in the alert macaque monkey to these stimuli over a range of speeds from 6 to 20 deg/sec. Although the response to local motion signals varies as a function of speed, we find no evidence for spatiotemporal interactions over one deg displacements (approx. 1/10 RF diameter). This is puzzling in light of the sophisticated processing attributed to many MT neurons. Yet for simple translation, our findings suggest that MT merely summates direction selective input over a broader spatial scale. [National Eye Institute (EY05603) and HHMI.]

531.3

SHORT TERM PLASTICITY OF NEURONAL AND PSYCHOPHYSICAL THRESHOLDS DURING REPEATED VISUAL STIMULATION. E Zohary*, S Celebrini KH Britten & WT Newsome. Dept of Neurobiology, Stanford University, Stanford, CA 94305.

We recorded from 274 neurons in areas MT and MST of four macaque monkeys while the animals performed a near-threshold direction discrimination task. Psychophysical thresholds improved by 20% on average during the first 300-500 trials of a given experiment. Remarkably, the sensitivities of single cortical neurons also improved during this time interval. Moreover, a similar improvement in neuronal sensitivity occurred in a naive monkey which simply maintained fixation during the stimulus presentation intervals. We measured the time course and magnitude of this effect by averaging the sensitivities of all cells for successive time intervals during an experiment. The average discrimination threshold for the neurons improved roughly linearly as the experiment progressed, saturating after about 400 trials. Neuronal thresholds were, on average, 14% lower during the last 200 trials as compared to the first 200 trials. The gain in sensitivity was highly significant for both neuronal and psychophysical performance. To determine whether the plastic effect occurs at the level of whole receptive fields or at the level of subunits, we presented an initial series of 100 stimuli in a subregion of the receptive field, S1, and then presented "test" stimuli in S1 and in an adjacent subregion, S2. Preliminary results indicate that the initial sequence of visual stimulation in S1 leads to improved sensitivity in both S1 and S2, suggesting that the observed plasticity depends upon mechanisms in MT and MST as opposed to earlier levels of the motion pathway. (Supported by NEI (05603), the McDonnell-Pew Program in Cognitive Neuroscience, and by the CNRS of France).

531.2

THE RELATIONSHIP BETWEEN DIRECTIONAL TUNING AND MOTION STRENGTH IN AREA MT. K.H. Britten* and W.T. Newsome. Center for Neuroscience, UC Davis, Davis, CA 95616 and Dept. of Neurobiology, Stanford University, Stanford CA, 94305.

We have attempted to model threshold psychophysical performance from the responses of MT neurons to variable strength motion stimuli. This effort requires estimation of the profile of activity within a population of MT neurons, which in turn depends on cell tuning properties. However, previous tuning measurements employed stimuli of maximum strength (100% correlation) rather than the near-threshold strengths relevant to our modelling efforts. We therefore measured direction tuning curves for motion stimuli of variable strengths.

We measured direction tuning curves over a range of correlation levels in 40 cells from one monkey. For these cells, stimulus strength did not strongly influence tuning bandwidth. Although response rate fell with decreasing stimulus correlation, the normalized tuning curves were superimposed in most cases, indicating linear scaling of the tuning curve with stimulus correlation. Bandwidth was estimated for each level by fitting Gaussian functions, and the dependence of σ on stimulus correlation was explored with linear regression. Only one cell showed a significant relationship, and the distribution of regression slopes was shifted slightly, but not significantly, towards negative values (decreasing bandwidth with increasing correlation). Thus, bandwidth appears to be roughly invariant with stimulus strength.

We found that neuronal thresholds (ROC analysis) for discriminating opposed directions of motion were elevated only modestly (roughly 70% on average) for motion axes up to 30° from the peak of the tuning curve. For any single axis of discrimination, then, perhaps 1/6 of MT neurons at the appropriate topographic location could provide reliable motion signals. Thus the number of sensitive neurons available during direction discrimination performance is quite large indeed. (Supported EY-05603).

531.4

USING BURSTS OF ACTION POTENTIALS AS EVENTS FOR NEURAL SIGNALING. W. Bair, C. Koch* Computation and Neural Systems, California Institute of Technology, Pasadena, CA 91125.

In a previous study of neurons in area MT (Newsome, Britten & Movshon, 1989), direction discrimination thresholds for an ideal observer (based on ROC analysis) counting the total number of spikes fired by the cell during a 2 sec stimulus are found to be similar to psychophysical thresholds measured simultaneously in alert monkeys.

Because about 2/3 of the 212 MT cells studied often fire action potentials in bursts, i.e. more clustered than expected from a Poisson process with refractory period, and because the number of spikes per burst is not tuned for the stimulus direction or coherence in the majority of these cells, we replaced spike count with "event" count as the information available to the ideal observer. Events are defined as the longest trains of consecutive spikes with interspike intervals < 4 msec and therefore may be bursts or single isolated spikes. We found that for the 41 most bursty cells, the neuronal threshold lowered (improved) by 8% on average, and for 3 cells, thresholds were roughly cut in half.

This result is consistent with a simple stochastic model in which (1) the number of events per stimulus period is Poisson distributed with mean rate depending on the stimulus coherence and direction and (2) the number of spikes in an event is a random variable independent of both the stimulus coherence and the number of spikes in any other event.

We have tried other schemes in which events are weighted as a function of their number of spikes (i.e., relative weightings of bursts to isolated spikes and weighting events by the square or square root of their spike count) but find the greatest improvement when events are weighted equally regardless of spike count. We stress that neither the code used to carry motion information nor whether post-synaptic cells differentiate between bursts and single spikes is known.

531.5

SUMMATION PROPERTIES OF MACAQUE MT AND MST NEURONS. S. Raiguel*, V. Marcar, D.-K. Xiao, H. Maes and G.A. Orban, Lab. Neuro- en Psychofysiologie, Medical School, KULeuven, B-3000 Leuven, Belgium.

We compared the summation properties of MT and dorsal MST cells for translating moving dot fields after centering the stimuli on the center of mass of 2-D spatial sensitivity profiles. Three series of stimuli were presented in interleaved fashion: a series in which the diameter of the moving dot field increased in 8 steps (summation series), a series in which a central disc of increasing diameter was removed (inverse summation) and a series of annuli corresponding to the successive steps in the first two series. In MT the summation series indicated that about half the cells had an antagonistic surround. In all cases the response decreased steadily in the inverse summation test. In MST the results of the summation series were similar, but the inverse summation series revealed cells with properties not seen in MT. In a number of cells without surround, the response in the inverse summation series was flat. These cells consistently responded better to the large annuli than to the small ones. Other MST cells showed reversals in preferred direction in the inverse summation series but not in the summation series. Some of these cells preferred opposite directions for an annulus and a disc. These results indicate that MST receptive fields are adapted to analyze wide field motion, even in cluttered environments.

531.7

CHROMINANCE VS. LUMINANCE AS TOKENS FOR DIRECTIONAL SELECTIVITY IN MACAQUE VISUAL AREA MT. KR Dobkins* and TD Albright. The Salk Institute for Biological Studies, La Jolla, CA 92037.

Although MT neurons do not exhibit traditional chromatic selectivity, many continue to signal direction of motion when stimulated with moving patterns defined solely by chromatic contrast. MT neurons are also highly sensitive to moving patterns defined solely by luminance contrast. To directly assess the relative virtues of chrominance and luminance as motion correspondence tokens, we have now compared responses of individual MT neurons elicited by heterochromatic vs. achromatic moving patterns that contained identical levels of luminance contrast. In doing so, we sought to determine whether chromatic contrast confers any benefit to motion processing when luminance contrast is also present in a moving stimulus.

We used apparent motion stimuli consisting of achromatic (yellow/black) and heterochromatic (red/green) sine-wave gratings repeatedly undergoing 1/4 cycle phase displacements (see Dobkins & Albright, 1993, *Vision Res*, 33: 1019). Luminance contrast of achromatic patterns was varied from 1.3% to 10%. For heterochromatic stimuli, luminance contrast was varied over a small range (10%) centered on each neuron's "isoluminant point". Indices of directional selectivity (DIs) were calculated using responses elicited by movement in preferred and anti-preferred directions.

Upon comparison of DIs elicited by heterochromatic vs. achromatic stimuli possessing identical luminance modulation, we found that at and near isoluminance, the addition of chromatic contrast markedly improved direction discrimination by MT neurons. At larger luminance contrasts (greater than ~4%), however, heterochromatic and achromatic DIs were not significantly different, suggesting that color provides little benefit when luminance contrast is sufficiently large. Furthermore, the relative strength of heterochromatic vs. achromatic responses did not vary as a function of receptive field eccentricity. Therefore, the central visual field representation in MT does not appear relatively more specialized for color than for luminance processing.

531.9

MSTd NEURONAL RESPONSES TO THE CENTER-OF-MOTION IN OPTIC FLOW FIELDS. C. J. Duffy* and R. H. Wurtz. Lab. of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892.

A prominent feature of optic flow fields is the focus of expansion in radial patterns or the center of rotation in circular patterns. Radial and circular flow fields can be shifted to displace the center-of-motion (COM) while preserving the global pattern. Such stimuli simulate the distribution of directional motion in optic flow fields seen when the observer's direction of self-movement does not match the direction of gaze. We studied the effect of a shift in the COM on the responses of neurons in the dorsal medial region of the medial superior temporal area (MSTd) of Rhesus monkey extrastriate cortex.

Stimuli consisted of white dots in patterned motion on a 100° x 100° projection screen. The COM in a radial or circular pattern was positioned at selected points on the screen while the monkey maintained centered visual fixation. MSTd neurons were found which responded specifically to each of the COM positions tested throughout the visual field, with increasing numbers of neurons responding to COMs closer to the fixation point. Some MSTd neurons responded best to stimuli in which the COM was directly over the fixation point with little response to stimuli with COMs shifted off that point. Other MSTd neurons responded best to stimuli in which the COM was displaced off of the fixation point. These neurons had a response preference for shifts a specific distance away from the fixation point and in a specific direction relative to the fixation point.

Thus, each neuron was activated by stimuli with a COM in any part of the visual field, limited with respect to distance and direction from the fixation point. The selectivity of these responses support the hypothesis that MSTd neurons might contribute to a neural representation of optic flow.

531.6

MT NEURONAL RESPONSES TO 1ST- AND 2ND-ORDER MOTION.

L. P. O'Keefe*, M. Carandini, J. M. H. Beusmans and J. A. Movshon† Center for Neural Science and †Howard Hughes Medical Institute, New York University, New York 10003.

Extrastriate cortical area MT is thought to process behaviorally important visual motion signals. Psychophysical studies suggest that there may be two motion systems. The 1st-order system responds to conventional motion targets, and the 2nd-order motion system can be probed through use of "drift-balanced" stimuli, whose motion is visible to human observers, but invisible to 1st-order motion sensors.

We wished to know if area MT is involved in the analysis of 2nd-order motion. We measured responses to 1st- and 2nd-order gratings of single neurons in the central visual field representation of area MT in anesthetized, paralyzed macaque monkeys. For each neuron, we measured directional and spatio-temporal tuning with luminance gratings and with drift-balanced gratings created by spatial modulation of the contrast of a random texture.

Cells whose receptive fields lay near the fovea often gave vigorous direction-selective responses to both luminance and drift-balanced gratings. However, cells whose receptive fields were further than a few degrees from the fovea usually responded weakly and with less direction selectivity to drift-balanced targets. This may explain the psychophysical observation that 2nd-order motion is easily detectable foveally, but weak or absent in the periphery. The results suggest that the very neurons in foveal MT that are thought to signal 1st-order motion are also capable of extracting 2nd-order motion, and that both kinds of motion may be signaled by a single system.

531.8

REPRESENTATION OF DEPTH FROM MOTION AND STEREO CUES IN MACAQUE CORTICAL VISUAL AREA MT. G.J. Carman* and T.D. Albright, Salk Institute Vision Center, San Diego, CA 92186.

Under natural viewing conditions, motion parallax (MP) and stereo parallax (SP) each provide cues to the distance (D) of surfaces relative to the fixation distance (FD). In order to determine how these cues support the representation of depth, we recorded from neurons in the superior temporal sulcus (STS) of alert *Macaca mulatta* viewing surfaces presenting gaussian distance profiles. These gaussian stimuli were delivered as dynamic, stereoscopic pairs of images rendered using random dots of constant density and limited life, and could be manipulated so as to present MP and/or SP cues. For each neuron, we determined the classical receptive field, direction selectivity, and disparity selectivity using conventional bar and planar random dot stimuli. We then recorded responses to gaussian stimuli for which D was varied relative to FD (e.g. $51 < D < 63$ cm at 57 cm FD). The majority of MT neurons responded either to near surfaces ($D < FD$) or to far surfaces ($D > FD$), and exhibited a monotonic increase in response to greater magnitude of relative distance ($RD = D - FD$) for stimuli presenting MP and SP cues. Some neurons exhibit strikingly linear ($r \sim 0.95$) response as a function of RD, with the slope of this response function being modulated by FD. Our results suggest that some neurons in area MT provide a linear representation of MP cues to relative distance, and use SP cues to disambiguate MP and to provide the variable gain necessary for perceptual depth constancy.

PURSUIT RELATED ACTIVITY IN MACAQUE VISUAL CORTICAL AREAS MST AND LIP IS MODULATED BY EYE POSITION
F. Bremmer* and K.-P. Hoffmann, Dept. Zoology & Neurobiology, Ruhr University Bochum, D-4630 BOCHUM, Germany

Saccade- and stimulus-related responses of neurons in monkey prestriate Lateral Intra Parietal Area (LIP) and area 7A (Andersen et al., 1990) as well as areas V3A and V6 (Galletti et al., 1989, 1991) are modulated by the position of the eye in the orbit.

Pursuit related responses have been shown for neurons in the Medial Superior Temporal area (MST), which is reciprocally connected to area LIP. In our study we tried to reveal whether pursuit related neurons exist in area LIP also and whether pursuit related activity of MST as well as LIP neurons is modulated by eye position.

Single unit recordings were done in 4 hemispheres of three monkeys. In a first step neurons were tested while the monkey pursued a target moving into different directions on a tangential translucent screen. 67 out of 112 LIP neurons and 81 out of 177 MST neurons tested showed a clear pursuit related activity. In order to test modulation of responsiveness of these neurons by the position of the eye in the orbit the monkey had to pursue the same target which started moving with the same velocity from different locations on the screen. For most of the neurons, 72% in area MST as well as 88% in area LIP, the pursuit related response was depending on the pursuit starting position. Response strength as a function of horizontal and vertical eye position could be fitted highly significantly by a two-dimensional linear regression plane.

531.11

DEFICITS OF NON-FOURIER MOTION PERCEPTION IN A PATIENT WITH NORMAL PERFORMANCE ON SHORT-RANGE MOTION TASKS. L.M. Vaina^{1,2*}, M.LeMay², N.M. Grzywacz³
Intelligent Systems Lab. & Neurology Dept.-Boston University¹, Health Sciences and Technology and Neurology Dept., M.I.T. and Harvard Med. School² Boston Ma 02215, Smith Kettlewell Institute of Visual Sciences, San Francisco, Ca. 94115³.

This study provides experimental evidence for the hypothesis that Fourier and long-range, non-Fourier, motion are carried out at different stages of processing in the human brain.

Chubb and Sperling introduced non-Fourier motion stimuli in which the expected power of any Fourier component moving in a given direction and speed is equal to the power of the same component moving in the opposite direction with the same speed. To measure subjects' sensitivity to non-Fourier motion we devised a stimulus consisting of a dense random-dot pattern and an imaginary square-wave grating drifting over it. The imaginary grating defined the probability that the contrast polarity of each dot would switch from frame to frame. The subjects' task was to determine in a 2AFC the direction of motion.

We show data from control subjects and a stroke patient, F.D., with a left posterior parietal-temporal lesion, who presented with severe deficits on this task, yet his perception on a large class of Fourier-type short range motion stimuli was normal, as were his contrast and temporal frequency discrimination. We will discuss possible anatomical correlates of this dissociation. Supported by NIH-NEI grant ROI EY07861

HUMAN COGNITION: ATTENTION AND MEMORY

532.1

MEMORY FOR TEMPORAL AND SPATIAL DISTANCES FOR NEW AND PREVIOUSLY LEARNED GEOGRAPHICAL INFORMATION IN HYPOXIC SUBJECTS. R.O. Hopkins* and R.P. Kesner, Department of Psychology, University of Utah, Salt Lake City, Utah 84112.

Hypoxic subjects and age matched control subjects were tested for memory for temporal and spatial distances for data-based (new information) and knowledge-based (prior knowledge) information. Memory for data-based spatial and temporal distance information was assessed using a map of New Brunswick. In the study phase subjects were presented with 8 cities, on a map of New Brunswick, one at a time, for 5 seconds each. In the test phase subjects were presented with the names of 2 cities and were asked to choose the city that occurred earlier in the sequence. Temporal distance was determined by the number of items that occurred in the study phase between the two test items. Temporal distances of 0, 2, 4 and 6 were assessed. In the spatial distance task the study phase was identical to that of the temporal distance task. In the test phase subjects were presented with the names of 2 cities and were asked to remember the city that was located further to the north, south, east or west. There were equal numbers of trials for each direction. Spatial distance was determined by the number of cities that were located between the two test cities, in the chosen direction. The knowledge-based tasks were identical to those of the data-based tasks, except that maps and cities in the United States were used. Both temporal and spatial distances were assessed. Results indicate that hypoxic subjects, relative to control subjects, were impaired across all distances on the data-based tasks, for both temporal and spatial distance information. Hypoxic subjects were impaired relative to control subjects for knowledge-based temporal distance memory. However, hypoxic subjects performed similar to control subjects for all distances in the knowledge-based spatial distance task. Thus, a relatively permanent representation of a spatial cognitive map does not appear to reside in the hippocampus.

532.3

ACCESS TO STORED BIOGRAPHIC INFORMATION FROM FACES AND PROPER NAMES: A PET STUDY. I. Sergent*, B. MacDonald, and E. Zuck, Cognitive Neuroscience Lab., Dept. of Neurology & Neurosurgery, McGill Univ., Montreal, Canada.

The functional organization of the brain is designed to accommodate a variety of factors and constraints which determine the locations and relations of the many processing structures that underlie cognition. To examine some of the principles governing this organization, normal adults were subjected to a series of cognitive tasks, on either faces or proper names, that made the same processing requirements and differed only by the nature of the incoming information to be processed. Variations in cerebral blood flow were measured with positron emission tomography during the performance of these tasks, and the pattern of cortical activation associated with the cognitive operations specific to each task was calculated with the subtraction method. As expected, the results showed that different cerebral hemispheres were engaged in the processing of faces and of names. Less expected was the asymmetric organization of the network underlying similar cognitive functions, as accessing biographic information from faces engaged the ventro-medial cortex of the right hemisphere whereas the lateral cortex of the left hemisphere was engaged with names. In addition, there was no overlap of cerebral activation in the face and the name semantic tasks, suggesting that the same biographic information may be accessed and stored in distinct regions of the brain.

532.2

LATERALIZATION OF FRONTAL LOBE ACTIVITY ASSOCIATED WITH WORKING MEMORY FOR FACES CHANGES WITH RETENTION INTERVAL: A PARAMETRIC PET-rCBF STUDY. J.V. Haxby*¹, B. Horwitz¹, L.G. Ungerleider², J. Maisog¹, D.G. Allen¹, M. Kurkjian¹, M.B. Schapiro¹, S.I. Rapoport¹, C.L. Grady¹ Lab. Neurosci., NIA¹ & Lab. Neuropsych., NIMH², NIH, Bethesda, MD 20892.

Regional brain activity associated with working memory for faces, defined as the retention of a face over brief, nondistracting intervals, was studied in 5 healthy, right-handed, young men. Changes in regional cerebral blood flow (rCBF) were measured with positron emission tomography (PET) using H₂¹⁵O, while subjects performed face working memory and control tasks. Five working memory scans were obtained with different retention interval lengths (1, 6, 11, 16, or 21 sec). Control tasks were a sensorimotor control and a nonmemory perceptual face matching control. All working memory tasks and the perceptual matching task were two alternative, forced choice, match-to-sample tasks. Bilateral foci in inferior prefrontal cortex (Brodmann 45) showed increased rCBF during working memory as compared to control tasks. With lengthening retention intervals, right frontal activity increased to a maximum at 11 sec and decreased to nonsignificant changes at longer intervals. By contrast, left frontal activity continued to increase with longer intervals. Direct comparison of short and long intervals showed significantly greater right frontal rCBF at short as compared to long intervals and significantly greater left frontal rCBF at long as compared to short intervals ($p < 0.001$, one-tailed, uncorrected). Longer retention intervals were also associated with rCBF decreases in ventral occipitotemporal cortex (Brodmann 37), probably due to decreased perceptual activity, and in left thalamus, and with rCBF increases in left precuneus, left motor cortex, and left inferior temporal cortex. These results suggest, in concert with subject reports of difficulty maintaining a clear mental image over the longer intervals, that the neural representation of working memory for a face may shift from a visual image (right frontal) to a verbally or analytically mediated representation (left frontal) with increasing retention interval.

532.4

OPTICAL IMAGING OF HIGHER COGNITIVE ACTIVITY FROM HUMAN RIGHT AND LEFT TEMPORAL LOBES. M.M. Haglund*, G.A. Ojemann, and D.W. Hochman, Department of Neurological Surgery, University of Washington, Seattle, WA 98195.

Awake neurosurgical procedures that expose eloquent cortex provide a unique opportunity to study the cortical organization of human cognitive functions. Previously, these localization studies could only be accomplished by cortical stimulation mapping (Ojemann, J Neurosci 1991); however, more recently, through the use of optical imaging of the intrinsic signal, cortical maps of language and sensory cortex have been obtained (Haglund et al., Nature, 1992).

In patients undergoing awake surgery for intractable epilepsy, a CCD camera was attached to the operating microscope and the exposed cortex illuminated with far red light (>690 nm). Optical images of the reflected light were obtained during a baseline task and then during the cognitive task of interest; and percentage difference maps calculated based on the difference between these images. A warping algorithm was used to compensate for small amounts of patient motion.

In nine patients, optical imaging was accomplished while the patient performed a series of tasks involving identification of facial expressions and matching of faces or complex figures. Cortical maps of optical changes during face matching and facial expressions. In a separate series of twelve patients, optical changes occurred in the left temporal lobe at specific sites with object naming and the initial retrieval from memory. Optical imaging of the human cortex has the potential to provide new insights into the cortical organization of higher cognitive functions. 532.5

ACTIVATION OF DORSOLATERAL PREFRONTAL CORTEX IN HUMANS DURING A WORKING MEMORY TASK USING FUNCTIONAL MRI. J. D. Cohen, S. Forman, B. J. Casey, D. Servan-Schreiber, D. C. Noll & D. A. Lewis*. Clinical Cognitive Neuroscience Lab, The University of Pittsburgh and Carnegie Mellon University, Pittsburgh, PA 15213.

Six subjects were studied while alternating between two versions of the continuous performance test (CPT). In both tasks, single letter stimuli appeared one at a time in a visual display. In the control task, subjects responded to any occurrence of the letter "X". In the experimental task, subjects responded whenever a letter reappeared separated by a different one (e.g., A-F-A, but not A-A or A-Q-G-A). Presentation rate, target frequency, and frequency of repeated letters were identical in the two tasks. Both the control and experimental tasks required encoding and evaluation of each letter, and a response to targets by pressing a button. However, the experimental task also required that the two previous letters be kept in mind in order to identify targets. Each task was performed for 60s blocks, which were alternated 10 times. During each block, T2*-weighted coronal images were acquired from 6 contiguous locations in prefrontal cortex using a spiral scan sequence on a standard 1.5T GE scanner. No shimming procedures nor any specialized hardware was used. Sets were acquired every 6s, for a total of 100 scans per location per task. Activation images were generated by performing pixel-wise t-tests between images acquired during each task, separately for the first and second halves of the data (split-halves method). Signal intensity was also plotted against time, in order to verify that periods of activation corresponded appropriately to the tasks. 5 out of 6 subjects showed significant, reliable areas of activation along the middle frontal gyrus (area 46 in the Talairach atlas). This was the most significant area of activation in all 5 subjects. Signal intensity varied consistently as a function of task in this area. The one subject who did not show activation was the subject who performed most poorly on the task. Activation also correlated significantly with performance within subjects. One subject was studied a second time using the same paradigm, and showed identical areas and amount of activation as in the first study.

532.7

MAPPING THE AUDITORY SELECTIVE ATTENTION GENERATORS USING A COMBINED BRAIN EVOKED POTENTIALS AND PET ACTIVATION STUDY. N. Tzourio*, F. El Massouli, L. Raynaud, B. Mazoyer, B. Renault, Groupe d'Imagerie Neurofonctionnelle, S.H.F.J., C.E.A., Orsay, 91406, C.H.U. Bichat, Université Paris 7, and L.E.N.A., C.N.R.S., La Salpêtrière, Paris, France.

We measured relative regional cerebral blood flow (RCBF) using PET and [15O]-water in 6 young right-handed healthy volunteers, during 2 runs of 3 different conditions: 1 - silent rest, 2 - passive dichotic listening of rare (20%) high (1790 Hz) and frequent low (750 Hz) tones randomly delivered to each ear, 3 - attending to and detecting right ear high tones. Simultaneous ERPs were recorded from five of these subjects during both condition 2 and 3 using a coronal montage of 5 electrodes. RCBF images were aligned with individual magnetic resonance images (MRI), and RCBF variations between pairs of measurements (N = 12) were computed in regions of interest with anatomical boundaries that were defined using a three dimensional reconstruction of each subject MRI data.

During the passive condition, we found a bilateral activation of the superior temporal gyrus (Right ST: 3.8 ± 2.9 , mean \pm SD in %, $p = .0009$, Left ST: 3.1 ± 2.5 , $p = .001$). During selective attention, in addition to a bilateral activation of the superior temporal gyrus (RST: 3.6 ± 3.6 , $p = .005$, LST: 3.9 ± 2.4 , $p = .0002$), we observed activations of the right anterior cingulate (RAC: 7.8 ± 8.2 , $p = .007$) and right supplementary motor area (RSMA: 6.5 ± 5.7 , $p = .002$). RSMA activation was significantly correlated with the 50 to 150 msec processing negativity (PN) amplitude of the right side electrodes, while RAC activation was significantly correlated with the 150 to 250 msec PN amplitude of bilateral frontal and temporal electrodes (Spearman $r < -0.89$, $p = .01$). (Supported by a grant from C.N.R.S./Cognisette)

532.9

THE NEUROPHYSIOLOGICAL BASIS OF SELECTIVE ATTENTION BASED ON THE TEMPORAL STRUCTURE OF NEURAL SIGNALS E. Niebur* & C. Koch, Computation and Neural Systems Program, Caltech 216-76, Pasadena, CA 91125.

We propose a model for the neuronal implementation of selective visual attention based on the temporal structure of neuronal activity. In particular, we set out to explain the electrophysiological data from areas V4 and IT in monkey cortex of Moran and Desimone (1985) using the "temporal tagging" hypothesis of Crick and Koch (1990). In our model, neurons in primary visual cortex respond to visual stimuli with a Poisson distributed spike train with an appropriate, stimulus-dependent mean firing rate. The firing rate is constant for neurons outside the "focus of attention" but it is temporally modulated for neurons whose receptive fields overlap with the focus of attention. This modulation is detected by inhibitory interneurons in V4 and is used to suppress the response of V4 cells associated with non-attended visual stimuli. We implement this tagging by either weakly modulating the Poisson spike rate using a 40 Hz modulatory signal or by influencing the temporal synchronization among V1 cells within the focus of attention. Both forms of tagging exhibit the experimentally observed suppression of unattended responses in V4 and the shrinking of receptive fields around the attended stimulus (Moran and Desimone, 1985). Pyramidal cells in V4 also exhibit the same form of temporal tagging (oscillations or synchronized activity) and can therefore transmit the "tagged" or "attended" signal to IT, the next stage of processing.

ACTIVATION OF THE ANTERIOR CINGULATE DURING THE STROOP CONFLICT PARADIGM USING FUNCTIONAL MRI. B. I. Casey*, J. D. Cohen, D. C. Noll, S. Forman, and J. L. Rapoport. Child Psychiatry Branch, NIMH, Bethesda, MD 20892.

The role of the anterior cingulate in the Stroop attentional conflict paradigm was examined using functional magnetic resonance imaging. Scanning was performed on a standard 1.5 T GE Signa magnet, using two 5" surface coils mounted on each side of the head. 7mm scans were obtained at six contiguous locations anterior to the anterior commissure. Each set of coronal images was acquired using a 10 interleaved T2* sensitive spiral scan sequence with a TR of 600ms, TE of 35 ms, flip angle of 45 degrees and a field of view of 24mm. No shimming procedures or specialized hardware was used. Subjects were asked to name the color of 3 different stimulus types: color words (e.g., the word "red" printed in "green"), neutral words (e.g., the word "table" printed in yellow"), and a series of X's (XXXX). Each condition was run for 60 seconds, during which 10 sets of scans were acquired. Each of the conditions was repeated 5 times in an alternating sequence. Pixel-wise t-tests (split-halves method) revealed reliable activation in the right anterior cingulate during both the color and neutral word conditions compared to the XXXXX condition. The comparison of the color and neutral word conditions revealed no differences in activation. The results are consistent with recent PET findings and provide further support for a proposed anterior attention system.

COMBINED PET AND ERP STUDIES OF VISUAL SPATIAL SELECTIVE ATTENTION IN HUMANS. G.R. Mangun*, H.J. Heinze*, W. Burchert*, H. Hinrichs*, M. Scholz*, T.F. Münte*, A. Gös*, H. Hundeshagen*, M.S. Gazzaniga* & S.A. Hillyard*§, UC Davis, *Medizinische Hochschule Hannover, FRG, §UC San Diego

The brain mechanisms of visual selective attention were investigated in normal human subjects using a combined electrophysiological (ERP) and positron emission tomographic (PET) approach. Stimuli consisted of bilateral arrays of symbols (two in the left and two in the right hemifields) that were briefly flashed on a video monitor: subjects continuously maintained fixation on a central point. In separate sessions, ERPs and PET measures of cerebral blood flow ($H_2^{15}O$) were obtained in two attention conditions (attend left and attend right): A passive viewing condition was also included. ERPs in the latency range of 90-140 msec post-stimulus were greater in amplitude over the lateral occipital scalp sites contralateral to the attended hemifield; topographic mapping of the voltage current density fields on the scalp indicated this ERP attention effect to be maximal over the lateral extrastriate cortex. In the PET session, significant increases were observed in cerebral blood flow (averaged images N=11) in lateral extrastriate cortex (area 19) contralateral to the attended hemifield for subtraction images (attend - passive, & att left - att right). No PET activation was obtained in striate cortex as a function of attention, however, activation was obtained in the anterior cingulate cortex. These data provide combined temporal (ERP) and functional-anatomical (PET) localization of modulations of sensory-cortical processing as a function of spatial selective attention. In humans, spatially focused visual attention alters the processing of incoming sensory stimuli by 90 msec post-stimulus in extrastriate area 19 as one mechanism for the early selection of inputs.

TEMPORAL CONSTRAINTS OF COGNITION: FURTHER EVIDENCE OF AUTOMATIC TEMPORAL INTEGRATION. N. v. Steinbüchel, E. Szalag, M. Reiser and E. Pöppel* Inst. f. Med. Psychol., LMU, Munich and Forschungszentrum Jülich, F.R.G.

On the basis of neuropsychological and psychophysical evidence it can be concluded that sensory information is not processed continuously, but in a discrete fashion. On a high-frequency level atemporal system states with a duration of approx. 30 ms are conceived of as providing a logistical basis for "primordial" events. On a hierarchically distinct level, successive system states are automatically linked together. This temporal integration appears to be limited to intervals up to approx. 3 seconds. Experimental evidence for this kind of presemantic integration comes from a number of different paradigms. For instance in sensorimotor synchronization subjects can anticipate stimulus occurrence up to approx. 3 seconds, but not beyond. Here we report experimental evidence on temporal constraints of information processing in brain-injured patients and control subjects using two different paradigms, i.e. temporal reproduction and spontaneous alternation rates of ambiguous figures. Either visual or auditory reversible stimuli were chosen; within both modalities a reversal could result in a percept of the same or a different semantic category (like the 2 perspectives of the Necker cube or vase vs. faces). On average the reversal rate for visual stimuli was higher than for auditory stimuli, and there was a tendency for the different semantic categories to be reversed faster.

532.11

PREFRONTAL CORTEX CONTRIBUTION TO THE CONTINGENT NEGATIVE VARIATION
S. K. Rosahl & R. T. Knight*. Dept. of Neurology and Center for Neuroscience,
University of California at Davis, VAMC, 150 Muir Road, Martinez, CA 94553.

The Contingent Negative Variation (CNV) is generated during the interval between a warning cue and an imperative stimulus. It is comprised of at least two components including an early phase with frontal predominance and a late phase maximal over fronto-central sites. The potential has been associated with anticipation, attention and response preparation (McCallum, 1988; Rockstroh et al., 1989).

We recorded the CNV in a classical auditory S1-S2 paradigm with a three second interstimulus interval. Subjects pressed a button upon detection of an acoustically cued imperative tone (S2, 1000 Hz, Go). Responses were withheld if the warning tone (S1, 1500 Hz in Go trials) was lower in frequency (500 Hz, NoGo). Subjects were eight neurological patients with damage centered in Brodmann areas 9, 44, 45 and 46 of the dorsolateral prefrontal cortex (PFCx) and age matched controls. All lesions were unilateral and due to infarction in the precentral branch of the middle cerebral artery. The average lesion volume was 51.8 cm³.

Patients responded more slowly (672 msec vs. 491 msec; $F=7.77$; $p<0.009$). Two averaging windows were set for statistical analysis of the early (500-700 msec post-S1) and late (200-400 msec pre-S2) CNV component. PFCx lesions resulted in focal reduction of the late phase of the CNV in electrodes located over areas of cortical damage ($F7=3.4 \mu V$, $F8=-10.3 \mu V$; $t=3.6$; $p<0.003$; $F3=-7.1 \mu V$; $F4=-15.2 \mu V$; $t=3.57$ $p<0.003$). Conversely, the early CNV was not reduced, but rather enhanced in amplitude over lesioned cortex ($F7=10.7 \mu V$, $F8=-6.1$, $t=2.3$, $p<0.04$).

Persistence of the early post-S1 negativity over areas of extensive cortical damage supports involvement of subcortical structures in this potential (Skinner & Yingling, 1977; Steriade, 1981). The current results indicate that functionally intact cortex is crucial for generation of the late component of the CNV.

Shifting attention: Comparison of autistic and cerebellar patients. E. Courchesne, N.A. Akshoomoff, J.P. Townsend, and O. Saitoh. Neuropsychology Research Laboratory, Children's Hospital Research Center, 3801 Frost Street, San Diego, CA 92123

MR and autopsy studies on autistic patients find evidence of early maldevelopment of the cerebellum. These findings raise the question of how cerebellar maldevelopment can contribute to the cognitive and social communication deficits seen in infantile autism.

Shifting of attentional focus is an essential operation in joint social attention, a milestone in the normal infant's development of social communication skills, and in the exploration and apprehension of the non-social environment. We had autistic patients perform tasks that required them to selectively, accurately and rapidly shift their focus of attention back and forth between visual and auditory stimuli. We previously reported that patients with acquired cerebellar lesions were impaired in this task. As compared to normal controls, autistic and cerebellar patients were similarly impaired at coordinating accurate and rapid mental shifts of attention, but given sufficient time, were able to correctly execute shifts. For more than 3 seconds following a command to shift attention from the current sensory modality, the autistic patients, like cerebellar patients, failed to fully inhibit attention to stimuli in that modality, and failed to detect a large percentage of stimulus information in the new modality of attention.

These findings are consistent with our proposal that the human cerebellum is involved in the voluntary coordination of selective, accurate, and rapid shifts of attention in a fashion analogous to its long-established analogous role in the coordination of movement. We suggest that cerebellar maldevelopment in autism may underlie the inability to control voluntary shifts of attention, undermining the normal operation of joint social attention, with the downstream consequence of impairing social and cognitive development.

GENERATION OF OLFACTORY RECEPTOR NEURONS IN VITRO: CHARACTERIZATION OF NEURONAL PROGENITOR CELLS AND THEIR MITOGENS. A.L. Calof¹, M. DeHamer¹, M. Adusumalli¹, J. Guevara¹, A. Lopez², and B. Olwin². ¹Dept. of Biological Sciences, U. of Iowa, Iowa City, IA 52242 and ²Dept. of Biochemistry, U. of Wisconsin, Madison, WI 53706.

The ability to generate new neurons is a unique property of the olfactory epithelium (OE) of adult mammals, and neurogenesis is robust in OE cultures as well. In explant cultures of OE purified from mouse embryos, the majority of 3H-TdR-incorporating, migratory cells divide once to generate 2 daughter cells in serum-free, defined culture medium; the daughter cells are immature olfactory receptor neurons, which express the neuronal cell adhesion molecule, NCAM, approximately 12 hrs after their precursors' terminal S phase. These precursor cells have been termed INPs, for Immediate Neuronal Precursors of olfactory receptor neurons. To understand further the cellular stages in this neurogenic pathway, we have characterized mitotically active cells in OE cultures and identified factors that affect their proliferation. Mitogenic effects on INPs are assessed by determining the number of migratory cells incorporating 3H-TdR from 24-48 hrs in culture, a period when neurogenesis has virtually ceased in the absence of growth factor stimulation. FGF1 and 2 (acidic and basic FGF, respectively) cause large increases (>2 fold) in this number, whereas PDGFaa, NGF, BDNF, and NT3 appear not to have a mitogenic effect. Pulse-chase experiments show that 85-90% of migratory cells incorporating 3H-TdR in FGF2-treated cultures also acquire NCAM immunoreactivity within 24 hrs, indicating that this population is composed primarily of INPs. Analysis of RNA prepared from OE indicates that tyrosine kinase FGF receptors FR1, 2, and 3 are expressed, providing a likely basis for observed effects of FGFs. Interestingly, a small subpopulation (3-4%) of migratory cells in OE cultures reacts with an antibody to the transcription factor MASH1, but these form only a fraction of mitotically-active cells. These MASH1-expressing cells may be a distinct subpopulation of OE progenitor cells, at a different stage of differentiation than the INPs. Supported by a seed grant from the Diabetes & Endocrinology Research Center of the University of Iowa.

NEURONAL STEM CELLS IN THE VOMERONASAL EPITHELIUM OF GARTER SNAKES ARE IDENTIFIED BY AN ANTIBODY FOR THE PSTAIRE REGION OF CELL DIVISION CYCLE KINASES. D.A. Holtzman* & C.L. Clarke. Neuroscience & Biopsychology Program, Oberlin College, Oberlin, OH 44074.

As in the olfactory epithelium of all vertebrates examined, the hypertrophied vomeronasal epithelium (VNE) of adult snakes is capable of generating new neurons as a result of normal turnover. Previous studies have shown that neuronal stem cells are located at the base of the VNE, incorporate 3H-thymidine (3H-T), and migrate apically through tall columns of bipolar, receptor cells as the cells age. An antibody was used which recognizes an evolutionarily conserved peptide sequence (PSTAIRE) within a family of cell division cycle homologous kinases (CDCs). CDCs have been shown previously to participate in the regulation of progression through the cell cycle in all cell types examined. In the present study, neonatal snakes were examined for anti-PSTAIRE immunoreactivity (IR) in relation to 3H-T labeling. After survival times of 1 h, 1 day, 1 week, 1 mo, and 2 mo post-3H-T injection, migration of 3H-T-labeled cells is observed from the base of the VNE (1h and 1 day) into the receptor cell columns (1 week-2 mo). After 2 mo post-3H-T injection, labeled cells are seen in the base of the VNE, which have not been seen previously in adults. Anti-PSTAIRE IR is only seen at the base of the VNE for all animals.

Incubation of antiserum pre-absorbed with p34^{cdc2} results in an absence of IR. In sections double-labeled for 3H-T and anti-PSTAIRE, all double-labeled cells are found at the base of the VNE, and the number of double-labeled cells/mm² decreases with increasing survival time. 15% of all 3H-T-labeled cells are not anti-PSTAIRE IR at 1 h post-3H-T injection, suggesting that only a subset of the total stem cell population is anti-PSTAIRE IR. The number of anti-PSTAIRE IR cells/mm² is significantly less in 5-6 mo old snakes (2 mo survival group) than in 2-4 mo old snakes (1h-1mo survival groups, $p<0.05$). We are currently examining both the number of anti-PSTAIRE IR cells in the adult snake VNE and the ratio of 3H-T-labeled cells to anti-PSTAIRE IR cells.

533.2

CHARACTERIZATION OF CULTURED NOESs (NEWBORN OLFACTORY EPITHELIAL SPHERES): AN IN VITRO SYSTEM OF MAMMALIAN NEUROGENESIS. S.K. Pixley*, M. Bage, V.M. Lee, D. Miller and M.L. Miller. Depts. of Anatomy and Cell Biology*, Environmental Health, Univ. of Cincinnati, Cincinnati, OH 45267-0521.

To obtain neurogenic olfactory cell cultures (Pixley, 1992 Neuron 8:1191), newborn Sprague Dawley rat nasal and olfactory cells were plated onto neocortical rat glial cells. Neurogenesis occurred predominantly in cellular aggregates that began to coalesce at 4 days and formed compact Newborn Olfactory Epithelial Spheres (NOESs) by 10-15 days after plating. These contained immature olfactory neurons (neuron specific tubulin-positive, olfactory marker protein-negative (OMP-)) and mature, OMP+, neurons. Here we show NOESs also contained dividing cells and four non-neuronal olfactory cell types. To examine internal organization, immunostained cultured cells were encapsulated in gelatin, plastic-embedded and sectioned (2 μ m). Most NOESs contained central cavities with multicellular walls. Neurons were primarily in outer 1-2 layers and sent dendritic processes centrally (confirmed by confocal microscopy). Cavity-lining cells were sustentacular (supporting), basal and Bowman's gland cells. Dividing cells were between neurons and non-neurons. NOESs also contained networks of glial cells and processes. Thus, olfactory cells *in vitro* re-created epithelial relationships similar, but not identical, to those *in vivo*. Double immunostaining showed that while almost all NOESs contained dividing cells and immature neurons, only the approximately 50% with OMP+ neurons contained the olfactory non-neurons. This suggests that olfactory non-neurons support neuronal maturation, but play little or no role in neurogenesis. [Support: NIH DC00347 to S.K.P.]

MAMMALIAN HOMOLOGS OF DROSOPHILA PRONEURAL AND NEUROGENIC GENES ARE EXPRESSED DURING RAT RETINAL DEVELOPMENT. J. Ahmad* and C.J. Barnstable. Dept. of Ophthalmology & Visual Science and Section of Neurobiology, Yale University School of Medicine, New Haven, CT.

An approach to understand the mechanism of the mammalian neuronal differentiation is to identify and study the expression of the mammalian homologs of *Drosophila* genes that are involved in neurogenesis. We have begun to identify and analyze the retinal expression of mammalian homologs of *Drosophila* proneural genes of *achaete-scute* complex and neurogenic gene, *Notch*. We have cloned a rat homolog of *achaete-scute* gene, *bHLHey1* which is expressed in the developing eye. *bHLHey1* gene is expressed in early embryo (E12) and postnatal stages. The presence of a functional bHLH transcription factor in retina was suggested by gel shift assays using PN1-retinal nuclear extract and an E-box element from the muscle creatine kinase (MCK) gene. The assay detected the formation of a complex which could be competitively inhibited by an excess of unlabeled E-box sequence, suggesting a role for bHLH transcription factor(s) in the regulation of retinal genes that may contain E-box element in their promoter. The homolog of *Drosophila Notch* which plays an important role in the determination of binary cell fate is expressed during retinal development. We have cloned *Notch* cDNA from rat E14 retina. The expression of *Notch*, which is observed as early as E12 in the developing eye vesicle is not detected in the postnatal retina. Preliminary immunocytochemical analysis using antibody raised against human *Notch* labels cells in the ventricular zone in E15 retina suggesting a role for *Notch* during the differentiation process in retina. PROLIFERATION ZONES IN THE BRAIN OF ADULT GYMNOTIFORM FISH: A QUANTITATIVE MAPPING STUDY. G.K.H. Zupanc* and I. Horschke. Department of Physical Biology, Max Planck Institute for Developmental Biology, 72011 Tübingen, Federal Republic of Germany.

In contrast to mammals, in fish the capability for the production of new neurons and glial cells in the brain during adulthood is very pronounced. In the present study, mitotic activity in the brain of *Apteronotus leptorhynchus*, a gymnotiform fish, was measured through the incorporation of 5-bromo-2'-deoxyuridine (BrdU) into DNA. Proliferation zones were visualized by employing an anti-BrdU antibody to frozen sections. In 5 fish analyzed quantitatively, the total number of cells generated in the brain within 2 hours varied between 66,000 and 128,000. For the following characterization of mitotic activity, the percentage of labelling found in the different cell groups was calculated relative to the total number of BrdU-labelled cells in the brain and averaged over the 5 individuals.

In the telencephalon and diencephalon, cell proliferation was low and totalled only 5 % in each of these two portions of the brain. Seven percent of all cells generated in the brain were localized in the mesencephalon. Proliferation was highest in the dorsal subdivision of the torus semicircularis (3 %) and in the optic tectum (2 %). In the rhombencephalon, the percentage of newborn cells totalled 14 %. The highest proliferative activity was found in the electrosensory lateral line lobe (4 %) and in the reticular formation (4 %). By far the greatest number of newborn cells, namely 70 %, were found in the different parts of the cerebellum. Cell proliferation was most pronounced in the molecular layers of the corpus cerebelli/eminencia granularis pars posterior (19 %) and of the valvula cerebelli (11 %) as well as in the eminentia granularis pars medialis (28 %). In contrast to the high proliferative activity in the molecular layers of the corpus cerebelli/eminencia granularis pars posterior and of the valvula cerebelli, the number of newborn cells was low in the respective granule cell layers (4 % and 2 %).

533.7

BIRTHDATE AND IDENTIFICATION OF SEROTONERGIC CELLS IN EMBRYONIC AND LARVAL APLYSIA. R. Marois*, P. Hofstadler, & T.J. Carew. Interdept. Neurosci. Progr., Depts. of Biol. and Psychol., Yale Univ., New Haven, CT 06520.

We previously described the emergence of five serotonergic (5HT) cells - an unpaired median (UM) and 2 bilateral pairs of cells - during the embryonic and larval development of *Aplysia* (Marois & Carew, 1990). Since 5HT is implicated in synaptic plasticity and growth cone motility, we wished to determine the functions of these cells in neuronal development. Here we focus on their birthdate, identity, fate, and central connections.

Based on whole-mount immunocytochemistry (ICC), we previously suggested that the 5HT cells were part of the cerebral ganglia. However, our ultrastructural studies now indicate that these cells are located in a hitherto unrecognized structure in *Aplysia* (but previously identified in other marine invertebrates: Bonar, 1978), the cephalic sensory organ. This structure is closely associated with the dorsal surface of the cerebral ganglia and its commissure. By hatching, this organ contains about 20 cells of various types, with the 5HT cells interspersed between 4 cells bearing sensory cilia that protrude to the animal's surface.

To trace the birth and fate of the five 5HT cells, we have exposed *Aplysia* to BrdU for 24 hr on each of the 11 days of embryonic development. Double-labeling ICC for both BrdU and 5HT showed that the UM cell is born on day 3 of embryogenesis, while the bilateral cells are generated between day 4 and 6. Although 5HT ICC suggests that the UM cell is resorbed at metamorphosis, we are currently assessing the fate of the other 5HT cells by looking for double-labeled cells in juvenile *Aplysia*.

We recently described the widespread projections of the 5HT cells at hatching (Marois et al., 1992). We now show that the 5HT profiles in the central ganglia are located both in the neuropil and on the surface of ganglion cells. This observation now enables us to examine the nature and function of these profiles during the development of the CNS of *Aplysia*.

EXPRESSION OF NEURON-SPECIFIC ANTIGENS DURING EMBRYONIC DEVELOPMENT OF THE LOBSTER.

V. Garzino*, S. Therianos and H. Reichert. Department of Zoology, University of Basel, CH-4051 Basel, Switzerland.

To investigate the developmental processes that generate the crustacean nervous system, we have produced several monoclonal antibodies that recognize specific neural epitopes in the developing embryonic nervous system of the lobster, *Homarus gammarus*. One of these antibodies recognizes an antigen expressed by all parts of the central and peripheral nervous system including the stomatogastric nervous system. This antigen, a 60 kD glycoprotein, is membrane associated and is localized either in the extracellular matrix or on glia that surrounds the cell bodies and processes of all neurons. The two other antibodies label different subpopulations of neurons as well as their neurites. The biochemical characterization of the antigens recognized by these two antibodies is in progress. The fact that all of these antigens are expressed with high specificity on developing neuronal cells suggests that they might play an important role in the formation of the lobster nervous system. Moreover, their specific expression during the embryonic development of the lobster nervous system makes them excellent cellular markers for investigations of neurogenesis and axogenesis in the crustaceans. (Supported by the Human Frontiers Science Program).

DEVELOPMENT OF NADPH DIAPHORASE IN THE CNS OF RAINBOW CICHLID FISH. Anne C. Rusoff*. Dept. of Biology, Montana State University, Bozeman, MT 59717.

Although Hope and Vincent (1989) did not find NADPH-diaphorase activity in the brain of any of the species of fish that they examined, this activity is plentiful in the brain of the rainbow cichlid, a perciform fish. Many clusters of cells and processes that are NADPH diaphorase + are present and clearly differentiated from neighboring non-positive cells and neuropil. The diaphorase activity first appears very early in development; 24 hours post-fertilization, when the eye is just visible, a cluster of diaphorase + cells is present on either side of the midline in the diencephalon. Additional clusters of diaphorase + cells gradually appear in a rostral to caudal gradient. The next cells appear in the hindbrain just rostral to the otic vesicle; before the embryos hatch, 3 clusters of diaphorase + cells are present in the hindbrain in the region of the otic vesicle and individual cells are seen in the rostral spinal cord. Gradually individual cells appear more caudally in the spinal cord--both near its dorsal and ventral margin. In the 3 days between hatching and swimming, many more diaphorase + cells are found in each of these areas, as well as in other regions, including other parts of the brainstem, the telencephalon, and the retina where some amacrine cells also become positive for NADPH diaphorase. GROWTH OF NEURONAL POPULATIONS DURING POSTEMBRYONIC DEVELOPMENT IN HELISOMA TRIVOLVIS. J. I. Goldberg* and K. J. Cavers. Dept. of Zoology, Univ. of Alberta, Edmonton, Alberta, Canada T6G 2E9.

In the CNS of various gastropod molluscs, the number of serotonin-immunoreactive neurons increases during specific periods of postembryonic development. These increases may result from the generation and differentiation of new neurons, the differentiation of extant precursor cells or the switching of neurotransmitter phenotypes. As a first step in distinguishing between these developmental pathways, we carried out neuronal cell counts on *Helisoma* ganglia at two stages of postembryonic development. Neurons were selectively stained with methylene blue and counted in wholemount preparations of the buccal, left parietal and visceral ganglia. In each of these ganglia, there was a significant increase in the neuronal population between postembryonic stages P3 and P10. Furthermore, the increase in neuron number was well beyond the corresponding increase in serotonin-immunoreactive neurons for each ganglion. Ganglia were treated with 5-bromodeoxyuridine (BrdU) and then processed for anti-BrdU immunofluorescence to test for intraganglionic cell divisions. Pairs of stained cells were observed in some ganglia. Moreover, the size of the stained cells was often larger than that observed for non-neuronal cells, indicating that at least some of the cell divisions generate neurons. These data suggest that neuron addition, possibly through intraganglionic cell division and differentiation, is a normal characteristic of postembryonic development in gastropod molluscs.

PERIPHERAL INDUCTION OF SEGMENT SPECIFIC NEURONS IN THE LEECH MEDIATED BY IDENTIFIABLE CENTRAL NEURONS.

T. Becker*, A.J. Berliner and E.R. Macagno. Dept. of Biological Sciences, Columbia University, New York, NY 10027 USA

Midbody ganglia (MG) 5 and 6 of the leech *Hirudo medicinalis* contain several hundred small neurons not found in other ganglia, the peripherally induced central (PIC) neurons. PIC neuron birth is induced by the male sexual organ during a critical period from embryonic day (E) 13 to 16 of leech embryogenesis. The mitogenic signal is conveyed by the so-called sex nerves that connect MG5 and MG6 to the male sexual organ. To test whether the signal is conveyed by either afferent fibers or efferent fibers we have undertaken a cellular analysis of the sex nerves in segments 5 and 6.

By staining with neuron-specific monoclonal antibodies we have determined that peripheral neurons in the male sex organ develop at about E15, but their axons do not reach the CNS before E20 and hence are unlikely to be involved in the induction.

By injection of the dyes Dil and DiO into the primordia of the male sex organ, we have mapped central neurons that are connected to this organ during the critical period. Both MG5 and MG6 contain a complement of 10 pairs of neurons, and MG6 an additional pair, that innervate the male genitalia. Single and pairwise ablations have shown that at least two of these neurons are involved in the induction in that their ablation interferes with subsequent PIC neuron birth in MG5 and MG6. Hence, a retrograde interaction of central neurons with the periphery leads to segment-specific neuron birth.

BRAIN NEUROBLASTS IN THE GRASSHOPPER EMBRYO: CELLULAR AND MOLECULAR CHARACTERIZATION.

H. Reichert*, L. Williams, D. Zacharias and T. Meier. Department of Zoology, University of Basel, CH-4051 Basel, Switzerland.

The brain neuroblasts in the embryonic grasshopper were studied by BUdR incorporation and immunocytochemistry and were mapped by reconstruction of serial sections. An array of large dividing neuroblasts is observed by the 25% stage. Each of these neuroblasts divides asymmetrically to produce a chain of ganglion mother cells, and each ganglion mother cell divides symmetrically to produce a pair of neurons. A set of 130 mitotically active, large neuroblasts are found in each brain hemisphere at the 30-45% stages. Through morphogenetic movements that occur between the 30-35% stages these neuroblasts become located in positions which are characteristic of the major regions of the mature brain. Many of the brain neuroblasts can be identified as individuals based on their stereotyped position in the neurogenic array. Immunocytochemical experiments with antibodies against, *engrailed*, fasciclin I and TERM-1 show that brain neuroblasts can also be characterized by their expression of cell-specific molecular labels. These studies indicate that many features of the insect brain derive from a surprisingly simple and stereotyped set of neuronal precursor cells. Thus, concepts and methods that have been used to study neurogenesis in the simpler segmental ganglia will also be applicable to the insect brain. (Supported by SNSF).

***pollux*, A Novel Membrane Protein, Is Concentrated In A Subset Of Axon Fascicles Within The Drosophila CNS.**

S. D. Zhang¹, J. A. Kassis², B. A. Olde¹, D. M. Mellerick³, A. J. Nazarali^{*3} and W. F. Odenwald¹ 1) Lab. of Neurochemistry, NINDS, NIH, Bethesda, MD 20892, 2) Ctr. for Biologics Evaluation and Research, FDA, Bethesda, MD 20892, 3) Lab. of Biochemical Genetics, NHLBI, NIH, Bethesda MD 20892

Enhancer-detection screening in flies has led to the discovery of a gene, *pollux*, which encodes a 77KD protein that contains an N-terminally-located RGD cell attachment sequence and a centrally-located transmembrane domain. The putative transmembrane protein also contains a leucine zipper motif and shares 43% identity (66% similarity) over 74 aa with the human oncogene *trc-1*. The significance of this high homology is currently unknown. Immunolocalization studies carried out with polyclonal antibodies raised against a full-length recombinant protein indicate that within the CNS, *pollux* is selectively concentrated in the axon fascicles which reside in the longitudinal connectives and the supraoesophageal commissure. Little or no protein is detected in axon fascicles which makeup other commissures. *pollux* message and protein are also detected in the trachea. Over expression in cultured *Drosophila* S2 cells does not induce cell-cell aggregation, indicating that *pollux* is not a homophilic adhesion molecule. We are currently testing the hypothesis that *pollux* may play a role in cell adhesion via its RGD motif.

CELL LINEAGE AND DETERMINATION: VISUAL SYSTEM

RETINOIC ACID INFLUENCES THE DIFFERENTIATION OF PHOTORECEPTOR CELLS IN EMBRYONIC RAT RETINA *IN VITRO*. M.W. Kelley* and T. A. Reh. Department of Biological Structure, University of Washington, Seattle, WA 98195.

The differentiation of specific cell types in the developing mammalian retina is influenced by environmental cues. However, the specific biochemical factors that determine individual cell types have not been identified. Retinoic acid has been demonstrated to effect determination of individual cell types during vertebrate development and is present in the embryonic retina.

The effects of retinoic acid on the differentiation of specific retinal cell types were examined by establishing embryonic retinal cells from different time points during development as high density dissociated cell cultures. Different concentrations of all-trans retinoic acid or of the retinoic acid vehicle (DMSO) were added to the culture media. After 6 or 8 days *in vitro*, differentiation of specific cell types was determined using immunocytochemistry. Based on immunolabelling with two different photoreceptor markers (Rho 4D2 and Recoverin), the application of retinoic acid caused a significant and dose dependent increase in the number of photoreceptor cells in each culture. This effect was observed in cultures established on E15, E18 and P4. The overall cell number did not change with retinoic acid treatment, and there was no increase in the number of amacrine cells or cone bipolar neurons.

In order to determine whether the effect of retinoic acid was to increase the rate of differentiation of already committed cells or to influence the commitment of uncommitted progenitor cells, whole E18 retinas were incubated in BrdU prior to establishment of dissociated cell cultures. Preliminary results indicate a significant increase in the number of double labeled rod cells in retinoic acid treated cultures.

The results of these experiments suggest that retinoic acid may play a controlling role in the determination of retinal progenitor cells as photoreceptor cells.

MUTATIONS IN *TROL* AFFECT NEUROBLAST DIVISION IN THE LARVAL CNS OF *DROSOPHILA MELANOGASTER*. S. Datta*

Dept. of Biochemistry and Biophysics and Center for Advanced Invertebrate Molecular Sciences, Texas A & M University, College Station, Texas 77843-2475

We are interested in the molecular mechanisms regulating neuroblast proliferation and differentiation in the CNS. We have previously shown that a hypomorphic mutation at the *trol* locus causes a 90% drop in the dividing cell population of the larval CNS (1). To investigate this further, we have used bromodeoxyuridine incorporation studies to determine if *trol* is required for the proliferation of specific neuronal lineages within the larval CNS or for the differentiation of a specific stage of development. Bromodeoxyuridine was applied topically or fed to staged mutant and control larvae. Incorporation patterns were visualized with primary anti-bromodeoxyuridine antibodies and secondary antibodies conjugated with horse radish peroxidase. Studies of the hypomorphic allele *trol^{sd}* suggest that low levels of *trol* expression are sufficient for the proliferation of some lineages in the larval lobes, but not for most lineages in the thoracic portion of the ventral ganglion. Studies with a null allele of *trol*, *trol^{sdm}*, are underway.

REGENERATION OF PHOTORECEPTORS IN GOLDFISH RETINA FOLLOWING LASER LESIONS. J.E. Braisted* & P.A. Raymond. Dept. Anat. & Cell Bio., Univ. Mich., Ann Arbor, 48109.

Adult goldfish were lenticomized and 2-4 lesions were placed in ventral retina with an argon laser. Cones were selectively killed in a ~220µm diameter patch after 130mw lesions, and both rods and cones in a ~300µm patch after 160mw lesions. To monitor cell proliferation, eyes were injected with bromodeoxyuridine (BUdR) at 3d and examined at 4d. Radial cryosections were double-labeled with anti-BUdR and RET1, specific for a nuclear antigen in some retinal cells in goldfish, or FGP2, specific for goldfish GFAP (from M. Schwartz). Within the lesions, most BUdR+ nuclei were in the photoreceptor (PR) layer. Some, which labeled with RET1 and FGP2, were Müller glia. To monitor regeneration, retinas were examined at 3-5 wks after multiple injections of BUdR. Regenerated cones (RET1+/BUdR+) were found in all lesions, and regenerated rods (RET1-/BUdR+) in 160mw lesions. To determine whether dopaminergic (DA) neurons regenerated if they were selectively killed in addition to PRs, eyes were injected with 6-hydroxydopamine, then lesioned (160mw). At 7-9 wks after multiple injections of BUdR, retinal wholemounts were triple-labeled with anti-tyrosine hydroxylase (for DA neurons), RET1, and anti-BUdR. Although PRs regenerated within the lesions, DA neurons did not. Together with our previous data, this suggests that PRs can regenerate if they are selectively lost, but regeneration of DA neurons requires substantial loss of both PRs and inner retinal neurons. Supported by EY04318 and MH10220.

REGENERATION OF NEURAL RETINA FROM RETINAL PIGMENTED EPITHELIUM (RPE) IN ADULT GOLDFISH. J.K. Knight* and P.A. Raymond, Neuroscience Program and Dept. Anat. & Cell Biology, University of Michigan, Ann Arbor, MI 48109.

In some species, under conditions such as addition of growth factors, differentiated RPE can transdifferentiate into neural retina. Here we present evidence that the RPE in adult goldfish can transdifferentiate into retina without exogenous growth factors.

The neural retinas of goldfish were removed by vacuum suction. To examine the time course of regeneration, bromodeoxyuridine (BrdU) was injected intraocularly at 4d to 18d, and retinas were examined 1d to 10d later. By 5d after retinal removal, RPE cells had begun to lose melanin granules and to incorporate BrdU. By 11d, a neuroepithelium had formed, which differentiated into a laminated but disorganized retina by 30 d. Regenerated retinas had three distinguishing characteristics: 1) They were labelled across their full extent by an anti-goldfish-vimentin antibody (from M. Schwartz) which in the intact eye labelled only the proliferative germinal zone of the retina and the RPE. 2) Some cones, inner nuclear layer neurons and ganglion cells in regenerated retinas were double-labelled with BrdU and a retina-specific antibody, RET1. 3) In all cases, a monolayer of RPE was present, and retinas were oriented correctly, with ganglion cells on the vitreal side.

Work by others has implicated basic fibroblast growth factor (FGF) in RPE transdifferentiation. We are currently using both antibodies and *in situ* hybridization to assay for endogenous changes in FGF and FGF receptor expression. Supported by NIH EY04318.

DIVERSITY OF IDENTIFIABLE RETINAL NEURONS DIFFERENTIATING IN MONOLAYER CULTURES. H.D. Hofmann* and V. Mückel, Institute of Anatomy, University of Freiburg, D-7800 Freiburg, Germany

On the basis of morphological, immunocytochemical and autoradiographic criteria we have characterized the phenotypes expressed by immature retinal neurons differentiating in monolayer cultures prepared from early postnatal rabbits. Survival of Thy 1-positive ganglion cells (1-2% of all cells) depended on the presence of neurotrophic factors. A morphologically heterogeneous cell population which showed GABA-IR and high affinity uptake of 3H-GABA was classified as GABAergic amacrine cells (6.5%). Different subpopulations could be distinguished according to their responsiveness to the glutamate receptor agonists NMDA, kainate and quisqualate as demonstrated autoradiographically. As *in situ* presumed dopaminergic neurons *in vitro* were low in number, had large dendritic fields and showed colocalization of tyrosine hydroxylase-IR and GABAergic markers. Presumptive glycinergic amacrine cells (18.5%) were rather uniform in size and released their transmitter in response to kainate and quisqualate, but not to NMDA. Cultured bipolar cells (4%) consisting of glutamatergic and glycinergic subpopulations were identifiable by specific monoclonal antibodies and by their characteristic bipolar cell-like morphology. Horizontal cells (approximately 1%) of both the A- and B-type were highly differentiated with respect to morphology, transmitter phenotype and expression of characteristic antigens (neurofilaments, calbindin-28kD). Incompletely differentiated photoreceptors (73%) took up 3H-glutamate and were recognized by antibodies to opsin.

These results demonstrate that in the artificial and largely homogenous environment of monolayer cultures a variety of retinal cell types are capable of expressing many of their specific phenotypic properties, apparently under the control of intrinsic programs.

EGF AND TGF α CONTROL CELL FATE DETERMINATION IN DEVELOPING RAT RETINA. R.M. Anchan* and T. A. Reh, Department of Biological Structure, University of Washington, Seattle, WA, 98195.

The mechanisms that control the choice of cell phenotype during retinal development are not well characterized. We previously reported that EGF and TGF α are mitogens for retinal progenitor cells (Anchan et al, 1991, Neuron). We now report that EGF and TGF α also selectively control the differentiation of particular retinal cell types. Using Bromo-deoxyUridine (BrdU) pulse labelling studies of embryonic day 13, 15, 17 and postnatal day 3 rat retinas grown for up to 17 days *in vitro*, we were able to identify dividing progenitor cells in our cultures. By coupling BrdU incorporation with the expression of specific neuronal antigens as determined by immunostaining, we followed the fate of these cells. Immunolabelling for rod photoreceptors revealed that the number of rods generated *in vitro* is concomitantly reduced in EGF treated embryonic cultures as evidenced by decreased BrdU-Recoverin, BrdU-Rho-4D2 immunostained cells. These populations were 50 and 10 percent of control cultures respectively. In contrast the number of double labelled C1+BrdU immunoreactive cells increased in the growth factor treated cultures nearly three fold that of controls. These results demonstrate that for embryonic cultures EGF or TGF α inhibit the production of Rho-4D2 and Recoverin immunoreactive cells while enhancing the generation of C1 immunoreactive cells. These data indicate that EGF and TGF α control differentiation of neuroepithelial cells into specific retinal phenotypes by influencing cell commitment during rat retinal development. NIH 2R01 NS28308-04

ENVIRONMENTAL FACTORS THAT INFLUENCE DETERMINATION OF THE GANGLION CELL PHENOTYPE IN DEVELOPING RETINA. D.K. Waid*, S.C. McLoon, Dept. of Cell Biol. and Neuroanatomy, Univ. of Minnesota, Minneapolis, MN 55455.

The mature retina consists of seven major cell types. Previous studies showed that all cell types can arise from common precursor cells. This suggests that cell fate is not determined solely by lineage dependent mechanisms. Moreover, other studies suggest that local environmental factors are important in the determination of cell fate. Ganglion cells are the first cell type to develop in the retina, and few ganglion cells are born late in development. It could be that the environment of the older retina is not conducive to ganglion cell determination. To test this, retinal cells from young (E4) chick embryos, an age prior to the genesis of most ganglion cells, were cultured in the presence of retinal cells from E4 or older (E9) embryos, an age by which most ganglion cells have been generated. The two cell populations were separated by a membrane that prevented direct cell-cell contact between the two populations but that allowed the passage of soluble molecules. After one or two days in culture, the cells were fixed, and immunohistochemistry with retinal ganglion cell specific antibodies was used to identify and quantify the number of ganglion cells in the test population. E4 retinal cells cultured in the presence of other E4 cells produced approximately twice as many ganglion cells as E4 cells cultured in the presence of E9 cells. This result suggests that the cells in the older developing retina produce some factor that actively inhibits development of the ganglion cell phenotype and/or promotes development of other cell types. Furthermore, it suggests that the factor responsible for this activity is diffusible. (Supported by EY07133 and EY09537.)

DEVELOPMENT OF NEUROPEPTIDE Y AND TYROSINE HYDROXYLASE AMACRINE CELLS IN TADPOLE RETINA: CELL LINEAGE AND SPATIAL DOMAINS. S. Huang* and S. A. Moody, Dept. Anatomy and Neuroscience Program, The George Washington University, Washington, D.C. 20037

The blastomere origin and the regional location of two amacrine neurotransmitter phenotypes in the tadpole retina were investigated to understand how neurotransmitter choices are made during development. Amacrine cells first become immunoreactive to Neuropeptide Y (NPY) and tyrosine hydroxylase (TH) shortly after the cells are generated (stage 39-40). By labeling retinal progenitors with a fluorescent dye, we show that the ancestral origin of these two neurotransmitter phenotypes is similar; both NPY and TH amacrine cells are proportionally derived from the same group of animal pole blastomeres that produces other retinal cell types (Huang and Moody, J. Neurosci., 1993). By mapping the location of these two amacrine neurotransmitter phenotypes, we demonstrate that the earliest detectable TH and NPY amacrine cells are scattered throughout the developing retina. There is no boundary between the two neurotransmitter phenotypes, but more TH amacrine cells are in the periphery, whereas more NPY amacrine cells are in the center. At later stages, when the TH and NPY cell numbers increase, the amacrine cells with same neurotransmitter phenotype tend to segregate as small cell clusters. The early scattered NPY and TH cells are joined by others with the same neurotransmitter phenotype. These data demonstrate that the neurotransmitter phenotype of amacrine cells is not determined by their ancestral origin but is under the influence of local cell interaction. Supported by NIH-EY10096.

INFLUENCE OF NATURALLY OCCURRING CELL DEATH ON APPARENT CLONE COMPOSITION IN RETINAL LINEAGE ANALYSIS. James T. Voyvodic* and Martin C. Raff, Biol. Dept., Univ. Coll. Lond., London WC1E 6BT, UK.

Cell lineage studies in the nervous system provide information about the developmental history of different cell types. Identifying branch points within a lineage helps to indicate the stages during development at which cell-identity decisions are made. Accurately determining such branch points, however, requires that all cells within a clone be identified. To what extent, therefore, might naturally occurring cell death confuse the analysis of lineage relationships by making the surviving members of a clone appear more closely related than they actually are?

A computer model of 1000 identical 8-cell "clones" was tested, varying the probability of cell death from 1% to 75%. With 20% death, 0.2% of clones had only 2 surviving cells, whereas at 50% death, 14% of 8-cell clones had 2 survivors. In these cases the surviving pair of cells were more likely to be distant cousins than siblings.

In the rat retina, we and others estimate normal death within some cell types to be over 60%. The model therefore predicts that analysis of retinal clone composition after the cell death period will indicate more lineage branching variability than may actually be the case.

THE β AMYLOID PRECURSOR PROTEIN FUNCTIONS IN NEURITE OUTGROWTH AND BINDS TO THE IKVAV ACTIVE SITE OF LAMININ. M.C. Kibbey, M. Jucker, B.S. Weeks, R.L. Neve, W.E. Van Nostrand, and H.K. Kleinman*. LDB, Natl. Inst. Dental Research, NIH, Bethesda MD 20892; Swiss Fed. Inst. Tech., Zurich Switzerland; McLean Hospital, Belmont MA 02178; UC@Irvine CA 92717.

We previously described a 110 Kd binding protein (LBP110) from mouse neonate brain for the IKVAV containing site of the laminin A chain. Due to similarities in localization of both LBP110 and the β amyloid precursor protein (APP) under both normal conditions and following injury, we investigated if LBP110 was a member of the APP family. Affinity-purified LBP110 was recognized by 4 different APP antisera and 2 different sources of APP were recognized by LBP110 antiserum. By ligand blot, APP specifically bound IKVAV-containing peptide. NGF-treatment of PC12 cells upregulated an LBP110-immunoreactive protein similar to that which has been reported for APP. PC12 cells transfected with APP antisense had decreased LBP110 and APP and reduced ability to form neurites on both laminin and IKVAV peptide. These studies suggest a normal function for APP in neurite outgrowth and binding to the IKVAV site of laminin.

CHARACTERISTICS OF GANGLIOSIDES INCLUDING O-ACETYLATED SPECIES IN GROWTH CONES. M. Igarashi¹, S. Saito¹, Y. Komiya², H. Waki¹, and S. Ando¹. ¹Department of Molecular and Cellular Neurobiology, Gunma University School of Medicine, Maebashi, Gunma 371, and ²Department of Membrane Biochemistry, Tokyo Metropolitan Institute of Gerontology, Itabashi, Tokyo 173, Japan.

Growth cones are thought to achieve accurate synaptogenesis through special molecular recognition systems, although most of these systems have not been characterized. Gangliosides, or sialic acid-containing glycolipids, are enriched in neural tissues and are believed to play roles in modulating cell functions. Certain specific gangliosides are expressed only at early developmental stages in nervous systems. O-acetyl-GD3, in particular, has been proposed to be involved in mammalian CNS development. To investigate the characteristics of gangliosides, including the O-acetylated species, we isolated the gangliosides from growth cone membranes (GCM) of rat brain at several developmental stages, without alkali saponification, and quantitatively analyzed them. At several stages, GCM contained significantly larger amounts of gangliosides than the other membrane subfractions. The absolute ganglioside content of GCM increased in amount with development, while the relative amount of GD3 gradually decreased, and that of GD1a dramatically increased. GCM had the higher ratio of GD1a to GM3 plus GD3 than the perinuclear fraction. There were three O-acetylated gangliosides in GCM: O-acetyl-GD3, O-acetyl-GT1b, and O-acetyl-GQ1b. The molar ratio of O-acetyl-GD3 decreased in GCM at later stages (5% of the total gangliosides at embryonic day 17 to 1% at postnatal day 5), however, the other O-acetylated species were almost constant (approximately 1.5% of the total). Our results show that there are significant differences in ganglioside content and composition between the membrane subfraction of growth cones and the perinuclear fraction, suggesting that several species of gangliosides, including O-acetyl-GD3, play a role in growth cone function.

INHIBITION OF AXONAL GROWTH BY SNAP-25 ANTISENSE OLIGONUCLEOTIDES IN VITRO AND IN VIVO Julie K. Staple, Astrid Osen-Sand, Marina Catsicas[#], Kenneth A. Jones, Guidon Ayala, Jonathan Knowles, G. Grenningloh and Stefan Catsicas*

Glaxo Institute for Molecular Biology, Geneva; and Institute of Anatomy[#], University of Lausanne; Switzerland.

Axonal elongation and the transformation of growth cones to synaptic terminals are major steps of brain development and the molecular mechanisms involved form the basis of the correct wiring of the nervous system. The same mechanisms may also contribute to the remodelling of nerve terminals that occurs in the adult brain, as a morphological substrate to memory and learning. Here we have investigated the function of the nerve terminal protein SNAP-25 during development. We show that SNAP-25 is expressed in axonal growth cones during late stages of elongation and that selective inhibition of SNAP-25 expression prevents neurite elongation by rat cortical neurones and PC-12 cells in vitro and by amacrine cells of the developing chick retina in vivo. These results demonstrate that SNAP-25 plays a key role in axonal growth. They also suggest that high levels of SNAP-25 expression in specific areas of the adult brain may contribute to nerve terminal plasticity.

535.2

ANTI-IDIDIOTYPIC ANTIBODIES TO GM1 ACT AS PROBES TO IDENTIFY GANGLIOSIDE BINDING PROTEINS AND ENHANCE CELL ADHESION. M.J. Riggott* and W.D. Matthew. Dept. of Neurobiology, Duke University Medical Center, Durham, NC 27710

Axon outgrowth during development and regeneration is accompanied by changes in ganglioside composition. Exogenously added gangliosides are potent stimulators of neurite outgrowth and sprouting and facilitate cell adhesion. Gangliosides may act by direct interaction of their carbohydrate moieties with membrane proteins. The study of ganglioside-protein interactions has been hampered by the lack of probes that recognize ganglioside binding proteins. We have used a novel immunological method to generate putative anti-idiotypic antibodies that bind the functional sites of GM1 binding proteins. These antibodies bind the beta subunit of cholera toxin, a GM1 binding protein. These antibodies facilitate cell adhesion of dissociated embryonic hippocampal neurons in *in vitro* bioassays. The antibodies recognize antigens on the cell surface. In Western blots, these antibodies bind proteins at 150, 66, 57 and 45 kD. The 150 kD protein is recognized only in homogenates of neural tissue. Cultured embryonic hippocampal cells treated with the antibody respond by protein tyrosine phosphorylation of proteins at 75 and 45 kD. The identity of the proteins recognized by the antibodies and the substrate of protein tyrosine phosphorylation will indicate whether anti-idiotypic antibodies can be used to determine the mechanism for ganglioside-protein interaction in cell adhesion and neurite outgrowth in the nervous system.

535.4

THE WSPWS MOTIF OF THROMBOSPONDIN PROMOTES NEURITE OUTGROWTH FROM EMBRYONIC NEURONS D.J. Osterhout⁺, V.M. Dixit, and K.S. O'Shea⁺, Departments of Pathology, and Anatomy and Cell Biology⁺, University of Michigan, Ann Arbor, MI 48109

Thrombospondin (TSP) is a trimeric glycoprotein which is enriched in the extracellular matrix during the development of the nervous system. The ability of TSP to modulate cell adhesion, migration and neurite outgrowth appears to be mediated by certain functional domains within the molecule. The VTCG and WSPWS sequences, for example, found in the type I repeats of TSP, support adhesion of various non-neuronal cells. Since A4.1, a monoclonal antibody directed to the type I repeat, can inhibit neurite outgrowth, both sequences were tested for their ability to promote neurite outgrowth.

When dissociated rat embryonic neurons were plated onto various synthetic peptides or TSP adsorbed to nitrocellulose, the WSPWS peptide stimulated neurite outgrowth in a dose dependent manner. Neurites formed on WSPWS were morphologically similar to those observed on intact TSP. Soluble WSPWS inhibited neurite outgrowth on TSP in a dose dependent manner; the VTCG peptide had no effect on process extension. Addition of soluble heparin was partially effective in inhibiting process extension on the WSPWS peptide, suggesting that this activity may be mediated by binding to a heparin-like moiety.

535.6

CHANGES IN MOLECULAR EXPRESSION OF LAMP ON LAMINA II NEURONS IN RAT SPINAL CORD AFTER DORSAL ROOT DEAFFERENTATION. B. Zhang*, P. Levitt and M. Murray. Department of Anatomy and Neurobiology, Medical College of Pennsylvania, Philadelphia, Pa 19129.

Limbic System Associated Membrane Protein (LAMP) is a 64 kd membrane protein expressed by neurons in limbic system or limbic system associated structures. In developing systems, LAMP is expressed on axons and on their target neurons. In adults, LAMP expression is confirmed to the post synaptic membranes. Changes in molecular expression of LAMP in lamina II neurons of adult rat spinal cord after deafferentation have been studied using immunocytochemical techniques. Dorsal roots were sectioned and dorsal root ganglia removed from L1 to S2 in 17 rats. Four unoperated rats and two sham operated rats served as controls. At 3, 10 or 60 days after deafferentation, rats were perfused with 4% paraformaldehyde, and the L4-5 segments of the spinal cord were removed and prepared for light and electron immunocytochemistry (LM-ICC and EM-ICC). LM-ICC demonstrated that the density of LAMP immunoreactivity in lamina II appeared normal compared with controls at 3 days postoperatively, but started to decrease at 10 days and had decreased still more by 60 days after deafferentation. LAMP is expressed on post-synaptic membranes in control, but is expressed on both pre- and post-synaptic membranes at 10 days after deafferentation. The decrease of LAMP immunoreactivity density indicates that molecular expression on the second order neurons of lamina II may be regulated by afferent information or changes in the pre-synaptic complement. The reexpression of LAMP on axonal profiles after deafferentation may identify axons that sprout in response to deafferentation.

Supported by NIH grant No. NS24707 and MH45507.

LAMP: A NOVEL GPI-LINKED PROTEIN INVOLVED IN CELL-TO-SUBSTRATUM ADHESION BY SPECIFIC NEURONAL POPULATIONS. *V. Zhukareva and P. Levitt** Department of Anatomy and Neurobiology, The Medical College of Pennsylvania, Philadelphia, PA 19129

We have recently shown that the limbic system-associated protein (LAMP) is a phosphatidylinositol (PI)-linked protein. Members of this family in the nervous system have been postulated to participate in a variety of recognition events, including cell adhesion. LAMP exhibits characteristics, such as an early and restricted pattern of expression and disruption of fiber-target interactions by anti-LAMP (Keller, et al, 1989), that are indicative of a developmentally significant protein. PI-specific phospholipase C (PI-PLC) can be used to release LAMP from membranes for subsequent affinity purification. To test the ability of LAMP to facilitate substrate adhesion and growth, we utilized a system developed by Lagenaur and Lemmon (1987). Methanol-solubilized nitrocellulose-coated dishes were dotted with affinity purified LAMP or poly-D-lysine (PDL) and embryonic brain cells from limbic and non-limbic areas were plated for 9 - 24 h. All population of neurons bind to and extend processes on the PDL. Perirhinal limbic cortical neurons bind specifically to substrate-bound LAMP, forming small cell aggregates with neuritic processes. Monoclonal anti-LAMP significantly reduces such binding and initiating of process growth. Almost all non-limbic fetal neurons from somatosensory cortex and olfactory bulb failed to bind, and those that bound did not extend neurites to any significant extent. The present results provide direct evidence that LAMP can specifically regulate adhesion and outgrowth of select neurons during development. Supported by NIMH grant MH45507.

535.9

REMOVAL OF POLYSIALIC ACID AFFECTS ARBORIZATION OF OPTIC AXONS DURING DEVELOPMENT IN XENOPUS LAEVIS TADPOLES. *J.K. Ivins*, M.J. Li, U. Rutishauser and S.E. Fraser.* Caltech and Case Western Reserve University.

The neural cell adhesion molecule NCAM is often coupled to long chains of α 2,8 linked sialic acid residues known as polysialic acid (PSA). NCAM-PSA has been implicated as a regulator of neurite outgrowth and branching both *in vitro* and *in vivo* by virtue of its ability to interfere with cell-cell interactions. We have determined the distribution of NCAM and NCAM-PSA during visual system development in *Xenopus laevis* tadpoles and have examined the effects of enzymatically removing PSA on the patterns of arborization of optic axons in living tadpoles. Immunohistochemical localization of NCAM and PSA in tadpoles showed that NCAM is present on both retinal ganglion cell axons and tectal neurons, while PSA is present only on tectal neurons. To examine the role of PSA in visual system development, tadpoles were injected intraventricularly between stages 45 and 47 with a highly specific endoneuraminidase, endo N, which cleaves PSA from NCAM. Individual retinal ganglion cells were labeled with dil and their axons visualized by low light-level video microscopy. We observed that the retinal ganglion cells in endo-N treated tadpoles sprouted consistently longer, typically unbranched terminal arbors than control animals. These observations are most consistent with a model in which PSA on the tectal neurons promotes fasciculation between optic fibers. Removal of PSA from the tectum may facilitate cell surface interactions between afferent fibers and the tectal neuropil, resulting in increased arbor growth.

SEVERAL CHEMICALLY DEFINED SURFACES ARE CONDUCTIVE TO THE ADHESION, SURVIVAL AND DIRECTED GROWTH OF EMBRYONIC HIPPOCAMPAL AND SPINAL CORD NEURONS IN VITRO. *A.E. Schaffner*¹, K. Foster², J.L. Hickman², D.A. Stenger³ and J.L. Barker¹*, Laboratory of Neurophysiology, NINDS, NIH, Bethesda, MD 20892¹, Science Applications International Corp., Mclean, VA 22102² and Naval Research Laboratory, Washington, D.C. 20735³.

Several trimethoxysilane derivatives were covalently attached to glass coverslips and compared to poly-d-lysine for their ability to support the adhesion and growth of embryonic neurons. Tissue from 19 day embryonic rat hippocampus and 15 day embryonic cervical, ventral spinal cord was enzymatically or mechanically dissociated and plated at a density of 350 cells/mm² on glass coverslips in serum-containing or serum-free medium. Surfaces were assayed qualitatively for neuronal survival and neurite outgrowth over a 2-week period. In general, cells did better after mechanical dissociation in serum-free medium and spinal cord neurons grew on a greater number of different chemically modified surfaces than did hippocampal neurons. Appropriate surfaces were later used to construct simple geometric patterns (such as parallel lines ~ 10-100 μ m apart). We were able to achieve directed growth of nerve cell processes on the patterned substrates. We are presently devising patterns and conditions that will allow us to manipulate synaptic interactions between defined neuronal phenotypes *in vitro*.

EXPRESSION OF THE GROWTH-RELATED NEURAL CELL ADHESION MOLECULE TAG-1/AXONIN-1 IN THE ADULT MAMMALIAN BRAIN *D.P. Wolfer*, A. Henchman-Beatty, R. Giger, P. Sonderegger and H.P. Lipp*

Departments of Anatomy and Biochemistry, University of Zurich, Switzerland

TAG-1/axonin-1, a member of the Ig-FNIII-superfamily of neural cell adhesion molecules, occurs in two forms, one axonally secreted, the other phosphoinositol-anchored to the cell membrane. It is expressed by neurons extending axons *in vitro* and, as an immobilised substratum, stimulates axonal growth. Soluble TAG-1/axonin-1 affects neurite fasciculation in culture. *In vivo*, in the rodent nervous system, axonin-1-like immunoreactivity is associated with the development of spinal and cranial nerves, with the formation of several, mostly long projecting, fibre tracts, and with the precerebellar neuronal migratory streams. cDNAs have been cloned for the homologues of TAG-1/axonin-1 in chick, mouse, rat and man.

A polyclonal antiserum against TAG-1/axonin-1 shows staining in the molecular layer of adult rodent and human cerebellum, if tissue is fixed with glutaraldehyde. Correspondingly, mRNA for TAG-1/axonin-1 can be visualised in cerebellar granule cells of 4 month old mice by *in situ* hybridisation using digoxigenin-labelled cRNA probes. Moreover, in the adult mouse brain, TAG-1/axonin-1 mRNA is detected in dentate granule cells, in pyramidal cells of hippocampal areas CA1 and CA3, as well as within scattered cells in some regions of the cerebral cortex and basal forebrain. Since no immunoreactivity is found in their axons, these cells may synthesise TAG-1/axonin-1 mostly or exclusively in its secreted form. In certain regions of the adult brain, expression of other growth-associated proteins, such as GAP-43, has been related to persistent neural plasticity or regenerative capacity. Further studies will clarify whether the expression of the growth-associated neuronal protein TAG-1/axonin-1 by specific neurons of the adult brain serves neural plasticity or regenerative capacity as well. (Supp. Swiss National Foundation for Scientific Research 31-27737.89)

ANALYSIS OF THE EFFECT OF THE STRUCTURE OF A PATTERNED GRID SUBSTRATE ON CELL DISTRIBUTION IN CULTURE. *E. M. Powell and H. M. Buettnner**, Dept. of Chem. and Biochem. Engg, Rutgers Univ., Piscataway, NJ 08855.

To investigate growth cone guidance at a laminin boundary, 8 day embryonic chick dorsal root ganglion (DRG) neurons were cultured on a patterned grid substrate of square (laminin) and lane (bovine serum albumin) regions, originally developed by Hammarback and Letourneau (Dev. Biol. 117:655 (1986)). The substrate was characterized with respect to laminin surface concentrations. The ratio of laminin concentrations in the square to the lane regions was determined by an indirect immunochemical staining technique using colloidal gold and was found to be in the range of 0.95 to 2.20, corresponding to applied laminin concentrations of 30.0 μ g/ml to 100.0 μ g/ml. Neurite lengths were measured and found to be beta distributed with a mean of 47.5 μ m. The locations of cells on the substrate were analyzed using statistical mechanics techniques, and the results suggest the lane regions form three-dimensional boundaries between adjacent squares, with an approximate height of 2.1 μ m as determined by optical measurements. Further analysis will elucidate the effects of the physical structure on cell behavior.

Supported by the Whitaker Foundation, and by a pre-doctoral fellowship to EMP through the NIH/Rutgers/UMDNJ Biotechnology Training Program.

CELL ALIGNMENT ON CHEMICALLY-PATTERNED SURFACES REVEALS A HIERARCHY OF PREFERENCES

B. Lom, K.E. Healy† and P.E. Hockberger#* Institute for Neuroscience, †Biomaterials and Biomedical Engineering Depts., and #Physiology Dept., Northwestern Univ. Medical and Dental Schools, Chicago, IL 60611.

A convenient method for evaluating the relative adhesivity of cells to different chemicals is to observe their distribution on chemically-patterned surfaces. While several patterning techniques have been described in the literature, each is limited in the number and types of molecules that can be patterned as well as in its precision. We have developed a versatile technique which allows the patterning of a wide variety of chemicals with submicron precision (Lom et al., *Soc. Neurosci. Abstr.* 18: 39, 1992). This technique combines silane coupling chemistry, photolithography, and protein adsorption to create well-defined, patterned surfaces. We tested the adhesivity of mouse neuroblastoma cells (N1E-115) on glass surfaces patterned with amines (ethylenediamine-propylsilane, EDA-PS), alkanes (dimethylsilane, DMS; octadecyl-dimethylsilane, OD-DMS), and proteins (collagen IV; fibronectin; laminin; bovine serum albumin, BSA) in the following combinations: alkane-glass, protein-glass, alkane-alkane, amine-alkane, amine-protein (other combinations have not been tested yet). From observations of cell distribution 24 hours after plating the following hierarchy of adhesive preference was established: collagen IV, fibronectin, laminin > EDA-PS, glass > DMS, OD-DMS, BSA. The low preference of neuroblastoma cells for BSA indicates that preference for extracellular matrix proteins was due to specific properties of these proteins. The preference for matrix proteins over EDA-PS indicated that this specificity was not simply due to positively-charged moieties on the matrix proteins. In the accompanying abstract (Soekamo et al.) we show that preference was correlated with greater overall attachment to surfaces even though parts of cells attached equally well to the non-preferred surface.

EVIDENCE FOR PREFERENTIAL ADHESION AS A MECHANISM FOR NEURONAL PATHFINDING IN CULTURE

A. Soekarno*, B. Lom, and P. E. Hockberger[#] Inst. for Neuroscience and

[#]Dept. of Physiology, Northwestern Univ. Med. Sch., Chicago, IL, 60611.
Pathfinding is a fundamental behavior that guides growth cones to their targets. One plausible pathfinding mechanism is growth cone attachment to and guidance along adhesive surfaces. Conversely, growth cones may be guided by and advance faster along less adhesive surfaces. An alternative to these "differential adhesion" models is guidance by a signal transduction mechanism. In this model the inherent adhesivity of materials is less important than the specific molecules that activate the signal transduction cascade. Since growth cone movement presumably requires adhesion, guidance would occur by "preferential adhesion" to surfaces with the appropriate signals. Here we present evidence in culture that supports the preferential adhesion model. We used interference reflection microscopy (IRM) to directly monitor the attachment of mouse neuroblastoma cells (N1E-115) to chemically-patterned surfaces. The patterns consisted of amine lines (5-15 μm -wide by 1 mm long) separated by either alkanes or laminin lines (see Lom et al., *Soc. Neurosci. Abstr.* 18: 39, 1992 for patterning technique). On amine-alkane patterns, cells and growth cones attached to and displayed similar adhesion profiles (focal and close contacts) on both surfaces, even though they were guided by the aminated pathways. Similarly, on amine-laminin patterns, most cells and growth cones (80%) adhered equally well to both regions though some (20%) adhered more tightly to laminin surfaces. On this pattern all cells and growth cones were guided by the laminin. Thus we were unable to find a consistent correlation between the pathway of choice and the degree of attachment. These results are inconsistent with both models of differential adhesion and instead support the model of preferential adhesion.

THE FORMATION OF HIPPOCAMPAL CA3 NETWORKS IN EXPLANT CULTURES OF NEONATAL RAT. K.L. Smith and J.W. Swann*. Cain Foundation Labs, Department of Pediatrics and Division of Neuroscience, Baylor College of Medicine, One Baylor Plaza, Houston, TX 77030.

The extent to which CA3 hippocampal pyramidal cells form local excitatory connections with each other has only recently been appreciated. Recurrent excitatory synapses likely play an important, but yet undetermined, role in normal hippocampal functioning. However recent results show these connections participate in the generation of epileptiform discharges. Moreover, recordings from immature rats have shown that these synapses are present early in postnatal life and likely contribute to the enhanced seizure susceptibility of neonatal rats. Studies were undertaken, to understand those factors that regulate the formation of CA3 recurrent excitatory axon and synapses. Slices from 5-day-old rat hippocampus were grown in culture in a defined media on Millipore millicell membranes. After only 24 hours in culture explants were capable of generating large and prolonged electrographic seizures when exposed to picrotoxin (10 μM). These were abolished by CNQX. This was surprising, since slices taken acutely from rat pups produce these discharges no earlier than postnatal day 8. Thus it appears that the formation of CA₃ recurrent collaterals is accelerated in culture compared to that occurring *in vivo*. In a second experiment, explants were grown in media containing 3 mM kynurenic acid (KYN). When KYN was washed from the recording media, explants were also capable of producing picrotoxin-induced seizure-like discharges. Thus KYN does not appear to prevent the formation of recurrent collaterals and synapses in hippocampal area CA₃. Indeed, in a number of instances electrographic seizures occurred spontaneously upon KYN washout and before picrotoxin application. Thus blockade of excitatory amino acid receptors may accelerate the proliferation of local circuit recurrent collaterals. (Supported by NIH grant NS18309).

SELECTIVE NEURITE OUTGROWTH OF CULTURED CORTICAL NEURONS ON SPECIFIC REGIONS OF BRAIN CRYOSTAT SECTIONS. M.C. Halloran* and K. Kalil. Neuroscience Training Program and Dept. of Anatomy, University of Wisconsin, Madison, WI 53706.

During neural development axons of the mammalian CNS show a high degree of selectivity in the territories into which they extend. To begin to address the mechanisms underlying this regional selectivity we tested the ability of developing cortical neurons to extend neurites onto specific regions of cryostat brain sections from early postnatal hamster. The goal of this work was to grow neurons on a natural brain substratum which could then be manipulated biochemically. Small cortical explants from newborn hamster were placed onto various regions of cryostat sections from 2-10 day postnatal brains. Neurite outgrowth was visualized 48 hours later with the fluorescent vital dye 5-(and-6)-carboxyfluorescein diacetate applied to the explants shortly before fluorescence microscopy. Results showed that cortical neurites avoided cerebellar regions of the section. These neurites were stunted and preferred to fasciculate with each other rather than grow onto the cerebellum. Preliminary results suggest that the inhibitory effects of the cerebellum increase with the age of the sections. Olfactory bulb also had an inhibitory effect on cortical neurite outgrowth. In contrast, explants plated onto the cerebral cortex as well as regions of the forebrain, midbrain, and brainstem extended many long neurites that were relatively unfasciculated. Results also suggest that neurites extending onto cortical regions showed a preference for growth in the radial orientation, perhaps following the processes of radial glia. These results show that cortical neurites respond to cell surface cues by growing upon regions of the sections permissive for their outgrowth *in vivo* but avoid regions that are not normally invaded by cortical axons. We are currently treating the sections with enzymes that remove specific glycoprotein moieties in order to classify cell surface molecules that determine specificity of cortical neurite outgrowth. PATTERNED MICROCIRCUITS OF HIPPOCAMPAL NEURONS: COMPARISONS OF PHOTORESIST VERSUS LASER ABLATION PROCESSES. B.C. Wheeler*¹, J.M. Corey¹, and G.J. Brewer².
¹Neuroscience Program, Univ. Illinois, Urbana IL 61801 and
²Southern Illinois Univ. Sch. Med., Springfield IL 62794.

Study of CNS neuron growth, development and synaptic specificity would be facilitated by limiting the number and direction of growing axons and dendrites. Although selective photoablation of polylysine coated substrates has been successful for us, the short shelf-life and suspected uneven coating led us to use more stable aminosilanes. Here we compare two techniques for patterning adhesive substrates with aminosilanes on glass coverslips: 1) UV laser photoablation through a quartz mask, and 2) photoresist patterning for selective deposition. Rat embryonic hippocampal neurons were dissociated and grown on these substrates in serum-free medium, GIBCO B27/Neurobasal. Variations in the laser process important for a well-defined adhesive path include laser energy density at 190 nm and the number of 30 ns pulses. In photoresist processing variation in the density of bonding of the aminosilane causes poor compliance of cells to paths less than 10 mm wide. An alternative approach of application of aminosilane, followed by selective photoresist development, appears more promising. Other considerations include equipment costs and processing time. These findings will aid applications to localize neurons over substrate electrodes and studies of linear process extension and synaptogenesis. Supported by NIH R03 RR06870 and SIUSM CRC funds.

TARGET-DERIVED INFLUENCES ON AXON GROWTH PATTERNS IN EXPLANT CO-CULTURES OF TRIGEMINAL GANGLIA. B. Erzurumlu¹, S. Jhaveri and R. McKay. Dept. Brain & Cog. Sci. M.I.T., Cambridge, MA, 02139

Co-cultures of embryonic trigeminal ganglia with "peripheral" and "central" targets provide an *in vitro* model for studying axon-target interactions. When E15 rat trigeminal ganglion explants are placed between peripheral (vibrissa pad) and CNS targets, peripheral processes of ganglion cells invade the vibrissa pad explants and form a circumfollicular pattern. Central processes of ganglion cells invade many isochronic CNS explants and form a fasciculated tract without any arbors (Erzurumlu et al., *PNAS*, 1993). We have examined the growth of E15 and E20 trigeminal axons in *heterotypic* and *heterochronic* co-cultures with various cutaneous (skin from the back, forepaw and vibrissa pad explants) and CNS (brainstem, parietal cortex, olfactory bulb) targets by DII labeling after 5-7 days in culture.

Peripheral axons from E15 ganglia are patterned differentially in all three cutaneous fields: they are organized around the follicles in vibrissa pads, course in thick fascicles between the digits in forepaw and are distributed diffusely in dorsal skin. Central axons invade various CNS targets and either elongate to form a tract, or arborize, depending on target maturity. In contrast to the unbranched elongation seen *in vivo* as well as in E15 brainstems, E15 trigeminal axons form collateral branches and arbors in more mature brainstem, neocortex or olfactory bulb slices.

On the other hand, central processes from E20 trigeminal ganglia (which normally arborize in the brainstem trigeminal nuclei) revert to an elongation mode of axon growth when challenged with younger (E15) brainstem explants. Their peripheral processes also invade E15 vibrissa pads and become arranged around the follicles, but in a more diffuse pattern than that seen with E15 ganglia. These observations suggest that growth pattern of trigeminal axons is strongly influenced by the target tissue. (Supp. by N.I.H. grants NS27678 and NS21991.)

GROWTH CONES IN THE PRIMARY VISUAL PATHWAY OF THE CHICK EMBRYO. S.A. Dunlop,¹ P.G. Nelson, W.M. Ross & M.M. Stewart. Dept. of Psychology, University of Western Australia 6009, ¹National Institute of Child Health and Human Development, NIH, Bethesda, MD 20892.

We have examined the morphology of retinal ganglion cell growth cones labelled with horseradish peroxidase in the chick embryo using Nomarski optics. At E3-4 growth cones arise from first-born ganglion cells and pioneer their way through a virgin pathway. In the optic stalk, growth cones are elongate and have a few short filopodia extending in front of the growth cone body, whereas in the presumptive chiasm they are spread and have large lamellipodia. Within the tract, growth cones are again elongate but have many filopodia extending from along their length; ipsilaterally projecting growth cones are common. At E10, growth cones arise from amongst the last-born ganglion cells and navigate along an established pathway towards the tectum. In the nerve, growth cones are elongate and have many long filopodia extending in front of the growth cone body. Growth cones in the chiasm and tract appear similar to the pioneer growth cones although ipsilaterally projecting growth cones are rare. As in the mouse (1) there are pronounced differences in growth cone morphology between regions of the developing visual pathway but, in contrast to the mouse, pioneer and later-born growth cones tend to have a similar morphology. 1. Bovolenta P. & Mason C.A. 1987. *J Neurosci.* 7,1447-1460.

DEVELOPMENT OF A BIOSYNTHETIC 3-D EXTRACELLULAR MATRIX EQUIVALENT FOR NEURITE OUTGROWTH. R. Bellamkonda*, J. Ranieri and P. Aebischer. Surgical Research Division, CHUV, Lausanne University, Switzerland.

The extracellular matrix (ECM) has been shown to play an important role in neuronal cell attachment, maintenance and differentiation. Our aim is to develop a simple, well defined, biosynthetic hydrogel based system capable of supporting neuronal cell attachment and differentiation in three dimensions. The particular suitability of a hydrogel as a biomaterial stems from the similarity of their physical properties to those of living tissues vis-a-vis their high water content, soft rubbery consistency and low interfacial tension. Cell attachment and differentiation promoting oligopeptides like GRGD, YIGSR and IKVAV, derived from ECM proteins like laminin and fibronectin, were covalently linked to transparent, thermoreversible agarose hydrogels using 1' Carbonyldiimidazole chemistry. Embryonic (E14) rat striatal cells were three dimensionally suspended inside the gels. Striatal cells were viable upto 10 days in culture as determined by a fluoroscein diacetate assay. At time points 24, 48 and 72 hrs, 42%, 52% and 55% of the cells extended neurites in three dimensions inside agarose gel. This was comparable to the striatal cell neurite extension in 100% Matrigel™, a commercially available basement membrane preparation extracted from the EHS mouse sarcoma. E8 chick ciliary ganglions also extended processes when suspended in three dimensions inside the agarose gel. Thus agarose and derivatized agarose gels are capable of supporting significant neurite extension from anchorage dependant primary neuronal cultures in three dimensions *in vitro*. This system may serve to enhance nerve regeneration when introduced into the various animal models. *In vivo* studies are currently in progress.

GROWTH CONE DYNAMICS AND NERVE ORIENTATION IN A SMALL ELECTRIC FIELD ARE SUBSTRATE DEPENDENT. C.D. McCaig, L. Erskine & M.N. Wallace* Department of Biomedical Sciences, University of Aberdeen, Aberdeen, Scotland. AB9 1AS.

Embryonic *Xenopus* neurites grown on tissue culture plastic turn cathodally in steady fields above 10mVmm⁻¹. The direction of orientation is substrate dependent; neurites grown on poly-L-lysine coated plastic selectively grew anodally (Rajnicek et al, Soc. Neurosci. Abstr. 15, (2):1036). These observations have been repeated and extended by studying growth cones at high resolution, with video enhanced contrast-differential interference contrast microscopy (VEC-DIC). *Xenopus* nerves grown on glass or on laminin-coated glass (10µgml⁻¹) and exposed to a small electric field (70 - 190mVmm⁻¹ for up to 3h), oriented cathodally; those on poly-L-lysine anodally. On all three substrates, filopodia were distributed asymmetrically, being both longer and more numerous on cathodal-facing than on anodal-facing sides of growth cones. Rates of extension towards either cathode or anode of sheets of growth cone lamellipodia did not differ on glass or on polylysine. On laminin however, lamellipodia from the cathodal-facing side of a growth cone extended at rates 19% faster than those extending from the anodal-facing side (p<0.001). It is concluded: 1. that galvanic nerve orientation is substrate dependent, 2. that filopodial asymmetry at the growth cone need not mandate the subsequent direction of nerve orientation and 3. that an electric field can induce asymmetric cytoskeletal polymerisation and/or membrane addition at the growth cone.

DEVELOPMENTAL EXPRESSION OF UROKINASE AND TISSUE PLASMINOGEN ACTIVATORS IN RAT NERVOUS SYSTEM. Y. Sumi*, R.J. Morris and M.A.R. Dent, Norman and Sadie Lee Centre, Laboratory of Neurobiology, National Institute for Medical Research, Mill Hill, London NW7 1AA, U.K.

The expression of urokinase and tissue plasminogen activators has been studied in developing cerebellum, hippocampus, cerebral cortex, olfactory bulb and olfactory mucosa of the rat by *in situ* hybridisation. All identifiable neurons express urokinase mRNA from an early stage in their development, and this expression appears to coincide with the onset of axogenesis. Glial cells generally do not express urokinase message, except for transient expression by oligodendrocytes in developing fibre tracts during the period of myelination. In contrast, although high levels of tissue plasminogen activator are found in the embryonic floor plate, in postnatal brain it is expressed only by ventricular ependymal cells.

536.2

Electric Field-Guided N1E-115 Neurite Growth: Is Calcium Influx Necessary And Sufficient? R.S. Bedlack Jr*, P. Amarante, M.-d. Wei and L.M. Loew. Univ. of Conn. Health Ctr., Farmington, CT 06030.

D.C. electric fields evoke localized membrane depolarizations, calcium influx and growth cone filopodial protrusions in N1E-115 cells; such actions might underlie electric field-directed neurite initiation, elongation, sparing from retraction and turning, which are also seen in these cells (Neuron 9, 393-403 (1992)). Temporal and spatial correlations between the described events support this hypothesis, but we are attempting to gain further proof. Here we report that prevention of field-induced calcium influx (by extracellular calcium removal or inorganic or organic calcium channel blockers) eliminates field-biased filopodial protrusions and field-directed growth in N1E-115 cells; however, this also causes diminished filopodial activity, growth cone collapse and neurite retraction in non-field treated cells. Conversely, agents which cause non-localized calcium influx (elevation of extracellular KCl or addition of calcium ionophores) are known to elicit non-localized increases in N1E-115 growth cone filopodia. We now demonstrate that these agents also evoke non-localized increases in N1E-115 neurite initiation, elongation and stability. Our results suggest that calcium influx is necessary for normal and field-directed N1E-115 neurite growth. Further, the observation that non-localized influx can create non-localized increases in growth suggests that localized calcium influx may be sufficient for explaining field-directed N1E-115 neurite initiation, elongation and sparing from retraction. (Supported by USPHS Grant ES05973).

CHONDROITIN SULFATE C ENHANCES GALVANOTROPIC ORIENTATION OF CULTURED FROG NERVES. J. Erskine and C.D. McCaig*. Department of Biomedical Sciences, University of Aberdeen, Aberdeen, Scotland. AB9 1AS.

In d.c. electric fields of 50 - 200 mVmm⁻¹ dissociated neurons from the neural tube of stage 18 to 20 *Xenopus* embryos orient cathodally on tissue culture plastic. *In vivo* the direction and number of neurites orienting may depend on interactions between endogenous fields and extracellular matrix components. Proteoglycans, components of the extracellular matrix of embryos, are highly negatively charged molecules that have been implicated in regulating nerve growth. The effect of the glycosaminoglycan chondroitin sulphate C (CSC) on field induced neurite orientation was therefore examined. In normal medium 62% (n=103) of neurites turned to grow cathodally in applied fields of 50 - 133 mVmm⁻¹. At higher field strengths (143 - 200 mVmm⁻¹) >80% oriented. A neurite was categorised as having turned if over a 5 hour observation period it showed a sustained deviation of >15 deg from its original direction of growth as measured from hourly photographs. Addition of 10 µgml⁻¹ CSC to culture medium 30 min after plating significantly enhanced the orientation response. At low field strengths (56 - 120 mVmm⁻¹) 85% (n=66) of neurites turned cathodally, a significant increase. A two fold increase in the mean total angle turned was also observed. At higher field strengths (166 - 175 mVmm⁻¹) the rate of turning was significantly faster than that observed in normal medium. Bioelectric fields and matrix components may therefore be interactive cues for neurite guidance *in vivo*.

536.6

TARGETING OF GONADOTROPIN-RELEASING HORMONE (GnRH) AXONS TO THE MEDIAN EMINENCE (ME): AN *IN VITRO* STUDY. I.J. Wu*, M.C. Rogers, M.J. Gibson and A.-J. Silverman. Dept. of Anatomy & Cell Biology, Columbia Univ., New York, NY 10032, and Dept. of Medicine, Mt Sinai School of Medicine, New York, NY 10029.

In mice, GnRH neurons complete their migration from the olfactory placode into the forebrain by E15/16 and are concentrated in the septal-preoptic area (POA). Upon entering the CNS, GnRH axons elongate and project along stereotyped paths to their target in the ME. A similar precision in targeting is observed following implantation of normal fetal POA into the third ventricle of adult hypogonadal (hpg) mice. Experiments involving cocults of fetal POA and ME in hpg mice suggested that the ME might exert a positive influence on GnRH axonal growth. To test the hypothesis that the ME produces a diffusible signal that alters the amount or direction of GnRH outgrowth, we have cocultured explants of POA and ME (which includes the mediobasal hypothalamus) within three-dimensional collagen matrices. In preliminary experiments, explants of E15 mouse POA were cultured alone (n=18) or cocultured (n=30) with an ME for 48-120 h. The ME was positioned near the rostral aspect of the POA at 1.0-1.5 mm. GnRH neurons (up to 300) were detected immunocytochemically in 85% of the POA explants and axonal growth into the collagen matrix (of both GnRH and unknown phenotype) was observed. In some cases, the GnRH axons reached the ME. To document the overall innervation of the ME by the POA explant, Dil crystals were placed in the ME after fixation and allowed to diffuse at 37 C for 10-14 days. Retrogradely labeled cells were found in the POA after 120-h of culture but not at 48-h. Placement of Dil on the POA revealed robust outgrowth after 120 h and only minimal outgrowth after 48 h. This culture system will be useful in demonstrating the presence of ME-derived agents responsible for the targeting of GnRH axons. NS220335 (MJG), T32 NS07062 (TJW).

RAT VOMERONASAL ORGAN AND OLFACTORY BULB COCULTURE.

T. Osada, M. Ichikawa, P.P.C. Graziadei and D.M. Easton*. Department of Biological Science, Florida State University Tallahassee FL 32306

The vomeronasal organ (VNO) and the olfactory bulb (OB) of rat were cocultured from E17 littermates on collagen in Dulbecco's Modified Eagle's Medium containing 5% fetal calf serum and 5% horse serum.

After 48 hrs, isolated fibres, presumably sensory, together with some large fascicles, were seen originating from the VNO. Their direction was random and did not appear to be affected by the OB presence. After 7 to 8 days, however, only the large bundles, mostly those connected to the OB, survived. Vicia Villosa agglutinin (VVA) when added to the culture medium at the start of the incubation inhibited the formation of large fascicles originated from the VNO.

We conclude that the establishment of connections between the VNO and the OB in coculture favors the survival of the large nerve fascicles, however, the presence of the OB does not determine the initial orientation of the fibres and fascicles from the VNO explant.

FORMATION AND SPECIFICITY OF SYNAPSES: RECEPTOR LOCALIZATION

537.1

MOLECULAR CHARACTERIZATION OF ZEBRAFISH ACETYLCHOLINE RECEPTOR MUTATION, *nic1*. Diane S. Sepich* and Monte Westerfield. Institute of Neuroscience, University of Oregon, Eugene, Oregon.

We are studying neuromuscular synapse assembly by characterizing a zebrafish mutant, *nic1*^[b107] which lacks functional muscle acetylcholine receptors (AChRs). In previous studies, we showed that *nic1* mutant embryos are paralyzed and that the *nic1* mutation acts autonomously within muscle cells to block AChR synthesis or clustering.

To learn whether the *nic1* mutation alters the genes encoding AChR subunits, we isolated the zebrafish AChR α subunit cDNA and performed Southern analysis. Restriction fragment length polymorphisms in this gene are linked to the *nic1* phenotype. We observed either smaller or fewer restriction fragments in *nic1* than in wild-type DNA, a pattern consistent with a deletion.

To test whether the *nic1* mutation is a deletion in the AChR α subunit gene and to learn how it might act, we isolated a genomic region spanning the suspected deletion in *nic1* and the corresponding region from the wild-type gene. The differences between the *nic1* and wild-type genes reside in an intron. Because preliminary Northern analysis shows that *nic1* AChR α subunit mRNA is present and larger than in wild-type embryos, we suggest that the mutation blocks intron excision.

These results suggest that the molecular defect of the *nic1* mutation is a deletion within the AChR α subunit gene. We suggest that the mutation acts by causing the mRNA to retain an intron which leads to a subunit protein that fails to form a functional receptor. Supported by NIH NS21132 and HD22486.

537.3

CHANGES IN THE DISTRIBUTION OF 43K PROTEIN DURING SYNAPSE ELIMINATION AT THE NEUROMUSCULAR JUNCTION. S.M. Culican*, J.B. Cohen, and J.W. Lichtman. Dept. Anatomy and Neurobiology, Washington Univ. Sch. of Med., St. Louis, MO 63110 and Dept. Neurobiol., Harvard University, Boston, MA 02115.

During naturally occurring synapse elimination at the developing neuromuscular junction (NMJ) and also following reinnervation in adults, nerve terminals associated with one axon and nearby post-synaptic acetylcholine receptors (AChRs) are removed from synaptic sites, with AChR loss preceding the removal of overlying nerve terminals (J. Neurosci. 9:1781-805,1989; 13:834-55,1993). To study the mechanism that leads to AChR loss we have examined the distribution of the receptor associated 43K protein in areas undergoing elimination in reinnervated mouse NMJs. AChRs at NMJs of reinnervated muscle fibers in the adult stemomastoid were labelled in a whole mount with rhodamine alpha-bungarotoxin. A monoclonal antibody followed by a fluorescein labelled secondary antibody was used to label the 43K protein. Areas of the endplate undergoing elimination had a lower density of AChRs relative to the rest of the endplate. At every site where AChRs were faintly stained, the density of 43K was also diminished as compared to the 43K staining in the rest of the junctional area. To determine whether 43K loss occurred before or after AChR loss, the relative intensity of faint and bright areas for both AChRs and 43K was compared. While the absolute intensity of the two labels varied from one endplate to another, at any one endplate the loss of staining in the faint areas was similar for each molecule, indicating that both are disappearing from the post-synaptic membrane at virtually the same rate. This result indicates that the loss of 43K and AChRs is closely coupled. Other molecules associated with the post-synaptic apparatus are currently under investigation.

537.2

REDISTRIBUTION OF ACETYLCHOLINE RECEPTORS AT INNERVATION SITES IN SHORT-TERM MAMMALIAN VENTRAL HORN-MUSCLE CULTURES. E. K. Dutton*, A.E. Schaffner, S. C. Fitzgerald and M. P. Daniels. Labs Biochem. Genetics, Neurophys., Dev. Neurobiol., NIH, Bethesda, MD 20892.

The mechanisms that regulate postsynaptic differentiation have been studied extensively in vitro. Mammalian nerve-muscle culture systems, however, have yielded little information about early events in neuromuscular synapse formation. We are investigating the redistribution of acetylcholine receptors (AChR) and the assembly of synaptic components at newly formed innervation sites using a novel mammalian coculture system. Ventral horn neurons were plated on myotube cultures containing few non-muscle cells (Daniels, J. Cell Science, 1991). Standard fluorescence labeling methods were used to visualize the distribution of AChR at nerve-muscle contact sites. Sixteen hr after neuron plating, substantial neurite outgrowth was seen as well as AChR redistribution. Neurite-induced AChR redistribution was maximal 24 to 48 hr after neuron plating and occurred predominantly on the ventral or substrate-apposed surface. AChR redistribution appeared in two patterns, both of which could be induced by the same neurite: 1) When neurites crossed pre-existing ventral AChR patches, the AChR density on the muscle surface directly apposed to the neurite was sharply reduced as if the neurite had "etched" the AChR patch, but the density within one μ m from the neurite edge was often higher than that of the surrounding ventral patch. 2) Newly aggregated AChR formed a 5-10 μ m wide swath along the neurite path in a bottle brush-like arrangement of AChR enriched domains, and, as seen with ventral patches, the AChR density was reduced directly over the neurite but increased within one μ m from the neurite edge. Neurons that induced AChR redistribution had both thick (dendrite-like) and thin (axon-like) neurites. AChR redistribution, however, was generally induced by thin neurites. The distribution of muscle cytoskeletal and extracellular matrix proteins was analyzed at neurite-induced aggregate sites. The 43 and 58 kd proteins and dystrophin were concentrated in neurite-induced AChR-enriched domains and reduced in concentration where neurites had "etched" pre-existing aggregates. Laminin was concentrated in some neurite-induced aggregates, in pre-existing aggregates, and it was "etched" from the neurite path.

537.4

DEVELOPMENTAL CHANGES IN EXPRESSION OF AGRIN mRNA SEQUENCE VARIANTS IN THE CHICK EMBRYO NERVOUS SYSTEM. E. Ma, B. Morgan and E.W. Godfrey*. Department of Cellular Biology and Anatomy, Medical College of Wisconsin, Milwaukee, WI 53226.

Agrin is a synapse-organizing protein externalized by motoneurons that aggregates acetylcholine receptors and other postsynaptic components found at the neuromuscular junction. In the nervous system, we found agrin mRNA most concentrated in motoneurons of spinal cord (SC), dorsal root ganglia (DRG), cerebellar Purkinje cells and retinal ganglion cells (Ma, Morgan and Godfrey, submitted). The agrin mRNA sequence varies by alternative splicing at two positions, A and B, near the 3' end of the coding region (Ruegg et al., Neuron 8:691, 1992). Most transcripts contain an insert at the A position, but we find four variants at position B, encoding no insert (B_0) or 8-, 11- and 19-amino acid inserts (B_8 , B_{11} , B_{19}). Expression of partial cDNAs indicates that chick agrin containing the B_{11} insert has synapse-organizing activity, while the B_0 isoform may not (Ruegg et al., 1992). Here we report developmental changes in agrin mRNA sequence variants in SC and DRG, and changes in the pattern of expression of agrin mRNAs in developing chick embryo cerebellum.

Using polymerase chain reaction (PCR), we detected only B_0 in E2 (Stage 15) SC, but by E4 (St 23), B_{11} and B_{19} transcripts were also expressed, correlating with a large increase in agrin mRNA in presumptive motoneurons seen by *in situ* hybridization. The B_8 variant appeared in SC by E14, while B_{11} levels decreased markedly from E14 to E20. In DRG, B_0 , B_{11} and B_{19} variants were present at E6 and E9, but decreased by E14. Thus, alternative splicing of agrin mRNA is developmentally regulated in embryonic spinal cord and DRG.

In cerebellum, agrin mRNA was seen by *in situ* hybridization as early as E9. Both external granule and Purkinje cell layers were labeled at E10. The signal gradually decreased in the external layer as it became thinner and increased in the cytoplasm of Purkinje cells, peaking at about E18, but it was still intense at 3 days after hatching. [Supported by NIH grants NS27218 and HD20743.]

SINGLE NEURONS EXPRESS MULTIPLE AGRIN mRNA ISOFORMS. M.A. Smith¹, C. Tran^{1,2}, and D.K. O'Dowd^{1,2}. Depts. of Anatomy and Neurobiology¹; Developmental and Cell Biology², UC Irvine, Irvine, CA 92717

Alternative splicing of an 8 and an 11 amino acid exon results in the expression of four distinct agrin transcripts designated agrin₀, agrin₁, agrin₁₁, and agrin₁₉. While the results of a number of studies suggest that agrin mRNA is present in both neurons and non-neuronal cells, the use of pan-specific probes in these studies has precluded analysis of the cellular localization of specific agrin isoforms. To address this issue we have used single cell PCR to determine the agrin mRNA profile of individual chick ciliary ganglion cells. Whole-cell recording pipets were used to obtain voltage-clamp and current-clamp recordings from isolated cells acutely dissociated from embryonic ciliary ganglia. Following electrophysiological measurements the contents of the cell were aspirated into the pipet, agrin mRNA reverse transcribed, and subjected to two rounds of amplification using nested primers flanking the region of alternative splicing. Analysis of cells dissociated from E14 ganglia reveals that while some neurons express a single agrin isoform, the majority of neurons express agrin₁₉ at high abundance together with one or more of the other agrin isoforms. In contrast, non-neuronal cells, identified by their small size and absence of voltage-gated currents, expressed only agrin₀. Based on these results we conclude that alternative splicing of agrin mRNA is regulated in a cell specific manner. Supported by a grants from the Plum Foundation and NS-27563 to M.A.S., and NS27501 to D.K.O'D.

CELL-CELL INTERACTIONS INFLUENCE AGRIN GENE EXPRESSION IN THE CHICK CILIARY GANGLION. W.S. Thomas¹, M.H. Jacob³, D.K. O'Dowd^{1,2}, M.A. Smith¹, Dept. Anat. and Neurobiol.¹; Dept. Dev. and Cell Biol.², UC Irvine, CA 92717; Worcester Fdn. for Exp. Biol.³, Shrewsbury, MA 01545.

We have previously demonstrated that in the chick ciliary ganglion (CG) both the levels of agrin mRNA and the pattern of alternative splicing are regulated during normal development. Expression of acetylcholine receptors and α -bungarotoxin binding sites on CG neurons have been shown to be influenced by signals derived from presynaptic inputs and target muscle tissues. In order to determine whether similar cell-cell interactions modulate agrin gene expression in the ganglion, we have used *in situ* hybridization to examine the effects of axotomy and denervation on levels of agrin mRNA. Surgery was performed on newly hatched chicks and ganglia examined 9 days after denervation and 5 days after axotomy. Our results demonstrate that denervation of the ganglion results in a two-fold increase ($p < 0.001$) in density of labelling over neuron cell bodies relative to neurons in contralateral unoperated control ganglia. In contrast, after ganglionic axotomy, agrin gene expression in neurons decreases to two-thirds of that in controls. The results indicate that preganglionic influences modulate agrin mRNA levels in the CG and suggest that target derived signals may have an effect as well. Supported by the Pfeiffer Foundation (M.H.J.), Plum Foundation (M.A.S.), NIH NS21725 (M.H.J.), NS27563 (M.A.S.), NS27501 (D.K.O.), and T32 NS07351 (W.S.T.).

537.6

REGULATION OF AGRIN GENE EXPRESSION BY SEIZURE ACTIVITY IN THE ADULT RAT CNS. L.T. O'Connor^{*}, J.C. Lauterborn, C.M. Gall, and M.A. Smith. Dept. Anatomy and Neurobiology, University of California, Irvine, CA 92717.

We have recently shown that agrin mRNA is expressed by neurons in the adult rat brain suggesting a role for agrin in formation and maintenance of synapses in the CNS. The expression of a number of proteins, including receptors for neurotransmitters, is regulated by synaptically mediated activity. We sought to determine whether agrin gene expression might be under similar control using a limbic seizure paradigm. In these studies, placement of an electrolytic lesion in the hilus of the dentate gyrus induces an episode (8-10 hrs) of recurrent limbic seizures. *In situ* hybridization studies reveal that levels of agrin mRNA in the CNS are altered both temporally and spatially following seizure activity. In comparison to paired controls, hybridization was increased in hippocampus, caudate/putamen, septum and intermediate layers of neocortex but markedly reduced in superficial layers of neocortex and piriform cortex. Within the olfactory tubercle and granule cell layer of hippocampus, increases in agrin mRNA were apparent 24 hrs postlesion and had not returned to control levels after 4 days. By contrast, decreases in agrin mRNA within piriform cortex were also observed 24 hrs after lesion placement but returned to control levels by 48 hrs. We have previously shown that four alternatively spliced agrin mRNAs are expressed in the adult rat brain. However, seizure activity does not appear to influence the relative levels of the different isoforms at 24 hrs postlesion. We conclude that the level of agrin mRNA but not alternative splicing may be regulated by synaptically mediated activity in the rat CNS. NEUROTROPHIC FACTORS: RECEPTORS AND CELLULAR MECHANISMS I

538.1

DEPOLARIZING STIMULI INCREASE *trk* B PROTEIN IN EMBRYONIC RAT HIPPOCAMPAL NEURONS. J.A. O'Keefe^{*}, Y. Goodman, and M.P. Mattson. Sanders Brown Center on Aging and Department of Clinical Sciences, University of Kentucky, Lexington, KY 40536.

Neurotrophic factors modulate neuronal growth, differentiation and survival and play a role in neural connectivity by binding to tyrosine protein kinase receptors. Complex interactions between trophic factors, their receptors, and neuronal activity have been hypothesized to account for mechanisms of neuroarchitecture establishment and learning and memory formation. *Trk* B (p145^{trkB}) is the functional high affinity receptor for brain derived neurotrophic factor (BDNF), a member of the neurotrophin family which is found in relatively high concentrations in the hippocampus. We employed cultured embryonic rat hippocampal neurons as a model system to test the hypothesis that *trk* B is regulated by neuronal activity. A depolarizing stimulus in the form of high extracellular K⁺ concentration [50 mM] elicited an approximately two-fold increase in the *trk* B protein in hippocampal dissociated cell cultures as determined by Western blot analysis using an affinity purified rabbit polyclonal antibody (Santa Cruz Biotech, Inc). Time course studies revealed increased protein production above control values by 6.5 hrs post K⁺ treatment with maximum levels of *trk* B evident by 24 hrs. These elevations in *trk* B protein levels were maintained through 48 hrs. Similar results were obtained in dissociated neocortical cultures. Current studies are directed towards investigating the effects of neuronal activity on *trk* B mRNA as well as underlying mechanisms for activity driven induction of this neurotrophin receptor. Our findings suggest that impulse activity may modulate the expression of the *trk* B protein, suggesting a complex paracrine or autocrine interaction between neurotrophic factors, their high affinity receptors and neurotransmitter molecules in activity dependent processes in the hippocampus.

BIDIRECTIONAL AXONAL TRANSPORT OF p140^{trk} HIGH AFFINITY NGF RECEPTOR. R. Loy^{*}, Dorota K. Poluha² and A.H. Ross². ¹Dept. Neurology, Univ. Rochester, Rochester, NY 14620, Canandaigua VAMC and ²Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545.

The major biological effects of nerve growth factor (NGF) are thought to be mediated by binding to high affinity cell surface receptors and retrograde transport to the cell body. We have used two polyclonal antibodies specific to p140^{trk} to look for build-up of immunoreactive antigen proximal and distal to a transection of the fimbria/fornix. Antibodies 679 and 683 were prepared against p140^{trk} peptide residues 160-176 and 379-394, respectively. These antisera react with p140^{trk} but not with p140^{trkB} or p140^{trkC} and both detect the *trk*-encoded protein in *trk*-virus-infected Sf9 cells but not in control cells. Male Sprague-Dawley rats received knife cuts of the fimbria/fornix between the hippocampus and medial septal nucleus and of the overlying cortex. Eight to 12 hours later, rats were perfused and the brains removed. 40 μ m frozen sections were cut and stained using antibodies 679 and 683. Diagonal band, medial septal and nucleus basalis cell bodies are p140^{trk}-immunoreactive, although few processes are stained. Both distally and proximally to the transection sites, there appear beaded and varicose p140^{trk}-immunoreactive fibers about 50-100 μ m in length. These look identical to transected fibers in adjacent sections stained for low-affinity NGF receptor using IgG192 and to axons ligated in the sciatic nerve in previous studies, indicating both anterograde and retrograde transport of p140^{trk}. Supported by AG 09231.

QUANTITATIVE ANALYSIS OF p140^{trk} mRNA EXPRESSION IN THE DEVELOPING RAT BASAL FOREBRAIN AND HIPPOCAMPUS. F. Cirulli¹, S. Levine¹, and E. M. Shooter². ¹Department of Psychiatry, and ²Department of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305.

In the central nervous system (CNS) Nerve Growth Factor (NGF) acts as a target-derived growth factor for developing cholinergic neurons of the basal forebrain. It has been shown that p140^{trk}, a receptor tyrosine kinase, mediates NGF biological activity. We have studied the mRNA expression of p140^{trk} in the developing septo-hippocampal system using a sensitive ribonuclease protection assay. Basal forebrain and hippocampus were dissected from rats at postnatal day (PND) 0, 4, 12, 16, 21 and 60. Total mRNA was extracted and hybridized with an antisense riboprobe. A standard curve was obtained hybridizing increasing amounts of synthetically transcribed sense mRNA. Our results show that mRNA for p140^{trk} was barely detectable at birth in both basal forebrain and hippocampus. A significant increase in mRNA occurred around PND 16 and levels increased steadily until adulthood (PND 60). These data indicate that the expression of p140^{trk} mRNA is developmentally regulated in both basal forebrain and hippocampus. The developmental increase in p140^{trk} mRNA parallels the maturation of the septo-hippocampal cholinergic system, suggesting that this receptor contributes to its functional organization.

538.5

EXPRESSION OF NERVE GROWTH FACTOR AND ITS HIGH AFFINITY RECEPTOR (trk) IN THE RAT AND MONKEY CORTEX. A.F. Pitts* and M.W. Miller. Depts. of Psychiatry & Pharmacology, Univ. of Iowa Coll. of Med., Iowa City IA 52242 and Dept. of Psychiatry and Res. Serv., V.A.M.C., Iowa City IA 52246.

Nerve growth factor (NGF) is required for the survival of neurons which project axons from the basal forebrain to neocortex. We used immunohistochemical procedures to identify the distribution of NGF and the NGF receptor, *trk*, both in the basal forebrain and neocortex. The procedures relied on polyclonal antibodies to NGF (courtesy of E.M. Johnson) and to *trk* (Oncogene). Some sections were stained with cresyl violet for cytoarchitectonic analyses. NGF-immunoreactive neurons in rat and monkey cortex were distributed in all layers. About one third of the neurons in a particular layer were NGF-positive. The staining was somatic and occasionally extended into the base of the apical dendrite. *trk*-immunoreaction was also identified in all layers of cortex, however, the staining was arranged in pericellular rings. Like NGF, *trk*-immunostaining was associated with about one third of the neurons. In the rat basal forebrain *trk*-immunostaining was cytoplasmic. Most of the cell bodies of basal forebrain neurons were *trk*-positive, and in contrast, only a fraction were NGF-positive. These data are consistent with the model that NGF is produced by cortical neurons which retrogradely maintain the basal forebrain projection neurons.

538.7

ANTIBODIES RAISED AGAINST HUMAN p140^{trkA} PEPTIDE SEQUENCES STAIN A DISTINCT SET OF NEURONS IN THE RAT PERIPHERAL AND CENTRAL NERVOUS SYSTEM.

M Hu-Tsai¹, C.J. Woolf¹, G. Evan², J. Winter^{3*}. ¹Dept. Anatomy, University College London, London WC1E 6BT, ²Imperial Cancer Research Fund, Lincoln Inns Flids, London WC2, ³Sandoz Institute for Medical Research, London WC1E 6BN, UK.

In order to study the distribution of the high affinity NGF receptor, we have raised antibodies in rabbits to 2 distinct 25aa peptide sequences (A₁ & A₂) of the human gp 140^{trkA} with no homology to trkB or trkC. These have partial homology with the corresponding rat gp 140^{trkA} sequences. The antibodies immunoprecipitate a 130-140k protein from lysates of PC-12 cells and neonatal rat DRG. Affinity purification of the antibodies was performed on CNBr-activated sepharose columns using the peptides. No cross reactivity was detected between A₁ serum and A₂ peptide. The flow through of A₁/A₂ serum through A₁/A₂ peptide bound columns lacked antipeptide activity and were used for immunohistochemical controls.

A similar immunohistochemical staining pattern was found for both antibodies. The majority of adult DRG, nodose and SCG neurons were immunoreactive. In the CNS high levels of staining were found in specific motoneuron pools, preganglionic neurons, the pontine nuclei, some hypothalamic nuclei, the geniculate body, particular reticular nuclei and hippocampal cells. The most immunoreactive cells were Purkinje cells in the cerebellum.

This distribution is not fully congruent with the distribution of NGF responsive cells, NGF high affinity binding sites or *in-situ* hybridization for gp140^{trkA} mRNA. Work is in progress to identify which rat *trk* these antibodies are recognizing.

538.4

NERVE GROWTH FACTOR RECEPTOR (NGFR) IMMUNOREACTIVITY IN THE DEVELOPING HUMAN BASAL FOREBRAIN. D.Klisovic (1), I.Delalle (1), M.Herlyn (2) and I.Kostovic*(1), (1) Croat. Inst. Brain Res., Sch. of Med., Univ. Zagreb, 41000 Zagreb Croatia, (2) Wistar Inst., Philadelphia, PA19104-4268, USA

Nerve growth factor (NGF) is a trophic factor for the cholinergic neurons in the human basal forebrain (Allen et al. '89). We applied NGFR-immunocytochemistry and Nissl staining on basal forebrain (BF) of 14 postmortem human brains ranging from 15 weeks of gestation (w.g.) to 25 years of life. From 15 to 25 w.g. Nissl stained sections revealed increase in perikaryal size, progressive somal hyperchromasia and the differentiation of all cell groups (Ch1-4) within BF. After 25 w.g. only minor perikaryal enlargement was observed. At the age of 15 w.g. NGFR immunoreactivity (NGFR-IR) was present in pars compacta of the nucleus basalis (Ch4). Positive fibers were noticed in the external capsule. In the subsequent ages increasing amounts of NGFR-IR within perikarya and dendrites of magnocellular somata in all BF subdivisions were found. Axonal pathways were noticed from the age of 25 w.g. onward in the external capsule, intramedullary laminae of globus pallidus, lateral portion of anterior commissure, longitudinal striae and fornices. Our results show a correlation between the morphological and trophic factor's activity maturation in the developing human BF. It is also evident that biochemical maturation of cholinergic neurons in BF is an early prenatal developmental event.

DEVELOPMENTAL PATTERN OF TRKB IMMUNOREACTIVITY IN THE MAMMALIAN CEREBRAL CORTEX. R.J. Cabelli, K.L. Allendoerfer, M.J. Radeke*, S.C. Feinstein* and C.J. Shatz. Dept. of Mol. Cell Biol., UC Berkeley, CA 94720, and *Neuroscience Research Institute, UC Santa Barbara, CA 93106.

TrkB, a tyrosine kinase that serves as a receptor for the neurotrophin BDNF, has been shown to be present in the developing mammalian brain. We have recently demonstrated the developmental regulation of trkB protein expression in ferret visual system, using cross-linking of iodinated neurotrophins to receptors (Allendoerfer et al., Soc. Neurosci. Abs. 1992). To determine the specific cellular localization of trkB, an immunohistochemical analysis was performed at ages from E24 to adult, using 2 anti-peptide antibodies directed against distinct epitopes in the extracellular domain of trkB. At prenatal ages, immunostained fibers were observed in the internal capsule and intermediate zone. Within the cerebral hemispheres two distinct fascicles, one deep and one superficial, are present. Fiber staining declined with increasing age, while staining of cell bodies increased with development. At E30 some cells in the preplate were stained. By P10, two populations of cortical neurons were stained: subplate cells and layer 5 pyramidal cells. By P45, the staining for trkB had extended to neurons in all cortical layers, although the intensity of the staining may have been somewhat reduced from that seen at P10. Radially oriented processes, shown by double-labeling with anti-vimentin at P10 to correspond to radial glia, were stained as early as E30. At P10 and, to a lesser extent, P24, we observed cellular staining in the subventricular zone, a mitotic zone thought to be the site of generation of glial cells. Staining of mature astrocytes was observed at P24 and later ages when higher concentrations of antibody were used. Staining of hippocampal and basal forebrain neurons was observed in postnatal animals, as expected. Both the fiber staining seen early in development and the cellular staining of neurons and glia seen later were completely blocked by preincubation of the affinity-purified antibodies with the peptides against which they were made. These data suggest that different subsets of cortical neurons, and both neurons and glia, may bind and respond to neurotrophins such as BDNF at discrete developmental times. [Supported by EY06327 (RJC), ACS grant S-68-91 (MJR), NSF grant IBN-9120836 (SCF), and EY02858 and the Alzheimer's Assn. (CJS)].

538.8

NEUROTROPHIN RECEPTORS IN THE DORSAL COLUMN NUCLEI: IMMUNOCYTOCHEMICAL LOCALIZATION AND HIGH AFFINITY BINDING ASSAYS. D.R. Foschini*, D.P. Crockett and M.D. Egger. Dept. of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Med. Sch., Piscataway, NJ 08854-5635.

Neurotrophin receptors have been immunocytochemically localized in the dorsal column nuclei (DCN) in the brainstem of the rat, suggesting that the DCN may be neurotrophin responsive. The DCN, which consist of the cuneate nucleus (CN) and the gracile nucleus (GN), possess immunoreactivity for 1) p75^{NGFR}, the common low affinity binding site for all neurotrophins, 2) trk A, the high affinity nerve growth factor (NGF) receptor, and 3) trk B, the high affinity brain derived neurotrophic factor (BDNF) receptor. In the CN, p75^{NGFR} immunoreactivity is confined to an intense blotchy pattern in the middle region. Trk A and trk B immunoreactivity is more disperse: trk A immunoreactivity is localizable to neuronal-like cell bodies in the CN and fibers in the cuneate fasciculus; trk B immunoreactivity is associated with fibers, astrocyte-like cells and neuron-like somata in the CN and external CN. Immunoreactivity for all three neurotrophin receptors is also present in the GN.

A high affinity NGF binding assay was performed on adult rat brainstem tissue. The middle region of the CN binds ¹²⁵I-NGF specifically.

The Trk family of tyrosine kinase receptors are the functional receptors for the NGF family of neurotrophins. The product of the *trk* proto-oncogene serves as the high affinity receptor for NGF, the *trkB* for BDNF and *trkC* for NT-3. Using homologous recombination techniques in ES cells, we generated mice that lack either the Trk, TrkB or TrkC kinase receptors. Heterozygous animals of all three mutant lines show no apparent defects when compared to wild-type animals. However, homozygous *trkB* (-/-) mice die within the first 48 hours, apparently of starvation/dehydration, since no milk is found in their stomachs. Examination of the neural pathways involved in feeding showed significant defects in the trigeminal ganglion and facial motor nucleus. Deficits were also present in two targets that have been shown to be responsive to BDNF, the dorsal root ganglia and motor neurons of the spinal cord. The abnormalities observed in the *trkB* (-/-) mice will be compared to those found in the *trk* (-/-) and *trkC* (-/-) mice.

538.11

DEVELOPMENTAL CHANGES IN FULL-LENGTH AND TRUNCATED *TRKB* RECEPTORS IN THE RAT CNS. R.H. Fryer^{*}, D.R. Kaplan¹, S.J. Rabin¹ and L.F. Kromer. Dept. of Anatomy & Cell Biol., Georgetown Univ. Medical Center, Washington, DC 20007 and ¹the ABL-BRP, NCI-FCRDC, Frederick, MD 21702

The neurotrophins BDNF and NT-4/5 presumably mediate their trophic effects through full-length *trkB* receptors which contain an intracellular signal transducing tyrosine kinase domain. A truncated form of the *trkB* receptor which lacks the intracellular kinase domain also has been identified in the adult CNS. This receptor appears to be highly expressed in the ependyma and choroid plexus, however, its function is unknown. Thus, the purpose of the present study was to further examine the distribution of truncated and full-length *trkB* receptors in various CNS regions and to compare the relative levels of these receptors during CNS development and maturation. Beginning at embryonic day 14 various regions of the CNS were dissected, proteins were separated by SDS-PAGE, and both types of *trkB* receptors were identified with an antibody against the extracellular domain of the receptor. All brain regions analyzed (ventral mesencephalon, neostriatum, septum, and retina) contain both full-length and truncated receptors. At early developmental time points the full-length receptor predominates. However, as development progresses there is a steady increase in the level of the truncated receptor so that beginning at about postnatal day 5-10, the truncated receptor predominates in most regions. The wide spread distribution of truncated *trkB* indicates that this receptor is expressed in either neurons or glia in addition to the ependyma. Moreover, developmental changes in the relative amounts of full-length and truncated *trkB* receptors suggest that both forms of the receptor may be important for the maturation and normal function of the adult CNS. Supported by NIH grant NS-31445.

538.13

EXPRESSION OF EXTRACELLULAR DOMAINS OF p140^{trkA} AND p145^{trkB} IN INSECT CELLS.

M. Ashcroft, D. Dawbarn, S.H. MacGowan, S.J. Allen, R. Feeney, S.M. Colebrook^{*}, Molecular Neurobiology Group, Dept. Med. (Care of the Elderly), Bristol Univ., Bristol, BS2 8HW.

Neurotrophic factors bind with high affinity (Kd of 10⁻¹¹ M) to specific protein tyrosine kinase receptors. These receptors have been designated p140^{trkA}, p145^{trkB}, p145^{trkC}, on the basis of their apparent molecular weight and their specificity for binding NGF, BDNF, and NT-3 respectively. PCR methodologies were used to generate the extracellular regions for the human p140^{trkA} and the rat p145^{trkB} receptors with stop codons added at the 3' end. These were subcloned into the baculovirus transfer vectors, pEVMXIV and pBlueBacHis and used to cotransfect Sf21 cells with BaculoGold™ linearized DNA. Positive plaques were identified and used to generate high titre recombinant viral stocks which were used to infect suspension cultures of insect cells for the production of recombinant secreted (pEVMXIV) and non-secreted (pBlueBacHis) proteins. The 3-dimensional structure of these proteins will be determined by X-ray crystallography.

538.10

DIFFERENTIAL DISTRIBUTION OF mRNAs ENCODING FOR TRKB VARIANTS IN DEVELOPING AND ADULT NERVOUS SYSTEM. M.P. Armanini^{*}, H.S. Phillips, E.J. Mufson, D.L. Shelton. Dept. Neuroscience, Genentech, Inc. S. S. F., CA 94080 and Dept. Neurological Sciences, Rush Presbyterian St. Lukes Med. Ctr., Chicago, Ill 60612.

trkB binds both BDNF and NT4/5 with high affinity and binding of these ligands leads to tyrosine phosphorylation and subsequent activation of the receptor. In the rat, there are two described truncated versions of trkB, t1 and t2, which do not contain tyrosine kinase domains. Although the function of these truncated receptors remains obscure, the high degree of homology reported here for mouse and human cDNA clones encoding t1 and t2 suggests a conserved biological role. In situ hybridization using probes specific for the tyrosine kinase containing (TK) or truncated forms (t1, t2) of trkB was used to study the distribution trkB mRNAs.

During embryonic development, both t1 and t2 were prominently expressed throughout the ventricular zone of the neural tube, while expression of TK was confined to regions of postmitotic maturing neurons. In the adult brain, TK expression remained confined to regions of neuronal perikarya, t1 was primarily expressed in choroid plexus and ependyma with lower expression in neurons, and t2 was limited to expression in neurons. Unexpectedly, although TK hybridization displayed a typical pattern of diffuse labeling throughout neuronal cell bodies, hybridization to t2 mRNA displayed a striking perinuclear localization. In a rodent model, age-related decreases of hybridization for t2, but not TK, were observed in hippocampal neurons, suggesting that probes specific for human trkB variants may be useful tools to study human pathological states.

538.12

Low Affinity Nerve Growth Factor Receptor (LNGFR) Immunoreactivity in the Dorsal Lateral Geniculate Nucleus (dLGN) of the Adult Cat. E.C. Foley^{*} and H.E. Pearson. Department of Anatomy and Cell Biology, Temple University School of Medicine, Philadelphia, PA 19140.

The LNGFR is one of the components involved in the biological actions of the neurotrophins. Therefore, the localization of the LNGFR within retinal ganglion cell (RGC) target areas is an important step in determining if RGCs can respond to any of the neurotrophins. In this study, we have used immunocytochemistry to localize the LNGFR within target regions of adult cat RGCs. 3 adult cats were perfused with 4% paraformaldehyde, and the dLGN and superior colliculus (S.C.) were sectioned on a vibratome at 40µm. Sections were incubated in BSA and triton in PBS, followed by incubation with a monoclonal antibody to LNGFR. The primary antibody was omitted in control sections. Sections were processed according to the Vectastain ABC immunoperoxidase method, mounted onto gelatin coated slides, dehydrated, and coverslipped. The density of LNGFR-like immunoreactivity in the dLGN and S.C. was determined, and statistical differences between LNGFR-like immunostaining and background staining in the optic tract were calculated. The density of LNGFR-like immunostaining within the dLGN was significantly different from background staining, but there were no differences between LNGFR-like immunostaining and background staining in the S.C. These results provide evidence that one of the components necessary in the actions of neurotrophins is located within the retinogeniculate pathway of the cat.

538.14

CLONING OF FGF RECEPTORS mRNA FROM RAT BRAIN. C.Andersson^{*} and F.Eckstein. Dept. of Cell Bio. & Anat., Ore. Health Sci. Univ., Portland, OR 97210.

Five fibroblast growth factor receptors (FGFR) genes are known. Structural features shared by the FGFR family include glycosylated immunoglobulin-like (Ig) loops in the extracellular domain and a conserved transmembrane tyrosine kinase domain. Several of the receptors in this family also exhibit alternate splice forms. However, the receptors have only been sequenced from human, mouse, *Xenopus*, *Drosophila*, and chick. In order to perform nuclease protection assays in rat, mRNA was isolated from postnatal and adult rat brain, reverse transcribed, and PCR amplified using three degenerate oligo-nucleotide primers. The first primer was from the conserved extra-cellular region; the second and third primers were from the conserved tyrosine kinase one and two regions, respectively. The third primer was used in conjunction with primer one or two. The resulting PCR products yielded two fragments at 500 and 1100 bp, which were subcloned, analyzed by restriction digests and sequenced. Restriction digests revealed a number of possible subtypes for FGFR1 and FGFR2. Sequence analysis reveals a considerable amount of sequence homology between rat FGFRs and FGFRs from other species.

538.15

DIFFERENTIAL EXPRESSION AND ALTERNATIVE SPLICING OF FIBROBLAST GROWTH FACTOR RECEPTORS IN THE CNS. E. Yamaguchi, H. Sava, J. Bruner, W. McKeehan and R.S. Morrison*. Dept. of Neurosurgery, M.D. Anderson Cancer Center, Houston, TX 77030.

Basic fibroblast growth factor (FGF) influences multiple cell types in the CNS. The underlying basis for the diversity of FGF actions on CNS cells is not understood, but may be related to cell type-specific expression of FGF receptors (FGFR). In the present study we evaluated FGFR expression in normal and neoplastic human brain using RT-PCR southern blotting and immunocytochemistry. FGFR1 mRNA expression was abundant in normal cortex (grey matter), but was expressed at low to non-detectable levels in normal white matter. Conversely, white matter expressed abundant levels of FGFR2. Consistent with its expression in white matter, benign astrocyte tumors also contained abundant levels of FGFR2 mRNA. However, FGFR2 expression diminished in astrocytic tumors in relation to their loss of differentiation. FGFR1 antibodies strongly labeled neurons in frozen sections of adult human brain but only stained short, delicate cell processes in normal white matter. Malignant astrocytes stained intensely for FGFR1. Normal cortex expressed an alternatively spliced form of FGFR1 mRNA containing three immunoglobulin (Ig) domains while malignant astrocytes expressed a form containing two Ig domains. The results of the present study suggest that 1) glial cells may preferentially express FGFR2 while, FGFR1 expression is principally restricted to neurons, 2) FGFR2 expression may be required for astrocyte differentiation and 3) transformed astrocytes express an alternatively spliced form of FGFR1 that may provide them with an increased growth advantage.

538.17

TRKB IMMUNOREACTIVITY BUT NOT TRKB mRNA IS MODULATED BY MONOCULAR DEPRIVATION DURING THE CRITICAL PERIOD. A. Cellerino, Y. Bozzi, R. Siciliano, L. Domenici and L. Maffei. Neurophysiol. Inst. (CNR) and Scuola Normale Superiore, Pisa, Italy.

Recently it has been reported that an exogenous supply of NGF prevents the effects of monocular deprivation (MD) suggesting a role for NGF and possibly other related neurotrophins in visual cortical plasticity. Here we investigated whether MD modulates neurotrophins receptors at the level of visual cortex. Ten hooded rats (Long Evans) were monocularly deprived under chloral hydrate anaesthesia at different ages of postnatal development (N=6 rats at P15, N=2 at P23 and N=2 at P30) for a period of two weeks. MD effects were evaluated using immunohistochemical (polyclonal antibody to TrkB, Santa Cruz, USA) and in situ hybridization techniques on tissue fixed slices. Polyclonal antibodies and riboprobes were directed versus the intracellular domain and both recognize the full length form of TrkB.

We found that TrkB like immunoreactivity is reduced in the visual cortex contralateral to deprived eye; this effect was present in the groups of animals deprived at P15 and P23 but not in animals deprived at P30. On the contrary TrkB mRNA was normal in MD animals. We conclude that MD modulates TrkB probably acting at a posttranslational level. This modulation is restricted to a time window of postnatal development overlapping the rat critical period for MD effects.

NEUROTROPHIN RECEPTORS DURING DEVELOPMENT OF THE CHICK AND RAT RETINA. Nestor G. Carr^{1,2}, Reg Williams², Anders Bäckström², Klas Kullander², Finn Hallböök and Ted Ebendal². Department of Developmental Biology², Biomedical Center, Uppsala University, Box 587, S-751 23 Uppsala, Sweden, and IMBICE¹, La Plata, Argentina.

The neurotrophin family is a group of distinct molecules which enhances neuronal survival and differentiation, including neurite outgrowth. However, little is known of the effects of these neurotrophins on the subpopulations of neurons within the embryonic retina, nor of the high-affinity receptors of the TRK family of tyrosine kinases that these cells are expressing during development. We used molecular methods to produce recombinant neurotrophins in order to analyse the effects of NGF, BDNF, NT-3 and NT-4 on fibre outgrowth from chick retinal explants at E6 and rat retinal explants at E16 put on collagen gels. The resulting neurite outgrowth was measured and dose-dependent responses to the neurotrophins were obtained. In particular, the retina responded well to BDNF and NT-3. To study the expression of TRKs we cloned and sequenced cDNAs encoding trk, trkB and trkC from the chick retina. The cellular expression of TRKs were then analysed by in situ hybridization using corresponding specific antisense oligonucleotides. The results revealed differential expression of the neurotrophin receptors in different cell layers of the retina at different stages of development, providing a base for the observed growth responses to the different neurotrophins seen in culture. It is concluded that different retinal neurons are the targets for several members of neurotrophin family thus likely to have developmental functions in the establishment of the visual pathways. (CONICET-PIB-BID 1431-91, Swedish NSF and MRC).

In Situ Hybridization of *trkB* in the Developing Chick Visual System and Brain J.E. Johnson¹, S.W. Wang¹, A. Garner², K. Baeshore², J. Large², S. McKay¹, R.W. Oppenheim¹. ¹ Dept. of Neurobiology and Anatomy, Bowman Gray School of Medicine of Wake Forest University, Winston-Salem, N.C. 27157 ² Dept. Neurosci., Case Western Reserve Univ. Sch. of Medicine, Cleveland, OH 44106

Results from previous studies have indicated that brain-derived neurotrophic factor (BDNF) can support the survival of isolated retinal ganglion cells *in vitro* (J. Neurosci. 6(10): 3031-3038). *TRKB*, a member of the *trk* family of tyrosine kinase receptors, appears to transduce the cell survival activity of BDNF. Recent observations from Garner and Large have revealed alternate 5' and 3' splice variants for both *trkB* and *trkC* in the chick. These include kinaseless variants similar to those reported in both rat and mouse.

In situ hybridization was performed with riboprobes prepared against the extracellular domain of *trkB* on the developing chick retina and brain to localize the production of the BDNF receptor during normal chick visual system development. Larger cells within the ganglion cell layer of the E18 chick retina showed specific labeling when compared with sense controls. In addition, a few cells on the inner margin of the inner nuclear layer were also specifically labeled. Interestingly, specific labeling was observed in the stratum griseum centrale of the optic tectum at a variety of ages. Labeling was also observed in a variety of other brain nuclei including midbrain nuclei associated with the visual system as well as non-visual areas. Results from these localization studies are consistent with the hypothesis that BDNF may play a role in the development of the chick visual system as well as other regions of the avian brain. Experiments are in progress to further map the expression of splice variants for both *trkB* and *trkC* during normal development in the chick visual system and brain.

LEVELS AND RATIO OF RGNTF AND ITS RECEPTOR CONTRIBUTE IN THE DETERMINATION OF GROWTH AND APOPTOSIS OF NEONATAL RAT RETINAL GANGLION CELLS. F Ren* and RMW Chau, Department of Anatomy, Univ. of Hong Kong, Hong Kong.

Survival of only 30% RGCs in neonatal rat retina depended on the supply of a retinal ganglion neuronotrophic factor (RGNTF) from the superior colliculus. The apoptosis of RGCs may be due to their own turn-off expression of RGNTF. RGNTF monoclonal antibody (MAB) was raised and used to raise anti-idiotypic antibody (Id Ab). These MAB and Id Ab were used to localize the RGNTF and its receptor in the retinas of rats aged E16 through P0 to adult. Results revealed that the RGNTF immunoreactivity in RGCs is highest at E16 about 3X of that at P0 or 4X of P12, while that for its receptor is highest at E18 about 16X higher than that at E16 or 2.6X of P0. Ratios of the immunoreactivities of RGNTF and its receptor is 3:1 at E16, and 2:1 at E18-P0. These results indicated that at E16 RGCs divide rapidly with a factor/receptor ratio at 3:1, while from E18 to P0 these RGCs undergo processes of migration, differentiation and maturation with the ratio at 2 to 1. It seems that besides other intrinsic or extrinsic factors, the ratio of RGNTF and its receptor contributes in the early proliferation and differentiation of RGCs while the apoptosis of neonatal RGCs is induced by the reduced expression of RGNTF and its receptor in embryonic RGCs as well as the reduced supply of RGNTF from the superior colliculus.

ISOLATION OF HIGH-AFFINITY TRK RECEPTORS, FROM THE CHICKEN AND THEIR EXPRESSION IN EMBRYONIC SENSORY GANGLIA. A. Bäckström, R. Williams, F. Hallböök and T. Ebendal*. Dept. of Developmental Biology, Biomedical Center, Uppsala University, Box 587, S-751 23, Uppsala, SWEDEN.

The neurotrophin family consists of four members, NGF, BDNF, NT-3 and NT-4/NT-5. All neurotrophins are able bind to the low-affinity NGF receptor p75, with similar affinity. However this receptor is unable to mediate a cellular response and hence its function is not clear. The functional response to the neurotrophins is mediated by high-affinity receptors, of which three receptors are currently known; trk, trkB and trkC which belong to the TRK family of tyrosine kinase receptors. Recent studies have also indicated the existence of different isoforms of trkB and trkC which are able to bind neurotrophins at high-affinity and yet, because these isoforms lack an intracellular kinase domain there is no signal transduction. Using degenerate oligonucleotides and PCR we have isolated DNA fragments for the different trk:s in chick. These fragments have then been used to screen cDNA libraries from different embryonic organs to get full-length sequences. From these sequences, it has been possible to design specific oligonucleotides for the different trk:s and their isoforms, for use in *in situ* hybridization. In this way we have looked at the mRNA expression in the sensory ganglia at embryonic day 9 in the chick. 5' primer extension reactions allowed for cloning of full-length sequences, genomic clones to allow for examination of promoter regions are now in progress.

538.21

mRNA EXPRESSION FOR THE HIGH-AFFINITY NEUROTROPHIN RECEPTORS DURING CHICK EMBRYONIC DEVELOPMENT. R. Williams*, A. Bäckström and T. Ebendal. Department of Developmental Biology, Uppsala University, Biomedical Centre, S-751 23 Uppsala, SWEDEN.

Antisense oligonucleotides specific for the high-affinity neurotrophin receptors *trk*, *trkB* and *trkC* were used to examine the expression of mRNA for these receptors during chick embryonic development. Special emphasis was placed on the high-affinity receptor expression in the developing sensory nervous system, on which an examination was performed from stage 15 through to E18. *TrkC* mRNA expression was observed in the newly forming trigeminal ganglion at stage 15, in the cells of the trigeminal placode and in the cells migrating from this placode. *TrkB* and *trk* mRNA expression within the sensory ganglia were first evident at consecutively later stages of development and in complementary neurons within this, and other ganglia. At all stages subsequent to the initial expression of the mRNA for each of these receptors, the continued expression was evident. In each of the sensory ganglia examined there existed a typical pattern of expression for each receptor mRNA which became increasingly evident as development progressed. At E18, the neurons expressing mRNA for each of the high-affinity receptors have been characterized in respect to the relative percentages and distribution of each within the ganglia and their neuronal diameter.

538.23

EVIDENCE THAT THE EFFECTS OF CILIARY NEUROTROPHIC FACTOR (CNTF) IN THE CENTRAL NERVOUS SYSTEM (CNS) ARE MEDIATED VIA ASTROCYTES. R.E. Clatterbuck*, D.L. Price and V.E. Koliatsos. The Johns Hopkins Univ. Sch. of Med., Balto., MD 21205.

The neural cytokine CNTF has effects on broad classes of neurons in both the CNS and peripheral nervous system as well as some glial cells *in vitro*. CNTF has also been shown to exert effects on various populations of neurons *in vivo*. In the CNS, the expression of both CNTF and its signal transduction proteins is widespread. To examine the possible role that astrocytes might play roles in CNTF signalling cascades, we have studied the model of anterior thalamic degeneration following cingulectomy. In this model, CNTF prevents the retrograde death of thalamic neurons [Clatterbuck et al., *Proc. Natl. Acad. Sci. USA* 90:2222, 1993]. Using immunocytochemistry for glial fibrillary acid protein (GFAP), we have demonstrated a profound transformation of astrocytic morphology following the rescue of anterior thalamic neurons with CNTF. These astrocytes are "gemistocytic" in appearance as compared to the reactive, fibrous astrocytes seen in CNS lesions. In addition, we have shown that the injection of CNTF into the undamaged CNS induces the expression of GFAP and the alteration of astrocytic morphology well beyond that seen in control injections. Using reverse transcriptase-polymerase chain reaction, we have also demonstrated the expression of mRNA for CNTF and for CNTF receptor α in the optic nerve, a pure population of CNS glia. Given that CNTF in the CNS is probably produced by astrocytes, we propose an autocrine role for this peptide in response of the CNS to neuronal injury.

538.25

NEUROTROPHINS BINDING TO *trkB* ARE TROPIC FACTORS FOR MAMMALIAN MOTOR NEURONS. M.H. Cayouette, R.E. Clatterbuck, L.R. Berkemeier, J.W. Winslow¹, A. Rosenthal, G.K. Gouras², D.L. Price and V.E. Koliatsos. The Johns Hopkins Univ. Sch. of Med., Balto., MD 21205 and ¹Genentech, South San Francisco, CA 94080, ²The Harvard Med. Sch., Boston, MA 02115.

Although earlier studies indicate that neurotrophins do not influence α -motor neurons, it appears that a subset of this family of peptides transduced via *trkB* (brain derived neurotrophic factor [BDNF] and neurotrophin-4/5 [NT-4/5]) are potent trophic factors for motor neurons. First, both BDNF and NT-4/5 are expressed in striated muscles during the period of developmental death of motor neurons and are regulated by injury (muscle denervation). Second, α -motor neurons express a catalytic isoform of *trkB*, the high-affinity receptor for BDNF and NT-4/5, throughout their postnatal life. Third, NT-4/5 and BDNF are transported retrogradely to α -motor neurons in a saturable manner; retrograde transport is not blocked by an excess of heterologous neurotrophins. Finally, BDNF and NT-4/5 promote the survival of α -motor neurons following axotomy in neonatal animals. The patterns of expression and effects of BDNF and NT-4/5 on α -motor neurons raise the possibility that some neurotrophins may be useful in treating patients with motor neuron disease.

Murine cell lines of septal origin are responsive to CNTF

P. Rajan, A. J. Symes, B. H. Wainer and J. S. Fink

Molecular Neurobiology Laboratory, Massachusetts General Hospital and Department of Neurology, Harvard Medical School, Boston, MA 02114; Department of Pathology, Albert Einstein College of Medicine, Bronx, New York.

Ciliary neurotrophic factor (CNTF) influences the survival and development of motor and sensory neurons, the differentiation of sympathetic neurons and the survival of some central nervous system (CNS) neurons after injury. We have previously shown that a 180 base pair cytokine responsive element (CyRE) mediates transcriptional activation of the vasoactive intestinal peptide (VIP) gene in response to CNTF in a human neuroblastoma cell line NBFL. To begin to elucidate the molecular mechanism of action of CNTF on cells derived from the CNS, we have employed cell lines (SN48 and SN56) derived by fusing N18TG2 neuroblastoma cells with murine septum. As CNTF has been shown to produce survival of rat septal neurons after transection of the fimbria-fornix, we reasoned that septal-derived cell lines may be CNTF-responsive. We tested whether the CyRE of the VIP gene (linked to luciferase) would mediate transcriptional activation in response to CNTF in SN48 and SN56 cell lines. CNTF treatment of SN48 and SN56 cells transfected with the CyRE-luciferase gene reporter increased luciferase activity 5 and 3 fold respectively. Our results indicate that the cell lines of septal origin are responsive to CNTF and suggest that common molecular mechanisms may mediate CNTF responsiveness in cell lines of CNS and PNS origin.

538.24

RETROGRADE TRANSPORT OF NEUROTROPHIN RECEPTORS. M.D. Ehlers¹, D.R. Kaplan² and V.E. Koliatsos¹. The Johns Hopkins Univ. Sch. of Med., Balto., MD 21205 and National Cancer Institute, Frederick, MD 21702.

The neurotrophin family of growth factors (of which nerve growth factor [NGF] is the prototype) consists of a group of small polypeptides that are synthesized by target tissues and that exert their influence on neurons at the nerve terminal. Although much is known about the local molecular signal transduction events mediated by neurotrophins, very little is known about the nature of the retrogradely transported neurotrophin signals sent from nerve terminals to cell bodies. The neurotrophins, as well as the low-affinity NGF receptor p75, are retrogradely transported. It is possible that, upon NGF binding, the NGF/NGF receptor complex is itself internalized and transported, representing the primary trophic signal. We have examined this hypothesis by studying the retrograde transport of the high-affinity NGF receptor, *trkA*, in the adult rat sciatic nerve. Following sciatic nerve ligation (18 hours), *trkA* protein accumulates distally to the ligation site, as determined by Western blot analysis. This accumulation is enhanced by injecting NGF into the rat footpad and is abolished by the injection of blocking NGF antibody. In addition, by immunoprecipitation and phosphotyrosine Western blot, we observe that *trk* species, which accumulates distally but not proximally to the ligation site, is tyrosine phosphorylated. NGF injection increases the accumulation of this tyrosine phosphorylated species, and blocking NGF antibodies abolish the accumulation. Taken together, our results provide *in vivo* evidence for the retrograde transport of *trkA* in a tyrosine phosphorylated state. These data suggest that active *trkA* tyrosine kinase could be the primary retrograde neurotrophin signal.

DIFFERENTIAL EXPRESSION OF *trk* AND *trkB* IN ENTERIC AND ENDOCRINE CELLS OF THE RAT DIGESTIVE SYSTEM. C. Sternini, D. W. Rickman, R. De Giorgio^{*} and N. C. Brecha. CURE and Depts. of Medicine and Anatomy & Cell Biology, UCLA and VAMC-West Los Angeles, LA, CA 90073.

We reported the presence of immunoreactivity (IR) for the neurotrophin high-affinity receptors, *trk* and *trkB*, in the developing enteric nervous system (ENS) of the rat, suggesting a role of neurotrophins in the developmental regulation of the rodent gut. We further investigated the sites of expression of *trk* and *trkB* in the fetal and adult rat digestive tract with single and double-label immunohistochemistry. *trk*- or *trkB*-IR is present in the developing myenteric plexus at low levels at embryonic day (ED) 14, and by ED 18-20 it is strong in both enteric plexuses, and in fibers in the gut wall, vasculature and pancreas. *trk*- and *trkB*-IR fibers and cell bodies are immunolabeled with neurofilament antibodies confirming their neuronal nature. The density of *trkB*-IR in the ENS decreases postnatally, whereas *trk*-IR remains abundant throughout adulthood. Interestingly, *trkB*-IR is also detected in gut and pancreatic endocrine cells from prenatal ages to adulthood. Pancreatic *trkB*-IR islet cells are distinct from somatostatin, insulin or pancreatic polypeptide cells, and are likely to be glucagon cells. *trkB*-IR in endocrine cells is not blocked by an excess of pancreatic hormones. *trk*- or *trkB*-IR is blocked by the homologous antigen. This study suggests that neurotrophins play a broader role than simply being target-derived neurotrophic molecules and that each neurotrophin has distinct functions in the gut.

TRKB mRNA EXPRESSION IN THE CHICK EMBRYO: CORRELATION WITH BDNF RESPONSIVENESS AND BINDING.

S. Biffo, G. Dechant, H. Okazawa and Y.-A. Barde. Max-Planck-Institute for Psychiatry, Dept. of Neurobiochemistry, D-82152 Planegg-Martinsried FRG.

Brain-derived neurotrophic factor (BDNF) allows the survival of a variety of embryonic neurons, as shown, for the most part, with cells isolated from chick embryos. In mammals, the tyrosine kinase *trkB* has been shown to be a receptor for BDNF. In order to examine the extent to which the cellular expression of *trkB* correlates with known targets of BDNF, *trkB*-encoding c-DNAs were isolated. *In situ* hybridisation studies were performed using sections of E3-E14 chicks and a riboprobe recognising a 9 kb transcript encoding for a full-length receptor. In all ganglia from the peripheral nervous system, a good correlation was found between BDNF responsiveness and *trkB* expression (e.g., trigeminal, acoustic, nodose, spinal sensory ganglia were positive, whereas sympathetic and ciliary ganglia were negative). In the CNS, low levels of expression were detected over the area of the spinal cord containing motoneurons (known to respond to BDNF *in vivo*). So far however, we were unable to detect *trkB* expression in developing retinal ganglion cells, which is surprising as these cells are known to respond *in vitro* to BDNF. Using a riboprobe detecting also truncated forms of *trkB*, expression was found (as in rodents) in non-neuronal cells such as ependymal and mesenchymal cells. In the developing acoustic system, the expression of truncated *trkB* was seen in cells forming a ring surrounding the sites of expression of both BDNF mRNA (developing cochlea) and of full-length *trkB* mRNA (acoustic ganglion). By receptor autoradiography on frozen sections with ¹²⁵I-BDNF (used at 3x10⁻¹¹ M), not only neurons expressing full-length *trkB*, but also the cells expressing truncated form of *trkB* were found to be labelled. We are currently investigating the extent to which binding of labelled BDNF matches with the expression of *trkB*, as investigated by *in situ* hybridisation.

NEUROTROPHIN RECEPTOR GENE EXPRESSION IN DEVELOPING DRGs. X. Mu, I. Silos-Santiago, R. Gertsen, W. D. Snider*

Dept. Neurology, Washington Univ., Med. Sch., St. Louis, MO 63110.

Expression of the neurotrophin receptors, *trkA*, *trkB*, *trkC*, and *p75* is thought to determine the neurotrophin (NT) responsiveness of different populations of central and peripheral neurons. In order to better understand the functions of these receptors during development, we have studied their expression in developing rat DRGs by *in situ* hybridization. Expression of *trks* is readily apparent by E12, only 24 hours after neurogenesis begins in DRGs. mRNA for these receptors appears to be diffusely expressed at E12. However, even at this early age, none of the *trks* is expressed by all DRG cells. By E15, distinct patterns of receptor gene expression in DRGs are apparent in that different *trks* are expressed by neurons whose soma areas show differing size-frequency profiles. These distinct patterns persist into adulthood. *p75* expression is also readily apparent by E12. Interestingly, *p75* was not expressed by all DRG neurons at any developmental stage. Comparisons of percentages of *p75* and *trk* expressing DRG neurons suggest that *p75* is not invariably co-localized with a member of the *trk* family. Surprisingly, at PN21, size-frequency histograms of *p75*-expressing neurons are skewed toward larger cell diameters. We have also examined expression of one truncated form of *trkB* neurotrophin receptor, *gp95trkB*. Expression of *gp95trkB* was observed in ependymal cells around the central canal. However, we did not detect expression of *gp95trkB* in spinal cord or DRG neurons at any developmental stage.

The expression of *trks* and *p75* in DRGs by E12 suggests that DRG cells are competent to respond to target-derived and locally expressed NTs from the earliest stages of DRG development. By E15, *trks* are expressed by DRG cells with differing morphologies suggesting responsiveness to specific NTs for different classes of DRG cells at later developmental stages. Finally, the pattern of expression of *p75* suggests that *trks* are not co-localized with *p75* in all DRG cells.

538.31

NEUROTROPHIN RECEPTOR (TRKA AND TRKC) mRNA EXPRESSION IN EARLY EMBRYONIC QUAIL TISSUES AND DORSAL ROOT GANGLIA (DRG). D. Zhang*, L. Yao, and P. Bernd.

Department of Anatomy and Cell Biology, State University of New York, Health Science Center, Brooklyn, NY 11203.

In situ hybridization was used to determine whether mRNA for the neurotrophin receptors *trkA* and *trkC* was expressed in neural crest cells and DRG of quail embryos. Examination of cryostat sections following *in situ* hybridization with ³⁵S labelled riboprobes (kindly provided by Dr. L. Parada) and radioautography revealed the presence of *trkC* mRNA in migrating neural crest cells (E2.5-3; stages 18-20), as well as in DRG throughout development. Control sections were hybridized with a labelled sense probe. The presence of *trkC* mRNA was also demonstrated by RT-PCR to be present in the neural tube of E2 (stages 12-14) quail, an age at which the neural crest is still adherent to the neural tube. The cellular localization of *trkC* mRNA in DRG varied during development. At early ages (E3-4.5; stages 22-25), *trkC* mRNA was homogeneously expressed on most cells in the DRG. These are small phase-dark cells which may represent neuroblasts and/or support cell precursors. At older ages (E5, 6.5, 7, 10; stages 27, 30, 32, 36), *trkC* mRNA is expressed in a subpopulation of large phase-bright neuron-like cells in the ventral part of the DRG. In contrast, *trkA* mRNA is homogeneously distributed in DRG throughout development. Furthermore, *trkA* mRNA appears to be less abundantly expressed at earlier stages (i.e. E3-3.5; stages 21-23). These results suggest that NT-3, the preferred ligand for *trkC*, may play an important role in neural crest cell migration and differentiation. Our accompanying abstract (Yao et al.) demonstrates the presence of NT-3 mRNA in early embryonic tissues. Supported by a grant from the Dysautonomia Foundation.

538.28

TRK EXPRESSION IN ADULT PRIMARY SENSORY NEURONES PROJECTING TO DIFFERENT PERIPHERAL TARGETS

S. B. McMahon¹, M. P. Armanini², L. H. Ling², H. S. Phillips²,
¹DeptPhysiology, UMDS, London SE1 7EH, and ²Dept Neuroscience, Genentech, South San Francisco, CA 94080.

Primary sensory neurones projecting to skin, muscle, and visceral targets were identified by applying fluorogold to the cut saphenous, gastrocnemius or pelvic nerves, respectively, in adult rats under pentobarbitone anaesthesia with sterile precautions. 48 hrs later the appropriate dorsal root ganglia (DRG) were fixed and removed. 14 micron cryostat sections of the ganglia were hybridized *in situ* with S³⁵-labelled cRNA riboprobes against *trkA*, or tyrosine kinase containing forms of *trkB* or *C*. After 3-4 weeks of emulsion autoradiography, fluorogold-containing cells expressing a particular *trk* could be clearly identified by the high concentration of silver grains distributed over the cell soma. Afferents innervating different targets exhibited distinct patterns of *trk* expression, as follows:

	cutaneous	visceral	muscle
<i>trkA</i>	35%	92%	20%
<i>trkB</i>	24%	91%	50%
<i>trkC</i>	16%	0%	73%

Clearly, some *trks* must be co-expressed in some afferents. Conversely, some afferents, notably at least about 30% of those innervating skin, do not appear to contain any known *trk*. This last conclusion was further supported by hybridizing some sections of L4/5 DRG with a 'cocktail' of antisense *trk* probes. 30% of neurones (small diameter) exhibited no labelling above background levels.

538.30

IMMUNOCYTOCHEMICAL LOCALIZATION OF TRKA IN RAT DORSAL ROOT GANGLIA AND SPINAL CORD. D.C. Molliver*, M. J. Radeke, Q. Yan, S.C. Feinstein, W.D. Snider.

UC Santa Barbara, Amgen, and Dept. Neurology, Washington Univ. Sch. Med., St. Louis, MO 63110.

One impediment to the study of neurotrophin actions has been the lack of immunocytochemical markers for the *trk* family of high-affinity receptors, which would allow the localization of receptor proteins within diverse populations of neurons. We used a recently generated antibody to the high-affinity nerve growth factor (NGF) receptor, *trkA*, to examine the distribution of the protein in dorsal root ganglia (DRG) and spinal cord of the rat. A polyclonal antibody to the intracellular domain of *trkA*, designated anti*trkIn*, has been generated against recombinant *trkA* intracellular domain and affinity-purified against full-length rat *trkA*. We tested the selectivity of anti*trkIn* by examining the pattern of *trkA*-like immunoreactivity (*trkA*-LI) in superior cervical (SCG) and nodose ganglia, two ganglia known to contain very different percentages of *trkA* mRNA-expressing neurons. Staining conformed to the results of *in situ* hybridization studies reported by Richardson et al (1992, *J. Neurosci.*, 12:4011-4022): virtually all SCG neurons were labelled, whereas only a very few cells were immunoreactive in the nodose ganglia. In contrast to labelling in nodose and SCG, *trkA*-LI in the DRG was restricted to a population of small and medium-size neurons, and was evident in embryonic ganglia by E-15. Most, but not all small cells were immunopositive. Size-frequency histograms of selected DRG sections indicated a mean soma area for immunoreactive cells of 318 μm^2 , as opposed to 615 μm^2 for negative cells. Consistent with the small size of labelled cells, immunoreactive fibers entering the spinal cord were restricted to lamina I and II of the dorsal horn, the target fields of A δ and C primary afferent fibers.

Colocalization of *trkA*-LI with other immunocytochemical markers should make it possible to characterize functional classes of DRG neurons that express *trkA* and are thus responsive to NGF.

DIFFERENTIAL DISTRIBUTION OF TRKC-POSITIVE SENSORY NEURONS IN SPINAL GANGLIA. R. A. Oakley*, A. S. Garner, T. H. Large and E. Frank.

Dept. of Neurobiology, University of Pittsburgh School of Medicine, Pittsburgh, PA 15261 and Dept. of Neuroscience, Case Western Reserve University, Cleveland, OH 44106.

In a previous study, neurotrophin-3 (NT-3) was found to support the survival of more chick sensory neurons from ganglia at limb levels than from thoracic ganglia. Moreover, identified muscle afferents survived best when cultured in NT-3 as opposed to other neurotrophins (Hory-Lee et al., PNAS 90:2613). These results suggest that NT-3 may be a selective neurotrophin for muscle afferents and that segmental differences in NT-3 responsiveness are due to the presence of more of these neurons in limb-level ganglia.

If NT-3 is a selective neurotrophin for muscle afferents, these neurons should express *trkC*, a receptor for NT-3. As a first step to determine if muscle afferents express *trkC*, we used *in situ* hybridization to compare the message levels for this receptor at limb vs. thoracic level dorsal root ganglia (DRG) in stage 36 chick embryos. The probes were complementary to the unique extracellular domain of *trkC* from chick. Although *trkC*-positive neurons populate both lumbar and thoracic DRG, they comprise a greater proportion of DRG cells at lumbar levels. More than 8% of the cells in lumbar ganglia were *trkC*-positive. In contrast, fewer than 3% of the cells in thoracic ganglia were *trkC*-positive. Since muscle afferents populate both thoracic and lumbar DRG but comprise a larger proportion of the neurons at lumbar levels, our findings are consistent with the hypothesis that muscle afferents express *trkC*. Moreover, virtually all of the *trkC*-positive cells we observed at both axial levels were large cells, consistent with the idea that they are muscle spindle afferents. To confirm the identity of these *trkC*-positive neurons we are using *in situ* hybridization in combination with retrograde labeling from either muscle or cutaneous nerves.

Supported by grants from the NIH.

538.33

MOLECULAR CLONING AND EXPRESSION OF HUMAN *trk*, *trkB*, AND *trkC*. D. L. Shelton*, J. Sutherland, K. Carroll, and S. Broz. Depts. of Neuroscience and Cell Genetics, Genentech, Inc. South San Francisco, CA. 94080.

In order to better understand their normal function and possible roles in neurodegenerative disease, human cDNA clones were isolated for each of the currently known members of the *trk* family of tyrosine kinase receptors. The sequence of these clones was determined and found to be very similar to that of previously isolated clones from other species. In addition to the tyrosine kinase containing forms of the receptors, clones encoding two forms of truncated *trkB* and one form of truncated *trkC* were obtained. In clones encoding the extracellular domains, two different sequences were obtained for both *trk* and *trkC*, presumably due to alternate splicing.

Protein was expressed for each of these members of the *trk* family by transfecting cDNA encoding the entire receptor into mammalian cells. Expression of the protein was confirmed by metabolic labeling, binding of neurotrophin and ligand induced or overexpression induced phosphorylation. In all cases, the appropriate size protein was synthesized, expressed at the cell surface, bound ligand and had tyrosine kinase activity. In separate experiments, fusion protein was produced which consisted of the extracellular domain of a *trk* fused to the *fc* tail of a human IgG. These were secreted into media, and demonstrated high affinity ligand binding.

538.35

EXPRESSION OF RECEPTOR TYROSINE PHOSPHATASE- σ (RPTP- σ) IN THE RAT NERVOUS SYSTEM. H. Wang*, H. Yan, O. Silvennoinen, A. Grossman, J. Schlessinger, J.M. Musacchio. Dept. of Pharmacology, N.Y.U. Med. Ctr., New York, NY 10016.

RPTP- σ , cloned from a rat brain stem cDNA library, has the typical structure of a type II receptor tyrosine phosphatase. The extracellular domain is composed of 3 immunoglobulin and 5 fibronectin type III-like repeats. The cytoplasmic portion has two phosphatase domains. A probe complementary to the cDNA of RPTP- σ from nucleotide 2918 to 2967 was synthesized, purified and 3'-end labeled with [α - 35 S]dATP. Northern blot and *in situ* hybridization studies indicated that RPTP- σ is expressed primarily in the CNS, where it can be detected at E12. RPTP- σ is expressed throughout development in most of the CNS, including the spinal cord and retina. The mRNA is also abundant in the trigeminal and dorsal root ganglia. The mRNA levels decrease progressively after birth. During the postnatal maturation of the cerebellum, the mRNA expression follows the migrating pattern of the granule cells. In the adult rat brain, the expression is seen in the hippocampus, cerebellum, olfactory bulb and cortex. Within the hippocampus, it is present in the pyramidal cell layer, and in the granular cell layer of the dentate gyrus. Labeling was also observed in several thalamic, pontine and oculomotor nuclei. The temporal pattern of RPTP- σ mRNA expression indicates that this phosphatase may play an important role in the development of the nervous system.

THE EXPRESSION OF RECEPTOR TYPE TYROSINE PHOSPHATASE- β (RPTP- β): EVIDENCE FOR A ROLE IN MORPHOGENESIS AND DEVELOPMENT OF THE NERVOUS SYSTEM. P.D. Canoll, G. Barnea, J.B. Levy, J. Sap, O. Silvennoinen, M. Ehrlich, J. Schlessinger, J.M. Musacchio*. Dept. of Pharmacology, N.Y.U. Medical Center, New York, NY 10016.

The recently cloned RPTP- β (Levy et al. Mol Cell Biol 13:1497, 1993) has a molecular structure indicative that it may function as a cell surface receptor. It has a large extracellular domain with a sequence strikingly homologous to carbonic anhydrase, and a fibronectin type III repeat. The extracellular domain is connected through a single transmembrane segment to a cytoplasmic portion that has two tandem catalytic phosphatase domains. *In situ* hybridization and immunocytochemical studies showed that RPTP- β is expressed predominantly in the developing nervous system, specifically in radial glia and in other forms of glial cells that play an important role as guides during neuronal migration and axonal elongation. High levels of RPTP- β are also seen in nerve fiber tracts throughout the central and peripheral nervous system during periods of axonal outgrowth. In the adult, low levels of RPTP- β are seen throughout most of the CNS. However, high levels of RPTP- β are seen in regions where there is continued neurogenesis and neurite outgrowth. The spatial and temporal pattern of RPTP- β expression suggest that it plays an important role in the morphogenesis and plasticity of the nervous system.

GENERATION OF ANTI-HUMAN NEUROTROPHIN-4/5 SPECIFIC MONOCLONAL ANTIBODIES. J.S. Hongo, A. Rosenthal* and B.M. Fendly. Departments of Medicinal and Analytical Chemistry and Neuroscience, Genentech, Inc., South San Francisco, CA 94080.

A panel of nine monoclonal antibodies (MAbs) specific to human neurotrophin-4/5 (hNT-4/5) have been developed and characterized. Mature hNT-4/5 has about 50-65% homology with nerve growth factor, brain-derived neurotrophin factor, neurotrophin-3 and Xenopus neurotrophin-4, and mediates its action through the *trkB* tyrosine kinase receptor. hNT-4/5 is expressed in many peripheral organs and its tissue distribution correlates with its putative role as a target-derived survival factor for peripheral neurons.

Conventional techniques were used to develop and characterize the MAbs, which included the analysis of purity and specificity, functional pairing, epitope specificity, affinity ranking and the ability of the MAbs to block hNT-4/5 binding to the *trkB* receptor.

Eight MAbs are capable of binding non-reduced and reduced protein. The MAbs have demonstrated the ability to pair in ELISA, appear to be directed against at least two distinct epitopes, and have demonstrated a wide range of relative affinities. Four MAbs appear to block binding of hNT-4/5 to the *trkB* receptor. Novel, specific MAbs to hNT-4/5 should be useful for studying the *in vivo* and *in vitro* expression of hNT-4/5.

538.36

CLONING OF RECEPTOR TYROSINE PHOSPHATASE SIGMA THAT IS HIGHLY EXPRESSED IN THE NERVOUS SYSTEM. H. Yan, A. Grossman, H. Wang, P. D'Eustachio*, K. Mossie*, J.M. Musacchio, O. Silvennoinen, R. Kris* and J. Schlessinger. Departments of Pharmacology and Biochemistry*, NYU Medical Center, New York, NY 10016; Sugen*, 515 Galveston Drive, Redwood City, CA 94063-4720

RPTP Sigma (RPTP- σ), a novel transmembrane receptor protein tyrosine phosphatase, was cloned from a rat brain stem cDNA library. The extracellular segment of RPTP- σ contains 824 amino acids and is composed of 3 Ig-like and 5 fibronectin type III (FNIII)-like repeats. The 627 amino acid cytoplasmic region of RPTP- σ consists of two catalytic domains oriented in tandem. RPTP- σ is most homologous to rat LAR, with 70% overall identity. It is a new member of the type II receptor tyrosine phosphatases. Northern blot analyses indicate that RPTP- σ is highly expressed in the brain as a 5.7 kb transcript. RPTP- σ is also expressed in the lung and intestine as a 6.9 kb transcript but at significantly lower level. *In situ* hybridization studies confirm that RPTP- σ is localized predominantly in the nervous system and can be detected in the rat as early as embryonic day 12 (E12). In adult rat brain, expression is mostly seen in the olfactory bulbs, the cerebellum, and hippocampus. Transfection of RPTP- σ cDNA into human embryonic kidney 293 cells results in the synthesis of a protein with an apparent molecular weight of 200 kDa as detected by immunoprecipitation and immunoblot analyses using polyclonal antibodies against the FNIII-like repeats present in the extracellular domain of RPTP- σ . RPTP- σ , like LAR and PTP- κ , undergoes proteolytic processing. The gene for RPTP- σ has been mapped to distal chromosome 17 in the mouse.

RETINOIC ACID-INDUCED DIFFERENTIATION OF IMMATURE CHICK SYMPATHETIC NEURONS.

A. v. Holst, A. Rodriguez-Tébar* and H. Rohrer*. Max-Planck-Institut für Hirnforschung, Abt. Neurochemie, Deutscherordenstr. 46, D-60496 Frankfurt/M., Germany; #Instituto Cajal de Neurobiología, Doctor Arce 37, E-28002 Madrid, Spain

The onset of survival response and dependence on nerve growth factor (NGF) is a critical step in the development of sympathetic neurons. Immature sympathetic neurons from embryonic day 6.5 (E 6.5) do not depend on NGF for survival, are unable to acquire NGF-responsiveness with time in culture, and die after 5 days *in vitro* even in the presence of NGF. However, addition of all-trans retinoic acid (RA) induces NGF-dependent survival and high-affinity NGF-receptors in E 6.5 cultures. This effect of RA on neuronal differentiation, leading to a more mature state, is observed at nanomolar concentrations of RA. The maturation effect of RA is also reflected by the inhibition of neuronal proliferation. The number of dividing sympathetic neurons is reduced when RA is added in a similar concentration range. A variety of differentiation markers analysed (e.g. tyrosine hydroxylase, N-CAM, F11 and neurofilament) were not affected by RA, suggesting a specific effect on sympathetic neuron development.

To understand the mechanism(s) of action of RA, we tested different RA analogues for their effects on proliferation and long-term survival. These analogues bind to the known retinoic acid receptor subtypes with different affinities, which leads to a selective activation of RA-responsive genes. We found that the antiproliferative effects are in part mediated by different analogues specific for retinoic acid receptors alpha (RAR α) and beta (RAR β) but they could not substitute for RA. However, the onset of NGF responsiveness is induced by RA analogues specific for RAR α , but not by agonists specific for RAR β or RAR γ . As an antagonist for RAR α inhibits the RA effect it is concluded that the induction of NGF responsiveness is mediated by RAR α .

Retinoic Acid and NGF in Embryonic Chick Sympathetic Neuronal

Development. L.A. Plum¹, P. Tsoulfas², L.F. Parada² & M. Clagett-Dame¹.¹School of Pharmacy & Interdepart. Grad. Prog. Nutr. Sci., Univ. of Wisconsin-Madison, WI 53706, & ²NCI-Frederick Cancer Res. Ctr., Frederick, MD 21702.

Studies were initiated to investigate the role of retinoic acid (RA) in promoting NGF-dependent neurite outgrowth and survival of chick embryonic sympathetic neurons. Sympathetic ganglia were isolated from chick embryos at days 6.5-7, 7.5-8, 8.5-9, 11 and 15 and used for *in vitro* culture experiments or to isolate RNA. Ganglia were dissociated and neurons were cultured in the presence of NGF (20 ng/ml), all-*trans* RA (5 nM), NGF+RA or vehicle. Neurons from 6.5-7 day embryos exhibited no outgrowth of neuritic processes and died within 4-5 days in the presence of NGF and/or RA. In contrast, neurons from chicks at embryonic days 7.5-8 and 8.5-9 showed extensive neurite outgrowth and survived for long periods (10-30 days) when exposed to NGF+RA. Neither NGF nor RA alone was able to promote neurite outgrowth or long-term survival of neurons.

To begin to delineate the mechanism of action of RA, chick RA receptor (RAR β and RXR γ) mRNAs were examined in ganglia by Northern blotting. The transcript for p140⁺ was also studied. The steady-state level of RXR γ mRNA (2.2 kb) was highest at day 6.5-7 and declined 2.5-fold by days 11 and 15. Transcripts for RAR β (3.1 and 2.7 kb) and p140⁺ (2.8 kb) increased 3- to 4-fold from embryonic day 6.5-7 to 8.5-9 and declined thereafter. It is noteworthy that both RAR β and p140⁺ mRNAs are highest at the time when the most dramatic response to RA+NGF is apparent in cultured neurons (embryonic day 8.5-9). Elevation of RAR β mRNA may suggest that endogenous retinoid is released by the embryo at this stage of development and could be involved in the development of neuronal responsiveness to NGF. Studies are underway to determine if RA regulates the expression of p140⁺ mRNA in cultured embryonic sympathetic neurons.

PLATELET-DERIVED GROWTH FACTOR RECEPTOR EXPRESSION IN PATCH MUTANT MICE AND NORMAL LITTERMATES. X. Zhang¹ and J.B. Hutchins².Depts. of ¹Anatomy and ²Neurology, University of Mississippi Medical Center, Jackson, MS 39216.

Platelet-derived growth factor (PDGF) has been shown to control differentiation and cell division of a number of mesenchymal cell types. Our laboratory and others have more recently provided evidence strongly indicating that PDGF plays a role in CNS development as well. PDGF is contained within developing neurons and the β receptor subunit is found on neurons both *in vitro* and in tissue sections. However, the role (if any) played by the α receptor in nervous system development is not clear. Other investigators have shown that oligodendrocytes, and possibly the glia-like sustentacular cells of olfactory epithelium, express this receptor subunit. In the heterozygous *Patch* mutant mouse, one copy of the PDGF receptor α subunit (PDGF-R α) gene is deleted. *Patch* homozygotes die *in utero*. *Patch* heterozygotes can be distinguished from their normally-pigmented, C57Bl littermates at postnatal day 2.5 (P2.5). Brain homogenates were prepared from C57Bl and *Patch* littermates at a range of postnatal ages. Blots of brain homogenates separated by SDS-PAGE were probed using antibodies selective for PDGF-R α and PDGF-R β . No apparent difference in PDGF-R α protein levels are seen between *Patch* mice and normal littermates. This suggests that the translation efficiency and/or stability of PDGF-R α transcript may be adjusted to equalize levels of receptor protein expressed. Based on the work cited above and further preliminary data, our working hypothesis is that, in addition to oligodendrocytes, astroglia also express PDGF-R α ; ongoing studies to support or refute this idea are in progress. NEUROTROPHIC FACTORS: RECEPTORS AND CELLULAR MECHANISMS II

539.1

BINDING AND FUNCTIONAL PROPERTIES OF CNTF RECEPTORS ON A HUMAN NEURAL CELL LINE. G. Lawrance, S. Gupta, P. Richardson, R. Dunn and R. Riopelle*. Apps Research Centre of Kingston General Hospital, Queen's University, Kingston CAN. K7L 2V7 (GL,RR), and Centre for Research in Neuroscience, McGill University, Montreal CAN. H3G 1A4.

A human neural cell line (LAN-2) was used to analyze the binding and functional interactions of CNTF with its receptors. Recombinant CNTF interacted with two classes of binding sites on the cell line; a high-affinity interaction (K_d, pM) was shared with the cytokine LIF while a low-affinity interaction (K_d, nM) was unique. Affinity cross-linking of [¹²⁵I]-CNTF revealed two putative receptors with approximate molecular masses of 70 and 150 kDa.

In serum-free conditions CNTF, LIF, and IL-6 had no influence on cell survival for periods as long as 16 days. During this time CNTF and LIF, but not IL-6 induced neurite growth and cholinergic differentiation that were half-maximally saturated at concentrations of ligand consistent with high-affinity receptor interactions.

The LAN-2 system may prove useful for study of CNTF regulation of intracellular mechanisms promoting cholinergic differentiation. The present results are consistent with previous indications that CNTF and LIF may have common receptor components.

EXPRESSION OF TYPE II ACTIVIN RECEPTOR mRNA IN RODENT

BRAINSTEM, HYPOTHALAMUS AND PITUITARY. Y.L. Trudeau¹, L. Pope¹, W.J. Giffin¹, J.P.deWinter², M.M. Matzuk³, R.J.G. Haché¹ and L.P. Renaud¹.¹Loeb Research Inst., University of Ottawa, Canada, ²Dept. Endocr. and Reprod., Erasmus University, Rotterdam, Netherlands and ³Dept. Pathol., Baylor College of Med., Houston, U.S.A.

Activin (Act; β_A/β_B -subunit dimers), a member of the TGF- β molecular family produced in brain, has been reported to promote neuronal survival, stimulate hypothalamic (HYP) corticotropin-releasing factor and oxytocin release, and modulate adenohypophyseal hormone release. A membrane-associated receptor serine/threonine kinase is believed to mediate the diverse actions of Act. The present study evaluated the production of receptor in brain. Total RNA (10-40 μ g) extracted from selected tissues was hybridized with a 260-base ³²P-labelled riboprobe for type II rat Act-receptor (ActRII). After digestion with S1-nuclease and separation by PAGE, a single 180-base protected fragment was visualized autoradiographically. ActRII mRNA was detected in Long-Evans rat brainstem (including nucleus tractus solitarius), HYP and pituitary. Similar levels of ActRII mRNA were found in HYP of young virgin, 7-day weaned and 15-day lactating female rats. Prepubertally castrated male rats had 2.5-fold higher HYP ActRII mRNA levels than 4-month old age-matched sham controls. Two week treatment of castrates with estradiol (200 ng/g, i.p. every 2 days) reduced HYP ActRII mRNA expression to control levels; the same dose of testosterone (T) had no effect. Castration increased brainstem ActRII mRNA levels 1.5-fold and T reduced ActRII mRNA expression. Comparable ActRII mRNA levels were detected in HYP of wild-type and α -inhibin gene-deleted mice with sex cord-stromal tumours (Nature 360: 313). These results demonstrate that ActRII mRNA is produced in rodent brain and suggest that the ActRII gene may be steroid-regulated. (Supported by AHFMR and MRC).

PROPERTIES OF INTERACTIONS OF TRKA, NGFR, AND NGF ON PC12 CELLS. G.M. Ross* and R.I. Riopelle. Apps Research Centre of Kingston General Hospital, Queen's University, Kingston CAN. K7L 2V7.

Nerve Growth Factor (NGF) interacts with distinct receptor proteins (trkA and NGFR) on PC12 pheochromocytoma cells. Radioligand binding studies with NGF demonstrate two discrete binding affinities on these cells; a high affinity state (K_d, pM), and a lower affinity state (K_d, nM). Both trkA and NGFR form homodimeric complexes with NGF suggesting that multiple affinity states might be due to receptor oligomerization. We have utilized a variety of chemical cross-linking reagents and immunoprecipitation with specific antireceptor antibodies to examine NGF binding to monomers and oligomers of both trkA and NGFR. Competition studies with unlabelled NGF reveal that both trkA monomers and homodimers display heterogeneous binding of NGF with K_d's in the pM and nM ranges, while the binding of NGF to NGFR monomers and homodimers is homogeneous with K_d in the nM range. These studies confirm that NGF participates in homodimer interactions of trkA and NGFR and indicate that receptor homodimerization is not a determinant of NGF binding affinity. The observations are consistent with recent observations on trkA and NGFR expression and co-expression in non-neural cells.

The observation that low levels of trkA-NGFR heterodimerization can be detected using novel cross-linking conditions raises the possibility that specificity of neurotrophin signalling is mediated by direct extracellular interactions between trk family members and NGFR.

SILENCING OF gp130 GENE EXPRESSION BY ANTISENSE RIBOZYME TECHNOLOGY BLOCKS CNTF SIGNAL TRANSDUCTION IN EMBRYONAL CARCINOMA CELLS. S.K. Gupta, S. Carbonetto, P.M. Richardson and R.J. Dunn*. Montreal General Hospital and McGill University, Montreal.

CNTF supports survival and neuronal differentiation of P19 murine embryonal carcinoma cells that otherwise die in the absence of serum. One signal-transducing subunit of the CNTF receptor complex has been tentatively identified as gp130, a component of the interleukin-6 receptor complex. To silence expression of the gp130 gene, a 22 base pair ribozyme (rz) motif was inserted into the 5'-end of murine gp130 cDNA: antisense transcripts bearing the rz motif were shown to cleave sense gp130 transcripts. Sense and antisense gp130 constructs bearing the rz motif were subcloned into an expression vector with the phosphoglycerokinase gene promoter and stable transfectants were obtained in P19 cells. The survival-promoting activities of CNTF were abrogated in cells transfected with the antisense-rz construct but were not diminished in cells with the sense-rz construct. The findings indicate that gp130 is required in P19 cells to mediate the trophic actions of CNTF.

ACETYL-L-CARNITINE ARGININE AMIDE IS A POSSIBLE AGONIST FOR THE HIGH-AFFINITY NGF BINDING SITE. G. Tagliatela*, D. Navarra, A. Olivi, M.T. Ramacci, I.R. Perez-Polo¹ and L. Angelucci². Inst. for Res. on Senescence Sigma Tau, 00040 Pomezia, Italy; ¹ Dept. of HBC&G, UTMB, Galveston TX, USA; ² Inst. of Pharmacology II, School of Medicine, "La Sapienza" Univ. of Rome, Italy

Senescence of the central nervous system is characterized by a progressive loss of neurons which may be due to lack of central neurotrophic activity. Thus, a proper pharmacological approach to these phenomena would be to support degenerating neurons with trophic factors. In the present paper we report that the arginine amide derivative of Acetyl-L-Carnitine (ST 857) stimulates differentiation and neurite outgrowth in the rat pheochromocytoma PC12 cells in a manner similar to NGF. The neurotogenic action of ST 857 requires *de novo* synthesis of mRNA, although it does not activate *c-fos* mediated nuclear pathways, and is independent from the presence of any other trophic substance, as it is exerted also in a serum-free environment. The integrity of the ST 857 molecular structure is essential for its action, as its moieties have no such effects on the cells. Also, slight chemical modifications of ST 857 abolish its neurotogenic effect. Lastly, ST 857 competes with the high affinity NGF binding in a dose dependent fashion.

These results suggest a possible role for ST 857 in those pharmacological strategies aiming to increase the trophic support to the nervous system.

539.7

BINDING SITES AND RETROGRADE TRANSPORT OF NEUROTROPHINS IN THE CHICK EMBRYO NERVOUS SYSTEM. S. Homma*, D. M. Prevette, Q. Yan and R. W. Oppenheim. Dept. of Neurobiol. and Anat., Bowman Gray Sch. of Med., Winston-Salem, NC 27157-1010, and Neurobiol. Program, Amgen Inc., Thousand Oaks, CA 91320.

Members of the neurotrophin family can promote the survival as well as differentiation of various neuronal cell populations. We have studied the binding sites and retrograde transport of NGF, BDNF and NT-3 in the chick embryo using ¹²⁵I-labeled neurotrophins. In the cervical spinal cord on E4, systemically injected neurotrophins bound to cells in the intermediate layer, including motoneurons, as well as to peripheral nerve and somite. On E7-8 all three neurotrophins were retrogradely transported to the motoneurons and dorsal root ganglion (DRG) following limb injections. Within the DRG, the ventrolateral cell population preferentially transported BDNF and NT-3, whereas the mediadorsal cell population preferentially transported NGF. We are currently studying the binding sites of neurotrophins in the brain during the period of naturally occurring cell death of responsive neuronal populations. The retrograde transport and binding sites of other putative trophic factors (e.g. IGF, PDGF, TGF) are also being studied.

539.4

STRUCTURE AND FUNCTION OF THE CNTF RECEPTOR. N. Stahl, T. Boulton, S. Davis, N. Y. Ip, and G. D. Yancopoulos*. Regeneron Pharmaceuticals, 777 Old Saw Mill River Rd. Tarrytown, NY 10591.

We have defined a three-component structure for the ciliary neurotrophic factor (CNTF) receptor, consisting of a specificity component (CNTFR α), and two 'β' subunits (gp130 and LIFRβ). Interleukin-6 (IL6) also uses gp130 and an IL6R α , while leukemia inhibitory factor (LIF) and oncostatin M (OM) use gp130 and LIFRβ, but apparently do not require an 'α' component. Thus the broad expression of gp130 and LIFRβ account for the widespread actions of LIF and OSM, while the restricted distribution of CNTFR α limits CNTF action and can be used to define novel targets for CNTF. We have found that the components of the tripartite CNTF receptor complex are initially unassociated, and come together in an ordered fashion following ligand exposure. The last step in complex formation - heterodimerization between gp130 and LIFRβ - initiates intracellular signaling; LIF and OM also heterodimerize gp130 and LIFRβ, while IL6 instead homodimerizes gp130. Hetero- or homodimerization of β subunits activates a cytoplasmic tyrosine kinase associated with the β subunits, and results in tyrosine phosphorylation of an apparently identical set of >10 proteins (called CLIPs) in a wide variety of cell types. Although some of the CLIPs (eg. the ERKs) may be activated by other classes of factors (such as NGF, EGF or FGF which utilize receptor tyrosine kinases), ERK activation by CNTF and its cytokine relatives occurs much later and through a different pathway. Interestingly, we have shown that the CNTF signaling pathway shows synergy with those of FGF and EGF. We find that CNTFR α is also one of the only known receptors that can function in soluble form, endowing CNTF-responsiveness to cells normally responsive only to LIF; this mechanism may be physiologically relevant since soluble CNTFR α is found in the CNS and is released from muscle after denervation.

539.6

INTERACTIONS OF THE NEUROTROPHINS WITH ALTERNATIVE FORMS OF TRK RECEPTORS IN NEURONAL AND NON-NEURONAL CELLS. N. Y. Ip*, T. N. Stitt, P. Hanzopoulos, D. Valenzuela, D. J. Glass and G. D. Yancopoulos. Regeneron Pharmaceuticals, Inc., 777 Old Saw Mill River Road, Tarrytown, New York 10591.

We have used a battery of approaches to explore the specificity of the three Trk receptors for the neurotrophins. In fibroblasts, NGF is a primary ligand for TrkA, NT-3 is a primary ligand for TrkC, and BDNF and NT-4/5 are primary ligands, and NT-3 is a secondary ligand, for TrkB. In neuronal populations, however, the specificity of the Trks is apparently altered. While in some neurons NT-3 may still act as a secondary ligand for TrkB, on other neurons it is incapable of activating the TrkB receptor; thus, the neuronal context can in some cases restrict the ability of TrkB to interact with its non-preferred ligand. Similarly, while both BDNF and NT-4/5 are equipotent in activating TrkB in some neurons, there are other neurons in which they have differing effects.

We have found that the specificity of the Trks for the neurotrophins may be modulated by accessory molecules found on neurons, such as the LINGR. In addition, we have defined naturally-occurring alternate forms of the Trk receptors that, in some cases, may allow for altered responses to the neurotrophins. These include truncated versions of TrkC lacking the kinase domain or full-length forms of TrkC with different-sized inserts in their kinase domains. The naturally-occurring truncated Trks can act as "dominant negatives" to modulate the activation of a full length Trk (e.g. TrkB) by a non-preferred ligand (e.g. NT-3). The insert-containing forms of TrkC retain the ability to autophosphorylate in response to NT-3, but they can no longer mediate proliferation in fibroblasts or neuronal differentiation in PC12 cells.

539.8

MUTAGENESIS DEFINES N-TERMINAL RESIDUES OF HUMAN NGF NECESSARY FOR TRKA RECEPTOR BINDING AND BIOLOGICAL ACTIVITY. J. W. Winslow*, G.R. Laramée, Ai Shih, C. Schmelzer, D.L. Shelton, L.E. Burton. Genentech, Inc., South San Francisco, CA 94080

In contrast to the reported interactions of NT3 with the trkA-NGF receptor kinase, we find that human NGF binds 500-fold more efficiently to trkA than does human NT3. Human NGF and NT3 differ in 52/120 amino acids; 44/52 (82%) of the differences are located within 7 regions representing the N- and C-termini, 4 beta-turns and one beta sheet. To determine the structural basis for specific hNGF and hNT3 receptor interactions, homolog- and alanine-scanning mutagenesis was performed on hNGF and analyzed by trkA, p75, and p75-trkA receptor binding (PC12 cells), trkA autophosphorylation, and PC12 cell differentiation. Twelve chimeric mutants, replacing these divergent regions within NGF with the corresponding NT3 sequences, were generated by oligonucleotide-directed mutagenesis and expressed in mammalian cells. Single or double regional chimeras in most cases display nearly normal trkA and p75 binding and activation of autophosphorylation. Significant loss of trkA binding and function resulted from N-terminal chimera between NGF and NT3 or BDNF. A single Ala or Asp replacement of His4 of hNGF also reduces trkA binding by 1000-fold while p75 binding is unaffected. N-terminally truncated forms (6-118) and (10-118) hNGF result in 10- and 300-fold reduction in trkA binding; p75 binding is reduced by 10-fold only in the (10-118) hNGF. The potency of trkA autophosphorylation and PC12 differentiation elicited by the N-terminally modified hNGF forms were consistent with trkA binding profiles. These results indicate that the specific N-terminal sequence of hNGF contributes to structural interactions necessary for trkA receptor binding and ligand-induced signalling. The absence of major functional losses by most of the chimera suggests that the multiple regions of sequence divergence between hNGF and hNT3 may all contribute to receptor binding specificity by determining the tertiary structure and geometry of contact residues that are possibly conserved among the neurotrophins.

539.9

BIOLOGICAL ACTIVITY AND INTERMOLECULAR TRANSPHOSPHORYLATION OF TNF-Trk CHIMERIC RECEPTORS. Marco Canossa, Giorgio Rovelli and Eric M. Shooter*. Department of Neurobiology, Stanford University School of Medicine, Stanford, CA 94305-5401

To explore the signal transduction mechanism of the Trk kinase receptors, chimeric molecules containing the extracellular domain of the tumor necrosis factor (TNF) receptor (p70) and the transmembrane and cytoplasmic domains of the neurotrophin receptors TrkA (p70-TrkA), TrkB (p70-TrkB) and TrkC (p70-TrkC) were produced. Transfected PC12 cells expressing the chimeric receptors showed TNF-dependent neurite outgrowth and cell survival. Chimeras containing a K547 mutation in the ATP binding site of the tyrosine kinase domain failed to show TNF-dependent effects. Together, these results suggest that ligand-mediated activation of the Trk kinase domain is both necessary and sufficient for induction of a neuronal phenotype in PC12 cells. It is known that the ligand-activation of Trk kinase receptors induces tyrosine autophosphorylation. COS7 cells were used to investigate the ligand-induced phosphorylation of the chimeras. When p70-Trk(A, B or C) were coexpressed with wild-type Trk(A, B or C), increased tyrosine phosphorylation was observed in both receptors in response to either TNF or NGF. Thus, the Trk kinase domain appears capable of Trk transphosphorylation activity irrespective of the extracellular domain present on the receptor, indicating that homologous cytoplasmic domains can mediate Trk receptor transphosphorylation.

Reciprocal regulation of estrogen and NGF receptor systems by their ligands in PC12 cells. Farida Sohrabi*, Lloyd A. Greene*, Rajesh C. Miranda* and C. Dominique Toran-Allerand*. Columbia University, Depts of Anatomy and Cell Biology¹ and Pathology², NYC, NY 10032.

Both estrogen and the neurotrophins influence neural development. We questioned whether some developmental actions of estrogen and the neurotrophins result from interaction of these factors, by examining the potential for reciprocal regulation of their receptor systems by these ligands. PC12 cells were grown in the presence (+) (2 weeks) or absence of NGF. NGF+ cells were then exposed to estrogen (E) (10^{-9} M) for 0-7 days. While specific nuclear estrogen-binding sites were present in both NGF+ and untreated PC12 cells, NGF elicited a 6-fold increase in estrogen-binding sites. Estrogen regulation of NGF receptor genes appeared to be time- and receptor-specific. In NGF+ cells, we found transient down-regulation of p75^{NGFR} mRNA by 3d of E-treatment, and a return to basal levels by 7 days. *trkA* mRNA, in contrast, increased 2-fold following 7 days of E-treatment. Regulation of estrogen and NGF receptor systems by their cognate ligand indicated that E-treatment of NGF+ cells down-regulated estrogen-binding, while NGF up-regulated p75^{NGFR} mRNA, but did not up-regulate *trkA* mRNA consistently. These data indicate that NGF may increase neuronal sensitivity to estrogen, and that estrogen, by differentially regulating p75^{NGFR} and *trkA* mRNA, may alter the ratio of the two NGF receptors, and, consequently, neurotrophin responsiveness. Given the widespread co-localization of estrogen and neurotrophin receptor systems in the developing CNS, the reciprocal regulation of these receptor systems by NGF and estrogen, seen in PC12 cells, may have important implications for processes governing neural maturation and the maintenance of neural functioning. (Supported by NIH(NIA), NSF and NIMH RSA (CDT-A))

LOCALIZATION OF NEUROTROPHIN RECEPTORS IN NORMAL AND DEGENERATING CAT RETINA. M.J. Radeke, G.P. Lewis, D. Blumberg, S.K. Fisher*, and S.C. Feinstein. Neuroscience Research Institute and Department of Biological Sciences, University of California, Santa Barbara, CA 93106.

Retinal detachment, as well as many other diseases of the eye, is marked by a rapid loss of photoreceptor outer segments and a proliferation of non-neuronal cells, in particular retinal pigment epithelia (RPE) and Müller cells. Recent evidence (LaVail et al., 1992, PNAS 89: 11249) obtained using light damage as a model for retinal degeneration has suggested possible roles for the neurotrophins BDNF and/or NT-3 for photoreceptor survival. In order to help determine which neurotrophins might be required for maintenance and repair of the retina, we have sought to ascertain the pattern of expression of the *trk* family of neurotrophin receptors in normal and detached cat retinas using a panel of anti-*trk* antibodies. In the normal retina, antibodies directed against either the extracellular or intracellular domain of *trkA* stain cones, Müller cells, ganglion cell bodies and the RPE. Antibodies specific for two different *trkB* extracellular peptides both label Müller cells, cones and rods, ganglion cell bodies and axons, astrocytes and RPE. Anti-peptide antibodies specific for full length *trkB* detect ganglion cell bodies and axons, whereas antibodies directed against two truncated forms of *trkB* stain photoreceptor outer segments, Müller cells, astrocytes and RPE. An antibody which detects full length forms of *trkC* identified photoreceptor outer segments and Müller cells. Following retinal detachment there is an apparent increase in labelling of truncated *trkB* associated with Müller cell hypertrophy and proliferation. In addition, localization of full length *trkB* in ganglion cell axons appears to decrease following chronic detachment. Our data suggest a role for neurotrophins in the maintenance and response to injury throughout the retina. Perhaps most interestingly, when taken together with the ligand binding specificities of the *trks* and the effect of BDNF and NT-3 on damaged retinas, it suggests a possible role for truncated *trkB* in the maintenance of photoreceptors. CHARACTERIZATION OF A NOVEL NGF HETERODIMER

J.L.S. Treanor, C. Schmelzer and L.E. Burton*
Genentech, Inc., South San Francisco, CA 94080

Current evidence suggests that NGF mediates its biological activity through a high affinity tyrosine kinase receptor (*trkA*). To investigate this further a novel NGF heterodimer (118:110-118rhNGF) has been produced. This group has previously shown that the amino terminal region of NGF is extremely important in the *trkA* receptor binding and ligand-induced signalling. Baseline separation of the heterodimer was achieved using HPLC cation exchange chromatography and its stability monitored at 4°C (2 weeks), 22°C and 37°C (>24 hours). The heterodimer was stable under these conditions when analyzed by HPLC.

Primarily, characterization of the heterodimer was carried out using *trkA* and p75-*trkA* (PC12 cells) receptor binding and autophosphorylation. A 2-fold loss in EC₅₀ of 125I-NGF displacement was seen in PC12 cell binding with the heterodimer, whilst a 10-fold loss was seen with *trkA* binding when compared to homodimeric 118:118rhNGF. Homodimeric 110:118:110-118rhNGF showed a 20-fold loss in PC12 cell binding and a 500-fold loss in *trkA* binding. Autophosphorylation of *trkA* expressing fibroblasts indicated a 10-fold loss with the heterodimer and a 500-fold loss with homodimeric 110:118:110-118rhNGF which paralleled the *trkA* binding data.

Further biological characterization data will be presented.

INCREASED PRODUCTION OF TRUNCATED NGF RECEPTOR FOLLOWING FORNIX LESIONS. D.D. Gordon*, M.D. Lindner, Y.S. Choe and R. Loy. Dept. of Neurology, Univ. Rochester School of Med., Rochester, NY 14620 and Canandaigua VAMC.

Peripheral nerve injury results in upregulation of both cellular and truncated forms of the low-affinity nerve growth factor (NGF) receptor, but it is not known if similar upregulation occurs after CNS injury. NGF-dependent basal forebrain cholinergic neurons atrophy in Alzheimer's disease, and we have found that in early stages of the disease the level of truncated receptor in urine is increased over controls. To see if degenerating central neurons could be contributing to this increase, we performed fornix transections on 19-month-old, female Sprague-Dawley rats to induce retrograde degeneration in septal neurons. We collected urine before surgery to gather a baseline and at seven other timepoints after transection to measure levels of the truncated form of the NGF receptor by ELISA. The urine levels of truncated receptor are increased three-fold at days seven and fourteen following transection. This provides support for the argument that the increase in truncated NGF receptor in early stages of AD can be influenced by basal forebrain neuron degeneration. Truncation may occur with increased receptor turnover or due to metabolism of cellular receptors in initial stages of neuron degeneration. Supported by AG09231.

LOW-AFFINITY NERVE GROWTH FACTOR RECEPTOR REEXPRESSION IN AXOTOMIZED FACIAL AND SCIATIC MOTOR NEURONS: DIFFERENCES BETWEEN NORMAL AND OLA MUTANT MICE

P. Bumham*, T. Hagg, S. Varon, M.A. Bisby# Dept. Biology, Univ. California San Diego, La Jolla; # Dept. Physiology, Queen's Univ., Kingston, Canada

The C57BL/Ola mutant mouse is characterized by delayed and slow Wallerian degeneration of lesioned distal peripheral and central nerves, apparently resulting from delayed axonal breakdown and lack of macrophage recruitment. As a result, motor and sensory regeneration is impaired. Spinal motor neurons express low-affinity NGF receptor (LNGFR) during development but not in the adult. After peripheral nerve injury, rat motor neurons temporarily reexpress LNGFR, probably during the process of axonal outgrowth. We compared in normal C57BL/6J and C57BL/Ola mice, the responses of sciatic motor neurons to nerve crush or transection and of facial neurons to crush injury. Several observations include: i) mice respond like rats, ii) LNGFR expression by Ola motor neurons is less robust (lower number, less intense staining) than normal, iii) LNGFR expression after a crush is maintained one week longer in sciatic motor neurons of Ola mice, consistent with slower axon regeneration, iv) facial neurons respond as rapidly as sciatic neurons, v) Ola facial neurons show a second phase of increase in LNGFR at 28 days, while normal ones show no LNGFR at this time, vi) LNGFR changes correlate in time with somal size changes in these neurons, suggesting a relation between LNGFR and a state of neuronal "growth". These findings are consistent with the idea that LNGFR expression is regulated by two different mechanisms, one related to the initial response to the injury and another related to the outgrowth phase of the neuron/axon. We wish to thank L. Reichardt and G. Weskamp for their LNGFR antibodies. Support: NINCDS grant NS16349, 27047 (SV); MRC Canada MT5198 (MAB)

DIFFERENTIAL EXPRESSION OF p140^{trk}, p75^{NFR} AND GAP-43 GENES IN NEURONS OF NUCLEUS BASALIS MAGNOCELLULARIS FOLLOWING CORTICAL DEVASULARIZATION. B.C. Figueiredo*, W. Tetzlaff*, M. Skup, L. Garofalo & A.C. Cuello, Dept. of Pharmacology and Therapeutics, McGill University, Montreal, and Dept. of Physiology*, University of Ottawa, Ottawa, Canada.

A loss of target-derived neurotrophic factors is hypothesized to be one of the major determinants of CNS neuronal vulnerability to degeneration. In order to gain more insight of early neuronal responses to injury, lesion-induced alterations in high or low-affinity nerve growth factor (NGF) receptors, as well as growth-associated protein (GAP-43) gene expression, in NGF-responsive nucleus basalis magnocellularis (NBM) neurons were studied.

For this purpose, adult rats were operated by unilateral cortical devascularization and received, i.c.v. via minipump, either vehicle or NGF (12 µg/day), and were sacrificed at 1, 3 and 7 post-lesion days. In situ hybridization studies, using ³⁵S-labeled oligonucleotide probes for p75^{NFR}, p140^{trk} and GAP-43, revealed that these genes were differentially regulated following the lesion. p140^{trk} gene expression was shown to be decreased while p75^{NFR} and GAP-43 mRNA levels were increased after lesion. Moreover, GAP-43 mRNA levels, but not p75^{NFR} or p140^{trk}, were largely increased in pyramidal neurons located in the remaining adjacent cortex of all decorticated animals. NGF treatment recovers levels of p140^{trk} mRNA in the lesioned NBM to values observed in the contralateral NBM. These findings suggest that p140^{trk} mRNA levels in NBM neurons of naive animals depend upon NGF.

DISTRIBUTION OF EXOGENOUS NEUROTROPHINS IN THE RAT CNS FOLLOWING ICV INJECTION. C.R. Matheson*, J. Sun, M.J. Radekeff, S.C. Feinstein†, J. Miller and O. Yan, Neurobiol. Dept., Amgen, Inc., Thousand Oaks, CA 91328; †Neurosci. Res. Inst. and Dept. of Biol. Sciences, Univ. of California, Santa Barbara, CA 93106.

To assess the potential effectiveness by which injected neurotrophins can diffuse throughout the CNS, we used autoradiographic and immunohistochemical techniques to examine the distributions of NGF, BDNF and NT-3 after a single injection into the lateral cerebral ventricle (ICV). As described previously, ¹²⁵I-NGF labeled cholinergic neurons in the basal forebrain. Only light labeling was detected in the brain parenchyma surrounding the lateral ventricle. In contrast, injection of ¹²⁵I-BDNF resulted in few or no labeled neurons in the basal forebrain or in the substantia nigra. However, a gradient of very intense labeling extended from the ventricular surface into the parenchyma for a distance of approximately 0.5 mm. ¹²⁵I-NT-3 distribution was intermediate between that of NGF and BDNF. No significant differences were detected in neonate versus adult animals. Complementary immunohistochemical studies utilizing anti-NGF and anti-BDNF antisera revealed that unlabeled neurotrophins injected into the ICV distributed in precisely the same manner as their iodinated counterparts. Consistent with the intense BDNF labeling of the ventricular surface, *in situ* hybridization analysis has confirmed previous studies showing that mRNA encoding the BDNF receptor (trkB) is highly expressed by ependymal cells lining the ventricular surface as well as by many neurons and glia. On the other hand, expression of the high affinity NGF receptor (trkA) is much more restricted. In addition, antisera specific for the trkA or trkB receptors demonstrated that their expression pattern closely reflects their mRNA distribution. These data suggest that the presence of the trkB receptor protein on the ependymal layer and its expression throughout the subependymal zone and brain parenchyma represents a significant impediment to the adequate diffusion of ICV injected BDNF into the brain for delivery to target neurons.

NEUROTROPHIC FACTORS: RECEPTORS AND CELLULAR MECHANISMS III

NGF-INDUCED TYROSINE PHOSPHORYLATIONS OF p140^{trk} AND ERK IN COMPARTMENTED CULTURES OF RAT SYMPATHETIC NEURONS. D.L. Senger and R.B. Campenot, Dept. of Anatomy and Cell Biology, University of Alberta, Edmonton, Alberta, T6G 2H7.

The first step in intracellular signaling that mediates all NGF responses is believed to be tyrosine phosphorylations by the NGF receptor, p140^{trk} (trk). Since trk is itself a substrate for its own tyrosine kinase activity, we used immunoprecipitation with a trk specific antibody and then western blot analyses using a phosphotyrosine antibody to assess trk tyrosine kinase activity. We found that after short-term NGF deprivation, increasing concentrations of 2.5S NGF (10-200 ng/ml) caused a concentration-dependent increase of tyrosine phosphorylation of trk in mass cultures of sympathetic neurons occurring within 10 minutes. Also, in compartmented cultures we found that trk was present in the distal neurites and that application of 200 ng/ml NGF to distal neurites caused a local increase in trk phosphorylation in the distal neurites within 10 minutes. Furthermore, we found that 500 nM K-252a and 100 nM staurosporine (both shown by others to inhibit trk phosphorylations in PC12 cells) inhibited the elongation of distal neurites when locally applied to them in compartmented cultures. However, neither K-252a nor staurosporine inhibited distal neurite elongation when these drugs were locally applied to cell bodies and proximal neurites. These data suggest that phosphorylations by trk play a role in mediating neurite elongation at or near the site of NGF interaction with the cell surface, but that trk phosphorylations proximal to the source of NGF may not be involved in mediating the neurite growth response. We have begun similar investigations into the role of ERKs (extracellular receptor mediated kinases, also known as MAP kinases) which so far indicate that ERKs are rapidly tyrosine phosphorylated in rat sympathetic neurons in response to NGF and are present in abundance in distal neurites.

EXPRESSION OF THE LOW AFFINITY, NEUROTROPHIN RECEPTOR, p75^{NFR}, IN THE DEVELOPING AND LESIONED OLFACTORY SYSTEM. Christopher P. Turner* and J. Regino Perez-Polo, Dept. Human Biological Chemistry & Genetics, Univ. Texas Med. Branch, Galveston, TX 77555-0652.

Using the monoclonal antibody, MAb192, we studied the distribution of p75^{NFR}-immunoreactivity (p75-ir) in the main olfactory bulb (MOB) of rat during development and under lesioned conditions. *Developmentally*, we observed an increase in intensity and organization in p75-ir in the glomerular layer (GL), which we interpret to be due to a developmental increase in peripheral input to the MOB. *Lesion 1* was a chemically induced, peripheral deafferentation of the MOB, employing a TX100, nasal irrigation procedure. Saline was used as a control. The distribution of p75-ir was monitored 1-16 weeks after the lesion. In the saline controls, p75-ir was abundant in the GL and relatively sparse in the olfactory nerve layer (ONL). After 1 and 2 weeks postlesion, TX100 produced a decrease in p75-ir in the GL and an induction of p75-ir in the ONL. After 8-16 weeks postlesion, the distribution of p75-ir later returned to that observed with saline controls, coinciding with the regenerative capacity of the peripheral input. *Lesion 2* was a unilateral bulbectomy (OBX; influencing both centrifugal and centripetal pathways of the MOB). Sham-lesioned animals served as controls. The distribution of p75-ir was monitored 1-16 weeks after the lesion. After 1-4 weeks postlesion, OBX animals showed no change in p75-ir in the remaining MOB. An increase in p75-ir in the GL was observed 8 and 16 weeks postlesion, as compared to sham controls. Elevated p75-ir was also observed in the ONL in the 16 week postlesion group. Thus p75-ir in the MOB is regulated under conditions of 1) increased peripheral input, 2) regeneration of peripheral input and/or 3) central pathway reorganization. Supported by NINDS grant NS18708.

NEURONAL RESPONSES TO NGF ARE SPATIALLY-REGULATED: NGF EXPOSURE AT TERMINALS VERSUS CELL BODIES DIFFERENTIALLY ALTERS NEURONAL GENE EXPRESSION. J.G. Toma*, D. Rogers, R.B. Campenot, and F.D. Miller, Dept. Anat. & Cell Biol., University of Alberta, Edmonton, Canada T6G 2H7.

We have previously demonstrated that NGF supplied to neuronal terminals *in vivo* can regulate gene expression in mature sympathetic neurons, and have documented NGF-induced increases in both p75 NGF receptor and tyrosine hydroxylase (TH) mRNAs in mass cultures of sympathetic neurons. To determine how an NGF receptor:ligand interaction at neuronal terminals can distally regulate gene expression in the cell body, we have turned to compartmented cultures of sympathetic neurons. In these experiments, neurons were established and maintained in 10 ng/ml NGF for 7 days, and were then "induced" with 200 ng/ml NGF a) in side compartments, which contain only neurites (distal addition), or b) in both center and side compartments (global addition). When 200 ng/ml NGF is added globally, both p75 NGF receptor and TH mRNAs increase significantly within 24 hours, and continue to rise until at least 48 hours postaddition, as previously observed in mass cultures. In contrast, levels of trkA mRNA do not change. However, when NGF is added distally, the pattern of response differs. Neither p75 NGF receptor nor TH mRNAs are altered 24 hours following increased NGF distally. By 2, 3, and 7 days postaddition, p75 NGF receptor mRNA levels are increased over controls, but remain significantly lower than those observed in sister cultures exposed to increased NGF globally. This differential regulation is even more striking for TH: increased terminal NGF elicits only a small increase in this mRNA versus a greater than 5-fold increase elicited by globally increasing the NGF. Thus, neuronal gene expression is regulated by NGF as a function of the spatial location of the activated receptor:ligand complexes. These data suggest that, *in vivo*, neuronal responses to NGF may differ as a consequence of the neurons spatial relationship with the cellular source of the neurotrophin.

540.3

LEUKEMIA INHIBITORY FACTOR (LIF), CILIARY NEUROTROPHIC FACTOR (CNTF) AND ONCOSTATIN M (OSM) ACTIVATE P21^{ras} IN A NEUROBLASTOMA CELL LINE. S.E. Lewis*, M.A. Schwarzschild, W.T. Dauer, L.K. Hamill, A.J. Symes, J.S. Fink and S.E. Hyman, Molecular and Developmental Neuroscience Lab, Mass. General Hospital, Charlestown, MA 02129.

The cytokines LIF and CNTF regulate survival and differentiation of many types of neurons. The receptors for LIF and CNTF associate with the same signal transducing subunit utilized by the IL-6 receptor, gp130. The receptor for OSM has not yet been identified, however, gp-130 binds OSM and appears to be necessary for its action. GP-130 has no known catalytic activity and the second messenger systems activated by this family of receptors are unknown. One putative intracellular effector, the product of the proto-oncogene *ras*, has been implicated in the signal transduction pathways of other growth factors and cytokines. We therefore investigated a role for Ras in LIF, CNTF and OSM responses in the neuroblastoma cell line NBFL.

In NBFL cells, these cytokines increase levels of activated Ras in a rapid, transient, and dose-dependent fashion. In addition, all three increase the tyrosine phosphorylation of several proteins. Similar phosphotyrosine bands and activation of Ras are induced by LIF and CNTF in cultures of rat sympathetic neurons. One effect of LIF, CNTF and OSM in the NBFL cells is induction of VIP mRNA. The protein kinase inhibitors staurosporine and K252a inhibit the cytokine-induced tyrosine phosphorylations, p21-Ras activation, and increase in VIP mRNA in NBFL cells. Our data suggest that Ras may be involved in the regulation of VIP gene expression by LIF, CNTF and OSM in this cell line.

540.5

ROLE OF *C-FOS* AND *C-JUN* IN INSULIN-MEDIATED STIMULATION OF RETINA NEURONAL DIFFERENTIATION. R.E. Hausman*, Y. Ren, Y. Ben-Shauf*, and B.H. Shah. Dept. of Biology, Boston University, Boston, MA 02215, USA; *Dept. of Immunology and Cell Biology, Tel-Aviv University, Tel-Aviv, Israel.

In chick embryo retina, insulin stimulates cholinergic and GABAergic differentiation. However, it does not affect succinic dehydrogenase or lactic dehydrogenase activity. These effects are stage-specific suggesting a neurogenic role for insulin in retina development. We investigated the mechanism of signal transduction. An early response was transcription of *c-jun* mRNA and its translation detected by Northern and Western blotting within minutes after insulin exposure. A rise in *c-fos* transcription and translation followed. These increases were transient and protein levels returned to normal by 45 min. Late gene expression, seen as an increase in glutamic acid decarboxylase (GAD) and choline acetyltransferase (ChAT) protein, occurred within 60 minutes. The increase in jun protein can be detected by immunocytochemistry in the ganglion cell and inner nuclear layers within 15 min after insulin addition and the increase in fos protein later. GAD and ChAT activity later increase in the ganglion, amacrine and displaced amacrine cells. Since these cells express neuronal insulin receptors, the above results suggest that fos and jun proteins, acting as an AP1 transcription complex, are causally involved in neurogenic differentiation of embryonic chick ganglion and amacrine cells. Experiments with phosphorothioate antisense oligonucleotides for *c-jun* and blockers of signal transduction suggest a causal but not necessarily direct role for *c-fos* and *c-jun* in the induction of cholinergic and GABAergic differentiation by insulin.

540.7

CNTF, LIF AND ONCOSTATIN M ACTIVATE VIP GENE EXPRESSION THROUGH A COMPLEX CYTOKINE RESPONSE ELEMENT. Aviva Symes, Prithi Rajan, Lisa Copus, E.M. Adler* and J. Stephen Fink, Molecular Neurobiology Laboratory, Massachusetts General Hospital and Department of Neurology, Harvard Medical School, Boston, MA 02114

The cytokines ciliary neurotrophic factor (CNTF), leukemia inhibitory factor (LIF) and oncostatin M (OM) are structurally and functionally related through similar protein structure, shared receptor subunits and overlapping functions. We have previously shown that a 180 bp cytokine response element (CyRE) mediates the transcriptional activation of the vasoactive intestinal peptide (VIP) gene to these cytokines in a human neuroblastoma cell line, NBFL.

To characterize further the molecular mechanisms of cytokine-mediated transcriptional activation we have identified functional domains within the CyRE and examined nuclear proteins in NBFL cells which bind to the CyRE both before and after cytokine treatment. One candidate transcription factor is c/ebp β (NF-IL6) as this is induced in response to IL-6, a related cytokine, in the hepatic acute phase response. Through gel shift and footprint analyses we show that members of the c/ebp family can bind to the 180 bp CyRE, and cotransfection experiments indicate that c/ebp family members are able to transactivate the CyRE. Transfections of CyRE deletion mutants linked to a luciferase reporter revealed that there are multiple functional regions within the 180 bp which contribute to the cytokine response in NBFL cells. Using these functional domains within the CyRE as probes, gel shift analysis showed that there are distinct DNA binding proteins which are induced after cytokine treatment. These results suggest that CNTF, LIF and OM induce VIP transcription in NBFL cells through a complex set of interacting DNA binding sites and transcription factors.

540.4

RAS-INDEPENDENT INDUCTION OF TYPE II NA CHANNEL EXPRESSION IN NGF-TREATED PC12 CELLS. G.R. Fanger* and R.A. Maue. Depts of Physiology and Biochemistry, Dartmouth Medical School, Hanover, NH 03755-3833.

The molecular mechanisms underlying the neuronal-specific responses to nerve growth factor (NGF) are not well understood, especially those responsible for the effects of NGF on neuronal ion channel expression. To determine if the activity of p21^{ras}, which has been implicated in the signal transduction pathways activated by NGF, is necessary for the NGF-mediated induction of sodium (Na) channel expression in rat pheochromocytoma (PC12) cells, we have analyzed Na channel expression in PC12 sublines stably overexpressing the dominant inhibitory mutant *c-Ha-ras* (Asn-17) (MM17-2, MM17-26; Szeberenyi et al., Mol. Cell. Biol. 10(1990): 5324). Northern blot analysis of total RNA from control and NGF-treated cells revealed 3- to 5-fold increases in the steady state level of Na channel mRNA in both PC12 and *ras*-deficient MM17-2 and MM17-26 cells. RNase protection assays using probes specific for type I, type II, or type III Na channel mRNA were also used to analyze Na channel mRNA in these cells. A probe directed against the 3' untranslated region of type II Na channel mRNA detected type II Na channel mRNA in control and NGF-treated PC12, MM17-2, and MM17-26 cells, with the NGF-mediated induction of type II Na channel mRNA comparable to that observed in the Northern blot. Similar results were obtained using a probe directed against the 5' untranslated region of the type II mRNA. In contrast, type I and type III Na channel mRNA were not detected in either control or NGF-treated PC12, MM17-2, and MM17-26 cells. Whole-cell patch clamp recordings verified that the NGF-mediated increases in Na channel mRNA in the MM17-2 and MM17-26 cells resulted in an increase in functional Na current density. Despite NGF-induced increases in the size of the MM17-2 and MM17-26 cells, as estimated by cell membrane capacitance, there were 3- to 5-fold increases in Na current density in the *ras*-deficient cells, comparable to that occurring in PC12 cells. The results suggest that *ras* activity is not necessary for the NGF induction of type II Na channel expression in PC12 cells, and provide further support for the existence of both *ras*-dependent and *ras*-independent mechanisms underlying neuronal differentiation. Supported by the Alfred P. Sloan Foundation and NIH NS28767.

540.6

THE PHOSPHORYLATION AND DNA BINDING OF THE DNA-BINDING DOMAIN OF THE TRANSCRIPTION FACTOR NGFI-B. Y. Hirata*, K. Kiuchi, H.-C. Chen, J. Milbrandt* and G. Guroff. Section on Growth Factors, NICHD, NIH, Bethesda, MD 20892 and *Department of Pathology and Internal Medicine, Washington University School of Medicine, St. Louis, MO 63110.

NGFI-B is an orphan member of the nuclear receptor superfamily encoded by an immediate-early gene. It is rapidly synthesized and phosphorylated in PC12 cells in response to nerve growth factor (NGF) and other agents and is differentially phosphorylated dependent upon the inducing stimulus. The DNA-binding domain (DBD) of NGFI-B has been expressed in bacteria and purified. It is phosphorylated by protein kinase A or by extracts from NGF-treated PC12 cells. The phosphorylated residues within the DBD have been identified as Ser340 and Ser350. The use of mutants in which either or both of these residues were replaced with alanines revealed that phosphorylation of Ser350, located within the "A box", a motif necessary for DNA binding by NGFI-B, resulted in a decrease in binding to the NGFI-B response element (NBRE), while phosphorylation of Ser340 had little or no effect. These findings demonstrate that phosphorylation of a nuclear receptor DBD results in a change in DNA binding and provides another potential mechanism for regulating NGFI-B activity.

540.8

REGULATION OF NEU EXPRESSION IN SCHWANN CELL-DORSAL ROOT GANGLION CO-CULTURES. P. Mason*, T. Neuberger, B. Attema, G.H. De Vries. Dept. of Biochemistry and Molecular Biophysics, Med. Coll. Va., Richmond, VA 23298.

The physiological significance of the proto-oncogene Neu is not known. Schwann cell (SC)-dorsal root ganglion (DRG) co-cultures provide a unique opportunity to investigate Neu expression, since the culture conditions can be manipulated to allow SC proliferation only (serum free cultures) or to allow SC differentiation (serum plus ascorbic acid). SC free-DRG cultures were obtained from E16 d rat ganglia. SC cultures were isolated from 2 d rat sciatic nerves. Co-cultures were prepared by adding SC to DRG cultures, followed by maintenance for 3 wks in either serum free media or media containing serum plus 5 μ g/ml ascorbic acid. Immunofluorescent localization of Neu showed cytoplasmic Neu immunoreactivity in neurites at 14, 26 and 35 days of culture of SC-free DRG. SC cultured alone showed strong immunoreactivity for both Neu and S100 protein. Neu could not be immunologically detected in S100 positive cells in contact with DRG neurites cultured under serum free conditions; however, cytoplasmic Neu immunoreactivity was still present in neurites. In SC-DRG cultures some SC at the periphery of the culture were not in contact with neurites. These SC continued to express strong Neu immunoreactivity. In myelinating media, a subpopulation of SC that are in contact with DRG neurites appeared to reexpress Neu antigen. These studies show that Neu is expressed in DRG neurites in both serum-free and serum-containing media. Our results suggest that Neu expression may be involved in SC differentiation and that axonal contact controls Neu expression in SC. (Supported by NS15408).

INDUCTION OF NFkB TRANSCRIPTION FACTORS IN RAT HIPPOCAMPAL ASTROCYTES BY INTERLEUKIN-1. W.J. Friedman¹, S. Thakur², and A. Rabson². ¹Dept of Neuroscience and Cell Biology and ²CABM, UMDNJ-Robert Wood Johnson Medical School, 675 Hoes Lane, Piscataway, N.J. 08854

Astrocytes in the central nervous system become activated in response to stimulation by cytokines such as interleukin-1 (IL-1) and tumor necrosis factor α (TNF α). Astrocyte activation results in increased proliferative activity and production of a variety of growth and trophic factors involving induction of gene expression. As an early event in the glial response to cytokine stimulation, we have examined expression and induction of the NFkB transcription factors in hippocampal astrocytes. The NFkB family of transcription factors consists of at least five proteins which dimerize to interact with specific NFkB binding sites in the promoter region of responsive genes. We have identified the specific NFkB mRNA's which are expressed and/or induced in hippocampal astrocytes by IL-1. Moreover, we have shown that upon IL-1 stimulation, nuclear extracts from hippocampal astrocytes contain proteins which specifically bind NFkB oligonucleotides, indicating the presence of functional NFkB proteins. These data suggest that an early event in the activation of astrocytes by cytokine stimulation may involve activation of NFkB transcription factors. Supported by NIH grant NS 31357-01.

LIGAND CONTROL OF NEUROTROPHIN RECEPTOR RESPONSIVENESS IN BRAIN CELLS. B. Knüsel*, F. Hefti, and D.R. Kaplan. University of Southern California, Los Angeles, CA 90089 and NCI-Cancer Research and Development Center, Frederick, MD 21701.

We recently observed pronounced developmental changes of the neurotrophin responsiveness of rat brain. In adult tissue only minimal Trk type receptor tyrosine phosphorylation is induced by the TrkB ligands BDNF, NT-3 and NT-4/5. Speculating that chronic stimulation by endogenous neurotrophins might down-regulate the TrkB response, we chronically treated cultures of embryonic rat cortex with neurotrophins for at least 3 days. After a recovery period, in absence of neurotrophin, the cultures were acutely treated for 4 min and abundance and tyrosine phosphorylation of Trk type proteins were tested by western blotting. Chronic treatment resulted in very low levels of Trk tyrosine phosphorylation. With BDNF or NT-5, no recovery of the effect of acute treatment with the same factor was observed up to 6 hrs after termination of the chronic treatment and after 1 day the acute response was 10-20% of the maximal response. In contrast, recovery after chronic NT-3 started immediately and after 1d was approx. 50%. Wheat germ lectin precipitation and specific TrkB probing showed pronounced reduction of the level of full length TrkB but no change in truncated TrkB protein with chronic treatment. mRNA for both forms was not changed. Since in adult brain TrkB protein is not reduced, the observed down-regulation of neurotrophin response in cortical cultures does not explain the virtual lack of receptor phosphorylation induced by TrkB ligands in adult brain. Our protein results also contrast with the reported increase of TrkA mRNA after NGF treatment in adult rats (Holtzman et al., Neuron 9:465-478, 1992). Present data suggest that the neurotrophins regulate the function of their receptors at transcriptional, translational and posttranslational levels.

540.13

BDNF RECEPTORS (TRKB) AND SIGNAL TRANSDUCTION IN PRIMARY CULTURES OF RAT CORTICAL ASTROCYTES. J. D. Roback*, H. N. Marsh, M. Downen, H. C. Palfrey and B. H. Wainer. Depts. Pathology and Pharmacological and Physiological Sciences, Univ. Chicago, Chicago, IL 60637.

BDNF has a widespread distribution in the nervous system and has trophic effects on several neuronal populations. Three types of BDNF receptor that are members of the TrkB family have been identified in rat: a full-length form possessing a tyrosine kinase domain (TrkB-TK⁺) and two truncated forms lacking the kinase domain (TrkB-TK⁻). These receptors have different distributions in the CNS (Klein et al., Cell 61: 647, 1990). We investigated TrkB receptors in cultured primary rat cortical astroglia and assessed the ability of BDNF to transmit signals in these cells. Immunoblot and immunocytochemical analysis of glial cultures with specific antibodies revealed the presence of abundant TrkB-TK⁻ protein in a majority of cells, but no detectable TrkB-TK⁺ receptors. Similarly, only *trkB-TK⁻* transcripts could be detected by RNA blot analysis; the levels of this receptor were sensitive to culture conditions and increased markedly if cells were growth-arrested in low serum. However, *trkB-TK⁺* transcripts were detected by RT-PCR, suggesting that astroglia may express low levels of the full-length receptor. BDNF treatment resulted in rapid increases in protein tyrosine phosphorylation, intracellular [Ca], MAP kinase activity and *c-fos* mRNA expression. NGF and NT-3 were without effect, but EGF had a large effect on protein tyrosine phosphorylation, MAP kinase activation and *c-fos* expression. Pretreatment of cultures with K252a (100 nM) abolished the BDNF effect, but not that of EGF, on MAP kinase activity. This result suggests that the BDNF response was mediated by TrkB-TK⁺ receptors. These data demonstrate that astroglia respond to BDNF and suggest that BDNF-initiated signal transduction is transduced via a small number of TrkB-TK⁺ receptors. However, a role for the much more abundant TrkB-TK⁻ receptors in BDNF signalling cannot be ruled out.

Nerve growth factor induces CREB phosphorylation and cyclic AMP response element-dependent transcription of *c-fos*. Azad Bonni, David D. Ginty, Anirvan Ghosh*, and Michael E. Greenberg. Dept. of Microbiology and Molecular Genetics, Harvard Medical School, Boston, MA 02115.

Nerve growth factor (NGF) promotes the survival and differentiation of specific populations of neurons in the peripheral and central nervous system. The biological actions of NGF result from intraneuronal biochemical cascades that are set in motion by NGF receptor activation. A major outcome of these signaling cascades is the transcriptional induction of the immediate early genes, the prototype of which is the proto-oncogene *c-fos*. The mechanisms by which NGF regulates the transcription of *c-fos* are addressed in this study. Previous studies have suggested that the serum response element (SRE), located at -300 nucleotides upstream of the *c-fos* transcriptional start site, is required for NGF-induced *c-fos* transcription. We now demonstrate that, in addition to the SRE, the cyclic AMP response elements (CREs) within the *c-fos* promoter are also required for NGF-induced transcription of *c-fos*. Using an RNase protection assay, we determined that in PC12 cells NGF efficiently induced transcription of CAT from a *c-fos*-CAT fusion construct (-356*fos*CAT) that contained 356 base pairs of the *c-fos* promoter. Transcription of a -356*fos*CAT construct lacking intact CREs was only poorly induced in response to NGF. In addition, transcription of a -356*fos*CAT construct lacking an intact SRE was reduced but not completely abolished. Previous studies have demonstrated that agents that increase intracellular levels of Ca²⁺ or cAMP, which activate *c-fos* transcription through the CRE induce the phosphorylation of the transcription factor, cyclic AMP response element binding protein (CREB). Phosphorylation of serine 133 on CREB is required for CREB-mediated *c-fos* transcriptional induction. Using antibodies that recognize specifically serine 133-phosphorylated CREB, we have discovered that, in addition to agents that increase intracellular levels of cAMP or Ca²⁺, NGF induces phosphorylation of CREB ser¹³³. In contrast to cAMP-induced CREB phosphorylation, NGF-induced CREB phosphorylation is dependent on activation of the small GTP binding protein Ras and occurs in PC12 cells deficient in the activity of cAMP-dependent protein kinase. These results demonstrate that CREB ser¹³³ is a target of an NGF-regulated protein kinase/phosphatase in neuronal cells and CREB phosphorylation may be critical for transcriptional activation of *c-fos* and other NGF-responsive genes.

PHOSPHOTYROSINE (p-Tyr)-IMMUNOREACTIVITY (IR) IN THE DEVELOPING RAT RETINA. Dennis W. Rickman* and Nicholas C. Brecha. Department of Anatomy and Cell Biology, UCLA and VAMC Los Angeles, CA. 90073

Previously, we described the expression of the *trk* oncogene family of high-affinity, tyrosine kinase, neurotrophin receptors in ganglion cells of the developing rat retina. To better understand the role of these and other tyrosine kinases (e.g. pp60^{src}) in retinal development, we have examined the pattern of expression of p-Tyr in the early postnatal rat retina using a mouse monoclonal antibody against p-Tyr and standard immunohistochemical methods. Staining specificity was determined by preabsorption of the antibody with excess O-phospho-L-tyrosine. On the day of birth (postnatal day-0, PND-0), specific p-Tyr-IR was present in sparsely distributed, medium to large neurons in the ganglion cell layer (GCL). These cells were densest at the peripheral retinal margin. At PND-2, in addition to cells in the GCL, many smaller, lightly-stained p-Tyr-IR cells were present at various strata of the inner nuclear layer (INL) and, occasionally, in the outer retina. At PND-5 and 10 heavy p-Tyr immunostaining was present in cells in the GCL and in many cells at different levels of the INL. No staining was observed in the nerve fiber layer, the optic nerve or the plexiform layers at any time studied. Also, no staining was seen in either normal or colchicine-treated adult retinas. This pattern of p-Tyr expression further suggests a role for tyrosine kinase receptors, and perhaps neurotrophins, during the period of cellular differentiation and synapse formation in the retina.

MULTIPLE INTRACELLULAR TYROSINE RESIDUES INVOLVED IN TRK A-MEDIATED NEURITE ELONGATION IN PC 12 CELLS. Naoyuki Inagaki*, Hans Thoenen, and Dan Lindholm, Department of Neurochemistry, Max-Planck-Institute for Psychiatry, 8033 Planegg-Martinsried, Germany

Trk-A, a tyrosine kinase receptor, acts as a receptor for NGF. In this type of receptors, specific tyrosines are phosphorylated after activation and they switch on the downstream signal events. However, little is known about the tyrosines involved in trk A-mediated signal transduction. Trk A, B, and C have 10 conserved tyrosine residues in the intracellular region. To identify those involved in trk-A induced neuronal differentiation, we made rat *trk A* (1) mutants in which these tyrosines are changed to phenylalanine, namely; Y499F, Y594F, Y643F, Y679F, Y683F, Y684F, Y704F, Y726F, Y760F, Y794F and analyzed the activity for neurite elongation using PC12nnr5, a PC12 cell mutant lacking *trk A* (2). All 10 mutants showed the same activity as the wild-type *trk A*. This suggests that multiple tyrosine residues are involved in *trk A* signal transduction. We are now making mutants in which multiple tyrosines are changed.

NOVEL RAT NERVOUS SYSTEM PROTEIN TYROSINE PHOSPHATASES.

J. Li, S. E. Snyder, and S. R. J. Salton*

Fishberg Research Center for Neurobiology, Mt. Sinai School of Medicine, New York, NY, 10029.

Tyrosine phosphorylation, an important regulator of protein function, is controlled by balancing the activities of specific protein tyrosine kinases with those of protein tyrosine phosphatases (PTP). Several transmembrane PTPs have been shown to contain cell adhesion domains, potentially allowing coupling of extracellular axonal guidance clues to intracellular signal transduction pathways. We have used PCR and differential library screening to isolate rat tyrosine phosphatase clones encoding mRNAs that are developmentally regulated and expressed with relative abundance in the developing nervous system. Sequence analysis and database comparison revealed that several of these cDNAs were most closely related to the transmembrane PTP rat LAR. RNase protection analysis revealed that the encoded RNAs were most abundant in the embryonic and postnatal brain, with detectable levels in adrenal, spleen, lung and testis. RNAs encoded by two additional clones were detected exclusively in nervous tissues. One of these is highly homologous to PTP- ζ , a human transmembrane tyrosine phosphatase containing a carbonic anhydrase-like extracellular domain. The mRNA is found most abundantly in cells of glial lineage *in vitro*. *In situ* hybridization indicates very high relative levels in the ventricular zones of embryonic spinal cord and brain, and in dorsal root ganglia, cranial ganglia, olfactory epithelium, and eye.

MC192 TREATMENT OF PC12 CELLS RESULTS IN REDUCED NGF-MEDIATED TRK AUTOPHOSPHORYLATION.

P.A. Barker* and E.M. Shooter, Department of Neurobiology, Stanford University, Stanford, CA, 94305.

NGF binds to two distinct receptors, trkA and LNGFR, on the surface of most responsive cells. The trkA receptor is a tyrosine kinase that appears to play a crucial role in transducing functional signals in response to NGF but the role of the LNGFR in mediating NGF signal transduction remains unclear. MC192, a monoclonal antibody directed against the LNGFR extracellular domain, reduces the ability of primed PC12 cells to respond to NGF (Chandler et al. JBC. 259. 6882) and attenuates the NGF-mediated c-fos response in PC12 cells (Millbrandt. PNAS. 83. 1950). We have undertaken a series of experiments to determine the mechanism by which MC192 affects NGF signal transduction.

PC12 cells were treated first with MC192 (8 ug/ml) for 30 minutes and then with MC192 and NGF (5 ng/ml) for 40 minutes. RNA was isolated from the treated cells and analyzed by Northern blot. As previously reported, the pretreatment of PC12 cells with MC192 strongly attenuates the c-fos mRNA induction. This effect is not specific to the c-fos gene; other early genes (NGFIA and VGF) were similarly affected by the MC192 treatment. EGF-dependent induction of immediate early (IE) genes was not affected by MC192 treatment, indicating that the MC192 effect is specific to the NGF pathway.

Ligand-mediated activation of many tyrosine kinase receptors results in IE gene induction. We therefore performed experiments to determine if the presence of MC192 affected NGF-induced trkA autophosphorylation in PC12 cells. In cells pretreated with MC192, the NGF-mediated (5 ng/ml) trk autophosphorylation response observed five minutes after NGF addition was sharply reduced as compared to controls. This effect of MC192 was reduced at 50 ng/ml NGF and not observed at 250 ng/ml NGF.

These results indicate that the effect of MC192 on NGF-mediated IE gene induction may be ascribed at least in part to a reduction in trkA activity.

LAR TYROSINE PHOSPHATASE RECEPTOR: ALTERNATIVE SPLICING OF A NOVEL 12 BASE PAIR CASSETTE EXON. J.S. Zhang and F.M. Longo* Dept Neurology, UCSF, San Francisco, CA 94143

The Leukocyte Common Antigen-Related (LAR) gene codes for a tyrosine-phosphatase receptor with extracellular domain sequence similarity to N-CAM. Tyrosine phosphatase receptors may influence neural growth or differentiation by modulating effects of growth factors acting through tyrosine kinase receptors. LAR is expressed by neurons and PC12 cells (Longo et al; Le Beau and Longo; Zhang and Longo, Soc Neurosci Abstrs; 17:762,1991; 18:949,1992). Screening an adult rat hippocampus cDNA library for additional LAR clones yielded several clones with sequence identical to LAR except for a 12 bp insert (designated LASE-b, LAR Alternatively Spliced Exon-b) 5 bases downstream from the transmembrane domain. LASE-b codes for amino acids SKQE. Sequence of flanking introns showed only 7/12 pyrimidines at the upstream intron splice-acceptor site, instead of the more typical consensus acceptor of 11-12/12 pyrimidines. RT-PCR and southern blot analysis of PCR products with LASE-b probes demonstrated that the majority of LAR transcripts do not contain LASE-b and that LASE-b splicing increased in the cortex and cerebellum during development. LASE-b splicing increased during NGF-induced PC12 differentiation and upon 3T3 fibroblasts reaching confluency. LASE-b was detected in muscle but not in other peripheral tissues. These observations indicate that both *cis*- and *trans*-acting factors control LASE-b splicing and provide a model for understanding nervous system specific regulation of alternative splicing in the context of a gene likely to regulate cell growth and development. (Supported by United Cerebral Palsy, NIH AG09873 and the VA).

NEUROTROPHIC FACTORS: RECEPTORS AND CELLULAR MECHANISMS IV

541.1

INHIBITION OF PROTEIN TYROSINE KINASES AFFECTS SURVIVAL AND NEURITE OUTGROWTH OF EMBRYONIC SENSORY NEURONS IN CULTURE H.J.L. Fryer*, M. Sahin and S. Hockfield. Sect. of Neurobiology, Yale Univ. Sch. of Med., New Haven, CT 06510

Growing evidence suggests that tyrosine phosphorylation plays a key role in neural development. The state of protein tyrosine phosphorylation is determined by the opposing actions of protein tyrosine kinases (PTKs) and protein tyrosine phosphatases. We have begun to examine the role of tyrosine phosphorylation in developing sensory neurons by culturing E15 rat dorsal root ganglion neurons in the presence of the PTK inhibitor, genistein, and its inactive analog, daidzein.

Genistein affects neuron survival in a concentration-dependent manner. At >50 μ M, genistein is toxic to DRG neurons in a 24-hour culture period. Because the toxicity of genistein can be overcome by incubating DRG neurons with high concentrations of NGF, genistein neuro-toxicity may be due to its functional inhibition of the trk PTK through which NGF exerts its effects. Between 3-50 μ M and below 0.3 μ M, genistein has no observable effect on neuron survival. Between 1-3 μ M, DRG neuron survival is increased even in the absence of NGF. Daidzein has no effect on neuron survival.

Genistein also affects neurite outgrowth of DRG neurons. Neurite outgrowth of chick ciliary ganglion neurons (Bixby and Jhavaia, 1992) is enhanced with genistein. Similarly, we find that, in a 4-hour culture assay, concentrations of genistein >30 μ M increase the number of rat DRG cells with neurites in a concentration-dependent manner. The neurite outgrowth promoting effect of genistein is enhanced in the presence of NGF. Daidzein has no effect on neurite outgrowth.

These results suggest that tyrosine phosphorylation is involved in the survival, death and neurite outgrowth of developing sensory neurons. Supported by NS22807.

Kinase inhibitors and the staurosporine paradoxical effect on neurite outgrowth in PC12 cells. X. Z. Campbell, L. Gollapudi, and K. E. Neet*, Dept. of Biological Chemistry, UHS/ The Chicago Medical School, North Chicago, IL 60064.

Staurosporine (STSP), a potent kinase inhibitor, inhibits nerve growth factor (NGF)-induced neurite outgrowth and stimulates fibroblast growth factor (FGF)-induced neurite outgrowth at low concentration but induces neurite extension by itself at higher concentration. In order to understand the action of STSP in both induction and inhibitory modes, we examined these PC12 cell bioassays with different protein kinase inhibitors. Phorbol 12-myristate 13-acetate (PMA) chronic treatment had no effect on NGF-, FGF- or STSP-induced neurite outgrowth. Bryostatin (BRYO) chronic treatment inhibited NGF- and FGF-induced neurites but not the higher concentration STSP-induced neurite outgrowth. Both sphingosine and 6-thioguanine inhibited NGF, FGF, and the higher concentration STSP-induced neurite outgrowth. K252a, which inhibits NGF stimulation of PC12 cells, did not affect FGF or STSP-induced neurite outgrowth. Thus, NGF, FGF, and the higher concentration STSP-induced neurite outgrowth go through different signal pathways, but may share certain later steps. Low concentrations of PMA or BRYO enhanced NGF- or STSP-induced neurite extension by shifting the dose response curve to lower concentrations. STSP inhibited PC12 cell DNA replication during neurogenic differentiation, as does NGF. These data indicate that STSP acts downstream in the signal pathway as well as at the Trk receptor level. This downstream step(s) must be past the bryostatin-sensitive step but before the sphingosine and 6-thioguanine sensitive steps. (Supported by NIH grant NS24380)

541.3

MONOAMINE-ACTIVATED α_2 -MACROGLOBULIN IS A SPECIFIC INHIBITOR FOR NGF-STIMULATED TRK-A AUTOPHOSPHORYLATION AND SIGNAL TRANSDUCTION. W.-S. Qiu and P.H. Koo*. Department of Microbiology and Immunology, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272.

Monoamine-activated α_2 -macroglobulin (α_2 M) has been shown to inhibit β -nerve growth factor (NGF)-promoted neurite outgrowth and other functions of embryonic neurons and pheochromocytoma PC12 cells, whereas normal α_2 M has little or no such activity. The objective of this study is to elucidate the mechanism and specificity of inhibition by monoamine-activated α_2 M. The binding of methylamine activated α_2 M (MA- α_2 M) to *trk*, which is a part of high-affinity NGF receptor, was studied with PC12(6-24) cells and NIH-3T3 fibroblasts over-expressing *trk* (*trk-3T3*). In each case MA- α_2 M readily forms stable complexes with *trk* *in vivo*, whereas normal α_2 M does not. As determined by the Western blottings and [γ - 32 P]-ATP incorporation assays, both 5-hydroxytryptamine-activated α_2 M (5HT- α_2 M) and MA- α_2 M also dose-dependently blocks NGF-promoted autophosphorylation of *trk* *in vivo*, whereas normal α_2 M is much less effective. Neither MA- α_2 M, 5HT- α_2 M nor normal α_2 M, however, blocks either platelet-derived growth factor-stimulated or epidermal growth factor-stimulated tyrosine phosphorylation of the respective receptors, nor does MA- α_2 M block fibronectin activation of focal adhesion kinase (FAK) via integrin receptors. NGF-promoted tyrosine phosphorylation of phospholipase C- γ 1 (PLC- γ 1) and extracellular signal-regulated kinase-2 (ERK-2) was also dose-dependently blocked by MA- α_2 M, whereas NGF-independent phosphorylation of FAK was unaffected. We conclude that monoamine-activated α_2 M may block neurite outgrowth and neuronal survival by its specific binding to NGF receptors, and its specific blocking of the NGF-promoted activation of intracellular second messenger pathways.

541.5

MIMICKING THE NEUROPROTECTIVE MECHANISM OF GROWTH FACTOR ACTION WITH LOW MOLECULAR WEIGHT AGENTS. M. P. Mattson, B. Cheng, Y. Goodman, V. L. Smith-Swintosky, J. W. Ashford* and J. Oelgen. Sanders-Brown Center on Aging and Dept. of Anatomy & Neurobiol., Univ. of Kentucky, Lexington, KY 40536.

Traditional and newly identified neurotrophic factors have recently been shown to protect various neuronal populations against excitotoxic, metabolic and free radical-mediated injury (*Sem. Neurosci.*, Fall, 1993 issue). Work in this laboratory indicates that in many cases the mechanism of action of the neuroprotective factors involves stabilization of intracellular free calcium levels ($[Ca^{2+}]_i$) and enhancement of free radical-neutralizing systems. For example, neurotrophins (NGF, BDNF and NT-3), bFGF, IGFs, TNF, and secreted forms of β -amyloid precursor protein protect cultured hippocampal neurons against hypoglycemic damage by preventing the late, NMDA receptor-mediated elevation of $[Ca^{2+}]_i$ (see: Cheng et al.; Barger et al.; Smith-Swintosky et al., this meeting). We now report that staurosporine, K-252a and K-252b (low M.W. compounds of microbial origin initially characterized as protein kinase inhibitors) can, at very low concentrations (100 fM - 100 pM), protect cultured hippocampal, septal and cortical neurons against a variety of insults including hypoglycemia and oxidative damage (initiated by exposure to iron or H_2O_2). We show that at neuroprotective concentrations these compounds stimulate tyrosine phosphorylation of multiple proteins and stabilize $[Ca^{2+}]_i$. The data suggest that the mechanism of action of these compounds may be similar to that of endogenous neuroprotective factors. (NIH, Metropolitan Life Foundation, and French Foundation for Alzheimer's Research support).

541.7

DOWN-REGULATION OF *trk* AND TYROSINE HYDROXYLASE IN PC12 CELLS BY ANTISENSE B-raf. M. Oshima*, U. R. Rapp, and G. Guroff. Section on Growth Factors, National Institute of Child Health and Human Development, Bethesda, MD 20892 and Viral Pathology Section, National Cancer Institute, Frederick Cancer Research and Development Center, Frederick, MD 21702-1201.

B-raf, the gene for one of the raf family of ser/thr kinases is expressed primarily in neuronal tissues. Previous work from these laboratories showed that PC12 cells contain a 95KDa B-raf protein kinase that is activated by treatment with nerve growth factor. In order to study the role of B-raf in the action of nerve growth factor, PC12 cells were transfected with antisense B-raf. Several clones of B-raf-negative cells were obtained and all showed, in addition, a marked decrease or a total absence of both p140^{trk}, the high affinity nerve growth factor receptor, and of tyrosine hydroxylase. Normal levels of p75^{NGFR}, the low affinity nerve growth factor receptor, choline acetyltransferase, and the epidermal growth factor receptor were present. Antisense B-raf did not alter the expression of either raf-1 or A-raf. The changes were reversible upon transient transfection. These results suggest that B-raf is involved in the expression of certain proteins that are crucial for neuronal development.

541.4

INVESTIGATION OF SIGNAL TRANSDUCTION EVENTS UNDERLYING THE RESPONSE OF PC12 CELLS TO NERVE GROWTH FACTOR USING THE CYTOSENSOR™ MICROPHYSIOMETER. S. Pitchford* & B.S. Glaeser, Molecular Devices Corp., Menlo Park, CA 94025.

Using the Cytosensor Microphysiometer we have demonstrated that PC12 cells respond to a 12 minute incubation with nerve growth factor (NGF) by increasing the cellular acidification rate of a low-buffered RPMI medium bathing the cells in an apparent dose-dependent fashion (*Soc Neurosci. Abstr. Vol. 18, Part 1, p614*). This increase in acidification rate was reduced in a dose-dependent manner (1-50 μ g/ml) by pre-incubation of the cells with genistein, an inhibitor of some tyrosine kinases and by incubation with the protein kinase C inhibitor staurosporine at 10 & 100nM. Pre-incubation of PC12 cells with 10 μ M Rp cAMPs, an inhibitor of protein kinase A, however, did not effect the response of cells to NGF. In addition, activation of cells by NGF in a glucose-free medium resulted in a transient increase in acidification rates (compared to the longer lasting response in glucose-containing medium). This transient peak was blocked by 10 μ M methylisobutyl amiloride (MLA), an inhibitor of the Na^+/H^+ antiporter, suggesting the involvement of this exchanger in the response. These data suggest that the early response of PC12 cells to NGF involves the interplay of a number of cellular and membrane bound events.

541.6

TNF- β AND TNF- α PROTECT AGAINST CALCIUM-MEDIATED NEURONAL INJURY IN HIPPOCAMPAL AND SEPTAL CULTURES. B. Cheng*¹, S. Christakos² and M. P. Mattson¹.

¹Sanders-Brown Center on Aging and Dept. of Anatomy and Neurobiology, Univ. of Kentucky, Lexington, KY 40536. ²Dept. Biochem. and Molec. Biol., UMD-New Jersey, Newark, NJ 07103. Increasing data indicate that cytokines serve a variety of roles in the nervous system. Since several growth factors including neurotrophins promote the survival of CNS neurons, and because the low affinity NGF receptor (p75) is homologous to tumor necrosis factor (TNF) receptor, we sought to determine whether TNFs influence the survival of CNS neurons. TNF- β and TNF- α (1 - 1000 ng/ml) protected cultured embryonic rat hippocampal and septal neurons against hypoglycemic injury. Calcium influx was involved in hypoglycemic injury since hypoglycemia caused an elevation of $[Ca^{2+}]_i$ and neurons were protected by incubation in calcium-deficient medium. The TNFs attenuated the hypoglycemia-induced elevation of $[Ca^{2+}]_i$. Our recent findings indicate that the mechanism of action of some excitoprotective growth factors may involve regulation of the expression of proteins involved in $[Ca^{2+}]_i$ homeostasis. In the present study TNF- β , TNF- α , and NT-3 caused a 5- to 8-fold increase in the number of neurons expressing calbindin D28k in hippocampal cultures. The data suggest roles for TNFs in development and neurodegenerative conditions. (supported by NIH, Metropolitan Life Foundation and French Foundation for Alzheimer Research).

541.8

PROTEIN KINASE C ISOFORMS IN NGF-SIGNALING. M.W. Wooten*, G. Zhou, M.L. Seibenhener, and E.S. Coleman Dept. of Zoology, Auburn University, AL 36849

Activation of cPKC compared to nPKC family members in response to PMA or NGF treatment of PC12 cells was examined. cPKC, δ and ϵ -nPKC isoforms were predominantly cytoplasmic (70-90%) while ζ -PKC was distributed in the nucleus (11%), cytoplasm (38%) and membrane (51%) fraction. PMA (40nM) translocated all PKC isoforms to the membrane fraction, while NGF translocated cPKC and ϵ -PKC, with no change in δ -PKC, whereas ζ -PKC translocated to the cytoplasm and was inhibited by sphingosine (2.5 μ M). Down-regulation of PKC (1 μ M PMA for 48hrs) resulted in depletion of all PKC isoforms except ζ -PKC and failed to inhibit NGF-stimulated increase in cytoplasmic ζ -PKC. PMA down-regulation did not inhibit NGF-induced neurite outgrowth whereas sphingosine (2.5 μ M) was a potent inhibitor. Immunocytochemistry revealed ζ -PKC localization in the cell body as well as neurite branch points. Findings will be presented: 1) addressing the role of Ca^{2+} in the redistribution of ζ -PKC and whether translocation reflects the activation state of the kinase and 2) the effect of ζ -PKC 'knock-out' on NGF-induced neurite outgrowth. Taken together, our findings clarify the role of PKC isoforms in NGF signalling and suggest a novel role for ζ -PKC upstream of p21ras.

541.9

REQUIREMENT FOR PROTEIN KINASE C DURING LEUKEMIA INHIBITORY FACTOR MEDIATED ACTIVATION OF THE MAP KINASE CASCADE. W.P. Schieman*, and N.M. Nathanson. Department of Pharmacology, Univ. of Washington, Seattle, WA 98195.

Leukemia inhibitory factor (LIF) is a member of the rapidly expanding family of multifunctional cytokines capable of stimulating a variety of physiological responses both in hematopoietic and non-hematopoietic cells, including neurons, myoblasts, hepatocytes, and adipocytes. While the identity of the cellular mediators involved during LIF signal transduction remains largely unknown, recent evidence implicates the activation of protein tyrosine kinases (PTKs) as possible initiators of LIF receptor (LIFR) signalling. Since stimulation of PTKs results in activation of the MAP kinase cascade in response to numerous growth factors and neurotrophic agents, we investigated if stimulation of LIFRs could similarly activate this cascade. We find that treatment of 3T3 L1 cells with LIF resulted in a 4-6-fold stimulation in cell extracts of several components of the MAP kinase cascade, including MAPKK, MAPK, and an S6K activity. Half-maximal activation of these kinases occurred at ~15 ng/ml. In response to saturating concentrations (100 ng/ml), kinase activities peaked at 15 min and declined rapidly to basal during the subsequent 15 min. Protein kinase C (PKC) activity was down-regulated in order to test its role in LIFR action. Chronic treatment of 3T3 L1 cells with PMA, but not the inactive phorbol ester PDD, attenuated LIF stimulated activation of MAPKK, MAPK, and S6K activities. Our results suggest that at least some of the cellular responses of LIF may be mediated by stimulation of the MAP kinase cascade, and that this process appears dependent upon the presence of PKC.

541.11

MODULATION OF NEUROTROPHIN- AND EGF-INDUCED PC12 CELL DIFFERENTIATION BY K-252 COMPOUNDS; ROLE OF PROTEIN KINASE C. E. Isono, F. Ohsawa*, F. Hefli and B. Knüsel. Andrus Gerontology Center, U.S.C., Los Angeles, CA 90089;

Effects of K-252a and b on differentiation-inducing activity of neurotrophins and EGF were examined in PC12 cells. K-252a and b inhibit the differentiation of PC12 cells induced by NGF and, at lower concentrations potentiate NT-3 induced neurite outgrowth. NT-3 alone resulted in less than 3% neurite bearing cells. In simultaneous presence with 10nM K-252a or 30 nM K-252b, up to 40% of neurite bearing cells were counted. BDNF and NT-5 did not induce neurite outgrowth in PC12 cells in absence or presence of K-252a or b. The effect of sub-optimal concentrations of NGF was not potentiated.

EGF in PC12 cells activates various second messengers similar to NGF, without inducing neurite outgrowth. Co-treatment with 100 - 1000nM K-252a, but not K-252b, induced neurite outgrowth in up to 80% of cells. A similar effect was obtained with PDBu or TPA, consistent with an involvement of protein kinase C in EGF potentiation by K-252a. The fact that K-252b was inactive, suggests a different mechanism for potentiation of EGF than NT-3.

Since K-252a, but not K-252b, penetrates into the cytosol, our findings suggest that some K-252 compounds can exert a neurotrophin potentiating effect by interacting with the extracellular or transmembrane portion of the trk molecule while other actions of these compounds might involve inhibition of intracellular kinases.

541.13

Molecular mechanisms of guanosine and GTP induced neurite outgrowth. J.W. Gysbers¹, D.P. Lamb¹, M.K. O'Banion^{2,3}, M.B. Martzen² and M.E. Rathbone¹. ¹Depts. of Biomed. Sci. and Med., McMaster Univ. Health Sci. Centre, Hamilton, Ont., Canada L8N 3Z5 and ²Depts. of Neurol. and ³Neurobiol. and Anat., Univ. of Rochester Med. Center, Rochester, NY 14642.

Guanosine (NeuroReport 3, 997-1000, 1992) or GTP enhances neurite outgrowth in NGF-treated rat pheochromocytoma (PC12) cells. Stimulation of neurite outgrowth by these purine compounds occurs even in the presence of the nucleoside transport inhibitors, dipyridamole or NBTI (5-(*p*-nitrobenzyl)-6-thioinosine). This suggests that the effects of guanosine and GTP may be mediated by extracellular receptors. These receptors have not been definitively identified.

We are comparing the intracellular molecular responses of PC12 cells treated with guanosine and GTP to those treated with NGF. Giant 2-D gel electrophoresis of phosphorylated proteins indicates that guanosine and GTP induce different phosphorylation patterns from those induced by NGF alone. We are assaying expression of several NGF-responsive genes and their corresponding proteins which are involved in neurite outgrowth, such as *c-fos*, *Ras*, *MAP2* and *GAP-43*. Preliminary results from assays of GAP-43 mRNA and protein expression suggest that GAP-43 may be modulated by the actions of guanosine and GTP. In addition, the ratio of activated Ras to inactive Ras was found to increase upon exposure of PC12 cells to extracellular guanosine or GTP, as it is with NGF. This indicates that GTP or guanosine may act via a similar second messenger pathway as one of those stimulated by NGF. Immunocytochemical studies indicate that NGF increases high molecular weight neurofilament proteins. In contrast, guanosine and GTP added alone to the cultures did not induce high molecular weight neurofilaments.

THE ROLE OF NGF/PROTEIN KINASE C INTERACTIONS IN DIFFERENTIATION VERSUS MAINTENANCE OF PC12 CELLS. E. J. Martin* and E. M. Meyer. Department of Pharmacology and Therapeutics, College of Medicine, Univ. of Florida, Gainesville, FL 32610-0267

Protein kinase C (PKC) is a phospholipid-dependent, calcium- and diacylglycerol-activated kinase that preferentially phosphorylates serine and threonine residues. This enzyme has been implicated in the second messenger pathways underlying trophic events in the brain, including those triggered by nerve growth factor (NGF) administration. However, to what extent PKC is involved in the events that take place secondary to NGF binding its receptor remains unclear. We therefore designed experiments to study the effects of NGF and phorbol ester (TPA) applied at different concentrations and for various periods of time. PC12 cells are a commonly accepted model system for studying the complex biological transduction processes initiated by NGF. Cultures of both undifferentiated and differentiated PC12 cells were assayed for PKC activity by permeabilization with digitonin. By permeabilizing the cells, it is possible to introduce a specific substrate peptide and phosphate source ([³²P]ATP) into the cells. These components interact with the intracellular environment in such a way that PKC-phosphorylated substrate can be collected on phosphocellulose filters and quantified. We have demonstrated in undifferentiated PC12 cells that 10 nM TPA was able to stimulate PKC activity within 15 minutes. This stimulation was attenuated with PKC inhibitor peptide [PKC (19-36)]. NGF (100 ng/ml) was also able to stimulate enzyme activity. However, this response was slower than that seen with TPA. These studies were repeated in serum-free cultures of differentiated PC12 cells. Together, the results of these enzyme activity assays in combination with assessment of cell viability indicate that PKC is partially involved in the differentiating effects of NGF and that protein kinase A may be involved in the neurite maintenance effects of NGF in PC12 cells.

GUANOSINE STIMULATES ACCUMULATION OF INTRACELLULAR CGMP IN PC12 CELLS. S. Hindley*, P.J. Middlemiss and M.P. Rathbone. Depts. Biomed. Sci. and Medicine, McMaster University Medical Centre, Hamilton, Ontario L8N 3Z5.

Rat pheochromocytoma cells (PC12) respond to nerve growth factor (NGF) by extending neurites and differentiating - assuming characteristics of sympathetic neurons. Extracellular guanosine also stimulates neurite outgrowth and synergistically enhances NGF stimulated neurite outgrowth in PC12 cells (Gysbers and Rathbone, NeuroReport 3:997, 1992). The signalling mechanism by which guanosine produces its effects is unknown. Recently guanosine was reported to increase intracellular cGMP in vascular smooth muscle (Vuorinen et al., Br. J. Pharma. 105:279, 1992). Therefore, we investigated whether guanosine stimulated intracellular accumulation of cGMP in PC12 cells. Papaverine, but not Zaprinast (an inhibitor of cGMP dependent PDE-MB 22948) inhibited PDE activity in PC12 cells. This is in agreement with Whalin et al. (Mol. Pharm. 39:711, 1991) who reported that only isouquinolines inhibit PDE activity in PC12 cells. Extracellular guanosine or vehicle control was added to the cultures for various periods (1-10 min). Basal cGMP levels were 0.59 pmol/mg protein. Addition of guanosine induced a rapid concentration-dependent increase in cGMP to 1.13 ± 0.04 pmol/mg protein after 2 minutes. cGMP levels then slowly decreased over the next 8 min. Guanosine (3.3-390 μ M) increased intracellular cGMP, more so at higher concentrations. We are investigating whether increases in intracellular cGMP are associated with stimulation of neurite formation by guanosine. Support: Hospital for Sick Children Foundation and Ontario Heart and Stroke Foundation.

EXPRESSION OF THE DUAL SPECIFICITY CLK KINASE INDUCES THE DIFFERENTIATION OF PC12 CELLS. M. Myers, M. Murphy and G. Landreth*. Alzheimer Laboratory, Depts. of Neurology and Neuroscience, Case Western Reserve University, Cleveland, OH 44106.

The discovery of a novel class of dual specificity kinases which phosphorylates serine/threonine and tyrosine residues has led to a substantial reevaluation of the functional properties of protein kinases. The identification of dual specificity kinases has resulted in the appreciation that these enzymes are central components of signal transduction pathways, operating immediately down stream of receptor-tyrosine kinases. We tested whether the founding member of this class, CLK (*click*; *cdc2*-like kinase), could intervene in NGF signal transduction cascades. The CLK gene was stably expressed in PC12 cells (PC-CLK4) under the control of the heavy metal-inducible promoter, MT1. PC12 cells do not normally express this gene. Incubation of PC12-CLK4 cells with Zn⁺⁺ CLK mRNA levels resulted in the induction of CLK mRNA to maximal levels within 3 hrs, the mRNA levels then declined over the next several hours. CLK kinase activity was detected by the appearance of a 55 kDa phosphoprotein and the enhanced phosphorylation of the exogenous CLK substrate, myelin basic protein. Sustained exposure of PC-CLK4 cells to Zn⁺⁺ resulted in the morphological differentiation of the cells with the development of neurites, similar to the effect of NGF.

Treatment of the cells with NGF initiates a cascade of signal transduction events and the serial activation of protein kinases. Similarly, induction of CLK expression resulted in the activation of the MAP kinases and two S-6 kinases, p85rk and S6PK. However, the activity of two other NGF regulated kinases, p70s6k and Fos kinase, were not affected. These data indicate that CLK can selectively regulate the activity of protein kinases involved in NGF-stimulated signal transduction and mediate the morphological differentiation of the cells.

SPECIFICITY OF NGF-*trk* ACTION: EFFECTS ON PI-3 KINASE AND PLC γ . D. Blumberg*, M.J. Radeke, and S.C. Feinstein. Neuroscience Research Institute and Dept. of Biological Sciences, Univ. of California, Santa Barbara, CA 93106.

Growth factor receptor tyrosine kinases (RTK) have emerged as a key element in the regulation of cell growth and differentiation. However, the specificity of RTK action remains poorly understood. Toward addressing RTK specificity within a single cellular context, we have used PC12 cells to examine tyrosine phosphorylation of early signal transduction molecules in response to NGF, EGF, and FGF, which induce neuronal differentiation, mitogenesis and partial differentiation, respectively. Toward addressing cell-type specific responses to a single ligand-RTK complex in different cell types, we have examined tyrosine phosphorylation in response to NGF activation of its *trk* receptor in PC12 cells and in NIH-3T3 cells stably transfected with *trk* (where NGF induces mitogenesis).

Several recent reports have approached these issues. However, considerable controversy remains. Our PC12 observations are (1) NGF and EGF induce distinct patterns of PI-3 kinase tyrosine phosphorylation; FGF induces little to none, (2) we find no evidence for a direct association between *trk* and PI-3 kinase following NGF treatment, (3) we find little to no change in the overall amount of PI-3 kinase activity resulting from NGF treatment and (4) NGF induces marked tyrosine phosphorylation of PLC γ , whereas FGF appears to induce none. Lastly, the qualitative pattern of NGF-*trk* induced PI-3 kinase phosphorylation is markedly different between PC12 cells and *trk* transfected NIH-3T3 cells. Taken together, these data are consistent with a model in which different biological outcomes of a given RTK activation event can be orchestrated both by unique interactions with downstream signal transduction elements and by interactions between particular RTK's and cell type specific elements. In addition, our NGF/*trk* data are consistent with a model in which the main effect of ligand binding to its receptor with regard to PI-3 kinase activity is not to modulate the overall level of the activity but rather to influence its sub-cellular localization by virtue of SH2 interactions. INSULIN (INS) AND INSULIN-LIKE GROWTH FACTOR I (IGF-I) ACTIVATE p21RAS IN CULTURED FETAL NEURONS. K.A. Heidenreich*, L. J. Robinson, J.W. Leitner, and B. Draznin. Depts. of Pharmacol. and Med., Univ. of Colorado Hlth. Sci. Ctr., and VAMC, Denver, CO 80262

We have previously shown that INS and IGF-I support the growth and differentiation of chick forebrain neurons and activate c-fos transcription by a PKC-mediated pathway in these cells. To explore other potential steps in the signalling pathway, we examined the ability of INS and IGF-I to activate p21ras by measuring increases in the amount of GTP bound to p21ras. Neurons prelabeled with 32p-orthophosphate were incubated with and without growth factor and cell lysates were immunoprecipitated with anti-ras antibodies (Y13-259, Oncogene). Pelleted 32p-labeled guanine nucleotides were separated by TLC. GDP and GTP spots were visualized by autoradiography and quantitated by liquid scintillation spectroscopy. INS and IGF-I increased GTP binding to p21ras by 21.2 +/- 4.7 and 22.6 +/- 3.3 percent, respectively. Ras activation by each peptide reached a maximum by 5 min. In the presence of INS, ras activation was sustained for 3 hr; whereas, in the presence of IGF-I, the activation was more transient. Maximal stimulation occurred at 10 ng/ml of each peptide indicating that both INS and IGF-I receptors mediate p21ras activation in these cells. The results suggest that p21ras activation represents an early step in INS and IGF-I signalling in neurons.

HORMONES AND DEVELOPMENT: NEUROANATOMICAL FINDING

542.1

DEVELOPMENTAL REGULATION OF ACTIVATIONAL HORMONE EFFECTS: AXOTOMY PREVENTS THE NORMAL DEVELOPMENT OF STEROID-SENSITIVITY IN MOTONEURONS. J.L. Lubischer* & A.P. Arnold. UCLA Brain Research Inst. and Dept. Psychol., Los Angeles, CA 90024-1563

Like other motoneurons, those in the spinal nucleus of the bulbocavernosus (SNB) recover poorly after axonal injury in development. Only 42% of SNB motoneurons survive axotomy on postnatal day 14 (P14). After axotomy at later ages (P21-adult), there is no significant SNB cell death. We asked whether motoneurons that survive axotomy at P14 show lasting effects not seen in motoneurons axotomized at later ages.

Six weeks after unilateral axotomy of SNB motoneurons, rats were castrated and given testosterone (T) or blank implants, then perfused 30 days later. As expected, the somata of SNB motoneurons contralateral to the axotomy were larger in rats given T implants ($p < .0001$). In contrast, motoneurons axotomized on P14 did not show a T-induced increase in soma size ($p > .5$). Target muscles on both sides were larger in T-treated rats ($p's < .05$). We then lengthened the time between P14 axotomy and hormone treatment, castrating and implanting rats at 5 months of age. In addition, a group of rats was axotomized on P21, then castrated and implanted at 5 months of age. Motoneurons axotomized on P21 responded to T treatment, as did their contralateral counterparts ($p's < .05$). Motoneurons axotomized on P14, however, did not show a significant response to T treatment, even at 5 months of age ($p > .05$).

SNB motoneurons axotomized (and thereby separated from their targets) early in development failed to develop normal adult sensitivity to T. Preliminary immunohistochemical evidence suggests that androgen receptors, initially down-regulated by axotomy, have recovered by the time of T-treatment in these studies. Thus, the mechanisms underlying the failure to develop T sensitivity after developmental axotomy remain unknown. Supported by NIH grant HD15021 and an NSF graduate fellowship.

MODULATION OF INTRACELLULAR Ca^{2+} IN CULTURED PURKINJE CELLS BY INSULIN-LIKE GROWTH FACTOR I. M. Villalba, J. Satrústegui, and I. Torres-Aleman¹. Molecular Biology Center, and ¹Cajal Institute, CSIC. Madrid. Spain.

A prolonged inhibition of glutamate-stimulated GABA release by Purkinje cells is found when IGF-I is co-administered with glutamate in vivo. This protracted inhibition is reminiscent of the functionally plastic phenomenon of long-term depression (LTD) known to occur in the cerebellar cortex. Since elevated intracellular Ca^{2+} levels ($[Ca^{2+}]_i$) are known to be necessary in LTD, we now investigated whether IGF-I modulates $[Ca^{2+}]_i$ fluxes in cultured Purkinje cells. We found that the addition of IGF-I elicits a dramatic, prolonged increase in $[Ca^{2+}]_i$ as measured by Fura-2 microfluorimetry. Other types of cells such as small neurons and astrocytes did not respond to IGF-I. Ca^{2+} entry from extracellular sources was not essential since in the absence of extracellular Ca^{2+} the increase in $[Ca^{2+}]_i$ after IGF-I, although somewhat reduced, was still present. Furthermore, $[Ca^{2+}]_i$ increases in response to 10 nM glutamate pulses were potentiated by co-administration of IGF-I. Since LTD is known to require an increase in $[Ca^{2+}]_i$ in Purkinje cells, the present results further reinforce the notion that IGF-I is the climbing fiber messenger involved in LTD.

542.2

DORSAL RHIZOTOMY DOES NOT ALTER DEVELOPMENT OF MOTONEURON MORPHOLOGY IN THE SPINAL NUCLEUS OF THE BULBOCAVERNOSUS. L.A. Goldstein*, A.C. Mills, and D.R. Sengelaub. Program in Neural Science, Indiana University, Bloomington, IN 47405.

Dendritic development of motoneurons in the spinal nucleus of the bulbocavernosus (SNB) in rats is biphasic--SNB dendrites grow exuberantly through four weeks of age and then retract to mature lengths by seven weeks of age. In several neural systems, afferents have been implicated in the development and modulation of dendritic morphology. To determine if dorsal root afferents might be involved in the development of SNB dendrites, we attempted to manipulate afferent availability using dorsal rhizotomy.

Dendritic development was examined in intact males and in males who received a unilateral dorsal rhizotomy (L5-S1) on postnatal day (P)7. SNB motoneurons were retrogradely labeled with cholera toxin-HRP at P28, when dendritic length is normally maximal (mean= 7034.5 μ m), and at P49, when dendritic lengths are mature (mean= 4266.5 μ m). Rhizotomy was confirmed using dorsal horn area measures and TMPase histochemistry. Dendritic length and soma size of SNB motoneurons were assessed with a computer-based morphometry system. Following rhizotomy, dendritic length of SNB motoneurons developed normally, reaching typical exuberant lengths at P28 (mean= 6028.3 μ m) and retracting to mature lengths by P49 (mean= 3910.2 μ m). Similarly, no differences in SNB soma size between intact (P28 mean= 818.5 sq μ m; P49 mean= 886.9 sq μ m) and rhizotomized animals (means= 920.3 and 972.4 sq μ m, respectively) were observed. These results suggest that dorsal root afferents to the SNB do not influence the development of SNB motoneuron morphology.

542.3

DORSAL RHIZOTOMY DOES NOT BLOCK ESTROGEN SUPPORT OF DENDRITIC DEVELOPMENT IN A SEXUALLY DIMORPHIC RAT SPINAL NUCLEUS. T.C. Hays, A.C. Mills, and D.R. Sengelaub*. Program in Neural Science, Indiana University, Bloomington, IN 47405.

The lumbar spinal cord of the rat contains two sexually dimorphic motor nuclei, the spinal nucleus of the bulbocavernosus (SNB) and the dorsolateral nucleus (DLN). Dendrites of motoneurons in the SNB and DLN grow postnatally and establish their adult lengths by seven weeks of age. This growth is hormone-dependent, and after castration SNB and DLN dendrites fail to grow, but growth is supported in castrates treated with testosterone. In the SNB, initial dendritic growth is also supported in castrates treated with either of testosterone's metabolites, estrogen or dihydrotestosterone. To determine if DLN dendritic growth could be regulated by the conversion of testosterone to estrogen, male rats were castrated on postnatal day (P)7 and given daily injections of estrogen. Developing DLN motoneurons were retrogradely labeled with cholera toxin-HRP and their morphology was assessed in three dimensions (Eutectics NTS). As in the SNB, estrogen treatment supported initial DLN dendritic growth, and at P28 DLN dendritic length in estrogen-treated castrates did not differ from that of intact males at the same age.

Because the dorsal root ganglia which innervate the SNB/DLN target musculature (L6/S1) appear to be estrogen sensitive (Mills and Sengelaub, '93), we attempted to block the estrogenic support of DLN dendritic growth by performing unilateral dorsal rhizotomy at P7 in estrogen-treated castrates. No differences in DLN dendritic length were observed at P28 (three weeks post-rhizotomy). Thus, while estrogen can support initial SNB and DLN dendritic development, this effect is likely not mediated through the dorsal root ganglia.

542.5

TESTOSTERONE REVERSES AGE-RELATED REGRESSIVE CHANGES IN AN ANDROGEN-SENSITIVE RAT SPINAL NUCLEUS. M.C. Clark*, M.W. Harvy, and D.R. Sengelaub. Program in Neural Science, Indiana University, Bloomington, IN 47405.

Motoneurons in the rat spinal nucleus of the bulbocavernosus (SNB) are sensitive to androgens. Castration of young adults significantly reduces SNB dendritic length, soma size, and target muscle weight, and these changes are reversed with androgen treatment. Androgen titers decline with normal aging in male rats, and we have previously reported concomitant regressive changes in the morphology of the SNB system. To determine if the changes were due to age or declining androgen, we examined the response of two aging neuromuscular systems to acute or chronic testosterone treatment.

SNB motoneuron morphology and target muscle weight were assessed at 22 months of age in normal males, and males castrated at either 16 or 20.5 months and implanted with testosterone-filled Silastic capsules. SNB motoneurons were retrogradely labeled with cholera toxin-HRP and their morphology was assessed in three dimensions (Eutectics NTS). Degree of labeling was comparable across groups, and no differences in arbor area or maximal radial dendritic extent were found. However, both chronic or acute testosterone treatment restored SNB dendritic length, soma size, and target muscle weight to young adult levels. In contrast, cholera toxin-HRP labeled motoneurons in the retrodorsolateral nucleus (RDLN) showed no changes in soma size with age or androgen treatment, and no changes in target muscle weight were observed. Thus, the regressive changes seen in SNB motoneurons and their target muscles are not common to all aging neuromuscular systems. Furthermore, the age-related regressive changes in the SNB are likely due to declining androgen levels, and can be reversed with androgen treatment. (Supported by NIH AG09309)

ONTOGENY OF SEX DIFFERENCES AMONG HVC PROJECTION NEURONS. M. J. Burek*, K. W. Nordeen, and E. J. Nordeen. Dept. of Psych. and Neurosci. Program, U. of Rochester, Rochester, NY, 14627.

Only male zebra finches sing and song-control nuclei exhibit estrogen (E2)-dependent sex differences in neuron number. One nucleus, the Higher Vocal Center (HVC) projects to two other sexually dimorphic regions, RA and Area X. Thus, while HVC contains some E2 target cells, it is not known if sex differences in HVC stem from direct hormone action, or rather arise indirectly through interactions with its sexually dimorphic targets. To explore this issue we determined when sex differences first develop among HVC projection neurons in relation to their interaction with RA and Area X.

We have shown previously that the number of HVC neurons labeled by ³[H]-thymidine injections on days 15 and 16 posthatch is greater in males than in females by 25 days posthatch (i.e. 9 days after their birth). By combining thymidine autoradiography with retrograde-labeling we also determined that many of these same neurons project to RA in adult males. Yet, we report here that these HVC neuronal cohorts are not labeled by Fluorogold (Flg) injections into RA in 25 day old males. Thus, sex differences in the number of HVC-RA projection neurons emerge before these cells innervate RA.

Anterograde tracing using Di-I shows that HVC axons first invade Area X-LPO about 12 days posthatch. Therefore, we studied how sex differences develop among HVC-Area X neurons by injecting Flg into the LPO of males and females at 12, 20, and 50 days posthatch. After a 5 day survival time there are far more Flg-labeled HVC neurons in males than in females, even at the earliest age examined (d17) when Area X is first apparent in males. This sex difference enlarges with age because the number of HVC-Area X neurons increases in males, but not females. Our results suggest that sex differences in the number of HVC projection neurons precede, and likely are independent of, interactions with their sexually dimorphic targets.

542.4

EFFECTS OF TESTOSTERONE METABOLITES ON NEURON NUMBER IN SEXUALLY DIMORPHIC RAT DORSAL ROOT GANGLIA. A.C. Mills* and D.R. Sengelaub. Program in Neural Science, Indiana University, Bloomington, IN 47405.

Penile reflexes in the rat are controlled by a sexually dimorphic neuromuscular system in which males have larger perineal muscles and more numerous motor and sensory neurons innervating those muscles than do females. These dimorphisms arise through hormonal action during development. For example, females treated with testosterone during a critical perinatal period retain the perineal muscles and have masculine numbers of motoneurons in the spinal nucleus of the bulbocavernosus (SNB) and in the L6/S1 dorsal root ganglia (DRG). The sex difference in motor and sensory neuron number is a result of hormone-regulated normally occurring neuron death. In the developing SNB, motoneurons are preserved by androgen but not estrogen; females treated with estrogen (E) during the perinatal period have feminine numbers of motoneurons. To determine if the critical hormone in DRG neuron preservation is testosterone or one of its androgenic or estrogenic metabolites, we treated female rats with either dihydrotestosterone (DHT, prenatal only) or E (pre- and postnatal), and counted DRG neurons over the period in which adult neuron numbers are established (embryonic day 22 through postnatal day 10). Preliminary results indicate that by postnatal day 10, DRG neuron number is fully masculinized in females treated with E, but is unaffected by DHT treatment. These results suggest that unlike SNB motoneuron number, L6/S1 DRG neuron number can be regulated by estrogens. (Supported by NIH NS08917 to AM)

542.6

VARIATION IN AXON DENSITY IN THE SPLENIUM OF THE RAT CORPUS CALLOSUM: POTENTIAL INFLUENCES ON SEX DIFFERENCES IN AXON NUMBER. J. H. Y. Kim* and J. M. Juraska. Neuroscience Program and Department of Psychology, University of Illinois at Urbana-Champaign, Champaign, IL 61820.

Previous research from our laboratory demonstrated a sex difference in axon number (female > male) in the splenium of adult rats raised from weaning in either the complex (EC) or the isolated (IC) environments (Juraska and Kopcik, 1988). We recently reported that the sex difference is present by weaning age (postnatal day 25) (Kim and Juraska, 1990).

In the present electron microscopy study, we extend these results to socially housed (SC) 60 day old animals and note large variation in axon density within the splenium (posterior tenth). There was a significant variation in axon density rostro-caudally and dorso-ventrally in this region. Unmyelinated axon density was highest ventrally and lowest dorsally; conversely, myelinated axon density was lowest ventrally and highest dorsally. Axon density was higher in the caudal-most portion of the splenium. Axon density was multiplied by the area of the posterior tenth to get axon number. Females had more unmyelinated axons than males while males had more myelinated axons. Because unmyelinated axons outnumbered myelinated axons by 7:1, total axon number was significantly greater in females. Thus, the sex difference in axon number in adult rats is present whether the animals are raised in EC, IC or SC. Also, if the splenium is not systematically sampled, the observed variation in axon density could potentially influence the calculation of sex differences in axon number.

542.8

EVIDENCE FOR POST-PUBERTAL ONSET OF THE VOLUMETRIC SEXUAL DIMORPHISM AND POST-PUBERTAL GROWTH OF THE ANTEROVENTRAL PERIVENTRICULAR NUCLEUS OF THE RAT HYPOTHALAMUS. E.C. Davis, N. Elihu, J.E. Shryne, and R.A. Gorski*. Department of Anatomy and Cell Biology and Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024.

This lab has reported that a sex difference in the volume of the anteroventral periventricular nucleus (AVPv) was apparent on day 90 (females larger than males), but not on day 15 or 30. A possible role for gonadal steroids at puberty was postulated. In this study, we determined more specifically when the sexual dimorphism of the AVPv develops. Intact male and female Sprague-Dawley rats were sacrificed at days 30, 40, 60, and 80. We observed a main effect of both sex ($p < 0.001$) and age ($p < 0.025$) on the volume of the AVPv. There was no sexual dimorphism at day 30. On days 40, 60, and 80, the AVPv volumes of males and females were significantly different (for day 40, $p < 0.05$; for days 60 and 80, $p < 0.01$). The volume of the AVPv in males does not change significantly with age; however, in females, the volume increases significantly (a 1.35-fold increase; $p < 0.01$) from day 30 to 60 and appears to level off between days 60 and 80. These findings indicate that the sex difference in AVPv volume does not appear until after puberty has occurred in the female and that the sex difference develops because the AVPv continues to grow after day 30 in females but not in males. Studies in progress examine the contributions of perinatal, pubertal, and postpubertal gonadal steroids to the sex difference in AVPv volume as well as the nature of the increase in AVPv volume with age in females. Supported by NIH grant HD-01182 and training grant HD-07228.

542.9

TIMING OF CELL BIRTH IN TARGET AREAS OF THE SEXUALLY DIMORPHIC VASOPRESSIN INNERVATION OF THE RAT BRAIN. A.M. Klein, H.A. Al-Shamma, G. J. De Vries, N. R. Carlson* Amherst College, Box 210, P.O. Box 5000, Amherst, MA 01002-5000. *Program in Neuroscience and Behavior, Univ. of Massachusetts, Amherst, MA 01003.

Previous evidence suggested that the density of vasopressin-immunoreactive (AVP-ir) fiber innervation in the lateral septum (LS) is two to three times greater in males than in females, whereas in the lateral habenular nucleus (LHb) this difference is much smaller. Since the fibers in the LS and LHb come from the same group of AVP-ir cells, it was hypothesized that temporal differences in the development of these target areas may influence the development of sexual dimorphism in their AVP-ir fiber innervation. To study whether there are differences in the time of the last division (birth date) of cells in the LS and LHb, embryos were exposed to the cell birth marker 5-bromo-2-deoxyuridine (BrdU) by injecting pregnant Long-Evans rats on one of nine gestational days ranging from embryonic day 10 to day 18 (E10 to E18). At three months of age, the labeled brains were removed, sectioned, and immunocytochemically stained for AVP as well as BrdU. In general, it was found that AVP-ir fibers innervate bands of cells within the LS and LHb with birth dates distinct from surrounding cells. Furthermore, in the LS these cells were born much later (E17) than in the LHb (E14). These findings are consistent with the earlier formulated hypothesis, and suggest that the AVP innervation of target cells born earlier, such as the LHb, is less sexually dimorphic than the innervation of target cells born later, such as the LS.

RECOVERY OF RAT HIPPOCAMPAL REGIONS FROM EARLY HYPOTHYROID RETARDATION: A STUDY OF VOLUME, SURFACE AREA, CELL NUMBER AND CYTOCHROME OXIDASE STAINING. A. Farahvar*, and E. Meisami, Physiology Dept., Univ. of Illinois, Urbana, IL 61801.

Effects of early hypothyroid retardation and recovery from this condition was studied in CA1-CA4 regions of the hippocampus in 25- and 90-day rats. Newborn rat pups were rendered hypothyroid [PTU (propylthiouracil, 0.1%) in drinking water] and studied at days 25 and 90. Some pups were allowed to recover by removal of PTU at day 25 and observed at day 90. The surface area and volume but not cell number of hippocampal regions increased significantly between days 25 and 90 in controls. In the latter, CA1-CA4 regions occupied 52, 8, 32, and 9% respectively of total hippocampal surface area. Early hypothyroidism significantly reduced surface area and volume of all regions; remarkably these deficits were substantially normalized in the recovery animals. The growth of the hippocampal regions in the recovery rats was compensatory. Cell counts indicated a selective loss of cells in the CA3 region of the hypothyroid rats which was not restored in recovery animals. These quantitative changes and the pattern of staining of rat hippocampal regions by cytochrome oxidase will be presented for the normal and experimental animals. Results indicate selective vulnerability as well as marked growth plasticity in hippocampal regions.

542.10

ONTOGENY OF THE MALE RAT CREMASTER NUCLEUS: A CT-HRP AND CGRP IMMUNOHISTOCHEMICAL STUDY. B.W. Newton* Department of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205

The cremaster nucleus (CN) lies in the L1,2 spinal cord and is involved in testicular descent and thermoregulation via the cremaster muscle. The adult male rat CN has a pattern of calcitonin gene-related peptide-immunoreactivity (CGRP-IR) which is *opposite* to the remainder of the ventral gray horn; i.e., most CN motoneurons lack CGRP-IR but are surrounded by CGRP-IR afferents. To determine the position of neonatal male Sprague-Dawley (S-D) rat CN motoneurons and when they receive CGRP-IR afferents, the CN was retrogradely-filled with CT-HRP and/or immunostained for CGRP, using the PAP technique, on postnatal days (P)1,2,4,6,10,12,21,42, and 60. CT-HRP reveals that CN motoneurons shift slightly from a lateral to a central position in the L1,2 ventral gray horn and that prominent medial and lateral dendritic extensions appear on P2 and P4, respectively. Dorsal dendritic extensions are not prominent in neonatal life. CGRP-IR afferents are present within the CN at all timepoints examined, but show great increases in numbers and arborizations on P6 and P12. An adult pattern of CGRP-IR afferents within the CN is achieved by P21-42. The numbers of CN motoneurons which express CGRP-IR very slowly increases as the pups age and reaches ca. 3.5% of the P60 S-D CN motoneuron population. These data show that CGRP-IR afferents present in the neonatal CN surround the dendrites and soma of CN motoneurons and can, therefore, modulate the activity of the neonatal CN. This research is supported by NSF Grant IBN-9211368.

542.12

ANTERIOR ROOF DEAFFERENTATION OF THE PREOPTIC AREA INCREASES EAR WIGGLING BUT NOT LORDOSIS IN 19-DAY-OLD FEMALE RATS. G.S. Benedict*, H. Grossman, & C.L. Williams Departments of Psychology, Columbia University & *Barnard College, New York, NY 10027.

During the first week of life, both male and female rats display lordosis and ear wiggling without prior hormone priming (Williams, Behav. Neurosci., 1987). Work from our lab has shown that lordosis and ear wiggling become sexually dimorphic and more dependent on ovarian hormones for elicitation by postnatal days (PD) 10-18. Defeminization ultimately results from the presence of perinatal testicular androgen, although behavioral consequences are not manifested until one week later perhaps following the maturation of inhibitory neural systems. Our previous work suggests that the development of serotonergic afferents to the ventromedial hypothalamus contributes to the defeminization and the maturation of hormonal dependence of lordosis but not of ear wiggling (Benedict & Williams, Soc. Neurosci. Abstr., 1992). Another possible source of inhibition may be forebrain afferents to the preoptic area, since dorsal deafferentation of this region unmasks both lordosis and ear wiggling in adult male rats (Yamanouchi and Arai, Neuroendocrin., 1985). Using a Halász knife, we deafferented the roof of the preoptic area bilaterally rostral to the anterior commissure in male and female rats on PD 17, then tested them for lordosis and ear wiggling two days later. The knife cut had little effect on lordosis. However, it significantly increased the frequency of ear wiggling in hormone-primed (1 µg estradiol benzoate + 0.5 mg progesterone) female rats. There were little or no effects of the knife cut in males or in oil-treated females. Taken together, these results combined with previous findings suggest that the sexual differentiation of lordosis and of accompanying preceptive behaviors such as ear wiggling is subserved by the hormonally-driven development of at least two different processes.

EXPRESSION AND REGULATION OF HEAT SHOCK PROTEINS FOLLOWING FACIAL NERVE AXOTOMY IN RATS. U.E. Olazábal*, M. Reddington and G.W. Kreutzberg, Max-Planck-Institute for Psychiatry, Martinsried, Germany.

Cellular heat shock proteins (hsp) are induced in response to various stresses, including neurotoxicity and mechanical injury. We carried out this study to investigate the expression of constitutive hsp70kD (hsp70c) and hsp60kD in the facial nucleus following transection of its nerve at the stylomastoid foramen in male rats. The operated and control facial nuclei were removed by microdissection from intact controls and at 1h, 3h, 6h, 12h, 24h, 3d, 7d, and 14d after axotomy (N=6 per group) prepared in SDS sample buffer and normalized with respect to total facial nucleus protein content. Hsp70c and hsp60 were detected by Western blotting using antibodies to these hsp (StessGen) and enhanced chemiluminescence. Densitometric analysis showed that hsp70c levels were induced in the facial nucleus as early as 6h after axotomy (25.7% increase), reached maximum levels at 3 days (47.5% increase) and remained elevated thereafter. No changes in immunoreactive hsp70c were noted in contralateral unoperated nuclei. Preliminary analysis of hsp60 levels has indicated a similar time course of induction following axotomy. These results suggest that axotomy induces heat shock proteins in cells of the facial nucleus and that these events may be important in the early dynamic phases of regeneration. Immunocytochemical studies are under way to determine which cell types may be participating in this regulation.

FLUTAMIDE BLOCKS THE EFFECTS OF ANDROGENS ON HAMSTER FACIAL NERVE REGENERATION. K.J. Jones* Departments of Physical Therapy, and Anatomy and Cell Biology, University of Illinois at Chicago, Chicago, IL 60612.

In adult male hamsters, systemic administration of androgens at the time of facial nerve crush at the stylomastoid foramen accelerates the rate of facial nerve regeneration. In this study, the hypothesis that androgens affect facial nerve regeneration through a receptor-mediated mechanism was tested using the anti-androgen, flutamide, which blocks binding of the steroid to its receptors. Three-5 days after castration, hamsters were subjected to right facial nerve crush axotomies at the level of the stylomastoid foramen, and divided into 3 treatment groups: 1 testosterone propionate (TP) subcutaneous implant, 1 TP implant plus 1 daily injection of flutamide (10 mg/0.1 ml propylene glycol), or blank implants. Postoperative times ranged from 3-7 days. Stereotaxic injections of 3H-amino acids into the right facial nucleus were done, and the radioactivity in 1-mm segments of the dissected nerves determined and plotted as a function of time after injury. The furthest distance point at which the radioactivity was ≥ 2 S.D. above background defined the outgrowth distance of the fastest growing axons. The results indicate that flutamide blocks the TP-induced increase in outgrowth distances of regenerating facial axons, such that the values obtained for the flutamide and TP-treated animals are equivalent to those values obtained from the castrated only animals and significantly lower than TP-treated animals. Supported by NIH grant NS28238.

LOCAL CEREBRAL PROTEIN SYNTHESIS IN THE REGENERATING HYPOGLOSSAL NUCLEUS IN EUTHYROID AND HYPERTHYROID RATS. C. R. Dermon, G. E. Deibler, J. Jehle, L. Sokoloff, and C. Beebe Smith*. LCM, NIMH, Bethesda, MD 20892.

The rate of protein synthesis in the developing central nervous system is stimulated by thyroid hormones whereas in the mature brain sensitivity to thyroid hormones is lost. Following axotomy cranial nerve cells undergo chromatolytic changes and increases in rates of both glucose utilization and protein synthesis. We hypothesized that during regeneration neurons revert to an earlier developmental state that includes re-establishment of sensitivity to thyroid hormones. This question was examined by determining rates of protein synthesis in regenerating hypoglossal nucleus after axotomy in euthyroid and hyperthyroid rats. In 12 female, Sprague-Dawley rats (160-250g) the right hypoglossal nerve was cut at the level of the digastric muscle. Following axotomy six rats were treated daily for seven days with 100 µg of L-thyroxine (i.p.) and six were treated with vehicle. On post-axotomy Day 7 local rates of cerebral protein synthesis (ICPS_{loc}) were determined with the *in vivo* autoradiographic L-[1-¹⁴C]leucine method (Smith et al., *PNAS* 85:9341, 1988). ICPS_{loc} was measured in the nucleus as a whole at the level of appearance of the central canal. In both the vehicle- and thyroxine-treated rats ICPS_{loc} was significantly increased in the axotomized hypoglossal nucleus (P < 0.002, paired t-tests). The percent increase, however, was not greater in the thyroxine-treated rats as we had hypothesized; in fact, it was somewhat smaller.

HUMAN MUSCLE FIBERS REGENERATING IN VIVO AND IN VITRO EXPRESS STRONG β-AMYLOID PRECURSOR PROTEIN mRNA WHILE NORMAL ADULT FIBERS DO NOT. E. Sarkozi¹, V. Askanas¹, J. McFerrin¹, S.A. Johnson², W.K. Engel¹. ¹USC Neuromuscular Center, U. So. Cal. School of Medicine, Los Angeles, CA 90017; ²Andrus Gerontology Center, USC.

β-amyloid protein (Aβ) may be important in the pathogenesis of Alzheimer's disease (AD). Although accumulation of Aβ and its precursor protein (βAPP) has been considered confined to brain and its blood vessels, we have recently demonstrated Aβ, βAPP and βAPP-mRNA accumulated in vacuolated muscle fibers of inclusion-body myositis (IBM) patients (Askanas, et al., 1992, Sarkozi, et al., 1993). We have now studied expression of βAPP mRNA in a) muscle biopsies of patients with polymyositis 6, IBM 10, morphologically nonspecific myopathy 3, Duchenne dystrophy 1, b) normal muscle biopsies 5, and c) muscle fibers cultured from satellite cells of normal biopsies. In the various diseases, regenerating muscle fibers, identified by strong desmin immunoreactivity, expressed very strong βAPP mRNA by *in situ* hybridization, utilizing a ³⁵S-labelled cRNA probe transcribed from a human βAPP-751 DNA clone (Ponté, et al., 1988). Adult normal (non-regenerating) muscle fibers did not have identifiable βAPP mRNA by *in situ* hybridization or northern blot. In contrast, cultured (regenerating) muscle fibers very strongly expressed βAPP mRNA by *in situ* hybridization and northern blot, the former showing more βAPP mRNA in myoblasts than in myotubes. **Conclusion:** generation of βAPP is greatly increased in regenerating muscle, suggesting that βAPP may play an important role in human muscle development.

MUSCLE REINNERVATION AFTER NERVE TRANSECTION AND ENTUBULATION REPAIR. F.C. Pereira and C.F. Da-Silva*. Neurobiology Lab., Dept. of Histology, University of Sao Paulo, Sao Paulo, Brazil.

The aim of the present study was to quantify the reestablishment of the neuromuscular junctions using the technique of entubulation repair as a paradigm to study peripheral nerve regeneration. Sixteen adult C57BL/6J mice received sciatic nerve transection at mid-thigh level and both proximal and distal nerves stumps were sutured into a 6 mm long polyethylene tube, ID 0.76 mm, leaving a nerve gap distance of 4 mm. Following 2 to 40 weeks after surgery, animals were perfused with fixative and the EDL muscle from the operated side was removed and processed histochemically for visualization of both cholinesterase sites and nerve fibers according to the protocol of Pestronk & Drachman (Muscle & Nerve, 1:70, 1978). Sixteen additional animals suffered sciatic nerve crush and were treated in the same fashion for comparison. A total of 2800 randomly selected synaptic areas were classified according to their innervation pattern. For morphometric analysis, camera lucida drawings of impregnated terminals were made and, with the aid of a computer system (Biographics), the number of branching points of terminal arborization and total length of terminal arborization from the first branching point were evaluated. Two weeks after nerve transection and repair, the EDL muscle was entirely denervated. After six weeks the muscle was reinnervated and axon sprouting among the muscle fibers led to polyinnervation of the EDL muscle. After 40 weeks, 80% of the muscle fibers were mono-innervated, and 80% of these endplates were mono-innervated by axons coming from the nerve trunk (a situation found in all muscle fibers of the EDL muscle from non-operated animals). Data from the morphometric analysis showed no difference in the nerve terminal branching pattern between non-operated and entubulated animals. It is noteworthy that the same ratio of mono to polyinnervated fibers (4:1) was also found in animals with the same survival time (40 weeks) in which the sciatic nerve was simply severed by crushing. These results show a similar pattern of long term muscle reinnervation after nerve transection with entubulation repair and crush lesion. (Supported by FAPESP Grant).

MATRIX REMODELING AND NERVE ACTIVITY AT FROG NEUROMUSCULAR JUNCTIONS. E.A. Connor*, K. Qin, H. Yankelev, and D. DeStefano. Univ. of Massachusetts, Amherst, MA.

Connective tissue in junctional regions of skeletal muscle undergoes striking remodeling after denervation. Interstitial cells accumulate near denervated neuromuscular junctions as do several matrix molecules including fibronectin and tenascin. This remodeling of matrix by interstitial cells may influence synapse regeneration. In previous experiments aimed at understanding the process that produces the connective tissue remodeling, we determined that postsynaptic blockade of muscle activity did not induce the interstitial cell accumulation. Here we examined the role of nerve activity in regulating connective tissue remodeling. Nerve activity was blocked by tetrodotoxin (TTX). Placebo or TTX pellets (9ug TTX) were placed adjacent to nerves to cutaneous pectoris muscles. Blockade of synaptic transmission was assessed by nerve stimulation proximal and distal to the pellet. Synaptic transmission was blocked for 14 days in TTX-treated muscles. We determined that presynaptic blockade of synaptic transmission by TTX did not induce an accumulation of interstitial cells. The distribution of interstitial cells in innervated muscles treated with either placebo or TTX pellets was not different from normal innervated muscles. In addition, there were no junctional accumulations of tenascin or fibronectin in TTX-treated innervated muscles. These data suggest that the loss of evoked nerve activity is not the signal that initiates the remodeling of connective tissue after denervation. Connective tissue remodeling in denervated muscle may occur by an activity-independent mechanism or by a mechanism activated by phagocytosis of degenerating axons.

543.6

IMMUNOCYTOCHEMICAL LOCALIZATION OF SKELETAL-MUSCLE-SPECIFIC TRANSCRIPTION FACTOR MEF2C IN HUMAN ADULT NORMAL AND PATHOLOGIC MUSCLE BIOPSIES.

V. Askanas¹, M. Bilak¹, D. Leifer², W.K. Engel¹. ¹USC Neuromuscular Center, Univ. of So. Cal. School of Medicine, Los Angeles, CA 90017; ²Dept. Neurol., Harvard Medical School.

Human MEF2C (myocyte-specific enhancer binding factor 2C) belongs to a new class of MADS-box factors that interact with the MEF2 regulatory element and may mediate cell lineage, myogenesis and muscle formation. The expression and role of muscle transcription factors in normal and diseased human muscle have not been studied to our knowledge. Using a well-characterized polyclonal antiserum against MEF2C, we immunocytochemically studied muscle biopsies of 16 patients: polymyositis 4; inclusion body myositis (IBM) 6; morphologically non-specific myopathy 1; Duchenne muscular dystrophy 2; amyotrophic lateral sclerosis 2; normal muscle 5. In normal muscle, all nuclei and the cytoplasm of the postsynaptic domain of neuromuscular junctions had strong MEF2C immunoreactivity (IR). Regenerating muscle fibers (identified by double-labeling with desmin), in all pathologic biopsies that contained them, had strong cytoplasmic MEF2C-IR in addition to strong MEF2C-IR in the nuclei. IBM vacuolated muscle fibers had increased MEF2C immunoreactivity in and around nuclei. **Conclusion:** Our studies demonstrate novel localizations of MEF2C, suggesting that in human muscle MEF2C may be involved in a) transcription of postsynaptic proteins, and b) selective pathological processes.

IN VIVO GROWTH OF SCHWANN CELLS THROUGH A SILICONE TUBE IN THE ABSENCE OF AXONS REQUIRES BOTH ISOLATED "NERVE" SEGMENTS TO BE LIVING. Roger D. Madison¹ and Simon J. Archibald². ^{1,2}Departments of Neurosurgery, ¹Neurobiology, Duke University Medical Center and ¹Veterans Affairs Hospital, Durham, NC 27710.

It is known that axons co-migrate with Schwann cells during successful peripheral nerve regeneration through a nerve guide tube, and there is evidence that axons will not regrow in the absence of Schwann cells. Conversely however, it has recently been shown that Schwann cells can form a tissue cable through a tubular prosthesis in the absence of any axonal ingrowth (A. A. Zaleski et al. *Neurosci. Abst.* 1990, 529.6). In the present study we tested the ability of cells to form a bridge within a 12 mm silicone tube connecting two isolated denervated "nerve" segments in 10 adult rats. An 8 mm segment of sciatic nerve was removed, a 4 mm segment of the nerve acted as a "proximal" segment and the remaining 4 mm of the nerve acted as a distal segment. Both segments were sutured into the tube and the other end of each segment was tightly ligated to prevent axonal ingrowth. In 5 animals one segment was frozen to kill all cells. Although tissue cables were formed in all animals, Schwann cells (by +S100 staining) were only found in animals with both segments living. The continuous bands of Schwann cells were highly upregulated for NGF receptor. NS22404-08 (RDM) and VA Merit Review Program.

TRAJECTORY OF REGENERATING AXONS ACROSS ENCLOSED GAPS
 GM Koschorke, V. Mathur, R. Sood, TM Brushart, Curtis Hand Center, Union Memorial Hospital, Baltimore, Maryland 21218, USA

Synthetic tubes have been used clinically to bridge gaps in peripheral nerve. Axons regenerate in adequate numbers across short gaps (up to 3cm in primate). However, axonal dispersion within the tube contributes to non-specific target reinnervation and poor function (NSci.Abst. 16: 806). This study was designed to measure the dispersion of axons crossing a gap and the effects of gap distance and distal stump orientation on this dispersion. In 20 female SD rats both sciatic nerves were cut and the tibial and peroneal fascicles were precisely oriented within silicon tubes. This was accomplished by sewing the adjacent proximal or distal stumps to opposite sides of a thin silicon sheet, and inserting the sheet partway in the end of the tube along a slit in the tube's diameter. Four groups were prepared: correct alignment (CA), 2mm and 5mm gap, reverse alignment (RA) (proximal tibial aligned with distal peroneal), 2mm and 5mm gap. After 6 weeks, HRP-WGA was applied to the peroneal nerve distal to the tube. Cross sections of the proximal tube were drawn and digitized to determine the percentage of distal peroneal fibers originating from proximal peroneal and tibial fascicles respectively. In the 2mm CA group, 34% of axons entering the peroneal fascicle distally had crossed the midline from the proximal tibial stump, while 44% had crossed at 5mm. In RA groups (preliminary data) 78% originated from co-linear tibial nerve at 2mm and 77% at 5mm. Conclusions: 1. axonal growth is initially straight 2. significant dispersion occurs at 2mm 3. no significant increase in dispersion is demonstrated between 2 and 5mm 4. no tropic or trophic mechanism corrects fascicular malalignment.

543.11

INFLAMMATORY CELLS AND MEDIATORS IN NERVE REGENERATION CHAMBERS. Lars B. Dahlin*, P. Thomsen and N. Danielsen. Dept. Hand Surg., Malmö Gen. Hosp., Univ. Lund, S-214 01 Malmö and Dept. Anatomy and Cell Biology, Medicinaregatan 3, Univ. Göteborg, S-413 90 Göteborg, Sweden.

The inflammatory response was quantitatively evaluated during peripheral nerve regeneration. The fluid accumulating in silicone nerve regeneration chambers (inserted in rats) was collected during the early period of regeneration of transected sciatic nerves. This fluid was analyzed with respect to inflammatory cells and mediators (leukotriene B₄; LTB₄, interleukin-1 α , IL-1 α). Leucocytes were detected during the entire observation period (up to 7 days after implantation). The highest concentration was detected after 24 h. The predominant cell type during the initial 5 days was the polymorphonuclear granulocyte. Analysis of the concentration of LTB₄ demonstrated two peaks, at 24 h and 5 days. The IL-1 α concentration displayed an early and relatively smaller peak after 24 h and a second and much larger peak after 7 days. The present study demonstrates that the early stage of nerve regeneration in the silicone chamber model is concomitant with an inflammatory reaction.

PREDEGENERATION ENHANCES NERVE REGENERATION IN A RAT SCIATIC Y-CHAMBER MODEL. Q. Zhao*, J. M. Kerns and N. Danielsen. Dept. Hand Surg., Malmö Gen. Hosp., Univ. Lund, S-21401, Malmö, Sweden and the Dept. Anat., Rush Med. Coll., Chicago, IL, USA

We studied rat peroneal and tibial nerve regeneration in a silicone Y-chamber model. The two distal nerves were either a 7 day predegenerated nerve segment (PNS) from the donor side or a fresh nerve segment (FNS). The proximal stump of the cut peroneal or tibial nerve was inserted into the proximal inlet of the chamber and the PNS and FNS of the corresponding nerve were inserted into the distal outlets. After 14 days survival, the regenerates in the distal tunnels were nearly equal in size (i.e. PNS=FNS) for both peroneal and tibial groups. A great number of cells, whose nuclei appeared with Acridine orange were located throughout the regenerates. Schwann cells identified by S-100 protein were more abundant close to the nerve stumps. At 28 days postoperative, the size of the regenerate towards the PNS was 26% greater than that towards the FNS for the tibial nerve group and 14% greater for the peroneal nerve group. The density and number of regenerated myelinated axons in the distal nerve segment was greater on the PNS side for both the tibial (97% and 88%, respectively) and peroneal (221% and 221%, respectively) nerve groups. In contrast, the elevated density and number of non-vascular nuclei (mainly Schwann cells) was relatively constant for both PNS and FNS. It is suggested that the early activation of Schwann cells in the PNS segment is responsible for the enhanced regeneration and maturation observed in this Y-chamber model.

543.10

NERVE EXPANSION: THE OPTIMAL ANSWER FOR THE SHORT NERVE GAP. T.G. Skoullis, J.K. Terzis.* MRC, EVMS, P.O. Box 1980, Norfolk, VA 23501.

The management of a short nerve gap still presents a dilemma to the reconstructive surgeon. Specific aims: to establish an experimental model of nerve gap, to investigate the effects of expansion on a normal nerve, as well as on the proximal vs the distal segment of a transected nerve prior to repair, and to correlate these data to 3 control groups: tension free nerve repair, end-to-end coaptation under tension and regeneration through an interposition nerve graft. The rats were randomized in 7 groups. I: expander placed under the nerve but not expanded. II: slow expansion of an intact nerve. III & IV: slow expansion of the distal or the proximal end of a transected nerve. V: interposition graft. VI: coaptation under tension. VII: tensionless coaptation of a transected nerve. The functional recovery was assessed by these modalities: Behavioral, Electrophysiological (CAP) and Morphological. Our findings suggest that significant elongation does take place. The CAP can be elicited from an expanded normal nerve as well as from a repaired nerve after proximal and/or distal expansion. The results were much better with a proximal expanded nerve segment. The functional return compared very favorably with the tension free repair.

543.12

TRANSCRIPTIONAL REGULATION OF INTRACELLULAR SIGNAL MEDIATOR ENZYMES AFTER NERVE INJURY. K. Ohno, T. Saika, and H. Kiyama* Dept. of Neuroanatomy, Biomedical Research Center, Osaka University Medical School, 2-2 Yamadaoka, Suita, Osaka 565, JAPAN.

In motoneurons, it is well known that peripheral nerve injuries enhance the expression of some neuropeptides. However, intracellular mechanism in the transcriptional regulation after the nerve injury remains unclear. In this respect, we focused on intracellular signal mediator enzymes, which are supposed to be involved in the regulation of gene transcription and intracellular signal transmission. The transcriptional regulation of these enzymes in the facial motor neurons was examined after the nerve injuries. Oligodeoxynucleotide probes specific to mRNAs of phospholipase C (PLC) isozymes, cAMP dependent protein kinase (PKA) subunits, calmodulin dependent kinase II (CaMKII) and protein kinase C (PKC) isozymes were labeled with ³⁵S-dATP at 3' terminal of the probes enzymatically and used for in situ hybridization histochemistry. After uni-lateral lesion the facial nerve, animals (male rats 150g) were sacrificed at various time points. The mRNA signal level was measured by image analyzer. Among all probes examined, PLC α and PKA regulatory subunits (RII α and β) mRNAs' level were significantly increased after the nerve injury, while PLC β mRNA was repressed. These results suggested that when nerves got injury, transcription of PKA was more up-regulated than those of PKC and CaMKII. Among PLC isozymes, PLC β is thought to play important role in intracellular signal transmission, while a function of PLC α has been unclear. The down-regulation of PLC β may lead to down regulation of IP₃/DG cascade, whereas up-regulation of PLC α may be indicating that an involvement of PLC α in the neuronal response against the nerve injury.

543.14

THE EFFECTS OF ACELLULAR GRAFTS ON NERVE REGENERATION. N. Danielsen*, J. M. Kerns, Q. Zhao, M. Kanje and G. Lundborg. Dept. Hand Surg. Malmö Gen. Hosp., Univ. Lund, S-214 01 Malmö; Dept. Animal Physiol., Univ. Lund, Sweden and Dept. Anatomy, Rush Med. Coll., Chicago, IL.

The use of nerve grafts to bridge a nerve defect is a well accepted clinical principle. The purpose of the grafting procedure is to offer the outgrowing axons the best possible microenvironment. The main candidates responsible for providing this microenvironment are the Schwann cells and the factors (e.g. basal lamina) these cells produce. We have examined the effects of various acellular grafts (created by repeated freeze/thawing) on early nerve regeneration. A 10 mm defect in the rat sciatic nerve was bridged by either acellular nerve grafts (ANG), or acellular muscle grafts (AMG), or acellular predegenerated grafts (APNG). The axonal regeneration distance was assessed by the sensory pinch test. The excised specimens were examined by immunohistochemistry for neurofilaments and conventional light microscopy. The results indicate that the APNG data best fitted a linear regression line with a delay period of 2.7 days. The data from the ANG and AMG groups were best expressed in exponential terms and both these groups had a prolonged delay period of at least 6 days. APNG grafts had a regeneration rate and delay period not significantly different from that of fresh (cellular) nerve grafts. The stimulatory effects of predegeneration may be due to an increase in the number of activated Schwann cells producing factors enhancing regeneration. Such factors apparently remain bound in the tissue stroma even if the cells are killed prior to grafting.

COLLATERAL SPROUTING FROM AN INTACT NERVE INTO AN ANASTOMOSED PREDEGENERATED STUMP. J.M. Kerns*, N. Danielsen, Q. Zhao, M. Kanje and G. Lundborg. Dept. Anatomy, Rush Med. Coll., Chicago, IL. and Depts. Hand Surg. Malmö Gen. Hosp., Animal Physiol., Univ. Lund, Sweden.

The ability of an attached nerve stump to attract collateral sprouts from an intact peripheral nerve was studied in the rat. Either a fresh (FNS) or predegenerated (PNS, 7d) segment was anastomosed end-to-side to an intact sciatic nerve midhigh with or without a perineural window. The presence of sprouts was evaluated by the sensory pinch test and histological examination. In another series the peroneal PNS was attached to the tibial fascicle and muscle contractility was measured at 90 dpo. Pinch test results showed a significantly greater response using PNS vs. FNS in the no-window group (5/8 vs. 0/5) at 14 dpo and in the window group (7/7 vs. 0/2) at 35 dpo. Microscopy showed new axons in the stump, presumably by collateral sprouting from intact axons rather than regeneration from damaged axons. Muscle tetanic force in the reinnervated tibialis anterior was greater using window anastomosis (69%) vs. no-window (49%). In conclusion, collateral sprouting can occur from an intact nerve, with or without a perineural window. Predegeneration may augment this via the neurotrophic action exerted by proliferating non-neuronal cells. This may have clinical application in nerve repairs. Supported by the Fogarty International Center and Swedish Medical Research Council.

TRANSECTED CORTICOSPINAL AXONS REGROW FOLLOWING CO-IMPLANTATION OF CARBON FILAMENTS AND CULTURED FETAL CNS TISSUE. M.F. Dauzvardis*, T. Khan, S. Sayers, T. Trausch, and B. Dunlap. Rehabilitation R&D Center, VA Hines Hospital, Hines, IL 60141.

Carbon filament implants have been shown to promote limited axonal regrowth following partial and total transection of the rat spinal cord. In an attempt to amplify the axogenic properties of carbon filaments we co-implanted small diameter carbon filaments with cultured fetal spinal cord or cortex into the site of a mid thoracic spinal cord lesion which had completely transected the corticospinal tract.

Fetal cortex or fetal spinal cord harvested from E-16 rat embryos was cultured on bundles of approximately 10 thousand, (5 micron diameter) carbon filaments which were affixed to the bottom of petri dishes. After 3 days the carbon was cut into 4 millimeter sections and implanted into midthoracic spinal cord lesion sites. Two animals received, cultured cortex/carbon filament implants and two received cultured spinal cord/carbon filament implants. After cortical injection of WGA-HRP, labeled axons were observed as far as 4 millimeters below the implant site in all 4 animals, a finding not observed in surgical control animals. These results indicate that enhancing carbon filaments with various fetal cell populations may lead to increased recovery following partial spinal cord transection.

Alternative Splicing of Fibronectin in Injury and Repair of the Rat Peripheral Nervous System. G.A. Mathews* and C. French-Constant. Wellcome/CRC Institute of Cancer and Developmental Biology, Tennis Court Road, Cambridge, CB2 1QR, U.K.

The primary gene transcript for fibronectin (FN) can be alternatively spliced in three regions to yield distinct forms of FN (Kornblith et al., 1985; Norton and Hynes, 1987). In rats two exons (EIIIA and EIIIB) can be either included or excluded, whereas a third (V) can be excluded (VO), or partially or completely included (V95 or V120). Inclusion of EIIIA & EIIIB in FN mRNA is associated with early embryogenesis (French-Constant & Hynes, 1989) and wound healing (French-Constant et al., 1989). We have assessed whether embryonic patterns of FN mRNA splicing are present following crush injury to the adult rat sciatic nerve, a model system for studying nervous system regeneration. RNase protection experiments were performed using probes designed to distinguish different splicing patterns of EIIIA, EIIIB and V. We have analysed RNA from 13.5 day rat embryos and from discrete segments of crushed and uncrushed nerves at four different time points after injury (1 day, 3 days, 1 week, and 2 weeks). Embryonic FN mRNA was largely EIIIA+, EIIIB+, and V120+. Compared to uncrushed nerve in which inclusion of EIIIA and EIIIB was insignificant, as early as 1 day post-crush the inclusion of both these regions in FN mRNA was upregulated in segments of nerve distal to and including the crush site. While control nerve RNA had comparable levels of V95+ and V120+ FN mRNA, crushing led to upregulation of the V120+ form. *In situ* hybridization experiments are underway to discover the cell types that synthesize these different FN variants and their localization within the nerve. These results show that embryonic forms of FN, which may be more appropriate for axon outgrowth and cell proliferation, are reexpressed as a result of peripheral nervous system injury.

SPECIFIC REINNERVATION OF VIBRISSELLA FOLLICLES AFTER PARTIAL DENERVATION OF THE WHISKERPAD IN ADULT MICE. M-E. Corthésy, E. Welker, H. Van der Loos*. Institute of Anatomy, University of Lausanne, 1005 Lausanne, Switzerland.

We previously established that after transection, in the adult mouse, of the sensory nerve to vibrissal follicles of row C, all regenerating fibers reinnervate the follicles of that row only (Corthésy et al., Soc. Neurosci. Abstr. '92). Do reinnervating fibers result from sprouting of axons innervating follicles of rows B and D? Fast blue (○), and diaminido-yellow (●) were injected in 7 mice 40 d. after transection (cartoon) and in 2 controls as follows: one tracer was injected in the 3 caudalmost follicles of row C and the other in those of each of rows B and D. Labeled cells were counted in the ganglion, and the results are summarized below.

CONTROLS	EXPERIMENTALS	Ganglion cells	Follicles
● 0.33 - 2.33 %	0 - 2.26 %		
○ 61 - 66 %	65 - 77 %		
● 34 - 35 %	19 - 35 %		
n= 301 - 307	n= 174 - 307		

Table: ranges of the percentages of blue (○), yellow (●) or double labeled (●) ganglion cells. 'n' is the range of total number of labeled cells per ganglion. The proportion of double-labeled cells is very similar in both groups of mice. Conclusion: reinnervation of row C is almost entirely due to specific regrowth of C row nerve fibers. Support: Swiss NSF 31-30932.

FK506, AN IMMUNOSUPPRESSANT, INCREASES FUNCTIONAL RECOVERY AND AXONAL REGENERATION IN THE RAT FOLLOWING AXOTOMY OF THE SCIATIC NERVE. B.G. Gold*†, A.T. Storm-Dickerson†, D.R. Austin†, and K. Kato†. †Center for Res. on Occup. & Environ. Toxicol. and †Dept. Cell Biol. & Anat., Oregon Health Sci. Univ., Portland, OR 97201.

FK506 is a new immunosuppressive agent isolated from *Streptomyces tsukubaensis*. The possibility that it may affect neurons is suggested by its ability to inhibit calcineurin since a prominent substrate for this phosphatase is the growth-associated protein, GAP-43. In fact, a preliminary report (Steiner et al., Soc. Neurosci. Abst. 12:603,1992) indicates that FK506 increases GAP-43 phosphorylation. Thus, we asked whether FK506 alters functional recovery in the rat sciatic nerve following nerve transection (axotomy). Rats given a sciatic nerve crush received daily subcutaneous injections of FK506 (10 mg/kg); axotomized control animals received saline. Clinical signs of recovery in the hind feet were manifested two days earlier in FK506-treated than in saline-treated animals; movement of the toes and walking (on the hind feet and toes) were first observed at 16 and 17 days, respectively, in saline-treated rats and at 14 and 15 days, respectively, in FK506-treated rats. Interdigit distances in the hind feet showed a return toward normal position of the toes (increased interdigit distances) at 18 days in FK506-treated rats. Light and electron microscopy (at 18 days) demonstrated that the sciatic nerve and its terminal branches from FK506-treated animals contained more myelinated fibers and larger regenerating axonal sprouts compared to saline-treated animals; myelination was further advanced, the endoneurium appeared more organized, and there were fewer remaining macrophages. Nerve outgrowth determinations (measured by radiolabeling the L5 dorsal root ganglion at 9 days and examining the distance traveled by fast axonal transport in sensory axons on day 10) indicated an increased rate of axonal elongation in FK506-treated rats. Taken together, the results suggest that FK506, by increasing the rate of axonal regeneration, may be beneficial for the treatment of peripheral nerve injuries. Supported by NS19611.

RECOVERY OF LOCOMOTOR FUNCTION AND RESTORATION OF DESCENDING BRAINSTEM PROJECTIONS IN SPINAL CORD-TRANSECTED LAMPREY. G.R. Davis* and A.D. McClellan, Division of Biological Sciences, Univ. of Missouri, Columbia, MO 65211.

Spinal-transected larval lamprey (*Petromyzon marinus*) recover the ability to swim. We studied locomotor activity in whole animals and in vitro brain-spinal cord preparations of normal animals and animals 2-32 wks after spinal cord transection at 10% of body length (BL). Also, brainstem neurons were retrogradely labeled by HRP applied to the spinal cord to correlate the number and extent of restoration of descending projections with behavioral recovery.

In normal animals, the amplitude of lateral displacement of the body during swimming increased toward the tail. Prior to 8 wks post-transection (PT), these amplitudes were attenuated in the caudal body but by 8 wks PT were restored to the normal range. Coordinated locomotor muscle activity was present at 20% BL at 2 wks PT, and first appeared at 40% BL at 3 wks PT, and at 60% BL by 4 wks PT. In vitro locomotor activity was recorded from ventral roots at 20% BL by 4 wks PT, and first appeared at 40% BL at 8 wks PT, and at 60% BL at 16 wks PT. In normal animals, HRP applied to 20%, 40%, and 60% BL retrogradely labeled about 1250, 900, and 825 brainstem neurons, respectively, in 12 nuclei. In spinal-transected animals, the mean number of cells labeled from 20% BL increased from 14 at 3 wks PT to 1086 (not different from normal animals) at 32 wks PT. The mean number of cells labeled from 40% BL increased from 17 at 8 wks PT to 430 (different from normal animals) at 32 wks PT. Approximately 50 brainstem neurons were labeled from 60% BL at 32 wks PT. Thus, some brainstem neurons, including some Muller cells, regenerate their axons more than 50mm caudal to the original transection (Davis & McClellan, *Br. Res.*, 1993).

In conclusion, locomotor muscle activity appeared at progressively more caudal body levels with increasing recovery time, but at greater distances below the lesion than would be predicted by the extent of anatomical regeneration of brainstem projections. Thus, regeneration, as well as other mechanisms such as mechanosensory inputs, contribute to the time course of behavioral recovery in spinal-transected lamprey.

CYCLOSPORIN EXPOSURE IS CYTOTOXIC TO CULTURED CORTICAL NEURONS. S.-I. Chi*, B. Sklow, M.P. Goldberg, and D.W. Choi. Tzu-Chi Med. Res. Ctr., Hualien, Taiwan, and Center for the Study of Nervous System Injury, Dept. of Neurology, Washington Univ. Sch. of Medicine, St. Louis, MO 63110

Cyclosporin A is a potent immunosuppressant which is widely used in organ transplantation, but can be associated with a neurological syndrome characterized by encephalopathy, seizures, and white-matter lesions. We examined whether cyclosporin exposure would exhibit direct neurotoxicity in murine cortical cell culture.

Application of cyclosporin injured neurons (but not astrocytes) in a time- and concentration-dependent manner. 24-72 hour exposure to 10-30 μ M cyclosporin caused progressive neuronal loss, assessed by phase-contrast microscopy and release of lactate dehydrogenase into the bathing medium. 1 μ M cyclosporin did not produce significant neuronal injury. The neuronal loss produced by 72 hour exposure to 30 μ M cyclosporin was partially attenuated by addition of the NMDA antagonist, MK-801 (0.5 μ M) and by the 21-aminosteroids, U74500A and U74600F (1-5 μ M).

These observations suggest that cyclosporin neurotoxicity may involve NMDA receptor activation and lipid peroxidation. The neurotoxicity of cyclosporin may be especially important in CNS transplantation studies, in which disruption of the blood-brain barrier might allow increased access of cyclosporin to potentially vulnerable neurons.

HUMAN DOPAMINERGIC GENE EXPRESSION IN COS CELLS.

F.G. Kaddis^{1,2}, C.R. Freed^{1,2*}, M.J. Weber³, C.K. Surratt², D.J. Vandenberg², J. Mallet⁴, P. Horellou⁴, G.R. Uhl². ¹Depts. Med. & Pharm., U. Col. Sch. Med., Denver, Col., 80262; ²Mol. Neurobiol. Br., ARC, NIDA, NIH & Depts. Neurol. & Neurosci., JHUSM, Balto., MD, 21224; ³CNRS, Toulouse, France; ⁴CNRS, Gif-sur-Yvette, France

cDNAs encoding 4 human genes selectively expressed in dopaminergic neurons, co-transfected into COS cells, can confer interesting dopaminergic properties. Full-length cDNAs for tyrosine hydroxylase (hTH), dopamine transporter (hDAT), and vesicular transporter (hSVMT) express well in COS cells using the CMV promoter expression plasmid pcDNA1. A functional L-aromatic amino acid decarboxylase (hDDC) cDNA was also produced by ligating partial cDNAs into pcDNA1. Transient hDDC expression, tested in COS cells electroporated 3 days before assay with 20 μ g of phDDC, revealed levels 600% of values in nontransfected cells. DDC in stably-expressing COS cells transfected with 6 μ g of hDDC, 12 μ g hTH and hDAT, 6 μ g of hSVMT, and 1 μ g of neomycin-resistance expression plasmids was tested after 2 weeks' neomycin selection. These cells express NSD-1015-reversible DDC activity at more than 400% background. These results point to the feasibility of CMV-promoter driven coexpression of these four dopaminergic genes in transfected cell populations. Multiply-transformed cells may prove useful for transplantation in Parkinson's disease.

THE EFFECT OF GLUTATHIONE PEROXIDASE TREATMENT ON CULTURED MESENCEPHALIC NEURONS. F. Pagan, C. A. Colton, and D. L. Gilbert*. Dept. of Physiology and Biophysics, Georgetown Univ. Med. School, Washington, DC 20007 and Clin. Neurosci. Branch, NINDS, NIH, MD 20892.

Neuronal survival was compared in the presence and absence of the antioxidant enzymes, superoxide dismutase (SOD) and glutathione peroxidase (GLP). Neuronal cultures were grown in the presence of SOD, GLP or under untreated, control conditions. Primary neuronal cultures were prepared from day 13 gestational (E13) rats using the papain digestion method. After 4 days, the cultures were fixed and immunocytochemical techniques using antibodies against tyrosine hydroxylase (TH) and microtubule associated protein 2 (MAP2) were used to assess the survival of dopaminergic neurons and the degree of branching. The intensity of antibody reactivity was analyzed using peroxidase-coupled secondary antibodies and a modified ELISA assay. Photomicrographs were taken to confirm the ELISA data. Results show that GLP increased the level of TH and MAP2 immunoreactivity in primary mesencephalic cultures. The survival of TH-positive neurons was increased. Also, the degree of neuronal branching was dramatically increased in the presence of GLP. Thus, survivability of transplanted neurons might be enhanced if anti-oxidant protection mechanisms are used.

5' BROMODEOXYURIDINE AS A PRELABEL FOR THE ANALYSIS OF SURVIVAL AND MIGRATION OF FETAL HIPPOCAMPAL SUSPENSION GRAFTS. A.K. Shetty*, R.D. Madison, J. Bradley and D.A. Turner. Neurosurgery and Neurobiology, DUMC and VAMC, Durham, NC 27710.

The efficacy of bromodeoxyuridine (BrdU) as a nuclear marker of grafted hippocampal cells for morphological and quantitative studies of graft development was investigated. Timed pregnant rats were labeled with daily pulses of BrdU (50 mg/Kg, bw/day) between gestation days 15 and 19, at which time hippocampal cell suspensions were either cultured or grafted into normal adult hippocampus. The survival and migration of the labeled cells in grafts were quantitatively analyzed by three-dimensional serial reconstruction of host brain sections (NeuroLucida).

Evaluation of cell cultures revealed labeling of 90% of all cells and 92% of neurons by the pulsed BrdU protocol; the development of labeled neurons appeared normal and comprisable to unlabeled neurons. In grafts, neuronal phenotypes predominated over astrocytes among labeled cells, as judged by morphology and double immunolabeling for BrdU and glial fibrillary acidic protein. Grafted neurons were generally confined to the transplant mass and showed minimal migration into the host. Absolute graft cell survival varied according to location: grafts projecting partly into the ventricle or white matter tracts (corpus callosum or fimbria) showed better absolute survival (20% and 25% respectively) than the grafts localized entirely within the hippocampus (8%). The results indicate that the pulsed BrdU labeling protocol consistently labeled a great proportion of neurons, which appeared to develop normally and were identifiable for quantitative studies of graft development.

Serial reconstruction of labeled cells proved useful to assess both migration and absolute survival of fetal grafts in host brain. The location of the grafts critically influenced the survival of grafted cells: white matter regions appeared to provide a more permissive local host environment than cell body layers within normal hippocampus. Supported by NINDS RO1 NS29482-01 and VAMC Merit Review.

REGULATION OF C-FOS GENE EXPRESSION OF THE TRANSPLANTED GENETICALLY MODIFIED CELLS IN THE RAT BRAIN. K. Asakuno^{1,2}, M. Isono^{1*}, S. Sato¹, K. Kohno¹ and S. Hori¹. ¹Dept. of Neurosurgery and ²Dept. of Biochemistry, Oita Medical University, Oita 879-55, Japan.

In many genetic diseases, replacement of the absent or defective protein provides significant therapeutic benefits. However it is very difficult, in vivo, to regulate the expression of genetically modified gene. In this study, we established the stable transfectant from normal rat kidney fibroblast (NRK-49F) which had been transfected with a human metallothionein promoter (hMT-IIA)/human genomic c-fos fusion gene to produce c-fos protein (Fos). In these cells, the c-fos basal level of expression was observed and its expression could be modified by addition of metals in vivo. We transplanted these cells into striatum of the rat brains and investigated whether the human Fos expression could be modified by extrinsic addition of Zinc in the brain. We found that the transplanted cells could survive relatively well. In addition, the cells in rats fed by water contained Zinc strongly expressed Fos compared to that in rats without Zinc. Our result suggested that the gene expression could be regulated in the brain by the external agents, and this model has implication for future gene therapy.

544.6

REINITIATED GROWTH FROM MATURE VENTRAL MESENCEPHALIC GRAFTS. I. Strömberg* and Maria Johansson. Department of Histology & Neurobiology, Karolinska Institutet, Stockholm, Sweden.

The ability of mature dopaminergic neurons in ventral mesencephalon to reinitiate growth after receiving an uninnervated target was studied in the intraocular grafting model. Fetal ventral mesencephalic tissue was grafted to the anterior chamber of the eye. Two weeks, six weeks or one year after the implantation, fetal striatal tissue was placed in contact with the nigral graft or grafted alone. Ingrowth of tyrosine hydroxylase (TH) immunoreactive nerve fibers into the caudate grafts were studied 6 weeks after grafting striatal tissue. The final size of the caudate grafts was significantly larger in eyes grafted with caudate alone than in eyes where striatal tissue was placed together with 1-year or 6-week-old dopaminergic grafts. Caudate grafted to 2-week-old nigra was larger, but not significantly, than that grafted to mature nigra. TH-immunohistochemistry revealed innervation of the caudate in all cases, except for the group where caudate was grafted alone. In caudate grafted to 2-week-old nigral transplants, TH-positive nerve fibers innervated a larger volume, had a patchy appearance and the density was higher than that seen in caudate transplants grafted to mature nigral grafts. In caudate grafts placed adjacent to 6 weeks old nigral grafts, the density and volume was larger than that seen in caudate grafted to 1-year-old nigra, but smaller than in caudate placed adjacent to immature nigral tissue. In striatal grafts placed together with 1-year-old nigra a tendency to patchy ingrowth was seen, but here the patches were large and the nerve terminal density was low. In conclusion, growth from nigral transplants can be reinitiated independent of age, but a lower density and smaller volume of the outgrowth is observed from mature grafts than from immature grafts.

HERPES SIMPLEX VIRUS VECTOR-MEDIATED GENE TRANSFER TO CNS NEURONS. M.A. Bender¹, N.A. Deluca¹, B.B. Kaplan^{2*}, R. Ramakrishnan³, M. Levine³, R.Y. Moore², W.F. Goins¹, and J.C. Glorioso¹. Dept. of Molecular Genetics & Biochemistry¹, Psychiatry², University of Pittsburgh, Pittsburgh, PA 15261, Dept. of Human Genetics, University of Michigan, Ann Arbor, MI 48109³.

We have developed herpes simplex virus (HSV)-based vectors for gene transfer to the CNS. HSV is attractive as a gene transfer vehicle for CNS neurons due to the natural propensity of the virus to establish lifelong latent infections within these neurons, and the virus can accommodate large amounts of foreign DNA. We have manipulated the virus vector to be non-neurotoxic by deletion of immediate early lytic gene functions, yet the vector readily establishes latency in substantial numbers of neurons in which the viral genome persists for the lifetime of the host. Using quantitative PCR techniques on DNA isolated from HSV-infected hippocampal tissue, we have demonstrated that the number of viral genomes remains relatively constant from 7 days to at least 8 weeks after infection.

We have employed a defective HSV vector, which contains an expression cassette with the strong human cytomegalovirus immediate early gene promoter (HCMV IEp) driving the β -galactosidase reporter gene (*lacZ*), to effect gene transfer to primary bovine adrenal chromaffin cells. Expression of the transgene can be detected in these cells in culture at 7 days. Stereotactic inoculations of the vector into rat CNS gives strong transgene activity only at early times (2-5 days), yet the recombinant viral genomes persist in the infected brain for at least 1 year after inoculation. In an attempt to achieve long-term expression of a foreign gene, we are testing a transcriptional activation system, GAL4-VP16, which is capable of inducing genes bound in chromatin structures. When binding sites for GAL4-VP16 are placed within a promoter, the GAL4-VP16 transactivator protein can stably boost transcriptional levels several hundred-fold, which we have observed in transient assays in culture. This system is currently being applied to the expression of the tyrosine hydroxylase gene in an attempt to achieve persistent TH expression from the defective HSV vector in the CNS.

COMPARISON OF THE RATE OF MATURATION OF NEURONAL CELLS DERIVED FROM THE HUMAN CELL LINE NT2 TRANSPLANTED INTO NEONATAL AND ADULT NUDE MICE. S.R. Kleppner¹, J.O. Trojanowski², K.A. Robinson³, V.M.-Y. Lee¹. Inst. of Neurological Sciences and Dept. of Path. and Lab. Med., Univ. of PA, Philadelphia, PA 19104

Immunohistochemical studies of neuronal cells derived from the NT2 cell line (NT2N cells) implanted into adult nude mouse brain reveal that these cells mature beyond their *in vitro* phenotype. Levels of highly phosphorylated heavy neurofilament (NF-H), and of adult isoforms of tau, increased dramatically between 6 weeks and 4-6 months post-implant respectively. Heavy phosphorylation of NF-H is a late developmental event, and adult isoforms of tau are not found in the fetus. Neither heavily phosphorylated NF-H nor adult tau is found in NT2N cells *in vitro*. Other properties of the implanted NT2N cells include neurite outgrowth and expression of many neuron specific proteins including MAP2, all three neurofilament proteins, tau, vimentin, and N-CAM. In addition, the immediate environment appears to influence the extent of neurite outgrowth. In this study we compare these findings with the results of implanting NT2N cells into neonatal animals. The cells appear to become incorporated more extensively into the young brain, often extending processes for greater distances. In addition, the cell bodies seem to be more widely distributed throughout the brain. While the NT2N cells initially express the same array of proteins as in the adult, they may mature at a faster rate. Our data suggest that the developing brain may provide a more amenable environment for the NT2N cells than the adult brain. Ongoing studies address the issue of the effect of the immediate environment on the phenotype of these cells.

NERVE GROWTH FACTOR-EXPRESSING PC12 BRAIN GRAFTS FOR USE IN ANIMAL MODELS OF PARKINSON'S AND ALZHEIMER'S DISEASES. D.C. Rohrer¹, V.I. Nipper², C.A. Machida^{2,3*}, G. Nilaver⁴. ¹Div. Neurosurgery and Depts. ²Neurology, ³Biochem. and Mol. Biol., Oregon Health Sciences University, Portland, OR 97201; ⁴Div. Neurosci., Oregon Regional Primate Res. Ctr., Beaverton, OR 97006.

An optimal cell line for use in transplantation models of Alzheimer's and Parkinson's diseases would: (i) be immortal and pluripotent; (ii) differentiate to functionally replace degenerating pathways; and (iii) induce localized neuronal sprouting of surviving host cells through the release of trophic factors. PC12 cells propagate in culture, neurodifferentiate in the presence of nerve growth factor (NGF), and produce dopamine and/or acetylcholine. However, while NGF-treated PC12 cells can ameliorate neurotransmitter deficits in rats, they degenerate post-implantation without sustained NGF availability. We have introduced an 820 bp cDNA recombinant encoding mouse NGF (mNGF), under control of the human metallothionein IIA zinc-inducible promoter, into PC12 cells via calcium phosphate transfection. Southern blot analysis of PCR products has verified incorporation of the transgene into the host genome in 36 stable transfectant cell lines. Northern blot analysis and mNGF immunocytochemistry (ICC) have identified several transfectants exhibiting substantial IIA promoter "off-on" response, and high inducibility of mNGF transcription/translation. Grafts into the striatum of dietary zinc-supplemented rats are being examined by *in situ* hybridization and ICC to verify inducible post-transplant neurodifferentiation. The potential application of these genetically-programmed cells for use in human neurodegenerative diseases is being explored in established rat models of Parkinson's and Alzheimer's diseases.

544.8

TRANSPLANTATION OF AN O-2A GLIAL PROGENITOR CELL LINE. P.L. Kuhn¹, J.L. Norman^{1*} and R.D. McKinnon², California State U., Chico, CA 95926¹ and R.W. Johnson Med.School, UMDNJ, Piscataway NJ 08854².

Transplantation of Central Glial-4 (CG-4) cells, an established line of bipotential oligodendrocyte type-2 astrocyte (O-2A) progenitors from rat cortex, was used to establish a paradigm for further analysis of the effect of trophic factors on CNS myelin formation. CG-4 cells were marked with the *E. coli* gene encoding β -galactosidase using a recombinant retroviral vector, then injected into the thalamus of post-natal day 2 (P2) rat pups. Brains from recipient animals were harvested at regular intervals, stained using X-gal reagent, then transplants (blue cells) were located by light microscope examination. Results provided evidence of migration of CG-4 cells *in vivo*. In a second procedure, unmarked CG-4 cells were injected into the thalamus of P2 Shiverer (*Shi*) mutant mice. Homozygous *Shi* mutants lack the gene encoding myelin basic protein (MBP), which forms the major dense line (MDL) in myelin membrane. *Shi/Shi* pups were identified by Polymerase Chain Reaction using oligonucleotide primers specific for the wild type and *Shi* MBP deletion. Recipient brains were harvested at various intervals, and immunohistochemical staining revealed the presence of transplanted CG-4 (MBP-immunoreactive) cells in the CNS of homozygous mutant tissue sections. The presence of MDL was examined by EM after ferrocyanide-reduced osmium tetroxide post-fixation and immunogold labeling of MBP. Results provide evidence of cell differentiation and expression of MBP, suggesting that CG-4 cells follow the normal *in vivo* development program of their O-2A counterparts. Supported in part by a Pilot Research Award to RMCK from the US National Multiple Sclerosis Society.

PURIFIED NEURONS CAN BE TRANSPLANTED IN THE ADULT CNS. J.CADUSSEAU¹, S. ROSTAING¹, V. DEVIGNOT², C.E. HENDERSON³ and M. PESCHANSKI^{1*}. ¹INSERM C1F91-02, Créteil; ²INSERM U261, Paris; ³UPR-CNRS8402/INSERM U249, Montpellier, France.

Fetal neural transplants generally include both a set of neurons and their cellular environment. This procedure restricts the number of neurons of interest that can be grafted and leads to the implantation of cells that may be not only unnecessary but also detrimental. This study was undertaken to determine whether purified neurons would survive transplantation into the adult host brain. Spinal neurons have been purified by the panning procedure which is based on the transient expression of the low affinity receptor for the NGF specifically on immature motoneurons. Fetal purified neurons were transplanted into the brain parenchyma of an adult host previously depleted of neurons by the injection of an excitotoxin. During the first week post-grafting the transplants were characterized by a high density of almost exclusively neurons. These neurons displayed an immature morphology. During the second week post-grafting the cellular density of the graft decreased, the neurons grew and non-neuronal cells appeared. Small capillaries were observed throughout the transplant. Astroglial processes entered from the periphery of the graft and proceeded within the clusters of neurons whereas highly reactive astrocytes were observed along the capillaries. At the end of the second week post-grafting, microglial cells were evenly distributed throughout the transplant. These cells displayed a quiescent morphology and a density similar to that observed in the normal parenchyma. Older transplants (31/2 months) contained heterogeneous neuronal populations with a majority of large multipolar cells particularly rich in Nissl bodies. Many neurons could be immunostained for CGRP, a typical marker of motoneurons. Purified neurons, deprived of their fetal environment and ectopically transplanted, are therefore able to mature and to acquire normal morphological and biochemical characteristics. The host integrates the graft by complementing it with astroglial, microglial and vascular elements.

REGULATION OF DIFFERENTIATION IN A NEURONAL CELL LINE DERIVED FROM MEDULLARY RAPHE. L.A. White¹, M.C. Castro, M.J. Eaton, & S.R. Whitemore, The Miami Project and Dept. Neurological Surgery, Univ. Miami, Miami, FL 33136

A neuronal cell line, RN46A, was derived by infecting embryonic day 13 rat medullary raphe with a retrovirus encoding the temperature-sensitive mutant of SV40 large T antigen (T-ag). At non-permissive temperature (33°C), RN46A cells express robust nuclear T-ag immunoreactivity. Low levels of neuron-specific enolase (NSE) and 160 kDa neurofilament protein (NF-M) were detected, while NF-L, NF-M, and glial-specific proteins were not expressed. After shifting to differentiating conditions, RN46A cells ceased dividing, differentiated with neuronal morphology and enhanced NF-L, NF-M, NF-H, and NSE expression. NF expression could be potentiated by activating protein kinase A. A subset of differentiated RN46A cells expressed tryptophan hydroxylase (TPH), which could be enhanced by treatment with ACTH₄₋₁₀. Differentiated RN46A cells did not survive beyond 8 days *in vitro* if grown on bare tissue culture plastic, but would survive through 10 days on collagen-fibronectin. This survival could be further potentiated with 0.1% rat serum. Initial experiments have shown that RN46A cells can survive at least 2 weeks *in vivo* following transplantation into the adult and neonatal CNS. Ongoing experiments are evaluating the factors which further potentiate RN46A survival and differentiation both *in vitro* and *in vivo*. Supported by The Miami Project to Cure Paralysis and NS26887.

THE ADULT CNS RETAINS THE POTENTIAL TO DIRECT SPECIFIC DIFFERENTIATION OF A TRANSPLANTED NEURONAL PRECURSOR CELL LINE. L.S. Shihabuddin*, S.R. Whittemore and V.R. Holets. The Miami Project, Univ. of Miami School of Medicine, Miami, FL 33136.

The survival and differentiation of the conditionally-immortalized neuronal cell line, RN33B, was examined following transplantation into the adult rat brain. RN33B cells were transplanted into the cerebral cortex, hippocampal formation, and cerebellum of allogeneic hosts. These three regions have well characterized and morphologically distinct laminar cell layers. Transplanted cells, identified using immunohistochemistry to detect β -galactosidase expression, were seen in animals up to 24 weeks post-transplantation (the latest time point examined). Stably integrated cells with various morphologies consistent with their transplantation site were observed. In the cerebral cortex, many RN33B cells had differentiated with morphologies similar to small and medium pyramidal neurons and stellate cells. In the hippocampal formation, many RN33B cells had differentiated with phenotypes similar to endogenous neurons at the integration site. They assumed morphologies similar to pyramidal neurons characteristic of CA1 and CA3 regions of the hippocampus, granular neurons of the granular cell layer of the dentate gyrus, and polymorphic neurons of the hilar region. In the cerebellum, RN33B cells integrated only in the granular layer. These results suggest that the RN33B cells have the developmental capacity to behave as neuronal precursor cells. Most interesting, these studies indicate that the adult brain retains the capacity to direct the differentiation of neuronal precursor cells in a direction which is consistent with that of endogenous neurons. Supported by The Miami Project to Cure Paralysis, The Daniel Heumann Spinal Cord Research Fund, and NS26887.

TRANSPLANTATION OF POLYMER ENCAPSULATED CALF CHROMAFFIN CELLS IN THE SHEEP SUBARACHNOID SPACE: A PRECLINICAL STUDY FOR THE TREATMENT OF PAIN. P. Aebischer^{1,2*}, V. Padrun¹, M. Burki¹, J. Favre¹, J.M. Joseph¹, F. Mosimann¹, M. Augstburger¹, J.P. Gardaz¹, A.D. Zurn¹, B. Winistorfer¹, J. Sagen², J. Mills³, B. Zielinski³, M. Goddard³. ¹Surgical Research Div., Lausanne Univ., Switzerland; ²Univ. of Illinois; ³Div. of Biology & Med., Brown Univ.

The transplantation of polymer encapsulated bovine chromaffin cells into the lumbar subarachnoid space has been recently reported to exert analgesic effects in various rat models (Sagen et al., J. Neurosci., in press). In order to prepare for adapting this technique for humans, sheep were implanted with encapsulated calf chromaffin cells. Adrenal glands were harvested surgically in 10 young calves. Chromaffin cells were isolated the same day using a digestion-filtration technique. The cells were then loaded 48 hrs later into thermoplastic-based permselective capsules which were subsequently mounted on a silicone catheter. The capsules were maintained separately in hormonally-defined media for 7 more days, during which time catecholamine release measurements and sterility tests were conducted. The capsule system was then implanted in the lumbar subarachnoid space of 10 adult sheep using a closed, cannula introducer system. Four weeks postimplantation the capsule system was retrieved. Comparable catecholamine release was detected from both the retrieved and the *in vitro* cohort capsules. The evoked catecholamine release from the densely loaded capsules (around 2×10^6 cells) reached 2 nM/capsule/30 min and was within 10% of the preimplant values. Good viability of densely packed cells was observed in the retrieved capsules. These data suggest that the technique of polymer encapsulation of bovine chromaffin cells can be scaled-up to a viable human size implant.

STABILITY OF XENOGENIC CHROMAFFIN CELLS TRANSPLANTED TO THE CNS FOLLOWING SYSTEMIC CHALLENGE BY SKIN GRAFTING. K. Czech¹, J. Sagen and G.D. Pappas. Dept. of Anat. & Cell Biol., University of Illinois at Chicago, Chicago, IL 60612.

The use of xenogenic sources for donor tissue in transplantation procedures has the potential to solve the problems associated with donor availability. One obstacle preventing use is the risk of a serious rejection episode. However, previous studies in our laboratory have shown that short-term immunosuppression with Cyclosporine A (CsA) can enhance long-term survival of bovine chromaffin cells transplanted to the CNS of Sprague-Dawley rats. The objective of this study was to assess the stability of xenogenic grafts in the CNS following systemic challenge. We transplanted isolated bovine chromaffin cells to the rat midbrain and analyzed survival 8 weeks later. All groups received CsA treatment beginning 2 days prior to transplantation. One group of animals received continuous CsA treatment, while another group received only 3 weeks CsA treatment. Half of the animals in each group were challenged systemically with bovine chromaffin cells injected intradermally six weeks following CNS implantation. We obtained robust and well-integrated transplants containing densely packed, healthy chromaffin cells in animals that were not systemically challenged. However, following challenge with systemic bovine chromaffin cell skin grafts in continually immunosuppressed animals, chromaffin cells in the CNS grafts were found in various stages of degeneration. Some apparently healthy chromaffin cells were also present. In addition, the graft and surrounding host tissue were edematous and the host-graft border was infiltrated by numerous astrocytic processes and cellular debris. Animals receiving only short-term immunosuppression at the time of systemic challenge showed no chromaffin cells surviving in the CNS grafts. The graft sites appeared cystic and vacuolated. In summary, systemic challenge with bovine chromaffin cells causes disruption of stable and well-integrated bovine chromaffin cell transplants in the CNS even with CsA treatment. Supported by NIH grants NS25054 and NS29831.

GENERATION OF PRIMATE NEUROSPHERES AND GENETIC MODIFICATION OF RAT NEUROSPHERES IN CULTURE. C.N. Svendsen*, J.Fawcett and S.B. Dunnett. Departments of Experimental Psychology and Physiology, University of Cambridge, England.

Mouse embryonic cells continually divide when grown in serum free culture conditions in the presence of epidermal growth factor (EGF) forming free floating balls described previously as neurospheres (Reynolds et al., J. Neurosci. 12:4565, 1992). We have taken striatal tissue from E16 rat and E79 marmoset embryos and grown them for 5-10 weeks in the presence of EGF (10-20ng/ml) on Teflon coated glass coverslips in serum free DMEM/F12 medium supplemented with B27 (GIBCO). Neurospheres formed rapidly in rat cultures (within 5 days) and needed to be passaged every week to avoid overgrowth but grew more slowly in marmoset cultures often taking 15-20 days for the first divisions to occur. After 5 weeks in culture rat neurospheres were passaged once before being genetically modified by infection with a recombinant retrovirus encoding the lac z gene and neomycin resistance. These infected neurospheres continued to divide in culture and staining for beta galactosidase at 2 days post infection revealed approximately 3% infection rate. 7 days following infection new spheres had developed and beta galactosidase staining showed that some of these contained over 70% infected cells while others were non-infected suggesting that infected cells continued to divide and form new spheres. Neomycin added to infected cultures for 4 days resulted in an increased number of infected cells relative to non infected cells. These results show that both rat and monkey neurospheres can be successfully generated from embryonic tissues and that rat spheres can be genetically modified using a retrovirus. We are currently assessing the stability of gene expression with time in culture and following transplantation into neonatal and adult rat brain.

OUTGROWTH FROM DIFFERENTIATED CHROMAFFIN CELLS INDUCED BY NGF-PRODUCING FIBROBLAST GRAFTS. G.R. Chalmers^{1*}, L.J. Fisher¹, K. Nijima², P.H. Patterson² and F.H. Gage¹. ¹Dept. of Neurosciences, UCSD, La Jolla, CA, 92093 and ²Biology Division, Caltech, Pasadena, CA, 91125.

Adrenal chromaffin cells (ACC) implanted within the striatum have been used as a point source of catecholamines in the dopamine depleted brain. One method to potentially enhance the effectiveness of such grafts may be to induce process outgrowth from the ACCs into the host brain. The present study examined whether ACC transdifferentiated to express a neuronal phenotype *in vivo* by NGF or bFGF could be induced to extend processes into host brain tissue. Adult 6-OHDA treated rats received injections into the denervated striatum of either: 1) ACC+NGF-producing fibroblasts, 2) ACC-control fibroblasts, 3) NGF-producing fibroblasts, or 4) control fibroblasts. Grafting was followed 8 weeks later by 3 adjacent grafts of NGF-producing or control fibroblasts. A further 8 weeks later grafts were processed for NGF receptor (NGFr), and tyrosine hydroxylase (TH) immunoreactivity (IR). Consistent with previous work, ACC cografed with NGF-producing fibroblasts developed extensive processes, whereas ACC cografed with control fibroblasts did not. Further, only the NGF grafts placed at a short distance from ACC+NGF cografes were TH and NGFr-IR. In contrast, NGF grafts placed distal to ACC-control fibroblast grafts were TH-IR negative. In a similar experiment, rats received grafts of ACC+bFGF-producing fibroblasts and adjacent grafts of either NGF-producing or control fibroblasts. ACC+bFGF grafts contained numerous TH-IR ACC only if adjacent to NGF-producing grafts. Further, the NGF grafts adjacent to ACC+bFGF cografes were TH and NGFr-IR, while control grafts adjacent to ACC+bFGF cografes were IR-negative. NGF thus appears to be capable of acting as a tropic factor for ACC, inducing process outgrowth from transdifferentiated ACC beyond the boundary of the grafted tissue and into the host brain *in vivo*. Further, once transdifferentiated, a source of NGF is required for the continued survival of implanted ACCs.

IN VIVO MICRODIALYSIS OF CHROMAFFIN CELL TRANSPLANTS POSSESSING ANTIDEPRESSANT ACTIVITY. C.E. Sortwell^{1*}, E. Petty², G. Kramer², M. Waddill² and J. Sagen¹. ¹Dept. of Anat. and Cell Biol., Univ. of IL at Chicago, Chicago, IL 60612; ²VVA Medical Center, Dallas, TX 75216.

Studies in our laboratory have demonstrated the ability of monoaminergic grafts in the frontal neocortex to alleviate depression in rodent models. Specific monoaminergic antagonists reverse these antidepressant behavioral effects, and immunocytochemical analysis has revealed robust survival of monoaminergic cells for at least six months after grafting. These findings indirectly suggest that the antidepressant effect of the monoaminergic grafts is due to the release of monoamines into the host parenchyma. The purpose of the present study was to more directly determine whether bovine adrenal chromaffin cell grafts release catecholamines locally to the surrounding host neocortex. Female rats were baseline assessed for immobility scores in the Forced Swimming Test (FST), a popular measure of antidepressant activity. All rats were then stereotaxically implanted with either isolated bovine chromaffin cells, isolated bovine adrenal fibroblasts, Hank's solution or no transplant to the right frontal neocortex. All rats were immunosuppressed daily with Cyclosporine A for three weeks. Five to six weeks following transplantation rats were again assessed for immobility scores in the FST. Only chromaffin cell transplanted rats displayed significantly lower FST immobility scores; no effect of the three control graft conditions was observed. Each rat was implanted with a dialysis probe at a 500 μ m distance away from the graft site and perfused through the probe with artificial cerebrospinal fluid for extracellular fluid sample collection. Perfusates from the chromaffin cell implanted rats contained significantly higher levels of catecholamines than the three control transplant conditions. Immunocytochemical results suggested that the grafts survived well. These results provide direct evidence that bovine chromaffin cells provide a releasable pool of catecholamines for antidepressant activity when grafted into the frontal cortex of rats. Supported by NIMH MH47491.

A LOCAL AREA NETWORK FOR THE TRANSPORTATION OF IMAGES FROM MICROSCOPY LABS TO GRAPHICS WORKSTATIONS. R. F. Gasser, Jr., G. B. Smith, K. J. Graham, R. F. Gasser, Sr., T. G. Weyand*, and R. R. Mize, Department of Anatomy and Computer Imaging Laboratory, Louisiana State University Medical Center, New Orleans, LA 70112.

The LSUMC Computer Imaging Laboratory (CIL) has developed an Ethernet based local area network (LAN) for the transportation of images from central imaging facilities to remote graphics workstations. The network includes a file server, five computer-based imaging stations (Magiscan MD image analyzer, Leica confocal laser microscope, 2 PC based image capturing and digitizing stations, JEOL JEM 1210 electron microscope), and three remote graphics workstations (Macintosh IICI, Quadra 950, and Silicon Graphics Personal Iris). The server and each of the workstations run PC, Macintosh, UNIX, or OS9 versions of NFS (Network File Server) and TCP/IP (Transmission Control Protocol/Internet Protocol). This software allows each station to send and receive files, remotely login to other machines, and to mount remote filesystems from NFS servers using the file transfer protocol (FTP). In practice, we transport images in a variety of formats (TIFF, TGA, PICT, raw) from each of our imaging devices to the Macintosh and Iris graphics workstations for further manipulation using NIH Image, Adobe Photoshop, Aldus Persuasion, Skandha, and Synu software packages. A variety of images are generated, including whole body and regional 3D reconstructions of human embryos, tissue sections labeled by antibody immunocytochemistry, tissue labeled by mRNA probes for *in situ* hybridization experiments, fluorescent labeled muscle fibers reconstructed from laser confocal optical sections, and electron micrographs. Once generated, images are archived on either Infinity optical disks or Exabyte DAT tapes. The system permits broad access to the instrumentation and promotes collaboration so that investigators can view and analyze images that have been generated at one site and transported via Internet to another. Supported by LEQSF 90-93RD-A-09 (RGSr), research equipment bond funds from the State of Louisiana, and RR-02800 and NIH EY-02973(RM).

UNBIASED STEREOLOGICAL ESTIMATION OF TOTAL SYNAPSE NUMBER AND TOTAL NEURONAL NUMBER IN THE NEOCORTEX OF THE CYNOMOLGUS MONKEY. P.R. Mouton*, L.C. Walker, C.A. Kitt and D.L. Price. The Johns Hopkins Univ. Sch. of Med., Balto., MD 21205

Using unbiased stereological methods, we have estimated the total number of synaptophysin-immunoreactive, presynaptic boutons (synapses) and the total number of neurons in the neocortex of a ten-year old male cynomolgus monkey (*Macaca fascicularis*). The monkey was perfused under deep Nembutal anesthesia with 4% paraformaldehyde followed by phosphate-buffered saline. The brain was blocked coronally *in situ* into 5-mm slabs (12 total slabs), using a specially designed stereotaxic blocking apparatus. From the rostral face of each slab, 40- μ m sections were cut on a freezing-sliding microtome. Systematically sampled sections were processed for synaptophysin immunocytochemistry or stained with cresyl violet. Particles (synapses or neuronal nuclei) were counted in unbiased, 3-D optical disectors spaced uniformly through the entire neocortex. We found ~ 1.5 - 2.0 trillion (10^{12}) total synapses and 1.5-2.5 billion (10^9) total neurons in the neocortex of the cynomolgus monkey. On systematically sampled and stained sections, these stereological analyses can be carried out in 2-3 hours with <10% within-sample variance. These and other unbiased stereological methods are being used currently to correlate neuropathological changes with indices of cognitive dysfunction in normal aging and Alzheimer's and Parkinson's diseases.

PROBABILITY RAT BRAIN ATLASES: A TOOL FOR INTERPRETING FUSED NEUROANATOMICAL MAPS. J. Nissanov¹, S. Bhasin¹, G. Gregorion¹, D. McEachron¹, B. Paz², L. Rioux³, O.J. Treliak¹. ¹Imaging and Computer Vision Center, Drexel U., Philadelphia, PA. ²Dept. de Biologia Celular, U. Complutense, Madrid, Spain. ³Dept. of Psychiatry, U. of Pennsylvania, Philadelphia, PA.

It is technologically feasible to align and average digital images of homologous brain section from different rats. If the images are of autoradiograms produced with the same ligand, the resulting image would offer an enhanced signal-to-noise ratio as well as other advantages. The impediment to this approach is interanimal variability: The same coordinate point in two homologous images of sections from different animals centered in a common coordinate system does not typically correspond to the same neuroanatomical location. We report on an approach to overcome this difficulty which utilizes probability templates to extract data from fused maps. The templates define areas on an average image likely to belong to a given region of interest.

This approach was tested by delineating 20 different structures 3 times by each of 4 neuroscientists on each of 4 animals. The multiple delineations defined a fuzzy map for each structure in each of the animals. The maps can be thought of as fuzzy sets with each pixel assigned a value, an association strength, equal to the inclusion frequency in the set of delineations.

For each structure, the fuzzy maps were averaged across homologous sections of different animals to produce a probability map. A template, defined as areas of greater than 50% probability, was generated and projected onto the fuzzy maps. It was found that the projected template defined a region of an average association strength of 73%. When compared to regions defined directly on the fuzzy maps by selecting pixels with a greater than 50% association strength, the regions defined by the probability template were about 70% smaller but sufficiently large to reliably analyze densitometrically. This demonstrates that probability templates could be used to extract data from fused maps. (Supported by NIH 2P41RR01638).

IN VIVO MICROELECTRODE LOCALIZATION IN THE BRAIN OF THE ALERT MONKEY. E.K.D.Nahm^{*1,2}, A.Dale², T.D.Albright¹, D.G. Amaral¹. The Salk Institute¹, La Jolla, CA, 92037, UCSD², San Diego, 92093.

We have developed a new technique for *in vivo* localization of microelectrodes during single-unit recording in the alert monkey. This technique utilizes a combination of x-ray and magnetic resonance imaging.

Four hollow glass beads were filled with a solution that rendered them visible in both x-ray and magnetic resonance (MR) images. The filled beads were surgically implanted on the skull of one monkey (*Macaca mulatta*). Three coronal MR scans offset by 1 mm along the AP axis were obtained. This yielded a total of 94 3-mm thick MR sections, which were subsequently displayed and stored on a graphics workstation. The subject was then implanted with recording chambers for single-unit studies. A microelectrode was advanced into the subject's brain and a series of x-ray images obtained. These images were used to reconstruct the 3-D position of the microelectrode relative to the four reference beads. The 3-D position of the microelectrode was then mapped onto the MRI data base using the reference beads for registration of x-ray and MR data. The microelectrode tip was visualized during the course of the experiment by an icon graphically superimposed on the appropriate MR section.

We attempted to verify the accuracy of this procedure for 10 microelectrode sites. Each site was marked with a microlesion. Post-mortem histological analysis revealed that the neuroanatomical loci of the microlesions were highly consistent with those predicted by our *in vivo* technique. This technique, which has a precision no less than 625 μ m, should prove especially useful in long-term neurophysiological and neuropsychological studies in which knowledge of the location of brain probes is of crucial importance.

Supported by the McDonnell-Pew Center for Cognitive Neuroscience at San Diego, National Eye Institute, and NIMH.

IMAGE ANALYSIS OF CYTOARCHITECTURAL VARIATION IN THE HUMAN PRIMARY VISUAL CORTEX. E. Armstrong^{*1} and M. Roos². Dept. of Cellular Pathology, A.F.I.P., Washington, D.C. 20306 and Dept. of Anatomy, Mahidol University, Bangkok, Thailand (1), Topographic Engineering Center, Fort Belvoir, VA 22060 (2).

The development of signatures and boundaries for cortical regions requires a better understanding of the architectural variation within a region. To analyze the variation in cellular arrangements, we digitized Gallyas perikarya stained sections at a resolution of 15 μ m per pixel. Cortical layers II-VI were segmented from the background and vectors were drawn from upper layer II to lower layer VI. Vectors were placed perpendicular to the pial surface where all 6 layers could be seen. The feature vectors, gray levels, were smoothed horizontally and resampled to 35 dimensions.

We were particularly interested in variation as a function of distance between profiles and that which is a function of rotation. The Mahalanobis distance was used to study the variance of the profiles while controlling for the correlation of the densities within the vectors. The smallest variation was between topographically close feature vectors.

A METHOD FOR THE COMPLETE STAINING OF IDENTIFIED NEURONS AT WILL. M. DESCHENES* AND D. PINAULT. Research Center for Neurobiology, Laval Univ. Sch. of Med. Québec City, Canada G1J 1Z4.

Since a long time neuroanatomists have used tracers *in vivo* to study the neuronal connections and the morphology of neurons. Currently available techniques have one major disadvantage; it is indeed difficult or impossible to trace all the fine processes that belong to a single cell labelled from an injection site. This is generally due to strong background staining or to a tangle of labelled neuronal profiles at the core of the injection site. Though complete labelling of a cell can sometimes be achieved by intracellular staining, distal axonal processes often remain unstained and this technique is difficult to perform *in vivo*. We present here a promising alternative which consists in the labelling of a small number of neurons (1-5 cells) by the extracellular iontophoresis of biocytin using fine micropipettes. Glass micropipettes (tip diameter= 2 μ m) were filled with a solution of K-acetate (0.5 M) plus 2% biocytin or neurobiotin. These electrodes had impedance of 15-25 M Ω and they were used to record extracellularly the activity of rat thalamic reticular neurons. Once a cell had been identified by electrophysiological criteria, the tracer was ejected extracellularly by iontophoresis (positive current pulses of 100-300 nA, 1 sec on / 1 sec off, for 10 to 30 min.). After a survival period of 1-4 hours rats were perfused and the tissue was processed histochemically according to the protocol described by Horikawa and Armstrong (J. Neurosci. Methods 25: 1-11, 1988).

This technique produced complete labelling of all the cellular processes of a small number of cells, including their axonal terminals. Very little deposit, if any, was observed at the injection sites. Because the extracellular iontophoresis of biocytin is easy to perform and because biocytin histochemistry is compatible with most immunohistochemical protocols, the above technique represents a powerful tool for the study of the fine structure of identified elements in the CNS. COMBINING INTRACELLULAR INJECTION OF NEUROBIOTIN WITH PRE-EMBEDDING IMMUNOCYTOCHEMISTRY USING SILVER-INTENSIFIED GOLD PROBES TO ANALYSE THE SYNAPTOLOGY OF FUNCTIONALLY-CHARACTERISED NEURONS. H.M. Young*, W.A.A. Kunze, S. Pompolo, J.B. Furness and J.C. Bornstein. Department of Anatomy & Cell Biology and Department of Physiology, University of Melbourne, Parkville, 3052, Victoria, Australia.

We have developed methods to examine the neurochemistry of synaptic inputs to functionally-characterized myenteric neurons in the guinea-pig ileum. Electrophysiologically-characterized myenteric neurons were filled with Neurobiotin using intracellular microelectrodes, and the tissue was fixed in 4% formaldehyde, 0.05% glutaraldehyde and 15% picric acid in phosphate buffer. The tissue was washed in 50% ethanol, exposed to 0.1% sodium cyanoborohydride, incubated in avidin-biotin-horseradish peroxidase and then exposed to antibodies against calbindin or calretinin. Thereafter, the Neurobiotin-filled neurons were revealed using the DAB reaction. The tissue was examined at the light microscope level to determine the morphology and projections of the Neurobiotin-filled neurons, and then incubated in gold-labelled secondary antibodies. Following osmication, the gold probes were silver intensified and the tissue was embedded flat in resin. The tissue was re-examined at the light microscope level. Neurons containing a DAB reaction product could be distinguished from neurons containing a silver-intensified gold reaction product using oblique lighting instead of transmitted light. Ultrathin sections were taken through the injected neurons and examined. At the ultrastructural level, Neurobiotin-filled cell bodies and their processes (labelled with DAB) were easily distinguished from the silver-intensified gold-labelled structures. Gold-labelled terminals of enteric interneurons were observed to make synapses and close contacts with Neurobiotin-filled nerve cell bodies and their processes. This technique is valuable for the neurochemical identification of synaptic inputs to morphologically- and/or functionally-characterized neurons.

FRACTAL DIMENSION OF DENDRITIC ARBORS OF GENICULATE NEURONS IN THREE-DIMENSIONAL SPACE. J. Gemmill*, L.A. Coleman and M.J. Friedlander. Neurobiology Research Center, University of Alabama at Birmingham, Birmingham, AL 35294 USA.

The fractal dimension (D) of neuronal dendritic structure is a useful measure of territorial coverage (Montague and Friedlander, *PNAS*, 86:7223-7227, 1989) and provides objective means for comparing neurons independent of scale. However, most such analysis has been limited to 2 dimensions (2D). Neuronal dendritic arbors cover 3 dimensional (3D) space, and thus calculation of D in 3D is a more appropriate descriptor. We estimated the 3D fractal dimension of Area 18 projecting dorsal lateral geniculate nucleus (LGNd) neurons in the developing cat. Area 18 projecting neurons in the LGNd A layers were identified by retrograde transport of fluorescent markers and injected with HRP to reveal their dendrites. Dendritic arbors of injected neurons at 5 ages were analyzed using a 3D reconstruction system. Various methods for measuring D in 3D were implemented and evaluated. The Barnsley "box-counting" method places 3D grids over the neuron and counts the total number of boxes intersected by the structure. Average D was found to be 1.65 over the range of scales 13-247 μ , and D was less than 1.12 over the range of scales 2-11 μ . A method for analyzing growth paths in 2D (Katz and George, *BMB*, 47:273-286, 1985) was extended to 3D using a Monte Carlo simulation for 3D random walks. D measured this way represents total length achieved by a dendritic segment within a volume, i.e. growth. If the measure is normalized to have the same number of sample points per segment, D can be used as a measure of "local wiggle". An additional method which finds the intersection of Scholl spheres with the branches of the neuronal structure to compute D (Schierwagen, *BMA*, 49:709-722, 1990) was determined to be too sensitive to noise. However, the frequency distribution of Scholl sphere intersections shows that although the number of branches remains constant with age, the density maximizes at distances farther away from the soma at older ages. Thus, measuring neuronal D in 3D results in an objective description of structural density.

IMAGING OTOCONIAL MICROSTRUCTURE USING THE ATOMIC FORCE MICROSCOPE. R. Hallworth*, J.B. Campbell, M.L. Wiederhold and P. Steyger. Dept. Otolaryngology -HNS, UTHSCSA, San Antonio, TX 78284 and *Southwest Research Institute, San Antonio, TX 78228.

Otoconia are small (1-20 μ m) calcium carbonate crystals found in the gravitation-sensing organs of the vertebrate vestibular system. A small percentage of the otoconial mass is protein, but is thought to be important in determining otoconial shape. We have employed an atomic force microscope (AFM) to examine the detailed structure of otoconia at very high resolution. The AFM (Digital Instruments Nanoscope II, at Southwest Research Institute, San Antonio, TX) measures the forces of attraction or repulsion between specimen and probe without the need for tissue processing methods. Otoconia from the red-bellied newt (*Cynops pyrrhogaster*) were examined. Amphibia exhibit two otoconial polymorphs. Prismatic otoconia are slab- or wedge-shaped and are found mainly in the saccule. Barrel-shaped otoconia are round, with tapered three-faceted ends and are found in the utricle. Prismatic otoconia are primarily of the calcium carbonate crystal form aragonite; barrel-shaped otoconia are calcite.

In both crystal isoforms, a series of fine parallel lines aligned with the long axis were observed. The lines were irregular in both width and spacing, ranging from 1-10 nm wide and 10-100 nm in separation. The surface also displayed a series of axial ripples of somewhat larger size. Transverse to these were a second series of parallel lines, similar to the axial lines, that follow the ripple contours. On edges or facets, the surface consists of small (10-50 nm) protuberances, ovoid in prismatic and rectangular in barrel-shaped otoconia, that appear to be the terminations of an underlying fibril extending axially along the otoconium. The observations suggest an internal structure of otoconia and a mechanism for their synthesis.

GABA AND GLYCINE INNERVATION OF ABDUCENS MOTONEURONS. A SERIAL ELECTRON MICROSCOPIC ANALYSIS. F. Lahjouji, H. Bras, A. Barbe and G. Chazal*. CNRS, UPR 418, 280 Bd Ste Marguerite, 13009 Marseille, France.

We report in this study the results concerning the GABA innervation of 13 somata, 63 proximal dendrites and axonal processes of abducens motoneurons. We also demonstrate the coexistence of GABA and glycine in the same terminals.

The motoneurons were retrogradely or intracellularly identified by HRP. The presence of GABA and glycine was detected using a post-embedding immunocytochemistry method on consecutive ultrathin sections. The percentage of synaptic covering was calculated for each motoneuronal compartments and terminal population.

The motoneuronal membrane was contacted by axon terminals (ATs) containing round or pleomorphic vesicles. The GABA ATs, filled with pleomorphic vesicles, were the largest of all the ATs. The percentage of synaptic covering was 33% on somata, 43% on proximal dendrites and reached 61% on axon hillock. It decreased to 18% on the initial segment. On all the motoneuronal compartments, the axon hillock had the highest GABAergic synaptic covering.

Glycine was detected in ATs in synaptic contact with the somata. On the population of ATs analyzed, 11% were GABAergic, 8% contain glycine and 9% contain both neurotransmitters. The double labeled ATs had the largest length of apposition. The percentage of synaptic covering ranged from 4.7 to 14% for the GABA ATs and from 2.2 to 12.1% for the glycine one.

These data showed that GABA and glycine both participate in the inhibition of abducens motoneurons.

545.10

TOMOGRAPHIC RECONSTRUCTION OF STRIATAL SPINY DENDRITES USING HIGH AND INTERMEDIATE VOLTAGE ELECTRON MICROSCOPY. C.A. Ingham¹, G.W. Arbuthnott¹, R.A. Baldock¹, S.J. Young², C.J. Wilson³, M.E. Martone⁴, G.E. Soto⁵, S.P. Lamont⁶, M.H. Ellisman⁷. ¹SPON: Brain Res. Assoc. ²PVS & MRC HGU, Edinburgh, U.K. ³SDMIR & Dept. Neurosci., San Diego, USA. ⁴Anat. & Neurobiol., UT Mem. Memphis USA.

Dendritic spines on rat neostriatal spiny neurons are small and densely packed so that accurate measurements of their density, shape and size are impossible using the light microscope (LM). Tomographic methods have been applied to derive 3D reconstructions of spiny dendrites in semi-thin sections imaged with a 1000 kv electron microscope (EM). The 3D data is then evaluated using computer aided visualization and analysis methods (Wilson et al, *Neuroimage* 1 (1992) 11-22). In the present study, similar procedures were employed to study images acquired with a 400 kv EM. The method was assessed using material previously analysed with the LM in which we compared equivalent parts of rat spiny cell dendrites from intact and dopamine denervated striata (Ingham et al, *Exp. Brain Res.* 93 (1993) 17-27). 3D reconstructions of 2 μ m sections of Golgi-stained, gold-toned dendrites showed that, although spine density estimates differ in the EM and LM, the relative decrease in spine density in denervated compared to control dendrites was similar. The results suggest that documenting changes in spine density, and perhaps spine shape, under experimental conditions will be possible using EM tomography.

IMAGING OF CNS-pHi WITH CELLULAR RESOLUTION: pHe INFLUENCES pHi IN CULTURED ASTROCYTES, ACUTE BRAIN SLICES AND THE INTACT BRAIN. A. Them, A. Villringer, A. Bernatowicz, U.R. Büttner*, U. Dirnagl. Dept. of Neurology, University of Munich, 8000 Munich 70, F.R.G.

We used the fluorescent dye BCECF and a confocal laser scanning microscope (Bio-Rad MRC 600; KrAr-Laser) to image the intracellular-pH (pHi) in brain cells. At λ_{exc} =488nm; the emission changes indicate relative changes in pHi. Wistar rats were used to obtain primary astrocytes in culture (age: 2-4 weeks; n=57 cells examined), brain slices (2-4 days; n=332) or an intact brain preparation of anesthetized rats with a closed cranial window implanted (2-3 month; n=9). The preparations were incubated with BCECF-AM (2 μ M in CO₂/HCO₃⁻ buffered artificial cerebrospinal fluid (aCSF); DMSO < 0.01% Molecular Probes) for 30 min. In slices and the intact brain, cellular resolution was achieved up to a depth of >50 μ m. pHi-changes were stimulated by switching the superfusing medium to aCSF equilibrated to different pCO₂'s, or 15mM NH₄Cl, or hypercapnia in the intact animal. In the slice, a rise of pHe from 7.4 to 7.9 and 8.3 influenced pHi in the same direction and corresponding magnitude in 97% of 94 stimulations and in 88% of 188 stimulations respectively. Alcalotic pHe and NH₄Cl caused acidosis upon return to normal pHe. Hypercapnia in the intact brain was associated with intracellular acidosis. The effect of pHe on pHi may indicate a large conductance for acid base equivalents or a sensitivity of pH regulating enzymes to pHe in the preparations studied.

Supported by the DFG and the Wilhelm Sander Foundation.

OPTICAL IMAGING OF INTRINSIC SIGNALS AND EXTRACELLULAR RESISTANCE IN HIPPOCAMPAL SLICES: CORRELATIVE MEASURES OF CELL SWELLING. J.S. Henn and D.A. Turner* Neurosurgery and Neurobiology, DUMC and VAMC, Durham, NC, 27710.

Repetitive synaptic stimulation and osmotic manipulation have both been previously shown to result in transiently altered light transmission through select regions of a hippocampal slice. We are investigating mechanisms that underlie these stimulation and osmolarity induced intrinsic optical signals, particularly the relationship between intrinsic signals, cell swelling and the relative ratio of intracellular and extracellular spaces in CA1, CA3 and DG.

Using a 12-bit cooled CCD camera and image subtraction, the absolute changes in light transmission through submerged slices were measured ($\Delta T/T$ in %). Extracellular resistance was also directly measured in CA1 stratum radiatum as an index of cell swelling ($\Delta R/R$ in %). When switching the bathing media from normal aCSF (290 mosm) to dilute aCSF (260 mosm, $n=3$), $\Delta T/T$ in CA1 radiatum increased $9.4 \pm 0.2\%$ while the overall $\Delta R/R$ increased $20.1 \pm 3.3\%$ ($14.3 \pm 4.1\%$ due to the dilute solution alone). These changes occurred throughout the hippocampus with $CA1 > CA3 > DG$. Increased osmolarity (320 mosm with either sucrose or dextrose; $n=6$) resulted in no net overall change in $\Delta T/T$ ($0.3 \pm 6.1\%$) but decreases in $\Delta R/R$ of $19.8 \pm 12.3\%$ (with increases of $4.8 \pm 1.2\%$ due to the solution alone). Control experiments (normal aCSF to normal aCSF, $n=3$) showed that $\Delta T/T$ in CA1 radiatum increased $3.2 \pm 1.7\%$ while $\Delta R/R$ increased $0.8 \pm 3.7\%$. Studies of afferent stimulation of CA1 radiatum showed increased light transmission of 10-15%, though similar signals could not be induced in CA3 or DG.

The asymmetry of these responses suggest that the baseline ratio of intracellular to extracellular space (particularly high in CA1) is critical to the generation of apparent cell swelling-induced optical signals, and that this ratio may be biased by osmotic manipulation. Supported by NINDS #29482 and VAMC Merit Review.

LOCALIZATION OF DOMOIC ACID INDUCED NEURAL DEGENERATION IN THE PRIMATE FOREBRAIN AS REVEALED BY CONVENTIONAL SILVER METHODOLOGIES AND BY A NOVEL FLUORESCENT TECHNIQUE.

L. Schmued*, A. Scallet, S. Ali, W. Silkner Jr. Division of Neurotoxicology, National Center for Toxicological Research, FDA, Jefferson AR 72079

Cynomolgus monkeys were given a single intravenous dose of the sea food contaminant, domoic acid (1 to 4 mg/kg), and the survivors were perfused with fixative one week later. The forebrains were first examined for evidence of neuronal degeneration using a modified de Olmos' cupric-silver technique. This technique revealed degenerating neurons within several forebrain regions. Within the hippocampus, extensive cell and terminal damage was found within Ammon's horn and the dentate hilar region, while the dentate granule cells exhibited limited degeneration and then only after the highest doses. Major hippocampal afferents such as the entorhinal cortex also exhibited noticeable degeneration. Some hippocampal efferent targets were also affected. Although no degeneration was seen in the mammillary bodies, extensive cell and terminal degeneration could be seen in the lateral septum. Conspicuous cell and terminal degeneration was also observed in the lateral dorsal nucleus of the thalamus. Degenerating cells and terminals were visible in the piriform cortex. Argyrophilia was also seen in the median eminence and the subfornical organ.

The aforementioned degeneration was confirmed by a recently developed novel fluorescent technique for revealing neuronal degeneration. The method employs a photo oxidized fluorescein derivative which we call Fluoro-Jade-D. This technique correlates well with the degeneration observed with the suppressed silver techniques, and is considerably less time consuming or capricious. It also appears to detect degeneration at shorter intervals after insult than is detectable with conventional methodologies. It may also be useful in resolving the role of oxidative free radicals in neurotoxicity.

545.17

REGIONAL DISTRIBUTION OF GFAP IN RAT AND MOUSE BRAIN. P.M. Martin¹ and J.P. O'Callaghan². Curriculum in Toxicology, Univ. of North Carolina, Chapel Hill, NC 27599 and Neurotoxicology Division, U.S. Environmental Protection Agency², RTP, NC 27711.

Traditionally, astrocytes in intact and damaged brains have been examined using immunocytochemistry, with changes in morphology and staining intensity used as indications of gliosis. Immunocytochemistry is a qualitative method, however, and there is a need for a simple and inexpensive method of quantifying changes in GFAP. Moreover, it would be useful to obtain both qualitative and quantitative data from the same animals, although aldehyde-based fixatives used to prepare brain tissue for immunocytochemistry make that tissue unsuitable for use in biochemical assays. One solution to this problem is to use ethanol as a fixative, which would permit both immunocytochemical and biochemical assays to be done on brain tissue from a single animal. The purpose of this study was to examine, quantitatively and qualitatively, the regional distribution of GFAP in normal adult rats and mice. Six Long-Evans rats and six C57B1/J mice were perfused with a 70% ethanol/saline solution. Half of each brain was dissected into eleven regions, and GFAP concentration was measured in each region using a sandwich ELISA. The other half of each brain was paraffin-embedded and used for GFAP immunostaining. Large regional differences occurred in the brains of both rats and mice, with the highest concentrations of GFAP found in the brainstem, and the lowest concentrations found in the striatum and cortex of both species. Rats, however, had lower concentrations of GFAP in the hippocampus, relative to the cerebellum and olfactory bulbs, while mice had higher concentrations of GFAP in the hippocampus compared to these two areas. Specific patterns of GFAP⁺ cells and fibers corresponded to the regional distribution of GFAP in both rats and mice, with the greatest number of GFAP⁺ cells found in the cerebellum, hippocampus, hypothalamus, and olfactory bulbs. GFAP⁺ fibers were found in the molecular layer of the cerebellum and in several regions of the brainstem. These data show that it is possible to assay GFAP concentrations in tissue prepared for immunocytochemical analysis. Assaying GFAP represents a simple approach to quantifying gliosis in the intact and injured central nervous system of rats and mice. (Supported by U.S. EPA Training Agreement T901915).

NEAR-INFRARED AND INFRARED SPECTROSCOPIC MEASUREMENTS OF ANIMAL CRANIA AND BRAIN CORTICAL SLICES. E. N. Lewis[†], A. M. Gorbach,^{‡§} A. W. Toga[§] and I. W. Levin[†] [†]Laboratory of Chemical Physics, National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD 20892. [§]Laboratory of Neuroimaging, UCLA Neurology, Los Angeles, CA 90024

In order to evaluate the feasibility of thermoencephalography (TES) based on the measurement of infrared (IR) radiation from an animal cranium and to provide a basis for the IR spectroscopic imaging of the brain, spectra were collected between 1-4 μm ($10,000\text{-}2,500\text{ cm}^{-1}$) of various preserved slices of monkey and rat brain tissue and of pieces of monkey, rat and human skulls and human dura matter. Transmission spectra were recorded using interferometers equipped with liquid nitrogen cooled indium antimonide (InSb) and mercury cadmium telluride (MCT) detectors for near-IR and mid-IR data collection. Samples were translated within the IR beams using a micro-manipulator. This technique provided a means to collect multiple spatially resolved spectra with a limiting spatial resolution of approximately 1 mm, although significantly higher spatial resolution is possible.

The spectra revealed the maximum transmittance for human crania to be approximately 0.5% between 1-1.2 μm and that the average transmission in the 3-5 μm spectral region was significantly less than 0.1%. The values are notably higher for both monkey and rat skulls. These data show that the TES signal is based on thermal conduction between the skull and cortex, and not on the direct measurement of photons through the skull. Transmission spectra collected from spatially resolved regions and different thicknesses of cortical slices show absorption bands due to lipids, proteins and peptides and reveal measurable differences between white and grey matter. The spectra will be interpreted in terms of variations in the biochemical makeup of different regions of the cortex. The feasibility of obtaining high fidelity vibrational spectroscopic images will be discussed.

NEUROTOXICITY OF DOMOIC ACID TO HIPPOCAMPAL MOSSY FIBERS OF CYNOMOLGUS MONKEYS: COMPUTER IMAGING AND MEASUREMENT OF SILVER DEGENERATION STAIN. R.L. Rountree* and A.C. Scallet Division of Neurotoxicology, National Center for Toxicological Research/FDA, Jefferson, AR 72079-9502

Domoic acid is a potent excitotoxin that is structurally related to glutamic acid and kainic acid. Domoic acid enters the food chain after production in certain algae or seaweed, which are then consumed by filter feeders such as mussels and clams that serve as human foods. Application of the Nadler and Evenson (1983) method, a silver stain specific for degenerating axon terminals and cell bodies, revealed a highly specific, dose-dependent and focal argyrophilic area restricted to the CA2 stratum lucidum (dose 0 - 1.0 mg/kg). Grains were defined by both size and optical density parameters and were counted by a semi-automated computer-based image analysis system. When the number of silver grains, from full-screen digital images from each of four to six sections per monkey (16 monkeys), was counted there was a significant relation ($p < 0.05$) between dose and grain count, based on Friedman's two-way analysis of variance. Compared to a control value of 444.6 ± 76.8 (mean \pm SEM), grain counts increased by 22%, 61% or 74% of control for the 0.25, 0.5 or 1.0 mg/kg dose levels respectively. This method of silver stain measurement should prove useful in the quantitative assessment of neurotoxicity risk from domoic acid.

GABA_B RECEPTORS ENABLE THETA PATTERN STIMULATION OF PERFORANT PATH TO INDUCE POLYSYNAPTIC LTP IN THE HIPPOCAMPAL FORMATION. D.V. Lewis* and D.D. Mott, Depts. of Pediatrics (Neurology), Neurobiology and Pharmacology, Duke Univ. Med. Center, Durham, N.C. 27710.

We have previously demonstrated that GABA_B receptors enhance signal transmission through the dentate gyrus when stimuli are delivered at 5-7 Hz, a frequency in the range of hippocampal theta rhythm. Here, we show that this enhancement of transmission enables LTP induction at multiple sites in the hippocampal circuitry (polysynaptic LTP).

Polysynaptic LTP was induced by delivering theta pattern stimulus trains (4 pulses x 100 Hz delivered at 5 Hz) to the perforant path in the hippocampal slice preparation. Throughout the train, population spikes in the granule cell layer of the dentate gyrus persisted, producing polysynaptic responses in area CA3. Following the train, both the EPSP slope and population spike in the dentate gyrus, evoked by a perforant path test stimulus, exhibited a lasting potentiation. In area CA3 the commissural/associational response to a Schaffer collateral test stimulus, but not the response to a mossy fiber test stimulus, showed a similar enhancement. Blockade of GABA_B receptors with CGP 35348 (1 mM) caused population spikes in the dentate gyrus to fade rapidly during the train. CGP 35348 blocked LTP induction in the dentate gyrus and by preventing transmission of the signal, blocked the development of LTP in area CA3 as well.

High frequency perforant path stimulation (100 Hz, 50 pulses) produced LTP in the dentate gyrus, but not in area CA3. We conclude that induction of polysynaptic LTP is dependent upon the stimulation paradigm, being preferentially induced by theta pattern stimulation, and that GABA_B receptors enable theta pattern stimulation to produce polysynaptic LTP.

MODIFICATION OF GABAergic SYNAPTIC RESPONSE FOLLOWING ASSOCIATIVE PAIRINGS IN RAT HIPPOCAMPAL SLICE. C.-J. Lee* and D. L. Alkon, NINDS, NIH, Bethesda, MD 20892.

Alkon *et al.* reported that an inhibitory GABAergic synaptic response is transformed into an excitatory response following pairings of exogenous GABA with postsynaptic depolarization in *Hermisenda* (PNAS, 89:11862). They suggested that the GABAergic inhibitory synapse may also play a role in associative learning in the mammalian nervous system. To initially explore this possibility, we examine here modification of GABAergic IPSPs following associative pairings of postsynaptic depolarization with presynaptic volleys. Intracellular recordings were made from CA1 pyramidal cells of an IPSP following EPSP to electrical stimulation of Schaffer collaterals. Pairing was effective with high frequency stimulation (100 Hz for 100 msec) of Schaffer collaterals while a postsynaptic cell was depolarized by the injection of a positive current step (200 msec, 1-2 nA). The pairing was repeated 10 times at 0.2 Hz. Our study showed that a new depolarizing component (NDC) emerged during the hyperpolarizing phase after the pairings. The appearance of the NDC after pairings is similar to the transformation of IPSP into EPSP observed in *Hermisenda* in that an initially inhibitory synaptic response to a given input was transformed into an excitatory response. This component elicited after each presynaptic volley persisted up to 30 mins. It appeared between 20 - 40 msec following each stimulus onset, and it did not develop after unpaired stimulation. Pharmacological studies showed that 1) the NDC appeared after pairings even in the presence of the non-NMDA receptor antagonist (DNQX) 2) the NDC did not appear in the presence of both non-NMDA (DNQX) and NMDA receptor antagonists (APV), and finally, 3) the NDC did not appear after pairings when the IPSP was initially absent in the postsynaptic response to Schaffer collateral stimulation. These findings suggest that the NDC is mediated through GABAergic receptors but also requires the activation of NMDA receptors during pairings.

LONG-TERM POTENTIATION OF INHIBITORY SYNAPTIC TRANSMISSION IN RAT VISUAL CORTEX. Y. Komatsu*, Dep. of Physiology, Kyoto Prefectural Univ. of Med., Kamigyoku, Kyoto 602, Japan.

Activity-dependent long-term modification of inhibitory synaptic transmission was studied in rat visual cortex slices. Inhibitory postsynaptic potentials (IPSPs) evoked by layer IV stimulation were intracellularly recorded from layer V cells while excitatory synaptic transmission was blocked by N-methyl-D-aspartate (NMDA) and non-NMDA receptor antagonists. High-frequency stimulation (50 Hz, 1 s) was applied to layer IV 10 times at 10 s intervals as a conditioning stimulation. The conditioning stimulation with intensity of 5 times the threshold intensity (5 T) to evoke an IPSP induced long-term potentiation (LTP) of IPSP in all tested cells (7/7) sampled from developing rats (P20-30 days). In mature rats (P60-70 days), the same conditioning stimulation (5 T) rarely induced LTP (1/7) and even stronger conditioning stimulation (10-15 T) induced LTP in only half of tested cells (3/6). This age dependence suggests that LTP of IPSPs contributes to the postnatal development of selective responsiveness of visual cortical cells through visual experience.

546.2

SYNAPTIC INHIBITION LIMITS ASSOCIATIVE INTERACTIONS BETWEEN AFFERENTS DURING THE INDUCTION OF LONG-TERM POTENTIATION AND DEPRESSION R.A. Tomasulo*, J.J. Ramirez, and O. Steward, Dept. of Neuroscience, Univ. of Virginia, Charlottesville, VA 22908

Long-term potentiation and associative long-term depression depend for their induction upon associative interactions between synapses that converge on individual dendrites. The presumed medium of intersynaptic communication is dendritic depolarization. We tested the hypothesis that GABA-A-mediated synaptic inhibition limits the spatial domain in which these interactions occur. Stimulating electrodes were placed in the medial and lateral entorhinal cortices of urethane-anesthetized rats, to activate inputs to the middle and distal portions of dentate granule cells. Two recording pipettes were placed in the ipsilateral dentate hilus. A control electrode contained only 0.9% NaCl. A test electrode containing 8 mM bicuculline methiodide in 0.9% NaCl was placed 1.5 mm posterolateral in the same dentate gyrus. This established a local blockade of GABA-A neurotransmission, as described previously (Brain Res 561:27). We measured the initial pEPSP slope of the responses from each input at each site during 4 20-minute periods separated by 3 sets of conditioning trains. The trains (8 400 Hz, 17.5 msec trains at 15 sec intervals) were delivered first to the lateral site, then the medial, then both simultaneously. Each experiment, therefore, yielded two examples of homosynaptic, heterosynaptic, and paired tetanization at each recording site. Bicuculline significantly enhanced synaptic plasticity in all three categories ($p = .012, .028, \text{ and } .018$ for homo-, hetero-, and paired respectively). Long-term depression averaged -16% at the bicuculline sites, while long-term depression did not appear at the control sites. We conclude that associative interactions are significantly constrained by synaptic inhibition. Support: BNS8818766 from NSF to OS and K08NS01438 from NINDS to RAT.

LTP IN HIPPOCAMPAL CA1 PYRAMIDAL CELLS IS ACCOMPANIED BY OPPOSITE PRE- AND POSTSYNAPTIC CHANGES OF GABAergic INHIBITION. R.Rai*, G. Kovacs and A. Stelzer, Dep. of Pharmacology, SUNY Brooklyn, Brooklyn, NY 11203.

Possible pre- and postsynaptic changes of synaptic inhibition during LTP were examined in the CA1 hippocampal subfield. To evaluate postsynaptic changes, intracellular recordings were performed in apical dendrites of CA1 pyramidal cells in stratum radiatum in the transverse hippocampal slice from adult guinea-pigs. Schaffer collateral stimulation revealed a decrease of the early IPSP in 48 of 57 apical dendrites (no change in 5 of 57 and increase in 3 dendrites) during LTP (>30 min following tetanization). The iontophoretic GABA_A response (both depolarizing and hyperpolarizing) was reduced in 20 of 23 apical dendrites (unchanged in 3 dendrites). Modification of the early IPSP and of the iontophoretic GABA_A response was not observed when the tetanus was applied in the presence of APV (50 μM). Interneuron excitability was measured in somatic recordings of interneurons in strata lacunosum / moleculare (L/M) and alveus / oriens (A/O) (identified by physiological and staining (LY) criteria). Tetanization produced a lasting (>30 min) increase in EPSPs in L/M interneurons in 12 of 15 cells (no change in 2 and a decrease in one cell) and in A/O interneurons in 23 of 26 (no change in 3 cells). In sum, LTP in CA1 pyramidal cells is accompanied by a reduction of GABA_A-receptor sensitivity, but enhancement of interneuron excitability. Impairment of GABA_A-receptor function may, however, represent the prevailing mechanism in the modification of synaptic inhibition during LTP and disinhibition may represent a pivotal factor underlying tetanization-induced long-lasting potentiation of excitability of CA1 pyramidal cells.

SYNAPTIC POTENTIATION IN CULTURED CORTICAL NEURONS: LONG-LASTING MODIFICATION OF SPONTANEOUS SYNCHRONIZED PERIODIC FIRING BY PATTERNED ELECTRICAL STIMULATION. E.Maeda¹, H.P.C. Robinson², Y.Kuroda³ and A.Kawana¹. ¹NTT Basic Research Laboratories, Midori-cho, Musashino-shi, Tokyo, 180 Japan, ²Physiological Lab., University of Cambridge and ³Tokyo Metropolitan Institute for Neuroscience.

In low $[Mg^{2+}]_o$, spontaneous synchronized bursts of action potentials and $[Ca^{2+}]_i$ transients are observed in cultured cortical neurons, depends on NMDA-type synaptic transmission (Robinson *et al.* submitted). We examined the effects of electrical stimulation on the efficiency of synaptic transmission under these conditions. Electrical activity of cultured neuron networks was recorded extracellularly using planar electrode array (PEA) substrates at 2-4 weeks after plating, from up to 16 electrodes simultaneously. The PEA was composed of 64 indium tin oxide electrodes in an 8x8 grid at 1 mm intervals, fabricated as described by Jimbo *et al.* (IEEE trans. on BME, in press). The source of each burst, as estimated from the relative delays between electrodes, varied from burst to burst. After section of the network in half using a UV laser spot, synchronous burst firing had different frequencies and phases in the two halves. In initially silent cultures, synchronous bursting could be induced by local electrical stimulation through the PEA.

The average interburst interval and its variance increased with $[Mg^{2+}]_o$ (0-200 μM). Synchronous bursts disappeared at 2mM $[Mg^{2+}]_o$ and only partial or weak synchronicity was observed at greater than 100 μM $[Mg^{2+}]_o$. Electrical stimulation simultaneously at several sites in weakly synchronized networks (single 100 μsec pulses at 0.1-1 Hz for 2-10 min) produced strongly synchronized bursting which lasted for at least 15 min after cessation of the stimulus. The frequency and duration of bursts were also increased. In some preparations, spontaneous synchronized bursts could be initiated by electrical stimulation even at 2 mM $[Mg^{2+}]_o$. These results suggest that long-lasting potentiation of synaptic transmission in cultured cortical neuron networks can be induced by focal electrical stimulation.

ONTOGENY OF LONG-TERM POTENTIATION. J.D. Bronzino¹, K.S. Abu-Hasaballah, R.J. Austin-LaFrance, and P.J. Morgane². Dept. of Engineering and Computer Science, Trinity College, Hartford, CT 06106; ²The Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545.

The LTP phenomenon has been studied in a host of animals and brain areas, however, studies examining the establishment and maintenance of LTP in the developing rat have been limited primarily to the *in vitro* slice preparation or intact, anesthetized animals. To date, no study has examined the development of LTP in the hippocampal formation in an intact, behaving preparation. This study was undertaken to examine the development of LTP at the perforant path/dentate granule cell synapse in freely-behaving rats during the preweaning (15 days of age), early post-weaning (30 days of age) periods of development, and adulthood (90 days of age). Population spike amplitude (PSA) measures showed significant enhancement 15 mins. after tetanization in all age groups. This measure was found to decay to baseline levels 5 hrs. after tetanization in 90-day old animals and 18-24 hrs. after tetanization in 30-day old animals. PSA measures obtained from 15-day old animals were still increasing at 96 hrs. after tetanization. EPSP slope measures enhanced by approximately 35% in all age groups 15 mins. after tetanization. This measure decayed to baseline by 5 hrs. post-tetanization in 90-day old animals and 18-24 after tetanization in 30-day olds. 15-day animals continued to show enhancement of the EPSP slope measure (to over +300%) throughout the post-tetanization period (96 hrs). The results indicate that the freely-moving 15- and 30-day old animals are capable of establishing and maintaining LTP of the perforant path/dentate granule cell synapse and that the levels of synaptic transmission enhancement are significantly greater in these younger animals than that reported in adults. This may indicate that GABAergic inhibition of dentate granule cell activity is not functionally mature at either 15- or 30-days of age.

546.9

LONG-TERM POTENTIATION OF SYNAPTIC DEPRESSION IN THE CNS OF THE SNAIL *HELIOSOMA TRIVOLVIS*. S. N. Chawla, T. Bloom, M. A. Peck, L. M. Aronica, D. D. Anderson and V. C. Kotak^{*}. University of Pennsylvania, Biological Basis of Behavior, Philadelphia, Pa 19104-6196.

In the hippocampus LTP model, enhancement in synaptic efficacy involves an excitatory glutaminergic pathway that may be important to learning and memory (Bliss and Lynch, 1988; Zalutsky and Nicoll, 1990). Induction of such LTP can be interrupted by co-activation of GABAergic neurons (Douglas et al. 1983). However, characterization of inhibitory LTP *per se* is ill defined. In goldfish, an inhibitory circuit for LTP mediated by glycine is recently demonstrated (Korn et al. 1992). To examine synaptic potentiation, the CNS ganglionic cells in an isolated preparation of the pond snail, *Heliosoma trivolvis*, were impaled while an afferent nerve trunk was stimulated extracellularly. A single high frequency tetanic shock to the nerve trunk (100Hz, 5 sec) produced prolonged depression recorded intracellularly. This inhibition included an at least 50% reduction in the baseline neuronal firing, and an increase in IPSPs. In other neurons, tetanic shock to the afferents completely silenced the action potentials. Such synaptic depression facilitated progressively for at least 15 minutes. Since direct afferent inhibition is unlikely, this result indicates a strong potentiation in an inhibitory neural pathway. Bath application of 500 μ M GABA produced a reversible inhibition while the GABA_A receptor antagonist picrotoxin depolarized the cells and increased their input resistance. In light of this, and the identification of GABA (Richmond et al. 1991) and FMRFamide (Haydon, 1991) in the CNS of *Heliosoma*, attempts are being made to characterize the tetanic inhibition in relation to these two transmitters/modulators.

A POSSIBLE 'PRIMING' REQUIREMENT FOR LOW-FREQUENCY STIMULATION-INDUCED HOMOSYNAPTIC DEPRESSION (LTD) IN AREA CA1 IN VIVO. B.R. Christie^{*}, W.C. Abraham and M.F. Bear. Department of Psychology, University of Otago, Dunedin, New Zealand.

Homosynaptic LTD of CA1 Schaffer collateral synapses has been shown to occur following 900 conditioning pulses at 1-3 Hz *in vitro* (Dudek & Bear, 1992, 1993). We investigated whether a similar effect could be demonstrated in the same pathway *in vivo*. 2-3 month old rats were anesthetized with sodium pentobarbital and prepared with stimulating electrodes in the stratum radiatum of CA1 of both hemispheres to activate separate CA3 afferents to a single population of CA1 pyramidal cells. Negative-going field EPSPs were recorded in stratum radiatum of one hemisphere, in response to alternating baseline stimulation of the two input pathways. Stimulation of the ipsilateral input at 1 Hz for 900 pulses, followed 45 min later by stimulation at 3 Hz for 900 pulses, induced a small (11% \pm 4%, n=6) but significant LTD that was input specific and lasted as long as it was tested (30 min). Curiously, 900 pulses at either 1 Hz (n=8) or 3 Hz (n=4) alone produced no significant changes, nor did 1800 pulses (given as 2 sets of 900 pulses 45 min apart) at 3 Hz (n=3). This suggested that homosynaptic LTD *in vivo* might require 'priming' stimulation, as has been shown for associative LTD in the lateral perforant path (Christie & Abraham, 1992). Thus 'priming' stimulation (5 Hz, 80 pulses) was first delivered to the ipsilateral input (producing no change by itself), and then 15 min later 900 pulses at 3 Hz were given to the same input. This protocol resulted in LTD of 13% \pm 4% (n=5), a magnitude similar to that observed in CA1 slices of adult rats (but without priming). Our experiments thus confirm the existence of low-frequency stimulation-induced homosynaptic LTD in field CA1 of intact rats, although in this preparation it appears to require 'priming' by prior synaptic activity.

LTD IN INTACT HIPPOCAMPUS: USE- AND NMDA RECEPTOR-DEPENDENCE. E. Thiels¹, G. Barrionuevo¹ and T.W. Berger². ¹Depts. of Behavioral Neuroscience and Psychiatry, U. Pittsburgh, Pittsburgh PA 15260, and ²Dept. of Biomedical Engineering, USC, Los Angeles CA 90089.

Induction of long-term depression (LTD) at cortical synapses studied *in vitro* has been shown to require (1) presynaptic activity contiguous with suppressed postsynaptic activity, and (2) postsynaptic calcium influx, mediated at some synapses by NMDA receptor activation. Here we describe properties of use-dependent LTD involving the commissural-CA1 pyramidal cell synapse in hippocampus of anesthetized rats.

Repeated paired-pulse stimulation (PPS; 0.5Hz) of commissural input to CA1 pyramidal cells *in vivo* using 25-ms interstimulus intervals (ISIs), which produce suppression of CA1 pyramidal cell activation to the second impulse, resulted in robust LTD: only 200 pairs caused the amplitude of CA1 population spikes (evoked using low frequency, 0.1Hz, single impulses) to decrease from a baseline level of 4.6 \pm 0.3mV to 0.7 \pm 0.2mV at 60min (N=12). This effect was specific to short ISIs: 200 pairs using 1000-ms ISIs, which produce comparable pyramidal cell activation by the first and second impulse, failed to reliably modify evoked response amplitudes; the corresponding values were 4.9 \pm 0.3mV and 4.9 \pm 1.4mV (N=6).

The LTD observed using 25-ms ISIs was long-lasting: response levels continued to be depressed to 1.0 \pm 0.5mV 180min after PPS (N=5). In addition, the LTD was reversible by brief high-frequency commissural stimulation (100Hz for 1s; HFS): response amplitudes increased from 0.7 \pm 0.3mV 60min after PPS to 7.7 \pm 1.2mV 30min after HFS (N=5). A second train of PPS caused responses to decline to 3.4 \pm 1.4mV 60min after PPS. Finally, induction of LTD was dependent on NMDA receptor activation: microinjection of the NMDA receptor antagonist D-APV (100 μ M) in str. radiatum near the recording site blocked development of PPS-induced LTD, whereas microinjection of vehicle solution (150mM NaCl) did not. Response amplitudes in the presence of APV were 3.1 \pm 0.3mV before and 3.5 \pm 0.5mV 30min after PPS (N=4), compared to 4.0 \pm 1.0mV and 1.6 \pm 0.5mV, respectively, in the presence of NaCl (N=4). Taken together, these findings suggest that principles of LTD induction identified in *in vitro* preparations apply to LTD in intact brain, and moreover, that the network properties of intact brain readily provide for the implementation of those principles. (Supported by ONR, AASERT, NIMH, NIH BMSR, and NS24288).

546.10

HOMOSYNAPTIC LONG-TERM POTENTIATION AND DEPRESSION OF CO-ACTIVE INPUTS ONTO SINGLE CA1 NEURONS *IN VITRO*. Michael Weliky^{*}. Duke University Medical School, Box 3209, Durham, NC 27710.

Different stimulus protocols have been required to induce homosynaptic long-term potentiation (LTP) and depression (LTD) in the hippocampus. LTP has been typically induced by short bursts of high frequency stimulation while LTD induction has required extended periods of low frequency stimulation. Experiments were performed in hippocampal slices prepared from rats (19-32 days). Bursts of high frequency stimulation, applied for 30 to 60 seconds to CA1 afferents, induced either LTP or LTD of synaptic responses in single CA1 pyramidal cells. A multielectrode array, consisting of sixteen 12.5 μ m wires arranged into two parallel rows, was used to stimulate multiple afferent pathways converging onto the apical dendrites of single CA1 pyramidal cells. After synchronous tetanization, both LTP and LTD were induced in different pathways (n=11 slices), or only LTP was induced (n=12 slices). When picrotoxin was applied (50-100 μ M) (n=9 slices) only robust LTP was induced in all slices except one, in which LTD was also induced. In both normal and PTX treated slices stimulus intensities were adjusted so that baseline synaptic responses spanned the same amplitude range of 15 to 130 pA. In normal slices, single responses could be alternately depressed or potentiated by pairing tetanization with intracellular current injection or voltage clamping to different membrane potentials (n=5 slices). Hyperpolarization increased the probability of inducing LTD while depolarization induced LTP. This suggests that 1) synchronous bursting of CA1 inputs, which occurs during sharp wave and theta EEG activity, can induce heterogeneous synaptic changes in target CA1 neurons, 2) these synaptic changes follow a Hebb rule of a covariance form, and 3) dendritic inhibition may play a role in regulating these changes by selectively hyperpolarizing local regions of the dendritic tree in which LTD is induced.

AN UNUSUALLY PROLONGED RESPONSE BY THE IMMEDIATE EARLY GENE KROX 20 TO LTP-INDUCING STIMULATION. W.C. Abraham^{*}, M. Dragunow, P. Lawlor, S.E. Mason, J. Demmer, W. Tate. Departments of Psychology and Biochemistry, University of Otago, Dunedin and Department of Pharmacology, University of Auckland Medical School, Auckland, New Zealand.

Tetanization leading to LTP at perforant path-dentate gyrus granule cell synapses was followed by a dramatic increase of mRNA and protein for the zinc-finger-containing transcription factor Krox 20, measured with Northern blots and immunohistochemistry. The induction was confined to the nuclei of cells in the ipsilateral dentate gyrus. Krox 20-like immunoreactivity increased within 20 min of tetanization of the perforant path, was maximal 1-8 h after stimulation, and was still elevated at 24 h before returning to baseline by 48 h after LTP induction. This prolonged time course of protein induction contrasts with the more transient induction after LTP of other immediate early genes, including the related molecule Krox 24. Krox 20 and Krox 24 showed a similar transient duration of mRNA induction (1-2 h), suggesting that the prolonged Krox 20 protein induction is due to greater stability of this protein. Low-frequency stimulation did not induce either LTP or Krox 20, and the induction of Krox 20 after tetanization was prevented by the NMDA antagonists CPP and MK801, which also blocked LTP induction. Stimulus paradigms known to induce LTP of differing durations produced corresponding differences in Krox 20 induction. Thus perforant path tetanization induces an NMDA receptor-mediated expression of Krox 20, which may play a role in the stabilization of LTP.

PROTEIN KINASE C (PKC)-DEPENDENT PHOSPHORYLATION ACCOMPANIES INDUCTION OF LONG-TERM POTENTIATION (LTP) IN CA3 OF THE RAT HIPPOCAMPUS. H. Son¹, Paul Davis² and D.O. Carpenter^{1*}

¹Wadsworth Labs, NYS Dept. of Health and School of Public Health, ²Dept. of Medicine, Albany Medical College, Albany, NY 12201.

LTP is a form of synaptic plasticity which may be an indicator of memory formation in the mammalian brain. We have applied physiological and biochemical measurements to determine the role of PKC in the process of LTP in the CA3-mossy fiber (MF) synapse of rat hippocampal brain slices. The MF synaptic terminals have PKC but not growth-associated protein 43 (GAP-43), while the pyramidal neurons have both. Brief high frequency stimulation (HFS) of mossy fibers induced LTP which lasted more than 90 min. The LTP was blocked by 10 μ M D-sphingosine, an inhibitor of PKC. Phorbol-12,13-diacetate (PDAC) (1 μ M), a PKC activator, increased the synaptic response by 395%. When HFS was given after full activation of PKC by PDAC, there was no post-tetanic potentiation or LTP. Double-pulse facilitation, which reflects available Ca²⁺ in the presynaptic terminal, was reduced by PDAC, suggesting involvement of presynaptic PKC in the induction of LTP. After LTP the phosphorylation of a 42 kd-protein was decreased for up to 10 min and increased after 30 min. This almost certainly is postsynaptic GAP-43. Phosphorylation of GAP-43 was also increased by phosphatidylserine and free Ca²⁺ at concentrations less than 10⁻⁶M, and decreased by calmodulin (CaM) in a concentration dependent manner. Calmodulin binding inhibitor reversed the decreased phosphorylation of GAP-43 at the early stages of LTP. Therefore, it is likely that presynaptic PKC is required for the induction of LTP whereas postsynaptic PKC and GAP-43 are necessary for the persistence of LTP. After HFS phosphorylation of GAP-43 by PKC may be regulated by CaM via internal [Ca²⁺]. Supported by NS23807-08.

B-50/GAP-43 AND NEUROGRANIN PHOSPHORYLATION AS MARKERS FOR PRE- AND POSTSYNAPTIC PKC-ACTIVITY DURING LTP. Ramakers, G.M.L., De Graan, P.N.E., Kraaij, D.A., Urban, J.J.A. and Gispen, W.H. (SPON: European Neuroscience Association) Rudolf Magnus Institute, Department of Medical Pharmacology, Utrecht University, Vondellaan 6, 3521 GD Utrecht, The Netherlands.

Several lines of evidence indicate that protein kinase C (PKC) plays an important role in the molecular mechanisms underlying long-term potentiation (LTP). However, the location of the PKC activity relevant for different phases of LTP is still largely unknown. To distinguish between pre- and postsynaptic PKC activity we monitored the in situ phosphorylation state of identified PKC substrates. As presynaptic marker we used protein B-50 (a.k.a. GAP-43, F1, neuromodulin), a protein implicated in different forms of synaptic plasticity and in the mechanism of neurotransmitter release. As postsynaptic marker we used neurogranin (a.k.a. p17, BICKS, RC3), a protein which shares an 18 amino acid sequence with B-50, containing the unique PKC-phosphorylation site.

Rat hippocampal slices (450 μ m) were labelled for 90 min with ³²P-orthophosphate and were stimulated either by tetanic stimulation (100 Hz, 1 sec) or by treatment with the phorbol ester 4- β -phorbol-12,13-dibutyrate (4- β -PDB, 10⁻⁶M). After field potential recordings, in situ B-50 and neurogranin phosphorylation were analysed in each individual slice by specific immunoprecipitation. An increase in B-50 phosphorylation could be detected 60 and 90 min, but not 120 min after the tetanus. 4- β -PDB stimulation induced a time- and concentration-dependent increase in B-50 and neurogranin phosphorylation, which could be blocked by PKC-inhibitors. 4- β -PDB induced stimulation of B-50 and neurogranin phosphorylation could be detected within 5 min and was maximal after 30 min. 4- α -Phorbol-12,13-didecanoate was ineffective in stimulating B-50 and neurogranin phosphorylation.

The time-course of B-50 phosphorylation resembles that reported for increased glutamate release during LTP. Whether these two phenomena are causally related remains to be determined. Our data confirm that neurogranin is an in vivo substrate for PKC and show that it is now possible to monitor temporal and spatial differences in the phosphorylation state of specific PKC substrates within a single slice during LTP.

LONG-TERM POTENTIATION IS ASSOCIATED WITH AN INCREASED ACTIVITY OF Ca²⁺/CALMODULIN-DEPENDENT PROTEIN KINASE II. K. Fukunaga^{1*}, D. Muller², L. Stoppini² and E. Miyamoto¹. ¹Dept. of Pharmacol., Kumamoto Univ. Sch. Med., Kumamoto 860, Japan, ²Dept. of Pharmacol., Centre Med. Univ., 1211 Genève 4, Switzerland.

Among the molecular mechanisms that have been proposed to contribute to long-term potentiation (LTP) in hippocampus are the activation and autophosphorylation of Ca²⁺/calmodulin-dependent protein kinase II (CaM kinase II). We investigated whether changes in CaM kinase II activity and autophosphorylation may occur as a result of LTP induction in hippocampus. High, but not low-frequency stimulation applied to two groups of CA1 afferents resulted in a long lasting increase in the Ca²⁺-independent and total activities of the enzyme as well as an increase in the ratio of Ca²⁺-independent to total activity. The effect was obtained using two different substrates and observed in both hippocampal slices and hippocampal organotypic cultures. It could be blocked by preincubation of slices with an NMDA receptor antagonist, D-2-amino-5-phosphonopentanoate. Treatment of slices with calyculin A, a phosphatase inhibitor, modified the activity of the enzyme, but LTP could still be induced and a further increase in Ca²⁺-independent CaM kinase II activity still be observed. Finally, in the experiment with ³²P-labeled slices, we demonstrated a significant increase in the autophosphorylation of the enzyme with the concomitant induction of LTP. In agreement with several previous studies, these results support the idea that CaM kinase II may contribute to LTP in CA1 region of hippocampus.

546.16

GENISTEIN REDUCES NOREPINEPHRINE-INDUCED LONG-LASTING POTENTIATION IN HIPPOCAMPAL DENTATE GYRUS

P.J. Voullas* and J.M. Sarvey, Department of Pharmacology, USUHS, Bethesda, MD 20814.

Tyrosine kinase inhibitors have been demonstrated previously to block LTP in CA1. Both β -adrenergic and NMDA receptors are required for induction of NELLP and LTP in the dentate gyrus. We examined (1) the effects of tyrosine kinase inhibitors on NELLP and (2) the effect of isoproterenol (IP) on tyrosine phosphorylation. Rat hippocampal slices were exposed in an interface chamber to 110 μ M genistein 30 min prior to bath application of 1 μ M IP. Pretreatment with genistein reduced potentiation of the medial perforant path granule cell population spike (PS) to 50% of that elicited in the absence of genistein. IP (1 μ M) transiently increased tyrosine phosphorylation of at least two proteins, detected by Western blot with an anti-phosphotyrosine antibody. The onset of increased phosphorylation directly parallels the increase in the amplitude of the PS, both peaking 5-10 min after exposure to IP. Phosphorylation decreased by 20 min, when the PS was still maximally potentiated. These results imply a similar underlying mechanism for the induction of LTP and NELLP.

LONG-TERM POTENTIATION VII

547.1

FURTHER CHARACTERISATION OF THE BLOCK OF LTP BY THE mGluR ANTAGONIST MCPG IN THE HIPPOCAMPAL CA1 REGION.

N. Berretta, Z.A. Bortolotto, Z.I. Bashir, E.J. Coan* & G.L. Collingridge, Dept. of Pharmacology - University of Birmingham - Birmingham B15 2TT (UK).

We have shown previously that the glutamate metabotropic receptor (mGluR) antagonist (+)- α -methyl-4-carboxyphenylglycine (MCPG) prevents the induction of LTP by a single tetanus (100 Hz, 1s) to the Schaffer collateral-commissural pathway (SCCP), but spares STP (Bashir *et al.*, Nature 1993 *in press*).

Further experiments have been performed in order to verify whether MCPG could block LTP under more extreme conditions of induction. Extracellular synaptic potentials were recorded from *stratum radiatum* of hippocampal slices. In the continuous presence of MCPG the induction of LTP was blocked even when tetanic stimulation consisted of 6 tetani (each comprising 100 Hz, 1s) delivered every 10 min. Following the tetani STP decayed to baseline in approximately 50 min (n=4). Moreover, a single tetanus (100 Hz, 1s) delivered in the presence of MCPG (500 μ M) and picrotoxin (50 μ M), to block GABA_A receptor-mediated inhibition, induced STP but not LTP in 3 out of 4 slices.

It has been reported that in the spinal cord (+)-MCPG is the active isomer (Jane *et al.*, Neuropharmacology 1993 *in press*). In order to investigate the stereoselectivity of MCPG in blocking LTP induction, tetanic stimulation of the SCCP was delivered in the presence of (+)-MCPG (500 μ M). In this experimental condition the tetanus induced only STP. However, after washout of (+)-MCPG a tetanus delivered in the presence of (-)-MCPG (500 μ M) induced LTP, which was followed for up to 60 min (n=3). (+)-MCPG was ineffective in blocking LTP of a separate input in the same slices when it was applied immediately after the tetanus suggesting that for the induction of LTP it is necessary that the mGluRs are active during tetanic stimulation.

547.2

ACTION OF A METABOTROPIC GLUTAMATE RECEPTOR ANTAGONIST ON LTP IN THE DENTATE GYRUS OF FREELY MOVING RATS. G. Riedel¹,

S. Vieweg and K. Revmann, Dept. Neurophysiol., Federal Institute for Neurobiology, POB 1860, 3010 Magdeburg, Germany

Long-term potentiation (LTP), a sustained increase in synaptic efficacy induced by high frequency electrical stimulation, requires postsynaptic activation of N-methyl-D-aspartate (NMDA) receptors (Collingridge *et al.* 1983, *J. Physiol.* 334:33-46) in CA1 and dentate gyrus of the hippocampal formation. Early reports supported an additional role for metabotropic glutamate receptors (mGluRs) for the late of LTP (Behnisch *et al.* 1991, *Neuroreport* 2:386-388). We investigated this hypothesis using the new selective and competitive mGluR antagonist (RS)- α -methyl-4-carboxyphenylglycine (MCPG; gift from J. C. Watkins) (Eaton *et al.* 1993, *Eur. J. Pharmacol.* 244: 195-197).

The drug (0.02mg in 5 μ l) was injected intracerebroventricularly in awake rats 30 minutes before application of the tetanus (10 bursts, 200 Hz, 15 pulses, bursts interval 10 s). The injection of MCPG has no effect on the baseline test responses. Tetanic stimulation of perforant path fibers resulted in a postsynaptic potentiation which lasted for 1 - 2.5 hours and showed a permanent decay in amplitude (n=6). After 2.5 hours, posttetanic test responses remained stable at baseline levels for up to 24 hours. Control experiments, in which saline (0.9%) was applied 30 minutes before the tetanus, showed stable LTP lasting for 24 hours or longer. These results suggest that in the dentate gyrus activation of mGluRs is essential for long-lasting synaptic changes in vivo. Blockade of the mGluR resulted only in a posttetanic and short-term potentiation (STP) of synaptic transmission. This confirms and extends the recent findings of Bashir *et al.* (1993, *Nature in press*) who proposed a role for mGluR in the induction of LTP in CA1 and CA3 in vitro.

547.3

SYNAPTIC ACTIVATION OF METABOTROPIC GLUTAMATE RECEPTORS IS INHIBITED BY LOW LEVELS OF NMDA. G. J. Pacelli* and S.R. Kelson, Department of Biological Sciences, Committee For Neurosciences, University of Illinois at Chicago, 60680.

Several subtypes of glutamate receptors have been shown to be involved in various phases of long term potentiation (LTP) in CA1 hippocampal cells. Recently Zorumski et al demonstrated that treatment of hippocampal slices with NMDA ($\leq 1 \mu\text{M}$) can inhibit LTP formation. One possibility for the mode of action of this low level NMDA is an effect on a metabotropic response. This hypothesis is suggested by the ability of NMDA to inhibit LTP even if it is applied after a high frequency stimulation normally capable of eliciting LTP. To test this hypothesis we attempted to physiologically activate metabotropic glutamate receptors. As a monitor we examined afterhyperpolarizations (AHPs) which normally are depressed with metabotropic receptor activation. We found that high frequency bursts applied to the Schaffer/commissural fiber system significantly depressed AHPs ($10.9 \pm 1.7 \text{ mV}$ before; $10.2 \pm 1.7 \text{ mV}$ after; $p=0.014$, $n=9$). These bursts also induced LTP of the synaptic response to a test stimulus on that pathway (mean change 159% of control, $n=9$). We also found that subsequent application of $1 \mu\text{M}$ NMDA to the bathing solution not only inhibited the formation of LTP (mean change 83% of control, $n=8$), but it blocked the stimulus-induced depression of AHPs ($7.9 \pm 1.3 \text{ mV}$ before; $8.3 \pm 1.1 \text{ mV}$ after; $p=0.164$, $n=5$). These results are consistent with a role of the metabotropic glutamate receptor in LTP formation. They also suggest that inhibition of LTP formation by low levels of NMDA may be mediated through an effect of NMDA on metabotropic responses. Supported by Klingenstein Foundation.

547.5

ON THE INDUCTION OF LTP BY mGluR ACTIVATION

Z.A. Bortolotto, W.W. Anderson* & G.L. Collingridge
Dept. of Pharmacology, Birmingham University, Birmingham, U.K.

In the CA1 region of the hippocampus, transient exposure to (1S,3R)-aminocyclopentane dicarboxylate (ACPD) can induce a slow-onset potentiation which occludes with tetanus-induced long-term potentiation (LTP). This potentiation is unaffected by the N-methyl-D-aspartate (NMDA) antagonist D-2-amino-5-phosphonopentanoate (AP5) but is prevented by kinase inhibitors (staurosporine and K-252b) and thapsigargin (Bortolotto & Collingridge, 1993 Neuropharmacology 32, 1-9).

We now report that ACPD-induced potentiation is not prevented by $50 \mu\text{M}$ nimodipine ($n=3$). ACPD induces potentiation of a pure α -amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA) receptor-mediated response ($n=3$) but not of a pure NMDA receptor-mediated response ($n=6$) (recorded in the presence of $50 \mu\text{M}$ picrotoxin and an appropriate excitatory amino acid receptor antagonist).

Low frequency stimulation (1 Hz, for 15 min) delivered immediately after the application of ACPD prevents the development of the slow-onset potentiation ($n=5$). This inhibition is prevented by the application of $50 \mu\text{M}$ AP5 ($n=4$), (2S, 3S, 4S)- α -(Carboxycyclopropyl)-glycine (L-CCG-1, $10 \mu\text{M}$; $n=8$), which is potent at activating mGluR2, does not mimic the effects of ACPD.

We conclude that ACPD can induce a component of LTP which involves modification of AMPA receptor-mediated synaptic transmission. This component is slow to develop fully and probably involves the stimulation of phospholipase C-coupled mGluRs.

A DEVELOPMENTAL SWITCH OCCURS IN THE LONG-TERM EFFECTS OF METABOTROPIC GLUTAMATE RECEPTOR ACTIVATION IN RAT HIPPOCAMPUS.

B.L. Trommer*, P.A. Colley, J.F. Pasternak, J.J. Kennelly and N.T. Slater. Departments of Pediatrics and Neurology, Evanston Hospital, Evanston, Illinois, and Physiology, Northwestern University Medical School, Chicago, Illinois.

Activation of metabotropic glutamate receptors (mGluRs) has recently been proposed to play a role in long-term potentiation (LTP) in the hippocampus and long-term depression (LTD) in the cerebellum. While mGluR-activated intracellular messenger systems display profound developmental changes, little is known of the physiologic correlates of these changes. Population spikes (PS) were recorded extracellularly in the CA1 and dentate gyrus (DG) cell body layers in response to electrical stimulation of the Schaffer collateral or medial perforant path in rat hippocampal slices. The 1S,3R-isomer of the mGluR agonist ACPD ($10 \mu\text{M}$) was bath applied for 20 min, and the effects on PS amplitude studied for a further 60 min after the washout of the drug. In the CA1, the effects of ACPD were age-dependent: in young rats (P10-15) ACPD produced a rapid depression of PS amplitude which did not reverse upon washout of the drug (20% of control), whereas in older animals (P29-33), a lasting potentiation was produced (156% of control). This switch in the actions of ACPD occurred between P16 and P24. Subsequent induction of LTP by tetanic stimulation could be achieved at all ages, with the degree of potentiation being greatest in the intermediate age group. In the DG, LTD (68% of control) was induced by ACPD in young animals, but in adults only a reversible reduction of PS amplitude was observed. These results demonstrate that the effects of mGluR activation in hippocampus are both age-dependent and region-specific: mGluR activation evokes LTD in immature DG and CA1, and LTP in adult CA1.

NOVEL NMDA ANTAGONIST NPC 17742 BLOCKS LONG-TERM POTENTIATION IN DENTATE GYRUS IN ANESTHETIZED RATS. D. Côté, P.A. Hetherington, F. Balcomb and M.L. Shapiro*. Dept. of Psychology, McGill University, Montréal, Québec, Canada, H3A 1B1.

NPC 17742 [2R,4R,5S-(2-amino-4,5-(1,2-cyclohexyl)-7-phosphonoheptanoic acid)] is a novel, competitive N-methyl-D-aspartate (NMDA) receptor antagonist and is the active isomer of NPC 12626 [2-amino-4,5-(1,2-cyclohexyl)-7-phosphonoheptanoic acid]. Because it crosses the blood-brain barrier, NPC 17742 is a convenient competitive NMDA antagonist for behavioral pharmacology studies of learning and memory. However, little is known about its physiological effects, specifically, its effect on long-term potentiation (LTP) in the hippocampus. The effect of peripherally administered NPC 17742 on the induction of LTP in the dentate gyrus was tested in male Long Evans rats, anesthetized with urethane and α -chloralose. NPC 17742 (i.p. in DMSO) prevented the induction of LTP of the perforant path - dentate gyrus synapses, 90 to 120 minutes after the injection. In some experiments, NPC 17742 decreased the population spike and increased slope of the EPSP, suggesting an increase in inhibition. NPC 17742 also blocked LTP in the hilar ipsilateral longitudinal associational pathway of the dentate gyrus. Furthermore, a block of LTP occurred with as little as 5 mg/kg i.p., given 90 minutes pre-tetanus. LTP was induced 90 to 120 minutes after control rats were injected with DMSO alone. The results of this study demonstrate the efficacy of NPC 17742 for preventing LTP by blocking NMDA receptors. The characteristics of NPC 17742 combined with the results of this study point to the usefulness of NPC 17742 as a tool for studying the involvement of NMDA receptors in learning and memory.

547.6

ACTIVATION OF METABOTROPIC GLUTAMATE RECEPTORS INDUCES LONG-TERM DEPRESSION OF GABAergic INHIBITION IN HIPPOCAMPAL CA1 NEURONS.

N.T. Slater*, Y.-B. Liu, J.R. Moyer and J.F. Distenfeld. Depts. of CMS Biology and Physiology, Northwestern Univ. Med. School, Chicago, IL.

The activation of metabotropic glutamate receptors (mGluRs) in hippocampal pyramidal neurons evokes a variety of effects on voltage- and transmitter-gated channels. We have examined the actions of the mGluR agonist 1S,3R-ACPD on CA1 pyramidal neurons in rabbit hippocampal slices *in vitro*. Slices were maintained at 31°C and cells were impaled with sharp microelectrodes for intracellular recording. The bath application of the mGluR agonist 1S,3R-ACPD (5 - $20 \mu\text{M}$) for 20 min produced a reversible depolarization, blockade of spike accommodation and increase of input resistance. Synaptic stimulation of the str. radiatum evoked epileptiform discharges in the presence of 1S,3R-ACPD which only partially reversed 60 min after washout of 1S,3R-ACPD. A long-lasting enhancement of the EPSP was also observed in the presence of the NMDA antagonist D-AP5 ($20 \mu\text{M}$). This mGluR-induced long-term potentiation of the AMPA-mediated EPSP could result either from a direct enhancement of EPSPs, as recently proposed (Bortolotto & Collingridge, 1993), or to a reduction of the temporally-overlapping GABA_A conductance. Both components of pharmacologically-isolated biphasic IPSPs were irreversibly reduced by 50% by 1S,3R-ACPD, whereas AMPA-mediated EPSPs were not potentiated by 1S,3R-ACPD. The long-term depression of IPSPs by 1S,3R-ACPD was not blocked by the external application of the PKC inhibitor calphostin C ($1 \mu\text{M}$), the mGluR antagonist L-AP3 (1 mM), or thapsigargin ($1 \mu\text{M}$). However, following intracellular injection of GTP- γ -S, 1S,3R-ACPD had no effect on the early GABA_A-mediated IPSP; the late, GABA_B-mediated component was directly blocked by GTP- γ -S injection (Andrade et al., 1986). These results demonstrate an important component of the long-term potentiation of synaptic excitability produced by activation of mGluRs may result from a G protein-mediated depression of GABAergic inhibition.

547.8

LATERAL PERFORANT PATH-CA3 LTP IS MU OPIOID RECEPTOR-DEPENDENT, NMDA RECEPTOR-INDEPENDENT AND LONG-LASTING

B. E. Derrick*, E. J. Barea-Rodriguez and J. L. Martinez, Jr.

Department of Psychology, The University of California, Berkeley, CA 94720.

Previously we reported that LTP of lateral perforant path-CA3 responses is naloxone-sensitive and displays onset kinetics similar to LTP observed at the mossy fiber-CA3 synapse (SNA 18: 1497, 1992). We investigated the receptors involved in perforant path-CA3 LTP in anesthetized rats and the development of perforant path LTP in awake rats. Lateral and medial perforant path-CA3 responses evoked selectively by stimulation of the dorsomedial and ventrolateral aspects of the angular bundle preceded the onset of dentate field EPSPs, phase reversed in the CA3 pyramidal layer, and followed brief trains of 100 Hz, and thus were monosynaptic and locally generated in area CA3. The non-competitive NMDA receptor antagonist (\pm)-CPP (1 and 10 nmol) blocked LTP of the field EPSP slope in medial perforant path responses (9/10 animals), but was without effect on lateral perforant path LTP (8/8 animals). Lateral perforant path responses were, however, blocked by the mu opioid receptor antagonist CTOP (3 nmol). The time course of LTP in these pathways was investigated in rats with implanted electrodes. Following 5-7 days of stable baseline responses and a single session of high-frequency stimulation (five 100-500 msec trains at 400 Hz), LTP of medial perforant path slopes decayed to baseline amplitudes by 2-3 days. By contrast, LTP of lateral perforant path slopes decayed initially over the first 5 days but remained at potentiated levels ($> 20\%$ increase) for over 10 days. Measures of EPSP slope were uncorrelated with activity. Thus lateral perforant path-CA3 is opioid receptor-dependent and NMDA receptor-independent. Importantly, opioid receptor-dependent LTP at lateral perforant path-CA3 synapses is relatively long-lasting as compared to the NMDA antagonist-sensitive LTP observed at medial perforant path synapses.

547.9

NMDA RECEPTOR ACTIVATION IS NOT ESSENTIAL FOR THE INDUCTION OF LTP AT THE LATERAL PERFORANT PATH-DENTATE GYRUS SYNAPSE. J.A. Reyes*, B.E. Derrick and J.L. Martinez, Jr. Dept. of Psychology, University of California, Berkeley, CA 94720.

Although LTP at lateral perforant path-dentate gyrus synapse is naloxone-sensitive, the sensitivity of LTP in this pathway to NMDA receptor antagonists is unclear. We investigated the role of NMDA receptors in LTP of perforant path-dentate gyrus responses evoked by selective stimulation of the dorsomedial or ventrolateral aspects of the angular bundle. Following high-frequency stimulation (400 Hz 100 msec X 5) medial perforant path-dentate EPSP slopes reached maximal amplitude immediately and remained stable over a 1-hr period, while lateral perforant path-dentate LTP increased in amplitude over a 1-hr period. This latter pattern is characteristic of LTP development at synapses sensitive to opioid receptor antagonists, such as lateral perforant path- and mossy fiber-CA3 synapses. Local application of (\pm)-CPP (10 nmol) to the dentate molecular layer blocked both medial and lateral perforant path LTP measured 20 min post tetanus. However, the blockade of lateral, but not medial, perforant path LTP could be reversed by increasing the stimulation current intensity. Systemic administration of the competitive NMDA receptor antagonist (\pm)-CPP (10 mg/kg i.p.) blocked completely LTP of medial, but not lateral, perforant path response induced with high-intensity stimulation. These data suggest that activation of NMDA receptors is essential for the induction of medial, but not lateral, perforant path-dentate LTP. We suggest NMDA receptors may modulate induction of opioid receptor-dependent LTP at the lateral perforant path-dentate synapse. This is in contrast to LTP at lateral perforant path- and mossy fiber-CA3 synapses, which is unaffected by NMDA receptor antagonists.

SEROTONIN SUPPRESSES LTP IN CA1 INDUCED BY THETA BURST STIMULATION. N. Otaky¹ and U. Staubli². ¹Dept. Psychology, McGill University, Montreal, PQ H3A 1B1; ²Center for Neural Science, New York University, New York, N.Y. 10003.

Much evidence has accumulated concerning the effects of NMDA receptor antagonists on learning, supporting the hypothesis that LTP is the neurobiological variable involved in information encoding. Drugs acting on serotonin (5-HT) receptors may also provide a means for testing the link between LTP and memory. It has been reported that agonists of the 5-HT receptor cause hyperpolarization of hippocampal neurons, possibly via an action on the potassium channels utilized by the GABA_A receptor. There is also evidence that 5-HT increases the excitability of GABA interneurons. This predicts that serotonin could increase the hyperpolarization present during the early stages of theta burst stimulation, which in turn would reduce the NMDA currents elicited by the early bursts. A recent report has confirmed that 5-HT is effective in blocking LTP induced by a single primed burst (Corradetti et al., 1992). Studies in our laboratory indicate that 5-HT substantially decreases the degree to which a theta burst response is increased by a prior burst given 200 msec earlier. It is well established that much of this between burst facilitation reflects the contribution of currents mediated by the NMDA receptor. Subsequent experiments conducted in the presence of APV confirm the interaction between 5-HT and the NMDA receptor mediated component of the burst response. The concentration range over which 5-HT is effective in this regard does not detectably affect dendritic field responses but reduces the magnitude of LTP produced by successive pairs of theta bursts. From these observations serotonin receptor agonists would be expected to impair learning. Considerable evidence in the literature suggests that this is the case.

547.13

P TYPE Ca CHANNEL BLOCKER ω -AgaIVA BLOCKS INDUCTION OF LONG-TERM POTENTIATION (LTP) AND REDUCES DEPOLARIZATION INDUCED Ca RISE IN HIPPOCAMPAL CA1 PYRAMIDAL NEURONS. H. Kato, K.I. Ito, H. Miyakawa. Dept. Physiol., Yamagata Univ. Sch. Med., Yamagata 990-23, JAPAN.

Although it has been shown that LTP in CA1 hippocampal pyramidal cells requires Ca elevation and can be blocked by APV, a NMDA receptor antagonist, source of Ca is still a matter of dispute. Ca imaging studies revealed that Ca entry through voltage-gated Ca channel is dominant over entry through NMDA receptor channel in synaptically induced Ca rise (Miyakawa et al., 1992), and that even APV sensitive component of Ca rise could be due to entry through voltage-gated Ca channels (Regehr & Tank, 1992). Here we report effects of synthesized ω -AgaIVA, a P type Ca channel blocker, on LTP induction and Ca accumulation, using extracellular recordings and Ca imaging technique in guinea-pig hippocampal brain slice preparation.

ω -AgaIVA (60nM) did not block Schaffer input induced EPSPs. With the presence of ω -AgaIVA, tetanic activation of Schaffer inputs (100Hz, 1sec) did not result in increase in field EPSP amplitude recorded at str. radiatum in CA1 field, while it induced increase in population spike amplitude. Nifedipine (50 μ M), L type Ca channel blocker, failed to block LTP. To measure transient rise in Ca related to depolarization induced spikes, we injected Fura-2, Ca indicator dye, to a single pyramidal neuron and measured fluorescence intensity simultaneously with membrane potential. Spike related Ca rise (Jaffe et al., 1992) was smaller with the presence of ω -AgaIVA (20% reduction) at the soma, proximal apical dendrites and basal dendrites. Nifedipine also reduced spike related Ca rise by 20%, but the reduction was restricted to the region closer to the soma.

This study strongly suggest that Ca entry through P type Ca channels plays crucial roles in inducing LTP in hippocampal CA1 pyramidal neurons.

547.10

ROLE OF NMDA RECEPTORS AND VOLTAGE DEPENDENT Ca²⁺ CHANNELS (VDCC) IN TEA INDUCED SYNAPTIC ENHANCEMENT. K.M. Huber*, M.D. Mauk, and P.T. Kelly, Dept. of Neurobiology and Anatomy, Univ. of Texas-Houston Medical School, TX 77225.

Our analyses of tetraethylammonium (TEA) induced synaptic enhancement (potentiation) in isolated hippocampal CA1 region has demonstrated two routes of Ca²⁺ entry into postsynaptic neurons which contribute to synaptic potentiation. In contrast to previous findings (Aniksztein & Ben-Ari, Nature 349:67-69; Huang & Malenka, J. Neurosci. 13(2), 568-76), we observed that TEA potentiation was attenuated, but not blocked by the VDCC antagonist nifedipine (20 \pm 8%; n = 8) compared to controls (41 \pm 8%; n = 9). Moreover, TEA potentiation was strictly dependent on NMDA receptor activation. TEA application in D-APV resulted in a slight depression of synaptic transmission (-15 \pm 8%). A second TEA application to the same slices in the absence of D-APV induced robust potentiation (62 \pm 7%; n = 10). TEA potentiation was also blocked by the noncompetitive NMDA antagonist MK-801 (11 \pm 6%; n = 9). One hallmark of NMDA-dependent LTP is its synapse specificity. The NMDA dependence of TEA potentiation predicts that its induction should require presynaptic stimulation with concurrent postsynaptic depolarization and display synapse specificity. When stimulation was stopped 5 minutes before and resumed 20-30 min after TEA applications, transmission did not potentiate (-8 \pm 4%, n = 5). TEA potentiation was also synapse specific. In two pathway experiments, we observed long-lasting potentiation only in the pathway that was stimulated during TEA application (32 \pm 5%, n = 8), while unstimulated pathways displayed short-lasting decremental potentiation (6 \pm 2%; n = 8). These results are consistent with the dependence of TEA potentiation on NMDA receptor activation. We also tested if TEA potentiation, like tetanus induced LTP, used similar Ca²⁺-dependent enzymes as such as protein kinases. Incubation of slices in the broad range and membrane permeable kinase inhibitor K-252a before and during TEA applications blocked potentiation (-15 \pm 7%; n = 10). These results indicate that TEA induced potentiation and LTP have many similarities including their dependence on NMDA receptor activation, protein kinase activity, and synapse specificity.

In contrast to results in isolated CA1 regions, TEA potentiation in slices with intact CA3-CA1 connections was only partially reduced by D, L-APV (35 \pm 9%, n = 9) compared to control potentiation (68 \pm 14%, n = 11). Moreover, nifedipine reduced, but did not block TEA potentiation in intact slices (43.4 \pm 9%, n = 7). Therefore, in intact slices, Ca²⁺ influx via VDCCs or NMDA receptors can contribute to TEA induced synaptic enhancement.

NONHYDROLYZABLE ANALOGS OF ATP INHIBIT INDUCTION OF LONG-TERM POTENTIATION (LTP) IN MOUSE HIPPOCAMPAL SLICES.

A. Wieraszko*. CSI/IBR Center for Dev. Neurosci., Dept. of Biol., CUNY at Staten Island, N.Y. 10301

We have previously reported that ATP is released from electrically stimulated hippocampal slices (Wieraszko et al. Brain Res., 485: 244, 1988), and that exogenous ATP was able to induce Long Term Potentiation (LTP) in hippocampal synapses (Wieraszko and Seyfried, Brain Res., 491: 356, 1989). One of the possible mechanisms of ATP-induced LTP could be an interaction of ATP with purinergic (P2) receptors. To evaluate this assumption the influence of nonhydrolyzable antagonists of P2 receptors on LTP induced by high frequency stimulation (HFS) was investigated in mouse hippocampal slices. Each of the antagonist tested was added to the slice chamber 30 min prior of HFS. 5'-adenylylimidodiphosphate (AMP-PNP), a slowly hydrolyzable analog of ATP completely blocked induction of LTP at 37.8 μ M, but was ineffective at 4.7 μ M. Cicarbon Blue, an antagonist of P2z receptor, while not effective at 10 μ M, blocked induction of LTP at 40 μ M. A potent antagonist of P2y receptors, 2-methylthio-ATP inhibited LTP at the concentration above 7.0 μ M. ATP- γ -S, a slowly hydrolyzable analog of ATP blocked induction of LTP at concentrations above 35.0 μ M. α - β -methyl ATP, an ATP receptor antagonist of P2x receptors was unable to block LTP even at 40.0 μ M. The pattern of LTP inhibition, exerted by ATP receptor antagonists was similar. While all of them blocked LTP, they were unable to block short lasting (2-5 min) increase of the potential immediately after HFS. These results suggest that P2 receptors, while not involved in triggering of short-lasting facilitation of synaptic transmission, play an important role in LTP. The research is in the progress to identify the subtypes of P2 receptors participating in LTP. Supported by NIH grant # NS27866 and PSC-CUNY grant #662171.

Angiotensin II and losartan modulation of posttetanic and long-term potentiation. D.L. Armstrong*, E. Garcia, B. Quinones, M. Villanueva, and M. J. Wayner. Division of Life Sciences, The University of Texas at San Antonio, San Antonio, Texas 78249-0662.

The results of these experiments demonstrate that angiotensin II (All) blockade of long-term potentiation in hippocampal slices can be inhibited by losartan application to the slice perfusion fluid. Previous *in vivo* experiments have shown that losartan, an AT₁ receptor antagonist, inhibits All actions in the hippocampus when administered peripherally, or when injected intrahippocampally in combination with the peptide. Transverse hippocampal slices were prepared using male, Sprague-Dawley rats and, after a 1-2 hr incubation period, slices were transferred as needed to a constant perfusion recording chamber. Population spikes were extracellularly recorded from the stratum granulosum following application of 0.1 ms duration stimulation pulses to the perforant path. The amplitude from the initial positive wave of the spike to peak negativity was measured once a minute for a 30 min baseline period. One second tetanic stimulation trains (100 Hz) were used to induce LTP. Under control conditions, a 30 to 40% increase in spike amplitude was observed in 7 out of 10 slices. In the presence of 487 nM All, both LTP and posttetanic (PTP) responses were blocked in all slices tested (n=8). Complete blockade of LTP, but not PTP, was observed with 47.8 nM All (n=5), while 4.78 nM All had minimal effect on LTP (n=4). When 2.48 μ M losartan preceded the All application, the effects of the peptide were eliminated (n=6). In experiments where only losartan was applied a 60% increase in PTP amplitude was observed. This interesting effect indicates that losartan could be acting at presynaptic sites on perforant path terminals.

Antidromically-Conditioned E-S Potentiation is not Blocked by GABA_A Inhibitors. Lee W. Campbell*, Jennifer M. Jester, Terrence J. Sejnowski. Computational Neurobiology Laboratory, Salk Institute, La Jolla, CA

Long-term potentiation (LTP) of the population spike in excess of that predicted by increase in the slope of the field excitatory post-synaptic potential (EPSP) has been described as a component of theta-burst LTP (Exp Brain Res 79:633-641). An increase in the ratio of excitation to inhibition, a reduction of tonic inhibition, and a decrease in spike threshold are thought to contribute to this EPSP-to-spike (E-S) potentiation. Associative LTP using antidromic stimulation as the conditioning stimulus produces a stable increase in the population spike amplitude, but no change in the slope of the EPSP (Soc Neuro Abstr 17:533.15). Do changes in tonic or synaptic inhibition underlie the associative form of E-S potentiation as they are thought to do in theta-burst E-S potentiation?

The EPSP and population spike were recorded from the CA1 layer of rat hippocampal slices. The antidromic conditioning stimulus was 50 bursts of 5 pulses at 100 Hz with an interburst interval of 200 ms delivered to the alveus. The Schaffer-collateral pathway was stimulated once per burst. In some slices the GABA_A blockers picrotoxin (10 μM) and/or bicuculline (10 μM) were added to the bath prior to testing. When paired together, the antidromic and orthodromic stimuli produced a potentiation of the population spike, even in the presence of the GABA_A blockers (138% ± 16.7; mean ± s.e.m.). In contrast, the E-S potentiation component of theta-burst LTP is blocked by GABA_A inhibitors.

Intracellular recordings from the CA1 layer reveal an increase in excitability following associative E-S potentiation. Paired t-tests suggest that a depolarization of the resting membrane potential (RMP) accounts for the increased excitability (ctrl -63.7 ± 0.326 mV, 15 min. post tetanus -61.2 mV ± 0.438; mean RMP ± s.e.m., P = 0.04, F₁ = 9.08). Spike threshold, input resistance, and time constant of the membrane were not affected by associative E-S potentiation.

DENDRITIC LOCALIZATION OF LTP AND LTD
C.M. Coussens* & T.J. Teyler, Neurobiology, NE Ohio Col. of Med., Rootstown, OH 44272.

This experiment analyzed the distribution of LTP and LTD in dendrites of CA1 hippocampus. A "rake" stimulating electrode was placed orthogonal to the Schaffer collaterals and a recording electrode was placed in the cell body layer. Baseline recordings were obtained from each of the 6 stimulating electrodes spanning stratum radiatum/stratum lacunosum-moleculare (every 100 μm). Then, a 50 Hz tetanus was delivered to a mid-point electrode ~300 μm from the fissure. At 20 min post-tetanus, LTP was seen at the tetanus site and at distal synapses, whereas LTD toward the cell body was rarely noted. LTD was seen in 4 out of 10 slices at sites adjacent to the boundary of potentiated synapses.

When depotentiating stimulation (3-5 Hz for 900 pulses) was given to the previously tetanized site, depotentiation was observed there and, to a lesser degree, at adjacent previously potentiated synapses. These results show that LTP is distributed over a large extent of the dendrite, but depotentiation is a more focal phenomenon. These results may reflect the anatomy of the afferents activated, diffusion of second messengers, or activation of voltage dependent processes along the dendrite.

THE SIGN OF LONG-LASTING EAP MODIFICATIONS IN THE DENTATE GYRUS IS PREDICTED BY THE SEQUENCE OF ISO-CCK APPLICATION TO THE RAT HIPPOCAMPAL SLICE. D. Dah* J. Li, and T. Anderson. The University of Texas at Dallas, Richardson, TX 75083.

Cholecystokinin (CCK) and baclofen (BAC, a γ-aminobutyric acid_B [GABA_B] agonist) similarly potentiate paired-pulse facilitation in the dentate gyrus (DG), suggesting the involvement of a common substrate. Given the synergy of BAC-isoproterenol (ISO-a β-adrenergic agonist) in induction of long-lasting potentiation in the DG, CCK-ISO modulation of neuronal responses may also be expected.

In the hippocampal slice preparation, application of 75 nM ISO for 15-30 min induced a potentiation of EAPs that reversed to baseline upon a 30 min wash with ISO-free artificial cerebrospinal fluid (ACSF). However, when the wash was followed by a 15 min application of 1 μM CCK, potentiation of the EAP reoccurred that persisted through a second 30 min of wash with drug-free ACSF.

When 1 μM CCK was added after 15 min of ISO, such that there was a concurrent application of ISO-CCK, then the ISO-induced potentiation reversed to a long-lasting depression that persisted through 30 min of wash with drug-free ACSF.

Concurrent application of ISO and a β-adrenergic antagonist (1 μM propranolol or 1 μM timolol) or the N-methyl-D-aspartate antagonist APV (10 μM) blocked the reversible ISO-induced potentiation and also the postwash potentiation associated with CCK. The depression associated with concurrent ISO-CCK was also blocked by application of the antagonists.

These results suggest an interaction between β-adrenergic receptors and CCK in the modification of DG granule cell responses.

DEHYDROEPIANDROSTERONE SULFATE AFFECTS LTP IN AREA CA1 OF THE RAT HIPPOCAMPUS. J.H. Meyer*, G. Wittenberg, R.D. Randall and D.L. Gruol. Dept. of Neuropharmacology and Alcohol Research Center, The Scripps Research Institute, La Jolla CA. 92037.

Neurosteroids such as dehydroepiandrosterone sulfate (DHEAS) affect both GABA_A-mediated IPSPs as well as excitatory neurotransmission. We have explored whether DHEAS can influence paired-pulse facilitation and long-term potentiation (LTP) in a rat hippocampal slice preparation.

Hippocampal slices from Sprague-Dawley rats were placed in an interface type slice chamber and perfused with artificial cerebrospinal fluid (ACSF). Extracellular synaptic field potentials in response to Schaffer collateral stimulation were recorded from the CA1 stratum radiatum. Paired pulse stimulation (inter-pulse interval 20-200 ms) was used during baseline recordings. Slices were then perfused with either ACSF (control slices) or 10 μM DHEAS (experimental slices) and paired pulse responses again obtained after a 1/2 hour period. Changes in synaptic responses of control slices were compared to changes noted in DHEAS-exposed slices. Subsequently, single pulse responses were recorded at 1 minute intervals in each slice both before and after induction of LTP. LTP responses noted in control slices were then compared to LTP responses seen in DHEAS-exposed slices. Analysis of the paired pulse responses indicated that DHEAS had no effect upon facilitation at any inter-pulse interval, arguing against any pre-synaptic effect of the steroid. DHEAS, however, did significantly augment the magnitude of LTP induced in area CA1. Such results may account for behavioral effects of DHEAS in which this neurosteroid has been noted to enhance memory (Soc. Neurosci Abstr 18; 1160). Supported by AA6420 and AA0756.

THE EFFECTS OF A NITRIC OXIDE SYNTHASE INHIBITOR ON LONG TERM POTENTIATION IN AREA CA1 OF RAT HIPPOCAMPUS
S. M. Nicola, J. A. Cummings and R. C. Malenka* Neuroscience Graduate Program, University of California, San Francisco, CA 94143

The search for a retrograde messenger thought to be necessary for LTP has focused recently on nitric oxide (NO). To test the hypothesis that NO production is required for LTP, we attempted to obtain LTP in area CA1 of hippocampal slices that had been incubated in the NO synthase inhibitor N^G-nitro-L-arginine (NOArg, 100-500 μM) for 1.5-11 hr at room temperature (21-23°C). The LTP induction protocol, given at 27-29°C, consisted of two 100 Hz, 1 s tetani at increased stimulus intensity. No significant reduction in LTP magnitude was observed in NOArg-treated (n=14) vs control (n=11) slices (LTP at 50-60 min post-tetanus: control=162±16%, NOArg=135±14%, P>.2). The study was then repeated in a blind manner, such that the experimenters did not know whether slices had been incubated in NOArg (100 μM) until after data analysis was complete. The induction protocol used in the blind study (four 100 Hz, 1 s tetani at control stimulus intensity, temperature 25-29°C, slices from 14-18 day old rats) resulted in LTP that was identical in magnitude in both control (n=11) and NOArg-treated (n=12) slices (control LTP=149±9%, NOArg LTP=148±12%, P>.5). To assess whether the NOArg was effective in permeating cells and inhibiting NO synthase, we incubated slices from 14 or 15 day old rats blindly in 100 μM NOArg or in control medium exactly as previously, applied 100 μM NMDA for 10 min at 27-29°C, and determined the level of cGMP per mg protein. Consistent with others' findings, NOArg completely blocked the NMDA-stimulated increase in cGMP observed in control slices (n=3). Our results suggest that NO synthase activity is not required for the induction of LTP under these experimental conditions.

THE INVOLVEMENT OF α-TOCOPHEROL IN LONG-TERM POTENTIATION.
Z. Xie* and B. R. Sastry. Neuroscience Research Laboratory, Dept. of Pharmacology and Therapeutics, The University of British Columbia, Vancouver, B. C., Canada, V6T 1Z3.

An increase in lipid peroxide content in hippocampus has been implicated in the impairment of learning ability in vitamin E-deficient rats. In the present studies, the ability of α-tocopherol phosphate (0.2 mM, applied for 5 min), a major antioxidant, to induce long-term potentiation (LTP) of the stratum radiatum stimulation-induced excitatory postsynaptic potentials (EPSPs) in CA1 neurons in guinea pig hippocampal slices was examined. α-Tocopherol induced a slowly developing LTP of the EPSP without changing the membrane potential and the input resistance (n=16), or the fast and the slow inhibitory postsynaptic potentials (IPSPs) (n=8). α-Tocopherol failed to induce a further potentiation of the EPSP during a pre-established tetanus-induced LTP (n=10). The chelation of postsynaptic Ca²⁺ with BAPTA (n=6) or the inhibition of protein kinase C (PKC) by sphingosine (n=6) or K-252b (n=6) prevented the α-tocopherol-induced LTP. AP3 (100 μM, n=8), but not APV (40 μM, n=6), blocked the α-tocopherol-induced LTP. α-Tocopherol also did not significantly alter the depolarization of CA1 neurons induced by glutamate (applied in normal medium containing APV, n=6) or by NMDA (applied in Mg²⁺-free medium containing CNQX, n=6). Tetanic stimulation of the stratum radiatum failed to induce LTP of the EPSP in hippocampal slices of vitamin E-deficient rats (n=10); application of α-tocopherol also did not induce LTP in these slices (n=6).

These results indicate that vitamin E is involved in LTP in the hippocampal CA1 neurons. The activation of the metabotropic glutamate receptors, postsynaptic Ca²⁺ and the activation of PKC may be required for this LTP. It appears that in vitamin E-deficient rats LTP-induction is compromised not only because α-tocopherol is depleted but also since something else is adversely affected.

MOLECULAR CHARACTERIZATION OF CALCIUM CHANNEL SUBTYPES EXPRESSED IN APLYSIA NEURONS. B.H. White* and L.K. Kaczmarek, Yale University School of Medicine, Dept. of Pharmacology, New Haven, CT 06510.

To study the localization and regulation of neuronal calcium channels in the sea hare *Aplysia californica* we have begun to develop molecular probes that will recognize them. As a first step we have used reverse transcription coupled to the polymerase chain reaction (RT-PCR) to amplify partial sequence of the Ca⁺⁺-channel α_1 -subunits expressed in *Aplysia* head ganglia, abdominal ganglion, and bag cell neurons. Primer sets targeting the regions IS6 to IIS5 and IVS1 to IVS6 amplify multiple Ca⁺⁺-channel fragments from *Aplysia* ganglia and bag cell neuron RNA. We have focussed our attention on two bag cell neuron Ca⁺⁺-channel fragments spanning the region from IS6 to IIS5 (BCCA-I and BCCA-II). These fragments are 50% identical at the amino acid level and appear to be related to distinct subtypes of mammalian neuronal Ca⁺⁺-channels. The BCCA-I sequence is 65% identical to an N-type α_1 -subunit from rabbit brain (BIII, Fujita et al. (1993) *Neuron* 10, 585-598) over the IS6-IIS5 region, while the BCCA-II sequence is 66% identical to an L-type rat brain Ca⁺⁺-channel found predominantly in neuroendocrine tissues (RB α_1 , Hui et al. (1991) *Neuron* 7, 35-44 and Chin et al. (1992) *FEBS Lett.* 299, 69-74). Fusion constructs containing the nonconserved I-II linker regions of BCCA-I and BCCA-II have been prepared for the generation of subtype-specific antibodies.

THE α_2 AND β SUBUNITS OF THE ω -CGTX GVIA RECEPTOR ARE REQUIRED FOR EFFICIENT CELL SURFACE EXPRESSION AND AFFECT THE ω -CGTX BINDING AFFINITY. P.F. Brust, S. Simerson, S. Schoonmaker, C. Deal, G. Velicelebi, E.C. Johnson* and S.B. Ellis, SIBIA, Inc., La Jolla, CA 92037.

The α_2 subunit of high-voltage-activated calcium channels has been shown to potentiate the current magnitude without a discernable change in the electrophysiological properties of the channel. In contrast, the β subunit potentiates the current magnitude with noticeable effects on both the current activation and inactivation kinetics. Previously, we showed that the α_{1B} - α_{2B} - $\beta_{1,2}$ subunit combination formed an ω -CGTX GVIA sensitive, N-type calcium channel when equimolar concentrations of each expression plasmid were transiently coexpressed in HEK293 cells. We have subsequently altered the molar ratios of α_{1B} , α_{2B} and $\beta_{1,2}$ plasmids to achieve equivalent mRNA levels. The effects of the altered plasmid ratios were assessed by ω -CGTX GVIA binding and electrophysiological analyses. Coexpression of the three subunits with the altered ratios resulted in 45,000 receptors/cell, whereas coexpression of the α_{1B} and $\beta_{1,2}$ subunits, the α_{1B} and α_{2B} , or the α_{1B} subunit alone resulted in significantly fewer receptors per cell, 5750, 2250 and 800 sites/cell, respectively. The difference in the current density observed between the α_{1B} - α_{2B} - $\beta_{1,2}$ combination was 94 pA/pF compared to 5.6 pA/pF for the α_{1B} - $\beta_{1,2}$ combination. These results suggest that coexpression of the α_{1B} , α_{2B} and $\beta_{1,2}$ subunits is required for efficient expression of the channel complex on the cell surface. The determined K_d value of each receptor combination for ω -CGTX GVIA also differed, 55 pM, 18 pM, 85 pM and 32 pM for the α_{1B} - α_{2B} - $\beta_{1,2}$, α_{1B} - $\beta_{1,2}$, α_{1B} - α_{2B} and α_{1B} combinations, respectively. These results demonstrate that both the α_{2B} and $\beta_{1,2}$ subunits affect the binding characteristics of ω -CGTX GVIA.

THE INVOLVEMENT OF N, P AND L-TYPE CALCIUM CHANNELS IN NEUROTRANSMITTER RELEASE INDUCED BY DIFFERENT DEPOLARIZATION STRENGTHS. I.A. Pullar*, J. Harvey, S. Wedley and J.D. Findlay, Lilly Research Centre Ltd., Eli Lilly and Company, Windlesham, Surrey, U.K.

Keith et al. (Biochem. Pharmacol. 1993, 45, 165-171) showed that the block of noradrenaline release by the N-type Ca²⁺ channel antagonist, ω -conotoxin GVIA (CGTx), depended on the degree of depolarization. We have investigated the Ca²⁺ channels involved in the release of acetylcholine (ACh) and 5-HT from rat cortical slices induced by 30 and 50mM K⁺. Slices (350 μ m), prelabelled with ³H-choline or ³H-5-HT, were exposed to the antagonists for 15min prior to depolarization with K⁺ for 4min. CGTx (0.3 μ M), which produced a maximal (c.50%) block of ACh and 5-HT release induced by 30mM K⁺, was less effective (max. 20%) at blocking 50mM K⁺ stimulated release. The block produced by the P-channel antagonist, ω -Aga IVA, (0.3 μ M), however, was independent of stimulus strength (10% ACh, 40% 5-HT). The L-type Ca²⁺ channel antagonist, nifedipine (1.0 μ M), was ineffective at blocking ACh or 5-HT release. The block of 5-HT release obtained with the two toxins was additive whereas with ACh synergism was observed. The results indicate that, when depolarized with 30mM K⁺, the Ca²⁺ required for 5-HT release enters through both the P and N channels whereas with ACh the P channel is not involved unless the N channels have been previously blocked. At 50mM K⁺ the P and N channels only account for 50-60% of release. L channels are not involved in the release of either of the transmitters.

548.2

CALCIUM CHANNEL β SUBUNIT SPLICE VARIANT ALTERS INACTIVATION KINETICS OF α_{1B} CALCIUM CHANNELS. E.C. Johnson, P.F. Brust, A.F. McCue, L.E. Chavez-Noriega*, S.B. Ellis, and M.M. Harpold, SIBIA, Inc. La Jolla, CA 92037.

HEK293 cells transiently expressing the α_{1B} - α_{2B} - $\beta_{1,2}$ recombinant calcium channel yield ω -CGTX GVIA sensitive, N-type calcium currents (Williams et al. 1992, *Science* 257:389-395). The deduced $\beta_{1,2}$ subunit amino acid sequence is identical to that of $\beta_{1,2}$ for 444 amino acids, they diverge for 34 amino acids and $\beta_{1,3}$ extends an additional 120 amino acids. We compared the properties of the whole cell currents of HEK cells expressing the α_{1B} - α_{2B} - $\beta_{1,2}$ and α_{1B} - α_{2B} - $\beta_{1,3}$ calcium channels. The current voltage curves from each were essentially identical, and peaked at 10-20 mV. Both have similar sensitivities to holding potential, with half maximal inactivation at approximately -57 mV. Both have similar voltage dependence of activation (measure from tail currents) with half maximal activation at approximately 5 mV. Both have similar kinetics of activation; the slowest kinetics, approx. 3 ms, occurs at approx. 0 mV. The tail currents in both could be well fit by a single exponential and had essentially identical voltage dependence (0.1 ms @ -100 mV to \approx 0.57 ms @ -30 mV). In contrast, the voltage dependence of the kinetics of inactivation is significantly different at all voltages examined. At a test pulse from -90 mV to 0, +10, +20 or +30 mV the single exponential fit of the inactivation was 85, 96, 135, and 180 ms respectively for α_{1B} - α_{2B} - $\beta_{1,2}$ and 202, 185, 268, 354 ms respectively for α_{1B} - α_{2B} - $\beta_{1,3}$. Not only is the inactivation substantially slower with the $\beta_{1,3}$ subunit ($p < 0.008$ @ +10 mV) but the standard deviation is up to 4.6 times larger in the $\beta_{1,3}$ calcium channel. These differences in the voltage dependence and variability of inactivation might be due to phosphorylation differences between $\beta_{1,2}$ and $\beta_{1,3}$.

548.4

PHARMACOLOGICAL PROPERTIES OF THE N-TYPE VSCC IN TRANSFECTED HEK 293 CELLS. D. Bleakman*, P.F. Brust, D. Bowman, C.J. Grantham, S.B. Ellis, R.J. Miller, & M.M. Harpold, Lilly Research Centre Ltd., Windlesham, Surrey, U.K. and SIBIA Inc. La Jolla, CA 92037, U.S.A.

Recently, Williams et al., (*Science* 1992, 257,389-395), cloned and transfected an N-type Ca²⁺ channel from human brain into a human kidney cell line (HEK 293). We have investigated the properties of this channel using combined whole cell voltage clamp electrophysiology and fura-2 based microfluorimetry. Cells were depolarized (V_h = -80mV to V_t = +10mV) and an increase in the [Ca²⁺]_i was observed concurrent with a rapidly activating, slowly inactivating current (range 150pA to 2 nA). Ca²⁺ currents were inhibited reversibly by Cd²⁺ (1 μ M) and irreversibly by ω -CGTXGVIA (5 μ M). Ca²⁺ influx was not observed in untransfected HEK 293 cells. ω -CGTX-GVIA produced concentration- and time- dependent inhibition of Ca²⁺ influx into transfected HEK 293 cells. The threshold for this effect was 1nM and complete inhibition of influx was observed at 1 μ M. In contrast, the P-type Ca²⁺ channel blocker ω -Aga IVA (300nM) had no effect on evoked Ca²⁺ influx. Flunarizine (1 μ M), a mixed function Ca²⁺ channel antagonist, inhibited Ca²⁺ uptake in these cells. However, the L-type calcium channel antagonists, nifedipine (1 μ M), verapamil (1 μ M) and diltiazem (1 μ M) were inactive. In conclusion, the transfected Ca²⁺ channel has characteristics of an N-type Ca²⁺ channel.

FATTY ACYLATION OF A PUTATIVE PRESYNAPTIC CALCIUM CHANNEL SUBUNIT FROM TORPEDO. C.B. Gunderson, A. Mastrogiacomo and J.A. Umbach, Dept. Pharmacology and Jerry Lewis Neuromuscular Research Center, UCLA School of Medicine, Los Angeles, CA 90024.

Recent investigations revealed that the candidate presynaptic calcium channel subunit (CCCS₁) of Torpedo is post-translationally modified (*Soc. Neurosci. Abst.* 18 435, 1992). While pilot investigations failed to provide evidence that this protein is glycosylated (Asn residue 25 being a candidate for N-glycosylation), subsequent efforts indicated that CCCS₁ is fatty acylated: First, when CCCS₁ cRNA is expressed in *Xenopus* oocytes, one can detect the presence of 27kDa and 34kDa immunoreactive species of CCCS₁. The 27kDa species is soluble while the 34kDa species is membrane bound. When the 34kDa species is treated either with 1M hydroxylamine (pH 7.0) or 0.1M KOH in methanol, its mass is reduced to 27kDa. This result is compatible with CCCS₁ being fatty acylated. Complementary experiments reveal that if ³⁵S-labeled CCCS₁ is injected into oocytes, approximately half of the injected protein is acylated within 24h to generate the 34kDa species. Moreover, this 34kDa species (but not the 27kDa species) is membrane bound. From these results, we conclude that oocytes harbor an acyltransferase that can fatty acylate CCCS₁, and that this acylation is responsible for the membrane association of this protein. Finally, similar experiments have revealed that CCCS₁ from Torpedo is fatty acylated and the identity of these acyl groups is being determined.

NEURONAL CALCIUM CHANNELS SUBTYPES EXPRESSED IN RAT INSULINOMA AND HUMAN PANCREATIC BETA-CELLS. A. Pollo*, V. Magnelli, M. Lovallo, E. Sher* and E. Carbone. Dept. of Anatomy and Human Physiology, Univ. of Turin, Italy. (P)CNR Ctr. Cytopharmacology, Univ. of Milan, Italy.

We have investigated the coexpression of different Ca channel subtypes in the rat insulinoma cell line RINm5F and in human pancreatic β -cells using whole-cell and single channel current recordings. Whole-cell currents in RINm5F cells could be attributed to at least one LVA and three HVA channel subtypes, similar for activation/inactivation kinetics and pharmacology to those already described in neurons. HVA Ba currents tended to activate at -30mV, peaked at +10 and reversed at +50. The dihydropyridine (DHP) antagonist nifedipine (10 μ M) reversibly blocked only 55% of the total current at 0mV, while ω -conotoxin (ω -CgTx, 3.2 μ M) irreversibly blocked a smaller fraction (10-20%). The residual DHP- and ω -CgTx-insensitive current was shown to be sensitive to ω -Agatoxin IV A which depressed 10-30% of the total currents. ω -Aga action was partially relieved by high and frequent depolarizations. In human β -cells, DHP action was stronger (85% block at -10mV), while ω -CgTx and ω -Aga were poorly effective. Single channel recordings in cell-attached and outside-out patches of RINm5F cells revealed a dominance of L-type channels with prolonged openings of large conductance (22-25pS in 100mM Ba) in the presence of Bay K 8644 (1 μ M). In 25% of the patches, however, L-type channels of smaller conductance (10-12pS) as well as DHP-insensitive channels were also observed. DHP-insensitive channels in ω -CgTx-treated cells showed prolonged activity for 300-500ms with short mean open times (1-2ms) and multiple conductance levels (9 to 20pS) that disappeared at low holding potential (-50mV).

548.9

THE α -1 SUBUNIT OF AN N-TYPE VOLTAGE SENSITIVE CALCIUM CHANNEL IS PRESYNAPTIC TO PURKINJE CELL DENDRITES. R. Dado¹, R. Feddersen², D.R. Witches³, C. Honda¹, H. Orr², K.P. Campbell³ and R. Elde¹. Dept. Cell Biol. and Neuroanat.¹, Lab. Med. and Path.², Univ. Minn., Minneapolis, MN 55455; Howard Hughes Med. Inst. & Dept. Physiol. & Biophys.³, Univ. Iowa, Iowa City, IA 52242

Ca²⁺ spiking in Purkinje cell (PC) dendrites is known to be mediated by P-type voltage sensitive calcium channels (VSCCs). However, Westenbroek et al., (1992) have recently suggested that dendritic Ca²⁺ spiking may also be conducted via an N-type channel. In the present study, we used *in situ* hybridization and immunocytochemistry to determine the identity of cells whose membranes contain N-type channels. *In situ* hybridization studies of PCs using oligonucleotide probes selective for each class of α -1 subunits (A, B, C & D; see Overstreet et al., Soc. Neurosci. Abstr., 1993) revealed abundant expression of transcripts for A and D classes, but class B and C transcripts were undetectable over PCs. However, transcripts for all 4 classes were expressed by neurons which provide synaptic input to PCs, including cerebellar granule cells and cells in the inferior olivary nucleus. Confocal microscopy of preparations stained with class B specific antibodies (see Elde et al., Soc. Neurosci. Abstr., 1993) in combination with antibodies to calbindin revealed a striking arrangement of class B α -1 immunoreactive (CBA-1-ir) puncta which were presynaptic to dendrites and spines of PCs. The position of many of these CBA-1-ir puncta was consistent with the known distribution of terminals of climbing fibers. Lesions of inferior olivary neurons (the source of most climbing fibers to the cerebellum) with 3-acetylpyridine destroyed a major portion of the CBA-1-ir puncta. In addition, CBA-1-ir puncta were present, but restricted to the shaft of climbing fiber axons in the cerebellum of transgenic mice lacking PCs due to the expression of the SV-40 large T antigen under a PC-specific promoter.

In conclusion, PCs express transcripts which encode α -1 subunits of P- and L-type VSCCs; they do not express a class B transcript which encodes an N-type VSCC. Thus, Ca²⁺ spiking in PCs is unlikely to be mediated by this N-type VSCC. Instead, the present data suggest that N-type VSCCs participate in neurotransmitter release from climbing fiber terminals. STRUCTURAL DETERMINANTS OF ION SELECTIVITY IN BRAIN CALCIUM CHANNEL Yasuo Mori* Man-Suk Kim†, Takashi Morii§ and Keiji Imoto† *Dept. of Pharmacology and Cell Biophysics, Univ. of Cinti., Cinti., OH 45267-0575 †Dept. of Medical Chemistry, Kyoto Univ., §Dept. of Polym. Sci., KIT, Kyoto 606, Japan Under physiological conditions, calcium channels must be highly selective in allowing large Ca²⁺ fluxes. Little direct information concerning the structural basis of this selective permeability has been available. To address this issue, Glu residues in the SS2 segment of the internal repeat III and IV of the brain calcium channel BI (Glu-1,469 and Glu-1,765) have been subjected to single point mutations. The mutants expressed in *Xenopus* oocytes were tested for macroscopic current properties and sensitivities to inorganic blockers using 40 mM Ba²⁺ as the charge carrier. The mutation that replaces Glu-1,469 with Gln (E1469Q) caused a marked shift in reversal potential to the negative direction (from +58 mV to +38 mV). Although smaller in degree, the mutation that replaces Glu-1,765 with Gln (E1765Q) also caused a shift (to +50 mV). While the IC₅₀ was considerably low for the wild-type (0.73 μ M), the mutation E1469Q made the IC₅₀ value for Cd²⁺ more than 200 times larger (201 μ M), without affecting sensitivities to other inorganic blockers very much. The mutation E1765Q did not significantly change sensitivities to inorganic blockers including Cd²⁺. These results indicate that the mutations altered the strict selectivity for divalent cations over monovalent cations, and imply that the Glu residues differentially take part in forming the selectivity filter of the calcium channel.

CODISTRIBUTION OF NCAM AND DIHYDROPYRIDINE RECEPTOR ALPHA-2 SUBUNIT DURING EARLY MYOGENESIS *IN VITRO*. F. Rieger* and S. Vandaele, Groupe de Biologie et de Pathologie Neuromusculaires, INSERM U.153/CNRS 0064, Paris (France) and Unité de neurocytologie moléculaire, Département de Pathologie, Université de Montréal (Canada).

We further characterized the monoclonal antibody (Mab) 3007 previously selected by its ability to immunoprecipitate dihydropyridine binding sites associated with voltage-dependent calcium channels of skeletal muscle (Vandaele et al., 1987). Mab 3007 immunoprecipitated only the α 2-subunit from iodinated solubilized T-tubule membranes, in conditions where the five subunits constituting the dihydropyridine receptor are dissociated. When used to immunocytochemically decorate rabbit muscle sections, Mab 3007 revealed a labelling pattern corresponding to the dihydropyridine receptor localization in the T-tubule network. Lastly, when incubated with solubilized membranes from ³⁵S-methionine-labelled rabbit muscle cell culture, Mab 3007 precipitated a unique polypeptide corresponding to the α 2 subunit.

Using Mab 3007 and an anti-NCAM polyclonal antiserum, the surface distribution of the α 2-subunit and its topographical relationship with the NCAM were then studied immunocytochemically during early myogenesis *in vitro*. On aligned myoblasts before fusion, the α 2-subunit and the NCAM appeared uniformly distributed. On contracting myotubes, both molecules were organized in clusters grouped into "super-clusters". A high percentage of α 2-subunits and of NCAM "super-clusters" were colocalized. Within the colocalized "super-clusters", NCAM and α 2-subunit cluster staining patterns were exactly superposed. These results suggest that, at this stage of myotube differentiation, the α 2-subunit is first directed towards the myotube plasma membrane before being restricted to the T-tubules, and that it may be cotransported with NCAM. It might also be possible that these two molecules interact during early myogenesis *in vitro*.

AXONAL TRANSPORT OF AN α -1 SUBUNIT OF AN N-TYPE VOLTAGE SENSITIVE CALCIUM CHANNEL IN SCIATIC NERVE AND DORSAL ROOTS OF RATS. R. Elde¹, R. Dado¹, D.R. Witches², C. Wetmore¹* and K.P. Campbell². Dept. of Cell Biol. and Neuroanat.¹, Univ. of Minn., Mpls, MN 55455; Howard Hughes Med. Inst. & Dept. Physiol. & Biophys.², Univ. Iowa, Iowa City, IA 52242.

Voltage sensitive calcium channels are importantly involved in neurotransmitter release. However, little is known concerning the mechanisms by which these channel proteins are targeted to the presynaptic membrane. Antisera were obtained from rabbits immunized with a peptide (residues 851-867 of the class B α -1 subunit; Dubel et al. 1992) coupled to thyroglobulin or a fusion protein (residues 720-1139; Witches et al. 1993). After affinity purification, immunostaining was observed in neurons which expressed transcripts for this subunit as determined by *in situ* hybridization (see Dado et al.; Overstreet et al., Soc. Neurosci. Abstr., 1993). Rats were deeply anesthetized and the sciatic nerve or lumbar dorsal roots were constricted with a tight ligature. After recovery ranging from 2-48 hrs, animals were sacrificed and longitudinal sections of sciatic nerves and dorsal roots were immunostained and observed using confocal microscopy. Class B α -1 immunoreactivity (CBA-1-ir) appeared as intensely stained, but sparsely distributed particles within the axoplasm of unperturbed nerves. After constriction of the sciatic nerve, CBA-1-ir appeared as large clusters of tightly packed particles within the axoplasm of individual axons proximal to the constriction. This suggested that the particles of CBA-1-ir travel by anterograde axonal transport, although not in the fastest phase, since the majority of CBA-1-ir clusters were located proximal to clusters of particles immunostained with antisera to neuropeptides (CGRP, SP), dopamine β -hydroxylase, and synaptotagmin. Distal to the constriction no CBA-1-ir clusters were observed, suggesting, that in contrast to neuropeptides, dopamine β -hydroxylase and synaptotagmin, retrograde transport of CBA-1-ir did not occur. Constriction of dorsal roots gave similar results. In addition, CBA-1-ir was observed in nerve fibers and terminals in the dorsal horn of the spinal cord and in the dorsal column nuclei, suggesting that CBA-1-ir is delivered to nerve terminals by anterograde axonal transport in primary afferent neurons. Supported by DA06299 and DA08131.

ELECTROPHYSIOLOGICAL AND PHARMACOLOGICAL COMPARISON OF A FAMILY OF NEURONAL CALCIUM CHANNELS. A. Steg*, T.W. Soong, C.D. Hodson, S.J. Dubel, W.J. Tomlinson, and T.P. Snutch, Biotechnology Laboratory, University of British Columbia, Vancouver, B.C., V6T 1Z3.

Several different Ca channel α 1 subunits have been cloned from rat brain (designated rBa, rBb, rBc, rBd, and rBe). Four of these channels have been expressed in *Xenopus* oocytes by nuclear injection of cloned DNA. The rBa current in 40 mM Ba rapidly activated ($\tau \sim 5$ ms) and showed slow inactivation ($\tau \sim 500$ ms), whereas the rBb current activated very slowly ($\tau \sim 60$ ms) and hardly inactivated over 800 ms. The rBc current showed variable activation rates ($\tau \sim 20$ ms) with little inactivation over 800 ms. The rBe-II current activated completely within 20 ms ($\tau \sim 3$ ms) and showed relatively fast inactivation ($\tau \sim 100$ ms). The voltage dependent properties of the four Ca channel α 1 subunits was significantly different. Half of the rBa and rBb currents were activated during a step to ~ -1 mV (holding potential -100 mV), while half the rBc current was activated at +4 mV. In contrast half the rBe current was activated at a more hyperpolarized potential of -15 mV. In 4 mM Ba the rBe current activated in the range of some low voltage-activated channels. The currents also differed in their sensitivity to holding potential. Approximately one-half of the rBa, rBb and rBc currents were inactivated at a holding potential of -30 mV while this potential completely inactivated rBe-II (half-inactivation ~ -60 mV). Pharmacological characterization showed the rBc current was sensitive to dihydropyridines (L-type). The rBb current was insensitive to dihydropyridines and highly sensitive to ω -conotoxin GVIA (ω -CgTx) identifying it as a N-type Ca channel. The rBe current was not affected by either dihydropyridines or ω -CgTx but was sensitive to Ni. The electrophysiological properties of rBe-II are similar to a subset of T-type channels in hippocampal and thalamic nuclei. The rBa current was not completely blocked by Ag⁺ at concentrations known to block P-type channels (200 nM).

Our results confirm that a family of Ca channel α 1 subunits encodes Ca channels with diverse electrophysiological and pharmacological properties.

548.13

EXPRESSION AND LOCALIZATION OF A CALCIUM CHANNEL WHICH IS A MEMBER OF THE LOW VOLTAGE-ACTIVATED FAMILY. T.W. Soong, A. Stea, C.D. Hodson, S.J. Dubel, S.R. Vincent, and T.P. Smutch*. Biotechnology Laboratory, University of British Columbia, Vancouver, B.C., V6T 1Z3.

A rat brain Ca channel previously cloned in this laboratory (designated rE-II) has a primary structure that is more related to the class A and B proteins (53-54% identity) than the class C or D proteins (~23% identity). Nuclear injections of the rE-II clone (in PMT2 vector) into *Xenopus* oocytes gave robust currents (average > 500 nA) with 4 mM Ba as the charge carrier. These inward currents activated quickly ($\tau \sim 2$ ms) and inactivated fairly rapidly ($\tau \sim 100$ ms). The threshold for activation of the rE-II current was -50 mV and more than half the channels were open at a step to -25 mV. In addition the rE-II current was very sensitive to holding potential with half the channels inactivated at a holding potential of -65 mV. Application of nifedipine (10 μ M), Bay K8644 (10 μ M), or ω -conotoxin GVIA (1 μ M) were without significant effect on the rE-II current. AgalVA (200nM) caused a small decrease in the current (~30%) which was not reversible with depolarizing pulses. Octanol (100 μ M) and amiloride (1 μ M) had little effect on the current. However both Ni and Cd at (10-30 μ M) blocked more than 50% of the rE-II current. Coexpression of a brain β subunit with rE-II caused no major changes in the waveform or pharmacology of the rE-II current but caused significant shifts in the voltage-dependent properties of this current. rE-II + β currents were half activated at a step to -30 mV (from -100 mV) and were half-inactivated at a holding potential of -80 mV.

In situ hybridization showed that high levels of the rE-II transcripts were found in the hippocampal pyramidal cells and the granule cells of the dentate gyrus. Moderate levels were found in the olfactory bulb, striatum, and amygdala. Expression was also noted in the intralaminar, parafascicular, and reticular nuclei of the thalamus and the substantia nigra and inferior olive. Cerebellar expression was in the granule and Purkinje cells. In many brain regions expressing rE-II low voltage-activated Ca conductances sharing some of the characteristics of rE-II have been described.

Taken together the electrophysiology, pharmacology, and localization of rE-II identify it as a novel type of low voltage-activated Ca channel.

ISOLATION AND CHARACTERIZATION OF HUMAN GENOMIC CLONES FOR VOLTAGE-SENSITIVE CALCIUM CHANNELS. H.H. Jung and H. Chin*. Lab of Neurochemistry, NINDS, NIH, Bethesda, MD 20892

Recent molecular cloning studies have identified the four distinct classes (α_1 -A, α_1 -B, α_1 -C, and α_1 -D) of cDNAs that encode the α_1 subunit of voltage-sensitive calcium channels. The α_1 -D cDNA, corresponding to the DHP-sensitive, L-type calcium channels, has been isolated from a variety of excitable and nonexcitable tissues, including brain, neuroblastoma cells, pancreatic β -cells, and kidney. In contrast, expression of the α_1 -B mRNA encoding the ω -conotoxin-sensitive, N-type channels seems to be restricted to the nervous system and the cells of neuronal origin.

Since comparative analysis of the 5' upstream regulatory region of the L- and N-type calcium channel genes is likely to yield insights into the molecular mechanisms involved in cell type- or tissue-specific expression of voltage-sensitive calcium channels, we have begun to isolate the corresponding human genomic clones. In an earlier study, we reported isolation of a human genomic clone containing 5' upstream region of L-type α_1 -D subunit gene, and mapped its location to the short arm of human chromosome 3 (Chin *et al.*, *Genomics* 11, 914-919). We have now obtained two overlapping human genomic clones (insert size, 12 kb and 14 kb), and sequenced a 2-kb genomic fragment. The latter contained a 5' upstream region of the N-type calcium channel α_1 -B subunit gene including the initiation methionine residue. Currently we are further characterizing the promoter regions of both the human α_1 -B and α_1 -D subunit genes to identify regulatory elements involved in neurospecific expression of N-type calcium channel genes.

DETECTION OF THE CARDIAC CALCIUM CHANNEL mRNA IN DEVELOPING SKELETAL MUSCLE BY IN SITU HYBRIDIZATION. Y. Yang* and N. Chaudhari, Dept. of Physiology, Colorado State University, Fort Collins, CO 80253.

During the early development of skeletal muscle, mRNA for the cardiac dihydropyridine-sensitive calcium channel is detectable in fetal skeletal muscle tissue (Devel. Biol., 155:507, 1993). To define the cellular sources of this cardiac calcium channel expression, we analyzed fetal mouse skeletal muscle tissue by in situ hybridization. A 151 base antisense RNA located in the loop between repeat II and repeat III was used as a probe. A 586 base antisense RNA from Myo-D was used as a positive control. All probes were labeled with 35 S. Autoradiography reveals that the cardiac calcium channel mRNA is expressed in cells that are Myo-D positive, i.e. myoblasts and myotubes. In addition, the cardiac calcium channel mRNA is expressed in cells that are presumably fibroblasts between muscle bundles. The concentration of the cardiac calcium channel mRNA diminishes during skeletal muscle development. We have also detected the cardiac calcium channel mRNA in the G-8 fetal skeletal myoblast cell line by Northern blot hybridization. These results demonstrate that the cardiac calcium channel mRNA is expressed in myoblasts, myotubes as well as fibroblasts in developing skeletal muscle and raise the question of whether this channel may be functionally important during the early development of skeletal myofibers. Supported by NIH grant GM42652.

548.16

MOLECULAR CHARACTERIZATION OF VOLTAGE-SENSITIVE CALCIUM CHANNELS EXPRESSED IN HUMAN RETINA GLIAL CELLS. J.-J. Hwang¹, D. G. Puro², and H. Chin¹. ¹Lab of Neurochemistry, NINDS, NIH, Bethesda, MD 20892 and ²Dept. of Ophthalmology and Physiology, Univ. of Michigan School of Medicine, Ann Arbor, MI 48105.

DHP-sensitive L-type calcium channel complexes, which are composed of α_1 , α_2 , δ , and β subunits, are present in a variety of excitable and nonexcitable tissues. The cDNA corresponding to the pore-forming α_1 subunit was initially isolated from skeletal muscle. Subsequently, two additional L-type α_1 subunit genes have been identified; the first gene (α_{1C}) encoding the cardiac and smooth muscle calcium channels, and the second (α_{1D}) corresponding to the L-type channels in neurons, endocrine cells and a number of other cell types. Our earlier electrophysiological study showed that glial cells also express DHP-sensitive L-type calcium channels (Puro and Mano, *J. Neurosci.*, 11: 1873, 1991).

To further examine the molecular identity of the glial L-type calcium channels, we have carried out RT-PCR using primers specific for the calcium channel subunits. RNA samples were isolated from the glial cells that had been derived from the adult postmortem human retina and maintained in culture. Immunocytochemical markers (a specific MAb, anti-glutamine synthetase, and anti-GFAP) indicated that virtually all of the cells in culture are Müller glial cells. Sequencing analysis of the PCR subclones has indicated that the L-type calcium channel α_1 subunit in Müller glial cells is identical to the α_{1D} that has been cloned from human neuroblastoma cells (Williams *et al.*, *Neuron* 8: 71, 1992). In addition, the brain-specific splice variant of the L-type α_2 subunit, α_{2B} , is also present in retinal glial cells. PCR products corresponding to either the N-type α_1 subunit or P-type α_1 subunit have not been detected. Further studies are currently underway to determine the subunit composition of glial L-type calcium channels.

CALCIUM CHANNEL PHYSIOLOGY

VOLTAGE-GATED CALCIUM CURRENTS IN POST-NATAL CAT RETINAL GANGLION CELLS. S.-J. Huang, D.W. Robinson*, R.P. Scobey, and L.M. Chalupa. Dept. of Neurology and The Center for Neuroscience, University of California, Davis, CA95616, USA.

We have previously reported data describing the development of sodium and the potassium conductances in fetal and early post-natal cat retinal ganglion cells (RGCs). In order to provide a quantitative description of the observed spiking properties of these cells it is important to understand the type and quantity of calcium conductances present. RGCs were isolated from the retina of post-natal cats by enzymatic dissociation after retrograde labeling with rhodamine latex microsphere injections into the LGN and SC. To date we have concentrated on the activation and inactivation of L-type calcium current. Whole-cell patch clamp recordings were made from identified RGCs and L-type calcium currents were isolated by ion substitution and holding potential. All RGCs expressed L-type current varying in magnitude from cell to cell (8-400pA). The normalized conductance-voltage relationship was well fitted in all cases by the Boltzmann equation, giving a half point of activation of -0.1mV and a slope of 7.5. Based on Hodgkin-Huxley kinetics, L-type calcium currents were fitted with m^2h and the time constants of activation obtained, ranged from 0.41ms at 27mV to 2.1ms at -20mV. Steady-state inactivation was fitted by a Boltzmann equation giving a half point of inactivation of -46mV and a slope of 13.

Supported by NIH grant EY-03991 and DWR is a HFSP Fellow.

549.2

USE OF THE RAT ADRENAL CHROMAFFIN CELL FOR THE STUDY OF ADRENERGIC EXCITATION-SECRETION COUPLING. B. Hollins & S.R. Ikeda*. Dept. of Pharmacology and Toxicology, Medical College of Georgia, Augusta, GA 30912.

Chromaffin cells were isolated from the adrenal medulla of male adult Wistar rats and used within 1 to 3 days. Studies were carried out to: 1) identify Ca^{2+} channel types and 2) detect vesicle release. Voltage-activated Ca^{2+} currents were studied with whole-cell voltage-clamp. Currents were activated from a holding potential of -80 mV with 10 mM Ca^{2+} in the external solution. Under these conditions, inward currents first appeared near -40 mV and reached a maximum near 0 mV. A prominent shoulder in the I/V curve was evident near -20 mV. The L-type channel blocker, nifedipine, and the N-type channel blocker, ω -conotoxin, each blocked about one third of the current. The remaining current was resistant to ω -Aga-IVA, a P-type channel blocker.

Quantal catecholamine release in response to several stimuli could be detected amperometrically from single chromaffin cells using carbon fiber electrodes (Chow *et al.*, *Nature* 356: 60-63, 1992). Release was evidenced by a series of discrete current spikes which appeared following application of acetylcholine, 55 mM K^+ , GABA or histamine. These results indicate that both Ca^{2+} currents and vesicular release of catecholamines are conveniently measured in rat adrenal chromaffin cells. The use of voltage-clamp combined with carbon fiber voltammetry should allow for the detailed study of adrenergic excitation-secretion coupling. Supported by NIH grant HL-43242.

549.3

BIOPHYSICAL PROPERTIES OF THE PURIFIED "N-TYPE" Ca^{2+} CHANNEL IN BILAYERS.

M. De Waard, D.R. Wiltcher, and K.P. Campbell*. Howard Hughes Medical Institute and Dept. of Physiology and Biophysics, Univ. of Iowa, College of Medicine, Iowa City, IA 52242.

The ω -conotoxin GVIA (ω -CgTx) receptor has been purified from rabbit brain. The receptor is composed of four subunits of molecular masses 230 K (α_1), 140 K (α_2), 95 K and 57 K (β_2) under reducing conditions. Immunoaffinity adsorption experiments using polyclonal antibodies directed to the unique cytoplasmic loop between domains II and III of an α_1 class B subunit indicates that the purified receptor solely contains ω -CgTx sensitive α_1 isoforms. The receptor has been reconstituted into lipid bilayer at the tip of patch electrodes and the biophysical properties of the channel have been analysed. Upon incorporation into lipids, the purified receptor displays properties similar and dissimilar to the native "N-type" Ca^{2+} channel. Conserved properties of the channel include selectivity ($\text{P}_{\text{Ba}}/\text{P}_{\text{Ca}}$, P_{Na} , P_{K}) and pharmacology (ω -CgTx sensitivity, DHP and phenylalkylamine insensitivity). Properties that are at variance include a sustainable activity without detectable signs of inactivation or "run-down", conductance variability and poor or absence of voltage-dependency. Our data suggest striking similarities between the properties of the purified ω -CgTx receptor from rabbit brain and the purified DHP receptor from rabbit skeletal muscle in bilayers. The results stress the importance of cellular regulatory components in the definition of some of the biophysical properties of the native "N-type" Ca^{2+} channel.

CALCIUM REGULATION OF INTRACELLULAR pH IN PRIMARY CULTURE PITUITARY INTERMEDIATE LOBE MELANOTROPES. SJ Morris*, DM Beatty and BM Chronwall Cell Biol. and Biophys. Div. and Mol. Biol. and Biochem. Div., SBS, Univ. of Missouri-Kansas City, Kansas City, MO 64110-2499

The regulatory activities of both intracellular calcium ($[\text{Ca}^{2+}]_i$) and intracellular pH (pH_i) have greatly increased interest in the study of their interdependence. We have designed an epifluorescence video microscope which will image the fluorescence from two ratio dyes, indo-1 (for $[\text{Ca}^{2+}]_i$) and SNARF-1 (for pH_i) at video rates. Using this imaging system, we examined primary cultures of pituitary intermediate lobe melanotropes loaded with both dyes. Following experimentation, cells were positively identified by fluorescence immunohistochemistry.

K^+ -induced depolarization of melanotropes produced increases in $[\text{Ca}^{2+}]_i$ due to activation of L-type Ca^{2+} channels. A secondary Ca^{2+} peak or oscillations were often seen. After treatment with CCCP, K^+ depolarization produced a rise in intracellular $[\text{Ca}^{2+}]_i$, as well as oscillations. After thapsigargin or cyclopiazonic acid treatment, K^+ depolarization produced a primary Ca^{2+} elevation but the secondary Ca^{2+} changes disappeared. This suggests that they were due to Ca^{2+} release from an endoplasmic reticulum-type of intracellular store.

All of these increases in $[\text{Ca}^{2+}]_i$ were also directly coupled to a rise in intracellular H^+ . The close association between intracellular Ca^{2+} and H^+ suggests that the observed pH_i changes were due to release of H^+ upon binding of Ca^{2+} to intracellular buffers. This direct, obligate coupling of intracellular Ca^{2+} and H^+ opens the possibility that pH-dependent cellular processes are directly activated by sudden increases in intracellular Ca^{2+} levels. This second-messenger type of signaling system would be activated whether the Ca^{2+} was released from intracellular stores or entered the cell via plasma membrane Ca^{2+} channels.

EFFECT OF SURFACE CHARGE ON PERMEATION IN N-TYPE CALCIUM CHANNELS OF FROG SYMPATHETIC NEURONS. W. Zhou and S. W. Jones*. Dept. Physiology and Biophysics, Case Western Reserve University, Cleveland, OH 44106.

The peak whole-cell calcium current appeared to saturate with increasing $[\text{Ba}^{2+}]_o$. However, the voltage-dependence of activation shifted, as expected for 1 negative surface charge per $\sim 110 \text{ \AA}^2$. If the pore is assumed to see the same surface charge as the voltage sensor, the current increases cooperatively with local concentration, with calculated $[\text{Ba}^{2+}]_o > 1 \text{ M}$ at the mouth of the channel. This seems unrealistic. Therefore, we estimated the surface charge seen by the channel pore, from the change in the instantaneous I-V for fully activated channels upon changes in ionic strength (replacing N-methyl-D-glucamine by sucrose). The surface potential change was estimated by adjusting the control I-V to match the I-V at a different ionic strength, allowing for (1) a change in local $[\text{Ba}^{2+}]_o$ and (2) a shift along the voltage axis. A surface charge of 1 per $\sim 1500 \text{ \AA}^2$ was calculated from the measured change in surface potential, using the Grahame equation. (Activation shifted with ionic strength as expected for 1 charge per $\sim 90 \text{ \AA}^2$). This suggests that the channel pore sees much less surface charge than the voltage sensor. Thus, as others have concluded, Gouy-Chapman theory is at best an approximation. The current-local $[\text{Ba}^{2+}]_o$ relation, corrected for the effective surface charge seen by the pore, shows a slight tendency to saturate at high $[\text{Ba}^{2+}]_o$.

OUTWARD CURRENTS CONTAMINATING LOW CALCIUM WHOLE CELL PATCH RECORDINGS FROM BULLFROG DORSAL ROOT GANGLION CELLS. A.M. Holohean*, C.A. Rodriguez, J.C. Hackman and R.A. Davidoff. DVAMC and Department of Neurology, Univ. Miami Sch. Med., Miami FL 33101.

Whole cell Ca^{2+} current recordings were made from acutely dissociated dorsal root ganglion cells (*Rana catesbiana*) using the following solutions: *Internal* (mM): 110 CsCl, 10 EGTA, 5 MgCl₂, 40 HEPES, 2 ATP-Mg, 0.3 GTP, pH 7.4 with CsOH; *External*: 5 CaCl₂, 135 TEA-Cl, 10 Glucose, 0.0007 TTX, pH 7.4 with TEA-OH. Currents were elicited by depolarizing the cell in 10 mV increments from a holding potential of -50 mV. When external Ca^{2+} was reduced to 0 mM, inward Ca^{2+} currents were eliminated and outward currents were isolated and studied. Two types of outward currents were identified. In one group of cells only a slow activating, non-inactivating, nifedipine-sensitive ($>95\%$ block) current (I_{slow} : $678.6 \pm 79.4 \text{ pA}$) was seen. A second group of cells exhibited a composite current consisting of a slow activating, non-inactivating, nifedipine-sensitive current (I_{slow} : $516 \pm 116 \text{ pA}$) as well as a fast-activating, transient, nifedipine-insensitive current ($I_{\text{transient}}$: $590.8 \pm 106.2 \text{ pA}$). Whole cell capacitance measurements (C_m) demonstrated that the former group of cells ($C_m = 74.2 \pm 7.7 \text{ pF}$) were larger than latter group of cells ($C_m = 41.3 \pm 2.7 \text{ pF}$). All outward currents were blocked by the addition of Cd^{2+} . (Supported by DVAMC Funds MRIS #1769 and #3369 and USPHS grant #NS17577).

REGULATION OF VOLTAGE-GATED NEURONAL L-TYPE Ca^{2+} CHANNELS BY MEMBRANE DEPOLARIZATION J. Liu, A. Rutledge and P. J. Triggle*. Department of Biochemical Pharmacology, School of Pharmacy, State University of New York at Buffalo, Buffalo, NY 14260

We defined the regulation of neuronal Ca^{2+} channels by membrane depolarization, a pathologic stimulus. Rat pituitary cells (GH4C1) were exposed to K^+ depolarizing medium for periods to 120 min. Radioligand binding, $^{45}\text{Ca}^{2+}$ flux and Western blot analysis revealed that L-type Ca^{2+} channels undergo a number of modifications in response to membrane depolarization. The most prominent modifications are the increased sensitivity of Ca^{2+} channels to 1,4-dihydropyridine antagonists and the rapid down-regulation of Ca^{2+} channels on the cell surface. Under depolarizing condition the affinity of Ca^{2+} channels for PN200-110 is increased approximately 20-fold, which arises from an increased association rate. Depolarization for 2 hr elicits an approximately 90% reduction of Ca^{2+} channels on the cell surface. Similar observations were made with chick retinal neurons and rat cerebellar granule cells. This down-regulation is rapid, recoverable, and the recovery does not require protein synthesis. This regulation involves a transient movement of channels to the cell interior since the total cellular content of channels was unchanged. Monoclonal antibody study showed that depolarization did not alter the level of Ca^{2+} channel α_2 subunit in the cell membrane, which suggests that Ca^{2+} channel regulation does not involve the whole channel complex. Additionally, depolarization induces an up-regulation of muscarinic receptors and Go α subunits. This study shows that prolonged stimulation of Ca^{2+} channels leads to removal of Ca^{2+} channels from cell surface and stronger inhibition. (Supported by NIH grant HL16003)

INTRAMEMBRANE CHARGE MOVEMENT IN PURKINJE CELL FROM NEW BORN MICE. T. SHIMAHARA*, R. BOURNAUD and K. MELLITI. Lab. of Neurobiol. Cell. Moléc, CNRS, 91198 Gif-sur-Yvette, France

It has been proposed that a large portion of the intramembrane charge movement recorded in skeletal muscle upon membrane depolarization is involved in the excitation-calcium release coupling mechanism. The intramembrane charge movement is likely to arise from a slight rearrangement of intramolecular charges within dihydropyridine (DHP) receptors, located in the t-tubule membrane. Immunocytochemical studies have revealed the presence of DHP-sensitive calcium channels in neuronal somata of rat brain. We have analysed the biophysical and pharmacological properties of intramembrane charge movement in Purkinje cells. Experiments were performed on enzymatically dissociated cells from 15-17 day-old new born mice. Asymmetric current was recorded with whole cell clamp technique. We observed that 1) the relationship between pulse potential and amount of charge movement was described by a two-state Boltzmann equation. 2) the maximum amount of charge movement at the onset of the depolarizing pulse ($Q_{\text{on max}}$) was $29 \pm 2.3 \text{ nC/pF}$ (n=18). 3) Nifedipine (1-5 μM) and -Aga-IVA (1 μM) blocked respectively 29.9 % and 19.4 % of $Q_{\text{on max}}$.

VOLTAGE-DEPENDENT CALCIUM CURRENTS IN YOUNG AND AGED RAT DORSAL ROOT GANGLION (DRG) NEURONS AND THE EFFECTS OF TETRAHYDROAMINOACRIDINE (THA). K.M. Kelly*, N. Esmaili* and R.L. Macdonald*[#], Depts. of Neurology* and Physiology*, U. of Michigan, Ann Arbor, MI 48104.

There is relatively little information available on aging-related changes in the function of individual voltage-dependent Ca²⁺ channels (VDCCs). Aging-related alterations in the function of these channels and increased Ca²⁺ influx to neurons may be involved in the development of significant cognitive dysfunction such as impaired learning and memory. We have compared VDCC currents in young and aged rat DRG neurons and have tested the effects of THA, a centrally active anticholinesterase that has been used in the palliative treatment of patients with Alzheimer's disease. THA also has effects on K⁺ and Na⁺ currents, and inhibits VDCCs in young rat DRG neurons (Kelly et al., Neurosci Lett 1991;132:247-250).

Whole cell patch clamp recordings were obtained from acutely dissociated rat DRG neurons at 20 d, 18 mo and 30 mo of age. Sprague-Dawley rats were used at 20 d and (F344xBN)F1 rats at 18 and 30 mo of age. Neurons from 30 mo old animals had T-type currents of decreased amplitude and decreased activation and inactivation rates compared to younger animals. High threshold currents had increased amplitudes compared to younger animals. Current block by nifedipine (L-type) and ω -conotoxin (N-type) was effective in all age groups but did not abolish all currents. THA (250 μ M) completely blocked all VDCC currents in all age groups. These results indicate aging-related changes of VDCCs in rat DRG neurons and the ability of THA to block these currents in both young and aged animals.

CHARACTERIZATION OF WHOLE CELL CALCIUM CURRENTS IN "INTACT" SUBSTANTIA NIGRA NEURONS. T. DeFazio*, L. Byerly and J.P. Walsh, Andrus Gerontology Center & Dept. of Biological Sciences, University of Southern California, Los Angeles, CA 90089-0191

Whole cell recordings were obtained from substantia nigra pars compacta (SNc) neurons using the thick slice patch clamp technique. In current clamp mode most cells exhibited broad action potentials (2-5 msec), tonic activity (~9 Hz), large afterhyperpolarizations, inward rectification, and low threshold calcium spikes (LTS). These properties are consistent with the electrophysiological criteria for identifying dopaminergic SNc neurons in brain slices. The input resistances were an order of magnitude greater than those observed using microelectrode techniques.

Voltage clamp recordings were contaminated by large fast biphasic current spikes, presumably due to action potentials escaping the poor voltage control of the membrane potential. Tetrodotoxin (TTX) and tetraethylammonium (TEA) attenuated the spikes in both voltage clamp and current clamp, but did not abolish them. Substituting cesium for potassium as the main cation in the internal solution eliminated the remnants of the uncontrolled spikes and permitted the isolation of labile voltage dependent inward currents. The currents were enhanced by substituting barium for calcium in the external solution, suggesting that this current is calcium mediated. The slow activation of the current may be due to the poor voltage control of the extensive dendritic arbor of these neurons and implies that at least some of the calcium channels are dendritically located.

VOLTAGE-DEPENDENT CALCIUM ENTRY IN RAT SOMATOTROPHS. B.T. Lussier and P. Mollard*. CNRS - URA 1200, Université de Bordeaux II, 33076 Bordeaux Cedex, FRANCE.

The hypothalamic neuropeptide, growth hormone releasing hormone (GHRH), stimulates the release of growth hormone from somatotrophs of the anterior pituitary. This action of GHRH is associated with a small depolarization and an increase in the concentration of free intracellular Ca²⁺ ([Ca²⁺]). Our aim was to investigate voltage-dependent Ca²⁺ entry in single purified rat somatotrophs. To this end [Ca²⁺], was measured using the Ca²⁺-sensitive fluorescent dye indo-1 while monitoring or clamping membrane potential using "perforated" patch-clamp techniques. The following observations were made: i) a 5 s exposure to 10⁻⁷ M GHRH produced two electrical responses consisting of either a delayed, small and prolonged depolarization (5 to 10 mV), or the initiation of action potentials; ii) the sustained depolarization was associated with a prolonged increase in [Ca²⁺], while action potential gave rise to transient [Ca²⁺], spikes; iii) increases in [Ca²⁺], were dihydropyridine (DHP)-sensitive whereas sustained depolarizations were not; iv) under voltage clamp conditions, short (1 s) depolarizing (-60 to -10 mV) steps produced [Ca²⁺], spikes, while long (20-30 s) depolarizing (-50 to -40 mV) steps produced detectable steady inward Ca²⁺ currents and the associated sustained DHP-sensitive elevations in [Ca²⁺],. We conclude that the two patterns of GHRH-dependent [Ca²⁺], increase in rat somatotrophs are due to voltage-dependent DHP-sensitive Ca²⁺ entry.

EXTRACELLULAR CALCIUM-INDUCED CHANGES IN THE MEMBRANE ELECTRICAL PROPERTIES OF THYROID PARAFOLICULAR CELLS. S.H. Hsuing, H. Tamir, & D.S. McGehee*. NY State Psych Inst. Dept of Anat & Cell Biol in the Ctr for Neurobiol and Behav, Columbia Univ P&S, 630 W 168th St, NY, NY 10032.

Increases in serum calcium levels are known to stimulate calcitonin and serotonin (5-HT) release from the parafollicular C-cells of the thyroid gland. Calcitonin is known to lower serum Ca²⁺ levels; however, relatively little is known about the mechanism of release of this hormone. We are examining the processes underlying the sensitivity of these cells to extracellular Ca²⁺ in isolated primary cultures. Assays of calcitonin and 5-HT release indicate that the threshold for Ca²⁺-induced release is approx. 5mM, with maximal stimulation at 10mM. Measurements of membrane potential, using whole cell perforated patch recording, indicate that 10mM Ca²⁺ induces a slow depolarization of the membrane with an associated increase in conductance. This leads to a rhythmic series of action potentials (APs) that continues until washout of the high Ca²⁺. The interspike interval is 5-10 sec and the half width of each AP is nearly 2 sec. In voltage clamp (V_m = -60mV), application of 10mM Ca²⁺ to these cells stimulates an inward current that does not return to baseline until washout. Ongoing experiments are directed at determining the possible role of voltage-gated Ca²⁺ channels (VGCCs) in this response. Pretreatment of the cells with the nonspecific Ca²⁺ channel blocker lanthanum (La³⁺, 20 μ M) completely inhibits 10mM Ca²⁺-induced depolarization. The dihydropyridine antagonist of L-type VGCCs nimodipine (10 μ M), also inhibited the depolarization induced by 10mM Ca²⁺, but to a lesser extent than the La³⁺. It is suggested that the Ca²⁺ induced changes in membrane electrical properties underly the observed increases in hormone release from these cells. LOCAL POSITIVE CALCIUM FEEDBACK MEDIATES AGONIST-EVOKED CALCIUM WAVE PROPAGATION. Samuel S.-H. Wang*, Adawia A. Alousi, and Stuart H. Thompson, Neurosciences Program and Hopkins Marine Station, Department of Biological Sciences, Stanford University, Pacific Grove, CA 93950.

In mouse neuroblastoma cells (line N1E-115), muscarinic receptor stimulation leads to the production of IP₃ and consequent calcium (Ca) release from stores. We used fluorescence video microscopy of fura-2/AM to view Ca waves in single cells. Exposure to 1 mM carbachol leads to steep Ca rises after a latency of 1-30 seconds. This latency was longer for lower agonist doses and was often followed by a Ca wave that crossed cells at speeds of 10 to >100 μ m/sec. Waves were slowed by heavy loads of the fast calcium buffers fura-2/AM and 5,5'-Br₂-BAPTA/AM (k_{on} \approx 10⁸ M⁻¹s⁻¹), but not by the slow buffer EGTA/AM (k_{on} \approx 10⁶ M⁻¹s⁻¹), showing that the rate at which a buffer binds Ca determines whether it is able to block wave propagation. Therefore, a limiting positive feedback step in wave propagation is the fast and local diffusion of Ca. Conversely, direct biochemical measurement and analysis of the latency to rise in Ca indicate that IP₃ is too long-lived (t_{1/2} \approx 10 seconds) to exist in the spatial gradients necessary for it to act as a rate-limiting messenger. We suggest that agonists cause global accumulation of IP₃ to threshold, followed by a regenerative wave in which Ca diffusion to neighboring release sites is one rate-determining step. SPATIAL PATTERNS OF CALCIUM ENTRY INTO CULTURED RAT CEREBELLAR NEURONS ARE CORRELATED WITH INITIATION SITES FOR DEGENERATION. V.P. Bindokas*, D. Bleakman*, and R.J. Miller, Dept. Pharmacol. and Physiol. Sci., Univ. Chicago, 947 E 58th St. Chicago IL 60637; *Presently: Lilly Research Centre, U.K.

Calcium overload in neurons is linked to excitotoxic damage manifested by alterations in cell shape and subsequent degeneration. We have studied the patterns of [Ca²⁺]_i increases in cultured neurons evoked by activation of voltage-sensitive or ligand-gated Ca²⁺ channels. Cultures enriched in Purkinje cells are described in detail (Brorson et al 1992, J. Neurosci 11:4024). Cells were loaded with either fura-2 AM or fura salt via patch pipet. A digital microfluorimetric imaging system was used to collect ratio pairs at 1Hz or log average Ca²⁺ data from regions of interest at 2Hz. Voltage-sensitive Ca²⁺ channels were activated by fast application of 50mM K⁺ while kainate-gated Ca²⁺ rises were isolated by KA (200 μ M) in Na⁺-free saline with 1 μ M TTX + 50 μ M TA3090 or by quenching of the fura-2 signal by KA-activated Co²⁺ entry. Based on observations from over 60 cells, the pattern of Ca²⁺ rise elicited by 50K or KA displays a range of overlap including examples of apparent segregation. The Ca²⁺ rise in Purkinje cell dendrites elicited by 50K was largely eliminated by 100nM ω -Ag₂VA. Sustained periods of high [Ca²⁺]_i (>700nM) often lead to swelling of neuronal somas and selective swelling (and pinching off) of neurites to produce beaded varicosities or "blebs". Often blebs formed at, or near, the sites of initial [Ca²⁺]_i rises produced by KA. Bleb loci were correlated with regions stained by the styryl dye RH414 which labels synaptic vesicles, with points of contact between neurites, and with regions rich in mitochondria as revealed by rhodamine 123 staining. These results support the notion that blebs tend to form in regions of Ca²⁺ overload and demonstrate spatial heterogeneity in Ca²⁺ signals.

CURRENT-DEPENDENT INACTIVATION OF A VERY LONG BARIUM TAIL CURRENT IN CULTURED RAT HIPPOCAMPAL NEURONS. M.L. Mazzanti*, O. Thibault, N.M. Porter and P.W. Landfield. Dept. Pharmacol., Univ. Kentucky, Coll. Med., Lexington, KY 40536.

In recent years we have described very long calcium (Ca^{2+}) tail currents in adult rat hippocampal slice neurons using sharp electrode voltage clamp. This tail current is dihydropyridine sensitive and is also sensitive to current-dependent inactivation, (Pitler, Landfield, 1987; Brain Res.; Campbell *et al.*, 1990; Soc. Neurosci.). Elsewhere in this meeting (Thibault *et al.*), we show that single L-type Ca^{2+} channel activity is closely correlated with these tail currents following repolarization.

The present studies utilized whole cell patch clamp methods to investigate similar very long tail current in cultured hippocampal neurons using 10 mM Ba^{2+} as the charge carrier. Whole cell recordings were evoked with 150 ms depolarizing steps to +10 mV from a holding potential of -70 mV. Tail currents lasting hundreds of milliseconds, with amplitudes between 50-200 pA, usually occurred following repolarization to -70 mV. In cells with a peak amplitude of at least 600-700 pA, the percent inactivation during step showed a highly significant negative correlation ($p < .005$) with long tail current amplitude. Parallel studies, using chelating agents, different concentrations of Ba^{2+} , and I-V analyses also show that the amplitude and duration of the tail currents are inversely proportional to the amount of Ba^{2+} current influx during the depolarizing step.

These studies indicate that the $\text{Ca}^{2+}/\text{Ba}^{2+}$ tail currents are highly sensitive to current-dependent inactivation and that long tail currents appear to show inactivation proportional to Ba^{2+} currents during the depolarizing step (Supported by AG10836, AG04542 and Miles, Inc.).

RECOVERY OF N-TYPE CALCIUM CHANNELS FROM INACTIVATION. M.A. Werz* and S.W. Jones. Dept. Physiol. & Biophys., Case Western Reserve Univ., Cleveland, OH 44106.

Whole-cell N-currents of frog sympathetic neurons (with 2 mM Ba^{2+}) have components inactivating at markedly different rates ($\tau = 0.15$ s, $\tau = 1.5$ s, and noninactivating on a ~3 s time scale). In cells dialyzed with the phosphatase inhibitor okadaic acid, a more rapidly inactivating component develops ($\tau = 15$ ms) (Soc. Neurosci. Abstr. 18:431, 1992). We are studying recovery from inactivation in control cells and cells dialyzed with okadaic acid, to determine the connectivity of the several inactivated states. Recovery was assessed using pairs of depolarizing steps to -10 mV, separated by a variable interval (10 ms - 60 s). Step durations of 35 ms, 0.35 s, and 3.5 s were used, to optimize selective inactivation of the different components. Following 3.5 s steps, three prominent components of recovery were observed ($\tau = 0.09$, 0.6, and 10 s). For shorter steps, a larger fraction of the recovery was rapid, without detectable changes in the τ 's. Recovery was similar for components inactivating at different rates (comparing the amplitudes of each component, for each pair of voltage steps). Recovery from inactivation was also similar in control and okadaic acid-dialyzed cells. We conclude that the different components of inactivation do not correspond to distinct, independent calcium channel types. If the components reflect "modes" of gating, either mode switching is relatively rapid, or each mode contains multiple inactivated states.

DISTRIBUTION OF IP3 AND RYANODINE RECEPTORS IN RAT NEOSTRIATUM. S. A. Alba, M. E. Martone*, M. H. Ellisman. Dept. of Neurosciences, Univ. California San Diego, CA 92093-0608.

In a previous study from this laboratory, two proteins that mediate the release of calcium from intracellular stores, the inositol 1,4,5-trisphosphate (IP3) and ryanodine receptors, were found to be differentially distributed in Purkinje cell dendrites: both proteins were found within the membranes of the endoplasmic reticulum in the dendritic shaft but only IP3 receptor was found in dendritic spines (Walton *et al.*, J. Cell Biol., 1991, 113, 1145). To extend these findings, we examined the distribution of the IP3 and ryanodine receptors in the rat neostriatum, which contains well-defined populations of spiny and aspiny neurons, to determine 1) which populations of striatal cells contain these two proteins and 2) whether they show a distribution within spiny dendrites similar to that found in cerebellum.

The distribution of IP3 and ryanodine receptors was studied at the light and electron microscopic levels in young adult rats by fluorescence and peroxidase immunocytochemistry using a polyclonal antiserum against IP3 (Mignery *et al.*, Nature, 1989, 342, 192; provided by Dr. T. Südhof) and a polyclonal antiserum against a synthetic peptide of dog cardiac ryanodine receptor (Witcher *et al.*, J. Biol. Chem. 1992, 267, 4963; provided by Dr. L. Jones). Within the neostriatum, labeling for both proteins was found within medium-sized cells with the ultrastructural characteristics of medium spiny neurons. In order to determine whether they were found in aspiny cells, some sections were also labeled for either choline acetyltransferase (ChAT) or parvalbumin, which mark two separate populations of striatal aspiny cells. Double-label immunofluorescence indicated that the ryanodine receptor colocalized with ChAT and parvalbumin while the IP3 receptor generally was not found in ChAT+ and parvalbumin+ cells. At the EM level, labeling for the IP3 receptor was found within cell bodies, dendrites and dendritic spines of spiny neurons. Ryanodine receptor labeling was seen in the cell body and proximal dendrites but did not appear to extend into spiny regions of the dendrite. Labeling for the ryanodine receptor also appeared to be present in astrocytic processes. The results of these experiments suggest that the IP3 receptor plays a specialized role in intracellular calcium regulation in spiny cells.

Prolonged High Open Probability of Hippocampal L-Type Calcium Channels Following Repolarization is Unmasked by Low Ba^{2+} and Ca^{2+} Concentrations. O. Thibault*, N.M. Porter and P.W. Landfield. Dept. Pharmacol., Univ. Kentucky College of Medicine, Lexington, KY, 40536.

Over the past several years, we have described long-lasting, dihydropyridine-sensitive, calcium (Ca^{2+}) tail currents in CA1 neurons of non-dissociated rat hippocampal slices. However the interpretation of these long tail currents is not fully clear. A few studies have seen single Ca^{2+} channel openings following a depolarization step, but these openings occurred with low frequency and often only in response to particularly strong depolarizations.

We report here that low concentrations of barium (Ba^{2+}) or Ca^{2+} in the pipette greatly enhance the probability of single L-type channel openings following a moderate depolarizing step. Single Ca^{2+} -channel currents were recorded in cultured neurons from rat hippocampus in the cell-attached patch configuration with pipettes filled with 110 mM Ba^{2+} , 20 mM Ba^{2+} or 5 mM Ca^{2+} . We found that repolarization openings (ROs) are infrequent in 110 mM Ba^{2+} , but substantially more frequent, and continue for hundreds of milliseconds following repolarization, in 20 mM Ba^{2+} . The ROs also are correlated with very long whole cell Ca^{2+} tail currents under a variety of conditions.

This increase in post-repolarization channel openings is seen also with 5 mM Ca^{2+} as the charge carrier, and occurs after brief depolarizations (5 ms) to physiological voltages (+10 mV). Thus, these data suggest that, under relatively physiological conditions, substantial Ca^{2+} channel activity normally persists long after a depolarization. (Supported by AG10836, AG04542 and Miles, Inc.).

REGULATION OF INTRACELLULAR CALCIUM CONCENTRATION AND ELECTRICAL BURSTING IN NEURONAL MODEL CELLS. Teresa Ree Chay*, Department of Biological Sciences, University of Pittsburgh, Pittsburgh, PA 15260.

A model that describes neuronal bursting activity is presented. This model is based on the hypothesis of use-dependent blocking of calcium-activated proteins (CAP) on the calcium channels. It is assumed that CAP may block the calcium channel only when it is in the open (conducting) configuration and that the rate limiting step is the conformational transformation between the blocked and unblocked states of the calcium channel. Since the charged CAP must bind/unbind to the charged channel pore, the conformational transformation depends not only on intracellular calcium ions but also on membrane potential. This slow conformational transformation gives rise to bursting of electrical activity. With this model we show how neurons respond to hormones and neurotransmitters by altering the electrical activity. This alteration brings about the change in levels of intracellular calcium concentration, which in turn influences the activity of various protein kinases.

IMMUNOCYTOCHEMICAL LOCALIZATION OF CLASS A CALCIUM CHANNELS IN ADULT RAT BRAIN. R.E. Westenbroek*¹, J.W. Hell¹, T. Sakurai¹, T.P. Snutch², and W.A. Catterall¹. ¹Dept. of Pharmacology, University of Washington, Seattle, WA 98195, and ²Biotechnology Laboratory, University of British Columbia, Vancouver, B.C., V6T 1W5.

The class A neuronal calcium channel gene encodes an $\alpha 1$ subunit expressed at high levels in cerebellar Purkinje cells like P-type calcium channels. A polyclonal antibody (CNA1) that recognizes the $\alpha 1$ subunit of the rB_A rat brain calcium channel specifically immunoprecipitates high affinity receptor sites for the spider toxin ω -AgalVa and recognizes a 260 kDa glycoprotein in rat brain membranes that is phosphorylated by cAMP-dependent protein kinase. CNA1 was used in combination with the immunofluorescence and indirect peroxidase-anti-peroxidase techniques to investigate the distribution of class A calcium channels in rat brain. Calcium channels recognized by CNA1 are localized in cerebellar Purkinje cell somas and along the entire length of the dendrites. There is also intense punctate staining along the extent of the Purkinje cell dendrites, apparently at synaptic sites. In addition, the CNA1 immunoreactivity is localized along the full length of apical dendrites of hippocampal pyramidal neurons with relatively little labeling of somata. In the dorsal cortex there is labeling of the apical dendrites of pyramidal cells. This staining is relatively even along the entire length of the dendrites. These observations contrast with the uneven pattern of dendritic labeling seen in cortical pyramidal neurons using an antibody to N-type calcium channels and with studies of L-type calcium channels which have been shown to be localized predominantly in the cell body and proximal dendrites of most neurons. These results indicate that the ω -AgalVa sensitive calcium channels recognized by CNA1 have a distinct distribution from L- and N-type calcium channels in central neurons, which may correlate with distinct functional roles for these channel subtypes.

OPEN CHANNEL CURRENT FLUCTUATIONS AND GATING OF Ca^{2+} -ACTIVATED K^+ CHANNELS. M.I. Glavinovic,^{*1} and J.M. Trifaro.² Depts. of Anesthesia,¹ Anesthesia Research¹ and Physiology,¹ McGill University, Montreal Que. and Dept. of Pharmacology,² University of Ottawa, Ottawa, Ont., CANADA.

Surface charges on the channel protein or on the lipids can through electrostatic interactions influence both gating and permeation of ion channels. The extent of these influences depends on the spatial relationship between the charges and the gate or the channel pore. It has been suggested for Ca^{2+} -activated K^+ channels that the greater the number of Ca ions bound to the ligand binding sites the longer the duration of the channel openings (Barrett et al., *J. Physiol.* 331,211-230,1982). Therefore the gating itself can through electrostatic forces influence permeation. The current flow through these channels shows considerable fluctuations that are voltage dependent and appear to be caused by conformational fluctuations of the segment of the channel protein (Glavinovic, Soc. Neurosci. Abstr. 16, 360, 1990). In this study we examine the relationship between the duration of the channel openings and the open channel current fluctuations.

In excised inside-out patches from bovine chromaffin cell membranes the variances of the current fluctuations, the critical frequencies and the zero frequency asymptotic values of the Lorentzians fitted to the power spectra were not dependent on the duration of the channel openings. This suggests that the segment of the channel protein that is the source of the current fluctuations (and possibly the whole channel) is/are electrostatically well screened from the Ca^{2+} binding sites.

550.3

CALCIUM BLOCK OF CALCIUM-ACTIVATED POTASSIUM CHANNELS. Kevin Chinn* and Cynthia Lee Martin. Searle, 4901 Searle Parkway, Skokie, IL 60077.

The mechanisms by which ions permeate and/or block membrane channels can influence both the physiology and pharmacology of the channel. It has previously been found in human T lymphocytes that calcium-dependent potassium current (I_{KCa}) exhibits a linear current-voltage (I-V) relationship between -100 mV and 0 mV (Nguyen et al., *Neurosci Abs* 18:74, 1992). In whole-cell voltage clamp experiments with activated human lymphocytes we have found using voltage ramps (-200 mV to +40 mV) that while I-V relationships positive to -100 mV are linear, at voltages more negative than -130 mV outward rectification occurred (decreased slope conductance). In fact, a distinct hook shape often occurred in the I-V curve at such voltages which cannot be explained by Goldman rectification. KCa current depended upon external Ca concentration ($[\text{Ca}]_o$). Increasing $[\text{Ca}]_o$ from 2 to 9 mM decreased I_{KCa} in the area of pronounced rectification by approximately 50%. Decreasing $[\text{Ca}]_o$ from 2 to 0.2 mM increased I_{KCa} by approximately 20%. Both rectification and Ca dependence might be explained by Ca block of the channel as occurs with Na channels (Yamamoto et al., *Biophys. J.* 45:337, 1984).

LEAD (Pb^{2+}) ENHANCES POTASSIUM CHANNEL ACTIVITY IN ACUTELY ISOLATED RAT CORTICAL ASTROCYTES. T.O.Jalonen*, M.Aschner¹, C.J.Charniga, A.J.Popp, and H.K.Kimelberg. Department of Surgery, and ¹Department of Pharmacology and Toxicology, Albany Medical College, Albany, N.Y. 12208.

It has previously been shown that Pb^{2+} (10 μM) causes swelling and enhances K^+ efflux in cultured, neonatal rat cortical astrocytes (Aschner et al., *Brain Res. Bull.*, 26:639,1991). To study the mechanisms of the direct effects of Pb^{2+} on the K^+ channel activity, we used the patch-clamp technique to record single-channel potassium currents in acutely isolated GFAP(+) rat cortical astrocytes. The cells were isolated from thin cortical slices of 3 to 30 days old rats with gentle papain treatment modifying the method described by Tse et al. (*J. Neurosci.*, 12:1781,1992). In control recordings one of the voltage-sensitive K^+ channels, similar to that known to exist in cultured rat cortical astrocytes (Jalonen and Holopainen, *Brain Res.*, 484:177,1989), was seen to open with occasional, fast single steps, being open only about 4 % of the time. Within two minutes after direct administration of 0.2 to 40 μM Pb^{2+} on either the extra- or intracellular side of an excised cell membrane, the K^+ channel was seen to open with up to a 9-fold increase in the channel open probability, an increase in opening frequency and multiple (2-4) simultaneous channel openings. This increased single-channel activity could partly explain the enhanced K^+ efflux seen in astrocytes upon Pb^{2+} exposure. (Supported by NS 23750 (H.K.K.), H.Schaffer Foundation (A.J.P.), NIHES05233 (M.A.) and BRSG grant NIHSO7RR05394-31 (T.O.J.)).

550.2

GATING AND SELECTIVITY OF APAMIN-SENSITIVE, Ca^{2+} -ACTIVATED K^+ CHANNELS OF SMALL CONDUCTANCE IN RAT ADRENAL CHROMAFFIN CELLS. YoungBae Park and Bertil Hillre² Dept. of Physiology & Biophysics. U. of Washington, Seattle, WA 98195

The ionic selectivity and gating of apamin-sensitive Ca^{2+} -activated K^+ (SK) channels was studied in dissociated rat adrenal chromaffin cells using whole-cell and inside-out macropatch recording technique. The pipette solution contained (mM): 120 KAsp, 20 KCl, 5 Mg_2Cl_2 , 20 HEPES, 0.1 EGTA, 3 K_2ATP , 0.1 Na_2GTP , and 0.08 leupeptin. Whole-cell tail currents following 1-2 s depolarization showed bell-shaped dependence on depolarization potential and were absent in Ca^{2+} -free external solution or in 100 μM external Cd^{2+} . Reversal potentials of tail currents changed 58 mV per 10 fold change in $[\text{K}^+]_o$. Tail currents were largely blocked by extracellular application of apamin (200 nM), (+)-tubocurarine (K_d , 23.6 μM) and TEA (K_d , 5.4 mM). The relative permeability (P_x/P_o) of SK channels estimated from reversal potential changes was: Ti^+ 1.87, K^+ 1.0, Rb^+ 0.81, Cs^+ 0.16, NH_4^+ 0.11, and Na^+ , Li^+ & methylamine < 0.01. With mixtures of Ti^+ and K^+ , reversal potential and zero-current slope conductance showed anomalous mole-fraction dependence. Ca^{2+} -sensitivity and voltage dependence of SK channel gating were tested using inside-out macropatches. K_d and Hill coefficient were $0.40 \pm 0.09 \mu\text{M}$ (n=6) and 1.68 ± 0.28 (n=6) at -80 mV, respectively and independent of membrane potential in the range of -120 to -20 mV. Supported by NS08174 and the McKnight and W.M.Keck Foundations.

550.4

CALCIUM INACTIVATION OF A SMALL CALCIUM-DEPENDENT POTASSIUM CHANNEL IN THE NEUROBLASTOMA-GLIOMA CELL LINE NG108-15. M. Harrington, S. Gutowski, P.C. Sternweis and F. Belardetti* Dept. Pharmacology, U.T. Southwestern, Dallas, TX 75235.

In NG108-15 cells, bradykinin (BK) transiently opens a Ca^{2+} -activated K^+ conductance ($\text{I}_{\text{K(Ca)}}$) through activation of phospholipase C (PLC) mediated by the G protein $\text{G}_{q/11}$ (Wilcz-Blaszczak et al., 1993). PLC in turn generates inositoltrisphosphate (IP_3) which raises $[\text{Ca}^{2+}]_i$, thus opening $\text{I}_{\text{K(Ca)}}$. We are investigating the detailed mechanism of regulation of this channel in inside-out patches bathed in K^+ /EGTA/ Ca^{2+} . Whereas a BK-sensitive K^+ channel is readily observed in cell-attached patches (Higashida and Brown, 1988), inside-out patches exposed even briefly to millimolar $[\text{Ca}^{2+}]_i$ during the patch isolation rarely contained Ca^{2+} -sensitive outward channels. In contrast, if $[\text{Ca}^{2+}]_i$ was maintained at or below micromolar levels, a voltage-independent 15-20 pS K^+ channel was reliably observed, whose P_o was steeply dependent on $[\text{Ca}^{2+}]_i$ (half-activation around 1 μM). Potentially, G proteins could also be directly involved in its regulation. In conclusion this neuronal channel is an interesting example of multiple, convergent modulatory actions. These actions form the basis for the fine-tuning of the cell's excitability.

550.6

IONIC CURRENT MODELING OF LIGHT RESPONSES FROM THE HERMISSENDA B PHOTORECEPTOR. K.T. Blackwell¹, H.P. Detmar¹, T.P. Vogl¹, D.L. Alkon². ¹Environmental Research Institute of Michigan, Arlington, VA 22209; ²Neural Systems Section, National Institute of Neurological Disorders and Stroke, NIH, Bethesda, MD

A lumped-parameter resistance-capacitance computer model of the four neuron circuit of *Hermisenda crassicornis* (Werness et al., *Biological Cybernetics*, 68:125, 1992) has been an excellent tool for examining the information flow and dynamics of biological associative learning. More detailed knowledge of mechanisms may be gained from examination of channel current interactions in a channel model of biological associative learning. Such a model requires characterization of the major voltage-dependent currents, which undergo persistent and progressive modification during associative learning, as well as the light-induced (CS) currents and GABA-induced (UCS) currents. We report here a channel level model of the light-induced currents of the *Hermisenda* B cell, which integrates the voltage-dependent currents modeled by Sakakibara, et al. (*Biophysical J.*, 1993, In Press.) and the light-induced sodium and potassium currents measured under voltage-clamp conditions by Chen & Alkon (*Soc. Neurosci. Abstr.* 13:1397, 1987). The sodium currents, whose kinetics are independent of membrane potential, but are dependent on light intensity, are modeled by assuming only a single rate-limiting chemical reaction between rhodopsin isomerization and channel activation. We develop a model of light-induced release of calcium which activates the calcium-dependent potassium current characterized by Sakakibara et al. The resulting calcium induced potassium currents have an early outward component and a later apparently inward component, whose time course and amplitude are consistent with the early and late light-induced potassium currents measured by Chen and Alkon.

FACILITATION OF CALCIUM DEPENDENT POTASSIUM CURRENT. *Stuart H. Thompson**. Hopkins Marine Station, Department of Biological Sciences, Stanford University, Pacific Grove, CA 93950.

Voltage clamp and Ca imaging methods were used to study the relationship between $[Ca]_i$ and potassium current activation in neurons isolated from the central nervous system of the nudibranch mollusc *Doriotopsilla*. In these neurons, the activation of Ca-dependent K current (I_C) provides a linear index of $[Ca]_i$ immediately adjacent to the membrane. Loose patch voltage clamp was used to record currents from patches enriched in I_C and it was found that the current facilitates by factors as great as 30X during depolarizing pulses repeated at 1 Hz. This process resembles the facilitation of neurotransmitter release. Outward current facilitation requires Ca channel gating and Ca influx, and it is blocked by injected Ca buffer. The Ca indicator fluo-3 and conventional fluorescence video microscopy were used to image Ca concentration changes near the membrane and the interpretation of data was aided by a computer simulation of Ca active transport, diffusion, and binding. Analysis indicates that the accumulation of residual Ca is responsible for outward current facilitation. Recovery from facilitation ($t_{1/2}$ app. 15 sec) is strongly temperature dependent and slowed by removing external Na. This result indicates that the near-membrane Ca signal is shaped by Na-Ca exchange. Supported by BNS-9021217.

GABA INHIBITION OF TRANSIENT POTASSIUM CURRENT (A-CURRENT) IN CULTURED MOUSE HIPPOCAMPAL NEURONS. *R.-L. Wu** and *M.E. Barish*, Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010.

We have observed in whole-cell voltage clamp recordings that application of γ -aminobutyric acid (GABA; 50 μ M) to cultured mouse hippocampal neurons results in reversible inhibition of A-current. Hippocampal cells were dissociated on embryonic days 15-17 and studied after 3-7 days in culture. Since GABA_A responses in embryonic neurons are depolarizing, two procedures were adopted to minimize the possible effects of GABA-induced depolarization of imperfectly-clamped membrane on availability of A-current: a) recordings were made using a potassium sulfate-based internal solution with which the reversal potential for the GABA_A-activated chloride current was approx. -72 mV, and b) A-current was measured after GABA_A-activated chloride current had desensitized to a steady state. Under these conditions the pharmacological profile of A-current inhibition indicated a dependence on GABA_A receptor activation - inhibition was mimicked by muscimol (50 μ M) and blocked by bicuculline (100 μ M), but not affected by phaclofen (100 μ M).

The mechanism of A-current inhibition is under investigation.

POTASSIUM CURRENT COMPOSITION AND KINETICS IN TOADFISH SEMICIRCULAR CANAL HAIR CELLS. *A. Steinacker¹* and *S.M. Highstein²*. ¹Institute of Neurobiology, Univ Puerto Rico Med. Sci. Cam. San Juan, PR 00901. ²Depts. Oto/Anat.Neurobiol. Wash. Univ. Sch. Med. St. Louis, MO 63110.

The response dynamics of the semicircular canals are commonly assumed to be slow in comparison to those of the auditory system. In the hair cell, response dynamics should be determined by the properties of the hair cell bundle and the ionic currents. We have therefore measured hair bundle length and ionic currents in the toadfish (*Opsanus tau*) semicircular canal hair cells and compare them to comparable measurements made in the same animal for auditory (sacculus) hair cells (Steinacker and Romero, *Brain Res.* 574: 229-236, 1991). Whole cell patch clamp was done at 15 °C from isolated canal hair cells using several voltage protocols, calcium concentrations and pharmacological agents to distinguish between the potassium currents. The pipette contained (mM) KCl 165, CaCl₂ 0.1, MgCl₂ 1.5, EGTA 10, HEPES 5, K⁺ ATP 2.5 at pH 7.2 and the bath teleost Ringer with 4 mM CaCl₂. Two major outward currents were found, an A current and a IKCa. Current activation and deactivation was rapid in comparison to sacculus hair cells. The A current, with rapid activation and inactivation at resting potentials, was a prominent feature of canal cells and rare in sacculus cells. Little evidence of the delayed rectifier so prominent in the sacculus cells was seen in the canal cells. Resonant frequencies of canal hair cells were significantly higher than in sacculus cells. Stereociliary length, is long (around 100 microns) in canal cells, as expected the slow response dynamics. Sacculus stereociliary lengths do not exceed 15 microns, except for those few in a peripheral border. These data suggests that canal and sacculus cells are coding different aspects of a sensory stimulus. The high resonant frequency and rapid current kinetics may play a role in determining the high acceleration sensitivity observed in canal afferents (Highstein and Boyle, *J. Neurosci.* 10: 1557-1569, 1990).

IDENTIFICATION OF THE RAPIDLY-ACTIVATING K⁺ CURRENTS, I_A AND I_D , IN NEURONS OF THE RAT BASOLATERAL AMYGDALA. *M.D. Womble** & *H.C. Moises*. Dept. of Physiology, Univ. of Michigan, Ann Arbor, MI 48109.

The rapidly activating K⁺ currents, I_A and I_D , differ in their decay rates and sensitivity to blockade by 4-aminopyridine (4-AP). These currents contribute to action potential repolarization and the regulation of firing patterns in several types of central mammalian neurons. We investigated the role of rapidly activating, 4-AP sensitive currents in neurons of the basolateral amygdala (BLA), recorded at room temperature in a slice preparation of the rat ventral forebrain. In current-clamp mode, low concentrations of 4-AP (50-100 μ M) produced a small broadening of current-evoked action potentials, a change that was further enhanced with subsequent application of 4-AP at higher concentrations (2-4 mM). In single-electrode voltage-clamp, low levels of 4-AP (50-100 μ M) inhibited a rapidly activating, slowly decaying outward current, with an average peak amplitude of 269 ± 77 pA (\pm S.E.M.) and decay tau of 415 ± 48 ms ($n = 7$). Increasing the 4-AP concentration to 2-4 mM resulted in inhibition of a second rapidly activating outward current, with a larger peak amplitude (612 ± 210 pA) and much more rapid rate of decay (tau of 51.6 ± 7.6 ms; $n = 5$). Thus, BLA neurons possessed 2 rapidly-activating outward currents, separable by their decay rates and 4-AP sensitivities, that contributed to action potential repolarization. These were a slowly decaying, 4-AP sensitive current similar to the I_D of other central neurons, and a rapidly decaying, relatively 4-AP insensitive current similar to I_A . CALCIUM-BINDING MOLECULES CREATE EXTREME SPATIAL AND TEMPORAL LOCALIZATION OF Ca^{2+} SIGNALLING IN SACCULAR HAIR CELLS OF *RANA PIPIENS*. *W.M. Roberts**. Inst. of Neuroscience, Univ. of Oregon, Eugene, OR 97403.

In this theoretical study, I investigate how the high concentration of a mobile cytoplasmic Ca^{2+} -binding molecule in frog saccular hair cells (W. Roberts, *Nature*, in press) creates an environment in which Ca^{2+} signalling is highly localized in space and time. By capturing Ca^{2+} in $<10 \mu$ s, it causes the local $[Ca^{2+}]_i$ to reach a new steady level nearly instantaneously after the opening or closing of each Ca^{2+} channel, and allows each K_{Ca} channel to respond only to Ca^{2+} influx from a few of its nearest neighbors within the dense cluster of Ca^{2+} and K_{Ca} channels at presynaptic active zones. The delay between the opening of Ca^{2+} channels and K_{Ca} channels, which is a crucial part of electrical resonance in these cells, must therefore depend entirely upon intrinsic properties of the K_{Ca} channels, and not partly on the time-course of Ca^{2+} accumulation as previously modelled by Hudspeth & Lewis (*J. Physiol.* 400:275-97). Their model can be modified to accurately reproduce voltage clamp data and electrical resonance assuming instantaneous changes in $[Ca^{2+}]_i$, but cannot be reconciled with other measurements of the K_{Ca} channels' steady-state Ca^{2+} dependence because it fails to take into account the random and extreme fluctuations in $[Ca^{2+}]_i$ that each K_{Ca} channel experiences as nearby Ca^{2+} channels open and close. To understand fast Ca^{2+} signalling in these cells, it is necessary to recognize that K_{Ca} channels and other Ca^{2+} receptors are exposed to stochastic changes in $[Ca^{2+}]_i$ that are much larger and more rapid than suggested by measurements of the whole-cell Ca^{2+} current. ACTION POTENTIALS ACTIVATE AN INTERNODAL POTASSIUM CONDUCTANCE IN RAT MYELINATED AXONS. *G. David**, *J.N. Barrett* and *E.F. Barrett*. Dept. of Physiology & Biophysics, Univ. of Miami Med. Sch., P.O. Box 016430, Miami, FL 33101.

Voltage changes associated with currents crossing the internodal axolemma of rat phrenic nerve fibers were monitored with a microelectrode inserted into the myelin sheath, to investigate activation of K channels in the internodal axolemma. Electrode location was verified by spread of ionophoresed dye throughout the myelin sheath of the impaled internode. The amplitude of the recorded action potential (AP) increased with increasing depth of microelectrode penetration into the myelin, but the resting potential remained near 0 mV.

Following ionophoresis of K⁺ (or Rb⁺, but not Na⁺) from the microelectrode, APs were followed by a prolonged negative potential (PNP, Fig. B) lasting hundreds of ms. PNP's also arose spontaneously. Spontaneous AP's sometimes occurred during the onset of the PNP (Fig. C), suggesting that the underlying axon was depolarized during the PNP. PNP's were associated with an increased conductance of the internodal axolemma, and were suppressed by tetraethylammonium (TEA) and 4-aminopyridine. These results suggest that PNP's are produced by a regenerative K current that enters the internodal axolemma via K channels opened by APs or subthreshold depolarizations. A similar mechanism may account for the ectopic APs observed after ischemia or prolonged repetitive firing, when extra-axonal $[K^+]_o$ may be greatly elevated.

APs recorded within the myelin sheath without artificially elevating $[K^+]_o$ were followed by a brief, positive, TEA-sensitive afterpotential, suggesting that APs can also activate internodal K channels under normal ionic conditions.

REMOVAL OF INTRACELLULAR POTASSIUM ALTERS K⁺ CHANNEL SELECTIVITY IN CHICK DORSAL ROOT GANGLION NEURONS. M.J. Callahan and S.J. Korn. Physiol. and Neurobiol. Dept., U. Connecticut, Storrs, CT 06269.

In whole cell patch clamp recordings from embryonic day 14 chick dorsal root ganglion neurons, replacement of intracellular K⁺ with NMG⁺ or Na⁺ resulted in the development of a slow inward tail current (*I*_{cat}) carried by Na⁺. *I*_{cat} was not observed when K⁺ was replaced by Cs⁺. *I*_{cat} was activated by step depolarization for as little as 1 ms to potentials more positive than -40 mV, and inactivated in a time and voltage-dependent manner with prepulse durations on the order of seconds. *I*_{cat} was blocked by external Ba²⁺ (2 mM), but was unaffected by removal of [Ca²⁺]_o, addition of Cd²⁺ (300 μM), or addition of intracellular EGTA (10 mM). Addition of as little as 3 mM K⁺ to the intracellular solution blocked *I*_{cat} by ~90%; 20 mM K⁺ blocked *I*_{cat} by 100%. *I*_{cat} was not blocked by 10 mM Cs⁺, TEA, or TEA_o, but was significantly blocked by 3 mM Rb⁺. Reversal potential measurements revealed that *I*_{cat} conducted Na⁺, Cs⁺, Rb⁺ and K⁺, but not Li⁺, NMG⁺, or TMA⁺. Taken together, these data suggest that *I*_{cat} is a Na⁺ conductance carried via a K⁺ channel whose selectivity was altered upon removal of intracellular K⁺. The activation and inactivation kinetics suggest that this channel may be a delayed rectifier K⁺ channel.

CHARACTERIZATION OF POTASSIUM CURRENTS IN PYRAMIDAL NEURONS ACUTELY DISSOCIATED FROM ADULT RAT NEOCORTEX. M. H. O'Regan and R.R. Gala. Dept. Physiology, Wayne State Univ. Sch. of Med., Detroit, MI 48201.

Potassium channels play a major role in regulating the excitability of mammalian central neurons. The ability of neurons to exhibit diverse firing patterns likely results from the presence of various potassium channels which differ in their voltage and calcium dependence and kinetics. The present study examined potassium currents using the whole cell configuration of the patch clamp technique. Cells were isolated from layers III to VI of rat sensorimotor cortex and were identified as regular spiking pyramidal neurons based upon their morphology and passive membrane characteristics. The most prominent outward current (recorded in the presence of TTX) activated rapidly, was sustained during the 150 ms test voltage pulse, and was sensitive to TEA. A transient current could be isolated which activated at more negative test potentials, was inactivated following a depolarizing prepulse, and decayed with a time constant of 9 ms. This current was reduced following the application of 4-AP. Blockade of Ca²⁺ channels by the addition of Co²⁺ to the bath solution resulted in an apparent enhancement of the transient current, presumably because of the loss of a counterbalancing inward Ca²⁺ current. Additionally, the sustained potassium current was reduced, indicating the presence of a sustained Ca²⁺ dependent component. The isolated currents displayed differences in their voltage dependence, activation and inactivation kinetics, and pharmacology which indicates varied roles in the regulation of neuronal activity. Since the activation of potassium channels is generally inhibitory, quiescent states in neocortex, such as that in the ischemic penumbra following the disruption of cerebral circulation, may result from the selective pathological influence of potassium currents.

EFFECTS OF POTASSIUM CHANNEL OPENERS ON CATECHOLAMINE SECRETION AND Ca²⁺ MOBILIZATION IN CULTURED BOVINE ADRENAL CHROMAFFIN CELLS. Y. Masuda, H. Houchi* and M. Oka. Dept. of Pharmacology, Tokushima Univ. Sch. of Med., Tokushima, 770, Japan.

Potassium (K⁺) channel openers have shown to produce relaxation of vascular smooth muscle. In contrast to the Ca²⁺-channel blockers which have direct actions on the voltage-dependent Ca²⁺ channel, K⁺ channel openers inhibit the voltage-dependent Ca²⁺ channels indirectly by activating the K⁺ channel. K⁺ channel openers may have additional actions on many excitable cells other than vascular smooth muscle. In cultured bovine adrenal chromaffin cells, K⁺-channel openers, cromakalim and pinacidil stimulated the efflux of ⁸⁶Rb⁺ from the cells. 31 mM K⁺ and carbamylcholine also increased the ⁸⁶Rb⁺ efflux which was dependent on the extracellular Ca²⁺. These K⁺-channel openers inhibited catecholamine secretion and ⁴⁵Ca²⁺ influx induced by 31 mM K⁺ and carbamylcholine. Moreover, these K⁺ channel openers were found to have inhibitory effect on Ca²⁺ release from the intracellular pools induced by carbamylcholine.

SPONTANEOUS FIRING IN THE NG108-15 NEUROBLASTOMA CELL LINE BY INTRACELLULAR pH ALTERATION. V. Kowcha*, K. Iwasa, H. Bryant, V. Krauthamer, D. Stenger. CSBE/NRL, Washington, DC, Dpt. Physiol., USUHS, Bethesda, MD, LCB/NIDCD/NIH, Bethesda, MD, & EB/DPS/OST/CDRH/FDA, Rockville, MD.

Clay et al., (20th Ann Soc. Neuroscience Meeting 16:361, 1990) have shown stable spontaneous firing in the giant squid axon induced by changes in intracellular pH. We have recently observed similar automaticity (firing frequency ~ 2 Hz) when the intracellular pH was altered in the NG108-15 cell line plated in defined reduced and serum-free culturing conditions. When the cells were bathed in 20-50 mM NH₄Cl for a period of 1-2 minutes, a transient depolarization was observed (~ 5mV). When the cells were reperused with normal extracellular recording medium (CONTROL), gradual hyperpolarization was observed (5-10 mV). The rate of hyperpolarization was a function of the NH₄Cl concentration. Stable spontaneous firing was observed in 3/8 attempts in both culturing conditions 15-20 minutes post CONTROL. Weak subthreshold oscillations were observed in cases where spontaneous firing was not observed. The changes in intracellular pH with the NH₄Cl pulse was characterized using SNARF-Calcein AM (pH sensitive dye, Molecular Probes, Eugene, OR). Intracellular pH was calibrated using a mixture of weak acid and weak base (butyric acid and trimethylamine) respectively (Thomas et al., Pflugers Arch. 413:550, 1987). The pH_i changes were biphasic, with an initial sharp increase followed by a slow rate of decline above baseline. With the reintroduction of CONTROL, a drop to near baseline and below was followed by a slow increase over baseline. In all cases, the threshold of firing was reduced and repetitive firing was observed at an increased current level.

OUABAIN-INDUCED HYPERPOLARIZATION OF MYENTERIC NEURONS INVOLVES ACTIVATION OF K⁺-CHANNELS. J.-Q. Kong, J.A. Leedham, W.V. Fleming and D.A. Taylor. Dept. Pharmacol. and Toxicol., WVU Hith. Sci. Ctr., P.O. Box 9223, Morgantown, WV 26506-9223.

A reduction in resting membrane potential (RMP) of 'S' neurons in myenteric ganglia has been associated with the development of tolerance to opioids (Leedham et al., JPET 263: 15, 1992). To examine the contribution of Na-pumping on the RMP of myenteric 'S' neurons, studies were undertaken to determine the effect of ouabain-induced pump inhibition on these neurons. Standard intracellular recording techniques were employed with neurons exposed to drug via superfusion in the physiological salt solution. Of the 40 neurons exposed to ouabain (0.1 - 5.0 μM), 16 were hyperpolarized by 9.7 ± 2 mV and the remaining neurons either unaffected (13/40) or depolarized (9/40) by ouabain (10.4 ± 2.8 mV). Higashi et al. (J. Physiol. 389: 629, 1987) observed similar effects of ouabain in rabbit nodose ganglion cells due to activation of K⁺-channels. To evaluate this possibility, the K⁺-channel antagonist, TEA was used. TEA (0.5 mM) alone evoked modest (< 5mV) and inconsistent changes in RMP of 'S' neurons. However, in the presence of TEA, ouabain (5 μM) led to a substantial (23.4 ± 2.4 mV) depolarization in 11 of 12 neurons and no hyperpolarizations. In 5 additional cells, impalements with electrodes containing sodium acetate were obtained to induce intracellular sodium loading and elevation in sodium pump activity which led to a substantial resting hyperpolarization of ≥ 20 mV and a marked increase in ouabain-induced depolarization (34.2 ± 6.2 mV) in the presence of TEA. These data suggest that ouabain may activate 'S' neuron K⁺-channels as well as inhibit the sodium pump. Under K⁺-channel blockade or accelerated pump activity, the inhibitory effect of ouabain can be clearly observed. Supported by PHS grant DA 03773.

INWARD AND OUTWARD POTASSIUM CURRENTS IN CULTURED MOTONEURONS. J. G. McLamont*, M. Michikawa and Seung U. Kim. Department of Pharmacology & Therapeutics, and Division of Neurology, Department of Medicine, Faculty of Medicine, The University of British Columbia, Vancouver, B. C., V6T 1Z3.

Electrophysiological studies have characterized unitary inward rectifier and calcium-dependent K⁺ currents in identified (by immunostaining) mouse motoneurons. A 25 pS inward rectifier channel K_(IR) was identified in cell-attached recordings with 140 mM K⁺ in the patch pipette. The mean open times of K_(IR) were decreased, with an exponential dependence, when patch hyperpolarization was increased. Channel open probability exhibited a sigmoidal dependence on potential with increased open probability at depolarizing potentials. Inactivation of K_(IR) was evident with hyperpolarizing steps and ensemble averaged currents were lower with increased patch hyperpolarization. The rate of inactivation was faster with larger hyperpolarizing potential steps. External Cs⁺ blocked K_(IR) in a manner consistent with the predictions of a sequential open channel block model. Unitary properties of a large conductance calcium-dependent K⁺ channel K_(Ca) were also studied using inside-out patches. Channel conductance was 220 pS with symmetrical (140 mM) K⁺ across patches and was 110 pS when external K⁺ was 5 mM. The mean open times of K_(Ca) were exponentially dependent on potential for both patch hyperpolarization and depolarization. Channel open probability exhibited a sigmoidal dependence on potential with increased open probability at depolarized patch potentials. External, but not internal, TEA blocked K_(Ca) currents at a concentration of 2 mM.

INWARD RECTIFIER CHANNELS IN EMBRYONIC SKELETAL MUSCLE CELLS IN CULTURE. F.L. Moody-Corbett*, S. Virgo, and S. Hancock. Division of Basic Medical Science, Memorial University of Newfoundland, St. John's, NF, A1B3V6.

Potassium inward rectifier (IR) current which is present in a number of cell types is important in establishing membrane excitability. Several lines of evidence suggest that there is more than one class of IR channels. We have previously described the macroscopic IR current in embryonic frog muscle cells in culture (Moody-Corbett and Gilbert, Dev. Br. Res., 55 (1990) 139). The purpose of the present study was to determine the characteristics of the IR channels underlying these macroscopic currents.

Skeletal muscle cells were dissected from stage 19-23 *Xenopus* embryos and grown in culture. Single channel events were recorded using a List patch clamp. Electrodes were filled with (in mM) 140 KCl, 5 NaCl₂, 1 CaCl₂, 10 HEPES, and .03 tetrodotoxin (TTX) and the extracellular recording solution contained (in mM) 140 NaCl, 5 KCl, 1 CaCl₂, 1.2 MgCl₂, 10 HEPES, and .03 TTX. The cells were held near resting membrane potential (RMP) and voltage steps applied for .1 or 5 sec.

Two classes of IR channels were analyzed. Both types had a high open probability at RMP and were seen together in a single patch. One class had a single channel γ of 26 pS, and was present in 60% of the patches examined. The other channel class had a γ of 10 pS and was much less frequently observed. Preliminary results suggest that the small γ channel was more prevalent in the youngest cells examined. The results suggest that at least two classes of IR channels exist in embryonic muscle cells.

550.20

THE EFFECT OF AXOTOMY ON K CHANNELS OF X-ORGAN NEURONS SOMATA. B. Mendiola, R. Godínez, R.F. Valdiosera and P. Huizar*. Depto. de Fisiología, CINVESTAV-IPN, México, D.F. 07000.

When X-organ neurons of the crayfish are axotomized at about 150 μ m from the cell body, the neurons hyperpolarize and the input resistance decreases to about half the control values. Also, the action potential disappears or a slow depolarizing response remains. These effects could be explained by the opening of a background potassium channel and the inactivation of the channels responsible for the action potential (Ca, I_K and I_A channels). These effects are reverted by the extracellular application of 2 mM dibutyryl cyclic AMP to the neurons. In this study we have used cell-attached and inside-out patch clamp recordings to characterize the effects of axotomy and cyclic AMP on potassium channels of these neurons. The results suggest that in axotomized neurons, the channel responsible for the hyperpolarization is an inward rectifier channel since it is the most frequently observed in membrane patches of these neurons. In inside-out recordings, the most prominent effect of the application of the catalytic subunit of PKA and ATP, is an increase in the number of open channels of the delayed rectifier type, with a decrease in the number of the inward rectifier type. (Supported by CONACYT grant 1245-N9203).

ACETYLCHOLINE RECEPTORS: EXPRESSION OF MUSCARINIC RECEPTORS

551.1

DIFFERENTIAL EXPRESSION OF MUSCARINIC ACETYLCHOLINE RECEPTOR mRNAs AND THEIR SUBTYPES DURING DEVELOPMENT OF EMBRYONIC CHICK HEART AND RETINA. L.A. Parenteau* and N.M. Nathanson. Department of Pharmacology, University of Washington, Seattle, Washington, 98195.

Previous studies have shown that there are two subtypes of muscarinic acetylcholine receptors (mAChR) expressed in embryonic chick heart, and suggested that at least two subtypes of mAChR are expressed in embryonic chick retina. We used solution hybridization to examine the level of mRNAs encoding cm2 and cm4 mAChR in chick heart and retina during embryonic development. There is five to ten times more cm2 mRNA than cm4 mRNA in heart at all stages examined. The levels of cm2 mRNA varied from 10 to 30 molecules per cell, while cm4 mRNA varied from 1 to 5 molecules per cell. In contrast, there is five to ten times more cm4 mRNA as cm2 mRNA expressed in retina. The levels of cm4 mRNA varied from 5 to 9 molecules per cell, while cm2 mRNA varied from 0.5 to 2 molecules per cell. The cm2 and cm4 receptor protein levels were measured by an immunoprecipitation assay using subtype specific antibodies generated against glutathione-S-transferase/mAChR fusion proteins. Data from these experiments confirmed that cm2 is the predominant subtype of mAChR expressed in embryonic chick heart, while cm4 is more highly expressed than cm2 in embryonic chick retina. In addition, our results suggest there is at least a third subtype of mAChR expressed in retina, since a significant fraction of the total population of mAChR in retina is not immunoprecipitated by anti-cm2 and anti-cm4 antibodies.

551.2

CHARACTERISATION OF THE MUSCARINIC RECEPTOR m4 GENE STRUCTURE AND ISOLATION OF ITS TRANSCRIPTIONAL CONTROL ELEMENTS. I.C. Wood, C.A. Harrington and N.J. Buckley. Dept of Physical Biochemistry, National Institute for Medical Research, London, NW7 1AA.

Gene cloning studies have revealed the presence of five subtypes of muscarinic acetylcholine receptors. The coding exons for each of these genes have been obtained but the precise gene structure and transcriptional control elements for these genes have not yet been determined.

In order to obtain the transcriptional control elements for one of these genes, the m4 gene, a cosmid clone containing the m4 coding region and approximately 25 kb of upstream DNA sequence was isolated from a rat genomic library. A functional analysis using stably transfected cell lines demonstrated that this clone contained the transcriptional start site for the m4 gene and at least some of the tissue specific regulatory elements.

As only DNA sequence information from the coding region was available the positions and sizes of the upstream exons had to be determined using a selection of techniques including nuclear run-on analysis, a modified RACE analysis and PCR sequencing strategies. The data indicate that the transcription start site for the m4 gene is approximately 6 kb upstream from the initiating ATG and that the 5' untranslated sequences are contained within two exons which are separated from the coding exon by a 5.5 kb intron. DNA sequence analysis of the region immediately 5' of the transcription start site shows that the m4 gene lacks both TATA and CAAT boxes, however several consensus binding sites for other transcription factors have been identified.

551.3

REGULATION BY NERVE GROWTH FACTOR OF m4 MUSCARINIC ACETYLCHOLINE RECEPTOR mRNA EXPRESSION IN PC12 CELLS. N.H. Lee* and C.M. Fraser. Department of Molecular and Cellular Biology, The Institute for Genomic Research, Gaithersburg, MD 20878.

PC12 cells undergo differentiation to sympathetic neuron-like cells in response to nerve growth factor treatment. Concomitant with this phenomenon is an up-regulation of m4 muscarinic acetylcholine receptors (mAChRs) in plasma membrane homogenates (Jumblatt and Tischler, Nature 297:152-154). We now report on the effects of nerve growth factor on m4 mAChR mRNA expression in PC12 cells. Steady state levels of m4 mAChR mRNA were quantitated by Northern blot analysis and normalized to glyceraldehyde-3-phosphate dehydrogenase mRNA levels. Incubation of cultures of PC12 cells with nerve growth factor (50 ng/ml) induced an up-regulation of m4 mAChR mRNA that was significant after day 3 (1.8-fold) and maximal by days 12-15 (3 to 4-fold). Quantification of m4 mAChRs in intact cells demonstrated that induction of m4 mAChR mRNA levels was correlated with m4 mAChR up-regulation. m4 mAChR density was 43 fmol/mg protein under basal conditions and maximally increased by approximately 3-fold on days 12-15 of nerve growth factor treatment. The contribution of transcriptional and post-transcriptional events on nerve growth factor-induced up-regulation of m4 mAChR mRNA is currently under investigation by utilizing nuclear run-on and RNase protection assays, respectively. Preliminary results indicate that nerve growth factor may stabilize m4 mAChR mRNA in PC12 cells. The half-life of m4 mAChR mRNA in untreated cells was 2 hours and increased 3-fold following 9 days of nerve growth factor treatment. This study indicates that nerve growth factor up-regulates m4 mAChRs by controlling the expression of receptor mRNA levels.

551.4

EXPRESSION OF MUSCARINIC RECEPTOR SUBTYPES IN PC12 CELLS: EFFECTS OF DEXAMETHASONE. R. Basiboina, C. Hale, and R. Strong*. Department of Cellular and Structural Biology, University of Texas Health Science Center and GRECC, Audie L. Murphy Memorial Veterans Hospital, San Antonio, TX 78284 and Abbott Laboratories, Abbott Park, IL 60064.

Our laboratory is studying the role of transmembrane signal transduction in modulation of tyrosine hydroxylase gene expression in the adrenal chromaffin cell. Our initial attempts to use PC12 cells, a cell line derived from a tumor of the rat adrenal medulla, as a model system to study the function of muscarinic cholinergic receptors were impeded by the fact that they possess relatively low numbers of receptors. We considered the possibility that they would express higher receptor numbers if they were grown under conditions that more closely approximate the hormonal environment of the adrenal medulla. PC12 cells grown in the presence of nerve growth factor (NGF) express a phenotype similar to that of sympathetic neurons and show an increase in both muscarinic and nicotinic cholinergic receptors. On the other hand, corticosteroids direct the PC12 cell toward a chromaffin cell-like phenotype. In the present study, we examined the effects of dexamethasone on the expression of muscarinic receptor subtypes.

Preconfluent PC12 cells were treated for 15 days with dexamethasone. Muscarinic receptor RNA was determined from Northern blots of poly-A RNA extracts using cDNA probes for the various receptors. Dexamethasone treatment doubled the total number of muscarinic receptors as measured by atropine displaceable ³H-QNB binding. Northern analysis of poly-A RNA extracts, using cDNA probes for the muscarinic receptor subtypes, detected the presence of only the m1 and m4 mRNA. However, dexamethasone treatment was only associated with an increase in the level of m4 mRNA. These findings parallel those of studies of the effects of NGF on muscarinic receptors and further show that the increase in muscarinic receptors is primarily due to an increase in the m4 subtype.

ENDOTHELIN-1 INCREASES MUSCARINIC ACETYLCHOLINE RECEPTOR mRNA AND c-FOS mRNA IN CEREBELLAR GRANULE CELLS. E. Fukumauchi^{1,2} and D.-M. Chuang² Medical Research Institute, Tokyo Medical and Dental Univ., 2-3-10, Kandasurugadai, Chiyoda-ku, Tokyo 101, Japan¹ and Section on Molecular Neurobiology, Biological Psychiatry Branch, NIMH, NIH, Bethesda, MD 20892, U.S.A.²

We have previously demonstrated that cerebellar granule cells express endothelin-1 (ET-1) receptors which mediate phosphoinositide hydrolysis and neurotransmitter release. To gain further insight into the functional role of ET receptors in these neurons, we have investigated the effects of ET on the mRNA levels for m2- and m3-muscarinic acetylcholine receptors (mAChRs). ET (10 nM) treatment of granule cells increased m2- and m3-mAChR mRNA levels with a maximal effect at 2 hr; the mRNA levels then declined and returned to the untreated level between 8 and 24 hr. The ET-induced up-regulation of m2- and m3-mAChR mRNAs was abolished by a 15-min pretreatment with phorbol dibutyrate (PDBu), a condition known to inhibit ET-induced phosphoinositide hydrolysis. Long-term (15 hr) treatment with PDBu, which was expected to deplete protein kinase C, also blocked the ET up-regulation, although PDBu alone elicited a significant increase of m3-mAChR mRNA. These results suggest a role of IP₃ production and/or protein kinase C activation in the effect of ET. The ET up-regulation was preceded by a transient increase of c-fos mRNA which peaked at 30 min after ET stimulation. Pretreatment with 2-aminopurine or cycloheximide abolished the ET-induced increase of c-fos mRNA as well as mAChR mRNAs and proteins, suggesting that induction of c-fos is involved in the ET-mediated mAChR up-regulation.

GENERATION OF HERPES SIMPLEX VIRUS RECOMBINANTS FOR ALTERING EXPRESSION OF NEUROTRANSMITTER RECEPTORS IN INFECTED CELLS.

L. Gatzke¹, W. W. -G. Jia¹, X. Wu¹, M. Cynader², and F. Tufaro^{1,2}. Departments of 1Microbiology and Immunology and 2Ophthalmology, University of British Columbia, B.C. Canada.

The efficient introduction of genes into nerve cells is important both for the study of brain function as well as for therapy of neurological disorders. We have generated several HSV recombinants that express the human m1 muscarinic acetylcholine receptor gene (vTKhm1). Expression from this gene is driven by the CMV major I/E enhancer promoter inserted into the TK gene of HSV-1 vhsA, which contains a lac Z gene in UL41. The insertion was confirmed by Southern blots, and transcription from the CMV promoter was measured by RNase protection assays. Muscarinic receptor transcripts originating from the CMV promoter were detected from 2 to 20 h post-infection in vero cells. Ligand binding experiments with radiolabeled N-methyl scopolamine show a fifty fold increase in receptor expression by 12 h post-infection compared with control cells infected with wild type virus. Moreover, new receptors appeared as early as four h post-infection. Efforts are underway to use this recombinant herpes virus for functional studies of neurotransmitter receptors in a variety of neuronal populations.

m2, m3 AND m5 MUSCARINIC ACETYLCHOLINE RECEPTORS mRNA EXPRESSION IN RAT MONONUCLEAR CELLS. P. Costa, D. J. Traver, A. F. Castoldi and L. G. Costa.* Dept. of Environmental Health SC-34, University of Washington, Seattle, WA 98195.

Several radioligand binding studies have demonstrated the presence of muscarinic acetylcholine receptors (mAChR) in lymphocytes from mice, rats and humans. The specific subtype(s) of mAChR present in rat lymphocytes are still unknown, although the m2 or m3 subtypes have been suggested. We analyzed the expression of m2, m3 and m5 mAChR subtypes in white mononuclear cells from rat blood and spleen. Northern blot hybridization and polymerase chain reaction on the reverse transcribed RNA (RT-PCR) were performed on the white mononuclear cells as well as other rat tissues used as positive controls (cerebral cortex, corpus striatum, hippocampus, brainstem, heart). No mRNAs for m2 or m3 subtypes could be detected by Northern blot in the white mononuclear cells. The more sensitive assay of RT-PCR gave a positive signal for the m3 subtype in both blood and spleen mononuclear cells. The level of expression of m3 was found to be about 1/1000 compared to the level of m3 mRNA in the hippocampus. No mRNA for m2 or m5 mAChR could be detected even using RT-PCR, suggesting the absence of the m2 and m5 subtypes in white mononuclear cells. (Supported in part by ES-04696).

ACETYLCHOLINE RECEPTORS: MUSCLE

Cloning of an Alpha-like Neuronal Acetylcholine Receptor (AChR) Subunit from *Aplysia californica*. R. E. McCaman¹ and J. K. Ono, Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010 and Dept. of Biological Science, California State University, Fullerton, CA 92634.

Studies of neurotransmitter receptors in *Aplysia* carried out on individual, identified neurons suggest a rich diversity of receptor subtypes differentiated by ionic selectivity and pharmacological sensitivity for each transmitter. Identification of the molecular bases of this diversity should provide unique insights into how structure relates to function in such arrays of neuronal receptors. Using a variety of techniques (polymerase chain reaction, screening a cDNA library from the circumesophageal ganglia, and 5' rapid amplification of cDNA ends) we have obtained a 2.5 Kb sequence (A15) that has 2 putative start codons. This sequence exhibits marked similarity to previously cloned sequences encoding AChR alpha-subunits from other species such as *Drosophila*, mouse and man. RNA extracted from specific *Aplysia* neurons was reverse transcribed using an A15 sequence-specific primer. The resultant cDNA served as a target for amplification with PCR using various pairs of A15 sequence-specific primers. The results of these experiments indicate that the message encoding our cloned sequence is specifically expressed by those neurons exhibiting the nicotinic AChR in *Aplysia* that selectively gates Na⁺ channels and is inhibited specifically by hexamethonium. These studies demonstrate the feasibility of correlating the structure of cloned subunits with the known functional types of native neurotransmitter receptors present in individual, identified neurons. Supported by NIH grants to REM and to JKO, Beckman Research Funds to REM and CSU mini-grants to JKO.

BINDING OF THE ACHR TO SH2 DOMAINS OF FYN AND FYK PROTEIN TYROSINE KINASES S. L. Swope* and R. L. Huganir. Dept. of Neuroscience, Howard Hughes Medical Inst., The Johns Hopkins Univ. Sch. of Med., Baltimore, Md. 21205

The nicotinic acetylcholine receptor (AChR) is phosphorylated on tyrosine both *in vitro* and *in vivo*. To identify the protein tyrosine kinase (PTK) which phosphorylates the receptor, we have cloned and characterized two PTK that are highly expressed in Torpedo electric organ, a tissue enriched in the AChR. One of the kinases was the homolog of neuronal fyn while the other was a novel kinase we have named fynk due to its homology to fyn and yes PTK. Both kinases were shown by coimmunoprecipitation to be specifically associated with the AChR. In this study, we examined the molecular basis for the interaction of fyn and fynk with the AChR. SH2 domains, originally identified in the src class of PTK, interact with phospho-tyrosine containing proteins. Therefore, fusion proteins containing the SH2 domains of fyn and fynk were prepared and used as affinity reagents. The SH2 domains of fyn and fynk specifically bound the AChR. The association of the AChR with the SH2 domains was blocked by phospho-tyrosine and phenylphosphate, but not by phospho-serine or phospho-threonine indicating that the interaction was dependent on tyrosine phosphorylation of the AChR. The AChR β , γ , and δ subunits are each phosphorylated on a single tyrosine on the major intracellular loop. Upon dissociation of the AChR into subunits, the δ but not the β or γ subunits bound to the SH2 domain of fyn and fynk. These data suggest that the association of the AChR with fyn and fynk is mediated by an interaction of the tyrosine-phosphorylated intracellular loop of the receptor δ subunit with the SH2 domain of the PTKs.

CYTOSKELETAL ELEMENTS MAY BE INVOLVED IN THE RESENSITIZATION OF THE MOTOR ENDPLATE FOLLOWING PROLONGED CARBACHOL EXPOSURE. J.C. Hardwick* and R.L. Parsons. Department of Anatomy and Neurobiology, University of Vermont, Burlington, VT 05405.

We have suggested that recovery of endplate sensitivity following a 5-10 min exposure to 540 μ M carbachol may require the recruitment of AChRs from a readily available pool to replace receptors which were irreversibly inactivated by prolonged agonist exposure (Hardwick & Parsons, Br J Pharmacol, 108:741, 1993). To test whether elements of the subsynaptic cytoskeletal system are involved in the recruitment of new receptors, we studied the influence of colchicine pretreatment (10^{-4} M for 16-18 hr) on the extent of MEPC amplitude recovery following a 10 minute application of 540 μ M carbachol. All experiments were done using potassium-depolarized twitch fiber endplates from snake costocutaneous muscles voltage clamped to -100 mV. In preparations treated with colchicine, but not exposed to carbachol, MEPC amplitudes and decay time constants were similar to control preparations. Following carbachol exposure, mean MEPC amplitude (but not the decay constant) was significantly less at colchicine-treated endplates than at control endplates. Prior to carbachol application, the single channel conductance was similar at control and colchicine-treated preparations. However, at colchicine-treated endplates, following recovery from carbachol exposure, large (41 pS) and small (28 pS) ACh-activated channels were recorded. These results suggest that colchicine, presumably by disrupting subcellular cytoskeletal organization, interferes with the conversion of the single channel conductance from a small to large conductance state in the replacement AChRs. Supported by NIH grants NS 06580 to J.C.H. and NS 23978 to R.L.P.

NICOTINIC ACETYLCHOLINE RECEPTOR ASSEMBLY MAY BE REGULATED THROUGH PHOSPHORYLATION OF A SECONDARY PROTEIN S. Jayawickreme and T. Claudio*. Dept. Cellular & Molecular Physiology, Yale Univ. Sch. of Med., New Haven, CT 06510.

The nicotinic acetylcholine receptor (AChR) is a pentameric complex composed of four different subunits with a stoichiometry of $\alpha_2\beta\gamma\delta$. The efficiency of AChR subunit assembly can be enhanced 2-fold by treating cells (either muscle cells or non-muscle cells expressing recombinant AChR) with the protein kinase A (PKA) activator, forskolin. We have shown that although γ and δ subunits undergo phosphorylation by PKA, only phosphorylation of the γ subunit correlates with an increase in assembly efficiency (Green et al. (1991) Neuron 7:659-666). The two consensus PKA sites (serine) of γ were singly or doubly mutated to alanines. Mouse L fibroblasts expressing wildtype $\alpha\beta\delta$ plus mutant γ were established. 32 P-orthophosphate labelling of cells showed phosphorylation of the two single mutant γ subunits. The expression of all three mutant receptors was, however, stimulated by forskolin demonstrating that phosphorylation of either or both sites does not lead to enhanced assembly of AChR subunits. To test whether or not phosphorylation of δ can assume the role of γ in stimulating assembly, a cell line expressing wildtype $\alpha\beta$ plus doubly mutant γ was established. When treated with forskolin, assembly of subunits was still enhanced, indicating that stimulation is not mediated through phosphorylation of AChR subunits and suggesting that it may occur through phosphorylation of a protein which is involved in AChR subunit assembly.

552.7

ACETYLCHOLINE RECEPTOR CLUSTERING IN MYOTUBES IS REDUCED BY ELEVATED LEVELS OF THE 43K PROTEIN. C. M. Yoshihara and Z. W. Hall*. Dept. of Physiology, University of California, San Francisco, CA 94143-0444.

A key event in the development of the vertebrate neuromuscular junction is the formation of high density clusters of acetylcholine receptors (AChR) in the postsynaptic membrane. AChR clustering has been thought to occur by their association with a cytoplasmic, peripheral membrane protein (43K protein) that occurs in approximately 1:1 stoichiometry with the AChR. We have sought to examine the regulatory role of the 43K protein in AChR clustering by overexpressing it in muscle cells, in which it normally occurs. We isolated C2 muscle cell lines in which some cells overexpress the 43K protein and found that myotubes with increased levels of the 43K protein have small AChR clusters and that those with the highest levels of expression have a drastically reduced number of clusters. The reduction in cluster size and number was not due to a decrease in AChR expression. Examination of surface AChR expression in individual myotubes by autoradiography revealed no difference between high and low expressors. Moreover, the 43K protein expressed in the myotubes appears to be functional. It is able to form co-clusters with AChRs in myotubes and in transiently transfected COS cells. Thus, increased expression of the 43K protein appears to interfere with normal AChR cluster formation by muscle cells. Our results suggest that the 1:1 stoichiometry of the 43K protein and the AChR is important for AChR clustering. This work was supported by grants from the NIH, the Muscular Dystrophy Association, and by a President's Fellowship from the University of California.

REMOVAL OF THE DISULFIDE LOOP STRUCTURE FROM *Torpedo* nAChR SUBUNITS ALTERS FUNCTIONAL PROPERTIES OF THE RECEPTOR. E.C. Walcott* T. Nishizaki, and K. Sumikawa. Dept. of Psychobiology, University of California, Irvine, CA 92717.

We have previously demonstrated that the formation of a conserved disulfide bond between Cys-128 and Cys-142 residues on β subunits of the *Torpedo* nicotinic acetylcholine receptor (AChR) is not necessary for receptor assembly; however, is required for efficient insertion of receptors into the plasma membrane. When site-directed mutant β mRNA was injected together with normal α, γ, δ mRNAs into *Xenopus* oocytes and assayed using two-electrode voltage clamp, expressed receptors show >94% reduction in ACh response as compared to normal AChRs, suggesting that many AChRs remain within intracellular compartments (*J Biol. Chem.* 267(9):6286, 1992).

To further investigate the role of tertiary structure in AChR function, we analyzed mutant receptors lacking the conserved disulfide loop structure in the β subunit at the single channel level, using patch clamp in the outside-out patch configuration. The single channel current/voltage (*I/V*) relations indicated that the conductance of mutant AChRs (17.1 ± 1.8 pS, $n=3$) was lower than that of wildtype AChRs (30.7 ± 4.9 pS, $n=23$). Mean open channel time (1.5 ± 0.3 ms, $n=3$) did not differ from normal AChRs. These results indicate that the extracellular tertiary structure of the β subunit of the AChR is important for receptor function. Current studies are aimed at defining the functional roles of tertiary structure in γ and δ mutant subunits. (Supported by NIMH-NRSA 14599-17 and the Muscular Dystrophy Association).

TYROSINE KINASE INHIBITORS BLOCK AGRIN-INDUCED ACETYLCHOLINE RECEPTOR CLUSTERING ON CULTURED CHICK MYOTUBE. Z. Qu* and R. L. Huganir, Howard Hughes Medical Institute, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

The nicotinic acetylcholine receptor (AChR) is a ligand-gated ion channel that mediates signal transduction at the neuromuscular junction. The AChR from *Torpedo* electric organ and mammalian skeletal muscle is a pentameric complex of four subunits in the stoichiometry of $\alpha_2\beta\gamma\delta$. A number of experiments have shown that phosphorylation of neurotransmitter receptors plays an important role in the regulation of synaptic transmission. Recent studies have demonstrated that the AChR is regulated by phosphorylation by several serine and tyrosine kinases. Our previous data suggest that tyrosine phosphorylation of the AChR is regulated by innervation and the neuronal protein agrin. Agrin, a synaptic basal lamina protein released by motor neurons, causes the AChR, a 43kDa protein and other components on cultured chick myotube to aggregate, forming specializations that resemble the postsynaptic apparatus at the neuromuscular junction. We have attempted to further define the relationship between tyrosine phosphorylation and acetylcholine receptor clustering. A specific tyrosine kinase inhibitor, herbimycin, has been used to inhibit agrin-induced tyrosine phosphorylation of the AChR and possibly other proteins and results in inhibition of agrin-induced AChR clustering. In addition, herbimycin disperses previously formed agrin-induced receptor clusters on cultured chick myotubes. These results suggest that tyrosine phosphorylation may play an important role in acetylcholine receptor clustering and developmental regulation of synaptic formation at the neuromuscular junction.

INCREASES IN THE PROPORTION OF SLOWLY DEGRADING ACETYLCHOLINE RECEPTORS IN RAT MUSCLE CELL CULTURES. J.P. O'MALLEY* & M.M. SALPETER Section of Neurobiology & Behavior, Cornell University, Ithaca NY 14853

Cultured rat myotubes express two AChR populations decaying with half-lives of 1 day (rapidly decaying AChRs or R_r) and 3 days (slowly decaying AChRs or R_s) in a ratio of 9:1 respectively, which is similar to that seen at the denervated neuromuscular junction (nmj). At the nmj reinnervation leads to a downregulation of R_r and an upregulation of R_s .

To determine if neuronal factors regulate the relative expression of R_r and R_s , we investigated the role of ATP (released from the nerve during transmission) and dB-cAMP (which resembles innervation in its effect on AChR stability [Salpeter et al. *Annals NY Acad Sci*, 1993]). Myotubes were treated with either 1 mM ATP or with 1 mM dB-cAMP three days after seeding on Matrigel substrates. Cultures plated on Matrigel can be maintained for prolonged periods of time, even after the initiation of spontaneous activity. The treatment was continued for 0 to 13 days before the AChRs were labeled with [125 I]- α -bungarotoxin. The loss of label was then measured for the next 13 days in the presence of the test drugs. We found that ATP progressively increased the expression of both R_r and R_s relative to controls, with the increase in R_s slightly exceeding that of R_r . Conversely dB-cAMP markedly suppressed R_r expression but had little effect on R_s .

Thus, like innervation, both cAMP and ATP increased the relative amount of R_s expressed in the myotubes. However cAMP suppressed R_r while ATP upregulated AChR favoring R_s . We are presently comparing these drug-induced changes in AChR expression with innervation to determine if alone, together or in combination with muscle activity they can induce the same developmental changes as innervation. Supported by NIH grant NS09315 (MMS) and MDA postdoctoral fellowship (JOM)

Heterogeneous Expression of Acetylcholine Receptor (AChR) Subunit mRNAs in Muscles is Independent of Fusion. X. Su, S. Berman, T. Sullivan and S. Bursztajn*. Mailman Research Center, McLean Hospital and Harvard Medical School, 115 Mill Street, Belmont, MA 02178.

Muscle progenitor cells differentiate into myoblasts and subsequently myotubes upon expression of muscle specific genes which are induced by myogenic factors. We have been interested in studying whether muscle specific genes are switched on uniformly in nuclei of myoblasts and myotubes. *In situ* hybridization study with myoD (myogenic factor) and U1 (intron splicing factor) gene probes showed uniform expression of these genes among nuclei of myoblasts, fusing myoblasts, and myotubes. However, study with AChR subunit (α , γ , δ) specific intron or exon-intron probes revealed that AChR subunit genes were expressed heterogeneously by the nuclei. The overall expression level of subunit genes was doubled after cell fusion and declined in mature muscle cells. The result indicates that the presence of myogenic factors does not induce full expression of AChR subunit genes in all muscle nuclei. The result can be interpreted to mean that the nuclei of muscle cells are programmed for heterogeneous expression of AChR genes before and after fusion.

552.11

TRANSCRIPTIONAL ACTIVATION OF THE MOUSE MYOGENIN GENE BY DENERVATION IS CONFERRED BY 5' CIS-ACTING ELEMENTS. G. Gibney, J. M. Sasner* and A. Buonanno. Laboratory of Developmental Neurobiology, NICHD, NIH, Bethesda, MD 20892.

Denervation of mouse hindlimb skeletal muscle results in a rapid accumulation of myogenin mRNA which precedes increases in nicotinic acetylcholine receptor (nAChR) subunit transcripts by 16-24 h. (Efimie *et al.* (1991) Proc. Natl. Acad. Sci. 88, 1349.) Since myogenin activates transcription of nAChR genes *in vitro* through E-box binding, it is probable that activation of the myogenin gene is more proximal to denervation in the pathway leading to induction of receptor subunit genes. We are employing *in vivo* and *in vitro* approaches to identify transcriptional regulatory elements of the mouse myogenin promoter-enhancer which confer activation by denervation. Transgenic mice have been created which carry a 3.7 kb upstream sequence of the myogenin gene driving a chloramphenicol acetyltransferase (CAT) reporter. These transgenic mice appropriately express reporter with respect to tissue- and developmental-specificity. Expression of the transgene (MYG3700.CAT) in adult hindlimb muscle increases 10-fold within 24 h after denervation; maximal levels of 40-fold are obtained by 4 d. We have generated stable C2 myoblast lines carrying successive 5'-deletion mutants of MYG3700.CAT as an efficient means of delineating *cis*-acting elements mediating the activity response. Effects of activity on myogenin gene transcription are analyzed by electrically stimulating C2 myotube cultures derived from the cell lines. To extend our analysis *in vivo*, we are testing the myogenin-CAT lines by myoblast implantation into mouse hindlimbs. Using this technique, we can demonstrate activation of nAChR α -subunit and myogenin reporter genes by denervation of the implanted hindlimb; in parallel experiments, activity of a myosin light chain reporter remains relatively unaffected by denervation. With this combined approach, we expect to determine which *cis*-acting control elements within the myogenin promoter confer differential gene expression with respect to electrical activity.

552.10

INFLUENCE OF SPONTANEOUS MUSCLE ACTIVITY ON ACETYLCHOLINE RECEPTOR EXPRESSION IN CULTURED MAMMALIAN MYOTUBES. C.G. Carlson*, A.K.O. Hasan, S.D. Adkins, M.J. Blake, A.M. Bode, S. Loyland. Depts. of Physiology and Pharmacology/Toxicology, Univ. N. Dakota School of Medicine, Grand Forks, N.D. 58202.

The influence of chronic exposure to tetrodotoxin (TTX) and Veratridine (VER) on Acetylcholine Receptor (AChR) expression was examined in long term cultures of mouse myotubes maintained on a laminin substrate. A significant effect ($p < 0.05$) of drug exposure (between Culture Day (CD) 7 and 17) on total surface AChRs (I-125 alpha - bungarotoxin binding) was observed in 6 of 7 individual culture runs. TTX significantly ($p < 0.05$) upregulated total surface AChRs by 54% on CD 13 in 3 of 5 culture runs and by 85% on CD 17 in 4 of 7 culture runs. VER failed to significantly influence total surface AChRs in 6 of 7 culture runs and produced a significant increase in only 1 of 12 comparisons performed at CD 13 and 17. Northern transfers indicated a substantial downregulation of embryonic AChR subunit mRNA's between CD 13 and 23 in VER treated myotubes. In contrast to effects on total surface AChRs, VER substantially downregulated and TTX produced only a slight increase in gamma subunit mRNA at CD 13 to 15 (2 of 2 culture runs). These results suggest that the disparate actions of TTX and VER on surface AChR expression are not due to opposing actions on a common activity - dependent mechanism (e.g., intracellular calcium accumulation) of AChR regulation. Supported by a grant from M.D.A.

THE TRANSMEMBRANE TOPOLOGY OF THE NICOTINIC ACETYLCHOLINE RECEPTOR: A MOLECULAR MODELLING APPROACH. M.O. Ortells* and G.G. Lunt*. Biochemistry Department, University of Bath, Bath, BA2 7AY, UK.

The nAChR is formed from five subunits, each with an extracellular N-terminal domain, a transmembrane region (TM), and an extracellular C-terminal domain. The TM is believed to be composed of four α -helices, M1 to M4. The four-helix bundle structure is based mainly on hydrophobicity profiles. The best characterised of the nAChR TMs is M2 and there is a wealth of information that identifies this as the region that lines the ion-channel. Most of these data are only compatible with an α -helix conformation for M2. The molecular modelling started from the ion channel region using the α -1 Torpedo sequence of M2. The final model of the ion-channel comprises a five helical bundle with a left-handed twist. The angle between adjacent helices is around 120°. The diameter of the narrowest part of the pore, from E237 to S240 is 7.5Å and its length is 8Å. The channel is wider at the extracellular end. When chlorpromazine is docked into the channel it can interact with three labelled residues in the Torpedo receptor.

To model the remainder of the TM, we used the X-ray structure of myohaemeryhrin as a template for a four-helix bundle. Five copies were superimposed onto the ion-channel using the shared M2 helix. In this model, M4 is the most exposed to the membrane, and the twist imposed on M2 allows it to be perpendicular to the membrane.

Interestingly M1 of one bundle overlaps in one region with M3 of the neighbouring bundle. Different orientations of the bundle (with the position of M2 fixed) gave the same results, although they superimpose in different regions. Given this conformation, it is also evident that M3 is quite exposed to the membrane environment, thus it is surprising that this segment has not been labelled by lipophilic reagents as much as M4.

Our models suggest may suggest that neither of these two transmembrane regions are α -helices but may be (partially) β -sheets. In this case, these two domains must protrude into either the extracellular or cytoplasmic regions. No models of these alternatives have yet been made (for example, to form a ten β -sheet barrel), but clearly this must be a high priority for future studies.

CYCLOTHIAZIDE POTENTIATION OF OXYGEN AND GLUCOSE DEPRIVATION-INDUCED ⁴⁵Ca UPTAKE AND LDH RELEASE IN CEREBROCORTICAL CELL CULTURE. A.W. Probert* and F.W. Marcoux. Neuroscience Pharmacology, Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Co. 2800 Plymouth Road, Ann Arbor, MI 48105.

Cerebrocortical culture exposures to combined oxygen and glucose deprivation ($+O_2/Gluc = 1\% O_2 / 1mM D-glucose$) increases ⁴⁵Ca uptake acutely and causes neuronal death (LDH release 24 hours later). During glucose deprivation, increasing hypoxic intervals (150 - 240 mins) increased ⁴⁵Ca uptake and LDH release. CPP (100 μM), an NMDA antagonist, blocked both measures effectively (90-100% inhibition) following $+O_2/Gluc$ intervals ≤ 210 minutes. NBQX (10 μM), an AMPA antagonist, was less effective than CPP, inhibiting ⁴⁵Ca uptake (45-54% inhibition) and LDH release (72-79% inhibition) up to 170 mins, but not thereafter. Cyclothiazide (30 μM), an inhibitor of AMPA receptor desensitization, potentiated (41-379% increase) both ⁴⁵Ca uptake and LDH release after $+O_2/Gluc$ of ≤ 170 mins, but that potentiation did not exceed levels observed after longer deprivation intervals (≥ 190 min) in controls. After $+O_2/Gluc$ intervals of 150-170 mins NBQX and CPP blocked cyclothiazide's potentiation of ⁴⁵Ca uptake and LDH release (83-100% inhibition). Following $+O_2/Gluc$ intervals of 190-210 mins, NBQX, which had no effect on ⁴⁵Ca uptake and LDH release in controls, partially blocked (54-60% inhibition) both measures in cyclothiazide treated cultures. CPP, which inhibited ⁴⁵Ca uptake and LDH release after $+O_2/Gluc$ of 190-210 mins in controls, partially blocked (64-86% inhibition) both measures in cyclothiazide treated cultures. Whereas CPP (38-61% inhibition) but not NBQX blocked ⁴⁵Ca uptake and LDH release after 240 mins of $+O_2/Gluc$ in controls, neither CPP nor NBQX inhibited these measures in cyclothiazide treated cultures. These findings suggest that AMPA receptors can potentiate ⁴⁵Ca uptake and LDH release after $+O_2/Gluc$ in cerebrocortical cultures.

CYCLOTHIAZIDE ENHANCES AMPA- AND KAINATE-INDUCED CELL DEATH IN CULTURED RAT CORTICAL NEURONS. G.W. Campbell* and D.M. Rock. Neuroscience Pharmacology Dept., Parke-Davis Research, Division of Warner Lambert Co., Ann Arbor MI 48106.

Cyclothiazide and related compounds, which are clinically useful anti-hypertensive agents, have been shown in electrophysiological studies to reduce glutamate-induced desensitization and prolong excitatory postsynaptic currents. We studied the effects of cyclothiazide on α -amino-3-hydroxy-5-methylisoxazole-4-propionic acid (AMPA)- and kainate (KA)-induced cell death in cultured rat cortical neurons. To quantify the degree of cell death, activity of the cytosolic enzyme lactate dehydrogenase (LDH) was measured from samples of medium taken from cultures following long applications (20-24 hrs) of either AMPA or KA in the presence or absence of cyclothiazide.

Cyclothiazide (10 and 30 μM) caused a pronounced shift in the EC₅₀ of both AMPA and KA concentration response curves and an increased the maximal responses of both AMPA and KA. CPP (100 μM), a competitive NMDA receptor antagonist, reduced the increase in maximal response, suggesting that the increase in maximal response may be due to the action of released glutamate on the NMDA receptor.

These studies suggest that cyclothiazide, which affects glutamate-induced desensitization, can cause pronounced effects making long applications of both AMPA or KA more effective in producing neuronal cell death.

BRAINSTEM INFUSION OF GLUTAMATE RECEPTOR ANTAGONISTS SUGGESTS A ROLE OF NON-NMDA RECEPTORS IN SPONGIFORM DEGENERATION OF THE GERBIL COCHLEAR NUCLEUS. B.T. Faddis* and M.D. McGinn, Dept. Otolaryngology, Univ. of Calif. Sch. of Med., Davis, CA 95616.

A naturally occurring spongiform degeneration of the gerbil cochlear nucleus has been shown to be strongly dependent on auditory functional activity, suggesting an excitotoxic origin. We previously showed that unilateral brainstem infusions of kynurenic acid reduced degeneration when compared to the contralateral side (Soc. Neurosci. Abst., 17:1484). Here we report that brainstem infusions of 100 μ M and 540 μ M CNQX, a non-NMDA receptor antagonist, reduces lesion number density by 28% compared to the contralateral side ($F_{1,27}=9.290$, $p=0.0052$ and $F_{1,27}=9.332$, $p=0.0052$). A mixture of 540 μ M CNQX + 10 mM MK-801 was also effective ($F_{1,27}=10.727$, $p=0.0032$), but no more so than CNQX alone. 10 mM 5,7-dichlorokynurenic acid (KYN) caused a 37% reduction in lesion number density ($F_{1,27}=7.761$, $p=0.0094$). Infusions of saline, 100 μ M and 10 mM MK-801 and 100 μ M KYN showed no significant effect. These results suggest that the induction of spongiform lesions is mediated by non-NMDA glutamate receptors and not by NMDA receptors.

ALTERATION OF THE GLUR-B AMPA RECEPTOR SUBUNIT FLIP/FLOP EXPRESSION AND STOICHIOMETRY IN KAINATE-INDUCED EPILEPSY AND ISCHEMIA. H. Pollard, A. Heron, J. Moreau, C. Charriaud, Marlangue, M. Khrestchatsky, J. Epelbaum*, and Y. Ben-Ari. INSERM, U 29, 123 Brd de Port Royal, 75014, Paris, France.

In the hippocampus, glutamatergic pathways are altered following seizure activity or transient global ischemia, both leading to selective neuronal degeneration. Glutamatergic receptors, and notably AMPA receptors, may play an important role in the pathological outcome. AMPA receptors are assembled from GluR-A, GluR-B, GluR-C and GluR-D polypeptides which exist in flop and flip variants, the latter allowing larger glutamate currents. Using *in situ* hybridization we show that following kainate administration (ip or intraamygdala) there is a rapid (3 hours) and transient increase (50%) of GluR-B flip mRNA levels in CA1, CA3 and dentate gyrus. This early phase is followed by a second, persistent (1-3 days), GluR-B flip increase in seizure-resistant areas (CA1 and dentate gyrus) and a 40% decrease in the vulnerable CA3 area. Following global ischemia, the levels of GluR-B flip and flop variants are dramatically reduced (90-100%) in the subiculum and CA1, two areas particularly sensitive to ischemic insult. In keeping with the properties of GluR flip variants, it is suggested that altered subunit stoichiometry may lead to long-lasting enhanced efficiency of synaptic transmission in the epileptic hippocampus. Since GluR-B containing receptors are Ca^{2+} impermeable, our results also suggest altered Ca^{2+} permeability in the vulnerable pyramidal neurons of areas CA3 and CA1 in the epileptic and ischemic hippocampi respectively. *Sponsoring author, INSERM, U 159. + CNRS, U 641.

GLUTAMATE-MEDIATED EXCITOTOXIC DEATH OF CULTURED STRIATAL NEURONS IS MEDIATED BY NON-NMDA GLUTAMATE RECEPTORS. Q. Chen*, C. Harris, C.S. Brown, D.J. Surmeier and A. Reiner, Dept. Anat and Neurobiol., Univ. of Tennessee - Memphis, Memphis, TN 38163.

Recent interest has focused on the role of glutamate-mediated excitotoxicity in neurodegenerative disorders of the basal ganglia. The *in vitro* data on the receptor mechanisms involved in mediating this process, however, have been inconclusive. Some studies have indicated that excitotoxins acting at NMDA receptors kill striatal neurons but others have indicated that NMDA receptor mediated excitotoxic death of striatal neurons is minimal in the absence of cortex (Galarraga et al., Brain Res., '90). In the present study, we used a pharmacological approach to carefully examine this issue in two week old cultures of striatal neurons dissociated from E17 rat embryos. The sensitivity of these neurons to 1hr exposure to glutamate agonists and antagonists was determined by monitoring cell loss in identified regions of the growth dishes 24hrs after exposure.

We found that glutamate was a moderately potent excitotoxin in striatal cultures devoid of cortical tissue. The EC50 for neuronal loss following glutamate exposure was near 100 μ M. At saturating concentrations (500-1000 μ M), glutamate produced a 20-40% loss of identified neurons. This effect did not appear to be the result of NMDA receptor activation for two reasons. First, the NMDA-agonist quinolinic acid (QA) at concentrations up to 10mM did not produce neuronal loss. Depolarization with 35mM KCl to relieve the Mg²⁺ block of NMDA channels did not alter QA toxicity. Second, the specific NMDA receptor antagonist AP-5 did not antagonize the glutamate-induced loss at concentrations up to 10 times that of glutamate. In contrast, the ionotropic glutamate receptor antagonist CNQX did attenuate the loss produced by 100 μ M glutamate. These results suggest that while glutamate at high micromolar concentrations is toxic to neostriatal neurons, non-NMDA receptors - rather than NMDA receptors - are crucial to its expression. ELECTROPHYSIOLOGICAL CORRELATES OF AMPA-INDUCED NEUROTOXICITY OF NEONATAL RAT PURKINJE CELLS (PCs).

I. C. Strahlendorf* and H. K. Strahlendorf, Depts of Physiology and Neurology, Texas Tech University Health Sciences Center, Lubbock, TX, 79430.

It is becoming increasingly evident that AMPA is a neurotoxin. The rat cerebellar PC is an excellent model neuron of AMPA toxicity because it is rich in AMPA receptors and relatively devoid of NMDA receptors. We electrophysiologically characterized the events associated with AMPA-induced toxicity utilizing whole cell patch clamp recordings of early postnatal PCs (5-21 days) in the rat cerebellum *in vitro* slice preparation.

AMPA exposure (30 μ M for 30 min., [trigger phase]) caused a marked depolarization (inward current) with increased conductance that displayed varying degrees of desensitization. During the expression phase (90 min following AMPA exposure), membrane potentials of PCs often returned to control levels; but within 65-80 min, a sustained depolarization preceded by Ca spikes and an increased frequency of inward synaptic currents was evident. These events and the morphological correlates could be prevented with the continuous application of the AMPA antagonist CNQX, although treatment during the trigger phase alone was ineffective. Furthermore, depolarization alone induced by voltage clamping PCs at -10mV for 30 min was ineffective in mimicking AMPA toxicity. These studies provide electrophysiological correlates for the morphological changes that previously have been described by Garthwaite and colleagues. 553.6

ENHANCED EXPRESSION OF THE GLUR6 KAINATE RECEPTOR SUBUNIT INDUCES EXCITOTOXIC LOSS OF CA3 AND HILAR NEURONS IN HIPPOCAMPAL SLICE CULTURES. P. Casaccia-Bonneli*, E. Benediktz, H. Shen, H.J. Federoff*, and P.J. Bergold, SUNY-Health Science Center at Brooklyn, Brooklyn, NY, 11203; *Albert Einstein School of Medicine, Bronx, NY, 10461

HSVGLuR6 microapplication into stratum pyramidale of CA3 induced epileptiform discharge both *in vivo* and *in vitro* (see Bergold, et al., and During, et al., these abstracts). PCR amplification was performed using primers specific to the HSVGLuR6 genome to assay the loss of HSVGLuR6-transduced cells. HSVGLuR6-transduced cells were lost between 3.5 and 4.5 hours after microapplication which is at a similar time as the end of the epileptiform discharges. 20-24 hours after microapplication loss of non-transduced CA3 and hilar neurons was observed. Non-transduced cell loss was blocked using NMDA antagonists or tetrodotoxin, suggesting that it required synaptic transmission and NMDA receptor activation. A threshold of HSVGLuR6-transduced cells was necessary to induce the delayed loss of non-transduced CA3 neurons. Microapplication of additional HSVGLuR6 virions resulted in a larger neuronal loss. Co-application of the GABA-A antagonist, picrotoxin, reduced the threshold of HSVGLuR6-transduced cells. Enhanced GluR6 expression in a limited number of neurons likely results in induction of an epileptiform discharge and loss of both HSVGLuR6-transduced and non-transduced neurons.

NIMODIPINE ATTENUATES KAINATE-INDUCED CELL DEATH AND INCREASES IN $[Ca^{2+}]_i$ IN MURINE CORTICAL CULTURES. A.D. Lindsay* and J.H. Weiss, Dept. of Neurology, University of California, Irvine, 92717.

High concentrations of dihydropyridine (DHP) Ca^{2+} channel blockers attenuate neurodegeneration of cortical cultures produced by prolonged AMPA/kainate exposures, (Weiss et al., Science 247:1474). The effect of chronic kainate exposure on intracellular calcium ($[Ca^{2+}]_i$) and cell death was studied in murine cortical cultures in the presence and absence of the DHP, nimodipine (NP).

FURA-2 imaging (25 $^{\circ}$ C, static 2 ml bath) revealed stable $[Ca^{2+}]_i$ levels of 10-50 nM for up to 8 hr. (maximum imaging duration for all experiments) in the absence of agonist. Addition of 30-100 μ M kainate (KA) caused an initial rapid increase in $[Ca^{2+}]_i$ of 80 to 400 nM followed by a decay over several minutes to a stable plateau level (-25-60% of the peak change in $[Ca^{2+}]_i$) which most cells were able to maintain for up to 8 hr. Both the peak and plateau levels varied widely between different cells. 24 hour exposure to 100 μ M KA at 25 $^{\circ}$ C killed 20-40% of the cells (as assessed by trypan blue staining of same cells used in imaging study). There was no correlation between the changes in $[Ca^{2+}]_i$ produced by KA and the likelihood of cell death.

20 μ M NP caused a very slight (<20 nM) decrease in resting $[Ca^{2+}]_i$ levels and a pronounced attenuation of both the peak (up to 60%) and plateau (up to 50%) KA-produced increases in $[Ca^{2+}]_i$ (as compared to sister cultures with no NP). NP also reduced or eliminated KA-induced cell death. This suggests that Ca^{2+} influx through DHP-sensitive Ca^{2+} channels may be instrumental in chronic kainate neurotoxicity. In addition, there was a small population of cortical neurons which NP did not protect from KA-toxicity or KA-induced increases in $[Ca^{2+}]_i$. Perhaps the primary source of KA-induced Ca^{2+} influx in these unusual cells is through either DHP-insensitive Ca^{2+} channels or through Ca^{2+} permeable AMPA/kainate channels.

Supported by grants from the Alzheimers Assoc. and the Paralysis Project.

KAINATE INDUCES DIRECT Ca^{2+} ENTRY IN A SUBPOPULATION OF CULTURED CORTICAL NEURONS. L.M.T. Canzoniero*, S. Sensi, D. Turetsky and D.W. Choi. Dept. of Neurology and Center for the Study of Nervous System Injury, Washington Univ. School of Medicine, St. Louis, MO 63110.

Kainate-stimulated Ca^{2+} uptake, a marker for divalent cation-permeable AMPA receptors, can be detected histologically on about 15% of neurons in murine cortical cell cultures, and these Ca^{2+} -positive cells exhibit heightened vulnerability to kainate toxicity (Turetsky et al., Soc. Neurosci. Abstr. 18: 81, 1992). Here we used fura-2 microfluorimetry to confirm that kainate can induce Ca^{2+} influx into Ca^{2+} -positive neurons directly via agonist-gated channels.

Most cortical neurons exposed to 50 μM kainate in normal buffer solution (130 mM Na^+) responded with a marked increase in intracellular free Ca^{2+} , $[\text{Ca}^{2+}]_i$. However, if extracellular Na^+ was replaced by equimolar N-methyl-D-glucamine to prevent Ca^{2+} influx occurring subsequent to Na^+ influx (for example, via voltage-gated Ca^{2+} channels, or reverse operation of the Na^+ - Ca^{2+} exchanger), only 20/160 neurons responded to kainate with an increase in $[\text{Ca}^{2+}]_i$. 18/20 of these responding cells took up Ca^{2+} during a subsequent kainate exposure. These results support the hypothesis that excess Ca^{2+} entry through Ca^{2+} -permeable AMPA receptors (presumably lacking the edited form of the GluR2/GluR-B subunit) mediates the kainate-induced death of Ca^{2+} -positive cortical neurons.

SUCCESSFUL TREATMENT OF EARLY EXCITOTOXIC/ISCHEMIC NEURONAL INJURY BY PERMEANT Ca^{2+} CHELATORS *IN VITRO* AND *IN VIVO*. M. Tymianski*, M.C. Wallace, I. Spigelman*, M. Uno, P.L. Carlen, C.H. Tator, M.P. Charlton. University of Toronto, Toronto, Canada and *UCLA School of Dentistry, Los Angeles, CA.

We report the first successful treatment of early excitotoxic and ischemic neurodegeneration *in vitro* and *in vivo* by cell permeant analogs of BAPTA (a Ca^{2+} chelator) having a range of Ca^{2+} affinities. The chelators attenuated glutamate-induced intracellular Ca^{2+} increases and early neurotoxicity in neuronal explant cultures. When infused intravenously in rats, permeant fluorescent BAPTA analogs accumulated in neurons in multiple brain regions, including cortical and hippocampal neurons. BAPTA-AM, infused into rats *in vivo*, reduced Ca^{2+} -dependent spike-frequency adaptation and post spike-train hyperpolarizations in CA1 neurons taken from treated animals. This effect was reproduced by direct injections of BAPTA into untreated neurons, illustrating the dependence of this phenomenon on intracellular Ca^{2+} buffering. The effects of three different chelators (BAPTA, 5,5'-difluoro BAPTA and 4,4'-difluoro BAPTA) on Ca^{2+} -dependent membrane excitability varied with their Ca^{2+} affinity (K_d), with higher K_d compounds having lesser effects. When the different chelators were used to treat rats prior to the induction of focal cortical ischemia, they were highly neuroprotective as gauged by significant reductions in cortical infarction volumes and neuronal sparing. The extent of the chelators' protective effects *in vivo* also paralleled their affinity for Ca^{2+} . These data provide a novel therapeutic approach to neuronal ischemia, and the most direct evidence to date that intracellular Ca^{2+} excess triggers early neurodegeneration *in vivo*.

ELEVATION OF INTRACELLULAR CALCIUM LEVELS IN DISSOCIATED NEWBORN RAT BRAIN CELLS CAUSED BY β -N-METHYLAMINO-L-ALANINE (L-BMAA). D.M. Brownson*, S.W. Leslie*, T.J. Mabry*, and J.S. Randall**¹ Dept. of Botany, Col. of Nat. Sci. and ²Div. of Pharmacol. and Toxic., Col. of Pharmacy; The Univ. of Texas, Austin, TX 78712.

This study investigated the ability of β -N-methylamino-L-alanine (L-BMAA), a non-protein amino acid present in edible seeds of the cycad plant *Cycas circinalis*, to increase intracellular calcium in dissociated newborn rat brain cells loaded with fura-2. In a dose-dependent manner, L-BMAA (in 10 mM NaHCO_3) produced an increase of intracellular calcium levels with an EC_{50} value of about 1 nM. The L-BMAA-mediated calcium increases were dependent on the extracellular calcium concentration. In the absence of extracellular calcium, L-BMAA did not increase intracellular calcium. These findings indicate that L-BMAA stimulated extracellular calcium entry but did not cause release of calcium from intracellular sources. L-BMAA-mediated calcium influx was not attenuated either by Mg^{2+} (1 mM) or MK-801 (400 nM), NMDA-receptor antagonists. L-BMAA-mediated calcium increases were highly dependent on the presence of bicarbonate (3-40 mM). The bicarbonate dependence was not due to the alkalization of the buffer medium or the increases in the sodium concentration. These results indicate that the neurotoxicity of L-BMAA is dependent upon the extracellular bicarbonate concentration and suggest the involvement of a carbamate derivative of L-BMAA. Since L-BMAA produces an elevation of intracellular calcium levels, the mechanism of neurotoxicity may be similar to that proposed for other excitatory amino acids although it does not appear to be NMDA receptor-mediated. (1S, 3R)-ACPD ATTENUATES NMDA-INDUCED NEURONAL CELL DEATH VIA A REDUCTION IN SUSTAINED Ca^{2+} ACCUMULATION. G.J. Birrell, M.P. Gordon, R.D. Schwarz and F.W. Marcoux* Neuroscience Pharmacology, Parke-Davis Pharmaceutical Research, Division of Warner-Lambert Co. 2800 Plymouth Rd. Ann Arbor, MI 48105.

Glutamate excitotoxicity is linked to increases in neuronal Ca^{2+} and although blockade of ionotropic receptors results in the inhibition of glutamate-induced neuronal injury, the role played by metabotropic receptor activation is unclear. This study examined whether (1S,3R)-ACPD, a potent and selective metabotropic receptor agonist is neurotoxic, and whether (1S,3R)-ACPD has any effect on NMDA-induced neuronal cell death in primary cerebrocortical cultures derived from fetal rats.

Although causing small increases in Ca^{2+} accumulation, exposure of cultures to (1S,3R)-ACPD alone was not neurotoxic. The presence of (1S,3R)-ACPD during exposure to NMDA attenuated the resulting sustained accumulation of intracellular Ca^{2+} and delayed neuronal cell death. Reductions in sustained Ca^{2+} accumulation were associated both with Ca^{2+} efflux, in the absence of neuronal degeneration, and inhibition of delayed Ca^{2+} influx. The protective effects of (1S,3R)-ACPD were blocked by pre-treatment of cultures with pertussis toxin.

These results suggest that activation of metabotropic glutamate receptors may stimulate intracellular processes capable of limiting excitotoxic neuronal damage.

ELECTROPHYSIOLOGICAL CONSEQUENCES OF INTRACELLULAR Ca^{2+} CHELATION IN HIPPOCAMPAL NEURONS *IN VITRO*.

I. Spigelman*, M. Tymianski* and M.P. Charlton. UCLA School of Dentistry & Brain Research Institute, Los Angeles, USA and *University of Toronto, Toronto, Canada.

Excessive increases in the intracellular concentration of free calcium ($[\text{Ca}^{2+}]_i$) are widely believed to be partial mediators of neuronal damage in cerebral ischemia. We have used intracellular Ca^{2+} chelators *in vivo* to prevent excessive neuronal $[\text{Ca}^{2+}]_i$ increases during ischemia. We showed that following intravenous injection, cell permeant (AM) analogs of BAPTA (1,2 bis-(2-aminophenoxy) ethane N,N,N',N'-tetraacetic acid) accumulate in hippocampal CA1 and neocortical neurons at concentrations sufficient to produce electrophysiologically measurable effects and act as neuroprotectants in experimental focal cerebral ischemia (Tymianski et al., this session). To further examine the actions of BAPTA-AM analogs, intracellular recordings were made from rat CA1 neurons in slices. Bath application of 30 μM BAPTA-AM (high Ca^{2+} affinity, $K_d \approx 100$ nM) had no significant effect on cell input resistance (R_i) or spike amplitude. However, BAPTA-AM decreased spike frequency adaptation and post-spike train slow afterhyperpolarizations (AHPs) measured after 20-30 min of drug application. Furthermore, BAPTA-AM reduced the peak amplitude of evoked excitatory postsynaptic potentials (EPSPs) by 68%. In contrast, similar applications of 5,5'-Br₂BAPTA (low Ca^{2+} affinity, $K_d \approx 3.6$ μM) reduced EPSPs only by 21% and had little effect on R_i , spike adaptation or AHPs.

These data confirm that the actions of BAPTA analogs on membrane excitability depend on their Ca^{2+} affinity. We hypothesize that the neuroprotective effects of BAPTA analogs occur through buffering of excessive $[\text{Ca}^{2+}]_i$ increases. Additional actions of BAPTA *in vivo* may be due to attenuation of synaptic transmission. The data also suggest that the use of low Ca^{2+} affinity chelators like 5,5'-Br₂BAPTA as neuroprotectants may be advantageous since they would buffer excessive increases in $[\text{Ca}^{2+}]_i$, while exerting little effect on membrane excitability and synaptic transmission.

553.14

GLUTAMATE INCREASES INTRACELLULAR FREE MAGNESIUM IN RAT CORTICAL NEURONS *IN VITRO*. S. Rajdev*, J. Brocard and L.J. Reynolds. Dept. Pharmacology, Univ. Pittsburgh, Pittsburgh, PA 15261 and Dept. de Neurobiol., Ecole Normale Supérieure, 75005 Paris, France.

Although Mg^{2+} plays an important role in many cellular functions, the factors regulating Mg^{2+} homeostasis are still not well understood. We investigated intracellular free Mg^{2+} ($[\text{Mg}^{2+}]_i$) changes in rat forebrain neurons using the Mg^{2+} -sensitive fluorescent dye, magfura-2. Resting $[\text{Mg}^{2+}]_i$ in neurons was 0.63 ± 0.03 mM ($n=94$). Addition of glutamate (with 1 μM glycine) increased $[\text{Mg}^{2+}]_i$ (by 0.4-11 mM) in all the neurons studied. The threshold glutamate concentration required to produce $[\text{Mg}^{2+}]_i$ increase was 3 μM and maximal response was approached with 100 μM glutamate. This effect of glutamate on $[\text{Mg}^{2+}]_i$ is apparently mediated by NMDA receptor activation, since it was blocked by dizocipine and 5,7-DCKU. The elevation of $[\text{Mg}^{2+}]_i$ by glutamate involved two separate processes. The principle component was independent of extracellular Mg^{2+} ($[\text{Mg}^{2+}]_o$), but was almost eliminated by removal of $[\text{Ca}^{2+}]_o$, and may be due to displacement of Mg^{2+} from intracellular sites by Ca^{2+} . A second smaller component was independent of $[\text{Ca}^{2+}]_o$, but required $[\text{Mg}^{2+}]_o$, and was potentiated by removal of $[\text{Na}^+]_o$, suggesting presence of a Na^+ - Mg^{2+} exchange mechanism.

Kainate, KCl and veratridine were much less effective in increasing $[\text{Mg}^{2+}]_i$. As the agonists that most effectively increase $[\text{Mg}^{2+}]_i$ are excitotoxic to neurons following short exposure, this data may indicate a role for $[\text{Mg}^{2+}]_i$ in glutamate excitotoxicity.

553.15

A PARADOXICAL REQUIREMENT FOR EXTRACELLULAR Mg^{2+} IN GLUTAMATE TOXICITY. K.A. Hartnett*, S. Raidev, P.A. Rosenberg, E. Aizenman & J.L. Reynolds, Depts. of Neurobiol. & Pharmacol., Univ. of Pittsburgh Sch. Med., Pgh, PA 15261, & Dept. of Neurol., Children's Hosp. & Harvard Med. Sch., Boston, MA 02115

The presence of extracellular Ca^{2+} is an obligatory requirement for neuronal death following exposure to glutamate in rodent cortical cultures (Choi, *J. Neurosci.* 7: 369; 1987). We recently observed that glutamate elevates intracellular Mg^{2+} in addition to Ca^{2+} in neurons. In this study we used conditions that elevate $[Mg^{2+}]_i$ independently of $[Ca^{2+}]_i$ to investigate a possible role for Mg^{2+} in excitotoxicity. In Ca^{2+} -free solutions, and with N-methyl-D-glucamine (NMDG) substituting for Na^+ , the presence of 9 mM Mg^{2+} was sufficient to produce neuronal death after a 20 min exposure to 100 μM glutamate. Under identical conditions, intracellular Mg^{2+} concentrations measured with Magfura-2, and neuronal cell volume, were both observed to increase following glutamate application. Toxicity was also induced by 200 μM NMDA and was prevented by: (i) 10 μM dizocilpine, (ii) omitting Mg^{2+} or Cl^- from the extracellular solution, and (iii) substituting choline for NMDG. Thus, in solutions devoid of Na^+ and Ca^{2+} glutamate-mediated neuronal death may be dependent on the influx of both Mg^{2+} and Cl^- .

EXPRESSION OF PARVALBUMIN IN CULTURED CORTICAL NEURONS USING A HERPES SIMPLEX VIRUS (HSV-1) VECTOR SYSTEM ENHANCES NMDA-INDUCED NEUROTOXICITY. Dean Hartley*, Rachael Neve, John Bryan, Donna Ullrey, Sun-Yung Bak, Matthew During, and Alfred Geller, Childrens Hosp, Boston, MA; McLean Hosp, Belmont, MA; Yale Univ. School Medicine, New Haven CT.

Glutamate neurotoxicity in cortical neurons is thought to primarily be mediated by the influx of calcium, consequently maintaining calcium homeostasis is of critical importance for cell survival. Parvalbumin is a small calcium-binding protein expressed in a subset of "rapid-firing" GABAergic neurons in the CNS. Using a HSV-1 vector system capable of introducing genes into post-mitotic neurons (TINS 14:428, 1991), we investigated whether expression of parvalbumin would alter NMDA-induced neurotoxicity. After two weeks, cultured cortical neurons were either mock infected or infected with pHSVlac (expresses β -galactosidase) or pHSVparv (expresses parvalbumin). After 24 hr the medium was exchanged with medium containing 0, 5, 10, 12.5, 15, or 300 mM NMDA + 10 mM glycine for an additional 24 hr. Cell death was measured by the efflux of lactate dehydrogenase into the medium. Interestingly, the introduction of parvalbumin into these cells significantly ($P < 0.05$) enhanced neurotoxicity at NMDA concentrations of 5, 10, and 12.5 mM when compared to cultures infected with pHSVlac or mock infected. This enhancement was attenuated by the addition of tetrodotoxin. Furthermore, expression of parvalbumin in cortical neurons enhanced the release of both aspartate and glutamate. These data suggest that the expression of parvalbumin in cortical neurons enhances neurotransmitter release and thereby augments NMDA neurotoxicity.

553.19

GLUTAMATE INDUCES APOPTOTIC CELL DEATH IN PRIMARY CULTURES OF THE NERVOUS SYSTEM. A.M. Marini*, E. Finiels-Martier, B. Dipasquale†, S. Paul and R. Youle‡. CNB, NIMH, and †Biochemistry Section, Surgical Neurology Branch, NINDS, Bethesda, Md 20895.

Primary cultures of cortical neurons and cerebellar granule cells are susceptible to the toxic effect of glutamate. We studied these neurons following exposure to toxic concentrations of glutamate using Nomarski optics which identifies apoptotic cells as round and highly refractive bodies. The control level of apoptotic refractive cells in cortical neurons was 3-5% whereas in cerebellar granule cells it was 20-30%. The percentage of apoptotic refractive cells increased to 15-20% in cortical neurons and up to about 50% in cerebellar granule cells following glutamate (150 and 30 μM respectively) exposure at 2 and 4 hours. Apoptotic refractive changes were attenuated by cycloheximide (1 $\mu g/ml$) or the NMDA receptor channel blocker MK-801 (1 μM); both reduced the percentage of apoptotic refractive cells to control levels. In thymocytes, the apoptotic refractive changes identified by Nomarski optics correlate with internucleosomal DNA degradation. Therefore, we extracted the DNA from glutamate-treated cultures, but found no evidence of the internucleosomal DNA degradation pattern. Our findings show that the early nuclear changes detected using Nomarski optics, characteristic of apoptotic cell death, result from glutamate exposure of the cultured neurons. However, we were unable to detect the DNA degradation pattern that other neurotoxins induce in cultured neurons (ref. Dipasquale et al., 1991, *Biochem. Biophys. Res. Commun.* 181:1442-1448).

553.16

DEPENDENCE OF NMDA NEUROTOXICITY IN CORTICAL CULTURES ON EXTRACELLULAR CHLORIDE AS WELL AS CALCIUM. M. Nguyen-Huynh, V. Zaleskas, and P.A. Rosenberg*. Dept. Neurol., Children's Hospital & Harvard Medical School, Boston MA 02115.

We are interested in the specific mechanisms underlying NMDA receptor mediated neurotoxicity (NNT). A previous study has shown that removal of chloride confers partial protection against NNT in addition to having shown the dependence of NNT on calcium [Choi (1987) *J. Neurosci.* 7: 369-379]. In this study we examine the chloride dependence of NNT further, as this might be important in understanding the mechanism of NNT.

Using thirty minute exposures of neuron-enriched astrocyte-poor cortical cultures to 0.5 - 1 mM NMDA in a tris buffered saline (pH 7.2), we found that removal of chloride (by substitution of sulfate salts for chloride salts, except for calcium chloride) provided complete protection against NMDA neurotoxicity, assayed by counting surviving neurons 20-24 hours after exposure (n=4). Similarly, removal of calcium also conferred protection in these cultures. In conventional astrocyte-rich cultures, removal of chloride provided substantial protection against NMDA toxicity, assayed by both counting of surviving neurons and by assay of 3H -ouabain binding ($71 \pm 22\%$ survival, n=15). Removal of calcium in the presence of chloride was also neuroprotective. In low chloride medium, increasing the external calcium concentration to 12 mM (by addition of the nitrate, acetate, or gluconate salts of calcium) did not consistently increase the toxicity of NMDA ($70 \pm 30\%$ survival versus $91 \pm 12\%$ survival in normal calcium, n=3).

It appears likely that one or more chloride transport pathways are involved in NMDA receptor mediated neurotoxicity.

EXCITOTOXIC NEURONAL DEATH IN CORTICAL CELL CULTURE IS NOT DUE TO APOPTOSIS R.F. Regan*, S.S. Panter, A. Witz, J.L. Tilly and R.G. Giffard Letterman Army Inst of Research, San Francisco, CA 94129 and Depts of Gyn and Ob, and Anesthesia, Stanford Univ Sch of Med, Stanford, CA 94305

Cell death by apoptosis, common during brain development, is also a postulated mechanism of pathologic neuronal loss. Neuronal injury after activation of glutamate receptors was evaluated for ultrastructural, biochemical, and pharmacologic evidence of apoptosis. Exposure to 500 μM glutamate for 10 min produced rapid mitochondrial swelling and disruption, increased nuclear and cytoplasmic lucency and dilatation of endoplasmic reticulum. Chromatin clumping without localization to the nuclear membrane and membrane lysis were marked by 2 hr. Exposure to low concentrations of AMPA or kainate for 3-6 hr resulted in distinctly different morphology. Both led to cytoplasmic condensation, vacuolization and moderate chromatin clumping throughout the nucleus. After 12 hr mitochondrial swelling and increased nuclear and cytoplasmic lucency were noted. No increase in internucleosomal DNA cleavage over baseline levels was produced by any of these injury paradigms, assessed by autoradiography after $3' P^{32}$ labelling and gel electrophoresis. Neuronal death was not attenuated by cycloheximide or actinomycin-D. These results suggest that exposure to exogenous excitatory amino acids does not induce apoptosis in primary cultures of murine neurons.

A FLUORIMETRIC ASSAY FOR THE DETERMINATION OF ANTHRANILIC ACID IN BIOLOGICAL MATERIALS. P. Guidetti¹ and R. Schwarcz. Md. Psych. Res. Center, Baltimore, MD 21228.

Anthranelic acid (ANA), a tryptophan metabolite present in urine and peripheral tissues, has been shown to provide a major source of 3-hydroxyanthranilic acid, an effective bioprecursor of the endogenous excitotoxin quinolinic acid, in the rat brain (J. Neurochem. 55: 738, 1990). Using a novel isolation procedure, we have now examined the presence of ANA in various rat tissues and body fluids. Tissue samples were homogenized (1:80, w/v), and serum and urine samples were diluted (1:80 and 1:4000, v/v, respectively) in water. After acidification and centrifugation, the supernatant was purified through a strong cation exchange resin. The fraction containing ANA was subjected to reversed phase HPLC. ANA was detected fluorimetrically (sensitivity limit: 50 fmoles) and identified by its retention time using three different mobile phases. ANA was thus found in serum (131 ± 7 nM) and urine (9.9 ± 1.8 nmol/mg creatinine). In peripheral organs, ANA levels were highest in the liver and in the kidney (1.8 pmol/mg prot.) and lowest in the adrenal (0.52 pmol/mg prot.). In the brain, only small regional differences in ANA were found among 10 brain areas, ranging from 0.51 to 0.98 pmol/mg prot. Residual blood was not responsible for the presence of ANA in tissue. The role of endogenous ANA in the biosynthesis and function of quinolinic acid remains to be examined.

ENHANCEMENT OF GLUTAMATE (GLU)-OR QUINOLINIC ACID (QUIN)-INDUCED EXCITOTOXICITY IN HIPPOCAMPAL CULTURES BY AMINOXYACETIC ACID (AOAA). W.Q. Whetsell, Jr.¹ and N.A. Shapira

The capacity of GLU and some of its chemically structural analogs to induce excitotoxic neurodegeneration in mammalian CNS has received increasing scientific attention over the past three decades. The low excitotoxic potency of GLU compared to other excitotoxic agents has also been of interest (JNEN 51:351, 1992) since there is evidence that excitotoxicity of GLU or some GLU-analogs may play a role in certain chronic human neurodegenerative disorders. The mechanism(s) by which excitotoxicity may act in neurodegenerative disorders is not understood. It has been suggested, that among other possibilities, interference with intraneuronal energy metabolism (J. Pharmacol. 257:870, 1991) sufficient to induce metabolic stress might predispose neurons to the effects of low concentrations of excitotoxic substances. In whole-animal experiments, administration of AOAA, a substance which may interfere with kynurenic acid synthesis (Synapse 9:129, 1991) or with intraneuronal energy metabolism (Annals Neurol. 31:119, 1992), has been shown to induce excitotoxic CNS lesions which can be prevented by specific excitotoxic-receptor antagonists. The present study examines the effects of AOAA on mature organotypic cultures of rat hippocampus either alone or in the presence of GLU or an endogenous GLU analog, QUIN. Results indicate that while AOAA (100 μ M) alone, GLU (100 μ M) alone or QUIN (10 μ M) alone produce little or no morphological change for at least three days, a combination of AOAA-plus-GLU or AOAA-plus-QUIN at the same concentrations (100 or 10 μ M) produce a 5- to 10-fold increase in post-synaptic dendritic area (compared to controls) as shown by ultrastructural image analysis and a 2- to 5-fold increase in percent of open space due to cell swelling as shown by light microscopic image analysis. This response is blocked by the NMDA-receptor antagonist, 2-amino-7-phosphonoheptanoic acid (APH). In this model, AOAA increases the susceptibility of hippocampal neurons to neurodegeneration induced by GLU or QUIN. (Supported by USPHS Grant NS-28236)

EXCITOTOXIC EFFECT OF QUINOLINIC ACID ON NIGROSTRIATAL DOPAMINERGIC NEURONS: MODULATION BY INHIBITION OF NITRIC OXIDE SYNTHASE? B.P. Connop¹, R.J. Boegman¹, K. Jhamandas¹, R.J. Beninger² and J.V. Milligan. Departments of ¹Pharmacology and Toxicology and ²Psychology, Queen's University, Kingston, Ont. K7L 3N6 (Canada)

Quinolinic acid (QUIN), a metabolite of the Kynurenine pathway has been implicated in a number of neurological disorders. QUIN has been found to be an potent excitatory amino acid which acts on the N-methyl-D-aspartate subtype of glutamate receptor.

Previous results show that the cholinergic neurons of the nucleus basalis magnocellularis are sensitive to QUIN with an EC(50) of 104 nmol infused. In order to determine the sensitivity of the dopaminergic neurons, QUIN was infused into the substantia nigra compacta of male Sprague Dawley rats in the absence and presence of a nitric oxide synthase inhibitor. Four days after the QUIN infusion, striatal tyrosine hydroxylase activity was found to decrease and had an EC(50) of 16 nmol. This suggests that the dopaminergic neurons are more sensitive than the cholinergic neurons to the excitotoxic effects of QUIN.

Initial studies were performed with the nitric oxide synthase (NOS) inhibitor N-nitro-L-arginine methyl ester (L-NAME). It was found that two interperitoneal injections of L-NAME eight hours apart caused a maximal inhibition of the NOS enzyme twenty four hours after the last injection. A dose-response curve of L-NAME showed that a dose of 250 mg/kg resulted in an 89% inhibition of the brain isozyme.

Preliminary studies indicate that 24 hour pretreatment of rats with 250 mg/kg L-NAME prior to infusion of 40 nmol QUIN did not offer any protection to the dopaminergic neurons projecting to the striatum.

EXCITOTOXIC EFFECTS OF ANTHRANILIC ACID IN MATURE ORGANOTYPIC CULTURES OF RAT HIPPOCAMPUS. N.A. Shapira, B. Schwarcz¹, B.C. Christie-Pope² and W.O. Whetsell, Jr. Dept. of Pathology, Vanderbilt Univ. School Med., Nashville, TN 37232 and ¹Maryland Psychiatric Research Center, Baltimore, MD 21228.

In the rat brain, 3-hydroxyanthranilic acid (3-HANA), the immediate bioprecursor of the excitotoxin, quinolinic acid (QUIN), is preferentially produced from anthranilic acid (ANA) (J. Neurochem. 55:738, 1990). Like 3-HANA (Soc. Neuroscience Abstr. 16:461.3, 1990), ANA may ultimately exert excitotoxic effects in the CNS after conversion to QUIN. To investigate this possibility, mature organotypic cultures of rat hippocampus were exposed to ANA. While relatively short exposure times (up to 2 days with up to 10 mM ANA) produced little or no morphological alteration as assessed by light- and electron-microscopy, longer exposure times (3-6 days with up to 10 mM ANA) resulted in dose-dependent neuronal damage. Changes characteristic of excitotoxic damage were observed with as little as 100 μ M ANA. At the highest dose used (10 mM), quantitative ultrastructural image analysis demonstrated an increase in post-synaptic dendritic area of more than 20-fold compared to controls. Concomitant incubation of sibling cultures with the selective NMDA-receptor antagonist, 2-amino-7-phosphonoheptanoic acid (APH) at 1 mM, prevented morphological changes induced by ANA (100 μ M, 1 mM or 10 mM). These results indicate that ANA, possibly through its conversion to QUIN, can function as an excitotoxin in brain. ANA, a regular biochemical constituent in brain (see Guidetti and Schwarcz, this meeting), may therefore have a role in the evolution of excitotoxic brain disorders (Lab. Invest. 68:372, 1993). Supported by USPHS grants NS16102 and NS28236.

554.4

ANTAGONISM OF QUINOLINIC ACID INDUCED TOXICITY ON STRIATAL DIAPHORASE NEURONS FOLLOWING ADMINISTRATION OF KYNURENINE, PROBENECID AND NICOTINYLALANINE. C.A. Harris¹, R.J. Boegman¹, K. Jhamandas¹ and R.J. Beninger². Departments of ¹Pharmacology and ²Psychology, Queen's University, Kingston, Ont. K7L 3N6.

Quinolinic acid (QUIN), an endogenous excitotoxin, and kynurenic acid (KYNA), a potent endogenous excitatory amino acid antagonist, are both synthesized via the kynurenine pathway which is the primary metabolic route of tryptophan to niacin.

In the present study we examined the sensitivity of striatal diaphorase (nitric oxide synthase) containing neurons to an infusion of QUIN (15 nmol) administered into the striatum of rats pretreated with various drug regimens aimed at elevating brain KYNA levels. The effects of increasing the accumulation of KYNA while inhibiting the synthesis of QUIN with ip or icv nicotinylalanine (NAL), precursor loading with ip kynurenine (KYN) and the blockade of organic acid transport with ip probenecid (PRO) were examined alone and in combination.

Rat brain KYNA levels increased from 61.8 ± 52.1 pmol/g wet wt to 5638.6 ± 1203.9 pmol/g wet wt following the administration of NAL (500 mg/kg), KYN (450 mg/kg) and PRO (200 mg/kg).

The survival of NADPH-diaphorase positive cells two days following an infusion of (15 nmol) QUIN was 11.9 ± 7.2 %. A combination of NAL + KYN + PRO increased the survival of diaphorase neurons to 50.4 ± 5.3 % following infusion of QUIN. These results show that it is possible to increase neuronal survival in vivo by altering endogenous levels of KYNA.

554.6

PROTECTION AGAINST QUINOLINIC ACID INDUCED NEURONAL DAMAGE OF STRIATAL DIAPHORASE NEURONS BY CO-INFUSION WITH PICOLINIC ACID. B.E. Kalisch, R.J. Boegman, K. Jhamandas, J. Goh¹ and R.J. Beninger¹. Department of Pharmacology and Toxicology and Department of Psychology¹, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

Lesions produced by acute administration of the endogenous neurotoxin quinolinic acid (QUIN) can be antagonized by co-injection with picolinic acid (PIC), a monocarboxylic acid originating from the same pathway that yields QUIN (Cockhill, J. et al., 1992, Brain Research, 599: 57-63). The present study examined the effects of long-term exposure to low doses of QUIN on diaphorase (nitric oxide synthase) containing neurons of the rat striatum. Exposure to QUIN (6 nmol/h) for 7 days resulted in a severe depletion of NADPH diaphorase-positive neurons. Infusion of PIC (18 nmol/h) for 7 days was not toxic to these neurons. Comparable co-infusion of PIC with QUIN prevented the depletion of NADPH diaphorase-positive neurons induced by QUIN. These results demonstrate that PIC can prevent neuronal damage induced by sub-chronic infusions of QUIN. The effects of long-term exposure to QUIN alone or in combination with PIC on nitric oxide synthase activity in rat striatum is currently under investigation.

ANTI-EXCITOTOXIC EFFECT OF 4-CL-KYNURENINE IN THE RAT HIPPOCAMPUS IN VIVO. H.-O. Wu*, F.G. Salituro¹ and R. Schwarcz. Md. Psych. Res. Ctr., Baltimore, MD 21228 and ¹Marion Merrell Dow Res. Inst., Cincinnati, OH 45215.

In the rat brain, 4-Cl-kynurenine (4-Cl-KYN) can be enzymatically converted to 7-Cl-kynurenine acid (7-Cl-KYNA), a potent antagonist of the glycine site associated with the NMDA receptor (Soc. Neurosci. Abstr. 18: 482.12, 1992). The neuroprotective properties of 4-Cl-KYN vis-à-vis the excitotoxin quinolinic acid (QUIN) were now studied in the rat hippocampus. Local co-infusion of 4-Cl-KYN (≥ 40 nmoles) or 7-Cl-KYNA (≥ 4 nmoles) with QUIN (8 nmoles) completely prevented QUIN-induced neuronal death, as assessed histologically and biochemically. Pretreatment for 2 h significantly enhanced the neuroprotective potency of 4-Cl-KYN (but not of 7-Cl-KYNA). The importance of the conversion of 4-Cl-KYN to 7-Cl-KYNA was further substantiated by local injection of the selective gliotoxin fluorocitrate (1 nmol/1 μ l). Fluorocitrate interfered with the production of 7-Cl-KYNA from 4-Cl-KYN and greatly attenuated the neuroprotective effect of 4-Cl-KYN without influencing the effect of 7-Cl-KYNA. These data demonstrate that astrocytes are responsible for synthesizing and releasing neuroprotective quantities of 7-Cl-KYNA from 4-Cl-KYN. More generally, astrocytes may therefore be targeted for the delivery of neuroprotective kynurenine acid analogs *in vivo*.

554.9

KYNURENINE PATHWAY ENZYMES FOLLOWING CNS IMMUNE STIMULATION (POLIOVIRUS INFECTION OF THE SPINAL CORD). K. Saito*, J.S. Crowley, M. Saito, S.P. Markey, J.H. Vickers¹, and M.P. Hayes Lab. of Clinical Science, NIMH; and Food and Drug Administration¹ Bethesda, MD 20892.

Quinolinic acid (QUIN), kynurenic acid (KYNA) and L-kynurenine (L-KYN) accumulate in brain following immune stimulation (*Brain* 115,1249), and are attributed to induction of indoleamine-2,3-dioxygenase (IDO). Direct conversion of L-tryptophan to QUIN by CNS tissue occurs in conditions of brain inflammation, but not by normal brain (*J. Neurochem* 60, 180). Therefore, to investigate whether induction of enzymes distal to IDO may determine L-KYN conversion to QUIN, poliovirus was inoculated directly into the spinal cord as a model of inflammatory CNS disease (*FASEB J.* 6: 2977). Induction of spinal cord IDO (35.9-fold) accompanied increases in kynurenine-3-hydroxylase (2.4-fold) and kynureninase (2.3-fold), which were highly correlated to CNS QUIN levels and measures of inflammatory lesions. 3-Hydroxyanthranilate-3,4-dioxygenase activity was unaffected. CSF KYNA accumulated in proportion to both IDO activity and L-KYN levels, whereas kynurenine aminotransferase activity was unaffected. Inhibitors of the kynurenine pathway, 6-chlorotryptophan and 4-chloro-3-hydroxyanthranilic acid (*Biochem. J.* 291 11), attenuated [¹³C₆]-QUIN formation when co-infused intracerebrally with [¹³C₆]-L-tryptophan in the infected animals. These results support roles for induction of IDO, kynurenine-3-hydroxylase and kynureninase in accelerating the synthesis of QUIN, L-KYN and KYNA during brain inflammation. Because macrophages can convert L-tryptophan to QUIN, and because kynurenine pathway enzymes may be localized in different cellular compartments, substrate flux may be regulated not only by local enzyme activities and the presence of inflammatory cell infiltrates, but also the cellular and sub-cellular distribution of substrate and enzymes.

554.11

Pretreatment with mega-dose methylprednisolone increases quinolinic toxicity in the rat striatum. T.A. Uhler, D.M. Frim, P. Pakzaban, J. Schumacher, W. S. Rosenberg* and O. Isacson. Neuroregeneration Laboratory, McLean Hospital, Belmont, MA, 02178; Neurosurgery and Neurology Services, Massachusetts General Hospital and Harvard Medical School, Boston, MA

The mechanism of neuronal death after ischemic or traumatic insult is unknown but may be due to energy depletion and glutamate toxicity. One possible pathway leading to cell death after such insults may be lipid peroxidation caused by inability to metabolize superoxides in an energy depleted state. High doses of glucocorticoids or lazaroids have been shown to be potent antioxidants, capable of mitigating the effects of superoxides on lipid membranes *in vitro*. We investigated these antioxidants for neuroprotective effects in a rat striatal excitotoxic lesion model. Animals were lesioned by striatal infusion of 60 nmol of quinolinic acid, an NMDA receptor agonist. Animals received twice daily i.p. injections of either normal saline, lazaroid U-78517F (Upjohn) (20mg/kg), or methylprednisolone succinate (MPSS) (Upjohn) (30mg/kg) beginning the evening before surgery and continuing through postoperative day 1. Animals were sacrificed 7 days after lesioning and brains were histologically evaluated for lesion size by Nissl staining of coronal sections. Mean maximal cross-sectional lesion area for saline treated animals was 3.62 ± 1.03 mm² (mean \pm S.D.; n=7). Treatment with lazaroid U-78517F did not affect lesion size (4.23 ± 0.92 mm²; n=8); however, MPSS caused a significant ($P < 0.05$) 56% increase in mean maximal cross-sectional lesion area (5.76 ± 1.17 mm²; n=8). The detrimental effect of mega-dose MPSS is likely due to deleterious glucocorticoid effects outweighing any positive antioxidant effect. The failure of lazaroid U-78517F to decrease lesion size may be due to poor intraperitoneal uptake or poor brain penetration. Alternatively, these findings are consistent with the possibility that oxidation damage may play only a minor role in NMDA receptor-mediated toxicity.

554.8

LIMBIC SEIZURES CAUSE INCREASE IN KYNURENIC ACID NEOSYNTHESIS AND ATTENUATION OF VULNERABILITY TO EXCITOTOXINS IN THE RAT STRIATUM. H. Baran* and R. Schwarcz, Maryland Psychiatric Research Center, Baltimore, MD 21228.

In rats, seizures induced by kainic acid (KA; 10 mg/kg, s.c.) cause increased striatal kynurenine aminotransferase (KAT) activity (+ 66%) one week later (Soc. Neurosci. Abstr. 17: 356.10, 1991). Since kynurenine acid, the product of KAT, is anticonvulsant and neuroprotective, we studied the vulnerability of striatal neurons to intrastriatal quinolinic acid (QUIN) or KA at 7 days after a systemic KA injection. Rats pretreated with KA proved to be substantially less vulnerable than controls to local injections of QUIN (60 and 120 nmoles) and KA (2.5 nmoles), as assessed both histologically and biochemically (decrease in glutamate decarboxylase activity). A sub-convulsive dose of KA (6 mg/kg) failed to increase KAT activity in the striatum and to protect against QUIN toxicity (60 nmoles). The correlation between increased striatal KAT and neuroprotection was further examined using another convulsant, pilocarpine (325 mg/kg, i.p.). Pilocarpine, too, elevated striatal KAT activity by 7 days (+ 90%) and attenuated the toxicity of intrastriatal QUIN (60 nmoles). Taken together, the resistance of the striatum to an excitotoxic insult following limbic seizures may be related to increased endogenous neuroprotection by kynurenine acid. These data may also pertain to the integrity of striatal tissue in epileptic disorders.

Supported by USPHS grant 16102.

554.10

CONTROL OF QUINOLINIC ACID BIOSYNTHESIS IN THP-1 CELLS. J.F. Reinhard Jr*, M. Jansen, J.B. Erickson, S.Y. Chang and E.M. Flanagan. Division of Pharmacology, The Wellcome Research Laboratories, 3030 Cornwallis Rd., Res. Triangle Park, NC 27709

Quinolinic acid (quin) is a neurotoxin formed *in vivo* from tryptophan (TRP). Quinolinate is synthesized in liver and in macrophages through a 5 enzyme pathway. The first step in quin formation is indoleamine dioxygenase (IDO). The present experiments were conducted to determine whether IDO was important for controlling extrahepatic quin synthesis. A human, monocytic leukemia-derived cell line (THP-1 cells) was pretreated for 48 hours with phorbol myristate acetate (PMA) before receiving human γ -interferon (IFN). Quin synthesis was determined by incorporation of [¹³C₆]-TRP into [¹³C₆]-quin using gas chromatography-mass spectrometry during the final, 48 hour, incubation. Kynurenine hydroxylase (KH) and IDO activities were determined on the cell pellets.

Treatment	IDO activity	KH activity	[¹³ C ₆]-QUIN
None (DMSO)	0.2 \pm 0.04	8.9 \pm 0.3	99 \pm 0.3
PMA	5.6 \pm 0.5	8.9 \pm 1.5	149 \pm 0.3*
IFN	31.9 \pm 3.5*	12.4 \pm 3.0	96 \pm 0.6
PMA + IFN	124.5 \pm 19.3*	14.7 \pm 2.6*	172 \pm 0.1*

(* = $p < 0.05$, compared with control). The data represent enzyme activity (pmol/min*mg protein) or media quin (nM) following a 48 hour incubation with 25 μ M [¹³C₆]-TRP. The media quin values are corrected for differences in cellular protein content. These data indicate that extrahepatic cellular quin synthesis is limited by factors other than IDO since increases in IDO did not result in equivalent increases in quin. The data suggest that other enzymes in the biosynthetic pathway, e.g. KH and kynureninase, are important for controlling quin synthesis.

554.12

NEURONAL DYSFUNCTION SECONDARY TO CHRONIC EXPOSURE OF QUINOLINIC ACID. T.J. Bazzett*, R.L. Albin, J.B. Becker & R.C. Falk. Depts of Neurology and Biopsychology, University of Michigan, Ann Arbor, MI 48014.

Rats received implants of bilateral intrastriatal chronic dialytic delivery devices. The right striatum received 185 nmol quinolinic acid (QUIN) per day for three weeks. The left striatum received buffered saline solution (VEH).

Nissl staining revealed loss of cells in a region approximately 200 μ m radial from the dialysis probe in the QUIN treated striatum. Cytochrome oxidase staining was reduced in this same area. Beyond this region, the number of nissl stained cells and cytochrome oxidase staining appeared normal. There was a marked decrease in parikarya that stained positive for calbindin or parvalbumin immunoreactivity throughout most of the QUIN treated striatum. Calbindin staining was reduced also in surrounding cortex and parvalbumin staining was reduced in the globus pallidus. The VEH treated striatum was normal. Previous work has shown that the decreased nissl and cytochrome oxidase staining persisted at least one month after QUIN treatment, indicating these changes are permanent. Experiments in progress will determine the relative permanence of decreased calbindin and parvalbumin staining after cessation of QUIN treatment. Supported by NS19613, NS01300, NS22157 and The Reproductive Science Program 5 T32 HD07048.

β -AMYLOID 25-35 (β A) AND QUINOLINIC ACID (QA) INJECTIONS INTO THE VENTRAL PALLIDUM/SUBSTANTIA INNOMINATA (VP/Sl) OF YOUNG MALE F344 RATS: BEHAVIORAL, NEUROCHEMICAL AND HISTOLOGICAL EFFECTS. E.M. Sigurdsson,^{1*} J.M. Lee,² and S.A. Lorenz.¹ Depts. Pharmacology¹ and Pathology,² Loyola Univ. Chicago Med. Center (Bldg. 135), Maywood IL 60153

Alzheimer's disease is associated with the loss of cholinergic neurons in the basal forebrain and is characterized histopathologically by amyloid deposition and neurofibrillary tangles in several, but not all, cortical and subcortical regions. In order to determine whether basal forebrain injections of β A are neurotoxic, we compared the effects of bilateral injections into the VP/Sl of β A (1.0 nmole/3.0 μ l) and of QA (75.0 nmole/3.0 μ l). Control rats received vehicle infusions (VEH; 3.0 μ l saline). Exploratory behavior in an open field (OF) and the acquisition of a one way (spatial) conditioned avoidance response (CAR) were analyzed 13-16 d postoperatively. QA rats were more active in the OF than either the β A or VEH rats (75%; $p < 0.12$), and, at the start of the test session, exited the central square more rapidly (mean = 7 sec; $p < 0.05$) than the VEH rats (20 sec). In contrast, the β A rats remained in the central square for a longer time (47 sec; $p < 0.05$) before moving to a wall square. The β A rats emitted their first CAR after fewer trials than the VEH rats (4.7 v 7.3; $p < 0.05$), while the QA rats committed fewer errors to reach criterion than the VEH animals (3.6 v 5.6; $p = 0.05$). The rats were sacrificed 22-23 d postoperatively. Choline acetyltransferase activity (ChAT-Act) in the QA rats was reduced in both the right and left amygdala (26-29%; $p < 0.05$), but not in the frontal cortex. β A did not affect ChAT-Act. Cavitation and glial proliferation (1.5 mm²) were observed surrounding the QA injection site. In contrast, no histological differences were discerned between the β A and VEH rats. These results suggest: 1) that intra-VP/Sl injections of QA can produce functional changes which are associated with histological evidences of neurotoxicity and a reduction in amygdaloid but not frontal cortical ChAT-Act; and, 2) that β A VP/Sl injections can induce behavioral alterations in the absence of histological or neurochemical signs of neurotoxicity.

EFFECTS OF DOMOIC ACID ON BRAIN METABOLIC MARKERS AND ANATOMY IN RATS. N.M. Appel,¹ J.P. O'Callaghan,¹ L.M. Freed,² S. Wakabayashi,³ S.I. Rapoport,⁴ J.J. De George and J.F. Contrera. FDA CDER DRT, Laurel, MD; NIH NIA LNS, Bethesda, MD and USEPA, Research Triangle Park, NC.

Domoic acid (Dom) is a neurotoxic excitatory amino acid (EAA) which appears to act as an agonist at the kainic acid subtype of EAA receptors. Dom has been identified as the contaminant in mussels causing adverse neurological and gastrointestinal effects, and in some cases death, to people who consumed them. Incorporation of [³H]palmitic acid ([³H]PA) and [¹⁴C]arachidonic acid ([¹⁴C]AA) has been used to study regional structural and functional integrity in brain by autoradiography. Glial fibrillary acidic protein (GFAP) and argyrophilia have been used as markers of neurotoxic effects of drugs and xenobiotics in brain. Seven days following i.p. Dom (2.25 mg/kg) regional [³H]PA incorporation was unchanged. In contrast [¹⁴C]AA incorporation was significantly increased throughout the brain. Moreover in Dom-treated rats that manifested seizures, [¹⁴C]AA incorporation was further increased in many brain regions (e.g. parietal cortex, thalamus, caudate putamen hippocampus, and septum) when compared to Dom-treated rats which did not display seizures. Widespread glial hypertrophy and increased regional concentrations of GFAP-like immunoreactivity were noted in Dom-treated rats but only in those rats manifesting seizures. Similarly only Dom-treated rats that manifested seizures displayed argyrophilia. Unlike the other markers, however, argyrophilia was discretely localized. These data suggest Dom causes widespread alterations in brain metabolism, which could be predictive of more focal neurotoxic effects.

554.17

DOMOIC ACID (DOM) PHARMACOKINETICS IN THE MONKEY: CORRELATION WITH NEUROPATHOLOGICAL EFFECTS. W. Slikker, Jr.*¹, J.A. Sandberg,¹ L. Holder,² Z. Binienda,² F.A. Caputo,² S. Hall,² M.G. Paule,² R.L. Rountree,² L. Schmued,² T. Sobotka² and A.C. Scallet.² Divisions of Neurotoxicology and Chemistry, NCTR/FDA, Jefferson, AR 72079 and CFSAN/FDA, Washington, D.C. 20204.

In order to develop a data-base for risk assessment of DOM, a seafood neurotoxicant, young (2.1 kg avg. wt.) and adult (4.9 kg) cynomolgus monkeys were administered a single bolus dose of DOM (0.25, 0.5, 1.0 and 4.0 mg/kg) or saline vehicle intravenously. Blood samples were collected before and up to 4 hrs after dosing. Model-independent pharmacokinetic analysis of HPLC-derived DOM plasma concentrations yielded the following values (mean \pm SE): V_d (l/kg), 0.19 \pm 0.03 and $T_{1/2}$ (hr), 0.99 \pm 0.13. AUCs (μ g/ml x hr) increased with dose (n=9; $r = 0.74$). For severe neuropathological subgroup (N=3), AUCs ranged from 16-91. For less severe neuropathological subgroup (N=4), AUCs ranged from 2.8-11.5, and were correlated with histological damage 7 days after dosing ($r = 0.94$). Clearance (ml/min/kg) ranged from 0.7-4.5 and inversely correlated with weight (age) of the monkeys ($r = 0.92$). These data indicate that DOM exposure, as measured by plasma pharmacokinetic analysis, is predictive of subsequent central nervous system damage and that young monkeys exhibit less exposure and less neurotoxicity than comparably dosed adults.

554.14

DOMOIC ACID NEUROTOXICITY IN CYNOMOLGUS MONKEYS: EFFECT OF DOSE ON HIPPOCAMPAL NEURONAL AND AXON TERMINAL DEGENERATION A.C. Scallet*, Z. Binienda, F.A. Caputo, S. Hall¹, M.G. Paule, R.L. Rountree, L. Schmued, T. Sobotka² and W. Slikker, Jr. Div. of Neurotoxicology, National Center for Toxicol. Research/FDA, Jefferson, AR 72079 and ¹Center for Food Safety & Applied Nutrition/FDA, Washington, DC 20204

Domoic acid (Dom, a seafood contaminant derived from certain algae and seaweed) is a tricarboxylic amino acid structurally related to kainic and glutamic acids. To identify neurohistological biomarkers of Dom exposure in relation to dose, adult and juvenile monkeys were given Dom (0.25-4 mg/kg, IV) or saline after an overnight fast and evaluated by a modified Fink-Heimer procedure, as well as GFAP and c-fos immunohistology. Juveniles tolerated up to 4 mg/kg Dom. Some adults (≥ 1 mg/kg) developed bradypnea, became moribund, and were perfused, revealing elevated c-fos expression within 3-7 hours of i.v. Dom. The remainder were perfused one week later; two adults (1 and 1.25 mg/kg) and one juvenile (4 mg/kg) had extensive neuronal and terminal degeneration and gliosis throughout the hippocampus and subiculum. Other adults (≤ 1 mg/kg) as well as juveniles (≤ 2 mg/kg) had small focal areas of terminal degeneration restricted to CA2 stratum lucidum. The results suggest that major hippocampal damage occurs only at near-lethal doses of Dom, while lower doses selectively target an area previously reported to contain the highest concentration of pre-synaptic Kainic-acid receptors in brain.

554.16

NEUROBEHAVIORAL ASSESSMENT FOLLOWING LOW DOSE EXPOSURE TO DOMOIC ACID (DOMA) IN THE RODENT. T.Sobotka*, R.Brodie, Y.Quander, S.Hall, M.Bryant and C.Barton. Food and Drug Administration, Washington, D.C.

DOMA, a kainic acid analog, has been identified as the neurotoxin in amnesic shellfish poisoning characterized by gastrointestinal and neurologic distress, the latter including seizure, loss of memory and neuropathology. The full spectrum of neurotoxicological changes elicited by DOMA is still poorly understood. Studies are being conducted to delineate the neurobehavioral profile of animals exposed to DOMA, particularly at the lower range of the dose-response curve. In the initial series of experiments adult male rats, dosed i.p. with 0, 0.25, 0.75 or 2.25 mg DOMA/kg, were tested for changes in motor behavior, sensory reactivity and behavioral inhibition at representative intervals over a period of 2 weeks after dosing. Animals were then necropsied for a standard pathological evaluation. Overt signs of neurotoxicity, ranging from mild salivation and scratching to profuse salivation, pronounced head/forebody jerking, tremor and clonus, were noted 1 to 4 hrs after dosing with 2.25 mg/kg. Approximately 43% of the animals at this dose became moribund or died within 2 days. Behaviorally, general motility was significantly affected by treatment in an apparent biphasic fashion. Animals were hypactive within 1 hour of dosing (0.75 mg/kg and 2.25 mg/kg) but then hyperactive at 6 hrs (2.25 mg/kg), 24 hrs (0.75 mg/kg) and 1 week (2.25 mg/kg) after dosing. Activity was at control level 2 weeks after dosing. Within the activity test sessions, habituation was significantly decreased immediately after dosing (0.75 mg/kg and 2.25 mg/kg) and at 24 hrs after dosing (2.25 mg/kg). Open field exploratory behavior was inconsistently affected by treatment. Auditory startle responding was unaffected but prepulse inhibition of startle was transiently enhanced 2 hours after exposure to DOMA but only at the 0.75 mg/kg dose. At term, neuropathological changes were in the hippocampus and the anterior cerebral hemisphere predominantly in the 2.25 mg/kg dose group. Significant treatment-related pathology was not found in other tissues examined.

Sigma sites 1 and 2 are not involved in neuroprotection governed by sigma ligands in primary hippocampal cultures. A.S. Lesage*, K. De Loore and J.E. Leysen. Dept. of Biochemical Pharmacology, Janssen Research Foundation, Belgium

Various sigma ligands were tested for their induction of protection against glutamate induced excitotoxicity when chronically added to neuronal cultures derived from rat embryonic hippocampal tissue. IC50 for protection were calculated as the dose resulting in 50% inhibition of specific release of lactate dehydrogenase. The IC50 values for binding to the sigma sites 1 and 2 were determined on hippocampal membranes, via displacement of [³H]-ditolyl-ortho-guanidine (DTG). We found that sabeluzole, opipramole, tiopirone, fenpropimorf and haloperidol were equipotent in binding to the sigma sites and protection against glutamate in hippocampal cultures. DTG and PD128298 showed high affinity for the sigma sites but were not protective up to a concentration of 10 μ M. To investigate whether protective compounds acted as agonists and non-protective compounds as antagonists, we incubated the hippocampal cultures with the protective compound in the presence of 900 nM non-protective DTG or PD128298. The neuroprotection of ifenprodil, opipramole, tiopirone, fenpropimorf, sabeluzole, and haloperidol was not affected by the presence of DTG or PD128298. This suggests that neuroprotective properties of sigma ligands are probably not governed through their binding at the sigma sites on hippocampal neurons in culture. Therefore the correlation between potency in neuroprotection and potency for sigma site binding of compounds, is not the result of agonism and antagonism.

554.19

ROLE OF SIGMA RECEPTORS IN DEXTROMETHORPHAN MEDIATED NEUROPROTECTION. M. DeCoster*, E. Knight and F. Tortella. Walter Reed Army Inst. Res., Washington, DC 20307.

The neuroprotective effects of dextromethorphan (DM) have been demonstrated in *in vitro* models of neurotoxicity and *in vivo* models of brain and spinal cord injury (Tortella, TIPS 10: 1989). The neuroprotective mechanism(s) of action for DM remain undefined although several possibilities, including non-competitive antagonism of NMDA receptors, blockade of calcium channels, attenuation of post-injury hypoperfusion, and selective activation of specific high-affinity DM binding sites and/or sigma receptors, have been suggested. Using an *in vitro* model of neuronal toxicity, i.e. glutamate-induced cell death of cultured rat cortical neurons, we have initiated studies exploring the possible role of sigma receptors in the mechanism of action of DM neuroprotection. LDH measurements obtained from 12-15 day old primary neurons exposed to 80 μ M glutamate for 45 minutes reveal significant neuronal death measured 24 h post glutamate. The neuroprotective EC_{50} for DM is 5 μ M. The mixed sigma/PCP ligand (+)-SKF10047 and the selective benzomorphan sigma-1 ligand (+)-pentazocine are also neuroprotective (EC_{50} s = 2 and 3 μ M, respectively). In contrast, the selective, non-benzomorphan sigma-1 ligand (+)-3-PPP is without effect at concentrations as high as 100 μ M. Preliminary results indicate that DTG, which expresses high affinity for sigma-1 and sigma-2 sites, is also neuroprotective (100% at 100 μ M) while carbetapentane, a ligand possessing high affinity to specific DM sites as well as sigma-1 sites, was weakly neuroprotective (11% at 100 μ M). Collectively, while certain sigma ligands are neuroprotective and others are not, their role in the neuroprotective mechanism of action of DM remains equivocal.

EXCITATORY AMINO ACIDS: EXCITOTOXICITY IV

555.1

EXCITOTOXICITY IN A NOVEL CONTINUOUS NEURAL CELL LINE. A. Cologer¹, S. Lu¹, N. G. Simon*¹ and G. I. Chovanes². ¹CMBB, Lehigh Univ., Bethlehem, PA 18015 and ²Lehigh Valley Hospital Center, Allentown, PA 18105.

Continuous neural cell lines that express glutamate receptors can potentially be used as an *in vitro* model for studying the mechanisms mediating excitotoxicity. Four major classes of glutamate receptors have been identified, along with subtypes of each. Pharmacological studies of a novel cell line, termed NH2 (a fusion between N18TG2 neuroblastoma and mouse hypothalamic neurons) indicate that it may express AMPA and/or metabotropic receptor subtype(s). Exposure to glutamate (2.5 mM to 20.0 mM) produced dose-dependent cell death (8.0% to 26.6%, respectively). Quisqualate (0.25 mM to 2.0 mM), a potent agonist targeting AMPA receptors and metabotropic receptor subtype linked to phosphoinositol, also produced dose-dependent death (17.7% to 52.1%). Additionally, exposure to ACPD, an agonist activating another metabotropic receptor subtype linked to cAMP, produced dose-dependent death (11.7% to 29.8% death in response to 0.03 to 1.0 mM ACPD). NMDA, however, did not have cytotoxic effects on NH2 cells. These findings suggest that NH2 cells may express AMPA and/or potentially two subtypes of the metabotropic receptor.

POSSIBLE ROLE OF POLYAMINES IN GLUTAMATE-INDUCED NEUROTOXICITY IN THE NT2 HUMAN CELL LINE. M. Munir*, V.M.-Y. Lee, L. Lu and P. McGonigle. Depts. of Pharmacology and Pathology, University of Pennsylvania, Philadelphia, PA 19104.

NT2 cells are a clonal line of human teratocarcinoma cells that are terminally differentiated into neuron-like cells following exposure to retinoic acid. The fully differentiated cells express both NMDA and non-NMDA glutamate receptors and exhibit an excitotoxic response to glutamate. In this study, we have further characterized the excitotoxic response to glutamate using LDH release and MTT reduction. In 4 week old differentiated cells, glutamate-induced toxicity was dose-dependent with an EC_{50} of 30 μ M and maximum toxicity produced at 3 mM. Increasing the duration of exposure to 5 mM glutamate from 0.5 hr to 6 hr did not significantly increase toxicity. The LDH release produced by a maximal dose of glutamate increased with the age of the differentiated cells. The density of NMDA receptors measured with [¹²⁵I]-MK-801 also increased with age suggesting that changes in receptor density may be primarily responsible for enhanced glutamate-induced toxicity in older cells. To examine the role of polyamines in excitotoxicity, cells were pretreated with the enzyme inhibitor DFMO to block the synthesis of polyamines. DFMO treatment significantly inhibited the toxicity produced by 2 mM glutamate and produced no toxicity when administered alone. In contrast, the parent polyamine putrescine enhanced the toxicity produced by glutamate and produced significant toxicity when administered alone. DFMO treatment did not attenuate the toxicity produced by putrescine. These results provide support for the hypothesis that induction of polyamine synthesis following NMDA receptor stimulation may play an important role in excitotoxicity. The NT2 cell line appears to be an ideal model system in which to study this phenomenon. (Supported by USPHS GM 34781)

555.3

Transfection of HEK 293 cells with cloned NMDA receptors leads to cell death. N.J. Aengawa, D. Lynch, M. Batshaw*, D. Pritchett. Depts. Pharmacology, Neurology and Pediatrics, Univ. of Pennsylvania, and Children's Seashore House, Philadelphia, PA 19104.

NMDA receptors have been implicated in cellular toxicity and recently, multiple putative NMDA receptor subunits have been cloned. We have investigated the effects of transfecting combinations of cloned NMDA receptors on cell viability. Human Embryonic Kidney 293 cells were transfected by the CaPO₄ method and 48 hrs after transfection, the number of viable cells were counted by trypan blue staining. Transfection with NR 1A and NR 2A cDNAs together resulted in dramatic cell death (37% of viable cells compared to plasmid transfected control). Transfection with NR 1a plus NR 2B or 2C resulted in lower levels of cell death (51 and 76% viable cells). Transfection of single subunits (NR 1a, 2A, 2B or 2C alone) did not result in cell death. Treatment with 1-10 μ M of MK 801 in the 1a+2A transfection partially protected the cells from degeneration (75% viable cells). However, 100 μ M APV or 100 μ M 7-Chlorokynurenate failed to protect the cells. Furthermore, transfecting NR 2A with a NR 1a cDNA in which asparagine (residue 598) was mutated to glutamine (a mutant known to decrease calcium permeability, Burnashev et al. Science 257: 1415, 1992) led to a decrease in cell death (71% viable cells). These results demonstrate that transfecting combinations of cloned NMDA receptor subunits can lead to Ca⁺⁺ dependent cell death. This work was supported by DA05432, Pfizer Fellowship.

555.4

GLUTAMATE RECEPTORS MEDIATE INWARD CURRENT, CYTOSOLIC CALCIUM ELEVATION, AND EXCITOTOXIC INJURY IN P19 CELLS. D.M. Turetsky*, J.E. Heuttner, L.M.T. Canzoniero, S.L. Sensi, M.P. Goldberg, D.I. Gottlieb and D.W. Choi. Depts. of Neurology, Cell Biology & Physiology, Anatomy & Neurobiology; and Center for the Study of Nervous System Injury, Washington Univ. Sch. of Med., St. Louis, MO 63110.

We examined the expression of glutamate receptor currents and receptor-mediated toxicity in P19 cells, a mouse teratocarcinoma cell line which can be induced to differentiate into glutamate receptor-bearing neuron-like cells by treatment with retinoic acid (MacPherson et al., Soc. Neurosci. Abst. 18, 612, 1992; Turetsky et al., J. Neurobiol., in press).

Undifferentiated P19 cells exposed to 10 μ M retinoic acid for 4 d in suspension culture, then plated onto primary cultures of cortical glia, developed neuronal morphology and immunoreactivity for neurofilaments. Patch clamp recordings from cells 7-10 days after plating revealed inward currents evoked by NMDA or kainate. The former were potentiated by glycine, and blocked by MK-801 or Mg²⁺; channels had a conductance of about 45 pS and permeability to both Na²⁺ and Ca²⁺. The latter were blocked by CNQX. Fura-2 microfluorimetry showed that NMDA, kainate, and high K⁺ all induced an increase in intracellular free Ca²⁺. Exposure to 500 μ M NMDA for 24 hours destroyed 80-95% of these P19 cells with EC_{50} about 70 μ M; death was blocked by MK-801 or D-APV. 24 hr exposure to 500 μ M kainate destroyed 60-75% of the cells; death was blocked by CNQX.

555.5

ACTIVATION OF CALPAIN BY NMDA RECEPTOR STIMULATION IN ORGANOTYPIC HIPPOCAMPAL SLICE CULTURE. S. Del Cerro*, Amy Arai, Markus Kessler, Ben Bahr, Peter Vanderklisch, Santiago Rivera and G. Lynch. Center for the Neurobiology of Learning and Memory, University of California, Irvine, CA 92717, U.S.A. We have shown before that activation of the calcium-activated protease calpain is involved in the development of neuronal damage after ischemia or hypoxia. The present experiments sought to determine whether hippocampal slice cultures provide a suitable preparation for further studies of this type examining whether calcium influx through NMDA receptors can elicit activation of calpain. Slices were prepared from 10 and 13 day old neonates and maintained in culture for 1-6 weeks. Calpain activation was monitored by the appearance of a prominent 150 kD breakdown product of spectrin (SBDP) on Western blots. The SBDP concentration rose rapidly during the first day after cutting but then decreased to a low level by day 7 (4-6% of total spectrin immunoreactivity) and remained stable thereafter. Application of 100-500 μ M NMDA for 5-30 min produced an increase in the SBDP proportional to the exposure time. The effect of NMDA was comparable at all culture durations (7-42 days) and was prevented with 20 μ M MK-801. NMDA-induced calpain activation was strongly dependent on the extracellular calcium concentration; spectrin breakdown was negligibly small at 2 mM but readily detectable and similar in magnitude at 4 and 6 mM calcium. These results indicate that activation of calpain in response to NMDA receptor stimulation is similar in organotypic hippocampal slice cultures and in acute slice preparations from adult animals, and that slice cultures are a potential model for studying processes involved in neuropathology.

POSSIBLE ROLE OF EXCITOTOXICITY IN DEGENERATIVE EFFECTS OF 3-AP. M.G. Pierson*, D. Li, D. Glaze and J. Kwon. Cain Foundation Laboratories, Dept. of Pediatric Neurology, Baylor College of Medicine, One Baylor Plaza, Houston, TX 77030.

Selective neuronal degeneration due to 3-acetyl pyridine (3-AP) primarily affects inferior olive, other extrapyramidal sites and hippocampus. We hypothesized such effects are mediated by excitotoxic rather than metabolic processes. Electroencephalography was performed of 30 d Wistar rats 3 h prior to, and for 6 h after injection at three doses (62, 125, and 250 mg/kg, i.p.). Both cortical surface electrodes and hippocampal depth electrodes were employed. Brain was examined for signs of localized excitatory/degenerative reactions during the first 24 h. Staining included immunostaining for Fos protein and heat shock protein (HSP₇₀), acid fuchsin staining for damaged neurons and cupric silver staining for degenerating neurons. Brain was also examined 1 week after injection to identify lesions.

Indications of excitatory and/or degenerative effects were dose-dependent. Following highest dosage, EEG's indicated seizure activity during first 6 h. Induced Fos immunoreactivity, which locates excitatory events, was visible in hippocampus, striatum, and raphe nuclei, but not in inferior olive 4 h after injection. These sites and inferior olive could be selectively stained by acid fuchsin at 4 h. Only in inferior olive did induction of HSP₇₀ occur so quickly. At 1 week there were lesions in all of the above sites, but especially in inferior olive.

Data suggest excitatory events precede lesions in all sites. The odd fact that HSP₇₀, but not Fos was induced at 4 h may indicate the speed with which inferior olivary cells are killed by 3-AP. Theoretically 3-AP may cause a buildup of quinolinic acid. Thus, the effects on toxicity of antagonism of NMDA type glutamate receptors were examined.

555.9

EXPOSURE TO OXYGEN FREE RADICALS POTENTIATES EXCITOTOXIC INJURY IN CORTICAL CULTURES. L.L. Dugan* and D.W. Choi. Dept. of Neurology and Center for the Study of Nervous System Injury, Washington Univ. School of Medicine, St. Louis, MO 63110.

Excitotoxicity and free radical damage have been separately implicated in the pathogenesis of neuronal cell loss in several neurological diseases. Nevertheless, these processes may not be separate: excitotoxicity may be partly mediated by free radical formation (Monyer et al., *Neuron* 5: 121, 1990), and free radical formation may enhance glutamate release (Pellegrini-Giampietro et al., *J. Neurochem.* 51: 1960, 1988). Here we examined the effect of oxygen free radicals on neuronal vulnerability to excitotoxicity.

Murine cortical cultures exposed to 40-60 μ M H₂O₂ exhibited a 10-40% loss of reduced glutathione after 30 min, and increased levels of hydroxyl radicals after 1 hr, but no evidence of cell damage by phase-contrast microscopy or lactate dehydrogenase efflux to the bathing medium. However, cell death after subsequent submaximal exposure to NMDA or oxygen-glucose deprivation was enhanced. The NMDA concentration-toxicity relationship was shifted to the left enough that some neurons were destroyed by low concentrations of NMDA normally lacking toxicity. Some potentiation of kainate toxicity was also seen.

These results suggest that levels of free radicals too low to produce injury in isolation, can enhance neuronal vulnerability to excitotoxic injury.

555.6

N-METHYL-D-ASPARTATE-INDUCED NEUROPROTECTION IN CEREBELLAR GRANULE CELLS: EVIDENCE FOR A DEVELOPMENTALLY-EXPRESSED NEUROPROTECTIVE PROTEIN(S). P. Damschroder-Williams and S. M. Paul*. Section on Molecular Pharmacology, NSB, NIMH, NIH, Bethesda MD 20892

Exposure of cerebellar granule cells to subtoxic concentrations of NMDA results in a robust neuroprotective state as measured by exposure to toxic concentrations of glutamate (Chuang et al., *Mol. Pharm.* 1992) or MPP⁺ (Marini and Paul, *PNAS* 1992). We have now characterized this neuroprotective state as to the kinetics of induction and reversal, sensitivity to protein synthesis inhibitors and time in culture. Preincubation of cerebellar granule cells with NMDA (10-100 μ M) results in a concentration-dependent (EC₅₀ = 25 μ M) neuroprotective state against glutamate toxicity. With continuous NMDA (50 μ M) exposure maximal induction occurs between 12-16 hours; where the EC₅₀ for glutamate toxicity is "right-shifted" almost 3 orders of magnitude (50 μ M in untreated vs. >50 mM in NMDA-treated cells). The t_{1/2} for reversal of the NMDA-induced neuroprotective state is ~ 24 hrs. As previously reported, preincubation of cells with cycloheximide blocks the neuroprotective state induced by NMDA. Finally, the neuroprotective state induced by NMDA decreases with time in culture; being maximal at 8-14 DIV and absent at >21 DIV. The ability of NMDA to induce the expression of a neuroprotective protein(s) in cerebellar granule cells may be developmentally regulated.

555.8

OXIDATIVE INJURY: A ROLE IN DICARBOXYLIC AMINO ACID-MEDIATED GLIOTOXICITY. R.J. Bridges*, J. Choi, L. Ralston, and M. Reyes. Department of Neurology, Irvine Research Unit in Brain Aging, Univ. California, Irvine, CA 92717.

In addition to being neurotoxic, several dicarboxylic amino acid analogs of glutamate have been identified as gliotoxic. Although the pathological mechanism through which these compounds damage glial cells is as yet not well characterized, it is clearly distinct from excitotoxic neuronal injury and appears to be dependent upon the intracellular accumulation of the toxic amino acids. In the present study we have begun to examine the potential role of oxidative injury as a contributing factor in gliotoxic pathology. Cultures of type I neonatal rat cortical astrocytes exposed to L- α -amino adipate or L-homocysteate, two of the most potent gliotoxic amino acid, exhibited i) a decrease in their intracellular levels of glutathione and ii) an increase in oxidative damage to proteins as measured by a decrease in tryptophan fluorescence. Furthermore, modification of the levels of antioxidants in the cultures strongly influenced the vulnerability of the astrocytes to gliotoxic-mediated cell lysis (quantified by a release of lactate dehydrogenase). Thus, astrocytes with low levels of glutathione, an endogenous antioxidant, were more vulnerable to injury, while supplementing the cultures with the antioxidant α -tocopherol attenuated the lysis of the astrocytes. These findings support the hypothesis that oxidative injury contributes to the underlying pathological events that are triggered by the accumulation of excessive levels of the gliotoxic dicarboxylic amino acids in astrocytes. This work was supported in part by NIA LEAD award F32 NS07876.

555.10

A FREE RADICAL MECHANISM OF KAINATE-INDUCED NEURO-EXCITOTOXICITY IN CELL CULTURE: POSSIBLE INVOLVEMENT OF XANTHINE OXIDASE ACTIVATION. Yu Cheng and Albert Y. Sun*. Dept. of Pharmacology, Univ. of Missouri, Columbia MO 65212.

Kainic Acid (KA) has been used to study the neuroexcitotoxicity produced by glutamate. Although the mechanism of KA toxicity is not completely understood, KA-induced membrane depolarization and intracellular Ca²⁺ elevation are thought to be essential in the toxicity. In our previous experiments we detected free radical formation following the administration of KA. In the present study the mechanisms involved in KA-induced free radical formation and cell degeneration were investigated using high density cortical neuron cultures. A free radical trapping agent, PBN, as well as the combined action of exogenously added superoxide dismutase and catalase attenuated KA neurotoxic effect. Both a voltage-gated Ca²⁺ channel blocker, verapamil, and a calpain inhibitor significantly protected cortical neurons from cell death. Increase in xanthine oxidase (XO) activity following calpain activation may be one of the free radical generating systems in response to KA stimulation since allopurinol, a XO inhibitor, also protected cortical neurons from KA-induced cell death. It is possible that KA stimulation induces a cascade by activating first a calcium-dependent protease which then activates xanthine oxidase, subsequently leading to the generation of hydroxyl free radicals. This free radical production may cause cell death and tissue damage associated with neurodegenerative diseases. (Supported in part by NIAAA Grant #2054.)

555.11

GLUTAMATE INDUCES THE PRODUCTION OF REACTIVE OXYGEN SPECIES IN SINGLE CULTURED NEURONS.

Ian J. Reynolds*, Michael J. Zigmond and Teresa G. Hastings, Departments of Pharmacology and Neuroscience, Univ. Pittsburgh, Pittsburgh PA 15261.

The excitotoxic effects of glutamate on central neurons may be mediated in part by the production of reactive oxygen species. The goal of this preliminary study was to investigate the time course and ionic dependence of glutamate-induced production of reactive oxygen species in single neurons cultured from fetal rat brain. Neurons were cultured from the cortex of e18 rat embryos and used after 21-28 days *in vitro*. Cells were loaded with 10 μ M dichlorodihydrofluorescein diacetate (DCF) for 15min at 37°C. Fluorescence was measured using a Meridian ACAS 570 confocal microscope using standard fluoroscein optics.

Addition of 100 μ M glutamate with 10 μ M glycine altered DCF fluorescence in approximately half of the neurons examined within 5min of glutamate application. Increases in fluorescence were typically localized to the margins of the cell soma, while decreases in DCF signal were often seen in the middle of the cell. Both effects of glutamate on DCF fluorescence were Ca²⁺-dependent. H₂O₂ (30mM) increased DCF fluorescence evenly across the cell soma in contrast to the glutamate-induced changes.

These results demonstrate the feasibility of detecting the production of reactive oxygen species at the level of a single neuron. The mechanisms underlying these changes are currently under investigation.

555.13

FREE RADICALS ENHANCE BASAL RELEASE OF [³H]-ASPARTATE BY CEREBROCORTICAL SYNAPTOSOMES. S.C. Gilman*, M.J. Bonner and T.C. Pellmar, Physiology Dept., AFRR, Bethesda, MD 20889-5603.

Increased free radical generation is associated with a number of pathological conditions. To investigate the effects of free radicals on basal and high K⁺-stimulated release of excitatory amino acids (EAAs) from presynaptic nerve terminals, synaptosomes were isolated from the guinea pig cerebral cortex. Peroxide generates hydroxyl free radicals by reacting with tissue iron (Fenton reaction). Iron alone also has been suggested to generate free radicals in neural tissue. We previously demonstrated that peroxide-generated radicals decrease Ca²⁺-dependent [³H]-glutamate release from synaptosomes while increasing basal release. The present study uses [³H]-aspartate, which is not taken up into the synaptic vesicles, to evaluate the release of EAAs from the cytoplasmic pool.

Pre-treatment with peroxide or iron alone or peroxide in the presence of iron significantly increased the calcium-independent basal release of [³H]-aspartate. Pre-treatment with the iron chelator desferrioxamine had little effect on its own but significantly limited the enhancement by peroxide. High K⁺ evoked release in the presence of Ca²⁺ was enhanced by peroxide but not by iron. These data suggest that peroxide increases non-vesicular basal release of EAAs through Fenton-generated hydroxyl radicals. This release could cause accumulation of extracellular EAAs and contribute to the excitotoxicity associated with some pathologies.

555.15

THE EFFECT OF NITRIC OXIDE SYNTHASE INHIBITOR ON THE BEHAVIOR AND BRAIN MORPHOLOGY, A DOSE RESPONSE STUDY.

S. Shapira*, B.A. Weissman and T. Kadar, Dept Pharmacology, IIBR, Ness Ziona IL-70450, Israel.

It has been shown that in spite of an obvious protective effect of nitric oxide synthase (NOS) inhibitor on ischemic brain tissue *in vitro*, no such effect can be confirmed *in vivo*. The present study was taken in order to explore the dose dependency of nitric oxide (NO) inhibition on brain ischemia *in vivo*. Groups of gerbils were given doses of the NOS inhibitor nitroarginine (5-50 mg/kg, ip). Four hours later, the animals were exposed to 5 min forebrain ischemia, and behavioral (up to 6 days post ischemia) and histological (at 6 days) parameters were evaluated. All nitroarginine treated groups showed significant decrease (10-12%) in body weight, starting with the 5 mg/kg group, and spontaneous hyperactivity, with the highest activity in the 25 and 50 mg/kg groups, in a dose dependent fashion. Marked ischemic injury was observed in all animals exposed to ischemia, but not in the nitroarginine (50 mg/kg, ip) treated gerbils that were not subjected to ischemia. A dose dependent pattern was observed also in a morphometric analysis of the dorsal hippocampus (cell count of CA1). It is concluded that gradual inhibition of NO production aggravates the ischemic brain injury already at a low (5 mg/kg) dose, and this effect reaches its peak between 25 and 50 mg/kg in a dose dependent manner. There is a distinct correlation between behavioral and histologic parameters.

555.12

ADDITIONAL INHIBITION OF GLUTAMATE UPTAKE BY ARACHIDONIC ACID AND OXYGEN RADICALS VIA TWO DISTINCT MECHANISMS

A. Volterra*, D. Trotti, C. Tromba & G. Racagni Ctr. Neuropharmacol., Inst. Pharmacol. Sci., University of Milan, 20133 Milan, Italy.

Massive arachidonic acid (AA) release, uncontrolled formation of reactive oxygen species (ROS) and enhanced extracellular levels of excitatory amino acids are important neurotoxic events triggered by brain insults such as ischemia and trauma. Several evidences suggest a link between these events. We have previously shown that both AA (Volterra et al., J. Neurochem, 59, 600-606, 1992) and ROS (Volterra et al., Soc. Neurosci. Abs., 18, 647, 1992) rapidly inhibit high-affinity glutamate (GLU) uptake. Here we study the interaction between AA and ROS effects in primary astrocytic cultures from rat cerebral cortex. Within 10 min GLU uptake is inhibited by 20% with 15 μ M AA, 35-40% with 50 μ M AA and 25-30% with ROS generated by xanthine(500 μ M)+xanthine oxydase(50 mU/ml) (XOXO); when added together, 15 μ M AA + XOXO reduce uptake by 45% and 50 μ M AA + XOXO by 60%. Potent uptake inhibition by AA + XOXO mixtures is not due to cell damage, since they do not increase extracellular LDH. Chemical reaction between AA and ROS to form new inhibitory species is unlike, because sequential addition of AA and XOXO leads to identical inhibition. On the other hand, AA and ROS effects are blocked by distinct agents: scavenger enzymes superoxide dismutase (SOD, 90 U/ml)+catalase (CAT, 3000 U/ml) or disulfide-reducing agent dithiothreitol (DTT, 2 mM) abolish ROS inhibition with no effect on AA, while albumin (BSA, 0.1%) blocks AA but not ROS. Moreover, progressive uptake decline during prolonged exposure to 15 μ M AA + XOXO is only partially reduced by agents acting on either AA or ROS alone, while is blocked by a mixture of them (SOD/CAT + DTT + BSA). Our data indicate that: (1) AA and ROS inhibit GLU uptake via two distinct mechanisms; (2) their effects are completely additive. Overlapping formation of AA and ROS during brain insults could lead to severe derangement of GLU uptake function.

555.14

KAINIC ACID (KA) INDUCED TOXICITY IN CULTURED NEURONS OVEREXPRESSING CU/ZN-SUPEROXIDE DISMUTASE. O. Bar-Peled*, L. Sklair-Tavran and Y. Groner, Molecular Genetics and Virology Dept., The Weizmann Institute of Science, Rehovot, Israel 76100.

The gene encoding Cu/Zn-superoxide dismutase (CuZnSOD), a key enzyme in the metabolism of oxygen free radicals, resides in the Down's syndrome (DS) region of chromosome 21. The possible involvement of CuZnSOD overexpression in the etiology of DS and in neuronal death was studied by analyzing neurons of transgenic (tg)-SOD mice harboring and overexpressing the human gene. Neurons derived from cortex and spinal cord of Tg-SOD and non-transgenic mouse embryos were cultured. Mature cultures were exposed to 50 μ M KA for 16 h and their sensitivity to excitotoxicity determined. It was found that Tg-SOD neurons, both cortical and spinal cord cultures, exhibited higher sensitivity to the treatment with KA as compared to non-transgenic cultures. To determine the contribution of glial cells to this differential vulnerability we examined glial-neuronal cultures from Tg-SOD and control embryos. On the average 50 percent more neurons died when astroglia from Tg-SOD mice were used as feeder layer, indicating that these cells play an important role in the apparent sensitivity of Tg-SOD neurons to KA toxicity. In spinal cord cultures, large motoneurons (LMN) were by far more sensitive to KA toxicity as compared to the cortical and spinal cord neurons, but no marked differences were observed between Tg-SOD and control LMN. The significance of these observations to Familial Amyotrophic Lateral Sclerosis will be discussed.

555.16

DELAYED NITRIC OXIDE PRODUCTION MEDIATES L-GLUTAMATE AND KAINATE NEURONAL DEATH IN CULTURED RAT CORTICAL NEURONS X. Viggé, A. Carreau, J.P. Nowicki and B. Scatton SYNTELABO RESEARCH, Biology Department, 31 avenue Paul Vaillant-Couturier, 92220 Bagneux, France.

We have evaluated the neuroprotective effect of N⁹-nitro-L-arginine (L-NNA) against L-glutamate (L-glu)- or kainate-induced neurotoxicity in cultured rat cortical neurons under different treatment schedules. A substantial nitric oxide (NO) synthase activity was detected in these cortical cultures. The NO-mediated increase in cellular cyclic GMP content induced by a 5 min treatment with either L-glu or kainate was fully antagonized by L-NNA (100 μ M). Treatment of neurons with either L-glu (500 μ M for 5 min) or kainate (100 μ M for 24 h) produced a delayed neuronal death at 24 h, as measured by LDH release. Addition of L-NNA (100 μ M) to the medium 5 min prior to and during L-glu exposure (5 min) decreased by only 23% (not significant) the amino-acid-induced neurotoxicity in spite of a complete inhibition of NO synthesis under these conditions. When added 5 min before L-glu and again just after L-glu removal and kept in contact with the neurons for the following 24 h, L-NNA (100 μ M) antagonized by 74% the L-glu-induced neurotoxicity (IC₅₀ = 4 μ M). Similarly, permanent application of L-NNA (100 μ M) protected neurons from kainate (100 μ M for 24 h) toxicity by 85%. MK-801 (1 μ M) completely antagonized both L-glu- and kainate-induced neurotoxicity, indicating that delayed neuronal death is mainly mediated by NMDA receptor activation.

These results demonstrate that in our experimental conditions, NO synthesized in response to NMDA receptor stimulation plays a major role in L-glu- or kainate-induced neurotoxicity. The increased efficacy of L-NNA with prolonged application indicates that neuronal death occurring during the maturation phase that follows L-glu exposure is due to a delayed production of NO.

NITRIC OXIDE TOXICITY IN XENOPUS OOCYTES: ROLE OF CALCIUM. J.D. Connor*, J.M. Nave, J.E. Smith, J.M. Lewis. Dept. of Pharmacology, Hershey Med. Cntr., Penn State Univ. Col. of Medicine, Hershey, PA 17033.

Nitric oxide may be a mediator of "excitotoxicity", a process in which unregulated binding of glutamate to its receptors leads to neuronal death. Glutamate increases the concentration of free calcium in cytoplasm which stimulates nitric oxide synthetase. We tested the hypothesis that Xenopus oocytes could serve as a model system for evaluating this series of events *in vitro*. Our specific goals were to characterize toxicity produced in oocytes by nitroprusside, a nitric oxide precursor, and to determine if calcium influences toxicity. Stages V and VI oocytes were kept in Modified Barth's Solution (MBS, a salt mixture containing calcium) or in calcium-free MBS. Dose-response and time-action data for nitroprusside toxicity were obtained. Toxicity was measured quantally by counting cells that failed to exclude trypan blue, 1%. Nitroprusside was toxic to oocytes in MBS in the range of 10 to 100 mM. Interbatch variability was considerable. In calcium-free MBS, the TD50 for nitroprusside was 65% of that estimated for normal MBS, and response variability was much reduced. In summary, nitroprusside in mM concentrations is toxic to oocytes, and the response is decreased by withholding extracellular calcium. Co-operativity between nitric oxide and free intracellular calcium may underlie the process of excitotoxicity.

CORRELATING CHANGES IN INTRACELLULAR FREE CALCIUM CONCENTRATION WITH EXCITOTOXICITY AT A SINGLE CELL LEVEL. A. F. Strautman*, J. S. Althaus, P. F. Vonvoigtlander CNS Diseases Research, The Upjohn Co. Kalamazoo, MI 49001.

An increase in the intracellular calcium concentration is a commonly accepted result of many types of CNS trauma. Its involvement in neurotoxicity has been described in a number of *in vitro* excitotoxicity models. We have developed a procedure for measuring the changes in intracellular free calcium concentration ($[Ca^{2+}]_i$) using fura-2 with an image analysis system and correlating these responses with viability in the same cells 24 hours later. We are testing the hypothesis that a particular pattern of changes in $[Ca^{2+}]_i$ may lead to cell death. We are using two related neurotoxic treatments with a primary culture of cerebellar granule cells: glutamate receptor analogs (NMDA, kainic acid, AMPA) and peroxynitrite, a recently described toxin that forms when nitric oxide and superoxide combine. We find that after a 30 minute exposure and washout of kainic acid a sustained elevation of $[Ca^{2+}]_i$ is indicative of cell death at 24 hours. Since peroxynitrite reacts very quickly at physiologic pH, we have developed a procedure to locally apply peroxynitrite to the cells using a micropipette and syringe pumps. We find that peroxynitrite increases $[Ca^{2+}]_i$ and, despite evidence that cerebellar granule cells are resistant to other nitric oxide generating agents, is toxic in this model. We are exploring the mechanisms of the peroxynitrite induced $[Ca^{2+}]_i$ increase and further characterizing the relationship to the sustained increase following excitotoxic exposure.

555.18

GLUTAMIC ACID (GLU) UPTAKE INHIBITION BY NITRIC OXIDE (NO). S. POGUN* and M.J. Kuhar. Neuroscience Branch, NIH-NIDA, Balto, MD 21224.

Glutamic acid is thought to be the major excitatory neurotransmitter in the brain, and GLU uptake is thought to be the mechanism of inactivation of released GLU. One effect of the stimulation of NMDA receptors is the production of NO which can act as a gaseous, diffusible messenger, with possible presynaptic action. In this study, we examine the effect of NO on 3H -GLU uptake in hippocampal synaptosomes from male, Sprague-Dawley rats. 3H -GLU uptake was carried out by standard procedures. Tissues were preincubated first at 37°C for 15 min and then at 30°C for 5 min. Uptake was begun by adding 3H -GLU (3 nM) and terminated 3 min later by adding cold sucrose and collecting the tissues by rapid filtration. NO inhibited 3H -GLU uptake in a time, temperature and dose-dependent fashion. Maximal inhibition was about 50% which occurred with 300 μ M NO. Inhibitions did not occur at 0°C. The inhibition was prevented by coincubation with reduced hemoglobin. Potassium ferro- and ferricyanide did not inhibit uptake but rather enhanced it. The inhibition by NO could be reversed by washing the synaptosomes by centrifugation and resuspension, although there was not a total reversal under our conditions. Thus, it seems clear that NO could, at least in principle, inhibit GLU uptake at synapses. This could have implications for and help explain glutamate neurotoxicity since NO production would have the effect of prolonging the presence of GLU in sensitive areas. Also, if NO is the retrograde messenger involved in long-term potentiation, inhibition of GLU uptake could contribute to the strengthening of the synapse which is characteristic of LTP. NO inhibition of GLU uptake is an interesting potential new mechanism in regulating synaptic activity.

555.20

NITRIC OXIDE (NO) INDUCES THE RELEASE OF INTRACELLULAR CALCIUM ($[Ca^{2+}]_i$) IN STRIATAL NEURONS. B.A. MacVicar*, S.A. Samanani, S. Duffy and S. Weiss. Neuroscience Research Group, University of Calgary, Calgary, Alberta, Canada T2N 4N1.

NMDA receptor activation in neurons releases NO which is implicated in excitotoxicity and synaptic plasticity. We have examined the role of NO in NMDA-induced changes of $[Ca^{2+}]_i$. Imaging and measurement of fura-2 fluorescence was used to estimate $[Ca^{2+}]_i$ in striatal neurons cultured from the embryonic mouse. Repetitive NMDA activation induced sustained increases in $[Ca^{2+}]_i$ in approximately 50% of neurons (13-15 DIV). Inhibiting NO synthesis with N ω -Nitro-L-arginine (NARG, 1 μ M) prevented the NMDA-evoked sustained increases in $[Ca^{2+}]_i$. L- but not D-arginine (100 μ M) prevented the actions of NARG suggesting that NO produced by NMDA activation induces sustained increases in $[Ca^{2+}]_i$. We therefore examined the actions of NO itself on $[Ca^{2+}]_i$. Striatal neurons were superfused with Hepes buffered solution that was degassed by bubbling with argon. NO containing stock solutions were obtained by bubbling degassed solutions with NO which were then diluted in degassed solution to the appropriate concentrations. Superfusion of striatal neurons for >30 min with either degassed solution alone or with nitrite (5-200 μ M) did not effect resting $[Ca^{2+}]_i$ in most cells. NO (5-50 μ M) induced increases in $[Ca^{2+}]_i$ which gradually developed over 4-5 min and reached a stable plateau in the continued presence of NO. The NO-induced $[Ca^{2+}]_i$ plateau persisted in 0 Ca^{2+} -EGTA solution but quickly decreased to control levels if NO was removed. These results indicate that NO induces Ca^{2+} release from internal stores and may transduce the sustained increases of $[Ca^{2+}]_i$ from NMDA receptor activation. Supported by MRC Canada and Ciba-Geigy.

EFFECTS OF THE NMDA ANTAGONIST KETAMINE IN SCHIZOPHRENIC PATIENTS. A.C. Lahti, D.J. LaPorte, B. Mokriski, C.A. Tamminga*, Maryland Psychiatric Research Center, University of Maryland at Baltimore, Baltimore, MD 21228

The non-competitive NMDA antagonist PCP produces an approximation of the signs and symptoms of schizophrenia in normal humans. Its psychotomimetic effect often extends beyond the half life of the drug. To evaluate the nature, dose characteristics, and time course of an NMDA antagonist on mental status in schizophrenic patients, we have administered the PCP analogue ketamine in a randomized double blind design using 3 dosages of ketamine (0.1, 0.3 and 0.5 mg/kg) and a placebo, each administered over 60 seconds. Patients received two sets of challenges: 1) after haloperidol stabilization treatment and 2) after 4 weeks of neuroleptic withdrawal. Patients were evaluated using the BPRS and the SANS global at baseline and 20, 90, and 180 minutes post injection. In haloperidol treated patients, ketamine induced a dose-related, short lasting worsening in mental status, often reminiscent of the patients' acute symptoms. The BPRS total score and psychosis subscale were significantly increased compared to the placebo at 20 minutes after the two higher doses. Preliminary data (N=3) fail to show that haloperidol blocks the ketamine-induced worsening in psychosis. Several subjects evidenced longer lasting psychotomimetic effects such as flashbacks, dreams, and prolonged psychosis worsening. Immediate recall of verbal and non-verbal information (Logical Memory and Figural Reproduction, Wechsler Memory Scale-Revised) and other cognitive measures were collected before and 30 minutes following drug. Ketamine had no effect on memory consolidation or on any of the other cognitive tasks.

556.2

DEXTROMETHORPHAN ATTENUATES AND REVERSES MORPHINE TOLERANCE. K.J. Elliott*, A. Hynansky and C.E. Inturrisi. Dept. of Pharmacology, Cornell U. Med. College, New York, NY 10021.

Dextromethorphan (DM) is an antitussive agent and a functional NMDA receptor antagonist. Infusion of morphine (MOR) (sc osmotic pump at 30 mg/kg/24 hrs) for 7 days resulted in a greater than seven fold decrease in MOR's potency as measured with sc cumulative dose response curves using the tailflick (TF) test in male CD-1 mice. The MOR ED50 value increased from 3.7 mg/kg (2.3-5.5, 95% CI) prior to the initiation of the MOR infusion to 27.1 mg/kg (17.8-41.8) on day 7 of the infusion. In contrast, co-administration of DM by sc infusion (12 mg/kg/24 hrs) attenuated the development of tolerance such that on day 7 the MOR ED50 of the DM + MOR treated group at 6.9 mg/kg (4.6-9.9) was not significantly different from the MOR ED50 on day 1. DM given alone as above for 1 or 7 days did not affect the TF response nor did it alter the MOR ED50. Tolerance (a 10 fold increase in the ED50) produced by the implantation of two 25mg MOR pellets for 4 days was completely reversed by DM (30 mg/kg tid for 3 days) while saline injected animals remained tolerant when tested on day 8. These results demonstrate that a clinically available drug which is an antagonist at the NMDA receptor may have utility in the modulation of MOR tolerance. Supported in part by DA01457 and CA09512.

556.3

NMDA RECEPTOR ANTAGONISTS ATTENUATE ANALGESIC TOLERANCE TO MORPHINE, BUT NOT TO KAPPA OPIOIDS. C.E. Inturrisi, K. Elliott, N. Minami, Y.A. Kolesnikov, G.W. Pasternak and K.M. Foley*. Depts. of Pharmacology, Neurology and Neuroscience, Cornell U. Med. Coll. and The Cotzias Lab. of Neuro-Oncology, MSKCC, New York, NY 10021.

Daily administration of 5 mg/kg sc of morphine (MOR), a mu-opioid agonist, or U50488H (U50), a kappa-opioid agonist, for 5 days in CD-1 mice results in a 2 to 3 fold shift to the right of the respective analgesic (tailflick, TF) dose-response curves, indicating the development of tolerance. Concurrent administration of the competitive NMDA receptor antagonist, LY274614 (LY) at 24 mg/kg/24 hr, sc infusion or daily 6 mg/kg ip, attenuates the development of MOR tolerance, when the response to saline plus MOR is compared on day 5 with LY plus MOR. Daily administration of the noncompetitive NMDA antagonist, MK801 (MK) at 0.3 mg/kg ip, also attenuated MOR tolerance. Neither of these drugs modify the TF response or alter the ED50 for MOR. In contrast, coadministration of LY or MK, as above, failed to attenuate the development of tolerance to U50 or to the kappa-opioid agonist, naloxone benzoylethylidone (NalBzoH). These results suggest that mu-opioid tolerance but not kappa, or kappa, opioid tolerance involves the mediation of NMDA receptors. Supported by DA01457, DA07242, CA09512 and the Winston Foundation.

(+)MK-801 PREVENTS THE DEVELOPMENT OF CHRONIC TOLERANCE TO ETHANOL ON A CIRCULAR MAZE TEST. S. Rafi-Tari, J.F. Liu, P.H. Wu, H. Kalant, J.M. Khanna and G.A. Cottrell*. Department of Pharmacology, University of Toronto, and Addiction Res. Foundation, Toronto, Ontario, Canada M5S 1A8

Much evidence indicates that the development of tolerance to ethanol involves learning. (+)MK-801 (MK) and ketamine, that disrupt learning and memory, also prevent the development of tolerance to the motor impairment effect of ethanol (E). However, in addition to its effect on learning, (+)MK-801 impairs motor function. Therefore the circular maze test, that depends on learning but is largely independent of motor function, was used to assess the effect of MK on chronic E tolerance. Forty male Sprague Dawley rats, trained and met criterion performance (21 ± 3 % of error responses) on a circular maze test, were ranked and divided into five balanced groups [saline (S)-saline; S-E; MK (0.15 mg/kg)-S; MK (0.15 mg/kg)-E (1.0 g/kg) or MK (0.075 mg/kg)-E (1.0 g/kg)]. The treatment consisted of an i.p. injection of S or MK followed 30 min later by another i.p. injection of S or E. Thirty min after S or E, rats were given a practice session on the maze. MK (0.15 mg/kg) given before the daily administration of E and practice on the maze, prevented the development of tolerance but a lower dose (0.075 mg/kg) of the drug did not. These results suggest that blockade of NMDA receptor activity prevents the development, rather than the expression, of tolerance to ethanol. Supported by NIAAA grant #1 R01-AA08212-03.

PARTIAL AGONISTS AT THE GLYCINE SITE COUPLED TO NMDA RECEPTORS AND INHIBITORS OF NITRIC OXIDE SYNTHETASE BLOCK LATE-PHASE FORMALIN-INDUCED LICKING IN MICE. L. Seguin, S. Le Marouille-Girardon and M.J. Millan*. I.D.R.S., 7 rue Ampère, 92800 Puteaux, France.

NMDA receptors in the dorsal horn of the spinal cord mediate amplification processes ('wind-up') underlying persistent pain and both channel blockers and NMDA recognition site antagonists display antinociceptive properties. The ion channel coupled to the NMDA recognition site also possesses a glycinergic site and recent data suggest that Nitric Oxide (NO) plays a role in the cellular expression of actions mediated by NMDA receptors. Thus, herein, we compared the antinociceptive actions of the following drugs: (+)-MK 801, a channel blocker; CPP, a NMDA recognition site antagonist; MDL 29,951, a glycine site antagonist; (+)-HA 966 and D-cycloserine, partial agonists at the glycine site and L-NAME and 7-nitroindazole, inhibitors of NO synthetase. Mice were injected in the dorsal hind paw with 20 µl of 5% formalin and licking quantified 0-5 min (early phase, EP) and 35-50 min (late phase, LP) thereafter. The rotarod test (in separate mice) was used to evaluate motor behaviour. Drugs were given s.c., 30 min pre-testing. Doses are Inhibitory Doses₅₀ (mg/kg, s.c.). (+)-MK 801 and CPP were equipotent against EP/LP pain at doses (0.03/0.03 and 2.1/2.4, respectively) close to those required for inducing ataxia, 0.05 and 2.9, respectively. In contrast, MDL 29,951 inhibited LP (1.0) but not EP licking (>10) and did not induce ataxia (>10). (+)-HA 966/D-cycloserine also selectively blocked LP (1.6/15.3) as compared to EP (33.3/ >40.0) licking. Further, (+)-HA 966 likewise blocked LP licking (2.2) when administered after the EP. (+)-HA 966/D-cycloserine were inactive in the rotarod test (>40.0 / >40.0). L-NAME/7-nitroindazole selectively blocked LP (2.8/9.8) versus EP (>40.0 / >40.0) licking without inducing ataxia (>40.0 / >40.0). In conclusion, as compared to channel blockers and NMDA antagonists, agonists and partial agonists at the glycine site and inhibitors of NO synthetase may elicit antinociception against prolonged pain in the absence of motor discoordination.

556.4

NMDA RECEPTOR AND PROENKEPHALIN GENE EXPRESSION ARE MODULATED BY CHRONIC MORPHINE ADMINISTERED ALONE OR IN COMBINATION WITH NMDA ANTAGONIST. M. Brodsky*, K. Elliott, A. Hynansky, N. Minami, and C.E. Inturrisi. Pharmacology, Cornell U. Med. Coll., NY, NY 10021.

Changes in N-methyl-D-aspartate (NMDA) receptor and proenkephalin (Ppenk) gene expression were studied in morphine (MOR)-tolerant and MOR-sensitive rats treated with the NMDA antagonist, LY274614 (LY) (Tiseo and Inturrisi, JPET, 1993). NMDAR1 (functional NMDA receptor subunit) and Ppenk mRNA were measured in selected CNS regions by solution hybridization. At one week NMDAR1 mRNA levels were significantly lower in spinal dorsal horn (SC) and higher in lateral thalamus (LT) of MOR-treated as compared to placebo. Coadministration of MOR with LY attenuated both the behavioral manifestations of tolerance and MOR-induced changes in NMDAR1 mRNA in SC and Nucleus Raphe Magnus (NRM), but not in LT. Ppenk mRNA levels were significantly higher in NRM and Nucleus Paragigantocellularis (PGi) of MOR-treated rats, and coadministration of MOR with LY prevented this induction in NRM but not in PGi. Infusion of LY for 7 days to placebo rats had no effect on behavior or on the NMDAR1 and Ppenk mRNA levels in these CNS regions. Altered NMDAR1 and Ppenk expression in CNS regions comprising nociceptive pathways may contribute to the development of tolerance to morphine and its attenuation by LY. Supported by DA05130, DA01457 and CA09152.

2-HEXYL-3-INDOLEACETAMIDE (FGIN-1-27) ACTING AT THE MITOCHONDRIAL DBI RECEPTOR COMPLEX (MDRC) ANTAGONIZES THE AMNESIC EFFECT OF MK-801. E. Romeo*, D. Konkel, I. Zivkovich, A. Korneev, and A. Guidotti. Fidia-Georgetown Institute for the Neurosciences, Georgetown Univ Med Sch, Washington, DC 20007.

FGIN-1-27, a specific ligand for the glial MDRC increases the rate of brain pregnenolone synthesis in a manner that is blocked by PK11195 (JPET 262:971, 1992). Here we examined whether FGIN-1-27 pretreatment, by modulating brain steroidogenesis, has an effect on MK801 (0.6 µmol/kg, i.p.) and triazolam (3.2 µmol/kg, i.p.) induced memory impairment in the passive avoidance test in rats. FGIN-1-27 is devoid of any anterograde or posterograde action but, in a dose dependent manner (57-228 µmol/kg, p.o.), prevents the learning impairment induced by MK801 but not by triazolam. Pretreatment with 47 µmol/kg, i.p., of pregnenolone sulfate (PS) - a steroid that positively modulates glutamate receptor function and has memory enhancing effects (PNAS 89:1567, 1992) - antagonizes the amnesic effect of MK801 but not that of triazolam. PK11195 (28 µmol/kg, i.p.), which per se is devoid of action, antagonizes the effect of FGIN-1-27, while flumazenil (3.1 µmol/kg, i.p.) antagonizes only the effect of triazolam. The antagonism of the MK801 amnesic action by FGIN-1-27 was reproducible in two other memory and learning rat models: the radial maze and the Morris water maze test. After injection of PS, this steroid reaches a brain concentration of approximately 1 µM which correlates well with the concentration of PS effective as a positive allosteric modulator at glutamate receptors (Mol. Pharmacol. 40:333, 1991). In addition we could demonstrate that 10^{-6} M PS decreases the binding of [³H]MK801 to rat cortical membranes in the presence or absence of glutamate and glycine. In contrast FGIN-1-27 was unable to modify the binding of [³H]MK801 in the same membrane preparation.

Supported in part by NIH grant RO 1 MH49486-01.

PREGNENOLONE SULFATE BLOCKS NMDA ANTAGONIST-INDUCED DEFICITS IN A PASSIVE AVOIDANCE MEMORY TASK IN RATS. G. Mathis*, S.M. Paul and J.N. Crawley. Section on Behavioral Neuropharmacology and Section on Molecular Pharmacology, National Institute of Mental Health, NIH, Bethesda, MD 20892.

Neurosteroids, including pregnenolone sulfate (PS), potentiate NMDA receptor activation and display memory-enhancing properties (Irwin et al., 1992; Flood et al., 1988). The present study investigates the ability of PS to enhance retention performance of a passive avoidance task and to prevent the behavioral deficits induced by an NMDA receptor antagonist, 3-(+/-)-2-carboxypiperazin-4-yl-propyl-1-phosphonic acid (CPP).

PS (0.084 - 1680 pmol) or CPP (0.8 - 1.6 nmol) was administered intraventricularly to previously cannulated rats, 15 minutes before the training trial of a step-through passive avoidance task. PS had no significant effect alone on the retention performance 24 hours later, at the doses tested, although there was a trend towards improved retention. CPP significantly impaired retention performance at the doses of 1.2 and 1.6 nmol.

Following the same behavioral procedures, combinations of CPP (1.2 nmol) with PS (0.084 - 840 pmol) were administered, to investigate the interactions of PS with an NMDA receptor antagonist. PS significantly reduced CPP-induced deficits on the retention performance at doses of 420 and 840 pmol. In addition, PS (840 pmol) prevented the ataxic effects of CPP (1.2 nmol) in a rotarod test.

These results demonstrate that the neurosteroid PS potently antagonizes deficits induced by an NMDA antagonist on a memory task and on motor function, and support a positive modulatory role for PS on NMDA receptors.

556.9

EFFECTS OF AN NMDA GLUTAMATE RECEPTOR BLOCKER ON THERMOREGULATION IN THE RAT. C. V. Gisolfi* and F. Mora. Dept. of Physiology & Biophysics, Univ. of Iowa, Iowa City, IA 52242, USA, and Dept. of Physiology, Faculty of Medicine, Univ. Complutense of Madrid, 28040 Madrid, SPAIN.

Because (a) N-methyl-D-aspartate (NMDA) glutamate receptors are located in the anterior hypothalamus (AH), (b) glutamate is a putative neurotransmitter in the AH involved in neurochemical circuits of hormone regulation, (c) dopamine is involved in temperature control and interactions between dopamine and glutamate exist in the brain, the possibility exists for glutamate to participate in thermoregulation. To test this hypothesis, we measured heart rate, blood pressure, activity, and core body temperature via telemetry in male Sprague-Dawley rats (n=8) exposed sequentially to 1 h periods at ambient temperatures of 22°C, 40°C, and 22°C after i.p. injections of saline and 25, 50, and 100 mg/kg D,L-2-amino-5-phosphopentanoic acid (AP5) administered randomly on different days. There were no effects of the NMDA blocker on heart rate, blood pressure, or activity. All doses of the blocker tended to elevate core body temperature above values observed following injection of the saline control, but there were no significant differences. We conclude that glutamate does not act in thermoregulatory pathways through NMDA receptors. Other glutamate receptors, such as AMPA and metabotropic receptors, are under investigation.

INTRACEREBRAL SPERMINE PRODUCES IFENPRODIL SENSITIVE HYPERACTIVITY IN RATS. Gh. Perrault, E. Audl, B. Zivkovic* and D.J. Sanger. Synthelabo Recherche (LERS), 31 ave P. V. Couturier, 92220 - Bagneux, France

The potential physiological importance of polyamines (such as spermine), in the central nervous system has been emphasized by the finding that these substances act at a site associated with NMDA receptors. However, few interactions between polyamine-induced effects and NMDA antagonists have been investigated in *in vivo* studies. In the present experiments, bilateral infusion of spermine (5, 10, 20 µg/side) into the nucleus accumbens produced in rats dose-dependent increases in exploratory activity (recorded in photobeam activity cages) which lasted for 60 min. This spermine-induced effect was antagonized by pretreatment, with an injection of ifenprodil (3, 10, 30 mg/kg, ip) an anti-ischaemic drug which shows NMDA antagonist properties probably mediated by activity at the polyamine site. These are the first behavioral findings showing the polyamine antagonist properties of ifenprodil, which, like other NMDA antagonists, shows anticonvulsant and central depressant effects but does not induce any behavioral stimulation or PCP-like discriminative stimulus properties. However, further experiments are needed to investigate whether this present effect is associated with the polyamine modulatory site of NMDA receptors or with other polyamine receptors.

STRYCHNINE-INSENSITIVE GLYCINE ANTAGONISTS ATTENUATE A CARDIAC ARREST INDUCED MOVEMENT DISORDER. D.D. Truong, M.J. Hussong, A. Starr* and R.R. Matsumoto. Department of Neurology, University of California Irvine, Irvine, CA 92717.

Until the recent development of several novel and selective glycine antagonists, our ability to rigorously test the relationship between glycine and myoclonus was hampered by the lack of pharmacological tools. We now report the efficacy of four strychnine-insensitive glycine antagonists (HA966, felbamate, ACEA1011, ACEA1021) in attenuating the auditory-induced myoclonus exhibited in our cardiac arrest-induced animal model of post-hypoxic myoclonus. Male Sprague Dawley rats underwent cardiac arrest and resuscitation, subsequently exhibiting post-hypoxic myoclonus with salient features similar to the human form of the disorder. After the arrest and resuscitation, vehicle injections (saline i.p., DMSO i.p., water p.o.) were all without effect on the auditory-induced myoclonus exhibited by these animals. However, there was a significant effect of dose (P<0.05) for felbamate (500, 1000 mg/kg p.o.; Carter Wallace, Cranbury, NJ), ACEA1011 (10, 25, 50 mg/kg i.p.; E. Weber, UCI, Irvine, CA) and ACEA1021 (25, 50 mg/kg i.p.; E. Weber, UCI, Irvine, CA). Preliminary studies with a single dose of HA966 (10 mg/kg; RBI, Natick, MA) also showed marked attenuation of myoclonus. These data suggest the potential therapeutic usefulness of these strychnine-insensitive glycine antagonists in myoclonus, and possibly other ischemia-related, seizure and movement disorders.

THE NMDA RECEPTOR ANTAGONISTS (±)-CPP AND CGS19755 ATTENUATE THE BEHAVIOURAL AND NEUROCHEMICAL EFFECTS OF AMPHETAMINE IN MICE. L.J. Bristow, L. Thom, P.H. Hutson and M.D. Tricklebank* Merck Sharp and Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Harlow, Essex CM20 2QR, U.K.

We have previously shown that the glycine/NMDA receptor antagonist, R(+)-HA-966, attenuates drug-induced mesolimbic dopaminergic hyperactivity in rodent brain. We now show that the competitive NMDA receptor antagonists, (±)-CPP AND CGS19755, have similar properties.

Mice were injected i.p. with (±)-CPP or CGS19755 (1 - 10 mg/kg) and 30 min later given (+)-amphetamine sulphate (5 mg/kg, s.c.). Motor activity was then recorded over the following 2 h using individual photocell cages. In separate groups of mice, dopamine synthesis was determined by measurement of DOPA accumulation following inhibition of aromatic acid decarboxylase with NSD 1015. Animals were injected with (±)-CPP (10 mg/kg, i.p.) or CGS19755 (5 mg/kg) 30 min prior to (+)-amphetamine (2.5 mg/kg, s.c.). Thirty min later, all mice received NSD 1015 (100 mg/kg, i.p.) and then killed after a further 30 min and the nucleus accumbens dissected.

The hyperlocomotion induced by (+)-amphetamine was dose-dependently antagonised by both (±)-CPP and CGS19755 at doses having no effect on locomotor activity *per se* (ED50s = 5.8 mg/kg and 2.4 mg/kg respectively). (±)-CPP and CGS19755 also reduced the amphetamine-induced increase in DOPA accumulation in the nucleus accumbens by 59% and 66% respectively and neither compound had any effect on dopamine synthesis in the absence of amphetamine.

The results provide further evidence that NMDA receptor antagonists attenuate the activation of mesolimbic dopamine systems by amphetamine.

KETAMINE-LORAZEPAM INTERACTIONS IN HEALTHY HUMANS. J.H. Krystal*, L.P. Karper, A. Abi-Dargham, D.C. D'Souza, A. Bennett, M.B. Bowers, D.S. Charney. Yale U. Dept. Psychiatry, VA Medical Center, West Haven, CT 06516

Lorazepam is a putative treatment for ketamine-induced psychosis, perceptual alterations, and cognitive impairments. To formally assess this capacity, the interactive effects of ketamine and lorazepam were studied in humans. **METHODS:**

In an ongoing study, healthy subjects (n=18) completed four test days in which they received pretreatment with lorazepam 2 mg or placebo two hours prior to ketamine (0.26 mg/kg i.v. bolus followed by 0.65 mg/kg/hr i.v.) or placebo. **RESULTS:** Lorazepam did not significantly reduce increases in BPRS "positive" or BPRS "negative" symptoms of psychosis. Lorazepam reduced ketamine-induced perceptual alterations similar to dissociative states. Neither medication reduced gross orientation or produced motor impairment on the finger-tapping test. Ketamine increased perseverative error on the Wisconsin Card Sorting Test, an effect reduced by lorazepam. Lorazepam exacerbated ketamine impairments in delayed recall. Lorazepam did not alter ketamine-induced increases in plasma levels of cortisol or prolactin.

IMPLICATIONS: Lorazepam is not an antidote for all ketamine effects. Lorazepam reduces ketamine effects on sensory integration and performance impairments on tests sensitive to frontal cortical impairment. However, lorazepam failed to improve ketamine-induced psychosis, negative symptoms, and memory impairments.

ANTI-PARKINSONIAN EFFECTS OF CENTRALLY-ADMINISTERED GLYCINE ANTAGONISTS. BARBARA S. SLUSHER*, KEVIN C. RISSOLO, PAUL E. JACKSON AND LINDA M. PULLAN. DEPARTMENT OF PHARMACOLOGY, CNS SECTION, ZENECA PHARMACEUTICALS, WILMINGTON, DE 19897.

There has been a recent surge of interest in the potential utility of glutamate antagonists in Parkinson's Disease (PD). Degeneration of nigrostriatal dopamine neurons in PD results in overactivity of the glutamate neurons of the subthalamic pathway. NMDA- and AMPA-type glutamate antagonists have been shown to reverse parkinsonian symptoms in several primate and rodent PD models. In theory, antagonists of the glycine site of the NMDA receptor should display similar antiparkinsonian activity, with less propensity for adverse side-effects. In this report, we examined the effects of glycine antagonists on reversal of akinesia associated with monoamine depletion in mice. Male Swiss-Webster mice were injected with 5 mg/kg reserpine (i.p.; t = -19 hr), 250 mg/kg α-methyl-tyrosine (i.p.; t = -30 min) and 20 mg of a glycine antagonist (i.c., at the level of the globus pallidus; t = 0). Motor activity was assessed for one hour using an Automex capacitance activity monitoring system. Known glycine antagonists including (R)-HA-966, Merck's L689560, 5,7-dichlorokynurenic acid and 7-chlorokynurenic acid caused a significant (720%, 599%, 390% and 324%, respectively; *p<0.01) stimulation of locomotor activity, compared to vehicle controls. ZENECA has recently reported a series of novel pyridiazinoindole glycine antagonists. Two compounds from this series, 7,9-dichloro-8-methoxy-pyridiazino[4,5-b]indole-1,4-dione and 7,9-dichloro-pyridiazino[4,5-b]indole-1,4-dione, also caused significant (349%* and 341%*, respectively; **p<0.05) stimulation of locomotor activity. Co-injection of glycine antagonists with the glycine agonist D-serine (100 mgs) completely blocked locomotor stimulation. D-Serine alone showed no effect. In addition, all glycine antagonists tested did not cause significant hyper-stimulation when centrally-administered to normal non-reseperinized mice. These data suggest that glycine antagonists may have therapeutic utility in the treatment of idiopathic PD.

AMPA PREVENTS NMA-INDUCED ELECTROPHYSIOLOGICAL CHANGES IN THE RAT CEREBRAL CORTEX - AN IN-VIVO STUDY. J. Addae*, L. Noray, S. Joseph, R. Saunders and G.N. Melville, Department of Physiology, The University of the West Indies, St. Augustine, Trinidad & Tobago.

It has been reported that the effect of topical application of N-methyl-D,L-aspartic acid (NMA) on the Somatosensory Evoked Potentials (SEPs) can be prevented by quisqualic acid (quis). This study set out to determine whether the effect of quis was via the ionotropic or metabotropic site. Male Sprague Dawley rats were anaesthetised with urethane. Following craniotomy, a cup of paraffin wax was constructed over the exposed cortex and the SEPs from forepaw stimulation recorded. Application of NMA at 0.5mM for 2 mins completely abolished the SEPs (n[number of rats]=20). Applying AMPA at 0.05mM for 5 mins increased the SEP amplitude by $18.9 \pm 4.3\%$ (mean \pm sem), and totally prevented the effect of 0.5mM NMA (n=11). AMPA at 0.01mM for 5 mins had no appreciable effect on the SEP amplitude or the subsequent application of 0.5mM NMA (n=5). In comparison, the lowest concentration of quis to prevent subsequent NMA (0.5mM) effect was 0.25mM (n=13). This concentration of quis increased the SEP amplitude by $18.3 \pm 4.3\%$. These results suggest that activation of the AMPA receptor-complex can inhibit NMA effects in the rat somatosensory cortex; this may be important in neuroprotection against NMDA-mediated neurotoxicity in the cerebral cortex.

EVALUATION OF THE REINFORCING AND DISCRIMINATIVE STIMULUS EFFECTS OF THE PUTATIVE POLYAMINE-SITE NMDA ANTAGONIST ELIPRODIL. K.S. Nicholson, R.L. Balster* and D.J. Sanger, Department of Pharmacology & Toxicology, Medical College of Virginia, Richmond, VA 23298 USA and Synhelabo Recherche, 92220-Bagneux, France.

Eliprodil (SL 82.0715) has been shown to have noncompetitive NMDA antagonist effects in a number of *in vitro* models and it has *in vivo* anticonvulsant and neuroprotectant effects. Evidence implicates the polyamine modulatory site on the NMDA receptor as the site for eliprodil's NMDA antagonist effects (Carter et al. J Pharmacol Exp Ther 253:475, 1990). Because noncompetitive NMDA antagonists of the PCP-type produce psychotomimetic effects and are abused, eliprodil was evaluated for PCP-like abuse potential in two animal models. Eliprodil was tested for *i.v.* self-administration in four rhesus monkeys who regularly lever-pressed for 10 μ g/kg injections of phencyclidine (PCP). When doses of 3-100 μ g/kg/injection of eliprodil were substituted for PCP for 4 consecutive days, rates of responding did not exceed those when saline or the emulphor vehicle were substituted, providing evidence that eliprodil did not have reinforcing effects under these conditions. Eliprodil (10 and 20 mg/kg *i.p.*) was also tested for substitution in eight rats trained to discriminate 3 mg/kg PCP from saline under a standard 2-lever drug discrimination procedure. None of the rats selected the PCP lever after either dose of eliprodil, yet 20 mg/kg decreased rates of responding showing that a behaviorally active dosage range was tested. These results suggest that eliprodil may not produce disturbing PCP-like subjective effects or abuse liability that would limit its clinical usefulness. Supported in part by NIDA grant DA-01442.

EFFECTS OF PHENCYCLIDINE TREATMENT IN VIVO ON THE PHENCYCLIDINE BINDING AND GLUTAMATE UPTAKE IN THE MOUSE CEREBRAL CORTEX. P. Saransaari*, S.M. Lillrank and S.S. Oja, Tampere Brain Res. Ctr., Dept of Biomed. Sci., Univ. of Tampere, SF-33101 Tampere, Finland.

The effects of a psychotomimetic drug, phencyclidine (PCP), on glutamatergic neurotransmission were studied in mice. The binding of tritiated 1-[1-(2-thienyl)cyclohexyl]piperidine (TCP) to cerebral cortical membranes and the uptake of [3 H]glutamate by cortical synaptosomal preparations were assessed after PCP treatment (1 mg/d/mouse for 3 days) with implanted minipumps. The binding capacity B_{max} of TCP significantly increased but the binding constant K_D remained the same after PCP exposure, indicating that more binding sites became available. The basic properties of the binding remained unaltered but the actions of glutamate, glutamate receptor agonists and glycine were potentiated in PCP-treated mice. The uptake of glutamate was saturable, consisting of both high- and low-affinity transport components. After PCP exposure the transport constant K_m of the high-affinity component increased but that of the low-affinity component was not changed. The maximal velocity V of the high-affinity transport increased while that of the low-affinity transport decreased. Moreover, inhibition by structural analogues was potentiated, suggesting modification of the glutamate transporter by PCP treatment. The results show that chronic PCP treatment, used as a model of psychosis, markedly affects the studied glutamatergic parameters.

Supported by the Emil Aaltonen Foundation, Finland.

SOME CORRELATES OF MK-801 TOXICITY WHEN ADMINISTERED TO PREWEANLING RATS. A. Weeks, T. Benevides, S. Rioux, G. McClenaghan, P. Frankham, B. Fairey, B. Milburn, L. Ridley, D. Bannerman, R. Telford, S. Kish and M.J. Saari*, Neuroscience Research Unit, Nipissing University, 100 College Drive, North Bay, Ontario, CANADA. This study examined the effects of chronic MK-801 injections during the early developmental period. Male Wistar rat pups received daily injections of MK-801 (1.0 mg/kg; 0.1 mg/kg or saline vehicle; *sc.*) on postnatal days 7 to 12. Significant mortality was observed following the 1.0 mg/kg but not the 0.1 mg/kg dose. On sacrifice, significant reductions in organ and body weights were seen but only with the 1.0mg/kg group. The mortality following the 1.0 mg/kg injections occurred four to six days following the termination of the injections. The toxic effects of the MK-801 injections were blocked by pre-administration of NBQX (10mg/kg; *sc.*). Activity levels were affected by the MK-801 in a dose related manner. ACKNOWLEDGEMENT: The authors would like to thank NOVO NORDISK for their contribution of NBQX.

556.18

THE DISCRIMINATIVE STIMULUS EFFECTS OF EXCITATORY AMINO ACID AGONISTS IN NMDA-TRAINED RATS. D.M. Grech*, H. Li, W.H.W. Lunn and R.L. Balster, Department of Pharmacology & Toxicology, Medical College of Virginia, Virginia Commonwealth University, Richmond, VA 23298 and Lilly Research Laboratories, Eli Lilly & Company, Indianapolis, IN 46285.

Sixteen male Sprague-Dawley rats were trained to discriminate 30 mg/kg *i.p.* NMDA from saline using a 2-lever operant procedure. Responding was maintained under a FR 32 schedule of food reinforcement. Substitution tests were completed with NMDA (3-56 mg/kg), the transmitter candidates: L-glutamate (30-560 mg/kg), L-aspartate (30-300 mg/kg), L-homocysteic acid (L-HCA) (100-1500 mg/kg) and L-cysteine (30-1000 mg/kg), monosodium glutamate (MSG) (100-3000 mg/kg), as well as kainic acid (0.1-3 mg/kg) and the selective NMDA receptor agonist, (D,L)-tetrazol-5-ylglycine (LY 285265) (0.01-1.0 mg/kg). Only NMDA and LY 285265 fully substituted for the NMDA training dose (30 mg/kg). LY 285265 was approximately 100 fold more potent than NMDA for producing NMDA-like discriminative stimulus effects. Partial substitution occurred with MSG, L-glutamate, and L-HCA, resulting in mean maximum levels of 49-59% NMDA-lever responding, however, response rate decreases were only obtained with 3000 mg/kg MSG suggesting that behaviorally active doses of the other compounds may not have been studied. L-cysteine, kainic acid and L-aspartate also failed to substitute for NMDA or produce decreases in response rates. Unlike the majority of the excitatory agonists tested, full substitution occurred only with NMDA and LY 285265, suggesting that selective NMDA receptor activation is the basis for the NMDA discriminative stimulus. These results also suggest that LY 285265 may be a potent systemically active selective agonist for NMDA receptor stimulation. This research was supported by NIDA grants DA 01442 and DA 07027.

DIFFERENTIAL EFFECTS FOLLOWING REPEATED ADMINISTRATION OF COMPETITIVE AND NON-COMPETITIVE NMDA RECEPTOR ANTAGONISTS ON STARTLE RESPONDING, NMDA-INDUCED CONVULSIONS AND LETHALITY IN MICE. J.P. Tizzano*, J.A. Johnson, K.I. Griffey and J.L. Grider, Lilly Research Laboratories, Eli Lilly and Company, Greenfield, IN 46140.

Competitive and non-competitive NMDA receptor antagonists protect against convulsions and neuronal injury in animal models. In this study, drug-related changes in auditory and tactile startle responding, NMDA-induced convulsions and lethality (12.5 nmol, intracerebral) were evaluated in mice following single or daily (7 days) injections with the competitive NMDA receptor antagonist, CPP (0, 10, 20, or 40 mg/kg, *i.p.*) or the non-competitive NMDA receptor antagonist, MK-801 (0, 0.1, 0.5, or 1 mg/kg, *i.p.*). CPP induced moderate tolerance to the depression in auditory startle responding at 40 mg/kg, whereas tactile startle responding was unaffected by repeated administration. In contrast, MK-801 induced a dose-related sensitization to the enhanced auditory and tactile startle response. Following an intracerebral injection of NMDA, mice treated repeatedly with CPP or MK-801, did not exhibit tolerance or sensitization to the anticonvulsant or lethal effects over this time period. The present results dissociate the effects of repeated CPP or MK-801 administration on auditory and tactile startle responding from those on NMDA-induced convulsions and lethality.

GLUTAMATE RECEPTOR EXPRESSION IN RAT STRIATUM: EFFECT OF DEAFFERENTATION

J.B. Penney, U. Wüllner, M.V. Catania, D.G. Standaert, C.M. Testa, G.B. Landwehrmeyer, L.S. Dure* and A.B. Young. Neurology Service, Massachusetts General Hospital, Boston, MA 02114.

Although the recent progress in molecular cloning has tremendously increased our knowledge about the diversity of glutamate receptors (GluR), little is known about the regulatory mechanisms that control GluR expression. Using *in situ* hybridization with oligonucleotide probes selective for the respective mRNAs, we studied GluR1-4 (flip/flop), NMDA R1, 2a, 2b, and mGluR1-5 subunit mRNA expression in the rat striatum after unilateral frontal cortical ablation. In addition, [³H]AMPA, [³H]Kainate and [³H]Glutamate (NMDA- and Metabotropic) ligand binding studies were performed. Striatal NMDA and AMPA but not kainate receptor binding sites were increased 3 days after cortical ablation and remained increased for at least 60 days. Metabotropic receptor binding to a low affinity quisqualate site was slightly, but significantly reduced. On the other hand, after a decrease at 3 days, only small increases of almost all GluR subunit mRNAs were found at 15 and 60 days in the dorsolateral striatum. No switch in subunit composition occurred. It is conceivable, that additional posttranscriptional mechanisms contribute to the increase in ligand binding sites. Contrary to the receptor subunits, GFAP mRNA expression was markedly enhanced at 3 days and returned to near normal at 60 days, indicating a distinct temporal reaction to deafferentation in astrocytes and neurons.

Supported by USPHS grant NS19613 and DFG grant WU184/1-1 and LA 702/2-1.

557.3

IN SITU HYBRIDIZATION ANALYSIS OF AMPA RECEPTOR SUBUNIT GENES IN THE DEVELOPING RAT SPINAL CORD. **M. W. Jakowec* and R. G. Kalb.** Dept. of Neurology, Yale University, New Haven, CT. 06510.

We have used *in situ* hybridization to study the areal and developmental expression pattern of the AMPA subtype of glutamate receptors genes in the rat spinal cord. Lumbar spinal cord from various postnatal ages and adults, were analyzed using riboprobes against the GluR1-4 subunits of the AMPA receptor. In the adult both GluR1 and GluR2 messages are highly expressed within the substantia gelatinosa but are essentially absent from all other regions of the spinal grey matter. The GluR3 and GluR4 messages are present in most adult spinal neurons (with the exception of the substantia gelatinosa which has only light staining with GluR4). In marked contrast, during early postnatal life the GluR1 and 2 messages are highly expressed throughout the entire grey matter and subsequently decline of the first months of life. The GluR3 and 4 messages are not developmentally regulated as they are present at stable levels throughout the grey matter in both neonates and adults. These findings suggest that AMPA receptors transiently expressed by neurons throughout the spinal grey matter during development. These AMPA receptors have a unique subunit composition with major contributions by GluR 1 and 2. The distinctive spatio-temporal expression of GluR 1-4 may confer unique electrophysiological properties upon developing spinal neurons that may have important implications for activity-dependent neuronal development. Supported by the NIH and the Muscular Dystrophy Association.

DISTRIBUTION OF NMDA RECEPTOR SUBUNITS ON RAT HIPPOCAMPAL, CEREBELLAR AND CORTICAL NEURONS IN CULTURE AND IN BRAIN SLICES USING SUBUNIT SPECIFIC ANTIBODIES. **B. Mulac-Jericevic, T.A. Benke, N.L. Peterson* and K.J. Angelides.** Department of Cell Biology, and Division of Neuroscience, Baylor College of Medicine, Houston Texas.

The distribution of N-methyl-D-aspartate (NMDA) receptors plays an important role in neuronal signaling. The complex can be assembled from several subunits. Previously, the distribution of these individual NMDA receptor subunit mRNA in mouse and rat brain has been examined by *in situ* hybridization. NR1 subunit mRNA was found to be widely distributed throughout most brain regions, while the expression of the NR2C mRNA was observed in cerebellum and olfactory regions exclusively. We have now studied the distribution of NMDA receptor subunits using NR1 and NR2C subunit specific-antibodies. Antibodies were generated against N-terminal synthetic peptides, and their specificity characterized by several methods. Cultured neurons from hippocampus and cerebellum were labelled with anti-NR1 peptide antibodies. The labelling pattern in cultured hippocampal neurons showed a homogeneous distribution of NR1 subunits with some punctuate regions on both cell bodies and dendrites. Antibodies specific for NR2C subunit strongly labelled cerebellar granule neurons but not hippocampal neurons consistent with the exclusive localization of NR2C mRNA. Cortical slices were examined using scanning laser confocal fluorescence microscopy after labelling with anti-NR1 and NR2C subunit specific antibodies. CA1 pyramidal cell bodies were strongly labelled while dendrites, identified by anti-MAP-2 antibodies, were labelled less by NR1 specific antibodies. Anti-NR1 subunit antibodies showed very weak labelling of CA3 region dendrites compared to cell bodies. In cerebellum anti-NR1 peptide antibodies labelled granule neurons in both the outer and inner molecular layers. Purkinje neurons were lightly labelled. Similarly, antibodies specific for NR2C peptide labelled granule neurons in both the outer and inner molecular layer of the cerebellum. The pattern of labelling confirms results of *in situ* hybridization but offers additional insight into the receptor organization on the neuron surface. Supported by NIH grant NS28072 and a Human Frontiers of Science Award to K.J.A.

LOCALIZATION OF NON-N-METHYL-D-ASPARTATE GLUTAMATE RECEPTORS IN NORMAL AND ALZHEIMER HIPPOCAMPAL FORMATION. **Anne B. Young,* John B. Penney, Craig D. Blackstone and Bradley T. Hyman.** Neurology Service, Massachusetts General Hospital and Harvard Medical School, Boston, MA 02114 and Department of Neuroscience, Howard Hughes Medical Institute Research Laboratories, Johns Hopkins University School of Medicine, Baltimore, MD 21205 USA.

The hippocampi and adjacent temporal cortices of 24 human brains were examined with antibodies to the GluR1, GluR2/3 and GluR4 subunits of the AMPA-preferring glutamate receptor. GluR1 immunoreactivity was most dense in dentate gyrus with lower density in other hippocampal and cortical regions. GluR 2/3 immunoreactivity was the most intense of the three antibodies, with high levels throughout most hippocampal subfields, where it was localized to cell bodies, proximal axons and dendrites. GluR4 immunoreactivity was very sparse in all regions. In Alzheimer's disease cases, the general pattern of staining was similar to that seen in controls. GluR1 and GluR4 immunoreactivity was seen in some but not all neuritic plaques. All 3 antibodies recognized some neurons undergoing neurofibrillary degeneration.

Supported by USPHS grants AG08487 (BTH), AG08671 (ABY, JBP), GM07309 (CDB), and the Howard Hughes Medical Institute (CDB).

557.4

GLUTAMATE RECEPTOR SUBTYPES ARE DIFFERENTIALLY EXPRESSED IN ASTROCYTES FROM DIVERSE BRAIN REGIONS. **D. Fan*, A.B. Johnson, J.A. Kessler and R.S. Zukin.** Dept of Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

Electrophysiological and pharmacological studies indicate that AMPA/kainate (non-NMDA) type glutamate receptors occur in astrocytes, whereas NMDA receptors do not. We used northern blot and *in situ* hybridization to examine the pattern of kainate/AMPA and NMDA receptor expression in astrocytes from different brain regions. Astrocytes from 1-2 day old neonatal rat hippocampus, striatum, cerebellum and cerebral cortex were maintained in culture in serum containing medium for 14-18 days. RNA harvested from these cultures was analyzed on northern blots and fixed monolayer cultures were hybridized *in situ* under conditions of high stringency with ³²P-labelled cDNA probes (northern analysis) or ³⁵S-labelled RNA probes (*in situ* hybridization) directed against GluR1, GluR2 and GluR3 (AMPA/kainate) and NMDAR1 receptor mRNAs. Under these conditions, there is no detectable cross-hybridization among these probes. In blots and cells hybridized to GluR1 and GluR3, labelling was observed in astrocytes from hippocampus, cerebellum and the cortex. In contrast, GluR2 and NMDAR1 expression were not detectable. In preliminary experiments (n=3), GluR1 expression was of highest density in the cerebellum and lowest in the hippocampus. These results indicate that GluR1 and GluR3 are the glutamate receptor subunits mRNA actively expressed in rat hippocampal, cerebellar and cortical astrocytes.

557.6

NMDA RECEPTORS AND SUBUNIT mRNAs EXPRESSED IN CULTURED CORTICAL NEURONS. **J. Zhong, S. L. Russell, D. B. Pritchett, P. B. Molinoff, and K. Williams*.** Department of Pharmacology, University of Pennsylvania School of Medicine, Philadelphia, PA 19104-6084.

Ifenprodil, a novel NMDA receptor antagonist, discriminates, with a >100-fold selectivity, two subtypes of NMDA receptor that are differentially expressed in rat forebrain during postnatal development (Williams *et al.*, *Neuron* 10: 267-278, 1993). The *in vitro* expression of NMDA receptor subtypes has been investigated using binding assays with [¹²⁵I]-MK-801 on membranes prepared from cultured cortical neurons. In cultures maintained for 7 days *in vitro*, ifenprodil inhibited the binding of [¹²⁵I]-MK-801 in a monophasic fashion with high affinity (IC₅₀ = 0.4 μM). In 21-day cultures, the inhibitory effects of ifenprodil were biphasic, having high- (IC₅₀ = 0.5 μM; 75%) and low-affinity (IC₅₀ = 100 μM; 25%) components. Expression of NMDA receptors having a low affinity for ifenprodil was reduced in cultures maintained for days 7-21 in medium with low concentrations of serum (1% or 0%). Serum deprivation did not alter the level of expression of receptors having a high affinity for ifenprodil. A solution hybridization/RNase protection assay was used to measure NMDA receptor subunit mRNAs in cultured neurons. The level of mRNA encoding the NR1 subunit increased during days 1-21 *in vitro*. NR2A mRNA was low or undetectable in 7-day cultures but increased progressively between days 7 and 21. NR2B mRNA levels remained relatively constant over time. NR2C mRNA was not detected in cultured cortical neurons. Delayed expression of the NR2A subunit in cultured neurons may be responsible for the generation of receptors having a low affinity for ifenprodil, as has been proposed for receptor expression in rat forebrain.

(Supported by USPHS grants NS 30000 and GM 34781).

557.7

IMMUNOAFFINITY PURIFICATION OF GLUTAMATE RECEPTORS OF THE NON-NMDA AND NMDA TYPE. N. Brose¹, G.P. Gasic¹, S.W. Rogers², T. Moran³, J.H. Morrison³, R. Jahn⁴ and S.F. Heinemann¹. ¹Salk Institute, La Jolla, CA 92037; ²Univ. Color. Health Sci. Ctr., Denver, CO 80262; ³Mount Sinai Sch. Med., New York, NY 10029; ⁴Yale Univ., New Haven, CT 06510.

We employed monoclonal antibodies directed against the non-NMDA glutamate receptor subunit Glu R2 and against the NMDA receptor subunit NMDA R1 to purify native non-NMDA- and NMDA-type glutamate receptors from rat brain membranes. Receptors were purified from detergent extracts using affinity columns that had been coupled with 6 mg immobilized IgG (either Cl 3A11 anti-Glu R2 or Cl 54.2 anti-NMDA R1). Purified fractions were analyzed by SDS-PAGE and Western blotting. Purified non-NMDA glutamate receptors contained several protein species, as judged by silver stain, with the predominant species exhibiting molecular weights of ~100-105 kDa. Purified NMDA receptors contained a major protein component of ~116 kDa and several less abundant proteins. Western blotting demonstrated that the major protein components of purified non-NMDA receptors corresponded to Glu R1-4, while the most abundant band in purified NMDA-receptors was NMDA R1. Western blots using antibodies to several known glutamate receptor subunits showed that NMDA receptors form distinct protein complexes and do not contain non-NMDA receptor subunits. Similarly, receptors containing Glu R2 do not contain NMDA receptor subunits or glutamate receptor subunits of the kainate-preferring type (Glu R 6 and 7, KA2). These data suggest the existence of at least three structurally distinct groups of glutamate receptor protein complexes.

557.9

DISTRIBUTIONS OF NMDA RECEPTOR SUBTYPES CORRESPOND TO SPECIFIC RECEPTOR SUBUNITS.

D. T. Monaghan*, H.C. Clark, and B.E. Schneider. Department of Pharmacology, Univ. Nebraska Medical Center, Omaha, NE 68198.

There are four pharmacologically-distinct populations of NMDA receptors. These are typified by receptors in the lateral thalamus ("antagonist-preferring"), medial striatum ("agonist-preferring"), midline thalamic nuclei and cerebellum. Using radioligand-receptor binding autoradiography and *in situ* hybridization of subunit-specific oligos, we find that the anatomical distribution of each of the four native receptor populations corresponds to a specific NR2 subunit. The NR2A transcript has a distribution very similar to the "antagonist-preferring" NMDA receptor subtype labelled by [³H]antagonists (CPP and CGP39653), both displaying high levels in the VP nucleus of lateral thalamus and the deep cerebral cortical layers. NR2B subunit messenger were the only NR2 species found in regions enriched in "agonist-preferring" sites (medial striatum and lateral septum). NR2C subunits were largely restricted to the cerebellum which contains a pharmacologically-distinct receptor subtype. NR2D subunits were restricted to those diencephalic nuclei which contain another pharmacologically-distinct NMDA receptor subtype (the midline thalamic nuclei: intermediodorsal, paratenial, & paraventricular, and the anteroventral and medial geniculate nuclei). In addition, NR1 subunit transcripts containing "insert 1" were found in many regions containing high affinity for antagonists (thalamus, deep parietal cortex). Together with pharmacological studies of NMDA receptor subunits expressed in *Xenopus* oocytes (see Buller et al. abstract), the NR2 subunits appear to account for much of the pharmacological diversity of native NMDA receptors. Supported by NIH grant NS 28966.

557.11

EXPRESSION OF METABOTROPIC GLUTAMATE RECEPTORS COUPLED TO ADENYLATE CYCLASE IN CEREBELLAR NEURONS. J.T. Wroblewski¹, S. Ikonovic¹, M.R. Santi¹, B. Wroblewska² and D.R. Grayson¹. ¹Fidia-Georgetown Institute for the Neurosciences and ²Department of Biology, Georgetown University, Washington D.C. 20007.

Primary cultures of cerebellar granule cells express metabotropic glutamate receptors (mGRs) coupled to the stimulation of phosphoinositide hydrolysis (mGR1 and mGR5) and those coupled to the inhibition of adenylate cyclase (mGR2, mGR3 and mGR4). Treatment of granule cells with forskolin in presence of the phosphodiesterase inhibitor 3-isobutyl-1-methylxanthine caused a dose-dependent increase of cAMP accumulation. This effect was inhibited in a dose-dependent manner by the mGR agonists glutamate, ibotenate, and *trans*-1-amino-1,3-cyclopentanedicarboxylic acid (ACPD), with the maximal inhibition reaching about 50% of the forskolin-induced response. The inhibitory action of these agonists was not prevented by Mg²⁺, MK-801 or CNQX, antagonists of ionotropic glutamate receptors, but it was blocked by pre-treatment of granule cells with pertussis toxin. The observed pharmacological profile suggested the presence of a G protein-coupled metabotropic receptor which closely resembled that reported for the expressed mGR2 and mGR3 receptors. The forskolin-induced cAMP accumulation was further decreased by 2-amino-3-phosphonopropionate (AP3) and 2-amino-4-phosphonobutyrate (AP4), suggesting the presence of mGR4 receptors. This pharmacological profile was compared with the appearance of mRNA for the particular mGRs. Using quantitative PCR assay with internal standards we have determined that cerebellar granule cells cultured for 9 days in 25 mM K⁺ exhibit the highest level of mRNA for mGR4, followed by a two-fold smaller level of mRNA for mGR3. In contrast, the level of mRNA for mGR2 was 50-fold smaller than for mGR3. It may be concluded that in cerebellar granule cells two metabotropic glutamate receptors, mGR3 and mGR4 contribute to the control of cAMP concentrations.

557.8

IMMUNOCYTOCHEMICAL LOCALIZATION OF A METABOTROPIC GLUTAMATE RECEPTOR IN NEURONAL CULTURES. P. CORSI*, Z. VIDNYANSZKY, T.J. GORCS, J. TAKACS and J. HAMORI. Ist. Fisiologia Umana, Medical School*, Bari 70100, Italy; Lab. Neurobiology, Semmelweis University, Budapest, Hungary.

In order to analyze the cellular localization of the metabotropic glutamate receptor (mGluR1a), the immunoreactivity to the mGluR1a at the light and EM levels has been investigated in primary neuronal cultures of cerebral cortex, hippocampus and basal forebrain from embryonic mouse. The polyclonal antibody utilized for the visualization of the mGluR1a were raised against the C-terminal amino acid sequence region 1194-1199 of the mGluR1a. At the EM level, a prevalent neuronal localization can be observed, the neuronal cell bodies with their processes appeared immunoreactive; the immunoreaction was mainly restricted to the cytoplasm, the nuclei devoid of staining. Similarly, the nerve terminals and the synaptic membranes appeared heavily stained accordingly with its predicted membrane localization. However, few differences can be pointed out in the different cultures, i.e. in the basal forebrain cultures the mGluR1a localization is both pre and post-synaptic, while in the hippocampal cultures it appears always post-synaptically with an enrichment at the post-synaptic density.

THE NR2 SUBUNIT CONTRIBUTES TO THE PHARMACOLOGICAL DIVERSITY OF NATIVE NMDA RECEPTORS

A.L. Buller*, R.A. Morrisett and D.T. Monaghan Dept. Pharmacology, Univ. Nebraska Medical Center, Omaha, NE 68198.

Four distinct NMDA receptors, identified in radioligand binding studies, are typified by receptors in the lateral thalamus (LTH; "antagonist-preferring"), medial striatum (MS; "agonist-preferring"), midline thalamic nuclei (MT) and cerebellum (CBG). The relationship between these receptor subtypes and recently identified NMDA receptor subunits (NR1a-g; NR2A-D) has not been determined. We now report that the pharmacological differences between native NMDA receptor subtypes depends, in large part, on the particular NR2 subunit present in the NR1-NR2 heteromer.

The pharmacology of heteromeric NMDA receptors expressed in *Xenopus* oocytes (NR1-NR2A, NR1-NR2B, NR1-NR2C) was compared to that of native receptor subtypes in the LTH, MS and CBG. The NR1-NR2A receptor displayed higher affinity for all antagonists tested, while the NR1-NR2B receptors showed higher affinities for agonists, patterns analogous to that observed for NMDA receptors in the LTH and MS, respectively. Relative to NR1-NR2A and NR1-NR2B, oocyte-expressed NR1-NR2C receptors had a lower affinity specifically for both D-3-(2-carboxypiperazin-4-yl)-1-propenyl-phosphonic acid (D-CPPene) and homoquinolinolone (HQ). These differences were identical to that observed for CBG versus forebrain NMDA receptors. Together with the observation that NR2 subunit mRNAs co-localize with distinct NMDA receptor subtypes (see Monaghan et al., this meeting), these data suggest that native NMDA receptor subtypes differ in their molecular composition and that NR2 subunits significantly contribute to the pharmacological diversity of NMDA receptor subtypes.

THE EXPRESSION OF AN NMDA RECEPTOR GENE IN GUINEA PIG MYENTERIC PLEXUS. D.L. Broussard*, X. Li, D.B. Pritchett, P.G.C. Bannerman, D. Pleasure. Children's Hospital of Phila, Univ. of PA Sch. of Med., Phila, PA 19104.

Glutamate may mediate the release of ACh within the enteric nervous system (ENS) via NMDA-type receptors (Am J. Physiol. 261:G693,1991). We investigated the expression of the gene for the NMDA receptor in guinea pig myenteric plexus using RT-PCR. Total RNA was isolated from guinea pig myenteric plexus (enteric neurons and glia), cultured guinea pig enteric glia and rat brain. Following reverse transcription, PCR was performed with primers that, in rat and human neural tissues, amplify a 332 nucleotide sequence that overlaps the L-glutamate binding site of the NMDA type 1 receptor (PNAS 90:2174,1993). UV illumination of an ethidium bromide gel demonstrated a PCR product from the myenteric plexus and brain, but not enteric glia. This band was positive by Southern blotting with a ³²P-labelled oligonucleotide homologous to a sequence that, in the rat, is flanked by the primers. This is the first report of the expression of an NMDA receptor gene within the ENS, and supports a glutamatergic neuronal pathway within the ENS. (NIH #HD28815 & R.W. Johnson Foundation)

ABSOLUTE AMOUNTS OF THE mRNAs ENCODING THE METABOTROPIC GLUTAMATE RECEPTORS IN CEREBELLAR GRANULE NEURONS *IN VITRO*. M.R. Santi^{1,2}, S. Ikonovic¹, J.T. Wroblewski¹ and D.R. Grayson¹. ¹Fidia-Georgetown Institute for the Neurosciences and ²Department of Biology, Georgetown University, Washington D.C. 20007.

We have designed receptor specific primer pairs and internal standards corresponding to unique regions of the mGR1, mGR2, mGR3, mGR4 and mGR5 metabotropic glutamate receptor cDNAs. Using a competitive PCR derived assay with internal standards, we have been able to quantitate the absolute amounts of each mRNA in cerebellar granule cells maintained in primary culture in different concentrations of KCl (10 mM vs. 25 mM KCl) as a function of time in each paradigm (i.e. 3, 6, 9 and 13 Days *In Vitro* (DIV)). Different concentrations of KCl depolarize cerebellar granule neurons to different extents which has been shown to affect their survival properties and their responsiveness to various glutamate receptor agonists. We determined that the amounts of the mGR1 mRNA were constant in 10 mM KCl (1.2 amol/ μ g RNA) and higher than the values obtained in cultures maintained in 25 mM KCl (maximum of 0.86 amol/ μ g RNA at 6 DIV). mGR2 mRNA levels were lower but increased to a maximum (0.8 amol/ μ g RNA) after 9 DIV. In 25 mM KCl, mGR2 mRNA is even lower attaining a maximum after 6 DIV (0.33 amol/ μ g RNA). mGR4 mRNA levels, which were consistently the most abundant, were approximately the same during the initial time periods in both paradigms but differed significantly by the 9th DIV (20 amol/ μ g RNA in 10 mM KCl vs. 9.3 amol/ μ g RNA in 25 mM KCl). Preliminary results obtained using mGR5 specific primers indicated that the content of this mRNA is also higher in cultures maintained in 10 mM KCl than in 25 mM KCl. In contrast, mGR3 mRNA levels were consistently higher in cultures maintained in 25 mM KCl (0.92 amol/ μ g RNA in 10 mM KCl vs. 4.9 amol/ μ g RNA in 25 mM KCl). Collectively, the data indicate a complex temporal pattern of expression of this gene family which correlates with known metabotropic second messenger responses (either the stimulation of InsP₃/Ca²⁺ cascade or inhibition of adenylate cyclase) to glutamate in the different KCl paradigms tested.

ALTERATIONS IN HIPPOCAMPAL GLUTAMATE RECEPTOR EXPRESSION FOLLOWING CHRONIC EPILEPTIFORM ACTIVITY *IN VITRO*. A. Gerfin-Moser, F. Grogg, B. H. Gähwiler, P. Streit* and S. M. Thompson. Brain Research Institute, University of Zürich, CH-8029 Zürich, Switzerland

We have used organotypic hippocampal slice cultures as a model system to investigate the long-term consequences of epileptic activity. Cultures were prepared with standard techniques from 5 day old rat pups, and allowed to mature for 14-18 days. Sustained epileptic activity was elicited by treatment with 500 μ M picrotoxin in serum-free medium for 2-3 days. The expression of glutamate receptor (GluR) mRNAs was examined after 48 hrs by *in situ* hybridization using ³⁵S-labelled oligonucleotides as probes. The most striking change in mRNA expression was observed for two AMPA-sensitive GluR subunits (GluR-A & GluR-B). mRNA levels for these subunits decreased in convulsant treated cultures to less than half the levels observed in control sister cultures. However, this downregulation was reversible if treated cultures were subsequently kept in normal medium for five days. mRNA expression reached almost control levels again, which shows clear evidence of recovery. Nissl staining of hybridized picrotoxin treated cultures showed virtually no nuclear or perikaryal damage to the neurons, indicating that cell death did not account for the decrease in hybridization signal intensity. The mRNA expression of various GABA_A receptor subunits was not found to be altered following long-term convulsant treatment, consistent with unaffected inhibitory synaptic transmission in CA3 pyramidal cells (Müller et al., 1993, Proc. Natl. Acad. Sci. USA, 90; 257-261). In further experiments, the mechanisms underlying modulation of GluR expression and their relation to excitotoxic injury will have to be established.

AGE, SEX, ESTROUS CYCLE AND STRESS DEPENDENT CHANGES IN HIPPOCAMPAL GLUTAMATE RECEPTORS. G.Ö.Peker*, L.Karut, O.Algan, N.Özdemir, B.E.Okur. Dept. of Physiol., Ege Univ. Sch. of Med., Bornova, 35100 İzmir, Turkey.

Glutamate (glu) receptor system is uniquely involved in development, learning-memory, neurodegeneration and neuroendocrine regulation. Hippocampus, in particular, is an important site for plasticity where different neurotransmitter systems interact with others and with various hormones under changing circumstances. This study was undertaken to investigate whether L-3H-glu binding is sexually dimorphic, prone to activation effects of gonadal and cortico-steroids and vulnerable to ageing induced changes. Beginning from their fourth week of life, 20 male and 25 female virgin Sprague Dawley rats were exposed to 45 min duration of immobilization and bright light, three times a day, five days a week, for 12-14 weeks. L-3H-glu binding was assayed in hippocampal homogenates of the experimental, age-matched control and 25 aged (20 months) male rats. Plasma corticosterone levels at decapitation were determined and vaginal smears were monitored for 30 days to assess estrous cycles. ANOVA revealed that hippocampal glu receptor binding (HGRB) is sexually dimorphic with higher values for males (p<0.012), estrus phase elevates binding (p<0.022) and chronic stress enhances binding dramatically (p<0.006). T-test showed a prominent (p<0.0005) decrease in aged rats. Our results imply that the HGRB is prone to manipulation by sex- and stress-related endocrine effects which may occur as organizational and/or activation-geometric action and glu receptors are highly involved in biological ageing.

STABLE MAINTENANCE OF GLUTAMATE RECEPTORS AND OTHER SYNAPTIC COMPONENTS IN ORGANOTYPIC HIPPOCAMPAL SLICE CULTURES. K.B. Hoffman¹, B.A. Bahr¹, S. Rivera², P.W. Vanderklish¹, R.A. Hall¹, M. Kessler¹, A. Arai¹, C. Gall¹ & G. Lynch¹. ¹Center for Neurobiology of Learning/Memory and ²Dept. of Anatomy and Neurobiol., Univ. of Calif., Irvine, CA 92717

Cultured hippocampal slices retain many *in vivo* features with regard to neuronal circuitry, synaptic plasticity (e.g. LTP), and pathology, while remaining accessible to a variety of manipulations. The present study characterized glutamate receptors and other synaptic markers in organotypic hippocampal slice cultures using 1) [³H]AMPA and [³H]MK-801 binding to membranes by filtration and autoradiography, 2) immunostaining with anti-GluR1, -R2/3, -R4, and -NMDAR1, and 3) *in situ* hybridization using [³⁵S]cRNA probes specific for receptor subunit mRNAs. Hippocampal slices (400 μ m) obtained from 11 days postnatal rats were cultured on Biopore membranes in serum-containing media at 37°C and harvested after 0.4 - 30 culture days (CDs). GluR1, GluR2/3, and NMDAR1 antigenicity levels as well as [³H]AMPA binding transiently decreased between 0.4 and 2 CDs, recovered by CD 5, and remained stable through at least CD 30. Similar profiles were exhibited by other synaptic markers (synaptophysin, NCAM₁₈₀, and NCAM₁₄₀) as well as by spectrin and MAP2. The GluR4 subunit, in contrast, was not detectable during the first 10 days in culture but then developed gradually. The slices expressed low (K_D = 500 nM) and high (12 nM) affinity [³H]AMPA binding sites at a ratio of 10:1, as found in the adult hippocampus. The expected astrocyte/GFAP response to the slice cutting occurred at CD 2-5; GFAP then remained stable through CD 30. In summary, following an initial and brief depression, synaptic components were expressed at steady-state expression levels in long-term hippocampal slice cultures, thus, allowing the investigation of their functional and regulatory properties (AFOSR 92-J0307 supported).

N-METHYL-D-ASPARTATE RECEPTOR (NMDAR) mRNA EXPRESSION IN NG108-15 CELLS UNDERGOING SYNAPSE FORMATION.

H. Yamamoto, K. Akama, D. Kersey and J. Moskal*. The Chicago Institute for Neurosurgery and Neuroresearch, Chicago, IL 60614.

NG108-15 cells provide an excellent model system to study molecular mechanisms underlying synapse formation. NG108-15s are a clonal cell line derived from murine neuroblastoma, N18TG2, and rat glioma, C6, cell lines. Upon dibutyryl-cyclic AMP (dBcAMP)-induced differentiation, NG108-15 cells become "synaptically competent" and make functional synapses when co-cultured with rat myotubes. We used this system to examine the expression of NMDAR mRNA by Northern analysis. A rat NMDAR cDNA was generously provided by Dr. S. Nakanishi (Moriyoshi et al., *Nature* (1991) 354, 31-37). NMDAR mRNA could be detected in dBcAMP-treated NG108-15 and N18TG2 cells, but was absent in rat myotube cultures. When non-synapse forming, dBcAMP-treated, N18TG2 cells were co-cultured with rat myotubes NMDAR mRNA levels were negligible. However, a marked (approx. 10-fold) increase in NMDAR mRNA levels was detected when the NG108-15 cells were co-cultured with rat myotubes, compared to NG108-15 cells cultured alone. These results suggest that, while NMDAR mRNA induction may be due to the influence of muscle-associated factors on NG108-15 cells, the increase could be a necessary component of the molecular events leading to the formation of functional synapses.

558.1

REGULATION OF NMDA RECEPTOR PHOSPHORYLATION BY ALTERNATIVE SPLICING OF THE C-TERMINAL DOMAIN. W.G. Tingley, L.A. Raymond, K.W. Roche, A.K. Thompson and R.L. Huganir*. Department of Neuroscience, Howard Hughes Medical Institute, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.

NMDA receptors in the brain trigger synaptic plasticity, modulate synaptogenesis, and induce excitotoxic neuronal damage. Precise regulation of NMDA receptors is therefore essential for normal brain function and for neuronal survival. A variety of studies have suggested that protein phosphorylation of NMDA receptors may regulate their function. Multiple NMDA receptor subunits have recently been cloned (NR1, NR2A-D). We have examined the phosphorylation of the NR1 subunit by Protein Kinase C (PKC) in cells transiently expressing recombinant NR1 and in primary cultures of cortical neurons. PKC phosphorylates several distinct sites on the NR1 subunit. The majority of these sites are contained within the C-terminal domain, and are deleted in several splice variants of NR1. We are currently examining the functional effects of phosphorylation of recombinant wild-type and mutant NMDA receptors expressed in human embryonic kidney (293) cells. Our results demonstrate that the major sites for PKC phosphorylation of NR1 are regulated by alternative splicing of NR1 mRNA, suggesting that alternative splicing of phosphorylation sites may represent a general mechanism for regulating the phosphorylation of glutamate receptors. In addition, these results imply that the C-terminal domain of NR1 is located intracellularly, which contradicts current topology models for glutamate receptors.

PHOSPHORYLATION OF GLUTAMATE RECEPTORS IN CULTURED HIPPOCAMPAL NEURONS. S.E. Tan and T.R. Soderling*. Vollum Institute, Oregon Health Sci. Univ., Portland, OR. 97201.

Recent gene ablation studies strongly support a role for CaM-kinase II in hippocampal learning and memory (Silva et al, Science 257:201-206, 206-209). ³²P-labeling of non-NMDA glutamate receptors (GluRs) was studied in cultured hippocampal neurons stimulated 2-15 min. with agonists which selectively stimulate either CaM-kinase II, protein kinase C (PKC) or cAMP-dependent protein kinase A (PKA). Treatment of neurons with glutamate/glycine (Glu/Gly), ionomycin (Iono), or 12-O-tetradecanoyl-phorbol-13-acetate (TPA) increased ³²P-labeling of immunoprecipitated GluRs (GluR1-4) by 145%, 180% and 227%, resp. Glu/Gly and Iono, but not TPA, also increased ³²P-labeling of CaM-kinase II by 175% and 195%, respectively. Of these three agonists, only TPA stimulated phosphorylation of MARCKS (225%), a specific substrate of PKC. Forskolin treatment gave a 3-4 fold increase in the active catalytic subunit of PKA but did not result in the ³²P-labeling of GluR1-4, CaM-kinase II or MARCKS. Phosphorylation of GluRs in response to Glu/Gly was blocked by a specific NMDA antagonist (APV) or by a cell-permeable inhibitor of CaM-kinase II (KN-62). These results are consistent with our hypothesis that Ca²⁺-influx through the NMDA-type ion channel can activate CaM-kinase II (Fukunaga et al. J. Biol. Chem. 267:22527-22533) which in turn can phosphorylate and enhance non-NMDA receptor ion channels (McGlade-McCulloh et al. Nature 362:640-642). Such a mechanism could contribute to the postsynaptic component of synaptic plasticity such as long-term potentiation. Supported by NIH grant NS 27037.

MODULATION OF NMDA RECEPTORS BY PROTEIN PHOSPHATASES IN CULTURED HIPPOCAMPAL NEURONS. L.-Y. Wang, B. A. Orser and J. F. MacDonald*. Depts. of Physiol., Pharmacol. and Anaesth. Univ. of Toronto, Toronto, Canada M5S 1A8

In the mammalian central nervous system, *N*-methyl-D-aspartate (NMDA) receptors play crucial roles in synaptic plasticity, neuronal development and neurotoxicity. Biochemical modulation of these receptors by protein kinases and phosphatases may have profound effects on the synaptic efficacy at excitatory synapses. We have investigated the actions of calyculin A, a potent inhibitor of phosphatase 1 (PP1) and 2A (PP2A) on NMDA receptors in nystatin perforated patches. Macroscopic currents activated by NMDA were potentiated by this phosphatase inhibitor. In the absence of added coagonist glycine, calyculin A also increased the rate of NMDA receptor desensitization. Single channel recording in the cell-attached configuration revealed that this inhibitor significantly increased channel open probability. In contrast, direct application of PP2A to cytoplasmic side of excised inside-out patches decreased the open probability of these channels. These data suggest that the inhibition of PP 2A by calyculin A may cause a net increase in the levels of phosphorylation of NMDA receptors. This effect is functionally similar to activating some protein kinases. Thus, synaptic efficacy can be potentially regulated by the endogenous activities of both protein kinases and phosphatases. *Supported by a grant to MRC of Canada Group in Nerve cells and Synapses.

PROTEIN TYROSINE KINASES (TKs) IN THE POSTSYNAPTIC DENSITY (PSD) AND PHOSPHORYLATION OF THE NMDAR1. S.Y. Lin^{1,2}, K. Wu^{1,2}, T.W. Kim^{1,2}, Y. Huang³, J.L. Xu¹, P.C. Suen^{1,2} and J.B. Black^{1,2}. ¹Dept. of Neurosci. & Cell Biol., UMDNJ/RWJ Med. Sch., Piscataway, N.J. 08854; ²Grad. Program in Physiol. & Neurobiol., Rutgers Univ., Piscataway, N.J. 08854 and ³Div. of Neurosci., NYSPJ, New York, N. Y. 10032.

Protein tyrosine kinases play critical roles in cell growth and differentiation. Recent studies showing high TK activity in rat brain suggest that the enzyme(s) may be involved in neural signal transduction as well. Remarkably, however, potential synaptic functions of specific TKs and substrates are unexplored. We examined TKs and substrates in the PSD, which is critical for synaptic function. Our initial results revealed that the specific TK activator, Mn²⁺/Vanadate, enhanced phosphorylation of several proteins in the PSD. The phosphate groups incorporated were resistant to treatment with 1M KOH, suggesting binding to tyrosyl residues. The presumptive TKs and substrates were greatly enriched in the cortical PSD, compared with those in the homogenate or synaptic membrane fractions. Western blot analysis, using highly specific rabbit anti-phosphotyrosine antiserum, indicated that the PSD isolated from cerebral cortex, cerebellum and olfactory bulb contained several region-specific phosphotyrosyl proteins. Since several lines of evidence suggest that tyrosine kinases and NMDA receptor(s) may be involved in long-term potentiation, we examined TK-mediated phosphorylation of NMDA receptor 1(NMDAR1), which we recently localized to the PSD. The receptor was phosphorylated in a Mn²⁺/Vanadate-dependent manner, and the phosphorylation was specifically inhibited by an antibody against the NMDAR1. Consequently, tyrosine phosphorylation may regulate NMDA receptor function. Taken together, our findings suggest that TKs and substrates are components of the PSD and that these synaptic molecules may play important role(s) in synaptic function through postsynaptic mechanisms. PERSISTENT INTRACELLULAR PHOSPHATASE ACTIVITY REGULATES NMDA RECEPTOR/CHANNEL FUNCTION. D.N. Lieberman¹ and L. Mody². ¹Dept. Neurology & Neurological Sci., Stanford Univ., Stanford, CA, and ²Depts. of Anesthesiology & Neurology, UT Southwestern Med. Ctr., Dallas, TX.

Currents through single NMDA channels were recorded in the cell-attached configuration from acutely dissociated adult rat dentate gyrus granule cells. L-aspartic acid (100-200 nM) and glycine (3 μM) were used to elicit openings primarily to the 50 pS level in an extracellular solution containing 1.8 mM Ca²⁺ but no Mg²⁺. When the phosphatase inhibitor okadaic acid (10 μM) was perfused onto the neurons, mean open time, burst, cluster and super-cluster durations increased significantly (61%, 150%, 1250%, and 162% respectively), as did the number of openings per these complex groupings (30-72%). No changes in mean channel conductance were detected. Dwell time distributions were not altered by lower concentrations of okadaic acid (0.5-1 μM) which are known to completely inhibit phosphatases type 1 and 2A. Thus, the low potency of okadaic acid on NMDA channel kinetics is consistent with the involvement of phosphatase 2B (the Ca²⁺-dependent phosphatase calcineurin) in the intracellular regulation of the NMDA receptor/channel complex. This hypothesis was tested by eliminating Ca²⁺ entry through the channel. When patch electrodes containing no Ca²⁺ and 10 mM EDTA were used to record channel activity, single channel conductance increased by 35%, but okadaic acid (10 μM) was ineffective in producing changes in channel kinetics. Furthermore, when extracellular Ca²⁺ was substituted by equimolar Ba²⁺, okadaic acid was equally ineffective.

These findings are consistent with the hypothesis that NMDA channels are regulated by a persistent phosphorylation/dephosphorylation process, and that Ca²⁺ entering via the channel reduces channel activity through the activation of an intracellular phosphatase.

Supported by NINDS grant NS-27528 (I.M.), and a Howard Hughes Predoctoral Fellowship (D.N.L.).

ATP PREVENTS 'RUNDOWN' OF WHOLE-CELL NMDA CURRENTS BY SUPPORTING PHOSPHORYLATION RATHER THAN BY LOWERING [Ca²⁺]. IN CULTURED RAT SPINAL DORSAL HORN NEURONS. Y.T. Wang*, Y. Pak and M.W. Salter. Div. Neurosci., Hosp. Sick Children and Dept. Physiol. Univ. Toronto, Toronto, Canada M5G 1X8.

Intracellular regulation of *N*-methyl-D-aspartate (NMDA) receptors was investigated by means of simultaneous patch-clamp recording and fluorescent measurement of [Ca²⁺]_i with fura2 in cultured spinal dorsal horn neurons. NMDA currents were evoked by pressure-ejection of L-aspartate (250 μM, 100 ms) at regular intervals every 1-2 min. During recordings using nystatin-perforated patch configuration NMDA currents were constant after stabilization of the perforation. However, during recordings using whole-cell configuration, when the intracellular solution contained BAPTA 10 mM, NMDA currents showed 'rundown': the currents declined progressively and stabilized at approximately 50% of the control level within 15 min of the start of recording. Also, each application of L-aspartate caused a transient increase in [Ca²⁺]_i. When Mg-ATP (4 mM) was included in the intracellular dialysate, the rundown of NMDA currents was prevented and there was an increase in current amplitude. In addition, ATP reduced baseline levels of [Ca²⁺]_i and prevented L-aspartate-evoked increases in [Ca²⁺]_i. These same effects on [Ca²⁺]_i were produced by raising the concentration of BAPTA to 30 mM without ATP. However, this concentration of BAPTA failed to affect the rundown of the NMDA currents. Inclusion of ATPγs, an ATP analog which is a substrate for phosphorylation, mimicked the effects of ATP on NMDA currents. But rundown was not affected by ATP-PNP, an ATP analog that is not a phosphorylation substrate. These results suggest that intracellular ATP prevents rundown of the NMDA currents not by lowering [Ca²⁺]_i but by supporting phosphorylation. (Supported by the Canadian MRC and the Nicole Fealdman Memorial Fund.)

A NOVEL MECHANISM OF AMPA RECEPTOR REGULATION: IONICALLY TRIGGERED KINASES & PHOSPHATASES

B.A. Pasqualotto*, R.A. Lanius, and C.A. Shaw. Departments of Physiology and Ophthalmology and Neuroscience Program. University of British Columbia, Vancouver, Canada.

Agonist or depolarizing stimulation induce decreases in AMPA receptor number in slices of adult rat neocortex. The dependency of these agents on protein phosphorylation (Pasqualotto, Lanius, & Shaw, *NeuroReport* 4(4), 1993) raises the question of how such stimuli can stimulate protein kinase activity. One common feature of these regulatory agents is that they both cause transient, but profound, changes in local ionic concentrations within the cell. The molecular cascade of events linking cellular stimulation to subsequent receptor regulation was examined by investigating the effect of changes in the concentrations of several ions on the specific binding of ^3H -CNQX in slices of adult rat neocortex. Ca^{2+} led to concentration-dependent decreases in ^3H -CNQX binding which could be blocked by the protein kinase inhibitors H7 and protein kinase inhibitor peptide. In contrast, Cl^- led to concentration-dependent increases in ^3H -CNQX binding which could be blocked by the phosphatase inhibitors sodium-ortho-vanadate and sodium- β -D-glycerol phosphate. K^+ and Na^+ had no effect on ^3H -CNQX binding. These results suggest that Ca^{2+} and Cl^- may be acting as signals which trigger kinase(s) and phosphatase(s) involved in the regulation of AMPA receptors. We suggest that such ionically triggered enzyme activity may play a key role in the regulation of many receptor populations.

558.9

SENSITIVITY OF CLONED NMDA RECEPTORS TO REDOX COMPOUNDS. A.Omerovic*, J.P.Leonard and S.R.Kelso. Dept. of Biol. Sci., Univ. of Illinois at Chicago, Chicago IL 60680.

We have studied the effects of redox compounds dithiothreitol (DTT), a reducing agent, and 5,5-dithio-bis-2-nitrobenzoic acid (DTNB) and nitric oxide (NO), oxidizing agents, on homomeric and heteromeric NMDA receptors expressed in *Xenopus* oocytes. NMDA currents were recorded under voltage clamp at -80 mV.

Redox modulation was observed in both homomeric (in oocytes injected with mouse zeta1 cRNA) and heteromeric (in cells coinjected with zeta1 and mouse epsilon1 or epsilon3 cRNA) NMDA receptors. In cells expressing homomeric receptors, DTT (4 mM; 5 minutes) induced an enhancement of the NMDA current to $138 \pm 6\%$ of control. The effect was completely reversible in 5 minutes after washout of DTT. DTNB and the NO donor S-nitrosocysteine (SNOC) did not significantly inhibit NMDA currents in these cells.

Heteromeric receptors (zeta1+epsilon1 and zeta1+epsilon3) showed a greater sensitivity to redox compounds: the average enhancement of the NMDA current by DTT was $154 \pm 11\%$ and $355 \pm 32\%$ of control, respectively. The effect was long lasting for both heteromers (in zeta1/epsilon3 it recovered only partially 60 minutes after washout of DTT). The increased NMDA current returned to control level only after DTNB application. SNOC (100 μM , 5 min) induced inhibition of the NMDA currents, but only after previous application of DTT. However, DTNB (1mM, 5 min) effectively reduced NMDA currents without previous reduction of receptor. Interestingly, both DTNB and NO effects were partially reversible, which would not be expected if they act solely on vicinal cysteine residues.

558.11

DEVELOPMENTALLY RELEVANT PROPERTIES AND INHIBITION BY LEAD (Pb^{2+}) OF NMDA-INDUCED CURRENTS IN POSTNATAL ACUTELY DISSOCIATED RAT HIPPOCAMPAL NEURONS. K. Ishihara¹ and E.X. Albuquerque^{1,2}. ¹Dept. Pharmacol. Exp. Ther., Univ. Maryland Sch. Med, Baltimore, MD 21201; ²Lab. Mol. Pharmacol., IBCCF, Fed. Univ. Rio de Janeiro, Brazil, 21944.

In previous studies using cultured fetal rat hippocampal neurons it was found that the amplitude of NMDA-induced currents increased with cell maturation, and that Pb^{2+} preferentially inhibited NMDA-induced currents in younger, cultured neurons (*JPET* 263:859 & 868, 1992). In this report, the ontogeny of the NMDA subtype of the glutamatergic receptor/ion channel, and developmental changes in its sensitivity to Pb^{2+} were investigated in hippocampal neurons acutely dissociated (with or without trypsin) from 3-30-day-old neonatal rats. NMDA-induced currents increased in amplitude until 10-12 days postnatal regardless of whether dissociation was carried out with or without trypsin. However, the NMDA-activated currents in the trypsin-treated group were smaller than those in the untreated group. The whole-cell currents induced by NMDA in the presence of glycine were composed of a fast and a slowly decaying current. The fast-decay component of the currents increased up to the age of 10-12 days after birth and then decreased, while the slow-decay component, also growing up to that point, plateaued instead. The current-voltage relationship for the NMDA-induced currents was not different between trypsin-treated and untreated groups. The EC_{50} s for NMDA and glycine in the enzyme-treated group were larger than in the other group. Pb^{2+} (10 or 30 μM) inhibited, dose dependently, NMDA-induced currents recorded from neurons dissociated at various stages of development. The Pb^{2+} -induced inhibition of NMDA-activated currents was not affected by trypsin treatment. The fast component, which was predominant at younger ages, was more susceptible to Pb^{2+} than the slow component, so that inhibition by Pb^{2+} was most pronounced in neurons dissociated at 3-4 days. These results indicate that sensitivity to NMDA of hippocampal neurons develops until the age of 10-12 days postnatal, and that Pb^{2+} is selectively toxic to immature neurons. Support: USPHS Grants ES05730 and NS25296.

PROTON SENSITIVITY OF RECOMBINANT NMDA RECEPTOR SUBUNITS. Stephen F. Traynelis* and Stephen F. Heinemann. Molecular Neurobiology Laboratory, Salk Institute, La Jolla, CA, 92037.

NMDA receptor function in mammalian neurons is strongly inhibited by extracellular protons. Reported IC_{50} values in neurons suggest that both physiological regulation of interstitial H^+ and pathological changes in extracellular pH will influence NMDA receptor (NR) function. In order to better understand the structural basis for H^+ modulation of NR function, we have studied the effects of extracellular $[\text{H}^+]$ on agonist-evoked currents recorded under voltage-clamp from the recombinant NR subunits expressed in *Xenopus* oocytes. Responses of homomeric NR1 subunits to glutamate (plus glycine) were inhibited by extracellular H^+ with an IC_{50} corresponding to pH 7.4 (40 nM; n=31). Three additional variants of NR1 that arise from differential splicing of the 3'-end of the RNA (NR1-2a,3a,4a) showed similar sensitivity to extracellular $[\text{H}^+]$ (n=22). However, the presence of an alternatively-spliced 63 bp exon near the 5'-end of the RNA markedly reduced proton inhibition, regardless of the exon configuration of the 3'-terminal. IC_{50} values for all NR1 splice variants with this 5'-insert (NR1-1b,2b,3b,4b) were similar (pH 6.6; 250 nM; n=41). The differential H^+ sensitivity imparted to NRs by the 63 bp 5'-exon, which codes for a highly charged amino acid sequence, suggests that receptors containing subunits with this insert will be insensitive to changes in interstitial pH. In contrast to the 50% inhibition at physiological pH of NR1 subunits lacking the 5'-exon, NR1 subunits that contain this insert are fully functional under normal conditions.

Coexpression of NR1 subunits with NR2A or NR2B did not alter the proton sensitivity of NR1 subunits either with or without the 5'-exon (n=38). Furthermore, proton inhibition was independent of voltage (n=44), extra/intracellular $[\text{Ca}^{2+}]$ (n=54), agonist (glutamate/aspartate/NMDA; n=113), or agonist (glutamate or glycine) concentration (n=69).

NMDA-RECEPTOR CURRENTS UNDERGO USE-DEPENDENT INACTIVATION MEDIATED BY INTRACELLULAR CALCIUM.

A.F. Schindler and M. Montal*. Dept. of Biology, UCSD, La Jolla, CA 92093.

Repetitive stimulation of glutamate (glu) receptors elicits increasingly smaller ionic currents in hippocampal neurons. To investigate mechanisms underlying this phenomenon, voltage clamp ($V_m = -80$ mV) whole-cell currents evoked by locally perfused glutamate (100 μM) were recorded on hippocampal neuronal cultures from rat embryos. Pharmacological studies show that these currents are mainly carried by NMDA-receptor channels. In presence of 2.2 mM extracellular Ca^{2+} ($[\text{Ca}^{2+}]_o$), repetitive glu applications of 4 s/min. elicited progressively smaller currents whose size and shape stabilized after 10 episodes (figure). When $[\text{Ca}^{2+}]_o$ was replaced by Ba^{2+} (2.2 mM) similar effects were obtained. Reducing $[\text{Ca}^{2+}]_o$ to 0.22 mM attenuated both the interepisode and intraepisode inactivation - as shown by the ratio between peak and steady state currents.

Inactivation was prevented by shortening the length of the glu pulse to 2 s. When the membrane potential was held at +50 mV during the interepisode intervals, inactivation was partially and transiently abrogated. We conclude that NMDA-receptor channels inactivate in presence of intracellular divalent cations. This may arise from Ca^{2+} binding either to the receptor or to closely associated regulatory proteins. This signaling pathway may involve a voltage-dependent phase.

VARIATIONS IN PHYSIOLOGICAL RESPONSES OF THE HETEROMERIC NMDA RECEPTOR SUBUNITS EXPRESSED IN 293 HUMAN EMBRYONIC KIDNEY CELLS. N. AGOPYAN*

Max-Planck Inst. f. med. Forsch., Abt. Zellphysiol., D-6900 Heidelberg, Germany.

When visualized by *in situ* hybridization, recently cloned heteromeric NMDA receptor subunits (NR1: Moriyoshi et al. 1991, *Nature*, 354:31; NR2: Monyer et al. 1992, *Science*, 256:1217) show differential expression patterns in the rat brain. To see whether or not the differences in regional expression patterns are also reflected in their physiological responses we recorded, in Mg^{2+} -free Ringer, 100 μM glutamate-induced whole-cell currents from 293 cells expressing heteromeric NR1-NR2 receptor channels.

In the absence of glycine, glutamate did not induce any detectable currents in NR1-NR2A, NR1-NR2B, and NR1-NR2C transfected cells. As the glycine concentration was increased NR1-NR2A, NR1-NR2B, and NR1-NR2C transfected cells produced an inward current which reached a maximum at 10 μM glycine. Dose-response curves revealed a higher glycine sensitivity in NR1-NR2C subunit ($K_d: 0.67$ μM). K_d s for NR1-NR2A and NR1-NR2B subunits were 4.15 μM and 1.12 μM respectively. Desensitization rate during a 1 sec pulse of glutamate and glycine was much faster in cells expressing the NR1-NR2A subunit than those expressing NR1-NR2B subunit. On the other hand cells expressing the NR1-NR2C subunit did not desensitize during the time course of application. The desensitization rate in NR1-NR2A and NR1-NR2B subunits was glycine dependent since in the absence of glycine preincubation NR1-NR2B did not desensitize while NR1-NR2A desensitized slower. The decay rate of the offset current after the glutamate pulse was also dependent on the subunit composition: In cells expressing NR1-NR2C and NR1-NR2B subunits offset rate was comparably slow (1.8 Hz) while in those expressing NR1-NR2A it was much faster (5 Hz). In conclusion the distinct physiological properties of heteromeric NMDA receptor subtypes may explain the existence of pharmacologically different NMDA receptors in the brain. Supported by NSERC of Canada.

PHARMACOLOGICAL PROPERTIES OF DOUBLE AND TRIPLE HETEROMERIC NMDA RECEPTOR COMBINATIONS. K.A. Wafford*, C.I. Bain, B. Le Bourdelles, P.J. Whiting and J.A. Kemp Merck, Sharp & Dohme Research Laboratories, Terlings Park, Harlow, Essex CM20 2QR, England

The NMDA receptor plays a critical role in the control of neuronal transmission and cDNAs encoding the subunits which make up this receptor have recently been identified. We have isolated a cDNA clone from a human hippocampal cDNA library encoding the NMDA-R1 (NR1) subunit and this has been coexpressed in *Xenopus* oocytes with the rat NMDA-R2A (NR2A) and NMDA-R2C (NR2C) cDNA clones. Receptors formed from NR1+NR2A had EC₅₀'s for glycine and glutamate of 3.4μM and 5.2μM respectively. Receptors formed from NR1+NR2C had EC₅₀'s for glycine and glutamate of 0.14μM and 0.79μM respectively. By coexpressing NR1+NR2A+NR2C and examining the concentration response elicited by glycine a unique receptor was found to be preferentially expressed with an EC₅₀ of 0.77μM together with a small proportion of NR1+NR2C receptors (<20%). Glutamate also had an intermediate affinity of 2.08μM on this receptor. As all three subunits coexist in the cerebellum, this trimeric combination may constitute a cerebellar form of the NMDA receptor.

IL-1β POTENTIATES NMDA MEDIATED CURRENTS IN XENOPUS OOCYTES. L.A. Leonard, G.E. Ringheim, M.C. Cornfeldt*, F. Wirtz-Bruggler Hoechst-Roussel Pharmaceuticals Inc., Somerville, NJ 08876-1258.

It has been proposed that a cytokine mediated acute phase inflammatory response may be involved in the neurodegenerative processes of Alzheimer's disease (AD). Many immune system proteins, including IL-1β, are elevated in AD (McGeer et al. *Neurology*, 42, 447-449, 1992). Excitatory amino acids (EAA) also play a pivotal role in chronic neuronal degeneration by inducing cytotoxicity. The potential synergistic relationship between EAA mediated currents and IL-1β was investigated in the present study. *Xenopus* oocytes microinjected with rat whole brain mRNA were incubated for 24 hours in culture solution (ND96+Ca⁺⁺) with or without the addition of 1nM m-IL-1β. These two populations of oocytes were then voltage clamped and perfused with various EAA's. The currents evoked by NMDA (100 and 500μM with 3μM glycine) were significantly potentiated (p>0.05) by 41 and 38 percent respectively in the IL-1β incubated group (N=48) as compared with controls (N=45). Currents elicited by GABA (50 and 100μM) and kainate (30μM) were unchanged by IL-1β. These findings may suggest a mechanism by which cytokines contribute to neurodegenerative processes in AD.

558.14

FUNCTIONAL EVIDENCE FOR DIFFERENT NMDA RECEPTOR SUBTYPES IN NEURONES CULTURED FROM TWO REGIONS OF RAT BRAIN. J.A. Kemp, R.G. Hill* and T. Priestley. Merck Sharp & Dohme Research Laboratories, Neuroscience Research Centre, Terlings Park, Eastwick Road, Harlow, Essex, CM20 2QR, U.K.

The discovery of multiple NMDA receptor subunits, some of which only occur in discrete brain regions, e.g. NR2C in the cerebellum, has highlighted the possibility of pharmacological subtypes of N-methyl-D-aspartate (NMDA) receptors. We have investigated this possibility by comparing the kinetics of NMDA receptor-mediated L-glutamate and glycine responses on whole-cell voltage-clamped rat cortical and cerebellar neurones in cell culture. There were marked differences between the two cell types in the time-constant for the agonist-evoked current relaxations (τ_{off}) (Table 1).

Table 1	Glutamate kinetics τ _{off} (ms)	Glycine kinetics τ _{off} (ms)
Cortex	467 ± 38 (11)	1107 ± 61 (19)
Cerebellum	170 ± 24 (12)*	285 ± 27 (14)*

* = significantly different from cortex, $\hat{P} < 0.0001$ (t test)

These data indicate that glutamate and glycine have different affinities for NMDA receptors in these two cell types and, thus, provide functional evidence to support NMDA receptor heterogeneity in the rat central nervous system.

558.16

MODULATION OF N-METHYL-D-ASPARTATE RECEPTOR FUNCTIONS BY THE PENTADECAPETIDE. V.K. Shukla, K.C. Marshall, H. Xiong, M. Dumont and S. Lemaire*. Departments of Pharmacology and Physiology, Fac. of Med., Univ. of Ottawa, Ottawa, Ontario, Canada K1H 8M5.

Histogranin, was originally identified as an adrenomedullary pentadecapeptide possessing N-methyl-D-aspartate (NMDA) receptor antagonist activity. A chemically more stable analog, [Ser¹]histogranin has also been synthesized and shown to be as potent as histogranin in a rat brain membrane binding assay. Binding of [³H]CGP-39653 to membrane preparations of rat brain was displaced by [Ser¹]histogranin in a biphasic manner with IC₅₀ of 10.4 nM and 16.4 μM, representing 42% and 58% of the binding sites, respectively. Saturation binding experiments with [³H]CGP-39653 in the absence and presence of [Ser¹]histogranin (2 μM) indicated that the inhibitory effect of the peptide was noncompetitive, producing a decrease in the B_{max} (from 93.2 ± 8.5 to 62.1 ± 7.2 fmol/mg protein). Pressure injection of NMDA (5 mmol) and DL-α-amino-3-hydroxy-5-methylisoxazole-4-propionic acid (AMPA) (5 mmol) on intracellularly recorded locus coeruleus neurons in an "in vitro" brain slice preparation induced pronounced increases in membrane depolarization amplitude and spike frequency. Cojection of [Ser¹]histogranin (12.5 μmol) strongly blocked (85-100%) the effects of NMDA in 100% of tested cells (n=11) but had no or lower effects (20-50% reduction) in 30% of cells stimulated with AMPA. In the mouse "in vivo" model, [Ser¹]histogranin (10-100 nmol/mouse, i.c.v.) produced a dose-dependent blockade of NMDA (0.5-2 nmol)-induced convulsions. These results suggest that [Ser¹]histogranin is an allosteric modulator of NMDA receptor binding activity and a specific blocker of NMDA receptor functions. Supported by MRC.

PEPTIDES: BIOSYNTHESIS, METABOLISM, AND BIOCHEMICAL CHARACTERIZATION I

559.1

ISOLATION AND MOLECULAR CLONING OF APLYSIA FURIN AND PC2, TWO CANDIDATE PROHORMONE PROCESSING ENZYMES. G.T. Nagle*, S.L. Knock, W.R.A. van Heumen, A.T. Garcia, E. Gorham, and A. Kurosky. Marine Biomedical Institute and Department of Human Biological Chemistry and Genetics, Univ. of Texas Med. Branch, Galveston, TX 77555.

The neuroendocrine bag cells and exocrine atrial gland of *Aplysia californica* express genes belonging to the egg-laying hormone (ELH) family and process the resulting precursor at mono-, di-, tri- and tetrabasic sequences. Some proportion of these cleavages may result from proteolysis by a furin-like or PC2-like enzyme; these enzymes have been identified in organisms as diverse as yeast and humans. The atrial gland is particularly interesting because the organ produces large amounts of ELH-related peptides and may be a relatively rich source of prohormone processing enzymes. An atrial gland λZAP cDNA library was constructed and screened using a furin-related PCR probe, and a clone encoding a furin-like protein was isolated. The insert has been partially sequenced, and is identical to a furin-related PCR product from the bag cells. The library was also screened using a *Lymnaea* PC2 probe (provided by A.B. Smit, Holland) and a clone encoding a PC2-like protein was isolated. These clones are relatively large as a result of extended 3' untranslated regions. Supported by NIH NS 29261 and the Robert A. Welch Foundation (H-1190).

559.2

SECRETORY CELL CHARACTERIZATION AND LOCALIZATION OF PROHORMONE PROCESSING ENZYMES IN THE ATRIAL GLAND OF APLYSIA CALIFORNICA. W.R.A. van Heumen, S.L. Knock*, G.T. Nagle, and A. Kurosky. Marine Biomedical Institute and Department of Human Biological Chemistry and Genetics, Univ. of Texas Med. Branch, Galveston, TX 77555.

Relatively little is known about the post-translational processing of egg-laying hormone (ELH)-related gene products in the atrial gland. A combination of morphologic techniques that included light microscopic histology and immunocytochemistry, transmission electron microscopy, and immunoelectron microscopy were used to localize ELH-related peptides in the atrial gland and to evaluate the characteristic morphology of their secretory cells. Results of these studies showed that there were at least three major types of secretory cells in the atrial gland one of which was immunoreactive to antisera against ELH-related precursor peptides. All three ELH-related precursor genes were expressed in type 1 cells and the processing of these precursors also occurred within the secretory granules of type 1 cells. In contrast to the bag cells, the N-terminal and C-terminal products of the ELH-related precursors of the atrial gland were not sorted into different types of vesicles. *In situ* hybridization studies confirmed the occurrence of furin and PC2 in the atrial gland. Supported by NIH NS 29261 and the Robert A. Welch Foundation (H-1190).

559.3

IDENTIFICATION AND CHARACTERIZATION OF THE LUQ PEPTIDES IN *APLYSIA CALIFORNICA*. R. S. Aloyz and L. DesGroseillers*. Department of Biochemistry, University of Montreal, Montreal, Canada, H3C 3J7.

We are investigating the role of neuropeptides in renal physiology. Left Upper Quadrant (LUQ) neurons and neuron L10 in the central nervous system of *Aplysia* have been shown to extensively innervate the kidney and regulate renal functions. Three neuropeptide precursor genes (LUQ-1, L5-67 and L10-M), which are differentially expressed in these cells, have previously been cloned. However, the nature of the physiologically relevant peptides is still unknown. We now report the characterization of the peptides isolated from the dorsal LUQ cells. Labelling of LUQ cells with radioactive amino acids and resolution of the peptide content of these cells on SDS-PAGE shows two prominent peptide bands of around 10 and 8 kd. The size of the bands roughly corresponds to the deduced molecular weights of the L5-67 propeptides and the longest of the mature products derived from it. To characterize the smaller -RFamide product, labeled peptides were separated on different HPLC systems. The major labeled peak comigrated with a synthetic peptide deduced from the cDNA sequence, on two different HPLC systems. Sequencing of the peak will confirm the nature of the peptide. We also looked for the presence of these two peptides in the kidney. Kidneys were first homogenized and the peptides were separated on Sephadex G-50. To identify the LUQ peptides, each fraction was screened by RIA, using antisera recognizing either the small -RFamide peptide or the longer peptide. These antisera will also be useful for determining the location of the peptide-containing cells by immuno-histochemistry.

559.5

STRUCTURE AND DISTRIBUTION OF RAT SUBTILISIN-RELATED ENDOPROTEASE PACE4 PREVALENT IN PITUITARY, BRAIN AND HEART. R. C. Johnson, D. N. Darlington* and R. E. Mains. Neuroscience Dept., The Johns Hopkins University School of Medicine, Baltimore MD 21205.

Low stringency screening of a rat hypothalamic cDNA library was performed using highly conserved 450 nt regions of rat prohormone convertases PC1, PC2 and furin. A clone containing a ~4 kb insert was identified which is about 90% identical to human PACE4 in amino acid sequence, with much lower similarity to rat PC1, PC2, furin, PC4, PC5 or PC6. The rat PACE4 sequence has the Asp-His-Ser catalytic site triad, the Arg-Gly-Asp routing signal and several sites for N-linked glycosylation. Rat PACE4 has a long COOH-terminal region which is very rich in Cys residues (15%). Rat PACE4 has a tissue and cell line distribution unlike any reported PC, with high expression in several brain regions, atrium, ventricle and anterior pituitary; little or no mRNA is detected in skeletal muscle, lung, liver, kidney, spleen, stomach, colon, duodenum, ovary, testes, pancreas and submaxillary gland. PACE4 mRNA is prevalent in AtT-20, GH3 and BRL cells, while undetectable in hEK-293, CHO, 3T3, COS, C127 and L cells using rat PACE4 probes. *In situ* hybridization revealed PACE4 mRNA in anterior and intermediate pituitary but not neural pituitary.

559.7

CPE, PAM, PC1 AND PC2 mRNAs ARE EXPRESSED IN SUBSTANCE P AND CGRP CONTAINING NEURONS OF THE RAT TRIGEMINAL GANGLION. C.M. Flores*, M.E. Goldstein and H. Gainer. Laboratory of Neurochemistry, NINDS, NIH, Bethesda, MD 20892.

The enzymatic, processing cascade leading to the formation of mature, bioactive peptides is thought to involve endoproteolytic cleavage of the propeptide precursor, removal of C-terminal basic residues and, in some cases, C-terminal amidation. Using *in situ* hybridization histochemistry in conjunction with immunocytochemistry, we determined whether the transcripts encoding any of the recently identified processing enzymes (i.e. CPE, PAM, PC1 and PC2) are coexpressed with the amidated neuropeptides SP or CGRP in neurons of the rat trigeminal ganglion (TGG). Consistent with investigations on other sensory ganglia, e.g. DRG (Goldstein et al., J. Neurosci. Res., 1991), the present studies demonstrate that the TGG contains two major cell types, distinguishable by their size and intermediate filament subtype expression: a population of relatively large cells that expresses NF-L (61%) and a population of relatively smaller cells that expresses peripherin (35%) with approximately 5% of cells coexpressing both proteins. The neuropeptides SP and CGRP were localized predominantly in the smaller, peripherin-positive population. Transcripts encoding each of the processing enzymes examined were detected in all TGG neurons, but only PAM mRNA appeared to be more highly expressed in SP and CGRP synthesizing cells. Moreover, each of these transcripts was detected as early as embryonic day 20 and increased throughout development, reaching maximal levels of expression in the adult animal, an ontogenetic profile similar to that observed for SP and CGRP. These data indicate that the mRNA transcripts encoding CPE, PAM, PC1 and PC2 are all coexpressed with their putative neuropeptide substrates SP and CGRP. The finding that each of these enzymes is also expressed in cells not containing SP and CGRP suggests the existence of other neuropeptide substrates in these cells or, possibly, as yet unidentified functions for these enzymes.

559.4

PROTEOLYTIC PROCESSING OF THE *APLYSIA* A PEPTIDE PRECURSOR IN AT-20 CELLS. P. A. Paganetti and R. H. Scheller*. Howard Hughes Med. Inst.; Dept. of Mol. and Cell. Physiol. Stanford Univ. Med. Center. Stanford, California 94305.

When the *Aplysia* ELH precursor is expressed in the neuroendocrine AtT-20 cells, the carboxyterminal derived peptides are packaged and stored in secretory vesicles, while the aminoterminal region of the precursor is constitutively secreted. When the highly homologous A peptide precursor is expressed in AT-20 cells, both the aminoterminal and the carboxyterminal derived peptides are packaged in storage granules. This is likely to be due to the fact that the initial cleavage of the A peptide precursor occurs more slowly than the ELH precursor. We propose that in the A peptide precursor, the first cleavage occurs after the sorting site resulting in co-packaging of the multiple products derived from a single precursor protein. To determine the structural features of the prohormone responsible for this differential sorting, we made chimeric precursors and determined the rates of initial cleavage as well as the efficiency of storing the peptides products.

From these studies, we conclude that the differential sorting is not due simply to the amino acid sequence of the first processing site, but is also determined by more global aspects of the precursor structure.

559.6

DISTINCT ROLES OF PC1 AND PC2 IN PROHORMONE AND PROENZYME BIOSYNTHETIC PROCESSING. A. Zhou, S.L. Milgram & R.E. Mains* Dept. of Neuroscience, The Johns Hopkins University School of Medicine, Baltimore MD 21205.

Our previous work showed that overexpression of prohormone convertase 2 (PC2) in AT-20 cells, a corticotrope cell line expressing high endogenous levels of PC1 and low levels of PC2, could alter endoproteolytic processing of proopiomelanocortin (POMC) into a melanotrope-specific pattern, characterized by enhancing 2 cleavage steps [producing ACTH(1-13)/NH2/CLIP and γ -LPH/ β -endorphin] and adding two new cleavages to produce Lys α - γ -MSH and β -endorphin(1-27). In a pulse-chase radiolabeling paradigm, the PC2 effects on processing were only seen after significant chase times. In the present study, PC1 was overexpressed in AT-20 cells by stable transfection of PC1 cDNA. Results show that, unlike overexpression of PC2, PC1 increased the rate of conversion of POMC to ACTH through an intermediate in the first 1-2 hours of chase, further confirming that PC1 alters POMC processing primarily at the early steps and that PC1 and PC2 function in a strict temporal order. AT-20 cells previously were established which stably expressed various forms of peptidylglycine α -amidating monooxygenase (PAM); PAM α -amidates peptides during biosynthesis. PAM itself is known to undergo endoproteolytic processing at several sites when expressed in AT-20 cells. When such PAM expressing AT-20 cells were stably transfected with PC2 cDNA (resulting in a double-transfected cell line), no additional cleavages were detected in PAM processing, while changes in POMC processing were seen as before, indicating a restricted substrate specificity for PC2.

559.8

RECOMBINANT β -PROTACHYKININ (β -PT) PRODUCED IN *E. COLI*: COMPARATIVE EXPRESSION AS β -PT AND AS A β -PT/MALTOSE-BINDING PROTEIN FUSION. A. Kohn*, B. Kannan, and V.Y.H. Hook. Dept. of Biochemistry, Uniformed Services University of the Health Sciences, Bethesda, MD. 20814.

Production of milligram amounts of recombinant neuropeptide precursors in *E. Coli* is desirable for studies of *in vitro* precursor processing at estimated *in vivo* precursor levels in the micromolar range. Expression of human β -protachykinin (β -PT) was accomplished with pET3c and pMAL-c expression vectors. The pET3c vector contains the T7 promoter and expresses the foreign protein, whereas the pMAL-c expresses the foreign protein as a fusion with the maltose binding protein (MBP). β -protachykinin DNA was amplified by PCR from the β -preprotachykinin cDNA with deletion of the signal sequence and with incorporation of appropriate restriction sites at 5' and 3' ends for subcloning into expression vectors. β -PT in the pET3c vector was expressed in BL21(DE3) cells containing the bacteriophage DE3 and the gene for T7. 35 S-Methionine labeling studies showed that intact β -PT was expressed upon induction with IPTG, but was rapidly degraded. Furthermore, β -PT could not be detected by immunoblots or by Coomassie protein staining of SDS-PAGE gels. In contrast, the β -PT/MBP fusion was expressed at high levels (milligrams), and was recognized by anti-PT (gift from Dr. J. Krause, Washington University) and anti-MBP sera. The β -PT/MBP fusion contains a thrombin cleavage site at the junction of the β -PT and MBP that may allow production of β -PT for *in vitro* processing studies.

559.9

IDENTIFICATION OF CARBOXYPEPTIDASE H TRANSCRIPTS BY ANTISENSE mRNA. S.-R. Hwang* and V.Y.H. Hook. Dept. of Biochemistry, Uniformed Services University, Bethesda, MD.

Carboxypeptidase H (CPH; EC 3.4.17.10) is a metallopeptidase involved in the processing of prohormones. Previously, northern analysis using cDNA as probe showed that a single transcript of 2.2 or 2.4 kb is present in rats and human, respectively. However, multiple CPH mRNAs of 2.2, 2.4, and 3.3 kb have been demonstrated in bovine. In our studies, a full length rat antisense CPH mRNA was used to re-examine CPH transcripts among different tissues by northern analysis. We find that (i) mouse brain and AtT-20 cells contain mRNAs of 5.9, 2.6, and 2.2 kb, with the 2.6 kb form being predominant; (ii) rat brain and pituitary possess the 2.2 kb form as the main form among three transcripts; (iii) rat adrenal medulla contains primarily a 2.2 kb species among two transcripts (5.9 and 2.2 kb); (iv) bovine adrenal medulla contains primarily the 5.9 kb form, while in bovine pituitary the 2.2 kb mRNA appears as the major form. These results show a new CPH transcript of 5.9 kb, and indicate tissue-specific expression of multiple CPH mRNAs. To analyze transcripts, cDNA libraries from bovine adrenal medulla and pituitary were constructed using lambda Uni-ZAP™MXR as vector. Northern analysis of transcripts generated from total library cDNAs by T3 RNA polymerase showed a distinct 4.2 kb transcript that was detected only from the adrenal medulla cDNA library. These results are consistent with the 5.9 kb mRNA in bovine adrenal medulla, but not in pituitary, and suggest that the 4.2 kb transcript may be generated from a cDNA representing the 5.9 kb CPH mRNA. Further studies will address differences among these transcripts.

559.11

CARBOXY-TERMINAL CLEAVAGE OF PROHORMONE CONVERTASE 1: MECHANISM AND POTENTIAL SIGNIFICANCE Y. Zhou and I. Lindberg*. Dept. of Biochem. and Mol. Biol. Louisiana State University Medical Center, New Orleans, LA 70112

Peptide hormones are initially synthesized in precursor form and must undergo a series of proteolytic processing events prior to release in biologically active form. Recent studies have revealed a new eukaryotic subtilisin-like proteinase family, of which prohormone convertase 1 (PC1) is a member. In both AtT20 and CHO cells, PC1 is synthesized as a glycosylated proprotein which undergoes a rapid amino-terminal cleavage to generate an 87 kDa form which is enzymatically active; at later times 87 kDa PC1 is converted to 74 and 66 kDa forms by carboxy-terminal cleavage (though this event is largely incomplete in CHO cells). In this work, possible mechanisms of this PC1 C-terminal cleavage event have been explored using homogeneous recombinant 87 kDa PC1. We found that 87 kDa PC1 could spontaneously convert to 74 and 66 kDa forms *in vitro*. The 74 kDa form apparently represented an intermediate product. These cleavages were calcium-activated, with a broad pH range. EDTA and PCMS could substantially block these conversions; so did D-Tyr-Ala-Lys-Arg-CH₂Cl and Cbz-Arg-Ser-Lys-Arg-AMC, implying that the cleavages might occur at dibasic residues. Dilution experiments suggested that an intermolecular interaction was involved in the cleavage; however, an intramolecular mechanism cannot be excluded at this point. Partially purified 74/66 kDa PC1 was characterized using Cbz-Arg-Ser-Lys-Arg-AMC. We found that 74/66 kDa PC1 was enzymatically active and activated by millimolar concentration of calcium. Compared to the 87 kDa form, 74/66 kDa PC1 exhibited a narrow pH optimum (between 5.0 and 5.5) and appeared to be more sensitive to PMSF. Unlike the 87 kDa form, 74/66 kDa PC1 had an activity lag phase which varied depending on protein and calcium concentrations. We are currently exploring the possibility that C-terminal processing of 87 kDa PC1 represents further activation.

559.13

INABILITY OF PC2 TO PROCESS PROSOMATOSTATIN (PSS) IN GRANULATED SECRETORY CELL LINES. Y.C. Patel, A.S. Galanopoulos, N.G. Seidah, S.C. Patel. Fraser Labs, McGill University and Clinical Research Institute, Montreal.

We have previously reported that PC1, but not PC2, can effect dibasic cleavage of rat PSS to SS-14 in constitutively secreting COS-7 cells (JBC, 268:6041, 1993). To test whether inactivity of PC2 in these cells reflects a requirement for secretory granules, we have now studied PSS processing in 3 secretory cell lines which express PC2 but not PC1 endogenously (GH3, GH4C1 rat pituitary; Y-1 mouse adrenocortical cells). PSS processing was correlated with PC2 mRNA under basal conditions or conditions that induced granule formation and/or which modulated PC2 expression (treatment of GH3/GH4C1 cells with EGF, insulin and β -estradiol; treatment of Y-1 cells with ACTH 10^{-7} M, 24 h). Cells were transfected with rat PSS cDNA in pKS5. Cell extracts and media were analysed by HPLC and RIAs. PC2 mRNA by Northern analysis was expressed as fold change compared to PC2 mRNA in control GH4C1 cells taken as 1.

	GH3	GH3 treated	GH4C1	GH4C1 treated	Y-1	Y-1 treated
PC2 mRNA	: 19	35	1	3	7	0.8
SS-14 (%)	: 100	100	25	13	80	100
SS-28 (%)	: 0	0	14	26	20	0
unprocessed (%)	: 0	0	61	61	0	0

CONCLUSIONS:(i) Induction of secretory granules has little effect on efficient PSS processing.(ii) Although basal expression of PC2 mRNA correlates with efficient PSS processing, the lack of coregulation of SS-14 conversion and PC2 levels argues against a functional role for this endoprotease in PSS processing and suggests the existence of other SS-14 convertases, possibly the recently discovered PC5.

559.10

ORDER OF DIBASIC PROCESSING IN PROENKEPHALIN. F. Liu, P.R. Housley and S.P. Wilson*. Department of Pharmacology, University of South Carolina School of Medicine, Columbia, S.C., 29208.

The opioid peptide precursor proenkephalin (PPE) contains seven enkephalin sequences and is synthesized by epinephrine-producing adrenal chromaffin cells and a variety of peripheral and central neurons. After removal of a signal peptide, PPE is further processed at dibasic sites to yield its final products. Processing of human PPE in bovine chromaffin cells was examined using recombinant plasmids containing the human PPE cDNA under the control of the cytomegalovirus immediate early gene promoter. Preliminary studies showed that efficient transient expression of *E. coli* β -galactosidase was obtained in chromaffin cells with this promoter. Following transfection of hPPE into chromaffin cells, several proenkephalin-immunoreactive bands were observed on Western blots with the monoclonal antibody PE25 that recognizes human, but not bovine, proenkephalin sequences (Spruce *et al.*, *EMBO J.* 9: 1787-1795, 1990). The pattern of proenkephalin-derived peptides observed was similar to that of bovine PPE processing products. Site-directed mutagenesis was then employed to make a series of recombinant plasmids containing mutations in the hPPE sequence at dibasic processing sites. Conversion of Arg to Gln at hPPE(229) or hPPE(236) did not alter the pattern of proenkephalin-immunoreactive peptides, suggesting that these particular sites may not be important for proenkephalin processing. Single and multiple mutations of other processing sites were also performed. These mutants will be used to determine the sequence of processing at the various dibasic sites of proenkephalin. Supported by the South Carolina Heart Association.

DISTRIBUTION AND CHARACTERIZATION OF A NEUROPEPTIDE PROCESSING ENZYME IN ADULT RAT BRAIN. E. Berman, K. Carr, L.D. Fricker, and L. Devi. Departments of Psychiatry and Pharmacology, New York University Medical Center, New York, 10016 and *Department of Molecular Pharmacology, Albert Einstein College of Medicine, Bronx, New York, 10461.

Many peptide hormone and neuropeptide precursors undergo post-translational processing at mono and/or dibasic residues. An enzymatic activity capable of processing prodynorphin at a monobasic processing site designated 'dynorphin converting enzyme' has been previously reported in rat brain and bovine pituitary. A carboxypeptidase designated 'carboxypeptidase E' subsequently removes C-terminal basic residues. In this study the distribution of dynorphin converting enzyme activity and carboxypeptidase E activity has been compared with the distribution of immunoreactive dynorphin B-13 in 10 regions of rat brain. The distribution of these enzyme activities generally matches the distribution of immunoreactive dynorphin B-13 in most but not all brain regions. The dynorphin converting enzyme activity in the rat brain was subjected to ion exchange chromatography. The chromatography behavior, peptide inhibitor profile and pH optima of the purified dynorphin converting enzyme activity are consistent with the previously reported enzyme from the bovine pituitary and pituitary-derived cell lines. Taken together, these data support the possibility that, like carboxypeptidase E, the dynorphin converting enzyme is involved in the maturation of dynorphins, as well as other neuropeptides, and peptide hormones.

RECOMBINANT PROENKEPHALIN: EXPRESSION, PURIFICATION, AND PROCESSING BY 'PROHORMONE THIOL PROTEASE'. M.B. Schiller*, K. Miller, and V.Y.H. Hook. Dept. of Biochemistry, Uniformed Services University, Bethesda, MD.

The major enkephalin precursor cleaving endoprotease in chromaffin granules has been identified as a novel 'prohormone thiol protease' (PTP). PTP cleaves at dibasic and monobasic processing sites to generate appropriate intermediates and the final (Met)enkephalin opiate peptide. Further studies of proenkephalin (PE) processing by PTP requires development of a radioassay with PE concentrations near estimated *in vivo* levels of 10^{-5} - 10^{-4} M. To obtain milligrams of PE for these studies, the pET3c vector containing the T7 promoter was used to express recombinant PE. The signal sequence of rat proenkephalin cDNA (gift from Dr.S.Sabol, NIH) was deleted and the PE DNA was subcloned into pET3c. PE expression in BL21(DE3) *E. coli* cells was demonstrated by IPTG induction of a 33 kDa band that was recognized by a monoclonal anti-PE antibody (gift from Dr.B. Spruce, UK). Purification of PE under denaturing conditions utilized DEAE-Sephacrose and preparative SDS-PAGE, followed by renaturation. ³⁵S-(Met)-PE was generated by the PE DNA in the riboprobe vector pSP65, followed by *in vitro* transcription and translation. Combination of purified bacterial PE and ³⁵S-(Met)-PE provides a radioassay with PE at μ M concentrations (1-20 μ M). PTP processing of PE estimates an apparent affinity for PE in the μ M range and an apparent turnover number. To our knowledge, these are the first studies of processing enzyme affinity and activity for authentic prohormone.

CHARACTERIZATION OF A NEUROENDOCRINE α_1 -ANTICHYMOTRYPSIN (ACT)-LIKE PROTEIN FROM PITUITARY AS AN INHIBITOR OF A NEUROPEPTIDE PRECURSOR PROCESSING ENZYME.

N. Tezapsidis*, T. Purviance, and V.Y.H. Hook. Dept. of Biochemistry, Uniformed Services University, Bethesda, MD. 20814.

A cascade of proteolytic steps is required for converting neuropeptide precursors into active peptide neurotransmitters and hormones. Control of cellular proteases is often realized through endogenous protease inhibitors. We find that the 'prohormone thiol protease' (PTP) is the primary activity responsible for enkephalin precursor processing in bovine chromaffin granules; PTP is also detected in secretory vesicles of bovine pituitary. Our investigations of the regulation of PTP demonstrate that the enzyme is inhibited by α_1 -antichymotrypsin (ACT) (human), and that ACT immunoreactivity is colocalized with PTP. The purified neuroendocrine ACT-like protein from pituitary potentially inhibited, at nM concentrations, both PTP and chymotrypsin. Interestingly, comparison of kinetic $K_{i,app}$ values showed the bovine neuroendocrine ACT-like protein to be 3-4 times more potent than human liver ACT in inhibiting PTP. However, determination of kinetic constants also showed that the human liver ACT was approximately 6 times more effective than bovine neuroendocrine (pituitary) ACT-like protein for inhibition of chymotrypsin. It is possible that the differential potencies of the bovine neuroendocrine ACT-like protein compared to human liver ACT in inhibiting PTP and chymotrypsin may reflect species differences in ACT or possible tissue specific isoforms of ACT.

DIFFERENTIAL PROCESSING OF SUBSTANCE P AND NEUROKININ A BY HUMAN VASCULAR SMOOTH MUSCLE. L.Wang, P.E.Ward and H.J.Cooke*. Department of Physiology, The Ohio State University, Columbus, OH 43210.

Substance P (SP) and neurokinin A (NKA) can be released from nerve terminals into the smooth muscle layer of the blood vessel wall, and produce significant cardiovascular effects. However, little is known about the subsequent metabolism of these transmitters. We have found that incubation of SP and NKA with cultured human aortic and pulmonary artery smooth muscle cells results in rapid hydrolysis of these peptides. SP hydrolysis was entirely due to neutral endopeptidase-24.11 (NEP-24.11; EC 3.4.24.11) (0.23 ± 0.03 nmol/min/ 10^5 cells), which converted SP to SP[1-7] and other fragments. In addition to NEP-24.11-mediated NKA metabolism (0.16 ± 0.04 nmol/min/ 10^5 cells), NKA was also subject to N-terminal hydrolysis by aminopeptidase M (AmM; EC 3.4.11.2) (0.26 ± 0.06 nmol/min/ 10^5 cells). NEP-24.11 and AmM-mediated metabolism could be completely inhibited by phosphoramidon and amastatin, respectively. The identity of the cell surface membrane bound AmM was confirmed via immunoelectrophoresis. These data demonstrate that two specific cell surface peptidases may play a significant role in metabolizing neurokinins released within the vessel wall. Supported by HL45791.

CORTICOTROPIN RELEASING FACTOR DEGRADATION BY PURIFIED PEPTIDASES. J.C. Ritchie* and C.B. Nemeroff. Depts. of Pharmacol. and Psychiatry, Duke Univ. Durham, NC 27710 and Emory Univ., Atlanta, GA 30322.

The metabolism of neuropeptides by peptidases has been postulated to be the primary mechanism for the deactivation of these neuromodulators. Much is known concerning the action of endopeptidases on the smaller neuropeptides (15 amino acids or less). Corticotropin-releasing factor (CRF₁₋₄₁) is a large neuropeptide that plays multiple roles in integrating the body's response to stress. In addition to its primary role as a hypophysiotropic hormone regulating pituitary ACTH synthesis and secretion, CRF has been shown to be widely distributed throughout the brain and to act as a putative neuromodulator.

In an attempt to elucidate the metabolism of CRF₁₋₄₁, we have performed controlled digestions of this neuropeptide with purified preparations of Angiotensin Converting Enzyme (ACE), Aminopeptidase M, Endopeptidase 24.11 (Neprilysin), Cathepsin D, and Chymotrypsin. Digestions were carried out at 37°C for varying time periods in the presence of excess CRF₁₋₄₁, appropriate cofactors, positive controls, and specific inhibitors. The reaction products were then characterized on an HPLC system optimized for the detection of r/h CRF₁₋₄₁ and its available synthetic fragments. All of the enzymes tested were capable of degrading CRF₁₋₄₁ to various degrees and produced very different fragment patterns. Incubations for various time intervals and with specific inhibitors altered the patterns of peak generation indicating secondary cleavage sites for some of the proteases within the CRF molecule. No evidence was found for the generation of the putative convulsant peptides from the N-terminal end of the CRF molecule. These results support the hypothesis that the actions of CRF are terminated by enzymatic hydrolysis (either inter or intracellularly) and that the CRF molecule is susceptible to degradation in at least 4 areas (the amino-terminus, positions 15-16, 20-21, and 35-36) by endogenous peptidases.

AGE-RELATED ALTERATIONS IN THE POSTTRANSLATIONAL PROCESSING OF β -ENDORPHIN (β -ENDO) IN THE HYPOTHALAMUS OF FEMALE C57BL/6J MICE. D.Joshi*, S.James, H.P.J.Bennett, M.M.Miller. Departments of Experimental Medicine, Anatomy, Obstetrics and Gynecology and Center for Studies on Aging, McGill University, Montreal, Quebec H3A 1A1, Canada.

β -endo (1-31), is the active opioid peptide product of proopiomelanocortin processing. Further processing of β -endo (1-31) yields β -endo (1-27), (1-26) and their acetylated forms which are inactive. β -endo modulates GnRH and LH levels during normal estrus cycles in rodents. The age-related decline in reproductive function has been linked to altered opiate influences on GnRH and LH. The purpose of this study was to determine whether differential processing of β -endo with age could contribute to the altered opiate activity in female C57BL/6J mice. Pooled (n=3) extracts of the arcuate nucleus (ARC) and the preoptic area (POA) of 3mo old normally cycling (diestrus), 12mo old irregularly cycling (diestrus), 24mo old persistent diestrus and 24mo old long-term ovariectomized (L-OVX) mice, and pituitary intermediate lobe standards were subjected in quadruplicate to reversed-phase high pressure liquid chromatography. Fractions corresponding to appropriate peaks were assayed for β -endo-like-immunoreactivity by sequence specific RIAs. The active as well as inactive forms of β -endo were present in both in the ARC and the POA at all ages although their ratio varied. β -endo (1-31) was the predominant form in young animals. However, by middle age, there was a significant ($p < 0.05$ ANOVA) increase in the proportion of inactive forms of β -endo associated with a decrease in the proportion of the active form. There was an increase in the ratio of inactive to active forms with age, which was partially reversed by L-OVX. These results suggest that there are marked alterations in the processing of β -endo by middle age in the C57BL/6J mouse. We conclude that changes in the proportional distribution of active and inactive forms of β -endo may in part account for the altered opiate influence on the LH surge with age. Supported by NIH RO1 AG07795 (MMM).

PEPTIDES: BIOSYNTHESIS, METABOLISM, AND BIOCHEMICAL CHARACTERIZATION II

ELECTROSPRAY MASS SPECTROMETRY ANALYSIS OF OPIOID PEPTIDE PRECURSORS. Dominic M. Desiderio*, Lin Yan, Genevieve Fridland, and Jih-Lie Tseng Department of Neurology and the Charles B. Stout Neuroscience Mass Spectrometry Laboratory, University of Tennessee, Memphis, 800 Madison Avenue, Memphis, TN, 38163.

The objective of this research program is to analyze selected human neuropeptidic systems, and to use mass spectrometry methods to provide the highest level of molecular specificity for qualitative and quantitative neuropeptide measurements. Recently, we have developed electrospray (ES) mass spectrometry methods to analyze intermediate-sized precursor molecules from proopiomelanocortin, POMC_{bovine, 1-265}, which contains BE. Gel permeation and RP-HPLC produced partially-purified fractions from bovine pituitary that showed ME-like immunoreactivity (ME-li) after treatment with trypsin and CNBr. ES-MS analysis of an immunoreactive fraction showed three major components, with M.W. of ca. 6550, 8440, and 9855. Trypsin treatment of this mixture, when analyzed by FAB-MS, showed the presence of ions at m/z 558 and 1134 (among others) which correspond to the tryptic peptides BE₂₀₋₂₄ (=POMC₂₅₄₋₂₅₈) and BE₁₀₋₁₉ (=POMC₂₄₄₋₂₅₃). After HPLC, all tryptic peptides will be sequenced by MS-MS so that the intermediate-sized precursors can be located within the preproenkephalin A_{bovine, 1-263} and the POMC_{bovine, 1-265} precursor molecules. NIH GM 26666.

A MODIFIED IMMUNO-POLYMERASE CHAIN REACTION METHOD TO MEASURE MINUTE CENTRAL NERVOUS SYSTEM ANTIGENS.

E.E. Bloom*, P.P. Sanna, E. Weiss, and E. Merlo Pich, Department of Neuropharmacology, The Scripps Research Institute, La Jolla, CA.

The immuno-polymerase chain reaction (I-PCR) system described recently (Sano, T. *et al.*, 1993, Science, 258:120-122) combines immunospecificity with PCR sensitivity to detect and quantify scant analytes. Originally, I-PCR was used to measure bovine serum albumin (BSA) immobilized on microtiter plates: a streptavidin-protein A fusion protein linked a reporter DNA to a specific anti-BSA antibody. The reporter DNA was then enzymatically amplified by PCR, greatly enhancing the sensitivity of a conventional ELISA assay. We have modified I-PCR and applied it to the measurement of TNF- α and other inflammatory peptides in the CNS. In our method, the target antigen is bound to a solid phase with an immobilized specific primary antibody. The captured antigen is then immunoreacted with a specific secondary antiserum (sandwich). These immune complexes are then incubated with a biotinylated tertiary antiserum which links the secondary antiserum to a biotinylated reporter DNA through an avidin bridge. The reporter DNA is then enzymatically amplified by PCR in the presence of a radiolabelled deoxynucleotide. The specific PCR products are then quantified by direct radioactivity measurement and microdensitometric analysis of the autoradiogram. Our I-PCR detects peptide in the pM concentration range, and may be useful for assessing any antigenic factor (i.e., cytokines, tumor antigens, etc.), especially in procedures such as intracranial microdialysis where sample volume is limiting. NEUROPEPTIDE IMMUNOLESIONS EFFECTS ON PEPTIDE LEVELS: IMPLICATIONS FOR NEURODEGENERATIVE DISORDERS. M.L.de Ceballos* and M.Pernas. Neurodegeneration Group, Cajal Institute, CSIC, Madrid, Spain.

Administration of peptide antisera to neonatal rats results in long-lasting changes in peptide content. Neuropeptides of interest were substance P (SP), met-enkephalin (met-enk) and neurotensin (NT), highly enriched in basal ganglia and known to be altered in Parkinson's and Huntington's diseases. Purified preimmune sera or antisera against SP (SP Ab), met-enk (met-enk Ab) or NT (NT Ab) (IgGs, 500 ug/rat sc) were given to P2 rats and peptide levels were measured by a combined HPLC/RIA method in striatum and substantia nigra of 3 month-old rats. Met-enk Ab administration decreased striatal met-enk and SP levels and nigral SP content. SP Ab reduced SP levels in striatum and s.nigra, met-enk in striatum but increased NT concentrations in s.nigra. NT Ab decreased nigral NT and striatal met-enk levels, while SP content was reduced in striatum but enhanced in s.nigra.

These results suggest colocalization of several peptides in striatum. Met-enk Ab and SP Ab administration reproduced some peptide alterations observed in degenerative diseases.

SELECTIVE PEPTIDASE INHIBITORS ENHANCE RECOVERY OF SUBSTANCE P AND CALCITONIN GENE-RELATED PEPTIDE RELEASED FROM RAT SPINAL CORD SLICES. J.L.Chen*, L.Barber, J.Dymshitz, M.R. Yasko. Dept. of Pharmacology & Toxicology, Indiana U. School of Medicine, Indianapolis, IN 46202.

The release of the neuropeptides, substance P (SP) and calcitonin gene-related peptide (CGRP) from sensory neurons is important in modulating nociception and inflammation. One potential problem in measuring release of these peptides is their rapid degradation by peptidases. This could significantly reduce the recovery of peptides released from neuronal tissues and contribute to the variability in results observed with different preparations. To determine whether peptidase activity affects the recovery of SP and CGRP, we studied the effects of various peptidase inhibitors on the release of these peptides from spinal cord slices.

Spinal cords from adult Wistar rats were rapidly removed, chopped into 300 micron pieces, and superfused with Krebs' buffer in the presence or absence of various peptidase inhibitors. Peptide release was stimulated by exposing the tissue to 500 nM capsaicin for 9 min. Superfusates were collected and assayed for SP and CGRP using radioimmunoassay. Release is reported as % of peptide content in the tissue/min.

The maximal recovery of peptides released from spinal cord slices was obtained by exposing the tissues to a combination of 20 µM bacitracin, 100 µM phenylalanylalanine (PHE-ALA) and 50 µM p-chloromercuriphenylsulfonic acid (PCMS). Resting and capsaicin-stimulated release of SP were 0.11±0.03 % and 0.44±0.06 %, respectively. Resting CGRP release was 0.20± 0.02 %, whereas capsaicin-stimulated release was 0.90± 0.11 %. When slices were exposed to 20 µM bacitracin alone or in combination with 1 µM phosphoramidon and 10 µM thiorphan, resting release of both peptides was approximately 5-fold less, while capsaicin-evoked release was approximately 2-fold less than maximal.

The results demonstrate that recovery of peptides released from spinal cord slices is dependent in part on peptidase activity. Moreover, the amount of peptides recovered during release experiments may vary depending on the specific peptidase inhibitors utilized. (Supported by PHS DA07176)

TIME-COURSE ADMINISTRATION OF NEUROLEPTICS DECREASES REGIONAL NEUROTENSIN METABOLISM IN INTACT RAT BRAIN SLICES. C.S.Konkoy* and T.P.Davis. Dept. Pharmacology, Univ. Arizona, Tucson, AZ 85724.

Treatment with antipsychotic agents has been shown to affect both neurotensin levels and the activities of enzymes implicated in the metabolism of neurotensin. In the present study, the effects of intraperitoneally administered antipsychotics and dopaminergic agents on neurotensin (NT) metabolism were examined in intact slices isolated from micropunched regions of rat brain. Significant degradation of NT 1-13 with the concomitant production of NT fragments, including NT 1-8, NT 1-11, and NT 9-13, occurred after incubating for 2h regionally dissected microslices with 100 µM NT 1-13. Degradation was high (nearly 50%) in nucleus accumbens (NA) and caudate-putamen (CP) and much lower in hippocampus and frontal cortex. Administration (i.p.) of haloperidol (3 mg/kg) 1h prior to slice preparation had no effect on levels of degradation in slices isolated from any of the four regions. Administration (i.p.) of haloperidol (3 mg/kg) or chlorpromazine (20 mg/kg) 24h prior to slice preparation significantly reduced the degradation of neurotensin in slices isolated from NA. Levels of degradation remained significantly reduced at 48h after haloperidol administration but returned to that of control levels at 96h. Neurotensin degradation in slices isolated from CP decreased following administration of haloperidol (3 mg/kg, 48h) or chlorpromazine (20 mg/kg, 24h), and increased following administration of methamphetamine (2 i.p. injections of 15 mg/kg, 12h). These data suggest that drugs which affect dopaminergic transmission influence the metabolism of neurotensin in specific brain regions. (Supported by NIH grant MH42600).

ACCUMULATION OF ADRENAL NEUROPEPTIDES AFTER ANTIBODY-MEDIATED DENERVATION. S. Brimijoin¹, A. Dagerlind², T. Hökfelt², P. Hammond¹ and G. M. Tyce^{1*}. ¹ Depts. of Pharmacology and Physiology, Mayo Clinic, Rochester MN 55905; ² Department of Histology, Karolinska Institute, Stockholm, Sweden.

Surgical denervation of the rat adrenal gland is known to cause accumulation of certain neuropeptides in chromaffin cells. We used radioimmunoassay to measure NPY-like immunoreactivity (NPY-IR) and methionine-enkephalin-like immunoreactivity (Met-Enk-IR) in adrenals from rats treated with anti-acetylcholinesterase IgG. This treatment destroys the cholinergic input from preganglionic sympathetic nerves. Within 2 days of antibody injection, Met-Enk-IR in the adrenal gland increased 9-fold, while NPY-IR increased 50%. The peptide response could reflect: 1) the chronic synaptic inactivation that follows the degeneration of presynaptic terminals, or 2) the acute activation that accompanies terminal degeneration. To test these possibilities, the experiment was repeated in the presence of two drugs that, together, block muscarinic and nicotinic receptors (atropine, 4 mg/kg/day + chlorisondamine, 20 mg/kg/day). When the drugs were given alone by osmotic infusion for 2 or 4 days, adrenal Met-Enk-IR was unchanged, while NPY-IR fell by 30%. Measurements of urinary catecholamine excretion showed that drug treatment did prevent the paroxysmal release of norepinephrine and epinephrine that normally follows injection of acetylcholinesterase antibodies. The treatment also prevented the antibody-induced rise in adrenal NPY-IR, but it did not reduce the rise of Met-Enk-IR. We conclude that different transsynaptic mechanisms are responsible for regulating Met-Enk and NPY in adrenal chromaffin cells. (Supported by Grant NS29646).

A NOVEL TRANSCRIPT ENCODING A SECRETED PROTEIN IS REGULATED BY SECRETAGOGUES IN THE PITUITARY. B.T. Bloomquist, D.N. Darlington, and B.A. Eipper*. Dept. Neuroscience, The Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

Gene regulation was studied in rat intermediate pituitary melanotropes consequent to 21 day chronic exposure to bromocriptine or haloperidol. These secretagogues are known to affect the expression of transcripts involved in the regulated secretory pathway. A novel transcript (#45) which has many characteristics of a secreted protein has been isolated. Expression of #45 mRNA is limited to neuroendocrine cell lines and tissues; tissue *in situ* hybridization analysis has shown #45 mRNA to be highly abundant in both the intermediate and anterior pituitary as well as in the paraventricular nucleus. Northern blot analysis and DNA sequencing have shown the #45 transcript to be about 720 basepairs in length not including the poly(A) tail. The cognate translation product of #45 would be 175 amino acids in length containing a putative signal sequence of about 30 amino acids. The mature sequence would contain two dibasic amino acid sites, two cysteine residues, one potential sulfation site, but no glycosylation sites. Neither the nucleic acid nor the amino acid sequences show any homology to reported sequences. *In vitro* translation has confirmed the presence of a signal sequence which, when cleaved, reduces the size of the *in vitro* translation product from 20 kDa to 18 kDa. Although #45 is coregulated with POMC, PAM, PC1, PC2, and CPE by dopaminergic input in the intermediate pituitary, #45 is regulated inversely to them in response to dexamethasone or CRH treatment in AT-20 cells. Support: DA-00266, -00098, -05404, and Scottish Rite.

CORRELATION BETWEEN TOLERANCE IN NEUROTENSIN GENE EXPRESSION AND CATALEPTIC RESPONSE IN RATS FOLLOWING CONTINUOUS HALOPERIDOL TREATMENT. K.M. Merchant* and D.J. Dobbie. Dept. of Psychiatry, Univ. of Washington, Seattle, WA 98195.

Our previous studies have demonstrated that only cataleptogenic antipsychotic drugs increase the expression of neurotensin/neuromedin N (NT/N) mRNA in the dorsolateral striatum (DLS) of the rat. Interestingly, this response of the NT neurons was significantly reduced following chronic (28 d) continuous administration of the neuroleptic, haloperidol. The present study examined the time course of tolerance in the NT/N mRNA expression after continuous haloperidol treatment and its correlation with cataleptic behavior in the same animals. Male Sprague Dawley rats were treated with haloperidol (1 mg/kg/d) or saline via subcutaneously implanted osmotic minipumps for 3, 7, 14 or 28 days. For comparison, separate groups of rats were given a single IP dose of haloperidol or saline and sacrificed at 1 or 7 hours after the treatment. Cataleptic response was studied by the horizontal bar test at 24 and 48 hr after commencing the treatment and again on the day of the sacrifice. Neostriatal gene expression was examined by *in situ* hybridization histochemistry.

Induction of NT/N mRNA levels in the DLS and catalepsy occurred after the acute treatment with haloperidol and appeared to persist following 3 days of continuous drug administration. However, by 7 days of drug treatment significant tolerance in both NT/N mRNA and cataleptic responses was observed. Statistically significant correlation was observed between tolerance in NT/N mRNA levels and that in cataleptic scores of each animal suggesting that haloperidol's induction of NT/N gene expression in the DLS may contribute to the drug-induced catalepsy. To investigate further the specificity of the apparent correlation between NT/N gene expression and cataleptic behavior, alterations in the expression of enkephalin and tachykinin genes in adjacent brain sections were examined and compared with those in NT/N mRNA. (Support: Scottish Rite Schizophrenia Research Program)

FACTORS REGULATING PRODUCTION OF NEUROPHYSIN BY NEUROENDOCRINE TUMORS. Andrew S. Friedmann, Michael J. Fay, Xiaoming Yu, Vincent Memoli and William G. North. Departments of Physiology and Pathology, Dartmouth Medical School, Lebanon, N.H. 03756. Tumor production of neurophysin (HNP) is abnormal and leads to the formation of Neurophysin-Related cell-Surface Antigen (NRSA) that becomes incorporated into the plasma membrane of the tumor cells. Recently, the levels of vasopressin mRNA in one long-term culture derived from small-cell carcinoma of the lung (SCCL) were found to be influenced by glucocorticoids and cAMP. In this study we used another long-term culture of SCCL (H 69) and examined the influence of: isobutyl-methylxanthine (IBMX, 5×10^{-4} M) plus forskolin (FSK, 25×10^{-6} M); IBMX and 8-bromo-cAMP (5×10^{-4} M); dexamethasone (DEX, 1×10^{-7} M); and a combination of IBMX, 8-bromo-cAMP, and DEX on the expression by these cells of immunoreactive HNP using quantitative immunocytochemistry. Cells were incubated with reagents or vehicle for 2 to 8 days. They were then fixed in acetone, reacted with affinity-purified rabbit polyclonal antibodies to HNP, and processed using the avidin-biotin method that included staining through peroxidase oxidation of 3,3'-diaminobenzidine (DAB). Staining for HNP was quantitated with a microcomputer imaging devise by relating the total area of scanned cells (AT) to the area stained for HNP (AS). Results demonstrate that glucocorticoids alone decrease the expression of neurophysin by SCCL, while cAMP increases this expression. Of particular interest was the finding that glucocorticoids, when used in combination with reagents that increase cellular cAMP, actually enhance the positive influence these reagents have on neurophysin expression by SCCL.

MICRODIALYSIS OF NEUROPEPTIDE Y USING THE DIFFERENCE METHOD. A.C. Thompson¹, J.B. Justice, Jr.², & J.K. McDonald¹. Dept. of Anatomy & Cell Biology¹, Emory Univ. Sch. of Med., & Dept. of Chemistry², Emory Univ., Atlanta, GA 30322.

Measurements of neuropeptide Y (NPY) by conventional microdialysis methods have been complicated by low levels of NPY recovery (< 1.5%, *in vitro*). An alternative microdialysis technique is the difference method (Lönnerth et al., *Am. J. Phys.*, 256:E250-E255, 1989) in which the estimate of extracellular concentration is determined independently from the level of recovery. We have tested the feasibility of using the difference method to measure NPY *in vitro*.

Several conc. of NPY (4.2- 58.9 pg/ μ l) were perfused serially through 3 microdialysis probes (1, 2, & 5 mm of active dialysis membrane) placed in an NPY solution (mean conc. 14.6 +/- 2.1 pg/ μ l) at room temperature (unstirred). Five 15-min samples were collected at each perfusate conc. (flow rate = 1 μ l/min) and assayed for NPY by RIA. The difference between NPY levels (C) in the perfusate (C_{in}) and NPY levels in the dialysate (C_{out}) were determined and the relationship between C_{in}-C_{out} and C_{in} was assessed by linear regression. The resulting regression lines were found to predict reliably the conc. of NPY in the solution surrounding the dialysis probe (predicted conc. 14.5 +/- 2 pg/ μ l vs. actual conc. 14.6 +/- 2.1 pg/ μ l). In contrast, conventional microdialysis (no NPY in the perfusate) yielded undetectable levels of NPY. Thus, using the difference method shifted the conc. of the samples into the detectable range of the assay, and also provided an estimate of the solution conc. The former represents a new application of the difference method.

These results show that the difference method improves the measurement of NPY by microdialysis *in vitro*, and may be a useful method for NPY microdialysis *in vivo*.

DESIGN AND ANALYSIS OF A CONFORMATIONALLY CONSTRAINED CYCLO(16, 20)-[Lys¹⁶, Asp²⁰]-BETA-ENDORPHIN ANALOGUE.

M.A. Scheideler¹ and J.W. Taylor Pharmaceuticals Division, Novo Nordisk A/S, 2760 Måløv, DENMARK¹ and Dept. of Chemistry, Rutgers State University, Piscataway, NJ 08855.

The 31-residue Beta-endorphin peptide is thought to consist of three basic structural units: The N-terminal (Met)enkephalin pentapeptide, a linker region (residues 6-12) and a potential C-terminal amphipathic sequence (residues 13-27) that contributes both to the receptor selectivity and potency of Beta-endorphin (properties reviewed by J.W. Taylor and E.T. Kaiser (1986) *Pharm. Rev.* 38, 291-315).

A Beta-endorphin analogue that is side-chain bridged in the C-terminal region was synthesized with the aim of confirming the requirement for an amphipathic helix, and establishing its role in receptor binding and signal transduction efficiency. CD spectra showed that this analogue possesses increased helical character in water. Receptor binding was comparable to that of Beta-endorphin (human) in a rat brain assay selective for the mu-opioid receptor, and in a neuroblastoma cell line (F11) which expresses this receptor. The peptides efficacy in inhibiting cAMP synthesis in F11 cells closely matched its affinity at the mu-opioid receptor expressed by these cells.

REGULATED SECRETION OF CGRP FROM THE CATECHOLAMINERGIC VESICLES OF TRANSFECTED PC12 CELLS. E. S. Schweitzer* and C.-J. Jeng. Dept. of Anatomy & Cell Biology, UCLA Medical School, Los Angeles, CA 90024.

We have introduced a construct (pTNDcal) containing the rat calcitonin gene under the control of the RSV LTR into PC12 cells. We examined the sorting and secretion of CGRP in stably transfected clones of this neuronal cell line by subcellular fractionation, immunofluorescence microscopy, and stimulation-release experiments. CGRP was quantitated using an RIA that is selective for CGRP and which does not detect calcitonin.

When transfected cell homogenates were subjected to fractionation on sucrose/ficoll density equilibrium gradients, the CGRP copurified with markers for the large, dense-core secretory vesicles that contain catecholamines. The CGRP did not appear to be associated with other vesicles, including the low-density cholinergic vesicles or the small, clear, synaptophysin-rich vesicles.

This localization was confirmed by double-label immunofluorescence microscopy, which indicated that the CGRP colocalized with secretogranin I, a marker for the catecholaminergic vesicles, but not with synaptophysin or SV2.

Carbachol-induced depolarization of transfected cells caused a dramatic increase in the rate of secretion of CGRP, similar to that observed previously for the endogenous transmitter norepinephrine or transfected human growth hormone. We therefore conclude that the CGRP is selectively packaged into the catecholaminergic vesicles of PC12 cells, from which it is released in a highly regulated manner.

Enzymatic Conversion of Pro-drug Forms of [D-Pen², D-Pen⁵]Enkephalin and [D-Pen², L-Cys⁵]Enkephalin. D.L. Greene*, V.S. Hau, V.J. Hruby, and T.P. Davis. Depts. of Pharmacology and Chemistry, The Univ. of Ariz., Coll. of Medicine, Tucson, AZ 85724.

To improve the blood-brain barrier (BBB) penetration of δ opioid receptor peptides [D-Pen², D-Pen⁵]Enkephalin (DPDPE) and [D-Pen², L-Cys⁵]Enkephalin (DPLCE), various pro-drug forms were synthesized to increase lipophilicity and drug delivery to the brain. This study examined the *in vitro* conversion of these pro-drug forms in serum and brain homogenate. Blood was collected from the rat/mouse abdominal aorta for serum harvesting and the brain resuspended at a 15% protein concentration. The peptide was added at a 100 μ M concentration to the serum or brain. The samples (in triplicate) were incubated at 37 \pm 0.1°C for 0, 30, 60, 120, and 240 min, and acetonitrile was added to stop all enzymatic metabolism. The samples were centrifuged, and supernatant was analyzed by HPLC. Resultant metabolic T_{1/2} (min) of the compounds examined are shown in the following table: These results show that

Pro-drug form	Peptide Structure	100% Serum	15% Brain
DPDPE	Phe-DPDPE	6.82	3.94
DPLCE have longer metabolic/ conversion half-lives in the serum than in the brain. Since the blood would carry these compounds to the brain, a longer half-life of conversion	DPDPE-Phe-Ala-NH-C ₆ H ₁₃	446.07	348.63
	N,O diacetyl-Phe-DPDPE	12.10	7.75
	Asp ⁶ -DPDPE	294.00	33.54
	DPLCE-Phe-OH	176.35	102.30
	DPLCE-Arg-Pro-Ala	316.57	9.21
	DPLCE-Arg-Gly-OH	53.08	40.45

in the serum than in the brain would allow more time for the pro-drugs to cross the BBB and be cleaved to the parent compound. Therefore, Asp⁶-DPDPE show the most promising results as a pro-drug of DPDPE and DPLCE-Arg-Pro-Ala is the most promising pro-drug of DPLCE. (N.I.D.A. #DA06284)

A TEN-FOLD MORE POTENT VIP AGONIST THAT DIFFERENTIATES TWO CNS VIP RECEPTORS. I. Gozes, G. Lilling, A. Davidson*, M. Fridkin and D.E. Brenneman. Chem. Path., Sackler Med. School, Tel Aviv Univ.; Israel; Weizmann Inst., Israel; Dev. Mol. Pharmacol. LDN, NICHD, NIH, Bethesda, MD, USA.

Vasoactive intestinal peptide (VIP) recognizes two functionally distinct receptors in the CNS, a low affinity receptor mediating VIP increases in cAMP formation and a high affinity receptor mediating VIP-associated maintenance of neuronal survival (*J. Pharmacol. Exp. Therap.* 257:959,1991; *J. Mol. Neurosci.* 4:1,1993). We have synthesized a conjugate of VIP and stearic acid (st-VIP; *J. Clin. Invest.* 90:810,1992), as a potential drug for noninvasive impotence treatment. We now show that st-VIP was 10-fold more potent than VIP in protecting spinal cord neurons against neuronal cell death induced by electrical blockade. This effect was sustained over a wide concentration range, in contrast to the VIP effect, which exhibited a narrow range of efficacy. Also, unlike VIP, st-VIP did not stimulate cAMP formation in astroglia. Binding experiments indicated increased affinity of st-VIP at the high affinity receptor and a decreased affinity to the cAMP-associated binding site. This strategy opens new avenues for design of analogues of therapeutic value. Supported by Fujimoto Corp.

NON RADIOACTIVE ASSAY FOR PROTEIN PHOSPHATASE 2B (CALCINEURIN) ACTIVITY USING A PARTIAL SEQUENCE OF THE SUBUNIT OF cAMP DEPENDENT PROTEIN KINASE AS SUBSTRATE. A. Enz*, G. Shapiro, M. Zurini and M. Luyten, Preclinical Research SANDOZ PHARMA Ltd., CH-4002 Basle/Switzerland.

Calcineurin is a Ca^{2+} /calmodulin dependent protein phosphatase (protein phosphatase 2B) regulating the dephosphorylation step of phospho-proteins, which play important roles in neurotransmission and immunosuppression. A suitable i.e. quite specific substrate for calcineurin is a partial sequence of the R-II subunit of cAMP dependent protein kinase. The current assay for the determination of calcineurin activity is based on the measurement of the release of ^{32}P -phosphate from this peptide following its phosphorylation with ^{32}P -ATP, catalyzed by the catalytic subunit of cAMP dependent protein kinase. This very sensitive method consumes a high amount of radioactivity and is therefore problematic as screening method for calcineurin inhibitors. We developed an alternative non radioactive enzyme assay where both reactions, phosphorylation by protein kinase and dephosphorylation by calcineurin, are controlled and monitored by the simultaneous quantitative determination of phosphorylated and nonphosphorylated peptide using HPLC on RP18 columns and UV detection. The method allows the measurement of enzyme kinetics as well as the characterization of potential inhibitors. Examples of calcineurin inhibition by several derivatives of the immunosuppressant cyclosporine complexed with the corresponding binding proteins and compounds known from the literature will be presented. The method, although less sensitive than the radioactive, is an attractive alternative, since calcineurin is commercially available and the substrate is easily accessible in sufficient amounts. An important advantage of this new method, in addition to the obviation of radioactivity, is the higher specificity (better identification of substrate and product).

PEPTIDES: BIOSYNTHESIS, METABOLISM, AND BIOCHEMICAL CHARACTERIZATION III

C-fos MEDIATES THE INCREASE IN STRIATAL NEUROTENSIN mRNA PRODUCED BY HALOPERIDOL. G.S. Robertson*, Department of Pharmacology, University of Ottawa, Ottawa, Ontario, Canada, K1H 8M5.

A single injection of the antipsychotic haloperidol dramatically elevates mRNA encoding the neuropeptide neurotensin (NT) in the dorsolateral striatum. This increase is preceded by enhanced expression of Fos, the product of the immediate-early gene *c-fos*. In order to determine whether these events are related, we examined a) the overlap between haloperidol-induced Fos-like immunoreactivity (FLI) and NT mRNA and b) the effect of inhibiting Fos expression on the haloperidol-induced increase in NT mRNA in the dorsolateral striatum. Nuclei displaying FLI were frequently found in striatal neurons expressing elevated levels of NT mRNA 2 hr after haloperidol (4 mg/kg). Injection of an antisense phosphorothioate oligonucleotide to *c-fos* into the striatum, 14 hrs prior to haloperidol administration (4 mg/kg), reduced both FLI and the *in situ* hybridization signal for NT mRNA observed in the dorsolateral striatum 2 hrs after haloperidol. However, the antisense oligonucleotide did not reduce either Jun-like immunoreactivity or enkephalin mRNA in adjacent sections. Furthermore, infusion of a sense phosphorothioate oligonucleotide to *c-fos* into the striatum did not reduce the increase in FLI and neurotensin mRNA produced by haloperidol (4 mg/kg). These results are consistent with the proposal of Merchant et al. (J. Neurosci., 12: 652, 1992) that *c-fos* mediates the increase in NT mRNA produced by haloperidol.

561.3

REGULATION OF THE TRANSCRIPTIONAL ACTIVITY OF DYNORPHIN AND TACHYKININ GENES IN RAT STRIATUM: A STUDY WITH DOPAMINE UPTAKE INHIBITOR GBR-12909. S.P. Sivam*, Department of Pharmacology & Toxicology, Indiana University School of Medicine, 3400 Broadway, Gary IN 46408.

This study examined the influence of the neurotransmitter, dopamine on the regulation of prodynorphin (PD) and preprotachykinin (PPT) peptidergic gene expression in the rat striatum. The dopamine uptake inhibitor, GBR-12909 (GBR) was administered daily (20 mg/kg) for one, two or four days to different groups of female Sprague-Dawley rats. The animals were killed one hour after injection. Striatal tissues were used for the biochemical determinations. The levels of peptides, dynorphin A (1-8) (DYN) and substance P (SP) were determined by radioimmunoassays. The abundance of PD-mRNAs and PPT-mRNAs was quantified by Northern blot analysis. The rate of transcription of PD and PPT genes was assessed by a nuclear transcription run-on assay using a nuclei preparation derived from fresh or frozen striatal tissue. The ^{32}P -labeled mRNA transcripts generated by the transcription run-on reaction were purified and hybridized to a slot-blotted membrane containing plasmids with rat cDNA for PD or PPT genes. GBR administration produced time-related increases in the levels of DYN and SP as well as PD-mRNA and PPT-mRNA. The increases in peptide and mRNA levels were temporally preceded by an induction of the rate transcription of PD and PPT genes as evidenced from the transcription run-on assays. The results further support the hypothesis that an enhanced dopaminergic activity positively regulate peptidergic activity in striatonigral DYN and SP neurons. Supported by USPHS grant NS26063.

RAT BRAIN TRANSGLUTAMINASE. Y. Takeuchi**, P. J. Bircbichler+, M. K. Patterson, Jr.+, B. Howell+ and Y. Ito#. +Biomed. Div. The Samuel Roberts Noble Fnd., Ardmore, Ok 73402 and #Tsukuba Res. Inst. in collaboration with Merck Res. Lab., Banyu Pharm. Co., Ltd., Tsukuba 300-33, JAPAN.

Transglutaminase (TGase) in neuronal system has been suggested to be involved in neurotransmitter release, long term potentiation, regeneration after nerve injury, and so forth. In order to have molecular basis on the enzyme in central nervous system, the enzyme was partially purified from the centrifugal supernatant of rat brain homogenate by ion-exchange, gel filtration and GTP-agarose affinity column chromatography. We found that two proteins with apparent molecular weight of 75-79kDa and 48kDa, respectively, which were immunopositive against tissue-type TGase. However, these proteins were not enzymatically active. GTP affinity chromatography showed that there are two different types of brain TGase. Partially purified enzyme was not immunologically detected by antibodies against various types of TGase including tissue type TGase, epidermal TGase and factor XIIIa. The results may suggest a novel type of TGase in mammalian brain.

561.2

EXPRESSION OF THE PROHORMONE-CONVERTING ENZYME GENE, PC2, IN *XENOPUS* BRAIN: POSSIBLE CO-LOCALIZATION WITH PRO-TRH IMMUNOREACTIVE NEURONS IN BRAINSTEM. L. P. Pu, S. Ghose, E. A. Neale*, J. F. Mill, W. P. Hayes and Y. P. Loh, Labs. of Dev. Neurobiology (NICHD) and Molec. Biology (NINDS), NIH, Bethesda, MD 20892.

Prohormone processing at paired-basic residues has been shown to be tissue-specific. However, it is as yet unclear which processing enzymes are involved for each prohormone. In mammal, neural and endocrine tissues express the prohormone convertase, PC2, which has been shown to appropriately cleave several prohormones (eg., POMC, insulin) at paired-basic residues. To better understand neuropeptide biosynthesis at the level of processing, we have studied the expression of PC2 with respect to its anatomical relationship with the pro-TRH system in frog brain.

Xenopus pro-TRH can generate up to 7 TRH tripeptides via cleavage at paired-basic residues (Bulant et al. 1992, *FEBS* 296, 292-296). Using a 600 base probe made by PCR and the published *Xenopus* PC2 sequence (Braks et al. 1992, *FEBS* 305, 45-50), RNA blots of frog brain showed two bands of ~3 kb and ~5 kb, which is similar to mammal. Moreover, our *in situ* hybridization histochemical studies using a cRNA probe, detected high levels of PC2 gene expression widely in *Xenopus* brain. Some of the highest concentrations of PC2 mRNA were found in known neuropeptide-rich brain regions, including some but apparently not all areas that also express TRH.

Colocalization studies of pro-TRH by immunocytochemistry using specific antiserum (pCC10) (Jackson et al., 1985, *Science* 229, 1097-1099) in combination with the PC2 cRNA probe produced the preliminary finding that PC2 may be colocalized with pro-TRH immunoreactive neurons in at least some brainstem regions. The evidence for a wide distribution of PC2 mRNA in frog brain and its possible colocalization with pro-TRH immunoreactivity in some neurons suggests that PC2 may be involved in the biosynthesis of TRH, as well as other neuropeptides in the CNS.

561.4

SUB-REGIONAL EFFECTS ON NEOSTRIATAL NEUROPEPTIDE EXPRESSION BY ADRENAL GLUCOCORTICOIDS AND CHOLINERGIC TONE. J. Angulo*, M. Ledoux and B. McEwen, *Dept. Biological Sciences, Hunter College of CUNY, New York NY 10021 and Lab. of Neuroendocrinology, The Rockefeller University, New York NY 10021.

We have evaluated the effect of cholinergic tone and glucocorticoids on the expression of protachykinin (PT) and proneurotensin (PNT) mRNAs in the caudate-putamen (CPU) and accumbens (NAc) of the rat brain by *in situ* hybridization histochemistry. Removal of circulating adrenal steroids by bilateral adrenalectomy (ADX) decreased PT mRNA abundance in the dorsal aspect of the CPU (22% below sham controls) and this decrease was blocked by corticosterone (CORT) replacement. PT mRNA in the ventral CPU was unaffected by either ADX or CORT. In addition, administration of the cholinergic antagonist scopolamine to ADX rats increased PT mRNA in dorsal CPU 33% above sham. Concurrent administration of CORT and scopolamine increased this message 80% above sham. No effects were observed in ventral or anterior CPU and NAc. In contrast, PNT mRNA abundance was decreased by ADX in ventral and dorsal aspects of the CPU (CORT replacement blocked this effect in both areas). Scopolamine alone or with CORT elicited no effect. These results demonstrate that circulating adrenal steroids and cholinergic tone affect neuropeptide expression in regionally-specific compartments of the striatum.

ACUTE RESERPINE TREATMENT DECREASES EXPRESSION OF PPT mRNA IN RAT STRIATUM. S.Kumar, M.B.Harrison*, C.A.Hubbard and J.M.Trugman. Dept. of Neurology, Univ. of Virginia, Charlottesville VA 22908.

Acute dopamine (DA) depletion with reserpine and AMPT enhances D1 agonist stimulation of regional cerebral glucose utilization in the substantia nigra pars reticulata within 24 hrs. This is one indicator of denervation supersensitivity and reflects heightened metabolic activity in striatonigral neurons. To determine if alterations in neuropeptide expression could be involved in acute development of supersensitivity, we examined expression of preproachykinin (PPT) and preproenkephalin (PPE) mRNA in the striatum 6 and 24 hrs following a single dose of reserpine. 11 rats received reserpine (5 mg/kg i.p. at time 0) and AMPT (100 mg/kg i.p. at 5 or 23 hrs) and were killed at 6 (n=6) or at 24 hrs (n=5), with 6 controls receiving vehicle. This protocol has been shown to produce 98-99% DA depletion. Alternate sections were processed for *in situ* hybridization with ³⁵S-labelled oligonucleotide probes for PPT and PPE mRNA, exposed to film and optical density values (OD) determined. Neither PPT nor PPE mRNA expression differed from control at 6 hrs (OD mean±se: PPT control 0.328±.027, 6 hr 0.342±.027; PPE control 0.423±.018, 6 hr 0.444±.028). At 24 hrs PPT mRNA expression had decreased to 62% of control (OD 0.202±.013; p<.002, ANOVA) while PPE was unchanged (OD 0.443±.023). In chronic DA depletion, PPT mRNA decreases and PPE increases. In the present study, the acute effects of DA depletion are selective for PPT. PPT mRNA is localized to striatonigral neurons which preferentially express D1 receptors and its product, Substance P, stimulates ACh release from striatal interneurons and increases DA release from nigrostriatal terminals. The selective decrease in PPT mRNA within 24 hrs of acute DA depletion suggests that decreased Substance P synthesis may mediate or correlate with enhanced sensitivity to D1 receptor stimulation.

561.7

BRAIN PROTEOLYSIS OF OXYTOCIN "IN VITRO" AND "IN VIVO" CHANGES DURING AGING IN MALE RATS. R. Stan-campiano, M.R. Melis & A. Argiolas*. Bernard. B. Brodie Dept. Neurosci., Cagliari Univ., 09124 Cagliari, Italy.

Oxytocin proteolysis was studied "in vitro" with purified synaptic membranes and "in vivo" after injection into the hippocampus of male Wistar Kyoto rats of different ages. When oxytocin was incubated "in vitro" with brain synaptic membranes obtained from 2, 6, and 12 month-old rats, no difference in the content of C-terminal and N-terminal fragments formed by aminopeptidase-like and endopeptidase-like enzymes, respectively, was found after HPLC separation and quantification by amino acid analysis. In contrast, the content of all fragments decreased by about 20-25% when membranes obtained from 18 and 24 month-old rats were used. When [³H-Tyr²]oxytocin was injected "in vivo" in the hippocampus of 2, 6, 12 and 18 month-old rats, no difference in the content of free [³H]-tyrosine and other [³H]-labelled fragments was found in the hippocampal peptidic extract after HPLC fractionation. However, the content of all radioactive fragments was about 50% lower in the extract from 24 month-old rats. The results suggest that oxytocin proteolysis in brain decreases during aging.

561.9

PITUITARY ADENYLATE CYCLASE ACTIVATING POLYPEPTIDES STIMULATE SUPERIOR CERVICAL GANGLION NEUROPEPTIDE Y AND CATECHOLAMINE EXPRESSION AND SECRETION. V. May*, C.A. Brandenburg and K.M. Braas. Dept. of Anatomy & Neurobiology, University of Vermont College of Medicine, Burlington, Vermont 05405.

The expression of specific superior cervical ganglion (SCG) neurotransmitters and neuropeptides in primary neuronal cultures is stimulus-dependent. Pituitary adenylate cyclase activating polypeptides (PACAP38 and PACAP27) stimulate neuronal differentiation and second messenger levels in sympathoadrenal cells. The regulation of SCG neuropeptide Y (NPY) and catecholamine expression and secretion by PACAP38, PACAP27 and VIP was examined in SCG neuronal cultures. Neurons were treated with 10⁻¹¹ to 10⁻⁸ M peptide for 2 to 25 days. NPY and catecholamine/tyrosine hydroxylase content, secretion and mRNA levels were compared. Nanomolar concentrations of PACAP27 and PACAP38 maximally stimulated sustained SCG neuronal NPY secretion throughout the 25 day treatment, while VIP required 1000-fold higher concentrations. The NPY secretory rate in PACAP treated neurons was 615.8 pg/ml medium/h compared to 67.25 pg/ml/h for control cells; secretion was linear with time. Neither PACAP38 nor PACAP27 changed SCG cell NPY content, although 10-fold stimulation of secretion was elicited. In contrast, NPY mRNA levels were increased by PACAP treatment. PACAP elicited concentration-dependent sustained stimulation of catecholamine secretion, similar to the stimulation of NPY secretion. Half-maximal release was attained with 10 nM PACAP38; maximal release at 100 nM PACAP38 was increased 6-fold. PACAP thus appears to be an important regulator of SCG NPY and catecholamine expression and secretion. (Supported by HD-27468)

OPPOSITE CHANGES IN TRH AND ITS DEGRADING ENZYME PYROGLUTAMATE AMINOPEPTIDASE II, DURING DEVELOPMENT OF KINDLING. P.de Gortari*, A. Fernández-Guardiola#, A.Martínez#, M. Cisneros*, J.L.Chari# and P.Joseph-Bravo**. #Inst. Biocología, Universidad Nacional Autónoma de México; #Inst. Mexicano de Psiquiatría and +U. Iberoamericana.

Pyroglutamate aminopeptidase II (PPII) is a neuronal ectoenzyme responsible for TRH degradation at the synaptic cleft. PPII is regulated under different endocrine conditions where TRH is involved (hyperthyroidism, estrous cycle) but only at the adenohipophyseal level; in vitro, TRH can downregulate PPII activity. TRH present in extrahypothalamic brain areas has been postulated to serve as a neuromodulator and levels of this peptide increase in amygdala, hippocampus and cortex after electrical stimulation. We were interested in studying whether brain PPII could be regulated in conditions that stimulate TRHergic neurons such as kindling. Male Wistar rats with indwelling bipolar electrodes placed in left temporal lobe amygdala (AM) and frontal cortex; amygdalae after discharge established (average 300 uAmp) and kindling (1sec, 60Hz, 1msec pulses) induced by daily electrical stimulation. EEG activity, duration and frequency of AM after discharge measured. Animals were sacrificed in behavioural kindling stages II, IV and V, brains kept at -80C. Regions (amygdala, hippocampus, n. accumbens, frontal cortex, medulla oblongata and hypothalamus) were dissected and assayed for TRH and PPII activity. TRH levels increased from stage II to V in amygdala, hippocampus and frontal cortex being significantly higher than sham animals. In n. accumbens a significant decrease, compared to sham was observed at stage II, but increased throughout to stage V. In contrast, PPII activity increased considerably at stage II in all regions studied, compared to sham, decreasing thereafter (amygdala data-table). These results suggest that PPII activity in the central nervous system can be regulated in conditions known to affect TRHergic neurons. Supported by DGAPA-UNAM.

	SHAM	II	IV	V
(TRH mg/prot)	585 ± 140	984 ± 118	980 ± 108	1105 ± 37
(PPII sp.act)	0.8 ± 0.3	7.3 ± 0.3	6.8 ± 0.9	2.1 ± 0.4

561.8

IN VIVO INDUCTION OF RAT C-FOS AND PREPROENKEPHALIN (PPENK) mRNAs BY PROTEIN SYNTHESIS INHIBITORS (PSI). Y.-S. Zhu* and C.E. Inturrisi. Dept. of Pharmacology, Cornell U. Med. College, New York, NY 10021.

In vivo, labile repressor(s) may regulate the immediate-early gene, c-fos. By use of specific, rapid and sensitive solution hybridization assays and Northern blot analysis, we demonstrate that treatment with PSI, either cycloheximide (CHX) or anisomycin (ANI), increased the levels of c-fos mRNA in the adrenal, liver, spinal cord, hippocampus and striatum, while the increase in PPenk mRNA was limited to adrenal and liver. Within 1 h after CHX (4 mg/kg, sc), c-fos mRNA was increased 20 fold and at 3 h it reached a peak 30 fold compared to saline and by 6 h it had declined to 10 fold. In contrast, PPenk mRNA was unchanged at 1 h after CHX, had increased 6 fold at 3 h and reached a peak (13 fold) at 6 h. A similar time course was observed after ANI treatment. Northern blot analysis indicates that the size of the c-fos & PPenk mRNAs was not altered by PSI. In adrenal, the CHX-induction of c-fos and PPenk mRNAs was dose-dependent in the range of 1 to 50 mg/kg, sc. Unilateral adrenal denervation did not alter the CHX-induction of c-fos or PPenk mRNAs in either adrenal medullae or cortex. These effects of PSI, which are tissue and gene specific, may be mediated by labile repressor(s) which regulate c-fos and PPenk gene expression *in vivo*. Supported by DA01457.

EXAMINATION OF THE ROLE OF THE GABAergic SYSTEMS IN REGULATION OF STRIATAL NEUROTENSIN GENE EXPRESSION IN THE RAT by K.P. Decker*, P.Roy-Byrne, and K.M. Merchant. Department of Psychiatry, ZA-99, HMC, University of Washington, Seattle, WA 98104.

Acute neuroleptic administration has been shown to increase expression of neurotensin/neuromedin (NT/N) gene in the dorsolateral striatum and nucleus accumbens. The purpose of the present study was to examine modulation of these neuroleptics' effects on neurotensin expression by GABAergic agents. Muscimol, a specific GABA_A agonist, was chosen for the current study. Adult male Sprague-Dawley rats were treated with; saline, haloperidol (1 mg/kg), muscimol (3.2 mg/kg), or haloperidol (1 mg/kg) plus muscimol (3.2 mg/kg). Animals were sacrificed one hour after medication administration. Expression of NT/N mRNA was examined by *in situ* hybridization using a [³⁵S]-labelled riboprobe complementary to NT/N mRNA.

In this acute treatment paradigm, densitometric analysis of film autoradiograms revealed that administration of muscimol alone had no effect on NT/N levels in the dorsolateral striatum. Additionally, muscimol did not appear to modulate haloperidol-induced increases in NT/N mRNA levels in the dorsolateral striatum. These data suggest that GABA_A receptors may not be involved in acute regulation of striatal NT/T gene expression in dorsolateral striatal neurons. Further studies are underway to examine the effect of augmenting GABAergic transmission in NT/N gene expression. (Supported by Scottish Rite Schizophrenia Research Program).

INHIBITION OF PRO-CHOLECYSTOKININ (CCK) SULFATION BY TREATMENT WITH SODIUM CHLORATE ALTERS ITS PROCESSING AND DECREASES CELLULAR CONTENT AND SECRETION OF CCK 8. M. C. Beinfeld*, Dept. Pharmacol. & Physiol. Sci., St. Louis Univ. School of Medicine., St. Louis MO.

Pro-cholecystokinin (CCK) has three sulfated tyrosine residues. Sulfation of the tyrosine residue in CCK 8 is known to be important for its activity at CCK A receptors. The role of these sulfated tyrosines in the sorting and processing of pro-CCK was examined by treatment of CCK-secreting rat thyroid medullary carcinoma cells with 10 mM sodium chlorate (a non-toxic inhibitor of tyrosine sulfation). This treatment caused a 50% decrease in the cellular content of immunoreactive CCK and an 80% decrease in its secretion. Sephadex G-50 chromatography of cellular extracts and culture media showed a selective depletion of CCK 8, and a comparative sparing of CCK 33 and larger molecular forms. The sulfation of the tyrosines of pro-CCK is clearly important for the correct sorting and/or processing of pro-CCK. The pattern of immunoreactive CCK peptides seen with chlorate treatment is consistent with the substrate specificity of a recently identified putative CCK cleaving enzyme and suggests that unsulfated pro-CCK is not efficiently processed to CCK 8 *in vivo*. The large decrease in CCK content and secretion observed with sodium chlorate may also be due to inefficient sorting of unsulfated pro-CCK into secretory vesicles. Supported by NIH NS18667.

561.13

SYMPATHETIC ACTIVATION IS INVOLVED IN NICOTINE- BUT NOT CAPSAICIN- AND BRADYKININ-INDUCED CGRP RELEASE FROM THE RAT TRACHEA. X.-Y. HUA*, E.A. CHIANG, S. IINNO & T.L. YAKSH Anesthesiology, Univ. of California, San Diego, CA 92093-0818

We have previously demonstrated that application of capsaicin (Caps), bradykinin (BK) and nicotine (NIC) to the rat trachea induces a dose-dependent increase in CGRP release. Activation of postganglionic sympathetic terminals and subsequent release of prostaglandins (PG) have been reported to mediate BK-induced inflammatory responses. The present study investigates the possible contribution of sympathetic nerve and mast cells to the effects of Caps, BK and NIC on CGRP release by using the isolated rat trachea model¹. The effects of BK (5x10⁻⁶M) and NIC (10⁻⁵M) but not Caps (10⁻⁷M) are significantly reduced by indomethacin treatment. 6-OHDA treatment, which depletes catecholamine in the rat trachea, does not alter Caps- and BK-induced CGRP release but significantly attenuates NIC's effect. 48/80 pretreatment, which causes degranulation of a majority of mast cells in the trachea, does not significantly change the effects of the three agents. Neither norepinephrine nor neuropeptide Y (10⁻⁵M) alter the basal or Caps-evoked CGRP release. ATP (10⁻⁵M) induces an increase in CGRP outflow from the rat trachea. In conclusion, (1) Caps-evoked CGRP release is not mediated by PG production or by activation of sympathetic terminals and mast cells; (2) The fact that indomethacin, but not 6-OHDA or 48/80 treatment inhibits BK's effect suggests that BK-induced CGRP release is mediated by PG synthesis, which is independent of the presence of sympathetic nerve or mast cells; (3) Sympathetic activation may be involved in NIC-induced PG-mediated CGRP release.

GENE EXPRESSION OF THE PROHORMONE CONVERTASES IN THE RAT BRAIN AND PITUITARY: COMPARATIVE DISTRIBUTION OF PC5 AND PACE4. R. Day*, M. Marcinkiewicz, M. Chrétien, N. G. Seidah. Clinical Research Institute of Montreal, Montreal, Quebec, Canada, H2W 1R7.

Recent advances in the molecular characterization of posttranslational processing enzymes have demonstrated a subtilisin-like enzyme family in mammalian tissues to be responsible for the endoproteolytic processing of inactive protein precursors to biologically active peptides, via selective cleavage of basic residues. Two of these processing enzymes or convertases, PC1 and PC2, are primarily expressed in neuronal and endocrine cells while another, furin, is ubiquitously expressed. PC5 and PACE4, two novel convertases, with very similar structures, have recently been described. Very little is known about their cellular distribution. In this study, we examined the mRNA expression of PC5 and PACE4 in the rat brain and pituitary by *in situ* hybridization using ³⁵S-labeled cRNA probes. The cellular distribution of PC5 was mostly neuronal. Brain regions expressing a relatively higher abundance of PC5 include the CA3 region of the hippocampus, discrete deeper cortical layers and the amygdaloid nuclei. As previously observed for PC1, the CNS gene expression of PC5 was less widespread and less abundant than that of PC2 mRNA. In the pituitary, PC5 mRNA was principally expressed in the anterior lobe gonadotrophs, though we could not exclude other endocrine cell types. Very little PC5 expression was observed in the intermediate and neural lobes. Thus, the localization of PC5 contrasts with that of PACE4, whose distribution appears to be ubiquitous. The observation of different combinations of convertase expression in distinct brain regions, suggests that specific convertase mixtures are involved in protein processing. Accordingly, particular combinations of convertases should yield region-specific differences in posttranslational processing.

SEROTONINERGIC AND ADRENERGIC REGULATION OF SOMATOSTATIN GENE EXPRESSION IN THE RAT HYPOTHALAMUS. G. Pelletier* and S. Li. MRC Group in Molecular Endocrinology, CHUL Research Center and Laval University, Québec, G1V 4G2, Canada.

The role played by the serotonergic and adrenergic systems in the regulation of somatostatin (SS) secretion is controversial. The aim of the present study was to evaluate the role of these two neurotransmitter systems on SS gene expression in the male rat periventricular nucleus. Quantitative *in situ* hybridization involving of a [³⁵S]-labeled cDNA encoding rat pre-proSS mRNA was performed at the cellular level to measure the amounts of SS mRNA per cell. The influence of the serotonergic system was studied following the chronic administration (2.5 days) of serotonin (5HT), the 5-HT₁₊₂ receptor antagonist methysergide, the 5-HT₂ receptor antagonist ketanserin and ondansetron, a 5-HT₃ receptor antagonist. 5HT induced a 17% increase in the number of silver grains/cell while ondansetron and methysergide decreased the hybridization signal by 27% and 11%, respectively. Ketanserin had no effect on mRNA levels. The role of the adrenergic system was evaluated by the 2.5 day administration of the α -1 and α -2-adrenergic receptor blockers, prazosin and yohimbine, and the β -adrenergic antagonist propranolol. While propranolol had no effect on SS mRNA levels, both prazosin and yohimbine induced a decrease of 46 and 18%, respectively, in the number of grains per cell. The present data indicate that SS gene expression is positively regulated by the serotonergic system probably via 5HT₂ and 5HT₃ receptors and the adrenergic system through α -1 and α -2 adrenergic receptors.

CATECHOLAMINE RECEPTORS: DOPAMINE RECEPTOR LOCALIZATION AND REGULATION

562.1

CELLULAR DISTRIBUTION OF D_{1A} AND D₂ DOPAMINE RECEPTORS USING FLUORESCENT DETECTION OF *IN SITU* cDNA SYNTHESIS. M.A. Ariano*, S. Nair, and J.H. Eberwine. Neuroscience, Chicago Medical School, N. Chicago, IL 60064; ¹Pharmacology, University of Pennsylvania, Philadelphia, PA 19104.

We have developed a fluorescence method to determine the *in situ* synthesis of cDNAs for different dopamine receptor clones by modifying the radionuclide-based *in situ* transcription (IST) technique (*Science* 240: 1661, 1988). The high sensitivity offered by fluorescent detection of labeled IST cDNA allows rapid cellular detection of low abundance mRNAs, such as those encoding the dopamine receptors.

Incorporation of rhodamine-coupled dUTP (FluoroRed™, Amersham) into dopamine receptor IST cDNA was performed after hybridization with 3' anti-sense DNA oligonucleotide primer generated against sequences in the third cytoplasmic loop of the dopamine receptors. Tissues were subsequently washed and examined using a fluorescent microscope, some 8 hours after initiation of the experiment. We could visualize fluorescent neurons in the neocortex, neostriatum, nucleus accumbens, and olfactory tubercle expressing nascent cDNA for the D_{1A} and D₂ receptor subtypes. The specificity of the fluorescent IST technique was further substantiated using stably transfected Chinese Hamster Ovary (CHO) cells, expressing only one of the dopamine receptor subtypes (PNAS USA 87: 6723, 1990). Controls included hybridization using neuron specific enolase to detect neuronal profiles, or oligo dT to ascertain cells with poly-A tailed mRNAs. Both experiments showed robust numbers of fluorescent cells. An additional negative control, omission of primer, demonstrated the low background signal in the tissue slice. The fluorescent method has distinct advantages: 1) rapidity of analysis, 2) use in double labeling, and 3) potentially improved sensitivity.

562.2

DOPAMINE RECEPTOR EXPRESSION IN NEOSTRIATAL OUTPUT NEURONS. E.A. Nansen, M.A. Ariano, D.R. Sibley, D. Birt, M.S. Levine. MRC UCLA, Los Angeles, CA 90024, Dept. Neurosci. Chicago Med. Sch. N. Chicago IL 60064; ¹Mol. Pharmacol. Unit ETB NINDS Bethesda, MD 20892.

The present study was designed to assess expression of dopamine (DA) receptors in neostriatal output neurons using fluorescent retrograde markers and polyclonal antibodies. Fluorescent labeled microspheres were stereotaxically injected into either the substantia nigra or the globus pallidus of rats. Following surgery (3-10 days), animals were sacrificed and brains were rapidly removed and frozen. Coronal sections (10-20 μ m) were cut from the forebrain and processed with polyclonal antibodies raised against specific peptide sequences for the D₁, D₂ or D₃ subtypes of DA receptors. The secondary antibodies were conjugated to fluorescent markers in order to localize the DA receptor immunoreactivity in the fluorescent labeled neostriatal output neurons. The slides were analyzed on a Biorad MRC 600 confocal microscope capable of producing <1 μ m thick optical sections.

The majority of identified striatopallidal neurons contained either D₁ or D₂ DA receptor immunoreactivity. It is possible, because striatonigral fibers also course through the pallidal injection sites, that some of the identified striatopallidal projection cells might be striatonigral output neurons if beads are transported in damaged axons. Most striatonigral neurons also contained immunoreactivity for either D₁ or D₂ DA receptors. D₃ immunoreactivity was localized to a smaller subpopulation of striatonigral cells than either the D₁ or D₂ immunoreactivity. These results provide evidence that different DA receptor subtypes are localized to both striatonigral and striatopallidal neurons. Supported by USPHS Grants NS 23079 (M.A.A.), HD 05958 (M.S.L.) and AG 10252 (M.S.L.)

562.3

Authoradiographic Localization of Dopamine Receptor Sites in Rat Brain Using [³H]-Quinelorane (LY163502). S. L. Gackenhaimer, J. M. Schaus and D. R. Gehlert. CNS Pharmacology, Lilly Research Laboratories, Indianapolis, IN 46285.

Quinelorane (LY163502) is a selective D₂ agonist which has been extensively studied for its effects on the sexual behavior of male rats. When infused into the medial preoptic area of the rat brain, or injected SC, quinelorane improved levels of male sexual behavior (mounting and copulation) (J. Neural Trans. 68:153-70, 1987). Recent studies suggest that quinelorane may also interact with cloned D₃ receptors expressed in cell lines (Eur. J. Pharm 225: 331-37, 1992).

In the present study, quinelorane was radiolabeled and evaluated as a ligand for autoradiographic localization of dopamine receptors in the rat brain. Optimal labeling conditions were determined by a series of biochemical studies using slide mounted sections of rat forebrain. Nonspecific binding was determined by including 1 μM quinelorane in the incubation buffer. Once the binding conditions were determined, sections were labeled and exposed against a sheet of Hyperfilm-³H for eight weeks. Quantitation of the binding was accomplished using ³H-Micro-scans (Amersham) which were placed against the film along with the labeled sections. Developed films were analyzed by densitometry using the MCID (Imaging Research, Ontario, Canada) image analysis system.

Saturation analysis using sections of rat forebrain indicated that [³H]quinelorane bound to a single site with an apparent K_d of 2 nM and a B_{max} of 40 fmol/mg tissue dry weight. On the concentration dependent portion of the curve, specific binding accounted for greater than 99 percent of the total binding. Gpp(NH)_p reduced binding in a concentration dependent manner with an almost complete inhibition of binding at 10 μM. Localization experiments revealed a binding distribution similar to the distribution reported for other radiolabeled D₂ receptor agonists and antagonists. A high level of specific binding was seen in the glomerular layer of the olfactory bulb, caudate-putamen and islands of Calleja. Moderate levels of binding were seen in the olfactory tubercle, nucleus accumbens, dorsal lateral septum, zonal layer of superficial gray, ventral tegmental area and lobe 10 of the cerebellum. Low levels of binding were observed in the medial preoptic area, substantia nigra compacta, dorsal raphe and nucleus of the solitary tract.

In conclusion, [³H]quinelorane binds to sections of rat brain with high affinity and exhibits very low nonspecific binding. The distribution of binding was consistent with the distribution of D₂ and D₃ receptors reported in rat brain. As such, [³H]quinelorane represents a useful tool for further pharmacological and anatomical characterization of D₂ and D₃ receptors in rat brain.

563.5

DISTRIBUTION OF DOPAMINE RECEPTOR MESSENGER RNA IN THE PRIMATE BRAIN. J. H. Meador-Woodruff*, J. Wang, S. P. Damask, and S. J. Watson. Mental Health Research Institute, University of Michigan, Ann Arbor, MI 48109-0720.

At least five dopamine receptor subtypes have been cloned, and each appears to have distinct pharmacological properties and a unique neuroanatomical distribution. In the rat, the D₁ and D₂ receptors appear to be enriched in motor, limbic, and neuroendocrine circuits, whereas the D₃ and D₄ receptors have been reported to be primarily localized to limbic regions. The D₅ receptor has a particularly unusual and restricted distribution. Most neuroanatomical characterization of the mRNAs encoding these receptors has been performed in the rodent; relatively little has been done to describe the anatomical distribution of these messages in the primate and human brain. As part of our ongoing efforts to characterize dopamine receptor systems in brain, we have mapped the distributions of the mRNAs encoding the five dopamine receptors in the brain of the old world monkey by *in situ* hybridization, using radioactively-labeled riboprobes synthesized from corresponding human cDNAs. While many similarities in the distributions of dopamine receptor mRNAs exist between the rat and the monkey, significant differences are also obvious. These differences suggest that the dopamine receptors may function differently in discrete neural circuits in the primate than in the rat, indicating that generalization of dopamine receptor message data from the rat to the monkey and human should be made with caution. Supported by MH00818 and MH42251.

563.7

FUNCTION AND REGULATION OF THE D₃ DOPAMINE RECEPTOR. D. Lévesque*, P. Sokoloff, M.-P. Martres, J. Diaz, V. Dimitriadou, C. Pilon and J.-C. Schwartz. Centre Paul Broca, INSERM U. 109, Paris 75014 and Lab. de Physiologie, Université René Descartes, Paris 75006, France.

The physiological role of the dopamine (DA) D₃ receptor has remained elusive because of the absence of functional correlates. We have transfected NG108-15 neuroblastoma X glioma hybrid cell line with a D₃ receptor cDNA. This cell line stably expresses D₃ receptors, which display high affinity for DA and low, but consistent regulation by guanine nucleotide. DNA synthesis, measured by incorporation of [³H]thymidine, is increased by 70-80% upon stimulation by DA (EC₅₀ = 2 nM), quinpirole (EC₅₀ = 1 nM) or (+)7OH-DPAT (EC₅₀ = 0.3 nM), and is antagonized by (+)UH 232. The effect of 100 nM quinpirole is nearly abolished by pretreatment with pertussis toxin, and is potentiated by co-stimulation of protein kinase C with the phorbol ester PMA (1 nM). There is no apparent coupling with classical intracellular second messengers. On the other hand, D₃ receptor activation transiently induces Fos immunoreactivity. Thus, transfected D₃ receptors in NG108-15 cells are coupled, through a pertussis toxin-sensitive G protein, to a so far unidentified primary effector that induces *c-fos* expression and mitogenesis. We also investigated the *in vivo* regulation of the D₃ receptor. Lesion with 6-OHDA produces a marked decrease of both D₃ receptor binding (-71%, with [³H]7OH-DPAT) and D₃ receptor mRNA level (-52%, with quantitative PCR and *in situ* hybridization) in the nucleus accumbens ipsilateral to the lesion, whereas chronic haloperidol treatment (20 mg/kg, b.i.d., for 2 weeks) is without effect. Thus, unlike D₂ receptors, D₃ receptors do not upregulated after interruption of DA neurotransmission, supporting the involvement of these receptors in the antipsychotic effects, for which there is no tolerance. DL is holder of a fellowship from the Natural Sciences and Engineering Research Council of Canada.

563.4

DETERMINATION OF DOPAMINE D₃ RECEPTOR DISTRIBUTION IN RAT BRAIN USING [¹²⁵I]-7-TRANS-OH-PIPAT P. McGonigle*, R.P. Artymyshyn, S. McElligott, M.P. Kung and H. Kung. Depts. of Pharmacology and Radiology, University of Pennsylvania, Phila., PA 19104.

D₃ receptors in sections of rat brain were measured with the new, D₃-selective radioligand [¹²⁵I]-7-Trans-OH-PIPAT (PIPAT). Preliminary characterization of the binding of the radioligand was performed in sections of tissue mash derived from nucleus accumbens and olfactory tubercle. At 22°C, binding of 0.3 nM [¹²⁵I]-PIPAT reached equilibrium in 90 min and remained stable for at least one hour. Scatchard plots of saturation data were linear and yielded a K_d of .52 ± .02 nM, consistent with densitometric measurements made in the nucleus accumbens and islands of Calleja. Displacement curves were monophasic and the pharmacological profile of 7-OH-DPAT > quinpirole > domperidone > dopamine > clozapine is consistent with the labeling of a D₃ receptor. The distribution of D₃ receptors was measured in 20 μm coronal and sagittal sections labeled with 0.2 nM [¹²⁵I]-PIPAT. Nonspecific binding was measured in the presence of 5 μM 7-OH-DPAT. Sections were apposed to film for 18 or 72 hours. The highest densities of labeling were observed in the islands of Calleja, the rostral part of the nucleus accumbens and the molecular layer of lobules 9 and 10 of the cerebellum. Lower densities of labeling were found in: the caudal nucleus accumbens, substantia nigra, inferior olive, bed nucleus of the stria terminalis, interpeduncular nucleus, and selected thalamic and hypothalamic nuclei. Labeling in the caudate putamen was low and restricted to its rostral and medial aspects. These results are in general agreement with the localization of mRNA coding for D₃ receptors as determined using *in situ* hybridization. (Supported by USPHS GM 34781 and NARSAD)

DOPAMINE RECEPTORS SUPERSENSITIVITY: EFFECTS OF CHRONIC L-DOPA AND CARBIDOPA TREATMENT IN RATS WITH 6-HYDROXYDOPAMINE LESION. Mir Ahamed Hossain and Norman Weiner. Dept. of Pharmacology, University of Colorado Health Science Center, Denver, CO 80262.

Intracellular cAMP accumulation in slices from striatum and substantia nigra was measured following 30 days of L-DOPA/carbidopa treatment in rats with unilateral 6-OHDA lesion (90%) of the nigrostriatal tract. Following 6-OHDA lesion the basal cAMP accumulation was increased significantly (92%) in the striatal slices ipsilateral to the lesion, while remaining unaffected in the ipsilateral substantia nigra as compared to the contralateral intact hemisphere. Dopamine (DA) and tetrahydrobiopterin (BH₄) levels were depleted by 99% and 70% respectively in the ipsilateral striatum as we reported previously (Brain Res., 598: 121, 1992). After 30 days of L-DOPA/carbidopa treatment, the elevated levels of cAMP accumulation in ipsilateral striatum reduced significantly and returned to the control levels of the contralateral intact side of vehicle-treated group. The D-1 receptor agonist SKF 38393 (10uM) increased cAMP accumulation in striatal slices from lesioned and intact hemispheres of both vehicle and treatment group which was completely inhibited by the D-1 antagonist SCH 23390 (10uM). In contrast, the ability of SKF 38393 to enhance the cAMP accumulation was blocked by the D-2 agonist quinpirole (10uM) in striatal slices from the intact hemisphere but not in tissues from the lesioned side. In substantia nigra, no significant differences in cAMP accumulation were observed in presence of the agonist or antagonist. Our data indicates that chronic L-DOPA/carbidopa treatment reverses the D-1 receptor supersensitivity seen following 6-OHDA lesions, suggesting a D-1 receptor mediated action of L-DOPA. Following 6-OHDA lesion there appears to be an uncoupling of the inhibitory D-2 receptor from D-1 receptor associated cAMP accumulation. Chronic L-DOPA/carbidopa treatment does not reverse this uncoupling of D-1 and D-2 receptor.

563.8

D₁ AND D₂ DOPAMINE RECEPTOR DENSITIES IN GRAFTED RAT STRIATUM AFTER CHRONIC INTERMITTENT L-DOPA AND/OR THE MAO-INHIBITOR DEPRENYL (SELEGILINE). C.E. Adams*, A.F. Hoffman, J.L. Hudson, B.J. Hoffer and S.J. Boyson. Depts. of Neurology and Pharmacology, Univ of Colo Health Sciences Center, Denver, CO 80262.

It has been proposed that deprenyl may prevent the long term oxidative stress on native or grafted nigral tissue which is hypothesized to be caused by the use of L-dopa in Parkinson's patients. We examined this question in unilaterally 6-OHDA-lesioned rats which were injected twice daily in the following groups: S/V (sham/vehicle); G/V (grafted/V); G/L (G/L-dopa & benserazide); G/L/D (G/L/deprenyl); and G/D. All animals received drugs or vehicle for two weeks prior to grafting or sham graft; drug treatment followed for an additional 2.5 months. Immediately following the treatment period, the brains were processed for quantitative autoradiography. D₁ receptors were labeled with ³H-SCH-23390 while D₂ receptors were labeled with ³H-spiroperone. Preliminary analysis of the data revealed significant increases in the density of D₂ but no change in the density of D₁ receptors within the lesioned compared to the intact striata of the S/V rats. Grafting of fetal nigral tissue normalized the density of D₂ receptors throughout the grafted striata of the G/V rats but led to a decrease in the density of D₁ receptors within the dorsomedial quadrant of the grafted striata compared to the intact side. Chronic treatment with L-dopa alone decreased the density of both D₁ and D₂ receptors within the ventromedial quadrants of the grafted striata in the G/L rats. Deprenyl treatment led to a lower density of D₁ receptors within the grafted compared to the intact striata of the G/D and G/L/D groups. Graft viability, as measured by reductions in apomorphine-induced rotations, was unaffected by drug treatments. Supported by NIH NS 09199 and NS 29203

562.9

LONG-TERM L-DOPA ADMINISTRATION TO RATS WITH 6-OHDA LESIONS: BEHAVIOR AND STRIATAL NEUROCHEMISTRY. S. R. Wachtel* and E. D. Abercrombie. Center for Molecular & Behavioral Neuroscience, Rutgers University, Newark, NJ 07102.

Despite the standard use of L-3,4-dihydroxyphenylalanine (L-DOPA) therapy for Parkinson's disease, the reasons for the emergence of dyskinesias and declining efficacy with long-term treatment are not understood. We hypothesize that these adverse effects derive from repeated exposure of the denervated striatum to unregulated, supranormal levels of extracellular dopamine (DA) formed from L-DOPA. We therefore examined the effects of a 28 day regimen of L-DOPA+benserazide (50 mg/kg each, bid) on behavior and striatal neurochemistry in rats with unilateral 6-hydroxydopamine (6-OHDA) lesions of the nigrostriatal DA pathway. Ipsilateral rotation, monitored at 1 week intervals, was increased 3-4 fold at day 8 and then continued to increase at a slower rate for the remainder of the treatment duration. Twenty-four hrs after the last L-DOPA injection, microdialysis probes were used to monitor extracellular levels of DA and acetylcholine (ACh) bilaterally in the striatum. The increase in extracellular DA elicited by L-DOPA (50 mg/kg) in the DA-depleted striatum was not altered by long-term L-DOPA treatment as compared to untreated controls, despite the enhanced rotational response in the former group. L-DOPA administration did not alter striatal ACh output on the intact or the lesioned side in untreated controls. In contrast, ACh output was stimulated by L-DOPA selectively in the lesioned striatum of rats that had received the chronic L-DOPA. Thus, long-term L-DOPA administration, in this model, produces a potentiation of behavioral responding that is associated with a corresponding increase in ACh output in the lesioned striatum but not an enhanced L-DOPA-induced increase in extracellular DA. This indicates that post-synaptic changes may be critically involved in the emergence of unwanted side effects associated with long-term L-DOPA therapy in Parkinson's disease. 562.11

CHANGES OF D1 AND D2 RECEPTORS IN ADULT RAT NEOSTRIATUM AFTER NEONATAL DOPAMINE DENERVATION: QUANTITATIVE RADIOLOGICAL BINDING, IN SITU HYBRIDIZATION AND IONTOPHORETIC DATA. F. Radja*, M. El Mansari, J.-J. Sophomonian, K.M. Dewar, A. Ferron, T.A. Reader and L. Descarries. Centre de recherche en sciences neurologiques (Départements de physiologie, psychiatrie et pathologie), Université de Montréal, Montréal, and Centre de recherche en neurobiologie, Université Laval, Québec, Québec, Canada.

The specific binding of [³H]SCH23390 to D1 and of [³H]raclopride to D2 dopamine (DA) receptors was measured by autoradiography in the rostral and caudal neostriatum (NS) of adult rats subjected to near total destruction of nigrostriatal DA neurons by intraventricular 6-hydroxydopamine soon after birth (3 days). Three months after this lesion, [³H]SCH23390 binding was slightly but significantly decreased in the rostral NS (22%), but unchanged in the caudal NS. In contrast, [³H]raclopride binding was considerably increased throughout the NS (10-40%). In the rostral NS, there were no parallel changes in D2 receptor mRNA levels, as measured by *in situ* hybridization on adjacent sections. Caudally, however, slight but significant increases in D2 mRNA were detected (10-20%). As assessed by quantitative iontophoresis, there was a marked enhancement (63%) of the inhibitory responsiveness of spontaneously firing units in the rostral NS to DA and the D1 agonist, SKF38393, in neonatally-lesioned versus control rats. On the other hand, responsiveness to PPHT, a potent D2 agonist, appeared to be unchanged. Such opposite changes in the number of D1 and D2 binding sites, expression of D2 receptor mRNA and electrophysiological responsiveness to DA and D1 and D2 agonists, suggested independent adaptations following the neonatal DA denervation of NS. They also emphasized that the effects of DA and D1 and D2 agonists in NS do not depend strictly on the number of D1 and D2 receptor sites. CHANGES IN DOPAMINERGIC FUNCTION FOLLOWING KINDLING. R.A. Fox, C.D. Applegate and D.A. Cory-Slechta*. Departments of Neurology and Environmental Medicine, University of Rochester School of Medicine and Dentistry, Rochester, NY 14642.

The kindling phenomenon, an animal model of epileptogenesis, has been shown to increase the number of both D2 dopamine (DA) receptors and mRNA in the striatum and nucleus accumbens of rats. To determine whether the increases in DA receptors are of functional significance, male rats were trained, using standard operant food-reinforced drug discrimination (DD) procedures, to discriminate the stimulus properties of an autoreceptor dose (0.05mg/kg i.p.) of the selective D2 agonist quinpirole (QUI) from saline, and QUI dose-effect curves were determined. Animals were then matched according to ED50 values, and one rat in each pair was kindled while the other was a sham-operated control. Subsequent redetermination of the dose-effect curves revealed a decreased QUI sensitivity in control but not kindled rats. Likewise, dose-effect curves for apomorphine (APO) substituted for QUI were left-shifted in kindled rats relative to controls. These data suggest that kindling-induced increases in D2 receptor number appear to compensate for the loss of D2 sensitivity produced in controls by continuous administration of QUI in the DD procedure, and are consistent with a kindling-induced functional D2 autoreceptor supersensitivity. In addition, head down, sniffing behavior in response to a high dose of APO was increased in kindled rats, consistent with a possible kindling-induced D1 supersensitivity. Kindling-induced changes in DA systems, therefore appear to have functional consequences. Supported by ES05903 and ES05017.

DOES 6-HYDROXYDOPAMINE (6-OHDA) LESION OF THE NIGROSTRIATAL PATHWAY AFFECT STRIATAL D2 DOPAMINE (DA) RECEPTOR mRNA LEVELS? K.-X. Huang*, T. Minowa, Y. H. Sohn, M.J. Twery, M.M. Mouradian and J.R. Walters. Exptl. Therap. Branch, NINDS, Bethesda, MD 20892.

The rat model of Parkinson's disease produced by 6-OHDA-induced lesion of the nigrostriatal DA pathway is associated with enhanced response to DA agonists and increased density of postsynaptic D2 receptors. Whether lesion alters steady-state levels of striatal D2 mRNA remains controversial. Solution hybridization/ribonuclease protection assay was utilized to address this issue. RNA was isolated from ipsilateral and contralateral striata. From a rat D2 cDNA clone, a ³²P-labelled antisense riboprobe was transcribed *in vitro* covering bases 404-829 which include the 87 bp alternatively spliced exon. Total RNA was hybridized with D2 and β-actin probes and digested by RNase A/T1. Protected hybrids were excised from the gel and radioactivity quantitated. In lesioned rats not screened by DA agonist injection, no significant differences were found in absolute counts for D2 long or D2 short mRNAs or in ratios of D2/β-actin mRNAs between lesioned and unlesioned striata in rats studied 2, 4, 8 or 19 weeks after lesion (n=4-8). As expected, the D2 messages in the substantia nigra on the lesioned side were undetectable. These results indicate that postsynaptic changes induced by DA denervation are not associated with alterations in steady-state levels of D2 mRNA and are inconsistent with reports of increases in striatal D2 receptor and mRNA levels as measured by other methods. However, rats utilized in these latter studies have typically been pretreated with apomorphine to test the effectiveness of the lesion. In view of the agonist- and l-DOPA-induced priming phenomenon observed in experimental animals and in patients with Parkinson's disease, future studies should also investigate D2 mRNA levels following DA agonist pretreatment of 6-OHDA-lesioned rats.

ONTOGENETIC SUPERSENSITIZATION OF DOPAMINE D1 RECEPTORS OCCURS WITHOUT A CHANGE IN D1 HIGH AFFINITY SITES. ¹L. Gong, ¹R.M. Kostrzewa, ²R. Brus, ¹E.A. Daigneault*, ³R.W. Fuller and ³K.W. Perry. ¹Dept. of Pharmacology, East Tennessee State Univ., Johnson City, TN; ²Dept. of Pharmacology, Silesian Academy of Medicine, Zabrze, Poland; and ³Lilly Research Labs, Eli Lilly Co., Indianapolis, IN.

To test whether SKF 38393 could ontogenetically prime dopamine D1 receptors, intact and neonatal 6-hydroxydopamine (6-OHDA) lesioned rats (134 μg i.c.v.; desipramine pretreatment) were treated daily for the first 28 days from birth with the D1 agonist, SKF 38393 HCl (3.0 mg/kg i.p.) or its vehicle. In intact rats SKF 38393 treatments had no effect on SKF 38393 HCl (3.0 mg/kg IP)-induced locomotor activity at 2 months. In D1 neonatally primed 6-OHDA rats, enhanced locomotor responses were seen with the first SKF 38393 challenge dose at 2 months. This response increased further with weekly SKF 38393 treatments. There was no change from control in the percentage of high affinity D1 sites in lesioned and primed rats. Striatal DA content was reduced >98% and 5-HT content was elevated >50% in neonatal 6-OHDA lesioned rats, regardless of whether SKF 38393 was co-administered ontogenetically. The findings indicate that ontogenetic SKF 38393 treatments partially prime D1 receptors, but that this effect is not associated with a shift in the high affinity binding status of D1 receptors. (Supported by NS 29505)

EXPRESSION OF D2 AND D3 RECEPTORS IN LIMBIC SYSTEM OF NORMALS, SCHIZOPHRENICS AND ALZHEIMER'S CASES

J.N. Joyce*, A. Murray, H. Ryoo, S. Goldsmith. Dept. Psychiatry, Lab. Chemical Neuroanatomy, Univ. Penn. Sch. Medicine, Philadelphia, PA

We have previously described the autoradiographic mapping of D2-like receptors with [¹²⁵I]epidepride in human brain (Joyce et al., JPET, 253:1253,1991), showing high expression in limbic regions. It is unclear to what extent we were labeling D3 receptors. We took advantage of the binding of [¹²⁵I]epidepride to D2 and D3 receptors in human brain in the presence and absence of compounds that have differing affinities for D2 vs D3 sites to visualize these receptors (Murray et al, 1992; EJP, 227:443). High ratios of D3/D2 receptors were found in the striosomes of the ventral striatum, the medial aspect of the internal globus pallidus, the basal forebrain, the A10 region of the midbrain. Within the limbic system there was high ratios in the central and amygdalo striato transition divisions of the amygdala and in the dentate gyrus (DG). The remainder of the hippocampus and medial temporal lobe show undetectable amounts of D3 receptors. Reductions in the number of D2-like receptors in the DG, subiculum and perirhinal regions are observed in Alzheimer's disease (Joyce et al, 1993; Neurosci. Lett). Changes in expression of D2-like receptors are not observed in the DG or subiculum in elderly schizophrenic cases. Altered laminar expression of receptors in the medial temporal lobe and within the "columns" of the temporal cortex were observed (Goldsmith and Joyce, this meeting). Even though elderly schizophrenics are demented, they do show similar patterns of D2 receptor expression. This is the first direct evidence that the expression of DA receptors is modified in the limbic lobe of the schizophrenics and could contribute to the psychotic symptoms. Examination of regions with high expression of D3 receptors are being examined in these same cases. Funded by MH 43880, AG 09215.

THE D_{2S} AND D_{2L} DOPAMINE RECEPTORS ARE DIFFERENTIALLY REGULATED IN CHO CELLS. Li-Juan Zhang*, Jean E. Lachowicz and David R. Sibley. Molecular Neuropharmacology Section, ETB, NINDS, NIH, Bethesda, MD 20892.

To investigate and compare the regulatory properties of the two isoforms of the D₂ dopamine receptor, we have stably expressed their cDNAs in Chinese Hamster Ovary (CHO) cells. Cell lines were selected which express similar levels of [³H]methylspiperone binding activity. Both isoforms mediate a dose-dependent and pharmacologically-specific inhibition of adenylyl cyclase activity in both intact cell and membrane preparations. Pretreatment of both D_{2L} and D_{2S} receptor expressing cells with 100 μM dopamine produces a ~5-fold shift (lower affinity) in the EC₅₀ for dopamine inhibition of cAMP accumulation with a ~25% decrease in the maximum response. Dopamine treatment also results in a ~20% decrease in the maximum receptor binding activity of the D_{2S} receptor expressing cells. In contrast, the D_{2L} receptors are up-regulated by about 3-fold in response to dopamine treatment. This difference in response between the D_{2S} and D_{2L} receptors is not cell line specific as other CHO clones expressing these isoforms show identical responses. The dopamine-induced up-regulation of D_{2L} binding is time-dependent, reaching maximal levels after 10 hr with a t_{1/2} = 4 hr. This response is blocked by prior treatment of the cells with 1 μg/ml pertussis toxin for 24 hr and is not mimicked by cAMP analogs. To test whether protein synthesis is required for the D_{2L} receptor up-regulation, we pretreated the cells with 5 μg/ml cycloheximide to block mRNA translation. This was found to completely inhibit the up-regulation of D_{2L} binding activity, however, there was no effect on the desensitization of the adenylyl cyclase response. Our data indicate that dopamine can positively regulate the synthesis of the D_{2L} receptor isoform in CHO cells. The mechanism underlying this regulation and its apparent absence for the D_{2S} isoform is currently under investigation.

ANALYSIS OF THE NEGATIVE MODULATOR OF THE RAT D₂ DOPAMINE RECEPTOR GENE PROMOTER. T. Minowa, M. T. Minowa and M. M. Mouradian*. Experimental Therapeutics Br., NINDS, Bethesda, MD 20892.

The D₂ dopamine receptor is classically recognized to be the primary mediator of the motor, behavioral and endocrine effects of central dopaminergic transmission. To investigate the molecular events leading to transcriptional regulation of the rat D-2 gene, we have cloned its 5' flanking region and identified multiple transcription initiation sites (Minowa et al, Biochemistry 31:8389, 1992). We found an Sp1-like positive modulator between bases -75 and -29 and a negative modulator between -218 and -76. In the present study, we analyzed this silencer region further. DNase I footprinting and gel mobility shift assays using nuclear extract from NB41A3 cells, which express D₂ binding sites, indicated that the region between -116 and -80 is the only sequence in the silencer recognized by nuclear factor(s). This sequence includes three GTGGG repeats and one Sp1 consensus sequence. Addition of this region to the D₂ promoter-CAT gene construct pCATD2-75 decreased promoter activity up to 50%. UV cross linking using GTGGG repeat oligonucleotide with NB41A3 nuclear extract and purified human Sp1 suggested that a non-Sp1 factor in NB41A3 cells binds to this sequence and negatively regulates the D₂ gene.

THE ROLE OF cAMP-DEPENDENT PROTEIN KINASE IN THE DESENSITIZATION OF THE HUMAN D₁ DOPAMINE RECEPTOR. E.M. Landau*, C.L. Ma, E.C. Healy, R.D. Blitzer and C. Schmauss. Department of Psychiatry Bronx VA Medical Center and Depts of Psychiatry and Pharmacology, Mt. Sinai Medical Center, New York, NY 10029.

The human D₁ dopamine receptor (D₁R) was cloned from genomic DNA using PCR, and its sequence ascertained. The full length D₁R insert was cloned into the expression vector pRC/CMV. This plasmid construct was used for transient transfection of HEK 293 cells by means of the DEAE-dextran procedure (Federman et al. Nature 356:159, 1992). Activation of adenylyl cyclase in the transfected cells was measured by the conversion of [α -³²P]ATP to [³²P]cAMP (Jacobowitz et al. J. Biol. Chem. 268:3829, 1993). When stimulated by dopamine (DA, 10⁻⁸ to 10⁻⁴ M, for 30'), the transfected cells responded by increased adenylyl cyclase activity in a dose-dependent manner. Pre-incubation of the cells with DA (10 μM) for 30 or 60 minutes resulted in a reduction of the response to DA (10⁻⁴, 30') by 34±7% (n=7) and 67±5% (n=4) respectively. When pre-incubated in the presence of the cAMP-dependent kinase (A-Kinase) inhibitor Rp-cAMPS (1 mM, 5 hours), the desensitizing effect of DA (10 μM for 1 hour) was decreased by 71±10%. Smaller concentrations of Rp-cAMPS caused a smaller block of desensitization, whereas increasing the Rp-cAMPS concentration to 3 mM did not increase the blocking effect. It is concluded that the D₁R desensitization is largely but not completely caused by activation of A-kinase. (Supported by a VA Merit grant and NIH MH 45212)

ANALYSIS OF THE ENHANCER REGION IN THE HUMAN D_{1A} DOPAMINE RECEPTOR GENE. M. T. Minowa, T. Minowa, J. R. Walters* and M. M. Mouradian. Experimental Therapeutics Branch, NINDS, Bethesda, MD 20892

We have previously reported that the human gene encoding the D_{1A} dopamine receptor has a housekeeping gene like promoter with multiple consensus sequences for Sp1 binding sites. The main enhancer activity is located between nucleotides -1197 and -1120 relative to translation initiation site where consensus sequences for AP2 are also present. Yet purified Sp1 does not bind to the enhancer of this gene as determined by gel shift and DNase I footprinting. Furthermore, nuclear factor(s) in two cell lines expressing this gene, NS20Y and SK-N-MC, which bind to the AP2-like sequence have a molecular size different than AP2 protein by UV cross linking. Our experiments suggest the existence of specific regulatory factors in D_{1A} expressing cells which bind to the regions between -1197 to -1154 and between -1154 to -1120 to enhance promoter activity. Mutations introduced at each of the putative AP2 sites supported this observation. Competitive co-transfection experiments indicated that plasmid vectors carrying these regions could effectively compete with the transcriptional activity of D_{1A} enhancer-CAT gene constructs.

CLONING OF EXON I OF THE RAT D₃ DOPAMINE RECEPTOR GENE. D.-O. Gao, T. Minowa, P. A. Jose*, M. M. Mouradian. Experimental Therapeutics Branch, NINDS, Bethesda, MD 20892 and Dept. of Pediatrics, Georgetown Univ. Med. Center, Washington, D.C. 20007.

The brain distribution and pharmacology of the D₃ type of dopamine receptors suggest important function in emotion, cognition and motor behavior. Understanding the molecular regulation of the gene coding for this receptor will assist in elucidating potential changes in its expression in pathological states. As an initial step in characterizing the promoter of the rat D₃ gene, we have cloned and sequenced the true exon I of this gene using an anchored RT-PCR technique with olfactory tubercle poly (A)⁺ RNA as template. The first gene-specific primer was based on the sequence of the most upstream exon published in which the first ATG codon is located (Giros et al, Biochem. Biophys. Res. Comm. 176: 1584, 1991). A clone having a novel sequence of 88 bp upstream of the first coding exon was isolated. RT-PCR using sense primer based on the new sequence indicated the presence of this exon I in the D₃ message in nucleus accumbens and striatum as well. The G+C content of the D₃ exon I is only about 50% unlike the very high G+C content of the D₂ exon I although the two genes are highly homologous in their coding region.

562.20

SUPERSENSITIVITY OF DOPAMINE D₂₄₄₃ RECEPTOR MEDIATED INHIBITION OF cAMP ACCUMULATION IN FORSKOLIN TREATED LTK- CELLS. A. Westlind-Danielsson* and M.H. Johansson. Department of Neuropharmacology, CNS Preclinical R & D, ASTRA ARCUS AB, S-151 85 Södertälje, Sweden.

Cultured cells expressing the different forms of recently cloned dopamine (DA) receptors have introduced the possibility of studying various aspects of DA receptor-effector coupling and regulation not readily examined *in situ* in brain. The DA D₂ receptors exists as two splice variants of the same gene, in rat denoted D₂₄₁₅ and D₂₄₄₄, in man denoted D₂₁₁₄ and D₂₄₄₃. Acute agonist activation of either form, examined in transfected cells, leads to inhibition of both adenylyl cyclase (AC) activity and cAMP accumulation. This response is markedly attenuated when mouse fibroblast Ltk- cells expressing D₂₄₁₅ are grown in the presence of quinpirole for 1-24 hrs, whereas D₂ antagonist treatment has no effect on the response (Bates et al., 1991, Mol. Pharmacol. 39:55-63). We used Ltk- cells expressing the D₂₄₄₃ receptor in order to examine whether direct and persistent activation of the AC itself (raising cAMP levels) with forskolin (FSK) would regulate D₂₄₄₃ receptor mediated inhibition in the opposite direction, that is producing a supersensitive receptor-effector response. FSK treatment for 4 hrs resulted in an increase of the maximal inhibition of cAMP accumulation (from 68 to 77%) produced by acute exposure to DA in the presence of FSK. Basal cAMP levels decreased by about 33% along with the maximal response to acute FSK challenge (~23%). The results imply that not only can receptor-effector supersensitivity be induced in cell culture by positively manipulating this signal transduction system at the level of AC but the treatment also leads to desensitization of some of the cAMP enhancing characteristics of the system in parallel.

SUBCHRONIC TREATMENT WITH A 5-HT 1A AGONIST ENHANCES THE RESPONSE OF MESOCORTICAL DOPAMINE NEURONS TO STRESS. B. A. Morrow* and R. H. Roth, Departments of Pharmacology and Psychiatry, Yale University School of Medicine, New Haven, CT 06510

We investigated the effects of a 7 day treatment of a 5-HT 1A agonist, 8-OH DPAT (2-dipropylamino-8-hydroxy-1,2,3,4-tetrahydronaphthalene), on basal and stress-activated dopamine (DA) and serotonin (5-HT) turnover in the medial prefrontal cortex (mPFC) and the nucleus accumbens (NAS). Rats were treated with saline or 8-OH DPAT, 0.5 mg/kg i.p., twice a day for 7 days. On the 8th day, rats were either restrained or left in the home cage for 30 min, then sacrificed, and the mPFC, NAS, and striatum were harvested for analysis by HPLC-EC. 8-OH DPAT treatment lowered basal 5-HT turnover (5-HIAA/5-HT) in the mPFC, but not the striatum or NAS. No change in basal DA turnover (DOPAC/DA) was noted in any region tested. Stress increased DA metabolism in the mPFC and NAS of saline treated rats, as expected. An important observation was that 8-OH DPAT treatment and stress lead to a significantly greater increase in DA turnover compared to saline treatment and stress in the mPFC only. In the NAS, 8-OH DPAT did not cause a change in basal 5-HT metabolism or in the stress-induced increase in DA turnover. Additional data obtained utilizing chemical lesions of 5-HT neurons will be presented. We conclude that subchronic treatment with 8-OH DPAT, a 5-HT 1A agonist, selectively affects the mesocortical DA and 5-HT systems and their response to stress without altering the mesoaccumbal systems. Support in part by MH-14092 & MH-14276.

SEROTONIN-DOPAMINE INTERACTION IN THE RAT VENTRAL TEGMENTAL AREA: AN ELECTROPHYSIOLOGICAL STUDY IN VIVO. E. Esposito*, S. Pagannone and S. Prisco. Istituto di Ricerche Farmacologiche "Mario Negri", Consorzio "Mario Negri" Sud, S. Maria Imbaro (Chieti), Italy.

In the present study the influence exerted by the serotonergic system on the activity of dopamine (DA) neurons in the ventral tegmental area (VTA) was investigated. Extracellular single unit recordings were performed *in vivo* on male Sprague Dawley rats, anesthetized with chloral hydrate. Dopamine neurons in the VTA were recorded using single barrel micropipettes and were identified by their location, waveform, firing rate and pattern. Cumulative intravenous injections of the mixed 5-HT_{1B}/5-HT_{1C} receptor agonists *m*-trifluoromethylphenylpiperazine (TFMPP) (1.25-160 µg/kg) and *m*-chlorophenylpiperazine (mCPP) (1.25-320 µg/kg) caused a dose-dependent inhibition of the firing rate of VTA DA neurons. The effect of mCPP (maximal inhibition 40%) was more pronounced compared to that of TFMPP (maximal inhibition 25%). Administration of the selective 5-HT_{1B} receptor agonist 7-trifluoromethyl-4-(4-methyl-1-piperazinyl)-pyrrolo[1,2-a]quinoxaline (CGS 12066B) (1.25-160 µg/kg, i.v.) did not cause any change in the basal firing rate of VTA DA neurons. Pretreatment with the specific 5-HT_{1B} receptor antagonist cyanopindolol (100 µg/kg, i.v.) did not modify the inhibitory effects of TFMPP and mCPP on DA neurons in the VTA. Cumulative intravenous injections of mesulergine (2.5-80 µg/kg) and mianserin (2.5-160 µg/kg), two selective 5-HT_{1C} receptor antagonists, produced a significant increase in the basal firing rate of VTA DA neurons. Administration of mesulergine (40 and 80 µg/kg, i.v.) dose-dependently antagonized the rate decreasing effect produced by mCPP on VTA DA neurons. Taken together, these data indicate that serotonin exerts an inhibitory action on DA neurons in the VTA through the 5-HT_{1C} receptor subtype.

PACEMAKER ACTIVITY OF NIGRAL DOPAMINE NEURONS; INVOLVEMENT OF GABA_B-RECEPTORS AND EFFECTS ON DOPAMINE RELEASE. H. Nissbrandt*, T. Kling-Petersen, A. Elverfors and G. Engberg, Department of Pharmacology, University of Göteborg, Medicinaregatan 7, S-413 90 Göteborg, Sweden.

Previous electrophysiological experiments have emphasized the importance of the firing pattern for the functioning of midbrain dopamine (DA) neurons. In the present study, extracellular recording techniques were used to investigate the significance of GABA_B-receptor activation for the firing properties of DA neurons in the substantia nigra (SN) in the rat. Intravenous administration of the GABA_B-receptor agonist baclofen in low doses (1-16 mg/kg), insufficient to decrease firing rate, was associated with a dose-dependent regularisation of the firing pattern, concomitant with a reduction in burst firing. Also, systemic administration of relatively low doses of γ -hydroxybutyric acid (GHBA; 50-300 mg/kg, i.v.) induced a regularisation of the firing pattern. Both the regularisation of the firing pattern and inhibition of firing rate produced by these drugs were antagonized by the GABA_B-receptor antagonist CGP 35348 (200 mg/kg, i.v.).

By combining electrophysiological recording of dopaminergic neurons in the SN and microdialysis in the striatum in the same rat and simultaneously it was possible to directly compare the effect of pacemaker-like activity on the extracellular DA concentration in the striatum. Systemic administration of a low dose of GHBA (200 mg/kg, i.v.), which did not change the firing rate of the dopaminergic neurons, but induced a pacemaker-like activity, decreased the DA efflux in the striatum with 30%.

The present results indicate that GABA_B-receptors are involved in the modulatory control of firing pattern, that relatively low doses of GHBA induces pacemaker-like activity and that pharmacologically induced pacemaker-like activity reduces the DA efflux in the striatum.

ELECTROPHYSIOLOGICAL RESPONSES OF MESENCEPHALIC DOPAMINE NEURONS TO DORSAL RAPHE STIMULATION IN 5-HT-DEPLETED RATS. J. Gervais and C. Rouillard*, Lab. of Neurobiology and Dept. of Pharmacology, Laval University, Québec, Canada G1J 1Z4.

Several lines of evidence indicate that 5-HT afferences from the dorsal raphe (DR) nucleus and 5-HT drugs can modulate the spontaneous activity of mesencephalic DA neurons. We have previously demonstrated that DR stimulation induced two different types of response in both SNpc and VTA. Some DA cells exhibited an inhibition-excitation sequence while in others DA neurons, the initial response was an excitation followed by an inhibition. In SNpc, 56% of the DA cells recorded were initially inhibited, 31% were initially excited and only 13% were not affected by DR stimulation. In contrast, 63% of the VTA DA cells recorded were initially excited, 34% were initially inhibited and 2% were not affected. However, the DR also contain a fair proportion of non-5-HT elements. Therefore, the main objective of the present study was to determine the specific contribution of 5-HT fibres to the effects recorded in the midbrain after electrical stimulation of the DR. To lesion the 5-HT system selectively, rats were injected i.c. with 5,7-DHT alone or in combination with a daily i.p. treatment with PCPA. At least 10 days were allowed for neuronal degeneration to occur before performing *in vivo* extracellular single unit recordings in chloral hydrate-anesthetized rats. DA neurons in the SNpc and VTA were recorded using single barrel micropipettes and were identified by their location, waveform, firing rate and pattern. DR stimuli consisted of monophasic square wave pulses of 800 µA intensity and 350 µsec duration delivered at a rate of 0.5 Hz. Destruction of DR 5-HT neurons almost completely abolished the inhibition in both SNpc and VTA (0 and 6% respectively), without important change in the number of DA cells excited. Consequently, the proportion of DA neurons which were not affected by DR stimulation have increased after 5-HT depletion (60% in SNpc and 31% in VTA). These data strongly suggest that the 5-HT input from the DR nucleus is mainly inhibitory and modulate in a different manner the DA neurons of nigrostriatal and mesolimbic systems.

ELECTROPHYSIOLOGICAL EFFECTS OF (-)HA-966: EVIDENCE FOR AN INTERACTION WITH GABA_A RECEPTORS. P.D. Shepard*, S.T. Connelly and K.C. Grobaski, MD Psychiatric Res. Cntr., Baltimore, MD 21228.

HA-966 (\pm 1-hydroxy-3-amino-pyrrolidinone-2) has been shown to produce marked changes in both the firing rate and discharge pattern of mesencephalic dopamine (DA)-containing neurons *in vivo* (Shepard and Lehmann, JPET 261:387, 1992). These effects do not appear to be mediated by the NMDA antagonist properties of (+)HA-966 but rather through a γ HB-like effect of the (-)enantiomer (McMillen et al., J. Neural Trans., 89:11, 1992). In the present series of experiments, electrophysiological techniques were used to explore the pharmacological mechanisms underlying the effects of (-)HA-966 on the activity of mesencephalic DA-containing neurons in the rat.

As previously reported, systemic administration of (-)HA-966 produced a dose-dependent inhibition in neuronal firing rate in chloral hydrate (CH) anesthetized rats (ED₅₀ = 5.5 mg/kg). Although similar results were obtained in ketaminized animals, the potency of the drug was significantly reduced (ED₅₀ = 13 mg/kg). Parallel experiments conducted using an *in vitro* brain slice preparation confirmed the ability of (-)HA-966 to suppress neuronal activity (EC₅₀ = 500 µM), however, addition of low concentrations of CH (10 µM) to the bathing media failed to potentiate the inhibitory effects of the drug. Bath application of the selective GABA_A antagonist CGP-35348 (100 µM), completely reversed the inhibitory effects of (-)HA-966 *in vitro*. CGP-35348 (200 - 500 mg/kg, i.v.) was also effective in antagonizing the inhibitory effects of (-)HA-966 *in vivo*, although neuronal firing rate failed to return to pre-drug levels. Taken together, these data suggest that the inhibitory effects of (-)HA-966 are mediated locally, possibly through an interaction with GABA_A receptors on DA-containing neurons. (Supported by NARSAD and MH-48543).

SUBTHALAMIC NUCLEUS LESIONS: EFFECTS ON MK-801 STIMULATION OF NIGROSTRIATAL DA NEURONS. A.R. West, J. Zhang, M.D. Kelland*, and A.S. Freeman, Cellular and Clinical Neurobiology Program, Dept. of Psychiatry, Wayne State Univ. Sch. of Med., Detroit, MI 48201.

Noncompetitive NMDA antagonists (e.g., MK-801, PCP, TCP) stimulate the firing rate of rat nigrostriatal (NSDA) and mesoaccumbal dopamine (DA) neurons after i.v. administration. The site(s) of the glutamatergic synapses involved in this effect is not known. It is known that the excitation is indirect, perhaps secondary to inhibition of midbrain interneurons (EJP 230:371, 1993). Because the subthalamic nucleus (STN) provides a glutamatergic input to the midbrain, and affects nigral DA and non-DA cell activity (Smith & Grace, Synapse 12:287, 1993), we have begun to evaluate its role in the effects of MK-801 on DA neuronal activity. Rats received unilateral injections of ibotenic acid or saline into the STN nucleus. After 7-9 days, rats were anesthetized and electrophysiological recordings were made from identified NSDA neurons. The response of NSDA cells to MK-801 (0.05-3.2 mg/kg, i.v.) was not significantly altered in lesioned rats (N=9) compared to controls (N=8). It was observed that nigral DA neurons were relatively scarce in the lesioned rats. A preliminary cells/track analysis revealed that the number of spontaneously active nigral DA neurons in lesioned rats (N=4) was about half that in controls; average firing rates were not altered. These results suggest that glutamatergic afferents from the STN nucleus are not essential for MK-801-induced stimulation of NSDA neuronal firing. It is possible, however, that remaining STN cells contribute to the effects of MK-801 in lesioned rats. Because the effects on MADA neurons are greater than on NSDA neurons, we are testing the effects of STN lesions on MADA cell responses to MK-801. (Support: DA07844, MH42136).

ELECTROPHYSIOLOGICAL EFFECTS OF THE SELECTIVE 5-HT-1A AGONIST, 8-OH-DPAT, ON MIDBRAIN DA NEURONS: A9/A10 DIFFERENCES. J. Zhang* and A.S. Freeman, Cellular and Clinical Neurobiology Program, Dept. of Psychiatry, Wayne State Univ. Sch. of Med., Detroit, MI 48201.

The 5-HT-1A agonist 8-OH-DPAT is known to excite a subpopulation of nigrostriatal (A9) DA neurons (Kelland et al., JPET 253:803, 1990). In the present study, *in vivo* single-unit recording methods were used to compare the effects of 8-OH-DPAT on A9 and A10 DA neurons in anesthetized rats. 8-OH-DPAT (4-128 μ g/kg, i.v.) stimulated the firing rates of 9 of 16 (56%) A9 DA neurons and 21 of 22 (95%) A10 DA neurons. The stimulatory effects were of greater magnitude on A10 DA neurons. 8-OH-DPAT (128 μ g/kg) also significantly altered A10 DA neuronal firing pattern, as evidenced by increased burst-firing and reduced regularity of firing. Sensitivity of A9 and A10 DA cells to quinpirole-induced inhibition was not altered by 8-OH-DPAT. Acute midbrain/forebrain hemitranssection did not alter 8-OH-DPAT-induced changes in DA neuronal firing rate or pattern. In contrast to the effects of i.v. 8-OH-DPAT, microiontophoretic administration did not increase DA neuronal firing rate. Microiontophoretic 8-OH-DPAT, however, selectively increased burst-firing of A10 DA cells, and reduced the regularity of A9 and A10 DA neuronal firing.

In summary, the excitatory effects of i.v. 8-OH-DPAT are more pronounced on A10 DA neurons compared to A9 DA neurons. As concluded previously for A9 DA cells (Kelland et al., 1990), the 8-OH-DPAT-induced increases in A10 DA cell firing rate appear to be indirect, perhaps via disinhibition secondary to inhibition of raphe 5-HT cells. The excitatory effects of 8-OH-DPAT on DA neurons do not appear dependent on actions at forebrain sites or DA autoreceptors. (Support: DA07844.)

563.9

VENTRAL TEGMENTAL AREA AND PREFRONTAL CORTEX UNIT FIRING AFTER ACUTE TREATMENT WITH GAMMA-HYDROXYBUTYRATE IN ANESTHETIZED RATS. P. Jelenic*, C. Labrie* and R. Godbout*, Département de psychologie* et de psychiatrie*, Université de Montréal, Montréal (Québec) Canada H4J 1C5

Gamma-hydroxybutyrate (GHB) is a naturally occurring fatty acid with peculiar hypnotic properties as it can readily induce REM sleep. It has been shown that GHB modifies dopamine (DA) synthesis while sparing 5-HT and noradrenaline. The medial prefrontal cortex (PFC) is densely innervated by DA afferents from the ventral tegmental area (VTA) and both structures contain GHB uptake and binding sites. To better understand the possible link between the effects of GHB on (REM) sleep and on DA neurotransmission, this study analyzed the consequences of acute administration of GHB on firing rates of VTA and PFC neurons in urethane-anesthetized rats.

Confirming previous studies, GHB (250 mg/kg, i.p.) inhibited reversibly VTA cell firing (latency to 50% inhibition: 19-28 min; maximal firing decrease: 100% of baseline; latency to 90% recovery of firing: 56-82 min). PFC firing was also reversibly inhibited by GHB (50-500 mg/kg) in 75% of the 28 neurons tested, in a dose-dependent manner (latency to 50% inhibition: 11-25 min; maximal firing decrease: 72-85% of baseline; latency to 90% recovery: 24-193 min).

Since DA normally inhibits PFC firing *in vivo*, PFC activity should have been increased after GHB. Various possibilities are presently considered to explain these results, including the involvement of non-DA mechanisms. We are also presently investigating possible targets of GHB-sensitive VTA cells, including structures involved in the triggering of REM sleep.

DOPAMINERGIC MODULATION OF THE INPUT/OUTPUT FUNCTION OF RAT PIRIFORM CORTEX PYRAMIDAL CELLS. R.E. Bergman*, E. Barkai and M.E. Hasselmo, Department of Psychology, Harvard University, Cambridge, MA 02138.

Computational models of schizophrenia which focus on dopaminergic modulation in cortical structures (Cohen and Servan-Schreiber, *Psych. Rev.* 99: 45-77) use an inaccurate representation of the input/output function of cortical pyramidal cells, implementing dopaminergic modulation as a shift in slope of a sigmoid function which is stable over time. In contrast, the input/output function of real cortical pyramidal cells depends strongly on previous activity. To obtain an accurate representation of dopaminergic modulation in biophysical simulations, we tested the effect of dopamine on the full *f/I* curve of piriform cortex pyramidal cells ($n = 10$, mean $V_m = -74.5$ mV, mean spike height = 98.7 mV, mean threshold = -50.2 mV).

All pyramidal cells showed adaptation of the spiking response to 1 sec. intracellular current injection at a range of amplitudes, with increased interspike interval at later stages of current injection. Perfusion with dopamine (10 μ M, $n=5$) decreased this adaptation, increasing the frequency of action potential generation. This effect appears to be due to suppression of an afterhyperpolarization (AHP) current with a reversal potential between 80 to 85 mV. In the presence of 200 μ M cadmium, the influence of dopamine on firing frequency and total spikes generated was blocked ($n=3$). Dopamine did not change the shape of action potentials generated. This data suggests that the influence of dopamine on neuronal adaptation is mediated by modulation of a calcium-dependent potassium current. In slices perfused with 20 μ M carbachol, causing partial suppression of adaptation, dopamine was still capable of increasing the spiking response, suggesting these modulators act on different systems. Dopamine appeared to increase the amplitude of EPSPs generated by stimulation of both afferent (layer 1a) and intrinsic (layer 1b) fibers.

ELECTROPHYSIOLOGICAL EFFECTS OF CCK PEPTIDES ON SUBSTANTIA NIGRA PARS RETICULATA NEURONS. A.S. Freeman* and J. Zhang, Cellular and Clinical Neurobiology Program, Dept. of Psychiatry, Wayne State Univ. Sch. of Med., Detroit, MI 48201.

The ventral tier of nigral (A9) DA neurons sends dendrites ventrally into the pars reticulata (SNr). The SNr contains interneurons and output neurons, and a regulatory role for dendritically released DA on SNr neurons is likely (Waszczak and Walters, *Science* 220:218, 1983). Because CCK-8S is contained in DA neurons and can be released dendritically, it too may influence SNr cell activity. In this study, the effects of i.v. CCK-8S, CCK-US and CCK-4 on the firing rate of antidromically identified nigrothalamic (NTh) SNr cells and footpinch-sensitive SNr cells (putative interneurons) were tested in anesthetized rats.

The CCK-A/CCK-B agonist CCK-8S (8 and 16 μ g/kg, $N=25$) produced short-lived (≈ 4 min) inhibitions of the activity of the majority of SNr neurons sampled. These effects were similar in time-course but opposite in amplitude to those it exerts on midbrain DA neurons. In contrast, the CCK-B receptor agonists, CCK-8US (8, 16 and 64 μ g/kg, $N=19$) and CCK-4 (8, 16, 64 μ g/kg, $N=12$), each produced slowly developing increases in the firing rate of SNr neurons. These results suggest that both CCK-A and CCK-B receptors influence SNr neuronal activity. The location of the receptors for these responses cannot be determined from the present experiments. Additional studies are required to assess possible effects of endogenous CCK-8S on SNr neuronal function. Almost all footpinch-excited neurons were identified as NTh cells. This clouds interpretation of the results on the strict basis of a sharp division between output cells and putative interneurons. This may be related to the fact that NTh cells have collateral branches in the substantia nigra. Support: MH42136.

NEURONAL INHIBITION BY IONTOPHORETICALLY APPLIED DOPAMINE OR GABA IN THE MEDIAL SEPTAL/MEDIAN PREOPTIC AREA IN RATS.

F.P. Marial, S.N. Thornton* and S. Nicolaidis, CNRS URA 637, Neurobiologie des Régulations, Collège de France, 11 pl. M. Berthelot, 75231 Paris Cedex 05, France.

The median septum/preoptic area has been implicated in hydromineral balance regulation. Our previous electrophysiological results have shown that neurons in this area are influenced by the hormones of this regulation ie angiotensin II and aldosterone (Society for Neurosciences abstract 561.1, 1991). GABA and dopamine are also known to modulate neuronal activity in this area. Therefore, we have investigated the effects of iontophoretic application of GABA, dopamine, D1 and D2 agonists on neuronal activity in this region.

Twenty-one male Wistar rats were anaesthetized with urethane and a 7 barrelled microiontophoretic electrode attached to an extracellular recording electrode was then advanced through the cortex into the medial septum/median preoptic area where unit activity was recorded.

In this area 115 spontaneously active neurons were tested for their responses to dopamine. Of these neurons 72 (62.6%) were inhibited, 2 (1.7%) were activated and the rest were not affected. Of the dopamine responsive neurons 12 were tested with the D1 agonist SKF 38393 which inhibited them all. The D2 agonist LY 171555 was tested in 19 of which only 11 (57.9%) were inhibited with no effect on the others. In the same area 53 spontaneously active neurons were tested with GABA of which 30 (56.9%) were inhibited. On 11 GABA responsive cells aldosterone was also applied iontophoretically and 8 had their sensitivity to GABA modified (either decreased or increased). The inhibition by dopamine was immediate whereas that of GABA slower.

These results suggest that the well known inhibitory effect of GABA can be modulated by aldosterone in the septo-preoptic area. Dopamine may also play an important role in this area as a potent inhibitor of neuronal activity (mostly through D1 receptors). (Supported by MH 43787)

EFFECTS OF DOPAMINE AND CAMP AGONISTS ON I_{Ca2+} AND $[Ca^{2+}]_i$ IN CATFISH ISOLATED CONE HORIZONTAL CELLS. F. Zinebi and B.N. Christensen*, Dept. of Physiology & Biophysics, University of Texas Medical Branch, Galveston, TX 77555-0641.

$[Ca^{2+}]_i$ and I_{Ca2+} were measured simultaneously in fura-2 loaded cells using the whole cell patch-clamp technique. Dopamine (DA), the DA1 agonist (SKF-38393), forskolin (For) and 8-bromoadenosine 3',5'-cyclic monophosphate (8bcAMP), were applied to the cell by pressure ejection or under concentration-clamp conditions in normal Ca^{2+} or in 15 mM barium. These cells are believed to express only the DA1 receptor. Our results indicate that: a) these drugs showed no significant effect on $[Ca^{2+}]_i$ when applied to the cell clamped at the resting membrane potential (-65 mV); b) when the I_{Ca2+} is maximally activated, DA can produce a simultaneous decrease or increase in I_{Ca2+} and $[Ca^{2+}]_i$ whereas those drugs that stimulate cAMP only decrease I_{Ca2+} and $[Ca^{2+}]_i$. We conclude that the decrease in both I_{Ca2+} and $[Ca^{2+}]_i$ is due to DA activation of cAMP. The DA-induced increase in I_{Ca2+} and $[Ca^{2+}]_i$ suggests a second role for this neurotransmitter that may involve a different regulatory pathway. Supported by grant NEI-01897.

ELECTROPHYSIOLOGIC EFFECTS OF 7-OH-DPAT ON NIGROSTRIATAL VS MESOLIMBIC DOPAMINE SYSTEMS. J.C. Liu, R.F. Cox¹, G.J. Greif, J.E. Freedman and B.L. Waszczak*. Dept. Pharm. Sci., Northeastern Univ., Boston, MA 02115 and ¹CNS Sect., Burroughs Wellcome Co., Research Triangle Park, NC 27709.

Since D₃ receptor mRNA has been localized in predominantly limbic regions, it was of interest to determine if 7-hydroxy-N,N-di-n-propyl-2-aminotetralin (7-OH-DPAT), a putative D₃-selective agonist, exhibits different effects in nigrostriatal and mesolimbic dopamine systems. Extracellular single unit activities of substantia nigra pars compacta (SNc) and ventral tegmental area (VTA) dopamine (DA) neurons, and caudate-putamen (CPU) and nucleus accumbens (NAC) postsynaptic neurons, were recorded in male rats anesthetized with chloral hydrate. I.v. (+)7-OH-DPAT (RBI) potently and completely inhibited the firing of both SNc and VTA DA neurons (ED₅₀'s: 3.5 ± 0.7 µg/kg, SNc; 3.9 ± 0.9 µg/kg, VTA). The active enantiomer, (+)7-OH-DPAT (BW Co.), was 2-3-fold more potent than the racemic drug (ED₅₀'s: 1.2 ± 0.3 µg/kg, SNc; 1.7 ± 0.4 µg/kg, VTA). There were no significant differences in potency for either drug in inhibiting SNc and VTA neurons. Effects were completely reversed by either i.v. haloperidol (2 mg/kg) or AJ-76 (1-8 mg/kg; Upjohn). In other studies, iontophoretically applied (+)7-OH-DPAT (0.01 M, pH 4, 1-64 nA) caused current-dependent inhibitions of spontaneously active or glutamate-driven CPU and NAC neurons (I₅₀'s: 5.6 and 4.3 nA, respectively). Again, no difference in potency between CPU and NAC cells was noted. Finally, in cell-attached patch-clamp recordings from freshly dissociated rat CPU neurons, an 85 pS K⁺ channel known to be activated by DA and the D₂-like agonist quinpirole was observed with (+)7-OH-DPAT (0.2-1 µM) applied in the patch pipette. Although D₃ receptors have been assumed to play an important role in limbic areas, these results suggest that 7-OH-DPAT behaves similarly to D₃ agonists and does not show significantly different effects on nigrostriatal and mesolimbic systems. Supported by NIH grants NS 23541 (BLW) and MH 48545 (JEF).

ALPHA-ADRENERGIC DEPOLARIZATION OF RAT MIDBRAIN DOPAMINE NEURONS J. Grenhoff*, S.W. Johnson and R.A. North. Vollum Institute, Oregon Health Sciences University, Portland, OR 97201

Interactions between brain noradrenaline and dopamine (DA) systems have been described with a variety of methods, but the cellular mechanisms involved have not been characterized. We used intracellular recording with microelectrodes from rat midbrain slices to study the adrenergic pharmacology of DA neurons in the substantia nigra and ventral tegmental area. The α₁-adrenoceptor agonist phenylephrine (PE; 1-100 µM) produced depolarization and excitation in 67 % of principal (DA) neurons. The depolarization was accompanied by an increase in input resistance and persisted in tetrodotoxin (0.5 µM). In voltage clamp experiments, PE induced an inward current. Neither the α₂ agonist UK 14304 (1 µM) nor the β agonist isoproterenol (10 µM) mimicked the effect of PE. The action of PE was antagonized by the α₁ antagonist prazosin (30 nM-1 µM). These results indicate the presence of excitatory α₁-adrenoceptors on midbrain DA neurons.

FACILITATION OF DENTATE GYRUS FIELD RESPONSES BY VTA STIMULATION IS ATTENUATED BY DOPAMINE ANTAGONISTS Henriksen, S.J.* Steffensen, S.C. and Criado, J.R., Scripps Research Institute, La Jolla, CA 92037

The dentate gyrus is the first processing stage in the hippocampal trisynaptic circuit and occupies a strategic location for subcortical biasing of neocortex-hippocampus-neocortex information throughput. It is heavily innervated by cholinergic and GABAergic fibers from the medial septum (MS) and to a lesser extent by afferents from the supramammillary nucleus, noradrenergic fibers from the locus coeruleus, serotonergic fibers from the dorsal/median raphe and dopaminergic fibers from the ventral tegmental area (VTA). The MS, however, receives a dense dopaminergic innervation. We sought to determine the extent of the physiological dopaminergic input to the dentate gyrus. Stimulation of the VTA in anesthetized rats elicited a small field potential (latency=15ms) recorded in the hilar region of the dentate that produced interval- and activity-dependent facilitation (140%) of perforant path to dentate population spike (PS) amplitudes, but had no effect on PS latency or field EPSPs. Microelectrophoretic application of either the α₂-antagonist, yohimbine, the β-antagonist, propranolol, the 5-HT_{1A} antagonist, NAN 190, the 5-HT₂ antagonist, ketanserin, the GABA_A antagonist, bicuculline, the GABA_B antagonist, saclofen, or muscarinic antagonists, atropine or scopolamine, into the dentate hilus had no effect on VTA facilitation. The ICV administration of the serotonin and noradrenaline neurotoxin, 5,7 dihydroxytryptophan, or the in situ MS injection of the neurotoxin, ibotenic acid, ten days prior to recording had no effect on VTA facilitation. Microelectrophoretic application of the D₂ antagonist, eticlopride, but not the D₁ antagonist, SCH23390, markedly decreased VTA facilitation (80%). Independent of VTA stimulation, eticlopride decreased PS amplitudes and increased recurrent inhibition, while SCH23390 increased PS amplitudes and decreased recurrent inhibition. These results suggest that there is a direct and important dopaminergic input from the midbrain that modulates dentate excitability. This work was supported by DHHS # P50-AA06420 to SJH.

NEUROLEPTIC-INDUCED INCREASE IN BURST FIRING OF DOPAMINE CELLS IS ATTENUATED BY HEMISECTION OF THE STRIATONIGRAL PROJECTION. M.L. Pucak* and A.A. Grace. Departments of Behavioral Neuroscience & Psychiatry, University of Pittsburgh, Pittsburgh, PA 15260.

Dopamine (DA) neurons can exhibit a burst-firing pattern which is associated with enhanced release of DA. In order to investigate whether DA antagonists increase burst firing via blockade of DA receptors within the substantia nigra, we have examined whether the increased percentage of spikes fired in bursts elicited by the DA antagonists haloperidol (HAL; 4 mg/kg, i.v.) or sulpiride (SULP; 32 mg/kg, i.v.) in anesthetized rats is attenuated by hemisection of the striatonigral projection. Hemisection did not significantly alter the effects of haloperidol on the percent of spikes fired in bursts (average difference: intact=1.9±4.7; hemisected=1.2±2.1); however, sulpiride was significantly less effective at increasing burst firing in hemisected rats (intact=4.2±1.6; hemisected=0.5±1.9; p<.05). In addition, a smaller number of neurons exhibited significant increases in burst firing in response to either drug (haloperidol: intact=2/12, hemisected=0/12; sulpiride: intact=4/19, hemisected=1/17). Haloperidol also caused decreases in the percent of spikes fired in bursts in some DA cells (2/12), and this effect was not abolished by hemisection (2/12). Sulpiride decreased burst firing only after hemisection (1/17). These results suggest that the ability of DA antagonists to increase burst firing may be partially mediated indirectly via blockade of DA receptors located in forebrain regions, whereas their ability to decrease burst firing may be mediated locally within the substantia nigra, perhaps by blockade of DA receptors located on descending terminals. Therefore, although we have shown previously that hemisection does not alter the effects of haloperidol and sulpiride on DA neuron firing rate, removing descending feedback afferents does alter the effects of DA antagonists on DA neuron firing pattern. α₁-ADRENOCEPTOR ANTAGONISM MODULATES THE CHANGES IN FIRING PATTERN AND TRANSMITTER RELEASE INDUCED BY A SELECTIVE DOPAMINE (DA)-D₂-ANTAGONIST IN THE MESOLIMBIC, BUT NOT IN THE NIGROSTRIATAL DA SYSTEM. J.L. Andersson*, M. Marcus and T.H. Svensson. Karolinska Institute, Dept. Pharmacology, Box 60400, S-10401 Stockholm, Sweden.

Most antipsychotic drugs are, in addition to being DA-D₂-antagonists, also relatively potent α₁-adrenoceptor antagonists. Here, we have studied the effects on midbrain DA neurons of the selective DA-D₂-antagonist raclopride, alone and in combination with the selective α₁-adrenoceptor antagonist, prazosin, utilizing extracellular single cell recording techniques. In addition, *in vivo* voltammetry was used to measure extracellular DA concentrations in the nucleus accumbens (NAC) and the dorsolateral striatum (STRI) in anesthetized rats during these drug treatments. Raclopride induced a dose dependent increase in firing rate in ventral tegmental area (VTA) DA neurons, significant already at 10 µg/kg, and in zona compacta, substantia nigra (ZC-SN), DA neurons, not significant until 2560 µg/kg. Burst firing was also increased in VTA DA neurons, at 40 µg/kg, as well as in ZC-SN DA neurons, at 640 µg/kg. A high dose of raclopride (2560 µg/kg, cumulated dose) induced a 900% increase in extracellular DA concentrations in NAC, but only a 300% increase in STRI, probably secondary to increased neuronal activity. Thus, our electrophysiological results and voltammetry data demonstrate some limbic selectivity for the selective DA-D₂-antagonist. Prazosin pretreatment (0.3 mg/kg, i.v. 15 min before) abolished the raclopride induced increase in burst firing in VTA DA neurons, while effects on ZC-SN DA neurons were unaffected. The prazosin pretreatment also caused a reduction in raclopride induced elevation of extracellular DA-concentrations in NAC, but not in STRI. Thus, α₁-adrenoceptors seem to modulate the effect of DA-D₂-antagonism preferentially in the mesolimbic, but not in the nigrostriatal DA-system.

INTRACEREBROVENTRICULAR (ICV) NOREPINEPHRINE, MICRODIALYSIS AND PERFORANT PATH-EVOKED POPULATION SPIKE POTENTIATION IN THE RAT DENTATE GYRUS. C.W. Harley*, M.D. Lallies and D.J. Nutt. Psychopharmacology Unit, School of Medical Sciences, Bristol University, Bristol, UK BS8 1TD

Norepinephrine (NE) exogenously applied to the hippocampus *in vivo* and *in vitro* potentiates the perforant path-evoked population spike in dentate gyrus. *In vitro* 10 µM NE is a threshold concentration for this effect (Lacaille, JC & Harley, CW (1985) Brain Res. 358: 210-220).

In the present study microdialysis probes and recording electrodes were implanted in dorsal dentate gyrus of urethane-anesthetized rats to monitor NE levels and perforant path-evoked potentials concurrently. NE, 5 µg in 2 µl artificial cerebrospinal fluid, which we previously found to be near threshold for icv NE-induced potentiation, was injected following a minimum of 60 minutes of baseline monitoring.

Exogenous levels of NE after the icv injection reached 30-700X basal NE levels in the first 15 minute sample. The increase in NE was accompanied by a step-wise potentiation of the population spike which was typically sustained during the postinjection period. NE levels declined steadily from the initial peak, falling by ca 50% in each 15 min sample after the first 30 minutes and returning to basal levels within two hours. Injections entering the medial, but not lateral, ventricles were ineffective in changing the population spike.

These data suggest effective exogenous concentrations for NE-induced potentiation *in vivo* are in the range of 3-1 µM. We hypothesize that similar concentrations might occur synaptically to produce the potentiation effect.

Characterization of a noradrenergic excitatory effect on cholinergic neurones of the nucleus basalis in guinea-pig brain slices. P. Fort, A. Khateb, A. Pegna, M. Mühlethaler and B.E. Jones*, Dept. of Physiology, CMU, 1211 Geneva 4, Switzerland and *Montreal Neurological Inst., McGill University, Montreal, Canada H3A 2B4.

Cholinergic neurones of the nucleus basalis represent a major relay of the ascending reticular activating system, receiving inputs from the brainstem and projecting in turn upon the cerebral cortex. One of the important-brainstem afferent inputs to the cholinergic cells derives from the noradrenergic locus coeruleus neurones. The potential influence of the noradrenergic input was examined by bath application of drugs onto identified cholinergic basalis neurones recorded by intracellular technique in guinea-pig brain slices. Noradrenaline (NA) consistently produced a strong membrane depolarization that was accompanied by an increase in membrane resistance and a marked increase in firing rate. The effects were mimicked by L-phenylephrine, an α_1 -receptor agonist, and blocked by prazosin, a selective α_1 -antagonist, whereas no effects were produced by clonidine, the α_2 -agonist. Isoproterenol, a beta agonist, also produced an effect upon the membrane, although weaker than that of NA or L-phenylephrine. Thus by potential action upon both α_1 - and beta receptors, noradrenaline produces a depolarization of the cholinergic basalis neurones, which would tend to promote and accelerate tonic firing in these cells. CONTROL OF CALCIUM CURRENT IN RAT TRIGEMINAL NEURON BY ADRENERGIC AND MUSCARINIC RECEPTOR AGONISTS. Seung-Yeol Nah* and Edwin W. McCleskey Dept. of Cell Biology and Physiology, Washington University School of Medicine, St. Louis, Missouri 63110, U. S. A.

The effect of adrenergic and muscarinic receptors agonists on Ca current of adult rat trigeminal ganglion neurons was investigated using whole-cell patch-clamp methods. The application of acetylcholine, carbachol, or oxotremorine ($50 \mu\text{M}$ each) produced rapid, reversible reduction of the Ca current by $17 \pm 6\%$, $19 \pm 3\%$, and $18 \pm 4\%$, respectively. Atropine, a muscarinic antagonist, blocked carbachol-induced Ca current inhibition to $3 \pm 1\%$. Norepinephrine ($50 \mu\text{M}$) reduced Ca current by $18 \pm 2\%$, while clonidine ($50 \mu\text{M}$), an α_2 -adrenergic agonist, inhibited Ca current by only $4 \pm 1\%$. Yohimbine, an α_2 -adrenergic antagonist, did not block the inhibitory effect of norepinephrine on Ca current, whereas prazosin, an α_1 -adrenergic antagonist, attenuated the inhibitory effect of norepinephrine on Ca current to $6 \pm 1\%$. This pharmacology contrasts with α -adrenergic modulation of Ca channels in sympathetic neurons, which is sensitive to clonidine but not blocked by yohimbine. Our data are consistent with modulation via an α_1 -adrenergic receptor, but we cannot exclude the possibility of a novel α -adrenergic receptor. Treatment with pertussis toxin (250 ng/ml) for 16 hours greatly reduced norepinephrine- and carbachol-induced Ca current inhibition to $2 \pm 1\%$ and $2 \pm 1\%$, respectively. These results demonstrate that norepinephrine, through an α -adrenergic receptor, and carbachol, through a muscarinic receptor, inhibit a Ca current in adult rat trigeminal ganglion neurons via pertussis toxin sensitive GTP-binding proteins.

SEROTONIN RECEPTORS: ONTOGENY AND REGULATION

564.1

TIME COURSE OF THE DOWNREGULATION OF SOMATODENDRITIC 5-HT_{1A} AUTORECEPTORS PRODUCED BY IPSAPIRONE TREATMENT. K. McMonagle-Strucko* and R.J. Fanelli. Inst. for Dementia Research, Miles Inc., West Haven, CT 06516.

Previous work found that rats treated twice daily with ipsapirone (10 mg/kg IP) for 3 weeks resulted in a large decrease in 5-HT_{1A} binding in the dorsal raphe nucleus. Additional experiments were performed to determine the time course for the development and duration of the effects of ipsapirone treatment on 5-HT_{1A} receptors. In an initial study, rats were treated twice daily with ipsapirone (10 mg/kg IP) for 1 day, 1 wk, or 2 wks and sacrificed 24 hrs after the final injection. In a second study, rats were treated for 3 wks and sacrificed 1, 48, 72 hrs or 7 days following the final treatment. Quantitative analyses were done of autoradiograms of *in vitro* [³H]8-OH-DPAT binding. The first study showed that the decrease in binding in the dorsal raphe nucleus was not apparent at times measured prior to 3 wks of treatment. In the second study, where rats were treated with ipsapirone for 3 wks and sacrificed at varying times following the final injection, large declines in 5-HT_{1A} were found in the dorsal raphe nucleus 1 and 48 hrs following treatment. When brains were obtained 72 hrs following ipsapirone treatment, 5-HT_{1A} binding was back to control levels.

564.3

INCREASED HIPPOCAMPAL SPROUTING OF 5,7-DHT LESIONED SEROTONERGIC NEURONS AFTER DELAYED TREATMENT WITH THE 5-HT_{1A} AGONIST TANDOSPIRONE. A. Shemer*, J. Bell, E. Azmitia and P.M. Whitaker-Azmitia, Pfizer, Inc., New York, New York 10017, Dept. of Biology, New York University, New York, NY, 10003 and Dept. of Psychiatry, SUNY, Stony Brook, New York, 11794.

Selective 5-HT_{1A} receptor agonists can release the growth factor S-100 β from immature astroglial cells. This growth factor promotes terminal growth of serotonergic neurons during critical stages of development. Adult serotonergic neurons are also capable of terminal re-growth after 5,7 DHT lesions - a process which takes approximately six weeks. The current study was undertaken to determine if a 5-HT_{1A} agonist could accelerate the re-growth of a lesioned adult brain, presumably through the release of S-100 β .

Adult male Sprague-Dawley rats were pretreated with desipramine and lesioned by 5,7 DHT ($4 \mu\text{g}/4 \mu\text{l}$) injection unilaterally into the cingulum bundle and into the fornix-fimbria. Animals were treated for 12 days postlesion with saline or 10 mg/kg tandospirone or with saline for 9 days followed by 3 days tandospirone. On day 12 postlesion, animals were perfused and immunohistochemically stained for S-100 β , 5-HT_{1A} receptor and serotonin. All of the lesioned animals showed increased S-100 β and 5-HT_{1A} staining above unlesioned. However, only the lesioned animals treated with saline for nine days and three days with tandospirone showed a recovery of serotonin immunoreactivity.

564.2

CHANGES IN SEROTONIN RECEPTOR SUBTYPES INDUCED BY SHORT- AND LONG-TERM ANTIDEPRESSANT TREATMENT. M. Frankfurt*, C.R. McKittrick and B.S. McEwen. Laboratory of Neuroendocrinology, The Rockefeller University, New York, NY 10021.

Fluoxetine, a 5HT uptake inhibitor, and tianeptine, a 5HT uptake enhancer, are both clinically active antidepressants. We compared the effects of these drugs on 5HT receptor binding, following both short- and long-term administration. Fluoxetine or tianeptine (10 mg/kg) or saline was administered *i.p.* to male rats daily for 4 or 21 days. Animals were killed 48 h after the last injection. Brains were frozen and sliced into $16 \mu\text{m}$ sections; adjacent sections were processed for quantitative autoradiography of various 5HT receptor subtypes. Receptor binding in 11 regions was analyzed using computer-assisted densitometry. Tianeptine treatment for 21 d, but not 4 d, significantly increases 5HT_{1B} receptor binding in the dorsomedial nucleus of the hypothalamus ($\uparrow 12.2\%$) and the sensory region of the parietal cortex ($\uparrow 14.3\%$). Fluoxetine has no effect at either time point. Fluoxetine, but not tianeptine, for 21 d significantly decreases binding of paroxetine, which labels 5HT uptake sites, in CA3 of hippocampus ($\downarrow 18.7\%$) and dentate gyrus ($\downarrow 19.1\%$). Neither drug affects 5HT_{1A} receptor binding after 4 d treatment. 5HT_{1A} binding following 21 d and paroxetine binding following 4 d treatment are currently being analyzed. The changes described above suggest that alterations in 5HT receptors are involved in the mechanism of action of these antidepressants. Further investigation is required to determine how the apparently opposing effects of these drugs converge to produce an antidepressant effect.

EXPRESSION CHANGE OF 5-HT_{1A} mRNA IN THE HIPPOCAMPUS OF THE LONG-TERM ADRENALECTOMIZED RATS. B. Liao*, B. Mlesak and E.C. Azmitia. Dept. of Biology, New York Univ., New York, N.Y. 10003

Age-matched female Sprague-Dawley rats weighing about 150 g were adrenalectomized (ADX) and maintained with free access to saline for two months. After two months, part of the ADX rats were given dexamethasone (dex) (10 ug/ml saline) 24 or 72 hr before perfusion. *In situ* hybridization histochemistry showed a dramatic decrease of 5-HT_{1A} mRNA in the dentate gyrus (DG) of the hippocampus in the ADX rats but no apparent change in the CA1 to CA4 regions compared to the sham ADX rats. The ADX rats given dex showed a progressive recovery of 5-HT_{1A} mRNA labelling in DG after exposure to dex for 24 and 72 hr. There was a corresponding decrease of Nissl stained cells in the granular cell layer of the DG in the ADX rats. Both the superior and inferior blades of the DG became shorter and thinner. Dex treatment reduced a recovery of Nissl staining, with a denser staining in the inferior blade than in the superior blade.

It has been suggested by Sloviter et al. that circulating adrenal steroids are essential for maintaining the structural integrity of DG granule cells in the hippocampus. We have found that the 5-HT_{1A} receptors in the hippocampus are linked to the production of S-100 β , which is a neurotrophic factor and a glial mitogen that serves important roles in CNS development and maintenance. The present study shows that the expression of 5-HT_{1A} mRNA as well as Nissl stained cells in the DG were reduced after long-term ADX rats and progressively recovered after exposed to dex. Therefore, we speculate that the manipulation of 5-HT_{1A} receptors by adrenal steroids may underlie the plasticity of the granular neurons in the long-term ADX rats. Supported by NSF 88-12892.

DEXAMETHASONE INCREASES 5-HT_{1A} RECEPTOR, VIMENTIN, p53, c-FOS AND CALBINDIN IMMUNOREACTIVITY IN HIPPOCAMPUS AND CORTEX OF THE LONG-TERM ADRENALECTOMIZED ADULT RAT.

E.C. Azmitia¹, J. Bell III¹, B. Liao¹ and P.M. Whitaker-Azmitia², ¹Lab. of Mol. Neuroplasticity, Dept. Biol., New York Univ., NY, NY 10003; ²Dept. Psychiat., SUNY, Stony Brook, NY 11794

Long-term adrenalectomy (LT ADX) leads to a loss in the number of neurons in the dentate gyrus and we have shown corresponding decreases in 5-HT_{1A} receptor mRNA in situ hybridization in the dentate gyrus (DG). Treatment with dexamethasone (dex) for 24-72 hours in the long-term ADX rats produces a recovery of 5-HT_{1A} receptor mRNA labeling and the reappearance of Nissl-positive cells in the granular layer. In this study, a variety of molecules associated with cell differentiation were tested in LT ADX with or without dex. for 72 hr.

Adult SD female rats (175-200 g) were bilaterally adx and kept on saline (Sal) for 2 months before being further divided into a saline group or a group given dex (10 µg/ml) in their saline drinking water for 72 hr. before death. A sham adx group was also studied. The animals were perfused transcardially with 4% paraformaldehyde, 0.1% MgCl₂ in 0.1M phosphate-buffered saline. The brains were removed and processed with antibodies raised against 5-HT_{1A} receptor, vimentin, c-fos, p53, S-100β, and calbindin. Sections were counter-stained with methyl green.

Astrocytic labeling in the hippocampus (dentate gyrus, cornu Ammonis (CA), subiculum, indusium griseum and fasciola cinerea) and cortex (temporal and parietal) were increased for 5-HT_{1A} receptors, vimentin, p53 and c-fos in LT ADX given dex compared to both sham ADX and LT ADX. S-100β labeling showed no apparent change in these cells. Calbindin stained neurons were decreased in LT ADX especially in the pyramidal dendrites of CA_{1,2} and the molecular layer of the superior blade of DG. These changes were reversed by dex. A number of pyramidal neurons in subiculum, fasciola cinerea and CA₄ were both c-fos and p-53 positive in LT ADX and their number was increased after dex. These results are consistent with glucocorticoid regulation of glial and neuronal differentiation in the adult brain. (Work supported by NIA Program Project AG10208)

564.7

EFFECTS OF DEXAMETHASONE ADMINISTRATION ON HIPPOCAMPAL 5-HT_{1A} RECEPTOR GENE EXPRESSION D.T.Chalmers*, J.Lopez, D. Yaquez and S.J.Watson. Mental Health Research Institute, University of Michigan, Ann Arbor, Michigan, 48109-0720.

We have previously reported that hippocampal 5-HT_{1A} receptor gene expression is increased in response to adrenalectomy (ADX) and is responsive to low dose corticosterone administration, implicating MR sensitivity. In the present study, we have employed dexamethasone (DEX), a selective GR agonist, to investigate the effects of GR occupation on 5-HT_{1A} mRNA expression.

Rats were ADX (12) or SHAM treated (11). Five ADX animals received daily injections of DEX (50ug, i.p.) for 1 week, remaining ADX animals received saline. SHAM animals received injections of saline (6) or DEX (5). After 1 week ADX, 5-HT_{1A} receptor mRNA expression was significantly increased in all hippocampal subfields. ANOVA analysis indicated significant effects of treatment in all subfields (p<0.01). In the same animals, 5-HT_{1A} binding exhibited parallel, though proportionally smaller, increases in all hippocampal subfields post-ADX. Administration of DEX at the time of ADX significantly attenuated increases in 5-HT_{1A} mRNA expression in all subfields (p<0.05, Fisher Test), although 5-HT_{1A} mRNA levels remained significantly higher than SHAM levels in all subfields with the exception of CA1. However, unlike 5-HT_{1A} mRNA expression, 5-HT_{1A} binding levels were responsive to DEX administration only within selective hippocampal subfields, CA1 and dentate gyrus. We conclude that GR occupation negatively regulates 5-HT_{1A} receptor mRNA expression within the hippocampus and that 5-HT_{1A} receptor sites are more sensitive to modulation in those hippocampal subfields expressing the highest levels of GR receptors, CA1 and dentate gyrus.

564.9

REGULATION OF THE 5-HT_{1A} RECEPTOR IN P11 CELLS EXPRESSING BOTH 5-HT_{1A} AND 5-HT₂ RECEPTORS. J.G. Hensler*, H.A. Miller and P.B. Molinoff. Depts. Psychiatry and Pharmacology, U. of Pennsylvania School of Medicine, Dept. of Veterans Affairs Medical Center, Phila., PA. 19104-6084.

P11 cells, which express 5-HT₂ receptors coupled to phosphoinositide (PI) hydrolysis (lvins *et al.*, Mol. Pharm. 37:622, 1990), were transfected with the gene for the human 5-HT_{1A} receptor. Expression of the 5-HT_{1A} receptor in P11 cells was verified by measuring the specific binding of ³H-DPAT (K_d = 0.7-1.2 nM, B_{max} = 100-500 fmol/mg protein). In P11 cells expressing the 5-HT_{1A} receptor, DPAT did not stimulate PI hydrolysis and 5-HT₂ receptor-mediated stimulation of PI hydrolysis was not modified. DPAT inhibited forskolin-stimulated cAMP accumulation in a concentration-dependent manner (EC₅₀ = 1-3 nM). Maximal inhibition by DPAT (1 µM) was approximately 70-80%. Incubation of P11 cells with the 5-HT₁ receptor agonist 5-carboxamidotryptamine (5-CT; 100 nM) for 18 hr resulted in a marked enhancement of forskolin-stimulated cAMP formation and a significant increase in the EC₅₀ value of DPAT to inhibit cAMP formation, with no change in the degree of maximum inhibition. The change in the potency of DPAT to inhibit forskolin-stimulated cAMP formation was not accompanied by changes in 5-HT_{1A} receptor affinity or number. Exposure of cells to 5-HT (10 µM) for periods of time (15 min, 30 min, or 1 hr) sufficient to maximally stimulate PI hydrolysis through 5-HT₂ receptor activation, did not alter the potency or efficacy of DPAT to inhibit forskolin-stimulated cAMP formation. Treatment of P11 cells with the phorbol ester PMA (1 µM, 15 min) resulted in a significant decrease in the maximum inhibition of cAMP formation by DPAT (Control: E_{max} = 70 ± 7%; PMA pretreated: E_{max} = 34 ± 3 %, n=4). However, this desensitization was not accompanied by changes in 5-HT_{1A} receptor affinity or number. These data suggest that although activation of protein kinase C by phorbol ester results in the desensitization of the 5-HT_{1A} receptor expressed in P11 cells, stimulation of 5-HT₂ receptor-mediated PI hydrolysis does not. (Supported by USPHS grant MH 48125 and Dept. of Veterans Affairs).

MINERALO- AND GLUCOCORTICOID RECEPTORS SYNERGISTICALLY MEDIATE THE ACTION OF CORTICOSTERONE ON 5-HT_{1A} mRNA EXPRESSION IN DENTATE GYRUS.

O.C. Meijer and E.R. de Kloet* Div. of Medical Pharmacology, Leiden/Amsterdam Center for Drug Research, University of Leiden, P.O. Box 9503, 2300 RA Leiden, The Netherlands.

Corticosterone (B) is well established as a regulator of several aspects of the serotonergic raphe-hippocampal system. The effect of different plasma concentrations of B on 5-HT_{1A} receptor mRNA expression in the hippocampus and the dorsal raphe nucleus (DRN) was studied, in order to differentiate between the actions mediated via the high affinity mineralocorticoid receptor (MR) and via the lower affinity glucocorticoid receptor (GR).

Male Wistar rats were adrenalectomized (ADX) and in two groups of animals either 20% (Low B) or 100% B (High B) pellets were implanted subcutaneously. This led to plasma B levels at which either predominantly the MRs or both MRs and GRs were occupied, respectively. One week post surgery, significant effects were measured only in the granule cell layer of the dentate gyrus, where a negative correlation between plasma B levels and 5-HT_{1A} receptor mRNA amounts was seen. ADX led to a 38% increase in expression, Low B replacement to normalization towards levels of sham-operated animals and High B to a pronounced decrease in expression of the message. A trend towards increased expression after ADX was observed for the CA3 pyramidal cells, whereas the neurons in the CA1 cell field and the DRN remained unresponsive.

These results suggest that endogenous B, via MR activation, suppresses 5-HT_{1A} receptor mRNA expression in the dentate gyrus, and that elevations in plasma B can further down-regulate the 5-HT_{1A} receptor mRNA via synergistic action of activated MRs and GRs.

EFFECT OF ADRENALECTOMY ON 5HT RECEPTOR SUBTYPE mRNA EXPRESSION IN THE RAT HIPPOCAMPUS AND RAPHE. M.C. Holmes*, K.L. French, J.L.W. Yau and J.R. Seckl. Dept Med, Western Gen Hosp, Edinburgh Univ, Scotland.

Glucocorticoids alter serotonergic (5HT) activity in the raphe-hippocampal (HC) system, thereby affecting mood. Following adrenalectomy (ADX) there is a rise in corticosteroid receptors and increased binding of ³H-5HT in HC subregions. We have investigated the effect of ADX on mRNA expression encoding 5HT_{1A}, 5HT_{1C} and 5HT₂ receptors. In the anterior HC, 5HT_{1A} receptor mRNA is highly and evenly distributed throughout the dentate gyrus and CA1-4 pyramidal cells, whereas 5HT₂ receptor mRNA is expressed only in the hilus, stratum oriens of CA1 and stratum pyramidale of CA3-4. 5HT_{1C} receptor mRNA expression is restricted to a few cells of the strata radiatum and oriens of CA3. None of the 5HT receptor subtype mRNA expression is altered by ADX at 6h, 2 or 14 days. In the posterior and ventral HC, 5HT_{1C} and 5HT₂ (but not 5HT_{1A}) receptor gene expression was more highly expressed and widely distributed than in anterior HC. 2 d after ADX, 5HT_{1C} receptor mRNA expression increased in the stratum pyramidale of CA3 (50±15% rise, p<0.01) and stratum oriens of CA1 (22±7%, p=0.05). Both dexamethasone and aldosterone replacement abolished the effect of ADX in CA3, only dexamethasone was effective in CA1. ADX did not alter 5HT_{1A} or 5HT₂ receptor gene expression in the posterior HC, nor 5HT_{1A} (autoreceptor) mRNA expression in the dorsal raphe nucleus. Increased sensitivity to 5HT_{1C}-mediated effects is seen in some models of depression; the glucocorticoid control of 5HT_{1C} mRNA expression in the posterior HC may provide the basis for corticosteroid-5HT interactions in affective disorders.

REGULATION OF SEROTONIN RECEPTORS AND S-100β IN PRIMARY CULTURES OF RAT CORTICAL ASTROCYTES. R. P. Helliandl*, J. P. Liu, M. B. Wilkie, and J. M. Lauder. Dept. of Cell. Biol. and Anat., Univ. of N. Carolina, Chapel Hill, NC 27599.

Previous studies have indicated the presence of functional serotonin (5-HT) receptors in rat astrocytes. Activation by serotonergic ligands can induce the release of S-100β, a calcium-binding protein, which may, in turn, serve as a trophic agent for serotonergic neurons (Whitaker-Azmitia *et al.*, '90; Liu and Lauder, '92). The current studies examined the potential role of serum factors, which include 5-HT, on the expression of astrocytic 5-HT receptors and how exposure to 5-HT receptor ligands may be correlated with intracellular levels of S-100β. Purified cortical astrocytes were plated on glass coverslips. To control for high levels of 5-HT present in serum, cultures were switched to either defined medium (N2) or fresh BME/10% fetal calf serum (BME/FCS) at 1 DIV and grown for an additional 1, 2, or 4 DIV. Serotonergic ligands were applied at 2 DIV and maintained for 6, 24, or 72 hrs. In cultures grown in serum, 5-HT_{1A} receptor protein/mg total protein was highest from 1-3 DIV and then significantly decreased by 5 DIV. This pattern was also found for S-100β protein. When maintained in N2, elevated levels of receptor protein were found at 5 DIV whereas S-100β protein remained unchanged. We were unable to detect 5-HT_{1A} receptor transcripts under any culture paradigm. Treatment of cultures with 10nM 8-OH-DPAT (a 5-HT_{1A} agonist) or DOI (a 5-HT_{1C/2} agonist) down-regulated S-100β protein following a minimum of 24 hours exposure while S-100β mRNA was reduced following 72hr DPAT treatment. DPAT also significantly affected cAMP levels at each exposure period. The 5-HT antagonists NAN190 or mianserin produced elevated levels of S-100β protein after 24 hrs. These data indicate that factors present in serum can downregulate astrocyte 5-HT_{1A} receptor expression. Receptor activation may be associated with the modulation of expression of S-100β, suggesting an astrocyte mediated mechanism regulating the viability of serotonergic neurons.

MODULATION OF CENTRAL 5-HT_{1A} AND 5-HT₂ RECEPTOR-MEDIATED FUNCTIONAL RESPONSES FOLLOWING 21 DAY TREATMENT WITH 8-OH-DPAT, AMITRIPTYLINE, DESIPRAMINE AND FLUOXETINE. *Lucy Rényi* and Patricia Jimenez.*

CNS Preclinical R&D, Department of Behavioural Pharmacology, Astra Arcus AB, S-151 85 Södertälje, Sweden.

We compared the modulation of some behavioural responses following 21 day treatment with the 5-HT_{1A} receptor agonist 8-OH-DPAT 2x0.1 mg/kg s.c., amitriptyline (AM) 2x30 mg/kg p.o., desipramine (DMI) 2x10 mg/kg p.o. and fluoxetine (FL) 2x2.5 mg/kg p.o. The following behavioural responses were evaluated: 1. the 5-HT_{1A} receptor-mediated inhibition of the cage-leaving response, elongated body posture, forepaw-treading. 2. the 5-HT₂ receptor-mediated wet-dog shakes (WDS) induced by DOI (1-(2,5-dimethoxy-4-iodophenyl)-2-amino-propane). 3. salivation (SAL) and male to male mounting (M-to-MM) with penile erection (PE) after a challenge dose of 8-OH-DPAT. All the four compounds produced tolerance to the 5-HT_{1A} receptor-mediated responses. To examine the degree of tolerance, various challenge doses of 8-OH-DPAT were used (0.1-3.0 mg/kg s.c.). The rank order was as follows: AM > FL > 8-OH-DPAT > DMI. The 21 day treatment with 8-OH-DPAT and AM, but not with DMI and FL, resulted in a supersensitivity of the WDS. A challenge dose of 8-OH-DPAT following 21 day treatment with 8-OH-DPAT, AM and DMI, but not with FL, produced SAL and M-to-MM with PE.

Thus, the 21 day treatment with 8-OH-DPAT produced a similar profile to that of AM. The pattern for DMI and FL was somewhat different.

DIABETES-INDUCED ALTERATIONS IN 5-HT RECEPTOR SUBTYPE ACTIVATION. *L.L. Bellush* & E. Huh,* Dept. of Psychology, Ohio University, Athens, OH 45701

Two experiments were conducted which compared the responses of streptozotocin-diabetic (STZ) rats and nondiabetic controls (CTRL) to selective 5-HT agonists. In Exp. 1, 8-OHDPAT-induced hypothermia and DOI-induced hyperthermia were measured in STZ and CTRL, half of which had been adrenalectomized (ADRX) 4 days prior to measurements. The response to 8-OHDPAT was attenuated, and the response to DOI exaggerated in STZ rats, while ADRX had opposite effects. The STZ-induced alterations resemble those previously associated with elevated circulating glucocorticoids (CORT) in clinical depression. Elevated CORT is also seen in STZ rats and could account for 5-HT receptor alterations, given the ADRX effects. In Exp. 2, STZ rats showed greater anxiety in a light/dark emergence test but responded to the anxiolytic effects of buspirone in a parallel fashion to CTRL. The differential sensitivity of STZ to 8-OHDPAT and buspirone, both 5-HT_{1A} agonists, may be due to differential pharmacological profiles of the two drugs.

564.15

Transfected Human 5-HT_{1C}, but not 5-HT₂, Receptors Modulate Naturally Expressed 5-HT_{1B}-like Receptor Function in CHO Cells. *Saul Maayani¹, Kelly A. Berg¹, Cynthia A. Saitstad¹ and Alan Saltzman².* Depts. of Anesthesiology¹, Mount Sinai Medical Center, CUNY, NY, NY 10029 and Molecular Biology², Rhone-Poulenc-Rorer, Collegeville, PA 19426.

We have found that wild-type CHO cells naturally express a 5-HT receptor which inhibits forskolin-stimulated (FS) cAMP formation in a pertussis toxin sensitive manner. 5-HT agonists inhibited FS cAMP accumulation with the following rank order of potency and % maximal inhibition (EC₅₀, nM; % inhibit): 5-Carboxamidotryptamine (5-CT, 4; 76%) ≥ 5-HT (6; 81%) > CP 93129 (18; 82%) > pindolol (39; 61%) > sumatriptan (160; 63%) >>> 8-OH-DPAT (not active at 100 nM). The response to 100 nM 5-CT was blocked by 1 μM methiothepin but was insensitive to 1 μM spiperone or mesulergine. This pharmacology is consistent with a 5-HT_{1B}-like receptor subtype. The cDNA for human 5-HT_{1C} and 5-HT₂ receptors were stably transfected separately into wild-type CHO cells and the effect of activation of these receptors on PI hydrolysis and on the 5-HT_{1B}-like response was measured. Accumulation of inositol phosphates in response to 5-HT were (E_{max}, EC₅₀) 600%, 30 nM and 400%, 430 nM for 5-HT_{1C} and 5-HT₂ lines, respectively. Co-activation of 5-HT_{1C} and 5-HT_{1B}-like receptors with 5-HT (0.1-100 nM) abolished the 5-HT_{1B}-like response which returned when the 5-HT_{1C} receptor was blocked with mesulergine (1 μM). Furthermore, the 5-HT_{1B}-like response to 5-CT was completely blocked by 1 μM DOI. In contrast, co-activation of 5-HT₂ receptors did not alter the 5-HT_{1B}-like response. Although 5-HT_{1C} and 5-HT₂ receptors are thought to activate similar second messenger pathways, we postulate that inhibition of the 5-HT_{1B}-like response may involve a second effector system that is coupled to the 5-HT_{1C} receptor but not to the 5-HT₂ receptor. (USPHS GM 34852; DA 06620; MH 48125)

564.12

EFFECT OF TREATMENT WITH ADINAZOLAM ON SEROTONIN RECEPTORS AND PHOSPHOINOSITIDE HYDROLYSIS IN RAT BRAIN. *Y. Dwivedi, S.C. Pandey, M.P. Dubey, X. Ren, J.M. Davis* and G.N. Pandey.* Illinois State Psychiatric Institute, Chicago, Illinois 60651

Adinazolam is an anxiolytic drug that also has antidepressant properties, but its mechanism of action is unclear. We determined the effect chronic treatment with adinazolam on serotonin and β-adrenergic receptors subtypes in rat brain and the phosphoinositide signalling system in choroid plexus. Rats were treated with two doses of adinazolam, 5 mg/kg and 10 mg/kg, for 21 days and were decapitated 24 hours after the last injection. We determined 5HT₂ and β-adrenergic receptors in cortex, 5HT_{1C} receptors and receptor mediated PI hydrolysis in choroid plexus, 5HT_{1C} receptors in hippocampus, and 5HT_{1A} receptors in cortex and hippocampus. Treatment with adinazolam significantly increased 5HT stimulated PI hydrolysis (68%) in choroid plexus as compared with control rats. However, it did not have significant effects either on β-adrenergic receptors as measured by [¹²⁵I]-Cyanopindolol in rat cortex or 5HT_{1A} receptors in cortex or hippocampus. It also had no significant effect on the number and affinity of 5HT₂ receptor binding sites in rat cortex. These results thus suggest that adinazolam is dissimilar to other antidepressants in its effects on 5HT₂ and β-adrenergic receptors. However, its effect on 5HT_{1C} receptors in choroid plexus and possibly hippocampus may be relevant to its therapeutic effects. We are currently in the process of determining 5HT_{1C} receptors in cortex, hippocampus and choroid plexus after chronic treatment with adinazolam.

5-HYDROXYTRYPTAMINE_{1B} RECEPTOR REGULATION AND ONTOGENY: BEHAVIORAL TOLERANCE AND DOWN-REGULATION OF [¹²⁵I]IODOCYANOPINDOLOL-LABELLED 5-HT_{1B} BINDING SITES IN THE CENTRAL NERVOUS SYSTEM. *M. R. Pranzatelli* and P. Razi,* Departments of Neurology, Pediatrics, and Pharmacology, Laboratory of Movement Disorder Pharmacology, The George Washington University, Washington, DC 20010.

Little is known about the regulation and ontogeny of 5-hydroxytryptamine_{1B} (5-HT_{1B}) receptors, a putative terminal autoreceptor in the central nervous system. We studied the response of [¹²⁵I]iodocyanopindolol ([¹²⁵I]ICYP)-labelled central 5-HT_{1B} sites to chronic treatment with 5-HT agonists and antagonists at a dose of 10 mg/kg/d i.p. for 30 consecutive days in the rat. RU 24969 significantly reduced B_{max} 23 - 63% in cortex, hippocampus, striatum, brainstem, and spinal cord without a change in K_d except for a 1.7-fold increase in cortex and spinal cord. The putative 5-HT_{1B} agonist TMPP, but not m-CPP or the 5-HT_{1B} antagonists pindolol or quipazine, also reduced the B_{max} of cortical 5-HT_{1B} sites. 100 μM GTPγS induced a significant 5-fold right shift in 5-HT affinity for striatal 5-HT_{1B} sites, but the magnitude of the shift was not altered by chronic treatment with RU 24969, m-CPP, or pindolol. The number of striatal 5-HT_{1B} sites increased with postnatal age through the first month. Neonatal 5,7-dihydroxytryptamine (5,7-DHT) lesions made by i.p. injection and shown to alter 5-HT uptake site density did not significantly alter 5-HT_{1B} binding site density in cortex, striatum, diencephalon, or brainstem. In behavioral studies, chronic treatment with RU 24969 but not m-CPP induced tolerance to RU 24969-evoked cage crossings. The data demonstrate functionally significant decreases in maximum number of 5-HT_{1B} receptors in response to chronic agonist treatments. They also suggest that m-CPP does not act as a 5-HT_{1B} agonist at the dose studied and the hypolocomotion it induces is not mediated by 5-HT_{1B} sites.

564.16

Rapid Desensitization of Human 5-HT_{1C} Receptors Stably Expressed in CHO Cells. *Kelly A. Berg¹, Barbara J. Ebersole^{1*}, Alan Saltzman², and Saul Maayani¹.* Depts. of Anesthesiology¹, Mount Sinai Medical Center, CUNY, NY, NY 10029 and Molecular Biology², Rhone-Poulenc Rorer, Collegeville, PA 19426.

Acute desensitization of receptor-mediated phosphatidylinositol turnover was characterized in a CHO cell line stably expressing 5-HT_{1C} receptors. CHO cells, transfected with a cDNA clone for the human 5-HT_{1C} receptor expressed a density of 170 fmol/mg protein as determined by mianserin-sensitive [³H]-mesulergine binding (K_d=1nM). Cells labeled for 24h with 1 μCi/ml [³H]-myosin and incubated with varying concentrations of agonist and 20 mM LiCl for 10 min at 37° C accumulated total inositol phosphates (IP's) with the following rank order of potency and intrinsic activities (EC₅₀,nM; intrinsic activity): LSD (20; 0.13) > 5-HT (30; 1.0) > DOI (80; 0.56) > quipazine (2500; 0.56). For desensitization studies, cells were incubated in the presence of maximal concentrations of 5-HT, DOI or LSD at 37° C for 15, 30, 45, 60 or 120 minutes. IP accumulation was measured after addition of 20 mM LiCl and a further incubation of 10 minutes. Treatment with 5-HT produced a rapid, homologous desensitization which was maximal by 15 min reducing total IP accumulation to 20% of control levels. Long term incubation (24h) with 1 μM PMA did not alter the desensitization in response to 5-HT indicating that PKC activation does not mediate this phenomenon. In contrast to the effect of the full agonist 5-HT, treatment with the partial agonists DOI and LSD produced less desensitization at a slower rate. The maximal IP accumulation in response to DOI occurred at 30 min and was 40% of control levels, while that for LSD occurred at 60 min and was 60% of control. Therefore we propose that the rate and magnitude of 5-HT_{1C} receptor desensitization is related to the relative drug efficacy of these 5-HT_{1C} agonists (5HT>DOI>LSD). (USPHS GM 34852; DA 06620; MH 48125)

564.17

DIFFERENTIAL REGULATION OF 5HT_{1C} RECEPTORS BY SEROTONIN ANTAGONISTS WITH AND WITHOUT NEGATIVE INTRINSIC ACTIVITY. E.L. Barker and E. Sanders-Bush. Dept. of Pharmacology, Vanderbilt Univ., Nashville, TN 37232.

Receptor antagonists are classically thought to share a common binding site with agonists, but have no intrinsic activity when added alone. However, emerging evidence from many receptor systems indicates that some antagonists actually possess negative intrinsic activity capable of producing effects opposite of those produced by agonists. Agonist-induced stimulation of 5HT_{1C} receptors activates the phosphoinositide (PI) hydrolysis signalling cascade. In NIH 3T3 fibroblasts transfected with 5HT_{1C} receptor cDNA, we have identified two classes of receptor antagonists based on their effects on basal PI hydrolysis, i.e., effects in the absence of agonist. The receptor antagonists mianserin, mesulergine and ketanserin are active antagonists, inducing a dose-dependent decrease in basal PI hydrolysis. (+)-2-Bromolysergic acid diethylamide (BOL) is a neutral antagonist with no effect on basal values. Because 5HT_{1C} receptors display paradoxical down-regulation when exposed to receptor antagonists *in vivo* and *in vitro*, it was of interest to determine if the active and neutral antagonists differ in their ability to induce down-regulation of the receptor. These studies utilized primary cultures of choroid plexus epithelial cells as a model for the study of 5HT_{1C} receptor regulation. The active antagonist mianserin, but not the neutral antagonist BOL, was capable of inducing atypical down-regulation of 5HT_{1C} receptors. These studies are the first to show direct evidence that the 5HT_{1C} antagonists that induce down-regulation are truly active at the receptor. This activity may result in conformational changes in the receptor, leading to an alteration in turnover via an unidentified pathway. (Supported by USPHS grant MH34007.)

CHRONIC LITHIUM GREATLY ENHANCES THE EXPRESSION OF C-FOS IN RAT BRAIN FOLLOWING ACTIVATION OF 5HT₂, BUT NOT 5HT_{1A} SEROTONIN RECEPTORS. R.A. Leslie*, J.M. Moorman, and D.G. Grahame-Smith. Oxford University-Smithkline Beecham Centre for Applied Neuropsychology, University Department of Clinical Pharmacology, Oxford, OX2 6HE, UK.

Lithium suppresses inositol-3 phosphate production by phosphatase inhibition. It also affects serotonergic function in the CNS; eg., downregulating 5-HT_{1A} and 5-HT₂ receptors. We studied these actions using c-Fos immunocytochemistry following selective activation of 5-HT receptor subtypes. The 5-HT₂ receptor agonist DOI (2,5-dimethoxy-4-kodophenylisopropyl-amine) produces a localised pattern of Fos-like immunoreactivity (FLI) in rat brain (Leslie et al., Neuroscience 53:457, 1993). We now show that the 5-HT_{1A} agonist 8-OH-DPAT (8-OH-2-[di-*n*-propylamino] tetralin) induces FLI in a very different pattern; furthermore, chronic lithium treatment greatly enhances FLI in the cerebral cortex following 5-HT₂, but not 5-HT_{1A} receptor activation. FLI was localised in 100µM brain sections of rats fed on control or lithium carbonate (0.1%) diet for one week prior to drug challenge (DOI = 8mg/kg, 8-OH-DPAT = 2mg/kg, or saline control i.p.). FLI was low to undetectable in controls. DOI alone produced a dense band of Fos-positive cells in layer Va of somatosensory cortex, while 8-OH-DPAT produced a much more homogeneous pattern in the cortex. Chronic lithium significantly enhanced FLI following DOI, but not 8-OH-DPAT, administration. The most marked effect was in the caudal piriform cortex, an area previously devoid of staining, where FLI was intense. Ritanserin (0.4mg/kg) completely abolished all FLI after DOI with or without lithium. Further studies are in progress to determine why lithium enhances serotonin receptor activity so selectively.

DOWN-REGULATION OF 5-HT_{1C} RECEPTORS AFTER CHRONIC CLOZAPINE TREATMENT - ROLE OF SPARE RECEPTORS. M. Kuoppamäki, E. Syvälahti, J. Hietala. Dept. of Pharmacology, University of Turku, SF-20520 Turku, Finland. Repeated administration of clozapine causes downregulation of 5-HT_{1C} receptors. This study further characterizes the down-regulation of 5-HT_{1C} receptors after chronic clozapine treatment (14 days, 68h withdrawal). 5-HT_{1C} receptor agonist and antagonist binding sites in rat choroid plexus were measured by using [¹²⁵I]DOI and [³H]mesulergine autoradiography, respectively. In addition, the 5-HT_{1C} receptor function was studied by measuring 5-HT-stimulated phosphoinositide hydrolysis. 5-HT_{1C} receptor agonist binding sites were significantly decreased by 29 % and 49 % after 10 and 25 mg/kg/day of clozapine, respectively, and 5-HT_{1C} receptor antagonist binding sites by 48 % and 59 % after these treatments. However, the 5-HT-stimulated phosphoinositide hydrolysis was, significantly decreased (- 27 %) only after the 25 mg/kg/day dose of clozapine. The results suggest a 20-30 % receptor reserve for 5-HT_{1C} receptors in rat choroid plexus.

564.20

REGULATION OF 5-HT₂ RECEPTORS AND 5-HT₂ RECEPTOR mRNA AFTER IRREVERSIBLE INACTIVATION WITH EEDQ. R.K. Raghupathi*, R.P. Artymyshyn, R.A. Habboushe and P. McGonigle. Dept. of Pharmacology, Univ. of Pennsylvania, Philadelphia, PA 19104.

5-HT₂ receptors respond in an anomalous fashion to treatments with various agents such as 5-HT reuptake blockers, depleting agents, neurotoxins and 5-HT₂ antagonists. To better understand the regulation of the 5-HT₂ receptor system, we administered (i.p.) the irreversible antagonist EEDQ (10 mg/ml) to rats (n = 42) which were subsequently sacrificed 0.5, 1, 2, 4, 7 and 14 days after injection. 5-HT₂ receptor densities were measured using [³H]-ketanserin under conditions that selectively labeled 5-HT₂ receptors. 5-HT₂ receptor mRNA levels were measured using *in-situ* hybridization with a 200-base [³³P]-labeled riboprobe directed against 5-HT₂ receptor mRNA. In cortical regions with a high density of 5-HT₂ receptors, receptor levels were decreased to 30% of control values 12-24 hrs after injection. Receptor levels gradually recovered to about 70% of control levels by day 7 but did not recover fully to control values by day 14. Cortical 5-HT₂ receptor mRNA levels declined to about 40% of control by 24 hours and showed a gradual increase to control values by day 4. The observation that mRNA levels decrease concomitantly with receptor inactivation suggests that 5-HT₂ receptor recovery after inactivation by EEDQ is mediated by post-translational regulatory processes and not by altered gene expression. This is in contrast to the 5-HT_{1A} system where we have observed an increase in mRNA levels preceding receptor recovery after EEDQ inactivation. (Supported by USPHS MH 43821)

SEROTONIN RECEPTORS: PHYSIOLOGY AND BEHAVIOR

565.1

5HT₄ AGONISTS: BIMU-1 AND BIMU-8 INDUCE ANALGESIA BY FACILITATING CENTRAL CHOLINERGIC TRANSMISSION. C. Ghelardini, L. Fanfani, N. Galeotti, A. Giotti, C.A. Rizzi and A. Bartolini. Depts. of Pharmacol., Univ. of Florence I-50143, Firenze and ¹Boehringer Ingelheim, Milan, Italy. SPON: European Brain and Behaviour Society. There is accumulating evidence indicating that certain benzimidazolone derivatives including BIMU-1 and BIMU-8 potentiate electrically-stimulated twitch responses in guinea-pig ileum longitudinal muscle strip through enhancement of acetylcholine (ACh) release from cholinergic nerve endings (Rizzi et al., 1990; Craig and Clarke, 1990). Moreover the increased electroencephalogram energy (theta rhythm) in the rats induced by the activation of 5-HT₄ receptors appears to be due to an amplification of ACh release (Boddeke and Kalkman, 1990). Since the amplification of cholinergic neurotransmission induces a central antinociceptive effect (Ghelardini et al., 1990, 1992), in the present work the ability of BIMU-1 and BIMU-8 for modifying pain threshold was investigated. The study was performed in both mice (hot-plate and acetic acid writhing test) and rats (paw-pressure test). Our data indicate that in all three tests BIMU-1 (10-30 mg/kg i.p.) and BIMU-8 (30 mg/kg i.p.) are able to induce antinociception without affecting either performance on rota-rod test or spontaneous locomotor activity measured with an Animex apparatus. The analgesic action of BIMU-1 (3 µg/mouse) and BIMU-8 (10 µg/mouse) occurs in the CNS, since also their intracerebroventricular administration yielded a statistically-significant increase in pain threshold. The analgesic action of both BIMU-1 and BIMU-8 was prevented by atropine (5 mg/kg i.p.), hemicholinium-3 (1 µg/mouse i.c.v.) and by the 5HT₄ antagonist SDZ 205-557 (10 mg/kg i.p.). These results suggest not only the possibility of inducing antinociception by 5-HT₄ agonists, but also that analgesia is mediated by the cholinergic system.

565.2

EFFECTS OF THE 5-HT₂ ANTAGONIST MDL 72222 ON CISPLATIN-INDUCED PERIPHERAL NEUROPATHY. P.M. Whitaker-Azmitia*, A. Borella and X. Zhang. Dept. of Psychiatry, SUNY, Stony Brook, NY, 11794.

5-HT₂ antagonists are reported to be efficacious in inhibition of cisplatin-induced emesis. However, their efficacy in treating another major side effect of cisplatin therapy - peripheral neuropathy - has not been tested. In this study, we report that the antagonist MDL 72222 increases toxic effects in a developing model of cisplatin neuropathy.

5-day old rat pups were treated twice weekly for four weeks with 1 mg/kg cisplatin or 3 mg/kg MDL 72222 or both. Cisplatin significantly increased tailflick latency at PD17 (4.1 sec vs. 13.0 p < .002) and PD21 (5.1 sec vs. 22.3 p < .005). This effect was not reversed by MDL 72222 at either timepoint. In addition to the tail flick changes, the animals also showed significant inward turning of the hindfeet which was quantified by measuring the average distance between the toes minus the average distance between the heels. For control animals, this was .632 ± .066 mm and for cisplatin, .456 ± .065 mm (p < .05). However, MDL72222 worsened this condition with the toe-heel distance reduced to .091 ± .1 (p < .001). Immunohistochemical analysis of spinal cord showed that cisplatin caused significant loss of CGRP-positive cells which was not reversed by MDL 72222. Our work suggests that the peripheral neuropathy induced by cisplatin is not prevented by 5-HT₂ antagonists.

SPIPERONE-INDUCED ACTIVATION OF SEROTONERGIC NEURONAL ACTIVITY CORRELATES WITH 5-HT_{1A} AUTORECEPTOR BLOCKADE IN AWAKE CATS. C.A. Fornal*, C.W. Metzler, W.J. Litto, F. Marrosu, and B.L. Jacobs. Dept. of Psychol., Prog. Neurosci., Princeton Univ., Princeton, NJ

Somatodendritic 5-HT_{1A} autoreceptors are believed to be involved in a negative feedback mechanism whereby the synaptic concentration of released serotonin can modulate impulse activity of central serotonergic neurons. These receptors apparently exert a tonic inhibitory influence on neuronal activity under physiological conditions, since systemic administration of the 5-HT_{1A} antagonist spiperone increases the firing rate of serotonergic neurons in awake animals (Jacobs & Fornal, *Pharmacol. Rev.* 43:563-578, 1991). The present study examined the relationship between spiperone-induced activation of serotonergic dorsal raphe (DRN) neurons and the 5-HT_{1A} autoreceptor-blocking actions of the drug. Neurons were recorded prior to, and for 6 hr following, spiperone injection (0.25 and 1 mg/kg, iv) using methods previously described (Fornal et al., *Am. J. Physiol.* 259:R963-R972, 1990). In addition, the inhibitory response of serotonergic neurons to a challenge dose (10 µg/kg, iv) of the selective 5-HT_{1A} agonist 8-OH DPAT was determined at 1-hr intervals for 6 hr after spiperone administration. Spiperone increased unit activity and blocked the action of 8-OH DPAT. Both effects were dose- and time-dependent. Furthermore, there was a strong positive correlation between these two actions of spiperone. These results suggest that the increase in DRN serotonergic neuronal activity produced by systemic administration of spiperone is due to blockade of the 5-HT_{1A} autoreceptor. Activation of this receptor represents the initial step in the engagement of a physiological negative feedback system. Supported by grants from the AFOSR (90-0294) and the NIMH (MH 23433).

EFFECTS OF 5HT_{1A} LIGANDS ON CORE TEMPERATURE IN THE CONSCIOUS DOG. J. Hallett, V.C. Middlefell and G. Stack¹, Wyeth Research UK Ltd, Taplow, Berks, SL6 0PH, ¹ Wyeth-Ayerst Research, Princeton, NJ

5HT_{1A} agonists and partial agonists induce hypothermia in the mouse and rat (Bill et al., 1991, *Br. J. Pharmacol.*, 103:1857-1864), and in man (Anderson et al., 1990, *Psychopharmacology*, 100: 498-503). The aim of this study was to determine whether a similar response was induced by 5HT_{1A} ligands in the conscious beagle dog.

Dogs of either sex were trained to stand in restraining slings while their rectal temperature (T) was continually recorded with a digital probe. In some experiments heart rate (HR) was derived from a lead II ECG. 8-OH-DPAT (10 µg/kg s.c.) or saline (100 µl/kg s.c.) was administered at 30 min intervals for 2h. The 5HT_{1A} partial agonist, gepirone (0.3 and 3.0 mg/kg p.o.), or lactose placebo was administered in gelatine capsules and the effects on T observed for 4h. The effects of the α₂ adrenoceptor agonist, UK14304 (30 and 100 µg/kg s.c.) were also investigated as a positive control.

8-OH-DPAT did not decrease HR or T but rather evoked a 0.2° C increase in T associated with body tremor, following the 3rd and 4th drug doses. Previous studies have shown marked behavioural effects are induced by 8-OH-DPAT (30 µg/kg i.v.). Gepirone (0.3 mg/kg) had no effect on T, whereas gepirone (3.0 mg/kg) evoked a 0.5° C decrease in T compared to controls 3 h after administration though this was accompanied by overt behavioural effects (panting, salivation, tremor and tucking in of the hind limbs) in one of the dogs. By comparison, UK14304 (30 and 100 µg/kg) evoked falls in T of 1° C (at 2h) and 1.4° C (at 4h) respectively with an accompanying sedation.

Thus, our studies failed to show a hypothermic effect of 5HT_{1A} ligands in the dog except at doses producing pronounced motor effects.

565.7

Chronic 5HT_{1A} agonist treatment produces a trans-receptor up-regulation in rat brain 5HT_{1D} receptor mRNA and expression: relationship to anxiolytic activity. M. Teitler*, K.J. Miller, C.T. Casey, and B.J. Hoffman@ Dept. of Pharmacology, Albany Medical College, Albany, NY 12208; @ Laboratory of Cell Biology, NIMH, Bethesda, MD 20892

Ipsapirone, buspirone, and gepirone, three 5HT_{1A} receptor agonists, display anxiolytic effects in preclinical animal models of anxiety as well as in humans. The effects in humans are noted after chronic treatment, indicating that the anxiolytic effects of the drugs are presumably due to some compensatory mechanisms. Benzodiazepines are anxiolytic, presumably due to their actions in potentiating GABAergic transmission. In order to ascertain whether chronic 5HT_{1A} agonist treatment could alter GABAergic activity through a serotonergic mechanism we examined the effects of chronic ipsapirone treatment on the expression of 5HT_{1D} (5HT_{1B}) receptors in rat brain, using *in situ* hybridization and autoradiographical radioligand binding studies. 5HT_{1D} receptors are highly expressed in the rat substantia nigra: the nigra receives a major GABAergic projection from the striatum. Two week treatment with 10 mg/kg ipsapirone, twice daily, s.c. produced a six-fold increase in striatal 5HT_{1D} receptor mRNA. Accompanying this dramatic increase in mRNA expression was a 30% increase in [¹²⁵I]-cyanopindolol-labelled 5HT_{1D} receptors in the substantia nigra. Acute treatments with ipsapirone did not produce any effects on mRNA or expressed receptor levels. The effects of other psychotropic drugs on 5HT_{1D} receptor mRNA and expression levels will be investigated. Supported by MH40716 (M.T.)

EFFECTS OF (+)WAY 100,135 ON BRAIN SEROTONERGIC UNIT ACTIVITY IN BEHAVING CATS. C.W. Metzler*, C.A. Fornal, S.C. Veasey and B.L. Jacobs. Prog Neurosci., Princeton Univ., Princeton, NJ 08544.

Brain serotonergic neuronal activity is modulated by 5-HT_{1A} autoreceptors. Recently, we have shown that spiperone, a 5-HT_{1A} antagonist, increases serotonergic neuronal activity in awake animals, suggesting that these neurons are under tonic feedback inhibition under physiological conditions (see Fornal et al., this meeting). The present study examined the effects of another putative 5-HT_{1A} autoreceptor antagonist, (+)WAY 100,135 on the spontaneous activity of serotonergic neurons in the dorsal raphe nucleus (DRN) in behaving cats. Serotonergic neurons were identified on-line by their slow and regular discharge activity, complete cessation of firing during REM sleep, and response to systemic administration of the 5-HT_{1A} agonist 8-OH DPAT. (+)WAY 100,135 was administered intravenously in doses of 100, 500, and 1000 µg/kg. Unit activity was monitored prior to, and for 2 hr following drug injection. In contrast to the effects of spiperone, administration of (+)WAY 100,135 produced a suppression of serotonergic unit activity. The effect was apparent within one min post-injection and lasted for approximately 15-30 min. All three doses of (+)WAY 100,135 maximally decreased neuronal activity by approximately 30-40%. Thus, the effect of (+)WAY 100,135 on serotonergic activity does not appear to be dose-related. Control saline injections had no significant effect on neuronal activity. These results indicate that (+)WAY 100,135, unlike spiperone, does not increase serotonergic neuronal activity in awake animals, suggesting that the drug is ineffective in blocking the inhibitory action of released serotonin at the autoreceptor. Supported by grants from the AFOSR (90-0294) and the NIMH (MH 23433).

EVIDENCE USING CONFORMATIONALLY RESTRICTED SUMATRIPTAN ANALOGUES, CP-122,288 AND CP-122,638, THAT 5-HT_{1D} RECEPTORS DO NOT MEDIATE BLOCKADE OF NEUROGENIC INFLAMMATION. W.S. Lee, F.M. Cutrer and M.A. Moskowitz*. Stroke Research Laboratory, Neurosurgery and Neurology Services, Massachusetts General Hospital, Harvard Medical School, 32 Fruit Street, Boston, MA 02114.

We compared the effects of two conformationally restricted sumatriptan analogues with sumatriptan (S) on the plasma protein extravasation within dura mater and the expression of c-fos protein in lamina I and II of trigeminal nucleus caudalis of pentobarbital-anesthetized guinea-pigs. The extravasation response (¹²⁵I-BSA) was induced by either unilateral trigeminal ganglion stimulation (0.6 mA, 5 ms, 5 Hz, 5 min) or substance P (SP; 1 nmol/kg, i.v.). The c-fos expression was elicited by the instillation of capsaicin (0.1 µmol) through a catheter placed into the cisterna magna.

In plasma protein extravasation response the threshold for CP-122,288 and CP-122,638 (1 and 0.1 pmol/kg, i.v., respectively) was remarkably lower than for S (7 nmol/kg), as was the dose at maximum response (1 and 0.1 nmol/kg for CP-122,288 and CP-122,638, respectively, and 240 nmol/kg for S). SP-induced plasma leakage was unaffected by either CP-122,288 or CP-122,638 or S, and metergoline (0.1 µg/kg) only partially (27%) reversed the effect of CP-122,288 (1 pmol/kg). Furthermore, CP-122,288 (1 nmol/kg) significantly reduced the number of c-fos labelled cells by 43.8%.

The marked potency differences between S and its analogues (despite similar 5-HT_{1D} receptor affinities) strongly suggest that the mechanism for all three drugs may well be distinct from their ability to activate the 5-HT_{1D} receptor subtype and that the two analogues are more selective for the prejunctional receptor.

565.8

5-HT-1C AGONISTS SUPPRESS APOMORPHINE-INDUCED LOCOMOTOR ACTIVITY P.B. HICKS*, R.J. ZAVODNY AND K.A. YOUNG. Department of Psychiatry & Behavioral Sciences, Texas A&M College of Medicine, Temple, Texas 76508.

We have previously reported that a low dose (0.1 mg/kg) of the 5-HT-1C antagonist mesulergine potentiates apomorphine-induced locomotor activity (AILA). This effect can be blocked by the 5-HT-1C/2 agonist DOI (*Psychopharmacology* 110: 97-102). However, DOI (agonist at both the 5-HT-1C and 5-HT-2 receptors) itself suppresses AILA at doses above 0.5 mg/kg. Recently, an antagonist (MDL 100,907) has been developed that is highly selective for the 5-HT-2 receptor. In the following experiments we tried to determine the role of 5-HT-2 and 5-HT-1C receptors in the suppression of AILA seen with DOI.

For the determination of AILA, serotonergic test drug(s) or vehicle were injected SC in Sprague-Dawley rats five minutes before administration of 0.25 mg/kg APO or vehicle and the number of times the animal crossed the lines of a test grid were counted in 5-min intervals. Ketanserin (5-HT-2 antagonist; 0.5 mg/kg) had no effect on AILA. Ketanserin (0.5 mg/kg) + DOI (1 mg/kg) resulted in marked suppression of AILA (p<.01). The potentiation of AILA by low dose mesulergine (0.1 mg/kg) was blocked by DOI at either 0.1 or 1.0 mg/kg (p<.05). MDL 100,907 had no effect on AILA. The suppression of AILA by DOI (1.0 mg/kg) was not reversed by MDL 100,907 (0.15 mg/kg). These data suggest that 5-HT-1C agonists suppress AILA, but are in direct conflict with a previous report that the 5-HT-1C agonist LSD markedly potentiated AILA (Fink and Oelssner, *Eur. J. Pharmacol.* 75: 289-296, 1981).

565.9

5-HT SYNTHESIS-SUPPRESSING AND DA SYNTHESIS-PROMOTING ACTIONS OF THE 5-HT_{1B} RECEPTOR AGONIST TFMP IN VIVO: PRE- VS. POSTSYNAPTIC 5-HT_{1B} RECEPTOR-MEDIATED EVENTS. S. Hjorth*, Department of Pharmacology, University of Göteborg, Medicinareg. 7, S-413 90 Göteborg, SWEDEN

5-HT_{1B} receptors are found pre- as well as postsynaptically to the 5-HT neurons in the rat brain, particularly in the DA-rich limbic and basal ganglia areas. In preliminary studies, the 5-HT_{1B} receptor agonist TFMP was found to decrease 5-HT synthesis but simultaneously enhance DA synthesis in rat brain *in vivo*. The present experiments were carried out in an attempt to clarify the mechanism(s) underlying these actions. Adult male Sprague-Dawley rats (250-350 g) were used in the studies. TFMP (0.1-10 mg/kg SC, 60 min. before death) dose-dependently reduced the 5-HT, and increased the DA, synthesis (5-HTP and DOPA accumul., respectively, after 30 min. decarboxylase inhibition) in the limbic forebrain and the corpus striatum. The 5-HT synthesis-suppressing action of TFMP proved resistant to axotomy (unilateral hemitranssection, 90 min. before death) and reserpine (5 mg/kg IP, 90 min. before death) pretreatment, indicating that the effect was directly mediated and independent of nerve impulses and intact monoamine stores. In contrast, the DA synthesis-promoting action of TFMP was abolished by either of these procedures. Taken together, the results indicate *i)* that the reduction of rat brain 5-HT synthesis after TFMP is mediated by 5-HT, tentatively 5-HT_{1B}, autoreceptors located on the serotonergic axon terminals, and *ii)* that the DA synthesis-promoting action of TFMP is independent of its effect on 5-HT synthesis, and apparently requires intact nerve impulse traffic. The effects of TFMP on 5-HT and DA synthesis may thus possibly reflect pre- and postsynaptic, respectively, 5-HT_{1B} receptor (heteroreceptor?)-mediated events.

RELEASE OF DOPAMINE FROM THE RAT OLFACTORY TUBERCLE IS MEDIATED BY ACTIVATION OF 5-HT₃ RECEPTORS. J. Del Rio* and A. Zazpe. Dept. of Pharmacology, University of Navarra Medical School, 31080-Pamplona, Spain.

Serotonin (5-HT) and specific 5-HT₃ receptor agonists release dopamine (DA) from the striatum and limbic regions. It has been suggested that DA is released through a carrier-related mechanism and is not a consequence of 5-HT₃ receptor activation. We have studied the effect of 5-HT₃ receptor stimulation and blockade on K⁺-evoked [³H]DA release from slices of rat olfactory tubercle, a terminal field of mesolimbic DA projections. After superfusion of the slices with high K⁺ (45 mM) and a washout period, tissue was incubated with [³H]DA (0.1 μM) for 30 min. When DA efflux was stabilized, slices were stimulated twice (S₁ and S₂, 30 min apart) with KCl (20 mM, 6 min). Drugs were added 15 min before S₂ and the effect calculated as change in the S₂/S₁ ratio. The 5-HT₃ agonist 2-Me-5-HT (1-10 μM) induced a significant and concentration-dependent increase in S₂/S₁. Phenylbiguanide (PBG) and 5-HT (2 μM each) also increased significantly this ratio. Low concentrations of the 5-HT₃ antagonist ondansetron (20-200 nM) blocked, also in a concentration-dependent manner, the effect of 2-Me-5-HT and of PBG. Other 5-HT₃ antagonists such as granisetron and tropisetron (200 nM) also blocked the [³H]DA efflux induced by 2-Me-5-HT (2 μM). Interestingly, the DA uptake blocker nomifensine (10 μM) did not modify at all the effect of 2-Me-5-HT (2 μM). The results suggest that, under conditions of K⁺-induced neuronal depolarization, enhanced release of DA by serotonergic agonists is a 5-HT₃ receptor-mediated effect.

565.13

Evidence that m-CPP-induced hyperthermia in rats is mediated by 5-HT_{1C} receptors.

P. Mazzola-Pomietto, C.S. Aulakh, K.M. Wozniak, D. Johnson* and D.L. Murphy. Laboratory of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892.

m-chlorophenylpiperazine (m-CPP), an active metabolite of the antidepressant trazodone (Caccia et al, 1982) possesses an approximately 10-fold higher affinity for 5-HT_{1C} versus 5-HT_{1A}, 5-HT_{1B} and 5-HT₂ sites (Hoyer et al, 1988). Intraperitoneal administration of m-CPP (2.5 mg/kg) to male Wistar rats produced hyperthermia with a peak effect at 30 min. Pretreatment with propranolol and CGP361A (β-adrenoceptor antagonists that also have binding affinity for 5-HT_{1A} and 5-HT_{1B} sites) as well as MDL-72222 and ondansetron (5-HT₃ antagonists) did not attenuate m-CPP induced hyperthermia. In contrast, pretreatment with metergoline (5-HT_{1/5-HT₂} antagonist), mesulergine, mianserin and ritanserin (5-HT_{1C/5-HT₂} antagonists) as well as spiperone (5-HT_{1A/5-HT_{2/2}} antagonist) significantly attenuated m-CPP-induced hyperthermia. Furthermore, daily administration of m-CPP (2.5 mg/kg/day) produced complete tolerance to its hyperthermic effect by day 3. However, there was no cross-tolerance to 1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane (DOI, a 5-HT₂ agonist that also has high affinity for 5-HT_{1C} receptors)-induced hyperthermia when m-CPP-treated (2.5 mg/kg/day x 5) animals were challenged with DOI on day 6. While the antagonist data alone suggest that either 5-HT_{1C} or 5-HT₂ might mediate m-CPP-induced hyperthermia, the lack of cross-tolerance to DOI strongly suggests that m-CPP-induced hyperthermia in rats is mediated by stimulation of 5-HT_{1C} receptors.

565.10

SEROTONIN (5-HT) HYPERSENSITIVITY ASSOCIATED WITH 5-HT HYPERINNERVATION IN ADULT RAT NEOSTRIATUM AFTER NEONATAL DOPAMINE (DA) DENERVATION. M. El Mansari, A. Ferron* and L. Descarries. Centre de recherche en sciences neurologiques (Départements de physiologie et de pathologie), Univ. Montréal, Montréal, Qc, Canada.

Destruction of nigrostriatal DA neurons by intraventricular 6-OHDA in newborn rats results in a 5-HT hyperinnervation of the adult neostriatum (NS) predominating in its rostral half. These rats also show a considerable increase in 5-HT₂ binding sites in the rostral but not the caudal NS, and enhanced neuronal responsiveness to iontophoresed 5-HT and its selective 5-HT₂ agonist DOI in the rostral NS. In view of recent results demonstrating that the 5-HT hyperinnervation is also present, although less prominent, in the caudal NS (Soucy et al., *this volume*), neuronal responsiveness to 5-HT and DOI was further assessed, by means of the IT₅₀ index, in the caudal NS of neonatally lesioned rats. The NS of rats similarly lesioned as adults and hence not 5-HT-hyperinnervated was also examined. As previously found rostrally, marked increases in inhibitory responsiveness to 5-HT and to DOI were measured in the caudal NS of neonatally lesioned rats. In contrast, 15-30 days after adult lesions, the sensitivity to 5-HT and DOI was not different from control. Enhanced responsiveness to 5-HT and DOI after neonatal lesion was therefore related to the 5-HT hyperinnervation rather than the DA denervation *per se*. Enhanced responsiveness to DOI in the caudal NS suggested an up-regulation of 5-HT₂ receptors, despite the earlier measurements of binding values equivalent to control. Indeed, some of these receptors are probably normally located on DA terminals, so that "control" values after DA denervation should be indicative of an increase in remaining intrastriatal locations. Since 5-HT₂ antagonists suppress the spontaneous hyperactivity seen in these rats (Luthman et al., *J. Psychopharmacol.* 5:418, 1991), it is likely that the enhanced neuronal responsiveness to 5-HT associated with the increase in neostriatal 5-HT₂ receptors is implicated in this abnormal behavior. (Supported by FCAR and MRC grant MT-3544).

565.12

Food intake, locomotor activity, temperature and neuroendocrine effects of DOM in rats.

J.L. Hill, C.S. Aulakh, P. Mazzola-Pomietto, A. Reid* and D.L. Murphy. Laboratory of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892.

Intraperitoneal administration of various doses of the phenylisopropylamine hallucinogen 1-(2,5-dimethoxy-4-methyl-phenyl)-2-aminopropane (DOM) to male Wistar rats produced dose-related decreases in one-hour food intake in the food-deprived-paradigm and locomotor activity. DOM also produced increases in rectal temperature and in plasma concentrations of prolactin, adrenocorticotropic hormone (ACTH) and corticosterone. DOM administration did not have any significant effect on growth hormone levels.

Since DOM has high affinity at both 5-HT₂ and 5-HT_{1C} receptor sites in radioligand studies, we further studied the effects of various 5-HT receptor subtype selective antagonists on DOM-induced changes in rectal temperature, food intake and plasma hormones. Pretreatment with propranolol (β-adrenoceptor antagonist that also has binding affinity for 5-HT_{1A}, 5-HT_{1B} and 5-HT_{1C} sites) or MDL-72222 (5-HT₃ antagonist) did not attenuate DOM-induced hyperthermia. In contrast, pretreatment with metergoline (5-HT_{1/5-HT₂} antagonist), mesulergine and ritanserin (5-HT_{1C/5-HT₂} antagonists) as well as spiperone (5-HT_{1A/5-HT_{2/2}} antagonist) significantly attenuated DOM-induced hyperthermia. These findings suggest that DOM-induced hyperthermia in rats is mediated by stimulation of 5-HT₂ receptors. We will also present data on the effects of 5-HT₂ antagonists on DOM-induced decreases in food intake and increases in plasma hormones.

565.14

Evidence that DOI-induced hyperthermia in rats is mediated by 5-HT₂ receptors.

D.L. Murphy, P. Mazzola-Pomietto, K.M. Wozniak, N.A. Garrick*, J.L. Hill and C.S. Aulakh. Laboratory of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892.

1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane (DOI) is a phenylisopropylamine hallucinogen which has been shown to compete strongly for [³H]-DOB-labelled 5-HT₂ receptors with a similar rank order of potency at [³H]-mesulergine-labelled 5-HT_{1C} receptors in homogenate binding assays (Tilley et al, 1988). Intraperitoneal administration of DOI (1.0 mg/kg) to male Wistar rats produced hyperthermia with a peak effect at 60 min. Pretreatment with propranolol and CGP361A (β-adrenoceptor antagonists that also have binding affinity for 5-HT_{1A} and 5-HT_{1B} sites) did not attenuate DOI-induced hyperthermia. In contrast, pretreatment with metergoline (5-HT_{1/5-HT₂} antagonist), mesulergine, mianserin and ritanserin (5-HT_{1C/5-HT₂} antagonists) as well as spiperone (5-HT_{1A/5-HT_{2/2}} antagonist) significantly attenuated DOI-induced hyperthermia. On the other hand, pretreatment with MDL-72222 and ondansetron (5-HT₃ antagonists) potentiated DOI-induced hyperthermia. Furthermore, daily administration of DOI (2.5 mg/kg/day) for 17 days did not produce either tolerance to its hyperthermic effect or modify m-CPP-induced hyperthermia in rats. These findings suggest that DOI-induced hyperthermia in rats is mediated by stimulation of 5-HT₂ receptors.

565.15

Lack of cross-tolerance for hypophagia induced by DOI versus m-CPP suggests separate mediation by 5-HT₂ and 5-HT_{1C} receptors, respectively. C.S. Aulakh, P. Mazzola-Pomietto, B. Hulihan-Giblin* and D.L. Murphy. Laboratory of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892.

In radioligand studies, 1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane (DOI) has been shown to have high affinity for 5-HT₂ and 5-HT_{1C} receptor sites (Titler et al, 1988) whereas m-chlorophenylpiperazine (m-CPP) possesses an approximately 10-fold higher affinity for 5-HT_{1C} versus 5-HT_{1A}, 5-HT_{1B} and 5-HT₂ sites. In the present study, we investigated the time course of development of tolerance to the hypophagic effects of DOI and m-CPP and furthermore, also checked for cross-tolerance between m-CPP and DOI. We studied the effects of daily injections of m-CPP (2.5 mg/kg), DOI (2.5 mg/kg) or saline in first hour food intake in separate groups of male Wistar rats using the food-deprived paradigm.

Intraperitoneal administration of DOI produced significant decreases in the first hour food intake on day 1 and on day 2 relative to saline-treated animals. Complete tolerance developed to DOI-induced hypophagia by day 3. However, there was no cross-tolerance to m-CPP-induced hypophagia when DOI-treated (2.5 mg/kg/day x 4) animals were challenged with m-CPP on day 5. Similarly, complete tolerance developed to m-CPP-induced hypophagia by day 3 but again, there was no cross-tolerance to DOI-induced hypophagia when m-CPP-treated (2.5 mg/kg/day x 4) animals were challenged with DOI on day 5. These findings suggest that m-CPP- and DOI-induced hypophagia is separately mediated by 5-HT_{1C} and 5-HT₂ receptors, respectively. We will also present data on 5-HT_{1C} and 5-HT₂ receptor binding in different brain areas in 4-day m-CPP (2.5 mg/kg/day) and DOI (2.5 mg/kg/day)-treated animals.

565.17

IN VIVO ASSESSMENT OF SUB-TYPE SPECIFIC 5HT₂ ANTAGONISTS. P.A. Wisler* and P.C. Doherty. Lilly Research Laboratories, Eli Lilly and Company, Indianapolis, IN 46285.

Homology among the subtypes of the 5HT₂ receptor (2A, 2B, and 2C) has made it difficult to assess the selectivity of agonists and antagonists for the members of this sub-family. Here we report on the effects of various 5HT_{2A/2C} antagonists on 1-(m-chlorophenyl)-piperazine (mCPP) induced penile erection, a response mediated by the 5HT_{2C} receptor, and 1-(2,5-dimethoxy-4-iodophenyl)-2-aminopropane (DOI) induced headshakes, a 5HT_{2A} mediated event. mCPP increased erections in a dose dependent fashion (0.1 to 1.0 mg/kg). DOI increased both the erectile response (0.1 to 0.3 mg/kg) and the number of head shakes (0.3 to 10.0 mg/kg). Induction of the latter response was associated with a significant decline in erections. A series of 5HT_{2A/2C} antagonists inhibited DOI induced (1.0 mg/kg) headshakes with the following order of potency: Mianserin > Ketanserin ≥ LY53857 > Ritanserin. Most of these antagonists were effective at blocking mCPP induced (0.3 mg/kg) erections: Mianserin ≥ LY53857 > Ritanserin. Ketanserin, at doses up to 30 mg/kg, had no effect on mCPP induced erections. However, it did unmask the ability of DOI to induce erections at doses greater than 0.3 mg/kg. These results suggest that this combination of behavioral tests can establish the in vivo selectivity of antagonists for the 5HT_{2A} and 5HT_{2C} receptors.

565.19

EXCITATION BY SEROTONIN (5-HT) OF INTERNEURONS IN PIRIFORM CORTEX: BLOCKADE BY A NEW, HIGHLY SELECTIVE 5-HT₂ ANTAGONIST.

G.J. Marek* and G.K. Aghajanian. Depts. of Psychiatry and Pharmacology, Yale University School of Medicine, New Haven, CT 06508.

Recent electrophysiological studies have revealed a subpopulation of interneurons located near the border of layers II and III in rat piriform cortex that are excited by serotonin (5-HT; Sheldon & Aghajanian, 1990). It has been suggested that this excitation is mediated by 5-HT₂ rather than 5-HT_{1C} receptors (Sheldon & Aghajanian, 1991). However, the pharmacological agents available for analysis were limited in specificity. In the present study, we tested a new, highly selective 5-HT₂ antagonist MDL 100,907 which has a 300 fold greater affinity for 5-HT₂ than 5-HT_{1C} or α₁ receptors (Schmidt et al., 1992).

Bath application of incremental concentrations of MDL 100,907 (1-10 nM) for 30 min periods potently blocked the activation by 5-HT of interneurons recorded from rat piriform cortex. Schild analyses resulted in a pA₂ ranging from 0.43-0.59 nM, which is close to the published K_d of 0.36 nM (Schmidt et al., 1992). In addition, parallel shifts in the 5-HT dose response curve were observed with MDL 100,907. Moreover, the effects of a 1 hr bath application of MDL 100,907 at 1 nM were largely reversed after a 20 min washout period. In contrast, a kinetic analysis of ritanserin, a 5-HT_{2/1C} antagonist, could not be performed as equilibrium was difficult to achieve, blockade continued to progress after the perfusion of the drug was completed, and no washout was observed. These data confirm that 5-HT₂ rather than 5-HT_{1C} receptors mediate the excitation by 5-HT of interneurons in the piriform cortex. In addition, these results suggest that MDL 100,907 may be an excellent tool in electrophysiological investigations to differentiate 5-HT₂ from 5-HT_{1C} responses.

INVOLVEMENT OF CENTRAL 5-HT₂ RECEPTORS IN THE MAINTENANCE OF TOLERANCE TO ETHANOL BY ARGININE-8-VASOPRESSIN. P.H. Wu, J.-F. Liu, A.J. Lanca, L.A. Grupp* and H. Kalant. Dept. of Pharmacology, Univ. of Toronto, and Addiction Res. Foundation of Ontario, Toronto, Canada.

AVP and some of its analogs can maintain tolerance to ethanol (EtOH) after EtOH administration ceases, but only if mesolimbic 5-HT pathways are intact. The type(s) of 5-HT receptor required for this AVP effect on EtOH tolerance is not known. Male Sprague Dawley rats (N=120) were trained to criterion performance on a moving belt, and then implanted with an intracerebroventricular (i.c.v.) cannula. Saline (S) or 5,7-dihydroxytryptamine (5,7-DHT) was injected i.c.v. After 2 weeks of recovery, the rats were treated daily with saline or EtOH (1.8 g/kg i.p.) followed by practice sessions on the belt, until the EtOH-treated rats showed tolerance. At this point, EtOH treatment was discontinued and for the next 2 wks S or AVP (10 µg) was given s.c. daily, together with S or various 5-HT receptor agonists i.c.v., via Alzet osmotic minipumps. All animals were then tested under EtOH. Immunocytochemistry revealed that 5-HT neuronal terminals were destroyed by the 5,7-DHT while the cell bodies in the raphe nuclei were spared. In the EtOH tests, tolerance was found to be maintained by AVP combined with i.c.v. infusion of 5-HT, α-methyl-5-HT (5-HT₂ agonist), or 2-methyl-5-HT (5-HT₂ agonist), but not with 8-OH-DPAT (5-HT_{1A} agonist). These results indicate relatively selective involvement of 5-HT₂ or 5-HT₂ receptors in the maintenance of EtOH tolerance by AVP. Supported by NIAAA grant #1 R01-AA08212-03.

5-HT₂ AND NOT 5-HT_{1C}-RECEPTOR ACTIVATION MEDIATES THE HEAD-TWITCH RESPONSE IN CRYPTOTIS PARVA. N.A. Darmani*, O.R. Mock, L.C. Towns, and C.F. Gerdes. Departments of Pharmacology and Anatomy, Kirksville College of Osteopathic Medicine, Mo 63501.

Our initial studies suggested that the 5-HT_{2/1C} agonist, DOI, produces both the head-twitch response (HTR) and the ear-scratch response (ESR) in mice via stimulation of 5-HT₂ receptors. However, challenge studies revealed that these behaviors are produced via two different receptors (possibly 5-HT₂ and 5-HT_{1C}) and due to a lack of selective agents one cannot designate a specific receptor for a particular response. The purpose of the present study was to investigate such behaviors in the least shrew (*Cryptotis parva*) which is more sensitive to DOI than rodents. Varying doses of DOI (0.31-2.5 mg/kg) was administered intraperitoneally to different groups of shrews and the induced behaviors were recorded cumulatively at 5-min intervals for the next 30 min. DOI produced a dose-dependent (bell-shaped) and time-dependent increase in the HTR frequency. The induced HTR was completely attenuated by the 5-HT_{2/1C} antagonists ketanserin and spiperone. The 5-HT_{1C} antagonist with 5-HT₂ agonist action, lisuride, also produced the HTR in a bell-shaped dose- (0.63-2.5 mg/kg) and time-dependent fashion. Central injections of both DOI (0.2 µg) and lisuride (0.5 µg) also induced the HTR. Both peripheral and central administration of lisuride failed to produce the ESR. DOI significantly induced the ESR only at the highest dose tested (2.5 mg/kg, i.p.). Centrally administered DOI (0.2 µg) produced more ESRs relative to vehicle controls, however, the difference did not attain significance. At low doses (0.31 and 0.63 mg/kg), DOI had no effect on locomotor activity but significantly attenuated the behavior at larger doses. Both low and high doses of lisuride increased the motor activity. Spiperone dose-dependently suppressed locomotion whereas ketanserin had no effect. The present results suggest that the HTR is a 5-HT₂ receptor-mediated event and changes in locomotor activity do not affect the induced-HTR.

FURTHER PHARMACOLOGICAL CHARACTERIZATION OF SIGMA RECEPTOR REGULATION OF NMDA-STIMULATED DOPAMINE RELEASE IN RAT STRIATUM. G. M. Gonzalez-Alvarez* and L. L. Werling. Dept. Pharmacology, The George Washington University Medical Ctr., Washington, D.C. 20037.

We have previously reported that (+)pentazocine inhibited NMDA-stimulated [³H]DA release from rat striatal slices in a concentration-dependent, biphasic manner. We have now investigated the effects of several additional sigma ligands, as well as atropine, in this system.

Striata were dissected, chopped, and washed in Mg²⁺-free modified Krebs-HEPES buffer, then incubated with 15 nM [³H]DA for 30 min. Slices were loaded into a superfusion apparatus and superfused with buffer to establish a low, stable baseline release. Tissue was stimulated to release [³H]DA by a 2 min exposure to 25 μM NMDA. After return to the non-stimulating buffer, tissue was stimulated a second time (S2) for 2 min in the presence or absence of test compound (drug).

BD737, a sigma agonist, was found to inhibit NMDA-stimulated DA release from rat striatal slices. In contrast, the novel sigma antagonist, BD1008, reversed inhibition of DA release by 100 nM (+)pentazocine. Further examination revealed that BD1008 reversed inhibition of DA release by all concentrations of (+)pentazocine tested. Since (+)pentazocine, at concentrations above 1 μM, has been reported to have activity at cholinergic receptors, we examined the effects of atropine on (+)pentazocine inhibition of DA release. Atropine did not antagonize the inhibition of DA release by (+)pentazocine, obviating any cholinergic receptor-mediated effects. In addition, since (+)pentazocine, at very high concentrations, has been reported to interact with the PCP receptor, we investigated the ability of BD1008 to antagonize the inhibition of DA release produced by the PCP receptor selective drug, MK-801. BD1008 did not reverse the inhibition of DA release by MK-801. These data suggest that both sigma and PCP receptors can regulate the release of DA from striatum. KAPPA OPIOID RECEPTOR ACTIVATION MODULATES EXCITATORY AMINO ACID RESPONSES IN ACUTELY ISOLATED NEURONS FROM THE DORSAL HORN. M. Kolaj*, R. Cerne and M. Randić. Dept. of Vet. Physiol. and Pharmacol., Iowa State University, Ames, IA 50011.

To understand how κ-opioid receptor agonists affect the excitability of spinal dorsal horn (DH) neurons, we examined the actions of Dynorphin A₁₋₁₇ (Dyn₁₋₁₇) and *trans*-3,4-dichloro-N-methyl-N-[2-(1-pyrrolidinyl)cyclohexyl]benzene acetamide (U-50,488H) on excitatory amino acids (EAA)-activated current responses of freshly isolated neurons from the spinal dorsal horn (laminae I-IV) of rats (8-13d) under whole-cell voltage-clamp conditions. Here we report that the inward current responses of DH neurons induced by α-amino-3-hydroxy-5-methyl-4-isoxazolepropionic acid (AMPA, 10-50 μM), kainate (KA, 10-100 μM) and N-methyl-D-aspartate (NMDA, 100 μM) were modulated by Dyn₁₋₁₇ and U-50,488H in a complex manner. When applied simultaneously with or prior to an EAA, Dyn₁₋₁₇ (5 pM-1 μM) reversibly reduced the responses of DH neurons to AMPA (85.7 ± 1.3% of control, 17/26 cells), KA (79.5 ± 6.5%, 8/12 cells) and NMDA (77.0 ± 0.7%, 5/9 cells). In addition, Dyn₁₋₁₇ reversibly enhanced latency and the rise time of the AMPA-induced current in 77% of the examined cells. The effects were antagonized by naloxone (0.1 μM, 5/7 cells) and κ₁-opioid receptor antagonist, nor-binaltorphimine (0.1-100 nM, 5/6 cells). Following removal of Dyn₁₋₁₇, the EAA-induced responses were potentiated (AMPA: by 120.1 ± 6.1%; KA: by 115.5 ± 4.4%; NMDA: by 121.8 ± 4.2%) in about half of the cells. U-50,488H (1 μM) had also two distinct effects on the peak amplitude of the initial transient component of the AMPA- and the NMDA-induced currents consisting of an initial depression (AMPA: to 89.5 ± 2.5%, 6/9 cells; NMDA: to 80.7 ± 5.3, 6/7 cells) followed by a potentiation (AMPA: by 119.7 ± 5%; 7/7 cells, NMDA: by 115 ± 5, 3/7 cells). These results indicate that κ-opioid receptor agonists modulate the AMPA, KA and NMDA receptors signaling function in a proportion of the rat spinal DH neurons (Supported by NS-26352 and IBN-9209462).

EFFECTS OF DIPYRIDAMOLE ON DOPAMINE UPTAKE AND RELEASE IN VITRO: POSSIBLE RESERPINE-LIKE ACTION. K.T. Delle Donne*, S. Devraj and P.K. Sonsalla. Department of Neurology, Univ. of Med. & Dent. of New Jersey-Robert Wood Johnson Medical School, Piscataway, NJ 08854.

Dipyridamole (DPR) is a drug commonly used as an adenosine transport inhibitor. To examine the effects of endogenous adenosine on dopamine (DA) release, mouse neostriatal slices were superfused with DPR *in vitro*. DPR (20 μM) caused a 65% inhibition of K⁺-evoked endogenous DA release, but only 8-10% of the inhibition could be blocked by 10 μM cyclopentyltheophylline, a potent adenosine receptor antagonist. This suggests that inhibition of DA overflow by DPR is not mediated primarily by adenosine actions. Furthermore, DOPAC overflow was enhanced 6-8 fold over basal during the 30-min pretreatment of the slices with DPR, which indicates substantially increased turnover of DA. Reserpine (10 μM) exhibited a similar profile. DOPAC overflow was increased 20-fold during the 30-min pretreatment and K⁺-stimulated DA release was decreased by 75%. [³H]DA uptake into mouse neostriatal synaptosomes was inhibited by DPR with an IC₅₀ of 23.4 ± 1.1 μM. Inhibition of [³H]DA uptake by nitrobenzylthioinosine (NBTTI), a more selective adenosine uptake inhibitor, was much less potent with maximal inhibition of 30 ± 8% at 100 μM. In contrast to DPR, amfonelic acid (10 μM), a classic DA uptake inhibitor, produced no change in DOPAC overflow and a 2-3 fold increase in basal DA outflow during the 30-min pretreatment; following K⁺ stimulation, DA overflow was enhanced 2.5-fold. These results suggest that, in addition to its effects on adenosine transport, DPR may also have DA-depleting effects similar to those of reserpine which decrease the ability of dopaminergic terminals to accumulate DA and to sustain the depolarization-sensitive pool of DA.

DIZOCLIPINE (MK-801) EXCITES NEOSTRIATAL NEURONS IN THE FREELY MOVING RAT. K.C. Hooper*, D.A. Banks, L.L. Johnson, and G.V. Rebec. Prog. Neural Science, Dept. Psychology, Indiana University, Bloomington, IN 47405.

In addition to dopaminergic innervation, the neostriatum receives glutamatergic input from neocortex and thalamus. The interactions among these inputs, however, are complex. For example, NMDA receptors on dopaminergic terminals inhibit dopamine release, and glutamate release is inhibited by D2 dopamine receptors on corticostriatal terminals.

We have previously shown that stimulation of D2 dopamine receptors with quinpirole inhibits the activity of striatal neurons in awake, behaving rats, whereas SKF-38393, a D1 receptor agonist, produces inconsistent effects (Hooper et al., *Soc. Neurosci. Abstr.* 18:995, 1992). As an extension of this research, we have begun a series of experiments to assess the electrophysiological effects of dizocilpine (MK-801), a non-competitive NMDA glutamate antagonist.

In contrast to quinpirole, MK-801 (0.10 or 0.25 mg/kg) increased the firing rate of neostriatal neurons, and this effect was accompanied by a dose-dependent increase in behavioral activation. These results suggest an important role for both D2 dopamine receptors and NMDA glutamate receptors in the regulation of neostriatal neuronal activity.

IN VIVO DOPAMINE RELEASE IN THE RAT PREFRONTAL CORTEX IS INCREASED BY STIMULATION OF THE MEDIODORSAL THALAMIC NUCLEUS. M.G.P. Feenstra, W.van der Weij, J.J. Hamstra, M.H.A. Botterblom and R.M. Buijs*. Graduate School Neurosciences Amsterdam, Neth. Inst. Brain Research, 1105AZ Amsterdam ZO, The Netherlands.

In the prefrontal cortex (PFC) dopaminergic (DA) projections from the ventral tegmental area (VTA) largely overlap with excitatory projections from the mediodorsal nucleus of the thalamus (MDT). We studied the possible involvement of the MDT in the regulation of DA release by using microdialysis in the medial PFC. Basal DA overflow in awake animals was 1.2 pg/50 μl (bilateral cannulae) or 0.6 pg/50 μl (unilateral). Both NMDA (1 mM, 20 min) and AMPA (0.1 mM) strongly increased DA overflow, but this was correlated with the induction of epileptic effects, suggesting massive, synchronized neuronal activity.

Stimulation of the MDT by local perfusion of bicuculline (0.1 mM for 20 min) through a dialysis cannula increased DA overflow in the PFC 2-5 fold without inducing epileptic activity. Thus, this experimental approach provides a more physiological means to increase excitatory input and demonstrates the facilitatory influence of the MDT on PFC DA release. Ongoing experiments are being carried out to test the possible involvement of presynaptic glutamate receptors on DA terminals vs polysynaptic activation of DA neurons.

THE EFFECTS OF DOPAMINE ANTAGONISTS ON THE CHANGES OF CCK-LIKE IMMUNOREACTIVITY INDUCED BY ACUTE METHAMPHETAMINE ADMINISTRATION IN THE RAT BRAIN. N. Kawaji¹, Y. Takamatsu¹, H. Yamamoto¹, A. Baba¹, T. Morojii¹ and K. Yoshikawa². 1; Dept. of Psychopharmacology, Tokyo Institute of Psychiatry, Tokyo 156, and 2; Dept. of Molecular Neurobiology, Tokyo Metropolitan Institute for Neurosci., Tokyo 183, JAPAN.

The effects of the dopamine D1- and D2-antagonists on the changes of CCK-like immunoreactivity (CCK-LI) induced by acute MAP-administration were investigated in the rat medial frontal cortex (MFC). Single administration of selective D2-antagonists, sulpiride (SUL) and YM-09151-2 (YM), and D1/D2-antagonist haloperidol (HP) reduced the CCK-LI in the rat MFC, while selective D1-antagonist SCH23390 (SCH) did not. Acute administration of MAP also reduced the CCK-LI in the rat MFC. This effect of MAP was reversed by SCH and HP, but not by SUL. Interestingly, another selective D2-antagonist YM completely reversed the effect of MAP. In the behavioral study, SCH, HP and YM blocked the stereotyped behavior induced by MAP-administration. SUL partially blocked the MAP-induced stereotyped behavior only with large doses (250 mg/kg). These results indicate the differential roles of dopamine D1- and D2-receptors in controlling the cortical CCK-containing neurons.

THE CCK ANTAGONIST, LORGLUMIDE (CR-1409), DOES NOT ALTER DOPAMINE LEVELS IN RAT CAUDATE AS MEASURED BY MICRODIALYSIS. K.A. Kedzie and K.J. Renner*. Dept. Biomedical Sciences, Southwest Missouri State Univ., Springfield, MO 65804.

Dopamine (DA) signals associated with 100 mM KCl-induced slow wave depolarization (SWD) in the rat caudate (CPu) are blocked by CCK-A receptor antagonists (*Brain Res.* 594:47, 1992). Failure to elicit KCl-induced DA signals following CCK-A antagonist treatments may be due to a CCK-DA interaction. We investigated this possibility by determining the effects of loglumide (LORG) on basal and locally stimulated levels of DA in the CPu. Dialysis probes were implanted into the CPu of male Sprague-Dawley rats anesthetized with chloral hydrate (400 mg/kg). Samples were collected at 20 min intervals and analyzed for DA using HPLC with electrochemical detection. LORG (640 µg/kg, Rotta Labs.) or saline were administered i.v. LORG did not significantly affect basal DA levels (n=9). Perfusion of 30 mM KCl 20 min following saline (n=8) or LORG (n=9) increased DA to 352 ± 51 and 386 ± 80 % of basal levels, respectively. The results suggest that CCK-A receptors do not mediate putative CCK-DA interactions in the CPu. The inhibition of SWD in the CPu by LORG does not appear to directly involve the dopaminergic system.

566.9

THE NITRIC OXIDE PRECURSOR, L-ARGININE, INCREASES DA AND 5-HT RELEASE IN MEDIAL PREOPTIC AREA OF MALE RATS. D. S. Lorrain and E. M. Hull*. Psychology Department, SUNY at Buffalo, NY 14260.

The gas nitric oxide (NO) is an intercellular messenger that has been implicated in glutamate-induced dopamine (DA) release in striatal slices (Hanbauer et al., 1992), and norepinephrine and acetylcholine release in hippocampal slices (Lonart et al., 1992).

In the present experiment, sixteen animals received the NO precursor L-arginine (100 µM) into the MPOA through a microdialysis probe; half of these also received the inactive isomer D-arginine (100 µM) for 3 samples before L-arginine administration. Seven additional animals received the NO synthesis inhibitor N-monomethyl L-arginine (NMMA, 400 µM) through the dialysis probe; four of these also received L-arginine (100 µM) plus NMMA.

L-arginine significantly increased extracellular levels of DA, serotonin (5-HT), and the DA metabolites DOPAC and HVA. Furthermore, these increases were completely blocked by co-administration of the NO synthesis inhibitor NMMA. The inactive isomer D-arginine was ineffective. NMMA by itself decreased DA below baseline.

These data suggest that NO may modulate the release of DA and 5-HT in the MPOA. Both DA and 5-HT in the MPOA have been implicated in the control of male sexual behavior, with DA facilitating and 5-HT generally inhibiting copulation and genital reflexes (Hull et al., 1986 & 1992; Pehek et al., 1989; Warner et al., 1991). The present data, together with those cited above, suggest that NO may enhance the release of several neurotransmitters. Its function in the MPOA may be to modulate the prolonged DA release that accompanies (and facilitates) copulation. The mechanisms of this enhancement and its generality are at present unknown.

566.11

ONTOGENY OF AN INTERACTION BETWEEN DOPAMINE AND κ OPIOID SYSTEMS: EFFECTS ON MOTOR ACTIVITY AND SENSORY RESPONSIVENESS IN THE FETAL RAT. D. K. Simonik*, S. R. Robinson, and W. P. Smotherman. Laboratory of Perinatal Neuroethology, Center for Developmental Psychobiology, Binghamton University, Binghamton, NY 13902-6000.

Milk has behavioral effects in the fetal rat that are caused by changes in the dopamine and κ opioid systems. Administration of dopaminergic and κ opioid drugs to the fetal rat suggests that these systems interact on E21 of gestation. In the present study, fetuses were observed on E19, E20 and E21 to characterize the effects of DA D1 and κ opioid agonists and antagonists on fetal motor activity and sensory responsiveness. Fetal subjects were observed to assess spontaneous motor activity and sensory responsiveness in two behavioral bioassays. Changes in motor activity and the incidence of elicited facial wiping were used to measure responses to tactile and chemosensory stimuli. To characterize possible interactions between the DA and κ opioid systems, fetal subjects were injected ip with a D1 agonist (SKF-38393) and κ antagonist (norbinaltorphimine), or a κ agonist (U50,488) and D1 antagonist (SCH-23390). Drug manipulations resulted in changes in fetal motor activity as well as responsiveness to tactile and chemosensory stimuli. The data support the interpretation that an interaction between the DA and κ opioid systems appears on E20 and is clearly present on E21; activity in the DA system promoted κ opioid activity to bring about changes in motor behavior and sensory responsiveness. A qualitatively different interaction between these two systems was evident on E19. These data suggest that pharmacological activation of the DA and/or κ opioid systems can produce behavioral effects in the rat fetus, and that the nature of the interaction between these two systems changes markedly during the last few days of gestation.

SYSTEMIC MORPHINE INCREASES DOPAMINE RELEASE IN THE MPOA OF MALE RATS. L. Matuszewich*, B. Finnerty, D. Lorrain and E. M. Hull. Department of Psychology, SUNY at Buffalo, Buffalo, NY 14260.

Morphine has been shown to affect dopamine activity in the mesolimbic dopamine (DA) tract. Infusions of morphine into the ventral tegmental area increased DA metabolism in the nucleus accumbens and also facilitated sexual behavior in male rat castrates (Mitchell & Stewart, 1990). Another brain site involved in the DA regulation of male copulatory behavior is the medial preoptic area MPOA (Hull, et al., 1986). This study examined the effects of morphine (15 mg/kg) on DA and its metabolites in MPOA.

The effects of a single systemic injection of morphine (15 mg/kg) were assessed through microdialysis. Samples collected every 20 minutes were analyzed using high performance liquid chromatography (HPLC) with electrochemical detection. Dopamine and its metabolites increased significantly in the MPOA following a morphine injection (DA, p<.05; DOPAC, p<.01; HVA, p<.05). This parallels the effects of systemic morphine on the mesolimbic DA tract.

NEUROKININS ENHANCE EXCITATORY AMINO ACID-INDUCED ACTIVATION OF THE NEONATAL RAT SPINAL CORD *IN VITRO*.

Urban, L.* Naeem, S. Patel, J.A. and Dray, A. Sandoz Institute for Medical Research, London WC1E 6BN, UK.

Neurokinins (NK) facilitate excitatory amino acid (EAA) induced currents in single dorsal horn cells (Rusin et al., *J. Neurophysiol.*, 68, (1992) 256). Here we have further studied the interactions between NKs and EAAs in the neonatal spinal cord.

Spinal cord with attached tail was prepared from 1-2 day old rats and maintained *in vitro*. Synaptic activity was recorded as a ventral root (VR) depolarization from the L4 ventral root following drug superfusion.

Submaximal VR-responses were evoked by 10s application of EAA agonists. In the presence of subthreshold concentrations of NK-A and SPOMe, but not substance P NMDA and quisqualate responses were enhanced significantly, while kainate responses were unaltered. The enhancement was selectively blocked by MEN10 376 and CP 96345 respectively. In the presence of a cocktail of endopeptidase inhibitors (captopril, thiorphan and bestatin, each 1.0µM) subthreshold doses of substance P significantly enhanced NMDA and quisqualate responses which could be blocked selectively by CP96 345. The possibility that the enhancement of EAA effects was mediated via protein kinase C (PKC) activation was tested using the inhibitor staurosporine (1.0µM). Staurosporine blocked the facilitation of the EAA responses after a 30 minutes perfusion. At this time all NK-evoked responses were blocked while EAA-evoked responses were not affected. These data suggest that NK-2 receptor activation selectively enhances NMDA and quisqualate evoked depolarization of the ventral root. In circumstances where an excess of SP occurs in the spinal cord NK1 receptors may also produce a similar effect. NK-induced enhancement of EAA responses is mediated via PKC activation.

CLOZAPINE PRODUCES DIFFERENT EFFECTS FROM THOSE OF FLUPHENAZINE-N-MUSTARD (FNM) ON RECEPTORS AND mRNAs ASSOCIATED WITH DOPAMINERGIC AND OPIOID PEPTIDERGIC SYSTEMS OF MOUSE BRAIN. J.-F. Chen*, S.-P. Zhang, T.A. Connell, L.-Y. Zhou, and B. Weiss. Division of Neuropsychopharmacology, Department of Pharmacology, Medical College of PA, Philadelphia, PA 19129.

Clozapine (CLZ) is a novel antipsychotic agent, having relatively few extrapyramidal side effects. To examine and compare the biochemical effects of CLZ with those produced by classical antipsychotics, we determined the effects of CLZ on the levels of D₁ and D₂ dopamine (DA) receptors and D₁ and D₂ receptor mRNAs, and on the levels of mu and delta opioid receptors and proenkephalin mRNA. Receptor densities were assayed by quantitative receptor autoradiography using radiolabeled ligands specific for each receptor. mRNA levels were measured by *in situ* hybridization histochemistry using [³⁵S]-labeled specific oligonucleotide probes. Continuous infusion of CLZ (19 µmol/kg/hr, s.c.) with Alzet minipumps increased the level of D₁ receptors in mouse striatum but failed to significantly change the levels of D₂ receptors or D₁ or D₂ mRNAs. Continuous treatment with CLZ also increased the densities of the mu and delta opioid receptors and increased the levels of proenkephalin mRNA. In contrast to the effects of CLZ, repeated administration of the relatively selective D₂ antagonist FNM slightly decreased D₁ receptors and markedly reduced D₂ receptors. It also reduced D₁ mRNA and increased D₂ mRNA. In addition, FNM decreased mu and delta opioid receptors and increased proenkephalin mRNA in rat striatum. This study shows that CLZ has effects on DA and opioid peptidergic systems that are different in some respects from those produced by selective D₂ DA antagonists. Further, the data support the hypothesis that altered opioid peptidergic activity may be involved in the antipsychotic activity of CLZ. Supported by MH42148.

TIME-COURSE OF CHANGES IN STRIATAL LEVELS OF DA UPTAKE SITES, DA D₂ RECEPTOR AND PREPROENKEPHALIN mRNAs AFTER NIGROSTRIATAL DOPAMINERGIC DENERVATION IN THE RAT. M. Chritin, C. Feuerstein and M. Savasta*. INSERM-LAPSEN U.318, Pavillon de Neurologie, CHU de Grenoble, BP 217, 38043 Grenoble cedex 9, France.

Changes in striatal dopamine uptake sites, D₂ receptor and preproenkephalin (PPE) mRNA levels provoked by unilateral 6-hydroxydopamine-induced lesion of the nigrostriatal dopaminergic (DA) pathway were studied by quantitative autoradiography and *in situ* hybridization (ISH) in rats sacrificed at different post-lesional delays.

The disappearance of DA terminals as visualized with the labelling of dopamine uptake sites with [³H]GBR 12935 became significant 36 hours after the lesion and was almost complete at a delay of 7 days. PPE mRNA amounts significantly increase (+24%) already at the shortest delay studied (9 hours after the lesion) while the labelling of the uptake sites on DA terminals was not affected. The time course increase of PPE mRNA levels was progressive until 21 days post-lesion where it reached its maximum (+132%) and remained stable up to the latest delay studied (60 days). Conversely D₂ mRNA contents remained unchanged up to 5 days post-surgery and then increased relatively quickly since at 7 days post-lesion their levels were near (+21%) the maximum observed which was reached at 21 days post-lesion (+32%).

In contrast with PPE mRNA variations, the amplitude of increase of D₂ mRNA contents were always weaker.

Moreover, whatever the post-lesional delay examined, quantitative modifications of DA uptake sites, D₂ and PPE mRNAs were globally more pronounced in the dorsolateral region of the striatum than in the medial one.

This study shows that 6-hydroxydopamine induced-lesion of the nigrostriatal pathway leads to the increase of the contents of the mRNAs coding for Met-enkephalin and DA D₂ receptor, but with a differential time course, the first one increasing quite immediately after the lesion while the second one is significantly modified only after 1 week. These results suggest a time-dependent differential sensitivity to the degree of DA denervation of both major components implicated in the striatopallidal output.

FUNCTIONAL EXPRESSION OF CLONED α_2 C4- AND β_2 -ADRENERGIC AND δ -OPIOID RECEPTORS IN *XENOPUS* OOCYTES. Angela K. Birnbaum*, Diane R. Wotta, Ping Y. Law, and George L. Wilcox. Dept. of Pharmacology, University of Minnesota, Minneapolis, MN 55455

The *Xenopus* oocyte is a useful functional expression system for many seven-transmembrane receptors coupled through G proteins. The majority of the receptors expressed and electrophysiologically detected in the oocyte couple through the IP₃ system via endogenous calcium-activated chloride channels. Although the oocyte has also been shown to be capable of expressing receptors that exert their actions through the cAMP second messenger system, electrophysiological detection was not possible in the absence of co-expressed cAMP-regulated ion channels. By injecting mRNA encoding the cystic fibrosis transmembrane conductance regulator (CFTR, a cAMP-regulated chloride channel), we have characterized the function of one opioid (δ) and two adrenergic (α_2 C4- and β_2) receptors: activation of these cloned receptors increases the IBMX-induced, cAMP-mediated generated chloride currents that can be recorded by two-electrode voltage clamp.

G protein-coupled receptors couple to different G proteins depending on concentration of expressed receptors. Using relatively large amounts of injected mRNA (10ng), we have observed enhancement of the IBMX-induced current responses by adrenergic and opioid agonists. Concentration-dependent responses were observed for the agonists UK14304 (α_2), DADLE (δ), and isoproterenol (β_2) and antagonized by idazoxan, naloxone, and propranolol, respectively. In most cell and neural tissue systems, activation of α_2 and δ receptors is generally observed to decrease levels of cellular cAMP via G_i proteins. By contrast, we observed enhancement of the IBMX response. However, the interaction we observe using isobolographic analysis of co-activation of co-expressed α_2 and β_2 receptors is inhibitory suggesting that G_i protein coupling can also be detected with this system. Functional expression of G_i- and G_s-coupled receptors in the oocyte system may prove to be a useful adjunct to parallel studies in neural systems. 567.1

SOLUBLE GLUTAMIC ACID DECARBOXYLASE (GAD) IS PRESENT MAINLY AS A DIMER IN BRAIN. S. N. Sheikh and D. L. Martin*. Wadsworth Center, New York State Dept. of Health and Dept. Environmental Health & Toxicology, SUNY, Albany, NY 12201-0509

GAD is present in brain as at least two forms, GAD₆₅ and GAD₆₇, which are the products of two genes. Current data indicates that GAD is a multimer and studies with denaturing polyacrylamide gels suggest that some GAD is dimeric, but the relative amount of multimeric and monomeric GAD in brain is unknown. We have investigated this by using non-denaturing gradient polyacrylamide (PAA) gels along with immunoblotting. Rabbit antisera were produced against synthetic peptides selected from the amino acid sequences of the two forms of GAD. Each antiserum produced a high level of anti-peptide antibodies when tested by ELISA and each recognized the appropriate form of GAD on immunoblots of SDS-PAGE gels. To investigate the subunit composition of soluble native GAD, rat brain supernatants were analyzed on 5-25% and 5-30% PAA linear gradient gels. Almost all soluble GAD was present in multimeric form; brain contains very little monomeric GAD. The molecular weight of multimeric native GAD was estimated as 134 ± 3.5 kDa, indicating that soluble GAD exists in a dimeric form in brain. The average molecular weight of native GAD on these gels did not change when brain supernatants were diluted, indicating that the GAD dimer does not result from an easily reversible aggregation of the subunits. Whether native GAD is present as both hetero- and homodimers is under investigation. Supported by grant MH35664 from USPHS/DHHS.

ATTENUATION OF HALOPERIDOL-INDUCED DOPAMINE RELEASE BY 8-OH DPAT IN THE RAT: A CORRELATE FOR THE ANTICATALEPTIC EFFECTS OF 8-OH-DPAT? H. Sommermeyer, J. De Vry, J. Gruel* and I. Glaser. Institute for Neurobiology, Troponwerke GmbH & Co. KG, Berliner Strasse 156, 51063 Köln, FRG

The classical neuroleptic haloperidol (HAL) has antipsychotic properties, but induces also extrapyramidal side effects. While the antipsychotic properties of neuroleptics may be due to their action on the mesolimbic and/or mesocortical dopamine system, their extrapyramidal side effects have been attributed to their action on the nigrostriatal dopamine system. It has been reported, that 8-hydroxy-2-(di-N-propylamino) tetralin (8-OH-DPAT), a selective serotonin_{1A} receptor agonist, blocks the HAL-induced catalepsy (Invernizzi et al. (1988) *Neuropharmacology* 27: 515-518). In Wistar rats, catalepsy induced by 1 mg/kg (s.c.) HAL was reversed by combined administration of 0.3 mg/kg (s.c.) 8-OH-DPAT. For getting insight into the underlying mechanism of the anticataleptic effects of 8-OH-DPAT, the effects of HAL, 8-OH-DPAT, and a combination of HAL and 8-OH-DPAT were characterized by microdialysis measurements of dopamine (DA) release in the striatum of freely moving Wistar rats. HAL (1 mg/kg, s.c.) increased DA release maximal 1.8-fold, whereas 8-OH-DPAT (0.3 mg/kg, s.c.) had no effect on the DA level in the striatum. Interestingly, after simultaneous administration of HAL (1 mg/kg, s.c.) and 8-OH-DPAT (0.3 mg/kg, s.c.) no changes in the extracellular DA level were detectable. The attenuation of HAL-induced DA release in the striatum by 8-OH-DPAT is possibly a correlate for the reversal of HAL-induced catalepsy by this serotonin_{1A} receptor agonist.

THE EFFECTS OF INTRACELLULAR CALCIUM AND EXTRACELLULAR AMMONIA ON ASTROCYTE INTERMEDIARY METABOLISM. WC Gamberino, WA Brennan, Jr* and KE LaNoue. Dept. of Cell. and Mol. Physiology, Penn State Coll. of Medicine, Hershey, PA 17033

Astrocytes play an important role in glutamine/glutamate metabolism and NH₃ fixation in the brain. However, the regulation of these pathways in astrocytes is not clear. In many cells, the level of intracellular calcium, [Ca²⁺]_i, is important in regulating glutamate metabolism through α -ketoglutarate (α KG) levels. CO₂ fixation furnishes citric acid cycle intermediates used in these pathways in astrocytes. In liver cells, increases in [Ca²⁺]_i indirectly stimulate CO₂ fixation. To elucidate the role of [Ca²⁺]_i in regulating astrocyte CO₂ fixation, secondary cultures of neonatal rat astrocytes were incubated with a modified Krebs Ringer bicarbonate buffer containing 15 mM H¹⁴CO₃ (10000 dpm/nmol) in one of three conditions: 1) low [Ca²⁺]_i of 80 nM induced by incubation with 5mM EGTA, 2) control resting [Ca²⁺]_i of 125 nM, and 3) high [Ca²⁺]_i of 350 nM induced by incubation with 100 μ M ATP. To determine how NH₃ fixation is affected by calcium levels, the same three conditions were applied to astrocytes in the same buffer containing 2mM NH₄Cl to simulate an ammonia load. The cellular extracts as well as the extracellular buffers were analyzed by anion exchange chromatography. The preliminary data indicate: 1) In contrast to hepatocytes, increased [Ca²⁺]_i does not increase CO₂ fixation in astrocytes. The most striking effect of increasing [Ca²⁺]_i was an increase in the rate of α KG efflux from astrocytes. This occurred at the expense of intracellular α KG and was specific for α KG. 2) The production of labelled pyruvate indicates that some of the fixed CO₂ cycles from oxalacetate back to pyruvate via phosphoenolpyruvate carboxylase and pyruvate kinase. Furthermore, this cycling appears to be stimulated by low [Ca²⁺]_i. 3) The presence of 2mM ammonia in the buffer doubled levels of labelled glutamine both inside and outside the cells, but caused no increase in CO₂ fixation nor any significant decrease in either α KG levels or glutamate levels. The results suggest [Ca²⁺]_i may be an important modulator of astrocytes' capacity to return to neurons carbon lost as glutamate.

GAD₆₇ PROTEIN IN RAT CEREBRAL CORTEX IS HIGHLY SENSITIVE TO CHANGES IN GABA CONCENTRATION. K. Rimvall and D.L. Martin. Wadsworth Center for Labs and Research, New York State Dept. of Health, Albany, NY 12201.

Increased intracellular GABA levels (> 2.5-fold) in rat brain lead to large decreases in the amount of GAD₆₇ protein (75-80%) through a mechanism involving either a change in GAD₆₇ protein stability or GAD₆₇ mRNA translation (Rimvall et al., J. Neurochem. 60:714-720, 1993). To determine whether more biologically relevant changes in intracellular GABA would still induce significant changes in GAD₆₇ protein levels, rats were injected with varying doses of γ -vinyl-GABA (GVG; Vigabatrin[®]) and GABA and GAD₆₇ protein levels in the cerebral cortices were determined by HPLC and quantitative immunoblotting. To distinguish between the neuronal pool of GABA and the whole-tissue GABA (i.e. neuronal and astrocytic), the analysis was done using both synaptosomal and whole-tissue preparations. After three daily injections of GVG (30 mg/kg and 150 mg/kg) both GABA- and GAD₆₇-levels reached steady-state. Whole-tissue GABA increased 1.5-fold (30 mg/kg) and 4-fold (150 mg/kg) and GAD₆₇ protein levels decreased by 25% and 75%. Rats were then injected with seven different doses of GVG (30 to 150 mg/kg) for 5 days. With increasing GVG, we observed a gradual increase in whole-tissue and synaptosomal GABA and gradual decreases in total GAD activity and GAD₆₇ protein levels. The levels of GAD₆₇ protein remained constant at all GVG concentrations. GAD₆₇ was very sensitive to GABA - for every 1% increase in nerve-terminal GABA we saw a 2% reduction in GAD₆₇ levels. Our results demonstrate that the GAD₆₇ protein is strictly controlled by intraneuronal GABA, and we suggest that this regulatory mechanism has important implications for the physiological regulation of inhibitory neurotransmission in the mammalian CNS. Supported by grant MH35664 (USPHS/DHHS).

REGULATION OF BRAIN L-GLUTAMATE DECARBOXYLASE BY PROTEIN PHOSPHORYLATION AND DEPHOSPHORYLATION. Jun Bao*, Britto Nathan and J.-Y. Wu. Physiology and Cell Biology, University of Kansas, Lawrence, KS 66045.

γ -aminobutyric acid (GABA) is the major inhibitory neurotransmitter in the vertebrate brain. In the brain, the rate limiting step in GABA biosynthesis is the decarboxylation of L-glutamic acid by L-glutamate decarboxylase (E.C.1.1.15, GAD). The level of GABA in the brain is highly regulated, primarily by GAD. Despite its importance, the precise mechanism underlying regulation of GAD activity is still not clear. Here we report that GAD activity was inhibited by the conditions favoring protein phosphorylation and this inhibition could be reversed by phosphatase treatment. Furthermore, this inhibition was resulted from the suppression of a Ca²⁺-dependent phosphatase in the system. Direct evidence of phosphorylation of GAD was demonstrated by incorporation of ³²P into GAD protein. These results indicate that GAD activity is regulated by phosphorylation and dephosphorylation in the brain. Finally, a Ca²⁺-dependent phosphatase, calcineurin, is implicated to be responsible for activation of GAD. [Supported in part by NIH grant NS-20978 and NSF grant BNS-88 20581]

IMMUNOLOGICAL TARGETING OF TOXINS TO CENTRAL NEUROPEPTID-ERGIC NEURONS: EXPRESSION OF VASOPRESSIN, OXYTOXIN AND CORTICOTROPIN RELEASING FACTOR mRNA STUDIED BY IN SITU HYBRIDIZATION IN THE TARGET NEURONS. A. Burette*, A. Rafai, B. Haumont-Pellaqri, F. Tilders, J.P. Nicolas and C. Burette. INSERM U308, 38, rue Lionnois - F 54000-Nancy (France).

We previously demonstrated that cellular toxins (ricin A chain and monensin) injected with a cytotoxic IgG2a monoclonal antibody (MAb) to a neuropeptide, namely vasopressin (AVP) or corticotropin releasing factor (CRF), may specifically penetrate the peptidergic neurons and induce disturbances of cellular functions. We studied here the effects of one microinjection of CRF-MAB, AVP-MAB or non specific IgG with toxins near the paraventricular nuclei (PVN) on the mRNA expression of AVP, oxytocin (OT) and CRF by in situ hybridization, using synthetic oligonucleotide probes labelled with dATP-³⁵S.

The immunological targeting of toxins to AVP neurons increased the mRNA expression of AVP and decreased the mRNA expression of OT in the target site when observed 24h later. One week after the injection, the mRNA expression of AVP in the PVN neurons was markedly decreased whereas the mRNA expression of OT was increased. In the same experiments, the impairment of cellular functions of AVP neurons in PVN differently modified the mRNA expression of AVP and OT outside the injection site, at the SON level for example. The immunological targeting of toxins to CRF neurons decreased the mRNA expression of CRF in the target site but differently altered the mRNA expression of AVP and OT, according to the post-injection time which was observed.

The evolution of the mRNA expression of the neuropeptides may be explained by the impact of the acute neutralization of the neuropeptide which preceded the long-term impairment of the neuron biosynthetic functions.

NEURONAL GLUTAMATE METABOLISM AND ATP DEPLETION IN HIPPOCAMPAL SLICES. J.E. Madl*. Dept. Anatomy & Neurobiology, CSU, Ft. Collins, CO 80523.

ATP depletion may release Glu and other transmitters by reversing uptake systems, resulting in excitotoxicity and neuronal death. However, Glu is also a key metabolite in many metabolic pathways, including several that are important in ATP production. Lack of Glu due to release might inhibit these pathways and decrease further ATP synthesis. Effects of metabolic inhibitors on Glu and ATP in rat hippocampal slices were quantified by HPLC and immunocytochemical localization of Glu was used to examine sites of metabolism and release. ATP depletion induced by inhibition of glycolysis resulted in Glu loss consistent with: 1) Glu release and 2) conversion of Glu to Asp by transamination and part of the Krebs cycle. Immunocytochemical localization of Glu suggested conversion occurred in neuronal cell bodies, dendrites and terminals. During hypoglycemia, conversion of Glu to Asp provided some ATP, but the depletion of ATP remained severe enough to produce a large release of Glu. Inhibition of a different Glu-utilizing pathway, the malate-aspartate shuttle (MAS), produced severe depletion of ATP and Glu. Depletion of Glu by MAS inhibition was consistent with Glu release without the conversion of Glu to Asp that was prominent during hypoglycemia. In contrast to neurons, some glia were able to retain or accumulate Glu during insults, suggesting differences between glial and neuronal metabolism may result in glial uptake of Glu during metabolic insults. Glu metabolism by MAS and the Krebs cycle can contribute to ATP synthesis and reduce Glu release.

567.6

D-AMPHETAMINE-INDUCED DISPLACEMENT OF [¹²³I]IBF EQUILIBRIUM BINDING IN NON HUMAN PRIMATES. M. Laruelle, A. Abi-Dargham, M. Al-Tikriti, S. S. Zoghbi, Y. Zea-Ponce, R. M. Baldwin, D. S. Charney, P. B. Hoffer, R. B. Innis. Yale Univ. and West Haven VA Medical Center, West Haven, CT 06516

We previously showed that an *in vivo* binding equilibrium state can be reached and sustained during constant infusion of a SPECT radiotracer (Laruelle et al., Eur J Pharmacol, 230:119-123, 1993). This paradigm can be used to evaluate the effect of pharmacological challenge tests. Four SPECT experiments were performed on two baboons to evaluate the ability of d-amphetamine to induce displacement of [¹²³I]IBF (iodobenzofuran), a high affinity dopamine D2 antagonist. [¹²³I]IBF was administered as a bolus (3.7 ± 0.3 mCi, ± SEM, n=8) followed by a constant infusion (1.8 ± 0.2 mCi/h) for 480 min. Data were acquired on the CERASPECT camera. Equilibrium was reached at 150 min. D-amphetamine was injected i.v. at 240 min. These injections induced a slow and prolonged decrease of the striatal / occipital ratio which stabilized at a lower level 120 to 180 min after d-amphetamine injection. In both animals, a 0.1 mg d-amphetamine dose induced a modest decrease of the striatal/ occipital ratio (5-7%). At higher doses (0.3 to 1 mg/kg), d-amphetamine decreased this ratio by 12 ± 2% in one baboon and 26 ± 2% in the other baboon (baboon 1 versus baboon 2, n=3, p=0.021). As d-amphetamine has little affinity for D2 receptors, this effect is presumably mediated by the release of endogenous dopamine. These studies suggest that dynamic, non invasive, *in vivo* receptor imaging techniques can be used to obtain information about endogenous transmitter release.

567.8

LONG-LASTING INHIBITION OF BRAIN NITRIC OXIDE SYNTHESIS BY SYSTEMIC ADMINISTRATION OF NITRO-L-ARGININE METHYL ESTER. X. Xu^{1,2}, F. Zhang¹, J. Hu², E. E. El-Fakahany² and C. Iadecola¹. Dept. of Neurology¹ and Psychiatry², Univ. of Minnesota, Minneapolis, MN 55455.

N^ω-substituted L-arginine analogues are widely used *in vivo* as inhibitors of brain nitric oxide synthase (NOS). However, the dose-response relationships and the time-course of the NOS inhibition after systemic administration have not been fully elucidated. We, therefore, studied the dose-response characteristics and the temporal profile of NOS inhibition induced by i.v. administration of nitro-L-arginine methyl ester (L-NAME). Rats were anesthetized with halothane and a cannula was placed in the femoral vein. After recovery from anesthesia, L-NAME was administered i.v. at 5, 10 or 20 mg/kg increments every 30 min until the desired cumulative dose was obtained (5, 10, 20 and 40 mg/kg; n=7 per dose). Rats were sacrificed 30 min after the last dose. NOS catalytic activity was assayed in forebrain homogenates using the method of Bredt and Snyder (PNAS, 86:9030, 1989). L-NAME attenuated brain NOS activity by 26±8% at 5 mg/kg (p<0.05), 40±5% at 10 mg/kg (p<0.05), 53±8% at 20 mg/kg (p<0.05) and 55±4% at 40 mg/kg (p<0.05). After L-NAME (20 mg/kg; single dose i.v.; n=5 per group) NOS activity was attenuated (p<0.05) by 33±6% at 30 min, 52±5% at 2 hrs, 55±2% at 24 hrs, 29±3% at 48 hrs and 24±3% at 96 hrs. We conclude that, intravenous administration of L-NAME leads to a dose-dependent and protracted inhibition of brain NOS catalytic activity. However, NOS inhibition is not complete even at the highest dose tested, a finding that may reflect a limited transfer of L-NAME across the blood-brain barrier. The finding that the inhibition persists for several days after a single administration is consistent with the hypothesis that nitro-L-arginine, the active principle of L-NAME, binds to NOS irreversibly (BBRC, 176:1136, 1991). Thus, L-NAME, administered systemically at concentrations commonly used in physiology experiments, leads to a partial but long-lasting inhibition of brain NOS activity *in vivo*. (Supported by the L. Sklarow fund and the American Heart Association)

PHOSPHOGLUCOMUTASE BECOMES GLYCOSYLATED AND MEMBRANE ASSOCIATED FOLLOWING DEPOLARIZATION IN PC12 CELLS AND CORTICAL SYNAPTOSOMES. N. A. Veyna*, P. Bounelis, and R. B. Marchase. Department of Cell Biology, The University of Alabama at Birmingham, Birmingham, AL 35294.

We have previously reported that the glycogenolytic enzyme phosphoglucosylated (PGM) is post-translationally modified by the addition of a glucose-1-phosphate moiety. In rat cortical synaptosomes and PC12 cells the levels of this cytoplasmic modification were greatly enhanced in response to secretory stimuli. We now present evidence that the stimulus-induced post-translational glycosylation of PGM is accompanied by the association of the protein with a membrane. Cortical synaptosomes that had been either maintained in control conditions (2.4 mM KCl) or exposed to depolarization (50 mM KCl) were fractionated into membranes and cytoplasm. Using Western blot analysis with a PGM-specific monoclonal antibody, increased immunoreactivity was found in the membranes of synaptosomes that had been depolarized for 5 seconds, with a concomitant loss of immunoreactivity in the cytoplasmic fraction. Under nondepolarizing conditions PGM immunoreactivity was present primarily in the cytoplasm. Freeze-thaw permeabilization was used to introduce [35 S]UDP-glucose into synaptosomes prior to depolarization and fractionation. Under depolarizing conditions virtually all incorporated radioactivity was located in the membrane fraction, while under nondepolarizing conditions very little radioactive label was incorporated into either fraction. In addition, nondepolarized PC12 cells that were permeabilized with Triton X-100 for 3 minutes prior to fixation displayed minimal PGM immunofluorescence. Following depolarization, however, PGM immunoreactivity was retained within the cell in a punctate pattern. These data suggest that the population of PGM that becomes glycosylated in response to depolarization also becomes associated with a membranous structure in both synaptosomes and PC12 cells.

HUMAN KYNURENE AMINOTRANSFERASE II: PURIFICATION FROM LIVER AND COMPARISON WITH THE BRAIN ENZYME. E. Okuno*, M. Nakamura, H. Baran, R. Schwarcz, and R. Kido. Wakayama Med. Coll., Wakayama 640, Japan and *Maryland Psychiatric Research Center, Baltimore, MD 21228.

Two kynurenine aminotransferases (KAT I and KAT II) are capable of producing the neuroinhibitory and neuroprotective compound kynurenic acid in the human brain. We have now purified KAT II to homogeneity from human liver using, in succession, heat treatment, (NH₄)₂SO₄ fractionation, DEAE-Sepharose, Butyl-cellulofine, Sephadex G-150, Hydroxyapatite and Mono-Q column chromatography. The purified enzyme showed a single protein band (MW 47kDa by SDS-PAGE). Purified liver KAT II was then compared to partially purified brain KAT II (cf. Brain Res. 542:307, 1991). Both enzymes showed virtually identical substrate specificity and inhibition by amino acids. Moreover, there was agreement between liver and brain KAT II with regard to activation by acetate, pH optimum, K_m values for amino acids and keto acids, and molecular weight (assessed by sucrose gradient centrifugation). Anti-KAT II antibodies were produced and partially purified. Subsequent immunoblotting analyses confirmed that KAT II from human liver and brain are immunologically identical. In immunotitration experiments, the anti-KAT II antibody did not recognize human brain KAT I. Pure KAT II and its antibody can be expected to serve as valuable tools in further studies of kynurenic acid production in the human brain. Supported by USPHS grants NS 28236 and MH 44211.

EXISTENCE OF NEUROSTEROIDS IN HYPOTHALAMUS. H. Yamada¹, K. Kurokawa¹, J. Ochi¹ & K. Kataoka^{2*}. ¹Dept. of Anatomy, Shiga Univ. of Med. Sci., Otsu 520-21, & ²Dept. of Physiol., Ehime Univ. Sch. of Med., Ehime 791-02, JAPAN

The synthesis of bioactive steroids in neural cells has not been researched in detail yet. We report here our serial histochemical studies on (1) endogenous digitalis-like substance (EDLS) which is newly identified as *cis-trans-cis* type steroid natively found in plants, and (2) cytochrome P450 enzymes for steroid synthesis.

Male Wistar rats (180-250g b.wt.) were transcardially perfused with buffered fixative containing formaldehyde, after they were anesthetized with intraperitoneal injection of sodium pentobarbital (20mg/kg b.wt.). Then hypothalamic sections were processed for histochemical staining.

(1) EDLS causes vasoconstriction and natriuresis as a result of inhibition of Na⁺,K⁺-ATPase. The distribution of EDLS was analyzed by an immunohistochemical technique using digoxin-antibody. EDLS was found in the hypothalamic magnocellular neurons in the supraoptic and paraventricular nuclei and nerve terminals in the median eminence.

(2) P450_{sc} (cholesterol side chain cleavage) and P450_{11β} (11β-hydroxylase) were immunostained. The antibodies were provided from Dr. S. Koinami & Dr. S. Takeori (Hiroshima Univ.). P450_{sc}-immunoreactivities were seen in the somata of periventricular area; and P450_{11β} were observed in the supraoptic and paraventricular neurons. The positive reactivities of both P450 enzymes were also found in the nerve terminals in the median eminence.

CONCENTRATION AND STORAGE OF BIOTIN IN THE OLFACTORY CORTEX. F. Scalia*, S. Eisner and J.Y. Lettvin. Dept. of Anat. & Cell Biol., SUNY-Health Sci. Cntr., Brooklyn, NY 11203 and Dept. of Bioengineering, Rutgers Univ., Piscataway, NJ 08855.

Further characterization of the subfield of olfactory cortex in which regenerating optic nerve axons can synapse involves study of its cellular organization, neural connections, and chemoarchitecture. Biotin (BT) (vit. H) is an essential dietary cofactor in carboxylation reactions. Although brain tissues are enriched in BT, little further is known about its specific localization and role in CNS function. BT was detected in brain sections of adult Rana pipiens, where it formed compact, spherical, intracellular aggregates of 0.5-2.0 μm diam., by means of incubation in avidin-HRP and subsequent reaction with Ni-Co-DAB, after glutaraldehyde fixation. In transverse sections, the aggregates formed a prominent, narrow layer positioned at the innermost level of layer I of the lateral prominence of the olfactory cortex. The plate extended as a ribbon along this boundary zone, separating the pars dorsalis and ventralis of the olfactory cortex for their full A-P extent. The prominence of this field was increased by intragastric or parenteral delivery of BT or biocytin (up to 100 μg/gm). The BT concentrating structures delimit the dorsal border of the optic recipient subfield of the olfactory cortex. (Supported by NIH grant EY05284.)

BIOSYNTHESIS OF CONJUGATES OF PHENYLACETIC ACIDS IN THE RAT STRIATUM. L. E. Dyck*, D. A. Durden and A. A. Boulton. Neuropsychiatric Research Unit, Dept. of Psychiatry, Univ. of Saskatchewan, Saskatoon, Canada S7N 0W0

The trace acids, phenylacetic acid (PAA), m-hydroxy-PAA (mHPAA) and p-hydroxy-PAA (pHPAA) are present and heterogeneously distributed in rodent brain. PAA added to cultures or injected into rats is neurotoxic. Endogenous PAA levels are normally low; two factors that might maintain low levels of PAA in vivo were investigated: first, formation of conjugates of PAA and second, transport of PAA out of the brain by a probenecid-sensitive system. The presence of conjugates of these acids was investigated by subjecting homogenates of rat striatum to hydrolysis. The transport inhibitor, probenecid, increased the concentrations of free mHPAA, free pHPAA and the total concentrations of all three acids indicating that all three trace acids can be removed from the rat brain by a transport system. PAA concentrations were increased ten-fold by hydrolysis (to 160 ± 27 ng/g). pHPAA increased only two-fold (to 54 ± 4 ng/g), and mHPAA was unaffected. These findings coupled with the failure of pargyline to decrease free or total PAA levels suggest that conjugation of PAA is an important factor regulating free PAA levels. The identity of the acid conjugates in the brain is unknown. Incubation of rat tissue homogenates with ³H-glycine or ¹⁴C-PAA showed that the kidney but not the brain could synthesize radiolabelled phenylacetyl-glycine. Supported by Saskatchewan Health.

NEUROSTEROIDS IN RAT RETINAE. P. Guarneri (a)*, R. Guarneri (a), C. Cascio (b), F. Pava (c), F. Piccoli (b) and V. Papadopoulos (c). (a) Inst. Experimental Medicine, CNR, Palermo; (b) Inst. Neuropsychiatry, 90129 Palermo, Italy; (c) Dept. Anatomy & Cell Biology Georgetown Univ., Washington D.C., 20007.

Brain glial cells are capable to synthesize steroids, named neurosteroids (Hu et al., PNAS 84:8215, 1987; Guarneri et al., PNAS 89:5118, 1992).

We used isolated rat retinae as a neural model to investigate neurosteroid synthesis and regulation independently from blood-borne steroids interference. Pregnenolone, progesterone and their metabolites (17α-OH progesterone, 17α-OH-pregnenolone, DGC, THDOC and 3α-OH-DHP) were identified. Using mevalonolactone (MVA) as steral precursor, we observed a time-dependent pregnenolone synthesis in intact retinae incubated in Krebs-Hepes solution at 37°C in the presence of 20 μM lovastatin to reduce endogenous MVA synthesis, and inhibitors of pregnenolone metabolism (20 μM trilostane and 10 μM SU 10603). The addition of 0.76 mM aminoglutethimide, an inhibitor of P450_{sc} enzyme involved in the cholesterol conversion into pregnenolone, blocked its formation; the addition of cAMP stimulants increase pregnenolone synthesis. Immunocytochemistry revealed a primary localization of P450_{sc} enzyme at retinal ganglion cells and bipolar cells. The results demonstrate that retinae is a favourable model for studying neurosteroidogenesis and its regulation independently from blood-borne steroids interference, and reveal for the first time the steroidogenic ability of neuronal cells.

568.1

COMPARISON OF SIGNAL TRANSDUCTION OF HUMAN DOPAMINE-D2- AND NEUROPEPTIDE Y-Y1-RECEPTORS EXPRESSED IN CHO CELLS. G. Weng¹, R.G. MacKenzie¹, D.H. VanLeeuwen¹, D. Larhammar², H. Ericson and C. Wahlestedt. Div. Neurobiology, Dept. Neurology and Neuroscience, Cornell Univ. Med. Coll., New York, NY 10021, ¹Dept. Pharmacology, Parke-Davis, Ann Arbor, MI 48106 and ²Dept. Med. Genetics, Univ. Uppsala, Sweden.

In many cells, dopamine-D2-receptors and neuropeptide Y-Y1-receptors show distinct similarities with respect to signal transduction and second messenger formation. We therefore sought to determine whether stably transfected chinese hamster ovary (CHO) cells would respond to dopamine and neuropeptide Y in an identical fashion. For this purpose, CHO cells were transfected with human D2- (Grandy *et al.*, *PNAS* 86:9762, 1989) or human Y1-receptor (Larhammar *et al.*, *J. Biol. Chem.* 267:10935, 1992) cDNA. Successful transfection was assessed by *de novo* expression of specific binding sites labeled by [¹²⁵I]-iodosulpiride and [¹²⁵I]-peptide YY.

Cells with similar B_{max} values for the respective radioligand were then used for second messenger studies: (1) Inhibition of cAMP accumulation, (2) potentiation of ATP-induced [³H]-arachidonic acid release, and (3) mobilization of Ca²⁺ measured by fura-2 fluorometry. While dopamine was capable of affecting all three second messenger phenomena in D2-receptor transfected cells, stimulation of Y1-receptor transfected cells by neuropeptide Y only resulted in [Ca²⁺] elevation. Since specific binding of the respective radioligands, as well as agonist-stimulated Ca²⁺ responses, were of a similar magnitude in the two types of transfected clonal CHO cells, it is possible that the two G-protein-coupled receptors under study might differ with respect to affinity to specific G-proteins rather than the stoichiometry of receptor:G-protein.

568.3

CHARACTERIZATION OF PHOSPHOLIPASE A₂ (PLA₂) IN RAT BRAIN. EVIDENCE FOR MULTIPLE MOLECULAR FORMS. R. Diaz-Arastia^{*}, M.A. Clark[#], and J.H. Schwartz. Center for Neurobiol. & Behav., Columbia Univ., New York, NY 10032, and [#]Schering-Plough Research Institute, Kenilworth, NJ 07003.

Release of arachidonic acid (AA) from membrane phospholipids in neurons is important in gating ion channels and also participates in long-term synaptic plasticity. The major enzymatic activity responsible for AA release is PLA₂. Studies in non-neural tissues demonstrate two classes of PLA₂s: high molecular-weight (MW) cytosolic enzymes and low MW secreted enzymes. Both classes are regulated in specific ways by a variety of physiologic conditions. To learn how neuronal PLA₂(s) are regulated, we undertook a biochemical analysis of the lipase(s) from rat brain. Brain tissue contains two major classes of PLA₂: (1) a high MW (M_r 100,000) enzyme which is both cytosolic and particulate, and (2) a low MW (M_r 14,000) enzyme which is soluble. The high MW enzyme is inactivated by deoxycholate, but is active in non-ionic detergents (200 μM Triton X-100). The enzyme is stable in thiol reducing reagents, is activated by Ca²⁺ ion in the micromolar range, and is optimally active at pH 8. The high MW enzyme preferentially hydrolyzes phosphatidylcholine (PC) over phosphatidylethanolamine (PE). Using conditions specific for the high MW enzyme, we have enriched activity 200-fold by hydrophobic column chromatography, ion-exchange chromatography, and gel filtration. In these respects the high MW enzyme resembles the cytosolic PLA₂ that has been cloned from monocytic cells. The low MW enzyme is active in the presence of ionic detergents (1 mM deoxycholate) and inactivated by thiol reducing reagents. It requires Ca²⁺ ion in the millimolar range and has a pH optimum of 9.5, and prefers PE > PC as substrate. It is thus similar to extracellular PLA₂s described in a variety of tissues. Since in non-neural tissues cytosolic PLA₂ are activated by phosphorylation while secreted PLA₂s are transcriptionally regulated, elucidation of how these enzymes are regulated in brain should yield important clues to mechanisms of signal transduction and synaptic plasticity.

DIFFERENTIAL EFFECTS OF CORTICOTROPIN RELEASING FACTOR (CRF) ON cAMP SYNTHESIS IN THE BASOLATERAL AND CENTRAL NUCLEI OF THE RAT AMYGDALA. T.D. Ely, P. J. Elliott^{*} and C. D. Kilts. Emory Univ. Sch. of Med., Atlanta, GA 30322 and Glaxo, Inc., Ware, UK

Accumulating evidence indicates that the central (ACe) and basolateral (BLA) nuclei of the rat amygdala represent functionally distinct fields of corticotropin releasing factor (CRF)-mediated neurotransmission. We compared the influence of CRF on adenylate cyclase (AC) activity in the ACe, BLA and frontal cortex (FC). CRF (10nM-10μM) produced a concentration- and GTP- dependent increase in cAMP synthesis in homogenates of the FC. In contrast, a bimodal effect of CRF on cAMP synthesis in the ACe and BLA was observed with the maximal effect in the ACe and BLA being 1/3-1/2 that of the FC. In the ACe, CRF (1μM) produced a significant stimulation while higher and lower concentrations were without effect. In the BLA, CRF stimulated AC activity at low nM concentrations with the effect plateauing at 1μM. These data indicate a heterogeneity of amygdaloid CRF receptors at the level of signal transduction mechanisms which may underlie the distinct effect of CRF on ACe and BLA neurons.(MH39967)

THE HUMAN NK1 RECEPTOR MEDIATES ARACHIDONIC ACID RELEASE IN TRANSFECTED CHO CELLS.

E. R. Jackson, K. Pratt, S. McLean & S.H. Zorn^{*}. Central Research Division, Pfizer Inc., Department of Neuroscience, Groton, CT 06340.

The human neurokinin-1 (NK1) receptor exhibits high affinity for the undecapeptide Substance P (SP), the non-peptide NK1 antagonist CP-96,345 and lower affinity for the NK2 receptor agonist, neurokinin-A (NKA) and the NK3 receptor agonists eldoisin and senkide. In CHO cells stably expressing the rat NK1 receptor subtype, SP stimulates both phosphatidylinositol turnover (PI) and activation of adenylate cyclase activity (AC) (Takeda *et al.*, *J. Neurochem.* 59, 1992). The present study was undertaken to study whether the human NK1 receptor also couples to multiple signal transduction pathways in CHO cells and also to arachidonic acid (AA) release. Substance P produced a dose-dependent release of arachidonic acid from cells prelabeled with [³H]-AA with an EC50 of 0.9 nM and a maximal response that was 8- fold higher than basal levels. The magnitude of this response was similar to that observed with 10 μM A23187 and 2 μM thapsigargin. Agonist concentration-response curves demonstrated a rank order of potency of SP> eldoisin>NKA>> senkide. The response to 3.3 nM SP was completely blocked by the (+) - but not the (-) -enantiomer of CP-96,345 (pK_i = 8.84 ± 0.06). Pertussis toxin had no effect on SP-induced AA release, PI turnover or AC activity. The AA response appeared to require the influx of calcium since it was sensitive to changes in the concentration of the divalent ion in the media. Although forskolin stimulated cAMP accumulation in these cells, it did not stimulate PI turnover or AA release. The results indicate that SP stimulation of the human NK1 receptor expressed in CHO cells leads to the activation of three second messenger systems (AC, PI, and AA release). The three responses are not mediated by pertussis toxin sensitive G-proteins. While the AA response is not due to stimulation of adenylate cyclase, cross-talk between the PI and PLA₂ systems could not be excluded.

CEINGE CLONE 3, A NEW IMMORTALIZED BRAIN CELL LINE, POSSESS BRADYKININ, ENDOTHELIN-1 AND PDGF RECEPTORS COUPLED TO INTRACELLULAR Ca²⁺ ELEVATION: A. Fatatis^{*}, S. T. Russo, A. Bassi, E. Iannotti, R. Caporaso, G.F. Di Renzo and L. Annunziato. Dept. of Pharmacology and [#]Dept. of Biochemistry, II School of Medicine, "Federico" II University of Naples, Naples ITALY.

CEINGE clone 3 (Cl 3) is a cell line obtained by immortalization of cells derived from 14 days old fetal rat brains. Cell infection was performed using a murine leukemia virus (PyMuLV) carrying the gene encoding the polyoma middle T antigen. CEINGE Cl 3 cells are able to grow in agar and to induce the formation of tumors when inoculated into nude mice. CEINGE Cl 3 displays immunocytochemical staining with antibodies directed against vimentin and S-100 whereas no staining was observed with antibodies against neurofilaments and glial fibrillary acid protein. About 20% of the cells were positive to anti-galactocerebroside C. Two different degrees of morphological differentiation were obtained using 10μM retinoic acid (RA) alone or followed by a treatment with 10-100μM forskolin (FK). In the first case, after a period of 3-5 days, cells became spindle-shaped forming parallel rows. Treatment of RA-differentiated cells with FK induced a dramatic morphological change, showing a stellate cellular shape and long processes forming an evident network. Using single-cell fura-2 microfluorimetry, bradykinin (BK) and endothelin-1 (ET-1) were found to be able to elicit an [Ca²⁺]_i increase in presence and in absence of extracellular Ca²⁺. Furthermore, CEINGE Cl 3 showed an [Ca²⁺]_i elevation when exposed to 10-30 ng/ml of Platelet Derived Growth Factor (PDGF). These results demonstrated that this immortalized brain-derived cell line displays both G protein-linked and tyrosine kinase-linked receptors on its plasmamembrane. (Supported by 40% and 60% MURST funds, CNR grants Progetto Finalizzato Biotecnologie to L.A. and G.F.D.R and A.I.R.C. grant to T.R.)

PHARMACOLOGICAL EVALUATION OF A STABLE HEXAPEPTIDE ANALOG OF NEURTENSIN.

H. C. Akumne^{*}, S. B. DeMattos¹, S. Z. Whetzel¹, D. L. Wustrow², M. D. Davis¹, J. X. He², W. L. Cody², L. D. Wise², T. A. Pugsley¹ and T. G. Heffner¹. Departments of Neuroscience Pharmacology¹/Chemistry², Parke-Davis Pharmaceutical Research Division of Warner-Lambert Company, Ann Arbor, MI 48105

Neurotensin (NT) is a tridecapeptide (pGlu-Leu-Tyr-Glu-Asn-Lys-Pro-Arg-Arg-Pro-Tyr-Ile-Leu) that displays a wide spectrum of biological actions both in the central and peripheral nervous system. Potential therapeutic applications of NT agonists include use in the treatment of psychosis, obesity and hypertension. Identification of small molecule ligands with high affinity to the physiologically relevant NT receptor site is desirable. The major signal transduction system for NT receptors in a number of different systems is the G-protein-dependent stimulation of phospholipase C leading to the mobilization of intracellular Ca²⁺ and stimulation of cGMP. We therefore studied both the binding and the functional actions of neurotensin analogs by quantitative measurement of cytosolic free Ca²⁺ concentration in HT-29 human colonic adenocarcinoma cells using the Ca²⁺-sensitive dye, Fura-2/AM and by effects on cGMP levels in rat cerebellar slices. The metabolically stable NT8-13 analog, NTE (NMeArg-Lys-Pro-Trp-tLeu-Leu) from Eisai, NTE, plus other NT analogs and related peptides (neurotensin, NT8-13, xenopsin, neuromedin N, NT9-13, kinetensin and D-Trp¹¹-NT) bound to HT-29 cell membranes; and increased the mobilization of intracellular Ca²⁺ in these cells indicating NT receptor agonist properties. In addition, NTE increased cGMP levels in rat cerebellar slices, confirming the latter findings. The binding affinities to the HT-29 cell membrane preparation showed a good correlation to the EC50 values for the mobilization of [Ca²⁺]_i (r=0.85). These results substantiate the *in vitro* NT agonist properties of the hexapeptide NT analog, NTE.

MELATONIN BINDING SITES IN RAT CIRCLE OF WILLIS ARTERIES ARE LINKED TO A G-PROTEIN. S. Capsoni, M. Viswanathan, A.M. De Oliveira and J.M. Saavedra*. Section on Pharmacology, Laboratory of Clinical Science, National Institute of Mental Health, Bethesda, MD 20892.

Melatonin is considered the most important hormone secreted by vertebrate pineal gland and is thought to be a biochemical transducer of photoperiodic variations in the environment. Autoradiography with 2-[¹²⁵I]iodomelatonin has revealed high affinity, specific melatonin receptors in rat arteries involved in thermoregulation, such as basal brain arteries forming the circle of Willis. Our autoradiographic studies show that co-incubation with increasing concentrations of a non hydrolyzable GTP analogue (GTP- γ -S) (10^{-7} - 10^{-6} M) provokes a dose-dependent and a specific inhibition of 2-[¹²⁵I]iodomelatonin binding in rat arteries from the circle of Willis. This result suggests that, similarly to what has been described in mammalian pars tuberalis and brain cortex, putative melatonin receptors in rat cerebral arteries are coupled to second messengers by G-protein.

568.9

FATTY ACID COMPOSITION AND ACTIVATION OF INOSITOL PHOSPHATE AND ARACHIDONIC ACID METABOLISM BY PAF IN ASTROGLIAL AND IN NEUROBLASTOMA SK-N-BE CELLS. A. Petroni, M. Blasevich, N. Papini, M.G. Marchini, S. Bergamaschi, S. Govoni and C. Galli. Institute of Pharmacological Sciences, University of Milan, via Balzaretti 9, 20133, Milan, Italy.

The activation of phospholipases leads to the formation of products such as Platelet-Activating Factor (PAF) and arachidonic acid (AA) metabolites, which are important mediators of physiopathological events in the CNS. The aim of our study was first to characterize the lipid composition of astroglial and neuroblastoma SK-N-BE cells. Secondly, to study the pathways generating after phospholipase activation by PAF. Astroglial cells were obtained from 1 day old rat brain cortex, SK-N-BE cells were differentiated with 10 μ M retinoic acid and compared with the undifferentiated ones. The inositol phosphate pathway was evaluated by incubating the cells with 3[H]-myo-inositol for 18 hours. After PAF stimulation, the supernatants were extracted and analyzed by HPLC connected with a detector for the evaluation of labeled inositol phosphates. In astroglial cells maximal production of inositol phosphates and formation of AA-cyclooxygenase metabolites was obtained at PAF concentration 10-8 M for 1 min stimulation, whereas in SK-N-BE inositol phosphate production and AA metabolism were less active. Protein kinase C (PKC) has been also investigated. Preliminary data have shown that in differentiated SK-N-BE soluble and particulate fractions, PKC enzyme activity was lower with respect to undifferentiated cells. Astroglial cells differently incorporated labeled fatty acids (FA) in PL classes. AA was mainly incorporated in diacyl-phosphatidylcholine (PC) and in phosphatidyl inositol (PI). In undifferentiated SK-N-BE, AA was 7.5 %, and after differentiation it reached 14 %, suggesting either greater incorporation of the FA in membranes highly enriched with AA, formed after differentiation, or greater formation of AA from precursors.

PHARMACOLOGIC CHARACTERIZATION OF MELATONIN RECEPTOR-MEDIATED PHOSPHOINOSITIDE HYDROLYSIS IN PIGEON BRAIN. U.L. Mullins and A.S. Eison*. CNS Special Projects, Bristol-Myers Squibb Co., Wallingford, CT 06492.

High densities of [¹²⁵I]-iodomelatonin binding sites are found in pigeon brain (Pang et al., 1990). Melatonin receptors are functionally linked to second messenger systems in other avian species (Dubocovich et al., 1991). The present study investigated the effects of several melatonin agonists on phosphoinositide (PI) hydrolysis levels in slices of ectostriatum, optic tectum, cerebellum, hypothalamus and pons medulla of the pigeon brain. White carneaux pigeons (*Columba livia*) were sacrificed 4 hours after lights on (12:12 L:D cycle). Inositol monophosphate (IP₁) accumulations (in the presence of 10 mM lithium) were collected by ion exchange chromatography. Relative potencies of melatonin receptor-mediated IP₁ accumulation induced by agonists in ectostriatum were as follows: 2-iodomelatonin > 6-chloro-melatonin > N-acetylserotonin > melatonin > serotonin. While 10 nM melatonin induced a 1.5 fold increase in PI hydrolysis over basal levels, similar concentrations of 2-iodo-, 6-chloromelatonin, and N-acetylserotonin increased PI hydrolysis 2.4 fold, 2.1 fold and 1.9 fold, respectively. Melatonin-induced PI hydrolysis was blocked by N-acetyltryptamine, a melatonin antagonist, but not by ketanserin, a 5-HT₂/5HT_{1C} antagonist demonstrating that the effects seen were not a result of 5-HT₂ or 5-HT_{1C} receptor stimulation. These data support the existence of a melatonin receptor in pigeon brain which is functionally linked to PI hydrolysis as a second messenger system.

568.8

G-PROTEIN-MEDIATED ACTIVITIES OF CANNABINOID RECEPTORS IN CEREBELLAR GRANULE CELLS. S.R. Childers*, M.B. Roy and S. Stark. Dept. Physiol./Pharmacol. & Neurosci. Program, Bowman Gray Sch. Med., Wake Forest Univ., Winston-Salem, NC 27157.

Cannabinoid (Can) receptors are present in high density in cerebellum, and Can-inhibited adenylyl cyclase (AC) has been characterized in cultured cerebellar granule (CG) cells (M. Pacheco et al. [1993], *Brain Res.* 603, 102). The present studies examined whether this system regulates glutamate release from these cells. Can agonists inhibited forskolin-stimulated cAMP levels in cultured CG cells by 50-60%. The potencies of Can agonists in inhibiting cAMP levels paralleled those in inhibiting AC, and in stimulating low K_m GTPase, in isolated cerebellar membranes. The GABA_B agonist baclofen inhibited cAMP levels to a similar extent, and Can and GABA_B effects on cAMP levels were non-additive, suggesting that these two G_{i/o}-linked receptors shared common effectors. Glutamate release was studied by preincubating cultured CG cells with [³H]-aspartate (D-asp), and stimulating release with 50 mM KCl, which released 8-9% of total radioactivity over 10 min. When cells were treated with the potent Can agonist WIN 55212-2 (1 μ M) for 10 min before adding KCl, potassium-stimulated release of [³H]-D-asp was inhibited by approx. 40%. The specificity of this response was confirmed by the finding that the inactive stereoisomer, WIN 55212-3, had no significant effect on [³H]-D-asp release. These data suggest that cannabinoid receptors exist on terminals of cerebellar granule cells and negatively modulate glutamate release from these cells.

BRADYKININ STIMULATES PHOSPHOLIPASE D IN PC12 CELLS BY A MECHANISM WHICH IS INDEPENDENT OF INCREASES IN INTRACELLULAR Ca²⁺. J. Horwitz*, B. A. Passarello and M. Corso. Dept. of Pharmacology, Medical College of Pennsylvania, Philadelphia, PA 19129

Previously published work from this laboratory, done in PC12 pheochromocytoma cells, has suggested a possible role for Ca²⁺ in the regulation of phospholipase D. Therefore, the present experiments were designed to correlate phospholipase D activity with the actual level of intracellular Ca²⁺. Phospholipase D activity was determined by measuring the production of [³H]phosphatidylethanol in cells whose phospholipids had been pre-labeled with [³H]palmitic acid. Intracellular Ca²⁺ was measured with the fluorescent Ca²⁺ chelator, Fura-2. Ionomycin at a concentration of 10 μ M caused a large unphysiological increase in intracellular Ca²⁺ and an increase in phospholipase D activity which was equal to or larger than that caused by bradykinin (10 μ M). However, when the concentration of ionomycin (50 nM) was adjusted so that the increase in intracellular Ca²⁺ was comparable to that caused by bradykinin, there was no effect on phospholipase D activity. Agents such as carbachol, ATP, and thapsigargin also increased intracellular Ca²⁺ but had no effect on phospholipase D activity. In other experiments, the intracellular Ca²⁺ concentration was manipulated by preincubating the cells under two different conditions: 1) Ca²⁺-free media plus EGTA (100 μ M); 2) Ca²⁺-containing media plus the intracellular Ca²⁺ chelator BAPTA/AM (80 μ M). These preincubations blocked the bradykinin induced increase in intracellular Ca²⁺. In contrast, these preincubations did not block bradykinin-stimulated phospholipase D activation. The response was attenuated by only 35%. These data suggest that physiological increases in intracellular Ca²⁺ do not mediate the effect of bradykinin on phospholipase D.

CHOLECYSTOKININ OCTAPEPTIDE ELEVATES INTRACELLULAR CALCIUM IN CULTURED SYMPATHETIC NEURONS

H. Xian, R.M. Lynch and D.L. Kreulen*. Departments of Pharmacology and Physiology, Coll. of Med., Univ. of Arizona, Tucson, AZ 85724.

Previous studies have demonstrated that cholecystokinin octapeptide (CCK-8) mediates excitatory synaptic transmission in mammalian prevertebral sympathetic ganglia by regulating membrane ionic currents. CCK may activate phospholipase C cascade through CCK_A receptors in sympathetic neurons. Also CCK-8 could mobilize intracellular calcium, thereby generating an intracellular signal to modulate cellular activities including membrane responses. We examined this hypothesis utilizing calcium fluorescence microscopic imaging (Calcium imaging) and whole-cell voltage clamp techniques. Sympathetic neurons from guinea pig celiac ganglia were enzymatically dissociated and remained in culture for 3 - 15 days. Celiac neurons were loaded at 37°C with the Fluo-3 AM (3 μ M; 50 minutes). In fifty-three percent of celiac neurons (n = 38), bath application of CCK-8 (0.3 to 1 μ M) induced a significant increase in intracellular calcium. The response to CCK was either transient or sustained more than 10 minutes. On average calcium increased by thirty percent at the peak of the responses. This was approximately twenty-seven percent of the maximal response elicited by subsequent depolarization with 80 mM KCl. In whole-cell voltage clamp recording, all celiac neurons displayed L-type calcium current. Pulse application (1 sec) of CCK-8 (1 μ M) did not increase the amplitude of the calcium currents in 7 cells tested. These results suggest that CCK-activated increase in intracellular calcium may be due to release from internal stores rather than influx through membrane calcium channels. (HL-27781 and DK-36289).

INVESTIGATION OF POTENTIAL INTERACTIONS BETWEEN SECOND MESSENGERS THAT MEDIATE SUBSTANCE P AND NOREPINEPHRINE STIMULATION OF GLYCOGENOLYSIS IN A HUMAN ASTROCYTOMA CELL LINE (UC11-MG). R.V.W. Dimlich, S. Medrano, and E. Gruenstein. Depts. of Emer. Med. and Mol. Gen., Biochem., and Microbiol., University of Cincinnati College of Medicine, Cincinnati, OH 45267-0769.

This study demonstrated for the first time in astrocytes that substance P (SP) induces glycogenolysis that is mediated through an increase in $[Ca^{2+}]_i$. The glycogenolytic response was measured as a release of 3H -glucose from glycogen. Changes in $[Ca^{2+}]_i$ were determined using video image analysis with fura-2. The effect of SP on $[^3H]$ -glycogen and $[Ca^{2+}]_i$ levels was dose-dependent with a maximum effect observed at 10^{-8} M. The SP receptor antagonist CP-96,345 inhibited both $[Ca^{2+}]_i$ increase and glycogenolysis suggesting that the SP effect is mediated by an NK₁ receptor. Our previous data indicated that norepinephrine (NE) stimulates glycogenolysis through cAMP in this cell line. Having two neurotransmitters that stimulate the same physiological response, each through a different second messenger, provided a model for testing if cross-talk occurs between $[Ca^{2+}]_i$ and cAMP as second messenger systems regulating glycogenolysis in these cells. Subsequent experiments determined that, contrary to what has been determined for other physiological responses, the glycogenolytic effects of SP and NE in UC11-MG cells were additive and not synergistic at suboptimal doses. In addition, there was no evidence of interaction between cAMP and either $[Ca^{2+}]_i$ or cAMP in regulating glycogenolysis in these cells. The data of this study support the use of this human cerebral cortical astrocytoma cell line as a model for exploring potential interactions among neurotransmitters and corresponding intracellular second messenger systems and for studying the role of astrocytic glycogen in the CNS. [Supported by NS-25635 (RWDD), NS27814 (EG), and Ohio AHA (SW-90-09) (RWDD)].

A RAPID ATTENUATION OF MUSCARINIC AGONIST-STIMULATED PHOSPHOINOSITIDE HYDROLYSIS PRECEDES RECEPTOR SEQUESTERATION IN HUMAN SH-SY-5Y NEUROBLASTOMA CELLS.

E.L. McEwen, D.M. Slowiejko and S.K. Fisher. Neuroscience Lab. & Dept. of Pharmacology, Univ. of Michigan, Ann Arbor, MI 48104-1687

The relationship between the kinetics of muscarinic receptor (mAChR)-stimulated phosphoinositide (PPI) hydrolysis and receptor internalization has been determined for human SH-SY-5Y neuroblastoma cells. The addition of 1 mM oxotremorine-M (Oxo-M) to cells prelabeled to isotopic equilibrium with 3H -inositol resulted in two kinetically distinct phases of PPI hydrolysis, as monitored by the release of a total inositol phosphate fraction (IP), in the presence of Li^+ . From the rate of $[^3H]IP_1$ formation, a PPI breakdown rate of 9.5%/min was obtained after 5s of Oxo-M addition. This initial phase of PPI hydrolysis was short-lived ($t_{1/2}=14s$) and after 60s the rate of inositol lipid breakdown had declined to a steady state level of 3.4%/min, which was maintained for at least 10 min. In the parent cell line, SK-N-SH, the rate of PPI hydrolysis observed after 5s of Oxo-M addition was also 2-3 fold greater than that obtained after 60s ($p<0.05$). Oxo-M addition to SH-SY-5Y cells also resulted in a 4-5 fold increase in the mass of $(1,4,5)P_3$ within 5-10s. After 60s, the net formation of $(1,4,5)P_3$ had declined to ~35% of that attained during the first few seconds of agonist addition and thereafter stayed constant for up to 5 min. Agonist occupancy of mAChRs on SH-SY-5Y cells also resulted in a rapid breakdown of phosphatidylinositol 4,5-bisphosphate (PIP_2 ; $t_{1/2}=12s$). Within 60s of agonist addition, however, a new steady state of $[^3H]PIP_2$ label was achieved and maintained for the next 10 min. In contrast to the rapid changes in receptor-stimulated PPI hydrolysis, no significant loss of cell surface mAChRs occurred before 5 min of agonist exposure. Thus a rapid, but partial, attenuation of PPI hydrolysis in response to mAChR activation occurs prior to mAChR internalization and may represent an important early adaptive response to chronic agonist stimulation. (NIMH 42652 and NIH 23831.)

CCK_B RECEPTORS MEDIATE PHOSPHATIDYLINOSITOL TURNOVER IN LATE PASSAGE RAT AR 4-2J CELLS. I.M. Morrone, K.G. Pratt, S. McLean* and S.H. Zorn. Pfizer Inc., Central Research Div., Department of Neuroscience, Groton, CT.

In AR 4-2J rat pancreatoma cells that express both CCK_A and CCK_B receptors, CCK-8 stimulates phosphatidylinositol (PI) turnover via CCK_A receptors (Pratt et al., Neurosci. Abstr. 18(1):452, 1992). However, recent studies suggest that with prolonged passaging of these cells the expression of CCK receptors and/or their coupling to PI turnover change with time. The present study was undertaken to characterize which CCK receptor is functionally coupled to PI turnover in late passage AR 4-2J cells. AR 4-2J cells prelabeled with $[^3H]$ -myo-inositol were exposed to the CCK receptor agonist pentagastrin (PG) in the presence and absence of selective CCK_A and CCK_B receptor antagonists. PG produced a dose-dependent stimulation of IP accumulation ($EC_{50} = 0.38$ nM), that was completely blocked by the selective CCK_B receptor antagonists CI-988, L-365,260 and LY-262,691 with K_i values of 2.4, 7.6, and 169 nM, respectively. The rank order of potency for blockade of PG-induced PI turnover was similar to that observed for inhibition of CCK_B receptor binding (IC_{50} values = 0.78, 8.1, and 90 nM, respectively). The CCK_A receptor antagonist L-364,718 inhibited the PG induced response with a $K_i > 100$ nM, consistent with its low affinity for the CCK_B receptor ($IC_{50} = 120$ nM). Thus, in contrast to that observed in early passage cells, CCK_B receptors mediate agonist induced PI turnover in late passage AR 4-2J cells.

568.14

DOWN-REGULATION OF MUSCARINIC RECEPTORS AND CARBACHOL-STIMULATED PHOSPHOINOSITIDE HYDROLYSIS IN SENESCENT RATS FOLLOWING ACUTE ADMINISTRATION OF CHLORPYRIFOS. W.R. Mundy¹, T.R. Ward¹, S. Padilla¹ and T.M. Freudenrich². ¹Neurotoxicology Division, U.S. EPA, RTP, NC 27711. ²ManTech Environmental Tech., Inc., RTP, NC 27709.

Acute treatment with the organophosphate chlorpyrifos (CPF) results in prolonged inhibition of blood and brain cholinesterase activity (ChE). This work examined age-related differences in the response to ChE inhibition in F-344 rats. Male rats aged 5 months (young) or 26 months (aged) were injected s.c. with 250 mg/kg CPF or peanut oil vehicle (controls) and sacrificed 21 days later. CPF administration resulted in an 80% inhibition of ChE activity in whole blood from both young and aged rats. In control animals ChE activity was less in the frontal cortex of aged rats (36.4 nmol acetylcholine hydrolyzed/mg protein/min) compared to young rats (42.1 nmol acetylcholine hydrolyzed/mg protein/min). However, CPF treatment resulted in a similar 80% reduction in brain ChE activity in both ages. Scatchard analysis of 3H -QNB binding was used to determine muscarinic receptor density (B_{max}) and affinity (K_d) in the frontal cortex. B_{max} was decreased 30% in both young and aged rats treated with CPF, with no change in K_d . The functional responsiveness of muscarinic receptors was measured in cortical brain slices as the accumulation of inositol phosphate (IP) following stimulation with the cholinergic agonist, carbachol. Carbachol (1-1000 μ M) resulted in a concentration-dependent increase in IP accumulation. IP accumulation was decreased in CPF-treated rats, and this decrease was the same in both ages. These results show that a single treatment with CPF which results in a prolonged inhibition of blood and brain ChE can induce muscarinic receptor down-regulation and a functional decrease in muscarinic receptor signal transduction which was not different in young and senescent rats.

BRADYKININ-STIMULATED PHOSPHOINOSITIDE TURNOVER AND PROSTACYCLIN PRODUCTION REGULATED BY PHORBOL ESTER AND CALCIUM IN CEREBRAL ENDOTHELIAL CELLS. J. Xu*, P.S. Zhang, S.A. Moore, C.Y. Heu and E.L. Hogan. Neurology Dept, MUSC, Charleston, SC 29425

Bradykinin (BK) stimulated phosphoinositide hydrolysis and prostacyclin (PGI_2) production in murine cerebral endothelial cell (MCEC) culture in a dose-dependent manner. A short exposure of MCECs to phorbol 12,13-dibutyrate (phorbol ester), an activator of protein kinase C (PKC), inhibited BK-induced inositol phosphates (IPs). Staurosporine, a potent inhibitor of PKC, reversed phorbol ester's inhibition. Long-term pre-exposure of MCECs to phorbol ester for various times (2-18 hrs) demonstrates reduced inhibition of BK-induced IPs as they are enhanced at 4 hrs and rise to 7-fold over the basal level 18 hrs after exposure. BK-induced IPs were decreased by the removal of calcium from the incubation medium. Pre-exposure of MCECs to BK itself for 8 hrs diminished BK's IPs response by 35%. On the other hand, BK-stimulated PGI_2 production does not appear in the presence of phorbol ester on BK- PGI_2 . Removal of calcium from the medium completely eliminated BK-stimulated PGI_2 .

These results suggest that BK-linked phospholipase C is down regulated by PKC, is partially calcium dependent and is desensitized by BK receptor(s). BK-stimulated phospholipase A₂ is also down regulated by PKC and is calcium dependent. Long-term pre-exposure of MCECs to phorbol ester decreased PGI_2 production with increasing time of exposure. BK stimulation gradually recovered over 18 hrs. Supported by NIH grant NS11066.

AUTORADIOGRAPHIC LOCALIZATION OF CARBACHOL-INDUCED PHOSPHOINOSITIDE TURNOVER IN DEVELOPING RAT NEOCORTEX. M.L. Robinson*, M.D. Hartgraves and J.L. Fuchs. Department of Biological Sciences, University of North Texas, Denton, TX 76203.

Neurotransmitter receptor binding in the developing rat neocortex has been well studied, but little is known about the functional ontogeny of these receptors. This is the first developmental study to describe the distribution of phosphoinositide (PI) turnover using an autoradiographic method (Hwang et al., 1990) which allows resolution to cortical layers. PI turnover was examined in slices of somatosensory cortex from rats aged postnatal days 4-16. $[^3H]CTP$ served as a precursor for the membrane-bound intermediate $[^3H]CDP$ -diacylglycerol; lithium was added to block recycling of this intermediate. The ACh agonist carbachol was used to stimulate PI turnover. The slices were subsequently frozen and sectioned for autoradiography.

On P4, the upper cortical plate was moderately dense, while deeper layers were lightly labeled. By P10, labeling was dense in layers II through upper IV, negligible in deep IV through upper V, and moderate in deep V through VI. The difference between deep and superficial layers diminished by P16. At all ages, layer VIIb was denser than VIa, and layer I was less dense than II-III. There was no apparent labeling in absence of carbachol. Agonist specificity is suggested by the observation that patterns induced by carbachol were quite different from those in adjacent slices exposed to the glutamate agonist ACPD. The laminar patterns of carbachol-induced PI turnover did not simply mirror those of muscarinic ACh receptor binding, although both receptor binding and PI turnover were lowest in layer IV to superficial V. These differences support the possibility of regional heterogeneity in the ontogeny of receptor coupling to second messengers systems. Supported by NIMH MH41865.

G-PROTEIN COUPLED RECEPTORS MEDIATE REDUCTION OF POTASSIUM CONDUCTANCES BY TRANS-ACPD AND MUSCARINIC AGONISTS IN CA3 PYRAMIDAL CELLS

Nathalie C. Guérineau, Beat H. Gähwiler, and Urs Gerber*

Brain Research Institute, University of Zürich, CH-8029 Zürich, Switzerland

Muscarinic agonists, acting at acetylcholine receptors, and trans-ACPD, acting at glutamate receptors, have been shown to elicit a variety of biochemical and electrophysiological responses involving the activation of G-proteins and are therefore termed metabotropic responses. However, it has never been established whether the receptors mediating the reduction of potassium conductances in mammalian CNS neurons are linked to G-proteins. We recorded from voltage-clamped CA3 pyramidal cells in rat hippocampal slice cultures using the whole-cell patch-clamp configuration in the presence of TTX. When cells were held at -50 mV, a 30 second bath-application of 1S,3R-ACPD (10 μ M) or methacholine (MCh; 0.5 μ M) activated an inward current associated with a decrease in gK. To determine if a G-protein is involved in mediating this response, cells were loaded with GDP β S (500 μ M), a non-hydrolyzable analog of GDP, through the patch-pipette. After allowing 10 to 15 minutes for diffusion, both 1S,3R-ACPD and MCh no longer induced inward current in 9 of 11 cells. Conversely, when GTP (100 μ M) or the non-hydrolyzable analog, GTP γ S (250 μ M), was included in the patch pipette the amplitude of ACPD- and MCh-induced currents was significantly enhanced: with GTP, 128% for ACPD and 69% for MCh; with GTP γ S, 370% for ACPD and 196% for MCh. These results demonstrate that both the glutamatergic and the muscarinic receptor subtypes mediating the reduction in gK in hippocampal pyramidal cells are functionally coupled to G-proteins.

FURTHER STUDIES REGARDING THE CHANGES IN CARBACHOL-STIMULATED INOSITOL PHOSPHATE RELEASE DURING RETINAL DEVELOPMENT IN THE RAT. P. Tandon¹, A.C. Nostrand², S. Willig³, and S. Padilla⁴, ¹CELMB, ²Curr. in Toxicology, Univ. of NC, Chapel Hill, NC, 27514; ³ManTech Environ. Ser., RTP, NC 27709; ⁴US Environ. Prot. Ag., RTP, NC, 27711.

Previous studies in our laboratory revealed a 5 fold increase in muscarinic receptor density in the pigmented rat retina between postnatal day (PND) 5 and adult which, curiously, does not correlate with the degree of carbachol-stimulated inositol phosphate (IP) release: carbachol-stimulated IP release peaks abruptly in the PND 10 retina and falls to adult levels by PND 15 (Tandon *et al.*, in press, *Exp. Eye Res*). To explore possible explanations for this dichotomy, we have been investigating the components of the second messenger cascade and the biochemical properties associated with the retinal muscarinic receptor. First, the phosphoinositide-specific phospholipase C activity of the retina during development does not parallel the developmental profile of the carbachol-stimulated IP release, and therefore does not explain the increased IP release at PND 10. In studies designed to explore the binding characteristics of the receptor, carbachol-stimulated IP release in the PND 10 retina was less sensitive to the muscarinic receptor blocker, atropine, than was the adult retina (EC_{50} =700nM for the PND 10 retina and 40 nM for the adult retina). These data indicate that some pharmacological aspects of the developing muscarinic receptor are unique from the adult receptor. Perhaps this is a partial explanation for the age-related differences in second messenger response to agonist stimulation in the retina.

BEHAVIORAL PHARMACOLOGY IV

569.1

BEHAVIORAL ACTIVITY OF NEUROSTEROIDS. R.F. Ritzmann*, A.J. Glasky, and C.L. Melchior. Olive View/UCLA Medical Center and West Los Angeles Veterans Administration Medical Center, Los Angeles, CA 90073

The behavioral effects of low doses of the neurosteroids dehydroepiandrosterone (DHEA), pregnenolone (PE) and their sulfates (DHEAS and PS), which act as allosteric antagonists in the GABA system, were explored in adult male C57BL/6 mice. Subjects were placed in a Stoelting activity monitor for a 20 minute adaptation period, then injected with neurosteroid or vehicle and returned to the activity monitor for a 20 minute test of motor activity. Thirty minutes post injection subjects were tested for anxiety on an elevated plus maze. The number of entries onto the open arms was utilized as the index of anxiety. Reactivity was then assessed by measuring the acoustic startle response.

Motor activity was not altered by these drugs at doses below 0.1 mg/kg, except for PE which, at a dose of 0.01 μ g/kg, increased motor activity. At doses of 0.5-20.0 mg/kg, DHEA produced a significant reduction of motor activity. On the elevated plus maze, PE at a dose of 0.01 μ g/kg and PS at 1 and 10 μ g/kg were anxiogenic. However, anxiolytic activity was found for DHEA at doses of 0.005-1.0 mg/kg, DHEAS at 0.05 and 0.5 mg/kg, and PS at 0.1 μ g/kg. Decreased acoustic startle response occurred at 0.01 and 10 μ g/kg PE and 0.1 μ g/kg PS.

These data show that these neurosteroids have a variety of behavioral effects at very low doses. The differences between the compounds may reflect their different sites of action in the GABA system. The anxiolytic and anxiogenic activities observed support the suggested roles for neurosteroids in stress.

INTRAVENTRICULAR INJECTION OF N^w-NITRO-L-ARGININE IMPAIRS LEARNING OF RATS IN A 14-UNIT T-MAZE. D.K. Ingram, E. Spangler, D. Roberts, H. Kametani, and E.D. London. NIA Gerontol. Res. Ctr., and NIDA Addiction Res. Ctr., NIH, Baltimore, MD 21224.

Peripheral injections of nitro-L-arginine compounds provided to laboratory rodents impair learning in a variety of tasks (Chapman *et al. Neuroreport* 3:567, 1992). These compounds presumably inhibit central activity of nitric oxide synthase (NOS) which retards nitric oxide (NO) generation that acts as a retrograde messenger to increase presynaptic glutamate release following postsynaptic stimulation of the glutamate receptor. Recent studies have questioned this hypothesis by observing no effects on performance in memory tasks with evidence of marked NOS inhibition (e.g., Barnes *et al. Neurosci Abs.* 18:1215, 1992). Using a 14-unit T-maze, we injected rats i.p. with N^w-nitro-L-arginine (NARG) to inhibit NOS activity (Ingram *et al. Neurosci Abs.* 18:1220, 1992) and observed impaired acquisition but not retention. Follow-up studies indicated that the NARG impairment may be related to vascular effects, since sodium nitroprusside, an NO generator causing marked vasodilation, could partially attenuate the NARG effect. Thus, to overcome possible peripheral vascular effects, we pursued studies in which NARG was injected i.c.v. Young (3 mo) male Sprague-Dawley rats were pretrained in 1-way active avoidance to a criterion (13/15 avoidances) in a straight runway. The next day about 1 hr before maze training, rats received injections of NARG (3 or 3.75 μ g/ μ l) or vehicle (artificial CSF) via a cannula implanted into the left lateral ventricle about a week before training. During 15 trials, rats were required to locomote each of 5 segments within 10 s to avoid footshock (0.8 mA). Performance variables included errors (deviations from correct pathway), runtime from start to goal, shock episodes and duration. Relative to controls, NARG-treated rats exhibited impaired performance in a dose-dependent manner. When treated with NARG during a retention test about 1 week later, rats showed no impairment. Therefore, central NARG treatment affected acquisition processes without evidence of nonspecific performance effects.

569.3

DISCRIMINATIVE STIMULUS (DS) EFFECTS OF NICOTINE IN HIGH (HA) AND LOW (LA) ACTIVITY RATS.

J. James*, S. Robinson, J. Rosecrans, L.

Hankansson, A. Nordberg, Dept. Pharmacol., VA Commonwealth Univ., Richmond, VA 23298 and Uppsala Univ., Uppsala, Sweden.

Previous research has shown that rats selected for differences in behavioral arousal (HA & LA rats) displayed a differential behavioral response (activity or habituation expts.) to nicotine; HA rats presented a more active forebrain serotonin system (5-HT). In the present study, HA rats again exhibited a more active 5-HT system (hippocampus). Dopamine (DA) turnover was faster in the HA rat (Striatum), but slower in the LA rat (hypothalamus; (metabolite/amine ratios). In contrast to previous work, nicotine elicited differential behavioral (VI-15 sec.) effects not related to HA or LA. Half of the rats in each activity group (Total N=32) elicited a biphasic pattern of responding (stimulation then depression), while the other half exhibited a dose-related depression of responding. A similar profile was noted in relation to tolerance and learning to discriminate nicotine. There were no differences in frontal cortex nicotine receptor binding between HA and LA rats. [Support-The German Research Council on Smoking and Health].

DISTANT ELECTROPHYSIOLOGICAL EFFECTS OF THE INTRACEREBRAL MICROINFUSION OF SALINE. D.C. Smith*, E.J. Barea, S.E. Krahl and K.B. Clark. Dept. of Psychology and School of Medicine, Southern Illinois University-Carbondale, IL 62901.

The explicit purpose for using the technique of intracranial microinfusion is to determine the effects of localized application of a chemical. The results are interpreted in terms of the effects of these agents at the specific location where they were delivered. Electrophysiological research being performed in our lab suggests that the microinfusion of a small volume (0.5 μ l) of saline at, by literature standards, a slow to moderate rate (0.5 μ l/2 min) into the locus coeruleus (LC) was causing the distant release of norepinephrine (NE) onto cells in the dentate gyrus (DG) of the hippocampus (HPC). This result seriously questions the ability to localize the effects of intracerebral microinfusions.

The effects of microinfusing 0.5 μ l of 0.9% NaCl (pH=7.0) into the LC on the amplitude of the perforant path (PP)-DG evoked population EPSP (pEPSP) in Urethane anesthetized (1.5 g/kg) Long-Evans rats were studied. Both experimental (n=10) and control (n=9) animals had a guide cannulae implanted directly above the LC and were allowed to stabilize for 1 hr. Then a recording electrode was lowered into the granule cell layer of the ipsilateral DG, a stimulating electrode into the PP, and the position of these adjusted so as to maximize the amplitude of the evoked pEPSP. After a 1 hr stabilization period, a baseline pEPSP (average of 10 PP stimuli) was obtained, saline was microinfused through an injection needle that did not extend beyond the guide cannula, and then two additional average PP-DG pEPSPs were collected (immediately and 5 min postinfusion). Control animals had the injection needle inserted into the guide cannulae, but no injection was made. Immediately following the infusion of saline, the pEPSP was enhanced 5.3% over baseline, and by 5 min postinfusion was increased 12.6% (p<.01). These results are like those seen in the HPC when the LC is stimulated and suggest that the pressure from injecting a 0.5 μ l volume at a relatively slow rate is stimulating the LC neurons sufficiently enough to cause the release of NE onto distant structures. Similar results have been obtained with medial septal microinfusions. We are currently examining these effects in unanesthetized animals.

569.5

S-ADENOSYLMETHIONINE AND METHIONINE INCREASE TAIL-FLICK LATENCY IN RATS. S.N. Young* and M. Shalchi. Department of Psychiatry and School of Dietetics and Human Nutrition, McGill University, Montreal, Canada H3A 1A1.

S-Adenosylmethionine (SAM) is an effective antidepressant with few side effects. As SAM increases brain serotonin and serotonin is involved in the gating of nociceptive afferents, we have studied the effect of SAM on tail flick latency to a thermal stimulus in the rat. Because methionine can raise brain SAM levels we also tested the effects of methionine. In a time course study rats were given 200 mg/kg SAM orally. Tail-flick latency was increased significantly 1.5 and 3 hours later. In a dose response study 200 and 400mg/kg but not 100mg/kg SAM increased tail flick latency significantly two hours after an oral dose. Methionine also increased tail flick latency with the peak effect occurring at 4 hours after oral administration. A dose response study revealed a significant effect of methionine at only 50mg/kg, a lower dose than that found with SAM. When methionine was added to rat chow to increase its level in the diet from 0.45% to 0.6% there was an increase in tail flick latency that reached significance after 21 days. Our results show that the tail-flick response which is a spinal reflex and is modulated in part by the activation of descending 5-HT systems is affected by SAM and methionine administration. SAM and methionine should be tested for their effects on clinical pain. In addition, because SAM is an antidepressant, and methionine shows a similar effect to SAM in the tail flick test, methionine should be considered for a possible antidepressant effect. (Supported by the Medical Research Council of Canada.)

569.7

EFFECT OF ACETYLCHOLINESTERASE INHIBITION ON BEHAVIORS IS AGE DEPENDENT IN *APLYSIA*. M. Srivatsan* and B. Peretz. Dept. of Physiology, Univ. of Kentucky Med. Cent. Lexington, Ky 40536.

Acetylcholinesterase (AChE) activity levels change with age in *Aplysia* (Peretz et al., Soc. Neurosci. Abstr. 18:583,1992; Srivatsan et al., J. Comp. Physiol. B, 162:29-37). To determine the effect of varying AChE levels, we tested two behaviors before and during AChE inhibition. We chose siphon/gill withdrawal reflex (S/GWR) that is age dependant and respiratory gill pumping movement (GPM) that is age independent (Hallahan et al., Neurobiol. Aging, 13:217-225,1992) to test in mature and old *Aplysia*. AChE activity levels were reduced by injecting a reversible specific AChE inhibitor BW284c51 into their hemocoel. The graded response of S/GWR to siphon stimulation of increasing water jet intensities and the rate of GPMs during 5 min. exposure to artificial sea water (ASW) of increasing acidity from pH7.8 to pH 3 were measured. Both behaviors were tested in the same animals with injection of filtered ASW (control) and two days later with injection of BW284c51 (experimental). A significant age effect was present in the behavioral responses to AChE inhibition. In mature *Aplysia* AChE inhibition seemed to affect both their sensory and motor functions as shown by a significantly shortened duration of S/GWR for all the stimulus intensities with a loss of the graded response to intensities between 1.25 and 2.5 Kg/cm². Their GPM rates were reduced and they were unable to differentiate pH7.8 and pH7. By comparison old animals were not sensitive to AChE inhibition as shown by the S/GWR response being the same for ASW and BW284c51 injection. Also, their GPM rates were unaffected by AChE inhibition. The results show that S/GWR is more sensitive to reduced AChE levels than GPM and the effects of AChE inhibition on both behaviors is age dependent. The effects of AChE inhibition on the physiological properties of neurons will be reported.

569.9

DISTRIBUTION OF SUBSTANCE P IN BRAIN AND ITS ROLE IN AGGRESSIVE BEHAVIOR IN GRAY SHORT-TAILED OPOSSUMS (*MONODELPHIS DOMESTICA*). B.H. Fadem*, K. Schubert, L. Taylor-Ali, J.M. Swann, M.B. Shaikh and A. Siegel. Laboratory of Limbic System & Behavior, Departments of Psychiatry and Neurosciences, N.J. Medical School and Graduate School of Biomedical Sciences, UMDNJ, Newark, N.J., 07103 and Department of Biology, Rutgers University, Newark, 07102.

It has recently been shown that substance P (SP) associated with limbic structures plays a central role in the onset of feline aggressive behavior. Since gray opossums display intense intraspecific aggression, the effects of systemic administration of the NK₁ antagonist, CP 96,345 on fight and threat behavior as well as the distribution of SP in brain were examined in this marsupial species. Preliminary behavioral analyses suggest that delivery of 4.0 mg/kg of CP 96,345 causes a decrease in threat and fight behavior in female but not in male gray opossums. Immunocytochemical analysis of brain revealed that SP positive neurons were located principally in the anterior aspect of the dorsomedial hypothalamus. In addition, SP fibers and preterminals were identified within the midbrain periaqueductal gray (PAG). The data suggest that descending fibers from the medial hypothalamus to the PAG mediate the expression of these forms of aggressive behavior in female gray opossums. EFFECTS OF DRUGS AND ⁶⁰CO IRRADIATION ON BRIGHTNESS DISCRIMINATION FOR RATS IN A CONTINUOUS Y WATER MAZE. J.L. Ferguson*, J.J. Burke and A.H. Harris. Department of Behavioral Sciences, AFRR, Bethesda, MD 20889.

Male Long-Evans rats were trained to approach lights in a triangular maze of water-filled alleys. At each apex a platform could be elevated to allow escape (correct answer) or to return the rat to the water (new trial). On odd trials (12/session) the light cue was put out 1 sec after the platform was lowered (positive offset); on even trials the light cue was put out 1 sec before (negative offset). Twenty minutes before each session rats were given (i.p.) haloperidol (0.1, 0.3 mg/kg), scopolamine (0.56, 1.0, 1.8, 3.0 mg/kg) and vehicle in 20 intervening sessions. Following the drug series the rats were exposed bilaterally to whole body gamma radiation (7.5 Gy ⁶⁰Co, 10 Gy/min) and tested at 2 hr, 5 hr and 1, 2 and 3 days. Haloperidol and scopolamine reduced the number of correct choices by 5-10%. Haloperidol (0.1 mg/kg) increased by more than 200% (p<.05) a measure of the rats' tendency to chose the alley that was correct on the prior trial. Following irradiation, at 2 hrs and at 3 days this measure of win-stay also increased by more than 200% (p<.05). These results relate to reports that ionizing radiation potentiates haloperidol-induced catalepsy and suggest a modified win-stay measure for the perseverative behavior sometimes observed in response to neurotoxins.

569.8

CHRONIC SENSORY STIMULATION HAS AGE RELATED EFFECTS ON ACETYLCHOLINESTERASE ACTIVITY. B. Peretz* and M. Srivatsan. Dept. of Physiology, Univ. of Kentucky Coll. Med., Lexington, KY 40536.

Chronically applied sensory stimulation (CSS) results in improved motor neuronal function in the old adult *Aplysia* (Zolman & Peretz, Behav. Neurosci. 101:524, 1987). As a step toward understanding how CSS results in improved neural function, we investigated if AChE (acetylcholinesterase) activity was affected by chronically applied siphon stimulation. Since AChE was released by tissues with depolarization and its inhibition altered the response to siphon stimulation, we focussed on AChE (Peretz et al., Neurosci Abstr. 18:583, 1992; Srivatsan et al., J. Comp. Physiol. 162:29, 1992; Srivatsan & Peretz, Soc. Neurosci. Abstr. 1993). CSS, water jet stimulus, of 2.5 kg/cm² for 1s., was applied daily for four weeks to the siphon of freely behaving young, mature and old *Aplysia*. CSS in old animals resulted in significantly increased AChE activity in both the CNS and serum (cell-free hemolymph), 18% and 30% respectively compared to the control group, (F(1,41)=5.6, p<0.025); CSS significantly altered the response to varying the intensity of siphon stimulation, from 0.018 to 2.5 kg/cm², F(4,112)=3.89, p<0.01. In contrast, the effects of CSS on young and mature animals were not significant, yet it resulted in reduced AChE activity in the serum of -19 and -20%, respectively, and in the CNS of -19% and -2.5%, respectively. Behavioral changes were not correlated with changes AChE activity in the two age groups. The control groups of the three ages appeared to show effects associated with daily handling which may be related to decreased AChE activity. These results show that chronically applied siphon stimulation affects AChE activity, and age along with the CSS appear to determine the level of the activity. Long-term environmental changes as detected by the nervous system are expressed by at least one serum protein. Effects of CSS and AChE on neuron function will be reported.

569.10

THE ATYPICAL ANTIPSYCHOTIC AGENT CLOZAPINE ANTAGONIZES THE MK-801 DISCRIMINATIVE STIMULUS CUE. T.A. Wetlauffer, F. Camacho, R.J. Fishkin, L.L. Kerman, A.T. Woods, & R. Corbett* Dept. Biol. Res., Neuroscience SBU, Hoechst-Roussel Pharm., Inc., Route 202-206, Somerville, NJ 08876-1258.

The non-competitive NMDA antagonists phencyclidine (PCP) and MK-801 induce a psychotomimetic state in man that closely resembles the positive and negative symptoms of schizophrenia. In addition, these compounds can produce a discriminative stimulus in rats and can generalize completely to each other. The atypical antipsychotic clozapine antagonizes MK-801-Induced Locomotion and Stereotypies (MK-801-ILS) in rats with an ED₅₀ value of 1.1 mg/kg, i.p. The aim of the present investigation was to determine whether clozapine can antagonize the MK-801-induced PCP-like discriminative stimulus cue in rats trained to discriminate MK-801 from saline in a two-choice, discrete-trial avoidance paradigm. Four male Wistar rats were trained to discriminate MK-801 (0.075 mg/kg, i.p.) from saline. MK-801 was administered 60 min prior to the test sessions and the various doses of clozapine (0.31, 0.63, 1.25, 2.5 and 5.0 mg/kg, i.p.) were administered 30 min after the injection of MK-801. Clozapine dose-dependently antagonized the MK-801 discriminative stimulus cue in all four subjects. Furthermore, these doses of clozapine are significantly less than those shown to antagonize dopaminergic D₂ behaviors exhibited in the Climbing Mouse Assay (CMA: clozapine ED₅₀ = 12.5 mg/kg, i.p.). Therefore, clozapine has a CMA/MK-801-ILS ratio of 11.2. These results suggest that clozapine antagonizes the MK-801 discriminative stimulus cue through mechanisms independent of dopamine D₂ antagonism.

569.11

BEHAVIORAL AND PHARMACOLOGICAL EFFECTS OF A PHENCYCLIDINE METABOLITE, (TRANS)-4OH-CYCLOHEXYL PCP.

A. Baba¹, T. Yamamoto¹, H. Yamamoto¹, T. Kawai¹, T. Suzuki¹, T. Moroi¹ and Y. Murashima^{2*}. ¹ Dept. of Psychopharmacology and ²Dept. of Neurophysiology, Tokyo Inst. of Psychiatry, Tokyo. 156, Japan.

The psychologic responses of normal human subjects to phencyclidine (PCP) administration include both delirium, with clouded consciousness or vivid psychotic symptoms, and affective responses with no altered consciousness. Delirious states can be both acute or chronic, the latter being well beyond the drug half-life. The drug action may be particularly prolonged because of the formation of active metabolites. In order to better understand this drug action, we examined behavioral and pharmacological activities of a major metabolite of PCP, (trans)-4OH-cyclohexyl PCP. Intraperitoneal injection of (trans)-4OH-cyclohexyl PCP to mice caused an increase in locomotor activity in a dose dependent manner. In the in vitro binding experiments, (trans)-4OH-cyclohexyl PCP as well as PCP had relatively high affinity for the dopamine (DA) uptake site but not for sigma or NMDA/PCP receptor complex. These observations indicate that (trans)-4OH-cyclohexyl PCP may also play a role in psychotomimetic actions of PCP through its inhibitory effect on the DA uptake site.

569.13

A CONSTANT SPEED ROTOROD TASK IS MORE SENSITIVE TO DEPRESSANT EFFECTS OF DRUGS THAN AN ACCELERATING SPEED ROTOROD TASK IN RATS. M. C. Grace, M. D. Crago and J. V. Cassella.* Neurogen Corporation, Branford, CT 06405.

The rotorod task in rodents has long been employed as a measure of muscle relaxing or motor impairing effects of drugs. In some studies animals are placed on a rod revolving at a constant speed while in other cases animals are placed on a stationary rod that then accelerates. It might be argued that these are two distinct tasks that may be differentially sensitive to drug effects. This study examined the effects of sedative and muscle relaxant drugs in rats tested on both accelerating (rats were placed on the stationary rod which then accelerated linearly to 80 rpm over a 4 min period) and constant speed task (rotating at 20 rpm). All compounds showed greater deficits on the constant speed task than on the accelerating task. The sedative hypnotic Zolpidem (0.06 - 1.0 mg/kg, IV) and anxiolytics Diazepam (0.25 - 2.0 mg/kg, IV) and Alprazolam (0.03 - 0.5 mg/kg, IV) produced a much greater impairment in the constant task than in the accelerating task. The muscle relaxants Baclofen (0.25 - 4.0 mg/kg, IV) and Dantrolene (0.5 - 4.0 mg/kg, IV) produced very little impairment in the accelerating task while producing a much greater impairment in the constant task. The Diazepam and Alprazolam constant speed effects are comparable to the effects produced by these compounds in a locomotor activity task (a 15 minute test session in the dark Omni Digiscan Activity Monitor). Therefore, the magnitude of the depressant effect of drugs is dependent upon whether an accelerating or constant speed paradigm is employed.

569.15

EVALUATION OF THE DISCRIMINATIVE STIMULUS EFFECTS OF THE NOVEL PUTATIVE SEDATIVE-HYPNOTIC CL 284,846. K. E. Vanover* and J. E. Barrett, American Cyanamid, Lederle Laboratories, CNS-Biology, Pearl River, New York, 10965.

CL 284,846, N-[3-(3-cyanopyrazolo[1,5-a]pyrimidin-7-yl)phenyl]-N-ethylacetamide, is a novel non-benzodiazepine putative sedative-hypnotic with benzodiazepine-like sedative effects, but with less liability for the usually accompanying undesired side-effects. In an effort to further characterize its pharmacological activity CL 284,846 was established as a discriminative stimulus (DS). Rats (n=7) were trained to discriminate CL 284,846 (3.0 mg/kg, i.p., 30 min pretreatment) from saline in a two-lever, sucrose-reinforced drug discrimination paradigm. CL 284,846 functioned as a DS in all rats and showed a dose-related (0.03 - 10.0 mg/kg) increase in drug-appropriate responding up to the training dose and a dose-related decrease in response rate. Once this discrimination was established, similarities among the DS effects of CL 284,846 and known sedative and anxiolytic drugs were examined. The benzodiazepine agonist, triazolam (0.03 - 1.0 mg/kg) substituted for CL 284,846 only at doses which also decreased response rate, while the benzodiazepine partial agonist, Ro 17-1812 (0.1 - 3.0 mg/kg) fully substituted for CL 284,846 with no effect on rate. Buspirone (1.0 - 10.0 mg/kg), a 5-HT_{1A} agonist, and pentobarbital (3.0 - 17.0 mg/kg), a barbiturate, failed to substitute for CL 284,846 up to rate-decreasing doses. A novel putative anxiolytic, CL 273,547 (3.0 - 56.0 mg/kg) was also tested and substituted in 3 of 5 rats at doses which also decreased response rate. Flumazenil (3.0 - 10.0 mg/kg, i.p.), a benzodiazepine antagonist, blocked the DS effects of CL 284,846 in 4 of 5 rats tested with no effect on response rate. Taken together, these results suggest that the DS effects of CL 284,846 are mediated via benzodiazepine receptors. CL 284,846, however, remains distinct from most sedatives in that its DS effects failed to generalize to pentobarbital. Further investigation is needed to clarify this distinction.

569.12

THE EFFECTS OF SKF525A TREATMENT ON THE DELAYED ANTICONFLICT ACTION OF MK-801 IN RATS. Z.C. Xie* and R.L. Commissaris. Dept. Pharmaceut. Sci., Wayne St. Univ., Detroit, MI 48202.

In female rats, MK-801 (dizocilpine) exerts a delayed anticonflict (i.e., anxiolytic-like) effect (PBB 43:471-477, 1992). One explanation for the delayed onset of action for MK-801 treatment is that MK-801 is a 'pro-drug' and the anticonflict effects are caused by one or more of its hepatically-generated metabolites (2OH-, 8OH-MK-801). The present studies were designed to address this possibility. In the first experiment, the effects of MK-801 administered IP were determined in female rats following a range of pretreatment intervals (0.5-48 hr). As observed previously, 0.2 mg/kg MK-801 exerted anticonflict effects at pretreatment intervals of 14-32 hr, but not before 12 hr or after 32 hr. In the second experiment, the hepatic microsomal drug metabolism inhibitor SKF525A (50 mg/kg, IP, 12-hr pretreatment) had no effect on conflict behavior when administered alone, nor did it prevent the delayed anticonflict effect produced by a single dose of MK-801 (0.2 mg/kg). In the third experiment, chronic treatment with MK-801 (0.2 mg/kg daily, administered IP immediately after testing) resulted in a robust anticonflict with no evidence of tolerance across three weeks of treatment. Administration of SKF525A did not prevent the anticonflict effect of this chronic MK-801 treatment. Together, these data are not consistent with the hypothesis that MK-801 exerts its delayed anticonflict effect via the formation of a P450-generated active metabolite. (Supported in part by MH 48171 to RLC).

DIFFERENTIATION OF SEDATIVE AND MUSCLE RELAXANT EFFECTS USING THE ACOUSTIC STARTLE RESPONSE AND LOCOMOTOR ACTIVITY MEASURE IN THE RAT. M. D. Crago, M. C. Grace, R. J. Primus* and J. V. Cassella. Neurogen Corporation, Branford, CT 06405.

Many behavioral paradigms are sensitive to the effects of sedative and/or muscle relaxant compounds in rats. While it is useful to know that a compound can depress certain behaviors, it is more informative to determine whether a compound is relatively more sedating or motor impairing (e.g. muscle relaxing). This study attempted to differentiate between sedative and muscle relaxant activity of drugs and compared the effects of these drugs in the acoustic startle paradigm and the locomotor activity test. The acoustic startle response was elicited by 20 stimuli at each of three intensities (85, 90, and 95 db; 50 ms duration) with each stimulus presented in a counterbalanced order every 30 seconds. Locomotor activity was assessed by an Omnitech digiscan system (infrared photo cells; animals tested under red light conditions; 62 db white noise; 15 minute test session). Rats were injected with either the sedative hypnotic Triazolam (0.0075 - 0.125 mg/kg, IV) or Zolpidem (0.03 - 2.0 mg/kg, IV) or the muscle relaxant Dantrolene (0.5 - 4.0 mg/kg, IV) or Baclofen (0.25 - 4.0 mg/kg, IV) 5 minutes prior to testing. All of these compounds reduced the amplitude of the acoustic startle response and decreased locomotor activity. However, the sedative hypnotics were much more potent in reducing locomotor activity than in decreasing startle amplitude while the muscle relaxants were relatively equipotent in reducing both behaviors. Therefore, the combined use of these paradigms could be used to determine the relative contribution of sedative or muscle relaxant properties of behavior-depressing compounds.

APPEARANCE OF CHOREIFORM MOVEMENTS IN MICE FOLLOWING ACUTE TREATMENT WITH HIGH DOSES OF CAFFEINE: AN ANIMAL MODEL FOR CHOREIFORM MOVEMENT. O. Nikodijevic, K. A. Jacobson, and J. W. Daly,* Lab. of Bioorganic Chemistry, NIDDK/NIH, Bethesda MD 20892.

Injection of caffeine at a dose of 35 to 70 mg/kg causes choreiform (dance-like) movements in NIH Swiss mice in a dose-dependent manner. This effect is less pronounced in mice that had ingested 1 g/kg caffeine in the drinking water for 7 days. The dopamine antagonist haloperidol decreased locomotor activity, and the L-type calcium channel blocker nitrendipine increased locomotor activity (effect following in chronic caffeine ingestion). Coadministration of haloperidol (1 or 3 mg/kg) and caffeine, or nitrendipine (50 or 100 mg/kg) and caffeine, markedly reduce the choreiform effect of caffeine. The A_{2A} selective adenosine agonist APEC, but not the A₁ selective agonist CHA, also diminishes choreiform movement. The data suggest involvement of dopaminergic and adenosine receptors as well as the calcium channel system in the appearance of choreiform movement. These animals could be used as a model for further investigation of the mechanism of choreiform movement as well as possible therapeutic approaches to certain choreas in humans related to disease states (e.g. Huntington's disease or Tourette syndrome) or side effects of drug treatment.

CAFFEINE DELAYS STARTLE HABITUATION IN HIGH CAFFEINE USERS E.J. Schicatanò and T.D. Blumenthal
Wake Forest University, Winston-Salem, NC 27109

Past studies have shown that caffeine delays startle reflex habituation in low caffeine users. The present experiment examined the effects of caffeine (4 mg/kg) on startle habituation in high caffeine users. Eyeblinks were measured in humans in a startle habituation paradigm in which 85 dB broadband noise stimuli were presented. Subjects were given a dose of caffeine (4 mg/kg), and then 24 hours later were administered either placebo or another dose of caffeine (4 mg/kg). In this respect, caffeine "withdrawal" was operationally defined as 24 hours without caffeine. The results demonstrated that caffeine delayed startle amplitude habituation. When comparing response amplitude in the first trial block for both caffeine and placebo conditions, no significant difference was demonstrated. Therefore, caffeine did not alter initial startle responding, instead, it affected plasticity of this response. Comparing first trial block response amplitude for high caffeine users given placebo, and low caffeine users given placebo (data from an earlier study), revealed a higher response amplitude for the high caffeine users (withdrawal condition). Thus, our data show that (1) Caffeine delays startle habituation in high caffeine users, and (2) withdrawal from caffeine in persons with a history of caffeine usage may render these individuals more sensitive to startle stimuli.

CHRONIC CLONIDINE TREATMENT EFFECTS ON CONFLICT BEHAVIOR AND FOOTSHOCK SENSITIVITY IN THE RAT. W.T. Repaskey and R.L. Commissaris†SPON: T.J. Hill, J. Dept. Pharmaceutical Sciences, Wayne State University, Detroit, MI 48202.

It has been reported previously that chronic clonidine administration produces a robust anticonflict effect in rats over the course of several weeks of treatment (Behav. Pharmacol. 1:201-208, 1990). The present studies were designed to examine the possible relationship between the effects of chronic clonidine treatment on conflict behavior and sensitivity to footshock. Subjects were trained for conflict testing in the conditioned suppression of drinking (CSD) conflict task, a repeated measures modification of the Vogel acute conflict task. Subjects received either chronic clonidine (40 µg/kg) or chronic saline treatment twice daily, once immediately after behavioral testing and again 12 hours later. Punished responding in clonidine-treated subjects did not differ from saline-treated controls for the first week of chronic treatment, but was significantly greater than in controls by the second week of chronic treatment. For shock sensitivity determinations, the same subjects were given brief footshocks (0.08 - 0.35 mA; 500 msec duration) and were rated for the presence or absence of a response (e.g., twitch, jump, vocalization, etc.) by a trained observer who was blinded regarding both treatment condition and shock intensity. As expected, this procedure revealed a robust current intensity versus response function. Chronic clonidine treatment did not affect sensitivity to unavoidable footshock. Moreover, there was no correlation between footshock sensitivity and punished responding in the conflict task for either saline- or clonidine-treated subjects. These data indicate that the anticonflict effect of chronic clonidine treatment is not the result of a decrease in sensitivity to footshock. (Supported in part by MH #47181 to RLC).

HYPOTHALAMIC-PITUITARY-GONADAL REGULATION: NEUROPEPTIDES AND TRANSMITTERS

570.1

NOVEL TRIPLE-LABELING METHOD COMBINING DUAL-LABEL IN SITU HYBRIDIZATION DETECTION OF LHRH AND GALANIN mRNAs WITH IMMUNOCYTOCHEMICAL DETECTION OF NUCLEAR FOS PROTEIN. E. Hrabovszky¹, M. Vrontakis², D. Keisler³ and S.L. Petersen¹. Depts. Anat. and Neurobiol.¹, and Ani. Sci.², Univ. Missouri, Columbia 65212 and Dept. Physiol., Univ. Manitoba, Winnipeg³.

Recently, a sensitive dual-label in situ hybridization technique was developed in this laboratory. Using this method, we simultaneously detected mRNAs encoding LHRH and the β_2 -subunit of the GABA_A receptor. Because of the well-known topographical and functional heterogeneity of LHRH neurons and our recent finding that only a subpopulation of LHRH neurons appears to express the β_2 -subunit, we deemed it important to find a way to determine whether subpopulations of LHRH neurons expressing receptors or other peptides were those involved in producing the LH surge on proestrus. To accomplish this aim, we performed dual-label in situ hybridization histochemistry in conjunction with immunocytochemical detection of Fos protein, a putative marker of increased LHRH neuronal activity. For methodological validation, the present application of the new triple-labeling technique combines non-radioactive detection of LHRH mRNA using a digoxigenin-labeled cRNA probe, autoradiographic visualization of galanin mRNA hybridized to a ³⁵S-labeled cRNA probe and immunocytochemical localization of Fos protein in the cell nuclei of activated LHRH neurons. Methodological aspects of combined immunocytochemistry and in situ hybridization histochemistry, as well as applications of the new triple-labeling technique are discussed in detail.

570.3

COLOCALIZATION OF GLUTAMATE RECEPTOR SUBUNIT GluR1 mRNA AND GALANIN IN RAT PREOPTIC HYPOTHALAMUS. Z. Cao¹, C. Ulibarri² and T.R. Akesson. Dept of Vet & Comp Anatomy, Pharmacology, & Physiology, Washington State University, Pullman, WA 99164.

Glutamate has been recently shown to play a hypothalamic role in the release of luteinizing hormone from the pituitary and there is evidence that this excitatory amino acid is active in circuits mediating sexual behavior. Galanin has also been recently implicated in the regulation of LHRH release; and in the preoptic area where this peptide is colocalized with estrogen receptors, galanin stimulates male sexual behavior. To identify sites where glutamate and galanin could interact to influence reproductive processes, we have used a double-labeling method combining immunohistochemistry and *in situ* hybridization. Two days after colchicine treatment, immunohistochemistry was used to visualize galanin immunoreactivity (GALir). The sections were then hybridized with GluR1 antisense RNA (gift of the Molecular Neurobiology Laboratory, Salk Institute) labeled with Dig-UTP that was detected after hybridization by anti-Dig alkaline phosphatase conjugate. The subsequent enzyme-catalyzed color reaction with x-phosphate and nitroblue tetrazolium salt produced an insoluble purple/blue precipitate in and around the nuclei of neurons containing GluR1 mRNA.

Coexistence of GALir and GluR1 mRNA was observed in the diagonal band of Broca, the ventral subdivision of the lateral septum, the anteroventral and preoptic periventricular nuclei, the medial preoptic nucleus, and the bed nucleus of the stria terminalis. Proportions of doubly-labeled neurons were highest in the medial preoptic nucleus where 40-60% of the GALir cells expressed GluR1 mRNA and in the preoptic periventricular nucleus where colocalization represented 50% of the GALir cells. These findings are consistent with the possibility that glutamate and galanin have a synergistic influence on processes that regulate reproductive functions. Supported by HD22869.

570.2

GALANIN GENE EXPRESSION IN THE BED NUCLEUS OF THE STRIA TERMINALIS AND MEDIAL AMYGDALA INCREASES ACROSS PUBERTY BUT LACKS SEXUAL DIMORPHISM. B. Planas^{*}, P.E. Kolb, M.A. Raskin and M.A. Miller. Department of Psychiatry and Behavioral Sciences, University of Washington, Seattle, WA 98195.

We have recently observed that galanin mRNA is co-expressed in the majority of vasopressin (VP) neurons of the bed nucleus of the stria terminalis (BNST) and the medial amygdala (AMe) of the male rat. We have shown that gonadal steroid-regulate both VP and GAL gene expression in the BNST of adult male rats. In the BNST, both VP immunoreactivity and gene expression exhibit sexual dimorphism. Here, we have used *in situ* hybridization and quantitative autoradiography to determine whether GAL gene expression in the BNST and AMe is sexually dimorphic and whether the level of expression changes across puberty. Male and female Wistar rats (24 d, 90 d) were sacrificed and their brains removed. Brain sections were hybridized with a ³⁵S-labeled 680 bp cRNA probe complementary to GAL mRNA. The number of labeled cells (unilateral) and the average number of grains/cell were compared in four atlas-matched sections per region across groups. No sex differences in GAL gene expression were detected in either region. In the BNST, more neurons ($p < 0.02$) were labeled in adult (male: 184±12, n=3; female: 190±8, n=5) compared to prepubertal rats (male: 128±8, n=5; female: 120±10, n=5). The average number of grains/cell was also higher ($p < 0.001$) in adult rats (ad male: 89±4; ad female: 108±10; prep male: 62±2; prep female: 61±4). In the AMe, no age difference was observed in number of cells (ad male: 75±4; ad female: 72±7; prep male: 69±6; prep female: 67±2); however, the number of grains/cell was increased ($p < 0.001$) across puberty in both sexes (ad male: 100±7; ad female: 107±7; prep male: 63±1; prep female: 56±3). A second experiment replicated the lack of a sex difference in the number of GAL mRNA expressing neurons in the adult BNST (male: 178±4, n=6; female: 171±9, n=6). These results indicate that GAL gene expression in these regions does not exhibit sexual dimorphism however, these pathways are activated across puberty.

570.4

MEDIAN EMINENCE IN VIVO RELEASE OF NPY AND LHRH BEFORE, DURING AND AFTER A PREOVULATORY LH SURGE IN EWES. J.P. Advis¹, C.D. Conover, J.K. McDonald, J. Rabii and S. Bailey. Dept of Animal Sciences and Dept of Exercise Physiology, Rutgers Univ, New Brunswick, NJ 08903, Dept Anatomy / Cell Bio, Emory Univ, Atlanta, GA 30322, and Dept Biological Sciences, Rutgers Univ, Piscataway, NJ 08855.

Neuropeptide Y (NPY) might play a role, at the median eminence (ME) in the neuroendocrine control of preovulatory release of luteinizing hormone (LH) - releasing hormone (LHRH) and LH. Using a synchronized estrous cycle model and sampling ME push-pull cannula (PPC) perfusate and jugular blood at 10-min intervals for 6h, we studied: a) basal *in vivo* PPC release of NPY and LHRH, and plasma LH throughout the cycle; b) *in vivo* ME-LHRH release in response to increasing concentrations of NPY infused through the ME-PPC probe (0, 2, 6, 18 µM) in luteal and follicular ewes; and c) *in vivo* ME-LHRH release in response to increasing concentrations of NPY antiserum (As) infused through the ME-PPC probe (NRS no As, 1:1000, 1:100) during the onset of the synchronized preovulatory surge of LH. Basal *in vivo* release of both LHRH and NPY increased from luteal to surging ewes (mean \pm sem (n), luteal vs surge, LHRH: 1.46±.43 (6) vs 18.3±1.22 pg/100 µl (6); NPY: 68.5±7.87 (6) vs 120±9.80 pg/100 µl (6); LH: 0.64±.04 vs 112±11.21 ng/ml (6)), predominantly due to increases in pulse amplitude ($P < 0.05$). ME infusion of NPY increased LHRH and LH release in a dose-dependent fashion in follicular but not in luteal ewes, with the largest dose inducing surge-like levels of LHRH and LH in late follicular ewes ($P < 0.05$). ME-infusion of NPY-As (1:100) decreased LHRH and LH release in late follicular ewes ($P < 0.05$). Furthermore, infusion of NPY-As during the ascending phase of the LH surge stopped and even decreased LHRH and LH release for as long as the As was infused (2h). When ME-NPY-As infusion ceased, the arrested ascending preovulatory release of LHRH and LH resumed. Thus, ME-NPY secretion stimulated LHRH release during the preovulatory surge of LHRH and of plasma LH (supported by NJAES - Hatch 06108 & USDA 89-37240-4587 to J.P. Advis).

C-FOS IMMUNOREACTIVITY AFTER INTRACEREBRO-VENTRICULAR NEUROPEPTIDE Y INJECTION IN IMMATURE FEMALE RATS. Fraley, GS*, G Torres, and DK Sarkar. Dept. VCAPP, Washington State University, Pullman, WA 99164-6520.

Neuropeptide Y (NPY), a member of the PP family, is known to be a strong modulator of hypothalamic function, particularly in food intake and reproduction. We have recently shown that NPY stimulates the onset of puberty in chicks and rats. In order to investigate the mechanism of NPY's action on the onset of puberty in rats we utilized the activation of the immediate early gene, c-fos, as an indicator of hypothalamic neural activation. Twelve immature Sprague-Dawley female rats had stainless steel cannulas implanted into the third ventricle at 24-days of age. During the afternoon of day 30, 10 µg of NPY was injected into the third ventricle of six animals and another six animals were injected with physiologic saline, the carrier agent for the NPY. This dose of NPY has been shown previously to initiate puberty within 4-5 days after injection. One hour after injection, the animals were perfused with heparinized physiologic saline followed by 4% paraformaldehyde and the brains removed and sectioned at 40 microns on a sliding microtome. Hypothalamic sections were stained immunocytochemically for c-fos gene product using a polyclonal primary antibody (Oncogene Science) following the ABC procedure (Vectastain). Results indicated a qualitative increase in c-fos immunoreactivity in the NPY injected animals as compared to controls within two major hypothalamic regions, the preoptic area (POA) and the paraventricular nucleus (PVN). We hypothesize that the NPY induction of puberty may either involve a direct stimulation of LHRH neurons within the POA or indirectly stimulate LHRH release via neurons within the PVN. Further colocalization studies of c-fos immunoreactivity will be needed in order to establish the neurotransmitters or neuromodulators involved with NPY to stimulate c-fos reactivity during the activation of reproductive function.

MORPHINE EFFECTS ON TYROSINE HYDROXYLASE (TH) mRNA LEVELS IN HYPOTHALAMIC DOPAMINE NEURONS AND THEIR ROLE IN LHRH RELEASE. C.A. Barraclough*, J. Molnar and J-R He. Dept. Physiol., Sch. Med., University of Maryland, Baltimore, MD 21201.

Morphine blocks icv NE-induced increases in LHRH mRNA and paradoxically, in these same rats, it amplifies LHRH release. We questioned whether altered hypothalamic dopamine (DA) secretion was involved in this phenomenon. Changes in TH mRNA levels in A15 to A12 DA neurons were used as an index of DA neuronal activity and used *in situ* hybridization histochemistry and quantitative image analysis methods. The data show that: (1) TH mRNA levels were not altered 1, 5 or 24 h after morphine in preoptic A15 or anterior hypothalamic A14 neurons; (2) TH mRNA levels in A13 cells increased significantly 1, 5 and 24 h after morphine; (3) message levels in tuberoinfundibular DA neurons (TIDA) also were increased at 1 and 5 but not at 24 h after morphine; (4) Preoptic DOPAC levels in microdialysis samples increased by about 217% following either sc or direct morphine infusions into A13 cells; (5) icv DA (20 µg) did not affect LH release and it neither augmented nor suppressed NE-induced LH release. We propose that NE directly stimulates median eminence terminals to release LHRH and local TIDA neurons modulate this response. Morphine initially suppresses TIDA secretion [plasma prolactin (Prl) increases] but by 1 h a rebound in TIDA neuronal activity occurs and as PrL declines, TH mRNA levels increase in these cells. A15 to A13 dopamine neurons do not appear to be important modulators of LHRH neuronal responsiveness to NE. Supported by HD-02138.

570.9

GLUTAMATE AND GABA NEURONS INTERACT EXTENSIVELY IN NEUROENDOCRINE REGIONS OF THE FEMALE MONKEY BRAIN. K.K. Thind* and P.C. Goldsmith. Reproductive Endocrinology Center, Univ. California Sch. of Med., San Francisco, CA 94143-0556.

With their wide distributions, glutamate (Glu) and GABA neurons have extensive antagonistic effects throughout the brain. Since their direct interactions could play a pivotal role in governing CNS function, we performed double-label immunostaining for Glu and glutamic acid decarboxylase (GAD) in hypothalamic sections from two adult female cynomolgus monkeys. Ultrastructural analysis of 785 immunoreactive (ir) profiles (63% Glu-ir, 28% GAD-ir, 9% Glu+GAD-ir) revealed strikingly consistent labeling of 2-4% somata (SOM), 65-80% dendrites (DEN), axons (AX), and 15-30% axon terminals (AXO) in the medial septum (MS), paraventricular nucleus (PVN), supraoptic nucleus (SON), arcuate-ventral hypothalamic tract (VHT1) and median eminence (ME). The three major types of labeled interactions showed regional differences in the processes involved:

ir Contact	MS	PVN	SON	VHT1	ME	
Glu/GAD	44.4%	50.0%	47.6%	50.0%	14.3%	
Glu/Glu	27.7%	0.0%	23.8%	14.7%	33.3%	
Glu/Glu+GAD	19.4%	16.6%	0.0%	23.5%	42.8%	
Region	MS	VHT1				
Processes	AXO/DEN	AX/DEN	DEN/DEN	AXO/DEN	AX/DEN	DEN/DEN
Glu/GAD	31.2%	18.7%	43.7%	17.6%	0.0%	82.3%
Glu/Glu	80.0%	0.0%	10.0%	80.0%	0.0%	20.0%
Glu/Glu+GAD	85.7%	0.0%	14.3%	75.0%	0.0%	12.5%

Since Glu-ir and GAD-ir elements also synapse ubiquitously with other neuroendocrine systems, their extensive interactions seem to represent a logical regulatory network for controlling developmental and functional activity of numerous neuroendocrine systems. Supported by HD10907 and HD11979.

TYROSINE HYDROXYLASE mRNA IN THE MONKEY HYPOTHALAMUS: LOCALIZATION AND REGULATION BY STEROIDS. S.G. Kohama* and C.L. Bethea. Div. Reprod. Sciences, Oregon Regional Primate Research Center, Beaverton, OR 97006.

Regulation of hypothalamic dopaminergic neurons by chronic steroid stimulation was examined in spay rhesus monkeys by *in situ* hybridization (ISH) for tyrosine hydroxylase (TH). Spay monkeys were treated for 28 days with: empty capsule (control), estrogen implant (E), or E supplemented with progesterone (P) for the last 14 days of treatment (E+P). The first set of brains was fixed by bath immersion whereas the second set was perfused-fixed. Hypothalamic blocks were then processed for ISH. Sections (10 µm) were hybridized with 35-S labelled antisense rat cRNA probe. Specific labelling in hypothalamic nuclei and substantia nigra coincided with TH-immunostained neurons on adjacent sections or colocalized with ISH. Grain counts over labelled nuclei were obtained with computer imaging of darkfield illuminated sections. Although both sets of tissue had similar patterns of hybridization, the perfusion-fixed brains displayed more labelled cells. Preliminary grain counts of perfused tissue revealed little TH mRNA regulation by E or E+P in areas previously shown to have P receptors (PR) such as the periventricular and dorsal arcuate nucleus. However, grain number decreased in the ventral arcuate dopamine neurons after E or E+P treatment although little PR occurs in this population suggesting indirect effects of steroids. Supported by HD17269, HD18185.

570.8

TESTOSTERONE STIMULATES ROSTRAL AND MEOBASAL HYPOTHALAMIC GABA TURNOVER IN THE CASTRATE MALE RAT. D.R. Gratian* and M. Selmanoff. Department of Physiology, University of Maryland, School of Medicine, Baltimore, MD 21201-1559.

We recently determined that castration specifically decreased GABA turnover in the rostral and mediobasal hypothalamus, an effect that was only partially reversed by an implant of testosterone (T). This study aimed to confirm that T could stimulate GABA turnover in hypothalamus of the castrate rat, and to investigate whether pulsatile T replacement might stimulate GABA turnover more effectively than the constant levels provided by an implant. Animals were divided into 4 experimental groups: intact, 48 h castrate, 48 h castrate + T capsules (2 x 30 mm Silastic implants, 0.062" id, 0.125" od), 48 h castrate + T injections (100 µg/kg, 3x daily). GABA concentrations were measured in 5 microdissected brain regions, and in the anterior, posterior and intermediate lobes of the pituitary, either before, or 60 minutes after inhibition of the GABA degrading enzyme GABA transaminase by injection of aminoxyacetic acid (AOAA, 100 mg/kg ip). The rate of GABA accumulation in the tissue following injection of AOAA was used as an index of GABA turnover. In the diagonal band of Broca, the medial preoptic nucleus and in the median eminence, GABA turnover was significantly reduced by castration. There was no effect of castration on GABA turnover in the cingulate cortex, or in the pituitary gland. Both modes of T replacement increased GABA turnover to values not significantly different from intact controls, but neither treatment fully reversed the effects of castration. Hence, it is possible that another factor from the testes may also be involved in promoting GABA turnover in these regions. Alternatively, it may be that since even our pulsatile T replacement does not exactly mimic the normal pulsatile and circadian variations in plasma T, GABA turnover in these T-sensitive neurons in the rostral and mediobasal hypothalamus is also not fully reinstated. (Supported by NIH Grant HD21351)

570.10

RELEASE OF GLUTAMATE AND ASPARTATE FROM THE PREOPTIC AREA DURING THE PROGESTERONE-INDUCED LH SURGE: IN VIVO MICRODIALYSIS STUDIES. D. W. Brann*, L. Ping, V. T. Wiedmeier and V. B. Mahesh. Dept. of Physiology and Endocrinology, Med. Col. of Georgia, Augusta, GA 30912

To examine the role of excitatory amino acid neurotransmitters in the regulation of LH and FSH secretion in ovariectomized (ovx) adult rats treated with estradiol and progesterone, we measured the release rates of glutamate and aspartate as well as the neurally inactive amino acid serine in microdialysis perfusate samples of the preoptic area (POA) of the hypothalamus collected at 30-min intervals during the LH surge induced by progesterone. The release rates of glutamate in the preoptic area increased at 1500h and 1600h and for aspartate at 1200h, 1300h, 1500h and 1600h in the progesterone treated estrogen-primed ovx rat as compared to estrogen controls. The increase in POA release rates of glutamate and aspartate in the progesterone treated rats occurred immediately prior to peak serum LH levels induced by progesterone. The neurally inactive neurotransmitter serine was unchanged by steroid treatment. Estradiol alone had no significant effect on the POA release rates. This study adds further evidence that excitatory amino acid neurotransmission is an important component in the neurotransmission line mediating gonadotropin surge expression in the female rat.

THROMBIN STIMULATES THE RELEASE OF INTRACELLULAR Ca^{2+} IN GT1-7 NEURONS. M.A. Javors,* T.S. King, X. Chang. Departments of Psychiatry, Pharmacology, and C&SB, University of Texas Health Science Center, San Antonio, Texas 78284.

Although best known for its effects on platelets, thrombin has been shown to bind to human brain and spinal cord and to produce intracellular biochemical effects through membrane surface receptors. Recently, immortalized GT1-7 neurons, which synthesize and secrete gonadotropin releasing hormone (GnRH), have been developed. The purpose of this study was to characterize thrombin-induced changes in cytosolic $[Ca^{2+}]_{cyt}$ in GT1-7 cells. GT1-7 neurons were loaded with fura-2 for the measurement of $[Ca^{2+}]_{cyt}$. Our results show that thrombin produced increases in $[Ca^{2+}]_{cyt}$ up to approximately 400nM in a concentration dependent manner between 0.025 to 0.2 units/ml. Chelation of extracellular Ca^{2+} with EGTA did not attenuate thrombin-induced $\Delta[Ca^{2+}]_{cyt}$. Indomethacin, an inhibitor of cyclooxygenase and prostaglandin synthesis, did not affect thrombin-induced $\Delta[Ca^{2+}]_{cyt}$. Hirudin, a specific inhibitor of thrombin's serine protease activity, partially inhibited thrombin-induced $\Delta[Ca^{2+}]_{cyt}$. These results suggest that a thrombin receptor on the surface membrane of GT1-7 neurons activates intracellular Ca^{2+} release, but not the entry of extracellular Ca^{2+} .

571.3

REGULATION OF GnRH GENE EXPRESSION BY THE EXCITATORY AMINO ACIDS KAINIC ACID (KA) AND N-METHYL-D,L-ASPARTATE (NMA) IN THE RAT. James L. Roberts* and Andrea C. Gore. Fishberg Ctr. for Neurobiology, Mt. Sinai Med. Ctr., New York, NY, 10029.

The glutamate analogs NMA and KA are involved in the regulation of GnRH and LH release in mammals. Our laboratory and several others have demonstrated that GnRH cytoplasmic mRNA levels increase 1 hour after NMA treatment. We also found that GnRH nuclear transcript levels remain unchanged under these conditions. In the present experiment we examined whether KA affects GnRH gene expression. Adult male rats were implanted with a jugular catheter. One to 2 days later, KA (2 mg/kg i.v.), NMA (14 mg/kg i.v.) or both substances were injected. Saline was injected as a control. Rats were decapitated 15 or 60 min later, the brains removed and the preoptic area dissected on ice and frozen. Cytoplasmic and nuclear RNA were extracted and assayed separately by RNase protection assay. As we previously found for NMA, KA increased cytoplasmic mRNA levels 1 hour after injection by about 30%. In the nucleus, no significant changes in GnRH primary transcript, processing intermediate or nuclear mRNA were observed following KA or NMA treatment. Therefore, excitatory amino acids regulate GnRH mRNA levels in the cytoplasm but not hnRNA levels in the nucleus. Since primary transcript levels presumably reflect GnRH gene transcription, and primary transcript levels do not change in the present study, these studies indicate that the regulation of GnRH gene expression by excitatory amino acids occurs at a post-transcriptional level, probably involving an increase in mRNA stability. We are currently examining the effects of administering KA and NMA together on GnRH gene expression. (Supported by NIH DK-39029).

571.5

THE ROLE OF NITRIC OXIDE IN THE STIMULATION OF LHRH RELEASE BY GLUTAMIC ACID. V. Rettori, A. Kamat and S.M. McCann*. Department of Physiology, The University of Texas Southwestern Medical Center, Dallas, TX 75235-8873.

The principal excitatory transmitter in the CNS is glutamic acid (GA). It is a physiologically significant stimulant of LHRH release. We discovered that norepinephrine-induced LHRH release is mediated by nitric oxide (NO). Consequently, we evaluated the role of NO in the stimulation of LHRH release by GA. Arcuate-median eminence fragments (A-MEs) from adult male rats were preincubated for 30 min in Krebs-Ringer bicarbonate glucose (KRBC) in a Dubnoff metabolic shaker (37°C, 95%O₂/5%CO₂). The A-MEs were then incubated with GA and/or other substances for 30 min. Media were assayed for LHRH by radioimmunoassay. Glutamic acid (10 mM) induced a highly significant release of LHRH which was blocked by the NO scavenger, hemoglobin (Hb, 20 µg/ml) which by itself had no effect on LHRH release. N⁶-monomethyl-L-arginine (NMMA) (300 µM), a competitive inhibitor of NO synthase blocked the action of GA but had no effect by itself. Sodium nitroprusside (500 µM), which spontaneously releases NO, produced a highly significant increase in LHRH release which was blocked by Hb. The results show that GA releases LHRH via stimulation of NO release from NOergic neurons. Whether or not this is an action of GA directly on the NOergic neurons or on them, plus the LHRH terminal, remains to be determined. (NIH grants DK10073 and DK43900).

HOMOLOGOUS REGULATION OF THE GnRH RECEPTOR: EVIDENCE FOR TRANSLATIONAL CONTROL. M. Tsutsumi*¹, S. C. Laws², and S. C. Sealfon³. Fishberg Center in Neurobiology (1,2) and Neurology (2), Mt. Sinai Sch. of Med., New York, NY 10029 and Health Effects Research Lab. (3), US EPA, Research Triangle Park, NC 27711.

Gonadotropin-releasing hormone (GnRH) receptor number either increases or decreases in response to GnRH depending on its concentration and the duration of exposure. The molecular basis of this regulation could involve a combination of modulation of gene transcription, RNA processing, translation, or degradation. To investigate the underlying mechanisms, the homologous regulation of GnRH receptor binding using radioligand binding assay, mRNA levels using solution hybridization/RNase protection assay and Northern blot analysis with the cloned mouse GnRH receptor (Tsutsumi et al., Mol. Endo. 6: 1163, 1992), and mRNA activity using *Xenopus* oocyte based bioassay (Sealfon et al., Mol. Endo. 4: 1980, 1990) was studied in the mouse gonadotrope cell line, α T3-1 cells (Windle et al., Mol. Endo. 4: 597, 1990).

GnRH-A radioligand binding assay results show that treatment of α T3-1 cells with 1 µM concentration of GnRH for 24 hours induce a significant decrease in the number of receptors. Despite changes in receptor number, cytosolic and total GnRH receptor mRNA levels were unchanged. In contrast, the measurements of mRNA activity in oocytes paralleled the changes observed in binding level. These data and the characterization of polysomes associated with GnRH receptor mRNA suggest that homologous regulation of GnRH receptor in this paradigm may occur at the level of translation. REGULATION OF LHRH AND OXYTOCIN GENE EXPRESSION IN CNS SLICE-EXPLANT CULTURES: EFFECTS OF SECOND MESSENGERS. S. Wray, S. Key, S. Bachus* and H. Gainer. Lab of Neurochemistry, NINDS, NIH, Bethesda, MD 20892.

A wide variety of postnatal, differentiated neuroendocrine cells survive and express specific neuropeptide genes in organotypic slice-explant cultures. Utilizing this model system, we are examining the regulation of luteinizing hormone releasing hormone (LHRH) and oxytocin (OT) genes in primary neurons. This *in vitro* model allows us to determine the second messenger system(s) capable of directly affecting these neuropeptide genes and whether all cells within these given phenotypes respond similarly. In this study, we examined the signal transductive pathways in LHRH neurons and OT neurons, by application of 2nd messenger analogs, which could directly alter neuropeptide mRNA levels. Brain slices from pn day 5 rats were cultured as previously described (Wray et al., Neuroendo. 54:327-339, 1991). On the 18th day, experimental cultures were exposed to either: 1) 0.1µM PMA (phorbol ester), 2) 24µM forskolin, 3) 0.1µM PMA + 24µM forskolin, or 4) 24µM forskolin + 0.5 mM IBMX, for either 4, 8 or 24 hrs and then processed for *in situ* hybridization histochemistry. After exposure to emulsion, semi-quantitative, densitometric single cell analyses of LHRH and OT neuronal mRNA levels were done. Preliminary data indicate that forskolin increases LHRH mRNA after 8 hrs but that this increase is reversed after 24 hrs of forskolin exposure (in the presence or absence of IBMX). Further analysis of LHRH and OT neuronal mRNA levels is currently in progress.

GONADOTROPIN-RELEASING HORMONE (GnRH) RELEASE AND EXCITATORY AMINO ACID RECEPTOR SUBTYPES IN MALE RAT DURING AGING. G. Aleppo, M.A. Sortino, U. Scapagnini and P.L. Canonico*. Institute of Pharmacology, University of Catania School of Medicine, Catania 95125, Italy.

Excitatory amino acids (EAAs) are largely recognized to be involved in the neuroendocrine regulation of the hypothalamo-pituitary-gonadal axis function by exerting their action directly at the hypothalamus. Excitatory neurotransmission participates to a variety of physiological and pathological processes also associated with aging. We have investigated the effect of different EAA receptor agonists on the release of GnRH from hypothalamic explants obtained from young (2-3 month-old) and aged (20-24 month-old) Wistar-Kyoto male rats. Basal release of GnRH did not differ in young and aged rats (32±8 and 35.2±5 pg/ml/30 min, respectively). All the hypothalami responded to stimulation of glutamate and α -amino-3-hydroxy-5-methyl-4-isoxazolepropionate (AMPA) to a similar extent, whereas the stimulation of GnRH secretion induced by N-methyl-D-aspartate (NMDA) was lower and that produced by kainate was more pronounced in hypothalami from aged rats (-70 and +161%, respectively). In addition, hypothalami from old rats, in contrast to young rats, when exposed to a maximal concentration of glutamate, were unable to respond to a subsequent challenge with glutamate. The present data suggest a differential involvement of the various glutamate receptor subtypes in the regulation of GnRH response to EAA during aging.

EFFECTS OF N-METHYL-D-ASPARTIC ACID (NMDA) ON LUTEINIZING HORMONE-RELEASING HORMONE (LHRH)-IMMUNOPOSITIVE NEURONS IN THE ARCUATE NUCLEUS OF MALE FERRETS. Y.P. Tang* and C.L. Sisk, Neuroscience Program and Department of Psychology, Michigan State University, East Lansing, MI 48824.

Intravenous injection of NMDA acutely stimulates LH release that is accompanied by a rapid, significant increase in expression of LHRH mRNA (Petersen et al., *Endo*, 129, 1679-81, 1991). The LH response is due to stimulation of neurosecretory activity of LHRH neurons projecting to the median eminence (ME). This study examined the effect of NMDA on LHRH neurons in the arcuate nucleus (ARC) of ferrets, since earlier studies indicated a functional heterogeneity within this population of neurons. In addition, to determine whether potential effects of NMDA might be selective to ME-projecting LHRH neurons, peripheral administration of the retrograde tracer Fluorogold (FG) was used to label neurons with axonal projections outside the blood brain barrier, e.g., the ME. Adult male ferrets received an iv infusion of either NMDA (10 mg/kg) or saline (SAL) on 2 consecutive days; an ip injection of FG (2.5 mg/kg) was given 10 min prior to each iv infusion. Ferrets were sacrificed 10 days after the second NMDA or SAL treatment. ARC LHRH cells were immunocytochemically identified using a rhodamine-tagged secondary antibody. The mean number of ARC LHRH neurons that did not contain FG was significantly larger in the NMDA group compared to the SAL group ($p < 0.05$). This resulted in a significantly lower proportion of ARC LHRH neurons that were FG-labeled in NMDA-treated ferrets compared to SAL-treated ferrets ($84.9 \pm 0.5\%$ vs $94.1 \pm 2.2\%$; $p < 0.05$). These results suggest that NMDA may stimulate LHRH synthesis in a subset of ARC neurons that do not project to ME, and provide additional evidence for heterogeneity among ARC LHRH neurons. EFFECTS OF ENDOTHELIN-1 AND -3, NOREPINEPHRINE, ANGIOTENSIN II, AND ARGININE VASOPRESSIN ON LHRH RELEASE IN MONKEY HYPOTHALAMI *IN VITRO*. A.M. Miller, D. Mitsushima, K. Hartberg, and E. Terasawa, Reg. Primate Res. Ctr., Univ. Wisconsin, Madison, WI 53715

Previously we have found that norepinephrine (NE) and neuropeptide Y (NPY) stimulate *in vivo* release of LHRH in the rhesus monkey. Since both NE and NPY are vasoconstrictors, we have hypothesized that vasoactive substances, especially vasoconstrictors, are generally stimulatory to LHRH release. To test this hypothesis, we examined the effects of various vasoactive substances, i.e. NE, endothelin-1 and -3 (ET-1 & ET-3), angiotensin II (Ang-II), arginine vasopressin (AVP), and galanin (GAL) on LHRH release from monkey hypothalami *in vitro* using a perfusion system. Tissue comprised of the stalk-median eminence and a small portion of the MBH was obtained from the Tissue Distribution program of WRPRC. The tissue was bisected sagittally at the midline, and placed into separate perfusion chambers kept at 37 °C. A defined medium with 95% O₂ and 5% CO₂ was infused through the chambers at a rate of 50 µl/min, and perfusates were collected at 10-min fractions. The test substances at various doses were infused for 10 min at 60-90 min intervals, and 56 mM K⁺ was challenged at the end of experiment to test tissue viability. LHRH in perfusates was measured by RIA. Results: 1) ET-1 at doses of 10⁻⁶, 10⁻⁷, 10⁻⁸, and 10⁻⁹ M stimulated LHRH release in a dose responsive manner, with a peak occurring at 10-20 min after the initiation of ET-1 infusion, while ET-3 did not cause significant effects; 2) Ang-II at 10⁻⁸ M stimulated LHRH release with a peak at 10 min; 3) AVP at 10⁻⁵ and 10⁻⁷ M also stimulated LHRH release with a peak at 10 min; 4) NE at 10⁻⁷ M clearly increased LHRH release; 5) GAL (10⁻⁵ to 10⁻⁹ M) did not cause consistent results. These results indicate that all vasoconstrictors examined except ET-3 are stimulatory to LHRH release, while a non-vasoconstrictor, GAL, was not. The mechanisms of action of vasoactive substances on LHRH release remain to be determined. (Supported by NIH grants HD15433, HD11355 & RR-00167).

ESTROUS CYCLE STAGE-DEPENDENT EFFECTS OF NEUROPEPTIDE Y (NPY) ON LHRH-STIMULATED LH AND FSH SECRETION FROM ANTERIOR PITUITARY FRAGMENTS *IN VITRO*. A.C. Bauer-Dantoin, K.L. Knox, N.B. Schwartz and J.E. Levine, Dept. of Neurobiology & Physiology, Northwestern University, Evanston, IL 60208.

We recently demonstrated that NPY potentiates LHRH-stimulated LH secretion *in vivo*, and that these actions of NPY are exerted only under the endocrine conditions leading to preovulatory LH surges. The present experiments tested the hypothesis that NPY's facilitatory actions are exerted directly at the level of the anterior pituitary gland (AP) and depend on *in vivo* exposure of gonadotropes to the preovulatory endocrine milieu. Animals were sacrificed at 1600h on either metestrus (MET) or proestrus (PRO). APs were rapidly removed, cut into eighths, and placed into perfusion chambers. APs were perfused with M199 for a total of 8 hours, and perfusate samples were collected every five minutes. After thirty minutes of equilibration, APs received hourly pulses of LHRH alone (10⁻⁶ M), NPY alone (10⁻⁶ M), or LHRH + NPY. Basal runs consisted of perfusion with M199 for 8 hours with no peptide treatments. Calculations of total hourly LH and FSH responses revealed that while LHRH significantly stimulated gonadotropin secretion from both MET and PRO pituitaries, NPY significantly enhanced LHRH-stimulated LH and FSH secretion only from PRO pituitaries, i.e. from tissue exposed to the endogenous endocrine milieu under which preovulatory gonadotropin surges are generated. NPY had no facilitatory effect on LHRH-induced gonadotropin secretion from MET APs. These results are consistent with our previous *in vivo* findings, and demonstrate that the facilitatory actions of NPY on LHRH-stimulated gonadotropin secretion *in vitro* are limited to the endocrine conditions under which preovulatory gonadotropin surges are generated (HD 20677, HD 28048, DK 08513, HD 21921).

ESTRADIOL AND ANDROGEN MODULATE LHRH RELEASE *IN VITRO*. Q. Li*, L. Tamarin, P.L. Levantine, and M.A. Ottinger, University of Maryland, College Park, MD 20742.

In vitro release of LHRH was studied during steroid exposure. Longitudinal slices (1mm) of medial basal hypothalamus (MBH) taken from young adult male Japanese quail were placed in short term perfusion in Media 199. Both pulsatile and norepinephrine (NE; 10⁻⁶ M) stimulated chicken LHRH-I (cLHRH-I) secretion were monitored. Release of cLHRH-I from MBH occurred in a pulsatile manner (average number of pulses = 2.09 ± 0.13 pulses/hr over 9.25 hrs of incubation with an amplitude of 4.03 ± 0.07 pg; n=6). cLHRH-I release significantly ($p < 0.05$) increased to a peak of 22.89 ± 1.06 pg with challenge by NE (15 min at hour 6 of perfusion). In a separate experiment, MBH slices were exposed to 17β estradiol (E; 10⁻⁶ M), 5α-dihydrotestosterone (5α-DHT; 10⁻⁷ M), or testosterone (10⁻⁷ M) during the perfusion. The effects of these steroids on NE stimulated cLHRH-I release revealed that short term E exposure significantly ($p < 0.01$) potentiated NE-induced cLHRH-I release. Testosterone and 5α-DHT did not affect NE stimulated cLHRH-I release. Static pretreatment of MBH slices with E (10⁻⁶ M) for 14 hours prior to perfusion significantly ($p < 0.05$) reduced the NE-induced cLHRH-I release. These results suggest that the avian hypothalamic LHRH-I pulse generating mechanism is located within the MBH. Further, these data provide evidence that E has dual effects on NE stimulated release relative to length of exposure.

BLOCKADE OF ENDOGENOUS OPIATES INCREASES PULSE DURATION, AMPLITUDE, AND INTERPULSE SECRETION OF GnRH IN THE OVARIECTOMIZED EWE. D.B. Parfitt*, N.P. Evans, G.E. Dahl and F.J. Karsch, Neuroscience Program, Reproductive Science Program, and Department of Physiology, University of Michigan, Ann Arbor, 48109.

Endogenous opioid peptides are postulated to inhibit gonadotropin-releasing hormone (GnRH) secretion. Previous studies, in which 10-min samples of pituitary portal blood were obtained from ovariectomized ewes, demonstrated that naloxone (an opiate receptor antagonist) increased the amplitude of GnRH pulses but did not alter GnRH pulse frequency. The present study employed rapid sampling of pituitary portal blood to characterize the effect of endogenous opiates on the shape, duration, and frequency of GnRH pulses. Ovariectomized ewes (n=4) were implanted with an apparatus for collection of pituitary portal blood. One week later, portal blood samples were collected at 1-min intervals for 4 hr immediately before and during a 4 hr naloxone infusion (1mg/kg, iv); jugular blood samples were obtained at 10-min intervals to monitor episodic luteinizing hormone (LH) secretion. Naloxone administration increased ($p < 0.01$) GnRH pulse duration from 9.0 ± 0.9 min/pulse to 16.2 ± 1.6 min/pulse, and increased ($p < 0.05$) the maximal GnRH value during a pulse from 14.6 ± 3.0 to 27.5 ± 5.2 pg/min. In addition, naloxone tripled ($p < 0.05$) detectable GnRH secretion between pulses from 0.2 ± 0.1 pg/min to 0.6 ± 0.1 pg/min. Naloxone did not alter GnRH or LH pulse frequency, but an increase in the amplitude of LH pulses was observed after naloxone. These results suggest that opiate inhibition of GnRH secretion acts through a mechanism which limits the amplitude and duration of GnRH pulses, as well as restraining interpulse GnRH secretion in the ovariectomized ewe. (Supported by NIH HD18337; HD18258; MH14279).

LOCALIZATION OF NEUROPEPTIDE-Y (NPY) IMMUNOREACTIVE (ir) NEURONS WHICH PROJECT TO AREAS CONTAINING GnRH NEURONS. T.M. McShane*, P.M. Wise, and L. Jennes, Dept. of Physiology and Biophysics, and Dept. of Anatomy, Univ. of Kentucky, Lexington, KY 40536

NPY is reported to play an important role in the regulation of GnRH secretion. NPY-ir is widely distributed throughout the CNS, with cell bodies located in several areas including cortex, hippocampus, amygdala, brainstem, and a high density of perikarya in the hypothalamic arcuate nucleus. The medial septum-diagonal band complex (MSDB) contains GnRH cell bodies and receives innervation from NPY neurons, however, the source(s) of this innervation is unclear. We used retrograde transport of fluorescent tracers combined with immunofluorescence to identify the location of NPY neurons that project to the regions containing GnRH perikarya. Among several areas investigated, we detected colocalization of retrograde tracer and NPY-ir in neuronal cell bodies within the noradrenergic cell group A1 and amygdala. Our results indicate that GnRH-neuron containing regions receive NPY innervation from anatomically, and probably functionally, heterogeneous sources. DISTRIBUTION OF VARIANT FORMS OF GnRH AND GTH IN THE BRAIN AND PITUITARY GLAND. L. Magliulo-Cepriano and M.P. Schreiber*, Graduate School-University Center and Brooklyn College Biology Department, C.U.N.Y., Brooklyn, New York 11210.

Immunoreactive (ir)-lamprey (l), mammalian (m), chicken II (chII), and salmon (s) gonadotropin-releasing hormone (GnRH) and ir-beta gonadotropin (GTH) I and II, have been localized in the brain and pituitary of *Xiphophorus maculatus*, the platyfish, at various stages of sexual development. Ir-GTH I was found in the pituitary of all stages examined. Ir-GTH II was seen only in pubertal and mature animals. Ir-sGnRH and -mGnRH were seen in the pituitary of all stages and in the brain of pubertal and mature animals. Ir-lGnRH was seen in the pituitary all stages studied but never in the brain. Ir-chIIGnRH was absent in all immature stages but seen in both the brain and pituitary of mature animals. Our results demonstrate that variant forms of GnRH and GTH are present at defined stages of development in specific regions of the brain and pituitary gland and suggest that different forms of GnRH and GTH regulate different aspects of reproductive system development and physiology. ANATOMICALLY AND BIOCHEMICALLY DISTINCT POPULATIONS OF GnRH-IR NEURONS ARE ASSOCIATED WITH DIFFERENT NEUROTRANSMITTERS. T.L. Dellovade*, V. Alones, and E.F. Rissman Dept. of Biology, NSF Center for Biological Timing, UVA, Charlottesville, VA 22903

The musk shrew (*Suncus murinus*) has three populations of GnRH-ir neurons which may be modulated by different neurotransmitter systems. The most rostral group is in the olfactory forebrain and contains the mammalian form of GnRH (mGnRH). Neurons containing GnRH-ir are present in the terminal nerve and ganglia (TN), the accessory olfactory bulb (AOB), and the taenia tecta (TT). Exposure to male chemical cues causes a 30-40% increase in the numbers of GnRH-ir cell bodies in this region. The AOB contains tyrosine hydroxylase (TH) neurons and fibers. The TN contains choline acetyltransferase (ChAT) and TH-ir fibers. The TT contains ChAT-ir fibers and is richly innervated by TH-ir fibers. The second major group of GnRH-ir neurons resides in the continuum between the vertical and horizontal limb of the diagonal band of Broca (DB), the medial septum (MS), preoptic area (POA), and is scattered in the hypothalamus (HT). These cells also contain mGnRH. GnRH-ir cell counts in this area vary relative to ovulation. This region is rich in ChAT-ir somata. The POA contains TH-ir cell bodies and fibers. The most caudal population of GnRH cells, residing in the linear caudal raphe (CLi), contains the chicken II form of GnRH (cGnRH II). These cells do not contain GnRH in any other mammal, however, a homologous population is present in several species of birds, amphibians and fishes. TH-ir cells and fibers are present in the central gray just dorsal to the GnRH-ir neurons. Also, TH-ir neurons and fibers reside in the CLi and ventral to it in the substantia nigra. TH-ir fibers appear to contact GnRH-ir cell bodies in the CLi. This work was supported by NSF grant BNS 9021226.

BINDING AND INTERNALIZATION OF FITC-LABELED NEUROTENSIN IN A SUB-POPULATION OF GnRH-CONTAINING NEURONS: A CONFOCAL MICROSCOPIC ANALYSIS. A. Beaudet*, K. Leonard, M.P. Faure, R.I. Weiner and G.C. Desjardins. Montreal Neuro. Inst. Montreal, Qué., Canada H3A 2B4 and Dpt. OBS/GYN, UCSF, CA 94143.

Several lines of evidence suggest that neurotensin (NT)-containing neurons in the rostral preoptic area mediate some of the stimulatory effects of estrogens on gonadotropin-releasing hormone (GnRH) secretion (Alexander et al., 1989). To determine whether this effect is exerted through a direct action of NT upon preoptic GnRH neurons, we have examined the binding and internalization of FITC-labeled NT (NT-FITC) to GnRH neurons: (1) in an immortalized GnRH producing cell line (Mellon et al., 1990) and (2) in slices of rat hypothalamus. GT1-7 cells were grown in DMEM for 10 days and incubated for 40 min. at 4°C and 37°C with 20 nM NT-FITC. All cells were then rinsed in buffer, fixed in paraformaldehyde and processed for GnRH immunocytochemistry using indirect immunofluorescence. Hypothalamic slices (350µm) were maintained at 35°C in oxygenated ringer, preloaded with 50nM of NT-FITC for 3 min, superfused with ringer for 30 min., fixed with 4% paraformaldehyde, and resectioned at 40 µm for GnRH immunostaining. All GT1-7 neurons showed intense GnRH immunostaining. A subset of these (30%) concomitantly exhibited NT-FITC labeling. The latter was mainly pericellular in sections incubated at 4°C and present throughout the cytoplasm at 37°C, in keeping with the occurrence of temperature-dependant ligand internalization. A small proportion of GnRH-immunoreactive neurons in slices of the preoptic area similarly internalized NT-FITC, indicating that they also harbored NT receptors. Taken together, these results indicate that a sub-population of rat GnRH neurons express NT receptors and suggest that NT-mediated effects on GnRH secretion may be exerted directly.

571.14

PRIMARY STRUCTURE AND BIOLOGICAL ACTIVITY OF A THIRD GONADOTROPIN-RELEASING HORMONE FROM LAMPREY BRAIN

S. A. Sower*, Y.C. Chiang¹, S. Lovas² and J. M. Conlon²

¹Dept. of Biochem. & Molec. Biol., Univ. of New Hampshire, Durham, NH, 03824 and ²Dept. of Biomed. Sci., Creighton Univ. School of Medicine, Omaha, NE 68178

Previous studies have led to the identification of two molecular forms of gonadotropin-releasing hormone (GnRH-I and II) in the brain of the sea lamprey, *Petromyzon marinus*. We have now isolated a third molecular form of GnRH (GnRH-III) from the brain of this species that is different from GnRH-I and -II. The primary structure of GnRH-III is pGlu-His-Trp-Ser-His-Asp-Trp-Lys-Pro-Gly-NH₂. A synthetic decapeptide with this amino acid sequence was chromatographically identical to natural GnRH-III.

Intraperitoneal injection of synthetic lamprey GnRH-III (0.1 µg/g) produced a significant elevation of plasma progesterone (31% over basal values) in female lampreys that was comparable to that produced by the same dose of lamprey GnRH-I (36% over basal). The elevation in plasma estradiol produced by lamprey GnRH-III (244% over basal) was significantly less than the elevation produced by GnRH-I (322% over basal). We propose based on the biological activity of lamprey GnRH-III in these studies and the occurrence of this peptide during metamorphosis in lampreys, that both lamprey GnRH-I and -III are neurohormones involved in reproduction in lampreys. (Supported by NSF #DCB-9004332 and DCB-8904919 and the Great Lakes Fishery Commission to SAS).

ENKEPHALINS MODULATE MEDIAN EMINENCE GnRH RELEASE THROUGH A DOPAMINERGIC MECHANISM: A MORPHOLOGICAL EVIDENCE. F. Vandembulcke, P. Ciofi, I. Dutriez, D. Deneux, J.C. Beauvillain*. U156 INSERM, Place de Verdun, 59045 Lille cedex (France).

The presence of enkephalinase (neutral endopeptidase, NEP, E.C.3.4.24.11) in membranes of nerve endings in the rat median eminence (ME) (*J. Neuroendocrinol.* 5(1993)205) suggests that neuropeptides, target for NEP, have paracrine and/or autocrine actions in this region. Although NEP is capable of hydrolysing *in vitro* a variety of regulatory peptides, *in vivo* studies indicate that in the brain this enzyme seems essentially implicated in the biological inactivation of enkephalins (ENK). The modulation of gonadoliberin (GnRH) release is one of the documented actions of ENK in the ME. However, it is at present unclear whether ENK act through dopamine (DA) endings, or directly on GnRH endings, or both.

As technical parameters and particularly the tissue fixation used to radioimmunodetect NEP with ¹²⁵I-labeled monoclonal antibodies are compatible with immunoperoxidase detection of GnRH and tyrosine-hydroxylase (TH), an ultrastructural pre-embedding double immunolabeling study was performed to determine if GnRH- and TH-containing nerve endings have NEP inserted within their plasma membrane, as visualized after radioautographic exposure of dipped, GnRH- or TH-stained ultrathin sections, by the presence of silver grains located over membrane appositions.

Results show that 60% TH-immunoreactive (ir) boutons display one or several grains over their membranes and that 27% GnRH-ir endings displayed one, but never more, silver grain, and this only in cases of apposition with other peroxidase-unstained nerve endings.

These observations are in favor of a location of NEP on TH-ir but not GnRH-ir nerve terminals and consequently provide morphological arguments 1) suggesting a paracrine and/or autocrine action of ENK on tuberoinfundibular DA nerve endings and 2) making it unlikely that the same opioid peptides act directly on GnRH periportal endings.

571.18

LACK OF EXPRESSION OF SEROTONIN RECEPTOR SUBTYPE mRNAs IN GONADOTROPIN RELEASING HORMONE PRODUCING NEURONS OF THE RAT. D.E. Wright* and L. Jennes. Dept. Anatomy and Neurobiology, Univ. of Kentucky Medical Center, Lexington, KY 40536-0084.

Serotonin is one of the neurotransmitters believed to participate in the regulation of gonadotropin-releasing hormone (GnRH) release at the level of the GnRH neuron. We therefore examined whether GnRH neurons produce mRNA encoding for the serotonin 1A, 1C, and 2 receptor subtypes using dual "in situ" hybridization. In the medial septum-diagonal band and rostral preoptic area, GnRH neurons were identified with digoxigenin-UTP labeled riboprobes. The number and distribution of GnRH mRNA-containing cells were similar to the GnRH neurons that were identified with a ³⁵S labeled riboprobe or with GnRH immunocytochemistry. Cells expressing serotonin 1A, 1C, and 2 receptor mRNA were detected with ³⁵S labeled riboprobes; all three receptor subtype riboprobes labeled select cells with distinct distributions in the medial septum-diagonal band and rostral preoptic area. However, no cells were detected that contain both GnRH mRNA and serotonin receptor mRNA in ovariectomized and ovariectomized-estrogen treated rats. In contrast, select GnRH neurons were detected that express mRNA for galanin. These results suggest that the effects of serotonin on GnRH release are not mediated by direct activation of serotonin 1A, 1C, and 2 receptors on GnRH neurons, but instead through other, yet unidentified serotonin receptor subtypes or through non-serotonergic intermediary neurons. Supported by NIH HD24697.

SEX-STEROID-DEPENDENT CHANGES IN THE MORPHOLOGY OF LUTEINIZING HORMONE-RELEASING HORMONE NEURONS IN THE MALE SYRIAN HAMSTER. H.F. Urbanski* and N.M. Lew. Division of Neuroscience, Oregon Regional Primate Research Center, Beaverton, OR 97006.

The luteinizing hormone-releasing hormone (LHRH) neurons of Syrian hamsters show morphological changes during puberty and also in response to changes in photoperiod. The aim of the present study was to examine the extent to which perikaryal size of LHRH neurons is dependent upon the sex-steroid environment. Adult male Syrian hamsters were orchidectomized and received either empty or testosterone-filled Silastic capsules, subcutaneously. All of the animals, plus intact controls, were killed 10 days later. Their brains were fixed with 4% paraformaldehyde, sectioned coronally with a Vibratome (50 µm), and processed for immunocytochemistry using a monoclonal antibody to LHRH (HU4H). Detailed morphometric analysis of the immuno-positive perikarya, using an IBAS 2000 image analyzer, revealed a significant decrease in size associated with removal of the testes (ca. 15% for mean surface area and 8% for mean diameter). In contrast, the mean plasma levels of luteinizing hormone and follicle-stimulating hormone increased markedly (>700%). Moreover, development of these neuronal and endocrine post-castration events was significantly inhibited in the testosterone-treated animals. Taken together, these findings demonstrate the existence of a negative feedback relationship between sex steroids and LHRH-secreting neurons which is manifested at the perikaryal level. It is suggested that enhancement of LHRH secretion after orchidectomy leads to a significant depletion of neuropeptide reserves which can be detected within the neuronal cell body as a decrease in the extent of immuno-positive staining.

ULTRASTRUCTURAL CHARACTERISTICS OF GnRH NEURONS IN PREPUBERTAL MALE RATS. J.W. Witkin, M-T. Romero*, A-J. Silverman, Dept. Anat. & Cell Biol., Columbia Univ., New York, NY 10032

The attainment of sexual maturity is dependent upon the appropriate functional integration of the hypothalamic-pituitary-gonadal axis. We compared the ultrastructural characteristics of GnRH neurons in prepubertal males (S-D rats, 20-23 d.o.) with those in sexually mature animals. GnRH immunoreactivity was demonstrated (LR1 antibody) and tissues examined electron microscopically (as in Witkin, '92, J. Neuroendocrinol. 4:428). Unlike sexually mature animals, in which the reaction product was characteristically scattered in the cytoplasm, in the prepubertals it was also heavily deposited in secretory granules. We quantified the synaptic input to a sample of 38 GnRH neurons from the preoptic area of 9 animals. The synaptic input to the GnRH neuronal soma was significantly less than that observed in adult rats, which itself is very sparse in comparison with other neurons in the same brain regions. Most strikingly, of the GnRH neurons examined, 6 had synapsing GnRH terminals on the cell body. This is in contrast to all of our earlier studies, in which although occasional GnRH-immunoreactive synapses were seen on GnRH dendrites, they were very rarely found on the GnRH soma. These findings suggest that the connectivity of the GnRH neuronal system alters with sexual development. AG05366 (JWW); DK42323 (AJS, JWW)

HYPOTHALAMIC-PITUITARY-GONADAL REGULATION: GONADOTROPINS, NEUROPEPTIDES, STEROIDS

572.1

GONADOTROPIC MODULATION OF ESTROUS AND HYPOTHALAMIC-PITUITARY-ADRENAL (HPA) AXIS FUNCTION IN THE LEW/N AND F344/N RAT. C.C. Smith, G. Cizza, M. Gomez, C. Greibler, P.W. Gold, and E.M. Sternberg*. Clinical Neuroendocrinology Branch, Nat'l. Inst. of Mental, Bethesda, MD 20892.

We have previously shown that LEW/N and F344/N rats' relative inflammatory disease susceptibility and resistance are associated with their relative HPA axis hypo- and hyperresponsiveness. In light of correlates linking gonadal hormone levels to HPA axis function, and a sexually dimorphic basis for differential stress and behavior, we examined the duration of estrous utilizing vaginal smears, and determined estradiol (E), progesterone (P), LH, and FSH plasma levels at the different phases of the estrous cycle in these two strains. LEW/N rats exhibit a trend towards a shorter estrous cycle relative to F344/N. Comparison of the duration of the component phases of estrous shows LEW/N rat metaestrous to be significantly longer than F344/N, while diestrous and estrous were significantly shorter. Proestrous was identical. Overall levels of E in LEW/N were significantly greater than in F344/N, however, only E in the estrous phase of the LEW/N cycle reached statistical significance compared to F344/N. Overall levels of P in the LEW/N rat were also significantly greater than in F344/N. The diestrous, proestrous, and estrous components of the LEW/N cycle had significantly greater P: metaestrous demonstrated a trend towards being greater. LH levels in the LEW/N rat were overall significantly greater than in F344/N, however, none of the component phases individually reached significance. FSH levels in the two strains did not differ. We conclude that the elevated levels of E and P observed in LEW/N rats could potentially affect gonadotropic and corticotropic systems at several levels. Direct E upregulation of GnRH could contribute to the elevated LH in LEW/N rats. Elevated E can also upregulate ACTH and cort through downregulation of MR and GR receptors. P can act stoichiometrically to competitively bind as an antagonist to MR and GR sites, also potentially upregulating ACTH and cort. However, the blunted ACTH and cort response in LEW/N rats suggests a failure of E and P to induce upregulation of ACTH and cort, and implies that gonadotropic actions in this strain are secondary to CRH hyporesponsivity.

572.3

INCREASED NEUROKININ B GENE EXPRESSION IN THE HYPOTHALAMUS OF LONG TERM OVARIETOMIZED RATS. N.E. Rance* and T.R. Utton. Departments of Pathology, Anatomy and Neurology. University of Arizona College of Medicine, Tucson, AZ 85724.

Hypertrophy and increased gene expression of tachykinin neurons occurs in the infundibular (arcuate) nucleus of postmenopausal women (Rance et al., *J. Clin. Endo. Metab.*, 71:79, 1990; Rance and Young, *Endocrinology*, 128:2239, 1991). To test whether these changes could be secondary to ovarian failure, we used *in situ* hybridization to examine neurons containing neurokinin B (NKB) and substance P (SP) mRNAs in the rat arcuate nucleus after ovariectomy. We examined four groups: intact proestrus (PRO); intact diestrus (DD1); 2 month ovariectomized (OVX); and rats which were injected with estradiol valerate two months prior to sacrifice to produce constant estrous (CE). Computer microscopy was used to determine cell profile areas, the number of tachykinin neurons and autoradiographic grain density of labeled neurons. We report marked changes in NKB gene expression among the various groups. The number of neurons expressing NKB gene transcripts was significantly greater in OVX rats (16.9 ± 1.2 labeled neurons/arcuate section, mean \pm SEM), than PRO (8.9 ± 1.2), DD1 (4.8 ± 1.2) or CE (2.9 ± 1.3) rats. In addition, the grain density of NKB neurons was almost doubled in the OVX group relative to all other groups. Finally, the mean profile area of NKB arcuate neurons was larger in conditions where blood levels of estrogen were low (DD1 and OVX) compared to PRO and CE rats. In contrast, the only change in SP arcuate neurons was atrophy in the CE rats. These data support the hypothesis that neuronal hypertrophy and increased NKB gene expression in the hypothalamus of postmenopausal women is due to ovarian failure. (NIH AG-09214 and ADRCC R-029)

572.2

CHARACTERIZATION OF CHRONIC ESTRADIOL TREATMENT IN VERVET MONKEYS. G.C. Desjardins*, J.R. Brawer, A. Beaudet and M.J. Meaney. Develop. Neuroendocrinology Lab., Douglas Hosp. Res. Center, Dept. of Psychiatry, McGill University, Montreal, Quebec, CANADA H4H 1R3.

Previous studies in the rodent have shown that chronic exposure to physiological levels of estradiol induced a series of hypothalamic-pituitary deficits which ultimately result in anovulatory polycystic ovaries (Brawer, 1990). Fundamental to this cascade, is the demonstration that 60% of hypothalamic beta-endorphin neurons degenerate in the 8 weeks following estradiol exposure (Desjardins, 1993). In order to investigate whether chronic estradiol exposure would result in similar effects in primates, 12 female vervet monkeys (St-Kitts, Behav. Sci. Foundation) were implanted with chronic release capsules containing 25mg of estradiol and yielding plasma estradiol concentrations of approximately 400 pg/ml. Estradiol (E₂)-implanted and cage-mate controls were sacrificed by anesthetic overdose and perfused with PBS. Ovaries from E₂-implanted animals displayed poor follicular development, occasional cysts and small atretic secondary follicles and were completely devoid of corpora lutea indicating a recent prolonged period of anovulation. In contrast, most controls exhibited the full range of normal follicular development, including large corpora lutea. Hypothalamic beta-endorphin concentrations were significantly reduced in the E₂-implanted animals as compared to controls (157 ± 91 vs 806 ± 356 pg/mg wet weight, respectively; $n=3$; $p<0.05$). In contrast, hypothalamic dynorphin concentrations were equivalent in both groups (8.32 ± 0.17 vs 11.93 ± 3.4). Spearman's correlational analysis of beta-endorphin concentrations versus degree of ovarian pathology indicated that these were inversely related. These studies indicate that chronic E₂-exposure in vervet monkeys results in hypothalamic and ovarian changes consistent with the E₂-induced degeneration of beta-endorphin neurons previously documented in rodents.

572.4

LHRH AND LH GENE EXPRESSION IN THE NEONATALLY ESTROGENIZED FEMALE RATS. E.S. SONG, S.H. CHO AND K. Kim*. Dept. of Molecular Biology, Coll. of Natural Sci., Seoul Nat'l Univ., Seoul 151-742 Korea.

The neonatal treatment of sex steroids such as estrogen induces sterility in female rats: Animals are characterized with tonic release of gonadotropin and fail to ovulate. Neonatal estrogenization is a useful model for analyzing interaction between LHRH and gonadotropin during the development. To delineate the mechanism underlying the neonatally induced sterilization, the present study examined LHRH biosynthesis in the hypothalamus and LH biosynthesis in the pituitary derived from the neonatally estrogenized (17β -estradiol, 10 µg, for 1-5 days after birth) sterile rats (ESR) at 50 days of age. LH mRNA levels were lower than those of intact rats, the amount of LHRH mRNA and LHRH content were significantly higher than those of control animals. During the perinatal period in which the LHRH neuronal system is organized, neonatal treatment with estrogen appears to modify the LHRH neuronal system. This study suggests that the sterility induced by estrogen is not due to aberrant synthesis of LHRH in the preoptic area but probably due to abnormal LHRH release from the mediobasal hypothalamus.

AROMATASE-IMMUNOREACTIVE CELLS ARE PRESENT IN THE MOUSE AND RAT BRAIN AREAS THAT EXPRESS HIGH LEVELS OF AROMATASE ACTIVITY. A. Foidart*, P. Absil, N. Harada and J. Balthazard, Lab. Biochemistry, Univ. Liège, B-4020 Liège, Belgium and Fujita Health University, Molecular Genetics, Toyoko, Aichi 470 11, Japan.

The aromatization of testosterone (T) into estradiol in the brain was discovered more than 20 years ago but it has been so far impossible to precisely localize the cells of the mammalian brain containing the enzyme aromatase which catalyzes this important aspect of T metabolism. We recently designed an immunocytochemical technique which allows the visualization of aromatase-immunoreactive (ARO-ir) cells in the quail brain. In this species, a marked increase in the optical density of ARO-ir cells was observed in subjects that had been treated with the aromatase inhibitor, R76713 or racemic vorozole. This increased immunoreactivity, associated with a total blockade of aromatase activity (AA), is unexplained at present but it was used as a tool in the present study in which the distribution of ARO-ir material was reassessed in the brain of mice and rats that had been pretreated with R76713. As expected, the aromatase inhibitor increased the density of the immunoreactive signal. In both species, strongly immunoreactive cells were found in the lateral septal region, in the bed nucleus of the stria terminalis, in the central amygdala and in the dorso-lateral hypothalamus. A slightly lighter signal was also present in the medial preoptic area, in the nucleus accumbens, in several hypothalamic nuclei (e.g. paraventricular and ventromedial nuclei), in all divisions of the amygdala and in several regions of the cortex, especially in the cortex piriformis. A lighter label was also detectable in many other regions. These data demonstrate that, contrary to previous claims, ARO-ir cells are present in all brain regions that contain a high AA. These had not been detected before either because the techniques were not sensitive enough or the antibodies that were used had a different specificity. There is, in fact, a good correspondence between the distribution of AA and of ARO-ir cells in the mammalian brain as previously demonstrated in quail. The intensity of the immunostaining in mice and rats is however not always directly related to the level of AA which suggests that either different forms of aromatase are present in the brain or that the subcellular distribution of the enzyme in some brain regions (e.g. preferential localization in fibers and presynaptic terminals) prevents its detection by the present technique.

AUGMENTED LH AND FSH SECRETORY RESPONSE TO A LOW DOSE OF GONADOTROPIN-RELEASING HORMONE (GnRH) IN OLDER VERSUS YOUNG MEN. A.D. Zwart, R.J. Urban, M.O. Thoner, J.D. Veldhuis, Department of Internal Medicine, Division of Endocrinology and Metabolism, University of Virginia, Charlottesville, VA.

LH and FSH secretion is regulated by GnRH. As men age, there is an increase in level of gonadotropins, while testosterone slowly declines. We have assessed the dose-dependent response of LH and FSH to GnRH in older (10) and young (9) men, who received 5 iv boluses of GnRH (range 10 to 100 ug) 2 hours apart. LH and FSH were measured every ten minutes for 12 hrs including a 2 hr baseline. Deconvolution analysis was performed to estimate gonadotropin secretory burst mass, amplitude, duration and LH/FSH half-life. Mean \pm SEM 2 hr baseline serum LH (IU/L) was not different in older vs young men (3.7 ± 1.7 vs 2.1 ± 0.3) while mean FSH was (5.9 ± 2.5 vs 3.8 ± 1.5 , $P < 0.05$). Mean 2 hr LH responses were higher in older men ($P < 0.05$) for the 25, 50 and 75 ug doses. Mean 2 hr FSH responses were also higher for 10 and 25 ug GnRH. LH and FSH half-lives were not significantly longer in the older men. No difference was seen in gonadotropin pulse duration. The increase in LH mass from the 10 ug dose to the 25 ug dose was higher in older men (5.2 IU/L vs 0.78 , $P < 0.05$). The mass of FSH secreted in response to 25 ug was higher in older men (4.0 IU/L vs 1.6 in young men, $P < 0.05$). FSH mass and amplitude increases secreted after 25 vs 10 ug GnRH also were higher in older men ($P < 0.01$). We conclude that gonadotropin secretory responses to GnRH in older men show increased sensitivity specifically to low doses of GnRH with no evident differences in maximal release rates, LH or FSH half-life, or burst duration. Whether these changes are due to diminished gonadal feedback or altered hypothalamic pituitary control mechanisms in healthy aging is not known.

NEUROENDOCRINE REGULATION: CATECHOLAMINE AND GABA

573.1

EXPRESSION OF D2 RECEPTORS COUPLED TO POTASSIUM CURRENTS IN GH4C1 CELLS EXPOSED TO EGF. R. Gardette*, R. Rasolonjanahary, C. Kordon and A. Enjalbert, INSERM U159, Paris

GH4C1 cells, a clonal cell line from a rat pituitary tumor, serve as a model to study the excitatory regulation of prolactin secretion. These cells however lack dopamine D2 receptors and are not suitable for exploring dopamine inhibition of prolactin secretion. Recently it has been shown that epidermal growth factor (EGF) is able to induce functional expression of D2 receptors in GH3 cells, a parental clonal cell line (Missale et al., *Endocrinology* 128, 1991).

We have undertaken a whole-cell patch-clamp study in order to check whether expression of D2 receptors coupled to potassium channels could be restored in GH4C1 cells exposed to EGF. Effects of dopamine on the non-inactivating voltage-dependent outward potassium current I_K were investigated both in control and in GH4C1 cells treated with EGF (10^{-9} M) for at least 4 days. The potassium current was not modified by EGF treatment by itself. In control cells, I_K current measured before and during dopamine application (100nM) was not changed. In contrast, dopamine markedly enhanced the potassium current in 69% of the EGF-treated cells (mean increase: $42 \pm 8\%$, $n=11$), without changing activation threshold. This effect was mimicked by the specific D2 receptor agonist bromocriptine (100nM) and blocked by sulpiride (1 μ M), a D2 receptor antagonist, indicating that the effect of dopamine was effectively due to the activation of D2 receptors.

These results bring further evidence that EGF-induced D2 receptors in clonal strains from rat pituitary tumors are functional and are coupled to the delayed outward potassium current I_K .

573.2

3H-SPIPERONE BINDING TO RAT PITUITARY: MODULATION AFTER 6-HYDROXYDOPAMINE. L.C. Saland*, A. Samora, A. Apodaca, D. Ramirez, and D.D. Savage+, Depts. of Anatomy and Pharmacology+, University of New Mexico Sch. Med., Albuquerque, NM 87131.

D-2 dopamine (DA) receptors are found in rat pituitary (PIT), with binding of 3H-spiperone (SPIP) to proopiomelanocortin (POMC) cells in the intermediate lobe (IL), as well as to anterior lobe (DeSouza et al, '85, *Endocrinol.* 119: 1534). We examined SPIP binding to rat PIT after 6-hydroxydopamine (6-OHDA)-induced degeneration of nerve terminals to POMC cells. Male rats were injected with 6-OHDA as previously described (Saland et al, '91, *Mol. Cell Neurosci.* 2:418). Cryostat sections of PIT were incubated with 0.4nM SPIP (DuPont, S.A. 21.6 Ci/mM) in Tris/HCl buffer with or without excess haloperidol or ketanserin. Under these conditions, ketanserin had no effect on SPIP binding. One week after 6-OHDA, when fibers have degenerated, specific binding in the IL was reduced 60% compared to controls. No difference in SPIP binding was found three weeks after 6-OHDA. Increased release of DA during degeneration may produce a transient down-regulation of DA receptors on target cells. INTRACELLULAR MESSENGERS SUPPORTING PROLACTIN REBOUND SECRETION FOLLOWING DOPAMINE REMOVAL. K.A. Gregerson* and R. Chuknyska, Dept. of Pediatrics, School of Medicine, UMAB, Baltimore, MD 21201.

Prolactin (PRL) release is tonically inhibited by dopamine (DA). Withdrawal of DA stimulates PRL release with transient secretory rates that exceed those observed prior to DA. Studies on the mechanism of this secretory rebound have demonstrated that both cAMP and inositol phosphates (IPx) levels increase following DA removal (Martinez de la Escalera and Weiner, 1988). In light of our findings that influx of extracellular Ca^{2+} is necessary for the PRL rebound, we have re-investigated the role of cAMP and IPx in this response. Cellular [cAMP] or IPx production was measured in pituitary cells from female rats. PRL release was also quantitated. Measurements were made either after a 20 minute incubation with test substances or 20 minutes after their removal. In the presence of 50nM DA, PRL release was significantly reduced (by 60%). Removal of DA doubled the rate of PRL release as compared to pre-DA levels. Cyclic AMP levels were also suppressed (by 50%) in the presence of 50nM DA and increased following DA removal, but only to pre-DA levels. Application of the K^+ ionophore valinomycin (10 $^{-9}$ M), to hyperpolarize the cells, produced inhibition and, after its removal, rebound of PRL release, mimicking the effects of DA. However, it produced no changes in [cAMP]. Inclusion of either 50 mM K^+ or 100 μ M quinine with DA (to block DA-induced hyperpolarization) blocked inhibition and rebound of PRL, while cAMP responses to DA were unaffected. This dissociation of PRL release and [cAMP] indicates that cAMP plays little or no role in producing the PRL secretory rebound following DA removal. Incubation with DA (50nM) had no acute effect on IPx while removal of DA increased IPx production by 60-70%. The Ca^{2+} channel blocker, verapamil, blocked both the PRL secretory rebound and the increase in IPx production produced by DA removal. The data indicate that both PRL release and IPx production stimulated by DA removal are secondary to influx of extracellular Ca^{2+} and support the hypothesis that enhanced Ca^{2+} influx into lactotropes following DA removal is a primary mechanism in producing PRL rebound secretion. [DK-40336]

573.4

EFFECT OF DOPAMINE REMOVAL ON CELLULAR Ca^{2+} IN RAT LACTOTROPE. M.-Y. Ho* and K.A. Gregerson, Dept. of Pediatrics, School of Medicine, UMAB, Baltimore, MD 21201

Dopamine (DA) tonically inhibits prolactin (PRL) secretion from lactotropes in the anterior pituitary. Removal of DA elicits a dramatic increase in PRL release to values above basal (pre-DA) rates. Our previous studies showed that lactotropes exhibited a period of increased Ca^{2+} -dependent spiking activity following DA withdrawal. We investigated the effect of DA removal on $[Ca^{2+}]_i$ during rebound secretion in single lactotropes isolated from female rats and identified by the Reverse Hemolytic Plaque Assay (RHPA). $[Ca^{2+}]_i$ was measured with fluorescent Ca^{2+} indicator fura2 1 to 3 days after cell dispersion at room temperature. Under unstimulated conditions, two distinct groups of lactotropes were observed: the first exhibited oscillatory $[Ca^{2+}]_i$ fluctuations probably due to spontaneous action potential and the second (quiescent cells) exhibited stable $[Ca^{2+}]_i$ levels ranging between 10 to 100 nM. Treatment with DA (100 nM) was found to affect $[Ca^{2+}]_i$ differently upon DA removal of the two groups of lactotropes. In cells with oscillatory Ca^{2+} fluctuations, DA resulted in a rapid decrease in $[Ca^{2+}]_i$ with the disappearance of the spontaneous Ca^{2+} fluctuations. Verapamil (Vp) can mimic the inhibitory effect of DA to some extent. Free Ca^{2+} was brought down by Vp to about two thirds of what was observed in the presence of DA. Upon DA (or Vp) removal, cells resumed oscillatory activities to about the same Ca^{2+} level as that observed prior to DA application. In quiescent cells, by contrast, DA exerted no effect on resting $[Ca^{2+}]_i$ but DA removal elicited a slow rise in $[Ca^{2+}]_i$ which eventually developed into oscillatory Ca^{2+} spikes at $[Ca^{2+}]_i$ levels much higher than observed before DA application. These findings are consistent with our previous report that application and removal of DA induced spontaneous Ca^{2+} -spiking activity in electrically quiescent cells. These data support the hypothesis that the rebound secretion of PRL is supported by the influx of extracellular Ca^{2+} after cells recover from DA-induced hyperpolarization. NIH DK-40336 and DK-02019.

573.5

CIRCADIAN CHANGES OF SERUM PROLACTIN LEVELS AND TUBEROINFUNDIBULAR DOPAMINERGIC NEURONS' ACTIVITIES IN OVARIECTOMIZED, ESTROGEN-TREATED RATS. Lee-Min Mai and Jenn-Tser Pan, Inst. Physiol. and Dept. Anat., Natl. Yang-Ming Med. Coll., Taipei, Taiwan 11221, R.O.C.

The objective of this study was to correlate the changes of serum prolactin (PRL) levels with tuberoinfundibular dopaminergic (TIDA) neurons' activities during the afternoon of estrogen-treated rats. Rats were decapitated each hour from 1200 to 1900 h, and their serum PRL and median eminence DOPAC or DOPA levels were determined by RIA and HPLC-ECD, respectively. A prominent PRL surge started and peaked around 1400-1500 h, and remained significantly high till 1900 h. Using either DOPAC concentration or DOPA accumulation in the median eminence as indexes for TIDA neuron's activity, we found significant decreases starting from 1400 till 1900 h, which correlated nicely with PRL levels. In ovariectomized rats with no estrogen replacement, however, neither PRL level nor TIDA neuron's activity had any change during the afternoon. We further found that both changes in PRL level and TIDA neuron's activity were not present in suprachiasmatic nuclei-lesioned rats either. We conclude that the estrogen-induced PRL surge is circadian in nature which may originate from changes in suprachiasmatic and TIDA neurons' activities.

573.7

ACTIVATION OF DOPAMINE (D2) RECEPTOR HYPERPOLARIZES MEMBRANE POTENTIAL AND REDUCES [Ca] IN SINGLE RAT MELANOTROPHS. A. K. Lee* Dept of Physiology and Biophysics, University of Washington, Seattle, WA 98195.

I have studied the effects of quinpirole, a dopamine (D2) receptor agonist on single rat melanotrophs of the intermediate pituitary. Dopamine inhibits secretion by melanotrophs. Melanotrophs were incubated with Indo-1 AM to measure free intracellular [Ca]. Nystatin perforated patch technique was used to measure and/or control membrane potential. The average resting membrane potential was -35 ± 2 mV (n=17) and the average [Ca] was 183 ± 11 nM (n=15). One μ M quinpirole hyperpolarized the cell by 30 ± 3 mV (n=17), and reduced [Ca] by 43 ± 7 nM, independently of external Na. Clearly the [Ca] decrease did not depend on Na/Ca exchange. Furthermore 100 μ M Cd also reduced [Ca]. When melanotrophs were voltage clamped between -60 and -40 mV, [Ca] increased. This confirms that melanotrophs have open voltage dependent Ca channels at their resting membrane potential. The calcium influx through these channels is probably responsible for basal secretion in melanotrophs. Dopamine could through hyperpolarization turn off these Ca channels and reduce [Ca], and thereby inhibit basal secretion. To determine if hyperpolarization is the only mechanism for reducing [Ca], melanotrophs were voltage clamped at -25 mV while 1 μ M quinpirole was applied. Intracellular [Ca] still decreased by 19 ± 5 nM (n=10). This decrease was seen in 8 of 10 cells. Apparently dopamine could reduce intracellular [Ca] not only by hyperpolarization but also by other mechanisms such as direct modulation of Ca channels or activation of Ca ATPases.

Supported by PHS NRSA T32 GM07270 from NIGMS.

ALPHA-2 ADRENERGIC RECEPTOR BINDING AND GALANIN CONTENT IN THE LOCUS COERULEUS OF ZUCKER DIABETIC FATTY (ZDFB/Drt) RATS. B. H. Hwang* G.-M. Wang and R. G. Peterson, Dept. of Anatomy, Indiana Univ., Sch. of Med. Indianapolis, IN 46202.

Non-insulin dependent diabetes mellitus (NIDDM) or type II diabetes is a common endocrine disorder and associated with a failure of pancreatic beta cells to meet an increased demand for insulin. However, its pathogenesis related to the central nervous system (CNS) is not understood. This study was thus aimed to explore how the locus coeruleus is associated with NIDDM. ZDFB obese (Obe) and their lean controls at 20-24 weeks of ages were studied. Animals were decapitated, and the locus coeruleus (LC) was cut with a cryostat into 14- μ m sections. When sacrificed, Obe rats were very diabetic with high plasma glucose and low insulin, as compared with lean controls. One set of animals (n=5) was processed for alpha-2 adrenergic receptor binding ($\times 1000$ cpm/mg protein) using [125 I]-iodoclonidine. We found that alpha-2 adrenergic receptor binding was significantly lower in Obe rats (33.7 ± 3.2 , n=5) than lean controls (66.0 ± 7.5 , n=5). Another set of animals was processed for studying galanin content ($\times 1000$ cpm/mg protein) with a radio-immunohistochemical assay. There was much more galanin content in Obe rats (95.6 ± 2.9 , n=3) than in lean controls (64.3 ± 2.4 , n=4). With severe diabetes characteristic of hyperglycemia, ZDFB obese rats had drastic changes in alpha-2 adrenergic receptor binding capacity and galanin content in the LC. This study suggests that CNS is closely associated with pathogenesis of NIDDM. Supported in part by NS-25087.

EFFECTS OF DOPAMINE, ENDOGENOUS OPIOID PEPTIDES AND THEIR ANALOGS ON HYPOTHALAMIC ARCuate NEURON'S ACTIVITY IN BRAIN SLICES. Jing-Ying Lin, Julie Y.H. Chan and Jenn-Tser Pan, Inst. Physiol., Natl. Yang-Ming Med. Coll., Taipei, Taiwan 11221, R.O.C.

Using extracellular single-unit recording technique in brain slices, we focused our recording on dorsomedial and ventrolateral side of the arcuate (ARC) nucleus where immunoreactive dopaminergic neurons are located, and compared slices obtained from ovariectomized or diestrous rats. Dopamine by itself inhibited 37% of 169 ARC neurons from ovariectomized rats. SKF-38393, a D₁-, and quinpirole, a D₂-receptor agonist also inhibited 31% (n=32) and 23% (n=39) of ARC neurons, respectively. Few neurons were excited by dopamine or its agonists, and most were not responsive. As for the effects of opioids on ARC neurons, most were inhibitory, viz., β -endorphin inhibited 54.5% (n=33); DAGO, 62% (n=21); Met-enkephalin, 35.2% (n=54); DPDPE, 50% (n=8); dynorphin-A, 55% (n=11); and U-50488, 36% (n=39). Other neurons were not responsive. DAGO, dynorphin-A and U-50488 were also slightly more effective in inhibiting ARC neurons in slices obtained from diestrous rats. We conclude that dopamine and opioids mainly exert inhibitory effects on responsive ARC neurons through multiple receptor types, and ovarian hormones may have an effect on ARC neuron's responsiveness to opioids.

573.8

IMPAIRED CATECHOLAMINE SECRETION FROM THE PERFUSED ADRENAL GLANDS OF BB-WISTAR RATS FOLLOWING ACUTE HYPOGLYCEMIA. R. A. Wilke and C. J. Hillard*, Department of Pharmacology, Medical College of Wisconsin, Milwaukee, WI 53226.

A subgroup of insulin-dependent diabetic humans eventually lose the capacity to secrete catecholamines from their adrenal medullae. Although a similar defect has been described in the spontaneously diabetic BB-Wistar rat, the causative pathophysiologic mechanism has not yet been elucidated. We hypothesized that this defect was due to functional changes occurring within the adrenomedullary chromaffin cells, secondary to iatrogenic hypoglycemia experienced by these animals during the course of their maintenance on insulin. To test this hypothesis, we variously manipulated the blood glucose levels of BB-Wistar rats with exogenous insulin, perfused their adrenal glands *ex vivo*, and determined the catecholamine content of the perfusate fractions by fluorometric analysis. When adrenal glands were harvested from non-diabetic rats after 3 hours of insulin-induced hypoglycemia, their catecholamine secretory response to nerve stimulation or perfusion with ACh was significantly lower than the response of adrenals harvested from matched euglycemic control rats. Furthermore, the overall adrenomedullary catecholamine content of these hypoglycemic rats was also significantly reduced with respect to euglycemic controls. Together, these results demonstrate that exposure to severe acute hypoglycemia *in vivo* can significantly impair the secretory function of the adrenal medulla, and they suggest that iatrogenic hypoglycemia may have been responsible for the catecholamine secretory defect described previously in spontaneously diabetic BB-Wistar rats maintained on insulin.

573.10

THE ROLE OF NITRIC OXIDE AND THE SYMPATHETIC NERVOUS SYSTEM IN MEDIATING THE EFFECTS OF ANGIOTENSIN II ON BLOOD FLOW TO CHOROID PLEXUSES OF THE RAT. A. Chodobski, J. Szymdynger-Chodobska, and C.E. Johanson, Program Neurosurg., Dept. Clin. Neurosci., Brown Univ. and R.I. Hospital, Providence, RI 02903.

We have previously shown that angiotensin II (AII) infused *iv* alters blood flow to choroid plexuses (CPs) with the peptide effects being dependent on both the AII dose and the anatomic location of CP. In the present study we investigated the role of the sympathetic nervous system in mediating the inhibitory effect of moderate AII doses (30 and 50 ng kg⁻¹ min⁻¹) on choroidal blood flow by using the alpha-blocker, phentolamine (iv, 1 mg kg⁻¹). To characterize the choroidal vascular regulatory mechanisms operating during *iv* infusion of AII at higher dose (300 ng kg⁻¹ min⁻¹) when choroidal blood flow was unchanged, we either blocked beta-receptors (propranolol, iv, 1 mg kg⁻¹) or inhibited the synthesis of nitric oxide (NO) by using N^G-nitro-L-arginine methyl ester (L-NAME, iv, 0.1 mg kg⁻¹). Blood flow to CPs of the lateral (LVCP), third (3VCP), and fourth (4VCP) ventricles was measured in rats anesthetized with pentobarbital (ip, 50 mg kg⁻¹) and artificially ventilated. [125 I]-N-isopropyl-p-iodoamphetamine was used as a marker. Phentolamine by itself did not alter choroidal blood flow, but it completely abolished the action of moderate doses of AII previously noted in LVCP and 4VCP. Propranolol by itself decreased blood flow to LVCP (from 3.19 ± 0.07 to 2.54 ± 0.18 ml g⁻¹ min⁻¹, P<0.01), 3VCP (from 3.90 ± 0.17 to 3.21 ± 0.12 ml g⁻¹ min⁻¹, P<0.02), and 4VCP (from 3.95 ± 0.11 to 3.23 ± 0.23 ml g⁻¹ min⁻¹, P<0.02). AII infused 5 min after propranolol, further decreased blood flow to all CPs, but the changes were not significant. L-NAME by itself lowered blood flow to 4VCP (by 16%, P<0.05), but did not affect other CPs. AII administered 5 min after L-NAME caused an additional decrease in blood flow to all plexuses (by 18-26%, P<0.01-0.05). It is concluded that activation of alpha-receptors is involved in the inhibitory action of AII on choroidal blood flow observed with moderate peptide doses. It appears that the concomitant release of NO and perhaps the activation of beta-receptors result in no changes in choroidal blood flow with higher AII dose. Supported by NIH Grant NS 27601.

LACK OF CATECHOLAMINE MEDIATION OF INCREASED LH RELEASE DURING BLOCKADE OF KAPPA OPIOID RECEPTORS IN THE RAT MEDIAL BASAL HYPOTHALAMUS (MBH). S.Zhen and R.V.Gallo* Dept. Phys. & Neuro., Univ. Connecticut, Storrs, CT 06269.

We have shown that kappa receptor blockade in the MBH with norbinaltorphimine (nBNI) stimulated LH release during midpregnancy. The literature indicates kappa receptor activation can decrease dopamine (DA) or norepinephrine (NE) release, and inhibiting NE synthesis blocks the increased LH release occurring in response to nonspecific opioid receptor blockade with naloxone. The goal of this study was to determine if DA or NE mediates the LH response to MBH kappa receptor blockade on days 13-17 of pregnancy in the rat. Push-pull perfusion + HPLC-ED was used to determine NE release in the MBH in response to CSF, CSF+nBNI (40ug/h), CSF + desipramine (DMI, a NE reuptake blocker, 10uM), or CSF+DMI+nBNI. CSF alone produced no change in LH release, and perfusate NE was undetectable. nBNI increased LH but perfusate NE remained undetectable. DMI increased perfusate NE but produced no change in LH release. nBNI+DMI increased LH secretion similar to nBNI alone, but produced no further change in MBH perfusate NE. Inhibition of NE synthesis with FLA-63 (25mg/kg), blockade of α -adrenergic receptors with phentolamine (5mg/kg), or DA receptor blockade with d-butacclamol (1mg/kg) did not affect the increased LH release occurring during MBH perfusion with nBNI. Thus neither NE nor DA mediates the increased LH release due to blockade of MBH kappa receptors. Supported by NIH HD17728.

FURTHER EVALUATION OF LAMINA TERMINALIS CONTRIBUTIONS TO THE GABAergic INNERVATION OF THE PARAVENTRICULAR AND SUPRAOPTIC NUCLEI. B.L. Roland* and P.E. Sawchenko, The Salk Institute, La Jolla, CA 92037.

We previously identified intrahypothalamic cell groups that participate in the GABAergic innervation of the paraventricular (PVH) and supraoptic (SO) nuclei (*J Comp Neurol* 332:123, 1993). Because these local sources appeared to account for a small fraction of GABA projections to the magnocellular neurosecretory system, we evaluated whether cell groups of the lamina terminalis, i.e., the subformal organ (SFO), median preoptic nucleus (MePO) and organum vasculosum (OVLT), might contribute substantially to this projection. In support of this, mRNAs encoding both the 65 and 67 kDa forms of glutamate decarboxylase (GAD) were localized in SFO, MePO and OVLT neurons identified in retrograde tracing studies as projecting to the region of the PVH (*Soc Neurosci Abstr* 18:823, 1992). In addition, injections of the anterograde tracer, PHA-L, centered in MePO or OVLT, labeled projections to the PVH and SO. Such anterogradely labeled terminals frequently co-stained for GAD-immunoreactivity. Attempts to evaluate these projections experimentally, by unilaterally transecting lamina terminalis outputs and comparing the GABAergic innervation on the ipsilateral and contralateral sides, provided limited support for the tract tracing data. Variations in post-lesion survival time over 3-25 days yielded minor reductions in the GABAergic innervation of the ipsilateral magnocellular nuclei, despite independent confirmation of the effectiveness of ablations by a lateralized reduction in salt-loading-induced immediate-early gene expression in magnocellular neurons, a phenomenon we have shown to depend on the integrity of descending lamina terminalis projections. It has been suggested that disruption of lamina terminalis projections to the hypothalamus may be compensated by synaptic remodeling (e.g., *Prog Neurobiol* 34:437, 1990). The discrepancy between the present anatomical and experimental data may be due to compensatory sprouting responses of as yet unidentified GABAergic neurons following interruption of lamina terminalis outputs.

OXYTOCINERGIC NEURONS OF THE MAGNOCELLULAR SYSTEM ARE TONICALLY INHIBITED BY GABA IN VIRGIN BUT NOT LACTATING RATS. J.Summy-Long*, S.Mantz and E. Koehler. Dept. of Pharmacol., M.S. Hershey Med. Ctr., Hershey, PA 17033.

GABAergic fibers synapse on oxytocin (OT) neurons and these increase in number during lactation. Modulation of OT release by GABA was studied in conscious virgin (V;n=56) and lactating (L;n=47) rats injected (sc,15 ml/kg) with saline or 2.5 M NaCl (HS) for osmotic stimulation 2h before decapitation. CSF(5 ul), GABA(100 ug) or bicuculline(Bic; 100 ng) was given intracerebroventricularly(icv) 5 min (GABA) or 10 min (Bic) before decapitation. OT in plasma was quantified by RIA. Differences were determined by 2 way AOV & Newman Keuls t test. Osmotic stimulation increased (saline vs HS; p<0.01) plasma OT (pg/ml;x \pm SEM) in V(CSF: 11 \pm 1 vs 109 \pm 10) but to a lesser (p<0.01) extent in L rats (CSF:8 \pm 1 vs 36 \pm 4). Bic blockade of endogenous GABA action raised (p<0.01) plasma OT in unstimulated V (19 \pm 2) but not L (9 \pm 0.4) rats. GABA icv decreased (p<0.01) OT levels after HS in V (109 \pm 10 vs 68 \pm 6) and L (36 \pm 4 vs 20 \pm 4) animals while Bic had no effect (V 109 \pm 10 vs 106 \pm 7; L 36 \pm 4 vs 36 \pm 5). Thus, a GABAergic system inhibits release of OT in normally hydrated V animals that also are more active and tense than L rats. This inhibition was removed during osmotic stimulation when exogenously applied GABA attenuated OT release regardless of reproductive state. In L rats, OT release was not modulated by a Bic-sensitive endogenous GABAergic system. (Supported by RO1-HD25498).

INVOLVEMENT OF BETA-ADRENERGIC RECEPTORS ON THE NATRIURESIS AND ATRIAL NATRIURETIC PEPTIDE (ANP) RELEASE INDUCED BY CENTRAL CHOLINERGIC ACTIVATION IN RATS. J.V. Menani, S.P. Barbosa, J. Antunes-Rodrigues, A.L.V. Favaretto, L.A. De Luca Jr., W.A. Saad, L.A.A. Camargo, J.E.N. Silveira and A. Renzi. Dept. of Physiology, School of Dentistry, UNESP, Araraquara, SP 14801-903 and Dept. of Physiology, School of Medicine, USP, Ribeirão Preto, SP 14049-900, Brazil.

In the present study we investigated the effect of previous treatment with propranolol (a beta-adrenergic antagonist) on the natriuresis, kaliuresis and ANP release induced by central cholinergic activation. Rats with stainless steel cannula implanted into the lateral ventricle were used. Previous intraperitoneal (IP) injection of propranolol (10 mg/kg b.w.) reduced the natriuresis (182 \pm 35 vs 480 \pm 58 uEq/2 h) and plasma ANP increase (107 \pm 27 vs 266 \pm 51 pg/ml) induced by intracerebroventricular (ICV) injection of the cholinergic agonist carbachol (7 nmol). No change in the kaliuresis, antidiuresis and pressor responses to ICV carbachol was observed after the treatment with propranolol. The present results suggest that a central mediation of natriuresis and ANP release may involve beta-adrenergic receptors and the sympathetic nervous system.

INHIBITORY GABAergic INPUTS TO NEURONS IN THE SUBFORMAL ORGAN IN VITRO. K. Inenaga*, L.-N. Cui, T. Nagatomo and H. Yamashita. Dept. of Physiology, Univ. Occupational & Environmental Health, Sch. of Med., Kitakyushu 807, Japan.

γ -Aminobutyric acid (GABA) is a widely accepted inhibitory neurotransmitter in the central nervous system. Recently Osaka et al.(1) have reported that inhibitory GABAergic interneurons intervene synaptic inputs to the SFO of cats and send tonic inhibition to the nucleus. For further investigation of the GABAergic inhibitory inputs to SFO neurons, intracellular recordings were made in rat brain slice preparations. Inhibitory postsynaptic potentials (IPSPs), which either were recorded spontaneously or were evoked by focal electric stimulation, were almost blocked by the GABA_A antagonists bicuculline or picrotoxin. Following the application of bicuculline or picrotoxin, resting membrane potentials were depolarized by 4-8 mV. GABA and the GABA_A agonist muscimol decreased membrane resistance and firing rate. The actions of muscimol persisted in the presence of TTX, suggesting that they were postsynaptic. The GABA_B agonist baclofen also showed similar inhibitory effects but its action was smaller than that by muscimol. These results suggest that tonic and inhibitory GABAergic inputs exist in the SFO and are mainly mediated through GABA_A receptors.

FREE TISSUE CATECHOLAMINES OF RAT CAROTID BODY, IN VITRO, DURING MATURATION AND FOLLOWING CHRONIC HYPOXIA.

D.F. Donnelly*, T.P. Doyle, Department of Pediatrics, Yale University School of Medicine, New Haven, CT, 06510

Free tissue catecholamine levels (CAT) were estimated using Nafion-coated, carbon fiber electrodes placed in rat carotid bodies, *in vitro*. Four groups of carotid bodies from normal rats (1d (n=6), 2d (n=6), 10d (n=7) and 20-30d (n=11)), and 1 group from rats (GHR, 20-28d, n=9) placed in a hypoxic environment at birth ($F_{IO_2} = 0.09$) were studied. During superfusion with HEPES saline ($PO_2 = 150$ Torr, $32-34^\circ C$), baseline CAT were significantly less in the normal 1-6d ($0.55 \pm 0.06 \mu M$) compared to normal 10d ($1.26 \pm 0.24 \mu M$) and normal 20-30d ($2.59 \pm 0.35 \mu M$). During 1 min hypoxia ($PO_2 = 0$ Torr, at nadir), peak CAT was less in the 1d ($1.46 \pm 0.42 \mu M$) and 2d ($2.6 \pm 0.5 \mu M$) compared to the 10d ($9.7 \pm 3.2 \mu M$) and 20-30d ($14.8 \pm 1.6 \mu M$). Peak single-fiber nerve response also increased with age from 4.5 ± 0.6 Hz in the 1d to 10.5 ± 1.6 Hz in the 6d and 15.5 ± 2.2 Hz in the 20-30d. GHR had elevated baseline CAT ($14.4 \pm 1.3 \mu M$) compared to similarly aged normal rats, and was relatively unchanged by hypoxia ($15.6 \pm 2.2 \mu M$). The magnitude of the change in nerve activity was approximately 40% of normal. We conclude that: 1) resting tissue catecholamine levels increase with age, 2) hypoxia causes an enhanced catecholamine release and the magnitude of release increases with post-natal age and 3) catecholamine levels of carotid bodies exposed to hypoxia after birth do not emulate the newborn.

ENDOGENOUS CARBON MONOXIDE (CO) AND CAROTID BODY SENSORY ACTIVITY. N.R. Prabhakar*, F.H. Agani¹, J.L. Dinerman² and S.H. Snyder³. ¹Departments of Medicine, Physiology and Biophysics, Case Western Reserve University, Cleveland, OH 44106, and ²Departments of Neurosciences and Medicine, Johns Hopkins School of Medicine, Baltimore, MD 21205.

Recently, it has been reported that carbon monoxide (CO) is synthesized in mammalian neurons and may act as a neurotransmitter in the central nervous system (Science, 259: 381-384, 1993). Carotid bodies are peripheral sensory organs that detect the changes in arterial oxygen. We examined whether CO is produced in the peripheral neuronal tissues, such as the carotid bodies, and assessed its possible effects on chemosensory activity. Experiments were performed on isolated perfused, superfused carotid bodies dissected from anesthetized adult cats. Sensory discharge from the carotid body was recorded from clearly identifiable action potentials using conventional electrophysiological techniques. Zn-protoporphyrin IX (ZnPP-IX), a potent inhibitor of heme oxygenase, an enzyme that catalyzes the formation of CO. We tested the effects of several doses of ZnPP-IX on chemosensory activity while perfusing the carotid bodies with normoxic medium ($PO_2 = 146$ mmHg; $PCO_2 = 3$ mmHg). ZnPP-IX (0.1, 0.3, 1, 3, and 10 μM) increased the chemosensory discharge in a dose-dependent manner (n = 6 carotid bodies). After switching the perfusion medium back to controls, sensory activity returned to initial values, suggesting that the effects of ZnPP-IX were reversible. These results suggest that carotid body synthesizes CO that seems to be inhibitory to the chemosensory activity. Supported by grants from NIH HL-45780 and HL-02599.

BRAINSTEM PATHWAYS TO RESPIRATORY MUSCLES OF THE LARYNX IDENTIFIED BY TRANSNEURONAL LABELING WITH PSEUDORABIES VIRUS (PRV). K.A. Gilbert*, R. Fay and R. Lydic, Departments of Anesthesia and Behavioral Science, Penn. State Univ., Col. of Med., Hershey, PA 17033.

Microinjection of carbachol into the medial pontine reticular formation (mPRF) of cat produces a REM sleep-like state and state-dependent hypotonia in the posterior cricoarytenoid (PCA) muscle of the upper airway (FASEB J. 3:1625, 1989). Since PCA primary motoneurons arise from the nucleus ambiguus (NA), which in the cat is ~9 mm from the mPRF, we hypothesized that the mPRF causes PCA muscle hypotonia via polysynaptic connections to NA. Injections of PRV were made into the PCA muscles of 3 rats (superior cervical ganglia removed) and 1 cat with survival times of 72-90 hrs in rat and 80 hrs in cat. In rat, dense primary labeling was observed in NA. Heaviest transsynaptic labeling was seen in nucleus of the solitary tract (NTS) and paratrigeminal nucleus. Moderate transsynaptic labeling was seen in laterodorsal tegmental (LDT)/pedunculo-pontine tegmental (PPT) nuclei, raphe magnus and obscuris, and gigantocellular reticular nucleus. Light transsynaptic labeling was seen in reticular nuclei of pontis oralis and caudalis and in central gray. In cat, primary labeling also was observed in NA, with lighter transsynaptic labeling in LDT/PPT, NTS, and gigantocellular, magnoocellular, and lateral reticular fields of the pons and medulla. These results are consistent with previous studies concerning the descending inhibitory pathways from pontine reticular regions to spinal motoneurons. The present findings also suggest that additional pathways from the mPRF to NA may mediate state-dependent hypotonia in the PCA muscle.

LACK OF PARALLELISM BETWEEN THE EFFECTS OF HYPOXIA ON THE GLOMUS CELL pH_i AND CAROTID CHEMOSENSORY RESPONSES.

D. K. Ray, A. Mokashi, M. Katayama, F. Botrè and S. Lahiri*. Department of Physiology, University of Pennsylvania School of Medicine, Philadelphia, PA 19104, USA.

Effects of graded levels of superfusate PO_2 hypoxia on pH_i of dissociated and cultured glomus cells of rat carotid bodies were measured to test whether pH_i responses correspond to the well-known chemosensory responses to hypoxia. The dissociated and cultured glomus cells (3 days old), plated on polylysine coated cover-slips, were loaded with pH-sensitive fluoroprobe, carboxy-SNARF-1 (5 μM), and were superfused with pre-equilibrated Tyrode's solution at $37^\circ C$. Dual emission signals at 590 nm and 640 nm with excitation at 540 nm were recorded. Effects of four levels of pH_o (7.40-7.20) at a constant PO_2 and three levels of PO_2 (140-16 Torr) at a constant pH_o were studied. For calibration, the high K^+ -nigericin method was used. The pH_i was 7.25 at pH_o of 7.40, and varied linearly with pH_o . Hypoxia ($PO_2 = 49$ Torr, 16 Torr) caused small and non-graded pH_i decreases (ΔpH up to 0.02), which fail to explain the well-known vigorous chemosensory responses to hypoxia. This lack of correspondence between pH_i response and the expected chemosensory activity indicates that pH_i does not mediate the chemosensory responses to hypoxia. (Supported in part by HL-43413-4 and HL-07027-18.)

CONCURRENT, DISTRIBUTED ALTERATIONS IN BRAINSTEM NEURAL ASSEMBLIES DURING INDUCTION OF LONG-TERM ENHANCEMENT OF RESPIRATORY ACTIVITY *IN VIVO* BY CAROTID CHEMORECEPTOR STIMULATION. K. F. Morris*, A. Arata, R. Shannon and B. G. Lindsey, Physiol. & Biophysics, Univ. South Florida Med. Ctr., Tampa, FL 33612.

Stimulation of carotid chemoreceptors results in long term enhancement (LTE) of respiratory activity (Millhorn et al., Resp. Phys. 41:87). In extending our previous observations (Soc. Neurosci. Abst. 17:103, 18:829), we tested the hypothesis that correlated assemblies of medullary cardiorespiratory neurons exhibit persistent changes following the induction of LTE. The amplitude of integrated efferent phrenic nerve activity increased for >10 min. after single or multiple injections of 200 μl of CO_2 saturated saline solution via the external carotid arteries of 5, anesthetized, vagotomized, artificially ventilated cats. Spike trains were recorded simultaneously (max.=30) in the medullary raphe n., ipsilateral n. tractus solitarius, rostral and caudal ventral respiratory group (VRG) and contralateral VRG. Data were analyzed with cycle-triggered histograms, spike triggered averages of phrenic activity, cross-correlograms and the gravity method. Means of several parameters measured during pre- and post-stimulus respiratory cycles were compared (n-test). Firing rates of 51% of neurons increased, 27% decreased and 22% were unchanged. Inspiratory duration decreased (n=5), expiratory duration decreased (n=3) and peak heart rate increased (n=5). Of 12 neurons in one assembly (34 concurrently correlated pairs), 10 increased and 2 decreased firing rates. Neurons with opposite firing rate changes during and following induction of LTE had short-time scale correlations. The results support the hypothesis that the expression of LTE requires a change in the set point of distributed equilibrium-seeking brainstem networks with excitatory and inhibitory effective connectivity appropriate for gain control. Supported by NS19814.

PHASIC RESPIRATORY EVENTS OF RAPID EYE MOVEMENT (REM) SLEEP ARE SIMILAR DURING THE CHOLINERGICALLY-INDUCED REM SLEEP-LIKE STATE. T.O. Leonard*, K.A. Gilbert, S.L. Shuman and R. Lydic, Dept. of Anesthesia, Penn. State Univ., College of Med., Hershey PA 17033.

Breathing during REM sleep is characterized by abrupt transitions between inspiration (I) and expiration (E) associated with bursts of muscle activity (EMG), eye movements (EM), or ponto-geniculo-occipital (PGO) waves. Microinjection of cholinomimetics into the medial pontine reticular formation (mPRF) causes a REM sleep-like state with similar respiratory phase switches. This study is quantifying these phasic respiratory events in cat (n=5) by comparing natural REM sleep (mPRF saline) and the REM sleep-like state caused by mPRF microinjection of carbachol (DCarb), bethanechol (DBeth), or neostigmine (DNeo). Respiratory phase switches (RPS) were defined as an irregular interruption in I or E. RPS were tabulated for 10 min in each state. Mean (\pm SD) RPS during REM following saline= 21.67 ± 5.51 ; DCarb= 17.00 ± 6.08 ; DBeth= 8.33 ± 6.51 ; and DNeo= 7.33 ± 1.53 . Using permutations of RPS with and without EM, PGO, or EMG, 13 dependent measures were compared. There were no significant difference in RPS comparing natural REM sleep, DCarb, or DBeth. DNeo differed significantly from both saline and DCarb for the min devoid of RPS and for the total number of PGO bursts occurring with RPS. DNeo was significantly different from natural REM sleep for RPS alone. Thus, quantitative comparison of phasic respiration during natural and cholinergically-induced REM sleep-like state revealed more similarities than differences. Ongoing studies will evaluate the possible dose-dependency of these effects. Support: Department of Anesthesia, HL-40881 (RL).

MANIPULATION OF SECOND MESSENGER SYSTEMS IN THE PONTINE RETICULAR FORMATION: EFFECTS ON SLEEP AND BREATHING. S. L. Shuman, H. A. Baghdoyan, and R. Lydic*.

Dept. Anesthesia, Penn. State Univ., Coll. Med., Hershey, PA 17033.

Microinjection of cholinomimetics into the medial pontine reticular formation (mPRF) of intact, unanesthetized cat causes a REM sleep-like state and state-dependent respiratory depression (*News Physiol. Sci.* 7:220, 1992). The mechanisms by which these changes occur are known to be G-protein-mediated, but the specific G-protein and second messenger system(s) involved are currently unknown. As a first step toward characterizing G-protein effects on sleep and breathing, microinjections (n=81) of 5-guanylyl-imidodiphosphate (GMP-PNP), cholera toxin, and carbachol were made into the mPRF of two cats. States of consciousness and breathing were then recorded for 2 hrs. Injections of cholera toxin or GMP-PNP had no immediate effect on the total time spent in REM sleep, latency to onset of REM, the total number of REM epochs, or the mean duration of REM epochs. Cholera toxin caused a delayed but long-term (mean=32.5 days) inhibition of the carbachol-induced REM sleep-like state. Return of REM sleep enhancement by carbachol occurred in a graded manner. GMP-PNP caused a significant decrease in respiratory rate during waking (-14.3%) and REM sleep (-13.8%) when compared to control. Cholera toxin significantly slowed respiration during waking (-26.5%) and non-REM sleep (-8.7%) but not during REM sleep (-5.9%). Thus, multiple types of G-proteins are likely to mediate pontine cholinergic control of sleep and breathing.

CO₂ MODULATES PACEMAKER NEURONS IN THE MEDULLARY RAPHE AND PARAPYRAMIDAL REGION OF THE RAT *IN VITRO*. G.B. Richerson*, Dept. of Neurology, Yale University & VAMC, West Haven, CT.

Central chemoreceptors constitute the major source of feedback for control of respiration in mammals, but it has been difficult to find evidence for chemoreceptors at the cellular level. I have used the amphotericin perforated patch-clamp recording technique in thin slices of the rat medulla to examine the response of neurons to changes in both CO₂. Stable recordings were obtained from > 100 neurons for up to 6 hrs (R_{in} = 300MΩ to > 2 GΩ). In the medullary raphe and parapyramidal region between the inferior olive and the pons, most neurons spontaneously fired action potentials at a monotonously regular rate of 1-10 Hz. This repetitive firing was similar to that seen in beating pacemaker neurons in the dorsal raphe, with a linear ramp increase in E_m between spikes. Repetitive firing continued in the presence of TTX (1 μM) with a slower rate and broader, smaller spikes, but was abolished in Cd²⁺ (100 μM). Most neurons in this region were not affected by changes in CO₂ between 3 and 9%. Some neurons (n = 15) were stimulated by CO₂. For example, increasing CO₂ from 5 to 9% increased the firing rate of one neuron from 4 to 7 Hz, and decreasing CO₂ from 5 to 3% decreased the firing rate from 2 to 0.4 Hz. Other neurons (n = 5) were inhibited by CO₂. When CO₂ was increased from 5 to 6%, the firing rate of one neuron decreased from 2.5 to 1.2 Hz, and when CO₂ was decreased from 5 to 4% the firing rate increased from 1 to 2 Hz. In both types of CO₂ sensitive neurons, the change in firing rate was associated with a change in slope of the linear ramp in E_m between spikes without a change in resting potential, suggesting that CO₂ modulates the pacemaker currents in these neurons. The high blood flow to this part of the medullary raphe and parapyramidal region, their projections to other respiratory nuclei, and the presence in this area of neurotransmitters known to have profound effects on breathing *in vivo* all suggest that these neurons are candidates for at least a subset of central respiratory chemoreceptors.

IDENTIFICATION OF THE PROPRIOSPINAL RESPIRATORY NEURONS WHICH RELAY THE RAPHE MAGNUS-INDUCED RESPIRATORY INHIBITION IN CATS.

M. Aoki*, T. Imai, Y. Nakazono and H. Satomi. Dept. Physiology, School of Medicine, Sapporo Medical University, Sapporo 060, Japan.

We previously demonstrated that chemical as well as electrical stimulation of the medullary raphe magnus (NRM) induces marked respiratory inhibition in pentobarbital anesthetized cats. In the present study, we examined whether the propriospinal respiratory neurons in the upper cervical cord (C1-C2 segments) are involved in mediating the NRM-induced respiratory inhibition. We employed a combined technique of anterograde and retrograde labelings to identify the pathways. 1) anterograde tracing of raphe-spinal fibers by injecting biocytin (5%) into the NRM. 2) retrograde labeling of propriospinal respiratory neurons and the ventral respiratory group (VRG) neurons in the medulla by applying WGA-HRP to the phrenic nerve. Retrograde transynaptic labelings of neurons were detected in the ipsilateral C1-C2 segments and contralaterally in the VRG. A number of anterogradely labeled raphe-spinal fibers were distributed in the C1-C2 segments and the VRG. Some terminal fibers were observed to make apparent contacts with the dendrites of the retrogradely labeled propriospinal respiratory neurons. The present study provides anatomical evidence that the NRM-induced respiratory inhibition is in part mediated by the C1-C2 propriospinal respiratory neurons as well as the VRG neurons.

574.8

PHOSPHATE-ACTIVATED GLUTAMINASE AND GLUTAMIC ACID DECARBOXYLASE IMMUNOHISTOCHEMISTRY WITHIN THE INTERMEDIATE LATERAL TEGMENTAL FIELD OF THE RAT.

H.H. Ellenberger*. Department of Anatomy & Neurobiology, Dalhousie University, Halifax, Nova Scotia, Canada B3H 4H7.

The intermediate portion of the medullary lateral tegmental field (LTF) contains neuron populations critical for control of the cardiovascular and respiratory systems. Neurons utilizing excitatory or inhibitory amino acid neurotransmitters could provide an anatomical substrate within the intermediate LTF for generation of rhythmic and tonic drives essential for cardiopulmonary homeostasis, and provide for both sensorimotor integration and coordination of efferent control of the respiratory and cardiovascular systems.

The location of putative glutamatergic and GABAergic neuronal perikarya and terminal varicosities within the intermediate LTF were identified in the present study by immunohistochemical reactions for phosphate-activated glutaminase (PAG) and glutamic acid decarboxylase (GAD). Neuronal axons and terminal varicosities immunoreactive for PAG or GAD were distributed throughout the intermediate LTF, including the regions of the nucleus ambiguus, ventral respiratory group and the caudo- and rostroventrolateral reticular nuclei. Neuronal somata immunoreactive for PAG or GAD formed a more limited distribution within restricted portions of the intermediate LTF. These results provide anatomical evidence of a role for excitatory and inhibitory amino acid neurotransmission within cardiorespiratory neuron populations of the intermediate LTF. Supported by the Medical Research Council of Canada.

PROJECTIONS FROM RAPHE TO MEDIAL PONTINE RETICULAR FORMATION (mPRF) AND PARABRACHIAL NUCLEI (PN) DEMONSTRATED BY RETROGRADE FLUORESCENT LABELING. D.B. Friedman*, L.H. Lee, and R. Lydic*.

Dept. Anesthesia, Penn State Univ., Coll. Med., Hershey PA, 17033.

Pontine cholinergic neurotransmission plays a key role in regulating both sleep and breathing (*Am. J. Physiol.* 264:R544, 1993). Since cholinergic/monoaminergic interactions are important for sleep cycle control, monoamine-containing nuclei are also likely to contribute to state-dependent respiratory depression. The present study is examining the hypothesis that the cholinceptive mPRF and respiratory-related PN receive input from the monoamine-containing raphe. The mPRF and PN of 10 cats were injected with 50 or 100 nl of the retrograde tracers True Blue (5%) or Fluoro-Gold (2%). After mPRF injections, retrograde labeling was observed in the raphe (inferior central magnus and obscurus, tegmental reticular, dorsal). Following PN injections, robust retrograde labeling was observed in the inferior central and central linear raphe. These data demonstrate projections from the raphe nuclei to cholinceptive regions of the mPRF and to the PN. These projections are consistent with previous retrograde tracing studies and with a large body of physiological data showing that cholinergic/monoaminergic interactions are important for regulating arousal states and breathing. Support: Department of Anesthesia, HL47749, HL40881(RL).

PERIODIC POLYPNEA DURING PREOPTIC/ANTERIOR HYPOTHALAMIC WARMING ACROSS SLEEP-WAKING STATES IN THE ADULT CAT AND KITTEN. H. Ni*, J. Zhang, R.K. Harper and R.M. Harper. Brain Research Institute and Department of Anatomy & Cell Biology, UCLA, Los Angeles, CA 90024.

We compared respiratory responses to preoptic/anterior hypothalamic (POAH) warming in 6 unanesthetized, unrestrained adult cats and in 16 kittens (10 to 49 days) during sleep and waking states. Under surgical anesthesia, electrodes were placed for warming the POAH and for recording EEG, diaphragmatic and neck EMG. The POAH was warmed (0.5MHz, 84-190mW) bilaterally by two electrode pairs (1-2mm inter-tip distance, 1-2 mm bared tip, and 0.3 mm in diameter). In both adult cats and kittens, threshold warming was similar (2.8±1.6°C vs 2.8±1.1°C).

In adult cats, POAH warming elicited constant panting during QS. Warming during REM produced slightly faster breathing or a periodic, mild fluctuation in respiratory rate, but no panting. In the kitten, POAH warming also induced panting across all ages during QS, and a diminished response in REM. However, in contrast to the adult, during QS, kittens developed periodic episodes of panting interspersed with episodes of slower respiration (periodic polypnea). These results confirm the presence of thermal panting in the very young kitten in response to POAH warming, and suggest that sleep-state related thermoregulatory mechanisms are more readily disrupted during QS in the younger animal. IN VITRO ELECTROPHYSIOLOGICAL RESPONSES OF CAUDAL HYPOTHALAMIC NEURONS TO HYPOXIA AND HYPERCAPNIA: NEONATAL AND ADULT. E.M. Horn* and T.G. Waldrop. Department of Physiology and Biophysics, Neuroscience Program, and College of Medicine, University of Illinois, Urbana, IL 61801.

Prior findings from this laboratory have shown that hypoxia and hypercapnia stimulate subpopulations of caudal hypothalamic neurons. Hypoxia stimulated 77% and hypercapnia stimulated 35% of the neurons studied in a brain slice preparation. The present goal was to determine if neurons in the neonatal caudal hypothalamus respond to hypoxia and hypercapnia in the same manner as in the adult. Brain slices (400-600 μ m thick) containing the caudal hypothalamus were obtained from both neonatal (<12 days) and adult (>21 days) Sprague-Dawley rats. The slices were placed into an interface chamber and perfused with nutrient media equilibrated with 95% O₂/5% CO₂. The current responses to hypoxia (10% O₂/85% N₂/5% CO₂ for 90 sec.) and to hypercapnia (7% CO₂/93% O₂ for 3 min.) of voltage-clamped, caudal hypothalamic neurons were obtained with whole-cell patch recordings; extracellular recordings were performed on some neurons. The average resting membrane potential of neonatal neurons tended to be lower than adult neurons. Forty-five percent of the neonatal neurons were excited by hypoxia as indicated by a net inward current in the whole-cell patch recordings or by an increase in discharge frequency in the extracellular recordings. Hypoxia did not inhibit and hypercapnia did not affect any of the neonatal neurons tested. In contrast, eighty-five percent of the neurons from the adult caudal hypothalamus were stimulated and fifteen percent were inhibited by hypoxia. In addition, hypercapnia stimulated twenty percent and inhibited forty percent of the adult neurons. These preliminary findings suggest that both hypoxia and hypercapnia affect a higher percentage of neurons in the adult than in the neonatal caudal hypothalamus. These differences may contribute to the different respiratory responses elicited by hypoxia in the newborn as compared to the adult rat. (Supported by NIH 32864 and AHA).

N⁶-L-PHENYLISOPROPYL ADENOSINE (L-PIA) DECREASES SLEEP-APNEAS IN RATS. D. Monti, D. W. Carley, J. Clancy, J. Trapp, R. Basner, E. Onal, M. Lopata, M. Radulovacki*. Departments of Pharmacology and Medicine, University of Illinois College of Medicine, Chicago, IL 60612

Spontaneous apneic events have been described in rats and compared to central apneas in man. In man, administration of adenosine stimulates respiration, presumably secondary to enhanced carotid body chemoreflexes. We tested the hypothesis that administration of L-PIA, an adenosine analog, decreases apneas in rats. We administered 0.3 mg/Kg, 1.0 mg/Kg and 1.5 mg/Kg of L-PIA to 9 adult male Sprague-Dawley rats implanted with EEG and EMG electrodes for sleep/wake scoring and placed in unrestrained body plethysmographs for respiratory monitoring. For each rat, sleep and respiratory activity were polygraphically recorded for 6 hours on 4 different days. Immediately prior to each recording, saline or drug was given by intraperitoneal injection. We defined apnea as cessation of respiratory effort for at least 2.5 seconds and expressed apnea indexes (AI) as apneas per hour. When apneas from all sleep stages were considered, the 2 highest doses of L-PIA were associated with equivalent and significant decreases in AI with respect to saline control (7.1 ± 1.6 - control; 2.5 ± 0.9 - 1.0 mg/Kg; 3.7 ± 1.6 mg/Kg - 1.5 mg/Kg; $p < .05$, repeated measures ANOVA). This L-PIA related decrease in AI was also observed when only slow wave sleep-related apneas were considered (9.2 ± 2.2 - control; 3.1 ± 1.0 - 1.0 mg/Kg; 4.6 ± 2.1 - 1.5 mg/Kg; $p < .05$, for each dose with respect to control). Similar effects of L-PIA on non-slow wave sleep-related apneas were observed, but did not achieve statistical significance. We conclude that administration of an adenosine analog is associated with significant decreases in central apneas in rats. We speculate that a sleep-related decrease in respiratory drive contributes to central apneas, and may be opposed by stimulation of carotid chemoreflexes. Adenosine analogs may offer a viable therapeutic intervention in certain sleep-related breathing disorders.

RESPIRATORY, AUTONOMIC, AND EEG CORRELATES OF TRANSCENDENTAL CONSCIOUSNESS EXPERIENCES DURING TRANSCENDENTAL MEDITATION PRACTICE. F. T. Travis*, Maharishi International University, Fairfield, IA 52557

Periods of apneustic breathing up to 40 seconds have been reported during content-free self-awareness, called transcendental consciousness (TC), in Transcendental Meditation practice, suggesting changed respiratory control^{1,2}. This study replicated and extended these findings. Of twenty TM subjects, five reported TC experiences. During these self-reported experiences: (1) respiration suspended for 5 to 16 sec's in four subjects, and breath volume abruptly decreased 40% in the fifth; (2) skin conductance levels decreased 0.75 μ mhos over the 1.5 min prior to breath changes, followed by a 1.77 μ mhos increase during periods of breath changes; (3) EEG patterns varied—increased frontal-central power and coherence in three subjects, central-parietal in one, and parietal in the other, with peak frequencies at 8-9.5 Hz in three subjects, 5.5-7.0 Hz in another, and 7-7.5 Hz in the last. Concomitant change in breath and skin conductance was not seen in subjects not reporting TC experiences.

Concomitant change in breath and skin conductance, which is also seen during orienting, could indicate orienting to the inner experience of transcendental consciousness. Breath and skin conductance are simple to measure, and could constitute an objective marker of this state.

MICRONEUROGRAPHIC ASSESSMENT OF SENSITIVE AND INSENSITIVE C-FIBERS IN A HUMAN SKIN NERVE. Handwerker H.O.², Schmidt R.¹, Forster C.², Schmelz M.², Traversa R.¹ and Torebjörk H.-E.¹. ¹Department of Clinical Neurophysiology, University of Uppsala, Sweden and ²Department of Physiology and Biocybernetics, University of Erlangen/Nürnberg, Germany.

In microneurography insensitive nociceptive or chemoceptive afferents have not been encountered with conventional search strategies. Here we have recorded from cutaneous fascicles of the peroneal nerve in healthy volunteers. Needle electrodes were inserted intracutaneously in skin sites from which C-fiber responses could be mechanically evoked. Electrical search stimuli were then used to recruit all C-fiber endings in the neighbourhood. The responses of single units to different types of natural stimuli or provocations of sympathetic reflexes were assessed by slowing of impulse conduction velocity in activated units. Though this search procedure is not entirely bias-free, it enabled us to characterize unit types which were missed in former microneurographic studies. Different C unit types are listed in the table. About 15% of the units were

type	n (%)	c. v. (m/s)	mech. thr. (g)
CMH	49 (43)	0.99 \pm 0.12	1.4 - 30
CM	35 (31)	0.86 \pm 0.14	1.4 - 8.5
CM _H	17 (15)	0.84 \pm 0.24	
Symp.	12 (11)	0.76 \pm 0.13	

mechanically and heat insensitive (CM_HH). Treating the skin with mustard oil (allyl-iso-thiocyanate, 100%) activated 3 of 7 CM_HH units which became responsive to mechanical and heat stimuli after that treatment. We conclude that a significant proportion of mechanically and thermally insensitive C-fibers, which have previously been described in the skin of monkey and rat, also exist in human skin and that they may play an important role in pain and hyperalgesia evoked by chemical stimuli.

BIPHASIC MODULATION OF MORPHINE ON SUBSTANCE P RELEASED FROM DISSOCIATED DORSAL ROOT GANGLION NEURONS. H. Suarez-Roca and W. Maixner*. Sec. of Neurochemistry, Instituto de Investigaciones Clinicas, Univ. of Zulia, Apartado 1151, Maracaibo 4001-A, Venezuela. Dental Research Center, Univ. of North Carolina, Chapel Hill, NC 27514.

We have previously reported that morphine produces a concentration-dependent multiphasic modulation (inhibitions and facilitations) of substance P (SP) release from trigeminal nucleus caudalis slices by activating distinct populations of μ -, δ - and κ -opioid receptors (Suarez-Roca and Maixner, *Brain Res.* 579:195, 1992). In the present study, we have examined a wide range of morphine concentrations on K⁺-evoked SP release from dissociated rat dorsal root ganglion (DRG) neurons in culture. Immunoreactive SP was measured in the media. Morphine produced biphasic effects on K⁺-evoked SP release without affecting basal release. Low concentrations of morphine (30 nM) facilitated SP release whereas high concentrations (1 μ M) suppressed release. These effects were abolished by opioid-receptor blockade with naloxone (30 nM). We conclude that an intact neuronal circuitry is not required for morphine to produce a bidirectional modulation of SP release and can act directly by stimulating opioid receptors located on primary afferents. ALTERATIONS IN THE NUMBER OF NADPH-DIAPHORASE-POSITIVE CELLS IN THE TRIGEMINAL NUCLEUS OF THE RAT FOLLOWING TMJ INSULT. A.L. Law, S.T. Meller, S. Murphy* and G.F. Gebhart. Dept. Pharmacology, Univ. of Iowa, Iowa City, IA 52242. The aim of this investigation was to evaluate the effect of tissue damage in the temporomandibular joint (TMJ) on changes in the number of NADPH-diaphorase-positive (NADPH-d+) cells in the trigeminal nucleus. Rats were divided into three groups: (1) 50 μ l 20% mustard oil in left TMJ; (2) 50 μ l mineral oil in left TMJ; and (3) anesthesia only (sodium pentobarbital; 50mg/kg, i.p.). Rats were sacrificed at 6, 24 or 48 hours following TMJ insult or control. Rats were perfused with 2% paraformaldehyde and every tenth section (40 μ m) of brainstem including the trigeminal nucleus (n. caudalis, oralis, and interpolaris) were processed for NADPH-diaphorase using standard histochemical techniques. Sections from each experimental group were matched for experimenter-blinded counting. There were no differences in the number of NADPH-d+ cells between or within groups 2 or 3 at any of the time periods examined. In all groups, the majority of cells were in n. caudalis; within n. caudalis, a majority of cells were in the outer laminae (I and II). In group 1 there was an increase in the number of cells ipsilateral to the TMJ insult over the contralateral side. The major increase was found in the outer laminae of n. caudalis. While there was an increase at 6 and 24 hours, the largest increase in NADPH-d+ cells was found at 48 hours following TMJ insult. The results suggest that tissue insult within the TMJ is associated with ipsilateral increase in NADPH-d+ cells in the trigeminal nucleus, and that the increase is greatest at 48 hours.

EFFECTS OF ACIDIC FIBROBLAST GROWTH FACTOR (aFGF) ON THE PAIN RELATED BEHAVIOUR OF RATS WITH AN EXPERIMENTAL PERIPHERAL NEUROPATHY. J.M.A. Laird*, S. Royce, S.A. Titmuss, F.D. Tattersall, K.A. Thomas+ and R.G. Hill. Neuroscience Research Centre, Merck, Sharp & Dohme Research Labs, Terlings Park, Harlow, U.K. and +Dept of Biochemistry, Merck Research Labs, Rahway, NJ 07065, U.S.A.

Loose ligation of one sciatic nerve in the rat produces a peripheral neuropathy characterised by symptoms indicative of abnormalities in pain sensation (Bennett & Xie 1988, Pain 33: 87). In this study we have examined the effects of i.v. administration of aFGF, a heparin-binding protein known to be neurotrophic, on the development of these symptoms over the first 14 days.

Six groups of rats (n=12 per group) were anaesthetised with pentobarbitone (60 mg/kg i.p.). One group received sham operations. The remainder received sciatic nerve ligations, and in 4 groups, osmotic minipumps were implanted s.c. delivering either heparin vehicle, 0.03, 0.3 or 3 μ g/kg/day aFGF i.v. The spontaneous behaviour and responses to noxious thermal and mechanical stimuli were examined at various times up to 14 days post-surgery (PS).

A dose-related effect of aFGF on heat hyperalgesia was seen at 7 days PS. The trend towards control (sham-operated) values was statistically significant ($p < 0.05$). Exploratory behaviour examined 3 days PS was significantly reduced in the nerve-injured rats, and this was partly reversed by 0.3 μ g/kg/day aFGF (significantly different from vehicle group, $p < 0.05$). There was no effect on posture of the injured limb examined at 3 days PS, nor on mechanical hyperalgesia. These results show that administration of aFGF may prevent the development of some of the abnormalities of pain behaviour associated with an experimental peripheral neuropathy.

REGIONAL INCREASES IN BRAIN METABOLIC ACTIVITY INDICATIVE OF PAIN IN RATS WITH PERIPHERAL MONONEUROPATHY. D.D. Price*, J. Mao, and D.J. Mayer. Dept. of Anesthesiology, Medical College of Virginia, Richmond, Virginia 23298

Regional changes in brain neural activity were examined in rats with painful peripheral mononeuropathy (chronic constrictive injury, CCI) by using the fully quantitative [14 C]-2-deoxyglucose (2-DG) autoradiographic technique. CCI rats exhibited demonstrable thermal hyperalgesia and spontaneous pain behaviors 10 days after sciatic nerve ligation when the 2-DG experiment was carried out. In the absence of overt peripheral stimulation, reliable increases in 2-DG metabolic activity were observed in CCI rats as compared to sham-operated rats within extensive brain regions that have been implicated in supraspinal nociceptive processing. They included cortical somatosensory areas, cingulate cortex, amygdala, ventral posterolateral thalamic nucleus (VPL), posterior thalamic nucleus (PO), hypothalamic arcuate nucleus, central grey matter, deep layers of superior colliculus, pontine reticular nuclei, locus coeruleus, parabrachial nucleus, gigantocellular reticular nucleus, and paraventricular nucleus. The increase in 2-DG metabolic activity was bilateral in most brain regions of CCI rats, but levels of 2-DG metabolic activity were reliably higher in the cortical hind limb area, VPL, and PO contralateral to the ligated sciatic nerve than in ipsilateral corresponding regions in CCI rats. In addition, patterns of increased neural activity found in the brain of CCI rats showed some similarities and differences to those found in the brain of rats exposed to acute nociception induced by noxious heat or formalin stimulation. Thus, these CCI-induced spontaneous increases in neural activity within extensive brain regions previously implicated in sensory-discriminative and affective-motivational dimensions of pain as well as centrifugal modulation of pain are likely to reflect brain neural processing of ongoing neuropathic pain. PRETREATMENT WITH PERINEURAL CAPSAICIN (CAP) REDUCES SPINAL DYNORPHIN (DYN) LABELING AFTER THE CHRONIC CONSTRICTION INJURY (CCI). Y.-O. Lee* and K.C. Kajander^{1,2,*}. Depts of ¹Oral Science, and ²Cell Biology & Neuroanatomy, and ³Graduate Program in Neuroscience, University of Minnesota, Mpls, MN 55455.

Spinal DYN increases maximally ten days after the CCI (Bennett and Xie, 1988; Kajander et al., 1990). We investigated the effects of pretreatment with perineural CAP on DYN A1-8-like immunoreactivity (DYN-LI) induced by the CCI. We also evaluated for a possible association between thermal hyperalgesia and DYN-LI. After baseline tests, using a hindpaw withdrawal method, rats (n=23) were assigned randomly to one of five groups. We applied perineurally around the left sciatic nerve one of the following solutions: group 1) 1.5% CAP in vehicle, group 2) vehicle, groups 3 & 4) 0.9% saline. Group 5 served as a testing control. Fourteen days after perineural treatment, the CCI was produced on the left sciatic nerve of the animals in groups 1-3, and a sham surgery was performed on the animals in group 4. Ten days after the CCI, animals (n=17) were sacrificed for immunocytochemistry of L4-L5 spinal segments. As compared with vehicle-pretreated rats, CAP-pretreated rats exhibited a smaller number of DYN-LI cells ($\bar{x} \pm$ S.E. of 10 sections from each rat; 10.8 ± 3.7 vs 5.1 ± 1.0). A significant, positive correlation existed between the degree of hyperalgesia and the number of DYN-LI cells ($r = 0.91$, $p < 0.01$) in groups 2-5. CAP-pretreated rats did not develop thermal hyperalgesia. In conclusion, CAP pretreatment prevents development of hyperalgesia and reduces DYN labeling after the CCI. Increased DYN is positively correlated with thermal hyperalgesia in rats not treated with CAP. Thermal hyperalgesia may be related to increased DYN in spinal neurons. (Research supported by NIH grant NS29567)

575.6

CHANGES IN SYNAPTIC ORGANIZATION OF THE SUPERFICIAL DORSAL HORN OF THE RAT AFTER EXPERIMENTAL PERIPHERAL MONONEUROPATHY. H.J. Ralston, III*, D.D. Ralston, J. Desmeules, and G. Guilbaud. Department of Anatomy, WM Keck Foundation Center for Integrated Neurosciences, University of California, San Francisco, Ca. 94143-0452 and Unite de Recherches, I.N.S.E.R.M., U161, Paris, France, 75014.

In a rat model of mononeuropathy (Bennet and Xie, '88), one sciatic nerve was ligated with four loose ligatures for 14 days producing behaviorally identified hyperalgesia and allodynia of the affected limb. All animals were cared for according to established protocols. Three days before euthanasia, the sciatic nerve was injected proximal to the ligature with 2 μ l of wheatgerm agglutinin horseradish peroxidase (WGA-HRP) or with cholera toxin-HRP. The anesthetized animal was perfused intracardially with aldehydes and sections of lumbar spinal cord superficial dorsal horn (laminae I and II) reacted for the presence of HRP for electron microscopic (EM) examination. In comparison to the synaptic organization of the normal rat dorsal horn, that of the mononeuropathy model exhibits major changes. 1) Myelinated axons of varying diameters, but primarily small to medium size, degenerate. 2) The usual clusters of non-myelinated axons are diminished in number, although signs of degeneration in these axons are not evident. 3) Glomerular or "scallop" shaped primary afferent terminals are greatly diminished in number and many of those that remain exhibit signs of continuing degeneration, such as oversized mitochondria, neurofilamentous hyperplasia, clustering of enlarged synaptic vesicles or increased electron density. The synaptic relationships of many of these degenerating terminals was preserved. 4) There appears to be a general reduction in overall synaptic contacts. 5) There is a notable reduction in normally abundant terminals in lamina II with dense-core synaptic vesicles, believed to contain neuropeptides. Possible synaptic reorganization, in response to the peripheral nerve injury will be quantitatively described using EM immunocytochemical methods. Supported by NS 21445 from N.I.H. and from I.N.S.E.R.M., U161.

RVM NUCLEI THAT MEDIATE MORPHINE ANTINOCICEPTION FROM THE PAG. M.O. Urban* and D.J. Smith. Depts. Anesth. & Pharmacol., WVU-HSC, Morgantown, WV 26506-9134.

The rostral ventromedial medulla (RVM) is an important relay in mediating descending pain inhibition from the periaqueductal gray (PAG). The area contains the n. raphe magnus (NRM), n. reticularis paraventricularis lateralis (NRGL), and n. reticularis paraventricularis (NRG). The contribution of these nuclei in morphine induced antinociception (tail flick reflex) from the PAG was studied using lidocaine (4%) to provide a localized neural block. Male Sprague Dawley rats were implanted with four guide cannulae - one over the PAG and three in the RVM 1 mm apart mediolaterally with the center cannula over the NRM (R-C, -2.0 mm; Paxinos and Watson, 1986). PAG morphine (6 nmol) produced an antinociceptive response that was unaffected by either a single lidocaine (0.5 μ l) injection into the NRM, bilateral injections into the NRGL, or triple injections into both sites. However, the response was completely inhibited by the administration of 1.0 μ l lidocaine into either the NRM or bilaterally into the NRGL. Triple injections of lidocaine (0.5 μ l) 1 mm dorsal into the NRG also completely inhibited morphine's response, while single or bilateral injections into these sites had no effect. These data suggest that a large area of the RVM, containing primarily the NRG, mediates morphine antinociception from the PAG. The all or none nature of the block suggests that a significant portion of this area contains redundant neural circuits.

575.9

EXPRESSION OF FOS IN A1 AND C1 NEURONS IN RESPONSE TO NOXIOUS HEATING OF THE FOOT IN RATS. R.W. Blair* and S.L. Jones. Depts. of Physiology and Pharmacology, Univ. Oklahoma Health Sciences Center, Oklahoma City, OK 73190.

We previously showed that noxious heating of the foot evoked Fos in the ventrolateral medulla (VLM), with a contralateral predominance. The goal of the present study was to determine whether VLM neurons expressing Fos also were catecholaminergic. Rats were anesthetized with pentobarbital, and the left hindpaw was immersed in 55-60° water for 10 sec for 30 consecutive trials at 2 min intervals. Following a 2 hr survival time, the rats were perfused, and the medulla was processed, using double-label fluorescence immunohistochemistry, for Fos- and DBH-like immunoreactivity, or for Fos- and PNMT-like immunoreactivity. As we found before, there were more Fos-like immunoreactive (Fos-LI) neurons on the side contralateral to the stimulus. Of the A1 neurons in 2 rats, 46% on the contralateral and 42% on the ipsilateral side contained Fos-LI. Of the neurons expressing Fos, 40% on the contralateral and 63% on the ipsilateral side also contained DBH-LI. Of the C1 neurons in 2 rats, 12% on the contralateral and 5% on the ipsilateral side also contained Fos-LI. Of the neurons expressing Fos, 21% on the contralateral and 32% on the ipsilateral side also contained PNMT-LI. Thus, noxious heating of the foot causes the expression of Fos in a significant proportion of A1 and C1 neurons. (Supported by HL29618 and DA07196)

575.11

PARABRACHIAL AREA NEURONS RESPOND TO COLORECTAL (CRD) AND ESOPHAGEAL (ED) DISTENSION. M.B. Burton*, R.J. Traub, G.F. Gebhart. University of Iowa, Iowa City, IA 52242.

Studies have shown that the parabrachial area receives noxious cutaneous as well as cardiovascular/respiratory input. The aim of this study was to characterize the response of neurons in this area to noxious and non-noxious visceral stimuli: CRD and/or ED.

Pentobarbital-anesthetized rats were artificially ventilated. Mean arterial pressure (MAP) was monitored via the femoral artery. Tungsten electrodes were used for extracellular recordings in the parabrachial area. Spontaneously active neurons were characterized as to cutaneous receptive field, and responses to CRD and ED.

CRD-sensitive units were inhibited (75%) or excited (25%). 75% of units which responded to CRD also respond to ED. The spontaneous activity of CRD-sensitive units ranged from 0.5 to 18 Hz. In these animals CRD produced a strong depressor response, while ED produced a weak pressor or depressor response. Sodium nitroprusside (SNP; 0.1 µg/kg i.v.) was administered to determine whether units responded to a change in MAP. Most cells did respond to SNP, however, some exhibited a greater response to ED than to SNP. A cutaneous receptive field was found for 20% of distension sensitive units.

In conclusion, parabrachial neurons respond to noxious visceral stimuli in both an excitatory and inhibitory manner, and receive convergent cutaneous (viscerosomatic) and visceral (viscerovisceral) inputs. Some of these neurons also respond to changes in MAP.

575.13

A NOVEL LONG-LATENCY RESPONSE OF LOCUS COERULEUS NEURONS MEDIATED BY PERIPHERAL C-FIBERS: POSSIBLE SOURCE OF NORADRENERGIC DESCENDING PAIN MODULATION. H. Hirata* and G. Aston-Jones. Div. Behav. Neurobiol., Dept. Mental Health Sci., Hahnemann Univ., Phila., PA. 19102.

Noradrenergic locus coeruleus (LC) neurons are phasically activated by a variety of stimuli including electrical foot shock (FS). The latencies of such responses (20-100 ms) in previous studies indicate rapid conduction velocities in afferent fibers (>2 m/s); FS responses indicative of C-fiber activation have not been documented. We report here a novel long-latency FS response of LC neurons and show that it is mediated by peripheral C-fibers.

In halothane anesthetized rats, extracellular recordings were obtained from individual LC neurons during FS stimulation. Stimulation with 0.5 or 2 ms pulses elicited responses 20 to 100 ms in latency, as previously observed. A new long-latency response (200-400 ms) prominently appeared with 5 ms FS stimuli. This late response was selectively abolished 42 min after application of capsaicin directly to the exposed proximal sciatic nerve. Thus, the late response resulted from peripheral C-fiber activation. The activation of LC neurons by C-fiber-mediated pain circuits may provide noradrenergic centrifugal feedback modulation of nociceptive processing, supporting previous proposals (Jones & Gebhart, 1986). The pharmacological mechanisms responsible for the late response are under study. Supported by PHS grant NS 24698.

575.10

RESPONSES OF NEURONS IN CAUDAL VENTROLATERAL MEDULLA TO NOXIOUS VISCERAL STIMULATION IN THE RAT. K.A. Follitt*, T. Ness, and T. Brennan. Depts. of Neurosurgery and Anesthesiology, Univ. of Iowa, Iowa City, IA 52242.

The role of the lateral reticular nucleus (LRN) in visceral nociception has not been investigated systematically. We evaluated responses of neurons in the region of LRN to noxious visceral stimulation in a rat model of visceral pain.

In Halothane-anesthetized rats, a microelectrode was placed stereotaxically into LRN to record the responses of single neurons to balloon distension of the colon (CRD) at pressures of 20, 40, 60, 80, and 100 mmHg. Neuronal activity was analyzed as peristimulus-time-histograms. In some animals, pentobarbital (15 mg/kg) was given following characterization of a neuron's responses to evaluate the effect of different anesthetic agents.

Twenty-four of 29 units studied were excited by CRD, 5 were inhibited. Responses were usually sustained after CRD termination. Phenylephrine-induced hypertension did not alter neuronal activity in instances in which CRD was accompanied by increases in blood pressure. All cells had cutaneous receptive fields (70% bilateral, 60% nociceptive specific, 40% nociceptive nonspecific). In 8 of 10 neurons studied, Pentobarbital administration abolished responses to CRD and cutaneous stimulation. Responses were facilitated in the other 2.

Neurons in the region of LRN respond to noxious visceral stimulation. This area may be involved in visceral nociception and may have a role in modulation of visceral nociception.

575.12

PREPROENKEPHALIN mRNA IN THE KÖLLIKER-FUSE NUCLEUS OF THE AWAKE RAT: VISUALIZATION IN PROJECTION NEURONS AND INCREASED EXPRESSION AFTER NOXIOUS CUTANEOUS STIMULATION OF DIFFERENT BODY SITES. O. Hermanson*, H. Ericson, D. Larhammar & A. Blomqvist. Dept of Cell Biology, Univ. of Linköping, Dept of Neuropharmacol., Astra Research Centre, Södertälje, and Dept of Medical Genetics, Univ. of Uppsala, Sweden.

Recent investigations with *in situ* hybridization have shown that neurons in the pontine Kölliker-Fuse nucleus (K-F) contain preproenkephalin mRNA (ppENK) (Hermanson et al., Soc. Neurosci. Abstr. 18:832, 1992). The purpose of this study was to investigate (i) if neurons in K-F with descending projections express ppENK, and (ii) if ppENK expression in the cell bodies of K-F is affected by nociceptive stimulation. Cholera toxin was injected into the spinal cord or ventrolateral medulla of male Sprague-Dawley rats. After immunohistochemical processing for the detection of retrogradely labeled neurons, the sections were hybridized with a ³⁵S-labeled cRNA probe to ppENK. A major part of the neurons retrogradely labeled from either target were found to express ppENK. Most of the double-labeled neurons were located in the middle third of the rostrocaudal extent of the ppENK-positive population. The effect of nociceptive stimulation on the ppENK expression in the K-F region containing the neurons projecting to the spinal cord or ventrolateral medulla was investigated in awake freely-moving rats that were pinched in the nape of the neck or the base of the tail. A third group of rats received non-noxious sensory stimulation (brush). A microcomputer image analysis system was used to quantify the number of neurons labeled by *in situ* hybridization. Cell bodies displaying a grain density >30 times background level over an area of >80 µm² were regarded as ppENK-positive. In both groups of stimulated rats, the number of cells expressing ppENK increased with 60% compared to the control group (ANOVA; p<0.05). The present findings demonstrate that the expression of ppENK in K-F neurons is increased by mechanical noxious stimulation and suggest that enkephalinergic K-F neurons are involved in descending regulation of autonomic functions.

TRANSNEURONAL LABELLING OF SMALL DIAMETER TRIGEMINAL GANGLION NEURONS AFTER PSEUDORABIES VIRUS (PRV) INJECTION INTO THE CENTRAL NUCLEUS OF THE AMYGDALA (CE). L. Jasinin*, K. Tarczy-Hornoch, H. Wang, J.D. Levine, A.I. Basbaum. Depts. of Anatomy, Medicine, Neurosurgery and Physiology and Keck Center for Integrative Neuroscience, UCSF, CA.

Although injection of the swine herpes virus PRV-Bartha into limb muscles results in very dense labelling of spinal cord projection neurons, motoneurons and interneurons, there is no labelling in the dorsal root ganglion (DRG), possibly because the virus enters latency in DRG cells (Rotto-Perceley et al. 1992). In the present study we demonstrate that when the virus is injected into the CNS, PRV-Bartha can be immunocytochemically detected in the DRG, implying lytic infection. Our studies focused on the pathway through which neurons of the CE receive nociceptive input. In previous studies we demonstrated that after injection of PRV into the CE, transneuronally labelled neurons can be identified in the lateral parabrachial nucleus and in marginal (lamina I) neurons of the medullary and spinal dorsal horn. In this study we specifically addressed the primary afferent input to the spino/trigemino-parabrachio-amygdaloid pathway.

The rats received a stereotaxic injection into the CE of 100 nl of PRV-Bartha (8 x 10⁴ pfu) mixed with 40nm colloidal gold particles. The gold particles allowed precise localization of the virus injection sites. Using immunocytochemistry with antisera directed against PRV and with the ABC-DAB technique we identified PRV-infected neural and non-neural (satellite) cells in 50µm sections of the trigeminal ganglia. Twelve percent of the ganglion neurons were PRV-immunoreactive. Of these, 64% were small (20µm), 28% medium (30µm), and 8% large (60µm) diameter cells. The predominance of labelling in small diameter neurons (some of which we have shown to be substance P-immunoreactive) is consistent with studies that demonstrated that many neurons driven by the spino-trigemino-parabrachial pathway are exclusively responsive to noxious stimuli. The labelling of larger neurons suggests, however, that WDR neurons also contribute inputs to the amygdala. Our results also suggest that the route of infection of the DRG (i.e. central vs. peripheral) critically affects whether PRV becomes lytic or latent in the infected cells. PATTERN OF IMMEDIATE EARLY GENE EXPRESSION IN RAT BRAIN FOLLOWING A NOCICEPTIVE STIMULUS. HB Gutstein,* WE Cullinan, RC Thompson, SI Watson, and H Akil. Dept. of Anesthesiology and MHRI, University of Michigan, Ann Arbor, MI, 48109.

Recently, both noxious and stressful stimulation have been shown to induce changes in immediate early gene (IEG) expression in relevant neuronal systems. Few studies have examined the supraspinal components of this response, however, and the majority of this work has been done in anesthetized animals. The present study was undertaken to determine supraspinal patterns of IEG activation in awake animals after noxious stimulation, and ultimately, to differentiate the effects of the nociceptive stimulus from the effects of associated stress.

Four male Sprague-Dawley rats underwent the injection of 0.05 ml of 2.5% formalin in the right hindpaw while awake, and were sacrificed by rapid decapitation 30 minutes later. Three animals served as unhandled controls. Brains were quickly frozen, then sectioned and subsequently fixed in paraformaldehyde. *In situ* hybridization histochemistry was then performed using a cRNA probe for c-fos.

Brain areas showing c-fos induction following this stimulus included: olfactory bulb, lateral septal nucleus, bed nucleus of the stria terminalis, hypothalamic paraventricular nucleus, dorsomedial hypothalamic nucleus, medial habenula, ventral posterior thalamic nucleus, and the hippocampus. Expression of c-fos mRNA was also detected in the cerebellum, posterior parietal and temporal cortices, as well as several limbic cortical regions (cingulate, orbitofrontal, and infralimbic).

These data suggest that awake noxious stimulation induces c-fos expression in many cortical and subcortical areas. Studies are currently underway contrasting these patterns of activation with those seen following non-nociceptive stress.

ELECTROPHYSIOLOGICAL AND NEUROANATOMICAL STUDIES OF THE ROLE OF THE NEOSTRIATUM AND GLOBUS PALLIDUS IN NOCICEPTION. E.H. Chudler, K. Sugiyama and W.K. Dong. Dept. of Anesthesiology, Univ. of Washington, Seattle, WA 98195.

Neuroanatomical experiments were performed to investigate the peptides contained within neurons in the neostriatum (CPu) and globus pallidus (GP) that project to the substantia nigra. Injections of the fluorescent tracer (Dil) into the substantia nigra retrogradely labeled neurons in the CPu and GP. When the same tissue sections were processed with immunocytochemical procedures, we found that some striatal and pallidal neurons that projected to the substantia nigra contained dynorphin and substance P.

The response properties of neurons in the CPu and GP to mechanical and thermal stimuli were studied in rats anesthetized with equithesin. Neurons responsive to noxious stimuli were concentrated along the border of the CPu and GP. Neuronal discharge elicited by noxious thermal and mechanical stimulation sometimes outlasted the duration of the stimulus. The receptive fields of nociceptive neurons were large and often bilateral. The trigeminal region was included in the receptive fields of almost all neurons. Wide-dynamic-range (WDR) neurons were able to encode a greater range of stimulus intensity than either nociceptive-specific (NS) or inhibited (INH) neurons in the CPu and GP. Nociceptive neurons in the neostriatum and globus pallidus may be involved with grading motor responses to noxious stimuli (WDR neurons) or signalling the occurrence of noxious stimuli and coordinating gross movements to noxious events (NS and INH neurons).

Supported in part by NIH grant NS29459 (WKD) and Univ. of Washington Graduate School Fund Award (EHC).

THE ROLE OF NOCICEPTIVE SUPERIOR COLLICULUS NEURONS IN APPROACH BEHAVIORS. P. Redgrave¹, M. Simkins¹, J.G. McHaffie², C.-Q. Kao², S.J. Goldberg³, and B.E. Stein² Depts. of Psychol. Univ. of Sheffield, U.K., and Physiology² and Anatomy³, Medical College of Virginia, USA

Nociceptive neurons are widely distributed in deep superior colliculus (Stein & Dixon, Brain Res. 158:65-73, 1978) and, along with their low threshold neighbors, are organized into topographic maps, each biased for an expanded representation of the face (McHaffie, Kao, & Stein, J. Neurophysiol. 62:510-525, 1989). Presumably, a nociceptive-activated withdrawal system in the SC evolved in concert with a low-threshold-activated approach system to adapt the rodent face for exploration. Thus, nociceptive SC neurons can protect the face from potentially damaging stimuli by simultaneously inhibiting the tendency to approach and initiating withdrawal. However using antidromic techniques in the present study it was evident that many (22/56) nociceptive SC neurons which were maximally responsive to persistent stimulation had axons which exited the SC via the crossed tecto-reticulo-spinal (TRS) tract, through which approach (i.e., orientation) responses are evoked. Subsequent behavioral experiments showed that TRS transection interfered with movements directed only toward a persistent noxious stimulus without altering its apparent perception. These results suggest that approach (and removal by biting), rather than withdrawal, may be a more adaptive way of dealing with a persistent noxious stimulus than continued attempts to withdraw. Different qualities of the stimulus (innocuous vs noxious) or the duration of a noxious stimulus (transient vs persistent) may be used differentially to determine access to SC efferent projections associated with approach and withdrawal responses. Supported by a grant from the Wellcome Trust Fund.

NOCICEPTIVE AND NON-NOCICEPTIVE THALAMIC RESPONSES IN BILATERAL PREFRONTAL DECORTICATED RATS. I. Ojamaa, B. M. Sanchez-Moreno, and M. Combes-Laba. DEPARTAMENTO DE NEUROFISIOLOGIA, DIV. INVEST. NEUROCIENCIAS, INSTITUTO MEXICANO DE PSIQUIATRIA, MEXICO 14370 D.F. MEXICO.

THE PREFRONTAL AND ADJACENT CORTICES ARE INVOLVED IN PAIN TRANSMISSION. THESE AREAS ARE THE PRINCIPAL PROJECTION SITES FROM MEDIAL AND INTRALAMINAR THALAMIC NUCLEI. IN ADDITION, FRONTO-PARIETAL AND CINGULATE CORTICAL ABLATIONS REDUCE THE AUTOTOMY EXPRESSION IN DEAFFERENTED RATS. IN THIS STUDY IT WAS ANALYZED THE EFFECTS OF BILATERAL PREFRONTAL DECORTICATION ON THALAMIC EVOKED RESPONSES TO NON NOXIOUS AND NOXIOUS STIMULI. TWENTY TWO MALE ALBINO WISTAR RATS (230-270g) UNDER PENTHOBARBITAL ANAESTHESIA (40 mg/kg i.p.) WERE DECORTICATED BY ASPIRATION. THALAMIC BILATERAL SIMULTANEOUS EXTRACELLULAR UNIT RECORDINGS WERE OBTAINED UNDER URETHANE ANAESTHESIA (1.5 mg/kg). EIGHTY FIVE RESPONSIVE UNITS WERE RECORDED, 14 (16%) CELLS RESPONDED TO NON NOXIOUS MECHANICAL STIMULI (BRUSHING OR LIGHT PRESSURE), 25 (30%) CELLS RESPONDED TO NOCICEPTIVE MECHANICAL (PRESSURE WITH SERRATE FORCEPS), NOCICEPTIVE THERMAL (IMMERSING TAIL IN HOT WATER AT 50 °C DURING 30 s) OR MECHANO-THERMAL NOXIOUS STIMULATION. FORTY SIX (54%) CELLS DISPLAYED POLIMODAL RESPONSES ENCODING STIMULI FROM NON-NOXIOUS TO NOXIOUS INTENSITY. 27 (32%) NOCICEPTIVE NEURONS FAILED TO RESPOND ONCE OR TWICE TO NOXIOUS STIMULATION; 10 (12%) CELLS DISPLAYED AFTERDISCHARGES (2 OR MORE MIN.) DRIVEN BY NOXIOUS STIMULATION; 6 (7%) CELLS EXHIBITED ENHANCED RESPONSES TO NON NOXIOUS AND NOXIOUS STIMULI. IN NORMAL RAT, THE INTRALAMINAR THALAMIC RESPONSES TO NOXIOUS STIMULATION CAN BE REPRODUCED IN A ORGANIZED FASHION. THE RESULTS SHOW THAT THESE CELLS DISPLAYED DISORGANIZED RESPONSIVENESS AFTER DECORTICATION.

NEURONS INTRINSIC TO THE AMYGDALA MEDIATE MORPHINE ANALGESIA IN THE FORMALIN TEST. B.H. Manning¹ and D.J. Mayer². Depts. of ¹Anatomy and ²Anesthesiology, Medical College of Virginia, Virginia Commonwealth University, Richmond, Virginia 23298

Morphine produces analgesia in the rat paw formalin test in part through action at sites within the brainstem and diencephalon (Manning et al, 1993; Neuroscience, in press), but the analgesic efficacy of these sites appears to depend on ascending projections to a critical site(s) in the telencephalon. To test the possibility that neurons intrinsic to the amygdala are critical mediators of this analgesia, we induced focal lesions by bilaterally microinjecting N-methyl D-aspartate (NMDA; 0.25M in phosphate buffer, 0.2 µl injection volume) into the rostro-dorsal amygdaloid complex of the rat. Post-surgical seizures were controlled with diazepam (1 mg/kg i.p.). Following one week of recovery, the analgesic effect of morphine sulphate (7 mg/kg; s.c.) was assessed using the formalin test. Control groups were as follows 1) rostro-dorsal amygdala lesion/systemic saline 2) rostro-dorsal amygdala sham lesion/systemic morphine 3) rostro-dorsal amygdala sham lesion/systemic saline 4) adjacent areas sham lesion/systemic morphine 5) adjacent areas sham lesion/systemic saline 6) adjacent areas sham lesion/systemic morphine 7) adjacent areas sham lesion/systemic saline. Formalin pain was simultaneously rated using 1) the traditional rating scale and 2) flinching of the injured paw. None of the lesions reliably affected base-line pain scores. Lesions of the rostro-dorsal amygdala, however, reliably attenuated analgesia. Control lesions in adjacent areas had no effect. The results indicate that the amygdala is critical for the production of morphine analgesia in the formalin test, thereby contributing to a growing body of evidence suggesting that opioid control of prolonged pain requires structures higher in the neuraxis than those required for control of brief, intense acute pain.

NEURONAL BURSTING IN LATERAL AND MEDIAL THALAMIC NUCLEI IN THE NAIVE RAT. M. Lis-Planells, P.C. Rinaldi*, C. Posch; Department of Neurological Surgery, University of California Irvine, CA 92717.

Thalamic neuronal bursting has been identified in patients during stereotactic procedures for relief of chronic pain. It is unknown whether these spontaneously bursting neurons are found in the thalamus of normal humans. Deafferentation animal models have also shown neuronal bursting, particularly in the dorsal horn and lateral thalamic nuclei. This study characterizes spontaneous thalamic activity in naive rats in lateral thalamic nuclei (primary somatosensory relay nuclei - VPM, VPL) and medial thalamic nuclei (MD, CM, CI, Re). Nine rats were sedated (chloral hydrate) and extracellular recordings were obtained from lateral thalamic nuclei (LThN) and medial thalamic nuclei (MThN). Peripheral receptive fields were tested bilaterally during recordings and single units were taped for computerized interval histogram and burst analyses. A total of 43 cells were analyzed (28 in LThN, 15 in MThN). Similar proportions of bursting activity were found in both LThN and MThN (60% & 61%, respectively). MThN neurons exhibited longer bursts (more spikes per burst), but durations of successive intervals between spikes were similar in both nuclear groups. In LThN 43% of the cells were responsive to pain and/or touch. In MThN most cells had no evoked responses and only one (7%) was responsive to pain. This study indicates that lateral and medial thalamic neurons exhibit spontaneous bursting activity in naive rats. The data support the concept that LThN and MThN show different responses to somatosensory stimulation but present similar electrophysiological properties. These analyses of cellular activity can form a basis on which to evaluate neural activity from the same nuclei in deafferentation and nociceptive animal pain models. They may also lead to further determining the role of neuronal plasticity in development of chronic pain.

COLUMNAR ORGANIZATION IN PAG: PHYSIOLOGICAL EVIDENCE FOR INTER-COLUMNAR INTERACTIONS. S.C. Chandler*, H. Liu, A.Z. Murphy, M.T. Shipley and M.M. Behbehani. Dept. of Physiology and Biophysics, Anesthesia and Anatomy and Cell Biology, U. of Cincinnati College of Medicine, Cincinnati, OH 45267-0576.

Recent studies indicate that the periaqueductal gray (PAG) is organized into distinct longitudinal input and output columns. Forebrain afferents target dorsomedial, lateral and ventrolateral columns in PAG; these columns contain neurons that project to the rostral ventral medulla (RVM). In this study we assessed physiological interactions between the dorsomedial (PAGdm) and ventrolateral (PAGvl) columns in an *in vitro* slice preparation.

Electrical stimulation (20-50 Hz) was applied to a bipolar stimulation electrode in the PAGdm. In some experiments PAGdm was chemically activated by injection of 100 nl of 5 mM D,L homocysteic acid applied from a pipette glued to the stimulation electrode.

Electrical stimulation of PAGdm produced inhibition that lasted for as long as eight minutes in 13/61 cells (21%) in PAGvl. Naloxone, applied next to the recording site, blocked this inhibition in 46% of the cells tested. Stimulation of PAGdm produced an excitatory response that lasted between 33 and 68 seconds in 9/61 (15%) of the cells in PAGvl. Chemical stimulation of PAGdm produced the same response as electrical stimulation in 7/10 cells tested. Stimulation of PAGdm caused no change in the firing rates of 39 cells (54%).

We conclude that: (1) PAGdm modulates the activities of PAGvl neurons. (2) The inhibitory action of PAGdm on cells in PAGvl is mediated in part by activation of opioid receptors. These results support the hypothesis that there are significant physiological interactions among longitudinal input-output columns in PAG. Supported by NIH grant #20643.

ACUTE MORPHINE CAUSES AN INCREASE IN ENKEPHALIN RELEASE DURING MICRODIALYSIS OF THE PERIAQUEDUCTAL GRAY. F.G. Williams*, M.M. Mullett, and A.J. Beitz. Department of Pathobiology, University of Minnesota, 1988 Fitch Ave., St. Paul, MN 55108

Opiate-induced antinociception in the periaqueductal gray matter (PAG) has been postulated to involve interneurons that employ GABA as their transmitter. In addition to this intrinsic PAG circuit, it is possible that endogenous opioids may be locally regulated as was observed in other regions of the nervous system. This study examined whether morphine altered the functional, dynamic release of enkephalin in the PAG of normal rats. Microdialysis probes containing Hospal acrylonitrile dialysis membrane (1mm length) were implanted in the ventrolateral PAG and perfused at 5 μ l/min. Baseline dialysate enkephalin levels, measured by radioimmunoassay 3 to 5 hours after the start of dialysis, averaged 1.20 \pm 0.22 pg/12 min. Following an IP morphine injection (12 mg/kgbw), enkephalin recovery increased significantly to 2.74 \pm 0.69 pg/12 min ($p < .05$, 1 way ANOVA). Following a second IP morphine injection (12 mg/kgbw), extracellular enkephalin levels in the ventrolateral PAG declined to 1.33 \pm 0.41 pg/12 min. This result suggests that endogenous opiates might be capable of amplifying enkephalin release in the PAG. Should the effect originate locally within the PAG, the results are consistent with the hypothesis that GABAergic neurons may exert a reciprocal tonic inhibition of opiate-containing neurons. Supported by NIH grants NS28016, DA06687, and DE06682.

INHIBITORY INFLUENCE OF NUCLEUS RAPHE OBSCURUS ON THE MIDBRAIN DEFENCE AREA. F.M. Semenenko, B.M. Lumb and T.A. Lovick (SPON: Brain Research Association). Depts. of Physiology, University of Bristol, BS8 1TD and University of Birmingham, Birmingham B15 2TT, U.K.

Experiments have been carried out to investigate the influence of nucleus raphe obscurus (NRO) on the activity of neurones in the dorsal half of the midbrain periaqueductal grey (dPAG), the midbrain defence area.

In initial electrophysiological experiments in urethane-anesthetized rats, selective stimulation of neuronal perikarya in NRO, by microinjection of an excitatory amino acid suppressed ongoing activity of 18/21 neurones tested in the dPAG. Iontophoretic application of 5-HT or the 5-HT_{1A} agonists 8, OH-DPAT and buspirone also inhibited these cells. Both the drug-induced and neurally-evoked inhibitions were potentiated in the presence of a 5-HT reuptake blocker.

Projections from NRO to the PAG were investigated in a second neuroanatomical study using retrograde transport of coumarin or rhodamine-labelled latex microspheres. There was no evidence for a direct projection from NRO to the dPAG. However, significant numbers of neurones in NRO were found to project to the ventrolateral sector of the PAG.

We conclude that activation of neurones in NRO produces an inhibitory serotonergic influence on the excitability of cells in the dPAG. The effect appears to be mediated indirectly, probably via activation of inhibitory interneurons in the ventrolateral PAG.

576.6

DORSAL RAPHE NUCLEUS EXERTS EXCITATORY AND INHIBITORY EFFECTS ON NEURONES IN THE DORSOLATERAL PERIAQUEDUCTAL GREY MATTER. V.V. Stezhka and T.A. Lovick (SPON: Brain Research Association). Dept. of Physiology, University of Birmingham, Birmingham B15 2TT, U.K.

The influence of the dorsal raphe nucleus (DRN) on the activity of neurones in the dorsolateral periaqueductal grey matter (PAG) has been studied in coronal slices of rat midbrain maintained *in vitro* in an interface chamber.

Topical application to the DRN of 15-100nl droplets of 1-10mM D,L-homocysteic acid (DLH), to selectively activate neuronal perikarya, produced suppression (n=5) or facilitation (n=4) of ongoing activity recorded extracellularly from neurones in the PAG. Two further cells responded with a biphasic response and 7 were unaffected.

In a second study, iontophoresis of DLH into the DRN (800-1300nA from 5 barrels of a micropipette) was used to produce a more localised stimulus. This form of stimulation evoked dose-dependent inhibitory and excitatory responses in the PAG. In both series of experiments, iontophoretic application of serotonin (0-30nA) directly to the neurones in the PAG always inhibited ongoing activity.

We conclude that viable excitatory and inhibitory projections from the DRN to the dorsolateral PAG are present within the midbrain slice preparation. Furthermore, serotonin may be involved in mediating the inhibitory projection.

HYPOTHALAMIC PROJECTIONS TO THE ROSTROVENTRAL LATERAL MEDULLA: ROSTROCAUDAL ORGANISATION. P.M. Hudson, F.M. Semenenko and B.M. Lumb (SPON: Brain Research Association). Physiology Dept., University of Bristol, BS8 1TD, U.K.

Hypothalamic integration of autonomic control and spinal processing of nociceptive inputs may be partly mediated via a relay in the rostromedial medulla (RVLm). The present study used retrograde transport techniques to investigate the organisation of projections from the hypothalamus to rostromedial subregions of the RVLm.

Rats were injected with 50-150nl of fluorescent latex microspheres into a region of the RVLm under sodium pentobarbitone anaesthesia (60mg/kg i.p.). Animals were allowed to recover and left for 5-7 days, reanaesthetised and perfused transcardially with 4% paraformaldehyde. Serial 50 μ m sections were examined under a fluorescence microscope to view injection sites and labelled cells.

Injections of tracer into either the retrofacial or juxtafacial RVLm labelled neurones throughout an area of the hypothalamus between the dorsomedial nucleus and the preoptic area. However, there were marked differences in the patterns of labelling from these two regions. Injections into the juxtafacial region gave rise to widespread labelling. In contrast, labelled neurones were more restricted following injections into the retrofacial RVLm, and formed discrete groups in the lateral hypothalamic area and in a region ventral to the ventromedial hypothalamus. We suggest that the different patterns of somato-autonomic changes that can be evoked from the hypothalamus may be mediated via relays in different regions of RVLm.

CATECHOLAMINERGIC INPUT TO SEROTONIN NEURONS PROJECTING TO THE SPINAL CORD IN THE RAT VENTROMEDIAL MEDULLA OBLONGATA. M. Tanaka, H. Okamura, Y. Tamada, Y. Tanaka, S. T. Inouye* and Y. Ibatata. Depts. of Anesthesiology and Anatomy, Kyoto Prefectural Univ. of Medicine, Kawaramachi-Hirokoji, Kmikyoku-ku, Kyoto 602, *Int. Brain Funct., Mitsubishi Kasei Inst. of Life Sci., Tokyo, Japan.

The midline of rostral ventral medulla (RVM) is the portion in which many serotonin neurons (nucleus raphe magnus and rostral nucleus raphe pallidus) and dense catecholamine (noradrenaline and adrenaline) fibers are distributed. These serotonin neurons are known to project to the spinal cord and to be involved in pain modulation and cardiovascular pressure control. In this study, we have investigated the connection between spinally projecting serotonin neurons and catecholaminergic fibers in the rat RVM by light and electron microscopic immunocytochemistry.

First, light microscopic immunocytochemistry using triple labeling method revealed that serotonin-immunoreactive (IR) neuron (visualized by avidin-biotin peroxidase complex and diaminobenzidine) which contains retrograde tracer (cholera toxin B subunit) injected in the cervical cord (labeled by FITC) was observed to be intimately surrounded by tyrosine hydroxylase (TH)-IR fibers (labeled by Texas Red). Second, Silver-gold intensified TH-IR axon terminals were detected to make synaptic contacts with serotonin-IR neuronal perikarya and dendrites by double labeling immunoelectron microscopy.

These results suggest that spinally projecting serotonin neurons concerned in pain modulation or cardiovascular control are directly regulated by catecholaminergic neurons at the level of RVM.

576.11

ULTRASTRUCTURAL EVIDENCE THAT SUBSTANCE P NEURONS MAKE SYNAPTIC CONTACTS ON NORADRENERGIC NEURONS IN THE A7 CELL GROUP THAT MODULATE NOCICEPTION. H.K. Proudfit* and M. Monsen. Dept. of Pharmacology, Univ. of Illinois at Chicago, Chicago, IL 60612.

We have demonstrated that substance P (SP) neurons in the ventromedial medulla project to noradrenergic neurons in the A7 catecholamine cell group. These SP neurons appear to produce antinociception by activating A7 neurons.

These experiments determined whether SP-containing axons make synaptic contacts on noradrenergic neurons in the A7 cell group. Pre-embedding immunocytochemistry combined with light and electron microscopic analysis was used to identify tyrosine hydroxylase (TH) antisera labeled with silver-intensified gold (SIG) and SP antisera labeled by the immunoperoxidase reaction.

TH labeling was found in perikarya, dendrites, and dendritic spines in the A7 region. SP labeled by SIG was found in axons and terminals. Some SP-labeled terminals made asymmetric synaptic contacts on TH-labeled dendrites and dendritic spines. SP-labeled terminals also contacted unlabeled dendrites and unlabeled terminals contacted TH-labeled dendrites and spines.

These results support the conclusion that stimulation of SP neurons produces antinociception by direct activation of noradrenergic A7 neurons. This work was supported by USPHS grant DA03980 from the National Institute on Drug Abuse.

IDENTIFICATION OF ON- AND OFF-CELLS IN THE RVM OF UNANESTHETIZED DECEREBRATED RATS. R. W. Clarke, M. M. Morgan, and M. M. Heinricher. (Spon: Brain Research Association) Dept. Physiology and Env. Sci., Univ. Nottingham, Sutton Bonington LE12 5RD, U.K., and Dept. Neurology, Univ. California, San Francisco, CA 94143-0114.

The rostral ventromedial medulla (RVM) is involved in the descending modulation of nociception. Two classes of RVM neurons which underlie this modulation have been identified in rats anesthetized with barbiturate (Fields et al., 1983) or halothane (Morgan & Heinricher, 1992). "On-cells" become active and "off-cells" inactive immediately prior to nociceptive reflexes, and appear to be involved in the facilitation and inhibition of nociception, respectively. The object of the present study was to determine the characteristics of these neurons in unanesthetized, decerebrated rats.

Male Sprague-Dawley rats were anesthetized with halothane, placed in a stereotaxic frame, and decerebrated by suction to the pre- or mid-collicular level. Radiant heat sufficient to elicit a withdrawal reflex was applied to the tail and the responses of RVM neurons recorded. Rats were tested while lightly anesthetized (0.5-0.8% halothane) and in the absence of anesthetic.

On- (n=16) and off-cells (n=9) were found in unanesthetized decerebrated rats. Ongoing cell activity increased in 53% of the on-cells and in 89% of the off-cells when the anesthetic was removed. The on-cell burst and off-cell pause preceding the tail flick reflex were seen regardless of anesthetic level. Mean tail flick latency fell from 7.0 to 6.2 s 5 min after removal of halothane.

These data show that the characteristic features of on- and off-cells are not dependent on structures rostral to the midbrain. Moreover, these neuronal classes are not an epiphenomenon of anesthesia as has been suggested by others (Oliveras et al., 1989). EFFECTS OF PERIAQUEDUCTAL GRAY (PAG) AND VENTROLATERAL ORBITAL (VLO) CORTEX STIMULATION ON NOCICEPTIVE NEURONS IN THE ROSTRAL VENTROMEDIAL MEDULLA (RVM) OF THE RAT. W.D. Hutchison*, L. Harfa and J.O. Dostrovsky. Dept. of Physiol., Univ. of Toronto, Canada M5S 1A8.

The On- and Off-cells of the RVM have been implicated in the modulation of nociception. The antinociceptive effects of PAG stimulation is thought to be mediated via a relay in the RVM (Vanegas et al., Brain Res. 321, 1984), but its effects on On- and Off-cells have not been studied extensively. In addition, a projection of VLO to PAG has been previously reported and therefore a possible role of VLO in modulation of RVM cells was investigated.

Recordings were made from 44 neurons in RVM and surrounding regions in barbiturate-anesthetized rats. Our studies confirmed the existence of the 3 types of neurons in RVM (On, Off, Neutral) on the basis of response characteristics to peripheral innocuous and noxious thermal and mechanical stimuli. Electrical stimulation of the PAG excited 16 and increased the response to noxious stimulation of one On-cell of the 29 tested. In contrast, PAG stimulation reduced the spontaneous firing of one Off-cell and the noxious stimulus-induced inhibition of 2 other of the 12 Off-cells tested. No effects were observed on the 3 Neutral-cells tested. In 4 experiments the VLO cortex was also stimulated but no significant effects were observed on the 12 On-cells and 3 Off-cells examined. Although the PAG-induced reduction of the inhibition of 2 Off-cells is consistent with the role of PAG and Off-cells in descending inhibition of nociception, the excitation of On-cells appears contradictory. Similar paradoxical effects on On-cells have been reported previously for PAG stimulation and for vagal afferent stimulation. It appears that VLO does not play a significant role in descending modulation of RVM nociceptive neurons. (Supported by MRC of Canada)

PROJECTIONS OF NORADRENERGIC NEURONS IN THE A5 CATECHOLAMINE CELL GROUP TO THE SPINAL CORD AND THE VENTROMEDIAL MEDULLA DETERMINED BY DOUBLE RETROGRADE TRACING COMBINED WITH IMMUNOCYTOCHEMISTRY: IMPLICATIONS FOR A ROLE IN NOCICEPTIVE MODULATION. G.C. Newsom*, J.I. Choca, and H.K. Proudfit. Dept. of Pharmacology, Univ. of Illinois at Chicago, Chicago, IL 60612.

It is well established that activation of neurons in the ventromedial medulla (VMM) produces antinociception. In addition, VMM neurons are tonically inhibited by norepinephrine, the source of which appears to be the A5 cell group. These A5 neurons facilitate nociception because bilateral electrolytic lesions of the A5 group produce antinociception.

In contrast, activation of some A5 neurons appears to reduce nociception because electrical or chemical stimulation of A5 neurons produces antinociception which is not blocked by microinjection of tetracaine in the VMM, but is antagonized by intrathecal administration of yohimbine. It is likely that this antinociception is produced by A5 neurons that project directly to the spinal cord.

This apparent dual role of A5 neurons in modulating nociception was investigated using double retrograde tracing combined with immunocytochemistry. Rats received injections of Fluorogold in the spinal cord and rhodamine-labeled microspheres in the VMM. Brain stem sections were processed for tyrosine hydroxylase (TH) immunocytochemistry. Preliminary results show that some TH-immunoreactive A5 cells project to the spinal cord, some project to the VMM, and some project to both areas. Thus, there may be separate populations of A5 neurons that serve different functions. (Supported by USPHS grant DA03980 from the National Institute on Drug Abuse)

576.14

AN IN VIVO INTRACELLULAR STUDY OF NOCICEPTIVE MODULATORY CELLS IN THE RAT ROSTRAL VENTROMEDIAL MEDULLA (RVM) A. Zagon*, X. Meng and H.L. Fields. Dept. Neurology, Univ. California, San Francisco, CA 94143-0114.

Extrinsic factors which influence the activity of nociceptive modulatory cells in the RVM have been extensively investigated. Very little is known however, about the intrinsic electrophysiological properties of these cells. The present work studied the intracellular properties of physiologically identified, nociceptive modulatory cells using *in vivo*, anesthetized preparations.

The spontaneous activity of 40 cells with resting potential above 50 mV (input resistance 7-33 M Ω) was analyzed. "On", "Off" and "Neutral" cells in the RVM were characterized according to their activity during the tail flick test. 4-16 action potentials were collected preceding each tail flick test and were averaged. The averaged action potentials were measured.

21 cells were distinguished by the presence of a short duration action potential (0.6 ms \pm 0.02ms) and a biphasic afterhyperpolarization (AHP) with an early peak at 0.6 ms \pm 0.03 ms latency to 4.0 mV \pm 0.6 mV and a 6.7 ms \pm 0.4 ms latency peak to 5.3 mV \pm 0.4 mV. All of these cells were nociceptive modulatory: 17 On and 4 Off.

In 19 cells, (7 On, 3 Off, 9 Neutral) the action potentials were significantly longer (1.0 ms \pm 0.1 ms, p<0.001) and were followed by an AHP of slower time course and larger amplitude: 2.3 ms \pm 0.2 ms, 8.5 mV \pm 0.7 mV. In 13 cases the AHP was biphasic, with a second peak at 11.4 ms \pm 1.1 ms latency to 6.2 mV \pm 0.6 mV. It is of interest that the average duration of the neutral cell action potential (n=9) was 1.2 ms \pm 0.2 ms, which is significantly longer than the average for all On and Off cells (0.65 \pm 0.2ms, n=31, p<0.001).

Our data suggest that different subpopulations of RVM neurons can be characterized by differences in their intrinsic electrophysiological properties. Supported by DA01949 and Bristol-Myers Squibb Co.

EVIDENCE THAT DISTINCT CATECHOLAMINE CELL GROUPS FORM THE PRIMARY SOURCE OF NORADRENERGIC PROJECTIONS TO THE VENTROMEDIAL MEDULLA IN SASCO VERSUS HARLAN STOCKS OF THE SPRAGUE-DAWLEY RAT. J.I. Choca*, M. Monsen and H.K. Proudfoot. Dept. of Pharmacology, University of Illinois at Chicago, Chicago, IL 60612.

Results from this laboratory have suggested that the A5 noradrenergic (NA) cell group constitutes the primary source of the NA projections to the ventromedial medulla (VMM). Nevertheless, evidence from other laboratories contradict our data and suggest that the majority of these fibers originate in the A6 cell group. The following experiments were performed to determine whether the neuroanatomical differences which occur across breeding stocks might account for the reported discrepancies.

Two groups of Sprague-Dawley rats (either Sasco or Harlan) received microinjections of rhodamine-labeled microspheres in the VMM, and brain stem sections were processed for tyrosine hydroxylase (TH) immunocytochemistry. These brain stem sections were examined for TH-immunoreactive cells which also contained the retrogradely-transported label (double-labeled cells). The results of these studies indicate that in the Sasco animals most of the double-labeled cells occur in the A5 NA cell group ($46 \pm 5\%$); whereas, in the Harlan animals most of the double-labeled cells occurred in the A6 NA cell group ($45 \pm 4\%$). These results demonstrate that neuroanatomical differences across breeding stocks can account for the reported discrepancies, and furthermore, they suggest a distinct physiological role for these cell groups in each stock. (Supported by USPHS grant DA03980 from the National Institute on Drug Abuse).

EFFECT OF PHENYLEPHRINE-INDUCED HYPERTENSION ON ROSTRO-VENTRAL MEDULLA NEURONAL ACTIVITY AND NOCICEPTION. JC Crews*, MA Cahall, MM Behbehani. Dept. of Anesthesia; University of Cincinnati; Cincinnati, Ohio 45267-0531.

Phenylephrine-induced hypertension has been previously reported to effect the activity of nociceptive-responsive neurons in the RVM. This study examined the effect of pain and hypertension on the cell firing rate (CFR) of RVM off cells in barbiturate-anesthetized rats.

Animals were prepared for extracellular recording of RVM neurons. Neurons were characterized as off cells based upon the response to noxious heat applied to the tail. The CFR of RVM off cells in 10 of 12 animals increased in response to phenylephrine-induced hypertension. In the same neurons, pain produced by a tourniquet applied to the leg and inflated to 300mmHg for 60 mins caused a decrease in CFR, despite moderate nociception-related increases in BP. Further increases in BP induced by phenylephrine infusion increased the CFR of the RVM off cells despite continued nociceptive stimulation. In a separate group of 10 animals, phenylephrine-induced antinociception was measured by determination of tail flick latencies. In 7 of 10 animals, there was no change in tail flick latency during phenylephrine infusion as compared to baseline. In the other 3 animals, an antinociceptive effect was noted (%MPE=100).

In conclusion this study supports previously reported data indicating that phenylephrine-induced hypertension increases the CFR of RVM off cells. This response is maintained in nociceptive-stimulated animals. These results suggest that the hypertensive response to pain modulates descending inhibitory pain pathways. Interanimal variability in response to phenylephrine in this study may be related to barbiturate anesthesia. PAIN MODULATION: PHARMACOLOGY IV

577.1

DEVELOPMENT OF A POLYMER-ENCAPSULATED CELLULAR IMPLANT FOR PAIN MODULATION. S.R. Winn¹, S.D. Sherman¹, S.A. Morrison¹, J. Harvey¹, A. Lee¹, J. Sagen², J.P. Hammang¹, and E.E. Baetge¹. ¹CytoTherapeutics, Inc. Providence, RI 02906; ²Department of Anatomy & Cell Biology, University of Illinois at Chicago, Chicago, IL 60612

Intrathecal implantation of polymer-encapsulated bovine adrenal chromaffin (BAC) cells has been shown to be an effective method for delivering analgesic compounds to the rodent CNS (Sagen et al., *J. Neurosci.* 13(6): 2415, 1993). The immunologic isolatory capability of the encapsulating membrane allows cross-species implantation without immune suppression. Also, recently developed device designs allow implant retrieval if necessary.

The present studies evaluated enkephalin and catecholamine release from encapsulated neonatal-sourced BAC cells maintained *in vitro*. BAC cell-loaded capsules maintained in various serum-free media were repeatedly characterized for catecholamine release under basal, 20 μ M nicotine-evoked, and 56 mM potassium-evoked conditions, with concurrent enkephalins measured. Results will be presented discussing the impact of serum-free conditions, matrix configurations, and membrane characteristics on the survival and function of BAC cell-loaded capsules. BAC cells thrive following encapsulation within appropriate 3 dimensional matrices and remain functional following retrieval from various implant sites in the CNS of xenogeneic hosts. In addition, studies are underway to evaluate appropriate cell lines and expression vectors for the production of stable cell lines capable of releasing catecholamines and enkephalin peptides. Development of a stable cell line releasing analgesic compounds would circumvent many issues related to primary tissues in transplantation treatment modalities.

577.3

ROLE OF OPIATE RECEPTOR SUBTYPES IN MEDIATING ANTINOCICEPTION BY ADRENAL MEDULLARY TRANSPLANTS IN THE RAT SPINAL SUBARACHNOID SPACE. H. Wang* and J. Sagen. Dept. of Anatomy & Cell Biology, University of Illinois at Chicago, Chicago, IL 60612.

Our previous studies have shown that adrenal medullary tissue is a candidate for grafting in the spinal cord subarachnoid space in order to reduce pain. Results from our behavioral, biochemical, and morphologic studies have indicated that, in addition to catecholamines, opioid peptides released by chromaffin cells in the adrenal medulla play important roles in reducing pain sensitivity. Mu, delta and kappa opiate receptor subtypes have been implicated in the production of analgesia by opioids at the spinal level. In order to assess the role of specific opiate receptor subtypes in the antinociception produced by adrenal medullary transplants, rats were implanted with either adrenal medullary tissue or equal volumes of control striated muscle tissue into the subarachnoid space at the lumbar enlargement. Pain sensitivity was assessed in these animals by use of the tail flick, paw pinch, and hot plate tests. Opiate antagonists were injected intrathecally, including the non-selective antagonist naloxone, naltrindole for delta receptor antagonism, nor-binaltorphine (norBNI) for kappa receptor antagonism, and β -funtaltrexamine (β -FNA) for mu receptor antagonism. Dose-related reductions in antinociceptive potency were assessed before and following stimulation with nicotine. Results indicated that both the mu and delta antagonists significantly attenuated antinociception in adrenal medullary transplanted animals in a dose-related fashion, while the kappa antagonist produced only weak effects. However the analgesia could not be completely blocked by any of the selective antagonists, even at high doses. In contrast to the complete blockade by non-selective antagonist naloxone, only a combination of mu, delta and kappa opiate receptor antagonists could completely block antinociceptive effects of adrenal medullary transplants. These findings suggest that all three spinal cord opiate receptor subtypes, particularly mu and delta, are involved in antinociception by adrenal medullary transplants. This transplanted chromaffin cells may release a combination of opioid peptides which interact with different host spinal opioid receptors to produce their analgesic effects (Supported by NS25054).

577.2

Opioid peptide gene delivery to neurally-derived cells using herpes virus vectors. G. Davar*¹, W. Bebrin³, R. Day⁴, A. Dupuy⁴, D.M. Coen³, and X.O. Breakefield^{1,2}. ¹Neurosci. Center, Mass. Gen. Hosp., ²Neurosci. Prog., and ³Dept. of Biol. Chem. and Molec. Pharm., Harv. Med. School, Boston, MA, USA; and ⁴Lab. of Biochem. Neuroendocrin., Clin. Res. Inst. of Montreal, Montreal, Quebec, Canada.

Thymidine kinase (TK) negative herpes simplex virus (HSV) vectors were constructed which were designed to express the opioid peptide precursor prodynorphin. The full length coding sequence for rat prodynorphin cDNA from pFLRD3 (gift of Dr. J. Douglass, Vollum Inst.) was placed downstream of the Moloney murine leukemia virus long terminal repeat promoter into the HSV tk gene. Vero cells were cotransfected with this plasmid and infectious strain KOS HSV DNA. Virus progeny were selected with acyclovir. Two isolates were shown by Southern blot analysis to contain the expected prodynorphin gene insertion. These recombinant viruses were named tkLTRdynA and B.

The pituitary tumor cell line, AtT-20, was infected with either tkLTRdynB or a similarly constructed lacZ-containing HSV vector for 8-24hr prior to harvesting cells. Prodynorphin expression was determined by radioimmunoassay for the C-terminal fragment of prodynorphin or dynorphin A 1-17. Preliminary results are consistent with the expression of prodynorphin in the range of .12-.68 nanomoles per tkLTRdynB-infected cell. Experiments are underway to examine for the expression of prodynorphin in mouse trigeminal ganglion neurons infected with tkLTRdynB by corneal inoculation.

These data are evidence that expression of prodynorphin can be achieved in culture using a HSV vector. This vector may also provide a method for delivering prodynorphin to sensory neurons *in vivo*.

577.4

INTRACEREBROVENTRICULAR (ICV) INJECTION OF MORPHINE (MOR) MODULATES ACTIVITIES OF DORSAL HORN NEURONS (DHN) IN THE SPINAL CORD IN THE CAT. U.T. Oh*, T.S. Moon, T.K. Ha and K.H. Ko. College of Pharmacy, Seoul National University, Seoul 151-742, Korea

ICV infusion of MOR is used as a pain treatment modality in certain cancer patients. The analgesia resulting from ICV MOR was suggested to be mediated by supraspinal inhibitory control on nociceptive afferent process in the spinal cord. Yet, evidence that ICV MOR inhibits activity of DHNs in the spinal cord is controversial. Thus, in the present experiment, effects of ICV MOR on the neural activity of DHNs were re-evaluated.

Thirty-eight cats were anesthetized with alpha-chloralose (60 mg/kg) and paralyzed with pancuronium bromide. Recordings were made from 58 DHNs that include 11 projection neurons in L4 to S1 and C2 spinal segments. Somatic response of DHNs were examined in 56 cells: 34, 13, 5 and 1 cells were WDR, HT, LT and DEEP cells, respectively. To test effect of ICV MOR on activity of DHNs, MOR (50 - 200 μ g) of 50 - 100 μ l in volume was slowly infused in the cerebral aqueduct or the 3rd ventricle. ICV MOR inhibited spontaneous activity of 11 (25%) of 44 cells studied and excited 6 (13%) DHNs. Twenty-seven (61%) DHNs were not affected by the ICV MOR injection. The inhibition was maximal 400 sec after MOR injection, and average cell activity was reduced to $41 \pm 8.7\%$ of control during this time. Heat stimuli of 44, 46, 48 and 50 $^{\circ}$ C were applied to the skin to test effects of ICV MOR on the heat response of DHN. Among 22 cells tested, heat responses of 9 (41%) cells were excited while 6 (27%) were inhibited by ICV MOR. Heat responses of seven (32%) DHNs was not affected by the MOR injection. Naloxone (NAL) (1.6mg/kg, iv) reversed the effects of MOR in 5 out of 11 cases, exaggerated them in 5 cases, and did not affect in 1 case.

In summary, ICV MOR inhibited and excited spontaneous as well as noxious heat response of DHNs, and the MOR response in part but not always was reversed by NAL. These data suggest that inhibition of DHNs by ICV MOR may implicate neural substrate of analgesia produced by ICV MOR. Supported by RCNDD grant of Korea.

577.5

ENDOGENOUS OPIOID MODULATION OF C-FOS EXPRESSION IN THE RAT SPINAL CORD FOLLOWING NOCICEPTIVE AFFERENT ACTIVATION. C. Cheng¹, V.L. Erickson, R. Stewart, L.A. Birder, M. Yoshizawa, J.R. Roppolo & W.C. de Groat Univ. of Pittsburgh, Pgh., PA 15261 & ¹Tri-Service General Hospital, Taipei, Taiwan.

A variety of behavioral and neurophysiological studies have suggested that endogenous opioid peptides can modulate nociception by their action within the central nervous system. This study examined the effect of naloxone (1mg/kg), an opioid antagonist, on the distribution of C-FOS positive neurons in the spinal cord of urethane (1.2gm/kg i.p.) anesthetized Wistar rats. Somatic nociceptive afferent activation of the L₄ spinal cord was produced by 0.2cc injection of 10% formalin into the hindlimb foot pad. Fifteen minutes prior to foot pad injection two groups of animals were given either naloxone (1mg/kg i.v.) or an equal volume of saline i.v. Two hours following foot pad injection the rats were perfused and spinal cord removed. Tissue was then processed for C-FOS (Cambridge antibody) and neurons with C-FOS positive nuclei (majority ipsilateral to injected foot pad) counted. Naloxone pretreatment produced a 48% increase (from control) in total C-FOS positive neurons in L₄ spinal cord. The medial dorsal horn, lateral dorsal horn and dorsal commissure all showed increases from control levels. The contralateral side of L₄ showed no increase in C-FOS. This study suggests that endogenous opioid mechanisms are involved in the inhibition of nociceptive neurons at the level of the spinal cord.

MORPHINE BLOCKS THE FORMALIN-INDUCED INCREASE IN DORSAL HORN NK-1 RECEPTOR mRNA EXPRESSION. K.E. McCarron* and L.E. Krause. Dept. of Anatomy & Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

The tachykinin Substance P (SP) contained in small diameter primary afferent neurons and NK-1 receptors (NK-1R) located in the dorsal horn of the spinal cord have been implicated in the transmission of nociceptive information. DRG SP-encoding mRNA levels are increased by nociception, and we have shown that adjuvant or formalin-induced nociception increases NK-1R mRNA levels in the dorsal horn. Opiate agonists block pain-related behaviors and inhibit SP release from primary afferent neurons, and opiate antagonists potentiate pain-related behaviors during the late phase of the formalin test. This study determined the effects of opiate receptor ligands on the regulation of NK-1R mRNA levels in the lumbar dorsal horn during formalin-induced nociception. Rats were given a subcutaneous pretreatment of either Morphine (MS) or Naltrexone (NX) 20min before injection of formalin into the right hind paw. Saline pretreated animals receiving a sham injection served as controls. This resulted in four treatment groups; saline-sham, saline-formalin, MS-formalin, and NX-formalin. Pain-related behaviors were quantitated by counting hindlimb flinches 30-40 min after hind paw treatment. Spinal cord tissues were removed 6hr after hind paw treatment and total RNA was isolated from the dorsal quarters of the lumbar enlargements. NK-1R mRNA levels were quantitated using solution hybridization-nuclease protection assays. Formalin injection significantly increased both the number of flinches and NK-1R mRNA levels compared to controls. Pretreatment with MS blocked the formalin-induced increases in nociceptive behavior and NK-1R mRNA levels. NX pretreatment potentiated the number of flinches after formalin compared to saline pretreated controls, but NK-1R mRNA levels in these subjects were similar to those in saline-formalin subjects. The results of this study indicate that the analgesia produced by MS during the formalin test can block the formalin-induced upregulation of dorsal horn NK-1R mRNA. These and our previous studies demonstrate the plasticity of dorsal horn NK-1R mRNA expression, and the molecular mechanisms of this regulation are currently under examination.

577.9

DELTA OPIOID RECEPTOR AND DPDPE-INDUCED ANTINOCICEPTION IN INBRED MICE. G.I. Elmer,² J.O. Pieper and S.R. Goldberg NIDA/Addiction Research Center, Behav. Pharm. & Genetics, Baltimore, MD, 21224.

Delta opioid receptor agonists are capable of modulating μ -agonist induced analgesia as well as producing analgesia when given alone. Recently, delta opioid subtypes have been proposed based upon differential antagonism and no cross tolerance between the delta agonists, DPDPE and deltorphin II. The purpose of this study was to investigate the degree of genetic variation in delta agonist induced analgesia and the degree of genetic covariation between the two proposed delta subtype selective agonists. Full dose-response curves for DPDPE and deltorphin II were determined in AKR/J, DBA/2J, BALB/cByJ, CXBH/ByJ and C57BL/6J mice. Each drug (0, 0.1, 0.3, 1.0, 3.0, 10.0 or 30.0 nmole) was given i.c.v. 10 min prior to antinociceptive testing on the hot-plate (55°C). Neither DPDPE nor deltorphin produced a fully efficacious analgesic effect in C57BL/6J mice (i.e. < 40% maximal effect). In the strains that did show an analgesic effect, the DPDPE ED₅₀ varied by greater than 10-fold between the least and most sensitive strains. Conversely, genotype did not significantly affect deltorphin II-induced analgesia in these inbred strains. The ED₅₀ for deltorphin II was approximately 1.52 nmole in these strains. The correlation between sensitivity to DPDPE- and deltorphin II-induced analgesia was not significant, $r = .08$. These results suggest a significant role of genotype in delta-agonist induced analgesia and support a pharmacological and genetic separation between the analgesic effects of DPDPE and deltorphin II.

577.6

MORPHINE DOES NOT BLOCK NOXIOUS STIMULUS-EVOKED INCREASES OF FOS-LIKE IMMUNOREACTIVITY (FLI) IN LAMINAE I AND IIO TRIGEMINO-PARABRACHIAL NEURONS. H. Wang, L. Jasmin, K. Tarczy-Hornoch, J.D. Levine, H.L. Fields*, A.I. Basbaum. Depts. Anatomy, Medicine, Neurosurgery, Physiology, Neurology and Keck Center for Integrative Neuroscience, UCSF, CA.

In a previous study we demonstrated that unilateral molar tooth extraction, a moderately noxious stimulus, evokes a bilateral increase of FLI in neurons of the subnucleus caudalis (SubC) of the medullary trigeminal complex. This increase is found throughout the SubC but is concentrated in laminae I and Iio, which is the projection zone of small diameter primary afferents from the operated tooth. High doses of systemic morphine produced behavioral analgesia and largely abolished the increase in c-fos gene expression in laminae V-VIII of SubC. In contrast, morphine did not prevent fos expression in a large number of neurons in laminae I and Iio. The present study assessed whether the residual FLI is found in SubC nociceptive relay cells, namely laminae I and Iio parabrachial projection neurons. The latter were retrogradely labeled after Fluoro-Gold (FG) injection into the right parabrachial nucleus. One week later, the rats were administered s.c. morphine (10 mg/kg; n=6) or physiological saline (n=4), 20 min before extraction of the two anterior maxillary molars. The surgery was performed under anesthesia with a mixture of 2% halothane and 50/50 O₂ and N₂O. After the animals awoke (5 min), their behavior was monitored for one hour, at which time they were perfused with 4% paraformaldehyde. A double immunocytochemistry protocol permitted visualization of immunoreactive Fos and FG, as black and brown reaction products, respectively. We found that morphine significantly ($p < 0.05$) reduced the total number of cells expressing Fos in laminae I + Iio ipsilateral to the tooth extraction. In contrast, there was no significant change in the number of double-labelled neurons, i.e., Fos-immunoreactive projection neurons ($p > 0.05$).

These results suggest that despite morphine analgesia, nociceptive messages are still relayed through SubC to higher brain centers, where they may trigger descending controls and/or influence the response to subsequent nociceptive inputs. Supported by NS 14627, DE/NIDA 08973 and the MRC (Canada).

577.8

EFFICACY AND AFFINITY OF MORPHINE AND ALFENTANIL IN THE RHESUS MONKEY WARM-WATER TAIL WITHDRAWAL. G.Zernig, E.R. Butelman, J. Lewis and J.H. Woods*. Dept. Pharmacol., U. Michigan, Ann Arbor, MI 48109.

The prototypical μ opioid agonists morphine and alfentanil were tested in a warm-water tail withdrawal antinociception assay at 50°C and 55°C. At 50°C, both agonists produced maximum antinociception (i.e. tail withdrawal latencies reached a 20 s cutoff). At 55°C, alfentanil was fully effective whereas morphine gave only 30% of the maximum response, indicating that morphine's effectiveness in this assay was lower than that of alfentanil. Dose response curves for either agonist were obtained at different times after administration of the irreversible μ opioid antagonist clocinnamox (0.1mg/kg s.c.). Analysis of these data according to Furchgott as modified by Black and coworkers showed that clocinnamox acutely decreased available μ opioid receptors by $\geq 88\%$. As expected, morphine's efficacy, e , was lower than that of alfentanil at both temperatures tested (means \pm SEM): 50°C, 12 ± 1 (n=9) vs 32 ± 1 (n=8); 55°C, 3 ± 1 (9) vs 8 ± 1 (6); $p < 0.0001$. The in vivo dissociation constant, K_A , was higher for morphine than for alfentanil. The respective log(mg/kg) values were: 50°C, 1.60 ± 0.09 vs. -0.19 ± 0.12 (40 vs. 0.7mg/kg); 55°C, 1.41 ± 0.22 vs. 0.08 ± 0.15 (26 vs. 1.2mg/kg; $p < 0.0001$).

577.10

SPINAL DELTA- BUT NOT MU-OPIOID RECEPTORS ARE INVOLVED IN INTRACEREBROVENTRICULAR β -ENDORPHIN-INDUCED ANTINOCICEPTION IN MICE. J.H.W. Suh*, J.D. K. Song, J.Y. H. Kim, and J. Leon F. Tseng. ¹Dept. Pharmacol. Coll. Med., Hallym Univ., Chunchon, Republic of Korea, and ²Dept. of Pharmacol. & Toxicol., Med. Coll. of Wisconsin, Milwaukee, WI, 53226, U. S. A.

The studies were designed to determine if delta- or μ -opioid receptors in the spinal cord are involved in intracerebroventricular (i.c.v.) administered β -endorphin-induced antinociception. The antinociception was assessed by the tail-flick test in male ICR mice. The experimental approach was to use β -Chlormaltrexamine (β -CNA) a nonselective opioid receptor blocking agent which binds irreversibly both μ - and delta-opioid receptors, and a selective delta-opioid receptor agonist, DPDPE, to protect the bindings of delta-opioid receptors and a selective μ -opioid receptor agonist, DAMGO, to protect the bindings of μ -opioid receptors by β -CNA. A combination of β -CNA (1 μ g) and DPDPE (10 μ g) and β -CNA and DAMGO (0.5 μ g) given intrathecally (i.t.) for 24 hrs blocks the antinociception induced by i.t. administered DAMGO and DPDPE, respectively, while the effects of i.t. DPDPE and DAMGO, respectively, remained intact. Intrathecal pretreatment with β -CNA or β -CNA coadministered with DAMGO attenuated the inhibition of the tail-flick response induced by i.c.v. administered β -endorphin. However, i.t. pretreatment with β -CNA coadministered with DPDPE did not affect the inhibition of the tail-flick response induced by i.c.v. administered β -endorphin. Intrathecal injection of β -CNA alone did not affect the inhibition of the tail-flick response induced by i.c.v. administered morphine. The results indicate that delta- but not μ -opioid receptors in the spinal cord are involved in i.c.v. administered β -endorphin-induced antinociception. The antinociception induced by i.c.v. morphine is not mediated by any type of opioid receptors.

577.11

THE SIGMA RECEPTOR LIGAND 1,3, di-*o*-tolylguanidine (DTG) DIFFERENTIALLY AFFECTS ACUTE AND TONIC FORMALIN PAIN.

B. Kest*, J. Mogil, W. Sternberg, R. Pechnick, and J.C. Liebeskind. Dept. of Psychology, University of California, Los Angeles, CA 90024.

We recently observed that the selective sigma ligand DTG produces antinociception on the tail-withdrawal test in mice. The tail-withdrawal test measures threshold for brief, phasic noxious heat. Since tests of nociception differ in stimulus quality, duration, and in their central substrates, results with DTG from the tail-withdrawal test may not be indicative of the role of sigma receptors in prolonged chemogenic pain. Therefore, male Swiss-Webster mice received DTG (10 mg/kg, IP) 15 minutes prior to administration of 20 μ l of 5% formalin into the plantar surface of one hindpaw. Pain-related behavior (time spent licking the injected paw) was then continuously rated 0-10 min (acute phase) and 30-50 min (tonic phase). DTG produced significant antinociception in the acute phase, but increased pain scores relative to saline controls in the tonic phase. In a separate group, DTG administered 45 min prior to formalin had no effect on acute pain. Thus, the longer latency between DTG administration and the onset of the tonic phase relative to the acute phase does not mediate the opposite effects produced by DTG on the two phases. The antagonism of DTG antinociception and hyperalgesia by both rimcazole (25 mg/kg, IP) and haloperidol (0.05 mg/kg, IP) administered prior to DTG supports a sigma receptor site of action in DTG's effects. Neither rimcazole nor haloperidol alone had any effect on the acute phase, but haloperidol alone decreased pain behavior in the tonic phase. These data suggest a modulatory role for sigma receptors in acute and tonic pain. Supported by an Unrestricted Pain Research Grant from the Bristol-Myers Squibb Company, NIH grant NS 07628 and NIMH Post-Doctoral Research Fellowship (BK) 5T32MH17140.

577.13

KAPPA-OPIOID RECEPTOR STIMULATION INHIBITS SUBSTANCE P (SP) RELEASE IN THE DORSAL HORN BOTH TONICALLY AND DURING A NOXIOUS THERMAL STIMULUS. V. Zachariou and B.D. Goldstein*, Dept. of Pharmacol & Toxicol, Medical College of Georgia, Augusta, GA 30912.

The undecapeptide SP is found in high concentrations in the dorsal horn of the spinal cord, especially in laminae I and II, where the small lightly myelinated or unmyelinated A δ - and C-fibers terminate. Activation of these fibers by noxious stimuli induces an increase in the release of immunoreactive SP in the dorsal horn, suggesting this peptide's role in the modulation of nociception. This study was undertaken to determine whether the κ -opioid peptide dynorphin (1-8) modulates the release of SP during the application of a nociceptive stimulus.

A push-pull canula was inserted into the dorsal horn of the lumbar enlargement in decerebrate/spinal transected rats. The spinal cord was perfused with artificial CSF, and SP levels were measured by RIA before and after the application of the nociceptive stimulus. All the drugs were applied through the perfusion apparatus.

Dynorphin (1 μ M) decreased the basal release of SP and inhibited the SP increase following a noxious thermal stimulus. The effect of dynorphin was reversed by the κ -antagonist, nor-binaltorphimine (Nor-BNI).

These data show that dynorphin acts at the kappa receptor to inhibit both basal release and nociception-induced release of SP from the primary afferent neuron in the dorsal horn.

577.15

IN VIVO EFFECTS OF THE PERIPHERALLY-SELECTIVE, ORALLY-ACTIVE, κ -OPIOID RECEPTOR AGONIST EMD 61 753. A. Barber, G.D. Bartoszyk*, R. Gottschlich, F. Mauler and C.A. Seyfried. Preclinical Pharmaceutical Research, E. Merck, 6100 Darmstadt, Germany.

EMD 61 753 (N-methyl-N-[(1S)-1-phenyl-2-((3S)-3-hydroxypyrrolidin-1-yl)-ethyl]-2,2-diphenylacetamide) is a novel κ agonist designed to have limited access to the CNS. It has potent, naloxone-reversible antinociceptive effects in tests of inflammatory pain (ID₅₀ values in mouse formalin (2nd phase) and rat hyperalgesic pressure pain tests were 0.24 and 0.08 mg/kg s.c., respectively), and also inhibited neurogenic plasma extravasation produced by antidromic electrical stimulation of the rat saphenous nerve. EMD 61 753 is less effective in the rat writhing test (ID₅₀ 6.3 mg/kg s.c.) and it reversed haloperidol-induced L-DOPA accumulation in the rat N. accumbens only at s.c. doses of and above 30 mg/kg. ID₅₀ values after p.o. application in the formalin (2nd phase), hyperalgesic pressure pain and writhing tests were 3.8, 3.1 and > 200 mg/kg, respectively. The action of EMD 61 753 in the pressure test was completely antagonised by injection of 100 μ g of the κ antagonist nor-BNI into the inflamed area, a dose of nor-BNI which produced no systemic inhibition of κ antinociception. Thus, EMD 61 753 may be able to produce peripheral inhibition of inflammatory pain at doses which do not elicit centrally-mediated antinociception and side effects (aversion, sedation, etc.).

577.12

Analgesic effects of dynorphin A mediated by κ_1 and κ_3 receptors. Dennis Paul* and Candice Jones. Dept. of Pharmacology, LSU Alcohol and Drug Abuse Center, and LSU Neuroscience Center, LSU Medical Center, New Orleans, LA 70112.

The dynorphin family of opioid peptides have been proposed as endogenous ligands for κ receptors. Using the mouse tail-lick assay, we assessed the possibility that dynorphin-A(1-13) (DYN-A) is an agonist at both the κ_1 and κ_3 receptor subtypes. Both i.c.v. and i.t. DYN-A produced analgesia dose-dependently. The non-selective kappa antagonist, quadazocine, was equally potent blocking i.c.v. and i.t. DYN-A analgesia (ED₅₀s=2.6 ng and 3.9 ng). In contrast, the κ_1 selective antagonist, nor-binaltorphimine, was 55-fold more potent as an antagonist of spinal (27 ng, i.t.) than supraspinal (1.5 μ g, i.c.v.) DYN-A analgesia. This is consistent with a spinal κ_1 analgesic mechanism and a supraspinal κ_3 mechanism. β -funtaltrexamine did not alter i.t. or i.c.v. DYN-A analgesia, indicating that the analgesia was not μ receptor-mediated. In cross-tolerance studies, the κ_1 agonist, U-50,488 (6 mg/kg, s.c.), was cross-tolerant with spinal, but not supraspinal DYN-A analgesia. Conversely, the κ_3 agonist, naloxone benzoylhydrazone (70 mg/kg, s.c.) was cross-tolerant with supraspinal, but not spinal DYN-A analgesia. Together, these results suggest that DYN-A is an agonist at both κ_1 and κ_3 opioid receptors.

EMD 61 753 IS A UNIQUE REPRESENTATIVE OF THE DIARYL-ACETAMIDES, A NOVEL CLASS OF K-OPIATE AGONISTS. B. Gottschlich*, K. A. Ackermann, A. Barber, G.D. Bartoszyk, H.E. Greiner, M. Stohrer. Dept. of Preclinical Pharmaceutical Research, E. Merck, 6100 Darmstadt, Germany

All the known k-opiate agonists (e.g. U 50488, PD 117302, EMD 60 400) possess the structural feature of N-disubstituted *m*-arylacetamides. In the frame of this study a series of novel substituted *d*-arylacetamides was synthesized and evaluated biologically. κ , μ and δ opioid binding was determined in the presence of [³H] U 69593, [³H] PL 017 and [³H][D-Per^{2,5}]enkephalin, respectively, with membranes from guinea-pig cerebellum (κ) and rat cerebrum (μ and δ). The formalin test was carried out on male NMRI mice as described by Hunskaar and Hole, 1987.

EMD 61 753 (N-Methyl-N-[(1S)-1-phenyl-2-((3S)-3-hydroxypyrrolidin-1-yl)-ethyl]-2,2-diphenylacetamide) showed high affinity for k-opiate receptors whereas the affinities for μ and δ receptors were at least 100 x weaker. In contrast to the *m*-arylacetamides, substitution of the aromatic rings in the *d*-arylacetamides as well as other structural variations of the molecule did not improve activity. EMD 61 753 - unlike the centrally acting k-opiate ICI 197067 - showed more pronounced antinociceptive activity in the second ("inflammatory") phase of the formalin test (ID₅₀ = 0.24 mg/kg s.c. and 3.8 mg/kg p.o.).

Thus, EMD 61 753 is a unique representative of a structurally novel class of k-opiate agonists. The data from the formalin test indicate that EMD 61 753 is biologically active after s.c. and p.o. application. Despite its lipophilic character EMD 61 753 seems to have limited access to the brain.

PERIPHERAL OPIOID MECHANISMS MEDIATING ANALGESIA AND INFLAMMATION. Y. Hong* and F.V. Abbott. Depts. of Psychiatry & Psychology, McGill Univ., Montreal, Quebec H3A 1A1.

The present study examined the effects of local injection of opioids on the different components of both pain and inflammation induced by injection of formalin. Opioid agonists (40 μ l) were injected SC into the plantar surface of one rear paw 5 min prior to injection of 50 μ l 1% formalin into the same site. The duration of pain behaviour were scored during 0-10 min (early phase) or 20-50 min (late phase). Extravasation was measured 10 or 50 min after formalin in separate rats by absorbance spectrophotometry following IV injection of Evans.

DAMGO (μ agonist; 1 μ g) reduced behavioral pain only in the later phase, although extravasation in both phases was reduced. U50,488H (κ agonist; 20 μ g) decreased both components of the pain response, but extravasation was enhanced in the early phase and decreased in the late phase. These effects were not mimicked by systemic injection of the agonists, and were blocked by pretreatment with SC naloxone methiodide. DPDPE (δ agonist; up to 80 μ g) did not produce any significant effects. The data indicate that peripheral opioid receptors modulate the pain and the inflammatory responses produced by formalin injection, and that the analgesic and anti-inflammatory effects are dissociable. The data also confirm that the early and later phases of formalin pain and inflammation reflect different physiological processes. (Supported by MRC)

OPIOID AGONISTS ON THE PAW FLICK TEST: MEASURES OF LATENCY AND TISSUE TEMPERATURE. P.E. Stewart and D.L. Hammond*, University of Chicago, Chicago, IL 60637

We recently observed that intrathecally-administered opioid agonists increased response latency in the uninfamed paw flick test to a lesser extent than in the tail flick test, even though baseline latencies were the same for both tests. This prompted an investigation of the relationships among stimulus intensity, response latency, tissue temperature, and the apparent efficacy of opioids. Sprague-Dawley rats were implanted with an intrathecal catheter. One week later, response latency was determined to one of four different heating rates applied to the plantar surface of a hindpaw. Response latency was inversely related to heating rate. Response latencies were then redetermined after i.t. injection of 0.3 µg DAMGO, a µ opioid agonist. The largest increase in response latency (16 sec) was obtained at the lowest heating rate, while the smallest increase in response latency (1.7 sec) was obtained at the highest heating rate. These data suggest that the efficacy of DAMGO is a function of stimulus intensity. However, measures of tissue temperature indicate that the withdrawal response occurs at the same tissue temperature (53 °C) for the three lowest heating rates and at 60 °C for the highest rate. Thus, it would appear that, in the paw flick test, the efficacy of DAMGO is not a function of stimulus intensity and measures of response latency may be misleading. Supported by PHS Grant DA 06736.

Characterization of Basal and Morphine-Induced Histamine Release in the Rat Periaqueductal Grey by In Vivo Microdialysis. K.E. Barke* and L.B. Hough, Dept. Pharmacology and Toxicology, Albany Medical College, Albany, NY 12184

The neurotransmitter histamine is thought to play a role in an endogenous system for pain relief. We have shown previously that antinociceptive doses of systemic morphine increase extracellular histamine levels in the periaqueductal grey (PAG). However, the cellular origin of basal and morphine-induced histamine release in the PAG was unknown. The neuronal origin of extracellular histamine in the PAG is important since histamine could be derived from other sources (i.e. mast cells), whereas pain relief mechanisms are thought to result from neuronal activity. Presently, treatment with alpha-fluoromethylhistidine (FMH, 100 mg/kg i.p.), the irreversible inhibitor of histamine synthesis, decreased basal histamine release in the PAG by 80%. Also, morphine (12.8 mg/kg s.c.)-induced histamine release was completely abolished by this FMH pretreatment. These results indicate that histamine release in the PAG depends on rapid histamine synthesis. In addition, perfusion of the PAG with the sodium channel blocker, tetrodotoxin (10⁻⁶ M) decreased basal histamine release by 50%, suggesting that a portion of the extracellular histamine in the PAG is released by propagation of action potentials. Thioperamide (5mg/kg i.p.), an H₃ antagonist, increased histamine release in the PAG to 250% of baseline levels, suggesting that basal histamine release in the PAG is under the regulation of the H₃ autoreceptor. Taken together, these results suggest that basal and morphine-induced histamine release in the PAG has a neuronal origin (Supported by DA-03816, and DA-05460).

THE ANTINOCICEPTIVE TAIL-FLICK RESPONSE IS IMPERVIOUS TO CHANGES IN TAIL-SKIN TEMPERATURE. A.H. Lichtman*, F.L. Smith and B.R. Martin, Department of Pharmacology and Toxicology, Medical College of Virginia-Virginia Commonwealth University, Richmond, VA 23298.

There is recent concern that a drug induced elevation in tail-flick latency could be the result of a change in tail-skin temperature rather than an attenuation in pain perception. Therefore, the purpose of this study was to test whether tail-skin temperature has a relevant impact on the tail-flick response by evaluating the antinociceptive potency of morphine or Δ⁹-THC in mice maintained at ambient temperature (23 °C) or placed in heated cages (38 °C). Although neither drug had an impact on tail-skin temperature, the tails of the subjects placed in the heated cages were 2 to 4 °C warmer than those kept at ambient temperature. The ED₅₀ values (with 95% confidence limits) of Δ⁹-THC were 2.6 (0.8 to 8.7) mg/kg for subjects kept at ambient temperature and 2.7 (2.0 to 3.8) mg/kg for mice placed in the heated cages. On the other hand, morphine was actually more potent in subjects kept at ambient temperature, 3.2 (1.2 to 3.1) mg/kg, than in those placed in the heated cages, 4.9 (3.6 to 6.7) mg/kg. If tail-skin temperature played a critical role in the tail-flick test, placement into the heated cages would have been expected to attenuate the antinociceptive potencies of each drug. These findings indicate that tail-skin temperature has a negligible influence on the antinociceptive tail-flick response. This research was supported by NIDA grants DA-03672, DA-05421, and DA-01647.

RETINA: FUNCTIONAL ORGANIZATION

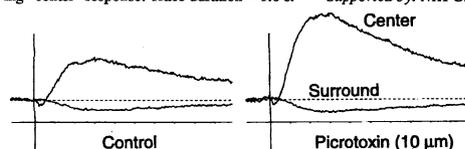

578.1

OPTICAL RECORDING OF LIGHT-EVOKED NEURAL ACTIVITY IN THE FROG RETINA

L. L. Crenshaw and D.M. Sensenar*

Div. of Life Sciences, Univ. of Texas at San Antonio, San Antonio, TX, 78249

We have demonstrated the feasibility of using optical recording techniques to monitor light-evoked activity in the vertebrate retina. To minimize bleaching of photoreceptors during recording, we used the absorbance dye, RH155, which yields its largest extrinsic voltage-dependent signal in the near infrared. Traces shown below were obtained from an isolated frog retina stained with a 0.3 mg/ml RH155 solution for 45 min. The stained retina was imaged with an improved light detector system that allow 464 contiguous regions to be monitor simultaneously with a temporal resolution of 1.6 ms and a spatial resolution of 43 µm. A Grass Photostimulator generated controlled light flashes that were focused as small spots (200 µm dia) on to the retinal surface via the microscope's epi-illumination system. As shown below, spot illumination at 540 nm evoked a net depolarization of neural elements within the center of the flash while surrounding regions responded with a net hyperpolarization. Bath application of the GABA-antagonist, Picrotoxin (10 µM), preferentially increased the amplitude of the depolarizing "center" response. Trace duration = 1.0 s. Supported by: NIH GM07717

COMPONENT POTENTIALS OF THE DARK-ADAPTED CAT ERG. J.G. Robson¹, L.J. Frishman¹, and L. Du, College of Optometry, Univ. of Houston, Houston, TX 77204; ¹Physiological Lab, Cambridge, CB2 3EG, UK

We have studied how the amplitudes of both vitreal and intraretinal ERGs of the dark-adapted anesthetized cat depend upon stimulus intensity and are affected by dim steady backgrounds. Using TTX and glutamate-receptor antagonists we find that the response evoked by a brief Ganzfeld flash delivering up to 10⁴ quanta.deg⁻² is the sum of at least four components. The contribution of each component (measured at a fixed time after each flash) appears to be proportional to flash intensity at low levels (voltage = intensity x sensitivity) but then saturates at some characteristic higher level (V_{max}). In order of their sensitivities the components are: a) a cornea-positive scotopic threshold response (pSTR) blocked by TTX (4-25 µM vitreal concentration); b) a slightly less sensitive negative scotopic threshold response (nSTR) also blocked by TTX; c) a negative scotopic response (nSR) having about one tenth the sensitivity and unaffected by TTX; d) the even less sensitive PII response. The pSTR and nSTR are both somewhat slower than the nSR. Although the sensitivities of the three most sensitive components are reduced in a similar way by backgrounds, the modelled V_{max} of the nSR is much more affected than that of the pSTR and nSTR. Complete suppression of these components requires application of a kainate-receptor antagonist (CNQX, 25 µM) as well as an NMDA-receptor antagonist (AP7, 200-400 µM). In intraretinal recordings the TTX-sensitive nSTR dominates the inner retinal response in the vicinity of the area centralis while the TTX-insensitive nSR prevails in the peripheral retina. Our findings suggest that the pSTR and nSTR are generated by spiking neurons, possibly Off- and On-center ganglion cells, while the nSR may originate from depolarizing amacrine cells. CURRENT SOURCE DENSITY (CSD) ANALYSIS OF THE b-WAVE OF THE ELECTRORETINOGRAM. X. Xu & C.J. Karwowski*, University of Georgia, Athens, GA 30602.

In some ways, the most important component of the ERG is the b-wave. This study attempts to gather information about the mechanism of origin of the b-wave. The CSD technique was used to locate the depths of its current sources and sinks in frog retina.

Our CSD profiles show a transient sink near the outer plexiform layer (OPL), and a slower, more sustained source at the inner limiting membrane (ILM). In the inner plexiform layer (IPL), there is a transient source, followed by a slower sink. This profile suggests for the b-wave an OPL sink and IPL source. The IPL sink and ILM source may underlie the M-wave. Pharmacological experiments using picrotoxin and barium support this view.

If the source-sink pair underlying the b-wave is due to K^+ spatial buffering through Muller cells, then the K^+ channels are relatively insensitive to Ba^{2+} (unlike the Muller cell K^+ channels underlying the M-wave, and unlike those in the pigment epithelial cells that underlie the c-wave). Another possibility is that bipolar cells directly generate the b-wave sink-source. Supported by NEI grant EY-03526.

A PAF ANTAGONIST BLOCKS PAF-INDUCED GLUTAMIC ACID RELEASE FROM DISSOCIATED RETINAL CELLS AS WELL AS FROM RETINAL SYNAPTOSOMES. N.G. Bazar*, P. Prouet, V.L. Marcheselli, LSU Eye Center and LSU Neuroscience Center, LSU Med. Ctr. Sch. Med., New Orleans, LA 70112

In experimental high intraocular high pressure, it has been shown that there is an increase in glutamic acid released from retinal perisynapses. PAF is also released in the retina during ischemia. Very active phospholipases are present in the retinal release of polyunsaturated fatty acid. Overstimulation of glutamic acid releases is involved in retinal excitotoxicity. Under experimental conditions, BN-52021 blocks the [3 H]-glutamic acid release, induced by PAF on dissociated retinal cells and on retinal synaptosomes which have been previously loaded with [3 H]-glutamic acid. A 25% release of the total [3 H]-glutamic acid uptake is obtained when 10 nM PAF is injected into a perfusion cell, into which the loaded cells or synaptosomes have been placed. [3 H]-glutamic acid was measured on perisynapses through an online radiochemical detector. 1 μ M BN-52021 inhibits control levels of glutamic acid release. 40 mM KCl induced a more than 30% release, which cannot be blocked by BN-52021. The uptake of [3 H]-glutamic acid by dissociated cells is three times higher than in the homogenates, and is almost the same as the subcellular fractions enriched in synaptosomes. Our studies show that the second messenger PAF is an activator of glutamic acid release in the retina through a presynaptic site. PAF antagonists may be a useful therapeutic strategy to protect the retina in rapidly progressive forms of glaucoma. Supported by NIH grant EY05121.

DOPAMINERGIC LIGANDS DO NOT ALTER HORIZONTAL CELL RECEPTIVE FIELDS IN CAT AND RABBIT RETINAS. R. Pflug and R. Nelson* Institut für allgemeine Physiologie, Universität Wien, Austria and Lab. of Neurophysiology, NINDS, NIH, Bethesda, MD 20892.

In fish and turtle retinas, D_1 receptor ligands uncouple horizontal cell (HC) gap junctions and reduce receptive field (RF) sizes. We have measured dopaminergic (DA) effects on HC RFs in mammalian retinas. In arterially perfused retina-eyecup of cat, or isolated rabbit retina, HCs were penetrated with sharp, KCL-filled, intracellular microelectrodes and responses to 200 μ m slits of red light at different RF positions measured. RF space constants were calculated from conductance-sheet model curves. After addition of DA agonists and antagonists, space constants were remeasured at intervals (continuing up to 20 m). In rabbit DA agonists in the range of 70-700 μ M slightly increased, whereas the D_1 antagonist SCH23390 slightly decreased, RF size. The D_2 antagonist sulpiride had no consistent effect. In cat DA itself slightly reduced RF size, while the unspecific DA receptor agonist apomorphine was without effect. None of the RF alterations exceeded 20%, a value similar to measurement repeatability. Since A-type horizontal cells in cat and rabbit retinas are extensively coupled, changes in RF size should be substantial, but only small changes were observed. Even these might be secondary, perhaps reflecting alteration of receptor coupling.

578.4

A COMPARISON BETWEEN CAT AND RABBIT PATTERN ELECTRORETINOGRAM (PERG) IN AN *IN-VITRO* PREPARATION

K.-H. Huemer* and R. Pflug Dept of General & Comparative Physiology, University of Vienna, A-1090 Vienna, Austria.

Retinae of rabbits and cats were isolated under dim red light, then put into a chamber and continuously superfused with oxygenated culture medium. Pattern-reversal electroretinograms were recorded using Ag-AgCl-electrodes in agar. Stimuli were directly projected onto the retina using the inverted ray path of a modified microscope. Recordings were averaged using AD-converter and computer. The averaging process was started after steady state-conditions were obtained.

This *in-vitro* method can be used to evoke PERGs in both species. The recordings had a much better signal-to-noise-ratio than *in-situ* recordings. The procedure allows a more precise and immediate analysis. In both species at low temporal frequencies (c. 2 Hz) a cornea-positive peak dominated the response showing features similar to luminance responses. We also found a second component of constant latency (not depending on temporal frequency) over the whole range examined (between 1.5 and 7 Hz).

The PERG is rather similar in both species. In cat the responses are slightly faster than in rabbit and the cornea-negative component is more pronounced. But these differences appear to be merely quantitative and the PERG generation sites are probably closely related in both species.

578.6

REGULATION OF ELECTRICAL COUPLING AND NEURITE OUTGROWTH IN HORIZONTAL CELLS BY CALCIUM AND CON A D.G. McMahon*, J.K. Crager and M.P. Mattson, Department of Physiology and Biophysics and Sanders-Brown Center for Ageing Research, University of Kentucky, Lexington, KY 40536

Teleost retinal horizontal cells display structural changes in response to light adapting signals, including changes in the density of gap junction channels at electrical synapses and elongation of dendritic processes called spinules. Recent results suggest that the Ca^{++} -activated enzyme PKC is involved in the structural plasticity of horizontal cells. In an effort to understand the role of cell calcium in these processes we have measured electrical coupling, neurite outgrowth and Ca^{++} in horizontal cells from the retina of the giant danio (*Danio aequipinnatus*).

Cells were dissociated and maintained using standard techniques. Junctional conductance was measured using dual whole-cell patch clamp recording, Ca^{++} by fura-2 imaging and cell morphology quantified by image analysis. In one set of experiments, cells were cultured in control (2.65mM) or low (0.125mM) Ca^{++} media. The proportion of cell pairs exhibiting electrical coupling was significantly lower in low Ca^{++} (6/21) versus control (14/21) and Ca^{++} was also significantly lower in low Ca^{++} (36 ± 12 nM, N=26 vs 55 ± 14 nM, N=36, $p < 0.05$ t-test). In a substantial proportion of cell pairs, individual cells exhibited striking differences in Ca^{++} . In a second set of experiments, cells were cultured in the presence or absence of the lectin concanavalin A. Con A (2 μ g/ml) increased the number of active growth cones/cell (2.5 ± 1.4 , N=28 vs 1.1 ± 1.2 , N=36) and the average cell perimeter (274 ± 63 μ m vs 232 ± 80 μ m), as well as increasing Ca^{++} (144.1 ± 8.6 nM, N=90 vs 91.1 ± 10.8 nM, N=85, all $p < 0.05$). The increases in growth cone number and Ca^{++} both persisted in the presence of DNQX or nifedipine.

These results indicate correlations between reduced Ca^{++} and reduced expression of coupling, and increased Ca^{++} and increased neurite outgrowth.

578.8

NMDA RECEPTORS REGULATE HORIZONTAL CELL COUPLING IN THE FISH RETINA. Y. Wang, K. Harsanyi and S.C. Mangel*

Dept. of Ophthalmology, Univ. of Alabama, Birmingham, AL.

The action of NMDA on cone horizontal cell electrical coupling was studied in intact, goldfish retinas, superfused with a Mg-free, bicarbonate-based Ringer's that contained D-serine (0.5 μ M), a glycine analogue. Horizontal cell coupling was assessed by monitoring responses to small (0.4 mm diam) spots of light.

NMDA uncoupled horizontal cells in a dose-dependent manner, with threshold at 10 μ M and saturation at 100 μ M. Application of the NMDA antagonist, AP7 (50 μ M), blocked the uncoupling action of NMDA (100 μ M), as did prior application of SCH23390, a dopamine D1 antagonist, or prior treatment of the retinas with 6-hydroxydopamine, a procedure which destroys dopaminergic neurons. Addition of Mg (1 mM) partially blocked the uncoupling effect of NMDA at 100 μ M and completely blocked it at 50 μ M. The uncoupling effect of NMDA (50 or 100 μ M) was also reduced, if it was applied without D-serine. Because flickering, but not sustained, light stimulation uncouples fish horizontal cells by increasing dopamine release, we tested whether NMDA receptors were involved. Prior application of AP7 blocked horizontal cell uncoupling due to flickering, but not sustained, light. These results indicate that flickering light releases dopamine and uncouples horizontal cells through activation of NMDA receptors.

A - CURRENT OF LUMINOSITY AND CHROMATIC HORIZONTAL CELLS IS MODULATED BY NEUROTRANSMITTERS AND CALCIUM
A. Akopian¹ * and P. Witkovsky^{1,2}, Depts. Ophthalmology¹ and Physiology & Biophysics², New York University Medical Center, New York, N.Y. 10016

Luminosity-type and chromatic-type horizontal cells (HC) were isolated from the Xenopus retina and studied by the whole cell version of the patch clamp technique. The A-current (I_A) of both HC types is prominent, (Akopian & Witkovsky, Soc. Neurosci. 352.16, 1992), particularly in the chromatic HC, and it helps shape the light response of the cell following the hyperpolarization evoked by a bright flash. The voltages for half inactivation and activation of I_A were, respectively -73 ± 3 mV and -20 ± 2 mV. We found, however, that V half-inactivation was shifted significantly towards more positive potentials (-57 ± 2 mV) when either GTP (100 μM) or GTPγS (100 μM) was added to the pipet solution. I_A activation was not affected by these substances.

The time constant of I_A inactivation varied from 27-34 mV in drug-free solution and was only slightly altered by the voltage level at which it was measured. Bath application of either glutamate (100 μM) or dopamine (20 μM) resulted in a 30-40% decrease in the time constant of I_A inactivation. The same effect was obtained with either the D1 agonist SKF 38393 (100 μM) or the D2 agonist, quinpirole HCl (20 μM). In addition, we found that in zero external calcium the peak I_A current was reduced by 30%. A comparable reduction was achieved by adding the dihydropyridine, nifedipine (10 μM) to the bath, indicating that influx of Ca through L-type channels is implicated in the control of I_A. Collectively our data suggest that *in situ*, where HC's are exposed continuously to glutamate and dopamine, and where intracellular concentrations of calcium and second messengers are subject to modulation, the amplitude and response kinetics of a prominent intrinsic membrane current, I_A, also will be shaped by a variety of modulatory influences. Supported by EY 03570 to P.W.

INTRACELLULAR RECORDING AND COMPUTER SIMULATIONS TO COMPARE ELECTRICAL AND DYE COUPLING IN NEURONS OF THE MUDPUPPY RETINA. T.J. Velte* and R.E. Miller. Dept. of Physiology, Graduate Program in Neuroscience, Univ. of Minnesota, Minneapolis, MN 55455.

We have studied dye coupling in mudpuppy neurons using Neurobiotin (Vector) as a cell tracer combined with intracellular recording in a perfused retina-eyecup preparation. A computer controlled light stimulus (Innisfree) was used to study receptive field properties through slit displacement techniques. The morphologies of stained cells were entered into the Eutectic Neuronal Reconstruction System which was connected to a Sun workstation and provided a means for detailed computer simulation studies. Computer simulations were carried out to model the spread of current through a single neuron or a small neural network. The cells were joined by a single resistor at locations on the cells where gap junctions were likely to be present. Modeling constraints varied the coupling resistance to match uncoupled versus heavily coupled paradigms.

This study has shown that Müller cells in the mudpuppy are extensively dye coupled. However, unlike previous studies in rabbit (Vaney, 91), neurons in the inner retina are at most coupled to a small number (1-2) of heterogeneous cells; yet most neurons in the mudpuppy are not dye coupled using this technique. When small neural networks were created from cells that exhibited dye coupling, current spread was maximized between cells with relatively few gap junctions (70), when a high membrane resistance (70,000 Ω cm²) was used. This suggests that few gap junctions are needed to enable electrical coupling in these cells and may offer an explanation for the infrequent dye coupling observed in this study.

FUNCTIONAL ARCHITECTURE OF HENLE'S LAYER IN PRIMATE FOVEA A. Hsu¹, Y. Tsukamoto¹, R.G. Smith, and P. Sterling, Dept. of Neuroscience, Univ. Pennsylvania, Phila., PA 19104 and ¹Hyogo College of Medicine, 663 Japan.

Axons connecting cones in the foveal center to their terminals in the periphery are numerous, creating a layer (Henle's layer) that occupies up to 46% of the retina's postreceptor thickness. Since the layer must decrease retinal efficiency by scattering and absorbing light, we wondered what constrains the individual axons to be so thick (up to 1.8 μm).

We simulated an isolated foveal cone using a compartmental model consisting of an outer segment conductance (1 nS) coupled a cable approximating the length (380 μm) and taper of a cone axon, and terminating in a sphere (7 μm diam.) representing the synaptic terminal. A photovoltage was generated by a small decrease (1%) in the outer segment conductance and voltage transfer was computed by dividing the photovoltage in the outer segment by that at the terminal. When R_i=200 Ω-cm and R_m=25 kΩ-cm², voltage transfer was 80%. Tripling the axon diameter (5.4 μm) marginally improved transfer to 90%; reducing the diameter by 3-fold (0.6 μm) decreased transfer to 55%. For a thin axon (0.6 μm), increasing R_m to 150 kΩ-cm² restored the transfer to 80%. However, since the photovoltage is generated by a conductance change, not an ideal current source, increasing R_m also decreased the photovoltage. Adding a chloride conductance (max 0.9 nS) at the synaptic terminal linearly decreased the resting potential but affected neither the magnitude of the photovoltage nor its transfer.

Apparently, the dimensions of the cone axon are optimal for transferring photovoltages when R_m≈25 kΩ-cm². A thinner axon would decrease the photovoltage and decrease transfer. A thicker axon would only marginally improve performance and degrade the optics. Supported by EY08124.

A WIDE-FIELD BIPOLAR CELL IN THE RABBIT RETINA. C.-J. Jeon* and R. H. Masland, Harvard Medical School, Boston, MA 02114

We have studied a wide-field bipolar cell labeled in the rabbit retina by accumulation of biocytin. Biocytin was injected intraocularly. Two days later the retinas were isolated, fixed, and prepared as wholemounts. Biocytin was visualized by conventional immunohistochemical methods.

A subgroup of bipolar cells was found to accumulate intraocularly injected biocytin. They had 2-4 proximal dendrites and a wide (100 - 300 μm) dendritic spread. Their axons descended to layer 5 of the inner plexiform layer, where they had wide branching similar to that in the outer plexiform layer.

When groups of neighboring cells were examined, their dendrites were found to co-fasciculate: the distal dendrites of one cell ran alongside those of a neighbor. Typically, two adjacent cells were apposed only for one pair of dendrites, but cases of more were observed. Occasionally there were small bulb-like structures at the points where the dendrites joined together. The same pattern was present for the axonal processes in layer 5 of the inner plexiform layer, with more frequent cell-to-cell appositions. The cells are thus co-fasciculated with their neighbors in both the outer retina and the inner retina.

Supported by EY05747 and a Fight for Sight fellowship.

FUNCTIONAL CONSEQUENCES OF REGENERATIVE MEMBRANE AND COUPLING IN THE AII AMACRINE CELL OF CAT RETINA. R.G. Smith*, N. Vardi Dept Neurosci, Univ. of PA, Phila PA 19104-6058.

At scotopic intensities, the AII cell is hypothesized to transmit quantal photon signals, which could be obscured by noise due to anatomical convergence from 500 rods. This raises the question of whether the AII network possesses special noise-reduction features. A quantal photon signal appears in 5 AII cells due to anatomical divergence, and the AII is interconnected by gap junctions into a network. Furthermore, the AII cell contains Na and K channels and produces action potentials under electrical stimulation.

To explore the significance of the AII coupling and membrane properties for signal/noise issues, we simulated a square array of AII cells as single compartments containing fast activating, slow inactivating Na, and slow K channels. Each cell received a resting "dark" signal through a noisy synapse. The central 5 cells received in addition a simulated photon signal of about 5 mV. Without gap junctions, noise of 5-10 mV evoked intermittent action potentials 30 mV in amplitude and 50 msec in duration. Coupling the AII cells with 200 pS gap junctions reduced noise by a factor of 2 and eliminated noise-evoked action potentials. AII cells that received the simulated photon signal simultaneously with their neighbors produced action potentials, but when only one coupled AII received the photon signal, no action potential ensued.

This suggests that regenerative membrane properties and electrical coupling might function cooperatively in the AII cell to improve the signal/noise ratio of the quantal photon signal. Supported by MH48168.

MINIMUM RATE OF TRANSMITTER RELEASE AT A "ONE-BIT" SYNAPSE. R. Rao^{1,2}, G. Buchsbaum², P. Sterling¹. Depts. Neurosci.¹ & Bioeng.², Univ. of Penn., Phila., PA 19104.

Neurons transfer signals by modulating quantal release of transmitter. Yet, how many quanta are required for any particular signal is unknown. At the mammalian rod synapse, both the signal and the transfer mechanism are identified. The signal is binary, representing the absorption (or not) of one photon; the transfer to the bipolar cell involves suppression of tonic release at the rod's single active zone. We calculated the minimum rate of tonic release required to reliably transmit this "one-bit" signal. Since the active zone is large (100 docking sites), the binomial statistics of quantal release become poisson, and the interrelease intervals should have an exponential probability density function whose decay depends uniquely on the release rate:

$$p(t) = pe^{-\rho t} \quad \text{where } \rho = \text{release rate}$$

Therefore, specifying a maximum allowable interval (T) and the probability of exceeding it (y) sets the shape of the distribution and hence the release rate that produces it:

$$\rho = -(\ln y)/T$$

We assumed for the bipolar cell a signal-to-noise ratio of 5 and a rod convergence of 20 (cat). Since the bipolar mpsc peaks and decays in time T, we used the shape of the mpsc (amphibian) and the rising phase of the bipolar cell light response (rabbit) to calculate T (~50ms). Taking the bipolar cell to have gaussian noise, we calculated y (~16%). It follows that transmission of the rod signal would require at least 40 quanta/s. If rod convergence were 100 (rabbit), the minimum rate would be 80 quanta/s. These release rates are at least an order of magnitude greater than what is generally reported at conventional active zones. To sustain this high rate for many hours (all night) may require a mechanism to facilitate reloading of the emptied docking sites. This may be the function of the large "ribbon" that serves as depot for ~700 vesicles.

BRAINACE: A DATABASE-HYPERMEDIA TOOL FOR NEUROSCIENTISTS
 Frank H. Eeckman*¹, Richard M. Durbin² and Jean-Thierry Mieg³. ¹ LLNL,
 Livermore, CA; ² MRC, Cambridge, England; ³ CNRS, Montpellier, France;

BrainAce is an object-oriented database based on ACEDB, a database system originally developed for the *C. elegans* genome project (JTM and RD). ACEDB has been successfully adapted to become the database of choice for genomic data from other organisms such as *Arabidopsis*, human chromosomes, wheat, etc. Although originally written for Unix/X windows, a Macintosh interface is available (FE and RD) that is functionally identical to the Unix version.

ACEDB consists of a core data manager and specific application code. Data are stored in objects that are organized into classes. The objects have extendable structure, so that arbitrarily large amounts of information can be stored in them. That information may include annotations of various sorts, comments, and cross-references. The schema specifying data structures can be extended during the lifetime of a database. There is a browser mode and a general search facility to provide maximal flexibility. In addition, displays can be output in Postscript for laser printing, or as plain text for transfer to other sources. We are currently working to extend the display functions of ACEDB to the needs of specific retinal research groups.

AMACRINE CELL CIRCUITS PRODUCE CENTER-SURROUND BEHAVIOR IN MODELS OF CAT RETINAL GANGLION CELLS. M.A.V. Gremillion* and B.L. Travis. Los Alamos National Laboratory, Los Alamos, NM 87545.

Although center-surround (CS) behavior in retinal ganglion cells is well-characterized mathematically and empirically, the circuitry mechanism(s) which produce it are uncertain. We constructed a model of the retina that explores amacrine cell circuitry interactions contributing to ganglion cell behavior. Structural properties of the cat retina such as cell densities and distributions, arbor sizes, and connectivity patterns were accurately modeled. Realistic dynamics govern most individual cellular behavior.

Feedforward and feedback inhibitory circuits using both GABA-A and GABA-B receptors were examined. Spatial CS behavior (concentric center and surround domains resulting in characteristic area-response curves) was easily achieved with wide variations of both kinds of circuits and all parameters. In contrast, qualitative temporal behavior of ganglion cells as shown by the general shape of PSTH's (e.g. transient and sustained components, approximate duration of transients) was attained by only small subsets of circuit parameters. Circuits were then tuned to match transient and tonic firing rates and transient duration for individual experimentally recorded cells. GABA-B K+ conductances with time constants between 25 and 45 msec gave the best fit to PSTH's of X-ON ganglion cells, while shorter time-constant GABA-A conductances yielded PSTH's that fit Y-cell temporal behavior. CS behavior in these simulations resulted from the interaction of population parameters such as the densities and arbor sizes of the excitatory (cone bipolar) and inhibitory (amacrine cell) input populations, coupled to the effects of inhibitory conductance time constants. As the stimulus' spatial extent changes, the recruitment rate and relative weighting of the two input populations changes over both space and time.

RETINA: GANGLION CELLS II

579.1

SIMULATING THE MIDGET GANGLION CELL CIRCUIT FOR GAIN CONTROL. E. Sterling* and R.G. Smith, Dept. of Neuroscience, Univ. of PA 19104-6058.

The midget ganglion cell responds linearly to contrast. This must require special circuitry since the small cell would have a high input resistance (~2 GOhm) and thus would tend to saturate. Assuming a single channel conductance of 20 pS and 15 channels/synapse, 1 quantum of transmitter (saturating) would depolarize the membrane potential (Em) by at least 10 mV. A simulation with poisson-distributed quantal events having a 1 msec rise and 5 msec decay, 30 bipolar synapses and a release rate of 4/sec/synapse gave the midget ganglion cell a resting potential of -53 mV with 7 mV noise (rms). To produce spikes, Em must lie between -60 and -40 mV, but to code a signal within this range requires minimizing noise from quantal fluctuation and thus a higher total quantal rate.

To accommodate a high rate and maintain Em within the range appropriate for spiking seems to require an inhibitory conductance. Each quantum from the bipolar terminal that excites the ganglion cell also excites an amacrine process presynaptic to the ganglion cell (Calkins et al. '92). This synapse (presumed GABAergic) would cause a conductance similar in magnitude to the excitatory one and tend to clamp the ganglion cell near the Em of -50 mV required for spiking. When amacrine synapses were added to the simulation and the release rate was increased to 35/sec/synapse, noise was reduced to less than 2 mV.

This gain control circuit might resolve the contradictory needs to minimize cell size and quantal fluctuation while maintaining linearity. Supported by EY08124 and MH48168.

PARTIAL CHARACTERIZATION OF A RAT RETINAL ~20 K MOLECULAR WEIGHT PROTEIN WHOSE PHOSPHORYLATION IS INHIBITED BY TAURINE: NATURE OF PHOSPHATE BOND AND EFFECT OF KINASE INHIBITORS. J.B. Lombardini*. Depts. of Pharmacology and Ophthalmology & Visual Sciences, Texas Tech Univ. Health Sciences Center, Lubbock, TX 79430.

Taurine (2-aminoethanesulfonic acid), is found in high concentrations in all mammalian tissues; however, there is little information concerning the function of taurine. The studies reported herein were designed to determine the nature of the phosphate bond in a retinal ~20 K protein whose phosphorylation is inhibited by taurine. Subjecting the ~20 K protein, after phosphorylation with [γ -³²P]ATP, to different treatments such as acetone, chloroform/methanol, NaOH (both 0° and 100°C), trichloroacetic acid (100°C), and pronase and ribonuclease A indicate that the phosphate moiety is incorporated into protein via a phosphoester bond. Digestion of the isolated ~20 K phosphoprotein with trypsin and 6 M HCl and analysis on 2-dimensional high voltage electrophoresis using cellulose plates demonstrate that serine and threonine residues are phosphorylated. Kinase activators and modulators such as cAMP, cGMP, phorbol ester, calmodulin, and Ca²⁺ have no effect on phosphorylation of the ~20 K protein. However, kinase inhibitors such as staurosporin and W-7 were found to be inhibitory. On the contrary, chelerythrine was determined to be a potent stimulator of phosphorylation. (Supported by the South Plains Foundation, Lubbock, TX)

579.2

MOLECULAR AND PHYSIOLOGICAL CHARACTERIZATION OF A cGMP-GATED CHANNEL IN RETINAL GANGLION CELLS SENSITIVE TO NITRIC OXIDE. T. Leinders-Zufall*, J. Ahmad, F. Zufall and C. J. Barnstable. Departments of Neurology and Ophthalmology and Section of Neurobiology, Yale University School of Medicine, New Haven, CT.

cGMP is the major second messenger in vertebrate phototransduction, coupling the enzymatic steps of the transduction cascade to cGMP-gated cation channels in photoreceptor cells. We now report that cGMP may also be an important regulator of the function of a subset of ganglion cells. Using in situ hybridization on adult rat retinal sections a photoreceptor-like cGMP-gated channel RNA has been detected in the ganglion cell layer. PCR analysis from a small pool of identified ganglion cells was carried out. Sequence analysis of cloned PCR fragments revealed two very homologous but different sequences one of which was identical to the rod photoreceptor cGMP-gated channel sequence. Using the whole-cell patch clamp technique we determined whether a functional cGMP-gated channel was expressed in individual ganglion cells. Internal perfusion of cGMP elicited in about 50% of the cells a non-desensitizing inward current of several hundred picoamperes due to the activation of nonselective cation channels. This current was completely but reversibly blocked by 3 mM external Cd²⁺. Activation of the channels was highly specific for cGMP over cAMP and external removal of divalent cations increased the current through cGMP-gated channels. Since ganglion cells contain a soluble guanylate cyclase we tested whether nitric oxide (NO) could be a regulator of cGMP-gated channels. External application of the NO-donor sodium-nitroprusside (100 μ M) resulted in the production of cGMP as measured by the induction of cGMP-gated channel activity. As a potential physiological source of NO within the retina we identified amacrine cells by using an enzyme stain for NADPH-diaphorase. We propose that nitric oxide is an important physiological messenger in the retina that regulates the activity of cGMP-gated cation channels in ganglion cells. This pathway is likely to be of major interest in other regions of the CNS as well. Supported by grants from the NIH.

Large and small synaptic events in On- β cells of the cat retina. Michael A. Freed* LNP, NINDS, NIH, Bethesda, MD.

Voltage noise was recorded from On- β cells under two conditions: darkness and illumination of the receptive field center with bars of bright red light (647 nm, 6 log(hv s⁻¹ μ m⁻²)) which caused a maximal depolarization. In either darkness or during illumination, there was negligible voltage noise due to photon absorptions. Negligible noise from bipolar cells was transmitted through their synapses upon the ganglion cell, since bipolar cells exhibit little voltage noise in bright light, and the synapses may fail in the dark. Action potentials were eliminated by depolarizing the cell. The voltage noise that remained showed evidence of large and small synaptic events.

Large depolarizing, events rose above the noise. These were fit by $f(t) = a(t/T)^{(k-1)} \exp[-(k-1)(1-t/T)]$ (eq. 1) and took about 10 ms (T) to reach a peak voltage (a) of 600 \pm 50 μ V (k=9). In one cell, the frequency of large events was increased by a bar illuminating the receptive field surround. In another cell, the bar was equally effective throughout the receptive field.

Large events caused the distribution of voltages to be skewed. When these events were deleted from the record, the remaining noise had a normal distribution, as if from randomly occurring small events. This noise increased with illumination. Difference spectra dropped off at high frequencies at a rate of 1/f^k, where k equaled 18-20. These spectra were compatible with an event (eq. 1) which took about 20 ms (T) to reach a peak amplitude (a) of 27 μ V.

The large events are intriguing and may be action potentials from neighboring ganglion cells filtered through small gap junctions between ganglion cells. The smaller events are probably due to release of quantal amounts of neurotransmitter at bipolar and amacrine cell synapses.

579.5

CHOLINERGIC INNERVATION OF RABBIT RETINAL ON-CENTER DIRECTIONAL GANGLION CELLS. C. Brandon*, Dept. of Cell Biology and Anatomy, Chicago Medical School, North Chicago, IL 60064.

A homogeneous population of rabbit retinal ganglion cells (GC's) projects to the medial terminal nucleus (MTN) of the accessory optic system (1,2); these cells almost certainly have ON-center, directionally-selective (DS) receptive fields (3). ON-DS GC's respond strongly to cholinergic agents (4), but morphological evidence for such input is conflicting (5,6). This study was undertaken to identify cholinergic synaptic inputs onto these presumed directional cells.

A mixture of FITC- and RITC-labeled latex microbeads was injected into the rabbit MTN (2); one week later, bead-labeled retinal cells were impaled and filled with Lucifer Yellow (LY). Neighbouring starburst cells (DAPI-labeled) were also injected and filled with LY. LY-filled cells were visualized in wholemount by LY immunocytochemistry.

The dendrites of LY-filled MTN-GC's stratify at about 65-70% depth in the IPL, the same depth as the proximal cholinergic stratum. In 50-micron cross-sections, these processes lie precisely within the proximal ChAT-immunoreactive sublamina. In planar views, the distal dendrites of LY-filled starburst cells and MTN-GC's are precisely co-stratified, with many contact sites marked by (probable synaptic) varicosities in the cholinergic dendrites. Synapses *en passant* are common. In fortuitous cases, the entire cholinergic arbor is contained within the GC arbor, so that the total number of synaptic contacts may be roughly estimated: each cholinergic amacrine makes synaptic contacts at about 50 sites on a given MTN-GC. The extensive overlap of cholinergic amacrine (ca. 20-70-fold) means that MTN-GC's receive an extremely dense cholinergic innervation. Supported by USPHS EY-05601.

NONLINEAR CONTRIBUTIONS TO THE STEP RESPONSES OF CAT RETINAL GANGLION CELLS. J.F. Cox* and M.H. Rowe, Program in Neurobiology, Ohio University, Athens, OH 45701.

Retinal ganglion cells typically respond to the abrupt contrast reversal of a stationary grating with a sudden increase or decrease in firing rate, depending on the configuration of the grating relative to the cell's receptive field. We have characterized the timecourses of such positive and negative step responses by examining filtered peristimulus time histograms of firing rate, collected following sudden contrast reversals. Positive step responses generally begin with a rapid rise in firing rate that is followed by a more gradual decline. However, in many Y-cells and Off-center X-cells the decline is interrupted by a second excitatory component that produces a hump in the step response profile. Thus, there are two components to many step responses, an early component and a late one.

Both components were evident at spatial frequencies that were well above the spatial resolution of the surround mechanism, ruling out any possible contribution of the surround. The late component was exhibited in both positive and negative step response profiles, indicating that it is the result of a rectifying mechanism. Furthermore, the late component does not vary with spatial phase. Thus, the late component of the step response has characteristics similar to those of the nonlinear rectifying subunits, previously described for Y-cells. When we subtracted the estimated contribution of this mechanism from the overall response profiles, the resulting profiles can be readily fit to a linear model (Shapley & Victor, *J. Physiol.* 318: 161, 1981) of center mechanism dynamics.

579.4

HOW NBQX ENHANCES NMDA CURRENTS IN RETINAL GANGLION CELLS. Weifeng Yu and Robert F. Miller* Dept. of Physiology, Univ. of Minnesota, MPLS, MN55455.

NBQX is the most selective non-NMDA antagonist yet available. We have previously shown that NBQX enhances NMDA-mediated synaptic currents in amphibian retinal ganglion cells (Coleman, Yu & Miller, *Society for Neuroscience*, #107.8, Vol.17, P256, 1991) in the presence of external Mg²⁺. In the present study, we have further analyzed this action of NBQX in retinal slice experiments, using both light and microperfusion stimulation (MHS) of the IPL, to synaptically activate third-order neurons. Whole-cell recordings were obtained from ganglion cells. At 10 μ M, NBQX had no effect on exogenously applied NMDA at different holding potentials (-30mV to -70mV), making it unlikely that NBQX directly effects NMDA receptor sensitivity. However, when strychnine and picrotoxin are added to the bathing medium, light and MHS evoke larger excitatory currents, indicating the presence of substantial inhibitory currents in each neuron and, under these conditions, the NBQX enhancement of NMDA currents is eliminated. We then increased internal [Cl⁻], to bring the Cl⁻ reversal potential to 0mV, giving inhibition and excitation the same reversal potential. If NBQX simply blocked postsynaptic inhibition, we would expect to see an NBQX-mediated decrease in NMDA current, but instead we saw an increase. This latter experiment suggests that postsynaptic, algebraic interactions between inhibition and excitation are not solely responsible for NMDA enhancement by NBQX. From these experiments, we conclude that NBQX effectively blocks both non-NMDA excitation and amacrine-mediated inhibition. However, this inhibitory action must exist at both post- and presynaptic sites and when eliminated, enhances release of glutamate at the presynaptic terminals as well as post-synaptic NMDA currents through the elimination of inhibition.

579.6

MORPHOLOGICAL AND PHYSIOLOGICAL IDENTIFICATION OF THE RABBIT RETINAL GANGLION CELL THAT PROJECTS TO THE SUPRACHIASMATIC NUCLEUS. D.S. Tjepkes, F.R. Amthor and D.C. Tucker*, Dept. of Psychology and NRC, Univ. of Alabama at Birmingham, Birmingham, Alabama 35294.

The retina has previously been shown to have a projection to the suprachiasmatic nucleus (SCN). SCN neurons have been shown to have a maintained firing rate that either has a sustained increase or decrease in its firing rate in response to increased illumination (Groos and Mason, *J. Comp. Physiol.*, 1980; Meijer *et al.*, *Brain Res.*, 1986). The goal of this research is to physiologically and morphologically identify the retinal ganglion cells that mediate these responses, which are likely to play a role in the photic entrainment of circadian rhythms.

Fluorescently labelled latex beads were stereotaxically injected into the suprachiasmatic nuclei of rabbits. The retinas containing retrogradely labelled ganglion cells were mounted in a fluorescence microscope and superfused with oxygenated Ames medium. The activity of the labelled cells was examined with extracellular electrodes while visual stimuli were projected through the microscope condenser. The cell was then intracellularly impaled with a pipette electrode and injected with HRP and processed to allow morphological examination.

It is hard to restrict injections to the SCN because of its proximity to the optic chiasm. Nevertheless, the first cells labelled exhibit a sustained rate of firing that increases with an increase in general illumination, with no sign of an antagonistic surround. These cells responded poorly to small flashing spots. These responses are consistent with a role of luminance coding. The cell's morphology is characterized by a small somata and very fine dendrites that are locally bistratified.

This research was supported by NEI grant EY05070.

LOCAL AND NON-LOCAL RECTIFIED RESPONSES OF PHASIC RETINAL W-CELLS OF THE CAT. M.H. Rowe* and J.F. Cox, Neurobiology Program, Ohio University, Athens, OH 45701-2979.

We have examined the receptive field profiles of cat retinal W-cells using narrow bars briefly presented at various locations within the receptive field. Each stimulus sequence consisted of 1000-10000 individual stimuli of fixed duration, e.g., 50 msec, presented with no interstimulus interval. The location and polarity (brighter or darker than background) of all stimuli within a sequence were randomized, and 2-dimensional (space-time) response profiles were generated by reverse correlation of the cell's spike train with the stimulus sequence (Jones and Palmer, *J. Neurophysiol.*, 58: 1987). All 28 cells studied to date had receptive fields consisting of one or more excitatory discharge zones, which we will refer to as either bright or dark depending on the polarity of the effective stimulus. Only 5 of these cells had receptive fields consisting of a single discharge zone. In 12 cells, two discharge zones, one bright and one dark, were present. In most of these cases, the two discharge zones were not in spatial register, indicating that they were produced by separate inputs. The remaining 11 cells had 2 or more (up to 5) discharge zones of common polarity (bright or dark). Nine of these 11 cells also had at least one discharge zone of opposite polarity, and discharge zones of opposite polarity were rarely in spatial register.

In 21 of the 28 cells, an additional mechanism was present that produced inhibition in response to both bright and dark bars at all stimulus locations. This mechanism appeared to have a spatial extent of at least 24 degrees, and to show no spatial structure within its boundaries. This non-local mechanism presumably corresponds to the suppressive field described previously.

PUPILLARY LIGHT REFLEX IN RCS RATS: AGE-RELATED CHANGES AND COMPARISONS WITH VISUAL ACUITY. S.J.O. Whiteley, M.J. Young, P.J. Coffey, and R.D. Lund*. Dept. of Anatomy, University of Cambridge, Cambridge CB2 3DY, U.K. †Dept. of Psychology, University of Sheffield, Sheffield S10 2UR, UK.

The Royal College of Surgeons (RCS) rat has been extensively studied in recent years as an animal model of human retinal degeneration and for studying replacement therapies using transplantation. We are studying the behavioural consequences of this retinal degeneration, expanding previous studies on the pupillary light reflex (PLR) using our pupillometer system to characterise these changes, and comparing these observations with acuity measurements.

Pigmented RCS animals from 3 age groups (4, 8, and 12 months old) were tested for both direct and consensual PLR. Age matched normal rats (Long Evans) served as the control group. Animals were lightly anaesthetised with halothane/nitrous oxide, and the pupil illuminated with infra-red light. The stimulus consisted of a fiber optic light source with a series of neutral density filters, and was controlled with a computer activated electronic shutter. The pupil was viewed through a CCD camera, and the data collected with an ISCAN pupillometer at 33 Hz. The data from these tests were then analysed for a number of parameters, including latency and amplitude of response, as well as rate of constriction. Following testing, animals also underwent a series of behavioural choice tests to measure visual acuity.

Animals tested up to age 12 months still possessed a vigorous PLR. Latency of response increases with age, with approximately a 50% increase between the ages of 4 and 8 months, although the latency of all age groups was substantially longer (~100%) than that seen in age-matched controls (Long-Evans). An interruption in the early phase of the pupillary response wave form was often seen at 4 months. Amplitude of response was less than controls at all times, but did not show a systematic reduction with age. These observations are being correlated with changes in morphological parameters and acuity measures during the course of degeneration.

SIMULATION OF THE SIGNALS OF GANGLION CELLS IN THE HUMAN FOVEA TO HYPERACUITY TASKS.

T. Wachtler, C. Wehrhahn* and B. B. Lee*. MPI für biologische Kybernetik, Tübingen and *MPI für biophysikalische Chemie, Göttingen, Germany.

We have simulated the discharges of retinal ganglion cells to hyperacuity stimuli in the human fovea. The image of the stimuli (a two-line vernier and a two-dot vernier) on the retina was computed due to the optical transfer properties of the human eye. The image was sampled by an array of cones similar to that found in the human fovea. Excitation of ganglion cells was determined by the spatial properties of their receptive fields. These were estimated on the basis of measurements of receptive fields in the parafovea of macaque monkeys. Considering the statistics of ganglion cell firing behavior we can predict the vernier thresholds of an observer exploiting the information in the signals of the ganglion cells. The results of the simulations show that the parvocellular-system cannot supply sufficient information to detect a vernier offset. In order to achieve hyperacuity thresholds of the range determined in human observers receptive field sizes of M-cells and the optical transfer function of the eye must be restricted to a limited range of variation. The 75% threshold for the detection of the relative localization of two lines or two dots then corresponds to a signal difference of one spike in two M-cells.

EFFECTS OF QUADRANT-DIRECTED RETINAL STIMULATION ON THE PUPILLARY LIGHT REFLEX IN HUMANS. W.B. Pickworth*, M. Butschky and M.W. Holden. NIDA, Addiction Research Center, Baltimore, MD 21224

The differential effects of Maxwellian and full field retinal stimulation suggested that separate neural mechanisms mediate measures of the light reflex (Pickworth et al, SN Abs, 1992). In the present study, quadrant-directed, Maxwellian stimulation was used to determine whether different retinal loci contribute equally to measures of the light reflex. Six drug-free volunteers were dark-adapted for 30 min prior to the study. The light reflex was evoked in five distinct conditions of ambient light (A) and a patch (P, or no patch, NP) over the contralateral eye: A=0, NP; A=30,P; A=30, NP; A=60,P; A=60, NP. In each of the conditions stimuli were delivered to: full field and to nasal and temporal superior and inferior quadrants. The stimulus was 40 units above the ambient level. Prestimulus diameter was significantly increased by decreasing A and after P. Constriction amplitude and velocity were significantly larger after stimulation of the nasal inferior quadrant. These findings indicate that the light reflex is differentially influenced by the retinal quadrant stimulated, whereas pupil size is determined by ambient light and patch condition. These data extend the concept that different neuronal mechanisms are involved in tonic and phasic aspects of the light reflex and that the differentiation may reflect dissimilar contributions from the retinal quadrants.

PHARMACOLOGY OF LIGAND-GATED CURRENTS OF CAT GANGLION CELL TYPES IN A RETINAL SLICE PREPARATION. E.D. Cohen and G.L. Fain Jules Stein Eye Institute, UCLA, Los Angeles, CA 90024-7008

We have examined the receptor pharmacology of ligand-gated currents of on- and off- α and β ganglion cells in a retinal slice preparation. Cat retinal slices were prepared by a procedure similar to Edwards et al. (Pflugers Arch. 1989 414:600-612) using HCO₃⁻ and HEPES-buffered solutions. Ganglion cells were voltage clamped in HEPES-buffered Ringer at -70mV. Agonists and antagonists were bath applied. Both on- and off- α and β types showed a similar distribution of receptors and pharmacology. In Mg²⁺-free Ringer containing 200 μ M Cd²⁺, the EAA agonist NMDA (200 μ M) elicited a large inward current. Application of 200 μ M AP7 totally blocked the NMDA-induced response. In 1mM Cd²⁺, kainate (10-30 μ M), AMPA (10-70 μ M) and quisqualate (0.1-30 μ M) all induced inward currents. These responses were all blocked by the quinoxaline 10 μ M CNQX, though for quisqualate at concentrations of \leq 3 μ M. Bicuculline MeCl (20 μ M) blocked the inward currents evoked by 200 μ M GABA on all cells. Baclofen, at (10-30 μ M) had no effect on voltage-gated Ca²⁺ or K⁺ currents. Glycine (200 μ M) also elicited an inward current, and these currents were blocked by 1 μ M strychnine. Application of ACPD or L-APB had no effect. Supported by EY01844

AUDITORY SYSTEM: COCHLEA

580.1

THE MAMMALIAN COCHLEA EXPRESSES mRNA FOR SUBUNITS OF THE L-TYPE CALCIUM CHANNEL. G. E. Green and D. G. Drescher*. Lab. of Bio-otology, Depts. of Otolaryngology and Biochemistry, Wayne State Univ. Sch. of Med., Detroit, MI 48201.

Dihydropyridine-sensitive, L-type calcium channels are composed of the subunits α_1 , $\alpha_2/6$, β , and sometimes γ . The α_1 subunit forms a functioning channel pore while the remaining subunits modify channel properties. In the cochlea, dihydropyridine-sensitive calcium channels are thought to play important roles in hair cell function, including control of neurotransmitter release and modulation of outer hair cell length. Hair-cell calcium channels possess unusually rapid kinetics of activation and deactivation, properties which may be necessary for conveying phase information of sound. In the present work, we utilized reverse transcription and the polymerase chain reaction (PCR) to detect expression of mRNA encoding calcium channel subunits in the cochlea of the 16 day-old CBA_J mouse. PCR primers for each subunit class were derived from a pair of conserved sequences flanking a variable region of appropriate reference cDNA. Cochlear mRNA was reverse-transcribed and resulting cDNA was amplified by PCR under the following conditions: 94 °C for 45 s, 53 °C for 1 min, and 72 °C for 1.5 min, with an extension of 2 s/cycle, for 40 cycles. PCR products ranged in length from 400 to 1000 base pairs. A comparison of banding patterns for amplified cDNA from the cochlea with patterns for similarly amplified cDNA from brain, heart, skeletal muscle and lung demonstrated that the cochlea possesses a distinctive set of β subunit variants. The cochlea was also found to express mRNA for the α_1 and $\alpha_2/6$, but not the γ subunits. The present results suggest that the unusual kinetic properties of the hair-cell calcium channel may be reflected in the characteristic set of calcium channel subunits found within the cochlea.

ASSOCIATION OF MINERALOCORTICOID BINDING SITES (TYPE I RECEPTORS) WITH COCHLEAR BLOOD VESSELS. P.K. Sinha, W.S. Quirk and D.Z. Pitovski*. Department of Otolaryngology-Head and Neck Surgery, Wayne State University School of Medicine, Detroit, MI 48201.

Classical physiology has confined the action of mineralocorticoids to the modulation of ion exchange in the distal tubules of the kidney. However, studies have shown significant evidence for a direct action at the blood vessel level as inferred by the presence of mineralocorticoid (Type I) receptors in vascular tissue (Funder et al, *Endocrinology*, 125: 2224-2226, 1989; Stumpf, *Experientia*, 46: 13-25, 1990). We have now localized mineralocorticoid binding sites (Type I receptors) to cochlear blood vessels by light microscopic autoradiography.

Microdissected lateral wall tissue from the cochleae of male Hartley guinea pigs were incubated with [³H]-aldosterone (60 nM) and a 500-fold excess of RU-28362 (30 μ M), a specific glucocorticoid agonist to prevent low affinity binding to glucocorticoid (Type II) receptors. Specific binding was determined by introducing a competitive control containing an additional 2000-fold excess of cold aldosterone (120 μ M). Tissues were then rinsed, fixed, dehydrated and embedded for sectioning. Sections were covered with autoradiographic emulsion and allowed to expose in light-tight boxes. Autoradiograms were developed and examined for grain densities with a computer-aided image analysis system.

Our results demonstrate a high density of silver grains associated with the capillary network of the lateral wall of the cochlea. The presence of specific mineralocorticoid binding sites (putative Type I receptors) suggests that mineralocorticoids play a role in the physiology of cochlear microvessels and may be a novel modulator of cochlear blood flow. CLONING NEURONAL RECEPTORS FROM THE SPIRAL GANGLION OF THE RAT. A.F. Ryan^{1,2} and A. Stein¹. Division of ¹Otolaryngology and ²Department of Neurosciences, UCSD Medical School and VA Medical Center, La Jolla, CA 92093.

There is considerable evidence that glutamate is the neurotransmitter between cochlear hair cells and spiral ganglion neurons. In a previous study, we found that of the several forms of non-NMDA glutamate receptors, only GluR2 and GluR3 could be detected by *in situ* mRNA hybridization in spiral ganglion neurons (Ryan et al., *NeuroRep.* 2: 643, 1991). To determine whether other non-NMDA glutamate receptor subunit isoforms are also expressed at levels undetectable by hybridization histochemistry, the spiral ganglion was isolated by rapid microdissection from the inner ears of young adult rats. mRNA was extracted and reverse transcribed. The resultant cDNAs were amplified by polymerase chain reaction (PCR) with probes specific for the 3' ends of GluR1-5 mRNAs. All five subunit isoforms were detected in the spiral ganglion with PCR. The results suggest that while GluR2 and GluR3 may be the most numerous non-NMDA subunit isoforms in the ganglion, other non-NMDA glutamate receptors are also expressed. They may contribute to spiral ganglion glutamate pharmacology by participating in hetero-oligomeric receptors.

Supported by grant DC00139 from the NIH/NIDCD and by the VA Research Service.

EVIDENCE FOR THE EXPRESSION OF A GLUTAMATE/ASPARTATE TRANSPORTER IN RAT COCHLEA. H.S. Li, A.S. Niedzielski, K.W. Beisel, H. Hiel, R.J. Wenthold and B.J. Morley*. Boys Town Nat'l Research Hospital, Omaha, NE 68131 and Neurochemistry Laboratory, Nat'l Institute of Deafness and Other Communication Disorders, Bethesda, MD 20892.

It is nearly certain that the neurotransmitter in the cochlear inner hair cells (IHCs) is an excitatory amino acid. Although there is substantial evidence to indicate that the neurotransmitter is glutamate, the data are not unequivocal. Unlike the brain, IHCs are not in juxtaposition to glial cells and therefore the mechanisms controlling glutamate neurotransmission may be unique. In preliminary studies using a rat cochlea cDNA library and cDNA synthesized from rat organ of Corti RNA we have found evidence for a proposed glial type of glutamate/aspartate transporter (GLAST) in the cochlea. For these studies, DNA from a rat cochlea, unidirectional cDNA library constructed in the ZAP XR vector was screened by polymerase chain reaction (PCR) using degenerate primers complementary to the conserved sequences in the coding region of the glutamate transporter family. PCR amplification products were then sequenced. The resulting sequence demonstrated that the PCR amplification products were identical with that of GLAST. In a subsequent study, cDNA was synthesized from total RNA isolated from rat organ of Corti and was amplified by PCR using specific primers. Studies are in progress to localize the expression of GLAST in the cochlea.

ALTERATIONS IN COCHLEAR ELECTRICAL POTENTIALS BY INTRACOCHELEAR ATP AND ANALOGS. S.G. Kujawa, M. Fallon and R.P. Bobbin*. Kresge Hearing Research Lab., LSU-MC, New Orleans, LA 70112

Several lines of evidence implicate a neuromodulator role for ATP in the cochlea. Previous experiments (Bobbin, et al., *ARO Abstr.* 16, 102, 1993) demonstrated reversible alterations in sound-evoked electrical and otoacoustic responses from the cochlea following intracochlear application of ATP. *In vitro*, outer hair cells are depolarized by ATP. The purinergic receptor mediating these effects remains unclear. Thus, we tested several ATP analogs for their effects on cochlear potentials.

Drugs (ATP, adenosine, 2-methylthio ATP, ATP- α -S, ATP- γ -S) were dissolved in artificial perilymph (3 μ M-1 mM) and applied by perfusing the perilymph compartment of the guinea pig cochlea at 2.5 μ l/min for 10 min. The compound action potential of the auditory nerve (CAP), cochlear microphonic (CM) and summing potential (SP) were recorded from an electrode in basal turn scala vestibuli. Potentials were evoked by 10 kHz tone bursts varied in intensity from 8-98 dB SPL in 6 dB steps.

CAP was suppressed and its latency increased, SP was suppressed at low and increased at high intensities and CM was essentially unchanged following perfusions. All effects were dose-responsive. The order of potency was: ATP- γ -S \gg ATP $>$ ATP- α -S $>$ adenosine $>$ 2-methylthio ATP. Results suggest that ATP, through activation of P2 purinergic receptors, may play a neuromodulatory role in shaping the cochlear response to sound.

MOLECULAR ANALYSIS OF GLUTAMATE RECEPTOR EXPRESSION IN COCHLEAR AND VESTIBULAR GANGLION CELLS. A.S. Niedzielski* and R.J. Wenthold, Laboratory of Neurochemistry, NIDCD, NIH, Bethesda, MD 20892.

Iontropic glutamate receptors are believed to mediate neurotransmission at the hair cell/eighth nerve synapse. On the basis of pharmacological and structural profiles of cloned receptor subunits glutamate-gated ion channels are presently categorized as being either AMPA, kainate or NMDA receptors. The AMPA receptors have been designated GluR1-4, the kainate receptors are classified as KA1&2 and GluR5-7, and the NMDA receptors are NMDAR1 and NMDAR2a-d. *In situ* hybridization, DNA amplification by PCR and immunocytochemistry were used to determine glutamate receptor subtype expression in the cochlear and vestibular ganglia of the rat.

The AMPA receptors GluR2-4, but not GluR1, were detected in inner ear neurons by *in situ* hybridization with subunit-specific oligonucleotides. Immunocytochemical studies using subunit-specific antibodies confirmed the presence of GluR2-4 in the cochlear ganglion. In addition, *in situ* hybridization and PCR analysis of cochlear and vestibular neurons detected high levels of mRNA for the NMDAR1 receptor and low or undetectable levels of mRNA for NMDAR2a-c. These results suggest that the neurons of the inner ear coexpress specific AMPA and NMDA receptor subtypes at the hair cell/afferent nerve synapse. Coexpression of AMPA, kainate and NMDA receptors may contribute to the unique pharmacology and physiology of the eighth nerve and may play a role in pathological conditions associated with hearing and balance disorders.

DEMONSTRATION OF THE A₁ ADENOSINE RECEPTORS IN RAT COCHLEA. V. Ramkumar¹, R. Ravi¹, M. Wilson¹, T. Gettys², C. Whitworth¹ and L. P. Rybak*¹. ¹Depts. of Pharmacology and Surgery, SIU School of Medicine, Springfield, IL 62794 and ²Dept. of Medicine, Duke Univ. Medical Center, Durham, NC 27710.

Adenosine (A₁) receptors (A₁ARs) are found in a variety of tissues in the body where their physiological roles have been identified. In the cochlea, the existence of these receptors has not been described previously. Membranes prepared from rat cochleas demonstrate high affinity and saturable binding of [¹²⁵I]APNEA, an A₁AR agonist, with B_{max} and K_d values being 40.5 \pm 0.5 fmol/mg protein and 1.28 \pm 0.03 nM, respectively. Various adenosine analogs competed for [¹²⁵I]APNEA binding sites with an order of potency indicative of these sites being the A₁AR. Covalent labeling of the receptor protein by the agonist photoaffinity probe ([¹²⁵I]AZPNEA) identified a 36 kDa receptor protein, labeling of which was inhibited by theophylline, an antagonist of the A₁AR. [¹²⁵I]APNEA binding was significantly reduced following pretreatment of membranes with pertussis toxin, suggesting the interaction of these receptors with the G_i and/or G_o proteins in cochlear membranes. Activation of the A₁AR with R-PIA led to inhibition of forskolin-stimulated adenylyl cyclase activity. These data indicate the presence of an important inhibitory receptor in the peripheral auditory system which may play a role in modulating auditory functions.

EMBRYONIC FORMS OF FIBRONECTIN mRNA ARE EXPRESSED TRANSIENTLY DURING POSTNATAL DEVELOPMENT OF THE RAT COCHLEA. N.K. Woolf*, D.V. Jacquish, F.J. Koehn and V.L. Woods. Depts. of Otolaryngology and Medicine, UCSD Medical Center and the VA Medical Center, La Jolla, CA 92093.

We previously reported the reappearance of alternately spliced forms of fibronectin with embryonic mRNA patterns in the postnatal rat cochlea: fibronectin mRNA synthesis was detected in the organ of Corti at one week postpartum, but not at birth or two weeks postpartum. In order to clarify the relationship between fibronectin gene expression and the ontogeny of the inner ear, patterns of fibronectin synthesis were examined within the organ of Corti at two day intervals, from embryonic day 16 through two weeks postpartum. *In situ* hybridization with segment-specific probes revealed embryonic forms of fibronectin mRNA were expressed briefly after birth in the mesothelial cells lining the basilar membrane. Postnatal synthesis of the embryonic-type of fibronectin coincided temporally with a period for significant auditory nerve fiber growth, nerve-hair cell synaptogenesis and organ of Corti morphogenesis. The results suggest a functional role for fibronectin in postnatal cochlear development.

PRESENCE OF NEUROACTIVE SUBSTANCES IN THE POSTNATAL COCHLEA. D.D. Simmons*, H.D. Moulding, and H. Adi Klein. Dept. of Biology and Brain Research Institute, UCLA, Los Angeles, CA 90024-1606.

During development, neurons undergo specific chemical and structural changes as they attempt to reach their target cells. The present study focuses on specific immunocytochemical changes in the postnatal cochlea of hamster which may be related to efferent neurons originating from the superior olivary complex in the brainstem. Antibodies against calcitonin gene-related peptide (CGRP), growth associated protein (GAP-43), synaptophysin (SYN), and nerve growth factor receptor (NGFR) were used to probe for the presence of such substances histochemically as well as with western blots. CGRP was identified within the cochlear nerve at postnatal day (P) 4 but not underneath hair cells until P6. GAP-43 was detected both within the nerve and underneath hair cells by P4. SYN was never detected within the nerve but was found underneath hair cells by P5. There is also evidence for NGFR immunoreactivity around P6. It is possible that these data correlate with the progression of efferent development in the cochlea. At the earlier ages, there are at least two separate efferent populations: those still growing in the nerve and those with mature synapses under hair cells. Efferents containing CGRP may be the last to innervate the hair cells. Our data are consistent with the hypothesis that distinct efferent populations sequentially innervate the developing cochlea.

DEVELOPMENT OF EFFERENT CONTACTS IN THE POSTNATAL RAT COCHLEA. L.L. Bruce* and M.A. Christensen. Dept. Biomedical Sci., Creighton Univ., Omaha, NE 68178.

The development of functional efferent contacts in the maturing cochlea was studied with DiI. DiI moves transcellularly when the plasma membranes of two cells are in direct contact allowing the identification and study of newly formed contacts. DiI was placed in the contralateral or midline brainstem of perfused rats 0-22 days of age (P0-22) and incubated at 37°C for 6 wks. Labeled profiles appeared in the cochlea in a sequence comparable to that reported for efferents in previous studies. However, transneuronal labeling of the spiral ganglion and cochlear hair cells also occurred in an age dependent pattern. At P0 numerous spiral ganglia and inner hair cells (IHCs) were transneuronally labeled. By P2 most IHCs and occasional outer hair cells (OHCs) in rows 1 and 2 were labeled. By P22 only spiral ganglia were transneuronally labeled. Fewer labeled hair cells and spiral ganglia were labeled after contralateral implants (which directly labeled only medial olivocochlear axons) than midline implants. Electron microscopic analysis revealed densely labeled profiles (efferents) directly contacting both IHCs and afferents with limited areas of membrane labeling including the plasma membrane across from the efferent contact, tight junctions and endoplasmic reticulum. This indicates that efferents including medial olivocochlear fibers grow into the cochlea, rapidly make contacts with nearby afferents and IHCs and later with OHCs. During maturation these specialized junctions with hair cells but not with afferents are lost.

AXONEMAL FORMS AND THE MORPHOGENETIC ROLE OF THE KINOCILIUM IN AUDITORY HAIR CELLS. H.M. Sobkowicz*, S.M. Slapnick and B.K. August. Dept. of Neurology, Univ. of Wisconsin, Madison, WI 53706 USA

Axonemal patterns in the auditory cilium ("kinocilium") were examined in 165 cross-sections. The study was done on the developing organ of Corti in the intact mouse and in culture, and on regenerating hair cells following mechanical injury to the organ in culture. The prevalent form (49%) of the auditory kinocilium consists of 9 + 0 microtubules. The 9 + 2 (single) form, previously thought to characterize the organelle, occurs only in about 6%. In the immature kinocilium, one of the peripheral doublets tends to move inward to form the modified 8 + 1 (double) configuration, resulting in an irregular microtubular distribution. The kinocilium is transitory, and it desintegrates around the tenth postnatal day. Exceptions are post-traumatic regenerating hair cells that reform their kinocilia during repair of their cuticular plates and regrowth of the stereocilia. Regenerating kinocilia repeat the initial developmental patterns.

During regeneration of the cuticular plate, the cytoplasmic area adjacent to basal bodies displays pericentriolar fibrous densities, growth vesicles, and microtubules, all surrounded by concentrating actin filaments. The growth vesicles may spread across the entire apical part of the cell. Pericentriolar bodies are associated with microtubules, evidently leading their nucleation. Microtubules appear to influence the alignment of actin filaments and participate in the formation of the filamentous matrix of the cuticular plate. We postulate that the enigmatic auditory kinocilium plays a morphogenetic role in the differentiation and regeneration of cuticular plates and stereocilia. (NIH Grant R01 DC00844)

POSTNATAL DEVELOPMENT OF HAIR CELLS AND THE ORGAN OF CORTI IN THE HAMSTER. J.A. Kaltenbach*, and P. Falzarano, Dept. of Audiol., Dept. of Otolaryngol., Wayne State Univ., Detroit, MI 48201

A morphometric analysis of the developing organ of Corti and its component hair cells was carried out in an age-graded series of Syrian golden hamsters using the scanning electron microscope. The purpose was to establish a quantitative framework that would provide insight into the rules and principles by which the mammalian cochlea attains its adult proportions. This study examined the postnatal development at two day intervals spanning the period from birth to 22 days after birth. Our analysis included measures of cochlear length, hair cell numbers, as well as measures of hair cell sizes in each of 5 sectors along the cochlear spiral. Our results demonstrate several fundamental principles of cochlear development: 1) The full 2 1/4 turns seen in the adult cochlea are already present at birth, but the cochlea continues to elongate for the next 12-14 days; 2) Development of hair cells in the apex generally lags that in the base. This is apparent in that basal turn hair cells are already differentiated at birth while those in the apex become differentiated postnatally. 3) Growth in cochlear length occurs mainly by increases in cell size rather than in cell numbers; while hair cells do increase in numbers during the first 10 days of cochlear growth, this increase involves addition of hair cells to pre-existing regions of the cochlear apex only. Moreover, the full complement of hair cells is established 4 days before the full size of the cochlea is attained; in contrast, cochlear elongation involves growth in cell size at all positions along the cochlear spiral. 4) The period of hair cell growth exceeds the period of organ of Corti growth and appears to be possible by decreases in intercellular spacing, primarily in the apical region of the cochlea; 5) Inner and outer hair cell neighbors remain constant at different ages indicating that the spatial relationships between the two hair cell populations is preserved as the cochlea grows.

α -DIFLUOROMETHYLORNITHINE (DFMO) INHIBITS COCHLEAR FUNCTION AND POLYAMINE METABOLISM IN DEVELOPING RATS. G. Henley*, C. Whitworth, L. Rybak, B. Lonsbury-Martin, #Dept. of Otorhinolaryngology, Baylor College of Med., Houston, TX 77030; † Depts. of Otolaryngology and Pharmacology, Southern Illinois U. Sch. of Med., Springfield, IL 62702; *Dept. of Otolaryngology, U. Miami Sch. of Med., Miami, FL 33101.

DFMO is an inhibitor of ornithine decarboxylase (ODC), a key enzyme in polyamine synthesis. Cochlear ODC activity increases during the maturation of hearing in neonatal rats (Henley, Hear Res 55:45-49,1991), and cochlear distortion-product otoacoustic emissions (DPOAEs), a measure of outer hair cell function, are significantly altered by DFMO (Henley, et al., J Cell Biochem, 14F:22, 1990). The purpose of this study was to correlate biochemical changes in cochlear polyamine metabolism with functional losses produced by DFMO. Rats were treated with DFMO (500 mg/kg/day) or saline during the period of increasing polyamine synthesis (days 1-10). ODC was determined by measuring the decarboxylation of ornithine and polyamines (putrescine, spermidine, spermine) were quantified by HPLC in cochlear tissues (stria vascularis, organ of Corti, cochlear nerve). Cochlear function was assessed using DPOAEs, click-evoked compound action potentials (CAP) and endocochlear potentials (EP). DFMO inhibited ODC in all cochlear tissues. DFMO depleted putrescine and spermidine in the organ of Corti and cochlear nerve which correlated with significant physiological deficits in DPOAEs and CAPs. In contrast, DFMO did not deplete polyamines in the stria vascularis nor did it affect EPs. Thus, biochemical effects of DFMO on putrescine and spermidine correlated well with functional deficits.

DEGENERATIVE PROCESSES ASSOCIATED WITH NEURONAL DEATH IN THE AGING SPIRAL GANGLION. M. L. Feldman*, Dept. of Anatomy & Neurobiology, Boston University School of Medicine, Boston, MA 02118.

The events leading to the death of spiral ganglion (SG) neurons were studied in an age-graded series of rat cochleas. Since these cells provide the entire auditory input to the CNS and exhibit marked age-related cell loss (Keithley & Feldman, '79), neuronal death in this locus is significant in understanding hearing loss in old age.

In contrast to age-dependent changes such as lipofuscin accumulation and axonal hypermyelination which have not been able to be clearly related to cell death, two frequently observed changes, affecting both Type I and II SG cells, appear to be lethal. Both may first appear in young adult animals. The first change involves the progressive enlargement of a cytoplasmic membrane-bound vacuole of unknown origin. This eventually compresses the nucleus and most of the perikaryon to the point where they occupy only a thin peripheral crescent under the perisomatic Schwann cell sheath, with further compression destroying the soma. The second change involves irregular vacuolization of the Schwann cell sheath, particularly within the innermost lamellae. This is followed by shrinkage of the soma, accompanied by distortion of the somal and sheath contours, and, eventually, disintegration of the neuronal plasma membrane. The cell body then degenerates and the sheath lamellae become severely disrupted. In the absence of an exogenous phagocytic cell, the neuronal debris probably is engulfed by the Schwann cell, forming a large lipofuscin deposit. The final marker of the former neuron is a thin shell formed by attenuated, spidery Schwann cell processes or the naked basal laminae extending from these processes. Further degenerative processes occur late in the lifespan. These include the formation of perinuclear skeins of packed microtubules and the development of multiple, irregular, non-membrane bound cytoplasmic lacunae. [Supported by NIH/NIA grant AG-06217]

DISTORTION PRODUCTS AT THE BASILAR MEMBRANE OF THE COCHLEA: DEPENDENCE ON STIMULUS FREQUENCY AND INTENSITY AND EFFECT OF ACOUSTIC TRAUMA. L. Robles*, M. A. Ruggero* and N. C. Rich*. *Dept. of Otolaryngology, Univ. of Minnesota, Minneapolis, MN 55455, U.S.A., and *Depto. de Fisiología y Biofísica, Fac. de Medicina, Univ. de Chile, Santiago, Chile

Basilar membrane (BM) vibrations in response to two-tone stimuli contain distortion products (DPs) of cochlear origin (Robles et al., 1991, *Nature* 349: 413-414). We have further investigated the generation of DPs in the chinchilla cochlea using a laser velocimeter focused on glass microbeads placed on BM sites with characteristic frequency (CF) of 8-10 kHz. For primary tones (frequencies: f_1 and f_2) presented at equally-low levels, the magnitudes of the DPs ($2f_1 - f_2$ or $2f_2 - f_1$, = CF) decreased rapidly with increasing f_2/f_1 ; at high stimulus levels, DP magnitudes decreased slowly for small f_2/f_1 but fell precipitously at higher f_2/f_1 ratios. With increasing stimulus level, $2f_1 - f_2$ DP phases tended to lag for large f_2/f_1 but changed little, or showed small leads, for small f_2/f_1 . With fixed f_2/f_1 and constant (moderate) level of one primary tone, the $2f_1 - f_2$ DP magnitude was a nonmonotonic function of the level of the other primary tone: it first increased at a faster-than-linear rate, peaked at f_1 levels 5-10 dB $> f_2$ levels and decreased at higher levels. Exposure of the ear to certain intense tones with frequency higher than CF induced substantial reductions (22-37 dB) of the magnitudes of the $2f_1 - f_2$ (= CF) DP, while affecting the $2f_2 - f_1$ (= CF) DP and responses to CF tones to a much smaller extent (7-13 dB). These results strongly resemble psychoacoustical findings and indicate that $2f_1 - f_2$ DPs originate near the BM sites of their primary frequencies and propagate to locations with CF = $2f_1 - f_2$. RESISTANCE TO NOISE-INDUCED HEARING LOSS IN THE MONGOLIAN GERBIL. F.A. Boettcher* and M.A. Grattan. Department of Otolaryngology, Medical University of South Carolina, Charleston, SC 29425.

The auditory system develops resistance to the ototraumatic effects of noise as a noise exposure is repeated. A model of resistance to noise-induced hearing loss (NIHL) will be described for the gerbil using the auditory brainstem response (ABR), distortion product otoacoustic emissions (DPOAE) and cochlear morphology. Young adult gerbils were exposed to an octave band of noise centered at 4 kHz on a 25% duty cycle. The average threshold shift at 8 kHz was 33 dB following the first 6-hour exposure, but was only 5 dB following the 12th daily exposure. ABR amplitudes were reduced and latencies were increased after the first exposure, but were near baseline levels following the 12th exposure. DPOAE amplitudes were reduced at 4-10 kHz on the first day of exposure but were similar to controls on the 12th day of exposure. Alterations in cochlear ultrastructure and biochemistry will be compared to physiological results in order to examine mechanisms of resistance to NIHL. Work supported by NIH-DC-00422.

DESCRIBING SCALP POTENTIAL DATA IN TERMS OF EQUIVALENT DIPOLE COMPONENTS WITH PHYSIOLOGICALLY PLAUSIBLE PARAMETERS: APPLICATION TO THE AUDITORY P50. H. L. Gillary*. Dept. of Physiology, Univ. of Hawaii, Honolulu, HI 96822.

A new procedure has been developed to describe segments of multi-channel scalp electrical potential data in terms of potentials generated on a homogeneous spherical volume conductor by parametric equivalent dipole current sources expected to mimic the real sources. It has been applied to an epoch of 14-channel band-pass filtered (10-50 Hz) auditory evoked potential data. The epoch of average-referenced data was segmented at time points of minimum variance (along channels) and dipole components (DCs) fit, using a simplex algorithm to minimize residual variance, to a tapered subepoch comprised of a segment corresponding to the P50 wave flanked by contiguous segments. Initially an 8-parameter DC with fixed location and orientation and a Gaussian time-dependent magnitude function was fit to each of the 3 segments, and subsequent DCs added by fitting each to the segment of the residual with maximum variance and then refitting all to the whole subepoch. Additional parameters were then added to DCs with peak latencies in the P50 segment to allow rotation and a more flexible magnitude function. The P50 segment was thus represented as the sum of a) DCs with peak latencies within 1t (primary DCs), b) the tails of DCs with peaks in adjacent segments, and c) a residual. When using 3 DCs with peaks in the adjacent segments, the respective residual variances for the P50 segment for 1) an 8-parameter primary DC, 2) a 10-parameter primary DC with linear rotation, or 3) 2 8-parameter primary DCs, were 11.5, 11.3, and 4.4%. For all 3 cases, the ratio of the mean powers of summed primary DCs to summed tails was about 3.7. The above procedure can be adapted to longer subepochs of data. It is also amenable to modifications involving more realistic head and current source models and other minimization algorithms, and shows promise as a general means to unravel scalp potential data into parametric components that represent separable physiological sources in real heads.

581.3

CHANGES IN AUDITORY EVOKED POTENTIALS DURING SLEEP AND WAKEFULNESS IN THE RAT. Meneses-Ortega, S.*¹, Brailowsky S.*¹ and Knight R.T.*², ¹Instituto de Fisiología Celular and Facultad de Psicología, U.N.A.M., México, D.F., ²Dept. of Neurology, Univ. of Calif., Davis, VAMC, Martínez, Calif. 94553, U.S.A.

Event-related potentials (ERPs) can assess the interrelationship between information processing and arousal level. The present study examined the effects of behavioral state on auditory evoked potentials. Experiments were carried out on male Wistar rats in which recording electrodes were placed over frontal and occipital cortex, and on the vertex. The reference electrode was placed on the far frontal sinus. Amplifiers were set at a bandpass of 1-300 Hz. Auditory ERPs were recorded in a sound attenuated chamber in response to clicks (square wave pulses, 0.1 msec duration, 50 dB above brainstem auditory evoked potentials threshold level). EEG and behavioral states were continuously monitored and recordings were made during waking (immobile and active) and during sleep (slow and REM sleep phases). Brainstem auditory evoked potentials (BSAEP, 0-5 msec) were unaltered by behavioral state. However, all middle and late components of the auditory evoked potentials, except for a negativity appearing at 17 msec latency (i.e. N17), were differentially affected by the behavioral state: during quiet waking a P30 component had maximum amplitude, whereas during slow wave sleep the N50, N80 and P130 components increased in amplitude. During REM sleep all components were reduced or abolished. No changes in the latency of the components were found. These findings demonstrate that the responsiveness to acoustic stimuli is modulated during sleep.

MIDLATENCY AUDITORY EVOKED RESPONSES: A COMPARISON OF MEASUREMENT TECHNIQUES. R. J. Erwin*. Dept. of Psychiatry, Univ. of Penn., Philadelphia, PA 19104.

Five techniques for measuring the P1 component of the auditory evoked potential were contrasted using data obtained from 15 normals at the Cz recording site with click stimuli presented at 3 stimulus rates (1/sec, 5/sec and 10/sec). Both mandible reference and current source density derived (CSD) data obtained using 1-300 Hz and 10-300 Hz bandpasses were examined. The measurements were: 1) Nb to P1 peak to peak amplitudes; 2) prestimulus baseline to P1 peak amplitudes; 3) Integrated amplitudes based on a signed mean of amplitudes; 4) Integrated amplitudes based a principal component analysis (PCA) latency window; 5) PCA factor scores. Overall, allowing for scaling differences, most of the methods resulted in comparable results across stimulus rates (amplitudes diminished at faster rates) with some exceptions. For the CSD visually integrated measures, the amplitudes did not vary across rates, possibly due to the difficulty in determining boundaries. Both integrated and baseline to peak methods resulted in greater P1 amplitudes for the 1-300 Hz mandible data sets across rates and for the 10-300 Hz mandible data set at the 10/sec rate. These differences might be due to component overlap from preceding stimuli. Overall the findings suggest that a number of methodological factors need to be considered in the determination of P1 component amplitude.

581.4

BINAURAL VERSUS MONAURAL AUDITORY EVOKED POTENTIALS IN RAT NEOCORTEX

S. DI* and D. S. BARTH Department of Psychology, University of Colorado, Boulder, Colorado 80309 USA

High spatial resolution epicortical recording techniques and numerical modeling were used to investigate laterality effects on the middle latency auditory evoked potential (MAEP) complex.

Our data confirm previous reports that auditory stimulus laterality has a consistent effect on the amplitude, timing, and spatial distribution of the MAEP complex. The earliest temporal components (P1a, P1b and N1) show the greatest sensitivity, and are absent during ipsilateral stimulation. The later positive slow wave (P2) is present at the same amplitude during all stimulation conditions. Generation of the P2 appears to be independent of prior activation of areas 36 and 41 reflected in the early components, suggesting its generation by a more diffuse thalamocortical pathway, possibly from the medial division of the medial geniculate. Serial versus parallel activation of rodent auditory cortex is discussed in the context of laterality sensitive MAEP components.

THE RAT P1 AUDITORY MIDDLE LATENCY EVOKED POTENTIAL. H. Miyazato, R.D. Skinner, E. Garcia-Rill, N. Reese and B. Hendricks. Department of Anatomy, University of Arkansas for Medical Sciences, Little Rock, AR 72205

The human P1 auditory middle latency potential is characterized by rapid habituation, sleep state dependence and is blocked by the cholinergic antagonist scopolamine. The P1 is abnormal in autism, Alzheimer's disease, schizophrenia and narcolepsy. Our aim is to identify and characterize the P1 potential in the rat in order to use this animal as a possible model for one or more of these diseases. Adult rats were implanted under anesthesia with skull screws for recording at the vertex bilaterally (1 mm lateral of the midline) and in the frontal sinus for reference. Rarefied click stimuli (64 trials) were used to average evoked auditory responses in alert rats in a sound attenuating chamber with background white noise. Thresholds for the early auditory evoked potentials (BAERs) was 50-55 dB and 70-75 dB for the P1 middle latency potential. The amplitude of the P1 potential was dependent on the frequency of stimulation (negative exponential). Using the averaged response at 0.2Hz as 100%, the averaged P1 amplitude was attenuated by 36% at 0.5Hz and by 81% at 2Hz frequency of stimulation. In a paired click paradigm (5 sec between trials), the amplitude of the averaged P1 response to the second click showed a linear relationship with the intersimulus interval (ISI). At ISIs of 1.0, 0.5 and 0.1 sec, the averaged response amplitude was 65, 44 and 10%, respectively, of the amplitude of the averaged P1 response to the first click. The cholinergic antagonist scopolamine reduced the P1 response in a dose dependent manner. Following i.p. injections of 5, 10 or 20 mg/kg, the amplitude of the averaged P1 response returned to within 1 standard deviation of the averaged control value (saline injection) at 45, 78 and 157 minutes, respectively. The latency of the P1 response in the rat peaked at 13 msec compared to 25 msec in the cat and 60 msec in the human. The characteristics of this potential (rapid habituation, state dependence and cholinergic modulation) in the rat match those evident in the cat and human at a longer latency. INHIBITION OF DISCHARGE COUPLED TO A DESCENDING PATHWAY IN THE AUDITORY SYSTEM OF CATS. M. Piesman, E. Chao, E. Gruen, C. Woody, E.G. Zotova*. UCLA Med. Ctr., Los Angeles, CA 90024.

Recordings of single unit activity were obtained from 457 neurons of the auditory system of conscious cats given 1 ms binaural click stimuli. A temporally related reduction of discharge was disclosed at three functionally related areas of the auditory pathway. Of 66 neurons studied in the secondary auditory cortex, 46 neurons (70%) showed inhibition of discharge during the 48-56 ms latency period after click. The posterior ectosylvian region of the auditory cortex showed a significant decrease in firing in the 40-56 ms post stimulus period, having 27 (64%) out of 42 cells with reduction of activity. In the inferior colliculus, a smaller but still significant percentage of cells (22%, 16 out of 72 cells) had decreased unit activity in the period 56-76 ms after click. Inhibition of discharge was measured by comparing numbers of cells with decreased firing in the experimental periods versus pre and post click control periods. The primary auditory cortex and the dorsal and ventral cochlear nuclei were also analyzed for comparable periods of inhibition, but none were found. These findings and the latency periods at which they were found led us to conclude that the inhibition was traveling in a descending direction.

ORGANIZATION OF PRIMARY AUDITORY CORTEX EVIDENT IN RESPONSES TO RIPPLED COMPLEX SOUND STIMULI. S.A. Shamma, H. Versnel* and N.A. Kowalski. Institute for Systems Research and Department of Electrical Engineering, University of Maryland, College Park, MD 20742.

We hypothesize that the primary auditory cortex (AI) encodes the profile of the acoustic spectrum by performing a local Fourier-like transformation, much the same way as in the primary visual cortex (VI) (De Valois and De Valois, Spatial Vision, Oxford Press, New York, 1990). In VI simple cells are tuned to the frequency and phase of sinusoidal visual patterns and from the frequency tuning curve, the receptive field (space domain) of a cell can be predicted by reverse Fourier transformation. In an analogous manner, we recorded responses of AI units to broadband sound complexes with sinusoidally modulated spectral profiles (ripple) in the ferret. The ripple frequency (expressed in cycles/octave), and the ripple phase were varied.

The results show that AI neurons are highly selective to ripple frequency and phase. Most cells are tuned to frequencies between 0.2 and 2 cycles/octave. The reverse Fourier transforms of the ripple tuning curves closely correspond to excitatory and inhibitory response areas determined with two-tone stimuli (Shamma, Fleshman, Wisner and Versnel, J. of Neurophysiol. 69: 367-383, 1993). This correspondence can be quantified in terms of best ripple frequency and phase. The spatial mapping of these parameters along the isofrequency axis is also described.

581.6

SURFACE EVOKED POTENTIALS MEASURED WITH A NOVEL MICRO-ELECTRODE ARRAY ON THE FERRET PRIMARY AUDITORY CORTEX. A.L. Owens, S.A. Shamma*, T.J. Denison. Institute for Systems Research and Dept. of Electrical Engineering, University of Maryland, College Park, MD 20742.

In order to elucidate the general principles that the primary auditory cortex (AI) uses to process sound stimuli, we have mapped the response areas in AI with a single tungsten electrode. Though quite useful in recording electrical activity, the method limits the amount of available data to the point of insertion. Hence, numerous insertions of the electrode are required to fully map the spatial properties of the cortical response areas. In addition, the time involved adds an unknown variable as the condition of the animal changes.

To circumvent these problems, we have developed a multi-electrode array using the techniques of silicon IC technology. A 5 X 5 matrix of gold electrodes with 210 μ m spacing between elements has been fabricated. Leads exit the array and travel 5 cm down a polyamide shank to a series of gold contact pads which provide a junction to external preamplifiers. The gold electrodes, leads, and contact pads are sandwiched between two layers of polyamide, which serves as a flexible insulator. Small holes are opened in the polyamide to access the electrodes and contact pads. When placed on the surface of the cortex, the flexible probe conforms to the shape of the brain and allows for the recording of cortical activity over a $1E+6 \mu$ m² area.

The micro-electrode array is used to generate surface maps of the following evoked potential parameters: best frequency for response, latency of response peak, excitatory bandwidth, and sensitivity to frequency sweep direction. Our results indicate that maps of the spatial distribution of these parameters correlate well with data from unit clusters. These parameters are important for modeling sound processing at the cortical level.

SPATIAL FREQUENCY FILTERS IN CAT AUDITORY CORTEX. B.M. Calhoun, C.E. Schreiner*, W.M. Keck Center of Integrative Neuroscience and Coleman Laboratory, UCSF, San Francisco, CA 94143.

Vocalizations and many other naturally occurring sounds are characterized by broad-band spectra with non-uniform spectral envelopes. We are currently investigating the processing of complex signals by cortical neurons and are using broad-band stimuli to determine receptive field properties.

One of the most distinguishing aspects of sounds is their spectral envelope. To allow a systematic approach for studying influences of spectral envelopes on the response characteristics of cortical neurons, 'ripple spectra' were generated. This type of stimulus has four main advantages: 1) it can be easily described by its parameters, 2) it has several characteristics in common with visual gratings used to study the spatial frequency processing in the visual system, 3) like vowels, it has a spectrum displaying several frequency regions with increased spectral energy (formants) separated by regions of decreased spectral energy, and 4) the ripple stimulus is similar to a single 'spatial frequency' in the spatial domain of the basilar membrane. By varying the ripple density, the 'spatial' filtering characteristics of the neuron can be determined. The standard stimulus characteristics used are: a harmonic series ($f_0 = 50$ to 200 Hz) with a 6 dB/octave decline of the component amplitudes (120 to 255 components) as carrier; a bandwidth of 3 octaves; the spectral envelope of the signal is represented by a sinusoid on a logarithmically scaled frequency axis; the frequency of the envelope sinusoid is referred to as ripple density (ripples/octaves); the modulation depth of the envelope (ripple depth) is linear on a dB scale.

The ripple transfer function is found by systematically varying the ripple density for two different envelope phases (0 and 90 degree). The resulting complex ripple transfer function is usually bandpass. A 'best ripple density' can be defined that is usually between 0.6 and 4 ripples/octave. The Fourier transform of the complex ripple transfer function is a spatial function similar to the excitatory/inhibitory receptive field obtained with two-tone stimuli. This new method for obtaining filter functions of cortical neurons takes into account the interaction of more complex spectral features. By comparing spatial frequency filtering qualities of neurons obtained with narrow-band and broad-band stimuli, some filtering properties of central auditory neurons can be more thoroughly characterized. REPRESENTATIONS OF NATURAL AND SYNTHETIC VOCALIZATIONS IN THE PRIMARY AUDITORY CORTEX OF AN ADULT MONKEY. X. Wang, R. Beitel*, C.E. Schreiner and M.M. Merzenich. Keck Center for Integrative Neuroscience and Coleman Laboratory, UCSF, San Francisco, CA 94143-0732.

As the first step in a series of experiments designed to determine the neural representations of communication sounds and the cortical plasticity that creates, modifies and sustains them, we studied responses of neuronal populations in the primary auditory cortex (AI) of anesthetized common marmosets (*Callithrix*), a New World monkey with a complex vocal repertoire, to behaviorally important natural vocalizations and their synthetically-created variations. Experimental stimuli included three specific vocalizations frequently produced by each monkey and a conspecific companion, and synthetic variations of these three vocalizations, in which the temporal or spectral features of these natural vocalizations were systematically altered. The distributed cortical representations of natural and synthetic time- or frequency-modified stimuli were then determined, using microelectrode mapping techniques in field AI.

Natural vocalizations evoked neuronal discharges that were synchronized much more closely to stimulus events -- and to the responses of other engaged cortical neurons -- than did synthetic vocalizations. Such preference for the time signature of natural vocalizations was observed for nearly all units that responded to these complex stimuli. Correspondingly sharp selectivity to spectral features was also recorded in some but not all studied hemispheres. Recorded response selectivity was marked by sharp continuum boundaries. Equally strong preference was recorded for the vocalizations of a socially important conspecific, e. g., a companion or mate.

These results suggest that: 1) Species-specific vocalizations are represented by the activities of distributed neuronal populations in AI. 2) The selective representations of specific natural vocalizations -- e. g., the highly specific representations of the vocalizations of a particular conspecific companion -- can emerge by the operation of plastic mechanisms in adult monkeys. 3) The specificity of these representations may reveal operation of mechanisms accounting for the categorical discrimination of communication sounds. SPATIAL REPRESENTATION OF PERIODICITY PITCH IN THE HUMAN AUDITORY CORTEX

¹G. Langner*, M. Sams, P. Heil, L.K. McEvoy, R. Hari, and A. Ahonen
Low Temp. Lab., Helsinki Univ. Technol., 02150 Espoo, Finland and
²Zoological Inst., TH-Darmstadt, 6100 Darmstadt, Germany

Neurons in the inferior colliculus of cats respond selectively to the modulation period of amplitude modulated sound and the preferred modulation periods are mapped orthogonally to the tonotopic gradient (Langner and Schreiner, 1988, *J. Neurophysiol.* 60, 1799 - 1840). However, the topographic representation of periodicity in the cortex is unknown as well as the representation in the human auditory system. Therefore, we utilized magnetoencephalography to study the responses of the human cortex to periodicity pitch stimuli.

Neuromagnetic fields were recorded from 5 subjects with a 122-channel neuromagnetometer which covers the whole head. The acoustic signals were composed of harmonics and had pitches from 50 Hz to 400 Hz. To avoid spectral cues as far as possible, all signals were synthesized with flat spectral envelopes and cutoff-frequencies of 400 and 5000 Hz. The 500-ms signals were presented monaurally.

The sounds elicited a 100-ms deflection (N100m) followed by sustained field (SF) in the supratemporal auditory cortex. The source of SF moved as a function of pitch about 10 mm rostro-caudally. Since spectral cues in the sounds were minimized, this may indicate that periodicity pitch is mapped in the human auditory cortex.

581.12

TEMPORAL PITCH MIGHT BE ALREADY PLACE-CODED TOGETHER WITH PLACE PITCH IN THE PRIMARY AUDITORY CORTEX OF THE JAPANESE MONKEY. H. Riquimaroux*, T. Takahashi and T. Hashikawa. Neural Systems Lab., Frontier Research Program, Inst. of Physical and Chemical Research (RIKEN), Wako, Saitama 351-01, Japan.

The present study has examined whether the temporal pitch known as the missing fundamental is co-place-coded with the place pitch in the auditory cortex. Adult Japanese monkeys (*Macaca fuscata*) were used. All surgeries were aseptically performed with anesthesia. A chamber was placed for chronic recordings on the left temporal part of the skull. The stimuli used were white noise bursts, tone bursts and bursts of a combination of higher harmonics of a low frequency. They were presented to the animal's right ear. Unit recordings were made with glass-coated Elgiloy electrodes from the primary auditory cortex (AI). During recordings, the animal was anesthetized with a mixture of nitrous oxide and oxygen, supplemented by ketamine and xylazine injections. PST (post-stimulus-time) histograms were analyzed. The present data have confirmed previously reported tonotopically, low frequency anteriorly while high frequency posteriorly, in the Japanese macaque's auditory cortex when the recording time window was short (< 20 msec) and the stimulus was at threshold levels. In the low frequency area (< 500 Hz), the same neuron responds both to the best frequency (BF) and to combinations of successive higher harmonics which create a temporal periodicity identical to the BF, but not to these higher harmonics themselves. The findings suggest that the temporally-coded pitch in the periphery appears to be already place-coded together with the place pitch by the same neuron to produce an identical pitch at AI. Thus, this evidence agrees well with previous psychoacoustical findings.

AUDITORY CORTEX II

582.1

NEURONAL RESPONSES TO FREQUENCY MODULATED SOUNDS IN THE POSTERIOR AUDITORY AREAS OF THE CAT'S CORTEX.

B. Tian* and J.P. Rauschecker. Laboratory of Neurophysiology, NIMH, Poolesville, MD 20837, U.S.A.

Frequency modulated (FM) sounds are important components of auditory communication signals in many different species, including birds, bats, and primates. In addition, FM sweeps are the auditory equivalent to moving light stimuli in the visual domain, which are most effective in driving visual cortical neurons. Last year (Tian and Rauschecker, *Soc. Neurosci.* 1992), we reported about the responses to FM sounds of neurons in the cat's anterior auditory field (AAF). This year we have extended the same approach to the study of the posterior auditory cortical areas.

Extracellular single unit recording was performed in areas PAF, VPAF, and DPAF of cats under halothane anesthesia. Neurons were assigned to different areas on the basis of histological track reconstructions (Reale and Imig, 1980). Most neurons (n=47) were recorded from area PAF. Of all neurons in the posterior auditory areas 24% (16/71) did not respond to pure-tone stimulation. However, virtually all of these same neurons (15/16=94%) responded well to FM sweeps with rates of 4 to 600 Hz/ms. In contrast to the anterior areas, only 27% of the units (18/66) responded best to the higher FM rates (high-pass neurons). About 60% of the neurons (39/66) showed band-pass characteristics with a preference for a certain range of FM rates, 8% (5/66) were low-pass units. Cells were considered FM-direction selective, if the response in one direction was at least twice as large as the response in the reverse direction. Almost one half of the cells (32/66) in the posterior areas showed FM-direction selectivity, when this criterion was applied.

While the anterior auditory areas of the cat's cortex seem to specialize in the processing of fast-changing transient sounds, neurons in the posterior cortical areas are more often band-pass tuned to the rate of frequency modulation. This suggests an even higher degree of specialization in the process of feature extraction for the purpose of auditory communication.

582.3

PROPERTIES OF VIRTUAL-SPACE RECEPTIVE FIELDS OF NEURONS IN CAT PRIMARY AUDITORY CORTEX. J.E. Brugge*, R.A. Reale, J.E. Hind, J.C.K. Chan, A.D. Musicant and P.W.F. Poon. Dept. Neurophysiology and Waisman Center, Univ. Wisconsin, Madison WI 53706.

We synthesized a set of signals (clicks) for earphone delivery whose waveforms and amplitude spectra, measured at the eardrum, mimic those of sounds arriving from a free-field source. The complete stimulus set represents 1800 sound-source directions, which together surround the head to form a 'virtual acoustic space' for the cat. Under barbiturate anesthesia neurons in AI cortex exhibit sensitivity to the direction of a sound in virtual acoustic space. The aggregation of effective sound directions forms a virtual space receptive field (VSRF). At 20 dB above minimal threshold, VSRFs fall into one of several categories based on spatial dimension and location. Most VSRFs were confined to either the contralateral (59%) or ipsilateral (10%) hemifield. Seven percent spanned the frontal quadrants and 16% were omnidirectional. Eight percent fit into no clear category and were termed 'complex'. The results are in essential agreement with free-field studies. The size, shape, and location of VSRFs remained stable over many hours of recording. VSRFs are shaped both by spectral information extracted by the cochlea and auditory nerve and by excitatory and inhibitory interactions of activity arriving from the two ears. Response strength and timing are not uniform throughout the VSRF. These features may encode additional directional information. (Supported by NIH Grants DC00116 and DC00398)

582.2

NEURAL PROCESSING OF FREQUENCY MODULATED (FM) SWEEPS IN CAT PRIMARY AUDITORY CORTEX (AI). J.R.

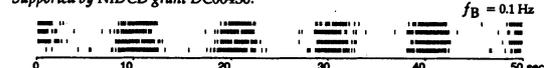

Mendelson*¹, C.E. Schreiner², K.L. Grasse³, M. Sutter⁴, ¹Div. Life Sciences, Univ. of Toronto, Scarborough, Canada; ²Dept. Otolaryng., UCSF Medical School, San Francisco, CA, ³Dept. Psych., York Univ., North York, Canada, ⁴Dept. Organismal Biology, Univ. of Chicago, Chicago IL

FM sweeps are an essential feature of naturally occurring auditory sounds such as communication signals and sound sources that move relative to an observer. We have previously shown that neurons in cat AI often manifest a preference for a particular speed (i.e., rate of change of frequency over time) and/or direction (i.e., changing from a low to a high frequency, or vice versa) of FM sweep. In addition, we have shown that these responses are systematically distributed along the dorsoventral extent of AI. To further examine FM sweep selectivity in AI, we have investigated the functional relationship between unit responses to FM sweeps, tone bursts and click stimuli along the dorsoventral axis of AI. To this end, single and multiunit activity were recorded from cat AI. Log FM sweeps (0.2-64.0 kHz) were presented in two directions at three different speeds. We found a number of response properties that were significantly correlated with preferred direction and/or speed of FM sweep. The results showed that direction selectivity was significantly correlated with integrated excitatory bandwidth (Q10 dB and Q40 dB), nonmonotonicity, and latency. Preferred speed was significantly correlated with integrated excitatory bandwidth, threshold, nonmonotonicity, click response and binaural response type. The functional relationships observed between these response parameters may reveal additional neural mechanisms underlying FM sweep selectivity in auditory cortex.

INTERAURAL DELAY TUNING IN CAT AI UNDER STATIC AND TIME-VARYING CONDITIONS. M.N. Semple* and M.W. Spitzer. Dept. of Anatomy & Neurobiology, Univ. of California, Irvine, CA 92717.

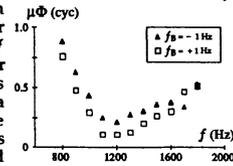

Most acoustic environments give rise to ongoing fluctuations in interaural phase disparity (IPD), a primary cue for sound localization. We studied single-unit responses to IPD in primary auditory cortex (AI) of lightly-anesthetized cats, under static and time-varying (IPD_t) conditions. Dichotically presented tones were calibrated for amplitude and phase; IPD_t was created with binaural beats or by phase-modulating the signal at one ear. Static stimuli often elicited ON- and OFF-responses with complementary IPD tuning (Fig.1). Most statically-tuned cells (and some that were uninfluenced by static IPD) were highly responsive to IPD_t. Under some conditions many neurons responded vigorously throughout a portion of each IPD cycle, maintaining much higher response rates than could be elicited statically. At low beat frequencies (fb) such responses were sustained for several seconds (Fig.2). In contrast, only 1-2 spikes were elicited in a given cycle with fb > 2 Hz, i.e., at very high rates of simulated motion (> 720°/s). With IPD sweeps restricted to depths of 45°, responses could often be elicited beyond the limits of the statically determined IPD tuning curve. These results reveal that time-varying IPD can have a profound influence on neurons in AI. Supported by NIDCD grant DC00450.

582.5

HETEROGENEOUS EFFECTS OF FREQUENCY, LEVEL AND DYNAMIC STIMULUS PARAMETERS ON INTERAURAL DELAY TUNING IN CAT AI. M.W. Spitzer* and M.N. Semple. Dept. of Anatomy & Neurobiology, University of California, Irvine, CA 92717.

Interaural phase disparity (IPD) is but one of many stimulus attributes that affect the discharge of neurons in low-frequency primary auditory cortex (AI). To assess IPD tuning of individual neurons across a broad range of stimulus conditions, we presented static and time-varying IPD stimuli, dichotically, to lightly-anesthetized cats. We systematically varied tone frequency (f), sound pressure level (SPL), modulation rate (or beat frequency, f_B) and direction of simulated motion. For some units sensitivity to IPD was evident throughout the entire response area, whereas for others it was restricted to a limited portion of the response area. In a few cases the relation between mean phase ($\mu\Phi$) and f was a linear function whose slope could be used to infer a characteristic delay. More typically $\mu\Phi$ was a complex function of f , sometimes consisting of two linear sub-components (see Fig.). The $\mu\Phi$ vs f curve was shifted as a function of SPL for some neurons, but more often it was unaffected. We commonly observed a systematic vertical shift of the $\mu\Phi$ vs f curve when the direction of modulation was reversed. Some neurons only responded to modulation in one direction, or showed a rate-dependent directional preference. The heterogeneous effects of f , SPL, modulation direction and rate on delay-tuning suggest a subdivision of IPD-sensitive cortical neurons into multiple response classes. Supported by NIDCD grant DC 00450.

582.7

MULTIPLE REPRESENTATIONS OF VELOCITY INFORMATION IN THE AUDITORY CORTEX OF THE MUSTACHED BAT. H. Teng* and N. Suga. Department of Biology, Washington University, St. Louis, MO 63130.

Constant-frequency components (CF_{1-4}) of biosonar pulses emitted by the mustached bat, *Pteronotus parnellii*, carry information of relative target velocity. In the auditory cortex of this species, the CF/CF area contains neurons specialized for the extraction of velocity information from certain combinations of CF components in pulse-echo pairs. Recent studies with anatomical tracers by J. Olsen and D. Fitzpatrick show that the CF/CF area projects to a small area, named the DIF area, which is located at the posterior bank of the dorsal portion of the fossa for the sylvian artery. The aim of this study was to examine the response properties of DIF neurons, and to compare these with the properties of CF/CF neurons.

Single-unit responses were recorded from the DIF and CF/CF areas with tungsten-wire electrodes. DIF and CF/CF neurons were sharply tuned to a particular combination of the pulse CF_1 and the echo CF_n ($n=2$ or 3) in frequency. They were suited for extracting velocity information. They were not suited for processing range information since they were broadly tuned to time intervals between the pulse CF_1 and the echo CF_n . There was no significant difference in sharpness of frequency or delay tuning between them. However, DIF neurons were different from CF/CF neurons in the following three aspects. (1) The best velocity was about 4 m/s faster for DIF neurons than for CF/CF neurons. (2) Most DIF neurons showed stimulus-locked responses only up to 20 paired stimuli/s, while most CF/CF neurons showed such responses up to 40 stimuli/s. (3) The best CF_1 amplitude and threshold for facilitation were about 20 dB higher for DIF neurons than for CF/CF neurons. Therefore, DIF neurons are suited for processing high relative velocities when the bat is emitting loud pulses at low repetition rates, whereas CF/CF neurons are suited for processing velocity information in the late search and approach phases of insect pursuits. Tonotopic Organization Of Temporal Response Patterns Reflecting The Voice Onset Time (VOT) Phonetic Parameter In Primary Auditory Cortex (A1). M. Steinschneider*, C.E. Schroeder, J.C. Arezzo and H.G. Vaughan, Jr., Albert Einstein College of Medicine, Bronx, NY, 10461.

Delineating the spatio-temporal distribution of cortical speech-evoked activity encourages a neurophysiologic framework for understanding speech perception. We investigated the relationship between temporal response patterns encoding VOT with the tonotopic organization of A1 by examining the current source density and multiunit activity evoked by the syllables /da/ and /ta/ and by tone bursts in 2 awake monkeys.

Two temporal response patterns encode VOT. In the first, responses are time-locked to stimulus and voice onset. Responses to the latter speech segment are usually present for VOTs of 40 and 60 msec (/ta/) and markedly diminished for a VOT of 20 msec (/da/). These responses correlate with the perceptual boundary and occur in low best-frequency locations. In contrast, the second pattern contains a component time-locked to stimulus onset followed by activity phase-locked to the syllable periodicity. This pattern does not correlate with the perceptual boundary and occurs at higher best-frequency sites.

We conclude that temporal patterns encoding VOT are segregated on the basis of the cortical tonotopic organization. The first pattern reflecting the perceptual boundary mirrors similar responses in the auditory nerve (Sinex et al., 1991), suggesting that the response is generated in the auditory periphery and transmitted to the cortex. This neural pattern helps reconcile hypotheses emphasizing temporal versus spectral aspects of VOT encoding. (supported by DC00657, MH06723 and the J.S. McDonnell Foundation)

COMPARISON OF AZIMUTH TUNING OF DIFFERENT CLASSES OF SINGLE UNITS DISTINGUISHED BY UNILATERAL EAR OCCLUSION IN PRIMARY AUDITORY CORTEX (AI) OF BARBITURATE ANESTHETIZED CATS. F.R. Samson, P. Barone, J.C. Clarey, and T.J. Imig*. Dept. of Physiol., Kansas University Med. Ctr., Kansas City, KS 66160-7401.

Azimuth-sensitive neurons ($n=131$, BFs 5 - 24kHz) were identified by their responses to noise bursts that varied in azimuth and over a broad range of sound pressure levels. Two main classes of neurons were distinguished using unilateral ear occlusion (plugging) that simulates monaural stimulation. Monaural directional (MD) cells (27/131) remained azimuth sensitive and most exhibited relatively minor changes in azimuth tuning with unilateral ear plugging, whereas binaural directional (BD) cells (53/131) became insensitive to azimuth, unresponsive, or exhibited substantial changes in azimuth tuning. Fifty-one cells were excluded from the analysis as their responses were unreliable. Ear plugging revealed that BD cells may exhibit excitatory/inhibitory (EI cells, 23/53), facilitatory (predominantly binaural or PB cells, 13/53), or a mixture of facilitatory and inhibitory (FI cells, 17/53) binaural interactions. MD, EI and FI cells exhibited lateral azimuth preferences. A large majority of MD and EI cells exhibited contralateral preferences, whereas FI cells were evenly split between contralateral and ipsilateral preferences. EI and FI cells were significantly more broadly tuned in azimuth than MD cells. PB cells responded preferentially to azimuths near the midline. Supported by NIDCD grant # DC00173.

582.8

FACILITATION OF CORTICAL DELAY-TUNED NEURONS IN THE FM-FM AREA IS NOT MEDIATED BY NMDA WITHIN THE CORTEX. A. Tanahashi, N. Suga*, Department of Biology, Washington University, St. Louis, MO 63130

The FM-FM area in the auditory cortex of the mustached bat, *Pteronotus parnellii*, receives a projection from the dorsal division of the medial geniculate body (MGBd) and is specialized for the representation of target distances between 7 and 310 cm. FM-FM neurons show a facilitative response to a combination of FM components in pulse-echo pairs. Each FM-FM neuron is tuned to a particular echo delay and echo amplitude. Neurons in the MGBd also show facilitative response. Their facilitative response greatly depends upon NMDA (N-methyl-D-aspartate) (Butman, 1992). The aim of the present study was to examine whether the responses of cortical FM-FM neurons simply reflect the responses of thalamic delay-tuned neurons or are enhanced by an additional NMDA mediated facilitation in the cortex.

In four unanesthetized mustached bats, single unit activity was recorded from 20 FM-FM neurons with multi-barreled carbon filament microelectrodes. APV (D-2-amino-5-phosphonovalerate), an antagonist of the NMDA receptor, was iontophoretically applied at the recording site. APV were applied with an electric current of -50 nA for 10 min and neuron activity was recorded before, during and after the application. This amount of APV was sufficient to suppress completely a burst of discharges evoked by an NMDA locally applied through the multi-barreled electrode. However it did not change delay-tuned facilitation of any of the 20 neurons studied. Our results indicate that NMDA is not related to facilitative responses observed in the FM-FM area. (Work supported by a research grant NIDCD DC00175)

582.10

CORTICAL NEURAL NETWORKS IN TONOTOPICAL ORGANIZATION OF GUINEA PIG AUDITORY CORTEX REVEALED BY OPTICAL IMAGING AND ANALYSIS. K. Fukunishi*, N. Murai, H. Uno, Advanced Research Laboratory, Hitachi, Ltd., Hatoyama, Saitama, 350-03 JAPAN.

Previously, the spatio-temporal neural activity evoked by clicks and pure tones in the guinea pig auditory cortex were observed using a 128-channel optical recording system with voltage-sensitive dye by the authors. The functional module were found in the dynamical neural traversing in the cortical field to click responses. In addition, the spatial relations between the responses to clicks and tones were discussed.

Here, the neural network structures of the tonotopical organization in the guinea pig primary auditory cortex are studied by observing evoked responses to the tone bursts. The temporal neural activities in the tonotopical patterns are analyzed by time series analysis using MAR (multivariable autoregressive) model. The results reveals the existence of synchronized oscillatory neural activities of about 30 Hz in the response regions to the tone bursts. The oscillatory sources can be obtained by decomposing the power spectral density to its contribution at each region by this method. The distribution pattern of the dominant sources (the cortical region) of the neural oscillation are identified. The existence of the mutual neural connections in the cortical field are found along the tonotopical band from the dorsal to the ventral. On the other hand, the oscillation may be propagated from the source region to the cortical region in the caudal or the rostral direction with one way neural connections. Thus neural networks of the tonotopical organization in the cortex can be estimated by spatio-temporal neural observation and analysis.

582.11

TONOTOPIC ORGANIZATION OF GUINEA PIG AUDITORY CORTEX DEMONSTRATED BY INTRINSIC SIGNAL OPTICAL IMAGING THROUGH THE SKULL. J. S. Bakin*, M. C. Kwon, S. A. Masino, N. M. Weinberger, and R. D. Frostig, Center for the Neurobiology of Learning and Memory, and Department of Psychobiology, University of California, Irvine, CA 92717

Optical imaging of intrinsic signals provides an activity-dependant high spatial resolution image of the functioning cortex. Here we report the first successful intrinsic signal optical imaging of primary auditory cortex (AC). Moreover, imaging was obtained through a thinned but intact skull.

The AC of sodium pentobarbital anesthetized adult male Hartley guinea pigs was imaged during random presentation of binaural tone bursts of several frequencies at various intensities. Immediately following several replications of the optical findings, the AC was mapped electrophysiologically (tungsten microelectrode, $\approx 1M\Omega$). For each cortical site 1) neural responses to the identical auditory stimuli used during imaging were determined, and 2) receptive fields (RF) were characterized by presenting an isointensity series of tone bursts (100ms on, 900ms off, 10ms rise/fall time) using a frequency range appropriate for the given units (selected from a range of 0.5 to 40.0kHz) and repeated across a large intensity range (0 to 90 dB).

Optical imaging revealed a tonotopic frequency organization. This organization was confirmed by determination of RFs; i.e., at a given site, optical and electrophysiological responses were evoked by the same frequency. These results provide the basis for application of optical imaging to the functioning of auditory cortex, including, but not limited to, its modification by learning and other related processes.

TWO POPULATIONS OF COMMISSURAL PROJECTIONS CONNECTING LIKE REGIONS OF THE INFERIOR COLLICULUS IMMUNOSTAIN FOR DIFFERENT AMINO ACID TRANSMITTERS. D.M. Caspary* and B.H. Helffer, Depts. of Pharmacology and Surgery, SIU School of Medicine, Springfield, IL 62794-9230

Tract tracing combined with immunocytochemistry was performed to identify neurotransmitters that may be used by the commissural projections between the inferior colliculi (IC). Three chinchillas received injections of the anterograde tracer biocytin (BCT) in the central nucleus of the left IC (CIC). After perfusion, brainstem sections through the IC were collected and the tracer was visualized using a metal-intensified, avidin-biotin-peroxidase method prior to osmication and embedment in plastic resin. Serial thin sections were cut from portions of the right CIC and external nucleus of the IC (EIC) containing BCT-labeled boutons, and collected on 400-mesh grids for electron microscopy. Alternate sections were immunolabeled for the inhibitory amino acid γ -aminobutyric acid (GABA) and the excitatory amino acid glutamate using post-embedding immunogold methods.

The BCT injections resulted in the bilaterally symmetrical labeling of boutons in the IC. This labeling was confined to distinct laminae in the CIC and EIC. Two populations of BCT-labeled synaptic terminals were observed contralaterally in both the CIC and EIC. One population contained pleomorphic vesicles, formed symmetric synapses with their targets, and exhibited an intense immunoreactivity for GABA. The other formed asymmetric synapses, possessed round vesicles, and contained heavy immunogold labeling for glutamate. These results suggest that specific areas in both the CIC and EIC receive both inhibitory (GABAergic) and excitatory (glutamatergic) input from corresponding regions in the contralateral IC.

AGE-RELATED CHANGES IN THE SYNAPTIC ORGANIZATION OF THE INFERIOR COLLICULUS OF THE FISCHER 344 RAT. B.H. Helffer^{1,2}, T.J. Sommer¹, C. Jeffery³, L.F. Hughes^{1,4}, and D.M. Caspary^{1,2}; Depts. of ¹Surgery, ²Pharmacology, ³Microbiology and Immunology, and ⁴Psychiatry, SIU School of Medicine, Springfield, IL 62794-9230

The numbers and distribution of both GABA- and non-GABA-immunoreactive synaptic terminals was assessed in the central nucleus of the inferior colliculus (CIC) of five 3-month-old (Y) and five 28-month-old (O) male Fischer 344 (F-344) rats. Thin sections were obtained from the right CIC from each animal and immunolabeled for GABA. Montages were constructed from electron micrographs taken of portions of the CIC from each animal contained in three randomly selected grid squares. After adjusting the field to more accurately reflect neuropil, each terminal was measured and categorized based on immunoreactivity to GABA and type of postsynaptic target.

There were significant age-related decreases in the number and density of synaptic terminals in the CIC (Y: \bar{x} = 246.33, O: 174.33, $P < .01$; Y: \bar{x} density = 13.57/100 μm^2 , O: 10.22/100 μm^2 , $P < .05$). However, the sizes and ratio of GABA+ and GABA- terminals did not differ as a function of age group. There was a significant age-related decrease in the density of both terminal types on small (<0.5 μm) and medium (0.5-1.5 μm)-caliber dendrites (Y: \bar{x} small = 0.65/100 μm^2 , O: 0.50/100 μm^2 , $P < .01$; Y: \bar{x} medium = 0.53/100 μm^2 , O: 0.36/100 μm^2 , $P < .002$). A loss of both GABA+ and GABA- neurons occurred in the aged group (Y: \bar{x} = 123.16, O: 87.17, $P < .02$), but their numerical declines were at equivalent rates. These results suggest that there is an age-related loss of both GABAergic and nonGABAergic synaptic terminals in the CIC of F-344 rats, and that this loss may be related to both a reduction in the population of target neurons and changes in the dendritic organization of surviving target neurons.

EFFECTS OF AGING ON GABA_A AND GLYCINE RECEPTOR BINDING IN THE INFERIOR COLLICULUS AND COCHLEAR NUCLEUS OF THE FISCHER 344 RAT: A QUANTITATIVE AUTORADIOGRAPHIC STUDY. J.C. Milbrandt¹, R.L. Albin², and D.M. Caspary¹, ¹Dept. of Pharmacology, SIU School of Medicine, Springfield, IL 62702. ²Dept. of Neurology, Univ. of Michigan, Ann Arbor, MI 48109.

Previous studies have demonstrated an age-related loss of both GABA and glycine in the brainstem of the Fischer 344 rat. To assess possible postsynaptic deficits, we used quantitative receptor autoradiography to determine changes in the binding profiles of the GABA_A receptor and the strychnine-sensitive glycine (GLY) receptor. Receptors were evaluated in three age groups of Fischer 344 rats: 3, 20, and 26 months. GABA_A receptor binding was localized and quantified in three primary subdivisions of the inferior colliculus (IC): dorsal cortex (DCIC), external or lateral cortex (ECIC), and central nucleus (CIC). GLY receptor binding was examined in two subdivisions of the cochlear nucleus (CN) that receive major glycinergic inputs: dorsal cochlear nucleus (DCN) and anteroventral cochlear nucleus (AVCN).

GABA_A receptor binding was assessed in the IC using ³H-muscimol, ³H-flunitrazepam, and ³H-TBOB. GABA_A receptor binding for all three ligands was significantly higher in the DCIC compared to the CIC and ECIC. In each subdivision of the IC, no significant age-related changes in receptor binding for the GABA_A receptor ligands were observed.

The glycine receptor was localized in the CN using ³H-strychnine. Binding was significantly higher in DCN compared to AVCN. An age-related decrease in ³H-strychnine binding was observed in AVCN and DCN for the 20 month and 26 month groups compared to the 3 month group. This age-related loss of GLY receptor binding in the CN, implying a loss of inhibition, could result in a decreased efficacy of complex signal processing.

OUTPUTS OF A FUNCTIONALLY-CHARACTERIZED REGION OF THE INFERIOR COLLICULUS OF THE CBA MOUSE MODEL OF PRESBYCUSIS. M.A. Armour, R.D. Frisina, J.P. Walton, W.E. O'Neill, and D.G. Flood, Otolaryngology Div., Surgery, Physiology & Neurology Depts., U. Rochester Sch. of Medicine & Dentistry, Rochester, NY 14642.

The CBA mouse has proven to be a useful animal model for behavioral and neurophysiological studies of presbycusis - hearing loss with age. However, there is little known about the anatomy of the central auditory system of the CBA. Therefore, initial investigations of the normal anatomy of young adults will serve as a basis for discovering the neuroanatomical changes underlying the behaviorally and physiologically measured age-related hearing loss of this strain. To further these goals, single unit responses to pure tones and temporal features of sounds were mapped in the central nucleus of the inferior colliculus (ICC) of 9 awake, tranquilized CBA mice ranging in age from 1.5 to 16 months. An anterograde and retrograde tracer (HRP, Sigma Type XII) was iontophored into the 16-20 kHz isofrequency lamina of the ICC, at the conclusion of a single-unit mapping experiment. Following a 24 hr survival time, the mice were anesthetized, intracardially perfused with heparinized saline, and fixed with glutaraldehyde/paraformaldehyde. These sets of coronal sections were cut at 60 μm . One set was reacted with DAB and counterstained with cresyl violet, the other two were reacted with TMB and one counterstained with safranin-O. Major ipsilateral outputs (labeled fibers and boutons) were observed in dorsal cortex of the IC (DC), brachium of IC (BIC), nucleus of BIC, all 3 major divisions of the medial geniculate body of the thalamus (MGB), and dorsal and ventral divisions of the ventral nucleus of the lateral lemniscus. Contralateral outputs were observed in a laminar pattern in the ICC, in patchy clusters of the DC, BIC, and all 3 divisions of MGB but to a lesser extent than ipsilaterally and not in all animals. A bilateral projection to the superior colliculus and periaqueductal gray was seen in some mice. We are currently contrasting these findings with those in other species and older animals.

Dextran-labeled Axons from the Cochlear Nucleus and their Contacts Visualized on Lucifer Yellow-Filled Projection Neurons in the Inferior Colliculus. D. L. Oliver, G. E. Beckius, and E.-M. Ostapoff, Dept. of Anatomy, University of Connecticut Health Center, Farmington, CT 06030-3405.

We have developed a method that combines tracing neural circuits and studying the cellular innervation patterns of identified neurons. Neurons in the inferior colliculus take up fluorescently-labeled latex microspheres injected into the medial geniculate body, and axons contacting those neurons are labeled by injections of rhodamine- and biotin-labeled dextran into the cochlear nucleus. Both the pre- and postsynaptic components are visualized with fluorescent optics in a fixed slice, where the dendritic morphology is revealed by intracellular injection of biotinylated Lucifer Yellow compounds. ABC histochemistry permanently preserves both components of this circuit.

This paper reports on 39 neurons from the inferior colliculus whose axons projected to the medial geniculate body. Twenty of these neurons received axonal contacts directly from the cochlear nucleus. Disc-shaped and stellate cells were identified, based on their dendritic morphology and the orientation of the dendrites relative to the dextran-labeled afferents. These data show that two cell types receive contacts from the cochlear nucleus and are part of the CN-IC-MGB circuit. Funded by NIH grants R01-DC00189, R01-DC00127, and P01-DC01366.

GABAergic AXOSOMATIC ENDINGS PREFERENTIALLY TARGET NON-GABAergic NEURONS IN THE CAT MEDIAL GENICULATE BODY. J.A. Winer, S.K. Khurana, J.J. Prieto, and D.T. Larue, Department of Molecular and Cell Biology, University of California, Berkeley, California 94720-2097.

The density of axosomatic GABAergic endings on GABA-positive and -negative neurons was studied with postembedding immunocytochemistry. The number and spatial arrangement of such endings has important implications for understanding how GABAergic cells—either intrinsic or extrinsic—exert inhibitory and disinhibitory effects in the auditory thalamus.

We counted GABA-immunostained axonal endings (puncta) contacting ventral division perikarya in immunostained, deplasticized 1-1.5 μ m-thick sections. The ventral division was identified in adjoining semi-thin sections stained with toluidine blue. One hundred GABA-positive and 100 immunonegative, mid-nucleolar neurons were drawn under oil immersion, and the GABAergic endings contacting their perikaryal membranes were counted.

Immunonegative neurons received six times more somatic endings/ μ m than GABAergic neurons. The same pattern was evident in thicker sections immunostained for GABA or GAD. This suggests a discrete convergence of axosomatic inhibition onto presumptive thalamocortical relay neurons. This pattern aligns them with cortical pyramidal neurons, which likewise receive many GABAergic axosomatic endings, and it suggests a common principle of inhibitory input to auditory forebrain projection cells. In contrast, many hindbrain GABAergic or glycinergic auditory neurons also receive GABAergic and/or glycinergic axosomatic endings, suggesting that disinhibition is more prevalent in the brain stem. Since some of these hindbrain cells are projection neurons, perhaps all such cells receive a more robust axosomatic inhibition than do local circuit neurons.

A STEREOLOGICAL ANALYSIS OF PARVALBUMIN-CONTAINING NEURONS IN AUDITORY NEOCORTEX. C.B. Smelser and N.T. McMullen, Department of Anatomy, University of Arizona College of Medicine, Tucson, AZ 85724.

Parvalbumin (PV) is a calcium-binding protein present in GABA-ergic cells in the cerebral cortex and in thalamic relay neurons. Within the auditory forebrain, parvalbumin immunocytochemistry (PVI) labels both the cells and neuropil of the ventral MGB and delineates the primary auditory cortex (AI). In the present study, the terminal-like labeling of PVI puncta within laminae III/IV was used to define the rostral and caudal limits of the auditory cortex. PVI (SWANT #235, 1:10K) was performed on 40 μ m thick frozen sections obtained from young rabbits. Serial coronal sections through the entire temporal pole and medial geniculate body were processed. We used a modification of the Cavalieri method, the fractionator and disector to obtain an unbiased estimate of neuron number within AI as well as the percent of neurons which contained PV. To estimate neuron density, a grid composed of 0.01mm² squares was superimposed over the ten selected sections from each animal with the aid of an image combining computer microscope. A single square within each layer in all sections was randomly selected for neuron counting at 400x. The mean volume of the auditory cortex was 26.9 mm³. The total number of neurons in rabbit AI was 1.48 x 10⁶ with a mean neuronal density of 53.9 x 10³/mm³. The mean neuronal density of PV neurons was 4960/mm³ indicating that approximately 9.2% neurons in AI contain PV. The percentage of PVI nonpyramidal neurons within each layer was as follows: lamina I: 3.9%, lamina II: 2.6%, lamina III: 5.5%, lamina IV: 10.2%, lamina V: 6.6%, lamina VIa: 6.6%, lamina 6b: 5%. Novel findings were the presence of PVI neurons within lamina I and lightly-labeled PVI pyramidal neurons in lamina VIa. (Supported by the NIH, ADCRC, DRF and Whitehall Foundation)

INPUTS TO COMBINATION-SENSITIVE NEURONS IN THE MEDIAL GENICULATE BODY OF THE MUSTACHED BAT. Jeffrey J. Wenstrup* and Carol D. Gross, Dept. of Neurobiology, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272.

This study used retrograde tracers (WGA-HRP, Fluoro-Gold, cholera toxin B subunit, and dextran-conjugated rhodamine) to examine sources of input to regions in the medial geniculate body (MGB) showing combination-sensitive responses to the bat's biosonar signals. Tracer-filled, micropipette electrodes recorded combination-sensitive, single and multiple unit responses in the MGB, then placed a single iontophoretic tracer deposit. Areas showing each major type of combination-sensitive response received tracer deposits, including CF/CF areas and FM-FM areas with both short and long best delays.

Three major inputs were found: the inferior colliculus (IC), the auditory cortex, and the thalamic reticular nucleus. In the midbrain, labeled cells were common in the central and external nuclei of IC and in the pericollular tegmentum. In the central nucleus (ICC), most labeled cells were in regions representing higher frequencies, i.e., the higher harmonic element to which combination-sensitive neurons respond. Very few neurons were labeled in regions tuned to frequencies between 25-32 kHz, whether in CF/CF or FM-FM experiments. Auditory cortical labeling in layer VI was centered in the more dorsal regions where combination-sensitive neurons have been recorded. A few experiments showed a broader distribution of cortical label, but it is uncertain whether this included 25-32 kHz regions of tonotopically organized auditory cortex. Retrogradely labeled cells in the thalamic reticular nucleus were limited to its dorsal and caudal parts, just ventral to the MGB. Within MGB, retrogradely labeled cells were rarely found beyond the deposit site.

These results support our previous work suggesting that ICC does not send direct, low-frequency input to combination-sensitive regions of the MGB; nor does this input appear to originate from other MGB regions. Strong candidates include the external nucleus of IC and pericollular tegmentum, the thalamic reticular nucleus, and, possibly, auditory cortex. (Supported by USPHS grant DC00937.)

EVIDENCE FOR DESCENDING PROJECTIONS FROM THE MEDIAL GENICULATE BODY TO THE INFERIOR COLLICULUS IN THE CAT. S. Paydar, D.T. Larue*, and J.A. Winer, Department of Molecular and Cell Biology, University of California, Berkeley, California 94720-2097.

For a study of the projections of the inferior colliculus to the medial geniculate body, we injected HRP-WGA or HRP into various subdivisions of the inferior colliculus and perfused the animals 18 hours later. Besides the anterograde granular transport in various medial geniculate nuclei and the orderly arrangement of brain stem and commissural input to the inferior colliculus, we found retrogradely labeled neurons in the medial division of the medial geniculate body, in the nucleus of the brachium of the inferior colliculus, and in peripeduncular and adjoining posterior intralaminar regions. Many were elongated multipolar neurons with long, sparsely branched and widely ramifying dendrites. They resembled cells associated with the posterior intralaminar system or the midbrain tegmentum more closely than they did thalamocortical relay neurons or Golgi type II cells.

The comparatively short survivals, the modest size of the injections, and the granular nature of the intracellular reaction product each suggest that transneuronal transport or direct damage to the medial geniculate body cannot explain these results. A similar pattern was observed in the rat, but not in the mustached bat.

No conceptual framework is available yet to place this finding in a functional context. As a working hypothesis, we suggest that geniculocollicular projections could provide rapid feedback to lemniscal and extralemniscal inferior colliculus subdivisions. Such input would be parallel to, and independent of, the massive corticocollicular projections. It could rapidly convey important limbic and integrative influences to the midbrain for postural adjustments or motor responses to sound.

We are grateful to J.C. Adams for suggesting the possibility of this pathway. We thank Dr. K.D. Games for access to her experiments. Supported by United States Public Health Service grant R01 NS16832-13.

583.10

INTRINSIC AND EXTRINSIC PROJECTIONS OF AAF NEURONS WITHIN THE IPSILATERAL AUDITORY CORTEX IN CAT. H. Ojima^{1,2*}, G. Hollrigel² and L.M. Kitzes² Neural Systems Laboratory, FRP, Institute of Physical and Chemical Research (RIKEN), Wako, Saitama, Japan¹; Dept. of Anatomy and Neurobiology, University of California Irvine, Irvine CA 92717²

Projections from the anterior auditory field (AAF) to other auditory cortical areas and intrinsic projections within AAF were studied and related to the tonotopic organization of target zones. After injections of PHA-L or neurobiotin into both deep and superficial layers of single AAF loci, the distributions of anterogradely labeled fibers and terminals were reconstructed in the tangential plane. The projections and tonotopic maps were super-imposed using lesions made during the mapping procedure.

There were mainly two streams of labeled fibers. One was oriented roughly anteroposteriorly and provided terminal fibers with boutons to the dorsal posterior area (DP) and dorsal parts of primary auditory cortex (AI). The other was oriented obliquely in a posteroventral direction and provided terminals to the secondary auditory field (AII) and ventral parts of AI. In each field, labeled terminal fibers formed several discrete patches along these streams. The density of fibers and terminals was much greater in one or two patches. In AI, the frequency representation of these high density patches corresponded to that at the injection site.

Intrinsic projections within AAF from the injection site are oriented between the dorsal tip of the anterior ectosylvian sulcus and the suprasylvian sulcus, roughly parallel to the isofrequency contours in the field.

MULTIPLE CORTICAL AUDITORY FIELDS IN THE FERRET DEFINED BY THEIR ARCHITECTONICS AND THALAMO-CORTICAL CONNECTIONS. Angelucci, A., Clascá, F., and Sur, M.*, Dept. of Brain & Cognitive Sciences, MIT, Cambridge, MA 02139.

In striking contrast with the auditory cortex of the cat, a single auditory field (AI) has been mapped electrophysiologically in the ectosylvian gyrus of the ferret (*Mustela putorius*). We have sought to define the extent and subdivisions of the cortical region receiving projections from the medial geniculate body (MGB), using multiple neuroanatomical techniques. Adult ferrets received small injections of retrograde tracers (Fluorogold, Fast Blue, Fluororuby and WGA-HRP) in the cortex or iontophoretic deposits of PHA-L in the MGB. Series of brain sections adjacent to those used to study the labeling were stained for Nissl substance, acetylcholinesterase, cytochrome-oxidase or myelin, in order to define cortical fields and thalamic nuclei.

We have found that in addition to AI, at least one other field is present in the posterior ectosylvian gyrus. Both fields receive heavy projections from the ventral and medial divisions of MGB. PHA-L injections show that axons arising from small cell groups in these divisions reach widespread zones of the cortex. The cortex of the ventral bank of the suprasylvian sulcus is also auditory, as revealed by its dense connections with the dorsal and medial divisions of MGB and the lateral division of the posterior nuclear complex. These data indicate the presence of multiple auditory cortical fields in ferrets as well, and represent a first step in clarifying the location of these fields and their thalamocortical associations.

583.13

CONNECTIONS OF FIVE AUDITORY CORTICAL FIELDS WITH THE STRIATUM AND THE AMYGDALA IN THE CAT. J.J. PRIETO* AND J.A. WINER, Department of Histology, University of Alicante, 03080-Alicante, Spain (J.J.P.), and Department of Molecular and Cell Biology, University of California at Berkeley, Berkeley, CA 94720-2097, USA (J.A.W.).

Connectional studies of the cat auditory cortex and basal forebrain in the cat are fragmentary and incomplete. We studied the afferent and efferent connections of cortical areas with the striatum and the amygdaloid nuclei. WGA-HRP was injected in AI, AAF, P, AII and temporal (Te) cortex, and the sections were processed with tetramethylbenzidine.

All fields but Te project to the caudate and putamen. In addition, AI and AII also send axons to the pallidus and the claustrum. Injections in AI, AAF, AII and P labeled many cells retrogradely in the putamen, pallidus and claustrum. On the other hand, Te cortex received only a tiny projection from the putamen and the globus pallidus. The caudate nucleus did not project to any area studied.

The basomedial amygdaloid nucleus projected to all areas but Te. AII and P also had reciprocal connections with the lateral amygdaloid nucleus. Temporal cortex, however, had strong reciprocal connections with the lateral, basolateral and central amygdaloid nuclei.

These findings suggest that there is both parallel processing of auditory information by some basal forebrain nuclei, and a segregation of input in other centers. Such projection patterns imply that, even among the tonotopically organized cortical fields, there are discrete patterns of corticoamygdaloid and corticostriatal connectivity. This supports the idea that these fields participate in different facets of auditory and limbic function. Supported by United States Public Health Service Grant RO1 NS16832-13, and DGICYT grants PB 91.0752 and PB 91.0754 from the Spanish Government.

583.15

ANATOMICAL ORGANIZATION OF AUDITORY EVOKED POTENTIALS IN THE RAT: AN HRP STUDY. B. Brett, S. Di, J. Rudy*, D. Barth, Dept. of Psychology, University of Colorado, Boulder, 80309.

The neurogenesis of cortical components of the auditory evoked potential (AEP) in the rat is not well established. Recent research in our lab using high resolution mapping of epicortical potentials and numerical analysis has suggested that these components may correspond to the activation of parallel fiber pathways which originate in subdivisions of the medial geniculate nucleus of the thalamus.

The object of the present study was to obtain anatomical validation of the neurogenesis of these components. Click evoked AEP's were mapped with an array of 64 platinum electrodes on the surface of the cortex. The electrodes were configured in a 3.5 x 3.5² mm matrix, with a distance of .5 mm between each electrode. The array was positioned to cover both primary (area 41) and secondary (area 36) regions of auditory cortex and provided a high resolution representation of the AEP complex. Temporal components were isolated using isopotential maps which depict the areas of maximal activity over the cortex during amplitude peaks. Horseradish peroxidase (Sigma VI, 10%) was injected into the location of maximal activation for each component of the AEP. Survival time was approximately 48 hours, then the subjects were perfused. The brains were removed and the medial geniculate nucleus (MGN) was sliced on a cryostat. The slices were then reacted with tetramethylbenzidine (TMB) and counterstained with neutral red.

Our results indicate that the shortest latency biphasic sharp waves localized over area 41 are generated by a fiber pathway which originates in the ventral division of the MGN. The longer latency monophasic sharp waves localized over area 36 are generated by a fiber pathway which originates in the dorsal MGN. The biphasic slow waves distributed over most of auditory cortex are generated by a third parallel fiber pathway which originates in the medial MGN.

583.12

DIRECT PROJECTION FROM THE PRIMARY AUDITORY CORTEX TO THE NUCLEUS SAGULUM, SUPERIOR OLIVARY COMPLEX AND COCHLEAR NUCLEUS IN THE ALBINO RAT.

M. Feliciano*, E. Saldaña and E. Mugnaini, Lab. of Neuromorphology, The University of Connecticut, Storrs, CT 06269-4154.

The auditory cortex (AC) is the startpoint of descending auditory pathways. It has generally been accepted that the descending projections of the AC do not extend beyond the inferior colliculus (IC) and, therefore, the cortical influence on lower auditory nuclei is necessarily conveyed by the IC. In the last 60 years, several isolated accounts reported that the ablation of the AC resulted in degenerating fibers in the lateral lemniscus (LL), superior olivary complex (SOC) and cochlear nuclei (CoN), thus challenging the previous tenet (e.g. Metter, 1935, J. Comp. Neurol. 63:25; Zimmerman et al. 1964, J. Comp. Neurol. 123:301). In an attempt to confirm the existence of direct cortical projections to subcollicular auditory nuclei, and to determine the trajectories, topography, morphology and possible targets of these projections, the anterograde tracer *Phaseolus vulgaris*-leucoagglutinin (PHA-L) and biotinylated dextran (BDA) were iontophoretically injected at different locations within the primary auditory cortex (Te1) of adult albino rats. Terminal anterograde labeling was found: 1) in the ipsilateral nucleus sagulum, horizontal cell group (which separates dorsal and ventral nuclei of the LL), and rostral and medial paralemniscal regions; 2) in different structures of the bilateral SOC, notably in the ventral nucleus of the trapezoid body and the lateral superior olive; and 3) bilaterally, in the granule cell domains surrounding the ventral CoN, and in the dorsal CoN. These findings demonstrate that indeed a direct projection from Te1 to subcollicular auditory nuclei exist and suggest that the neocortex may have a direct influence in the processing of sound at the initial stages. METABOLIC MAPPING OF THE AUDITORY SYSTEM OF MICE USING QUANTITATIVE CYTOCHROME OXIDASE HISTOCHEMISTRY.

A. Cada* and F. Gonzalez-Lima, Dept. of Psych and Inst. for Neurosci, Univ of Texas, Austin TX 78712 USA

We measured the metabolic capacity of the primary auditory system with a quantitative histochemical method based on an image analysis system calibrated with internal standards of known cytochrome oxidase activity determined spectrophotometrically (Gonzalez-Lima & Garrosa, Neurosci Lett 122:251, 1991). Staining quality among nuclei was also assessed using the Wong-Riley's qualitative scale (Trends Neurosci 12: 94, 1989). Generally, the most peripheral nuclei had the highest activity and the greatest percentage of cell body staining. Higher nuclei demonstrated less activity and most of their activity resided in the neuropil. The cochlear nuclei and the superior olivary/ trapezoid body complex had the highest activity collectively, while the trapezoid body nucleus was the single structure with the most activity. This nucleus exhibited prominently active cell bodies with little evidence of dendritic or axon terminal staining. The anterior portion of the ventral cochlear nucleus and the ventral half of the ventral lateral lemniscus had lower activities and consisted of medium neuropil with less cell body staining. The central and external divisions of the inferior colliculus displayed an active dorsal-to-ventral band in each subdivision. These activity patterns may correlate with the frequency range of vocalizations for these animals. The dorsal inferior colliculus, medial geniculate body, and auditory cortex exhibited the least activity overall. These areas contained light to medium neuropil staining with less than 1% of active cell bodies. The possible functional significance of the variations in cytochrome oxidase activity among auditory structures is presented. (Supported by RO1 MH43353).

CEREBRAL LATERALITY IN HOMOSEXUAL MALES. M. Reite*, J. Sheeder, D. Richardson, P. Teale, University of Colorado Health Sciences Center Denver, Colorado 80262

The 100 msec latency auditory magnetic evoked field component M100 is generated in Heschl's gyri on the superior aspect of the superior temporal gyri. M100 localization appears to be a sensitive indicator of cerebral laterality. Significant interhemispheric sex differences are found in M100 localization, with sources further anterior in the right hemisphere of normal males compared to normal females. This study examined interhemispheric symmetry of M100 source location in 8 medically healthy homosexual males, and 8 age and education matched heterosexual males. MEG fields evoked by auditory tone pips were recorded from left and right hemispheres in response to contralateral ear stimulation. Source estimates were based on a modified Gauss-Newton method of least squares minimization, and referenced to bony landmarks using a sonic digitizer system capable of ± 1.0 mm accuracy, and worst case operational accuracy of ± 3.0 mm. Sources in the normal males were significantly further anterior in the right hemisphere ($t = -5.2$, $p = .0001$). Sources in the homosexual males did not exhibit significant interhemispheric asymmetry, being similarly located on both hemispheres ($t = -1.6$, $p = .13$). In addition, source location variance was significantly higher in the homosexual subjects. These findings suggest a possible anatomic and/or functional difference in the superior temporal gyrus of at least some homosexual male subjects. Supported by USPHS MH47476 and MH46335.

CYCLIC-AMP INCREASES A MEMBRANE CONDUCTANCE IN RAT TASTE CELLS. M. Scott *Herness** Indiana University School of Medicine, Muncie, IND. 47306.

Cyclic nucleotide-gated ion channels have been reported in many sensory systems. Second messenger systems utilizing cyclic nucleotides are thought to be important in gustatory transduction. This report suggests promising evidence for the occurrence of cyclic nucleotide-gated channels in gustatory receptor cells. Inside-out patches, excised from dissociated rat taste receptor cells and bathed in symmetrical buffered saline solutions responded with an increase in conductance when bath solution was replaced with buffered saline containing concentrations of cAMP ranging from 10 - 500 μ M. Signals were filtered with a four-pole Bessel filter at 2 kHz (-3db) before being digitized with a sampling rate of 20 mHz. This conductance increase was reversible when rinsed. A current voltage plot, constructed by calculating amplitude histograms, yielded a conductance of 30 pS. More frequent transitions appeared to occur at negative potentials than at positive potentials. In at least one patch conductance was also elicited by cGMP. Discrete single unit events have not been observed.

Supported by NIH DC00401.

NERVE-DEPENDENT GLYCOCONJUGATES ARE PRESENT IN TASTE BUDS AND ON THE BOUNDARIES BETWEEN TASTE BUDS. O. ZENG, Z. SHAO and B. OAKLEY* DEPT. OF BIOLOGY, UNIV. OF MICHIGAN, ANN ARBOR, MI 48109.

We screened 12 lectins on rat tongue sections to obtain information on carbohydrate expression in taste buds and the surrounding gustatory epithelium. After fixation in acid-alcohol or 4% paraformaldehyde, cryostat sections of rat tongue were treated with biotinylated lectins followed by an avidin-biotin-peroxidase complex and diaminobenzidine. Four lectins had interesting selective staining patterns: *Bauhinia purpurea* (BPA), *Helix pomatia* (HPA), *Lotus tetragonolobus agglutinin* (LTA) and *Ulex europaeus agglutinin* (UEA-I). UEA-I bound to the surface of fungiform papillae and to cells of its taste bud. HPA reacted with more than half of vallate or foliate elongated taste cells. LTA reacted with less than a third of elongated taste cells. Double-stained tissue sections suggest that keratin 18 and carbohydrates recognized by LTA may be co-expressed, because many LTA-positive cells were members of the subset of cells with keratin 18-like immunoreactivity. BPA selectively stained the boundaries between taste buds, but not the elongated taste cells. In electrophysiological recording, summated taste responses of the gerbil chorda tympani nerve were unaffected by exposure of the tongue to 200 μ g/ml BPA, or HPA or LTA. Gustatory denervation eliminated UEA-I BPA, HPA, and LTA reactivity of elongated taste cells and the BPA reactivity of cells between taste buds. Evidently, carbohydrate expression of lectin-positive cells comprising the boundaries between taste buds and as well as the elongated cells within taste buds is nerve-dependent. MODULATION OF RECEPTOR CELL FUNCTION BY BASAL CELLS IN *NECTURUS* TASTE BUDS. Douglas A. Ewald* & Stephen D. Roper Dept. of Anatomy & Neurobiology, Colorado State U., Fort Collins CO 80523 and the Rocky Mountain Taste & Smell Center, Denver CO 80262

Basal cells, which comprise only 10% of the total cell population of *Necturus* taste buds, are involved in the majority of morphologically identifiable synapses in the taste bud (Delay & Roper, J. Comp. Neurol. 277: 268, 1988). In thin slices of lingual epithelium that contain taste buds, focal chemical stimulation (140 mM KCl) of the apical tips of taste receptor cells elicits receptor potentials in taste receptor cells and postsynaptic responses in basal cells (Ewald & Roper, J. Neurophysiol. 67: 1316, 1992). Merkel-like basal cells in the *Necturus* taste bud contain serotonin (5-HT; Delay, Taylor, & Roper, submitted). In simultaneous intracellular recordings from a basal cell and a receptor cell, we have tested whether direct depolarization of basal cells elicits synaptic responses in receptor cells. No synaptic responses were observed during single electrical depolarizations applied to basal cells (up to 1-sec duration, to -0 mV). However, repetitive basal cell stimulation (5/min.) produced long-term effects on receptor cells in 11 out of 23 experiments. Specifically, repeated basal cell stimulation increased receptor cell input resistances (mean \pm S.D. = +27 \pm 11%) and receptor potentials elicited by chemosensory stimulation (+19 \pm 5%) 1 min. after a 1 min. stimulation. Receptor cells were also hyperpolarized (2-10 mV) by repetitive basal cell stimulation. Identical stimulation of pairs of receptor cells did not produce these effects. All of the effects of repetitive basal cell stimulation were mimicked by applying 100 μ M 5-HT to the bath. These findings suggest that basal cells, when repetitively depolarized, can enhance the electrotonic propagation of receptor potentials from the apical (chemosensitive) tips of receptor cells to the basal (synaptic) regions. We propose that 5-HT, released from basal cells, mediates these modulatory effects on taste bud function. Supported by NIH DC01238.

Expression of mRNA for amiloride-sensitive sodium channel in the rat taste tissues. X.J. Li*, P. M. Hwang, S. Blackshaw and S.H. Snyder, Department of Neuroscience, Johns Hopkins Medical School, Baltimore, MD 21205.

Although experiments to date indicate that salty taste involves interaction of sodium with a passive, apical Na^+ channel that can be blocked by the diuretic drug amiloride, the molecular structure and localization of this channel in the tongue remain unknown. We report the expression of amiloride-sensitive Na^+ channel gene in the taste tissues of rat tongue. Utilizing the polymerase chain reaction (PCR) technique with primers based on the sequence of a recently cloned amiloride-sensitive epithelial Na^+ channel (Canessa et al Nature 361, 467, 1993), we have identified the PCR products encoding this sodium channel from rat taste tissues including taste buds in the circumvallate papillae. We have also isolated the identical cDNA for this channel from a rat taste cDNA library, which was constructed from the circumvallate papillae of rat tongue. Reverse transcription-PCR assay and Northern blot indicate that mRNA for amiloride-sensitive Na^+ channel is present in the rat taste, olfactory and skin tissues, although it is most abundant in the lung, distal colon and kidney. The preliminary *in situ* hybridization studies show that the amiloride-sensitive Na^+ channel is distributed in the taste papillae as well as the tongue epithelium. Further characterization of its localization in the tongue is underway. The existence of epithelial Na^+ channel in the taste tissues indicate an involvement of this channel in the salty taste transduction.

MERKEL-LIKE BASAL CELLS IN AMPHIBIAN TASTE BUDS ARE HOMOLOGOUS WITH TYPE III CELLS IN MAMMALIAN TASTE BUDS. Dae-joong Kim, Rona J. Delay & Stephen D. Roper* Dept. of Anatomy and Neurobiology, Colorado State University, Fort Collins CO 80523 and the Rocky Mountain Taste and Smell Center, Denver CO 80262

A number of investigators have shown there is a subpopulation of taste bud cells that contain serotonin (5HT). In amphibia, these cells are small oblate basal cells, thought to be related to cutaneous Merkel cells and hence termed Merkel-like basal cells. In contrast, mammalian 5HT-containing cells are elongate and resemble receptor cells. Ciges et al ('76) and Takeda & Suzuki ('83) concluded that serotonergic cells in mammalian taste buds were Type III cells, believed by some to be the gustatory receptor cells. We have conducted an immunocytochemical survey of taste buds from *Necturus*, hamster, rabbit, rat and mouse, seeking to identify 5HT-containing cells and to draw comparisons among the different species. Basal cells in *Necturus* were intensely immunopositive for 5HT and formed a distinctive ring at the peripheral base of the taste bud. We found some taste cells in rabbits stained only faintly with antisera to 5HT. Taste cells in rats, mice and hamsters were not immunopositive for 5HT. Antisera to tryptophan hydroxylase, a key biosynthetic enzyme for serotonin, did not react with mammalian taste buds, although it produced intense immunostaining in known serotonergic nuclei in the brain. However, after pretreating animals with 5HTP or injecting L-tryptophan, taste cells even in mammals other than rabbits were immunopositive for 5HT. 5HT-immunoreactive cells were elongate and were disposed to the peripheral boundary of taste buds, identical to how Royer & Kinnamon ('91) described type III cells in their EM analysis of rabbit taste buds. Based on the similarity in immunostaining for 5HT and upon their identical dispositions within the taste bud, we postulate that amphibian Merkel-like basal cells and mammalian type III cells are homologous and that they may mediate the same neuromodulatory function in taste buds (see abstract by Ewald & Roper). STIMULATION OF THE GERBIL'S GUSTATORY RECEPTORS BY THE SUPER SWEETENER 4-CYANOPHENYL-CYCLONONYL GUANIDINE ACETIC ACID (SUCRONONIC ACID) R. CRUZ, L. SOMENERAIN, W. JAKINOVICH JR.* Dept. of Biol. Sci., Lehman College and the Graduate School, City Univ. of New York, Bronx, NY 10468 J.M. TINTI, and C. NOFRE Universite Claude Bernard, Lyon, France.

The purpose of this study was to figure out how the gerbil responds to the artificial sweetener 4-CYANOPHENYL-CYCLONONYL GUANIDINE ACETIC ACID (sucrononic acid). First, the gerbil's chorda tympani nerve responses were obtained to sucrononic acid and sucrose. As in the human, sucrononic acid (threshold = 1×10^{-8} M) was observed to be a more effective stimulant than sucrose in the gerbil (threshold = 1×10^{-3} M). Next, conditioned taste aversion studies were conducted and it was observed that gerbils trained to avoid sucrononic acid generalized an avoidance to sucrose, but not NaCl, HCl or quinine. These results show that to the gerbil sucrononic acid tastes like sucrose as it does in the human. (Supported by R01-NS2538-01 of NINCDS, NIH and S06 RR08225 of MBRS, NIH)

NEURAL RESPONSES OF THERMAL-SENSITIVE LINGUAL FIBERS TO BRIEF MENTHOL STIMULATION. Robert F. Lundy Jr. and Robert J. Contreras*. The Florida State University, Dept. of Psychology, Tallahassee, FL, 32306-1051.

Electrophysiological responses to anterior tongue stimulation (10 s) with menthol and several standard taste solutions were obtained from 45 thermal-sensitive lingual fibers in rats. Cold (6 °C, 15 °C) water significantly increased and 45 °C warm water significantly decreased the discharge rate of single fibers adapted to room temperature water (22-24 °C). Weak menthol concentrations (0.0128 mM, 0.064 mM, 0.128 mM) elicited a response in more fibers (91%) during the first 2 s of stimulation compared to the first and second 5 s of stimulation. In contrast, stronger menthol concentrations (0.64 mM, 1.28 mM) increased discharge frequency throughout stimulus duration. Contrary to prior observations, a significant increase in discharge frequency was not evident during the ensuing period after menthol off-set. Most taste solutions (NaCl, glucose, quinine-HCl, citric acid) significantly suppressed neural discharge frequency during the first 2-5 s of stimulation, but not during the second 5 s of stimulation. Unlike prior observations, strong menthol concentrations increased the discharge frequency of thermal-sensitive lingual nerve fibers during brief stimulus presentation. Possible explanations for the highly variable response of thermal-sensitive fibers to weak menthol concentrations are discussed.

EFFECT OF PROTEIN PHOSPHORYLATION AND CALMODULIN INHIBITORS ON CHEMORECEPTOR FUNCTION IN THE RABBIT CAROTID BODY. J. Chen*, L. He, B. Dinger and S. Fidone. Dept. of Physiol., Univ. of Utah Sch. of Med., Salt Lake City, UT 84108.

Previous investigations have implicated protein kinases and calmodulin in the regulation of neurotransmitter release, and the modulation of specific ion channel conductances. In the present experiments we have investigated the effects of an inhibitor of calcium/calmodulin dependent protein kinase II, KN-62, and a calmodulin inhibitor, trifluoperazine (TFP), on ³H-catecholamine release (³H-CA synthesized from ³H-tyrosine) and carotid sinus nerve (CSN) activity evoked by hypoxia or nicotine (100 μM) from rabbit carotid bodies superfused *in vitro*. TFP (10 μM) inhibited ³H-CA release evoked by hypoxia (69% ± 7% inhibition; $\bar{X} \pm$ SEM, p<0.0005) and nicotine (47% ± 10%, p<0.025). TFP likewise inhibited CSN activity evoked by these stimuli. In contrast to these findings, KN-62 (10 μM) did not alter hypoxia-evoked ³H-CA release or CSN discharge, but this drug did significantly inhibit nicotine-evoked ³H-CA release (48% ± 2%; p<0.05) and chemoreceptor activity. In preliminary experiments ³H-CA release and CSN activity evoked by either hypoxia or nicotine were decreased in the presence of H-7 (300 μM), an inhibitor of cyclic nucleotide protein kinases and protein kinase C. Our data indicate that protein phosphorylation and calmodulin activity play significant roles in chemoreceptor activation, and further, that specific signal transduction pathways are mediated by selected protein kinases. PARAMECIUM CHEMORECEPTION OF IMP AND GLUTAMATE Wan Qing Yang and Judith Van Houten* Dept. of Zoology, University of Vermont Burlington, VT 05405-0086

Paramecium is repelled by inosine monophosphate (IMP), as measured by T-maze assays. Two purine nucleotides, AMP and GMP, interfere with *Paramecium's* behavioral response to IMP, while CMP and cAMP do not, indicating that the IMP-induced response is purine nucleotide-specific. Glutamate is an attractant in T-maze assays and inhibits *Paramecium's* response to IMP, but not vice versa. Glutamate analogs (NMDA, KA and QA) inhibit the response to glutamate, but not the response to acetate, indicating that the inhibition is specific and that the glutamate receptor in *Paramecium* might be ionotropic.

³H-glutamate binding to whole cells saturates by 60 min and the K_d is ~103 μM. The 5'-ribonucleotides IMP, GMP and AMP all partially displace glutamate binding, but CMP and cAMP do not. These results are consistent with the T-maze assays. QA displaces glutamate binding, while NMDA, L-AP4, ACPD and KA displace only at higher concentration or not at all. Combinations of ligands with IMP in glutamate binding studies suggest that AMP and GMP may share a binding site with IMP and that QA may share a different glutamate site.

Intracellular cAMP RIA measurements show that IMP decreases cAMP level by 50%, while glutamate increases it about three fold, compared to the controls. Therefore, cAMP may be a second messenger for IMP and glutamate stimulation or adaptation.

RESPONSE OF GENICULATE GANGLION CELLS TO TASTE NERVE INJURY. S.T. McGlathery, B.G. Manion and M.C. Whitehead*. Department of Surgery, Division of Anatomy, UCSD, La Jolla, CA 92093.

Damage to peripheral taste nerves results in degeneration of central axonal endings in the nucleus of the solitary tract (NST) (McGlathery and Whitehead, Soc. Neurosci. Abstr., '92). Degeneration of central endings after nerve injury in the gustatory system resembles that in other sensory systems (e.g. trigeminal, vestibular, auditory). In this study, fluorescent labelling was used to determine whether the central degeneration results from ganglion cell death. Fast blue (0.4%) was injected bilaterally (60 μl per side) into the tongues of 5 golden hamsters. The chorda tympani was transected unilaterally 7 days post-injection, and the animals allowed to survive an additional 13-14 days. Pink-Heimer staining of the NST showed heavy degeneration on the experimental side, verifying the nerve cut in each case. Geniculate and trigeminal ganglia were sectioned and Fast blue-labelled cells counted. Numbers of labelled cells in experimental geniculate ganglia (221 ± 133) did not differ significantly from those in control ganglia (240 ± 81). Consistency of tongue injections, between sides, was evaluated by counting labelled trigeminal ganglion cells which did not differ significantly between experimental (1508 ± 539) and control sides (1680 ± 533). We conclude that the degeneration of central axonal endings after nerve transection results from a transganglionic process. Geniculate ganglion cells survive nerve section and could, therefore, regenerate nerve fibers both centrally and peripherally. (Supported by NIH Grants DC00452 and DC01901).

NITRIC OXIDE (NO) MEDIATES EFFERENT NEURAL INHIBITION OF CAROTID BODY CHEMORECEPTORS. Z.-Z. Wang*, B. Dinger, L.J. Stensaas and S.J. Fidone. Dept. of Physiology, Univ. of Utah of Utah Sch. of Med., Salt Lake City, UT 84108

Previous anatomical studies revealed an extensive plexus of NO synthase (NOS)-immunoreactive axons arising from the carotid sinus nerve (CSN), and neurophysiological experiments indicated NO is a potent inhibitor of chemoreceptor discharge. The present study demonstrates that N^o-nitroarginine methylester (L-NAME, 0.1 mM), which blocks NO synthesis in the carotid body, is able to reversibly block the increase of cGMP which occurs in vascular smooth muscle and type I cells following CSN stimulation. In *in vitro* superfused and vascularly perfused carotid bodies in which chemoreceptor activity was recorded from axons split from the CSN, electrical stimulation of the CSN induced rapid inhibition of the steady-state chemoreceptor discharge and increase in cGMP formation in blood vessels; both were reversible by 0.1 mM L-NAME. In contrast, in the *in vitro* superfused cat carotid body, CSN stimulation did not alter the steady-state chemosensory discharge, but attenuated the dynamic chemoreceptor response to hypoxia following 5 min of CSN stimulation. This delayed inhibition paralleled a delayed cGMP production in type I cells and was also reversible by L-NAME. These data thus reveal two distinct NO-mediated efferent neural pathways that inhibit carotid body chemoreceptors. (Supported by USPHS grants NS12636 and NS07938)

BRAINSTEM CONNECTIVITY OF THE HAMSTER CHORDA TYMPANI DEMONSTRATED WITH BIOTINYLATED DEXTRANS. A.P. Knox* and M.A. Barry. Department of BioS ture and Function, UCONN Health Center, Farmington, CT 06030-3705.

The connectivity of the chorda tympani branch of the facial nerve (CT) of adult-male golden Syrian hamsters was investigated with biotinylated dextran (BD) (10 kDa, Molecular Probes). The chorda tympani was exposed in the middle ear and crystals of BD were applied to the cut end of the nerve. Survival times varied from 2-15 days. The ABC reaction (Vector, standard kit) was utilized to reveal transported BD in transverse 50 μ m brain sections.

Multiple fascicles of transganglionic (anterograde) labeled fibers entered the rostral medulla and extended caudally to the level of the area postrema, where terminals were found in the commissural nucleus. Retrograde label was confined to the preganglionic parasympathetic cells of the superior salivatory nucleus. Terminal label was extremely dense at the rostral pole of the solitary nucleus (NST), but was also very dense at caudal levels of the rostral NST where it overlapped with gustatory projections of nerve IX. The appearance of most fibers and terminals was similar at 2 and 15 days, but by 15 days some vesiculated fibers were seen. The persistence of apparently the majority of terminal fibers 15 days following nerve section shows that most fibers do not undergo complete transganglionic degeneration, and that the loss of acetylcholinesterase staining in the NST after CT damage (Barry and Frank, Exp. Neurol. 115:60, 1992) is not due primarily to a loss of fibers. For anterograde transport, BD was superior to other tracers such as HRP, Cholera toxin, and WGA-HRP because of high sensitivity, rapid transport, temporal stability, and particularly the "Golgi-like" character of the label.

585.3

CELL TYPES IN THE NUCLEUS OF THE SOLITARY TRACT? AN HISTORICAL PERSPECTIVE. L. Schwelzer*, X. Zhang, Z. Jin, H. Dulger and W.E. Rehehan Dept. of Anatomical Sciences and Neurobiology, Univ. of Louisville Sch. of Med., Louisville, KY 40292 and Div. of Gastroenterology, Henry Ford Health Sci. Ctr. Detroit, MI 48202

A major emphasis in the field of neuroanatomy has been to determine the relationship between the structure of neurons and their function. The end product of many of these endeavors has been to establish "cell types" within functional subdivisions of the brain. Cell types have provided a useful construct for organizing data and exploring the mechanisms underlying the reception, processing and transmission of information in the nervous system. Efforts to determine morphologic cell types in the rostral aspect of the nucleus of the solitary tract (NST) have been constrained by the neuroanatomical methods used. The first studies employed Nissl stains and thus features like somatic cross-sectional area and form factor were used as the defining characteristics with which to type cells. Shortly thereafter, Golgi impregnation and retrograde HRP tract-tracing techniques were employed and dendritic branching patterns and axonal projections gained favor as the characteristics of choice. Most recently we have employed intracellular physiology/neurobiotin injection and three-dimensional computer reconstruction paired with a statistical technique known as cluster analysis to investigate cell types in the NST. Cluster analysis allows us to assess the utility of individual features of cellular morphology, and thus certain cell typing strategies, for grouping cells. How these cell types relate and the value of features previously employed for defining cell types will be reviewed and compared to our own results.

Supported by NIH-NICDC Grant #01074.

EFFECTS OF NEED-FREE SODIUM APPETITE ON TASTE RESPONSES IN THE NUCLEUS OF THE SOLITARY TRACT OF RATS. R. Tamura and R. Norgren* Dept. Behavioral Science, College of Medicine, Penn State Univ., Hershey, PA 17033

Intracranial injection of renin rapidly induces intake of hypertonic saline in rats that are otherwise in sodium balance. It is known that need-induced sodium appetite alters gustatory responses both on the periphery and in the nucleus of the solitary tract (NST). To determine whether these changes in responsiveness were due to the appetite itself or to sodium imbalance, gustatory neurons in the NST were tested with a battery of sapid stimuli after renin injections into the third ventricle. The rats were chronically prepared, but lightly anesthetized during the recording procedure. The effectiveness of the renin injections was assessed by measuring intake of 0.5M NaCl on the day following the recording session. Eighty-five gustatory neurons were tested; 46 after renin injections, 39 after vehicle injections. Except for the 2 hypertonic concentrations saline, neuronal responses to sapid stimuli did not differ significantly between the 2 conditions. When the rats were treated with renin, the average responses to 0.3 M and 1.0 M NaCl were 74% and 70%, respectively, of those after vehicle injections. A similar tendency was evident for the subsample of NaCl-best neurons, but the effect was smaller. In some respects, these results resemble the effects produced by dietary sodium restriction, but are opposite those produced by acute sodium loss. Supported by MH 43787 and MH 00653.

585.2

IN VITRO WHOLE CELL RECORDINGS FROM THE GUSTATORY ZONE OF RAT NUCLEUS OF SOLITARY TRACT DEMONSTRATE IMMATURE INTRINSIC PROPERTIES IN NEURONS AT THREE WEEKS POSTNATAL. H. Bao, R.M. Bradley and C.M. Mistretta* School of Dentistry, Univ. of Michigan, Ann Arbor, MI 48109.

Second order taste neurons in the rostral portion of rat nucleus of solitary tract (NST) continue to mature morphologically through about 65 days postnatal and demonstrate increases in response frequencies to chemical stimuli to about 60 days after birth. In initial attempts to learn when intrinsic electrophysiological properties mature, we have used whole cell recordings in the rostral portion of gustatory NST in two groups of rats: P15 (15-16 days postnatal; n = 9 cells) and P20 (18-22 days postnatal; n = 16 cells). Recordings were made from *in vitro* slices of the brainstem, and data on postnatal rats were compared with adult data previously reported (Bradley and Sweazey, J. Neurophysiol., 1992). Resting membrane potentials averaged about -47 mV across P15, P20 and adult groups, whereas input resistance averaged 446, 500 and 336 M Ω , respectively --- a developmental decrease. Membrane time constants (fast, slow) also decreased, from longer values at P15 and P20 (5, 32; 5, 31 ms) to shorter (2, 21 ms) in adults. Action potential amplitudes were similar across groups (80; 75 mV). However, spike numbers in response to a 1500 ms, 100 pA depolarizing pulse increased from 29 at P15, to 54 and 50 in P20 and adult animals. Of the four intrinsic firing patterns reported in adult NST, typical examples of patterns II and III were apparent in P15 and P20 neurons. Cells that could be categorized with pattern I also were observed, but the patterns were very irregular and appeared immature. Neurons with pattern IV were not observed. In summary, intrinsic electrophysiological properties of rat NST cells are not yet mature at postnatal day 20, indicating a rather lengthy maturation period for these characteristics. Supported by NIH Grant DC00456.

BIOPHYSICAL PROPERTIES OF MORPHOLOGICALLY CHARACTERIZED NEURONS IN THE ROSTRAL NUCLEUS TRACTUS SOLITARIUS (rNTS). M.S. King* and R.M. Bradley. Univ. of Michigan, Ann Arbor, MI 48109.

We have determined the biophysical properties of morphologically characterized neurons in the rat rNTS. Whole-cell recordings were made with biocytin-filled pipettes in a brain slice preparation of the rat medulla. 58 neurons were reconstructed using the Eutectic Neuron Tracing system and the neurons were separated into three morphological groups (ovoid, multipolar and elongate) as described by other investigators using the Golgi technique. Most neurons (49%) were classified as ovoid, while 35% were multipolar and only 16% were elongate. The passive membrane properties of the three groups were similar, except that the input resistance of the ovoid neurons was highest. While a high percentage (42-56%) of all three types of neurons responded to a 1200 ms, 100 pA depolarizing current pulse with a repetitive spike train, 31% of the ovoid neurons responded with a short burst of action potentials and 44% of the elongate neurons showed a delay in the onset of the spike train following a hyperpolarizing prepulse. Less than 16% of the multipolar neurons demonstrated either of these firing characteristics. Stimulation of the solitary tract in the brain slice caused EPSPs, IPSPs and mixed responses in rNTS neurons. These synaptic inputs were not specific to a morphological type. The responses of the three types of neurons to substance P, GABA and NMDA were also tested. A high percentage (57-100%) of each type responded to one or more of these neurotransmitters. Since the inputs and outputs of the three morphological groups are similar, they may not represent functionally-distinct groups. Instead, subpopulations of these three groups, which display different firing patterns, may subservise different functional roles. The same input in these subpopulations would produce different outputs. (Supported by NIH DC00288).

THE INFLUENCE OF GUSTATORY CORTEX ON TASTE CELLS OF THE SOLITARY NUCLEUS OF THE HAMSTER. H. Liu*, M. M. Behbehani and D. V. Smith. Depts. Otolaryngology and Physiology, Univ. Cincinnati Coll. Medicine, Cincinnati, OH 45267.

In this study we determined the influence of electrical stimulation of the gustatory (insular) cortex on the ongoing spontaneous discharge of taste responsive-cells in the NST in urethane-anesthetized hamsters. The sensitivities of 13 single neurons to three basic taste stimuli (0.032 M NaCl; 0.1 M KCl and 0.1 M sucrose) presented to the anterior tongue were determined. Of the 13 cells, 5 were NaCl-best, 4 were sucrose-best and 4 were KCl-best. Microinjection of D,L-homocysteic acid (DLH; 50 nl, 10 mM) into insular cortex excited 2 cells (1 NaCl-best; 1 sucrose-best), inhibited 5 cells (2 NaCl-best, 1 KCl-best and 2 sucrose-best) and had no effect on 6 cells (3 KCl-best, 1 sucrose-best and 2 NaCl-best). The onset of DLH-evoked responses ranged from 3 to 28 seconds; the duration of responses ranged from 1 to 8 min. Low-frequency, single pulse electrical stimulation of insular cortex had no effect on the NST cells sampled. Trains of high-frequency (100 Hz, 100 μ A, 10 sec) electrical stimulation produced results similar to the DLH stimulation of the insular cortex except for one cell which was unresponsive to train stimulation but inhibited by chemical stimulation. In 4 cells (2 NaCl-best and 2 sucrose-best) bicuculline methiodide blocked the inhibitory response evoked by both high frequency and DLH stimulation of the insular cortex. It is concluded that 1) insular cortex neurons have a synaptic influence on NST cells; 2) high-frequency train stimulation or chemical stimulation of the insular cortex is more effective in altering the firing pattern of NST neurons than single-pulse stimulation, and 3) inhibitory responses are possibly mediated by a GABAergic system. Further experiments will address the organization of this descending system and its specific influences on gustatory-elicited responses. Supported by DC-00066 and DC-00353.

GUSTATORY-ELICITED EXPRESSION OF C-FOS IN BRAINSTEM NUCLEI. M.I. Harrer, M. Dinkins, J.B. Travers, and S.P. Travers. Depts. of Oral Biology and Psychology, Ohio State University, Columbus, OH 43210

Understanding the topographic organization of the gustatory system has been impeded by the difficulties inherent in using neurophysiological techniques to study small neurons in these small nuclei, coupled with problems of adequately stimulating the entire taste bud population. We have begun to study the organization of brainstem gustatory regions using immunocytochemical techniques to detect the expression of *c-fos* after taste stimulation in awake, behaving rats. Water-deprived rats were stimulated with alternate deliveries of 1.0M sucrose and 0.03M quinine HCL, separated by distilled water rinses, delivered through intraoral cannulae during a 30-45 min period. These stimulations elicited behavioral ingestion and rejection. At 1-2 hrs following stimulation, rats were deeply anesthetized with pentobarbital (150 mg/kg), perfused, and brainstem tissue processed using standard immunocytochemical techniques. Taste stimulation produced Fos-like immunoreactivity (Fos-LI) in the rostral division of the nucleus of the solitary tract (rNST), the subjacent reticular formation, and the medial and ventral lateral subnuclei of the parabrachial nucleus. Labelled NST nuclei formed a continuous distribution that spanned the rNST, but was limited to the medial half of the central subnucleus, i.e., the region overlapping neurophysiological gustatory responses. Interestingly, Fos-LI was not marked in the lateral half of the central or the lateral subnuclei, regions responsive to oral somatosensory stimulation. Thus, this approach appears to provide a sensitive, specific method for studying the functional activation of first- and higher-order neurons participating in gustatory processing. Supported by NIH DC00416 and DC00417.

585.9

CONDITIONED TASTE AVERSIONS ARE RETAINED AFTER LESIONS OF THE PARABRACHIAL NUCLEI. P.S. Grigson*, T. Shimura, and R. Norgren. Dept. Behavioral Science, College of Medicine, Penn State Univ., Hershey, PA 17033

In phase I, 42 rats were given 15 min access to 0.3 M alanine (conditioned stimulus; CS) followed by an ip injection of the unconditioned stimulus (US), either 0.15 M LiCl (1.33 ml/100 g b.w.) or saline. Following 3 CS-US pairings, all rats that received LiCl demonstrated a strong conditioned taste aversion (CTA) to alanine. In phase II, the saline and LiCl injected animals were divided into 3 groups that received either (1) electrophysiologically-guided bilateral electrolytic lesions of the nucleus of the solitary tract (NST), (2) electrophysiologically-guided bilateral ibotenic acid lesions of the parabrachial nucleus (PBN), (3) or appropriate control procedures. In phase III, retention of the preoperatively acquired CTA was evaluated in a 2-bottle, 15 min test during which the rats had simultaneous access to dH₂O and 0.3 M alanine. In Phase IV, all rats were retrained in a CTA using 0.1 M NaCl as the CS and LiCl as the US. As demonstrated previously, the results showed that PBN lesions, but not those in the NST, disrupted postoperative acquisition of a CTA. When acquired preoperatively, however, both groups of rats demonstrated full retention of the CTA after their lesions. Supported by DC 00047, DC 00240, and MH 00653.

TIME COURSE OF DISCRIMINATION OF TASTE STIMULI IN THE PARABRACHIAL PONTS OF THE RAT. P.M. DiLorenzo*, G.S. Hecht, and S. Monro. Dept. of Psychology, SUNY at Binghamton, Binghamton, NY 13902.

At the core of traditional analyses of the electrophysiological responses to taste is the response measure. This consists typically of the number of spikes that occur during some arbitrary interval of time when a tastant is on the tongue. However, when activity is summed over time, the dynamic aspects of the responses are lost. Moreover, the critical interval of measurement is problematical. Despite evidence that a taste stimulus can be identified within 200 msec of contact with the tongue, virtually all theories of taste coding are based on response measures taken over 3-5 sec of response. We recorded the electrophysiological responses of 38 neurons in the parabrachial nucleus of the pons (PbN) in urethane anesthetized rats to a range of concentrations of representatives of the four basic taste qualities: NaCl, HCl, quinineHCl and sucrose. We then analyzed the pairwise differences in across neuron patterns of response as they were elaborated over the time course of the response. By changing the interval over which the response was measured, it was possible to chart the degree of difference between 2 across neuron patterns over time. These differences were largest and occurred earliest (peak about 750 msec) in comparisons of the pattern of response to sucrose with that evoked by all other tastants. The discrimination of different types of tastants appeared to be accomplished within different time frames over the first 3 sec of response. When tastants were presented at near threshold concentrations, responses to all tastants were most discriminable within the first 500 msec of response. These data suggest that different judgements regarding taste discrimination may have different time frames and that the appropriate interval for analysis of PbN taste responses may depend on the particular taste quality. CHEMOSENSORY BRAIN MECHANISMS OF LEARNING IN GOLDFISH R.J. Arcement* and D.J. Ingle. Columbia Univ.-Teachers College, N.Y., NY 10027 & M.I.T., Cambridge, MA 02139

This study examined the effects of single and multiple ablations of the gustatory and olfactory brain centers on chemosensory discrimination ability. Surgery included ablations of the olfactory tract (OT), telencephalon (T), facial lobe (FL) and vagal lobes (VL). Goldfish were trained to discriminate between two extracts (diluted 1:100) of raw fish flesh; bluefish vs beef. This was done by habituating fish to one extract while rewarding for snapping at the source of the second extract. Critical tests for discrimination compared the amount of time a fish spent at each extract tube. After goldfish were trained to selectively approach either an extract of fish or beef, ablations were made of either OT, T, FL, VL, or combinations of these regions. We found that ablation of OT or FL alone or combined removal of FL plus OT or FL plus VL did not abolish this chemosensory discrimination capability. Only when all three centers were removed (FL plus VL, then later OT) was that capability abolished in one group and much reduced in two others. These results indicate that input via either OT or VL is sufficient for this particular discrimination between food extracts. Furthermore, even with both gustatory lobes removed, near total ablation of T does not abolish this olfactory discrimination. Presumably OT projections to the hypothalamus mediates this residual ability, a finding which extends the earlier work of Wright and Harding in the mouse (*Science*, 1982, 216, 322-323).

RODENT VENTRAL STRIATUM: 5'-NUCLEOTIDASE, CELL CLUSTERS, AND INFRAALIMBIC CORTICAL INNERVATION. M.G. Laubach* and D.J. Woodward. Dept. of Physiology and Pharmacology, Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157.

The goal of this study was to describe the distribution of 5'-nucleotidase (5'NT) within the ventral striatum and to compare terminal fields of deep and superficial layer projections from the infralimbic cortex with respect to 5'NT. Biotin-dextran was iontophoresed in infralimbic cortex and terminals were visualized using standard methods. Sections were counter-stained for Nissl substance. The distribution of 5'NT was determined on adjacent sections using the method of Schoen and Graybiel ('92). Additional brains were stained for 5'NT, calbindin, substance-P, and leu-enkephalin. Three-dimensional surface images of 5'NT were reconstructed from serial sections in four brains using the Biographics Workstation. In the core, 5'NT is localized to several contiguous patchy structures surrounding the anterior commissure which are in register with leu-enkephalin positive zones and are continuous with the 5'NT zones of the dorsal striatum. In the shell, 5'NT is concentrated in a longitudinal band along the septal border, extending from the rostral pole of the ventral striatum to the bed nucleus of the stria terminalis. The ventral portion of this zone is coincident with an area of high cell density. A second 5'NT zone along the shell/core border is coincident with an area of high cell density and is most evident at caudal levels. The infralimbic cortical innervation was denser in the shell than in the core. In the shell, infralimbic fibers from the superficial layers tended to avoid the 5'NT-rich cell clusters. By contrast, fibers from the deep layers densely innervated the 5'NT-rich cell clusters. Thus, this study extends the principles proposed by Gerfen '89 to the infralimbic cortex and the shell of the ventral striatum. (MH 44339, DA 02338, & AFOSR 90-0146 to DJW and DA 07246 to MGL)

GLUTAMATE AND ASPARTATE INPUTS TO THE RETROSPLLENAL GRANULAR CORTEX (RSg) AND THE ANTERIOR THALAMIC NUCLEI (ATN) IN THE RAT.

A. Gonzalo-Ruiz*, A.R. Lieberman and J.M. Sanz. Dept. of Anatomy, School of Physiotherapy, Soria, Spain and Dept. of Anatomy, UCL, London, England.

We have examined the organization and transmitter-related characteristics of projections to the RSg from the ATN by retrograde labelling with WGA-HRP and glutamate (Glu)/aspartate (Asp)-immunohistochemistry. Iontophoretic injections of WGA-HRP were placed into different parts of the RSg in adult albino rats anesthetized with Nembutal (45mg/Kg). The animals were reanaesthetized 1-2d later, and perfused with fixative. Brains were sectioned coronally at 50µm using a Vibratome. The sections were reacted sequentially for the histochemical detection of WGA-HRP (using DAB as chromogen) and the immunocytochemical localization of either Glu or Asp, using the ABC method. After injections located in superficial layers (I-III) of the dorsal and ventral RSg, Glu+HRP and/or Asp+HRP containing neurons (possible non-overlapping populations) were present in the ipsilateral anterodorsal (AD) and anteroventral (AV) subnuclei of the ATN. All such injections also produced, in ipsilateral AD and AV, significant numbers of neurons which were only HRP+. Thus the thalamocortical projections from ATN may be heterogeneous with respect to transmitter content. Injections of WGA-HRP confined to deep layers (V-VI) of the dorsal and ventral RSg produced anterograde HRP (and light Glu or Asp) labelling predominantly in the ipsilateral AD and AV. The small varicosities seen with the light microscope in ATN lie within, and presumably form synaptic contacts mainly in, the neuropil. Some labelled terminals also lie close to neuronal cell bodies. Ultrastructural studies combining HRP labelling and Glu/Asp-immunohistochemistry will be required to confirm that such terminals contain Glu and/or Asp and to assess their synaptic organization within the ATN; the possible transmitter heterogeneity of the ATN-RSg projections also calls for further investigation. (Supported by DGICYT PM92-0139).

SPATIAL DISTRIBUTION OF CHEMICALLY-IDENTIFIED INTRINSIC NEURONS IN RELATION TO PATCH AND MATRIX COMPARTMENTS OF RAT NEOSTRIATUM. Y. Kubota* and Y. Kawaguchi. Laboratory for Neural Systems, Frontier Research Program, RIKEN, Wako, Saitama 351-01, Japan

The spatial distributions and dendritic branching patterns of chemically identified subpopulations of striatal intrinsic neurons, defined by immunoreactivity for choline acetyltransferase (ChAT), neuropeptide Y or parvalbumin, were studied in relation to patch and matrix compartments of rat neostriatum.

ChAT- and parvalbumin- immunoreactive cells and fibers showed an uneven pattern of distribution in the striatum. Parvalbumin immunoreactivity was denser in the neuropil of lateral and caudal parts than of the medial part. Neuropeptide Y immunoreactivity was uniform. Certain neuropeptide Y cells (about 20%) were also immunoreactive for calbindin D28k, indicating that at least a small population of calbindin D28k immunoreactive cells are medium aspiny cells.

Cells immunoreactive for ChAT, neuropeptide Y or parvalbumin showed basically similar distribution patterns in relation to the patch and matrix compartments. Most stained cells were located in the matrix, but some were located at the borders of patches and a few were inside patches. Most primary dendrites of stained cells in the matrix or patches remained confined to these compartments, but cells on the borders invariably extended dendrites into both compartments. The striatal intrinsic neurons form chemically differentiated neuronal circuits within the matrix and the patches and those whose dendrites cross the borders may contribute to associational interconnections between the two compartments, unlike the spiny projection neurons whose dendrites are confined to one or other compartment.

THE CORTICO-PALLIDAL PROJECTIONS IN THE RAT: AN ANTEROGRADE TRACING STUDY WITH BIOTINYLATED DEXTRAN AMINE. A. Naito, H. Nakanishi* and H. Kita Dept. of Anatomy and Neurobiology, Col. of Medicine, Univ. of Tennessee Memphis, Memphis, TN 38163.

As a result of studies on the corticofugal pathways in the rat using an anterograde tracing technique, we have found a direct cortical projection to the globus pallidus (GP). Biotinylated dextran amine (BDA, 2%) dissolved in 0.01 M phosphate buffer (pH 7.2) was pressure injected into various cortical areas of 34 male Sprague-Dawley rats (280-390 g). After a survival period of 5-8 days, the rats were fixed with 4% paraformaldehyde and the brains were sectioned on a Vibratome. The sections were processed for visualization of BDA containing fibers utilizing the ABC-method. A number of BDA-labeled thin fibers with small boutons were found in the ipsilateral GP after BDA injections into the frontal agranular cortex. However, only a few fibers were labeled after an injection into other cortical areas. Injection of BDA in the medial and the lateral cortical areas resulted in labeling in the medial and the lateral regions of the GP, respectively. Injection of BDA in the rostral and the caudal cortical areas resulted in labeling in the ventral and the dorsal GP regions, respectively. A number of labeled boutons were also observed in the entopeduncular nucleus and the substantia innominata after BDA injections into the rostral part of the frontal cortex. These findings indicate: 1) that the cortex projects to the ipsilateral GP, 2) that the main projection arises from the frontal agranular cortex, and 3) that the cortico-pallidal projections are topographically organized.

AXON COLLATERALS OF PARS RETICULATA PROJECTION NEURONS SYNAPSE ON PARS COMPACTA NEURONS. M. Damlama*, J.P. Bolam* and J.M. Tepper. Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ USA 07102 and *MRC, Anatomical Neuropharmacology Unit, Oxford University, Oxford, U.K.

Nigral dopaminergic (DA) neurons in pars compacta have been suggested to receive inputs from GABAergic pars reticulata (PR) neurons as well as from neostriatum and globus pallidus. Although electrophysiological evidence implies such a local nigral interaction, synaptic contacts have not yet been demonstrated. Furthermore, since inputs could arise from PR interneurons and/or projection neurons, the identity of the PR neurons projecting to the pars compacta DA neurons needs to be determined.

Adult male Sprague-Dawley rats were anesthetized with urethane (1.3 g/kg i.p.). Intracellular recordings were obtained with micropipettes filled with 3% biocytin in 1 M potassium acetate from PR projection neurons identified by antidromic activation from thalamus and/or superior colliculus at short latency (0.6-3.4 ms). Following identification, neurons were intracellularly filled with biocytin. Serial sections through the substantia nigra were processed to reveal biocytin using DAB as a chromogen and TH immunocytochemistry using BDHC as a chromogen.

Antidromically identified PR projection neurons possessed medium sized polygonal to fusiform cell bodies. The axon usually issued from the cell body and formed extensive collaterals within a few hundred μ m of its origin. Collaterals exhibited intermittent clusters of varicosities, both in PR and pars compacta, and had long stretches with no varicosities. Some of the varicosities were in close apposition to DA dendrites. In the electron microscope the varicosities were identified as large (2-2 μ m) synaptic boutons that contained several mitochondria, and pleomorphic vesicles. The boutons formed symmetric synapses. Individual labeled collaterals were observed to form multiple synaptic contacts with single neurons in the pars compacta. Supported by MH 45286 (JMT) and the MRC (JPB).

GABAergic AXONS IN THE RAT VENTRAL FOREBRAIN: A LIGHT AND ELECTRON MICROSCOPIC STUDY.

H.T. Chang*, Q. Tian, and P. Herron, Department of Anatomy & Neurobiology, The University of Tennessee, Memphis, College of Medicine, 875 Monroe Ave., Memphis, TN 38163

The ventral forebrain region, including the ventral striatum (VS), the ventral pallidum (VP), and the substantia innominata (SI), has been shown to be an important link between the basal ganglia, the limbic system, as well as the basal forebrain cholinergic system. Although previous studies have shown that this region is richly innervated by GABAergic fibers, little is known with respect to the relative densities of GABAergic to non-GABAergic axon terminals in this region. To address this issue, we have developed a specific rabbit antiserum to GABA and used a postembedding immunocytochemical reaction to analyze the quantitative distribution of GABA-like immunoreactive axon terminals in the rat VS, VP and SI. We found that 9.5% of the axon terminals in VS, 85.5% in the VP, and 64.8% in the SI are GABAergic. These results are consistent with previous findings that a majority of inputs to VS are excitatory, and that a majority of inputs to VP are inhibitory. Moreover, our result shows that GABA may play an important role in the SI where both the cholinergic and the non-cholinergic neurons reside within a neuropil innervated by many different noncholinergic fibers.

IDENTIFIED TARGETS OF THE PALLIDOSTRIATAL PROJECTION IN THE RAT. B. D. Bennett, S. Bacon* and J. P. Bolam. MRC Anatomical Neuropharmacology Unit, Department of Pharmacology, Oxford University, Oxford, United Kingdom.

The globus pallidus (GP) is known to project to the striatum and it has been demonstrated that lesions of the GP produce a decrease in NADPH-diaphorase (NADPH-d) staining in the striatum (Staines and Hinckle '91 Soc. Neurosci. Abst. 17, 456). These findings imply that the pallidostriatal projection may exert a direct effect on NADPH-d cells. The object of the present study was to test directly whether GP cells form synaptic contact with NADPH-d cells of the striatum.

Rats received iontophoretic deposits of PHA-L in the GP. Sections of the striatum were processed to reveal the anterogradely transported tracer and then incubated to reveal NADPH-d-containing structures. In some sections the NADPH-d activity was revealed first. In the light microscope, anterogradely labelled fibres were sparse but were observed in many areas of the striatum. These fibres gave rise to clusters of large boutons which were sometimes observed to form baskets around unlabelled perikarya. The proximal dendrites of NADPH-d cells were seen to be apposed by labelled terminals. Correlated light and electron microscopy confirmed that the anterogradely labelled terminals apposed to the dendrites of NADPH-d cells formed symmetrical synaptic contact with these neurones. The PHA-L injections in the GP also resulted in the retrograde labelling of some striatal projection neurones. Although the pallidostriatal terminals had a distinct morphology, the possibility cannot be excluded that some of the labelled boutons arose from collaterals of the retrogradely labelled spiny cells.

Thus, in addition to spiny neurones (Kita et al. '91 Soc. Neurosci. Abst. 17, 453) NADPH-d cells are one of the synaptic targets of pallidostriatal neurones. The identity of other classes of neurones postsynaptic to the pallidal fibres in the striatum is under investigation.

GABAergic INHIBITION OF NIGROSTRIATAL DOPAMINERGIC NEURONS BY SELECTIVE ACTIVATION OF PARS RETICULATA PROJECTION NEURONS. D. R. Anderson, W. Li and J. M. Tepper*. Center for Molecular and Behavioral Neuroscience, Rutgers, The State University of New Jersey, Newark, NJ USA 07102

The spontaneous activities of substantia nigra pars compacta dopaminergic (DA) neurons and a population of pars reticulata (PR) non-DA neurons are reciprocally related. This reciprocity has been postulated to be due to inhibition of dopaminergic neurons by a specific type of PR interneuron (Grace & Bunney, *Brain Res.* 333:271, 1985). However, it is possible that reciprocity exists between DA neurons and GABAergic PR projection neurons, mediated by axon collaterals of the latter. Therefore, we examined the response of DA cells to selective activation of PR projection neurons achieved by antidromic stimulation of their projection sites *in vivo*.

Adult male Sprague-Dawley rats were anesthetized with urethane, and bipolar stimulating electrodes were implanted in the anterior-lateral neostriatum, thalamus, and superior colliculus. Extracellular single unit activity of antidromically identified DA nigrostriatal neurons was recorded by conventional means, and responses to single pulse stimulation (0.25 - 1 mA) of thalamus or superior colliculus were analyzed with peristimulus time histograms.

Forty one of 44 DA neurons were inhibited at short latency by antidromic activation of PR from thalamus (mean onset 1.8 ms; duration of inhibition 52.1 \pm 8.3 ms; inhibition 44 \pm 5%) or tectum (mean onset 0.8 ms; duration of inhibition 38.9 \pm 5.1 ms; inhibition 32 \pm 5%). Bicuculline methiodide (20 mM) filled microelectrodes completely blocked tectal- or thalamic-induced inhibition of DA neurons (n=13) and caused a dramatic increase in burst firing, even in the absence of increased spontaneous firing rate. These data demonstrate that PR projection neurons inhibit pars compacta dopaminergic neurons through a monosynaptic GABA_A synapse and that tonic GABAergic input, acting through a GABA_A receptor and most likely originating from extrastriatal sources, serves to suppress burst firing in DA cells *in vivo*. Supported by MH 45286.

SOMATOSTATIN, NADPH-DIAPHORASE AND STRIATAL COMPARTMENTALIZATION IN THE RAT. W.J. RUSHLOW*, N. RAJAKUMAR, K. ELISEVICH, C.C.G. NAUS and B.A. FLUMERFELT. Dept. of Anatomy, University of Western Ontario, London, Canada, N6A 5C1.

Heterogeneity is now a widely recognized feature of the striatum. Consistent with this concept, we have previously demonstrated that the somatostatin (SOM) neuron population is composed of several smaller subpopulations based on the distribution of various proSOM-derived peptides. Neurons that contain SOM 28, SOM 14 and SOM 28(1-12) are found predominantly in the matrix compartment of the ventral striatum while neurons that contain only SOM 28 are more numerous in the patch compartment and dorsolateral striatum. SOM fibre labelling is most abundant in the ventromedial striatum and least dense in the patch compartment and dorsolateral striatum. However, this pattern of fibre distribution has been determined using antisera directed against SOM 14, SOM 28(1-12) or other SOM antibodies that cross-react with these peptides. Unfortunately, these antisera do not label the entire population of SOM neurons. NADPH-diaphorase labelled fibres, in contrast, are homogeneously distributed across the striatum including the patch compartment. These fibres are morphologically identical to SOM fibres and retrograde tracing studies indicate that there is no external source providing NADPH-diaphorase labelled fibres to the striatum. Given that SOM 28 is 100% colocalized with NADPH-diaphorase in the perikarya, these results suggest that neurons that contain SOM 28, SOM 14 and SOM 28(1-12) innervate the matrix compartment while neurons that contain only SOM 28 innervate the patch compartment and the dorsolateral striatum. Supported by MRC (B.A.F.), NSERC (C.C.G.N.) and Huntington's Society of Canada (W.J.R.).

586.11

TOPOGRAPHICAL ORGANIZATION OF THE CORTICOSTRIATAL PROJECTION IN THE RAT. K. Elisevich, N. Rajakumar, A.W. Hryciwshyn and B.A. Flumerfelt, Department of Anatomy, University of Western Ontario, London, Ontario, Canada, N6A 5C1.

The topographical organization of the corticostriatal projection in the rat is not conclusive, as most studies have employed either degeneration or retrograde tracing methods. In the present study, projections from the primary motor (Fr1), sensory (Pa1), forelimb (FL) and hindlimb (HL) areas, the prefrontal cortex (PF) and association areas of frontal (Fr2), parietal (Pa2), temporal (Te2) and occipital (Oc2) cortices were traced in adult rats employing the anterograde tracers biotinylated dextran (BD) and/or rhodamine dextran (RD) in combination with calbindin immunolabeling. The results revealed that the Pa1, FL, HL and Fr1 projections are extensively overlapped. The Pa1, FL and HL fibers were sparse and confined to the calbindin-poor area of the dorsolateral striatum (CPDS) while those of Fr1 were dense and occupied the dorsolateral quadrant of the striatum. The PF fibers occupied the medial half of the striatum and overlapped extensively with the Te2 and Oc2 fibers which occupied the ventromedial and dorsomedial areas, respectively. The Fr2 fibers were seen in the lateral half of the striatum other than the CPDS, overlapping extensively with Fr1 and Pa2 fibers which occupied the central region. Although the corticostriatal projections were bilaterally symmetrical, the density of fibers varied greatly. The Fr1, Fr2 and PF areas provided substantial inputs to the contralateral striatum whereas the other projections were sparse. The present study indicates that the CPDS receives converging inputs from primary sensorimotor areas whereas the remainder of the striatum receives inputs from association and prefrontal cortices that converge in an orderly manner. [Supported by MRC Canada]

586.13

ORGANIZATION OF THE PROJECTIONS FROM SUBSTANTIA NIGRA TO HIPPOCAMPAL FORMATION IN THE RAT. A. Gasbarri*, R. Innocenzi, E. Campana and C. Pacitti, Department of Science and Biomedical Technology, Laboratory of Human Physiology, Collemaggio, 67100 L'Aquila, Italy.

Anterograde, retrograde tracing experiments and degeneration studies following midbrain lesions showed that the hippocampal formation (HF) receives projections from ventral tegmental area and substantia nigra (SN), which contain the dopaminergic (DA) neurons of the A10 and A9 respectively. The ascending projections from the substantia nigra (SN-A9) to the hippocampal formation were investigated in the rat by means of tracing techniques. Iontophoretically injected *Phaseolus vulgaris*-leucoagglutinin (PHA-L) into SN resulted in labeling primarily in subiculum and adjacent CA1 field of caudal HF. Very few scattered labeling was found in the rostral HF. The distribution of SN hippocampally projecting neurons was also examined by injecting retrograde fluorescent tracers (Fluoro Gold, Fast Blue and Nuclear Yellow) in different hippocampal areas. The results of these experiments show that the caudal HF receives afferents from medial SN, pars compacta (SNc), whereas very few SNc cells appear to project to the rostral HF. It is established that central dopaminergic system in the basal ganglia, in particular the mesostriatal and the mesolimbic DA pathways, arising from the mesencephalic A9 and A10 cell groups, play a role in the control of locomotor activity. It is also generally accepted that nigral projections are involved in the control of locomotor activity. It could thus be postulated that the retention of an acquired locomotor behavior might involve the nigro-hippocampal pathway.

586.10

SEGREGATED CONNECTIONS AND POSSIBLE FUNCTIONAL HETEROGENEITY OF STRIOSOMES OF THE RAT STRIATUM. B.A. Flumerfelt, N. Rajakumar and K. Elisevich, Dept. of Anatomy, University of Western Ontario, London, Ontario, Canada, N6A 5C1.

Striosomes receive inputs from the prefrontal cortex and project to dopaminergic neurons of the substantia nigra. However, these connections are mostly restricted to striosomes situated in the medial part of the striatum. Recently, we described projections from striosomes in the lateral part of the striatum to neurons of the entopeduncular nucleus (EPN) that project to the lateral habenula, thereby indicating an involvement of striosomes in the regulation of serotonergic neurons of the dorsal raphe (J. Comp. Neur. '93, 331:286). In the present study injections of fluorogold into the lateral part of the striatum in adult rats resulted in labeling of neurons in sensorimotor and frontal association (Fr2) areas, suggesting a possible connection between these areas and striosomes that project to the EPN. Placement of the anterograde tracer, biotinylated dextran, into the Fr2 region in combination with calbindin immunolabelling showed a preferential projection to striosomes while fibers traced from the primary sensorimotor area avoided the striosomes. Combined anterograde tracing from the Fr2 region and retrograde tracing from the EPN resulted in overlapping labeling which indicated a possible involvement of the Fr2 region in the control of serotonergic neurons via striosomes in the lateral part of the striatum. Similar injections of tracers into the prefrontal cortex and substantia nigra pars compacta demonstrated an overlap of labeling within the striatum. This suggests a functional heterogeneity of striosomes: the medial striosomes are involved in the control of nigral dopamine neurons and receive inputs from the prefrontal cortex; the lateral striosomes are involved in the control of serotonergic neurons of the dorsal raphe and receive inputs from the frontal association cortex. [Supported by MRC Canada]

THE EARLY-FORMING PROJECTIONS OF THE SUBSTANTIA NIGRA IN THE MUTANT MOUSE *WEAVER*. B. Martin and S. Roffler-Tarlov, Program in the Neurosciences, Tufts Univ. Sch. of Med., Boston, MA 02111.

Weaver is an autosomal recessive mutation in mouse. The nigrostriatal system of *weaver* is affected by arrested differentiation and death of dopamine-containing neurons in the substantia nigra after the first postnatal week. The early-forming dopamine islands present in the neonatal *weaver*'s caudoputamen degenerate several weeks later leaving tyrosine hydroxylase (TH)-weak ghosts. In order to examine the striatal cell clusters that are targets of the dopamine island fibers and to provide retrograde labelling of nigral cells in the midbrain, the right rostral striatum of 2 day-old *weaver* and wild-type pups was infused with fluorescent dye (Fluoro-Gold, .1 µl of a 4% solution) (Snyder-Keller, Neurosci. Let. 91, 1988, 136-141). The injected pups were perfused on postnatal day 7. The brains were cut into a series of transverse sections that were examined for localization of Fluoro-Gold and TH immunoreactivity. Islandic deposits of Fluoro-Gold that corresponded to regions of TH-positive staining were found in the caudoputamen of both *weaver* and wild-type mice. The disposition and numbers of cells in the midbrain that contained Fluoro-Gold also were equivalent in 7 day-old *weaver* and wild-type mice. Fluoro-Gold labelling appeared both in populations of TH-positive neurons spared in the adult *weaver* and in cell groups that die. The results indicate that projections from both vulnerable and spared neurons in *weaver*'s substantia nigra have reached target regions in the neonatal period and that the normal clustering of islandic targets takes place in *weaver* neonates. NIH NS20181

586.14

NIGRAL INNERVATION OF CHOLINERGIC AND NON-CHOLINERGIC CELLS IN THE RAT MESOPONTINE TEGMENTUM: A DOUBLE LABEL EM STUDY. I. Grofova* and M. Zhou, Department of Anatomy, Michigan State University, East Lansing, MI 48824.

Pontomesencephalic tegmentum surrounding the superior cerebellar peduncle contains a prominent component of cholinergic neurons which are believed to control motor functions as well as behavioral states such as wakefulness and sleep. The core of this region is the pedunculopontine tegmental nucleus (PPN) which receives a major afferent input from the pars reticulata of the substantia nigra (SNr). However, it remains unclear whether the nigral afferents distribute evenly to both cholinergic and non-cholinergic components of the nucleus. We have addressed this issue in experiments involving anterograde labeling of nigral fibers with PHA-L combined with ChAT immunohistochemistry at both light and electron microscopic levels. The double labeled light microscope preparations showed an extensive overlap between the PHA-L labeled nigral fibers and the cholinergic cells in the PPN. However, the densest patches of nigral terminal varicosities were not in register with groups of cholinergic cell bodies. In the electron microscope, the majority of nigral terminals synapsed on unlabeled dendrites and cell bodies while synapses on ChAT positive dendrites and cell bodies were quite rare. These results strongly suggest that the nigral input to the mesopontine tegmentum is preferentially related to the non-cholinergic neurons. Supported by NIH NS 25744.

586.15

EFFERENT CONNECTIONS OF THE RETRORUBRAL FIELD (AS): A PHA-L STUDY IN THE RAT. S. J. SHAMMAH-LAGNADO*, M. COSTA, M. GOTO, A. PERACOLI and N. S. CANTERAS. Inst. Biomed. Sci., Univ. São Paulo, São Paulo, SP, 05508-900, Brazil.

Deposits of *Phaseolus vulgaris* leucoagglutinin (PHA-L) were placed in the retrorubral field (RRF), defined as containing the A8 dopaminergic cell group, in 20 rats. RRF fibers ascend mainly via the medial forebrain bundle and, besides providing a massive input to the striatal complex (caudate putamen, *fundus striati*, accumbens, olfactory tubercle, and amygdalostratial transition area), project to many other structures, among which the ventral pallidum, the substantia innominata, the anterolateral and anteroventral areas of the bed nuclei of the stria terminalis, the anterior basomedial and the medial part of the central amygdaloid nuclei, the lateral preoptic and the lateral and dorsal hypothalamic areas, the zona incerta, the centromedial, parafascicular (medial part), mediadorsal (caudal pole), ventromedial and midline thalamic nuclei, the central gray substance, the ventral tegmental area, the substantia nigra compacta, the interfascicular, rostral linear, caudal linear and dorsal nuclei of the raphe. Descending RRF fibers distribute to several reticular districts, the pedunculopontine and dorsolateral tegmental nuclei, the parabrachial area, and the nucleus of the solitary tract. Thus, RRF projections are in many respects similar to those of the ventral tegmental area and appear closely related to viscerolimbic circuitry. (Supp. FAPESP grant 91/0450-5)

MORPHOLOGICAL DEVELOPMENT OF RAT NEOSTRIATAL MEDIUM SPINY NEURONS INTRACELLULARLY LABELED WITH BIOCYTIN F. Trent* and J.M. Tepper. Center for Molecular and Behavioral Neuroscience, Rutgers The State University of New Jersey, Newark, NJ USA 07102

As part of an ongoing investigation of the postnatal development of the neostriatum, intracellular recordings were obtained in urethane anesthetized Sprague-Dawley rat pups ranging in age from postnatal day 6 (PD6) to PD40 and in adults. Using micropipettes filled with 3% biocytin or 2% neurobiotin in 1M potassium acetate, cells were filled by injecting 1-3 nA depolarizing current at a 50% duty cycle for 3-10 minutes. Cells were visualized using DAB and camera lucida reconstructions of representative examples from each age group were drawn from serial sections under a 60X or 100X oil immersion lens.

Although the maximal dendritic extent, mean number of proximal dendrites and dendritic tips were not age-dependent, spine density increased dramatically through PD29 with a sharp rise during the 3rd postnatal week. Prior to PD15, dendrites were thin, highly varicose and essentially aspiny, although cells bore sparsely distributed spines on both the soma and proximal dendrites that disappeared by the end of the 3rd week. Growth cones were not detected on either axonal or dendritic tips. Mean somatic cross-sectional area remained constant over development.

The local axon collateral field was as extensive in the youngest recovered neuron (PD8) as in adults. As is frequently observed in adults this collateral plexus was often positioned asymmetrically with respect to the parent neuron. In most cases the main axon could be traced through the internal capsule verifying that the neurons possessing thin and heavily varicose aspiny dendrites observed in young pups were indeed medium spiny neurons. The morphological development of the axonal system precedes the simultaneous appearance of the long-lasting hyperpolarization following cortical stimulation and the increase in spine density by 2 weeks. These data suggest that this hyperpolarization is independent of the axon collateral system, but is dependent on the development of spines and presumably axospinous inputs, consistent with the idea that the hyperpolarization is a disfacilitation. DEVELOPMENT OF THE RAT NEOSTRIATAL SYNAPTIC NEUROPIIL N.A. Sharpe* and J.M. Tepper. Aidelman Research Center, Center for Molecular and Behavioral Neuroscience, Rutgers University, Newark, NJ USA 07102.

Neostriatal neurophysiology and neuroanatomy undergoes significant postnatal developmental changes in the rat. We have previously shown that corticostriatal synapses are distributed differently at P14 than in adults. In the present study, the distribution of asymmetric neostriatal synapses in rats was compared at ages P10 and P21.

At the light level corticostriatal afferents labeled with biocytin terminated in clusters in P10 rats. This type of clustering was not seen in P21 or adults rats. At P10 the neostriatal neuropil appears immature with little myelination apparent and loosely packed synaptic vesicles in presynaptic terminals. The P21 neuropil appears similar to that in the adult with capsular fibers showing a relatively high degree of myelination and boutons relatively densely packed with synaptic vesicles. The total synaptic density at P10 (12.6 ± 0.9 synapses/100 μm^2) was less than at P21 (20.4 ± 1.3 synapses/100 μm^2) rats, $df = 20$, $t = -2.1$, $p < 0.05$. Most asymmetric synapses at P10 terminated on dendrites (67%) while at P21 relatively few asymmetric synapses were found on the dendrites (20%) with most synapses ending on spine heads (63%). The absolute axospinous synaptic density at P10 (2.1 ± 0.5 synapses/100 μm^2) was also lower than at P21 (12.6 ± 1.1 synapses/100 μm^2), $df = 20$, $t = -4.0$, $p < 0.01$. The axodendritic synaptic density at P10 (8.4 ± 0.7 synapses/ μm^2) was slightly but significantly less than that at P21 (11.9 ± 0.8 synapses/100 μm^2 ; $df = 20$, $t = 2.2$, $p < 0.05$). Comparison of synaptic vesicle size in axodendritic and axospinous presynaptic terminals revealed that vesicles were significantly larger at P10 ($43.5 \text{ nm} \pm 7.4 \text{ nm}$, $40.6 \text{ nm} \pm 5.9 \text{ nm}$ respectively) than at P21 ($37.6 \text{ nm} \pm 6.9 \text{ nm}$, $34.3 \text{ nm} \pm 4.2 \text{ nm}$ respectively) for both axodendritic ($df = 97$, $t = 4.0$, $p < 0.01$) and axospinous ($df = 106$, $t = 5.1$, $p < 0.01$) synapses. These data support previous anatomical and electrophysiological studies, indicating that in the first few postnatal weeks excitatory synapses in neostriatum are relatively undeveloped and that by P21 the neuropil has many of the ultrastructural attributes of the adult neostriatum. DIRECT CORTICONIGRAL PROJECTIONS IN THE RAT. Y. Shinonaga¹, M. Takada^{2*}, and N. Mizuno². ¹Department of Anatomy and Cell Biology, Faculty of Medicine, University of Toronto, Toronto, Ontario, Canada M5S 1A8. ²Department of Morphological Brain Science, Faculty of Medicine, Kyoto University, Kyoto 606, Japan.

Earlier anatomical and physiological studies have failed to unequivocally the presence of direct corticonigral projections, mainly due to the technical limitations at the times. Accordingly, no detailed systematic studies on direct projections from the cerebral cortex to the ventral midbrain tegmentum (VMT) have been available at all. Thus, employing both more sensitive retrograde and anterograde tracers, cholera toxin and *Phaseolus vulgaris*-leucoagglutinin, we made an attempt to examine how the corticofugal projections to the VMT are topographically organized in the rat. Cells of origin of these projections were located in extensive cortical fields including the prelimbic, infralimbic, lateral and medial precentral, agranular insular, orbital and anterior cingulate cortices. Terminal distribution of these cortical fibers were simplified into five different areas in the VMT, including the ventral tegmental area, medial, central and lateral zones of the substantia nigra, and retrorubral field. Furthermore, some of the fibers were passing through the VMT to reach the deep layers of the superior colliculus, periaqueductal gray and midbrain reticular formation. These results indicate that the direct corticofugal projections to the VMT are more extensive and well organized than have hitherto been considered in the rat. These cortical fibers may play an important role to provide another access rout to the VMT and these cortical information may influence directly upon the VMT. This work is partially supported by the Ministry of Education, Science and Culture of Japan.

CORTICOSTRIATAL PROJECTIONS FROM THE LATERAL SUPRASYLVIAN CORTEX OF THE CAT DEMONSTRATED WITH BIOCYTIN AND CALBINDIN IMMUNOHISTOCHEMISTRY. J.G. McHaffie^{1,2*}, K. Hoshino¹, M. Norita¹, and B.E. Stein². Dept. Anatomy, Niigata University School of Medicine, Niigata 951, JAPAN¹ and Dept. Physiology, Medical College of Virginia, Richmond, VA 23298².

We have demonstrated recently (McHaffie et al. *Prog. Brain Res.*, 1993) that regions along the lateral bank of the lateral suprasylvian (LS) sulcus, which modulates the activity of neurons in the deep laminae of the superior colliculus (SC), also projects to the striatum (ST). Presumably, these fibers form the first neuronal link in an 'indirect' projection that links the cortex with the SC. However, it has not yet been established if these corticostriatal fibers terminate on output neurons in the matrix of the ST. In the current experiments, we used the anterograde tracer biocytin in combination with calbindin immunohistochemistry, which specifically stains GABA-ergic output neurons in the matrix that project to the substantia nigra, pars reticulata or the globus pallidus. Injections of biocytin into the lateral bank of LS resulted in label in both the ST and the SC. In the ST, labeled fibers and terminals were found in the dorso-caudal aspect of the head of caudate (CA) and in the caudal part of the putamen (Put). In the CA, terminals were concentrated in the matrix, often in close apposition to calbindin-positive soma; few terminals were seen in the calbindin-negative 'patches'. In the Put, terminals were concentrated in a region adjacent to the external capsule. While these data demonstrate that corticostriatal fibers from LS terminate predominately in the matrix of the ST as delimited by calbindin immunohistochemistry, it remains to be determined with electron microscopic techniques if these terminals make direct contact with calbindin-positive output neurons. Supported by NSF grant INT-9211589 and NEI grant EY06562.

INTRINSIC EXCITATORY AND INHIBITORY CIRCUITS INTERCONNECT DIFFERENT FUNCTIONAL REGIONS OF THE CAUDATE NUCLEUS OF THE CAT. James S. Wilson*, Dept. Anat., Howard Univ. Col. Med., Washington, D.C., 20059.

Based on its cortical afferents, the neostriatum can be divided into different functional zones which include a dorsolateral motor region, an intermediate associational area and a medial limbic area. The purpose of this study was to determine if these different areas are interconnected by intrinsic circuits. An intrastriatal stimulating electrode was placed in the limbic area of the caudate (Cd) nucleus. An intracellular recording electrode was angled at 45° such that all functional areas of the Cd nucleus was traversed in a single electrode pass. In 42 neurons recorded in four cats, we found that 1) a single site of intrastriatal stimulation produced responses in all functional areas of the Cd nucleus, 2) an initial EPSP was recorded in 100% of the responsive neurons (40), and 3) the closer the recorded neuron was to the site of stimulation, the shorter was its response latency and larger was the amplitude of the EPSP. In addition, in 21 neurons, IPSPs were also recorded following the EPSPs. Because our recording electrode ran perpendicular to intrastriatal fiber bundles and because responses were recorded outside of the topographic area stimulated, we conclude that intrinsic excitatory and inhibitory circuits interconnect different functional areas of the Cd nucleus. In light of past experiments, we suggest that intrinsic circuitry can recruit assemblies of neurons not defined by extrinsic-afferent connections alone resulting in a stimulus evoked synchronization of neuronal activity.

FINE STRUCTURE OF EXTERNAL PALLIDAL TERMINALS WITHIN THE MONKEY THALAMIC RETICULAR NUCLEUS. **C. Asanuma*** Laboratory of Neurophysiology, National Institute of Mental Health, NIH Animal Center, Poolesville, MD 20837.

The external pallidal projection to the squirrel monkey thalamic reticular nucleus (TRN) was examined in the electron microscope following injections of WGA-HRP into the external segment of the globus pallidus and immunohistochemistry for GABA. In brief, vibratome sections through the brains were processed for anterogradely transported WGA-HRP, and blocks of tissue through the TRN processed for electron microscopy. Thin sections were immunohistochemically stained for GABA directly on the grids with colloidal gold.

The most common GABAergic synaptic profiles within the monkey TRN neuropil are large boutons packed with many pleomorphic vesicles as well as mitochondria. These boutons stain densely for GABA, are always presynaptic, and establish *symmetric* synaptic contacts upon the somata and dendrites of TRN neurons. This GABAergic terminal type thus displays several features of the previously described F terminals in monkey dorsal thalamic nuclei and F1 terminals in the cat lateral geniculate and perigeniculate nuclei. A small number of GABAergic profiles which participate in serial synapses was also found within the TRN neuropil. These profiles are in receipt of synapses and establish *symmetric* synaptic contacts upon TRN dendrites. The GABA staining within these profiles is weak and they contain fewer vesicles and mitochondria than the F terminals. The external pallidal terminals, labeled with HRP, arise from thinly myelinated axons, and resemble F terminals; viz. they are large, packed with many pleomorphic vesicles and mitochondria, are always presynaptic, stain densely for GABA, and establish *symmetric* synapses. The pallidal terminals are frequently presynaptic to the somata and proximal dendrites of TRN neurons. HRP reaction product is never seen in profiles which participate in serial synapses.

These observations indicate that the external pallidal terminals within the monkey TRN resemble F terminals and establish *symmetric* synaptic contacts frequently upon the somata and proximal dendrites of TRN neurons. The fine structure and cellular relationships of other GABAergic synaptic profiles within the TRN, arising from both extrinsic and intrinsic sources, remain to be detailed.

587.5

SHELL AND CORE IN THE PRIMATE VENTRAL STRIATUM IDENTIFIED WITH ANTIBODIES AGAINST CALBINDIN. **G.E. Meredith¹, A. Pattiselanno¹, H.J. Groenewegen¹ and S.N. Haber²**. ¹Department of Anatomy, Faculty of Medicine, Vrije Universiteit, Amsterdam, The Netherlands and ²Department of Neurobiology and Anatomy, University of Rochester Medical Center, Rochester, N.Y. 14642.

Shell and core subdivisions, which are recognized in nucleus accumbens of the rat ventral striatum, differ in the distributions of various neurochemicals and receptors and in their patterns of connectivity. In particular, the shell has been most closely associated with inputs from the limbic system. To explore whether comparable striatal regions exist in primates, we immunoreacted striatal sections of marmoset and Rhesus monkey brains for calbindin and stained adjacent sections for Nissl. In the ventral striatum of both primates, a medial and ventral zone can be distinguished; in the Rhesus monkey, this zone is consistently poor in calbindin-immunostaining whereas in the marmoset, it appears more inhomogeneous. In both species, the cell density is lower than the more central zone. In the rat ventral striatum, a medial and ventral calbindin-poor zone which is also low in cell density, i.e. the shell, extends into the rostralmost parts of the striatum, whereas in both primates, this zone first appears a few millimeters caudal to the striatal rostral pole. As in the rat, this region in the primate extends into the caudalmost nucleus accumbens. For both primates, the staining and cytoarchitectural characteristics suggest a "shell" identity for the region. When compared to the rest of the striatum, however, the full extent of the primate shell appears to be proportionally smaller than that of the rodent. In both primates a rich but unevenly immunostained region, the "core", lies central to the shell. It is not possible to discern a clear border between the core and the ventral caudate nucleus or the putamen.

587.7

ORGANIZATION OF CHEMICAL COMPARTMENTALIZATION IN THE HUMAN STRIATUM. **D.J. Holt*, A.M. Graybiel, and C.B. Saper**. Comm. on Neurobiology, Univ. of Chicago, Chicago, IL 60637, Dept. of Brain and Cognitive Science, MIT, Boston, MA 02139, and Dept. of Neurology, Harvard Medical School/Beth Israel Hospital, Boston, MA 02115.

We recently demonstrated a pattern of cholinergic innervation of the human striatum that extends the traditional "striosome-matrix" model by recognizing the presence of three compartments with distinct levels of innervation. We now compare the compartmental segregation of other chemically-defined fiber systems, as defined by immunocytochemical staining of adjacent sections for choline acetyltransferase (ChAT) vs. met-enkephalin, tyrosine hydroxylase, or calbindin. The boundaries of the cholinergic compartments were largely respected by the other three markers, but the relationships of staining intensities were often quite complex. For example, previous studies have often assumed that striosomal and matrix compartments are identical, whether defined by cholinergic or calbindin staining. We found that, in the putamen and nucleus accumbens, regions representing the lighter staining compartments in ChAT sections were often calbindin-rich. The reversal of relative staining intensities suggests that the varying combinations of different chemical markers in the striatal compartments allow regionally specialized, transmitter-specific processing.

587.4

THE (VENTRAL) PALLIDOSTRIATAL PATHWAY IN THE MONKEY: EVIDENCE FOR INTEGRATION OF BASAL GANGLIA CIRCUITS. **W.P.J.M. Spoooren*, E. Lynd-Balta, S. Mitchell, & S.N. Haber**. Dept. of Neuro. & Anat., Univ. of Rochester, Rochester NY 14642, U.S.A.

Current theories suggest that the basal ganglia consist of functionally segregated circuits which form parallel pathways from cortex via striatum to pallidum and substantia nigra and via the thalamus back to the cortex. However, this hypothesis incorporates an idea of unidirectional flow of information through the basal ganglia which lacks consideration of important feedback information. For instance, it has been shown that the pallidum projects back to the striatum, i.e. the pallidostriatal pathway, suggesting a bi-directional flow of information between the striatum and the pallidum. The pallidostriatal pathway has been investigated to some extent in the rat and the cat. However, relatively little is known about this pathway in the monkey. Understanding of the organization of this pathway in the monkey is important for the integration of this connection into theories on basal ganglia function. Accordingly we studied the pallidostriatal pathway in the monkey with special emphasis on the striatal projections of the ventral pallidum. Small circumscribed injections of both retrograde (HRP & Lucifer yellow (LY) and anterograde tracers (PHA-L, LY & tritiated amino acids) were made into various regions of the ventral and dorsal pallidum as well as into the striatum. The results demonstrate that the pallidostriatal pathway is an extensive pathway in the monkey. It is organized in a topographic manner preserving a general, but not strict medial to lateral and ventral to dorsal organization. The terminal arrangement of pallidostriatal fibers is widespread such that non-adjacent pallidal regions send fibers to the striatum that show considerable overlap in the striatum suggesting convergence of terminals from different segregated pallidal regions. Moreover, the pallidostriatal pathway is found to have a reciprocal but also a large non-reciprocal component to the striatopallidal pathway. Thus segregated pallidal regions converge in the striatum. On the basis of these data it is concluded that segregation of so-called cortico-basal ganglia-cortical pathways is maintained in the striatopallidal direction but not in the pallidostriatal direction. HIGHLY RESTRICTED INPUTS TO STRIOSOMES FROM PREFRONTAL CORTEX IN THE MACAQUE MONKEY. **F. Eblen* and A.M. Graybiel**. Dept. of Brain & Cogn. Sci., MIT, Cambridge, MA 02139.

We have previously demonstrated that the caudal orbital cortex is a major source of striosomal afferents in macaque monkey, whereas the remaining orbitofrontal cortex and nearby convexity strongly innervate the matrix. To continue our investigation of the prefronto-striatal projection, we made intracortical deposits of anterograde tracers (L-[35S]-methionine and WGA-HRP) in various areas of medial prefrontal and dorsolateral prefrontal cortex of 6 adult cynomolgus monkeys (*Macaca fascicularis*). Tracer distributions were studied in relation to striosome/matrix compartments demonstrated by stains for enkephalin and acetylcholinesterase.

The results indicate that most medial prefrontal areas, and dorsolateral prefrontal cortex, project predominantly to the striatal matrix. Only medial prefrontal cortex immediately rostral to the tip of the corpus callosum projected to striosomes. Striosomes labeled were mainly in the caudate nucleus; farther ventrally, enkephalin-rich zones, apparently matrix, were also labeled. Striosomes were never labeled in the dorsolateral caudate nucleus and most of the putamen. The projection fields from most prefrontal areas partially overlapped, with dorsolateral prefrontal cortex projecting the most laterally and prefrontal cortex medially along the ventricular wall.

The present findings are reminiscent of the results obtained with orbital injections. Only preorbitocortex labeled striosomes, the more dorsal striosomal projection was accompanied by ventral matrix labeling but the nucleus accumbens was spared. The sets of striosomes in the ventromedial caudate nucleus and parts of the ventral matrix targeted by posterior orbital and precallosal cortex may comprise a "prelimbic" area of the primate striatum.

587.8

THE ORGANIZATION OF TEMPORAL LOBE LIMBIC INPUTS TO THE VENTRAL STRIATUM IN MACAQUE MONKEYS. **D.P. Friedman*, J.P. Aggleton*, R.C. Saunders*, & S. Vinsant**. Bowman Gray School of Medicine, Wake Forest University, Winston-Salem, NC 27157, *Dept. Psychology, University of Durham, Durham, UK, and *Clin Brain Disorders Branch, NIMH, Bethesda, MD.

The projections to the ventral striatum from the hippocampus, rhinal sulcus, and amygdala were examined using both anterograde and retrograde tracers. The patterns of these inputs were then related to the distributions of neurochemical markers revealed by immunohistochemistry.

The hippocampal inputs arise primarily from the subiculum and adjacent regions of CA1. They terminate throughout the rostro-caudal extent of nucleus accumbens (NAS), but are almost exclusively restricted to the medial and ventral portions of this structure. Only light projections were found in the striatal portion of the olfactory tubercle. The entorhinal and perirhinal regions had a very similar pattern of NAS terminations, but they also provide an input to the olfactory tubercle.

Inputs from the amygdala, by contrast, are dense in the olfactory tubercle. A lighter projection to NAS, which arises primarily in the basal nucleus, is most dense in the caudal and ventral portions of this structure. Whereas there is considerable overlap between the amygdala, rhinal, and hippocampal inputs, there are differences. In particular, the distribution of the hippocampal and rhinal inputs appears to correspond closely to the calbindin-poor regions in the NAS. Furthermore, these projections also mapped onto a less cell-dense portion in medial and ventral accumbens that may correspond to the so-called "shell" region. The amygdala projections were more widespread and were not confined to the calbindin poor zone. Supported by NIDA 07955.

THE CINGULOSTRIATAL PROJECTION IN THE MONKEY: RETROGRADE TRACING STUDY. K. Kunishio* and S.N. Haber, Dept. of Neurobiology and Anatomy, Univ. of Rochester, Rochester, NY 14642

The ventral portion of the striatum receives input from structures related to the limbic lobe, and the dorsolateral region receives input from sensorimotor cortex. As part of a larger study to understand the organization of limbic-related striatal input, we studied the organization of the cingulostriatal projections in the monkey using the retrograde tracers such as Lucifer yellow (LY) and horseradish peroxidase conjugated to wheat germ agglutinin (HRP-WGA) that were injected into the different regions of the ventral and dorsolateral striatum. Routine immunocytochemistry was performed on 50µm sections. The rostroventral part of the caudate nucleus receives input from the rostral part of the anterior cingulate cortex. The ventral part of the putamen receives input from both anterior and posterior cingulate cortex. Projections to the core of nucleus accumbens are derived from the anterior cingulate cortex (areas 25, 24a, 24b, and 24c). However, labeled neurons in area 24c are found mainly in the medial portion of the lower bank of the cingulate sulcus. The shell of the nucleus accumbens receives fibers from areas 25, 24a, and 24b. In contrast, dorsolateral striatum receives projections from areas 24c and 23c, mainly from the lateral portion and the fundus of the cingulate sulcus. The results indicate that the lateral portion and the fundus of areas 24c and 23c project to the dorsolateral striatum, and the medial portion projects to the ventral striatum. It is possible that areas 24c and 23c are associated with the different functions such that the lateral portion and the fundus of each area are related to the motor function, whereas the medial portion is associated with limbic related function. Supported in part by MH45573

587.11

THE RETICULAR THALAMIC NUCLEUS (RTN) PROJECTS CONTRALATERALLY TO THE CENTROMEDIAN/PARAFASCICULAR COMPLEX (CM/Pf) IN PRIMATES, BUT NOT TO THE PARAFASCICULAR NUCLEUS (PF) IN RODENTS. L.-N. Hazrat*, D. Pinault, and A. Parent, Lab. of Neurobiology, University Laval, Québec, Canada, G1J 1Z4

Retrograde and anterograde tracing studies have been conducted to investigate the contralateral RTN projection to the CM/Pf in squirrel monkeys and to Pf area in rats. In monkeys, injections of the fluorescent retrograde tracer true blue (TB) into CM/Pf area labeled RTN cells on both ipsilateral and contralateral sides. However, the labeled cells were less numerous (1/5) contralaterally than those seen on the ipsilateral side. Anterograde tracing with biocytin in monkeys lead to the labeling of very few RTN fibers that crossed the midline and arborized in the contralateral thalamus. These observations demonstrated that the RTN projections to contralateral thalamus exists in squirrel monkeys, but are not very extensive. In Sprague-Dawley rats, we did not observe any labeling in the contralateral RTN following TB injection in the Pf. However, in these experiments a heavy labeling of cell bodies was observed on the ipsilateral side. In addition, a few cells were seen in the contralateral side, specifically in an ill-defined area that borders the RTN and zona incerta (ZI). The use of cholera-toxin as retrograde tracer combined to parvalbumin (PV) and calbindin (CaBP) immunohistochemistry demonstrated that these few cells were located in the CaBP-rich ZI and were not in the PV-rich RTN. Anterograde tracing experiments with biocytin in rats, did not lead to the labeling of any RTN fiber on the contralateral side, thus confirming the results obtained with retrograde labeling technique. In summary, this study has revealed the presence of a discrete contralateral RTN projection to the CM/Pf area in squirrel monkeys, whereas the contralateral projection to Pf could not be confirmed in rodents. The negative results in rodents do not preclude the possible existence of contralateral RTN projections to other thalamic nuclei, as reported previously. Nevertheless, we believe that contralateral projections of RTN should be reviewed for each of the thalamic nuclei in various species so as to delineate the functional significance of such contralateral projections.

587.13

RETICULAR THALAMIC NUCLEUS INPUT TO THE NUCLEI OF THE MONKEY THALAMUS: LIGHT AND ELECTRON-MICROSCOPIC STUDY. H. Yi, I.A. Ilinsky*, and K. Kultas-Ilinsky, Dept. of Anatomy, Univ. of Iowa Coll. Med. Iowa City, IA, 52242.

The reticular nucleus of the thalamus (RNT) is believed to regulate the flow of information between the thalamus and cortex. Yet, its synaptic relationships with thalamocortical projection neurons (PN) and local circuit neurons (LCN) are largely unknown, especially in primates. In this study, iontophoretic injections of WGA-HRP or PHA-L were made at different RNT locations, and labeled fibers and terminals were traced in limbic and motor thalamic nuclei. Additionally, postembedding immunocytochemistry with anti-GABA antibody was performed in WGA-HRP labeled tissue.

The results demonstrate that single RNT fibers travel distances of several millimeters posteriorly from the injection site, giving off occasional short thin branches terminating with enlargements. In none of the nuclei studied were RNT boutons seen to form pericellular baskets; instead, they appeared to be distributed randomly in the neuropil. EM analysis confirmed that RNT terminals made a few synaptic contacts at all levels of somadendritic membrane of PN as well as LCN. Internuclear differences in the ratio of RNT contacts on PN and LCN, and the overall bouton distribution pattern and density were noted suggesting functional differences in the mode of RNT interaction with different thalamic nuclei. Supported by NSF Grant 9109065.

POST-ROLANDIC CONNECTIONS OF THE MEDIAL PULVINAR IN THE RHESUS MONKEY. D.F. Siwek* and D.N. Pandya, E.N.R.M. Veterans Administration Hospital, Bedford, MA, 01730

Retrograde (HRP) and anterograde (RLAA) neuronal pathway tracers were injected into the thalamus of 5 adult rhesus monkeys to examine the pattern of the connections between the medial pulvinar (Pul_m) and the cerebral cortex. The results showed that an injection of HRP that encompassed the medial pulvinar, labeled neurons in the inferior parietal lobule (areas Opt, PFG), superior temporal gyrus (TS1, TS2, TS3), superior temporal sulcus, STS (areas TPO₁₋₃, IPa, PGa, OAA) and Insula. Additionally, labeled neurons were found on the medial surface (areas 23, PGm, and retrosplenial cortex) and in the parahippocampal gyrus (areas TF, TH, and TL and presubiculum). A similar injection of RLAA showed a nearly identical pattern of labeling indicating that these projections are reciprocal. When the injection was limited to the central portion of Pul_m, label was observed only in the polymodal cortex, areas TPO_{2&3}, within STS and in area TS1 and TS2 to a slight extent. When a similar injection extended dorsally in Pul_m, the pattern of labeling in the STS was the same, but label also occurred in retrosplenial cortex, area 23, Presubiculum, TL and TH.

These data show that whereas neurons in the central portion of Pul_m are reciprocally connected with the polymodal cortex of the STS, thalamic cells lying in more peripheral locations within the Pul_m are connected with post-Rolandic parasensory association areas of the temporal and parietal cortices. (Supported by NIH grant 16841 and the ENRM VA Hospital, Bedford, MA, 01730)

587.12

THE THALAMIC RETICULAR NUCLEUS (TRN) IN THE MONKEY: A CYTOARCHITECTONIC AND MORPHOLOGICAL STUDY. J. Lübke*, Department of Human Anatomy, University of Oxford, Oxford OX1 3QX, UK.

The monkey TRN is a sheet of GABAergic neurons which surrounds most of the dorsal thalamus. The main body of TRN consists of 5-8 layers of cells bordering from rostral to caudal, the lateral part of the anteroventral, ventrolateral and ventrobasal nuclei and the lateral geniculate nucleus. The continuity of the TRN with the zona incerta is obvious in coronal sections. In a region assigned to the perireticular nucleus in cats only a few scattered small cells could be observed in the adult monkey TRN. To investigate whether neurons differ morphologically in certain sensory parts (sectors) of the TRN I have injected neurons intracellularly with Lucifer yellow using a fixed slice preparation. Neurons in the caudal (visual) and intermediate (somatosensory) sectors of the TRN have a fusiform, elongated morphology. Neurons have round, ovoid or elongated somata ranging in area between 625-900 µm². In general, 3-7 primary dendrites, often with a very thick initial segment, emerge from the two poles of the soma, which then run parallel to the two borders of the nucleus for up to 500 µm. Only a few, shorter dendrites run perpendicular to the plane of the nucleus. The dorso-rostral part (motor, limbic) of the TRN contains some neurons with a multipolar morphology, but they are intermingled with fusiform neurons. Some of the smooth 1st order dendrites give rise to 2nd order dendrites (7-12) which branch into shorter 3rd order dendrites (2-5). Spine-like protrusions and/or hair-like processes as well as dendritic varicosities are mainly found on 2nd and 3rd order dendrites. In contrast to reported heterogeneity of TRN neurons in somatostatin and calbindin-immunoreactivity in the cat and monkey and the expression of calbindin in a discrete population of rat TRN neurons during development we have found no basis for classification of monkey TRN neurons according to their dendritic morphology. *Supported by the Wellcome Trust.

SYNAPTIC RELATIONSHIPS OF CEREBELLAR AFFERENT TERMINALS IN THE MONKEY THALAMUS STUDIED IN SERIAL SECTIONS AND 3D RECONSTRUCTIONS. A. Mason, S. Beck, H. Yi, K. Kultas-Ilinsky* and I.A. Ilinsky, Dept. of Anatomy, Univ. of Iowa, Coll. of Med., Iowa City, IA 52242.

Previous EM studies of cerebellar afferent terminals to the monkey thalamus have demonstrated their engagement in a variety of complex synaptic relationships with dendrites of projection (PN) and local circuit neurons (LCN). However, the analysis of single ultrathin sections at random did not allow to appreciate the real spatial organization of these synaptic arrangements.

In this study WGA-HRP injections were made in dentate nuclei bilaterally. Labeled cerebellar boutons (CB) in the ventrolateral thalamic nucleus were analyzed both quantitatively and qualitatively in serial ultrathin sections. Then the outlines of CB and associated structures were digitized, aligned and reconstructed into 3-dimensional images using Silicon Graphics hardware and Alies Studio software.

Our results indicate that a single CB contacts no more than 2 PN dendrites but up to 5 vesicle containing LCN dendrites. The number of synaptic contacts established on each PN dendrite by a single CB can be as high as 12, whereas on a single LCN dendrite it is usually 1, or 2 at most. Dendro-dendritic contacts between LCN and PN dendrites contacted by the same CB were found but infrequently. In contrast, dendro-dendritic synapses between LCN dendrites receiving synapses from the same CB were significantly more frequent.

These results further illustrate the complexity of thalamic circuits processing cerebellar information prior to its transmission to the cortex. Supported by RO 1 NS 24188.

GLUTAMATERGIC INPUTS FROM THE PEDUNCULOPONTINE NUCLEUS TO THE MIDBRAIN DOPAMINERGIC NEURONS IN PRIMATES: A LIGHT AND ELECTRON MICROSCOPIC STUDY. A. Charara*, Y. Smith and A. Parent. Centre de Recherche en Neurobiologie, Hôpital de l'Enfant-Jésus, Québec, Canada, G1J 1Z4.

The present study was undertaken to investigate the pattern of synaptic innervation of the midbrain dopaminergic neurons by the ascending fibers from the pedunculopontine nucleus (PPN) in primates. For this purpose, adult squirrel monkeys (*Saimiri sciureus*) were used, and the anterograde transport of *Phaseolus vulgaris*-leucoagglutinin (PHA-L) was combined with immunohistochemical techniques for the visualization of tyrosine hydroxylase (TH) and the calcium binding protein calbindin D-28K (CaBP) at both light and electron microscopic levels. At the light microscopic level, injections of PHA-L in the PPN were seen to produce a dense anterograde labeling of fibers and axonal varicosities that arborized profusely throughout the rostrocaudal extent of the substantia nigra pars compacta, ventral tegmental area and retrorubral area, but much less so in the substantia nigra pars reticulata. The anterogradely labeled varicosities were often closely apposed on the surface of dendritic shafts and perikarya that displayed TH or CaBP immunoreactivity. At the electron microscopic level, the PHA-L-immunoreactive terminal boutons were found to be heterogeneous in size (ranging from 0.5 to 1.5 µm in maximum diameter), contained numerous densely packed round electron lucent vesicles, a few dense core vesicles and 1-2 mitochondria. These terminals formed asymmetric synapses predominantly with dendritic shafts displaying TH immunoreactivity. Moreover, postembedding immunogold techniques demonstrated that some of these terminals expressed glutamate immunoreactivity.

Our findings provide the first ultrastructural evidence for the existence of a glutamatergic input from the pedunculopontine nucleus to the midbrain dopaminergic neurons in primates. This excitatory brainstem input may play a crucial role in the functional organization of the basal ganglia, in both normal and pathological conditions. (supported by the MRC and FRSQ)

DIGITIZED ANATOMY CORRELATED WITH [18F]fluoro-L-DOPA-PET IN MONKEY.

A. W. Toga*, W.P. Melega, M.J. Raleigh, S.C. Huang, D.C. Yu, M.E. Phelps, B. Quinn, B.A. Payne, and K. Ambach

Laboratory of Neuro Imaging, Dept of Neurology, Pharmacology and Psychiatry, UCLA Sch. of Med. Los Angeles, CA. 90024

Interpretation of functional anatomic scans is hampered by low resolution and limited structural detail. Mapping functional or metabolic data upon its anatomic counterpart helps accurately identify the site action. We have been able to improve delineation of regions of interest of [18F]fluoro-L-DOPA (FDOPA) PET data by mapping onto higher resolution digital anatomic data from the same animal.

An adult male monkey (vervet) received a pre-amphetamine control FDOPA scan followed by 10d of chronic amphetamine treatment (incremental dose from 4mg/kg/d to 18mg/kg/d; i.m.). A post-drug FDOPA scan was obtained at one week and one month and the animal immediately sacrificed. The head was rapidly frozen in liquid nitrogen and cryosectioned on a modified PMV cryomicrotome. High resolution color images (1024², 24-bit per pixel) were digitized directly from the cryoplaned blockface at 300 micron intervals (Quinn *et al.*, Soc. Neurosci., 1992). Anatomical images were reconstructed into a three dimensional (3D) volume that served as a reference template for interpretation of PET data. Pre- and post-drug FDOPA scan data were mapped to this anatomic data using a global matching transformation. Significant reductions of [18F] activity were identified in striatal structures. Higher resolution digitized anatomy and multimodality mapping enabled us to be more specific in the localization of sites of action and appreciate greater detail in metabolically active dopaminergic structures.

CORTICAL AND SUBCORTICAL INPUTS TO THE CENTROMEDIAN-PARAFASCICULAR THALAMIC COMPLEX IN PRIMATES. P.-Y. Côté*, A. Charara and A. Parent. Centre de Recherche en Neurobiologie, Hôpital de l'Enfant-Jésus, Québec, Canada, G1J 1Z4.

Recent studies in our laboratory documented the relationship between the centromedian-parafascicular thalamic complex (CM-Pf) and the basal ganglia in primates. From these studies emerged the concept that the thalamus actively participates in information processing through the basal ganglia. The aim of the present study is to examine the cortical and subcortical afferents to the CM-Pf complex, using the retrograde tracers WGA-HRP and cholera toxin B subunit. After injections centered upon the CM-Pf complex, retrograde cell labelling occurred in both cortical and subcortical structures. At cortical levels, retrogradely labelled neurons were found principally in cingulate, parietal, temporal, frontal and prefrontal cortices. Cortical labelled cells were large, polymorphic and distributed according to a specific laminar pattern. Most labelled neurons occurred in layer V, where they displayed a pyramidal shape, whereas smaller, oval neurons were found principally in layer VI. At subcortical levels, labelled cells were encountered in the following structures: reticular thalamic nucleus, internal pallidum segment, basal accessory amygdaloid nucleus, substantia nigra, and brainstem nuclei including the pedunculopontine nucleus, laterodorsal tegmental nucleus, central and dorsal raphe nuclei, and locus coeruleus. Labelled cells also occurred contralaterally in the rostradorsal half of the reticular thalamic nucleus, in the anterior and middle regions of the cingulate cortex and in brainstem nuclei.

These findings indicate that the major inputs to the CM-Pf complex come from a highly heterogeneous set of structures among which the ipsilateral cerebral cortex, reticular thalamic nucleus and brainstem are the most prominent. The results of our current studies should help to refine the emerging concept suggesting that CM and Pf are respectively associated with the "motor" and "associative" aspects of basal ganglia function via two distinct, parallel circuits.

A COMPARISON BETWEEN PROJECTIONS OF ORBITAL CORTEX AND AMYGDALA TO THE MEDULLARY LATERAL TEGMENTAL FIELD IN THE CAT. B. F. M. Blok, L. J. Mouton* and G. Holstege. Dept. Anatomy, Groningen, Netherlands.

Recently a new concept was presented to divide into the motor system in three subsystems (Prog. Brain Res., vol. 87, 1991, p. 398). A basic motor system exists containing premotor interneurons, and a somatic motor system controlling proximal and distal muscles. The third system is the emotional motor system (EMS) with a medial component determining the gain setting of motoneurons, and a lateral component involved in eliciting specific emotional behavior. The orbitofrontal cortex, the central nucleus of the amygdala (CA) and the bed nucleus of the stria terminalis (BNST) are thought to be part of the lateral component of the EMS. The question arises what the relation is between these parts of the lateral components. In 4 cats 10-50 nl WGA-HRP was injected into the medullary lateral tegmental field (LTF). Retrogradely labeled cells were observed bilaterally in the orbital gyrus (OG), and ipsilaterally in the CA and the lateral part of the BNST (BNSTL). After a large injection in dorsal parts of the LTF at the level of the facial nucleus retrograde labeling was observed in lamina V in the lateral bank of presylvian sulcus, the orbital gyrus and coronal gyrus. The CA and the BNSTL were extensively filled with retrogradely labeled cells. After a small injection in the LTF dorsal to the facial nucleus retrogradely labeled cells were observed only in lamina V of the ventral part of the lateral bank of the presylvian sulcus and in the medial part of the OG. Labeled neurons were present in the central parts of CA and in the most ventral and lateral parts of BNSTL only. The results suggest that the medullary LTF receives afferents from the OG, the CA and the BNSTL in a topically organized manner. A major difference between the projections of the OG and the CA and the BNSTL to the LTF is that the OG projects bilaterally, and the CA and BNSTL ipsilaterally. The similarity between the OG, CA and BNSTL projections to the medullary LTF suggests that all three areas are involved in similar emotional motor systems, but the bilaterality of the OG projections suggests a more specific projection system originating in the orbital gyrus.

AFFERENTS TO THE NUCLEUS MAGNOCELLULARIS OF THE MEDULLA. Y. Y. Lai*, J. R. Clements and J. M. Siegel. Dept Psychiat, UCLA and Neurobiol Res, VAMC, Sepulveda, CA 91343, Dept Vet Anat, Texas A&M Univ, College Station, TX 77843.

The nucleus magnocellularis (NMC) had been found to relate to both motor and cardiovascular activities. NMC glutamate receptors are involved in motor activation and inhibition, while both glutamate and acetylcholine receptors participate in cardiovascular regulation. This experiment was designed to identify the afferent projections to the NMC. Fifty nanoliters of 2.5% WGA-HRP was injected into the NMC. After 2 days, cats were sacrificed and their brainstems processed with TMB, NADPH-d and glutamate immunohistochemistry. Heavy concentrations of WGA-HRP neurons were found in nuclei reticularis pontis oralis and caudalis, Edinger-Westphal, Kolliker-Fuse, and paraventricular; moderate concentrations in periaqueductal gray, mesencephalic reticular formation, retrorubral, paralemnisal tegmental field, cuneiformis, subcoeruleus and parvocellularis; light concentrations in pedunculopontine (PPN), trigeminal sensory, gigantocellularis, vestibular complex, lateralis reticularis, and medullae oblongatae centralis. Double-labeled WGA-HRP/glutamate and WGA-HRP/NADPH-d neurons could be found throughout the brainstem nuclei. However, no cholinergic neurons (LDT/PPN neurons with NADPH-d staining) double labeled with WGA-HRP.

BURST ACTIVITY IN THE LATERAL MEDULLARY RETICULAR FORMATION OF THE TURTLE. *L. N. Eisenman*, R. Sarrafizadeh, and J. C. Houk.* Department of Physiology, Northwestern University Medical Center, Chicago, IL 60611-3008.

It is believed that burst activity in the cerebellorubral network is supported by positive feedback transmitted through recurrent excitatory connections. Recent anatomical studies (Sarrafizadeh et al. *Neurosci. Lett.* 149:59, 1993) have demonstrated the existence of the lateral reticular nucleus (LRN) in the lateral medullary reticular formation (LMRF) of the turtle. To further understand bursting in the cerebellorubral network, we initiated extracellular recording studies of the cells in the LMRF.

The *in vitro* brainstem-cerebellum was prepared from freshwater pond turtles (*Chrysemys picta*), and stimulating electrodes were placed in the spinal cord (SC) and cerebellar cortex (CB). Recordings were made from 31 cells at depths from 300 to 1000 μ m from the ventral surface. Electrode tracks and lesions suggest that we were recording in the region of the LRN. The cells show little spontaneous activity so they were located by their responses to single pulses or trains to either SC or CB. Short latency responses to single pulses to the SC were recorded from 6 cells with latencies varying between 2.5 and 40 ms, and 16 cells burst to 100 Hz SC stimulation. 10 cells showed short latency responses to CB stimulation with latencies varying between 4 and 30 ms, and 19 cells burst to 100 Hz stimulation of CB. Bursts outlasted the stimulus by as much as several seconds and achieved frequencies up to 50 Hz.

Since these cells displayed activity similar to that seen in red nucleus (RN), we attempted simultaneous recording. In four cases we isolated single units in the contralateral RN while recording from LMRF. In our best case both cells burst simultaneously in response to 100 Hz train stimulation of SC. The cells displayed tapered bursting behavior where the firing was initially vigorous and then slowly tapered off. In some trials, the bursts were not tightly linked. The variability of the responses may result from differing levels of activity in the multiple recurrent pathways affecting each of the cells. Simultaneous RN and putative LRN bursts with similar temporal patterns support the recurrent network concept.

CONNECTIVITY PATTERNS OF SINGLE LAST-ORDER PAD MEDIATING INTERNEURONS WITH TWO BRANCHES OF THE SAME GROUP I FIBER. *J. N. Quevedo*, J. R. Equibar, I. Jiménez and P. Rudomin.* Dept. of Physiol. CINVESTAV and ICUAP, México 07000.

In the anesthetized cat, we have analyzed the connections of single last-order interneurons mediating PAD with two intraspinal branches of the same afferent fiber. A pair of stimulating micropipettes was introduced into the intermediate nucleus, with tips separated 0.5-5 mm, to produce antidromic responses in both branches. PAD in each branch was detected as a reduction of the intraspinal threshold. Last-order PAD mediating interneurons were directly activated through the same micropipettes used for excitability testing. At short conditioning-testing stimulus intervals (1.5-2 ms) the PAD evoked by conditioning microstimulation (μ S) is monosynaptic (MS-PAD). In 10/14 of fibers, μ S with a low strength (below that required to antidromically activate the proximal branch of the afferent fiber), produced MS-PAD in the proximal but not in the distal branch. When the strength of the intraspinal stimulus was increased, the MS-PAD elicited in the proximal branch grew by 2-3 discrete steps, suggesting recruitment of additional interneurons. Some (but not all) of these interneurons appeared to be connected also with the distal branch ($n=2$). In one fiber μ S applied through one micropipette produced MS-PAD in the distal branch but not in the proximal branch, whereas μ S applied through the other micropipette produced MS-PAD in both branches. This observation discards the possibility that the effect of μ S was due to a non-synaptic mechanism (i.e., local responses). Our results suggest a) that some of the PAD mediating interneurons make selective contacts with a single branch while others may have contacts with at least two branches of the same afferent fiber; b) that a single branch can be target of more than one interneuron and c) that the effects produced by interneurons synapsing with one branch can be rather discrete and may not spread to the other branch. This arrangement could be the basis for the selectivity in the control exerted by the motor cortex on PAD-mediating interneurons shown in the accompanying presentation. CHANGES IN POLYSYNAPTIC INPUTS TO MOTONEURONS DURING A REVERSIBLE COLD BLOCK OF THE DORSOLATERAL CAT SPINAL CORD. *J.F. Miller*, K.D. Paul, W.Z. Rymer and C.J. Heckman.* Physiology, Northwestern Univ. & Veterans Administration, Lakeside Hospital, Chicago IL 60611

A reversible cold block of the dorsal thoracic spinal cord of the cat was employed to study the effects of dorsolateral descending pathways on synaptic inputs to hindlimb motoneurons. This technique allows intracellular recordings of synaptic potentials to be obtained before and during the block in the same cell. Two afferent input systems have been studied thus far: the ipsilateral cutaneous sural nerve and the contralateral tibial nerve. Both nerves generate a mixture of excitation and inhibition in extensor motoneurons.

In the precollicular decerebrate preparation prior to cold block, the excitatory components of these inputs are dominant. Prolonged electrical stimulation (1s, 50-100 Hz) of either nerve resulted in a powerful reflex excitation of the cat medial gastrocnemius (MG) muscle. However, during the cold block, the reflex excitation was either markedly reduced or, in 2 of 6 experiments, actually converted to net inhibition. Similarly, intracellular recordings of the synaptic potentials elicited by these two inputs in MG motoneurons before and during cold block have shown that the inhibitory components of the PSPs were substantially increased (10-80%) in 6 of 8 cells. This increased potency of the inhibitory pathways may partially account for the changes in recruitment seen in surgical lesions of the dorsolateral quadrants (Powers and Rymer, *J. Neurophysiol.* 45: 1540, 1988).

SOME NEW OBSERVATIONS ON THE RUBROSPINAL TRACT IN THE CAT, LIGHT- AND ELECTRONMICROSCOPICAL STUDIES. *Suus Brugman, B. Vos, V. van der Horst, H. de Weerd and G. Holstege.* Dept. Anatomy, Groningen, Netherlands.

In 5 cats 10-20 nl WGA-HRP was injected in a large portion of the caudal red nucleus and immediately adjacent areas. In all 5 cases labeled fibers were observed to descend contralaterally in the dorsolateral funiculus throughout the length of the spinal cord. Some labeled fibers were also found s2in the ipsilateral dorsolateral funiculus, and in one case a few continued into the sacral cord. Contralaterally, labeled rubrospinal fibers were observed to terminate in laminae V to VII and in two cases in laminae III and IV, but only at the level C8-T1. In all 5 cases labeled fibers were found among motoneurons in the dorsolateral part of lamina IX at the transition level C8-T1. In one of the 5 cases the WGA-HRP red nucleus injection was combined with a retrograde HRP injection in the intrinsic forepaw muscles. The C8 and T1 segments were processed for EM, according to the TMB method of Ralston and Milroy (1991). In semithin sections anterogradely labeled fibers were observed around retrogradely labeled motoneurons. In EM sections heavily labeled terminals with axodendritic and axosomatic synaptic contacts, and many rounded vesicles were found in the intermediate zone. In the area of the labeled motoneurons several labeled terminals were found making contacts with labeled dendrites and somata. A relatively small number of mainly rounded vesicles were present in these terminals. Very rarely some flattened, coated and dense core vesicles were observed. The number of rounded vesicles in these terminals appeared smaller than in the terminals in the intermediate zone and much smaller than in the rubromotoneuronal terminals in the monkey (Ralston et al.; *N.S. Lett.*, 95:102). The EM-results indicate that direct, probably excitatory rubro-motoneuronal projections exist in the cat. The paucity of the rounded vesicles in the terminals suggests that the rubro-motoneuronal projections are less concentrated in the cat than in the monkey.

DIFFERENTIAL CONTROL EXERTED BY THE MOTOR CORTX ON THE SYNAPTIC EFFECTIVENESS OF TWO INTRASPINAL BRANCHES OF THE SAME GROUP I AFFERENT FIBER. *J. R. Equibar*, J. N. Quevedo, J. Jiménez and P. Rudomin.* Dept. of Physiol. CINVESTAV and ICUAP, México 07000.

We have shown previously that stimulation of the motor cortex has rather selective effects on the PAD of group I muscle afferents (*Neurosci. Abstr.*, 17:1024, 1991). We now report the effects of cortical and sensory nerve stimulation on the PAD of two intraspinal branches of the same single afferent fiber in the anesthetized cat. To this end two micropipettes were introduced in the intermediate nucleus region of the lumbar spinal cord. Antidromic responses of afferent fibers were recorded from a gastrocnemius or semitendinosus fine nerve filament. Collision tests were used to ensure that the antidromic responses were produced by activation of two intraspinal branches of the same afferent fiber. Stimulating pulses were delivered in alternation through each micropipette and stimulus current was automatically adjusted to produce antidromic firing with a constant probability (0.5) in each branch. Altogether we analyzed the effects of conditioning inputs on two branches of 11 Ia and 2 Ib fibers. PBSt conditioning stimulation (4 shocks, 300 Hz, > 2xT) reduced the intraspinal threshold of both branches to about the same extent. However, in 5/13 fibers, PBSt stimulation with low strengths (< 1.4 x T), produced larger PAD in one branch than in the other branch. Differential inhibition of PAD elicited in two branches of the same Ia fiber was also obtained by stimulation of the motor cortex (8 shocks, 700 Hz) or cutaneous nerves ($n=4$). The asymmetry of the cortical and cutaneous actions depended on the magnitude of the background PAD. In one Ib fiber we observed that cortical stimulation could reduce the intraspinal threshold of one branch practically without affecting the threshold of the other branch. Our observations suggest that two branches of the same afferent fiber can be the targets of different sets of PAD mediating interneurons and that these interneurons have rather selective connections with the intraspinal terminals of the fibers. This arrangement could be the basis for a differential control of presynaptic inhibition exerted by segmental and supraspinal inputs. Partly supported by NIH NS09196 and CONACYT 039-N9107.

EXCITATION OF LUMBAR MOTONEURONS BY THE MEDIAL LONGITUDINAL FASCICULUS IN THE *IN VITRO* BRAINSTEM SPINAL CORD PREPARATION OF THE NEONATAL RAT. *M.K. Floeter* and A. Lev-Toy¹.* Lab of Neural Control, NINDS, NIH, Bethesda, Maryland, 20892 and ¹Department of Anatomy, Hebrew University Medical School, Jerusalem, Israel

The excitation of lumbar motoneurons by reticulospinal axons traveling in the medial longitudinal fasciculus (MLF) was examined in the newborn rat. Injections of the tracer Dil into the MLF of 6 day old rats labeled a small number of fibers within the lumbar enlargement. Using *in vitro* preparations of the brainstem and spinal cord of rats 1-6 days postnatal, the MLF was stimulated and intracellular recordings were made from lumbar motoneurons. MLF stimulation excited motoneurons through long latency pathways in most motoneurons and through both short (<40 ms) and long latency connections in 16 of 40 motoneurons studied. Short and longer latency components of the excitatory response were evaluated using mephenesin to reduce activity in polysynaptic pathways. Paired-pulse stimulation of the MLF revealed a modest temporal facilitation of the short latency EPSP at short inter-stimulus intervals (20-200ms). Trains of stimulation at longer interstimulus intervals (1-30 seconds) resulted in a depression of EPSP amplitude. The short latency excitation from the MLF was reversibly blocked by CNQX, an antagonist of non-NMDA glutamate receptors, except for a small CNQX-resistant component.

588.9

PROJECTION PATTERNS OF SINGLE PONTINE RETICULOSPINAL AXONS IN THE CERVICAL AND LUMBAR ENLARGEMENTS IN THE CAT. K. Matsuyama, Y. Kobayashi and S. Mori. Department of Physiology, Asahikawa Medical College, Asahikawa, 078, JAPAN.

In this study, we examined the projection patterns of single reticulospinal axons in the cervical and lumbar enlargements (CE and LE) of the cat spinal cord. For this purpose, we injected an anterograde neural tracer, Phaseolus vulgaris leucoagglutinin (PHA-L, 5% solution, 0.4 μ l) into the left pontine reticular formation in one cat (P1.5, H-3.5, L1.5). After a survival period of 8 weeks, the animal was perfused and both the brain and the spinal cord were immediately removed. Serial transverse sections (50 μ m) of the brainstem and the spinal cord (C1 to T2 and L4 to S2) were cut on a cryotome and were stained according to a PHA-L immunohistochemical procedure. In this example, pontine reticulospinal axons, including their collaterals and terminal fibers, could be traced as far as the sacral level. We were able to fully reconstruct the collateral branchings of three axons descending in the left ventral funiculus of the CE and a further three axons in the LE. In the CE, each axon gave off a minimum of one, and a maximum of four collaterals in each segment. In the LE, the maximum number of collaterals was two, and in some segments no collateral branching was observed. All collaterals reconstructed from two axons in each enlargement projected only to the left (ipsilateral) gray matter. Collaterals from the remaining axon in each enlargement projected to both the left and the right gray matter. In addition, collaterals from any one axon always showed similar termination patterns in the different segments.

THE SYNAPTIC CONNECTIONS BETWEEN VENTROLATERAL FUNICULUS AXONS AND α -MOTONEURONS IN THE NEONATAL RAT SPINAL CORD. M. Pinco* and A. Lev-Tov. Dept. of Anatomy, The Hebrew University Medical School, Jerusalem, Israel.

Stimulation of ventrolateral funiculus axons (VLF) in the *in vitro* spinal cord preparation of the neonatal rat, elicited compound PSPs in lumbar α -motoneurons. Bath application of specific blockers of excitatory and inhibitory amino acid receptors, resolved a non-N-methyl D-aspartate (non-NMDA) and an NMDA receptor mediated, short- and long-latency EPSPs, as well as GABA_A- and glycine-mediated IPSPs. The short-latency EPSPs elicited by VLF stimulation in the presence of the polysynaptic blocker mephenesin, the NMDA receptor blocker 2-amino-5-phosphonovaleric acid (APV), and the glycine and GABA_A receptor blockers strychnine and bicuculline, did not exhibit the prolonged synaptic depression which is characteristic of EPSPs elicited during low-frequency activation of dorsal root afferents. Double pulse and tetanic stimulation induced facilitation and potentiation of EPSP elicited by VLF stimulation, and at the same time caused a severe depression of EPSPs produced by dorsal root afferents. High frequency stimulation of VLF axons in low-calcium Krebs saline exhibited an enhanced potentiation, reaching maximal values of 600-800% above the pretetanic control, and a substantial post-tetanic potentiation (PTP). Stimulation of dorsal root afferents under the same conditions resulted in 30-60% EPSP potentiation followed by PTP. It is suggested that synapses formed by propriospinal and reticulospinal tract fiber (which are the main descending constituents of the VLF, and are known to develop at an early embryonic stage) on lumbar α -motoneurons, are functionally specialized, and their high level frequency potentiation helps to maintain efficacious segmental and inter-segmental connectivity in the embryonic and the neonate mammalian spinal cord.

DISTRIBUTION OF GABA-IMMUNOREACTIVE PREMOTOR NEURONS FOR THE TRIGEMINAL MOTOR NUCLEUS IN THE RAT. O. TAKAHASHI*, T. SATODA AND T. UCHIDA. Dept. Oral Anatomy II, School of Dentistry, Hiroshima University, Hiroshima 734, Japan

It appears to be established that the pontine and medullary reticular formation are one of the relay nuclei among the descending pathways for jaw movement. This study was undertaken to clarify GABAergic projection from these nuclei including the parvocellular reticular nucleus (PCrT), one of key structures of the mastication control system, to the trigeminal motor nucleus (Vm). After iontophoretic injection of cholera toxin B subunit (CTb) into the Vm, a substantial number of retrogradely-labeled neurons were found predominantly in the contralateral supratrigeminal nucleus (sV) and bilateral PCrT. In this area, CTb-positive neurons were distributed throughout the rostrocaudal extent. Sequential double immunofluorescence histochemistry for GABA and transported CTb revealed that the vast majority of sV and PCrT neurons retrogradely labeled with CTb injected into the Vm showed GABA-like immunoreactivity. It is conceivable that the GABAergic projections from the PCrT to the Vm may constitute a link in the intrinsic control system for jaw movement.

EXCITATORY POSTSYNAPTIC POTENTIALS EVOKED BY VENTROLATERAL FUNICULUS STIMULATION IN NEONATAL RAT MOTONEURONS IN VITRO. M. Y. Wang* and R. Zhu. Cell Electrophysiology Lab, Wannan Med. College, Wuhu, Anhui 241001, China.

Intracellular recordings were made from 25 antidromically identified motoneurons (MNs) in transverse thoracolumbar spinal cord slices (500 μ m) from neonate rats (7-16 days). In 20 MNs, a depolarization potential (EPSP) was evoked by ventrolateral funiculus stimulation. When recorded at resting potential, the mean latency, time-to-peak, amplitude, half-decay time and duration of 1.2 ms, 2.7 ms, 14 mV, 5 ms and 33 ms, respectively, was obtained from the EPSPs elicited by suprathreshold stimuli. The EPSPs were graded and also the amplitude was membrane potential-dependent with mean reversal potential of -8 mV. The constant latency of EPSPs was observed at 0.1-5 Hz stimuli, while the amplitude was eliminated by stimuli of > 20 Hz. Low Ca/high Mg solution attenuated but Mg-free solution enhanced the EPSPs, which were depressed by kynurenic acid (0.5-1 mM) and partially by ketamine (50-100 μ M), APV (1-10 μ M) or DNQX (1 μ M). The results suggest that MNs are possibly excited by the descending fibers via releasing excitatory amino acids. (Supported by China NNSF No.38970295)

MONOSYNAPTIC INNERVATION OF OROFACIAL MOTOR NEURONES BY NEURONES OF THE PARVICELLULAR RETICULAR FORMATION. D. Mogoseanu, A.D. Smith* and J.P. Bolam. MRC Anatomical Neuropharmacology Unit, Mansfield Road, Oxford, OX1 3TH, United Kingdom.

The parvicellular reticular formation (PcRt), one of the subcortical premotor regions, projects to the cranial motor nuclei that innervate the orofacial muscles. In order to determine whether the PcRt has the potential to directly influence the orofacial motor neurones a combined anterograde and retrograde study was carried out in the rat.

Rats received injections (10 μ l) of cholera toxin B conjugated to horseradish peroxidase (CB-HRP) in the masticatory muscles or facial muscles and stereotaxic injections of biocytin in the PcRt. After 24h they were anaesthetised, perfuse-fixed and sections of the trigeminal motor nucleus (TMN) or facial motor nucleus (FMN) were incubated to reveal the retrogradely transported CB-HRP and the anterogradely transported biocytin. The sections were then examined by light and electron microscopy.

The sections of the motor nuclei contained many retrogradely labelled neurones interspersed among fibres and terminals that were anterogradely labelled with the biocytin from the PcRt. In the electron microscope the retrogradely labelled neurones were seen to receive synaptic input from many terminals. The biocytin labelled terminals, in both the TMN and FMN had similar morphologies: they were 1-2 μ m in diameter, contained several mitochondria and were packed with many round vesicles. In the TMN anterogradely labelled terminals formed both symmetrical and asymmetrical synapses with both retrogradely labelled or unlabelled dendrites and perikarya of neurones. In the FMN the anterogradely labelled terminals were observed to form mostly asymmetrical synapses with both retrogradely labelled or unlabelled perikarya and dendrites.

It is concluded that the neurones of the PcRt that project to the orofacial motor nuclei form direct synaptic contact with motor neurones that project to orofacial muscles. This synaptic organisation represents a route whereby the PcRt can influence orofacial movements directly.

ANATOMICAL CHARACTERISTICS OF PREMOTOR INTERNEURONS IN RAT SPINAL CORD. B. Jiang*, K. E. McKenna and W. Z. Rymer. Department of physiology, Northwestern University, Chicago, IL 60611.

Previous work has focused on the neural mechanisms underlying impaired reflex responses following incomplete spinal cord injury, such as the clasp-knife reflex. Our neurophysiological data has shown that enhanced responsiveness of inhibitory interneurons in the intermediate nucleus of the spinal cord, which were activated by free nerve endings in muscle and tendon, is responsible for these abnormalities. The present study seeks to identify the anatomical location and characteristics of these interneurons.

A retrograde transneuronal tracer, pseudorabies virus (PRV) was injected (3 μ l) into the left medial gastrocnemius muscles (MG) of rats. Four to five days later the rats were perfused. Tissue sections (50 μ m) of the spinal cord were processed for immunohistochemical detection of PRV. Fluoro-Gold was also used in another set of rats to confirm the location and morphology of the MG motoneuron pool.

As expected, PRV labelled α -motoneurons were found in the lamina IX of segments L4/L5 ipsilateral to injection site. Labelled interneurons were seen throughout the dorsal, intermediate and ventral cord of segments L2-L6. However, the majority of labelled interneurons were observed in the lamina V, VI, VII and X. Most of interneurons were labelled ipsilaterally, but in a few cases they were labelled bilaterally. This study anatomically demonstrated the location of spinal interneurons involving the control of the MG motoneurons. Ongoing work seeks first to identify the neurotransmitters of these interneurons, and then to investigate whether these interneurons receive free nerve ending mechano-receptor input from muscle.

SPINAL PREMOTOR INTERNEURONS IN BEHAVING MONKEYS: RESPONSE PATTERNS & OUTPUT LINKAGES TO MUSCLES. S.I. Perlmuter* & E.E. Fetz, Physiology & Biophysics, and Regional Primate Research Center, U. of Washington, Seattle, WA

Activity of 210 task-related C7-T1 spinal neurons was recorded in 2 macaques generating isometric ramp-and-hold flexion-extension torques about the wrist. Spike-triggered averages (STA) of EMG from 12 forearm muscles detected post-spike effects for 54 neurons. 8 were classified as motoneurons based on location and characteristic STA features, and 46 as premotor interneurons (PM-INs). Single-pulse microstimuli in the cord produced wide-spread output effects and identified the shortest latency for post-spike effects. Broad STA peaks or troughs, often beginning before the trigger, were common, and are attributed to synchronous firing of other premotor neurons. 63% of PM-INs had output effects only in flexors, 13% only in extensors, 24% in both (7 cofacilitation; 1 cosuppression; 3 reciprocal). Most had divergent effects, on average in 54% of non-redundant coactivated muscles. Response patterns of PM-INs were tonic (46%), phasic (13%), phasic-tonic (13%), decrementing (11%), unmodulated (9%), and phasic inhibition (7%). PM-INs had more tonic and fewer phasic responses than other interneurons. 70% of PM-INs had output effects consistent with their task-related modulation. Pyramidal tract input was clearly present for 10/16 PM-INs, a higher proportion than for other interneurons. PM-INs exhibit many properties previously seen in other premotor populations (e.g. rubromotoneuronal cells also include unmodulated and bidirectionally active cells, and can cofacilitate antagonists [Cheney et al., Prog Br Res 87:213]), but the overall profile of response types and linkages to muscles of PM-INs differed from premotor cells in motor cortex, red nucleus and dorsal root ganglia. ULTRASTRUCTURAL LOCALIZATION OF NEUROPEPTIDE Y-LIKE IMMUNOREACTIVITY IN THE LATERAL NUCLEUS OF THE AMYGDALA. C. R. Farb* and J. E. LeDoux. Center for Neural Science, NYU, NY, NY 10003.

The lateral nucleus of the amygdala (AL) has been implicated as the site of formation of emotional memories. Memory processing in the AL is thought to involve glutamate as a neurotransmitter. Neuropeptide Y (NPY), which is present in AL (McDonald 1989), might also play a role in synaptic transmission, possibly by inhibition of glutamate release (Colmers, 1988). NPY-like immunoreactivity (NPY-LI) in AL was examined at the electron microscopic level. NPY-LI was seen in perikarya, dendrites, axons and axon terminals. The majority of terminals with NPY-LI formed symmetric (inhibitory?) synaptic junctions on small, unlabeled dendrites. Often these dendrites were simultaneously contacted by other unlabeled terminals making asymmetric (excitatory?) synapses. Labeled terminals also formed symmetric synaptic junctions with perikarya and proximal dendrites. A small number of labeled terminals formed asymmetric synaptic junctions on dendritic spines. Frequently, labeled terminals were closely apposed to unlabeled terminals. Unlabeled terminals often made asymmetric synaptic contacts on NPY-labeled dendrites. Post-embedding studies revealed that some, but not all, NPY-immunoreactive terminals were also immunoreactive for GABA. These results suggest that NPY and GABA, either separately or together within the same neuron, might play a role in inhibition and modulation of synaptic transmission in AL, possibly through both pre- and postsynaptic mechanisms. Supported by MH38774 & MH46516.

DISTRIBUTION OF DOPAMINERGIC FIBERS IN THE CENTRAL AMYGDALOID NUCLEUS AND BED NUCLEUS OF THE STRIA TERMINALIS OF THE RAT. L. J. Freedman* and M. D. Cassell². ¹Neuroscience Program and ²Department of Anatomy, University of Iowa, Iowa City, IA 52242.

The distribution of dopaminergic fibers in the principal components of the central extended amygdala (Central amygdaloid nucleus (Ce), substantia innominata, and bed nucleus of the stria terminalis (BNST)), was studied using immunocytochemistry against tyrosine hydroxylase, dopamine β -hydroxylase and dopamine. Dopamine and tyrosine hydroxylase immunoreactive fibers were found most densely distributed in the dorsolateral subdivision of the BNST and the medial part of the lateral division of Ce. Smaller numbers of dopaminergic fibers were found in the rest of the central extended amygdala. In contrast, dopamine β -hydroxylase fibers were virtually absent from the dorsolateral bed nucleus of the stria terminalis and lateral part of the central amygdaloid nucleus, but were distributed in a moderate density in the medial part of Ce, dorsal substantia innominata and posterolateral BNST. Our results show that dopamine fibers are most concentrated over those regions of the central extended amygdala with large numbers of GABAergic neurons whose projections remain within the central extended amygdala, while noradrenergic fibers are most heavily concentrated over those regions containing a large proportion of brainstem projection neurons. That dopamine fibers are concentrated over regions with GABAergic medium spiny neurons suggests that those regions might be organized as a striatal parallel.

589.2

GABAergic PROJECTIONS FROM THE INTERCALATED CELL MASSES (ICMs) TO THE CENTROMEDIAL (CM) AMYGDALOID COMPLEX AND BASAL FOREBRAIN (BF). ¹D. Paré*, ²Y. Smith, and J.-E. Paré. ¹Dept. Physiol., Fac. Medicine, Univ. Laval and ²Neurobiol. Res. Ctr., Enfant-Jésus Hospital, QUÉ., CANADA.

The ICMs are dense clusters of small GABAergic cells interposed between the basolateral (BL) and CM nuclear groups. Up to now, the ICMs have been largely ignored in anatomical studies of the amygdaloid complex. These experiments were thus undertaken to identify some of their targets with tract tracing methods in the cat.

Intra-amygdaloid projections of the ICMs: Small iontophoretic injections of cholera toxin (CTX) were performed in the central medial (n=2), central lateral (n=2), medial (n=2), BL and/or lateral (n=4) and basomedial (n=1) nuclei as well as in the ICMs (n=2). Moderate to massive retrograde labeling was seen in the caudal ICMs after CTX injections in the central and medial nuclei. Evidence for a light projection to the BL nucleus and other ICMs was also obtained. **Extra-amygdaloid projections of the ICMs:** WGA-HRP deposits were placed in numerous cortical areas (n=3) and dorsal thalamic nuclei (n=28), in stria terminalis and anterior commissure nuclei (n=3) as well as in lateral and preoptic hypothalamic areas (n=4). Very few retrogradely labeled cells were seen in the ICMs following these injections. In contrast, massive labeling was found after injections involving the substantia innominata and diagonal band. Furthermore, most labeled intercalated cells were also GABA-immunoreactive. These results were confirmed by iontophoretic injections of PHA-L in the ICMs.

Considering that the CM complex and BF constitute two of the main output stations of the amygdala, the ICMs have the necessary connections to play a pivotal role in gating extra-amygdaloid influences. Supported by MRC grants MT-11562 and MT-11237.

589.4

INTRAAMYGDALOID CONNECTIONS OF THE RAT BASOLATERAL AMYGDALA. C.-I. Shi* & M.D. Cassell. Dept. of Anatomy, Univ. of Iowa, Iowa City, IA 52242.

The amygdala functions to integrate sensory inputs with appropriate behavioral and somatic reactions. While the extended central and medial amygdala appear to contribute to the expression of a variety of reactions through their hypothalamic and brainstem projections, the basolateral amygdala seems to be the major recipient of sensory information from cortex and thalamus. The question therefore arises as to what are the pathways that sensory information uses to access and converge on the extended central and medial amygdala. To address this question, the intrinsic amygdaloid connections of the basolateral amygdala in rat were investigated using the biocytin anterograde tracing method. The results show that the lateral nucleus gives few direct projections to the extended amygdala, but heavy innervation of the posterior basomedial and posterolateral cortical nuclei and moderate labeling in the basolateral nucleus. The basolateral nucleus (BL), mainly its very caudal part, projects massively to the extended central amygdala, including all parts of the central amygdaloid nucleus (Ce), dorsal substantia innominata and lateral part of the bed nucleus of stria terminalis (BNST), but not to the extended medial amygdala. The anterior basomedial nucleus projects both extended central and medial amygdala except posteriodorsal part of the medial amygdaloid nucleus and posteromedial part of the BNST. The posterior basomedial nucleus mainly projects to the extended medial amygdala as well as the lateral capsular part of the Ce. The morphology of neurons that project to the extended amygdala was evaluated with intracellular staining techniques. Only class I and II neurons within the BL provide these intraamygdaloid connections. The data suggested sensory information is carried through polysynaptic intraamygdaloid pathways before accessing output nuclei. Supported by NIH NS25139.

COMPARATIVE ANATOMY OF THE PRIMATE AMYGDALA: A HISTOCHEMICAL AND IMMUNOCYTOCHEMICAL STUDY. D.R. Brady*, Lab. of Neurosci., NIA/NIH, Bethesda, MD 20892.

The amygdala is a subcortical structure occupying a strategic position in the circuitry of the limbic system, linking neocortical sensory input with neural systems associated with emotions and vegetative status. The basolateral division of the primate amygdala has developed phylogenetically in tandem with the expansion of neocortical association areas, with the greatest increase observed in human. On-going studies of the amygdaloid complex are directed toward identifying unique biochemical features of these nuclei. Coronal sections through the amygdaloid complex of new and old world monkeys, gorilla, chimpanzee and human were histochemically stained for the nitric oxide synthase marker NADPH-diaphorase (NADPH) and immunocytochemically reacted with antibodies to: calcium-binding protein, parvalbumin (PV); a lectin forming pericellular nets around PV neurons, *Wisteria floribunda* (WF); a non-phosphorylated neurofilament protein that identifies cortico-cortical projection cells, SMI32; neuropeptide Y (NPY) and somatostatin 1-28 (SOM). The morphology of NADPH, PV, NPY and SOM was similar between species, consisting of stellate, multipolar and fusiform cells that were spiny or sparsely spiny. While NPY and SOM were observed in all amygdaloid nuclei, few NADPH cells stained in the central nucleus and the majority of PV and WF labeled cells occupied lateral (L) and basal (BL) nuclei. Labeled fibers mimicked the cellular distribution for each antibody. SMI32 labeled medium to large pleomorphic neurons in L, BL and accessory basal (AB) nuclei, with the greatest density in BL and L nuclei. Our results suggest that L, BL and AB amygdaloid nuclei, those connectionally related to neocortex, share similar cytochemical characteristics that may relate to their phylogenetic development.

589.7

LOCALIZATION OF NEUROPEPTIDE Y AND SOMATOSTATIN-LIKE IMMUNOREACTIVITY IN NEURONS OF THE MONKEY AMYGDALA. A.J. McDonald*, F. Mascagni and J.R. Augustine, Dept. of Cell Biology and Neuroscience, Univ. of South Carolina Sch. of Med., Columbia, S.C. 29208

Neurons in the monkey amygdala exhibiting neuropeptide Y (NPY) and somatostatin (SOM) immunoreactivity were identified using ABC immunohistochemistry. Co-existence of the two peptides was demonstrated using two-color immunoperoxidase and adjacent section methods. Numerous NPYir neurons were observed in the basolateral and superficial amygdaloid nuclei. A moderate number of NPYir neurons was seen in the medial subdivision of the central nucleus but only a few neurons were observed in the lateral subdivision. Numerous SOMir neurons were stained in all major amygdaloid nuclei and always outnumbered NPYir cells. Approximately 90% of NPYir neurons also exhibited SOMir; the percentage of SOMir neurons that exhibited NPYir varied in different nuclei. In the superficial amygdaloid nuclei, the medial subdivision of the central nucleus, and most portions of the basolateral nuclei, the predominant cell type stained with both the NPY and SOM antibodies was a spine-sparse nonpyramidal neuron. In the dorsomedial subdivision of the lateral nucleus most peptide-positive neurons had spiny dendrites. This study demonstrates that specific cell populations in the primate amygdala contain NPY, SOM, or both peptides. Most peptide-positive neurons in the basolateral and superficial amygdaloid nuclei appear to be local circuit neurons. The finding of neurons with spiny dendrites in the dorsomedial portion of the lateral nucleus suggests that these cells may be functionally different from peptide-positive neurons in other portions of the basolateral amygdala. The lateral subdivision of the central nucleus is distinguished from other amygdaloid nuclei by containing a large population of SOMir neurons that do not exhibit NPYir. Supported by NIH Grant NS19733.

THE CAT'S LATERAL AMYGDALOID NUCLEUS AS A SENSORY-LIMBIC RELAY.

Llamas, A., Clascá, F., Román-Guindo, A., and Mateo-Sierra, O. Dept. of Morphology, Sch. of Med., Autónoma Univ., Madrid SPAIN

The lateral amygdaloid nucleus (L) is the main gateway for neocortical and thalamic inputs to the amygdala. In turn, L sends heavy projections to some neocortical areas as well as to the entorhinal cortex (EC), basal and cortical amygdaloid nuclei (ABC), and, in cats, to hippocampal sector CA1 (Llamas et al., Soc. Neurosci. Abstr. 471, 1991). We have investigated the spatial overlap between these multiple afferents and efferents within L, using axonal tracers in adult domestic cats. Afferents from auditory, gustatory and visual thalamus end in separate portions of L. Perirhinal and association auditory cortex project massively to the medial and posterior portion of L. Sylvian ("insular") neocortex projects to a more restricted anterior and dorsal zone of L. Some of these projections are not reciprocal. Amygdalo-neocortical connections arise from dorsolateral parts of L. Projections to EC arise from central and medial parts of L, throughout the anteroposterior extent of the nucleus. Neurons projecting to ABC lie ventrolaterally in the anterior third of L and laterodorsally in its posterior third. Efferents to CA1 arise from a central and dorsal portion of L. Connections with CA1, EC and ABC are non-reciprocal. Thus, sensory inputs and outputs to limbic targets are to a great extent segregated within L. These findings highlight the pivotal position of intranuclear connections within L for sensory-limbic interactions through the amygdala.

ORGANIZATION OF CORTICAL INPUTS TO THE LATERAL NUCLEUS OF THE MONKEY AMYGDALA. L. Stefanacci* and D.G. Amaral, The Salk Institute and Group in Neurosciences, UCSD, La Jolla, CA 92037.

The amygdaloid complex is a cytoarchitecturally heterogeneous structure that has been implicated in the mediation of affective responses to perceived stimuli. In an effort to chart the sources of cortical sensory information to the amygdala, we have begun a comprehensive examination of inputs to the lateral nucleus of the amygdala in *Macaca fascicularis*. We placed discrete injections of the retrograde tracers Fast blue and Diamidino yellow into different rostrocaudal and dorsoventral levels of the lateral nucleus in 19 monkeys. In general, retrogradely labeled cells were identified in insular, temporal, and prefrontal cortical areas after all injections. Labeled cells were observed in hitherto unreported sources of inputs to the lateral nucleus such as the parahippocampal and posterior inferior temporal cortices. The projections to the lateral nucleus were topographically organized. Prefrontal areas, for example, originated stronger projections to more caudal regions of the lateral nucleus than to more rostral regions. The caudal insula and area 10 of the prefrontal cortex originated stronger projections to more dorsal regions of the lateral nucleus than to more ventral regions. Area TE, or rostral inferotemporal cortex, projected most heavily to rostral and dorsal parts of the lateral nucleus. We also observed that the caudal ventral lateral nucleus received significantly fewer cortical inputs than any other part of the nucleus. These results demonstrate that the lateral nucleus receives inputs from a wider variety of cortical regions than previously thought and that these inputs are differentially distributed to different portions of the nucleus.

PREFRONTAL CORTICAL INNERVATION OF THE BASOLATERAL NUCLEUS OF THE AMYGDALA: AN ELECTRON MICROSCOPIC STUDY. M.B. Reed, A.J. McDonald and F. Mascagni*, Dept. of Cell Biology and Neuroscience, Univ. of South Carolina School of Med., Columbia, SC 29208.

Prefrontal cortex projections to the basolateral nucleus of the amygdala (ABL) in the rat were investigated using the Phaseolus vulgaris leucoagglutinin (PHA-L) anterograde tract tracing technique. Iontophoretic injections of PHA-L were made into the prelimbic, infralimbic and agranular insular cortices. After a two week survival, animals were perfused and 75-micron-thick sections were cut with a vibratome. The avidin-biotin peroxidase immunohistochemical technique was used to demonstrate PHA-L labeled fibers and terminals in the ABL. Electron microscopic evaluation revealed that labeled terminals contained round synaptic vesicles and made asymmetrical synapses. Virtually all labeled terminals made synaptic contacts with dendritic spines; a few contacts were seen with small dendrites. These findings indicate that prefrontal inputs target spiny pyramidal neurons in ABL; these neurons have projections to the ventral striatum and prefrontal cortex. The morphology of the synapses (Gray's Type I) suggests that they are excitatory. Prefrontal inputs may interact with other specific neuronal elements that target dendritic spines of ABL neurons. These putative interactions might play a role in synaptic plasticity in the amygdala. (Supported by NIH Grant NS-19733).

AMYGDALOID PROJECTIONS TO THE VENTROMEDIAL NUCLEUS OF HYPOTHALAMUS: A RETROGRADE LABELING STUDY USING CHOLERA TOXIN B SUBUNIT. G. Rajendren* and R.L. Moss, Dept. Physiol., The Univ. Texas Southwestern Med. Ctr., Dallas, TX 75235-9040.

The projections of various subdivisions of the amygdala into the ventromedial nucleus of hypothalamus (VMH) were studied in 6 ovariectomized rats unilaterally injected (50 nl) with cholera toxin (CTX) B subunit into the VMH. Ten days after the injection of the tracer, the females were sacrificed and the brains were processed immunocytochemically. In two rats the injections were localized at the dorsal part of the VMH, and the injection extended into the dorsomedial nucleus of hypothalamus in one of these two rats. In another two rats the injections were confined to the lateral part of the VMH. In the fifth rat the injection covered the entire extent of the VMH. In the sixth rat the injection covered the lateral edge of the VMH and parts of the lateral hypothalamus. In all the six rats, the maximum density of CTX labeled cells was found in the ipsilateral medial amygdala, the anteroventral and the posteroventral subdivisions of the ipsilateral medial amygdala showing intense staining. Scattered CTX-filled cells were observed throughout the anterodorsal and posterodorsal subdivisions of the ipsilateral medial amygdala. The anteroventral subdivision of the contralateral medial amygdala was also labeled in all 6 rats. In all six rats, cells labeled with CTX were observed in the ipsilateral posterior basomedial nucleus, anterolateral amygdalohippocampal area, posteromedial amygdalohippocampal area and the subiculum. These structures contralateral to the injection were not labeled.

The present studies provide a more detailed picture of the amygdaloid projection into the VMH. Supported by NIH Grant MH41784.

CONNECTIONS OF THE ADULT RAT PREFRONTAL CORTEX REVEALED BY INTRACEREBRAL INJECTION OF A SWINE ALPHA HERPESVIRUS. L.W. Enquist¹, P. Levitt² and J.P. Card³. ¹Dupont Merck Pharmaceutical Co., Wilmington, DE, ²The Medical College of Pennsylvania, Philadelphia, PA, and ³The University of Pittsburgh, Pittsburgh, PA.

Alpha herpesviruses are transported through the nervous system in a circuit specific pattern following injection into peripheral nerves and their targets. We have examined the behavior of two strains of a swine alpha herpesvirus (pseudorabies virus, PRV) injected into the medial prefrontal cortex of adult rats. Wild type (PRV-Be) and attenuated (PRV-Ba) virus were both transported from the site of injection in a pattern entirely consistent with the known connectivity of the prefrontal cortex. However, the two strains of virus exhibited differences in the direction of viral transport from the injection site. PRV-Be virus was transported in both the anterograde and retrograde direction and ultimately infected neurons in all areas known to either project to or receive projections from the prefrontal cortex. In contrast, the attenuated strain of virus was only transported retrogradely from the injection site, even at substantially longer post inoculation intervals. With advancing survival, both strains of virus also passed transneuronally to infect circuits of neurons in a predictable temporal sequence in patterns consistent with retrograde viral transport. The data demonstrate that intracerebral injection of different herpesvirus strains can be effectively used to analyze aspects of neuronal circuitry. Furthermore, the well characterized genetic differences present in the two strains of virus used in this analysis provide a basis for examining the factors which influence specific uptake and transport of PRV in the central nervous system.

DISCHARGE PROPERTIES OF NEURONS OF THE SUPRAMAMMILLARY NUCLEUS AND MAMMILLARY BODY: RELATIONSHIP TO HIPPOCAMPAL THETA RHYTHM. B. Kocsis*, R.P. Vertes and J.S. Thinschmidt. Center for Complex Systems, Florida Atlantic University, Boca Raton, FL 33431

The supramammillary nucleus (SUM) and the mammillary body (MB) are intimately connected with the hippocampal formation (HF) -- the SUM via ascending projections primarily to the dentate gyrus and the MB via descending HF to MB projections through the fornix. We proposed that the SUM may serve as an important link from the pontine reticular formation to the septum-hippocampus in the generation of the theta rhythm. Kirk and McNaughton (Neuroreport 2:723, 1991) recording multi-unit activity described a population of SUM cells that fired synchronously with the theta rhythm of the HF. Alonso and Llinas (J. Neurophysiol. 68:1321, 1992) recently identified rhythmically bursting cells in the MB in the guinea pig slice that they suggest may be related to theta.

Extracellular single unit recordings were taken from the SUM, MB and surrounding regions of the diencephalon in urethane anesthetized rats. Hippocampal EEG activity was recorded with stainless steel electrodes implanted in the dorsal hippocampus. 170 neurons were recorded in 40 rats. Of these, 29 cells discharged synchronously with the theta rhythm (theta cells); 141 showed no relationship to theta (non-theta cells). Twenty of 29 theta cells were histologically localized to the SUM/MB (13 in SUM, 7 in MB); 83 of 141 non-theta cells were located outside of the SUM/MB. Eleven of 20 theta cells were "complex spike" cells -- 6 in SUM, 5 in MB. The results show that a large percentage of SUM/MB neurons discharge synchronously with theta, whereas, few if any diencephalic cells outside of the SUM/MB exhibit this characteristic. Theta-related SUM/MB neurons may be involved in the generation of the theta rhythm and/or transfer of theta rhythmicity from the HF to other parts of the CNS.

SEROTONERGIC SYNAPTIC INPUT TO GABAERGIC SEPTOHIPPOCAMPAL NEURONS IN THE RAT: A PRE-EMBEDDING TRIPLE-LABEL ELECTRON MICROSCOPIC STUDY. Takashi Honda* and Kazuo Semba. Dept. of Anat. & Neurobiol., Dalhousie Univ., Halifax, N.S., B3H 4H7 Canada.

The hippocampus is known to receive projections from GABAergic and cholinergic neurons in the medial septum-diagonal band region. To understand the transmitter-specific regulation of the activity of GABAergic septohippocampal neurons, wheatgerm agglutinin conjugated with 10 nm gold (WGA-G) was injected into the hippocampus. Parvalbumin, a marker for GABAergic septal neurons, was then immunohistochemically visualized with PAP and DAB methods, and serotonin visualized with an immunogold (1 nm) method, followed by silver intensification for both gold labels. In the medial septum, serotonin-immunoreactive axon terminals labeled with small granules contained clear round vesicles and a few dense-core vesicles. They made synaptic contacts with cell bodies that were labeled for both WGA-G (large granules) and parvalbumin (diffuse electron-dense label). In addition, many serotonin-positive axon terminals made synaptic contacts with unlabeled dendrites and somata. These results provide a morphological basis for synaptic regulation of GABAergic septohippocampal neurons by serotonin. Supported by the Medical Research Council and Scottish Rite Charitable Foundation of Canada.

PHA-L ANALYSIS OF ASCENDING PROJECTIONS FROM THE POSTERIOR HYPOTHALAMUS IN THE RAT. R.P. Vertes*, A.M. Crane, L.V. Colom and B.H. Bland. Center for Complex Systems, Florida Atlantic Univ., Boca Raton, FL 33431, Div. of Neuroscience, Baylor College of Medicine, Houston, TX 77030, and Dept. of Psychology, Univ. of Calgary, Calgary, Alta., Canada T2N 1N4.

Regions of the posterior hypothalamus (PH), particularly the supramammillary nucleus (SUM), are thought to serve as an important relay between the brainstem and septum-hippocampus involved in the generation of the hippocampal theta rhythm. We previously showed (Vertes, J. Comp. Neurol. 326:595, 1992) that the SUM projects densely to the dentate gyrus of the hippocampus (HP) as well as to several structures intimately connected with the HP including nucleus reuniens (RE) of the thalamus, medial and lateral septum, entorhinal cortex and endopiriform nucleus. The aim of the present report was to examine ascending projections from regions of the PH adjacent to the SUM and to compare them with SUM projections.

Single injections of PHA-L were made into regions of the PH in 35 male rats, and patterns of projections analyzed. We found that injections in the PH dorsomedial/dorsolateral to SUM produced moderate to dense labeling in the following structures: the periventricular gray, the periventricular nucleus of thalamus (Th), the fields of Forel/zona incerta, the dorsomedial hypothalamic area, RE, mediodorsal nucleus of Th, lateroposterior nucleus of Th, medial and lateral preoptic region, bed nucleus of stria terminalis, substantia innominata, and medial and lateral septum. In contrast to SUM projections, the PH is the source of few, if any, projections to the HP, entorhinal cortex or endopiriform nucleus.

The findings indicate that the PH can influence the HP indirectly through projections to RE and the septum but not directly through monosynaptic projections to the HP.

PROJECTIVE SEPTAL NEURONS ARE IMMUNOREACTIVE FOR THE ESTROGEN-SYNTHESIZING ENZYME AROMATASE. ARE THERE "ESTROGENIC" NEURAL PATHWAYS IN THE BRAIN? R.L. Jakab*¹, N. Harada², and F. Naftolin³. ¹Sect. Neurobiol. and ³Dept. Ob/Gyn, Yale Univ., Sch. Med., New Haven, CT 06510, U.S.A.; and ²Molec. Genetics, Fujita-Gakuen Health Univ., Sch. Med., Toyoake, AICHI 470-11, Japan.

Mapping studies of several research groups have concluded that the distribution of neurons displaying aromatase-immunoreactivity (AR-IR) and the areas exhibiting AR enzyme activity do not completely overlap in the mammalian brain. For instance, in the rat anterior hypothalamic area (AH) which has high enzyme activity, we have detected AR-IR only in axons and not in somata. Conversely, in the lateral septum where enzyme activity is low, AR-IR neurons are abundant (Jakab et al., J. Steroid. Biochem. 1993, 44:481-498). This and similar discrepancies found in other brain regions suggest that the action of the AR-IR neurons is, at least partly, manifested in their projection target areas.

In the present study, we tested this hypothesis focusing on the septo-hypothalamic pathway.

Experimental: To verify whether AR-IR lateral septal neurons project to the AH, small amounts (0.05-0.1 μ l) of the retrograde tracer horseradish peroxidase (HRP; 30% in saline) were stereotaxically injected to this hypothalamic area of adult rats. After two-day survival, large populations of lateral septal neurons were found to contain HRP granules. Light and electron microscopic immunostaining demonstrated AR-IR in many of these retrogradely-labeled cells.

Conclusion: This finding supports the notion that brain-derived estrogen may not exclusively act locally, but may affect remote areas via neural pathways.

CABP-D28K AND NADPH-DIAPHORASE COEXISTENCE IN THE GUINEA PIG LATERAL SEPTUM. O. Doutrelant, P. Ciofi* and P. Poulain. INSERM U 156, Pl. de Verdun, 59045 Lille (France).

The lateral septum (LS) is recognized as an important integrative unit receiving a variety of afferents. Its mediolateral part (LSml) contains a well-defined group of neurons identifiable by their somatic spines. In the rat, these LSml somatospiny neurons contain calbindin D-28K (CaBP) and receive excitatory glutamatergic hippocampal projections. In the guinea pig, we have shown that some LSml somatospiny neurons are CaBP-positive and also receive an enkephalineric innervation from the perifornical hypothalamus.

The aim of the present study was to determine whether CaBP coexists with NADPH-diaphorase (ND), an enzymatic cofactor implicated in the nitric oxide synthesis, CaBP and ND being known to protect neurons against excitotoxicity. Light microscopic double-immunostaining for CaBP and met-enkephalin combined with ND histochemistry was performed on cryostat frontal sections cut throughout the LS of female guinea pigs.

Our results show that 1) CaBP and ND are present on delimited territories of the LS, 2) overlapping occurs in discrete territories, including the LSml, 3) coexistence of CaBP and ND is observed for some neurons in the LSml, and 4) enkephalineric fibers contact CaBP, ND or CaBP-ND neurons.

Our data show a selective pattern in the topographical distribution of CaBP cells, ND cells and enkephalineric fibers suggesting specific physiological functions for these different populations of neurons.

PROPOSED SUBDIVISION OF THE MEDIAL SEPTAL COMPLEX OF THE MACAQUE MONKEY BASED ON CYTOARCHITECTONIC, CHEMOARCHITECTONIC AND CONNECTIONAL DATA. H. M. Stroessner-Johnson* and D.G. Amaral. The Salk Institute, La Jolla, CA 92037; UCSD, Group in Neurosciences, La Jolla, CA 92037.

The medial septal complex (MSC) has traditionally been subdivided into two regions: the medial septal nucleus (MSN) and the nucleus of the diagonal band of Broca (DBN). Currently, there is no consensus on a precise, anatomically defined border between these two regions. Morphometric analyses of the MSC in young and aged monkeys has prompted us to reinvestigate the organization of the MSC.

We have analyzed Nissl, myelin, and immunohistochemical preparations using antibodies directed against choline acetyltransferase, glutamate decarboxylase, calbindin and parvalbumin. In addition, we have used preparations (n=31) from our laboratory's library of retrograde dye (Fast blue and Diamidino yellow) injections into levels spanning the rostrocaudal extent of the hippocampal formation for our analysis of the distribution of projection cells in the septohippocampal pathway.

Based on cell size, orientation, packing density, presence of immunolabeled cells and fiber density, and distribution of retrogradely labeled cells after dye injections into the hippocampal formation, we have identified as many as seven subdivisions in the MSC. For example, the MSN-Dorsal region does not contain cholinergic cells or retrogradely labeled cells but does contain GABAergic cells. The MSN-Intermediate group contains a moderate density of small to medium sized oval, multipolar and fusiform cholinergic cells whereas the MSN-Ventral magnocellular group has a very high density of medium to large sized multipolar cells. There are three subdivisions associated with the NDB: (Ventral parvocellular stream, Dorsal parvocellular stream, and Magnocellular stream), three associated with the MSN: (Dorsal, Intermediate, and Ventral magnocellular) and one in the transitional area (MSN/DBN-Lateral).

589.19

DIENCEPHALIC ORIGINS OF MELANIN-CONCENTRATING HORMONE IMMUNOREACTIVE (MCH-ir) PROJECTIONS TO THE LATERAL PART OF THE MEDIAL MAMMILLARY NUCLEUS (MMN). V.C.G. FURLANI⁽¹⁾ AND J.C. BITTENCOURT^(1,2). (1) Dept. of Anatomy ICB/USP and (2) Nucleus of Neurosciences and Behavior, Institute of Psychology/USP, Sao Paulo, SP - BRAZIL - CEP 05389-970

The MMN is subdivided by pars lateralis, pars basalis, pars medialis, pars medianus and pars posterior. The lateral division (pars lateralis) of the MMN is constituted by a group of small cells between the medial division of MMN and the lateral mammillary nucleus. The MMN receives afferents mainly from dorsal and ventral subiculum, medial pre-frontal cortex, ventral tegmental nucleus, nucleus centralis superior (pars compacta), entorhinal medial cortex, medial septal area, tuberomammillary nucleus, ventral and dorsal pre-mammillary nuclei, supramammillary nucleus and dorsolateral hypothalamic area. The mammillary nuclei have received a considerable attention for the relationship with association procedures and spatial memory, the elaboration of emotion expression and possibly act on the aggressive behavior specific-specimen. Moreover, it can announce in the sexual behavior, regulation of the autonomic activities, the beginning of the attack activity and the defense behavior. Bittencourt et al (1992) described an extensive MCH/NEI-ir fibers on the MMN, and MCH/NEI-ir cells on the dorsolateral hypothalamic area, zona incerta, olfactory tubercle and pontine reticular formation. In order to determine the origins of the MCH/NEI-ir innervation of MMN, we have combined immunohistochemical and neuronal fluorescent retrograde tracer methods (5% solution of True-Blue in distilled water, crystalline deposits in the MMN). We have found condensed groups of double-labeled (MCH/NEI-ir) neurons in the following regions: dorsolateral hypothalamic area and tubular subdivision of tuberomammillary nucleus.

DOES THE LIMBIC SYSTEM AFFECT STRIATAL FUNCTION VIA THE NIGROSTRIATAL PATHWAY?

B.H. Turner*, Dept. of Anatomy, Howard University College of Medicine, Washington, DC 20059.

Anatomical studies show that diverse limbic structures provide the major afferents to the dopaminergic A8, A9, and A10 cells. To investigate a functional role of this circuit, the intracellular responses of caudate (Cd) neurons to stimulation of the preoptic area and frontal cortex of anesthetized cats was recorded. It was found that a single or multipulse stimulation of the preoptic area produced a response in Cd neurons, characterized by a long latency, slowly depolarizing potential. This response disappeared with the administration of the dopaminergic neurotoxin, MPTP, while leaving the corticostriate response unaffected. It was also found that intracellular injection of current into Cd neurons caused a train of action potentials, the frequency of which almost doubled with concurrent preoptic stimulation. We conclude that limbic stimulation affects striatal function via the nigrostriatal pathway.

Expression of c-fos in the mamillary body following injections of muscimol into the dorsal and ventral tegmental nuclei of Gudden in the rat. L. Shim* and D. Wirtshafter, Dept. of Psych., University of Illinois at Chicago, Box 4348, Chicago, IL 60680.

In a previous study, we have shown that the projections from the ventral tegmental nucleus of Gudden (VTN) to the medial mamillary nucleus, and from dorsal tegmental nucleus (DTN) to the lateral mamillary nucleus, contain a substantial GABAergic component. Since GABA appears to act as an inhibitory transmitter, these findings raised the possibility that reducing the activity of cells in the VTN and DTN would result in a disinhibition of the cells in the mamillary body. The present study examined this possibility by studying the expression of Fos, the protein produced by the c-fos proto-oncogene, in the mamillary body following injections of the GABA agonist muscimol into VTN or DTN. The expression of Fos has been used to map functionally and anatomically related neural pathways.

Unilateral injections into the VTN produced a significant increase in Fos immunoreactivity in the ipsilateral medial mamillary nucleus. In contrast, injections into the DTN resulted in a great increase in lateral mamillary nucleus. These results strongly suggest that projections from tegmental nuclei to mamillary body are inhibitory, and are in agreement with other studies demonstrated that the VTN and DTN project to the medial and lateral mamillary nuclei, respectively.

IDENTIFICATION OF AFFERENTS TO THE SEROTONINERGIC NEURONS OF THE DORSAL RAPHE NUCLEUS USING FLUORESCENT TRACT TRACING IN THE RAT. Roger P. Dilts* and Margaret C. Boodie-Biber, Dept. of Physiology Medical College of Virginia-VCU, Richmond, VA 23298-0551

The purpose of this study was to identify the afferent connectivity of the ascending serotonergic neurons of the dorsal raphe nucleus. Fluorogold (50-100 nl, 2% in saline) was pressure injected using a 31 ga. injection cannula. Six to 21 days after the injections animals were sacrificed by lethal injection and perfused with Ca⁺⁺-free Tyrode's buffer followed by 4% paraformaldehyde and 0.01% glutaraldehyde in phosphate buffered saline (PBS). Brains were bi-sectioned and post-fixed for 2 hours in 4% paraformaldehyde/PBS, transferred to 20% sucrose/PBS and serial sectioned from +4.0 mm to -13.00 mm respective of Bregma at 40 microns using a freezing stage microtome. Sections were mounted and counter stained using a 0.02% solution of Neutral Red in 70% ethanol buffered with imidazole to pH 7.2-7.4. Injections which included the dorsal raphe and extended into the surrounding regions were compared to injections into the surrounding regions which excluded the dorsal raphe. Neurons were identified using a Zeiss Axioskop equipped with filter sets 00, 17 and 18 at 50-400x magnification and charted with reference to Paxinos and Watson ('86). Neurons labelled with fluorogold following injections into the dorsal raphe were identified in the prefrontal cortex, claustrum, as well as in regions immediately associated with the medial forebrain bundle including; the horizontal limb of the diagonal band, anterior amygdala area, the perifornical region of the lateral hypothalamus, parafascicular nucleus of the thalamus, supramammillary nucleus, posterior hypothalamus, ventral tegmental area, substantia nigra and central gray. Sparsely labelled neurons were identified throughout the pons and medulla including the parabrachial complex and locus coeruleus. Neurons labelled by injections which excluded the dorsal raphe nucleus were found in similar regions but with a different topography. This study provides evidence that the serotonergic neurons within the dorsal raphe nucleus receive a characteristic pattern of innervation from the telencephalon and diencephalon. Supported by NIH grant # NS14090 to M.C.B.B.

AXOSOMATIC INPUTS TO PREFRONTAL CORTICAL PYRAMIDAL NEURONS PROVIDING ASSOCIATIONAL OR CALLOSAL PROJECTIONS IN MONKEY. D.S. Melchitzky¹, S.R. Sesack, and D.A. Lewis. Depts. of Behav. Neuroscience & Psychiatry, Univ. Pittsburgh, Pittsburgh, PA, 15213.

Pyramidal cells, the major class of cortical excitatory neurons, can be divided into different classes based upon the target region of their axonal projection. Local circuit neurons are critical regulators of the activity of pyramidal neurons through primarily inhibitory synaptic inputs. However, little is known about how inputs from local circuit neurons differ among populations of pyramidal neurons in the highly differentiated prefrontal cortex of primates. In this study, WGA-HRP was injected into area 9 of monkey (*Macaca fascicularis*) prefrontal cortex. Retrogradely labeled pyramidal neurons furnishing callosal or associational projections were then identified in layers III and V of areas 9 and 46. The morphological features of callosally-projecting neurons in layer III (smooth or slightly indented nuclei, abundant cytoplasm and organelles, sparse Nissl substance) were comparable to those previously described in callosal neurons located in other regions and species. Obvious differences between callosal and associational neurons in these characteristics were not detected. The somatic membrane of callosal and associational cells was contacted by axon terminals that: (1) contained primarily pleomorphic vesicles and formed symmetric axosomatic synapses; (2) were morphologically similar but did not exhibit synaptic specializations in the single sections analyzed; or (3) contained primarily spherical vesicles and formed asymmetric synapses on adjacent dendritic targets. Preliminary examination suggests that callosal and associational neurons in the monkey prefrontal cortex receive a similarly dense axosomatic input. However, quantitative assessment of a larger cell sample is needed to confirm this qualitative impression.

CALRETININ MAY DEFINE THALAMOCORTICAL CONNECTIONS BETWEEN THE HUMAN LIMBIC THALAMUS AND CINGULATE CORTEX. B.A. Vogt¹, E.A. Nimchinsky², J.H. Morrison² and P.R. Hof². ¹Dept of Physiology and Pharmacology, Bowman-Gray Sch of Med, Winston-Salem, NC 27103, and ²Fishberg Res Ctr for Neurobiology, Mount Sinai Sch of Med, New York, NY 10029.

An antibody to the calcium-binding protein calretinin (CR) was used to analyze the distribution of this protein in the human cingulate cortex and its associated thalamic nuclei. Although the distribution of CR-immunoreactive (ir) interneurons did not vary appreciably in the rostrocaudal axis of the cingulate cortex, the anterior cingulate cortex (ACC) was characterized by an intensely CR-ir neuropil. Layer I, in particular, was broad and intensely labeled. Midline and intralaminar thalamic nuclei, including the centrolateral and parafascicular nuclei, which project to this area in the primate were strongly CR-ir. Area 23 of the PCC was characterized by a thin, intense band of CR-ir fibers in layer Ia. Neurons in the lateroposterior and medial pulvinar nuclei which project to PCC in the primate were similarly CR-ir. Areas 29 and 30 in PCC were characterized by a prominent band of CR-ir neuropil staining in layer II-IV. Cells of the laterodorsal and anterodorsal nuclei, which project to areas 29 and 30 in the primate, were CR-ir. There are large numbers of CR-ir fibers in the cingulum bundle, which directly enter layer I of ACC and at more caudal levels penetrate the cortex to reach the superficial layers. These data support the notion that thalamocortical projections might be responsible in part for CR immunoreactivity in the cingulate cortex and indicate that CR may be a potent tool for studying select neuronal systems in the human cerebral cortex.

INTRINSIC ELECTROPHYSIOLOGY AND MORPHOLOGY OF NEURONS IN PERIRHINAL CORTEX. J.M. Baggus¹ and E.W. Kairiss. Department of Psychology and Center for Theoretical and Applied Neuroscience, Yale University, Box 11A, Yale Station, New Haven, CT 06520.

Studies of cortical neurons have sought to classify cells on the basis of their intrinsic membrane properties and morphology. We have extended this effort in two ways. First, we have examined rat perirhinal cortex, which is a transitional form of cortex situated between one-layered archicortex of the hippocampus and six-layered neocortex. Second, we have directed our statistical analyses to see if cells were grouped into distinct classes (as previous studies have suggested), or whether there was a continuous distribution of cell characteristics.

Intracellular recordings were made from over 90 cells from an *in vitro* preparation of rat areas 35 and 13. Single-electrode current clamp recordings with intracellular electrodes were used to study membrane responses to hyperpolarizing and depolarizing current steps. Analysis of the resulting membrane voltages included a variety of features: action potential width, rate of rise and fall, decay time constant, spike frequency adaptation, and first interval as a function of injected current. In addition, latencies and amplitudes of the afterhyperpolarizations (AHPs) and depolarizing afterpotentials (DAPs) were measured. Distributions of these features were unimodal to a first approximation, and no single variable or group of variables could be found to partition the data set into distinct classes. Thus, there is a continuum along features with "regular spiking" (RS) and "intrinsically bursting" (IB) cells representing extremes. Another type of cell was infrequently recorded and showed distinctly higher firing rate and low spike frequency adaptation, similar to "fast spiking" (FS) cells found in other studies.

Injection of 5% carboxylfluorescein into some of the recorded cells revealed that those with regular spiking responses were pyramidal with small apical dendrites, while those with bursting responses were also pyramidal with large apical dendrites. Preliminary results with fast spiking cells indicate that they have stellate morphology. (Supported by NIH and Yale University)

PSTNATAL DEVELOPMENTAL CHANGES IN DENDRITIC SPINE DENSITY ON LAYER III PYRAMIDAL NEURONS IN MONKEY PREFRONTAL CORTEX. S.A. Anderson¹, J. Classey², D.A. Lewis¹ and J.S. Lund². ¹Depts. of Psychiatry and Behav. Neurosci., University of Pittsburgh, Pittsburgh, PA, 15213 and ²University of London.

Normal cortical development in primates appears to involve an initial overproduction of synapses, followed by synapse elimination until adult levels are achieved. Previous electron microscopy studies in primary sensory and motor cortical regions have demonstrated that these changes in synaptic density involve primarily asymmetric, presumably excitatory synapses, the majority of which are located on the dendritic spines of pyramidal neurons. The timing of synapse reduction remains unclear, but may occur largely during adolescence. However, the timing and extent of changes in synaptic input to subpopulations of pyramidal cells has not been determined. In this study, the rapid Golgi technique was used to identify pyramidal neurons located in mid-layer III of areas 9 and 46 of monkey (*Macaca mulatta*) prefrontal cortex. Tissue was examined from neonatal, adolescent, and adult animals; some of the adolescent animals were characterized endocrinologically, and were known to be either prepubertal or pubertal. Neurons were reconstructed using the Eutectics Neuron Tracing System. Preliminary observations revealed that spine density increased substantially during the first months of life, then declined markedly during adolescence, with most of the reduction occurring after the onset of puberty. For example, on the apical dendritic tree, spine density decreased 30% between prepubertal and adult animals. While additional studies are necessary to confirm these findings, they may be relevant to the hypothesis that schizophrenia can result from an abnormality in the process of synapse elimination during adolescence.

PROJECTIONS FROM THE ANTEROMEDIAL NUCLEUS OF THE THALAMUS TO THE LIMBIC AND VISUAL CORTICES. T. van Groen^{*} and J.M. Wyss. Dept of Cell Biology, University of Alabama, Birmingham, AL 35294

Previous studies indicate that the anteromedial (AM) nucleus of the thalamus primarily projects to the anterior cingulate cortex (area infraradiata; IR); but, our retrograde tracing studies suggest that many AM axons extend beyond this cortical area. In this study we have used anterogradely and retrogradely transported tracers to characterize the projections of AM. Injections into the rostral part of AM reliably label a terminal field extending from ventrocaudal IR α to rostral IR β cortices. In addition to the IR projections, rostral AM injections densely label axons and terminals in area 18b and rostral "retrosplenial granular a" cortex (Rga) and less densely label terminal fields in ventral subicular, caudal entorhinal and perirhinal cortices. In contrast, injections into caudal parts of AM consistently label terminal fields in dorsal IR α , caudal IR β , and precentral agranular (Preag) cortices. Thus, AM projections display a general topographical organization, e.g., rostral parts of AM project to rostral parts of IR β , whereas caudal parts of AM project to caudal parts of IR β . Further, rostral parts of AM project to caudal limbic cortex (i.e., Rga, subicular and entorhinal cortices); the medio-caudal parts of AM project to Preag but not to posterior limbic cortex, and the medioventral parts of AM project to area 18b. Axons of AM terminate primarily in layers I and IV in most cortical areas, but the AM projections to the caudal entorhinal and perirhinal cortices terminate in the deep layers (i.e., layers V-VI). These results demonstrate that AM projects to diverse cortical areas, and to different laminae in each area. This suggests that the projections of AM to each cortical area are functionally distinct.

SYNAPTIC PHYSIOLOGY OF NEURONS IN PERIRHINAL CORTEX. E.W. Kairiss^{*} and J.M. Baggus. Department of Psychology and Center for Theoretical and Applied Neuroscience, Yale University, Box 11A, Yale Station, New Haven, CT 06520.

Perirhinal cortex and amygdala are known to have reciprocal projections (McDonald & Jackson, *J. Comp. Neurol.*, 262:59-77, 1987) and have been implicated as necessary for expression of fear-potentiated startle in rats (Rosen et al., *J. Neuroscience*, 12:4624-33, 1992). To study interactions between these areas, we have developed an *in vitro* preparation designed to maintain their connectivity. We are interested in the following issues: Are there monosynaptic connections between these areas that can be contained in the slice? Can plasticity be induced at these connections? What cell types receive and send these projections?

Our preliminary results indicate that stimulation of the lateral nucleus of the amygdala (50 μ A) can elicit postsynaptic potentials (psps) in cells recorded intracellularly in perirhinal cortex. These psps had a latency of 4.85 \pm 0.32 ms (mean \pm SD), and followed consistently at this latency when stimulated at 50, 100, and 200Hz. Knife cuts in the slice to determine the pathway of these fibers reveal that they are not passing through the angular bundle. Together, these data suggest that there is a monosynaptic connection that can be contained in the slice from the lateral nucleus of the amygdala to perirhinal cortex via the external capsule.

To determine whether cells in perirhinal cortex support synaptic plasticity, high frequency stimulation (50, 100, 200Hz) was applied from the underlying white matter and from intracortical sites. In 8 experiments where such stimulation was given, long-term potentiation was obtained in 2/8 cases, long-term depression was obtained in 2/8 cases, and no change was observed in 4/8 cases. The incidence of LTP and LTD reported here is similar to that reported for neocortex proper.

This *in vitro* preparation affords the opportunity to study the physiology and pharmacology of cortico-limbic plasticity. These studies pave the way for more detailed experiments that will focus on the interactions between higher-order cortex and the amygdala. (Supported by NIH and Yale University)

591.1

SYNCHRONIZATION OF SLEEP RHYTHMS IN MULTI-SITE THALAMIC AND CORTICAL RECORDINGS. M. Steriade* and D. Contreras. Lab. of Neurophysiol., Laval University, Quebec, Canada G1K 7P4.

Sleep spindles (7-14 Hz) are generated by synaptic operations within the reticular thalamic (RE) nucleus and are modulated by inputs from thalamocortical (TC) and cortical cells, whereas delta potentials (1-4 Hz) arise from the interplay of two intrinsic currents of TC cells. A recently described slow (<1 Hz) cortical oscillation is reflected in RE and TC neurons and assists in grouping thalamic-generated rhythms within slowly recurring sequences (Steriade et al., J. Neurosci., 1993a-c). Here we report data on RE-, TC-, and cortical-cells' synchronization by means of multi-site, simultaneous intra- and extracellular recordings in anesthetized cats.

(a) Synchronization among RE cells, and between RE and TC cells, was demonstrated by cross-correlograms (CCs) of spindle oscillations evoked by cortical stimulation. That synchronization is due to synaptic linkages between RE and RE & TC neurons was shown by the shift predictor test. (b) Rhythmic spike-bursts at delta frequency occurred spontaneously in RE neurons and could also be triggered by depolarizations from a holding V_m of -90 mV. Simultaneously, target TC cells displayed IPSPs that were closely time-related to RE-cell's spike-bursts. This suggests that, besides the intrinsically generated delta rhythm, an oscillation with a similar frequency may arise through inhibitory synaptic coupling from RE to TC cells. (c) CCs indicated that the slow rhythm was synchronized between RE and neocortical cells, between various RE neurons recorded at a distance of ~ 1-1.5 mm (with in-phase or 180° out-of-phase relations), and between an intracellularly recorded RE cell and an adjacent neuron recorded across the membrane. Most TC cells were also synchronized at the slow rhythm with cortical and RE neurons, in phase or with a delay of 100-200 ms. The coherence between cortical and thalamic cells varied in parallel with the synchronization state of the EEG. These data indicate that various sleep rhythms, previously viewed as generated by properties of different structures, are united by interacting thalamic and corticothalamic networks.

591.3

CELLULAR SUBSTRATES OF EEG BURST-SUPPRESSION PATTERNS. R. Curró Dossi*, F. Amzica, D. Contreras and M. Steriade. Lab. of Neurophysiol., Laval University, Quebec, Canada G1K 7P4.

The EEG pattern of burst-suppression (BS) is defined as transient sequences of high-voltage slow waves with intermingled sharp waves, alternating with periods of depressed background activity or complete flatness. While this aspect was observed under a variety of experimental and clinical conditions, there is no available data as to the associated neuronal events.

We have recorded intra- and extracellularly cortical neurons (from areas 17 & 18, 5 & 7, and 4 & 6) with identified thalamic or callosal projections ($n=42$), as well as reticular thalamic (RE) and thalamocortical (TC) neurons from various dorsal thalamic nuclei ($n=48$), under different types of anesthesia. BS was induced by the administration of the same or other anesthetics upon an already synchronized EEG. (a) All tested neocortical cells entered BS pattern. The V_m hyperpolarized by 8-10 mV as a precursor sign of EEG-BS, the cells displayed sequences of phasic depolarizing events appearing exclusively during the EEG wave-bursts, and the periods of EEG flatness were associated with a complete electrical silence of neurons. (b) At variance with cortical cells, only 70% of RE and 60% of TC cells displayed an activity closely related to the EEG-BS. Those thalamic neurons that deviated from the EEG-cell correspondence were mainly TC elements that, during flat EEG periods, discharged rhythmic spike-bursts within the delta frequency range (1-4 Hz). It is known that this is an intrinsic oscillation of TC cells, arising at a V_m more negative than -75 mV. With further deepening of the EEG-BS pattern (silent periods of >30 s), thalamic cells ceased firing during blackout phases of the EEG. Single shocks applied to the thalamus or cortex could replace the periods of electrical silence by apparently normal EEG and neuronal activity.

VISUAL AND SPATIAL INFORMATION PROCESSING IN HUMAN PARIETAL ASSOCIATION CORTEX: USING MEG.

S. Murakami*, S. Kuriki¹, O. Ohshiro¹, M. Fujii, R. Fukatsu and N. Takahata. Dept. of Neuropsychiatry, Sch. of Medicine, Sapporo Medical University, Sapporo 060, Japan and ¹ Research Institute for Electronic Science, Hokkaido University, Sapporo 060, Japan

The neural function of the parietal association cortex (PAC) is known to be related to the visual spatial cognition. We reported the magnetic field responses in PAC to visual stimulation (Neurosci. Res. 16 (1993):225). In this study, we investigate the influence of the eye position to the magnetic field responses to retinal visual stimulation for the purpose of analyzing the neural mechanism of visual spatial cognition in PAC. The subjects for experiments were studied in a magnetically shielded room to record the responses to visual stimulation with a 37-channel SQUID magnetometer system (BTi), from PAC. Two LEDs were set, one as a visual stimulation and the other as a gazing point, which was used for the eye position change in orbita. The stimulation LED was lit for 0.5 sec at random intervals of 1-1.5 sec and located 3 degrees away from the gazing point. The magnetic field responses to visual stimulation, were averaged from 256 sweeps. Main magnetic field responses peaking at 140-180 msec after stimulating LED onset were recorded in all subjects. A change in the magnetic field responses with the eye position, which was changed by gazing LED, was not found in the latency but found a little in the amplitude of the main responses. The estimated current dipole sources of the main responses were located in the almost one region of PAC, but the direction of the current was different.

591.2

SYNCHRONIZATION OF THE SLOW (≈ 0.3 Hz) OSCILLATION IN CORTICAL NETWORKS. F. Amzica* and M. Steriade. Lab. of Neurophysiol., Laval University, Quebec, Canada G1K 7P4.

A slow oscillation (<1 Hz) of cortical and thalamic neurons was recently described under various anesthetics as well as in brainstem-disconnected animals and during natural quiescent sleep (Steriade et al., 1993a-c, J. Neurosci., 13: in press). Intracellular recordings showed that this oscillation arises from cortical networks even in the absence of the thalamus and has a pivotal role in grouping the thalamic-generated sleep spindles (7-14 Hz) and delta potentials (1-4 Hz) within the ≈ 0.3 Hz rhythm.

Here we report data on the synchronization of this slow oscillation, resulting from multi-site (up to 6 channels) simultaneous extra- and intracellular recordings of cortical neurons (areas 6, 4, 5, 7, 21, 19, 18 and 17) in cats maintained under ketamine-xylazine anesthesia. Correlation and spectral analyses were performed from spikes, focal or intracellular waves, and EEG components. There was a close temporal relation between spikes' and waves' oscillatory patterns in 75% of neuronal groups.

The repartition of the slow oscillation over different areas revealed that in 40% of cases the rhythm appeared with the same weight in FFTs from all areas. In the remaining 60% of cell-groups, a clear prevalence of this rhythm was observed in visual areas 21 & 18 and suprasylvian areas 5 & 7 over pericruciate areas 6 & 4. (a) Multiple recordings within the same area, with tracks separated by 1-2 mm, showed that in 80% of cell-groups the depolarizing envelopes and/or spike-trains in caudal foci preceded those in more rostral sites, with time lags of 5-35 ms. (b) With simultaneous recordings from distant areas, a preferred sequential pathway was observed in $\approx 60\%$ of triple or more numerous recordings from posterior, middle suprasylvian, and pericruciate areas. Time lags in distant recordings ranged from 10 to more than 100 ms. Long delays could well have involved inhibition-rebound sequences in thalamic neurons projecting back to the neocortex. These data suggest that the slow rhythm is distributed through short- and/or long-range synaptic linkages across intracortical and corticothalamic networks.

591.4

INTRALAMINAR NUCLEI AND THE WHERE OF AWARENESS.

J.E. Bogen*, Dept. of Neurol. Surg., Univ. of So. Calif., Los Angeles, CA 90033

How certain neural mechanisms (Mc) momentarily endow with conscious awareness (C) percepts represented elsewhere is more likely to be solved when structures essential to Mc are identified. The loss of C with bilateral thalamic lesions involving the intralaminar nuclei (ILN) contrasts with retention of C after large cortical ablations depriving C of specific contents. A role of ILN in the perception of poorly differentiated (i.e., not cortically computed) sensations (e.g., crude pain) is suggested by their afference of directly ascending pathways. A role for ILN in awareness of cortical activity is suggested by their widespread afference from cortex, a property shared with striatum. A role for ILN in volition is suggested by their heavy projection to striatum. Unlike striatum, ILN also project widely to almost all neocortex, enabling an effect on ideation; this last property is in common with other structures (e.g., locus coeruleus) but none of them have the same direct cortical afference. And passage through n. reticularis (NRT) of ILN efferents to cortex could impact the attention selective action of NRT. These five anatomical facts are supportive of the inference from clinical observation.

591.6

AUDITORY AND VISUAL REPRESENTATIONS IN HUMAN PREFRONTAL CORTEX. ¹J.M. Clarke*, ²P. Chauvel, ³J.-M. Scarabin and ⁴E. Halgren. ¹Dept. Psychology, Univ. North Texas, Denton, TX, 76203; ²INSERM C9F90-12 & ³INSERM U335, Univ. Rennes I, 35033 Rennes, France.

Electrophysiological findings of auditory and visual representations in the prefrontal cortex were apparent from intracerebral 'depth' recordings of focal, sensory-evoked spike-wave complexes in an epileptic patient. In addition to clinical monitoring, the patient participated in behavioral evoked potential studies involving auditory and visual discrimination tasks. Inspection of evoked-potential recordings from different medial-to-lateral sites revealed overlapping, but non-identical evoked-spike topographies for the two sensory modalities (located approximately at the intersection of Brodmann's areas 9 & 46). Maximal sensory-evoked spike responses were localized 7mm more laterally for auditory than for visual stimuli, and had an earlier latency for auditory presentations ($M=83$ ms following stimulus onset) than for visual ones ($M=115$ ms). Effects of sensory habituation were seen; evoked spikes were less frequent following repeated presentations of an unchanging tone than when tones alternated in pitch, or when a tone followed an omission in stimulus presentation. Visual hemifield effects were found, with greater prefrontal responsiveness to presentations in the contralateral visual hemifield. These results are consistent with electrophysiological findings in animals indicating overlapping auditory and visual representations in prefrontal cortex. SYNAPTIC INHIBITION AND DIS-INHIBITION IN RAT AUDITORY THALAMUS.

B. HU, D. Mooney, V. Senatorov. *Loeb Research Institute, Ottawa Civic Hospital, Ottawa, Ontario, Canada. K1Y 4E9*

Synaptic inhibition and disinhibition are important regulatory mechanisms underlying thalamocortical information processing. Using a newly-developed *in vitro* explant preparation, we have examined the synaptic events underlying cell inhibition in the auditory thalamus.

Electrical stimulation of the brachium of the inferior colliculus (BIC) elicited an early EPSP followed by a biphasic IPSP in the ventral (n=24) or dorsal (n=11) divisions of the medial geniculate body (MGB). The early phase of the IPSP was chloride-dependent. It had a reversal potential of -63 ± 2 mV and was fully blocked by the GABA_A receptor antagonists picrotoxin or bicuculline (20 μ M respectively). The occurrence of the second phase of the IPSP required a higher intensity of stimulation. The second phase reversed its polarity around E_{Cl} (-84 ± 2 mV) and was partially antagonized by the GABA_B receptor blocker phaclofen (30 μ M).

Bath application of muscarine (10-20 μ M; n=12) consistently and reversibly blocked both GABA_A and GABA_B components of the evoked IPSPs. This prominent disinhibition was nevertheless quasi-complete (with ~15% residual IPSPs) and invariably associated with a 25-40 percent increase of membrane resistance. Muscarine lacked a direct antagonistic effect on hyperpolarizations evoked by GABA applied exogenously, nor did it affect glutamatergic synaptic potentials.

We conclude that inhibition in rat MGB involves chiefly GABA receptor activation. Muscarine suppresses GABAergic IPSPs likely via inhibition of local GABAergic interneurons (McCormick and Pape, 1988). *Supported by Parkinson Foundation of Canada, Ontario Mental Health Foundation and MRC of Canada.*

591.9

INTEGRATION OF SENSORY SIGNALS BY ASSOCIATION CORTEX IN THE MILLISECOND RANGE.

Kiyohiko Nakamura*. Grad. Sch. of Information Sci.

Univ. of Electro-Communications, 1-5-1 Chofugaoka, Chofu Tokyo 182, Japan.

The cerebral cortex is capable of processing different sensory signals in a few hundred milliseconds to produce correct response. Previous work has presented a mechanism of cortical circuits, *temporal competition*, which is an optimal parallel processing using firing timing of several milliseconds. Latency of cortical response to sensory stimuli varies with sensory modality in the range of tens of milliseconds, however. This report presents a hypothetical mechanism which enables the cortical circuits to integrate neural signals of different latencies. The mechanism assumes a long-term potentiation (LTP) of cortical cells coactivated by multi-modal inputs. A test of the mechanism by computer simulation of a model circuit is presented. The mechanism suggests: (1) intracellular processes of the LTP may hold effects of inputs of short latencies, (2) the LTP produced by coactivation of inputs may determine onset of the temporal competition among the inputs of different latencies, and (3) after the onset, the competition may restrict firing to cells activated first. It follows from these that the cortical processing of temporal competition is capable of integrating sensory signals of different latencies in several milliseconds.

591.11

NEURONAL AND SLOW WAVE ACTIVITY IN CEREBRAL CORTEX PRECEDING SPONTANEOUS AND EVOKED ELEVATIONS OF CEREBRAL BLOOD FLOW. **E.V. Golanov*** and **D.J. Reis.** Div. of Neurobiol., Cornell Univ. Med. Coll., New York, NY 10021.

We sought to determine in rat if elevations of cerebral blood flow (rCBF) in cerebral cortex appearing spontaneously or evoked from rostral ventrolateral medulla (RVL) or fastigial nucleus (FN) were associated with local neuronal events. Rats were anesthetized with 1.6-1.75% isoflurane, rCBF measured by laser-Doppler flowmetry and EEG recorded. At rest, rCBF spontaneously fluctuated (4-6/min) with each flow wave preceded by a EEG burst reflected simultaneously across cortex. Signal averaging revealed that bursts consisted of triphasic positive-negative-positive complexes followed, 1.4 ± 0.4 sec later, by a transient elevation of rCBF. Identical burst-rCBF complexes were evoked after 33 or 48 msec by single shocks of RVL or FN, respectively. The polarity of the triphasic complex was reversed in cortical laminae IV-V. Evoked responses were inhibited for 30-40 msec by a preceding spontaneous burst-rCBF complex. Spontaneously discharging (1.2-2.6 Hz) neurons, comprising 9.1% of active neurons, were recorded extracellularly in laminae IV-V which invariably discharged (2-4 spikes) 25-3 msec after spontaneous or evoked burst-wave responses and during the negative component of the triphasic complex. We conclude: (a) elevations in cortical rCBF elicited from FN and RVL or appearing spontaneously with EEG bursts share a common electrophysiological signature, a triphasic vasculature-associated complex; (b) this complex reflects activity of neurons in laminae IV-V; (c) their discharge appears to predict associated elevations in rCBF. They may represent cortical neurons acting as a common final pathway in transducing intrinsic neuronal signals into cortical vasodilation not coupled to metabolism.

MULTISENSORY CONVERGENCE AND INTEGRATION IN RAT CORTEX. **R. Ramachandran¹, M.T. Wallace², H.R. Clemons² & B.E. Stein².** Departments of Biomedical Engineering¹ & Physiology², Medical College of Virginia/Virginia Commonwealth University, Richmond VA 23298

A grid of electrode penetrations (n=81) was made across occipital, temporal, and parietal cortices in 26 adult rats. Recordings were made from 843 neurons, and although the traditional divisions of these cortices into visual, auditory, and somatosensory domains was apparent, multisensory neurons (n=93) were encountered within each region of cortex. The incidence of multisensory neurons was highest near the borders between 'unimodal' regions, with the multisensory convergence patterns matching the modalities represented in the border zones. In addition, a focus of multisensory neurons was found in rostral parietal cortex, near the border with motor cortex. Regardless of a neuron's location or modality convergence pattern, it could be shown to integrate information from the different sensory modalities. Thus, stimuli that originated from similar points in sensory space resulted in response enhancement, whereas spatially disparate stimuli either failed to produce an interaction or resulted in response depression. Multisensory interactions were multiplicative and could take place within a wide (up to 400 msec) temporal window. The spatial, temporal, and multiplicative features governing these interactions are similar to the principles governing multisensory interactions in other species and in subcortical areas as well as cortical areas. Thus, many of the principles of multisensory integration appear to supersede structure, function and species. Supported by NIH grant NS 22543.

PREDICTION OF THE EEG BY A NOVEL NEURAL NETWORK SUGGESTS CHAOTIC DYNAMICS IN THALAMOCORTICAL CIRCUITRY. **G. Jandó, G. Buzsáki* & R. M. Siegel.** CMBN, Rutgers University, Newark, NJ 07102.

A two-layer linear network, a four-layer standard back-propagation feed-forward network and a novel highly interconnected linked autoassociator network were trained to predict different states of the electroencephalogram recorded from the neocortex. The latter network, termed as linked autoassociator, consisted of one input and one output layer and four hidden layers of autoassociator units. All the units in the hidden layers received signals from the input layer and the previous hidden layer. The fourth hidden layer signaled to the first hidden layer. The autoassociator units had sigmoidal input-output characteristic and a time dependent capacitance. Connections between layers, the capacity and non-linear function were optimized using simulated annealing. In all networks the input signals were time delayed values of the EEG based on Takens theorem which states that time-delayed signals are a complete representation of the dynamics of a multi-element system. The output neuron predicted the value of the EEG 10 msec forward. Thus, the network was trained to extract predictive components from the EEG signal. The linked autoassociator was based upon the hippocampal network. In particular, the direct inputs to the hidden layer units corresponded to the feed-forward perforant path connection, while the autoassociator corresponded to CA3. The feedback corresponds to the subiculum-entorhinal intracortical connection.

The training sets for the three types of networks consisted of sinusoids, known chaotic data (Duffing equation), oscillatory states of EEG (e.g. spindling, slow wave sleep) and desynchronized EEG. The first two sets were used to test that the networks could learn known dynamics. As expected, the linear network could only learn the sinusoid. Although both the feed-forward and the linked autoassociator could learn the Duffing chaotic data, the spindling and the slow wave sleep, the performance of the linked autoassociator was superior. None of the networks were able to learn the desynchronized EEG. Once the networks learned the temporal characteristics of the different types of signals, the learning was turned off and the networks were used to explore the encapsulated dynamics. This was done by feeding the network's predicted values back into the input of the network. These artificially generated signals had the same wave shape and frequency components of high voltage spike and wave spindles.

Further exploration of long time series of the artificial signals using standard analysis drawn from chaos theory (e.g. phase plot, Poincaré sections) reveal a striking similarity to data from other natural chaotic systems. This suggest that the neural signals are truly chaotic (i.e. aperiodic yet have a strong predictive component) and that it may be possible to represent the dynamics of certain EEG patterns by a simple deterministic set of equations. Supported by ONR N00014-93-1-0334 and NS-27058.

SEASONAL PATTERNS OF NEUROGENESIS IN THE HIPPOCAMPUS OF ADULT FOOD-CACHING BIRDS AND THEIR POSSIBLE RELATION TO SPATIAL LEARNING.

A. Bamea* F. Nottebohm, The Rockefeller University, N.Y., 10021.

Recent evidence suggests that the avian hippocampus plays an important role in spatial memory and that it is functionally related to food caching behavior (Krebs *et al.*, 1989). Black-capped chickadees (*Parus atricapillus*) store food items during fall and winter in a scattered distribution within their home range and use memory to retrieve them. We used free ranging adult chickadees to test the hypothesis that there is a seasonal peak in the incidence of hippocampal adult neurogenesis which correlates with food storing behavior. Birds were captured and injected intramuscularly with a single dose of 50 μ Ci of 3H-thymidine. These birds were released and then recaptured six weeks later. At that time birds were killed and their brains were processed for autoradiography and histology. Different birds were injected during August, September, October, December, February, and March.

The great majority of labeled hippocampal neurons was found in a 350 μ m thick layer of the tissue dorsal to the dorsal wall of the lateral ventricle. These neurons were relatively large (mean nuclear diameter of 11.4 μ m \pm 1.17, n=308). Labeling index, determined by the percentage of labeled hippocampal neurons, differed between times of year: it peaked at the end of summer and became less significant as winter gave way to spring. These results correlate with the occurrence of food-storing behavior which starts in early autumn and decreases as winter progresses. We suggest that new neurons become available shortly before they are needed to encode new food storing information and that the neurons and the information they hold are replaced, perhaps at yearly intervals.

592.3

MORE HIPPOCAMPAL NITRIC OXIDE SYNTHASE IN FOOD-STORING THAN IN NON-STORING BIRDS.

A.D. Székely and J.B. Krebs (SPON: Brain Research Association) Departments of Pharmacology and Zoology, University of Oxford, Oxford OX1 3PS, United Kingdom

Nitric oxide (NO) has been hypothesised to be involved in the induction of long-term potentiation (LTP), which is a putative cellular basis of memory in the mammalian hippocampus. Neurons releasing NO can be detected by NADPH-diphosphorase histochemistry.

In birds, the hippocampal formation (HP) is the morphological equivalent of the mammalian hippocampus. Functionally this region is involved in the processing of memory associated with spatial behaviour. Long-term enhancement of synaptic response has also been observed in the avian HP. To study the distribution of NADPH-diphosphorase staining, the birds (4 marsh tits and 4 blue tits of either sex) were anaesthetised and perfused through the heart. Coronal sections of 50 μ m were reacted in the presence of NADPH and nitro blue tetrazolium. In both species, the staining was seen in neurones and in strongly labelled neuropil which revealed circumscribed brain areas including the neostriatum, archistriatum, lobus parolfactorius, nucleus of the diagonal band and the nucleus rotundus. In HP, a few elongated neurones were stained, situated mainly in the vicinity of the lateral ventricle and along the lateral border. In the HP of marsh tits, the level of diffuse neuropil staining was substantially higher, highlighting the entire structure, than in the blue tits where the HP could not be distinguished from the surrounding regions. The higher level of labelling found in the HP of food-storing birds suggests a specific role for NO in hippocampal processing of spatial information.

EFFECT OF HIPPOCAMPAL LESIONS ON PLACE LEARNING IN PIGEONS. T. Fremouw*, P. Jackson-Smith, C. P. Shimp, and R. P. Kesner. Dept. of Psychology, Univ. of Utah, Salt Lake, UT 84112.

We studied how the hippocampus affects pigeons' (Columba livia) performance in a dry land version of the Morris water maze when searching for a single hidden food location. The maze was a 2m-diameter circular arena with eight foodwells drilled in the floor. The entire floor was covered with sawdust which concealed the eight foodwells. Intramaze cues consisted of pictures on the inner wall of the arena. Extramaze cues consisted of pictures on the room walls, a door, and shelving. Hippocampal and control pigeons were pretrained to search for food hidden in all eight of the foodwells. After the pigeons learned to search for food, a single food location was chosen (one of the eight foodwells) and, thereafter, food was placed only in that hole. Four trials per day were then given, with each trial lasting a maximum of four minutes. If a bird did not find the food within that time the food location was uncovered and the bird was allowed to eat a small portion of the food there. Hippocampal birds learned the food location significantly slower than controls. However, by day 20 hippocampal and control birds were performing at similar levels. On day 21 a new food location was chosen. Again, hippocampal birds learned the location significantly slower than the controls. Finally, a probe trial was conducted in which the maze was rotated 180 degrees. The performance of both groups of pigeons was unaffected by this rotation suggesting that both groups used extramaze cues. Hippocampal lesions in pigeons produce learning deficits in a place learning task that are similar to those produced by hippocampal lesions in rats.

592.2

SEASONAL CHANGES IN TELECEPHALON VOLUME IN A FOOD-STORING BIRD (BLACK-CAPPED CHICKADEE *Parus atricapillus*). T.V. Smulders, A.D. Sasson, and T.J. Devoogd*. Department of Psychology, Uris Hall, Cornell University, Ithaca, NY 14853.

Like many members of the Paridae, black-capped chickadees scatter-hoard food-items. Anecdotal field data suggest that this behavior is more frequent in fall and in winter than it is in spring and in summer. Because the avian hippocampus is involved in the spatial memory for stored food items (Sherry & Vaccarino, 1989; Krebs, 1990), we decided to look for seasonal changes in the volume of the hippocampus, in parallel with the seasonal changes in behavior. Our hypothesis predicts a larger hippocampus in the food-storing season.

Birds were caught at 4 different times of the year and hippocampal volumes from Nissl-stained tissue were compared among the groups. Hippocampal volume and overall telencephalon volume differ significantly with season. However, both are larger when average temperature is higher. The effect on the hippocampus can be totally accounted for by the effect on the telencephalon as a whole. Therefore, we find no specific effect on hippocampal volume, related to seasonal food-storing activity. The relation between temperature and telencephalon size could be explained by either a direct effect of temperature on the brain, or through food-availability, which parallels temperature over the season (Goutis & Winkler, 1992). Alternatively, both could be due to a lagging effect of daylength. Supported by MH-48926 and a Philips award from the Belgian-American Education Foundation.

592.4

HIPPOCAMPAL LESIONS IMPAIR SUN COMPASS LEARNING IN HOMING PIGEONS. V.P. Bingman* and T.J. Jones. Department of Psychology, Bowling Green State University, Bowling Green, OH 43403.

The hippocampal formation of birds and mammals is a brain structure known to be critical for spatial memory and the learning of environmental maps. But how is a spatial map learned and what is the role of the hippocampal formation in the learning process? The ability to use the sun to define directions in space, or sun compass, is perhaps the most ubiquitous, naturally occurring spatial orientation mechanism found in the animal kingdom. In addition to guiding movement, the sun compass of birds may serve as a directional reference system that enables animals to learn about the spatial distribution or location of other stimuli in the environment. Thus, the sun compass may play a critical role in map learning. We report that homing pigeons with hippocampal lesions are unable to use the sun compass to learn the location of a food reward. The results indicate that the importance of the hippocampal formation in map learning may be related to its participation in a neural process in which information from a directional reference system, in this case the sun compass, is used to register the location of other stimuli that are normally components of some type of map.

592.6

IMPAIRED COLOR-REVERSAL LEARNING IN PIGEONS AFTER LESIONS OF THE HYPERSTRIATUM VENTRALE. L. Chaves and W. Hodos*. Dept. of Psychology, University of Maryland, College Park, MD 20742.

Lesion studies of color-reversal learning in pigeons show that an impairment results when (1) the tectofugal visual pathway is damaged at either the thalamic level (nucleus rotundus) or the telencephalic level (ectostriatum), or (2) the thalamofugal visual pathway is damaged at the telencephalic level (the visual Wulst). An impairment does not result, however, when the thalamic source of thalamofugal input to the visual Wulst (OPT) is damaged. These results suggest that in pigeons, the Wulst maintains a role in color-reversal learning by receiving visual information routed from the tectofugal pathway via other visual areas in the telencephalon such as the hyperstriatum ventrale (HV). In the present study, medial and lateral regions of HV were ablated. Pigeons were trained post-operatively to discriminate two colors presented simultaneously. After reaching criterion, they were required to perform a series of discrimination reversals in which the positive and negative stimuli were interchanged. An impairment in color-reversal learning resulted when lateral HV was damaged in conjunction with damage to the frontothalamic tract (FT), which carries ascending visual input from OPT to the visual Wulst. No deficits were observed when either lateral HV or FT were damaged alone. Lesions of medial HV resulted in impaired performance of a color-discrimination task (i.e., original learning), but did not affect discrimination reversal. These findings suggest that the visual Wulst requires input from both the tectofugal pathway (via lateral HV) as well as from the thalamofugal pathway in order for its role in color-reversal learning to be maintained.

592.7

MEMORY IN THE CHICK: MULTIPLE CUES, DISTINCT BRAIN LOCATIONS. T.A. Barber (Patterson)*. Department of Psychology, Dickinson College, Carlisle, PA 17013.

Biochemical, electrophysiological, and morphological changes in the intermediate medial hyperstriatum ventrale (IMHV) of chicks trained on a one-trial passive avoidance task suggest that the IMHV is an important site of memory storage. However, post-training lesions of the IMHV are not amnesic (Patterson, Gilbert and Rose, 1990).

The effects of post-training IMHV lesions in a two-color discrimination task were examined. Lesions impaired discrimination between aversive and non-aversive beads but did not impair ability to peck non-aversive or novel beads, indicating that IMHV lesions disrupt the association between color and the aversive taste.

These data suggest that the IMHV processes and/or stores the association of color and aversion. Post-training IMHV lesions do not "impair" retention; chicks can successfully avoid the aversive bead on the basis of other components such as the shape or size. This interpretation explains why significant alterations occur in the IMHV after training, because they are involved with forming the color-specific aspect of the multiple representations of the aversive bead.

These results suggest that memory is comprised of different forms of representation that are processed and stored in different areas of the chick forebrain and even simple associations can be stored in the brain in the form of multiple, dispersed representations.

DEVELOPMENT OF SONG SYSTEM NUCLEUS HVC IN JUVENILE MALE ZEBRA FINCHES DEPRIVED OF SONG.

C. E. Collins*, E. Wallhäusser-Franke, R.P. Clower and T.J. DeVoogd

Department of Psychology, Uris Hall, Cornell Univ., Ithaca, NY 14853

Songbird species learn aspects of their song. In many of these species, this learning occurs in a juvenile sensitive period. Songs heard during this interval are used as models for the song that the young bird will later produce. If the juvenile does not hear song, the sensitive period for acquiring a model may be prolonged (Eales, '85, '87). Several labs have noted neural events that occur in phase with song learning that could provide a substrate for the learning. The present study manipulates the opportunity for song learning and searches for consequent ultrastructural changes in HVC, a song-related brain area.

Zebra finch pairs raised young in a sound proof room. Four to five days after the young hatched, the adult male was removed. At independence the young were housed together. At 30 or 55 days, males were perfused and song-related area HVC was prepared for electron microscopy. Serial section analyses were conducted using the unbiased disector stereological method (Sterio, '84). Preliminary results suggest that at 55 days the number of synapses in HVC is higher in song deprived than in control birds. Thus, learning a song may be associated with the loss of synapses, or preventing this form of learning may selectively preserve synapses, in accord with recent theories on synapse selection (Scheich, et al, '91). Supported by HD-21033.

BILATERAL L-MAN LESIONS DISRUPT SONG CONSOLIDATION AT SONG ONSET IN ADULT MALE WHITE-CROWNED SPARROWS. S. Benton, P. Marler*, D.A. Nelson and T.J. DeVoogd. Neurobiology & Behavior, Cornell Univ., Ithaca, NY 14853; Dept. Zoology, Univ. Calif., Davis, CA 95616.

The function of nucleus l-MAN in adult male songbirds is incompletely understood. Lesioning l-MAN during song learning in juvenile birds disrupts learning, while the same lesions made in singing adults produce no immediate deterioration in stereotyped song. However, when l-MAN is lesioned in adult canaries on a short-day light cycle, the birds produce aberrant songs when put on long-days (Suter et al., 1990; Hill et al., 1992). We have made bilateral l-MAN lesions in adult (3 yr. old) male white-crowned sparrows (*Zonotrichia leucophrys oriantha* and *Z. l. nuttalli*) on short-days. White-crowned sparrows are sensitive-period learners that maintain a stable song pattern through adulthood. Substantial unilateral to complete bilateral lesions have minimal effects on song structure but appear to affect other aspects of song consolidation. When put on long-days, lesioned males appear to experience a prolonged plastic period of up to two months before the onset of full song. This plastic phase is characterized by periods of no song, low volume song, and periods during which song elements are embedded among call notes. These results are consistent with the hypothesis that l-MAN may modify song consolidation via NMDA receptors in RA. It has been suggested that input from l-MAN may selectively reinforce and refine the output from RA through postsynaptic NMDA receptors (Mooney, 1992). This mechanism could account for refinements made to established song during the plastic period experienced at song onset each spring. Supported by HD21033.

CLASSICAL CONDITIONING ENHANCES THE EXPRESSION OF THE IMMEDIATE EARLY GENE ZENK IN RESPONSE TO CONSPECIFIC SONG Erich D. Jarvis, Claudio Mello and Fernando Nottebohm*. Lab. of Animal Behavior, The Rockefeller University, New York, N.Y. 10021

A classical conditioning paradigm was developed to see if induction of the immediate early gene ZENK in response to playbacks of conspecific song (Mello et. al., 1992) could be influenced by context. Canaries were placed into a plexiglass box with a metal bar floor and no perches. They learned to avoid a mild (200uA) shock to their feet delivered at the end of each song stimulus by fluttering and thus breaking contact with the metal floor. The stimuli used were short (1.8-4.0 sec) fragments of canary song presented once every 30 sec. At the end of 45 min. birds trained in this manner were responding correctly and avoiding shock 80-90% of the time. They were then killed and their brains prepared for in-situ hybridization with canary ZENK, an immediate early gene encoding a transcription factor. Results were quantified by densitometric analysis of X-ray film autoradiograms. Pairing song with shock avoidance training doubled the level of ZENK expression in two telencephalic auditory regions, the caudomedial neostriatum (NCM) and the mediocaudal hyperstriatum ventralis (HVMC), as compared with the effectiveness of presenting song alone or in random association with shock. We infer that the up-regulation of ZENK expression in NCM-HVMC by exposure to conspecific song is influenced by the context in which the song occurs.

STRESS: NEUROCHEMISTRY

AMYGDALA LESIONS BLOCK PSYCHOLOGICAL STRESS-INDUCED METABOLIC ACTIVATION OF THE DOPAMINE, NOREPINEPHRINE, AND SEROTONIN SYSTEMS IN THE RAT PREFRONTAL CORTEX: A BEHAVIORAL, NEUROENDOCRINE, AND NEUROCHEMICAL STUDY.

LE Goldstein, AM Rasmusson, BS Bunney, RH Roth*. Yale Medical School, Depts. Psychiatry and Pharmacology, New Haven, CT 06510

When exposed to threatening stimuli, rats exhibit a species-specific defense reaction which includes freezing behavior, ultrasonic vocalization, and elevation of serum corticosterone. Exposure to psychological stress is also known to selectively activate dopamine, serotonin, and norepinephrine utilization in the anteromedial prefrontal cortex (mPFC). Neuroanatomical site(s) providing afferent control of the stress activation of these mPFC biogenic amine systems is at present unknown. Using a conditioned stress model in which rats are trained to fear a sub-startle threshold tone previously paired with footshock, the present study demonstrates that: (1) conditioned stress-induced metabolic activation of the mPFC dopamine, serotonin, and norepinephrine systems persists for at least two weeks after training, and (2) combined post-training N-methyl-D-aspartate (NMDA) excitotoxic lesions of the basolateral and central nuclei of the amygdala block metabolic activation of these biogenic amine systems. In addition, amygdala lesions abolished conditioned stress induced freezing behavior, ultrasonic vocalization, and elevation of serum corticosterone. Pre-training NMDA lesions of the amygdala also completely blocked ultrasonic distress vocalizations during the conditioning period. In contrast, NMDA excitotoxic lesions of the mPFC do not block the behavioral or adrenocortical responses to conditioned stress. In fact, lesion of the mPFC potentiates conditioned ultrasonic distress vocalization. These data provide evidence of amygdalar afferent control of the mPFC monoaminergic system responses to conditioned stress. In addition, these experiments suggest that the mPFC may modulate the subcortical circuitry coordinated by the amygdala. Supported by USPHS grant MH 14092.

EFFECTS OF CHRONIC SOCIAL STRESS ON SEROTONIN RECEPTOR BINDING. C.R. McKittrick*, D.C. Blanchard, R.J. Blanchard, B.S. McEwen, and R.R. Sakai. Rockefeller University, New York, NY 10021, University of Hawaii, 2430 Campus Rd., Honolulu, HI 96822 and University of Pennsylvania, Philadelphia, PA 19104.

Mixed-sex rat colonies (5 male, 2 female) housed in a visible burrow system for 14 d have been used to determine the effects of chronic social stress on brain 5HT receptors. The male rats quickly form dominance hierarchies consisting of one dominant (DOM) and four subordinates; the subordinates can be further subdivided into stress responsive subordinates (SRS) and nonresponsive subordinates (NRS) based on analyses of corticosterone responses to 1 hour of novel restraint stress. Glucocorticoids and stress have been shown to affect binding to various 5HT receptor subtypes. We have found that 5HT1A receptors are downregulated in several areas of hippocampus in colony-housed animals as compared to individually-housed age- and weight-matched controls (CON). In CA1, 5HT1A binding is significantly decreased in DOM and SRS animals ($\downarrow 24\%$ and 19% , respectively, compared to CON), while there is no corresponding change in the NRS. However, in CA3, binding is decreased in all colony animals compared to CON (DOM: $\downarrow 22\%$; SRS: $\downarrow 24\%$; NRS: $\downarrow 18\%$). In contrast, only SRS have significant decreases in binding in CA2 ($\downarrow 20\%$) and the dentate gyrus ($\downarrow 18\%$). The chronic social stress also affects 5HT2 receptors, as binding is increased in layer IV of parietal cortex of both SRS ($\uparrow 64\%$) and NRS ($\uparrow 72\%$). The changes observed in both receptor subtypes are consistent with those seen following CORT or ACTH administration. [Supported by: NARSAD (RRS), NSF BNS9111524 (DCB) and MH41286(BMC)]

593.3

THE EFFECT OF CHRONIC SOCIAL STRESS ON GENE EXPRESSION IN THE RAT HIPPOCAMPUS. H.M. Chao*, D.C. Blanchard, R.J. Blanchard, B.S. McEwen, and R.R. Sakai. The Rockefeller University, New York, NY 10021, University of Hawaii, Honolulu, HI 96822 and University of Pennsylvania, Philadelphia, PA 19104

The housing of rat colonies in a visible burrow system, provides an effective method by which the behavioral and neuroendocrine effects of social stress can be examined. Subordinate rats have been shown to exhibit elevated plasma corticosterone relative to the dominant rat in the colony. Moreover both dominant and subordinate rats in this system have higher basal corticosterone levels than singly housed controls.

Previous studies have indicated that glucocorticoids negatively regulate the expression of the mRNAs encoding the glucocorticoid receptor (GR), the mineralocorticoid receptor (MR) and the growth-associated protein, GAP-43. This study examines the effect of social stress, and the resulting sustained increase in steroid levels, on gene expression. Our results indicate that GR, MR and GAP-43 mRNAs are decreased in subordinate rats relative to controls, in the CA1 region of the hippocampus. No statistically significant differences in mRNA expression are observed in other hippocampal subfields. The dominant rats, which have levels of circulating glucocorticoids intermediate between control and subordinate rats, exhibit intermediate levels of these mRNAs. These findings suggest that the stress of group housing elicits changes in hippocampal gene expression consistent with those previously demonstrated by surgical or pharmacological manipulation of adrenal steroid levels. NEUROTENSIN BLOCKS THE SOUND STRESS INDUCED ACTIVATION OF THE ASCENDING SEROTONINERGIC NEURONS OF THE DORSAL RAPHE NUCLEUS. M.C. Roadle-Biber*, M. Novitzki and R.P. Dilts. Dept. of Physiology, Medical College of Virginia-VCU, Richmond, VA 23298-0551

In this study we investigated the effects of the tridecapeptide, neurotensin (NT), on tryptophan hydroxylase (EC 1.14.16.4) (TrpH), the rate limiting enzyme in serotonin biosynthesis. Rats (125-150 g), were implanted with 27 ga. guide cannulae directed towards the lateral ventricles (A/P -1.0, M/L 1.5, D/V 3.2 mm from bregma), fitted with 31 ga. arbiters, and allowed to recover for at least three days. Animals were subsequently habituated to handling for two days and on the third day were left untreated or infused with either 0.5 ul saline or 0.3 - 10 nmols of NT in 0.5 ul saline. Five minutes after the infusion, rats were injected with the amino acid decarboxylase inhibitor, m-hydroxyhydrazine (I.P. 100 mg/kg), and placed into the sound stress chambers. Rats were either exposed to one-half hour of random 110 dB sound or no sound (control) and subsequently decapitated. Brains were rapidly removed, frozen and subsequently analyzed by HPLC-EC. Results were analyzed using random ANOVA with $p < 0.05$ and post-hoc analysis. Sound stress significantly increased the accumulation of 5-HTP within the midbrain (473.5 ± 35.5 ; mean \pm S.E.M.) compared to controls (277 ± 14.4) as well as in the terminal fields of striatum, cortex and hippocampus. NT at all doses blocked the sound stress induced increase in 5-HTP within the midbrain, as well as within all the terminal fields. Ten nmol of NT significantly reduced 5-HTP values below controls in both sound and sham treated midbrain (111 ± 9 & 158 ± 7 , respectively). Neither stress nor NT affected TrpH activity in the hindbrain. These results suggest a role for NT in modulating the ascending serotonergic systems of the dorsal raphe nucleus. This work is supported by NIH grant #NS14090 to M.C.B.B..

593.7

EFFECT OF A PHARMACOLOGICAL STRESSOR ON THE EXTRACELLULAR LEVEL OF EXCITATORY AMINO ACIDS IN THE PREFRONTAL CORTEX AND STRIATUM. M. Karreman, B. Moghaddam, Department of Psychiatry, Yale Univ. Sch. of Med., VA Medical Center, West Haven, CT 06516.

Previous studies from our laboratory have shown that exposure to restraint and swimming stress increases the neuronal release of excitatory amino acids in several regions of the rat brain. The stress-induced increase in the excitatory amino acid levels was shown to be more profound in the prefrontal cortex as compared to other regions in the basal ganglia. In the present study we wished to determine whether pharmacological stressors have similar effects on the extracellular levels of excitatory amino acids. Thus, we used the technique of intracerebral microdialysis to assess the effect of the anxiogenic β -carboline FG 7142 (20 mg/kg, i.p.) on the extracellular levels of excitatory amino acids in the prefrontal cortex and striatum. FG 7142 significantly increased the extracellular level of glutamate in the prefrontal cortex, whereas there was no significant change in the extracellular glutamate level in the striatum. Pretreatment with the benzodiazepine agonist, diazepam (5 mg/kg, i.p.), blocked the effect of FG 7142 in the prefrontal cortex. Diazepam alone did not cause a significant change in the extracellular level of aspartate or glutamate in the prefrontal cortex; however, it increased the extracellular glutamate level in the striatum. This study provides direct evidence that anxiogenic drugs such as FG 7142 preferentially increase the extracellular level of glutamate in the prefrontal cortex as compared to the striatum, and that this effect can be reversed with diazepam.

593.4

EVIDENCE FOR THE INVOLVEMENT OF GABA AND DOPAMINE IN THE SOUND STRESS INDUCED ACTIVATION OF THE ASCENDING SEROTONINERGIC NEURONS OF THE DORSAL RAPHE NUCLEUS. Karl C. Corley*, Roger P. Dilts and Margaret C. Roadle-Biber. Dept. of Physiology, Medical College of Virginia-VCU, Richmond, VA 23298-0551

We have previously demonstrated that sound stress increases the activity of tryptophan hydroxylase (E.C. 14.12.16.4) (TrpH), the rate limiting enzyme in serotonin biosynthesis, using both an *ex vivo* and *in vivo* assay to monitor the accumulations of the enzymatic product, 5-hydroxytryptophan (5-HTP). In an attempt to delineate some of the pharmacology and neurotransmitters mediating the increased enzyme activity produced by stress we have studied the effects of drugs (I.P.) known to affect serotonin, GABA and dopamine neurotransmission, respectively. The serotonin uptake inhibitor, fluoxetine (8.0 mg/kg) blocked the *ex vivo* stress induced increase in TrpH. Consistent with these findings, the increase in 5-HTP produced by sound stress *in vivo* is blocked by the administration of the 5-HT_{1A} agonists, gepirone (1.0 mg/kg) and 8-OH-DPAT (0.1 mg/kg) with similar effects *ex vivo*. Administration of the 5-HT₂ antagonist nefazadone (100 mg/kg) also blocked the stress induced activity in TrpH measured *ex vivo*. The benzodiazepine, diazepam, dose dependently attenuated and blocked (0.25-1.0 mg/kg) stress induced TrpH activity. Administration of the typical neuroleptic, haloperidol (0.5 mg/kg) or the atypical neuroleptic, clozapine (10 mg/kg), blocked both the *in vivo* and *ex vivo* increases in TrpH activity produced by sound stress. The actions of fluoxetine, as well as, the 5-HT_{1A} agonists, are consistent with our hypothesis that sound stress increases the firing and metabolic activity within the serotonergic neurons of the dorsal raphe nucleus. These data also support a role for GABA and dopamine in mediating the effects of sound stress. Supported by NIH grant #NS14090 to M.C.B.B.

IS THE STRESS-INDUCED ACTIVATION OF DOPAMINE RELEASE IN THE PREFRONTAL CORTEX MODULATED BY EXCITATORY AMINO ACIDS? H.P. Jedema and B. Moghaddam, Department of Psychiatry, Yale University School of Medicine, VA medical Center 116A/2, West Haven, CT 06516.

The dopaminergic projection to the prefrontal cortex (PFC) is known to be activated by mild stress. The excitatory amino acid (EAA) systems in the PFC have recently been shown to be activated by restraint, swimming, as well as pharmacological stressors. Similar to dopamine, the stress-induced activation of EAAs is much more profound in the PFC than regions in the basal ganglia such as striatum and nucleus accumbens. It has been hypothesized that the stress-induced activation of dopamine in the PFC may be due to an initial increase in the release of EAAs which will then release dopamine by acting on EAA receptors that modulate dopamine release in this region. We have studied the effect of EAA antagonists on the stress-induced release of dopamine in the PFC. Thus, NMDA or non-NMDA antagonists (AP5 and CNQX respectively) were locally perfused into the PFC through the microdialysis probe while the response of extracellular levels of dopamine to a 20 minute exposure to restraint was assessed. This stressor increased the dopamine levels in the PFC by nearly 100%. Perfusion of 50 μ M CNQX or 200 μ M AP5 during restraint did not lead to a decrease in this response. Currently, we are investigating the effect of higher concentration and longer time of perfusion of these antagonists to ensure that the EAA receptors were sufficiently blocked prior to the stress procedure. Nevertheless, considering the present data, it remains unclear whether the stress-induced activation of dopamine in the PFC is dependent on the activation of EAA systems. Supported in part by MH-48404 and Department of Veterans Affairs Centers for PTSD and Schizophrenia.

DOPAMINE RELEASE IN THE NUCLEUS ACCUMBENS DURING SOCIAL STRESS: AN *IN VIVO* MICRODIALYSIS STUDY. J.W. Tidey*, C.A. Cohen, R. Kream and K.A. Miczek. Department of Psychology, Tufts University, Medford MA 02155 and Department of Anesthesiology, Tufts University School of Medicine, Boston MA 02111.

Paradoxically, exposure to both aversive and reinforcing events increases mesocorticolimbic dopamine (DA) release. The present study utilizes an ethologically valid model, namely exposure to an aggressive male rat, to examine the effects of social stress on DA, DOPAC and HVA release using *in vivo* microdialysis in freely moving rats. Following 6 20-min baseline samples, each subject is placed in the empty home cage of a rat which had previously attacked and defeated it. Forty minutes later, the aggressive stimulus rat is returned to its home cage; samples are collected while the subject is physically protected with a wire mesh enclosure but can see, hear and smell the stimulus rat. One hour and forty minutes later, the subject is returned to its home cage and samples are collected until dialysate levels return to baseline. Preliminary results suggest that placement of the subject into the cage of an aggressive stimulus rat results in heightened DA and DOPAC release relative to controls placed in a clean novel cage; DOPAC levels remain elevated after DA levels return to baseline. Increased DA release is correlated not with motor hyperactivity but with defensive vocal and postural responses, suggesting that mesocorticolimbic DA may be important in initiating biologically significant behavior.

ACTIVATION OF NOREPINEPHRINE RELEASE IN CORTEX AND HYPOTHALAMUS BY NITROPRUSSIDE INFUSIONS.

Gennady N. Smagin, Artur H. Swiergiel, R. Don Brown*, Adrian J. Dunn. Department of Pharmacology, Louisiana State University Medical Center, Shreveport, LA 71130-3932.

Intravenous infusion of sodium nitroprusside (NP) decreases blood pressure and results in a hemodynamic stress that accelerates the firing rate of noradrenergic neurons in the locus coeruleus (LC). We tested whether NP increased the release of norepinephrine (NE) in the medial prefrontal cortex (PFM) and medial hypothalamus (MHT) as measured by microdialysis and HPLC. Rats were anesthetized with pentobarbital and urethane and microdialysis probes were inserted into the PFM and/or the MHT. NP infused into the femoral vein at a dose of 10 µg/30 µl/min for 15 min rapidly decreased blood pressure by 48%. During NP infusion the concentrations of NE in the cortical and hypothalamic microdialysates were elevated by 41% ($p < .001$) and 67% ($p < .05$) of the pre-infusion value, respectively. After infusion, PFM NE rebounded to 127% (ns) and MHT NE to 133% ($p < .05$). MHT MHPG increased by 51% ($p < .05$) but PFM MHPG and concentrations of DOPAC, 5-HIAA and HVA from PFM or MHT were not significantly affected by the infusion.

We conclude that hemodynamic stress activates NE neurons projecting to the PFM and MHT. We presume that the increase in cortical NE release is due to activation of the LC and may reflect a behavioral aspect of the stress. The hypothalamic response may be involved in the autonomic regulation of blood pressure.

STRESS-INDUCED ALTERATIONS IN PERIPHERAL BENZODIAZEPINE RECEPTORS IN RATS: CONTRIBUTIONS OF GENDER AND ACTIVITY. R. Drugan*, S. Luczak, H. Oh, R. Ferland and P. Holmes. Dept. of Psychology, Brown University, Providence, R.I. 02912

There are two distinct types of benzodiazepine receptors. The central benzodiazepine/GABA receptor complex (BGRC) is located in brain and is involved in actions of minor tranquilizers and the pathophysiology of anxiety. The peripheral benzodiazepine receptor (PBR) is found in both brain and peripheral tissue and is thought to be involved in steroid synthesis and energy metabolism.

Similar to the BGRC, the PBR in both brain and peripheral tissue can be rapidly altered by stress. Our laboratory has examined the cause for these changes and have targeted the renin-angiotensin system as an important factor. A sexual dimorphism in the renal PBR response to stress is evident and differential reactivity of the renin-angiotensin system appears to be critical. Recent microdissection studies in kidney also reveal a differential regional distribution of stress effects in males and females.

Since the PBR is located on the outer mitochondrial membrane, the possibility of activity/metabolic influences during stress may be critical. We employed both experimental and pharmacological tools for increasing activity independent of stress and examined PBR alterations. D-amphetamine administration and forced running produced changes opposite to stress in cardiac and olfactory bulb PBR, respectively. Supported by a PHS grant MH 45475 to RCD.

GLUCOSE RESTORES THE ACQUISITION OF RESPONSE CHAINS DISRUPTED BY COLD AIR EXPOSURE IN RATS. J. Schrow*, S.T. Ahlers. Naval Medical Research Institute, Bethesda, MD 20889, and Joel L. Davis. Office of Naval Research, Arlington, VA 22217.

Exposure to cold environments disrupts memory processes. These decrements can be reversed by glucose administration. The interaction of cold and glucose on the acquisition of behavior has been less well studied. In this study, a repeated acquisition procedure was used to investigate the effect of glucose (50 or 100 mg/kg, ip) administered preceding exposure to air temperatures of 2 or 22°C on the acquisition of four-member response sequences in rats. The results indicate that error and timeout responding increased during cold exposures. A biphasic response pattern of acquisition followed by performance was observed during control sessions. Acquisition was characterized by frequent error responses while performance was characterized by extended runs of errorless sequence completions interspersed with occasional error responses. Exposure to cold air disrupted this pattern, the onset of the performance phase was delayed and the magnitude of the error bursts increased. The administration of glucose at doses of 50 or 100 mg/kg preceding cold air resulted in an overall pattern of responding that more closely resembled control responding. Similar results were observed of timeout responses. The repeated acquisition procedure contains elements of both working and reference memory. Working memory is requisite for acquiring the novel sequence of lever presses each day, while reference memory is invoked by the timeout stimulus. Cold exposure disrupted both working and reference memory aspects of the procedure. Glucose administration reversed the effects of cold exposure on both aspects of the procedure. These results are consistent with findings that glucose facilitates memory consolidation and they support the hypothesis that glucose enhances memory encoding.

COLD STRESS EXPOSURE ALTERS HIPPOCAMPAL CHOLINERGIC NEUROTRANSMISSION. M.J. Stillman¹, B. Shukitt-Hale¹, A. Levy², and H.R. Lieberman. Military Performance and Neuroscience Division, United States Army Research Institute of Environmental Medicine, Natick, MA 01760-5007, ¹GEO-CENTERS, INC., Newton Centre, MA 02159, and ²IIBR, Ness Ziona, ISRAEL.

Few *in vivo* investigations have been conducted to assess the effects of stress on the cholinergic system. This study examined the time course of the effect of cold stress on hippocampal cholinergic neurotransmission. Hippocampal extracellular acetylcholine (ACh) and choline levels were evaluated using *in vivo* microdialysis in male Fischer 344 rats before, during, and following 80 min cold stress. Measurements were taken in two groups of rats immersed in a water bath: normothermic restrained (N-REST) rats (37 °C water), and cold restrained (C-REST) rats (20 °C water). Results were also compared to normothermic freely moving (N-FREE) rats. C-REST rats displayed decreased ACh levels relative to both N-REST and N-FREE rats at the onset of cold exposure. By the end of cold exposure and following removal from cold, ACh levels approximated baseline values. N-REST rats had levels similar to N-FREE rats, except for a marked increase in ACh following removal from 37 °C water. C-REST rats displayed a gradual elevation in choline levels during cold stress, whereas N-REST and N-FREE rats both displayed gradual decreases during the microdialysis session. These findings indicate that cholinergic neurotransmission can be influenced by the application of and removal from an acute stressor.

EFFECT OF COLD STRESS ON NEURONAL EXCITABILITY AND LTP IN THE DENTATE GYRUS OF FREELY MOVING RATS

J.M. Sarvey¹, T. Southard¹, S.T. Ahlers² and C.R. Bramham¹. ¹Department of Pharmacology, Uniformed Services University, and ²Naval Medical Research Institute, Bethesda, MD.

Exposure to relatively mild cold (4°C) can impair working memory. The effect could result from a disruption in hippocampal function at the level of neuronal transmission, at the level of synaptic plasticity, or both. Rats were chronically implanted for unilateral stimulation of the perforant path and recording of evoked field potentials in the dentate hilus. Animals were handled and then habituated on 3 consecutive days to a standard recording chamber and to an adjacent experimental chamber. Baseline field potentials, input-output curves and paired-pulse tests were obtained in the standard chamber. Rats were then transferred to the cold chamber (4°C) where tests were repeated, and after a 90 min exposure, high-frequency stimulation (HFS) was applied to the perforant path and field potentials were monitored for 2h. A control group received identical treatment except the temperature in the experimental cage was 23°C. All field potentials were collected when the rat was awake and motionless. HFS evoked LTP of the EPSP slope and population spike and there was no difference between groups in the magnitude or time course of LTP. However, there was a 25% reduction in population spike amplitude and an enhancement in paired-pulse facilitation upon transferring rats from the standard to the experimental cage in both cold and control groups. The results suggest that cold exposure does not affect the capacity for synaptic modification in the dentate gyrus as assessed by LTP induction.

PERIPHERAL β-1 ADRENORECEPTORS ARE INVOLVED IN STRESS-INDUCED HYPERCHOLESTEROLEMIA IN RATS. F. X. Brennan, Jr., C. L. Cobb, L. H. Silbert, L. R. Watkins, & S. F. Maier. Psychology Department, University of Colorado, Boulder, CO, 80309.

Increases in plasma cholesterol are now accepted as a significant risk factor for the development of Coronary Heart Disease (CHD). Plasma cholesterol levels may become elevated as a result of exposure to stressful stimuli. We have recently reported that rats exposed to three 2 hr sessions of inescapable tailshock, one session per day for three successive days, show a robust 40% increase in total plasma cholesterol. Other data has shown that rats given injections of epinephrine show comparable elevations in total plasma cholesterol. The purpose of the following experiments was to investigate whether catecholamines were involved in the stress-induced rise in cholesterol, by using adrenergic receptor antagonists.

In experiment 1, propranolol (25 mg/kg, s.c.), a standard beta-adrenoreceptor blocker, was injected prior to each of the daily stress sessions. Propranolol attenuated the cholesterol increase in stressed rats, but increased the cholesterol levels of nonshocked animals. This finding is in line with some data that suggests that in certain situations, propranolol can itself produce increases in plasma cholesterol. We therefore, in Experiment 2, examined whether the same dose of propranolol injected prior to the final stress session only would eliminate the stress-induced increase in cholesterol. Results indicated that propranolol attenuated the increase in cholesterol in stressed animals, while producing no increase in nonshocked animals.

Propranolol antagonizes both β-1 and β-2 adrenoreceptors, and also readily crosses the blood-brain barrier. Available data implicate peripheral β-1 adrenoreceptors as relevant for cholesterol metabolism. We therefore, in Experiment 3, injected atenolol (10 mg, s.c.), a peripherally restricted β-1 specific antagonist. Results indicated that atenolol blocked the cholesterol increase induced by stress, while having no effect in the absence of stress. The experiments support the idea that peripheral β-adrenoreceptors, particularly β-1 receptors, are involved in stress-induced increases in plasma cholesterol.

DIFFERENTIAL REGULATION OF RAT BRAIN C-FOS EXPRESSION IN RESPONSE TO ACUTE VS REPEATED STRESS. K.R. Melia*, A.E. Ryabinin, R. Schroeder, M.C. Wilson, and F.E. Bloom. The Scripps Research Institute, La Jolla, CA 92037. @TSRI and P.K. Anokhin Institute of Normal Physiology, Moscow, Russia 103009.

Acute stress activates the hypothalamic-pituitary-adrenal (HPA)-axis increasing serum levels of corticosterone. In contrast, repeated presentation of a homotypic stressor results in habituation of this response. To elucidate the neural systems which regulate activation and habituation of the HPA-axis, we examined the pattern of CNS c-fos expression, as a marker for altered neuronal activity, in response to acute (2h) vs repeated (2h/day for 4 or 9 days) restraint stress. On day 1 restraint stress increased plasma levels of corticosterone and c-fos mRNA in the cortex, hippocampus, hypothalamus and septum, but not the amygdala or brainstem. On day 4 stress-induced increases in plasma corticosterone and CNS expression of c-fos mRNA were significantly smaller than on day 1, and were completely habituated by day 9. The inability of restraint to induce c-fos mRNA in repeatedly stressed rats is not due to a general nonresponsivity of the c-fos gene since exposure to a novel stressor (20 m swim stress) could induce c-fos in restraint habituated rats. The induction of c-fos mRNA in the CNS in response to acute restraint stress, and the complete habituation of this response in repeatedly restrained rats, is not secondary to changes in corticosterone levels since the same pattern of induction and habituation was seen in adrenalectomized rats.

These results support the hypothesis that differential responding of the HPA-axis to acute vs repeated stress is due to changes in the activity of neural structures which innervate CRF neurons in the paraventricular nucleus of the hypothalamus. Understanding the neural systems which regulate this axis may provide insight into the biological basis of those psychiatric disorders which are characterized, in part, by dysregulation of the HPA-axis. EFFECT OF UNILATERAL OR BILATERAL DEPLETION OF PREFRONTAL CORTICAL DOPAMINE ON STRESS ULCER DEVELOPMENT IN RATS. R.M. Sullivan* and H. Szechtman. Dept. of Biomedical Sci., McMaster Univ., Hamilton, Ontario, CANADA, L8N 3Z5.

The mesocortical dopamine (DA) system in rats is known to be activated by a variety of stressors, and may do so in an asymmetric manner. The present study investigates the functional significance of this system in the ability to cope with aversive situations. Sixty-six male Sprague-Dawley rats were assessed for direction of amphetamine-induced rotation and distributed evenly among groups. Rats then received vehicle (n = 21) or 6-hydroxydopamine infusions in left, right or bilateral cortex (n = 15/group), following desipramine pretreatment. Three injection sites/side were used (12 ug 6-OHDA/side), aimed at the most dense DA innervation (0.2-3.0 mm ant. to bregma). Fourteen days later rats were food-deprived (24 h) and placed in Plexiglas restrainers at 4° C for 3 h. They were then sacrificed, stomachs examined microscopically for gastric mucosal lesions, and brain regions dissected out for biochemical analysis. Mean total gastric pathology differed significantly across groups ($F_{3,82} = 3.22, p = 0.029$). Left and bilateral lesions aggravated ulcer development relative to controls, but marginally failed to reach significance, while right lesion effects were more pronounced ($t = -2.89, p < 0.01$). An additional group of operated but unrestrained shams showed no pathology. The results suggest that right prefrontal cortical DA may be preferentially involved in affording protection against the pathological consequences of stress exposure. (Supported by NSERC)

TYROSINE INCREASES HYPOTHERMIA-INDUCED NOREPINEPHRINE (NE) RELEASE IN RAT HIPPOCAMPUS ASSESSED BY IN VIVO MICRODIALYSIS. S. Luo*, E.T.S. Li¹ and H.R. Lieberman. U.S. Army Research Institute of Environmental Medicine, Natick, MA 01760;

¹ Nutritional Sciences, University of Toronto, Ontario, Canada M5S 1A8.

Previous studies have shown that hypothermia-induced behavioral depression is reversed by the NE precursor, tyrosine. To examine the mechanisms of action of tyrosine in cold stress-induced behavioral depression, extracellular levels of NE were monitored in the hippocampus of male Fischer rats. Two experiments were performed. First, NE release was determined in hypothermic rats. Animals with implanted dialysis probes (n=6) were restrained and immersed in a water bath (17°C) for about 20 min. until a core body temperature (T_c) of 30°C was obtained. The control group (n=6) consisted of restraint and immersion in a 36°C water bath for 20 min, which did not alter normal T_c . Second, the effects of tyrosine on NE release in hypothermic rats were determined. Twelve naive rats with implanted dialysis probes were given either tyrosine (400 mg/kg, ip) or saline prior to hypothermia. In both experiments, dialysate samples were collected every 10 min ranging from 30 min before to 50 min after immersion in water, and the samples were immediately analyzed by high performance liquid chromatography with electrochemical detection. Restraint and hypothermia increased NE efflux to 204% and 329% of baseline, respectively ($p < 0.05$). Tyrosine administration enhanced the NE release of hypothermic rats compared to saline treatment ($p < 0.05$). The results indicate that extracellular release of NE increases during acute hypothermia and that of tyrosine's beneficial behavioral effects may be mediated by the noradrenergic system.

593.18

HABITUATION AND SENSITIZATION OF PLASMA CATECHOLAMINE RESPONSES IN AGED RATS. T.B. Mabry*, P.E. Gold, and R. McCarty. Department of Psychology, University of Virginia, Charlottesville, VA 22903.

This study examined age-related alterations in habituation and sensitization of plasma CA responses in chronically stressed (CS) animals. Fischer 344 male rats (ages 3 and 22 months) were restrained in individual Plexiglas tubes for 30 minutes per day for 26 days. Age-matched controls (HC) were handled but not restrained. After the last restraint session, all animals were prepared with chronic tail artery catheters. Two days after surgery, the CS animals were again restrained. Blood samples were collected under basal conditions and at intervals during and after restraint. The next day, the CS rats were exposed to a novel stressor: immersion in 25° C water for 15 minutes. Blood samples were collected under basal conditions and at 0, 15, 30, and 45 minutes post-immersion. HC rats received both experimental treatments in a counterbalanced order. Plasma samples were later assayed for content of norepinephrine (NE, pg/ml) and epinephrine (EPI, pg/ml) as a measure of sympathetic-adrenal medullary activity. Data for plasma catecholamines were analyzed by computing an area under the curve (AUC, pg/ml x minutes) for each animal. The AUC provides a measure of each animal's catecholamine response profile which includes the period during and immediately following stressful stimulation. For both restraint stress and water immersion, there was a significant age-related difference in overall NE and EPI AUCs, with older rats having significantly higher response profiles. For restraint, stress history did not affect AUC measures within age groups. For water immersion, stress history was a strong predictor of potentiation of NE and EPI AUCs. Plasma levels of NE and EPI remained significantly elevated throughout the cold water immersion sampling period for both CS age groups when compared to handled controls. These data are consistent with the view that aged rats display exaggerated sympathetic-adrenal medullary responses to stressful stimulation. These exaggerated physiological responses may underlie in part the inability of aged animals to adapt to, or, in some cases, to survive significant environmental challenges. Supported by NIA (AG 07648).

NEUROPEPTIDES AND BEHAVIOR: VASOPRESSIN, NPY, NEUROTENSIN, AND OTHERS

594.1

A PHYSIOLOGICAL ROLE FOR VASOPRESSIN IN FEAR CONDITIONING. J.D. Stoehr* and W.G. North. Department of Physiology, Dartmouth Medical School, Lebanon, NH 03756.

We have previously shown that homozygous Brattleboro rats display deficits in the conditioned freezing paradigm. These deficits may be due, in part, to inappropriate emotional and autonomic responses to novel stimuli. If this is so, normal Long Evans rats treated with vasopressin, or with vasopressin antagonists, should exhibit respective enhancements, or deficits, in this conditioning paradigm. Long Evans rats injected with the V_1 antagonist 2-(O-methyl)-tyrosine-AVP intracerebroventricularly (ICV, 3 ng) or peripherally before testing (sc, 2 µg) displayed significantly lower levels of freezing ($p < 0.05$), while rats treated peripherally (sc, 1 µg) or ICV (10 ng) with intact AVP displayed significant elevations in freezing when compared with vehicle-treated controls ($p < 0.05$). The data therefore imply that both central and peripheral vasopressin may be involved in the expression of appropriate behavioral responses to conditioned fear.

594.2

THE ROLE OF SEPTAL VASOPRESSIN INNERVATION IN PATERNAL BEHAVIOR IN PRAIRIE VOLES (*MICROTUS OCHROGASTER*). Z.X. Wang¹, C. F. Ferris², M. Bamshad¹, and G. J. DeVries¹. ¹Neurosci. Behav. Prog., Dept. of Psychol., Univ. of Mass., Amherst, MA 01003. ²Physiol. Dept., Univ. of Mass., Med. Ctr., Worcester, MA 01665.

Monogamous male prairie voles (*Microtus ochrogaster*) show an increase in paternal behavior three days after being paired with females. This increase is correlated with a decrease in density of central vasopressin-immunoreactive (AVP-ir) projections of the bed nucleus of the stria terminalis (BST) and the medial amygdaloid nucleus (MA) (Bamshad et al., 1992). Here we present the results suggesting that the AVP pathways are activated in male prairie voles by cohabitation with females, and are implicated in paternal behavior. In a first study, males that were paired with females for three days had more AVP mRNA labeled cells in the BST, more grains per labeled cell, and a higher level of testosterone than sexually naive males. Females did not show differences in their AVP mRNA expression. This suggests that in males the AVP pathways are activated by mating, and that the earlier observed decrease in AVP-ir fiber density in the lateral septum may be related to an increase of AVP release. In a second study, castration not only reduced AVP expression in the projections of the BST and MA, but also reduced paternal behavior of male prairie voles. This effect could be reversed when castrated voles were treated with testosterone. Although this suggests that paternal behavior as well as AVP expression in the BST and MA are enhanced by testosterone, it does not necessarily mean that testosterone influences paternal behavior by acting on AVP projections of the BST and MA. In a third study, septal injections of AVP enhanced spontaneous paternal behavior of sexually naive males while the injection of V_1 antagonist, d(CH₂)₅Tyr(Me)AVP, reduced paternal behavior. This suggests that septal AVP indeed enhances paternal behavior of prairie voles by a V_1 receptor-mediated mechanism.

594.3

EFFECT OF WATER TEMPERATURE ON THE PORSOLT SWIMMING TEST IN RATS. D. Jefferys* and J.W. Funder. Baker Medical Research Institute, Melbourne, Australia 3004.

When rats and mice are forced to swim under conditions from which they are unable to escape they become progressively more immobile over a 15 min test period, and remain immobile for ~70-80% of the 5 min retest period next day. This pattern of acquisition and retention was seen when mice were swum at 20° or 25°C; at 30° or 35° retention was impaired, and adrenalectomy impaired retention at 25° but not 20°C (1). The present studies examine the effect of water temperature on swimming responses in the rat, to explore commonalities and possible differences with mice. Rats swum at 30°C show patterns of acquisition and retention identical to 25°C. At both these temperatures the antiglucocorticoid RU486, and the κ -selective opioid antagonist MR2266, were without effect administered alone, but together impaired retention to the low levels seen in adrenalectomized rats. At 20°C, acquisition was very low (15-25% immobility), with retention rates higher (35-40%), both substantially lower than in rats swum at 25°C, and uninfluenced by administration of thyroxine, dexamethasone, ketocyclazocine or glucose. We conclude that substantial differences exist between mice and rats in terms of the temperature dependence of the Porsolt swimming test, and that the failure of acquisition of the immobile response at 20°C in rats reflects the operation of pathways other than the glucocorticoid/opioid/thyroid hormone mechanisms subserving this behavioral response at higher temperatures.

594.5

INFLUENCE OF AMBIENT TEMPERATURE ON THE EFFECTS OF NPY ON BODY TEMPERATURE AND FOOD INTAKE. F. B. JOLICOEUR*, S. M. BOUALI, D. J. McGRATH, D. P. MÈNARD, A. FOURNIER¹ AND S. ST-PIERRE¹. Depts of Psychiatry and Pharmacology, University of Sherbrooke, Sherbrooke, Qué, Canada, J1H 5N4 and ¹INRS-Santé, pointe claire, Qué, Canada.

The functional relationship between food intake and thermoregulation is well known. Since control of body temperature in the *milieu interne* depends in a large part on ambient temperature in homeothermic animals, food intake is thus related to temperature of the *milieu externe*. Because thermoregulation and food consumption are interrelated and because thermoregulation processes are influenced by ambient temperature, we examined the effects of neuropeptide Y (NPY) on both body temperature and food intake in various thermal environments following ICV administration of 20 μ g. Results reveal that the prominent effects of NPY on body temperature and food intake in relatively thermoneutral environments are drastically altered at more extreme ambient temperatures. NPY produced hypothermia in animals placed at 4, 12 and 21°C, and actually increased body temperature in animals subjected to 30 and 38°C temperature. On the other hand, in comparison to ambient temperatures of 12 and 21°C, ambient temperatures of 4 and 30°C significantly reduced the stimulatory effect of NPY on food consumption. Moreover, at 38°C, the effect of NPY on food intake was totally abolished. These data demonstrate that ambient temperature has a critical influence on central actions of NPY. Supported by the Medical Research Council of Canada, Grant PG 11125

594.7

EFFECTS OF NEUROTENSIN ON BEHAVIORS INDUCED BY INTRA-STRIATAL AND INTRA-ACCUMBENS ADMINISTRATION OF N-N-PROPYLNORAPOMORPHINE (NPA). D.J. McGRATH*, S.M. BOUALI, D.P. MÈNARD AND F.B. JOLICOEUR. Depts. of Psychiatry and Pharmacology, University of Sherbrooke, Sherbrooke, Qué., Canada, J1H 5N4.

Neurotensin has been shown previously to affect hyperactivity but not stereotypy induced by various, peripherally administered, dopamine stimulating drugs, thus pointing to a specific action on mesolimbic dopaminergic processes. To further investigate this selective influence we have examined, in rats, the effects of intracerebroventricular administration of 0.9 to 15.0 μ g neurotensin (NT) on behaviors produced by either bilateral intra-striatal or bilateral intra-accumbens injections of 20 μ g NPA, a potent and selective dopamine D₂ receptor agonist. At both injection sites NPA produced hyperactivity and stereotyped behavior consisting mostly of continuous sniffing. These results were somewhat unexpected considering the traditional assumption that the nucleus accumbens and striatum control hyperactivity and stereotypy respectively. NT was found to more potently reduce the hyperactivity induced by intra-striatal than by intra-accumbens injection of NPA. Furthermore NT reduced stereotypy elicited by injections of NPA at both sites. From these results it can be concluded that: a) dopaminergic stimulation of both the striatum and the nucleus accumbens can elicit hyperactivity and stereotypy, pointing to more complex control mechanisms for these behaviors and b) that NT can not only antagonize hyperactivity but also stereotypy elicited by injections of NPA into both nucleus accumbens and striatum; and furthermore that NT's antagonism of hyperactivity is more potent when this hyperactivity is elicited from striatal dopaminergic stimulation.

Supported by the Medical Research Council of Canada.

FAMOTIDINE TREATMENT INDICATES THAT BLOCKADE OF THE POEF EFFECT BY GASTRIC VAGOTOMY IS LIKELY DUE TO A DISRUPTION ONLY OF AFFERENT PROCESSES. I.M. Robinson, P. Abbott and M.B. Kristal. Behavioral Neuroscience Program, Dept. of Psychology, University at Buffalo, Buffalo, NY 14260.

Ingestion of placenta or amniotic fluid by rats has been shown to enhance opioid-mediated analgesia such as that produced by morphine, vaginal stimulation, and late pregnancy. The active substance in placenta and amniotic fluid (POEF for Placental Opioid-Enhancing Factor) apparently has no analgesic effect by itself. We recently showed that the POEF effect in rats requires (a) peroral administration of POEF (in placenta or amniotic fluid), (b) an intact gastric vagus nerve, and (c) the central actions of opioids. To determine whether vagal involvement depended on afferent information arising from gastric receptors, or on an efferent effect on digestion (was POEF manufactured or activated during digestion?), we examined the amount of enhancement of vaginal-stimulation-induced analgesia that occurred after placenta ingestion in rats that had received orogastric infusion with either vehicle or with 5 or 10 mg/kg famotidine, a potent H₂-receptor antagonist that severely reduces gastric secretory activity. Rats that ingested placenta showed significantly more antinociception than did rats fed a control substance, but famotidine had no effect on POEF activity. These results suggest that gastric secretions are not required for POEF to be effective, and that vagal afferent pathways are involved.

EFFECTS OF PERTUSSIS TOXIN ON FEEDING AND BODY TEMPERATURE CHANGES INDUCED BY NPY AND NPY2-36. S. M. BOUALI*, A. FOURNIER¹, S. ST-PIERRE¹ AND F. B. JOLICOEUR. Depts of Psychiatry and Pharmacology, University of Sherbrooke, Sherbrooke, Qué, Canada, J1H 5N4 and ¹INRS-Santé, pointe claire, Qué, Canada.

Many effects of NPY have been attributed to a decrease in the activity of adenylate cyclase. Pre-treatment with pertussis toxin (PTx) has been shown to inhibit many pharmacological effects of NPY including increased feeding following administration in the paraventricular nucleus (PVN). In the present study, we examined the influence of PTx pre-treatment on the effects of NPY on food consumption and body temperature following administration in the preoptic (POA), perifornical (PeF), lateral hypothalamus (LH) and PVN. The effects of the same pre-treatment on the actions of NPY2-36 were also studied since we have found that this fragment produced opposite effects on body temperature to that of NPY when injected in the POA, whereas the effects on food intake were similar (Bouali et al. 1992, *Soc Neurosci* 18:895). In each region, PTx was administered three days prior to the injection of NPY and NPY2-36 in doses equal to those of the peptides for producing a significant effect on body temperature and food intake. The results shows that the effects of NPY and NPY2-36 on food intake, after administration in the PeF, are not affected by PTx pre-treatment. Interestingly, the effects of NPY on body temperature following administration in the POA were completely inhibited by PTx whereas the effects of NPY2-36 were partially affected. These results are important as they provide evidence that, in the POA at least, the receptors mediating the hypothermic effects of NPY could be biochemically different from those mediating the hyperthermic effect of NPY2-36. Furthermore, these results raise the intriguing possibility that these variable effects of PTx pre-treatment depend on the site where NPY is administered since the PTx inhibition of NPY-induced feeding occur when the peptide was injected in the PVN and LH. Finally, it appears that the receptors mediating the thermal and feeding responses induced by NPY and NPY2-36 possess different mechanisms of coupling to their effectors. EFFECT OF SR 48692 A NON PEPTIDE NEUROTENSIN RECEPTOR ANTAGONIST ON BEHAVIOURAL AND NEUROCHEMICAL CHANGES INDUCED BY NEUROTENSIN. R. Steinberg, M. Fournier, P. Brun, M. Poncelet, J. Souillac, J.P. Terranova, D. Gully, G. LeFur* and P. Soubrie. Sanofi Recherche, F-34184 Montpellier, France.

Unilateral microinjection of neurotensin (NT) in the ventral tegmental area (VTA) of the rat (2.5 μ g/0.5 μ l) or in the mouse striatum (10 μ g/1 μ l) produced behavioural excitation illustrated by contralateral circling. Given orally, SR 48692 (IC₅₀ = 1nM on ¹²⁵I NT specific binding to guinea pig brain) significantly reduced these rotations according to a triphasic dose-effect relationship. Inhibition occurred at 0.05 and 0.1 mg/kg, intermediate doses producing no significant antagonism and at doses \geq 5 mg/kg, a second phase of antagonism was observed. Blockade of amphetamine-induced locomotion in rats by NT applied in the nucleus accumbens was dose-dependently reduced by SR 48692 (from 0.1 to 1 mg/kg). Applied in the VTA, NT (2.5 μ g/0.5 μ l) increased DOPAC/DA ratios measured by HPLC and NT (1 μ g/65nl) stimulated DA efflux detected by *in vivo* electrochemistry in the nucleus accumbens. Neither of these biochemical changes were affected by SR 48692 (0.1, 1, 10 mg/kg).

These results indicate complex interactions between NT and mesolimbic and nigrostriatal DA systems. More particularly, the differential ability of SR 48692 to affect NT-evoked behavioural vs biochemical changes support the concept of neurotensin receptors heterogeneity.

TASTE REACTIVITY TO ISOTONIC SALINE FOLLOWING CENTRAL INJECTION OF NK3 TACHYKININ AGONISTS IN RATS. C. Polidori*, R. Seely¹, R. Ciccocioppo, M. Massi and G. De Caro. University of Camerino, MC, Italy and ¹ University of Pennsylvania, Philadelphia, PA, U.S.A.

Previous studies have shown that central injection of NK3 tachykinin (TK) agonists inhibit salt intake in rat. To further describe the mechanism of this inhibition the taste reactivity test was used in the present study. Replete male rats (325-350 gr) were fitted with a cannula in the third cerebral ventricle, for TKs injection, and a small intraoral tube to deliver 1 ml of 0.9% NaCl solution over a period of 1 minute. The animals were injected with [Asp5,6,MePhe8] substance P 5-11, and Suc-[Asp6,MePhe8] substance P 6-11 both selective NK3 agonists at the dose of 100 and 30 ng/rat. The results have showed that both doses of the two TKs diminished the number of ingestive responses and reduced the latency to onset of passive dripping. On the other hand, the number of aversive responses remained low following injection of the two peptides and was similar to that of controls. These findings are in keeping with the reported effect on NaCl intake of NK3 agonists in rat. Further studies, employing also non preferred of NaCl concentrations, are needed to fully describe the effects of TK on salty taste evaluation.

HYPOTHALAMIC INSULIN CHANGES IN RELATION TO PERIPHERAL INSULIN INFUSION AND FEEDING AS REVEALED BY MICRODIALYSIS. K. Gerozissis, M. Orsoco, A. Pelé, C. Rouch and S. Nicolaidis*. Neurobiologie des Régulations, URA 637 CNRS, Collège de France, 11, place Marcelin-Berthelot, 75231, Paris CEDEX 05, France.

Insulin was measured by a sensitized radioimmunoassay in microdialysates from the hypothalamic nuclei VMH-PVN of freely moving, freely feeding Wistar and lean (FaFa) or obese (faFa) Zucker rats.

Basal hypothalamic immunoreactive insulin levels were similar in Wistar and lean Zucker rats (57 ± 0.4 and 64 ± 8 pg/ml respectively) but significantly lower (38 ± 5 pg/ml) in obese animals. When 0.5 U of insulin was infused i.v., hypothalamic insulin doubled in the obese rats but increased less in the lean Zucker and Wistar rats. Furthermore, hypothalamic insulin was increased in relation to meals in the Wistar and the obese Zucker rats, although more dramatically in the latter.

These data raise again the question of the origin (central or peripheral) of brain insulin in the present microdialysates. The already observed relatively short latency and the high amplitude of response in the insulin resistant obese Zucker rat, favor the idea that, at least part of the peptide comes from a central origin.

EFFECT OF AT-1 AND AT-2 ANGIOTENSIN II (AII) RECEPTOR ANTAGONISTS ON DIPOSOGEN-INDUCED FOS-LIKE IMMUNOREACTIVITY (FLI) IN RAT BRAIN. B.-H. Li*, N.E. Rowland and G. Smith. Psychology, Univ. of Florida, Gainesville FL 32611-2065.

Administration of AII to rats either intravenously (iv) or intracerebroventricularly (ic) causes drinking and induction of prominent FLI in subfornical organ (SFO), median preoptic (MnPO/OVLT), paraventricular hypothalamic (PVN), and supraoptic (SON) nuclei. The FLI is similar by both routes except for preferential activity in posterior SFO after iv AII and in anterior SFO after ic AII. Administration of the AT-1 antagonist, losartan (ic), abolished AII-induced FLI in SFO, MnPO and PVN, with a partial block in SON. Administration of the AT-2 antagonist, PD123319 (ic), did not affect AII-induced FLI in MnPO and SFO, but produced partial blocks in SON and PVN. This suggests that the AT-2 antagonist PD 123319 has either direct or indirect actions in PVN and SON. We will consider these data in relation to the antidipsogenic actions of both antagonists. IC injection of the cholinergic agonist and dipsogen, carbachol, induces FLI in the same regions as AII; the effect of the AT-1 and AT-2 antagonists are under investigation.
