

SOCIETY FOR NEUROSCIENCE

ABSTRACTS

VOLUME 19, PART 2

23RD ANNUAL MEETING

WASHINGTON, D.C.

NOVEMBER 7-12, 1993

1993 © Society for Neuroscience

Made in the United States of America.

International Standard Book Numbers:

Part 1 ISBN 0-916110-40-0

Part 2 ISBN 0-916110-41-9

Part 3 ISBN 0-916110-42-7

All parts ISSN 0190-5295

Library of Congress Catalog Card Number 75-7761

Proper citation form for this volume:

Soc. Neurosci. Abstr., Vol. 19, Part 2, p. xxx, 1993.

Thematic List of Sessions	xv
Abstracts in Session Order*	
Wednesday, November 10–Friday, November 12.....	899

* 10,975 volunteer abstracts, 18 symposia abstracts, 17 history of neuroscience abstracts, and 56 teaching of neuroscience abstracts.

Please note that due to the increase in abstract submissions this year, the *Abstracts* Volume 19 is printed in **three** parts. The three parts will be mailed, one part at a time, starting in mid-August. The *Abstracts* Volume 19 Part 3, the last part to be mailed, includes the Key Word Index and the Author Index.

1993 Program Committee

Dennis W. Choi, M.D., Ph.D.

Chairperson

Washington University School of Medicine

Irwin B. Levitan, Ph.D.

Incoming Chairperson

Brandeis University

David G. Amaral, Ph.D.

The Salk Institute

Andrew G. Bulloch, Ph.D.

University of Calgary Health Science Center

Marc G. Caron, Ph.D.

Duke University Medical Center

Michael E. Goldberg, M.D.

National Eye Institute, NIH

Mark W. Hamblin, M.D., Ph.D.

University of Washington

Seattle VA Medical Center

Harvey J. Karten, M.D.

University of California, San Diego

Darcy B. Kelley, Ph.D.

Columbia University

James E. Krause, Ph.D.

Washington University School of Medicine

Jean M. Lauder, Ph.D.

University of North Carolina School of Medicine

James O. McNamara, M.D.

Duke University Medical Center

and VA Medical Center

Charles B. Nemeroff, M.D., Ph.D.

Emory University School of Medicine

Mary L. Oster-Granite, Ph.D.

University of California, Riverside

John L.R. Rubenstein, M.D., Ph.D.

University of California, San Francisco

Clifford B. Saper, M.D., Ph.D.

Beth Israel Hospital

Gary Charles Schoenwolf, Ph.D.

University of Utah School of Medicine

S. Murray Sherman, Ph.D.

SUNY, Stony Brook

Roger P. Simon, M.D.

University of California, San Francisco

W. Thomas Thach, Jr., M.D.

Washington University School of Medicine

Leslie G. Ungerleider, Ph.D.

National Institutes of Health

Charles J. Vierck, Ph.D.

University of Florida Health Science Center

Monte Westerfield, Ph.D.

University of Oregon

Richard E. Zigmond, Ph.D.

Case Western Reserve University

School of Medicine

Ira B. Black, M.D., *ex officio*

UMDNJ/RWJ Medical School

Lynn T. Landmesser, Ph.D., *ex officio*

University of Connecticut

Larry R. Squire, Ph.D., *ex officio*

VA Medical Center, San Diego

CHRONOLOGICAL LIST OF SESSIONS

(See page xv for Thematic List of Sessions)

Session Number & Title	Page	Session Number & Title	Page
SUNDAY, NOVEMBER 7			
Panel — 3:00 p.m.			
1. Panel on Responsible Conduct in Science	No Abstract	28. Glia and other non-neuronal cells: CNS development	42
Decade of the Brain Lecture — 8:00 p.m.			
2. To be announced	No Abstract	29. Sensory systems I	45
MONDAY, NOVEMBER 8			
Symposia — 8:30 a.m.			
3. Gender and the Brain		30. Cerebral cortex and limbic system: molecular determinants and molecular markers	48
<i>Chaired by:</i> N.C. Andreasen	1	31. Visual system: retina	51
4. Unraveling the Serotonergic System: Insights from Molecular Biology		32. Transplantation I	55
<i>Chaired by:</i> T.A. Branchek	1	33. Neuroglia and myelin I	59
Warner-Lambert Lecture — 11:45 a.m.			
5. Modulation of the NMDA Responses by Extracellular and Intracellular Signals		34. Cytoskeleton transport and membrane targeting I	61
P. Ascher	No Abstract	35. Gene structure and function I	65
Slide Sessions — 8:30 a.m.			
6. Neuropeptides and behavior: CRF, oxytocin, and other peptides	1	36. Excitatory amino acids: receptors I	68
7. Uptake and transporters I	3	37. Opioids: receptors I	72
8. Neurotrophic factors: expression and regulation I	5	38. Catecholamine receptors: dopaminergic agonists and antagonists	75
9. Mental illness I	7	39. Catecholamine receptors: dopamine I	78
10. Acetylcholine receptors	8	40. Catecholamines I	81
11. Calcium channel structure, function, and expression I	10	41. Other biogenic amines and purines: histamine and melatonin	84
12. Chemical senses: peripheral mechanisms	12	42. Other biogenic amines and purines: purines	86
13. Subcortical visual systems	14	43. Regional localization of receptors and transmitters I	89
14. Invertebrate learning and behavior I	16	44. Osmotic regulation	92
15. Degenerative disease: Alzheimer's— β -amyloid I	18	45. Neural-immune interactions: immune mediators in normal CNS	95
16. Epilepsy: basic mechanisms I	20	46. Neural-immune interactions: nervous system pathology	97
17. Second messengers I	22	47. Thermoregulation and fever	99
18. Excitatory amino acids: excitotoxicity I	24	48. Somatic and visceral afferents I	102
19. Visual cortex: extrastriate—cognitive mechanisms I	26	49. Somatosensory cortex and thalamocortical relationships I	105
Poster Sessions — 8:30 a.m.			
20. Genesis of neurons and glia I	28	50. Pain modulation: anatomy and physiology I	108
21. Cell lineage and determination: gene expression and growth factors	31	51. Pain modulation: pharmacology I	111
22. Cell migration and motility: cell-surface molecules	33	52. Retina: immunocytochemistry	114
23. Cell shape and differentiation: activity	35	53. Chemical senses: peripheral olfactory mechanisms	118
24. Process outgrowth, growth cones, and sprouting I	37	54. Chemical senses: olfactory bulb	121
25. Axon guidance mechanisms and pathways I	38	55. Chemical senses: central olfactory mechanisms	125
26. Axon guidance mechanisms and pathways II	40	56. Basal ganglia and thalamus I	127
27. Formation and specificity of synapses: visual system	41	57. Basal ganglia and thalamus II	130
		58. Basal ganglia and thalamus III	134
		59. Vestibular system: anatomy and pharmacology	135
		60. Vestibular system: neurophysiology	138
		61. Reflex function I	140
		62. Reflex function II	143
		63. Control of posture and movement I	145
		64. Control of posture and movement II	148
		65. Muscle: fiber types	152
		66. Muscle: gene transfer, contractile properties, fatigue	153
		67. Hypothalamus	156
		68. Comparative neuroanatomy I	159
		69. Neural plasticity: cerebral cortex	162
		70. Neuroethology: invertebrate	165
		71. Stress: neuroendocrine mechanisms	168

CHRONOLOGICAL LIST OF SLIDE AND POSTER SESSIONS

Session Number & Title	Page	Session Number & Title	Page
72. Hormonal control of reproductive behavior: hormones and metabolites	171	103. Axon guidance mechanisms and pathways III	235
73. Neuropeptides and behavior: CCK, CRF, vasopressin, and somatostatin	172	104. Peptides: receptor molecular biology	237
74. Drugs of abuse: ethanol, benzodiazepines, barbiturates I	175	105. Visual system	239
75. Aging: functional anatomy	179	106. Long-term potentiation I	241
76. Developmental disorders of the nervous system I	181	Poster Sessions — 1:00 p.m.	
77. Degenerative disease: Alzheimer's— β -amyloid II	184	107. Cell shape and differentiation: immortalized cells and cell lines	243
78. Degenerative disease: Alzheimer's—cognitive function: neuropsychology	187	108. Neurotrophic factors: expression and regulation II	245
79. Degenerative disease: Alzheimer's—cognitive function: imaging and neuropathology	189	109. Neurotrophic factors: expression and regulation III	249
80. Degenerative disease: Alzheimer's—neuropharmacology and neurotransmitters I	190	110. Neurotrophic factors: expression and regulation IV	253
81. Degenerative disease: Alzheimer's—other I	192	111. Neurotrophic factors: expression and regulation V	256
82. Degenerative disease: other I	195	112. Molecular and pharmacological correlates of development I	261
83. Neuromuscular disease	197	113. Glia and other non-neuronal cells: PNS development	264
84. Mental illness II	199	114. Neuroglia and myelin II	266
<i>(History and Teaching Posters will be posted the entire week.)</i>		115. Membrane composition and cell-surface macromolecules I	268
85. History of neuroscience	203	116. Synaptic structure and function I	270
86. Teaching of neuroscience I	206	117. Postsynaptic mechanisms I	271
87. Teaching of neuroscience II	209	118. Pharmacology of synaptic transmission I	274
88. Teaching of neuroscience III	212	119. Ligand-gated ion channels: glutamatergic	277
Symposia — 1:00 p.m.		120. Ligand-gated ion channels: non-glutamatergic	279
89. Phosphorylation Cascades, Neurofibrillary Tangles, and Alzheimer's Disease <i>Chaired by:</i> P.D. Coleman	215	121. Sodium channels I	283
90. Functional Organization of Human Visual Cortex <i>Chaired by:</i> A. Burkhalter	215	122. Acetylcholine: neuroanatomy	286
History of Neuroscience Lecture — 1:00 p.m.		123. Acetylcholine receptors: neuronal nicotinic I	288
91. Neural Integration at the Mesoscopic Level: Highlights of Half a Century T.H. Bullock	No Abstract	124. Excitatory amino acids: pharmacology I	291
Special Lecture — 4:15 p.m.		125. Excitatory amino acids: receptors II	294
92. Peripheral Neuropathies and Nerve Regeneration: Common Molecular Themes? E.M. Shooter	No Abstract	126. Serotonin: neurochemistry	297
Slide Sessions — 1:00 p.m.		127. Transmitters in invertebrates: biogenic amines	300
93. Serotonin receptors: pharmacology, localization, regulation	216	128. Interactions between neurotransmitters I	301
94. Pattern formation, compartments, and boundaries I	217	129. Regional localization of receptors and transmitters II	304
95. Uptake and transporters II	219	130. Second messengers II	307
96. Degenerative disease: Alzheimer's—neuropathology and neurotransmitters	221	131. Hypothalamic-pituitary-gonadal regulation: control of LH secretion	311
97. Gene structure and function II	223	132. Cardiovascular regulation: sympathetic system	312
98. Neural-immune interactions: cytokine effects on the nervous system	225	133. Cardiovascular regulation: vagal system	315
99. Degenerative disease: Alzheimer's—other II	227	134. Autonomic regulation: supraspinal control	318
100. Retina: photoreceptors and interneurons	229	135. Autonomic regulation: spinal and peripheral mechanisms ...	321
101. Catecholamine receptors	231	136. Somatic and visceral afferents II	323
102. Pain modulation: anatomy and physiology II	233	137. Subcortical somatosensory pathways: spinal cord and brainstem	326
		138. Subcortical visual systems: pretectum and pulvinar	330
		139. Striate cortex: functional organization I	332
		140. Striate cortex: functional organization II	334
		141. Invertebrate sensory systems I	336
		142. Invertebrate sensory systems II	338
		143. Vestibular system: psychophysics	342
		144. Oculomotor system: pursuit and optokinetic nystagmus	344
		145. Oculomotor system: vergence and accommodation	346
		146. Circuitry and pattern generation I	347
		147. Limbic system I	350
		148. Limbic system II	354
		149. Limbic system III	357
		150. Learning and memory: systems and functions I	358
		151. Learning and memory: systems and functions II	362

Session Number & Title	Page
152. Learning and memory: systems and functions III	365
153. Learning and memory: pharmacology—monoamines	367
154. Learning and memory: pharmacology—opioids	370
155. Motivation and emotion I	371
156. Neuroethology: electroreception	374
157. Drugs of abuse: ethanol, benzodiazepines, barbiturates II	377
158. Psychotherapeutic drugs: clozapine	382
159. Aging	385
160. Genetic models of nervous system disorders I	389
161. Epilepsy: human studies and animal models I	392
162. Degenerative disease: Alzheimer's— β -amyloid III	395
163. Degenerative disease: Alzheimer's— neuropharmacology and neurotransmitters II	399
164. Degenerative disease: Parkinson's—free radicals	401
165. Degenerative disease: Parkinson's—neurotoxicity I	404
166. Degenerative disease: Parkinson's—neurotoxicity II	406
167. Degenerative disease: other II	408
85. History of neuroscience	203
86. Teaching of neuroscience I	206
87. Teaching of neuroscience II	209
88. Teaching of neuroscience III	212

Animals in Research Panel — 5:30 p.m.

168. Animal Activism in the '90s: What Have We Learned and What Can We Expect?	No Abstract
--	-------------

Presidential Symposium — 8:00 p.m.

169. Brain Plasticity: Molecules and Maps	
Cortical Representational Plasticity: Contributions to Learning	
M. Merzenich	No Abstract
New Molecular Mechanisms of Neurotrophin Action	
M.V. Chao	No Abstract
Regeneration in the Adult Central Nervous System	
F.H. Gage	No Abstract
Neural Transplantation in the Basal Ganglia: Neuronal Replacement and Reconstruction of Lesioned Circuitry	
A. Bjorklund	No Abstract

TUESDAY, NOVEMBER 9

Symposia — 8:30 a.m.

170. Role of Calcium in Stimulus-secretion Coupling	
Chaired by: J.R. Lemos	411
171. Molecular Plasticity to Psychotropic Drugs	
Chaired by: E.J. Nestler	411

Special Lecture — 11:45 a.m.

172. Steering Responses of Neuronal Growth Cones to <i>In Situ</i> Guidance in an Insect Embryo	
D. Bentley	No Abstract

Session Number & Title	Page
Slide Sessions — 8:30 a.m.	
173. Learning and memory: physiology I	411
174. Hypothalamic-pituitary-adrenal axis regulation: focus on CRF and glucocorticoid receptors	414
175. Neurotrophic factors: biological effects I	416
176. Neuroglia and myelin III	418
177. Opioids: receptor physiology and sigma sites	420
178. Regeneration I	422
179. Striate cortex: functional organization III	424
180. Oculomotor system: physiology and psychophysics of saccades	426
181. Receptor modulation, up and down regulation I	428
182. Degenerative disease: Alzheimer's— β -amyloid IV	430
183. Long-term potentiation II	432
184. Cardiovascular regulation: supramedullary control	434
185. Process outgrowth, growth cones, and sprouting II	435
186. Learning and memory: systems and functions IV	437

Poster Sessions — 8:30 a.m.

187. Neuronal death I	440
188. Pattern formation, compartments, and boundaries II	443
189. Glia and other non-neuronal cells: response to injury	446
190. Glia and other non-neuronal cells: microglia/macrophage	449
191. Visual system: optic tectum/superior colliculus	452
192. Aging processes I	455
193. Membrane composition and cell-surface macromolecules II	459
194. Acetylcholine receptors: muscarinic antagonists and agonists	460
195. Acetylcholine receptors: neuronal and α -bungarotoxin-sensitive	463
196. Excitatory amino acids: anatomy and physiology I	466
197. Excitatory amino acids: pharmacology II	470
198. Excitatory amino acids: receptors III	472
199. GABA receptors: structure	475
200. Peptides: physiological effects I	478
201. Peptides: physiological effects II	481
202. Opioids: anatomy and physiology I	483
203. Catecholamines II	486
204. Transmitters in invertebrates: amino acids	489
205. Interactions between neurotransmitters II	491
206. Uptake and transporters III	494
207. Receptor modulation, up and down regulation II	497
208. Neural-immune interactions: neurochemical effects of immune stimulation	501
209. Neural-immune interactions: neurophysiological response to immune stimulation	502
210. Neural-immune interactions: CNS effects on immune response	504
211. Neural-immune interactions: endocrine effects on immune response	507
212. Autonomic regulation: genital innervation	508
213. Autonomic regulation: urinary system innervation	509
214. Somatic and visceral afferents III	512

CHRONOLOGICAL LIST OF SLIDE AND POSTER SESSIONS

Session Number & Title	Page
215. Subcortical somatosensory pathways: thalamus	515
216. Pain modulation: anatomy and physiology III	518
217. Pain modulation: pharmacology II	521
218. Lateral geniculate nucleus: structure and function	524
219. Lateral geniculate nucleus: biophysics and pharmacology ...	526
220. Subcortical visual pathways: retinofugal and retinopetal systems	528
221. Subcortical auditory pathways I	530
222. Subcortical auditory pathways II	532
223. Subcortical auditory pathways III	534
224. Spinal cord and brainstem I	537
225. Spinal cord and brainstem II	539
226. Control of posture and movement III	543
227. Control of posture and movement IV	546
228. Control of posture and movement V	548
229. Control of posture and movement VI	551
230. Control of posture and movement VII	554
231. Circuitry and pattern generation II	556
232. Human cognition: hemispheric laterality, gender differences	559
233. Human cognition: attention	561
234. Learning and memory: pharmacology—other I	565
235. Biological rhythms and sleep I	567
236. Biological rhythms and sleep II	571
237. Neuroethology: audition	575
238. Invertebrate learning and behavior II	578
239. Ingestive behaviors I	581
240. Ingestive behaviors II	583
241. Hormonal control of reproductive behavior: male/female/parental	584
242. Monoamines and behavior: sexual behavior	588
243. Monoamines and behavior: gene expression	590
244. Monoamines and behavior: serotonin	591
245. Drugs of Abuse: ethanol, benzodiazepines, barbiturates—GABA	594
246. Psychotherapeutic drugs: antipsychotics	596
247. Aging: memory and cognition	599
248. Epilepsy: human studies and animal models II	602
249. Epilepsy: basic mechanisms II	605
85. History of neuroscience	203
86. Teaching of neuroscience I	206
87. Teaching of neuroscience II	209
88. Teaching of neuroscience III	212

Symposia — 1:00 p.m.

250. Integration in Central Somato-visceral Processing <i>Chaired by:</i> A.D. Craig and A.D. Loewy	609
251. Microglia and Neuronal Injury <i>Chaired by:</i> C.A. Colton and W.J. Streit	609

Presidential Special Lecture — 1:00 p.m.

252. Attention and Distributed Neural Systems in Higher Brain Function M.I. Posner	No Abstract
---	-------------

Session Number & Title	Page
-----------------------------------	-------------

Presidential Special Lecture — 4:15 p.m.

253. How Language Works S. Pinker	No Abstract
--	-------------

Slide Sessions — 1:00 p.m.

254. Drugs of abuse: alcohol, barbiturates, benzodiazepines	609
255. Presynaptic mechanisms I	611
256. Cell lineage and determination: immortalization, transplants, cortex	613
257. Sensory and motor systems	615
258. Hypothalamic-pituitary-gonadal regulation: control of GnRH secretion	618
259. Process outgrowth, growth cones, and sprouting III	620
260. Degenerative disease: Alzheimer's—other III	622
261. Excitatory amino acids: receptors IV	624
262. Molecular and pharmacological correlates of development II	626
263. Striate cortex: response properties I	628
264. Degenerative disease: Parkinson's	630
265. Serotonin receptors: molecular biology I	632
266. Neuronal death II	633
267. Ischemia I	635

Poster Sessions — 1:00 p.m.

268. Cell lineage and determination: telencephalon	637
269. Cell lineage and determination: neural crest	639
270. Formation and specificity of synapses: motor neuron muscle interaction	641
271. Formation and specificity of synapses: neuronal target interaction	642
272. Formation and specificity of synapses: motor neuron to muscle	644
273. Formation and specificity of synapses: telencephalon	646
274. Neurotransmitters and channels: glutamate and GABA	648
275. Neurotrophic factors: biological effects II	651
276. Neurotrophic factors: biological effects III	656
277. Neurotrophic factors: biological effects IV	662
278. Neurotrophic factors: biological effects V	665
279. Neuronal death III	668
280. Glia and other non-neuronal cells: neurotransmitters and ion channels	671
281. Cerebral cortex and limbic system	673
282. Regeneration II	676
283. Regeneration III	679
284. Transplantation II	682
285. Neuroglia and myelin IV	685
286. Membrane composition and cell-surface macromolecules III	689
287. Blood-brain barrier: structure/function	691
288. Blood-brain barrier: permeability/transport	693
289. Gene structure and function III	696
290. Synaptic structure and function II	699
291. Calcium channel pharmacology and modulation I	701
292. Potassium channel structure, function, and expression I	704
293. Potassium channel pharmacology	707
294. Potassium channel modulation	710

CHRONOLOGICAL LIST OF SLIDE AND POSTER SESSIONS

Session Number & Title	Page	Session Number & Title	Page
367. Hormones and development: androgens	882	416. Hormonal control of reproductive behavior: immediate early gene expression	1019
368. Neuronal death IV	883	417. Drugs of abuse: opioids and others—opioids: neurochemistry	1021
369. Sensory systems II	887	418. Drugs of abuse: opioids and others—opioids: behavior	1024
370. Visual system: LGN and cortex	890	419. Epilepsy: human studies and animal models III	1027
371. Aging processes II	895	420. Epilepsy: basic mechanisms III	1030
372. Membrane composition and cell-surface macromolecules IV	898	421. Degenerative disease: Alzheimer's— β -amyloid VII	1033
373. Presynaptic mechanisms II	900	422. Degenerative disease: Alzheimer's— β -amyloid VIII	1037
374. Long-term potentiation III	903	423. Degenerative disease: Alzheimer's—neuropharmacology and neurotransmitters III	1039
375. Long-term potentiation IV	906	424. Degenerative disease: Alzheimer's—other IV	1042
376. Long-term potentiation V	910	425. Degenerative disease: Alzheimer's—other V	1044
377. Acetylcholine	913	426. Degenerative disease: Parkinson's—human neuropharmacology and pathology	1047
378. Acetylcholine: ChAT and AChE	915	427. Degenerative disease: Parkinson's—functional morphology	1048
379. Excitatory amino acids: anatomy and physiology II	918	428. Degenerative disease: Parkinson's—human performance and primate models	1050
380. Excitatory amino acids: pharmacology IV	921	429. Degenerative disease: Parkinson's—transplantation and glia	1052
381. Excitatory amino acids: receptors VI	925	85. History of neuroscience	203
382. Catecholamines: anatomical and developmental aspects	927	86. Teaching of neuroscience I	206
383. Transmitters in invertebrates: peptides	929	87. Teaching of neuroscience II	209
384. Storage, secretion, and metabolism I	932	88. Teaching of neuroscience III	212
385. Uptake and transporters V	935		
386. Second messengers III	938	Symposia — 1:00 p.m.	
387. Hypothalamic-pituitary-adrenal axis regulation: basic and clinical studies	941	430. Thalamocortical Mechanisms Underlying Generalized Absence Seizures <i>Chaired by:</i> D.A. Prince	1054
388. Neural-immune interactions: sympathetic regulation of immune response	944	431. Cortical Oscillatory Responses and Feature Binding <i>Chaired by:</i> J.A. Movshon	1054
389. Neural-immune interactions: other neurotransmitters in immune tissues	946	Special Lecture — 1:00 p.m.	
390. Cardiovascular regulation: ventrolateral medulla	950	432. Survival, Regrowth, and Reconnection of Injured Neurons in the Adult Mammalian CNS A.J. Aguayo	No Abstract
391. Cardiovascular regulation: descending control	953	Special Lecture — 4:15 p.m.	
392. Cardiovascular regulation: hypothalamic control	956	433. Spinal Cord Mechanisms of Opioid Analgesia and Tolerance A. Basbaum	No Abstract
393. Autonomic regulation: central gastrointestinal control	959	Slide Sessions — 1:00 p.m.	
394. Autonomic regulation: peripheral gastrointestinal control	962	434. Biological rhythms and sleep III	1054
395. Pain modulation: anatomy and physiology IV	964	435. Ischemia III	1056
396. Pain modulation: pharmacology III	966	436. Cytoskeleton transport and membrane targeting II	1058
397. Visual cortex: extrastriate—anatomy	969	437. Serotonin: anatomy, regulation, and clinical studies	1059
398. Visual cortex: extrastriate—cognitive mechanisms II	973	438. Potassium channel structure, function, and expression II	1061
399. Basal ganglia and thalamus V	977	439. Catecholamine receptors: dopamine II	1063
400. Cerebellum I	979	440. Invertebrate learning and behavior IV	1065
401. Cerebellum II	981	441. Peptides: posttranslational processing	1067
402. Spinal cord and brainstem III	983	442. Neuroendocrine regulation: gene expression and co-localization	1069
403. Spinal cord and brainstem IV	986	443. Neuro-oncology I	1071
404. Control of posture and movement VIII	989		
405. Control of posture and movement IX	991		
406. Circuitry and pattern generation III	994		
407. Comparative neuroanatomy II	996		
408. Learning and memory: systems and functions V	998		
409. Learning and memory: systems and functions VI	1001		
410. Learning and memory: systems and functions VII	1004		
411. Learning and memory: physiology V	1005		
412. Learning and memory: pharmacology— benzodiazepines	1008		
413. Learning and memory: pharmacology—excitatory amino acids	1009		
414. Neural plasticity II	1012		
415. Neuroethology: bird vocalization	1015		

Session Number & Title	Page	Session Number & Title	Page
444. Pain: pathways I	1072	491. Spinal cord I	1195
445. Synaptic structure and function III	1075	492. Retina: invertebrate	1197
446. Cardiovascular regulation: brainstem integration	1076	493. Retina: choroid, pigment epithelium, and photoreceptors	1199
447. Learning and memory: systems and functions VIII	1078	494. Auditory system: central anatomy—brainstem	1202
Poster Sessions — 1:00 p.m.		495. Sensorimotor cortex: functional stimulation, models, and behavior	1205
448. Process outgrowth, growth cones, and sprouting VI	1081	496. Sensorimotor cortex: functional imaging	1208
449. Process outgrowth, growth cones, and sprouting VII	1084	497. Sensorimotor cortex: neuroanatomy	1210
450. Axon guidance mechanisms and pathways IV	1086	498. Motor cortex: neuropharmacology	1213
451. Axon guidance mechanisms and pathways V	1089	499. Cerebellum III	1214
452. Neurotransmitters and channels: acetylcholine, amines, peptides, G-proteins	1092	500. Brain metabolism and blood flow: miscellaneous	1217
453. Neurotrophic factors: biological effects VI	1095	501. Brain metabolism and blood flow: blood flow	1219
454. Neurotrophic factors: biological effects VII	1099	502. Brain metabolism and blood flow: PET	1222
455. Neurotrophic factors: biological effects VIII	1103	503. Brain metabolism and blood flow: nitric oxide	1224
456. Pattern formation, compartments, and boundaries III	1106	504. Learning and memory: systems and functions IX	1226
457. Molecular and pharmacological correlates of development III	1109	505. Learning and memory: systems and functions X	1229
458. Staining, tracing, and imaging techniques: confocal microscopy	1112	506. Learning and memory: systems and functions XI	1231
459. Staining, tracing, and imaging techniques I	1113	507. Learning and memory: pharmacology—other II	1234
460. Neuroglia and myelin V	1116	508. Ingestive behaviors IV	1237
461. Gene structure and function IV	1119	509. Monoamines and behavior: stimulants	1240
462. Presynaptic mechanisms III	1123	510. Monoamines and behavior: stress and depression	1243
463. Calcium channels: effects of transmitters and hormones	1126	511. Drugs of abuse: opioids and others—opioids: withdrawal	1246
464. Chloride and other ion channels	1129	512. Drugs of abuse: opioids and others—developmental effects	1249
465. Acetylcholine receptors: muscarinic subtypes	1130	513. Degenerative disease: Alzheimer's— β -amyloid IX	1250
466. Acetylcholine receptors: nicotinic receptor expression	1132	514. Degenerative disease: Alzheimer's— neuropharmacology and neurotransmitters IV	1252
467. Excitatory amino acids: receptors VII	1134	515. Degenerative disease: Alzheimer's—other VI	1254
468. GABA receptors: function: GABA _A	1137	85. History of neuroscience	203
469. GABA receptors: function—molecular modeling II	1140	86. Teaching of neuroscience I	206
470. GABA receptors: function—benzodiazepines	1141	87. Teaching of neuroscience II	209
471. GABA receptors: function—GABA _B , GABA _C	1144	88. Teaching of neuroscience III	212
472. GABA receptors: development	1146	THURSDAY, NOVEMBER 11	
473. Peptides: anatomical localization II	1148	Symposia — 8:30 a.m.	
474. Peptides: anatomical localization III	1150	516. GABA as a Developmental Signal <i>Chaired by:</i> J.L. Barker	1256
475. Opioids: receptors II	1152	517. Neuronal Functions of Calmodulin-dependent Protein Kinase II <i>Chaired by:</i> T.R. Soderling	1256
476. Opioids: receptors III	1154	Special Lecture — 11:45 a.m.	
477. Opioids: anatomy and physiology II	1156	518. Object-oriented Action: A Neuro-behavioral Approach M. Jeannerod	No Abstract
478. Opioids: anatomy and physiology III	1159	Slide Sessions — 8:30 a.m.	
479. Catecholamines: release	1162	519. Retina: ganglion cells I	1257
480. Serotonin receptors: molecular biology II	1163	520. Gene structure and function V	1259
481. Serotonin receptors: pharmacology and localization	1166	521. Ion channel modulation and regulation II	1261
482. Serotonin: neurotoxins, behavior and physiology	1169	522. Ingestive behaviors V	1263
483. Transmitters in invertebrates: nitric oxide	1172	523. GABA receptors: function: <i>in vivo</i> studies	1265
484. Interactions between neurotransmitters III	1173	524. Brain metabolism and blood flow I	1267
485. Second messengers: nitric oxide and calcium	1175		
486. Behavioral pharmacology III	1179		
487. Receptor modulation, up and down regulation III	1182		
488. Hypothalamic-pituitary-adrenal axis regulation: POMC and steroid receptor studies	1185		
489. Neuroendocrine regulation: CRF, gonadal and adrenal steroids	1189		
490. Respiratory regulation: medullary and spinal cord mechanisms	1192		

CHRONOLOGICAL LIST OF SLIDE AND POSTER SESSIONS

Session Number & Title	Page	Session Number & Title	Page
525. Peptides: receptor physiology	1269	567. Storage, secretion, and metabolism II	1384
526. Formation and specificity of synapses	1271	568. Second messengers IV	1387
527. Transmitters in invertebrates	1273	569. Behavioral pharmacology IV	1390
528. Degenerative disease: Alzheimer's— β -amyloid X	1275	570. Hypothalamic-pituitary-gonadal regulation: neuropeptides and transmitters	1393
529. Cerebellum IV	1277	571. Hypothalamic-pituitary-gonadal regulation: releasing hormones	1395
530. Osmotic regulation/chemical senses: central pathways	1280	572. Hypothalamic-pituitary-gonadal regulation: gonadotropins, neuropeptides, steroids	1398
531. Visual cortex: extrastriate—motion processing	1282	573. Neuroendocrine regulation: catecholamine and GABA	1399
532. Human cognition: attention and memory	1284	574. Respiratory regulation: carotid body, pons, hypothalamus, miscellaneous	1402
Poster Sessions — 8:30 a.m.			
533. Genesis of neurons and glia III	1286	575. Pain: pathways II	1404
534. Cell lineage and determination: visual system	1288	576. Pain modulation: anatomy and physiology V	1407
535. Process outgrowth, growth cones, and sprouting VIII	1290	577. Pain modulation: pharmacology IV	1410
536. Axon guidance mechanisms and pathways VI	1293	578. Retina: functional organization	1413
537. Formation and specificity of synapses: receptor localization	1294	579. Retina: ganglion cells II	1416
538. Neurotrophic factors: receptors and cellular mechanisms I	1295	580. Auditory system: cochlea	1418
539. Neurotrophic factors: receptors and cellular mechanisms II	1302	581. Auditory cortex I	1421
540. Neurotrophic factors: receptors and cellular mechanisms III	1305	582. Auditory cortex II	1423
541. Neurotrophic factors: receptors and cellular mechanisms IV	1308	583. Auditory system: central anatomy—midbrain, thalamus, and cortex	1425
542. Hormones and development: neuroanatomical finding	1311	584. Chemical senses: peripheral gustatory mechanisms	1428
543. Regeneration IV	1313	585. Chemical senses: central gustatory mechanisms	1430
544. Transplantation IV	1317	586. Basal ganglia and thalamus VI	1431
545. Staining, tracing, and imaging techniques II	1320	587. Basal ganglia and thalamus VII	1434
546. Long-term potentiation VI	1323	588. Spinal cord and brainstem V	1437
547. Long-term potentiation VII	1325	589. Limbic system V	1440
548. Calcium channel structure, function, and expression II	1329	590. Association cortex and thalamocortical relations I	1444
549. Calcium channel physiology	1331	591. Association cortex and thalamocortical relations II	1446
550. Potassium channel physiology	1335	592. Learning and memory: systems and functions XII	1448
551. Acetylcholine receptors: expression of muscarinic receptors	1338	593. Stress: neurochemistry	1449
552. Acetylcholine receptors: muscle	1339	594. Neuropeptides and behavior: vasopressin, NPY, neurotensin, and others	1452
553. Excitatory amino acids: excitotoxicity II	1341	595. Ethanol and benzodiazepines: tolerance, dependence, withdrawal	1455
554. Excitatory amino acids: excitotoxicity III	1345	596. Drugs of abuse: opioids and others—miscellaneous	1458
555. Excitatory amino acids: excitotoxicity IV	1348	597. Developmental disorders of the nervous system II	1461
556. Excitatory amino acids: pharmacology V	1351	598. Epilepsy: human studies and animal models IV	1464
557. Excitatory amino acids: receptors VIII	1355	599. Epilepsy: basic mechanisms IV	1467
558. Excitatory amino acids: receptors IX	1358	600. Degenerative disease: Alzheimer's— β -amyloid XI	1470
559. Peptides: biosynthesis, metabolism, and biochemical characterization I	1360	601. Degenerative disease: Alzheimer's—other VII	1473
560. Peptides: biosynthesis, metabolism, and biochemical characterization II	1363	85. History of neuroscience	203
561. Peptides: biosynthesis, metabolism, and biochemical characterization III	1366	86. Teaching of neuroscience I	206
562. Catecholamine receptors: dopamine receptor localization and regulation	1368	87. Teaching of neuroscience II	209
563. Catecholamines: electrophysiology	1372	88. Teaching of neuroscience III	212
564. Serotonin receptors: ontogeny and regulation	1375	Symposia — 1:00 p.m.	
565. Serotonin receptors: physiology and behavior	1378	602. Neurotransmitter Transporters <i>Chaired by:</i> M.J. Kuhar	1475
566. Interactions between neurotransmitters IV	1382	603. Prefrontal Mechanisms of Disordered Cognition: Relevance to Schizophrenia <i>Chaired by:</i> P.S. Goldman-Rakic	1475

Session Number & Title	Page	Session Number & Title	Page
Presidential Special Lecture — 1:00 p.m.		643. Spinal cord II	1563
604. MK-801 (Devazepide): Catalyst for Interchange Between Industry and Academia L.L. Iversen	No Abstract	644. Somatosensory cortex and thalamocortical relationships III	1565
Special Lecture — 4:15 p.m.		645. Somatosensory cortex and thalamocortical relationships IV	1568
605. Psychophysical Studies of Visual Attention K. Nakayama	No Abstract	646. Pain: pathways III	1570
Slide Sessions — 1:00 p.m.		647. Striate cortex: response properties II	1573
606. Neurotrophic factors: receptors and cellular mechanisms V	1476	648. Striate cortex: response properties III	1575
607. Calcium channel pharmacology and modulation II	1478	649. Auditory, vestibular, and lateral line: hair cells	1577
608. Axon guidance mechanisms and pathways VII	1480	650. Basal ganglia and thalamus VIII	1581
609. Neurotoxicity I	1482	651. Basal ganglia and thalamus IX	1584
610. Cardiovascular regulation: spinal and peripheral control ...	1483	652. Cerebellum V	1587
611. Trauma	1485	653. Oculomotor system: neuroanatomy	1591
612. Biological rhythms and sleep IV	1487	654. Oculomotor system: vertical movements, integration, torsion	1592
613. Respiratory regulation	1489	655. Control of posture and movement X	1594
614. Vestibular system	1491	656. Circuitry and pattern generation IV	1596
615. Brain metabolism and blood flow II	1493	657. Invertebrate motor function	1599
616. Motor cortex	1495	658. Human cognition: vision, methods	1603
617. Drugs of abuse: cocaine	1497	659. Human cognition: electrophysiology	1605
618. Visual cortex: extrastriate—functional architecture	1499	660. Learning and memory: models	1608
619. Excitatory amino acids: excitotoxicity V	1501	661. Motivation and emotion III	1610
Poster Sessions — 1:00 p.m.		662. Biological rhythms and sleep V	1613
620. Neuronal death V	1503	663. Neuroethology: behavioral strategies	1617
621. Motor systems	1506	664. Stress: behavioral studies	1619
622. Regeneration V	1509	665. Hormonal control of reproductive behavior: neuropeptides and transmitters	1622
623. Transplantation V	1511	666. Psychotherapeutic drugs: antipsychotics and other agents	1623
624. Synaptic structure and function IV	1514	667. Genetic models of nervous system disorders II	1626
625. Presynaptic mechanisms IV	1517	668. Epilepsy: anticonvulsant drugs	1630
626. Postsynaptic mechanisms II	1521	669. Degenerative disease: Alzheimer's— β -amyloid XII	1633
627. Pharmacology of synaptic transmission II	1524	670. Degenerative disease: Alzheimer's—other VIII	1636
628. Sodium channels II	1527	671. Ischemia: acidosis	1639
629. Ion channel modulation and regulation III	1529	672. Ischemia: calcium	1640
630. Acetylcholine receptors: neuronal nicotinic II	1532	673. Ischemia: drug treatment I	1642
631. Acetylcholine receptors: nicotinic antagonists and agonists	1534	674. Ischemia: drug treatment II	1645
632. GABA receptors: function—neurosteroids	1537	675. Ischemia: glia	1648
633. GABA receptors: function—anesthetics	1540	676. Ischemia: heat shock protein	1649
634. Peptides: receptors IV	1541	677. Ischemia: models	1652
635. Peptides: receptors V	1544	678. Ischemia: molecular biology/immunocytochemistry	1655
636. Peptides: physiological effects III	1546	679. Ischemia: neonatal	1657
637. Peptides: physiological effects IV	1548	680. Ischemia: neurochemistry I	1660
638. Opioids: receptors IV	1550	681. Ischemia: neurochemistry II	1663
639. Serotonin receptors: cell biology and effector mechanisms	1554	682. Ischemia: neurophysiology	1666
640. Serotonin: other	1556	683. Ischemia: temperature	1669
641. Hypothalamic-pituitary-gonadal regulation: steroid receptors	1558	684. Infectious diseases	1671
642. Neuroendocrine regulation: miscellaneous	1559	685. Neurotoxicity: metals	1675
		686. Neurotoxicity II	1678
		85. History of neuroscience	203
		86. Teaching of neuroscience I	206
		87. Teaching of neuroscience II	209
		88. Teaching of neuroscience III	212

Session Number & Title	Page
FRIDAY, NOVEMBER 12	
Symposia — 8:30 a.m.	
687. View of a Neural System in the Blink of an Eye: The Eyeblink Reflex—Control, Learning, and Cellular Mechanisms <i>Chaired by:</i> J.R. Bloedel	1681
688. The Contribution of Identified Neurons to Neuroscience: A 25-Year Retrospective <i>Chaired by:</i> J.L. Leonard	1681
Special Lecture — 10:00 a.m.	
689. <i>Hox</i> Homeobox Genes and Patterning of the Vertebrate Nervous System R. Krumlauf	No Abstract
Slide Sessions — 8:30 a.m.	
690. Neurotrophic factors: biological effects IX	1681
691. Neural-immune interactions: neuroendocrine control of immune response	1683
692. Control of posture and movement XI	1685
693. Auditory system	1687
694. Genetic models of nervous system disorders III	1689
695. Catecholamines III	1691
696. Hypothalamus and autonomic regulation	1693
697. Ingestive behaviors VI	1694
698. Excitatory amino acids: excitotoxicity VI	1696
699. Gene structure and function VI	1698
700. Circuitry and pattern generation V	1700
701. Biological rhythms and sleep VI	1702
702. Somatosensory cortex and thalamocortical relationships V	1704
703. Long-term potentiation VIII	1706
Poster Sessions — 8:30 a.m.	
704. Genesis of neurons and glia IV	1708
705. Cell shape and differentiation: morphogenesis	1711
706. Process outgrowth, growth cones, and sprouting IX	1712
707. Axon guidance mechanisms and pathways VIII	1715
708. Neurotransmitters and channels: channels	1716
709. Other factors and trophic agents I	1719
710. Other factors and trophic agents II	1722
711. Other factors and trophic agents III	1726
712. Hormones and development: other	1730
713. Nutritional and prenatal factors	1731
714. Molecular and pharmacological correlates of development IV	1734
715. Regeneration VI	1738
716. Transplantation VI	1740
717. Aging processes III	1742
718. Gene structure and function VII	1745
719. Presynaptic mechanisms V	1748
720. Calcium channel pharmacology and modulation III	1750
721. Calcium channel pharmacology and modulation IV	1753
722. Ion channel modulation and regulation IV	1756
723. Ion channels: cell function	1759
724. Acetylcholine: release	1763
725. Acetylcholine receptors: muscarinic	1765

Session Number & Title	Page
726. Acetylcholine receptors: mutagenesis of muscarinic and nicotinic receptors	1768
727. Excitatory amino acids: excitotoxicity VII	1770
728. Excitatory amino acids: excitotoxicity VIII	1773
729. Excitatory amino acids: excitotoxicity IX	1776
730. Excitatory amino acids: pharmacology VI	1779
731. Excitatory amino acids: receptors X	1782
732. Opioids: behavior	1785
733. Catecholamine receptors: α - and β -adrenergic	1788
734. Hypothalamic-pituitary-gonadal regulation: regulatory aspects	1791
735. Neuroendocrine regulation: oxytocin, vasopressin, fluid balance, and the pineal	1793
736. Pain modulation: pharmacology V	1796
737. Striate cortex: development and plasticity	1799
738. Visual psychophysics and behavior II	1802
739. Auditory behavior	1804
740. Human cognition: audition and language II	1806
741. Learning and memory: pharmacology—acetylcholine	1810
742. Biological rhythms and sleep VII	1813
743. Ingestive behaviors VII	1818
744. Hormonal control of reproductive behavior: neuroanatomy	1824
745. Monoamines and behavior: nucleus accumbens	1825
746. Monoamines and behavior: transmitter release	1828
747. Monoamines and behavior: dopamine and movement	1829
748. Monoamines and behavior: electrophysiology	1832
749. Drugs of abuse: ethanol—development	1833
750. Drugs of abuse: ethanol—monoamines	1835
751. Drugs of abuse: cocaine—behavior	1838
752. Drugs of abuse: cocaine—cell membrane	1841
753. Drugs of abuse: cocaine—glutamate	1843
754. Drugs of abuse: cocaine—locomotor	1845
755. Drugs of abuse: cocaine—microdialysis	1847
756. Drugs of abuse: cocaine—monoamines	1849
757. Drugs of abuse: cocaine—neonatal	1851
758. Drugs of abuse: cocaine—neurophysiology	1855
759. Drugs of abuse: cocaine—nucleus accumbens	1856
760. Drugs of abuse: cocaine—other drugs	1858
761. Drugs of abuse: cocaine—self-administration	1861
762. Drugs of abuse: cocaine—miscellaneous	1863
763. Psychotherapeutic drugs: anxiolytics and antidepressants	1866
764. Epilepsy: basic mechanisms V	1869
765. Trauma: cord	1872
766. Trauma: treatment	1875
767. Trauma: miscellaneous I	1878
768. Trauma: miscellaneous II	1882
769. Mental illness IV	1884
770. Neurotoxicity III	1886
771. Neurotoxicity IV	1889
772. Neurotoxicity V	1892
773. Neuro-oncology II	1895
85. History of neuroscience	203
86. Teaching of neuroscience I	206
87. Teaching of neuroscience II	209
88. Teaching of neuroscience III	212

THEMATIC LIST OF SESSIONS

(Includes slide and poster sessions, and symposia only)

Session Number	Session Title	Type	Mon.	Day and Time				
				Tue.	Wed.	Thu.	Fri.	
THEME A: DEVELOPMENT AND REGENERATION								
192.	Aging processes I	Poster		tAM				
371.	Aging processes II	Poster			wAM			
717.	Aging processes III	Poster					fAM	
25.	Axon guidance mechanisms and pathways I	Poster	mAM					
26.	Axon guidance mechanisms and pathways II	Poster	mAM					
103.	Axon guidance mechanisms and pathways III	Slide	mPM					
450.	Axon guidance mechanisms and pathways IV	Poster			wPM			
451.	Axon guidance mechanisms and pathways V	Poster			wPM			
536.	Axon guidance mechanisms and pathways VI	Poster				thAM		
608.	Axon guidance mechanisms and pathways VII	Slide				thPM		
707.	Axon guidance mechanisms and pathways VIII	Poster					fAM	
356.	Cell lineage and determination: cellular and molecular specification	Slide			wAM			
21.	Cell lineage and determination: gene expression and growth factors	Poster	mAM					
256.	Cell lineage and determination: immortalization, transplants, cortex	Slide		tPM				
269.	Cell lineage and determination: neural crest	Poster		tPM				
268.	Cell lineage and determination: telencephalon	Poster		tPM				
534.	Cell lineage and determination: visual system	Poster				thAM		
22.	Cell migration and motility: cell-surface molecules	Poster	mAM					
362.	Cell migration and motility: neural plate and crest derivative	Poster			wAM			
361.	Cell migration and motility: olfactory neurons	Poster			wAM			
23.	Cell shape and differentiation: activity	Poster	mAM					
107.	Cell shape and differentiation: immortalized cells and cell lines	Poster	mPM					
705.	Cell shape and differentiation: morphogenesis	Poster					fAM	
281.	Cerebral cortex and limbic system	Poster		tPM				
30.	Cerebral cortex and limbic system: molecular determinants and molecular markers	Poster	mAM					
526.	Formation and specificity of synapses	Slide				thAM		
270.	Formation and specificity of synapses: motor neuron muscle interaction	Poster		tPM				
272.	Formation and specificity of synapses: motor neuron to muscle	Poster		tPM				
271.	Formation and specificity of synapses: neuronal target interaction	Poster		tPM				
537.	Formation and specificity of synapses: receptor localization	Poster				thAM		
273.	Formation and specificity of synapses: telencephalon	Poster		tPM				
27.	Formation and specificity of synapses: visual system	Poster	mAM					
516.	GABA as a Developmental Signal	SYMP				thAM		
20.	Genesis of neurons and glia I	Poster	mAM					
360.	Genesis of neurons and glia II	Poster			wAM			
533.	Genesis of neurons and glia III	Poster				thAM		
704.	Genesis of neurons and glia IV	Poster					fAM	
28.	Glia and other non-neuronal cells: CNS development	Poster	mAM					
113.	Glia and other non-neuronal cells: PNS development	Poster	mPM					
190.	Glia and other non-neuronal cells: microglia/macrophage	Poster		tAM				
280.	Glia and other non-neuronal cells: neurotransmitters and ion channels	Poster		tPM				
189.	Glia and other non-neuronal cells: response to injury	Poster		tAM				
367.	Hormones and development: androgens	Poster			wAM			
365.	Hormones and development: estrogens	Poster			wAM			
366.	Hormones and development: glucocorticoids	Poster			wAM			
542.	Hormones and development: neuroanatomical finding	Poster				thAM		
712.	Hormones and development: other	Poster					fAM	

THEMATIC LIST OF SESSIONS

Session Number	Session Title	Type	Day and Time					
			Mon.	Tue.	Wed.	Thu.	Fri.	
112.	Molecular and pharmacological correlates of development I	Poster	mPM					
262.	Molecular and pharmacological correlates of development II	Slide		tPM				
457.	Molecular and pharmacological correlates of development III	Poster			wPM			
714.	Molecular and pharmacological correlates of development IV	Poster						fAM
621.	Motor systems	Poster					thPM	
187.	Neuronal death I	Poster		tAM				
266.	Neuronal death II	Slide		tPM				
279.	Neuronal death III	Poster		tPM				
368.	Neuronal death IV	Poster			wAM			
620.	Neuronal death V	Poster					thPM	
452.	Neurotransmitters and channels: acetylcholine, amines, peptides, G-proteins	Poster			wPM			
708.	Neurotransmitters and channels: channels	Poster						fAM
274.	Neurotransmitters and channels: glutamate and GABA	Poster		tPM				
175.	Neurotrophic factors: biological effects I	Slide		tAM				
275.	Neurotrophic factors: biological effects II	Poster		tPM				
276.	Neurotrophic factors: biological effects III	Poster		tPM				
277.	Neurotrophic factors: biological effects IV	Poster		tPM				
278.	Neurotrophic factors: biological effects V	Poster		tPM				
453.	Neurotrophic factors: biological effects VI	Poster			wPM			
454.	Neurotrophic factors: biological effects VII	Poster			wPM			
455.	Neurotrophic factors: biological effects VIII	Poster			wPM			
690.	Neurotrophic factors: biological effects IX	Slide						fAM
8.	Neurotrophic factors: expression and regulation I	Slide	mAM					
108.	Neurotrophic factors: expression and regulation II	Poster	mPM					
109.	Neurotrophic factors: expression and regulation III	Poster	mPM					
110.	Neurotrophic factors: expression and regulation IV	Poster	mPM					
111.	Neurotrophic factors: expression and regulation V	Poster	mPM					
538.	Neurotrophic factors: receptors and cellular mechanisms I	Poster					thAM	
539.	Neurotrophic factors: receptors and cellular mechanisms II	Poster					thAM	
540.	Neurotrophic factors: receptors and cellular mechanisms III	Poster					thAM	
541.	Neurotrophic factors: receptors and cellular mechanisms IV	Poster					thAM	
606.	Neurotrophic factors: receptors and cellular mechanisms V	Slide					thPM	
713.	Nutritional and prenatal factors	Poster						fAM
709.	Other factors and trophic agents I	Poster						fAM
710.	Other factors and trophic agents II	Poster						fAM
711.	Other factors and trophic agents III	Poster						fAM
94.	Pattern formation, compartments, and boundaries I	Slide	mPM					
188.	Pattern formation, compartments, and boundaries II	Poster		tAM				
456.	Pattern formation, compartments, and boundaries III	Poster			wPM			
24.	Process outgrowth, growth cones, and sprouting I	Poster	mAM					
185.	Process outgrowth, growth cones, and sprouting II	Slide		tAM				
259.	Process outgrowth, growth cones, and sprouting III	Slide		tPM				
363.	Process outgrowth, growth cones, and sprouting IV	Poster			wAM			
364.	Process outgrowth, growth cones, and sprouting V	Poster			wAM			
448.	Process outgrowth, growth cones, and sprouting VI	Poster			wPM			
449.	Process outgrowth, growth cones, and sprouting VII	Poster			wPM			
535.	Process outgrowth, growth cones, and sprouting VIII	Poster					thAM	
706.	Process outgrowth, growth cones, and sprouting IX	Poster						fAM
178.	Regeneration I	Slide		tAM				
282.	Regeneration II	Poster		tPM				
283.	Regeneration III	Poster		tPM				
543.	Regeneration IV	Poster					thAM	
622.	Regeneration V	Poster					thPM	
715.	Regeneration VI	Poster						fAM
344.	Regulation of Oligodendrocyte Development	SYMP			wAM			

Session Number	Session Title	Type	Mon.	Day and Time			Fri.
				Tue.	Wed.	Thu.	
257.	Sensory and motor systems	Slide		tPM			
29.	Sensory systems I	Poster	mAM				
369.	Sensory systems II	Poster			wAM		
32.	Transplantation I	Poster	mAM				
284.	Transplantation II	Poster		tPM			
357.	Transplantation III	Slide			wAM		
544.	Transplantation IV	Poster				thAM	
623.	Transplantation V	Poster				thPM	
716.	Transplantation VI	Poster					fAM
105.	Visual system	Slide	mPM				
370.	Visual system: LGN and cortex	Poster			wAM		
191.	Visual system: optic tectum/superior colliculus	Poster		tAM			
31.	Visual system: retina	Poster	mAM				
THEME B: CELL BIOLOGY							
288.	Blood-brain barrier: permeability/transport	Poster		tPM			
287.	Blood-brain barrier: structure/function	Poster		tPM			
34.	Cytoskeleton transport and membrane targeting I	Poster	mAM				
436.	Cytoskeleton transport and membrane targeting II	Slide			wPM		
35.	Gene structure and function I	Poster	mAM				
97.	Gene structure and function II	Slide	mPM				
289.	Gene structure and function III	Poster		tPM			
461.	Gene structure and function IV	Poster			wPM		
520.	Gene structure and function V	Slide				thAM	
699.	Gene structure and function VI	Slide					fAM
718.	Gene structure and function VII	Poster					fAM
115.	Membrane composition and cell-surface macromolecules I	Poster	mPM				
193.	Membrane composition and cell-surface macromolecules II	Poster		tAM			
286.	Membrane composition and cell-surface macromolecules III	Poster		tPM			
372.	Membrane composition and cell-surface macromolecules IV	Poster			wAM		
33.	Neuroglia and myelin I	Poster	mAM				
114.	Neuroglia and myelin II	Poster	mPM				
176.	Neuroglia and myelin III	Slide		tAM			
285.	Neuroglia and myelin IV	Poster		tPM			
460.	Neuroglia and myelin V	Poster			wPM		
517.	Neuronal Functions of Calmodulin-dependent Protein Kinase II	SYMP				thAM	
459.	Staining, tracing, and imaging techniques I	Poster			wPM		
545.	Staining, tracing, and imaging techniques II	Poster				thAM	
458.	Staining, tracing, and imaging techniques: confocal microscopy	Poster			wPM		
THEME C: EXCITABLE MEMBRANES AND SYNAPTIC TRANSMISSION							
291.	Calcium channel pharmacology and modulation I	Poster		tPM			
607.	Calcium channel pharmacology and modulation II	Slide				thPM	
720.	Calcium channel pharmacology and modulation III	Poster					fAM
721.	Calcium channel pharmacology and modulation IV	Poster					fAM
549.	Calcium channel physiology	Poster				thAM	
11.	Calcium channel structure, function, and expression I	Slide	mAM				
548.	Calcium channel structure, function, and expression II	Poster				thAM	
463.	Calcium channels: effects of transmitters and hormones	Poster			wPM		
464.	Chloride and other ion channels	Poster			wPM		
295.	Ion channel modulation and regulation I	Poster		tPM			
521.	Ion channel modulation and regulation II	Slide				thAM	
629.	Ion channel modulation and regulation III	Poster				thPM	
722.	Ion channel modulation and regulation IV	Poster					fAM

THEMATIC LIST OF SESSIONS

Session Number	Session Title	Type	Day and Time					
			Mon.	Tue.	Wed.	Thu.	Fri.	
723.	Ion channels: cell function	Poster						fAM
119.	Ligand-gated ion channels: glutamatergic	Poster	mPM					
120.	Ligand-gated ion channels: non-glutamatergic	Poster	mPM					
106.	Long-term potentiation I	Slide	mPM					
183.	Long-term potentiation II	Slide		tAM				
374.	Long-term potentiation III	Poster			wAM			
375.	Long-term potentiation IV	Poster			wAM			
376.	Long-term potentiation V	Poster			wAM			
546.	Long-term potentiation VI	Poster					thAM	
547.	Long-term potentiation VII	Poster					thAM	
703.	Long-term potentiation VIII	Slide						fAM
118.	Pharmacology of synaptic transmission I	Poster	mPM					
627.	Pharmacology of synaptic transmission II	Poster					thPM	
117.	Postsynaptic mechanisms I	Poster	mPM					
626.	Postsynaptic mechanisms II	Poster					thPM	
294.	Potassium channel modulation	Poster		tPM				
293.	Potassium channel pharmacology	Poster		tPM				
550.	Potassium channel physiology	Poster					thAM	
292.	Potassium channel structure, function, and expression I	Poster		tPM				
438.	Potassium channel structure, function, and expression II	Slide			wPM			
255.	Presynaptic mechanisms I	Slide		tPM				
373.	Presynaptic mechanisms II	Poster			wAM			
462.	Presynaptic mechanisms III	Poster			wPM			
625.	Presynaptic mechanisms IV	Poster					thPM	
719.	Presynaptic mechanisms V	Poster						fAM
170.	Role of Calcium in Stimulus-secretion Coupling	SYMP		tAM				
121.	Sodium channels I	Poster	mPM					
628.	Sodium channels II	Poster					thPM	
116.	Synaptic structure and function I	Poster	mPM					
290.	Synaptic structure and function II	Poster		tPM				
445.	Synaptic structure and function III	Slide			wPM			
624.	Synaptic structure and function IV	Poster					thPM	
THEME D: NEUROTRANSMITTERS, MODULATORS, TRANSPORTERS, AND RECEPTORS								
377.	Acetylcholine	Poster			wAM			
10.	Acetylcholine receptors	Slide	mAM					
551.	Acetylcholine receptors: expression of muscarinic receptors	Poster					thAM	
725.	Acetylcholine receptors: muscarinic	Poster						fAM
194.	Acetylcholine receptors: muscarinic antagonists and agonists	Poster		tAM				
465.	Acetylcholine receptors: muscarinic subtypes	Poster			wPM			
552.	Acetylcholine receptors: muscle	Poster					thAM	
726.	Acetylcholine receptors: mutagenesis of muscarinic and nicotinic receptors	Poster						fAM
195.	Acetylcholine receptors: neuronal and α -bungarotoxin-sensitive	Poster		tAM				
123.	Acetylcholine receptors: neuronal nicotinic I	Poster	mPM					
630.	Acetylcholine receptors: neuronal nicotinic II	Poster					thPM	
631.	Acetylcholine receptors: nicotinic antagonists and agonists	Poster					thPM	
466.	Acetylcholine receptors: nicotinic receptor expression	Poster			wPM			
378.	Acetylcholine: ChAT and AChE	Poster			wAM			
122.	Acetylcholine: neuroanatomy	Poster	mPM					
724.	Acetylcholine: release	Poster						fAM
310.	Behavioral pharmacology I	Poster		tPM				
311.	Behavioral pharmacology II	Poster		tPM				
486.	Behavioral pharmacology III	Poster			wPM			

Session Number	Session Title	Type	Mon.	Day and Time			
				Tue.	Wed.	Thu.	Fri.
569.	Behavioral pharmacology IV	Poster				thAM	
101.	Catecholamine receptors	Slide	mPM				
733.	Catecholamine receptors: α - and β -adrenergic	Poster					fAM
39.	Catecholamine receptors: dopamine I	Poster	mAM				
439.	Catecholamine receptors: dopamine II	Slide			wPM		
562.	Catecholamine receptors: dopamine receptor localization and regulation	Poster				thAM	
302.	Catecholamine receptors: dopamine receptors—molecular biology	Poster		tPM			
38.	Catecholamine receptors: dopaminergic agonists and antagonists	Poster	mAM				
40.	Catecholamines I	Poster	mAM				
203.	Catecholamines II	Poster		tAM			
695.	Catecholamines III	Slide					fAM
382.	Catecholamines: anatomical and developmental aspects	Poster			wAM		
303.	Catecholamines: biosynthesis and degradation	Poster		tPM			
304.	Catecholamines: dopamine release	Poster		tPM			
563.	Catecholamines: electrophysiology	Poster				thAM	
479.	Catecholamines: release	Poster			wPM		
196.	Excitatory amino acids: anatomy and physiology I	Poster		tAM			
379.	Excitatory amino acids: anatomy and physiology II	Poster			wAM		
18.	Excitatory amino acids: excitotoxicity I	Slide	mAM				
553.	Excitatory amino acids: excitotoxicity II	Poster				thAM	
554.	Excitatory amino acids: excitotoxicity III	Poster				thAM	
555.	Excitatory amino acids: excitotoxicity IV	Poster				thAM	
619.	Excitatory amino acids: excitotoxicity V	Slide				thPM	
698.	Excitatory amino acids: excitotoxicity VI	Slide					fAM
727.	Excitatory amino acids: excitotoxicity VII	Poster					fAM
728.	Excitatory amino acids: excitotoxicity VIII	Poster					fAM
729.	Excitatory amino acids: excitotoxicity IX	Poster					fAM
124.	Excitatory amino acids: pharmacology I	Poster	mPM				
197.	Excitatory amino acids: pharmacology II	Poster		tAM			
296.	Excitatory amino acids: pharmacology III	Poster		tPM			
380.	Excitatory amino acids: pharmacology IV	Poster			wAM		
556.	Excitatory amino acids: pharmacology V	Poster				thAM	
730.	Excitatory amino acids: pharmacology VI	Poster					fAM
36.	Excitatory amino acids: receptors I	Poster	mAM				
125.	Excitatory amino acids: receptors II	Poster	mPM				
198.	Excitatory amino acids: receptors III	Poster		tAM			
261.	Excitatory amino acids: receptors IV	Slide		tPM			
297.	Excitatory amino acids: receptors V	Poster		tPM			
381.	Excitatory amino acids: receptors VI	Poster			wAM		
467.	Excitatory amino acids: receptors VII	Poster			wPM		
557.	Excitatory amino acids: receptors VIII	Poster				thAM	
558.	Excitatory amino acids: receptors IX	Poster				thAM	
731.	Excitatory amino acids: receptors X	Poster					fAM
472.	GABA receptors: development	Poster			wPM		
523.	GABA receptors: function— <i>in vivo</i> studies	Slide				thAM	
468.	GABA receptors: function—GABA _A	Poster			wPM		
471.	GABA receptors: function—GABA _B , GABA _C	Poster			wPM		
633.	GABA receptors: function—anesthetics	Poster				thPM	
470.	GABA receptors: function—benzodiazepines	Poster			wPM		
351.	GABA receptors: function—molecular modeling I	Slide			wAM		
469.	GABA receptors: function—molecular modeling II	Poster			wPM		
632.	GABA receptors: function—neurosteroids	Poster				thPM	
199.	GABA receptors: structure	Poster		tAM			
3. Gender and the Brain		SYMP	mAM				
128.	Interactions between neurotransmitters I	Poster	mPM				

THEMATIC LIST OF SESSIONS

Session Number	Session Title	Type	Day and Time					
			Mon.	Tue.	Wed.	Thu.	Fri.	
205.	Interactions between neurotransmitters II	Poster		tAM				
484.	Interactions between neurotransmitters III	Poster			wPM			
566.	Interactions between neurotransmitters IV	Poster					thAM	
343.	Molecular Biology of Neuropeptide Receptors: How Different Are They?	SYMP			wAM			
171.	Molecular Plasticity to Psychotropic Drugs	SYMP		tAM				
602.	Neurotransmitter Transporters	SYMP					thPM	
202.	Opioids: anatomy and physiology I	Poster		tAM				
477.	Opioids: anatomy and physiology II	Poster			wPM			
478.	Opioids: anatomy and physiology III	Poster			wPM			
732.	Opioids: behavior	Poster						fAM
348.	Opioids: receptor molecular biology	Slide			wAM			
177.	Opioids: receptor physiology and sigma sites	Slide		tAM				
37.	Opioids: receptors I	Poster	mAM					
475.	Opioids: receptors II	Poster			wPM			
476.	Opioids: receptors III	Poster			wPM			
638.	Opioids: receptors IV	Poster					thPM	
41.	Other biogenic amines and purines: histamine and melatonin	Poster	mAM					
42.	Other biogenic amines and purines: purines	Poster	mAM					
301.	Peptides: anatomical localization I	Poster		tPM				
473.	Peptides: anatomical localization II	Poster			wPM			
474.	Peptides: anatomical localization III	Poster			wPM			
559.	Peptides: biosynthesis, metabolism, and biochemical characterization I	Poster					thAM	
560.	Peptides: biosynthesis, metabolism, and biochemical characterization II	Poster					thAM	
561.	Peptides: biosynthesis, metabolism, and biochemical characterization III	Poster					thAM	
200.	Peptides: physiological effects I	Poster		tAM				
201.	Peptides: physiological effects II	Poster		tAM				
636.	Peptides: physiological effects III	Poster					thPM	
637.	Peptides: physiological effects IV	Poster					thPM	
441.	Peptides: posttranslational processing	Slide			wPM			
104.	Peptides: receptor molecular biology	Slide	mPM					
525.	Peptides: receptor physiology	Slide					thAM	
298.	Peptides: receptors I	Poster		tPM				
299.	Peptides: receptors II	Poster		tPM				
300.	Peptides: receptors III	Poster		tPM				
634.	Peptides: receptors IV	Poster					thPM	
635.	Peptides: receptors V	Poster					thPM	
181.	Receptor modulation, up- and down-regulation I	Slide		tAM				
207.	Receptor modulation, up- and down-regulation II	Poster		tAM				
487.	Receptor modulation, up- and down-regulation III	Poster			wPM			
43.	Regional localization of receptors and transmitters I	Poster	mAM					
129.	Regional localization of receptors and transmitters II	Poster	mPM					
308.	Regional localization of receptors and transmitters III	Poster		tPM				
17.	Second messengers I	Slide	mAM					
130.	Second messengers II	Poster	mPM					
386.	Second messengers III	Poster			wAM			
568.	Second messengers IV	Poster					thAM	
309.	Second messengers: PKC, calcium, and IP3	Poster		tPM				
485.	Second messengers: nitric oxide and calcium	Poster			wPM			
639.	Serotonin receptors: cell biology and effector mechanisms	Poster					thPM	
265.	Serotonin receptors: molecular biology I	Slide		tPM				
480.	Serotonin receptors: molecular biology II	Poster			wPM			
564.	Serotonin receptors: ontogeny and regulation	Poster					thAM	
481.	Serotonin receptors: pharmacology and localization	Poster			wPM			

Session Number	Session Title	Type	Mon.	Day and Time			Fri.
				Tue.	Wed.	Thu.	
93.	Serotonin receptors: pharmacology, localization, regulation	Slide	mPM				
565.	Serotonin receptors: physiology and behavior	Poster				thAM	
437.	Serotonin: anatomy, regulation, and clinical studies	Slide			wPM		
305.	Serotonin: electrophysiology	Poster		tPM			
126.	Serotonin: neurochemistry	Poster	mPM				
482.	Serotonin: neurotoxins, behavior and physiology	Poster			wPM		
640.	Serotonin: other	Poster				thPM	
384.	Storage, secretion, and metabolism I	Poster			wAM		
567.	Storage, secretion, and metabolism II	Poster				thAM	
527.	Transmitters in invertebrates	Slide				thAM	
306.	Transmitters in invertebrates: acetylcholine	Poster		tPM			
204.	Transmitters in invertebrates: amino acids	Poster		tAM			
127.	Transmitters in invertebrates: biogenic amines	Poster	mPM				
483.	Transmitters in invertebrates: nitric oxide	Poster			wPM		
383.	Transmitters in invertebrates: peptides	Poster			wAM		
4.	Unraveling the Serotonergic System: Insights from Molecular Biology	SYMP	mAM				
7.	Uptake and transporters I	Slide	mAM				
95.	Uptake and transporters II	Slide	mPM				
206.	Uptake and transporters III	Poster		tAM			
307.	Uptake and transporters IV	Poster		tPM			
385.	Uptake and transporters V	Poster			wAM		
THEME E: ENDOCRINE AND AUTONOMIC REGULATION							
393.	Autonomic regulation: central gastrointestinal control	Poster			wAM		
212.	Autonomic regulation: genital innervation	Poster		tAM			
394.	Autonomic regulation: peripheral gastrointestinal control	Poster			wAM		
135.	Autonomic regulation: spinal and peripheral mechanisms	Poster	mPM				
134.	Autonomic regulation: supraspinal control	Poster	mPM				
213.	Autonomic regulation: urinary system innervation	Poster		tAM			
446.	Cardiovascular regulation: brainstem integration	Slide			wPM		
391.	Cardiovascular regulation: descending control	Poster			wAM		
392.	Cardiovascular regulation: hypothalamic control	Poster			wAM		
610.	Cardiovascular regulation: spinal and peripheral control	Slide				thPM	
184.	Cardiovascular regulation: supramedullary control	Slide		tAM			
132.	Cardiovascular regulation: sympathetic system	Poster	mPM				
133.	Cardiovascular regulation: vagal system	Poster	mPM				
390.	Cardiovascular regulation: ventrolateral medulla	Poster			wAM		
312.	Hypothalamic-pituitary-adrenal axis regulation: CRF	Poster		tPM			
488.	Hypothalamic-pituitary-adrenal axis regulation: POMC and steroid receptor studies	Poster			wPM		
387.	Hypothalamic-pituitary-adrenal axis regulation: basic and clinical studies	Poster			wAM		
174.	Hypothalamic-pituitary-adrenal axis regulation: focus on CRF and glucocorticoid receptors	Slide		tAM			
349.	Hypothalamic-pituitary-gonadal regulation: cellular and molecular aspects	Slide			wAM		
258.	Hypothalamic-pituitary-gonadal regulation: control of GnRH secretion	Slide		tPM			
131.	Hypothalamic-pituitary-gonadal regulation: control of LH secretion	Poster	mPM				
572.	Hypothalamic-pituitary-gonadal regulation: gonadotropins, neuropeptides, steroids	Poster				thAM	
570.	Hypothalamic-pituitary-gonadal regulation: neuropeptides and transmitters	Poster				thAM	
734.	Hypothalamic-pituitary-gonadal regulation: regulatory aspects	Poster					fAM
571.	Hypothalamic-pituitary-gonadal regulation: releasing hormones	Poster				thAM	

THEMATIC LIST OF SESSIONS

Session Number	Session Title	Type	Day and Time				
			Mon.	Tue.	Wed.	Thu.	Fri.
641.	Hypothalamic-pituitary-gonadal regulation: steroid receptors	Poster				thPM	
696.	Hypothalamus and autonomic regulation	Slide					fAM
250.	Integration in Central Somato-visceral Processing	SYMP		tPM			
210.	Neural-immune interactions: CNS effects on immune response	Poster		tAM			
98.	Neural-immune interactions: cytokine effects on the nervous system	Slide	mPM				
211.	Neural-immune interactions: endocrine effects on immune response	Poster		tAM			
45.	Neural-immune interactions: immune mediators in normal CNS	Poster	mAM				
46.	Neural-immune interactions: nervous system pathology	Poster	mAM				
208.	Neural-immune interactions: neurochemical effects of immune stimulation	Poster		tAM			
691.	Neural-immune interactions: neuroendocrine control of immune response	Slide					fAM
209.	Neural-immune interactions: neurophysiological response to immune stimulation	Poster		tAM			
389.	Neural-immune interactions: other neurotransmitters in immune tissues ...	Poster			wAM		
388.	Neural-immune interactions: sympathetic regulation of immune response	Poster			wAM		
489.	Neuroendocrine regulation: CRF, gonadal and adrenal steroids	Poster			wPM		
573.	Neuroendocrine regulation: catecholamine and GABA	Poster				thAM	
442.	Neuroendocrine regulation: gene expression and co-localization	Slide			wPM		
642.	Neuroendocrine regulation: miscellaneous	Poster				thPM	
735.	Neuroendocrine regulation: oxytocin, vasopressin, fluid balance, and the pineal	Poster					fAM
44.	Osmotic regulation	Poster	mAM				
530.	Osmotic regulation/chemical senses: central pathways	Slide				thAM	
613.	Respiratory regulation	Slide				thPM	
574.	Respiratory regulation: carotid body, pons, hypothalamus, miscellaneous	Poster				thAM	
490.	Respiratory regulation: medullary and spinal cord mechanisms	Poster			wPM		
47.	Thermoregulation and fever	Poster	mAM				
THEME F: SENSORY SYSTEMS							
739.	Auditory behavior	Poster					fAM
581.	Auditory cortex I	Poster				thAM	
582.	Auditory cortex II	Poster				thAM	
693.	Auditory system	Slide					fAM
494.	Auditory system: central anatomy—brainstem	Poster			wPM		
583.	Auditory system: central anatomy—midbrain, thalamus, and cortex	Poster				thAM	
580.	Auditory system: cochlea	Poster				thAM	
649.	Auditory, vestibular, and lateral line: hair cells	Poster				thPM	
585.	Chemical senses: central gustatory mechanisms	Poster				thAM	
55.	Chemical senses: central olfactory mechanisms	Poster	mAM				
54.	Chemical senses: olfactory bulb	Poster	mAM				
584.	Chemical senses: peripheral gustatory mechanisms	Poster				thAM	
12.	Chemical senses: peripheral mechanisms	Slide	mAM				
53.	Chemical senses: peripheral olfactory mechanisms	Poster	mAM				
431.	Cortical Oscillatory Responses and Feature Binding	SYMP			wPM		
90.	Functional Organization of Human Visual Cortex	SYMP	mPM				
141.	Invertebrate sensory systems I	Poster	mPM				
142.	Invertebrate sensory systems II	Poster	mPM				
219.	Lateral geniculate nucleus: biophysics and pharmacology	Poster		tAM			
218.	Lateral geniculate nucleus: structure and function	Poster		tAM			
530.	Osmotic regulation/chemical senses: central pathways	Slide				thAM	
577.	Pain modulation: pharmacology IV	Poster				thAM	
736.	Pain modulation: pharmacology V	Poster					fAM

Session Number	Session Title	Type	Mon.	Day and Time			
				Tue.	Wed.	Thu.	Fri.
50.	Pain modulation: anatomy and physiology I	Poster	mAM				
102.	Pain modulation: anatomy and physiology II	Slide	mPM				
216.	Pain modulation: anatomy and physiology III	Poster		tAM			
395.	Pain modulation: anatomy and physiology IV	Poster			wAM		
576.	Pain modulation: anatomy and physiology V	Poster				thAM

316.	Visual psychophysics and behavior I	Poster		tPM			
738.	Visual psychophysics and behavior II	Poster					fAM

THEMATIC LIST OF SESSIONS

Session Number	Session Title	Type	Day and Time					
			Mon.	Tue.	Wed.	Thu.	Fri.	
THEME G: MOTOR SYSTEMS AND SENSORIMOTOR INTEGRATION								
56.	Basal ganglia and thalamus I	Poster	mAM					
57.	Basal ganglia and thalamus II	Poster	mAM					
58.	Basal ganglia and thalamus III	Poster	mAM					
320.	Basal ganglia and thalamus IV	Poster		tPM				
399.	Basal ganglia and thalamus V	Poster			wAM			
586.	Basal ganglia and thalamus VI	Poster				thAM		
587.	Basal ganglia and thalamus VII	Poster				thAM		
650.	Basal ganglia and thalamus VIII	Poster				thPM		
651.	Basal ganglia and thalamus IX	Poster				thPM		
400.	Cerebellum I	Poster			wAM			
401.	Cerebellum II	Poster			wAM			
499.	Cerebellum III	Poster			wPM			
529.	Cerebellum IV	Slide					thAM	
652.	Cerebellum V	Poster					thPM	
146.	Circuitry and pattern generation I	Poster	mPM					
231.	Circuitry and pattern generation II	Poster		tAM				
406.	Circuitry and pattern generation III	Poster			wAM			
656.	Circuitry and pattern generation IV	Poster					thPM	
700.	Circuitry and pattern generation V	Slide						fAM
63.	Control of posture and movement I	Poster	mAM					
64.	Control of posture and movement II	Poster	mAM					
226.	Control of posture and movement III	Poster		tAM				
227.	Control of posture and movement IV	Poster		tAM				
228.	Control of posture and movement V	Poster		tAM				
229.	Control of posture and movement VI	Poster		tAM				
230.	Control of posture and movement VII	Poster		tAM				
404.	Control of posture and movement VIII	Poster			wAM			
405.	Control of posture and movement IX	Poster			wAM			
655.	Control of posture and movement X	Poster					thPM	
692.	Control of posture and movement XI	Slide						fAM
657.	Invertebrate motor function	Poster					thPM	
616.	Motor cortex	Slide					thPM	
498.	Motor cortex: neuropharmacology	Poster			wPM			
65.	Muscle: fiber types	Poster	mAM					
66.	Muscle: gene transfer, contractile properties, fatigue	Poster	mAM					
322.	Oculomotor system: eye-head control	Poster		tPM				
653.	Oculomotor system: neuroanatomy	Poster					thPM	
180.	Oculomotor system: physiology and psychophysics of saccades	Slide		tAM				
144.	Oculomotor system: pursuit and optokinetic nystagmus	Poster	mPM					
321.	Oculomotor system: saccades and superior colliculus	Poster		tPM				
354.	Oculomotor system: superior colliculus and brainstem	Slide			wAM			
145.	Oculomotor system: vergence and accommodation	Poster	mPM					
654.	Oculomotor system: vertical movements, integration, torsion	Poster					thPM	
61.	Reflex function I	Poster	mAM					
62.	Reflex function II	Poster	mAM					
318.	Sensorimotor cortex: behavioral correlates of neuronal discharge	Poster		tPM				
496.	Sensorimotor cortex: functional imaging	Poster			wPM			
495.	Sensorimotor cortex: functional stimulation, models, and behavior	Poster			wPM			
497.	Sensorimotor cortex: neuroanatomy	Poster			wPM			
319.	Sensorimotor cortex: neuronal interactions	Poster		tPM				
317.	Sensorimotor cortex: plasticity	Poster		tPM				
224.	Spinal cord and brainstem I	Poster		tAM				
225.	Spinal cord and brainstem II	Poster		tAM				

Session Number	Session Title	Type	Day and Time				
			Mon.	Tue.	Wed.	Thu.	Fri.
402.	Spinal cord and brainstem III	Poster			wAM		
403.	Spinal cord and brainstem IV	Poster			wAM		
588.	Spinal cord and brainstem V	Poster					thAM
614.	Vestibular system	Slide					thPM
59.	Vestibular system: anatomy and pharmacology	Poster	mAM				
60.	Vestibular system: neurophysiology	Poster	mAM				
143.	Vestibular system: psychophysics	Poster	mPM				
THEME H: OTHER SYSTEMS OF THE CNS							
590.	Association cortex and thalamocortical relations I	Poster					thAM
591.	Association cortex and thalamocortical relations II	Poster					thAM
524.	Brain metabolism and blood flow I	Slide					thAM
615.	Brain metabolism and blood flow II	Slide					thPM
502.	Brain metabolism and blood flow: PET	Poster			wPM		
501.	Brain metabolism and blood flow: blood flow	Poster			wPM		
500.	Brain metabolism and blood flow: miscellaneous	Poster			wPM		
503.	Brain metabolism and blood flow: nitric oxide	Poster			wPM		
68.	Comparative neuroanatomy I	Poster	mAM				
407.	Comparative neuroanatomy II	Poster			wAM		
67.	Hypothalamus	Poster	mAM				
147.	Limbic system I	Poster	mPM				
148.	Limbic system II	Poster	mPM				
149.	Limbic system III	Poster	mPM				
352.	Limbic system IV	Slide			wAM		
589.	Limbic system V	Poster					thAM
THEME I: NEURAL BASIS OF BEHAVIOR							
159.	Aging	Poster	mPM				
75.	Aging: functional anatomy	Poster	mAM				
247.	Aging: memory and cognition	Poster		tAM			
235.	Biological rhythms and sleep I	Poster		tAM			
236.	Biological rhythms and sleep II	Poster		tAM			
434.	Biological rhythms and sleep III	Slide			wPM		
612.	Biological rhythms and sleep IV	Slide					thPM
662.	Biological rhythms and sleep V	Poster					thPM
701.	Biological rhythms and sleep VI	Slide					fAM
742.	Biological rhythms and sleep VII	Poster					fAM
254.	Drugs of abuse: alcohol, barbiturates, benzodiazepines	Slide		tPM			
333.	Drugs of abuse: amphetamine and other stimulants—amphetamine	Poster		tPM			
335.	Drugs of abuse: amphetamine and other stimulants—amphetamine derivatives	Poster		tPM			
334.	Drugs of abuse: amphetamine and other stimulants—amphetamine: behavior	Poster		tPM			
336.	Drugs of abuse: amphetamine and other stimulants—nicotine	Poster		tPM			
337.	Drugs of abuse: amphetamine and other stimulants—phencyclidines and other	Poster		tPM			
617.	Drugs of abuse: cocaine	Slide					thPM
751.	Drugs of abuse: cocaine—behavior	Poster					fAM
752.	Drugs of abuse: cocaine—cell membrane	Poster					fAM
753.	Drugs of abuse: cocaine—glutamate	Poster					fAM
754.	Drugs of abuse: cocaine—locomotor	Poster					fAM
755.	Drugs of abuse: cocaine—microdialysis	Poster					fAM
762.	Drugs of abuse: cocaine—miscellaneous	Poster					fAM
756.	Drugs of abuse: cocaine—monoamines	Poster					fAM
757.	Drugs of abuse: cocaine—neonatal	Poster					fAM

THEMATIC LIST OF SESSIONS

Session Number	Session Title	Type	Day and Time					
			Mon.	Tue.	Wed.	Thu.	Fri.	
758.	Drugs of abuse: cocaine—neurophysiology	Poster						fAM
759.	Drugs of abuse: cocaine—nucleus accumbens	Poster						fAM
760.	Drugs of abuse: cocaine—other drugs	Poster						fAM
761.	Drugs of abuse: cocaine—self-administration	Poster						fAM
595.	Drugs of abuse: ethanol and benzodiazepines—tolerance, dependence, withdrawal	Poster					thAM	
74.	Drugs of abuse: ethanol, benzodiazepines, barbiturates I	Poster	mAM					
157.	Drugs of abuse: ethanol, benzodiazepines, barbiturates II	Poster	mPM

372.3

A PRIMITIVE NA,K-ATPASE IN TENTACLES OF THE SEA ANEMONE *STICHODACTYLA HELIANTHUS*. S.C. Specht*, R. Lopez-Rosado and C. Santos-Berrios. Dept. Pharmacol. Inst. Neurobiol. Univ. PR Sch. Med., San Juan, PR 00901.

Although the Na, K-ATPase is an highly conserved integral membrane enzyme, it has never been described in sub-Arthropod species. We have found that the innervated tentacles of *S. helianthus* contain a ouabain-sensitive Na,K-ATPase. Like the mammalian enzyme, it is phosphorylated by 32 P-ATP in the presence of 100 mM NaCl and is 70% dephosphorylated by 20 mM KCl. The M_r of the catalytic subunit is 105 kD, similar to the rat $\alpha 3$ isoform. The ouabain sensitivity is very low, $K_i = 10^{-4}$ M. The affinity for Na^+ is lower than the rat enzyme, although similar to that described in several species of crab, $K_{0.5} = 24$ mM. The affinities for K^+ and Rb^+ are similarly low, $K_{0.5} = 3$ mM compared to the rat. In addition, the selectivity for K^+ and Rb^+ vs Cs^+ and NH_4^+ is low, with only a 2-fold difference in affinity compared to 8-fold in the rat. Li^+ is unable to substitute for either Na^+ or K^+ . The reduced cation selectivity may represent a true primitive characteristic. [Supported in part by NIGMS grant SS RR 08224].

HUMAN NA,K-ATPASE CATALYTIC ALPHA SUBUNIT HAS SOLUBLE DERIVATIVES FOUND IN BODY FLUIDS OF DISEASED PATIENTS. J.H.F. Peng*. Univ. of Missouri-Kansas City Sch. of Med., Kansas City, MO 64108.

Na,K-ATPase plays a pivotal role in many important biological functions, and has been a subject of intense investigation. In order to study the possible role of Na,K-ATPase in neurological diseases, such as epilepsy and Alzheimer's disease, polyclonal antisera to the purified human brain holoenzyme, alpha subunit, and 40- & 60-kDa alpha fragments have been prepared. In this study, Western blotting, immunoaffinity purification, and electroelution were used to study the presence of soluble alpha subunit derivatives in the human plasma and cerebrospinal fluid (CSF) employing antiserum to 40 kDa protein. Western blotting reveals that soluble derivatives with molecular weight (mol. wt.) of 59-, 54-, 52-, 50-, and 46-kDa are present in the CSF of eight *Pseudotumor cerebri* and six control patients. Soluble derivatives with mol. wt. of 68-, 66-, 64-, 57-, and 56-kDa are also found in the plasma of thirty-six patients suffering from various illnesses. Antibodies to 40 kDa protein were purified from antiserum by ammonium sulfate precipitation and DEAE-Sephacrose chromatography, and used to prepare immunoabsorbant by coupling to CNBr-activated sepharose. Soluble alpha protein derivatives in the plasma were bound tightly to the immunoabsorbants in the presence of 0.5% Triton X-100. Bound proteins were purified by electroelution. Major proteins eluted had mol. wt. of 68-, 64-, 57-, and 56 kDa. Antibodies to 40 kDa could be useful for isolation and quantitation of alpha subunit derivatives. These observations offer the opportunity of using antibodies to alpha protein fragments to probe the role of Na,K-ATPase in various human diseases.

SUBCELLULAR DISTRIBUTION OF RAT CEREBELLAR CALRETININ: DISSOCIATION OF CALRETININ BOUND TO SYNAPTIC MEMBRANES BY EGTA. L. Winsky* and J. Kuznicki. Lab. of Clinical Sciences, NIMH Bethesda, MD 20892

Calretinin was quantitated by radioimmunoassay (RIA) in subcellular fractions obtained in the presence of 0.1 mM calcium or 1 mM EGTA from rat cerebellum. Although the majority of the total calretinin was associated with the cytosolic fraction, there was a significant association with several membrane fractions including synaptic membranes, synaptic vesicles and microsomes with least amounts in mitochondria. In addition, cytosol prepared in the presence of EGTA contained more calretinin than when calcium was added to the extraction buffers and there was an apparent increase in calretinin associated with synaptic membranes prepared in the presence of calcium. These results were confirmed by immunoblot which revealed greater intensity of calretinin label in synaptic membrane and synaptic vesicle fractions prepared in the presence of calcium. Overnight incubation of synaptic membranes with EGTA caused a greater release of calretinin from synaptic membranes than when incubated with additional calcium. These results suggest that calcium binding to calretinin could result in membrane association and suggest a direction of future research into the function of this brain enriched calcium binding protein.

LOCALIZATION OF ALPHA 1 ISOFORM OF (NA, K)-ATPase IN SPINAL CORD MICROVASCULATURE BY *IN SITU* HYBRIDIZATION. S.T. Sayers*, J. Khan, G.J. Siegel, N.B. Chauhan, and M.F. Dauzvardis. Rehabilitation R&D Center and Neurology Service, Hines VA Hospital, Hines, IL 60141 and Loyola University Medical School, Maywood, IL 60153.

Expression of (Na, K)-ATPase alpha (catalytic) subunit isoform mRNAs has been established in various cell types in different regions of the central nervous system (CNS). Alpha 1 isoform is found in certain neuronal as well as non-neuronal cells, including choroid plexus ependyma, however its mRNA has not been resolved in CNS capillaries. Immunocytochemical data have supported the presence of alpha 1 isoform in cerebral microvessels. In the present study, we report the expression of alpha 1 isoform in the microvasculature of the spinal cord.

Wistar rats were anesthetized with Ketamine and Xylazine, perfused transcardially with 200 ml saline followed by 500 ml 4% paraformaldehyde in 0.1M phosphate buffer and then with 100 ml 10% sucrose. The spinal cords were removed, cut into small segments and placed in 30% sucrose at 4°C overnight. Ten micron frozen sections were cut on a cryostat. *In situ* hybridization was performed using 35 S-labeled complimentary riboprobe transcribed from the cDNA clone which codes for the alpha 1 isoform of (Na, K)-ATPase. Our preliminary results show that most of the capillaries in the spinal cord gray and white matter were labeled with this probe. Due to the limitation of resolution of the microscope, it is very difficult to distinguish whether labeling is in the endothelium or in pericytes around the microvessels. Studies with additional probes, and at the electron microscopic level, are required. Since the blood-brain-barrier is imposed by the specialized structure of the CNS microvessels, regulation of (Na, K)-ATPase alpha 1 isoform in capillaries, or their investing cell processes, may be critical to CNS volume and solute homeostasis.

DIFFERENTIAL AXONAL TRANSPORT OF INDIVIDUAL (NA,K)-ATPase CATALYTIC (α) SUBUNIT ISOFORMS IN RAT SCIATIC NERVE. M. Mata*, C.F. Jin, S. Datta, and D.J. Fink. Dept. of Neurology and GRECC, VAMC, University of Michigan, Ann Arbor, MI 48105.

Three isoforms of the catalytic (α) subunit of the ubiquitous membrane enzyme (Na,K)-ATPase, products of 3 different members of a multigene family, have been identified in the nervous system. We have found that all neurons appear to contain the $\alpha 2$ and $\alpha 3$ isoform mRNAs, and some neurons also contain $\alpha 1$ mRNA. Glial cells contain only $\alpha 1$ and $\alpha 2$ isoform mRNAs. In order to define the dynamics of isoform distribution within the axon, we exploited the phenomenon of axonal transport to study the movement of individual isoforms within the axon.

Two ligatures were placed 1 cm apart along the sciatic nerve of male Sprague Dawley rats, and at 24hrs the amount of isoform-specific peptide in sequential 3 mm segments determined by quantitative Western blot using commercially available polyclonal antibodies directed against the $\alpha 1$, $\alpha 2$ or $\alpha 3$ peptides (UBI).

There was substantial accumulation of immunoreactive $\alpha 1$ peptide immediately proximal to the first ligature, consistent with the rapid axonal transport of that isoform. Neither $\alpha 2$ nor $\alpha 3$ peptides accumulated proximal to the ligature. $\alpha 3$ therefore appears to be relatively stable in the membrane, with only small amounts added incrementally over the 24 hour period. Because $\alpha 2$ is also found in Schwann cells, the relative contribution of glial and axolemmal peptide cannot be determined. There was no evidence for significant retrograde axonal transport of any of the isoform peptides.

Supported by grants from the NIH, VA, and the Zynga foundation.

RECOMBINANT CALRETININ BINDS TO HYDROPHOBIC RESINS AND W-7 (CALMODULIN ANTAGONIST) IN A CALCIUM INDEPENDENT MANNER. J. Kuznicki, L. Winsky, D.M. Jacobowitz* Laboratory of Clinical Sciences, NIMH, Bethesda, MD 20892.

Calretinin is a neuronal calcium binding protein similar to calbindin D28K. Recombinant calretinin (rCR) binds calcium ions and exhibits calcium-dependent conformational changes. This was shown by differences in binding of rCR to DEAE-cellulose, in proteolytic cleavage, and in ability to aggregate in the presence and absence of calcium. The series of aminoalkyl-agarose resins (C₅₋₁₂), phenyl-agarose and W7-agarose were used to analyze if hydrophobic region(s) of rCR are exposed by Ca²⁺-binding. In the presence of calcium and 0.15 M NaCl rCR bound to octyl-, dodecyl- and W7-agarose, but not to phenyl-, pentyl- and hexyl-agarose. The binding of rCR to these resins appeared to be calcium-independent since the majority of the protein was not eluted when the calcium concentration was decreased by EGTA, and the elution could be achieved only using strong agents such as SDS. Moreover, rCR also bound to decyl- and W7-agarose in the absence of calcium. These observations seem to indicate that rCR does not exhibit major changes of hydrophobicity upon calcium binding. It is therefore suggested that any such changes exhibited by native calretinin would be due to possible posttranslational modifications.

SYNAPTOTAGMIN-DEFICIENT MUTANTS OF *C. elegans*. Michael L. Nonet, Kiely Grundahl, John R. McManus, Barbara J. Meyer and James B. Rand². Program in Molecular and Cell Biology, Oklahoma Medical Research Foundation, Oklahoma City, OK 73104, and Dept. of Molecular and Cell Biology, University of California, Berkeley, CA 94720.

Synaptotagmin is an abundant synaptic vesicle-associated protein, proposed to be involved in release of neurotransmitters. We have identified the *C. elegans* synaptotagmin structural gene and named it *snt-1* (formerly called *ric-2*). *snt-1* mutants are slow-growing, uncoordinated, small, and impaired in pharyngeal pumping and defecation. Nevertheless, they are active and capable of propagating limited body waves. The mutants are also very resistant to cholinesterase inhibitors and their acetylcholine levels are elevated approximately three-fold. 17 alleles of *snt-1* have been isolated so far; genetic and molecular analyses suggest that many of them are null.

In *C. elegans* neurons, synaptotagmin is localized to regions known to be rich in synapses, and appears to be associated with synaptic vesicles. Preliminary immunohistochemical and hybridization experiments suggest the absence of other synaptotagmin genes in *C. elegans*. We therefore conclude that synaptotagmin is not absolutely required for release of neurotransmitters, although it is clearly necessary for normal synaptic function.

ON THE STRUCTURE OF THE NEUROSECRETOSOME: EVIDENCE FOR A SYNTAXIN/ α -LATROTOXIN RECEPTOR/SYNAPTOTAGMIN/ Ca^{2+} CHANNEL COMPLEX. V.M. O'Connor, O. Shamotienko, U. Ernberger*, M.J. Duggan, A. Siebert, K. Bommert and H. Betz. Max-Planck-Institut für Hirnforschung, 6000 Frankfurt a.M. 71, Germany.

Small synaptic vesicles (ssvs) are clustered at specialized regions of the presynaptic membrane called active zones. The ssv protein synaptotagmin is associated with three distinct presynaptic membrane proteins, the α -latrotoxin (α -Ltx) receptor (Petrenko et al., 1991, Nature 353, 65), syntaxin (Bennet et al., 1992, Science 257, 255) and Ca^{2+} channels (Leveque et al., 1992 Proc. Nat. Acad. Sci. 89, 3625). These interactions are thought to participate in the docking of ssvs at the active zone.

We have been able to co-purify the α -Ltx receptor, synaptotagmin and syntaxin on an α -Ltx affinity column, indicating that these proteins exist within a complex. This was confirmed by the immunoprecipitation of ¹²⁵I- α -Ltx binding from solubilized brain extracts by syntaxin antibodies. The same antibodies immunoprecipitate ¹²⁵I- ω -conotoxin binding (Yoshida et al., 1992, J. Biol. Chem. 267, 24925) indicating that Ca^{2+} channels exist within this complex. In favour of this idea α -Ltx receptor antibodies immunoprecipitate ¹²⁵I- ω -conotoxin binding. Taken together these results indicate an association between syntaxin, α -Ltx receptor, synaptotagmin, and Ca^{2+} channels in a complex we propose to call the neurosecretosome. Syntaxin has been reported to be a plasmamembrane receptor for fusion-competent vesicles that are primed through a mechanism common to all stages of the secretory pathway (Söllner et al., 1992, Nature 362, 318). Thus, the neurosecretosome may represent the specialization of an ubiquitous fusion mechanism to suit the requirements of fast synaptic transmission.

CELLUBREVIN: A SUBSTRATE FOR TETANUS TOXIN FOUND ON A CONSTITUTIVE VESICLE RECYCLING PATHWAY IS A HOMOLOGUE OF SYNAPTOBREVIN. H.T. McMahon¹, H. Niemann, R. Jahn², T.C. Südhof¹

¹Howard Hughes Medical Institute, UT Southwestern Medical Center, Dallas TX 75235; ²Howard Hughes Medical Institute, Yale University, New Haven CT 06510

We have identified a ubiquitous 16kDa protein found on vesicles undergoing constitutive recycling. This protein has 59% amino acid sequence identity to the mammalian small synaptic vesicle-specific synaptobrevin proteins (also called VAMPs). We have named this protein cellubrevin, because it is presence in all cell. We show that the protein is enriched more than 100-fold in coated vesicles, and by immunofluorescence and organelle immunoprecipitations from cultured CHO cells it co-distributes with the transferrin receptor. Like synaptobrevin II, cellubrevin is proteolysed by tetanus toxin, which inhibits synaptic vesicles exocytosis. By analogy, cellubrevin may function in a fusion complex for constitutive vesicular pathways and so the potential function is now being studied. Our results demonstrate that constitutive and regulated vesicular pathways use homologous proteins for membrane trafficking.

FUNCTIONAL ARCHITECTURE OF SYNAPTOTAGMIN C2 DOMAINS REVEALED BY PEPTIDE BLOCK OF TRANSMITTER RELEASE. W.M. DeBello*, K. Bommert, M.P. Charlton, G.J. Chin, H. Betz, and G.J. Augustine. Dept. Neurobiology, Duke Medical Center, Durham, NC 27710 and MBL, Woods Hole, MA.

Synaptotagmin, an integral membrane protein of synaptic vesicles, possesses 2 copies of a motif known as a C2 domain. C2 domains are found in a number of other proteins (including kinase C, phospholipase C, phospholipase A2 and others) and are believed to mediate binding of these proteins to Ca, lipids and to other proteins. The goal of this work was to identify parts of the C2 domains responsible for these functions. To probe for protein-protein interactions, synthetic peptides mimicking different parts of the C2 domains of squid synaptotagmin were microinjected into squid giant presynaptic terminals. Previous work has shown that such peptides can inhibit transmitter release, presumably by competing with the binding of vesicle-associated synaptotagmin to an acceptor protein involved in release (Nature 363, in press). C2 domains contain several regions that are conserved in all C2 domain proteins (Cell 65, 1043) and an additional region of basic amino acids whose sequence is not conserved among members of the C2 domain protein family. A peptide corresponding to one of the conserved amino acid sequences was ineffective in blocking transmitter release. However, peptides corresponding to the variable basic regions of synaptotagmin were potent blockers of release. These results suggest that the basic regions of C2 domains are responsible for protein-protein interactions, with their variable nature conferring binding specificity upon individual C2 domain proteins. In contrast, the conserved regions of C2 domains may mediate Ca and lipid binding. Supported by NIH grant NS-21624 to GJA, MRC grant to MPC, and DFG grant to HB.

373.4

SYNAPTOPHYSIN EXISTS IN DIFFERENT OLIGOMERIC FORMS. M.J. Duggan, V.M. O'Connor, J. Bormann*, and H. Betz. Max-Planck Institute for Brain Research, 6000 Frankfurt a. M. 71, Germany.

Synaptophysin is the major integral membrane protein found in small synaptic vesicles. It is known to be an oligomeric protein, but the degree of oligomerization is controversial, and has been reported as tetrameric [Rehm, H. et al. (1986) EMBO J. 5, 535-541], or hexameric [Thomas, L. et al. (1988) Science 242, 1050-1053].

We have attempted to resolve this dispute using a combination of crosslinking and hydrodynamic measurements on a number of different preparations. Freshly solubilized synaptophysin from synaptic vesicles has hydrodynamic properties consistent with a trimeric structure. Purified synaptophysin, however, forms a stable structure with the sedimentation velocity of a hexameric structure. Crosslinking experiments indicate that while freshly-solubilized synaptophysin appears to be trimeric, synaptophysin in synaptic vesicles can exist in larger complexes at least pentameric in size. All crosslinking of crude preparations shows that a 14 kDa protein is associated with synaptophysin, even after sucrose density sedimentation. These results suggest that synaptophysin is a novel type of integral membrane protein that can exist in multiple oligomeric states.

373.6

Staurosporine blocks destaining of frog motor nerve terminals labelled with FM1-43, but does not block transmitter release.

A. Henkel and W.J. Betz*. Dept. of Physiology, Univ. of Colorado Med. School, Denver, CO 80262.

The fluorescent dye FM1-43 stains motor nerve terminals in an activity-dependent fashion, apparently by staining membranes of recycled synaptic vesicles. Destaining of prestained terminals is also activity-dependent. FM1-43 is thus a useful tool for studying synaptic vesicle trafficking in living nerve terminals. We have investigated the effects of a variety of cytoskeletal drugs on dye movements in frog *cutaneus pectoris* nerve terminals. Drugs that affect the level of protein phosphorylation had the most significant effects. Here we report the effects of staurosporine, a kinase inhibitor.

Preparations were first stained with FM1-43 (2 μ M in normal frog Ringer; nerve stimulation at 10 Hz for 5 min; wash for 30 min). Next, control intracellular recordings and images were taken, and then staurosporine (2 μ M) was added. Further images and recordings were made for 1 hour, after which the nerve was stimulated at 10 Hz for 10 min. This last procedure caused complete destaining of control (no staurosporine) preparations. However, most preparations treated with staurosporine failed to destain, as if stained synaptic vesicles had been immobilized. To our surprise, however, nerve-evoked and spontaneous transmitter release were only modestly reduced. These results suggest that either FM1-43 does not stain synaptic vesicles, or that stained vesicles do not mediate a significant portion of transmitter release.

373.7

ACTIN ASSEMBLY AND EXOCYTOSIS IN CULTURED NEURONS. B.W. Bernstein*, M. DeWit, and J.R. Bamberg. Department of Biochemistry and Molecular Biology and The Program in Neuronal Growth and Development, Colorado State University, Ft. Collins, CO 80523

We have studied the role of actin assembly in neurosecretion from cultured cells and have compared these results to a model based on our earlier synaptosomal studies. Two day cultures of neurons, dissociated from lumbo-sacral sympathetic ganglia of chick embryos and grown in 50 μ l, paraffin-sealed glass coverslip chambers, show extensive networks of interconnecting processes. Recycled synaptic vesicles in terminals of these processes were stained with a styryl dye (FM1-43; Molecular Probes, Eugene, OR), thus allowing monitoring of exocytosis in real time. The vesicle membranes were labelled through endocytosis that follows exocytosis stimulated by a depolarizing K⁺ buffer. Depletion of dye fluorescence, indicating exocytosis, was stimulated electrically. Fixed cells were stained with rhodamine phalloidin, which binds specifically to the filamentous form of actin. Confocal fluorescence microscopy of rhodamine phalloidin stain in exocytotically active areas indicated that actin filaments undergo reversible disassembly during 2 min depolarization. Moreover, if filaments are stabilized by loading cells with phalloidin before stimulating secretion, the rate and extent of exocytosis is reduced. **These data are consistent with our model based on synaptosomal studies and have been confirmed ultrastructurally;** actin filament disassembly is necessary for maximal transmitter release, and reassembly is necessary for modulating release during sustained depolarization. GM35126, NS28338, and NS28323 from the NIH.

373.9

SURFACE TOPOGRAPHY AND LOCALIZATION OF CALCIUM CHANNELS AT A CHOLINERGIC PRESYNAPTIC NERVE TERMINAL RELEASE FACE BY ATOMIC FORCE SCANNING MICROSCOPY. P.G. Haydon, E.R. Henderson, R.T. Doyle, and E.F. Stanley. +Signal Transduction Training Group ISU; *Section on Synaptic Mechanisms NINDS NIH.

There is considerable evidence that transmitter release sites are composed of specific structures that include calcium channels but this membrane surface can not be visualized directly. We have applied Atomic Force Scanning Microscopy to the release face of the chick ciliary ganglion calyx-type nerve terminal to view the surface topography of the release area and to search for membrane-associated particles.

Ciliary ganglia were acutely dissociated and calyces were identified by specific dye staining (J. Neurosci. 11:985; Neuron 7:585) and were fixed for scanning. The presynaptic areas generally had very smooth surfaces but with small mounds that, by comparison with transmission EM, we tentatively identified as release sites. Calcium channels in this nerve terminal are blocked by ω -conotoxin GIVA (ω -CTX). We treated the terminals with biotin- ω -CTX followed by streptavidin-30 nm gold. At high resolution scanning, clusters of particles were apparent that presumably reflect the location of the presynaptic calcium channels. Our results suggest that this technique allows a detailed examination of the nerve terminal transmitter release face topology.

373.11

A CATION CHANNEL ACTIVATED BY EXTRACELLULAR APPLICATION OF ADENOSINE 5' TRIPHOSPHATE (ATP) ON A PRESYNAPTIC NERVE TERMINAL. X.P. Sun and E.F. Stanley*. Section on Synaptic Mechanisms, NINDS, NIH, Bethesda MD 20892.

Several studies have suggested that ATP may act as a neurotransmitter substance via a purinergic receptor. We have used the patch clamp technique to examine the possibility that such receptors are present on a cholinergic presynaptic nerve terminal (See J. Neurosci 11:985).

Application of ATP (0.1-1 mM) to the presynaptic calyx in the whole-cell patch clamp configuration induced a fast-activating and slow-inactivating inward current (6/18) with a reversal potential close to 0 mV. A single channel with a conductance of 50-100 pS was recorded in the cell-attached mode in the presence of 0.1 mM ATP.

Thus, the presynaptic nerve terminal in this cholinergic synapse contains an ATP-sensitive cation channel. Since ATP and ACh are both stored in secretory vesicles and are presumably co-released, ATP may be involved in the feed-back modulation of nerve terminal function.

373.8

EXOCYTOSIS MONITORED BY CAPACITANCE AND AMPEROMETRY. Ch. Heinemann¹, R.H. Chow¹, R.S. Zucker², and E. Neher¹. ¹Membrane Biophysics Div., MPI for Biophysical Chemistry, Am Faßberg, D-3400 Göttingen, Germany. ²Molec. & Cell Biol. Dept., Univ. of Calif., Berkeley, CA. 94720.

Catecholamine release from single vesicles of adrenal chromaffin cells was detected by carbon fiber electrodes at the same time that membrane capacitance (C_m) was monitored. When calcium (Ca^{2+}) was elevated by flashing "caged" Ca^{2+} to give $>50 \mu M$ free Ca^{2+} , C_m rose immediately with multiple exponential components, the fastest with a time constant of 20-40 ms and a rate of about 40,000 fF/s. The rate increased monotonically with increasing Ca^{2+} , with a power dependency greater than one, and it had reached a plateau for concentrations $> 50 \mu M$. For cases in which C_m rose with a time constant faster than 30 ms, the carbon-fiber signals occurred with delays that were statistically longer than expected based on C_m ; however, analysis was complicated by a flash-induced carbon-fiber artifact and by the occurrence of multiple, overlapping events. When step depolarizations were used to activate secretion, many carbon-fiber signals occurred even after the rise in C_m had ceased. One possible explanation for discrepancy in the time courses of C_m and amperometry is that the early fusion pore connecting the vesicle interior and the cell exterior is sufficiently large to allow immediate detection of a vesicle fusion as a step in C_m , but too small for the release of catecholamine until the pore dilates to a certain threshold radius -- that is, the time of fusion must be distinguished from the time of release. Supported by NIH and Deutsche Forschungsgemeinschaft.

STRATEGIC LOCATION OF Ca^{2+} -GATED K^+ CHANNELS AT RELEASE SITES OF THE FROG NEUROMUSCULAR JUNCTION.

R. Robitaille*, M.L. Garcia, G.J. Kaczorowski and M.P. Charlton. Dept. Physiol., Univ. of Toronto, Canada and Dept of Mem. Biochem. and Biophys., Merck Inst. for Therapeutic Res., New Jersey, USA.

We examined the distribution of Ca^{2+} -gated K^+ channels (gKca) relative to the location of Ca^{2+} channels and transmitter release sites at the frog neuromuscular junction. Charybdotoxin (ChTX), a blocker of gKca channels, increased transmitter release by itself (J Neurosci 12, 297-305, 1992) and when applied after nerve terminals were loaded with a slow Ca^{2+} buffer (EGTA-AM) but not after loading with fast buffers (DMBAPTA-AM, BAPTA-AM). The differential effect of the buffers indicates that the gKca channels must be located close to the Ca^{2+} channels.

Similar to labeling of Ca^{2+} channels with ω -CgTX GIVA (Neuron 5, 773-779, 1990), labeling of gKca channels with ChTX-biotin revealed a series of bands at an interval of 1 μm matching those formed by the cholinergic receptors labeled with fluorescent α -BuTX. ChTX labeling is not blocked by ω -CgTX but is blocked by several treatments known to reduce ChTX affinity and is absent after denervation. We conclude that gKca and Ca^{2+} channels are colocalized at transmitter release sites and that the 10 nm particles at the active zone may include both Ca^{2+} channels and gKca channels. This organization allows a quick and functional narrowing of the AP which helps terminate transmitter release by arresting Ca^{2+} entry.

RAPID, TRIGGERED ENDOCYTOSIS IN A NEUROENDOCRINE CELL. W. Almers*, J.G. Wong & P. Thomas. Max-Planck-Inst. f. Medizin. Forschung, 6900 Heidelberg, Germany

Single rat melanotrophs were loaded through a patch pipette with the photolabile chelator Ca-DM-nitrophen (Ca-DMn), plus fura-2 or fura-pra. We transiently raised cytosolic [Ca], Ca(i), by flash photolysis of Ca-DMn, and tracked the ensuing exo-/endocytic changes in cell surface area via the membrane capacitance, C. Rapidly repeating flashes caused exhaustive exocytosis and raised C by 1-2 pF. Thereafter C slowly declined with a time constant ($\tau > 150$ s) that was independent of Ca(i) (0.2-80 μM) and typical of the slow, constitutive membrane retrieval seen with other methods. But after single flashes, C increased and then declined so rapidly that up to 10% of the cell surface were retrieved in 1 s. This was most obvious after cytosolic acidification (pH=6.2) had abolished all but the "exocytic burst", the fastest component of exocytosis in melanotrophs. Endocytosis then lowered C well below the preflash level (excess endocytosis, EE). The effect remained in cells depleted of Mg and ATP. EE was seen only after the first flash; later, the C changes caused by exo- and exocytosis were equal. Probably, EE retrieved membrane that had reached the cell surface during a previous exocytic episode. EE shows that membrane marked for rapid endocytosis can accumulate and wait until a new flash triggers its retrieval. The rate of endocytosis grows steeply with the amplitude of the exocytic burst but is independent of Ca(i). Hence the trigger is not Ca but a substance appearing in the course of exocytosis. The resistance to pH 6.2 and independence of MgATP indicates that the rapid endocytosis seen here is not due to clathrin-coated pits. Its speed suggests a novel mechanism of membrane retrieval.

373.13

DEPHOSPHIN: A POTENTIAL REGULATOR OF VESICLE DYNAMICS. E.M. Fykse¹, J.M. Sontag¹, J.P. Liu², P.J. Robinson², and T.C. Südhof¹. ¹Department of Molecular Genetics and Howard Hughes Medical Institute, University of Texas, Southwestern Medical Center, Dallas, Tx, 75235. ²Endocrine Unit, John Hunter Hospital, Locked Bag 1, Hunter Region Mail Centre, Newcastle, NSW, 2310, Australia.

We are studying the potential role of phosphorylation in synaptic vesicle (SV) exocytosis and recycling. Synaptotagmin and P96 (Dephosphin) are both phosphoproteins with potential key roles in these processes. Dephosphin is located in the nerve terminal. It is rapidly and quantitatively dephosphorylated during depolarization induced calcium influx. Dephosphin is a major substrate for protein kinase C (PKC), and phosphorylation of purified dephosphin with purified PKC showed that one or two sites were phosphorylated. Dephosphin consists of a protein doublet of 94 and 96 kDa. Molecular cDNA cloning and immunoprecipitation showed that this heterogeneity is caused by alternative splicing. A peptide antibody raised against the C-terminal of the short form recognized only the 94 kDa band in brain.

373.15

SYNAPSIN IN MÜLLER AXONS IN THE LAMPREY SPINAL CORD.

V. A. Pieribone*, T. H. Müller, L. Brodin#, A. J. Czernik, O. Shupliakov#, E. Schaeffer, S. Grillner#, P. Greengard, The Rockefeller University, New York, NY 10021 and #Karolinska Institutet, Stockholm, Sweden.

Terminal injection of dephosphorylated but not phosphorylated synapsin I into the squid giant synapse reduces the size of the PSP evoked by presynaptic stimulation (Llinás et. al., *J. Physiol.* 436:257-82, 1991).

We have now used immunocytochemical, biochemical and physiological methods to examine the role of synapsin-like proteins in lamprey synapses. The Müller axon/spinal neuron synapse in the lamprey spinal cord is a well characterized synapse with physiological and pharmacological properties similar to those found in mammals and as such is suitable for paired-recording studies.

In tissue sections, antibodies directed against mammalian synapsins strongly cross-reacted with terminal-like structures specifically in the lamprey CNS and not in peripheral organs. Injections of fluorescent-labeled mammalian synapsins were found to be anterogradely transported in axons (see Müller et. al., this volume). Initial results indicate that injection of mammalian dephosphosynapsin I into presynaptic axons results in a specific suppression of the chemical but not the electrical component of the evoked EPSP. These results support the hypothesis that synapsin-like protein(s) are present in the CNS of a cyclostome, and may function in synaptic transmission.

373.17

IDENTIFICATION AND CHARACTERIZATION OF THE SMALL GTP-BINDING PROTEIN RAB3 IN HELISOMA. R.T. Doyle*, Y. Fang, S. Durgerian, D. Larson, and P.C. Haydon. Department of Zoology and Genetics, Iowa State University, Ames, IA 50011

The small GTP-binding protein rab3A is implicated in regulating vesicular transport in the synapse. To experimentally test for a role for this protein in the synapse we have previously microinjected into Helisoma synapses peptides with sequences corresponding to the rat effector domain of rab3A (Richmond and Haydon, 1992, Soc. Neurosci. Abst). This demonstrated that rab peptide injection does selectively perturb the secretory pathway. As a next step in this study we have now identified the presence of an endogenous rab3 protein in Helisoma neurons using immunocytochemistry and molecular cloning strategies.

An antibody (Cl 42.2; provided by R.Jahn) raised against rat rab3A was found to cross-react with Helisoma cultured neurons. Rab3A immunoreactivity was localized within neurites with intense staining in varicosities, the site of synaptic connections.

Using degenerate oligonucleotides corresponding to conserved regions of rab3 we cloned a 300 base pair fragment of rab3 by PCR. Helisoma rab3-specific primers from this sequence were used for PCR sequencing and cloning the remainder of the rab3 coding region from a Helisoma central ganglia cDNA library. The Helisoma rab3 open reading frame is 660 base pairs, coding for a protein of 220 amino acids. Helisoma rab3 is 85% identical to Drosophila rab3, 77% to rat rab3 and 76% human rab3A, and contains characteristic rab domains such as the GTP binding motifs and C terminal prenylation site.

TRANSPORT OF SYNAPSIN I IN AXONS OF THE LAMPREY SPINAL CORD. T.H. Müller*, V.A. Pieribone, A.J. Czernik, L. Brodin#, S. Grillner#, P. Greengard, Laboratory of Molecular and Cellular Neuroscience, Rockefeller University, New York, NY 10021. ¹Nobel Institute of Neurophysiology, Karolinska Inst., Stockholm, Sweden.

The neuronal phosphoprotein synapsin I appears to modulate synaptic efficiency by controlling the fraction of synaptic vesicles available for neurotransmitter release (Greengard et al., *Science* 259:780, 1993). We have studied the mobility of fluorescently labeled synapsin I in axons of the lamprey spinal cord.

The spinal cord was removed and placed in a recording chamber cooled to 7°C. Dephosphorylated bovine synapsin I was labeled with Texas Red and injected into axons by iontophoresis or pressure. Dye epifluorescence was monitored with a low-light camera system. During continuous injection, synapsin I spread more rapidly in the anterograde than in the retrograde direction. In contrast, both rhodamine-labeled HRP and Texas Red-labeled avidin diffused similarly in both directions. The average anterograde transport velocity for synapsin I, determined from bolus injections, was 0.16 µm/s (14 mm/24h). Adjusting for temperature, using a Q₁₀ of 2-3 reported for neuronal transport, yields values of -100-400 mm/24h at 37°C. These rates correspond to those observed for the fast component of axonal transport in mammalian neurons, and suggests that at least part of the injected synapsin I is transported by this component.

NICOTINE-INDUCED SYNAPSIN I PHOSPHORYLATION AND ENDOGENOUS ACETYLCHOLINE RELEASE IN CHOLINERGIC NERVE ENDINGS. Sean O'Shea and Enrique L.M. Ochoa * Dept. of Pediatrics, University of California at Davis, Davis CA 95616.

Synapsin II phosphorylation is correlated with the nicotine-induced release of catecholamines from chromaffin cells (Haycock et al., *J. Neurosci.* 8:3233, 1988). The present experiments were conducted to test whether nicotine effects both synapsin I phosphorylation and acetylcholine (ACh) release in CNS cholinergic nerve endings. Rat frontal cortex synaptosomes were pre-incubated with ³²P_O₄ and SDS-PAGE was performed. Endogenous phosphorylation of two protein bands of 80 and 85 kDa, identified as synapsin I, were demonstrated by autoradiography and quantitated either by densitometry or phosphorimaging. Nicotine-induced endogenous, Ca²⁺-dependent ACh release was monitored by a continuous fluorometric technique. Synapsin I was rapidly and transiently phosphorylated by (-) nicotine with a maximum at 1 minute. The effect was blocked by pre-incubation with 10 µM mecamylamine but not 10 µM atropine. The increase in phosphorylation was not evident at concentrations lower than 10 µM (-) nicotine, but the EC₅₀-nicotine for ACh release was in the µM range. Pre-incubation of the synaptosomes with 35 µM veratridine and in the presence of EGTA, abolished ACh release or synapsin I phosphorylation. In contrast, the (-) nicotine-induced phosphorylation also occurred in the presence of EGTA. Alpha-bungarotoxin (0.1 µM) blocked neither (-) nicotine-induced ACh release nor phosphorylation, whereas 0.1 µM k-bungarotoxin blocked ACh release but had inconsistent blocking effects on phosphorylation. We conclude that (-) nicotine requires external Ca²⁺ to induce ACh release, but Ca²⁺ is not essential for synapsin I-phosphorylation. (-)Nicotine may induce synapsin I phosphorylation through a nicotinic neuronal receptor present in rat frontal cortex nerve terminals. STIMULATION OF PROTEIN KINASE C INCREASES INHIBITORY SYNAPTIC TRANSMISSION IN THE RAT HIPPOCAMPUS. M. Capogna, M. Scanziani*, B. H. Gähwiler and S. M. Thompson

Brain Research Institute, Univ. of Zurich, 8029 Zurich Switzerland

Activation of protein kinase C (PKC) facilitates excitatory neurotransmitter release, affects LTP, and modulates ionic channels. The influence of PKC on inhibitory synaptic transmission is less well known. We have addressed this question on evoked and spontaneous GABA_A receptor-mediated synaptic transmission in area CA3 of hippocampal slice cultures. Stimulation of PKC with phorbol ester PDBu (0.5 µM) enhanced the amplitude and duration of evoked monosynaptic IPSPs (in CNQX and AP5) and the frequency of spontaneous miniature IPSCs (in CNQX, AP5 and TTX). PDBu did not change the distribution of miniature IPSC amplitudes, suggesting a purely presynaptic mechanism of action. The increase of miniature IPSC frequency by PDBu was antagonized with staurosporin (1 µM), a protein kinase inhibitor. Preliminary data indicate that PDBu did not enhance GABA release from presynaptic endings by recruiting axon terminal Ca²⁺ channels: PDBu caused an equivalent increase in mIPSC frequency in the presence of the Ca²⁺ channel blocker Cd²⁺.

DEPHOSPHORYLATION OF THE SYNAPTIC PHOSPHOPROTEIN DEPHOSPHIN IS MEDIATED BY CALCINEURIN. R.A. Nichols, J.M. Brown and G.R. Suplick. Department of Pharmacology, Medical College of Pennsylvania, Philadelphia, PA 19129.

Changes in the state of phosphorylation of a number of presynaptic proteins occur during stimulation of brain nerve terminals, and these changes may serve to modulate nerve terminal function. Dephosphin (P96) is one prominent phosphoprotein present in brain nerve terminals, which undergoes stimulation-induced, Ca²⁺-dependent dephosphorylation. As yet, the protein phosphatase mediating dephosphin phosphorylation has not been clearly demonstrated. We have used a pharmacological approach to help identify the dephosphin phosphatase. Synaptosomes were isolated from rat cerebral cortices, labeled with [³²P]-inorganic phosphate, and then treated with various selective phosphatase inhibitors. The effect of the presence of inhibitors on subsequent stimulation-induced dephosphorylation of dephosphin was determined by resolving ³²P-labeled synaptosomal proteins in SDS gel electrophoresis followed by autoradiography. Treatment with either cyclosporin A (CsA) or L-683,590 (FK-520, a derivative of FK-560), both highly selective inhibitors of the Ca²⁺/calmodulin-dependent protein phosphatase calcineurin, prior to elevated K⁺-depolarization of ³²P-labeled synaptosomes attenuated the Ca²⁺-dependent decrease in ³²P-labeled dephosphin. CsA (1 μM) inhibited the K⁺-induced decrease in ³²P-labeled dephosphin by an average of 76% of control, whereas FK-520 appeared to be less effective. The attenuating effects of CsA and FK-520 were dose- and time-dependent. Similar results were obtained when the calcium ionophore ionomycin was used in place of K⁺-depolarization to induce Ca²⁺ entry. Moreover, CsA and FK-520 were without effect on elevated K⁺-induced increases in intrasynaptosomal Ca²⁺, as measured using fura-2. These results implicate calcineurin as the mediator of dephosphin dephosphorylation during stimulated Ca²⁺ entry into brain nerve terminals. (Supported by NS30577)

RYANODINE DECREASED THE AMPLITUDE AND INCREASED THE RATE OF DECAY OF NERVE-EVOKED CA²⁺ TRANSIENTS AT THE PRESYNAPTIC TERMINALS OF BULLFROG SYMPATHETIC GANGLIA. Y.-y. Peng* Dept. of Pharmacol. & Physiol. Sci., Univ. of Chicago, Chicago, IL. 60637.

In bullfrog sympathetic ganglia, morphological studies have shown that the peptide containing large dense-core vesicles (LDCV) tend to be away from the plasma membrane (Taxi, 1967; Belhumeur & Tremblay, 1986). This localization of the LDCV's might make peptide release from these vesicles sensitive to the Ca²⁺-induced Ca²⁺ release (CICR) and Ca²⁺ uptake processes of the intracellular organelles. This hypothesis was tested in intact isolated bullfrog sympathetic ganglia using fura-2 fluorimetry. Presynaptic terminals were selectively filled with fura-2 in its membrane impermeant form (Peng & Zucker, Neuron, 10: 465-473). Ca²⁺ elevation at the presynaptic terminals was evoked by electrical shocks to the preganglionic fibers at 20 Hz, a frequency found to be optimal for evoking peptide release in these terminals (Peng & Horn, J. Neurosci. 11: 85-95). Ryanodine (1 μM) caused up to 50% decrease in the peak amplitude of Ca²⁺ elevation. It increased the rate of the decay of this elevation as well. These findings are consistent with the hypothesis that ryanodine sensitive CICR occurs and is involved in regulating peptide release at these intact presynaptic terminals. LONG-TERM POTENTIATION III

374.1

THE ROLE OF N- AND P-TYPE CALCIUM CHANNELS IN MOSSY FIBER (MF) SYNAPTIC TRANSMISSION IN THE HIPPOCAMPUS. P.E. Castillo, M.G. Weisskopf and R.A. Nicoll* Depts. of Pharmacol. and Physiol., UCSF, San Francisco, CA 94143-0450.

The MF synapses in the hippocampus exhibit an NMDA-receptor independent form of long-term potentiation. We have presented evidence that both the induction and expression of this form of LTP may be entirely presynaptic (Zalutsky and Nicoll, Science 248:1619, 1990). We carried out two sets of experiments using extracellular field potential recordings in hippocampal slices from guinea pigs to characterize further this form of LTP. First we compared the effect of completely blocking (even during the tetanus) synaptic transmission, either presynaptically (0 mM Ca²⁺/6 mM Mg²⁺) or postsynaptically (10 mM kynurenatate) on LTP induction. Only the former manipulation blocked LTP indicating that Ca²⁺ entry into the presynaptic terminal is essential for MF LTP. In the second set of experiments we examined the effects of Ca²⁺ channel blockers on MF synaptic transmission and LTP. Nifedipine (30 μM) (L-type) had little effect on baseline MF responses or on LTP. ω-CgTx (1 μM) (N-type) reduced baseline MF responses to ~30% and LTP could still be evoked. ω-AgaTx (1 μM) (P-type) caused a nearly complete blockade of baseline MF responses but LTP-inducing tetani could still enhance transmission in some preparations. Subsequent ω-CgTx application blocked all remaining response.

These results suggest that MF LTP induction requires presynaptic Ca²⁺ entry. The induction and expression of LTP can occur, at least to some extent, after blockade of either N-type or P-type Ca²⁺ channels. Transmitter release involves both N- and P-type Ca²⁺ channels, although the P-type appears to play the primary role in glutamate release at MF synapses.

374.3

A NECESSARY ROLE FOR POSTSYNAPTIC FACTORS IN EXPRESSION OF LONG-TERM POTENTIATION. K. Shahi* and M. Baudry, Neuroscience Program, USC, Los Angeles, CA 90089-2520.

One of the arguments supporting a postsynaptic mechanism for the maintenance phase of long-term potentiation (LTP) has been the absence of changes in paired-pulse facilitation (ppf) at potentiated synapses. This argument has been confounded due to the lack of knowledge regarding the exact mechanism underlying ppf. To examine the relationship between LTP and ppf independently of the mechanism responsible for ppf we evaluated the effects of the competitive antagonist of the AMPA receptor, DNQX, on control, facilitated and potentiated synaptic responses in field CA1 of hippocampal slices. DNQX differentially affected the responses to the first and second pulse delivered 50 msec apart to a single pathway. The slope and amplitude of the population excitatory postsynaptic potential (epsp) from the first pulse were decreased more than those from the second pulse in the presence of a submaximal concentration of DNQX. However, when the second pulse was delivered to an independent pathway that had previously been potentiated, the two evoked epsps were equally sensitive to DNQX. These results indicate that ppf is due, at least partly, to an increase in the concentration of glutamate in the synaptic cleft. As this effect is not observed in potentiated synapses, the results indicate that postsynaptic modifications are more likely to underlie LTP maintenance. (Supported by grant BNS 9110377 from NSF).

A POSTSYNAPTIC- AND NMDA RECEPTOR-RELATED SHORT-TERM POTENTIATION IN RABBIT DENTATE GYRUS X. Xie*, T.W. Berger* and G. Barriounevo*. Dept. of Biomedical Engineering and Program in Neuroscience, Univ. of Southern California, Los Angeles, CA 90089, and *Depts. of Behavioral Neuroscience & Psychiatry, Univ. of Pittsburgh, Pittsburgh, PA 15260.

In the hippocampus, tetanic stimulation of presynaptic axons could induce four forms of STP¹ which correspond in decay time constants to the STPs earlier found in neuromuscular junctions² including facilitation I and II, augmentation and potentiation. These forms of STP have been proved to be presynaptic in origin. More recently, a new type of STP was found in the hippocampal CA1 and dentate gyrus^{3,4}. In our experiments, rabbit hippocampal slice was perfused with medium including 0.1 mM Mg²⁺ plus 3μM alphaxalone, a GABA_A receptor allosteric agonist. Immediately after high frequency stimulation (50 Hz, HFS) delivered through the same stimulating electrode placed on perforant path axons, the EPSP amplitudes intracellularly recorded from granule cell increased by 73 ± 6% (SEM) and decayed to a stable level with time constant at about 3.66 min (n=4). While one HFS would result in LTP to its saturated level; the same HFS could induce the STP repetitively. The STP could be blocked by D-APV and hyperpolarization of post-synaptic neuron indicating that both forms of use-dependent synaptic plasticity share the same induction mechanism. Preliminary data showed that the paired-pulse facilitation which has been considered as pre-synaptic in origin was reduced during the STP indicating that changes in presynaptic release is probably involved in its expression. HIPPOCAMPAL SYNAPTIC PLASTICITY AND MODULATION OF AMPA RECEPTORS IN MICE RESISTANT (C57BL/6J) AND SENSITIVE (DBA/2J) TO AUDIOGENIC SEIZURE. M.F. Toungny, R. Ward and G. Massicotte*. Département de Chimie-Biologie, Université du Québec à Trois-Rivières, C.P. 500, Québec, Canada, G9A 5H7.

Histological and biochemical abnormalities of the hippocampus have been described in several species with epileptic disorders. In this study, we compared formation of hippocampal long-term potentiation (LTP) and modulation of AMPA receptors by phospholipase A₂ (PLA₂) in two inbred strains of mice that differ in their ability to exhibit audiogenic seizure on first exposure to sound. The magnitude of both short term potentiation (STP) and LTP induced by a theta burst stimulation (TBS) paradigm was substantially enhanced in area CA1 of hippocampal slices from mice sensitive DBA/2J to audiogenic seizure when compared to the resistant C57BL/6J strain. However the initial stage (20 sec) of the STP that follow TBS was not affected in DBA/2J mice suggesting that similar degree of NMDA receptor activation is present in both inbred strains. PLA₂ treatment of tissue sections has been reported to modify properties of AMPA receptors by increasing ³H-AMPA binding and we proposed that PLA₂-induced changes of AMPA receptors is a necessary step in LTP formation (Massicotte and Baudry, Neurosci. Biobehav., Rev. 15: 415, 1991). Exogenous PLA₂ (0.5 μg/ml) and calcium (4.0 mM) were applied at physiological temperature to thin (15 μm), thaw-mounted sections of frozen mice brains and binding properties of AMPA receptors was determined in 10 brain structures by quantitative autoradiography of ³H-AMPA. The quantitative analysis reveals that PLA₂-induced increase in ³H-AMPA binding was significantly enhanced in areas CA3 and CA1 of hippocampus and molecular layer of cerebellum in the sensitive DBA/2J strain. The present results support the idea that PLA₂-induced modification of AMPA receptors is an important component of synaptic plasticity. This work was supported by NSERC Canada.

SUSTAINED INCREASE IN BASAL AND STIMULUS-DEPENDENT GLUTAMATE EFFLUX DURING LTP IN DENTATE GYRUS: REAL-TIME *IN VIVO* MEASUREMENTS USING A DIALYSIS ELECTRODE. P.T. Galley† M.L. Errington and T.V.P. Bliss*, †Department of Metabolic Medicine, St Mary's Hospital Medical School, London W2 1PG, UK, and Division of Neurophysiology and Neuropharmacology, National Institute for Medical Research, Mill Hill, London NW7 1AA, UK.

We have used a novel glutamate-sensitive electrode (Albery, Boutelle and Galley, J.Chem. Soc. Chem.Comm., 12, 900-901,1992) to study the release of glutamate during LTP in the dentate gyrus of the anaesthetized rat. The dialysis electrode combines microdialysis with *in vivo* voltammetry and centres around a platinum electrode positioned inside a hollow semi-permeable fibre, allowing the micro-environment around the electrode to be controlled. The removal of interference from electroactive species such as ascorbate and dopamine can be achieved by electropolymerising a coating of polyphenylene diamine onto the platinum and perfusing the enzyme ascorbate oxidase into the probe. Addition of the enzyme glutamate oxidase allows measurement of endogenous extracellular glutamate. In the presence of glutamate the enzyme generates hydrogen peroxide, which is oxidised on the electrode at +650mV, and the resulting current can be measured with a custom designed potentiostat.

To study glutamate release during LTP in the dentate gyrus, stainless steel recording electrodes were attached to the dialysis electrode, and the electrode assembly positioned in the molecular layer of the dorsal dentate gyrus. An increase in glutamate-generated current was routinely obtained when the rate of stimulation of the perforant path was increased to 2Hz from the test frequency of 0.033Hz. Following the induction of LTP by tetanic stimulation there was a sustained increase in basal signal and an approximately two-fold increase in the peak of the stimulus-dependent 2Hz signal measured 60 min after induction. Both LTP and the increase in basal and stimulus-dependent glutamate release were blocked by the intraventricular injection of D-AP5.

374.7

NMDA RECEPTOR-MEDIATED PRESYNAPTIC INHIBITION IN THE CA1 REGION OF THE HIPPOCAMPUS. O. Manzoni¹, T. Manabe and R.A. Nicoll² Depts. Pharmacol. and Physiol., UCSF, San Francisco, CA 94143-0450.

Previous studies have found that application of NMDA transiently depressed synaptic transmission in the CA1 region of the hippocampus (Collingridge et al. J. Physiol. 334:33-46, 1983; Kauer et al. Nature 334:250-252, 1988; Manabe et al. Nature 355:50-55, 1992). We have used both whole-cell and field recordings to investigate in more detail the mechanism of this depression.

Application of NMDA (10-50 μ M) depressed EPSP(C)s with a time course that can outlast the direct postsynaptic actions. This depression was due, at least in part, to a presynaptic inhibition, since paired-pulse facilitation (PPF) was increased during the depression.

Local high intensity tetanic stimulation caused heterosynaptic depression lasting from a few to 15 min (cf. Bashir and Collingridge. Eur. J. Neurosci. 4:485-490, 1992). This depression was blocked or significantly reduced by 50 μ M D-APV, was also associated with an increase in PPF and was not blocked by the GABA_B antagonist CGP 35348 (500 μ M).

These findings indicate that activation of NMDA receptors in the slice can result in a presynaptic inhibition of EPSP(C)s. Presumably, either glutamate can directly activate presynaptic NMDA receptors on nearby excitatory synaptic terminals and decrease transmitter release, or some diffusible factor and/or change in the extracellular ionic environment can mediate this depression. The precise mechanism is currently under investigation.

374.9

CHANGES IN POSTSYNAPTIC AMPA SENSITIVITY DURING LONG-TERM POTENTIATION

Nikolai B. Fedorov, Klaus G. Reymann*

P.O.B. 1810, Federal Institute for Neurobiology, Magdeburg, Germany

The maintenance of LTP in the CA1 region of the hippocampus might involve a slow increase of the postsynaptic sensitivity of AMPA/glutamate receptors. The question is: are these changes mediated by a population of extrasynaptic or synaptic receptors? To answer this question we employed the recently developed one-electrode method for simultaneous local pressure ejection and field potential recording, which allows a more localized site of AMPA ejection and recording. Responses to iontophoretic AMPA ejection were clearly potentiated with a time delay after tetanization of about 10 min, confirming the findings of Davies et al. (1987). AMPA responses to local pressure ejection (fPRs) recorded with the same pipette exhibited more variable changes. Thus, in only 5 of 32 cases which clearly exhibited LTP of the fEPSP there were also increases in the amplitude of fPRs after tetanization. However, in 12 cases a short or long lasting depression of the fPRs (up to 30%) could be seen after LTP induction. In picrotoxin containing solution (20 μ M) no long- or short-lasting depressions were observed (n=9), while the long-lasting potentiation of the fPRs was seen in 2 out of 7 cases. These results allow us to suggest that the direction of the changes probably depends on the locus of recording and AMPA ejection and that both the increases as well as the decreases in the sensitivity of neurons to AMPA might be related to LTP. It could be speculated that the increase in the AMPA sensitivity could be mediated by synaptic receptors, while the decrease in sensitivity might be related to changes in receptors on extrasynaptic membrane, where excitatory and inhibitory processes are interacting.

374.6

INTERACTION BETWEEN ANIRACETAM AND LTP IN "DISINHIBITED" SLICES. A. Kolta¹, J. Ambros-Ingerson, J. Larson and G. Lynch. Center for neurobiology of learning and memory, Univ. of California Irvine, Irvine, CA, 92717.

The drug aniracetam, which slows the desensitization of AMPA receptors is reported to have different effects on the waveform of synaptic responses following induction of LTP (Staubli et al., *Hippocampus*, 1992), a result which suggests that LTP itself modifies the kinetics of the receptor channel. If so, then the interaction between aniracetam and LTP should be still more evident under conditions in which AMPA receptors mediated currents are isolated from other currents normally present in hippocampal responses to afferent stimulation. The present experiments tested this point in mini-CA1 slices where inhibition was blocked with 50 μ M picrotoxin and 100 μ M of 2-OH-saclofen. Tetrodotoxin (10 μ M) was locally injected near the cell body layer to prevent recurrent spiking. Aniracetam (1.5 mM) was perfused before and after the induction of LTP with theta burst stimulation. In several experiments, aniracetam was perfused twice before the induction of LTP. Aniracetam typically produced 3 clearly defined effects on control waveforms recorded under these conditions; namely, an increase in amplitude, rise time and decay time constant (DTC). However, aniracetam effects on waveform's amplitude and rise time were significantly smaller after LTP induction, whereas the increase in DTCs were significantly larger. The effects of aniracetam on control responses were similar after a second perfusion arguing against the possibility that several exposures may alter the receptor responsiveness to the drug. These results support the hypothesis that LTP alters the kinetics of the AMPA receptor.

This work was supported by a NSERC fellowship for A. K. and an AFOSR grant.

374.8

THE ROLE OF NMDA AND NON-NMDA RECEPTORS IN SYNAPTIC TRANSMISSION AND LONG-TERM POTENTIATION IN RAT MOTOR CORTEX. L. Yi, W.T. Greenough and R. Swain*. Neurosci. Prog., Beckman Institute, Univ. of Illinois, Urbana, IL 61801.

To determine whether N-Methyl-D-aspartate (NMDA) and non-NMDA receptors mediate synaptic responses in rat motor cortex, we tested the effects of D-2-amino-5-phosphonoveralate (APV) and 6,7-dinitro-quinoxaline-2,3-dione (DNQX) on evoked field potentials and induction of long-term potentiation (LTP). In extracellular recording, the field potential elicited in layer II/III of motor cortex in response to stimulation of somatosensory cortex consisted of an EPSP, an apparent population spike (PS) and a second EPSP. Iontophoretic application of APV slightly decreased the amplitude of the first EPSP and PS, whereas the second EPSP was completely depressed. In the presence of DNQX, the amplitude of the first EPSP and PS were greatly reduced, suggesting that the first EPSP and PS include both NMDA receptor-mediated and non-NMDA receptor-mediated components. Tetanic stimulation of sensory cortex in control medium (n=12) induced both LTP of the first EPSP and PS (8 cases), and LTD (3 cases). Tetanic stimulation in the presence of APV (n=12) also induced both LTP of EPSP and PS (4 cases), and LTD (6 cases). It appears that LTD is more likely to occur in the presence of NMDA receptor blockage. LTP of the first EPSP and PS (2 cases), LTD (2 cases), and no significant change (7 cases) were observed in the presence of DNQX (n=11). These data indicate that non-NMDA receptor-mediated component also plays an important role in the occurrence of LTP in motor cortex. In addition, these findings provide evidence for the induction of both LTP and LTD of NMDA receptor-mediated synaptic transmission in motor cortex and demonstrate that the blockade of NMDA receptors favors the occurrence of LTD. ASYNCHRONOUS PRE- AND POSTSYNAPTIC ACTIVITY INDUCES LONG-TERM DEPRESSION IN HIPPOCAMPAL CA1 NEURONS IN VITRO.

Dominique DEBANNE, Beat H. GÄHWILER and Scott M. THOMPSON*

Brain Research Institute, University of Zurich, 8029 ZÜRICH Switzerland.

A novel form of associative long term depression (LTD) has been induced in CA1 neurons in hippocampal slice cultures by repeatedly (100 times) stimulating the Schaffer collateral pathway at low frequency (0.3 Hz) after brief periods of postsynaptic firing imposed by injection of depolarizing current pulses. The decrease in excitatory postsynaptic potential amplitude 1) lasted more than 30 minutes, 2) could be reversed by induction of potentiation in the depressed input, 3) could be induced at previously potentiated inputs, 4) was input specific (LTP of another pathway could be induced at the same time) and 5) did not require potentiation of other inputs. The associative character of this LTD was demonstrated by the dependence of the magnitude of the depression upon the interval between postsynaptic depolarization and presynaptic stimulation (maximal LTD = 31% with 800 ms interval). No depression was obtained for intervals <500 or >2000 ms. LTD could not be induced in neurons recorded with BAPTA (25 mM) filled micropipettes or in the presence of the NMDA-receptor antagonist AP5 (40 μ M) during the conditioning procedure, suggesting that voltage-dependent calcium influx alone is not sufficient for LTD induction. We conclude that associative LTD is induced as a result of NMDA-receptor activation and Ca²⁺ influx, when postsynaptic depolarization is followed by synaptic activity within a limited time window.

374.11

LONG-TERM POTENTIATION OF DUAL COMPONENT EPSCS IN THE RAT HIPPOCAMPAL SLICE. K.A. Clark and G.L. Collingridge*. Dept. of Pharmacology, The Medical School, Birmingham University, Birmingham, U.K.

Long-term potentiation (LTP) is a long lasting increase in synaptic efficiency typically induced by high frequency (tetanic) stimulation. While there is general agreement that the site of LTP induction is post-synaptic, the relative increases in AMPA and NMDA receptor-mediated synaptic components and the site of LTP expression remains controversial. We have used whole-cell patch-clamp recording from CA1 pyramidal neurones to investigate LTP of AMPA and NMDA receptor-mediated conductances simultaneously. To optimise measurement of EPSCs, synaptic inhibition was blocked using picrotoxin (50 μ M) and CGP 35348 (200 μ M) in the perfusing medium and QX-314 and caesium in the patch solution. Current-voltage plots ($n=12$), CNQX or NBQX (1-10 μ M, $n=17$) and D-AP5 (50 μ M, $n=9$) were used to define the initial slope of the EPSC as primarily AMPA receptor-mediated and the amplitude measured at 100 ms post-response onset as primarily NMDA receptor-mediated. Neurones, voltage clamped at -60 mV, were dialysed for a minimum of 45 mins, tetanised (100 Hz/1 s) and followed for a further 30 mins. Neurones were sub-divided into two populations on the basis of whether potentiation of the AMPA receptor-mediated component was sustained or not ($n=9$ and $n=6$, respectively). In both cases, potentiation of the NMDA receptor-mediated component was similar in amplitude to and paralleled that of the AMPA receptor-mediated component. If following dialysis for 30 mins at -60 mV, neurones were voltage clamped at -50 mV for the rest of the experiment we were unable to obtain LTP of either component ($n=8$), presumably due to over activation of the NMDA receptor-complex. This study shows LTP is manifest as a parallel increase of the AMPA and NMDA receptor-mediated components of the EPSC. The ability of a neuron to express LTP seems to be independent of factors that would be easily dialysed out of a neuron.

K.A. Clark is a Wellcome prize student.

SYNAPTIC PLASTICITY IN THE NUCLEUS ACCUMBENS *IN VITRO*: DIFFERENTIAL REGULATION OF AMPA AND NMDA RECEPTOR-MEDIATED SYNAPTIC TRANSMISSION. S. B. Kambian* and R. C. Malenka. Depts. of Psychiatry and Physiol., University of California, San Francisco, CA 94143.

The nucleus accumbens (NA) is an important limbic-motor interface that is thought to be involved in many complex behaviors. Principal projection cells of NA are quiescent and depend on strong glutamatergic excitation from cortical and subcortical limbic regions. We have examined the mechanisms of activity-dependent changes in NMDA and non-NMDA (AMPA) receptor-mediated synaptic responses, recorded from the "core" region in an *in vitro* parasagittal slice preparation. Field EPSPs and whole cell EPSPs/EPSCs were evoked by stimulation of prefrontal cortical afferents in the presence of picrotoxin (25 μ M).

Long-term potentiation (LTP) was consistently induced in both field (14/17 slices; 62 \pm 20%) and whole cell EPSPs (17/21 cells; 68 \pm 9%) by high frequency stimulation (100 Hz-1 sec, given 1 or 2 times separated by 10 sec) at twice the baseline and spike threshold stimulus strengths, respectively. Pairing postsynaptic depolarization with low frequency synaptic stimulation (2 Hz for 2 min) also elicited LTP (7/11 cells; 60 \pm 6%). Application of D-APV (25 μ M) reversibly blocked LTP ($n=6$). Loading cells with BAPTA (10 mM; $n=4$) also prevented the induction of LTP by tetanic stimulation in slices in which LTP was elicited in simultaneously recorded field EPSPs. The same tetanic stimulation and pairing protocols consistently produced a long-term depression (LTD) of the NMDA receptor-mediated EPSP recorded in the presence of CNQX (10 μ M; 11/14 slices; 48 \pm 12%). The induction of LTD was blocked by D-APV ($n=3$) and by loading cells with BAPTA (10 mM; $n=7$). Recording EPSCs at resting potential (-80 mV) and at 30 mV in a single cell permitted simultaneous monitoring of the AMPA (-80 mV; peak current) and NMDA (-30 mV, late component at 75 msec) mediated EPSCs. Low frequency stimulation at 30 mV produced LTD of the NMDA component and LTP of the AMPA component (35 \pm 5% and 55 \pm 10% respectively, $n=6$). These results suggest that at these synapses, an NMDA receptor-mediated rise in Ca^{2+} can cause markedly different effects on AMPA and NMDA receptor-mediated synaptic transmission. MULTIPLE ISOFORMS OF NEURONAL NITRIC OXIDE SYNTHASE. I.M. Dawson, J.P. Steiner, J.A. Mong, and S.H. Snyder. Departments of Neuroscience & Neurology, Johns Hopkins University School of Medicine., Baltimore, MD 21205

Nitric oxide (NO) is a recently identified messenger molecule in the central nervous system. NO is produced upon activation of the calcium/calmodulin dependent enzyme, NO synthase (NOS), by a variety of stimuli, including glutamate receptor activation. The major isoform of NOS has been purified to homogeneity, molecularly cloned and its anatomical distribution mapped in detail. Since NO has been implicated in diverse neuronal processes such as long term potentiation (LTP) in the hippocampal formation, but NOS immunoreactivity is absent from CA1 pyramidal neurones, we attempted to identify alternative isoforms of neuronal NOS, which could account for these discrepancies. We purified NOS protein, from rat forebrain and have identified two additional isoforms of molecular mass of 130 Kd and 160 Kd, as well as the major 150 Kd isoform. Peptide antibodies generated against the N-terminal region of the molecularly cloned 150 Kd NOS recognize the purified alternative isoforms and reveal a distinct regional heterogeneity as determined by Western blot analysis and immunohistochemistry. These additional isoforms may be regulated in distinct ways and have unique functions and DNA sequences.

METABOTROPIC GLUTAMATE RECEPTOR-MEDIATED LTP IN THE LAMPREY RETICULOSPINAL SYSTEM. Simon Alford* and Réjean Dubuc. Dép. Kinanthropologie, U. du Québec à Montréal H3C 3P8 and CRSN U. de Montréal H3C 3J7 Québec Canada and *Dep. Physiology Northwestern Univ. Med. School Chicago IL 60611 USA.

This study was conducted to investigate plasticity of synaptic transmission from vestibulospinal (VS) to the reticulospinal (RS) neurones of the lamprey. RS neurones of the posterior rhombencephalic reticular nucleus were recorded with microelectrodes or with whole-cell patch electrodes. Stimuli were applied to the basal plate of the 4th ventricle to stimulate VS axons of the ipsilateral octavomotorius intermediate (OMI) or contralateral octavomotorius posterior (OMP) nucleus. Low frequency stimulation of either pathway evoked a monosynaptic PSP comprising a glutamergic and electrical component and an inhibitory component. In all cases, using microelectrode recording, tetanic stimulation of the pathway (20 or 50 shocks for 1 s, test intensity) led to a sustained enhancement in amplitude of the PSP (mean increase 42 \pm 12 %; $n=11$). This enhancement was not sustained if the neurone was recorded using a patch pipette ($n=6$), implying that the potentiation required a diffusible mechanism in the recorded neurone. The tetanus induced enhancement, in synaptic transmission, was pathway specific. Additionally, the sustained enhancement was insensitive to blockade by application of the NMDA receptor antagonist (R,S)AP5 (200 μ M; mean increase of 47 \pm 15%; $n=9$) but was abolished by the application of the metabotropic glutamate receptor (mGluR) antagonist 4C3H-PG (100 μ M; $n=4$). Taken together, the latter results indicate that mGluR but not NMDA receptor activation is responsible for evoking this LTP. The response was, however, insensitive to pretreatment with pertussis toxin (mean increase 50 \pm 30%; $n=3$) indicating that the mGluR involved is not coupled to a pertussis toxin sensitive G protein (eg G_i, G_o). In conclusion, inputs to brainstem reticulospinal neurones are capable of use-dependent plastic changes mediated by activation of an mGluR. These changes are likely to play an important role in adapting the activity of brainstem motor systems which are responsible for the initiation and control of locomotion. LONG-TERM POTENTIATION (LTP) AND NMDA RECEPTORS IN CHICK FOREBRAIN *IN VITRO*. X. Wang* and H. Scheich. Institute for Neurobiology, Brenneckestr. 6, O-3090 Magdeburg, Germany.

A series of *in vitro* LTP experiments was carried out in the auditory imprinting-relevant area MNH (mediorostral neostriatum and hyperstriatum ventrale) of the domestic chick. Sagittal slices of 250-300 μ m thickness were prepared from forebrain of 0- to 10-day-old chicks. Extra- and intracellular recordings were made in the MNH region. The stimulation was delivered in lobus parolfactorius underneath MNH to the main afferent MNH pathway from the thalamus. A population spike potentiation was recorded extracellularly in about 25% of the tested MNH neurones after application of the afferent tetanic stimulation. There are different neuron types in MNH, only one of which can be potentiated as shown by final intracellular dye-filling. Using intracellular recordings, EPSP potentiation and EPSP-spike (E-S) potentiation was identified. A suitable afferent tetanus could lead to a large depolarization of the postsynaptic membrane. Following this depolarization, the neuronal activity was often increased. The mechanism of these phenomena was investigated with excitatory amino acids and their antagonists. The application of N-methyl-D-aspartate (NMDA, 1 μ M, 1 mM) dissolved in the medium near the slice induced many spikes, bursts and a large depolarization of the membrane potential with temporal and amplitude characteristics similar to the tetanus induced depolarization. These effects were blocked by 50 μ M APV (DL-2-amino-5-phosphonovaleric acid). These results demonstrate the existence of a large population of NMDA-sensitive cells in the MNH. An activation of NMDA receptors may play a crucial role for induction of LTP in MNH.

Nitric Oxide Inhibitors Facilitate the Induction of Hippocampal Long-term Potentiation by Modulating NMDA Responses. K. Kato, D.B. Clifford and C.F. Zorumski*. Departments of Psychiatry and Anatomy & Neurobiology, Washington Univ., School of Med., St. Louis, Mo 63110

The effects of the competitive nitric oxide (NO) synthase inhibitor, L-nitroarginine (L-NOArg), on synaptically activated N-methyl-D-aspartate (NMDA) currents and the induction of long-term potentiation (LTP) were studied in the CA1 region of 25-30 days old rat hippocampal slices at 30°C. Whole cell recording techniques were used to measure NMDA currents in the presence of 50 μ M picrotoxin and 10 μ M CNQX. Application of 10 μ M L-NOArg increased the amplitude of NMDA currents by 48.8 \pm 4.6% ($N=7$) in the presence of 2 mM extracellular Mg^{2+} at -70 mV. This augmentation occurred within minutes of L-NOArg administration and was readily reversible on removal of the drug. L-arginine (100 μ M), which did not change baseline NMDA responses ($N=3$), overcame the enhancement produced by L-NOArg ($N=5$). At 5-100 μ M, a 10-25 min application of L-NOArg also facilitated the induction of LTP produced by a single 100 Hz, 300 ms tetanus (+32.0 \pm 5.5% change in field EPSP at 10 μ M, $N=5$; +36.7 \pm 5.1% change at 100 μ M, $N=7$). In control slices, the 100 Hz, 300 ms tetanus was insufficient to induce LTP (+8.4 \pm 2.5%, $N=8$). The development of LTP in L-NOArg-treated slices was inhibited by 50 μ M D-2-amino-5-phosphonovalerate (D-APV), and the effects of 100 μ M L-NOArg were overcome by ten-fold higher concentrations of L-arginine (+5.3 \pm 1.8, $N=9$) but not by D-arginine (+36.0% \pm 4.3, $N=5$). Hemoglobin, an agent that binds NO extracellularly, also facilitated the development of LTP when administered for 10 min at 10 μ M (+37.1 \pm 6.3%, $N=3$). 10 μ M L-NOArg administered for 20 min without a tetanus also induced a slowly developing potentiation (+23.7 \pm 2.3%, $N=5/7$). These results suggest that tonically released NO modulates the threshold for synaptic plasticity in the CA1 hippocampal region by diminishing NMDA receptor-mediated responses.

NITRIC OXIDE SYNTHASE INHIBITORS BLOCK LTP INDUCED BY WEAK BUT NOT STRONG TETANIC STIMULATION. J.E. Haley*, P.L. Malen and P.E. Chapman. Department of Psychology and Graduate Program in Neuroscience, University of Minnesota, Minneapolis, MN 55455.

Nitric oxide (NO) production during high frequency tetanic stimulation has been implicated in the induction of long-term synaptic potentiation (LTP) in the hippocampus. The dependence of LTP on NO is controversial, however, due to the difficulty in blocking the induction of LTP with NO synthase inhibitors under some experimental conditions. We have attempted to describe the key factors determining the efficacy of NOS inhibitors by testing the potentiating effects of relatively weak and strong tetanic stimulation in the presence of L-nitro arginine (NARG).

Rat hippocampal slices were prepared and field potentials elicited by Schaffer collateral/commissural stimulation were recorded in stratum radiatum. All experiments were performed at 31°C. Pretreatment for 30 minutes with NARG (0.01-1mM) blocked the induction of LTP resulting from subsequent weak tetanic stimulation (2 trains of 100Hz for 250ms, 5 sec intertrain interval) but did not prevent the enhanced synaptic response elicited by a stronger tetanus, where either the duration of the train or the stimulation strength was doubled during tetanus. All three protocols produced LTP of similar magnitude in controls and the size of the response during tetanus was unaltered by NARG. LTP elicited by weak tetanic stimulation was blocked by 50µM AP5, confirming that the enhancement seen in controls was NMDA dependent.

That NO synthase inhibition produces a differential effect on synaptic enhancement produced by weak and strong tetani, may help to explain the controversy surrounding NO and LTP, and raises the possibility that qualitative differences exist between cellular processes activated by different tetanic stimuli.

PROTEIN SYNTHESIS INHIBITORS AND LONG-TERM POTENTIATION (LTP) IN THE INTACT MOUSE: IMPORTANCE OF CONSTITUTIVE RATHER THAN SYNTHETIC PROCESSES. U. Namgung and A. Routtenberg. Cresap Neuroscience Laboratory, Northwestern University, Evanston, IL 60208.

Does the maintenance of LTP require new synthesis or the presence of existing proteins? We attempted to resolve this controversy (e.g. Neurosci., 28:519, 1989 vs Synapse, 1:90, 1987) by studying LTP in the anesthetized subcutaneously 30 min or 4 hr prior to LTP.

Population responses of dentate gyrus cell layer were obtained by perforant path stimulation from entorhinal cortex. Population spike amplitudes, before and after high frequency stimulation (HFS), were compared among saline, CXM and ANI injected-mice. Initial potentiated responses were similar for all 3 groups, i.e., 200% of baseline spike amplitude 20 min after HFS. This implies that CXM or ANI does not affect the induction stage of LTP in contrast to prior reports (J. Neurosci., 4:3080, 1984 & Synapse, 1:90, 1987). Injection of CXM 4 hr before HFS resulted in a decay of LTP that appeared at 90 min. The decreased responses remained at a lower level (60%) for 4 hr after HFS (p<0.01). ANI when injected 4 hr before HFS did not change the potentiated responses. CXM or ANI injected 30 min before HFS had no effect on the response at 4 hr after HFS though the response was temporarily lowered after HFS in the 40-90 min period for both inhibitors.

These results demonstrate that the inhibition of protein synthesis by CXM but not by ANI blocks the maintenance of LTP. In contrast, another study using rats (Neurosci., 28:519, 1989) found ANI to impair LTP maintenance. This inconsistency may reflect different methods or species used. Since CXM injected 4 hr before HFS but not 30 min before blocked LTP persistence, this implies that protein(s) constitutively present at the time of HFS with a half-life of more than 30 min and less than 4 hr is necessary for LTP maintenance. Moreover, the absence of an effect at 30 min suggests that new protein synthesis is not required. [supported by MH25281-18 and AFOSR90-0240]

LONG-TERM POTENTIATION IV

375.1

LONG-TERM POTENTIATION IN ENTORHINAL CORTEX INDUCED BY THETA-PATTERN STIMULATION OF CA1. T.Otto* and H.Eichenbaum. Dept. of Psychology, University of North Carolina, Chapel Hill, NC 27599

The present study sought to determine whether stimulation of the hippocampus, in a pattern consistent with both the learning-related firing patterns of hippocampal neurons (Otto et al., 1992) and the stimulation parameters that optimally induce LTP within the hippocampus itself (Larson et al., 1986), would result in potentiation of the EPSP elicited in a primary cortical target of hippocampal output cells.

Six urethane-anesthetized rats were implanted with a bipolar stimulating electrode in the CA1-subiculum border of the mid-septotemporal hippocampus and a recording electrode positioned in the deep layers of ipsilateral lateral entorhinal cortex (LEC). Single-pulse stimulation of CA1 produced a reliable, monosynaptic EPSP in the LEC that peaked between 5-7ms. Stimuli of an intensity sufficient to evoke an EPSP roughly one-half its maximum amplitude (mean EPSP amplitude = 0.29mV; mean stimulation intensity = 141µA) were delivered to the hippocampus every 15 sec, and the slope of the initial descending phase of the resultant cortical EPSP was measured. Following establishment of a stable baseline, "theta-burst" stimulation of CA1 (2 bouts of 14 bursts [4 pulses at 100Hz], 140ms between bursts [7Hz], 10 sec between bouts) resulted in a brief post-tetanic potentiation followed by stable LTP in entorhinal cortex as indicated by a reliable increase in the slope of the EPSP. The average potentiation at 30min was 161.3% of baseline responses. Responses could be enhanced further by subsequent bouts of theta-burst stimulation. These data are consistent with the hypothesis that learning-related firing patterns of hippocampal output cells support plastic changes in their cortical targets, and could thereby subserve the extrahippocampal consolidation of hippocampal-dependent memory.

PATHWAY SPECIFIC E-S POTENTIATION IS ENHANCED BY BACLOFEN. D.D. Mott* W.A. Wilson, H.S. Swartzwelder and D.V. Lewis. Depts. of Pharmacology, Medicine (Neurology), Psychology, Pediatrics (Neurology) and Neurobiology, Duke Univ. and V.A. Med. Centers, Durham, N.C. 27710.

As originally described by Bliss and Lomo (1973), long term potentiation (LTP) consists of both a lasting increase in EPSP slope as well as a long term increase in the ratio between the slope of the EPSP and the amplitude of the associated population spike (E-S Potentiation). We and others have previously demonstrated that GABA_B receptor activation can regulate the potentiation of EPSP slope. We now examine the effect of GABA_B receptor activation on the induction of E-S potentiation.

E-S potentiation was studied in the dentate gyrus of the rat hippocampal slice. In control slices a long stimulus train (0.5 s, 100 Hz), delivered selectively to the medial perforant path (MPP), produced long term slope and E-S potentiation in that pathway. As previously described, following the MPP train, the non-tetanzed lateral perforant path (LPP) exhibited E-S potentiation and a heterosynaptic depression of EPSP slope. In contrast, a brief stimulus train to the MPP (0.1 s, 100 Hz) produced no change in either pathway, most likely because of the short train duration. However, application of baclofen (10 µM) during the brief MPP train, enabled the train to produce a lasting E-S potentiation, but no synaptic potentiation, in the MPP. The non-tetanzed LPP was not affected. These results indicate that baclofen can selectively facilitate the induction of pathway specific E-S potentiation and suggest that GABA_B receptors may play a role in the mechanism underlying this form of neural plasticity.

375.2

STRESS IMPAIRS LTP OF THE EPSP IN THE DENTATE GYRUS 2 HOURS AND NOT 24 HOURS AFTER STRESS, BUT ALTERS THE THETA BURST RESPONSE AT BOTH TIME POINTS.

T.J. Shors* and E. Dryver. Department of Psychology and Program in Neuroscience, Princeton University, Princeton, NJ 08544

Since the effect of stress on hippocampal plasticity and learning bears resemblance to the effect of LTP on similar measures, we tested whether the effect of stress on LTP was long-lasting, as is LTP. In addition, we tested whether stress alters the theta burst response (Larson, Wong, Lynch, 1986) in a manner similar to a previous induction of LTP. Sprague-Dawley rats (n=28) were exposed to 1 hour of restraint and 60, 1 s, 1 mA tail shocks and returned to their home cage. Stimulating the dentate gyrus via the perforant path, rats were tetanized 2 and 24 hours after exposure to the stressor. Unstressed controls (n=23) were tetanized once and then again 2 hours later. Stress impaired EPSP LTP 2 hours (P<0.05), but not 24 hours after stress.

In contrast, exposure to the stressor at both time points altered the response to subsequent theta burst stimulation (10, 40 ms bursts at 100 Hz, each separated by 200 ms). While unstressed controls exhibited a decline in the amplitude and area (excluding burst 2) of each successive burst, both stressed groups exhibited no such decline in amplitude, a pattern remarkably similar to that observed in unstressed rats exposed to a second tetanus (P<0.01). Assuming dentate LTP lasts longer than 24 hours using these stimulation parameters, these results dissociate stress from dentate LTP with regards to time, but associate stress and LTP with regards to neuronal responsiveness to theta burst stimulation.

CURRENT SOURCE DENSITY ANALYSIS OF ANGULAR BUNDLE-EVOKED RESPONSES IN HIPPOCAMPUS. J.L. Stringer* and C.M. Colbert. Dept. of Pharmacology, Baylor College of Medicine, Houston, TX 77030

Both anatomical and in vitro electrophysiological data suggest that monosynaptic excitation of CA1 pyramids by entorhinal cortical afferents exists. However, available in vivo field potential evidence of monosynaptically driven CA1 cell firing is equivocal because interpreting laminar maps of extracellular voltages is difficult and can be misleading. Current source density (CSD) analysis allows the position of current sinks to be localized more precisely. Here we report, using CSD analysis, that multi-phasic potentials recorded in the CA1 cell layer evoked by stimulating the angular bundle (AB) correspond to sinks in the dentate gyrus (DG). Adult male Sprague-Dawley rats (n=6) were anesthetized with urethane. Stimulating electrodes placed in ipsilateral or contralateral CA3 and the AB were used to evoke extracellular responses recorded by a glass micropipette. Twelve laminar maps were recorded through CA1 and the DG at intervals of 25 μ m or 30 μ m. Four responses were averaged to produce the voltage trace at each depth. CSD analysis was performed offline by computer. Stimulating CA3 resulted in current sinks within CA1. Stimulating the AB, however, consistently evoked sinks that localized to the DG. Although there is good evidence that an entorhinal cortex to CA1 pathway exists, these experiments suggest that the multiphasic potentials recorded in CA1 in vivo do not represent activation of this pathway. This work was supported in part by NIH grant NS 28871.

375.5

DELAYED SIGNAL CONDUCTION FROM CA3 TO CA1 VIA THE CA2 REGION IN RAT HIPPOCAMPAL SLICES REVEALED BY OPTICAL RECORDING.

Y. Sekino*^{1,2}, M. Tanifuji^{1,3} and K. Obata¹. ¹Lab. Neurochem., National Inst. for Physiol. Science, Okazaki 444, ²Dept. of Mol. & Cell. Neurobiol. Tokyo Metropolitan Inst. for Neurosci., Fuchu-shi 183, ³Dept. Information Sci., Fukui Univ., Bunkyo, Fukui 910, Japan.

Many electrophysiological studies using hippocampal slices are based on the anatomical concept of a direct pathway from CA3 to CA1 via the Schaffer collaterals. Anatomical studies, however, show that there could be other CA3 - CA1 pathways, which have not yet been verified by electrophysiological studies. We addressed this problem by optical imaging of activity; using voltage-sensitive dyes. Hippocampal slices of 500 μ m thickness were prepared from the temporal part of the rat hippocampus with Schaffer collaterals and mossy fibers in the same preparation. After staining with an absorptive voltage-sensitive dye, RH482, electrical stimulation was applied to the mossy fibers and the neuronal activity was monitored using a SD1001 optical recording system (Fujifilm Microdevices, Ltd.). Two signal pathways from CA3 to CA1 were observed, which were temporally and spatially different. One was rapid conduction in the distal part of the stratum radiatum, probably through the Schaffer collaterals, starting at 6 ms after the stimulation of the mossy fibers. The other was excitation of the CA2 area with subsequent spread of the excitation to the stratum oriens and the proximal stratum radiatum in CA1. The delay in the excitation of CA2 was about 3 ms. The CA1 region can thus be activated by two different pathways, the direct pathway via the Schaffer collaterals and the delayed pathway via the CA2 region.

HIPPOCAMPAL EPs HAVE STRONGEST RELATION WITH MOLECULAR RSA OSCILLATION AT MEDIUM STIMULATION INTENSITY. E.L. Hargreaves, F. Boon, and D.P. Cain. Dept. Psychology, Univ. Western Ontario, London, CANADA, N6A 5C2.

That hippocampal EPs recorded during Rhythmical Slow-wave Activity (RSA) are different from those recorded during Large-amplitude Irregular Activity (LIA) has been well documented. Similarly, others have shown that EPs vary systematically within RSA oscillations. We have shown that the RSA/LIA related EP differences change across the I/O curve (Hargreaves and Cain, 1991). Here, we demonstrate a similar change across the I/O curve in EPs recorded during RSA oscillations. Male rats (n=8) were implanted with stimulating and recording electrodes in the perforant-path and dentate-gyrus, respectively. The recording electrodes were bipolar and staggered such that the tips straddled the granule cell layer, enabling the continuous monopolar recording of molecular RSA, in addition to the recording of granular or hilar EPs. Abbreviated I/O curves were recorded during Type I exploratory behaviors at Lo (\bar{x} =152 μ A; se=54.6) Med (\bar{x} =289 μ A; se=73.1) Hi (\bar{x} =725 μ A; se=75) stimulation intensities. EPs were triggered manually and identified along with 6-12 Hz filtered RSA on a polygraph tracing, allowing digitized EP measures to be matched with RSA phase. Averaged 2nd order regressions indicated that EP measures recorded at the medium intensity gave the strongest curvilinear relationship to RSA phase. Supported by NSERC to DPC.

375.4

ORIGINS OF THE VARIATIONS IN LONG-TERM POTENTIATION BETWEEN SYNAPSES IN THE BASAL VS APICAL DENDRITES OF HIPPOCAMPAL NEURONS. A. Arai*, J. Black and G. Lynch. Center for the Neurobiology of Learning and Memory, University of California, Irvine, CA 92717.

Factors which control the magnitude of LTP are of interest as they may be linked to particular features of memory. In apical dendrites of field CA1, the maximum potentiation produced by theta patterned stimulation is in the range of 50%; neither additional stimulation nor employing a smaller initial response can transcend this 'ceiling' value. The present study examined whether the rules which govern LTP in basal dendrites differ from those established for apical dendrites.

Stimulation by ten consecutive bursts produced more than twice as much LTP in basal dendrite field EPSPs as in their apical counterparts. Similar results were obtained with whole-cell clamp recording which indicates that the synapses on the two dendritic arbors of the same neuron differ in their LTP ceiling. In addition, basal synapses required a smaller number of theta bursts to reach their ceiling. Intracellular recording revealed significant differences between basal vs apical responses to trains of bursts: the within burst depolarization was greater and the between burst hyperpolarization was smaller for the basal dendritic responses. These two variables have previously been proposed to influence the magnitude of LTP and the observed differences between basal vs apical synapses are in accord with this hypothesis. Together with recently described immunocytochemical results, the findings reported here suggest that variations in LTP across dendritic subfields of hippocampus reflect a differential distribution of a subclass of GABAergic interneurons. (Supported by ONR grant N00014-89-J-1255).

BASAL AND APICAL DENDRITIC SYNAPSES OF HIPPOCAMPAL CA1 PYRAMIDAL CELLS EXHIBIT DIFFERENT LTP PROPERTIES. L.R. Roth* and L. Stan Leung. Dept. Physiology and Clin. Neuro. Sci., Univ. Western Ontario, London, N6A 5A5, Canada.

Long-term potentiation (LTP) at the basal and the apical dendritic excitatory synapses of CA1 pyramidal cells was examined in urethane-anesthetized rats by stimulation at CA1 str. oriens and str. radiatum, which selectively activated afferents to the basal and apical dendrites respectively. Averaged evoked potentials (AEP) were recorded extracellularly at 50 μ m depth intervals in ipsilateral CA1, and a one-dimensional current source density (CSD) was estimated by a second order spatial differencing. Following baseline recording, the afferent pathway was tetanized with theta-frequency primed bursts (8 bursts of one pulse followed 190ms later by 10 pulses at 100Hz) of either high intensity (400 μ A), or low intensity (40-70 μ A). Area under the excitatory sinks 2ms after onset was calculated before and 30 min after the tetanus. Stimulation of str. oriens resulted in significant potentiation of the basal dendritic excitatory sink for both the high intensity (35 \pm 10%, mean \pm SEM, n=7, p<0.05) and the low intensity tetanus (78 \pm 19%, n=7, p<0.05). Stimulation of str. radiatum resulted in significant potentiation of the apical dendritic sink for the high intensity (73 \pm 46%, n=6, p<0.05), but not the low intensity tetanus (-22 \pm 22%, n=9, p>0.1). These results suggest that the apical and basal dendritic excitatory synapses of CA1 pyramidal cells may have distinct LTP characteristics; the basal synapses show robust potentiation at low tetanus strengths, however the apical synapses exhibit weak potentiation only following a high intensity tetanus. (supported by NSERC).

EFFECTS OF CONDITIONING INPUTS ON THE TRANSMISSION OF NEURAL ACTIVITY IN TRISYNAPTIC CIRCUIT OF HIPPOCAMPUS DETECTED WITH OPTICAL MEASUREMENTS. Tetsuro Kondo, Michinori Ichikawa, Syuuji Akiyama, Gen Matsumoto* and Toshio Iijima. Electrotechnical Lab., Molecular and Cellular Neurosci. Sect., Tsukuba, Ibaraki 305, Japan

The main excitatory pathway in the hippocampus is composed of three different groups of neurons (dentate granule cells, CA3 and CA1 pyramidal cells) connected in series with plastic synapses (trisynaptic circuit). We applied conditioning inputs to the beginning of this circuit (perforant path) and studied their effects on the transmission of test input applied also to the perforant path of a rat hippocampal slice. The responses of neurons in the circuit to a test input was monitored simultaneously with high spatio-temporal resolution by applying optical recording which covered almost all surface of a hippocampal slice. A conditioning input of 100 Hz for 1 sec caused LTP in both CA3 and CA1 region. The enhancement of synaptic strength not only had an effect on the amplitude of response of neurons but also on the speed of signal transmission in the trisynaptic circuit. These potentiated synaptic connections were most effectively reduced by the conditioning input of 1 Hz for 1 min. However the conditioning input of 0.5 Hz for 2 min had little effect on the synaptic connections in both CA3 and CA1 regions.

LIKELIHOOD SURFACES ILLUMINATE UNCERTAINTY IN QUANTAL ANALYSIS. A.C. Greenwood¹, Z.Xiang², E.M. Landaw³, and T.H. Brown^{1,2}. Depts. of Physiol.¹ and Psych.², Yale Univ., New Haven, CT 06520; Dept. of Biomath.³, U.C., Los Angeles, CA 90024

We developed a maximum likelihood (ML) approach to quantify uncertainty within several testable models of synaptic transmission. ML theory provides standard errors and likelihood ratio tests, as well as parameter estimates. Monte Carlo simulations amplify the method's power and justify each application of ML theory.

Populations of synaptic responses were analyzed by plotting the dependence of model likelihood on any two quantal parameters in iso-likelihood contour plots. We used the plots to examine the uncertainty in estimates of mean quantal size (q) and content (m) for simulated data. A similar analysis was applied to whole-cell recordings of paired pulse facilitation (PPF) in the rat hippocampal mossy fiber (mf) synapse.

The analysis of simulated data showed that increasing set size and decreasing noise had very different effects. The analysis of the mf PPF data was able to reject the hypothesis that q increased as much as m ($P < 0.05$). It is common practice to test hypothetical LTP mechanisms by extrapolation from pre-induction parameter values, without regard for their uncertainty. This practice leads to false confidence, especially in multi-parameter models. The likelihood contour analysis of mf PPF illustrated these errors (which are not unique to ML analysis) and two satisfactory alternatives (which are). The second derivatives at the ML were found to provide a fast way to screen hypothetical plasticity mechanisms. *Supported by NIMH & ONR.*

MOSSY FIBER POTENTIATION DECREASES SPONTANEOUS MINIATURE EPSC FREQUENCY IN CA3 PYRAMIDAL NEURONS. D.A. Henze^{*} and G. Barrionuevo. Depts. of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, Pittsburgh, PA 15260.

Previous work has shown that the locus of induction and expression of mossy fiber (MF) potentiation is presynaptic. The underlying mechanisms of presynaptic mossy fiber potentiation could be reflected in a change in the amplitude and/or frequency of spontaneous miniature EPSCs. This study sought to address this issue by recording the frequency and amplitude of spontaneous mossy fiber miniature EPSCs from hippocampal CA3 pyramidal neurons using the whole-cell patch clamp technique.

It has been reported by Randall et al. (1991) that the amplitude range of spontaneous EPSCs in CA1 is 1.3 to 15 pA. In our CA3 recordings, the range of events was 1 pA to 165 pA. Since the mossy fibers are located electrotonically close to the soma, their synaptic currents should be of a larger amplitude than all other events. In an attempt to restrict the analysis to only MF spontaneous EPSCs, events were selected to have amplitudes greater than 15 pA. Events also were selected to have 10-90% rise times greater than 500 μ sec and 50% halfwidths of at least 2 ms. It was found that there was no significant change in the average, median, or modal values for three minute epochs both pre- and 15 minutes post-MF tetanus. However, the frequency of the events decreased from 2.13 sec^{-1} to 1.08 sec^{-1} ($n=5$). All data were collected in the presence of 10 μ M bicuculline and 10 μ M picrotoxin. The whole-cell electrode solution consisted of 120 mM CsF, 10 mM CsCl, 10 mM EGTA, and 10 mM HEPES. Mossy fiber (MF) tetanus was given in 10 μ M MK-801 to block NMDA dependent potentiation of the CA3 collaterals. Supported by NS 24288 and an NIMH predoctoral traineeship.

LONG-TERM POTENTIATION INDUCES HETEROSYNAPTIC EFFECTS ON MEDIAL AND LATERAL PERFORANT PATHWAYS IN SINGLE VOLTAGE-CLAMPED DENTATE GRANULE NEURONS. S. Wang^{*} and J.M. Wojtowicz. MRC Group, Dept. of Physiol., Univ. of Toronto, Toronto, Ont. Canada M5S 1A8.

In this project we asked whether the interactions between medial and lateral perforant pathways reported *in vivo* can be observed in single neurons in an *in vitro* slice preparation. Synaptic transmission in the lateral and medial perforant pathways was monitored with extracellular field recordings or whole-cell voltage-clamp recordings from granule neurons. In all experiments 10 μ M bicuculline was included in the bath to block inhibitory inputs. Long-term potentiation (LTP) was induced in one of the two pathways while the synaptic transmission of the other one was monitored simultaneously. Voltage-clamped neurons were depolarized to -20 mV and tetanized with four 0.5 s trains of 100 Hz afferent volleys, delivered at 10 s intervals. With this method the success rate of LTP induction was 55% in medial pathway and 30% in lateral pathway. LTP in medial pathway (253% increment) increases the untetanized transmission in lateral pathway by 24% ($n=7$), while LTP in lateral pathway (99% increment) depresses the transmission in medial pathway by 19% ($n=5$). Analogous heterosynaptic interactions but with different time courses were seen during field potential recordings of synaptic transmission. Results suggest that the interactions can occur in single neurons but additional effects may be a property of the cell population. Supported by MRC of Canada.

KINETIC ANALYSIS OF THE SPONTANEOUS MINIATURE EPSC OF THE HIPPOCAMPAL CA3 PYRAMIDAL NEURON. S. Smerin^{*}, D. Henze, M. Fleck, T.R. Chay and G. Barrionuevo. Departments of Behavioral Neuroscience, Psychiatry, and Biological Sciences, University of Pittsburgh, Pittsburgh, PA 15260.

Toward analyzing long-term potentiation at the four types of glutamatergic synapse -- mossy-fiber, fimbrial, collateral, and perforant-path -- on the hippocampal CA3 pyramidal neuron, we seek to identify the synapse of origin of an EPSC by its kinetics. Since the kinetics of the evoked EPSC are obscured by the asynchronous release of numerous synapses, we are focusing on a quantal EPSC -- the spontaneous miniature EPSC.

The hippocampus of the rat was sliced and maintained *in vitro*. Action potentials were blocked with tetrodotoxin. Spontaneous miniature EPSCs were recorded from the CA3 pyramidal neuron in whole-cell voltage clamp.

The amplitude and 10-85% rise-time for each of at least 500 spontaneous miniature EPSCs were determined for each CA3 pyramidal neuron. Rise-time was calculated as $(0.75 \times \text{amplitude})/(\text{rise-time})$. Amplitude ranged from 4-45 pA, with a mean of 18 pA. Rise-time ranged from 0.4-5 msec, with a mean of 1.4 msec. Rise-rate ranged from 2-112 pA/msec, with mean at 12 pA/msec. Cluster analysis is now underway to determine whether the amplitude and rise-rate correlate, and whether spontaneous miniature EPSCs having a given combination of amplitude and rise-rate can be attributed to one of the four types of glutamatergic synapse on the CA3 pyramidal neuron. Supported by NS24288 and NIMH predoctoral fellowships.

FURTHER ELECTROPHYSIOLOGICAL CHARACTERIZATION OF THE LONGITUDINAL ASSOCIATION PATHWAY IN THE RAT DENTATE GYRUS. P.A. Hetherington^{*}, F. Balcomb, K. Austin and M.L. Shapiro. Dept. of Psychology, McGill University, Montréal, PQ, Canada, H3A 1B1.

The hilar ipsilateral longitudinal association pathway (HILAP) arises in the hilus and projects along the longitudinal axis of the dentate gyrus to synapse in the inner one-third of the molecular layer. Here, we better characterize the physiology of this pathway in rats anesthetized with urethane and α -chloralose. Two electrodes were placed to stimulate both perforant path and the HILAP, and a recording electrode was placed in the inner molecular layer of the dentate gyrus, about 1.2 mm temporal to the site of hilar stimulation. Laminar profiles of responses to both perforant path and HILAP stimulation showed that these systems are distinct. The perforant path evoked population negative EPSP was maximal in the middle 1/3 of the molecular layer in contrast to that evoked by hilar stimulation, which was maximal in the inner 1/3 of the molecular layer. The HILAP response was assumed to be excitatory because maximal responses in the molecular layer were negative-going. However, as a further verification that these synapses are excitatory, we performed experiments to observe the effect of GABA antagonists on these responses. Under bicuculline, both perforant path and HILAP responses were affected similarly and potentiation was readily elicited. We also performed experiments where the hilus and the perforant path were stimulated simultaneously such that the population EPSPs coincided. This experiment resulted in a summation of the two responses -- not a cancellation as would be predicted if hilar stimulation were invoking an inhibitory projection system. Finally, potentiation of both the HILAP and perforant path responses was blocked by the competitive NMDA antagonist NPC 17742 (see Côté et al., this meeting). These experiments demonstrate that the HILAP makes excitatory synapses on dentate granule cells.

QUANTAL BASIS OF FACILITATION AND LONG-TERM POTENTIATION IN RAT HIPPOCAMPAL MOSSY FIBER SYNAPSES. Z. Xiang¹, A.C. Greenwood², & T.H. Brown^{1,2}. Department of Psychology¹, Department of Cellular and Molecular Physiology², Yale University, New Haven, CT 06520

Mossy fiber (mf) synapses are ideal for voltage-clamp recording because of their electrotonic proximity to the soma. The complex circuitry of the CA3 region of the hippocampus, however, makes it difficult to record uncontaminated mossy fiber responses. We devised a set of minimal criteria for eliciting and identifying mf excitatory postsynaptic currents (EPSCs) (Xiang et al. *Neurosci. Abstr.*, 17, 1991; Claiborne et al. *Hippocampus*, 3(2), 1993). Here, we evaluate the quantal basis of paired-pulse facilitation (PPF) and LTP in 5 cells that satisfied our criteria.

Rat hippocampal slices were prepared in the conventional manner and maintained in an interface chamber at 32°C. Whole-cell voltage-clamp recordings were made from CA3 pyramidal cells and mf EPSCs were evoked by minimal stimulation of the dentate gyrus. The quantal basis of the synaptic changes was evaluated using the graphical variance method, which plots the normalized ratio of the mean squared/variance of the EPSCs against the normalized mean of the EPSCs.

In all 5 cells, the data points for PPF and LTP were on or above the diagonal, suggesting that both forms of plasticity reflect an increase in quantal content (m). An alternative interpretation of this result, a plasticity-induced decrease in nonstationarity (Yamamoto et al. *Neurosci. Lett.*, 138, 1992), was unsupported by the "runs test" of stationarity. We also examined the interaction between PPF and LTP. The null hypothesis—that LTP and PPF operate on separate parameters that multiply—could be rejected in three of the five cells ($p < 0.05$). In these 3 cells, the slopes of the graphical variance plots for PPF (before and after LTP) and for LTP (of the first and second responses) were qualitatively consistent with a shared mechanism of increased release probability.

The results suggest that both PPF and LTP are due to an increase in m , independently of whether the interaction test implicates a shared quantal parameter. The interaction test alone may not furnish a reliable guide to the locus of LTP expression. *(Supported by ONR and NIMH).*

A METHOD FOR SIMULTANEOUSLY RECORDING THE CA1 POPULATION SPIKE AND DENDRITIC EPSP IN THE INTACT HIPPOCAMPUS B.J. Branch*, G.M. Rose, K.R. Harris and D.M. Diamond. Dept. of Pharmacology, UCHSC, and Medical Research, VAMC, Denver, CO 80220

Hippocampal connections possess an unusual capacity to show use-dependent changes in strength. This phenomenon, termed long-term potentiation (LTP) or enhancement, has long been considered a physiological model of memory. Electrical stimulation of CA1 pyramidal cell afferents produces a negative EPSP in the dendritic regions and a positive EPSP with a superimposed population spike (PS) in the cell layer. High frequency stimulation of CA1 afferents can produce LTP of both the EPSP and the PS. Experimenters normally record either the EPSP or the PS, thereby limiting an analysis of similarities and differences between these two measures of LTP. This issue is significant because some authors have suggested that the PS is an inadequate measure of LTP. In an accompanying abstract we have addressed this issue directly. Here we present a method that provides for simultaneous recordings of the negative EPSP and the PS in area CA1 *in vivo*. We have developed a dual electrode system consisting of a pair of 50 μ diameter, teflon insulated stainless steel wires, which are glued together with a tip separation of 250-280 μ . The electrodes are used in both acute recordings and in a microdrive system for chronic recordings in behaving rats. Simultaneous recordings both EPSP and PS measures may provide significant information concerning potentially different forms of hippocampal plasticity.

PRIMED BURST POTENTIATION IN THE DENTATE GYRUS. A.K. Wiser* and G.M. Rose. Neuroscience Training Program and Department of Pharmacology, UCSHC, and Medical Research, VAMC, Denver, CO 80220

Long lasting hippocampal plasticity, as exemplified by long-term potentiation (LTP), is often used as a model of memory encoding. Because of an emerging awareness of the unphysiological nature of LTP stimulation, interest is increasing in the use of physiologically based patterned stimulation paradigms to generate hippocampal plasticity. One such paradigm, Primed Burst (PB) potentiation, consists of a single pulse followed 170 ms later by 4 pulses at 200 Hz (5 pulses total). PB potentiation has been well characterized in area CA1, but few studies have examined the efficacy of patterned stimulation in the dentate gyrus. The current work compared the effects of PB stimulation in CA1 and the dentate gyrus in pentobarbital anesthetized rats. PB potentiation was generated in the CA1 pyramidal cell layer by stimulating the commissural/associational afferents, and in the dentate granule cell layer by stimulation of the medial perforant path inputs. In experiments to this point, we have observed comparable effects of PB stimulation in both regions. Significant increases in population spike amplitude were seen in 6/8 cases in the dentate, versus 15/26 in CA1. For the successful cases, the average amplitude increase was 58% and 74%, respectively. Positive field EPSP slopes changed less frequently: in the dentate, 3/8 cases showed an increase averaging 13%; in CA1, 3/26 cases had an average increase of 11%. These results reinforce the utility of PB potentiation as method to study hippocampal plasticity.

MUSCARINE BLOCKS LTP OF THE LATERAL PERFORANT PATH IN THE RAT HIPPOCAMPAL SLICE. K. Pang* and J.M. Sarvey. Department of Pharmacology, Uniformed Services University of the Health Sciences, Bethesda, Maryland 20814.

Studies of the cholinergic modulation of long-term potentiation (LTP) may provide insight into how the cholinergic system modulates memory. LTP of the medial perforant path - dentate granule cell synapse (MPP) requires activation of NMDA receptors, whereas LTP of the lateral perforant path - dentate granule cell synapse (LPP) requires activation of opioid receptors. In a previous study, 1 μ M muscarine, a cholinergic agonist, enhanced LTP induction in the MPP following subthreshold high frequency stimulation (HFS), but had no effect following suprathreshold HFS. 10 μ M muscarine had no effect following either HFS condition. The present study examined the effect of muscarine on LTP of the LPP. In the control condition, suprathreshold HFS induced LTP [population spike (PS): 221%, EPSP: 133%, n=5]. 1 μ M muscarine had no effect on LTP of the LPP [PS: 242%, EPSP: 126%, n=4], whereas 10 μ M muscarine blocked the induction of LTP [PS: 72%, EPSP: 102%, n=4]. The results provide evidence that the cholinergic system may enhance NMDA-dependent LTP and diminish opioid-dependent LTP. The effect of muscarine following subthreshold HFS of the LPP is currently being examined. Supported by NS 23865.

THE POPULATION SPIKE IS A VALID MEASURE OF HIPPOCAMPAL LONG-TERM POTENTIATION. G.M. Rose*, B.J. Branch, A.G. Humphreys, C.I. Moore and D.M. Diamond. Dept. of Pharmacology, UCHSC and VAMC, Denver, CO 80220

Long-term potentiation (LTP) has long been considered a physiological model of memory. As described in the original report by Bliss and Lomo (1973), LTP is manifested in several ways, including increases in measures of the field excitatory postsynaptic potential (EPSP), population spike (PS) and unit activity. Subsequent authors have asserted that the term LTP (or LTE) should be restricted to measures of EPSP plasticity, because only this measure reflects the specificity of the effect. However, this view is not supported by published accounts of cellular measures of LTP, (e.g., *J. Neurosci.*, 8:4079, 1988; *Science.*, 232:988, 1986; *Nature*, 266:736 and 266:737, 1977).

We have addressed this issue further by examining the relationship between the negative field EPSP and PS in hippocampal area CA1. Experiments were conducted on the hippocampus *in vitro* and *in vivo* (urethane-anesthetized or unanesthetized rats). In all cases, recording methodology allowed simultaneous examination of both the negative EPSP and PS in response to stimulation of commissural/associational afferents. Long-term plasticity was induced using the primed burst stimulation paradigm, which consists of a single pulse followed 170 msec later by a burst of four pulses at 200 Hz (five pulses total). There was a significant within-subject correlation between the two measures. These results suggest that the EPSP and PS are equivalent indicators of hippocampal LTP.

375.18

LONG-TERM POTENTIATION REDUCES AUDITORY GATING IN THE CA3 REGION OF THE HIPPOCAMPUS. C.L. Miller*, G.M. Rose, A.K. Wiser, R. Freedman and P. Bickford. Depts. of Pharmacology and Psychiatry and Neuroscience Training Program, U. of Colorado. Health Sciences Center., and Medical Research, VAMC, Denver, CO 80220

A large negative evoked potential (N40) can be recorded in the CA3 region of the hippocampus in response to auditory stimulation. If two stimuli are given at a 0.5 sec interval, the response to the second is reduced compared to the first. This phenomenon is termed auditory gating. Hippocampal connections possess an unusual capacity to show use-dependent alterations in strength, as is best exemplified by long-term potentiation (LTP). The present study was undertaken to assess the potential interaction between LTP and auditory gating in the hippocampus. Experiments were performed in chloral hydrate anesthetized rats. A recording electrode was placed in the CA3 pyramidal cell layer; commissural/associational afferents were activated via a stimulator located in the ventral hippocampal commissure. Paired tone pips were delivered via hollow earbars. Sets of 16 tone pairs were used to establish that auditory gating was present. After this, LTP stimulation (3 trains of 250 Hz for 1 sec) was given. LTP reduced auditory gating by decreasing the response to the first tone and increasing the response to the second. This effect was not observed if LTP failed to develop following high-frequency stimulation. These results indicate that LTP produces functional alterations in hippocampal information processing.

A CALCIUM CHANNEL WITH NOVEL PHARMACOLOGY SUPPORTS SYNAPTIC TRANSMISSION AND PLASTICITY IN THE HIPPOCAMPUS. D.B. Wheeler*, R.W. Tsien & A.D. Randall. Department of Molecular & Cellular Physiology, Beckman Center, Stanford University Med. School, Stanford, CA 94305

We have assessed the importance of various Ca²⁺ channels in excitatory synaptic transmission in area CA1. Extracellular recordings were made in s. radiatum of hippocampal slices (3-4 wk rats) during stimulation of the Schaffer collateral-commissural pathway (2/min). EPSP slopes were irreversibly depressed (-46 ± 1%, n=30) by the N-type channel blocker ω -CTX-GVIA at saturating doses (1 μ M). Neither the P-type channel blocker, ω -Aga-IVA (3 or 30 nM, n=4 or 10), nor the L-type channel blocker, nimodipine (5 μ M, n=6), altered either basal transmission or that recorded after application of ω -CTX-GVIA. In contrast, the response remaining after ω -CTX-GVIA was abolished by ω -CTX-MVIIc, a potent blocker of Q-type Ca²⁺ channels in cerebellar granule cells (Randall *et al.*, Soc. Neurosci. Abs. 1993) and α_{1A} Ca²⁺ channels expressed in *Xenopus* oocytes (Sather *et al.*, Soc. Neurosci. Abs. 1992). ω -CTX-MVIIc block of transmission was potent (complete at ≥ 150 nM, n=20) and developed slowly (20 min to half-block at 500 nM, n=2), like block of oocyte-expressed α_{1A} channels. Interestingly, 150 nM ω -CTX-MVIIc applied alone strongly reduced basal synaptic transmission (-76 ± 2%, n=4). The small remaining response was eliminated by ω -CTX-GVIA. Thus, excitatory transmission at the CA3 \rightarrow CA1 synapse is dominated by Ca²⁺ channels with pharmacology like Q-type channels in granule cells and α_{1A} channels in oocytes.

Transmission mediated solely by α_{1A} /Q-type Ca²⁺ channels could be readily modulated. This transmission supported enhanced paired-pulse facilitation (+63 ± 7% vs. +39 ± 5% in control; 40 ms interpulse interval; n=8, p < .01, paired t-test). LTP (+38 ± 1%, 30 min post-tetanus, n=5), and inhibitory modulation by 1S,3R-ACPD (-51 ± 4%, 200 μ M, n=4), carbachol (-53 ± 5%, 10 μ M, n=4), 2-chloroadenosine (-84 ± 5%, 5 μ M, n=4) and (-)-baclofen (-76 ± 3%, 5 μ M, n=8), whilst (+)-baclofen (5 μ M, n=4) was ineffective. After application of ω -CTX-GVIA, addition of PDBu (1 μ M), but not 4 α -PDBu, potentiated transmission (+222 ± 31%, n=4) and prevented inhibition by the aforementioned modulators.

376.1

STRUCTURAL CORRELATES OF CHEMICALLY INDUCED LONG-TERM POTENTIATION IN HIPPOCAMPAL CA1 AND DENTATE GYRUS.

A. Y. Klintsova*, J. Wenzel, S. Otani, W. B. Levv and N. L. Desmond. Dept. of Neurosurgery, Univ. of Virginia, Charlottesville, VA 22908.

Morphological correlates of chemically induced long-term potentiation (LTP) were studied in the CA1 and dentate gyrus (DG) of the rat hippocampus in vitro. Bath application of 25 mM tetraethylammonium (TEA) for 5 min increased the Schaffer collateral-CA1 pEPSP slope by 80% and the perforant path-DG pEPSP slope by 40%. 60 min after TEA application, slices were fixed using a mixed aldehyde phosphate-buffered solution and processed conventionally for EM. We looked for changes in the number and size of axospinous synapses in CA1 s. radiatum and the middle third of the DG molecular layer (ca. 800 μm^2 was sampled in each region of each slice). The percentage of concave axospinous synapses decreased greatly (ca. 50%) with TEA-induced LTP in CA1 s. radiatum and slightly increased (16%) in the DG molecular layer. The size of nonconcave synapses decreased both in CA1 and the DG. The size of the concave axospinous synapses, however, changed in opposite directions in the two regions: decreasing in CA1 and increasing in the DG. These results are similar to results obtained in previous experiments correlating morphological changes with stimulation-induced LTP in the DG and in CA1 by various labs. These results suggest the existence of different mechanisms underlying LTP in these two hippocampal regions.

376.3

LONG-TERM POTENTIATION AND ASSOCIATIVE MEMORY FUNCTION IN A BIOPHYSICAL SIMULATION OF PIRIFORM CORTEX.

E. Barkai*, G. Horvitz, R.E. Bergman and M.E. Hasselmo, Dept. of Psych., Harvard Univ., Cambridge, MA 02138.

Using brain slice experiments and biophysical simulations, we have explored how physiological parameters influence the possible function of the olfactory (piriform) cortex as an associative memory for odor patterns. A simulation of this region with 240 3-compartment pyramidal cells and 58 each of two types of inhibitory interneurons was developed using GENESIS. Hebbian synaptic modification of excitatory intrinsic fiber synapses during learning allows the network to store afferent input patterns and perform completion on degraded versions of these patterns during recall. Afferent input patterns activated 20 neurons each for 500 msec. during learning. Completion was quantified by the dot product between the recall activity in response to the full learned pattern and in response to a degraded pattern, minus the dot product between the response to the full pattern and the response to other stored patterns. Without learning, recall of patterns missing 30% of input gave a performance of 0.685 (5 patterns stored), which improved to 0.815 after learning. Cholinergic suppression of intrinsic synaptic transmission (70%) was required during learning to prevent runaway synaptic modification, which caused a strong homogeneous response to all patterns during recall (performance=0.0). Experimental data on cholinergic modulation of adaptation was modeled by a 40% decrease in M current $g(\text{max})$ and a 30% decrease in AHP current $g(\text{max})$. This change enhanced the learning of new patterns from performance=0.551 to 0.680 (recall patterns missing 70% of input).

Associative memory function in this model depends on synaptic modification of intrinsic synapses. We recorded intracellularly from piriform cortex pyramidal cells during 5Hz stimulation of intrinsic fiber layer coupled synchronously with intracellular current injection. Long-term potentiation was observed in 6 out of 6 neurons tested during perfusion of 20 μM carbachol (60% average), but only 1 out of 6 tested without carbachol. These results suggest that acetylcholine is necessary for associative memory function in the piriform cortex.

EXCITATORY SYNAPTIC TRANSMISSION IS MODULATED BY EXTRACELLULAR H⁺ BUFFERING IN RAT HIPPOCAMPAL SLICES

T. Taira*, S. Smirnov, J. Voipio and K. Kaila. Department of Physiology and Department of Zoology, 00014 University of Helsinki, Finland.

There is evidence that activity-induced alkaline transients within the interstitial space of nervous tissue are largely due to net fluxes of acid-base equivalents across postsynaptic receptor-gated ion channels. In view of the marked pH sensitivity of certain receptor channels, it has been frequently postulated that synaptically-evoked H⁺ shifts might play a neuromodulatory role. We provide here the first evidence to support the above hypothesis in showing that extracellularly and intracellularly recorded glutamatergic responses in area CA1 of rat hippocampal slices are potentiated upon inhibition of fast extracellular H⁺ buffering by a poorly-permeant carbonic anhydrase inhibitor, benzolamide (10 μM). Experiments with glutamate receptor antagonists and Mg²⁺-free solutions suggest that the action of benzolamide is largely mediated by the H⁺ sensitivity of N-methyl-D-aspartate (NMDA) receptor channels. In agreement with the idea that NMDA receptors provide a target for the intrinsic neuromodulatory action of H⁺ ions also under control conditions, addition of the H⁺ buffer HEPES (20 mM) produces a selective attenuation of NMDA receptor-mediated responses. An additional interesting possibility to be studied in future work is that the postsynaptically generated alkaline transient acts as a retrograde signal to enhance the influx of Ca²⁺ across presynaptic voltage-gated calcium channels, thereby promoting an increase in transmitter release.

376.2

THE HIPPOCAMPAL-PREFRONTAL CORTEX PATHWAY IN THE RAT: LONG-TERM POTENTIATION AND IMPLICATION IN ASSOCIATIVE LEARNING. E. Burette, T.M. Jay* and S. Laroche. Chaire de Neuropharmacologie, INSERM U114, Collège de France, 75231 Paris, France; NAM, CNRS URA1491, Université de Paris-Sud, 91405 Orsay, France.

We have previously shown that the glutamatergic pathway from the hippocampus to the prefrontal cortex (PFC) supports long-term potentiation (LTP) in the rat. The present experiments were aimed at investigating (1) the involvement of the N-methyl-D-aspartate (NMDA) receptor in the induction of LTP in the anesthetized rat, (2) the duration of LTP in the freely moving rat, and (3) variations in the evoked potentials in the PFC during associative learning. In experiment 1, a push-pull cannula was used to perfuse artificial cerebrospinal fluid into the prelimbic area of the PFC while recording field potentials evoked by stimulation (0.033Hz) of the CA1-subicular region of the hippocampus. High-frequency stimulation (2 series, 6 min apart, of ten 250Hz-200ms trains at 0.1Hz) elicited LTP in the PFC that was blocked by perfusion of D-2-amino-5-phosphonopentanoate (AP5). In experiment 2, field potentials were recorded in the PFC for several days before and after high-frequency stimulation of CA1-subiculum. LTP was induced as in the preceding experiment and found to persist for at least 3 days. Series of 5 short trains (200Hz-50ms) at 7.7Hz, mimicking the theta bursting pattern of CA1 neurons, resulted in LTP lasting for at least 24 hrs. In experiment 3, field potentials were monitored during a tone-footshock associative learning task. Rats were submitted to 4 daily sessions of 8 paired (conditioned group) or unpaired (pseudoconditioned group) stimulus presentations. A decrease in the amplitude of the evoked potential was seen in pseudoconditioned rats, whereas the main effect in the conditioned group was a delayed increase in the evoked potential, occurring on average 30 min after conditioning sessions. The results support the view that LTP-like mechanisms on this pathway may be involved in a process of late consolidation by which the hippocampus can help the stabilization of a cortical representation of the learned association. Supported by grant from the EEC (SC1-CT910685).

CHRONIC DEVELOPMENTAL LEAD INCREASES LTP THRESHOLD IN RAT DENTATE GYRUS IN VIVO. M.E. Gilbert and S.M. Lasley, ManTech Envir. Tech., RTP, NC, 27709 and U. Ill. Coll. of Med., Peoria, IL 61656.

Childhood lead (Pb) exposure has been associated with impaired cognitive function. This study examined the effects of chronic developmental Pb exposure in rats upon the induction of long-term potentiation (LTP), an electrophysiological model of learning and memory. At birth, dams received 0.2% Pb acetate in the drinking water to yield hippocampal Pb levels of 350-400 ng/gm (ca. 35 $\mu\text{g}/\text{ml}$ whole blood) of offspring maintained on the same solution until adulthood. Field potentials were recorded from the dentate gyrus following stimulation of the perforant path under urethane anesthesia. Threshold for inducing LTP was determined by delivering a set of 15 4-pulse trains at a frequency of 5 Hz of increasing stimulus intensities (100, 200, 400, 600, 1000 μA). The degree of potentiation of the population spike (PS) was measured 15 m after each train, and 15, 30 and 60 m following the final train. LTP, defined as an increase in PS amplitude >25%, was observed in all animals tested. No difference between Pb and control rats was seen in PS threshold prior to train delivery (311 vs 280 μA , respectively), or the magnitude of LTP recorded 1 hr after the final train (84 and 117%, respectively). However, a 3.5-fold increase in the intensity of the train required to induce LTP was observed in Pb compared to control animals (489 and 170 μA , respectively). Only 1 of 10 controls required a train intensity higher than 200 μA to induce LTP, whereas 8 of 9 Pb-exposed rats required intensities of 400 μA or greater. These data suggest that the detrimental effects of developmental Pb exposure on cognitive function may be due to its interference with the synaptic processes underlying LTP.

376.6

LOWERING EXTRACELLULAR pH OR INCREASING pCO₂ SUPPRESSES SYNAPTIC TRANSMISSION, BLOCKS LONG-TERM POTENTIATION (LTP) AND ATTENUATES EPILEPTIFORM ACTIVITY INDUCED BY LOW EXTRACELLULAR MAGNESIUM. L. Yelisek, J.P. Dreier, S.L. Moshé, P.K. Stanton*, Albert Einstein College of Medicine, Bronx, NY 10461, U.S.A.

Recent studies have demonstrated that acidifying extracellular pH reduces NMDA channel conductance. Therefore, lowering extracellular pH, or raising tissue pCO₂, should influence the magnitude of LTP elicited by submaximal stimulation, as well as suppress epileptiform events elicited by removing extracellular [Mg²⁺]. To test this hypothesis, Schaffer collateral-evoked population spikes and epsp slopes were recorded in CA1 of hippocampal slices (Ringer solution bubbled with 5% CO₂/95% O₂, pH 7.3) and high frequency stimulation (1x100 Hz/1 s) was applied to elicit LTP. We tested two levels of increased pCO₂ (20.6% CO₂ = pH 6.7 or 10.6% CO₂ = pH 7.1). To examine NMDA-mediated epileptiform discharges, [Mg²⁺]-free Ringer was perfused, while recording in entorhinal cortex. To distinguish between actions of high pCO₂ not related to lowered pH, in some experiments Ringer was acidified by lowering [HCO₃⁻]. Both high pCO₂ and acidic pH suppressed normal Schaffer collateral synaptic transmission (population spike amplitude to 10-70% and epsp slope to 50-70% of baseline). When evoked potentials had stabilized, tetanic stimulation elicited only transient post-tetanic potentiation of both population spikes and epsps, while LTP assessed 30 min post-stimulus was completely blocked. When pH or pCO₂ were returned to baseline values, population spikes and epsp slopes recovered to their original values, and robust LTP now could be elicited. Lowering pH and raising extracellular pCO₂ also increased the interval and decreased the amplitude of low [Mg²⁺]-induced seizure-like events (SLE) in entorhinal cortex. Very low pH (6.2) blocked SLEs completely, as well as status-like recurrent discharges. All these effects were fully reversible. The data suggest that processes leading to local intracerebral pH/pCO₂ changes may have a serious impact on low-frequency synaptic transmission, synaptic plasticity and also seizure generation. GLUCOSE METABOLISM AND HIPPOCAMPAL LONG-TERM POTENTIATION Y. Izumi, D.B. Clifford & C.F. Zorumski, Dept. of Psychiatry, Washington Univ. Medical Sch., St. Louis MO 63110

Previously we observed that NMDA blocks the induction of long-term potentiation (LTP) by promoting untimely release of nitric oxide (NO) (Science 257: 1273, 1992). Although the mechanisms underlying this LTP inhibition are uncertain, recent biochemical studies indicate that NO may alter glucose metabolism via ADP ribosylation of glyceraldehyde-3-phosphate dehydrogenase (GAPDH) (PNAS 89: 9382, 1992). This prompted us to investigate the effects of glucose and its metabolites on synaptic transmission and LTP induction in the CA1 region of rat hippocampal slices.

When extracellular glucose was decreased from 10mM to 2mM, baseline synaptic responses showed little change. However, in 2mM glucose a single 100Hz x 1s tetanus failed to induce LTP in 5 slices ($+6.8 \pm 9.2\%$ change in EPSP slope). Similarly, 5 μ M iodoacetate (IA), an inhibitor of GAPDH, did not alter baseline responses but blocked LTP ($-2.2 \pm 3.7\%$ change, N=5). The inhibitory effect of IA was overcome by coadministration of 10mM pyruvate ($+34.9 \pm 16.1\%$ change, N=4) but not by 10mM lactate ($-6.4 \pm 4.4\%$ change, N=4). Furthermore, substitution of 10mM pyruvate for glucose in normal recording solutions permitted robust LTP ($+63.1 \pm 31.1\%$ change, N=5) whereas 10mM lactate failed to permit LTP ($+6\%$ change, N=2).

These results suggest that glucose metabolism plays an important role in synaptic function beyond maintaining baseline transmission.

AT TEMPERATURES DOWN TO 17°C LTP CAN OFTEN BE ESTABLISHED IN A HIGH CALCIUM MEDIA (4.5 mM Ca⁺⁺) IN THE HAMSTER HIPPOCAMPAL SLICE. S.N. Yang and J.M. Horowitz*, Section of Neurobiology, Physiology and Behavior, Univ. of Calif., Davis CA 95616.

Previously we found that LTP can not be established with tetanus at 20°C in the hamster, a hibernator, in 2.0 mM Ca⁺⁺, but the effect of raised extracellular Ca⁺⁺ was not fully explored (Brain Res. 520:115-122, 1990). Here we determined if calcium-induced LTP could be developed at these low temperatures. Field postsynaptic potential (PSP) slopes were recorded in 2.0 and 4.5 mM Ca⁺⁺ in CA1 hippocampal pyramidal cells using single-shock Schaffer collateral/commissural stimulation. Bath temperature was fixed at levels between 17°C and 25°C. PSPs were recorded (1) in 2.0 mM Ca⁺⁺ (controls), (2) when the bath calcium was then raised to 4.5 mM Ca⁺⁺ for 15 minutes, and (3) throughout a final 60 minute period at 2.0 mM Ca⁺⁺. At 20°C PSP slope at the end of this final period varied between 135 and 165% of control and averaged $160.5 \pm 4.2\%$ [F(9,80) = 3.8, p<0.05]. At lower temperatures the enhanced PSPs often showed a biphasic response over the 60 min period -- about 15 minutes into the 60 min period the PSP slope decreased markedly, and then, after about 10 min, again increased to peak values. We conclude that, at 20°C and down to 17°C, calcium-induced LTP can often be established as shown by enhanced PSPs at the end of the 60 minute period. [NASA grant NAG-2-788].

ENHANCED NEUROTROPHIN RECEPTOR EXPRESSION FOLLOWING LONG-TERM POTENTIATION. I. Cavus*, L. Grover & T. Teyler, Neurobiology, NE Ohio Coll. Med., Rootstown, OH 44272

Tetanic stimulation leading to induction of a form of long-term potentiation (LTP) resulted in increased expression of the *trkB* neurotrophin receptor in area CA1 of rat hippocampal slices. *TrkB* expression was assayed by immunohistochemistry using a polyclonal antibody (gp145^{trkB}) raised against the cytoplasmic tyrosine kinase domain of the mouse *trkB* receptor. We compared *trkB* expression 5 hr following induction of two forms of LTP in CA1 dendritic layer: (1) NMDA receptor independent LTP (200 Hz tetanic stimulation in 50 μ M APV) or (2) NMDA receptor dependent LTP (25 Hz tetanic stimulation). Induction of NMDA receptor independent LTP lead to greatly enhanced immunoreactivity in CA1 pyramidal cell apical dendrites and somata. *TrkB* immunoreactivity following induction of NMDA receptor dependent LTP was not distinguishable from low frequency stimulated and non-stimulated control slices.

These results provide additional evidence for neurotrophin involvement in LTP, and suggest differential regulation of *trkB* receptor/tyrosine kinase during different forms of LTP.

TEMPERATURE-INDUCED ALTERATIONS IN LONG-TERM POTENTIATION. T.L. Ivanco*, K.-A. Moore, and R.J. Racine, Department of Psychology, McMaster University, Hamilton, ON, Canada, L8S-4K1.

Moser et al. (Science, 259 (1993) 1324-1326), reported that changes in extracellular potentials may be correlated with changes in brain temperature. In order to investigate the effects of temperature on response amplitude, as well as on plasticity, we manipulated temperature while monitoring responses evoked in the dentate gyrus by perforant path stimulation. Male, hooded rats were urethane-anesthetized and implanted with electrodes in the perforant-path and dentate gyrus. Following recording of baseline dentate responses at normal temperature, body temperature was elevated, lowered, or maintained in all animals. A second baseline was then taken. Half of the animals in each temperature condition then received a basic 'theta' pattern stimulation (i.e. 5 bursts/s), to induce LTP. The remaining animals were used as controls and remained unstimulated. Responses were retested, after which the body temperature was returned to normal and baseline responses retested for the final time. Results indicated that evoked responses could be potentiated by temperature elevation alone, and this potentiation remained after temperature was returned to normal levels. The addition of stimulation trains did not appear to induce any additional LTP.

A PRESYNAPTIC ALTERATION SUPPORTING LTP IN HIPPOCAMPAL NEURONS: CONTRAST WITH EFFECT OF α -LATROTOXIN. A. Malgaroli*, D.B. Wheeler, E. Naldi, A. Ciardo, A. Bergamaschi & R.W. Tsien, Ist. Scientifico Raffaele, Dibat, Univ. Milano, Italy & Dept. Mol. Cell. Physiol., Stanford CA.

In CA3-CA1 hippocampal cell cultures, robust LTP can be triggered by a brief application of glutamate (0 Mg²⁺). Like the amplitude of evoked responses, the frequency of spontaneous minis was strongly increased; such potentiation is induced postsynaptically and expressed presynaptically (Malgaroli & Tsien, Nature 1992). We have compared LTP of mini frequency to elevated mini frequency triggered by α -latrotoxin (α LTX). Presynaptic events leading up to exocytosis were probed by rapid changes in external tonicity or by manipulation of presynaptic Ca²⁺ entry. In unpotentiated synapses, hypertonic solutions (500-600 mOsm) increased mini frequency 50-100-fold above basal (normotonic) levels. While the basal release was augmented with mini LTP or α -latrotoxin, the degree of response to hypertonicity was comparably reduced. Evidently, both LTP and α LTX increase the basal frequency without elevating a release ceiling attained by strong, sustained stimulation. Hypotonic challenges (250 mOsm) reveal interesting differences: after α LTX (as in the unpotentiated case), hypotonicity was largely ineffective in suppressing basal mini frequency; with LTP, hypotonicity decreased mini frequency several-fold. The α LTX results are expected if some release sites lose an inhibitory constraint and support a presumptive [Ca²⁺]_i-independent exocytosis, thus generating a pedestal of mini frequency, insensitive to tonicity. In contrast, mini LTP appears associated with a leftward displacement of the stimulus-response curve, toward lower values of tonicity. These data are consistent with enhanced [Ca²⁺]_i-sensitivity of the secretory machinery. Such a mechanism is supported by experiments studying evoked LTP in area CA1 of hippocampal slices. With LTP, the degree of increase in EPSP slope upon raising [Ca²⁺]_o from 2 to 4 or 5 mM was significantly reduced relative to control. Thus, the EPSP slope vs. [Ca²⁺]_o curve was displaced toward lower [Ca²⁺]_o, as if the [Ca²⁺]_i sensitivity of the secretory machinery were enhanced.

376.12

THE EFFECTS OF PRIOR ACTIVITY ON LONG-TERM POTENTIATION (LTP) IN RAT DENTATE GYRUS IN VIVO. E. Sklar*, M.J. Bianchetti, D.D. Stellwagen, & M.E. Bear, Dept. of Neuroscience, Brown University, Box 1953, Providence, RI 02912.

One theory of synaptic plasticity (Bienenstock et al., J. Neurosci. 2:32) postulates that plasticity is regulated by a threshold level of postsynaptic activity that must be surpassed for LTP to occur in response to presynaptic activation, and that this threshold is modulated as a function of recent cell activity. Since LTP is triggered by calcium influx postsynaptically, one possible mechanism for this "sliding threshold" involves the activity-dependent regulation of postsynaptic calcium buffers. Recent evidence suggests a physiological basis for such a sliding threshold. Lowenstein et al. (1991, Neuron 6:627) found that sustained tetanic stimulation ("2/20 stimulation") of the perforant path caused an increase in the postsynaptic expression of the mRNA to calbindin-D28k, a high-affinity calcium-binding protein. It is known that intracellular injection of calcium buffers such as EGTA interferes with LTP. We hypothesized that an activity-dependent increase in calbindin would have the same effect.

In urethane-anesthetized rats, field potentials were recorded in dentate gyrus as the perforant path was stimulated. After establishment of a 30 min. stable baseline, 1h of 2/20 stimulation was applied, followed by another hour of baseline, and then theta-burst stimulation (TBS) designed to elicit LTP was given. 2/20 stimulation had no lasting effect on synaptic efficacy of baseline responses as measured by EPSP initial slope. However, subsequent TBS produced only a 9% potentiation of EPSP initial slope (25 min. post-tetanus, n=8), as compared to 26% LTP under control conditions (n=6). This reduction in the magnitude of TBS-induced LTP is significant (p<0.05).

2/20 stimulation showed differential effects on population spike amplitude (PSA), however. PSA was significantly depressed (34% depression, p<0.05) 50 min. after 2/20 stimulation, and subsequent TBS produced a potentiation that was significantly higher than in unconditioned controls (121% v. 35%, p<0.01). Work in progress is aimed at determining the extent to which the differential effects of conditioning stimulation on EPSP slope and PSA are due to network properties or to cellular adaptive processes such as calcium buffering.

CHARACTERIZATION OF EVOKED RESPONSES IN PERFORANT PATH AFFERENTS TO HIPPOCAMPAL AREA CA1 *IN VIVO*.

R.V. Hernandez, B.E. Derrick, E.J. Barea-Rodriguez & J.L. Martinez, Jr.*
Department of Psychology, University of California, Berkeley CA 94720.

Area CA1 of the hippocampus receives monosynaptic input from the entorhinal cortex via the perforant/temporoammonic pathway arising primarily from layer III cells. Field EPSPs evoked *in vivo* in the rat by stimulation of the medial aspect of the angular bundle were maximal approximately 300 μ m below the CA1 layer, followed high-frequency trains, phase reversed in the pyramidal layer, and displayed depth profiles that differed greatly from commissural CA3-CA1 responses; thus these responses are likely monosynaptic perforant path-CA1 responses. Local application of lidocaine (1 μ l of 5% solution) in the stratum radiatum of area CA1 eliminated CA1 responses without altering perforant path responses simultaneously recorded in area CA3 or the dentate gyrus. Thus perforant path-CA1 responses were not volume conducted from these sites. Perforant path-CA1 responses were preceded by antidromic spikes, which may reflect direct CA1 projections to entorhinal cortex. Previous reports (Brain Res. 333: 305-310, 1985) indicate that LTP can be induced in this pathway *in vitro*. We are investigating parameters necessary for LTP induction *in vivo*.

THE ACTION OF THE RNA-SYNTHESIS INHIBITOR ACTINOMYCIN D ON A LATE STAGE OF LTP IN HIPPOCAMPAL NEURONS *IN VIVO* AND *IN VITRO*. Uwe Frey*, Thomas Seidenbecher and Manfred Krug. Inst. Neurobiol., Gene Regul. & Plasticity, Brennecke-Str. 6, P.O. Box 1860, 3010 Magdeburg; Inst. Pharmacol. & Toxicol., Leipziger Str. 44, 3090 Magdeburg, Germany.

Hippocampal long-term potentiation (LTP) is thought to serve as an elementary mechanism for the establishment of certain forms of explicit memory in vertebrates. As it is the case with behavioral memory, LTP in the CA1 and in the dentate gyrus has stages: a short-term early potentiation (E-LTP) lasting 1-3 hours and is independent of protein synthesis, precedes a later, longer lasting stage (L-LTP), which requires protein synthesis and which can be simulated by analogues of cAMP and dopamine.

Here we present further physiological properties of L-LTP in the CA1 region *in vitro* and in the dentate gyrus *in vivo*. So, L-LTP was prevented, when actinomycin D, a RNA-synthesis inhibitor, was applied during induction of LTP at a concentration, which blocked about 90% of total RNA-synthesis.

Moreover, application of a further tetanization to potentiated neurons on top of an established L-LTP caused the induction of a newly generated potentiation. Conventional E-LTP which lasts 1-3 hours normally precludes a further potentiation. This result demonstrates that L-LTP is really maintained by different mechanisms compared to E-LTP.

In conclusion, the maintenance of L-LTP depends not only on protein- but also RNA-synthesis similar to stages observed during the consolidation of behavioral memory.

LONG-TERM POTENTIATION (LTP) CAN BE INDUCED, BUT IS NOT MAINTAINED, IN HIPPOCAMPAL CA1 AFTER CHRONIC BENZODIAZEPINE (BZ) TREATMENT. M.S. Mohammed*, X. Zeng and E.L. Tietz, Dept. of Pharmacology, Med. Col. of Ohio, Toledo, OH 43699

Chronic flurazepam (FZP) treatment reduces GABA inhibition in CA1 region of *in vitro* hippocampal slices of BZ tolerant rats. Since GABA antagonists facilitate LTP induction and BZs interfere with induction and maintenance of LTP elicited by theta burst stimulation (TBS) we tested the hypothesis that LTP is altered in CA1 region of hippocampal slices (400 μ m) from FZP-treated (100 mg/kg X 3 days; 150 mg/kg X 4 days, p.o. in .02% saccharin) rats. TBS (10 bursts of 4 pulses (100 Hz); 200 ms inter-burst interval) was produced in slices 2 days after treatment, when residual BZs are no longer detectable in hippocampus. The experimenter was blind to rats' treatment histories. Baseline half-maximal EPSPs (CON: 0.81 \pm .04; FZP: 0.81 \pm .05 mV; p = .95) and population spikes elicited by Schaffer collateral stimulation were recorded extracellularly (glass micropipettes, 2M NaCl, 2-5 m Ω). EPSP initial slope (CON: .57 \pm .12; FZP: .48 \pm .08 mV/ms, p = .56) was measured as percent change from baseline, 30 sec-60 min after TBS. The percent increase in maximal EPSP slope induced by TBS (CON: 151.8 \pm 9.5%; FZP: 144.5 \pm 7.1%) was not different (p = .88) between groups. In treated slices, EPSP slope declined to 50% of baseline (122.01 \pm 6.6%) by 30 min and to baseline by 45 min (104.6 \pm 7.9%). EPSP slope was still elevated in control slices after 60 min (144.1 \pm 13.2%). Baseline population spike amplitude in treated slices was greater prior to (CON: 4.5 \pm .05; FZP: 7.6 \pm 0.7 mV, p < .01), but not after, LTP induction (p \geq .13). Reduced inhibition in CA1 after chronic BZ treatment may be related to the failure to maintain LTP. Supported by NIDA grant RO1-DA04075 and RSDA K02-DA00180 to EIT.

MAINTENANCE BUT NOT INDUCTION OF MOSSY FIBER LTP DEPENDS ON NEW PROTEIN SYNTHESIS. E.J. Barea-Rodriguez*, B.E. Derrick and J. L. Martinez, Jr. Department of Psychology, The University of California, Berkeley, CA 94720.

Others reported that the maintenance but not the induction of NMDA-receptor LTP is dependent on protein synthesis (Neuro. Letters 106:175-180,1989). In the present study, we investigated the mechanisms involved in the maintenance of mossy fiber LTP (MF-LTP). Mossy fiber responses were obtained from anesthetized rats as previously described (JPET 263:725-733,1992). Once a stable baseline was obtained, 5 μ g/ μ l of the protein synthesis inhibitor anisomycin was administered 30 min prior to the administration of a tetanizing stimulation (100 Hz, 2x). The time course of LTP was affected and LTP began to decay about 30 min after the conditioning train, and returned to baseline at 60-100 min after induction. Anisomycin did not affect field potentials evoked by low frequency stimulation. These findings indicate that the maintenance of MF-LTP depends on new protein synthesis and agrees with previous findings suggesting that a long-lasting potentiation exists at this synapse. Supported by DA #04195 and Chancellor's Postdoctoral Fellowship (EJBR).

LTP-DEPENDENT REGULATION OF GENE EXPRESSION: SOME BIOCHEMICAL CONSIDERATIONS. A.A. Hicks, T. Smirnova, S. Larocche*, M.L. Errington, T.V.P. Bliss and J. Mallet, LGN, CNRS UMRC9923 91198 Gif-sur-Yvette, France; NAM, CNRS URA1491, Univ. Paris Sud, 91405 Orsay, France; Division of Neurophysiology and Neuropharmacology, MRC NIMR, London NW71AA, U.K.

Long-Term Potentiation (LTP), the activity-dependent enhancement of synaptic efficacy often evoked as a model of a process involved in the mechanism of learning and memory, can be established following Ca²⁺ entry through the NMDA subtype of glutamate receptor. The biochemical changes elicited by this Ca²⁺ and which support the induction and maintenance of the potentiation remain obscure. We have identified a number of genes whose expression is regulated in a LTP-dependent manner. One of these encodes a protein of 78 amino acids which, due to the conservation of the calmodulin-binding domain and protein kinase C phosphorylation sequence found in neuromodulin, we refer to as neuromodulin-2 (NM2). We have seen an up-regulation of NM2 gene expression at both 5 and 24 hours after LTP induction in the dentate gyrus *in vivo*. Using anesthetized rats, we have shown that at 5 hours the change in gene expression is accompanied by changes in the amount of NM2 protein and that this increase in both mRNA and protein can be prevented by the presence of D(-)-aminophosphonate (APS) at the time of attempted LTP induction. The involvement of NM2 with Ca²⁺-dependent processes and its pattern of temporal regulation highlight its probable role in the maintenance of LTP. Another of these up-regulated genes encodes a novel membrane-associated protein which may be involved in the biochemistry of transmitter release. The importance of modifications in synaptic transmission produced by alterations in the expression of these proteins after induction of LTP will lead to a greater understanding of the biochemical mechanisms underlying synaptic plasticity. Supported by grants from HFSP and EEC (SC1-CT910685).

DIAGONAL BAND STIMULATION INDUCED FOS & SEIZURES IN PIRIFORM CORTEX ARE BLOCKED BY SCOPOLAMINE
L.A. Zimmer, M. Ennis, M. El Eiri and M.T. Shipley

Dept. Anatomy & Cell Biology, Univ. Cincinnati, Col. of Med., Cincinnati, OH 45267

Considerable evidence suggests that seizures induced by organophosphate nerve agents are initiated in piriform cortex (PC) by sustained release of unhydrolyzed acetylcholine (ACh). We have previously shown that systemic, convulsive doses of the irreversible acetylcholinesterase inhibitor, soman, causes the rapid induction of the immediate early gene product, Fos, in neurons in layers II and III of PC. PC is heavily innervated by ACh inputs originating in the basal forebrain, specifically from the nucleus of the diagonal band (NDB). Both muscarinic and nicotinic receptors are present in PC. ACh, acting at muscarinic receptors has been shown to increase the excitability of cortical neurons, an effect that makes them hyper-responsive to other excitatory inputs. PC cells receive and send excitatory amino acid (EAA) synapses. We hypothesize that sustained hypercholinergic stimulation of PC neurons following soman triggers Fos expression and seizures in PC; seizure activity could then spread to hippocampus and cortex. This hypothesis predicts that sustained release of ACh from NDB terminals in PC should cause seizures and selective Fos expression in layer II-III PC neurons as does soman. To test this prediction, microwire electrodes were chronically implanted in NDB to stimulate cholinergic cell bodies, thus causing release of ACh in PC. Shortly after stimulation of NDB (12 Hz; 5 sec on/3 sec off; 20-40 min; 400-500 uA), rats displayed: (a) large amplitude spike & wave EEG activity and (b) intense gnawing, salivation, sniffing, unilateral eye-blinking, rearing, and forepaw reaching. Forty-five minutes following initial NDB stimulation, tissue was processed for immunocytochemical localization of Fos. There was selective, robust induction of Fos in neurons of layers II and III of PC and the hippocampus. Non-stimulated controls had no Fos. Systemic administration of the muscarinic antagonist, scopolamine (2 mg/kg, i.p.), blocked the behavioral signs of NDB stimulation and, in addition, completely blocked or substantially attenuated the expression of Fos. These results demonstrate that activation of NDB, the source of ACh input to PC, produces cortical seizure activity and patterns of Fos expression comparable to soman. The ability of scopolamine to block NDB evoked behaviors and Fos expression indicates that these effects are mediated by muscarinic receptor stimulation of PC. Effects of Subchronic Nicotine on Rat EEG. R.J. Radek*, C. Briggs, J. Sullivan, C.H. Kang, S.P. Americ. Neuroscience, Pharmaceutical Products Division, Abbott Laboratories, Abbott Park, IL, 60064-3500

Acute administration of nicotine activates cortical EEG which is evident by a reduction of slow wave activity. Chronic nicotine exposure associated with cigarette smoking is implicated in the disruption of sleep, an effect consistent with nicotine-induced cortical activation. This study sought to determine the effects of a continuous two week subcutaneous administration of nicotine on EEG in rats.

Rats were implanted with recording electrodes over the frontal cortex. Osmotic minipumps containing saline or 24mg/ml nicotine (2ml/pump) were implanted into the rats. Nicotine plasma levels, determined by HPLC, and 4 hour EEG recordings and were obtained on days 1, 8, and 15 following minipump implantation. A within subject treatment design was used in this experiment such that each rat was recorded for a 15 day period with saline minipumps (control) and another 15 day period with nicotine minipumps. EEG recordings also were obtained 2 and 8 days following termination of nicotine treatment. FFT frequency analysis was used to determine total power for the 1-4 Hz band during each 4 hour recording session.

Average nicotine plasma levels were 67.7±6.2, 67.8±5.8, and 74.6±8.0, on days 1, 8, and 15, respectively. Nicotine treatment significantly lowered (vs. control, p<0.05, n=8, within subject ANOVA) 1-4 Hz power by 23.5±8.1%, 16.1±9.3%, and 19.4±7.0% on days 1, 8, and 15, respectively. There were no detectable levels of plasma nicotine and 1-4 Hz activity returned to control levels after nicotine treatment was withdrawn.

These results show that subchronic nicotine produces an attenuation of 1-4 Hz EEG activity, an effect similar to that of acute nicotine administration. Subchronic nicotine exposure may result in physiological consequences of prolonged reduction of cortical slow wave activity.

377.5

SCOPOLAMINE ATTENUATES MIDDLE LATENCY, VERTEX AUDITORY EVOKED POTENTIALS IN THE RAT. C.E. Kalmbacher, C.D. Specht, T.R. Gregg, and K.A. Campbell*. Dept. of Psychology, Univ. of Delaware, Newark, DE 19716.

In the freely moving rat, vertex auditory evoked potentials (AEPs), recorded over posterior cingulate cortex, yielded the prominent components P20 and N40 from the averaged waveform. Under pentobarbital anesthesia, rats (n=8) were implanted with skull screw electrodes at vertex (bregma: -4.5 mm A-P, 1 mm M-L) and a far frontal reference (+7 mm). Following a two week recovery, rats were placed in a Plexiglas chamber, and AEPs were recorded in response to a 1 second, 10 kHz tone at 75 dB (ISI = 20-50 seconds): 100-trial averages were obtained before and after s.c. injections of scopolamine and, on the following day, saline vehicle. Each of four doses of scopolamine (0.1, 0.2, 0.5, 1.0 mg/kg) was administered twice, in ascending order, one week apart. Similar procedures were used for administration of methyl-scopolamine (0.5, 1.0 mg/kg) to test for peripheral effects.

Scopolamine produced a significant decrease in amplitude for both the P20 and N40 components in overall tests (p<.05). N40 amplitude also showed a significant decrease at each dose of scopolamine (p<.0125), and the magnitude of the amplitude decrement was dose dependent. At 23 hours after scopolamine, only N40 amplitude remained significantly depressed overall (p<.05). There were no effects of saline injection. These results confirm that middle latency vertex AEPs in the rat are attenuated by muscarinic receptor blockade, consistent with previous findings in cats (Dickerson & Buchwald, 1991).

377.2

CHOLINERGIC INTERNEURONS INHIBIT TACHYKININ- AND ENKEPHALIN-mRNA EXPRESSION IN THE RAT STRIATUM L.R. Lucas* and B.E. Hadan. Neuroscience Training Program and Dept. of Anatomy, Tulane Univ. Sch. of Med., New Orleans, LA 70112.

The influence of cholinergic interneurons on neuropeptidergic projection neurons in the striatum is poorly understood. Previously, we have described the effects of the indirect agonist, physostigmine, and the muscarinic antagonist, scopolamine, on SP/NKA-mRNA (substance P/neurokinin A) expression in the striatum (Soc. Neurosci. Abstr. 18:1205, 1992). Chronic treatment with scopolamine resulted in a 46% increase in tachykinin-mRNA expression. To test further the role of cholinergic interneurons, adult male Sprague-Dawley rats were lesioned by an intracerebroventricular injection of AF64A (an aziridinium ion cholinotoxin) prepared stoichiometrically (Moos et al., Drug Dev. Res., 23:253-260, 1991). The injection site was in the caudate-putamen (CPU) at the level of the lateral septum running medially along the CPU. After 14 days recovery, rats were perfused and coronal cryostat sections were cut for *in situ* hybridization for neuropeptide mRNA- and immunocytochemistry for choline acetyltransferase- (ChAT) detection. The AF64A lesioned CPU resulted in a 63% increase in SP/NKA-mRNA and a 26% increase in preproenkephalin-mRNA (PPE) expression as compared to the vehicle treated hemisphere. Levels of mRNA after AF64A treatment were greatest along the track left by the injection, but were not higher than the highest levels found in the ventrolateral CPU on the vehicle treated side. The difference between the lesioned and vehicle treated sides decreased in magnitude with increasing distance from the injection site. The increase in neuropeptide expression in the lesioned side was complemented by a decrease in ChAT-immunoreactive neurons along the track of the injection. These results suggest that acetylcholine in the striatum may inhibit levels of SP/NKA- and PPE-mRNA expression. Supported by NS24148 and DA06194.

CHRONIC NICOTINE PREVENTS NEOCORTICAL NEURONAL LOSS RESULTING FROM NUCLEUS BASALIS LESIONS. D.J. Socci* and G.W. Arendash. Dept. of Biology & Institute for Biomolecular Science, University of South Florida, Tampa, FL 33620.

We have previously shown that cholinergic denervation of the neocortex through nucleus basalis (NB) excitotoxic lesioning results in a significant 19-28% loss of neurons in neocortical Layer II long-term (≥ 5 months) postlesioning (*Science* 258:952, 1987). The purpose of the present study was to determine whether chronic activation of nicotinic receptors on or near neocortical neurons could rescue them from NB lesion-induced degeneration. Young (2 month old) rats received unilateral infusions of ibotenic acid (5 ug/1 ul PBS) at two sites within the NB. Beginning immediately after lesions, rats received daily i.p. injections of either nicotine (0.2mg/kg) or vehicle. Treatment continued for 5 months, at which time animals were sacrificed and their brains processed histologically. Image analysis of neocortical Layer II at the mid-parietal level from lesioned, vehicle-treated rats revealed a significant 22% neuronal loss ipsilaterally. By contrast, those NB lesioned animals that received chronic nicotine treatment had only a non-significant 9% neuronal loss in Layer II ipsilaterally. These results indicate that: 1) chronic nicotine treatment can provide a cytoprotective action on neocortical neurons following loss of their endogenous cholinergic innervation, and 2) chronic lack of nicotinic receptor activation in neocortex may play an important role in NB lesion-induced loss of neocortical neurons.

IONIC FLUXES UNDERLYING NEOCORTICAL SLOW WAVES AND NUCLEUS BASALIS - MEDIATED ACTIVATION: WHOLE-CELL RECORDINGS *IN VIVO*. Raju Metherate* and John H. Ashe. Departments of Neuroscience and Psychology, University of California, Riverside, CA 92521.

Slow, rhythmic membrane potential (V_m) fluctuations occur spontaneously in cortical neurons *in vivo*, and underlie EEG activity in the same low-frequency (1-4 Hz) range. Nucleus basalis (NB) stimulation modifies V_m and EEG fluctuations by way of cortical muscarinic acetylcholine receptors, and these changes likely contribute to neocortical activation (Metherate et al., J. Neurosci. 12:4701, 1992).

To investigate the nature of spontaneous V_m fluctuations and their modification by NB stimulation, we have obtained intracellular recordings from the auditory cortex of urethane-anesthetized rats using the whole-cell recording technique. Based on similarities between spontaneous and thalamic-evoked potentials, we hypothesized that spontaneous V_m fluctuations consist of intermixed rapid depolarizations, rapid Cl⁻-mediated hyperpolarizations, and long-lasting, K⁺-mediated hyperpolarizations. NB-mediated cortical activation might then result from muscarinic suppression of K⁺ conductance, allowing rapid depolarizations and Cl⁻-mediated hyperpolarizations to continue uninterrupted. Tests indicated that: 1) Blockade of K⁺ channels by Cs⁺ from the recording pipette suppressed spontaneous, long-lasting hyperpolarizations. 2) Effects of NB stimulation summated with partial Cs⁺ blockade of long-lasting hyperpolarizations, whereas complete Cs⁺ blockade occluded NB actions. 3) When Cl⁻ fluxes were blocked by intracellular picrotoxin, NB stimulation elicited large amplitude depolarizations. These data support the proposed hypothesis, and suggest ionic bases for cortical slow waves and activation.

Cholinergic Agonists Modify Neuronal Excitability in Intralaminar Thalamic Nuclei of the Rat. C.L. Cox*, J.R. Huguenard and D.A. Prince, Dept. Neurology & Neurological Sciences, Stanford University School of Medicine, Stanford, CA

Intralaminar thalamic nuclei (IL) send a widespread projection to the neocortex, and functionally have a role in synchronizing regional neocortical activities. Stimulation of mesopontine nuclei *in vivo* produces cholinergically-mediated changes in IL activity, however the mechanisms underlying these effects are unknown. We investigated the actions of cholinergic agonists and effects of local extracellular stimulation upon IL neurons *in vitro*.

Whole cell recordings were obtained in slices from parafascicular and caudal central lateral nuclei. Brief pressure application (10-100 ms) of carbachol (10-20mM) or methacholine (10-20mM) produced a membrane hyperpolarization followed by a depolarization. The hyperpolarization lasted 10-20s, was associated with a decrease in input resistance, and was attenuated by the specific M₁ subtype muscarinic antagonist methoctramine. The 20-60s depolarization could lead to spike discharge, was associated with little or no change in input resistance, and was attenuated by the selective M₁ subtype antagonist pirenzepine. These data suggest that ACh, by way of different muscarinic receptor subtypes, can produce long-lasting changes in membrane excitability of IL neurons.

Local electrical stimulation evoked a multiphasic synaptic potential consisting of an early EPSP, early IPSP and a late EPSP. The early EPSP was attenuated by the non-NMDA antagonist, CNQX (10µM), whereas the late EPSP was decreased by the NMDA antagonist, D-APV (20µM). The IPSP was blocked by the GABA_A antagonist bicuculline (5-10µM). The cholinergic actions described may modulate subsequent synaptic activity of IL neurons and potentially influence subcortical control of neocortical function.

NATRIURESIS INDUCED BY ATROPINE MICROINJECTION INTO THE III CEREBRAL VENTRICLE OF THE RAT. Vergara Aragón, P.* Díaz-Pérez, R., Gutiérrez-Mejía, R. and Barrera-Mera, B. Dept. of Physiology, Fac. de Med., UNAM. A.P. 70-250, 04510 México, D.F. MEXICO.

Acetylcholine (ACh) intervenously applied to atropinized female dogs has been used to provide additional evidence on the existence of a reflex secretion of vasopressin. Those experiments showed that water diuresis was inhibited during its increasing phase by injecting 5-40 mg i.v. ACh, recovering entirely 60 min. later. The data led us to study the effect of atropine on the mechanisms for hydrosaline regulation in the rat. Our purpose was to block the cholinergic effect on water and sodium elimination. Wistar rats, chronically implanted cannula in the bladder and another into the III cerebral ventricle (III CV), were used. They had free access to water and food until the beginning of the test. They remained quietly conscious. Urine samples were collected in 15 min. periods. After the two initial periods the rats received distilled water by stomach tube (3% b.w.), and 15 min. after hydration, 1 µg atropine sulfate was injected into the III CV during 15 min. The sodium excretion increased .02 to .10 µEq/min. Instead of achieving sodium retention, we obtained an abundant elimination of this ion. This suggests a cholinergic nature in the antinatriuretic mechanisms in the rat. We think this intense natriuresis was induced by the blocking of the sodium sensing mechanisms.

IBOTENIC ACID LESIONS LOCALIZED TO NUCLEUS BASALIS CELLS PROJECTING TO TEMPORAL CORTEX DISRUPT CONDITIONAL PAIRING OF TONE AND SHOCK. Nancy J. Woolf*, Laboratory of Chemical Neuroanatomy, Dept. of Psychology, UCLA, Los Angeles, CA 90024-1563, U.S.A.

The cholinergic system projects topographically to modules of isocortex and allocortex (Woolf, *Prog. Neurobiol.*, 37: 475, 1991). Cholinergic cells in modules of temporal cortex are altered by Pavlovian conditioning to tone (Woolf et al., *Soc. Neurosci. Abstr.*, 17: 480, 1991). To test if cholinergic afferents are critical for the conditioning correlated with cholinergic cell changes, cholinergic neurons innervating temporal cortex were ablated. Female Sprague-Dawley rats were used for this study. Ibotenic acid (5 µl/1µl) was bilaterally infused into the inferolateral quadrant of the posterior part of the nucleus basalis at 1.8 mm posterior and 3.5 mm lateral to bregma and 6.3 mm ventral to the pial surface of the brain (n = 5). Other rats (n = 5) received infusions of saline into the same site. Following complete recovery from the surgery, rats were trained with an 80 dB 2KHz tone presented for 30 sec and a 1 sec 1 mA shock. The intertrial interval was 10 min. Rats were trained in 4 trials on day 1. On day 2, rats extinguished conditional responding (CR) to the context after receiving context without shock. CR to tone and to context was scored for each animal on test day 3. Saline infused animals showed a significant increase in CR to tone above that to context (p < .05), whereas lesioned animals did not. Thus, cholinergic innervation of temporal cortex was critical to this conditioning to tone. [Support: Sigma Kappa Foundation]

INHIBITORY ACTION OF MUSCARINIC AGONISTS ON NEURONS IN THE RAT LATERODORSAL TEGMENTAL NUCLEUS *IN VITRO* R.W. Greene*, J.L. Luebke, and R.W. McCarley, Neuroscience Lab., Harvard Med. School and VAMC, Brockton, MA 02401

The effects of the mixed cholinergic agonist carbachol and the muscarinic agonist methacholine (MCh) on neurons of the laterodorsal tegmental nucleus (LDT) were studied using intracellular and whole cell patch clamp recordings in a rat brainstem slice preparation. Neurons were classified into one of two categories: those that displayed a prominent low threshold calcium burst (LTB, 60%) and those that did not (non-LTB, 40%). Neurons were filled with biocytin, visualized with Texas-red avidin and identified as cholinergic or non-cholinergic with NADPH-diaphorase histochemistry. Eighty percent of the LTB neurons processed in this manner were cholinergic and sixty percent of the non-LTB neurons were cholinergic.

Carbachol elicited an outward current that reversed near the equilibrium potential for potassium and displayed marked inward rectification in 95% of the cells tested. The conductance/voltage-relationship was fit to the Boltzmann equation with a V_{1/2} = -73 +/- 4mV and a k value of 10 +/- 4. The carbachol evoked current was fully blocked by extracellular barium, mimicked by MCh, and blocked by high concentrations of the muscarinic receptor antagonist pirenzepine (IC₅₀ = 580nM). These data indicate that the muscarinic agonist evoked inhibition of LDT neurons is due to the activation of an inwardly rectifying potassium current mediated by a non-M1 muscarinic receptor.

SEROTONIN DEPLETION DECREASES THE PERFORMANCE IMPROVING EFFECT OF CHOLINERGIC DRUGS IN MECAMYLAMINE TREATED OR BASAL FOREBRAIN-LESIONED RATS. P. Riekkinen Jr*, M. Riekkinen, and J. Sirviö. University of Kuopio, Dept. of Neurology, P.O.B. 1627, SF-70211 Kuopio, Finland.

The present study was designed to investigate the pharmacological consequences of combined cholinergic and serotonergic dysfunctions. Water maze (escape distance, spatial bias) and passive avoidance (entry latency) tests were used to assess behavior. The extent of basal forebrain lesioning (electrolytic medial septal and quisqualic acid nucleus basalis lesions) was investigated from cresyl violet stained coronal sections. The degree of cholinergic cell loss was analysed by the use of hippocampal and cortical choline acetyltransferase activity. P-chlorophenylalanine (3 x 400 mg, i.p.) induced cortical and hippocampal serotonin depletion was measured by HPLC. In intact rats nicotine and tetrahydroaminoacridine did not facilitate water maze or passive avoidance acquisition. Mecamylamine (nicotinic cholinergic antagonist 7.5 mg/kg, i.p.) and basal forebrain lesioning induced passive avoidance and water maze defects were dose-dependently alleviated by nicotine (0.1, 0.3 mg/kg, i.p.) and tetrahydroaminoacridine (1, 3 mg/kg, i.p.). Serotonin lesioning blocked the therapeutic effects of nicotine in mecamylamine and basal forebrain-lesioned rats. However, THA facilitated performance in rats subjected to combined blockade of cholinergic (mecamylamine, basal forebrain lesion) and serotonergic systems.

SELECTIVE CHOLINERGIC DEAFFERENTATION FOLLOWING INTRACORTICAL INFUSIONS OF THE IMMUNOTOXIN 192 IgG-SAPORIN. M. Sarter¹, L.A. Holley¹, R.G. Wiley², and D.A. Lappi³. ¹Dept. Psychology, Ohio State Univ., Columbus, OH 43210, ²DVAMC & Depts. Neurol. & Pharmacol., Vanderbilt Univ., Nashville, TN 37212, and ³Whittier Inst., La Jolla, CA 92037.

192 IgG-saporin consists of a monoclonal antibody to the rat NGF receptor coupled to saporin, a ribosome-inactivating protein (Wiley 1992). Thus, intracortical infusions of 192 IgG-saporin were expected to result in the internalization of this toxin by cholinergic terminals and the selective destruction of cholinergic afferents. Rats received multiple unilateral intracortical infusions (1 or 0.5 µl/infusion) of 0.01 or 0.05 µg 192 IgG-saporin/1 µl Dulbecco's saline (vehicle was infused contralaterally). Parallel brain sections were stained for cells (cresyl violet), AChE (Kutscher 1990), and normal fibers using Vogt's (1974) reduced silver stain. Nissl-stains did not reveal any effect of the toxin in the cortex. AChE-stained sections demonstrated the concentration and volume-dependent loss of cortical cholinergic inputs. Loss of cholinergic fibers and cells was also observed in the basal forebrain. The extent of the lesion-induced reduction of cortical cholinergic fiber density appeared to account for the decreases in silver-stained normal axons, suggesting a selective loss of cholinergic inputs. 192 IgG-saporin appears to be a significant tool for the examination of the effects of selective cholinergic deafferentation.

THE PHOSPHATASE INHIBITORS CALYCUIN A AND OKADAIC ACID ALTER PRESYNAPTIC CHOLINERGIC FUNCTION IN RAT BRAIN
A.M. Issa*, S. Gauthier and B. Collier. Depts. Neurology & Pharmacology, McGill University, Montreal, Canada H3G 1Y6

It is generally accepted that a tight coupling exists between acetylcholine (ACh) synthesis, storage and release. The underlying mechanisms involved in the process are not well understood, although protein phosphorylation and dephosphorylation have been implicated. We examined the effects of the serine/threonine phosphatase inhibitors okadaic acid (OKA) and calyculin A (CA) on parameters of central cholinergic function in brain slice and synaptosome preparations from adult male Sprague Dawley rats. Both OKA and CA produced significant depletion of endogenous ACh content in brain slices in a concentration-dependent manner. OKA (10^{-8} M) depleted the endogenous ACh content of hippocampal slices by 49% and CA (50 nM) produced a 53% depletion. This finding suggested that inhibition of phosphatases 1 and 2A (PP 1 & 2A) by OKA or CA could produce ACh content depletion by either increasing ACh release or inhibiting ACh synthesis. Spontaneous and K^{+} -evoked ACh release were not directly affected by either OKA or CA ($p > 0.05$). Studies were undertaken to determine whether inhibition of PP 1 & 2A would alter choline acetyltransferase (ChAT) activity or high affinity 3H -choline uptake, two parameters involved in the modulation of ACh synthesis. Both of these parameters were significantly decreased ($p < 0.05$ and $p < 0.001$ respectively) in a concentration-dependent manner. In slices pre-loaded with 3H -choline (1 μ M), CA (50 nM) produced a 69% depletion of 3H -ACh content. This decrease was comparable in magnitude to the inhibition of high affinity 3H -choline uptake produced by the same concentration of CA. Taken together these results suggest that inhibition of PP 1 & 2A may deplete tissue ACh content by inhibiting high affinity choline uptake and subsequent ACh synthesis.

IMMORTALIZATION OF A CHOLINERGIC CELL LINE DERIVED FROM MURINE CORPUS STRIATUM M.S. Wainwright*, W-Y Wang, L. A. Won and A. Heller Dept. of Pharmacol. and Physiol. Sci., The University of Chicago, IL 60637.

A cholinergic clonal neuronal cell line was generated from embryonic mouse corpus striatum (CS) by somatic cell fusion techniques. Embryonic day 18 CS cells were fused with the murine neuroblastoma N18TG2 and 23 fusion products were generated. One cell population expressing choline acetyltransferase (ChAT) activity was subcloned. Among the 27 subcloned cell lines, one cell line (X52) expressed substantial ChAT activity and was further characterized. This cell line expressed markedly higher levels of ChAT activity (921.3 ± 97.4 pmol/min/mg protein) than the parent N18TG2 cells (4.3 ± 0.4). The hybrid cells, in contrast to the N18TG2 cells, contain acetylcholine (ACh) (49.6 ± 4.2 ng/mg protein). The hybrid cells spontaneously release ACh which is increased by exposure (20 min) to 70 mM K^{+} . While both the hybrid cell line and the N18TG2 cells exhibit sodium-dependent choline uptake, this is partially inhibited in the CS cell line, but not the N18TG2 cells, in the presence of a specific choline uptake inhibitor (hemicholinium-3, 100 μ M). Following treatment for 2 days with 10 μ M forskolin or 5 days with 1 mM n-butyrate, the hybrid cells express neurite-like processes which are immunoreactive to the neuronal marker, neurofilament protein (NFP) but not to glial fibrillary acidic protein (GFAP). These results suggest that this immortalized cell line exhibits some of the properties of fetal CS cholinergic interneurons and may facilitate study of cholinergic function in the developing CS. VITAMIN E ATTENUATES THE EFFECTS OF BOTH REVERSIBLE AND IRREVERSIBLE INHIBITORS OF HIGH-AFFINITY CHOLINE TRANSPORT IN VIVO. T.J. Walsh*, R.W. Stackman & A.C. Bartolomeo. Department of Psychology, Rutgers University, New Brunswick, NJ 08903.

High-affinity choline transport (HACHT), the rate limiting step in the synthesis of acetylcholine (ACh), is modulated by a variety of endogenous factors, including free fatty acids such as arachidonic acid and the enzyme phospholipase A2 (PLA2) (Boksa et al., *J. Neurochemistry* 1988; Saltarelli et al., *J. Neuroscience* 1990). Several compounds have been shown to inhibit HACHT in either a reversible or irreversible manner. AF64A produces an irreversible inhibition of HACHT, a long-lasting cholinergic hypofunction and related cognitive deficits after icv injection. Vitamin E (VE) pretreatment attenuates the behavioral and neurochemical toxicity of AF64A (Walsh et al., *SFN Abs.* 1992). VE has a variety of biological effects that might alter the dynamics of HACHT and the drugs that bind to this site. For example, VE inhibits (i) oxidative stress and lipid peroxidation, (ii) arachidonic acid synthesis, and (iii) PLA2 activity. The following studies examined the effects of VE on the decrease in HACHT induced by either AF64A, an irreversible inhibitor of HACHT, or hemicholinium-3 (HC-3) a reversible inhibitor. Adult male rats were pretreated with VE (50 mg/kg, i.m.) 24 hrs and 15 min before icv AF64A (0.75, 1.5, 3.0 nmoles) or CSF AF64A (1.5 & 3.0 nmoles) produced significant 25-40% decreases in hippocampal HACHT that were attenuated by the VE pre-treatment. In a second experiment, rats were pretreated with VE as above, and infused icv with HC-3 (20 μ g) or CSF. HACHT in HPC was assessed 30 mins, 4, 12, or 24 hrs after infusion. HC-3 produced a time-dependent decrease in HACHT that recovered within 24 hrs and was significantly attenuated by VE. VE attenuated the effects of both an irreversible and a reversible inhibitor of HACHT without affecting uptake in CSF-injected controls. The mechanisms underlying this effect of VE are currently being explored. Supported by a Busch Bequest Grant to TJW.

ACETYLCHOLINE: ChAT AND AChE

EXPRESSION OF CHOLINE ACETYLTRANSFERASE WITHIN SPINAL MOTORNEURON FOLLOWING BRACHIAL PLEXUS AVULSION. Y. Wu, J.K. Terzis, W. Wu, K. Han, W. Bass*, MRC, EVMS, Norfolk, VA.

Total avulsion of brachial plexus is a devastating lesion with major neuronal loss. Previous research in our laboratory revealed that immediate reimplantation of PNS tissue into the rat spinal cord following total plexus avulsion allowed the return of motor function (Han and Terzis, 1991). However, the ability of avulsed motor neurons to synthesize neurotransmitter has not been addressed. Immunohistochemistry was used to examine the expression of the choline acetyltransferase (ChAT) within spinal motorneurons over time following brachial plexus avulsion in 22 Sprague-Dawley rats. The results demonstrated that the intensity of the immunoreactivity of ChAT in neuropil in the lesion side increased during the first three days after avulsion, then gradually decreased. The mean number of positive neurons per section is decreased over time post-avulsion; positive neurons on the avulsion side versus the normal side is 84.4% within the first three days following avulsion, 49.7% in the second week, 44.1% in the third week and 24.8% in the sixth week. The reduction of the number of the ChAT-positive neurons was permanent.

CHOLINE ACETYLTRANSFERASE EXPRESSION IN DROSOPHILA cDNA TRANSFORMANTS. K. Yasuyama, T. Kitamoto* and P.M. Salvaterra. Division of Neurosciences, Beckman Research Institute of the City of Hope, 1450E. Duarte Rd. Duarte, CA 91010

Using a monoclonal antibody specific for *Drosophila* choline acetyltransferase (ChAT), we have examined the distribution of ChAT-like immunoreactivity (ChAT-IR) in the cephalic and the subesophageal ganglion of *Drosophila* transformed with wild type ChAT cDNA. Expression of the transgenic ChAT cDNA was controlled by different lengths (7.4, 1.2 and 0.8 kb) of 5' flanking ChAT genomic DNA. Transgenes were carried in animals with a presumptive null genetic background for endogenous ChAT alleles in order to assure that all staining could be attributed to transgenic ChAT. Wild-type flies show a widespread and predominantly neuropile distribution of ChAT-IR. Only a few cell somata, such as bilaterally paired cells in the posterior portion of the protocerebrum, are consistently stained. Some of the same structures stained in wild type flies (e.g., antennal lobe, the noduli and the bilaterally paired somata) also show ChAT-IR in cDNA transformants. In other parts of the ganglia, for example in the central complex, we see distinctive differences in staining of transformants when compared to wild type flies. Although the overall pattern of optic lobe ChAT-IR is preserved in most transformants, different 5' flanking DNA appears to result in altered amounts of ChAT-IR in various layers of medulla, lobula and lobular plate. Our observations support the hypothesis that different parts of the 5' flanking region of the ChAT gene contain separable regulatory elements for various subsets of cholinergic neurons. (Supported by NIH-NIDS)

378.3

HYDROPHILIC AND AMPHIPHILIC FORMS OF CHOLINE ACETYLTRANSFERASE EXIST IN *DROSOPHILA* AND ARE ENCODED BY A SINGLE mRNA. N. Salem, J. Medilanski, N. Pellegrinelli, M. Schorderet* and L. Eder-Colli. Department of Pharmacology, CMU, 1211 Geneva 4, Switzerland.

We showed that in the nervous system of the fly *Drosophila melanogaster* choline acetyltransferase (ChAT) exists as hydrophilic and amphiphilic activity. This was based on the demonstration of different interactions with non denaturing detergents. Sequential extraction of *Drosophila* heads produced low salt soluble (87%) and detergent soluble (6%) activities. Sedimentation analysis of detergent soluble ChAT was found to be influenced by the type of non-ionic detergent used (Triton X-100 and Brij 96), whereas this was not the case for soluble ChAT. Using Triton X-114 fractionation of *Drosophila* heads, we found that 76% of the total ChAT activity is hydrophilic and 12% is amphiphilic. We cloned a full length ChAT cDNA from *Drosophila* heads (4.2 kb) and expressed in *Xenopus laevis* oocytes and different type of mammalian cell lines (rat fibroblasts 3T3 and human neuroblastoma SK-NBE). Triton X-114 fractionation of injected oocytes and of transfected cells revealed that 10% and 4% of the total ChAT activity expressed partitioned as amphiphilic enzyme, respectively. Other enzyme activities were assayed among which lactate dehydrogenase (LDH), a soluble marker. Less than 1% of LDH partitioned in the detergent phase suggesting that the presence of amphiphilic ChAT was not due to contamination of the detergent phase by the aqueous phase. Some properties of the hydrophilic and the amphiphilic native and recombinant ChAT were analyzed. The two forms differ in their sensitivity to inhibition by increasing concentrations of acetylcholine and to heat inactivation. In conclusion, we have shown that an amphiphilic form of ChAT exists in *Drosophila* and that hydrophilic and amphiphilic ChAT activities appear to be encoded by a single cDNA.

CHOLINE ACETYLTRANSFERASE IS ASSOCIATED WITH SYNAPTIC VESICLES IN RAT HIPPOCAMPAL TISSUE. P.T. Carroll*, Department of Pharmacology, Texas Tech University Health Sciences Center, Lubbock, TX 79430.

The goal of the present study was to determine whether the membrane-bound choline-O-acetyltransferase (EC 2.3.1.6.; ChAT) in rat hippocampal nerve terminals might be associated with synaptic vesicles. Initially, the subcellular distribution of ChAT was compared with that of occluded acetylcholine (ACh) in rat hippocampal nerve terminals subjected to sucrose density gradient centrifugation. Both non-ionically bound ChAT and occluded ACh peaked in the 0.4 M sucrose fraction of the gradient. This fraction contained almost all of the synaptic vesicle specific SV₂ protein. Immunobeads coated with an antibody directed against the SV₂ protein immunoprecipitated ChAT and occluded ACh from the 0.4 M sucrose fraction, but no other. Immunobeads coated with an anti-ChAT antiserum only immunoprecipitated an anti-SV₂ immunoreactive protein from the 0.4 M sucrose fraction. Pretreatment of the anti-ChAT immunobeads with purified ChAT blocked this response. Identical results were obtained when the subcellular fractions were incubated with anti-ChAT immunobeads and the immunoprecipitates probed for synaptophysin. These results suggest that some ChAT is non-ionically bound to synaptic vesicles in rat hippocampal nerve terminals. (2R01NS21289-09)

THE ALL-TRANS AND 9-CIS ISOMERS OF RETINOIC ACID (RA) STIMULATE ACETYLCHOLINE (ACh) SYNTHESIS BY INCREASING THE ABUNDANCE OF CHOLINE ACETYLTRANSFERASE mRNA IN A MURINE SEPTAL CELL LINE. W.A. Pedersen¹, B. Berse², U. Schüller¹, B.H. Wainer³ and J.K. Blusztajn^{1*}. ¹Boston Univ. Sch. Med., Boston, MA 02118, ²Harvard Med. Sch. Boston, MA 02215, and ³Albert Einstein Col. Med., Bronx, NY 10467.

We developed a cell line (SN56.B5.G4) derived from fusion of mouse septal neurons with murine neuroblastoma cells, N18TG2 [*Dev. Brain Res.* 52:219 (1990)], which exhibits several features of cholinergic neurons, including choline acetyltransferase (CAT) activity, sodium-dependent-high-affinity uptake of choline, and depolarization-evoked ACh release [*J. Neurosci.* 12:793 (1992)]. Treatment of the cells with 1 μ M of either all-trans RA (which binds to the RA receptor) or 9-cis RA (which binds to the retinoid X receptor) for 48 hours resulted in an increase in the expression of CAT mRNA by 3-fold that of controls. Both isomers (at 1 μ M) increased the cellular levels of ACh and CAT activity by 3-fold. These effects were time- and dose-dependent (EC₅₀ values were 20-30 nM for both isomers). A combined treatment with both isomers at concentrations evoking maximal stimulation of cellular ACh content had no additional effect. These results suggest that the cholinergic phenotype is enhanced similarly by activation of the retinoic acid and the retinoid X receptor response pathways.

THE HUMAN CHOLINE ACETYLTRANSFERASE GENE ENCODES TWO PROTEINS. D.D. Grosman*, M.V. Lorenzi, and W.L. Strauss. Dept. of Pharmacology, Univ. of Miami, Miami, FL 33101.

Two mRNAs are generated by alternative splicing of the primary transcript from the human gene for choline acetyltransferase (ChAT), the enzyme that synthesizes acetylcholine. Based on the sequences of the corresponding cDNA clones, the 2300 nt transcript was predicted to encode the 68 kDa human ChAT enzyme. The sequence of the cDNA derived from the 6000 nt mRNA is identical to that corresponding to the 2300 nt mRNA, except for the absence of an 178 bp protein coding exon. This causes a shift in the frame of translation which predicts the synthesis of an ~27 kDa protein consisting of the 203 NH₂ terminal residues of the ChAT enzyme followed by a unique 9 amino acid carboxyl terminus. Based on differences in the amino acid sequences predicted from each transcript, peptides were synthesized for use in the production of polyclonal antibodies specific for each protein. As expected, an antibody raised to the product of the 2300 nt mRNA recognized the 68 kDa human ChAT enzyme. An antibody raised to the product of the 6000 nt mRNA detected a 27 kDa protein in homogenates prepared from human nucleus basalis, but not from a variety of peripheral tissues. The 27 kDa protein can be separated from the ChAT enzyme by either immunoprecipitation or gel filtration and lacks the ability to synthesize ACh. The abundance of the 27 kDa protein was inversely related to ChAT activity in regions of the human CNS known to contain cholinergic elements. These data demonstrate that human brain contains a protein that is immunologically related to ChAT. Possible roles for this protein in ACh synthesis are being examined.

KN-62, A Ca²⁺/CALMODULIN KINASE INHIBITOR, REGULATES CHOLINE ACETYLTRANSFERASE ACTIVITY IN PC12 CELLS.

P. W. Scates, C. R. Baitinger and H. L. White*. Div. of Pharmacology, Burroughs Wellcome Co., Research Triangle Park, NC 27709.

In order to determine whether Ca²⁺/calmodulin kinase II (CaM kinase II) may play a role in the regulation of choline acetyltransferase (ChAT), the effects of the specific CaM kinase II inhibitor, KN-62, 1-[N,O-Bis(5-isoquinoline sulfonyl)-N-methyl-L-tyrosyl]-4-phenylpiperazine, were studied in PC12 cells. Decreases in ChAT activity to approximately half of control values were observed following 48-hour incubations with KN-62 at 0.1-1 μ M, a concentration range that corresponds with its inhibition of CaM kinase II. KN-62 at 10 μ M did not inhibit ChAT directly when added to cell lysates or to partially purified enzyme. Increases in ChAT activity induced by nerve growth factor (NGF) were blocked by KN-62, while NGF-induced neurite outgrowth appeared to be enhanced. Incubation of PC12 cells with the serine/threonine phosphatase inhibitor, okadaic acid, also produced an increase in ChAT activity, which was completely blocked by 1 μ M KN-62. At higher concentrations, KN-62 potentiated the toxic effects of okadaic acid so that cell viability was decreased. Protein phosphorylation patterns were obtained by SDS-PAGE to investigate whether phosphorylation states of ChAT, calmodulin kinase II, and other proteins might be correlated with changes in ChAT activity. We conclude that regulation of ChAT activity in PC12 cells, and perhaps in other systems, is at least partly mediated by calmodulin kinase II.

378.8

EFFECTS OF DITHIOBIURET (DTB) ON REGULATION OF TRANSMITTER SYNTHESIS AND RELEASE IN PC12 CELLS. L.M. Ireland* and W.D. Atchison. Dept. Pharmacol. Toxicol., and Neurosci. Program, Michigan State Univ., E.Lansing, MI 48824.

In rats, intraperitoneal administration of DTB appears to affect cholinergic motor neurons selectively, resulting in neuromuscular weakness. Sensory function seems to be largely unaffected by DTB. The apparent selectivity of DTB may result from a specific disruption of acetylcholine (ACh) release. PC12 cells were used to compare the effects of DTB on the content and release of endogenous stores of ACh and dopamine (DA), both of which are released by these cells. Levels of these neurotransmitters were measured using HPLC coupled to electrochemical detection. Incubation of PC12 cells with 50, 100 or 500 μ M DTB for 24 hr decreased K⁺-evoked release of ACh to 60, 40, or 55% of control, respectively. The inhibition of K⁺-evoked ACh release by 500 μ M DTB was potentiated by supplementing the culture media with choline chloride. Neither cellular nor vesicular ACh content was significantly altered by the same 24 hr incubation with DTB. Conversely, cellular DA levels were significantly decreased by 24 hr incubation with DTB. Both 20 and 50 μ M DTB decreased total cellular DA content to 25% of control. Vesicular DA content was unaffected by these concentrations of DTB. DOPAC is the major metabolite of DA degradation by monoamine oxidase. Changes in DOPAC content reflect alterations in DA metabolism. Since DTB application tends to decrease both DOPAC and DA levels in the cell, this suggests that DA synthesis is diminished. In spite of decreased DA synthesis, K⁺-evoked release of DA is unaltered by DTB. Thus, both ACh and DA stores are affected by DTB but only ACh release is disrupted. This work is supported by NIH grant NS20683.

SYNTHESIS AND RELEASE OF MUSCLE ACETYLCHOLINE FROM CLONAL CULTURES OF HUMAN SATELLITE CELLS. J.P. Ternaux¹*, M. Hamann², M.C. Chamoin¹, A. Baroffio², P. Portaliere¹, H. Widmer² and C.R. Bader¹. ¹: Unité de Neurocybernétique Cellulaire, UPR 418 CNRS, 13009 Marseille, France. ²: Département de Physiologie, Centre Médical Universitaire, 1211 Genève 4, Suisse.

Purified satellite cells (SC) were obtained from various human skeletal muscles biopsies following cytometric cell sorting. Acetylcholine (ACh) was extracted with TCA within 12 hours after dissociation, before the start of proliferation. The chemiluminescent assay for ACh revealed the presence of 133 pmoles/10.000 SC (n=2). SC were manually cloned and cultured for proliferation during 4 to 8 weeks. Under such conditions, endogenous level of ACh was 63 ± 76 pmoles/well of 100.000 SC (n=9). Following fusion of the SC into myotubes, ACh content was 33 ± 22 pmoles/well (n=9). When cells were cultured in presence of an esterase inhibitor (10 µM phospholine, 24 hours), the ACh amount was enhanced respectively 2- and 3-fold in proliferative and differentiated state. Conversely, cultivating the cells in presence of bromoACh, a potent inhibitor of choline acetyl transferase (ChAT), gave a 54 ± 19 % (n=5) decrease of ACh content. Presence of ChAT was demonstrated in both proliferative and differentiated states using immunohistochemistry method. Finally, release of ACh was detected in the supernatant of SC or myotube cultures, following a 15 min incubation. Measured levels of ACh were respectively 3 and 7 pmoles/well/min. These results demonstrate that SC and myotubes synthesize and release ACh. In addition, presence of ACh in freshly dissociated SC is in favour of the "in situ" existence of a muscular pool of ACh.

REGIONAL VARIATION OF ACETYLCHOLINESTERASE ACTIVITY AND SPECIFIC MRNA IN ADULT RAT BRAIN.

R. Rao, C. Koenigsberger, and S. Brimjoin*. Dept. of Pharmacology, Mayo Clinic, Rochester MN 55905.

Expression of acetylcholinesterase (AChE) varies by region across the nervous system. To investigate this phenomenon, we compared AChE activity with steady state levels of AChE mRNA in different parts of the adult rat brain. RNA was extracted with guanidine isothiocyanate from freshly dissected material, and PolyA⁺-RNA was isolated by chromatography on oligo-dT cellulose. Following denaturation and electrophoresis on 1.2% agarose, mRNA was blotted onto nylon membranes. Blots were exposed to Kodak XAR-5 film after incubation for 36-40 hr at 42°C with a random prime ³²P-labeled cDNA probe for murine AChE (bases 542-1140 of the full length cDNA). The AChE probe hybridized to a 2.4 kb mRNA transcript in all regions (a weaker 3.2 kb band was also seen). AChE mRNA bands were normalized to the density of cyclophilin mRNA bands in the same lanes. Densitometry of the 2.4 kb AChE mRNA showed the following regional abundance: cortex 1.0, striatum 2.4, cerebellum 10, medulla 10.6, thalamus 18, pons 32. Relative abundance of AChE activity in detergent-extracts of the same brain samples also varied greatly: cortex 1.0, striatum 8.0, cerebellum 1.1, medulla 2.7, thalamus 3.0, pons 2.8. Modest AChE activity in the pons contrasted with a high level of message. Even more striking was the low mRNA level of striatum despite the high AChE activity. Possibly, the pons is a net exporter of AChE, while much striatal AChE may be imported by axonal transport from elsewhere in the brain. Regional differences in AChE turnover could also explain these findings. (Supported by Grant NS29646).

HISTOCHEMICAL, BIOCHEMICAL, AND PHARMACOLOGICAL STUDIES OF ACETYLCHOLINESTERASE IN THE NEMATODE *CAENORHABDITIS ELEGANS*. Y. KAMIYA*, S. HARADA, S. OKOYAMA, H. YAMAMOTO & R. HOSONO. Dept. of Biochemistry and Dept. of Anatomy, School of Medicine, Kanazawa University, Kanazawa, Ishikawa 920, JAPAN.

In *Caenorhabditis elegans* [*C. elegans*], there are three kinetically distinct acetylcholinesterase [AChE] classes (A, B and C). To investigate the role of each class, developmental changes in AChE activity, acetylcholine [ACh] levels, and the sensitivity to AChE inhibitor trichlorfon were examined in mutants which possessed only one of the three AChE classes. Both class A and class B AChE activity were about one half of the total and sufficient for normal locomotion and maintaining normal ACh levels. Class C AChE occupied less than 2% of the total activity and was insufficient for normal locomotion and ACh levels but insensitive to trichlorfon. Although class A AChE localized at the head region, class B enzyme was distributed throughout the head and the body region as seen in wild type. Class C AChE localized at the body region. These results suggest that class B AChE plays a major role, and class A and class C are supplementary.

TRANSLATION OF THE 6000 NT TRANSCRIPT OF THE HUMAN CHOLINE ACETYLTRANSFERASE GENE MAY BE REGULATED. A.C. Trinidad* and W. L. Strauss. Dept. of Pharmacology, Univ. of Miami, Miami, FL 33101.

A 2300 nt mRNA encodes human choline acetyltransferase (ChAT), the 68 kDa enzyme that synthesizes acetylcholine. Transcription of the human ChAT gene produces a second, 6000 nt, mRNA that encodes a 27 kDa protein of unknown function, but with high identity to the NH₂ terminus of the ChAT enzyme (D. Grosman *et al.*, this vol.). We have found that a ChAT enzyme positive human neuroblastoma cell line, CHP134, contains both the 2300 nt and 6000 nt ChAT gene transcripts, but does not express the 27 kDa protein. In contrast, the 27 kDa protein is readily detected on immunoblots of proteins from nucleus basalis, a brain region containing amounts of both ChAT mRNAs comparable to those measured in the CHP134 cells. These data suggest that the translation of the 6000 nt mRNA may be regulated. This hypothesis is supported by our inability to detect the 27 kDa protein in homogenates of human ventral spinal cord, which expressed ChAT enzyme (100 pMol ACh synthesized/min/mg protein) and contained both ChAT gene transcripts as measured by RT-PCR. We speculate that the apparent difference in translational efficiency observed between the 2300 nt and 6000 nt mRNAs may derive from the length of their respective 3'-untranslated regions (~200 nt for the 2300 nt mRNA vs. >5000 nt for the 6000 nt mRNA). To test this hypothesis we currently are evaluating the translation of the 27 kDa protein from cRNAs with truncated 3'-untranslated domains.

EVOLUTIONARY ORIGINS OF CHOLINESTERASE DUALITY IN THE VERTEBRATES. Leo Pezzementi*, David Sutherland, Michael Sanders, Weily Soong, and Harry Giles. Birmingham-Southern College, Birmingham, AL

Gnathostome vertebrates possess two evolutionarily related cholinesterases (ChE), acetylcholinesterase (AChE) and butyrylcholinesterase (BuChE). AChE hydrolyzes acetylcholine at cholinergic synapses; the function of BuChE is unknown. The two ChE can be distinguished kinetically and pharmacologically. Differences between the two ChE appear to correlate with position on the phylogenetic scale; in lower gnathostomes, they resemble one another more closely. Also, in the agnathan vertebrates, the lamprey and the hagfish, as well as in the cephalochordate, amphioxus, only one ChE is found. These data have led to the suggestion that the two ChE have evolved as a result of a gene duplication event early in vertebrate evolution, with subsequent structural and functional divergence. To study this question, as well as the molecular basis of the distinction between the AChE and BuChE, we have undertaken a biochemical, pharmacological, and molecular biological investigation of the ChE activities of the hagfish *Myxine glutinosa*, and of the invertebrate chordate, amphioxus (*Branchiostoma* spp.). We have determined the substrate specificity of the enzymes and their inhibition by diagnostic AChE and BuChE inhibitors. We have also used the polymerase chain reaction with degenerate primers to clone 1 kb fragments of the ChE genes from the hagfish and amphioxus, comparing these sequences with those of ChE from other vertebrates and invertebrates, and constructing a phylogenetic tree. Additionally, we have conducted a fine-structure analysis of the sequences in terms of crucial aromatic amino acids found in the catalytic site of ChE. The data have provided insights into the evolution of the enzymes and the molecular basis of AChE and BuChE activity. Supported by NSF-RUI grant BNS-9010710 and an NIH-French CNRS Fellowship to L.P.

EFFECTS OF DIMETHOXY BENZYLIDENE ANABASEINE (DMXB) AND NICOTINE ON AChE EXPRESSING SEPTAL NEURONS IN FIMBRIAL/FORNIX TRANSECTED ANIMALS. K.S. PANICKAR*, M.A. KING, E.H. MEYER¹ and B.E. HUNTER. Department of Neuroscience, and Department of Pharmacology and Therapeutics, University of Florida College of Medicine, Gainesville, FL 32610-0244.

Nicotine has been shown to have cytoprotective actions in the brain. We therefore conducted a preliminary study using DMXB, a nicotinic agonist, to investigate if DMXB could protect cholinergic neurons in the septum following fimbria-fornix lesions. In the present study 12 male Long-Evan rats were surgically operated for unilateral fimbria-fornix lesions. Following the lesions the animals were injected daily intraperitoneally with 1 mg/ml DMXB (n=4) or 0.2 mg/ml Nicotine (n=4) or saline (n=4). Two weeks following the lesions the animals were sacrificed and the brains removed. Brain sections approximately 40 microns thick were cut and stained using AChE histochemistry. Neurons in the medial septum were counted using a computer-assisted program. Results show that there was a decrease in the number of cells in the ipsilateral side of the lesioned animals when compared to the contralateral side in all three groups. The results from this preliminary study suggest that DMXB does not appear to have a cytoprotective action at this dose. However, there was an increase in the number of stained cells in the unlesioned side in the DMXB and Nicotine groups when compared to the control group suggesting a possible upregulation of this enzyme. Further studies using a wide range of doses of DMXB are suggested. Supported by NIA grant P01AG10485 and Taiho Pharmaceuticals.

AB-21: A NOVEL BISQUATERNARY DIOXIME FOR THE REACTIVATION OF ORGANOPHOSPHORYL-INHIBITED AChE. G. Amitai*, L. Raveh, I. Rabinovitz, G. Cohen, B. Manistersky, G. Zomber, R. Adani, Y. Harari and H. Leader, IIBR, Ness Ziona, Israel.

Combined treatment with oximes and atropine confers antidotal protection against highly toxic organophosphorus (OP) poisoning. We have developed a series of quinuclidine containing bisquaternary pyridine mono-oximes designated AB-oximes. The protection ratio (PR) obtained against soman poisoning for AB-8 was higher than AB-13 in guinea pigs and dogs. AB-13 is a more potent reactivator of tabunyl-AChE and more efficacious against tabun poisoning. A new dioxime compound: 1-(2,4-dialdoxime pyridine) 1'-(3-quinuclidinone) dimethylether dichloride (AB-21) was prepared. AB-21 was designed as a molecular combination of AB-8 and AB-13 so that it will be equi-efficacious against both soman and tabun. AB-21 reactivates tabunyl-FBS-AChE at a higher rate than AB-13 and HLo-7 with the following reactivation bimolecular rate constants (k_2) 48, 12 and 18 $M^{-1}min^{-1}$, respectively. Diethylphosphoryl-FBS-AChE was reactivated rapidly by AB-21 ($k_2=111 M^{-1}min^{-1}$). Antidotal studies in mice conducted with AB-21 (40 mg/kg, im) together with atropine and benactyzine as post exposure treatment and pyridostigmine as pretreatment demonstrate protection against soman (PR=5.1) and tabun (PR=2.8). Thus, the introduction of two oxime groups into the pyridine ring in AB-21 enhances reactivation potency for inhibited AChE and may increase its antidotal efficacy against OP poisoning.

EXCITATORY AMINO ACIDS: ANATOMY AND PHYSIOLOGY II

379.1

NON-NMDA GLUTAMATE RECEPTOR (GluR) SUBTYPES IN MONKEY HYPOTHALAMUS ARE SELECTIVELY DISTRIBUTED. S.D. Ginsberg*, L.I. Martin, C.D. Blackstone, R.L. Haganir and D.L. Price. The Johns Hopkins Univ. Sch. of Med., Balto., MD 21205.

Glutamate is a physiologically dominant neurotransmitter within discrete hypothalamic circuits. However, the cellular targets for this excitatory synaptic input have not been evaluated systematically. In this study, antipeptide antibodies were used to assess the relative distributions of GluR subtypes throughout the rostrocaudal extent of the macaque hypothalamus (n=7). Antibodies were directed against AMPA (GluR1-GluR4), kainate (GluR6-GluR7), and metabotropic (mGluR1 α) receptors. The results indicate that the monkey hypothalamus contains several discrete, differentially distributed populations of AMPA GluR-immunoreactive neurons. Specifically, GluR1-immunoreactive neurons are observed in the posterior hypothalamus and mammillary complex. GluR2/3-immunoreactive neurons have a broader distribution, including the medial preoptic area, arcuate nucleus, lateral hypothalamus, and mammillary complex. GluR4, GluR6/7, and mGluR1 α are expressed minimally within monkey hypothalamus. In contrast, GluR3 immunoreactivity is found exclusively in a population of magnocellular neurons within the paraventricular, supraoptic, and accessory magnocellular nuclei and in axons of the hypothalamo-neurohypophysial tract. Double-labeling experiments suggest that GluR3 immunoreactivity is colocalized to a greater degree with oxytocin-containing neurons than vasopressin-containing neurons. The highly selective localization of GluR subtypes within hypothalamic circuits is likely to be related to physiological functions of excitatory synaptic interactions on neuronal targets that are believed to mediate diverse behaviors, including stress, reproduction, osmoregulation, and appetitive responses.

379.3

NON-NMDA GLUTAMATE RECEPTOR (GluR) PROTEINS ARE EXPRESSED DIFFERENTIALLY IN SUBREGIONS OF THE HIPPOCAMPAL FORMATION IN RAT AND PRIMATE. L.I. Martin*, C.D. Blackstone, S.D. Ginsberg, R.L. Haganir and D.L. Price. The Johns Hopkins Univ. Sch. of Med., Balto., MD 21205.

GluR are essential for the physiological functions of hippocampal circuitry and are believed to mediate synaptic mechanisms of learning and memory. To evaluate the cellular and subcellular localizations of non-NMDA GluR in the hippocampal formations of adult rat and rhesus monkey, immunoelectron microscopy was employed using antibodies that detect AMPA receptor subunits (GluR1; a common epitope on GluR2 and GluR3; GluR3; and GluR4), high-affinity kainate receptor subunits (a common epitope on GluR6 and GluR7), and a metabotropic receptor (mGluR1 α). In hippocampus, GluR1 and GluR2/3 were most abundant, GluR6/7 and mGluR1 α were expressed moderately, and GluR3 and GluR4 expressions were low or not detectable. GluR1 and GluR2/3 were enriched within dendritic shafts and spines in CA1, CA2, CA3, CA4, dentate gyrus, and subiculum also showed intense immunoreactivity. Most pyramidal neurons expressed both GluR1 and GluR2/3. GluR6/7 was enriched selectively within proximal dendrites in the stratum lucidum of CA3 and in astrocytic processes enveloping synaptic complexes. mGluR1 α was localized to nonpyramidal neurons and dendrites within the stratum oriens of CA1 and the polymorph layer of the dentate gyrus. GluR4 was detected within hippocampal astrocytes; hippocampal pyramidal neurons were not GluR4 immunoreactive. These results demonstrate that GluR subtypes are localized differentially to neurons (pyramidal and nonpyramidal) and glia within the hippocampal formation. We conclude that cellular targets within hippocampal circuits can utilize different molecular strategies to transduce glutamatergic synaptic influences.

379.2

EXPRESSION OF THE GluR1 GLUTAMATE RECEPTOR IN DEVELOPING RAT BRAIN. C.D. Blackstone*, R.L. Haganir, D.L. Price, and L.I. Martin, The Johns Hopkins Univ. Sch. of Med., Balto., MD 21205.

Ionotropic glutamate receptors (GluR) are thought to have important functions in the developing brain and to harbor potent neurotoxic potential for neuronal damage in the immature central nervous system. This study evaluates, using immunoblotting and immunocytochemistry (ICC), the cellular localization and temporal expression of the GluR1 subunit of the AMPA receptor in developing rat brain. Immunoblots of brain homogenates with anti-GluR1 antibodies showed a single band of protein at 106 kD; there were no cross-reacting proteins with other molecular weights at any developmental stage. GluR1 was first detected at E15.5, and expression increased progressively during late embryonic and early postnatal periods. ICC showed that GluR1 expression within different brain regions is regulated developmentally and that distinct populations of cells show widely different temporal profiles of expression during maturation. In general, mature patterns of GluR1 localization are not reached until approximately postnatal day (P) 21. Cerebral cortex and hippocampus show low levels of GluR1 at P1 and a progressive growth-related enrichment, whereas striatum shows high levels of GluR1 at birth and a gradual reduction during maturation. In cerebellum, radial glial fibers show intense GluR1 immunoreactivity. GluR1 is highly expressed transiently by granule cells (P0-P11) and Purkinje cells (P13-P19), but, by P21, these neurons show scant GluR1 immunoreactivity. These results show that brain development in the rat is accompanied by both rapid and gradual changes in the regional and cellular expression of GluR1. These changes in AMPA GluR expression in the developing brain may be the result of cellular maturation or aspects of complex mechanisms that participate directly in cytodifferentiation.

379.4

ENTERIC NEURONS EXPRESS mRNA FOR THE NMDAR1 RECEPTOR. G.A. Burns* and K.E. Stephens. Department of VCAPP, Washington State University, Pullman, WA 99164-6520.

The distribution of glutamatergic neurons has been described in the central nervous system (Greenamyre, *et al.*, *J. Neurosci.*, 1984 48:2133-44). More recent electrophysiological results indicate that glutamate may be an important excitatory neurotransmitter in the enteric system as well. Exogenous L-glutamate induces contraction of ileal longitudinal smooth muscle/mesenteric plexus preparations, principally via NMDA receptors (Wiley, *et al.*, *Am. J. Physiol.*, 1991 261:G693-G700). However, an actual glutamatergic enteric neuronal subpopulation remains to be identified. In this study, samples from the jejunum, ileum, cecum, and descending colon of perfused, adult Sprague-Dawley rats were processed for *in situ* hybridization histochemistry. Serial, longitudinal (10 μ) sections from these samples were hybridized with a 1.4 kb riboprobe, cleaved from a recently characterized NMDAR1 receptor clone (Moriyoshi, *et al.*, *Nature*, 1991 54:31). The riboprobe was transcribed in the presence of digoxigenin-UTP. An enzyme-catalyzed nitroblue tetrazolium color reaction was employed to detect digoxigenin-labeled hybridization products. Enteric neurons expressing mRNA for the NMDAR1 receptor were present within myenteric and submucosal ganglia at all the sites sampled. Discrete, labeled nerve cell bodies were typically nestled among many non-reactive perikarya in any given ganglion. These data localize a population of neurons capable of manufacturing NMDA receptors to the enteric nervous system.

379.5

NMDA R1 RECEPTOR mRNA EXPRESSION IN THE HYPOTHALAMUS OF INTACT, CASTRATE AND DHT-TREATED MALE RATS. L.Kus¹, A.J. Beitz¹, J.E. Kerr², R.J. Handa². Dept. Vet. Pathobiology¹, Univ. of Minnesota, St. Paul, MN 55108 and Dept. Cell Biology, Neurobiology and Anatomy², Loyola Univ. Chgo., Maywood, IL 60153.

Glutamate is believed to be the main excitatory neurotransmitter within the hypothalamus. Administration of glutamate to hypothalamic fragments *in vitro* has been shown to stimulate the release of several hormones including GnRH, α MSH, AVP and somatostatin. This study examines the distribution of mRNA for the glutamate receptor subtype NMDA R1. Using a ³³P-dATP labeled antisense oligonucleotide probe, we examined the distribution and regulation of NMDA R1 mRNA in the hypothalamus of intact, castrate, castrate-DHT (2.5 cm Silastic implant) and intact-DHT-treated adult male Sprague-Dawley rats. Rats were sacrificed 21 days after castration and brains were processed for *in situ* hybridization. In intact rats, the highest levels of NMDA R1 mRNA were observed in the supraoptic, suprachiasmatic and paraventricular nuclei; intermediate levels were observed in the arcuate nucleus, ventromedial nucleus and medial preoptic area; and low levels were observed in the bed nucleus, lateral preoptic area, lateral hypothalamic area and lateral septum. This distribution correlates with the known effects of glutamate on hormone secretion. Neither castration nor DHT treatment had an effect on NMDA R1 mRNA expression in any of the areas examined. This suggests that expression of NMDA R1 mRNA in the hypothalamus is not under the control of testosterone. (NSF BNS 9109226, NIH DA06687, DE06682, DC01086)

379.7

CELLULAR LOCALIZATION OF NMDAR-1 IMMUNOREACTIVITY IN THE CNS. T. Görcs¹, Z. Vidnyánszky¹, Z. Katarova², J. Háromi¹, and I. Mody³. ¹Neurobiology Laboratory, United Res. Org. Hung. Acad. Sci. & Semmelweis Univ., Budapest, Hungary, ²Biol. Res. Ctr. Hung. Acad. Sci., Szeged, Hungary, and ³Depts. of Anesthesiology & Neurology, UT Southwestern Med. Ctr., Dallas, TX.

The physiology, pharmacology, distribution and molecular biology of NMDA receptors is relatively well established. However, no information is available about the ultrastructural localization of these receptors in the mammalian CNS. To determine the cellular localization of NMDA receptors, polyclonal antibodies were raised in rabbits against two unique extracellular domains of the NMDAR-1. The two antibodies immunolabeled the same molecular mass (\approx 100 kDa) protein band in Western blots of rat brain synaptosomal and microsomal membrane preparations. Light microscopic immunohistochemistry revealed a localization of NMDAR-1 immunoreactivity (NMDAR-1-IR) consistent with previous ligand autoradiography and *in situ* hybridization studies. For example, in the hippocampal formation, the CA1 and dentate regions were diffusely but heavily labeled whereas the CA3 region showed only light immunoreactivity.

At the electron microscopic level, the NMDAR-1-IR was confined to postsynaptic structures and subsynaptic apparatus of asymmetrical synapses. In the hippocampal formation, the immunoreactivity could be observed on dendritic spine heads. NMDAR-1-IR was never found to be associated with symmetrical synapses.

The availability of antibodies to NMDAR-1 and their use for simultaneous immunohistochemical studies with anti-mGluR antibodies will constitute a valuable tool in elucidating the ultrastructural correlates of long-term alterations in neuronal excitability such as LTP and LTD.

379.9

THE DISTRIBUTION OF GLUTAMATE RECEPTOR SUBTYPES IN THE NORMAL HUMAN ENTORHINAL CORTEX.

J. T. Noga*, T.M. Hyde, R.C. Saunders, D.R. Weinberger, J.E. Kleinman. Neuropathology Laboratory, Clinical Brain Disorders Branch, NIMH, Washington, D.C. 20032

Glutamate receptors are involved in numerous fundamental brain processes. They may play a role in disease processes in Alzheimer's disease, hypoxic brain injury, amyotrophic lateral sclerosis, schizophrenia, and Huntington's disease. The entorhinal cortex (EC) is greatly affected in Alzheimer's disease and likely in schizophrenia; it receives and sends fibers linking associative sensory regions, limbic structures, and cortical regions. We examined the distribution of several glutamate binding sites (tritiated MK-801, CNQX, and kainic acid to label NMDA, AMPA, and kainate receptor sites, respectively; and tritiated D-Aspartate as a label for glutamate terminals) using autoradiography. Twenty micron thick coronal sections of normal human brain were taken from five post-mortem specimens throughout the rostral-caudal extent of the EC and hippocampus. Sections were incubated and apposed to film to make autoradiograms. Review of the autoradiograms, comparing specific to nonspecific binding, revealed the following: MK-801 specific binding was uniformly greater throughout EC without a selective laminar pattern; CNQX bound markedly in a consistently laminar pattern in superficial layer 3 and in layers 5/6 throughout the rostral-caudal extent of EC; kainate strongly labeled layers 5/6 of EC consistently, with less strong, nonlaminar binding in other layers; D-Asp labeled EC layers 1, superficial 3, and 5/6 in a consistently laminar pattern. We conclude that there is a differential mapping in human EC of the glutamate receptor subtypes studied.

379.6

DIFFERENTIAL LOCALIZATION OF A METABOTROPIC GLUTAMATE (mGluR1 α) AND THE NMDAR-1 RECEPTOR IN THE CEREBELLAR CORTEX: AN IMMUNOCYTOCHEMICAL STUDY. Z. Vidnyánszky¹, J. Háromi¹, D. D. Schoepp², I. Mody³, and T. Görcs¹. Neurobiology Laboratory, United Res. Org. Hung. Acad. Sci. & Semmelweis Univ., Budapest, Hungary, ²CNS Research, Eli Lilly & Co., Indianapolis, IN, and ³Depts. of Anesthesiology & Neurology, UT Southwestern Med. Ctr., Dallas, TX.

Polyclonal antibodies raised against the C-terminus of mGluR1 α and NMDAR-1 receptors were used for the immunocytochemical localization of these receptors within the cerebellar cortex. mGluR1 α was mostly found in Purkinje cells, though some immunolabeling was also observed in basket and Golgi neurons. Most conspicuous was the labeling of dendritic spines, and particularly of postsynaptic specializations in contact with the glutamatergic presynaptic terminals of parallel fiber axons. Golgi cell dendrites in the granular layer were also strongly stained, while granule cells, their processes, as well as glial cells remained unstained. Conversely, the NMDAR-1 antibody labeled the dendrites of granule cells, the presynaptic parallel fibers, and a moderate number of glial processes in the molecular layer.

The postsynaptic localization of the mGluR1 α receptor at parallel fiber-Purkinje cell synapses may constitute the morphological basis for the long-term depression of synaptic transmission seen in the cerebellar cortex. The NMDAR-1 receptors are predominantly localized to another excitatory synapse: the synapse between the glutamatergic mossy terminals and granule cells.

Supported by the OTKA S-6066 (Z.V.), 26172 (J.H.), 1107 (T.G.), NINDS grants NS-27528, and the Pimley Research Fund (I.M.).

379.8

CELLULAR LOCALIZATION AND LAMINAR DISTRIBUTION OF NMDAR1 mRNA IN THE RAT CEREBELLAR CORTEX. E. Contini*, A. Minelli*, M. Molnar*, and N.C. Brecha*. ¹Institute of Human Physiology, University of Ancona, Via Ranieri, I-60131 Ancona (Italy), and ²Depts. of Anatomy and Cell Biology and Medicine, UCLA School of Medicine, Los Angeles, CA 90073 (USA)

The cellular localization and laminar distribution of NMDAR1 mRNA have been studied in the neocortex of adult rats by *in situ* hybridization using cRNA probes.

Sections incubated with ³⁵S-labeled sense RNAs were used for specificity controls and for assessing the background level using a semiquantitative analysis. The vast majority of neurons from these series were associated with 5 or less grains. This value was considered as the background level of labeling. In sections incubated with ³⁵S-labeled antisense RNAs, few cells were negative, some were associated with few grains, while a large number of cells were associated with numerous silver grains. The vast majority of cells not associated with silver grains were immunoreactive to a antibody to GFAP, thus indicating that astrocytes do not contain or have low levels of NMDAR1 mRNA. A semiquantitative evaluation of 2,789 neurons revealed that 1.4% were not associated with silver grains, and that the remaining 2,749 neurons were associated with a variable number of grains. The number of grains was counted and neurons were grouped into 5 classes: A (\leq 5 grains), B (6-15), C (16-25), D (26-35), and E (\geq 36). The number of neurons belonging to each of these classes were then evaluated as a function of cortical layer. In layer I most neurons were in classes A and B, whereas in layers II-III and V-VI the majority of neurons were in classes B-E. In contrast, most layer IV neurons were in classes A-C, while only a few were in class E.

These results indicate that virtually all cells containing NMDAR1 mRNA in the cerebral cortex of adult rats are neurons, that about 90% of cortical neurons express NMDAR1 mRNA and that they can be divided into several groups on the basis of the levels of mRNA. The existence of several classes of neurons expressing NMDAR1 indicates that the amount of mRNA, and thus the number of NMDA receptors, may be a critical factor for determining the effect of NMDA receptor activation, while the differential laminar distribution of the several classes suggests that NMDA receptors affect differentially the various stages of cortical processing.

379.10

IDENTIFICATION OF GLUTAMINE SYNTHETASE mRNA FROM RAT SPINAL CORD. B. Srinivasan* and K.E. Miller. Dept. Anatomical Sciences, Oklahoma Center for Neuro-Sciences, Univ. Oklahoma Health Sciences Center, Oklahoma City, OK 73190.

Glutamine synthetase (EC 6.3.1.2) is the enzyme that catalyzes the amidation of glutamate to glutamine and is a key component of the glutamate/glutamine cycle. Immunohistochemical studies have demonstrated that glutamine synthetase is localized to glia in the CNS (A. Martinez-Hernandez, K.P. Bell, M.D. Norenberg, *Science* 195:1356, 77). As part of a coordinated approach to the study of the genetic regulation of the glutamate enzyme system in the spinal cord, the present study examined the mRNA for glutamine synthetase using slot blot and Northern blot analysis. Spinal cords, brains, and kidneys from rats were rapidly removed, polyA⁺ mRNA was extracted, and a slot blot and Northern blot were prepared. ³²P-labelled glutamine synthetase cDNA (source: ATCC; 1.6 KB insert, plasmid pBR322, PstI site, ϕ M Burns, ...R.E. Miller, *Bioch. Biophys. Res. Comm.* 134:146, '86) was used to probe RNA blots. Glutamine synthetase mRNA was found in high abundance in spinal cord, brain, and kidney. The abundance in spinal cord was higher than our previous report for glutaminase mRNA. Northern blot analysis showed 3 bands: one corresponding to 6Kb and dimers of 2Kb and 1.8Kb. *In situ* hybridization studies are in progress to localize glutamine synthetase mRNA in spinal cord sections. Supported by NS27213 (KEM).

379.11

COLOCALIZATION OF TYROSINE HYDROXYLASE AND GLUTAMATE IN LOCUS COERULEUS: A FLUORESCENCE IMMUNOHISTOCHEMICAL STUDY IN THE RAT, MOUSE, AND KITTEN. V.K. Reddy, S.J. Fung*, R.-H. Liu, Z. Wang and C.D. Barnes. Dept. of VCAPP, Washington State University, Pullman, WA 99164-6520. The central noradrenergic nucleus locus coeruleus (LC) with its diverse axonal trajectories is well-known for its chemically heterogeneous nature (Reddy et al., *Prog. Brain Res.* 88: 103, 1991). In addition to the peptide cotransmitters, the putative excitatory transmitter glutamate (GLU) has also been demonstrated in the LC neurons. In this study we attempted to compare the extent of colocalization of tyrosine hydroxylase (TH) and GLU in LC neurons of the mouse, rat and kitten. Subsequent to perfusion, frozen (coronal) sections of the brainstem were processed, under proper immunostaining control conditions, by the method of Wessendorf and Elde (*J. Histochem. Cytochem.* 33: 984, 1985). Further experiments were performed, in rats, to demonstrate the colocalization of TH and GLU in coeruleo-cortical neurons by using the combined retrograde tracing (with rhodamine-labeled latex microspheres) and dual immunofluorescence labeling techniques (Zhuo et al., *J. Chem. Neuroanat.* 5: 1, 1992).

TH neurons that contain GLU were present in the LC of all three species. In addition, in the kitten such colocalization of TH and GLU was also evident in several nuclear groups of the dorsolateral pontine tegmentum. Preliminary data from these studies indicate that a majority (90%, kitten; 75%, mouse; 56%, rat) of TH immunoreactive neurons in the LC also cocontain GLU. Our data in the rat also demonstrated a substantial population of coeruleo-cortical neurons to cocontain TH as well as GLU. These data provide an anatomical substrate for LC regulation of its target neurons by the release of GLU and NE at axon terminals.

DISTRIBUTION OF N-ACETYL-ASPARTYL-GLUTAMATE (NAAG)- AND NAALADASE-IMMUNOREACTIVITIES IN PERIPHERAL NERVOUS SYSTEM. U. V. Berger*, R. E. Carter and J.T. Coyle. Laboratory of Molecular and Developmental Neuroscience, Massachusetts General Hospital, Boston, MA 02129.

The acidic dipeptide NAAG is localized to neurons, released upon electrical stimulation and catabolized to free glutamate by the peptidase, NAALADase. Though the function of NAAG in the CNS is unknown, it may serve as a neurotransmitter, neuromodulator and/or precursor for synaptic glutamate. Several studies have described the distribution of NAAG and NAALADase in the CNS, yet little is known about their localization and function in the peripheral nervous system. Thus, the anatomical distribution of NAAG and NAALADase was investigated in rat retina, dorsal root ganglion (DRG), sciatic nerve, and phrenic nerve at the level of diaphragmatic innervation, using an affinity-purified polyclonal antiserum against NAAG and a specific polyclonal antiserum against NAALADase. Consistent with previous findings in retina, NAAG-like immunoreactivity (LI) was seen in retinal ganglion cells, cells of the inner nuclear layer and in inner and outer plexiform layers. NAALADase-LI was also localized to inner and outer plexiform layers, supporting previous proposals that NAAG may have physiologic actions in the visual system. Consistent with previous findings in the DRG, NAAG-LI was present in ganglion cell bodies and in dorsal and ventral root fibers. NAALADase-LI was localized in DRG to a subset of Schwann cells and to satellite cells supporting the ganglion cells. In sciatic and phrenic nerves, NAAG-LI was observed in virtually all axons, while NAALADase-LI was localized to Schwann cells. In the diaphragm, both NAAG- and NAALADase-LI appeared to be present at the neuromuscular junction. These results suggest that in peripheral nerves NAAG is broadly distributed in axons, while NAALADase appears to be localized primarily to Schwann cells.

ESTRADIOL REGULATES HIPPOCAMPAL DENDRITIC SPINE DENSITY VIA AN NMDA RECEPTOR DEPENDENT MECHANISM. C.S. Woolley* and B.S. McEwen. Lab. of Neuroendocrinology, Rockefeller Univ., New York, NY 10021.

We have previously shown that the density of dendritic spines and synapses associated with dendritic spines on hippocampal CA1 pyramidal cells in the adult female rat are sensitive to ovarian steroids: Ovariectomy results in a decrease in spine and synapse density which can be prevented by administration of estradiol. Furthermore, there is a naturally-occurring fluctuation in the density of hippocampal spines and synapses as ovarian steroid levels rise and fall during the estrous cycle. These morphologic changes correlate well with estradiol effects on hippocampal excitability and seizure susceptibility.

The apparent lack of receptors for estradiol in CA1 pyramidal cells suggests that the effects of this hormone on spine and synapse density may be mediated indirectly, perhaps by an afferent population. In order to investigate the possibility that either excitatory amino acid or cholinergic neurotransmission is involved in the effects of estradiol on dendritic spine density, we have analyzed the density of dendritic spines on Golgi-impregnated CA1 hippocampal pyramidal cells in ovariectomized animals treated concurrently with estradiol and specific excitatory amino acid or cholinergic receptor antagonists. Treatment with the non-competitive NMDA receptor antagonist, MK 801 (0.2 mg/kg) inhibits the effect of estradiol on dendritic spine density. This result was confirmed using a competitive NMDA receptor antagonist. In contrast to treatment with NMDA receptor antagonists, treatment with either the AMPA receptor antagonist, NBQX (30 mg/kg) or the muscarinic receptor antagonist, scopolamine (2 mg/kg) fails to inhibit the effect of estradiol. These results demonstrate that the effects of estradiol in regulation of dendritic spine density require activation of NMDA, but not AMPA or muscarinic, receptors.

N-ACETYLASPARTYL-GLUTAMATE (NAAG) STUDIED IN MEDIAL PREFRONTAL CORTEX IN RATS USING *IN VIVO* MICRODIALYSIS. S. Fuhrman* and J. H. Neale. Department of Biology, Georgetown University, Washington, DC 20057.

N-acetylaspartylglutamate (NAAG), a highly prevalent peptide in the vertebrate nervous system, may function in neurotransmission. It is hydrolyzed to N-acetylaspartate (NAA) and glutamate by a membrane-bound peptidase, which has been shown to be extracellular in brain cell cultures. This peptidase may inactivate NAAG after synaptic release of the peptide. Conversely, NAAG may act as an alternate source of glutamate.

The level of NAAG in the extracellular space was studied using the technique of *in vivo* microdialysis to sample the extracellular fluid. Using anesthetized rats, microdialysis probes were stereotactically inserted into the medial prefrontal cortex, while the probes were perfused with artificial cerebrospinal fluid. Microdialysate fractions were collected and assayed for NAAG using a radioimmunoassay. The concentration of NAAG in the dialysate was approximately 0.5 μ M at a perfusion flow rate of 1 μ l/min. The basal NAAG level in the extracellular space was calculated to be approximately 10 μ M, based on the relative recovery of NAAG from a standard concentration of NAAG *in vitro* at room temperature. The extracellular NAAG concentration in cortex may be compared with the overall concentration in microdissected samples of cortex of approximately 330 μ M (4.7 nmol/mg soluble protein).

Using microdialysis, the synaptic release of NAAG, glutamate, and NAA, as well as the role of peptidase activity against NAAG, will be investigated in the cerebral cortex of the rat.

PTERIN-DEPENDENT MONOOXYGENASE AND NITRIC OXIDE SYNTHASE COFACTOR EXPRESSION: LOCALIZATION OF GTP CYCLOHYDROLASE I (GTPCH) mRNA IN THE RAT BRAIN. S.I. Lentz*, K. Hirayama and G. Kapatos. Cellular and Clinical Neurobiology Program, Dept. of Psychiatry, Wayne State Univ. Sch. of Med., Detroit, MI 48201

GTP cyclohydrolase I (GTPCH) is the first and rate-limiting enzyme in the tetrahydrobiopterin (BH4) biosynthetic pathway. BH4 is the essential cofactor for the pterin-dependent monooxygenases which include tyrosine and tryptophan hydroxylase, enzymes that are rate limiting in the biosynthesis of catecholamines and indolamines. BH4 is also required as a cofactor for the family of nitric oxide synthases. The *in situ* hybridization technique was used to study the cellular localization and the relative level of expression of GTPCH mRNA in the rat brain. Coronal sections of 10 μ m were taken every 0.4 mm between the diencephalon and the myelencephalon. A 302 bp coding portion of GTPCH cDNA was cloned and used to generate ³⁵S-CTP-labelled antisense cRNA probe for the hybridization reaction. For autoradiography, slides were dipped in nuclear track emulsion, exposed at 4°C for 4 to 6 weeks, developed, counterstained, and visualized under darkfield illumination. The nomenclature first described by Dahlström and Fuxe in 1964 was used to identify catecholamine and 5-hydroxytryptamine containing cell groups. Neurons containing GTPCH mRNA in the rat brain corresponded to the known monoaminergic cell groups. The level of GTPCH mRNA expression varied across cell groups with high levels seen in serotonergic neurons (B1-B9) and noradrenergic neurons (A6), moderate levels in dopaminergic neurons (A5, A7, A8, and A10), and low levels seen in dopaminergic neurons (A9, A12-A15). Under the hybridization and autoradiographic conditions used in this study, GTPCH mRNA could not be unequivocally localized to any cell-type within the olfactory bulb, cerebellum or hippocampus, brain regions known to contain large numbers of nitric oxide synthase-positive neurons. GLUTAMATE RELEASE IN RAT STRIATUM PROMOTED BY STIMULATION OF THE CORTICOSTRIATAL PATHWAY IN A COMPLEX SLICE PREPARATION. S. Bernath*, T.W. Berger* and M.J. Zigmond. Univ. Pittsburgh, Pittsburgh, PA 15260 & *Univ. Southern California, Los Angeles, CA 90089

Traditionally, *in vitro* studies of transmitter release use electrical and chemical stimuli which depolarize the entire preparation. We have developed an experimental preparation to study the release of glutamate by selectively stimulating the corticostriatal pathway in a complex slice. Horizontal slices (400 μ m) containing the striatum and the adjacent anterior cortex of rat brain were cut with a Vibratome. Slices were transferred to a submerged plexiglass recording chamber, and maintained at a temperature of 35°C. Bipolar stimulating electrodes made from teflon-coated silver wire (50 μ m in diameter) were placed in the subcortical white matter. Neuronal fibers were stimulated, and extracellular responses of single action potentials were recorded to test the integrity of stimulated pathway within the slice. Next, a glass capillary was positioned above the activated striatal area and 20 sec samples were collected. Corticostriatal fibers were stimulated twice for 30 sec by unipolar square wave pulses (0.6 mA, 100 μ sec pulse duration, 10 Hz) with 25 min between the two stimulation periods. Samples were analyzed for their amino acid content by HPLC with fluorometric detection. Stimulation of afferent nerve fibers elevated the extracellular concentration of endogenous glutamate about 6-fold (5.7 \pm 1.4; n=4). A similar response usually was observed to the second stimulation. These results demonstrate that glutamate can be released via stimulation of glutamatergic nerve fibers. REGULATION OF 3H-D-ASPARTIC ACID (3H-D-ASP) UPTAKE IN TEMPORAL CORTEX AND HIPPOCAMPAL SLICES. M.J. MELDRUM*, N. NWANNA, P.M. PETTY. Dept. of Pharmacodynamics, Univ. of Florida, Gainesville, FL 32610

Endogenous excitatory amino acid induced excitotoxicity has been implicated in several neurodegenerative diseases. In previous studies on endogenous glutamate release using KCl as the stimulus, the release increased in a linear fashion up to KCl concentrations of 100 mM. This data suggested that depolarization with KCl may have an effect on the uptake system which was reflected as increased release. We have therefore tried to characterize the uptake system using 3H-D-Aspartic acid (3H-D-ASP) (an unmetabolized marker for glutamate uptake) in the same slice system used to measure release. Slices were prepared and preincubated for 30 min. in 1 ml Krebs-Ringer-Bicarbonate buffer at 37° C and bubbled with 95%O₂/5%CO₂. Total uptake was measured after a 5 min exposure to 3H-D-ASP (650,000 DPM). Non-specific uptake was measured in similar slices incubated at 4° C. At the end of the 5 min incubation period the slice were filtered rapidly over GF/C glass fiber filters and washed twice with 5 ml of ice-cold buffer. The slices were then placed in scintillation vials with 10 ml cocktail and vigorously vortexed several times. The vials then allowed to sit overnight were vortexed again and counted. Specific uptake was the total minus that at 4° C. Specific uptake was time and temperature dependent and dose dependently inhibited by glutamate and D-Threo-B-hydroxyaspartic acid. Uptake was inhibited in a dose dependent fashion by KCl (56-100mM), uptake was inhibited to the same extent with CH₃COOK suggesting the role of potassium. Veratridine (20 μM) also inhibited uptake. The uptake was also very sensitive to O₂ as either the bubbling of the buffer with nitrogen or the removal of the O₂ tube from the solution decreased uptake to the same extent. These data suggest that the regulation of 3H-D-ASP uptake is very sensitive and can be modified easily and may need to be taken into account when glutamate activity in slices is measured. SYNAPTOSOMAL PRESENCE OF THE GLYCINE-SITE AGONIST OF THE NMDA RECEPTOR, D-SERINE, VERSUS REGIONAL WHOLE-TISSUE LEVELS. M.L. Chouinard*, D. Gaitan and P.L. Wood.

Research Dept. Mayo Clinic, Jacksonville, FL 32224

Glycine, which has several metabolic fates and which modulates diverse neuronal signals is thought to serve as the most probable coagonist of the NMDA receptor. However, the recent discovery of endogenous D-serine (D-S), at levels rivaling free glycine in cortex of adult rat brain (Hashimoto et al. 1992, 1993), indicates that D-S needs to be assessed as an alternative NMDA receptor glycine-site agonist.

The observation of endogenous D-S in several rat brain regions has been extensively reconfirmed in our laboratory with highest levels observed in neocortex where D-S was 35% of the free L-S and levels. In an effort to further evaluate the tentative role of D-S as an excitatory transmitter, D-S was measured relative to L-S and glycine in two astrocytic cell lines (Cambier & Pessac, 1987) and in P2 synaptosomal preparations in an effort to localize specific cellular and subcellular pools of D-S. We observed extremely low levels of D-S in cerebellar type III (granular) and type II (molecular) layer-derived astrocytes, similar to levels in cerebellum, which coincides with the observation of high levels of D-amino acid oxidase in normal type II and type III astrocytes. Recently D-S has been proposed as the major physiological substrate for D-amino oxidase in mouse cerebellum (Y. Nagata, 1992). The distribution of synaptosomal levels of D-S was similar to that observed in whole tissue with highest levels in cortex followed by hippocampus, striatum, septum and cerebellum. However, D-S levels in cortical synaptosomes, when expressed relative to L-S, were 15-19% higher than in whole tissue. Thus, considering the diverse metabolic fates of glycine and the synaptosomal levels of D-S relative to L-S (a direct glycine precursor), we conclude that D-S is a potential alternative to glycine as a NMDA receptor coagonist in several brain regions.

ATP RELEASES EXCITATORY AMINO ACIDS FROM CULTURED GLIA IN A CALCIUM-DEPENDENT MANNER. E.Liu*, K.Jefitnjia, and S.Jefitnjia. Department of Veterinary Anatomy and Neuroscience Program, Iowa State University, Ames, IA 50011, USA.

Although it has been shown that adenosine 5'-triphosphate (ATP) induces changes in intracellular calcium in glia, relatively little is known about the processes that are influenced by increases in intracellular calcium in glial cells. The specific objective of this study was to study the mechanism by which ATP releases excitatory amino acids (EAA) from cultured peripheral and central glia. Disassociated rat sciatic nerve schwann glia and cerebral cortical glia cultures were grown on polylysine coated coverslips. Cultures were mounted in a perfusion chamber and perfused at a rate of 200 μl/min, with gassed Ringer solution at 36±1° C. Quantification of amino acids was performed by high performance liquid chromatography utilizing fluorescence detection and pre-column OPA-derivatization. Following a period of culture equilibration, 1 min, 200 μl samples were collected. Baseline concentrations of Asp and Glu in schwann glia cultures were 6.7±0.6 nM (mean±SEM) and 26.6±2.1 nM, respectively. Perfusion application of 100 μM ATP for 1 min to schwann glia resulted in an 179±4% increase of Asp and 21±10% increase of Glu release. A second application of ATP 10 min after first application resulted in a increase in the release of both EAAs that was at the level of 42% of that from the first application. Five min application of ATP to glial resulted in a peak increase in the release followed by a decline to a plateau significantly higher than baseline release. Bath application of adenosine (100 μM) was without effect on release of EAA suggesting involvement of P₂ receptors. Similar results were obtained with cortical glia (>90% GFAP positive). The release of EAA evoked by ATP was not abolished in low Ca-EGTA solution. Pretreatment of the glia cultures with 50 μM BAPTA-AM abolished the effect of ATP. Our results show that ATP selectively evokes the release of EAAs from cultured glia by activating intracellular calcium stores. Work was supported by NIH Grant NS27751.

ASPARTATE (ASP) AND GLUTAMATE (GLU) MODULATION OF GH SECRETION IN THE PIG: POSSIBLE SITE OF ACTION.

C.R. Barb*, R.M. Campbell, J.D. Armstrong, N.M. Cox. USDA-ARS, Athens, GA 30613, Hoffmann-LaRoche, Nutley, NJ 07110, North Carolina State Univ., Raleigh 27695 and Mississippi State Univ., Starkville 39762

In Exp I four female pigs each (70.6 ± 1.3 kg), received iv 50, 100 or 150 mg/kg BW of ASP or GLU. In Exp II OVX female pigs (163 ± 10 kg) immunized against GRF (1-29; n=4) or vehicle (V; n=5) received 150 mg/kg BW ASP or GLU iv in a 2 x 2 factorial design then repeated in a crossover design. In Exp III pig pituitary cells in culture were treated with 10⁻⁸, 10⁻⁶, or 10⁻⁴ M ASP or GLU. In Exp I GH response was greater (P<0.01) after ASP than GLU. Prior to treatment, GH was 1.8 ± 0.1 ng/ml but increased (P<0.01) to 3.8, 4.4, and 9.2 ng/ml (SEM = 0.4) and 2.4, 2.8 and 5.2 ng/ml (SEM = 0.4) after 50, 100 and 150 mg doses of ASP and GLU, respectively. In Exp. II GH increased (P<0.01) only in V pigs and avg. 1.2 ± 0.2 ng/ml before and 5.0 ± 0.4 ng/ml and 4.0 ± 0.3 ng/ml first h after ASP or GLU, respectively. In GRF pigs, GH avg. 1.2 ± 0.1 ng/ml and was unchanged. In Exp. III relative to controls (40 ± 6 ng/ml), GH increased (P<0.01) 1.9, 2.1 and 2.4 fold and 2.2, 2.2 and 2.5 fold after 10⁻⁸, 10⁻⁶ and 10⁻⁴ M ASP or GLU, respectively. Therefore, ASP is a more potent secretagogue of GH secretion than GLU, while modulation of GH secretion may occur at both pituitary and brain.

EXCITATORY AMINO ACIDS: PHARMACOLOGY IV

IN VIVO MONITORING OF GLUTAMATE BY MICRODIALYSIS, CAPILLARY ELECTROPHORESIS AND LASER INDUCED FLUORESCENCE DETECTION. L. Hernández*, S. Tucci, E. Murzi, X. Paez and T. Baptista. Laboratory of Behavioral Physiology, Medical School, Los Andes University, Mérida 5101, Venezuela

Low mass sensitivity of the analytical techniques hinders *in vivo* monitoring glutamate by microdialysis. HPLC and Electrochemical Detection has picomole (10⁻¹² moles) detection limit. For this reason, long collection times (one or more minutes) and large sample volumes (5 microliters or more) are required, resulting in poor time resolution. In addition, high flow rates of perfusion (1 microliter/minute or more) cause neurotransmitter depletion around the probe [1]. Capillary electrophoresis with confocal laser induced fluorescence detection (CE-LIFD) has zeptomole (10⁻²¹ moles) detection limit [2]. Sample volumes for CE-LIFD are nanoliters or less. We successfully measured, with microdialysis and CE-LIFD, release of glutamate every five seconds in the striatum during prefrontal cortex electrical stimulation, release of glutamate in the nucleus accumbens every minute during amygdaloid kindling and release of glutamate every 20 minutes during acute administration of neuroleptics. After electrical stimulation of the prefrontal cortex or the amygdala, glutamate increased in striatal and accumbens dialysates. Acute haloperidol administration, decreased glutamate in striatal dialysates. CE-LIFD improves time resolution of brain microdialysis and lowers the perfusion flow rate to 100 nanoliters/minute or less, to prevent neurotransmitter emptiness around the probe.

380.2

IN VIVO RELEASE OF ARGININE FROM RAT VENTROBASAL THALAMUS EVOKED BY SENSORY AFFERENT STIMULATION. 1.K.Q. Do*, 2.S.A. Eaton, 2.K.E. Binns and 2.T.E. Salt, ¹Brain Res. Inst., Univ. of Zürich, ²Dept. Visual Science, Inst. Ophthalmology, London EC1V 9EL, UK

We have investigated the possibility that various amino acids may be transmitters of sensory transmission in thalamus. Dual cannulae were introduced in the ventrobasal thalamus of urethane-anaesthetised rats. This allowed extracellular recording of neurone activity in response to either electrical or natural stimulation of vibrissa afferents together with push-pull perfusion (15-20 μl/min) of the surrounding brain tissue. Successive 1 minute perfusion fractions were assayed with precolumn derivatization HPLC which allowed detection of amino acids at the femtomole level. The extracellular level of arginine (Arg) was raised above levels already present in the perfusate (4-12 pmol/min) during or after a 4 minute period of either electrical or air jet stimulation within the receptive field of neurones which could be recorded near the perfusion site. In some experiments, it was also possible to detect increased levels of glutamate or aspartate during or after stimulation. In separate experiments, iontophoretic application of L-Arg onto thalamic neurones was found to inhibit responses to sensory stimulation, and iontophoretically applied NMDA or AMPA. However, on some neurones, it was possible to observe a facilitatory action of L-Arg at lower iontophoretic application currents. This stimulation-induced Arg release could reflect either an intercellular messenger role of Arg or an intercellular transfer of Arg, possibly as a precursor for nitric oxide, due to metabolic demand.

380.3

RELEASE OF EXCITATORY AMINO ACID NEUROTRANSMITTERS AND GLUTAMINE WITH AGE IN THE NEOSTRIATUM OF THE CONSCIOUS RAT. A. Porras, C.V. Gisolfi, and F. Mora* Dept. Physiology, Faculty of Medicine, Univ. Complutense of Madrid, 28040 Madrid, SPAIN and Dept. Physiology, Univ. of Iowa, Iowa City, IA 52242, USA.

The effects of age on the extracellular concentrations of glutamate [GLU], aspartate [ASP], and glutamine [GLN] were studied in the neostriatum of the conscious rat. For that a modified continuous push-pull perfusion system was used. After baseline for levels of amino acids was established (50 min), 10 min samples were collected for a total time of 30 min. Groups of rats of 3-4, 12-13, 21-24, and 32-34 months of age were used. Amino acids were analyzed as OPA-derivatives with an HPLC-fluorometric detection technique. The extracellular [GLU] showed an age-related decrease ($r = -0.17$, $p < 0.05$, $n = 191$) while [GLN] showed an age-related increase ($r = 0.19$, $p < 0.01$, $n = 198$). Extracellular [ASP] did not change during aging ($r = 0.08$, N.S., $n = 191$). Since astrocytes are the main source of GLN in the brain and also these cells are the main compartment for GLU reuptake, the increase in [GLN] and the decrease of [GLU] with age could indicate an increase of astrocyte activity and/or astrocyte proliferation in the neostriatum of the rat during aging. Also the possibility exists for the decrease of [GLU] be a consequence of the degeneration of the cortico-striatal glutamatergic pathway during aging.

SLOW RHYTHMIC BURSTS PRODUCED BY CA3 NEURONAL CIRCUIT IN THE HIPPOCAMPUS. R. Bianchi* and R.K.S. Wong. Dept. of Pharmacology, SUNY-HSCB, Brooklyn, NY 11203.

In septo-hippocampal slices acutely isolated from adult guinea-pigs, we have recently shown that the muscarinic receptor activation by carbachol application or by electrical tetanic stimulation of the septal area induced slow rhythmic, synchronized depolarizations with spike discharge in CA3 hippocampal pyramidal cells (CA3 HPCs). Each bursting event (called 'phasic burst'; PB) lasted 8-50 s and repeated every 0.3-8.6 min. We observed a similar activity in CA3 HPCs of transverse hippocampal slices (18 out of 19) following addition of picrotoxin (50 μ M) to a solution containing excitatory amino acid receptor blockers (CNQX and CPP, 10-20 μ M each) and 4-aminopyridine (70 μ M). Such activity consisted of action potential discharge elicited by depolarizations (PBs) that lasted 6-28 s and repeated rhythmically every 2.9-9.7 min for up to 3 hours. Simultaneous intracellular recordings from two CA3 HPCs and paired intra- and extracellular recordings showed that the PBs were synchronized in the CA3 field. Paired CA3/CA1 recordings showed PBs in both fields; each PB in CA1 followed the one recorded in CA3 by 1-6 s. If the Schaffer fibers were cut, PBs were recorded only in CA3 and not in CA1. Phasic burst activity was also observed in 'minislices' containing only the CA3 field. These data indicate that the CA3 hippocampal neural network is able to produce a rhythmic, synchronized, excitatory activity in the presence of ionotropic excitatory and inhibitory amino acid receptors blockers.

380.7

ANESTHETIC ACTIONS ON GLUTAMATE AND GABA_A PATHWAYS: COMPOUNDS WHICH VIOLATE THE MEYER-OVERTON RULE J.J. Kendig, E.I. Eger II, P. Ionescu, M.J. Laster, and E.G. Giffard* Depts. of Anes., Stanford Univ. Sch. of Med., Stanford, CA 94305/UCSF, San Francisco, CA 94143

The Meyer-Overton rule relates general anesthetic potency to lipid solubility, but some compounds with large oil/gas partition coefficients are not anesthetics. To probe essential anesthetic actions, we compared two halogenated cyclobutanes, one an anesthetic and one not, on glutamate and GABA_A-mediated synaptic transmission in isolated neonatal rat spinal cord. 1-chloro-1,2,2-trifluorocyclobutane (Tri FCB) (1.7%) is anesthetic in rats (predicted minimal anesthetic concentration [MAC] 0.8%); 1,2-dichlorohexafluorocyclobutane (Hex FCB) (10%) is not anesthetic (predicted MAC 4.6%) and increases desflurane MAC by 30%. Spinal cords from 1 - 6 day old rats were arranged to record the monosynaptic reflex (MSR), AMPA-kainate; slow ventral root potential (sVRP), predominantly NMDA; and dorsal root potential (DRP), GABA_A. Tri FCB (0.8%) depressed sVRP (70%) and increased MSR latency with no effect on amplitude. Hex FCB (4.6%) slightly depressed sVRP, decreased MSR latency with no effect on amplitude and had no effect on DRP. Anesthetics previously tested markedly depress sVRP; some also enhance DRP. Depression of glutamate transmission may be essential to anesthesia, and increase in GABA_A contributory. MSR latency decrease by Hex FCB may be an anti-anesthetic effect.

380.4

DIFFERENTIAL REGULATION AND ION DEPENDENCE OF GLUTAMATE AND ASPARTATE RELEASE FROM CA1 SYNAPTOSOMES. C.P. Duncan*, M. Zhou and J.V. Nadler. Depts. Pharmacology and Neurobiology, Duke Univ. Med. Ctr., Durham, NC 27710.

Slices and synaptosomes prepared from hippocampal area CA1 release both glutamate and aspartate in a Ca²⁺-dependent manner. Previous studies of CA1 slices indicated that release processes for the two amino acids can be differentially altered. Because amino acid release studies in slices can be confounded by uptake processes and indirect effects, we continued this work with a CA1 synaptosome preparation. Synaptosomes were exposed twice for 1 min to 25 mM K⁺; test solutions were substituted for control medium beginning 4 min before the second exposure to elevated K⁺.

ISR,3RS-ACPD (100 μ M) selectively depressed glutamate release. 1S,3R-ACPD and 1R,3S-ACPD (50 μ M) were about equipotent, and the depression was reversed by 100 μ M L-AP3. Aspartate release was significantly depressed by 1SR,3RS-ACPD and L-AP3 together, but not by either ligand alone. NMDA increased and D-AP5 depressed aspartate release, but neither ligand affected the release of glutamate. A 4-min exposure to Na⁺-free medium (Na⁺ replaced by choline and tris; 1 μ M atropine) increased K⁺-evoked glutamate overflow from CA1 slices by 12-fold, presumably due to prevention of uptake, but had no effect in the synaptosome preparation. In contrast, Na⁺-free medium enhanced K⁺-evoked overflow of aspartate from CA1 slices by only 4-fold and it reduced synaptosomal aspartate release by 56%. These results suggest that glutamate and aspartate release processes are regulated by different autoreceptor mechanisms and that aspartate release depends on Na⁺ as well as Ca²⁺. (Supported by NIH grant NS 16064.)

GLUTAMATE: POSSIBLE TRANSMITTER ROLE IN APLYSIA CNS

JacSue Kehoe¹ and Ian Cooke*² ¹Laboratoire de Neurobiologie, Ecole Normale Supérieure, 75235 Paris Cedex 05, France; ²Békésy Laboratory of Neurobiology, University of Hawaii, Honolulu, HI 96822.

It has been known for decades that L-glutamate (Glu) can activate at least three distinct responses (K⁺, Cl⁻, and cationic) on central molluscan neurons. Kehoe (1978) showed quisqualate (Quis) selectively activates the K⁺- and ibotenate the Cl⁻-dependent response, whereas the cationic response was shown to be selectively transformed by conoanavalin A (ConA). Recent work confirmed these findings and showed that the Quis-sensitive K⁺ response could be blocked by arginine (Bolshakov et al. 1991) and induced by an agonist (Katz & Levitan 1993) of the metabotropic response in mammalian neurons. Using classical methods of Glu application, the cationic response could be observed on only a few cells, and often only on axonal membrane. After exposure to ConA it was present on most if not all neuronal somata. We now find, using fast (<20 ms) perfusion-stream switching, that a transient cationic response is detected on almost all cells. Recording during application of ConA, we observe the transformation of the transient to a sustained response; desensitization disappears. This receptor has resisted pharmacological characterization, being insensitive to agonists known to activate the five major categories of Glu receptors in mammalian neurons. However, CNQX, possibly a partial agonist on this receptor, selectively blocks this response. The revelation by the fast-perfusion technique of the prevalence of the cationic Glu response and use of new pharmacological tools has contributed to the identification in the buccal ganglion of *Aplysia* of presumed glutamatergic synapses. URETHANE DEPRESSES GLUTAMATE BUT DOES NOT ALTER GABA_A TRANSMISSION IN NEONATAL RAT SPINAL CORD

L. M. Gibbs*, A. P. Lozier, and J. J. Kendig, Dept. of Anes., Stanford Univ. Sch. of Med., Stanford, CA 94305

Urethane is an anesthetic commonly used in physiology but itself little studied. We compared urethane to other anesthetics in isolated spinal cord of neonatal rats. Cords were arranged to record the monosynaptic reflex (MSR), AMPA-kainate; slow ventral root potential (sVRP), largely NMDA; and dorsal root potential (DRP) evoked directly by muscimol (GABA_A) or through an interneuronal pathway from an adjacent dorsal root (glutamate and GABA_A). Urethane 20-40 mM reduced MSR amplitude and increased latency; 2-40 mM reduced sVRP amplitude and area under the curve. Muscimol evoked DRP was unaffected; dorsal root-evoked DRP was slightly reduced (20-40 mM). Effects were concentration-dependent and reversible. Isoflurane 0.2-1.2% reduced sVRP; 0.6-1.2% reduced MSR amplitude and increased latency. Isoflurane 1% increased muscimol-evoked but steeply reduced dorsal root-evoked DRP. Isoflurane is anesthetic at 1.4%; reported urethane anesthetic levels are 10-15 mM. Urethane is thus less effective than isoflurane in depressing AMPA-kainate pathways but acts similarly on sVRP. Unlike isoflurane, urethane does not affect GABA_A receptors. Caution should be used in employing urethane as an anesthetic in studies in which glutamate, particularly NMDA, synaptic transmission is a factor.

TRIPLE WAVELENGTH AND DIFFERENCE SPECTROPHOTOMETRIC DETERMINATION OF NITRIC OXIDE: AN *IN VITRO* AND *IN VIVO* MICRODIALYSIS STUDY. A. Balciglu* and T. J. Maher Mass. College of Pharm., Dept. of Pharmacology, Boston, MA., 02115.

We have previously developed and demonstrated the utility of an improved triple wavelength spectrophotometric technique for the quantification of nitric oxide (NO). The present study determined the applicability of this technique to microdialysis. Using a concentric microdialysis probe perfused with $1\mu\text{M}$ oxyhemoglobin, the exposure to the thiol-independent NO-generating agent sodium nitroprusside (1mM) enhanced the production of NO as determined by methemoglobin production. Additionally, we implanted such microdialysis probes into the CA3 region of hippocampus in urethane-anesthetized rats where the coordinates were AP - 5.3, RL 4.8, V 6.5 according to Paxinos and Watson. Following treatment with the known excitatory amino acid receptor agonist, kainic acid (13mg/kg, i.p.) increased the methemoglobin concentration from $2.2 \pm 0.1\text{nM}$ to $13 \pm 1.2\text{nM}$ ($p < 0.01$). Co-administration of the NO-synthase inhibitor, L-NMMA (50mg/kg, i.p.) attenuated the kainate-induced increase in NO concentration ($3.8 \pm 0.5\text{nM}$) ($p < 0.05$), compared to kainic acid.

These studies demonstrate the utility of hemoglobin trapping of NO in microdialysis applications, both *in vivo* and *in vitro*.

DIRECT AND INDIRECT MEASUREMENT OF NITRIC OXIDE. A.K. Stout* and J.J. Woodward. Dept. of Pharmacology, Medical College of Virginia, Richmond, VA 23298.

Previous studies in our lab have utilized nitric oxide (NO) generators to determine the effects of NO on N-methyl-D-aspartate-stimulated release of preloaded tritiated norepinephrine from rat hippocampal slices. The relative NO-generating ability of these compounds was indirectly determined by measuring their ability to stimulate cyclic guanosine monophosphate (cGMP) formation in cultured cortical neurons. We have now directly measured NO production by these compounds using a commercially available NO microelectrode. In oxygenated Krebs buffer, S-nitroso-N-acetyl-D,L-penicillamine (SNAP) produced approximately ten times more NO than an equimolar solution of sodium nitroprusside (NP). Nitroglycerin solutions did not produce detectable amounts of NO, even in the presence of tissue. These results were in agreement with the cGMP data. NMDA-stimulation of brain tissue did not produce detectable amounts of NO as measured by the microelectrode. However, NMDA did stimulate significant increases in cGMP levels in neuronal tissue. These results suggest that the NO meters which are currently available may not be sensitive enough to detect NO generated by physiologically relevant mechanisms. Supported by NIAAA AA08089, DA 07027, and a grant from the Alcoholic Beverage Medical Research Foundation.

FURTHER EVIDENCE THAT THE PRIMING EFFECT OF QUISQUALATE IS MEDIATED VIA UPTAKE AND RELEASE OF QUISQUALATE. E.W. Harris*, CNS Biology Dept., Fisons Pharmaceuticals, Rochester, NY 14603

Quisqualate (QQ) has the curious ability to sensitize *in vitro* CNS tissue to certain glutamate analogs, such as 2-amino-4-phosphonobutyrate (AP4): AP4 depolarizes quisqualate-treated tissue at $\sim 50\mu\text{M}$, but does not depolarize naive tissue at up to $1000\mu\text{M}$. The AMPA/KA receptor blocker CNQX reduces depolarization by AP4 in QQ-treated slices, but does not block the induction by QQ of sensitivity to AP4. This evidence points to the involvement of a QQ-sensitive site other than AMPA/KA-preferring receptors, and other than the metabotropic QQ receptor, since only a small sensitization is induced by the metabotropic receptor agonist TACPD. The hypothesis that this puzzling phenomenon is mediated by an unknown uptake site for which AP4 and QQ are ligands has been investigated further.

In addition to being sensitive to AP4, hippocampal slices exposed briefly to QQ showed also exhibited "primed" sensitivity to the following known uptake-site ligands: D- α -amino adipate, α -aminosuberate, cystathionine, L-cystine, and 2-amino-6-phosphonohexanoate (AP6). Furthermore, CNQX and pentobarbital, at concentrations that abolish responses to AMPA, only partially blocked the effects of QQ, and of AP4 in QQ-treated slices.

Inclusion of an uptake site ligand, such as AP6, greatly potentiated the effects of QQ (but not of AMPA), and reduced the induction of sensitivity to AP4. In addition, the effects of AP4 or AP6 faded with prolonged applications, but could be restored by re-"priming" with QQ. Finally, the sensitivity to AP4 persists longer if tested in a chamber in which buffer is recirculated than in a "flow-through" chamber continuously superfused with fresh buffer.

These data indicate that uptake and release of underlie "priming" effect of QQ.

ANTAGONISM OF KETAMINE-ANESTHESIA BY INHIBITORS OF NITRIC OXIDE SYNTHETASE. R.A. Mueller, M.D., Ph.D.*, R. Hunt, B.S., Dept. of Anesthesiology and Pharmacology, UNC at Chapel Hill, Chapel Hill, NC 27599.

Ketamine is a non-competitive antagonist of NMDA type glutamate receptors, and some NMDA receptor dependent responses utilize nitric oxide as a second messenger system. It has been shown that acute administration of an inhibitor of nitric oxide synthetase (NOS), such as nitroarginine methylester (NOA), reduces the apparent MAC of rats to halothane (Anesthesiol. 77:779,1992). The present experiments were designed to see if inhibition of NOS by the administration of NOA would increase the sensitivity of rats to the anesthetic effects of ketamine.

Sprague-Dawley rats of either sex received NOA or saline 30 minutes before administration of i.m. or s.q. (25-75 mg/kg) ketamine. A behavioral scoring system was used at 15 minute intervals to assess the speed of onset and depth of ketamine anesthesia and return to normal behavior. Brain NOS was measured in various areas of brain by the method of Bredt and Synder (Proc. Nat. Acad. Sci. 87:682,1990). Ketamine blood levels were measured by HPLC with UV detection by a slight modification of previously reported methods (Anesthetist 41:619,1992).

Single or repeated (1/day x 3 days) administration of NOA (20 mg/kg i.v.) did not affect the time course of onset, depth or duration of ketamine anesthesia (25-75 mg/kg). Daily 50 mg/kg NOA i.p. for 2 days, and again 30 minutes before ketamine prevented the animals from losing their righting reflex to a ketamine dose of 75 mg/kg s.q. (all saline pretreated rats lost their righting reflex). NOS *in vitro* activity in cerebellum, cerebral cortex and caudate nuclei was inhibited only 40-50% ($p < 0.01$) after the repeated intravenous dosing schedule but over 85% in all areas ($p < 0.01$) given the i.p. repeated dosing schedule. Blood levels of ketamine were significantly different in the control and NOA pretreated rats given 75 mg/kg ketamine.

It is possible that NOA may alter blood levels of ketamine and explain the antagonistic effect of NOA on ketamine induced anesthesia.

EMBRYONIC DEVELOPMENT AND POSTNATAL CHANGES IN FREE D-FORMS OF ASPARTATE AND SERINE IN THE HUMAN PREFRONTAL CORTEX. A. Hashimoto*, T. Nishikawa, S. Kumashiro, T. Oka and K. Takahashi. Precursory Res. for Embryonic Sci. and Tech. (PRESTO), Research Development Corporation of Japan, Tokyo, 100 Japan and Dpt. of Mental Disorder Res., Natl. Inst. of Neurosci., NCNP, Tokyo, 187 Japan.

We have measured free D-amino acids in the human frontal cortex of developing and aged brain (from 14 weeks gestation to 101 years of age) by HPLC with fluorometric detection. Extremely high contents of free D-aspartate (0.36 $\mu\text{mol/g}$, n=2) and D-serine (0.26 $\mu\text{mol/g}$, n=2) were demonstrated in the fetal cortex at gestational week 14. The content of D-aspartate dramatically decreased to a trace level by gestational week 41 and then remained very low during postnatal stages. In contrast, a persistently high level of D-serine was observed in the frontal tip throughout the embryonic and postnatal life. Because D-aspartate and D-serine are known to interact selectively with the N-methyl-D-aspartate (NMDA) type excitatory amino acid receptor, the present findings suggest that these D-amino acids might play a pivotal role in cerebral development and functions which are related to the NMDA receptor.

UTILIZATION OF L-AP6 AS A SELECTIVE AGONIST FOR A UNIQUE QUISQUALATE-SENSITIZED RECEPTOR. M.K. Schulte¹, R.J. Roon^{1*}, D.C. Sunter², and J.F. Koerner¹.

¹Dept. of Biochemistry, Univ. of Minnesota, Minneapolis, MN 55455, and ²Dept. of Pharmacology, Univ. of Bristol, BS8 1TD, UK.

Brief exposure of rat hippocampal slices to quisqualic acid (QUIS) sensitizes neurons to depolarization by the α -amino- α -phosphonate EAA analogues AP4, AP5, and AP6. These phosphonates interact with a novel QUIS-sensitized receptor [Brain Res. 605, 85-92, (1993)]. While L-AP4 and D-AP5 cross-react with other EAA receptors, DL-AP6 is relatively selective for the QUIS-sensitized receptor. This specificity of DL-AP6, in conjunction with the apparent preference of the sensitized receptor for L-isomers, suggested that the hitherto unavailable L-isomer of AP6 would be a highly potent and specific agonist for this receptor. We have measured the pharmacological responses of KAIN/AMPA, NMDA, lateral perforant path L-AP4 receptors, and CA1 QUIS-sensitized receptors to the D- and L-isomers of AP4, AP5, and AP6. D-AP6 and L-AP6 were prepared by fractional crystallization of the L-lysine salt of DL-AP6. The D-isomers of AP4, AP5, and AP6 were 5, 3, and 15-fold less potent for the QUIS-sensitized receptor than their respective L-isomers. While L-AP4 and L-AP5 cross-react with NMDA and L-AP4 receptors, L-AP6 is highly potent and specific for the QUIS-sensitized receptor ($\text{IC}_{50} = 40\mu\text{M}$). Its IC_{50} values for KAIN/AMPA, NMDA, and L-AP4 receptors were >10 , 3, and 0.8 mM, respectively. As with AP4 and AP5, sensitization to L-AP6 was reversed by α -amino adipate. However, reversal of sensitization to L-AP6 occurred at a slower rate, suggesting greater efficacy of L-AP6 for the QUIS-sensitized receptor. (NIH NS 17944)

380.15

L-HOMOQUISQUALATE SENSITIZES HIPPOCAMPAL NEURONS TO DEPOLARIZATION BY L-AP4 AND L-AP6. J.F. Koerner¹*, S. Venkatraman², R.J. Roon¹, and R.L. Johnson². Depts. of ¹Biochemistry and ²Medicinal Chemistry, Univ. of Minnesota, Minneapolis, MN 55455.

The ability of L-quisqualic acid (L-QUIS) to sensitize neurons to depolarization by α -amino- ω -phosphonate analogues of excitatory amino acids is a highly specific phenomenon. In previous studies of more than 50 analogues, only L-QUIS produced a strong and long-lasting sensitization. For this study we synthesized L-homoquisqualic acid (an analogue of L-QUIS with one additional methylene group in the side chain) from N-Boc-L-aspartic acid α -benzyl ester by the following sequence of reactions: (1) reduction to the alcohol, (2) oxidation to the aldehyde, (3) reductive amination with BnONH₂, (4) acylation with EtO₂CN=C=O, (5) cyclization, and (6) deprotection. When hippocampal slices were exposed to 20 μ M L-homoquisqualic acid for 20 min and extensively washed with fresh medium, the CA1 pyramidal neurons exhibited a 5-fold increase in sensitivity to depolarization by L-AP4 and 25-fold to L-AP6. The sensitization persisted more than one hour and was reversed by exposure to α -aminoadipic acid. These observations suggest that L-homoquisqualic acid is taken up by the neurons and induces sensitization in a manner analogous to L-QUIS [Brain Res. 605, 85-92, (1993)] but with 10-fold lower potency. (Supported by NIH grant NS 17944.)

HIPPOCAMPAL SYNAPTIC FUNCTION AFTER CHELATION OF VESICULAR ZINC. J.D. Easley, D.W. Moncrieff, D.L. Cassel, S.H. Juo, and C.J. Frederickson*. UT-Dallas, Richardson TX, 75080.

Neurons with zinc (and glutamate) in their presynaptic boutons innervate much of the cerebral cortex. In hippocampal field CA1, staining for vesicular zinc suggests that pyramidal apical dendrites receive both zinc-rich inputs (proximally, in s. radiatum) and zinc-free inputs (distally, in s. lacunosum-moleculare).

We are testing the effects of zinc chelation upon synaptically-driven field potentials in CA1. For input to the zinc-rich dendritic zone in radiatum, we stimulated Schaffer collaterals, for the zinc-free input in l-m, the perforant path. Stimulation pathway isolation was routinely confirmed by laminar source-sink analysis.

Schaffer collateral responses evoked by slow, repetitive (0.2 Hz) stimulation were unaffected by chelation of vesicular zinc with either TPEN (up to 20 μ M) or DEDTC (up to 1.0 mM). Input/output curves spanning threshold to saturation for the EPSP showed no consistent change in either EPSP slope or population spike amplitude after up to 1 hr of perfusion with chelators. However, subsequent histofluorescent tests with zinc probes (TSQ and TFLZ; Texas Fluorescence Labs, Austin, TX) showed that both TPEN and DEDTC had effectively chelated the vesicular zinc of CA1.

These findings fit prior evidence that vesicular zinc is not directly involved in low-frequency classical neurotransmission at EAA synapses. Whether zinc is involved in high-frequency and use-dependent synaptic phenomena (kindling, STP, LTP, LTD, etc.) remains to be explored.

ORALLY ADMINISTERED SEMISYNTHETIC GLYCOSPHINGOLIPID LIGA20 PROVIDES MORPHOLOGICAL AND BEHAVIORAL PROTECTION AGAINST FOCAL ISCHEMIC BRAIN DAMAGE IN RATS. A. Kharlamov, I. Zivkovic, A. Polo, D. M. Armstrong, A. Guidotti and E. Costa*. Fidia-Georgetown Institute for the Neurosciences, Georgetown Univ Med Sch, Washington, DC 20007.

LIGA20 (GM1 with N-dichloroacetyl-sphingosine) added to neuronal cultures of newborn rats prevents glutamate neurotoxicity with a potency 10 fold higher than that of the natural ganglioside GM1 (J. Pharmacol. Exp. Ther. 252:419, 1990). In the present study the antiexcitotoxic effect of LIGA20 was examined *in vivo* using the model of photochemically-induced thrombotic cortical lesion. The size of the infarcted area was analyzed 7 days after the thrombotic insult using the SAMBA4000 computerized imaging system and SigmaScan software in brain slices stained with 2,3,5, triphenyl-tetrazolium chloride. LIGA20 administered via several different treatment paradigms resulted in a considerable reduction of the infarcted area. Oral pretreatment with LIGA20 (70 to 200 μ mol/kg/day) for 3 days before the lesion caused up to 30% reduction of the infarcted area. A single intravenous (i.v.) administration of LIGA20 (34 μ mol/kg) given 6 hrs after the injury was also neuroprotective resulting in a 20 to 25% reduction of the infarcted area. When this delayed single i.v. injection of LIGA20 was combined with an oral administration of LIGA20 (50 to 200 μ mol/kg) a further reduction up to 40% of the infarcted area was observed. The protective action of LIGA20 given orally was related to the brain concentration of this drug. Behavioral studies in rats receiving bilateral cortical lesions demonstrated a clear correlation between the size of the brain lesion and the decreased performance on a water maze. Moreover, a LIGA20 treatment that reduced the size of the infarcted area also improved the rat performance on the water maze.

Supported in part by NINDS grant 2P01 NS 28130-04.

DUAL EFFECTS OF L-NAME ON RESPONSES OF DORSAL HORN NOCICEPTIVE NEURONS TO EXCITATORY AMINO ACID AGONISTS. D. Budai*, K.F. Kitto and A. A. Larson. Department of Veterinary Pathobiology, University of Minnesota, Saint Paul, MN 55108.

Nitric oxide (NO) appears to mediate many actions evoked by excitatory amino acids (EAAs) and play a role in pain. We examined the effect of iontophoretically administered N- ω -nitro-L-arginine methyl ester (L-NAME), an inhibitor of nitric oxide synthesis, on N-methyl-D-aspartate (NMDA)-, (R,S)- α -amino-3-hydroxy-5-methylisoxazole-4-propionate (AMPA)- and kainic acid (KA)-evoked single-cell firing using extracellular recording from dorsal horn nociceptive neurons in the rat. Ejection currents for NMDA, AMPA and KA were selected to produce similar intensities of spike discharges in neurons responding to both noxious and innocuous peripheral stimuli. High doses of iontophoretically applied L-NAME was able to completely inhibit the firing evoked by NMDA, AMPA or KA. In contrast, low doses of L-NAME increased cell firing evoked under similar conditions. The enhancement of EAA-evoked responses by L-NAME usually lasted for 20-30 min. Enhancement of non-NMDA- (AMPA- and KA-) responses by L-NAME was greater, in terms of both magnitude and duration, than that of NMDA. Similar effects of L-NAME were observed on KA-induced behavioral responses in mice. Pretreatment with L-NAME doubled the number of behaviors in response to a single injection of KA but inhibited KA sensitization at high doses of L-NAME. We hypothesize that L-NAME may exert two opposing effects on EAA activity that may be important in nociceptive transmission. (Supported by USPHS grants DA04090 and 00124.)

380.18

SPECIFICITY OF CYSTEINE SULFINATE DECARBOXYLASE (CSD) FOR SULFUR CONTAINING AMINO ACIDS (SAA). ¹M.L. Tappaz, ¹K. Almarghini, ²M. Cuénod* and ²K.O. Do. ¹INSERM 171, CHU LYON-Sud, Pierre-Bénite, France; ²Brain Res. Inst., Univ. of Zürich, Switzerland

CSD which decarboxylates cysteine sulfinic acid (CSA) to form hypotaurine, is thought to be involved in the biosynthesis of taurine. It was recently localized in astrocytes in the cerebellum by immunocytochemistry. This location closely resembled that of another SAA, homocysteic acid (HCA). We therefore investigated the specificity of CSD versus CSA, HCA, as well as related analogs, homocysteine sulfinic acid (HCSA) and cysteic acid (CA). CSD was immunotrapped from brain and liver tissue extracts, using a specific anti-CSD antiserum and incubated with the various SAA. Reaction products were identified and quantified by precolumn o-phtalaldehyde derivatization HPLC. CA and HCA (10 mM) inhibited the formation of hypotaurine from CSA (0.25 mM) by about 70%, while HCSA (10 mM) elicited no inhibition. Incubation with 25 mM of CSA or CA led to the formation of hypotaurine and taurine. The amount of taurine was about 10-fold lower than that of hypotaurine. In contrast, the amount of 3-amino-1-propanesulfonic acid, the decarboxylated reaction product of HCA (25 mM) was less than 1000-fold that of hypotaurine formed from CSA in the same conditions. These results show that CSD has a high specificity for CSA and CA which are the SAA involved in the biosynthesis of taurine. HCA is an inhibitor of CSD but does not appear to be a substrate for CSD *in vitro*. Accordingly, CSD is unlikely to play a role in the metabolism of HCA *in vivo*.

381.1

NEONATAL MICE LACKING FUNCTIONAL NMDA RECEPTORS GENERATE RESPIRATORY OSCILLATIONS *IN VIVO* AND *IN VITRO*. J.L. Feldman^{1,2}, Y. Li¹, G.D. Funk³, J.C. Smith³, X.-W. Dong³, S.M. Johnson³, J. Lai³, S. Hsu¹ & S. Tonegawa¹. ¹Center for Cancer Research, MIT, Cambridge, MA 02139 & ²Dept. Physiol. Sci., UCLA, LA, CA, 90024-1527.

NMDA receptors are important in many CNS functions. We investigated the role of NMDA receptors in the neural control of respiration using mice (129/sv X C57BL/6) with deletions in the NMDAR1 gene of the NMDA receptor (NMDAR1 knockout). The knockout mice generate rhythmic breathing movements from birth. Brainstem-spinal cords (and medullary slices) isolated from control and knockout neonatal (Day 0) mice generated rhythmic motor output in cranial (IX, X, XII) and spinal (C1, C4, C5, T2) nerves. *In preparations from control mice:* (i) Local application of AMPA (200 μ M) and NMDA (2 mM) over the C4 and C1 motoneuron pools produced a tonic sustained discharge on the corresponding ventral root. (ii) Application of AMPA and NMDA to the ventrolateral surface of the medulla (at the level of the pre-Bötzinger Complex) produced a rapid, dose-dependent increase in respiratory frequency. *In preparations from knockout mice:* (i) Application of AMPA to the spinal cord and medulla produced similar effects to that in control, whereas NMDA produced no effects. (ii) NMDA did not induce inward currents in hypoglossal motoneurons; AMPA did. We conclude that: i) Functional NMDA receptors are not present in the knockout mice and the NMDAR1 subunit is essential for NMDA receptor activity; ii) NMDA receptors are not essential for development of the neuronal circuitry for respiratory rhythm generation; and, iii) NMDA receptors are not necessary for respiratory rhythm generation or drive transmission to cranial and spinal motoneurons. Supported by NIH Grants HL37941, NS24742, HL40959, and HHMI.

381.3

INDUCTION OF A NOVEL NMDA RECEPTOR BY KINDLING IN CA3 IS NOT RELATED TO ALTERATIONS IN NMDAR TRANSCRIPT LEVELS.

J.E. Kraus, G.C. Yeif, Y. Watanabe, D. Bonhaus, J.V. Nadler, and J.O. McNamara. Duke and VA Medical Centers, Durham, NC.

Kindling is an animal model of epilepsy whereby periodic administration of an initially subconvulsant stimulus results in long lasting neuronal hyperexcitability. Enhanced function of excitatory synapses using the NMDA subtype of glutamate receptor (NMDAR) may contribute to the persistence of this hyperexcitability. We have previously shown that kindling induces a novel NMDAR with an increased number of binding sites (B_{max}) for the NMDA receptor antagonist CPP, as measured in whole hippocampal membranes prepared 1 month after the last kindled seizure. Our goals were to determine: (1) the hippocampal region of increased CPP binding; (2) the time course of increased CPP binding; and (3) whether alterations in the expression of distinct genetic isoforms of the NMDAR underlie the properties of the novel NMDAR induced by kindling. To address these goals, we generated equilibrium binding isotherms using [³H]CPP on microdissected hippocampal membranes and used quantitative in-situ hybridization techniques to examine transcript levels of NMDAR subunits. We report that: (1) increases in B_{max} for CPP were specific to region CA3; (2) binding over control was increased 36% at 24 hours and 300% at 28 days after the last kindled seizure; and (3) transcript levels of NMDAR1, NR2A, NR2B, and NR2C were the same in kindled and control animals at both 24 hours and 28 days after the last kindled seizure.

The direction, time course, and location of the kindling-induced increase in CPP binding suggest that this novel receptor may underlie the increased sensitivity of CA3 neurons to NMDA observed in kindled animals (Martin, et. al., *J Neuroscience* 12:1928, 1992). We have not yet elucidated the molecular mechanisms underlying these changes.

THE NMDA RECEPTOR, NMDAR1, IS LOCALIZED TO THE POSTSYNAPTIC DENSITY (PSD) OF RAT BRAIN. P.C. Suen^{1,2}, K. Wu^{1,2}, T.W. Kim^{1,2}, S.Y. Lin^{1,2}, Y. Huang³, R.J. Wenthold⁴, J.L. Xu¹ and I.B. Black^{1,2}. ¹Dept. Neurosci. and Cell Biol., Robert Wood Johnson Med. Sch.; ²Program in Physiol. and Neurobiol., Rutgers-The State Univ. of N.J., Piscataway, NJ 08854; ³Div. of Neurosci., NYSPI, New York, N. Y. 10032; ⁴Lab of Neurochem., NIDCD, NIH, Bethesda, M.D. 20892.

Receptors for NMDA (N-methyl-D-Aspartate) are acknowledged to be involved in many physiological and pathological processes in the brain. However, the molecular characteristics of the receptor protein and its exact synaptic function at the postsynaptic site are unknown. We examined NMDAR1, which serves as a fundamental subunit necessary for the NMDA receptor-channel complex, in the PSD, a critical synaptic organelle. Binding of (³H)MK-801 was performed initially to determine whether the PSD contains the receptor. Adult rat cerebral cortical (CTX) PSD contained a single high affinity (³H)MK-801 binding site with a B_{max} = 21 pmoles/mg protein and a K_D = 0.135 μ M. To examine regional distribution, Western blot analysis, using specific polyclonal anti-C terminal NMDAR1 antiserum, was performed on total tissue homogenate, synaptic membrane and PSD fractions isolated from cerebral cortex, cerebellum, olfactory bulb and hippocampus. There was no NMDAR1 expression in the cerebellum. In the other three brain regions, NMDAR1 protein was expressed in a region-specific manner and was highest in the PSD. Moreover, the NMDAR1 increased dramatically from postnatal day 4 to day 10, raising the possibility that the receptor may be involved in synaptic maturation. Finally, Western blot analysis revealed that the NMDAR1 in CTX-PSDs of mouse and rat are structurally similar, if not identical. Our findings suggest that the NMDAR1 may exert its physiological role through postsynaptic mechanism involving the PSD.

381.2

ANTISENSE OLIGODEOXYNUCLEOTIDE TO THE NMDA-R1 RECEPTOR CHANNEL REDUCES FOCAL CEREBRAL ISCHEMIA INFARCTIONS IN RAT. D.J. Reis, E.V. Golanov, S. Yamamoto, H. Ericson, C.E. Inturrisi and C. Wahlestedt*. Div. Neurobiol., Dept. Neurol. & Neurosci and ¹Dept. Pharmacol., Cornell Univ. Med. Coll., New York, NY 10021.

We have recently observed that antisense oligodeoxynucleotides (ODN) directed against the amino terminus of the primary structure of the NMDA receptor R1-subunit are neuroprotective in rat cortical cell culture (Wahlestedt et al., *Soc. Neurosci. Abstr.* 22:391.7, 1992). We investigated here whether an NMDA-R1 receptor antisense ODN would offer protection *in vivo*.

ODNs were administered intracerebroventricularly in spontaneously hypertensive rats twice daily for 2-3 days. Animals were then subjected to middle cerebral artery (MCA) occlusion and 24h later they were killed and the distribution and volume of the infarction computed. Groups consisted of rats receiving: (a) Antisense ODN (15 nmol, n=6); (b) Matching sense ODN (15 nmol, n=6); or (c) Vehicle (control, n=5). (d) In a fourth group, MK-801 (1 mg/kg) was injected intravenously 30 min after the MCA occlusion (MK-801, n=5) and animals were killed 24h later. Both antisense ODN and MK-801 treatments significantly reduced lesion volume, the former by 43.5% and the latter by 31.4% over controls. Sense ODN was without effect. In separate groups of animals (n=8) treated with ODNs in an identical fashion, it was found that antisense ODN caused a significant ($\geq 35\%$ vs. controls) reduction of the B_{max} of cortical NMDA binding sites, labeled by [³H]-CGS19755. Cortical NMDAR1 mRNA concentrations were unaffected by antisense ODN treatment.

The results are consistent with the view that NMDA receptors may participate in the neurotoxicity elicited by focal cerebral ischemia. Antisense ODNs for specific neuronal molecules may be useful for analyses of roles of specific molecules in ischemic lesions and conversely neuroprotection.

DOWN REGULATION OF THE GLUR2 SUBUNIT PROTEIN IN AMYGDALOID KINDLING. H.K. Prince, P.J. Conn, C. Blackstone, R. Huganir and A.I. Levey*. Departments of Neurology and Pharmacology, Emory University, Atlanta, GA 30322, and Department of Neuroscience, The Johns Hopkins University, Baltimore, MD 21205.

Previous studies using autoradiography have suggested changes in glutamate receptor density in kindling. More recently, it has been shown that changes in the subunit composition of AMPA receptors (subunits GluR1-4) can result in striking electrophysiological differences in the cell. Based on these data we investigated possible changes in the abundance and distribution of the AMPA receptor subunits in amygdaloid kindling. The GluR1-4 subunits were examined in four brain regions (hippocampus, entorhinal cortex, pyriform cortex/amygdala and limbic forebrain) by quantitative immunoblotting using subtype-specific antibodies. Immunoblots revealed a marked decrease in GluR2/3 immunoreactivity in all four brain regions using an antibody directed against a common epitope, which further analysis with subunit specific antibodies revealed was due to a decrease in GluR2. In contrast, GluR1 and 4 remained constant. The largest change was seen in a region including pyriform cortex and amygdala (32% of control). Immunocytochemistry did not demonstrate any qualitative changes in the cellular or subcellular distribution of the subunits. Because the presence of GluR2 in hetero-oligomeric complexes prevents calcium permeability, our results suggest that decreased GluR2 in kindling may possibly increase neuronal excitability and may contribute to seizure activity.

EXPRESSION PATTERN OF FIVE METABOTROPIC GLUTAMATE RECEPTOR SUBTYPES IN THE RAT BRAIN UNDER NORMAL CONDITIONS AND FOLLOWING GLOBAL ISCHEMIA. L. Iversen(\$), E. Mulvihill(#), B. Haldeman(#), F. Kaiser(\$), M. Sheardown(\$), L. Frank(&), N. Diemer(&) and P. Kristensen(\$)(*). (#) Zymogenetics Inc., Seattle; (\$) Institute of Neuropathology, University of Copenhagen and (\$) Pharmaceuticals Division, Novo Nordisk A/S, Måløv, DK-2760 Denmark.

The distribution of the mRNA for each of the metabotropic glutamate receptor subtypes was analysed by *in situ* hybridisation. The glial subtype (mGluR3) showed the highest level of expression in white matter tracts, while the other four subtypes each had a distinct pattern of expression. For example in hippocampus different subsets of metabotropic receptor types were expressed in different areas: CA1 mGluR1(weak) and mGluR5; CA2: mGluR1(weak), mGluR4 and mGluR5; CA3: mGluR1 and mGluR5. In the dentate gyrus mGluR1, mGluR2 and mGluR5 mRNA could be detected. 24 hours after global ischemia in the neck-cuff and four-vessel occlusion models the expression pattern of mGluR1-mGluR5 mRNA was investigated. In both models the mRNA levels for mGluR1, mGluR2, mGluR3 and mGluR5 were either unchanged or lower following ischemia. In contrast, the mRNA level for the mGluR4 metabotropic receptor was found to be increased in all parts of the hippocampus (except CA2 where it was unchanged) and in the parietal cerebral cortex. These findings together with our recent demonstration that L-AP4 is a strong agonist at the mGluR4 further indicate that mGluR4 is a presynaptic receptor regulating glutamate release and is upregulated following the increase in extracellular glutamate caused by ischemia.

IMMUNOCHEMICAL STUDIES OF A METABOTROPIC GLUTAMATE RECEPTOR (mGluR5) IN RAT BRAIN. C. Romano¹, M.A. Sesma³, C.T. McDonald², M.T. Price², and J.W. Olney² Depts. of Ophthalmology¹ and Psychiatry², Washington University School of Medicine and School of Optometry³ UM-St. Louis; St. Louis, MO.

The mGluRs are a family of G-protein coupled receptors that interact with a variety of effector systems. Two of these receptors, mGluR1 and mGluR5, stimulate phosphatidylinositol hydrolysis when expressed in model systems. An antibody selective for mGluR5 was developed using the anti-peptide antibody approach. Western blots of rat cortical synaptic membranes showed a single polypeptide of 148 kD, consistent with the molecular weight predicted from the sequence. The mGluR5 polypeptide was most abundant in cortex, hippocampus, striatum and olfactory bulb, with less in midbrain and little detected in cerebellum and brainstem. This distribution closely matches that found for mGluR5 mRNA (Abe *et al.*, 1992). The dearth of mGluR5 detected in the cerebellum verifies the specificity of the antibody, as mGluR1 α is most abundant in cerebellum.

Immunocytochemical studies using either fluorescent or ABC-peroxidase labeling reveal abundant neuropil staining, especially in striatum, lateral septum, and olfactory bulb. Throughout cerebral cortex, labeled puncta and varicose fibers are distributed in layer 2/3. The puncta and fibers may originate from large mGluR5 positive bipolar and multipolar cells in superficial cortical layers. Similar cells and puncta are seen in hippocampus where the puncta encircle unlabeled profiles in the pyramidal layer. mGluR5-positive neuronal somata in the cortex and hippocampus are rare but all resemble local circuit neurons with sparsely branching long dendrites. Distinct puncta and fibers in cortex and hippocampus suggest that mGluR5 is present on presynaptic axon terminals. In the basal forebrain, a small population of mGluR5-positive neurons is found in cholinergic cell groups. Supported in part by Research to Prevent Blindness (to DOVS-WUMS); RSA MH 38894; U.M. Weldon Spring Fund (to MAS).

GLUTAMATE RECEPTOR TRANSCRIPTION IN EMBRYONIC SPINAL MOTONEURONS. R. Temkin^{*}, D. Lowe, P. Jensen, and D.O. Smith. Neuroscience Training Program and Dept. of Physiology, Univ. of Wisconsin, Madison, WI 53706.

Embryonic chick spinal motoneurons respond to AMPA, kainate and NMDA, indicating that receptors for each of these glutamate agonists is present. To determine which known glutamate receptor gene products (GluR) might underlie these responses, we screened cDNA obtained from highly enriched (>92%) motoneuron populations using PCR-based gene amplification. Primers derived from rodent cDNA sequences were used to test for GluRs 1-7 and NMDAR1. Each of these receptor subtypes was detected. Primers designed to distinguish between the *flip* and *flop* splice variants of GluR1 and restriction digests of GluR1 fragments yielded ambiguous results that may indicate slight sequence differences in chick. Sequence analyses of 14 clones encoding GluR6 detected only arginine (and not glutamine) at the site (621) known to regulate Ca²⁺ permeability, thus demonstrating extensive mRNA editing. Since all genes encoding glutamate receptor subtypes appear to be transcribed, synaptic diversity may involve highly regulated translation or intracellular distribution. Supported by NIH grant NS13600.

RNA EDITING OF AMPA RECEPTOR SUBUNIT (GluR-B) mRNA. C.M. Burns, P.S. Obermiller and R.B. Emeson^{*}, Department of Pharmacology, Vanderbilt University, Nashville, Tennessee 37232-6600.

L-glutamate, the major excitatory neurotransmitter in the vertebrate central nervous system, opens cation channels that mediate fast excitatory responses. Recent studies have indicated that the calcium permeability of the AMPA glutamate receptor is dependent upon channel subunit composition. AMPA GluR-B subunit mRNA encodes a critical arginine residue in the second transmembrane spanning domain (TM2) which determines ion flow, yet the GluR-B gene contains a glutamine (CAG) rather than an arginine (CGG) codon at this position. The conversion of the genomic adenosine moiety to the guanosine found in the cDNA has been attributed to RNA editing.

To detect the single nucleotide change and quantitatively assess the extent of GluR-B editing, we have developed a sensitive assay based upon the polymerase chain reaction (PCR) which results in the formation of an artificial restriction fragment length polymorphism (A-RFLP) by introducing Alu I and Hae III restriction endonuclease sites into nonedited and edited templates, respectively. First strand cDNA synthesis was generated from whole mouse brain total RNA using a GluR-B-specific intron primer and the resulting cDNA was PCR amplified using intron-specific primers that spanned the exon encoding TM1 and TM2. DNA sequence and A-RFLP analyses revealed that the GluR-B pre-mRNA transcript was edited, indicating that RNA editing is a nuclear event occurring prior to, or coincident with, RNA splicing. Using this assay, we have also identified a rat glioma cell line which endogenously expresses GluR-B mRNA and edits >75% of the mature transcripts. We are currently using this tissue culture system to identify the *cis*-active regulatory elements controlling RNA editing by transfection of mutant GluR-B transcription units.

IMMUNOCYTOCHEMICAL DISTRIBUTION OF NMDA AND NON-NMDA IONOTROPIC EXCITATORY AMINO ACID (EAA) RECEPTORS IN MONKEY HIPPOCAMPUS. S.J. Siegel¹, W.G. Janssen¹, N. Brose², S.W. Rogers³, T. Moran¹, G.P. Gasic², R. Jahn⁴, S.E. Heinemann² and J.H. Morrison¹, 1 Fishberg Res. Ctr. for Neurobio., Mt. Sinai Sch. of Med., New York, NY 10029, 2 Mol. Neuro. Lab., Salk Inst. for Bio. Studs., La Jolla, CA 92037, 3 Dep. of Pharm. Univ. of Colorado, Denver, CO, 80262, 4 H.H.M.I Yale Univ. New Haven, CT, 06510

The regional, cellular and subcellular distributions of several EAA receptor subunits were investigated in monkey hippocampus using monoclonal antibodies specific for GluR2, GluR5-7 and NMDAR1, members of the pharmacologically defined AMPA/kainate, kainate and NMDA ionotropic receptor categories, respectively. Virtually all pyramidal cells in Ammon's horn, as well as granule cells and polymorphic cells in the dentate gyrus, were labeled with all three antibodies. However, the intensity of immunoreactivity was not constant across regions and strata with each of the antibodies, suggesting a possible variation in the amount and/or subcellular localization of each receptor subunit present in the various cell classes. Dentate granule cell somata and dendrites were intensely labeled with all three antibodies. Additionally, the mossy fibers were labeled with the NMDAR1 antibody, which may correspond to presynaptic receptors. Pyramidal cells in both CA1 and the subiculum were intensely labeled for all three receptor subtypes in virtually every somatic and dendritic segment examined. CA3 pyramidal cell bodies and dendrites were immunoreactive for GluR5-7, and faintly labeled with antibodies directed against GluR2 and NMDAR1. Ultrastructurally, NMDAR1 labeling in the stratum lucidum was localized to mossy fiber axons and terminals, but was not seen in postsynaptic densities, which may explain the NMDA independent nature of long term potentiation in CA3 secondary to mossy fiber stimulation. However, within the molecular layer of CA3, the strata radiatum and moleculare of CA1, and the dentate molecular layer, NMDAR1 labeling was localized to postsynaptic densities, primarily if not exclusively on spines. The data suggest regional and subcellular specificity for each of the three receptor subtypes which may correspond to discrete inputs. These patterns may underlie the individual response profiles of various hippocampal cell types to a variety of physiological, pharmacological and toxicological conditions.

EFFECTS OF EXCITATORY AMINO ACIDS ON INTRACELLULAR CALCIUM IN SH-SY5Y HUMAN NEUROBLASTOMA CELLS.

K. Savolainen, P. Nykqvist, M. Tuomala, M.-R. Hirvonen^{*} and J. Naarala. Natl. Publ. Hlth. Inst., Dept. Toxicol., Kuopio, Finland.

Free intracellular calcium ([Ca²⁺]_i) regulates many signal transduction processes in cells, including the activation of protein kinase C and calcium/calmodulin dependent protein kinase. It also activates phospholipase C, which generates two second messengers, diacylglycerol and inositol-1,4,5-trisphosphate, from the phosphatidylinositol-4,5-bisphosphate. [Ca²⁺]_i also plays a critical role both in the toxic cell killing and programmed cell death. We have studied the effects of excitatory amino acids (EAAs; L-glutamate, NMDA, kainate, AMPA and 1S,3R-ACPD) on [Ca²⁺]_i in SH-SY5Y neuroblastoma cells. The cells were exposed to graded doses of EAAs (100 μ M - 3 mM). Changes in [Ca²⁺]_i by L-glutamate, NMDA and kainate were biphasic, i.e. an increase in [Ca²⁺]_i was followed by a decrease. L-glutamate, NMDA and kainate all increased [Ca²⁺]_i in a concentration-dependent manner. The time for reaching a peak in [Ca²⁺]_i was dose-dependent for both L-glutamate and kainate; at low concentrations (300 - 500 μ M) the peaks were at 29 and 6 sec whereas at high concentrations (3 mM) the time points for the corresponding peaks were at 19 and 3 sec for L-glutamate and kainate, respectively. Subsequent to the increase in [Ca²⁺]_i, L-glutamate, NMDA and kainate all caused a decrease in [Ca²⁺]_i, but this effect was not concentration dependent. The decrease took place 2-3 minutes after the cells were exposed to EAAs. 1S,3R-ACPD and AMPA also caused a slight increase, followed by a decrease, in [Ca²⁺]_i, but the changes in [Ca²⁺]_i were small as compared to those induced by the other EAAs. The present results suggest that [Ca²⁺]_i is modulated in SH-SY5Y neuroblastoma cells in response to EAAs. These results also suggest that both the ionotropic and the metabotropic EAA receptors may be responsible for EAA-induced changes in [Ca²⁺]_i in SH-SY5Y neuroblastoma cells. DEVELOPMENTAL CHANGES IN mRNA EDITING OF GLUTAMATE RECEPTORS. D. Lowe^{*} and D.O. Smith. Neuroscience Training Program and Dept. of Physiology, Univ. of Wisconsin, Madison, WI 53706.

The extent of mRNA editing that occurs in the TMII region of glutamate receptors GluR2, 5, and 6 was measured in various regions of the mammalian CNS and at multiple ages. Functional analysis of recombinant channels assembled from edited (R) and unedited (Q) forms of GluR2 and 6 indicate that this site is a determinant of divalent cation permeability. GluR6-specific cDNA fragments were subcloned into M13mp18RF-DNA, transformed, and plated. Multiple recombinant plaques were sequenced to determine the ratio of edited to unedited subunits present. In hippocampus, a significantly (0.05 level) greater number of plaques contained the unedited form at post-natal day 8 than at 2- or 24-months of age. 33% of the plaques sequenced from 8-day animals were unedited, while 5 and 0% of the plaques were edited in animals aged 2 and 24 months, respectively. Regional and developmental regulation of the editing process may play an important role in neuronal maturation and degeneration. Supported by NIH NS13600.

NEUROCHEMICAL IDENTIFICATION OF EFFERENT PROJECTIONS OF A₁₃ INCERTOHYPOTHALAMIC DOPAMINERGIC NEURONS IN THE RAT. M.J. Eaton*, C.K. Wagner, K.E. Moore and K.J. Lookingland. Dept. Pharmacology/Toxicology, Michigan State University, East Lansing, MI 48824

Anterograde tract tracing from the medial zona incerta (MZI) reveals projections to many limbic structures including the horizontal limb of the diagonal band of Broca (HDB) and the central nucleus of the amygdala (cAMY). The purpose of the present study was to determine if these projections are incertohypothalamic dopaminergic (DA) originating from the A₁₃ cell group in MZI by examining changes in the concentrations of dopamine or 3,4-dihydroxyphenylacetic acid (DOPAC) in the HDB and cAMY after bilateral stimulation or lesion of the MZI, or administration of γ -butyrolactone (GBL) or its active metabolite γ -hydroxybutyric acid (GHBA). For comparative purposes, the nucleus accumbens (N. Acc.), which contains terminals of A₁₀ mesolimbic DA neurons but no projections from A₁₃, was also examined. Bilateral electrolytic or knife ablation lesions of the MZI reduced dopamine concentrations in the HDB and cAMY, but not in the N. Acc. whereas, electrical stimulation of the MZI increased DOPAC concentrations in HDB and cAMY, but not in N. Acc. Systemic administration of GBL increased the concentrations of dopamine in the MZI, HDB, cAMY and N. Acc., and this action was reversed by apomorphine. Intracerebral injection of GHBA into A₁₃ increased dopamine concentrations in the HDB and MZI, whereas its injection into A₁₀ increased dopamine concentrations in the HDB and N. Acc. These results suggest that A₁₃ DA neurons project to the HDB and cAMY and that the HDB receives a dual DA innervation from both A₁₃ and A₁₀ cell groups. (Supported by NIH grants NS 15911 and NS 07279).

CATECHOL-O-METHYLTRANSFERASE IN THE HUMAN NIGRAL COMPLEX AND STRIATUM: AN IMMUNOHISTOCHEMICAL STUDY. A. Kastner, P. Anglade, E.C. Hirsch*, C. Bonnaix, P. Damier, F. Javoy-Agid, N. Bromet, Y. Agid. INSERM U289, Hôpital de la Salpêtrière, Paris, France; Biotec Centre, Orleans, France.

The role of pre- and post-synaptic neurons in the degradation of synaptic released dopamine is not well understood, since the location of catechol-O-methyltransferase (COMT), a major enzyme of dopamine metabolism, is controversial. In the present study, we analyzed the cellular distribution of COMT in the nigral complex and the striatum of human brain *post mortem* by means of immunohistochemistry, at the light and electron microscope level.

In the nigral complex, COMT immunostaining was detected in some dopaminergic melanized neurons in the ventral tegmental area and the substantia nigra pars lateralis, but not in the substantia nigra pars compacta. In the striatum, using light microscopy, COMT immunostaining was detected in numerous cells, which at electron microscope level, were identified as glial cells and neurons. Immunonegative putative dopaminergic nerve terminals were observed in synaptic contact with these striatal immunopositive neuronal cell bodies and dendritic spines.

The data suggest that: 1) In the striatum, COMT is not present in the dopaminergic terminals, whereas it is expressed in striatal neurons. Thus, the elimination of striatal released dopamine by its O-methylation may involve GABAergic post synaptic neurons but not the dopaminergic presynaptic neurons. 2) In the nigral complex, COMT is expressed by some dopaminergic neurons with an heterogeneous distribution from one mesencephalic region to another. In this context, it is interesting to note that the neurons containing COMT are located in the dopaminergic regions, which are relatively well preserved in Parkinson's disease, suggesting that the absence of COMT in the dopaminergic nigrostriatal neurons might contribute to their susceptibility to the disease.

382.5

SYNAPTIC ASSOCIATIONS BETWEEN DOPAMINE TERMINALS AND GABA INTERNEURONS IN RAT AND MONKEY CORTEX

S.R. Sesack*, C.L. Snyder, and D.A. Lewis, Departments of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, Pittsburgh, PA 15260

Dopamine (DA) terminals regulate the excitability of cortical pyramidal cells via direct synaptic input to dendritic spines. However, it is not known if DA also modulates pyramidal cell activity indirectly through synapses on GABA interneurons, and whether such inputs differ across species. We sought to determine the ultrastructural basis for modulatory interactions between DA and GABA in the prefrontal and motor cortices of rats (Sprague-Dawley) and monkeys (*Macaca fascicularis*). Fixed brain sections were processed according to a dual, peroxidase/gold pre-embedding immunostaining technique. In regions of the neuropil where both markers were detected, terminals containing peroxidase immunoreactivity for DA or tyrosine hydroxylase (TH) synapsed primarily on spines and small dendrites lacking immunogold labeling for GABA. However, DA or TH-labeled (DA/TH) terminals were frequently in direct apposition to GABA-immunoreactive dendrites and in some cases, synaptic specializations were detected at these junctions. Convergence of DA/TH and GABA terminals on common dendrites, some of which were immunoreactive for GABA, was also observed. Axo-axonal appositions, but not synapses, were occasionally detected between DA/TH and GABA terminals. These results demonstrate that DA terminals directly innervate GABA interneurons, as well as pyramidal neurons, in the cortex of both rats and monkeys. These observations also suggest that DA and GABA interact through multiple cellular substrates in the regulation of cortical activity. This work was supported by USPHS grants MH50314, MH00519, and MH43784.

382.2

EFFERENT PROJECTIONS OF NEURONS IN THE MEDIAL ZONA INCERTA: A PHASEOLUS VULGARIS LEUCOAGGLUTININ ANTEROGRADE TRACING STUDY IN THE RAT. C.K. Wagner, M.J. Eaton, K.E. Moore and K.J. Lookingland. Dept. Pharmacology/Toxicology, Michigan State University, East Lansing, MI 48824.

The purpose of the present study was to determine efferent projections of A₁₃ incertohypothalamic dopaminergic neurons by examining the distribution of labelled fibers following unilateral injections of the anterogradely transported lectin *Phaseolus vulgaris* leucoagglutinin (PHA-L) into the medial zona incerta. PHA-L-labelled fibers were differentially distributed throughout the brain with the heaviest labelling occurring in the lateral septum, vertical and horizontal diagonal bands, lateral preoptic and hypothalamic areas, midbrain central gray, and ipsilateral parvocellular region of the paraventricular nucleus. Moderate labelling was observed in central amygdala, lateral bed nucleus of the stria terminalis, and in the contralateral parvocellular region of the paraventricular nucleus and the medial zona incerta. Light labelling was detected in the medial preoptic nucleus, supraoptic nucleus, and the dorsomedial aspect of the ventromedial nucleus; whereas little or no labelled fibers were present in the dorsomedial nucleus or magnocellular region of the paraventricular nucleus. These results suggest that neurons in the medial zona incerta project via the lateral hypothalamus to regions in the rostral diencephalon, and to the central amygdala. Additional studies are ongoing to determine if these represent projections of A₁₃ incertohypothalamic dopaminergic neurons. (Supported by NIH grants NS 15911 and NS 07279).

382.4

THE POSTNATAL DEVELOPMENT OF THE DOPAMINERGIC INNERVATION OF MONKEY PREFRONTAL CORTEX IS PROTRACTED AND REGION-SPECIFIC. D.R. Rosenberg* and D.A. Lewis, Depts. of Psychiatry and Behav. Neurosci., Univ. of Pittsburgh, Pittsburgh, PA 15213.

Developmental abnormalities in the dopaminergic (DA) innervation of the prefrontal cortex (PFC) have been implicated in the pathophysiology of certain neuropsychiatric disorders. In this study, we used immunocytochemical methods to characterize quantitatively the density and laminar distribution of tyrosine hydroxylase (TH)-labeled axons and varicosities in the PFC of 17 monkeys (*Macaca mulatta*) ranging in age from newborn to adult. The anti-TH antibody used in this study has been previously shown to selectively label DA axons in monkey neocortex. In the dorsomedial PFC (area 9), labeled axons were present predominately in layers I-II and V-VI in animals less than 1 month of age, and the density of these axons did not change substantially during early development. In contrast, during the second and third postnatal months, the density of labeled axons increased nearly 4-fold in the middle cortical layers. Axon density in these layers continued to increase with age, reaching a peak (over 6 times newborn values) in animals 2-3 years of age. Fiber density in these layers then declined about 30% in adult animals. The density of labeled varicosities showed similar developmental changes. In contrast, in the adjacent area 46, developmental changes in the distribution of TH-positive axons were much less striking. These findings demonstrate that the development of the DA innervation of monkey PFC is regionally- and laminarily-specific, continues through adolescence into adulthood, and exhibits the greatest degree of change during infancy and around the time of puberty (2-3 years of age).

382.6

DOPAMINE SYNAPTIC ORGANIZATION IN THE MONKEY CAUDATE: MEASUREMENT OF SYNAPSE SIZE AND CHARACTERIZATION OF POSTSYNAPTIC PROCESSES. J.E. Smiley* and P.S. Goldman-Rakic, Section of Neurobiology, Yale Univ. Sch. of Med., New Haven, CT 06510.

Despite strong clinical interest in the local circuitry of dopamine neurotransmission in the basal ganglia, a detailed ultrastructural description of dopamine axons in primate caudate is lacking. We therefore measured several morphological parameters of dopamine-immunoreactive axons in the macaque anterior caudate, visualized with a silver precipitation technique which allowed unobscured visualization of the labeled axons. The results from multiple tissue samples were remarkably consistent. As in the rat, dopamine axons were characteristically filled with approximately round clear synaptic vesicles, were never seen to contain dense core vesicles, and formed symmetric synapses. Serial section analysis demonstrated that dopamine synapses were quite small, typically present in only 1 or 2 serial sections, and rarely seen in more than 3 serial sections. Processes receiving dopamine synapses were also characterized by serial section analysis. Fifty percent of postsynaptic profiles were dendritic spine heads, which also received unlabeled asymmetric synapses, similar to the rat (Freund et al., Neurosci. 13:1189, 1984). The remaining dopamine synapses were on dendritic shafts, which were usually seen to be densely spinous when followed in serial sections. The consistent synaptic organization of dopamine axons in the caudate of the nonhuman primate provides a foundation for future ultrastructural analysis of this dopamine system in human pathological states. Supported by MH 44866.

ORIGINS OF STRIATAL CATECHOLAMINERGIC AFFERENTS IN TWO AMPHIBIANS, THE ANURAN RANA RIDIBUNDA AND THE URODELE PLEURODELES WALTII. A. González, M. Muñoz, A. Muñoz, A. Terrés, O. Marín, B. Navarro, R. M. Paz* and W. J. A. J. Smeets*. Dept. Cell Biology, Univ. Complutense de Madrid, Spain and *Dept. Anatomy Fac. Medicine, Vrije Univ. of Amsterdam, The Netherlands.

The distribution of striatal catecholaminergic (CA) immunoreactivity is studied by means of antibodies against dopamine, noradrenaline and tyrosine hydroxylase (TH). In addition, striatal afferents are revealed by retrogradely transported horseradish peroxidase, Fluorogold or fluorescent dextranamines. Double labeling techniques demonstrate the origins of CA projections to the striatum. The CA innervation in *Rana* is strong in the nucleus accumbens but only moderate in the striatum where it is primarily confined to the periventricular cell plate. Differently, in *Pleurodeles* the striatum contains the densest CA innervation arranged in patches whereas the nucleus accumbens is poorly immunoreactive. The striatal afferents in both amphibians originate from the dorsal thalamus, amygdala, hypothalamus, reticular nuclei in the brainstem and the raphe. Remarkably, in the urodele additional afferents from cells in the midbrain tegmentum and in the proximity of the fasciculus solitarius are also present. The present study reveals that in the urodele the mesostriatal CA system is particularly well developed, with additional components from the hypothalamus and the nucleus of the fasciculus solitarius while in the anuran such system seems to be absent and the CA innervation is found to be derived exclusively from the hypothalamic CA cell groups. (Supported by the DGICYT, PB90-0628)

QUANTITATIVE SURVIVAL OF DOPAMINERGIC NEURONS IN REAGGREGATE TISSUE CULTURE. A. Heller*, S. Price and L. Won. Dept. of Pharmacological and Physiological Sciences, University of Chicago, Chicago, IL 60637.

Three-dimensional reaggregate tissue culture provides a means for the examination of a variety of trophic interactions between dopaminergic (DA) neurons and their target cells. In the present study, an attempt was made to determine the extent of survival of the population of DA neurons cultured in the presence of corpus striatum cells. For this purpose, flasks of reaggregates were prepared from mesencephalon and corpus striatum of individual C57Bl/6J mouse embryos at 14 days of gestation. After 3 weeks in culture, reaggregates were collected for neurochemical analysis and determination of the total number of tyrosine hydroxylase (TH) positive cells present in the cultures. The reaggregates contained DA at a level of 13.8 ± 1.2 ng/mg protein and released the neurotransmitter as evidenced by the presence of 25.5 ± 2.1 ng of DOPAC per ml in the media. In order to determine the level of survival of DA neurons in the reaggregates, the numbers of such neurons in the cultures were compared to that in the mesencephalon of 2 month old C57Bl/6J mice. The total number of TH positive cells in the reaggregates (7868 ± 1030 , $n=5$) was not significantly different from that observed in intact brain. The reaggregation of cells from individual brains therefore provides an approach to the estimation of DA cell numbers in the mouse brain as well as a means for maintaining essentially all of the mesencephalic DA neurons over a fairly extended period of culture during which they continue their morphologic and neurochemical development. Supported by MH28942.

EFFECTS OF MAZINDOL AND NOMIFENSINE ON NIGRO-STRIATAL DOPAMINE NEURONS DURING POSTNATAL DEVELOPMENT. G. Zhang* and D. K. Pitts. Dept. of Pharmaceutical Sciences, College of Pharmacy & A.H.P., Wayne State University, Detroit, MI 48202.

Amphetamine can inhibit mesencephalic dopamine (DA) neuronal impulse flow by enhancing both the stimulation of somatodendritic autoreceptors by dendritically released DA and the activity of inhibitory forebrain feedback pathways which are activated by DA. These effects are the result of the ability of amphetamine to both cause catecholamine release and inhibit its reuptake. Previous extracellular electrophysiological studies examined the effects of amphetamine on spontaneously active nigrostriatal dopamine (NSDA) neurons during postnatal development in the rat. When given by the *i.p.* route, amphetamine had inhibitory effects on NSDA neuron discharge rate which were of equal magnitude across ages 2-days-old through adulthood. However, the time course for the inhibitory effects differed significantly among the various age groups. In contrast to amphetamine which can cause catecholamine release and inhibit reuptake, mazindol and nomifensine are relatively selective DA reuptake inhibitors which do not displace transmitter stores. Therefore these agents are useful for examining the physiological status of the dopamine transporter during postnatal development. In the present extracellular electrophysiological studies using urethane anesthetized rats both *i.p.* mazindol ($3.2-12.8$ mg/kg) and *i.p.* nomifensine ($6.4-12.8$ mg/kg) caused a dose-dependent inhibition of spontaneous NSDA neuron activity. NSDA neurons from 2-week-olds were found to be significantly more sensitive to the inhibitory effects of mazindol and nomifensine than NSDA neurons from adults. These results are discussed in the context of previous amphetamine findings. [Supported by MH47857 to DKP]

382.8

RETROGRADE TRACING THE PROJECTIONS OF PRE-ADOLESCENT TYROSINE HYDROXYLASE NEURONS IN EXTENDED AMYGDALA. C.A. Beltramino¹, G.F. Alheid² and L. Heimer* Depts of ¹Otolaryngology and ²Psychiatric Medicine, Univ. Virginia Health Sciences Center, Charlottesville, Va 22908

In the preadolescent rat, tyrosine hydroxylase (TH) containing cells are found in the extended amygdala, particularly in the intermediate division of the bed nucleus of the stria terminalis (BSTI) and in the central nucleus of the amygdala (CeA). The expression of this transmitter is down-regulated in the adult, so that in rats (over 60 days) few or no catecholamine neurons can be found. Little is known about the functional significance of these neurons, but one starting point is to identify the brain structures that are innervated by these cells. Accordingly, we have initiated a retrograde tracing study using fluorescent tracers (FITC or RITC beads and Fluorogold), combined with TH immunofluorescence (with Texas red or AMCA). Our current results indicate that after retrograde tracer injections in the central and medial amygdala, no double labeling with TH occurred in the BSTI despite dense retrograde cell labeling, nor did these forebrain TH cells appear to project to the parabrachial region, a target common to the BSTI and the CeA. Currently, we are extending these experiments to include especially the medial and lateral hypothalamus, as well as several additional targets of the extended amygdala. Supported by USPHS grant NS17743.

382.10

AMPHETAMINE AND MAZINDOL EFFECTS ON NIGROSTRIATAL DOPAMINE NEURONS DURING POSTNATAL DEVELOPMENT: HEMI-TRANSECTION OF FOREBRAIN/ MIDBRAIN CONNECTIONS. D. K. Pitts* and G. Zhang. Dept. of Pharmaceutical Sciences, College of Pharmacy & A.H.P., Wayne State University, Detroit, MI 48202.

Amphetamine (AMP) inhibits mesencephalic dopamine (DA) neuronal impulse flow by enhancing both the stimulation of somatodendritic autoreceptors by dendritically released DA and the activity of inhibitory forebrain feedback pathways which are activated by DA. During postnatal development synaptogenesis is still occurring in the rat forebrain. The physiological status of the forebrain feedback pathways during development is not well understood. Extracellular electrophysiological techniques were used to examine the effects of AMP on nigrostriatal dopamine (NSDA) neurons during postnatal development in the urethane anesthetized rat. When given *i.v.*, AMP (3.2 mg/kg) elicited a similar inhibition of spontaneous NSDA neuron activity in adults and 2-week(wk)-old rats. Hemitranssections of the midbrain/forebrain (MF) connections, however, significantly accelerated the recovery of adult NSDA neurons from the rapid inhibitory effects of *i.v.* amphetamine without affecting the recovery of NSDA neurons from 2-wk-old rats. M/F hemitranssections significantly enhanced the slowly developing inhibitory effects of *i.p.* AMP (6.4 mg/kg) on 2-wk-old NSDA neurons with a small more complex effect on adult NSDA neurons. M/F hemitranssections significantly attenuated the slowly developing inhibitory effects of *i.p.* mazindol (6.4 mg/kg; see Zhang and Pitts, Soc. Neuros. Abs., 1993), in adult NSDA neurons with a much smaller marginally significant attenuation in 2-wk-old NSDA neurons. These results suggest that forebrain feedback pathways are still undergoing development in 2-wk-olds and that responses to indirect agonists are dependent on MF connections, route of administration and the ability to cause catecholamine release. [Supported by MH47857 to DKP]

POSTNATAL DEVELOPMENT OF MESOACCUMBENS DOPAMINE NEURON SOMATODENDRITIC AUTORECEPTORS. L. Wang* and D. K. Pitts. Dept. of Pharmaceutical Sciences, College of Pharmacy & A.H.P., Wayne State University, Detroit, MI 48202.

Previous studies of nigrostriatal dopamine-containing (NSDA) neurons indicated that in 2- and 4-week(wk)-old rats these neurons were less sensitive to the inhibitory effects of *i.v.* apomorphine (APO, D2/D1 agonist) on discharge rate than neurons from adults. The sensitivity of NSDA neurons to *i.v.* quinpirole (QUIN, D2/D3 agonist), however, was not found to be age dependent. *Iontophoretic* studies indicated that NSDA neurons from early postnatal periods and those from adults were equally sensitive to the inhibitory effects of APO (1-wk-old to adult) or QUIN (2-wk-old to adult). This data suggests that the sensitivity of somatodendritic autoreceptors on NSDA neurons during early postnatal development is similar to that of adults. In the present studies extracellular recordings of single antidromically identified mesoaccumbens dopamine-containing (MADA) neurons were made from 2-wk-old and adult rats anesthetized with chloral hydrate. MADA neurons from 2-wk-olds were found to be less sensitive to *i.v.* APO than the neurons from adults. Preliminary evidence suggests a similar age-dependent difference in sensitivity for *i.v.* QUIN. However, *iontophoretic* studies using 7OH-DPAT (D3/D2 agonist) found no significant differences in sensitivity when comparing either MADA or NSDA neurons from 2-wk-olds to similarly identified neurons from adults. The above findings suggest that the differences in sensitivity seen when agonists are given either by the *i.v.* route or by *iontophoresis* is the result of the latter technique reaching a more restricted DA receptor population (e.g., that on the soma & proximal dendrites of DA neurons & neighboring afferents). Further *iontophoretic* and *i.v.* studies with other agonists are currently underway. [Supported by MH47857 to DKP]

THE NEUROPEPTIDE FMRFAMIDE MODULATES NEURONAL EXCITABILITY IN THE POND SNAIL *HELISOMA*. W.L. Smith*, F. Bahlis, and P.G. Haydon. Dept of Zoology and Genetics, Iowa State University, Ames, IA 50011.

FMRFamide, through multiple presynaptic pathways, reduces the amount of transmitter released at the synaptic terminal. These pathways result in a decrease in the activity of high-voltage-activated calcium channels, a decrease in the responsiveness of secretory machinery to calcium, and an increase in an outward potassium current which is mediated by metabolites of arachidonic acid. Current studies are focused on FMRFamide's effects on the excitability of neuron B5 from the buccal ganglia of the pond snail *Helisoma trivolvis*. Two possible effects of the increased potassium current are i) a change in excitability and ii) a change in the duration of action potentials. We have determined that FMRFamide application does result in a decrease in excitability with no apparent change in action potential duration.

Bath application of 10^{-6} M FMRFamide to cultured B5 neurons results in a large decrease in excitability as assayed by the number of action potentials evoked in response to a 5 second depolarizing stimulus. The observed effects are reversible upon washout of FMRFamide. We are currently studying the role of the arachidonic acid pathway in mediating the modulation of neuronal excitability. While FMRFamide decreases excitability, the half-amplitude duration of single action potentials remains unaffected.

A SENSORY NEURON IS SENSITIVE TO ITS ENDOGENOUS PEPTIDE. A. Wenning*¹ and R.L. Calabrese². ¹Fak. f. Biologie, Univ. Konstanz, 78434 Konstanz, Germany; ² Dept. of Biology, Emory Univ., Atlanta, GA 30322.

Sensory and neurosecretory innervation of each leech nephridium is accomplished by a single neuron, the nephridial nerve cell (NNC). These peripheral neurons contain FMRFamide which they probably release on three targets: the urine-forming cells of the nephridium, the muscles of the urinary bladder sphincter and central neurons (Wenning et al., J Exp Biol, in press). The role of FMRFamide, for example whether it modulates ion transport in the nephridium, is yet unknown. Resting potential and activity of the NNC depend on the extracellular chloride concentration. The NNC is spontaneously active in normal, low blood chloride. It hyperpolarizes and its spike rate decreases in high blood chloride, for example after a blood meal (Wenning & Calabrese, J Comp Physiol, 168:53, 1991).

As shown by extracellular recordings from the NNC in isolated preparations (including nephridium and bladder) bathed in low chloride saline, FMRFamide (bath applied at 10^{-7} M) completely suppresses spike activity. Intracellular recordings from superfused preparations show that the NNC hyperpolarizes when FMRFamide (10^{-5} M) is focally applied to its soma or dendrites. Through its sensitivity to the endogenous peptide, the NNC may modulate its peptide release.

THE STRUCTURE-ACTIVITY RELATIONS OF FMRFAMIDE DEPEND ON THE ASSAY USED TO MEASURE THEM. M.J. Greenberg*, K.E. Doble, W. Lesser, B.M. Dunn and D.A. Price. Whitney Lab, Univ. of Florida, St. Augustine, FL 32086-8623.

We have synthesized 76 of a series of 80 FMRFamide analogs in which each residue in the tetrapeptide is substituted one at a time by the other 19 amino acids. These peptides were bioassayed on the isolated radula protractor muscle (RPM) of a whelk, *Busycon contrarium*, and the isolated, perfused heart of a pulmonate snail, *Helix aspersa*. Radioimmunoassay (RIA) was with two antisera: S253, raised in rabbits to YGGFMRFamide; and Q2, raised to pQDPFLRFamide and DDPFLRFamide. The RPM bioassay and the S253 RIA were most similar, with strict requirements for an Arg³ and a C-terminal Phe, but with significant tolerance for substitutions at Met². The snail heart assay differed in its substantial tolerance for variation at Phe⁴, as well as at Phe¹; the data suggest that the C-terminal tetrapeptide of the SCPs - FFRMamide - would be about 8 times more active than FMRFamide, and that a few of the peptides were, in fact, acting at the SCP receptor of the *Helix* heart. Finally, the Q2 RIA is distinct in being very tolerant of changes at Phe⁴ and even at Arg³; but the C-terminal Phe is strictly required. The variability in structure accepted by receptors may be related to the narrowness of the limits within which the tissue functions. Supported by NIH HL28440.

ALTERATIONS IN THE POST-EMBRYONIC EXPRESSION OF FMRFAMIDE IN *DROSOPHILA*. J.S. Silber and P.H. Taghert*. *Anat. & Neurobiology*, Washington Univ. Med. Sch., St. Louis, MO 63110.

Drosophila melanogaster expresses FMRFamide in a discrete, stereotyped pattern in the central nervous system. We examined FMRFamide expression by staging 1st, 2nd, 3rd instar larvae and pupae in 12 hour increments. The expression pattern of the proFMRFamide protein was examined and compared to FMRFamide-lacZ expression in a P-element line known as WF3-Y (Chin et al., 1990, DNA Cell Biol. 9:263; Schneider et al., 1993, Neuron 10:279). Our studies indicate that changes in FMRFamide and FMRFamide-lacZ expression occur on a cell by cell basis. With the exception of one cell type, both patterns are constant from the beginning of the 1st instar through the first half of the 3rd instar. While some cell types continue to express FMRFamide consistently, others exhibit dramatic changes in immunoreactivity. Alterations in the expression pattern occur in at least two different time periods of the 3rd instar. These events take place shortly before, and after, onset of the wandering 3rd instar stage. Changes in the pattern continue through the pupal stages; some cells express FMRFamide and FMRFamide-lacZ consistently, others decrease their expression, and at least one cell type begins to exhibit immunoreactivity late in pupal development. These changes in the FMRFamide pattern should help provide insights into mechanisms regulating post-embryonic transmitter phenotypes.

383.4

STRUCTURE - ACTIVITY RELATIONSHIP OF FMRFAMIDE RECEPTOR BINDING IN SQUID (*LOLIGO*) OPTIC LOBE.

G. J. Chin*¹, K. Payza², D. A. Price³, K. E. Doble³, and M. J. Greenberg³. ¹LDN, NICHD, Bethesda, MD, 20892; ²LBG, NIMH Neuroscience Center at St. Elizabeths, Washington, DC 20032; ³Whitney Lab, University of Florida, St. Augustine, FL, 32086.

FMRFamide (Phe-Met-Arg-Phe-amide) is a neuropeptide transmitter in many invertebrates. Previously we presented evidence for high-affinity, G protein-coupled FMRFa receptors in membranes of squid optic lobe. In this study we characterized the ligand binding site of the receptors by using ¹²⁵I-daYFnLRFa as radioligand and performing competition experiments with a large series of FMRFa analogs substituted in each of the four amino acid positions. Of the tetrapeptide analogs tested, FMRFa was the most potent ligand (IC₅₀ = 0.4 nM). The first position was very selective for Phe, since all substitutions were >500-fold less potent except for Tyr (IC₅₀ = 5 nM). The Met² position showed a range of tolerance to substitution, but the C-terminal Arg, Phe, and amide were highly critical for binding activity. Intact and CHAPS-solubilized receptors shared the same binding specificity and G-protein coupling. The CHAPS-solubilized ¹²⁵I-daYFnLRFa binding sites thus appear to be genuine FMRFa receptors.

FMRF-NH₂ EVOKES AN INWARD CURRENT IN HEART INTERNEURONS OF THE LEECH. Joachim Schmidt, Ted W. Simorf* & Ronald L. Calabrese. Dept. of Biology, Emory University, Atlanta, GA 30322

Pairs of interneurons (HN cells) in the 3rd and 4th ganglion in the CNS of the leech constitute the timing oscillator for heartbeat. These HN cells form reciprocal inhibitory synapses across the ganglion, that lead to a rhythmic bursting in HN cells (Peterson 1983, J. Neurophysiol. 49:256). Bath application of FMRF-NH₂ (10^{-8} to 10^{-6} M) accelerates the rhythm of HN cells and eventually disrupts the bursting pattern (Simon et al. 1992, J. Neurosci. 12:525). FMRF-NH₂ acts in part by hyperpolarizing shifts of steady state activation and inactivation of a K⁺ current, I_K.

Focal application of FMRF-NH₂ (10^{-6} M) for 5 to 10 s onto the somata of HN cells causes a depolarizing effect of FMRF-NH₂. This response was subject to strong desensitization. Similar to bath application of FMRF-NH₂, we also observed acceleration of the rhythm after focal application. Membrane properties underlying the depolarization were characterized using the single electrode voltage clamp technique. Focal application of FMRF-NH₂ increased membrane conductance, causing an inward current. This inward current appeared to be voltage dependent. Focal application of FMRF-NH₂ did not depolarize HN cells that were bathed in Na-free saline, but did depolarize HN cells when Li⁺ was substituted for Na⁺. These experiments indicate, that the inward current is carried by Na⁺.

Reduction of the normal 1.8 mM Ca²⁺ concentration to 0.1 mM Ca²⁺ in the bathing saline did not effect the responsiveness of HN cells to focal FMRF-NH₂ application. This result indicates that the response does not depend on external Ca²⁺. When 1.8 mM Co²⁺ substituted for Ca²⁺ in the bathing saline the depolarizing response of the HN cells was blocked.

ISOLATION OF pQYRFamide FROM SNAIL GANGLIA. D.A. Price¹, K.E. Doble¹, W. Lesser¹, M.J. Greenberg¹, G.A. Cottrell^{1,2}, K.M. Swiderek², T.D. Lee², E.M. Lutz², J. Somerville². Whitney Lab., St. Augustine, FL 32086, ¹City of Hope, Beckman Res. Inst., Duarte, CA and ²Dept. of Biol., University of St. Andrews, Scotland, UK.

We have isolated and sequenced two different cDNAs that encode FMRFamide-related peptides from a snail (*Helix aspersa*) ganglia library. Both begin with the same stretch of 250 identical bases which includes the 5' non-coding region and the first 25 amino acids, but the sequences diverge thereafter, so we assume that they are products of alternative splicing as was previously found for the homologous mRNAs in *Lymnaea* (Saunders et al., *J. Neurosci.* 12:1033, 1992). One precursor encodes the two tetrapeptides FMRFamide and FRRFamide as well as the pentapeptide pQYRFamide. The other precursor encodes a number of heptapeptides, most conform to the consensus sequence XDP(F/Y)LR(F/I)amide. Since the tetrapeptide precursor is expressed by neurons that innervate the heart, we tested synthetic pQYRFamide on the isolated heart and found it to be a more potent cardioexcitator than FMRFamide. We have isolated a peptide from ganglion extracts by HPLC which has the expected elution position, immunoreactivity and UV absorbance for pQYRFamide. Electrospray mass spectrometric analysis of this peak showed a prominent, protonated molecular ion at 742.6 daltons in agreement with the calculated value of 742.9 for pQYRFamide confirming the predicted structure.

MOLECULAR ORGANIZATION AND EXPRESSION OF THE *DROSOPHILA MELANOGASTER* DROSULFAKININ GENE. R. Nichols¹* and S.A. Schneuwly². ¹Biological Chemistry Department, University of Michigan, Ann Arbor, MI 48109 and ²Der Universität Würzburg, Germany. The *Drosophila melanogaster* drosulfakinin gene (Dsk) can be predicted to encode three peptides, DSK 0, DSK I, and DSK II. Based on sequence similarity, DSK I and DSK II are cholecystokinin homologues, while DSK 0 is not. The Dsk transcript has been shown to be expressed in all developmental stages by *in situ* tissue localization and Northern blot analysis. Sequence-specific antisera to DSK I and DSK II indicate that the *Drosophila* cholecystokinin homologues are expressed throughout development from late embryo through adult in the central nervous system. The entire nucleotide sequence of the Dsk gene and surrounding DNA has been obtained for *Drosophila melanogaster* and a single P element enhancer trap line insertion near the Dsk gene.

BEHAVIORAL ANALYSIS OF RESPIRATION IN *LYMNAEA STAGNALIS*. L.L. Moroz¹, S.U. Hasan¹, A.G. Bulloch¹, K. Lukowiak¹ and N.I. Syed². University of Calgary, Neuroscience, Reproductive Medicine and Respiratory Research Groups, Calgary, Alberta, CANADA.

Gas exchange in fresh water snail, *Lymnaea stagnalis* primarily occurs via the lung through episodic opening and closing of the lung orifice, the pneumostome. Although the neuronal network of the respiratory central pattern generator of *Lymnaea* has recently been identified *in vivo* and subsequently reconstructed *in vitro* by Syed et al (Science; 250, 1990), little is known about the peripheral component of this network or the normal respiratory behavior. Therefore, we investigated the respiratory behavior of the *Lymnaea* under normoxic, hypoxic, hyperoxic, hypercapnic states and following administration of principal neurotransmitters. Under normoxic (control) conditions, the pH, PCO₂ and PO₂ of the hemolymph were 7.97±0.05, 9.49±0.18 torr and 27.0±0.9 torr (Mean±SD) respectively. During control periods, animals (n=8) visited the water surface 5±1.3 times per hour, the duration of each stay was 6±2.3 min., the pneumostome opened 5±1.3 times per h (once per visit) and for 25±15 seconds whereas during hyperoxia (100% O₂; n=12), these variables changed to 8±3.2 visits per h, 4±1.8 min./ stay, 3±1.6 times/h and <1 second (p<0.001) respectively. Under anoxic conditions, the animals (n=7) constantly stayed above the water surface, and the opening frequency and duration of the pneumostome were 15±4.0 per hour and 80±40 sec respectively (p<0.01). During hypercapnia, the animals (n=6) visited the water surface 11±5.2/h and stayed there for 7±3.2 minutes whereas the frequency and duration of the pneumostome opening were 9±3.6/h and 30±19 sec respectively. FMRF-amide suppressed the opening of pneumostome whereas dopamine initiated the breathing cycles. These studies provide a model system in which the control of breathing can be studied from behavioral to cellular level.

EFFECTS OF NEUROPEPTIDES ON CRAYFISH HEART. M. Srivastava and A.J. Mercier*. Dept. of Biol. Sci., Brock University, St. Catharines, Ont., L2S 3A1.

Effects of four neuropeptides on isolated crayfish hearts were examined. The FMRFamide-related peptide DRNFLRFamide (DF₂) and proctolin increased the frequency and amplitude of cardiac contractions, while met-enkephalin and leu-enkephalin did not alter cardiac activity. Chronotropic effects presumably arise from peptide action on the cardiac ganglion; inotropic effects may potentially result from actions on the cardiac ganglion (via changes in number or frequency of impulses within bursts), on motor nerve terminals or on myocardial cells.

Intracellular recording from myocardial cells was used to characterize the effects of DF₂ in more detail. Muscle potentials exhibited a wave of depolarization, due to summated EPSP's, and an action potential. DF₂ increased the amplitude and duration of such waves and increased the width (but not amplitude) of the action potential. Input resistance did not change. Attempts are being made to examine myocardial effects by obliterating cardiac ganglion activity and stimulating myocardial cells with extracellular electrodes. Procaine (at 10⁻⁹ to 10⁻⁴ M) is ineffective at blocking cardiac ganglion activity. Contractions can be elicited by stimulating preparations in which the dorsal myocardium (containing the cardiac ganglion) is excised. These experiments may provide some evidence for direct effects on cardiac muscle cells.

Supported by NSERC Canada.

DROSOPHILA MELANOGASTER DROMYOSUPPRESSIN. J. McCormick* and R. Nichols. University of Michigan, Ann Arbor, MI 48109-1048. We have previously reported the isolation of an abundant peptide TDVDHVFLRFamide from *Drosophila melanogaster*. Based on structure similarity, this peptide has been designated dromyosuppressin (DMS). The myosuppressin peptides isolated to date from other organisms are highly conserved being either identical or differing only by the N-terminal amino acid residue. Studies indicate that myosuppressin peptides inhibit gut and oviduct motility. We have generated and characterized sequence-specific antisera to DMS. Our immunocytochemical study indicates that DMS is expressed throughout all developmental stages in the central nervous system and the gastrointestinal tract, indicating that expression is under developmental and tissue-specific regulation. A cDNA encoding DMS has been amplified from *Drosophila melanogaster* adult head RNA using a sequence-specific primer. This amplified cDNA has been used as a hybridization probe to screen a genomic library to isolate the Dms gene. The cDNA has also been used to cytologically localize the Dms gene to the left arm of the second chromosome.

PARAMETERS WHICH DETERMINE THE RELEASE OF PEPTIDE COTRANSMITTERS (SCPS) VARY BETWEEN *APLYSIA* MOTOR NEURONS. M.D. Whim* and P.E. Lloyd. Dept. Pharm. Physiol. Sci. & Comm. on Neurobiol. Univ. Chicago, Chicago, IL 60637.

Aplysia motor neurons B1, B2 and B15 were placed in primary culture. Newly synthesized peptides were labeled with [³⁵S]-methionine. Using a combination of HPLC and liquid scintillation counting, the release of peptides by intracellular stimulation was monitored. It is known that the SCPs can be released from B1 and B2 in a stimulation- and Ca-dependent manner (Lloyd et al, 1986). We now find that stimulation of B15 at 12 Hz with 4 sec bursts and 3 sec interburst intervals results in the release of authentic SCPA, SCPB and buccalin A, in a stimulation- and Ca-dependent manner. We then examined the effect of spike pattern on the release of the SCPs from B15. Spike number was kept constant and spike pattern was varied. We compared the effects of stimulating B15 at a tonic 5 Hz to 50 Hz for 1 sec with 9 sec interburst intervals. About 6-fold more peptide was released per spike by the latter paradigm. When we compared 5 Hz tonic firing to -9 Hz with 4 sec bursts and 3 sec interburst intervals (a more physiological pattern; Cropper et al, 1990), the bursting pattern was still more effective at eliciting peptide release. In contrast the release of the SCPs per spike from B1 and B2 neurons in culture is pattern-insensitive over the physiological range. To ensure that this release was from neurites we compared the release of the SCPs from the soma and from intact B1 and B2 neurons. We conclude that peptide release is predominantly from the neurites. Thus the parameters which determine the release of the same peptides differ from neuron to neuron.

383.13

MODULATION OF PYLORIC NETWORK ACTIVITY BY TWO FAMILIES OF TACHYKININ-LIKE PEPTIDES. D.M. Blitz and M.P. Nusbaum. Neurobiology Research Center and Dept. of Physiology & Biophysics; Univ. of Alabama at Birmingham; Birmingham, AL 35294.

The stomatogastric ganglion (STG) of the crab, *Cancer borealis*, is innervated by modulatory neurons that contain many different neuropeptides. One of these peptides is a Substance P-like peptide (Goldberg et al., Cell & Tiss. Res. 252:515-522, 1988). Many of these peptides elicit distinct motor patterns from the pyloric neural network in the STG. However, bath-application of Substance P (SP) elicits no response from the pyloric network. Recently, two families of tachykinin-like peptides, including eight leucokinin and two locustatachykinins, were identified in insect nervous systems (Holman et al., Comp. Biochem. Physiol. 88C:31-34, 1987; Schoofs et al., FEBS 261:397-401, 1990).

Exogenous application of members from both peptide families (10^{-8} M) excites the pyloric rhythm. Each peptide increased both the pyloric cycle frequency and the impulse activity in the LP neuron. Thus far, the leucokinin assayed include L-I, III, IV, VI and VIII. L-I was the only one of these peptides to also reproducibly elicit rhythmic bursting in the DG neuron, a member of the gastric mill network within the STG. Neither of the locustatachykinins (LOM TK-I & TK-II) elicited bursting activity in the DG neuron. In preliminary experiments aimed at determining whether either peptide family represents the source of the SP-like immunolabeling (SPLI) in the STG, we preincubated the SP antiserum with either L-I (10^{-4} M) or LOM TK-II (10^{-4} M, 10^{-3} M). SPLI was not blocked by preincubation with L-I, but was partially blocked with the lower and completely blocked with the higher concentration of LOM TK-II. We are continuing to characterize the effects of these peptides on the STG networks, and are working to determine which members of each family are the native peptides within the stomatogastric nervous system. Supported by BNS-8909613 & HFSP (MPN).

PHARMACOLOGICAL CHARACTERIZATION AND HORMONAL MODULATION OF VOLTAGE-GATED CURRENTS IN *APLYSIA* BAG CELLS. L.A. Fieber. NIEHS Marine and Freshwater Biomedical Sciences Center, Univ. of Miami, Rosenstiel School of Marine and Atmospheric Science, Miami, FL 33149.

The bag cells of the marine gastropod *Aplysia* are neurosecretory cells that when stimulated undergo extended periods of action potential discharge culminating in the release of bag cell hormones that bring about egg laying behavior. Egg laying is a stereotyped behavior that supersedes foraging and all other activities for several hours, and presumably is tightly regulated. The voltage-gated currents contributing to the depolarizing phase of the action potential in bag cells are found only in cells from sexually mature animals. When maintained in short term tissue culture and studied via whole cell voltage clamp, inward currents for Na^+ and Ca^{2+} were found in 67% and 86%, respectively, of bag cells from mature *A. brasiliana* but were not present in cells from immature *Aplysia*. The Na^+ current activated at -20 mV and peaked at approximately +10 to 20 mV. Na^+ currents were absent in Na^+ -free medium and reversibly inhibited by tetrodotoxin (10 μM), but were not blocked by Cd^{2+} (100 μM). The Ca^{2+} current, using 11 mM Ba^{2+} as the current carrier, activated at -20 mV, peaked at +20 to 30 mV, and was reversibly inhibited by nifedipine (5 μM). ω -conotoxin (10 μM) produced a slight inhibition. Both Na^+ and Ca^{2+} currents were insensitive to holding voltage in the range of -70 to -40 mV. Both currents were strongly inhibited by bath applied α -bag cell peptide (5 μM), a hormone released from bag cells, while the outward currents were slightly inhibited. Bag cell ionic currents are modulated by intracellular second messengers found elevated in bag cells undergoing action potential afterdischarge (Conn et al., 1989, J. Neurosci., 9: 473-479). A phorbol ester which may mimic the effects of protein kinase C on these cells, phorbol 12-myristate 13-acetate (25 nM), increased both inward currents for Na^+ and Ca^{2+} , and the outward currents.

THE ALLATOSTATINS INFLUENCE THE GASTRIC SYSTEM OF THE CRAB, *Cancer borealis*. P. Skiebe-Corrette*, J. C. Jorge-Rivera and E. Marder. Dept. of Biology, Brandeis University, Waltham, MA 02254.

The allatostatins (AST)1-4 are a family of amidated peptides that share a C-terminal sequence. These peptides were isolated from brains of virgin female cockroaches (Woodhead et al 1989, Proc Natl Acad Sci USA 86, 5997). In cockroaches, the ASTs inhibit the synthesis and release of juvenile hormone. In crabs, AST 1-4 inhibit the pyloric rhythm, and the presence of one or more allatostatins-like peptides in the stomatogastric nervous system was shown by immunocytochemical studies with an antibody raised against AST 1 (Skiebe-Corrette and Schneider, in preparation).

We now show that the ASTs influence both the gastric mill rhythms and the neuromuscular junctions of gastric mill muscles. 10^{-7} to 10^{-6} M AST inhibits ongoing gastric rhythms in *in vitro* preparations of the stomatogastric nervous system. DG neuron bursts decrease in frequency, and LG activity is inhibited. Moreover, pyloric/gastric interactions characteristic of "switching" are modified by the ASTs.

AST-3 reduces the gain of gastric motor neuron to muscle interactions. 10^{-8} M AST-3 reduces the tension evoked by stimulation of the motor nerve in the gm 9 and gm8 muscles. AST-3 also reduces the amplitude and modifies the facilitation of nerve-evoked Excitatory Junctional Potentials (EJPs) in gm8.

In summary, the ASTs appear to inhibit motor function at multiple sites within the stomatogastric system.

LIGHT LEVEL AND ULTRASTRUCTURAL ANALYSIS OF A PUTATIVE NEUROHEMAL ORGAN IN THE COMMISSURAL GANGLION OF THE CRAB, *Cancer borealis*. V.L. Kilman, A.E. Christie, and E. Marder. Dept. of Biology, Brandeis Univ., Waltham, MA 02254.

Many peptides have neuromodulatory effects on the pattern generating networks of the crustacean stomatogastric nervous system. Substance P-like immunoreactivity is found throughout this system in cell bodies, in neuropil regions, and in a large club shaped structure in each commissural ganglion (CG) (Cell and Tiss Res 252:515, 1988). The club originates from fibers in the commissure anterior to the CG, follows the anterior-medial edge of the CG to the level of the inferior esophageal nerve (ion), and then curves back into the center of the ganglion and ends. Its function is unknown. We are using confocal microscopy of immunolabeled whole mounts along with sectioned toluidine-blue stained tissue to study this structure.

Confocal microscopy of the antibody-labeled club shows fibers entering the CG which contain elongated swellings. Posteriorly these swellings become larger, denser, and less discrete as individual structures. The maximum cross-sectional diameter of these swellings is 6-18 μm , consistently larger than the varicosities stained by this antibody in the neuropil region. Serial optical sections show the club is fenestrated by tubular unstained regions.

Toluidine-blue stained 2 μm sections show a concentration of large darkly staining structures in the club region of the CG. There is a gradation in length of these structures from 4 μm near the commissure to 6-15 μm near the ion. They are distinctly different in size and location from the smaller neuropilar varicosities. The most posterior of these structures cluster around empty lacunae but do not contact cell bodies or enter the fine neuropil region. Ultrastructure of this region will be presented.

At present our findings suggest that this structure may mediate non-directed neurohemal release of a substance P-related peptide in the commissural ganglion.

ANATOMY AND PEPTIDE IMMUNOREACTIVITY OF THE NEUROSECRETORY CELLS OF THE SUBESOPHAGEAL GANGLION OF *MANDUCA SEXTA*. N.T. Davis*, H.K. Lehman, P.E.A. Teal, and J.G. Hildebrand. Div. of Neurobiology, Univ. of AZ, Tucson, AZ 85721.

Four groups of neurosecretory cells residing in the subesophageal ganglion (SEG) and projecting to neurohemal release sites in the corpus cardiacum (CC) were identified. Two anterior median pairs of cells (MdAM) are in the mandibular neuromere, and a pair of ventral median triplets (MxVM) are in the maxillary neuromere. These cells project contralaterally to the CC via the ventral nerve of the CC. A pair of lateral neurosecretory cells (MxL) in the maxillary neuromere and a ventral median pair (LbVM) in the labial neuromere project contralaterally to the brain and thence to the CC via nerve 3 of the CC. Cells MdAM, MxVM, and LbVM were immunoreactive to antisera against Pheromone Biosynthesis Activating Neuropeptide (anti-PBAN) at all stages of postembryonic development of males and females. Anti-PBAN also stained 2 pairs of interneurons closely associated with the MxVM cells; these interneurons descend in the ventral nerve cord, provide branches to the dorsal neuropil of each of the ganglia, and branch extensively in the terminal ganglion. The 3 groups of median neurosecretory cells were also stained by anti-FMRamide Anti-Proctolin stained only the MdAM and MxVM cells; anti-Pigment Dispersing Hormone stained only the LbVM cells; anti-Crustacean Cardioaccelerator Peptide stained the MxL cells. Staining for PBAN was especially intense in the middle stages of adult development but diminished in late stages. During this period of development, a corresponding change in concentration of PBAN immunoreactivity of a fraction isolated from the SEG was demonstrated by competitive ELISA; early to middle stages contained 0.38-0.42 pmoles/SEG, whereas young adults contained 0.13 pmoles/SEG. Studies are underway to determine if there is neurohemal release during late development of the adult. [Supported by the Whitehall Foundation (to NTD).]

NEUROFIL ARBORIZATION AND TRANSMITTER COMPLEMENT OF A MODULATORY PROJECTION NEURON. A.E. Christie*, B.J. Norris*, M.J. Coleman*, E. Marder*, and M.P. Nusbaum*. Dept. of Biology, Brandeis Univ., Waltham, MA 02254, Neurobiology Research Center & Dept. of Physiology & Biophysics; Univ. of Alabama at Birmingham; Birmingham, AL 35294.

The peptide proctolin excites the pyloric and gastric mill rhythms when bath-applied to the stomatogastric ganglion (STG) of the crab, *Cancer borealis*. There are three distinct proctolin neuron pairs that innervate the STG. At least two of these pairs have different effects on the STG rhythms, which include separate subsets of the proctolin-application effects. This suggests that, within the STG neuropil, (1) these proctolin neurons may arborize in spatially separate regions, (2) there are restricted spheres of influence of neurally-released proctolin, and/or (3) each neuron has different co-transmitters that modify the proctolin effects. We are studying these issues by analyzing the arborization of a proctolin neuron, Modulatory Commissural Neuron 1 (MCN1), within the STG.

Using confocal microscopic analysis of Lucifer yellow (LY) dye-fills of the MCN1 arbor in the STG neuropil, we have found LY-labeled neurites and varicosities throughout the peripheral neuropil. Sectors densely-packed with MCN1 arbor often alternate with nearly empty regions. In ganglia that were also immunolabeled with proctolin antisera, MCN1 varicosities were double-labeled, and areas near those lacking MCN1 branches were replete with proctolin-immunoreactivity. There is thus no large scale segregation of branches from each proctolin neuron, although there may be distinct microdomains for each one. We have also found that MCN1 exhibits Substance P-like immunoreactivity (SPLI), and that it is the sole source of SPLI in the STG. This SPLI indicates that MCN1 has a co-transmitter unique among the proctolin neurons. Thus, both branching patterns and cotransmitters may contribute to the distinct effects of each proctolin neuron within the STG. Supported by NS29436 (MPN), NS17813 (EM) & HFSP.

THE DISTRIBUTION OF MYOMODULIN-LIKE IMMUNOREACTIVE MATERIAL IN THE NERVOUS SYSTEM AND PERIPHERAL TISSUES OF THE RAGGED SEA HARE, *BURSATELLA LEACHII*. M.W. Miller*. Institute of Neurobiology, Univ. of Puerto Rico, Blvd. del Valle 201, San Juan, PR 00901.

The neuropeptide myomodulin A was originally identified in the neuromuscular system underlying feeding behavior of *Aplysia californica*, where it was proposed to act as a modulatory cotransmitter (Cropper et al., 1987). Immunocytological studies showed that myomodulin-like immunoreactive material is present in specific neurons throughout the central nervous system of *Aplysia* and in fibers and varicosities on target organs belonging to several additional physiological systems (Miller et al., 1991). In order to begin to assess the degree to which the functions of myomodulin-related peptides have been evolutionarily conserved, the distribution of myomodulin-like immunoreactive material was examined in *Bursatella leachii*, a member of the Aplysidae family (Subfamily: Notarchinae). Cell bodies containing myomodulin-immunoreactive material were located in each of the central ganglia. The visceral ganglion, which in *Bursatella* is fused with the circumesophageal ring, contains a large immunoreactive neuron that may be homologous to the L10 interneuron of *Aplysia*. In the buccal ganglion, immunoreactive material was located in eight to ten large neurons in a region corresponding to the ventral motor neuron cluster of *Aplysia*. In addition, a very large spherical structure (400-600 μ m in diameter) was present in the most ventrolateral part of each hemiganglion. This structure may be an extraordinarily large neuron or may be a capsule in which several neurons are encased. Its surface was covered with branching fibers containing immunoreactive material. Myomodulin-like immunoreactivity was also observed in peripheral sensory and motor systems. In the eye, labelling occurred in a population of widely-dispersed monopolar neurons and in several fibers in the optic nerve. Finally, branching immunoreactive nerve fibers were present on a well-developed bilateral longitudinal muscle running the entire length of the animal, from the mouth region to the tail. Experiments in progress are directed toward the functional characterization of myomodulin-immunoreactive neurons in *Bursatella*.

STORAGE, SECRETION, AND METABOLISM I

STEREOSELECTIVITY OF NICOTINE TO INDUCE DOPAMINE (DA) RELEASE FROM SUPERFUSED RAT STRIATAL SLICES: DEPENDENCE UPON PRIOR DA LOADING. L.H. Teng, S.T. Buxton, P.A. Crooks and L.P. Dwoskin*. Graduate Center for Toxicology and College of Pharmacy, University of Kentucky, Lexington, KY 40536.

In agreement with previous reports, in the current study nicotine (1.0 nM - 100 μ M) enhanced [3 H]overflow from rat striatal slices preloaded with [3 H]dopamine (DA) in a concentration-dependent and stereoselective manner, in both the absence and presence of nomifensine (10 μ M) and pargyline (10 μ M) in the superfusion buffer. Determination of the effect of S(-) and R(+) nicotine on endogenous DA release revealed a concentration-dependent increase in dihydroxyphenylacetic acid (DOPAC) overflow, in both the absence and presence of nomifensine (10 μ M) in the superfusion buffer. In contrast, the effect of nicotine on endogenous DA release was not stereoselective. Furthermore, when pargyline (10 μ M) was included in the buffer, nicotine no longer enhanced DA release. Moreover, when striatal slices were loaded with cold DA (0.1 μ M) rather than loading with [3 H]DA (0.1 μ M), stereoselectivity of the effect of nicotine on DA release was observed. The results suggest that nicotine releases DA from two separate pools within the DA terminal. The effect of nicotine on the newly uptaken pool of DA is stereoselective and probably receptor mediated. Whereas, the effect of nicotine on the DA storage pool is not stereoselective and may not be receptor mediated. Generalization of results from experiments using [3 H]DA as a tracer to load DA terminals and subsequently monitor DA release should be interpreted with caution. (Supported by a grant from the Tobacco & Health Research Institute, Lexington, KY).

384.3

MYOSIN MAY BE INVOLVED IN THE NEUROTRANSMITTER RELEASE MECHANISM AT THE SYNAPSE FORMED BETWEEN RAT SYMPATHETIC NEURONS IN CULTURE. S. MOCHIDA^a, Y. NONOMURA^b, H. KOBAYASHI^a and B. LIBET^c. ^aDept. of Physiology, Tokyo Med. Coll., Tokyo 160, ^bDept. of Pharmacology, Univ. of Tokyo, Sch. of Med., Tokyo 113 and ^cDept. of Physiology, Univ. of California, Sch. of Med. San Francisco, CA 94143.

Some evidence pointed to the possibility that myosin could be involved in the neurotransmitter release, because it was found that myosin light chain kinase (MLCK) seemed to play a role in exocytosis of secretory cells^{1,2}. Therefore, we looked at the histochemical distribution of myosin in neuronal terminals and tested its possible role in synaptic transmitter release by depression of MLCK activity and by antibody on myosin itself at the synapse formed between cultured sympathetic ganglion cells in which some cells make functional synaptic contacts with other ganglionic cells. Myosin antibody recognized at the same synaptic terminals that showed synaptophysin presence with its antibody. Myosin antibody or SM-1, the pseudosubstrate inhibitor of MLCK, introduced into the presynaptic neuron inhibited the synaptic activation of the post synaptic cell. Wortmannin, a selective inhibitor of MLCK, also inhibited transmitter release when applied into the presynaptic neuron or to the bath solution. These results indicate that phosphorylation of myosin by MLCK may be necessary for transmitter release.

pH-JUMP UPTAKE OF ACETYLCHOLINE BY SYNAPTIC VESICLES. M. L. Nguyen and S. M. Parsons*. Neuroscience Research Institute, University of California, Santa Barbara, California 93106.

Cholinergic synaptic vesicles purified from the electric organ of *Torpedo californica* can be loaded with buffers of known pH by hyposmotic lysis. [3 H]ACh is taken up in a vesamicol-sensitive manner when the vesicle lumen is set at pH 5.5 and the external pH is jumped to 7.8. Uptake of [3 H]ACh is dependent on the vesicular pH gradient, as less uptake occurs at higher luminal pH values and uptake is blocked by very low concentrations of nigericin. The maximal uptake at five minutes after the pH-jump saturates at 13 nmol/mg with a K_M of 200 μ M, which is very similar to the K_M for ATPase driven uptake of ACh. After five minutes the occluded [3 H]ACh leaks out of the vesicles; this leakage is blocked by vesamicol added at the peak of uptake, indicating that the leakage occurs through the ACh transporter. The pH gradient as monitored by the absorbance of acridine orange substantially dissipated over the time course of the experiment, suggesting that the efflux of [3 H]ACh is due to reversal of the uptake mechanism. Nonradioactive ACh (50mM) added at the peak of uptake does not stimulate the rate of leakage of the [3 H]ACh, which suggests that efflux is rate-limited by reorientation of the loaded ACh transporter from the inside to the outside of the vesicle. The pH-jump approach to inducing active transport of ACh will simplify mechanistic study of the transporter by removing the dependence of transport on the V-type ATPase.

384.4

IMMUNOPHILIN REGULATION OF NEUROTRANSMITTER RELEASE. J.P. Steiner*, T.M. Dawson and S.H. Snyder. Dept. Neuroscience, Johns Hopkins University Sch. of Med., Baltimore, MD 21205.

The immunophilins, FK506-binding protein (FKBP) and cyclophilin, mediate the immunosuppressant actions of drugs such as FK506 and cyclosporin A, respectively. In the brain, the immunophilins occur in substantially higher concentrations than in the immune tissues and are highly localized in discrete neuronal populations together with the calcium/calmodulin-dependent protein phosphatase, calcineurin, whose activity is inhibited by immunosuppressant drug-immunophilin complexes. The immunophilins regulate exocytosis of secretory granules in mast cells and regulation of synaptic functions such as neurotransmitter release may be a function for immunophilins working with calcineurin in the brain. FK506 enhanced the release of dopamine, norepinephrine, serotonin, GABA and glutamate from striatal synaptosomes in a dose dependent manner evoked by potassium depolarization. Concentrations of FK506 as low as 100 pM significantly enhanced the release of the transmitters. Rapamycin, which interacts selectively with FKBP to inhibit effects of FK506, blocked the FK506-induced increases in transmitter release. Cyclosporin A also potentiated the release of these neurotransmitters. Since immunophilins colocalize with and regulate the activity of calcineurin, we measured the levels of phosphorylation in synaptosomes in response to FK506 and depolarization. Phosphorylation of several synaptic vesicle proteins was enhanced by FK506, indicating that they are calcineurin substrates and thus might mediate the enhancement of transmitter release elicited by FK506. Our results suggest that a major function of the immunophilins may be to regulate neurotransmitter release.

TACHYKININ RELEASE FROM RAT VENTRAL SPINAL CORD IS HIGHLY FREQUENCY-DEPENDENT. J. FRANCK, E. BRODIN(1) and G. FRIED*. Departments of Physiology and Pharmacology(1), Karolinska Institutet, S-104 01 Stockholm, Sweden.

The release of endogenous 5-hydroxytryptamine (5-HT), substance P (SP) and neurokinin A (NKA) from superfused tissue slices of rat ventral lumbar spinal cord, where SP and NKA coexist with 5-HT in terminals of descending bulbospinal neurons, was investigated. Electrical field stimulation was carried out using square-wave pulses with 2 ms duration and 30 mA stimulus intensity. Four different patterns of stimulation were used; 2 Hz continuous, 20 Hz continuous, 20 Hz intermittent and 50 Hz intermittent stimulation. 5-HT was measured in the slice superfusates by high performance liquid chromatography with electrochemical detection (HPLC-ED). SP and NKA were measured by radioimmunoassay (RIA). The release of 5-HT was significantly enhanced using all stimulation paradigms and the evoked release of 5-HT per pulse was independent of the stimulation frequency. The release was found to be calcium-dependent and there was no increase in the efflux of 5-hydroxy-indole acetic acid (5-HIAA) in response to stimulation. At 2 Hz (continuous) no significant increase in the release of SP was observed. Stimulation at higher frequencies yielded a significant increase in the release of SP per pulse. At 20 Hz, the release was increased by 73% (continuous) and 74% (intermittent), and at 50 Hz (intermittent) by 175% of basal efflux. The evoked release of NKA was also frequency dependent. At 2 Hz (continuous), no significant increase in the release of NKA was observed. At 20 Hz (intermittent), the evoked release per pulse was increased by 33% and at 50 Hz (intermittent) by 53% compared to the basal efflux of NKA. The results suggest that coexisting neurotransmitters/neuromodulators in the spinal cord may be released in different proportions depending on the stimulation frequency, and that only 5-HT is released when the nerve terminal is activated by low frequency stimulation.

ACTIVATION OF PROTEIN KINASE C (PKC) POTENTIATES K⁺-STIMULATED 5-HT RELEASE IN RAT REGIONAL BRAIN AREAS. D.J. Jones*, A. Biediger and V. Gandhi. Dept. Anesthesiology, Univ TX Hlth Sci Ctr, San Antonio, TX 78284

Previous studies from our laboratory and others demonstrated that phorbol esters which activate PKC enhance either electrical or K⁺-stimulated release of various neurotransmitters. As a prelude to studies evaluating the role of PKC activation in transmitter release in brain ischemia, we evaluated the effects of the phorbol ester, phorbol 12-myristate 13-acetate (PMA), on K⁺-stimulated [³H]5-HT release from slices of regional brain areas of the rat.

Slices (300 μm) were prepared from regional brain areas and superfused with control (5 mM K⁺) or depolarizing (15 mM K⁺) buffer. K⁺-stimulated release was lowest in the medulla/pons (0.74 ± 0.06% total [³H]) and highest in the corpus striatum (2.69 ± 0.22%). The percent enhancement of K⁺-stimulated release was dependent on the concentration of PMA in the incubation medium. Depending on the brain area, 0.1 μM PMA enhanced K⁺-stimulated release 25-55%. The highest increase occurred in the midbrain and hippocampus. PMA alone in the absence of K⁺-depolarization produced no increase in release. Biologically inactive phorbol produced no enhancement. Receptor selectivity was demonstrated by blockade of the PMA-enhancement with the PKC-inhibitor staurosporine (0.1 μM). The present studies demonstrate that PKC modulates the voltage-dependent release of 5-HT in rat brain. Supported by Miles Laboratories.

QUANTITATIVE AUTORADIOGRAPHY OF (3H) BEFLOXATONE BINDING SITE IN RAT BRAIN. O. CURET* AND C. SAUVAGE Centre de Recherche Delalande Groupe Synthelabo 92500 Rueil Malmaison FRANCE

Befloxatone is a new potent, reversible, selective and competitive MAO-A inhibitor. Previous binding studies in Rat brain membranes have shown that (3H) Befloxatone is a selective and a high affinity radioligand for MAO-A. In the present studies the autoradiographic distribution of (3H) Befloxatone was performed in the presence of Harmaline (10 μM) to determine specific binding. The specific binding of (3H) Befloxatone to brain sections was saturable, reversible and of high affinity. Scatchard analysis revealed a single binding site with a K_d of 1.3nM and a B_{max} of 7.5 fmol/mg protein. In competition binding studies with (3H) Befloxatone, the displacing potency of substrates and MAO-A inhibitors correlated highly and positively with their corresponding values from MAO-A inhibition assays. The rank of (3H) Befloxatone binding sites densities was: locus coeruleus >> interpeduncular nucleus > habenula, solitary tract nucleus, paraventricular thalamus > dorsal raphe and median hypothalamus. Low levels of binding were detected in white matter. In conclusion, (3H) Befloxatone is a valuable radioligand for quantitative autoradiographic distribution of MAO-A in Rat brain.

384.6

EFFECT OF NICOTINE ON NEUROTRANSMITTER RELEASE FROM THE RAT HIPPOCAMPUS. R. Miyoshi*, J. Semba, S. Kito, M. Furutsu, A. Ando and L. Shimada, *Department of Pharmacology, Tokyo Women's Medical College, Tokyo 162, Division of Health Sciences, University of the Air, Chiba 261, Japan.

Nicotine receptors are contained in the hippocampus in a high density. On the other hand, there are several papers published in which nicotine is considered to have beneficial effects on impaired memory function.

In order to directly assess the changes of release of endogenous amino acids, acetylcholine (ACh) and catecholamines from rat hippocampus induced by systemic administration of nicotine, we measured release of these substances using an intracerebral microdialysis technique.

A dialysis probe of Carnegie Medicine was inserted into rat hippocampus of a Wistar strain. ACh was assayed by HPLC with an electrochemical detector and amino acids with a fluorescence detector.

Intraperitoneal injection of nicotine caused decrease of glutamate and increase of GABA release. Aspartate and glycine release remained unchanged. ACh also stayed at the same level after the injection, while norepinephrine decreased.

It is assumed that these effects of nicotine on neurotransmitter release from the hippocampus may be related with its cytoprotective effect on hippocampal neurons.

384.8

PROPERTIES OF GLYCINE AND β-ALANINE RELEASE FROM HIPPOCAMPAL SLICES FROM DEVELOPING AND AGEING MICE. S.S. Oja* and P. Saransaari, Tampere Brain Res. Ctr., Dept of Biomed. Sci., Univ. of Tampere, SF-33101 Tampere, Finland.

The release of two structurally related amino acids, glycine and β-alanine, was studied from hippocampal slices from developing and ageing mice. The spontaneous and potassium-stimulated releases were monitored using a superfusion system. The response of glycine release to potassium ions (50 mM), an about 1.2-fold increase, remained fairly similar throughout the whole life-span of the mice studied (from 7-day- to 22-month-olds). Potassium stimulation evoked more β-alanine release from slices from adult mice than from slices from immature animals, this response being thereafter of the same order of magnitude until 22 months of age. The release processes of both glycine and β-alanine were not markedly Ca²⁺- or Mg²⁺-dependent, but they were affected by the glutamate receptor agonists. The release of glycine was potentiated by kainate, N-methyl-D-aspartate (NMDA) and quisqualate in developing mice but only kainate was effective in adults. The effect of kainate was abolished by CNQX and that of NMDA by MK-801. The release of β-alanine was also stimulated by the three agonists only in the immature hippocampus. The actions of kainate and quisqualate were again antagonized by CNQX and that of NMDA by MK-801. The results point out similarities in the releases of glycine and β-alanine, showing that both processes are similarly affected by the three subtypes of the glutamate receptor in the developing hippocampus.

DOPAMINE AND SEROTONIN METABOLISM IN THE DA-DENERVATED AND 5-HT-HYPERINNERVATED NEOSTRIATUM OF ADULT RAT AFTER NEONATAL 6-OHDA. E. Molina-Holgado*, K.M. Dewar, L. Descarries, L. Grondin and T.A. Reader. Centre de recherche en sciences neurologiques et Départements de physiologie, psychiatrie et pathologie, Université de Montréal, Montréal, Québec, Canada.

Dopamine (DA) and serotonin (5-HT) metabolism were studied in the rostral neostriatum (rNS) of 3-month-old rats, following neonatal DA denervation by intraventricular 6-OHDA (lesioned) or saline injection in littermates (controls). 5-HTP and L-DOPA were measured by HPLC at times 0 and 30 min after inhibition of aromatic amino acid decarboxylase (AAAD) by NSD-1015 (100 mg/kg). DA and 5-HT were similarly measured after 0, 5, 10 and 20 min of monoamine oxidase (MAO) inhibition by pargyline (75 mg/kg). In the lesioned rNS (DA-denervated and 5-HT-hyperinnervated), inhibition of AAAD induced an accumulation of L-DOPA equivalent to 4.5% of that in controls (0.62 compared to 14 nmol/g/h), for an L-DOPA/DA ratio of 0.63, 187% above that in controls. 5-HTP accumulation was 79% greater than in controls (4.44 vs. 2.47 nmol/g/h), for a 5-HTP/5-HT ratio of 0.45, 54% lower than in controls. MAO inhibition induced total DA accumulations over 20 min that were equivalent to 30% of initial, normal values in the controls (35.4 nmol/g/h), and 70% of initial, depleted values in the lesioned rNS (1.38 nmol/g/h). Total 5-HT accumulations represented 66% of initial, normal values in the controls (4.32 nmol/g/h), and 30% of initial, elevated values in the lesioned rNS (6.0 nmol/g/h). Expressed as % of initial values at each time interval after pargyline, these measurements indicated a higher rate of DA and lower rate of 5-HT accumulation in the lesioned than control rNS. It could therefore be concluded that the turnover rate of DA was increased and that of 5-HT decreased in the DA-denervated and 5-HT-hyperinnervated tissue, in keeping with the respective L-DOPA/DA and 5-HTP/5-HT ratios. (Supported by MEC, Spain, and grants MT-3544 and 6967 from MRC, Canada).

CONTROL OF EVOKED DOPAMINE OVERFLOW IN THE BASOLATERAL AMYGDALOID NUCLEUS AND CAUDATE-PUTAMEN. P.A. Garriss* and R.M. Wightman. Department of Chemistry and Curriculum in Neurobiology, University of North Carolina, Chapel Hill, North Carolina, 27599-3290.

The pharmacology of evoked dopamine (DA) overflow was compared in the basolateral amygdaloid nucleus (BAN) and caudate-putamen (CP). Extracellular DA concentration was measured *in vivo* in anesthetized rats by fast-scan cyclic voltammetry at carbon-fiber microelectrodes and elicited by electrical stimulation of ascending DA fibers over the frequency range of 10 to 60 Hz. The DA antagonist, haloperidol (0.5 mg kg⁻¹ i.p.), and the reuptake inhibitor, nomifensine (25 mg kg⁻¹ i.p.), elicited marked increases in extracellular DA in the CP. The increases were most pronounced at lower frequencies and were approximately 500% above control at 20 Hz for both drugs. The DA agonist, apomorphine (2 mg kg⁻¹ i.p.), reduced the effects of haloperidol by about half. Much smaller effects of haloperidol, apomorphine or nomifensine were observed in the BAN. In addition, the monoamine oxidase inhibitor, pargyline (75 mg kg⁻¹ i.p.), had no effect on evoked DA overflow in either region. In conclusion, the regulation of extracellular DA levels in the BAN is distinct from that in the CP.

384.13

THE EFFECT OF RESERPINE PRE-TREATMENT UPON L-DOPA AND AMPHETAMINE EVOKED DOPAMINE AND DOPAC EFFLUX FROM SUPERFUSED STRIATAL TISSUE. D.E. Dluzen* and B.-J. Liu. Department of Anatomy, Northeastern Ohio Universities College of Medicine, Rootstown, OH 44272-0095.

Male rats were treated with reserpine (5 mg/kg) or its vehicle at 24 hours prior to sacrifice and superfusion of the corpus striatum. Two different modes of L-DOPA (5 μM) and amphetamine (10 μM) stimulation, a brief 10-minute and a continuous 60-minute infusion, were tested for their ability to evoke striatal dopamine and DOPAC efflux. Reserpine significantly reduced the amount of basal dopamine and DOPAC released from superfused striatal tissue fragments of male rats. Although basal release rates were significantly reduced, the amount of dopamine and DOPAC released in response to *in vitro* L-DOPA infusions (10 or 60 minute infusions) was equivalent between reserpine and vehicle treated animals. In contrast, amphetamine stimulated DA release was significantly reduced in male rats treated with reserpine. For both L-DOPA and amphetamine, significantly greater amounts of dopamine were obtained with the 60- versus 10-minute infusion modes. These results demonstrate that the capacity for L-DOPA, but not amphetamine, to evoke dopamine efflux is unaltered under conditions when monoamine storage ability is diminished.

MONOCLONAL ANTIBODIES REACTIVE WITH A MONOAMINE TRANSPORTER PREPARATION PURIFIED FROM BOVINE ADRENAL CHROMAFFIN GRANULE MEMBRANES. J.A. Near*, C.E. Ody and X. Li. Medical Sciences Program and Department of Pharmacology, Indiana University School of Medicine, Bloomington, IN 47405.

Western blotting and ELISA data obtained using polyclonal serum from a mouse immunized with a highly purified chromaffin granule monoamine transporter preparation (*Mol. Pharmacol.* 40:889) yielded data consistent with the presence of antibodies to the transporter. Hybridomas produced by fusing spleen cells from the mouse with X63/Ag8.653 myeloma cells were screened in an ELISA. Positive wells were sub-cloned by limiting dilution, stocked, grown up in mouse ascites, and antibodies purified on immobilized Protein A. Immunoreactivity with a mixture of the 6 antibodies coincided with dihydrotetrazine (TBZOH) binding activity in fractions eluted from all columns employed in the transporter purification. Antibody from one of the clones was capable of removing TBZOH binding activity from a partially purified preparation of transporter. Studies are currently under way to confirm that the monoclonal antibodies are reactive with the transporter and not with a component that co-purifies with the transporter. Supported by the Indiana University Project Development Program.

384.12

MODULATION OF STRIATAL DOPAMINE SYNTHESIS AND RELEASE BY ANTIPSYCHOTIC AGENTS: EVIDENCE FOR SEROTONERGIC INVOLVEMENT. C. Wiley Aretha, R.E. Arthur, Jr., L.D. Alphas and W.A. Wolf. V.A. Medical Center, Allen Park, MI 48101 and Cellular and Clinical Neurobiology Program, Dept. of Psychiatry, Wayne State University, Detroit, MI 48201.

Haloperidol is a typical antipsychotic with a propensity for eliciting movement disorders. Clozapine is an atypical antipsychotic which elicits little or no extrapyramidal side effects. It has been suggested that differential alterations in central serotonergic tone may be relevant to clozapine's clinical profile. A comparative analysis of the ability of haloperidol and clozapine to modify the synthesis and release of dopamine (DA) in specific brain regions was undertaken. In superfused rat striatal slices, haloperidol (30 nM) increased electrically stimulated release of endogenous DA to 200% of control. However, under the same conditions of stimulation, clozapine (300 nM - 3 μM) did not significantly alter DA release. Studies on a possible serotonergic involvement in this differential local control of striatal DA release will be presented. With respect to DA synthesis, it is established that acute haloperidol administration activates striatal DA synthesis and turnover and that tolerance to synthesis activation occurs upon chronic administration. In the present study, pre-treatment with the 5-HT₂ antagonist, zatosetron (100 μg/kg i.p., 30 min prior to haloperidol), antagonized the ability of haloperidol (2 mg/kg i.p., 60 min prior to sacrifice) to activate tyrosine hydroxylase (TH) in rat striatum (Km for the cofactor, tetrahydrobiopterin = 78 ± 7 μM, 55 ± 4 μM, and 74 ± 4 μM for vehicle, haloperidol and haloperidol + zatosetron, respectively). These results are consistent with the hypothesis that 5-HT₂ blockade can inhibit the neuronal activation of midbrain DA neurons. The ability of zatosetron to modify the chronic effects of haloperidol on TH activity (i.e. tolerance to activation by drug challenge) is currently under investigation. The importance of serotonergic mechanisms in modulating the effects of haloperidol and clozapine on DA neurotransmission will be discussed.

REAL TIME DOPAMINE OVERFLOW IN BEHAVING RAT MEASURED BY FAST CYCLIC VOLTAMMETRY. Z.L. Kruck*, J.G. Williams & P. Willner. Dept. Pharmacology, Queen Mary & Westfield College, Mile End Rd, London E1 4NS UK

We report voltammetric measurement of electrically stimulated dopamine (DA) overflow in conscious rats for up to 17 days using the same electrodes. A miniaturised carbon fibre electrode, a Ag/AgCl reference and steel auxiliary electrodes, were permanently implanted, and fast cyclic voltammetry (Millar et al 1985, *Eur. J. Pharmacol.* 109, 341) was used to measure electrically stimulated endogenous dopamine (DA) overflow in the nucleus accumbens, in response to electrical stimulation (50Hz; 30 to 100μA; 0.5 to 5s) of the ipsilateral ventral tegmental area in conscious rats. DA overflow was stimulus intensity and duration dependent, and ranged from 50 nMolar to 5 μMolar equivalent DA; the limit of detection *in vitro* was 10 nMolar DA. All connections to the rat were by a multi way swivel. Voltammetric, electrophysiological, anatomical and pharmacological evidence indicate that DA overflow could be measured for up to 17 days.

CYTOCHROME b₅₆₁ REDUCTION BY ASCORBATE: CONCERTED PROTON/ELECTRON TRANSFER. Patrick M. Kelley* and David Njus. Dept. of Biological Sciences, Wayne State Univ., Detroit, MI 48202

Ascorbic acid (vitamin C) is regenerated by cytochrome b₅₆₁ in chromaffin vesicles. The ascorbate reacts with the cytochrome via a mechanism that we have termed concerted proton/electron transfer. This mechanism differs from the purely electron-transfer type of reaction by which ascorbate reacts with cytochrome c. The dianion of ascorbate (pK=11.3) reduces cytochrome c by a reaction which is strongly dependent upon pH. The reaction is faster at higher pH but quite slow at physiological pH. Cytochrome b₅₆₁, by contrast, reacts very rapidly at physiological pH even though its midpoint potential is 120 mV lower than that of cytochrome c. Moreover, the reaction is much less dependent on pH, suggesting that cytochrome b₅₆₁ is reduced by the ascorbate monoanion, the predominant form at physiological pH. These observations argue that cytochrome b₅₆₁ oxidizes the ascorbate monoanion to the semidehydroascorbate radical directly by extracting both the proton and the electron from ascorbate in a single step. In accordance with the concerted transfer of both the proton and the electron together, substitution of a deuterium for the proton should significantly affect the rate of reduction of the cytochrome by ascorbate. Initial results show that the rate of reduction is approximately 2.5 times faster in H₂O than it is in D₂O at pH 6.8. The change in the rate of reduction of cytochrome c is insignificant under these conditions. The possibility of a direct effect of D₂O on the cytochrome rather than on the concerted H⁺/e⁻ transfer itself has not yet been excluded. Cytochrome b₅₆₁ may be a paradigm for reactions between ascorbate and other ascorbate-requiring enzymes, all of which may react via concerted proton/electron transfer.

NEUROCHEMICAL EFFECTS OF NOVEL COCAINE ANALOGS ON CULTURED NEURONS. *B.A. Bennett*, C.E. Hyde, J.R. Pecora, E. Sakali and H.W. Davies*, Dept. Physiol/Pharmacol, Bowman Gray Sch. Med. and Dept. of Chemistry, Wake Forest Univ., Winston-Salem, NC 27157

A unique scheme utilizing vinylcarbenoid precursors has been developed for the synthesis of novel tropane analogs of cocaine. These studies describe the ability of several analogs to inhibit dopamine (DA) and/or serotonin (5HT) transport in cultured neurons. We examined analogs that

showed selective affinity for either the DA transporter, the 5HT transporter, or were equipotent at both. Inhibitory potencies (IC₅₀'s) were determined and are shown in the table. As shown, all of these compounds have a much higher potency for inhibiting DA transport than does cocaine (IC₅₀ = 540 nM).

We have previously determined that repeated cocaine administration to cultures does not alter dopamine or serotonin transporter function (no change in K_m or V_{max}). We exposed DA and 5HT cultures to these analogs for 5 days and examined amine uptake and cell survival. While DA or 5HT cell survival was unaffected, there were significant reductions in transporter activity. The results indicate that these analogs interact with the transporters and bind with such high affinity that a long washout period (approximately 24 hrs) is necessary in order to resume normal transporter function. Structure activity relationships of these compounds and that of cocaine will be discussed. Supported by NIDA grants 05073, 06634 (BAB), 07246 (CEH) and 06301 (HWD).

SEX, ESTROUS CYCLE AND GONADECTOMY INFLUENCE STRIATAL DOPAMINE UPTAKE SITES. *M. Morissette* and T. Di Paolo*. School of Pharmacy, Laval University and Department of Molecular Endocrinology, CHUL Research Center, Ste-Foy, Quebec, Canada.

Reuptake of dopamine (DA) into nerve terminals is the primary mechanism of inactivation of this neurotransmitter in the synaptic cleft. We investigated the hormonal modulation of rat striatal DA uptake sites. During the estrous cycle, peak density of striatal DA uptake sites labelled with [³H]GBR-12935 occurred in the morning of proestrus in coincidence with peak DA, serotonin, dihydroxyphenylacetic acid and 5-hydroxytryptophan levels pointing to a pre-synaptic effect of gonadal hormones. Striatal homovanillic acid and 5-hydroxyindoleacetic acid levels as well as [³H]GBR-12935 binding affinity remained unchanged throughout the estrous cycle. Density of [³H]GBR-12935 striatal binding sites was lower in ovariectomized rats compared to intact female rats during the estrous cycle, whereas it was similar in ovariectomized rats, gonadectomized and intact male rats. Binding affinity was in general similar for all groups of rats examined. The affinity of DA for striatal [³H]GBR-12935 binding sites was similar in males and ovariectomized females, and did not change during the female estrous cycle. In summary, striatal DA uptake sites density was lower in male compared to intact female rats and fluctuated during the female estrous cycle. Gonadectomy left unchanged striatal DA uptake sites in male but decreased density in female rats indicating a specific effect of female sex hormones. These results suggest that gonadal hormones could influence the activity of psychoactive drugs acting on neuronal DA uptake sites. Supported by a MRC of Canada Grant to T. D. P.

HUMAN DOPAMINE TRANSPORTER cDNA: COMPARISON OF [³H]DOPAMINE UPTAKE AND [³H]WIN 35,428 BINDING. *Z.B. Pristupa*, J.M. Wilson, B.J. Hoffman*, S.J. Kish, and H.B. Niznik*, Labs of Mol. Neurobiol. and Human Neurochem. Pathology, Clarke Institute of Psychiatry, Toronto, Ontario, Canada MST 1R8, and Lab. Cell Biol., NIMH MD

Dopamine (DA) reuptake is thought to be involved in several neuropsychiatric disorders as well as in the reinforcing effects of drugs of abuse such as cocaine and amphetamine. Some evidence in the literature suggests that various inhibitors of DA uptake interact with the DA transporter at pharmacologically distinct sites. To assess this possibility, we compared the ability of various DA uptake blockers and substrates to inhibit [³H]DA uptake and [³H]WIN 35428 binding to COS-7 cells expressing the cloned human DA transporter. [³H]DA uptake was concentration dependent and saturable, with K_m of 1.4 μM. Similarly, [³H]WIN 35,428 binding was saturable with an estimated K_d of 6 nM. [³H]DA uptake was inhibited by numerous compounds in a concentration dependent and uniphasic manner with the following rank-order of potency: (+) diclofenac > amfonelic acid > Lu 19,005 = GBR 12,909 = WIN 35428 > methylphenidate > mazindol = nomifensine > (-) diclofenac > cocaine = bupropion > dopamine > norepinephrine > serotonin. Most compounds inhibited the binding of [³H]WIN 35428 in a uniphasic manner except for Lu-19005, WIN and DA in which two affinity states were clearly evident. For both Lu-19005 and WIN the IC₅₀ for the high affinity site [4 and 15 nM, respectively] correlates well with functional values obtained for DA uptake (~13nM) while for dopamine the IC₅₀ of the low affinity site [~4 μM] matches well with that of uptake [1.7 μM]. While data on the cloned DA transporter suggests strong pharmacological homology between DA uptake and [³H]WIN binding, comparisons of [³H]WIN binding to the cloned transporter and to membrane preparations from human caudate reveal some differences specifically with dopamine, GBR 12,909, and amfonelic acid, each of which exhibits affinities for the native receptor ~10 fold lower than that of the cloned protein. Given possible differences in assay conditions and/or membrane composition to account for these alterations, we conclude that the binding of [³H]WIN to the cloned DA transporter and to human caudate membrane preparations appears to be pharmacologically similar.

SUGARS ENHANCE THE BINDING OF THE COCAINE ANALOG, WIN 35428 IN RAT STRIATUM. *A.L. Kirifides*, J.A. Harvey and V.J. Aloyo* Dept. of Pharmacology, Medical College of PA, Philadelphia PA, 19129.

WIN 35428 (WIN) has been employed in both phosphate and Tris buffers to characterize the striatal dopamine transporter. When investigating WIN membrane binding, many researchers add sucrose to the incubation mixture. Our study focused on the effects of sucrose on WIN binding under conditions of single-site kinetics (Kirifides et al. Life Sci. 1992). Binding assays were performed using crude membrane fraction prepared from fresh rat striatum at 0°C in 20 mM buffer (Phosphate, Hepes, Tris or Tris with NaCl), pH 7.4, at 0°C with or without sucrose. Nonspecific binding was defined as the binding remaining in the presence of 30 μM cocaine. In all four buffers 0.32M sucrose increased specific binding without altering nonspecific binding. The effect of sucrose was not due to an increase in osmolality since NaCl and choline chloride inhibited WIN at iso-osmolar concentrations. Furthermore, other sugars (glucose, glycerol, mannitol as well as sucrose) also increased WIN binding in a concentration dependent manner. Scatchard analysis revealed that in all three buffers sucrose significantly increased WIN's affinity without altering the B_{max}. Thus we conclude that the presence of sugars enhances WIN binding by altering the affinity state of the dopamine transporter. (Supported by NIDA Grant DA06871-01).

385.4

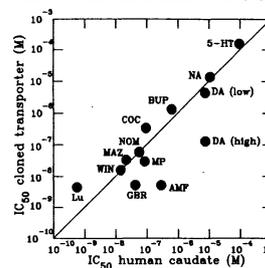

DOPAMINE TRANSPORTER ACTIVITY IN THE RAT MIDBRAIN: RELATIONSHIP TO CALBINDIN-D_{28k}-CONTAINING DOPAMINERGIC NEURONS. *M.K. Sanghera*, K.F. Manaye, C.-L. Liang, A.M. Iacopino, M.J. Bannon, and D.C. German*. Dept. of Psychiat., UT Southwestern Med. Cntr., Dallas TX; Dept. of Biomedical Sci., Baylor Col. of Dentistry, Dallas, TX; Dept. of Psychiat., Wayne State Univ., Detroit, MI.

The dopamine transporter is the site at which MPP⁺, the neurotoxic metabolite of MPTP, gains access to the midbrain dopaminergic (DA) neurons. The midbrain DA neurons that contain the calcium-binding protein, calbindin-D_{28k} (CaBP), are less vulnerable to MPTP toxicity, compared to the DA neurons that lack CaBP (German et al., 1992). The present study sought to determine whether there is comparable dopamine transporter activity among the DA cells with and without CaBP. Using *in situ* hybridization with a riboprobe from the human dopamine transporter, and immunohistochemical staining techniques, we found markedly less mRNA activity over neurons in the ventral tegmental area (VTA; a region with many CaBP-containing neurons) than over the substantia nigra neurons (a region lacking CaBP-containing neurons). These data suggest that VTA neurons are spared, following MPTP administration, because of a less active dopamine transporter.

385.6

[³H]WIN 35,428 BINDING IN HUMAN CAUDATE: PHARMACOLOGICAL PROFILE. *J.M. Wilson*, Z.B. Pristupa, H.B. Niznik and S.J. Kish*, Clarke Institute of Psychiatry and University of Toronto, Ontario, Canada.

[³H]WIN 35,428 (WIN) is a cocaine analogue which has been used to label the dopamine (DA) transporter in brain of experimental animals. Since little information is available on the pharmacological profile of [³H]WIN binding in human brain, we assessed the rank orders of various displacers in inhibiting [³H]WIN binding in human caudate (n = 2 to 4). Our preliminary results show that the rank order potency was Lu 19005 > WIN > mazindol > GBR12,909 > nomifensine > methylphenidate > cocaine > amfonelic acid > bupropion > DA > NA > 5-HT. As shown in the figure, this rank order correlated (r = 0.87) with that observed in COS-7 cells transfected with the cDNA for the human DA transporter, with the exception of amfonelic acid, DA (high) and GBR 12,909 which were 10-100 fold more potent in inhibiting [³H]WIN binding to the cloned transporter than native transporter in human caudate. Despite these pharmacological differences, which could be accounted for by minor variations in assay conditions and/or composition of membrane preparations, [³H]WIN appears to recognise the same site on the cloned and native DA transporter. (US NIDA DA07182).

RAPID INCREASE OF STIMULANT BINDING TO THE DOPAMINE TRANSPORTER AFTER ACUTE COCAINE ADMINISTRATION: PHYSIOLOGICAL BASIS OF DRUG CRAVING? M.M. Schwertl, Div. Basic Med. Sciences, Mercer Univ. Sch. Med., Macon, GA 31207.

Although cocaine is thought to exert its reinforcing effect via stimulant binding sites on the dopamine (DA) transporter, little is known regarding the actual molecular basis of the drug's powerful addicting effects. These studies used the radiolabeled stimulant, [³H]methylphenidate ([³H]MP), to probe the acute response of stimulant binding sites to cocaine in drug-naïve rats. Binding of [³H]MP was found to be 17% higher in unwashed striatal tissue homogenates from rats treated 1 hr previously with 15 mg/kg cocaine HCl (i.p.), compared to saline-injected controls (38,600 ± 1,050 vs 33,100 ± 900 CPM's/mg protein; p<0.005, Student's independ. t-test). This increase persisted when the tissue was washed twice with 50 mM Tris-Cl assay buffer before determination of [³H]MP binding. Scatchard analyses of twice-washed tissue showed that both the affinity and receptor density were significantly affected: the K_D decreased 22% (from 109 ± 15 nM to 85 ± 14 [p<0.03]) and the B_{MAX} increased 11% (from 6.4 ± 0.4 to 7.1 ± 0.5 pmols/mg protein [p<0.02]) in samples from vehicle- and cocaine-treated rats, respectively (paired t-test, 4 separate experiments). If future work shows that DA transport is affected in a parallel manner, a homeostatic mechanism may be hypothesized to underlie cocaine craving, as follows. The cocaine-induced rise in synaptic DA may trigger a compensatory increase in the efficiency of the transporter in order to reduce DA levels to normal. If the increased efficiency continues after cocaine is no longer present, however, synaptic DA concentrations may be reduced below baseline levels, leading to renewed cocaine use to counteract the resulting dysphoria.

SPECT IMAGING OF DOPAMINE TRANSPORTERS IN NON-HUMAN PRIMATE STRIATUM WITH 123I-MMG 142(E). R.T. Malison*, M.P. Kung, W. McElgin, G. Romaniello, H.I. Kim, M.M. Goodman, H.F. Kung. Depts. of Psychiatry and Radiology, Univ. of Pennsylvania School of Medicine and VA Medical Center, Philadelphia, PA 19104, and Dept. of Radiology, Univ. of Tennessee Medical Center, Knoxville, TN 37920.

The regional distribution, kinetics, and pharmacological specificity of uptake of a new radioiodinated cocaine analog, N-(E)-3-iodoproprenyl-2-yl-2β-carbomethoxy-3β-(4-chlorophenyl) tropane (123I-MMG 142(E)) were examined in brain SPECT studies (n=12) of non-human primates. Synthesis and purification of the iododestannylation trialkyltin precursor yielded the tracer at greater than 90% radiochemical purity and high (>20,000 Ci/mmol) specific activity. Cynomolgous monkeys were injected with 7.0 ± 0.4 mCi (mean ± SEM) of the tracer, and serial 10-minute images were acquired on the Picker PRISM 3000 (total scan time=170 ± 10 min). Images were reconstructed as transaxial slices (2 mm) using restorative techniques (Wiener prefiltering). Radioactivity concentrated quickly in striatal regions (time of peak =26±4 min) and cleared gradually thereafter (6.9 ± 1.9%/hr). Striatal to cerebellar ratios of 2.4 ± 0.5 (n=12), 5.4 ± 0.8 (n=12), 8.4 ± 1.1 (n=7), and 16.7 ± 4.4 (n=4) were observed at time of peak and 1 hr, 2 hr, and 3 hr p.i., respectively. In contrast, extrastriatal activity peaked earlier and at lower levels, cleared more rapidly, and resembled time-activity curves seen for the cerebellum. Displacing doses of non-specific antagonists of monoamine transporters (mazindol and β-CIT) showed that 95% of striatal 123I-MMG 142(E) binding was reversible, while selective antagonists (e.g., paroxetine, nisoxetine, and GBR 12909) suggested that striatal activity was specifically associated with dopamine transporters. These results indicate that 123I-MMG 142(E) may be a useful radioligand for *in vivo* SPECT imaging of striatal dopamine transporters.

SPECT IMAGING AND *EX VIVO* AUTORADIOGRAPHIC EVALUATION OF [¹²³I]ISOPROPYL β-CIT OF MONOAMINE UPTAKE SITES IN BABOON. M.S. Al-Tikriti*, B.E. Scanley, S.S. Zoghbi, Y. Zea-Ponce, R.M. Baldwin, M. Laruelle, P.B. Hoffer, J.L. Neumeyer, R.B. Innis, Yale University and VA Medical Center, Psychiatry Dept. West Haven, CT 06516.

Several ligands have been synthesized to image the DA transporter site *in vivo*. CIT is an iodinated cocaine analog with an affinity for DA uptake site almost 10-fold>CFT. However, CIT also binds to 5-HT sites. IPCIT (Isopropyl 3 β-(4-iodophenyl)tropane-2 β-carboxylate) is more selective for DA uptake site than to 5-HT and NE sites. The purpose of this study was to evaluate IPCIT as *in vivo* brain imaging ligand in primates. Three SPECT scans were conducted in baboons (10 kg *Papio anubis*). Animals were injected with 11.1±5.7 mCi i.v. of [¹²³I]IPCIT and scanned on the CERASPECT device for 460±34.6 min. Highest activities were seen in striatum, reaching peak level at 280 min p.i.. At 2h p.i. the striatal/occipital ratio was 1.66±0.1(n=3). Parent compound in plasma was 60±20% compared to 30±10%(n=4) for β-CIT. Plasma clearance was 99±18 L/h vs 138.6±19 L/h for β-CIT. Afterwards, striatal activity was monitored over 200 min and washout rate was negligible (1%/h and T_{1/2}=47 h). *Ex vivo* autoradiography was carried out in a baboon injected with 18 mCi, scanned for 2 h then sacrificed. Autoradiograms showed highest radioactivity in caudate and putamen. The ratio of putamen/occipital cortex was 3.2, and for caudate/occipital was 3, the cortical grey/white matter ratio was 1.9. Autoradiograms showed no increased activity associated with regions enriched in 5-HT transporter, like the colliculi. The *Ex Vivo* studies demonstrate selectivity of IPCIT for DA transporters and suggest that imaging with [¹²³I]IPCIT may be used to quantify DA transporters *In Vivo*.

385.8

EVALUATION OF DOPAMINE UPTAKE INTO THE SUBSTANTIA NIGRA, VENTRAL TEGMENTAL AREA AND STRIATUM OF THE RAT: EFFECTS OF COCAINE TREATMENT. Ivory Baker, Richard J. Wyatt and Joseph M. Masserano*. Neuropsychiatry Branch, NIMH Neuroscience Center, Washington, D.C. 20032.

This study evaluates and compares dopamine uptake into cell body regions (substantia nigra and ventral tegmental area) with that into a nerve terminal region (striatum). Kinetic analysis of [³H]dopamine uptake was linear for all three brain regions indicating the presence of one form of dopamine uptake in the slices that is apparently of the high affinity type. The apparent Km for dopamine uptake is 0.36 μM for the striatum, 0.49 μM for the substantia nigra, and 0.84 μM for the ventral tegmental area. The apparent Vmax for dopamine uptake in the striatum was 39.0 pmols/min/mg protein and was approximately 8-fold higher than the Vmax in the substantia nigra (5.3 pmols/min/mg protein) and ventral tegmental area (4.1 pmols/min/mg protein). IC50 values for GBR12909 (5x10⁻⁷), cocaine (5x10⁻⁶), and WIN, 528 (5x10⁻⁷) are similar in all three brain areas. The administration of cocaine 10 mg/kg, i.p., twice a day for 7 days produced no differences in the uptake of [³H]dopamine in the three brain areas compared with saline treated rats at 1 or 6 weeks after the last injection. Previous studies have shown a decrease in dopamine uptake in the frontal cortex after cocaine treatment. These data illustrate a selective uptake of dopamine in the dopaminergic cell body regions of the mesencephalon that is not affected by cocaine administration.

385.10

COMPARISON OF β-CIT ENANTIOMERS USING HOMOGENATE BINDING AND SPECT IMAGING. B.E. Scanley, R.M. Baldwin, M. Laruelle*, M.S. Al-Tikriti, Y. Zea-Ponce, S. Zoghbi, S.S. Giddings, S. Wang, Y. Gao, J.L. Neumeyer, P.B. Hoffer, R.B. Innis, Yale Univ. & VA Med Ctr, West Haven, CT 06516 and Research Biochemicals Int., Natick, MA.

β-CIT, (2β-carbomethoxy-3β-(4-iodophenyl)tropane; also designated RTI-55) is an analogue of cocaine which has been developed as a SPECT radiotracer that labels dopamine and serotonin transporters. We have prepared the [¹²⁵I] and [¹²³I] labeled (R)- ("active") and (S)- ("inactive") enantiomers of β-CIT. Total [¹²⁵I](S)-β-CIT homogenate binding to rat striatum (0.24±0.01 fmol/mg tissue, ±S.E.M.) and cortex (0.08±0.004 fmol/mg) was approximately equal to nonspecific binding of the active isomer (0.23±0.02 and 0.06±0.01 fmol/mg in striatum and cortex, respectively) and much lower than total binding of the active isomer (7.9±0.25 and 1.1±0.03 fmol/mg in striatum and cortex, respectively). *In vivo*, the plasma clearance of [¹²³I](S)-β-CIT (121±15 l/h, n=4) was not significantly different than that of [¹²³I](R)-β-CIT (138±19 l/h, n=4). SPECT imaging was performed in two baboons. A bolus dose of cold (R)-β-CIT (0.94 μmol/kg) rapidly displaced uptake of [¹²³I](R)-β-CIT. However, during a prolonged [¹²³I](S)-β-CIT equilibrium infusion, this same dose of cold (R)-β-CIT did not appreciably displace activity in any region. Peak uptake of the active isomer in striatum, normalized to injected dose and weight (μCi/cm³/μCi/g) was double uptake of the inactive isomer, (7.0±0.5, n=4 and 3.5±0.4, n=4, respectively). Peak normalized occipital activity was not significantly different between the isomers (3.7±0.2, n=4 vs 3.1±0.4, n=4; active and inactive isomers, respectively). Percent washout from peak was significantly faster and time to peak was earlier for the inactive isomer in all regions (striatal time to peak: 17±2 vs 168±60 min and striatal washout rate: 26±5 vs 1±0.6 %/h, inactive and active isomers, respectively). These studies demonstrate β-CIT stereoselectivity using both homogenate binding and *in vivo* imaging and suggest that the inactive enantiomer may be a useful measure of the kinetics of blood brain barrier transport and nonspecific binding.

APPARENT RECEPTOR-LINKED REGULATION OF SEROTONIN UPTAKE IN THE HUMAN PLATELET.

G.M. Anderson*, L.M. Hall, and J.X. Yang, The Child Study Center & Department of Laboratory Medicine, Yale Univ. School of Medicine, New Haven, CT 06510.

We have previously reported (Anderson & Horne, BBA 1137:331-337, 1992) that activation of protein kinase C (PKC) decreases serotonin (5HT) uptake in the human platelet. This finding, and reports of receptor-linked control of other transporters, has prompted us to study possible receptor-linked regulation of platelet 5HT uptake.

We have observed that adenosine diphosphate (ADP) causes a rapid decrease (to 42.3 ± 11.4 % of controls, N = 15) in the V_{max} of platelet 5HT uptake without significantly affecting the K_m value. The IC₅₀ for ADP determined from dose-response studies was 24 ± 15 μM (N = 5). Time course studies showed the effect to be very rapid, with ADP pre-incubations as short as 2.5 sec bringing about the maximum effect.

Studies on the mechanism have strongly indicated that the effect is not mediated through changes in cytosolic pH or Ca²⁺, cAMP inhibition, PKC activation, or the cyclooxygenase pathway. The implications of an apparently closely-coupled receptor-linked regulation of 5HT uptake will be discussed. Supported by NIMH grant MH30929 and Gettner Research Fund.

385.13

EFFECT OF (±) 3,4-METHYLENEDIOXYMETHAMPHETAMINE (MDMA) ON SEROTONIN AND DOPAMINE UPTAKE IN RAT HIPPOCAMPUS AND STRIATUM. R. Lew*, K.E. Sabol, G. Vosmer, J.B. Richards, K. Layton and L.S. Seiden, Dept. Pharmacol. and Physiol., Univ. Chicago, Chicago, Ill 60637.

The present study examines the long term effects of MDMA on serotonin and dopamine uptake in synaptosomal preparations of rat hippocampus and striatum. Age-matched Holtzman Sprague-Dawley rats (275 - 300 g) were injected with either saline (0.9% ; control) or MDMA (20 mg/kg free base; treated) twice daily (12hrs apart) for four days and sacrificed 2, 8, 16, 32 or 52 weeks after the final injection. On the day of sacrifice, striatum and hippocampus were removed from control and treated animals and synaptosomes were prepared in 0.32 M sucrose. For serotonin uptake, ³H-5-HT (10 nM final ; spec. act = 26.4 Ci/mmol) was preincubated in buffer with unlabeled 5-HT for 10 min at 30 °C before addition of hippocampal synaptosomes (170 µg protein). Uptake was terminated after 5 min by addition of 3 ml ice-cold 0.32 M sucrose and then filtered through GF/B filters. Dopamine uptake was performed in a similar manner except uptake was terminated 3 min after addition of striatal synaptosomes (50 µg protein). Preliminary experiments showed uptake in striatal and hippocampal synaptosomes was temperature dependent and had pharmacological profiles typical of dopamine and serotonin uptake. In dopamine uptake studies, no significant difference was observed between control and treated animals sacrificed 2, 8, 16, 32 and 52 weeks after treatment. In contrast, serotonin uptake in treated animals was 33.3 ± 1.4 % of control animals after 2 weeks recovery (control: Bmax = 9.37 ± 0.57 pmol mg prot; MDMA treated: Bmax = 3.09 ± 0.12 pmol/mg prot). By 16 weeks, serotonin uptake had recovered to 74.1 ± 3.7 % of that in control animals. However full recovery was not observed by 52 weeks as serotonin uptake in treated animals was 84.6 ± 4.5 % of control. Consequently serotonin uptake in hippocampus is reduced after MDMA treatment. However, since dopamine uptake was not affected by MDMA treatment, it appears that there is no relationship between dopamine and serotonin uptake systems. (This work was supported by research grant DA 00085; L.S.S is supported by RSA MH-105 62)

385.15

MODULATION OF DOPAMINE TRANSPORT BY NITRIC OXIDE (NO).

M.J. Kuhar* and S. Pöggün, Neuroscience Branch, NIH-NIDA, Balto., MD 21224.

The dopamine transporter (DAT) terminates the action of dopamine (DA) by removing the released transmitter from the synaptic cleft. In this study, we report the modulation of the DAT by NO, a diffusible messenger with possible presynaptic action which is present in brain regions containing dopaminergic terminals. The effect of NO on ³H-DA uptake was examined in striatal synaptosomes from male Sprague Dawley rats using standard procedures. Tissue was preincubated at 37°C for 15 min and then at 30°C for 5 min. Uptake was begun by adding ³H-DA (0.5 nM) and terminated in 3 min by adding cold sucrose. Sodium nitroprusside (SNP) which generates NO independent of the enzyme nitric oxide synthase inhibited ³H-DA uptake in a time, temperature and dose dependent fashion: At a concentration of 300 µM, uptake was inhibited 60%. In the absence of calcium, a condition which inhibits release of DA and activates guanylate cyclase, the observed inhibition by NO was more pronounced: 95% at 300 µM and 84% at 30 µM SNP concentration. Potassium ferricyanide had no effect on DA uptake. The effect of SNP was prevented by reduced Hb and methylene blue, and augmented by superoxide dismutase. Dibutyl cAMP (dbt-cGMP) mimicked the effect of NO on uptake: a 60% inhibition was observed at a concentration of 100 µM. Evaluation of the effect of NO on the kinetics of DA uptake revealed that NO increases K_m and reduces V_{max} in a dose dependent manner; dbt-cGMP also has a similar effect. DAT binding is not affected by either SNP or dbt-cGMP. Our results suggest that NO can inhibit DA transport in vivo and alter dopaminergic neurotransmission. This mechanism could be functionally important and may be involved in neuropsychiatric disease.

CYCLIC AMP INHIBITION OF CATECHOLAMINE UPTAKE BY PHEOCHROMOCYTOMA CELLS. S. Onozawa, N. Nakanishi, R. Matsumoto, H. Hasegawa* and S. Yamada. Dept. of Biochem., Meikai Univ. Sch. Dent., Sakado, Saitama 350-02, and ¹Dept. of Biosci., Nishi-Tokyo Univ., Uenohara, Yamanashi 409-01, Japan.

Dibutyl cAMP (dBcAMP) increases dopa content but decreases cellular dopamine (DA) in PC12h cells, a subclone of PC12. This decrease was accompanied by a large increase in DA in the culture medium, suggesting a modulation by cAMP of some transport process of catecholamine. We have examined how dBcAMP affected the intra- and extra-cellular DA. dBcAMP did not induce the exocytotic DA release. dBcAMP was inhibitory to the uptake of exogenous norepinephrine (NE) by the cells while no stimulation occurred in exocytotic or non-exocytotic release of NE pre-loaded. The uptake inhibition by dBcAMP was compared to those by reserpine and nomifensine. The inhibition profile was similar to that of reserpine but to that of nomifensine; inhibition was observable after a certain amount of NE was accumulated inside the cells, suggesting that the inhibition took place at the step of transportation from inside the cytosol to the vesicle. The same results were obtained with other cAMP-elevating agents, forskolin and cholera toxin. This type of inhibition increases DA concentration outside the cell by reducing reuptake capacity and hence by enhancing the leakage out from the cells.

PHORBOL ESTERS DECREASE DOPAMINE UPTAKE AND COCAINE ANALOG BINDING IN COS CELLS EXPRESSING RAT DOPAMINE TRANSPORTER. S. Kitayama*, G.R. Uhl², and T. Dohi. Dept. of Pharmacology, Hiroshima Univ. Sch. Dentistry, Hiroshima 734, JAPAN, ¹Mol. Neurobiol. Lab., ARC/NIDA and Depts. of Neurology and Neuroscience, JHUSM, Baltimore, MD 21224.

Recent elucidation of the amino acid sequence of the dopamine transporter(DAT) reveals several consensus sequences for phosphorylation by protein kinases. To test possible roles of protein kinase C in modulating transporter function, we investigated the effect of phorbol esters on the function of DAT expressed in COS cells. Cell treatment with phorbol 12-myristate 13-acetate(PMA) reduced the affinity of binding of the radiolabeled cocaine analog [C]T without affecting B_{max}. The velocity of uptake of [³H]dopamine was reduced by the treatment with PMA without affecting affinity. There was also a small reduction of affinity for Na⁺. These results demonstrate that activation of protein kinase C alters dopamine transporter function in ligand recognition and substrate translocation, and suggest that the regulation of transporter activity might provide important synaptic fine tuning under physiological conditions.

ATP-DEPENDENT MONOAMINE UPTAKE BY DIGITONIN-PERMEABILIZED PC12 WAS INHIBITED BY DIBUTYRYL CYCLIC AMP PRETREATMENT OF THE CELLS. N. Nakanishi*, S. Onozawa, R. Matsumoto, H. Hasegawa and S. Yamada.

Dept. of Biochem., Meikai Univ. Sch. Dent., Sakado, Saitama 350-02, Japan, and ¹Dept. of Bioscience, Nishi-Tokyo Univ., Uenohara, Yamanashi 409-01, Japan.

In pheochromocytoma, dibutyl cyclic AMP (dBcAMP), forskolin and cholera toxin extremely elevate the extracellular dopamine. We found that inhibition of vesicular catecholamine transport by cAMP was a key to understand this process. In order to elucidate the mechanism of this cAMP effect, an assay system specific to vesicular monoamine uptake was developed applicable to PC12 cells by permeabilizing plasma membranes with digitonin. The permeabilized cells retained the ability to uptake exogenous serotonin (5HT) in an ATP-dependent manner. The ATP-dependent 5HT uptake by the permeabilized cells treated with dBcAMP prior to the permeabilization was decreased to about 50% of the control value. However, an addition of dBcAMP into the incubation medium for 5HT uptake by the permeabilized cells did not inhibit the uptake. The results indicated that the inhibition of vesicular monoamine transport by dBcAMP was not due to a direct effect but was mediated by some process. Protein phosphorylation was suggested to be involved in such process.

DIFFERENTIAL REGULATION OF RAT NOREPINEPHRINE TRANSPORTER AND TYROSINE HYDROXYLASE EXPRESSION FOLLOWING RESERPINE. J.F. Cubells*, K.S. Kim, T.C. Wessel, T.A. Houpt, and T.H. Joh. Burke Med. Res. Inst., and Dept. of Psychiatry, Cornell U. Med. Coll., White Plains, NY 10605.

The norepinephrine transporter (NET) terminates the synaptic action of norepinephrine, thereby playing a critical role in noradrenergic transmission. To study the regulation of NET expression in rats, we used PCR to amplify a rat cDNA fragment that hybridized on Northern blots to PC-12 cell mRNA of the same size as the major band recognized by human NET (H-NET) probe, and was almost 90% identical in sequence to bp 988-1512 of H-NET cDNA (Pacholczyk, et al., 1991, *Nature*, 350: 350). *In situ* hybridization of this probe to rat tissue sections labeled both locus ceruleus (LC) and adrenal medulla (AM), but neither substantia nigra nor dorsal raphe. It therefore appears to be a fragment of rat NET (R-NET) cDNA.

Reserpine 10 mg/kg s.c., administered to rats 24 hr prior to perfusion and *in situ* hybridization, caused almost no change in LC and AM levels of R-NET mRNA, but consistent with previous findings (Wessel and Joh, 1992, *Molec. Brain Res.*, 15, 349), robustly induced tyrosine hydroxylase (TH) mRNA in both of those tissues. Thus, *in vivo* the TH and R-NET genes exhibit differential expression in response to acute catecholamine depletion. Supported by a Reader's Digest Fellowship to JFC and MH49762.

CHLORPROMAZINE BLOCKS THE UPTAKE OF HISTAMINE INTO PRESYNAPTIC TERMINALS OF BARNACLE PHOTORECEPTORS AND AFFECTS SIGNALS GENERATED IN THE POSTSYNAPTIC CELL. Ann E. Stuart*, Elizabeth C. Schmid and Harold E. Mekeel, Dept. of Physiology, Univ. of North Carolina, Chapel Hill, NC 27599-7545.

Barnacle photoreceptor (PR) synapses function by disinhibition: postsynaptic cells preferentially signal a decrease in the cleft concentration of the PR's transmitter, histamine (HA). Uptake appears to be the primary mechanism for quickly decreasing the cleft concentration of this inhibitory transmitter. Using autoradiography, we found that chlorpromazine (20uM) but not phenoxybenzamine (7uM), desipramine (100uM), or cocaine (100uM), consistently blocked uptake of 3H-histamine into PR terminals. In each of 6 preparations incubated in 20uM chlorpromazine, PR terminals did not take up 3H-HA; 2 preparations incubated in 7uM showed only light labeling compared to normal. From dose-response curves, 20uM chlorpromazine was found to reduce specific 3H-HA uptake to one-third its original value of 72.2 +/- 5.7 pmol/mg protein and 50% block could be achieved at 0.7 uM. Chlorpromazine did not affect presynaptic voltage or Ca influx into the PR presynaptic terminals, as measured by Ca spikes induced in the presence of tetraethylammonium ion, but it did dramatically affect the postsynaptic response. The PRs' inhibition of the postsynaptic cell was abnormally prolonged so that disinhibitory responses, normally evoked by hyperpolarization of the PRs, could not be generated. These results suggest that the drug inhibits the uptake of HA, causing it to accumulate in the cleft during presynaptic depolarization and to saturate postsynaptic receptors. They argue for a crucial role of the HA transporter in the generation of the postsynaptic response at this synapse. Supported by EY03347.

ALLOSTERIC EFFECTS OF MONOVALENT IONS ON THE BINDING OF INHIBITORS TO AMINE TRANSPORTERS. L. Raymon*, M. Eldefrawi Pharmacol., Univ. of MD Sch. Med., Baltimore, MD 21201.

Amine uptake is Na⁺ and Cl⁻ dependent and regulated by other ions. This study investigates the ionic regulation of the binding of uptake inhibitors to the transporters.

The effects of NaCl, KCl, NaHCO₃ and KHC0₃ on binding of BTCP to the dopamine transporter (DAT), desipramine (DMI) to the norepinephrine transporter (NET), citalopram (CTL) to the serotonin transporter (5HTT) and cocaine (COC) to the three transporters in rat whole brain less cerebellum was studied in 1mM NaH₂PO₄. BTCP specific binding to DAT increased 3-fold with increasing concentrations of NaCl whereas DMI, CTL and COC specific binding decreased. Addition of KCl to the buffer decreased the specific binding of all 4 ligands. When HCO₃⁻ was the anion, the specific binding of BTCP to DAT increased at low doses of the salt, then decreased at higher concentrations. A mirror image was observed for DMI. The binding of both CTL and COC decreased with increasing concentrations of NaHCO₃ or KHC0₃. Non specific binding of all inhibitors decreased to similar values with increasing NaCl or KCl. However, non specific binding of BTCP and COC increased 8- and 1.5 to 2-fold, respectively, when HCO₃⁻ was present.

CSF is buffered by HCO₃⁻. It is therefore important to study binding and uptake in HCO₃⁻ buffers, preferably artificial CSF, for physiological relevance. (This research was funded in part by NIDA grant DA03680)

DISTRIBUTION OF G PROTEIN α SUBUNITS AND THEIR COUPLING TO CLONED ADRENERGIC α -1 RECEPTORS IN COMMONLY USED TRANSFECTION HOSTS. J.A. Salon*, J.A. Bard, C. Forray, R.L. Weinschenk, and T.A. Branchek. Synaptic Pharmaceutical Corp., Paramus, NJ 07652.

The G protein-coupled receptor (GPCR) superfamily mediate neurotransmitter activity by coupling highly specific receptor binding events to finite cellular responses via the action of the intracellular G protein complex. The α subunit of the heterotrimeric G protein complex is believed to confer receptor and effector specificity. The importance of this specificity is critical for efficient coupling of heterologously expressed receptors. It would therefore be advantageous to know a priori which α subunits are required for a particular receptor and what G proteins are expressed in commonly used transfection hosts. To this end we have examined the G α mRNA content of 12 commonly used host cells and their coupling to transiently expressed human α -1 adrenergic receptors (AR).

Using northern analysis and PCR we have found that both G α 11 and G α q subunits are expressed in varying amounts in all lines tested with some evidence for message heterogeneity of the G α q subunit. Coupling to cloned AR α -1a, b, and c was also examined and found to be dependent upon both receptor and cell line. Intracellular calcium and PI turnover was demonstrated with α -1b and α -1c in LMTk-, CHO, and NIH3T3 lines while α -1a was functionally responsive in HEK 293 hosts only.

This cataloging of G protein expression in transfectant cell hosts should benefit the characterization of cloned GPCRs. Failure to couple efficiently, as seen with α -1a AR in multiple transfection hosts, may indicate the need for additional cellular components or very strict requirements for receptor/G protein interaction which are selectively expressed in mammalian cells. Supported by NIH grant 1R43AG10653-01.

PURIFICATION OF FUNCTIONAL GL1 α AND GL2 α CO-EXPRESSED WITH $\beta\gamma$ SUBUNITS IN A BACULOVIRUS EXPRESSION SYSTEM. F. Nakamura, M. Kato, K. Kameyama, T. Nukada, and T. Haga*. Dept. Biochem., Inst. Brain Res., Fac. Med., Univ. Tokyo, Hongo, Tokyo 113 Japan

We have previously cloned cDNAs encoding two kinds of G-protein α subunits, GL1 α and GL2 α , which correspond to mouse G α 14 and G α 11 of the Gq subfamily of G-proteins (Nakamura et al. J. Biol. Chem. 266, 12676-12681 (1991)). To characterize these proteins, we have expressed GL1 α and GL2 α in Sf9 cells using a recombinant baculovirus expression system. GL1 α and GL2 α were expressed as major proteins in the particulate fractions but were not significantly solubilized in buffers containing 1% sodium cholate or 1% Lubrol PX. By contrast, when Sf9 cells were co-transfected with a recombinant baculovirus that expressed bovine G-protein β 1 and γ 2 subunits, the α and $\beta\gamma$ subunits could be solubilized together in buffers containing 1% sodium cholate. The trimeric forms of G-proteins were partially purified by sequential DEAE-sephacel and heptylamine sepharose column chromatography. Purified trimers containing either GL1 α or GL2 α activated phospholipase C- β purified from bovine brain in the presence of GTP γ S or aluminium fluoride. This procedure, thus, provides a new way to obtain relatively large amounts of functional GL1 α and GL2 α proteins.

SELECTIVE EXPRESSION OF A NOVEL G-PROTEIN γ 7 SUBUNIT IN THE RODENT NEOSTRIATUM. J.B. Watson*, P.M. Coulter II†, J.E. Margulies†, L. deLecea‡, M.G. Erlender‡, and J.G. Sutcliffe†. †Mental Retardation Research Center, Department of Psychiatry and Biobehavioral Sciences, UCLA School of Medicine, Los Angeles, CA 90024, ‡Department of Molecular Biology, The Scripps Research Institute, La Jolla, CA. 92037.

G-protein γ subunits in the form of β - γ dimers modulate phospholipases, ion channels, and adenylate cyclases after their dissociation from α subunits. We used subtractive hybridization to clone a new G-protein γ subunit, named γ 7, that is expressed almost exclusively in the rodent striatum. Northern blot analysis detects two rare, brain-specific mRNAs of 3.0 Kb and 0.6 Kb, expressed predominantly in the striatum. Conceptual translation of the nucleotide sequences of full-length cDNA clones of each mRNA reveals a novel 69 amino acid sequence which is highly similar to the sequences of previously identified γ subunits. *In situ* hybridization detects the γ 7 subunit mRNA primarily in medium-size neurons of the neostriatum and nucleus accumbens, neurons of the olfactory tubercle and ventral pallidum, and at low levels in the dentate gyrus of hippocampus and laminae II,III,VI of the neocortex. The γ 7 subunit's selective pattern of mRNA expression is highly reminiscent of those of the striatum-enriched adenylate cyclase AC_{ST}, the dopamine receptors subtypes D1 and D2, and the α subunit of G_{OLF α} . This suggests that, in striatum, γ 7 is a subunit of a G_{OLF α} -containing G-protein that couples dopamine receptors selectively to AC_{ST}. This putative selective coupling pathway to cAMP production in medium-size spiny neurons represents a potential site of dysfunction in basal ganglia-selective disorders. Supported by the NIH, HD25831 (J.B.W.), and the Hereditary Disease Foundation (J.B.W.).

386.4

CHIMERIC G PROTEINS DEFINE G-PROTEIN-TUBULIN INTERACTION SITES IN β -ADRENERGIC ACTIVATION OF ADENYLATE CYCLASE. J.S. Popova*, G.L. Johnson² and M.M. Rasenick¹. U. Illinois College of Medicine¹ Chicago, IL 60612-7342 and Nat'l. Jewish Cr. for Immunology², Denver CO 80206.

The cytoskeletal protein, tubulin [Tub], has been shown to bind to G α s and G α i1, but not to G α i2, G α i3 or G α o. Tub with hydrolysis-resistant GTP analog bound (Tub-GppNHp) has also been found to activate adenylate cyclase [AC] in permeable C6 glioma cells, bypassing the β -adrenoceptor [β -AR]. Nucleotide transfer from Tub and thus direct activation of G α s was hypothesized to explain this. In order to determine the role of Tub as an intracellular signal transducing protein, we studied the effects of GppNHp and Tub-GppNHp on AC activity in permeable COS-1 cells after transient overexpression of wild type and chimeric G α proteins. Concomitant β -AR stimulation was assessed with (-)-isoproterenol [(-)-iso]. In naive COS-1 cells, Tub-GppNHp was significantly more potent and twice as efficacious as GppNHp in augmenting (-)-iso-stimulated AC activity. COS-1 cells overexpressing the chimeric protein G α s/i(38) [G α s 1-356; G α i2 357-392] demonstrated a 13-fold increase in AC activity upon GppNHp or Tub-GppNHp addition and (-)-iso caused no further increase in activity. The chimera G α i5/(bam) [G α i2 1-212; G α s 213-292] was found to be nearly identical to naive COS-1 cells in activating AC upon GppNHp or Tub-GppNHp stimulation. However, (-)-iso was found to potentiate GppNHp and not Tub-GppNHp responses. A third construct, G α i(bam)/i(38) [G α i2 1-212; G α s 213-356; G α i2 357-392] was poorly responsive to GppNHp or Tub-GppNHp and unresponsive to (-)-iso. Permeable COS1 cells expressing these constructs as well as chimera G α i(54)/s [G α i2 1-54; G α s 55-396] were exposed to tubulin with the hydrolysis-resistant photoaffinity probe, (³²P)-AAAGTP (azidoanilido GTP) bound, to study the ability of Tub to bind to G protein and transfer nucleotide. The results obtained support the view that: a) the loss of the C-terminal part of G α s molecule inhibits β -AR potentiation of Tub-guanine nucleotide stimulation of AC activity and b) the region between the 54th and 212th amino acids of G α s is important for guanine nucleotide binding and transfer from Tub as well as Tub-GppNHp stimulation of AC.

SUBSYNAPTIC LOCALIZATION OF GTP-BINDING PROTEINS. R.S. Cohen*, M.M. Rasenick and D.R. Manning. Dept. of Anatomy and Cell Biology and Dept. of Physiology and Biophysics, U. of Illinois at Chicago, Chicago, IL 60612 and Dept. of Pharmacology, U. of Pennsylvania, Philadelphia, PA 19104.

To localize GTP-binding proteins at the subsynaptic level, we used affinity purified antibodies to detect G_{α_i} , G_{α_o} , and G_{α_s} using the immunoperoxidase method on vibratome sections of rat cerebral cortex and hypothalamus. Following the reaction, the tissue was processed for EM. G_{α_i} , G_{α_o} , and G_{α_s} were localized at both pre- and postsynaptic sites. Synaptic vesicles (SVs) of some, but not all, presynaptic terminals were labeled in both brain regions. Dense-cored vesicles in the hypothalamus also showed reaction product. In addition to the presynaptic membrane, the presynaptic dense material was labeled. In postsynaptic processes, the postsynaptic membranes (PSMs) and postsynaptic densities (PSDs) were labeled by all the antibodies, although not all PSMs and PSDs showed reaction product. Some unlabeled PSMs and PSDs were adjacent to labeled ones and, in the case of G_{α_s} , a single presynaptic terminal was seen in association with both an unlabeled and labeled PSM and PSD. Subjunctional bodies beneath PSDs showed reaction product. The antibodies also labeled the membranes around and cytoskeleton within dendritic spines. Microtubules of dendritic synapses were also reactive. Preliminary observations of tubules in the two regions showed differences in the labeling patterns of G_{α_i} and G_{α_o} compared to G_{α_s} . The two former proteins appeared in a punctate pattern around cell bodies, while the latter appeared to show some cytoplasmic reactivity. Significant labeling by G_{α_i} was seen in glia. The presynaptic localization of these proteins suggest a possible role in docking of SVs and in other events related to vesicular transport. At the postsynaptic site, these proteins may undergo membrane-cytoskeletal interactions which modify signal transduction. Supported by NIH grants HD24553, MH39595, and GM34781.

EFFECT OF CHRONIC ANTIDEPRESSANT TREATMENT ON TUBULIN FUNCTION IN RAT BRAIN. H. Kamada¹, T. Saito^{1*}, H. Ozawa¹, S. Hattz², E. Hashimoto¹, T. Ashizawa¹, M. M. Rasenick³ and N. Takahata¹. Dep. of Neuropsychiatry¹ and Pharmacology², Sapporo Med. Univ., Sapporo, Japan 060. Dep. of Physiology and Biophysics, Univ. of Illinois³, Chicago, Ill 60608.

Tubulin, the cytoskeletal element, is a GTP-binding protein (G protein) with similarities to other G proteins. Tubulin, polymerized with the hydrolysis-resistant GTP analog, 5'-guanylylimidodiphosphate (GppNHP), can promote inhibition of rat cerebral cortex synaptic membrane adenylate cyclase. Although dimetric tubulins have been implicated as modulators of the adenylate cyclase system, the total mechanism of this regulation has not been clear. In this study, the effect of a chronic antidepressant on tubulin function in rat brain was examined. Male SD rats aged 1 to 6 months were treated with amitriptyline (AMT) by intraperitoneal injection (10mg/kg) for 21 days. Tubulin-GppNHP was prepared according to the method of Shelanski. The quantity of tubulin in cerebral cortical membranes was measured by immunoblotting. Adenylate cyclase (AC) activity was determined by the method of Salmon. GppNHP-stimulated AC activity was increased in the cortical membranes from AMT-treated rats. Tubulin-GppNHP prepared from AMT-treated rats was more potent than that from control rats in stimulation of cortical membrane AC from both AMT-treated rats and control rats. The amount of tubulin in cortical membranes of rats was not altered by AMT treatment. These results indicated that altered tubulin function, at least in part, contributed to an increased AC activity in chronic antidepressant-treated rats.

DIACYLGLYCEROL ANTAGONIZES THE INHIBITORY EFFECT OF ARACHIDONIC ACID ON THE GTPase ACTIVATING PROTEIN. P. Homayoun* and D.W. Stacey, Dept. of Mol. Biol., Cleveland Clinic Foundation, Cleveland, OH 44106.

The Ha-ras proto-oncogene product p21 participates in the transduction of proliferative signals by a mechanism that is largely unknown. P21 is active when bound to GTP and becomes inactive upon GTP hydrolysis. A cytoplasmic protein, GTPase activating protein (GAP) has been shown to stimulate the rate of hydrolysis of p21-bound GTP. Stimulation of DNA synthesis by ras has been shown to require protein kinase C (PKC) activity in many cell types. In fact, transformation of cells by oncogenic ras results in stimulation of phospholipid metabolism, the release of diacylglycerol (DG), arachidonic acid (AA) and stimulation of PKC. Since *in vitro* studies have shown that AA, but not DG, inhibits GAP activity, we were interested to determine if DG has a synergistic effect with AA in inhibiting GAP activity. Ras protein was loaded with [α -³²P]GTP and incubated in the presence of GAP alone or with lipids substrates. The rate of hydrolysis of p21-GTP was measured by precipitation of ras-bound-nucleotides by anti-ras antibody and the separation of ras-GTP from ras-GDP by thin-layer chromatography and measured by phosphorimager analysis.

Results have shown that: 1) DG (1-stearoyl, 2-arachidanoyl) did not affect GAP activity even at high concentrations (200 μ g/ml). 2) AA inhibits GAP activity in a dose dependent manner and reaches a saturation point at 200 μ g/ml. 3) DG antagonizes the inhibitory effect of AA on GAP in a dose dependent manner (IC₅₀=75 μ g/ml). These results suggest that a rise in DG concentration in cells not only stimulates protein kinase C activity but may also indirectly modulate the activation of GAP.

PARTICIPATION OF TUBULIN IN Gs-MEDIATED SIGNAL TRANSDUCTION THROUGH THE ASSOCIATION OF Gs PROTEIN. S. Hattz*, H. Ikeda, T. Saito, and H. Ohshika. Depts. of Pharmacology and Neuropsychiatry, School of Medicine, Sapporo Medical University, Sapporo 060, Japan.

Previously, we have demonstrated that tubulin dimers (Tu) interact with and transfer guanine nucleotide (GN) to G_i, and thereby inhibit adenylyl cyclase (AC) in rat cerebral cortex membranes (CCM). Under conditions used in those experiments (23°C/1 mM MgCl₂), transfer of GN to G_s from Tu was not observed. In this study, we examined the association between Tu and G_s, and effects of Tu on G_s-mediated signal transduction in rat CCM. Tubulin was prepared by polymerizing with GppNHP (Tu-GppNHP) or photoaffinity GTP analog, AAGTP (Tu-AAGTP) from rat brains. Incubation of CCM with Tu-[³²P]AAGTP at 30°C with 5 mM MgCl₂ resulted in incorporation of [³²P]AAGTP into G_s and G_i, indicating transfer of AAGTP from Tu to both G_s and G_i. Tu-GppNHP decreased agonist binding affinity for the β -adrenergic receptor (i.e., right shifted the isoproterenol competition curves of [³H]CGP12177 binding) with potency similar to that of GppNHP. Furthermore, Tu-GppNHP activated AC and stimulated isoproterenol-sensitive AC activity in CCM. These results suggest that in rat cerebral cortex, Tu participates in the regulation of G_s-mediated signal transduction by transferring GN to G_s as well as affecting G_i-mediated pathway.

ENDOTHELINS-INDUCED CALCIUM MOBILIZATION IN CANINE TRACHEAL SMOOTH MUSCLE CELLS. C.M. Yang* and Y.-L. Yo. Department of Pharmacology, Chang Gung Medical College, Taiwan, R.O.C.

Endothelins (ETs)-mediated rises of intracellular Ca²⁺ ([Ca²⁺]_i) were monitored in cultured canine tracheal smooth muscle cells (TSMCs) using a fluorescent Ca²⁺ indicator fura-2. ET-1, ET-2, ET-3 and S6b elicited an initial peak and followed by a sustained elevation of [Ca²⁺]_i, in a dose dependent manner. In the absence of external Ca²⁺, only an initial peak of [Ca²⁺]_i was seen, the sustained elevation of [Ca²⁺]_i can then be evoked by addition of 1.8 mM Ca²⁺. Ca²⁺ influx was required for the changes of [Ca²⁺]_i, since the Ca²⁺-channel blockers, diltiazem, verapamil, and Ni²⁺, decreased both the initial and sustained elevation of [Ca²⁺]_i in response to these peptides. TSMCs pretreated with phorbol 12-myristate 13-acetate (PMA, 1 μ M) for 30 min attenuated Ca²⁺ mobilization induced by ETs. While long-term (24 hr) PMA treatment resulted in a recovery of responsiveness. These results suggest that the inhibitory effect of PMA was mediated through the activation of protein kinase C. The changes of [Ca²⁺]_i induced by ETs were attenuated by cholera toxin pretreatment, but not by pertussis toxin. These results conclude that the initial detectable increase in [Ca²⁺]_i stimulated by these peptides is due to the release of Ca²⁺ from internal stores, whereas the contribution of external Ca²⁺ follows and is involved in a diltiazem- and verapamil-sensitive process. (supported by NSCB2-0412-B182-007 and CMRP-340).

DIFFERENTIAL LOCALIZATION OF p42 AND p44 MAP KINASES IN ADULT BRAIN. R.S. Fiore*, J.S. Fosnaugh, and J.M. Baraban. Department of Neuroscience, Johns Hopkins Univ. Sch. of Med., Baltimore, MD 21205.

p42 and p44 mitogen-activated protein (MAP) kinases are expressed at high levels in brain and are activated rapidly following neurotransmitter or growth factor receptor stimulation. To help determine their role in neuronal function, we have localized these isoforms immunohistochemically in rat brain sections. In previous studies, we found that p42 MAP kinase is prominently expressed in neuronal cell bodies and dendrites, where it is associated with microtubules (Fiore et al., *Neuroscience*, in press). Preliminary light-microscopic studies with antibodies selective for p44 MAP kinase suggest that this isoform is also found in neuronal cell bodies and dendrites. In addition, intense staining for p44 MAP kinase appears to be localized in oligodendrocytes and axons in several brain areas. Results indicating that p44 MAP kinase is present in axons support recent *in vitro* biochemical studies suggesting that tau, which is associated with axonal microtubules, is a substrate for MAP kinase (Drewes et al., *EMBO J.*, 1992) and suggest that the p44 isoform may be preferentially involved in regulation of tau.

386.11

TYROSINE PHOSPHORYLATION OF PLC- γ_1 INDUCED BY ELECTROCONVULSIVE SHOCKS IN RAT BRAIN. Y. M. Ahn¹, Y. H. Lee², P. G. Shu², S. H. Ryu², J. B. Park³, H. L. Kim⁴, and Y. S. Kim¹, Departments of ¹Psychiatry and ²Biochemistry, Seoul National University College of Medicine, Seoul, Korea 110-460, ³Division of Neurobiology, Department of Life Science, Pohang Institute of Technology, Pohang, Korea 790-784. ⁴LMB, NINDS, NIH, Bethesda, MD USA 20814.

Electroconvulsive shock(ECS) has long been used in psychosis but it's mechanism of action is still unclear. So we studied the possible involvement of PLC signal transduction system in rat brain by ECS.

The authors report here that ECS increased tyrosine phosphorylation of PLC- γ_1 in rat cerebral cortex and hippocampus. The tyrosine phosphorylation of PLC- γ_1 began to increase at 0.5 min. At 2 min, it showed further increase, reached peak at 10-20 min and returned to the baseline after 60 mins. However, the amount of PLC- γ_1 assessed with immunoblotting showed no difference. And the degrees of PLC- γ_1 tyrosine phosphorylation were not reflected on the PLC activity that was measured with PLC- γ_1 immunoprecipitates. These findings suggest that tyrosine phosphorylation of PLC- γ_1 could be observed in the brain of an intact animal, providing a way to access the mechanism of ECS with tyrosine kinase and PLC- γ_1 .

SUPERSENSITIVE DOPAMINERGIC BEHAVIORAL RESPONSES FOLLOWING 6-HYDROXYDOPAMINE LESIONS OF THE SUBSTANTIA NIGRA ARE ASSOCIATED WITH ALTERED PHOSPHORYLATION OF CREB IN RAT STRIATUM D. Cole*, C. Konradi, S. Hyman Lab. of Molecular and Developmental Neurobiology, MGH East, Charlestown, MA 02129

Following destruction of the substantia nigra (SN), rats develop a repertoire of supersensitive behavioral and cellular responses to dopaminergic (DAergic) drugs. Levodopa (L-DOPA) induction of *c-fos* expression in the striatum of these rats occurs via D1 receptors but without D1 receptor upregulation, suggesting that altered post-receptor signal transduction plays a role in DA receptor supersensitivity. A cAMP and calcium responsive element that binds CREB mediates *c-fos* expression when CREB is phosphorylated by protein kinase A or CaM kinase II *in vitro*. We have begun to test the hypothesis that SN ablation alters CREB phosphorylation in striatal neurons by L-DOPA *in vivo*.

Rats received unilateral 6-hydroxydopamine lesions of the SN. Rats rotating ≥ 5 times/min contralateral to the lesion after receiving apomorphine were given carbidopa/levodopa and perfused. Tissue was prepared for immunohistochemistry using polyclonal antibodies that recognize either 1) CREB regardless of phosphorylation state or 2) only CREB phosphorylated at serine-133 (PCREB; antibodies courtesy of M. Greenberg and D. Ginty). Staining on the lesioned side was compared with staining on the unlesioned (control) side.

Preliminary results revealed copious PCREB immunostaining in the nuclei of striatal neurons ipsilateral to the lesioned SN and a paucity of immunostaining contralaterally. CREB immunostaining was robust and symmetric on the two sides.

These preliminary results suggest that SN destruction alters DAergically mediated phosphorylation of critical signal transduction proteins, such as CREB. Modification of post-receptor pathways associated with supersensitive responses *in vivo* may play an important role in these responses.

386.15

INTRACEREBROVENTRICULAR FORSKOLIN INCREASES PHOSPHORYLATED-CREB AND FOS IMMUNOREACTIVITY IN RAT STRIATUM. J.N. Simpson*, W. T. Bohler, and J. F. McGinty, Department of Anatomy and Cell Biology, East Carolina University School of Medicine, Greenville, NC 27858-4354.

Activation of the adenylate cyclase/cAMP cascade leads to an increase in phosphorylation of cAMP responsive element binding proteins (CREBs) on Ser¹³³. Phosphorylated-CREBs (P-CREBs) then bind to cAMP responsive elements (CREs) in the promoter regions of several genes and induce their transcription. Intracerebral infusion of forskolin, an activator of adenylate cyclase, has been shown to induce striatal preproenkephalin (PPE) and preprodynorphin (PPD) mRNA signal (Simpson et al., Soc. Neurosci. Abst. 18: 1006, 1992). Because promoter regions of PPE, PPD, and *c-fos* genes contain CREs, the effect of forskolin on phosphorylated-CREB- and FOS-immunoreactivity (ir) was examined.

Five male Sprague Dawley rats (220-240 g) received intracerebroventricular (ICV) injections of forskolin (1 mM in 10 μ l ACSF) in their right ventricle and ACSF alone (10 μ l) in their left ventricle. One hour following ICV injections, rats were transcardially perfused with 4% paraformaldehyde and 50 μ m serial sections were collected through the striatum for immunocytochemistry. Incubation with polyclonal antisera against CREB, P-CREB (kindly donated by D. D. Ginty, Dept. Microbiology and Molecular Genetics, Harvard Medical School) and FOS (Oncogene Sci.) was followed by avidin-biotin peroxidase reagents (Vectastain Elite kit).

Although striatal CREB-ir was not altered by forskolin treatment, striatal P-CREB-ir was markedly increased on the forskolin-treated side as compared to the vehicle-treated side. In addition, striatal FOS-ir was induced only on the forskolin-treated side.

These results strengthen the hypothesis that forskolin acts through the adenylate cyclase/cAMP second messenger cascade to induce striatal opioid gene expression *in vivo*. Supported by DA 05470 (JNS) and DA 03982 (JFM).

CYCLIC AMP/VANADATE-SENSITIVE PHOSPHORYLATION OF SYNAPTOSOMAL PROTEINS. M.A.N. Edgar & L.A. Dokas*, Depts. of Biochemistry & Molecular Biology & Neurology, Medical College of Ohio, Toledo, OH 43699.

The central nervous system exhibits elevated levels of protein phosphorylation relative to other tissues, reflecting higher activities of protein kinases, as well as higher concentrations and larger numbers of substrates. The role of many of these proteins in maintenance and regulation of neuronal function remains unclear. A combination of immunoblotting and alkali digestion of SDS/PAGE-resolved [γ -³²P]ATP-labelled phosphoproteins reveals the presence of three prominent proteins with apparent molecular masses of 39, 50, and 58 kDa in the synaptosomal (P2) and synaptic plasma membrane (SPM) fractions of rat cortex. The 58 kD protein has been further separated by SDS/PAGE and one component corresponds to pp60^{src}. Further studies have revealed two cAMP-sensitive phosphoproteins in the P2 fraction with apparent molecular masses of 37 kD (IEP: 6.3) and 32 kD (IEP: 5.1). Phosphorylation of these two proteins is dependent upon both cAMP and vanadate. Phosphorylation of both proteins is maximal by 1 min., followed by dephosphorylation to basal levels by 5 min. Analysis of a number of brain regions demonstrates a widespread distribution of these proteins. Amino acid analysis indicates multiple phosphorylation sites for most of these proteins, ³²P-labelling occurring on serine, threonine and tyrosine residues. Supported by NIH grant NS30792.

DOWN-REGULATION OF CREB EXPRESSION IN A "LOCUS COERULEUS(LC)-LIKE" CELL LINE. K.L. Widnell* and E.J. Nestler. Laboratory of Molecular Psychiatry, Depts. of Psychiatry and Pharmacology, Yale School of Medicine, New Haven, CT 06508.

The cAMP response element binding protein (CREB) and its related proteins belong to a family of leucine zipper transcription factors which bind DNA as dimers. We have found that CREB is expressed in a newly derived "LC-like" cell line. This cell line, developed by Suri et al., exhibits a noradrenergic neural phenotype (*J. Neurosci.*, 13:1280, 1993). Moreover, Duman et al. have found that the cells, like the LC *in vivo*, possess VIP- and CRF-stimulated-, as well as opiate-, α_2 -adrenergic-, and NPY-inhibited-adenylyl cyclase (*Soc. Neurosci. Abs.* 18:343.5, 1992). In the current study, we addressed the effects of acute perturbation of the cAMP pathway on cell regulation. It is generally believed that the CREB gene is constitutively expressed and not subject to regulation. However, we have shown a 50% down-regulation of CREB mRNA levels after two hours of forskolin treatment, which was still present at six hours. This decrease in CREB mRNA was not observed when the cells were treated with 1,9-dideoxyforskolin, an analogue of forskolin which does not activate adenylyl cyclase. Short-term forskolin exposure causes these cells to differentiate modestly. However, two observations suggest that the forskolin-induced decrease in CREB mRNA is not a consequence of this differentiation per se: CREB mRNA levels were comparable in undifferentiated LC-like cells and in cells that were differentiated by serum starvation; and forskolin down-regulated CREB mRNA to the same extent in undifferentiated and differentiated cells. This study represents the first demonstration that CREB expression is subject to dynamic regulation, in this case mediated by the cAMP pathway.

TRACING THE SIGNAL TRANSDUCTION CASCADE BY WHICH S100 β INDUCES FOS PROTEIN IN GLIA. Stefan Strack and Linda J. Van Eldik*, Dept. Pharmacology, Vanderbilt Univ., Nashville, TN 37232-6600.

S100 β is a glia-derived protein that stimulates proliferation when added to cultures of rat primary astrocytes and the C6 glioma cell line (1). S100 also induces a transient rise in intracellular calcium (2) and *c-fos* mRNA (1). We have developed a rapid assay for measurement of *fos* protein expression in order to study early events in S100-stimulated second messenger cascades. C6 glioma cells are serum-starved and pulse-labeled with ³⁵S-amino acids in the presence of S100, and expression of *fos* protein is quantitated by immunoprecipitation with a *fos* antibody. Following stimulation of cells with low nanomolar S100, there is a transient increase in *fos* labelling that is maximal at 60 minutes and still slightly above baseline at 90 minutes after stimulation. *Fos* induction by S100 is somewhat delayed when compared to induction by PDGF in the same cells (peak at 45 minutes, baseline levels after 60 minutes), suggesting that these two growth factors induce *fos* via different pathways. Consistent with our previous results (1,2,3), disulfide-linked dimers of S100 are more potent than monomeric S100. We have begun to investigate the role of calcium transients in the S100-induced *fos* response. Preincubation with the intracellular calcium chelator BAPTA blunts S100-induced *fos* expression almost to control levels, suggesting that a rise in intracellular calcium is an obligatory step. Experiments are also in progress to investigate the potential contribution of protein kinase A and C activation and tyrosine phosphorylation to the mechanisms of S100-stimulated signal transduction. NEUROANATOMICAL DISTRIBUTION OF *DUNCE* HOMOLOGS IN THE MOUSE. J.A. Cherry* and R.L. Davis. Center for Learning and Memory, Beckman Neuroscience Center, Cold Spring Harbor Laboratory, Cold Spring Harbor, NY 11724.

In *Drosophila*, the *dunce* gene codes for a low Km, cAMP-specific phosphodiesterase. Flies bearing mutations at this locus perform poorly in a variety of associative learning tasks, including negatively-reinforced olfactory conditioning. Recently, 4 separate homologs of the *dunce* gene have been identified in both rats and humans. As a first step in determining whether a conservation exists in the function of *dunce* genes in flies and mammals, we have begun to examine the distribution of *dunce* in mouse brains. Using sequence obtained from rat (kindly provided by G. Bolger and M. Wigler), primers directed to the 3' region of each of the 4 genes were constructed. PCR was then used to amplify mouse brain cDNA; the product of each reaction was cloned into pGEMEX vectors (Promega) and sequenced to verify homology. Fusion proteins for each gene were expressed in *E. coli*, gel purified, and injected into rabbits. Resultant polyclonal antibodies were purified on affinity columns and are being used for immunohistochemistry (Vector Labs) of mouse brain tissue sections. Preliminary evidence for one of these proteins, the mouse homolog of the rat clone RD1 (Davis et al., PNAS 86:3604, '89), suggests that it is specific for olfactory sensory neurons. Strongest immunoreactivity (IR) is seen in axon bundles that project to the olfactory bulb and in dendritic knobs. Moderate IR occurs in dendrites and the cytoplasm of these neurons; little staining of nuclei occurs. The only staining that we have yet observed in brain is in the olfactory nerve layer that surrounds the olfactory bulbs and terminates in the olfactory glomeruli. Continued characterization of the neural distribution of *dunce* homologs in mouse will help direct future studies aimed at determining the function of these genes in mammals.

IMMUNOHISTOCHEMICAL LOCALIZATION OF CAM II KINASE IN THE SPINAL CORD OF THE HEN K. E. Jensen*, R. P. Gupta and M. B. Abou-Donia. Neurotoxicology Division, HERTL, U. S. EPA, RTP, NC 27711 and Dept. Pharmacology, Duke University, Durham, NC 27710

CaM II kinase has been hypothesized to be involved in the regulation of numerous aspects neural structure and function including the cytoskeleton, ion channels, gene regulation and neurotransmitter release. Previous immunohistochemical studies have emphasized that this enzyme is particularly abundant in the forebrain and less abundant in more caudal structures such as the brainstem. Such studies, however, have usually employed antisera recognizing the alpha subunit. In this study we employed an antiserum that recognizes both the alpha and beta subunits of hen CaM II kinase (Gupta et al., 1992, Biochem. Pharmacol. 43:1975). With this antiserum substantial CaM II kinase immunoreactivity was detectable in more caudal regions of the hen brain and was particularly abundant in the spinal cord. The difference between our findings and previous studies may be related to differences the ratios of alpha and beta subunits in different brain regions. This finding is particularly important since some neurotoxic organophosphates that produce spinal cord pathology, such as TOCP, also produce dramatic increases in CaM kinase II activity.

HYPOTHALAMIC-PITUITARY-ADRENAL AXIS REGULATION: BASIC AND CLINICAL STUDIES

387.1

PRENATAL STRESS AND ADOPTION HAVE OPPOSITE LONG-TERM EFFECTS ON HYPOTHALAMO-PITUITARY-ADRENAL AXIS ACTIVITY. S. Maccari*, C. Henry, M. Kabbal, P.V. Piazza, H. Simon and M. LeMoal. INSERM U259-Rue Camille St Saëns, 33077 Bordeaux, France.

Stressors during pregnancy result in offspring with morphological and behavioral alterations. Recently, we have also shown that prenatal stress increases the propensity to develop intravenous amphetamine self-administration in adult offspring. The hypothalamo-pituitary-adrenal (HPA) axis may play a critical role in these behavioral alterations. This study addressed two questions (i) Could prenatal restraint stress during the last week of pregnancy produce long-term alterations in stress-induced corticosterone secretion via modification of hippocampal type I and type II corticosteroid receptors? and if so (ii) is this effect due to a direct effect of prenatal stress on the offspring or is it mediated by altered maternal behavior? In order to answer these questions half of the animals were raised by their biological mother while the other half were assigned at birth to a foster mother. Our results show that in adult offspring: i) prenatal stress induces a prolonged corticosterone secretion in response to novelty exposure and a decrease (60%) of type I corticosteroid receptors ii) adoption per se decreases stress-induced corticosterone secretion iii) adoption and prenatal stress interact such that adoption totally reverses the effect of the prenatal stress procedure on corticosterone secretion and on type I corticosteroid receptors. In conclusion we might suggest that long lasting modifications of HPA axis activity may be one of the biological mechanisms by which the early environment influences behavior of the adult animal. Furthermore, prenatal and postnatal events seem to exercise opposite effects on HPA axis activity.

387.3

ADRENOCORTICOTROPIN STRESS RESPONSE IN CONGENITALLY LEARNED HELPLESS RATS. S.Y. Nguyen, R.V. Thompson and E. Edwards. Dept. Pharmacology & Toxicology, University of Maryland at Baltimore, Baltimore, MD 21201.

The learned helpless (LH) rat is an animal model of depression and/or anxiety. Through a genetic breeding program, we have established two strains of rats demonstrating susceptibility (cLH) or resistance (cNLH) to helpless behavior. We have compared the stress response of adult males cLH and cNLH rats to three different stressors: 40 min, 0.8mA footshock; 60 min restraint and 1 min ether exposure. Stress responsiveness was assessed by monitoring the changes in plasma levels of adrenocorticotropin hormone (ACTH). Shock exposure resulted in a significant 3 to 5 fold increase in plasma ACTH levels for both cLH and cNLH rats. However, cLH rats exhibited a blunted ACTH response as compared to cNLH rats ($p < 0.001$). Similarly, restraint stress produced a significant rise in ACTH levels in both cLH and cNLH rats (17 to 26 fold). Plasma ACTH levels were again lower in cLH rats as compared to cNLH. By contrast to footshock and restraint, 1 min ether exposure only cause a slight change (50-52% 1) in ACTH plasma levels of both cLH and cNLH rats. In addition, no strain differences were observed. A similar pattern of stress responsivity was observed in cLH and cNLH female rats for all three stressors. We have previously demonstrated a differential corticosterone stress response in cLH rats. This similar stress responsiveness to various stressors at the level of the pituitary is of potential significance suggesting that the pituitary gland may be one potential site for the dysfunctional HPA axis which characterizes the cLH rat.

387.2

ALTERED HYPOTHALAMIC-PITUITARY-ADRENOCORTICAL AXIS IN ADULT RATS AFTER PRENATAL IMMUNE CHALLENGE. J.M.H.M. Reul*, J. Stec, G.J. Wieggers, M.S. Labeur, A.C.E. Linthorst, E. Arzi and F. Holsboer. Max Planck Institute of Psychiatry, Clinical Institute, Department of Neuroendocrinology, Munich, Germany.

The Hypothalamic-Pituitary-Adrenocortical (HPA) axis plays a pivotal role in the maintenance of homeostasis. Cytokines, released from immune and other cells by immune challenges, not only coordinate the host defense reaction but also stimulate HPA axis activity. Both cytokines and HPA axis hormones play crucial roles during pregnancy. Maternal-fetal immune interactions are important for maintenance of gestation and maternal adrenocortical secretions influence fetal brain development. It remains unknown whether maternal cytokines also affect fetal brain development. We investigated whether prenatal immune stimulation affects fetal brain development and causes an altered HPA axis when adult. Pregnant rats were injected i.p. with lipopolysaccharide or human erythrocytes (HE) to stimulate their immune system by T-cell-independent and T-cell-dependent mechanisms. Adult male progeny of both groups had increased basal plasma corticosterone levels, whereas ACTH concentrations were unchanged. In addition, the HE group showed an increase in plasma ACTH and corticosterone in response to stress. Both immune-challenged groups had decreased levels of mineralocorticoid and glucocorticoid receptors in the hippocampus, a brain structure critical for HPA axis regulation. Infection during pregnancy can thus induce anomalies in fetal brain development and subsequent maladaptive adrenocortical responses to stress in adulthood.

387.4

EFFECTS OF PRENATAL DEXAMETHASONE ADMINISTRATION ON BRAIN BIOGENIC AMINE AND 3H-PAROXETINE BINDING CAPACITIES IN RAT OFFSPRINGS. K. Muneoka, M. Mikuni, T. Higuchi*, K. Takahashi and K. Matsumoto. Div. of Mental Disorder Res., Natl. Inst. of Neurosci., NCNP, Tokyo, 187 and Dept. of Neuropsychiatry, Fac. of Med., Kagoshima Univ., Kagoshima 890.

In this study, we have investigated whether, or not, glucocorticoid receptor activation in an immature brain can result in permanent changes in monoamine metabolism and receptor function once that brain is mature. Pregnant rats were given 0.05mg/kg (lower dose) or 0.2mg/kg (higher dose) of dexamethasone (DEX) on gestational days 17, 18 and 19. Brain biogenic amines including 5-HT, NE and 5-HIAA were measured by HPLC with ECD in hypothalamus of the offsprings at postnatal 21-day (P21D) and 12 weeks of age (12Ws). In addition, 3H-paroxetine binding assay was also performed for hypothalamus of male offsprings at 12Ws. In male rats at P21D, lower dose group showed significantly higher concentration of 5-HT compared to control and higher dose groups while higher dose group showed significantly higher 5-HT levels than control. 5-HIAA levels showed no significant changes among each groups. NE levels increased significantly in lower dose group compared to the other groups. At 12Ws, similar dose-specific effects of prenatal DEX treatment such as P21D on 5-HT levels of hypothalamus were seen in male offsprings. But NE levels showed no significant changes at this period. 3H-paroxetine binding capacities increased significantly in lower dose group rather than control. Higher dose group showed a tendency to be increased in 3H-paroxetine binding sites compared to control, but not significant. These results indicated that prenatal DEX administration altered brain biogenic amine levels and influenced the development of serotonergic neurons.

FISCHER AND LEWIS RAT STRAINS DIFFER IN CORTICOSTERONE REGULATION OF TYROSINE HYDROXYLASE AND OTHER PHOSPHOPROTEINS IN THE VENTRAL TEGMENTAL AREA. J. Ortiz and E. J. Nesler. Laboratory of Molecular Psychiatry, Dept. of Psychiatry, Yale Univ. School of Medicine, New Haven, CT 06508.

Fischer and Lewis inbred rat strains show different inherent preference for cocaine, alcohol and opiates. They also differ in their hypothalamic-pituitary-adrenal (HPA) responses to several pharmacological agents, with the Lewis strain being hyporesponsive as compared to the Fischer strain. We have studied HPA activity by measuring plasma concentrations of corticosterone (CORT) at different time points of the circadian cycle. We have also examined CORT regulation of several phosphoproteins that show Fischer-Lewis differences in the ventral tegmental area (VTA), locus coeruleus (LC) and dorsal raphe (DR), by means of back-phosphorylation and 2D gel electrophoresis, and immunoblotting techniques.

Naive male Lewis rats did not show an evening rise of plasma CORT, which indicates a clear impairment of HPA axis function. However, after the implantation of subcutaneous CORT pellets, plasma CORT increased 60% more in Lewis than in Fischer rats. This suggests that slower CORT metabolism might counteract partially a deficiency in CORT release in Lewis rats. In the brain regions studied, CORT administration regulated tyrosine hydroxylase (TH), glial-fibrillary acidic protein (GFAP) and a protein of Mr-70Kd whose identity is unknown. TH levels increased in the VTA of Fischer rats by 40-70%, abolishing pretreatment differences between these strains. GFAP back-phosphorylation increased in the VTA of Fischer rats and decreased in the DR and LC of Lewis rats, in a similar tendency to abolish inherent strain differences. The 70Kd protein showed increased back-phosphorylation in the VTA and DR of Fischer rats. No CORT regulation of neurofilament proteins was observed. Studies are currently underway to correlate CORT regulation of VTA phosphoproteins with behavioral measures of cocaine preference in Lewis and Fischer rats.

SOCIOREGULATORY EFFECTS ON SQUIRREL MONKEY PITUITARY-ADRENAL ACTIVITY. D.M. Lyons* and S. Levine. Dept. of Psychiatry and Behavioral Sciences, Stanford Univ. Sch. of Med., Stanford, CA 94305.

Squirrel monkeys show unusually prolonged elevations in plasma cortisol when separated from like-sex social companions. To determine whether this sustained hypersecretion of cortisol reflects a deficiency in neuroendocrine feedback mechanisms that normally inhibit the prolonged activation of the pituitary-adrenal axis, we collected simultaneous measures of plasma cortisol and plasma corticotropin (ACTH) from 30 juvenile monkeys (15 males, 15 females) over a 9-week period while animals were living in previously established groups, in individual cages, and in newly-formed groups. As found in recent studies of adults, mean cortisol titers were consistently higher in individually housed animals than when the same animals were housed in small like-sex social groups. When cortisol was elevated, however, ACTH titers were significantly and chronically reduced. These results suggest that elevated cortisol does indeed inhibit ACTH synthesis or release, and that hypercortisolism in squirrel monkeys living without social companions is not a consequence of chronic elevations in ACTH. Similar peculiarities in pituitary-adrenal activity have been noted in clinical studies of anorexia and endogenous depression.

387.9

STRESS-SPECIFIC EFFECTS OF CHRONIC INTERMITTENT STRESS ON TUMOR GROWTH IN NEONATALLY HANDLED AND NONHANDLED RATS: CORRELATES WITH HPA ACTIVITY

M. Walker, A. Steverman, S. Bhatnagar, N. Shanks* & M.J. Meaney, Depts. of Psychiatry & Neurology and Neurosurgery, Douglas Hospital Research Centre, McGill U., Montreal, Quebec H4H 1R3 CANADA

It has previously been demonstrated that elevated plasma corticosterone (B) levels support increased growth of Fujinami sarcoma virus (FSV) transfected fibroblasts in adult rats. Neonatal handling is known to permanently alter HPA responding such that nonhandled (NH) animals exhibit greater hypothalamic-pituitary-adrenal (HPA) responding to stress as adults than do neonatally handled (H) animals. We assessed the impact of two chronic intermittent stressor regimens (cold and restraint) on tumor incidence and growth in adult H and NH rats following inoculation with FSV transfected cells. Cold stress increased the incidence of tumors in both H and NH rats, whereas restraint stress did so only in the NH animals. Following 3 weeks of daily cold (4 hours, 4°C), H or NH plasma B and ACTH responding were similar to that seen on the first day of responding. In contrast, following 3 weeks of restraint (20 minutes daily) plasma B and ACTH responding was reduced in H animals relative to responses seen following the first stress exposure. Diurnal HPA activity was not affected by the chronic stressor exposure in either H or NH animals. Glucocorticoid receptor binding was determined for tumors and spleens, and did not vary across treatment groups. However, thymus binding was decreased in restraint stressed H animals, but was not altered in the other stress groups. These data indicate a greater incidence of tumors following a chronic stressor regimen when HPA adaptation was not observed and a lower incidence when HPA stress responding is dampened.

387.6

RAT LINES GENETICALLY SELECTED FOR DIFFERENTIAL RESPONSIVENESS OF THE DOPAMINERGIC SYSTEM DISPLAY DISTINCTLY DIFFERENT PITUITARY-ADRENAL CHARACTERISTICS. N.Y. Rots^{1,2}, M. Oitzl^{1,2}, A. Berod¹, W. Rostene³, A.R. Cools¹, E.R. de Kloet¹. ¹Dept. Pharmacol., Nijmegen Univ., 6500 IIB Nijmegen; ²Div. of Medical Pharmacology, Cent. Biopharm. Sci., Leiden Univ., 2300 RA Leiden, The Netherlands; ³INSERM U339, Hôpital Saint-Antoine, 75571 Paris-Cedex 12, France.

Rats of a normal outbred Wistar population were selected after an injection with the dopamine agonist apomorphine which induces a gnawing response. Apomorphine susceptible rats (apo-sus) showed an increased locomotor activity and a fleeing response in a defeat test while the apomorphine unsusceptible (apo-unsus) rats display a freezing response under the same conditions. Our studies were aimed to examine the neuroendocrine reactivity of the hypothalamic-pituitary-adrenal system of the two rat lines in order to obtain more insight into the physiological basis of their different behavioral performance. Apo-sus rats have the following characteristics (i) increased tyrosine hydroxylase mRNA in the dopaminergic A₉ cell group and altered features of striatal dopamine D₂-receptors, (ii) enhanced and prolonged ACTH release in response to a conditioned emotional stimulus, while total plasma corticosterone was similar, (iii) reduced basal and enhanced stress induced free corticosterone; binding of corticosterone to CBG was reduced, furthermore, the in vitro responsiveness of the adrenocortical secretion to ACTH was increased, (iv) MRs in the hippocampus assessed with quantitative in vivo autoradiography showed increased retention of radiolabeled corticosterone. In conclusion: This study with genetically selected rat lines suggests that increased nigro-striatal dopaminergic responsiveness is correlated with enhanced pituitary-adrenal reactivity.

387.8

RESISTANCE OF PLASMA CORTICOSTERONE LEVELS TO SUPPRESSION BY DEXAMETHASONE IN A TRANSGENIC MOUSE MODEL FOR MAJOR DEPRESSION. N. Barden*, F. Holsboer, J.M.H.M. Reul and I. Stec. Max Planck Institute of Psychiatry, Clinical Institute, Department of Neuroendocrinology, Munich, FRG and Molecular Psychogenetics Laboratory, Department of Physiology, Laval University Hospital Research Centre, Ste Foy, Québec, Canada.

Transgenic mice bearing a transgene expressing antisense RNA complementary to a fragment of the glucocorticoid receptor cDNA have hypothalamic-pituitary-adrenal (HPA) axis changes similar to those seen in depression including a hyperactive HPA axis as demonstrated by elevated early morning plasma corticosterone and ACTH levels, a reduced glucocorticoid binding capacity and, as a result, a deficient glucocorticoid feedback inhibitory mechanism¹. We have further investigated these changes in HPA axis regulation by use of different neuroendocrine challenge tests including a dexamethasone suppression test (DST) and/or stress. Transgenic mice required a ten fold higher dose (20 µg/100g BW) of dexamethasone to suppress the basal corticosterone levels than did normal mice. Pre-treatment of normal mice with 10 µg dexamethasone/100g BW completely suppressed their corticosterone stress response to a 15 minute exposure to a novel environment. In contrast, transgenic mice pre-treated with 0-20 µg dexamethasone 6h before exposure to the same stress paradigm always responded with an increase of plasma corticosterone levels. These findings are similar to those often observed in depressed patients who show no suppression in the DST and an increase of cortisol in a combined DST-corticotropin-releasing hormone challenge test² and support the hypothesis of a defective corticosteroid feedback mechanism in depressive illness.

387.10

HYPOTHALAMIC PITUITARY ADRENAL RESPONSES TO ENDOTOXIN IN CHRONIC INTERMITTENTLY COLD STRESSED NEONATALLY HANDLED AND NON HANDLED ANIMALS. S. Sharma*, S. Bhatnagar, N. Shanks, S. Gelber and M.J. Meaney. Developmental Neuroendocrinology, Lab., Douglas Hosp. Res. Ctr., McGill Univ., Montreal, Quebec, Canada H4H 1R3.

As adults, neonatally handled (H) rats secrete less corticosterone (B) and adrenocorticotropin (ACTH) following exposure to acute stress than non-handled (NH) animals. We have previously shown that when H and NH animals exposed to chronic intermittent cold stress (4°C for 4 h a day for 21 days; H CHR and NHCHR) are presented with a novel, heterotypic stressor (20 min restraint), NH CHR hypersecrete both ACTH and B compared to NH control (CTL) but H CHR are not different from H CTL. In the present study, we attempted to determine if this facilitation of HPA responses to novel stressors in NH animals extends to a stimulus that is thought to activate the HPA axis through the immune system. We administered endotoxin (*Salmonella enteritidis*; 1mg/kg) intravenously and examined the time course of plasma B and ACTH responses. Peak B and ACTH responses were seen at 1 or 2 h after endotoxin injection in all groups. However, neither H CHR nor NH CHR exhibited facilitation of B or ACTH responses to the endotoxin. Indeed, integrated B and ACTH levels suggested that prior exposure to chronic stress decreased responsiveness to endotoxin. These data suggest that facilitation of, and individual differences in, HPA responses to novel stressors in chronically stressed animals are dependant on the nature of the novel stress.

387.11

EFFECTS OF REPEATED ELECTROCONVULSIVE SHOCK (ECS) ON TYROSINE HYDROXYLASE ACTIVITY IN STRESSED RATS. Linda S. Brady* and Sung-Kwan Hong. Section on Functional Neuroanatomy, NIMH, Bethesda, MD 20892.

It is thought that the locus coeruleus (LC)-norepinephrine (NE) system may play a role in the therapeutic efficacy of ECS treatment for human depression, which may be associated with elevated NE activity in the CNS and periphery. We compared the effects of repeated ECS on tyrosine hydroxylase (TH) enzyme activity in stressed and unstressed rats. The treatment groups were: *stress* (immobilized for 2 h), *ECS* (80 mA, 0.5 sec, via earclips), *stress+ECS* (in immediate succession), and *control* (handled daily) for 7 days. All rats were sacrificed 24 h after the last treatment. The *stress* animals showed non-significant increases in adrenal weights and in TH enzyme activity in the adrenal gland and the LC. In both *ECS* and *stress+ECS* groups, the adrenal glands were enlarged (27% increase, $P < 0.05$), adrenal TH activity was increased (4.5-fold, $P < 0.001$), and LC TH activity was increased (4-fold, $P < 0.001$) relative to *control*. TH enzyme activity in the adrenals and LC of *stress+ECS* animals was ~2-fold greater ($P < 0.05$) than in *stress* animals but did not differ from activity in *ECS* animals. Thus, ECS effects on TH activity do not differ in stressed and unstressed rats. Repeated ECS does not restore TH activity to control levels in stressed rats, as might be predicted from its therapeutic effects in depression.

387.13

NEUROTENSIN/NEUROMEDIN N mRNA LEVELS ARE SELECTIVELY REGULATED BY CORTICOSTERONE IN FOREBRAIN CELL GROUPS. A.G. Watts* & G. Sanchez-Watts. NIBS Program & Dept. of Biol. Sci., USC, Los Angeles, CA 90089.

Recent results from our laboratory have identified changes in neurotensin/neuromedin N (NT/NMN) gene expression in a number of forebrain cell groups after disturbance to fluid homeostasis in the rat. Increased plasma osmolality leads to decreases in NT/NMN mRNA levels in the central nucleus of the amygdala (CEA), increases in neurons in parts of the lateral hypothalamic area (LHA), but no changes in the hypothalamic paraventricular nucleus (PVH). However, hypovolemia induced by subcutaneous (sc) injection of polyethylene glycol (PEG) leads to increases in NT/NMN mRNA levels in CRH neurons in the medial paraventricular PVH, in neurons of the periventricular nucleus (PV), but little change in neurons in the LHA. A feature common to both types of dehydration is increased plasma concentrations of corticosterone (CORT). To investigate the potential role of CORT in mediating these changes in NT/NMN mRNA levels we have used *in situ* hybridization to determine the regulation of NT/NMN mRNA levels by CORT. Male SD rats were bilaterally adrenalectomized under halothane anesthesia and 4 days later implanted sc with either a placebo pellet or a pellet containing 50mg, 100mg or 200mg of CORT (Innovative Research of America). Seven days later animals were anesthetized, and perfusion-fixed. Frozen 15µm coronal sections were cut through the forebrain and hybridized using a cRNA probe for NT/NMN. Analysis of the dipped slides (8 day exposures) and X-ray autoradiographs showed that CORT did not alter the levels of NT/NMN mRNA in the CEA or the LHA. In the PVH no NT/NMN mRNA was detected after any of the treatments. However in the PV immediately caudal to the PVH, substantial dose-dependent increases were observed. The location of these neurons raises the possibility of colocalization of NT in the tyrosine hydroxylase-containing neurons found in this same region. These results suggest that alterations in NT/NMN gene expression seen in the LHA and CEA after osmotic stimulation are not dependent on increased plasma CORT. The increases seen in the PVH after hypovolemia are also CORT-independent. However, CORT may mediate the increases seen in PV neurons after osmotic stimulation or hypovolemia. (Supported by NS 29728)

387.15

REVERSAL OF SEX DIFFERENCES IN HPA RESPONSE TO ENDOTOXIN CHALLENGE IN THE NEONATE BY GONADECTOMY. C.M. McCormick¹, N. Shanks², & M.J. Meaney². ¹Dept. of Psychology, Bates College, Lewiston ME 04240, & ²Dept. of Psychiatry, Douglas Hospital Research Centre, McGill University, Montreal PQ H4H 1R3.

The interaction between gonadal and adrenal steroids in their roles as immunoregulators is unclear. We recently reported a sex difference in HPA responsiveness in rat pups to immune challenge with endotoxin. In the present study, we assessed the effects of neonatal gonadectomy on the sex difference in HPA responsiveness. One-day-old pups were gonadectomized or subjected to sham surgery. At three days of age, pups were injected i.p. with .05mg/kg *salmonella enteritidis* endotoxin. Four hours later, we collected trunk blood and tissues. Sham females showed higher levels of plasma ACTH and corticosterone compared to sham males. The reverse was found in gonadectomized animals: Males showed elevated, whereas females showed decreased, corticosterone levels relative to sham same-sex controls. Gonadectomy did not change ACTH response to endotoxin in males, and elevated ACTH response in females. The reduction in CRH levels of gonadectomized animals following endotoxin did not differ between the sexes. These data suggest that sex differences in HPA response to immune challenge may be mediated at the level of the CNS in females, but may be due to altered adrenal sensitivity in males. Currently we are investigating the role of circulating sex steroids on immune/HPA function via gonadectomy and sex steroid replacement, and via administration of sex steroid antagonists.

CHRONIC ANTIDEPRESSANT TREATMENT IMPROVES SPATIAL MEMORY PERFORMANCE IN YOUNG BUT NOT AGED RATS. J.L.W. Yau*, T. Olsson, R.G.M. Morris¹, M.J. Meaney² and J.R. Seckl. Dept Med, Western Gen Hosp and ¹Dept Neuroscience, Edinburgh Univ and ²Douglas Hosp Res Centre, Montreal, Canada.

The emergence of cognitive deficits in a subgroup of aged rats is associated with increased hypothalamic-pituitary-adrenal axis activity, decreased hippocampal glucocorticoid receptor (GR) expression and neuronal loss. Neonatal manipulations that permanently increase hippocampal GR expression prevent these age-related deficits. We have previously shown that chronic antidepressant treatment increases GR gene expression in the hippocampus and have now investigated whether antidepressants improve spatial memory in young and aged rats. Lister-hooded rats aged 8 and 22±1 months were ranked according to performance in a watermaze (4 trials/day for 4 days followed by a free swim probe trial). In each group matched pairs of rats were treated with amitriptyline (10 mg/kg, i.p.) or saline daily for 9 wks. Thereafter the rats were reassessed in the water maze. Amitriptyline treatment significantly improved spatial memory in the young rats (30% increase in probe transfer time, $p < 0.05$ vs previous test and saline-treated controls). By contrast, in aged rats amitriptyline had no effect, either in rats showing normal or impaired spatial memory (compared to young controls). Our data indicate that antidepressant drugs improve spatial memory in young but not aged rats, presumably reflecting a loss of plasticity of cognitive function that precedes overt deficits and neuron loss. The relationship of this to hippocampal GR expression is currently being assessed by *in situ* hybridization.

REGULATION OF VASOPRESSIN AND OXYTOCIN GENE EXPRESSION IN PARVOCELLULAR NEURONS OF THE PVN BY STRESS AND STEROIDS IN THE HYPOSMOLAR RAT. T.G. Sherman*, J. Dohanics† and J.G. Verbalis†. Departments of Behavioral Neuroscience and †Medicine, University of Pittsburgh, Pittsburgh, PA 15260.

Chronic hyposmolality induces a down regulation of hypothalamic magnocellular vasopressin (AVP) and oxytocin (OT) synthesis. A first-order decay of AVP and OT mRNA levels results in only 10-15% of the mRNA content of control rats by day 14 of hyposmolality. Although the ability of the hypothalamo-neurohypophyseal system to down-regulate has important implications for studies of magnocellular physiology, it is also an attractive model for studies of the hypothalamic-pituitary-adrenal axis. We have previously shown that the effects of parvocellular-specific stressors on ACTH secretion are not impaired in hyposmolar rats. Hyposmolality, therefore, may prove to be an effective means to study parvocellular AVP and OT gene expression in the absence of the dominating influence of magnocellular AVP and OT. Measures of hypothalamic AVP and OT transcriptional activity, as measured by intron-directed *in situ* hybridization, were undetectable in 14 day hyposmolar rats, consistent with results from nuclear run-on studies. In hyposmolar rats, a dramatic increase in AVP primary transcript levels occurred 60 min after a single sc injection of metyrapone or after a 30 min restraint stress. Neither of these stimuli resulted in detectable changes in AVP or OT mRNA levels when measured by exon-directed *in situ*. The metyrapone-induced increases in nuclear AVP transcripts were mostly confined to parvocellular neurons, whereas the restraint-stress increases, while also largely parvocellular, resulted in magnocellular expression as well. These results demonstrate that using intron-directed *in situ* hybridization in hyposmolar rats enables detection of rapid up-regulation of AVP and OT transcription in parvocellular neurons of the PVN.

ORIGIN OF NEUROHYPOPHYSEAL NEUROPEPTIDE FF. E.A. Majane*, J. Zhu, A.A. Aarnisalo†, P. Panula#† and H. Y.T. Yang. Lab. Biochem. Genetics, NIMH, Washington, DC 20032, Univ. of Helsinki# and Abo Akademi Univ., Finland.†

Neuropeptide FF (FLFQPQRF-NH₂) is an FMRF-NH₂-like peptide with morphine modulating activity. Neuropeptide FF (NPFF) is unevenly distributed in the rat CNS with the highest concentrations found in posterior pituitary and spinal cord. In rat pituitary, NPFF is found exclusively in the neural lobe where it is localized in nerve terminals and fibers suggesting that hypothalamus is the source of neural lobe NPFF. In this study we investigated the origin of neurohypophyseal NPFF using electrolytic lesion studies and an anterograde tracing experiment. Lesions of the supraoptic nucleus (SON) caused a 50% reduction in pituitary NPFF while the lesion of a prominent NPFF cell body group found in the medial hypothalamus failed to alter NPFF content in neural lobe. HPLC analysis of punches taken from the SON confirm the existence of authentic NPFF in this area. An anterograde tracing experiment, showing that Phaseolus vulgaris-leucoagglutinin injected to SON is found in NPFF positive fibers in neurohypophysis, also supports the hypothesis that at least part of neural lobe NPFF originates from SON.

HYPOTHALAMIC/PITUITARY/ADRENAL AXIS RESPONSES TO AN EXERCISE CHALLENGE IN WOMEN WITH PERIMENSTRUAL MOOD ALTERATIONS. C.A. Cahill, J. Mallory, C. Thomas and K. Zuninga. University of Kansas Medical Center, School of Nursing, Kansas City, KS 66160.

The search for a neuroendocrine cause of altered mood states in some women during the late luteal phase of the menstrual cycle has traditionally focused on alterations in gonadal axis hormones. Yet, there is no evidence that women with perimenstrual symptomatology experience greater incidence of infertility or other gynecologic disorders. This suggests that altered gonadal axis function is not involved in mood changes. Psychosocial studies of causes of perimenstrual symptoms suggest that daily life stressors are predictive of perimenstrual symptom occurrence and severity. Recent evidence of stress axis and gonadal axis interaction suggests that the interface between these axes may be involved in perimenstrual symptom etiologies. Using the Stress Diathesis Model of Depression as an analogous paradigmatic for the investigation of stress axis function in perimenstrual symptomatology, we propose to describe the effects of a physical challenge (physical exercise) on plasma ACTH, prolactin and cortisol levels during the follicular phase of the menstrual cycle and the late luteal phase of the menstrual cycle. Five women who report few symptoms during both phases of the cycle will serve as the control group. Five women with low symptoms in the follicular phase and severe symptoms during the late luteal phase and 5 women with moderate symptoms during the follicular phase and severe symptoms during the late luteal phase will form the 2 experimental groups. Comparison of the hormone responses between cycle phases and among groups will be done to determine the tone and responsiveness of the stress axis in women with perimenstrual symptoms.

IMPLICATIONS OF MODEL SIMULATIONS DESIGNED TO REPLICATE OBSERVED PLASMA ACTH PULSATILE PHENOMENA IN HUMANS. B.M. Goodman, M. Carnes, S.J. Lent, and B.R. Brooks*. GRECC Service, Middleton VA Hospital and Dept. of Medicine, Univ. of Wisconsin, Madison, Wisconsin 57606.

ACTH is secreted in a pulsatile fashion forming a complex signal in the plasma compartment. Using high intensity venous sampling (1-2 min intervals) we have observed rapid short term (less than 10 min) elevations and suppressions in plasma ACTH concentrations in rats and human subjects which can not readily be explained by accepted ACTH clearance kinetics. We performed model simulations of pulsatile ACTH secretion using bi-compartmental clearance with time invariant parameters and were unable to replicate observed plasma ACTH phenomena. We were, however, able to generate the observed rapid fluctuations in plasma concentration by allowing the fraction of the ACTH signal shunted between the two clearance mechanisms (decay times of 3 and 30 min) to be modulated according to the rate of pulsatile bursts, independent of sign. This modeling work will be presented and its physiological implications discussed.

NEURAL-IMMUNE INTERACTIONS: SYMPATHETIC REGULATION OF
IMMUNE RESPONSE

388.1

THE EFFECT OF CHEMICAL SYMPATHECTOMY ON PRIMARY ANTIBODY RESPONSE IN YOUNG AND OLD F344 RATS. A.L. Langsam, C.L. Low, K.S. Madden, S.Y. Felten, D.L. Felten* & D.L. Bellinger, Dept. of Neurobio & Anat. Univ. of Rochester Sch. Med., Rochester NY 14642.

Studies from our laboratories, as well as others, have demonstrated noradrenergic (NA) sympathetic innervation of primary and secondary lymphoid organs. Further, we have shown a striking progressive decline in the density of NA nerves that distribute to spleens from old F344 rats, and a greater than 50% decline in splenic NE content. The time course of this age related loss of NA innervation of the spleen parallels an age-related decline in cell-mediated immunity. In the present study, we have examined the role of NA innervation of the spleen in primary antibody response in young and old F344 rats following chemical sympathectomy (SympX) with 6-hydroxydopamine (6-OHDA). KLH-induced antibody proliferation of splenocytes and serum antibody titers for keyhole limpet hemocyanin (KLH) were assessed at 2, 4, 5, 7, and 14 days after SympX (or vehicle injection) and subsequent immunization with KLH (150 µg i.p.). The number of anti-KLH secreting splenocytes was reduced, but serum antibody titers (both IgM and IgG) were elevated in vehicle-treated 17-mo-old rats compared with their young adult controls. SympX in both young and aged F344 rats altered both KLH-induced proliferative response and serum KLH antibody levels. The finding of altered primary antibody response in aged SympX animals demonstrates that NA sympathetic innervation is still capable of altering immune response with age, despite the significant age-associated decline in innervation. Uncertainty in Hormone Concentration Estimation: Advantages of Complete Error Propagation Through Standard Curves by Coupling to a Discrete Variance Function Martin Straume¹, Michael L. Johnson^{1,2}, Johannes D. Veldhuis¹ and David J. Hudson³, Center for Biological Timing and ¹Dept. of Med./Int. Med., ²Dept. of Pharm., ³Dept. of Biol., Univ. of Virginia, Charlottesville, VA 22901

Uncertainty in experimental determination of hormone concentration is quantified by coupling (i) discrete estimates of standard deviation in observed response from standard curves (*model-independent empirical variance "function"*) with (ii) nonlinear asymmetric error propagation through standard curve model parameters (*complete variance space mapping*). Advantages include (a) statistically accurate uncertainty estimation even from *single* data (precision improves as replicate number increases), (b) reliable estimation of concentration and uncertainty for hormone levels approaching zero, and (c) rigorous quantitation of *all* factors contributing to uncertainty. Many commonly encountered biasing and error-causing limitations are overcome by explicitly accounting for the contribution of (ii), not requiring replicate measurements, not basing uncertainty solely on variance from replicate measurements, and not requiring any particular analytical function for the variance model.

RESPONSIVENESS OF THE HYPOTHALAMIC-PITUITARY-ADRENAL AXIS TO A GLUCOSE CHALLENGE IN ALZHEIMER'S DISEASE. ¹R.A. Mulnard*, ²S. Moore, ²C.A. Sandman, ¹C.W. Cotman. Irvine Research Unit in Brain Aging¹, and Department of Psychiatry and Human Behavior², University of California Irvine.

As previously reported by Gold and associates, glucose has been shown to enhance memory function in well young and elderly subjects as long as glucose metabolism is normal. But, abnormal glucose metabolism, characterized by severe elevations in serum glucose, causes memory impairment. In elderly subjects with Alzheimer's disease (AD), enhancement of memory function under glucose conditions is demonstrated by improved performance on the Weschler Paragraph test for narrative memory. DeLeon has also reported that cortisol response to glucose as a biological challenge in AD subjects was characterized by a sustained rise in the hormone up to two hours after ingestion of the glucose solution. Our work aims to combine both of these projects by stimulating memory capabilities and the HPA axis with a biological challenge of 75 grams of glucose solution consumed over a ten minute period of time. 16 patients (10 AD and 6 non-AD) were tested with a modified Gold protocol. A wide range of neuropsychological tests were utilized to discriminate the effect on memory in the demented population. HPA axis response (ACTH, cortisol and B-endorphin) was measured in 10 patients at baseline and at the peak peripheral glucose level. The results, while preliminary in nature, have facilitated a revision in the original protocol and have shown a diversity of responses among the subjects, perhaps a phenomenon related to proposed physiological subtypes of AD.

388.2

IMMUNOCYTOCHEMICAL AND NEUROCHEMICAL ANALYSES OF SYMPATHETIC NERVES IN RAT BONE MARROW. K.L. Gibson-Berry, C. Richardson, S.Y. Felten*, D.L. Felten, Dept. Neurobiol. & Anat., Univ. Rochester Sch. Med., Rochester, N.Y. 14642

The innervation of femoral and tibial bone marrow was investigated utilizing immunocytochemical staining of fixed and decalcified tissue sections from normal Fisher 344 rats. Staining was achieved with antibodies recognizing PGP 9.5, a general neural marker, tyrosine hydroxylase (TH), the rate limiting enzyme in the synthesis of catecholamines, and neuropeptide Y (NPY), a neuropeptide often co-localized with norepinephrine in sympathetic fibers. Many PGP 9.5-, TH- and NPY-immunoreactive (ir) fibers were observed in association with the vasculature with a smaller number of fibers coursing in the parenchyma adjacent to hematopoietic elements. PGP 9.5-ir fibers appeared to be more abundant than either TH- or NPY-ir fibers suggesting that the TH- and NPY-ir fibers are only one component of the total innervation. To further investigate the neural origin of TH- and NPY-ir fibers, rats were chemically sympathectomized with the 6-hydroxydopamine (6-OHDA), with similar immunocytochemical analyses as described above. The vast majority of TH- and NPY-ir fibers were depleted by 6-OHDA treatment. Relatively fewer PGP 9.5-ir fibers were destroyed and these are believed to represent fibers containing additional neuropeptides such as substance P and CGRP. Additionally, fresh frozen samples of tibial and femoral marrow are being analyzed for norepinephrine content by HPLC, and for NPY content by radioimmunoassay. Extensive reduction in norepinephrine and NPY levels is anticipated in sympathectomized rats compared with control rats. Bone marrow from sympathectomized mice demonstrate enhanced proliferative responses (Madden et al., submitted for publication). Thus, we hypothesize that the presence of noradrenergic fibers and other peptidergic fibers in the parenchyma of the marrow and along the vasculature provides the anatomical substrate for neurotransmitter signaling of the hematopoietic marrow, and for potential central nervous system modulation of marrow proliferation, differentiation, or cell trafficking. INTERLEUKIN-2-INDUCED POTENTIATION OF IMMUNE FUNCTION IS MEDIATED BY THE SYMPATHETIC NERVOUS SYSTEM. S. Zalcman*, J. Green-Johnson, L. Murray, W. Wan, D.M. Nance & A.H. Greenberg. Manitoba Institute of Cell Biology, and *Department of Pathology, University of Manitoba, 100 Olivia St., Winnipeg MB, Canada, R3E 0V9.

Interleukin (IL)-2, a lymphokine produced by activated T cells, stimulates T and B cell responses, including antigen-specific immunoglobulin production. We have shown that peripherally administered recombinant IL-2 also induced marked increases in hypothalamic norepinephrine (NE) utilization but did not affect plasma corticosterone levels in mice. The hypothalamus mediates sympathetic outflow to lymphoid organs, and catecholaminergic stimulation during the early phases of the *in vitro* IgM plaque forming cell (PFC) response enhances the peak splenic PFC response (see Sanders and Munson, 1985). Hence, we assessed whether the effects of IL-2 on the IgM PFC response are mediated through the sympathetic nervous system. IL-2 (100 or 200 ng) administered ip to mice and rats either 1 day before or immediately prior to sheep red blood cell (SRBC) immunization markedly enhanced the subsequent peak splenic IgM PFC response, compared with controls receiving vehicle. IL-2 administered at a later time frame after immunization (i.e., 2 days) did not affect the number of antibody-forming cells. Intact sympathetic innervation of the spleen was required for the IL-2-induced immunoenhancement to occur in that cutting the splenic nerve (which reduced splenic NE content by approx. 98%) blocked the enhancing effects of IL-2 on the IgM PFC response in rats. The IL-2-induced immunopotential was likewise blocked in mice administered the β -adrenergic antagonist propranolol (5 mg/kg) immediately and 1 day after IL-2 administration. The α -adrenergic antagonist phentolamine (5 mg/kg) had no effect. Taken together, these data suggest that IL-2-induced potentiation of the IgM PFC response requires intact sympathetic innervation of the spleen and is blocked by β -adrenergic antagonists. It is suggested that lymphokines released during the early phases of the IgM PFC response may activate the sympathetic nervous system which in turn potentiates the ongoing immune response. Supported by NIMH and MRC of Canada.

CUTTING THE SPLENIC NERVE DIFFERENTIALLY AFFECTS CATECHOLAMINE AND NEUROPEPTIDE LEVELS IN THE SPLEEN. C.Y. Vriend*, W. Wan, A.H. Greenberg and D.M. Nance. Depts. of Psych. and Path. and Inst. of Cell Biol., Univ. of Manitoba, Winnipeg, MB, R3E 0W9

Sympathetic innervation of the spleen has been demonstrated, and norepinephrine (NE) and the neuropeptide Y (NPY) have been shown to be colocalized in splenic nerve fibers. In addition, vasoactive intestinal peptide (VIP) as well as substance P (SP) fibers have been identified in the spleen. Further, splenic lymphocytes have been shown to bear receptors for these neurotransmitters. We have previously shown that cutting the splenic nerve abrogates the immunosuppressive effects of footshock, and central injection of IL-1 β . In addition, splenic nerve cuts attenuate the immunoenhancement resulting from the peripheral injection of IL-2. To determine the effects of surgical denervation on splenic neurotransmitters, splenic nerve cuts or sham operations were performed on male S/D rats. One week later, spleens were removed and NE was assayed by HPLC. NYP and VIP were assayed by RIA. Previous attempts to assay SP by RIA failed to detect measurable quantities of this peptide so SP was not assayed in nerve cut rats. As expected, the NE content in spleens of nerve cut animals was reduced 90-100%. However, there was no change in NPY or VIP content. Additional nerve cut and sham operated animals were perfused and spleens were processed for immunocytochemistry of dopamine-beta-hydroxylase (DBH) and NPY in order to localize NE/NPY fibers. Staining for DBH/NPY fibers was eliminated in nerve cut animals. The discrepancy between the RIA data and the immunocytochemical data for NPY could be the result of endogenous production or increased uptake from the circulation in response to deinnervation. It could also be a result of differences between the antibodies used in the two methods. The possibility of an alternate source of splenic NPY should be further examined as well as the disposition of VIP and SP before and after nerve cut. Supported by MRC and NIMH.

388.7

CHEMICAL SYMPATHECTOMY AND THYMECTOMY EFFECTS ON SPLENIC ANATOMY IN THE FROG *XENOPUS LAEVIS*. K.S. Kinney*, S.Y. Felten, J.D. Horton, and N. Cohen. Univ. of Rochester Sch. of Med. and Dent., Rochester, NY 14642 and Univ. of Durham, Durham DH1 3L3, U.K.

The spleen of the adult frog *Xenopus laevis* is separated into clearly defined compartments of red pulp and lymphopoietic white pulp, much as is seen in mammals. Also similar to mammals, sympathetic innervation of the spleen is noradrenergic (NA) and largely confined to the white pulp. To further characterize the resemblances to and differences from the mammalian system, selective depletion of portions of the nervous or lymphoid components of the spleen were performed. 6-Hydroxydopamine (6-OHDA) selectively destroys noradrenergic nerve fibers. Treatment of adult frogs with 6-OHDA results in a striking loss of NA fibers in the spleen, as assessed by SPG histofluorescence. This observation has been confirmed using immunocytochemistry directed against tyrosine hydroxylase and PGP 9.5, a pan-neuronal marker. Regeneration of the sympathetic nerve fibers occurs during the next two months.

To examine the possible influences of T-cells on splenic innervation, *Xenopus* larvae were thymectomized at 7 days post-fertilization. This results in a loss of T-lymphocytes and T-cell dependent immunity which persists through metamorphosis into adult life. In such frogs overt sympathetic innervation develops as in intact controls (i.e., at the end of metamorphosis) despite the lack of T-cell compartments.

388.4

ENHANCED CATECHOLAMINERGIC INNERVATION OF LYMPHOID TISSUES IN NGF TRANSGENIC MICE. D. Beiting, K.M. Albers, B.M. Davis and S.L. Carlson*. Depts. of Anatomy & Neurobiology and *Pathology, University of Kentucky Medical Center, Lexington, KY 40536-0084

Lymphoid tissues are innervated by the sympathetic nervous system with a distinctly compartmentalized distribution of fibers. Nerve growth factor (NGF) is essential for the maintenance of peripheral sympathetic neurons, however the mechanism by which the pattern of innervation of lymphoid tissues is determined remains unknown. We have examined the lymphoid tissues of NGF transgenic mice to determine if the presence of increased NGF modifies the pattern of innervation. These transgenic mice express high levels of NGF in the skin starting late in prenatal development and continuing into adulthood. To study the sympathetic innervation of the spleen and lymph nodes (peripheral and mesenteric), 30 μ M sections were stained with anti-tyrosine hydroxylase. The immunoreactivity in the spleen and peripheral lymph nodes of the transgenic mice is tremendously enhanced compared to controls, but maintains the compartmentation of the innervation patterns. In control spleens, the central artery innervation is more prominent than that in the marginal zone, and fibers are rarely found in the red pulp. In the spleens of transgenic mice, the fibers are very dense in the marginal zone, with somewhat less than normal innervation surrounding the central artery. In some spleens, many fibers are found in the red pulp as well. The peripheral lymph nodes of control mice have sympathetic innervation in the medulla in association with vessels. In contrast, the peripheral lymph nodes of the transgenic mice have extremely dense innervation in the medulla and capsule, with the fibers sometimes ringing B-cell follicles but not extending into the cortex or paracortex. Interestingly, innervation of the mesenteric lymph nodes of the transgenic mice is not much different than in controls. In summary, these transgenic mice may provide a good model system to study the factors that direct the pattern of innervation of these tissues and the consequence of hyperinnervation on immune function. 388.6

NORADRENERGIC INNERVATION OF MURINE SPLEEN: NE CONTENT AND CONCENTRATION SHOW MINOR STRAIN DIFFERENCES AND MINIMAL OR NO DIURNAL VARIATION. S.P. Kelley, L.J. Grota, S.Y. Felten, K.S. Madden*, D.L. Felten. Dept. Neurobiol. & Anat. Univ. Rochester Sch. Med., Rochester, NY 14642.

Strain differences have been invoked to explain differing results when studying neural-immune interactions in laboratory animals. Recently, Lyte et al. (J. Neuroimmunol. 1991. 31:1-8) reported 6-fold strain differences in norepinephrine (NE) concentration (conc.) in C57BL/6 compared with DBA/2 mice. We investigated the splenic NE content and conc. in 3 strains of male mice (BALB/C, C57BL/6, & DBA/2), as well as possible diurnal variability in this innervation. Mice were housed on a 12 hr on/12 hr off light/dark cycle for 3 weeks, then sacrificed at one of 6 times during the 24 hr. cycle, and spleen NE total content and concentrations were determined using high performance liquid chromatography with electrochemical detection. We found a small but significant difference between strains in total resting spleen NE content (BALB/C > C57BL/6 > DBA/2) and in resting NE conc. (C57BL/6 > BALB/C > DBA/2). This may reflect differences in spleen weight (BALB/C > DBA/2 > C57BL/6). We were unable to find more than subtle differences in NE content or concentration based on the time of day sampled; it is unlikely that NE innervation of spleen shows conspicuous diurnal variation for these parameters.

Strain	Total NE (pMoles)	NE (pMoles/mg)	Spleen Wt. (mg)
BALB/c	340.7 \pm 58.4	3.26 \pm 0.73	108 \pm 27
C57BL/6	216.4 \pm 43.8	4.49 \pm 1.99	52 \pm 12
DBA/2	174.9 \pm 59.8	2.37 \pm 0.76	73 \pm 11

SPLENIC REDUCTION IN NOREPINEPHRINE IN MRL-LPR/LPR MICE IS PREVENTED WITH CYCLOPHOSPHAMIDE. S.M. Breneman*, I.A. Moynihan, L.L. Grota, S.Y. Felten. Depts Neurobiology & Anatomy, Psychiatry and Immunology, Univ. Rochester Sch. Med., Rochester, NY 14642.

The MRL-lpr/lpr mouse has been used extensively as a murine model of systemic lupus erythematosus. These mice develop an autoimmune disease characterized by increased anti-DNA titers, hypergammaglobulinemia, glomerulonephritis, marked lymphadenopathy and splenomegaly. The increased size in the lymphoid organs is due to a massive expansion of a subset of T-cells which are CD3+, CD4-, and CD8- (double negative, DN) which has been shown previously to be reduced with treatment by the DNA alkylating agent, cyclophosphamide (Cy).

Sympathetic involvement in neural communication with the immune system has been examined by our lab in this autoimmune model as well as others (arthritis). We have shown previously that the NE sympathetic innervation of the MRL-lpr/lpr spleen was reduced as the disease developed. Eight week old female MRL-lpr/lpr and their congenic control strain, MRL-+/+ were treated weekly with 100mg/kg i.p. of Cy. Treatment continued through 17 wks and the animals were sacrificed at 18 wks. Cy treated lpr/lpr animals had disease measures equal to untreated +/+ and total splenic NE (as measured by HPLC) equal to untreated +/+ indicating that the innervation reduction is not a direct genetic effect or an epiphenomenon but rather a direct result of disease state. This work supported by grants from the Whitehall Foundation and the NIMH, MH10347.

BETA-ADRENERGIC RECEPTOR REGULATION OF MACROPHAGE (MO)-DERIVED TUMOR NECROSIS FACTOR (TNF) PRODUCTION IN EXPERIMENTAL ARTHRITIS. R.C.Chou, M.W.Stinson, C.M.Smith* and R.N.Spengler. Depts. of Pathology, Microbiology, and Pharmacology and Therapeutics, SUNY-Buffalo, Buffalo, NY 14214.

The nervous system may play a role in the pathogenesis of rheumatoid arthritis (RA). It is also known that TNF is found in the synovial fluid of RA patients. In the present study, we have determined that β -adrenergic agonists inhibit lipopolysaccharide (LPS)-stimulated TNF production and gene expression in complete Freund's adjuvant (CFA)-elicited female Lewis rat peritoneal MOs. Therefore, we examined β -adrenergic regulation of LPS-induced TNF production in female Lewis rats with streptococcal cell wall (SCW)-induced arthritis. Peritoneal MOs were harvested from rats with chronic arthritis and from non-arthritic CFA rats. Elicited MOs were stimulated with LPS (100ng/ml) and the β -adrenergic agonist regulation of TNF production was assessed. MOs from both groups showed similar TNF production after LPS stimulation alone. Upon addition of isoproterenol (ISO), a β -adrenergic agonist, MOs from the CFA group showed a concentration-dependent inhibition by ISO of LPS-stimulated TNF production. A change in β -adrenergic sensitivity was produced after pretreatment of the CFA group MOs with appropriate agonists/antagonists for one hour before LPS challenge. However, MOs from the SCW group did not show similar inhibition of TNF production upon addition of ISO. Furthermore, changes in sensitivity could not be induced in MOs from SCW group as compared to CFA group. Results of our studies show that MOs from the SCW group are unable to transduce the β -adrenergic signals into effector function, which may help explain the elevated TNF levels in rheumatoid synovium. (Supported by Arth Fdn and in part by AHA)

388.11

CATECHOLAMINES INHIBIT LYMPHOCYTE BINDING TO ENDOTHELIAL CELLS. C. Kioni, K. Abell, J.P. McGillis* and S.L. Carlson. Dept. of Anatomy & Neurobiology and *Microbiology and Immunology, University of Kentucky Medical Center, Lexington, KY 40536-0084

The autonomic nervous system, through the catecholamines norepinephrine and epinephrine, can modulate a variety of immune responses. Little is known, however, of the exact mechanisms by which this occurs. One hypothesis is that catecholamines may alter the patterns of lymphocyte migration or homing to lymphoid tissues or inflammatory sites. Lymphocyte homing is accomplished through the interaction of adhesion molecules expressed by lymphocytes and specialized endothelial cells (high endothelial cells, HEC) lining postcapillary venules in lymphoid tissues or at inflammatory sites. To examine the possibility that catecholamines can alter these interactions, we have studied lymphocyte binding to ECs *in vitro*. ECs were isolated from human umbilical vein (HUVEC), and cultured in 24 well plates until confluent. On the day of the experiment, half of the HUVECs were preincubated with 1U/ml interleukin-1 β (IL-1 β) for 4 hours to enhance their expression of adhesion molecules. Human peripheral blood T-cells were isolated, loaded with a fluorescent dye, then added to the HUVEC cultures, with or without the addition of various concentrations of epinephrine (Epi) or the β -adrenergic agonist isoproterenol (Iso). After 30 or 60 minutes incubation, the non-adherent lymphocytes were washed away, and the adherent cells counted using a fluorescence microscope. IL-1 increased the number of T-cells bound by two fold compared to adhesion to unstimulated HUVECs. The presence of Epi or Iso inhibited lymphocyte binding to the IL-1 stimulated HUVECs by up to 50%, with a dose response over the range of 1-100nM. Preincubation of only the lymphocytes or HUVECs with Epi or Iso prior to the adhesion assay did not change the number of lymphocytes bound. It is known that some of the adhesion molecules change to a high affinity state during the process of lymphocyte-EC binding. Thus catecholamines may modulate the dynamics of the interactions between adhesion molecules expressed on the lymphocytes and ECs. (Supported by R29 MH48644)

TRYPSIN ENHANCES 6-HYDROXYDOPAMINE-INDUCED NEUROGENIC PLASMA EXTRAVASATION IN THE RAT KNEE JOINT: EVIDENCE FOR A PEPTIDE INHIBITOR OF EXTRAVASATION FROM THE SYMPATHETIC NEURON.

Paul G. Green*, Jian Luo, Elena R. Hammond and Jon D. Levine
Depts. Oral and Maxillofacial Surgery, Anatomy and Medicine, UCSF, San Francisco, CA 94143

Perfusion of 6-hydroxydopamine through the rat knee joint causes an increase in plasma extravasation by activation of sympathetic postganglionic neuron (SPGN) terminals. Similarly, the increase in plasma extravasation in the rat knee joint produced by the inflammatory mediator bradykinin is dependent on the SPGN. There is evidence that both 6-hydroxydopamine and bradykinin release a number of mediators, some of which appear to enhance plasma extravasation and some which inhibit it. We attempted to determine the nature of inhibitory factor(s) by co-infusing trypsin (which rapidly cleaves peptides) with 6-hydroxydopamine. We observed a marked enhancement of 6-hydroxydopamine-induced plasma extravasation by trypsin. This effect appeared to be specific to neurogenic plasma extravasation since trypsin alone had little effect on plasma extravasation and trypsin did not affect non-neurogenic plasma extravasation (that produced by platelet activating factor). Taken together, the data suggests that 6-hydroxydopamine not only releases mediators from the SPGN that enhance plasma extravasation, but also an inhibitor(s) of plasma extravasation that is peptide in nature.

NEURAL-IMMUNE INTERACTIONS: OTHER NEUROTRANSMITTERS IN IMMUNE TISSUES

COMPARISON OF CHOLINE-O-ACETYL TRANSFERASE (ChAT) IN ADULT MOUSE BRAIN, THYMUS, AND SPLEEN. M. Badamchian*, T. Damavandy, and K. Bulloch. Department of Biochemistry and Molecular Biology, The George Washington University School of Medicine and Health Sciences, Washington, DC 20037. Department of Psychiatry School of Medicine, University of California San Diego, La Jolla, CA 92161.

Recently, we characterized the ChAT in BALB/C mouse thymus anatomically and biochemically (Badamchian et al., *Progress in Neuroendocrinology*, 5(4), 1992). In this present study: 1) we continued to analyze the possibility of cholinergic immunomodulation of immune tissues by determining if ChAT is also present in the BALB/C mouse spleen, and 2) we compared the biochemically characterized ChAT in the adult BALB/C mouse brain, thymus and spleen. ChAT activity in the spleen extract was found to be 0.05 nmoles/min/mg protein compared to the 0.035 and 0.1 nmoles/min/mg protein found in the thymus and whole brain extract controls, respectively. Western Blotting and immunochemical visualization of ChAT using the anti ChAT monoclonal antibody, MB16, demonstrated two bands with molecular weights of 28 and 59 kDa in the brain membrane-bound ChAT. In contrast, the spleen and thymus demonstrated only one identical band with a molecular weight of 28 kDa. Immunoprecipitation of the enzyme from the brain, thymus and spleen resulted in a recovery of 59%, 60% and 60% of the activity, respectively.

389.2

CHOLINERGIC- AND β -ADRENERGIC RECEPTOR INVOLVEMENT IN NICOTINE'S IMMUNOSUPPRESSIVE EFFECTS C.G. McAllister, A.R. Caggiula, S. Knopf, L.H. Epstein, A.L. Miller, S.M. Antelman, K.A. Perkins, and D.J. Edwards*. *Univ. of Pittsburgh and Pittsburgh Cancer Institute, Pittsburgh, PA 15213*

We have reported that acute nicotine (NIC) produces a dose-dependent decrease in the response of rat peripheral blood leukocytes (PBL) to mitogens (Caggiula et al, *Drug Dev Res* 26 1992), and a similar, but less consistent effect on splenic leukocytes (SL; Knopf et al, *Soc Neurosci Abst.* #288.8, 1992). In the present work, male rats were given 1 mg/kg of mecamylamine (MEC), an antagonist of central and peripheral nicotinic cholinergic receptors 10 min before 1.32 mg/kg (free base) of NIC. MEC antagonized NIC's effects on PBL responses to both concanavalin A and phytohemagglutinin (PHA), and SL responses to PHA. Currently we are using MEC and chlorisondamine, a peripheral blocker, to determine the involvement of central vs peripheral cholinergic receptors. In a second study, the β -adrenergic antagonist propranolol (2 mg/kg, 30 min before NIC) attenuated the suppressive effects of NIC on the SL response to PHA but did not antagonize NIC's effects on the PBL mitogenic response. These initial results suggest that while both SL and PBL effects of NIC are mediated by cholinergic receptors, activation of β -adrenergic mechanisms is more important for the SL than for the PBL action. Supported by DA07546.

CELLULAR LOCALIZATION OF QUINOLINIC ACID IN THE RAT
MG Espey, JR, Moffett, SJ Gaudet*, and MAA Nambodiri. Dept. of Biology, Georgetown University, Washington, DC 20057.

Quinolinic Acid (QUIN) is an endogenous neurotoxin of unknown origin and is thought to be involved in a variety of neuropathological conditions. QUIN is a metabolite in the kynurenine pathway of tryptophan degradation and is produced in large amounts in response to immune stimulation via an interferon gamma mechanism, resulting in increased levels in the brain and peripheral tissues. In the present study, we have determined the cellular localization of QUIN using a highly specific polyclonal antibody preparation recently produced in our laboratory.

Polyclonal antibodies against QUIN were made in a New Zealand white rabbit using protein coupled and gold absorbed QUIN. The antiserum was purified by preabsorption with carbodiimide (CDI) coupled protein conjugates of glutamic, nicotinic, and picolinic acids and with CDI treated brain protein homogenate. Anesthetized Sprague-Dawley rats were perfused transcardially with an aqueous solution of CDI (6%), DMSO (5%), and N-hydroxysuccinimide (1mM) to covalently couple QUIN to tissue proteins. Immunohistochemistry was performed on frozen cryostat tissue sections using the ABC-peroxidase method. No significant QUIN immunoreactivity was detected in the brain. In contrast, strong QUIN immunoreactivity was detected in the spleen, thymus, lymph node, bronchial and gut associated lymphoid tissue, skin, and intestinal villi. QUIN immunoreactive cells have the morphology of macrophage and dendritic cells. These findings indicate a specific involvement of QUIN in the immune system and support a role for this NMDA receptor agonist as a unique cytokine involved in antigen processing.

DECREASES IN PERIPHERAL-TYPE BENZODIAZEPINE BINDING SITES IN SPLEEN OF BULBECTOMIZED RATS. T. Dennis*, V. Beauchemin and N. Lavoie. Department of Psychiatry, McGill University, Montréal, Canada.

Numerous parallels can be drawn between the behavioral and biochemical changes observed in rodents following bilateral olfactory bulbectomy (OBX), and in patients presenting with major depression. Several studies have shown that these patients present an immunitary dysfunction. The *in vitro* and *in vivo* immunomodulatory effects of peripheral-type benzodiazepine binding site (PBBS) ligands are consistent with the high densities of these sites on cells of the T- and monocytic lineages in the rat immune system organs (Benavides *et al. J. Pharmacol. Exp. Ther.* 249: 333, 1989). In the present study, we investigated the effects of OBX on PBBS densities and autoradiographic distribution in rat thymus and spleen.

Four weeks after OBX or sham surgery, male Sprague-Dawley rats were sacrificed by decapitation, organs were quickly removed, weighed and frozen on dry ice. Tissue sections were processed for autoradiography, PBBS were labelled with 1 nM [³H]PK-11195. Thymus glands from OBX rats showed a significant involution. PBBS were heterogeneously distributed throughout the thymus tissue with higher densities of [³H]PK-11195 binding sites in medulla than in cortex. There was no alteration in PBBS binding densities in the thymus following OBX. Similar to thymus, spleen weights from OBX rats were significantly decreased. In control animals, higher densities of [³H]PK-11195-labelled PBBS were found in the white pulp compared to the red pulp. Following OBX, PBBS densities were decreased in both regions of the spleen.

The present results confirm that cell lines of the rat immune system possess high densities of PBBS and are consistent with the notion that OBX in rats may induce an immunitary dysfunction similar to that found in major depression in humans.

SUBSTANCE P (SP)-POSITIVE NERVE FIBERS IN INTERSTITIAL CYSTITIS (IC) - J. Marchand*, X. Pang*, G.R. Sant*, R.M. Kream* and T.C. Theoharides*. Departments of Pharmacology and Experimental Therapeutics¹, Anesthesiology² and Urology³ Tufts University School of Medicine and New England Medical Center, Boston, MA 02111, USA

IC is a painful bladder disorder occurring mostly in women and is characterized by frequency, nocturia, suprapubic pain and sterile inflammation. Most prevalent pathologic findings are those of mucosal tears, and increased numbers, as well as activation of bladder mast cells over controls. Experimental studies using perfusion of human biopsies showed bladder mast cell activation with SP.

Immunohistochemistry was performed blindly on 10 biopsies which were immersed immediately in 4% paraformaldehyde/0.1 M phosphate buffer for 24 hr at 4°C, and transferred to 20% sucrose/0.1 M phosphate buffer for 24 hr at 4°C. Cryostat sections were cut at 7 µm, thaw-mounted, and incubated for 48 hours with rabbit anti-SP primary antibody and visualized using the ABC technique (Vector). A dense plexus of SP-positive fibers was evident in the submucosa, immediately deep to the epithelia and often perivascularly. Numerous SP-positive fibers were also found surrounding bundles of smooth muscle in the muscularis lamina. SP may, therefore, be involved in mast cell activation, as well as in the painful and inflammatory aspects of IC.

SPONTANEOUS LOSS OF T CELL SELF TOLERANCE TO GLUTAMATE DECARBOXYLASE IS A KEY EVENT IN THE PATHOGENESIS OF MURINE INSULIN-DEPENDENT DIABETES. J. Tian, P.V. Lehmann, T. Forsthuber, G. S.P. Ting, D. Newman, M.A. Atkinson, E.E. Sercarz, A.J. Tobin, M. Clare-Salzler and D.L. Kaufman* University of California, Los Angeles, CA 90024

Insulin-dependent diabetes mellitus (IDDM) in the nonobese diabetic (NOD) mouse results from a T lymphocyte mediated destruction of the insulin producing β cells of the pancreas and serves as a model for human type 1 diabetes. While a number of autoantibodies have been associated with IDDM, it is unclear whether, when and to what β cell antigens (βCAs) pathogenic T cells actually become activated *in vivo* during the spontaneous disease process. We report that a T helper 1 (Th1) response to glutamate decarboxylase (GAD) develops in NOD mice concurrent with the onset of lymphocytic infiltration into the islets (insulinitis). This T cell response is initially confined to the carboxy-terminal region of GAD, but later spreads intramolecularly to additional GAD determinants. Subsequently, T cell reactivity arises to other βCAs, consistent with the intermolecular diversification of the autoimmune response. Experimentally induced tolerance to GAD blocked the development of T cell responses to GAD, the spread of autoimmunity to secondary antigens, insulinitis and IDDM. Thus, tolerization to key early targets of autoimmunity can prevent expansion of the autoimmune repertoire and the ensuing β cell destruction. As a similar autoimmune progression is also likely to occur during the development of human IDDM, these findings will be useful for the design of immunotherapies.

MODULATION OF THE *IN VIVO* ANTIBODY RESPONSE BY THE BENZODIAZEPINE INVERSE AGONIST (DMCM) ADMINISTERED CENTRALLY OR PERIPHERALLY.

M. Fleshner*, M. M. Brohm, M. L. Laudenslager¹, L. R. Watkins, S. E. Maier, Dept. of Psychology, Univ. of Colorado, Boulder, CO 80309, Univ. Colorado Health Sci. Ctr., Denver, CO1.

Stressors can result in changes in immune function. Although there is increasing information concerning the peripheral hormonal and neural mediators of stress-induced changes in immune function, there is little information concerning the central nervous system mechanisms which lead to the peripheral changes. The following experiments examined the possible involvement of the benzodiazepine-GABA_A-chloride complex in modulation of the *in vivo* antibody response. Rats were given either peripheral or intracerebral ventricular injections of methyl-6,7-dimethoxy-4-ethyl-beta-carboline-3-carboxylate (DMCM), a drug which has been shown to act at the benzodiazepine-GABA_A complex and produces a behavioral state similar to "anxiety". Rats were then immunized with keyhole limpet hemocyanin (KLH) and serum levels of KLH-specific antibody were measured for two weeks after immunization. Both peripheral and central administration of DMCM modulated the *in vivo* antibody response. The dose-response relationship of DMCM and changes in antibody levels was non-monotonic, with high doses resulting in an increase in serum antibody levels and moderate doses resulting in a decrease in serum antibody levels. A possible role of the benzodiazepine-GABA_A system in stress-induced immunomodulation is currently being investigated. NIH-MH45045

FLOW CYTOMETRIC FLUORIMETRY REVEALS THAT SUBSTANCE P CAUSES CHANGES IN MEMBRANE POTENTIAL AND CYTOPLASMIC CALCIUM CONCENTRATION IN THYMIC LYMPHOCYTES. C. B. Lacey¹, D. Maric², J. Maric², G. D. Lange³, B. Elda¹ and J. L. Barker². ¹Dept. of Cell Biol. and Neuroanat., Univ. of Minn., Mpls, MN 55455 and ²Lab. of Neurophys. and ³Instrumentation and Computer Sect., NINDS, NIH, Bethesda, MD 20892.

Substance P has been implicated as a neuromodulator in the communication between the nervous and immune systems. In the present study we have begun to examine possible mechanisms by which SP may function in cellular signal transduction in thymocytes. To study the effects of this neuropeptide on membrane potential and Ca²⁺ regulation, we utilized the voltage-sensitive oxonol dye, DiBAC4(3) and the Ca²⁺ indicator dye, fluo-3. Single cell suspensions were prepared from embryonic (E20-22) and maternal adult rat thymus by mechanical dissociation and separated according to their specific buoyant densities by selective centrifugation on a four-step discontinuous Percoll gradient. The fluorescence (FL) distributions of the indicator dyes were monitored by flow cytometric analysis. The resting membrane potential (RMP) was estimated by adding 1µM gramicidin to oxonol-stained cells while varying the [Na⁺]_o and correlating to the Nernst equation. The RMP's were -82 ± 3 mV and -70 ± 7 mV (mean ± S.E.M.) for embryonic and adult thymocytes, respectively, and were at least partially dependent on [K⁺]_o. SP produced a hyperpolarization of the RMP in both cell populations in a dose-dependent relationship. This effect was blocked by the SP-antagonist [D-Arg¹, D-Phe, D-Trp^{7,9}, Leu¹¹]-SP. Doses of SP that hyperpolarized cells also produced an elevation of the resting cytoplasmic levels of Ca²⁺ ([Ca²⁺]_i) in a subpopulation of embryonic thymocytes. This was seen as an increase in the fluo-3 FL signal and converted into quantitative estimates of [Ca²⁺]_i. These results indicate the possibility that SP released from peripheral nerve fibers may interact with receptors on thymocytes to change Ca²⁺ homeostasis and this may be related to changes in membrane potential. IN VITRO AND IN VIVO SUPPRESSION OF CON A INDUCED PROLIFERATION OF CD4 BUT NOT CD8 BY CALCITONIN GENE RELATED PEPTIDE. K. Bulloch*, S. Graeber, A. Diwa and S. Baird. Dept. of Psych. and *Path. UCSD, San Diego, CA 92093. Calcitonin Gene Related Peptide (CGRP) nerve fibers and their corresponding receptors have been characterized in the mouse thymus. Our *in vitro* studies show that CGRP significantly suppressed (55%) a Con A induced proliferation of murine thymocytes at physiological doses. Furthermore, CGRP was found to inhibit proliferation of murine lymphoid cells by 30% in a mixed lymphocyte reaction. These doses are within the physiological range of the Kd for the receptor in the thymus. In the present study we have extended these findings by examining the effect of CGRP on subsets of thymocytes. The results of these experiments show CGRP has no effect on unstimulated thymocytes either at 24 hrs or 72 hrs. When thymocytes are stimulated with Con A in the presence of CGRP the CD 4 cell response is inhibited by 50% compared to thymocytes stimulated with Con A alone. There was no detectable change in CD 8 cell proliferation. Injections of 24 ul of 10^{-8} M and 10^{-7} M CGRP directly into the thymus produced similar inhibitory effects when thymocytes harvested from these mice were stimulated with Con A. Since CGRP is reported to inhibit IL 2, TNF, and IFN- γ in murine T cells, it is possible that in the thymus CGRP selects against TH1 cells.

THE EFFECT OF EXOGENOUSLY ADMINISTERED METHIONINE ENKEPHALIN ON T CELL DEVELOPMENT IN SPECIFIC STRAINS OF MICE. Ching-Fing Ho, Joseph Acosta, Frank Andriani, Conrad Cean, Leslie David and (Marie Metlay)*. SUNY/College at Old Westbury, Old Westbury, N.Y 11568.

Previously we had shown that the level(s) of endogenous (met)-enkephalin bound to receptors on both developing and mature T lymphocytes depended upon the age, genetic background, and disease state of the animal. We had demonstrated that as mice of the RF/J strain aged and or developed spontaneous thymomas, the level of endogenous (met)-enkephalin bound to receptors on T cells significantly increased. In contrast, mice of Balb/C strain exhibited an undetectable level of (met)-enkephalin binding at any stage of their life. In this study we are reporting on the effect of exogenously administered (met)-enkephalin (via a subcutaneous osmotic pump) on the T lymphocytes in the mice of both the RF/J and Balb/C strains. The drug was administered at physiological levels over a 7 day period, and developing T cells (thymocytes) and T lymphocytes of the peripheral lymph nodes were analyzed by flow cytometry. The results indicated that exogenously administered drug alters the ratio of CD4⁺ to CD8⁺ T cells in both an age-dependent and strain-dependent manner. The effect, an increase of CD4⁺ cell, was observed in aged RF/J mice, but not in age-matched mice of the Balb/C strain. An interesting observation was that an increase in CD4⁺ cells can be induced in Balb/C mice if the animals are heat stressed. This research was supported by NIMH MARC-17138 and NIGMS-MBRS-08180.

DIFFERENTIAL ROLE OF MET-ENKEPHALIN ON ANTIBODY PRODUCTION WHEN B LYMPHOCYTES ARE STIMULATED WITH DIFFERENT MITOGENS. K.P. Das, J.S. Hong* and V.M. Sanders. Neuropharmacol. Sect., Lab. Integr. Biol., Natl. Inst. Env. Hlth. Sci., Res. Tri. Pk., NC 27709.

The amount and isotype of antibody secreted by high density mouse splenic B lymphocytes stimulated *in vitro* with lipopolysaccharide (LPS) or LPS/dextran sulfate (LPS/DxS) in the presence of met-enkephalin (ME) was studied. These mitogenic stimuli were chosen since LPS and LPS/DxS, respectively, stimulate either one-third or the majority of B cells to differentiate. Increasing concentrations of ME (10^{-16} - 10^{-8} M) were added to cultures at 0, 3, 6 and 24 hr after mitogen. At all time points of ME addition, LPS/DxS stimulation shifted the dose response curve for an inhibition of IgM secretion to lower concentrations of ME (10^{-16} - 10^{-10} M) as compared to cells stimulated with LPS alone (10^{-12} - 10^{-10} M). Both mitogens induced a biphasic inhibition in that IgM production returned to control levels at 10^{-8} M. In LPS/DxS-stimulated cells only, a concomitant biphasic decrease in IgG3 production occurred after all times of addition, while IgG2a production decreased only when ME (10^{-14} - 10^{-8} M) was added at 24 hr. No significant changes occurred in either IgG1 production or B cell proliferation under any of the culture conditions. These data show a differential sensitivity of B cells to ME depending on the type of B cell stimulus used. We suggest that LPS/DxS, in contrast to LPS, activates a subpopulation of B cells that is either more responsive to ME receptor stimulation or secretes ME to elevate the *in vitro* exposure concentration of ME above that added exogenously.

389.10

INVOLVEMENT OF CHOLECYSTOKININ IN THE DEVELOPMENT OF TOLERANCE TO MORPHINE-INDUCED IMMUNOSUPPRESSION. X-Z. Ding¹, D-M. Chuang² and B. M. Bayer¹. ¹Dept. of Pharmacology, Georgetown Univ. Med. Center, Washington DC 20007. ²Biological Psychology Br., NIMH, MD 20892.

The possible role of neuropeptide cholecystokinin (CCK) in the development of tolerance to immunosuppressive effect of morphine was investigated. Tail-flick latency was used as a monitor to examine the development of tolerance to the morphine analgesia. Rats were injected with increasing doses of morphine (10-40mg/kg, s.c.) twice a day for 6 days. The analgesic effect induced by a challenge dose of morphine (6 mg/kg) was significantly decreased from 3 to 6 days after the morphine injection. Two hours following acute exposure to morphine (6-10mg/kg), concanavalin A stimulated whole blood lymphocyte proliferation (WBLP) was inhibited by 80 percent. However, following 4 to 6 days of morphine injections, no suppression in WBLP was apparent. The measurement of CCK biosynthesis showed that levels of both CCK mRNA and peptide were significantly increased by 2-3 fold selectively in the hypothalamus, brain stem and in the spinal cord in morphine tolerant animals. In order to further determine whether the increase of CCK biosynthesis was directly related to the development of tolerance to morphine-induced immunosuppression, the effect of selective antagonists L-365260 (CCK-B) and MK-329 (CCK-A) were examined. Chronic pretreatment of L-365260 (0.5mg/kg, s.c.) 10 min before the daily morphine injection was found to be accompanied by a significantly suppressed WBLP compared to the response of morphine tolerant animals. In contrast to L-365260, chronic pretreatment of MK 329 (1mg/kg) had no significant effect on WBLP in morphine tolerant animals. Neither L-365260 nor MK 329 alone, acutely or following chronic treatment, had a significant effect on WBLP. These results suggest that changes in central CCK biosynthesis may be involved in the development of tolerance to the immunosuppressive effect produced by morphine through the CCK-B receptor.

389.12

POTENTIAL ROLE OF THE AUTONOMIC NERVOUS SYSTEM IN THE IMMUNOSUPPRESSIVE EFFECTS OF ACUTE MORPHINE ADMINISTRATION. L.R. Flores, B.B. Wolfe* and B.M. Bayer. Dept. of Pharmacology, Georgetown Univ. Med. School, Washington D.C., 20007.

These studies investigated the mechanism by which acute morphine administration inhibits peripheral blood lymphocyte proliferation in rats. We have previously reported that morphine administration inhibits Concanavalin A stimulated lymphocyte proliferation by a centrally mediated mechanism which appears to be independent of the hypothalamic-pituitary-adrenal axis. In the current studies we investigated the role of the autonomic nervous system (ANS) in mediating the immunosuppressive effect of morphine. To determine the contribution of the ANS, rats were pretreated with the ganglionic blocker chlorisondamine (CHL, 5 mg/kg) prior to morphine (7 mg/kg) administration. Ganglionic blockade with CHL completely antagonized the inhibitory actions of morphine, suggesting that intact ganglionic transmission is required for the inhibition to occur. In an attempt to identify the postganglionic mechanisms involved, a pharmacological approach was utilized. Blockade of postganglionic parasympathetic neurotransmission with atropine methylbromide (1 mg/kg) did not attenuate the suppressive effects of morphine. Similarly, blockade of sympathetic neurotransmission with the α -adrenergic antagonist phentolamine (1 mg/kg) failed to antagonize the suppression of lymphocyte activity observed following morphine treatment. Blockade of β -adrenergic receptors with propranolol (2.5 mg/kg) resulted in partial antagonism, but this action was not shared by the peripherally acting β antagonists nadolol (6 mg/kg) or atenolol (15 mg/kg). These results suggest that the inhibitory effect of morphine on blood lymphocyte proliferation may be mediated through activation of the ANS, however, individual blockade of either the parasympathetic or sympathetic division of the ANS was not sufficient to attenuate this immunosuppressive effect.

MORPHINE ATTENUATES THE SURGERY-INDUCED INCREASE IN TUMOR CELL RETENTION: EVIDENCE FOR NATURAL KILLER (NK) CELL MEDIATION. G.G. Page¹, S. Ben-Elvahu, V. Shabanzadeh, & J.C. Liebeskind. UCLA Dept. of Psychology, Los Angeles, CA 90024.

Painful stressors such as surgery have been shown to suppress immune function and to enhance tumor development although the role immunity plays in tumor development remains unclear. Further, the role of pain per se is not known. To explore these issues, we used the MADB106 tumor cell line, syngeneic to the Fischer 344 rat and known to be sensitive to natural killer (NK) cell control. Rats were either subjected to abdominal surgery with anesthesia or anesthesia alone, and were either treated or not with morphine. Morphine was administered pre- and postoperatively in saline and in a slow release suspension, respectively. Normal and LGL/NK-depleted (using the mAb 3.2.3) rats were assigned to the above 4 groups with the rationale that if LGL/NK cells were necessary to mediate an event, then in their absence, that event would not occur. Four h after surgery, all animals were injected i.v. with 10^5 radiolabeled MADB106 tumor cells. Lungs were removed 20 h later and radioactive content assessed in a gamma counter. In normal animals, there was a significant interaction of morphine and surgery such that morphine attenuated the surgery-induced increase in tumor cell retention without affecting tumor cell retention in the anesthesia groups. In the LGL/NK-depleted animals however, although there was a main effect of surgery, morphine had no effect on the surgery-induced increase in tumor cell retention. These results imply that: (a) factors in addition to LGL/NK cells play a role in the surgery-induced increase in tumor cell retention; and (b) LGL/NK cells mediate morphine's attenuating effects on the observed surgery-induced increase in tumor cell retention. Supported by the UCLA Psychoneuroimmunology Program and NIH grant NS 07628.

EQUIANALGESIC DOSES OF SYSTEMIC BUT NOT INTRATHECAL MORPHINE ALTER RAT LYMPHOCYTE PROLIFERATION. J.G. Hamra*, and T.L. Yaksh. Dept. of Anesthesiology, UCSD, LaJolla, CA 92093.

Surgical trauma and opiates are linked with suppression of immune function. Evidence suggests a probable supraspinal action of opiates which mediates effects upon the immune system. However, the role of spinal systems in morphine-induced immunosuppression have not been evaluated. In this study, we compared the effects of equianalgesic doses of systemic and intrathecal morphine on lymphocyte proliferative responses and phenotypic expression of lymphocyte cell surface markers in rats. Equianalgesic doses of subcutaneous (10 mg/kg) or intrathecal (30 µg, by a chronic intrathecal catheter) morphine were given twice (at time 0 and 2.5 hours) to give a 5 hour period of analgesia. Immediately following the five hour period, spleens were harvested and lymphocytes isolated by density gradient centrifugation. The lymphocytes were then incubated with the mitogens Concanavalin A (ConA), phytohemagglutinin (PHA), pokeweed mitogen (PWM) and lipopolysaccharide (E. Coli, LPS) or labeled with monoclonal antibodies directed at cell surface markers (T cell, B cell, CD4+, CD8+, CD25+). Systemic morphine dramatically suppressed lymphocyte proliferation to the mitogens PHA, PWM, and ConA, but not LPS. The number of lymphocytes expressing the CD4+ receptor were modestly increased. Morphine did not alter the ability of the lymphocytes to express the IL-2 receptor (CD25+ cells) following stimulation with either PHA or ConA, suggesting that morphine inhibition of proliferation does not occur through decreased IL-2 receptor expression. Intrathecal morphine did not alter lymphocyte proliferative responses to any of the mitogens, nor did it change the expression of cell surface markers. These results suggest that spinal opiates may have theoretical benefits for the analgesic management of both normal and immunocompromised patients.

Development of Cellular Immunity Following Fetal Alcohol Exposure A.N. Taylor*, M. Pilati, R. Yirmiya, D. Tio & F. Chiappelli. Dept. Anatomy & Cell Biology, UCLA-1763, & West Los Angeles VAMC, Brentwood Research, Los Angeles, CA 90024.

Age-associated differences exist in proliferative responses to concanavalin A (ConA) of thymocytes (Wong et al, 1990; Chiappelli et al, 1992) and splenocytes obtained from fetal alcohol exposed (FAE) male Sprague Dawley rats compared to control animals (Norman et al, 1989, 1991). The proliferation of thymocytes from prepubertal (day 44) FAE rats is significantly greater than control, but this difference disappears by day 72. ConA responses of FAE splenocytes are significantly suppressed compared to control in prepubertal and young adult rats. We have tentatively attributed these differences to the maturation stage of thymocytes and splenocytes; but we find no age-associated outcomes of FAE on ConA proliferation by blood mononuclear cells. These important differences in T lymphocyte populations among immune compartments are now being characterized functionally and phenotypically. (VA Medical Research Service; UCLA Psychoneuroimmunology).

FLOWCYTOMETRIC CROSSMATCH TEST AS A METHOD FOR COMPARISON OF PERIPHERAL ANTIBODY PRODUCTION TO MULTIPLE INJECTION SITES IN GUINEA PIGS. P.M. KRUEGER*, F.A. KAPLAN, D.E. EMERICH. CytoTherapeutics, Inc., Providence, RI 02906.

The purpose of this study is to compare peripheral guinea pig anti-rat IgG and IgM antibody production in guinea pigs using multiple injection sites. Previous studies in our lab using immunocytochemical evaluation have demonstrated that rat adrenal pheochromocytoma (PC12) cells injected into the brains of guinea pigs are rejected within 1 to 3 weeks. PC12 cells at a concentration of $10^6/4\mu\text{l}$ resuspended in phosphate buffered saline (PBS) were injected into either the brain (striatum), intraperitoneally, or subcutaneously (nape of the neck). Serum samples were collected from all animals prior to, and at 1, 7, 23 and 51 days following implantation and then frozen at -70°C until testing. Flowcytometric crossmatches (FCXM) were done using target Lewis rat spleen cells at a concentration of $3 \times 10^5/100\mu\text{l}$ which were incubated with 10ul of sequential guinea pig sera in dilutions from neat to 1:32 for 1 hour at room temperature. Cells were washed twice with PBS + 0.25% bovine serum albumin (BSA). Cells were then incubated with 100ul of FITC-labeled goat anti-rat IgG (Fab) $_2$ and anti-rat IgM (mu chain) for 1 hour in the dark at room temperature. After incubation, cells were washed twice with PBS + 0.25% BSA, resuspended in 500ul of wash solution and analyzed by fluorescence intensity over 256 channels with LYSIS I software. Comparing the shift in the mean channel fluorescence of tested samples over the negative control was used for data analysis. Anti-rat IgG antibody production was demonstrated to occur in animals who received implants either in the striatum or intraperitoneally. No significant shift was observed in the subcutaneous group. The FCXM has proven to be both a very sensitive and reproducible method for demonstration of antibody production.

AGE- AND SEX-DEPENDENT EFFECTS OF (+)JFENFLURAMINE (d-FEN) ON SPLENIC MONOAMINE METABOLISM, RECEPTORS AND IMMUNE FUNCTION. S.A. Lorens^{1,*}, M. George¹, C. Dersch², J. Clancy² and R. Zaczek³. Depts. Pharmacology¹ and Anatomy², Loyola University Chicago Medical Center, Maywood IL 60153, and NIDA-ARC³, P.O. Box 5180, Baltimore MD 21224.

Subchronic administration of the serotonin (5-HT) releaser and reuptake inhibitor, d-fenfluramine (d-FEN), enhances some splenic immune functions, especially natural killer cell (NK) activity, only in young males and old females. The objective of the present study was to determine whether these effects of d-FEN were associated with alterations in splenic monoamine turnover and receptor binding. F344 rats (5 and 21 mo old at sacrifice) received d-FEN (old rats, 0.6 mg/kg/day, p.o.; young rats, 1.2 mg/kg/day, p.o.) for 30-38 days. d-FEN treatment did not affect body weight or water intake. Although the concentration of 5-HT in the spleen was 3.5 fold greater than the level of NE, splenic NE turnover (MHPG/NE ratio = 0.88) was higher than 5-HT turnover (5 HIAA/5-HT ratio = 0.25). d-FEN treatment increased splenic NE turnover (41-61%) and decreased 5-HT synthesis in both young and old rats. In contrast, subchronic d-FEN affected splenic [^3H]5-HT, [^3H]paroxetine and [^3H]hydroalpranolol binding in an age and sex dependent manner: increasing (14-40%) binding in the young male rats, and reducing (24-46%) binding in the old female rats. These effects were not due to differences in splenic drug and metabolite concentrations. 5HT immunoreactive elements are densely distributed throughout the splenic red pulp (RP). This is in marked contrast to the reported localization of NE fibers predominantly in the white pulp (WP). d-FEN thus may augment splenic NK activity by modifying splenic 5-HT availability and/or receptor density in the RP, and may enhance splenic T and B cell function by altering NE metabolism and/or β -adrenergic receptor number in the WP. The age and sex related nature of these effects suggest, moreover, that d-FEN will enhance splenic immune functions only if plasma testosterone levels are high (young males) or estrogen levels are low (old females).

CHANGES IN BRAIN MAST CELLS DURING DEVELOPMENT IN DOVES X. Zhuang^{1,*}, H. Machuga², and R. Silver^{1,2}. ¹Columbia University and ²Barnard College, New York, N.Y. 10027.

Mast cells originate in the bone marrow and migrate to tissues where they differentiate. We previously reported that few mast cells expressing GnRH-like ir are present in the medial habenula (MH) of isolated ring doves, but they are detected after courtship. To understand their origin, we studied mast cells in doves aged 1 day to 10 mo. Alternate brain sections were stained with toluidine blue (a classical mast cell marker), antiserum to GnRH (LR-1), alcian blue (specific for low sulfated glycosaminoglycans characteristic of mucosal and immature mast cells) and safranin (specific for highly sulfated heparin characteristic of serosal mast cells). In 2-3 mo. birds Indian ink/gelatin infusions were made to demonstrate blood vessels. Mast cells stained by alcian blue and toluidine blue are seen in the pia and choroid plexus at 2 days, rapidly increase in number within the first week, and decrease thereafter. A few mast cells expressing GnRH-ir can be seen in the pia mater after 6 days. Mast cells expressing GnRH-ir are detectable in the dorsal most aspect of MH at 21 days and gradually increase in number. They occur outside Indian ink delineated blood vessels in MH. By 4 months, mast cells (visualized with antiserum to GnRH-ir, alcian blue or toluidine blue) are distributed throughout MH, and a few remain in the surrounding pia. Safranin positive mast cells are only seen in MH, and only in adults (10 mo). The sequential appearance of mast cells first in the pia and the choroid plexus, then at the tip of MH, and ultimately throughout MH, suggest that they migrate into MH. Granule contents show a biochemical alteration during ontogeny. The physiological function of parenchymal mast cells remains to be explored. Supported by NIMH grant 29380 (to RS).

ELECTRICAL ACTIVITY AND SYNAPTIC RESPONSES OF RAT ROSTRAL VENTROLATERAL MEDULLA NEURONS IN VITRO. S. Y. Wu* and N. J. Dun. Dept. Anatomy, Medical College of Ohio, Toledo, OH 43614

Whole-cell patch recordings were obtained from rat rostral ventrolateral medulla (RVLM) neurons of 500 μ m coronal slices. RVLM neurons had a resting membrane of -55 to -60 mV and input resistance of 300 to 700 M Ω . Some of the neurons exhibited a time-dependent anomalous rectification that was sensitive to cesium. When labeled intracellularly with lucifer yellow, RVLM neurons appeared oval and had few cell processes. In addition, some of the labeled neurons seemed to be dye-coupled. The majority of RVLM neurons exhibited spontaneous discharges, some of which were blocked by Ca-free solution, indicating that they were synaptic in origin. The discharges recorded in about 30% of RVLM neurons were not blocked by Ca-free solution nor by the excitatory amino acid antagonists CNQX and AP5, indicating that they were intrinsic in origin. Na-free and tetrodotoxin blocked the spontaneous activities. Electrical stimulation of the nucleus of the solitary tract (NTS) elicited, after a synaptic delay of several to over 10 ms in most cases, an excitatory synaptic current (EPSC), an inhibitory synaptic current (IPSC) or a mixed EPSC and IPSC in spontaneously active and quiescent RVLM neurons. EPSCs had a reversal potential close to 0 mV and were largely suppressed by the non-NMDA receptor antagonist CNQX. IPSCs had a reversal potential of -70mV and were blocked by bicuculline in some cells and by strychnine in others. The results indicate that a population of rat RVLM are intrinsically active and may subserve a role of pacemaker neurons. This type of neurons also receives excitatory and inhibitory inputs following stimulation of the NTS. On the basis of synaptic delays, neurons in the NTS appear to contact RVLM neurons via a polysynaptic pathway. Glutamate, GABA and glycine appear to be the excitatory and inhibitory transmitters to the RVLM neurons.

390.3

ROLE OF SEROTONIN AND CATECHOLAMINES IN SYMPATHETIC RESPONSES EVOKED BY STIMULATION OF ROSTRAL MEDULLA.

D.Huangfu*, T.A.Riley and P.G.Guyenet. Dept. of Pharmacology, Univ. of Virginia, Charlottesville, VA 22908.

In halothane-anesthetized and paralyzed rats, single-pulse stimulation of the rostral end of nuc. raphe pallidus/obscurus (NR) produced an excitatory response in i) the discharge of the lumbar sympathetic nerve (ISND; peak latency: 210 \pm 14 ms) and splanchnic nerve (sSND; peak latency: 161 \pm 5 ms), and ii) the activity of lumbar sympathetic vasoconstrictor neurons (LSVNs). Stimulation of the rostral ventrolateral medulla (RVL) produced two excitatory responses in ISND, sSND, and LSVNs activity. These consisted of an early peak (RVL peak I; latency: 98 \pm 8 ms for ISND and 62 \pm 2 ms for sSND) followed by a second smaller one (RVL peak II; latency: 210 \pm 15 ms for ISND and 160 \pm 6 ms for sSND). NR peak (sSND) was attenuated by i) intracisternal (i.c.) 5,7-dihydroxytryptamine (200 μ g, 2 weeks, 76% decrease), or ii) acute intrathecal (i.t.) methiothepine (10 μ g, 69% decrease) or methysergide (40 μ g, 72% decrease). These treatments had no effect on RVL peak I but modestly attenuated RVL peak II. 6-Hydroxydopamine (200 μ g, i.c., 2 weeks) attenuated neither NR peak nor RVL peak II. The α -adrenergic blockers phentolamine (20 μ g, i.t.) or prazosin (20 μ g, i.t.) massively reduced RVL peak II (95% or 94% respectively) and also attenuated NR peak (67% or 46% respectively). The excitatory amino acid (EAA) receptor antagonist kynurenic acid (i.t.) produced proportionately larger reduction of RVL peak I than raphe peak or RVL peak II. Interpretations: i) LSVNs receive convergent excitatory inputs from NR and RVL; ii) bulbospinal serotonergic neurons mediate most of the sympathoexcitation evoked from NR and a portion of RVL peak II; iii) slow conductive adrenergic cells may mediate most of RVL peak II and a portion of the NR response; iv) the short-latency RVL peak I is predominantly mediated by an EAA.

390.5

IRREVERSIBLE HYPOTENSION ASSOCIATED WITH KAINATE LESIONING OF A ROSTRAL VENTROLATERAL MEDULLARY VASOMOTOR SITE IN THE CAT. L.M. Sexcius*, D.G. Bernard, R.M. Douglas, R. Millis, C.O. Trough. Department of Physiology & Biophysics, Howard University, College of Medicine, Washington, D.C. 20059

Electrical stimulation (40 Hz, 1 msec, 1-5 V) of the brainstem of cats 3 mm below the rostral ventrolateral medullary surface (rVMS) consistently resulted in a marked increase in systemic arterial blood pressure (BP) and heart rate (HR). Respiratory effects were inconsistent and not predictable. Occlusion of either the carotid or vertebral artery resulted in an increase in blood pressure as well as increases in the activity of neurons recorded extracellularly at this site and from neurons at the caudal respiratory chemosensitive area. Electrolytic (10-20 μ A for 10-15 sec) or chemical (2.7 mM kainate) lesioning of this site bilaterally resulted in an irreversible fall in blood pressure despite carotid or vertebral arterial occlusion. This site appears to be located in the nucleus reticularis parvocellularis of the cat.

ROLE OF A5 NORADRENERGIC NEURONS IN CAROTID-SYMPATHETIC CHEMOREFLEX. N. Koshiya*, D. Huangfu and P.G. Guyenet. Department of Pharmacology, University of Virginia, Charlottesville, VA 22908.

Splanchnic sympathetic nerve discharge (SND), phrenic nerve discharge (PND) and the activity of A5 reticulospinal neurons (A5 units) were recorded in urethane-anesthetized vagotomized rats without aortic baroreceptor afferents. Carotid chemoreceptor stimulation (CCS) with 8 - 12 sec N₂ inhalation increased SND by 117 \pm 14% (sympathetic chemoreflex, SCR) and PND (amplitude and rate), raised MAP by 27 \pm 5 mmHg and increased discharge rate of A5 units from 1.9 \pm 0.2 to 6.0 \pm 0.7 spikes/sec. During chemoreceptor activation, SND and most A5 units displayed a pronounced post-inspiratory peak with inspiratory depression. Bilateral microinjection of the GABA_A agonist, muscimol (Mus, 175 pmol in 100 nl) into the A5 area attenuated the SCR by 65 \pm 4% while reflex activation of PND by CCS was unchanged. SCR was also attenuated by 61 \pm 7% in 2 hrs after bilateral microinjection of the noradrenergic neurotoxin 6-hydroxydopamine (6-OHDA, 4 μ g in 200 nl) into upper thoracic cord, while resting SND level was unchanged. Intraspinal 6-OHDA also blocked antidromic activation (ADA) of A5 units from spinal segments caudal to the injection while ADA of sympathetic premotor neurons in the rostral ventrolateral medulla (RVLM) was preserved. Rats chronically treated with intracisternal 6-OHDA (250 μ g, 2 wks) had reduced SCR (71 \pm 21% increase in SND) which was not altered by acute injection of Mus (175 pmol) into the A5 area.

These results suggest that A5 neurons are activated by the bulbar respiratory center and that their spinal projections contribute to SCR.

390.4

EFFECT OF OPIOIDS ON CARDIORESPIRATORY FUNCTION IN THE RAT: AN ELECTROPHYSIOLOGICAL STUDY. S.C. Baraban* and P.G. Guyenet. Dept. of Pharmacology, University of Virginia, Charlottesville, VA 22908

In chronic studies, we measured naloxone-precipitated changes in phrenic nerve discharge (PND), mean arterial pressure (MAP) and splanchnic sympathetic nerve discharge (sSND) in urethane-anesthetized, vagotomized, paralyzed and artificially ventilated rats. Sprague-Dawley rats (310-380g) were implanted with morphine pellets (75 mg; NIDA) or placebo pellets over a 2 day regimen. In morphine-dependent rats (n=6) naloxone (1 mg/kg i.v.): i) raised resting MAP (+13 mmHg), ii) increased resting PND (+301%), iii) increased T_e (+122%), iv) decreased T_i (-51%), and v) increased the respiratory modulation of sSND. A significant naloxone-precipitated increase in resting sSND (+43%) was revealed only when MAP was artificially lowered to the pre-naloxone level. Naloxone exerted no effect in placebo-treated rats (n=5). Clonidine (5 μ g/kg i.v.) lowered MAP and sSND in both morphine-dependent and placebo-treated rats. Clonidine pretreatment did not alter the naloxone-precipitated increase in MAP nor the respiratory activation. However, clonidine was effective in reducing the sympathoactivation associated with withdrawal. The naloxone-precipitated rise in MAP could be reversed by subsequent injection of an arginine-vasopressin antagonist, O-Et-AVP (50 μ g/kg i.v.). Thus, clonidine pretreatment reduces SND and its activation by withdrawal but appears to exert only minor effects on vasopressin release and respiratory changes.

In acute studies, we examined the effect of morphine on the activity of clonidine-sensitive, sympathetic premotor neurons of the rostral ventrolateral medulla (RVLM) using extracellular recording techniques *in vivo*. These cells had a low discharge rate (2-9 spikes/sec) and a slow conduction velocity (2.9-5.1 m/sec). Morphine (1-7 mg/kg i.v.) dose-dependently inhibited (50-100%) the firing rate of most of these neurons (8/10). Naloxone (1 mg/kg i.v.) reversed this effect. These findings support the hypothesis that the sympathoactivation produced during morphine withdrawal may be mediated, in part, by activation of clonidine-sensitive neurons of the RVLM.

RVLM IS HYPERSENSITIVE TO NMDA IN THE SPONTANEOUSLY HYPERTENSIVE RATS. Y. Wang*, J.C.Lin, W.L.Tsao. Department of Pharmacology, National Defense Medical Center, Taiwan.

The purpose of this study is to investigate the cardiovascular effects of NMDA (N-methyl-D-aspartate) in rostral ventral lateral medulla (RVLM) of spontaneously hypertensive (SH) rats. Adult SH rats and their normotensive controls (Wistar Kyoto, WKY) were anesthetized with urethane (1.25g/kg, i.p.), cervical vagotomized and placed on a sterotaxic frame. We found local application of electrical stimuli or NMDA produced hypertension in both animals. SH rats had a greater pressor response to NMDA and electrical stimuli than their normotensive controls. Local injection (4 nmole) of AP5 (2-amino-5-phosphonovalerate), a specific NMDA antagonist, to the RVLM, did not affect resting blood pressure, however, did antagonize the electrical (5-20 Hz) evoked hypertension in WKY and SH rats. The high blood pressure evoked by the high frequency stimulation (60 Hz), on the other hand, were not affected by AP5. Interestingly, AP5 also abolished the difference of evoked hypertension between WKY and SHR during low frequency (5-10 Hz) electrical stimulation. The difference during high frequency (60Hz) was not affected by AP5. We previously found that NMDA is involved in carotid clamping induced hypertension and neuronal excitation in the RVLM. In the present study, we found that local applied AP5 in RVLM antagonized carotid clamping evoked hypertension in SHR and WKY at the same extend. These suggested that the hypersensitivity of RVLM to the low frequency stimulation in SH rats involved NMDA. High frequency stimulation or carotid clamping may involve NMDA and other mechanisms.

390.7

ACTIVATION OF THE ROSTRAL VENTROLATERAL MEDULLA (RVLM) IN DOGS ELICITS AN INCREASE IN ARTERIAL PRESSURE (BP) WITHOUT AN INCREASE IN HEART RATE (HR). L.W. Dickerson,*F.E. Kuhn, W.H. Panico, W.P. Norman, R.A. Gillis. Departments of Pharmacology and Medicine, Georgetown University, Washington, D.C. 20007.

Studies in the cat indicate that stimulation of the RVLM, specifically, neurons in the subretrofacial nucleus (SRFN), increases BP and HR, and enhances sympathetic tone in specific vascular beds. To determine whether the SRFN exerts a similar influence in the dog, these neurons were activated by microinjection of L-glutamic acid (L-glu) into a site approximately 8.0 mm caudal to the foramen cecum, 5.0 mm lateral to the midline, and 1.5 mm below the ventral surface while monitoring BP, HR, renal and femoral arterial flows in vagotomized, pentobarbital-anesthetized animals. Microinjection of L-glu produced increases in BP (+40±5 mm Hg, p<0.05, N=8) (from a baseline of 123±7 mm Hg), femoral resistance (+60±1%, p<0.01), and renal resistance (+41±11%, p<0.05). There was no increase in HR (+3±2 beats/min, p>0.05) from a baseline of 162±10 beats/min. These data suggest that neurons in the SRFN in the dog, as in the cat, influence vascular tone, but unlike the cat, have no effect on sinus rate. [NIH Grant R01-DA-05-333].

α2A-adrenergic receptors are present in noradrenergic, adrenergic and serotonergic spinally projecting cells of rat pons and medulla. R.L. Stornetta, P.G. Guvenet, T. Riley, F.N. Norton, D.R. Rosin, K.R. Lynch. Dept. of Pharmacology, Univ. of Virginia Sch. of Med., Charlottesville, VA 22908.

The brainstem distribution of the α2A-adrenergic receptor (α2AR) has been previously characterized using a subtype specific antibody. We sought to determine whether some of these receptors are located in the catecholaminergic or serotonergic spinally projecting neurons known to contribute to the control of sympathetic tone. 12 μm frozen sections were cut on a cryostat and reacted sequentially with the α2AR antibody and with commercially available antibodies to either tyrosine hydroxylase (TH) or serotonin (5HT). In some cases α2AR-like immunoreactivity (LIR) was visualized with a nickel enhanced DAB reaction (black), TH- or 5HT-LIR was visualized with DAB (brown). In other cases, α2AR-, TH- and 5HT-LIR was detected by immunofluorescence. Cells immunopositive for α2AR, TH and 5HT were plotted using the NeuroLucida software in conjunction with Ludl motor stage controllers and maps of the exact location of these cells in medulla were constructed. All 5HT immunopositive cells in raphe pallidus and obscurus contained α2AR-LIR and virtually all TH positive cells showed α2AR-LIR. Only 22% ± 2.4% of cells with α2AR-LIR in RVL were also TH positive. Bulbosplinal neurons were tagged in some rats by retrograde labeling with FITC-conjugated latex microspheres injected at T3 (7-15 days prior). The brainstem was processed for simultaneous fluorescent detection of α2AR-LIR (Texas Red), TH (AMCA)(n=3) or 5HT (AMCA)(n=3) in combination with the FITC microspheres. Virtually all (>90%) spinally projecting C1 cells, and all A5 and lower brainstem serotonergic cells contain α2AR-LIR. Thus α2ARs are present in a majority of the bulbospinal neurons which are presumed to provide an excitatory drive to the sympathetic outflow and this may explain the profound effects of clonidine on sympathetic nerve activity.

390.11

BULBOSPINAL BAROSENSITIVE NEURONS IN ROSTRAL VENTROLATERAL MEDULLA ARE EXCITED BY ABDOMINAL VAGAL STIMULATION. J.P. Messenger, Z.I. Gieroba and W.W. Blessing*. Centre for Neuroscience, Flinders University, Bedford Park, SA 5042, Australia.

Electrical stimulation of the abdominal vagus increases arterial pressure. We have tested, in rabbits anesthetized with urethane (1.5 g/kg, i.v.), whether the discharge rate of bulbospinal neurons in the rostral ventrolateral medulla (RVLM) is affected by electrical stimulation of the abdominal vagus (cuff electrode at the level of the diaphragm, 0.5 ms, 200 Hz, 1-3 cathodal pulses). RVLM neurons were identified by antidromic activation from the ipsilateral dorsolateral funiculus of the thoracic spinal cord, and by a collision test. Peristimulus time histograms relating vagal stimulation to RVLM neuronal discharge were constructed using an ITC16 interface and a Macintosh IIx computer. Recordings were made from 31 RVLM neurons. Conduction velocity of the descending axons was 7.5 ± 0.6 m/s. Discharge rate of the RVLM neurons was 3.5 ± 0.6 spikes/s. Twenty three neurons (74%) were excited by stimulation of the vagus, 6 were unaffected and 2 were inhibited. The latency to maximum excitation was 255 ± 7 ms (vagal conduction velocity 0.6 m/s) and was followed by inhibition lasting approximately 240 ms. Sixteen neurons excited by the vagus were tested for baroreceptor sensitivity; 14 were inhibited by activation of baroreceptors using intravenous phenylephrine (discharge rate reduced to 0.8 ± 0.2 spikes/s) and those tested showed cardiac-related rhythmicity. These results indicate that the majority of bulbospinal neurons in the RVLM, with properties of sympathoexcitatory barosensitive neurons, are excited by electrical stimulation of the abdominal vagus. Our study shows a direct involvement of RVLM neurons in the reflex pathway in which abdominal vagal stimulation increases arterial pressure.

390.8

Alpha₂-adrenoceptor-mediated inhibition of bulbospinal barosensitive cells of rat rostral medulla. Patrice G. Guyenet* and Andrew M. Allen. Dpt. of Pharmacology, University of Virginia, Charlottesville, VA, 22908.

Bulbosplinal barosensitive neurons of the rostral ventrolateral medulla (RVLMbb cells, presumed sympathetic vasomotor premotor neurons) were recorded with iontophoretic electrodes in urethane-anesthetized rats. The majority of RVLMbb cells were insensitive to i.v. clonidine (clo, up to 20 μg/kg) and insensitive to iontophoretically applied clo or α-methyl norepinephrine (αMNE). These cells (n=47/76) had a spinal conduction velocity of 4.1 ± 0.2 m/s and a mean firing rate of 20 ± 1 spikes/s. A second population (n=29) was powerfully inhibited by i.v. clo (5-10 μg/kg, activity decreased by 83 ± 11%), iontophoretically applied clo (decreased by 51 ± 7%) and iontophoresis of αMNE (decreased by 69 ± 3%). These cells had a slower conduction velocity (2.0 ± 0.3 m/s) and a much slower discharge rate (6 ± 1 spikes/s). Both populations were pulse-synchronous at resting AP. The inhibitory effects produced by iontophoresis of αMNE or clo were reduced to the same degree (86 - 98%) by iontophoresis of idazoxan (an α₂-adrenergic antagonist with imidazoline structure) and by iontophoresis of piperoxan (65-77%, a non-imidazoline α₂-antagonist). The inhibition of RVLM cells by i.v. clo was reversed by iontophoresis of idazoxan and by i.v. injection of yohimbine (non-imidazoline α₂-antagonists). This data suggests that: i) i.v. clo only inhibits a subpopulation of RVLM sympathetic premotor neurons, possibly the C1 adrenergic cells, ii) this effect of clo is due to activation of α₂-adrenergic receptors rather than "non-adrenergic imidazoline" binding sites, iii) these α₂ receptors are located on or close to the clo-sensitive cells and these cells may be tonically inhibited by endogenously released catecholamines.

390.10

ABDOMINAL VAGAL STIMULATION INDUCES FOS IMMUNOREACTIVITY IN RABBIT MEDULLARY A1 AND C1 CATECHOLAMINE-SYNTHESIZING NEURONS. Z.I. Gieroba* and W.W. Blessing. Centre for Neuroscience, Flinders University, Bedford Park, SA 5042, Australia.

Stimulation of the abdominal vagus nerve (AVN) in the rabbit increases plasma vasopressin and arterial pressure. The A1 and C1 catecholamine-synthesizing medullary neurons could be involved in these reflexes. We tested, in unanesthetized rabbits, whether electrical stimulation of the AVN induces fos immunoreactivity in A1 and C1 neurons. Rabbits were anesthetized with thiopentone (30 mg/kg i.v.), then with halothane (1.5%). The anterior trunk of the AVN was cut and placed inside a cuff electrode. The rabbit recovered from anesthesia. After 24 hours the AVN was electrically stimulated (0.5 ms, 20 Hz, 500 μA, 4.5 min on, 0.5 min off, 2 hours). One hour later rabbits were perfused with 4% paraformaldehyde. Brains were cut (40 μm) and processed for demonstration of fos (Cambridge Research Biochemicals, 1:1000) and tyrosine hydroxylase (TH) immunoreactivity (Instar Corp., 1:25000) by a two-color immunoperoxidase procedure. Fos-positive nuclei were observed within the nucleus tractus solitarius, (78% on left side). TH was present in 9 ± 1% (n = 5) of fos-positive cells (A2 neurons). The ipsilateral caudal and intermediate ventrolateral medulla contained 16 ± 3 fos-positive nuclei per section (90% left side). TH was present in 70 ± 6% (n = 10) of fos-positive cells (A1 neurons). The rostral ventrolateral medulla contained 34 ± 4 (n = 4) fos-positive neurons per section, (82% left side) and 54 ± 5% neurons were double labeled for TH (C1 cells). Our results indicate that stimulation of the abdominal vagus in unanesthetized rabbits activates A1, A2 and C1 medullary cell groups.

390.12

PHENYLEPHRINE DECREASES OPTICAL REFLECTANCE IN THE KITTEN VENTRAL MEDULLARY SURFACE. R.K. Harper*, D. Gozal, X.-W. Dong, D.M. Rector and R.M. Harper. Brain Res. Inst. & Dept. Anat. & Cell Biol., UCLA Sch. of Med.; Div. Neonatol. & Ped. Pulmonol., Childrens Hosp., USC Sch. of Med., Los Angeles, CA.

Regional neuronal activation on the ventral medullary surface (VMS) of 10, 20, and 30 day old kittens during phenylephrine-induced blood pressure elevation by optical recording procedures. The VMS was exposed through a ventral surgical approach under pentobarbital anesthesia. Arterial pressure, end-tidal CO₂, costal diaphragmatic EMG, and ECG were monitored. A coherent image conduit, coupled to a charge-coupled device camera, was positioned over the VMS. Reflected 660nm light was digitized continuously at 2-3 sec intervals triggered by the peak of ECG during a baseline period, and after 10, 20, and 40 μg/kg i.v. phenylephrine injection. Forty images within each epoch were averaged, and were subtracted from baseline. Regional differences within the image were determined by ANOVA procedures (α=.05). Phenylephrine induced a significant, transient elevation of blood pressure concomitant with diminished respiratory EMG activity. A pronounced dose-dependent decrease in optical reflectance (increased neural activity) was found over widespread regions of the VM surface during the early pressor response with a subsequent return to baseline values. We conclude that pharmacologically-induced rapid blood pressure elevation results in a generalized increase in neural activity within the VMS, in contrast to the decreased activity found in adult animals.

THE A1 CATECHOLAMINE CELL GROUP: FINE STRUCTURE AND SYNAPTIC INPUT FROM THE NUCLEUS OF THE SOLITARY TRACT. C.A. Peto, R.K.W. Chan and P.E. Sawchenko*. The Salk Institute, La Jolla, CA 92037.

Preembedding immunostaining methods were used to characterize tyrosine hydroxylase-immunoreactive (TH-ir) elements in the caudal ventrolateral medulla, and to determine whether neurons of the A1 cell group are innervated by projections of the nucleus of the solitary tract (NTS). Immunoperoxidase-stained TH-ir neurons in the A1 region were medium-sized and multipolar, giving rise to 1-3 primary dendrites. They possessed rounded nuclei with infrequent invaginations, well-developed Golgi apparatus, high cytoplasmic densities of mitochondria and lysosomes, and a low-moderate tendency for rough endoplasmic reticulum (RER) to align in parallel stacks. Reaction product was distributed diffusely through the cytoplasm, but avoided regions occupied by Golgi and RER. A1 cell bodies were commonly juxtaposed to TH-positive and TH-negative neurons, myelinated profiles, glia and/or vascular elements, but close membrane appositions with any of these were rare. Synaptic input to A1 neurons was predominantly asymmetric in type, provided virtually exclusively by non-TH-ir terminals, and directed principally to dendritic shafts; TH-ir somata were sparsely innervated. In a second experiment, silver-intensified immunogold localization of TH-ir was combined with immunoperoxidase labeling for anterogradely transported PHA-L, following tracer injections in the caudal aspect of the medial division of the NTS. These experiments revealed a small proportion of PHA-L-labeled axon terminals that contacted postsynaptic TH-ir elements. Dually labeled synapses most commonly comprised asymmetric contacts between anterogradely labeled axon terminals and dendritic shafts of TH-ir neurons, mimicking the overall pattern of synaptic input to A1 neurons. These results suggest that the fine structure and synaptic input of A1 neurons is somewhat distinct from that of rostrally-situated the C1 catecholamine neurons (cf. Milner et al., *Brain Res.* 411:28, 1987). In addition, they document a direct NTS-A1 projection that may participate in the interoceptive control of vasopressin secretion.

390.15

CAUDAL VENTROLATERAL MEDULLA MEDIATES CARDIOVASCULAR RESPONSES EVOKED FROM THE CAUDAL PRESSOR AREA. R.R. Campos Jr., O.S. Póssas, S.L. Cravo*, O.U. Lopes and P.G. Guertzenstein. Dept. of Physiology, Escola Paulista de Medicina, 04023-900 São Paulo, Brazil.

Recent evidences show that the caudal pressor area (CPA) contains tonically active neurons involved in arterial blood pressure (AP) regulation. CPA stimulation produces hypertension while its inhibition evokes falls in AP. The present study was designed to determine whether neurons in caudal ventrolateral medulla (CVL) are involved in these responses. Adult rats (Wistar, 250-350 gr) were anesthetized (urethane 1.2 gr/kg, IP) and AP was recorded. Dorsal medullary surface was exposed and microinjections (200 nl) were made through microcannulae. Results showed that: a) CPA excitation with glutamate (50 nmol) produced pressor responses (44 ± 5.7 mmHg, $n = 6$); b) previous microinjections of bicuculline (200 pmol) in the CVL reduced these responses significantly (7 ± 2.5 mmHg, $P < 0.01$); c) inhibition of the CPA by application of glycine (100 nmol) evoked hypotension (-40 ± 5.2 mmHg, $n = 6$); d) these falls in AP were virtually abolished by microinjections of kynurenic acid (4 nmol) in the CVL (-3 ± 1.7 mmHg, $P < 0.01$). We conclude that CVL mediates cardiovascular responses evoked from CPA responses and that both GABA and glutamate synapses are involved.

390.17

NTS EFFERENT TERMINALS SYNAPSE ON NEURONS IN THE CAUDAL VENTROLATERAL MEDULLA THAT PROJECT TO THE ROSTRAL VENTROLATERAL MEDULLA. S.A. Aicher*, O.S. Kurucz, D.J. Reis and T.A. Milner. Dept. Neurol. & Neurosci., Cornell Univ. Med. Coll., NY, NY 10021.

The caudal ventrolateral medulla (CVL) contains neurons that are vasodepressor and are a critical component of the baroreceptor reflex arc. Electrophysiological studies suggest that CVL neurons are intercalated in the baroreceptor pathway between the nuclei of the solitary tract (NTS) and the rostral ventrolateral medulla (RVLM) (Jeske, et al., *AJP*, 264, '93). However, synaptic contacts between NTS efferents and CVL neurons that project to the RVLM have yet to be demonstrated. In the present study, the retrograde tracer wheat germ agglutinin-*apo*-horse radish peroxidase conjugated to gold (WAHG) was pressure injected into the RVLM (10-30nl) and the anterograde tracer biocytin (1.5%) was iontophoresed into the NTS (5 μ A, 7s on/off, 15 min) of anesthetized rats. After 4-6h rats were perfused transcardially with 3.75% acrolein in 2% paraformaldehyde and sections through the CVL were processed for both markers. By light microscopy, WAHG-labelled cells were seen in the CVL, LTF, NTS and the area postrema. Numerous biocytin-labelled varicose processes overlapped neurons containing WAHG in the CVL. By electron microscopy, biocytin was found in myelinated and unmyelinated axons and in terminals (0.2-0.4 μ m) that contained primarily small clear vesicles. These terminals formed both asymmetric and symmetric synapses primarily on large dendrites within the CVL. Many of these post-synaptic dendrites contained WAHG associated with lysosomes and multivesicular bodies. Some dendrites received contacts from 2 or more biocytin-labelled terminals. These data indicate that (1) NTS efferents terminate in the CVL; and (2) some of the target neurons project to the RVLM. These data support the hypothesis that CVL neurons are intercalated between the NTS and the RVLM in the baroreceptor reflex pathway. (Support: NIH HL08251 & HL18974).

EFFECTS OF CLONIDINE AND RILMENIDINE ON CNS NEURONS ACTIVATED BY BARORECEPTOR UNLOADING IN CONSCIOUS RABBITS. Y.-W. Li* and R.A.L. Dampney. Dept. of Physiology, University of Sydney, NSW 2006, AUSTRALIA.

Intravenous injection of the centrally-acting anti-hypertensive drugs clonidine and rilmenidine has been shown to inhibit pressor neurons in the rostral ventrolateral medulla (RVLM) that are normally excited by baroreceptor unloading. We have found that baroreceptor unloading also causes neuronal activation (as indicated by the expression of Fos) in several other brain regions, including the nucleus tractus solitarius (NTS), A1 and A5 areas, locus coeruleus and subcoeruleus, lateral parabrachial nucleus, and various forebrain nuclei (Dampney and Li, Society for Neuroscience Abstracts, this meeting). The purpose of this study was to determine whether neuronal Fos expression that is normally induced by baroreceptor unloading within these brain regions could be affected by clonidine or rilmenidine. In conscious NZW rabbits, baroreceptor unloading was produced by i.v. injection of clonidine (7-10 μ g/kg) or rilmenidine (140-200 μ g/kg) followed by continuous i.v. infusion of sodium nitroprusside sufficient to lower arterial pressure by 20-25 mmHg for 1 hr. Compared with experiments in which the same degree of baroreceptor unloading was produced by sodium nitroprusside alone, pre-treatment with clonidine or rilmenidine greatly reduced the number of Fos-labelled cells (by at least 70%) in the RVLM, A1 and A5 areas, locus coeruleus and subcoeruleus, but not in other brain regions. The findings suggest that both drugs selectively suppress Fos expression in pontomedullary catecholamine cell groups.

EFFECT OF LESIONS IN THE CAUDAL VENTROLATERAL MEDULLA ON FREQUENCY COMPONENTS OF SYMPATHETIC NERVE ACTIVITIES. H.M. Wilfeht, D.R. McCrimmon* and S.F. Morrison. Dept. of Physiology, Northwestern Univ. Med. Sch., Chicago, IL 60611.

Interruption of neuronal activity in the periambigular region of the caudal ventrolateral medulla (CVLM) produces a large increase in splanchnic sympathetic nerve activity (SNA) resulting from elimination of both a tonic sympathoinhibition and the vasomotor component of the baroreceptor reflex. The present study was performed to determine whether a shift in the frequency components of SNA contributes to this increase and whether CVLM lesions produce differential changes in the SNAs to functionally distinct targets. The power spectra of SNA were compared before and after microinjection of kainic acid into the CVLM of chloralose/urethane-anesthetized, artificially ventilated rats. Lesions of CVLM neurons consistently produced both an increase in the total power and an upward shift in the mean frequency components of splanchnic SNA that was particularly evident when CVLM lesions were made in baroreceptor-denervated animals. In comparison to splanchnic SNA, CVLM lesions resulted in greater increases in cardiac SNA and smaller increases in cervical SNA. We conclude that elimination of the sympathoinhibitory influences of neurons in the CVLM increases both the number and the discharge frequency of active elements within sympathetic generating networks and that there is a differential influence of this inhibitory system on the sympathetic outflow to different organs. Supported by NIH HL47196.

A METABOTROPIC GLUTAMATE RECEPTOR IS RESPONSIBLE FOR MEDIATING EXCITATORY AMINO ACID NEUROTRANSMISSION IN THE CAUDAL VENTROLATERAL MEDULLA (CVLM) OF THE CAT. K. Chen, K.L. Dretchen* and R.A. Gillis. Dept. of Pharmacology, Georgetown Univ. Washington, DC 20007

Neurons in the CVLM exert an important role in controlling cardiovascular function. Excitation of these neurons results in hypotension and bradycardia due primarily to a decrease in sympathetic outflow. In our previous study we demonstrated that microinjection of a glutamate uptake inhibitor L-trans-2,4-pyrrolidine dicarboxylic acid (L-trans-2,4-PDC) into the CVLM (0.2 nmol/side) decreased mean arterial blood pressure (MAP) and heart rate (HR) of chloralose-anesthetized cats (FASAB, 7:A552, 1993). The responses were not prevented by blockade of NMDA and non-NMDA ionotropic glutamate receptors. Furthermore, microinjection of 1S,3R-ACPD (0.08 nmol/side), a specific agonist of the metabotropic receptor, into the CVLM mimicked the effect of L-trans-2,4-PDC on MAP and HR. These data suggested the presence of a metabotropic receptor at the CVLM. To obtain supportive evidence, we determined whether inhibitors of guanine nucleotide binding protein (which links the metabotropic receptor to its second messengers) would counteract the BP and HR effects of L-trans-2,4-PDC and 1S,3R-ACPD. The two inhibitors tested were pertussis toxin (PTX, 50 ng/side) and N-ethylmaleimide (NEM, 5 nmol/side). PTX pretreatment reduced the MAP and HR effects of L-trans-2,4-PDC from -65 ± 8 mmHg to -35 ± 2 mmHg ($P < 0.05$, $N = 5$) and -27 ± 3 beats/min to -14 ± 3 beats/min ($P < 0.05$), respectively. NEM pretreatment exerted a similar antagonistic effect on L-trans-2,4-PDC ($N = 8$) and also counteracted the hypotensive and bradycardiac effects of 1S,3R-ACPD ($N = 4$). These results indicate that a metabotropic receptor exerts a major role in mediating cardiovascular response in the CVLM.

AUTONOMIC RESPONSES TO STIMULATION AND INHIBITION OF THE INSULAR CORTEX IN SPONTANEOUSLY HYPERTENSIVE AND WISTAR RATS. *K.S. Butcher* and D.F. Cechetto*, Roberts Research Institute, Univ. of Western Ontario, London, ON, Canada N6A 5K8.

Lesion of the insular cortex (IC) results in elevated renal sympathetic nerve activity (RNA) and arterial pressure (AP) in the Wistar rat, while the opposite effect is observed in the spontaneously hypertensive rat (SHR). In order to further test the hypothesis that the IC differs between the two strains, acute changes in AP, heart rate (HR) and RNA were measured in propofol-anesthetized and chronically instrumented Wistar (n=15) and SHR (n=17) rats during pressure injection of D,L homocysteic acid (DLH; 100 mM) and lidocaine (LID; 20 mg/ml) into the IC. DLH injections (200 nl) into the rostral posterior IC of anesthetized Wistar rats resulted in a significant increase in AP (mean change = +27 ± 7 mmHg; p<0.05), and a significant decrease in HR (-22 ± 9 BPM) and RNA (-11 ± 4 μv.s). DLH injections into the IC of anesthetized SHR did not significantly affect AP or RNA, but HR did decrease significantly (-6.5 ± 3 BPM). LID injections (200 nl) throughout the IC of anesthetized Wistar and SHR rats did not result in any significant autonomic changes. DLH injections (500 nl) into the IC of conscious and freely moving Wistar and SHR rats did not result in significant autonomic changes, although AP and HR were elevated in 3 of the 4 Wistar rats. LID injections (500 nl) into the IC of conscious Wistar rats resulted in a significant increase in HR (64 ± 42 BPM), but had no effect in SHR. These results confirm a difference in the excitability of the IC in Wistar and SHR rats which may be related to the different responses to lesion of the IC. PREFRONTAL STIMULUS-PRODUCED HYPOTENSION: MEDIATION BY HYPOTHALAMO-MEDULLARY RELAYS? *S.G. Patrick Hardy^{1,2} and Paul J. May²*. Depts. of Physical Therapy¹ and Anatomy², Univ. of Miss. Med. Ctr., Jackson, MS 39216.

Stimulation of the rat prefrontal cortex (PFC) results in a pronounced degree of hypotension (Hardy and Holmes, 1988; Sun, 1992). This prefrontal stimulus-produced hypotension (SPH) occurs secondary to the inhibition of cardiovascular, reticulospinal neurons within the rostromedial medulla (RVL) (Sun, 1992). In addition, prefrontal SPH is dependent upon neurons residing within the posterolateral hypothalamus (Hardy and Mack, 1990). It is therefore conceivable that prefrontal SPH is mediated over hypothalamic relays to the RVL. To test this hypothesis, a series of anatomical experiments were performed, using a variety of tracers. Within the posterolateral hypothalamus, orthogradely labeled PFC axon terminals and retrogradely labeled hypothalamic neurons, projecting to the RVL, were observed to co-exist with an overlapping distribution. This finding supports the hypothesis that prefrontal SPH is mediated by hypothalamic relays to cardiovascular centers of the RVL.

To better understand this pathway, studies incorporating electromicroscopy have recently been initiated. It was observed that PFC terminals, within the posterolateral hypothalamus, typically were small and contained clear, round synaptic vesicles. These axon terminals made asymmetric synapses, primarily upon small caliber dendrites. Hypothalamo-medullary neurons typically contained a prominent Golgi apparatus and an indented nucleus. LONGITUDINAL COLUMNAR ORGANIZATION OF FOS-REACTIVE NEURONS IN THE PERIAQUEDUCTAL GRAY FOLLOWING CHANGES IN BLOOD PRESSURE.

A.Z. Murphy¹, M. Ennis, M.T. Shipley and M.M. Behbehani, Depts. Physiol. and Anat. & Cell Biol., Univ. of Cincinnati Col. of Med., Cincinnati, OH 45267. The midbrain periaqueductal gray (PAG) plays an important role in autonomic function, including cardiovascular regulation. Recent studies suggest that PAG is comprised of anatomically and functionally defined longitudinally (rostrocaudally) oriented neuronal columns. Activation of neurons in the lateral column of PAG elicits pressor responses; activation of neurons in the ventrolateral column evokes depressor responses. However, it is not known if there are PAG neurons that respond to changes in blood pressure (BP). If BP responsive cells exist it is of further interest to know if they are selectively located in functionally appropriate columns, i.e. are pressor-depressor responsive neurons restricted to columns that cause pressor-depressor responses, respectively? We have addressed these two issues by determining the distribution of PAG neurons expressing the immediate early gene product, Fos, following pharmacologically selective induction of high or low blood pressure.

In 15 anesthetized rats, a femoral artery and vein were cannulated for BP measurement and iv infusion (flow rate 1 ml/hr) of either the vasoconstrictor, phenylephrine (5 μg/ml), the vasodilator, sodium nitroprusside (5 μg/ml), or physiological saline. Animals were sacrificed 60 min later and the brain was processed for immunocytochemical detection of Fos-like-IR (FLI). Pressor and depressor drugs produced robust, selective FLI in neurons confined to discrete, longitudinally-organized columns within PAG. Specifically, vasoconstriction resulted in extensive FLI cells within the lateral column in PAG; in contrast, vasodilation resulted in extensive FLI located almost exclusively within the ventrolateral column in PAG. Importantly, far fewer FLI cells were found in PAG after saline infusion indicating that volume receptor activation does not account for the pressor/depressor evoked FLI in PAG. These results demonstrate that PAG neurons activated by pressor/depressor stimulation are restricted to as separate, discrete longitudinally organized columns, similar to those functionally defined by Bandler and colleagues. Specifically, pressor responses preferentially activate neurons in the lateral column while depressor responses activate neurons in the ventrolateral column. POWER SPECTRUM ANALYSIS OF HEART RATE VARIABILITY IN PATIENTS WITH INSULAR CORTEX LESIONS

*WM Martin and SM Oppenheimer**, Cerebrovascular Program, Dept of Neurology, Johns Hopkins Univ. Sch of Med. Baltimore MD 21287

The insular cortex likely is important in control of cardiac rhythm. Predominant lateralisation of cardiovascular sympathetic sites is demonstrable in the right insula and parasympathetic sites in the left. In an ongoing investigation, we devised a new portable platform to record ECG, arterial pressure and respiration non-invasively in 3 patients with destructive insular lesions. Heart rate variability was determined by spectral and RR distribution analysis. Results were compared with matched control groups. Sequential spectra were elicited over 5 minute time bins for 1 hour in supine relaxed patients breathing spontaneously. The two left insular patients had increased stability of low frequency spectral peaks over the hour compared with the right insula patient or controls. High frequency peaks were reduced in left insular lesions compared with right insular lesions or controls. Distribution analysis indicated decreased heart rate variability with left insular lesions. Pulse rate was higher in the left insular patients but blood pressure was not noticeably lower than that of the control groups. These preliminary data suggest that destructive left insular lesions decrease parasympathetic cardiac tone which may predispose towards cardiac arrhythmogenesis.

PHARMACOLOGICAL STUDY OF RECEPTORS MEDIATING THE DEPRESSOR RESPONSES TO INTRA-HIPPOCAMPAL INJECTION OF DYNORPHIN-A(1-8) AND L-GLUTAMATE IN CONSCIOUS SPONTANEOUSLY HYPERTENSIVE AND WISTAR-KYOTO RATS. *Q. Wang, A.J. Ingenito and J.P. DeVanzo**, Department of Pharmacology, East Carolina Univ. Sch. of Med., Greenville, NC 27858.

In conscious and unrestrained spontaneously hypertensive rats (SHR) and normotensive Wistar-kyoto (WKY) rats, receptors which mediate the depressor responses to microinjection of dynorphin-A(1-8) (Dyn) and l-glutamate (Glu) into hippocampal formation (HF) were studied by using receptor antagonists. Dyn (10 nmol) and Glu (10 nmol) unilaterally injected into the dorsal HF decreased mean blood pressure by -25.3±2.4 (Dyn) and -27.1±3.4 (Glu) mmHg in SHRs and -15.8±1.7 (Dyn) and -17.8±2.6 (Glu) mmHg in WKY rats, but without significant alteration of heart rate in both strains. In both strains of rats, while pretreatment of the HF with kappa opioid receptor antagonist nor-binaltorphimine (nor-BNI, 2 nmol) considerably antagonized the depressor responses to intra-HF Dyn but not Glu, pretreatment of the HF with glutamate subclass N-methyl-D-aspartate (NMDA) receptor antagonist 2-amino-5-phosphopentanoic acid (AP-5, 5 nmol) markedly blocked the depressor responses to intra-HF Glu but not Dyn. The depressor responses to intra-HF injection of either Dyn or Glu were found to be insensitive to antagonism by non-NMDA subclass receptor antagonist 6-cyano-7-nitroquinoxaline-2,3-dione (CNQX, 4 nmol) in SHRs as well as WKY rats. All three antagonists injected alone into the HF showed no significant effect on basal blood pressure and heart rate in SHRs and WKY rats. The results indicate that kappa opioid and NMDA receptors selectively process the depressor responses to intra-HF Dyn and Glu in SHRs and WKY rats.

391.6

THE MIDBRAIN PERIAQUEDUCTAL GRAY (PAG) DENSELY INNERVATES MEDULLARY REGIONS CONTAINING CHOLINERGIC VAGO-CARDIAC NEURONS

M. Ennis¹, S.-j. Xu, T.A. Rizvi, M.M. Behbehani & M.T. Shipley, Dept. Anatomy & Cell Biology, Univ. Cincinnati Coll. Med., Cincinnati, OH 45267. Activation of PAG elicits selective pressor and depressor responses. PAG projections to the rostral ventrolateral medulla sympathoexcitatory zone is a likely substrate for PAG-evoked depressor responses. Circuits mediating PAG-evoked depressor responses are less clear. Here, we report PAG projections to the rat nucleus ambiguus (NA) and periaqueductal area (pNA), a potential depressor region in the ventral medulla.

WGA-HRP and PHA-L injections into lateral and ventrolateral PAG labeled a rostrocaudally oriented, longitudinal fiber plexus that densely innervates the entire rostrocaudal axis of NA and pNA. Labeling begins at the level of the facial nucleus, corresponding to the compact formation of NA; labeled fibers at this level are primarily located in the region immediately surrounding, and to a lesser extent, within NA. The density of labeled fibers increases along the rostro-caudal axis of pNA, terminating most heavily in the loose and caudal, external formation of pNA. Both NA and pNA contain cholinergic vagal neurons that project to the heart. To directly assess the relationship between PAG projections and these cholinergic neurons, anterograde tracing was combined with immunohistochemical staining for choline acetyltransferase (ChAT), the synthetic enzyme for acetylcholine. Anterogradely labeled fibers terminated among ChAT-positive neurons in NA and the loose and caudal, external divisions of pNA. Additional double labeling studies assessed PAG projections in relation to neurons labeled after Fluorogold injections into 1-2 cardiac ganglia. PAG terminal projections were intermingled among labeled neurons in caudal, external formation of pNA.

These results indicate that PAG has direct, robust connections with NA and pNA. This projection terminates most heavily in the caudal pNA region that contains preganglionic parasympathetic cholinergic neurons that project to the heart. This PAG→NA projection may comprise a direct anatomical substrate that mediates the potent depressor responses produced by PAG stimulation. In addition, the projection from PAG to the rostral, compact division of NA may mediate PAG-evoked respiratory and vocalization responses. (Support: NS29635 & NS20643)

VIGILANCE REACTION ELICITED BY ELECTRICAL STIMULATION OF THE MIDBRAIN PERIAQUEDUCTAL GRAY AND THE HYPOTHALAMUS MAY INVOLVE SEPARATE NEURAL PATHWAYS IN RABBITS. Y-F. Duan*, P. M. McCabe, R.W. Winters, E.J. Green, Y. Huang, and N. Schneiderman. Department of Psychology, University of Miami, Coral Gables, FL, 33124.

The vigilance reaction (VR), characterized by behavioral freezing, increased alertness, an increase in blood pressure, bradycardia, and respiratory apnea or shallow tachypnoea, can be elicited by electrical stimulation of the hypothalamus. It has been suggested that the midbrain periaqueductal gray (PAG), instead of the hypothalamus, may be the integrative site for the VR. The present study was conducted to assess the functional relationship between the PAG and the hypothalamus in the integration of the VR.

Adult New Zealand albino rabbits were anesthetized with pentobarbital. Electrical stimulation of the PAG and hypothalamus was accomplished via separate bipolar stainless electrodes (50-400 μ A, 100 Hz, 0.5 ms duration, 10 s train). In selected animals surgical transection of the caudal PAG was performed stereotactically. Arterial blood pressure, EKG, and respiratory signals were recorded.

The hypothalamic and PAG vigilance areas were identified by cardiorespiratory responses to electrical stimulation. Concurrent stimulation of the PAG and hypothalamic VR areas yielded a larger VR. Ipsilateral and bilateral lesions of the PAG VR areas did not seem to affect the hypothalamic VR response. Transection of caudal PAG attenuated VR of the rostral PAG without affecting the hypothalamic VR. These findings suggest that the VR elicited by hypothalamic stimulation is mediated by a neuronal pathway that is different from the one that mediates the VR elicited by stimulation of the PAG. (Supported by NIH HL 36588 and HL 07426).

NEUROCHEMICAL ORGANIZATION OF THE PARABRACHIAL NUCLEUS IN CARDIOMYOPATHIC INBRED AND NORMAL HAMSTERS. Gary V. Allen* and David A. Hopkins, Department of Anatomy and Neurobiology, Dalhousie University, Halifax, N.S., Canada, B3H 4H7.

In animals born with a genetic predisposition for cardiomyopathy, sensory signals from diseased heart tissue would likely differ from that of normal heart tissue. It is hypothesized that this difference would affect the rate of synthesis and release of specific neurochemicals in autonomic structures. In order to test our hypothesis, the brains of normal golden hamsters, albino hamsters (strain CF-148, Canadian Hybrid Farms) and cardiomyopathic inbred hamsters (strain CHF-146, Canadian Hybrid Farms) were prepared for the immunohistochemical localization of antibodies to the catecholamine-synthesizing enzyme, tyrosine hydroxylase (TH), and serotonin (5-HT). Brain sections from each group were processed identically and simultaneously. Central autonomic regions were surveyed for differences in immunohistochemical staining. The results show that there were striking differences among strains with respect to the two neurochemicals examined. In golden hamsters and albino control hamsters, a small cluster of TH-positive cell bodies and a few TH-positive fibers were found in the lateral portion of the parabrachial nucleus (Pbl). In contrast, TH-positive fibers and cell bodies were dense in the Pbl of the cardiomyopathic hamsters (CF-146). 5-HT labeled fibers were dense in the Pbl of the CF-146 and CHF-148 strains but there was no detectable staining of 5-HT in the PB of the golden hamster. Because the parabrachial nucleus is known to receive visceral afferent input from the nucleus of the solitary tract (Mantyh and Hunt, '84; Hubert et al., '90), it is possible that the differential distribution of TH and 5-HT in the PB of the different groups of animals may reflect varying afferent input from the heart, other autonomic changes or genetic differences. 391.11

THE EFFECTS OF CHEMICAL BLOCKADE OF THE LATERAL PARABRACHIAL NUCLEUS ON THE BAROREFLEX. R.B. Fekler*, A.L. Pence and L.E. Hayward, Cardiovascular Center and Dept. of Internal Med. University of Iowa College of Medicine, Iowa City, IA 52242

Previous studies have shown that electrical or chemical activation of the lateral parabrachial nucleus (LPBN) produces an increase in arterial pressure and sympathetic nerve activity and an attenuation of baroreflex control of blood pressure and heart rate. Electrolytic lesion of the LPBN produces an augmentation of baroreflex control of heart rate and increases in plasma norepinephrine and renin activity. Since electrolytic lesions destroy fibers of passage in addition to cell bodies, the present study was designed to clarify the role of the LPBN in the control of the sympathetic nervous system. In 5 urethane anesthetized Sprague Dawley rats, mean arterial pressure (MAP) and renal sympathetic nerve activity (RSNA) responses to electrical stimulation of the left aortic depressor nerve (L-ADN) were recorded before and following chemical blockade of the ipsilateral LPBN (200 nl of 2 mM kainic acid [KA]) microinjected into the left LPBN. Immediately following chemical blockade of the left LPBN there was a significant increase in resting MAP (77.5 vs 97.9 mmHg; pre vs post KA block; $p < 0.05$; mean \pm SE) and an increase in RSNA. (100 vs 113 \pm 5% $p < 0.2$). Before chemical blockade, L-ADN stimulation at 2, 5 and 10 Hz (10 V, 0.2 ms) resulted in a 12, 18 and 19 mmHg drop in MAP and a 26, 44 and 37% decline in RSNA. Two minutes following chemical blockade 2, 5 and 10 Hz L-ADN stimulation resulted in a 14, 24*, 25 mmHg drop in MAP (* significantly different from control; $p < 0.05$) and a 12, 61 and 76% decline in RSNA. The results suggest that the LPBN may produce some tonic inhibition of baroreflex control of arterial pressure and RSNA in the anesthetized animal. (Support: HL44546 & HL14388)

SYMPATHOEXCITATORY RESPONSES ELICITED FROM THE AREA OF THE CUNEIFORM NUCLEUS IN THE RAT.

A.J.M. Verberne*. University of Melbourne, Clinical Pharmacology and Therapeutics Unit, Austin Hospital, Heidelberg 3084, Australia.

Electrical stimulation of the area of the cuneiform nucleus (CNF) in the rat produces elevations in arterial blood pressure. In this study, the effect of electrical and chemical stimulation of the CNF on lumbar sympathetic nerve discharge (LSND) and on putative sympatho-excitatory, medullospinal neurones of the rostral ventrolateral medulla (RVLM) in halothane-anesthetized, paralysed rats has been examined. Twin pulse stimulation (0.5 Hz, 0.5 ms duration, 3 ms pulse interval, 150-300 μ A) of the CNF produced sympathoexcitation with an onset latency of 78 ± 4 ms ($n=6$). Electrical (50 Hz, 0.5 ms, 25-100 μ A, 10 s) and chemical (DL-homocysteic acid 0.16M, pH 7.4, 25-50 nl) stimulation of the CNF produced pressor responses accompanied by sympathoexcitation. Twin pulse stimulation of the CNF also activated 8/10 RVLM barosensitive neurones (resting firing rate = 24 ± 4 spikes/s, range = 6-35 spikes/s, $n=10$) with an onset latency of 15 ± 3 ms. Train stimulation of the CNF produced an intensity-dependent excitation of RVLM neurones. Non-barosensitive neurones within the RVLM were not excited by CNF area stimulation ($n=5$). These studies suggest that CNF stimulation produces a sympathoexcitatory response which is mediated by putative premotor sympathoexcitatory neurones of the RVLM. (Supported by the NH&MRC of Australia).

NEUROPEPTIDE CHANGES IN THE PARABRACHIAL NUCLEUS FOLLOWING CERVICAL VAGAL STIMULATION.

TAREK M. SALEH* and DAVID F. CECHECQ. Roberts Research Institute and the University of Western Ontario, London, Ontario, Canada N6A 5K8

Previous studies in our laboratory have shown that the peptides; neurotensin (NT), cholecystokinin (CCK), substance P (SP) and calcitonin gene-related peptide (CGRP), have a role in modulating ascending visceral sensory information ascending relaying in the parabrachial nucleus (PB). In this investigation, we examined the changes in the levels of these peptides detected by immunohistochemistry in response to cervical vagal stimulation in the inactin-anesthetized male Wistar rat. Paired control and experimental animals were instrumented to monitor blood pressure and heart rate. The vagus nerve was stimulated for 0.5, 2 or 4 hours after which time the animals were perfused and the brains were processed immunohistochemically for the peptides NT, CCK, SP and CGRP. Vagal stimulation produced a depletion in the immunolabeling of NT and CCK in the external lateral (el) and external medial (em) subnuclei. This depletion increased with the length of vagal stimulation. In contrast, the immunolabel of the peptides SP and CGRP increased after one half hour reaching a maximum after two hours of vagal stimulation in the el and em subnuclei. After four hours of vagal stimulation, the immunolabel for SP and CGRP was depleted in the two PB subnuclei. Thus, the neuropeptides NT, CCK, SP and CGRP, which modulate the visceral sensory information in the PB, are also influenced by the level of activity in the vagus nerve. (Supported by the Heart & Stroke Foundation of Ontario).

RESPIRATORY MODULATION OF SPLANCHNIC SYMPATHETIC NERVE ACTIVITY IN RAT AFTER PONTINE LESIONS THAT PROLONG INSPIRATION. S.F. Morrison* and S.L. Cravo, Dept. of Physiology, Northwestern Univ. Med. Sch., Chicago, IL, 60611.

Respiratory modulation of the amplitude of sympathetic nerve activity provides an indication of the neural circuitry by which the central respiratory generating networks can influence those controlling sympathetic nerve activity (SNA). To determine which class of neuron involved in respiratory control might be responsible for the respiratory modulation of splanchnic SNA, the temporal characteristics of this modulation were examined in vagotomized, decerebrate, unanesthetized rats ($n=7$) before and after pontine lesions which increased the mean phrenic burst duration from 380 ± 12 ms to 1371 ± 240 ms. Relative to the onset of the phrenic burst, averages of splanchnic SNA prior to pontine lesions contained an excitatory potential with an onset of 49 ± 7 ms and a mean latency of 111 ± 10 ms. Neither the duration of the sympathoexcitation nor the temporal relationship between the onset of inspiration and enhanced SNA was significantly different during the prolonged phrenic bursts produced by pontine lesions. We conclude that this respiratory-linked sympathoexcitation is mediated by neurons in the respiratory generating network that exhibit a change in discharge pattern synchronized to the onset of inspiration. Supported by NIH HL47196.

REGIONAL HAEMODYNAMIC EFFECTS OF URAPIDIL IN NORMOTENSIVE ANAESTHETIZED RATS: COMPARISON WITH FLESINOXAN, PRAZOSIN AND CLONIDINE. H. Dabiré, K. Chaouche-Teyara, P. Lacolley* and M. Safar. INSERM U337, 15, Rue de l'École de Médecine, 75270 Paris 06, France.

Using pulsed Doppler technique, we have compared i.v. and i.c.v. systemic and regional haemodynamic effects of urapidil (U, α_1 -antagonist/5-HT_{1A} agonist), flesinoxan (F, 5-HT_{1A} agonist), clonidine (C) and prazosin (P). The results observed [Table: decrease (Dec.), increase (Inc.) or no change (-)] suggest that 1) I.v. U, F and P decreased mean arterial pressure (MAP) by a reduction in total peripheral resistance

	MAP	HR	CO	TPR	HQVR	MVR	RVR
U (0.1-3 mg/kg i.v.)	Dec.	-	-	Dec.	Dec.	Dec.	-
F (3-300 μ g/kg i.v.)	Dec.	Dec.	-	Dec.	Dec.	-	-
P (1-100 μ g/kg i.v.)	Dec.	-	-	Dec.	Dec.	Dec.	Dec.
C (1-100 μ g/kg i.v.)	Dec.	Dec.	Dec.	-	Inc.	-	Inc.
U (10-300 μ g/kg i.c.v.)	Dec.	-	-	Dec.	Dec.	-	-
F (3-30 μ g/kg i.c.v.)	Dec.	-	-	Dec.	Dec.	-	-
P (0.1-3 μ g/kg i.c.v.)	-	-	-	-	-	-	-
C (1-10 μ g/kg i.c.v.)	Dec.	Dec.	-	Dec.	Dec.	-	-

(TPR) and C cardiac output (CO). The hindquarters vascular bed is the main contributor to the reduction in TPR. 2) U, F, P and C have differential effects on hindquarters (HQVR), mesenteric (MVR) and renal (RVR) vascular resistances. 3) Central administration smooths these differences. 4) U resembles more closely F than P and C. The combined peripheral and central properties of U may explain its effectiveness to decrease blood pressure.

RENIN-ANGIOTENSIN SYSTEM INVOLVEMENT IN STRESS-INDUCED HYPERTENSION. D.C. Hattori², S.C. Coste, Y. Qi and D.A. McCarron. Oregon Health Sciences University, Portland, OR 97201

Daily exposure to air jet stress (AJS) has been shown to cause sustained elevations of blood pressure in borderline hypertensive rats (BHR). Both AV3V lesions and renal denervation have been shown to prevent the development of stress-induced hypertension in this strain suggesting that altered fluid balance regulation may be responsible. This study assesses the involvement of the renin-angiotensin system in stress-induced hypertension. Eight and nine week old rats were randomized to 4 groups receiving either captopril or vehicle with and without AJS. Captopril was administered in the drinking water (100mg/l) throughout the study. Water intake data indicated that the average daily dose was 6.2 mg/day. After 10 days of stress, catheters were placed in the femoral artery and the animals were allowed 48 hrs for recovery before measuring BP. Mean arterial pressure in conscious, restrained animals were as follows: vehicle/AJS = 148±5; captopril/AJS = 130±3; vehicle/no stress = 138±2; captopril/no stress = 134±2 mmHg. ANOVA indicated that AJS caused a significant elevation of blood pressure in the vehicle/AJS group but not in the captopril/AJS group. Circulating norepinephrine was significantly lower in captopril/AJS rats than vehicle/AJS rats during exposure to stress (850±91 vs 551±66 pg/ml) but not during baseline (443±65 vs 432±181 pg/ml). A similar trend was seen for epinephrine. The outcomes suggest that the formation of angiotensin II may be critical in the development of stress-induced hypertension and that the influence may be exerted through sympathetic nervous system activity. Supported by the Medical Research Foundation of Oregon and NHLBI grant 5 T32 HL07332.

COMPARATIVE EFFECTS OF INTERMITTENT AND STEADY AIR JET ON BLOOD PRESSURE IN SPRAGUE-DAWLEY RATS. E. S. Halas* and L. M. Klevay. USDA, ARS, Grand Forks Human Nutrition Research Center, Grand Forks, ND 58202.

Prior research has shown that steady or intermittent air jet (Drolet, G., Laforest, S. and Bachelard, H. *Soc. Neurosci. Abstracts* 1992; 18: 1183) effectively raises blood pressures of borderline hypertensive rats. These rats were restrained; our research (Klevay, L.M. and Halas, E.S. *Physiol. Behav.* 1991; 49: 309-314) has shown that chronic restraint is capable of elevating blood pressure in normotensive rats. Experiment 1 utilized three groups of adult, male rats. Group 1 was restrained and subjected to a steady air jet for 30 minutes a day, five days per week for eight weeks. A second group was restrained similarly while the third group (control) was left in their cages. No significant difference in blood pressure measured by tail-cuff was found. Experiment 2 was similar except that exposure to air jet was randomized by computer both in intertrial interval (10 to 60 sec.) and duration (0.5 to 10 sec.). All groups had a mean blood pressure of 110 mmHg at the start of the experiment. After two weeks, mean (SE) blood pressures were 119 ± 3.0, 111 ± 2.2 and 103 ± 4.2 for the respective groups. Most of the significance by ANOVA ($p < 0.008$) was attributed to a difference between the extreme values as adjacent pairs were not different ($p > 0.05$) by Tukey's standardized range test. Intermittent air jet is far more effective in raising blood pressure than steady air jet, which has been used in most prior studies. Most experiments have used borderline or Spontaneous Hypertensive Rats; these results show that normotensive rats respond to this stress with increased blood pressure. This method should be useful in nutritional experiments related to human hypertension.

391.14

CHARACTERIZATION OF RECEPTORS INVOLVED IN THE CARDIOVASCULAR ACTIONS OF CENTRALLY-ADMINISTERED NICOTINE (N). R. Chen and S.E. Robinson*. Department of Pharmacology & Toxicology, Medical College of Virginia, VCU, Richmond, VA 23298-0613.

Intracerebroventricular injection (i.c.v.) of N exerts multiphasic actions on the cardiovascular system at doses too small to be acting peripherally. The ability of nicotinic receptor antagonists to block the cardiovascular effects of i.c.v. N was studied in male Sprague-Dawley rats (300-350 g), which had lateral ventricular cannulae implanted under Equithesin anesthesia 3 days prior to the experiment. Blood pressure (BP) and heart rate (HR) were measured in urethane-anesthetized rats via a polyethylene cannula (PE 50) inserted in the femoral artery and connected to a pressure transducer coupled to a cardiograph and a polygraph recorder. I.c.v. injection of N (160 nmol/2 μ l artificial CSF) produced a triphasic effect on BP, consisting of an initial brief increase, followed by a decrease, and then a prolonged increase in BP, and a biphasic effect on HR, consisting of a decrease and then an increase in HR. Mecamylamine (M, 108 nmol/2 μ l artificial CSF, i.c.v.) alone had no effect on BP and HR, and neuronal bungarotoxin (n-btx, 4.5 μ g/2 μ l artificial CSF, i.c.v.) alone produced slight, but significant increases in BP and HR. Both M and n-btx blocked the hypertensive responses when injected i.c.v. 10 or 30 min, respectively, prior to N. M also reduced the hypotensive response. M blocked the bradycardia, but not the tachycardia, response to N. n-Btx did not block HR responses to N. Thus, multiple receptor subtypes are involved in the cardiovascular actions of N. (Supported in part by a Staton Heart Fund Fellowship).

CARDIOVASCULAR RESPONSES TO CIGARETTE SMOKE EXPOSURE IN RESTRAINED CONSCIOUS RATS. A.A. Houdi*, R.T. Dowell, M. Welch and J.N. Diana. Coll. of Pharmacy and Dept. of Physiology, Coll. of Med. and THRI, University of Kentucky, Lexington, KY 40546.

The mechanism(s) responsible for cigarette smoke- or nicotine-induced changes in cardiovascular functions have not been fully characterized. In this study, we investigated the effect of cigarette smoke exposure with different nicotine content on cardiovascular functions using a nose exposure system in conscious restrained rats. Male Sprague-Dawley rats (300 ± 25 gm) were exposed to 3,6,9 puffs during the "break in" period and 10 puffs the day of experiment (day # 4). Blood pressure (BP), heart rate (HR) and cardiac output (CO) were recorded continuously throughout the experimental period. On the day of the experiment, rats exposed previously to cigarette smoke generated from high nicotine cigarette (2.19 mg/cig.) showed a marked decrease in HR (-35%) and CO (-23%) and an increase in TPR (+100%) and BP (+9%) in response to restraint stress. Whereas rats exposed previously to air puffs showed a lesser decrease in HR (-14%) and CO (-17%) and an increase in BP (+20%) and total peripheral resistance (TPR, +44%). In addition, cigarette smoke exposure produced a further fall in HR (-67%) and in CO (-55%) with marked increase in BP (+60%) and TPR (+290%). Air puffs exposure had no effect on these parameters. This effect of cigarette smoke was dose dependent on the nicotine content of the cigarette and antagonized by pretreatment with mecamylamine or hexamethonium. Pretreatment with atropine methyl bromide blocked the bradycardia in response to both restraint stress and cigarette smoke exposure and produced a mild increase in HR, indicative of sympathetic activation. These data further support the involvement of specific nicotinic receptors in mediating the effects of cigarette smoke on cardiovascular functions by activating both sympathetic and parasympathetic systems. Supported by KTRB.

AUTONOMIC AND METABOLIC CHANGES WITH EXERCISE IN CHRONIC FATIGUE SYNDROME. S. Sisto, D. Cordero, M.T. Bergen, S. Drastal, W.N. Tapp, B.H. Natelson. Neurobehavioral Unit, EOVMC 127-A, East Orange, NJ 07018.

Chronic Fatigue Syndrome (CFS) is a disabling illness of unknown etiology that often strikes middle aged women. Earlier work noted an abnormal heart rate response to exercise. To study this further, CFS patients and sedentary controls walked on our treadmill protocol consisting of alternating stages of exertion and rest (1 mph, 2, rest, 1.5, 2.5, rest, 3, 3.5). Subjects continued exercising until they reached maximal workloads. Electrocardiogram, respiration, and expired gases were collected for autonomic and metabolic analysis.

We analyzed the area under the heart rate spectrum at frequencies greater than .15 Hz to estimate the parasympathetic component in heart rate variability. As expected, vagal power dropped when subjects, control or CFS, exercised ($p < 0.05$). Initial resting vagal power was not different between groups. However, during the rest periods following submaximal exercise, controls recovered parasympathetic power more than CFS subjects ($p < 0.01$).

VO₂ in CFS subjects was elevated above controls at 2.5, 3 and 3.5 mph 0% grade ($p < 0.01$). O₂ pulse (VO₂ / heart rate) was also elevated compared to normals during exercise ($p < 0.01$). No other metabolic parameters showed significant differences across groups. These differences in metabolic and autonomic responses to exercise suggest an organic etiology for CFS which requires further investigation. Supported by NIH (U01-AI32247) and VA medical research funds.

IMPAIRMENT OF CARDIOVASCULAR AUTONOMIC REGULATION IN AMYOTROPHIC LATERAL SCLEROSIS. T. Kiauta*, B. Žvan and S. Šega. Dept. of Neurology, University Medical Centre, SLO-61105 Ljubljana, Slovenia.

Few studies of autonomic nervous system function in amyotrophic lateral sclerosis (ALS), performed in a limited number of patients and yielding conflicting results, can be found in the literature. The aim of this study was to apply a standardised battery of cardiovascular tests to a sizable group of ALS patients and healthy controls.

The Valsalva manoeuvre, deep breathing test, sustained handgrip test, orthostatic test and spectral analysis of heart rate variability were tried in a group of 15 ALS patients, 7 of them female, aged 36 to 69 years (mean \pm S.D.: 54.7 \pm 9.0 years). All of them had both upper and lower motor neuron signs, while brainstem involvement was found in 7 patients. In all cases the diagnosis of ALS was confirmed electrophysiologically and gross symptoms of autonomic involvement were absent. Several patients were not up to performing the complete testing battery because of muscular weakness.

No abnormalities were found in 7 patients, while in the remaining 8 patients combinations of test results suggesting both sympathetic and parasympathetic hypofunction were established.

CARDIOVASCULAR REGULATION: HYPOTHALAMIC CONTROL

392.1

CHEMICAL TOPOGRAPHY OF EFFERENT PROJECTIONS FROM THE MEDIAN PREOPTIC NUCLEUS TO PONTINE MONOAMINERGIC CELL GROUPS IN THE RAT.

A.M. Zardetto-Smith*, T.G. Beltz and A.K. Johnson. Depts. of Psychology and Pharmacology, Univ of Iowa, Iowa City, IA 52242.

The median preoptic nucleus (MnPO), a major cell group in the anteroventral third ventricular (AV3V) region, is hypothesized to be a critical integrative area for hydrational information derived hormonally from blood-borne angiotensin II (ANG) acting on the subfornical organ, and neural volume/pressure information relayed from visceral receptor input to the brainstem. Previous anatomical studies in our laboratory demonstrated the MnPO is densely innervated by dopamine-beta-hydroxylase (DBH) immunoreactive fibers, and behavioral studies have indicated that norepinephrine must be present in this area to elicit normal drinking and pressor responses to exogenously administered ANG. In addition to this major noradrenergic input, the MnPO also receives efferents from brainstem serotonergic groups. Using anterograde tracing combined with glucose oxidase immunocytochemistry, this study focused on the reciprocal innervation of noradrenergic/serotonergic cell groups in the upper brainstem by efferents from the MnPO. Small deposits of *Phaseolus vulgaris* leucoagglutinin (PHA-L) were iontophoretically placed within the MnPO of male, Long-Evans rats. PHA-L fibers and terminals were visualized using the avidin-biotin immunoperoxidase technique. Monoaminergic cell bodies were localized using antibodies to dopamine-B-hydroxylase or serotonin (5-HT) and visualized with a glucose-oxidase nitro blue tetrazolium reaction. The results indicate that the A6 group was the most densely innervated of the upper brainstem catecholamine groups, with sparser innervation of the A5 and A7 groups. The B6 and B7 serotonergic groups received moderate innervation, with light innervation of the B8 group. Efferents from the MnPO to these groups may provide feedback important in modulating the forebrain projections originating from these areas. PARAVENTRICULAR NUCLEUS NEURONS PROJECTING TO THE SPINAL CORD IN THE RAT ARE INFLUENCED BY SUBFORNICAL ORGAN STIMULATION. J.S. Bains* and A.V. Ferguson. Department of Physiology, Queen's University, Kingston, Ontario, Canada, K7L 3N6.

The subfornical organ (SFO) is an important site in mediating the central nervous system actions of angiotensin II (ANG). Peripheral administration of this peptide results in: increased blood pressure, increased circulating levels of neurohypophysial hormones, as well as increased drinking behaviour. Anatomical studies have shown the presence of efferent projections from SFO to the paraventricular nucleus (PVN). Electrophysiological as well as cardiovascular studies suggest that SFO neurons projecting to the paraventricular nucleus (PVN) are influenced by ANG. The actions of this peptide at SFO can be mimicked by electrically activating this structure. It has been suggested, based on anatomical evidence, that a component of the pressor response may be mediated by PVN projections to the intermediolateral cell column (IML) in the spinal cord.

The present study carried out in urethane anaesthetized (1.4 g/kg), male, Sprague-Dawley rats, examined the effects of systemic angiotensin and SFO stimulation on PVN neurons antidromically identified as projecting to IML. Recordings were made from a total of 44 cells which were antidromically activated from the spinal cord. The antidromically evoked action potentials showed a mean latency of 102.3 \pm 7.6 ms, while the mean threshold for activation was 1.61 \pm 0.14 mA. Systemic ANG administration had no effect on the excitability of these neurons (n=18). A total of 13 neurons were also tested for responses to stimulation of SFO. Stimulation of SFO resulted in excitation (n=8), or had no effect (n=5). These findings suggest SFO efferents provide excitatory input to PVN neurons projecting to IML, although ANG apparently does not activate this pathway in this preparation.

392.2

ACTIVITY OF ANTERIOR HYPOTHALAMIC NEURONS IS INCREASED BY HIGH DIETARY NaCl IN SPONTANEOUSLY HYPERTENSIVE RATS. I. Kadisha, K. King, T. van Groen, S. Oparil* and J. M. Wyss. Departments of Cell Biology and Medicine, University of Alabama at Birmingham, Birmingham, AL 35294.

Previous data from our laboratory indicate that the anterior hypothalamic area plays an important role in NaCl-sensitive hypertension in the spontaneously hypertensive rat (SHR) on a high NaCl diet. In the NaCl-sensitive SHR (compared to NaCl-resistant rats) neurons in the anterior hypothalamic nucleus appear to be less responsive to a high NaCl diet, and this results in a lack of restraint on the sympathetic nervous system and a subsequent rise in arterial pressure. To more precisely test this hypothesis, 6 week old SHR were placed on a diet containing either 8% or 1% NaCl for 4 weeks. After the 4 weeks on the diet, arterial pressure was significantly elevated in the SHR on the 8% (192 \pm 5 mm Hg) NaCl diet compared to the SHR on the 1% (150 \pm 4 mm Hg) NaCl diet. Subsequently, the rats were perfused, the brains were removed and sectioned, and the sections were stained for cytochrome oxidase, an indicator of neuronal activity. In the SHR on the 1% NaCl diet, cytochrome oxidase labeling was present in the anterior hypothalamic area, but the labeling was light. In contrast, in the SHR on the 8% NaCl diet, cytochrome oxidase labeling in the anterior hypothalamic nucleus was more distinct and moderately elevated, suggesting that neuronal activity in the anterior hypothalamic nucleus was increased in these rats.

392.4

CHARACTERIZATION OF CARDIOVASCULAR RESPONSES TO PARAVENTRICULAR NUCLEUS (PVN) INJECTIONS OF A μ OPIOID AGONIST IN CONSCIOUS RATS. Hélène Bachelard* and Guy Drolet. Unité de Recherche sur l'Hypertension, Centre de Recherche du CHUL, Université Laval, Québec, G1V 4G2

The present study was designed to investigate the mechanisms of the cardiovascular responses produced by a μ opioid agonist, D-Ala², MePhe⁴, Gly⁵-ol-enkephalin (DAGO), bilaterally injected into the PVN of conscious Wistar Kyoto rats. The rats were chronically instrumented with intracerebral cannulae, intra-vascular catheters and pulsed Doppler flow probes in a three step surgery. PVN microinjection of artificial CSF had no consistent effects whereas DAGO produced dose-related cardiovascular effects. DAGO (1.0 nmol) produced significant increases in mean arterial blood pressure (MAP) (+24 \pm 4 mm Hg) and heart rate (+97 \pm 15 bpm), falls in renal (-28 \pm 5%) and mesenteric (-38 \pm 4%) vascular conductances and an increase in hindquarter (+91 \pm 15%) vascular conductance. In the presence of phentolamine injected i.v. DAGO (1 nmol) produced a decrease in MAP (-24 \pm 5 mm Hg), while the renal and mesenteric vasoconstrictor responses to DAGO were inhibited. The heart rate response and hindquarters vasodilatation to DAGO were unchanged in the presence of phentolamine. In the presence of propranolol injected i.v. only the tachycardic and hindquarters vasodilator responses to DAGO (1 nmol) were inhibited, while the others responses were unchanged. However following intravenous pretreatment of rats with a mixture of phentolamine and propranolol the cardiovascular responses to DAGO (1 nmol) were completely inhibited, while intravenous pretreatment of rats with captopril or a V1 vasopressin receptor antagonist had no effect on the cardiovascular responses to DAGO (1 nmol). Together these results suggest the participation of the sympathetic nervous system to the cardiovascular responses elicited by PVN injection of DAGO in conscious rats. The work was supported by the FRSQ, FQMC and the MRC.

392.5

NITRIC OXIDE AFFECTS BLOOD PRESSURE AND AMINO ACID RELEASE WITHIN THE PARAVENTRICULAR NUCLEUS. T. Horn*, P.M. Smith, B. McLaughlin, L. Bauce, G. Marks, O. J. Pittman and A. V. Ferguson.; Univ. of Leipzig, Germany; Queen's University, Kingston, Canada & Neuroscience Research Group, Univ. of Calgary, Canada.

Nitric oxide (NO) synthase immunoreactivity in neurons of the hypothalamic paraventricular nucleus (PVN) implicates a possible role of NO as an important messenger in central cardiovascular regulation within this area. Thus, we have tested whether sodium nitroprusside (SNP), a NO donor, affects blood pressure when microinjected into the PVN of urethane anaesthetized rats. A dose of 50 pmol SNP resulted in a significant decrease in mean arterial blood pressure (MAP, mean response -3312 ± 1189 mmHgsec over 330 sec response time, $p < 0.05$), but no significant change in heart rate. Furthermore, we delivered artificial cerebrospinal fluid (aCSF), which was pre-gassed with a mixture of 5% NO in nitrogen (NO-aCSF), via microdialysis bilaterally into the PVN in order to distinguish between effects due to the action of SNP or free NO. Perfusions of the PVN with NO-aCSF over a period of 30 min resulted in a statistically significant decrease of MAP (-5121 ± 817 mmHgsec, $p < 0.005$) when compared with the MAP during a control perfusion (aCSF). The perfusates of the PVN microdialysis were collected and subsequently analyzed for amino acids by HPLC. The levels of aspartate (432%), glutamate (1158%), taurine (344%) and GABA (2536%) in samples, obtained from perfusions with NO-aCSF, were found to be significantly elevated when compared with controls (aCSF) whereas alanine, glutamine, and serine concentrations of the perfusates did not change. Our study provides the first direct evidence that NO may play a significant role in the regulation of cardiovascular function within the PVN.

NEUROTRANSMITTER MEDIATING HYPOTENSION INDUCED C-FOS EXPRESSION IN THE SUPRAOPTIC NUCLEI OF RATS. E. Shen*, X. Sun and Z.H. Jiang, Shanghai Brain Research Institute, Shanghai 200031, China.

It has been reported that hemorrhage or hypotension induces Fos-immunoreactivity (Fos-IR) in the supraoptic (SO) and paraventricular nuclei of the hypothalamus in rats, mostly in vasopressin-containing cells (Shen et al., Soc. Neurosci. Abstr. 18:1176, 1992). The aim of the present study is to explore the neurotransmitter mediating this effect. Adult male Sprague Dawley rats anesthetized with nembutal were used. The hypotension induced Fos-IR in the SO was suppressed by microinjection of the alpha-adrenergic blocker phentolamine (1-5ug) into the SO 10min before intravenous infusion of nitroprusside (2mg/ml), but not by the beta-adrenergic blocker propranolol (2-10ug) microinjected into the SO. The hypotension induced Fos-IR in the SO was also diminished by microinjection of the alpha-2 blocker yohimbine (0.1-lug) into the SO. Microinjection of the norepinephrine (NE) reuptake blocker desipramine (2ug) into the SO to accumulate the spontaneously released NE in the SO could induce Fos-IR in the SO. It is concluded that the hypotension induced Fos-IR in the SO is mainly mediated by NE via alpha receptors. (Supported by the Chinese Academy of Sciences Grant ks852024 and the National Natural Science Foundation of China Grant 39270241)

392.9

C-FOS IMMUNOREACTIVITY IN THE FOREBRAIN AND THE MEDULLA AFTER INTRAVENOUS HYPERTONIC SALINE INFUSION IN ANESTHETIZED RATS. M.L. Weiss* and M.J. Kenney, Dept of Anatomy and Physiology, Kansas State University, Manhattan, KS 66506-5602.

Intravenous hypertonic saline (HTS) infusion increases arterial blood pressure, but the mechanism of this pressure increase is not well established. We employed c-fos immunocytochemistry as a marker for neurons activated by iv HTS in chloralose-anesthetized rats. Mean arterial pressure (MAP) and heart rate (HR) were recorded continuously during the 30 min intravenous infusion of 2.5M NaCl (10µl/100gBW/min) and the subsequent 20-40 min period. HTS infusion increased MAP (24 ± 4 mm Hg, N=7) but did not affect HR. In the forebrain, many c-fos immunoreactive (IR) neurons were found in areas involved with cardiovascular regulation: the anteroventral wall of the third ventricle (AV3V) region (median preoptic nucleus, organum vasculosum lamina terminalis, periventricular region), the subfornical organ, and the hypothalamic magnocellular neuroendocrine system. In the medulla, c-fos IR cells were found within the area postrema, the medial nucleus of the solitary tract and within the ventral lateral medulla after iv HTS. While there was no difference in the pattern of c-fos IR in the brain between animals injected ip or iv, there was more intense staining after ip injection. We conclude that neurons within sites involved with blood pressure regulation contain c-fos IR after iv HTS. This technique may provide insight into the mechanisms responsible for the blood pressure increases seen during peripheral hyperosmolality.

392.6

Selective Loss of Hypothalamic Neurons in Spontaneously Hypertensive rats (SHR). R. Eilam, R. Malach*, Brain Research, The Weizmann Institute of Science, Rehovot, Israel 76100

The likelihood that the brain undergoes severe morphological changes during the development of hypertension is indicated by a marked loss in brain weight and volume in SHR. We have found a specific cell loss in the PVN of 3-6 months old SHR; immunohistochemical studies revealed a gradual reduction in vasopressin (VP+) parvocellular (P) cells but not in tyrosine hydroxylase P cells in this region when compared to normotensive (WKY) rats. Alternate sections stained for Nissl or vasopressin revealed a loss in the number of cells and appearance of pycnotic cells in regions of the PVN normally reach in VI+ P cells. The cross-sectional area profile of VP+ P neurons was markedly reduced. This phenomenon was already significant in 2 months old SHR. Our findings strongly indicate that VP+ P cells undergo a degenerative process (possibly programmed cell death) characterized by cell contraction in their initial stage of dying.

392.8

FOREBRAIN FOS STAINING PRODUCED BY CAROTID SINUS NERVE (CSN) STIMULATION IN NEMBUTAL (NEM) AND URETHANE (URE) ANESTHETIZED RATS. J.T. Cunningham*, A.M. Zardetto-Smith, M.Z. Cicha, A.K. Johnson & S.J. Lewis, Depts. of Pharmacol., Psych. and the Cardiovascular Center, Univ. of Iowa, Iowa City, IA 52242.

This study examined the central expression of the protein product of the intermediate-early gene *c-fos* as an indicator of cellular activation (*fos*-IR) following electrical stimulation of the CSN in anesthetized rats. Adult male rats were anesthetized with either NEM (50 mg/kg i.p.) or URE (1.5 g/kg i.p.) and a catheter was placed in their left femoral artery for blood pressure measurement. Their left CSN was isolated and a bipolar stimulating electrode was placed on it for 20 min. In control rats (SHAM) no current was passed through the electrode while stimulated rats received CSN stimulation for 20 min (5 V, 2 ms duration, 2 pps). All rats were perfused one hour after the 20 min test period. The *fos*-IR was localized immunocytochemically (ABC, Vector) and visualized with a nickel-intensified DAB reaction. In SHAM rats anesthetized with NEM, *fos*-IR was observed in the lateral septum, the OVLT, the subfornical organ, the central nucleus of the amygdala (CeA), the medial amygdala, the proximal supraoptic nucleus of the hypothalamus (SON), the paraventricular nucleus of the hypothalamus (PVN), and paraventricular thalamus. In CSN stimulated rats anesthetized with NEM, *fos*-IR was also observed in the lateral hypothalamus and the pattern of staining was altered in the SON, the PVN and the CeA. In general, URE anesthetized rats showed more background *fos*-IR and slightly higher stimulated *fos*-IR levels than NEM anesthetized rats. In addition to the regions listed above, CSN stimulated, URE anesthetized rats also demonstrated *fos*-IR in the diagonal band of Broca. These results indicate that, while surgical stress and anesthesia can affect the levels of *fos*-IR, CSN stimulation influences *fos*-IR differentially in the hypothalamus and the basal forebrain. (Supported by HL 4546 and HL 14388).

392.10

INCREASED c-FOS STAINING IN MULTIPLE HYPOTHALAMIC REGIONS AFTER SLOW HEMORRHAGE. M.L. BLAIR*¹ AND J.A. OLSCHOWKA², Departments of Physiology¹ and Neurobiology and Anatomy², University of Rochester School of Medicine, Rochester, NY 14642.

Immunohistochemical localization of the oncoprotein Fos was employed to identify hypothalamic regions which respond to a slow hemorrhage (HEM). Conscious male Sprague-Dawley rats were subjected to blood withdrawal, 0.8 ml/kg/min, to a cumulative loss of 12.8 ml/kg bwt. HEM caused a transient decrease in mean arterial pressure (93 ± 1 mm Hg to 76 ± 6 mm Hg, $p < 0.05$) and a sustained 3-fold increase in plasma renin activity ($p < 0.01$). The hypothalamic Fos distribution of HEM rats ($n=5$) was compared with that of control rats ($n=5$) for which arterial pressure was measured but no blood was withdrawn. HEM rats showed a significant increase in the number of Fos immunoreactive cells ($p < 0.05$), as compared with control rats, in the magnocellular and parvocellular paraventricular nuclei, supraoptic nucleus, ventromedial nucleus, dorsomedial nucleus, arcuate nucleus, posterior hypothalamic nucleus, and supramammillary area, but not the posterior lateral hypothalamus. In conclusion, Fos immunoreactivity indicates that neuronal activity is increased by HEM in multiple hypothalamic regions which include, but are not restricted to, those known to be involved in regulation of extracellular fluid volume and arterial pressure. 392.11

CARDIOVASCULAR EFFECTS OF MICROINJECTION OF KAINIC ACID OR BICUCULLINE INTO THE DORSOMEDIAL OR PARAVENTRICULAR HYPOTHALAMIC NUCLEUS IN ANESTHETIZED RATS. J.A. DiMicco, Dept. Pharmacol. & Toxicol., Ind. Univ. Sch. of Med., Indianapolis, IN 46202.

We have previously reported that microinjection of either GABA_A receptor antagonists, such as bicuculline methiodide (BMI), or excitatory amino acid receptor agonists into the dorsomedial hypothalamic nucleus (DMH) elicits marked tachycardia and modest increases in arterial pressure in anesthetized and conscious rats. However, others have reported similar effects upon microinjection of BMI into the neighboring paraventricular nucleus (PVN). To assess whether the cardiac effects of microinjections into the DMH might be a consequence of diffusion to the PVN, BMI 5 pmol/15 nL (5 rats) or kainate (KA) 1-3 pmol/15 nL (5 rats; dose kept constant in a given experiment) was injected at each of three sites in random order at 30-40 min intervals in urethane-anesthetized rats. Target stereotaxic coordinates corresponded to (1) the PVN, (2) the DMH, and (3) an intermediate site equidistant to each, and were confirmed histologically at the end of each experiment. Mean maximal increases in heart rate (Δ HR; beats/min \pm SEM) and changes in arterial pressure (Δ BP; mmHg \pm SEM) evoked at each site were:

Agent	DMH		Intermediate		PVN	
	Δ HR	Δ BP	Δ HR	Δ BP	Δ HR	Δ BP
BMI	64 \pm 7	7 \pm 3	30 \pm 10	-3 \pm 2	14 \pm 3	-2 \pm 2
KA	59 \pm 6	1 \pm 3	28 \pm 8	-1 \pm 3	8 \pm 6	2 \pm 2

These data suggest that the tachycardia observed after microinjection of these agents into the DMH is not attributable to diffusion or spread to the neighboring PVN. Rather, the tachycardia seen after microinjection of these agents at higher doses and in larger volumes into the PVN may result from diffusion to the DMH, a region recently implicated in the generation of the cardiovascular response to stress. ROLE OF CORTICOTROPIN-RELEASING FACTOR IN MEDIATING CARDIOVASCULAR RESPONSES TO BLOCKADE OF GABA_A RECEPTORS IN THE HYPOTHALAMIC DORSOMEDIAL NUCLEUS. F. Onat, A. Dedeoğlu and L.A. Fisher*, Department of Pharmacology, College of Medicine, University of Arizona Health Sciences Center, Tucson, AZ 85724.

Disruption of GABAergic neurotransmission in the hypothalamic dorsomedial nucleus (DMN) elicits cardiovascular changes that are characteristic of the defense reaction, a patterned response to stressful stimuli. Likewise, corticotropin-releasing factor (CRF) acts within the central nervous system (CNS) to produce stress-like changes in cardiovascular function. CRF-containing neurons are located within the DMN and hence the purpose of the present study was to test the hypothesis that blockade of GABA_A receptors in the DMN produces cardiovascular activation through disinhibition of CRF-containing neurons. All experiments were performed in conscious, unrestrained male Sprague-Dawley rats (220-250 g) instrumented with intracerebroventricular (icv) and/or intraparenchymal (aimed at the DMN) guide cannulas for drug administration and iliac arterial catheters for direct measurement of arterial pressure (AP) and heart rate (HR). Icv administration of bicuculline methiodide (BMI), a GABA_A receptor antagonist (0.01-0.3 nmol), produced dose-related increases in AP (5-17 mm Hg) and HR (10-70 beats/min) that were not altered appreciably by pretreatment with the CRF receptor antagonist, α -helical CRF₄₁₋₄₁ (9 nmol, icv). When injected into the DMN (250 nl), very small doses of BMI (0.0025-0.01 nmol) were required to elicit robust changes in AP (3-13 mm Hg) and HR (20-110 beats/min) that were attenuated by 50-70% after pretreatment with α -helical CRF₄₁₋₄₁ (9 nmol, icv). These results suggest that GABAergic mechanisms within the DMN tonically inhibit CRF-containing neurons and that BMI-induced cardiovascular elevations of AP and HR are in part mediated by the release of CRF.

THE INFLUENCE OF HYPOTHALAMIC NUCLEAR STIMULATION ON ROSTRAL VENTROLATERAL MEDULLA CARDIOVASCULAR NEURONS OF THE RAT. T.P. Wong, Y.S. Chan* and T.M. Wong. Department of Physiology, Faculty of Medicine, The University of Hong Kong, Sassoon Road, Hong Kong.

The contribution of the hypothalamic nuclei to the arterial blood pressure and the spontaneous activity of cardiovascular neurons in the rostral ventrolateral medulla (RVL) was investigated in pentobarbital-anesthetized rats. Extracellular activities of RVL neurons and arterial blood pressure were recorded simultaneously during the experiments. Only RVL neurons which exhibited cardiac-locked activity as well as barosensitivity to phenylephrine were classified as cardiovascular neurons. Electrical microstimulation of the paraventricular nucleus of hypothalamus (PVH) increased the discharge rate of 90% of the RVL cardiovascular neurons tested. About 60% of these was accompanied by pressor response while 30% was associated with depressor response. Electrical microstimulation of the dorsomedial nucleus of hypothalamus (DMH) also elicited changes in both the discharge rate of RVL cardiovascular neurons and arterial blood pressure. Most neurons also exhibited an increase in discharge rate in response to the stimulation of DMH. Microinjection of L-glutamate, an amino acid which is known to stimulate the soma without exciting the axons of passage, into PVH or DMH also elicited alterations in both the firing rate of RVL cardiovascular neurons and arterial blood pressure changes. These results indicate that RVL cardiovascular neurons, which mediate the baroreceptor reflex, are under the influence of inputs from the hypothalamic nuclei. DISINHIBITION OF POSTERIOR HYPOTHALAMIC NEURONS ELICIT SPLANCHNIC MICROVASCULAR CONSTRICTION. R.W. Stremel* and I.G. Joshua.

Department of Physiology & Biophysics, School of Medicine, University of Louisville, Louisville, KY 40292.

Inhibition of γ -aminobutyric acid (GABA) receptors within the posterior hypothalamus (PH) elicits an "exercise-like" redistribution of blood flow. This redistribution should be reflected at the microvessel level and thus splanchnic vasoconstriction is predicted. To test this, we observed microvessels of the intestinal serosa during PH activation (GABA_A receptor antagonist, bicuculline methiodide (BMI)). Sprague-Dawley rats, anesthetized with pentobarbital (50 mg/kg, ip), were prepared for video microscopic observation of microvessels within intestinal smooth muscle suspended in an oxygenated, pH balanced tissue bath. Arterioles of 10 to 30 μ were observed before and after microinjection of 15 - 45 nl of BMI (5 ng/nl) into the region of the PH. The expected increases in blood pressure (44% \pm 10, average \pm sem increase in mean arterial pressure), heart rate and locomotor activity were observed, as was vasoconstriction of intestinal smooth muscle microvessels (-35% \pm 2, mean \pm sem reduction in diameter). These results support the concept that the PH is responsible for eliciting a "central command" for exercise and a redistribution of blood flow at the microvessel level. Supported by American Heart Association.

α_2 -ADRENERGIC REGULATION OF HYPOTHALAMIC PROOPiomELANOCORTIN (POMC) mRNA AND BLOOD PRESSURE (BP) IN THE RAT.

M.N. Scanlon, S-J. Li, E. Lazar-Wesley, K. Varga, N.S. Gantenberg and G. Kunos*. Dept. of Pharmacol. & Toxicol, Med. Coll. of Virginia, Richmond, VA 23298

Several lines of evidence indicate that activation of central α_2 -adrenergic receptors (α_2 AR) by clonidine or α -methyl-dopa (α MD) reduces BP in part through the release of β -endorphin and subsequent stimulation of opiate receptors in the brainstem. Lesion studies suggest that the source of the β -endorphin released is neurons that originate in the arcuate nucleus of the mediobasal hypothalamus (MBH). To obtain an indicator of the activity of these neurons, we have measured steady state levels of POMC mRNA in the MBH of rats, and correlated drug-induced changes in BP measured by the tail cuff technique with changes in POMC mRNA levels, measured by a DNA excess solution hybridization assay as well as by *in situ* hybridization histochemistry. α MD, 200 mg/kg/day i.p. for 4 days, reduced BP and significantly increased POMC mRNA levels compared to vehicle-treated controls, in an area of the MBH limited to the arcuate nucleus. In animals treated with yohimbine (2 mg/kg/day) + α MD, there was no change in BP, and POMC mRNA levels were similar to that in controls. In animals treated with naltrexone (2 mg/kg/day) + α MD, BP remained unchanged, but POMC mRNA levels were increased to the same extent as with α MD alone. Hydralazine, 2 mg/kg/day for 4 days, decreased BP but did not modify POMC mRNA levels. We conclude that the opioid-mediated component in the hypotensive action of α MD is related to an α_2 AR-mediated activation of endorphinergic neurons in the arcuate nucleus.

HYPVOLEMIA INCREASES THE LEVELS AND THE EXTENT OF COLOCALIZATION OF NEUROTENSIN AND ENKEPHALIN mRNAs IN HYPOTHALAMIC CRH-CONTAINING NEURONS. G. Sanchez-Watts*, S.M. Tanimura & A.G. Watts. NIBS Program & Dept. of Biol. Sci., USC, Los Angeles CA 90089.

Disturbances of fluid homeostasis lead to widespread alterations in neuropeptide gene expression suggesting that altered peptidergic function makes important contributions to the different components of fluid balance regulation. Iso-osmotic hypovolemia caused by subcutaneous (sc) injections of polyethylene glycol (PEG) leads to a well-documented series of physiological and behavioral responses, including increased vasopressin (VAS) and corticosterone secretion, hematocrit, thirst and sodium appetite. Here, using *in situ* hybridization (ISH), we report the time-course and extent of neuropeptide and immediate-early gene mRNA response in the forebrain to PEG-induced hypovolemia. We have also used combined digoxigenin- and ³⁵S-labeled cRNA probes to investigate the effects of hypovolemia on the colocalization of peptide mRNAs in the hypothalamic paraventricular nucleus (PVH). Groups of male SD rats (280-300g BW) were anesthetized and injected sc with 5mls of either 30% (w/v) PEG in 0.9% saline or vehicle alone. At various times up to 24h after PEG injections animals were anesthetized and perfusion-fixed. Frozen 15µm coronal sections were cut through the forebrain and hybridized with a cRNA probe for CRH, proenkephalin (ENK), c-fos, neurotensin (NT), oxytocin or VAS. Sections from animals perfused 18-20h after PEG were also hybridized with a digoxigenin-UTP labeled (DIG) cRNA probe for CRH cocktail with a ³⁵S-UTP labeled cRNA probe for either NT, ENK or VAS. Analysis of the dipped slides and X-ray autoradiographs showed significant increases in the levels of c-fos, CRH, NT and ENK mRNAs in the medial parvocellular PVH. No increases were seen in the LHA. Increased c-fos mRNA levels were also seen in the supraoptic nucleus and other limbic forebrain regions. Combined DIG and ³⁵S ISH showed a significant percentage of the increased levels of ENK and NT mRNA occurred in CRH neurons, suggesting that increased peptidergic colocalization in the PVH regulated part of the neuroendocrine response to hypovolemia. These results are also in marked contrast to changes in PVH mRNA levels seen after hyperosmotic dehydration, when decreases in CRH mRNA occur without concomitant increases in NT or ENK gene expression. A CENTRAL ACTION OF ADENOSINE IN A HYPOTHALAMICALLY EVOKED CARDIOVASCULAR RESPONSE. K.M. Spyer*, J.H. St. Lambert, M.S. Dawid-Milner, L. Silva-Carvalho., Dept. of Physiology, Royal Free Hospital School of Medicine, London NW3 2PF.

In pentobarbitone anaesthetised cats and rats, stimulation in restrictive sites in the hypothalamus elicits a characteristic cardiovascular response that is an integral component of the defense reaction. The evoked rise in arterial pressure is reduced significantly (47.43%, p<0.01 in the cat; 33.53%, p<0.05 in the rat) by the intravenous injection of the A₁ adenosine antagonist DPCPX but not by 8-SPT; the former enters the CNS but not the latter. In the cat, DPCPX also reduces the pressor response, but not the respiratory changes, to carotid body stimulation and facilitates the baroreceptor reflex lowering of arterial pressure. These observations are consistent with adenosine release being involved in mediating these cardiovascular responses. The pattern of action of the A₁ antagonist is suggestive of a site of action within the nucleus tractus solitarius, and this possibility is under investigation.

LATERAL HYPOTHALAMIC LESIONS PRODUCED BY N-METHYL-D-ASPARTATE OR IBOTENIC ACID INDUCE GASTRIC EROSIONS IN RATS. C. V. Grijalva*, J. Rios-Jimenes and J. Landeira-Fernandez. Dept. of Psychol., Univ. of California, Los Angeles, CA 90024

Bilateral electrolytic lesions of the lateral hypothalamus (LH) produce gastric erosions. However, electrolytic lesions destroy both neurons as well as axonal fibers of passage. Because several fiber tracts course through the LH area it is unclear whether the formation of gastric erosions following LH lesions is due to damage to intrinsic neurons or to the interruption of certain fibers systems. The present study was conducted to examine whether damage to intrinsic LH neurons induced by microinfusion of N-methyl-D-aspartate (NMDA) or ibotenic acid (IBO) could also produce gastric erosions. In Experiment 1, LH lesions were produced by IBO (10 µg/µl) or electrolytic current (1.2 mA, 10 sec). Rats receiving electrolytic lesions displayed motor impairments while those receiving IBO lesions did not. Both electrolytic and IBO lesions produced eating deficits and gastric erosions 24 h after surgery. In Experiment 2, bilateral LH lesions were produced by NMDA (20 µg/µl). Again, both electrolytic and NMDA lesions produced gastric erosions and eating deficits but only electrolytic lesions induced motor impairment. In Experiment 3, the extent of LH neuronal damage was varied by infusing different doses of NMDA (20 µg/µl or 10 µg/µl). Both doses reliably produced gastric ulceration and the magnitude of the effect was dose dependent. It is concluded that damage to intrinsic LH cell bodies are responsible for the induction of gastric erosion formation.

VASOPRESSIN-MEDIATED PRESSOR RESPONSE TO THE INTRA-VENTRICULAR NORADRENALINE IN CONSCIOUS RATS. F.M.A. CORRÊA* Dept. Pharmacol., School Medicine Ribeirão Preto, Univ. of São Paulo, Ribeirão Preto, SP, Brazil, 14049-900.

The i.c.v. injection of noradrenaline (NA) causes blood pressure increase in unanesthetized rats that is blocked by i.v. injection of vasopressin antagonists (Corrêa et al., *J. Neuropharmacology* 24: 831-838, 1985). Presently we observed similar responses when NA was injected into the III or IV ventricles and dose-effect curves were generated. Similarly to the lateral ventricle, responses were blocked by i.v. injection of a vasopressin antagonist suggesting a common mediation via vasopressin release into the systemic circulation. Obstruction of selected ventricular spaces with cream plugs were performed to identify the ventricular area involved in the pressor response to centrally injected NA. NA injections were followed by injections of Evan's blue dye for macroscopic observation of the distribution of drug within ventricles. Obstructions of the III ventricle or the aqueduct blocked the pressor response to NA injected into the lateral ventricle. Obstructions of the IV ventricle, although less conclusive, indicated that the access to the ventral portion of the brainstem is essential for the response.

N-METHYL-D-ASPARTATE LESIONS IN THE SUBSTANTIA NIGRA BUT NOT IN THE VENTRAL TEGMENTAL AREA PRODUCES GASTRIC EROSIONS IN THE RAT. J. Landeira-Fernandez* and C. V. Grijalva. Department. of Psychology, University of California, Los Angeles, CA 90024

Bilateral electrolytic lesions in the substantia nigra (SN) or ventral tegmental area (VTA) lead to stomach ulceration (Roland & Grijalva, *Brain Res*, 1993, 605, 110-120; Ray, Henke & Sullivan, *Physiol and Behav*, 1988, 42, 359-364). However, electrolytic lesions destroy both neurons as well as axonal fibers of passage. Recently we showed that damage to intrinsic lateral hypothalamic (LH) neurons are involved in the formation of gastric erosions (Grijalva, Rios-Jimenes & Landeira-Fernandez, *Soc. Neurosci. Abstr.* 1993). Because descending fibers from the LH travel through the region of the SN and the VTA (Berk & Finkelstein, *Brain Res Bull*, 1982, 8, 511-526) it is unclear whether the formation of gastric erosions following SN and VTA lesions are due to damage to intrinsic neurons or due to the interruption of the descending LH fibers systems. The present study was conducted to examine whether damage to intrinsic SN and VTA neurons by microinfusion of N-methyl-D-aspartate (NMDA, 20 µg/µl) could also produce gastric ulceration. A control group received microinjections of the vehicle either in the SN or VTA. It was found that bilateral NMDA lesions in the SN but not in the VTA reliable produced gastric erosions 24 h after surgery. These results indicate that intrinsic neurons in the SN play an active role in the development of gastric mucosal injury.

VIRAL TRANSNEURONAL LABELING OF THE VISCERAL NEURAXIS AFTER LONG SURVIVAL TIMES FOLLOWING DIFFERENT ALIMENTARY STRUCTURE INJECTIONS. M. Yang*, X. Zhao and R.R. Miselis, Dept. of Animal biology, School of Veterinary Medicine, University of Pennsylvania, Phila., PA 19104

Brainstem labeling by Bartha pseudorabies virus (PRV) following long survival periods after injections of the stomach, esophagus or cecum retains a high degree of viscerotopic labeling of primary motoneuronal pools. Secondary and/or tertiary labeling within the nucleus of the solitary tract (NTS) progressively increases with longer survival times with the stomach injection producing the most labeling. Differences in the number of neurons labeled and their topography are also retained over long survival periods. Parvocellular subnuclei of paraventricular n. of the hypothalamus are virally labeled following the above injections with only small differences in topography. Greater differences in the number of neurons labeled occurs in the tuberomammillary n., juxtapeduncular n., dorsal medial and lateral hypothalamus, central n. of the amygdala, substantia innominata, preoptic area, bed n. of the stria terminalis, and insular cortex. In all cases the labeling within any nucleus was greatest with the stomach injections and least with the cecum. Labeling progressed from normal morphological appearance to the gradual occurrence of cytopathology. In most cases cytopathology did not occur before upstream labeling of another order of neurons began to label indicating specific transsynaptic passage of PRV. Supported by GM 27739.

TRANSNEURONAL LABELING OF NEURONS IN THE BRAIN AFTER INJECTION OF PSEUDORABIES VIRUS (PRV) INTO THE RAT ESOPHAGUS. X. Bao, R. Barrett and S.M. Altschuler*, Children's Hospital of Phila., Univ. of Pa. Sch. of Med., Phila., PA 19104.

Premotor neurons (PMNs), through contact with both afferents and motoneurons, initiate and control swallowing. The location and connectivity of PMNs innervating the esophagus were determined using a Bartha strain of PRV. In 30 rats, PRV injections were made into the esophagus. Following a 48-120 h survival, brain sections were processed immunocytochemically for PRV. Neuronal labeling was limited to the compact formation (c) of the NA for survival times of 48-52 h. At 60-62 h survivals, PRV-labeled 2nd order neurons (PMNs) were localized to the central subnucleus (cen) of NTS. At longer survivals, labeling occurred in adjacent subnuclei of the NTS, PTI, dorsal and ventral medullary reticular formation, spinal trigeminal complex, raphe nucleus and forebrain. Esophageal PMNs are localized to the cenNTS, the site of termination of esophageal vagal afferents, and have direct synaptic contact with cNA motoneurons. The pattern of labeling at longer survivals suggests widespread CNS control over esophageal peristalsis. Supported by NIH grant DK-44487.

EVIDENCE FOR AN INDEPENDENT ACTION OF SEROTONIN AND SUBSTANCE P MICROINJECTED INTO THE NUCLEUS RAPHE OBSCURUS (NRO) ON INTRAGASTRIC PRESSURE IN THE RAT. P.J. Hornby* and Z.K. Krowicki, Dept. of Pharmacology, Louisiana State University Medical Center, New Orleans, LA 70112.

Serotonin (5-HT) microinjected into the NRO increases and substance P (SP) decreases intragastric pressure (IgP) in the rat (Krowicki and Hornby, J. Pharmacol. Exp. Ther., 265:468-476, 1993; Soc. Neurosci. Abstr., 1277, 1992). Since 5-HT is co-localized with SP we attempted to test whether rapid sequential administration of these transmitters into the NRO would alter their effect on IgP. Intragastric pressure was monitored in α -chloralose anesthetized rats before and after sequential (30 sec intervals) microinjections of vehicle, 5-HT (0.6 and 6.0 nmol) and SP (135 pmol) into the NRO in a volume of 60 nl. Changes in IgP were quantified as areas of the response below (-) or above (+) baseline levels. The results (cm²) are shown in two tables below as avg \pm SEM (n). The substances injected first are given in left column.

Treat.	5-HT 0.6	SP	Treat.	5-HT 6.0	SP
Veh.	0.4 \pm 0.1(5)	-1.7 \pm 0.5(9)*	Veh.	1.0 \pm 0.2(7)*	-1.7 \pm 0.5(9)*
5-HT0.6	0.3 \pm 0.1(3)	-1.6 \pm 0.4(4)*	5-HT6.0	0.7 \pm 0.3(2)	-1.6 \pm 0.4(6)*
SP	0.4 \pm 0.1(3)	-0.6 \pm 0.3(7)	SP	1.2 \pm 0.4(6)*	-0.6 \pm 0.3(7)

* Significantly different from control

Our results indicate that 5-HT and SP act independently in the NRO to affect IgP. Supported by PHS grant DK41714 and A.P. Sloan Foundation.

393.4

MIDBRAIN LABELING FOLLOWING BARTHA PSEUDORABIES VIRUS (PRV) INJECTIONS OF ALIMENTARY STRUCTURES.

R. R. Miselis*, X. Zhao and M. Yang, Dept. of Animal biology, School of Veterinary Medicine, University of Pennsylvania, Phila., PA 19104

Analysis of midbrain labeling by PRV following injections of the stomach, esophagus and cecum were focused on in this study. Rats were injected with PRV and sacrificed at 48, 60, 72, 84, 90, and 96 hours post injection. Initial labeling of the central gray occurs at 72 hrs p.i. following stomach or esophagus injections and at 84 hrs after cecal injections. Subsequently labeling increases throughout the rostro-caudal extent of central gray and occurs in the dorsal raphe and ventrolateral region of the mesencephalic reticular nucleus and lightly in the ventral tegmental area. Esophageal injections resulted in distinct pattern differences in labeling of the central gray and greater labeling of the caudal linear raphe nucleus, retrorubral field and ventral tegmental area. For all organs injected labeling continues into the lateral aspects of the pontine reticular formation. The earliest time of labeling of neurons of the midbrain suggest that they could be second to third order neurons from the dorsal or ventral vagal complex. These data indicate that midbrain neurocircuitry is more involved in esophageal control than either gastric or cecal control. Supported by GM 27739.

393.6

NITRIC OXIDE SYNTHASE INHIBITION REDUCES THE EFFECT OF SUBSTANCE P MICROINJECTED INTO THE NUCLEUS RAPHE OBSCURUS ON INTRAGASTRIC PRESSURE IN THE RAT. Z.K. Krowicki* and P.J. Hornby, Dept. of Pharmacology and Experimental Therapeutics, Louisiana State University Medical Center, New Orleans, LA 70112.

We have demonstrated that the inhibitory effect of substance P (SP) microinjected into the nucleus raphe obscurus (NRO) on intragastric pressure (IgP) can be completely abolished by bilateral vagotomy but only slightly reduced by atropine (Krowicki and Hornby, Soc. Neurosci. Abstr., 1277, 1992). Since nitric oxide (NO) may be an inhibitory vagal transmitter to the stomach (Allescher et al., Am. J. Physiol. 262:G695-G702, 1992) we tested the hypothesis that the gastric inhibitory effect of SP (135 pmol), microinjected into the NRO, could be abolished by N³-nitro-L-arginine (L-NAME; 10 mg/kg, i.v.) alone, or in combination with systemic cholinergic blockade by atropine (1 mg/kg i.v.). The IgP inhibition was quantified by measuring the area of the response (cm²) below the baseline using a computer-based imaging system. The decreases in IgP evoked by microinjection of SP into the NRO in two groups of animals were -1.43 \pm 0.24 (n=7) and -1.46 \pm 0.33 (n=8). The response to SP microinjected into the NRO 15 min after L-NAME or atropine was significantly reduced to -0.74 \pm 0.19 (n=7) and -0.61 \pm 0.18 (n=8), respectively. Microinjection of SP into the NRO 15 min after atropine with subsequent L-NAME or after L-NAME with subsequent atropine, did not evoke any changes in IgP when compared with vehicle. These findings indicate a role of NO in the decrease in IgP induced by microinjection of SP into the NRO. Supported by PHS grant DK42714.

393.8

MICROINJECTION OF L-ARGININE AND S-NITROSO-AMINOPENICILLAMINE (SNAP) INTO THE ROSTRAL DORSAL MOTOR NUCLEUS OF THE VAGUS (DMV) PRODUCES AN INCREASE IN GASTRIC MOTILITY. W.H. Panico, R.A. Travagli, A. Raines*, D.M. Armstrong, C. Nguyen, S.B. Benjamin, and R.A. Gillis, Georgetown Univ. Medical Center, Washington D.C. 20007

Electrophysiological studies performed in our laboratory with the use of the patch clamp technique on thin slices have shown an excitation of DMV neurones upon treatment with drugs that produce NO (L-Arginine and SNAP). The purpose of the present study was to confirm this finding in an *in vivo* cat preparation. For this purpose L-Arginine (40nl of a 2M solution) and SNAP (60nl of a 0.5M solution) were microinjected unilaterally into the DMV of chloralose-anesthetized cats while monitoring antral and pyloric motility using extraluminal force transducers. Microinjections of L-Arginine caused increases in motility of both the antrum and the pylorus. Minute motility index (MMI) of the antrum increased from 1.3 \pm 1.1 to 9.4 \pm 1.2 (p<0.05, N=8), while MMI of the pylorus increased from 3.0 \pm 1.6 to 9.7 \pm 2.7 (p<0.05, N=8). Similar increases were observed after microinjection of SNAP. Ipsilateral vagotomy was effective in abolishing the increases in MMI elicited by NO producing drugs. These results suggest that NO acting on DMV neurones can evoke vagally-mediated increases in gastric motility.

393.9

FUNCTIONAL HETEROGENEITY OF NEURONS OF THE DORSAL MOTOR NUCLEUS OF THE VAGUS (DMNV) R. Fogel*, W.E. Renchan and X. Zhang. GI Div., Henry Ford Hosp., Detroit MI 48202

Stimulation of gastric and duodenal mechanoreceptors initiates a number of vagally-mediated changes in gastrointestinal function including gastric and intestinal motility and gastric acid secretion. It is currently unknown 1) whether individual DMNV neurons are affected by distention of both the duodenum and stomach and 2) whether all DMNV neurons projecting to the abdomen respond to distention in the same manner. To enhance our understanding of the function of the DMNV, we investigated the response of DMNV neurons to gastric and duodenal distention. Glass micropipettes filled with 2% Neurobiotin (Vector Labs) were used to label individual physiologically-characterized DMNV neurons. Neurons were reconstructed using the Eutectics Neuron Tracing System. Fifty one DMNV neurons were studied: 3 cells were unaffected by distention; 8 neurons responded to only one stimulus; and 40 neurons responded to both stimuli. Twenty eight of the 40 neurons had an inhibition of firing rate, 2 increased firing rate and 10 neurons had a mixed response- excitation by one stimulus, inhibition by the other. Forty nine of 51 neurons sent axons out of the brainstem. The morphology of the neurons that were inhibited by both stimuli was compared to the group with a mixed response. No significant differences in soma-dendritic morphology were detected. These results support a functional heterogeneity of DMNV neurons. The nature of the response to duodenal and gastric distention is not associated with soma-dendritic morphology.

393.11

PANCREATIC POLYPEPTIDE IN THE DORSAL VAGAL COMPLEX STIMULATES GASTRIC ACID SECRETION AND MOTILITY. D.M. McTigue and R.C. Rogers* Dept. of Physiology College of Medicine, Ohio State University, Columbus OH 43210

Pancreatic polypeptide (PP), an endocrine hormone released from the pancreas during all phases of digestion, has specific receptors located within the dorsal vagal complex (DVC) in regions known to contain fenestrated capillaries. Since the DVC participates in vagal regulation of gastric activity, the present studies were designed to examine the effect of PP microinjected directly into this region on gastric function. Rats were equipped for recording of either gastric acid secretion or gastric antral motility. Following establishment of baseline values, 20 nl of 0.9% saline or PP [4.0 pmol, 0.04 pmol, or 0.004 fmol] was microinjected into the DVC and acid secretion or antral motility was monitored for 2 hours. Microinjection of PP into the DVC resulted in a dose-dependent increase in gastric acid secretion and gastric motility that was sensitive to atropine (0.2mg/kg) and vagotomy. Thus, PP placed into the DVC increases gastric acid secretion and motility by stimulating vagal cholinergic pathways. Preliminary data from our laboratory suggest that PP administered intravenously also enhances gastric acid secretion. These results provide an interesting model in which a hormone produced in the periphery interacts directly with brainstem autonomic nuclei leading to altered gastric functions. (NS 30803 to RCR)

393.13

PREPRO-TRH-(160-169) POTENTIATES TRH IN THE DMN-INDUCED STIMULATION OF GASTRIC ACID SECRETION. H. Yang* and Y. Taché. CURE/VA Wadsworth Medical Center, Dept. of Medicine and Brain Research Institute, UCLA, Los Angeles, CA 90073.

Prepro-TRH-(160-169) (Ps4) is distributed in similar area as TRH and is generated from the processing of TRH prohormone. Ps4 potentiates TRH-induced TSH release in quartered rat anterior pituitaries (Proc. Natl. Acad. Sci. USA, 87:4439, 1990). The possibility that Ps4 modulates TRH action in medullary nuclei was studied by co-injection of Ps4 with TRH into the dorsal motor nucleus of the vagus (DMN) or the nucleus ambiguus (Amb). In urethane anesthetized rats, gastric acid secretion (GAS) was determined by flushing the stomach every 10 min and heart rate (HR) was measured with a polygraph through a PE-90 cannula inserted into the cervical artery. Peptides were microinjected using a glass pipette. TRH (50 ng/50 nl) microinjected into the DMN induced an increase in GAS which was dose-dependently potentiated by co-injection of Ps4. The net GAS ($\mu\text{mol}/60$ min) were 13.5 ± 3.1 after TRH alone ($n=13$) and 15.4 ± 3.6 ($n=7$), 23.8 ± 1.2 ($n=8$) and 38.2 ± 8.7 ($n=8$) in groups in which Ps4 was co-injected with TRH at 100, 150 and 200 ng respectively. Microinjection of Ps4 alone (200 ng/167 pmol) did not influence basal GAS (net GAS was 2.0 ± 1.8 , $n=7$). By contrast, co-injection of TRH with prepro-TRH-(178-199) in the DMN (438 ng/167 pmol) did not modulate TRH induced GAS (15.4 ± 3.3 , $n=8$). When Ps4 (200 ng) was co-injected with TRH into the Amb, it did not modulate TRH (50 ng) induced GAS (net $\mu\text{mol}/60$ min: 19.9 ± 5.3 TRH alone, $n=9$, vs 18.5 ± 3.7 , TRH + Ps4, $n=10$). However, three min after microinjection of TRH alone, the HR (beat/min) was 234 ± 86 ($n=8$) whereas it was 326 ± 10 in TRH + Ps4 group ($n=9$). These results indicate that Ps4 potentiates the action of TRH in the DMN to stimulate GAS and its effect is site and peptide specific.

393.10

TUMOR NECROSIS FACTOR (TNF α) IN THE DORSAL VAGAL COMPLEX (DVC) SUPPRESSES GASTRIC MOTILITY G.E. Hermann* and R.C. Rogers, Dept. of Physiology, College of Medicine, Ohio State University, Columbus, OHIO 43210

TNF α is one of the proinflammatory cytokines released in response to antigenic challenge. TNF α has been demonstrated to increase plasma CORT levels, increase body temperature, suppress appetite and cause nausea and vomiting when injected systemically. Thus, it appears that TNF α may be responsible for provoking many of the autonomic signs associated with critical infectious illness. Receptors for TNF α have been localized within the brainstem. The DVC are brainstem nuclei which participate in vagal regulation of gastric function and have fenestrated capillaries which may allow entry of large "afferent" peptide signals from the bloodstream. Our present studies demonstrate that microinjection of TNF α (20 femtomoles) into the DVC significantly suppresses gastric motility for prolonged periods of time (in excess of 30 min) even in TRH-stimulated preparations.

Resolution of infectious challenges requires coordinated patterns of systemic responses by the host involving interactions of immune-neuro-endocrine systems. TNF α may be one of the cytokines that provide afferent information from the immune system to the CNS which can elicit appropriate physiologic or homeostatic responses. (Supported, in part, by NIH NS 30803 to RCR)

393.12

TUMOR NECROSIS FACTOR (TNF α) IN THE MEDIAL NUCLEUS TRACTUS SOLITARIUS (NTS) DECREASES ARTERIAL PRESSURE, HEART RATE, AND EFFERENT SYMPATHETIC NERVE ACTIVITY. C.M. Heesch*, G.E. Hermann and R.C. Rogers, Dept. of Physiology, College of Medicine, The Ohio State University, Columbus, OHIO 43210.

TNF α , a cytokine produced by macrophages during septic shock and following myocardial infarction, is a potential endogenous mediator of untoward cardiovascular effects. Intravenous administration of TNF α results in systemic hypotension in animals and humans and a peripheral vasodilatory action has been described. The current study was performed to determine if a central nervous system (CNS) effect of TNF α on cardiovascular pathways could contribute to the cardiovascular depressant actions. Unilateral microinjections of TNF α (20-30 femtomoles in 20-30 nl) into the medial NTS resulted in significant decreases in mean arterial pressure (-17 ± 5.5 mmHg) and heart rate (-48 ± 10.8 bpm) in 6 male Long-Evans rats. In four rats efferent renal sympathetic nerve activity was also recorded and decreased by 22 ± 5.0 % following microinjection of TNF α into the NTS. Thus, in addition to vasodilatory effects on vascular smooth muscle, circulating TNF α may also depress autonomic function through an action at central nervous system sites with an incomplete blood brain barrier. (Supported by NIH HL-36245 to CMH and NIH NS-30803 to RCR)

INTRACISTERNAL (IC) INJECTION OF PANCREATIC POLIPEPTIDE (PP) STIMULATES GASTRIC SECRETION THROUGH THE VAGUS NERVE IN RATS. T. Okumura, T.N. Pappas* and J.L. Taylor, Department of Surgery and Gastroenterology, Duke University Medical Center, Durham, NC 27710

It has been recently demonstrated that PP can bind to the dorsal vagal complex in the medulla oblongata. There is however little evidence whether PP has a central effect on gastrointestinal functions. The present study was carried out to examine the effect of IC administered PP on gastric secretion. Under isoflurane anesthesia, 24 hr -fasted male Sprague-Dawley rats, weighing 250-300 g, received IC (10 μl) or intraperitoneal (0.5 ml) injection of rat PP or BSA-Saline and the pylorus was ligated. Rats were sacrificed 2 h after pylorus ligation and gastric acid secretion was measured. IC injection of PP dose-dependently increased gastric acid output. In contrast, intraperitoneal injection of PP failed to change gastric acid output.

PP	Gastric acid output ($\mu\text{Eq}/2$ hr) (n)	
Dose (ng)	Intracisternal	Intraperitoneal
0 (BSA-Saline)	146 \pm 16 (6)	183 \pm 14 (6)
62.5	206 \pm 5 (4)*	
250	259 \pm 28 (4)*	186 \pm 12 (4)
1000	362 \pm 67 (4)*	184 \pm 17 (7)
2500		179 \pm 18 (4)

Mean \pm SEM, * p < 0.05 vs BSA-Saline

In acute bilateral gastric branch vagotomized rats, IC injection of PP (1000 ng) did not alter gastric acid output. These results suggest that central PP stimulates gastric acid secretion at a dose-dependent manner in conscious rats. It is also demonstrated that increase in gastric secretion by central PP was prevented by vagotomy. These results suggest that PP may have a physiological role in central regulation of vagal-mediated gastric secretion.

394.1

THE NEUROANATOMICAL BASIS FOR VAGAL CONTROL OF GASTRIC EMPTYING. M.C. Holst* and T.L. Powley, Purdue University, West Lafayette, IN 47907.

Physiological studies have highlighted the importance of the vagus in pyloric mechanisms of gastric emptying. In this study, vagal afferents and efferents of the rat's pyloric region were labeled by injections of DiI into the nodose ganglion (left, right or both) or dorsal motor nucleus of the vagus (DMNX; right, left or both) respectively. Other animals had injections of DiA in the DMNX and DiI in the nodose. The DMNX, nodose ganglia and enteric neurons were counterstained by an i.p. injection of Fluorogold. Transverse or longitudinal sections (140 µm) of the pylorus were examined with epifluorescence and confocal microscopy. Vagal preganglionic fibers and terminals are prominent in an extensive complex of ganglia which extends from the myenteric plexus into the enlarged circular muscle layer (the torus) of the pyloric region. Additional vagal efferents are in a second plexus specific to the inner part of the torus. Only the outer plexus is continuous with those in the antrum and duodenum. Vagal preganglionics also occur in ganglia of the sparse submucosal layer, including a plexus over the thickened muscularis mucosa at the base of the pyloric glands. Vagal afferent fibers and endings are found in ganglia of both parts of the torus and the submucosa. In cases with double label, some neurons, particularly in the inner plexus of the torus, are innervated by both vagal afferents and efferents. Vagal afferents are also abundant in the mucosa, especially in the duodenal villi and the distal torus. In the latter, they form a dense network of fibers and terminals intimately associated with the processes of interstitial cells of Cajal in a distribution resembling that of pyloric CCK binding sites. The unique pattern of vagal fibers in the torus provides the anatomical basis for physiologically defined pyloric mechanisms. NIH DK27627.

VAGAL AND ENTERIC INNERVATION OF THE RAT ESOPHAGUS. W.L. Neuhuber*¹, J. Wörli, B. Mayer² and H.R. Berthoud³, 1Dept. Anatomy, Univ. Erlangen-Nuremberg, D-8520 Erlangen, FRG, 2Dept. Pharmacol.&Toxicol., Univ. Graz, A-8010 Graz, Austria, and 3Pennington Biomed. Res. Ctr, Baton Rouge, LA 70808

The act of deglutition is thought to be controlled by a bulbar swallowing center in concert with vago-vagal reflexes (Cunningham et al., *Dysphagia* 5:35-51, 1990). However, the presence of a myenteric plexus also in striated portions of the esophagus is puzzling. Using anterograde DiI and DiA tracing, NADPH-diaphorase and AChE histochemistry, and immunocytochemistry for NO synthase and CGRP, we attempted to elucidate the distribution of efferent and afferent vagal fibers, as well as the intrinsic wiring of enteric neurons in the wall of the rat esophagus. DiA injections into the dorsal motor nucleus labeled the rare varicose fiber in no more than 16% of all myenteric ganglia, while DiI injections into nodose ganglia led to profuse labeling of afferent terminals in up to 100% of enteric ganglia. Afferent fibers were sparse in mucosa and virtually absent from outer and inner muscle layers proper. DiI injections into the nucleus ambiguus resulted in anterograde labeling of motor endplates. No convincing terminal labeling in myenteric ganglia was seen. Most of enteric neurons were NADPH-diaphorase/NO synthase positive. They represent the most likely source for nitric oxide fibers in about two thirds of motor endplates where they could be distinguished from CGRP immunoreactive motor terminals. In conclusion, there is extensive co-innervation of esophageal striated muscle fibers from nucleus ambiguus (cholinergic) and myenteric plexus (nitric oxide), while myenteric ganglia appear to be influenced mainly by vagal afferent rather than efferent terminals. If these afferent terminals are considered a mechanosensor-local effector device influencing enteric neurons as suggested previously (Neuhuber, *J Auton. Nerv. Syst.* 20:243-255, 1987), a local reflex arc involving nitric oxide co-innervation of motor endplates might be proposed for the fine-tuning of peristalsis in the striated esophagus.

PERIPHERAL CCK AND BOMBESIN INFLUENCES AFFERENT ACTIVITY OF GASTRIC VAGAL TERMINALS RESPONSIVE AND NOT RESPONSIVE TO GASTRIC DISTENSION: SINGLE UNIT ANALYSIS. T.J. O'Lee, E. Yoshida-Yoneda, Y. Taché* and J.Y. Wei, CURE/DDC VA Wadsworth Medical Center, Dept. of Medicine and Brain Research Institute, UCLA, Los Angeles, CA 90073.

We previously reported that different mechanisms are involved in gastric distension, bombesin (bom), and CCK induced stimulation of gastric vagal afferent discharge (*Gastroenterology* 102:A537, 1992). It is not clear, however, whether all responsive terminals have the same responsiveness to iv bom and CCK injection and gastric distension. **Purpose:** To assess, with single unit analysis, the sensitivity of gastric distension responsive vagal afferent terminals to iv bom and CCK injection. **Methods:** Male SD rats (280-320 g) were anesthetized with urethane (1.5 g/kg, im). Gastric afferent activity was recorded from a nerve filament dissected from distal cut end of ventral gastric branch of the vagus nerve. A single unit was isolated with a window discriminator and monitored on a digital oscilloscope. Consecutive responses to gastric distension, 100 ng or 1 µg of bom or CCK and saline (0.2 ml) were assessed. **Results:** 25 units were analyzed, 15 units were activated by gastric distension. 12 of these 15 units (80%) showed sensitivity to all doses of iv bom and CCK. 2 units were unaffected by small doses of bom, 1 of the 2 was also unaffected by small doses of CCK. 1 unit showed no response to large dose of bom. 10 of the 25 units analyzed were not sensitive to gastric distension. 7 of the 10 were sensitive to all doses of bom and CCK (70%). 3 were unaffected by low doses of bom, 2 of the 3 were also unaffected by low doses of CCK. **Conclusions:** 1. All gastric afferent units responding to CCK also responded to bom; 2. bom and CCK actions can be exerted on units responding and not responding to gastric distension (Supported by NIH grants NS28433 & DK 30110).

394.2

VAGAL EFFERENT PROJECTIONS TO THE ENTERIC NERVOUS SYSTEM: COMMAND NEURON HYPOTHESIS RECONSIDERED. D.B. Boyd, J.B. Kelly, D.L. Kim, M.C. Holst and T.L. Powley*. Purdue University, West Lafayette, IN 47907.

The proposal that a limited subset of enteric neurons with widespread integrative functions are targeted selectively by vagal preganglionics, i.e. the mother cell (Langley) or command neuron (Wood) hypothesis, is based largely on the relative numbers of preganglionic and enteric neurons. However, the number of postganglionics or ganglia in the gut contacted by vagal motor fibers has not been directly determined. To assess the extent of divergence in this parasympathetic outflow, male rats received injections of DiI or PHA-L in the dorsal motor nucleus of the vagus. Three weeks after tracer administration, animals were injected (ip) with 2mg of Fluorogold to counterstain the enteric nervous system. Five days later, animals were perfused. Sections of medullas (56µ) and whole mounts of stomachs, small intestines, and ceca were prepared and examined with conventional epifluorescence and confocal microscopy. Individual motor fibers were identified as they entered the target organs and then traced and digitized in their entirety (Eutectics Neuron Tracing System). In the viscera, vagal axons travel long distances, collateralize frequently, ramify extensively, and make putative contacts on large numbers of postganglionic neurons in numerous enteric ganglia. In the stomach, which receives the densest and most extensive vagal motor innervation, virtually all myenteric ganglia receive vagal projections, and most neurons within these ganglia are contacted by varicosities of vagal efferents. The finding that vagal preganglionics project so divergently within the enteric nervous system strongly suggests that the pre- to postganglionic interface might be better considered a station in an extensively interconnected neural network, rather than a relay in a command neuron circuit. NIH DK27627.

VAGALLY-MEDIATED SEROTONIN (5HT) RELEASE INHIBITS GASTRIC ACID SECRETION VIA RECEPTORS OF THE 5HT₂ FAMILY. K.J. LePard and R.L. Stephens Jr.*, Dept. of Physiology, Ohio State Univ., Columbus, Ohio 43210.

Vagal stimulation releases 5HT into the portal circulation. Exogenous 5HT inhibits gastric acid secretion, and it is proposed that endogenous 5HT in the gut exerts an inhibitory tone on acid secretion. Therefore, the physiologic effect of 5HT released from gut stores on acid secretion was determined. In urethane-anesthetized rats with acute portal vein cannula, 5HT in the portal circulation was elevated 90% by vagal stimulation with the TRH analogue RX77368 (100 ng, i.c.) [mean ± SEM, µg/30 min, (n=5): basal, 135 ± 19; stimulated, 256 ± 35]. To characterize possible sites of action, the effects of various 5HT antagonists on exogenous 5HT-induced inhibition of acid secretion were determined. Pretreatment with methysergide (5HT_{2/1}), methiothepin (5HT₁) or spiperone (5HT_{2/1A}) but not ritanserin (5HT_{2/1C}), renzapride (5HT_{1P/3}) or ICS 205-903 (5HT_{1A}) significantly reversed 5HT-induced inhibition of acid. Moreover, methysergide augmented RX77368 (30 ng, i.c.) stimulated acid secretion by 267%. Therefore, vagally-mediated release of 5HT from the gut appears to provide an inhibitory tone on acid secretion via activation of receptors of the 5HT₂ family. Supported by NIH DK 42880.

ORIGIN OF NITRIC OXIDE SYNTHASE-CONTAINING TERMINALS IN THE COELIAC GANGLION OF THE GUINEA PIG. C.R. Anderson*, J.B. Furness and S.L. Edwards, Department of Anatomy and Cell Biology, University of Melbourne, Parkville, Australia, 3052.

The distribution of nitric oxide synthase (NOS)-containing terminals in coeliac ganglia from guinea pigs of either sex was studied using the NADPH diaphorase procedure and NOS immunohistochemistry, both of which showed identical patterns of staining. Some groups of postganglionic nerve cell bodies were surrounded by dense pericellular baskets of NOS-containing terminals. The proportion of nerve cell bodies forming such groups was highest in the medial parts of the ganglion (> 50%) and lowest in the lateral parts (<10%). In addition, all groups of postganglionic neurons were surrounded by a relatively sparse plexus of weakly stained NOS-containing fibres. Injection of Fast Blue into the coeliac ganglia of guinea pigs anaesthetized with sodium pentobarbitone, fentanyl and droperidol resulted in labelling of preganglionic neurons in the thoracolumbar spinal cord. More than 40% of the Fast Blue-labelled preganglionic neurons were positive for both NOS-IR and NADPH diaphorase and were predominantly in the lateral parts of the intermediolateral column. Severing of the nerves connecting the coeliac ganglion with the gut resulted in degeneration of the dense pericellular baskets of NOS-containing terminals, which are hence of enteric origin, but spared the sparse plexus of less intensely stained NOS-containing terminals, which are hence likely of preganglionic origin. Studies using double-labelling histochemistry showed that the NOS-containing fibres of enteric origin terminated around somatostatin-containing postganglionic neurons, which have previously been identified as noradrenergic neurons that control intestinal fluid transport.

EXTRINSIC DENERVATION INCREASES NADPH DIAPHORASE STAINING BUT NOT CITRULLINE PRODUCTION BY NITRIC OXIDE SYNTHASE IN MYENTERIC PLEXUS OF GUINEA PIG ILEUM. A.M. Yunker*, J.B. Moldovan, M.L. Contreras, and J.J. Galligan, Dept. Pharmacol. and Toxicol. and Neuroscience Program, Michigan State University, E. Lansing, MI 48824.

The functions of the small intestine are controlled by the enteric nervous system and extrinsic nerves. At least one population of enteric neurons contains nitric oxide synthase (NOS) and NADPH diaphorase (NADPH d.), and has been reported to co-localize with vasoactive intestinal polypeptide immunoreactivity (VIP-ir). We tested the hypothesis that extrinsic denervation alters NADPH d. staining in enteric neurons. Seven weeks after extrinsic denervation, the number of vasoactive intestinal peptide immunoreactive (VIP-ir) (6 ± 1.2 cells/ganglia) and NADPH d. stained neurons (0 cells/ganglia) in the submucosal plexus was not significantly different from either normal or control preparations. In control myenteric plexus, 9 ± 1 cells/ganglia contained NADPH d. and 3 ± 0.03 cells/ganglia contained VIP-ir. However, 7 weeks after extrinsic denervation the number of NADPH d. stained neurons increased by 85%, whereas the number of VIP-ir neurons did not change. To determine if the increase in NADPH d. staining correlated with an increase in NOS activity, we examined the formation of L-[¹⁴C] citrulline from L-[¹⁴C] arginine in normal and denervated small intestine. Following denervation, citrulline production decreased by 47% (7.6 ± 0.67 pmole citrulline/100 µg protein) as compared to control preparations (13.3 ± 1.9 pmole citrulline/100 µg). The NOS antagonist N^G-nitro-L-arginine methyl ester (0.01 M) decreased citrulline production in both control (80%) and denervated (79%) tissues. Although EGTA (0.001 M) decreased citrulline production 96% in control tissues, 34% of citrulline production remained in denervated tissues, implying a denervation-induced Ca²⁺-independent form of NOS. These data suggest extrinsic denervation alters NOS found in enteric neurons. This alteration may be part of the adaptive process that allows normal digestive functions to continue in the absence of extrinsic nerves. (Supported by NIH DK 40210 and a grant-in-aid from the American Heart Association.)

NEUROTRANSMITTER CONTENT OF NEURONS IN GANGLIA OF THE GUINEA PIG SPHINCTER OF ODDI. D.G. Wells*, E.K. Talmage and G.M. Mawe, Dept. of Anatomy and Neurobiology, University of Vermont, Burlington, VT 05405.

The sphincter of Oddi (SO) is a smooth muscle sphincter that regulates the flow of bile into the duodenum. To identify potential chemical coding in SO neurons, immunohistochemistry and histochemistry were employed to assay for putative neurotransmitters and related synthetic enzymes in whole mount preparations, with and without colchicine treatment. Immunoreactivity (IR) for Leu-enkephalin (L-ENK), substance P (SP), vasoactive intestinal peptide (VIP), neuropeptide Y (NPY), calcitonin gene-related peptide (CGRP), and tyrosine hydroxylase (TH), was demonstrated within the SO ganglionated plexus. Most SO neurons expressed either SP- or VIP-IR, and most SP-IR neurons were also L-ENK-IR. The VIP-IR neurons also stained for NADPH-DA activity [a form of nitric oxide synthase], but neurons that contained L-ENK- or SP-IR did not stain for NADPH-DA. A small contingent of non-SP-IR SO neurons was immunoreactive for NPY. Although CGRP-IR neurons were not observed in SO ganglia, CGRP-IR fibers that were also SP-IR were observed. A vast network of TH-IR fibers was seen throughout the ganglionated plexus of the SO; however, no TH-IR cell bodies were seen in SO ganglia. These results indicate that most neurons in SO ganglia are either SP-IR or VIP-IR with NADPH-DA activity. We propose that these classes of neurons represent excitatory and inhibitory motor neurons, respectively. Neural and/or hormonal input to these sets of neurons may be an important means of regulating SO tone. Supported by DK-45410.

394.11

CAPSAICIN (C) INHIBITS RAT SMALL INTESTINAL ALANINE ABSORPTION. N.E. Saadé*, K. Barada, J. Atallah, S. Itani, L. Abdallah, S. Nayfeh and C.F. Nassar, Departments of Physiology and Internal Medicine, American University of Beirut, Beirut, Lebanon.

Capsaicin sensitive primary afferents (CSPA) are involved in gastric mucosal defense mechanisms and gastrointestinal-motility through the release of peptides and neurotransmitters. The effects of capsaicin on L-alanine absorption across the rat small intestine were investigated using the single pass perfusion technique and the two compartment incubation system.

Intraluminal perfusion of 160 and 800 µM C produced a sustained and significant decrease in alanine jejunal absorption. Acute block of vagal CSPA increased basal alanine absorption and reduced the C inhibitory effect, while neonatal treatment produced a decrease of both basal alanine absorption and the C inhibitory effect. Incubation of intestinal strips with different concentrations of capsaicin (100-2400 µM) produced a dose dependent inhibitory pattern of intracellular alanine accumulation, which was maximal at 1600 µM. Mucosal scrapings incubated with 1600 µM capsaicin did not show a similar effect. We conclude that capsaicin exerts a CSPA mediated decrease in rat small intestinal alanine absorption. (Supported by the Lebanese National Research Council and the D.T. Sabbagh Fund).

394.8

EXPRESSION OF FOS RELATED ANTIGENS BY ENTERIC NEURONS: EFFECTS OF INTESTINAL TRANSECTION. T. Karaosmanoglu, E. Blaugrund, P. R. Wade, V.M. Tennyson*, M.D. Gershon Dept. of Anatomy and Cell Biology, College of P & S, Columbia University, New York, NY 10032 USA.

The enteric nervous system (ENS) is capable of mediating intestinal reflexes in the absence of connections to the CNS. The activity of enteric neurons is thought to mediate the inhibition of myogenic muscle contraction and patterned activity (e.g. migrating myoelectric complexes and the peristaltic reflex). Nuclear immunoreactivity for Fos, a 62 kDa protein encoded by the *c-fos* proto-oncogene, has previously been used to visualize activated enteric neurons. We have attempted to use a commercial antibody to Fos (Oncogene Sciences Ab2) to investigate the effects of sectioning the intestine on the activity of neurons in the ENS. Fos immunoreactivity (F-IR) was found in virtually all neuronal nuclei in ganglia of both submucosal and myenteric plexuses in preparations fixed immediately after removal from guinea pigs and rats. Demonstration of all myenteric neurons by staining with quinolinic phthalocyanine (cuprolinic blue) revealed that neurons with F-IR comprised a subset (50-70%) of all neurons. Following transection and reanastomosis of the rat ileum, no nuclear F-IR was observed for up to 2 wks post-surgery in a zone 5 cm above and below the anastomotic site. In order to determine if the antibodies were detecting Fos, immunoblots were prepared and segments of guinea pig ileum small and large intestine were subjected to treatments known to affect expression of *c-fos*. These preparations were exposed either to cold or to tetrodotoxin (TTX) in order to decrease expression of Fos, or they were incubated with veratridine to increase it. None of the treatments altered the pattern of F-IR seen in the tissue. No 62 kDa immunoreactivity was detected in immunoblots, which revealed instead immunoreactive material of lower molecular weight, the amount of which could not be altered by exposure of tissue to TTX or veratridine. We conclude that this antibody does not react with Fos in the ENS, but probably with one or more Fos related antigens (FRA). FRA expression thus characterizes a subset of enteric neurons and is abolished by transecting the bowel. Supported by NIH grant NS12969.

INTRACELLULAR CALCIUM-LOWERING EFFECT OF CGRP ON INTESTINAL MUSCLE. Y.D. Sun and C.G. Benishin* Dept. of Physiol., Univ. of Alberta, Edmonton, Canada T6G 2H7.

Calcitonin gene-related peptide (CGRP) is a neuropeptide which shares the same gene with the calcium-regulating hormone, calcitonin. CGRP relaxed the tension induced by different stimulants of longitudinal muscle of guinea pig ileum. In the present study, we investigated the effect of CGRP on intracellular calcium concentration ([Ca²⁺]_i) of the muscle by using the tension-[Ca²⁺]_i simultaneous recording technique. Histamine (0.5 µM) and KCl (30 mM) increased both tension and [Ca²⁺]_i. CGRP decreased the tension (by 78% and 85% respectively) while it showed minimal reduction of [Ca²⁺]_i (by 25% and 0% respectively). In histamine pre-contracted tissue, forskolin (0.5 µM), an activator of adenylate cyclase, decreased the tension (by 93%) to a larger extent than [Ca²⁺]_i (by 58%) while nifedipine (10 nM), a calcium antagonist, lowered both tension and [Ca²⁺]_i to similar extent (by 100% and 97%). CGRP and forskolin, unlike nifedipine, caused a dissociation between force and [Ca²⁺]_i, indicating that they may interfere with other process(es) involved in the muscle contraction in addition to the [Ca²⁺]_i-lowering effect. CGRP, similar to forskolin, was found to increase cAMP level. These results suggest that CGRP may affect the muscle tension by a mechanism similar to forskolin.

394.12

SUBSTANCE P DEPOLARIZES GALLBLADDER NEURONS BY OPENING CATION CHANNELS. G.M. MAWE* Dept. of Anatomy and Neurobiology, The Univ. of Vermont, Burlington, VT, USA 05405

In the guinea pig gallbladder, substance P (SP) is coexpressed with CGRP in sensory nerves and it is synthesized by most neurons. SP-immunoreactive nerve fibers are abundant in gallbladder ganglia, where they appear to surround the neurons. Since SP is thought to be a major mediator of slow excitatory postsynaptic potentials (EPSPs) in the gut, and since slow EPSPs occur in gallbladder, experiments were done to determine whether SP could mediate these synaptic events in the extrahepatic biliary system. Intracellular voltage and current recordings were made from neurons in ganglia of the guinea pig gallbladder, and SP was applied by pressure microinjection (0.1 mM; 15 PSI, 100-1000 msec) or superfusion (0.1 - 100 nM). SP caused a prolonged depolarization that was accompanied with a decrease in input resistance and an increase in excitability. The magnitude of the SP response increased as the duration of pressure microinjection was increased. When applied to gallbladder neurons in the single electrode voltage-clamp recording mode, SP caused an inward current. Using both current- and voltage clamp recordings the responses to SP had a reversal potential between 0 and 10 mV. Also, the inward current elicited by SP was diminished in a low Na⁺ solution. The NK1 antagonist CP96345 (Pfizer; 1.0 µM) decreased the responsiveness of cells to SP and decreased the amplitude of slow EPSPs. These results indicate that SP may be a mediator of slow EPSPs in ganglia of the gallbladder. Since CP96345 decreased the responsiveness of SP and the amplitudes of slow EPSPs, it is likely that SP mediates its effect by acting at NK1 receptors. Supported by NS26995 and NS45410.

CONTRASTING EFFECTS OF INTRACEREBROVENTRICULAR (ICV) AND INTRATHECAL (IT) ADMINISTRATION OF YOHIMBINE ON NALOXONE POTENTIATION OF NOVELTY-INDUCED HYPOALGESIA. J. Rochford, Dept. Psychiatry, McGill University, Montreal, Quebec.

Exposure to novel stimuli, such as a hot plate apparatus, has been shown to induce hypoalgesia. With repeated exposure, novelty-induced hypoalgesia (NIH) habituates. Naloxone administration has been found to attenuate the rate at which NIH habituates. Thus, by the fourth or fifth exposure to the hot plate, naloxone-treated animals appear hypoalgesic relative to saline-treated controls. Moreover, it has been found that the hypoalgesia observed in naloxone-treated animals is mediated, at least in part, by noradrenergic substrates. The present series of experiments were conducted to determine the relative contribution of supraspinal and spinal noradrenergic substrates in the mediation of this effect.

Male, Wistar rats (275-300g) were implanted either with a ventricular canula (right lateral ventricle) or an IT catheter. Following recovery, animals were administered (s.c.) either saline or 10 mg/kg naloxone, 30 min prior to placement on a 48.5°C hot plate once a day for 8 days. The paw lick latencies for saline-treated animals declined over tests, whereas the latencies in naloxone-treated animals did not. These results confirm previous findings demonstrating that naloxone attenuates the habituation of NIH. On days 9-10, animals were administered, in counterbalanced order, either vehicle, or the alpha-2 noradrenergic antagonist yohimbine (7.5-30.0 µg) IT or ICV 15 min prior to their allotted s.c. injection. ICV yohimbine administration enhanced the paw lick latencies in naloxone-treated animals, whereas IT administration inhibited them. Yohimbine was without effect in saline-treated animals. These results suggest that the contributions of spinal and supraspinal noradrenergic pathways to naloxone's effect on NIH are qualitatively different (Funded by NSERC).

395.3

THE EFFECT OF LATERAL HYPOTHALAMIC STIMULATION ON TAIL-FLICK AND BOTH PHASES OF THE FORMALIN PAIN RESPONSE. P.N. Fuchs* and V.C. Cox. Dept. of Psychology, Univ. of Texas, Arlington, TX 76019-0528.

The purpose of the study was to employ a between and within-subjects design to investigate the effect of lateral hypothalamic (LH) stimulation on pain responding during the tail-flick test and during both phases of formalin induced pain responding. Experiment 1 examined the effects of LH stimulation on both phases of formalin induced pain responding. LH stimulation which produced analgesia during the second phase of the formalin pain response did not produce analgesia during the first phase of the formalin pain response. Experiment 2 examined the effects of LH stimulation on tail-immersion thermal pain and the second phase of the formalin pain response. Only posterior LH stimulation sites were effective in both increasing tail-flick withdrawal latencies and attenuating the second phase of the formalin pain response. The results indicate that the first and second phase of pain responding during the formalin test are mediated by functionally distinct neural substrates that are differentially responsive to LH stimulation. In addition, electrode sites that were effective in attenuating spinally mediated phasic pain responses, in the same subject, also attenuated tonic pain response.

395.5

SELECTIVE ANTINOCICEPTIVE EFFECTS OF THE SUBSTANCE P ANTAGONIST CP96,345 ON RESPONSES TO LOW SKIN HEATING RATES. D. C. Yeomans* and H. K. Proudfit. Dept. of Pharmacology, U. Illinois at Chicago. Chicago, IL 60612.

We have previously provided evidence that foot withdrawal responses to low rates of radiant skin heating are mediated by the activation of C-fiber mechanoheat nociceptors. In contrast, high rates of skin heating evoke foot withdrawal responses that are mediated by myelinated A-fiber nociceptor activation. This hypothesis is supported by the following evidence: 1) Topical capsaicin, which selectively sensitizes C-fiber nociceptors, selectively decreased foot withdrawal latencies (FWL) for low skin heating rates. 2) Topical DMSO, which selectively sensitizes A-fiber nociceptors, selectively decreased FWL for high skin heating rates. 3) Low doses of systemic morphine (0.01 to 1.0 mg/kg), which selectively attenuate nociception produced by C-fiber activation, increased FWL only for low heating rates.

Substance P is a putative neurotransmitter released from the central terminals of C-fiber nociceptors by noxious stimulation. CP96,345 (Pfizer), a highly selective substance P antagonist with subnanomolar affinity for NK1 receptors, would reduce nociceptive responses mediated by the activation of C-fiber nociceptors. To provide additional evidence that responses to low heating rates are mediated by activation of C-fiber nociceptors, we determined whether intrathecal administration of CP96,345 would selectively increase FWL evoked by high or low skin heating rates. CP96,345 (0.2 to 200 µg) produced dose-dependent FWL increases for low skin heating rates, but did not effect responses evoked by high skin heating rates. These results are consistent with our hypothesis that low skin heating rates evoke responses that are mediated by C-fiber nociceptors, and that responses to high heating rates are mediated by the activation of A-fiber nociceptors.

INJECTION OF APV INTO RAT HIPPOCAMPAL DENTATE GYRUS PRODUCES ANALGESIA IN THE FORMALIN TEST. J.E. McKenna* and R. Melzack. Department of Psychology, McGill University, 1205 Dr. Penfield Ave., Montreal, Que. Canada, H3A 1B1

Previous research indicates that prolonged noxious stimulation causes NMDA-mediated changes in the CNS; glutamate and aspartate are released in the dorsal horns of the spinal cord after peripheral formalin injection, and the competitive NMDA antagonist dl-2-amino-5-phosphonovaleric acid (APV) produces analgesia when applied intrathecally to rats or mice in the formalin test. Recent studies in our laboratory have indicated that lidocaine block of the dentate gyrus significantly decreases formalin pain scores. In the present experiment Long-Evans rats received 0.75 µl intracranial injections of APV (5.0 µg/µl) or saline via infusion pump, either before or after an injection of 2.5% formalin acetate into one hindpaw. Intratentate injection of APV caused a significant reduction in pain scores for 20-40 min. These results indicate that the NMDA receptor ion complex may be implicated in supraspinal pain mechanisms. Effect of Midbrain Stimulation on the Magnitude of a Rat Operant Response to Noxious Thermal Stimuli. D.K. Douglass* & E. Carstens. Section of Neurobiology, Physiology & Behavior, Univ. of California, Davis, CA 95616.

We have used our previous method, measuring the magnitude of an operant response elicited by a range of noxious thermal stimulus intensities, to investigate effects of stimulation in midbrain analgesia areas.

Under barbiturate anesthesia, male Sprague-Dawley rats were implanted with bipolar stimulation electrodes in midbrain periaqueductal gray (PAG) and lateral reticular formation (LRF). After recovery, rats were trained to push up on a lever with the nose in response to a brief (5 s) 55°C heat pulse on the tail. The external end of the lever was connected to a force transducer interfaced with a computer to measure push magnitude (peak; area under force trace).

Responses to 55°C stimuli were recorded at 2 min intervals without and during PAG or LRF stimulation (3 100 Hz trains/s, 0-300 µA). Response magnitude tended to increase with stimulus temperature from 51-59°C. PAG and LRF stimulation significantly suppressed response magnitudes at all temperatures. Response magnitude was often "quantally" suppressed with a 50 µA increase in PAG (8/10 rats) or LRF (5/7 rats) stimulation intensity.

The results show that the operant response can be suppressed by midbrain stimulation. However, previously reported parametric differences in PAG and LRF-evoked suppression of nociceptive responses and dorsal horn neurons were not seen with our present model, possibly because of the apparent quantal suppression of the operant response.

We are grateful for Dr. L. R. Watkins' help in developing this model.

DELTA AND KAPPA OPIATE RECEPTORS MEDIATE ANTINOCICEPTION IN THE RAT TAIL FLICK TEST PRODUCED BY NOXIOUS THERMAL STIMULATION OF THE HIND PAW. G.M. Pitcher, K. Yashpal* and J.L. Henry, Departments of Physiology & Psychiatry, McGill Univ., Montreal, Quebec H3G 1Y6

Noxious thermal stimulation of one hind paw in the lightly anaesthetized rat produces a transient (< 6 min), naloxone-reversible antinociception in the tail flick test. The present study was done to determine the specific type of opiate receptor involved in mediating this antinociceptive response. Sprague-Dawley rats (250-300g) were lightly anaesthetized with Na-pentobarbital (20mg/kg) and chloral hydrate (120 mg/kg) i.p. After recording baseline readings at 3 min intervals in the tail flick test, the animals were administered 10 µl of one of the following intrathecally to the lumbar spinal cord: artificial CSF (n = 7); the kappa opiate receptor antagonist, nor-binaltorphiminedihydrochloride (nor-BNI; 6.5 nmol in CSF; n = 11); the highly specific delta opiate receptor antagonist, H-Tyr-Tic-Phe-Phe-OH (TIPP; 6.5 nmol in CSF; n = 6; generously supplied by Dr. P. Schiller, IRCM, Montreal; PNAS 89:11871, 1992). Three min later one more reading was taken and then one hind paw was immersed in water at 55°C for 1.5 min; subsequent readings of tail flick latency were taken at 3 min intervals, beginning 30 s after the immersion. In the group of rats given CSF, the full antinociceptive response was observed. However, in the two groups pretreated with the opiate antagonists, readings after immersion did not differ from the baseline readings. The data indicate that at least two types of opiate receptor, delta and kappa receptors, are involved in eliciting the antinociceptive response to extrasegmental aversive sensory inputs to the spinal cord. ANTINOCICEPTION EVOKED BY HIGH INTENSITY, LOW FREQUENCY PERIPHERAL STIMULATION IN INTACT AND SPINAL RATS: MEDIATION BY NK-1 AND OPIATE RECEPTORS Y.V. Romita* and J.L. Henry, Departments of Physiology & Psychiatry, McGill Univ., Montreal, Quebec H3G 1Y6

In on-going experiments on an animal model of electroacupuncture, in intact rats lightly anesthetized with Na-pentobarbital (20mg/kg) and chloral hydrate (120 mg/kg) i.p., high intensity, low frequency electrical stimulation was applied for 20 min at 20 X threshold to evoke muscle contraction. Stimulation of hind limb meridian points *femur-fuu* (ST-32) and *fengshi* (GB-31), but not of non-meridian points, increased tail flick latency during stimulation and produced a long lasting antinociceptive effect which lasted greater than one hour. In unanesthetized, chronic spinal transected rats, this stimulation evoked a similar though smaller effect. Both the substance P (NK-1) receptor antagonist, CP-96,345 (5 mg/kg, s.c., n=6), and the opiate antagonist, naloxone (25 mg/kg, i.p., n=8), attenuated the antinociception during the stimulation and blocked the post-stimulation antinociception in intact rats. In addition, CP-96,345 applied intrathecally (65 nmoles, n=5) at the lower lumbar level also attenuated the evoked antinociception, implicating the action of the antagonist at the spinal level. In chronic spinal rats, CP-96,345 (5 mg/kg, s.c., n=17) attenuated and naloxone (25 mg/kg, i.p., n=11) blocked the evoked antinociceptive response. These results suggest that the antinociception evoked by electroacupuncture-like stimulation is mediated via activation of NK-1 and opiate receptors in the spinal cord, and that the spinal cord is capable of independently maintaining mechanisms of antinociception. "SECONDARY" HYPERALGESIA (CAPSAICIN) MEDIATED BY C-NOCIPTORS. J. Serra, M. Campero, J. Ochoa*, Depts. of Neurology and Neurosurgery, Good Samaritan Hospital, Oregon Health Sciences University, Portland, OR 97210.

The "secondary" hyperalgesia (2y-H) that develops surrounding an area of skin injury is generally described to be selective to mechanical stimuli and to disappear with A-fiber block; it is attributed to activation of pain-evoking CNS cells by innocuous input from A- β afferents.

Methods: We gave intradermal capsaicin to 15 healthy volunteers and made the following rigorous measurements 15-70° mm beyond the injection site: mechanical (von Frey's hairs) and heat (1 cm² Peltier thermode) pain detection thresholds; mechanical and heat suprathreshold pain magnitudes; "touch" (von Frey's hairs) detection threshold; and maximal area of the flare (thermography and naked eye).

Results: In the area of 2y-H: 1) The subjective detection thresholds did not change significantly for touch, mechanical pain nor heat pain. 2) Stimuli above threshold for touch perception, but below the threshold for pain found prior to capsaicin, evoked touch but not pain. 3) The magnitude of suprathreshold pain evoked by quantified punctate mechanical or heat stimuli was exaggerated in the same area. 4) The volatile maximal area of flare matched the areas of mechanical hyperalgesia (MH) and heat hyperalgesia (HH).

Conclusions: 1) The tight spatial match of MH, HH and flare suggest C nociceptor mediation for all three phenomena. This is in keeping with our selective nerve fiber blocks and intraneural microstimulation studies (unpublished). 2) The unchanged threshold for pain in the area of "secondary" MH and HH indicates that C nociceptors in that area do not have sensitized receptors. 3) The increased mechanical and heat suprathreshold pain magnitudes in the area of "secondary" hyperalgesias suggests amplification of afferent responses at a site (proximal to receptors) theoretically inclusive of CNS and not exclusive of the nociceptor axon. 4) Capsaicin-induced "secondary" MH in response to punctate mechanical stimuli is probably not mediated by low threshold mechanoreceptors. 5) Several alternatives may explain disappearance of C-mediated hyperalgesia during apparently "selective" A-fiber block.

DO THE EFFECTS OF REPETITIVE TRANSCUTANEOUS ELECTRICAL NERVE STIMULATION (TENS) ON EXPERIMENTAL PAIN CUMULATE OVER TIME? L. Liu and C.W.Y. Hui-Chan*, School of physical and Occupational Therapy, McGill University, Montreal, Quebec, Canada H3G 1Y5.

The objective of this study was to determine whether the effects of repeated TENS applications on the human flexion reflex (FR) and subjective pain sensation would cumulate over time.

Ten young healthy subjects were randomly assigned to either a TENS or a placebo group. Ten daily 60 min TENS or placebo stimulation was applied to the lumbro-sacral region over a two week period. The FR was elicited by electrically stimulating the sole of subject's right foot and recorded electromyographically from the biceps femoris (BF) and tibialis anterior (TA). Subjective pain sensation was measured using the visual analogue scale (VAS). ANOVA and Tukey tests were used to analyze the data obtained prior to, during, and up to 60 min after TENS or placebo stimulation, and to compare the data obtained on day₁, day₅ and day₁₀ of the treatment period between the two groups.

For the BF FR area on day₁, a significant inhibition of the group mean value ($p < 0.01$) was found after TENS in the treatment group (to 71.8% of control value), but not in the placebo group (to 86.1%). Of interest is that the pre-TENS control value itself was decreased significantly from a mean of 100% on day₁ to 52.4% on day₁₀ ($p < 0.01$) in the TENS group. This reduction was significantly greater ($p < 0.01$) than that found in the placebo group, who showed a mean of 82.7% on day₁₀. Similar results were obtained for the TA FR area and VAS scores.

The above results indicated that repeated daily TENS applications produced cumulative inhibitory influence on both FR responses and subjective pain sensation over a two week period. Such a gradual development probably implicates plastic changes in the neural pathway.

This study was financed by the Fonds de la Recherche en Sante du Quebec.

EXPOSURE TO WHITE NOISE RESULTS IN DECREASED SENSITIVITY TO THERMAL STIMULI IN HUMANS.

N.A. Johnson* and F.J. Helmstetter Dept. of Psychology, University of Wisconsin Milwaukee, Milwaukee, WI 53201

Previous research has demonstrated a decreased sensitivity to nociceptive stimuli in humans following exposure to a noxious environmental stimulus (e.g., shock). The present study was designed to determine whether similar changes could be produced in response to the presentation of a non-noxious stressor. Withdrawal and detection latency were measured to a radiant heat source focused on the index finger of the subject's right hand. Independent groups of subjects were exposed to either a 0dB, 70dB, or 90dB white noise for 20 seconds. Exposure to high intensity noise resulted in a significant increase in withdrawal latency relative to baseline. This increase in latency correlated with stress related galvanic skin response, which was recorded simultaneously. These results are consistent with previous studies from our laboratory on anxiety and thermal pain responsivity in humans, which demonstrated an increase in withdrawal latency in subjects reporting high state anxiety, as well as with recent animal data which indicates that white noise hypoalgesia depends on brain mechanisms critical for fear and anxiety.

395.10

THERMAL SECONDARY HYPERALGESIA IS INDUCED BY APPLICATION OF MUSTARD OIL TO THE TAIL OF THE SPINALIZED RAT. C.L. Cleland* and G.F. Gebhart, Dept. of Pharmacology, Univ. of Iowa, Iowa City, IA 52242

Noxious stimuli, such as mustard oil (MO), can induce long-lasting hyperalgesia to distant cutaneous stimuli. Alterations in central processing are likely to underlie such secondary hyperalgesia. The aim of these studies is to develop a spatio-temporal description of the hyperalgesia evoked by the application of MO to the tail of the spinalized rat in order to provide insight into the underlying central mechanisms.

Male Sprague-Dawley rats were anesthetized with pentobarbital and spinalized at T8-T10. Following recovery (24-48 hrs), MO (25-100 μ l, 50-100%) or vehicle (mineral oil) was applied to the tail. Thermal sensitivity was tested every 6 min by immersing the lower part of the tail (40-80 mm below MO) into warm water (47-51°C) and measuring the latency to withdrawal.

MO produced a long-lasting decrease in the latency to withdrawal from warm water, while vehicle had no effect. Typically, thermal hyperalgesia exhibited distinct early and late components. The early component (0-18 min, 80% baseline) coincided with the expected duration of C-fiber activity evoked by MO, suggesting that a portion of the hyperalgesia was due to peripheral activity. The late component (45-60 min, 85% baseline) was most likely due to central changes because: 1) hyperalgesia persisted after MO evoked activity should have ended, and 2) the long separation of MO application warm water (80 mm) argues against peripheral sensitization.

In contrast to other studies that have shown mechanical but not thermal secondary hyperalgesia in response to chemical C-fiber activation, our results show that centrally-mediated thermal secondary hyperalgesia can be evoked by MO. Further studies will investigate the spatio-temporal features of warm, cold and mechanical hyperalgesia evoked by MO.

EVIDENCE THAT THE TAIL-FLICK RESPONSE IS SPINALLY MEDIATED IN RATS IRRESPECTIVE OF TEST TEMPERATURE. T.E. KING*, M. PAYNE, & J.W. GRAU, Department of Psychology, Texas A&M University, College Station, TX 77843.

Researchers frequently test pain reactivity in rodents by measuring the latency at which subjects withdraw their tail from a radiant heat source (the "tail-flick test"). It is commonly held that this response is spinally mediated when the heat source is intense, but depends on supraspinal mechanisms when intensity is decreased (Jensen & Yaksh, 1986). Contrary to this claim, we report that the tail-flick response is spinally mediated over a wide range of test conditions.

Rats (N=16) were tested a day after they experienced either a spinal transection (at T2) or a sham operation. Testing was conducted with a radiant heat tail-flick device while subjects were loosely restrained in tubes. Each subject was tested at 4 different intensities, the order of which was counter-balanced using a latin square design. At each intensity, the subjects received 3 tail-flick tests at 2 m intervals. The mean tail-flick latencies (\pm SE) observed in sham operated rats were: 3.50 (\pm .35), 4.47 (\pm .48), 5.71 (\pm .43), and 9.92 (\pm .74) (from hottest to coolest). Similar values were obtained from spinalized subjects: 3.77 (\pm .52), 5.32 (\pm .87), 6.91 (\pm .56), and 11.07 (\pm .98). An ANOVA confirmed that changing the heat intensity had a significant impact ($p < .0001$). Neither the main effect of operation ($p > .20$), nor its interaction with heat intensity ($p > .76$), approached statistical significance. Supported by MH48994 to J.W.G.

A SUPRA-THRESHOLD TAIL-FLICK TRIAL INDUCES HYPERALGESIA IN PENTOBARBITAL ANESTHETIZED RATS BUT NOT IN AWAKE RATS. C.F. Kallina*, T.E. King, & J.W. Grau, Department of Psychology, Texas A&M University, College Station, TX 77843.

The tail-flick test is frequently employed to test pain reactivity in rats. To reduce variability, and to monitor the time course of effects, researchers often repeatedly test the same subjects. This methodology poses no problem unless the test itself affects pain reactivity.

Interestingly, Baldwin et al. (*Neurosci. Abstracts*, 18, 292) recently showed that a single supra-threshold exposure to radiant heat induces hyperalgesia on subsequent tests in pentobarbital anesthetized rats.

Experiment 1 was designed to replicate this effect and evaluate whether a change in tail temperature was responsible for the hyperalgesia. We placed pentobarbital-anesthetized (40 mg/kg) rats in restraining tubes and administered 5 tail-flick tests at 1 m intervals (mean=4.7). Half of the subjects (n=10) then received a supra-threshold exposure to heat. This manipulation was achieved by manually preventing the rat from flicking prior to 6 s. Ten more tail-flick tests were given at 1 m intervals. Tail temperature was also monitored. We found a supra-threshold exposure induced hyperalgesia and that this effect could not be accounted for by a change in tail temperature.

Experiment 2 assessed whether a similar effect could be observed in spinally transected (T2) rats. No change in tail-flick latencies were observed suggesting the hyperalgesic effect is supraspinally mediated.

Experiment 3 tested whether a supra-threshold exposure to radiant heat affects pain reactivity in intact/awake rats. We found it had no effect on pain reactivity in awake subjects.

FORMALIN INDUCED NOCIFENSIVE BEHAVIOR IS INCREASED DURING FEVER IN RATS. N.E. Ferguson* and P. Mason. Dept. of Pharmacological & Physiological Sciences and Committee on Neurobiology, University of Chicago, Chicago, IL 60637.

Although febrile humans report somatic aches and pains, nociceptive responsiveness has not been well studied during experimental fever. To determine whether exogenous pyrogen administration increases nociceptive responsiveness in rats, nocifensive behavior evoked by the formalin test was compared in rats that received pretreatments of yeast, lipopolysaccharide (LPS) or vehicle.

Male Sprague-Dawley rats (240-360g) were handled and exposed to the formalin testing chamber for 2 days prior to testing. To induce fever, rats received either an i.p. injection of LPS or a s.c. injection of yeast. When a fever was established, 19-20 hrs after the yeast injection or 2 hrs post-LPS, rats were briefly anesthetized with halothane in order to inject formalin or saline, s.c., into the ventrum of the left hind paw. Upon recovery from the anesthetic, animals were placed into the testing chamber and behavioral scoring, on a 4 point scale, commenced. Core body temperature, measured using either a thermistor probe in the colon or a telemetric transmitter implanted in the peritoneal cavity, was recorded at 5 min intervals. All testing was done between 0900-1630 h at ambient temperatures of 22-23 °C.

Core temperature in yeast-injected rats was significantly higher than in control rats. Pain scores for rats receiving formalin in the hind paw were higher in those pretreated with yeast or LPS than in rats pretreated with vehicle. Rats injected with saline in the hindpaw did not exhibit significant nocifensive behavior in any group studied (yeast, vehicle). These results are evidence that nociceptive responsiveness increases during fever in the rat.

Kainate and AMPA Enhance Capsaicin-Evoked Release of iCGRP from Rat Dorsal Horn. J. Durnett Richardson, M.G. Garry, K.M. Hargreaves,* Univ. of MN, Depts. of Restorative Sciences and Pharmacology, Minneapolis, MN.

A number of studies suggest a role for glutamate receptors in nociception. Most studies have focused on the role of the NMDA receptor subtype in mediating spinal mechanisms of hyperalgesia. In contrast, little is known about the roles of the kainate and AMPA receptor subtypes in nociception. In the present study, we evaluated the effect of kainate and AMPA on evoking release of immunoreactive calcitonin gene-related peptide (iCGRP), a marker for activation of certain primary afferent neurons. Briefly, rat spinal cords were removed using hydraulic extrusion. The dorsal horn of the lumbar region was dissected, chopped into 200µm cubes and placed in chambers for *in vitro* superfusion. Tissue was superfused with oxygenated Krebs buffer (pH 7.4, 37°C). After allowing for baseline recovery, tissue was superfused with 100µM kainate or 10µM AMPA for 6 minutes. Twenty-one minutes later, the tissue received 10µM capsaicin (CAP), a neurotoxin which selectively stimulates certain nociceptive fibers. The levels of iCGRP in the superfusates were measured using radioimmunoassay. Data were analyzed with ANOVA. The results indicate that neither kainate nor AMPA alone affected the spontaneous release of iCGRP. Both kainate and AMPA, however, significantly increased the release of iCGRP in response to CAP when compared to a group which received only CAP. Specifically, the release of iCGRP evoked by CAP was 7953 ± 913 fmol/g/3min while the release in response to CAP pretreated with kainate was 27,936 ± 6179 fmol/g/3min. In addition, release of iCGRP in response to CAP pretreated with AMPA was 18,038 ± 3170 fmol/g/3min ($F_{(3,24)}=5.47$; $p<0.01$). These results demonstrate that kainate and AMPA enhance CAP-evoked release of iCGRP from the dorsal horn. These data support the hypothesis that kainate and AMPA have a modulatory effect on certain primary afferents containing iCGRP. This research was supported by a Predoctoral Fellowship from the Howard Hughes Medical Institute and DE09860.

396.3

ANTAGONISM OF THE HEMODYNAMIC AND MOTOR RESPONSE TO INTRATHECAL (IT) N-METHYL D-ASPARTATE (NMDA) IN RATS. H. El Sayed-Awad, T.L. Yaksh, and M.B. Weinger*, Department of Anesthesiology, University of California, San Diego, La Jolla, CA 92093-0818

NMDA receptors play a role in pain transmission at the spinal level. We studied the effects of spinal NMDA receptor activation in the halothane (1%) anesthetized rat on blood pressure (BP), heart rate (HR) and truncal EMG activity. IT injection of NMDA (3µg/10µl) caused a short-lasting increase in HR, BP and EMG that could be reliably repeated at 30 min intervals. The pharmacology of this effect was investigated by giving escalating doses of a single agent IT, each dose 5min before each of the 4 sequential injections of IT NMDA, each 30 min apart. In the present study, NMDA (MK801 or AP-5), non-NMDA (CNQX) and NMDA-glycine site (7-chlorokynurenate) antagonists produced dose dependent reductions in the elevations in HR/BP and EMG otherwise produced by the IT NMDA. In contrast, ketamine at the highest doses was ineffective. To investigate the role of nitric oxide synthase in this model, IT L-NAME was given and found to suppress the evoked EMG but not the BP/HR response. These data suggest that the spinal action of NMDA receptors may evoke a facilitated state of processing in the anesthetized animal that has been described for dorsal horn windup and in unanesthetized animal models of protracted afferent input, such as on the formalin test. (DA02110)

An Evaluation of the Effects of Excitatory Amino Acids in Bovine Dental Pulp. D.L. Jackson*, L.M. Aanonson†, J.D. Richardson, H.G. Geier, K.M. Hargreaves. Dept. of Rest. Sci., Univ. of Minnesota, and †Dept. of Biol., Macalester College, Minneapolis MN. 55455.

Noxious stimuli are capable of increasing the release of glutamate and other excitatory amino acids within the spinal cord and it is currently thought that these amino acids may contribute to the development of centrally mediated hyperalgesia. While there is considerable information about the release profile and the receptor types involved in the centrally mediated excitatory amino acid effect, relatively little is known about the activity of these compounds in peripheral tissue. The previously described method of *in vitro* bovine dental pulp superfusion (Hargreaves et al. *Abstr. Soc. Neurosci.* 17:1371, 1991) was used to investigate the role of excitatory amino acids in the secretion of immunoreactive CGRP (iCGRP) from capsaicin sensitive peripheral tissue. Dental pulp tissue was obtained from the mandibular incisors of freshly slaughtered holstein cows. The tissue was cut into 200µm cubes and placed into 1.0cc superfusion chambers through which physiologic Krebs's buffer (37°C @ pH 7.4) was continuously pumped. Following baseline collections the tissue was stimulated with either 50mM potassium or kainic acid (100µM). The superfusate was collected for subsequent analysis with a validated radioimmunoassay for iCGRP. Additionally, amino acids were measured by pre-column derivatization with NDA followed by HPLC with fluorescent detection. Data was analyzed using Student's-t tests and expressed as mean ± s.e.m. The administration of 50mM potassium resulted in a greater than five-fold increase in the release of glutamate relative to baseline levels (89.52 ± 21.86 nmol/ml vs. 15.9 ± 2.72 nmol/ml). This stimulus did not produce significant increases in the levels of asparagine, serine, glycine/tyrosine, alanine, or arginine, thus ruling out cell lysis as an explanation of this result. The glutamate analogue kainic acid produced a 231.8 ± 114.7% increase in the secretion of iCGRP from dental pulp relative to controls receiving no stimulant ($p<0.05$). Collectively, these results suggest that glutamate is released in stimulated peripheral tissue and is capable of eliciting the release of iCGRP from a select population of primary afferent fibers. This research was funded by: K16-DE0027-03, DE10096, and P3ODE09737.

396.4

NMDA EVOKES SPINAL RELEASE OF AMINO ACIDS AND PROSTANOIDS IN THE ANESTHETIZED RAT. L.S. Sorkin*, Anesthesiology Research Lab., Univ of CA at San Diego, La Jolla, CA. 92093-0818.

Activation of N-methyl-D-aspartate (NMDA) receptors in the spinal cord dorsal horn has been linked to initiation of hyperalgesia. In order to examine the pharmacological sequelae of NMDA receptor occupancy, this study measured the spinal release of glutamate, glycine, citrulline (as an indirect measure of NO production), prostaglandin E2 and thromboxane B2 in response to intrathecal (IT) NMDA. Rats with IT catheters were anesthetized with halothane, implanted with transverse dialysis probes across the dorsal horns of the rostral lumbar enlargement and dialyzed with artificial CSF (5µl/min). End-tidal halothane was maintained at 2-2.5% during surgery and then reduced to 1.1%; incisions were treated with 0.5% bupivacaine. After 3 hrs of washout and 2 basal samples (1 hr), 3 µg of NMDA was given IT and 3 samples taken in the next 1.5 hrs. In some experiments, IT administration of MK-801 (NMDA antagonist), L-NAME (NO synthase inhibitor) or ketorolac (cyclooxygenase inhibitor) preceded the NMDA. Following NMDA, mean peak responses of Glu, Cit, Gly, PGE2 and TxB2 were significantly elevated over baseline. Pretreatment with MK-801 prevented all evoked release. L-NAME, but not its inactive stereoisomer D-NAME, blocked the evoked release of both Glu and Cit and reduced, but did not eliminate the release of PGE2 and TxB2. Ketorolac blocked the NMDA-induced increase in PGE2 and TxB2 and reduced the basal and evoked release of Cit. These data support the hypotheses that spinal release of Glu, NO and prostanooids participates in the generation of hyperalgesia and that Glu release is secondary to NO production. While prostanoid and NO release appear to be interrelated, the relationship is not clear. This work was funded in part by an Arthritis and Prostaglandin Research Challenge Grant from GD Searle & Co.

MK-801 REDUCES PERSISTENT HINDLIMB FLEXION SUBSEQUENT TO INDUCTION R.D. Moore, D.J. Mokler, and B.J. Winterson*, Depts. Physiol. & Pharm., UNECOM, Biddeford, ME 04005

NMDA receptors have been implicated in spinal nociceptive transmission and the induction of persistent hindlimb flexion (PHF). NMDA receptors may be involved in the maintenance of PHF. PHF was induced in Long-Evans rats with constant current square wave pulses (7ms, 2 mA, 100Hz) across the thigh for 60 min. PHF was assessed by adding weight until stimulated and unstimulated leg lengths were equal. After flexion measurements on day 0, rats were assigned to 4 groups (n=9-12) in which a rat either received an i.p. injection of saline (Controls) or MK-801 (0.1 mg/kg, 1 mg/kg or 3 mg/kg). Flexion was measured at 1 hr and rats were allowed to recover. On day 1, rats were anesthetized, flexion measured, then given saline or MK-801 (same dose as day 0) and flexion was measured at 1 hr. On day 2, rats received an injection of saline or MK-801 (same dose as day 0) without anesthesia or measurement. On day 3, following anesthesia, flexion was measured. Rats were spinalized at T7 and flexion was measured. All rats showed flexion after stimulation but Controls showed no change in flexion after saline injection nor any significant change in mean flexion over 3 d. Rats that received 0.1 mg/kg MK-801 did not show a significant effect on day 0. However, mean flexion significantly dropped by day 3 (6.5 to 3.5gm). Rats that received 1 or 3 mg/kg MK-801 showed a drop in mean flexion on day 0 (1:9.3 to 6.3 gms; 3:10.7 to 7.5 gms). On day 3 mean flexion had dropped in rats receiving 1 or 3 mg/kg MK-801 (1: 3.8 gms, 3: 5 gms). These results suggest that the maintenance as well as induction of PHF involves NMDA receptors. (supported by the American Osteopathic Association)

396.7

MECHANISMS OF ACUTE THERMAL AND MECHANICAL HYPERALGESIA: RECEPTOR SUBTYPES AND CELLULAR EVENTS A. Burnett*, S.T. Meller, C. Dykstra and G.F. Gebhart, Dept. Pharmacol., Univ. Iowa, Iowa City, IA 52242, USA.

This study examined the excitatory amino acid (EAA) receptor subtypes and the cellular events that mediate acute thermal and mechanical hyperalgesia in the rat. Rats were injected with EAA agonists through a chronically implanted intrathecal (i.t.) catheter, and tested 0.5, 1, 2, 5, 10 and 15 min post-drug. Receptor antagonists or blockers of intracellular enzymes were tested against agonists that produced thermal or mechanical hyperalgesia. Only NMDA produced a dose-dependent thermal hyperalgesia; it was blocked by APV but not by DNQX or AP3. In contrast, QA or a 1:1 combination of AMPA + trans-ACPD, but not NMDA, AMPA or trans-ACPD alone, produced a dose-dependent mechanical hyperalgesia; DNQX or AP3, but not APV, attenuated the mechanical hyperalgesia. Thermal hyperalgesia was attenuated in a dose-dependent manner by L-NAME, methylene blue (MB), hemoglobin (Hb), H-7 or chelerythrine chloride (CC) but was unaffected by mepacrine, neomycin, baicalin, NDGA or indomethacin. Mechanical hyperalgesia was unaffected by L-NAME, MB, Hb, H-7, CC, neomycin or baicalin, but was dose-dependently attenuated by mepacrine, NDGA or indomethacin. In conclusion, acute thermal and mechanical hyperalgesia are produced by activation of NMDA and AMPA + metabotropic receptors, respectively. Thermal hyperalgesia is produced by activation of NOS, GC-S and PKC, but not PLA₂ or PLC or cyclooxygenase or lipoygenase products. Mechanical hyperalgesia is mediated produced by activation of PLA₂ and production of cyclooxygenase products, but not by NO, cGMP, lipoygenase products or activation of PKC or PLC.

396.9

INHIBITION OF THERMAL HYPERALGESIA BY L-NAME FOLLOWING UNILATERAL HINDPAW INFLAMMATION. R.J. Traub*, S.T. Meller and G.F. Gebhart.

Dept. Pharmacology, Univ. of Iowa, Iowa City, IA 52242.

Carrageenan-induced unilateral hindpaw inflammation results in thermal and mechanical hyperalgesia of the inflamed hindpaw. Studies from our laboratory have suggested that nitric oxide (NO) mediates thermal hyperalgesia associated with sciatic nerve injury and pharmacologically-induced facilitation of the thermal withdrawal reflex. The role of NO in hyperalgesia following hindpaw inflammation was examined.

Male Sprague-Dawley rats were injected in the left hindpaw with 100µl 2% carrageenan. L-NAME (2, 20, 200 nmol), D-NAME (200 nmol) or saline were injected intrathecally (2 µl, 10 µl saline flush) 20 min prior to (and again 2 hrs later; pre-treat) or 4 hrs following (post-treat) carrageenan.

Carrageenan produced inflammation and thermal and mechanical hyperalgesia that peaked at 3 hrs and persisted beyond 12 hrs. Post-treatment with L-NAME produced a dose-dependent attenuation of the thermal, but not mechanical, hyperalgesia that lasted 3-5 hrs. There was no effect upon the non-inflamed hindpaw. D-NAME and saline had no effect. Pre-treatment with L-NAME (all doses) delayed the onset of thermal hyperalgesia by 3 hrs.

L-NAME blocks NO production. These data suggest that NO mediates thermal but not mechanical hyperalgesia and is necessary for the development and maintenance of hyperalgesia resulting from hindpaw inflammation.

396.6

THE COMPETITIVE NMDA ANTAGONIST CPP PLUS NON-NMDA ANTAGONIST DNQX POTENTIATES ANTINOCICEPTION MORE THAN MK-801 PLUS DNQX IN FORMALIN PAIN MODEL. Y.M. Goettl* and A.A. Larson, Graduate Program in Neuroscience, University of Minnesota, St. Paul, MN 55108, U.S.A.

Activity at *N*-methyl-D-aspartate (NMDA) and non-NMDA excitatory amino acid receptors has been implicated in the acute phase and NMDA receptors in the tonic phase of the formalin pain model at the spinal cord level. How these two receptor systems interact to transmit pain is not known. Using doses at about ED₅₀ values, we injected 6 nmoles of DNQX, a competitive non-NMDA antagonist, 80 pmoles of CPP, a competitive NMDA antagonist or 1 nmole of MK-801, a PCP ligand and non-competitive NMDA antagonist, individually or in combination in 23-30 g male Swiss-Webster mice. Drugs were administered intrathecally 5 min before injecting 20 µl of 5% formalin s.c. in the dorsum of the rear foot. All three drugs individually were antinociceptive in the acute phase (0-5 min) inhibiting behaviors to 45-60% that of control mice. While MK-801+DNQX decreased behaviors to 34% of control, CPP+DNQX was profoundly antinociceptive with decreases to 5% of control. CPP+DNQX also produced hind limb paralysis or paresis that appeared to dissipate by the tonic phase. In the tonic phase (20-30 min), CPP and MK-801 each significantly decreased behaviors to 38% and 64% of control, respectively, while DNQX had no effect. CPP+DNQX decreased behaviors to 7% of control whereas MK-801+DNQX was not antinociceptive. DNQX interacts differently with MK-801 than with CPP suggesting that MK-801 has activity not linked to inhibition of NMDA receptors. (Supported by NIDA training grant T32 DA07234, NIDA 04190, 04090 and 00124.)

396.8

CHARACTERIZATION OF THE SPINAL MECHANISMS OF THERMAL AND MECHANICAL HYPERALGESIA FOLLOWING INTRAPLANTAR ZYMOBAN S.T. Meller*, C. Dykstra and G.F. Gebhart, Dept. Pharmacol., University of Iowa, Iowa City, IA 52242.

The excitatory amino acid (EAA) receptor subtypes and the intracellular cascade of events produced following intraplantar injection of zymosan A were investigated in awake rats.

Intraplantar zymosan A produced a rapid onset (< 30 min), long-lasting (24-72 h) and dose-dependent (0.0625-5 mg) thermal and mechanical hyperalgesia accompanied by edema. Three hours after zymosan, the effect of EAA receptor antagonists (MK-801, APV, DNQX or AP3) or blockers of intracellular enzymes (L-NAME, hemoglobin, mepacrine, chelerythrine chloride or indomethacin), injected through a chronically implanted intrathecal catheter, were examined. APV, MK-801, L-NAME, hemoglobin and chelerythrine chloride attenuated or blocked the thermal but not the mechanical hyperalgesia produced by zymosan. In contrast, DNQX and AP3 attenuated both the thermal and mechanical hyperalgesia and mepacrine or indomethacin attenuated the mechanical but not the thermal hyperalgesia. None of the antagonists or enzyme blockers produced any change in latencies or thresholds in sham rats.

These data suggest that (1) zymosan produces reliable and reproducible, rapid onset and long-lasting thermal and mechanical hyperalgesia, (2) the thermal hyperalgesia is produced by activation of NMDA, AMPA and metabotropic glutamate receptors, production of NO and activation of PKC, and (3) mechanical hyperalgesia is produced by activation of AMPA and metabotropic glutamate receptors, activation of PLA₂ and production of cyclooxygenase products, but not by NMDA receptors, production of NO or activation of PKC or PLC.

396.10

POTENTIATION OF (+)-CIS-DIOXOLANE ON ANTINOCICEPTION INDUCED BY I.C.V. β-ENDORPHIN IS MEDIATED BY NO-CGMP IN THE MOUSE. J.Y. Xu and L.F. Tseng*, Department of Pharmacology and Toxicology, Medical College of Wisconsin, Milwaukee, WI 53226.

(+)-*cis*-Dioxolane (CD), a muscarinic receptor agonist, at doses (0.5-2 µg, i.c.v.) produced a dose-dependent inhibition of the tail-flick response (TF) and at subantinociceptive doses (0.25 µg, i.c.v.) potentiated i.c.v. administered β-endorphin(β-EP)-induced TF inhibition in male ICR mice. The potentiation of β-EP-induced antinociception by CD is attenuated by hemoglobin (120 µg), *N*-nitro-L-arginine (1 µg) or methylene blue (5 µg), given i.c.v., indicating that NO-cGMP system is involved in the potentiation. The same treatment of mice with hemoglobin, *N*-nitro-L-arginine or methylene blue also blocked CD-, but not β-EP-induced TF inhibition. CD selectively potentiated the TF inhibition induced by β-EP, an ε receptor agonist, but not morphine or DAMGO, μ receptor agonists, DPDPE, a δ receptor agonist, or U50,488H, a κ receptor agonist. It is concluded that β-EP-induced antinociception is selectively potentiated by the activation of muscarinic receptors by CD which is mediated by NO-cGMP system (supported by NIH grant DA 03811).

396.11

INVOLVEMENT OF GLYCINE IN SPINALLY-MEDIATED NOCICEPTION
CHRISTIE MCNICKLE and LIN AANONSEN*, Department of Biology,
 Macalester College, St. Paul, MN 55105.

Previous studies indicate that glutamate, acting at the NMDA receptor, may be involved in spinally-mediated nociception. Since glycine has been shown to enhance the effects of glutamate at the NMDA receptor complex, we hypothesized that intrathecal (i.t.) glycine may also be involved in spinally-mediated nociception. In addition to glycine's effect at the NMDA receptor complex, glycine also acts at a lower affinity site where it is thought to be one of the major inhibitory neurotransmitters in the spinal cord. To eliminate activation of this site by glycine, we used the selective antagonist strychnine. For activation and antagonism of the glycine site linked to the NMDA receptor complex, we used the agonists glycine and serine and the selective antagonist 7-chlorokynurenic acid (7-CK). We proposed that the agonists, acting at the NMDA receptor complex, would produce hyperalgesia, while the antagonist would be analgesic. To test this we administered the drugs (i.t.) in mice. The pain threshold was determined by placing the mouse on a hot-plate and measuring the latency to lick its hind-paw. At low doses, strychnine alone produced hyperalgesia, which could be blocked by the noncompetitive NMDA antagonist PCP. 7-CK ($\geq 2.72\text{mM}$) increased hot-plate latencies, but animals also displayed motor impairment. The glycine dose response curve was biphasic; at low doses glycine produced hyperalgesia which could be attenuated by PCP and at high doses, glycine was analgesic. These results support the presence of a high affinity and a low affinity glycine site in the rat spinal cord. The results also suggest that endogenous pools of glycine can be experimentally shifted to activate the NMDA site, and thereby enhance pain responses.

MORPHINE AND EXCITATORY AMINO ACID ANTAGONISTS DISTINGUISH ALLODYNIA FROM OTHER PAIN STATES
S.E. Sherman* and C.W. Loomis, School of Pharmacy,
 Memorial Univ., St. John's, NF, Canada A1B 3V6

The effects of intrathecal (i.t.) morphine and excitatory amino acid antagonists on i.t. strychnine (STR)-dependent allodynia were investigated in the lightly anesthetized rat. With i.t. STR (40 μg), normally innocuous hair deflection (HD) evoked a motor withdrawal response, a pressor response and tachycardia; responses that are normally evoked by noxious pinch or heat, but not HD alone. I.t. morphine (50 μg) blocked responses to noxious heat and pinch but was ineffective against STR-dependent responses to HD. These HD-evoked, STR-dependent responses were significantly attenuated by the non-selective excitatory amino acid antagonist gamma-D-glutamylglycine (i.t.), and the AMPA-selective antagonist NBQX (i.t.). The failure of i.t. morphine to inhibit HD-evoked, STR-dependent responses indicates that allodynia is not mediated via a conventional nociceptive pathway. Since non-NMDA receptor antagonists are reported to be ineffective in experimentally-induced hyperalgesia, sensitivity to NBQX distinguishes allodynia from hyperalgesia. (Supported by MRC Canada)

NITRIC OXIDE (NO) MEDIATED MUSCARINIC ANALGESIA: SITES OF NO SYNTHASE AND GUANYLYL CYCLASE mRNA-CONTAINING NEURONS IN RAT ROSTRAL VENTRAL MEDULLA.
E.T. Iwamoto*, L.J. Marion, R.M. Booze, and M.C. Tyler*, Dept. of Pharmacology, Univ. of Kentucky Col. of Med., Lexington, KY 40536, and ⁶Du Pont Res. and Devel./NEN Products, Boston, MA 02118.

To investigate the hypothesis that the analgesia produced by microinjections of the muscarinic agonist (+)-*cis*-methylpiperazine (CD) into the rostral ventral medulla (RVM) is mediated by nitric oxide (NO), we studied the effects of the NO synthase inhibitor L-N⁶-nitroarginine (N⁶LA). Five min preadministration of 6 nmol N⁶LA antagonized CD-produced antinociception in both the 52°C hot-plate and tail-flick tests. The NO precursor L-arginine (LR), but not D-arginine (DR), reversed the N⁶LA-induced inhibition of CD-produced antinociception. The guanylyl cyclase inhibitor methylene blue also significantly decreased CD antinociception. Dibutyl cGMP or 8-bromo cGMP produced antinociception when injected alone in the RVM; buffer, N⁶LA, DR, or methylene blue alone were without effect. As a morphologic test of our hypothesis, the sites of NO synthase (NOS) and soluble guanylyl cyclase (sGC) in the RVM were localized using *in situ* hybridization histochemistry with ³²P-labeled oligonucleotide probes complementary to NOS or sGC mRNA. Significant levels of NOS and sGC mRNA were localized in a region that includes both the gigantocellular reticular nucleus pars alpha and the lateral paragigantocellular nucleus. The data support the hypothesis that muscarinic antinociception is mediated by a LR/NO/cGMP cascade in the RVM. (Supported by NIH NS 28847)

396.12

INTRATHECAL CPP AND DAMGO ACT SYNERGISTICALLY TO DECREASE THERMAL HYPERALGESIA IN INFLAMED RAT HINDPAW
G.M. Williams*, R.M. Caudle, K. Ren, D.A. Thomas, and R. Dubner, Neurobiol. Anesth. Br., NIDR, NIH, Bethesda, MD 20892.

We have demonstrated that both intrathecal NMDA antagonists (EJP 219:235) and intrathecal opioid agonists (EJP 194:135) reverse the hyperalgesia produced by complete Freund's adjuvant (CFA) injection into the rat hindpaw. Here we investigate if co-administration of a competitive NMDA antagonist ((±)-3-(2-carboxypiperazin-4-yl)-propyl-1-phosphonic acid; CPP) and a μ opioid agonist ((D-Ala²-MePhe⁴-Gly⁵-OH) enkephalin; DAMGO) produces a supra-additive antinociceptive action. An isobolographic approach was utilized to analyze for synergism.

Rats were cannulated intrathecally and received a unilateral hindpaw injection of CFA to produce thermal hyperalgesia (paw withdrawal latency inflamed paw = 4.5 ± 0.2 sec; contralateral = 9.5 ± 0.2 sec). Dose-response curves for DAMGO alone (0.01 - 10 nmol), CPP alone (0.3 - 3000 nmol) and CPP + DAMGO were determined. CPP + DAMGO combinations were administered in a constant dose-ratio of 62 nmol CPP/1 nmol DAMGO, with the total drug dose ranging from 0.26 - 26 nmol. The doses estimated to produce paw withdrawal latencies of 12.2 sec on the inflamed paw (half-way between inflamed baseline and 20 sec cutoff) were: CPP, 62 nmol; DAMGO, 1.5 nmol; and CPP + DAMGO, 4.4 nmol. This CPP + DAMGO value is 7-fold lower than that predicted for a simple additive interaction (isobolographic prediction using the individual dose-response curves). After transforming the data to account for the potency difference between CPP and DAMGO, general linear modelling of the individual and combination dose-response curves showed that the supra-additive interaction was statistically significant ($p < 0.05$). The finding of a synergistic interaction suggests that NMDA antagonist/opioid agonist combination therapy may provide increased pain relief, decreased toxicity, or both, in a clinical setting.

NITRIC OXIDE AND N-METHYL-D-ASPARTATE RECEPTORS: ROLE IN SPINAL REFLEXES AFTER PERIPHERAL INFLAMMATION
M.L. Semos and P.M. Headley, SPON: Brain Research Association. Physiology Dept., University of Bristol, BS8 1TD, U.K.

Single motor unit activity was recorded electrophysiologically under α -chloralose anaesthesia in both spinalized and non-spinalized rats. The flexion withdrawal reflex was evoked with noxious pinch stimuli applied to the hindpaw receptive field (2.2N/4mm² intact; 2.8N/4mm² spinalized, every 3 mins). The NMDA receptor contribution to the reflex was first tested with ketamine, a non-competitive NMDA antagonist. Inflammation of the hindpaw was induced by topically applied mustard oil (100%) and a ketamine test repeated. The role of nitric oxide (NO) was then assessed using the NO synthase inhibitor N⁶-nitro-L-arginine methyl ester (L-NAME) given in a dose-doubling regime to 40mg/kg i.v.. Drug effects are expressed as the mean % of control pre-drug values (\pm s.e.m.).

All drugs significantly affected the reflex to a greater degree in non-spinalized animals. Ketamine 6.7mg/kg i.v. significantly inhibited the pinch reflex ($33 \pm 6\%$, n=8 intact; $61 \pm 8\%$, n=6 spinalized). Mustard oil significantly enhanced responses ($219 \pm 70\%$, n=12 intact; $128 \pm 10\%$, n=6 spinalized). There was no difference in either group in the effectiveness of ketamine in the hyperalgesic state. Without inflammation, L-NAME 40mg/kg had no effect on reflexes to noxious pinch in intact rats (Semos & Headley, 1993, J. Physiol. 459, 503P). However, in the hyperalgesic state L-NAME significantly inhibited this reflex, but only when the cord was intact ($70 \pm 8\%$, n=10 intact; $113 \pm 6\%$, n=6 spinalized).

These data indicate that there is no enhancement of the NMDA receptor contribution to reflexes after acute inflammation, whereas NO pathways are activated. There is thus no clear link between NO and NMDA mechanisms in this system. The role of NO in nociception with peripheral inflammation is predominantly supraspinal.

NADPH-DIAPHORASE STAINING IN THE SPINAL CORD OF MONONEUROPATHIC RATS IS REDUCED WITH ADRENAL MEDULLARY TRANSPLANTS.
A.T. Hama and J. Sagen, Department of Anatomy and Cell Biology, Univ. of Illinois at Chicago, Chicago, IL 60612.

Previous work in our laboratory has shown that adrenal medullary tissue transplanted into the subarachnoid space of rats with unilateral painful peripheral neuropathy reduces thermal allodynia and thermal hyperalgesia. Adrenal medullary transplants may alleviate pain directly by releasing opioid peptides and catecholamines and, possibly indirectly, by inhibiting or reducing the neurochemical changes that lead to the chronic pain state. Increased activity or synthesis of nitric oxide synthase (NOS), leading to increased levels of nitric oxide, could increase and prolong abnormal pain sensations. Thus, levels of NOS, NADPH-diaphorase (NADPH-d) in spinal cord may serve as a marker for cellular activity. By loosely ligating the right sciatic nerve in rats, various pain symptoms such as thermal hyperalgesia and cold allodynia were induced. Animals were given either adrenal medullary or control striated muscle transplants two weeks after nerve ligation. One week after transplantation, animals that received adrenal medullary tissue showed significantly reduced hyperalgesia and allodynia in contrast to control transplanted animals. After behavioral evaluation, transplanted animals and age-matched animals that received no surgery were perfused, and histochemistry for NADPH-d was performed on spinal segments L₁-L₆. In control transplanted animals with nerve ligation, there was a marked increase in NADPH-d stained cells and processes in medial superficial dorsal horn, in laminae IV-VII and in lamina X ipsilateral to the side of nerve ligation. In contrast, in animals with adrenal medullary transplants, NADPH-d staining was similar to non-ligated control animals. The number and intensity of stained cells and processes were reduced in all three spinal regions of adrenal transplanted animals compared to animals with control transplants. These results suggest that adrenal medullary transplants may reduce chronic neuropathic pain by decreasing spinal levels of NADPH-d/NOS and levels of nitric oxide, which has been implicated in long-term persistence of intractable pain. SODIUM NITROPRUSSIDE POTENTIATES CAPSAICIN-INDUCED RELEASE OF PEPTIDES FROM CULTURED RAT SENSORY NEURONS. J. Dymshitz*, M.R. Yasko, Dept. of Pharmacology and Toxicology, Indiana U. School of Medicine, Indianapolis, IN 46202.

Administration of substances that spontaneously release nitric oxide (NO) onto the spinal cords of rodents results in an increased sensitivity to noxious stimuli. One possible mechanism for these hyperalgesic actions of NO donors is that NO enhances the release of neurotransmitters from nociceptive sensory neurons. To address this issue, we examined whether sodium nitroprusside (SNP), a donor of NO, could alter the resting or stimulated release of substance P (SP) and of calcitonin gene-related peptide (CGRP) from rat sensory neurons grown in culture.

Dorsal root ganglia were dissected from rat fetuses (E15-17), mechanically dissociated after incubation with collagenase, and the cells were grown for 10-12 days in DMEM supplemented with fetal bovine serum, NGF and mitotic inhibitor. Release experiments were performed by incubating sensory neurons with a HEPES buffer containing 3.5 mM KCl (resting release) or buffer containing various concentrations of SNP (0.1 μ M - 1000 μ M) for 10 min. The cells were then exposed to 50 nM capsaicin in the presence or absence of SNP.

When neurons were treated with SNP, the resting release of CGRP was not significantly altered, whereas 1 mM SNP increased SP release 3 fold. Pretreating cells with 10 μ M or 100 μ M SNP (concentrations that did not alter resting release) enhanced the release of SP and CGRP evoked by 50 nM capsaicin approximately 2-3 fold. Exposure of the cells to 100 μ M potassium ferrocyanide did not alter resting or stimulated release of the peptides. Furthermore, the stimulatory actions of SNP were not mimicked by a 1 hr pretreatment with 500 μ M 8'-bromo-cGMP.

These results suggest that NO enhances the capsaicin-evoked release of SP and CGRP from primary sensory neurons. Because 8'-bromo-cGMP does not augment release, the effect of NO may not be mediated through an increase in intracellular cGMP. (Supported by PHS DA07176)

396.19

POTENTIAL ROLE FOR NITRIC OXIDE IN THE DEVELOPMENT OF HYPERALGESIA PRODUCED BY CAPSAICIN. H.D. Gilchrist^{1,2*}, B.A. Allard¹ and D.A. Simone^{1,2}. ¹Neuroscience Research in Psychiatry and ²Graduate Program in Neuroscience, Univ. of Minnesota, Minneapolis, MN 55455.

Intradermal (ID) injection of capsaicin (CAP) in humans produces cutaneous hyperalgesia to heat and mechanical stimuli, and enhances excitability of primate dorsal horn neurons. In order to study underlying pharmacological mechanisms, a similar model of hyperalgesia was developed in rat. Rats received one ID injection of vehicle or CAP (1, 10 or 30 μ g in 10 μ l Tween saline) into the plantar surface of one hindpaw. Nociceptive responses evoked by heat and mechanical stimuli (von Frey monofilaments) applied to the plantar surface of both hindpaws were assessed before and after injection. Hyperalgesia to heat and mechanical stimuli was defined as facilitation of withdrawal responses (decreased withdrawal latency to heat and increased withdrawal response frequency to von Frey stimuli). CAP produced a dose-dependent decrease in withdrawal latency and increased the frequency of withdrawal responses. Withdrawal latency decreased 50% and withdrawal response frequency increased 60-70% following the 30 μ g dose. Facilitation of withdrawal responses typically lasted 1-3 hr.

Additional rats were pretreated 30-60 min before CAP with the nitric oxide (NO) synthesis inhibitor N-nitro-L-arginine methyl ester (L-NAME) either systemically (100 mg/kg, IP) or into the plantar hindpaw at the site of the subsequent CAP injection (200 μ g in 30 μ l, ID). Systemic L-NAME decreased the magnitude of hyperalgesia to both heat and mechanical stimuli. L-NAME injected directly into the paw did not alter the development of hyperalgesia. We conclude that 1) ID injection of CAP in rats is a useful model of hyperalgesia, and 2) NO in the CNS plays a role in the development of hyperalgesia following CAP. Supported by NIH NS31223 and the Minnesota Medical Foundation.

APPLICATION OF L-NITRO-ARGININE METHYL ESTER ATTENUATES THE SENSITIZATION OF STT NEURONS FOLLOWING ACUTE ARTHRITIS. H. Rees*, J. Palecek and W.D. Willis, Marine Biomedical Institute, UTMB, Galveston, Texas 77555-0843.

The sensitization of STT neurons following acute arthritis was studied in 8 anesthetized adult monkeys (*Macaca fascicularis*). STT neurons were recorded with single barreled carbon fibre microelectrodes and identified by antidromic activation from the contralateral thalamus. Cells were selected with large receptive fields on the hind limb and which also showed some response to knee stimulation. Control responses to graded cutaneous stimuli (brush, press, pinch & heat) as well as joint flexion were established. Acute arthritis was then induced by injection of kaolin/carrageenan into the knee capsule. Following injection, the knee joint was flexed for 15 min periods every 30 mins for 4 h. The responses to cutaneous stimuli and flexion were then retested. The responses of the same STT cells to flexion of the knee joint were increased markedly for all degrees of flexion tested. The responses to cutaneous mechanical stimuli at sites distant from the inflamed knee were also significantly increased. There was little change in the responses to intense mechanical or thermal cutaneous stimuli. The nitric oxide synthase inhibitor L-nitro-arginine methyl ester (L-NAME) was then administered via a microdialysis fiber previously inserted in the dorsal horn of the spinal cord. L-NAME significantly attenuated the increases in responses to mechanical cutaneous stimuli while application of the inactive isomer D-NAME did not. The results suggest that acute arthritis sensitizes STT cells, increasing the efficacy of the input from low threshold mechanoreceptors. This sensitization is partly reversed by central administration of L-NAME, which indicates that the process is at least partly dependent on the production of nitric oxide in the spinal cord. However, the enhanced responses to flexion were unaltered by L-NAME, suggesting that peripheral sensitization was more important than central effects in increasing these responses. NERVE GROWTH FACTOR ALLEVIATES A PAINFUL PERIPHERAL NEUROPATHY IN RATS. D. Thomas*, K. Ren and R. Dubner, Neurobiology and Anesthesiology Branch, NIDR, NIH, Bethesda, MD 20892.

Nerve growth factor (NGF) reverses some effects of axotomy and prevents toxic neuropathy in adult rodents. We tested the possibility that NGF may block behavioral signs of hyperalgesia and allodynia resulting from a chronic constriction injury (CCI) of the sciatic nerve. CCI was induced in rats by ligation of the sciatic nerve under sodium pentobarbital (50mg/kg) anesthesia. This procedure produced behavioral hyperalgesia from post-operative day (POD) 1-3 as demonstrated by a quicker paw withdrawal from a noxious thermal stimulus on the side of injury, when compared to the contralateral hindpaw. The mechanical sensitivity of the ipsilateral hindpaw, assessed with von Frey filaments, was also significantly increased. A cuff was placed around the sciatic nerve at the site of ligation and 2.5S NGF was infused into the cuff via an Alzet osmotic pump at a rate of 0.5 μ g/ μ l/h for 7-10 days. When NGF infusion was started immediately after the nerve ligation, thermal hyperalgesia was significantly reduced or abolished from POD 5 up to the end of the test period (POD 42), when compared with rats receiving vehicle infusion. CCI-induced increase in mechanical sensitivity was also abolished by NGF infusion. Delayed infusion of NGF (POD 4) failed to block thermal hyperalgesia. Infusion of NGF had no significant effect on paw withdrawal latency of the rats that had no CCI. Thermal hyperalgesia developed, but was not enhanced in CCI rats receiving an infusion of anti-NGF antiserum. These results suggest that alterations in neurotrophic factor(s) may contribute to the development of behavioral hyperalgesia in an animal model of neuropathy and that NGF may have therapeutic value in the treatment of neuropathic pain.

Little cells ending on big cells: An Oligosynaptic Retino-tectopulvinar system in Pigeon. H.J. Karten, K. Cox, J. Mpodozis, H.J. Bischof, T. Shimizu* Dept. Neurosciences, UCSD, La Jolla, CA 92093-0608; Dept. Psychology, USF, Tampa, FL 33620.

The retino-tectopulvinar system appears to be one of the most ancient of visual pathways to the telencephalon of all vertebrates. The projections upon the rotundus/pulvinar (RtPl) from layer 13 of the tectum has been confirmed with injection of Cholera Toxin B (CTb) into the RtPl of pigeons. In addition to dense bilateral retrograde labeling of cells of layer 13 of the tectum, we observed massive retrograde filling of widely arborizing dendrites in layer 5b of the tectum. Layer 5b is the recipient of a dense retino-tectal input of small ganglion cells. We have tentatively identified the specific retinal ganglion cells terminating in layer 5b as extremely small neurons with somal diameters of 4.5-6 μ m, and dendritic fields of 25 μ m. The cells of layer 13 are exquisitely motion sensitive and have extremely large receptive fields (>50 degrees), whereas the retinal ganglion cells that appear to terminate upon their distal dendrites are extremely small neurons. The morphology of layer 13 neurons is similar to the tectopulvinar neurons of squirrel (May et al., 1982) and of lizards (P. Ramon, 1896). These findings suggest the common presence of a "fast" throughput pathway from retina upon the thalamus. (Supported by NS-24560 and EY-06890 to H.J.K.)

ANATOMICAL CONNECTIONS OF SOME VISUAL CORTICAL AREAS IN THE MONGOLIAN GERBIL (*Meriones uinguiulatus*). L. I. Cudmore*, C. G. Ellard and A. I. Long, Department of Psychology, University of Waterloo, Waterloo, Ontario, CANADA N2L 3G1.

Despite a growing corpus of experimental studies of visual behaviour in the gerbil, relatively little is known about the anatomical organization of the visual system in this species. Small quantities of 1% wheat germ agglutinated horseradish peroxidase (0.1-0.2 ml) were micro-injected into various locations in the posterior neocortex of the gerbil. Following a survival period of 48 hours, gerbils were perfused. Brains were sectioned at 40 μ m and three adjacent series of sections were saved. One series was reacted with a modification of HRP histochemistry, using tetramethylbenzidine as the chromogen. Adjacent sections were stained with galloyanin for Nissl substance. A third series was stained with a gold chloride stain for axons. Results from the three stains were correlated in order to describe the cytoarchitectonics of visual cortex in the gerbil and its connectational organization. Results suggested that there are at least two distinct visual cortical areas adjacent to primary visual cortex in the gerbil. Each of these areas has distinct patterns of reciprocal connections with the lateral geniculate nucleus and with the lateral posterior nucleus of the thalamus. Of particular note was our finding of a cortical zone lateral and anterior to primary visual cortex with high myelination. This zone, which may be analogous to area TP in the squirrel as defined by Sereno et al. (1991) and area MT in the primate, is presently being tested for its motion sensing properties.

PATTERN AND LAMINAR DISTRIBUTION OF INTRINSIC CONNECTIONS IN CAT LATERAL SUPRASYLVIAN CORTEX. A.J. Cook and G. Einstein. Dept. of Neurobiology, Duke Univ. Med. Ctr., Durham, NC 27710.

The topographic map and receptive field properties of neurons in the cat's posterior medial lateral suprasylvian cortex (PMLS) are quite different from those of area 17. While different inputs may account for these unique properties, these may also be contributed to by differences in intrinsic circuitry. In order to investigate this possibility, we made small, focal injections of biocytin into layers 2, 3, 5, and 6 of area PMLS and reconstructed injection sites and filled axons through serial sections cut in the coronal plane. We found that in pattern and extent, the intrinsic connections of PMLS resembled those of area 17. Injections restricted to layer 2 revealed axons that traveled horizontally in the superficial layers for long distances (up to 3 mm) terminating in tufts at 500 μ m intervals. Injections restricted to layer 3 revealed axons that traveled horizontally for long distances (upwards to 3.5 mm) but which also traveled vertically, tufting in layer 5 before entering the white matter. Injections restricted to layer 5 filled axons that traveled horizontally in layer 5 for 2-3 mm and coursed obliquely for 1-2 mm terminating in layer 3. Injections restricted to layer 6 filled axons that formed a cup around the injection site, traveling vertically to terminate in layer 2, obliquely to terminate in layer 3, and horizontally for long distances along the 5/6 border terminating in periodic light tufts. These results suggest that there may be a typical pattern of intrinsic connections throughout visual cortex. However, at most AP levels, 3.5 mm of PMLS represents a larger region of visual space than 3.5 mm of area 17. Thus, horizontal connections in PMLS may serve to connect more disparate regions of visual space. Supported by NEI grant EY07840.

LOCAL PATCH PYRAMIDAL NEURONS ARE DISTINCT FROM CORTICOCORTICAL AND CALLOSAL CELLS IN CAT AREA 18. J.A. Matsubara^{1,2}, R. Chase³, J. Zhang¹ and D.M. Thejomayan². Depts Ophthalmology¹ and Anatomy², U.B.C., Vancouver, B.C.; Dept of Biology³, McGill University, Montreal, P.Q. CANADA.

Intrinsic, callosal and corticocortical pathways are distributed in patches within the upper layers of cat visual cortex. Our earlier studies showed that local patch pyramids and callosal cells form separate cell populations, but not separate patch networks. Here, we compare the corticocortical (area 18 to area 17) cells to local patch pyramids in 18. Using intracellular injections into prelabeled targets in fixed slices, cells were filled with lucifer yellow and imaged en bloc with confocal microscopy.

The vast majority of corticocortical neurons were pyramidal cells (99 of 105 cells), but a small number of nonpyramidal (3/105) and fusiform (3/105) cells were also observed. The most common pyramidal cell type was the standard pyramid (80/99), but 'armed' standards (8/99), modified (7/99), star (2/99) and inverted (2/99) types were present. All three projection populations contained standard pyramids, but of different size ranges. Modified and star pyramids were only found in the corticocortical and local patch populations, while 'armed' standards were only found in the callosal and corticocortical populations. Although cell types often overlapped, double labeled studies show less than 5% of the local patch neurons also project corticocortically, while none of the local patch neurons project callosally. These results suggest that most local patch pyramidal cells are distinct from projection pyramids. Whether it is cell lineage or chemotropic factors that dictate if a cell becomes a local patch or projection pyramid remains unknown. This work was funded by MRC (Canada) and NSERC.

AMPLIFICATION OF THE PATHWAY FROM AREAS 20 AND PS TO LATERAL SUPRASYLVIAN CORTEX AFTER REMOVAL OF AREAS 17 & 18 IN THE NEWBORN CAT. M.A. MacNeil*, S.G. Lomber and B.R. Payne. Department of Anatomy & Neurobiology, Boston University School of Medicine, Boston, MA 02118.

Visual areas 17 & 18 provide the major cortical input to lateral suprasylvian (LS) cortex in the cat. If these visual areas are removed in the adult, functional deficits result that are not observed when the same type of damage is incurred shortly after birth. The purpose of our study was to determine whether anatomical rewiring of cortico-cortical projections to LS cortex may help explain the behavioral compensation following neonatal ablations of areas 17 & 18.

Retrograde tracers were injected into LS cortex and the pattern of cortical labelling seen in intact adult cats was compared to that present in adult cats which had incurred lesions of visual areas 17 & 18 either on the day of birth (P1 group) or during adulthood (adult group). When equating animals by injection size, the P1 group had at least 30% more cells labelled throughout cortex compared to either the intact or adult groups. In addition, the projection from areas 20 and PS to LS cortex in the P1 group was significantly increased. Comparisons between intact and adult groups yielded no significant differences.

Our results indicate that removal of areas 17 & 18 on the day of birth leads not only to a numerical compensation in the numbers of cells projecting to LS, but also to an increase in the magnitude of visual projections from ventral extrastriate regions. These shifts may be responsible for behavioral compensation demonstrated in neonatally damaged cats. (Supported by MH44647 and NS07152)

A CROSS-CORRELATION STUDY OF FUNCTIONAL CONNECTIVITY BETWEEN AREA 17 AND LATERAL SUPRASYLVIAN AREA IN CATS. N. Katsuyama, H. Sato, H. Tamura and T. Tsumoto*. Dept. Neurophysiol., Osaka Univ. Med. Sch., Suita, Osaka, 565 Japan.

The posteromedial lateral suprasylvian area (PMLS) of cat's cortex is one of extrastriate visual areas, and is believed to be involved in visual motion perception. The PMLS receives main cortical inputs from area 17 (V1) and sends feedback outputs to V1. To assess the functional significance of this reciprocal connection between PMLS and V1, we carried out cross-correlation analysis of neuronal spike trains recorded simultaneously from the both areas. Adult cats were anesthetized with a mixture of 70 % N₂O, 30 % O₂ and 0.3 - 0.5 % halothane. Animals were paralysed and maintained under artificial ventilation. Visual stimuli were presented on a computer display. Positions of receptive field center of V1 cells were located at foveal and parafoveal areas of the visual field, and those of cells in the posterior and anterior portions of PMLS tended to locate at foveal and peripheral visual fields, respectively. Among 84 pairs of cells recorded so far, significant correlation of firings was observed in some of the cases when receptive fields of both cells were completely overlapped. Typical significant correlograms obtained without visual stimuli had peaks at center (time zero), indicating common excitatory inputs and/or synchronized activities. Some correlograms showed an asymmetric positive peak, which indicates an excitatory drive from V1 to PMLS cells. (supported in part by a HFSP grant to T.T.)

NOVEL AND EXPANDED VISUAL THALAMIC PROJECTIONS TO LATERAL SUPRASYLVIAN CORTEX FOLLOWING REMOVAL OF AREAS 17 & 18 FROM THE DEVELOPING CAT. S.G. Lomber*, M.A. MacNeil and B.R. Payne. Dept. of Anatomy & Neurobiology, Boston University School of Medicine, Boston, MA 02118.

Both behavioural and physiological studies have implicated lateral suprasylvian (LS) cortex in the sparing of visual functions following the removal of areas 17 & 18 in the developing cat. We tested the hypothesis that thalamic projections to LS cortex expand following removal of immature areas 17 & 18 on P1 or P28 by injecting retrograde tracers into LS cortex when the cats were at least six months of age or older. Patterns of cell labelling were then compared to the patterns in intact cats and cats which underwent comparable lesions in adulthood.

Compared to intact cats, lesions on both P1 and P28 result in an increase in the numbers of labeled neurons and a change in their distribution. In the dorsal lateral geniculate nucleus, lesions induce novel projections from the A-laminae and increase projections from the C-complex. In the extrageniculate visual nuclei of the P1 group, there is a 100% increase in projections from the medial division of the lateral posterior nucleus. The magnitude and pattern of labelling in the adult lesion group is indistinguishable from that in the intact cat.

These results show that visual thalamic inputs to LS increase following lesions of immature visual cortex and it is likely that the magnitude of the visual signals conveyed along these pathways is increased. These signals may contribute to the spared functions attributed to LS cortex following removal of areas 17 & 18. (Supported by MH44647 and NS07152)

COMPARISON OF INPUTS FROM AREA V2 TO AREAS V4, MT AND PO IN CEBUS. R. Gattass, S. Nascimento-Silva, M. Fiorani Jr. and A.P.B. Souza. Dept. Neurobiologia, IBCCF, UFRJ, Rio de Janeiro, RJ, 21941-900, Brazil.

To investigate the differential inputs from area V2 to areas V4, MT and PO in Cebus monkeys we injected multiple retrograde tracers and analysed the distributions of labeled neurons in V2. We sectioned one brain in the parasagittal plane, one in the coronal plane and in the last one we used flattened preparations of the cortex. In V2 we found labeled neurons arising from V4, MT and PO. Both V4- and MT-projecting neurons were located in stripes running orthogonal to the V1/V2 border. As in the macaque MT-projecting neurons were located in the cytochrome oxidase-rich thick stripes, and V4-projecting neurons were in both cytochrome oxidase-rich thin stripes and interstripes regions. Most of the PO-projecting neurons were found in the thick stripes, but they were also found in thin stripes and in the interstripe regions. PO-projecting neurons were occasionally intermingled with those from MT and V4. The results indicate that three distinct visual pathways arise from different sets of modules in V2. CORTICAL CONNECTIONS OF INFEROTEMPORAL AREA CITV OF MACAQUE MONKEYS. E. McClendon* and D.J. Felleman. Dept. of Neurobiology and Anatomy, Univ. of Texas Med. School, Houston, TX 77030.

Area CITv was first identified as one of the four projection zones of V4 in inferotemporal cortex (IT). To compare the connections of CITv to previously studied connections of PITv (Felleman and McClendon, '91), and to investigate further the organization of anterior IT, we examined the distribution and laminar patterns of labeled cells and/or terminals following injections of neuroanatomical tracers into CITv and PITv in 5 hemispheres. The distribution of callosal projecting neurons and/or myeloarchitecture served as an independent reference for various areal borders. In 2 monkeys, paired CITv injections of nuclear yellow (NY) and bisbenzamide (BB) produced multiple patches of labeled cells in layer 3 of areas V4 and VOT, and in layers 3 and 5 of areas PITv and PITd. A complementary injection of ³H-proline into CITv yielded robust bilaminar terminations indicative of clear feedback projections in areas V4, VOT, and PITv, and weak terminations in area PITd. Dense reciprocal connections were observed between area CITv and several projection zones within anteroventral IT and temporal polar cortex, while weaker connections were observed to anterior IT within the STS. Paired PITv injections of NY and BB produced multiple clusters of cells in areas V4 and VOT, and in contrast to CITv injections, also labeled cells in areas V3A, V4t, VTF, and TH. PITv connections with anterior IT were less robust and were more restricted to posterior regions of anterior IT than the CITv projections. These data reinforce our views of hierarchical processing within the inferotemporal cortex and suggest the presence of multiple subdivisions within the anteroventral portion of IT. INTRINSIC CONNECTIONS IN THE MACAQUE INFEROTEMPORAL CORTEX: ANATOMICAL SUBSTRATE FOR FUNCTIONAL COLUMNS. I. Fujita^{1,2} and T. Fujita², ¹PRESTO, Research Development Corporation of Japan, and ²Laboratory for Neural Information Processing, Frontier Research Program, RIKEN, Wako, Saitama 351-01, Japan

Neurons in area TE of the monkey inferotemporal cortex are arranged into columns according to visual features of objects to which they respond (Fujita et al., *Nature*, 360:343-346, 1992). Multiple columns appear to be selective for similar object features, because 2 or 3 separate clusters of cells respond to similar stimuli along a tangential recording penetration. To explore anatomical substrate for this organization, we made extracellular iontophoretic injections of biocytin into area TE of Japanese macaques.

After injections into single or restricted layers (2-3, 3-4, 4, 5 or 6), most retrogradely labeled cells were found above or below the injection site to make a columnar appearance. Labeled cells were distributed through layers 2-6, except that those after layer 6 injection avoided layer 4. In addition to this radial labeling, a smaller number of cells were labeled lateral to the injection site, especially in layers 2 and 3. These cells, mostly pyramidal type, tend to cluster within terminal arbors of axons which radiated horizontally from the injection site.

A single injection produced more than 15 patches of terminal arbors in successful cases. The diameter of the patches was 0.5±0.2 mm (range: 0.3-0.9 mm). The mean center-to-center distance between adjacent patches was 0.7 mm (range: 0.5-1.8 mm). The distribution of the patches around the injection site was elongated in a direction parallel to the superior temporal sulcus.

Strong vertical connections between layers may contribute to the shared stimulus selectivity within a column. The results show that intrinsic horizontal axons in area TE arborize in a clustered manner as in the striate and prestriate cortices. Size and spacing of the terminal patches are, however, larger than those reported for V1 and V2, and roughly correspond to those of TE cell clusters with similar selectivity measured in physiological studies. We thus suggest that horizontal axons may link columns with similar stimulus selectivity.

397.13

ORGANIZATION OF PROJECTION FROM THE ANTERIOR TE (TEa) TO THE PERIRHINAL (AREAS 35/36) AND FRONTAL CORTICES IN THE MACAQUE MONKEY: PHA-L STUDY. K.S. Saleem*, K. Cheng and K. Tanaka, RIKEN, Wako-shi, Japan.

Area TE of the inferotemporal cortex is located at a latter portion of the ventral visual pathway, which is thought to play a crucial role in visual discrimination and recognition of objects. We previously reported that single site in TEo projects to several focal columnar regions in TE (Soc Neurosci Abstr, 1992; Vol 18, p 294). In the present study, we analyzed how the output of TE to perirhinal and frontal cortices is organized. We made a single iontophoretic injection of PHA-L into the ventral part of the anterior TE (medial bank of armts) in two Japanese monkeys (*M. fuscata*). The injection sites were 0.7 mm in width and involved layers 2-6.

Projection to the lateral part of the perirhinal cortex (area 36) was restricted to several (4-7) focal regions. The clustering of labeled terminals extended through all the cortical layers in these foci, although terminals were denser in layers I-IV. These foci measured 0.3-0.9 mm mediolaterally, and 0.5-2.2 mm anteroposteriorly. The space between neighboring foci was up to 3.3 mm, and the foci were distributed over a large part of area 36. Projection to the medial part of the perirhinal cortex (area 35) was more distributed. The labeled terminals were denser in the upper layers and were distributed continuously through most of the mediolateral extent of the area 35.

Projection to the prefrontal cortex was directed to the basoventral prefrontal area (area 11) in the medial and lateral bank of the medial orbital sulcus, as others reported previously using HRP. The terminals were restricted to one focal region in one case and 3 foci in the other case. The foci were 0.2-0.4 mm in diameter, and separated by 1.5-1.6 mm in the second case. The terminals were mostly limited to layers I-III.

These different organizations of projections from anterior TE to areas 36, 35, and 11 may suggest that the information from TE is used in different ways in these target regions.

397.10

INTRINSIC CONNECTIONS OF ROSTRAL INFERIOR TEMPORAL CORTEX IN SQUIRREL MONKEYS. R. E. Weller* and G. E. Steele. Dept. of Psychology, Univ. of Alabama at Birmingham, Birmingham, AL, 35294.

On the basis of cortical and subcortical connections, rostral inferior temporal cortex (ITR) of squirrel monkeys may be homologous to anterior inferotemporal cortex (IT) or area TE (TEa) of macaques, an area important in visual recognition and memory. Neurons in TE are unusual in possessing large receptive fields and complex stimulus selectivities. The present study examined the intrinsic connections of ITR of squirrel monkeys (genus *Saimiri*), following pressure injections of wheat germ agglutinin conjugated to horseradish peroxidase (WGA-HRP) or iontophoretic injections of biocytin in ITR.

Injections of WGA-HRP in ITR resulted in an irregular distribution of surrounding label that sometimes formed patches. Anterograde label was more extensive than retrograde, and was most extensive in layer I. Reconstruction of axons individually labeled by the biocytin injections revealed that axons exhibited en passant boutons that included all layers of cortex. Individual axonal terminal fields ranged from 400-600 microns in areal extent, or were not particularly widespread. Patterns of intrinsic connections in ITR of squirrel monkeys thus appear similar, in general, to those reported for other areas of visual cortex in primates.

NEUROCHEMICAL GRADIENT ALONG THE VENTRAL VISUAL PATHWAY IN THE MACAQUE MONKEY: CALBINDIN POSITIVE PYRAMIDAL NEURONS IN LAYERS II AND III OF AREAS TE, TG, AND 35/36. H. Kondo¹, T. Hashikawa¹, K. Tanaka¹, and E.G. Jones^{1,2}, ¹RIKEN, Wako, Japan and ²Univ. California, Irvine, USA.

V1, V2, V4, TEo, and TE compose a serial chain called the ventral visual pathway. This pathway is thought to be essential for object vision, and the receptive fields become larger and the complexity of stimulus selectivity increases towards the anterior. TE projects to areas 35/36 and TG, which in turn project to the hippocampus via area 28. To obtain clues to the relative roles of the different areas in this serial pathway, we compared neurochemical properties among the areas. Three Japanese monkeys (*M. fuscata*) were used. Sections were cut parallel to the superior temporal sulcus so that all the areas of interest were contained within single sections. They were stained immunocytochemically for calcium-binding proteins; calbindin (CB), parvalbumin (PV), and calretinin, as well as for GABA and with SMI32. Remarkable regional differences were found in CB and PV immunoreactivity. In sections stained for CB, besides densely stained nonpyramidal neurons, there were more lightly but definitely stained pyramidal neurons in the anterior areas. Their number gradually increased from V1 to TE, and was also large in 35/36 and TG. These CB immunoreactive pyramidal neurons were mostly confined to layers II and III. Similar CB immunoreactive pyramidal neurons were also dense in area 28 and the hippocampus. The number of CB immunoreactive nonpyramidal neurons was relatively constant from V1 to TE. PV immunoreactive neurons were all nonpyramidal. Their number was rather constant from V1 to TE, but with fewer in area 35/36. The density of neuropil stained for PV gradually decreased from V1 to TG and 35/36.

The CB immunoreactive pyramidal neurons in layers II and III, which were predominant in the anterior areas, may play a crucial role in integration of information or memory.

397.14

PHA-L STUDY OF THE SUBCORTICAL PROJECTIONS OF THE MACAQUE INFEROTEMPORAL CORTEX. K. Cheng*, K.S. Saleem and K. Tanaka, RIKEN, Wako, Japan.

Area TE of the inferotemporal cortex is a latter stage of the ventral visual pathway, which is essential for discriminating and recognizing visual images of objects. Previous studies have demonstrated global structures of the connections from TE to the subcortical areas. Especially, some degree of topography has been shown for projections from TE to the striatum and the amygdala. To analyze the detailed organization of these projections, single focal PHA-L injection was made iontophoretically into the ventral part of TEa (medial bank of the anterior middle temporal sulcus; 2 cases), TEp (1 case) and TEo (1 case) in Japanese monkeys (*M. fuscata*). The size of injection sites was 0.7-1.0 mm in diameter. The injections involved layers 2 to 6.

After injections into TEa and TEp, labeled terminals were mainly found in the tail of the caudate and its adjacent ventrolateral part of the putamen, whereas sparse labeling was observed only in the tail of the caudate after TEo injection. Injections into TEa, TEp, and TEo gave rise to labelings at different rostrocaudal levels in the tail of the caudate, which were topographically arranged. In particular, these labelings were more restricted in the anterior-to-posterior plane (TEa: 2.5mm; TEp: 2.8mm; TEo: 0.5mm) compared to labelings in the previous studies based on mass injections in TE. However, in the two TEa cases, the mediolateral (1.5 and 1.6 mm) and dorsoventral (3.1 and 3.5 mm) extents were comparably close to those described previously. Thus, the projection is not organized in a point-to-point, but a considerably distributed fashion. The divergent termination pattern was also revealed by serially reconstructed single axons (n=4). A single axon branched upon arriving in the striatum, and often terminated in a number of arbors (6-10), which was more than that in the corticocortical projections (2-4). The size of arbors typically measured 200-300µm in diameter. In addition to terminating in the striatum, some axons also sent collaterals to the lateral nucleus of the amygdala, and formed arbors there similar to those in the striatum.

TRANSIENT INPUTS TO INFERIOR TEMPORAL CORTEX IN INFANT MACAQUES. H.R. Rodman*, K.L. Nace, T. M. Woods, C.G. Gross, and N. S. Hebbmann. Dept. Psychology, Princeton Univ., Princeton NJ 08544.

Inferior temporal (IT) cortex is a "high-order" visual area involved in pattern perception and recognition in adult primates. We previously reported (Rodman et al., *ARVO Abs.*, 1990) that the pattern of inputs to IT from posterior, visual cortical regions is adult-like at 7-18 weeks, an age range we have also studied physiologically. Here we report apparently transient inputs from more anterior cortical zones at the same ages. Injections of the retrograde tracers WGA-HRP or cholera toxin B-subunit (CTB) were made in *M. fascicularis* at 6-7 weeks (n=3), 13-18 weeks (n=3) or in adulthood (n=2). 1) Projections from lateral and ventral frontal cortex (areas 46 and 12) derived from both hemispheres at 6-7 weeks, but only from ipsilateral areas in older animals. 2) Substantial inputs from the ipsilateral insula were seen in all infants but one of the 18 week olds and not in adults. 3) Label was found in ipsilateral cingulate cortex in WGA-HRP infant cases, but not in the smaller CTB injection cases in infants or adults; cingulate label was also seen contralaterally in the 7 week WGA-HRP case. 4) At 6-7 weeks, a small but significant number of labeled cells was observed in infragranular layers of contralateral IT, as well as the heavy label in supragranular layers also seen in older infants and adults. More widespread inputs to IT from contralateral cortices in infant monkeys, including the deep layer projection from contralateral IT, may reflect the development of connectivity needed for large bilateral receptive fields in IT and behaviorally for perceptual equivalence of objects in the two visual half-fields. More generally, the data suggest that development of mature patterns of connectivity between IT and cortical areas that are not primarily visual in function may be important in the emergence of IT's role in pattern recognition.

397.17

CORTICOSTRIATAL PROJECTIONS OF THE PRESTRIATE REGIONS IN RHESUS MONKEYS. E.H. Yeterian* and D.N. Pandya. Dept. of Psychology, Colby College, Waterville, ME 04901, E.N.R.M. V.A.M.C., Bedford, MA 01730, and Boston University School of Medicine.

In 18 animals, radioactively labeled amino acids were injected into various subdivisions of the prestriate cortex. The results show that the ventrolateral prestriate and caudal inferotemporal regions project preferentially to the ventral portion of the body, to the genu, and to the lateral portion of the tail of the caudate nucleus, and also to the caudoventral portion of the putamen. The projection from the caudal bank of the superior temporal sulcus (area MT) is directed mainly to the central and lateral sector of the body of the caudate nucleus, to the genu and the tail, as well as to the caudal portion of the putamen. In contrast, the dorsolateral prestriate region is related strongly to the dorsal and lateral portions of the head and the body, and to the genu of the caudate nucleus, as well as to the dorsal sector of the putamen. The medial prestriate region, like the dorsolateral areas, projects predominantly to the dorsolateral sector of the head and the body of the caudate nucleus, and to the dorsal portions of the genu and of the putamen. The ventromedial prestriate cortex is connected to the dorsal portions of the head and the body of the caudate nucleus and of the putamen, as well as to the genu and to the lateral sector of the tail. Thus, it seems that the ventrolateral prestriate and caudal inferotemporal regions subserving central or object vision have a differential distribution of corticostriatal connections compared to dorsolateral, dorsomedial, and ventromedial regions that are involved in peripheral or spatial visual processes. (Supported by the Dept. of Veterans Affairs, NIH grant 16841, and Colby Coll. grant 01 2203.)

PHYSIOLOGICAL AND CONNECTIONAL EVIDENCE FOR FUNCTIONAL SUBDIVISIONS IN POSTERIOR CINGULATE CORTEX OF THE RHESUS MONKEY. S.Y. Musil*, M. K. Smith, & C.R. Olson. Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD 20892, and Department of Anatomy, University of Maryland at Baltimore, Baltimore, MD 21201.

Neurons in posterior cingulate cortex (CGp) of the rhesus monkey carry signals related to recent eye movements and current eye position and they respond to physically salient visual stimuli. In the experiments described here, we have explored the distribution within CGp of neurons carrying oculomotor and visual signals and have correlated their location with patterns of connectional topography.

We have analyzed the efferent connections of CGp by placing deposits of multiple distinguishable retrograde tracers in distant cortical areas (area 7a, area 7b and prefrontal area 9). We have found that neurons projecting to these areas are concentrated in distinct subregions of CGp. Neurons projecting to area 7a are most numerous caudally; those projecting to area 9 are concentrated at ventral levels; and those projecting to area 7b tend to be located rostrally and dorsally.

We have compared the distribution of physiologically characterized neurons to subdivisions defined by efferent connectivity in three monkeys. We have found that neurons with oculomotor, and especially those with visual, properties are located at caudal levels where connections with area 7a are predominant.

397.16

TRANSIENT SUBCORTICAL CONNECTIONS OF INFERIOR TEMPORAL CORTEX IN INFANT RHESUS MONKEYS. M.J. Webster*, J. Bachevalier¹ and L.G. Ungerleider. Lab. Neuropsychol., NIMH, NIH, Bethesda, MD 20854 & ¹Dept. Neurobiol. & Anat., Univ. Texas Medical School, Houston, TX 77025.

Previously we reported transient projections in infant monkeys from inferior temporal (IT) cortex to several medial temporal-lobe regions, including those from posterior IT cortex (area TEO) to the amygdala and parahippocampal cortex and from anterior IT cortex (area TE) to perirhinal and parahippocampal cortex (Webster et al., *J. Neurosci.*, 1991, 11:1095). Here we report that the projections of IT cortex to subcortical structures are similar in infant and adult monkeys, but some appear to undergo refinement during development. Quantitative analyses showed that: 1) whereas the projection from TE to the superior colliculus is consistent (5/5 cases) and widespread in infants, it is unreliable (2/7 cases) and limited in areal extent in adults; 2) although the projections from TE to n. medialis dorsalis and the tail of the caudate are present in infants and adults, they are reduced in adults; 3) there appears to be a projection from TE to n. paracentralis in infants (2/5 cases), but it is absent in adults (0/7 cases); and 4) TEO receives input from the dLGN in both infants and adults, but the number of cells giving rise to this projection is fewer in adults. No such differences between infants and adults were apparent in a number of other subcortical projections, including those to the pulvinar, reticular nucleus, claustrum, and putamen.

397.18

PARVALBUMIN STAINING DELINEATES SUPERIOR TEMPORAL POLYMODAL CORTEX IN MACACA MULATTA. B. Seltzer*, M. Cola, C. Weldon, M. Masee, and C.G. Cusick. Depts. of Psychiatry & Neurology and Anatomy, Tulane Univ. Sch. of Med., V.A. Med. Ctr., New Orleans, LA 70112.

Thalamic areas staining heavily for parvalbumin (PVA) project to layer IV of the cerebral cortex so that PVA fiber plexuses reflect the thalamic input to a given cortical region (DeFelipe and Jones, '91). To examine this aspect of cortical organization within the superior temporal sulcus (STS), and relate it to cortical connections, we performed PVA staining on hemispheres in which injections of 1 or more anterograde tracers had been made into cortical areas that project to the STS.

Cortex in the caudal upper bank of the STS, at the level of area MT, exhibits marked depletion of PVA staining in layer IV compared to adjacent cortices of the temporal lobe. At the level of primary auditory cortex, the upper bank has a lateral division, with poor layer IV staining, and a medial, where layer IV is better demarcated. All 3 zones are the targets of overlapping and nonoverlapping input from prearcuate cortex, the superior temporal gyrus, inferior parietal lobule, and intraparietal sulcus, thus identifying the caudal sector as "caudal area TPO," the lateral zone as "mid TPO," and the medial zone as "area PGa" (Seltzer and Pandya, '89). The medial pulvinar, which connects with area TPO (Yeterian and Pandya, '91), also stains lightly for PVA.

Supported by the V.A., N.I.H. grant EYO8906, and Tulane University.

397.20

Occipital Projections to the Cingulate Motor Cortex from the Anterior Calcarine Region in the Rhesus Monkey: Evidence for Direct Prostriate and Parastriate Input to M3 (Area 24c). R.J. Morecraft*, K.S. Rockland* and G.W. Van Hoesen^{2,3}. Dept. of Anatomy and Structural Biology¹, Univ. of South Dakota, Vermillion, SD 57069 and Depts. of Anatomy² and Neurology³, Univ. of Iowa, Iowa City, IA. 52242

It has long been assumed that the organization of medial visual cortex connectivity is similar to the well-established organization of the lateral visual cortex. However, little information is available to support this supposition.

As part of an investigation on the connectivity of cortex forming the depths and lower bank of the cingulate sulcus, we observed direct projections to the cingulate motor cortex (M3 or area 24c) arising from the anterior part of the calcarine fissure. These findings were based on injections of retrogradely transported fluorescent dyes in 5 rhesus monkeys. Correlation of labeled fields with Nissl, myelin, acetylcholinesterase, and cytochrome oxidase stained sections demonstrated that the labeled cortex in the anterior calcarine fissure corresponded to a portion of V2 that adjoins the anterior part of V1 and to Sanides' area prostriata. Prostriate cortex is anterior to V1 and also adjoins the posterior parasubiculum. In V2, labeling occurred in layer 3 and spanned a distance of 0.1 mm in a rostrocaudal direction and 2 mm in a dorsoventral direction. Within area prostriata, labeled neurons occurred in layers 3 and 5/6, spanning a distance of 3.5 mm in a rostrocaudal direction and 2 mm in a dorsoventral direction. The heaviest distribution of labeling occupied the deep laminae. V2 and prostriate cortex did not project to area 23c, but only to M3.

These results document an unexpected, direct linkage from medial visual cortex to cortex which gives rise to corticospinal axons. This projection may originate from areas subserving the peripheral visual field and be involved in photic detection. (Support by NS 14944 and PO NS 19632, EY 07058).

PROGRESSIVE CHANGES IN SYNAPTIC BOUTON ORGANIZATION IN THE VISUAL CORTEX: FROM RAT TO HUMAN. G. Kenan-Vaknin*, O. Varlamov, G.E. Ouaknine, N. Razon, Z. Rappaport, R. Malach. Neurobiology Department, Weizmann Institute, Rehovot, 76100, Tel-Aviv and Beilinson Medical Centers, Israel.

What characterizes the progressive elaboration of cortical circuitry in different mammalian species? To begin addressing this question, the density and distribution of synaptic boutons on biocytin-labeled axon collaterals of layers II-III neurons in rat, cat, monkey and human were studied. A total of 2700 boutons in 93 axons were quantitatively analyzed. Two bouton populations were studied: axonal varicosities and bouton-bearing stalks. Moving from rats to humans, the incidence of stalks increased progressively from 9.1% in the rat through 49% (cat), 93% (macaque) and 93.5% (human). Average inter-bouton interval also showed progressive increase from $4.2\mu\text{m} \pm 2.5$ (±S.D) in the rat to 10.8 ± 8.4 , 11.7 ± 6.9 , 16 ± 12.2 in cat, monkey and human respectively. The size of the most frequent inter-bouton interval appears more stable, ranging from 2-4 μm in the rat to 4-6 μm in humans. These results may help define the significant parameters for high level information processing in cortical circuits.

DISSOCIATIONS AND LOCALIZATION OF MOTION PERCEPTION AND PURSUIT AFTER HUMAN CEREBRAL HEMISPHERIC LESIONS. J.L.S.Barton, J.A.Sharpe*, J.Raymond. Division of Neurology, University of Toronto, Toronto, Ontario, Canada M5T 2S8, and Department of Psychology, University of Calgary, Calgary, Alberta, Canada.

We investigated motion perception and pursuit in 20 patients and correlated defects with lesion sites on CT or MRI. We hypothesized that abnormal pursuit could occur with normal motion perception but abnormal motion perception would always impair pursuit. We tested motion perception with random dot cinematograms, using a staircase method that varied directional coherence of motion to determine a coherence perceptual threshold. We obtained foveal thresholds for the four cardinal directions separately and we tested 16 points in the peripheral field while monitoring fixation. Smooth pursuit gain was measured to predictable sinusoidal targets to find directional defects and during pursuit initiation to step-ramp targets to find retinotopic defects. We compared directional and retinotopic symmetry in perceptual and motor tasks to those of normal controls.

Six patients had directional asymmetries of motion perception, all worse for motion towards the side of their lesions: 5 of the 6 had symmetric smooth pursuit. Five had hemianopias which excluded retinotopic testing. The overlap region for the directional motion perception defect was the junction of Brodmann areas 19 and 37. Three other subjects with parietal and internal capsular lesions had ipsidirectional pursuit defects despite symmetric motion perception. We did not find any retinotopic defects. Since lesions in monkey MT/MST cause similar defects, we conclude that the 19/37 area may be the human homologue of MT, MST or their inputs. A double dissociation exists between smooth pursuit and perception of coherent motion.

ATTENTIONAL MODULATION OF NEURONAL RESPONSES IN MT AND MST OF A MACAQUE MONKEY PERFORMING A VISUAL DISCRIMINATION TASK. G. H. Recanzone*, R. H. Wurtz, and U. Schwarz. Laboratory of Sensorimotor Research, National Eye Institute, Bethesda, MD, USA 20892.

The primate visual system has been proposed to be comprised of a ventral, shape and color processing pathway and a dorsal location and motion processing pathway. We examined the responses of single neurons in the dorsal pathway (areas MT and MST) in a behaving Rhesus monkey that was trained to discriminate either the location or the shape of two moving visual stimuli.

All stimuli were $2 \times 2^\circ$ shapes projected onto a tangent screen by a video projector. The monkey was trained to fixate a lone stimulus, then to visually track a target which was one of two extrafoveal moving stimuli that appeared after 300-800 msec. One stimulus was always inside the receptive field (RF) of the neuron under study and the other was in the opposite visual hemifield. In the location task, before the start of each trial a stimulus was briefly presented in the location at which the target stimulus would appear. In the shape task, the shape of the fixation stimulus matched one of the two extraretinal stimuli (the target), but no location cue was given. Neuronal responses were compared between trials with identical visual stimuli in the RF of the studied neuron when the target was inside vs. outside of the RF.

In area MT, the response of approximately 3/4 of the neurons was modulated for stimuli moving in at least 1 of 8 directions in the location task, as was the response of nearly 9/10 of the neurons in the shape task. Of these, approximately 2/3 had a decreased response when the target was inside the RF. Similar changes were observed in MST for the location task. In both areas, the spontaneous activity of approximately 3/4 of the cells was also modulated in the location task. We conclude that attention to a visual stimulus can modulate the responses of neurons in the dorsal pathway for both location and shape-discrimination tasks.

CORTICAL REGION RELATED TO VISUAL MOTION PERCEPTION IN HUMAN SUBJECTS. Y. Nakamura, K. Ohtsuka*, H. Maekawa, M. Kiyosawa, T. Kawasaki, and K. Ishii. Dept. of Ophthalmology, Sapporo Medical Univ. and Tokyo Medical and Dental Univ., Dept. of Radiology, Tokyo Metropolitan Medical Research Institute, Sapporo 060, Japan

Previous studies indicated that the MT of the monkey is related to the visual motion perception. In the present experiment, we investigated the cortical region related to the visual motion perception in human subjects. Transcranial magnetic stimulation (TMS) in healthy human subjects can produce transient visual motion sensation or specific reversible defects of visual motion perception. Single TMS pulses were applied systematically at various locations over the occipital, parietal and temporal cortex using a magnetic stimulator with an 8 shaped coil at an intensity of 1.5 Tesla. We identified the location where visual motion sensation is elicited in two subjects. At the same location TMS degraded motion direction detection of random dot stimuli. The effective area was marked on the head by a vitamin-D tablet which produces high signal intensity on T1 images of MRI. We made 3-D MRI of the brain in each subject. In addition, we also used positron emission tomography (PET). Images of regional cerebral blood flow were obtained by using intravenous infusions of H_2^{15}O . The subjects viewed computer displays of moving or static random dot patterns. We coregistered statistical parametric maps (SPMs) of PET onto the respective MRI. It was located ventrolaterally in the anterior part of the occipital lobe.

Modulation of visual and non-visual neuronal responses in area MT and MST by monkeys behavior in a direction discrimination task

A.Thiele*, A.Wachnowski, K.-P.Hoffmann, Dept. Neurobiol., Ruhr-University Bochum, D-4630 Bochum, Germany

Area MT and MST contain direction selective cells and MT neurons are essential for direction discrimination near threshold (Newsome et al.1990, Komatsu and Wurtz 1988). To investigate whether the monkeys behavior is influenced by responses of neurons in area MT and MST or vice versa, the monkey had to perform a peripheral detection task while fixating a central target. Unidirectional moving bars (4 directions) were presented in the receptive field near contrast threshold (5 luminances) with randomly varying onset. Detected or guessed movement directions were indicated by arm movements (4 touch bars), whereafter fixation and stimulus presentation were continued for another 500 ms.

In area MT 44/56 neurons responded to stimulus presentation. This response was reduced in 17/44 neurons following the monkeys decision. The response of 89/165 MST neurons was related to stimulus presentation (visual neurons). 35/89 of these MST neurons changed their activity with the monkeys behavior. 26/165 MST neurons were characterized as non-visual neurons. Their activity was only related to the monkeys behavior. 13 of these neurons started to fire after the monkeys behavior. Another 13 cells were active before (100-0ms) or during the arm movement of the monkey.

The modulation of the visual response in MT and MST seems to be an attentional effect. The activity of non-visual cells in MST could be induced by higher cortical areas related to the decision or arm movements of the monkey. Supported by DFG Neurovision

PURSUIT EYE MOVEMENTS, OPTIC FLOW, AND VISUAL CORTEX: A NETWORK MODEL OF HEADING DETECTION. M. Lappe*, Dept. Zoology & Neurobiology, Ruhr University Bochum, D-44780 Bochum, Germany

Humans are able to recover their direction of heading from optic flow during ego-motion even in the presence of eye movements. While often the retinal flow pattern alone seems sufficient to perform this task, some situations also require extraretinal information. A recently proposed, purely visual, neural network model (Lappe and Rauschecker, *Neural Computation* 5, 1993) accounts for results of human psychophysics and generates neurons that exhibit selectivities to expanding, rotating and translating random dot patterns, similar to a class of cells found in monkey visual area MSTd. However, MSTd appears to also contain nonvisual information: Visual tracking neurons are active during smooth pursuit even in the absence of visual stimulation. The present work extends the model to include extraretinal eye movement information. The network starts out with a layer of direction selective neurons, modelled after area MT and assumed to contain a population encoding of the optic flow field. In a second layer the direction of heading is recovered by populations of neurons with selectivities for various optic flow patterns, resembling cells in MSTd. In addition, a population of tracking neurons independently provides the second layer cells with the direction of an eye movement. Eye speed, on the other hand, is available only with a variable gain factor. Zero gain amounts to no extraretinal input at all.

While the network is usually able to detect the direction of heading without the need for extraretinal information, it reproduces a characteristic deficiency of humans when being subject to a self-movement towards a vertical plane: Heading direction is correctly recovered only as long as the eye movement input is present. Without extraretinal information the network yields large errors by erroneously choosing the direction towards the fixation point. Reliable eye speed information, however, is not required. Instead, the network performs even better with imperfect gain that is smaller than one. Simulations of single neurons of the second layer reveal a behavior also described for MSTd: Neurons respond directionally selective to translating visual stimuli, but fail to respond to retinal image motions generated by an eye movement, i.e. they discriminate between active, self-induced and passive, real-world motion.

CUE-DEPENDENT DEFICITS IN CONTOUR ORIENTATION DISCRIMINATION AFTER V4 LESIONS. L.G. Ungerleider*, P. De Weerd, M. Mishkin & R. Desimone. Laboratory of Neuropsychology, NIMH, NIH, Bethesda, MD 20892.

We investigated the effects of V4 lesions involving one quadrant of the visual field on orientation discrimination in two fixating rhesus monkeys using low frequency, phase-randomized gratings. The gratings were defined by luminance, color, texture or occlusion cues. The texture gratings consisted of either a 90-degree orientation difference between the line elements of adjacent texture patches or by a size difference between random dots. The occlusion-defined grating (illusory contour) consisted of opposing line segments of matched orientation but shifted in phase. Relative to orientation thresholds in control quadrants, there was a 104% increase in thresholds in the lesion quadrant for the texture- and occlusion-defined gratings, but only a 35% increase for the color- and luminance-defined gratings. Control experiments showed that the greater deficits with texture gratings and illusory contours were caused neither by reduced acuity nor by differences in difficulty among perceptual tasks. These results demonstrate a role for V4 in the processing of second-order boundaries, and open the possibility that neuronal responses to such boundaries previously described in areas V1 and V2 might be due in part to feedback from area V4.

RESPONSES OF MONKEY LOCUS COERULEUS (LC) NEURONS TO CS+ STIMULI REFLECT COGNITIVE PROCESSING: DELAYED ACTIVITY DURING ACQUISITION IN A VIGILANCE TASK. P. Kubiak*, J. Rajkowski and G. Aston-Jones. Div. Behavioral Neurobiol., Dept. Mental Health Sci., Hahnemann University, Philadelphia, PA 19102.

LC neurons respond preferentially to CS+ stimuli in a vigilance task (Aston-Jones et al., *Prog. Brain Res.* 88: 501, 1991). Here we report the effect of reversal training on such LC responses.

Two cynomolgus monkeys were overtrained in a vigilance task with vertical and horizontal bars on a video display as CS+ or CS-. The animal was required to release a pedal shortly after presentation of infrequent CS+ stimuli (10-20% of trials) to receive juice reward, and withhold responding to CS- stimuli. Upon reaching criterion (< 10% errors) stimulus meaning was reversed. Acquisition of this new task was followed by re-reversal, etc. Monkeys more rapidly acquired reversal with continued reversal training. LC responses became selectively driven by the new CS+ stimuli in parallel with behavioral acquisition of the new response contingency. However, LC and behavioral responses (pedal release latency and cue directed gaze) were markedly prolonged (+0.2 s) during reversal acquisition. Improvements in task performance were accompanied by shorter response latencies of LC neurons. However, the delay in LC and pedal responses to target stimuli persisted for many trials after criterion performance was re-established. Prolonged processing of cues during reversal acquisition may be responsible for the delays in behavioral and neural activities. These results indicate that recognition of target stimuli results in phasic activation of LC cells during a vigilance task, and that such LC responses are more cognitively- than sensorially-driven. COLOUR CONSTANCY IN V4 MONKEYS, NORMAL MONKEYS AND HUMAN OBSERVERS. Y. Walsh*, J.J. Kulikowski, S.R. Butler & D. Carden Dept Exp Psychol, Oxford Uni, Oxford OX1 3UD, UK & Visual Sciences Lab, UMIST, Manchester, M60 1QD, UK.

Colour constancy is the ability to identify a surface colour despite changes in the spectral content of the illuminant, the location of the surface and the angle from which the surface is viewed. We tested three groups of subjects (humans, normal macaque monkeys and monkeys with lesions of visual area V4) for the ability to identify surface colours when only the spectral content of the illuminant was changed. The human subjects were shown a coloured patch under one illuminant and asked to select the patch under a different illuminant from an array of distractors. The monkeys were required to select a particular coloured patch for a food reward in a WGTA testing apparatus. Human subjects showed good but not perfect colour constancy. They showed a tendency to select patches that belonged to the same perceptual colour category as the target item. Normal monkeys also showed good constancy. Monkeys with V4 lesions, however, did show a deficit in colour constancy, sometimes selecting a colour from a different colour category. The size of the errors was much greater than, and thus cannot be explained by, the limits of the animals' wavelength discrimination abilities. Analysis of the human data suggests that colour constancy, like colour memory, is organized within fundamental perceptual colour categories. It is argued that while monkeys with V4 lesions have access to the categorical information, they cannot correct for changes in the viewing conditions to maintain the stability of these categories.

EFFECTS OF FOCAL ATTENTION ON RECEPTIVE FIELD PROFILES IN AREA V4. C.E. Connor*, J.L. Gallant and D.C. VanEssen. Dept. of Anatomy and Neurobiology, Washington University School of Medicine, St. Louis, MO 63110.

Moran and Desimone (1985) demonstrated that stimulus-evoked responses of cells in areas V4 and IT of macaque cortex are diminished when attention is focused on a second, ineffective stimulus inside the classical receptive field (CRF). This effect was interpreted as a shrinkage of the receptive field around the attended stimulus. We undertook to measure changes in V4 receptive field profiles as a function of the position of focal attention relative to the CRF. The attentional focus was manipulated by altering the position of a behaviorally relevant ring-shaped stimulus. Concurrently, a behaviorally irrelevant optimal bar stimulus was used to map the receptive field of the cell under study. The ring stimuli were part of a serial size discrimination task. Each ring was flashed briefly, and after a 100 msec delay a bar stimulus was flashed at one of a range of positions inside and outside the CRF.

Shifts of attention produced alterations in receptive field profiles for over half the cells studied. In most cases the receptive field center of gravity translated towards attentional foci in or near the CRF. Changes in width and shape of the receptive field profile were also observed, but responsive regions were not typically limited to the location of the attended ring stimulus. Attention-related effects often included enhanced responses at certain locations as well as diminished responses at other locations. These observations impose significant constraints on models of focal attention.

CORRELATIONS BETWEEN LOCUS COERULEUS (LC) NEURAL ACTIVITY, PUPIL DIAMETER AND BEHAVIOR IN MONKEY SUPPORT A ROLE OF LC IN ATTENTION. J. Rajkowski*, P. Kubiak and G. Aston-Jones. Div. Behav. Neurobiol., Dept. Mental Health Sci., Hahnemann Univ., Philadelphia, PA 19102.

We reported that during prolonged recording sessions (0.5 to 2 hours) in a vigilance task LC neurons varied tonic discharge rates in close relation to varying levels in task performance, e.g., as indicated by foveations to initiate trials (*Abst. Soc. Neurosci.* 18:538, 1992). Here we report that other experimental variables indicative of changing levels of attentiveness are also closely related to LC tonic activity.

Several eye-related signals (eye movements, eye blinks, pupil diameter; ISCAN video eye tracking system), along with task codes and discharges of individual LC neurons, were recorded from 2 cynomolgus monkeys performing a vigilance task. This task required that the animal foveate a spot on a video monitor to initiate each trial, and release the lever within 700 ms of an infrequent visual CS+ (10% of trials). Performance epochs were defined by plotting averaged measures of the signal detection parameters β (decision criterion) and d' (discriminability) in 10 min bins. Periods of good performance (few false alarms and misses = high β and d') were best correlated with epochs of low tonic LC discharge, whereas periods of worst performance, as indicated by frequent false alarms, occurred during elevated LC activity. Pupil diameter also varied throughout the recording session, was directly correlated with the rate of LC tonic discharge, and was consistently smaller during periods of high β and d' . Poor performance was characterized by frequent intertrial bar releases, larger amplitude eye movements and pupillary dilation. It is proposed that high tonic LC activity corresponds to a labile or scanning mode of attention, associated with high autonomic arousal as reflected in pupil diameter. Conversely, focused attention is associated with lower autonomic arousal and moderate LC tonic activity. Supported by AFOSR Grant F49620-93-1-0099.

EFFECT OF STIMULUS TRANSFORMATIONS ON SHORT-TERM MEMORY MECHANISMS IN INFERIOR TEMPORAL CORTEX. A. Lueschow, E.K. Miller and R. Desimone* Lab Neuropsychology, NIMH, Bethesda, MD 20892.

We are typically able to recognize a previously seen object even if it is transformed in size or location on the retina. Thus, a horse is a horse (of course) even if we can also see that it is large or small or that it is present in central or peripheral vision. We sought evidence for a neural basis of this object invariance in recordings from inferior temporal (IT) cortex in two rhesus monkeys. The task was a delayed matching-to-sample task, in which the monkey had to match a test stimulus to a previously seen sample. Several intervening nonmatch stimuli could occur between the sample and final match. The stimuli were digitized pictures of complex objects, such as faces, several of which were tested on each cell. On some trials, the final match stimulus was identical to the sample and on other trials it was larger or smaller or at a different retinal location. The monkeys immediately recognized the transformed object as the same. As was found in previous studies, responses to the test stimuli were a joint function of the current stimulus and the memory trace. For most of these cells, responses to a stimulus that matched the sample were suppressed. These cells also showed suppressed responses to the transformed matching stimuli, although the amount of suppression was often less than if the stimulus was an identical match. Information about both the object and its transformation may therefore be available in the responses of IT neurons.

398.13

DUAL MECHANISMS OF SHORT-TERM MEMORY: VENTRAL PREFRONTAL CORTEX. L. Chelazzi*, E.K. Miller, A. Lueschow, R. Desimone. Lab Neuropsychology, NIMH, Bethesda, MD 20892

In a companion study, we recorded the responses of neurons in inferior temporal (IT) cortex during performance of a short-term memory (STM) task that revealed dual passive and active memory mechanisms. Since prefrontal cortex has also been linked to STM (Wilson et al., 1993; Fuster, 1973) and because its ventral portion (below the principal sulcus) is anatomically connected with IT cortex, we recorded from this ventral region in one rhesus monkey during the same task.

Unlike in IT cortex, the responses of some cells appeared to be related to the monkey's behavioral response. Otherwise, many prefrontal neurons had properties similar to those of IT neurons, including stimulus selective responses and either suppressed or enhanced responses to items that matched the sample. As in IT cortex, the enhanced responses were specific for the stimulus that matched just the sample item, suggesting an active memory mechanism. Further, many prefrontal cells showed either non-specific or sample-selective activity during the delay intervals of the task (delay activity). However, unlike IT cortex, prefrontal delay activity conveyed sample information across intervening stimuli. Thus, delay activity in prefrontal cortex seems to reflect maintenance of the sample in memory. While an intervening stimulus typically interrupted the ongoing delay activity, it quickly recovered in subsequent delay intervals. Some cells showed increasing delay activity with increasing trial length and some did not show any delay activity until after at least one intervening stimulus occurred.

These results suggest that prefrontal neurons participate in actively maintaining a memory trace and that STM is mediated by interactions between prefrontal and IT cortices. Prefrontal neurons may prime certain IT cells to give enhanced responses to stimuli matching the sample memory.

398.15

BEHAVIORAL PERFORMANCE IN PATTERN DISCRIMINATION AND PATTERN SELECTIVITY OF INFERIOR TEMPORAL NEURONS OF MONKEY. J. WATANABE AND A. KITAOKA Dept. of Behav. Physiol. Tokyo Metropol. Inst. Neurosci., Tokyo 183, Japan

We studied a relation between behavioral performance in visual pattern discrimination and neuronal selectivity to patterns in the inferior temporal area, which is thought to be an important center of pattern perception. Monkeys were trained to perform a modified delayed non-matching to sample task, in which a sample pattern was presented on a color CRT for 0.5s with 1s interval repeatedly up to 4 times. On each trial, a stimulus-pair was selected randomly from 8 patterns, which were made up of 4 originals (+, Square, Y, and H) and their rotated figures (x, Diamond, inverted-Y and laid-H). Monkeys responded with a longer reaction time and made more omission errors at square/diamond, +/x, Y/inverted-Y or H/laid-H discrimination, i.e. they had a difficulty in discrimination of rotated patterns. In addition, the performance was poor at +/square, +/diamond, x/square, or x/diamond pairs. A trial with either H or inverted-H was performed with a relatively short reaction time and less omission error.

Single neuronal activity from the inferior temporal area (TEO) of one monkey performing the task was recorded through a chamber attached on a lateral skull with a glass-coated Elgiloy electrode. Of 938 neurons recorded, 242 neurons gave excitatory responses to pattern stimuli: 63 neurons responded to one or two patterns, 131 to three to five patterns, and 84 to six to eight patterns. The neurons preferred H most and laid-H second; this finding might be related to the high behavioral performance at pairs including either H or laid-H. However, our neurophysiological data did not explain the behavioral findings fully.

398.12

DUAL MECHANISMS OF SHORT-TERM MEMORY: INFERIOR TEMPORAL (IT) CORTEX. E.K. Miller* and R. Desimone. Lab Neuropsychology, NIMH, Bethesda, MD 20892.

Consistent with a role in short-term memory (STM), responses of IT neurons are determined jointly by current stimuli and memory traces. Psychological studies suggest multiple components mediating STM and we sought evidence for such mechanisms in IT recordings in two rhesus monkeys. The task was a modified delayed matching-to-sample (DMS) task, in which stimuli could intervene between the sample and match. On some trials (standard trials), the only stimulus that was repeated was the sample/match stimulus. These trials could be solved using a repetition or recency rule. On other trials (ABBA trials), two of the intervening nonmatch stimuli matched each other. On such trials, the monkey had to ignore these "repeated nonmatch" stimuli and respond only to the match. Both monkeys were initially trained using standard trials only. When ABBA trials were first introduced, the monkeys mistakenly responded to the repeated nonmatch, suggesting that they had learned a repetition rule. After training on the ABBA trials, about half the cells responded differently to a stimulus depending on whether or not it matched the sample. Similar to previous studies, a majority showed a suppression of their responses to the match. However, these "suppression" neurons also showed suppression to the repeated nonmatch, even though the monkey had learned not to respond to it. By contrast, the remaining neurons with memory effects showed enhanced responses to only the match. These results suggest that IT cortex contains at least two mechanisms mediating STM: passive suppression that is sensitive to repetition and active enhancement that mediates working memory. The greater incidence of such enhancement effects compared to previous studies suggests that learning the ABBA strategy resulted in a shift from the suppression to the enhancement mechanism.

398.14

EFFECTS OF ADULT LEARNING ON THE STIMULUS SELECTIVITY OF CELLS IN THE INFEROTEMPORAL CORTEX. E. Kobatake*, K. Tanaka, G. Wang & Y. Tamori. RIKEN, Wako-shi, Japan

The anterior part of the macaque inferotemporal cortex (TE), which is situated at a latter stage of the ventral visual pathway, contains cells which selectively respond to various visual object-features. To determine whether the stimulus selectivity changes with changes in the visual environment, two adult Japanese monkeys (*Macaca fuscata*) were trained to discriminate new stimuli: one monkey was trained with a set of shape stimuli and the other with color stimuli. The shape set was composed of 28 shapes made by superimposing 2 or 3 primitive shapes (circles, squares, triangles and bars). The color set was composed of 18 stimuli made by combining 9 colors with two primitive shapes (circle or square). One of the stimuli was presented as the sample, and the monkey was required to select it from among 5 (shape) or 15 (color) stimuli presented together after a delay period (~16s). After reaching a saturated level of performance, the monkeys were overtrained for more than two months, and then recording was begun. During recording, monkeys were anesthetized with N2O and isoflurane and immobilized. For each cell, the most effective object-stimulus was selected from dozens of 3D models of animals and plants, and then the response to the object stimulus was compared with responses to the shape or color stimuli used in the training. Control recordings were made in two monkeys which were not trained with either the shape or the color set. Effects of the shape training were evident. A large number of cells recorded in TE of the trained monkey were most strongly activated by some of the 28 shapes (39% of 44 cells), while such cells were rare (9% of 67 cells) in the untrained monkeys. Effects of the color training were smaller if present. The cells which were most strongly activated by some of the 18 color stimuli comprised 11% of 19 TE cells in the trained monkey and 3% of 67 TE cells in the untrained monkeys. We conclude that the stimulus selectivity of TE cells can be changed by training in the adult. The degree of change, however, depends on the type of stimulus used in the training.

RETRIEVAL OF CONCURRENT VISUAL DISCRIMINATIONS WHILE INFEROTEMPORAL CORTEX IS SUPPRESSED WITH COLD. James A. Horel* and Geoffrey M. Stegner. Anatomy & Cell Biology, & Neuroscience Training Program, SUNY HSC Syracuse, NY 13210

Three *Macaca fascicularis* monkeys were trained on three sets of concurrent 8 visual discriminations and tested for their recall while inferotemporal cortex (IT) was suppressed with cold. Cryodes covered IT from the superior temporal sulcus to the anterior middle temporal sulcus, from the temporal pole to the border of TEO. The two-choice visual discriminations were presented on a computer monitor equipped with a touch screen. Forty eight complex colored images were scanned into the computer from magazine and catalogue illustrations. Touching a correct stimulus produced a food pellet. The discriminations were presented in sets of 8, with 8 pairs presented together, one pair at a time, in random order. The three sets of 8 were presented separately. The animals performed these nearly perfectly without IT suppression, but were significantly impaired during cooling. However, performance on many of the pairs was unaffected, while a few were strongly affected, performance on some pairs was consistently below chance. The pairs that produced the strong deficits varied from animal to animal. Some of the stimuli that were particularly difficult for an animal were removed and run by themselves in concurrent 2 or 4. The animals continued to be impaired on these stimuli for the most part, although not consistently so. When these stimuli were replaced into the set of 8, performance was improved on these, but the impairment shifted to others that had not previously shown an impairment. Since different animals were impaired on different stimuli, and experience with the stimuli could shift the impairment to others that were not impaired, it suggests the impairment relates more to experience with the stimuli than to their particular physical dimensions. (supported by NIH, RO1 NS1829)

THE DIRECTION OF GAZE IN FACE STIMULI LEADS TO A MODIFICATION OF „FACE-RESPONSIVE“ COMPONENTS (P3) IN VISUALLY EVOKED EEG-POTENTIALS. S. Bork, L. Fuhr, O.-J. Grüsser, Margitta Seck (SPON: European Brain and Behaviour Society), Dept. Physiol., Freie Univ., W-1000 Berlin 33 (FRG).

In former studies components of visually evoked EEG-potentials (EPs) related to the presentation of faces were described. In 16 volunteers (8 male, 8 female; 23-31 years) EPs were recorded through the electrodes F3, F4, T5, T6, Cz and Oz with reference to linked mastoids (intern. 10/20 system). 160 slides (4" x 6") were projected onto a white screen. Stimulus change lasted less than 6 ms. Duration of stimulus presentation varied randomly between 2.2 and 4.2 sec.

Four stimulus categories were applied: (1) face and line of sight turned sideways; (2) face directed straight ahead, but line of sight sideways; (3) face turned sideways, but line of sight directed to the viewer; (4) face and line of sight directed to the viewer.

The face-responsive component with a maximum through electrode Cz was confirmed, consisting of a pronounced positive peak (P2) at about 160 ms with a rapidly following negativity. Both of the „dissociated face“ categories (line of sight and face are turned in different directions) led to a slow positive potential between 250 and 400 ms (P3). This potential was most prominent with bipolar recordings Cz-T6 ($p < 0.01$, fig. 1).

ELECTROPHYSIOLOGICAL STUDIES OF FACE RECOGNITION IN HUMAN EXTRASTRIATE CORTEX. T. Allison*, H. Ginter, G. McCarthy, A.C. Nobre, A. Puce, M. Luby, K. McCarthy and D.D. Spencer. Neuropsychology Laboratory, Veterans Administration Medical Center, West Haven, CT 06516 and Depts. of Neurology, Neurosurgery, Biology and Psychology, Yale University, New Haven, CT 06510.

Recognition and identification of faces is a complex but normally effortless task. However, patients with lesions in the temporal-occipital region may lose the ability to recognize familiar faces (family members, famous faces, or their own mirror image), suggesting that a region of visual cortex is specialized for processing of facial information. Here we report the first study of face recognition with recordings made directly from the cortical surface of patients with indwelling electrodes for localization of an epileptogenic region.

Ten patients with a total of 576 electrodes on the inferior and lateral cortical surface viewed a video monitor which at 2 sec intervals displayed unfamiliar faces, scrambled faces (face pixels rearranged to be unrecognizable), cars, scrambled cars, words, and butterflies. Locally generated evoked potentials were recorded simultaneously from 32 or 64 locations, digitized at 250 Hz, and averaged for each stimulus type.

Major results are: 1) Portions of inferior extrastriate cortex respond only to faces with a large-amplitude (100-200 μ V) negativity at about 200 msec. 2) Across subjects, the responsive locations (determined by MRI) include mid to posterior portions of the fusiform and inferior temporal gyri, but in individuals the face-responsive region is small, perhaps 1-3 cm^2 . 3) Similar potentials were recorded from the left and right hemispheres. 4) Other discrete regions of inferior cortex respond to cars or words. 5) Cortical stimulation (5 sec trains, 50 Hz, 2-10 mA) via the same electrodes which recorded face-specific potentials sometimes produced a transient prosopagnosia. These results suggest a remarkable degree of "modularity" in the processing of faces and other categories of complex objects.

FUNCTIONAL BRAIN MRI OF CORTICAL AREAS ACTIVATED BY VISUAL MENTAL IMAGERY. S. Ogawa¹, D.W. Tank¹, B. Menon², J.M. Ellermann², H. Merkle² and K. Ugurbil². ¹AT&T Bell Laboratories, Murray Hill, NJ 07974 and ²U. of Minn. Medical School, Minneapolis, MN 55455

We have used Magnetic Resonance Imaging (MRI) of Blood Oxygenation Level Dependent (BOLD) contrast to provide functional brain maps of cortical areas activated by two mental imagery tasks. Imaging experiments were performed on 10 normal subjects using a Siemens/SIS 4T system (FLASH pulse sequence: 5 sec/image; 40 msec echo time; 1.6x3.3mm in-plane resolution). Areas in the occipital pole were examined along two slice orientations: an oblique plane located along the calcarine fissure and a sagittal plane located 1-2 cm off midline. Areas were defined as activated if the average signal intensity in a pixel during the mental imagery period increased above the average in a control period at the .01 t-test confidence level.

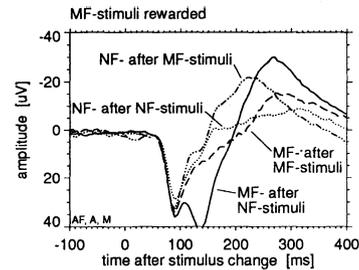

Imagination of simple, static objects from auditory cues produced variable results depending upon the subject. In some subjects, small (~2%), but statistically significant, signal changes were observed in areas of primary visual cortex that were also strongly activated by direct visual stimulation (alternating red/green checkerboard; 8 Hz; ~3 fold larger signal change). However, in many subjects, no signal change was observed that was statistically significant given present signal-to-noise ratios.

An imagery task in which the subject was instructed to mentally navigate through a known complex environment produced activation of a previously uncharacterized, highly localized region in the parietal lobe. The region activated is on the parietal side of the occipital/parietal sulcus approximately 2 cm from the midline and 5 cm from occipital pole in a plane parallel to the calcarine fissure. In three subjects signal changes of 2 to 7% were always observed that were easily visible in the activation map. Three others showed occasional statistically significant localized changes in this same area. Activated areas were not observed in the remaining 4 subjects. In subjects that showed a robust parietal lobe response, no activation of this area was produced by imagination of static objects or scenery, or direct visual stimulation.

DEPENDENT ON STIMULUS CATEGORY SEQUENCES, FIRST-ORDER MARKOV-CHAIN PROPERTIES APPEAR IN FACE-RELATED COMPONENTS OF JAVA MONKEY VISUAL EVOKED POTENTIALS. L. Fuhr, O.-J. Grüsser, W. Seidler, Dept. Physiol., Freie Univ., Arnimallee 22, W-1000 Berlin 33 (FRG).

EPs were recorded with seven epidural electrodes implanted above the right hemisphere of a Java monkey trained to distinguish monkey faces (MF) from complex non-face stimuli (NF; b/w slides 5.1° diameter). One set consisted of 53 MF- and 59 NF-stimuli which were applied three times per session. Either MF- or NF-stimuli were rewarded. Stimuli were presented within a randomized time slot of 2.9-4.1 s. EPs were averaged according to the category of the current and the preceding stimulus. The fig. illustrates the grand averages of EP-responses over the temporal lobe from eight sessions. MF-stimuli preceded by MF-stimuli evoked responses more similar to those of NF-stimuli preceded by either NF- or MF-stimuli.

SIGNIFICANCE OF CATEGORY-RELATED DIFFERENCES IN EEG-POTENTIALS OF MAN EVOKED BY FACE-, HAND- AND "NON-BODYPART"-STIMULI AND EVALUATED WITH THE WAVELET ANALYSIS. Elke Heusser, L. Fuhr, O.-J. Grüsser, Dept. Physiol. Freie Univ. 1 Berlin 33, FRG (SPON: European Neuroscience Association)

The evoked potentials related to the presentation of b/w-photographs of hand-, face- and "non-bodypart"-stimuli were investigated. 160 diapositives (40 each category) were presented in random order for 2.1 - 4 sec each to 19 subjects (10 males, 9 females). The EPs were analyzed with the wavelet method (Ditberner et al. Vision Res. submitted 1993): To describe the significance of category-related differences of the resulting grand averages, they were compared with the "random-shuffled-grand average", i.e. the average of 30 x 19 EPs over all 4 categories. The 4 resulting grand averages and the "random-shuffled-grand average" were convoluted by wavelets of different widths and compared

with each other. Areas exceeding the ± 3 SD-range of the random-shuffled EPs were defined as significant. In the 2-dimensional contour-plots these significant ranges are depicted (fig.). For faces significant responses appeared between 150-300 ms after stimulus change and within a temporal frequency range between 3 and 15 Hz.

BINDING FORMS A CEREBRAL CODE WHICH ERROR CORRECTS: Scattered Feature Detectors Generate a Hexagonal Code via Synchronizing Excitation among Pyramidal Neurons. WILLIAM H. CALVIN* Univ. of Washington NJ-15, Seattle WA 98195

Pyramidal neurons of the superficial neocortex are excitatory to other pyramids and, since they tend to cluster axon terminals at a standard distance ("0.5mm"), some corticocortical cell pairs will mutually re-excite. Though refractoriness should prevent reverberation, even weak positive coupling can entrain oscillators when cells are active for other reasons. Because each pyramid sends horizontal axons in many directions, simultaneous arrivals may recruit a 3rd and 4th pyramid at 0.5mm from the synchronized parental pair. A triangular mosaic of synchronized superficial pyramids could thus form, extending for some mm (Calvin, *Abstr.* '92). Consider N neuron pairs responding to different aspects of an apple, scattered across extrastriate areas, forming N triangular mosaics that interdigitate. There is thus a recycling temporal pattern (since synchrony is not needed across pairs) imposed on a widespread cortical area. It has a spatial repeat, an elementary spatiotemporal pattern of N neurons which, for geometric reasons, is no larger than a 0.5mm hexagon. This compact pattern becomes standardized across the mosaic (a variant must overcome six simultaneous EPSPs); such pattern "crystallization" is a form of error correction. The synchrony could induce longer-term NMDA connectivity changes; later, partial patterns could "pop out" the complete spatiotemporal pattern for *Apple* by resonance with this connectivity pattern, even in cortex lacking the original feature detectors. A hexagonal matrix could thus house a Hebbian cell assembly and function as a cerebral code.

MODULATION OF SPINDLING OSCILLATIONS BY SYNAPTIC INPUTS. D. Contreras* and M. Steriade, Lab. of Neurophysiol., Laval University, Quebec, Canada. G1K 7P4.

Sleep spindles are generated in the thalamus and distributed to wide cortical territories. To explore the influence of synaptic inputs on spindles in urethane or ketamine-xylazine anesthetized cats, stimulating electrodes were inserted in the rostral intralaminar (CL) thalamus and the pericruciate motor cortex, and multi-site intracellular and extracellular simultaneous recordings were performed in the anterolateral sector of the reticular thalamic (RE) nucleus and from thalamocortical (TC) neurons in ventroanterior-ventrolateral (VA-VL) thalamic nuclei as well as in the pericruciate cortical areas. Crosscorrelations between action potentials and focal or intracellular waves were done.

Spindle oscillations induced by cortical or thalamic stimulation were similar to those appearing spontaneously. Cortical and RE cells responded with a short-lasting EPSP followed by a hyperpolarization lasting for 60 to 250 ms that led to a series of depolarizing waves at 8 to 12 Hz. TC cells responded with an EPSP followed by a hyperpolarization of similar duration, leading to a rebound spike-burst and a sequence of cyclic (8-12 Hz) IPSPs. Cellular events were correlated to the EEG from the pericruciate cortex: a surface-negativity (depth-positivity) was coincident with the cellular hyperpolarization, followed by surface-positive (depth-negative) waves at 8-12 Hz that were correlated with cortical- and RE-cell firing or TC-IPSPs. Variations in the duration of the initial EEG surface-negativity were strictly followed by the three cell-types. A decrease in the intensity of cortical or thalamic stimulation led to a progressive decrease in the amplitude of the oscillation, but not in its frequency, until a single EPSP was elicited by the testing volley. These results suggest that the magnitude of synaptic inputs to the pacemaker RE thalamic nucleus effectively modulates the strength of the oscillation and that a generalized inhibitory phenomenon is used by the network to correctly time the spindle oscillation.

SYNAPTIC INTERACTIONS BETWEEN THE DOPAMINERGIC AFFERENTS AND THE CORTICAL OR THALAMIC INPUT AT THE SINGLE CELL LEVEL IN THE STRIATUM OF MONKEY. Y. Smith*¹, B.D. Bennett², J.P. Bolam², A. Parent¹ and A.F. Sadikot¹. ¹Centre de Recherche en Neurobiologie, Hôp. Enfant-Jésus and Univ. Laval, QUÉBEC, CANADA; ²MRC Unit, Univ. Dept of Pharmacology, OXFORD, UK.

The anterograde transport of *Phaseolus vulgaris*-Leucoagglutinin (PHA-L) or biocytin (Bio) was combined with the immunostaining for tyrosine hydroxylase (TH) to test the possibility that the dopaminergic afferents converge with cortical or thalamic inputs on single neurones in the sensorimotor sector of the primate striatum (St). In a series of squirrel monkeys, PHA-L was delivered into the centromedian nucleus (CM) of the thalamus whereas in other animals, Bio was injected in the primary motor cortex. After the appropriate survival period, sections including the St were processed to reveal the anterograde tracers and TH immunoreactivity in material suitable for light and electron microscopic analysis. Although TH-immunoreactive fibres and terminals invaded the entire extent of the St, the cortical and thalamic inputs formed bands that were confined to the post-commissural region of the putamen. Electron microscopic analysis revealed that more than 80% of the TH-positive terminals formed symmetric synapses with dendritic shafts, whereas the cortical and thalamic terminals formed asymmetric synapses predominantly with the heads of dendritic spines and with dendritic shafts, respectively. Examination of striatal regions where the cortical or thalamic inputs overlapped with the TH-immunoreactive structures revealed that the cortical boutons form synapses onto striatal elements that also receive inputs from TH-positive terminals. In contrast, none of the striatal structures examined received convergent synaptic inputs from thalamic boutons and TH-positive terminals.

These results suggest that the dopaminergic afferents interact differently with the cortical and thalamic input to influence the neuronal activity in the sensorimotor sector of the striatum in primate. Supported by the Canadian and UK MRCs and NATO.

BASAL GANGLIA REGULATION OF THALAMOCORTICAL ACTIVITY: VENTRAL PALLIDUM EXERTS OPPOSITE ACTIONS ON MEDIODORSAL AND DORSAL THALAMIC NUCLEI. A. Lavin* and A.A. Grace, Depts. Behavioral Neuroscience and Psychiatry, Center for Neuroscience, Univ. Pittsburgh, Pittsburgh, PA 15260.

The primary output pathway of the accumbens occurs via the ventral pallidal projections to the thalamus. Studies indicate that this pathway innervates the mediodorsal nucleus (MD) and the reticular nucleus (RTN) within the thalamus. Using *in vivo* intracellular recording and staining in rats, we investigated the effects of ventral pallidal (VP) stimulation on the activity of thalamic cells identified by Lucifer yellow injection.

VP stimulation caused a short-latency inhibition of neurons in the MD (ipsp latency = 2.2±1.0 msec; amplitude = 6.9±1.6 mV), with repetitive stimuli causing a tonic hyperpolarization of MD cells. Similarly, VP stimulation also elicited short-latency ipsp (latency = 2.7±1.1 msec, 5.4±1.1 mV amplitude) in approx. 70% of the RTN cells recorded. In contrast, approx. 60% of the neurons recorded in the dorsal thalamic nuclei responded to VP stimulation with longer-latency epsps (latency = 3.5±2.7 msec; amplitude = 5.2±4.7 mV). Furthermore, repetitive stimulation caused a tonic depolarization which often led to spike firing.

In schizophrenics, either hypofrontality or increased dopamine inhibition of the accumbens should result in activation of the VP. In this study, VP activation caused: 1) a direct inhibition of the MD thalamic nucleus which, in the absence of other excitatory inputs, should augment the hypofrontality, and 2) a disinhibition of the dorsal thalamic nuclei secondary to direct RTN inhibition. The latter action could conceivably contribute to the breakdown of thalamic filtering hypothesized to occur in schizophrenia.

SPONTANEOUS SYNAPTIC POTENTIALS INDUCED BY 4-AMINOPYRIDINE IN NEOSTRIATAL NEURONS.

Flores-Hernández J., Galarraza E., Pineda J. C. and Bargas J.*, Departamento de Neurociencias, Instituto de Fisiología Celular, UNAM, AP.: 70-253, México DF, 04510.

Of the fast synaptic actions, GABA_A, GLU, and ACH-nicotinic, GLU comes from neurons extrinsic to the neostriatum. CNQX/AMPA and NMDA receptors have been characterized using orthodromic responses. However, it is believed that a special dissection is needed to preserve GLU transmission. Intracellular recordings from an *in vitro* slice preparation were used to analyze the spontaneous synaptic potentials (SSPs) that appear after superfusion with 4-AP (1µM-1mM). Normally, the frequency of SSPs recorded in neostriatal neurons is low: less than one event per second. However, 4-AP increases this frequency in a dose-dependent manner (e.g., > 5 per second after 4-AP 100 µM): SSPs appeared in a random manner, with frequency oscillations, and for more than 60 min. Either 0.5 µM TTX or 400 µM Cd²⁺ blocked the SSPs. Bicuculline (BIC 4µM) or CNQX (10 µM)+2APV (100 µM) decreased their frequency. When BIC and CNQX+APV were given together SSPs and basal noise decreased. However, in a few cases some SSPs potentials remained after these blockers. It is concluded that: 1) extrinsic glutamatergic transmission is greatly preserved in slices, for some time, even if most fibers are cut, 2) 4-AP induces both GABA- and GLU-SSPs, 3) Most 4-AP-induced SSPs require action potential firing and [Ca²⁺]_i, and 4) 4-AP could be used to study transmitter release with electrophysiological methods.

CONVERGENCE OF THALAMIC AND CORTICAL INPUTS IN THE SENSORIMOTOR SECTOR OF THE STRIATUM IN MONKEY. J.P. Bolam¹, Y. Smith², B.D. Bennett¹, A. Parent² and A.F. Sadikot². ¹MRC Unit, Univ. Dept of Pharmacology, OXFORD, UK; ²Centre de Recherche en Neurobiologie, Hôp. Enfant-Jésus and Univ. Laval, QUÉBEC, CANADA.

The anterograde transport of *Phaseolus vulgaris*-Leucoagglutinin (PHA-L) was combined with that of biocytin (Bio) to determine whether the thalamic input from the centromedian nucleus (CM) and the cortical afferents from the primary motor cortex (MC) converge onto single elements in the striatum of squirrel monkey. After simultaneous injections of PHA-L in CM and Bio in MC, rich plexuses of anterogradely labelled fibres and terminals occurred in the post-commissural region of the putamen. Although both sets of anterogradely labelled elements formed patches rostrally, they aggregated in the form of bands that largely overlapped in the caudal half of the putamen. Occasionally, the two sets of labelled fibres overlapped with striatopallidal neurones that had been identified by retrograde transport of the lectin-conjugated horseradish peroxidase from the internal pallidum. At the electron microscopic level, the cortical terminals were found to be heterogeneous in size (max. diam. 0.5-2.0 µm), contained round synaptic vesicles and formed asymmetric synapses with the head of dendritic spines. The thalamic terminals had a small to medium size (max. diam. 0.3-1.0 µm), contained pleomorphic vesicles and formed asymmetric synapses predominantly with dendritic shafts and less frequently with spines. Electron microscopic analysis of striatal regions where the two sets of anterogradely labelled terminals overlapped revealed that the cortical and thalamic afferents form synapses on different neuronal elements. Therefore, despite the fact that the cortical and thalamic afferents largely occupy the same territory in the sensorimotor sector of the primate striatum, our results suggest that they terminate on different post-synaptic targets. The possibility that the cortical and thalamic inputs innervate different regions of single striatal neurones is currently under investigation. Supported by the Canadian and UK MRCs and by NATO.

EFFECTS OF DOPAMINE DEPLETION ON DYE- AND TRACER-COUPPLING BETWEEN SPINY CELLS AND BETWEEN ASPINY CELLS IN STRIATUM. S.-P. Onn* and A.A. Grace, Depts. of Behavioral Neuroscience and Psychiatry, University of Pittsburgh, Pittsburgh, PA 15260.

Previous studies using *in vivo* intracellular recording have shown that injection of the dye Lucifer yellow (LY) into single striatal neurons (18%) results in labelling of pairs of neurons of the medium spiny class. In contrast, when coupling was assessed using intracellular injection and subsequent histochemical localization of Neurobiotin (NB), a significantly higher proportion of neurons (LY=18%; NB=47%) and more cells per injection (2-4 cells) were found to be coupled. However, although LY did not reveal coupling between spiny cell types (n=5), in each case in which NB was injected into an Aspy I or Aspy II cell, the cell was found to be coupled to neighboring cells of the same morphological class (n=4).

In rats which had received 6-hydroxydopamine-induced depletions of striatal DA (95-99% loss of tyrosine hydroxylase immunoreactivity), there was a substantial increase in the incidence (92% coupling) and the extent (14/16 cases of 3 or more cells labelled per injection) of dye coupling revealed by LY injection, including a case of coupling among a cluster of 3 spiny neurons. In contrast, DA depletion produced little alteration in the incidence (52% coupling) or the extent (2-3 cells coupled/injection) of tracer coupling revealed by NB injection. Therefore, although DA depletion produced an up-regulation in the incidence and the extent of dye coupling revealed by LY injection, it did not have a significant impact on the level of tracer coupling revealed by NB injection. This finding is consistent with the hypothesis that LY is only transferred between neurons when the gap junctions are in a high-conductance state, whereas NB appears to be capable of crossing gap junctions in either the open or the closed configuration. MICROINJECTION OF BICUCULLINE TO THE CAT STRIATUM PRODUCES INHIBITION OF SINGLE UNIT DISCHARGES IN THE SUBSTANTIA NIGRA.

H. Yamada, K. Fujimoto* and M. Yoshida.

Dept. of Neurology, Jichi Medical School, Minamikawachi-machi, Tochigi, 329-04, Japan

By the unilateral injection of bicuculline (BIC) into the putamen (Put), dystonia of the neck was produced in accordance with spike discharges of the Put. On the other hand, by the unilateral injection of BIC into the caudate nucleus (Cd), locomotor hyperactivity was produced in accordance with spike discharges of the Cd. The response of the single unit activity of the substantia nigra pars reticulata (SNr) during these BIC injections was studied. Tubes for injections of BIC and recording electrodes were inserted stereotaxically into the Cd and Put. Single unit discharges in the SNr were recorded with an Elgiloy-electrode. Injection as well as recording sites were histologically identified. Shortly after the BIC (3 µg/1.5 µl) injection into the Put or Cd, SNr neurons showed marked inhibition in correspondence with the spikes in the Put or Cd. The striatum exerts GABAergic inhibition on the SNr and SNr in turn exerts GABAergic inhibition on the ventromedial nucleus of the thalamus, tectum and other structures. Thus the excitation of the striatum is hypothesized to stimulate the structures receiving influences from the basal ganglia output and produces dystonia or locomotor hyperactivities. We confirmed this hypothesis electrophysiologically by recording single unit activities in the SNr.

DOPAMINE D1 RECEPTOR ACTIVATION REDUCES CA²⁺ CURRENTS IN ACUTELY DISSOCIATED RAT NEOSTRIATAL NEURONS. D. J. Surmeier*, Jose Vargas and A. R. Howe. Dept. of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, Memphis, TN 38163.

The actions of dopamine in the neostriatum are mediated by a family of G-protein coupled receptors that can pharmacologically be divided into D1- and D2-classes. The D1-class receptors are positively coupled to adenylyl cyclase through G_s-family proteins. This signaling pathway is coupled to ion channel modulation in many excitable cells. Previous electrophysiological studies have reported that D1-class receptor activation produces a reduction in evoked discharge produced either by intracellular current injection or cortical stimulation. Consistent with this modulation, we have shown that Na⁺ currents are reduced by D1-class agonists in neostriatal neurons. We set out to determine whether Ca²⁺ currents, which also contribute to spike generation and patterning, were also modulated by D1-class receptors.

Neostriatal neurons from young adult rats (3-8 weeks postnatal) were acutely dissociated and whole-cell voltage-clamped at room temperature as previously described by our group. Only medium-sized neurons that previous work had shown to be projection neurons were examined. D1 receptor agonists (SKF 38393, SKF 82958) reduced peak Ca²⁺ currents in over 80% (n=100) of neurons studied. This modulation was blocked by the D1 receptor antagonist SCH 23390 but not by the 5-HT₂ antagonist ketanserin. Inclusion of GTP-γ-S in the patch pipette prevented reversal of the D1 modulation, suggesting G-protein mediation. Application of membrane permeant cAMP analogs (CPT-cAMP, Sp-cAMPS) mimicked the modulation produced by receptor stimulation. Co-application of the phosphatase inhibitor calyculin A with either cAMP analog potentiated their effects, implicating protein phosphorylation in at least a portion of the modulation. AGED-RELATED DECLINE IN PAIRED-PULSE FACILITATION IN THE RAT STRIATUM: ROLE OF GABA MODULATION AND CALCIUM HOMEOSTASIS. X. Qu* and J. P. Walsh. Andrus Gerontology Center & Dept. of Biological Sciences, Univ. of Southern California, Los Angeles, CA 90089-0191

Our previous work has shown that there is an age-related loss of paired-pulse facilitation at the corticostriatal synapse. In the present study we tested the hypothesis that this change may be due to an alteration in GABAergic influence. Coronal slices (450 µm) from young (2-6 mo) and aged (24-26 mo) male Fisher 344 rat neostriatum were used. We gave two cortical stimuli to the corpus callosum at various interstimulus intervals and recorded the EPSPs from striatal neurons. Bicuculline (20 µM) and saclofen (400 µM) were added to the artificial cerebral spinal fluid (ACSF) to block GABA_A and GABA_B receptors respectively. Facilitation was slightly enhanced by the GABA receptor antagonists in both age groups, but the age-related difference in synaptic facilitation still persisted (p < 0.01). These data indicate that a change in GABAergic modulation can not account for the age-related difference in paired-pulse facilitation.

We next tested the hypothesis that the age-related loss of paired-pulse facilitation was due to an increase in intracellular Ca²⁺. Slices from young and aged rats were bathed in a reduced Ca²⁺ ACSF. This solution significantly increased facilitation in both age groups (p < 0.01). These data indicate that multiple Ca²⁺ ions cooperate in the release process and that this mechanism may be saturated in aged corticostriatal terminals. Supported by NIA grant 5 P01 A60979.

CA²⁺-DEPENDENT MODULATION OF L-TYPE CA²⁺ CURRENTS IN ACUTELY DISSOCIATED RAT NEOSTRIATAL NEURONS. A. R. Howe* and D. J. Surmeier. Dept. of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, Memphis, TN 38163.

We have recently reported that L-type Ca²⁺ currents are modulated by muscarinic receptor activation in acutely-dissociated rat neostriatal neurons based upon the ability of muscarine to modulate the BayK 8644 enhanced tail current. As previously reported for sympathetic ganglion neurons (Mathie et al., 1992), the modulation of L-type current in neostriatal neurons was dependent on the absence of high levels of Ca²⁺ chelator. This dependence suggested that fluctuations in intracellular Ca²⁺ levels were crucial to the modulation. However, photometric studies in sympathetic ganglion neurons have suggested that an elevation in intracellular Ca²⁺ is not a necessary antecedent to L-current modulation. We have followed-up this work in neostriatal neurons by asking 1) how Ca²⁺ currents are affected by elevating intracellular BAPTA concentration and 2) how they are altered by Ca²⁺ mobilizing agents.

Whole-cell voltage-clamp recordings from acutely dissociated neostriatal neurons employed conventional techniques at room temperature. Elevations in intracellular BAPTA from 0.1 to 20 mM had several effects on whole-cell Ca²⁺ currents, including increasing peak currents, slowing de-activation kinetics and reducing the effects of BayK 8644. Ca²⁺ mobilizing agents, such as thapsigargin and caffeine, produced potent reductions in Ca²⁺ currents, including BayK 8644 enhanced tail currents, but in preliminary experiments these modulations were not strongly attenuated by high internal BAPTA concentrations. The impact of dialysable chelators on these modulations and those of other Ca²⁺ mobilizing agents (IP3, ryanodine) is currently being pursued. This work is supported by USPHS grants NS 28889 (DJS) and GR MH-10400-01 (ARH).

399.10

MECHANISM FOR AGE-RELATED DECREASE IN THE DURATION OF CA²⁺-MEDIATED PLATEAU POTENTIALS IN STRIATAL NEURONS. F. A. S. Villar, R. Dunia, T. H. McNeill, and J. P. Walsh*. Andrus Gerontology Center & Dept. of Biological Sciences, University of Southern California, Los Angeles, CA 90089-0191.

Plateau potentials induced in striatal neurons from aged rats (> 24 mo.) are significantly shorter in duration than those obtained from young rats (3-6 mo.) (Dunia and Walsh, 1992). We tested the hypothesis that the reduced duration of plateau potential may be due to an age-related increase in the basal intracellular Ca²⁺. To test this hypothesis slices were bathed in an extracellular medium where Ca²⁺ was replaced by Ba²⁺. The Ba²⁺-saline increased the average duration of the plateau potentials in neurons from young rats by 300% (500 to 2000 msec). By contrast, the Ba²⁺-saline increased the average duration of plateau potentials in neurons from aged rats by only 40% (190 to 270 msec). These data indicate that the age-related reduction of the plateau potential is not due to a Ca²⁺-mediated inactivation of Ca²⁺ currents.

Plateau potentials were tested separately for their sensitivity to NMDA (2 µM). NMDA reversibly reduced the duration of the plateau potentials, suggesting that NMDA may act to modulate Ca²⁺ currents in striatal neurons.

Neurons tested for plateau potentials were also filled with biocytin and reacted for HRP histochemistry. Measurements were then made of the total dendritic length. The data suggests that the duration of the plateau potential reflects the size of the neuronal dendritic field. Research was supported by a grant from the NIA (5 P01 AG0979).

COMPUTER SIMULATION OF SPONTANEOUS MEMBRANE POTENTIAL SHIFTS IN STRIATAL NEURONS.

C. J. Wilson* Dept. of Anat. and Neurobiol., Univ. of Tennessee, Memphis, TN.

Striatal spiny neurons exhibit spontaneous membrane potential transitions from a hyperpolarized (down) state (-70 to -90 mV) to a depolarized but still subthreshold (up) state (-45 to -55 mV). State transitions require excitatory synaptic transmission in the corticostriatal and thalamostriatal pathways but have been shown to be shaped by nonlinear properties of the striatal neuron. Biophysical data suggest two classes of potassium channels, one inwardly rectifying and activated at hyperpolarized membrane potentials, and one outwardly rectifying and activated by depolarization, are dominant over the relevant range of membrane potentials. Computer simulations of somatic current injections and synaptic excitation were employed using a morphologically accurate model of the striatal spiny neuron to assess the expected behavior of the cell based solely upon these two classes of channel.

No passive model of the striatal neuron could duplicate the voltage transients evoked in the striatal spiny neurons by small current pulses. Model neurons containing the two potassium channels accurately reproduced the behavior of the cells in the subthreshold range of membrane potentials, but only if both channels were placed on the dendrites.

Simulated noisy synaptic input could produce discrete up and down states in the model neurons when both potassium channels were included in the dendritic membrane, but not if one or both channels were selectively located in the soma. Voltage sensitivity of state transitions duplicated that seen *in vivo*. The voltage attained in the up state was determined by a dynamic interaction between synaptic input and outwardly-rectifying potassium channels located on the dendrites. Depolarizations resulting from increased synaptic excitation increased potassium conductance and the electrotonic length of the dendrites, while reductions in excitatory input reduced potassium conductance, making the remaining synapses more effective. The relatively constant membrane potential in the up state was thus due to dynamic adjustment of the effective electrotonic length of the striatal cell dendrites by the outward rectifier. ONR N00014-92-J-1113

ANALYSIS OF BISTABLE-LIKE SPONTANEOUS SHIFTS OF MEMBRANE POTENTIAL REVEALS SIMILAR PATTERNS IN STRIATAL AND CORTICOSTRIATAL NEURONS.

E. A. Stern^{1*}, C. J. Wilson² and A. E. Kincaid² ¹Neurobiology Dept., Life Sciences Inst., Hebrew University, Jerusalem, Israel, ²Dept. of Anatomy and Neurobiology, University of Tennessee, Memphis, TN.

Spontaneous bistable-like shifts of membrane potentials have been recorded in identified striatal and corticostriatal neurons in rats anaesthetized with urethane. These shifts appear to be caused by interactions of synaptic inputs with membrane properties. We have analyzed their occurrence using standard statistical methods.

We find that, for both striatal and corticostriatal cells, the time of occurrence of each depolarized (up) state is independent of the duration of the previous hyperpolarized (down) state, as well as the history of state transitions. This allows us to treat times of occurrence of these states as a Poisson process with a distribution of delays, and develop unbiased estimators of the phenomena.

The times between state transitions were similar in the striatal and corticostriatal cells, as were the amounts of time spent in the two states. However, the variance of the times spent in the two states was significantly greater for the corticostriatal neurons, as was the bandwidth of the membrane potential fluctuations in the depolarized state. These differences are consistent with the more linear membrane properties of the corticostriatal neurons. The voltage dependence of the dwell time in each state was analyzed for both types of neurons. Time in the up state increased in both cell types when the cells were depolarized with constant current.

Noise analysis was performed on the membrane potential fluctuations of striatal neurons in the up state to characterize the underlying unitary events. The parameters of the synaptic inputs, which were modeled with a distribution of Γ functions, changed as a function of membrane depolarization. This suggests that the membrane noise in the up state is not a result of changes in the number of synaptic inputs alone but also membrane properties of the cell that produce a selective amplification of individual synaptic events along the dendritic tree.

SPACING OF BOUTONS ALONG CORTICOSTRIATAL AXONS DIFFERS IN PATCH VS MATRIX COMPARTMENTS. A.E. Kincaid* and C.J. Wilson. Department of Anatomy and Neurobiology, College of Medicine, University of Tennessee, Memphis, TN 38163.

Cortical neurons that innervate the striatum are thought to preferentially innervate either the patch compartment or the matrix compartment. While we know the laminae and the area of cortex that give rise to the corticostriatal axons that innervate specific compartments, interpretation of axonal population tracing studies requires information about arborization patterns of single axons. We compared the pattern of innervation and the density of axonal varicosities along corticostriatal axons that were found in the patch or matrix compartments.

Corticostriatal axons were labeled with either an extracellular injection of biotinylated dextran amine or an intracellular injection of biocytin, and striatal compartments were identified using calbindin immunocytochemistry. Corticostriatal axons were identified in either the patch or matrix compartment and the distance between boutons was measured using a computer based image analysis program. Comparisons were made between axons that were found in the patch compartment and those found in the matrix compartment in both the axonal population studies and the intracellularly stained axons.

Patch compartments innervated by corticostriatal axons were more densely innervated than equal areas of matrix, in animals that received equivalent injections of extracellular tracer in patch vs matrix parts of cortex. Axons that were located in the patch compartment had a shorter inter-varicose distance, on average, than those axons that were located in the matrix compartment in both the population studies and the intracellularly stained axons. These results suggest that a given length of corticostriatal axon in a patch compartment will make more synapses than an equal length of corticostriatal axon in the matrix. Supported by NS20743.

STRIATAL SPINY NEURONS POSSESS TWO TYPES OF INWARDLY-RECTIFYING CURRENTS. E.S. Nisenbaum* and C.J. Wilson. Department of Anatomy and Neurobiology, College of Medicine, University of Tennessee-Memphis, Memphis, TN 38163

An identifying electrophysiological property of striatal spiny neurons recorded *in vivo* or *in vitro* is the pronounced rectification of their membranes in response to hyperpolarizing current pulses. Several types of inwardly-rectifying currents have been identified and include a fast, barium-sensitive K^+ current (I_{Kf}) and a time-dependent, cesium-sensitive mixed Na^+/K^+ current (I_H). The present experiments have investigated the potential contribution of I_{Kf} and I_H to the inward rectification of striatal spiny neurons in an *in vitro* slice preparation.

In control slices, inward rectification was observed as an asymptote in the amplitude of voltage deflections produced by intracellular hyperpolarizing current pulses (0.1-1.0 nA in amplitude, 400 ms duration). Blockade of inward Na^+ and Ca^{2+} currents with TTX (1 μ M) and cadmium (400 μ M) did not alter the rectification. In contrast, application of barium (100 μ M) produced a membrane depolarization and abolished much of the inward rectification in these neurons. In addition, rebound depolarizing responses were evoked at the offset of large hyperpolarizing current pulses in the presence of barium. These rebound depolarizations are indicative of I_H , and accordingly could be blocked by extracellular cesium (3 mM). Cesium also produced a further increase in input resistance and decrease in resting membrane potential. These results indicate that striatal spiny cells possess both I_{Kf} and I_H . In addition to contributing to the resting potential of spiny neurons, these currents account for the low input resistance and short time constant of these cells at hyperpolarized membrane potentials and thus would be predicted to reduce the efficacy of spatially and/or temporally discrete synaptic inputs. CHANGES OF CAT CEREBELLAR FIELDPOTENTIALS EVOKED BY CONDITIONED LIMB MOVEMENTS FOLLOWING INJECTION OF BOTULINUM TOXIN TYPE A INTO THE TRICEPS MUSCLES. F.P. Kolb*, J.R. Bloedel*, V.Bracha*, E. Wiedemann, W.H. Fischer. Institute of Physiology, University of Munich; W-8000 Munich 2, Germany; *Barrow Neurological Institute, Phoenix, AZ 85013.

By using the operant conditioning paradigm tame cats were trained to stand still on four strain gauges-equipped platforms. Following an auditory stimulus the cat had to perform a step to a fifth platform situated frontally. Ful-filling predefined parameters the animal was rewarded by food. Field-potentials from the left cerebellar anterior lobe were recorded from a chronically implanted multielectrode for a period of up to eight weeks. Electromyographic activity was obtained via chronically inserted wires from biceps and triceps muscles of both forelimbs. Botulinum toxin (12ng) injected into the triceps muscles evoked a transient muscular weakness. It was derived and quantified from a statistical analysis of biomechanical parameters of the step. The resulting impediment caused the animal to transiently change its strategy when performing the step. Changes in some of the fieldpotentials recorded at different depths within the cerebellar cortex could be related to changes in the biomechanical data. This findings suggest that the cerebellar cortex is, beside its well known ability of correcting ongoing and short lasting mismatches between the planned and executed motor programs, also involved in long term and plastic processes within the sensory motor system. Supported by Deutsche Forschungsgemeinschaft. SFB 220, D9.

EFFECTS OF TEMPORARY INACTIVATION OF THE SPECIFIC CEREBELLAR NUCLEI ON THE ORGANIZATION OF EMG ACTIVITY DURING A COMPLEX FORELIMB MOVEMENT IN CATS. M.S. Milak*, V. Bracha, J.R. Bloedel. Barrow Neurological Institute, Phoenix, AZ 85013.

These experiments were designed to analyze the specific involvement of individual cerebellar nuclei in the organization of muscular activity required for the execution of a complex forelimb movement. Each animal was trained to reach for a manipulandum and move it through a template consisting of 2 straight segments. The effects of muscimol injected into individual cerebellar nuclei ipsilateral to the performing forelimb were assessed. Dentate nucleus injections resulted in an inability to modify the EMG pattern in a task-dependent manner, and the flexor activity related to bar contact was greatly diminished, resulting in the cat often losing its grasp of the bar. Blocking anterior interposed nucleus output produced a dissociation of the EMG activity between the proximal and distal muscle groups. Although the inhibition of the posterior interposed nucleus caused dysmetria, the relative pattern of muscle activity did not show qualitative changes. Inhibition of the fastigial nucleus had no significant effect on the EMG onset time at paw lift-off, but its duration and amplitude increased as the movement through the template was executed. The data demonstrate that the effective performance of the complex forelimb movement is dependent on the functional integrity of all cerebellar nuclei. However, the differential effects of local nuclear inactivation on forelimb EMG patterns suggest that the individual cerebellar nuclei play a selective and specific role in organizing the muscle activity required for a movement and its task-dependent reorganization. NIH NS21958, NS30013.

400.3

UNIF ACTIVITY OF CEREBELLAR NUCLEI NEURONS DURING A CONDITIONAL MOTOR TASK WITH DELAY.

L. Germain* and Y. Lamarre. CRSN, Dept. of Physiology, Univ. de Montréal, Montréal, Québec, Canada.

In order to demonstrate functional differences between the dentate and the interpositus nuclei of the cerebellum one monkey was trained to perform a conditional motor task with delay. Each behavioral trial was composed of a 500 msec control period, an auditory signal of 400 msec duration (1000 Hz 400 Hz tone, 70 dB) a randomized delay period of 500 to 1500 msec duration, a go-signal (small torque pulse to the manipulandum) and finally execution of an elbow flexion or extension according to the auditory instruction (1000 Hz flexion, 400 Hz extension). A sample of 85 cells were recorded from the interpositus nucleus and a sample of 66 cells were recorded in the dentate nucleus.

In our sample of dentate neurons 30% (20/66) showed auditory responses, 41% (27/66) changed their firing rate during the instructed delay, 89% (59/66) were activated before and during movement execution. Among these cells only 27% (16/59) had their activity correlated with peak angular acceleration. In our sample of interpositus neurons none displayed auditory responses, 26% (22/85) changed their firing rate during the instructed period and all of them were activated during movement execution. Among these cells 59% (50/85) had their activity correlated with peak angular acceleration. These data suggest that the dentate nucleus is involved in the processing of directional information during preparation for an intended movement and that the interpositus is involved in the control of movement parameter during its execution (supported by MRC of Canada and FRSQ).

COMPLEX SPIKE ACTIVITY IN THE AWAKE BEHAVING MONKEY: NON-CLOCK-LIKE DISCHARGE. J.G. Keating* and W.T. Thach. Dept. of Anatomy, Washington Univ. Sch. Med. St. Louis, MO 63110.

We have recorded from Purkinje cells in 3 Rhesus monkeys during the performance of up to 16 different visually cued wrist rotation tasks.

Interspike intervals for all complex spikes recorded for a unit were placed in 5ms bins. Autocorrelation analysis was done. As a control, a "noisy" clock was created by moving the times of CS discharge from one cell to the nearest 10 Hz clock beat, and -20 to 20ms was randomly added to each spike. Even with noise over 40% of its cycle time the clock-like discharge is clearly visible on the Fourier transform of the autocorrelation (fig 1). Analysis of the actual discharge of this unit is shown in fig 2. No periodicity could be seen for any of the 65 units analyzed. Fourier analysis of the autocorrelations failed to reveal any periodicity up to 100Hz. The results from 48 units from one monkey are overlain in fig 3. Units with large numbers of complex spikes (1000's) gave flatter more even histograms than those with fewer (100's), suggesting a random discharge pattern.

The failure to observe clock-like timing in awake behaving animals, and in particular the random nature of complex spike discharge observed, questions the physiological significance of quasi-periodic IO discharge in other preparations. (support NIH grant NS12777)

IMPAIRED PINCH AND PRESERVED REACH AFTER LESION OF CEREBELLAR THALAMUS. A.J. Bastian* and W.T. Thach. Dept of Anatomy, Program in Physical Therapy, The IWJ Institute for Rehab. Research, Wash. Univ. Sch. of Med., St. Louis, Mo. 63110.

This 50 y/o man has had postural and action tremor since age 8. MRI showed an old infarct in the left ventral lateral thalamus. Motor impairments were restricted to the right arm; all sensory modalities including proprioception were normal. We examined limb kinematics during reach and pinch tasks.

The seated patient reached to a target at shoulder height in front of him. He was videotaped with markers at the tip of the index finger, shoulder, elbow, and wrist joints. Marker positions were digitized and joint angles and trajectories calculated. Wrist trajectories were normal. There was no target overshoot. 3-6 Hz tremor at the elbow and shoulder occurred during movement and increased while holding at the target. Elbow and shoulder angles changed simultaneously.

The patient was also videotaped pinching a quarter protruding from a narrow slot, with markers on the tip of the thumb, thumb DIP, thumb MCP, wrist, index MCP, index PIP, and tip of the index finger. Position of the markers were digitized and the trajectories for the tip of index and thumb calculated. 3-6 Hz tremor of the tip of index and thumb was marked during this task. The patient successfully retrieved the coin 64% of trials; control successes were 100%. Time between thumb and index contact of the coin was greater for patient vs control, (p=.05) indicating decomposition of pinch into separate thumb and index movements.

The ventral lateral thalamus receives overlapping projections from the 3 deep cerebellar nuclei (Asanuma et al 1983). The dorsal column-lemniscal system projects separately and more posteriorly to ventral posterolateral thalamus. Absence of somatosensory deficits would argue for exclusive involvement of the cerebellar thalamus. Kinematic analysis showed an impaired pinch with preserved reach. Goodkin and Thach (Soc Neurosci Abst. 544.14, 1990) reported a dentate lesion resulting in pinch and reach deficits. This patient shows that cerebellar output pathways influencing reaching and pinching may be dissociated. (NIH grant NS12777).

400.4

CLIMBING FIBER ACTIVITY IN THE LATERAL CEREBELLAR CORTEX (CRUS II) DURING VOLUNTARY ARM MOVEMENT IN MONKEY. J.P. Pellerin*, M.T. Parent, C. Valiquette and Y. Lamarre, Centre de Recherche en Sciences Neurologiques, Université de Montréal, Montréal (Qc), Canada, H3C 3J7.

Climbing fiber responses (CFR) were recorded in the cerebellar cortex (crus II) of a monkey trained to perform flexion or extension of the elbow in response to randomly presented visual, auditory and somesthetic cues. Task related CFR were movement related and occur 40 to 100 ms before the onset of movement. Even though the movements triggered by the 3 sensory signals were the same, only about 25% of the cells responded with the 3 "go" signals. Responses were seen most frequently with the visual "go" signal only (52%). Other cells responded to the visual and somesthetic cues (10%), visual and auditory (5%) and somesthetic only (8%). The probability of occurrence of CFR was highest with modal reaction time. A number of cells were also recorded when the monkey performed spontaneous movements similar to the triggered movements. In all instances, CFR were abolished or strongly reduced and more variable in time with spontaneous movements as compared to triggered movements. Considering the topographical organization of the olivocerebellar and cerebello-nuclear projections, we suggest that crus II, by its relationship to the Dentate nucleus, may be part of a circuit regulating the initiation of the movement triggered by external stimuli. In self-initiated movements, crus II would not exert the same influence on the movement initiation. These results suggest that the olivocerebellar projections in crus II may provide a more precise timing control of movement initiation in response to external events, particularly those triggered by visual stimuli. Supported by MRC grant of Canada.

CEREBELLAR NEURON DISCHARGE DURING SIMPLE AND COMPOUND MOVEMENTS. H.P. Goodkin* and W.T. Thach. Department of Anatomy and Neurobiology, Washington Univ. Sch. of Med., St. Louis, MO 63110.

A rhesus monkey (*Macaca mulatta*) was trained in one set of tasks (constrained finger tasks - "simple") to close microswitches in response to LED display by flexing the thumb (T) or the index finger (I) or the two together in a pinch (P). In another task (unconstrained food well task - "compound"), the monkey reached and pinched food bits from within a food well. The simple tasks required movement at fewer joints than did the compound task, but EMG analysis showed activity throughout the entire upper extremity for both the simple and compound tasks. Inactivation of the cerebellar dentate nucleus by muscimol injection has been shown to impair the performance of reaching and pinching (compound tasks) but negligibly that of the simple tasks (Goodkin and Thach, Soc Neurosci Abs, 218.11, 1992). Correspondingly, some units (8/26) fired in relation to the compound task and not the simple tasks, and of those related to both tasks (17/26) a third fired at much higher frequencies during the compound task. Nevertheless, many units did discharge in relation to the simple tasks (33/76); and although most of these discharged in the same pattern for T, I, and P, 2 related to T and P but not I and 2 related to I and P but not T (none related only to P). The discrepancy between the inactivation and the single unit recording data suggests that the cerebellum controls much activity during simple constrained movement that is not essential for its successful performance which becomes essential for the performance of compound unconstrained movements. This, in turn, suggests that the specific controlled variable may be predominantly or even exclusively antagonists and synergists -- "support" muscles -- rather than the agonist prime movers. (NIH grant NS12777).

400.8

STORAGE OF MULTIPLE GAZE-HAND CALIBRATIONS. T.A. Martin*, J.G. Keating, H.P. Goodkin, A.J. Bastian, and W.T. Thach. Dept. of Anatomy and IWJ Rehab. Res. Inst., Wash. Univ. Sch. Med., St. Louis, MO, 63110

Wearing wedge prism spectacles while throwing at a target results in a recalibration of the gaze direction and the throwing direction to hit the target. Base right prisms bend the optic path to the right and the eyes and head (gaze) turn to the left to fixate the target. The arm, calibrated with gaze direction, throws to the left of the target. With time, the throws shift towards the right, until they consistently fall on target. Following removal of the prisms, the adaptation is apparent on the first throw -- the gaze is now on-target, but the subject misses the target in the opposite direction by a distance almost equal to the initial error. Previous work demonstrates that the adaptation is impaired in patients with damage of cerebellar cortex, inferior olive, or mossy fibers of the middle cerebellar peduncle (Thach et al., Soc. Neurosci. Abs., 551.2, 1991), and is specific to the throwing arm (right or left) and the type of throw (underhand or overhand) (Thach et al., Soc. Neurosci. Abs., 218.12, 1992).

Following extended training with a specific diopter strength of wedge prism spectacles, subjects stored two eye-hand calibrations (no-prisms and trained-prisms). Trained subjects throw successfully on-target immediately upon donning the trained-prisms and immediately upon removing them. When donning a novel pair of prisms, subjects adapt as in the naive state (above): they throw off-target in the direction of the prism-bent gaze, gradually adapt throws onto target, and then throw off-target in the opposite direction when the novel prisms are removed. This adaptation affects both the no-prisms and trained-prisms calibrations; each must be independently re-adapted. This suggests that 2 (or more) gaze-hand calibrations may be stored simultaneously. Prior work suggests cerebellar cortex as the site of storage (Thach et al., Ann. Rev. Neurosci., 1992) (NIH grant NS12777).

400.9

DISTURBANCES OF KINESTHESIA IN PERSONS WITH CEREBELLAR DISORDERS. Stephen E. Grill¹, Cheryl Marcus¹, Mark Hallett¹, Jau-Shin Lou^{1*}, and Lisa M. McShane², Human Motor Control Section¹ and Biometry and Field Studies Branch², NINDS, NIH, Bethesda, MD, U.S.A.

Voluntary control of movement is likely dependent on perception of kinematic variables. It is possible that deficits in persons with movement disorders are in part due to impaired perception. We compared the perception of kinesthetic stimuli in persons with cerebellar degenerations to normal age-matched volunteers. We also recorded the discharge of muscle spindle afferents and cutaneous mechanoreceptors from the radial nerve during imposition of the stimuli to identify which receptors are able to provide the afferent information.

We evaluated separately perception of duration, amplitude, and velocity by imposing three types of kinesthetic stimuli about the metacarpophalangeal joint of the right index finger. For the duration task, pairs of abrupt displacements of 1 degree but variable durations (100, 125, 150, 175, 200, or 225 msec) were employed. For the amplitude task, abrupt displacements of different magnitudes (0.95, 1.08, 1.21, 1.34, 1.47, or 1.60 deg) were employed. For the velocity task, the finger was moved at one velocity (10, 15, 20, 25, 30, or 35 deg/sec) for 500 msec and the speed of the movement then abruptly changed for another 500 msec. Subjects were instructed to respond by saying which one of the pair of stimuli was longer, larger, or faster. The study design was a randomized permuted blocks design using 10 blocks of size 36. Statistical analysis involved logistic regression techniques. Persons with cerebellar disorders performed significantly worse than normal subjects for the duration ($p=0.018$) and the velocity ($p=0.020$) task but not for the amplitude task ($p=0.053$). Microneurographic recordings during the presentation of the stimuli indicate that muscle spindle afferents provide a more reliable signal than do mechanoreceptors.

Deficits of cerebellar subjects in voluntary control may in part be related to a deficit in processing kinesthetic signals. The kinesthetic signals are likely to arise largely from muscle spindle afferents.

400.11

THE CEREBELLUM AND TIMING OVER TWO DIFFERENT TEMPORAL RANGES. J. Grinband, R. B. Ivry*, and S. Roberts. Dept. of Psychology, Univ. of Calif. at Berkeley, Berkeley, CA 94720.

Previous research has indicated that human patients with cerebellar lesions are impaired in judging the duration of intervals shorter than 1 sec. To explore the short-range timing task, rats (*rattus norvegicus*) were simultaneously trained on two time perception tasks. In the short-range timing task, rats were trained to discriminate intervals between 200 and 850 ms. In the long-range timing task, the intervals ranged from 25 to 40 sec. The durations were signaled by lights, with different lights used for each task. After psychometric functions were established, bilateral electrolytic lesions targeted at the lateral cerebellar nuclei were made. Control animals received sham lesions. Rats with cerebellar lesions were more variable than controls on the short-range timing task with minimal change in the point of subjective equality. In contrast, no differences were observed between the groups on the long-range task. The differential effects of the lesions on the two tasks suggest that the processing of temporal information over these two ranges involves different neural mechanisms. However, the effects of the lesions were transient: after one week of post-surgery testing, most of the experimental animals had returned to pre-surgery levels of performance. It is not clear whether the recovery reflects the extensive training given the animals (approximately 2800 trials per rat per week) or indicates that the cerebellum does not play a critical role in perceptual timing in the rat.

400.10

STRETCH REFLEX MODULATION DURING SINUSOIDAL TRACKING IN CEREBELLAR ATAXIA. Johnson, M.T.V., Amrami, K., Kipnis, A.N., Mendez, A., Poppele, R., and Ebner, T.J.* Departments of Neurosurgery, Neurology and Physiology, University of Minnesota and EMPI, Inc., Mpls., MN 55455.

Our previous study showed that patients with Parkinson's disease exhibit a characteristic abnormality in the modulation of their stretch reflexes during volitional movements (Johnson, et al., Brain 114: 443-460, 1991). Extending this original study, we evaluated in subjects with cerebellar ataxia the modulation of reflex activity during volitional wrist movement. Eight subjects with cerebellar ataxia, 14 with Parkinson's disease and 10 normals were studied. Cerebellar ataxia and Parkinson's disease were established by physical examination and history. The subjects were asked to track a visually presented sinusoid with their wrist. Perturbations of the movement with torque transients at random times occurred at 45° and 90° intervals. Flexor and extensor reflex and volitional EMG and wrist displacement were recorded as a function of tracking phase. Subjects with cerebellar ataxia exhibited several abnormalities in the modulation of their reflexes. In some subjects this included increased amplitude of the short latency reflex components and/or delayed long latency reflexes. However, the pattern of the reflex modulation relative to the volitional tracking cycle was relatively normal. In three patients with cerebellar ataxia reflex modulation was virtually absent. In contrast subjects with Parkinson's disease exhibited an abnormal pattern of modulation in which the reflex activity relative to the tracking cycle was shifted by as much as 180°. These results suggest that the cerebellum contributes to the modulation of reflexes occurring during wrist movements and unique deficits in reflex modulation may characterize different movement disorders. Supported in part by NIH Grant R43-NS28633.

CEREBELLUM II

401.1

TRANSIENTS IN SIMPLE SPIKE ACTIVITY FOLLOWING COMPLEX SPIKES OF FLOCCULAR PURKINJE CELLS DURING COMPENSATORY EYE MOVEMENTS. D.H. Wang*, C.I. De Zeeuw, D.R. Wylie, and J.I. Simpson. Dept. Physiology and Biophysics, NYU Medical School, New York, NY, 10016.

Complex spikes (CS) of Purkinje cells (P-cells) of the cerebellum are followed by a pause (inactivation period) in simple spikes (SS) that can, in turn, be followed by a transient enhancement or reduction of the SS activity for up to 100 msec (McDevitt, Ebner and Bloedel, '82). Using cross-correlation of CS and SS activity, we examined the occurrence of these transients in vertical axis P-cells of the flocculus of the awake, pigmented rabbit during sinusoidal rotation (0.1 Hz) in the light (VOR-light) and dark (VOR-dark). Sinusoidal and constant velocity optokinetic stimuli (OKS) were also used. The SS are modulated under all conditions, but the CS activity is modulated only during VOR-light and OKS. The CS modulation is reciprocal to the SS modulation. In about half the cells a transient enhancement was present during spontaneous activity, VOR-light, VOR-dark and OKS. From inspection of the cross-correlograms, it is apparent that the transient SS modulation, whether an enhancement or a reduction, makes only a small contribution to the overall SS modulation during the VOR-light and OKS. During VOR-dark SS transients are present in the cross-correlogram, but like the CS activity, they are unrelated to the sinusoidal SS modulation. From these data it is not clear what the transient SS modulations, either enhancing or reducing, contribute to the compensatory eye movements, as customarily measured.

401.2

PHASE RELATIONS OF PURKINJE CELLS IN THE RABBIT FLOCCULUS DURING COMPENSATORY EYE MOVEMENTS. J.S. Stahl*, C.I. De Zeeuw, D.R. Wylie, D.H. Wang, and J.I. Simpson. Dept. Physiology and Biophysics, New York University Medical School, New York, NY, 10016.

In previous studies we found that during sinusoidal rotation of the alert, pigmented rabbit the phase of flocculus receiving neurons (FRNs) in the medial vestibular nucleus leads that of the nonFRNs (Stahl and Simpson, '92). If the FRN phase lead is produced by the signal contributed by the floccular Purkinje cells (P-cells), then the P-cells should in effect lead the FRNs. To test this hypothesis, we recorded the simple spikes (SS) of P-cells in the vertical axis zones of the flocculus in alert, pigmented rabbits. Single unit SS activity of P-cells was identified by the presence of a pause of SS after complex spikes. The animals were rotated sinusoidally about the vertical axis in the light (0.05 to 0.8 Hz) and the dark (0.1 Hz to 0.4 Hz). We calculated the phase of the SS activity using spectral analysis and linear multivariate regression. During rotation in the light the P-cells showed a phase lead re contra head position that increased with frequency (median 53° at 0.05 Hz; 73° at 0.8 Hz). The P-cells led the FRNs significantly at all frequencies except 0.8 Hz. The difference was greatest at 0.05 Hz (difference of medians = 16°, $p < 0.001$) and progressively decreased with increasing frequency (0.1 Hz, 14°, $p < 0.001$; 0.2 Hz, 12°, $p < 0.001$; 0.4 Hz, 9°, $p < 0.01$; 0.8 Hz, 1°, n.s.). In the dark, the P-cells had a greater phase lead re contra head position than in the light (median 88° at 0.1 Hz; 85° at 0.4 Hz). The phase of the P-cells led the FRNs at all frequencies (0.1 Hz, 18°, $p < 0.005$; 0.2 Hz, 21°, $p < 0.01$; 0.4 Hz, 12°, $p < 0.05$). These findings are consistent with the hypothesis that the floccular output increases the phase lead of the net premotor signal. The phase lead of the floccular signal may be created by enhancing the velocity components of signals originating in the vestibular nuclei.

401.3

THE FIFTH WHEEL OF THE FLOCCULUS. J.L. Simpson*¹, D.R. Wylie¹, C.I. De Zeeuw^{1,2}, P.L. DiGiorgi¹, and J. Tan². (1) Dept. Physiology & Biophysics, NYU Medical Center, NY, NY, 10016. (2) Dept. Neuroanatomy, Erasmus University Rotterdam, 3000DR, Rotterdam, The Netherlands.

The rabbit flocculus can be divided into five zones (zones 1, 2, 3, 4, and C2) using AChE histochemistry. Zones 1 to 4 are involved in compensatory eye movements and the relations of their Purkinje cells with the inferior (IO) and cerebellar or vestibular nuclei (CN/VN) are known. The corresponding anatomy for the fifth floccular zone, C2, is unknown. In the present study, we determined in the rabbit the connections of this zone with the IO and CN/VN by means of anterograde tracing techniques. Small biocytin injections were made into the C2 zone, which was recognized by the absence of a climbing fiber response to visual stimulation. This physiological identification of the C2 zone was anatomically confirmed by AChE staining. The individually labeled axons of the C2 Purkinje cells innervated the interposed posterior nucleus (IPN), either alone or together with a collateral innervation of dorsal group y (Dy). Injections of WGA-HRP into Dy and the adjacent IPN resulted in anterograde labeling in the rostral tip of the contralateral medial accessory olive (rMAO), the ventrolateral outgrowth (VLO), and the rostral dorsal cap (rdc). Injections of WGA-HRP into these different olivary subnuclei showed that the rMAO projected to the C2 zone in the flocculus while both the VLO and rdc projected to zones 1 and 3. It can be concluded that the floccular C2 zone is like the great majority of cerebellar parasagittal zones in that it is part of a three-element loop composed of sequential projections from the IO to Purkinje cells to the CN/VN and back to the corresponding olivary subnucleus. For the non-visual part of the flocculus this loop consists of the C2 zone, IPN and Dy, and rMAO.

401.5

DECREASES IN NITRIC OXIDE (NO) PRODUCTION AFTER INJECTION OF N-MONO-METHYL ARGININE INTO THE VESTIBULO-CEREBELLAR REGION OF GOLDFISH REDUCES VESTIBULO-OCULAR REFLEX GAIN.

ADAPTATION. J.G. McElligott^{1*}, Jun Li² and Sheryl Smith². ¹Dept. of Pharmacology, Temple University School of Medicine, Phila., PA 19140, and ²Dept. of Anatomy and Institute of Neuroscience, Hahnemann University Phila, PA 19102

The vestibulo-ocular reflex (VOR) has been studied as a model system for investigating adaptive neuroplastic changes in the sensori-motor system. Work in our lab has shown that a non-NMDA antagonist, CNQX, (Soc. Neurosci. Companion Abstr. 1993) but not a NMDA antagonist, MK-801, (Soc. Neurosci. Abstr. 18 #215.3, 1992) will prevent VOR gain adaptation when injected locally into the vestibulo-cerebellum. Other agents, most notably nitric oxide (NO) has also been implicated in playing a role in other forms of neuroplastic changes in the central nervous system. In the work presented here, we investigated the effect of injecting N-mono-methyl arginine (NMMA) which decreases NO production via the NO synthase reaction. Goldfish were restrained in a cylindrical test aquarium which was sinusoidally rotated about the vertical axis at 1/8 Hz \pm 20°. Projection of visual stimuli (random dot pattern) onto the wall of the aquarium at the same frequency, but double the amplitude, and 180° out of phase with the vestibular stimuli produced VOR gain increases (towards 3X). The gain of the VOR was assayed by measuring the movements of both eyes using the electro-magnetic search coil technique. Fish were trained to increase VOR gain over several hours during which time the VOR in both the light and the dark was measured. Direct injection of NMMA bilaterally (12.5 μ g/0.5 μ l/side) into the vestibulo-cerebellum of goldfish had no effect on the normal non-adapted VOR gain in the light and the dark. However, injection of NMMA prevented the robust adaptive VOR gain increase that is normally observed within the first hour of training in control injected goldfish. In addition, after 3 hours of continuous VOR adaptive gain training there was a profound and significant reduction in the adaptive gain increase. Since NO has been shown to be released in the cerebellum, our results would indicate that NO mediates the development of adaptive VOR gain increases within the vestibulo-cerebellum. VARIABILITY OF CLIMBING FIBER EFFECTS ON DEEP CEREBELLAR NUCLEAR NEURONS DURING SPONTANEOUS AND EXPERIMENTALLY-INDUCED EYE AND EYELID MOVEMENTS. A. Gruart*, A. Pastor and J.M. Delgado-García. Lab. de Neurociencia. Univ. de Sevilla. 41012-Sevilla, Spain.

Field potentials induced in deep cerebellar nuclei by the electrical stimulation of the contralateral red nucleus (RN), pontine nuclei (PN), restiform body (RB) and inferior olive (IO) were recorded in alert cats during eye and eyelid movements. Upper eyelid and eye movements were recorded with the search-coil technique. Recording sites were selected according to their relationships with spontaneous and/or experimentally-induced eye and eyelid movements, and identified by the antidromic field potentials induced by RN and/or RB stimulations. Control field potentials induced in selected cerebellar nuclear areas consisted of two negative waves at 0.5-1 ms and 2-3 ms followed by a late (4-6 ms) positive wave. It was observed in acute experiments that the two negative waves corresponded, respectively, to the antidromic and the synaptic activation of cerebellar nuclear neurons. The delayed positivity corresponded to the inhibitory effect of Purkinje cells on the subjacent nuclear neurons. The presentation of novel stimuli (flash lights, tones) to the alert behaving animal increased by 5-10 times the amplitude of the second negativity, and less noticeably, that of the delayed positivity. This increase in synaptic field potential amplitude fade out following the repeated presentation of the stimuli. When recording in the fastigial nucleus, the amplitude of the second negativity was modulated 120 deg in advance during sinusoidal rotation of the animal at 0.5 Hz. The increase in the synaptic field potential was experimentally evoked using a 50 μ s conditioning stimulus in the PN 5-20 ms prior to the IO stimulation. A similar increase was observed during the acquisition of an eyelid response during a classical conditioning paradigm. These results suggest the involvement of mossy and climbing fiber responses on deep cerebellar nuclei neurons during motor response adaptations to novel stimuli.

401.4

CEREBELLECTOMY REVEALS THAT STORAGE AND EXPRESSION OF VESTIBULO-OCULAR REFLEX ADAPTATION OCCURS IN THE BRAINSTEM. A.M. Pastor*, R.R. de la Cruz & R. Baker. Dept. of Physiology and Biology, Univ. of Seville, Spain, NYU Med. Ctr., NY, NY 10016.

The role of the vestibulo-cerebellum in vestibulo-ocular reflex (VOR) adaptation was determined in normal, adapted and cerebellectomized goldfish. Combined visual and vestibular stimulation was employed to alter the ratio of eye to head velocity (VOR gain). The time course of eye velocity responses to head velocity steps consisted of an early dynamic component followed by a plateau of constant velocity. Control and adapted dynamic VOR responses diverged at the earliest detected latency of 18ms during both high and low VOR gain states demonstrating modification of the shortest latency VOR pathways. Acute cerebellectomy after VOR adaptation revealed that the adapted and post-lesion responses overlapped for 50ms in the low and 70ms in the high gain VOR paradigms. Thus the cerebellum is not the storage site for altered eye velocity since brainstem pathways alone are sufficient for adapted VOR expression. The latency of vestibulo-cerebellar Purkinje cell responses to head and eye velocity steps exhibited a mean of 43ms and 70ms, respectively. Vestibulo-cerebellar activity therefore is not necessary for the expression of altered dynamic responses. However, in chronic cerebellectomized animals, the dynamic component was not modifiable. As a result, we conclude that the vestibulo-cerebellum is necessary for the induction, but not the maintenance, of the adapted VOR dynamic response. By contrast, the plateau of constant velocity could be significantly adapted and hence its brainstem pathways are modifiable in the absence of the cerebellum. Altogether, these findings favor the view that a continuous integration of visual and vestibular sensory signals with an internal representation of eye velocity occurs in the cerebellum to produce a signal that induces VOR adaptation in the brainstem.

VESTIBULO-OCULAR REFLEX GAIN ADAPTATION IS BLOCKED FOLLOWING INFUSION OF CNQX, A NON-NMDA ANTAGONIST, INTO THE VESTIBULO-CEREBELLUM OF THE GOLDFISH.

T.L. Carter* and J.G. McElligott

Dept. of Pharmacology, Temple University School of Medicine, Phila., PA 19140.

Antagonists to glutamate receptors (NMDA and/or non-NMDA) have been found to interfere with hippocampal long-term potentiation, cerebellar long-term depression and developmental visual cortex plasticity. Our previous work has shown that systemically administered MK-801, a NMDA antagonist, delays the onset and reduces the rate of adaptive vestibulo-ocular reflex (VOR) gain increases but not gain decreases. In addition, when MK-801 was injected directly into the vestibulo-cerebellum, normal VOR gain adaptation occurred. The study reported here examines the influence of a cerebellar-infused, non-NMDA antagonist, CNQX, on VOR adaptation. Goldfish were restrained in a cylindrical aquarium which was sinusoidally rotated about the vertical axis at 1/8 Hz \pm 20°. The fish were trained to increase gain (toward 3x) or decrease gain (toward 0x) by altering the phase and amplitude of the visual stimuli projected onto the wall of the test aquarium. The gain of the VOR was assayed by measuring the movements of both eyes using the electro-magnetic search coil technique. Fish were trained to change VOR gain over a 3 hour period during which time the VOR in both the light and the dark was measured at 15 minute (1st hour) and 30 minute intervals (2nd and 3rd hours). After initial VOR measurements, CNQX was infused bilaterally into the vestibulo-cerebellar region (0.5 μ l/side @ 0.1 μ l/min). Post-infusion measurements of the VOR were taken before the initiation of VOR adaptive training. CNQX (145ng/side @ 1.25mM) or a corresponding vehicle (1:5 Tris/artificial CSF) when administered into the vestibulo-cerebellum of the goldfish did not alter non-adapted VOR gain prior to adaptive training. However, CNQX but not the control treated animals experienced a complete inhibition of both VOR adaptive gain increases and decreases during the entire three hour training period. This work suggests that the non-NMDA receptors (AMPA/quisqualate and possibly kainate) located in the vestibulo-cerebellar region of the goldfish brain are involved in VOR neuroplasticity. 401.8

DISCHARGE PROPERTIES OF IDENTIFIED DEEP CEREBELLAR NUCLEI NEURONS RELATED TO EYELID MOVEMENTS IN THE ALERT CAT. J.M. Delgado-García* and A. Gruart. Lab. de Neurociencia, Univ. de Sevilla, 41012-Sevilla, Spain.

The activity of cerebellar nuclear neurons was recorded in the alert cat during blinks induced by corneal air puffs, light flashes and tones. Recorded neurons were identified by their antidromic activation from various projection sites. Upper eyelid movements were recorded with the search-coil technique. Eyelid response to 100 ms air puffs consisted of an early (16.5 \pm 2.7 ms) and fast (\leq 1.200 deg/s) downward movement followed by 2-3 downward sags that occurred at constant latencies. Blinks induced by flashes or tones presented longer latencies (52.6 \pm 4.8 and 50.1 \pm 8.0 ms). Type A neurons (n=90) increased their discharge rate in coincidence with the beginning of the blink, regardless of the stimulus modality. The late downward inflexions were also accompanied by corresponding increases in the neuronal firing rate. Type A neurons projected to the red nucleus (50%), restiform body (25%), pontine nuclei (15%) and through the medial longitudinal fascicle (10%). Type B neurons (n=32) showed a brief and irregular burst of spikes slightly preceding the eyelid response followed by a significant decrease in their firing rate. The firing response of type B neurons was always related to the motor response and not to the sensory modality. Type B neurons projected to the red nucleus (50%), oculomotor complex (25%) and restiform body (15%). No precise temporal coupling was found between the beginning of type A and B neural response and the start of either the stimulus or the motor response. However, significant relationships between mean firing rate of type A and B neurons and eyelid position, velocity and/or acceleration were demonstrated by linear regression analysis. Type A and B neurons seem to be directly involved in the execution of reflex blinks following the smaller details of eyelid displacements. The opposite behavior of type A and B neurons could be related to reciprocal roles of the different muscles involved in eye blinks.

DENDRITIC MORPHOLOGY OF RAT PHRENIC MOTONEURONS VISUALIZED BY RETROGRADE TRACING WITH CHOLERA TOXIN-B SUBUNIT (CTB). K.G. Smithson*, Y.S. Prakash and G.C. Sieck. Departments of Anesthesiology, Physiology and Biophysics, Mayo Clinic and Foundation, Rochester, MN 55905

Previous descriptions of rat phrenic motoneuron morphology (Goshgarian, H.G. et al. *J. Comp. Neurol.* 201:441,1981; Lindsay, A.D. et al. *J. Comp. Neurol.* 308:169,1991.) have employed horseradish peroxidase (HRP) as a retrograde tracer. Cholera toxin (CTB), however, is a more sensitive tracer particularly with respect to revealing distal dendritic morphology. In the present study phrenic motoneuron morphology has been reinvestigated with CTB to evaluate the fine dendritic ramifications of these neurons, and to provide a framework from which to study dendritic plasticity. The right hemidiaphragm of six adult male rats was injected with 1-2 μ l of 1-2% CTB. Following a survival period of 48-72 h animals were fixed, and tissue sections prepared, after which the CTB was detected immunocytochemically. The CTB-label revealed many stained neurons within the cervical spinal cord. In these cells, staining extended to at least third order dendrites and in some cases up to fifth order labeling could be seen. Several features of phrenic motoneuron morphology not previously reported were observed. Frequently, distal dendrites were observed crossing the midline to ramify in the contralateral ventral horn. Also observed were fine varicose processes coursing rostrocaudally between and along motoneuron somata. These processes appeared to end abruptly in bulbous "terminations". These results suggest that adult motoneurons receive afferent input from the contralateral spinal cord—a feature previously thought to be restricted to the developing rat. The presence of bulbous "terminations" and fine processes around phrenic motoneuron somata suggest the possibility of local circuits which may be modulated by these motoneurons. (Supported by NIH grants HL37680, HL34817 and GM08288)

DENDRITIC STRUCTURE OF RENSHAW CELLS AND IA INHIBITORY INTERNEURONS IN THE CAT'S SPINAL CORD. M. J. Sedivec*, D. E. Dewey and R. E. W. Fyffe. Dept. of Anatomy, Wright State University, Dayton, Ohio 45435, and Dept. of Biology, Appalachian State University, Boone, N.C. 28608.

The dendritic trees of interneurons that mediate recurrent (Renshaw cells; RCs) and reciprocal (Ia afferent evoked; IaIn) inhibition of motoneurons (MNs) have been analyzed previously (Lagerback & Kellerth, 1985, *J. Comp. Neurol.* 240:368; Rastad et al, 1990, *Anat. Embryol.* 181:381), but the sample of fully reconstructed cells is limited. This work analyzes physiologically identified interneurons, intracellularly stained with horseradish peroxidase. Multipolar RCs form a homogeneous population, with an average of 5.4 stem dendrites per cell and total cell surface areas of about 24,000 μ m². In contrast, IaIn (average of 5.3 dendrites/cell), have greater surface areas (mean 93,000 μ m²) but individually exhibit great variability. For both cell types, dendritic stem diameter correlates with cell surface area, total dendritic length and the number of end branches. The combined dendritic trunk parameter of RCs equals 1.0 for a distance of about 300 μ m from the soma, whereas in IaIn this parameter decreased monotonically as a function of distance. In some respects the branching and equivalent cable structures of IaIn resemble those of γ -MNs whereas RCs have some structural features in common with α -MNs. Supported by NIH grant NS25547.

DIFFERENTIAL DISTRIBUTION OF GLYCINE RECEPTORS ON INTERNEURONS IN THE CAT SPINAL CORD. R. E. W. Fyffe*, F. J. Alvarez and D. Harrington. Dept. of Anatomy, Wright State University, Dayton, Ohio 45435

Several types of interneurons in the mammalian spinal cord, including those mediating reciprocal (Ia afferent evoked; IaIn) and recurrent (Renshaw cells; RCs) inhibition of motoneurons (MNs) use glycine as their neurotransmitter. These interneurons are themselves subject to inhibitory control, possibly also mediated by glycine. Using intracellular staining with neurobiotin to label physiologically identified interneurons, and a monoclonal antibody against a 93 kDa glycine receptor (Gly-R) associated protein, we show that ventral horn interneurons, including IaIn, RCs and neurons with contralaterally projecting axons, exhibit a high density of Gly-Rs over their cell bodies and dendrites. The density of Gly-R labelling is higher than observed for MNs using similar techniques. The soma and proximal half of the dendritic tree of RCs is densely covered by large receptor clusters, many of which form perforated disks, but fewer Gly-Rs are seen on the distal dendrites. In contrast, the soma and proximal dendrites of IaIn and other interneurons have a high density of small Gly-R clusters that become progressively larger on distal dendrites, a size gradient that is also observed for Gly-Rs on α -MN dendrites. The dense distribution of Gly-Rs on soma and dendrites of all the interneurons suggests that they are subject to very powerful inhibition, probably from a variety of sources. Supported by NIH grant NS25547

402.2

EXPECTED VALUES ON MOTONEURON DENDROGRAMS W. B. MARKS* LAB OF NEURAL CONTROL, NINDS, BETHESDA, MD 20892

Our stochastic model of motoneuron dendrites (Burke, Marks, and Ulfhacker 1992) generates sample dendrograms by sequentially appending 25 μ m (ΔL) segments taken randomly from urns containing pieces only of the appropriate diameter and distance from soma. Each urn contains pieces that continue, terminate, and branch (into various diameters), in proportions that fit observations. Each dendrogram so constructed is a unique statistical sample. Here we calculate the expected shape of averages over these dendrograms, directly from the parameters of the model. The vector $m(n)$ whose i th component is the expected number of branches whose diameter is in bin i at distance bin n , can be used to compute total dendrite area, volume, or the equivalent cable (with $p=1, 2$ or $3/2$) from $E(\sum a_i(n)^p) = m(n) \cdot a^p$, where $E(\cdot)$ is expectation and vector a is the set of bin-centered diameters. In the differential limit $n\Delta L$ approaches L , the distance from the soma. The parameters of the stochastic model are the diagonal matrices $M(L)$ and $B(L)$, the probabilities of terminating and branching, and D , the daughter-parent diameter array. Given $m(L=0)$,

$$\frac{\partial m}{\partial L} = \frac{\partial m}{\partial a} \frac{\partial a}{\partial L} + (-M - B + 2DB)m,$$

gives $m(L>0)$. Here " a " represents diameter, and the first term is the effect of taper. By setting taper $\partial a/\partial L = \text{const}/\sqrt{a}$, L becomes electrotonic length. The expectation of more complex functions on branching processes can be computed using the generating function $g(s, n)$ of the complex vector s . For $Z_i(n)$ = the occupancy of diameter bin i at distance n , $g(s, n) = E(\sum Z_i(n)s_i)$. For example, variances of functions of m require $E(a_i a_j) = \partial^2 g(s, n) / \partial s_i \partial s_j$. In this we hope to address questions like "What physiological functions are maximized by motoneuron dendrites?"

402.4

SEROTONERGIC INNERVATION OF MOTONEURONS IN THE CAT'S LUMBAR SPINAL CORD. J. C. Pearson*, F. J. Alvarez, D. E. Dewey, D. Harrington and R. E. W. Fyffe. Dept. of Anatomy, Wright State University, Dayton, Ohio 45435.

The bistable properties of lumbar spinal motoneurons (MNs) are dependent on intact serotonergic innervation of the spinal cord (e.g. Hounsgaard et al, 1988, *J. Physiol.* 405:345-367). The L7 ventral horn receives profuse innervation from serotonergic axons (Arvidsson et al, 1990, *Synapse* 6:237-270) but it is not known how many serotonergic boutons contact MNs directly, or, where on the complex MN dendritic tree the synaptic contacts are made. We have combined intracellular staining of MNs with horseradish peroxidase and immunocytochemical staining of serotonergic axons and terminals to permit quantitative light microscopic analysis of these issues. Some selected appositions between serotonin immunoreactive boutons and identified MN dendrites were confirmed by electron microscopic examination to be genuine synaptic contacts. Each MN received between 900 and 1500 presumed contacts from serotonin containing axons. The contact sites were widely distributed over the soma and dendrites, including dendrites that extended into the white matter. Contact density was highest on 1st-4th order dendrites within 500 μ m from the soma, with dendritic contacts tending to be larger than those on the soma. Some presynaptic axons generated multiple contacts along dendritic branches. We conclude that serotonergic systems contribute a major direct input to spinal MNs. Supported by NIH grant NS25547.

402.6

DISTRIBUTION OF GLYCINE RECEPTORS ON SINGLE INTRACELLULARLY LABELED MOTONEURONS OF THE CAT LUMBAR SPINAL CORD. F. J. Alvarez*, D. Harrington, D. E. Dewey, and R. E. W. Fyffe. Dept. of Anatomy, Wright State University, Dayton Ohio 45435

Glycine is recognised to be the neurotransmitter utilized by a variety of inhibitory pathways involved in the regulation of motoneuron firing. Elegant electron microscopic immunocytochemical studies (e.g. Triller et al, 1985, *J. Cell Biol.* 101: 683-688) have demonstrated the presence of glycine receptors (Gly-Rs) on the soma and proximal dendrites of neurons in the ventral horn of the rat spinal cord. Here, using an antibody (R7A) that recognises the 93 kDa Gly-R associated protein, we have determined the distribution of Gly-Rs over the whole somadendritic surface of physiologically identified α - and γ - motoneurons. Electron microscopic examination confirms the labelling to be restricted to post-synaptic densities apposed by boutons containing flattened or pleomorphic vesicles. Gly-Rs are present, in α -motoneurons, on the soma, proximal and distal dendrites, including branches in the white matter, and on some dendritic swellings and spines when the latter structures are present. The discrete receptor clusters are smaller on the soma and proximal dendrites than on more distal dendrites, although receptor density is higher proximally. In contrast, γ -motoneurons express relatively few Gly-Rs, and they are generally absent from the more proximal dendritic segments and the cell bodies. Supported by NIH grant NS25547

402.7

PEPTIDERGIC AND GABAERGIC INNERVATION OF THE VENTROLATERAL DENDRITIC BUNDLE IN THE CAT S1 SPINAL CORD SEGMENT

V. Ramírez-León (1)*, T. Hökfelt (2) and B. Ulfhake (1), Departments of (1)Anatomy, and (2)Histology and Neurobiology, Karolinska Institutet, S-104 01 Stockholm, Sweden.

The motoneurons (MNs) in the ventrolateral nucleus (VLN) of the upper sacral spinal segments in the cat supply the external sphincters and the ischiocavernosii muscles. The dendrites of the MNs in the VLN are arranged into rostro-caudally oriented bundles (ventrolateral dendritic bundle; VLB). In this study we describe the distribution and synaptic arrangement of thyrotropin-releasing hormone (TRH)-, substance P (SP)-, enkephalin (ENK)- and GABA-immunoreactive (IR) axonal boutons. This was accomplished using the peroxidase-antiperoxidase (PAP) technique (Sternberger et al., 1970).

IR axonal boutons were not randomly distributed within the dendritic arborizations in the VLB. SP- and TRH-IR boutons had a wide distribution, including both thin distal branches and thick proximal dendrites. ENK-IR and GABA-IR boutons were more restrictedly distributed, apposing mainly medium-sized and large dendrites.

A frequent finding in the VLB, valid for the neuropeptides and GABA, was that one and the same IR-bouton made synaptic contact with 2 adjacent dendrites. The postsynaptic dendrites involved in such arrangements often disclosed also dendro-dendritic contacts.

402.9

GLUTATHIONE RECEPTORS IN HUMAN SPINAL CORD: A POTENTIAL ROLE IN NORMAL AND ABNORMAL FUNCTION?

R. Wagey*, R.A. Lanius, C. Krieger, and C.A. Shaw. Depts. of Medicine, Ophthalmology, and Neuroscience, University of British Columbia, Vancouver, B.C., Canada.

Glutathione (GSH) is a tripeptide which is widely distributed in the human nervous system and is believed to be an important antioxidant. GSH binding sites have been detected in rodent brain, largely within the white matter where they are localized to glial cells. Since GSH may be involved in diseases associated with free radical production in man, eg. spinal cord trauma, we have characterized GSH binding sites in human spinal cord.

Quantitative autoradiography of ³⁵S-GSH binding in spinal cord demonstrates specific binding largely within the grey matter, including both the dorsal and ventral horns. ³⁵S-GSH labelled a high affinity binding site showing a K_d of approximately 2.5 nM. ³⁵S-GSH binding to the high affinity site reached equilibrium by 60 min at 4°C. Competition studies showed that ³⁵S-GSH binding was displaceable by GSH>cysteine> hexyl GSH.

Glutamate and N-methyl-D-aspartate were ineffective as displacers. The present results show that GSH receptors are present in human spinal cord. Given the antioxidant and potential neurotransmitter roles of GSH, these data suggest that this peptide may play an important role in normal neural function, and that alterations in GSH or GSH receptor levels may contribute to abnormal function.

402.11

THE INFLUENCE OF TONICALLY ACTIVE VOLTAGE-DEPENDENT POTASSIUM CHANNELS ON THE ELECTROTONIC PROPERTIES OF SPINAL MOTONEURONS. D. Campbell and P.K. Rose*. MRC Group In Sensory-Motor Physiology, Department of Physiology, Queen's University, Canada K7L 3N6

The electrophysiological properties of spinal motoneurons are consistent with the presence of a leak at or near the soma. The cause of this somatic leak is unknown. Tonicity active, voltage-dependent potassium channels located on the soma may be one of the factors which contribute to this leak. The objective of the present experiment was to block these channels using intracellular injections of cesium and thus determine their contribution to the somatic leak. The injection of cesium into neck motoneurons of anaesthetized cats caused a progressive broadening and increase in the amplitude of antidromic action potentials. These changes were taken as evidence that some or all voltage-dependent potassium channels were blocked. This block caused a decrease (30 to 40%) in the "resting" input conductance of the motoneurons. Preliminary estimates indicated that the somatic leak was less than the somatic leak measured in a control population of motoneurons. These results demonstrate that voltage-dependent potassium channels influence the electrotonic properties of motoneurons at "rest" and are partly responsible for their somatic leak. (Supported by MRC of Canada).

DISTRIBUTION OF SYNAPTIC VESICLE PROTEINS IN THE MONKEY (Macaca fascicularis) SPINAL CORD WITH EMPHASIS ON THE 5-HT AND GABA SYSTEM IN THE MOTOR NUCLEI

U. Arvidsson*, F. Piehl, B. Meister, O. Shupliakov, L. Brodin, T. Hökfelt and S. Cullheim. Department of Neuroscience and Anatomy, Karolinska Institutet, Stockholm, Sweden.

Spinal cord motoneurons receive information from a large number of different sources and rough calculations indicate that one single motoneuron is contacted by at least 50,000-100,000 nerve terminals. So far, only few inputs to motoneurons have been identified with respect to their content of transmitter substances. One such system, however, the descending 5-HT raphe-spinal system seems to constitute one of the largest inputs to the spinal motor nuclei. 5-HT-immunoreactive nerve terminals in this part of the cord harbor also to a variable degree other neuroactive compounds such as several peptides. In contrast to the 5-HT system the GABAergic innervation of motoneurons seems to have its origin mainly from neurons at spinal cord levels. No coexistence between GABA and other neuroactive compounds including 5-HT has been described. Thus, the serotonergic and GABAergic systems represent inputs to spinal cord motoneurons which differ with respect to both origin and degree of coexistence with other neuroactive compounds. In order to study possible molecular differences between different types of terminals/synapses on motoneurons we have here analyzed with immunohistochemistry 5-HT- and GABA-containing (analyzed with GAD) nerve terminals in the ventral horn of the grey monkey with regard to their contents of the synaptic vesicle proteins: synapsin, synaptophysin, rab3, synaptobrevin and synaptotagmin. A large number of varicosities contained synapsin-, synaptophysin-, rab3, synaptobrevin- and synaptotagmin-LI in the motor nuclei. In general, immunolabeling of all synaptic vesicle proteins outlined unstained somata and dendrites and cross-sectioned processes in the neuropil. The distribution pattern and density for each compound was not identical, however. Instead a specific staining pattern and also a variation in density for each compound was seen. Double labeled sections, analyzed with a confocal microscope, indicate that none of the synaptic vesicle protein-LIs could be found in 5-HT-IR terminals, whereas GAD-IR terminals exhibit all synaptic vesicle protein-LIs with the exception of synaptotagmin-LI. The results of this study suggest that 5-HT terminals differ from GABA terminals in the monkey motor nuclei with respect to their content of synaptic vesicle proteins. This could reflect that the exocytotic machinery in 5-HT terminals differs from that of GABA terminals.

EPILEPTIFORM ACTIVITY INDUCED BY SUDDEN COOLING OF TOAD SPINAL CORD IS INHIBITED BY NMDA ANTAGONISTS. N.L. Daló, J.C. Hackman and R.A. Davidoff*. Dept. Basic Sci. Universidad Centroccidental, Barquisimeto, Venezuela and DVAMC and Dept. Neurol. Univ. Miami School of Medicine, Miami FL 33101.

Sudden cooling of the spinal cord induces seizures in the South American toad, *Bufo marinus*. The mechanism was investigated in a hemisectioned spinal cord preparation, mounted in a sucrose gap apparatus, and superfused with HCO₃⁻-buffered Ringer at 21°C. Recordings were made from dorsal (DR) and ventral roots (VR). A rapid temperature change in the spinal cord caused by the rapid addition of cold Ringer (6-8 °C), produced a large depolarization (up to 18 mV) of afferent terminals and motoneurons. This was followed by a slow decline of the depolarization lasting from 6 to 23 min. During the decline, irregular, spontaneous depolarizing oscillations ("epileptiform" activity) were recorded. The spontaneous activity was more marked in the VR. Adding the NMDA (N-methyl-D-aspartate) antagonists, APH (DL-2-amino-7-phosphonoheptanoate, 10 μM, 15 min) or Mg²⁺ (1 mM), to the Ringer suppressed the epileptiform activity without reducing the large slow depolarization. The presence of 10 mM Mg²⁺ or 1 mM kynurenatine in the Ringer reduced but did not abolish the cold-induced depolarization. The cold-induced depolarization and the epileptiform activity were not changed by addition of 10 μM dihydro-ouabain, a sodium pump inhibitor. Low temperatures prolonged DR and VR potentials evoked by single DR stimuli. Prolongation was reversed by adding APH (10 μM) or Mg²⁺ (1 mM). In sum, the release of excitatory amino acids and activation of NMDA receptors appear necessary for the generation of the epileptiform activity evoked by sudden cooling of the toad spinal cord. DEVELOPMENT OF REPETITIVE FIRING IN SPINAL MOTONEURONS OF NEWBORN RATS. B.-X. Gao*, and L. Ziskind-Conhaim. Dept. of Physiology and Ctr. for Neuroscience, Univ. of Wisconsin, Madison WI, 53706.

The development of repetitive firing and the changes in the ionic mechanisms that underly it were studied in spinal motoneurons in a thin slice preparation of embryonic and neonatal rats. Prolonged depolarization (90-300 ms) generated 1-2 action potentials in embryonic motoneurons (E16-E18), but a train of action potentials lasting as long as the depolarizations was produced in neonatal motoneurons (P1-P3). Whole-cell voltage-clamp recordings were used to determine the developmental changes in the ionic currents that contributed to the repetitive firing. Despite the difference in the firing pattern of embryonic and neonatal motoneurons, at both ages only one peak of inward current was recorded during the prolonged depolarization. The repetitive firing in neonatal motoneurons was not due to a shorter refractory period. To determine whether K⁺ outward current contributed to the frequency of repeated action potentials, K⁺ current was blocked by substituting Cs⁺ for K⁺ in the recording pipette. Blocking the outward current resulted in motoneuron depolarization which was associated with bursts of spontaneous action potentials. In neonatal motoneurons, which were held at -60 mV, a prolonged depolarization failed to produce a train of action potentials, and similar to embryonic motoneurons, only 1-2 action potentials were generated. Elimination of K⁺ current increased the durations of both the total inward current and the refractory period. These findings suggested that K⁺ currents contributed to the repetitive firing of neonatal motoneurons. Subsequent studies will determine the developmental changes in inward and outward currents and their role in generating the repeated action potentials. Supported by RCDA (NS01314) and NS23808 to L. Z.-C.

ELECTROTONIC CHARACTERISTICS OF CAT GAMMA-MOTONEURONS. R. E. Burke*, R. E. W. Fyffe and A. K. Moschovakis. Lab. of Neural Control, NINDS, NIH, Bethesda, MD 20892 and Dept. of Anatomy, Wright State Univ., Dayton, OH 45435.

Electrophysiological estimates of cell input resistance ($R_N=8.6$ and $10.0 \text{ M}\Omega$) and tail time constant ($\tau_{\text{tail}} = 13.2$ and 14.0 ms) were obtained from two hindlimb γ -motoneurons (MNs) that were then injected with HRP and fully reconstructed. We used these data ($\pm 10\%$ shrinkage correction) in compartmental computer models^{1,2} to estimate the specific resistance of the somatic (R_{ms}) and dendritic (R_{md}) membrane, using biologically plausible values of specific cytoplasmic resistance ($R_i=60$ to $200 \text{ }\Omega \text{ cm}$) and membrane capacitance ($C_m=0.8$ and $1.0 \text{ }\mu\text{F/cm}^2$). Values of $R_{\text{ms}} \leq R_{\text{md}}$ that matched¹ experimental R_N were used to construct unbranched equivalent cable models² to explore the parameters that produced transients with the observed τ_{tail} , using NODUS³. Final estimates were then confirmed in models with full branching structure. In both γ -MNs, best fits were found for $R_i = 60 - 70 \text{ }\Omega \text{ cm}$, $C_m=0.8$ or $1.0 \text{ }\mu\text{F/cm}^2$ and $R_{\text{ms}} \ll R_{\text{md}}$, implying significant somatic shunts ($G_{\text{shunt}} > 98\%$ of total G_{soma})^{1,2}. For $C_m=0.8 \text{ }\mu\text{F/cm}^2$, R_{md} was $60 - 75 \text{ K}\Omega/\text{cm}^2$ (giving average dendritic path L^1 of $0.54 - 0.85$). For $C_m=1.0 \text{ }\mu\text{F/cm}^2$, R_{md} was $30 - 35 \text{ K}\Omega/\text{cm}^2$ (average path L : $0.88 - 1.16$). Like α -MNs^{1,2}, γ -MNs appear to have compact electrotonic architectures and large somatic shunts when studied with conventional micropipettes.

CHARACTERIZATION OF OUTWARD CURRENTS IN GUINEA PIG TRIGEMINAL MOTONEURONS (TMNs) RECORDED IN VITRO. C.F. Hsiao*, L.J. Goldberg, and S.H. Chandler. Depts. of Physiological Science and School of Dentistry, UCLA, Los Angeles, CA 90024.

The underlying outward currents responsible for spike repolarization and slow AHP in TMNs were examined using sharp electrodes in combination with single electrode voltage clamp techniques (SEVC) from brainstem slices. Three outward currents were identified on the basis of their kinetics and pharmacological sensitivities to 4-AP, TEA and low $\text{Ca}^{++}/\text{Mn}^{++}$ solutions containing TTX. A transient outward current (TOC) was observed which was activated by depolarizing command potentials between -40 and -55 mV , peaked within 7 ms of the onset the voltage step, inactivated with a time constant of $3-9 \text{ ms}$ and was blocked by bath application of 4-AP (5 mM) but persisted in solutions containing low $\text{Ca}^{++}/\text{Mn}^{++}$ and 20 mM TEA . Voltage-dependent steady-state inactivation was characterized by a Boltzman function with a slope factor (k) between -4 and -7 and half-inactivation ($V_{1/2}$) occurring between -54 and -76 mV . Two sustained currents were observed in response to long ($> 1 \text{ sec}$) depolarizing step command potentials from holding potentials between -40 and -45 mV in the absence of the TOC. In the presence of TTX a slowly activating and deactivating outward current (time constant $> 200 \text{ ms}$) was reduced substantially following bath application of low $\text{Ca}^{++}/\text{Mn}^{++}$ containing solutions. The remaining sustained current activated and deactivated more rapidly and was reduced by $1-10 \text{ mM TEA}$ or $1-5 \text{ mM 4-AP}$ application.

These data demonstrate the presence of at least 3 pharmacologically and kinetically distinct outward currents which could contribute to spike repolarization and slow AHP production in TMNs. Supported by NIH grants DE06193, DE04166 and DE 07212.

RAT MOTONEURONAL CHOLINE ACETYLTRANSFERASE (ChAT) mRNA LEVELS ARE INCREASED BY EXPOSURE TO SUPRAPHYSIOLOGICAL AMOUNTS OF AN ANABOLIC-ANDROGENIC STEROID. P. E. Micevych*, P. Popper, and C. E. Blanco. Dept. of Anatomy & Cell Biology, Laboratory of Neuroendocrinology, UCLA School of Medicine, Los Angeles, CA 90024-1763.

ChAT mRNA levels in motoneurons which innervate the sexually dimorphic androgen sensitive bulbocavernosus/levator ani muscle complex of the rat are decreased in castrated males and are maintained at intact male levels by testosterone (T) replacement therapy. The purpose of this study was to determine whether the expression of ChAT mRNA in spinal motoneurons could be elevated by supraphysiological levels of the anabolic-androgenic steroid, T propionate (TP). Serum T levels were elevated by subcutaneous implantation of TP containing silastic capsules into gonadally intact males. Four weeks after implantation, blood was drawn for the determination of serum T levels and the animals were killed by transcardial perfusion under pentobarbital anesthesia. The spinal cords were removed and subsequently processed for ChAT *in situ* hybridization histochemistry using a ³⁵S-labelled ribonucleic acid probe. The average serum T levels were 2 ng/ml for intact male rats, 10 ng/ml for animals implanted with a single TP capsule, and 20 ng/ml for those treated with 2 TP capsules. Compared to intact untreated males, ChAT mRNA levels were unaltered in L2-L4 motoneurons, and significantly greater in L5 motoneurons for the males treated at the lower TP dose. At the higher TP dose, motoneuronal ChAT mRNA levels were significantly greater when compared to untreated males and the low TP dose group throughout the lumbosacral spinal cord. These data demonstrate that supraphysiological levels of anabolic-androgenic steroids alter the expression of specific motoneuronal mRNAs. Furthermore, these results also suggest that anabolic-androgenic steroids act to influence skeletal muscles at the level of the motoneuron. Supported by HD 7228 and NS 21220.

TWO DIFFERENT FIRING PATTERNS OF TRIGEMINAL MOTONEURONS IN THE GUINEA PIG BRAIN STEM SLICE. E.R. Morales*, P. Castillo, J.K. Engelhardt and M.H. Chase. Departamento de Fisiología, Facultad de Medicina, Universidad de la República, Montevideo (Uruguay), Department of Physiology, Department of Anatomy and Cell Biology and the Brain Research Institute, UCLA School of Medicine, Los Angeles, CA 90024-1746

The firing pattern of a neuron depends on the interplay of a multitude of factors. Among these are the nature of the synaptic input to the neuron and the intrinsic properties of the neuronal membrane itself. In the present work we studied the pattern of discharge of motoneurons of the trigeminal motor pool in the guinea pig brain slice in response to long (typically 1 sec) pulses of depolarizing current. The results presented here are based on observations in 39 motoneurons with membrane potentials of at least -50 mV and action potential amplitudes $\geq 60 \text{ mV}$. Two different firing patterns were observed. In 74% of the neurons studied, the frequency of discharge was greater at the beginning of the current pulse with progressive accommodation toward the end of the pulse. In contrast, in 26% of the neurons, the first action potential of the train appeared with a substantial delay following the beginning of the pulse (delayed excitation) followed by an acceleration of the discharge frequency toward the end of the pulse. Neurons with these two types of firing patterns did not exhibit any statistically significant differences in membrane potential or action potential amplitude. Bath application of $100 \text{ }\mu\text{M}$ 4-aminopyridine converted the delayed excitation-accelerating type firing pattern into the accommodating type firing pattern. We attribute these different firing patterns to a type of potassium (A) current that is present in a subpopulation of trigeminal motoneurons at resting potential and is slowly inactivated during the depolarization produced by a long pulse of current. (Supported by NS 09999)

N-METHYL-D,L-ASPARTATE (NMA) INDUCED VOLTAGE OSCILLATIONS IN GUINEA PIG TRIGEMINAL MOTONEURONS RECORDED IN VITRO. Y.I. Kim and S.H. Chandler*. Dept. of Physiological Science, UCLA, Los Angeles, CA 90024.

NMDA receptors in trigeminal motoneurons (TMNs) have been implicated in the production of rhythmical masticatory-like activity induced by repetitive stimulation of the masticatory cortex (Katakura and Chandler, 1990). Whole cell patch or sharp electrode recordings were obtained from TMNs to study the effects of bath applied NMA on the resting potential and membrane properties of these neurons. In TMNs NMA led to small depolarizations ($2-7 \text{ mV}$) and a modest increase in apparent input resistance ($20-100\%$) prior to the onset of rhythmic burst discharges. The duration of the burst discharge ($2 \text{ sec}-2 \text{ min}$) and interburst phase ($5 \text{ sec}-3 \text{ min}$) were voltage dependent; the burst phase was longer and the interburst phase was shorter when the cell was depolarized, and eliminated when the cell was hyperpolarized artificially beyond -70 mV . TTX eliminated the spike discharges during the burst phase leaving the underlying rhythmical depolarizing and repolarizing shifts in membrane potential and depolarizing ramp voltage clamp commands produced NMA induced inward rectification. Ringer solution containing 0 Mg^{++} transformed the rhythmic NMA induced burst discharges into continuous discharge or maintained depolarizations, while 0 Ca^{++} containing ringer solutions blocked all rhythmic activity.

These results demonstrate that in TMNs continuous NMDA receptor activation can produce voltage and Mg^{++} dependent rhythmical membrane potential oscillations and burst discharges which are consistent with the known properties of the NMDA channel described in other regions of the CNS. Furthermore, the data suggest that NMDA induced voltage oscillations and burst discharges should be considered when models of central pattern generators for mastication are proposed. Supported by NIH grants DE06193 and DE07212.

FIRING PATTERNS AND THEIR MODULATION BY NOREPINEPHRINE IN THE NUCLEUS AMBIGUUS NEURONS IN SLICES FROM GUINEA PIGS. Y. Nishimura*, T. Asahara, M. Muramatsu, K. Yoshioka, T. Tanaka and T. Yamamoto. Department of Physiology, School of Medicine Mie University, Tsu, Mie 514 and ¹Department of Physiology, Fukui Medical School, Fukui 910-11, Japan.

Intracellular recording was done in the ambiguous neurons (AMBs) in slices from guinea pigs with a glass microelectrode filled with 3 M-KCl or 5% Lucifer yellow (LY) dissolved in 0.1 M LiCl . AMBs were identified by intracellular staining with LY. The subthreshold depolarizing current pulse evoked a slow depolarization of $200-300 \text{ msec}$ duration, which was insensitive to $1 \text{ }\mu\text{M}$ tetrodotoxin, but was blocked by replacing Ca^{2+} with Co^{2+} . Injection of the suprathreshold depolarizing current induced a continuous tonic firing in 40% of 86 AMBs (tonic cells). Fifty-two cells (60%) discharged spikes at the onset of the current injection, which were followed by the depolarization without spikes (phasic cells). The afterdepolarization following a train of spikes could be seen more often in the phasic cells. Replacement of Ca^{2+} with Co^{2+} prolonged the duration of the train of spikes to change the phasic pattern to the tonic one, and reduced the afterhyperpolarization (AHP) following a train of spikes. Norepinephrine ($\text{NE}: 100 \text{ }\mu\text{M}$) prolonged the duration of the train of spikes and reduced AHP in both types of AMBs. We suppose that the Ca-mediated K current [$\text{IK}(\text{Ca})$] and Ca-sensitive slow depolarization contributed to the control of the firing behavior and that NE modulated the firing patterns by affecting the $\text{IK}(\text{Ca})$ in the AMBs.

SHORT TERM DEPRESSION AND NON-LINEAR TEMPORAL SYNAPTIC INTERACTIONS IN VAGAL MOTONEURONS. R. Nitzan*, I. Segev, and Y. Yarom. Dept. of Neurobiology, Inst. of Life Sciences, The Hebrew University of Jerusalem, Jerusalem 91904, ISRAEL.

Temporal interactions between evoked synaptic potentials in motoneurons from the Dorsal Motor Vagal Nucleus (DMVN) were studied by conventional intracellular recordings from submerged brain stem slices. Detailed model of DMVN motoneurons (Nitzan et al., *J. Neurophysiol.* 63:333-346, 1990) was used to quantify the non linearity of synaptic interaction expected in passive models. Synaptic potentials were elicited by nonspecific stimulation in the nucleus surroundings. Short trains of various frequencies and duration were used. In 50% of the neurons, inter-train depression was clearly observed. The maximal potential of the synaptic response to a train of stimuli was reached after the first stimulus in the burst. The amplitudes of the successive synaptic potentials in the burst were smaller than that of the first response. The depression was a function of the duration and the frequency of the stimuli. It reached a maximum value of 60% decrease in amplitude in the 6th response to a 90Hz stimuli. Introducing GABA blockers to the physiological solution (picrotoxin, bicuculline, saclofen) had no effect on these results.

Simulations of electrically proximal or distal synapses activated at frequencies similar to the experimental conditions have shown a 10-50% decrease in the amplitude of successive synaptic potential in the train. Maximal affect was measured when the synapses were activated at high frequency on distal dendrites. The decline in the amplitude of the synaptic potentials expected from the passive model, however, can only partially account for the experimentally observed depression. A good match to the experimental results could be obtained when the maximal synaptic conductance was decreased by 50 to 70% after the first stimulus.

We conclude that high frequency synaptic input to motoneurons of the DMVN is accompanied by a fast decrease in the synaptic efficacy.

RESONANCE BEHAVIOR OF OLIVARY NEURONS. I. Lampl and Y. Yarom*. Dept. of Neurobiology, Life Science Institute, Hebrew University, Jerusalem ISRAEL.

The ability to generate subthreshold membrane potential oscillations in neurons from the inferior olive (I.O) nucleus has been attributed to the electrical properties of these neurons as well as to the properties of the network. Thus, this oscillatory behavior is independent of the membrane potential, occurs simultaneously in a large number of neurons, is TTX insensitive and is abolished by calcium blockers. In the present *in-vitro* study we implemented the ZAP method to analyze the properties of olivary neurons in the frequency domain in an attempt to characterize those properties that contribute or support the oscillatory activity.

The ZAP function (Puil et al. 1985) is a sine wave of continuously (and linearly) increasing (or decreasing) frequency which lasts for a given duration. This signal was injected, as current, into I.O neurons via an intracellular microelectrode which was also used to measure the voltage responses of the neurons. Following a Fast Fourier Transform (FFT) of both the current wave form and the neural response to such current, we calculated the impedance of the neuron and described it as a function of frequency (Z-F curve).

We found that the Z-F curves of olivary neurons demonstrate a peak impedance (resonance) at a frequency of 4-6 Hz. This peak, which is higher than the DC resistance, is: independent of the membrane holding potential; TTX insensitive; unaffected by K^+ channels blockers; and almost completely blocked in the presence of Co^{++} in the physiological solution. In several experiments, where the ZAP method was applied while the cells oscillated spontaneously, it was found that the peak resonance is similar to the frequency of the spontaneous oscillation. Furthermore, changing the temperature in the recording chamber result in a corresponding change in the resonance frequency as well as the frequency of the spontaneous oscillations.

These results indicate that neurons from the I.O nucleus have resonance behavior that reflects the mechanism that underlies the spontaneous subthreshold oscillations.

THE EFFECT OF TOOTH DISPLACEMENT ON MASSETER MOTONEURONS. Dean Dessem* and Revers Donga, Department of Physiology, U. of Maryland Dental School, Baltimore, MD 21201

Cats were anesthetized with sodium pentobarbital, paralyzed with gallamine and respired. Recordings were made using microelectrodes filled with 2M KAcetate while displacing the maxillary canine teeth. Forces were applied in a variety of directions and ranges of force (0.3-0.46N). Stable intracellular recordings were made in 48 neurons (MP>50mV) during tooth displacement. Twenty-seven of these were identified as being from masseter motoneurons by fixed, short-latency (0.9-1.1ms), antidromic activation following stimulation (58-160 μ A) of the masseter nerve. Some motoneurons showed a reproducible, short-latency (3.95-6.68ms) depolarization (0.8-9.5mV), which in some cases was large enough to generate spikes. Typically this depolarization was followed immediately by a brief inhibitory period. Early inhibitory responses in motoneurons impaled with 3M KCl-filled electrodes, were reversed into depolarizing responses after 3 minutes implying a chloride dependent component to the inhibition. In some motoneurons sustained (100ms) tooth displacement produced a prolonged depolarization which generated multiple spiking. These results demonstrate that tooth displacement is capable not only of eliciting a variety of effects in trigeminal motoneurons but that these responses differ from those elicited by electrical stimulation of the alveolar nerves. SUBTHRESHOLD SYNAPTIC ACTIVITY INFLUENCING LUMBAR NEURONES IN THE CHRONIC CAT. P.J. Soia*, J.-I. Oka, and M. Fragozo. *Fac. Pharm. Sci., UBC, Vancouver, BC, Canada V6T 1Z3.*

Previous studies in our laboratory have demonstrated that sciatic nerve-evoked volleys recorded extracellularly within the spinohalamic and spinoreticular tracts are markedly suppressed during the behavioral state of active sleep (AS) when compared to quiet sleep (QS) or wakefulness (W). (*Soc. Neuroscience Abst.* 18: 61, 1992). The present study was performed to record intracellularly the membrane potential activity of individual lumbar neurons in the chronic, unanaesthetized cat during W, QS, and AS.

Three adult cats were prepared for chronic intracellular recording of lumbar neuronal activity using methodologies developed previously (*Physiol. Behav.* 27: 355-362, 1981; *ibid.*). Bevelled glass micropipettes filled with 2M K^+ -citrate were lowered into the spinal cord at stereotaxic coordinates corresponding to the intermediate nucleus as evidenced by the presence of a sciatic or sural nerve-evoked orthodromic field potential (*Soc. Neuroscience Abst.* 18: 61, 1992). Neurons impaled exhibited membrane potential and action potential amplitudes exceeding -50mV and 55mV, respectively. Most neurons displayed spontaneous spike activity upon impalement that subsequently subsided or ceased upon the sustained injection of constant hyperpolarizing current (0.5-2.0nA). Three of these neurons were identified as spinal sensory tract neurones since antidromic spikes could be evoked from the lateral medullary reticular formation. During W and QS, membrane potential activity consisted predominantly of frequently occurring large amplitude (2.5-3.5mV) "simple" depolarizing synaptic potentials which varied markedly in their risetime and decay parameters. "Compound" potentials, i.e. those with inflexions on their rising phase, were also recorded. During AS, there was a marked increase in depolarizing and hyperpolarizing synaptic activity.

The present results suggest that individual sensory tract neurones undergo an marked increase in conductance during the state of active sleep. Supported by a MRC Development Grant (DG-399).

ACTIVITY OF ROSTRAL TRIGEMINAL NEURONES IN THE AWAKE CAT. B.E. Cairns*, M. Fragozo, & P.J. Soia. *Fac. Pharm. Sci., University of British Columbia, Vancouver, BC, Canada V6T 1Z3.*

The present study was performed to record the extracellular unit activity of trigeminal nucleus oralis sensory neurones in the chronic, unanaesthetized cat during the behavioral state of wakefulness.

Three adult cats were prepared for chronic extracellular recording of trigeminal neurones using methodologies developed previously (*J. Neurophysiol.* 44: 349-357, 1980). Glass micropipettes filled with 2M NaCl were lowered in tracts directed to the subnucleus oralis, wherein low-intensity stimuli applied to the ipsilateral alveolar nerve (IAN), maxillary or mandibular canine tooth pulp (TP) afferents evoked an orthodromic field potential (*Sleep Res.* 22: 424, 1993).

Suprathreshold search stimuli (*ibid.*) applied to the IAN or TP resulted in a short synchronous burst of action potentials with interspike intervals ranging from of 1.0-1.25msec that were superimposed on the decay phase of the field potential. Such stimuli often resulted in a longer latency (20-40msec) train consisting of 4-6 asynchronous action potentials. The latency-to-onset of a single spike following threshold stimuli ranged from 3-4msec for IAN or maxillary TP and 5-7msec for mandibular TP volleys, respectively. Stimulation of the digastric (Dig) muscle or VII nerve evoked long-latency (8-40msec) asynchronous spike trains indicating that these cells also receive convergent input from diverse orofacial receptive fields. No antidromic spikes could be evoked upon VII or Dig stimulation indicating that the recorded neurones were not VII or V motoneurons. Evoked activity of individual neurones could often be held for greater than 30 minutes. None of the recorded neurones exhibited spontaneous discharge activity during wakefulness.

The present results corroborate data obtained from studies performed in "acute" preparations and demonstrate the feasibility of exploring further the activities of IAN or TP-driven trigeminothalamic tract and V (commisural) premotor neurones across various behavioral states. Supported by grants from the MRC and BChRF.

ELECTRICAL STIMULATION OF THE CHOLINERGIC LATERODORSAL TEGMENTAL NUCLEUS (LDT) ELICITS EPSPs IN MEDIAL PONTINE RETICULAR NEURONS IN THE CAT. H. Imon*, K. Ito, L. Dauphin, & R. W. McCrley. Lab Neurosci., Dept. Psychiatry, Harvard Med. Sch./Brookton VAMC, Brockton MA 02401

Our laboratory has described cholinergic projections from LDT/PPT to the pontine reticular formation (PRF) and there is now considerable evidence that such cholinergic projections play a key role in the induction and maintenance of the REM phase of sleep. However, a key element supporting this REM sleep role of mesopontine cholinergic neurons has been missing, namely a demonstration of excitatory synaptic effects of LDT/PPT stimulation upon the presumed effector neurons in PRF. Accordingly we examined the effects of LDT electrical stimulation in acute cats under urethane anaesthesia and with artificial ventilation. After removal of a portion of the cerebellum, surface landmarks and stereotaxic techniques were used to place stimulating electrodes bilaterally in the LDT (location histologically verified). A transverse cut throughout the reticular formation was made 1-2 mm rostral to LDT to diminish the possibility of polysynaptic stimulation from rostral effects. Electrical stimulation parameters were 0.1 mS duration for a single pulse and 300-700 uA intensity. Intracellular recordings were made of pontine reticular formation neurons. LDT stimulation produced two EPSPs, one of very short latency (about 0.6 mS) and presumably arising from activation of rapidly conducting fibers, perhaps reticulo-reticular and MLF fibers. A second EPSP was of longer latency, 2-3.7 mS, and had a mean conduction velocity of about 2 m/S, within the conduction range reported for cholinergic fibers. This second EPSP was abolished by a cut just caudal to the LDT nuclei and juxtaposed between them and the recording sites of the neurons. These data suggest that cholinergic mesopontine neurons provide excitatory synaptic input to PRF neurons.

ORDER OF REM SLEEP FIRING RECRUITMENT CORRELATES WITH SOMA SIZE OF PONTINE RETICULAR FORMATION NEURONS: INTRACELLULAR RECORDING AND LABELING IN THE NATURALLY SLEEPING CAT.

K. Ito*, H. Imon, L. Dauphin, & R.W. McCarley. Lab. Neurosci., Dept. Psych., Harvard Med. Sch./VAMC, Brockton Ma 02401.

Acute intracellular labeling studies in our laboratory have examined the projections of giant cell field pontine reticular formation (FTG) neurons. Type I neurons had primarily reticulo-spinal projections, relatively few collaterals, and most had soma diameters $\geq 47.5 \mu\text{m}$. Type II neurons projected to brainstem reticular sites, often had collaterals, and had soma diameters $< 45.7 \mu\text{m}$. The present study used intracellular recording and intracellular labeling (PhAL, biocytin, or neurobiotin) in naturally sleeping, chronic cats to determine if the "lead time" of onset of markedly increased discharge rate prior to REM was correlated with soma size. Soma diameter was determined from digitizer measurements of cross-sectional area (inter- and intra-rater variation $< 5\%$), and done blind to the physiology. RESULTS. Diameters of the 20 labeled neurons ranged from $43 \mu\text{m}$ to $88 \mu\text{m}$ (soma size range: $1500 = 6000 \mu\text{m}^2$). Within this range there was a strong positive linear correlation between diameter and "lead time", which ranged from near zero minutes to about six minutes. That larger neurons had longer "lead times" was contrary to our expectation that smaller neurons, which might be Type II neurons with abundant reticular projections, would show earlier recruitment. It was also expected from the inverse size dependence of recruitment order in alpha motoneuronal pools. Earlier recruitment of larger neurons may reflect a stronger cholinergic excitatory input.

403.7

RESPIRATORY MODULATION OF MEMBRANE RESISTANCE IN INSPIRATORY HYPOGLOSSAL (XII) MOTONEURONS (Mns). G.Woch, L.Kubin, R.O.Davies* and A.I.Pack. University of Pennsylvania, Philadelphia, PA 19104.

Genioglossal Mns, the tongue protruders, frequently show an inspiratory modulation of their discharge. The source and the nature of the synaptic inputs that cause this modulation (i.e., whether providing inspiratory EPSPs, expiratory IPSPs, or both) remain unknown. To begin distinguishing among these possibilities, we have measured the changes in membrane resistance of XII Mns with respect to the respiratory cycle. In paralyzed, vagotomized and artificially ventilated cats, we recorded intracellularly from 8 Mns. The mean respiratory modulation of their membrane potential was $5.3 \text{ mV} \pm 2.1(\text{SD})$. The difference in voltage responses to hyperpolarizing current pulses (1-2 nA) applied during mid-inspiration and late expiration were measured using a computerized data acquisition system. We observed inconsistent changes in membrane resistance, with an expiratory decrease in 4 and an increase in the remaining 4 Mns (mean: $0.3 \text{ Mohm} \pm 0.9(\text{SD})$ decrease in expiration). We compared these results to the effects of lingual nerve stimulation, which evokes an amino acid-mediated IPSPs in XII Mns. The IPSPs (mean: $4.3 \text{ mV} \pm 2.5$; 7 Mns) were consistently associated with a membrane resistance decrease (mean: $1.1 \text{ Mohm} \pm 0.5$). These results suggest that a somatic, amino acid-mediated inhibition in expiration, if present, plays a minor role in shaping the membrane potential trajectory of inspiratory XII Mns. (Supported by HL-42236 & HL-47600.)

INDEPENDENT CIRCUITS INNERVATE PROTRUDER AND RETRACTOR MUSCLES OF THE TONGUE IN ADULT RAT. E.G. Dobbins* & J.L. Feldman, Systems Neurobiology Lab., Dept. of Physiological Science, UCLA, Los Angeles, CA 90024-1527.

Muscles of the tongue are separated into protruders (genioglossus, genioglossus) innervated by the medial branch of the hypoglossal (XII) nerve and retractors (hyloglossus, styloglossus, mylohyoid) innervated by the lateral branch. Protruders, stabilize the pharynx and maintain an open airway during inspiration; retractors aid in the initiation of swallowing. These functional differences are paralleled by segregation of motoneurons (Krammer et al., *Brain Res.* 170 (79): 533). Innervation of protruder and retractor muscles was evaluated in locally deafferented, ganglionectomized adult rats by transneuronal transport of pseudorabies virus. Consistent with previous reports, injections into the medial (protruder) or lateral (retractor) branch of XII nerve labeled motoneurons in the ventral and dorsal quadrants of XII nucleus, respectively. Premotoneurons were in the tegmental field (TF) lateral to XII nucleus. Neurons premotor to retractor muscles were predominately dorsal to those premotor to protruder muscles. Dorsal neurons in the tegmental field extended from XII nucleus to spinal trigeminal nucleus. A few neurons were in the ventrolateral TF. In contrast, neurons afferent to the protruder motoneurons were concentrated in ventrolateral TF. Nuclei or regions associated with autonomic control (raphe magnus and obscurus, A5 region, Kölliker-Fuse, lateral parabrachial, locus coeruleus and subcoeruleus) project to both motoneuron populations. These results suggest that distinct circuitry underlies the functional differences in activity of tongue muscles. We are grateful to L.W. Enquist, Ph.D., Du Pont Merck Pharmaceutical Co., for his generous gift of PRV and antibody. Supported by NIH Grant NS24742.

SEROTONIN (5HT) MICROINJECTED INTO THE HYPOGLOSSAL (XII) NUCLEUS REDUCES THE DEPRESSION OF XII NERVE ACTIVITY DURING REM SLEEP-LIKE ATONIA. L.Kubin*, C.Reignier, G.Woch, H.Tojima, A.I.Pack and R.O.Davies. Department of Animal Biology and Center for Sleep and Respiratory Neurobiology, University of Pennsylvania, Philadelphia, PA 19104.

We have demonstrated that XII motoneurons are under an endogenous excitatory drive mediated by 5HT (Neurosci.Lett.92,139:243) and the 5HT level is reduced in the XII nucleus region during the postural atonia and respiratory depression induced by pontine carbachol microinjections (REM sleep atonia)(Soc.Neurosci.Abst.92,18:1528). In the present study, we assessed if serotonergic agonists microinjected into the XII nucleus can effectively reduce the depression of the XII nerve activity induced by pontine carbachol. In 7 decerebrate, paralyzed, vagotomized and artificially ventilated cats, 5HT or 5CT (5HT agonist), injected into one XII nucleus (mean: $130 \text{ nl}, 1-5 \text{ mM}$), augmented the peak XII nerve activity on the treated side to $193\% \pm 50(\text{SD})$ of control. Then the atonia of REM sleep was induced by pontine carbachol. This reduced the activity on the treated side to $66\% \pm 24$ of the precarbachol level and that on the untreated side to $19\% \pm 11$. Both tonic (expiratory) and phasic (inspiratory) activities on the treated side were similarly affected. The agonist-enhanced XII nerve activity could be depressed by lingual nerve stimulation. These studies are consistent with the possibility that locally applied appropriate 5HT receptor agonists act by substituting for the reduced 5HT release during the carbachol induced atonia. (Supported by HL-47600 & HL-42236.)

IDENTIFICATION OF LINGUAL MUSCLE INTERNEURONS USING PSEUDORABIES VIRUS. R.Fay* & R.Norgren, Neuroscience Program & Department of Behavioral Science, College of Medicine, The Pennsylvania State University, Hershey, PA 17033.

The lingual musculature is involved in a variety of functions associated with ingestion, swallowing, respiration, and phonation. Movement of the tongue involves the complex coordination among three sets of muscles - retractors, protruders, and intrinsic tongue muscles. In order to identify the interneuronal connections in the brainstem involved in the control of each of the tongue muscles, we injected pseudorabies virus (PrV) into the hypoglossus and styloglossus muscles (retractors), the genioglossus and genioglossus muscles (protruders), and into the tongue itself in Sprague-Dawley rats. The animals were allowed to survive between 72 and 90 hours. Prior to viral injection, the superior cervical ganglia were removed bilaterally. In those animals receiving injections into the tongue, the chorda tympani and lingual root of the glossopharyngeal nerves also were sectioned ipsilaterally. Injection volumes ranged from $1-12 \mu\text{L}$ at an average titre of $5 \times 10^8 \text{ pfu/mL}$. Primary infections were restricted to the hypoglossal nucleus (Mo 12) in a predictable myotopic pattern. Secondary infections appeared in neurons known to project monosynaptically to Mo 12 including the subcoeruleus and supratrigeminal areas, the principal sensory trigeminal nucleus, and the pontine and medullary parvocellular reticular zones. Nevertheless, for each of the injected muscles, the pattern of labeling differed within these areas. Polysynaptic connections were revealed to the pedunculopontine, laterodorsal tegmental, oral pontine, gigantocellular, lateral paraventricular, rostromedial, and paratrigeminal nuclei following the longest survival periods. Labeled neurons also were found within and surrounding the nucleus ambiguus and the nucleus of the solitary tract. Supported by PHS grants DC 00240 and MH 00653.

A FUNCTIONAL MAPPING OF THE HYPOGLOSSAL NUCLEUS IN RAT. E.E. Gilliam*, J.R. McClung, and S.J. Goldberg, Department of Anatomy, Medical College of Virginia-Virginia Commonwealth University, Richmond, VA 23298.

The rat's tongue, like man's, is composed of extrinsic and intrinsic muscles which function to protrude and retract the tongue. Anatomical studies have shown that the hypoglossal nucleus and nerve are basically "compartmentalized" into protrusive and retrusive subdivisions (nucleus) or branches (nerve). The medial branch of the nerve innervates the extrinsic genioglossus muscle and the lateral branch innervates the extrinsic styloglossus and hypoglossus muscles. Both branches innervate the intrinsic tongue muscles. This study was designed to physiologically examine the organization of the hypoglossal nucleus.

The lateral and medial branches of the hypoglossal nerve were stimulated separately. The resulting antidromic field potential was recorded in the ipsilateral hypoglossal nucleus (200 and 400 microns lateral to the midline and at various depths). Localized stimulation of those motoneurons proximal to the field was done with single and tetanic stimulation (20-170 Hz) using a 10 micron tip glass microelectrode. The protrusive and/or retrusive forces produced were measured using a sensitive force transducer attached by silk suture to the tip of the tongue. The geography of the protrusive and retrusive motoneuron areas could then be delineated within the XIIth nucleus.

Protrusive (genioglossus) forces result from stimulation of rostral and ventral areas of the nucleus with the medial branch of the nerve intact. Retrusive (hypoglossus and styloglossus) forces result from stimulation of rostral and dorsal areas of the nucleus with the lateral branch of the nerve intact. There is, however, significant overlap between these protrusive and retrusive *extrinsic* motoneuron areas.

Forces resulting from stimulation of *intrinsic* motoneuron areas were observed as generally weak retrusions with either the medial or lateral nerve branch intact. There was considerable overlap of these intrinsic areas of the nucleus, but this overlap was generally found caudally.

We are continuing to analyze the tension and speed related properties of all responses. [Supported by EY-07924]

NOREPINEHRINE (NE) ACTIONS ON HYPOGLOSSAL MOTONEURON (HM) FIRING BEHAVIOR AND THE PHARMACOLOGY OF THE RESPONSE.

M.A. Parkis*, D.A. Bayliss, and A.J. Berger. Department of Physiology and Biophysics, University of Washington, Seattle, WA 98195

Previously we showed that HMs in slices from rat brainstem responded to NE with depolarization, increased input resistance (R_N), lowered current threshold for minimum repetitive firing (I_{THR}), and, in some cells, an increase in the slope of the relation between firing frequency and injected current (*Soc. Neurosci. Abstracts*, 18:512, 1992). Here we further characterize NE's effect on HM firing behavior, and determine the adrenoceptor subtype mediating the response.

Bath-applied NE (100 μ M) caused an increase in the delay to the first spike in response to I_{THR} (avg. delay 2.9 msec in control, 79 msec in NE, n=10). This result suggests that NE may increase a depolarization-activated K^+ -current similar to I_A . In 5 of 12 cells which showed firing frequency adaptation in response to a 1-second constant-current pulse in control, NE decreased or eliminated that adaptation.

Prazosin (10 μ M) attenuated the NE response in all cells tested (n=4), whereas propranolol (10 μ M) had no effect (n=4). Phenylephrine (10-20 μ M) mimicked the effects of NE on HMs, causing a reversible depolarization and an increase in R_N (n=8). Isoproterenol (20 or 100 μ M) produced no change in the membrane potential, R_N , or firing behavior of HMs (n=4). These findings indicate that NE acts on HMs via the α_1 -adrenoceptor subtype. Because of the similarity of the responses of HMs to NE and to thyrotropin releasing hormone (TRH, *J. Neurophys.*, 68:1733-45), we investigated whether these agents share an intracellular mechanism of action in these cells. When TRH (1 or 5 μ M) was present in the bathing solution, the depolarizing response to focally-applied NE was either abolished (n=1) or greatly diminished (to an average of 24% of control, n=4). Upon washout of TRH, the response to NE returned to near control levels. These data suggest that the responses of HMs to TRH and NE share a common intracellular pathway. (Supported by HL-49657.)

Calcium Currents and Calcium Channels in Visually Identified

Hypoglossal Motoneurons (HMs). M. Umeyama and A.J. Berger. Dept. Physiology and Biophysics, University of Washington, Seattle, WA 98115.

Whole-cell Ca currents and single Ca channel activities were recorded using patch clamp techniques in a thin-slice preparation of the medulla from neonatal rats (P1 to P5). HMs were identified visually by their location within the hypoglossal nucleus, and by their size and shape. Previously this laboratory has shown that neonatal HMs have both low-voltage activated (LVA) and high-voltage activated (HVA) Ca currents (Viana et al., *J. Neurophysiol.*, in press). The purpose of the present study was to characterize these currents at the single-channel level, and to identify components of whole-cell Ca currents.

Using the on-cell recording configuration, three channel types were identified by their single channel conductance. A 7-pS channel was activated at the lowest potential, around -50 mV. The largest channel (22 pS) activated at potentials positive to -5 mV and channels of intermediate conductance (14 pS) were activated around -10 mV.

In whole-cell recording, an LVA calcium current and at least three components of HVA calcium current were identified by their activation and pharmacological characteristics. The LVA Ca current began to be activated around -50 mV and was blocked by 100 μ M Cd²⁺. The peak amplitude of the HVA current was reduced 13 \pm 8.2% (mean \pm SD, n=20) with nifedipine or nimodipine, by 38 \pm 15.8% (n=23) with ω -CgTx, and by 45 \pm 15.6% (n=9) with ω -AgaTx-IVA. HVA Ca currents were abolished by 50 μ M Cd²⁺.

The results demonstrate that motoneurons from neonatal rats possess a diversity of Ca channel types, including a P-type and N-type channel that are responsible for a large proportion of the HVA current. (Supported by NS 14857.)

AREA POSTREMA ACTIVITY STUDIED IN FERRET BRAIN SLICES. D.O. Carpenter, N. Hori and N.L. Strominger. Wadsworth Center for Laboratories and Research, NY State Dept. of Health and School of Public Health, Albany, NY 12201 and Dept. of Anatomy, Albany Medical College, Albany, NY 12208.

Brain stem slices (450 μ m), prepared from deeply anesthetized ferrets, were preincubated in oxygenated Krebs-Ringer and then mounted in a recording chamber submerged on a plexi mesh. Extracellular recordings of spontaneous activity of area postrema (AP) neurons were obtained for up to ten hours and responses to bath applied or ionophoresed agents were determined. Most neurons showed a low frequency spontaneous discharge. When β -estradiol was bath perfused at low concentrations (10⁻⁹-10⁻⁸M), activity increased, while at concentrations \geq 10⁻⁶M, it diminished. With ionophoresis of glutamate from an independent micropipette, a brief excitatory response was obtained. In contrast, ionophoresis of apomorphine resulted in very long latency, prolonged excitation. These observations are similar to those from *in vivo* studies in dogs. In some slices, injections of HRP or WGA-HRP were made in attempts to study local AP connections. Reciprocal relations were seen only between AP and the immediately adjacent solitary complex.

403.12

THE MECHANISM MEDIATING THYROTROPIN-RELEASING HORMONE (TRH) EFFECTS ON MOTONEURONS INVOLVES G-PROTEINS BUT NOT PROTEIN KINASE C, IP₃ OR INTRACELLULAR CALCIUM. D.A. Bayliss*, F. Viana and A. J. Berger. Dept. Physiol. & Biophys., Univ. of Wash., Seattle 98195.

Effects of TRH on clonal pituitary cells are mediated by GTP-binding proteins (G-proteins), involve activation of protein kinase C (PKC) and increases in intracellular inositol trisphosphate (IP₃) and calcium (Ann NY Acad Sci 553:191, 1989). We used conventional intracellular recording in brainstem slices to test whether a similar mechanism mediates the TRH-induced depolarization and increase in input resistance (R_N) of hypoglossal motoneurons (HMs). TRH-induced depolarization recovered quickly (within ~8-10 min) and could be repeated with modest tachyphylaxis (\downarrow by ~20%) when HMs were impaled with electrodes containing 3 M KCl (n=12) or 30 mM GTP (in KCl; n=7). However, with GTP γ S-containing electrodes (10 mM; n=4) the depolarization induced by TRH was long-lasting (up to 1 h), and with GDP β S-containing electrodes (20 mM; n=5) tachyphylaxis with repeated TRH application was exaggerated (\downarrow by ~60%). Phorbol dibutyrate (PdBu; 10 μ M in perfusate), an activator of PKC, neither mimicked nor occluded the effects of TRH (n=3); in control experiments, as expected, 10 μ M PdBu decreased a slow after-hyperpolarization (AHP) in CA1 hippocampal neurons. There was no effect on membrane potential, R_N or the response to TRH in HMs during long recordings with electrodes containing IP₃ at high concentration (60 mM; n=2). The effect of TRH was not blocked in HMs impaled with electrodes containing calcium chelators (0.1 M EGTA, n=3; 5 mM BAPTA, n=2) despite a nearly complete abolition of the calcium-dependent AHP. Together, these results indicate that G-proteins mediate the response of HMs to TRH but that the effects of TRH do not involve activation of PKC or increases in intracellular IP₃ and calcium concentration. Involvement of other intracellular signaling pathways (e.g. cAMP, arachidonic acid) remain to be tested. (Supported by NS14857 and Francis Families Foundation.)

CHARACTERISTICS AND DEVELOPMENT OF I_h IN RAT HYPOGLOSSAL MOTONEURONS. M.C. Bellingham*, D.A. Bayliss, F. Viana and A.J. Berger. Dept. Physiol. & Biophys., Univ. Washington, Seattle, WA 98195.

Adult rat hypoglossal motoneurons (HMs) recorded from brainstem slices exhibit a slowly activating inward current during prolonged membrane hyperpolarization. Using current and voltage clamp methods, we examined the characteristics of this current to determine if it is the hyperpolarization-activated cationic current (I_h) seen in other neurons. I_h of young adult (P21-65) rat HMs was measured as the difference between the current at the beginning and the end of a long (1-2 sec) negative voltage step from a holding potential of -55 to -60 mV. I_h showed a reversal potential of -38 \pm 6 mV (mean \pm SD, n = 5), estimated from the intersect of I/V plots from two different holding potentials, indicating the current was carried by a mixture of cations. Bath application of 0.5 or 2 mM Ba²⁺ reduced I_h at half activation by only 15-25% (n = 2) or 40 \pm 16% (n = 3) respectively, whereas bath application of 3 mM Cs⁺ reduced I_h by 89 \pm 4% (n = 3). These properties are characteristic of I_h in other neurons. Tail current analysis showed voltage-dependent activation of I_h beginning at -65 to -75 mV and maximal at -95 to -110 mV, with half activation at -80 \pm 2 mV (n = 10). Time constants (τ , single exponential fitting of current records) of I_h activation and deactivation showed voltage dependence. As more negative voltages were reached, activation proceeded more quickly (i.e., activation τ decreased) and deactivation was slower (i.e., deactivation τ increased). We also determined the time course for the development of I_h during the neonatal to young adult period. In adult HMs, I_h amplitude at half activation was -1.9 \pm 0.6 nA (n = 15), while in neonatal (P2-8) HMs, it was -0.16 \pm 0.11 nA (n = 7). As HMs only show a 4-fold increase in resting membrane conductance and doubling of total membrane area (*Soc. Neurosci. Abstr.*, 18:1049) during the same period, the 10-fold increase in I_h is due, at least in part, to an increase in I_h current density during development. PERIAQUEDUCTAL GRAY (PAG) STIMULATION INCREASES C-FOS EXPRESSION IN SELECTED BRAIN STEM AREAS

P. Room, R. Dantuma and G. Holstege. Dept. of Anatomy and Embryology, Faculty of Medicine, University of Groningen, Groningen, The Netherlands.

The midbrain periaqueductal gray (PAG) exerts a strong influence on somatic and autonomic motoneurons. Physiological studies have shown that stimulation in the PAG results in motor activities such as defense behavior, vocalization and locomotion. The main projection from the PAG is to the ventromedial tegmentum of caudal pons and medulla (*Progr. in Brain Res.* 87, p307, 1991). We used *c-fos* immunoreactivity as a marker of neural activity to determine the pattern of activated neurons in the lower parts of the brain stem following stimulation in different parts of the PAG. Rats were anaesthetized (urethane 1- 1.5 g/kg) and the PAG was electrically stimulated for 45 minutes (100 μ A, 80 Hz, 1 sec on/9 sec off). During stimulation EMG's, heart rate and blood pressure were monitored. In rats which were surgically prepared for brain stimulation but not stimulated, small numbers of *c-fos*+ cells were observed in the cuneiform nucleus, the nucleus raphe pallidus and raphe magnus, the ventrolateral medulla and the solitary tract nucleus. Following stimulation in the PAG, the number of *c-fos*+ cells was much higher in these areas and *c-fos*+ cells were also observed in the nucleus raphe dorsalis, raphe medianus and raphe pontis, the locus coeruleus, Barrington's nucleus and in the nucleus retroambiguus. We conclude that stimulation in the PAG increased *c-fos* expression in selected parts of the brainstem which in part corresponds with those previously shown in tracing studies.

THE VENTROLATERAL TEGMENTAL NUCLEUS IN THE RAT: ANALYSIS OF THE AFFERENT AND EFFERENT CONNECTIONS. A. Klepper* and H. Herbert. University of Tübingen, Dept. Animal Physiology, 72076 Tübingen, Germany.

The ventrolateral tegmental nucleus (VLTg), a subdivision of the oral pontine reticular nucleus, is discussed as a part of a neuronal circuit that mediates acoustically elicited behavior. In order to shed light on the potential role of the VLTg as a sensorimotor interface, we analyzed the afferent and efferent connections of this reticular nucleus by using the retrograde fluorescent tracer Fluoro-Gold and the anterograde tracer *Phaseolus vulgaris*-leucoagglutinin, respectively.

The VLTg is reciprocally connected with various nuclei along the neuraxis, including the zona incerta, the superior colliculus, the central gray, and various mesencephalic, pontine, and medullary reticular nuclei. Moreover, the VLTg receives a prominent input from various auditory nuclei: the cochlear root nucleus, the dorsal and ventral cochlear nuclei, the external cortex of the inferior colliculus, and the secondary auditory cortex. Furthermore, the VLTg projects to facial motoneurons which innervate the pinna muscles.

In summary, the VLTg receives projections from a variety of brain areas including prominent inputs from auditory nuclei and, in turn, projects to reticular nuclei containing premotor neurons, as well as to the facial nucleus. We therefore conclude that the VLTg integrates sensory information and participates in mediating audiomotor behavior like the pinna reflex and the acoustic startle response.

ANOXIC RESPONSE OF MEDULLARY PARAPYRAMIDAL NEURONS. M. Patil, D. Durand, and M.A. Haxhiu*. Applied Neural Control Lab., Dept. of Biomedical Engineering, and Dept. of Medicine, Case Western Reserve University, Cleveland, OH - 44106.

Parapyramidal neurons, located at the ventral surface of the medulla and lateral to the pyramids, have been identified as higher-order neurons within the baroreceptors and chemoreceptor reflex pathway. This identification was based on their *c-fos* protooncogene expression (Erickson & Millhorn, 1991). The present study is being conducted to investigate the electrophysiological effects of anoxia on these parapyramidal neurons. Neonatal (7 to 20 days) and adult rats were used to obtain medullary slices, which were dissected and the ventral half was used. Intra-cellular recordings were obtained *in vitro* from four parapyramidal cells in control conditions, 95% O₂ and after exposure to 95% N₂ in a bicarbonate buffer. Anoxic response was observed within a few seconds after exposure to nitrogen. Depolarization of 10 to 20 mV was observed in both, adult and neonatal cells after the first anoxic insult which lasted for 5-7 mins. In neonatal cells, which were found to fire spontaneously at a rate of about 3 spikes/sec, anoxia abolished all spontaneous activity. However, electrical stimulus could generate action potentials, whose shape or size did not appear to change significantly compared to control. In comparison, spontaneous activity was absent in the adult neuron impaled. Anoxia decreased the somatic firing threshold. A transient decrease in the input resistance was also observed in anoxia. Complete recovery was obtained by switching to 95% O₂ in both neonates (within 5mins) and adults (within 10 mins). Subsequent anoxic insults did not produce a significant change in the resting potential. Neonatal cells survived in anoxia for >45 mins, whereas in adults, survival was up to 30 mins. Preliminary results indicate that anoxia produces depolarization and abolishes spontaneous activity.

A METHOD TO APPLY AN EXTERNAL PERTURBATION TO THE HUMAN ANKLE JOINT DURING ANY POINT OF THE GAIT CYCLE. T. Sinkjær* and J. B. Andersen. Dept. of Medical Informatics and Image Analysis, University of Aalborg, Fr. Bajersvej 7D, 9220 Aalborg SO, Denmark.

Previous investigations based on the H-reflex have shown that the short latency spinal reflexes of the human ankle extensors are highly modulated during gait. The H-reflex study is a relatively easy method to achieve results from the spinal reflex system. However, it is only possible to probe central factors since the electrical stimulation bypass the muscle and the fusimotor system, which might contribute to the reflex modulation.

A system able to apply a stretch reflex perturbation to the muscles around the human ankle during gait were developed. The two link system consists of a mechanical joint, strapped to the shin and the foot of the subjects (See Figure). The mechanical joint is revolving around the ankle joint and by means of bowden wires it is connected to a motor placed next to a treadmill where the subject is walking. By a position feedback from the mechanical joint the motor is regulated in such a way that it follows the movement of the ankle without influencing the gait pattern. When wanted, the system is designed to impose an ankle rotation with a displacement of up to 20°, a speed of 150 °/s and a torque of up to 200 Nm during any time of the gait cycle. The weight of the total system attached to the leg of the subject is 0,9 kg.

KINEMATIC CHANGES AFTER UNILATERAL ANTERIOR CRUCIATE LIGAMENT TRANSECTION IN THE DOG: COMPENSATORY RESPONSES OF THE CNS. J.A. Vilensky*, B.L. O'Connor and K.D. Brandt. Depts. of Anatomy and Medicine (Rheumatology), Ind. Univ. Sch. of Med., Ft. Wayne and Indianapolis, IN 46805/46202

Presumably, subsequent to anterior cruciate ligament transection (ACL), the CNS uses sensations of pain and/or instability to modify movements to preserve ambulation while protecting the unstable joint from the rapid degeneration that occurs in dogs whose limb is deafferented prior to ACL (1). This study characterizes the kinematic changes after ACL. Six dogs underwent left ACL and were filmed before and 1-26 weeks after ACL. The dogs showed reduced left knee and ankle joint flexion during stance (less "yielding"), but flexion of the right knee and ankle was increased. Additionally, the left hip was more extended during stance. The forelimb joints showed only slight changes. The ACL dogs also exhibited greatly increased vertical movements of the sacrum. The CNS apparently partially compensates for knee instability by reducing the stance phase movements of the ipsilateral ankle and knee and increasing those of corresponding contralateral joints, causing increased vertical body movements (limping). The similar responses of the ankle and knee of each side (decreased flexion ipsilaterally and increased contralaterally) suggest biomechanical and/or neurological linkages in the actions of these joints. 1) J Bone Jt Surg 67A:562, 1985 (Supported by PHS P60AR20582).

1STREPTOMYCIN VESTIBULOTOXICITY IN PIGMENTED RATS. ¹G. Meza, ²N. Daunton, ¹L. López-Griego and ³M. Salas. ¹Dept. Neurociencias, IFIC, UNAM. Apdo. Postal 70-253, 04510 México, D.F. MEXICO.

To investigate the vestibular target organ of streptomycin (STP), postrotatory nystagmus (PN), righting reflex (RR) and swimming behavior (SB) were studied in STP-300-500 mg/kg - i.m - daily-long period-treated pigmented rats. Audition alteration was followed by auditory evoked brainstem potential (AEP) evaluation. Regardless of treatment length and dose, AEP remained same as controls. PN response was slightly affected only at 500 mg/kg and at the longest timespan. In contrast, even at 300 mg/kg STP, RR and SB were deeply affected, since the time of righting and resurfacing was considerably higher than controls. These results corroborate STP vestibulotoxicity and strongly suggest a specific otolith organ STP action never reported before in the rat now being checked by other methodology.

Financed partly by DGPA-UNAM (México) IN201791 to G.M. ²N.D. is at Ames Research Center (NASA) and ³M.S. at the I.I. Biomédicas (UNAM, México).

IDIOPATHIC MIRROR MOVEMENTS. L.M. Harrison, M.J. Mayston, J. Gibbs and J.A. Stephens. *Dept. of Physiology, University College, London. WC1E 6BT.

Intense mirror movements are not usually seen in normal adults. We have investigated the neurophysiology of such movements in a 15 year old male with no dysmorphic features. Surface EMG was recorded from the first dorsal interosseous muscle (IDI) during repetitive index finger abduction. EMG commenced at the same time in the IDI of both the voluntarily abducted finger and the mirroring finger. To investigate whether this simultaneous EMG is due to a common drive to L and R motoneuron pools, cross-correlation analysis of multiunit EMG from co-contracting L and R muscle pairs (IDI, forearm extensors (Fext), triceps and deltoid) was performed. All correlograms exhibited a short duration central peak centred around time zero. The size of this peak showed a distal to proximal gradient, being larger for distal muscle pairs. No central peak was present in correlograms constructed from data recorded from normal 5-6 yr olds with moderate mirroring. Focal magnetic brain stimulation of the L and then the R motor cortex of our subject revealed bilateral responses in IDI and Fext; the contralateral response was larger than the novel ipsilateral response. Cutaneous-muscular reflexes were recorded from L and R IDI whilst stimulating the digital nerves of the L and then the R index finger. The reflex E2 component, which is dependent upon the integrity of the pyramidal tract, was recorded contralaterally in addition to the normal ipsilaterally recorded response. Taken together, the results indicate the presence of pyramidal tract fibres that have branched and innervated homologous L and R motoneuron pools.

TRAJECTORY FORMATION AND INTERJOINT COORDINATION OF DRAWING MOVEMENTS IN NORMAL AND HEMIPARETIC SUBJECTS. M.F. Levin*, M. Horowitz, J. Jurrius, C. Lamothe, A.G. Feldman, Research Centre, Rehabilitation Institute of Montreal, Montreal, Quebec, Canada. H3S 2J4

Movements can be organized at the interjoint level and in terms of extrapersonal space (trajectory planning). We investigated how interjoint coordination is related to trajectory formation. Arm movements were studied in 7 normal and 7 hemiparetic subjects. Data from affected arms of hemiparetic subjects were compared to those from their non-affected arms and to data from normal subjects. Subjects were seated in front of a horizontal surface adjusted to the height of the sternal notch with the trunk immobilized to the back of the chair. In one series of experiments, subjects made planar arm reaching movements (20 and 40 cm) to 4 different targets inlaid on the table. In the other, subjects traced 40 cm diameter circles on the plane with their index finger. Kinematic and electromyographic data from the finger, wrist, elbow and shoulder were recorded with a 3D optical tracking system. Results showed that movement amplitudes were lower and movement times were longer in the affected arms. Trajectories were marked by deviations from smooth lines and characterized by segmentation, hysteresis and abrupt changes in tangential velocity. The degree of disruption of interjoint coordination between the elbow and shoulder was related to spasticity and functional activity scores. Results of these studies may have implications for the rehabilitation of hemiparetic patients.

404.7

THE EFFECT OF COGNITIVE DEMANDS ON POSTURAL CONTROL IN ELDERLY FALLERS AND NON-FALLERS.

A. Shumway-Cook*, M. Baldwin, K. Kerns, M. Woollacott, Northwest Hospital, Seattle, Wa 98133

This study compared attentional requirements of stance postural control in young vs elderly adults. A dual task design measured the effects of cognitive tasks (Judgement of Line Orientation and Sentence Completion) on postural sway in 20 young, 22 elderly non-fallers, and 22 elderly fallers. A forceplate measured center of gravity while subjects stood for 30 seconds on a firm or compliant surface. Repeated-measures was used to analyze change in sway path (mm).

There was a significant main effect of cognitive tasks, and a task x group interaction. In young controls both tasks affected sway on the compliant but not the firm surface. In elderly non-fallers both tasks affected sway on the firm surface but not the compliant surface. In elderly fallers cognitive tasks affected sway on both firm and compliant surfaces.

Results suggest that competing demands for attentional resources by cognitive and postural systems may contribute to instability in the elderly.

404.9

LIMB TRAJECTORY IN NON-DISABLED SUBJECTS UNDER TWO CONDITIONS OF EXTERNAL CONSTRAINT COMPARED WITH THE NON-PARETIC LIMB OF SUBJECTS WITH HEMIPARESIS

CA Giuliani*, PA Genova, JL Purser, KE Light, Motion Analysis Lab., University of North Carolina at Chapel Hill, Chapel Hill, NC 27499-7153

The purpose of this study was to test our hypothesis that weakness and difficulty constraining degrees of freedom were elements underlying arm control deficits in subjects with unilateral brain lesion. To test this hypothesis 8 non-disabled (ND) subjects and 8 subjects with right CVA were instructed to tap vertically on a Fitts board as fast as possible for 10 seconds using a hand-held stylus. All subjects tapped with their right dominant limb. ND subjects performed this task under two additional conditions of wrist immobilization and fatigue (a mass of 6% body weight attached to the limb). All trials were videotaped and the stylus trajectory was digitized at 60 Hz. Variables chosen for comparison that quantify phase plane characteristics were: up/down velocity ratio, timing ratio of peak velocity, peak amplitude phase, cycle frequency, and the ratio of amplitude/velocity slopes. Significant differences ($p < .05$) were found between free and fatigued conditions for all variables and no significant differences were found between the free and immobilized conditions for ND subjects. No significant differences were found between ND subjects in the fatigue condition and right CVA subjects for all variables except cycle frequency and slope ratio. That there was no effect of immobilization suggests that ND subjects were using a predominant elbow strategy. Fatigue in ND subjects appeared to alter the dynamics of an otherwise stable motor control system. The similarity between the non-paretic limb of subjects with right CVA and the ND subjects during the fatigue condition provides support for the hypothesis that weakness contributes to deficits in motor control in the non-paretic limb of subjects with unilateral brain lesion.

THE INFLUENCE OF ATTENTION ON POSTURAL CONTROL W.E. McIlroy*, and B.E. Maki, Sunnybrook Health Science Centre, University of Toronto, Toronto, Ontario, CANADA. M4N 3M5

This study addresses the potential relationship between attention and the control of posture in young adults using a dual-task paradigm. Postural responses were measured using EMG's and ground reaction forces. To address concerns about confounding due to arousal, we monitored skin conductance and assessed trait and state anxiety, using S-R GTA and PARQ questionnaires. A first study quantified postural responses during unperturbed stance in 41 subjects while they performed either: 1) no secondary task, or 2) a cognitive task (backward counting by 7's). Results revealed a significant increase in mean anterior-posterior center-of-pressure displacement when performing the secondary task. In the second experiment, subjects tracked either an auditory or visual signal. Use of a continuous, quantifiable secondary task allowed us to document occurrences of attention switching. Significant differences in the performance of the postural tasks (one-foot standing, pseudorandom platform perturbation) were measured within individual subjects as changes in frequency and variability of postural responses. Furthermore, performance on the tracking task was seen to decrease with increasing postural challenge. This appeared to be due, in part, to transient pauses in the tracking behavior associated with brief periods of relative postural instability, possibly revealing transient shifts in allocation of attentional resources. The present results confirm the potential importance of attention in the determination of postural responses, and suggest that use of continuous and quantifiable secondary tasks, such as tracking, may help to reveal details of the dynamic attentional requirements of maintaining upright stance.

404.8

USE OF FUNCTIONAL ELECTRICAL STIMULATION TO ENHANCE PARALYZED CAT HINDLIMB MUSCLES. J. Mao, N. Tyreman, R.B. Stein*, T. Gordon, Div. of Neuroscience, Univ. of Alberta, Edmonton, CANADA T6G 2S2.

An optimal regime is to be established for using functional electrical stimulation (FES) to enhance muscle strength and endurance. FES was applied to cat hindlimb muscles under different conditions. In 8 free-moving cats, the (non-paralyzed) medial gastrocnemius (MG) muscles were stimulated at 20 Hz and 50% of daily time through cuff electrodes implanted around the MG nerves. Once or twice per week the MG muscles were recorded for their forces, speeds, and endurance. These chronic recordings show that fatigue resistance and contraction time both increased while the maximum tetanic force decreased. In 3 free-moving cats which were hemispinalized and (ipsilaterally) deafferented, the paralyzed MG muscles were stimulated with different patterns (20 Hz or 100 Hz, 5% or 50% of daily time). The fatigue resistance increased with both 20 Hz/50% and 100 Hz/5% stimulation but not with 20 Hz/5% stimulation. Still, the maximum tetanic force decreased. In order to prevent the decay in muscle force while maintaining the increased endurance, a metal boot was made for fixing the muscle length and providing resistance while the muscle was stimulated to contract. For 2 hrs/day and 5 days/week, the metal boot fixed the paralyzed hindlimb of one cat so that its tibialis anterior (TA) muscle was lengthened and its MG shortened. During this period 20 Hz stimuli (2 s on and 2 s off) were applied alternately to the paralyzed TA and MG muscles each contracting against the resistance. Initial data of long-term recordings show that the maximum tetanic force of the lengthened TA muscle was not decaying while its fatigue resistance gradually increased. In contrast, the muscle force and endurance of the shortened MG did not increase significantly. These results suggest that muscle length and contraction against resistance should be considered in using FES to enhance paralyzed muscles. (Supported by MRC and NCE of Canada).

SIGNIFICANT REDUCTIONS IN UPPER LIMB SPASTICITY IN HEMIPARETIC STROKE SUBJECTS USING CUTANEOUS LEVELS OF ELECTRICAL STIMULATION. L.P.A. Dewald*, J.D. Given, D. Yamada and W.Z. Rymer, Sensory Motor Performance Program, Rehab. Institute of Chicago, and Dept. of Physical Medicine and Rehabilitation, Northwestern University Medical School, Chicago, IL.

In order to investigate the effect of different electrical stimulation protocols on spasticity in a hemiparetic test population (n=7), pre-stimulation torque responses of the impaired upper limb were measured during slow ramp perturbations of the elbow and compared with torque responses obtained immediately following stimulation over the antagonistic muscle. The subject's arm was positioned in 120° of elbow extension or 60° of elbow flexion depending on whether the stiffness in flexors or extensors was estimated (180° is designated as full extension). The arm was moved through an arc of one radian (57.3 degrees) at a constant angular velocity, which was determined by the level of spasticity in the arm. In addition, EMG signals of biceps, brachioradialis, and triceps muscles were collected. The electrical stimulation was applied to skin over the biceps muscle for a period of ten minutes at a 20 Hz frequency, pulse duration 0.1 ms, with an intensity level below motor threshold, but above sensory threshold. The joint extensions and/or flexions were performed immediately after electrical stimulation, and subsequently at several intervals up to 30 minutes after cessation of the stimulation. In some cases, subjects were again given electrical stimulation, but at a level which was just above motor threshold.

In all subjects, cutaneous stimulation over the elbow flexors at submotor levels significantly reduced the torque in both elbow flexors and extensors, while stimulation slightly above motor threshold resulted in significant reductions in extensor torques, but significant increases in flexor torques. These effects remained statistically significant for at least 30 minutes following stimulation although the positive effects diminished with time.

The observed reductions in spasticity (by as much as two-thirds of pre-stimulation peak torque levels) were determined to be due mostly to changes in stretch reflex threshold as opposed to gain. These reductions in spasticity hold significance not only by avoiding side effects of drugs such as Dantrolene (i.e., generalized weakness), but also because the most efficacious level of stimulation is the best tolerated. USE OF A SERVO MOTOR DEVICE TO QUANTIFY SPASTIC PLANTARFLEXOR MUSCLE CHARACTERISTICS. L.D. Abraham*, S.C. Allison, P.A. Anderla and C. Stanford. Kinesiology & Health Education and Institute for Neuroscience, University of Texas, Austin, TX 78712 and Healthcare Rehabilitation Center, Austin, TX 78745.

Objective measurement of spasticity in the ankle plantarflexors is important clinically, given the devastating effect of plantarflexor spasticity on gait and functional mobility in patients with upper motor neuron lesions. We have developed a torque motor device to provide mechanical perturbations to the ankle joint and to measure kinetic, kinematic and physiological responses. The magnetic servo motor receives command strings relayed from a desktop computer, which are processed through the servo controller using a digital PID control algorithm. This system allows for independent control of angular velocity, angular acceleration and angular displacement. The apparatus allows fine adjustment of motor position for alignment with the ankle rotational axis. Patient safety is assured through three safeguards: (1) software positional limits to prevent motion beyond safe ranges, (2) adjustable mechanical stops to prevent unsafe motion and (3) limited (30 N-m) maximum torque-generating capacity of the motor.

The system is designed to produce mechanical perturbations concurrent with procedures such as tendon vibration, H-reflex testing and voluntary muscle activation. LabView (National Instruments, Inc.) software was used to create a customized virtual instrument which controls the servo motor device and also collects the analog data. Using the computer for both control and data collection provides flexibility and allows for a wide variety of measures, both direct and derived. We are currently using the system to measure reflex threshold angles and effects of tendon vibration or antagonist muscle activation on maximum H-reflex amplitudes. The aims of this testing are to reveal potential neurophysiological mechanisms underlying spasticity and eventually to develop a quantitative spasticity measurement scale.

SENSORIMOTOR GATING IN BOYS WITH TOURETTE'S SYNDROME (TS) AND ATTENTION DEFICIT HYPERACTIVITY DISORDER (ADHD). F.X. Castellanos, E.J. Fine, D.L. Kayser, P.L. Kozuch, S.D. Hamburger, J.L. Rapoport*, and M.Hallett Child Psychiatry Branch, NIMH, Bethesda MD 20892.

Gating deficits have been ascribed to corticostriatal dopaminergic dysfunction in schizophrenia and obsessive compulsive disorder. Utilizing supraorbital nerve electrical stimulation, we conditioned the blink reflex with a sensory threshold stimulus at baseline, and 30, 60, 90, 120 and 250 ms before an adequate stimulus elicited a blink reflex. At 90 and 120 ms, seven TS + ADHD boys exhibited significantly reduced inhibition of the blink reflex ($p < .003$, and $p < .01$, respectively) compared to 9 age-sex matched, normal controls. There were no statistical differences at intervals of 30, 60 or 250 ms. We have demonstrated the feasibility of this technique in pediatric patients. These data extend Smith & Lees (1989) finding of abnormal blink recovery in TS, suggesting a disturbance of basal ganglia input to brainstem interneurons.

DISCHARGE PATTERN OF MOTOR UNITS (MUS) DURING MOTOR PREPARATION FOR A TASK PERFORMED AGAINST LOADS. L. Rispal-Padell*, and S. Mellah. C. R. "Cerveau et Cognition", CNRS, Faculté de Médecine, Toulouse, France.

Slow biceps MUs become active during the motor preparation for a forearm flexion movement (Mellah et al., 1990). To determine whether this activity is correlated with the forthcoming muscular force to be developed we examined the patterns of activity of MUs during the preparation for and execution of a flexion movement. The monkey had to overcome static loads of various weights during the movement execution but during the preparatory period, an abutment was placed behind the cradle supporting the forearm to compensate for the load.

The discharge frequency of the "slow tonic" MUs which were active during the preparatory period under normal conditions increased during this period when heavier loads were to be overcome during the forthcoming movement. Changes occurred in the frequency as well as the duration of the preparatory discharge pattern. At very high loads when the discharge frequency was at its maximum, the discharge onset continued to occur more and more early on.

Under anisometric conditions, the discharge frequency plays an important part in the force grading processes. When the movement is preceded by a preparatory period, however, the temporal component of the discharge constitutes an additional mechanism which seems to be of importance mainly when the load to be overcome is heavy.

INTERACTIONS OF MULTIPLE UNITARY EMG POTENTIALS AT DIFFERENT LEVELS OF MOTOR DRIVE USING AN ACUTE EXPERIMENTAL SIMULATION. S. Day, P. Sjölander, M. Hulliger and G. McVill-Jones. Dept. of Clinical Neurosciences, Univ. of Calgary, Canada T2N 4N1.

The EMG is a complex interference signal, composed of the unitary action potentials contributed by each active motor unit. As the level of motor drive is increased, by recruitment and/or rate modulation, the contribution of each single unit may change.

An acute cat soleus muscle preparation was used to study the isometric EMG - force relationship, including an analysis of unit EMG contributions to whole muscle EMG. The ventral roots containing soleus motor units were divided into 10 filament units (FU) each unit containing 10-20 motor units (MU). Together, using a recruitment and rate modulation strategy imitating the size principle, these FU were stimulated over the entire physiologic range of soleus MU firing rate using pseudo-random pulse trains with a degree of variability, to simulate normal muscle activation and avoid the problems associated with synchronization. To assess the importance of the level of motor drive on the characteristics of the individual FU muscle membrane potentials recorded by surface and indwelling electrodes, each ventral root filament was stimulated individually and together (combined) with the other filaments. For selected FU's, a spike triggered averaging (STA) technique was used to differentiate the waveform of the FU from an aggregate signal composed of a number of FU's.

The EMG recorded during the stimulation of each individual filament was algebraically summed and the results were compared to the EMG trace of the combined stimulation trial. The results are qualitatively similar, suggesting largely linear summation of EMG potentials, and also an absence of any significant changes in the characteristics of individual muscle membrane potentials, as the level of motor drive increases. Indeed, preliminary evidence from STA data of individual FU's suggests that no systematic changes occur in the shape of the muscle membrane potentials with increased motor drive. This indicates that, as muscle activation increases, any changes in whole muscle impedance are small enough not to alter the individual FU contributions to the EMG, and it suggests that linear summation of single MU potentials for EMG modeling is, after all, justified. MOTOR UNIT ACTIVITY DURING HUMAN ARM MOVEMENTS AND MATCHED ISOMETRIC CONTRACTIONS. S.J. Garland, T. Ivanova, and K.J. Miller. Dept. of Physical Therapy, University of Western Ontario, London, Ontario, Canada, N6G 1H1

Most of the studies of human motor unit behavior have been performed using isometric contractions. However, most daily activities executed by humans require movement. The purpose of this study was to determine whether the motor unit activity would be comparable between the conditions of movement and isometric contractions. Surface EMG recordings were obtained from biceps and triceps brachii muscles. Motor unit activity was recorded from the lateral head of the triceps brachii muscle using a subcutaneous fine-wire electrode. Subjects performed 100 alternating flexion and extension elbow movements (50°-130°) in a horizontal plane. Utilizing phase-plane tracking, the arm movements had pre-determined acceleration and deceleration characteristics. After the movements were completed, the wrist was secured onto an isometric force transducer that kept the arm in the horizontal plane. The acceleration and deceleration profiles from the movements could be reproduced in the isometric setting by presenting the kinematic profiles as force pulse templates. Following adjustment of the amplitude of the voluntary isometric contractions of elbow flexor and extensor muscles, the surface EMG activity was equivalent in both the movement and the isometric paradigm. This ensured that the muscular tension produced in both paradigms was comparable. The same motor units could be identified in both paradigms. Thus, these motor units were not "task-dependent". It may be possible to make inferences regarding movement based on isometric paradigms given the appropriate contraction parameters. Supported by NSERC (Canada).

POSSIBLE RECEPTOR MECHANISMS RESPONSIBLE FOR THE GAIN COMPRESSION OF GOLGI TENDON ORGAN RESPONSE TO FORCE. P. Sjölander, M. Hulliger, Y. Coifon, U.B. Windhorst* and E. Otten. Dept. of Clinical Neurosciences, Univ. of Calgary, Canada T2N 4N1 and Dept. of Medical Physiology, Univ. of Groningen, NL-9712 KZ Groningen.

The discharge rate of Ib afferents is known to saturate at relatively small muscle forces. This has led to the suggestion that they are unlikely to provide a reliable estimate of whole muscle force. However, in recent experiments we have demonstrated that staggered stimulation (imitating recruitment) of soleus motor axons produces discharge rates of Ib afferents which increase monotonously, if non-linearly, with muscle force. The present study investigated encoder and transducer properties of the Ib receptors which may contribute to the saturation and summation effects previously demonstrated.

Responses of single Ib's from the soleus muscle were recorded in dorsal root filaments of anaesthetized cats. The L7 and S1 ventral roots were divided into a number of filaments containing soleus motor axons. The tetanic force elicited by each bundle varied between 2 and 25% of the maximum tetanic force. Pairs of filaments which individually excited a Ib afferent were activated under isometric conditions, using a ramp-shaped (5-25/s) stimulation for one and rectangular-shaped patterns (12, 17, 30/s) for the other, either alone or in combination.

Comparisons of the effects of individual and combined filament stimulation showed: 1) for most filament pairs pronounced sub-linear summation of Ib biasing was found; 2) occasionally complete absence of summation (occlusion) was observed; 3) the degree of summation on a given Ib afferent varied considerably between different filament pairs; 4) inverting the stimulation patterns between the filaments a pair could alter the extent of summation significantly; 5) neither the absence of summation nor the degree of summation was related to the force produced by the filaments.

While complete occlusion of single filament biasing effects would be compatible with competition between parallel encoding sites on myelinated terminal branch trees, the variation of the degree of partial occlusion upon inversion of inputs is not, and might arise from non-linear compartmentalized receptor terminal activation.

FORCE CODING BY A POPULATION OF CAT GOLGI TENDON ORGAN AFFERENTS: THE ROLE OF MUSCLE ACTIVATION PATTERNS. M. Hulliger, Y. Coiton, P. Sjölander, U.R. Windhorst, E. Otten¹ and T.E. Feashy². Dept. of Clinical Neurosciences, Univ. of Calgary, Canada T2N 4N1 and Dept. of Medical Physiology¹, Univ. of Groningen, NL-9712 KZ Groningen.

While firing rates of single Golgi tendon organ (GTO) afferents often poorly reflect whole muscle force and even the force generated by the motor units (MU) which excite them, it has long been postulated that ensemble responses might monitor whole muscle force more reliably. This was confirmed for various forms of distributed or temporally dispersed activation of large fractions of the cat soleus MU pool (Soc. Neurosci., Abstr. 18, 1407, 1992): the population response-whole muscle force relations were monotonous, yet revealed different degrees of gain compression non-linearity, with the least non-linear relation resulting from a combination of staggered activation (of subsets of MUs) and rate modulation. The present study was undertaken to determine which of the three, recruitment, rate-modulation, or size of biasing effect on GTOs, were most influential in linearizing the input-output characteristics of the GTO population response.

Subsets of MUs were activated through 8 ventral root filaments of widely ranging size (2-25% of maximum soleus force), using staggered activation (imitating recruitment), distributed stimulation (for pure rate modulation), or a combination of the two.

Least significant was the size of biasing effects elicited by individual filaments, since inversion of filament rank order had minimal effects on the GTO firing vs force relation. Pure rate modulation tended to enhance, while staggered activation reduced gain compression non-linearity. This suggests that temporally dispersed activation (recruitment) of MUs was most significant in linearizing the population response-force relation and in extending the range of operation (in terms of resolving force input) of ensembles of GTO afferents.

PROPRIOCEPTIVE TUNING CURVES L.A. Jones¹ and I.W. Hunter². School of Physical & Occupational Therapy¹ and Dept. Biomedical Eng.², McGill University, 3654 Drummond St., Montreal, Canada H3G 1Y5.

In both the tactile and auditory sensory modalities, the ability to detect a particular amplitude of vibration depends on the frequency of the stimulus being presented. The relation between stimulus frequency and the smallest amplitude that is detected at a given frequency is known as a tuning curve. A comparison of these curves for audition and touch reveals that the amplitudes for detection are much higher for the skin than for the ear, and that the auditory system can detect very small movements of the eardrum over a much larger range of frequencies. The tactile system is, however, good at detecting changes in amplitude at low frequencies.

The objective of the present experiment was to determine the tuning curve for the proprioceptive sensory modality using a procedure similar to that employed in audition and touch. Subjects were seated in an apparatus with each forearm coupled to a linear motor that was under computer control. Movements of the same frequency but varying in amplitude were imposed on each arm, and subjects were required to indicate which vibratory stimulus had the larger amplitude. A transformed up-down procedure, which seeks a stimulus level that corresponds to 71% correct performance, was used to track the subject's threshold at each frequency.

The results indicate that the ability to detect changes in the amplitude of a vibratory movement imposed on the forearm depends on the frequency of the movement, with lower thresholds being associated with movements of higher frequencies (i.e. above 5 Hz). These findings are consistent with those obtained using unidirectional movements of varying velocity, for which it has been found that performance is optimal for velocities between 2-80°/s (Hall & McCloskey, J. Physiol. 1983). The proprioceptive tuning curve resembles those derived for touch in that they are clearly U-shaped functions.

IDENTIFICATION OF TIME-VARYING NEUROMUSCULAR SYSTEMS. R.F. Kirsch^{*} and R.E. Kearney. Dept. of Biomedical Engineering, McGill University, Montréal, Québec, Canada H3A 2B4.

The nervous system produces coordinated movements by modulating muscle activation patterns and reflex properties across time, making a time-varying description of neuromuscular dynamics natural and potentially useful. Special techniques must be used to characterize time-varying neuromuscular properties, however, since standard time-invariant methods are unable to separate system dynamics from rapid changes in these dynamics with time.

We have developed a time-varying identification technique which characterizes linear dynamic systems by estimating a set of impulse response functions, one for each time instant during some nonstationary behavior. A sample-to-sample tracking speed is achieved by performing the estimation at each time across an ensemble of many similar trials rather than across time in a single trial; in each trial, an independent stochastic perturbation is imposed upon the input and the evoked output is measured. Digital and analog simulations have verified the accuracy and tracking speed of our algorithm.

We have used this technique to characterize human ankle joint stiffness and the triceps surae stretch reflex during two simple time-varying behaviors. Rapid changes in isometric contraction level were found to produce large changes in the magnitude of the stretch reflex, but its dynamics were unaffected and magnitude changes were tightly synchronized to activation level. Joint stiffness could be described by a 2nd order mechanical system during steady-state conditions, but not during changes in contraction level; furthermore, stiffness initially declined as torque increased before increasing to the appropriate steady-state level. A rapid stretch imposed upon the active triceps surae produced a large reflex EMG response, after which stretch reflex magnitude was nearly completely suppressed for 60 - 80 ms. Joint stiffness during the stretch was complex, initially increasing, then abruptly declining until stretch termination, and finally reaching a new, higher steady-state value.

DYNAMICS OF MUSCLE SPINDLE PRIMARY ENDINGS: MECHANICS AND IONICS. E. Otten, M. Hulliger^{*} and K.A. Scheepstra. Dept. of Medical Physiology, Univ. of Groningen, NL-9712 KZ Groningen, and Dept. of Clinical Neurosciences^{*}, Univ. of Calgary, Canada T2N 4N1.

Modelling the dynamics of spindle primary endings mainly on mechanical events, Schaafsma et al. (J. Neurophys. 65, 1297-1312, 1991) had to infer exaggerated dynamic properties of intrafusal muscle fibres. It is very likely however, that a considerable fraction of the spindle dynamics is of ionic origin. In order to see whether dynamics can arise from specific ionic currents activated by deformation of the ending, a mathematical model of a mechanoreceptor terminal was formulated.

The kernel of this model consists of the Frankenhaeuser-Huxley (FH) equations (describing the generation of action potentials in myelinated axons). Two modifications were implemented: first, the four permeability constants (K⁺, Na⁺, non-specific and leak currents) were changed simultaneously (using automated tuning), to introduce low-rate repetitive firing capability (down to 15/s), while minimizing the deviations from the original FH values. Second, a slow repolarizing (potassium) conductance was added, to model properties of longer duration (e.g. accommodation) than those required for individual action potentials.

The ionic model reproduced several functional features of primary endings, such as band-pass filter properties with phase advance below and phase lag above 12 Hz and a peak in gain around 20 Hz. Unlike the mechanical model of Schaafsma et al., its dynamics are moderate, comparable to those of spindle secondary endings. However, when the two models were integrated and the ionic (sensory ending) component was activated by the output of the mechanical model component (length variation of the ending), exaggerated dynamics emerged. The mechanical component was therefore returned, with the result that the dynamic properties of intrafusal fibers were less overrated, i.e. much closer to those of extrafusal fibers.

Experiments are currently under way to determine quantitatively the relative contribution of ionic and mechanical processes to the dynamics and overall behaviour of muscle spindle primary afferents.

COMPENSATION FOR LOAD INSTABILITY: LIMITS OF JOINT STIFFNESS. T.E. Milner^{*} and C. Cloutier. Institut de Réadaptation de Montréal, 6300 Darlington Ave., Montréal, Canada H3S 2J4.

In order to investigate the practical limit of mechanical stability that could be achieved by the neuromuscular system, an experiment was carried out in which subjects were required to stabilize a wrist manipulandum that was made mechanically unstable by means of positive position feedback to a torque motor (negative stiffness). For 9 of the 10 subjects, the limit was between -0.16 and -0.25 Nm/deg; for the remaining subject it was -0.4 Nm/deg.

At the end of the stabilization period the wrist was rapidly flexed by 3° and held in this position by means of a position servo to measure wrist stiffness. The measured wrist stiffness was almost always equal to or greater than the magnitude of the negative load stiffness. As the magnitude of the negative stiffness increased, wrist stiffness increased as the result of increased co-contraction of wrist flexor and extensor muscles during stabilization. An increase in flexor muscle activity was observed following muscle stretch.

Subjects were also asked to voluntarily co-contraction wrist flexor and extensor muscles maximally with no load. The wrist stiffness measured in this situation was often slightly less than that achieved at the limit of mechanical stability. The maximum stiffness achieved by co-contraction of wrist flexors and extensors under any condition was only about half that predicted from the stiffness of maximally activated extensor muscles combined with the stiffness of flexor muscles generating an equal but opposite joint torque. We suggest that this limitation was due to mutual reciprocal inhibition of flexor and extensor muscles.

NEUROMUSCULAR COMPARTMENTS AS FUNCTIONAL MECHANICAL UNITS IN MOTOR CONTROL. J. H. Lawrence, III^{*}, T. R. Nichols, and A. W. English. Depts. of Physiology and Anatomy and Cell Biology, Emory University Atlanta, GA 30322.

Traditionally, the force vector of a given muscle has been presumed to be constant over all levels of recruitment: definable by a single line connecting a point of origin with a point insertion. English and Ledbetter (*Anatomical Records* 204, 180-193, 1982) showed that the nerve to lateral gastrocnemius (LG-n) branches to innervate four (4) anatomically discrete regions of the muscle. We stimulated muscles crossing the ankle joints in cats deeply anesthetized with pentobarbital, and used a multi-axis force-moment sensor to measure the resulting isometric torques. The control position for the cat hindlimb was a 120° knee angle with the ankle fixed at 110° extension, 0° adduction and 0° eversion (110,0,0).

We have found that there is a change in the degree of off-sagittal torque within triceps surae when separate regions of MG and LG are denervated. At the control orientation, there was a 10% decrease in off-sagittal (ad/abduction) torque for MG when the proximal portion of the muscle (MG-1) was denervated. Moreover, we saw a 40% increase in off-sagittal torque for LG when the medial compartment (LG-m) was denervated. These torque vector %changes were not constant as the ankle orientation was varied in the ad/abduction direction. Therefore, the force vector output of a muscle is dependent upon the activation state of the neuromuscular compartments and the ankle joint orientation.

A SPIKING NEURAL NETWORK MODEL FOR NEURONS CONTROLLING WRIST MOVEMENT. M.A. Maier*, L.E. Shupe and E.E. Fetz, Dept. of Physiology & Biophysics, University of Washington, Seattle, WA, 98195.

Dynamic neural networks of units with time-varying activity can be trained to simulate sensorimotor behavior from examples using backpropagation; this algorithm requires units with differentiable "sigmoidal" input-output functions. The time-varying activity of such units usually represents the firing rates of neural populations. To simulate more realistic neural activity we used "spiking units", which integrate synaptic input (triangular EPSPs and IPSPs) to threshold and fire discrete spikes that elicit delayed PSPs in their target units. Our spiking units also incorporate a refractory period and a mechanism for adaptation to sustained input. To combine the trainability of continuous networks with the realism of spiking networks, we transformed the weights derived by the former to construct the latter. To obtain spiking networks whose output activity resembled desired patterns and had adequate dynamic range, we found it necessary to derive the weights from trained networks whose units had non-standard sigmoid functions that matched the input-output transform of spiking neurons.

This strategy was applied to networks that incorporate anatomical constraints and simulate target tracking with wrist responses: input representations of step changes in target location were transformed into 8 different motor unit firing patterns observed during wrist flexion/extension movements in the monkey. The networks incorporate appropriate connections and activations of several neuronal populations, including cortical and rubral cells and segmental interneurons and afferents. SIMULATION OF RENSHAW CELL-MEDIATED EFFECTS ON MOTONEURON SYNCHRONY, FORCE AND EMG.

M.G. Maltenfort*, R.E. Druzinsky, C.J. Heckman and W. Z. Rymer, Rehabilitation Inst. of Chicago, and Depts. of Physical Medicine and Rehabilitation, Physiology and Biomedical Engineering, Northwestern University, Chicago, IL 60611.

In our previous study (Maltenfort and Rymer, 1992) simulations of a motor pool firing in the steady-state suggested that a small amount of current from Renshaw cells (RCs) is sufficient to desynchronize motoneurons (MNs). In the new study, the simulation has been revised to include a more realistic number of RCs. Simple models of force and EMG production have been added.

The magnitudes of IPSPs are comparable to those produced by RCs *in vivo*. RC IPSPs reduce the mean firing rate of all MNs by 1 pps, but have little or no effect on recruitment.

Synchronized MN firing was linked to increased EMG amplitude and variability in EMG and force. The force effects only appeared when force production was $\geq 15\%$ maximal, with 80% of MNs recruited, and may have been due to untetanzied firing of type FF units. MN desynchronization was present from 40% MN recruitment onward.

Ongoing work will examine the effect of changing RC firing rates on the force level at which force effects appear; transient changes in force development from a step activation; and RC interactions with correlated and uncorrelated inputs to the MNs.

The Computation of Position-Sense From Mono- and Multiarticular Muscle Spindles. S.H. Scott* and G.E. Loeb, MRC Group in Sensorimotor Physiology, Dept. of Physiology, Queen's University, Kingston, Ont. CANADA K7L 3N6

It is known that muscle spindles provide the majority of information about limb position, but little is known about how position-sense is computed from their signals. We have begun to analyze the computational aspects of transforming noisy spindle signals from multi-segmented limbs into different putative reference frames. A musculoskeletal model was developed containing mono- and multiarticular muscles. A fixed number of spindles were distributed amongst the muscles; the signals from each sensor were assumed to contain Gaussian noise. The number of sensors in each muscle were varied systematically and the amount of sensor noise transmitted into different reference frames was computed. The optimal distribution of sensors amongst the mono- and multi-articular muscles depended strongly on the coordinate frame in which the computations were computed. The model was then modified to reflect the actual morphometry of the human upper limb. With this adjusted model, the optimal distribution of spindles computed for each coordinate frame was always close to the actual distribution of spindles in the various arm muscles. We also estimated the relative accuracy of the upper and lower limb joints for estimating joint flexion/extension and the position of the end of the limb based on the actual numbers of spindles spanning each joint. There is a descending gradient in the numbers of spindles spanning proximal to distal joints, which corresponds to a gradient in angular resolution, but which only partially compensates for the fact that angular errors in proximal joints would result in larger uncertainties about end-point position. The predicted values based on the spindle counts in the upper limb are surprisingly similar to the psychophysical results of Hall and McCloskey (1983).

SYNCHRONIZATION OF MOTONEURON ACTIVITY AFTER RENSHAW CELL BLOCKADE. R.E. Druzinsky*, M. Maltenfort and W. Z. Rymer, Departments of Physiology, Biomedical Engineering, and Physical Medicine and Rehabilitation, Northwestern University Medical School, Chicago, IL 60611.

Several studies from this laboratory and others have tested the hypothesis that recurrent inhibition functions to desynchronize the output of a motoneuron pool. Recent simulations (see companion abstract: Maltenfort, *et al.*, 1993) have confirmed that Renshaw cells are capable of decreasing synchronization among tonically activated motoneurons. Our current studies are attempting to elucidate the conditions under which active desynchronization is present *in vivo*.

Triceps surae muscles were studied in decerebrate cats, before and after the administration of the anti-cholinergic agents mecamylamine and atropine. Activity of a pair of motor units was recorded along with EMGs, muscle force, and length during ramp and hold stretches.

Force and EMG were averaged over several trials, and time-varying coefficients of variation (V) of these quantities were calculated. Changes in Vs of the EMG and force records were detected even when no comparable changes in unit-to-unit correlations were apparent. Thus, pairwise analysis may not be a sensitive measure of synchronous activity within a large population of active motor units. Preliminary results demonstrated that significant desynchronization of motoneuron output occurred at high levels of activation (when forces were high).

MOTOR UNIT RECRUITMENT PATTERNS IN HETEROGENIC REFLEXES OF THE DECEREBRATE CAT. S.M. Dacko*, A.J. Sokoloff, and T.C. Cope, Dept. Physiology and Biophysics, Hahnemann Univ., Philadelphia, PA 19102

An interesting divergence of activity among triceps surae muscles in decerebrate cats has been recently reported by Nichols (*J. Physiol.* 410:263, 1989): ramp-and-hold stretches of the medial gastrocnemius (MG) muscle imposed on a background of crossed extension reflex activation produced excitation of the MG muscle but inhibition of its synergist, the slow contracting soleus (SOL) muscle. Here we test the possibility that underlying this behavior is a coordinated inactivation of slow twitch motor units in both MG and SOL muscles. Physiological properties and firing responses were recorded for 6 slow-twitch and 2 fast-twitch motor units in decerebrate cats. Ramp-and-hold stretches (4mm) applied to the MG during activation of a crossed extension reflex produced inhibition of SOL as reported by Nichols. All MG units, both fast and slow, were recruited by stretch even during periods of SOL inhibition. Additionally, the instantaneous rates of stretch-evoked firing for these MG units were not slower during SOL inhibition than they were when there was no inhibition. These findings support our assertion that units are not selectively inhibited on the basis of their slow twitch character, instead, the observed patterns of inhibition represent the separate control of different motor pools. (Supported by NIH Grant NS21023).

405.16

THE INHIBITION OF MAXIMAL FORCE DURING A VOLUNTARY BILATERAL EFFORT: A CENTRAL OR PERIPHERAL EFFECT. L.E. Tremblay*, J. Bélanger, L. Laganère, J. Viau and Y. Lessard, Physical Therapy Dept. Health Sc. Faculty, Ottawa Univ., Ottawa, Canada.

In a voluntary situation, the maximal torque produced during a bilateral (BL) effort of the quadriceps femoris (QS) is less than the sum of the torques recorded by each QS separately (ULR or L, unilateral right or left). This inhibition has always been thought to be dependent on the CNS (supraspinal influence). Electrical stimulation (ES) allows us to re-examine this hypothesis. ES induces the development of muscle tension while bypassing the CNS. The aim of the study was to determine if the torque induced by ES in the BL situation was similar to the sum of the torques induced ULR + ULL. The maximal torques recorded in the QS of 15 male subjects were induced by an electrical muscle stimulator «Respond Select», using a biphasic, symmetrical wave with a pulse width of 300 microsec. The torques were measured with the help of the «Cybex 6000» machine. The angular velocity was 0° per sec at an angle where the torque was maximum. All the subjects tolerated the maximal intensity delivered by the stimulator (100 mA). This was applied with silicone-carbon electrodes (5x10cm), applied following a standard procedure. The ratio of BL torques over ULR + ULL torques during a voluntary effort were 0.89 ± 0.07 ($P < 0.01$). The ratios of BL torques (ES) were 0.91 ± 0.07 ($P < 0.01$). Additional tests using ES were performed in order to demonstrate that the inhibition is probably peripheral and spinal cord in origin. The motor nuclei of the right QS appears to be inhibited by approximately 4.5% during stimulation of the left QS and the same is true for the left QS. We believe that the motor nuclei of both QS appear to be mutually inhibited each by half the amount of the inhibition observed in the BL ES situation. This inhibition could possibly originate from the recruitment of the 1a afferent fibres and the activation of the 1a inhibitory interneurons which make tri or polysynaptic transcommissural relays with contralateral motor neurons.

THE UNIT-TO-AGGREGATE (UTA) COHERENCE APPROACH FOR ANALYSIS OF SYNCHRONY IN NEURAL POPULATIONS. **C.N. Christakos*** Dept. Basic Sci., Med. School, Univ. Crete, Heraklion, Greece, and Ctr. Neurobiol., Col. Phys. & Surgeons, Columbia Univ., New York, USA

Theoretical analysis based on the spectral relationships between unitary and population-aggregate activity, as well as extensive computer simulations of a uniform neuron population, indicate that: (1) For a subset of uncorrelated units in a population, the UTA coherence is very low at all frequencies. (2) For a subset of units that are correlated at some frequency f_s , the value of the UTA coherence at f_s reflects the strength and extent of the synchrony within the population, the degree of phase concentration of these units, and the numerical size of the population; and it remains substantial for a wide range of values of these parameters (e.g., the extent can be as low as 10%). (3) The UTA coherence for this subset is very low at other frequencies where there is no synchrony (except for harmonics of f_s).

These properties make the UTA coherence function a useful tool for analysis of population synchrony. Such computations for a sample of recorded units enable: the detection of synchrony and the estimation of its extent within the population, inferences on other characteristics of synchrony, and the study of changes in synchrony as conditions are altered (including pathological conditions). The main advantage of this approach is that from readily recorded neural activities, it efficiently identifies correlated units, and provides information on characteristics of synchrony at every frequency within the range of interest. Applications are presented for rhythmic neural activities.

DETERMINANTS OF POST-SPIKE FACILITATION OF EMG ACTIVITY. **P. A. Fortier*** Department of Anatomy and Neurobiology, University of Ottawa, Ottawa, Ontario, Canada, K1H 8M5.

Several measures are used (e.g. Lemon et al. 1987; Mewes and Cheney 1991) to calculate the size of post-spike or -stimulus facilitation (PSF) of EMG in order to estimate the magnitude of descending effects on motoneuron (MN) pools. The lack of a standard measure is because there is no report of the factors which determine PSF size. These factors include MN-EPSP size, EMG noise, motor-unit action-potential (MUAP) cancellation, and both MUAP height and duration. One cannot examine these factors individually in the animal, but they can be thoroughly tested in computer simulations. The results showed that overlap of MUAPs with opposite polarity caused 25% EMG cancellation, but this did not affect the linear relationship ($r = 0.99$) between MN-EPSP height and PSF area because cancellation was relatively constant when only MN-EPSP amplitude was varied. Under normal conditions, however, other factors vary. Increases in EMG noise raised the baseline of the spike-triggered average but had minimal effect on the PSF, however, increases in MUAP amplitude and duration had significant effects on the PSF which reduced its reliability as an estimate of the magnitude of the descending effects on MN pools. Several methods of normalizing the PSF were tested. The best method was the "mean bin amplitude of PSF above baseline / baseline standard deviation", yet it was only a moderate estimate of descending effects when wide fluctuations in all factors existed. [Funded by Canadian MRC]

CIRCUITRY AND PATTERN GENERATION III

406.1

SENSORY INDUCED PHASE SWITCHING IN THE MOTOR PATTERN OF THE LOBSTER GASTRIC CIRCUIT *IN VITRO*. **D. Combes, J. Simmers, P. Meyrand & M. Moulins** Laboratoire de Neurobiologie et Physiologie Comparées, Université de Bordeaux I & CNRS, Place Peyneau, 33120 Arcachon, France.

We are investigating the nature and mechanisms of mechanosensory feedback from a unineuronal tendon organ, the Anterior Gastric Receptor (AGR), to the gastric mill central pattern generator (CPG) in the stomatogastric nervous system (STNS) of *Homarus gammarus*.

We have found that AGR, which is activated by contraction of the powerstroke muscle of the gastric medial tooth, has access to the gastric CPG via direct excitation of two in-parallel interneurons, one (CG) excitatory, the other (GI) inhibitory. In the spontaneously active STNS *in vitro*, moderately intense bursts (spike frequency <25Hz) evoked in AGR in time with homonymous motoneurons reinforces the ongoing gastric rhythm in which medial and lateral teeth powerstroke motoneurons fire in phase. With intense rhythmic bursts in AGR, however, these phase relations switch so that the medial and lateral powerstroke motoneurons now burst in antiphase. These bimodal effects of AGR can be simulated by direct intracellular stimulation of the two intercalated interneurons: rhythmic gastric-timed bursts in CG alone reinforces the ongoing motor pattern while simultaneous activation of CG and GI causes the phase switch in pattern seen during elevated receptor discharge.

Our results suggest that these effects on the gastric mill rhythm depend on the balance of firing in interneurons CG and GI, and that "selection" of the pathway resides in their different postsynaptic sensitivities to AGR. While high intrinsic firing rates in CG ensure that the excitatory pathway is predominant during low to moderate levels of sensory input, strong synaptic facilitation in GI favours the inhibitory pathway during high levels of receptor activity.

406.3

INTERACTIONS OF CENTRAL PATTERN GENERATORS ARE ALTERED BY MULTIPLE MODULATORS. **P.S. Dickinson* and C. Meeas.** Dept. of Biology, Bowdoin College, Brunswick, ME 04011.

We previously showed that two neuropeptides, proctolin and red pigment concentrating hormone (RPCH), interact in modulating the cardiac sac motor pattern in the spiny lobster, *Panulirus interruptus* (Soc. Neurosci. Abst. 16: 724, 1990). When bath applied to the isolated stomatogastric ganglion (STG), proctolin alone had no effect on the cardiac sac pattern, whereas proctolin applied shortly after the effects of RPCH had washed out caused rhythmic activity in the cardiac sac network to be initiated. We also previously showed that bath application of RPCH to the isolated STG caused the cardiac sac and gastric mill patterns to 'fuse', and thus provoked a new conjoint rhythm (Nature 344: 155-158, 1990). A large increase in the amplitude of the post synaptic potentials (pSPs) from the inferior ventricular (IV) neurons of the cardiac sac network onto the neurons of the gastric mill pattern generator mediated these changes. We have now shown that, when the cardiac sac pattern is induced by the bath application of proctolin after RPCH, 'fusion' of the gastric mill and cardiac sac patterns likewise occurs. As is the case in RPCH alone, this fusion appears to be mediated largely by an increase in the amplitude of the pSPs from the IV cells to the neurons of the gastric mill network.

406.2

ACTIVITY OF THE STOMATOGASTRIC NETWORKS IN FREE MOVING CRABS. **H.-G. Heinzel*, D. Weigelt, and H. Böhm.** Institute of Zoology, University Bonn, 53115 Bonn, Germany.

Chronically implanted cuff-electrodes were used to monitor gastric and pyloric motor patterns and the activity of the anterior gastric receptor (AGR) from stomatogastric nerves of the crab *Cancer pagurus* for the first time. Recordings were performed for periods of up to one week from the dorsal ventricular (dvn), dorsal gastric (dgn) and medial ventricular nerve (mvn) while the animal was free to move around in its aquarium carrying its leash of electrode wires.

All animals (n=37) showed a continuous pyloric rhythm with a period duration between 1 and 2s. Spontaneous bouts of gastric activity had period durations between 5 and 30s. Gastric activity always caused strong modulation of the pyloric rhythm as the pyloric inferior cardiac (IC) and the ventricular dilator neurons (VD) stopped firing during each burst of the gastric mill motoneurons (GM). Pyloric modulations of the gastric rhythm were found in the bursts of GM, the lateral gastric (LG) and surprisingly in the dorsal gastric (DG) motoneuron. This points out that gastric-pyloric interactions may even play a stronger role than inferred from *in vitro* studies where especially DG did not show any pyloric modulations (Weimann et al., J. Neurophysiol. 65, 111, 1991).

During quiescence of the gastric system the AGR stretch receptor fired actionpotentials at a constant rate of 2-5Hz which travelled from the stomatogastric ganglion (STG) towards the receptor ending. With regular rhythmic gastric activity AGR bursts were generated during each GM burst with AGR spikes now travelling to the STG. Strong GM bursts led to increased firing of AGR and a subsequent omission of the next GM burst in a series of alternating DG-GM bursts. Our experiments under the closed loop situation in the animal thus prove the realisation of the reflex reversal which has been suggested from *in vitro* studies (Simmers & Moulins, J. Neurophysiol. 59, 757, 1988).

PATTERNS OF CYCLIC GMP IMMUNOREACTIVITY IN THE CRAB STOMATOGASTRIC NERVOUS SYSTEM. **N. L. Scholz, L. M. Hurley, J. W. Truman, and K. Graubart*** University of Washington, Dept. of Zoology, NU-15, Seattle, WA 98195.

Chemical inputs often act on target neurons by activating cyclic nucleotide cascades. In the crustacean stomatogastric nervous system (STNS), modulatory inputs shape the motor patterns produced by central pattern generating networks. However, specific roles for second messengers in mediating these effects are not yet understood.

We have used an antibody that recognizes cGMP (de Vente et al., 1987, Neuroscience 22:361) to map the cellular distribution of this second messenger in the STNS of the crab, *Cancer productus*. Upon *in vitro* stimulation of the STNS with sodium nitroprusside (SNP) in the presence of isobutylmethylxanthine (IBMX), subsets of cells in the commissural, esophageal, and stomatogastric ganglia (STG) show cGMP immunoreactivity. Neuronal cell bodies and their projections appear to label equally. The immunostaining is blocked by preincubation of the antisera with cGMP (10^{-7} M) but not with cAMP or GMP (10^{-5} M). Labeling is strongest in the STG, where approximately one-third of all neurons (10-12 cells) stain for cGMP. Individual neurons in the gastric and pyloric circuits have been identified by tracing axons to their respective target muscles; e.g. PD and GM cells stain consistently. Also, certain nerves do not contain labeled fibers, suggesting that cGMP is not being activated in cells that project in these tracts (e.g. PY, VD, and IC cells). Preliminary electrophysiological analyses indicate that SNP is not producing a cytotoxic effect, since cells continue to burst in the presence of SNP. We are currently investigating the potential role of cGMP in mediating the effects of known neuromodulators, and the physiological consequences of elevated cGMP in these central pattern generator networks. Supported by NIH grants (NS15697 to K.G. and NRSA to N.S.), NSF grants (IBN-9242993 to J.T. and a predoctoral fellowship to L.H.) and by the Human Frontiers Science Program (to K.G.).

SHAB GENE EXPRESSION IN IDENTIFIED NEURONS OF THE PYLORIC NETWORK IN THE LOBSTER STOMATOGASTRIC GANGLION. D.J. Baro,* A.R. Zarrin, T.R. Podleski, and R. M. Harris-Warrick. Section for Neurobiology and Behavior, Cornell University, Ithaca, NY 14850

Identified pyloric neurons in the stomatogastric ganglion of the lobster *Panulirus interruptus* display cellular variation with respect to K^+ currents. We are examining the differences in gene expression which may underlie these electrophysiological differences using *in situ* hybridization on whole mounts of the ganglion. We constructed a probe specific for the lobster *shab* gene, one of the genes that encode delayed rectifier-like channels. The probe was synthesized by transcription with digoxigenin-UTP. Hybridization to mRNA was visualized using anti-digoxigenin antibodies conjugated to alkaline phosphatase followed by a chromogenic reaction. The specificity of the probe was confirmed by Southern blot hybridization. The *in situ* hybridization was carried out under the same stringency conditions as the Southern blot hybridization ($T_m - 15^\circ$) to prevent detection of other Shaker family members. Differential staining of the cells within the ganglion was observed. Of the six major cell types that comprise the pyloric network, only AB, PD, and some PY cells possess enough *Shab* mRNA to be easily detected by *in situ* hybridization. VD, LP, IC, and some PY cells show low or undetectable levels of *Shab* gene expression under these conditions. We are currently trying to confirm these data with quantitative single cell PCR, as well as expand our study to include other members of the Shaker family. Supported by NIH grant NS25915

PHASE-SETTING IN A MODEL OF THE GASTRIC MILL CPG IN THE LOBSTER. P.F. Rowat* and A.I. Selverston. Biology Department, U.C. San Diego, La Jolla, CA 92093-0322.

We have constructed a simplifying, biologically constrained, network model of the gastric mill CPG which shows that only a few basic mechanisms are sufficient to produce the relatively complex patterns characteristic of the cycling gastric mill. These mechanisms include a cell model having a fast current with an N-shaped I-V curve and slow inward and outward currents with linear steady-state I-V curves; graded synaptic transmission; and "slow" synapses. The cell model captures important characteristic behaviors of gastric mill cells such as plateau potentials, post-inhibitory rebound, and endogenous oscillations. The reciprocal inhibitory pair is an essential sub-network of the gastric mill network, which enables the model network to produce a pattern whether or not the individual cells are endogenous oscillators. In the model network, the relative phases of cells were adjusted by manipulating the gains of slow currents in individual cells and by the use of slow synapses. Phase relationships can also be set by changing synaptic strengths. The relative phase of two cells can be modified by approximately 15% by adjusting the slow current gains, and by approximately 5% by changing the ratio of synaptic strengths. Larger changes in phase are obtained by the use of slow synapses. We also present other results on the effectiveness of these mechanisms for manipulating relative phases in cells arranged in pairs, in chains, and in more complex networks of cells.

SPECIFIC MUSCARINIC MODULATION OF IDENTIFIED STOMATOGASTRIC CPG NEURONS IN PRIMARY CULTURE. T.A. Cleland* and A.I. Selverston. Dept. of Biology 0322, U. Calif. San Diego, La Jolla, CA 92093-0322.

The gastric mill network within the stomatogastric ganglion of the spiny lobster drives the movements of three teeth within the stomach. *In vitro*, the network is quiescent without modulatory input; specific modulators initiate and sustain characteristic gastric rhythms. The rhythm initiated by the muscarinic agonist pilocarpine has been shown to be based on a "kernel circuit" of endogenously oscillatory neurons (Elson and Selverston 1992). The muscarinic modulation of isolated, identified gastric neurons was studied in primary culture using voltage clamp techniques. Primary culture offers the twin advantages of unambiguous cellular isolation from the network and a resolution of the space-clamp limitations that hinder such studies on most STG cells *in situ*. We show that one effect of pilocarpine is to reduce neurons' net potassium conductance; preliminary evidence indicates, however, that different identified cells respond quantitatively differently to this muscarinic modulation. Efforts are underway to further elucidate the nature of these differences and how they contribute to the distinct and complex voltage behaviors of these bursting cells and their impact on network motor output.

406.6

A SLOWLY INACTIVATING POTASSIUM CONDUCTANCE UNDERLIES DEPOLARIZATION-INDUCED TRANSITIONS BETWEEN TONIC AND BURSTING BEHAVIOR IN REAL AND MODEL NEURONS. L.E. Abbott*, G.G. Turrigiano, and E. Marder. Depts of Physics and Biology, Brandeis University, Waltham, MA 02254.

Many neurons undergo transitions between tonic and bursting states, and the transmission and integration of information is strongly influenced by which state the neuron is in. We have been studying the role of a slowly inactivating potassium conductance in such transitions. Many cultured STG neurons fire tonically at the start of a constant depolarizing current pulse, but over the course of several seconds of depolarization the spikes inactivate and the neuron begins to oscillate. In voltage clamp experiments we have isolated a slowly inactivating outward conductance that inactivates with a time course similar to the time course of the transition from tonic to bursting behavior. This conductance displays cumulative inactivation; that is, it inactivates slowly during repeated short depolarizing pulses, making it susceptible to slow inactivation during phasic activity in STG neurons. We have incorporated this conductance into a conductance-based model of an STG neuron, and have found that it is sufficient to reproduce the transition from tonic to bursting that we observe during prolonged depolarization of the real neurons. While this conductance de-inactivates rapidly at membrane potentials below -60 mV, it de-inactivates only very slowly at membrane potentials above -50 mV. The most hyperpolarized membrane potential of STG neurons can vary from -50 to -70 mV, depending on the neuromodulatory state of the system. This suggests that neuromodulators or other inputs that simply change the resting potential of STG neurons can change their response to rhythmic input from tonic to bursting. We are currently using the model to predict how this conductance will help shape the response of STG neurons to patterned inputs. Supported by MH-46742 to L.F.A. and BNS-9009251 to E.M.

406.8

SLOW SYNAPTIC POTENTIALS MEDIATING INTERACTIONS OF GASTRIC PATTERN-GENERATING NEURONS IN THE STOMATOGASTRIC GANGLION OF SPINY LOBSTERS.

R.C. Elson* and A.I. Selverston. Department of Biology, UCSD, La Jolla CA 92093.

We are studying the properties of chemical synapses within the gastric mill central pattern generator, a network of 10 identified motor neurons and one interneuron (Int 1) in the stomatogastric ganglion (STG) of spiny lobsters. Four gastric motor neurons (including the important Lateral Gastric cell) are thought to use glutamate as a neuromuscular transmitter. At their central outputs, these neurons evoke inhibitory synaptic responses of two types. Type (1) are fast, unitary IPSPs (rise-time 10-20 ms) that are mediated by an increased chloride conductance and blocked by picrotoxin. They resemble the glutamatergic IPSPs described elsewhere in the STG (Marder & Eisen 1984). Type (2), however, are slow inhibitory potentials (rise-time 1-2 s) lacking unitary components, mediated by a conductance increase to potassium and resistant to picrotoxin. At some synapses, type (1) or type (2) occur singly; at others they occur together, producing biphasic potentials. Int 1 also has diverse synaptic actions. In some followers, it drives type (1) IPSPs; in others, it evokes slow excitation. In the Dorsal Gastric neuron, the excitation comprises unitary EPSPs that summate slowly and are picrotoxin-resistant.

Slow synaptic potentials seem tuned to the slow bursts and long cycle periods of the gastric motor pattern. We plan further study of their pharmacology and integrative significance.

QUANTIFYING THE CONTRIBUTION OF THE PSRs IN SENSORY INDUCED GASTRIC MILL ACTIVITY IN THE INTACT LOBSTER.

M.E.T. Boyle and A.I. Selverston* Dept. of Biol. UCSD, La Jolla, CA 92093.

The lobster gastric mill (GM) consists of three teeth in the stomach, two lateral and one medial, which masticate food and is under control of the stomatogastric ganglion (STG). Heretofore, GM activation in the intact restrained animal has required injection of neuromodulators. Here we demonstrate the ability to induce GM activity by activation of the posterior stomach receptors (PSRs), one of six groups of sensory receptors in the foregut, and quantify their contribution to the GM response. We use an endoscope to observe, quantify, and compare GM movement patterns produced by sensory stimulation in the intact and deafferented animal.

Intact lobsters were restrained while an endoscope with an irrigation tube was inserted through the esophagus and into the cardiac sac region. Irrigation pump levels between 3 and 8 (10 being the strongest) activated a quiescent GM in 9 out of 10 cases and change GM ongoing activity in 8 of 10 cases. The most striking feature was that there was no predominant chew type as seen with CCK or proctolin. Additionally, there could be up to five different chew types in one minute when GM activity was first initiated. In all cases, GM chewing frequency, mode, and strength changed when the pump was turned on and off.

PSRs are mechanoreceptors which monitor medial tooth activity. Bipolar sensory neurons are located in the posterior stomach nerve (psn). The dorsal psn (d-psn) is the most specific nerve associated with the PSRs. In 5 preparations the d-psns were bilaterally cut while monitoring pressure induced GM activity. Minutes after the d-psns were cut GM activity was substantially lower. No increased GM activity was seen with increased pump levels. These preliminary results suggest that the PSRs may mediate pressure induced chewing. Supported by ONR N00014-91J-1720 and NIH RO1-09322.

CELLULAR PROPERTIES UNDERLYING PHASE AND DUTY CYCLE REGULATION IN THE LOBSTER PYLORIC NETWORK. S.L. Hooper*. Dept. of Biological Sci., Ohio University, Athens, OH 45701

Rhythmic motor patterns (e.g., walking) are produced over a wide range of cycle frequencies. As frequency changes, the relative time (phase) and length (duty cycle) of the motions must be regulated to maintain motor pattern integrity. I am using the pyloric network to identify the mechanisms underlying this regulation. Current injection into the pyloric pacemaker neuron induces up to a four-fold variation in pyloric cycle frequency. Over most of this range, phase and duty cycle is maintained within 0.1 phase units; the pyloric network is thus a constant phase and duty cycle network.

The pyloric pacemaker neuron group maintains constant duty cycle by as yet unknown mechanisms. This group inhibits all other pyloric neurons; these follower neurons fire as a result of post inhibitory rebound. As cycle frequency changes, both the duration and the amplitude of the inhibition received by the follower neurons change. The follower pyloric neurons maintain constant phase because their delay to firing changes appropriately in response to these changes in inhibitory input.

My results show that some pyloric followers specifically respond to changes in either inhibition duration or amplitude. If hyperpolarizing current pulses of various timings and amplitudes are injected into Lateral Pyloric (LP) neurons isolated from the pyloric network, delay to firing in the neuron appropriately changes as inhibition amplitude changes, but is unaffected by altering inhibition duration. Alternatively, delay to firing in isolated Pyloric (PY) neurons changes appropriately with inhibition duration, but is insensitive to altering inhibition amplitude. Pyloric phase regulation is thus at least partially due to inherent properties of the network's neurons (as opposed to details of the network's synaptic connectivity), and different neurons use different cues (duration vs. amplitude of inhibition) to "sense" changes in overall pattern frequency.

406.12

DYNAMIC CLAMP DISSECTION OF THE MECHANISMS OF PROCTOLIN MODULATION OF THE PYLORIC RHYTHM. A.A. Sharp* and E. Marder. Bio. Dept., Brandeis Univ., Waltham, MA 02254.

Bath application of proctolin and stimulation of proctolinergic inputs to the STG have previously been shown to activate or increase the frequency of the pyloric rhythm. Photoinactivation and pharmacological blockade of inhibitory synapses have revealed the pyloric target neurons for proctolin in the STG, and provided insight to the mechanisms underlying the response of the entire network to proctolin (Hooper and Marder, 1987, *J. Neurosci.* 7:2097). Activation of a voltage-sensitive inward current by proctolin underlies the pyloric response to proctolin (Golowasch and Marder, 1992, *J. Neurosci.* 12:810).

We now use the Dynamic Clamp (Sharp et al., 1993, *J. Neurophys.* 69:992) to introduce an artificial proctolin conductance (I_{proc}) into the AB, LP and IC neurons individually and in pairs in order to determine the role each neuron plays in generating proctolinergic modulation of the pyloric rhythm. I_{proc} , which was measured in the LP and IC, is sufficient to increase the amplitude and frequency of AB oscillations without depolarizing the baseline potential. I_{proc} increases the firing rate, burst duration and baseline potential of the LP and IC neurons. The responses seen in the individual neurons are strongly dependent on the characteristics of the activation curve of I_{proc} . I_{proc} in the AB increases the pyloric frequency. I_{proc} in the LP or IC has little to no effect on the pyloric frequency, but it causes marked effects on the phase relationships of the pyloric neurons. In quiescent preparations, I_{proc} in the AB alone can initiate a two phase rhythm (AB/PD with PY), but activation of the LP and IC only occurs if they also receive I_{proc} . This method allows us to separate the frequency and duty cycle effect of proctolinergic modulation.

HISTOCHEMICAL MAPPING OF NADPH-DIAPHORASE IN THE TURTLE BRAIN. R. Sarraffzadeh*, T. Braun, and J. C. Houk. Department of Physiology, Northwestern University Medical Center, Chicago, IL 60611-3008.

Neuronal NADPH-diaphorase is likely to be a nitric oxide (NO) synthase (Hope et al. Proc. Natn. Acad. Sci. 88, 2811-2814), and cells containing NO synthase are selectively spared following hypoxic ischemia (Ferriero et al. Ann. Neurol. 24, 670-676). We have studied the distribution of neurons containing NADPH-diaphorase in the turtle brain as a first step in understanding the unusual resistance of the turtle brain to hypoxia. Anesthetized turtles were perfused with 0.2M phosphate buffered saline (PBS) followed by 4% paraformaldehyde. The brain and rostral cervical spinal cord were then dissected, gelatin embedded, post-fixed for 30 minutes, washed for 24 hours in PBS and cryoprotected overnight in 30% sucrose. Coronal sections 50 μ m thick were cut and reacted in PBS containing 0.1 mg/ml nitroblue tetrazolium, 0.1 mg/ml B-NADPH and 0.3% Triton X-100 for 30 minutes at room temperature, after which the sections were washed in PBS and mounted on gelatin-coated slides.

In the telencephalon moderate label was seen in Area d, nucleus of the diagonal band of Broca, and the lateral nucleus of the olfactory tract, together with lighter label in other sites. The globus pallidus and the central and basal nucleus of the amygdala showed modest label in the basal ganglia. In the diencephalon the lateral geniculate nucleus was moderately labeled. The substantia nigra was heavily labeled in the mesencephalon, whereas more modest label appeared in the red nucleus, the nucleus of the medial longitudinal fasciculus, the periventricular stratum griseum and the nuclei of the torus semicircularis. In the pons the locus coeruleus and the parvocellular nucleus isthmi were heavily labeled, and the lateral and medial cerebellar nuclei, the principal trigeminal nucleus and pontine reticular formation neurons were moderately labeled. The dorsal column nuclei and the vestibulocochlear nucleus showed modest label, while the lateral reticular nucleus and other sites showed light label in the medulla. Labeling was heaviest in lamina VII of C1 spinal cord.

The patterns of NADPH-diaphorase staining in the turtle and rat appear similar, but not identical. Staining of red nucleus, lateral cerebellar nucleus and lateral reticular nucleus suggests a potential role for NO in the turtle rubro-cerebellar network.

407.3

CONVERGENCE OF THALAMIC AND CHOLINERGIC PROJECTIONS IN THE DENTATE AREA OF LIZARDS.

Hoogland, P.V., and E. Vermeulen-VanderZee, (SPON: European Neuroscience Association) Dept. of Anatomy and Embryology, Free University, Van der Boechorststraat 7, 1081 BT Amsterdam, The Netherlands.

The small-celled part of the medial cortex (Cxms) in lizards is the equivalent of the mammalian hippocampal area dentata. As in mammals most of the afferents to this cortical area are arranged in sharply delimited laminae. In reptiles this lamination pattern is species-specific. In the lizards *Tupinambis nigropunctatus* and *Podarcis hispanica* projections from the multisensory dorsolateral thalamic nucleus (Dla) terminate in the middle one third of the outer plexiform layer throughout the whole rostro-caudal extent of Cxms. In the lizard *Gekko gekko* Dla projects to only the rostral one third of Cxms where the fibers terminate in the superficial half of the outer plexiform layer and in the deep half of the inner plexiform layer. To find out whether the species related variation of thalamic projections to Cxms is a solitary phenomenon or that it is related to variations of other afferents of Cxms, we studied the relationships between the thalamic and cholinergic projections from the basal telencephalon in the medial cortex of the lizards mentioned above. Therefore, we performed acetylcholinesterase and choline acetyltransferase stainings on Cxms of these lizards. It appears that the cholinergic afferents terminate approximately in the same subregion and the same laminae as the Dla projections. Therefore, there seems to be a close association between thalamic and cholinergic afferents in the Cxms of lizards, irrespective of their precise location in the cortex of the various species. This suggests a functional relationship between these two afferents of the dentate area in lizards.

407.2

ON THE LAMINAR ORGANIZATION OF THE SUPERFICIAL DORSAL HORN OF ALLIGATOR MISSISSIPPIENSIS. C. Jeffery Woodbury*, Dept. of Ornithology, American Museum of Natural History, 79th and CPW, New York, NY 10024 and Dept. of Anatomy, University of Utah School of Medicine, Salt Lake City, UT 84132.

Two types of laminar organization are found in the dorsal horn (DH) of birds, a truly laminar (i.e., Rexed-type) pattern and a novel (i.e., Brinkman and Martin-type) pattern in which lamina III lies medial to laminae I/II. Recent taxonomic studies in birds revealed that each DH type characterizes a specific subset of higher avian taxa (Woodbury, Soc. Neurosci. Abst. 17, 652, 1991). In the present study of crocodilian DH, horseradish peroxidase (HRP)/HRP-ligand tract-tracing, along with cytoarchitectonic and immunohistochemical techniques, were used to determine laminar topology in order to polarize the character variation in birds using outgroup comparison for phylogenetic systematic analyses of these data.

Unlike birds and mammals, the DH of alligators exhibits only minor elaboration of the substantia gelatinosa and thus appears like that of other reptiles examined (e.g., turtles and lizards) despite the fact that alligators are more closely related to birds. Nevertheless, application of HRP to a cutaneous nerve labels two separate projections across the mediolateral axis; further, each of these separate projections appears to be somatotopically organized, as seen when different nerves are labeled bilaterally. Moreover, wheat germ agglutinin-HRP and cholera toxin B-HRP preferentially label the lateral and medial projections, respectively, when applied to a cutaneous nerve or injected under the skin. These findings suggest, therefore, that lamina II lies lateral to lamina III (supported also by cytoarchitectonic and immunohistochemical data), and that cutaneous afferents form two separate somatotopic maps across the mediolateral axis of the superficial DH, as in chickens and many other birds. As analyses of the DH of dinosaurs is obviously out of the question, the most parsimonious explanation is that the 'novel' DH lamination pattern of birds is not novel at all but was present in the common ancestor of both birds and crocodilians and is therefore primitive to birds. The truly laminar DH appears to have evolved at least two separate times in amniotes, once in mammals and again within birds.

407.4

GAD IMMUNOREACTIVITY IN REPTILIAN THALAMUS. M.B. Pritz* and M.E. Stritzel. Dept. of Neurosurgery, Univ. of Calif. Irvine Med. Ctr., Orange, CA 92688.

Previous experiments in *Caiman crocodilus* that utilized a polyclonal antibody to GABA or GAD found that certain thalamic nuclei that projected to the telencephalon lacked GABA(+) or GAD(+) neurons. These nuclei were: nucleus dorsolateralis anterior (Dla), nucleus dorsomedialis anterior (Dma), nucleus rotundus (Rt), nucleus reuniens pars centralis (Rc) and pars diffusa (Rd), nucleus diagonalis (D), and the medialis complex (MC). The present study investigated immunoreactivity to monoclonal antibodies to GAD in these same 7 thalamic nuclei in *Caiman* and in a closely related Crocodilian, *Alligator mississippiensis*, as well as immunoreactivity to a polyclonal and monoclonal antibodies to GAD in the dorsal part of the lateral geniculate nucleus (Gd) in *Caiman*.

Immunoreactive puncta to the GAD monoclonal antibodies were observed in the following thalamic nuclei in *Caiman* and *Alligator*: Dla, Dma, Rt, Rc, Rd, D, and MC. GAD immunoreactivity in *Alligator* was more robust than in *Caiman*. GAD-2 immunoreactivity was more intense than immunoreactivity to GAD-1 or GAD-5. GAD(+) puncta were most intense in Dla and Dma; significant but less intense in MC and D; and less intense but present in Rt, Rc, and Rd. No GAD(+) neurons were identified in any of these 7 thalamic nuclei with any GAD monoclonal antibody epitope in either *Caiman* or *Alligator*.

In the Gd of *Caiman*, GAD(+) neurons, although sparse, were identified with the polyclonal but not the monoclonal antibodies. GAD(+) puncta were found throughout this nucleus with both GAD antibodies.

The findings of GAD(+) neurons and puncta in the Gd of *Caiman* and the lack of GAD(+) cells in the 7 other thalamic nuclei in *Caiman* and *Alligator* are similar to the results of previous reports in other reptiles. The presence of GAD(+) puncta in these 8 thalamic nuclei, coupled with the sparse number of GAD(+) thalamic reticular neurons in *Caiman*, suggests that this GAD input may arise from an extra-thalamic source.

COMPARISONS OF FOREBRAIN GROUPS AMONG TETRAPODS. T.J. Neary* and L.L. Bruce. Dept. Biomed. Sci., Creighton Univ., Omaha, NE 68178.

New data on hypothalamic and olfactory connections in reptiles and amphibians, combined with connectional, histochemical, and topological data reveal unexpected similarities between thalamic, amygdalar, and pallial groups in tetrapods. 1) The amphibian medial pallium is comparable to both medial and dorsal cortex of reptiles, which are comparable to the hippocampal formation and subiculum of mammals, respectively. Furthermore, the mammalian isocortex may be derived from the same anlage as the reptilian dorsal cortex, rather than from DVR. 2) Major mammalian pallial amygdalar groups appear to be represented in the reptilian telencephalon. The reptilian DVR and lateral amygdala are comparable to the mammalian basolateral and lateral amygdala, and basomedial amygdalar nuclei, respectively. 3) The amphibian caudal striatum is comparable to the reptilian striatoamygdalar area and mammalian central amygdala. 4) Subdivisions within the lateral amygdala of amphibians are comparable to the medial dorsal, medial ventral, and a ventromedial portion of the external amygdala of reptiles, which are comparable to the anterior dorsal medial, anterior ventral medial, and posterior medial groups of the mammalian olfactory amygdala, respectively.

HISTOCHEMICAL MAPPING OF NITRIC OXIDE SYNTHASE IN THE QUAIL BRAIN. F. Sánchez¹, R. Arévalo¹, J.R. Alonso¹, N. Aste², C. Viglietti-Panzica³, and G.C. Panzica². ¹Dept Cell Biology & Pathology, and ²Dept Human Anatomy & Histology, Univ. of Salamanca (Spain); ³Dept Human Anatomy & Physiology, Univ. of Torino (Italy).

The distribution of NADPH-diaphorase activity (ND), an enzyme recently identified as the nitric oxide synthase, was histochemically investigated in the Japanese quail brain. In the telencephalon, the paleostriatal-paraolfactory lobe complex demonstrated the highest presence of both positive cells and processes. They were observed also in several regions of the hyperstriatum, as well as in the archistriatum nucleus taeniae. Some regions were totally lacking of positive elements: i.e. the ectostriatum and the hippocampus. In the diencephalon, the magnocellular hypothalamic system did not show any particular accumulation of reaction product. On the contrary, retino-recipient areas, such as the visual suprachiasmatic nucleus and the lateral geniculate complex demonstrated a composite structure of both positive neurons and processes. The brainstem revealed a large ND positive population extending from the ventral mesencephalon to the dorsal pons. In the optic tectum fusiform positive elements were distributed within the stratum griseum and superficialis. In the medulla, a dense terminal field within the nucleus of the solitary tract, and scattered neurons in the reticular nuclei were observed. Although the staining of neurons and tracts for ND was highly selective, they did not correspond to any single known neurochemically identified system. The findings of the present study reveal that the ND containing systems in the avian brain are organized according to a pattern comparable, for its complexity, to that observed in mammals. However, important interspecific differences were observed suggesting that this novel neural system could be implicated in diverse tasks.

BASAL FOREBRAIN PROJECTION TO THE CHOLINERGIC NEURONS OF THE TEGMENTAL PEDUNCULOPONTINE NUCLEUS IN PIGEONS. L. Medina* and A. Reiner. Dept. Anat. & Neurobiol., U.T. Memphis, TN 38163.

The cholinergic neurons of the tegmentum-pedunculopontine nucleus (TPP) have widespread forebrain and midbrain projections, and thereby exert an important modulatory influence on diverse neural functions. In mammals, the TPP has been found to be under the influence of the basal forebrain via projections from the ventral pallidum (VP) and the substantia innominata (SI). Since our previous studies in birds have revealed the existence of a cholinergic cell group in the isthmus tegmentum comparable to the mammalian TPP, in the present study we have investigated the presence of a basal forebrain-TPP projection in pigeons by means of: (1) BDA injections in the basal forebrain combined with immunohistochemistry for choline acetyltransferase (ChAT); and (2) LM and EM analysis of the innervation in the TPP of normal animals and of animals with a lesion in the basal forebrain projection bundle, using single- and double-label immunocytochemistry for ChAT, substance P (SP), dynorphin (DYN) and glutamic acid decarboxylase (GAD). After BDA injections in the basal forebrain, numerous labeled fibers could be traced to a large terminal area in the midbrain/isthmus tegmentum which includes the ChAT+ cell field of the TPP. Plexuses of SP+, DYN+ and GAD+ fibers were found to overlap the ChAT+ neurons in the TPP of normal animals. EM analysis indicated the existence of synaptic contacts between SP+ terminals and ChAT+ perikarya and dendrites. Unilateral lesions of the basal forebrain projection bundle produced a dramatic loss of the SP, DYN and GAD innervation in the TPP in the lesion side, compared to the normal levels observed in the control side. Our results provide evidence for the presence of a basal forebrain-TPP projection in birds, and suggest that this projection utilizes SP, DYN and GABA.

DUAL ELABORATION HYPOTHESIS OF DORSAL THALAMIC EVOLUTION AND DUAL EXPANSION HYPOTHESIS OF DORSAL PALLIAL EVOLUTION: CLADISTIC ANALYSIS OF THE FOREBRAIN. A.B. Butler*, I.T.N.I., 4433 N. 33rd St., Arlington, Va. 22207.

A previous cladistic analysis of the dorsal thalamus in jawed vertebrates (*Brain Res. Rev.*, in press) revealed two fundamental divisions: the lemnothalamus (LTh) and the collothalamus (CTh), predominantly in receipt of lemniscal and midbrain roof inputs, respectively. In amniotes, these divisions both comprise multiple migrated nuclei. For the present cladistic analysis of the pallium, the distribution of 27 traits was analyzed among amniotes; outgroup comparisons were made to identify the traits present in ancestral captorhinomorph amniotes, allowing a reconstruction of subsequent dorsal pallial evolution.

In ancestral tetrapods, the LTh projected to medial and dorsal pallia, and the CTh projected to the striatum. In captorhinomorphs, expansions of the medial part (Dm) and lateral part (Dl) of the dorsal pallium occurred in correlation with the elaboration of the LTh and CTh, respectively. Also, CTh inputs to Dl were gained.

In ancestral mammals, marked expansion of both Dm and Dl continued, and an inside-out migration pattern was gained. The Dm pallial field gives rise to cortices that include the subicular, cingulate, entorhinal, prefrontal, primary sensorimotor, and striate cortices, i.e. those cortices that are in receipt of LTh projections. Dl gives rise to the CTh-recipient cortices, including extrastriate cortices and auditory and insular cortices. In ancestral non-synapsid amniotes, continued expansion of Dl was greater than that of Dm. Dm gives rise to the dorsal cortex, including the pallial thickening, and Dl gives rise to the dorsal ventricular ridge.

ULTRASTRUCTURAL STUDY OF THE TARGETS OF CORTICAL AFFERENTS IN THE AVIAN STRIATUM. C.L. Veeman* and A. Reiner. Dept. of Anatomy & Neurobiology, Univ. of Tennessee, Memphis, TN, 38163.

Previous retrograde and anterograde tracing studies showed that the outer rim of the avian 'neocortex' projects to the caudate/putamen. To determine the targets of these corticostriatal projections at an ultrastructural level, we injected the anterograde tracer biotinylated dextran amine (BDA) in dorsomedial and dorsolateral regions of the outer rim of the pigeon 'neocortex'. Abundant anterograde transport was obtained by placing three pressure injections of 0.1µl 5% BDA spaced 0.5mm apart in each of these separate neocortical areas. The injection sites were marked by numerous filled neurons, while retrograde transport was negligible. Light microscopy showed numerous BDA-labeled terminals in the caudate/putamen appearing as strings of varicosities beaded along labeled axons. Electron microscopy showed that the labeled terminals were characterized by densely packed, unlabeled vesicles embedded in an otherwise uniformly BDA filled cytoplasm. Distinct postsynaptic densities were observed where BDA-labeled corticostriatal terminals contacted the heads of spines. Such postsynaptic densities, however, were not evident at appositions between labeled terminals and dendritic shafts or perikarya. No obvious differences between terminations of the corticostriatal projections from the two different 'neocortical' regions were seen at light or electron microscopic levels. Thus, avian corticostriatal fibers appear to selectively synapse on the heads of spines of striatal neurons. These asymmetrical synapses suggest that avian corticostriatal terminals excite spiny striatal neurons, as is true of mammalian corticostriatal terminals. Supported by NS-19620 & NS-28721 (A.R.)

SITES OF GENE EXPRESSION AND RECEPTORS FOR VASOACTIVE INTESTINAL POLYPEPTIDE THROUGHOUT THE CHICK BRAIN. W.J. Kuenzel¹, S.K. McCune¹, R.T. Talbot², P.J. Sharp² and J.M. Hill¹. ¹Dept. Poultry Sci., Univ. Maryland, College Park, MD 20742; ²Lab. Devel. Neurobiol., NICHD, NIH, Bethesda, MD 20892; ³Dept. Reprod. Devel., AFRC, IAPGR, Roslin, Midlothian, Scotland, U.K.

The gene for vasoactive intestinal polypeptide (VIP) has been cloned in the chick. A synthetic cDNA sequence corresponding to nucleotides that code for nearly half of the VIP peptide was made and labeled with ³⁵S. In situ hybridization was then performed using brain tissue that was frozen immediately after birds were sacrificed. In addition, in vitro autoradiography was performed using ¹²⁵I-VIP with and without VIP and GMP-PNP. VIP message was found in the lateral septal organ (LSO) pars medialis (contains cerebrospinal fluid contacting neurons), medial preoptic region, bed n. of the pallial commissure (nCPa), anterior hypothalamic (hypo.) n., lateral hypo. n. (displayed most extensive and dense message), periventricular hypo. n., lat. to paraventricular n. and ventromedial hypo. n., stratum cellulare externum, inferior hypo. n., infundibular hypo. n., stratum griseum et fibrosum superficiale (SGFS), hippocampus and area parahippocampalis, area ventralis of Tsai, neurohypophysis, substantia nigra, intercollicular n. (ICo), ventral gray (GC), locus ceruleus, parabrachial n. (PB), ventrolateral medulla (VLM) and n. tractus solitarius. Receptors were found in the LSO pars lateralis, hyperstriatum ventrale, paleostriatum augmentatum, archistriatum, lat. ant. thalamic n., base of third ventricle, nCPa, n. septomesencephalic tract, piriform cortex, area corticoidea dorsolateralis, ICo, GC, SGFS, PB, raphe n. and VLM. VIP is found in structures associated with the visceral forebrain and brainstem respiratory-vocal pathway. Supported by USDA Grant #90-37240-5506.

DOES PURKINJE CELL COMPLEXITY REFLECT EVOLUTIONARY CHANGE? B.R. Krauss, D.R. Chialvo, A.V. Apkarian* and B.J. Serog. Dept. of Neurosurgery SUNY Health Science Center at Syracuse, NY 13210.

Cerebellar Purkinje cells have the most extensive dendritic arborization in the CNS. These arbors are confined to a single plane, perpendicular to the main axis of the folium. We reexamined a recently postulated (Takeda et al. *Neurosci. Res.*, 13:19, 1992) relationship between phylogeny and the complexity of the Purkinje cell dendritic field by measuring its fractal dimension (D_f).

Fractal geometry provides a basis for the analysis and interpretation of complex forms found in nature. The invariance of shapes over different scales gives statistical self-similarity, quantified by D_f . This quantity indicates the space filling properties of the object. The D_f of Purkinje cells from 12 species with diverging eras spanning 6 million years were measured.

Fractal dimension of Purkinje cells were determined from photocopies of camera-lucida drawn golgi-impregnated cells and digitized video images of human Purkinje cells. The images were scanned with an HP Scanjet Plus and a personal computer used for calculations. Standard box-counting method was used to estimate D_f .

The correlation ($y=mx+b$) between diverging era (in years $\times 10^8$) and D_f for water creatures was $m=-0.057$, $b=1.792$, and for land creatures $m=-0.096$, $b=1.779$. The slope of the water creatures line was not significantly different from zero ($F=0.8$, $p<0.41$) but the slope of the land creatures was ($F=10.89$, $p<0.02$).

Purkinje cell complexity and phylogenetic evolution seem related in land creatures, which qualitatively agrees with Takeda et al.. This relationship is not evident in water creatures. Moreover, we found that small variations in data collection and analysis can dramatically change the D_f . This emphasizes the necessity of standardized data processing to obtain meaningful comparisons.

INTER-INDIVIDUAL VARIABILITY OF THE SULCAL PATTERN IN THE ANTERIOR CINGULATE REGION.

F. Tomaiuolo, T. Paus, R. Morris, D. McDonald, M. Petrides* and A.C. Evans. Institute of Human Physiology, University of Verona, Italy and Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada.

Brain magnetic-resonance images (MRI) were obtained from 305 young healthy volunteers and transformed into standardized stereotaxic space (Talairach and Tournoux 1988). With an interactive 3-D software, the presence of the paracingulate sulcus (PCS) and the course of the cingulate sulcus (CS) were examined in 238 hemispheres. An uninterrupted PCS was present in 35/121 left and 19/117 right hemispheres. The caudal limits of the PCS were located at the level of $Y=14 \pm 12$ and $Y=21 \pm 12$ mm for the left and right PCS. Approximately at the level of the anterior commissure, the CS was either interrupted and/or it gave off a vertically oriented branch (left: 47/102; right: 50/97). The rostrocaudal location of this abrupt change in the course of the CS was $Y=-1 \pm 6$ and $Y=2 \pm 8$ mm for the left and right CS. In another 16 left and 19 right hemispheres, two vertical branches were observed in the same portion of the CS (rostral branch: $Y=6 \pm 6$ mm; caudal branch: $Y=-8 \pm 5$ mm). The implication of the above defined variability in the CS pattern for functional neuroimaging was examined in the accompanying PET/MRI study.

Consequences of reduced eye size on the visual and photoperiodic systems in the blind mole rat, *Spalax ehrenbergi*.

M. Herbin*, S. Richard, J.P. Rio, J. Repérand, E. Nevo and H.M. Cooper. INSERM U-371, Cerveau et Vision, 69500 Bron; Lab. Anatomie Comparée, M.N.H.N., INSERM U-106, 75005 Paris, FRANCE; Inst. of Evolution, 31905 Haifa, ISRAEL.

Although the subterranean mole rat is considered to be completely blind, thermal and circadian activity rhythms are synchronized by the external light cycle. The subcutaneous eye measures 600-700 μ m in diameter and the optic nerve (50 μ m diam.) contains 900-1000 unmyelinated fibers only (EM study). In vitro application of HRP to the optic nerve labels a population of 850 ganglion cells (RGC), homogeneously distributed in the retina. Cell soma size distribution is unimodal (6-16 μ m) and RGC's appear immature with sparsely branched dendritic trees. Intracocular injection of CT-HRP shows that all structures known to be innervated by the retina in other mammals, receive retinal projections in *Spalax*. The vLGN, dLGN, pretectum, superior colliculus and accessory optic system all receive a sparse bilateral retinal projection, are highly reduced in size, and show a poor cytoarchitectural organization. Injection of HRP in the colliculus labels RGC's distributed over the entire surface of both retinas, suggesting a lack of topographic organization. Geniculo-cortical connections, revealed by multiple injection of fluorescent tracers in area 17, were also poorly organized. In contrast to other mammals, the suprachiasmatic nucleus (SCN) and the bed nucleus of the stria terminalis receive a significant proportion of retinal projections (> 30%). Histochemical and immunohistochemical studies show that the SCN is organized similar to that of other rodents, and contains cells immunoreactive to VIP, VP, and SOM as well as 5-HT, MET-ENK and NPY immunopositive fibers. These results demonstrate that adaptive evolution in the subterranean niche has led to a mosaic of regressive and progressive features: structures related to form vision, motion analysis, and visuomotor function, are hypoplastic, whereas structures related to photoperiodic light detection and circadian neuroendocrine regulations are relatively hypertrophied and conserve a normal pattern of intrinsic organization.

THE CORPUS CALLOSUM IN CHILDREN AND ADOLESCENTS: EFFECTS OF

GENDER AND AGE. J.N. Giedd, P.L. Kozuch, F.X. Castellanos, C.A. King, S.D. Hamburger, A.J. Allen*, and J.L. Rapoport. Child Psychiatry Branch, NIMH, Bethesda, MD 20892

The midsagittal cross-sectional area of the corpus callosum was measured from magnetic resonance images of children and adolescents (41 males and 43 females) age 5 to 18 free of developmental, psychiatric, or medical illness. Subjects were divided into pre (Tanner stage ≤ 1) or post (Tanner stage >1) pubertal groups based on physical examination at the time of the scan. Results indicate significant gender effects (male > female), most pronounced in the anterior midbody and splenium, areas implicated in attention deficit hyperactivity disorder and dyslexia. Age effects were significant for pre-pubertal but not post-pubertal groups.

LEARNING AND MEMORY: SYSTEMS AND FUNCTIONS V

408.1

SINGLE UNIT MAPPING OF THE CEREBELLAR DEEP NUCLEI IN WELL TRAINED RABBITS FOLLOWING NM CONDITIONING.

L. Tracy* & R.F. Thompson. Neurosciences Program, University of Southern California, Los Angeles, CA 90089-2520.

We have previously shown that the lateral interpositus and medial dentate nuclei of the cerebellum receive convergent projections from peripheral auditory and somatosensory stimuli (Tracy et al., 1991, *Neurosci. Abs*). Convergence of these stimuli (1 KHz tone and a corneal airpuff) is expected if associational mechanisms for classical conditioning of the rabbit nictitating membrane (NM) response are present in these structures. Single cells which respond to either the tone, the airpuff, or both, are congregated near the lateral edge of the anterior interpositus nucleus and the medial dentate. The single units which respond to both types of stimuli are located in the dorsal-most aspect of this region.

Currently, unit recordings in the well training animals, those who have reached a learning criteria of 90% CRs and received one day of overtraining, indicate that specific regions of the cerebellar nuclei respond to the training stimuli with a neural model time-locked to the conditioned behavior. These responsive areas appear to be in the same columnar region of the lateral interpositus/medial dentate nuclei in which convergent responses to peripheral stimuli are found, but tend to be more ventral. These responses tend to be biphasic, with the first part of the neural model preceding the CR and showing an onset latency which predicts the onset of the blink response. (Supported by ONR N0001488K0112 & NSF BNS-8718300 to R.F.T.)

408.2

EFFECTS OF MOTOR CORTEX LESIONS ON ACQUISITION OF TRACE EYEBLINK CONDITIONING.

D. Ivkovich* and R.F. Thompson. Neurosciences Program, University of Southern California, Los Angeles, CA 90089-2520

Rabbits were classically conditioned using an auditory click conditioned stimulus (CS) followed by a 500 ms trace interval and an airpuff unconditioned stimulus (US; 100 ms, 3 psi). Seven rabbits received bilateral motor cortex lesions and 7-10 days recovery prior to training. Six surgically naive control animals underwent identical behavioral training procedures. Each training session consisted of 108 trials, 12 blocks of 1 CS-alone trial followed by 8 paired CS-US trials. There was no significant difference in learning rates of the two groups (average trials-to-criterion = 962). First, middle and criterion days of training were compared using a between groups repeated measures ANOVA. Lesions did not affect percent conditioned responses or measures of conditioned or unconditioned response amplitude. There was a significant increase across days for all these measures. Reflexive eyeblinks to 4 different US intensity levels (1, 2, 3, & 4 psi) measured in lesioned animals exhibited characteristic enhancement over the course of training and were unaffected by motor cortex lesions. A significant effect of lesion was observed, however, for conditioned response latency on CS-alone test trials ($F_{1,16}=6.5$). Onset latencies were consistently slower for lesioned animals. Although motor cortex lesions have been reported to prevent acquisition of short-latency conditioned responses in cats (Woody et al., 1974), the current study suggests these same lesions have no effect on learning of the trace eyeblink response in rabbits, though performance may be slightly affected. (Supported by NSF BNS-8718300 and ONR N0001488K0112 to R.F. Thompson)

408.3

CEREBELLAR CORTICAL STIMULATION AS BOTH CS AND US IN CLASSICAL CONDITIONING. P.G. Shinkman*, R.A. Swain, and R.F. Thompson. Neurosciences Program, Univ. Southern California, Los Angeles, CA 90089-2520.

Previously we reported classical conditioning of discrete motor responses of the facial and neck musculature a) when electrical stimulation of white matter underlying cerebellar lobule HVI is used as the US, and b) when weak electrical stimulation of cerebellar cortex, producing excitation of parallel fibers but no observable behavioral response, is used as the CS in conjunction with the white matter electrical US. These findings point to critical roles for both cerebellar cortex and deep cerebellar nuclei in classical conditioning, and suggest that such conditioning is mediated by an interaction between cortical and subcortical cerebellar circuits. The present experiment was designed to further establish and elucidate the nature of cortical participation in the conditioning process. New Zealand white rabbits were implanted chronically with bipolar stimulating electrodes placed within the cerebellar cortical layers. Threshold measurements were made for the elicitation of discrete motor responses. During subsequent conditioning trials, subthreshold stimulation was used as the CS and suprathreshold stimulation through the same electrode was used as the US. In this preparation, we observed conditioning, extinction upon the introduction of CS-alone trials, and reacquisition with savings. These results, together with previous findings, strongly implicate cerebellar cortical efferent connections to the deep cerebellar nuclei in the neuronal plasticity manifested in classical conditioning. (Supported by NSF BNS 8718300, ONR N00014-88K-0112, and the McKnight Foundation, to R.F. Thompson, and by the BDRF, Univ. North Carolina.)

408.5

EFFECTS OF REVERSIBLE LESIONS ON EXTINCTION OF THE RABBIT'S CLASSICALLY CONDITIONED EYEBLINK RESPONSE. D.J. Krupa*, R.E. Thompson. Neurosciences Program, Univ. of So. Calif., LA, CA 90089.

Reversible inactivation with muscimol was used to identify neural substrates which might mediate extinction of the rabbit's conditioned eyeblink response. Naive rabbits, implanted with cannulae aimed at (i) ipsilateral interpositus (IP), (ii) contralateral red nucleus (RN), or (iii) dorsal aspect of the ipsilateral facial nucleus (FN), were well-trained using tone-airpuff conditioning. Following acquisition, rabbits received injections of muscimol into either the IP, RN, or FN prior to the first 3 or the first 6 days (only IP and FN) of CS alone extinction training. Muscimol infusions completely abolished CRs during these extinction sessions. Controls received saline alone infusions into the IP. Following these sessions, all animals received 4 additional extinction sessions without infusion followed by 1 session of reacquisition training (paired tone-airpuff). Controls extinguished to baseline responding by day 4. Subjects that received muscimol in the IP for 3 days responded with significantly fewer CRs on day 4 than controls on day 1, indicating that some extinction had occurred. Animals infused with muscimol into the RN or FN for 3 days responded (on day 4) at levels equal to day 1 of controls and subsequently extinguished at rates identical to days 1-4 of controls. Animals infused with muscimol in the IP for 6 days were responding (on day 7) at baseline levels, equivalent to day 7 of controls; they appeared to have completely extinguished. In marked contrast, animals infused with muscimol into the FN for 6 days responded (on day 7) at levels equivalent to day 1 of controls and subsequently extinguished at rates equal to days 1-4 of controls; extinction was completely prevented by FN muscimol inactivation. All animals robustly reacquired the CR on the reacquisition day. Disruption of the tone CS by muscimol infusions into the FN is unlikely: infusions of 3H-muscimol do not label structures of the CS pathway and identical infusions have no effect on the animal's ability to acquire the CR. Muscimol infusion into the IP, which has been shown to completely block acquisition of CRs, does not appear to block extinction; whereas infusions into the FN, which do not block acquisition of CRs, do prevent extinction. These results are consistent with the hypothesis that extinction results in the formation of a separate memory and indicate that areas of the brainstem in and around the FN may be critically involved in this form of learning. Support: NSF BNS-8718300, ONR N0001488K0112 & McKnight to RFT.

408.7

THE EFFECT OF HIPPOCAMPAL LESIONS ON THE RETENTION OF A TRACE EYEBLINK CONDITIONING. J. J. Kim*, R. E. Clark & R. F. Thompson. Neurosciences Program, University of Southern California, Los Angeles, CA 90089-2520.

Water-deprived New Zealand male rabbits underwent trace eyeblink conditioning. Animals were presented daily with 100 pairings of a tone (250 ms) followed by an airpuff (100 ms) with a 500 ms trace period between the termination of the tone and the onset of the airpuff and an inter-trial interval of 40 ± 10 s. Water deprivation considerably facilitated learning on the trace paradigm compared to non-water deprived subjects. Upon learning, animals received hippocampal aspirations on that day. After 7 postoperative days of recovery, rabbits were retested on the trace paradigm. Our results show that hippocampal lesions completely abolished adaptive conditioned responses (CRs). These same animals, however, acquired CRs on a standard delay eyeblink conditioning. Thus, the hippocampus appears to be important for the retention of trace CRs.

408.4

BACLOFEN INFUSION INTO THE CEREBELLUM REVERSIBLY BLOCKS RETENTION AND ACQUISITION OF THE CLASSICALLY CONDITIONED EYEBLINK RESPONSE IN THE RABBIT. A.E. NORDHOLM*, O.A. RAMIREZ, D.J. KRUPA & R.F. THOMPSON. Neurosciences Program, University of Southern California, Los Angeles, CA 90089-2520.

It has been recently reported (Krupa, et al., *Science*, 1993) that cerebellar infusion of the GABA-A agonist muscimol reversibly blocks acquisition and retention of the classically conditioned eyeblink response. In the present study we sought to determine what role the GABA-B receptor has in this learning paradigm.

All animals were implanted with cannulae aimed at the dorsolateral anterior interpositus nucleus. In well trained animals, infusions of a GABA-B agonist baclofen completely blocked retention of the conditioned eyeblink response. This effect was eliminated 24 hours later.

During the acquisition phase of the experiment animals received 6 days of training, 3 days of infusion with baclofen (N=5) or saline (N=5) and 3 days of no infusion training. The baclofen group showed no learning on days 1-3 (infusion) and no savings on day 4. The rate of acquisition for the baclofen group on days 4-6 (no infusion) was similar to that of the saline group on days 1-3. Infusion of ^3H -baclofen revealed that the baclofen remained in the cerebellum. Furthermore, the effect of baclofen was partially reversed with the GABA-B antagonist phaclofen, suggesting that the effect of the baclofen were receptor specific. This result is consistent with a large body of literature that implicates the cerebellum as the site for the formation, storage and retrieval of the classically conditioned eyeblink response. (Supported by ONR N0001488K0112 & NSF BNS-8718300 to R.F.T.)

408.6

INACTIVATION OF MOTOR NUCLEI BLOCKS EXPRESSION BUT NOT ACQUISITION OF RABBIT'S CLASSICALLY CONDITIONED EYEBLINK RESPONSE. J.K. Thompson*, D.J. Krupa, J. Weng, & R.F. Thompson. Neurosciences Program, University of Southern California, Los Angeles, CA 90089.

The facial (FN) and accessory abducens (ACC) nuclei were reversibly inactivated by microinjections of muscimol in order to further study their role in eyeblink conditioning. Naive rabbits, implanted with cannulae aimed at the dorsal aspects of the ipsilateral FN, received injections of muscimol (0.4 μg in 0.4 μl saline) prior to the start of the first 6 days of tone-airpuff conditioning (airpuff: 3 psi; ISI 250 ms). Muscimol completely inactivated facial musculature including eyelid reflexes and also abolished eyeball retraction, indicating that both the FN and ACC were inactivated. Both conditioned (CRs) and unconditioned responses (URs) were completely blocked throughout the 6 infusion sessions (measured via minitorque potentiometer attached to nictitating membrane with suture). On day 7, training was continued but no infusion administered. Rabbits performed CRs at asymptotic levels from the start of training; they had fully learned the CR despite having not performed any CRs or URs during previous training sessions. Control rabbits infused with saline showed no impairment in CR or UR amplitude and had fully learned the CR by day 3. Infusions of 3H-muscimol following training indicated that the drug diffused throughout the FN, the ACC, and neighboring regions of reticular formation. These results demonstrate that the association between the tone and the airpuff cannot be formed or stored in the motor nuclei or surrounding regions of reticular formation, since inactivation of these regions has no effect on the rabbit's ability to learn the CR.

Muscimol injections into 2 other rabbits significantly reduced but did not completely abolish the UR. These rabbits acquired the CR normally, i.e., both reached learning criterion by day 2. Interestingly, the CR amplitude was equal to or greater than the UR amplitude, indicating that the strength of the neural input to the motor nuclei which drives the CR is equivalent to that which drives the UR.

ABOLITION OF THE RABBIT NICTITATING MEMBRANE CONDITIONED RESPONSE BY REVERSIBLE INACTIVATION OF BRAIN STRUCTURES. Georges Tocco, Oscar Ramirez, Alan Nordholm, Michel Baudry and Richard F. Thompson*. University of Southern California, Neurosciences Program, Los Angeles California 90089-2520.

While the cerebellum is necessary and sufficient for the learning of the classical conditioning of the nictitating membrane in the delay paradigm, the hippocampus is required for the learning in a trace paradigm when at least 300 msec separate the end of the CS and US onset. The relative importance of these two brain structures for the retention of the learned response in a trace paradigm are however not well understood. In an attempt to answer this question, reversible inactivation of the hippocampus or the interpositus nucleus were achieved by infusion of different drugs (lidocaine, muscimol, CNQX, AP5, ...)

Male New Zealand white rabbits were implanted with one cannula in both hippocampi as well as a cannula in the interpositus nucleus ipsilateral to the stimulated eye. Rabbits were then trained on a trace paradigm until they reached criterion (8 out of 9 consecutive trials). Retention of the conditioned responses were subsequently tested after infusion of different drugs. Infusion of lidocaine or CNQX, an AMPA receptor antagonist in both hippocampi abolished the conditioned response, leaving the unconditioned response intact. This effect seem to decrease in time. Abolition of the conditioned response is also obtained by infusion of CNQX, muscimol (a GABA_A receptor agonist) or lidocaine in the interpositus nucleus.

Our results further stress the importance of the hippocampus as well as the cerebellum for the expression of a learned response in a trace paradigm. This work was supported by ONR N00014-91-G-1796 to MB and ONR N00014-88-K-0112 & NSF BNS-8718300 to RFT.

LEARNING RELATED UNIT ACTIVITY IN THE CEREBELLAR CORTEX IS ABOLISHED WITH REVERSIBLE INACTIVATION OF THE INTERPOSITUS NUCLEUS. R.E. Clark,* E.B. Gohl, and D.G. Lavond. Neuroscience Program, University of Southern California, Los Angeles, CA 90089-2520.

Learning related activity develops in the cerebellar cortex, over the course of classical conditioning of the rabbit eyeblink response, which has a similar shape and time course as the learned behavioral response and precedes this response in time (unit model). This cortical activity could be the source of the essential plasticity associated with this type of learning, or it could receive this information from some other structure. The interpositus nucleus has been implicated as the essential site for this plasticity. A cooling probe was implanted just lateral to the interpositus nucleus to create a reversible lesion of that structure. Rabbits were classically conditioned using our standard paradigm. A microelectrode driver was used to search the contralateral and ipsilateral cerebellar cortex for learning related activity. A reversible lesion was created in the interpositus by activating the cooling probe and the cerebellar cortical activity was then reassessed. Our results show that learning related unit activity developed in cerebellar cortex bilaterally and that interpositus inactivation abolished both the learned behavioral response and the associated unit activity. Some recordings from the anterior ipsilateral cortex showed tone evoked responses followed by a unit model. During cooling the unit model is abolished while the tone evoked response remains unchanged. These results suggest that the cortex receives the learning related activity from the interpositus and cooling does not prevent auditory information from reaching the cortex.

DIFFERENTIAL EFFECTS OF HEMICEREBELLECTOMY PERFORMED ON POSTNATAL DAY (PND) 10 OR 20 ON EYEBLINK CONDITIONING IN THE DEVELOPING RAT. J.H. Freeman, Jr.^{1*}, C.S. Hendrix², & M.E. Stanton,^{1,2} ¹Neurotoxicology Div., US EPA, RTP, NC 27711; ²Psychology Dept., UNC, Chapel Hill, NC 27599.

The present study was undertaken to further characterize the role of the cerebellum in the ontogeny of eyeblink conditioning (EBC) in the developing rat (Stanton, et al., 1992, *Behav. Neurosci.*, 106, p. 657; Freeman & Stanton, 1992, *Soc. Neurosci. Abs.*, 18, p. 1559). In the adult rabbit, lesions of the cerebellum ipsilateral to the trained eye abolish EBC, while leaving conditioning with the contralateral eye intact (Lincoln et al., 1982, *Brain Res.*, 242, p. 190). We sought to determine whether cerebellar circuitry supporting EBC in the developing rat is also lateralized. Evidence from other studies has shown that cerebellar projections to the red nucleus are altered by hemicerbellectomy performed around PND10 but not after later lesions. Thus, early cerebellar lesions may result in reorganization of cerebellar projections that are detrimental to EBC performance. In Experiment 1, pups were given sham surgery, lesions of the contralateral or ipsilateral cerebellar hemisphere on PND10, and given EBC training on PND24 (see Freeman & Stanton, *ibid.*, for methods). Pups given lesions of either the ipsilateral or contralateral hemisphere were impaired on EBC. This experiment led to the notion that lesions given early in development may produce different effects on EBC than lesions performed in more mature animals. In Experiment 2, lesions of the ipsilateral or contralateral cerebellar hemisphere were performed on PND10 or 20 and pups were trained on EBC on PND34. Pups given ipsilateral cerebellar lesions on either PND10 or 20 were impaired on EBC. In contrast, pups given contralateral cerebellar lesions on PND10 were impaired on EBC, while pups given the same lesion on PND20 were unimpaired. Early hemicerbellectomy may produce reorganization of cerebellar projections that impairs EBC.

RED NUCLEUS PROJECTIONS TO CEREBELLAR CORTEX: IMPLICATIONS FOR CLASSICAL EYEBLINK CONDITIONING. M.E. Rosenfield and J.W. Moore.* Dept. of Psychol., Univ. of Mass., Amherst, MA 01003.

Conditioned eyeblink responses are presumably learned in the cerebellum and relayed to motoneurons via the red nucleus (Thompson, *Science*, 233:941, 1986). Projections from the red nucleus to cerebellar cortex (Larsell's HVI) could be important for shaping temporally adaptive features of conditioned responses (Moore et al, *Biol. Cybern.*, 62:17, 1989). We implanted WGA-HRP (Sigma L3892) unilaterally into HVI in 8 albino rabbits (Mori et al, *Brain Res. Bull.*, 6:19, 1981). The pipette remained *in situ* for 45 hours before sacrifice. Animals were perfused transcardially (descending aorta clamped) with approximately 2 L of .9% saline followed by .5 L of 10% formalin and then 3 L of 12% sucrose solution at 4 degrees C. Brains were blocked immediately on extraction (saving only the brain stem and cerebellum), placed in 30% sucrose in .1 M phosphate buffer (pH = 7.2), and stored at 4 degrees C for 20 h. The cerebellum was embedded in gelatin. Frozen sections were cut transversely at 60 μ , mounted on subbed slides, and reacted with TMB. Implantations met our criterion for inclusion if (a) diffusion did not involve cerebellar deep nuclei; (b) retrogradely labeled neurons were seen in the pontine nuclei, spinal trigeminal nucleus par oralis, and the dorsal accessory olivary nucleus. Four criterion cases showed an average of 16 retrogradely labeled cells in contralateral red nucleus at the level of the 3rd nerve within subregions implicated in eyeblink conditioning by lesioning (Rosenfield & Moore, *Behav. Brain Res.*, 10:393, 1983) and recording (Desmond & Moore *Neurosci. Res.*, 10:260, 1991) studies. These observations are consistent with previous reports (Dietrichs & Walberg, *Exp. Brain Res.*, 50:353, 1983; Rosenfield & Moore, *Soc. Neurosci. Abstr.*, 17:870, 1991) and also with the hypothesis that learning in the red nucleus is precursor to learning in the cerebellum. 408.10

LEARNING RELATED UNIT ACTIVITY IN THE LATERAL PONTINE NUCLEI IS ABOLISHED WITH REVERSIBLE INACTIVATION OF THE INTERPOSITUS NUCLEUS. E.B. Gohl, R.E. Clark, and D.G. Lavond.* Neuroscience Program, University of Southern California, Los Angeles, CA 90089-2520.

Several studies have implicated the lateral pontine nuclei as a relay for auditory conditioned stimulus (CS) information. However, other studies have shown that learning related activity develops in this area over the course of training. This suggests that the pontine nuclei could be involved with the learned response, or simply "informed" of the learned response by some afferent structure. The interpositus nucleus has been implicated as the essential site of plasticity associated with this type of learning, therefore it could serve as the source of the learning related activity seen in the pontine nuclei. A cooling probe was implanted just lateral to the interpositus nucleus to create a reversible lesion of that structure. Rabbits were classically conditioned using our standard paradigm. A microelectrode driver was used to search the lateral pons for learning related activity. A reversible lesion was then created in the interpositus by activating the cooling probe and the pontine activity was then reassessed. Our results show that in well trained animals, some recordings from numerous regions of the lateral pons showed a clear tone evoked phasic response followed by unit activity that modeled the learned behavioral response. During interpositus inactivation the learned behavioral response and the unit model were abolished, while the tone evoked response remained unchanged. These data lend further support to the notion that the lateral pontine nuclei relay auditory CS information to the cerebellum and provides new evidence that this region is simply informed of the learned response by the interpositus nucleus.

ONTOGENY OF LATENT INHIBITION OF EYEBLINK CONDITIONING IN THE RAT. C.S. Hendrix², J.H. Freeman, Jr.², & M.E. Stanton^{1,2*}, ¹Neurotoxicology Div., US EPA, RTP, NC 27711; ²Psychology Dept., UNC, Chapel Hill, NC 27599.

Eyeblink conditioning may reveal how interactions between the developing hippocampus and cerebellum contribute to the ontogeny of learning. The cerebellum appears to subservise delay conditioning of the eyeblink response. While the hippocampus is not critically involved in the acquisition of delay conditioning, it may interact with the cerebellum to modulate the acquisition of "higher order" eyeblink conditioning phenomena such as latent inhibition (LI). This study sought to determine if there is an ontogenetic profile to LI in eyeblink conditioning, e.g., is there a point in development when delay conditioning is present in the absence of LI. Rats aged 20, 24, and 32 days postnatal were selected for testing as this represents ages which precede, coincide with, and follow emergence of delay conditioning in the developing rat (Stanton et al., 1992, *Behav. Neurosci.*, 106, p. 657). Rats at each age were randomly assigned to groups which received either 450 trials of preexposure to a 2.8KHz 80dB tone CS, or chamber exposure only, followed by 150 trials of delay conditioning in which a 380ms CS preceded and co-terminated with a 100ms eyeshock US (see Stanton et al., *ibid.*). CR amplitude was compared between the groups at each of the ages to assess strength of conditioning. In 24- and 32-day-olds the degree of LI was equivalent with the CS preexposed group showing impaired conditioning relative to the non-preexposed group. However, the 20-day-olds showed a reversal of this effect as the CS-preexposed group showed facilitation of delay conditioning relative to the non-preexposed group. These results show that LI of eyeblink conditioning can be demonstrated in the developing rat and is present at a point in development when delay conditioning first emerges. Further studies of this kind may help reveal how the developing cerebellum and hippocampus interact in the ontogeny of learning and memory.

CLASSICAL EYELID CONDITIONING IN RABBITS WITH TEMPORAL UNCERTAINTY. J-S Choi¹, M.J. Hiri¹, and J.W. Moore. Neuroscience and Behavior Program, University of Massachusetts, Amherst, MA 01003.

In order to challenge and extend real-time computational models of CR waveforms (e.g., Desmond & Moore, *Biol. Cybern.* 58: 405, 1988), we investigated the timing of conditioned eyelid movement as a function of temporal uncertainty. In two experiments, rabbits were trained with randomly varying ISIs with a mean ISI of 500 ms. The CS was a 300-ms 1-kHz 80-dB tone, and the US was a 2.5-mA 1-ms dc pulse to the periorbital tissue of the right eye. There were 100 trials/session at a rate of 3/min, with every 10th trial a CS-alone probe. Independent variables were W, the range of possible ISIs in milliseconds, and m, the number of possible ISIs within W. Dependent variables included CR latency (L), time of peak CR amplitude (P), and movement time (MT = P - L).

In Experiment 1, W = 0, 50, 100, 200, and 400. For W = 0, m = 1; for W \geq 50, m = W/2. Each of 4 animals experienced all Ws. There were 12 sessions under the initial W (W = 0 or 400) and 10 for each subsequent W. The results from the last 5 sessions/W were: (a) probe-trial CR topographies spanned W; (b) MT was constant for W = 0 and 50 but increased linearly with W for W \geq 100, with P increasingly overshooting the mean ISI of 500 ms; (c) Pearson correlation coefficients between L and P, computed for each animal from probe trials, averaged .25 and were unrelated to W.

In Experiment 2, W = 400 and m = 2, 3, 4, or 5 for different animals. Probe-trial CR topographies after 20 sessions spanned W. They were bimodal for m = 2 (ISIs 300 and 700) but unimodal for m = 3-5, and P was an inverted-U function of m. On CS-US trials, CRs began to return to baseline immediately upon the occurrence of the US, suggesting it had become a conditioned inhibitor. THE CEREBELLUM AND RED NUCLEUS ARE NOT REQUIRED FOR CLASSICAL CONDITIONING OF AN IN VITRO MODEL OF THE EYE-BLINK REFLEX. L. Keifer* Dept. of Physiology, Northwestern Univ. Medical School, 303 E. Chicago Ave., Chicago, IL 60611.

The role of the cerebellum in the acquisition of conditioned responses has been a controversial issue. Lesion data from behaving animals have suggested that the interpositus nucleus is an essential component of the neural circuitry involved in acquisition, while the role of the cerebellar cortex has been more difficult to define. Alternative interpretations view these findings as more consistent with the general involvement of the cerebellum in movement control, rather than in learning. In previous reports we have introduced the in vitro turtle brainstem-cerebellum preparation as a model system in which to study the classically conditioned eye-blink response (Soc. Neurosci. Abs. 16: 763, 1990; 18: 1560, 1992). In the present study, the minimal amount of tissue required to support conditioning was examined. The entire cerebellum, including the cerebellar nuclei, and the red nucleus bilaterally, were surgically removed. The preparation was presented with the standard delay training protocol of a 1 s CS to the auditory nerve immediately preceding a single shock US to the trigeminal nerve. In 3 of 7 preparations tested, acquisition of conditioned abductor nerve responses was recorded. Extinction of CRs was produced by applying control stimuli of alternate CS and US. These preparations were generally unstable, producing highly variable responses and having a shortened period of viability. Interestingly, 2 preparations that demonstrated conditioning also exhibited UR suppression. These data suggest that the cerebellum and red nucleus are not embedded in the essential neural pathways that support acquisition of CRs, although they are likely to play some role. The results emphasize the importance of examining the basic eye-blink reflex pathway itself and its connections with the reticular formation as potential sites of synapse modification. Moreover, the results do not support theories that UR suppression is mediated by the red nucleus as this phenomenon was observed in the absence of this neuronal structure. Supported by NSF BNS-9109572.

THE IMPORTANCE OF EQUATING FLEXION FORCE WHEN STUDYING "INSTRUMENTAL LEARNING" IN SPINALIZED RATS. D.G. Barstow, J.W. Grau, & M.W. Meagher. Dept. of Psychology, Texas A&M Univ., College Station, TX 77843.

Evidence suggests spinal mechanisms are capable of supporting instrumental conditioning. In these studies, one group of spinalized rats (Exp) can terminate hindlimb shock by exhibiting a flexion response. A "Yoked" group (Yok) experiences the same shock irrespective of leg position. Although we were previously able to obtain an Exp/Yok difference (Parker et al., *Neurosci. Abs.*, 18, 1026) we failed to replicate important details of past studies. These include: 1) an increase in response duration in Exp Ss; and 2) poor learning after non contingent shock (a "learned helplessness" effect). In the present study we show that these effects are observed if response force is matched prior to training. A day after subjects (N=24) received a spinal transection at T2, they were placed in restraining tubes. For half the subjects, shock intensity was then adjusted so that it elicited a flexion with a force of 0.4 N; the other half experienced a shock intensity required to elicit a flexion of 0.6 N. Subjects then received 30 m of contingent shock (Exp), non contingent shock (Yok), or no shock (Unshk). Subjects in the Exp group, but not the Yok group, exhibited leg flexions that steadily increased in duration across training. At the end of training, response force was again equated across subjects. All subjects then received 30 m of contingent shock. Both the Exp and Unshk groups acquired the flexion response whereas subjects in the Yok group did not. Supported by MH48994 to J.W.G.

LEARNING AND MEMORY: SYSTEMS AND FUNCTIONS VI

409.1

PET STUDIES OF A CUED RECALL EXPLICIT MEMORY TASK. R.L. Buckner*, S.E. Petersen, F.M. Miezin, J. Ojmann, L. Squire†, and M.E. Raichle. Washington Univ. Sch. of Med., Box 8111, St. Louis, MO 63110. †UCSD Dept. of Psychiat., VA Med. Ctr., San Diego, CA, 92161.

Areas of the normal human brain used during an explicit memory task were identified using positron emission tomography (PET). In three independent experiments, scans were obtained during a RECALL task in which subjects explicitly retrieved prescan study words using uppercase visual word stems as cues. A BASELINE task, in which subjects produced the first word that came to mind when presented with word stems, and a FIXATION task were used as control conditions. Across experiments the format of the study words was varied. In the "Case-Same" experiment, study words (COURSE) were presented in the same uppercase visual font as the stem cues (COU). In the "Case-Change" experiment, study words (course) were presented in a lowercase visual font. In the "Auditory" experiment, study words were presented aurally. As compared to the FIXATION task, the BASELINE task activated several regions in response to the reading and production demands of the task including a region in left lateral prefrontal cortex (at or near area 44 or 45). Across all experiments, the RECALL task activated the same regions as the BASELINE task, and in addition activated a region in anterior right frontal cortex (at or near area 10). None of the three experiments produced left medial temporal lobe activation. An activation in the right hippocampal region (including the parahippocampal gyrus) was observed only in the Case-Same experiment where study words and recall cues were visually identical. These findings show that the frontal lobes play a functional role in explicit, cued-recall across three different experiments. Medial temporal lobe activation was detected in only one of the three experiments.

409.2

PET STUDIES OF A WORD STEM COMPLETION IMPLICIT MEMORY TASK. S.E. Petersen*, R.L. Buckner, L. Squire†, F.M. Miezin, and M.E. Raichle. Washington Univ. Sch. of Med., Box 8111, St. Louis, MO 63110. †UCSD Dept. of Psychiat., VA Med. Ctr., San Diego, CA, 92161.

In the preceding abstract, we reported data from three PET experiments which studied cued-recall explicit memory tasks based on word stems. In two of these experiments, an implicit memory version of the stem completion task was also studied (PRIMING). In the PRIMING task, subjects produced the first word that came to mind when presented with uppercase visual word stems (IDE). Half of the stems were the beginnings of words from a study list presented three minutes prior to the scan. In the first "Case-Same" experiment, study words were visually identical to test stems (IDEAL). In the second "Case-Change" experiment, study words were visually different from test stems (ideal). Subjects produced 71% and 53% of the study words, respectively, during the two PRIMING tasks. When the PET data from the two experiments were combined, no regions increased blood flow in the PRIMING task compared to the BASELINE control task described in the previous abstract. Regions in bilateral occipital temporal cortex showed blood flow reductions, which appeared approximately symmetrical in magnitude. When experiments were analyzed independently, right lateralized reductions were larger in magnitude than left reductions for both experiments. Post-hoc inspection of the data revealed that the right posterior reduction localizes to two slightly different regions in the two experiments and thus appeared attenuated when data were combined. Behavioral data indicated that study words were produced more quickly than novel words. These blood flow reductions and behavioral data suggest a neurobiological effect of priming: following exposure to a stimulus, subsequent perceptual processing is more efficient, producing quicker response times and requiring less neural activity.

409.3

REGIONAL CEREBRAL BLOOD FLOW (rCBF) DURING ACQUISITION OF PROCEDURAL MEMORY. L. Metz*, J. Singh, J.D.E. Gabrieli, D. B. Willingham, D. Dooley, M. Jiang, C.-T. Chen, and M. Cooper. University of Chicago, Chicago, IL 60637.

The serial reaction time (SRT) task measures a pattern-specific form of sensorimotor skill learning and retention. SRT learning is considered to be implicit or procedural and to depend upon a fronto-striatal network. We examined the neural network underlying normal SRT learning by using O-15 labeled water in PET studies to measure rCBF at different stages of SRT learning.

11 young adults performed the SRT while lying in a PET VI scanner. Subjects pressed buttons in response to boxes changing colors on a computer screen. Initially, subjects saw a block (144 trials) in which the 4 horizontally displayed boxes turned on randomly (R1). This was followed by 7 blocks in which boxes turned on according to a 12-unit repeating pattern (P1 through P7). Finally, there was another random block (R2). rCBF was measured during blocks R1 and R2, and P1, P3, P5, and P7.

RT decreased from R1 through P7 by 154 msec, then increased again at R2 by 96 msec. Subjects reported little awareness that there was any pattern in the blocks. Image data obtained during the performance of each block were masked, normalized, correlated with MRI, transformed into Talairach space, and averaged across subjects. Averaged images from R2 were subtracted from the averages for each of the other blocks. Bilateral regions of the medial and lateral frontal cortex, thalamus, and basal ganglia showed gradual increases in rCBF from P1 through P7. The anterior cingulate was active throughout the pattern scans. Visual cortex was active initially (R1 and P1), then decreased before increasing slightly at P7.

The correlation between SRT learning and sites of apparently progressive neural activity are consistent with patient findings in defining a fronto-striato-thalamic loop as a critical neural substrate for the acquisition and retention of procedural sensorimotor skill in humans.

409.4

CHANGES IN REGIONAL CEREBRAL BLOOD FLOW ASSOCIATED WITH A NON-PATTERNED PROCEDURAL MEMORY TASK. L. Singh*, J. Metz, J. D.E. Gabrieli, D. B. Willingham, D. Dooley, M. Jiang, C.-T. Chen, & M. Cooper. The University of Chicago, Chicago, IL 60637.

In a companion abstract, "Regional Cerebral Blood Flow (rCBF) During Acquisition of Procedural Memory," Metz et al., we reported that the changes associated with the acquisition of a procedural memory skill receive major contributions from the fronto-striato-thalamic loop. We now report the rCBF changes associated with a non-patterned procedural memory task that does not involve an imbedded pattern.

We used our previous serial reaction time (SRT) paradigm in which subjects see four boxes displayed on a computer screen. Subjects are required to push buttons corresponding to a box which changes color. In that experiment, the subjects were exposed to 1 random and 7 repeating-sequence patterns, and another random block. In the present study, the subjects were exposed only to random blocks (144 trials per block; total number of blocks: 9). We studied 3 healthy normal young subjects (age range, 23-36 yrs). Subjects performed the task while lying in the PET scanner. A bolus of 60-80 mCi O-15-labeled water was injected 20 sec before the start of blocks Ran-1 to Ran-9; 10 sec after injection, a 50-sec PET scan was begun. Image data were normalized, transformed into Talairach space, masked, and averaged across all subjects.

Behavioral data indicated that there was a small, but steady decrease in the reaction time (with a slope only about 1/3 as steep as in the patterned SRT paradigm), but in the current experiment, the increase in the RT during the last random block observed in the SRT-patterned paradigm was absent. Imaging results indicated that the thalamus and basal ganglia were active as in the first study, but there was no activation in the frontal cortex. These pilot data raise the possibility of a major contribution of the frontal cortex to the pattern-specific memory, whereas the simple sensori-motor task may depend upon the thalamo-striatal loop.

409.5

FUNCTIONAL ACTIVATION OF RIGHT HIPPOCAMPUS DURING AN OLFACTORY RECOGNITION MEMORY TASK. M. Jones-Gotman*, R.J. Zatorre, A.C. Evans and E. Meyer. Montreal Neurological Institute, McGill University, Montreal, Quebec, Canada, H3A 2B4.

The neural substrate of human olfactory memory was studied by examining cerebral blood flow (CBF) changes with positron emission tomography. In the experimental condition, nine normal right-handed subjects were scanned while they smelled a series of odorants birhinally and indicated, by pressing a key, which ones had been presented earlier. The baseline condition consisted of inhalation and key pressing but with no odor present. Anatomical localization was provided by matched magnetic resonance imaging. Subtraction of the obtained images indicated CBF increases bilaterally in the piriform cortex and unilaterally in the right orbitofrontal cortex, replicating our earlier observations, and suggesting a relative functional asymmetry in olfactory processing. In addition, a region corresponding to the hippocampus and parahippocampal gyrus on the right side also demonstrated increased CBF, despite birhinal presentation. This area, not activated during passive odor inhalation, is likely involved specifically in some aspect of olfactory memory, in agreement with our findings from patients with excision in the right medial temporal region.

409.7

WORD LIST LEARNING IN PATIENTS WITH FRONTAL LOBE LESIONS. D.T. Stuss*, M.P. Alexander, C. Palumbo, L. Buckle, L. Sayer and J. Pogue. Rotman Research Institute of Baycrest Centre, Toronto, M6A 2E1; University of Toronto, Toronto, Ontario; Braintree Hospital, Braintree, MA; Boston VAMC.

The effect of frontal lobe damage on verbal learning was explored in 32 patients with localized frontal lesions (13 bilateral, 10 left and 9 right). Patients were given three word lists to learn; the lists differed in their intrinsic semantic organisation. Results: 1) Recognition verbal memory was mildly but significantly impaired for left and bilateral cases; 2) Free recall was impaired in the same two groups; 3) All frontal groups had impaired higher order organisational processes; 4) Perseverations were significant only in the right frontal group. Conclusion: While not 'amnesic', patients with frontal lesions have impaired verbal learning, and this deficit is highly multidetermined due to damage to a variety of frontal processes.

409.9

REDUCED WORKING MEMORY CAPACITY IN PATIENTS WITH GLOBAL AMNESIA: EVIDENCE FOR A LIMBIC/DIENCEPHALIC CONTRIBUTION TO WORKING MEMORY PERFORMANCE. J.D.E. Gabrieli*, M.M. Keane and G.T. Stebbins. Department of Psychology, Stanford University, Stanford, CA 94305 and Memory Disorders Research Center, Boston VA, Boston MA 02130.

Working memory (WM) is a multi-component psychological system that supports the temporary processing and storage of information needed to perform complex cognitive tasks. WM is an important component of human cognitive architecture, and is often used as an explanatory concept for understanding individual differences in problem-solving ability, age-related changes in cognition, the usefulness of tests for personnel selection, and cognitive impairment in patients with frontal-lobe lesions, Parkinson's disease, Huntington's disease, and schizophrenia. Animal studies implicate two major neural systems constituents of WM: a frontal-striatal component and a hippocampal component. Prior studies with patients confirm the participation of a frontal-striatal component in human WM, but there is little evidence concerning the role of medial-temporal and related diencephalic structures. We examined this issue by administering a test of WM capacity to 10 patients with global amnesia (AMN) (5 with Korsakoff's syndrome, 4 with medial-temporal lesions, and 1 with a thalamic lesion), and comparing their performance with 9 age- and education-matched control (CON) subjects (5 normal controls and 4 alcoholic controls). Subjects answered questions about auditorily presented sentences (processing) while trying to remember the final word of each sentence (storage) for a subsequent recall test. Subjects began with 1 sentence before recall, and proceeded with increasingly larger numbers of sentences (2, 3, etc.) until they failed 2 of 3 trials for a given number of sentences. WM capacity was defined as the longest span (i.e., largest number of sentences) at which subjects recalled the words correctly for at least 2 of the 3 trials. AMN patients (mean of 1.3) had an impaired WM capacity that was about half of that of control subjects (mean of 2.3); patients with medial-temporal or diencephalic etiologies of amnesia performed similarly. The digits spans of the AMN patients were unimpaired. These results suggest that brain structures important for declarative memory play an important role in WM performance. It may be that when information demands on a WM task exceed specialized primary memory buffers in frontal and other cortical regions, information is stored temporarily in secondary declarative memory stores. WM deficits in AMN patients may reflect impairment in the use of declarative memory stores. Supported by ONR grant N00014-92-J-184 and NINDS grant 26985.

409.6

EFFECTS OF SEMANTIC DISTINCTIVENESS ON TEMPORAL ORDER MEMORY IN FRONTAL PATIENTS. J. A. Mangels*, A. P. Shimamura. Dept. of Psychology, University of California, Berkeley, 94720.

Patients with frontal lobe lesions often exhibit deficits on tests of memory for temporal order. However, recent studies demonstrate that memory for temporal order can be improved to the level of control subjects by encoding manipulations aimed at increasing distinctiveness (e.g. subject performed tasks). To date, stimulus distinctiveness has not been manipulated along the semantic dimension.

We compared memory for temporal order in 7 patients with dorsolateral prefrontal lesions and 12 age and education matched control subjects. Subjects were presented with a serial list of 15 concrete words or pictures. After a 30 second distractor task, subjects reconstructed the temporal order of the list from a random array of the same stimuli. Groups did not differ on memory for temporal order when lists consisted of stimulus items from different categories. However, when categorized lists were used (a list of three items from each of five categories, randomly ordered), the temporal order memory of frontal patients was significantly impaired for both pictures and words. Results suggest that the deficit observed in frontal patients on tests of temporal order memory may be attributed to high susceptibility to semantic interference. EARLY BLIND'S SPATIAL REPRESENTATIONS: ROUTES OR MAPS? C. Thinus-Blanc* & F. Gaunet. Lab. of Cognitive Neurosciences, CNRS, 31, Ch. J. Aiguier 13402 Marseille France.

Three groups of subjects (early, late and blindfolded sighted subjects) were submitted to an experiment inspired by Rieser, Guth and Hill (1986)'s study: they were guided from a reference starting location in an unfamiliar room toward target places according to a specific path. Then the task consisted to point, then, to walk toward each target location and to verbally estimate the distances between them, even if they have not travelled between some of the places (inference). The same estimations were required after 1)having imagined that they had walked to the opposite corner of the room and 2)having actually moved to the opposite corner.

The early blind participants made much more errors in angle estimate during the pointing task but not when they had to actually walk toward the targets. Deep deficits were also recorded in this group when the task required to imagine oneself pointing from the opposite corner of the room whereas no differences were observed between groups after the subjects had been actually guided to the new place. Finally, unlike the late blind and sighted blindfolded groups which improved their spatial memory performance during the course of the experiment, no learning occurred in the early blind group.

These results, together with the data collected during the interviews following the experiment, suggest that early blind persons' spatial strategies rely on proprioceptive memory and not on an overall map which would have allowed greater behavioral flexibility.

DISSOCIATION BETWEEN TWO KINDS OF VISUAL WORKING MEMORY IN PARKINSON'S DISEASE. B. B. Postle*, S. Corkin and J. H. Growdon. Department of Brain and Cognitive Sciences and the Clinical Research Center, Mass. Institute of Technology, Cambridge, MA 02139.

Physiological and behavioral evidence from monkeys suggests that visual working memory is divided into two dissociable subsystems, one for remembering the spatial location of stimuli (subserved by dorsal areas of prefrontal cortex, including the principal sulcus), and one for remembering the characteristics of shapes (subserved by ventral and orbital areas of prefrontal cortex). We proposed that visual working memory in humans also comprises spatial and shape recognition components, each having different neural substrates within frontal cortex. We selected subjects with PD to test our hypothesis because PD disrupts the circuitry linking dorsolateral prefrontal cortex, basal ganglia, and thalamus, thus creating a functional deafferentation of dorsolateral prefrontal cortex, while sparing other regions of prefrontal cortex. PD subjects (Hoehn & Yahr Stage II) and age-matched control subjects (NCS) performed two working memory tasks, in which subjects learned arbitrary associations between stimulus pairs, relying on spatial cues in one task and shape cues in the other. On the spatial test, PD subjects made more errors than NCS ($p < .05$) and required more trials to criterion ($p < .05$); but on the shape test PD subjects did not differ from NCS, either in errors ($p = .26$) or trials to criterion ($p = .12$). These results show a dissociation between two kinds of visual working memory: one for spatial location (impaired in PD) and one for shape recognition (normal in PD). We suggest that working memory systems are domain specific, and not dependent upon a central processor.

409.11

HETEROGENEITY IN MEMORY DISORDER AND LESION SITES WITH ACoA ANEURYSM. S.M. August¹, P.J. Eslinger³, L.M. Grattan¹, D. Rigamonti², & A. Depatri². Depts. of Neurology¹ and Neurosurgery² Univ. of MD Med. Sch., Baltimore, MD, 21201 & ³Penn State Univ. College of Med., Hershey, PA 17033

Significant learning and memory disturbances have been associated with rupture and clipping of anterior communicating artery (ACoA) aneurysms. Commonly referred to as "basal forebrain amnesia" these acute learning and memory impairments have been ascribed to distortions in the spatial-temporal processing of information. The purpose of this investigation was to prospectively examine a consecutive series of patients with ACoA aneurysms (n=12) during acute recovery (within 1 month). Patients with ruptured aneurysms in different vascular distributions (n=10) comprised the comparison group. Neuropsychological measures included standardized assessments of learning and memory supplemented by experimental procedures designed to probe the spatial-temporal components of memory. Neurobehavioral findings indicated that the ACoA group produced significantly more confabulatory responses than the comparison group. However, there were no significant differences on standard and experimental measures of learning, memory and spatial-temporal ordering for verbal or visual information. Results of neuroanatomic studies indicated that 75% of the ACoA group had lesions outside of the basal forebrain region. The lack of clear cognitive differences between the groups in acute recovery may be related to marked heterogeneity among the ACoA patients with respect to neuroanatomic lesion and performance on cognitive measures. Defining memory disturbance from medical etiology of vascular patients may be problematic in studies of learning and memory.

409.13

THE LATE NEGATIVE SLOW ERP IS ENHANCED PRIOR TO CORRECT SYNONYM RECOGNITION MEMORY PERFORMANCE. D.M. Rice*, R. Bella, A. Pham
Andrus Gerontology Center and Program in Neural, Information and Behavioral Sciences, University of Southern California, Los Angeles, CA 90089-0191.

We reported at last year's meeting that a postresponse late negative slow ERP is selectively enhanced by the repetition of words as opposed to pronounceable nonwords in a short term visual recognition memory task (Rice and Locke, SNA, 1992). This suggested that this late negative slow wave enhancement at retrieval relative to encoding reflects a short term reflective memory process related to stimulus meaning. We now present further evidence to support this hypothesis. Sixteen young adults had recognition performance and nose-referenced ERPs recorded during a short term synonym recognition memory task. All words were presented and then followed by their synonyms within 6-18 seconds in a continuous recognition memory paradigm. Subjects made repeat-novel responses on the basis of stimulus meaning. Across subjects, the late negative slow wave over the average of the 19 leads was significantly ($p < 0.01$) enhanced at retrieval relative to encoding. This enhancement began at approximately 700 msec poststimulus and continued until about 1100 msec poststimulus; the onset of this enhancement was about 400 msec prior to the average synonym recognition response. Thus, unlike a word recognition memory task, a synonym recognition memory task is associated with a late negative slow wave enhancement prior to the correct recognition memory response. This is consistent with our interpretation that the retrieval-related enhancement of the late negative ERP in a recognition memory task reflects a short term conscious recollective memory process associated with stimulus meaning.

MEMORY IMPROVEMENT BY AN AYURVEDIC CNS-RASAYANA-MENTAT. V. Patel, A. Agarwal, G.P. Dubey, and B. Garg*
Department of Pathology and Neurology, I.U. School of Medicine, Indianapolis, IN 46202 and Psychosomatic Biofeedback Laboratory, Banaras Hindu Univ. Varanasi, India.

Ayurveda, a dynamic ancient medical system of India, continues to provide healthcare to over 600 million people of India. The CNS-Rasayana "Mentat" is a mixture of Ayurvedic herbal preparation traditionally used for memory enhancement, relieving anxiety and management of depression and behavioral disorders. We carried out a preliminary double-blind placebo-controlled study to investigate these effects of Mentat. Twenty normal subjects were selected in each of the three age groups (Table), 10 receiving placebo and other 10 receiving mentat. Change in short-term memory quotient (MQ) was measured by word memory test before the initiation and after 3 months of oral treatment. The ingestion of Mentat (4 grams: 2 grams morning and evening) brought about significant ($P < 0.05$) increase in short-term MQ (Table). There also was significant ($P < 0.05$) reduction in anxiety score (determined by Hamilton's scale) and neuroticism index (Eysenck's Inventory Index).

Table: Change in MQ of Adult Subjects Before and After 3 months of Treatment

Treatment Age groups	Placebo		Mentat	
	Before	After	Before	After
15-25 yrs	88.4±3.3	90.1±2.8	89.1±2.6	98.3±1.8*
35-45 yrs	82.4±3.1	83.1±3.4	84.2±2.4	93.9±1.9*
55-65 yrs	82.3±3.6	83.1±2.8	80.75±1.8	89.5±1.6*

*These preliminary findings warrant further studies on the use of Mentat in memory dysfunction disorders.

409.12

THE POSSIBLE CONTRIBUTION OF THE SEPTAL REGION TO HUMAN MEMORY. H. J. Markowitsch¹, D. Y. von Cramon² and U. Schuri² (SPON: European Neuroscience Association). ¹Physiol. Psychol., University of Bielefeld, D-33501 Bielefeld, ²Dept. of Neuropsychology, City Hospital, Munich-Bogenhausen, D-8000 Munich, Germany.

A particularly well documented, intelligent patient (H.I.) with very selective, minute, but most likely bilateral damage of the basal forebrain including the septal region is presented. Though behavioral progress was found for a number of areas, she remained deficient, especially in long term memory. The severest and largely modality-nonspecific deficits were observed in recall (as opposed to recognition) situations. As a peculiar finding which we would attribute to septal damage, H.I. was mainly involved and affected in tests containing emotional (especially emotionally negative) stimuli, or certain flavors. While this involvement might have helped her in memorizing material judged as positive, it was of negative influence under other circumstances. The septal area may serve as an interface contributing a specific combination of emotional flavor and evaluating (feedback) judgement to a larger (septo-hippocampal-amygdalar) memory and learning processing network.

409.14

SPATIO-TEMPORAL DYNAMICS OF HUMAN CORTICAL EEG DURING SOMATOSENSORY PERCEPTION. C. Barczys¹* and W.J. Freeman². ¹Biophysics Group and ²Neurobiology Division, Univ. of California, Berkeley, CA 94720.

Previous research in the rabbit olfactory bulb and monkey visual cortex demonstrated that EEG segments recorded from 64-electrode arrays during a discrimination task could be sorted by stimulus type by using the spatial patterns of amplitude of a global carrier waveform. To test whether these results could be extended to human somatosensory perception, a neurosurgical patient fitted for diagnostic purposes with an 8x8 subdural electrode array at spacings of 1 cm on the somatosensory cortex was trained to perform a somatosensory discrimination task. The EEG traces were digitized at 256 Hz, filtered (20-56 Hz), and edited. Segments were classified by stimulus type after Fourier decomposition with a Euclidean-distance measure in 64-space. Classification accuracy of the training sets was $83 \pm 4\%$ for the post-stimulus "perceptual" segments versus $66 \pm 3\%$ for the pre-stimulus segments, but at chance levels in cross-validation with test sets. A Genetic Algorithm for detecting outliers increased the accuracy on the training sets to 96% but did not improve the cross-validation results. Animated computer graphics of the 8x8 traces and phase portraits showed differing domains of EEG activity in the array with transitions to less chaotic activity during the 200-400 msec post-stimulus time period for perception. The results show that perceptual patterns found in 4x4 mm arrays in animals are not revealed in 8x8 cm arrays in humans.

SPATIAL LEARNING IN FORNIX TRANSECTED AND SEPTAL DAMAGED RHESUS MONKEYS. M.E. Weber, D.L. Rosene*, and M.B. Moss. Department of Anatomy & Neurobiology, Boston University School of Medicine, Boston, MA 02118.

The fornix (Fx) is the principal subcortical efferent pathway from the hippocampal formation (HF). It also carries afferents to the HF including axons from the cholinergic cells of the medial septum/diagonal band (MSDB). Previous studies in monkeys have demonstrated that the hippocampus is important in spatial learning and memory (Mahut, 1972; Parkinson et al., 1988). In the current study, we attempted to dissociate the effects of Fx transection which disrupts both HF afferents and efferents from an ibotenic acid lesion of the MSDB that removes only the cholinergic input to the HF.

A total of thirteen animals were used for this study. Three sustained transection of the Fx (N=3) and three received ibotenic acid lesions of the MSDB (N=3). Their performance on the spatial condition of the Delayed Recognition Span Task (DRST) and on a spatial reversal task was compared to unoperated control monkeys (N=7, DRST; N=5, spatial reversal). On the DRST, both MSDB and Fx animals were significantly impaired relative to controls ($p < 0.05$) but were not different from each other. On the spatial reversal task, Fx animals were significantly impaired relative to controls on reversals 1 and 2 ($p < 0.01$) but not on reversal 3. While the MSDB animals obtained elevated error scores, the difference did not reach significance on any of the three reversals. These results indicate that the cholinergic input to the HF is critical for performance on the recognition span test, a memory loading task, but may not be critical to performance on spatial reversals, a set shifting "executive function" task. Furthermore, these data suggest that either HF efferents in the Fx or non-septal Fx afferents are important for reversal performance. Supported by NIH grants AG04321 and NS16841.

410.3

EFFECTS OF RHINAL CORTICAL LESIONS COMBINED WITH HIPPOCAMPECTOMY ON VISUAL RECOGNITION MEMORY IN RHESUS MONKEYS. M. Meunier*, W. Hadfield, J. Bachevalier and E.A. Murray. Lab. Neuropsychology, NIMH, NIH, Bethesda, MD 20892.

Murray and Mishkin (J. Neurosci., 1986, 6:1991) reported that monkeys with rhinal cortex (Rh) ablations combined with hippocampectomy were only mildly impaired in visual recognition memory as measured by the delayed nonmatching-to-sample (DNMS) task with trial-unique objects, whereas monkeys with Rh lesions combined with amygdalectomy were severely impaired. More recently, however, monkeys with Rh lesions alone have been found to have a severe loss in visual recognition memory. Consequently, the results of the former study have been reevaluated: in that study, the Rh ablations sustained by the monkeys also receiving hippocampectomy (but not those receiving amygdalectomy) spared the rostralmost portion of the rhinal cortex, and resulted in removal of only about 3/4 of the rhinal cortex, hence we will refer to them as H+3/4Rh. To determine whether the good performance of Group H+3/4Rh was due to the incomplete rhinal cortex removal or, paradoxically, to the combination of rhinal and hippocampal damage, we prepared a new group of monkeys with H+complete Rh lesions (H+Rh), and assessed their visual recognition memory using DNMS. Group H+Rh scored 76% correct responses across the 6 conditions of the DNMS performance test (which employed longer delays between sample and choice, and longer lists of items to be remembered) as compared with 93% for their controls, which corresponds to an average loss, in terms of d' (see Ringo, Behav. Brain Res., 1991, 42:123), of 0.82. Group H+3/4Rh scored 84% (d' loss = 0.49), and Group Rh scored 67% (d' loss = 1.08). Analysis of the memory loss in terms of d' indicates that Group H+Rh performed significantly worse than Group H+3/4Rh, but significantly better than Group Rh. Thus, whereas the comparison of Groups H+Rh and H+3/4Rh indicates that sparing of the rostralmost portion of the rhinal cortex contributed to the relatively good performance of Group H+3/4Rh, the comparison of Groups H+Rh and Rh suggests that other factors contributed as well.

A NOVEL TEST OF SPATIAL WORKING MEMORY IN PRIMATES: EFFECT OF PREFRONTAL DOPAMINE DEPLETION. P. Collins, A.C. Roberts, B. J. Everitt* and T.W. Robbins. Departments of Experimental Psychology and Anatomy* University of Cambridge, Cambridge, CB2 3EB, U.K. (SPON:European Brain and Behaviour Society).

Patients with Parkinson's disease have impaired performance on a self-ordered search task designed to measure spatial working memory. This frontal-like deficit may result from degeneration of the mesocortical dopamine pathway associated with Parkinson's disease. The present study is concerned with the development of a primate analogue of this task and an assessment of the role of prefrontal dopamine in its performance. The task is run on a touch sensitive visual display unit which, on any given trial, presents a pre-defined number of identical blue squares at random sites across the screen. On each trial a marmoset has to touch each square, once and once only, in a self determined sequence to obtain reward. In control animals performance declined from 90% correct on sequences of one and two squares to 40% correct on sequences of 5 squares. Injection of 6-hydroxydopamine into the prefrontal cortex of marmosets pretreated with specific noradrenaline (NA) and serotonin (5-HT) uptake blockers, resulted in selective depletion of dopamine (DA) (90% loss of DA, < 50% loss of NA, < 10% loss of 5-HT) and impaired performance on a classical manual spatial delayed response task (SDR). The effect of the lesion on the self-ordered search task will be compared to that on SDR, the traditional test of spatial working memory in non-human primates, and to the performance of patients with Parkinson's disease and frontal lobe excision.

410.2

EFFECTS OF COMBINED MEDIAL TEMPORO-PREFRONTAL LESIONS ON VISUAL RECOGNITION IN MONKEYS. D.M. Kowalska, J. Bachevalier*, and M. Mishkin. Lab. Neuropsychology, NIMH, Bethesda, MD 20892.

Large bilateral lesions of either the medial temporal lobe (MT) or the ventromedial prefrontal cortex (VMPF) yield a severe, and almost equal, loss in visual recognition, whereas damage to only half of these large brain areas, i.e. anterior vs posterior medial temporal lobe (A vs P) or ventral vs medial prefrontal cortex (V vs M), yield a much milder impairment (Mishkin, Nature, 1978, 273:297; Bachevalier & Mishkin, Behav. Brain Res., 1986, 20:249). Because each of the MT components was thought to be anatomically connected mainly with one of the two VMPF components (A with V and P with M), it was hypothesized that crossed lesions (i.e. A+M and P+V) should produce a visual memory loss greater than uncrossed lesions (i.e. A+V and P+M) and equal to that found after either complete MT or complete VMPF lesions. To test this proposal, we prepared four groups of 3-4 monkeys each, in which lesions of each of the two components in MT was combined with each of the two components in VMPF. These monkeys were tested preoperatively on delayed nonmatching-to-sample with trial-unique objects, retrained on the task postoperatively, and then given a performance test with increasing delays (30, 60, 120 sec) or lists (3, 5, 10 objects). Monkeys in each of these four groups (A+M, P+V, A+V, and P+M) were significantly impaired across the 6 conditions of the DNMS performance test (averaging 76%, 70%, 69%, and 79%, respectively), as compared to unoperated controls (97%) and to monkeys with lesions of only one of the components in the MT and VMPF regions (range: 80% to 90%). Nevertheless, in none of these four groups was the loss in recognition memory as severe as the memory loss that follows the complete MT (59%) or VMPF (65%) lesions. Moreover, the losses after the crossed lesions were not greater than those after the uncrossed lesions. The results indicate that each of the two components in the medial temporal lobe must interact functionally with each of the two components in the ventromedial prefrontal cortex.

410.4

LONG-TERM EFFECTS OF NEONATAL HIPPOCAMPAL LESIONS ON VISUAL RECOGNITION MEMORY. M. Beauregard* and J. Bachevalier. Dept. Neurobiology and Anatomy, Univ. Texas Science Center, Houston, Tx 77225.

We examined the performance of three adult monkeys (7-8 years of age) that had sustained early lesions of the hippocampal formation (Group H) and four adult normal controls (Group N) in delayed nonmatching-to-sample with trial unique objects, and compared it with the performance of the same animals obtained when they were tested at 10 months of age in the same recognition task. In the performance test, including delays of 10, 30, 60, and 120 sec, there were no differences within groups between scores obtained at 10 months versus those obtained at 7 years of age. Likewise, at the two ages, there were no differences between Groups H and N. However, there was a significant Group and Delay interaction, indicating that, whereas scores of animals in Group N did not change across all delays, performance of animals in Group H decreased with increasing delays. Overall, the data suggest that lesions of the hippocampal formation, done either in infancy or in adulthood (Clower et al., 1991), do not yield a visual memory loss, at least when the delays are short (i.e. 2 min or less).

410.6

PRIMATE ANALOGUE OF THE WISCONSIN CARD SORT TEST (WCST): A BEHAVIOURAL AND MICRODIALYSIS STUDY OF DOPAMINERGIC MECHANISMS IN THE MARMOSET. A. C. Roberts*, M. A. De Salmia, L. S. Wilkinson, P. Collins, J. L. Muir, T. W. Robbins and B. J. Everitt† Departments of Experimental Psychology and Anatomy†, University of Cambridge, Cambridge, CB2 3EB, U.K.

Degeneration of the dopamine projection to prefrontal cortex may contribute to the frontal-like cognitive impairments associated with Parkinson's disease (PD) and schizophrenia. The present study investigated the effects of 6-hydroxydopamine lesions of the prefrontal cortex, in the marmoset, on two tests of prefrontal cognitive function, spatial delayed response (SDR) and attentional set-shifting. The latter test provided a componential analysis of the WCST, a commonly used test of frontal lobe function in man. The lesion produced a marked depletion of dopamine restricted to the prefrontal cortex and led to a long term adaptive change in the striatum such that extracellular dopamine in the caudate nucleus, as measured by *in vivo* microdialysis, was elevated in response to potassium stimulation. This was accompanied by an improvement in the ability to *shift* attention from one dimensional property of a stimulus to another whilst the ability to *maintain* attention towards one particular dimension was unchanged. In contrast, SDR performance was impaired in agreement with previous results. It is proposed that attentional set-shifting is mediated by a balanced interaction between prefrontal and striatal dopamine and that elevated dopamine contributes to the improvement in attentional set-shifting ability. This interpretation is consistent with the impaired attentional set-shifting ability of patients with PD using the same test as used here for non-human primates.

410.7

HIPPOCAMPAL AND CORTICAL ACETYLCHOLINE LEVELS IN CONSCIOUS, BEHAVING PRIMATES AS MEASURED BY *IN VIVO* MICRODIALYSIS.

T. D. Smith,* Y. L. Hurd, D. R. Weinberger and R. C. Saunders. NIMH Neuroscience Center at St. Elizabeths, Clinical Brain Disorders Branch, Washington, D.C. 20032.

In vivo microdialysis was adapted for measurement of acetylcholine (ACh) and choline levels in discrete brain regions of awake, behaving primates. Rhesus monkeys (*Macaca mulatta*) were trained to perform a series of behavioral tasks in an automated testing apparatus. Microdialysis probes were positioned into hippocampus and prefrontal cortex (principal sulcus) of unanesthetized monkeys through specially designed probe guides previously fixed to the skull. Probes were perfused with artificial CSF containing 10 μ M or 30 μ M neostigmine at a rate of 1.1 μ l/min. Dialysate was collected every 20 min beginning either 1 hr or 20 hr after probe placement and was analyzed for ACh and choline concentrations using HPLC coupled with electrochemical detection. A stable baseline for cortical and hippocampal ACh levels was established 3 hr after acute implantation and 1 hr following overnight placement of microdialysis probes and maintained for at least 5 hr in both preparations. Infusion of 10 μ M tetrodotoxin (TTX), a sodium channel blocker, reduced ACh overflow by 50-75% within 1 hr in both brain regions. In contrast, choline levels remained unaffected by 1 hr of TTX infusion. Systemic administration of the muscarinic antagonist, scopolamine hydrobromide (5.0-60.0 μ g/kg, IM), dose-dependently increased ACh overflow 0-400% within 1 hr. Choline levels were only slightly enhanced. Thus, extracellular levels of ACh are (1) detectable and stable for many hours (2) from neuronally derived pools and (3) responsive to systemic and local pharmacological manipulation. Following initial characterization of ACh and choline overflow, neurochemicals were measured during performance on the behavioral task, delayed-nonmatch-to-sample. Hippocampal and cortical ACh levels increased 2-18% above baseline during performance and continued to rise (16-28%) following completion of the task. ACh overflow declined to baseline values within 60-100 min post-task. Choline levels were unaffected by task performance. These data demonstrate the feasibility of characterizing dynamic neurochemical events in discrete brain regions and correlating these changes with performance on behavioral tasks.

410.8

A PRIMATE MODEL OF SCHIZOPHRENIA-LIKE NEUROPHYSIOLOGICAL DYSFUNCTION: EVIDENCE FOR THE PCP/NMDA MODEL OF SCHIZOPHRENIA. Javitt DC*, Shelley AM, Schroeder CE, Steinschneider MS, Arezzo JC and Vaughan HG, Jr. Departments of Psychiatry and Neuroscience, Albert Einstein College of Medicine, Bronx, NY 10461.

Schizophrenic subjects show severe impairments in cognitive functioning and information processing that are resistant to pharmacotherapy and persist despite overall clinical improvement. P300 (P3) is a long-duration cognitive event-related potential (ERP) component that indexes cortical response to unexpected, behaviorally relevant stimuli and provides a "window" into the cognitive dysfunction associated with schizophrenia. P3 is elicited most commonly in an "oddball" paradigm in which a sequence of repetitively presented standard stimuli is interrupted by an unexpected, physically deviant stimulus. In an auditory oddball paradigm, P3 is preceded by two negative components that reflect earlier stages of information processing, mismatch negativity (MMN) and N2. MMN indexes preattentive, automatic detection of stimulus deviance within auditory cortex and so represents the earliest stage of cognitive information processing within cortex, whereas N2 indexes attention-dependent stimulus classification events. Monkeys generate cognitive ERP components that closely resemble human MMN, N2 and P3 in terms of latency, scalp distribution and sensitivity to stimulus and task manipulations. The present study investigates the generation of MMN and N2 in schizophrenics in order to determine the earliest stages at which cortical information processing are impaired. Parallel studies in monkeys demonstrate that abnormalities of cognitive ERP generation similar to those seen in schizophrenics can be induced by focal infusion of phencyclidine (PCP)-like antagonists of NMDA receptor-mediated neurotransmission into primary auditory cortex, suggesting that NMDA receptor dysfunction might be pathophysiologically implicated in the cognitive information processing abnormalities associated with schizophrenia. CAUDATE ACTIVITY IN THE EXECUTION OF OCULOMOTOR HABITS

P.F. Dominey^{a,b}, J.P. Joseph^{a,b}, and M.A. Arbib^a

a. CNE, NIBS, University of Southern California, Los Angeles, CA 90089-2520
b. Vision et Motricité, INSERM Unité 94, 69500 Bron, France.

We recorded 60 task-related cells from the head of the caudate nucleus in a primate trained to associate centrally-fixed visual cues with saccades to one of two peripheral targets (choice). A delay between cue onset and saccade dissociated cue- from saccade-related activity. After a correct saccade and peripheral fixation, the cue re-appeared at the correct peripheral location (peripheral cue), and the reward was given. We also studied a saccade-without-overlap task in which onset of a single peripheral target indicated the direction of the saccade (no choice).

Purely cue-related responses were observed in 4 (7%) cells. Sustained peri-cue activity that reliably predicted saccade direction (oculomotor set) was seen in 16 cells (27%). Cues associated with the same saccade evoked similar activity in all 7 of these cells tested. Peri-saccadic activity was recorded in 34 cells, with 17 (28%) spatially selective. 13 of 17 displayed sustained discharge until the reward. Of the 17 non-spatially selective cells, 15 showed sustained discharge until the reward, suggesting activity related to expectation of peripheral cue and reward, respectively. Six cells (10%) showed peri-saccade inhibition. Few task-related cells clearly distinguished cue-guided from visually guided saccades.

The small number of purely cue-related cells might suggest that caudate does not participate in this primarily cortical task. Alternatively, we could consider that oculomotor set demonstrates that IT corticostriatal projections convey cue-related activity to saccade-related caudate cells via plastic synapses that are strengthened by learning. We present neural network models for both mechanisms and compare them with our data in consideration of the view that striatum participates in the formation and execution of S-R habits via corticostriatal plasticity.

411.3

INVOLVEMENT OF THE CEREBELLAR NUCLEI AND THE RED NUCLEUS IN THE CONTROL OF THE EYEBLINK REFLEX IN THE RABBIT: THE ROLE OF GABA-A RECEPTOR MEDIATED NEUROTRANSMISSION. N.K. Winters, M.L. Webster, K.B. Irwin, V. Bracha* and J.R. Bloedel. Barrow Neurological Institute, Phoenix, AZ 85013.

The purpose of the present study was to examine the effects of modifying the GABA-a receptor mediated neurotransmission in the cerebello-rubral system on the performance of the classically conditioned (CR) and unconditioned (UR) eyeblink reflexes. The deep cerebellar nuclei and the red nucleus were injected with either muscimol or bicuculline on separate days and the effects of both drugs on the previously learned CRs and on the URs were compared in 20 trained rabbits. Injections of the GABA-a agonist muscimol in the dentate-interposed cerebellar region as well as in the red nucleus disrupted the performance of CRs. This effect was in most cases paralleled by reduced amplitudes and increased latencies of the URs. Interestingly, the application of the GABA-a antagonist bicuculline into identical injection sites in the cerebellar nuclear region led to qualitatively analogous behavioral effects - depression of both CRs and URs. Although similar behavioral effects of bicuculline were observed in most animals after infusion in the red nucleus, in some rabbits the GABA-a antagonist enhanced performance of both responses.

These observations indicate that the GABA-a synaptic transmission within the cerebello-rubral circuits is involved in the control of both conditioned and unconditioned eye-blink reflexes.

411.2

DEVELOPMENTAL STUDIES OF EYEBLINK CONDITIONING AND RELATED NEURONAL ACTIVITY IN MOTOR CORTEX. C. Woody* and E. Gruen. UCLA Med. Ctr., MRCC, BRI, Los Angeles, CA 90024.

Some forms of Pavlovian conditioning are not acquired in mammals such as cats until after three weeks of age (Spear, N.E. and Campbell, B.A., *The Ontogeny of Learning and Memory*, Hillsdale, N.J., Erlbaum, 1979). We determined if this was so for short and long latency eyeblink conditioning, and tested the hypothesis that failure of development might depend on inability of neurons of the motor cortex to learn. Each of three cats tested at 14-17 days of age failed to learn a blink CR after pairing click with glabella tap and electrical stimulation of the lateral hypothalamus (Aou et al. *J. Neurosci.* 1992). Each of three cats tested at 4-5 weeks of age developed blink CRs. The 14-17 day old cats responded to the UCS with blink URs and also showed increased cortical spike activity to click CS.

When tested for conditioning by pairing click as CS with local ionophoretic application of glutamate as UCS, single cortical units developed spike activity CRs in cats of both 2 and >4 weeks of age. The "inability to learn" the behavioral CR may thus reflect an inability to integrate cortical outputs in such a way to permit expression of the short latency components of the CR that require the cortex for their development. Other forms of Pavlovian conditioning can be learned and expressed prenatally. (Supported by HD05958; we also thank S. Soltysik and E. White for their contributions to these studies.)

411.4

HEART RATE CONDITIONING AND THE CEREBELLAR VERMIS IN RATS. R. N. Leaton* and J. M. Kelso. Dept. of Psychology, Dartmouth College, Hanover, NH 03755.

Lesions of the cerebellar vermis block Pavlovian fear-conditioned heart changes in the rat (Supple & Leaton, 1990). The superior cerebellar peduncle (SCP) provides the major ascending projection from the cerebellum, providing a vermal-thalamic-hypothalamic pathway of possible significance in these conditioning changes. However, a preliminary analysis (Leaton & Kelso, 1992) found no significant effect of lesions of the SCP on conditioned bradycardia.

The present experiment compared conditioned bradycardia in 3 groups of rats. Group VER (n=10) - aspirated lesions of the cerebellar vermis; Group SCP (n=10) - knife-cut lesions of the SCP; and Group Sham - sham surgery. Animals were tested in a Plexiglas restraining tube. They were adapted to the restraint in 2 daily 20-min sessions, baseline heart rate was measured in 3 daily 30-min sessions, unconditioned response to the CS was measured during 3 daily sessions of 8 trials on a variable 3-min ITI, and conditioning was assessed over 6 daily sessions of 8 trials on a variable 3-min ITI. The compound CS (10-s duration) was the onset of the 7.5-W house light and a 90-dB, 1-kHz tone. The UCS was a 0.5 ma, 1-s tail shock.

Groups SCP and Sham showed significant conditioned bradycardia over the 6 training days and were not statistically distinguishable on any measure. Group VER showed impaired acquisition and the impairment was significantly related to the size of the vermal lesion. The effects of vermal lesions on conditioned bradycardia are not mediated by the ascending projection through the SCP.

Changes in Conditioning-Related Neuronal Activity in Rabbit Lobule HVI of Cerebellar Cortex and Interpositus Nucleus During Discrimination and Reversal Conditioning. T.J. Gould* & J.E. Steinmetz, Dept. of Psych., Prog. in Neural Science, Indiana Univ., Bloomington, IN 47405.

At least two areas of the cerebellum (i.e., lobule HVI of cerebellar cortex and interpositus nucleus (INP)) are believed to be involved in acquisition of a classically conditioned response (CR). Discrimination conditioning is a classical conditioning procedure requiring animals to differentiate between 2 conditioned stimuli (CSs). Single units have been recorded from both HVI and INP after discrimination training (Berthier & Moore, *Exp. Brain Res.* 63, 1986; 83, 1990) but changes in activity that occur throughout discrimination and subsequent reversal conditioning have not been examined in these areas. Twelve animals received discrimination training until they performed for 2 days at criterion (i.e., 70% or more CRs to CS+ and 30% or less CRs to CS-) and then the CSs frequencies were reversed (i.e., reversal training). Animals were again trained until they reached 2 days at the discrimination criterion. Multiple unit activity in HVI or INP was monitored during training. The INP was lesioned after the last day of training in 3 animals and they were tested with both CSs to see if CRs remained. Both HVI and the INP developed CR-related multiple unit activity evoked by CS+ during discrimination and reversal conditioning but no CR-related activity to CS-. During reversal conditioning, however, INP CR-related activity was somewhat attenuated. The INP lesions prevented CRs to both CSs. These results suggest HVI and INP are involved in discrimination and reversal conditioning but that the two areas are not activated equally during both phases of the learning. DEVELOPMENT OF A RABBIT ANESTHETIZED CLASSICAL CONDITIONING PREPARATION. B.J. Anderson*, D.P. Miller, M.T. Allen, & J.E. Steinmetz, Dept. of Psych. and Prog. in Neural Sci., Indiana Univ., Bloomington, IN 47405

The interpositus nucleus and cerebellar cortex appear to be important sites of plasticity for the classically conditioned eyeblink response. Single-unit and multiple-unit recordings in these structures have revealed neuronal activity that precedes and models the CR. To better understand the development of CR-related activity over phases of conditioning, and to use intracellular recording techniques to study the mechanisms that underlie the development of the CR-related activity across conditioning, an anesthetized conditioning paradigm would be beneficial. We are currently investigating parallels between neuronal activity in conditioned animals in the awake and anesthetized state. Animals are being trained with a click as the CS and airpuff or inferior olive stimulation as the US. Neuronal activity from the abducens nucleus, interpositus nucleus and red nucleus in the awake rabbit is being compared to activity induced by the click in anesthetized animals given CS presentations.

An acute anesthetized conditioning preparation is also being investigated. This work involves giving paired or unpaired presentations of pontine stimulation as a CS and inferior olive stimulation as a US in anesthetized rabbits. Baseline evoked CS and US activity in the cerebellum, red nucleus and abducens nucleus are being compared with evoked activity recorded after 400-700 presentations of pontine and inferior olive stimulation. Early results show that training-related changes can be seen in the anesthetized animals given paired training but not in rabbits given unpaired training. These preparations should prove valuable for future intracellular recording studies.

FAST HABITUATION OF AUDITORY EVOKED POTENTIALS TO PAIRED TONE STIMULI IN THE RAT. C.M. Specht* and D.W. Shucard Department of Neurology, SUNY @ Buffalo, 100 High Street (D-6), Buffalo, NY 14203.

Fast habituation of the auditory evoked potential (AEP) in humans was first described by Callaway (1973) as a general reduction in evoked potential amplitude that occurs to the second of a pair of auditory stimuli when both stimuli are presented with an interstimulus interval (ISI) of no more than 10 seconds. When auditory stimuli are presented in pairs with an ISI of 2 seconds and an interpair interval (IPI) of approximately 10 seconds, reduction in amplitude to the second tone occurs by as much as 30 to 50 percent. In addition, it has been shown that fast habituation may depend somewhat on a subject's anticipation of the stimulus. Studies in our laboratory have demonstrated this decrement in amplitude to the second tone of a pair in human infants, children and adults and have explored the implications of this finding with respect to attentional processes. In this investigation we describe an animal model of the fast-habituation methodology and subsequent findings of AEPs associated with paired tone stimuli delivered to adult male Sprague Dawley rats chronically implanted with skull electrodes. AEPs were recorded in awake restrained rats using a method previously developed in our laboratory (Church and Shucard, 1987). Rats were presented with pairs of auditory tones (1000Hz, 100msec duration, approximately 90dB, 2 second ISI) with an IPI less than 10 seconds. Findings showed 1) an AEP waveform with four to six distinct peaks occurring between 25 and 400 milliseconds after stimulus onset, and as for humans, 2) a marked amplitude decrement from tone 1 to tone 2 in recordings obtained from left and right cerebral hemispheres. This methodology may prove useful for studying the development of attention, attentional systems, and the mechanism(s) of fast habituation using techniques not possible in humans.

MULTIPLE-UNIT ACTIVITY IN THE PARABRACHIAL NUCLEUS DURING CLASSICALLY CONDITIONED BRADYCARDIA IN THE RABBIT.

W.F. Supple, Jr.*, and L. Sebastiani, Dept. of Psych, Univ. of Vermont, Burlington, VT 05405*. Dept. of Physio & Biochem, Univ. of Pisa, Italy.

The amygdala central nucleus (ACE) and anterior cerebellar vermis (ACV) are both importantly involved in conditioned bradycardia. The pontine parabrachial nucleus (PBN) is anatomically connected to both the ACE and ACV, and stimulation of the PBN modifies heart-rate. This study recorded the evoked activity from neurons in the PBN during the acquisition of differentially conditioned bradycardia. Multiple unit electrodes were implanted in the PBN in 10 rabbits. Training consisted of two phases: evocation and habituation of the HR orienting response (OR) (unreinforced tone presentations) and differential classical conditioning. The initial HR OR was bradycardia that subsequently habituated. The differentially conditioned HR CR consisted of bradycardia during the CS+ with minimal HR change to the CS-. Recordings of PBN unit activity during the OR found some placements with phasic excitatory responses that rapidly habituated. There was evidence of conditioning-related activity in the PBN with some placements showing differential evoked responses consisting of a short-latency (~20 ms) phasic excitation followed by a sustained inhibition of discharge to the CS+ but not to the CS-. Other placements showed simple, short-latency increases in activity to CS+ but not CS-. These data suggest that neurons in the PBN change their activity as a function of Pavlovian differential conditioning, and indicate that the PBN may be part of a larger neuroanatomical circuit mediating Pavlovian fear conditioning in the mammalian brain. Supported by NIMH grant MH47307.

MODULATION OF NEURONAL ACTIVITY IN THE MEDIAL GENICULATE DURING AUDITORY TRACE CONDITIONING.

K.N. O'Connor*, T.L. Allison, M.E. Rosenfield and J.W. Moore, Dept. of Psychol., Univ. of Mass., Amherst, MA 01003.

In classical trace conditioning the acquisition of a CR is dependent on neural coding of the CS following its termination. There is evidence that the medial or magnocellular region of the medial geniculate nucleus (mMGN) is one area where this coding may occur; it is essential to the acquisition and maintenance of successful discrimination of auditory stimuli in the conditioning of bradycardia in rabbits (Jarrel et al., *Brain Res.*, 382:199, 1986), and multi-unit responses to reinforced tones in this region increase during conditioning in comparison to non-reinforced tones (Disterhoft & Olds, *J. Neurophys.*, 35:665, 1972).

Single cell activity was recorded from the MGN during differential trace conditioning of the rabbit nictitating membrane response (NMR). Rabbits were first trained to discriminate between a reinforced CS+ and nonreinforced CS- (75 dB tones of 600 or 1200 Hz) 150 ms in duration followed by a 200-ms trace interval. The US was electrostimulation to the periorbital region of the eye. The rabbits were then prepared for subsequent recording; under anesthesia the dura was exposed, and a recording chamber cemented in place.

Most cells in the mMGN displayed changes in activity during both the CS and trace interval. These changes were largest for CS+ trials in which a CR was made. Examination of probe CSs of short (50 ms) and long (600 ms) duration suggests that changes in activity in the trace interval is time-locked to CS-offset rather than onset and may be needed for appropriate CR timing and topography during trace conditioning.

RECOVERY OF VISUAL DISCRIMINATION IN LESION RATS AFTER COMPOUND OR CROSS-MODAL CONDITIONING. E.R. Delay* and T.D. Tran, Dept. Psychology, Regis Univ., Denver, CO 80221.

Postoperative compound training with haptic and visual cues hampers relearning of visual decorticate rats in a brightness discrimination maze task (LeVere & LeVere, *Physiol. Psychol.*, 14, 165-174, 1982), whereas postop training with auditory cues aids relearning of a visual avoidance task (Delay, *Neuropsychologia*, 26, 661-671, 1988). To directly compare these training procedures, rats were trained on a brightness avoidance task before visual decortication. Six days postop, lesion rats were given either auditory intensity or compound auditory and visual intensity training. The next day, all rats were retrained on the brightness discrimination. Results showed that lesion rats given cross-modal training with the auditory intensity cue relearned the brightness discrimination more effectively than lesion control rats. However, deficits in relearning the brightness discrimination were observed for visual decorticate rats after compound conditioning. Depending upon the temporal contiguity of the cues from each modality, postoperative training can facilitate or hinder behavioral recovery. Compound conditioning biased the lesion rat away from cues requiring the damaged visual system, whereas cross-modal training produced a learning set which aided the rat when it had to use the damaged system.

411.11

GLUTAMATE AND GABA ROLE IN RAT BASAL FOREBRAIN NEURON RESPONSES TO A VISUAL CONDITIONED STIMULUS. J.H. Pirch*, Department of Pharmacology, Texas Tech University Health Sciences Center, Lubbock, TX 79430.

Extracellular recordings were obtained from single neurons in the basal forebrain of rats during classical associative conditioning. Medial forebrain bundle (MFB) stimulation was paired with a 2-sec light stimulus (CS+) to one eye, or a similar light stimulus (CS-) was presented to the other eye without MFB stimulation. Event-related slow potentials were recorded from the frontal cortex to monitor development and maintenance of discrimination between CS+ and CS-. Recordings were obtained while the animals were anesthetized with urethane (1.3-1.5 g/kg with supplementation). Neurons in the substantia innominata, medial globus pallidus, and nucleus basalis magnocellularis responded differentially to CS+ and CS-, demonstrating significantly larger responses to CS+ (Pirch, Brain Res. Bull. 31:73-83, 1993). Some neurons were excited by CS+, and others were inhibited. Microiontophoretic application of the non-selective excitatory amino acid antagonist, kynurenic acid, significantly reduced the excitatory response to CS+ in 8 of 14 cells that demonstrated discriminative conditioning. Ionophoretic application of the selective NMDA receptor antagonist, AP-5, significantly reduced the excitatory response to CS+ in 5 of 8 cells tested in separate experiments. Bicuculline, an antagonist at GABA_A receptors, attenuated the inhibitory response to CS+ in 7 of 11 neurons. These studies provide preliminary evidence that glutamate and GABA are involved in conditioning-related responses of basal forebrain neurons. The glutamate role appears to be mediated via NMDA receptors, and GABA's influence is mediated at least partly through GABA_A receptors. Demonstration of an effect of kynurenic acid and AP-5 on these conditioning-related neural responses indicates that an action in the basal forebrain may contribute to the effect of systemically-administered NMDA antagonists on memory tasks. TRAINING CHICKS ON A PASSIVE AVOIDANCE TASK TRANSIENTLY INCREASES IN VITRO CALCIUM FLUX IN A SPECIFIC FOREBRAIN NUCLEUS, THE IMHV. M.P. Clements and S.P.R. Rose*, Brain & Behaviour Research Group, Open University, Milton Keynes, MK7 6AA, U.K. (SPON: Brain Research Association)

Day-old chicks which peck spontaneously at a bright bead coated in the bitter-tasting methylanthranilate (MeA) learn on a single trial to avoid similar but dry beads subsequently. This learning paradigm initiates a molecular cascade in a specific forebrain region, the Intermediate Medial Hypothalamus Ventrale (IMHV). Within 30min of the aversive experience NMDA glutamate receptor activity is upregulated and there are changes in the phosphorylation state of the presynaptic membrane PKC substrate B50 (GAP43). Memory for the avoidance is blocked by MK801, PKC inhibitors and the nitric synthase inhibitor nitroarginine, implying that NO may function as a retrograde messenger in this learning task. This cascade, initiated *in vivo*, continues *in vitro* in tissue prisms prepared from the IMHV; thus there are changes in inositol phosphate labelling compatible with NMDA up-regulation. These findings suggested that the early sequelae of the learning experience could include changes in synaptic calcium flux. To test this hypothesis, chicks were trained on either water or MeA coated bead, and tested 5 and 30min, 3 and 24hr subsequently; birds trained on water pecked, and on MeA avoided on test. Tissue prisms were immediately prepared from left and right IMHV and incubated with ⁴⁵Ca²⁺ for 5min in an oxygenated, glucose-containing, phosphate-bicarbonate buffered medium, pH 7.4, 37°. There was no effect of MeA training in prisms cut 5 min after the training experience. Ca²⁺ uptake was significantly elevated in both hemispheres in the 30min slices and in left IMHV after 3hr. This elevation was transient however and was at control levels by 24hr.

We suggest that this enhancement of calcium flux consequent on training activates the next step in the cascade: IEG expression.

P3-LIKE POTENTIALS RECORDED FROM THE CORTICAL SURFACE OF RATS IN PASSIVE AND ACTIVE ODD-BALL TASKS. E. Jodo, S. Hoshino* and Y. Kayama, Dept. of Physiol., Fukushima Med. Col., Fukushima 960-12, Japan.

This study examined whether P3-like event-related potentials could be recorded through an electrode placed on the frontal cortex of awake rats in passive and active auditory odd-ball tasks. In both tasks either 1000 Hz infrequent target tone (30%), or 2000 Hz frequent standard tone (70%), was pseudo-randomly presented at interstimulus intervals of 2-5 sec, with the constraint that the target tone did not occur consecutively. The tone duration was 1 sec (in passive task) or 0.8 sec (in active task). In the passive task an intracranial electrical stimulation (ICS) was given to the medial forebrain bundle (a reward area) only after the cessation of target tone regardless of behavior, while in the active task the ICS was given only when rats pressed the key within 1 sec after the cessation of target tone. In both tasks a P3-like positive slow deflection at a peak latency around 300 msec was elicited, with a larger amplitude to the target than to the standard tone; the P3-like potential in the active task was much more distinct than that in the passive task. These results suggest that a P3-like potential similar to the human P3b can be recorded from the cortical surface of awake rats.

411.12

VASOPRESSIN CONTENT IN THE CNS CHANGES DURING MAINTENANCE OF CONDITIONED TASTE AVERSION K.C. Chambers*, E.A. Brownson and R.D. Brinton, Neurobiology, Psychology & Mol Pharmacology & Toxicology, Univ of Southern California, Los Angeles, CA

The rate of extinction of a conditioned taste aversion (CTA) is significantly faster than normal in fluid deprived male rats. Because vasopressin (AVP) is involved in fluid balance and in enhanced memory function, we hypothesized that changes in AVP content in the CNS modulate the extinction rate of a CTA.

Male Fischer 344 rats were assigned to one of two treatment groups: non fluid deprived and 23hr fluid deprived. Each group received the same CTA paradigm. Animals from both groups were sacrificed following 23 hr of fluid deprivation, following 10 days of fluid deprivation + acquisition of the CTA + one day of extinction trial during which animals demonstrated a strong aversion, and 50-75% extinction of the CTA in the fluid deprived animal. A nondeprived animal was always sacrificed with a deprived animal. Micropunches of 8 different brain regions were made and AVP levels determined by quantitative RIA.

Following 23 hrs of fluid deprivation, a significant ($p < .0000$) increase in AVP content occurred in the paraventricular nucleus (PVN). AVP content was significantly lower in the PVN of deprived animals when compared to nondeprived animals three days following acquisition of the CTA ($p < .03$) and at the time of extinction ($p < .0000$). AVP levels in deprived animals was also significantly lower in the medial amygdala at the time of extinction ($p < .05$). Surprisingly, in the nondeprived-nonextinguished animals, AVP levels increased significantly over time in the PVN ($p < .007$), in the medial amygdala ($p < .04$) and in the bed nucleus of the stria terminalis ($p < .0004$). These data support the hypothesis that AVP regulates maintenance of a CTA and demonstrate that when AVP levels do not increase animals more rapidly extinguish a CTA whereas increases in AVP content in select brain regions are associated with long-term maintenance of the CTA.

THE NMDA-RECEPTOR ANTAGONIST MK-801 BLOCKS NAVIGATIONAL LEARNING IN HOMING PIGEONS. L.V. Ritters* and V.P. Bingman, Bowling Green State University, Bowling Green, OH 43402.

The present study employed the NMDA receptor antagonist MK-801 to begin to investigate the possible importance of NMDA-mediated LTP for naturally occurring spatial learning in birds by exploiting the navigational ability of homing pigeons. Control pigeons released from two unfamiliar release sites displayed vanishing bearings that were poorly oriented. However, when released a second time from the same sites they displayed good homeward orientation. The control birds apparently learned something about the spatial relationships of stimuli at the release sites on the first releases and used that information to orient better when released a second time from the same locations. Experimental pigeons given the NMDA receptor antagonist MK-801 initially behaved as controls, orienting poorly when released for the first time from the two sites. In contrast to controls, the experimental birds failed to show significant improvement in orientation when released again from the same sites without MK-801. Results of a simple operant chamber task suggest the impairments observed are specific to learning rather than non-specific drug effects. The data indicate that blocking NMDA receptors can disrupt navigational learning in homing pigeons. As such, the results are consistent with the hypothesis that NMDA mediated LTP plays an important role in spatial learning in birds.

411.16

AUDITORY ERP_s DISSOCIATE EARLY AND LATE MEMORY PROCESSES L. Nielsen-Bohman*, L.L. Chao & B.T. Knight, Dept. of Neurology & Ctr. for Neuroscience; U.C. Davis, VAMC 150 Muir Road; Martinez, CA 94553-4695.

Working memory has been dissociated into rapid and delayed processes in the visual modality. We examined whether similar mechanisms were engaged during auditory recognition. Event-related potentials (ERPs) recorded from 15 subjects (age 21±1) were used to examine changes in neural processing during early and late stages of recognition memory. Digitized environmental sounds were presented binaurally in 4 blocks (111 to 114 sounds per block, 700 msec duration, 1200 msec ISI). Twenty percent of the sounds were presented once and 80% were presented twice. The repeated sounds occurred at delays of either 1.9 seconds (short delay) or 4 to 12 seconds (long delay). Subjects indicated whether they had heard the sounds before by pressing a 'yes' or 'no' button.

In all conditions, auditory stimuli generated a long duration negative potential (628 msec) over frontal sites. This negativity was larger for the initial presentation and long delay stimuli than for short delays (Fpz: initial presentation=-4.8µV, long delay=-4.5µV, short delay=-2.9µV, $p < 0.001$). Short delay repetitions generated an early positive component (404 msec) with a broad posterior scalp distribution. Initial presentations and long delays generated a reduced early positivity (Pz: initial presentation=1.9µV, long delay=3.9µV, short delay=7.3µV, $p < 0.001$) and an additional late positivity (544 msec). An N400 component was generated only at initial presentation and long delays (Cz: initial presentation=-3.1µV, long delay=-2.1µV, short delay=-0.9µV, $p < 0.001$). These results parallel those obtained in the visual modality. The findings indicate that the early positivity indexes a rapid working memory process and the late positivity reflects delayed processes. Increased reaction times and a drop in accuracy at the long delay condition suggest that subjects had greater difficulty with this condition than with the short delay condition. The longer latency of the late positivity may be due to the duration of stimulus evaluation. The N4 component was generated only during initial presentation and long delays and may index a search of long term memory. These data support the idea that working memory processes can be dissociated into early and late components and this dissociation may be modality independent.

412.1

EFFECTS OF PHARMACOLOGICAL MANIPULATIONS OF THE GABA-ERGIC SYSTEM ON CONFLICT LEARNING AND MEMORY IN THE MOUSE. M.E. Judge*. Pharmaceuticals Division, Novo Nordisk A/S, DK-2760 Måløv, DENMARK.

Memory processes are profoundly influenced by enhancing GABA-ergic neurotransmission, the main action of anxiolytics, sedatives, and anticonvulsants. The effects of these drugs were evaluated in a conflict memory test in mice. Thirsty NMRI mice (9 wk ♀) were injected i.p. and trained 30 min later. They were given 5 min to drink for 5 sec. Side effects at high doses inhibited drinking. Few compounds affected the next phase, delivery of mild shocks until drinking ceased. Memory was tested the next day (latency to drink). Pre-training treatment with benzodiazepine (BZ) agonists did not impair learning, but did impair memory. Diazepam and midazolam produced anterograde amnesia at 2-3 mg/kg; alprazolam and lorazepam were moderately potent and triazolam was over 10 times more potent. This corresponds well with what is seen in human testing, as does the fact that BZ's given pre-test did not impair retrieval. Similar effects were seen with the GABA-uptake inhibitor NNC 05-0711 and the GABA_A agonists muscimol and THIP, as well as the barbiturates (at very high doses). The barbiturates differed from the other compounds in producing learning and retrieval impairment at doses lower than anterograde amnesia producing doses. These results indicate that approach-avoidance conflict memory testing in mice can be used to model the cognitive impairing effects of pharmacological enhancement of GABA-ergic function in man.

412.3

THE ELEVATED T MAZE, A NEW ANIMAL MODEL OF ANXIETY AND MEMORY. F.G. Graeff, M.B. Viana and C. Tomaz*. Lab. of Psychobiology, Univ. of São Paulo, 14040-901 Ribeirão Preto, SP, Brazil.

In rats placed in a T maze, consisting of an enclosed arm at a right angle with two open arms elevated 50 cm above the ground, diazepam (DZP; 1-4 mg/kg, ip) abolished the delay of withdrawal from the enclosed arm towards the open arms, measured by retesting in the presence of the drug soon after training, as well as by further retest 72 h later, in the absence of drug. In rats re-injected with 2 mg/kg of DZP before retest no evidence of state dependency was found. Thus, DZP had both an anxiolytic and an amnesic effect in this inhibitory avoidance task. However, in the same animals DZP did not affect the latency of withdrawal from one of the open arms towards the closed arm on the first day. Moreover, the latency of this escape response decreased in the retest performed 72 h later irrespective of drug treatment, indicating that memory of this task was resistant to DZP. These results support the view that the anxiolytic and the amnesic effects of DZP are closely related, and suggest that the T maze model may be useful for simultaneous measurement of drug effects on anxiety and memory. [Supported by FAPESP 90/3474-0].

ENHANCED SENSITIVITY TO THE AMNESIC EFFECTS OF DIAZEPAM IN AGED RATS. R.W. Skelton, R.K. McNamara, & T.M. Davis. Dept. Psychology, Victoria, Victoria, BC, Canada, V8W 3P5.

The elderly are primary consumers of benzodiazepine drugs and yet may be hypersensitive to many of their side-effects. The present study examined the amnesic effects of diazepam (DZP) on young (~6 month old) and old (18-24 month old) hooded rats, using the Morris water maze.

Rats were trained undrugged using 4 trials per day, first to a stationary visible platform (2 days), then to a submerged platform in the same location (5 days), and then to a reversed platform location (3 days). Probe trials were given post-acquisition and post-reversal. Rats were then tested on alternate days in an 8 trials/day spatial-learning-set procedure in which the location of the submerged platform was varied between days. On alternate test days, each rat received vehicle or one dose of DZP (1, 2, 5 mg/kg in ascending order) ½ hr before testing. Rats were also tested with vehicle and DZP (5 mg/kg) with a visible platform, and finally, with a submerged platform 1 full hour after vehicle or DZP (5 mg/kg) injections.

Undrugged old rats showed slower initial acquisition, but comparable probe performance, reversal learning, and learning-set performance. At 1 mg/kg, neither age was impaired. At 2 mg/kg, old rats were impaired but young rats were not. At 5 mg/kg, both groups were impaired when injected ½ hr before testing, but only the old rats were impaired when injected 1 hr before testing. Neither group was impaired on the visible platform test. These results suggest that DZP impairs spatial learning at lower doses and for longer periods in old rats relative to young rats. (Supported by grants from NSERC CANADA and BC Health Research Foundation).

412.2

THE EFFECT OF GABA AGONISM AND UPTAKE INHIBITION AND BENZODIAZEPINE AGONISM AND BLOCKADE ON AVOIDANCE LEARNING IN THE RAT. A. D. Kastello, L. Rajachandran* and J. V. Cassella. Neurogen Corporation, Branford, CT 06405.

It is well known that benzodiazepines (BZ) modulate GABA's effects in the central nervous system and that actions at both of these receptors influence learning and memory processes. In animals, as well as humans, BZ agonists interfere with the acquisition and retention of information acquired under the influence of the drug. In addition, GABA agonism and antagonism are known to influence memory in certain tasks. This study examined the interaction of the GABA_A/BZ receptor complex, as well as the GABA_B receptor, on learning and memory in rats. In dose response studies, drugs were administered 15 min prior to the first acquisition trial. Retention was measured 24-hours later under drug free conditions. The GABA_A agonist Baclofen (2.0-8.0 mg/kg, IP) impaired both acquisition and retention of a repeated-trial step down passive avoidance task in adult male Sprague Dawley rats. Muscimol (1.0-2.0 mg/kg, IP), a GABA_A agonist, impaired retention only. The BZ agonist Diazepam (0.625-5.0 mg/kg, IP) dose dependently impaired acquisition and retention. The deficits produced by Diazepam (2.5 mg/kg, IP), given 30 min prior to training, were reversed by pretreatment (40 min) with either the BZ antagonist Ro 15-1788 (10.0 mg/kg, IP) or the BZ partial inverse agonist CGS 8216 (5.0 mg/kg, IP). Administration of a GABA uptake inhibitor 30 min prior to training produced both acquisition and retention deficits, while pretreatment (40 min) with Ro 15-1788 partially reversed the retention deficits. These studies demonstrate the involvement of GABA_A and GABA_B receptors in learning and memory processes and suggest a modulatory influence of the BZ receptor on GABA's effect on learning and memory.

412.4

CHLORDIAZEPOXIDE IMPROVES PERFORMANCE OF SEPTAL LESIONED ANIMALS IN A MORRIS MAZE H.T. Farber*, E. Thomas, H. Grishkat, and S.E. Choi. Dept. of Psychology, Bryn Mawr College, Bryn Mawr, PA 19010.

Human studies have demonstrated an inverse relationship between state anxiety and performance on memory tasks. We investigated the effects of lateral septal lesions (shown to be anxiogenic) upon a spatial memory task in rats. In addition we examined the effects of chlordiazepoxide (CDP) in septally lesioned animals in the same task.

Forty-six rats were subjected to lesions of the lateral septum or to sham lesions. One-half of each group was given CDP (2 mg/kg) or saline and tested in a Morris water maze, 5 trials/day over 3 days.

When compared to their sham controls, animals which received septal lesions showed significantly impaired learning in the Morris maze. Lesioned animals given a low dose of CDP were superior to those given saline. CDP itself in non-lesioned animals had no statistically significant effect upon performance.

The fact that CDP improves performance in lesioned animals suggests that this improvement may be due to emotional factors, such as anxiety, rather than direct effects upon memory. The Morris maze task may be useful in the study of emotional effects on cognitive performance.

412.6

MIDAZOLAM IMPAIRS RETENTION OF A REWARD INCREASE. L.A. Salinas*, H. Dickinson-Anson & J.L. McGaugh. Center for the Neurobio. of Learning & Memory and Dept. of Psychobiol., U. of Calif., Irvine, CA 92717-3800.

We reported previously that midazolam (MDZ) administered immediately prior to a reduction in reward magnitude impairs the retention of the aversive consequences of such a decrease. Such findings are consistent with other evidence indicating that benzodiazepines induce anterograde amnesia. An alternative interpretation of this result is that MDZ's anxiolytic properties decreased the aversiveness of the reward reduction. To clarify the basis of the effect the present experiment examined benzodiazepine effects on memory of a nonaversive change in reward. Male Sprague-Dawley rats (175-200g) that were food deprived and maintained at 80% of body weight were trained to run a straight alley (six trials per day) for either ten 45 mg food pellets or one 45 mg food pellet until asymptote was reached. Half the animals in the high reward condition were then trained for one day at the low reward level. These animals displayed a sharp increase in response latencies on that day. Twenty minutes prior to the next day's training session, half of all animals received 1 mg/kg MDZ or saline (i.p.). On the training session animals that had previously had their reward reduced were returned to the high reward condition and the reward conditions were maintained for an additional day of training. No further injections were given. On the day following injection, the latencies of shifted animals given saline were comparable to those of unshifted controls. Comparable recovery in performance was not displayed by the shift/MDZ animals on that day. Thus, MDZ injected immediately prior to an increase in reward magnitude impaired the retention of such an increase. The findings indicate that the memory impairing effects of midazolam are not due to the drug's anxiolytic properties.

LACK OF EFFECT OF BENZODIAZEPINE RECEPTOR LIGANDS ON SIMULTANEOUS VISUAL DISCRIMINATIONS OF VARIABLE DIFFICULTY. L. DiNardo, P. Dudchenko, B. Gordon, M. Keckley, and M. Sarter. Dept. Psychology, Ohio State Univ., Columbus, OH 43210.

Benzodiazepine receptor (BZR) agonists produce impairments in tasks measuring attentional abilities. As these tasks typically involve demands on discriminative abilities, BZR agonists have been proposed to disrupt these abilities. However, previous studies were frequently based on go-no go paradigms and therefore failed to dissociate between effects on discriminative abilities and response inhibition. Rats were trained to discriminate between two simultaneously flashing lights in an operant chamber. One group of animals was trained to respond to the faster flashing light in each of 5 pairs of stimuli (1.25, 1.67, 2.5, 3.75, 4.17 Hz vs. 5 Hz); while a second group was rewarded for responding to the slower flashing light in each of 5 pairs (1.25, 1.46, 1.67, 2.5, 3.75 Hz vs. 5 Hz). Decreasing differences between the frequency of both stimuli resulted in decreasing accuracy. The BZR-agonist CDP (1.56, 6.25, 9.38 mg/kg) produced a dose-dependent increase in errors of omission, but did not result in an increase in incorrect responses. These data do not support the hypothesis that BZR agonists affect simultaneous discriminative abilities. Thus, drug-induced impairments in signal detection tasks may not be due to a general disruption of sensory abilities.

412.9

ATTENTIONAL EFFECTS OF INFUSIONS OF BENZODIAZEPINE RECEPTOR LIGANDS INTO THE SUBSTANTIA INNOMINATA OF THE BASAL FOREBRAIN. J. Travers, J. McGaughy, and M. Sarter. Dept. Psychology, Ohio State Univ., Columbus, OH 43210.

The attentional impairments produced by benzodiazepine receptor (BZR) agonists are hypothesized to be mediated via basal forebrain GABA-cholinergic interactions. Accordingly, studies have demonstrated that the behavioral effects of intrabasalis infusions of the GABA-agonist muscimol are attenuated by systemic co-administration of physostigmine (Dudchenko & Sarter 1991; Muir et al. 1992). To determine the role of endogenous GABA, the effects of intrabasalis infusions of BZR ligands on attentional abilities were tested in animals trained to detect visual stimuli presented for 25, 50, 100, or 500 ms. Guide cannula (26 gauge) were implanted to allow for repeated bilateral infusions of drugs into the basal forebrain. Infusions of the BZR agonist chlordiazepoxide (CDP; 20, 40 $\mu\text{g}/0.5 \mu\text{l}/\text{hemisphere}$) or of the inverse agonist $\beta\text{-CCM}$ (1.5, 3 $\mu\text{g}/0.5 \mu\text{l}/\text{hs}$) impaired and facilitated, respectively, the animals' performance in this task. These data support the hypothesis that attentional abilities are correlated with increases in activity in basal forebrain GABAergic inputs, or in their target neurons. In addition, decreases in GABAergic transmission (as a result of infusions of $\beta\text{-CCM}$) result in the facilitation of attentional abilities.

412.8

CROSSMODAL DIVIDED ATTENTION IN RODENTS. J. Turchi, J. McGaughy, B. Givens and M. Sarter. Dept. Psychology, Ohio State Univ., Columbus, OH 43210.

"Divided attention" is a psychological construct that hinges on assumptions about a fixed finite capacity of subjects to simultaneously process multiple sets of information. A model of a crossmodal divided attention task was developed in rats. Initially, rats were trained consecutively in operant auditory and visual conditional discrimination tasks. The final task consisted of two successive blocks of 20 trials per modality (modality certainty), followed by 60 trials consisting of a semi-randomized sequence of stimuli of both modalities (auditory or visual) and qualities (flashing/pulsing or constantly turned on; modality uncertainty). In comparison to unimodal blocks of trials, performance in the mixed condition was assumed to reflect the demands on the parallel processing of two sets of stimulus-response rules. Response latencies were generally longer in the bimodal condition. Administration of scopolamine (SC; 0.03, 0.06, 0.1 mg/kg) or chlordiazepoxide (CDP; 1, 3, 5, 8 mg/kg) increased response latencies, and this effect was greater in the mixed condition. Both drugs produced qualitatively similar effects; however, SC was more potent in increasing the absolute divided attention costs than CDP. These data support hypotheses about the comparable effects of benzodiazepine receptor agonists and muscarinic antagonists on brain information processing capacity.

BASAL FOREBRAIN-LESION INDUCED BLOCKADE OF THE EFFECTS OF BENZODIAZEPINE RECEPTOR LIGANDS ON VIGILANCE. P. Dudchenko, C. Apple, T. Conti, and M. Sarter. Dept. Psychology, The Ohio State Univ., Columbus, OH 43210.

Based on the general hypothesis that the attentional effects of benzodiazepine receptor (BZR) ligands are mediated via basal forebrain GABA-cholinergic interactions, it was predicted that BZR-agonists no longer interact with the residual attentional abilities of basal forebrain-lesioned rats. Animals were trained in a task that required the animals to detect visual stimuli presented for 25, 50, 100, or 500 ms. Following training to a specified criterion, animals were assigned to one of three groups: 1) quisqualate-induced lesions of the region of the nucleus basalis/substantia innominata of the basal forebrain; 2) lesions of the head of the nucleus caudatus; 3) sham lesions of both the basal forebrain and the caudate. Unexpectedly, the performance of basal forebrain lesioned animals largely recovered. In both sham-lesioned and caudate-lesioned animals, the administration of the BZR-agonist chlordiazepoxide (CDP; 1.56, 3.13, 6.25, 9.38, 12.5 mg/kg) dose-dependently impaired the animals' performance in this task. However, the potency of CDP to impair performance in basal forebrain-lesioned animals was greatly reduced. These data suggest that basal forebrain neurons are critically involved in the mediation of the attentional effects of BZR-ligands. The neuronal basis of the behavioral recovery in lesioned animals remains unsettled.

MK-801 BLOCKS ACQUISITION AND EXPRESSION OF CLASSICALLY CONDITIONED RESPONSES IN THE RABBIT NICTITATING MEMBRANE PREPARATION. E.J. Kehoe, J. Cox, R. Guthrie, M. Macrae, and I. Gomezano*. School of Psychology, University of New South Wales, Kensington, NSW 2033 Australia.

MK-801, an antagonist of neurotransmission via N-methyl-D-aspartate receptors, was given (0.1 mg/kg IV) to rabbits either before or after sessions of classical conditioning. The conditioned stimuli (CSs) were a pure tone and a flashing light. The unconditioned stimulus (US) was a 100-ms, 3-mA, 50-Hz AC current to the skin near the right eye. The measured response was closure of the nictitating membrane. The animals that received the MK-801 before the session showed little acquisition of a conditioned response (CR). When MK-801 administration was suspended, responding remained at a low level. In contrast, the animals that received MK-801 after the session showed high levels of CR acquisition. When they were tested by administration of the MK-801 before a single session, they showed a large deficit in responding. Responding returned to its former level when MK-801 was suspended. In all animals, tests for motor deficits caused by MK-801 proved negative.

413.2

D-CYCLOSERINE ENHANCES HIPPOCAMPALLY-DEPENDENT EYEBLINK CONDITIONING IN AGING AS WELL AS YOUNG RABBITS. J.E. Disterhoft, L.T. Thompson, G.I. Halperin, and T. Lanthorn*. CMS Biology, Northwestern University Medical School, Chicago, IL 60611 & *NDR, G.D. Searle & Co, Skokie, IL 60073.

Previous work demonstrated that daily treatment with D-cycloserine (DCS; 6 mg/kg) facilitated acquisition of hippocampally-dependent trace eyeblink conditioning in young rabbits (Thompson et al., *Nature*, 359, 638-641). Aging rabbits exhibit severe deficits in acquiring the same task as compared to young controls. DCS crosses the blood-brain barrier readily, and its behavioral facilitation is hypothesized to be mediated at least in part by its effects on hippocampal neurons. The present study evaluated the effects of a broad range of doses of DCS on acquisition by both young and aging subjects.

Immediately after treatment with 0.75, 1.5, 3.0, 6.0, or 12.0 mg/kg of DCS, daily training occurred, with 80 trial presentations of a 100 ms tone CS followed after a 500 ms ISI by a 150 ms airpuff US. Aging (37.4 \pm 0.3 mo) and young (3.4 \pm 0.2 mo) rabbits were trained in pairs in the trace eyeblink conditioning task in a soundproofed chamber until a criterion of 80% conditioned responses (CRs) was attained. CR and UR amplitudes, latencies, and other parameters were scored by a PC-based data acquisition system.

Aging control subjects required up to three times as many trials on average to acquire hippocampally-dependent trace eyeblink conditioning. DCS, a partial-agonist of the glycine coagonist binding site on the NMDA receptor/channel protein, significantly improved acquisition in both young and aging rabbits. Optimal doses improved acquisition by more than 50% as compared to controls, without effects on the UR. The improvement in aging subjects was particularly dramatic, restoring acquisition at optimal doses to levels essentially indistinguishable from that of young control subjects. Activation of neuronal NMDA receptors plays a critical role in many forms of associative learning, including eyeblink conditioning, and is greatly facilitated by treatment with DCS. ANESTHETIC-DEPENDENT ENHANCEMENT OF TASTE AVERSION LEARNING IN UTERO. G.A. Mickley*, J.D. Lovelace, S.T. Farrell, and K.S. Chang. Armstrong Laboratory, Brooks AFB, TX 78235-5324.

Rat fetuses (E18) can learn a taste aversion *in utero* when exposed to a sweet flavor (10.0 μ L of 0.3% saccharin = SAC) followed by an i.p. injection of lithium chloride (5.0 μ L of 0.19M solution = LiCl). Here we report that this phenomenon can be significantly modulated by the type of anesthesia administered to the pregnant dam before the conditioning procedure.

Dams were anesthetized with either Sodium Pentobarbital (50 mg/kg, i.m.) or a combination of Ketamine Hydrochloride (100 mg/kg, i.m.) and Xylazine (10 mg/kg, i.m.). Fetuses received pairings of SAC+LiCl or one of the following control combinations: SAC+Saline, H₂O+LiCl; H₂O+Saline. At age 15 days neonatal rats were given a taste preference test by allowing them to select nipples painted with either saccharin or vehicle (H₂O). After weaning, rats were given an additional taste preference test where they were allowed to drink from bottles filled with either 0.15% saccharin or water.

Neonates that received SAC+LiCl injections under the influence of Ketamine (KET group) showed a stronger conditioned taste aversion than did those from dams injected with Sodium Pentobarbital (NaPent group). The taste aversion measured in the KET group was also detectable later in development (i.e., during the bottle test); whereas, the taste aversion could not be detected later in the NaPent group. Thus, *in utero* taste aversion learning is a more-potent phenomenon in KET rats than NaPent rats. Since Ketamine blocks N-methyl-D-aspartate (NMDA) glutamate receptors, and these receptors have been implicated in neural plasticity during development, our data suggest the testable hypothesis that NMDA antagonism can potentiate fetal learning.

413.5

IDENTIFICATION OF THE POSTTRAINING PERIOD WHEN GLUTAMATE RECEPTOR BLOCKADE IMPAIRS OLFACTORY LEARNING IN RAT PUPS. D. A. Weldon* and G. G. Fedorcik. Dept. of Psychology, Hamilton College, Clinton, NY 13323.

Glutamate receptors appear to play an important role in early olfactory conditioning in neonatal rats. Impairment of olfactory learning in rat pups can be produced by immediate posttraining injections of the noncompetitive N-methyl-D-aspartate (NMDA) receptor antagonist MK-801 (Weldon & Lorusso, *Soc. Neurosci. Abstr.*, 16: 486, 1991). The purpose of the present experiment was to investigate the specific time period when NMDA receptor blockade would have this effect.

Six day old Sprague-Dawley rat pups were exposed to peppermint odor paired with tactile stimulation (stroking the skin with a paint brush) for 20 10-sec conditioning trials over a 60 min training session. Pups received an injection of MK-801 (0.1 mg/kg, i.p.) 0, 10, 30, or 60 min after the training period. The next day, the pups were placed in a testing chamber for a total of 6 min, and the amount of time that they spent over the conditioned odor was recorded. In comparison with the performance of pups treated with saline immediately after training, there was a statistically significant reduction in the preference for the conditioned odor in the animals receiving MK-801 immediately following the training period. Treatment with the drug at the other intervals did not produce an impairment in performance. The data indicate that immediate posttraining activation of NMDA receptors is required for normal olfactory learning in neonatal rats.

413.7

APV AND CNQX DISRUPT BOTH WATER MAZE ACQUISITION AND SENSORIMOTOR PERFORMANCE ABILITIES RELATED TO THE WATER MAZE TASK. D.P. Cain*, D. Saucier, E.L. Hargreaves, F. Boon, J. Hall, J. DeSouza, and E. Wilson. Dept. Psychology, Univ. Western Ontario, London, CANADA, N6A 5C2.

The effects of intraventricular APV (10 or 30 μ g) and CNQX (2, 10, 30 μ g) were tested on the acquisition of the Morris water maze (hidden and visible platforms), and on walking along a narrow wooden beam (balance task). Behaviors incompatible with adequate maze performance were documented: thigmotactic swimming (swimming > 80% of a trial within 15 cm of the wall), and platform deflections/walk-overs (encountering but failing to mount or remain on the platform). APV elevated escape latencies in both the hidden (10 & 30 μ g) and visible (30 μ g) versions. However, post-acquisition probe trials revealed that the 10 μ g rats spent as much time in the vicinity of the platform as the control rats. The poor maze performance of rats receiving either dose of APV was correlated ($p < .05$) with a high incidence of thigmotactic swimming, platform deflections, and poor performance on the balance beam task. Data for CNQX were similar. These results suggest that sensorimotor abilities related to behaviors required to perform the task were disrupted and may account for a portion of the observed water maze deficit. Thus, putative blockade of glutamate transmission (NMDA or AMPA receptor subtypes) may induce a more global dementia and not a specific learning deficit. Supported by NSERC to DPC.

NMDA ANTAGONIST IN THE BASOLATERAL AMYGDALA IMPAIRS TASTE-POTENTIATED ODOR AVERSION LEARNING. T. Hatfield* and M. Gallagher. Department of Psychology, University of North Carolina, Chapel Hill, NC 27599.

The present study examined the effects of direct infusion of the NMDA antagonist, d-APV, into the basolateral amygdala (ABL) on taste-potentiated odor aversion learning (TPOA). TPOA is a form of learning that relies on information processing in two sensory modalities, taste and odor. Unlike taste aversion learning, odor aversions are not readily acquired in conditioning paradigms using delayed illness as the unconditioned stimulus. However, presenting the odor and taste together as a compound conditioned stimulus potentiates learning of the odor aversion. ABL neurotoxic lesions impair this form of learning (Hatfield et al., *Behav. Neurosci.*, 106, No. 2, p.286-293).

Canulae were surgically implanted in rats to target the ABL. D-APV (1.0 μ g) was directly infused into the ABL just prior to TPOA conditioning. Infusion of d-APV caused a significant impairment in odor potentiation learning as compared to both surgical and vehicle control groups. At the same dose, the inactive stereoisomer, l-APV, did not produce an impairment in odor potentiation. All groups, including those rats infused with d-APV, showed equivalent learning of the taste aversion. These results suggest that the particular associative demand of the TPOA task requires the integrity of NMDA function in the basolateral amygdala. [Supported by NIMH-35554 to M.G. and T.H.]

SPATIAL LEARNING DEFICIT IN EPILEPTIC RATS MAY BE DEPENDENT ON THE LOSS OF HIPPOCAMPAL NMDA RECEPTORS. H. Lahtinen*, A. Ylinen, I. Sirviö, R. Miettinen and P.I. Riekkinen Sr. Dept. of Neurology, University of Kuopio, P.O.B. 1627, SF-70211 Kuopio, Finland.

Sustained electrical stimulation (60 min, 2 mA) of the perforant pathway (PP) was used to induce hippocampal seizures in conscious rats. PP-stimulation lead to pyramidal cell degeneration of hippocampal CA1 and CA3c regions, loss of hilar somatostatin-immunoreactive (SOM-IR) neurons and impaired spatial learning, as reported earlier. CGP 39551, a competitive NMDA receptor antagonist administered as a single dose (10 mg/kg, i.p.) 4.5 h prior to the stimulation totally reversed the water maze learning deficit of the stimulated animals but only partially protected from the pyramidal cell damage and had no effect on the SOM-IR cell loss. Furthermore, contrary to the saline group, the CGP 39551 pretreated rats did not show a significant loss of NMDA-sensitive [³H]glutamate binding in the strata oriens and radiatum of the CA1 area. Acquisition in the spatial learning and memory test (water maze swimming latencies) were dependent on the NMDA receptor binding in CA1 (ANOVA: $F_{1,7}=8.0$, $p=0.025$) but not on the degree of pyramidal cell degeneration ($F_{3,7}=1.3$, $p>0.05$). However, the loss of receptor binding correlated with the degree pyramidal cell damage ($r=-0.69$, $p=0.004$). Thus, our results suggest that while the hippocampal pyramidal cell degeneration in the PP-stimulated epileptic rats is likely to account for the loss of NMDA receptors in the dendritic field as well, the learning ability of these animals may ultimately be dependent on the adequate NMDA receptor functioning in the CA1 region.

MILACEMIDE TREATMENT IN C57BL/6J MICE: EFFECTS ON THE ACQUISITION OF A MORRIS WATER MAZE TASK. L.E. Finkelstein¹, H.L. Petri², E.L. Bresnahan^{3*}, and D.K. Ingram¹. ¹Gerontol. Res. C, NIH-NIA; ²Towson St. U.; ³Essex Comm. College, Baltimore, MD 21224.

The N-methyl-D-aspartate (NMDA) subtype of the glutamate receptor appears to be involved with processes of learning and memory. A neutral amino acid binding site is known to exist on the NMDA complex. Glycine binds with high affinity to this site and has been found to potentiate NMDA activity (Bonhaus et al., *Molec. Pharm.*, 36: 273, 1989). Milacemide (2-N-pentylaminoacetamide HCl) is a glycine agonist which has been found to enhance performance of rodents in passive and active avoidance tasks (Quartermain et al., *Pharmacol., Biochem., Behav.*, 39: 31, 1991). and has improved the performance of humans in several word retrieval tasks (Schwartz et al., *Clin. Neuropharm.*, 15: 114, 1992). We evaluated the effects of milacemide on the performance of male C57BL/6J mice in a complex spatial task, the Morris water maze. Because NMDA receptor activation appears involved in induction of long-term potentiation, it was hypothesized that milacemide administration would be involved in task acquisition. Therefore, mice were treated with either milacemide (10 mg/kg) or vehicle 1 hr prior to training on each of 4 consecutive days. Results indicated that mice treated with milacemide learned the task significantly faster than controls over 4 days of training, as measured by mean distance (cm) to reach the goal platform. Therefore, agonism of the glycine site on the NMDA receptor appears to facilitate performance of learning in a spatial memory task.

PHENCYCLIDINE (PCP) IMPAIRS TEMPORAL ORDER MEMORY FOR SPATIAL LOCATIONS IN RATS. Long, J.M., and Kesner, R.P. Dept. of Psychology, Univ. of Utah, Salt Lake City, UT. 84112

Previous research has shown that hippocampal lesions in the rat disrupt memory for temporal order information for spatial location (Chiba, Kesner, & Reynolds, 1993). In some, but not all tasks in which hippocampal lesions disrupt memory, administration of NMDA antagonists (ie. AP5, MK-801, PCP) result in similar impairments. The present study was designed to assess the role of the NMDA receptor complex in memory of temporal order information for spatial location. In the study phase Long Evans rats were trained on an eight arm radial maze to visit each of eight arms in a randomly selected order. In the test phase the rats had to choose which of two arms presented occurred earlier in the study phase sequence. The arms presented as test arms varied according to temporal lag. Rats were given IP injections of saline or PCP (3-4 mg/kg) on a double alternation schedule. The results indicated that with PCP injections rats were impaired across all temporal lags relative to saline injections. A second experiment showed that PCP had no effect on the ability of rats to discriminate 3-dimensional objects, a task that is not sensitive to hippocampal dysfunction. The data suggest that NMDA receptors, probably located in the hippocampus, are important in mediating temporal order memory for spatial location, but not visual discrimination learning.

413.11

MK801 DISRUPTS LONG-TERM MEMORY FORMATION IN THE 2-DAY OLD CHICK. D. R. Smith, S. C. Fromont, M. R. Rosenzweig*, and E. L. Bennett. Department of Psychology, University of California, Berkeley, CA 94720.

MK801 is a non-competitive antagonist of the NMDA receptor which acts by blocking the influx of Ca^{2+} via the NMDA receptor complex. The onset of amnesia produced by MK801 was determined using 2 day-old chicks trained on a 1-trial passive avoidance task. Chicks were given bilateral injections into the intermediate medial hyperstriatum ventrale 30 minutes pre-training, of either saline or 0.15mM MK801, and tested either 90 min, 2 h, 3 h, 4 h, or 24 h, post-training. Our results show that 0.15mM produced significant amnesia 4 h and 24 h post-training compared to saline controls ($p < .01$). MK801 did not produce amnesia at any other test time, and previous tests showed that amnesia was not apparent before 90min post-training. Whereas it had been reported that amnesia produced by MK801 starts at some time between 30 min and 3 h post-training (Burchuladze & Rose, 1992), our finding demonstrates that MK801 causes an onset of amnesia significantly later than do protein synthesis inhibitors. These results suggest that NMDA receptor activation, along with Ca^{2+} and Ca^{2+} -dependent processes, are important for long-term memory formation in the chick, and that these processes are important for the retrieval of a passive avoidance task.

413.13

EFFECTS OF INTRA-HIPPOCAMPAL NMDA BLOCKADE AND KINASE INHIBITION ON SPONTANEOUS ALTERNATION AND PERFORANT PATH - DENTATE GYRUS EVOKED POTENTIALS. D.L. Walker* and P.E. Gold. Dept. Psychology, University of Virginia, Charlottesville, VA, 22903.

We previously reported that spontaneous alternation (SA) is disrupted by systemically administered NMDA antagonists. Others have suggested that spatial learning deficits produced by NMDA blockade are attributable to a direct impairment of endogenous hippocampal long-term potentiation (LTP)—a view consistent with evidence that intra-hippocampal infusion of NMDA antagonists disrupts spatial learning and also interferes with LTP induction. In the present study, we have attempted to determine if SA is also disrupted by the circumscribed blockade of hippocampal NMDA receptors, and have examined the effects of a second class of compounds which disrupt LTP, protein kinase inhibitors, on this behavior.

When injected into the rat hippocampus 15 min prior to the 8 min test, the NMDA antagonists CPP and D,L-AP5 each decreased alternation rates. The specific protein kinase C inhibitor, NPC 15437, also disrupted alternation behavior whereas the more general kinase inhibitor, PMXB, did not. Interpretation of these data was complicated by the additional findings that intra-hippocampal administration of L-AP5 (which is inactive with respect to NMDA receptors) also disrupted SA (albeit at a higher dose), and that both the D- and L- isomers of AP5 as well as each kinase inhibitor dramatically disrupted evoked responses (manifest as a decrease of population spike amplitude and EPSP slope, and an increased spike latency).

These data indicate that behaviorally effective doses of AP5 may have effects which extend beyond NMDA blockade. Moreover, the effects of these compounds on hippocampal transmission, in general, suggest that attribution of the amnesic consequences of their administration to impaired LTP may be unwarranted. [Supported by NIA (AG 07648), NSF (BNS 9012239), and by an NIMH training grant (MH 1811)].

413.10

EFFECTS OF PHENCYCLIDINE ON LEARNING OF A 12-ARM SPATIAL CONTINUOUS RECOGNITION MEMORY TASK.

M. Dakis, R. P. Kesner, F. Matsuo* Dept. of Psychology, Univ. of Utah, Salt Lake City, UT 84112

In order to test the role of NMDA receptors in the hippocampus on the acquisition of a spatial continuous recognition memory task, rats were injected bilaterally with 1 μ l of 36 or 54nM concentrations of PCP (a non-competitive NMDA antagonist), or isotonic saline directly into the CA-1/dentate gyrus region of the hippocampus. While under the influence of the drug, the rats were each allowed sequential access to 12 arms of the maze from the central platform. Access required that the rat orient to a cue on a clear Plexiglass door of the designated arm; upon orientation, the door was opened and latency to reach the end of each arm was measured. Of the 12 presentations, three or four of the arms were repeated, but did not contain reinforcement. Repeated arms were presented with lags ranging from 0 to 6 (from 0 to 6 different arm presentations between the first and the repeated presentation). The dependent variable consisted of the difference in latencies between the first and the second presentation of a repeated arm. All animals received 16 sessions for a total of 8 presentations of each lag. Results indicate that compared with saline and 36nM, the 54nM PCP group could not learn the task. The acquisition deficit is not likely due to any sensory-motor effects, since none was observed with 54nM injections. The results support the hypothesis that the NMDA receptor mediates the consolidation of spatial information in the CA-1/dentate gyrus region of the hippocampus.

413.12

A DIFFERENTIATION BETWEEN THE EFFECTS OF MK-801 ON SENSORY PROCESSING VERSUS MOTORIC ACTIVATION: IMPLICATIONS FOR THE ROLE OF GLUTAMATE IN LEARNING & MEMORY. Huilian Dai* and Robert J. Carey Res. & Devel. Serv. -151, VA Medical Center, Syracuse, NY 13210

A frequently used pharmacological tool for understanding the behavioral functions of glutamate is the drug MK-801 which is a non-competitive NMDA antagonist at the ion channel complex. Increasingly, the interaction of glutamate and dopamine systems in the striatum have been investigated and the induction of a drug related hyperlocomotion by MK-801 has been suggestive of an inhibitory modulatory effect of glutamate on dopamine activity. This focus on the locomotor effects of MK-801, however, fails to consider the sensory gating role of the striatum. In order to assess the impact of MK-801 on this function of the striatum, a behavioral test was developed in which sensory-motor effects could be distinguished using a video tracking system. A zone composing 1/9 of the floor area was monitored independently from the rest of the area. Intermittently, a 2"x2" styrofoam cube was placed in the small zone. The presence of the object reliably increased the duration in the small zone but did not affect either the number of visits to the small zone, or overall locomotion behavior. MK-801 0.01 to 0.3 mg/kg dose range produced a dose dependent decrease in object zone time and an increase in locomotion. Importantly, the interference with the investigation of the stimulus object occurred at 0.03 mg/kg whereas hyperlocomotion did not develop until a 0.1 mg/kg dose level was administered. The interference in sensory processing by MK-801 at a dose well below that required for a locomotion behavioral change point to an important function for the glutamate system in attentional mechanism which would impact substantially upon tests involving learning and memory.

413.14

INTRACAUDAL INJECTION OF L-PYROGLUTAMIC ACID IN RATS IMPAIRS REVERSAL OF A LIGHT DISCRIMINATION TASK. Jennie C. Johannesen, Jennifer L. Geelmuyden and Richard E. Musty*. Department of Psychology, Univ. of Vermont, Burlington, VT 05405

The effect of bilateral, intracaudal injections of L-pyroglyutamic acid (L-pga) on the ability of rats to acquire and reverse an appetitive light discrimination task was evaluated. Seven female Wistar rats received bilateral, intracaudal injections of 3 μ l of L-pga (25.8 mg/ml), while 7 others received 3 μ l injections of 0.9% saline. Eight female Wistars received sham lesions. All rats were trained to traverse a Y-maze for food reinforcement; in the acquisition phase, they entered a randomly alternated lit arm for a food reward and in the reversal phase, they entered the dark arm to obtain the reward. All subjects were trained to a criterion of 5 out of 6 trials correct on two consecutive days. Data analysis revealed that whereas rats injected with L-pga acquire the task as rapidly as the control animals, they are significantly impaired on the reversal phase ($p < .01$). The results obtained resemble those of Kirkby (1969, *Physiol and Beh.*, 4, 451-454) who reported similar findings in rats with electrolytic lesions of the caudate. This deficit and the fact that L-pga acts at glutamate receptors, supports the theory that L-pga may be a useful model of neurodegenerative diseases like Huntington's disease.

414.1

AMPHETAMINE FACILITATES RECOVERY OF SOME ASPECTS OF MOTOR FUNCTION FOLLOWING UNILATERAL CORTICAL LESIONS IN THE RAT. T.D. Schmanke*, R.A. Avry and T.M. Barth. Department of Psychology, Texas Christian University, Ft. Worth, TX 76129.

Previous studies suggest that amphetamine facilitates recovery of hindlimb sensorimotor function following cortical damage, if the animal receives task-specific experience while under the influence of the drug (amphetamine + practice). The majority of these studies used a beam walking task where the rat traversed a narrow wooden bridge. The present study was designed to determine if the amphetamine + practice effect generalizes to forelimb sensorimotor function. Rats received unilateral electrolytic lesions in the sensorimotor cortex (SMC) that included the caudal forelimb representation. Beginning twenty-four hours following surgery, the animals received a regimen of amphetamine (2 mg/kg) and experience on forelimb tactile placing tasks as well as the bilateral tactile stimulation test. During the period immediately following drug administration, amphetamine intoxicated animals were not significantly different from saline treated control animals. For example, amphetamine treated animals failed to exhibit tactile placing with the forelimb contralateral to the lesion. However, amphetamine facilitated recovery on this task and had no effect on recovery from somatosensory asymmetry. In experiment 2, rats received large SMC lesions that included both the forelimb and hindlimb representations. The aim of this study was to replicate the effects on the beam walking task as well as test the same animals on a task requiring negotiation of an elevated grid floor (foot-fault test). During the period of drug intoxication, amphetamine treated animals negotiated the narrow beam significantly better than saline treated animals. The amphetamine treated animals continued to show a facilitation of recovery on subsequent test days. In contrast, there was no amphetamine effect on the foot-fault test. These data suggest that amphetamine does not affect recovery on all sensorimotor tasks and that performance during the period of drug intoxication does not predict subsequent recovery (i.e. tactile placing).

EFFECTS OF CORTICAL LESIONS ON APOMORPHINE-INDUCED ROTATIONAL BEHAVIOR. A. Herranz*, R.C. Heim, M. Pollorak, M. Giordano, H.E. Cannon-Spoor and W.J. Freed. NIMH Neuroscience Center at St. Elizabeths, Washington, DC 20032.

The afferents to the neostriatum from the cerebral cortex and the substantia nigra (SN) are largely coincident on the same neurons. We evaluated the effects of corticostriatal deafferentation on a behavior mediated by striatal dopaminergic synapses. Apomorphine-induced rotation in rats with unilateral lesions of the SN was used as a behavioral measure, to avoid the complicating influence of presynaptic effects on dopamine release. Right SN lesions were performed by stereotaxic administration of 4 µg of 6-OHDA. The animals were then screened for rotational behavior after administration of 0.1 mg/kg of apomorphine HCl. After obtaining stable baseline rotational behavior over 8 weeks, cortical lesions were performed by aspiration ipsilateral to the SN lesion. Lesions extended from 3mm anterior to 3mm posterior to the bregma. "Small" lesions extended 2-3 mm laterally from the midline and "large" lesions extended laterally to 5-7 mm. Animals were tested over a period of 28 weeks following the cortical lesions. The large cortical lesions reduced rotation by approximately 55%, while a 35% reduction was induced by the small lesions. The decreases were stable over the 28 week testing period. We conclude that the cortical input to the striatum can modulate the behavioral manifestations of activation of the nigrostriatal dopamine system, even in the absence of presynaptic dopamine terminals.

MULTIPLE INJECTIONS OF MK-801 AFTER RECOVERY FROM LESIONS IN THE SOMATIC SENSORIMOTOR CORTEX REINSTATE FORELIMB PLACING DEFICITS IN THE RAT. S. Barbay* and T.M. Barth. Department of Psychology, Texas Christian University, Ft. Worth, TX 76129.

Unilateral lesions in the rat somatic sensorimotor cortex (SMC) produce a syndrome that includes impairments in tactile placing with the forelimb contralateral to the lesion and an ipsilateral sensorimotor asymmetry on a bilateral tactile stimulation test. These symptoms eventually recover. Following the recovery, a single injection of the noncompetitive NMDA antagonist MK-801, reinstates the contralateral impairment in tactile placing for 7-14 days (reinstatement effect). However, a previous study demonstrated that a regimen of MK-801 beginning 16 hrs after the lesion prevented the reinstatement effect. It was suggested that MK-801 administered shortly after the lesion prevents the degeneration of neurons distant from the lesion site. Thus, the transneuronal degeneration may be necessary for the reinstatement effect to occur. An alternative to the "neuroprotective hypothesis" is that multiple injections of the drug desensitize the animal to the later postrecovery administration of MK-801. The present study investigates this alternative hypothesis by beginning the regimen of MK-801 after recovery is complete.

Rats received unilateral SMC lesions, allowed to recover, and then received injections of MK-801 (1 mg/kg) on three consecutive days. This produced a profound reinstatement of the contralateral placing deficits which endured for 14-28 days. Following recovery from the reinstatement, the rats were given a single injection of MK-801 (1 mg/kg). Once again, contralateral forelimb placing deficits were reinstated. In some cases the second reinstatement appeared to be permanent (at least 60 days). These data fail to support the idea that multiple injections of MK-801 desensitize the animal to future treatments of the drug. Moreover, the working hypothesis (that neuroprotective effects of early MK-801 treatment prevent later reinstatement), appears to be tenable.

414.2

THE EFFECTS OF CUEING ON THE SENSORIMOTOR ASYMMETRY FOLLOWING UNILATERAL LESIONS OF RAT ANTEROMEDIAL CORTEX: MANIPULATIONS OF CUE SIZE AND CUE-TRIAL INTERVAL. B.B. Marks* and T.M. Barth. Department of Psychology, Texas Christian University, Ft. Worth, TX 76129.

Following unilateral lesions of the anteromedial cortex (AMC), rats exhibit an ipsilateral sensorimotor asymmetry as measured by a bilateral tactile stimulation test (e.g. contacting an adhesive patch placed on the forelimb ipsilateral to the lesion before contacting a simultaneously applied contralateral patch). A previous experiment demonstrated that a tactile cue presented 5s prior to the bilateral tactile stimulation test neutralizes this asymmetry. These data support the view that the sensorimotor asymmetry observed after unilateral AMC lesions may reflect an impairment in the allocation of attention to stimuli presented on the side contralateral to the lesion. The present study examined the effects of manipulating the size of the cue and the time interval between cue presentation and the test trial (cue-test interval).

Rats received unilateral electrolytic lesions of the AMC and were tested one or two days following surgery. First, the animals received the bilateral stimulation test without a cue, in order to determine the presence of an ipsilateral asymmetry (contacting the ipsilateral patch before the contralateral patch on at least 80% of the trials). Animals exhibiting an ipsilateral asymmetry were then given a series of trials with a cue presented prior to the bilateral stimulation test. Cue size was varied by increasing or decreasing its size by 75% of the standard patch. The cue-test interval was either 5s, 30s, or 60s. The results were that the size of the cue had little effect in neutralizing the asymmetry. In contrast, the cue-test interval proved to be very important, with cues having the largest effect at 5s, a mild effect at 30s, and no effect at 60s. These data support previous findings that suggest the neutralizing effects of the cue are transitory.

N-METHYL-D-ASPARTATE ANTAGONIST MK-801 BLOCKS AMPHETAMINE INDUCED BUT NOT PHENCYCLIDINE INDUCED BEHAVIORAL SENSITIZATION. X. Xu and E.F. Domino*. Dept. of Pharmacology, University of Michigan, Ann Arbor, MI 48109-0626.

Recent studies have demonstrated that behavioral sensitization to amphetamine and cocaine requires activation of the N-methyl-D-aspartate (NMDA) class of glutamate receptors because sensitization is blocked by MK-801, a non-competitive NMDA receptor antagonist. The present study reexamined the effects of daily injection of phencyclidine on locomotor activity and stereotypy, and investigated whether MK-801 blocked behavioral sensitization to phencyclidine. Female Sprague-Dawley rats were injected i.p. once daily with phencyclidine, d-amphetamine, 0.9% NaCl, or MK-801 followed 30 min later by phencyclidine or d-amphetamine. Locomotor activity and stereotypy were measured automatically with the Digiscan system. The results confirmed an earlier finding that four daily injections of phencyclidine induced sensitization to both locomotor activity and stereotypy. Moreover, MK-801 did not block behavioral sensitization to phencyclidine although it blocks behavioral sensitization to d-amphetamine. The present research suggests that the development of behavioral sensitization to phencyclidine may be mediated by neuronal mechanisms different from those underlying sensitization to amphetamine and cocaine. (Supported in part by NIDA Grant DA-01531.)

SCOPOLAMINE FACILITATES RECOVERY OF FORELIMB PLACING BEHAVIOR FOLLOWING UNILATERAL CORTICAL LESIONS IN THE RAT. R. M. Saponic*, S. Barbay, M. R. Hoane, S. L. Irish and T.M. Barth. Department of Psychology, Texas Christian University, Ft. Worth, TX 76129.

Following brain injury there is an excessive nonspecific release of excitatory neurotransmitters (i.e. N-methyl-D-Aspartate [NMDA]; acetylcholine) that may lead to secondary cell death proximal and distal to the site of trauma. Although much research effort has focused on the excessive release of excitatory amino acids, acetylcholine is also released in excess. Recent studies have suggested that excitatory neurotransmitter receptor antagonists may be effective neuroprotective agents (i.e. MK-801) and facilitate recovery of function. The present experiment was designed to determine whether administration of scopolamine (a muscarinic receptor antagonist) could facilitate behavioral recovery following unilateral lesions of the rat somatic sensorimotor cortex (SMC).

Rats received unilateral electrolytic lesions in the SMC and a regimen of scopolamine (1mg/kg) or saline beginning 15 min after the damage. The behavioral tests included tasks sensitive to forelimb motor and sensory function. Rats treated with saline showed the expected severe contralateral impairments in forelimb placing as well as an ipsilateral somatosensory asymmetry on the bilateral tactile stimulation test. In contrast, the magnitude of the initial forelimb placing deficit was significantly reduced in animals treated with scopolamine, and the rate of subsequent recovery was facilitated when compared to saline treated controls. Scopolamine had no effect on the somatosensory asymmetry. These data support the idea that muscarinic receptor stimulation may play a role in the pathophysiological responses associated with brain injury. Future studies will compare the relative effectiveness of MK-801 and scopolamine as neuroprotective agents.

414.7

THE AMELIORATIVE EFFECT OF REPEATED INJECTIONS OF SCOPOLAMINE HYDROBROMIDE ON RECOVERY FROM BRAIN DAMAGE: AN ANALYSIS OF AGE. **A.M. Schneider***, E. Thomas, E. Cardemil, C. Carr, M. Jacobs, M. Criden, Depts. of Psychology and Biology, Swarthmore College, Swarthmore, PA 19081 and Bryn Mawr College, Bryn Mawr, PA 19010

In neurodegenerative diseases such as Parkinson's disease and perhaps Alzheimer's and Huntington's disease, synaptic adaptations are the likely explanation for the symptoms not appearing until the degenerative process is almost complete. Thus, the symptoms appear to be "masked" by synaptic compensation.

We present an animal model of the "masking" effect in the cholinergic system and evidence indicating that the effect declines with age. We found in younger (3 month) and older (10-12 month) rats that repeated injections of scopolamine hydrobromide (a procedure that produces upregulated muscarinic receptors), if given prior to surgery, "masked" the amnesic effects of nucleus basalis magnocellularis (NBM) lesions. Specifically, in the younger rats repeated injections of a low dose of scopolamine (4 mg/kg) reduced the amnesic effects of lesions of NBM in a passive-avoidance test. In the older rats the lower dose was ineffective, but a higher dose (8mg/kg) was effective in ameliorating the amnesic effects of the lesions.

These findings suggest that there is greater plasticity in younger rats than in older rats in the mechanisms that may compensate for the effects of brain damage.

INHIBITION OF PERSISTING RAT HIND-LIMB FLEXION (SPINAL FIXATION) BY PREVIOUS HIND-LEG STIMULATION. **M.M. Patterson***, K. Perkins, M. Feizelli and M.J. Bartelt, College of Osteopathic Medicine and Department of Psychology, Ohio University, Athens, OH 45701

Previous work has demonstrated that 40 minutes of 2-4 ma, 100 Hz stimulation to a spinalized rat's hind leg generates a spinal flexion alteration (spinal fixation) which is readily measurable as persisting hind leg flexion following stimulus termination (Steinmetz, et al., 1981, *JCPP*). In the present study, we explored the influence of pre-stimulating unspinalized rats' hind legs on the amount of hind leg flexion induced by restimulating the leg 72 hours later, immediately following spinal section.

Sixty-nine rats were anesthetized with Nembutal (50 mg/kg, ip) and then stimulated on the upper right hind leg with either 1.5 or 2.5 ma, 100 Hz, 7 msec pulses for 30 minutes or were simply placed in the experimental apparatus for the equivalent time. They were then returned to their home cages. Seventy-two hours later, all rats were re-anesthetized, spinalized at T7 and stimulated with either 1.5 or 2.5 ma for 40 min. Following the stimulation, the spinal fixation was assessed by determining the amount of weight required to pull the stimulated (flexed) leg even with the unstimulated leg.

The study resulted in 4 experimental groups, plus controls. The 1.5 ma control (0, 1.5 ma stimulation) had 23.2 gms of flexion as opposed to 47.0 gms for the 2.5 ma control group (0, 2.5 ma stimulation), values usual for these parameters. The 1.5, 1.5 ma stimulation group had 14.2 gms, the 1.5, 2.5 had 11.5 gms, while the 2.5, 1.5 had 9.0 gms, and the 2.5, 2.5 ma group had 49.0 gms. Except for the 2.5, 2.5 ma group, the prestimulation reliably reduced the amount of persisting hind limb flexion to the following fixating stimulus. This result is somewhat surprising since it might have been expected that the initial stimulation period would summate with the later stimulation to produce additional fixation. It is possible that the initial stimulation caused alterations of the spinal interneurons which made them less plastic to further alterations, except for the combination of higher stimulus intensities with both stimuli. Alternatively, the effects of stimulation on cortical function may influence the effects of later stimulation through descending influences. The effects of time between stimulation periods, and stimulus intensity parameters are now being explored. Supported by American Osteopathic Association Grant 92-08-319.

METABOLIC CHANGES SCANNED BY MR IMAGING IN THE HYPOTHALAMUS OF RATS WITH L-LYSINE DEFICIENCY AFTER L-LYSINE ADMINISTRATION INTRAPERITONEALLY. **T. Yokawa¹, E. Tabuchi¹, T. Inubushi², T. Ono³ and K. Torii^{1,4*}**, ERATO, JRDC, Japan¹. Mole. Neurobiol. Res. Center, Shiga Med. Univ., Japan². Dept. Physiol., Toyama Med. & Pharmaceu. Univ., Japan³. Central Research Lab., Ajinomoto Co. Inc., Japan⁴.

Each L-amino acid (AA) in plasma and brain remains unchanged all day long while normal diet is available. Once L-lysine (Lys) deficient diet offered to rats, Lys in plasma and brain declined. When solutions of AAs were offered, they selected the Lys solution and their food intake and growth normalized. The single neuron activity in the lateral hypothalamic area of these rats suggested that the neural plasticity occurred, specifically responding to Lys, iontophoretic application and during ingestion of AA. Non-invasive magnetic resonance imaging (MRI) has been developed to monitor changes in cerebral blood flow (CBF) and oxygenation. MRI signal intensity changes in T2* weighted images of the brain of rats with Lys deficiency were studied using MR Imager (4.7 tesla, 40 cm bore in diameter) with a handmade volume coil. Wistar strain male rats (6 weeks of age, N=6 in each group) fed with Lys deficient diet for 4 days were used. When they received a Lys injection intraperitoneally (0.2 M, 10 ml/kg) higher signals in the medial and lateral hypothalamus were appeared in T2* weighted images. This higher signal in the hypothalamus caused by the Lys treatment lasted for 30 min, and then gradually decreased. There were no signal changes in the case of saline injection as control. These results suggest that the medial and lateral hypothalamus in an essential AA deficiency may play an important roles to response to particular deficient nutrient intake during recognition processes.

ACCELERATION OF RECOVERY FROM CORTICAL HEMIPLEGIA BY TWO GINKGO BILOBA EXTRACTS. **S. Brailowsky***, T. Montiel and L. Medina-Ceja, Instituto de Fisiología Celular, U.N.A.M., 04510 México D.F., MEXICO

In a previous study (Restor. Neurol. Neurosci., 3:267, 1991) we reported on the beneficial effects of a Ginkgo biloba extract (EGb761-IPSEN) on two models of cortical hemiplegia in rats. Being interested in identifying the active principle responsible for these effects, we studied the motor behavior (elevated beam test) of rats having sustained unilateral motor cortex aspiration. Two extracts were assayed: EGb-761, 100 and 50 mg/kg p.o., and a EGB extract containing no terpenes (100 mg/kg p.o.). Both treatments were given 24 h after the lesion and for 7 days. Both extracts produced a faster recovery than that observed in lesion-only rats. The treated groups also showed smaller ventricles on the lesion side, suggestive of reduced edema.

We conclude that the active substance(s) participating in this beneficial effect of EGb-761 extract are non-terpenes and that a dose 50% smaller than the one used previously is sufficient to accelerate recovery from a cortical lesion.

ENERGY METABOLISM CHANGES ACCOMPANYING RECOVERY FROM UNILATERAL NEGLECT IN THE RAT AS MEASURED BY CYTOCHROME OXIDASE. **M.F. Novotny¹, L.J. Cudmore, C.G. Ellard, and D.P. Crowne**, Department of Psychology, University of Waterloo, Waterloo, Ontario, Canada, N2L 3G1.

Contralateral neglect induced by unilateral lesions to the parietal or frontal cortex eventually recovers. The deficits can be reinstated following transection of the corpus callosum suggesting a possible role of the intact contralateral hemisphere in recovery. In this study, cortical activity changes were assessed during recovery from neglect in rats using cytochrome oxidase. Adult Long Evans male rats underwent either unilateral medial frontal or posterior parietal lesions. They were tested for unilateral neglect with a modified version of the polysensory test for neglect. The animals were tested prior to and 3 times per week following surgery. At either 2 days or 7 days postoperatively (PO), animals were perfused and tissue was reacted for cytochrome oxidase using a modified version of the Wong-Riley technique. The pattern of cytochrome oxidase staining appeared to be different for parietal and frontal lesions. In the medial frontal group, the cortex ipsilateral to the lesion showed a decrease in cytochrome staining compared to the intact contralateral hemisphere. However, in the parietal lesion group the cortex adjacent to the lesion site was more darkly reacted, much like the contralateral hemisphere. Unilateral lesions to the frontal and parietal cortex both produce unilateral neglect, but have differential cortical activity changes during recovery.

This research was funded by grants to DPC and CGE from the Natural Sciences and Engineering Research Council of Canada.

RESPONSES OF LATERAL HYPOTHALAMIC NEURONS IN LYSINE DEFICIENT RATS DURING INGESTION OF AMINO ACIDS AND NaCl. **T. Kondoh¹, E. Tabuchi¹, T. Vovnikov¹, T. Yokawa¹, T. Ono², A. Nijijima^{3*} and K. Torii¹** Torii Project, ERATO, JRDC, Yokohama, Japan, ²Dept. Physiol., Toyama Med. & Pharmaceu. Univ., Toyama, Japan, ³Dept. Physiol., Sch. of Med., Niigata Univ., Niigata, Japan.

Rats fed the L-lysine (Lys) deficient diet selectively ingest Lys solution, after learning and memorizing the taste. In the present study, we first confirmed that Lys-deficient rats learned to selectively ingest Lys, and then recorded single neuron activity from the lateral hypothalamus (LHA) of these rats during discrimination of conditioned cue tone stimuli associated with amino acids (0.2M Lys, 0.15M monosodium L-glutamate (MSG), 0.05M L-arginine, 0.5M L-glycine), 0.15M NaCl (saline) and water, and their subsequent ingestion. More LHA neurons responded to Lys ingestion, its cue tone, and to saline; and fewer responded to arginine ingestion during Lys deficiency than in control. Typically, during Lys deficiency, neurons that responded to Lys or to MSG also responded to saline. Neurons that differentiate cue tone and/or ingestion of the solutions were located more in the dorsal and lateral LHA. The results suggest that preference for a deficient amino acid and NaCl during Lys deficiency and for MSG in normal protein nutrition might be mediated through the LHA, and learning and memory could affect these processes. Chronic recordings of LHA neuron activity in freely behaving rats are currently under investigation to demonstrate possible neural plastic changes.

ESTROGEN-INDUCED ACCELERATED SPECTRIN PROTEOLYSIS IN THE RAT ARCULATE NUCLEUS. M.C. de Lacoste* & C.E. Lewis Dept. Ob. Gyn., Yale University Medical School, New Haven, CT 06510.

Reportedly, estrogen can induce synaptic plasticity in the central nervous system (e.g., Frankfurt & McEwen, 1992; Naftolin et al., 1990). However, the mechanisms underlying this plasticity remain to be deciphered. This study was undertaken to determine if post-translational modification, i.e., calpain cleavage, of the spectrin-based neuronal cytoskeleton may serve as a central molecular mechanism underlying some of the morphological changes seen in association with estrogen-induced synaptic plasticity. **Methods:** 22 adult normal cycling Sprague-Dawley rats were used: 18 of the animals received a single subcutaneous injection of 1.0mg estradiol valerate (1cc of 10mgEV/ml in sesame oil) at 70-75 days of age (ET animals) while 4 served as untreated controls. Animals were sacrificed 4, 6, 8 and 32 weeks later and perfusion-fixed. Blocks of tissue containing the rostral hypothalamus were vibratome-sectioned and processed for both light (LM) and electron microscopic (EM) immunocytochemistry using standard ABC immunoperoxidase techniques and the RA150 antibody. The RA150 antibody, an antibody made to a synthetic peptide characterizing the C-terminus of the calpain-I cleavage site of alpha fodrin, serves as a specific marker of spectrin proteolysis. **Results:** Little or no immunostaining was seen throughout the arcuate nucleus of untreated animals. In contrast, at the LM level RA150 immunodecoration of arcuate neuropil could be discerned in the 4, 6, 8 and 32 wk ET animals. At the EM level, the immunoreactive neurites could be easily identified as dendrites. Hence, it appears that within the arcuate nucleus, estrogen induces proteolysis of the spectrin neuronal cytoskeleton. These findings parallel results obtained in other laboratories which indicate that long-term potentiation is associated with spectrin breakdown. *The RA150 antibody was kindly provided by Dr. Jon Morrow.*

HYPERAMMONEMIA DECREASES PROTEIN KINASE C-DEPENDENT PHOSPHORYLATION OF MICROTUBULE-ASSOCIATED PROTEIN 2 AND INCREASES ITS BINDING TO TUBULIN. V. Felipo*, M. D. Miñana and E. Grau. Instituto de Investigaciones Citológicas. Amadeo de Saboya, 4. 46010 Valencia. Spain.

Chronic hyperammonemia increases the tubulin content in brain. The synthesis of tubulin is regulated by the level of free tubulin and its polymerization in brain is mainly controlled by the binding of microtubule-associated protein 2 (MAP-2) and Tau proteins, which stimulate polymerization. The ability of these proteins to bind tubulin is in turn controlled by their phosphorylation. In studies to clarify the mechanism by which high ammonia levels induce tubulin synthesis we found that chronic hyperammonemia increases the polymerization of microtubule and that changes in polymerization precede those in tubulin synthesis.

We show now that the binding of MAP-2 to microtubules as well as the capacity of MAPs to stimulate polymerization of tubulin is increased in hyperammonemia and that protein kinase C-dependent phosphorylation of MAP-2 is markedly diminished. This could explain the increased binding of MAP-2 to tubulin and the enhanced polymerization of brain microtubules in hyperammonemic rats. The results reported also indicate that physiological or pathological changes in vivo can lead to alterations in cytoskeletal function which, in turn, could act as mediators in neurological alterations such as those reported in hyperammonemia.

MICRODIALYSIS REVEALS DOPAMINE RELEASE IN THE NUCLEUS ACCUMBENS OF NEONATAL DOPAMINE DEPLETED RATS RECEIVING CAUDAL LINEAR NUCLEUS STIMULATION AS ADULTS. Kulraj Sidhu*, Janet Nunnally, James R. Stellar, Daniel Fisher, Megan Fisher. Departments of Psychology and Pharmacy, Northeastern University, Boston MA 02115

Previously we had demonstrated that adult rats receiving 6-OHDA treatment (ICV 50 ug, each side) at neonatal day 3, have a novel dopamine (DA) projection from the caudal linear nucleus (CLi) of the Raphe to the nucleus accumbens core (ACC) that is not seen in normal adult rats (Sidhu et al *NS Abstracts*, 1992) or vehicle treated controls. In this study, day 3 6-OHDA or vehicle treated rats were subjected as adults to ACC microdialysis (collinear probe design, 2.0mm active collection area, 5.0ul samples with 1.0ul/minute CSF flow). Samples were analyzed for DA and DOPAC with microbore HPLC-ED methods. Rats were conscious and unrestrained. Animals received 10mg/kg, IP, of the DA reuptake blocker GBR12909. Also, direct CLi stimulation through a chronic electrode was imposed using parameters that were within normal self-stimulation ranges. ACC DA and DOPAC was detected at up to 50% above basal levels after combined GBR12909 and CLi stimulation treatment. Unlike vehicle treated rats GBR12909 had little or no effects on its own. These results reinforce the notion that the novel CLi-ACC pathway may play a role in sparing of reward function in these rats.

DENDRITIC BRANCHES OF A RAT ABDUCENS MOTONEURONE FORM CLUSTERS WITH SIMILAR SOMATOFUGAL SPREAD OF ELECTROTONUS. H. Bras¹, S.M. Korogod², V.N. Sarana², P.Gogan¹ and S. Tyc-Dumont^{1*}. ¹CNRS UPR 418 13009 Marseille France, ²State University, Dnepropetrovsk 320625, Ukraine.

Following high spatial resolution description of 3D geometry of the dendrites of an abducens motoneurone intracellularly labelled with HRP, we simulated the distribution of electrotonic voltage over the whole dendritic tree in response to steady state depolarisation of the soma. Stochastic local non-uniformities of the branch diameter and asymmetries of the branchings led to corresponding local non-monotonous voltage decay along the somatofugal dendritic pathways. Part of dendritic branches had similar electrotonic behavior over a relatively long pathway at a given distance from soma, resulting in their grouping. A cluster analysis (K-means clustering method) was performed to estimate quantitatively this grouping. Each of the 63 studied branches (> 50 µm) were characterized by 4 parameters: electrotonic voltage and gradient, mean and standard deviations. The results revealed good distinction between 4 clusters, which corresponded to the 4 observed groupings. In the parametric Euclidean space, distances between the clusters ranged from 1.66 to 5.68. Within clusters, the distance from the center varied between 0.087 and 0.85. The less compact cluster was formed by 8 of the most proximal branches of 7 dendrites. Two other clusters contained 18 and 24 branches respectively, corresponding mainly to 5 dendrites. The fourth cluster was formed by 13 of the most distal branches of the same dendrite. The clustering of the branches survived under variation of the specific membrane resistivity ranging from 1 to 10 KOhm.cm².

GEL ELECTROPHORESIS OF PROTEINS TRANSPORTED BY FAST AXOPLASMIC FLOW IN THE SCIATIC NERVE OF EXERCISE-TRAINED RATS. C.-M. Kang, P.-A. Lavoie* and P. F. Gardiner. Départements d'Éducation Physique et de Pharmacologie, Université de Montréal, Montréal, Québec, Canada, H3C 3J7.

A previous study in our laboratory showed that endurance training increased the quantity of protein subjected to fast axonal transport in the sciatic motor axons of rats. The aim of the present study was to determine whether it is an overall increase of all proteins or a selective increase of some protein(s), as in nerve regeneration. Rats were trained on treadmill for 11 to 13 weeks (27 m/min with 10% grade, 2 h/d, 3 days out of 4 by the 7th week). ³⁵S-methionine (450 µCi) was injected bilaterally into the ventral horn of the L₄-L₅ spinal cord segments, and a ligature was placed on both sciatic nerves about 70 mm from the cell body 5½ h later. Three hours after ligation, the nerve outside the spine was removed and sliced into 3-mm segments. The segment most proximal to the ligature was prepared for gel electrophoresis, and the other 8 segments were processed for liquid scintillation counting. The proteins with molecular weight between 15 kd and 190 kd were analyzed on 7.5% or 12.5% polyacrylamide gels. The percentage of each protein did not differ significantly between trained and control. It seems that, unlike nerve regeneration, exercise training produces a uniform increase among the transported protein species. (Supported by NSERC Canada and FCAR Québec).

NEONATAL CASTRATION BLOCKS THE CHOLINE INDUCED INCREASE IN SIZE OF SEPTAL NEURONS IMMUNOREACTIVE FOR NGFR. E. Gorry¹, R. Loy², W.H. Meck³, & C.L. Williams^{4*}. College of Physicians and Surgeons¹, Depts. of Psychology, Barnard College² & Columbia University³, NY, NY 10027 and Canandaigua NY and Dept. of Neurology, University Rochester², Rochester, NY 14620.

Recent work has shown that choline chloride administered during ED 12-17 and PD 16-30 produces a long-term enhancement of visuospatial memory in male rats. This organizational effect of perinatal choline on memory appears to be dependent upon exposure to neonatal steroids; castration at birth, but not at 50 days of age, prevents the improvement in memory following perinatal choline supplementation. We have also found that hippocampal NGF is elevated in choline-treated rats castrated as adults, while neonatally castrated rats do not show the choline-induced increase in NGF (Gorry et al., *Soc. Neurosci. Abstr.*, 18, 1992). In addition, perinatal choline supplementation increases basal forebrain cell size (Loy & Choe, *Soc. Neurosci. Abstr.*, 17, 1991). We now report that the size of medial septal neurons immunoreactive for nerve growth factor receptor (NGFR_R) is influenced by both neonatal steroids and perinatal choline supplementation. Choline administered from ED 12-PD 30 increased both the perimeter and the area of NGFR_R medial septal neurons in adult (7 mo) castrated rats. This choline-induced increase in cell size was blocked by neonatal castration. These data suggest that there is an interaction between organizational effects of gonadal steroids and organizational effects of supplemental choline on the developing basal forebrain cholinergic system and visuospatial memory. (Supported by PO1 AG09525)

DOES THE PIGEON HAVE A NUCLEUS UVAEFORMIS (UVA), OR THE SONGBIRD A NUCLEUS DORSOLATERALIS POSTERIOR THALAMI, PARS CAUDALIS (CDLP)? J.M. Wild*, Dept. of Anatomy, School of Medicine, University of Auckland, Auckland, New Zealand.

Uva in songbirds is thought to be involved in song learning or song control circuitry primarily by virtue of its direct and indirect projections upon the High Vocal Center (HVC), which is only two synapses away from vocal motoneurons. Uva is composed of cells of similar size and location to those of cDLP in pigeon, both nuclei lying within the crook of the elbow of the habenulo-interpeduncular tract and dorsal to the nucleus spiriformis medialis. The sources of input to cDLP in pigeon are known to be lamina 13 of the optic tectum, and the dorsal column nuclei (DCN). cDLP projects upon the "neostriatum", where the region of its terminal field anterolateral to the auditory Field L contains a somatosensory representation of the body. To determine whether Uva has similar inputs to those of cDLP, injections of cholera toxin B-chain conjugated to HRP were made into either the DCN or the deep tectum in greenfinches, zebra finches, and Java sparrows. Both DCN and tectal injections produced dense and specific anterograde labelling of Uva, predominantly contralaterally and ipsilaterally, respectively. Injections centered on Uva produced retrogradely labelled cells in DCN, tectal lamina 13, and in the rostroventrolateral medulla. They also produced a terminal field within the "neostriatum" anterolateral to Field L which has been previously identified as nucleus interfascialis (NIF). Somatosensory evoked potentials were recorded from Nif, and injections of retrograde tracers were made at the recording site. Retrogradely labelled cells were found in only two thalamic nuclei: Uva, particularly its ventral portion, and ventrolateral parts of nucleus ovoidalis. These results confirm precisely those found previously in the pigeon somatosensory system, but they are difficult to interpret in terms of a supposed role of Uva in the control of song. One of their implications could be, however, that HVC - to which Nif projects - is functionally heterogeneous. Supported by Whitehall Foundation, Inc.

AUDITORY RESPONSE PROPERTIES OF FIELD L IN THE ZEBRA FINCH D. Lim*, Division of Biology, California Institute of Technology, Pasadena, CA 91125.

The connections of field L and its auditory response properties to various kinds of stimuli were studied in adult male zebra finches (*Poephila guttata*). Biotinylated dextran amine was injected in three subdivisions--L1, L2, and L3, for both anterograde and retrograde tracing. In all three layers, most of afferent projections were found in the shelf area around HVC. Layer L3 projected to the neighboring area of RA. There were also reciprocal connections between L1 and L3. To study the physiological response properties of each layer, a total of 417 units were collected from 39 animals. These recordings showed a relatively simple stereotyped responses in L2 while L1 and L3 layers exhibited widely varying responses. Different kinds of stimulus selectivities were identified in these two layers, such as preference for song, white noise, and FM. These subdivisions also contained most of the neurons that responded selectively to the direction in which song or FM signals were presented. The responses of neurons in L1 and L3 to signals composed of two harmonic frequencies differed from the linear sum of their responses to individual components, whereas the neurons of L2 showed no significant interactions. L2 neurons occurred in tonotopic sequences, whereas such orders were not found in L1 and L3. The contributions of L1 and L3 to the selectivity of HVC neurons for song were examined by injection of a local anesthetic into these layers while HVC song-selective neurons were monitored. The results show that HVC needs L1 and L3 for the maintenance of song selectivity. This work was supported by International Human Frontier Science Program.

FREE-FIELD RELEASE FROM NOISE MASKING IN PARAKEETS.

O.N. Larsen*, M. Dent and R.J. Dooling, Dept. of Psychology, Univ. of Maryland, College Park, MD 20742.

The auditory system is constantly faced with the task of detecting biologically important sounds against a spatially diffuse background of environmental noise. In a few cases, such as close to running water, the environmental noise is dominated by a single source. In humans, speech intelligibility and signal detection is generally improved as such a masker and the signal are spatially separated. We wished to learn to what extent signal detection is improved with spatial separation of signal and masker in birds with small head widths and consequently with little sound diffraction in the biologically important frequency range.

Two adult male parakeets (*Melospitacus undulatus*) were trained using operant conditioning techniques to peck keys for food reinforcement in response to the presentation of pure tone stimuli (frequencies 2.86 and 4.00 kHz, duration 400 ms) embedded in continuous, broadband noise (1.5 to 10 kHz) with a spectrum level of 10 dB/Hz. Trained birds were tested using the method of constant stimuli (step size 3 dB) at seven sound pressure levels with the noise source fixed in front of the bird (azimuth = 0°) and the tone source in one of 12 azimuth positions (step size 30°). As a control absolute thresholds for these tone signals (i.e. no masking noise) were measured in all 12 azimuth positions. Additional experiments were conducted with the noise located at 90°, 180°, and 270° and the tone source at either 0°, 90°, 180°, or 270°.

Results show that detection of signals in noise improves when noise and signal sources are spatially separated. The improvement is about 6 dB at a signal and noise separation of 90° with less improvement at other azimuth angles. This pattern of masking release is qualitatively similar to that found in mammalian species.

HIERARCHICAL ORGANIZATION OF BRAIN AREAS MEDIATING ZEBRA FINCH LEARNED VOCALIZATIONS. E. T. Vu*, M. E. Mazurek, and Y. Kuo. Division of Biology, Caltech, Pasadena, CA 91125.

Although several lines of evidence suggest that the stereotyped sequencing of syllables in adult zebra finch song arises from a central motor representation of song, the neural basis for this is not well understood. Using chronically implanted stimulating electrodes, we probed for the existence and location of a neural representation of this feature of song behavior, syllable sequencing. Individual nuclei in the song motor pathway were briefly stimulated during singing (7 pulses at 400 Hz, 0.4 ms duration). We hypothesized that if the precise sequencing of song syllables required peripheral feedback or required precisely timed neural activity in all parts of the motor pathway then experimentally altering the firing pattern at any point of the motor pathway would change the syllable sequence. Alternatively, if a localized central representation of syllable sequence existed then stimulating some nuclei but not others would result in altered syllable sequencing. Stimulating song nucleus RA distorted an ongoing syllable without changing the order or timing of ensuing syllables, whereas stimulating nuclei higher up the motor pathway (i.e. HVC and NIF) altered both ongoing syllables and the ensuing song pattern. Specifically, birds suspended a song phrase they were singing soon after the stimulus was applied and rapidly resumed at the beginning of the phrase. HVC stimulation in a deafened bird had the same effect. These findings suggest that syllable sequencing during singing is organized in nuclei above RA, and that the resulting pattern is imposed on and unaffected by activity in lower structures of the motor pathway.

EFFECT OF DEAFENING ON THE CONTACT CALL OF ADULT BUDGERIGARS. J.T. Heaton and R.J. Dooling*. Dept. of Psychology, Univ. of Maryland, College Park, MD. 20742-4411.

Auditory feedback is necessary for the development of normal song and contact calls in budgerigars. Here we report that auditory feedback is also required for the maintenance of species typical contact calls in adult budgerigars.

Six adult budgerigars were deafened by bilateral extirpation of the basilar papillae after removal of the columella and supportive structures. Deafened birds vocalized less frequently than normal birds, and their calls showed abnormalities in acoustic structure within a few weeks of surgery. Within several months, nearly all contact calls produced by deafened birds were strikingly abnormal, and by 5 months none of the birds in our sample produced normal contact calls. Several birds, however, continued to produce alarm calls that were very similar to those produced prior to deafening. It was also noted that some of the deafened birds would assume a singing posture, which included head and throat movements indicative of vocalization, without making a sound. These data raise interesting questions about whether different neural mechanisms are involved in the production of different call types in the budgerigar vocal repertoire.

415.6

USE OF A PARTICLE-BASED MAGNETORECEPTOR BY THE BOBOLINK. R.C. Beason*, N. Dussourd, M.E. Deutschlander and C.A. Augonis. Biology Dept., State Univ. of New York, Geneseo, NY 14454.

The effect of a brief magnetic impulse on magnetic perception was tested on the bobolink (*Dolichonyx oryzivorus*), a transequatorial migratory bird. The effect of the treatment on the magnetoreceptor was assayed based on the migratory orientation of each bird. Birds were tested in a planetarium without any visible cues available. Each bird served as its own control before treatment, and the effect of the treatment for each bird was computed as deviations in orientation away from its control direction. Birds treated such that the tip of the bill (if it were a magnetic material) would attract the south end of a compass (north-anterior birds) had a deviation of 105° CCW and those treated in the opposite direction (south-anterior) showed a deviation of 51° CW. Birds treated with the polarity vertical through the head and all birds magnetized a second time opposite their original polarity were axially bimodal or were not significantly oriented. These results indicate that treatment with a strong (0.5 T) magnetic impulse affects a magnetic receptor in this species. The material most likely involved in this process is the magnetite which has been reported previously in this species. These results also indicate that the sensory information from the modified receptor is being interpreted by the bird and not ignored. Funding provided by NSF (BNS 9011840).

415.7

BLOCKADE OF NMDA RECEPTORS IN RA DISRUPTS LEARNED VOCALIZATIONS IN ADULT MALE ZEBRA FINCHES. A. Lombardino* and E. Nottebohm. Rockefeller Univ. Field Research Cr., Millbrook, NY 12545

Male zebra finches learn their song and long call by reference to external models. Their nucleus robustus archistriatalis is a key telencephalic nucleus for the production of learned song. RA neurons have NMDA receptors that respond readily to excitatory amino acid stimulation from IMAN. IMAN is necessary for song learning, but electrolytic lesion of IMAN in adulthood does not affect the production of learned vocalizations. Consequently, D,L-APV and MK-801, which are NMDA receptor antagonists, should have little effect on the song and long call of adult birds when administered to RA. To our surprise, this is not the case. Bilateral microinfusion of nanomolar concentrations of D,L-APV or MK-801 into RA reversibly blocked directed song and disrupted the morphology of the long call; song introductory notes were still produced, and depending on the dosage their morphology was unchanged or degraded. The first two or three notes of song were given unchanged and repeated monotonously at drug concentrations below those able to block the whole song motif. There was no effect of these treatments on the unlearned long call of female zebra finches. Control infusions of saline or L-APV had no effect on male vocalizations. Electrolytic lesion of LMAN days or weeks prior to treatment did not abolish these effects. Similarly, lidocaine (8%) microinfusion into IMAN did not interfere with the production of learned vocalizations, nor did it alter the effect of the NMDA receptor antagonists in RA. Taken together, our results suggest that NMDA receptor-mediated glutamatergic transmission in and/or around RA and from non-IMAN sources-- HVC, RA interneurons, or other unidentified afferents-- is important for the production of learned vocalizations in the adult zebra finch.

OPIOID BINDING SITES IN A PASSERINE SONG SYSTEM. C.C. Gullledge* and P. Deviche, Inst. Arctic Biology, Univ. Alaska Fairbanks, Fairbanks, AK 99775.

Specific brain regions, known as the song system, control avian vocalizations. These regions include Area X, n. intercollicularis (ICo) and the Higher Vocal Center (HVC). Some song nuclei contain immunoreactive opioid peptides, but the presence of opioid receptors in these regions has not been examined. We employed *in vitro* autoradiography to localize specific opioid receptors in brain tissues of adult male dark-eyed juncos (*Junco hyemalis*). Tritiated DAMGO, pCI-DPDPE and EKC were used to label μ , δ and κ receptors, respectively. Receptor densities were measured by computerized microdensitometry. Our data show song regions containing high opioid receptor densities, the relative density of binding sites in each region being receptor type-specific. Area X has high μ receptor densities. ICo has relatively high μ and δ receptor densities. The HVC also has relatively high μ and δ receptor densities, but binding is not limited to the region, as adjacent areas of the neostriatum have similar levels. κ receptor densities were low in all the song regions analyzed. Previous studies indicate that opioids have an effect on vocalizations in mammals and chicks. Our results suggest that in passerines this influence depends on direct opioid effects on song nuclei. Further, each opioid receptor type may control different aspects of vocal behavior. Supported by NSF Award BNS-9121258.

THE VOCAL CONTROL PATHWAYS IN BUDGERIGARS ARE STRIKINGLY DIFFERENT FROM THOSE IN SONGBIRDS. G.F. Striedter*, Div. of Biology, California Institute of Technology, Pasadena, CA 91125

Vocal learning has evolved in both oscine songbirds and parrots, but the neural circuits underlying vocal learning are only superficially similar in the two taxa. Injections of biotinylated dextrans into nuclei "MAN", "HVC" and "RA" of budgerigars revealed that "RA" projects bilaterally to the hypoglossal nucleus, that "HVC" projects topographically to "RA", and that "MAN" projects only weakly to both "HVC" and "RA", but heavily to an area immediately surrounding "HVC" and "RA". Nuclei "MAN", "HVC" and "RA" receive inputs from three apparently distinct populations of cells within nucleus "DLM" in the rostradorsal thalamus. All of these connections differ from those observed in songbirds. Most importantly, none of the above-mentioned nuclei receive inputs from the principal telencephalic auditory area, Field L, which provides the auditory input to the vocal control system in songbirds. However, dextran injections into the physiologically identified auditory portions of nucleus basalis revealed that nucleus basalis projects to the overlying frontal neostriatum, which in turn projects to a shelf area surrounding the dorsal portion of "HVC". Some neurons in this shelf area project into "HVC", and some neurons in "HVC" extend dendrites into the shelf area. These data suggest that "HVC" in budgerigars may receive the auditory feedback required for vocal learning via an auditory pathway through nucleus basalis. Physiological recordings from "HVC" in freely moving, vocalizing budgerigars reveal multi-unit bursts of activity preceding each vocalization by an average of 39 ms (sd=21ms), providing the first neurophysiological evidence that nucleus "HVC" in budgerigars may be involved in generating natural vocalizations.

CONTRIBUTIONS OF PHOTOPERIOD AND TESTOSTERONE TO SEASONAL CHANGES IN SONG CONTROL NUCLEI. G.T. Smith*†, E. A. Brenowitz†‡, and J.C. Wingfield†. Depts. of †Zoology and ‡Psychology, Univ. of Washington, Seattle, Washington 98195.

Bird song, like many reproductive behaviors, changes seasonally. Brain regions controlling song also change seasonally in several songbird species. We independently manipulated photoperiod and testosterone (T) in castrated male Gambel's white-crowned sparrows to determine the roles of these variables in mediating seasonal changes in the song control regions (SCRs).

Sixteen adult males were captured during fall migration and kept initially on short days (SD, 8L16D). All males were castrated. Half of the males received implants containing T, and the other half received blank (BL) implants. Half of each group was transferred to long days (LD, 20L4D), while the other half was kept on SD. This created 4 groups (LD+T, LD+BL, SD+T, SD+BL) of 4 males each. We collected blood samples during the study to determine plasma concentrations of T. Birds were sacrificed after 6 weeks. Nissl-defined volumes of the SCRs HVC, RA, X, LMAN, and nXII and of 3 regions not involved in song (SPM, Rt, and Pt) were measured.

HVC, RA, and X were larger in T males than BL males, regardless of photoperiod treatment. T-treated males also had larger neurons and less densely spaced neurons in RA than BL males. T had no significant effects on the volumes of any other brain region. Photoperiod did not have a significant effect on the volume of any of the brain regions measured. These results suggest that testosterone plays the dominant role in mediating seasonal effects on the SCRs. GTS is an HHMI Predoctoral Fellow.

SYNAPTIC ACTIVITY OF NEURONS IN ZEBRA FINCH SONG NUCLEUS HVc IN RESPONSE TO AUDITORY STIMULI. M.S. Lewicki and A.J. Doupe*, Division of Biology, Caltech, Pasadena, CA 91125

Neurons in the caudal nucleus of the ventral hyperstriatum (HVC) of the zebra finch have responses that are sensitive to the temporal structure of the bird's own song. Extracellular studies have shown that the responses can depend on the order of song syllables. Furthermore, the neurons are capable of preserving auditory information over periods greater than several hundred milliseconds after the offset of the stimulus. To investigate the mechanisms underlying these computations, we used *in vivo* intracellular and whole cell patch recordings of adult male HVC neurons in response to a variety of auditory stimuli. The intracellular records exhibit response patterns similar to those observed extracellularly. Some neurons show a strong preference for the bird's own song over both the reversed song and over the normal syllables presented in reverse order. We observed both excitatory and inhibitory potentials with time scales lasting from tens of milliseconds to several seconds following the stimulus. Single song syllables can evoke both excitatory and inhibitory post-synaptic potentials which are present in the absence of spiking and have voltage-dependent amplitudes. Synaptic responses to a single syllable can outlast the stimulus by more than a second. We have observed a variety of synaptic responses which in concert provide a basis for understanding the characteristic sensitivity of HVC neurons to the temporal structure of song.

LESIONS OF mMAN PRODUCE SLIGHT DISRUPTIONS IN VOCAL BEHAVIOR OF JUVENILE MALE ZEBRA FINCHES. E.F. Foster* and S.W. Bottler, University of Southern California, Los Angeles, CA 90089-2520.

The medial magnocellular nucleus of the anterior neostriatum (mMAN) is a small nucleus of the songbird forebrain which sends an axonal projection to the Higher Vocal Center (HVC), a nucleus known to be critical for normal song production in adult birds. mMAN also receives a single afferent projection from neurons in the dorsal thalamus. In order to assess the role of mMAN in vocal behavior, it was lesioned bilaterally using ibotenic acid in adult and juvenile zebra finches. Complete lesions of mMAN in adult birds did not produce any disruption of vocal behavior. Two juvenile males that received lesions at 42 days of age showed slight disruption of their adult song behavior. The overall stereotypy of note sequencing was maintained, however, lesioned birds produced fewer notes than did normal controls and individual notes tended to be either omitted or repeated within a song bout. The quality of some individual notes tended to be poor and notes were of longer duration compared to notes typical of normal birds. The lack of a behavioral effect of mMAN lesions in adults is especially interesting because lesions of HVC, the only known efferent target of mMAN, dramatically disrupt song behavior in adults. The effect of mMAN lesions in juveniles may correspond to the time when HVC axons are establishing synapses with one of its main targets, RA, which in turn projects to the motor neurons innervating the vocal organ.

CHANGES IN CATECHOLAMINE LEVELS AND TURNOVER IN THE BRAINS OF MALE ZEBRA FINCHES DURING DEVELOPMENT. S.R. Barclay, C.F. Harding*, and S. Waterman. Biopsychology Program, Hunter College, CUNY, New York, NY 10021

In adult zebra finches, catecholamine (CA) levels and turnover in hypothalamic and vocal control nuclei (VCN) are modulated by gonadal hormones. In adults, initiation of courtship singing is dependent on norepinephrine (NE) levels in particular VCN. The primary goal of the current project was to quantify CA levels and turnover in ten behaviorally-relevant brain nuclei (6 VCN, 2 hypothalamic, 2 auditory) at four critical points during development of the VCN and the sensitive period for vocal learning. Aviary-housed finches were sacrificed at 25, 35, 55, and 90 days of age. Some birds were pretreated with alpha-methyl-para-tyrosine to allow estimation of CA turnover. Preliminary study showed that this method worked as well in juveniles as in adults. Brain nuclei were microdissected and CA levels quantified by HPLC-EC. In most nuclei, CA function varied profoundly over development. In most VCN, NE function was highest at days 25 and/or 35, while in hypothalamic nuclei, NE function was maximal at day 90. In most brain nuclei, dopaminergic (DA) function showed clear peaks early in development. In a given nucleus, peak NE and DA function did not coincide. Further research is necessary to determine whether these changes in CA function are related to sexual differentiation of these brain areas and/or to vocal learning.

EUROPEAN STARLINGS SHOW DEVELOPMENTAL CHANGES IN RECEPTOR DENSITY AND VOLUME OF SONG CONTROL NUCLEI AS DEFINED BY AUTORADIOGRAPHY FOR MUSCARINIC CHOLINERGIC RECEPTORS AND α_2 -ADRENERGIC RECEPTORS J.M. Casto*, D.J. Bernard and G.F. Ball Dept of Psychology, Johns Hopkins University, Baltimore, MD 21218, USA

Four song control nuclei, the hyperstriatum ventralis pars caudalis, the nucleus robustus archistriatalis, the magnocellular nucleus of the anterior neostriatum, and area X (HVC, RA, MAN, and X respectively) in adult European starlings can be discerned from the surrounding neural tissue based on the density of both muscarinic cholinergic and α_2 -adrenergic receptors. In adults, area X and HVC have high muscarinic and α_2 -adrenergic receptor densities relative to surrounding structures and MAN and RA are defined by low muscarinic receptor density but high α_2 receptor density relative to surrounding structures. We used *in vitro* receptor autoradiography for muscarinic cholinergic (defined by N-methyl scopolamine binding) and α_2 -adrenergic receptors (defined by p-amino clonidine binding) in order to compare the distribution of these receptor sub-types in 20-day old and adult starlings. All four nuclei in 20-day old starlings are characterized by a high density of α_2 -adrenergic receptors relative to surrounding tissue. Juvenile and adults had similar α_2 receptor densities in RA. The volumes of RA and HVC as assessed from the density of α_2 receptors were 2-5 times larger in adults than in juveniles. In 20-day olds, unlike adults, RA is characterized by high muscarinic receptor density relative to the surrounding archistriatum. Mean muscarinic receptor density in RA is 6-7 times higher in juveniles than in adults. Thus, during starling development muscarinic receptor density in RA decreases, α_2 receptor density remains constant, and the volumes of RA and HVC increase. Such developmental changes in the song system may provide insight concerning the neurochemical prerequisites for song learning and behavior.

415.17

BRAIN SPACE FOR LEARNED PRODUCTION BUT NOT PERCEPTION OF SONG IN MARSH WRENS. E. Brenowitz*, B. Nalls, C. Horning, and D. Kroodsmo. Depts. of Psychol. & Zool., Univ. of WA, Seattle, WA 98195 & Dept. of Zool., Univ. of MA, Amherst, MA 01003.

The song nuclei HVC and RA are larger in male birds that produce larger song repertoires. These nuclei act both in song production and perception. In singing birds it is difficult to determine the extent to which the size of these nuclei reflects a commitment of brain space to producing or perceiving song repertoires. We tested the hypothesis that species differences in the size of song nuclei are related to the need to perceive conspecific song by comparing HVC and RA in nonsinging females of two marsh wren species (*Cistothorus palustris* eastern & western). Western male wrens have larger song repertoires than eastern males.

Using Nissl-stained sections, we measured the absolute volumes of HVC and RA, as well as their volumes relative to the thalamic nucleus Rt and to the entire telencephalon of males and females. We also measured density, number, and somal area of HVC neurons. To determine whether Nissl stain accurately identified the borders of HVC, we incubated sections with the H222Py monoclonal antibody to the human estrogen receptor (Abbott).

Western and eastern female wrens did not differ in any measured attributes of HVC or RA. The volumes of HVC and RA, and cellular attributes of HVC, however, were greater in western males than in eastern males. Also, these nuclei were much larger in males than in females. Female wrens thus do not provide evidence of anatomical specializations for perceptual processing of conspecific male song.

ORGANIZATION OF SELECTIVE AUDITORY RESPONSES IN A VOCAL NUCLEUS OF THE ZEBRA FINCH. D.S. Vicario* and S.J. Chew. The Rockefeller University, New York, NY 10021.

Songbirds learn their songs by imitating models that they hear. In the zebra finch, the long call is also learned through imitation. Production of these learned vocalizations depends on a specialized vocal control pathway in the songbird brain. Nuclei on this pathway, including nucleus robustus archistriatalis (RA), are known to respond to auditory stimuli, and to respond preferentially to the bird's own song (BOS). We wanted to further characterize the effective features of auditory stimuli, including calls, and to compare the auditory preferences of neurons located in subregions of RA known to have different brainstem projections.

Single and multi-unit recordings were carried out in adult male zebra finches, either awake or anesthetized with urethane. The birds heard BOS, the bird's own call (BOC), degraded versions of BOS, and the songs and calls of conspecifics. Of the 43 units at 15 recording sites analyzed so far, 81% had strong selective responses to specific components of BOS, consistent with earlier reports. Most units also responded vigorously to BOC. At each site, we were able to discriminate 2-6 (median=3) single units; however, not all units at a given site responded to the same stimulus component(s). Response patterns also differed between recording sites.

These results confirm earlier reports of song-selective responses in RA, and extend them to the learned long call, which is acoustically similar to song syllables. The spatial data suggest that RA is not topographically organized into local zones specific to a given syllable.

TWO INDEPENDENT MARKERS DEMONSTRATE AN INCREASED VOLUME OF HVC IN SHORT-DAY PHOTOSENSITIVE RELATIVE TO LONG-DAY PHOTOREFRACTORY EUROPEAN STARLINGS D.J. Bernard* and G.F. Ball Department of Psychology, Johns Hopkins University, Baltimore, MD 21218, USA

Seasonal changes in the volume of several song control nuclei observed in song birds are believed to arise as a result of fluctuating levels of circulating testosterone (T). Although T is elevated in "spring" birds, there may also be extra-gonadal effects of long days. For example, T treatment results in greater masculinization of nucleus robustus archistriatalis (RA) of female canaries on long than on short days (DeVoogd et al., 1985). In this experiment we dissociated the effects of long day lengths and elevated T levels. We placed photosensitive male European starlings (*Sturnus vulgaris*) on 11L:13D or 16L:8D photoperiods for 5 months. On 11L:13D (a day length characteristic of shortening days in late October), there is gradual recrudescence of the gonads such that after 3 to 4 months they approach maximal size. Thus, starlings in this condition have elevated T titres even though they are experiencing short days. In contrast, starlings maintained on 16L:8D initially show marked gonadal growth. However, after about 4 weeks the birds become photorefractory and the gonads regress. These starlings have low T titres even though they are on long days. At sacrifice the 11L:13D and 16L:8D birds had mean left testis volumes of 303.18 and 6.59 mm³, respectively. Comparison of the high vocal center (HVC) from Nissl stained sections revealed that the volume was approximately 40% larger in the 11L:13D than in 16L:8D birds. Previous work (e.g., Gahr, 1990) has indicated that "seasonal" changes in HVC volume evident in Nissl stained tissue may not be apparent when investigated with independent cytoarchitectural criteria. The density of α_2 -adrenergic receptors as determined by *in vitro* receptor autoradiography with [³H] p-amino-clonidine (PAC) is higher in HVC than in the surrounding neostriatum, clearly defining the boundaries of the nucleus. We reconstructed the volume of HVC using PAC autoradiography on adjacent sections. The results were identical to those from the Nissl stained tissue. While these results do not rule out the possibility of T-independent effects of long days, they indicate that the effects of T on HVC volume are more dramatic than the effects of long days alone.

SONG LEARNING IN ISOLATED ZEBRA FINCHES: ADULT LEARNING AND CONVERGENCE OF SIBLING SONG. S.E. Volmar and H. Khanna. Dept. of Zoology, The Ohio State University, Columbus OH 43210.

Zebra finches reared in isolation from an adult male tutor develop an isolate song that is less stereotyped than the song of normal adults. It has been reported that such birds can learn as adults when exposed to a song tutor (Eales, 1985). We have repeated these experiments and found that isolate birds did, sometimes, learn new song within 2-3 weeks after a tutor was introduced after at least 90 days of song isolation. However, adult learning occurred under only some circumstances. In our experiments, male birds (N=10) isolated with male siblings were never successfully tutored as adults, and only some birds that were isolated and then tutored alone changed their songs. Furthermore, the song of lone-male birds was, on average, less stereotyped at 90 days than that of males reared together, and the songs of group-reared birds were often more similar to their sibling's songs than expected from previous reports, although they remained less stereotyped than the songs of normal adult males. These results suggest that lack of song stereotypy is not necessarily correlated with a zebra finches' ability to modify its song as an adult. They also suggest that siblings can, to some extent, learn song from each other during the normal sensitive period if an adult song tutor is not present.

FUNCTIONAL PARTITIONING OF SYRINGEAL HALVES DURING SONG. S.E. Allan and R.A. Suthers. Medical Science Program and Center for the Integrative Study of Animal Behavior, Indiana University, Bloomington, IN 47405.

Bronchial airflow and thoracic air sac pressure were recorded in brown-headed cowbirds (*Molothrus ater ater*) during song. The right and left syringeal halves control the production of different aspects of the song. The left side of the syrinx produces the low constant frequency (0.5-1.5 kHz) syllables of the introductory notes. The right side of the syrinx produces higher frequency (1-6 kHz) syllables with more pronounced frequency modulation within the introductory notes, as well as, the final whistle (5-13 kHz). Inspiration during song is predominantly controlled by the left side of the syrinx. The correlation coefficients of pressure and flow patterns provide a measure of stereotypy in the motor dynamics, permitting song matching within and across individuals. The partitioning of the frequency range and inspiratory contributions is consistent across all birds tested. The functional significance of this partitioning is unknown, but it may facilitate the production of the wide dynamic range typical of cowbird song (0.5- 13 kHz). Supported by NIH #NS29467 & NS09229

DIFFERENCES BETWEEN MOTOR RECRUITMENT AND AUDITORY RESPONSE PROPERTIES IN ZEBRA FINCH HVC NEURONS. C.-H. Yu*, D. Margoliash, Com. Neurobiology, Dept. Organismal Bio. & Anat., University of Chicago, Chicago, IL 60637.

We have characterized the motor and auditory properties of single HVC neurons in male zebra finches (*Taeniopygia guttata*). Birds were chronically implanted with microwire bundles. Single units were extracted from multiunit recordings using spike waveform template matching techniques. Auditory stimuli included the bird's own song (BOS), modifications of BOS, and conspecific songs.

When birds sang, all neurons analyzed were active throughout the song. Neuronal activity increased 60-70 msec preceding the onset of each song, and terminated 30-70 msec before the end of each song. Motor recruitment histograms were unique for each syllable type and independent of the position of the syllable in the song.

In contrast, excitatory auditory responses to playback of BOS tended to be phasic, and correlated with specific syllable types of BOS. Auditory responses were dependent on the position of the syllable in BOS, and were weaker in response to the time reversed BOS or to conspecific songs. There was no apparent correlation between auditory response and motor recruitment histograms.

The spontaneous activity immediately preceding and following song production was higher than the spontaneous activity during non-singing periods. We observed a gradual transition of the spontaneous activity level, lasting 2-5 sec, from non-singing periods to pre-singing activity level. Thus, the same single units may be recruited with different network properties during production and perception of song.

EARLY ISOLATION FROM CONSPECIFIC SONG DOES NOT SUSTAIN ENHANCED MK-801 BINDING IN AN AVIAN SONG NUCLEUS. K.W. Nordeen*, S.M. Aamodt and E.J. Nordeen. Psychology Dept., Univ. of Rochester, Rochester, NY 14627.

In many avian species, birds are most likely to reproduce songs heard during a restricted developmental period. In male zebra finches, this sensitive learning period correlates with an age-related decline in NMDA receptors within the lateral magnocellular nucleus of the anterior neostriatum (IMAN), a brain area necessary for song learning. In the IMAN, binding of the NMDA receptor antagonist [³H]MK-801 is twice as high in 30 day males within the sensitive period as in adults (Aamodt et al., 1992). To test the hypothesis that the sensitive period for song learning is linked to the high NMDA receptor binding typical of juveniles, we measured [³H]MK-801 binding in young adult male zebra finches (80 days) that had been isolated from an appropriate song model from 10 days posthatch. This early isolation interferes with normal song development and reportedly extends the sensitive period for song learning beyond its normal closure around 60 days of age (Eales, 1987).

Early isolation from song did not affect NMDA receptor binding at 80 days of age. [³H]MK-801 binding within IMAN of controls (0.106 ± 0.003 pmoles/mg tissue, N=11) was not significantly different from that in isolates (0.107 ± 0.005 pmoles/mg tissue, N=10). If isolates, but not controls, are capable of acquiring new songs at 80 days of age (a prediction we are now confirming), our data suggest that the sensitive period is not defined by levels of NMDA receptor binding within IMAN.

ESTROGEN-INDEPENDENCE OF NEUROGENESIS IN THE ADULT CANARY FOREBRAIN. A. Hidalgo*, S.A. Goldman, Dept. of Neurology and Neuroscience, Cornell Univ. Medical College, New York, NY 10021.

The vocal control nucleus HVC of the songbird brain exhibits persistent neurogenesis in adulthood. In females, the rate of neurogenesis is not affected by testosterone (Goldman and Nottebohm, *PNAS* 80:2390-94, 1983), despite androgen induced neuritic arborization, angiogenesis and gliogenesis. We asked whether estrogens might influence adult neurogenesis, by assessing the effect of ovariectomy (OvX) upon neuronal production in the canary HVC. Fifteen adult females were separated into groups of ovariectomized (OvXed; n=4), estradiol silastic-replaced OvXed (n=8), and sham-operated birds (n=3). In order to label dividing cells and their progeny, the birds were injected bidaily for 8 days with ³H-thymidine, sacrificed 32 days later, and their brains autoradiographed. We found no difference in the HVC neuronal labeling indices (LI) between untreated OvXed birds (LI=8.1±4.18%) and estrogen-replaced OvXed birds (LI=8.0±3.00%). Interestingly, a small but significant fall in the NLI was noted in the sham-operated birds (LI=3.9±2.94%), relative to their ovariectomized counterparts. Among estrogen-replaced OvXed birds, the Lis were no different between birds given estradiol before (7.7±2.95%) and after (8.4±3.05%) ³H-thymidine. RIA confirmed that serum estrogen levels were reduced in the castrated (25 pg/ml), compared to the estrogen-replaced (269 pg/ml) and gonadally-intact birds (88 pg/ml). Since cells within the HVC exhibit estrogen receptor immunoreactivity (ER-IR), we asked whether the new neurons or their precursors expressed ER-IR. Two female canaries were given ³H-thymidine for either 4 or 14 days, then sacrificed, probed for ER-IR, and autoradiographed. ³H-thymidine+ cells displayed no detectable ER-IR within their first 2 weeks of postmitotic life. Rather, during migration from the ventricular zone, the new neurons appeared to traverse a layer of mitotically-quiet, ER+ subventricular cells. These results suggest that estrogen does not influence the rate of neuronal production or the early postmitotic survival of the newly generated neurons of the adult canary brain. ACUTE BLOCKADE OF N-METHYL-D-ASPARTATE (NMDA) RECEPTORS DURING SONG EXPOSURE PREVENTS SONG LEARNING IN ZEBRA FINCHES. S.M. Aamodt*, E.J. Nordeen and K.W. Nordeen. Psychology Dept., Univ. of Rochester, Rochester, NY 14627.

During avian vocal learning, birds memorize a conspecific song model and then use auditory feedback to match their vocalizations to that model. Since experience-dependent behavioral and synaptic plasticity have been linked to activation of N-methyl-D-aspartate (NMDA) receptors, recent studies have addressed their role in avian vocal learning. In zebra finches, NMDA receptors are present in song control nuclei, and NMDA receptor binding declines with age in one brain region specifically implicated in song learning (Aamodt et al., 1992). We report here that blocking NMDA receptors during song memorization impairs song development.

From 21 to 50 days, all birds were housed with a singing tutor for two hours every other day. No other song model was available at any time. Experimental birds (MK-exp, N=7) were injected with the noncompetitive NMDA receptor antagonist MK-801 (0.1 mg/kg) just before tutoring and with saline on nontutoring days. One control group (N=4) received saline before tutoring and MK-801 on nontutoring days, while another control group (N=4) received saline on all days. Finally, to control for motoric side effects of MK-801, some birds (N=3) received the dopamine receptor antagonist haloperidol (0.08 mg/kg) before tutoring and saline on nontutoring days.

In adulthood, no MK-exp bird shared any song notes with the tutor. In contrast, most control birds had copied elements of the tutor's song. Songs produced by MK-exp birds contained abnormal notes that resembled those of birds never exposed to a song model. Moreover, at 120 days, over a month after normal birds develop stereotyped adult song, the songs of MK-exp birds were still changing. We are now determining if these same birds can learn a new song model in adulthood.

THALAMIC AUDITORY INPUT TO VOCAL CONTROL NUCLEI IN THE BUDGERIGAR. S. E. Durand, W. S. Hall and S. E. Brauth*. Dept. of Psychology, Univ. of MD., College Park, MD. 20742.

Auditory projections derived from cell groups surrounding core neuronal populations of the auditory midbrain and thalamus may provide parallel input to vocal control nuclei in the budgerigar. Neurons along the medial margin of the inferior colliculus project axons to peri-ovoidal cell groups in the thalamus that contain acoustically responsive units. These include the n. dorsomedialis (DMP) and dorsolateralis posterior and the external shell of n. ovoidalis. All three cell groups are afferent to the ventral paleostriatum which projects directly to the magnocellular nucleus of the anterior neostriatum (MAN) in the budgerigar. In addition, DMP projects directly to MAN. In the oscine song system, MAN is critical to the acquisition of vocal patterns, a capacity exhibited by adult budgerigars in response to changes in their social environment. A second pathway from the peri-ovoidal thalamus appears to directly target the archistriatal (motor) nuclei of the budgerigar vocal system.

Lesions that involve the ventral paleostriatum and peri-ovoidal thalamus disrupt vocal learning in young budgerigars who have not yet learned to produce contact calls. These results argue that direct thalamotelencephalic pathways to paleostriatal and vocal motor nuclei may play a critical role in the acquisition of vocalizations by auditory experience. EFFECTS OF HYPERSTRIATAL LESIONS ON IMPRINTING IN GENETICALLY VARIABLE QUAIL J.K. Kovach*, Dept. of Research, Menninger Clinic, Topeka, KS. U.S.A.

Imprinting has been long recognized as an outstanding model system in which to study early attachment and the related mechanisms of learning and memory (Hess, 1959, *Science*, 130: 133). The present study tested earlier indications that the medial region of the hyperstriatum ventrale (IMHV) may play a critical role in avian imprinting (Bateson, et al., 1973, *Science*, 181: 576; Horn, G., 1985, *Memory, imprinting, and the brain*, Oxford: Clarendon Press). Post-imprinting performances were compared in genetic control and artificially selected Japanese quail chicks (*C. coturnix japonica*) of variable imprintabilities, with and without bilateral ablation of the medial hyperstriatum by series of stereotaxic radio-frequency lesions. Learning was examined by effects of 1st post-hatch day lesions on subsequent imprinting. Retention was studied by effects of 3rd day lesions in subjects that exhibited strong stimulus preferences due to prior imprinting. Data indicated highly significant and genetically variable learning in all preparations. Systematically variable small deficits in Hi imprintability selected subjects indicated stimulus specific lesion effects in learning, and differential mediation of the learning and retention of imprinted memory. Earlier inferences about hyperstriatal functions are examined in the light of the data, and the uses of genetic variability for modeling the mechanisms of learning and memory are discussed.

LOCAL INTRACEREBRAL IMPLANTS OF ESTROGEN MASCULINIZE SOME ASPECTS OF THE ZEBRA FINCH SONG SYSTEM. W. Grisham*, G.A. Mathews, & A.P. Arnold. Dept. of Psychology and Brain Research Institute, UCLA, Los Angeles, CA. 90024-1563.

Estrogen administration during an early critical period has long been known to masculinize the morphology of sexually differentiated brain areas in both song birds and mammals. This study investigated sites of estrogen action on morphology using localized microimplants of estradiol benzoate (EB).

Female zebra finch nestlings 10-13 days old were implanted with Silastic pellets containing 2 µg EB near the higher vocal center (HVC) (n=7), in the brain distant from HVC (n=12), or in the periphery under the skin of the breast or in the peritoneal cavity (n=9). Controls were either unimplanted (n=5) or implanted near HVC with blank Silastic pellets without hormone (n=7). The brains were fixed by perfusion at 60 days, removed, sectioned at 30 µm, and thionin-stained. Cross sectional areas of HVC, RA, and IMAN neurons were measured.

HVC neurons were larger (more masculine) in the HVC-implanted group than in the other groups, which did not differ among themselves. This result suggests that implants near HVC were at or near the site of estrogen action. The distance of the EB pellet to HVC was inversely correlated with the degree of masculinization of RA and IMAN soma size across brain-implanted groups. To our knowledge, this is the first demonstration of localized implants causing morphological masculinization. Supported by NIH NRSA 1 F32 NS09040 to W.G. and USPHS DC002179-09 to A.P.A.

HORMONAL CONTROL OF REPRODUCTIVE BEHAVIOR: IMMEDIATE EARLY GENE EXPRESSION

416.1

A D1 ANTAGONIST DECREASES COPULATION-INDUCED C-FOS EXPRESSION IN MPOA. L. A. Lumley¹, T. J. Bazzett² and E. M. Hull¹. ¹Department of Psychology, SUNY at Buffalo, Buffalo, NY 14260; ²Department of Biopsychology, University of Michigan, Ann Arbor, MI 48104

Copulation increases the expression of the immediate-early gene c-fos in several steroid-concentrating areas, including the MPOA, in male rodents (Baum & Everitt, 1991; Kollack & Newman, 1991; Robertson et al., 1991). Dopamine agonists, such as cocaine or amphetamine, also increase immunoreactivity to Fos, the protein product of c-fos, in the striatum; this effect was blocked by a dopamine D1 antagonist, suggesting that stimulation of D1 receptors may be an obligatory step in this process (Graybiel et al., 1990; Young et al., 1991).

Copulation-induced expression of Fos in the MPOA may also depend on stimulation of D1 receptors. Copulation increases dopamine release in the MPOA (Blackburn et al., 1992; Hull et al., 1993). We administered a D1 antagonist (SCH-23390), a D2 antagonist (raclopride) or vehicle to male rats 30 min before they copulated to one ejaculation. Control animals were injected with vehicle, but were not allowed to copulate. Animals were sacrificed one hour after ejaculation, or 90 min after injection of controls.

Copulation significantly increased the number of Fos-immunoreactive cells in the MPOA. Pretreatment with the D1, but not the D2, antagonist decreased the number of labeled cells, compared to the vehicle-copulation animals. Thus, stimulation of D1 receptors in the MPOA contributes to the copulation-induced increase in Fos reactivity.

416.3

CASTRATION DECREASES c-FOS LABELLING IN THE MPN mgn FOLLOWING EXPOSURE TO FEMALE HAMSTER VAGINAL SECRETIONS (FHVS). J.M. Swann*, Department of Biological Sciences, Rutgers University, Newark, N.J. 07102.

In male Syrian hamsters exposure to vaginal secretions from females stimulates anogenital investigation and copulatory behavior. This behavior appears to be mediated by three central areas of the vomeronasal pathway. Using c-fos as a marker for neuronal stimulation, we found an increase in the number of c-fos neurons in the posteromedial bed nucleus of the stria terminalis (BNSTpm), posterior medial nucleus of the amygdala (Mp) and the magnocellular medial preoptic nucleus (MPN mgn) of gonadally intact male hamsters following exposure to FHVS. Copulatory response to FHVS is dependent on circulating gonadal steroids. To determine if neuronal stimulation in response to FHVS is dependent on testosterone we compared c-fos levels in the vomeronasal pathway of castrated males to that of intact males and castrated males treated with testosterone.

Male Syrian hamsters that were intact (n=3), castrated for 15 weeks (n=3), or castrated for 9 weeks and treated with testosterone for 6 weeks (n=3) were given a cotton swab with FHVS and perfused one hour later. Brains were then removed, sectioned and processed for c-fos immunocytochemistry. The number of c-fos labelled neurons does not differ among all treatment groups in rostral and caudal M, BNSTpm, BNST posterior intermediate, and the medial MPN. However, exposure to FHVS stimulated fewer neurons in the MPN mgn of castrated animals than that of intact or testosterone treated castrates (p < .05). These data suggest that castration prevents exposure to FHVS from stimulating neurons in the MPN mgn. Previous studies indicate that this nucleus regulates copulatory behavior in male hamsters. Thus, our results suggest that testosterone regulates the expression of copulatory behavior by regulating chemosensory input to this nucleus. Supported by NIH R29HD28467.

416.2

C-FOS IN THE SEXUALLY DIMORPHIC AREA (SDA) OF THE GERBIL HYPOTHALAMUS, AND RELATED AREAS, DURING SEXUAL ACTIVITY. M. M. Heeb* and P. Yahr. Dept. of Psychobiology, Univ. of California, Irvine, CA 92717.

The SDA is necessary for male sexual behavior but may also serve other functions. It projects to 70+ areas of the brain and is reciprocally connected to most of them. One way we are identifying the pathways that mediate sex behavior is to determine which areas express c-fos during sexual activity. Groups of 4 male gerbils matched for sexual experience are prepared for immunocytochemistry after exposure to a female and ejaculating, intromitting, mounting or only investigating. Sexually experienced males were also studied without testing. The mating environment induced c-fos in the SDA, nucleus accumbens, caudomedial bed nucleus of the stria terminalis, posterodorsal medial amygdala, ventral preammygdala nucleus, paraventricular nucleus of the hypothalamus, central tegmental area and retrorubral field (RRF). Ejaculation produced the most labeling and investigation the least. Two areas, the posterodorsal preoptic nucleus (PDPN) and the projection field of the RRF in the ventral pallidum (VP), expressed c-fos only after minimum levels of sexual activity are attained. To date, only males that intromit and/or ejaculate have labeled cells in VP; only those that ejaculate have labeled cells in the PDPN.

REDUCED MOUNTING RATES IN MALE MICE WITH A NULL MUTATION OF THE c-FOS PROTO-ONCOGENE. M.J. Baum*, J.G. Brown², E. Kica², B.S. Rubin³, R.S. Johnson³ and V.E. Papaioannou⁴. Dept. of Biology¹, Boston University, Boston, MA 02215, Dept. of Pathology² and Dept. of Anatomy⁴, Tufts University School of Medicine, Boston, MA 02111 and Dana-Farber Cancer Institute³, Harvard Medical School, Boston, MA 02115.

Mount latencies were longer and subsequent mounting rates with estrous females were significantly lower in male mice homozygous for a null mutation of the c-fos proto-oncogene than in heterozygous mutant or wild-type controls. Even so, an equivalent percentage of mounts led to penile intromission, an equivalent number of intravaginal thrusts was displayed, and the incidence of ejaculation was similar among males of the three genotypes. The nuclear protein product (FOS) of c-fos was visualized immunocytochemically in the brains of heterozygous male mutants which were killed 1h after they ejaculated. Compared with unmounted controls, increased FOS immunoreactivity was present in neurons of the medial amygdala, the bed nucleus of the stria terminalis, the medial preoptic area (mPOA), the paraventricular nucleus, and the midbrain central tegmental field. Thus, in male mice, as in several other rodent species, c-fos expression increases in limbic and midbrain circuits which convey olfactory/vomeronasal as well as genital/somatosensory information to the mPOA following contact with an estrous female. These increments in neural c-fos expression may normally contribute to the initiation and maintenance of masculine sexual arousal during a series of mounts and intromissions leading to ejaculation. Supported by HD21094, MH00392 (MJB) and HD27295 (VEP).

416.5

CELL BODY LESIONS OF THE VENTRAL PREMAMMILLARY NUCLEUS DISRUPT MALE COPULATORY BEHAVIOR WITHOUT ALTERING BEHAVIORAL ACTIVATION OF HYPOTHALAMIC C-FOS. S.G. Truit*, T. R. Akesson, and C. Ulibarri, Dept of VCAPP, WSU, Pullman, WA 99164

Afferent and efferent connections of the ventral premammillary nucleus (PMv) interact with other hypothalamic nuclei to make up a system that is involved in the regulation of male copulatory behavior. After male copulatory behavior the early response oncogene, c-fos, is activated in nuclei that project to and receive projections from the PMv. If some of the behavioral deficits that result from PMv lesions were due to decreased interactions with other hypothalamic nuclei, after PMv lesions, we would expect reduced c-fos activation in hypothalamic nuclei that are efferent to the PMv.

To test this hypothesis, sexually experienced male Long Evans rats were castrated and implanted with Silastic capsules containing testosterone. Lesions were created by bilateral infusion of NMDA into the PMv (n = 13). Control rats received sham surgeries (n = 9). Rats were tested weekly for five weeks for male sexual behavior with receptive females. Rats with lesions showed increased intromission latency, ejaculation latency, postejaculatory interval, mount and intromission number as compared to control rats. Copulatory rate and efficiency were decreased relative to control rats. Mount latency was unaffected.

After the last test, rats were killed by aldehyde perfusion either 1 (n = 10) or 1.5 (n = 12) hr after ejaculation. Coronal sections were processed for c-fos immunoreactivity (fos-ir). In comparisons between control and treated rats, similar patterns of fos-ir were seen in the preoptic area, bed nucleus of the stria terminalis, and medial amygdala. These findings suggest that reductions in male copulatory behavior produced by PMv lesions did not affect activation of other nuclei to produce c-fos after copulation. Alternatively, PMv lesions affected cells that did not show c-fos activation after copulation. Supported by HD22869.

416.7

CHEMOSENSORY FACTORS FROM MALE PRAIRIE VOLES INCREASE C-FOS EXPRESSION IN FEMALE CONSPECIFICS

C.A. Moffatt, G.F. Ball, and R.J. Nelson*. Department of Psychology, Johns Hopkins University, Baltimore, MD 21218, USA

Unlike the majority of laboratory rodent species, female prairie voles do not exhibit regular estrous cycles; rather, female prairie voles are induced into estrus by chemosensory stimuli contained in the urine of male conspecifics. Female prairie voles come into contact with these chemosensory factors when they groom the ano-genital region of unfamiliar males. Contact with male urine elicits a surge in luteinizing hormone (LH) release that reaches a peak approximately 30 min after initial contact with the urine.

In the present study, c-fos immunoreactivity was measured to determine which areas of the brain were stimulated in response to exposure to the estrus-inducing stimuli found in male urine. We hypothesized that c-fos immunoreactivity would be greatest in regions of the brain important for the mediation of mating behavior and control of LH release. To test this hypothesis, female prairie voles had a single drop of either male urine or water placed on their external nares. Thirty minutes after exposure to the urine or water, the females were killed and perfused. The brains were processed for immunocytochemistry of c-fos antigen. Females exposed to male urine had a greater amount of c-fos immunoreactivity in nuclei associated with control of LH release than females exposed to water. Specifically, females exposed to male urine had greater numbers of c-fos immunoreactive neurons in the accessory olfactory bulbs, medial preoptic area, lateral preoptic area, and lateral septum than females exposed to water. Exposure to urine also increased c-fos expression in the main olfactory bulbs, anterior olfactory nucleus, and primary olfactory cortex. These results indicate that exposure to male urine stimulates regions of the brain important for the regulation of LH release.

416.9

REDUCED OLFACTORY AND SOMATOSENSORY INPUT DOES NOT DECREASE FOS-LIKE IMMUNOREACTIVITY IN THE MEDIAL PREOPTIC AREA (MPOA) OF MATERNALLY ACTIVE POST-PARTUM FEMALE RATS. A. Fleming*, C.J. Walsh, A. Lee, & M. Korsmit, Dept. of Psych., Erindale College, Univ. of Toronto, Mississauga, ONT L5L 1C6

The expression of the immediate-early gene c-fos in neurons is regulated with great anatomical specificity by a variety of pharmacological and environmental stimuli. The distribution of Fos protein in the brain can be used as a marker to help map functional neural systems involved in sensory processing and behavior.

Previous research shows that postpartum animals who receive a one hour interactive experience with pups exhibit higher density of cells showing Fos-ir in medial preoptic area (MPOA) and medial and cortical amygdala than do other groups receiving a variety of other social and olfactory experiences (Fleming, Korsmit, Suh, and Rusak, Neuroscience, 1992; see also Numan & Numan, Neuroscience, 1992).

This study explores the effects on MPOA and limbic Fos-ir of removing or reducing olfactory and somatosensory input to dams during a post-partum maternal experience. Pregnant females underwent either 1) olfactory desensitization: olfactory bulbectomy or zinc sulfate treatment, 2) ventral somatosensory desensitization: thelectomy (nipple removal) or ventral anaesthetizations, or 3) sham treatments.

Results replicate earlier findings that indicate that dam-litter interactions produce elevated Fos labelling in MPOA and amygdala and show further that a reduction of olfactory or ventral somatosensory stimulation does not significantly decrease Fos-ir in the MPOA. We are currently investigating the effects of both single and combined olfactory and somatosensory desensitization on Fos-ir not only in MPOA, but also in olfactory, limbic, and cortical structures.

416.6

C-FOS EXPRESSION IN FEMALE HAMSTER BRAIN FOLLOWING LORDOSIS AND AGGRESSIVE BEHAVIORS. M. A. Ioppa* and R. L. Meisel. Department of Psychological Sciences, Purdue University, West Lafayette, IN 47907.

In this experiment we determined the expression of c-fos immunoreactivity in areas of the female hamster brain which concentrate estrogen and progesterone, and are critical for lordosis and aggression. Ovariectomized hamsters were given 1) estradiol and progesterone treatment (E+P), but no behavior test, 2) E+P plus a lordosis behavior test, 3) oil treatment plus an aggressive behavior test, or 4) oil treatment, but no behavior test. Immunocytochemistry for c-fos protein was conducted using a primary antibody to human c-fos protein (Oncogene Sciences) and a peroxidase-based Vector ABC Elite kit. Preliminary results show that within the lateral ventromedial hypothalamus (VMH), c-fos expression appeared to be higher in animals given no hormones and tested for aggression than in all other groups. No differences were found in c-fos immunostaining in the central VMH between the 4 groups. Animals treated with E+P and tested for lordosis expressed significantly more c-fos labeled cells in the medial preoptic nucleus than any other group. Cellular activation in forebrain nuclei depend upon the specific social behavior displayed, rather than the female's hormonal status.

Supported by NIH grant HD-21478.

416.8

C-FOS EXPRESSION IN NEUROCHEMICALLY-IDENTIFIED, ESTROGEN RECEPTOR-CONTAINING NEURAL POPULATIONS IN THE FEMALE RAT AFTER MATING. A. E. Herbison (SPON: Brain Research Association) Laboratory of Neuroendocrinology, AFRC Babraham Institute, Cambridge CB2 4AT, U.K.

Recent work in the female rat has demonstrated that estrogen receptors (ERs) are located within 70-80% of the sexually dimorphic calcitonin gene-related peptide (CGRP)-containing neurones in the preoptic area (POA; Herbison et al, Neuroendo, 56, 761) and approximately 60% of somatostatin (SOM) neurones in the ventrolateral division of the ventromedial nucleus (VMN; Herbison, unpublished). The functional roles of these neural populations are not understood. This study, using immunocytochemical detection of FOS as a marker of neuronal activation, has examined whether these SOM and CGRP populations are part of the neural network involved in regulating female sexual behaviour.

Female rats were ovariectomized, treated with estradiol and progesterone, and either placed alone in a testing chamber or paired with a male rat until 10-15 intromissions were observed. In the POA of mated females, a marked increase in FOS immunoreactivity was detected predominantly in the medial preoptic nucleus, as reported previously (Erskine et al., Soc. Neurosci. 1992). Double-labelling of sections revealed that over half of all LHRH neurones were FOS-positive in both female groups while 12±3% of CGRP neurones contained FOS in control animals compared with 30±5% in mated animals (P< 0.05). In the ventrolateral VMN, only a small increase in the numbers of FOS-positive cells was observed. However, in preliminary double-labelling experiments, no SOM neurones were found to contain FOS in non-mated rats compared with approximately 15% of SOM neurones in mated animals.

These results show that neurones in the ER-containing CGRP and SOM cell populations in the POA and VMN respectively, are immunoreactive for FOS after mating and suggest that both neurochemically-defined cell groups may be part of the steroid-sensitive neural network controlling sexual behaviour in the female rat.

416.10

FOS PRODUCTION IN PREOPTIC NEURONS CORRELATED WITH DIFFERENT ASPECTS OF MATERNAL BEHAVIOR IN RATS. M. Numan* and M.J. Numan. Dept. Psychology, Boston College, Chestnut Hill, MA 02167.

Lesion and hormone implant studies have shown that the preoptic area (POA) is essential for maternal behavior. These procedures, however, are not capable of identifying specific POA neurons. In this study we use Fos immunocytochemistry to detect neurons whose activation is associated with maternal behavior. Lactating rats received a 2-hr exposure to the following. Full maternal behavior (FMB): females were allowed to retrieve and nurse pups. Partial pup stimulation (PPS): females were exposed to pups suspended from their cages in a nylon mesh bag. These females could see, hear, and smell (primary olfactory input) the pups but could not perform maternal activities. Candy control (CC): females were exposed to candy pieces in nylon bag. Females were perfused and the presence of Fos-like immunoreactivity was determined. FMB females had more cells labeled with Fos in the medial POA and ventral bed nucleus of stria terminalis than did females in the remaining groups. Fos labeling in the PPS and CC females was low. These results suggest that direct interactions with pups, which involve both maternal performance and pup stimulation (suckling; vomeronasal input) is necessary to activate the POA. Subsequent studies are examining Fos labeling in the POA of females that are only allowed to retrieve or nurse, and in maternally behaving bulbectomized and thelectomized rats.

C-FOS EXPRESSION AND NEUROTRANSMITTER RELEASE IN BRAIN STRUCTURES INVOLVED IN THE INDUCTION OF MATERNAL BEHAVIOUR IN SHEEP. A. Da Costa, K. Broad, R. Guevara* & K.M. Kendrick, AFRC Babraham Institute, Cambridge CB2 4AT, UK; Fac Med. *UNAM, Mexico 04510

In order to identify the neural substrates involved in controlling the induction of maternal behaviour in sheep, the changes in the expression of the immediate early gene, *c-fos*, were mapped. In addition, neurochemical changes occurring during the induction of maternal behaviour and the formation of the ewe/lamb bond were monitored in two areas found to express high levels of *c-fos* mRNA, using microdialysis. The effects of lamb separation followed by the exposure to the odours of an alien or own lamb were also investigated. A ³⁵S labelled oligonucleotide probe was used to map *c-fos* mRNA *in situ*. High expression was found in medial preoptic area, supraoptic nucleus, septum (S) bed nucleus of the stria terminalis, paraventricular nucleus (PVN) and ventromedial hypothalamus of ewes that had maternal behaviour induced by parturition or by artificial stimulation of the vagina and cervix (VCS). Microdialysis employed CMA-10 probes placed over the S and PVN. Ringer was pumped through these probes at 5 µl/min and samples collected every 5 min. Amino-acids and monoamines were measured by HPLC. In both the S and PVN, aspartate (Asp), glutamate (Glu) and GABA release increased during the period 60 to 30 minutes pre-partum or after artificial VCS. Release of noradrenaline (NA), serotonin (5-HT) and dopamine (DA) also peaked at parturition. Similar increases in the release of these neurotransmitters occurred after VCS. The release of NA, adrenalin (AD), DA and 5-HT in the S, and of NA, DA and 5-HT in the PVN increased 5-15 minutes after the removal of the ewe's own lamb. Exposure of the ewe to the odours of an alien lamb specifically increased the concentration of AD in the S and NA in the PVN, whereas similar exposure of the ewes to the odours of their own lambs increased the release of AD in the PVN. Release of NA and DA in the S, and of AD, DA and 5-HT in the PVN, occurred irrespective of whether the lamb presented to the ewe was its own or an alien one. The PVN may be acting through oxytocin release and the S through its connections with the olfactory bulb, hippocampus and preoptic region. (Supported by JNICT, Portugal and MAFF, U.K.)

SEXUAL STIMULATION INDUCES FOS PROTEIN WITHIN GnRH-CONTAINING NEURONS OF THE FEMALE RAT PREOPTIC AREA.

J.G. Pfäus*^{1,2}, S.P. Kleopoulos², A.L. Jakob¹, R.B. Gibbs² & D.W. Pfaff¹.
¹Center for Studies in Behavioral Neurobiology, Department of Psychology, Concordia University, Montréal, Québec, Canada; and ²Laboratory of Neurobiology and Behavior, Rockefeller University, New York.

We and others have shown that sexual stimulation (copulation with intromission, or vaginocervical stimulation) induces *c-fos* mRNA and Fos-like immunoreactivity (IR) within estrogen-concentrating and non-concentrating regions of the female rat forebrain, including regions that contain GnRH cells in the septum and anterior preoptic area. These effects do not appear to require treatment with estrogen or progesterone. Because vaginocervical stimulation facilitates lordosis and increases the release of luteinizing hormone, the present study examined whether hormone treatment or sexual stimulation increase Fos-like IR specifically within GnRH-containing neurons. Ovariectomized rats were administered estradiol benzoate (10 µg) 48 hr and progesterone (500 µg) 4 hr (N=30), or the oil vehicles (N=30), before either 1 hour of copulation (n=5/group), 50 vaginocervical stimulations with a glass rod distributed over 1 hour (n=5/group), or no stimulation (n=5/group). Fos-like IR was found within a significant number of GnRH neurons largely in the anterior preoptic area following copulation with intromission or vaginocervical stimulation compared to no stimulation. Few GnRH cells coexpressed Fos following hormone treatment alone; however, this treatment enhanced the number of GnRH neurons that coexpressed Fos following vaginocervical stimulation, suggesting that estrogen and progesterone may augment the responsiveness of certain GnRH neurons to sexual stimulation.

METABOLIC VERSUS HORMONAL REGULATION OF HAMSTER GnRH NEURONAL ACTIVITY. T.L. Thomas* and G.N. Wade, Dept. of Psychology and Neuroscience and Behavior Program, Univ. of Massachusetts, Amherst, MA 01003.

Separate "pulse-associated" and "surge-associated" GnRH neurons have been posited to exist in Syrian hamster forebrain. These two populations have been hypothesized to be differentially responsive to fuel availability and estrogen levels, respectively. Food deprivation on estrous cycle days 1-2, when LH secretion is pulsatile, interrupts ovulatory cycles, while food deprivation on days 3-4, just prior to the LH surge, does not. *Fos* expression in "pulse-associated" caudal POA GnRH neurons is suppressed following food deprivation on days 1-2 and remains suppressed after 2 days refeeding. Since hamsters do not increase their food intake following deprivation, we speculated that *Fos* activity remains suppressed due to enduring metabolic effects of food deprivation. Experiment 1 found some support for the hypothesis that two days of food deprivation while estrogen levels are high (days 3-4) also results in suppressed *Fos* expression in "pulse-associated" GnRH neurons after two days of refeeding. In addition, we report whether food deprivation while estrogen levels are high differentially suppresses GnRH *Fos* expression in the two populations. Also, since an LH surge can be restored by estradiol (EB) replacement on day 3, following two days food deprivation, we report whether EB differentially restores *Fos* expression in the two populations of GnRH neurons.

A MORPHINE METABOLITE MAY MEDIATE EFFECTS IN THE CENTRAL NERVOUS SYSTEM. J. Mørland*, I. Aasmundstad, R. Paulsen, A. Fallgren and F. Fonnum. Natl Inst Forensic Toxicol and NDRE-TOX, Oslo, Norway.

Morphine (M) is rapidly metabolized by glucuronidation in the liver and gut of several species. The glucuronidation may take place in the '3'-or'6'-position of M. Morphine-6-glucuronide (M6G) has been demonstrated to be a more potent agonist than M. Since M6G is rapidly formed *in vivo* and reaches concentrations higher than M, we wanted to investigate the ability of M6G to cross the blood-brain barrier. We studied freely moving rats implanted with microdialysis tubing in the striatum. After s.c. administration of 1 mg M6G per 100g rat, the concentration of M6G peaked in serum after approximately 20 min at 15 µM, and was about 5 µM after 60 min. The microdialysate concentration of M6G peaked after 60 min at about 0.02 µM and decreased gradually to about 0.003 µM during the subsequent 3 hours. No free M was detected in serum or microdialysate. The dialysate M6G concentration time curve roughly paralleled respiratory depression and analgesia. It is concluded that M6G may cross the blood-brain barrier and mediate some of the central nervous actions of M.

MICRODIALYSIS OF ENKEPHALIN RELEASE IN THE GLOBUS PALLIDUS/VENTRAL PALLIDIUM AFTER SYSTEMIC MORPHINE ADMINISTRATION. M.F. Olive*, M. Bertolucci, C.J. Evans and N.T. Maidment. Neuroscience Ph.D. Program & Dept. of Psychiatry, NPI & BRI, UCLA School of Medicine, Los Angeles, CA 90024.

We have previously demonstrated the feasibility of monitoring opioid peptide release *in vivo* using microdialysis linked to sensitive solid-phase radioimmunoassay procedures (*Neuroscience* 33:549-557). Preliminary experiments on unanesthetized freely moving rats have shown that acute injection of morphine (10 mg/kg i.p.) produces a 3-fold increase in recovered enkephalin levels over a 2-hour period from probes implanted in the globus pallidus/ventral pallidum. This effect was dose-dependent, with no effect being observed with lower (2 mg/kg i.p.) or higher (40 mg/kg i.p.) doses, and also site-specific with negative results being obtained in the caudate and nucleus accumbens. Pretreatment of rats for 16 days with morphine (10 mg/kg i.p.) resulted in tolerance to the effect of a subsequent challenge of the drug.

Experiments designed to examine the time-course of the tolerance phenomenon showed that this was not a rapid effect. Naive rats (n=5) implanted with dialysis probes into the globus pallidus/ventral pallidum were injected with morphine (10 mg/kg i.p.) at 3-hr intervals for a total of 4 injections, and the effect of the 4th administration was not significantly different from that of the 1st. Rats injected with saline (n=6) i.p. showed no elevated levels of enkephalin release.

These data demonstrate the potential of this methodology for studying both the basic pharmacology of opioid peptide release regulation and the role of these peptides in reward pathways.

SPECIFIC EFFECTS OF MORPHINE AND NICOTINE ON NEURONAL RESPONSES TO VENTRAL PALLIDUM AND FIMBRIA STIMULATION IN THE NUCLEUS ACCUMBENS. C. Eyl and R.L. Hakan*. Dept. Psych., Univ. of North Carolina at Wilmington, NC 28403

The effects of systemic nicotine and morphine on neuronal activity in the nucleus accumbens (NAS) of halothane anesthetized rats were examined. Normally inactive NAS neurons antidromically activated by ventral pallidum (VP) stimulation, had mixed responses to nicotine: 8 were inhibited, 5 excited and 2 unaffected. However, NAS units antidromically activated by VP stimulation were consistently inhibited by nicotine ($n=7$) while saline injections had no effect ($n=6$). Similarly, morphine had mixed effects on NAS-VP projection neurons (6 inhibited, 3 excited and 3 unaffected) but reliably inhibited orthodromic responses to VP stimulation (9/10).

Previous studies (SNS, #229.2, 1992) have demonstrated that systemic nicotine inhibits orthodromic responses of NAS units evoked by fimbria stimulation (fimbria-driven) but has no effect on spontaneous NAS activity. In contrast, morphine inhibits spontaneous NAS activity but does not affect fimbria-driven responses. The present study also re-assessed the effects of nicotine and morphine on fimbria-driven and spontaneously active NAS units. Again, fimbria driven NAS units were inhibited by nicotine (7/8) but unaffected by morphine (12/13) while spontaneous activity was unaffected by nicotine (8/10) but inhibited by morphine (6/8). These results demonstrate specificity in the pattern of NAS neuronal responses to drugs of abuse. Moreover, until recently the VP-NAS feedback pathway had been unacknowledged. These results begin to describe the neuropharmacology of this NAS afferent.

REGION SPECIFIC INCREASE IN BRAIN ADENYLYL CYCLASE mRNA IS INVOLVED IN MORPHINE DEPENDENCE

L. Matsuoka¹, R. Maldonado^{2*}, J. Hanoune¹ and B.P. Roques². ¹Dpt. de Pharmacologie et Physiologie Hépatique, U99 INSERM, Hôpital Henri Mondor, 94010 Créteil, France. ²Dpt. de Pharmacochimie Moléculaire et Structurale, U266 INSERM - URA D1500 CNRS, Faculté de Pharmacie, 75006 Paris, France.

Acute administration of opioids decreases adenylyl cyclase activity by acting on Gi-proteins coupled receptors. It has been therefore proposed that during chronic exposure to morphine the neurons could dramatically increase their adenylyl cyclase activity to overcome the constant inhibition of the enzyme leading to an enhancement in neuron excitability. In this study, we examined the effects of chronic infusion of morphine on "in situ" hybridization signals of adenylyl-cyclase and calmodulin in the mouse brain. The present results provides the first direct evidence that chronic morphine treatment induces a selective increase in adenylyl-cyclase mRNA transcript in the locus coeruleus, the amygdala and the thalamus. These changes were observed as early as 12h after morphine chronic treatment. Interestingly, locus coeruleus and amygdala are respectively involved in the expression of physical signs and motivational reactions of morphine abstinence. In addition, the overexpression of adenylyl-cyclase mRNA in thalamic nuclei could participate to morphine tolerance. Moreover, the time course of morphine-induced change in adenylyl-cyclase mRNA is correlated with the severity of morphine withdrawal syndrome. These results are all the most relevant as there was not change in another marker, calmodulin. These findings offer the first mechanistic explanation of morphine dependence at the molecular level.

417.7

MORPHINE INDUCTION OF FOS IN STRIATUM IS MEDIATED BY NMDA AND D1 DOPAMINE RECEPTORS. J. Liu*, J. Nickolenko, F.R. Sharp, Dept. Neurology, Univ. of California and SFVAMC, San Francisco, CA 94121.

Immediate early genes (IEGs) form transcription factors that produce long-term changes in gene expression. Since morphine associated tolerance and addiction can be blocked by MK801, and since NMDA receptor activation can induce IEGs, this prompted a study of morphine.

Morphine (10mg/kg) induced c-fos mRNA, assessed using in situ hybridization, and Fos protein, assessed using immunocytochemistry with the LA041 monoclonal antibody, in medial striatum and nucleus accumbens of adult rats. AP-1 activity was increased in striatum within 1h post morphine. Morphine induction of c-fos mRNA and Fos protein was blocked by MK801 (2mg/kg) and morphine induction of Fos protein was blocked by SCH23390 (1mg/kg), a D1 antagonist. This data suggests that morphine activation of striatal mu receptors cannot induce Fos without the coordinate activation of both D1 and NMDA receptors. If Fos is induced in neurons with mu, D1, and NMDA receptors, the fact that NMDA should act on the SRE in the Fos promoter, and D1 should act on the CRE element in the Fos promoter, suggests that combined activation of SRE and CRE might be required in vivo to induce the Fos gene. Alternatively, the D1 and NMDA receptors might be located on separate neurons both of which would need to be activated in order to induce the Fos gene.

417.4

INTERACTION OF MORPHINE AND THE 5-HT₃ ANTAGONIST, GRANISETRON, ON DOPAMINE AND NON-DOPAMINE CELLS IN THE VENTRAL TEGMENTAL AREA. A.N. Gifford* and R.Y. Wang Dept. Psychiatry, SUNY at Stony Brook, NY 11794.

5-HT₃ antagonists have been found to be effective in suppressing morphine induced place-preference. Moreover, injection of the 5-HT₃ antagonist, tropisetron, into the VTA reverses the morphine-induced increase in extracellular DA levels in the nucleus accumbens. The present study was undertaken to examine whether the latter effect of 5-HT₃ antagonists is mediated by a blockade of the morphine-induced increase in A10 DA cell firing rate. In chloral hydrate anesthetized rats acute granisetron (0.1 mg/kg or 0.5 mg/kg i.v.), failed to attenuate the increase in DA cell firing rate to morphine (cumulative dose 2-4 mg/kg i.v.). Both granisetron and tropisetron were also unable to reverse the rate-increasing effects of morphine when given in exponential increasing doses (up to 0.8 mg/kg, i.v.) immediately after morphine (2 mg/kg, i.v.), whereas naloxone (0.1 mg/kg, i.v.) induced a rapid reversal. These results thus do not support a blockade of morphine's excitation of A10 DA cells as an explanation for the suppression of morphine reward by 5-HT₃ antagonists.

In a second study in which rats were treated chronically for 4-6 weeks with granisetron (0.1 mg/kg s.c. per day) there was also no attenuation in the A10 DA cell firing rate increase to morphine, applied iontophoretically. However, preliminary findings indicated that there appeared to be a shift the response of non-DA VTA cells to iontophoretic morphine from primarily inhibition in control rats (15 cells inhibited, 2 excited, 2 no response) to either no response or excitation in the granisetron treated rats (2 cells inhibited, 11 excited, 15 no response; $P < 0.001$, Chi-square test comparing proportion cells inhibited in control versus treated rats).

CHRONIC MORPHINE TREATMENT INDUCES c-JUN mRNA EXPRESSION IN RAT DORSAL ROOT GANGLION NEURONS. D. Besse, K. Ren and M.A. Ruda* NAB, NIDR, NIH, Bethesda, MD 20892.

In order to assess the molecular basis of morphine tolerance, the effects of chronic intrathecal (i.t.) morphine on transcription factor regulation were examined in dorsal root ganglia (DRG).

In one study, a cannula was inserted into the spinal subarachnoid space in anesthetized adult male rats. The next day, an osmotic pump (Alzet® 2001) filled with either saline (SAL) or morphine (MOR, 10µg/hr) was subcutaneously implanted and connected to the i.t. canula of rats exhibiting no motor impairment ($n=3$ per group). L2 to L6 DRG were collected bilaterally after 4 days. Total RNA was extracted and Northern blots were performed using a ³²P-labeled 51-mer oligonucleotide probe complementary to bases 2810-2861 of rat c-Jun. The characteristic c-Jun hybridization bands at 2.7 and 3.1 Kb were found in each experimental group (naive, SAL and MOR). For both bands, the level of mRNA expression was similar in the SAL and naive groups. However, in the MOR group, c-Jun mRNA levels were increased for both the 2.7 (100%) and 3.1 (59%) Kb bands as compared to the SAL group. In a parallel study, 2 days after repetitive subcutaneous injections of morphine (40mg/kg, every 12 hrs), the c-Jun mRNA induction was 57% and 47% for the 2.7 and 3.1 Kb bands, respectively.

The morphine-induced increase in c-Jun mRNA may be related to behavioral tolerance, since the initial morphine-induced increase in paw withdrawal latency from radiant heat had returned to control (naive or SAL) values by 4 days. Furthermore, since µ opioid receptors are numerous on spinal Aδ- and C- afferent fibers, the long-term binding of morphine to spinal µ opioid receptors may produce a modification in the second messenger cascade leading to a transcription factor regulation in the DRG.

INJECTIONS OF METHYLNALOXONIUM INTO THE LOCUS COERULEUS PRODUCE CEREBRAL HYPERMETABOLISM IN MORPHINE-DEPENDENT RATS. A.S. Kimes*, R. Maldonado, G.F. Koob, E. Ambrosio†, and E.D. London†‡. †Addiction Res. Ctr., NIDA, NIH, Balto., MD, 21224; ‡Pharmacochimie Moléculaire, INSERM U266, Paris, France; §Dept. Neuropharmacol., The Scripps Res. Inst., La Jolla, CA.; ¶UNED, Madrid, Spain, †Dept. Radiology, Johns Hopkins Sch. Med., Balto., MD 21204; and ‡Dept. Pharmacol. Exp. Ther., Univ. of Maryland Sch. Med., Balto., MD 21201.

Opioid withdrawal (OW), produced by systemic naloxone, induces a typical behavioral syndrome and cerebral hypermetabolism, particularly in the central amygdaloid nucleus, the locus coeruleus (LC) and thalamic and hypothalamic nuclei (Kimes & London, *J. Pharmacol. Exp. Ther.* 248:897). Behaviors characteristic of the classic OW syndrome are produced by intracerebral injections of methylnaloxonium (MN), an opioid antagonist, into the LC (Maldonado et al., *J. Pharmacol. Exp. Ther.* 261:669). The present work tested whether MN injection into LC produces cerebral hypermetabolism comparable to that produced by systemic naloxone. The purpose of the work was to clarify the role of LC in OW.

Intracerebral cannulae were implanted bilaterally, directed toward the LC of anesthetized male Fischer-344 rats. Within 4 weeks of cannulation, rats were made morphine-dependent by s.c. implantation of 75 mg morphine pellets (1 pellet on day 1; 2 pellets on day 4). On day 8, rats ($n = 7$ /group) received 0.5 µl/min of saline or MN (1 µg/µl), infused into LC for 1 min. Immediately thereafter, metabolic rates for glucose were determined in 42 brain regions by the deoxyglucose method (Sokoloff et al., *J. Neurochem.* 28:897). MN stimulated glucose metabolism (1.25% > control) in the n. accumbens, caudate putamen, central and medial amygdaloid nuclei, thalamic and hypothalamic nuclei, hippocampal areas, substantia nigra pars reticulata, dorsal and ventral tegmental areas, and the cerebellar vermis. As local injections of MN into the LC produce cerebral hypermetabolism and behaviors that are characteristic of OW in dependent rats, it appears that the LC is a primary site of OW.

417.9

ANTAGONIST ACTION OF BUPRENORPHINE ON LC UNIT ACTIVITY IN MORPHINE DEPENDENT RATS. S.J. Grant*, G. Sontj, Dept. Psychology and Neuroscience Prog., Univ. Delaware, Newark, DE. 19716.

Buprenorphine, a synthetic opioid proposed as a potential treatment for opioid and cocaine craving, has potent agonist actions on the impulse activity of noradrenergic and dopaminergic neurons in drug naive rats. We have now extended these studies to opioid dependent subjects.

Rats were chronically treated with either buprenorphine (0.5 mg/kg s.c.) or morphine pellets (75mg) for 5 days. Saline injections and sham pellets were used as controls. Two days after the last drug treatment extracellular recordings were obtained from noradrenergic neurons in the Locus Coeruleus (LC) *in vivo*. Either buprenorphine (BUP: 0.025-8 mg/kg), morphine (MORPH: 0.5 - 32 mg/kg), or naloxone (NAL: 0.001-64 mg/kg) were administered systemically (i.v.).

LC neurons exhibited tolerance to both MORPH and BUP after chronic BUP treatment, but the tolerance to BUP was greater than to MORPH. NAL produced a slight increase in impulse activity, but only at high doses (>10 mg/kg) that produced similar increases in firing rate in control animals.

In contrast, BUP acted as an antagonist in MORPH dependent subjects. In fact, BUP (0.05-1 mg/kg) produced as much hyperactivity as NAL (<0.05 µg/kg). On the other hand, there was tolerance to MORPH challenge.

These results suggest that BUP is a partial agonist whose intrinsic efficacy is less than MORPH. The agonist action of BUP in drug naive animals may therefore be due to the high degree of receptor reserve on LC neurons.

417.11

EFFECTS OF PEDUNCULOPONTINE NUCLEUS (PPN) LESIONS ON THE ACQUISITION OF IV HEROIN SELF-ADMINISTRATION. M.C. Olmstead*, E.M. Munn and R.A. Wise. Dept Psychol McGill Univ (M.C.O) and Ctr Stud Behav Neurobiol and Dept Psychol, Concordia (E.M.M. and R.A.W.), Montreal, Canada H3G 1M8.

The PPN is a brainstem nucleus projecting to and receiving projections from the mesolimbic structures implicated in opiate reward. PPN lesions have been reported to block opiate-conditioned place preferences, and we studied their effect on a drug-reinforced lever-pressing task. Adult male Long-Evans rats were prepared with chronic intravenous catheters and excitotoxin (0.5 µl of 0.1M NMDA injected bilaterally over 10 minutes) lesions. Two weeks later they were given the opportunity to lever-press for intravenous heroin (0.1 mg/kg/inj infused at a rate of 0.25 ml/28 sec) on an FR-1 schedule of reinforcement for 4h per day. Three animals with good bilateral lesions failed to learn to lever-press for IV heroin within 15 days, whereas animals with sham lesions learned in the first week. While lesioned animals showed no such responses, sham-lesioned animals subsequently increased responding when saline was substituted for heroin and returned to normal self-administration patterns when drug was reinstated. Asymmetrical lesions and lesions of adjacent structures had variable effects. While additional animals must be tested, our initial results suggest that PPN plays a role not only in the stimulus-learning of the place preference paradigm but also in the response-learning of the instrumental paradigm.

417.13

RESPONSE PROPERTIES OF VENTRAL TEGMENTAL NEURONS DURING HEROIN SELF-ADMINISTRATION IN THE RAT. H.Zhang* and E.A. Stein. Depts. of Pharmacology & Psychiatry, Medical College of Wisconsin, Milwaukee, WI 53226.

The mesocorticolimbic dopamine (DA) system, with cells of origin within the mesencephalic ventral tegmental area (VTA), is believed to play a critical role in the mediation of behaviors reinforced by both natural (eg food) and artificial reinforcers such as drugs of abuse. Few studies, however, have examined the activity of the system with techniques capable of sufficient temporal resolution in order to follow neuronal activity during the behavior. A recent voltammetric study demonstrated an apparent increase in nucleus accumbens DA concentration immediately preceding heroin self administration (SA) and a decrease after drug administration (Kiyatkin et al, Synapse 1993). The present study directly measured VTA neuronal activity during heroin SA behavior. Changes in cell activity before SA behavior may be reflective of an animals arousal/motivational state, while response following drug delivery should reflect a combination of the reinforcing and pharmacologic drug effects. Rats were prepared with a chronic jugular catheter and four modified "ear bar" receptacles, constructed of dental acrylic, were mounted on their skull for subsequent atraumatic fixation in the correct stereotaxic plane. Bilateral burr holes over the VTA were sealed with silicone rubber between recording sessions. Rats SAed heroin by breaking a photocell beam across a licking spout. Extracellular recordings from both DA projection and non DA interneurons were made through NaCl filled glass microelectrodes. DA cell identification was based on such standard criteria as waveshape, firing rate and pattern and histologic reconstruction. Rats rapidly learned to SA heroin (60 or 100 µg/kg/inj) during the first session. Approximately 40% of recorded neurons to date have been identified as DA cells. Preliminary data indicates most identified DA cells responded to heroin with an increase in activity while non-DA cells decreased their activity; these drug-induced alterations generally returned to baseline prior to each SA. Clear firing changes in DA cells immediately prior to heroin SA have also been observed (Supported in part by grant DA 05012).

417.10

INCREASED DOPAMINE EFFLUX IN THE NUCLEUS ACCUMBENS DURING MANUAL AND SELF-ADMINISTRATION OF HEROIN AS MEASURED BY *IN VIVO* CHRONOAMPEROMETRY. GW Hubert*, AG Phillips, HC Fibiger, and CD Blaha, Dept. Psych., Univ. British Columbia Vancouver, BC, Canada V6T 1Z4.

The effects of heroin (HER) intravenous self-administration (IVSA) on dopamine (DA) efflux in the N. accumbens (Nac) was examined using chronoamperometry (CA; 1s pulse/120s) with stearate-modified graphite paste recording electrodes. Rats trained to bar press for food (FR2-schedule) were implanted with a jugular catheter and bilateral electrodes. IVSA sessions began with a 5s flash of cage-lights and priming dose of HER (0.03mg/0.1ml). After drug-prime, cage-lights remained on over the entire IVSA session with the exception of 30s time-out (lever-inactive) periods after each HER infusion. Rats were then allowed to bar press on an FR2 schedule for 12 additional HER infusions. The CA signal due to the oxidation of DA consistently increased to a maximum level (12.4±1.7nA) after an average of 8 infusions of HER. A second experiment was performed in which doses of HER were manually administered i.v. Four different doses of HER (30, 60, 120, and 180 mg/kg) induced dose-related increases of the CA signal (2.8, 5.6, 7.8, and 10.3nA), respectively. These data are consistent with a role for DA in the rewarding properties of opiate drugs.

417.12

DECREASES IN EXTRACELLULAR NUCLEUS ACCUMBENS DOPAMINE DURING INTRAVENOUS HEROIN SELF-ADMINISTRATION IN RATS. S.E. Hemby*, T.J. Martin, C.Co., S.I. Dworkin, & J.E. Smith. Center for Neurobiology of Drug Abuse, Dept. of Physiology and Pharmacology, Bowman Gray Sch. of Med., Wake Forest Univ, Winston-Salem, NC, 27157

Acute administration of mu opiate receptor agonists increase extracellular nucleus accumbens (NACC) dopamine concentrations. The present study determined whether acute response-independent intravenous (IV) heroin infusions and chronic IV heroin self-administration would also increase extracellular dopamine in the NACC. Drug-naive male Fisher (F-344) rats were randomly divided into three groups to receive two IV infusions of saline (n=3) or heroin (60 or 100 µg/kg/infusion; n=8 & 6, respectively) spaced one hour apart. Extracellular dopamine concentrations in the NACC were not significantly increased from baseline following saline or 60 µg/kg heroin; however, 100 µg/kg of heroin significantly increased extracellular dopamine to approximately 180% above baseline values. A second group of subjects were trained to self-administer 60 or 100 µg/kg/infusion (n=5 & 7, respectively) on a fixed ratio 10 (FR10) schedule of reinforcement. Microdialysis samples were collected in five minute intervals 15 minutes prior to the session (baseline), during the 2 hour self-administration session, and 30 minutes after the session (rebaseline). Furthermore, IP naloxone (10 mg/kg) administered one hour after the session did not induce signs of opiate withdrawal, suggesting that this dose did not induce physical dependence. For the 60 µg group, extracellular dopamine decreased approximately 10-25% from baseline, while this reduction was approximately 50% in the 100 µg group. These results suggest that response-independent administration of abused drugs may not be the most appropriate model for investigating the neural substrates mediating the reinforcing effects of these compounds (research by DA-01999, DA-00114).

417.14

MICRODIALYSIS ASSESSMENT OF NUCLEUS ACCUMBENS DOPAMINE AND METABOLITES DURING IV HEROIN SELF-ADMINISTRATION: CHANGES WITH UNIT DOSE. R. Rivest*, K. Leeb, P. Leone, and R.A. Wise. Ctr Stud Behav Neurobiol, Concordia University, Montreal, Quebec, Canada, H3G 1M8.

Self-administered IV heroin has been found to increase dopaminergic cell firing and to elevate dopamine (DA) turnover in nucleus accumbens (NAS). At unit dosages of 100 or 200µg/kg/injection, rats adjust their response rate to maintain a relatively constant hourly drug intake; at these unit doses relatively constant elevations of NAS DA are seen. However, Hemby et al. (SN Abstr 1992) reported that at 60 µg/kg/inj self-administration was maintained in the absence of elevated DA. Our aim was to explore the regulation of heroin intake and the correlated levels of DA across a more extended range of unit dosages. Rats with NAS guide cannulae were trained to self-administer heroin HCl at one of four unit dosages: 50, 100, 200 or 400 µg/kg/inj. NAS DA and metabolites were sampled at 10- or 20-min intervals by microdialysis and measured using HPLC with electrochemical detection. Rats tested at the 50µg/kg/inj dosage simply took multiple injections each time they went to the lever, giving themselves the same amount of drug and elevating NAS DA levels to the same degree as did animals working for the 100 and 200µg/kg/inj dosages. However, hourly drug intake was greater in animals given the 400µg/kg/inj dosage and DA levels were increased to as much as 500% in this case. These data suggest that compensatory response adjustments for changes in unit dosage may characterize self-administration of only a narrow range of low dosages. The high dosage data make it clear that such low-dosage "regulation" is not due to a ceiling on the ability of heroin to elevate NAS DA.

417.15

A GAS CHROMATOGRAPHY-MASS SPECTROMETRY (GCMS) METHOD FOR IBOGAINE. S.M. Keefner, L.B. Hough, C.A. Gallagher, A. Seved, Mozaffari, S. Archer, and S.D. Glick*, Dept. Pharmacology and Toxicology, Albany Medical College, Albany, NY 12208 and ¹Dept. Chemistry, Rensselaer Polytechnic Institute, Troy, NY 12180.

A sensitive method for measuring ibogaine, an agent claimed to be effective in treating opiate and stimulant addiction, has been developed. Supernatant aliquots from brain homogenates (0.4 N HClO₄) containing ibogaine standards (50-500 ng) or unknowns were spiked with O-[CD₃]-ibogaine (250 ng), alkalized (10 N KOH), and extracted into hexane. Following back extraction into HCl (0.01 N) and evaporation to dryness, residues were derivatized in trifluoroacetic anhydride (50 μ l, 30 min, 60 $^{\circ}$), evaporated to dryness and resuspended in toluene (50 μ l). Analysis by capillary GCMS (splitless mode, 5% phenyl methyl silicone, 90-250 $^{\circ}$) in SIM mode detected ibogaine (m/e 406,391) and O-[CD₃]-ibogaine (m/e 409,394). The 406/409 ratios were linear with ibogaine standards from 0 to 500 ng, with an approximate lower limit of sensitivity of 50 ng. One hr after administration in rats (40 mg/kg, i.p.), brain ibogaine levels were 1.3-4.7 μ g/g, considerably lower than previously reported by others using less accurate spectrofluorometric methods. This method allows for greatly improved detection and quantification of ibogaine in biological samples and may lead to a better understanding of its mechanisms of action (supported by DA03817).

CHRONIC OPIOID RECEPTOR ACTIVATION RESULTS IN NEURONAL SUPERSENSITIVITY IN CULTURED CATECHOLAMINERGIC NEURONS. E. Ronken, A.H. Mulder and A.N.M. Schoffelmeer, Dept. of Pharmacology, Free University, Van der Boechorststraat 7, 1081 BT Amsterdam, The Netherlands.

Central catecholaminergic neurotransmission in the rat brain is known to be modulated by activation of opioid receptors. Thus, in brain slices stimulated release of [³H]dopamine (DA) is inhibited exclusively by activation of κ -opioid receptors whereas that of [³H]noradrenaline (NA) is subject to inhibition exclusively through μ -opioid receptors. In this study, we investigated the adaptive changes upon sustained activation of opioid receptors in cultured DAergic neurons from the ventral mesencephalon (VM) and in NAergic neurons from the locus coeruleus (LC). Chronic activation of μ -opioid receptors on LC by morphine (1 μ M) for 4 days induced a 55-150% increase in [³H]NA release by K⁺ (25 mM)- or NMDA (100 μ M)-induced depolarization upon opioid withdrawal. Moreover, μ -opioid receptors on LC were found to be resistant to desensitization as no change in release inhibiting properties of DAMGO were found (EC₅₀ 10-12nM, maximal inhibitory effect about 80-90%). Similarly, sustained activation of κ -opioid receptors for 4 days in VM by the κ receptor agonist U69593 (1 μ M) resulted in a 70% increase in K⁺- and NMDA-stimulated [³H]DA release without κ receptor desensitization (EC₅₀ 3-6 nM; maximal inhibitory effect 50%). Neuronal supersensitivity was not found upon chronic autoreceptor activation with clonidine (1 μ M, LC, α_2) and with LY171555 (1 μ M, VM, D₂) suggesting that observed adaptive changes in neuronal excitability upon chronic opioid receptor activation are a characteristic feature of opioid receptors. Therefore, as μ - and κ -opioid receptors appear to be resistant to desensitization upon chronic activation, its tonic activation in vivo by endogenous opioid peptides may play a role in regulation of long-term neuronal excitability towards various excitatory stimuli such as EAA. Moreover, these phenomena may play a role in the acquisition and maintenance of drug abuse.

STRUCTURE-ACTIVITY RELATIONS OF NEUROPEPTIDE FF RECEPTOR BINDING IN RAT SPINAL CORD MEMBRANES.

K. Payza* and H.Y.T. Yang, Laboratory of Biochemical Genetics, NIMH Neuroscience Center at St. Elizabeths, Washington, DC 20032.

Neuropeptide FF (FLFQQRamide, NPFF) modulates opiate analgesia, tolerance, and withdrawal. An NPFF antagonist could be useful in augmenting morphine analgesia and attenuating tolerance and withdrawal. The development of NPFF antagonists first requires information on the structure-activity relations of NPFF receptor binding. Therefore we characterized the ligand binding site of NPFF receptors with a radioligand binding assay. We found that the Arg-Phe-amide was critical for binding activity, and that tetrapeptides bound to NPFF receptors with high affinity if they contained this C-terminal, such as PQRamide (K_i=12 nM), FMRamide (1.8 nM), PMRamide (0.54 nM), FFRamide (0.25 nM), and FWRamide (0.42 nM); compare to NPFF (0.26 nM). The potent binding of FMRamide explains the similar bioactivities of FMRamide and NPFF. Substitutions at the first and second positions of FMRamide, particularly with aromatic residues, were tolerated much better than substitutions at the third and fourth positions. These findings are expected to aid the development of high affinity NPFF antagonists.

μ AND κ - OPIATE RECEPTOR BINDING CHARACTERISTICS AND ADENYLATE CYCLASE ACTIVITY IN RAT SPINAL CORD. Poluru L. Reddy* and Hemendra N. Bhargava, Dept. Pharmacodyn., Univ. Ill., Chicago, IL 60612.

Considerable evidence suggests that the spinal cord is an important site for the mediation of the antinociceptive action of opiates. Although opioid receptor binding sites have been well characterized in spinal cord, the effector systems coupled to these receptors to produce their responses are less well understood. The present study was undertaken to examine whether there is any correlation between the number of binding sites (B_{max}) of μ and κ -opioids and their effect on adenylate cyclase (AC) activity in spinal cord of adult male Sprague-Dawley rats. ³H-DAMGO and ³H-EKC were used to label μ - and κ -opioid receptors respectively. AC activity was determined using radioligand binding assay. The B_{max} values (fmole/mg protein) of ³H-DAMGO and ³H-EKC in spinal cord were 51.68 \pm 3.98 and 36.65 \pm 3.64 respectively. At 10 μ M concentration, k-agonist (U-50,488H), μ -agonist (DAMGO) inhibited the AC activity by 35 and 11%, respectively. Thus, compared to μ agonist, k-agonist is more potent inhibitor of AC activity in spinal cord despite the less number of bindings sites. It is concluded that there may be no correlation between the number of opiate receptor binding sites and the degree of inhibitory effect on AC activity in spinal cord of the rat (Supported by a grant DA-02598 and a Research Scientist Development Award K02-DA-0130 from the NIDA).

DRUGS OF ABUSE: OPIOIDS AND OTHERS—OPIOIDS: BEHAVIOR

LACK OF BRAIN REWARD FACILITATION BY THC BEFORE OR AFTER SUBCUTE MORPHINE IN LEWIS RATS. B. Hine* and M. Borrero, U. of Puerto Rico Sch. Pharmacy, San Juan, P.R. 00936.

Male Lewis rats, implanted with platinum bipolar electrodes in the ventral tegmentum, received training in a brain stimulation reward (BSR) procedure similar to that reported by Gardner (Psychopharm. 96:142, 1988; Pharmacol. Biochem. Behav. 48:571, 1991) to demonstrate BSR threshold decreases to a 1.5 mg/kg acute dose of Δ^9 -tetrahydrocannabinol (THC) 15 min after injection. After three months of stabilization of BSR thresholds and stimulation-delivery response rates, calculated over 10-min periods of the 40-min training and THC vehicle injection sessions, rats were given THC doses of 0.25-2.0 mg/kg in separate sessions, interspersed with vehicle sessions. After a two-week period of daily s.c. morphine sulfate (MS) injections (cumulative dose = 960 mg/kg), these rats were challenged with THC (0.25-1.0 mg/kg) over a period of 5-13 days after termination of MS injections. Consistent with previous reports from this laboratory (FASEB J. 5:703, 1991; Soc. Neurosci. Abstr. 17:1433, 1991), no evidence of reliable BSR threshold decreases or response-rate increases by THC was observed before MS, and 2 mg/kg produced marked rate depression, relative to vehicle data. Subacute MS also produced no BSR facilitation to THC challenge, except for slightly increased rates at 0.25 mg/kg. Rate depression at 1 mg/kg was profound. The reason for the discrepancy between these data and the report of BSR facilitation by THC are unknown. Supported by GM 08224.

INTRA-ACCUMBENS DPPE LOWERS THE THRESHOLD FOR BRAIN-STIMULATION REWARD. C.L. Duvauchelle,* S.M. Fleming and C. Kornetsky, Lab. of Behavioral Pharmacology, Boston University School of Medicine, Boston, MA 02118.

Intraventricular application of delta receptor specific agonists have been shown to induce conditioned place preferences and increase response rates for brain stimulation reward (BSR). However, neither delta agonists or antagonists have been reported to affect intravenous self administration of heroin. In order to more specifically determine the role of a delta agonist on the brain reward system the present study examines the effects of intra-accumbens microinjections of the delta agonist, DPPE on BSR to the ventral tegmental area. The thresholds for BSR were determined 45 minutes after the infusion of DPPE (0.0, 2.5, 5.0 and 7.5 μ g/.5 μ l/side) into the nucleus accumbens. DPPE significantly lowered the threshold for BSR while vehicle infusions had no effect. These findings indicate that DPPE increases sensitivity to rewarding electrical stimulation of dopamine cell bodies, supporting the hypothesis that delta opiate receptor ligands have rewarding effects. 418.3

ACQUISITION OF INTRAVENOUS HEROIN SELF-ADMINISTRATION IN LEWIS AND FISCHER RATS. K. Leeb and R.A. Wise. Center for Studies in Behavioral Neurobiology, Concordia University, Montreal, Quebec, Canada, H3G 1M8.

Lewis (LEW) and Fischer 344 (F344) rats have been reported to differ in their sensitivities to and preferences for a variety of drugs. Among other findings, orally self-administered cocaine, etonitazine and morphine are reported to be stronger reinforcers for LEW than for F344 rats. The aim of the present study was to determine if these strain differences in drug reinforcement would be apparent when the more effective intravenous (IV) route of administration was used. Male LEW and F344 rats with chronic intravenous catheters were trained to lever-press for 0.1mg/kg infusions of heroin in 4h daily sessions. LEW and F344 rats did not differ in the rate at which they learned to self-administer IV heroin. Preliminary data indicate that Sprague-Dawley and Long-Evans rats acquire self-administration at similar rates. In order to compare drug intake, we switched the animals to a VDI paradigm after 15 days of acquisition testing. In this paradigm the dosage of heroin (0.025, 0.05 or 0.1mg/kg/infusion) is irregularly varied from trial-to-trial and inter-response times are correlated with the preceding dosage. LEW and F344 rats did not differ in regulation of drug intake; the two strains responded with similar inter-response times across the range of tested dosages. Thus it appears that when heroin is given by intravenous injection it is a potent reinforcer for both Lewis and Fischer strains. Differences in response to oral opiates may be unique to doses or routes of administration that are marginally reinforcing and not likely to be subject to abuse.

418.5

BLOCKADE OF KAPPA OPIATE TOLERANCE BY MK-801, AN NMDA RECEPTOR ANTAGONIST, IN THE MOUSE. Sanjay N. Thorat* and Hemendra N. Bhargava, Dept. Pharmacodyn., Univ. Ill., Chicago, IL 60612.

The effect of MK-801 (0.25 to 1.0 mg/kg, ip) on tolerance to the analgesic and hypothermic effects of U-50,488H, a k-opiate receptor agonist, was determined in the mouse. Male Swiss Webster mice were injected twice daily with either saline or MK-801, 30 min prior to the injection of U-50,488H (25 mg/kg, ip) for 9 days. The tail-flick latency and colonic temperature of mice were determined 60 min after the injection of U-50,488H on days 1, 3, 5, 7 and 9. Tolerance to the analgesic and hypothermic effects of U-50,488H was evident on day 5 of the treatment. Concurrent injections of MK-801 in all doses used prevented the development of tolerance to the pharmacological effects of U-50,488H as evidenced by reappearance of the prolongation of tail-flick latency and hypothermic response. MK-801 by itself either on acute or chronic administration did not affect the analgesic and hypothermic actions of acutely administered U-50,488H. It is concluded that NMDA receptor antagonist can block the tolerance to the pharmacological actions of k-opiate agonist in the mouse (Supported by grant DA-02598 and a Research Scientist Development Award K02-00130 from the National Institute on Drug Abuse).

418.7

EFFECTS OF NOVEL KAPPA OPIOIDS ALONE AND IN COMBINATION WITH OPIOID ANTAGONISTS ON SHOCK TITRATION IN SQUIRREL MONKEYS. B.C. Pitts and L.A. Dykstra. Dept. of Psychology, Univ. of N. Carolina, Chapel Hill, NC 27599-3270.

Effects of three novel kappa-selective compounds, spiradoline, CI-977, and U69,593, were assessed alone and in combination with the opioid antagonists quadazocine and β -funaltrexamine (β -FNA) in squirrel monkeys responding under a shock-titration procedure. In this procedure, shock intensity increased every 15 s from .01 mA to 2.0 mA in 30 increments. Five lever presses during any given 15 s shock period produced a 15 s shock-free period after which shock resumed at the next lower intensity. When given alone, spiradoline, CI-977, and U69,593 produced dose-dependent increases in the intensity below which the monkeys maintained shock 50% of the time (median shock level, MSL) and decreases in the rate of lever pressing. When given in combination with these kappa agonists, quadazocine produced rightward shifts in the dose-effect functions (both MSL and rate) for spiradoline, CI-977, and U69,593. In contrast, β -FNA failed to shift the dose-effect functions of any of the kappa agonists. Apparent pA_2 values obtained for quadazocine on MSL ranged between 6.12 and 6.68 and were similar to those obtained previously for quadazocine in combination with the kappa agonists U50, 488 and bremazocine in squirrel monkeys responding under the shock-titration procedure (Dykstra & Massie, 1988). Supported by grants DA02749 and DA00033 from NIDA.

418.4

RESPONSES OF NUCLEUS ACCUMBENS NEURONS TO NOVELTY STIMULI AND HEROIN SELF-ADMINISTRATION IN THE FREELY-MOVING RAT R.-S. Lee*, S. C. Steffensen, G. F. Koob, R. L. Howard, R. Lintz, G. Berg and S. J. Henriksen, Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

The nucleus accumbens (NAcc) has been hypothesized to function as an integrator of motor and complex limbic information. Other evidence indicates that the NAcc may be critical for reward-seeking behaviors. To further explore NAcc physiological correlates of several classes of motivated behaviors, we have employed two paradigms: (1) Naive rats were placed and allowed to move freely in an open field (opaque Plexiglas box fitted with nosepoke holes), while novelty stimuli (food and non-food items) were presented to the subjects; (2) Rats were further trained to self-administer heroin intravenously (0.06 mg/kg/injection through an indwelling catheter) by bar pressing (FR-1 schedule) in another operant chamber. NAcc neuronal activity was recorded using stainless steel microwires (62 μ) implanted into the NAcc under anesthesia. The spontaneous firing rate of sampled NAcc neurons (N=34) ranged from 0.21 to 18.23 spikes/sec (median=1.21 Hz). In the open field, NAcc neurons (N=4) responded during prolonged nosepoking events by a decrease in spontaneous activity. Just prior to entry into a hole the firing rate of most cells was briefly elevated above baseline. Some neurons (N=3) repeatedly decreased their discharge rate during focused attention as well as during feeding with a favorite novel food morsel (popcorn), supplied by the experimenter. The inhibitory response was strong and long-lasting. In addition, similar to our earlier report (Soc. Neurosci. Abstr., Vol 18: 373, 1992) drug-related bar-pressing events were followed by decreased NAcc neuronal activity lasting up to one minute (N=7). These data suggest that NAcc neuronal discharge is actively modulated during specific novel exploratory behaviors, during consummatory events and during heroin self-administration behavior. The direction in the change of neuronal activity (decrease) is similar during each of these behavioral events. (Supported by DA-03665 and TRD 183 to SJH).

Conditioned Tolerance To Intravenous (iv) Morphine: Demonstration and Spinal Mediation.

J.E. Grisel, E.P. Wiertelak¹, R.J. Frohardt, H.-Y.T. Yang², S.F. Maier & L.R. Watkins. Dept. of Psychology, University of Colorado, Boulder, CO 80309; ¹Macalester College, St. Paul, MN 55105¹; ²NIMH, Washington, D.C. 20032².

Tolerance to morphine can be divided into two classes. The present experiments distinguish between "non-associative" or dispositional tolerance and "associative" or conditioned tolerance using 3 groups of rats: those tested for morphine analgesia in a context they have been conditioned to associate with morphine (5mg/kg daily for 5 consecutive days), a second group given identical morphine injections but conditioned to associate the test context with saline injections, and a third group of pharmacologically naive but similarly handled rats. Exper. I found only dispositional tolerance following sc morphine, but both dispositional and associative tolerance following iv drug. Exper. II suggested a compensatory mechanism underlying conditioned tolerance using iv morphine since a hyperalgesic state resulted in animals conditioned to expect morphine, but given saline. The remaining experiments investigated spinal mechanisms of conditioned morphine tolerance. Antagonists of putative endogenous anti-opiates were injected intrathecally prior to analgesia testing (tailflick) on the test day after 5 days of conditioning. Three doses of the CCK β antagonist L-365,260 given prior to morphine had no effect on conditioned tolerance. In contrast a neurotensin antagonist (D-Trp11) abolished conditioned tolerance without effecting dispositional tolerance. Studies on FMRFamide are in progress.

MORPHINE INDUCED ANALGESIA, ABSTINENCE, REWARD AND AVERSION IN THE FAWN HOODED RAT. G.S. Borszcz* and C.P. Johnson, Department of Psychology, Dartmouth College, Hanover N.H. 03755

The Fawn Hooded (FH) rat strain has been shown to possess altered central serotonergic function. Because many of the behavioral effects of morphine treatment are partially mediated by central serotonergic pathways the present study was designed to characterize the FH rat's sensitivity to this drug.

Morphine analgesia was assessed by determining the thresholds of motor reflexes and vocalizations elicited by tailshock. Morphine abstinence was evaluated by scoring the behavioral syndrome elicited by naloxone (5 mg/kg, sc) administered 1 hr following repeated morphine injections. Separate groups received either low or high doses of morphine. The schedule of morphine administration was: 0 hr = 10 mg/kg, 4 hr = 20 mg/kg, 24 hr = 20 mg/kg, 28 hr = 20 or 30 mg/kg, 48 hr = 20 or 30 mg/kg, 52 hr = 20 or 40 mg/kg, 72 hr = 20 or 40 mg/kg. Morphine reward was determined using the conditioned place preference paradigm. On alternate days for 8 days morphine (5mg/kg, sc) or saline injections were paired with one of two distinctive sides (horizontal vs vertical stripes) of a shuttle box. On the 9th day place preference was scored by recording the amount of time animals spent on each side of the shuttle box during a 15 min free choice period. Aversion generated by morphine withdrawal was assessed using the conditioned place aversion paradigm. Animals were given repeated injections of morphine on the schedule previously described for induction of morphine abstinence (low dose group). Following naloxone (5 mg/kg, sc) administration they were placed on one side of the shuttle box for 1 hr. The following day place aversion was scored as the time spent on each side of the shuttle box during a 15 min free choice period.

Compared to Long-Evans (LE) rats, FH rats exhibited reduced sensitivity to the analgesic and rewarding properties of morphine. Alternately, no differences were observed between strains in the capacity of morphine to induce abstinence or aversion. These results indicate that the FH rat may be a useful model for evaluating the mechanisms by which narcotics influence behavior.

418.9

MORPHINE-INDUCED CONDITIONED ANALGESIA USING A TASTE CUE IN RATS. J. M. Valone* and M. T. Bardo.

Department of Psychology, University of Kentucky, Lexington, KY 40506.

In a Pavlovian paradigm, morphine was paired with a taste which served as the conditioned stimulus (CS) in rats. Conditioned taste aversion and conditioned analgesia were assessed using either 0, 1, 3, 10 or 30 mg/kg morphine. Results showed that 3, 10 or 30 mg/kg morphine produced a taste aversion, whereas only 30 mg/kg produced conditioned analgesia as measured by a hot plate test. Another experiment was designed to assess the effect of a delay between CS presentation and morphine administration. Results showed that delaying morphine for six hours after CS presentation eliminated both the conditioned taste aversion and the conditioned analgesia. A third experiment tested conditioned analgesia using either a 50°C or 54°C hot plate. This experiment found a conditioned analgesic response at both temperatures but less variability at 54°C. The analgesic response to acute doses of lithium (0, 3, 10 and 30 mg/kg) were compared to an acute dose of morphine (15 mg/kg). Results showed that, in contrast to morphine, none of the lithium doses produced an analgesic response. When paired with saccharin, lithium produced a conditioned taste aversion but no conditioned analgesic response. Taken together, these results indicate that a conditioned taste aversion is not sufficient to produce a conditioned analgesic response. (Supported by USPHS Grants DA-05312 and DA-07746).

418.11

QUININE BLOCKS THE BEHAVIORAL AND NEUROCHEMICAL EFFECTS OF HYDROCODONE BUT NOT HYDROMORPHONE. B. Gomez-Mancilla*, S. Cheung, S.V. Otton, E.M. Sellers. Addiction Research Foundation, Departments of Pharmacology, Medicine and Psychiatry, University of Toronto, Toronto, Ontario M5S 2S1.

Several opiates of abuse are converted by cytochrome P450 2D6 (CYP2D6) to metabolites of much greater pharmacological potency than the parent compound (i.e. hydrocodone to hydromorphone, codeine to morphine). The activity of human CYP2D6 is genetically variable (absent in about 7% of Caucasians) and can be inhibited by several compounds (quinine, quinidine). Using Sprague-Dawley rats, we compared the locomotor activity and dopamine release in the n. accumbens produced by hydrocodone and hydromorphone given alone and 60 minutes after quinine (40 mg/kg i.p.). The administration of hydrocodone (0.01, 0.1 and 1 mg/kg s.c.) and hydromorphone (0.001, 0.01, and 0.1 mg/kg s.c.) produced a dose-related increase in locomotor activity. Hydrocodone (1 mg/kg s.c.) and hydromorphone (0.1 mg/kg s.c.) increased dopamine release $38 \pm 8.8\%$, and $78 \pm 13\%$, respectively. Quinine pre-treatment reduced locomotor activation 70% and dopamine release in the n. accumbens to $11 \pm 4.9\%$ compared with the administration of hydrocodone given alone. When hydromorphone was given, there was no effect of quinine on locomotor activity or dopamine release in the n. accumbens. These results suggest that CYP2D6 activity may be an important determinant in the pharmacologic effects of hydrocodone (including abuse liability) mediated through hydromorphone, its active metabolite.

CONDITIONED PLACE PREFERENCE WITH BUPRENORPHINE: INTERACTIONS WITH NALTREXONE, MORPHINE AND AMPHETAMINE

J.K. Rowlett*, T.R. Gibson, J.M. Valone & M.T. Bardo, Department of Psychology, University of Kentucky, Lexington, KY 40506.

The rewarding effect of the opioid mixed agonist-antagonist buprenorphine alone and combined with various drugs was assessed using conditioned place preference (CPP). In one experiment, rats were given one of four doses of buprenorphine (0.001, 0.01, 0.1, 1.0 mg/kg) or saline paired with the white compartment of a CPP chamber. Significant CPP was obtained for 1.0 mg/kg buprenorphine after four trials and for 0.1 and 1.0 mg/kg buprenorphine after eight trials. The effects of combined treatments during conditioning of buprenorphine with the opioid receptor antagonist naltrexone, the opioid receptor agonist morphine, and the psychostimulant amphetamine also were assessed. Pretreatment with 1.0 mg/kg naltrexone blocked CPP produced by six pairings of 0.1 mg/kg buprenorphine. Buprenorphine treatment (1.0 mg/kg) produced additive effects on CPP produced by three pairings of either 0.3 mg/kg morphine or 0.5 mg/kg amphetamine. Taken together, these results indicate that buprenorphine, similar to full opioid agonists, produces CPP that follows a linear dose-response function and is reversed by naltrexone. Buprenorphine elicited additive effects when combined with morphine or amphetamine, also consistent with full agonist effects on reward. (Supported by USPHS grants DA05312 and DA07746).

BUPRENORPHINE DRUG DISCRIMINATION IN OPIATE-DEPENDENT ANIMALS: AN ASSESSMENT OF THE KAPPA ANTAGONIST PROPERTIES OF BUPRENORPHINE. S. Pournaghash* and A. L. Riley. The American University, Washington D.C. 20016

In work on drug discrimination learning with buprenorphine (see Pournaghash & Riley *Neurosci. Abst.*, 41.4, 1991), stimulus control by buprenorphine appears to be mediated by its activity at the mu receptor. Specifically, animals trained to discriminate buprenorphine from distilled water generalized this control to the mu agonist morphine but not the kappa antagonist MR2266. Given that opiate tolerance has been reported to alter the involvement of various receptors in mediating the effects of drugs on behavior (see Negus, Picker & Dykstra *Psychopharmacology* 98:141-143, 1989), the present experiment assessed the effects of opiate tolerance on the receptor bases of the discriminative control by buprenorphine. Specifically, opiate-tolerant rats were trained to discriminate buprenorphine from distilled water and then tested for the generalization of this control to the mu agonist morphine and the kappa antagonist MR2266. Exposure to morphine shifted the morphine generalization function to the right (indicating tolerance), yet MR2266 continued to fail to substitute for buprenorphine. The present study finds no evidence for the ability of buprenorphine's kappa activity to support drug discrimination learning, even in opiate-tolerant subjects.

418.12

MORPHINE, CHLORDIAZEPOXIDE, AND PENTOBARBITAL AFFECT APPETITIVE PAVLOVIAN CONDITIONING OF MOTOR ACTIVITY IN RATS.

J.D. Valentine*, P. Tollison and L.L. Hernandez Univ. of S. Carolina, Dept. of Psychology, and V.A. Medical Center, Columbia, SC, 29201

Rats were subjected to 15 daily appetitive pavlovian conditioning sessions while under the influence of a relatively low dose of morphine, chlordiazepoxide, or pentobarbital. Morphine dose-dependently increased baseline motor activity (BMA), whereas chlordiazepoxide and pentobarbital dose-dependently decreased BMA. All 3 of the drugs dose-dependently enhanced the magnitude of the conditioned motor-activity (CMA) response, an effect that developed as conditioning proceeded.

The rats were then subjected to 10 daily extinction sessions that were not preceded by any treatments. The group differences in BMA and CMA that were observed during conditioning did not carry over into extinction training, and no other significant group differences developed during these 10 extinction sessions.

Finally, an additional extinction session was conducted before which each rat was administered the same treatment that it had received before each of the conditioning sessions. The chlordiazepoxide and pentobarbital treatments dose-dependently decreased BMA, but did not affect CMA; however, re-administering morphine completely reinstated the dose-dependent increases of BMA and CMA observed during conditioning. Re-administering saline had no effect on either BMA or CMA.

This work was supported by USPHS Grant R01-DA06676 and DVA Medical Research Funds.

418.14

ASSOCIATIVE FACTORS IN STRESS-INDUCED SENSITIZATION TO THE BEHAVIORAL ACTIVATING EFFECTS OF MORPHINE.

Y. Shaham*, J.E. Kelsev, and J. Stewart. Center for Studies in Behavioral Neurobiology, Department of Psychology, Concordia University, Montreal, Quebec, Canada H3G 1M8.

A recent report (Shaham, 1993) showed that associative factors may contribute to the stress-induced increase in oral opioid consumption. We examined whether similar learning factors might also be involved in the stress-induced sensitization to the behavioral activating effects of morphine. Forty-eight male rats were divided into 6 groups in a 2 (drug condition: morphine/saline) x 3 (stress condition: Control [C], Paired-Stress [PS] and Unpaired-Stress [UPS]) factorial design. Prior to tests for sensitization to a low dose of morphine (7 sessions, 48 h apart), PS rats were restrained for 15 min prior to the morphine (10 mg/kg) or saline injections and were then placed in the locomotor activity boxes for 90 min. UPS rats were restrained in the animal colony 24 h after each session. Three separate tests for morphine or stress sensitization of locomotor activity were conducted with 1) a low dose of morphine (3 mg/kg), 2) morphine + paired stress, and 3) saline + paired stress. C groups were not exposed to stress in any of the tests for sensitization. On these tests, the behavioral activating effects of morphine were enhanced in animals previously exposed to paired-stress, but not in animals previously exposed to unpaired-stress. Exposure to stress did not affect locomotor activity in the absence of morphine. These results indicate that the learned association between exposure to stress and opioid drugs may contribute to the stress-induced changes in the behavioral activating effects of these drugs.

418.15

CONDITIONED TASTE AVERSIONS TO COMPOUNDS WITH OPIATE AGONIST/ANTAGONIST ACTIVITY AT SPECIFIC OPIATE RECEPTOR SUBTYPES. C. M. Ferrari*, P. M. Melton and A. L. Riley. Psychopharmacology Laboratory, The American University, Washington, D.C., 20016.

Given Self and Stein's (*Pharmacol. & Toxicol.* 70:87-94, 1992) recent conclusion that the reinforcing and aversive properties of the opiates are mediated by different receptor subtypes (μ and κ , respectively), the present study examined the ability of compounds with various activity at opiate receptor subtypes, e.g., naloxone (μ), MR2266 (κ), nalorphine (mixed μ/κ) and buprenorphine (mixed μ/κ) to condition taste aversions in rats, an index of the aversive properties of drugs (Riley & Tuck, *ANYAS* 443:272-292, 1985). Specifically, rats were given a novel saccharin solution to drink followed within 15 min by an injection of one of a range of doses of the aforementioned compounds. None of the opiates conditioned aversions to the associated saccharin solution, even with high doses and repeated conditioning trials. Although it might be expected that the compounds with μ agonist (buprenorphine) and κ antagonist (buprenorphine and MR2266) activity would be ineffective in conditioning aversions, it was surprising that compounds with κ agonist (nalorphine) and μ antagonist (nalorphine and naloxone) activity were without effect in this design.

EPILEPSY: HUMAN STUDIES AND ANIMAL MODELS III

419.1

¹H MRS AND T2 RELAXOMETRY OF THE CONTRALATERAL TEMPORAL LOBE FOLLOWING EPILEPSY SURGERY. D.G. Gadian, A. Connolly, C.L. Johnson, G.D. Jackson, C.F. Polkey, A. Incisa della Rocchetta and F. Vargha-Khadem. (SPON: European Brain and Behaviour Society). Inst. of Child Health and Hospital for Sick Children, Gt. Ormond Street, London WC1N, and ¹Maudsley Hospital, London, UK.

Resection of temporal lobe structures can cure cases of intractable temporal lobe epilepsy. Several types of operation are possible; for example, if preservation of the maximal amount of neural tissue is considered important, then selective amygdalohippocampectomy may be performed. Magnetic resonance imaging (MRI) and spectroscopy (MRS) can be used post-operatively to define the degree of surgical removal and to assess the integrity of the contralateral mesial temporal structures.

¹H spectra were obtained at 1.5T from 2x2x2cm cubes within the mesial temporal lobes contralateral to the side of temporal lobe resection, using a water-suppressed spin echo sequence with TE=135ms and TR=1600ms. The dominant signals are from N-acetylaspartate (NAA), creatine + phosphocreatine (Cr), and choline-containing compounds (Cho). Since NAA is believed to be present primarily within neurons, a reduction in NAA or in the NAA/Cho+Cr ratio is interpreted in terms of neuronal loss or damage. T2 relaxation times, which are sensitive to abnormalities of the hippocampus, were measured from 16-echo T2 maps.

NAA/Cho+Cr ratios in the temporal lobe contralateral to the resection were abnormally low in five of the eight patients examined, suggesting the presence of diffuse neuronal damage. This damage can be detected independently of hippocampal abnormalities, which were seen by T2 relaxometry in only two of the patients. The prognostic implications of these findings will be evaluated by following the outcome in this patient group.

419.3

CORRELATION BETWEEN AMYGDALOID AND HIPPOCAMPAL VOLUME AND MEMORY REPRESENTATION IN TEMPORAL LOBE EPILEPSY (TLE). Imad M. Najm*, Youssef G. Comair and Hans O. Luders. Depts of Neurology and Neurosurgery, Cleveland Clinic, Cleveland, OH 44195.

Impaired memory performance during the intracarotid amobarbital procedure (IAP) may reflect severe hippocampal damage. Moreover, pathological studies from patients with Temporal Lobe Epilepsy (TLE) have demonstrated the existence of a relationship between hippocampal volume and neuronal damage. In view of the role of the hippocampus in memory we investigated the relationship between the hippocampal volume and the IAP memory scores in patients with TLE. Volumetric MRI studies of hippocampal formation (HF) and amygdala from 15 patients with TLE were performed. As previously shown, the difference between the right and the left HF volume was considered evidence of lateralized HF atrophy if the difference was below -0.2 cm^3 or above $+0.6 \text{ cm}^3$ and indeterminate if the difference was between -0.2 and $+0.6 \text{ cm}^3$. These results were compared to IAP memory scores. In 8 patients, the atrophic side was correlated with an impaired ipsilateral IAP memory performance. In 4 patients, an indetermined atrophy was associated with a bilateral memory representation. In 3 patients, no correlation was found between the memory representation and the HF volume. No significant correlation was found between amygdala volume and memory representation. These results show a good correlation between HF volume and memory representation in 12/15 patients evaluated for TLE. Thus, HF volume measurement may be used as a non-invasive method to predict or to confirm memory dominance in TLE.

RELATIONSHIP OF COGNITIVE DYSFUNCTION TO ¹H MRS ASSESSMENT OF TEMPORAL LOBE PATHOLOGY. F. Vargha-Khadem, A. Connolly, J.H. Cross, G.D. Jackson, E.B. Isaacs and D.G. Gadian. (SPON: European Brain and Behaviour Society). Inst. of Child Health and Hospital for Sick Children, Gt. Ormond Street, London WC1N, UK.

Children with intractable epilepsy may demonstrate impaired cognitive function with deterioration over time, but the pathological basis of this process remains unclear. Magnetic resonance techniques can be used to investigate the underlying pathology.

Magnetic resonance and neuropsychological investigations were carried out on 22 right-handed children with intractable complex partial seizures. The neuropsychological measures included the assessment of performance and verbal IQ using Wechsler intelligence scales. ¹H spectra were obtained at 1.5T from 2x2x2cm cubes within the left and right mesial temporal lobes using a water-suppressed spin echo sequence with TE=135ms and TR=1600ms. The dominant signals are from N-acetylaspartate (NAA), creatine + phosphocreatine (Cr), and choline-containing compounds (Cho). Since NAA is believed to be present primarily within neurons, a reduction in NAA or in the NAA/Cho+Cr ratio is interpreted in terms of neuronal loss or damage.

The performance IQ was 96 ± 24 (mean \pm SD; range 50-142), and the verbal IQ was 87 ± 18 (range 51-117). The difference between performance and verbal IQ measurements was calculated for each subject, and plotted against the difference between the NAA/Cho+Cr ratios obtained from the right and left mesial temporal lobes. A highly significant correlation was observed ($r=0.65$, $p=0.001$), suggesting that neuronal loss or damage is associated with cognitive dysfunction in these children.

419.4

CONSERVATION OF GROSS MOTOR FUNCTION FOLLOWING FUNCTIONAL HEMISPHERECTOMY IN HUMAN. H. Sveistrup¹, T.B. Hoshizaki¹, S. Brien², E. Spyro¹, and J.G. Villemure³. ¹McGill University, ²Jewish General Hospital, ³Montreal Neurological Institute, Montreal, Canada.

Functional hemispherectomy is used as an alternative intervention to anatomical hemispherectomy for the treatment of seizures. It consists of complete callosotomy, complete disconnection of the frontal and parieto-occipital lobes in the coronal plane, and a temporal lobectomy (Villemure, In: *Epilepsy Surgery*, Ed. H. Luders, Raven Press: New York, 1991, pp 569-578). We studied the effect of this surgery on kinematic and kinetic parameters of three gross motor tasks: leg extension-flexion, arm extension-flexion, and locomotion (walking) in a 33-year-old female injured from birth.

Differences between ipsi- and contralateral side movements were recorded pre-surgery with greater motor dysfunction (i.e., decreased range of motion, decreased leg extension-flexion torque) observed on the side contralateral to the surgery. Following functional hemispherectomy, no changes were recorded in the kinetic and kinematic variables studied. The contralateral side remained more dysfunctional than the ipsilateral side. These data suggest that the surgical intervention did not alter the ability of the patient to perform these specific tasks.

It is possible that during development, the control of gross motor behaviors was integrated into the ipsilateral hemisphere. Alternatively, the specific movements studied may not require contributions from the neural structures functionally removed.

NEUROACTIVE AMINO ACIDS IN SYNAPTOSOMES FROM FOCAL AND NONFOCAL TEMPORAL LOBE TISSUE BIOPSED FROM PATIENTS WITH INTRACTABLE COMPLEX PARTIAL SEIZURES. D. Labiner¹, P.-L. Lley², M. E. Weinand³ and R. J. Huxtable², Departments of Neurology¹, Pharmacology² and Surgery³, University of Arizona College of Medicine, Tucson, Arizona 85724.

Temporal lobe tissue was obtained from 8 patients undergoing surgery for medically intractable complex partial seizures. Tissue from the epileptic focus was removed by suction, and nonfocal tissue was removed *en bloc*. Synaptosomes (P₂ fraction) were prepared from both tissues and analyzed for the major neuroactive amino acids. Concentrations ($\mu\text{Mol/g}$ protein) and percent changes in P₂ from the focus (compared to nonfocal P₂) were: Glu 2.99* (67%); Asp 2.39 (91%); Gly 1.16 (108%); GABA 0.57 (63%); Ala 0.27* (39%); Tau 0.26* (34%); and Gln 0.28* (14%) [*p<.05]. Total concentrations of the 7 amino acids were 12.47 \pm 2.56 $\mu\text{Mol/g}$ protein in nonfocal P₂ and 7.91 \pm 2.40 in focal P₂. A larger decrement was seen in the neuroinhibitory amino acids, GABA+Tau (to 41% of nonfocal P₂), than in the neuroexcitatory amino acids, Asp+Glu (to 71% of nonfocal P₂). This resulted in a marked elevation in the ratio of excitatory to inhibitory amino acids in P₂ from the focal area (the ratio being 7.12 in focal and 4.69 in nonfocal P₂). The other marked change was a large decrease in Gln in focal P₂, the Gln/Glu ratio dropping from 0.47 \pm 0.13 in nonfocal synaptosomes to 0.08 \pm 0.07 in synaptosomes from focal tissue. The significance of these findings for the neurochemistry of intractable complex partial seizures await study of the effects of the differing surgical treatments of focal and nonfocal tissue. However, the implications are that, in this well-defined group of patients with medically intractable complex partial seizures, there are underlying changes in neuroactive amino acids consistent with increased excitability in the focal region.

PREFERENTIAL LOSS OF NEURONS IN LAYER III OF THE ENTORHINAL CORTEX IN PATIENTS WITH TEMPORAL LOBE EPILEPSY. F. Du¹, W.O. Whetsell, Jr.¹, B. Abou-Khalil¹, B. Blumenkopf¹, E.W. Lothman² and R. Schwarcz², Maryland Psychiatric Research Center, Baltimore, MD 21228, ¹Vanderbilt Univ. School Med., Nashville, TN 37232 and ²Univ. Virginia Med. Ctr., Charlottesville, VA 22908.

Experimental and human clinical studies have suggested that the entorhinal cortex (EC) may participate in the generation and/or propagation of limbic seizures. Therefore, we have examined, by light microscopy, surgical specimens containing the EC obtained from 6 patients with complex partial seizures during temporal lobectomy. In Nissl-stained sections, a loss of neurons was observed in the anterior portion of the EC. Cell loss was particularly evident in layer III, but was also observed in layer II. This pattern of neurodegeneration was consistent in all specimens studied, though the degree of cell loss varied between patients. The laminar lesion described here was mainly seen in the medial EC, but was also noticed in the lateral EC. Ammon's horn sclerosis was also detected in all 6 patients. These results provide neuropathological evidence for a role of the EC in temporal lobe epilepsy. Since the EC occupies a pivotal position in gating hippocampal input and output, our results support previous suggestions that dysfunction of this region may contribute, either independently or in concert with Ammon's horn sclerosis, to epileptogenesis in humans.

PROLONGED GABA RESPONSES IN DENTATE GRANULE CELLS OF PATIENTS WITH TEMPORAL LOBE SCLEROSIS. A. Williamson¹, G.M. Shepherd and D.D. Spencer, Section of Neurosurgery, Yale University School of Medicine, New Haven, CT.

Human medial temporal lobe sclerosis is characterized by extensive anatomical and neurochemical reorganization throughout the entire hippocampal formation as well as by hyperexcitability in both the granule cell and pyramidal cell populations. In order to assess other changes in the excitable properties of these cells, we have compared the sclerotic hippocampi with those of patients with temporal lobe tumors (TLE) in which there is no neurochemical or anatomical reorganization, and in which the cells do not exhibit hyperexcitability.

We have compared the electrophysiological effects of focally applied GABA (1-10 mM) on granule cells from both types of hippocampus maintained in the slice preparation using intracellular recording techniques. In both types of tissue, GABA produced large depolarizations associated with an approximately 60% conductance increase when measured at rest. However, the GABA responses in the sclerotic tissue were significantly prolonged relative to those seen in the TLE tissue. The mean duration of the GABA responses were 46.7 \pm 11.6 sec (n=11) in the sclerotic tissue but only 9.08 \pm 3.6 sec (n=7) in the TLE tissue. The duration of the GABA response in the TLE tissue is comparable to that seen in rat granule cells.

This variation in the duration of the responses could be seen in a single case. Cells which were not hyperexcitable and which were found in more posterior sections of the hippocampus had shorter GABA responses than the more excitable cells found in anterior slices from the same patient. Thus these changes may be quite local and specific.

We hypothesize that this prolongation of the GABA response in the sclerotic tissue may be due to a reduction in the GABA uptake system. This change in the cellular responsiveness to GABA may represent an adaptation to neuronal injury associated with granule cell hyperexcitability.

SELECTIVE NEURONAL LOSS IN LAYER III OF THE MEDIAL ENTORHINAL CORTEX IN THREE RAT MODELS OF EPILEPSY. T. Eid, F. Du, E.W. Lothman¹, C. Köhler², R. Schwarcz², Md. Psych. Res. Ctr., Baltimore, MD 21228, ¹Dept. Neurology, Univ. Virginia Med. Ctr., Charlottesville, VA 22908 and ²Preclin. CNS Res., Hoffman-La Roche, Basel, Switzerland.

We recently showed that neurons in layer III of the medial entorhinal cortex (EC) are preferentially vulnerable to the convulsant aminooxyacetic acid (Neurosci. Lett. 147: 185, 1992). Since neurons in layer III of the EC also preferentially degenerate in human temporal lobe epilepsy (cf. Du et al., this meeting), we have examined the EC, by light microscopy in Nissl-stained sections, in 3 models of experimental epilepsy. Adult, male rats were either electrically stimulated in the ventral hippocampus for 90 minutes to produce limbic seizures or injected with kainic acid (10 mg/kg, s.c.) or pilocarpine (325 mg/kg, i.p.). After 24 hours, the brains of all rats that had acute behavioral seizures showed neuronal degeneration in the EC in addition to lesions in other limbic areas. In the EC, neurodegeneration was almost exclusively restricted to layer III. Typically, this laminar lesion was particularly pronounced in the medial part of the EC, though the lateral EC was often affected as well. Notably, surviving neurons were frequently seen in the lesioned layer. These data suggest a possible involvement of exquisitely vulnerable EC neurons in the mechanisms underlying limbic seizures.

ACCUMULATION OF β -AMYLOID PRECURSOR PROTEIN (β APP) AND INTERLEUKIN-1 α (IL-1 α) IN HUMAN TEMPORAL LOBE EPILEPSY. J.G. Sheng, C.R. Rovnaghi, F.R. Boop, R.E. Mrak, and W.S.T. Griffin*, Depts. of Anatomy, Neurosurgery, and Pathology, Univ. of Arkansas for Med. Sci., Little Rock, AR 72202.

Excessive expression of β APP is not only a neuropathological feature of Alzheimer's disease (AD) but also of heart disease, head trauma, and HIV infection. Elevation of β APP levels is associated with excessive growth of neurites and neuronal degeneration, both of which occur in focal epilepsy. IL-1 stimulates excessive expression of β APP. We measured the expression of β APP and IL-1 in resected temporal lobes from a group of patients with intractable epilepsy. By SDS-page immunoblot analysis, we identified three distinct β APP immunoreactive (β APP⁺) bands (MW 120-135 kD). Epileptic tissue showed 3 fold (P<0.05) and 4.5 fold (P<0.001) elevations of β APP⁺ product in the 135 and 130 kD bands, respectively, over analogous regions of autopsy tissue from non-epileptics of similar age (AMC); the amounts in the β APP⁺ 120 kD band were not different. In immunoreacted tissue sections from epileptics, the number of β APP⁺ neurons was higher than in analogous sections from AMC (133 \pm 12/mm² vs 8 \pm 3/mm²; P<0.001), and the levels of β APP⁺ product in these cells were greater than in β APP⁺ neurons in AMC. In addition, clusters of β APP⁺ dystrophic neurites were observed in some epilepsy cases, but not AMC. IL-1 α ⁺ microglia (GFAP⁺/S100 β) were more numerous in tissue sections from epileptics than AMC (80 \pm 8/mm² vs 25 \pm 5/mm²; P<0.001). IL-1 α ⁺ microglia in epileptic tissue were activated and had elevated levels of IL-1 α ⁺ product. IL-1 α ⁺ and β APP⁺ cells in temporal lobe from epileptics were similar in appearance to those observed soon after acute head injury, a risk factor for development of the neuropathology and dementia of AD. These findings may improve our understanding of the neuropathophysiological changes observed in epilepsy. Supported in part by NS27414 and AG10208.

SUBPOPULATIONS OF SMI32-IMMUNOREACTIVE PYRAMIDAL CELLS ARE DIFFERENTIALLY INNERVATED BY PARVALBUMIN-IMMUNOREACTIVE CHANDELIER CELL AXONS IN THE HUMAN NEOCORTEX. M.R. Del Río and J. DeFelipe*, Instituto Cajal (CSIC), 28002-Madrid, Spain.

Chandelier cells are considered to be one of the most powerful types of cortical inhibitory interneuron. These cells form synapses exclusively with the axon initial segment of pyramidal cells and are the major source of these synapses. Immunocytochemical studies in the primate neocortex have shown that particular populations of pyramidal cells and chandelier cells are labeled, respectively, using the antibody SMI32 that recognizes a non-phosphorylated epitope of neurofilament proteins and an antibody directed against the calcium-binding protein parvalbumin (PV). Therefore, we studied the relationships between these pyramidal cells populations and chandelier cells in the human neocortex. Cortical tissue was obtained during surgical treatment of epileptic patients. After resection, the tissue was immersed in a solution of 4% paraformaldehyde in phosphate buffer, then cut at 100 μm , and processed for immunocytochemistry using the above two antibodies sequentially in the same sections. We found four pyramidal cells subpopulations with regard to the immunocytochemical staining for SMI32 and the innervation of their axon initial segments by chandelier cell axons (Chax): (1) SMI32-positive pyramidal cells/ PV-positive Chax; (2) SMI32-positive pyramidal cells/ PV-negative Chax; (3) SMI32-negative pyramidal cells/ PV-positive Chax; (4) SMI32-negative pyramidal cells/ PV-negative Chax. Furthermore, there were differences in the concentration and proportion of the different subpopulations across cortical layers. (Supported by DGICYT grant PM92-0021).

ANTI-EPILEPTIC EFFECTS OF ORGANIC CALCIUM CHANNEL BLOCKERS ON EPILEPTIFORM ACTIVITY IN HUMAN NEOCORTEX (*IN VITRO*). E.-J. Speckmann^{1,2}, H. Straub¹, R. Köhling¹, A. Lücke¹, D. Moskopp¹, H. Wassmann¹. ¹Institut für Physiologie, Universität, Robert-Koch-Str. 27a, 48149 Münster, Germany; ²Institut für Experimentelle Epilepsieforschung, Universität, Hüfferstr. 68, 48149 Münster, Germany; ³Klinik und Poliklinik für Neurochirurgie, Universität, Albert-Schweitzer-Str. 33, 48149 Münster, Germany.

Epileptic activity in neuronal populations is accompanied by typical field potentials (EFP). In several animal experiments it has been demonstrated that a calcium ion inward current is essentially involved in the generation of epileptic events. Consequently, epileptic activity was suppressed by application of organic calcium channel blockers. The present investigations aimed to clarify whether this antiepileptic calcium antagonism can also be found in human neocortical tissue.

The experiments were performed on 23 slices (400-500 μm) of human neocortex. Tissue used was a small portion of that which is normally removed for the treatment of brain tumor. EFP were induced by superfusion with Mg^{2+} -free artificial cerebrospinal fluid (CSF) or bicuculline (10 $\mu\text{mol/l}$)-containing CSF. Verapamil and flunarizine were added to the superfusate. All values of time represent means.

EFP appeared spontaneously upon superfusion of Mg^{2+} -free CSF and stimulus-triggered upon application of bicuculline. Low Mg^{2+} -induced EFP were suppressed by 40 $\mu\text{mol/l}$ verapamil within 126 min and by 60 $\mu\text{mol/l}$ verapamil within 65 min. During wash-out of verapamil, EFP reappeared within 10 min. With superfusion of 10 $\mu\text{mol/l}$ flunarizine, EFP were irreversibly abolished within 175 min. Bicuculline-induced EFP were suppressed by 60 $\mu\text{mol/l}$ verapamil within 190 min and returned with wash-out of verapamil within 40 min.

The observations indicate that calcium currents and calcium-dependent currents are essentially involved in human epileptogenesis.

GREATER SYNCHRONY OF NON-BURST THAN BURST FIRING IN HUMAN EPILEPTIC TEMPORAL LOBES. B.W. COLDER*, R.C. FRYSSINGER, C.L. WILSON, AND R.M. HARPER. Dept. of Anatomy and Cell Biology, Dept. of Neurology, and Brain Res. Inst., UCLA School of Med., Los Angeles CA 90024.

The synchronous bursting of neurons in an epileptic focus is hypothesized to generate seizures by recruiting additional interconnected neurons to also fire synchronous bursts. We reported that cells more likely to fire in bursts and cells in the same hemisphere as the seizure onset have a greater tendency to show cross-correlations indicating synchronous discharge. Most spike trains, however, include both burst and non-burst firing patterns. It is unclear how each of these discharge components participates in the formation of cross-correlations showing synchrony and how that participation is affected by proximity to an epileptogenic region. We examined recordings of inter-ictal activity from temporal lobes of patients undergoing chronic depth electrode recording for diagnostic purposes. Cross-correlations were calculated between all pairs of simultaneously recorded cells. Spike trains of cells that took part in a cross-correlation showing synchrony were decomposed into "burst" and "singleton" trains. Burst trains contained all bursts, while singleton trains contained all non-burst firings. Cross-correlations were then calculated between all burst trains and between all singleton trains. In the epileptogenic hemisphere, synchrony was more often observed between singleton trains than burst trains, while the opposite was true for the contralateral hemisphere. These findings suggest that while synchronous firing near the epileptic focus may be a feature of both ictal and inter-ictal activity, the synchronization of bursts may be an ictal phenomenon. QUANTIFICATION OF DENDRITIC DEGENERATION AND ITS RELATION TO AXONAL REGENERATION IN SINGLE DENTATE GRANULE CELLS OF EPILEPTIC HIPPOCAMPUS. M. Isokawa*. Brain Research Institute, CHS, University of California, Los Angeles, CA 90024-1761.

Dendritic degeneration is one of morphological changes in human epileptic hippocampus (Scheibel et al. 1974). Intracellular recordings from human epileptic dentate granule cells (DGCs) suggested that an increased excitatory synaptic action, mediated by the NMDA receptor, was associated with this degeneration (Isokawa et al. 1991). In the present study, dendritic degeneration was quantified by injecting biocytin intracellularly and measuring spines, swellings, summed dendritic lengths (SDL), and the height of dendritic trees (H) in 16 DGCs. When spines were regularly present (N=5), their density was amazingly constant: 0.457 spines/ μm \pm 0.007 SEM, and the density of swelling was low: 0.045/ μm \pm 0.005 SEM (SDL: 6024.7 μm \pm 642.2 SEM; H: 1164.9 μm \pm 129.1 SEM). In 2 neurons, spine density declined to 0.290/ μm \pm 0.010, which coincided with the shortening of dendrites (SDL: 3018.0 \pm 195.4; H: 406.3 \pm 65.6). However, swelling density was not different (0.04/ μm \pm 0). When spines were largely lost (N=2), dendrites consisted of a series of swollen compartments (7.7 to 24.2 μm in size; 0.17 swellings/ μm \pm 0.06; SDL: 1666 \pm 1117.9; H: 368 \pm 92.0; 0.009 spines/ μm). In the latter two groups of neurons, no aberrant axon collaterals were detected. In 3 neurons in the first group, aberrant collaterals were detected among dendrites. In these neurons, swelling density increased 3-fold (0.12/ μm \pm 0.09) without affecting spine density (0.45/ μm \pm 0.006). This result suggests that swelling can occur independent of spine loss in epileptic DGCs, and axonal regeneration may be involved in this process. Dendritic degeneration may not simply be a consequence of a general decline of viability in epileptic hippocampus. Supported by a grant from NIH (NS02808).

PHASE RESETTING OF NEURONAL ACTIVITY IN THE HIPPOCAMPUS D. Durand*, E. Warman, Kate Greene and Paul Kammermier, Dept of Biomedical Engineering, Case Western Reserve University, Cleveland, OH, 44106.

The theory of phase resetting can predict the response of spontaneous oscillators to external perturbations. Some oscillators have the property known as strong resetting in which a perturbation applied during the period of oscillation can shift the occurrence of the next period and thereby reset the oscillation. It has been mathematically shown that systems with this property also present a singularity in the perturbation response. At the singularity, the response on the system is unpredictable and the perturbation often leads to annihilation of the response or induces a chaotic state.

We have applied the theory of phase resetting to quasi-periodic signals generated by epileptogenic agents in the hippocampus *in-vitro*. The purpose of the study was to determine whether the resulting oscillatory systems had the property of strong resetting and whether a singularity could be found. Orthodromic stimulation of the CA1 region in the hippocampal slice, in the presence of penicillin, generates interictal-like activity with 4 to 7 population spikes at a frequency of 200Hz. By stimulating the CA1 region extracellularly, we have shown that this quasi-periodic system does display strong resetting. Moreover, we also have been able to detect the presence of a singularity for which complete annihilation of the extracellular response is observed. In another set of experiments, perfusion of the hippocampal slice with high potassium solutions generates quasi-static periodic activity with a period of 1 to 2 Hz. This spontaneous interictal-like activity was also tested by stimulating the slice with an electrode located within the CA1 layer. The results indicate that this system also displays the property of strong resetting. However, we have not yet been able to find the singularity.

This analysis of two types of epileptiform activity has shown that the oscillatory waveforms generated in two animal models of epilepsy are vulnerable and could potentially be annihilated with electrical stimulation. Supported by NSF grant # BNS 8809504.

BURST PATTERNS IN SINGLE CELL DISCHARGE AS A FUNCTION OF PROXIMITY TO EPILEPTIC AREAS IN HUMAN TEMPORAL LOBE. R.C. Fryssinger*, B. Colder, C. Wilson and R.M. Harper. Depts. of Anatomy and Cell Biology, Neurology, and the Brain Research Institute, UCLA Med. School, Los Angeles, CA 90024.

Synchronization of action potential bursts has been proposed as part of the mechanism of epileptogenesis, and burst patterning has been suggested as a marker of cells involved in seizure propagation. Hippocampal neurons are known to show burst patterns in normal animals, and the relationship of "normal" to "pathogenic" burst patterns is of considerable theoretical interest. We recorded spike trains from 310 cells in 18 patients with epilepsy undergoing depth recordings of mesial temporal EEG. Bilateral recordings were performed in amygdala, anterior and mid pes hippocampi, anterior and posterior perihippocampal cortex, and transitional cortex. Spike trains producing a statistically significant peak in the autocorrelation within 40 ms of the origin were considered "bursting," and the area beneath the peak and the duration of the burst were recorded and categorized by side (ipsilateral or contralateral to seizure onset) and region. Mean burst area and duration was considerably larger for cells recorded on the contralateral side of all regions, corresponding to a larger number of spikes per burst. The percentage of bursting cells was somewhat lower on the ipsilateral side of pes hippocampi, but higher in transitional cortex. These results suggest that mesial temporal neurons on the epileptogenic side of humans with complex partial seizures have fewer spikes per burst and are generally less likely to show a bursting pattern. Supported by NS 02808.

420.1

ENHANCED SEIZURE SUSCEPTIBILITY YET IMPAIRMENT OF KINDLING DEVELOPMENT IN α -CALCIUM-CALMODULIN KINASE II MUTANT MICE. L. Butler¹, A. Silva², S. Tonegawa³ and J.O. McNamara¹. ¹Departments of Neurology and Neurobiology, Duke University Medical Center, Durham, NC 27710. ²Cold Spring Harbor Laboratory, Cold Spring Harbor, NY 11724. ³Center for Cancer Research, Massachusetts Institute of Technology, Cambridge, MA 02139.

Kindling is an animal model of epilepsy produced by focal electrical stimulation of the brain. Available evidence suggests that formation of long term potentiation (LTP) contributes to kindling development. Since formation of LTP is impaired in transgenic mice carrying a null mutation for the α -subunit of Calcium Calmodulin Kinase II (α -CaMKII), we compared kindling development in wild type (+/+), heterozygous (+/-), and homozygous (-/-) mutants. The development of kindling did not occur in -/- mutants despite large numbers (60) of stimulations. This result is consistent with the idea that LTP is necessary for the development of kindling. Unexpectedly, -/- mutants also exhibited profound hyperexcitability; that is, a tiny, normally subconvulsive stimulation of the amygdala triggered prolonged seizures and/or repeated and sometimes fatal seizures. Combining genetic manipulations with phenotypic analyses of mouse behavior and the underlying cellular and molecular correlates provides an opportunity to elucidate the mechanisms of these striking yet paradoxical phenotypes. Our findings underscore the value of gene targeting strategies for understanding nervous system disorders.

420.3

VIRAL VECTOR SYSTEMS--NEUROTOXICITY OF THEIR COMPONENTS Sheri L. Fink, Matthew S. Lawrence, Dora Y. Ho, Jeremy R. Tompkins* and Robert M. Sapolsky. Dept. of Biological Sciences, Stanford University, Stanford, CA 94305

Viral vectors can be used to import genes into neurons, with the potential to protect against neurodegenerative insults. Reports using such vectors generally note no cytopathicity, often citing as evidence the lack of behavioral changes in subjects, or lack of ventricular enlargement. However, we have investigated the cytopathic effects of components of viral preparations in greater detail, and find evidence for cytopathicity.

In Experiments I and II, one of the following was infused unilaterally into the hippocampus or striatum: PBS; a herpes simplex virus type 1 (HSV-1) deletion mutant [*d1120*, lacking an essential immediate early protein, ICP4; at low (2.5x10⁶ PFU/ul) and high (5.0x10⁷ PFU/ul) titer]; an HSV-1 temperature sensitive virus (ts756, with a mutation in ICP4, minimally permissive at 37 C; same titers); and debris from the E5 and Vero cells used to propagate viral amplicons. In Experiment II, one day after these manipulations rats were microinjected with kainate (33 nmol in the hippocampus) or quinolinic acid (7.9 nmol in the striatum). Rats were killed five days later and neurons were counted to determine whether any of these components caused loss of neurons (Exp. I), or increased the damage caused by excitotoxin injection (Exp. II). We also studied the effects of the vector system components on neuronal survival in hippocampal culture.

ts756 at high titer caused neuron loss in CA4 and dentate gyrus near the injection site. Cell debris caused cell loss in dentate gyrus only and *d1120* at high titer lead to near significant cell loss in CA1 and CA4. There was no striatal damage, or worsening of excitotoxic damage in either area. Both ts756 and *d1120*, at MOI's > 1, caused neuron loss in vitro, as did cell debris and cell supernatant. Thus, caution should be given in selecting the mutant viral vector and its titer; experimental and control vectors should be matched for titer, and viral preparations should be devoid of contaminating cell debris and supernatant.

420.5

ELEVATED BDNF mRNA EXPRESSION IN THE HIPPOCAMPUS OF AN EPILEPTIC MUTANT MOUSE, STARGAZER X. Qiao* and J.L. Noebels. Developmental Neurogenetics Laboratory, Section of Neurophysiology, Department of Neurology and Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

We have previously discovered hippocampal mossy fiber sprouting in the inner molecular layer of the dentate gyrus and in the stratum pyramidale of the CA3 region associated with a selective reduction of the hilar cell population following the onset of inherited spike-wave seizures in the mutant mouse *stargazer* (*stg*). To test the hypothesis that the neurotrophic factor BDNF may participate in the mechanisms underlying granule cell synaptic reorganization, *in situ* hybridization of BDNF ³⁵S-cRNA was performed in +/+ and *stg/stg* mouse brain at different ages. The overall pattern of the labelled neurons in +/+ mouse CNS is very similar to that described in rat brain. At 4 weeks of age (10 days after the seizure onset), *stg/stg* mice express higher levels of BDNF mRNA in the hippocampal CA3 pyramidal cells and dentate granule cells than those observed in the control mice. However, in adults, there is no obvious difference in the cellular distribution of BDNF mRNA between the two genotypes. Compared to other acutely-induced convulsive seizure models, the increase of BDNF mRNA in the *stg* mutant with chronic non-convulsive seizures is less intense. These initial results indicate that BDNF mRNA upregulation is associated at an early stage with spike-wave seizure activity and subsequent mossy fiber sprouting in the hippocampus.

420.2

A DEFECTIVE HERPES SIMPLEX VIRUS VECTOR EXPRESSING THE GLUCOSE TRANSPORTER GENE PROTECTS NEURONS FROM METABOLIC DECLINE AND CELL DEATH DURING GLUCOSE DEPRIVATION. D. Y. Ho*, M. S. Lawrence and R. M. Sapolsky. Dept. of Bio. Sciences, Stanford Univ., Stanford, CA 94305.

Defective herpes simplex virus (HSV) vector system can be used for gene transfer into neurons. We have previously shown that vE1GT, a HSV vector carrying the glucose transporter (GT) gene (Glut-1 isoform), can deliver the GT gene into various cell types in vitro (including rat hippocampal neurons and astrocytes), and into the rat hippocampus in vivo. Furthermore, GT gene delivery is associated with enhanced GT expression and glucose uptake. In this study, we investigate the effects of vE1GT infection on cell survivorship and metabolism during glucose deprivation. Ten day-old mixed hippocampal cultures were maintained with various glucose concentrations and surviving neurons were identified by immunocytochemical staining against MAP-2 antigen. Significantly more neurons survived low glucose conditions in vE1GT-infected cultures as compared to cultures infected with vE1bgal, a similar HSV vector carrying the E. coli lacZ gene in place of GT. Neuronal metabolic response to varied glucose levels was measured by the use of a microphysiometer. Five day-old mixed hippocampal cultures were maintained in DMEM containing 20 mM glucose, and their metabolic rates were measured. When the glucose concentration was dropped to 0.2 mM, a concomitant decrease of metabolic rate was observed within 5 minutes. vE1GT infection significantly lessened the decrease in metabolic rate as compared to vE1bgal-infected or uninfected controls. Thus, the increased glucose transport resulting from vE1GT infection can protect neurons from the decline in metabolism and the death that follows glucose deprivation.

OVEREXPRESSION OF THE GLUCOSE TRANSPORTER GENE WITH A HERPES VIRAL VECTOR PROTECTS AGAINST A HIPPOCAMPAL EXCITOTOXIC INSULT IN VIVO. M. S. Lawrence, D. Y. Ho and R. Sapolsky. Dept. of Biological Sciences, Stanford University, Stanford, CA 94305.

Due to their postmitotic nature, neurons are not addressable by conventional gene therapy techniques. The use of a defective herpes simplex virus (HSV) offers an attractive alternative. HSV is both neurotropic and capable of packaging large amounts of DNA for delivery to CNS neurons. We have generated a herpes simplex vector, designated α 4GT, bearing the rat brain glucose transporter gene (GT) under the control of the HSV α 4 promoter. In previous studies microinfusion of such vectors into the rat hippocampus results in localized overexpression of the glucose transporter as assessed by *in situ* hybridization, and enhanced [¹⁴C]2-deoxyglucose uptake (Ho, et al., PNAS, in press). When α 4GT was microinfused into the hippocampus 12 hours before a microinfusion of the excitotoxin, kainate, at the same location, cell damage (as quantified by size of lesion) was reduced by 27% relative to a contralateral uninfected cell field also exposed to kainate. Under varied glucose regimes, α 4GT was most protective against kainate in hypoglycemic rats, less so in normoglycemic rats and least in hyperglycemic rats. Control rats receiving unilateral infusions of a β -galactosidase-bearing HSV vector demonstrated no reduction in kainate-induced damage. These results suggest that metabolic distress is an important contributor to the neuropathology of excitotoxic damage in the hippocampus. From a broader therapeutic perspective, they suggest that HSV vectors offer a promising means of delivering neuroprotective genes to the CNS.

IMMEDIATE-EARLY GENE PROTEIN EXPRESSION IN A MUTANT MOUSE MODEL OF SPIKE-WAVE EPILEPSY, STARGAZER W.K. Nahm, J.L. Noebels* Developmental Neurogenetics Laboratory, Dept. of Neurology, Div. of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

Abnormal patterns of depolarization and bursting enhance the transcriptional activation of immediate-early genes (IEGs) in neurons. To determine whether the IEG protein expression profile differs with the absolute pattern of synaptic synchronization, we compared the nuclear staining pattern of polyclonal antibodies to Fos and Jun induced by kainic acid to that expressed in a genetic model of generalized non-convulsive epilepsy that shows frequent (mean 130/hour) intermittent bursts of 6/sec spike-waves. Two hours after seizures induced by kainic acid (30mg/kg i.p.), +/+ mice show intense Fos staining in all hippocampal subregions and in neocortex, entorhinal cortex, thalamus, and septum. In contrast, *stg/stg* and +/+ control brains showed no hippocampal Fos staining. To exclude the possibility that spontaneous seizures were too infrequent to elicit IEG proteins, we examined *stg/stg* mice treated with CPP (40 μ M/kg) that displayed a continuous pattern of spike-wave bursting for 1-2hrs. CPP treated *stg/stg* mice showed IEG protein staining patterns identical to untreated *stg/stg*. To determine whether refractory mechanisms contributed to the lack of IEG protein response in the mutants, their chronic seizures were blocked for 30 hours with ethosuximide, followed by immunohistochemistry 2 hours after seizures returned. There was no consistent difference compared to untreated *stg/stg* brains. Additionally, kainic acid induced strong IEG protein expression in *stg/stg* mice. These experiments show clear differences in IEG protein expression between two distinct patterns of abnormal neuronal synchronization, and demonstrate that the two seizure types differentially regulate neuronal gene expression in the brain. Since IEG protein expression is dependent on free intracellular Ca²⁺ levels, these data may reflect underlying differences in Ca²⁺ mobilization and Ca²⁺-activated mechanisms between convulsive and spike-wave seizures.

IN VITRO ELECTROPHYSIOLOGY OF SPONTANEOUS AND INDUCED EPILEPTIFORM DISCHARGES REVEALS INCREASED CORTICAL EXCITABILITY IN THE MUTANT MOUSE, STARGAZER. K.D. Keegan* & J.L. Noebels. Developmental Neurogenetics Laboratory, Dept. of Neurology, Div. of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

Extra- and intracellular current-clamp recordings were performed in the hippocampus, thalamus and cortex of adult *stargazer* mice (*stg/stg*) and their coisogenic controls (+/+). The aim of this study was to investigate the excitability defect underlying the generation of inherited spike-wave discharges in mice homozygous at the *stg* locus. Field recordings from oblique hemisectioned thalamo-cortical brain slices maintained at 32°C in normal ACSF [3.5mM K⁺] revealed the presence of low frequency (< 1/min) abnormal spontaneous network discharges with an irregular rhythm in all layers of the mutant cortex (8/10 mice) but not in +/+ cortex (0/33). Bursting was present in cingulate, neo, and prepyriform cortices. Intracellular recordings from layer 4-5 neurons showed a giant epsp (PDS) during each discharge. No spontaneous field activity was observed in other regions of the mutant slice. In 0 Mg⁺⁺ saline, similar field discharges and associated PDS's were observed in the cortex and hippocampus of both +/+ and *stg/stg* slices; the most obvious difference between the genotypes was the less regular burst pattern associated with more pronounced afterdischarge activity in the cortex of the mutant. Both spontaneous and 0 Mg⁺⁺ induced cortical bursting persisted following surgical isolation of the *stg/stg* cortex from the remainder of the slice. Bath application of 50µM APV in 0 Mg⁺⁺ produced a 90% reduction in the extracellular burst amplitude in both +/+ and *stg/stg* slices, consistent with the involvement of NMDA receptors. These initial studies point to a diffuse increase in cortical network excitability in the *stargazer* brain.

THE SPATIAL DISTRIBUTION AND MORPHOLOGICAL CHARACTERISTICS OF SPROUTED MOSSY FIBER AXONS IN THE DENTATE GYRUS OF KAINATE-TREATED RATS P. Zhang, G. Golarai, T. Sutula* The Neuroscience Training Program, and Dept. of Neurology, Univ. of Wisconsin, Madison, WI 53792

The anatomical features and spatial distribution of sprouted mossy fiber collaterals in the dentate gyrus were directly demonstrated by study of the axonal arbors of granule cells individually filled *in vitro* with biocytin, and *in vivo* with the anterograde lectin tracer PHA-L. Sprouted axon collaterals extended from the hilus into the supragranular layer in 10 of 12 biocytin filled granule cells from 3 kainate-treated rats. The sprouted collaterals had small diameters, and formed an extensive supragranular plexus with numerous terminal boutons that were smaller than the giant mossy boutons in the hilus. In 4 of the 10 granules cells, sprouted collaterals crossed the hilus and extended as far as 400 microns to the supragranular layer of the opposite blade. The axonal projection of granule cells filled *in vivo* with PHA-L included a dense plexus of axons in the hilus and CA3, with sprouted collaterals of small diameter which extended into the supragranular layer as far as 600 microns from the injection site along the septotemporal axis. The recurrent circuits formed by sprouted mossy fiber collaterals project along the transverse and septotemporal axes of the dentate gyrus, and possess anatomical features that could have powerful synchronizing effects.

420.11

MORPHOMETRIC AND ELECTROPHYSIOLOGICAL ANALYSIS OF HIPPOCAMPUS IN RATS WITH LONG-TERM PILOCARPINE SEIZURES T. Nagao, Z. Liu, C. Desjardins, M. Avoli, and P. Gloor*. MNI and McGill University, Montreal, QC, Canada H3A 2B4

Systemic administration of pilocarpine (380 mg/kg, i.p.) to adult male Sprague-Dawley rats induced an acute, prolonged state of seizures (status epilepticus) lasting several hours followed by complete neurological recovery. Spontaneous recurrent seizures of shorter duration appeared 2-2.5 weeks later and continued up to the sacrifice of the animals. Cell loss in the dorsal hippocampus was measured by an unbiased stereological technique. In areas CA1 and CA3, significant neuronal loss was observed 3 weeks after pilocarpine injection. However no progressive neuronal loss was detected when cell numbers were compared 6 and 12 weeks after pilocarpine injection after the rats had displayed recurrent seizures. There was no neuronal loss in the granule cell layer of the dentate gyrus. We used extracellular field potential recordings to analyze the spontaneous activity generated by hippocampal slices obtained from these rats during perfusion with 4-aminopyridine (4AP, 50 µM). The rate of occurrence of interictal discharges induced by 4AP was significantly lower in rats that had received pilocarpine 3 and 12 weeks earlier than in normal rats. Cutting the connections between CA1 and CA3 caused interictal discharges in CA1 area to disappear in both normal and 3 weeks post-pilocarpine rats. By contrast, 12 weeks after pilocarpine, there were interictal discharges in CA1 following the cut, though at a lower rate than before.

Our data indicate that the neuronal loss in CA1 and CA3 areas primarily results from the initial status epilepticus and that further recurrent chronic seizures do not produce any additional cell loss in these sectors. However, our electrophysiological data suggest that some neuronal network rearrangement might occur during the period of chronic recurrent seizures.

420.8

LACK OF MOSSY FIBER SPROUTING IN A RODENT MODEL OF PETIT MAL EPILEPSY. A.Kandel*, M.Hsu and G.Buzsáki. CMBN, Rutgers, The State University of New Jersey, Newark, NJ 07102

Generalized non-convulsive epilepsy is believed to result primarily from excessive population oscillation of the thalamocortical system, although neurons of several other systems are recruited during the spike and wave discharges. Several recent works reported on the involvement of the hippocampus and it was suggested that physiological and/or anatomical alterations in the hippocampus are either causally related to the occurrence of spike and wave episodes or that the pathological changes in the hippocampus occur parallel with the development of spike and wave activity.

In this study we sought to quantify the amount of mossy fiber sprouting, using Timm staining, and compare it to the estimated lifetime duration of petit mal seizure activity. The rats in the study represented different animal models for generalized non-convulsive epilepsy (WAG/Rij, F344, and Brown Norway x F344 offspring).

The main finding was that mossy fiber sprouting increased with age but was not correlated with the amount of seizures. The oldest rat (F344; 28 months) had the densest Timm staining in the inner molecular layer of the dentate gyrus but had a relatively low amount of seizures. WAG males (11 months) and BNxF344 females (24 months) had the same amount of Timm staining but the WAG group had significantly more seizures. The older WAG group (11 months) had denser Timm staining than the younger WAG group (8 months) even though both groups had comparable amounts of seizures. We conclude that mossy fiber sprouting increases with age in all strains tested but no reliable relationship exists between mossy fiber sprouting and the duration of petit mal seizures.

420.10

AXONAL SPROUTING OF ADULT RAT NEOCORTICAL PYRAMIDAL CELLS IN CHRONIC EPILEPTOGENIC LESIONS. P. Salin*, J. Parada, S.N. Hoffman, G.F. Tseng, D.A. Prince, Dpt. of Neurology & Neurological Sciences, Stanford University School of Medicine, Stanford, CA 94305.

Sprouting of mossy fibers is prominent in dentate gyrus of epileptogenic temporal lobe in animals and humans and has been suggested as a mechanism underlying the development of epilepsy. We performed experiments to determine whether similar sprouting occurs in chronic neocortical epileptogenic lesions. Partially isolated somatomotor neocortical slabs prepared *in vivo* generated epileptiform discharges when studied 2-6 wks. later *in vitro* (Prince and Tseng J. Neurophysiol. 69:1276, 1993). 39 layer V pyramids were labeled intracellularly with biocytin in slices of injured epileptogenic cortex and 52 cells from the same cortical area and lamina in unlesioned cortex served as controls. 43 of the most completely filled neurons (17 injured and 26 control) were reconstructed and analyzed. Somata of injured cells were significantly smaller ($200 \pm 15.5 \mu\text{m}^2$ SEM) than those of controls ($266 \pm 19.8 \mu\text{m}^2$, $p < 0.025$). Axonal arborizations revealed several features suggesting significant reorganization: 1) In a subgroup of cells (6 injured and 7 control) the number of axon collaterals was significantly higher in epileptogenic slices (59 ± 1.5) than in control (35 ± 4.3 , $p < 0.02$). 2) The total axonal length was increased in neurons of injured slices ($5.58 \pm 1.3 \text{mm}$) versus control ($3.26 \pm 0.5 \text{mm}$, $p < 0.05$). 3) The number of boutons was also significantly increased in injured cells (1090 ± 281) versus control (459 ± 83 , $p < 0.05$). 4) The area of distribution of boutons was larger in lesioned slices ($0.313 \pm 0.08 \text{mm}^2$) than in control ($0.156 \pm 0.03 \text{mm}^2$), suggesting that pyramids in injured cortex may contact more distant neurons than in control cortex. These results suggest that sprouting of axon collaterals occurs in adult neocortical neurons after injury. If such reorganization provides enhanced functional recurrent excitation, it would be a powerful factor in development of post-traumatic neocortical epileptogenesis. The relative contribution of axotomy, deafferentation and epileptic discharges *per se* to this anatomical remodeling remains to be explored. Supported by NIH grant NS12151 from the NINDS, the Morris Research Fund and a Pinley Fellowship.

EPILEPTIFORM ACTIVITY IN MODEL OF PARTIAL EPILEPSY IN RAT PIRIFORM CORTEX SPREADS TO HIPPOCAMPAL, AMYGDALOID, AND ENTORHINAL CORTEX. K.L. Ketchum* and L.B. Haberly. Dept. of Anatomy, Univ. of Wisc., Madison, WI 53706.

An anesthetized preparation has been developed that reproduces features of partial (focal) epilepsy including a slow spreading recruitment of adjacent cortex into the generation of epileptiform activity and self-sustaining electrographic seizures (Ketchum & Haberly, Soc. Neur. Abs. 18:910). In this model shocks to afferent fibers pace interictal events in a disinhibited focus created by picrotoxin injection into ant. piriform cortex (PC) of urethane anesthetized rats. At 1 Hz a large stereotyped epileptiform response develops in successive trials which spreads over the full extent of PC at a low rate (~0.001 m/s). Previous study (Ketchum & Haberly, Soc. Neur. Abs. 15:1033) suggests that, after this induction phenomenon, PC outside the disinhibited focus becomes involved in self-regenerative activity mediated by intrinsic associational fibers. It is proposed that this induction process is involved in the generalization of seizure activity evoked by injection of picomolar quantities of convulsant drugs into the deep part of ant. PC in unanesthetized rats (Piredda & Gale, Nature 317:623). If the induction phenomenon has this role then it must spread to other cortical areas to which the PC projects by mono- or multi-synaptic pathways. Simultaneous multiple site recordings revealed that the induction process continued into amygdaloid and entorhinal cortex and subsequently reached the CA1 region of the hippocampus. By manipulating the stimulation rate these areas could be made to repeatedly induce and recover during a single focal application of picrotoxin within the PC. Large abnormal potentials that were time-locked to epileptiform events in PC were also recorded in neocortex. These results indicate that the induction phenomenon can continue into cortical regions with direct projections from the PC (entorhinal and amygdaloid cortex) and in the case of hippocampus, an area that is polysynaptically removed. THE ROLE OF GLUTAMATE RECEPTOR SUBTYPES IN THE INDUCTION AND PROPAGATION OF SEIZURE ACTIVITY IN THE HIPPOCAMPUS AND OLFACTORY CORTEX OF THE GUINEA-PIG ISOLATED WHOLE BRAIN. P. Federico* and B.A. MacVicar. Neuroscience Res Group, Univ of Calgary, CANADA T2N 4N1.

Unilateral stimulation of the lateral entorhinal cortex (5 or 10 Hz; 5 or 10 sec) of the guinea-pig isolated whole brain evokes tonic-clonic-like seizure activity that can be recorded bilaterally for 1 min in the ventral hippocampus and entorhinal cortex using electrical and intrinsic imaging techniques (measurements of reflectance changes at 450 nm; $\Delta R/R_0 = 4-10\%$). This seizure activity propagates consistently to the posteromedial cortical amygdaloid nucleus. Since glutamate is the main excitatory neurotransmitter of hippocampal and entorhinal afferents, we examined the role of glutamate receptor subtypes in the induction and/or propagation of this seizure activity. When the non-NMDA receptor antagonist CNQX (20 μM) or the metabotropic receptor agonist trans-ACPD (150 μM) were added to the brain perfusate for 10-20 min, all seizure activity measured optically or electrically was completely or significantly suppressed. Perfusion of the NMDA receptor antagonists MK-801 (20 μM), AP-5 (100 μM), or AP-7 (200 μM), on the other hand, did not affect the electrophysiological or optical recordings of the seizure activity. These results suggest that activation of non-NMDA receptors is necessary for the generation of tonic-clonic seizure activity in the hippocampus/entorhinal cortex and that activation of metabotropic receptors depresses seizure activity. Activation of NMDA receptors, however, does not have a role in the induction or propagation of this seizure activity. Supported by MRC (Canada).

PROPAGATING EPILEPTIC AFTERDISCHARGES IN THE DISINHIBITED HIPPOCAMPAL SLICE R.D. Traub*, J.G.R. Jefferys & R. Miles. IBM Watson Res. Ctr., Yorktown Heights, NY 10598, St. Mary's Hospital Med. Sch., London W2 1PG, U.K. and Institut Pasteur, Paris 15, France.

A model has been proposed for the generation of synchronized afterdischarges (ADs) during GABA_A blockade (Traub, Miles & Jefferys, *J. Physiol.* 461: 525-547, 1993): a population burst develops via spread of firing along recurrent excitatory connections; NMDA currents then elicit dendritic oscillations to give a train of 2nd bursts. Phasic AMPA inputs maintain the synchrony of the bursts. Both initial bursts and later bursts are known to propagate along slices at about 0.15 m/s, slower than axon velocity, and propagation of the initial burst appears to depend on the spatial restriction of recurrent axons (Knowles et al., *Neuroscience* 21: 441-455, 1987; Miles et al., *J. Neurophysiol.* 60: 1481-1496, 1988). Our model of the temporal pattern of ADs predicts that the spatial pattern of 2nd bursts can behave differently than for the initial burst, because the dendrites are depolarized during the former. We tested this in a model of 8,000 compartmental neurons, with statistically localized interconnections containing AMPA and NMDA receptors. Under uniform baseline conditions, initial and 2nd bursts propagated with the same pattern at about the same velocity, as in Knowles et al. Other observed patterns were replicated by changing the conductance of NMDA synapses or by introducing a gradient in some synaptic property (NMDA or AMPA conductance, connection density): the failure of 2nd bursts to propagate along the whole array, the existence of a preferred direction of propagation for 2nd bursts, or propagation of 2nd bursts in different directions during the same afterdischarge. In all cases, the initial burst propagated uniformly away from the stimulus, as in experiments. In conclusion, our model of afterdischarges in the disinhibited slice predicts the voltage pattern in time and in space.

MULTI-SITE OPTICAL RECORDINGS OF EPILEPTIFORM BURSTS IN ORGANOTYPIC CULTURES OF RAT CEREBRAL CORTEX. T.S. Donta* and J.A. London. Center for Neurological Sciences, and the Dept. of Biostructure and Function, The Univ. of Connecticut Health Center, Farmington, CT 06030.

In an epileptic seizure, groups of cortical neurons that are normally independently active fire in synchronous bursts. Voltage-sensitive dyes and a 122-element photodiode array were used to record the spread of this excitation across cortical layers in organotypic cultures of rat brain slices. Long-Evans hooded rat pups were anesthetized by hypothermia and their brains removed for sectioning in either the transverse, sagittal, or horizontal planes. Sections (300 μm thick) were transferred onto tissue culture membrane inserts (Millipore) in 6-well dishes containing 1 ml of media, and incubated at 37°C. Cultures were used for recording after 2 weeks to 2 months *in vitro*. The fluorescent styryl dye RH795 (Molecular Probes) was applied to the cultures at 0.2 mg/ml for 1 hour. Optical signals have been recorded after application of bicuculline methiodide, a GABA antagonist that elicits synchronous, epileptiform bursting. Bursting was observed to travel from the deep to the shallow cortical layers, and from the agranular cortex to the granular cortex at speeds of approximately 0.2 m/s. Ongoing studies will analyze seizure origin and spread with greater spatial and temporal detail.

MULTIFOCAL SPONTANEOUS EPILEPTIC ACTIVITY IN THE LIMBIC SYSTEM OF THE ISOLATED IN VITRO GUINEA PIG BRAIN.

Marco de Curtis*, Gerardo Biella, Matteo Forti, Ferruccio Fanzica. Dept. Neurophysiology, Ist. Nazionale Neurologico, Milano, Italy.

An acute model of partial epilepsy (Piredda and Gale, *Nature*, 317:623, 1985; Ketchum and Haberly, *Soc. Neurosci. Abstr.* 378:12, 1992) has been utilized to study spontaneous epileptiform activity in the olfactory cortex of the *in vitro* isolated guinea pig brain (de Curtis, Pare' and Llinas, *Hippocampus*, 1:341, 1991). Local bicuculline applications at the anterior piriform cortex (APC) induced an increase in neuronal excitability restricted to the site of ejection. The APC epileptogenic focus generated spontaneous "interictal" epileptic potentials, while prolonged self-sustained "ictal" discharges were never observed. Current source density analysis of the spontaneous events recorded over the cortical depth at different antero-posterior sites in the piriform cortex demonstrated that epileptic potentials propagated from the APC focus throughout the piriform lobe along associative fibers. Secondary foci of spontaneous epileptiform activity were observed in the posterior piriform cortex within one hour from the APC bicuculline ejection. The independence of the secondary foci from the primary APC focus was demonstrated after surgical isolation of the latter. Propagated spontaneous and evoked epileptiform activities were abolished at the site of the isolated primary cortical focus after cutting LOT and associative fibers, while spontaneous epileptiform potentials persisted in secondary foci.

OPTICAL RECORDINGS REVEAL THAT EPILEPTIFORM ACTIVITY IN NEOCORTICAL SLICES SPREADS PREFERENTIALLY THROUGH UPPER CORTICAL LAYERS. B. Albowitz and U. Kuhnt*. Dept. of Neurobiol., Max-Planck-Inst. Biophys. Chem., 37018 Göttingen, FRG.

A characteristic feature of epileptiform activity is the spread of synchronous discharge across large areas of neuronal tissue. The pathways responsible for horizontal spread in the neocortex were investigated in sensory neocortical slices by use of an optical recording technique. Coronal slices (350 μm) from sensory neocortex of guinea pigs were stained with the fluorescence voltage-sensitive dye RH795. Epileptiform activity was induced in a bath medium containing 20 μM bicuculline by single pulse electrical stimulation of the white matter or layer I. Voltage dependent fluorescence changes were monitored by a 10x10 photodiode array. The system provided a spatial resolution of 94 μm and a temporal resolution of 0.4ms. Two vertical cuts (parallel to the axis of pyramidal neurones), one sectioning upper layers (I-IV), the other lower layers (V, VI, and the white matter), were made at different positions in the slice.

In intact slices, the latency of epileptiform potentials at specific medio-lateral positions was always shortest in upper cortical layers as compared to lower layers if epileptiform activity was evoked from layer I. If activity was evoked from the white matter, no consistent pattern was found. In sectioned slices, regardless of the point of stimulation, the pattern of spread was not significantly different from that in intact slices if epileptiform activity had to spread across a section through lower cortical layers. However, epileptiform potentials either did not at all spread past a cut through upper cortical layers or spread with significant jumps in latency.

The detailed analysis of spatio-temporal activity patterns in intact and sectioned slices revealed that epileptiform potentials spread to a certain degree independently through upper and lower cortical layers. However, the pathway through upper cortical layers appears to be more powerful and usually predominates.

MULTIPLE PACEMAKERS IN THE CA2-CA3 REGION OF THE GUINEA PIG HIPPOCAMPUS INITIATE EPILEPTIFORM ACTIVITY. L.V. Colom* and P. Saggau. Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

Groups of neurons generating abnormal bursts of action potentials can act as pacemakers for interictal-like epileptiform activity. The localization of such aggregates is critical for understanding the origin and spread of epileptiform discharges. Voltage-sensitive dyes and fast multi-site optical recording techniques were used to monitor spatiotemporal patterns of spontaneous epileptiform activity in transverse guinea pig hippocampal slices. Three *in vitro* animal models of epilepsy were studied: 1) high bath potassium concentration (8 mM K⁺), 2) 4-aminopyridine (100 μM 4-AP), and 3) the GABA_A antagonists bicuculline and picrotoxin (20 μM BIC, 50 μM PTX). When BIC-PTX was employed, discharges consistently started in the CA2-CA3a region. However, with high K⁺ or 4-AP, activity originated in both the CA2-CA3a and CA3c region. Surgical lesions separating these regions demonstrated that both can act as independent pacemakers, showing spontaneous discharges of different frequencies. The slower pacemaker discharged more frequently when separated from the faster. In the CA2-CA3a region, two independent pacemakers were occasionally observed. Although BIC-PTX only generated discharges in the CA2-CA3a region, a subsequent increase in K⁺ resulted in additional discharges in the CA3c region, revealing a latent pacemaker. In summary, we demonstrated: 1) the existence of multiple pacemaker areas capable of generating epileptiform discharges in the guinea pig hippocampus, 2) interaction between those pacemakers, and 3) the expression of such pacemakers depending on the epilepsy model used. Supported by a grant of the Cain Foundation to P. Saggau.

420.19

OPTICAL IMAGING OF CARBACHOL-INDUCED SPONTANEOUS EPILEPTIFORM OSCILLATIONS IN GUINEA PIG HIPPOCAMPAL BRAIN SLICES. S.S. Patel*, L.V. Colom and P. Saggau. Division of Neuroscience, Baylor College of Medicine, Houston, TX 77030.

Cholinergic epileptiform activity in hippocampal brain slices frequently shows oscillations in the theta frequency range. Spatio-temporal characteristics of spontaneous oscillatory activity induced by carbamylcholine chloride (carbachol, 50 μ M) were studied. Voltage-sensitive dyes and fast multi-site optical recording techniques were used to monitor these events in transverse guinea pig hippocampal slices. A versatile PC-based optical workstation was developed, to handle multiple photodetectors of different spatio-temporal resolution, providing high-speed data acquisition, processing and visualizing of neural activity in a windows-based graphical environment. Here, a 10x10 photodiode array coupled to a low-noise multichannel amplifier unit together with a CCD camera was used. During experiments, neural activity was displayed as a matrix of temporal traces overlaid on a video image of the preparation, allowing one to form spatially averaged functional or anatomical clusters. Spatio-temporal dynamics of activity were examined by viewing continuous sequences of interpolated high resolution images (200x200 pixels). Epileptiform discharges lasting 100 ms to several seconds were recorded. Such activity originated at multiple sites within the CA2-CA3 region. Oscillatory activity with an average frequency of 9.06 \pm 2.88 Hz was observed in 44% of the cases. The degree of synchrony of such discharges differed among hippocampal regions. Typically, the CA2-CA3a region showed pronounced oscillations, while area CA3c was less synchronized. A computational neural network is being developed to model the spatio-temporal system dynamics.

420.20

METABOTROPIC GLUTAMATE RECEPTORS MODULATE AND PRODUCE EPILEPTIFORM ACTIVITY IN THE HIPPOCAMPUS. P.A. Rutecki* and Y. Yang. Dept. of Neuro., Neurosci. Training Prog., U. of Wis., Madison, WI 53792.

Depending on the preparation, activation of glutamate metabotropic receptors by *cis*-(\pm)-1-aminocyclopentane-1,3-dicarboxylic acid (ACPD) results in stimulation of different second messenger systems and modulation of various ion channels. We studied the effect of ACPD on epileptiform activity produced by 4-aminopyridine (4-AP, 25 μ M in 2.5 mM [K⁺]_o) or bicuculline methiodide (BMI, 10 μ M in 2.5 or 5 mM [K⁺]_o) in hippocampal slices prepared from adult rats. Using extracellular recording techniques, the rate of spontaneously occurring epileptiform discharges in the CA3 region of the hippocampus was monitored before and after bath application of ACPD. At 30 μ M, ACPD increased the BMI-induced burst rate by 87% (0.15 \pm 0.02 vs 0.28 \pm 0.02 Hz) and increased the 4-AP-induced burst rate by 44% (0.42 \pm 0.04 vs 0.59 \pm 0.05 Hz). At 100 μ M, ACPD resulted in a 390% increase in rate for BMI (0.59 \pm 0.09 Hz) and 83% increase for 4-AP-induced discharges (0.77 \pm 0.07 Hz). The discharge rate returned to control values after a 20-30 min wash-out. The acceleration of BMI-induced bursting was not blocked by 50 μ M D,L-APV or 1 μ M timolol. In the absence of convulsants, 100 μ M ACPD generated spontaneously occurring epileptiform discharges in the CA3 region of the hippocampus that did not readily wash out. The acceleration of epileptiform discharge rate is consistent with a decrease in potassium currents, a recognized effect of ACPD on CA3 neurons. ACPD-induced epileptiform activity may result from blockade of potassium channels and a reduction in GABA_A inhibition. Supported by the NIH and Veterans Administration.

CLONING OF A PROTEIN THAT BINDS TO A RECOGNITION SEQUENCE IN THE APP PROMOTER. A.A. Vostrov¹, W.W. Quitschke^{1*}, A.L. Schwarzman¹, A. Blangy², F. Cuzin², U.V. Wesley¹, N.G. Hagag¹, D. Goldgaber¹. ¹School of Medicine, SUNY at Stony Brook, Stony Brook, NY 11794-8101. ²Unité 273 de l'INSERM, Université de Nice Sophia Antipolis, 06108, Nice FRANCE.

There is a very strong similarity between a specific DNA recognition sequence in the proximal human APP promoter (Quitschke and Goldgaber, J. Bio. Chem., 267:17362;1992) and the murine CDEI-like element. Recently, a murine DNA binding protein that recognizes the murine CDEI-like sequence was cloned (Vidal et al., BBRC, 189:1336;1992). This protein showed extensive local similarities to APP.

Oligonucleotides that contained the APP promoter element and oligonucleotides that contained the murine CDEI-like element were analyzed by a mobility shift assay. Each oligonucleotide successfully competed with the other but not with the control altered oligonucleotides. We found that the cloned murine DNA binding protein that binds to the murine CDEI-like element also binds to the APP promoter element.

Using the mouse cDNA clone as a probe, we identified and sequenced several clones from the human brain cDNA library. Comparison of the human and murine sequences showed in a very high level of conservation. Work is currently in progress to determine the chromosomal localization of the human gene which codes for this DNA binding protein.

REGULATION OF THE PROMOTER ACTIVITY OF THE APP GENE IN PC12 CELLS BY GROWTH FACTORS AND RETINOIC ACID. D. K. Lahiri* and C. Nall. Lab of Molecular Neurogenetics, Institute of Psychiatric Research, Indiana University School of Medicine, Indianapolis, IN-46202

Abnormalities in gene regulation of β -amyloid precursor proteins (APP) might be an important factor in the neuropathology of Alzheimer's disease. We have studied the effects of nerve growth factor (NGF), basic fibroblast growth factor (bFGF) and all-trans-retinoic acid (RA) on the promoter activity of the APP gene. Recombinant plasmid containing a 1.2 kb fragment of the promoter part of the APP gene linked to a reporter gene, chloramphenicol acetyl transferase (CAT), was constructed. Then the promoter activity of the APP gene was tested by transient expression in PC12 cells. The transfection of DNA into cells was done by the electroporation method which minimizes and in some experimental sets eliminates the variation of transfection efficiency among different plates. We have set up an efficient procedure for transfection in differentiated cells. Transfection of DNA was done into cells which were part of three types of treatment groups. The first group was pretreated with factors, a second group was treated with factors only after transfection and a third set was treated with factors before and after transfection. Transfected cells were assayed for the CAT activity at various days of post transfection.

We have found that the promoter activity was increased when cells were treated with either NGF or bFGF and the promoter activity decreased when cells were treated with RA. The degree of increase or decrease of the promoter activity depends on the number of days of treatment with the factors prior to transfection. The promoter activity was also found to be dependent on the duration of treatment with the factors after cells were transfected. Our results suggest a possible participation of a growth-factor (s) mediated transcription element in the regulation of the gene expression of APP. Supported by the N.I.H. grant PHS R01 AG10297-01A1.

APP mRNA ISOFORMS WITHOUT EXON 15 (L-APP mRNA) ARE UBIQUITOUSLY EXPRESSED IN RAT TISSUES INCLUDING BRAIN, BUT NOT IN NEURONS. R. Sandbrink, C. L. Masters and K. Beyreuther*. Center for Molecular Biology Heidelberg, Univ. of Heidelberg, Germany. The BA4-amyloid protein precursor (APP), a glycoprotein with a single transmembrane spanning domain, is the source of BA4-amyloid, which is deposited in the brains of individuals with Alzheimer's disease. APP constitutes a family of different isoforms that are generated by alternative splicing of the 19 exons encoding APP gene. While exon 7 and exon 8 are well known to be alternatively spliced, APP mRNA isoforms without exon 15 were only recently identified in leukocytes and rat brain microglial cells and therefore denoted as L-APP mRNA. Since a detailed analysis of the individual L-APP mRNA isoforms has not been performed yet, we designed a quantitative polymerase chain reaction from reverse transcribed RNA allowing us to analyze the complete region between exon 6 and 16 of the APP gene. This strategy enabled us to distinguish between most of the APP splice isoforms generated by alternative splicing of exons 7, 8 and 15. To answer the open question of L-APP expression *in vivo*, we then applied this method to perfused rat tissues. In all peripheral tissues examined, L-APP mRNA isoforms were detected comprising between 25% (skeletal muscle) and about 70% (aorta, pancreas) of total APP transcripts. All four possible APP mRNA isoforms lacking exon 15 could be shown to exist, i. e. L-APP752, L-APP733, L-APP696 and L-APP677. L-APP expression in the central nervous system (about 4% of all APP mRNAs in total brain) was then studied in more detail by analyzing different brain regions and tissues and correlated with data from primary cell cultures. The only cell type, which was shown not to express L-APP mRNA to a detectable level, is the neuronal cell. Therefore, we suggest that the functional consequence of L-APP mRNA expression may be studied in neurons.

RELATION BETWEEN β /A4 SECRETION AND A 12 kDa COOH-TERMINAL DERIVATIVE OF THE ALZHEIMER'S AMYLOID PRECURSOR PROTEIN. J.T. Durkin*, S. Murthy, S. Mistretta, E.K. Hoffman, T. Levins, B.D. Greenberg, R.W. Scott, and R. Siman. Cephalon, Inc., 145 Brandywine Parkway, West Chester, PA 19380.

The amyloid protein of Alzheimer's disease, β /A4, is produced by one of several possible pathways for processing the β -amyloid precursor protein (APP). Among the COOH-terminal derivatives of APP (CTDs) is a 12 kDa derivative that co-migrates with APP(652-751) (numbered after APP751), and therefore likely includes the intact β /A4 domain (see also Cheung et al., 1992, *Soc. Neurosci. Abstr.*, 18(1), 764). Only the 12 kDa CTD, and not larger or smaller derivatives, is recognized on immunoblots by an antibody raised against β (1-9). The antibody likely recognizes its epitope only with a free NH₂-terminus, suggesting that the 12 kDa CTD begins precisely at β /A4. We have shown by metabolic labelling and immunoprecipitation that different clones of 293 cells stably overexpressing APP751 secrete different amounts of β /A4 protein. Immunoprecipitation of cell lysates shows that the clone secreting more β /A4 protein also accumulates more 12 kDa CTD at steady-state. The same correlation holds for clones of CHO cells stably overexpressing APP751:K651N/M652L, the double mutation associated with Alzheimer's disease in a Swedish family. The correlation, coupled with the antibody labelling suggesting that β /A4 protein and the 12 kDa CTD have the same NH₂-terminus, suggests that the 12 kDa CTD may be an intermediate in the production of β /A4 protein.

DECREASED SOLUBLE AMYLOID PRECURSOR PROTEIN IN FAMILIAL ALZHEIMER'S BRAIN (APP717 VAL-ILE MUTATION) N. Nukina^{*}, K. Hashimoto, I. Kanazawa, and H. Mizusawa Department of Neurology, University of Tokyo, Tokyo, Japan 113

The amyloid core in senile plaques of Alzheimer's disease is composed of beta protein. Recent discovery of familial Alzheimer's diseases which are linked to APP mutations suggests that the beta protein accumulation is a primary pathology. It is important to clarify whether the processing of APP in those cases with the mutation is different from the processing in other cases. In this study we investigated the APP and beta protein amount in AD with mutation using western blot.

Antibodies used in this study were the following: monoclonal antibody against beta protein (A61) which reacts with beta 1-17, monoclonal antibody 22C11 (Boehringer Mannheim), polyclonal antibodies against APP synthetic peptides 666-695 (anti-C). Tissue from 2 cases with the mutation (APP717 Val-Ile), 4 sporadic cases and 4 control cases were used.

Tris Saline soluble fraction, Triton soluble fraction, SDS soluble fraction and SDS insoluble fractions were examined by ECL western blot kit (Amersham) using antibodies. We could not detect specific bands in AD with mutation. The amounts of beta protein in SDS insoluble fractions and membrane bound APP of AD with mutation were not different from those of sporadic ADs and controls. However APP amount of TS soluble fraction was decreased in AD with mutation. The result suggests that the amount of secretory APP is decreased and there is abnormal metabolism of APP in AD with mutation.

Apolipoprotein E and Alzheimer's β -amyloid fibril formation. Thomas Wisniewski, Adam Golabek, Jorge Ghiso and Blas Frangione^{*} New York University Medical Center, New York, New York, 10016

Apolipoprotein E (Apo E) and Alzheimer's β -protein ($A\beta$) show high affinity binding both with $A\beta$ in senile plaques and the normal soluble $A\beta$ ($sA\beta$) found in biological fluids. Apo E is highly expressed in the brain and is the major lipoprotein in the cerebrospinal fluid (CSF), where it is an acute phase reactant. Apo E belongs to a group of amyloid-associated proteins, or "pathological chaperones"; by this we mean a group of biochemically unrelated proteins that mediate fibril formation but are not themselves part of the final fibril. Apo E is coded for by a single gene on chromosome 19 at a locus that has been linked with disease in some familial Alzheimer's disease (AD) families. Nine different Apo E alleles are known. Homozygosity for $\epsilon 4$ is associated with both sporadic and familial AD. When synthetic peptides homologous to $sA\beta$ are bound to either nylon membranes or cyanogen bromide activated Sepharose and CSF is passed through, Apo E, as well as another apolipoprotein, Apo J, bind. We show with an assay for amyloid formation in solution that Apo E can promote fibril formation; this was not seen with Apo J under the conditions tested. Therefore Apo E may influence whether $A\beta$ remains in solution or forms an amyloid fibril.

TRANSCRIPTIONAL ACTIVITY AND REGULATION OF THE RAT AMYLOID PRECURSOR PROTEIN (APP) PROMOTER. J. M. Chernak^{*} and P. W. Hoffman. Molecular Neurobiology Unit, National Institute on Aging, Gerontology Research Center, Baltimore, MD 21224

β -amyloid plaques are present in the brains of Alzheimer's patients, Down's Syndrome patients and to a lesser extent in apparently healthy older humans, but not in the brains of aged or memory-impaired rodents. Expression of the APP gene which gives rise to β -amyloid may therefore be regulated differently in rodents than humans. Since Down's patients carry an extra copy of the gene and have elevated levels of APP mRNAs, increased transcriptional expression may contribute to the appearance of plaques in humans. Thus, it is of great interest to understand the transcriptional regulation of the APP gene in different species. The 5' upstream regulatory region of the rat APP gene has been cloned and investigated by sequence analysis and by assays of transcriptional activity from extracts of cells transfected with wild type and mutant promoter/reporter gene fusions. This region lacks a TATA box and a CAAT box, has a G+C content of 68%, and is 80-90% homologous to the corresponding nucleotide sequence of the mouse and human APP genes. It contains a variety of putative regulatory DNA elements, including SP1, AP1, AP2, AP4, and GCF sites, GC-rich boxes, and six potential stem-loop secondary structures near the probable transcriptional start point. While a series of elements which are well-conserved between rat, mouse and human may serve similar functions in all species, a variety of species-specific differences are present which could be relevant to the production of amyloid plaques in humans but not in rodents. We have shown that the rat upstream region can act as a functional promoter in both rat PC12 cells and human SHSY5Y neuroblastoma cells, and that its activity is at least ten-fold that of the SV40 promoter in PC12 cells. A series of mutations deleting or altering putative regulatory sites has been constructed and analyzed for transcriptional activity. Additional mutagenesis, gel mobility shift assays and footprinting experiments will be used to identify specific sites on the DNA which interact with age-specific, species-specific, and/or tissue-specific nuclear proteins. We are also investigating the effects of nerve growth factor and retinoic acid on the transcriptional activity of the rat APP promoter in different cell lines.

MUTATIONS ASSOCIATED WITH FAD ALTER THE PROTEOLYTIC PROCESSING OF CYTOSOLIC APP ISOFORMS. A. Weidemann, C. Czech, T. Hartmann, R. Prior^{*}, C. L. Masters^o and K. Beyreuther

Center for Molecular Biology, University of Heidelberg (ZMBH), Im Neuenheimer Feld 282, D-6900 Heidelberg, F.R.Germany. ^{*}Department of Pathology, University of Melbourne, Parkville, Victoria 3052, Australia.

The $\beta A4$ protein, which forms amyloid aggregates in Alzheimer's disease is released from its cognate precursor (APP) by at least two proteolytic cleavage events, one in the ectodomain of APP the other within the transmembrane domain. Here we report that initiation of APP translation is not restricted to the first AUG start codon preceding the signal peptide sequence which specifies membrane insertion of APP. To a minor extent, further downstream AUG codons are also used for initiation of translation leading to APP derivatives targeted to the cytosol. The latter are not membrane embedded and are therefore at the putative transmembrane domain accessible for proteases. The catabolism of these cytoplasmic APP derivatives includes proteolysis around the C-terminus of the $\beta A4$ sequence. Additionally, the catabolism is affected by APP mutations described for hereditary forms of Alzheimer's disease.

A REL-RELATED REGULATORY PROTEIN CONTROLS EXPRESSION OF THE AMYLOID PRECURSOR PROTEIN (APP) GENE. M. Gilli^{*}, A. Alberici and P. E. Spano. Pharmacology Sec., Dept. of Biomed. Sci. & Biotech., Univ. of Brescia, Italy.

Several reports in the literature suggest the potential role for increased or dysregulated APP gene expression in the pathogenesis of Alzheimer's disease. For this reason it becomes very important to address questions about the participants in the transcriptional control of the APP gene and in particular to identify: i) cis regulatory elements in the gene; ii) transcription factors able to bind these sequences; iii) physiological signals they respond to.

We report the finding that a protein belonging to the well-known family of NF κ B/Rel transcription factors is involved in regulating expression of the APP gene. Members of this family (referred to as p50, p65, c-Rel, p49, RelB) show high homology to the Rel oncogene and are able to form homo- and hetero-dimers which process and integrate a wide variety of extracellular signals and transmit the information to the transcriptional machinery by directly binding to a range of different DNA sequences in gene control regions.

We have identified two identical sequences located in the APP gene regulatory region which can bind a nuclear factor which is present in various rat brain regions, in primary cultures of cerebellar granule cells and in PC12. By several criteria (competition analysis, affinity properties, immunogenicity) this factor seems very similar to the p-50 homodimer belonging to the NF κ B/Rel family. To further prove the molecular nature of the factor recombinant p50 protein expressed by bacteria was obtained and proved to bind the oligonucleotide sequences contained in the APP region. Since in other systems (i.e. IL-2 gene) the p50-p50 homodimer acts as a repressor of gene transcription we are currently investigating the functional role of the APP- κ B sequence by transfecting various cell lines with plasmid constructs in which this sequence has been linked to the reporter gene CAT.

TRANSGENIC RAT AND IN-VITRO STUDIES OF β -AMYLOID PRECURSOR PROTEIN PROCESSING Kevin M. Felsenstein, Allison Treloar, Janet M. Roome, Lisa W. Hunihan, Kim M. Ingalls, and Susan B. Roberts CNS-Drug Discovery, Bristol-Myers Squibb Pharmaceutical Research Institute, Wallingford, CT 06492

We have previously reported the use of a novel recombinant reporter system for β -amyloid precursor processing which utilizes the human placental alkaline phosphatase (HPLAP) gene fused to various C-terminal regions of the β -amyloid precursor protein (β -APP). The fusion of the C-terminal 164 amino acids of β -APP has been characterized as being proteolytically processed in a similar manner to actual β -APP. We have used this system to characterize the proteolytic activities involved in the processing of β -APP, including the biochemical characterization of the activities and mutational analysis of the processing events including analysis of the FAD mutations. An advantage afforded by this system is the ability to measure both qualitatively and quantitatively (immunologically or enzymatically). In the effort to develop animal models for AD pathology the use of such a fusion protein may provide an alternative approach.

We are currently attempting to generate transgenic rat models based on the overexpression of β -APP, C-terminal protein derivatives, e.g. APPC-100, and the HPLAP- β -APP fusion protein. Transgenic rat lines have been established and the status of these studies will be reviewed. Expression of the transgenes has been measured by RNA analysis and in the case of HPLAP- β -APP transgene by direct enzymatic measurements. Pathological and behavioral analyses are currently underway. These rat transgenics may potentially provide useful models to study the effects of chronic overexpression of potentially amyloidogenic protein fragments and the development of an Alzheimer-like pathology.

421.11

ALZHEIMER-LIKE DIFFUSE AMYLOID PLAQUES CAN BE INDUCED IN TRANSGENIC MICE EXPRESSING HUMAN α 1-ANTICHYMOTRYPSIN. R.O. Kuljis*, R.D. Beech, S.R. Ross and C-Y. Yeung. Dept. Neurology, University of Iowa and V.A.M.C., Iowa City, IA 52242-1053 and Depts. of Genetics and Biochemistry, University of Illinois at Chicago, IL 60612.

Large numbers of amyloid-containing plaques are an important histopathological feature of Alzheimer's disease (AD). Some have felt that these may be the initial lesions that lead to senile plaques, neurofibrillary tangles, neuronal loss and reactive gliosis. Three independently derived outbred ICR transgenic mouse strains carrying a human α 1-antichymotrypsin (ACT) transgene were generated. Expression of the transgene in each strain was verified by a reverse transcriptase/polymerase chain reaction technique, *in situ* hybridization and immunolabeling. The murine homolog of the ACT gene is not normally expressed in the brain. However, *in situ* hybridization revealed expression of the human ACT transgene throughout the CNS. In 8-month-old specimens, the silver impregnation method of Campbell et al. (Soc. Neurosci. Abstr. 13:678) and a panel of antibodies to β A4 amyloid, its precursor protein and ACT reveal massive numbers of deposits that co-contain these proteins throughout the CNS in all three transgenic mouse strains. These lesions are morphologically and immunocytochemically indistinguishable from diffuse amyloid plaques in AD. Thus, constitutive overexpression of ACT alone is sufficient to induce the formation of amyloid plaques in the brain, and further aging or additional experimental manipulations may result in additional Alzheimer-like pathology.

421.13

NEURON-SPECIFIC EXPRESSION OF HUMAN BETA-AMYLOID PRECURSOR PROTEIN (APP) IN TRANSGENIC MICE. D.S. Howland¹, D.A. Schwartz¹, M.J. Savage¹, F.A. Huntress², R.E. Wallace², L.R. Pinsky¹, R. Coffey², D.J. Kiehn², L.J. DeGennaro³, B.D. Greenberg¹, R. Siman¹, M.E. Swanson², and R.W. Scott¹. ¹Cephalon Inc., West Chester, PA 19380, ²DNX Inc., Princeton, NJ 08540, and ³University of Massachusetts Medical School, Department of Neurology, Worcester, MA 01655.

Accumulation of β A4 protein in brain is a hallmark of Alzheimer's disease. In attempting to develop an animal model for β A4 protein processing and deposition, we have produced transgenic mice employing transgenes which fused the neuron-specific rat synapsin I promoter to native APP751, APP751 containing the V to I or KM to NL familial Alzheimer's disease (FAD) mutations, and the E to Q mutation for hereditary cerebral hemorrhage with amyloidosis, Dutch type. APP695 transgenes containing native and FAD mutation KM to NL were also constructed. DNA-positive F1 mice from each founder analyzed to date by both RNA PCR and quantitative RNase protection assays indicate that transgene mRNA expression is brain-specific. Furthermore, *in situ* hybridization analysis on transgenic brain sections has shown that the transgene is expressed exclusively in neurons. Transgene expression levels in brain varied up to 400-fold between lines and, therefore, animals were prioritized for further analysis starting with those exhibiting highest expression. Comparative RNase protection analysis utilizing mouse probes for both synapsin I and APP have indicated that transgene mRNA levels in brain from the highest expressing lines were equivalent to endogenous synapsin I mRNA but approximately 3 to 5-fold lower than total endogenous APP mRNA. Western blot analysis has revealed that human APP751 protein is overexpressed in transgenic brain relative to endogenous APP751 (see adjacent abstract, Savage et al.). Several transgene templates are currently being microinjected for transgenic rat production.

Expression of Human Alzheimer's Amyloid Precursor Protein in Transgenic Mice
I. Lieberburg, L. McConlogue, J. Zhao, L. Paganini, L. Bickerstaff, T. Oltersdorf, and L. Refolo*, Athena Neurosciences, Inc.

Alzheimer's disease (AD) is a neurodegenerative disorder characterized histopathologically by neuronal loss and two lesions, namely neurofibrillary tangles (NFTs) and senile plaques (SPs). An animal model which mimics the AD associated neuropathology would facilitate our understanding of the pathophysiological mechanisms leading to AD and aid in the development of AD therapeutics. SP formation is believed to be an early and critical event in the pathophysiology of AD. The A/ β peptide is thought to be the pathophysiological active component of the SP. This peptide is proteolytically derived from a family of proteins known as the Alzheimer's amyloid precursor proteins (APPs). Recent data indicate that mutations in APP are responsible for some forms of familial AD, suggesting that APP is central to the disease process. Our approach to developing an animal model for AD has been to construct APP transgenic mouse lines which express the familial AD mutations. Using the NSE promoter we have constructed lines expressing wild type, Dutch and Swedish APP751. Data on human APP expression will be presented.

421.12

YET MORE TRANSGENIC MOUSE STUDIES OF ALZHEIMER AMYLOID PRECURSOR (APP). Greenberg B.D.^{1,2}, Schwartz D.¹, Savage M.¹, Pinsky L.¹, Howland D.¹, Ali S.M.^{2*}, Gonzalez-DeWhitt P.A.², Altman R.A.², Siedlak S.³, Perry G.³ & Scott R.¹ ¹Cephalon, Inc., West Chester, PA, USA.; ²Upjohn Labs, Kalamazoo, MI, USA; ³Institute of Pathology, Case Western Reserve University, Cleveland, OH, USA

As an attempt to develop an animal model for Alzheimer-type pathology, we have produced transgenic mice which express the following human APP derivatives:

Line	Promoter	Signal Seq.	cDNA	3'-flank
NAN	mMl-1	bGH	hAPP C-104	bGH
SAR	mMl-1	rGH	hAPP-695 (18-695); (18-639)	rGH
MP-SAR	mAPP	mAPP	hAPP-695 (18-695); (18-639)	rGH
LBM-SAR	mAPP	mAPP	hAPP-695 (18-695); (18-639)	mAPP

Legend: bGH = bovine growth hormone; C-104 = C-terminal 104 amino acids of the APP; hAPP = human APP; mAPP = mouse APP; mMl-1 = mouse metallothionein-I; rGH = rat growth hormone; numbers in parentheses = range of APP segment.

NAN mice express the transgene mRNA at levels up to 6-fold higher than the endogenous APP gene. This expression appears to be linked to an accumulation of endogenous APP within pyramidal neurons of the cortex and hippocampus. SAR mice expressed minuscule quantities of transgene mRNA. Expression was only slightly better in the MP-SAR mouse brains, despite very high levels of MP-SAR RNA and protein in transfected cells. The LBM-SAR transgene, however, appears to be expressed at high levels within transfected cells and transgenic mouse brains. Hence, the 3'-flanking sequence plays a critical role in determining the expression level of APP transgenes in mouse brains.

421.14

HUMAN AMYLOID PRECURSOR PROTEIN EXPRESSION IN TRANSGENIC MICE AS A MODEL OF ALZHEIMER'S DISEASE: SEARCH FOR PATHOLOGY. M.J. Savage¹, L.R. Pinsky¹, D.S. Howland¹, D.A. Schwartz¹, F.A. Huntress², R.E. Wallace², B.D. Greenberg^{1*}, R. Siman¹, M.E. Swanson², and R.W. Scott¹. ¹Cephalon, Inc., West Chester, PA 19380, ²DNX Inc., Princeton, NJ 08540.

In an attempt to generate an animal model of Alzheimer's disease (AD), transgenic mice were constructed containing various forms of HuAPP751 (see previous abstract, Howland, et al.). RNase protection was used to demonstrate a range of HuAPP751 message levels in the transgenic animals. *In situ* hybridization was used to localize the message to neurons. Using R7, a polyclonal antibody specific for the KPI domain (obtained from N. Robakis), overexpression of APP751 protein was detected in temporal cortex of transgenic mice using Western blots. Overexpression of APP on frozen tissue sections was more variable than the Western blot data, as demonstrated by immunohistochemistry using antibodies to the KPI region of APP. Heterozygous mice ranging in age from 3-11 months were examined for amyloid-related pathology using methods developed in AD tissue. Mice were perfusion-fixed in 4% paraformaldehyde. Brains were split down the hemisphere and each half was processed further for either frozen or paraffin sections. A panel of antibodies generated against regions of the β A4 protein was used for immunohistochemistry. In addition, silver-based periodic acid methenamine and Reusche methods were used. To date, we have seen no evidence of amyloid deposition either intracellularly or extracellularly. In conclusion, mere overexpression of HuAPP751 in mouse brain neurons is insufficient to produce amyloid deposition. Selected high expressing lines are being bred to homozygosity to provide large numbers of animals for aging studies and for examination of other markers of neurodegeneration.

421.16

INTESTINAL β -AMYLOIDOSIS IN TRANSGENIC MICE. K. Fukuchi*, D.D. Kunkel¹, C.E. Ogburn, A.C. Smith, N-T. Dang, T. Ohman, C.E. Furlong², S.S. Deeb², D. Nochlin, S.M. Sumi and G.M. Martin. Depts. of Pathology, Neurosurgery¹, and Medicine², Univ. of Washington, Seattle, WA 98195.

Cell culture experiments support the hypothesis that a C-terminal fragment of the β -amyloid precursor protein (β PP) is amyloidogenic and neurotoxic. A cDNA for a signal sequence of human β PP plus the 99 amino acid sequence from the C-terminus was placed under the control of a CMV enhancer and a chicken β -actin promoter. Very high levels of expression of mRNA from the transgene were observed in virtually all tissues examined of transgenic mice. On the Western blots, approximately 10- to 15-kDa protein products from the transgene were observed in lung, muscle, intestine, liver, and kidney of the transgenic mice, but no corresponding fragments were found in control mice. A 3- to 4-fold increase of the C-terminal fragments was found in brains of the transgenic mice compared to the controls. Sbx-, 9-, 13- and 16-month-old transgenic mice were sacrificed for immunohistochemical and histopathological analyses. Using antibodies to β -amyloid protein (β A), extensive A β deposits were found in the lamina propria of small intestine in transgenic mice older than 12 months. These deposits were positive for Congo red staining (dichroic birefringence). The deposits were also stained with antibodies to mouse serum amyloid P component and to α 1-anti-chymotrypsin. In spite of a 3- to 4-fold increase of the C-terminal fragments (Western blots) in the transgenic animals, immunohistochemical analyses using antibodies to β PP and A β revealed no obvious differences between the brains of the transgenic mice and those of control nontransgenic mice. Although the transgenic mice have not developed pathological regions in the brain (up to the age of 16 months), the animals can be used for discovering factors that modulate the progress of β -amyloidosis. This work was supported by the NIH and the Alzheimer's Association, Inc.

NMDA AND AMPA RECEPTORS IN TRANSGENIC MICE EXPRESSING HUMAN β -AMYLOID PROTEIN
Richard H. P. Porter*, Faheem A. Sandhu, Robert V. Eller, Mohammad Salim, Sayeeda B. Zain & J. Timothy Greenamyre
University of Rochester, Rochester, NY 14642

The human β -amyloid protein may play an important, possibly primary, role in the pathogenesis of Alzheimer's disease (AD), and it appears to potentiate the susceptibility of neurons to excitotoxicity. Alzheimer's disease is associated with alterations in the N-methyl-D-aspartate (NMDA) and α -amino-3-hydroxy-5-methylisoxazole-4-propionic acid (AMPA) subtypes of glutamate receptors, and it has been suggested that excitotoxicity may play a role in neuronal damage in AD. In this study, we have used quantitative receptor autoradiography to examine NMDA and AMPA receptors in transgenic mice that contain the gene for the carboxyl-terminal 100 amino acids of the human amyloid precursor protein, beginning with the β -amyloid region, which is under the control of the JC viral early region promoter. Reverse transcriptase polymerase chain reaction confirmed that the brains of transgenic mice expressed β -amyloid mRNA and that control mice did not. NMDA receptors, assessed with [3 H]MK-801, were unchanged in the transgenic compared to the control mice. In the transgenic mice, there were no significant changes in [3 H]AMPA receptor binding compared to controls. This study represents the first attempt to evaluate in transgenic mice the *in vivo* interaction between β -amyloid expression and excitatory amino acid receptors. (NS01487, AG02126, T32 GM07356, CA11198 and the American Academy of Neurology.)

β -AMYLOID PROTEIN-INDUCED NEUROTOXICITY IN WILD TYPE MICE AND IN TRANSGENIC MICE WITH ELEVATED CuZn SUPEROXIDE DISMUTASE ACTIVITY. A.L. Friedlich¹, T.W. Farris¹, E. Carlson², C.J. Epstein², and L.L. Butcher¹. ¹Dept. of Psychology, UCLA, Los Angeles, CA 90024 and ²Dept. of Pediatrics, UCSF, San Francisco, CA 94143.

The *in vivo* neurotoxicity of the Alzheimer β -amyloid protein (β AP) remains controversial. Because of the possible involvement of free oxygen radicals in β -amyloidosis (Friedlich and Butcher, *Neurobiol. Aging*, in press), we investigated the effects of the superoxide radical scavenger, CuZn superoxide dismutase (SOD), on β AP-induced neurodegeneration. β AP (81-40, 7.5 μ g) in water or acetonitrile was injected into the hippocampus of wild type mice and mice homozygous or heterozygous for the CuZn SOD transgene 218/3. One week after surgery, β AP deposits were identified with anti- β AP immunocytochemistry and thioflavin S staining. In Nissl-stained material from each mouse type, the necrosis produced by β AP in acetonitrile was similar to that produced by vehicle injections. No neuronal Alz-50 reactivity was observed with β AP in acetonitrile. With the water vehicle, β AP-induced necrosis was significantly greater than that produced by vehicle or reverse peptide injections in wild-type ($p < .001$) but not transgenic animals. Also with water vehicle, control injections did not induce neuronal Alz-50 immunoreactivity, but dendritic and somal Alz-50 positivity juxtaposed β AP deposits in 88% of the wild type, 50% of the heterozygous, and 15% of the homozygous mice. We conclude that β AP can induce a specific neuropathology *in vivo* to which increasing CuZn SOD activity confers resistance. (Supported by USPHS NS-10928 to L.L.B. and AG-08938 to C.J.E.).

ELEVATED IL-1 β AND IL-6 mRNAs AND β -AMYLOID PRECURSOR PROTEIN (β -APP) LEVELS DURING BRAIN DEGENERATION PROCESS IN THE CEREBELLUM OF STAGGERER MUTANT MICE.

B. Brugg¹, Y. Lemaigre-Dubreuil¹, G. Huber³, E. Wollman², N. Delhaye-Bouchaud¹ and J. Mariani¹. ¹Université P. & M. Curie, Institut des Neurosciences CNRS URA 1488, Paris. ²Hopital Cochin, INSERM U 283, Paris. ³Hoffman La Roche, Basel.

Recent findings indicate that cytokines, well known immuno-modulating factors, have important functions in developmental, pathological and regenerative processes in the brain. We are using the *staggerer* mutant mice as a model system to investigate the role of cytokines and β -APP in neuronal degeneration processes. The homozygous *staggerer* mutant shows a severe deficit in the numbers of Purkinje cells associated with a fast and almost complete degeneration of granule cells and olivary neurons during the first postnatal month. We used polymerase chain reaction (RT-PCR) to detect and quantify IL-1 β and IL-6 mRNAs levels in different brain regions of *staggerer* mutant and control mice. In 30 day-old homozygous *staggerer* mutant, in which the degeneration is very pronounced, we observed a strong increase of IL-1 β and IL-6 mRNAs in the cerebellum. In the cerebral cortex, IL-1 β mRNA levels were not different in the mutant and in the age matched controls. IL-6 mRNA was only detected in *staggerer* cerebellum but not in cerebral cortex or equivalent brain tissues of controls. These results showed that IL-1 β /IL-6 induction parallels the degenerative process and is restricted to brain regions where neuronal degeneration is observed. Using antibodies against synthetic peptides of different regions of the β -APP protein, we showed by western blot analysis that the amount of β -APP is increased during the degenerative process in the cerebellum of *staggerer* mutant mice. Further investigations are on the way to characterize at the mRNA and protein levels the different APP forms induced during the degenerative process, and to look for a potential link between cytokines and β -APP expression.

CHARACTERIZATION OF A 33KD PROTEIN FROM STABLE TRANSFECTED PC12 CELLS, TRANSGENIC MICE AND HUMAN BRAIN. T. Honda¹, E. Sandhu², S. Zain², A. Pope^{1*} and R.A. Nixon¹. ¹McLean Hospital, Harvard Medical School, Belmont, MA 02178 and ²Department of Biochemistry and Cancer Center, University of Rochester, School of Medicine, Rochester, NY 14642.

To examine the processing of APP, two cell lines, which stably express an A4-C100 fragment under the control of SV40 promoter, were created. Antibodies to the amyloid region and intracellular domain of APP stained these cells more strongly than untransfected control PC12 cells. Transfected cell lines overproduced a 16kD protein stained with the amyloid antibodies. The antibody TC2, which was raised against the synthetic peptide C2(APP644-676), intensely stained 33kD bands in the lysates from transfected cells; this same band in control PC12 cell was faintly stained. Staining of the 33kD band was diminished when the antibody was preabsorbed with C2 peptide. After CNBr cleavage of the 33kD protein, the smaller 21kD band was stained with two antibodies to the amyloid region of APP. The purified 33kD protein was stained with the antibody to C-terminal of APP. Moreover, sequence analysis of this protein revealed that the major constituent of this band starts just after the first methionine of the predicted gene product. Although the size of this protein was unexpectedly large, neither glycosylation nor ubiquitination could be detected. These data suggested that this 33kD protein may be an aggregated form of A4-C100. The increased levels of the same size of protein were found in transgenic mice brains, which express A4-C100 specifically in brain (Sandhu, et al., *J. Biol. Chem.*, 266, 21331-34, 1991). This protein was also present in human brain homogenates, where it was found in increased levels in the insoluble fraction of Alzheimer brains.

THE ROLE OF β /A4-AMYLOID IN THE NEURODEGENERATION OF TRISOMY 16 MICE. I.A. Rabin, W.C. Mobley, D.M. Holtzman,* Depts. of Neurology, Pediatrics, and the Neuroscience Program, UCSF, San Francisco, CA 94143 and Scios Nova, Inc., 2450 Bayshore Parkway, Mountain View, CA 94043.

Mouse trisomy 16 (Ts16) is an animal model of Down Syndrome (DS). We have previously shown that cholinergic neurons from fetal Ts16 basal forebrain (BF) transplants undergo time-dependent atrophy similar to that observed in DS and Alzheimer's disease (AD). Despite cholinergic atrophy, there was no evidence of β /A4 deposition. The lack of β /A4 deposition in this and other rodent models may be secondary to differences between the rodent and human β /A4 sequence. We therefore asked whether Ts16 BF and hippocampal transplants that are transgenic for the human APP₇₅₁ gene would produce β /A4 deposition and enhance neurodegeneration. We transplanted BF and hippocampus from transgenic or nontransgenic Ts16 and control fetuses into the brains of young adult mice. Grafts were then examined for evidence of β /A4 deposition, neurofibrillary tangle formation, and neurodegeneration at 1 and 6 months. Nontransgenic transplants have been examined at one and six months and show good graft survival but no evidence of plaques or tangles. Transgenic transplants are currently being assessed.

INTERLEUKIN-1 (IL-1) INDUCED EXPRESSION OF ALZHEIMER DISEASE-RELATED PROTEINS IN RAT BRAIN. J.H. Wu, J.G. Sheng, R.A. Skinner, L.C. Stanley, P.T. Wall,* and W.S.T. Griffin. Depts. of Pediatrics, Physiology, and Anatomy, Univ. Arkansas for Med. Sci., Little Rock, AR 72202

Excessive expression of interleukin-1 (IL-1) and S100 β and β -amyloid-precursor-protein immunoreactive (β APP⁺) dystrophic neurites in plaques are features of both Down's syndrome (DS) and Alzheimer's disease (AD). Interleukin-1 stimulates endothelial cell synthesis of β -APP and induces astrocyte proliferation and activation *in vitro*; activated astrocytes synthesize and release elevated amounts of a neurite growth factor S100 β . Whether IL-1 induces expression of these proteins in the brain *in vivo* is unknown. S100 β ⁺ astrocytes surround the shell of overgrown dystrophic neurites in neuritic plaques in AD, and biologically active S100 β is present in temporal lobe of patients with AD. The present experiment was performed to determine if the increase in IL-1 expression in AD may be related to β -APP and S100 β expression. Two μ l of either IL-1 β (1 U/ μ l) or PBS were injected into the right hemisphere of rats (n=10 and 7, respectively); hemispheres from un-operated rats (n=3) served as controls. Using SDS-page immunoblot analysis, we identified two distinct β APP⁺ bands (120-140 kD) and an S100 β ⁺ band that co-migrated with synthetic S100 β in extracts collected 3 days post injection. Relative to PBS injection, IL-1 β injection resulted in a 40 percent increase in the level of S100 β (p \leq 0.05). By similar comparison, there was a 100 percent increase in the level of the lower molecular weight β -APP (p \leq 0.001) and a 30 percent (p \leq 0.003) increase in the level of the higher molecular weight β -APP. We suggest that excessive expression of IL-1 in DS and AD is related to the excessive expression of S100 β and the overgrowth of β -APP⁺ dystrophic neurites in these diseases. Supported in part by NIH AG10208 and NS27414.

INCREASED IONIC CONDUCTANCE ELICITED WITH β AMYLOID PEPTIDE IS DEPENDENT UPON PEPTIDE SECONDARY STRUCTURE. W. Y. Li and L. K. Simmons,* Lilly Research Labs, Eki Lilly & Company, Indianapolis, IN 46285.

One of the pathological hallmarks of Alzheimer's disease (AD) is the extracellular deposition of amyloid β peptide (A β) in the brain. A β is believed to be involved in the neurodegeneration that occurs in AD, and we recently showed that A β (1-40) is maximally toxic *in vitro* when it adopts a β -sheet conformation. We have investigated the effects of different conformations of A β (1-40) on ion channel activity in primary cultures of embryonic rat hippocampal cells.

Freshly prepared A β is weakly toxic and has a random coil conformation. Aging the peptide in water at 37 $^{\circ}$ C for several days initiates a conformational change from random coil to β -sheet structure, and significantly enhances A β neurotoxic potency. Using the whole-cell voltage-clamp paradigm, we tested the effects of freshly prepared and aged A β on currents elicited with voltage step protocols that did not activate voltage-dependent currents in rat hippocampal neurons. Extracellular application of 1 - 10 μ M aged A β elicited a slow decrease in cell input resistance as determined by an increase in leakage current. The reversal potential of the leakage current remained unchanged, suggesting that A β might be acting as an ionophore. Similar concentrations of freshly prepared A β or lower concentrations of aged peptide (100 nM) did not induce any changes in cell input resistance. Ion substitution experiments are underway to characterize the ionic selectivity of A β in more detail. Our findings suggest that increased membrane permeability to ions is a possible mechanism underlying A β -dependent neurotoxicity.

COMPARATIVE DISTRIBUTION OF STRIATAL DIFFUSE PLAQUES AND SELECTED NEUROPEPTIDE MARKERS IN ALZHEIMER'S DISEASE (AD). M. Gearing* and S. S. Mirra. Veterans Affairs Medical Center and Emory University School of Medicine, Atlanta, GA 30322.

Although neuritic and diffuse plaques generally coexist in AD neocortex, the overriding predominance of diffuse plaques in striatum has prompted interest in environmental factors which may affect amyloid deposition and plaque formation. Could regional differences such as those existing within the striatal mosaic play a role? To investigate the relationship between diffuse plaques and regional neuropeptide distribution, we performed a series of double immunohistochemical labeling procedures using an antibody to β -amyloid (kindly provided by H. Wisniewski) in combination with antibodies to met-enkephalin (INCSTAR) or somatostatin (Chemicon). As expected, the striatum in all the neuropathologically-confirmed AD cases showed numerous β -amyloid immunoreactive plaques. Colabel with anti-met-enkephalin, a patch marker, did not reveal any obvious association between the striatal mosaic and diffuse plaque distribution. Similarly, striatal diffuse plaques did not colocalize with somatostatin-immunoreactive neurons. Comparison of "pure AD" cases (n=12) with those showing coexistent Parkinson's disease (PD) neuropathology, i.e. nigral degeneration with Lewy bodies at any site, ("AD+PD"; n=5) revealed no differences between these two groups in the distribution of diffuse plaques or the above neuropeptide markers. These preliminary observations suggest that the striatal mosaic appears to be preserved in AD, regardless of the presence or absence of coexistent PD changes. Moreover, the apparent lack of topographic relationship between diffuse plaques and the above neuropeptide markers is true for both the "pure AD" and "AD+PD" groups. These results further suggest that striatal amyloid deposition in AD is not influenced by potential environmental factors associated with the striatal mosaic, or by the somatostatin-immunoreactive neurons which are present in both patch and matrix compartments. Supported by AG10130 and VA Merit Award.

INCREASED SERINE PHOSPHORYLATION OF APP ON THE EXTRACELLULAR DOMAIN ACCOMPANIES PHORBOL ESTER MEDIATED STIMULATED SECRETION J. Knops, S. Gandy#, P. Greengard#, I. Lieberburg, J. Anderson* & S. Sinha. Athena Neurosciences, South San Francisco, California 94127; #The Rockefeller University, New York, NY 10021

The secretion of APP, which involves the cleavage of the full-length holoprotein (FL-APP) to release most of the large ectodomain (s-APP) into the conditioned medium (CM), can be strongly stimulated by activation of protein kinase C either by phorbol esters or activation of specific receptor-mediated signaling pathways. In order to investigate whether this stimulation was accompanied by a change in the putative phosphorylation status of FL-APP, 293 cells stably transfected with APP751 were labeled with ³²P *o*-phosphate. Stable ³²P incorporation was detected in the mature FL-APP either in the absence or presence of 50 nM PMA, with increased ³²P incorporation into [³²P]-APP in the presence of the drug. Surprisingly, ³²P-phosphate is primarily incorporated in the secreted ectodomain, and this incorporation in s-APP is stable to treatment with a large excess of PNGase F, suggesting that N-linked oligosaccharide sites do not account for phosphate incorporation. Phosphoamino acid analysis of the [³²P]-s-APP resulted in the recovery of [³²P]-phosphoserine as the preponderant species. PMA treatment increased the total amount of [³²P]-s-APP secreted, by direct stimulation of total s-APP released, and also apparently by increased stoichiometry of phosphorylation, but did not otherwise alter the phosphorylation pattern. Brefeldin A completely inhibited the release of [³²P]-s-APP, but did not inhibit the incorporation of ³²P into the FL-APP, suggesting that the phosphorylation events occur early in the Golgi. It is possible that increased serine phosphorylation of FL-APP in the ectodomain region provides a signal for stimulated cleavage and secretion.

RELEASE OF AMYLOID β -PROTEIN PRECURSOR DERIVATIVES FROM VARIOUS BRAIN REGIONS IS STIMULATED BY ELECTRICAL DEPOLARIZATION. J.G. Schulz, R.M. Nitsch, S.A. Farber, A.M. Graybiel*, J.H. Growdon and R.J. Wurtman. Dept. of Brain & Cognitive Sciences, M.I.T., Cambridge, MA 02139 and Dept. of Neurology, Mass. General Hospital, ACC 830, Boston, MA 02114.

We have shown that electrical depolarization increases secretion of large N-terminal amyloid β -protein precursor derivatives (APP^s) from hippocampal slices in a tetrodotoxin-sensitive and frequency-dependent manner, indicating that action potentials regulate APP processing. In cell culture, activation of cell-surface receptors linked to phosphatidylinositol turnover also increases APP^s secretion. These results suggest that APP processing may be coupled to neurotransmission in the brain. Individual brain regions vary with respect to the neurotransmitters they contain. In order to determine whether electrical depolarization affects APP^s secretion differently in individual brain regions, we prepared rat brain tissue slices from cortex, striatum and hippocampus. Slices were superfused (Warner Inst.) and depolarized by electrical field stimulation (30Hz, 1ms pulses, 4.95mA/mm²). Unstimulated control slices were run in parallel. Secreted proteins were purified by ultrafiltration and APP^s was measured by Western blot (mAb 22C11), ECL, and densitometry. Basal, unstimulated APP^s release from cerebral cortex was 1.7 times higher than that from striatum. Electrical depolarization increased APP^s secretion from cerebral cortex 2.5 fold; APP^s release from hippocampus and striatum were increased 1.7-2.0 fold by stimulation. These results show that APP^s is released throughout the brain and that individual brain areas may vary in the amount of APP^s released basally. They also show that basal APP^s release can be stimulated throughout the brain by electrical depolarization, and suggest that the magnitudes of these effects vary among brain regions. Supported by NIMH, NIA, CBMSCT.

NEURITIC (NP) PLAQUES IN DIFFERENT AREAS OF ALZHEIMER DISEASE (AD) NEOCORTEX SHARE COMMON MOLECULAR FEATURES. M.L. Schmidt, G. DiDario, L. Ocvos, Jr., V.M.-Y. Lee, & J.Q. Trojanowski* Dept. Path. & Lab. Med., Univ. Of Penn. Sch. Of Med., Phila., PA 19104

β -amyloid (β /A4) accumulates in plaques in AD and non-demented elderly patients. Diffuse plaques (DPs) contain extracellular non-fibrillar β /A4, lack dystrophic neurites, do not elicit gliosis and occur in similar numbers in AD and control brains, while NPs are dominated by fibrillar accumulations of β /A4, contain dystrophic neurites rich in neuronal cytoskeletal proteins or amyloid precursor protein (APP) domains flanking the β /A4 peptide, and are associated with gliosis and neuron loss. To determine if NPs in diverse areas of the AD neocortex contain similar or distinct molecular components, we analyzed the composition of NPs in six different neocortical areas of AD and non-demented control brains using quantitative immunohistochemistry and antibodies to proteins (β /A4, APP domains outside β /A4, neuronal cytoskeletal and synaptic proteins) found in subsets of amyloid plaques.

The molecular composition of NPs in diverse neocortical areas was similar and the density of NPs was more AD specific than that of DPs. Thus, the elucidation of mechanisms leading to the convergence of β /A4 with cytoskeletal proteins in NPs may clarify the role of NPs in neuron dysfunction and death in AD.

THE AMYLOID β PROTEIN IN CEREBROSPINAL FLUID FROM ALZHEIMER'S DISEASE PATIENTS. T. Oosawa, M. Shoji, Y. Harigaya, T.T. Cheung, L. Shaffer, L.H. Younkin*, S.G. Younkin, S. Hirai, Dept. of Neurology, Gunma Univ. Sch. of Med., Maebashi, Gunma 371, Japan. *Case Western Reserve University, Cleveland, OH 44106.

The 4-kilodalton amyloid β protein (β AP), which is deposited as amyloid in the brains of patients with Alzheimer's disease, is produced by normal proteolytic processing of the amyloid β protein precursor. The β AP is also released into living human cerebrospinal fluid (Shoji M. et al., Science 258: 126-129). Here we report the amount of β AP in CSF from 59 subjects, which include 27 patients with sporadic Alzheimer's disease (AD), 14 patients with other CNS disease, and 11 normal volunteers. We examined 3-ml samples of CSF using immunoprecipitation by SGY2134 and detected β AP on 4G8 immunoblots. The amount of β AP is 3.18 ± 1.52 pmol/ml (mean \pm S.D.) in AD group, 4.49 ± 3.14 pmol/ml in normal control group. There is no significant difference between AD and normal control groups. There is considerable interindividual variation in the amount of β AP in CSF from all groups. Both clinical stage and progress of dementia are not correlated with the amount of β AP in CSF. Our study suggests that the amount of β AP in CSF is not directly associated with brain pathology in sporadic AD.

SELECTIVE LOCALIZATION OF THE AMYLOID PRECURSOR LIKE PROTEIN (APLP) IN THE BRAIN POSTSYNAPTIC DENSITY (PSD) OF RAT AND HUMAN CEREBRAL CORTEX. T.W. Kim^{1,2}, K. Wu^{1,2}, W. Wasco³, R.E. Tanzi³, J.L. Xu¹, S. Zhong⁴ and I.B. Black^{1,2}. ¹Dept. of Neurosci. and Cell Biol., UMDNJ/RWJ Med. Sch., Piscataway, N.J. 08854; ²Graduate Program in Physiol. and Neurobiol., Rutgers-The State Univ. of N. J., Piscataway, N.J. 08854; ³Molec. Neurogenetics Lab., Mass. Gen. Hosp. East, Charlestown, MA. 02129; ⁴Dept. of Cell and Dev. Biol., Rutgers-The State Univ. of N.J., Piscataway, N.J. 08854

Senile plaques and neurofibrillary tangles are hallmarks of Alzheimer's disease. The plaques contain amyloid β -peptide (A β), which is generated from the larger β -amyloid precursor protein (APP) encoded by four different transcripts. In addition to the APPs, several APP-related genes have been recently identified in *Drosophila* and rat. Deficiency of the amyloid precursor protein-like (Aplp) gene product causes behavioral deficits in *Drosophila*, implicating a role in brain function. Moreover, a mouse cDNA clone encoding amyloid precursor-like protein has been identified and exhibits extensive sequence similarity to the *Aplp* and APP genes. To define the potential role of the APLP in the mammalian brain, we sought to directly localize the APLP within the complex cortical synaptic structure. We now report that the 90 kDa APLP protein is localized to the PSD isolated from adult rat cerebral cortex, using an antibody against a specific APLP peptide. During cortical development, the 90 kDa APLP selectively increased significantly from postnatal day 7 to 14, suggesting a role in synaptogenesis or synaptic maturation. The anti-APLP antibodies also recognized a 30 kDa protein which was expressed predominantly at early postnatal stages, but was undetectable in the adult PSD. Moreover, the 90 and 30 kDa proteins exhibited differential regional expression in adult rat brain, implying regionally specific roles. Our observations raise the possibility that the homologue of APLP, which appears to be necessary for normal behavior in *Drosophila*, also participates in brain synaptic function in mammals.

NON- β REGION APP ANTIBODIES DETECT A SUBSET OF A β -POSITIVE DIFFUSE PLAQUES AND BLOOD VESSELS IN AD AND DS CEREBELLUM. C.A. Lemere, J.J. Schildkraut* and D.J. Selkoe. Harvard Medical School, Brigham and Women's Hospital and *Mass Mental Health Center, Boston, MA 02115.

We examined the presence of non- β region APP epitopes in A β -bearing diffuse plaques and blood vessels of briefly-fixed, paraffin-embedded AD and DS cerebellum. Because APP antibodies can detect dystrophic neurites in cortical plaques, cerebellum was selected for its near absence of neuritic plaques. Cerebellar sections from 10 cases (6 AD, 2 DS, 2 Ctrl) were serially immunostained with antibodies to A β and non- β APP epitopes. A small fraction of R1280 (A β)-positive diffuse plaques in cerebellar molecular layer were also recognized by a non- β region APP₄₄₄₋₅₉₂ antibody, B5, and by a Mab (1G5) to this region. A subset of the B5+ plaques were also detected by two Mabs to the APP ectodomain and by an antiserum to APP₁₈₋₃₃ (N-terminus). Some B5+ plaques and some B5-plaques showed ubiquitin immunoreactivity. However, other neuritic markers (tau and NF) failed to detect any cerebellar plaques. In addition, a moderate percentage of R1280+ blood vessels were positive with mid-region antibodies, B5 and 1G5, and with the N-terminal antiserum. Both plaques and blood vessels were all negative with the C-terminal antibody, C7. Thioflavin detected vascular amyloid but not plaques, with the exception of a small subset of plaques in one DS case. We interpret the non- β region APP reactivity of blood vessel walls to indicate the presence of part or all of APP₃ at local sites of A β deposition. Similarly, a small minority of plaques contain these epitopes in the apparent absence of dystrophic neurites. Our findings suggest that metabolic derivatives of BAPP besides A β can accumulate at sites of A β deposition.

422.8

AUTOMATED DETECTION AND MEASUREMENT OF SENILE PLAQUES IN ALZHEIMER'S DISEASE. L.S. Hibbard* and D.W. McKeel, Jr., Departments of Neurology and Neurological Surgery, and Pathology, Washington University School of Medicine, St. Louis, MO 63110.

Senile plaques (SP) are the most characteristic neuropathologic lesions of Alzheimer's Disease (AD) and many studies of plaque cortical distribution, density, and morphology have been undertaken to gain new information about the origin and pathogenesis of AD. We have developed an automated computer image analysis program to detect SP, and to measure SP size, shape, population density, and fractional area or load in digital micrographs of silver and β /A4 immunostained tissue sections. Candidate SP features are detected by adaptive thresholding, and size and shape measures are used to discriminate SP from other stained features. This program requires no user interaction. Measures of SP density, and load are readily calculated from the pixel values of the detected SP features, and in comparisons with manual counts, the program produced false positive and false negative error rates of 4% and 2%, respectively. All the SP size and shape properties formed skewed, monomodal frequency distributions with maxima near the origins of the property axes. This program was used to study the SP density and load variation in one AD case examining 220 images (16,000 SP) from nine neocortical sections spaced 60 μ m apart.

LOW CONCENTRATIONS OF ¹²⁵I-BA4 DEPOSIT ONTO BOTH PLAQUES AND A NON-PLAQUE COMPONENT IN ALZHEIMER DISEASE CEREBRAL CORTEX

P.W. Mantyh, J.R. Ghilardi, S.D. Rogers, E.R. Stimson, C.J. Allen, H.V. Vinters, M.W. Dysken*, J.E. Maggio. Mol. Neurobio. Lab (151) and GRECC, VA Med. Cntr., Mpls., MN 55417; Dept. Pathol., UCLA, LA, CA 90024; Dept of Biol. Chem. and Mol. Pharm., Harvard Med. School, Boston, MA 02115

A salient pathological feature of Alzheimer disease (AD) is the presence of a high density of amyloid plaques in the brain tissue of victims. The plaques are predominantly composed of beta amyloid peptide (A β), a 40-mer whose neurotoxicity is related to its aggregation. Recently several reports have suggested that normal cells synthesize and release A β and that low concentrations (6.0×10^{-10} M) of A β are present in normal human CSF. To determine the sites at which low concentrations of A β deposit in the human brain, we radiolabeled human A β and developed an *in vitro* assay using 10^{-10} M ¹²⁵I-A β and thin sections of human cerebral cortex. Low concentrations of ¹²⁵I-A β clearly bind to plaques (diffuse, neuritic and compact) and cerebrovascular deposits in AD brain. In addition, ¹²⁵I-A β shows significant binding to a non-plaque component present within specific laminae of the grey matter of AD cerebral cortex. Currently, we are characterizing the chemical nature of this non-plaque component. These studies suggest the sites at which physiological concentrations of A β deposit onto both plaque and non-plaque components in AD brain. While the functional significance of this non-plaque component is currently unknown, it may provide an initial site which promotes A β aggregation and deposition in the AD brain. Supported by the NIH and the VA.

422.12

AMYLOID PLAQUES IN CEREBELLAR CORTEX AND THE INTEGRITY OF PURKINJE CELL DENDRITES. Y.-T. Li¹, D.S. Woodruff-Pak¹, J.O. Trojanowski². Lab. of Cognitive Neuroscience¹, Phila. Geriatric Ctr., Phila., PA 19141, Dept. of Psychology¹, Temple Univ., Phila., PA 19122, & Dept. of Path. and Lab. Medicine², Univ. of Pennsylvania School of Medicine, Phila., PA 19104.

To investigate the pathological consequences of β /A4 deposits and their relationship to Purkinje cells (PC) in the postmortem cerebellum of 13 AD, 10 older DS patients, and 9 age-matched, non-AD controls, we probed serial and near serial sections of cerebellum using single and double labeling immunohistochemistry and a panel of antibodies to defined amino acid sequences in peptides and proteins found in neuritic amyloid plaques. Antibodies to ubiquitin, synaptic proteins, and other polypeptides that are perturbed by or incorporated into neuritic plaques also were used. Data confirmed that β /A4 deposits in cerebellum of AD and older DS adults form diffuse plaques, and the density of β /A4 lesions per unit area of molecular layer correlated with the number of PC per unit length of subjacent PC layer in double immunostained sections ($r = .85$; $p < .001$). About 65% of β /A4 immunoreactive deposits in these preparations were in physical contact with 1st, 2nd, and 3rd order PC dendrites. Notably, no β /A4 plaques were found in the cerebellum of controls, while β /A4 deposits were most abundant in the cerebellum of older DS patients. Despite the abundance of β /A4 deposits in the cerebellar cortex of AD and older DS patients, neither PC bodies nor PC dendrites in physical contact with β /A4 lesions showed evidence of structural abnormalities of PC. Finally, none of these β /A4 lesions induced astrogliosis, a hallmark response of astrocytes to nearly all CNS injuries. This study demonstrates that the deposition of β /A4 peptides in cerebellum of AD and older DS patients does not alter the integrity of PC, but frequent association between β /A4 plaques and PC dendrites suggests that these neuronal processes could be a source of extracellular β /A4 in the cerebellar molecular layer. Supported by AG9752 and IIRG-91-059 from the Alzheimer's Assoc. to DSW-P and AG09215, AG09399 and NS-18616 to JQT.

ALZHEIMER'S DISEASE PATHOLOGY IN THE AMYGDALOID SUBNUCLEI. L. F. Luc*, S. Byttner, L. Sue, and J. Rogers. Sun Health Research Institute, Sun City, AZ 85351.

We have examined the amygdaloid complex in Alzheimer's disease (AD) and nondemented elderly control (ND) patients in an effort to elucidate potential relationships among various pathologic phenomena and among connectionally related amygdaloid subnuclei. Pathologic phenomena studied were compacted plaques, diffuse plaques, neurofibrillary tangles, and early (C4d) and late (C5b-9) stages of complement activation. Amygdaloid subnuclei examined were the lateral nucleus, basal nucleus (parvicellular division), and periamygdaloid cortex. In general, connectional hypotheses of AD pathology were not supported by the data: there were no meaningful correlations of any of the pathologic indices in one amygdaloid subnucleus with those in the other amygdaloid subnuclei. Although tangles were highly correlated among the subnuclei, it is difficult to construct any simple connectional basis for such a result. Likewise, across nuclei there were no obvious relationships between the expression of any one pathologic entity and the development of another. For example, there was no significant correlation of tangles with compacted plaques, and only a weak ($P = .075$) correlation of tangles with diffuse plaques. Among the subnuclei, the lateral nucleus exhibited the lowest densities of plaques (diffuse and compacted) and tangles, as well as significantly reduced immunoreactivity for complement proteins. Taken together, these data suggest that there is no causal association between the development of neurofibrillary tangles and neuritic plaques in AD, and that pathology in one brain area does not necessarily dictate pathology in a closely connected brain area. By contrast, complement immunoreactivity appears to be a reasonable predictor of the development of neuritic plaque and neurofibrillary tangle pathology in a structure.

THE INCIDENCE OF CEREBRAL β -AMYLOIDOSIS IN AGED CAPTIVE RHESUS MONKEYS. H. Uno* and L.C. Walker. Primate Research Ctr. and Dept. of Pathology, University of Wisconsin, Madison, WI 53715, and The Johns Hopkins University, Baltimore, MD 21205.

During the past 12 years, the population in our aging colony of rhesus monkeys (aged over 20 years) had an annual average of 93 live animals and 15 deaths. By 30 years of age 50 to 70% of each cohort group had died, and maximum longevity was 36 years. We examined the presence of senile plaques and cerebral angiopathy in 51 brains of rhesus monkeys aged 25 to 36 years. The sections of the basal prefrontal, hippocampal, frontoparietal gyri, and the amygdala were examined by immunocytochemistry with amyloid- β protein antibody (10D5) and amyloid precursor protein. Twenty of 51 aged brains had no detectable plaque formations and angiopathy in examined brain regions. Among 31 plaque-positive cases, 21 were found in brains aged 25 to 30 years (56% positive) and 10 in ages over 31 years (71% positive). Overall sexual differences were 7 positive cases in 10 male (70%) and 22 positive cases in 41 female brains (53%). The density of plaques per 1 mm² area of section varied greatly in each region and individual. The basal prefrontal gyri (area 10, 11, 25) generally contained the highest incidence and density of plaques; approximately 30% of brains showed an average of 12 plaques per 1 mm². The amygdala was the next highest region and the hippocampal and pre- and post-central (area 4.3-1.) gyri contained sporadic plaques. The formation of senile plaques in the aged macaque brain has been widely reported. Although the neurofibrillary tangles are generally absent in the monkey brain, a homology and immuno cross-reactivity of beta-amyloid and its precursor proteins between monkey and human brains suggests that aged macaques are a good model for human Alzheimer's disease.

DEGENERATIVE DISEASE: ALZHEIMER'S—NEUROPHARMACOLOGY AND NEUROTRANSMITTERS III

423.1

PROBING THE STATUS OF MUSCARINIC RECEPTOR SUBTYPES IN ALZHEIMER'S DISEASE WITH SUBTYPE-SELECTIVE ANTISERA. D.D. Flynn*, A.L. Levey, G. Ferranti-Dileo, and D.C. Mash. Depts. of Pharmacology & Neurology, Univ. of Miami School of Medicine, Miami, FL., 33101 and Dept. Neurology, Emory Univ. School of Medicine, Atlanta, GA 30322.

Subtypes of muscarinic receptors have been identified on the basis of the unique pharmacological profiles of certain antagonists. To date, most of the pharmacological approaches for characterizing muscarinic receptor subtype alterations in Alzheimer's disease have been inadequate because the overlapping drug affinities do not permit the selective detection of any one receptor subtype. We have measured the relative levels of m1 - m5 receptor subtype proteins using quantitative immunoprecipitation with subtype-selective antisera (Levey et al., 1990). Immunoprecipitation of receptor proteins by subtype-specific antisera was examined in the frontal, temporal, parietal and occipital cortices, the dentate gyrus of the hippocampus, and the nucleus basalis in patients with Alzheimer's disease and age-matched control subjects. In agreement with previous studies, the m1 receptor subtype was found to be abundant throughout the human cerebral cortex comprising 35% of the total muscarinic receptor density estimated from [³H]-NMS binding. The m2 receptor subtype was enriched in the occipital cortex and nucleus basalis. High densities of m4 receptors were measured in the nucleus basalis, hippocampus and parietal cortex. The m3 and m5 receptor proteins were detected at significantly lower levels in all brain regions examined. In Alzheimer's disease, the levels of immunoprecipitated m1 receptors were found to be significantly decreased in frontal and temporal cortices. This observation is in contrast with the normal densities of M1 receptor subtype measured with [³H]-pirenzepine. The levels of m2 receptors were decreased in the frontal cortex and nucleus basalis, while there was a trend toward elevated densities of the m4 receptor subtype in frontal and parietal cortices. These results demonstrate that subtype-specific antisera are suitable for studies of receptor structure and regulation in Alzheimer's disease. (Funded by NS19065 & NS30454).

THE AGE ONSET OF AMYLOID PLAQUE FORMATION IN THE DOG. M. Bobik¹, S. A. Benjamin², L. S. Chubb², M. J. Russell¹. ¹Dept. of Anesthesiol., Univ. Calif. Davis, Davis, CA 95616, and ²Dept. of Pathol., Univ. of Colo., Fort Collins, CO 80523.

Aged beagles exhibit neuropathological changes similar to those seen in Alzheimer's patients. As part of an ongoing effort to develop the canine as an animal model, we have examined the age at onset of amyloid accumulation in a group of lab-raised beagles of known age and history. We have previously reported that between the ages of 13 and 17 years there is no relationship between amyloid accumulation and age. In this study we examined two age groups of beagles. The younger group were 12 dogs ranging from 8.2 to 8.9 years, and the older group were 16 dogs from 11.1 to 12.7 years old. Formalin fixed and paraffin embedded tissues were sectioned at 10 μ m and deparaffinized. The sections were stained by the modified Bielschowsky method and examined for amyloid formation in the hippocampal and parahippocampal regions. Amyloid accumulation was found in one of the 12 animals in the younger group and in 5 of the 16 animals in the older group. The one animal in the younger group was found to have diffuse amyloid plaques in the hippocampal region. One of the five dogs in the older group showed compact, possibly neuritic, plaques. None of the animals examined had tangles. Taken together these data indicate that plaque formation may occasionally occur before the age of eight in the beagle, but that for most beagles plaque accumulation occurs between the age of 8.3 and 12.

423.2

IMPAIRED CHOLINERGIC MUSCARINIC RECEPTOR-STIMULATED PHOSPHOINOSITIDE HYDROLYSIS IN ALZHEIMER'S DISEASE. Xiaohua Li*, M.D., Ph.D., Ling Song, M.D., Richard S. Jope, Ph.D., and Richard Powers, M.D. Dept. of Psychiatry and Behavioral Neurobiology, Univ. of Alabama, Birmingham, AL 35294.

The effect of Alzheimer's disease on the activity of the second messenger-producing system of receptor-coupled phosphoinositide hydrolysis was studied by measuring the hydrolysis of [³H]phosphatidylinositol (PI) incubated with membranes prepared from postmortem human prefrontal cortex. This second messenger system consists of receptors coupled with G-proteins which activate phospholipase C. The activity of phospholipase C, assessed in membranes by stimulation with calcium, was similar in Alzheimer's disease and control tissue. Activation of G-proteins with GTP γ S, a stable analog of GTP, and activation of cholinergic muscarinic receptors with carbachol resulted in less [³H]PI hydrolysis in Alzheimer's disease than control membranes. Western blots demonstrated that the concentration of Gq, the G-protein most likely functional in phosphoinositide metabolism, was unchanged in Alzheimer's disease compared with controls, indicating that the function of the receptor-G-protein complex was the site of the impairment in Alzheimer's disease. These results indicate that postsynaptic muscarinic receptor responses are impaired in Alzheimer's disease, a finding that may explain in part the limited therapeutic responses achieved by administration of cholinomimetics to patients with Alzheimer's disease. Also, this assay provides a means to identify cholinomimetics that are most efficacious in activating muscarinic receptor-coupled phosphoinositide hydrolysis in Alzheimer's disease brain, agents which should have the greatest potential for providing therapeutic responses.

423.3

SUBTYPE SELECTIVE MUSCARINIC AGONISTS: 'IN VITRO' PHARMACOLOGY OF A SERIES OF 1-AZABICYCLO-[2.2.1]HEPTAN-3-ONE OXIMES. R.E. Davis*, P.D. Doyle, J.C. Jaen, D.J. Lauffer, C. Raby, R. Schwarz, H. Teclé and A.J. Thomas, Parke-Davis Pharmaceutical Research, Warner-Lambert Co., Ann Arbor, MI 48105.

The 'in vitro' biochemical profile of a series of novel 1-azabicyclo-[2.2.1]heptan-3-one oximes was assessed. These compounds bind with agonist-like properties to muscarinic receptors in membranes from rat neocortex. In genetically engineered CHO cells selectively expressing a single muscarinic receptor subtype, these compounds exhibit between 2 and 18 fold higher affinity for m₁ relative to m₂ muscarinic receptor subtypes. In most cases these agents bind with equal affinity to m₁, m₃ and m₄ receptor subtypes. However, some compounds from this series stimulate accumulation of phosphatidylinositides in cells selectively expressing the m₁ receptor (CHO_{m1}) but not in cells expressing the m₃ and m₅ receptor subtypes. Further, these agents do not inhibit forskolin-stimulated accumulation of c-AMP in cells selectively expressing m₂ (CHO_{m2}) and m₄ receptors subtypes. Several compounds from this series also increase cellular metabolic activity in CHO_{m1} but not CHO_{m2} cells. Based on these 'in vitro' properties, selected compounds from this series appear to be functional agonists in CHO_{m1} cells and antagonists or weak partial agonists in CHO_{m2-4} cells.

423.4

SUBTYPE SELECTIVE MUSCARINIC AGONISTS: 'IN VIVO' PHARMACOLOGY OF A SERIES OF 1-AZABICYCLO-[2.2.1]HEPTAN-3-ONE OXIMES. M. J. Callahan*, W. J. Lipinski, J. C. Jaen, D. J. Lauffer, H. Teclé, A. J. Thomas and R. E. Davis, Parke-Davis Pharmaceutical Research Div., Warner-Lambert Co., Ann Arbor, MI 48105.

A series of novel subtype selective m₁ muscarinic agonists were assessed for effects on peripheral and central cholinergic activity in rodents and rhesus monkeys. In rats at high doses (>32.0 mg/kg) core body temperature and total power in neocortical EEG activity was decreased in a manner similar to nonselective muscarinic agonists. Unlike other muscarinic agonists however, gastrointestinal motility was decreased rather than increased at these high doses. In addition, overt increases in salivation, lacrimation and diarrhea were not seen at any dose up to 320.0 mg/kg. No changes were seen in neocortical EEG activity in rhesus monkeys at doses up to 3.2 mg/kg. At low doses (1.0-10.0 mg/kg), selected compounds from this series improved the water maze performance of C57/B10 mice. These data suggest that compounds from this series have unique pharmacologic profiles that are divergent from non-selective muscarinic agonists. Selected compounds from this series improve cognitive performance without increasing muscarinic activity in the periphery. At low doses these compounds appear to act as m₁ agonists while at higher doses these compounds possess muscarinic antagonist-like properties.

THE MEMORY ENHANCER LINOPIRDINE INCREASES C-FOS EXPRESSION IN CEREBRAL CORTEX OF AGED RATS. G. Dent*, S.W. Tam and R. Grzanna, CNS Diseases Research, The Du Pont Merck Pharmaceutical Company, Wilmington, DE 19880-0400.

The induction of the immediate-early gene c-fos has become a widely used tool to identify the sites of action of pharmacological agents in the central nervous system. This study was conducted to determine the response of the c-fos gene in neurons of cerebral cortex to the memory enhancer linopirdine in 2 month and 30 month old rats. Rats received i.p. injections of either vehicle (distilled water) or 10 mg/kg of linopirdine. Two hours later animals were perfused and brain sections were processed for immunohistochemistry using an antibody that recognizes Fos but not Fos related antigens.

In 2 month old vehicle-injected rats, Fos positive nuclei were present in several cortical areas including anterior cingulate, piriform, auditory and entorhinal cortex. Linopirdine did not noticeably increase Fos staining in this age group. Compared to Fos staining in young rats, staining in 30 month old vehicle-injected rats was decreased in all cortical regions and nearly undetectable in anterior cingulate and piriform cortex. Linopirdine dramatically increased Fos staining in cerebral cortex in this age group. The effect was most pronounced in anterior cingulate, somatosensory, piriform, visual and auditory cortex.

The results reveal substantial changes in c-fos gene expression with aging. The striking effect of linopirdine on c-fos in cortical neurons of aged rats may be related to the memory-enhancing effects of this drug.

423.7

Effects of Linopirdine (DuP 996) on the KCl, Veratridine, NMDA and Electrically Induced Release of [³H]Acetylcholine from Superfused Brain Slices. R. Zaczek*, C. Maciag and W. J. Tinker, The Du Pont Merck Pharmaceutical Co., Wilmington, Delaware.

Linopirdine, a drug which improves the performance of rodents in several learning paradigms, has been shown to enhance the K⁺-stimulated release of [³H]acetylcholine ([³H]ACh), [³H]dopamine and [³H]serotonin from slices prepared from several rat brain areas without affecting their basal efflux. The present series of studies was performed to assess the ability of the drug to enhance the release of [³H]ACh stimulated by means other than high K⁺ concentration. In contrast to the effects of linopirdine to enhance K⁺ stimulated release, 10 μM linopirdine had no effect on [³H]ACh release from striatal slices exposed to 10 to 100 μM NMDA. The drug also failed to enhance electrically induced [³H]ACh release from cortical slices under a variety of conditions such as different stimulating currents, durations of stimulation and linopirdine concentrations. In experiments run in parallel with linopirdine, the potassium channel blocker 4-aminopyridine (10 μM) enhanced release by 165% over control demonstrating that, under the conditions used, electrically induced [³H]ACh release can be enhanced by potassium channel blockade. The effects of linopirdine on cortical [³H]ACh release stimulated by the sodium channel agonist veratridine were similar to those observed in experiments using 25 mM K⁺ to stimulate release. Linopirdine enhanced the release with an EC₅₀ of approximately 5 μM and gave rise to a maximal effect of approximately 300% of control values. The linopirdine dose response curves for enhancing K⁺- and veratridine-stimulated release were somewhat different at high concentrations of the drug. While the enhancement of K⁺-stimulated [³H]ACh release decreased as the concentration of linopirdine was raised above 10 μM, no decrease in release enhancement was observed when using veratridine as the stimulus. The results of the present study suggests that linopirdine enhances the release of [³H]ACh evoked by agents giving rise to a sustained depolarization (high K⁺ and veratridine). The drug was not effective when the stimulus was pulsatory as in the case of electrically induced release or when the stimulus involved opening channels that allow the direct entry of calcium as is the case with NMDA.

423.8

Effects of Linopirdine (DuP 996) on Hippocampal Extracellular Levels of Acetylcholine in Freely Moving Animals. M. Marynowski*, C. Maciag and C.M. Rominger, D. Rominger, S.W. Tam and R. Zaczek, The Du Pont Merck Pharmaceutical Co., Wilmington, Delaware.

Linopirdine, a drug which improves the performance of rodents in several learning paradigms, has been shown to enhance the release of several transmitters in vitro. While epidural cup experiments have described increases in extracellular acetylcholine (ACh) levels after the administration of linopirdine, the central effects of the drug on brain ACh levels in vivo have not been described. In the present study, microdialysis was utilized to determine the effect of linopirdine on apparent ACh release in vivo. Dialysis probes were placed into the dorsal hippocampus and were perfused with artificial CSF containing 100 μM physostigmine. ACh levels were measured using on-line HPLC with EC detection at a platinum electrode. Doses of 1, 5 and 10 mg/kg were injected peripherally into freely moving rats. Preliminary data indicated that 1 mg/kg linopirdine had no effect on extracellular ACh levels. At 5 mg/kg, linopirdine produced a maximum 42% increase in extracellular ACh levels 40 min after drug administration. ACh levels remained elevated (~20% over basal release) up to 100 min, but were back to control levels by 2 hours after dosing. A 59% increase in ACh levels over basal was observed 40 min after the administration of 10 mg/kg linopirdine; extracellular ACh levels plateaued at 25-30% over basal and remained elevated for the duration of the experiment (2 hours). Brain concentrations of linopirdine following peripheral administration were measured using [³H]linopirdine. Levels of linopirdine equivalent to 1.1 μM were observed in the hippocampus 40 min after a 10 mg/kg, i.p. dose. This concentration is consistent with that at which release enhancement has been observed in in vitro release assays (EC₅₀ ~5 μM). In summary, linopirdine at doses of 5 and 10 mg/kg produced increases in hippocampal extracellular ACh in freely moving rats. The concentrations of hippocampal linopirdine resulting in increased extracellular ACh levels in vivo are consistent with those resulting in enhanced release in vitro.

423.9

The role of Ca²⁺ Channels, Adenosine, and Ca²⁺ Stores on KCl Evoked Acetylcholine Release and Linopirdine (DuP 996) Release Enhancement in Rat Hippocampal Slices. L.A. Saydoff* and R. Zaczek. The Du Pont Merck Pharmaceutical Co., Wilmington, DE 19880.

We used a paradigm of K⁺-stimulated [³H]acetylcholine release from superfused rat hippocampal slices to test for possible interactions between the neurotransmitter release enhancer linopirdine and known Ca²⁺ channels, adenosine receptors or intracellular Ca²⁺ stores. Linopirdine (10 μM) increased (> 200% of control) 25 mM K⁺-evoked acetylcholine (ACh) release. The nonspecific Ca²⁺ channel antagonist +/-verapamil (5-200 μM) dose-dependently blocked ACh release and linopirdine release enhancement completely. The N type Ca²⁺ channel antagonist ω-conotoxin GVIA (250 nM) and the P type Ca²⁺ channel antagonist, ω-agatoxin IVA (400 nM) each blocked ACh release by 50% and 30% respectively and were additive. However, ACh release enhancement by linopirdine was unaffected by N and/or P type Ca²⁺ channel blockade. The L type Ca²⁺ channel antagonist nitrendipine (5 μM) did not affect ACh release or linopirdine release enhancement. While adenosine agonists acting through type 1 receptors inhibited ACh release by 30%, blockade of adenosine 1 and/or 2 receptors did not alter ACh release. Adenosine receptor blockade or stimulation or phosphodiesterase inhibition (100 μM IBMX) did not influence the release enhancing effects of linopirdine. Presumed depletion of caffeine sensitive intracellular Ca²⁺ stores with 20 mM caffeine decreased ACh release 25% and attenuated the release enhancing effects of linopirdine by 35%. These results suggest that K⁺ evoked release of hippocampal ACh is under the control of N and P, but not L type Ca²⁺ channels and that linopirdine does not interact with these channels. Adenosine 1 receptor stimulation can inhibit K⁺ evoked ACh release. Linopirdine does not enhance ACh release via adenosine receptors or phosphodiesterase inhibition. Further studies are required to establish whether caffeine sensitive Ca²⁺ stores may contribute to K⁺ evoked hippocampal ACh release. The effects of caffeine and verapamil in combination with linopirdine on [Ca²⁺]_i are under study.

423.11

IN VIVO MICRODIALYSIS AND PHARMACOKINETIC STUDIES WITH DuP-996. T.M. Smith*, A.D. Ramirez, S.D. Heck, V.J. Jasys, R.A. Volkman, J.T. Forman, D.R. Liston Pfizer Central Research, Groton, CT 06340.

A reduction in cholinergic function is a consistent neurochemical finding in Alzheimer's disease (AD). Neurotransmitter release enhancers such as DuP-996 (3,3-bis(4-pyrindinylmethyl)-1-phenylindolin-2-one) may restore cholinergic function by increasing the extracellular pool of acetylcholine (ACh). *In vitro*, DUP-996 enhances the potassium-evoked release of ACh, dopamine and serotonin with an EC₅₀ of 1-2 μM. To assess whether this activity is sufficient to stimulate neurotransmitter release *in vivo*, brain exposure to DuP-996 was determined in conjunction with *in vivo* microdialysis studies. Rats were injected with DuP-996 (10 mg/kg, s.c.); at 10, 30 and 60 minutes plasma and whole brain were sampled and analyzed by HPLC. Drug levels were as follows:

time (min)	plasma (μM)	Brain (μM)	B/P ratio
10	3.8	1.2	0.33
30	3.6	0.9	0.25
60	1.6	0.6	0.37

For *in vivo* microdialysis, samples were collected every 30 min; after a 2 hr baseline period, DuP-996 was administered (10 mg/kg, s.c.) and dialysis continued for an additional 3 hr. ACh levels were determined by HPLC. DuP-996 produced a 30-40% increase in the extracellular concentration of ACh. These studies show that the peripheral administration of DuP-996 (10 mg/kg) produces detectable brain levels of drug resulting in an increase in ACh release, suggesting that these agents have potential for the treatment of AD.

423.13

DISTRIBUTION OF NEUROFIBRILLARY TANGLES IN ALZHEIMER'S DISEASE STRIATUM. N. Selden*, C. Geula and M.-M. Mesulam, Harvard Medical School, Boston, MA 02215.

The distribution of neurofibrillary tangles (NFT) was surveyed in the striatum of Alzheimer's disease (AD) cases (n=9) using the fluorochrome, Thioflavin-S. NFT were more densely distributed in the nucleus accumbens (175/cm²), olfactory tubercle (249/cm²) and tail of the caudate nucleus (323/cm²) than in the head of the caudate nucleus (54/cm²), body of the caudate nucleus (81/cm²) or putamen (44/cm²). Senile plaques (SP) with a prominent amyloid core showed a similar pattern of distribution to NFT. By contrast, non-cored SP were densely distributed in all striatal territories. The concentration of NFT in the nucleus accumbens and olfactory tubercle was not likely to result from contraction atrophy: the area of the nucleus accumbens and olfactory tubercle in AD cases was 99%, of the caudate nucleus 92%, and of the putamen 88% of control values. In aged, neurologically normal controls and a case of Pick's disease, no NFT and few SP were observed in the striatum. The nucleus accumbens, olfactory tubercle and tail of the caudate nucleus all receive dense projections from temporolimbic cortical regions which are selectively vulnerable to the pathology of AD. Our findings suggest that the 'limbic' striatum is preferentially vulnerable to damage in AD.

423.10

EFFECTS OF LINOPIRDINE AND DUP 921 ON AGE-RELATED IMPAIRMENTS IN MEMORY AND ON THE CHOLINERGIC SYSTEM. M. G. Baxter*, K. W. Rohrbach*, S. W. Tam*, R. Zaczek*, and D. S. Olton*. *Department of Psychology, The Johns Hopkins University, Baltimore, MD 21218, and *CNS Diseases Research, The DuPont Merck Pharmaceutical Company, Experimental Station, Wilmington, DE 19889-0400.

Linopirdine (DuP 996) enhances learning and memory, which may be due to its ability to enhance potassium-stimulated release of acetylcholine, dopamine, and serotonin. The present study assessed the ability of linopirdine and a related compound, DuP 921 (5,5-bis(4-pyridinylmethyl)-5H-cyclopenta-[2,1-b:3,4-b']dipyridine), to ameliorate age-related memory deficits. A parallel study assessed the effects of both compounds on *in vitro* potassium-stimulated acetylcholine release, acetylcholinesterase activity, and muscarinic and nicotinic receptor binding in cerebral cortical tissue from young rats. Aged male Fischer-344 rats (24 months old) were given either vehicle or one of 5 doses (0.085-8.5 mg/kg) of linopirdine or DuP 921 prior to testing; young rats (4 months old) served as controls and received vehicle prior to testing. Place discrimination and repeated place acquisition were tested in the water maze. Sensorimotor skills were assessed in separate tests. Age-related impairments occurred in all tasks. Linopirdine and DuP 921 moderately improved place discrimination performance at some doses, but were ineffective in repeated acquisition or sensorimotor tasks. Both linopirdine and DuP 921 enhanced potassium-stimulated release of acetylcholine from rat cerebral cortical tissue. Neither compound produced significant acetylcholinesterase inhibition, muscarinic or nicotinic binding. These results support the hypothesis that linopirdine and DuP 921 ameliorate age-related memory impairments through an enhancement of acetylcholine release. These compounds have potential therapeutic uses in treating disorders involving cognitive impairment.

423.12

SYSTEMATIC REGIONAL VARIATIONS IN THE LOSS OF CORTICAL CHOLINERGIC INNERVATION IN ALZHEIMER'S DISEASE. C. Geula* and M.-M. Mesulam. Department of Neurology, Harvard Medical School, Boston, MA 02215.

The relative density of AChE- and ChAT-positive cortical cholinergic fibers was determined in whole hemispheric sections of brains from Alzheimer's disease (AD) patients and controls. The areas with the greatest loss (>75% reduction) of cholinergic innervation were all in the temporal lobe and included areas 20, 21, 22 and 28 of Brodmann. The frontal and parietal association areas as well as the insula and temporal pole showed an intermediate magnitude of loss (40-75%). The anterior cingulate gyrus, primary motor, primary somatosensory and primary visual cortex displayed less than 30% loss of cholinergic fibers. Within the CA1 sector of the hippocampal formation and the subiculum, fiber density was reduced by 41-48%. In the amygdala, the lateral nucleus displayed a marked depletion of ChAT-positive neurites (88%) whereas the basolateral (41%) and particularly the central nucleus (21%) displayed relatively little change. These results indicate marked and consistent regional variations in the loss of cortical cholinergic fibers in AD.

423.14

RETROGRADE DEGENERATION OF BASAL FOREBRAIN CHOLINERGIC NEURONS FOLLOWING HIPPOCAMPAL IMMUNOTOXIN INJECTIONS. T. Ohtake, S. Heckers, C. Geula, S. Weintraub*, R.G. Wiley+ and M.-M. Mesulam. Dept. of Neurology, Harvard Medical School, Boston, MA 02215; +Dept. of Veterans Affairs, Medical Center, Nashville, TN 37212.

Intracerebroventricular injection of the 192 IgG antibody against the p75 nerve growth factor receptor (NGFR) conjugated with saporin destroys the NGFR-containing cholinergic neurons of the basal forebrain. We injected this immunotoxin directly into the hippocampus and studied its retrograde effect upon the cholinergic neurons of the medial septum and diagonal band region (MS-DB).

After 7 days, there was a nearly total depletion of cholinergic axons within the hippocampus and a marked ipsilateral decrease in the number of cholinergic neurons of the MS-DB. At longer survival times, these changes were more pronounced and seemed to have spread to the contralateral side. These findings are consistent with those of Kudo et al. (Neurosci. Lett. 102:125; 1989).

These observations suggest that injected 192 IgG-saporin is transported retrogradely from the hippocampus to the cholinergic neurons in the MS-DB and provide a model for the retrograde degeneration of basal forebrain cholinergic neurons following cortically based pathological processes. Such retrograde degeneration may be responsible for the involvement of cortically projecting subcortical cell groups in Alzheimer's disease.

423.15

NEUROGLIAL CHOLINESTERASES IN THE NORMAL BRAIN AND IN ALZHEIMER'S DISEASE: RELATIONSHIP TO PLAQUES, TANGLES AND PATTERNS OF SELECTIVE VULNERABILITY. C.I. Wright, C. Geula and M.M. Mesulam*. Department of Neurology, Beth Israel Hospital, Harvard Medical School, Boston, MA 02215.

Butyrylcholinesterase (BChE) and an altered form of acetylcholinesterase (AChE) accumulate in the plaques and tangles of Alzheimer's disease (AD). The sources for these plaque and tangle-bound cholinesterases have not been identified. We now report that AChE and BChE activities with pH preferences and inhibitor selectivities identical to those of plaque and tangle-bound cholinesterases are found in the astrocytes and oligodendrocytes of control and AD brains. In non-AD control brains, the ratio of BChE to AChE glia was higher in entorhinal and inferotemporal cortex, two regions with a high susceptibility to the pathology of AD, than in primary somatosensory and visual cortex, two areas with a relatively lower susceptibility to the disease process. In comparison to age-matched control specimens, AD brains had a significantly higher density of BChE glia and a lower density of AChE glia in entorhinal and inferotemporal regions but not in the primary somatosensory or visual areas. These results suggest that glia constitute a likely source for the cholinesterase activity of plaques and tangles, and that a high ratio of BChE to AChE glia may play a permissive or causative role in the neuropathology of AD.

423.16

COMPARATIVE INHIBITION BY TACRINE AND RELATED AMINOACRIDINES ON ACETYLCHOLINESTERASE AND BUTYRYLCHOLINESTERASE. K.A. Skau*. U. Cincinnati College of Pharmacy, Cincinnati, OH 45267.

Aminoacridine derivatives are undergoing clinical trials to alleviate symptoms of Alzheimer's disease. Although the effectiveness of these drugs is believed to be due to inhibition of acetylcholinesterase (AChE), they have a number of actions on other enzymes and receptor proteins. We have investigated the inhibitory action on the related enzyme butyrylcholinesterase (BuChE). Rat brain AChE and BuChE were purified on trimethyl-m-phenylenediamine and procainamide affinity columns. Enzyme activity was estimated with a colorimetric assay using acetylthiocholine as substrate. Tacrine, SM10888 and HP029 exhibited the same rank order of inhibition on both enzymes. IC50's for AChE vs BuChE were (nM): tacrine 67 vs 38; SM10888 190 vs 100; HP029 640 vs 330. Kinetic analysis showed a mixed inhibition by these drugs on both enzymes. Replots indicated that the non-competitive inhibitory constant was lower than the competitive constant for both enzymes. A tacrine affinity column bound AChE but not BuChE. These results suggest that aminoacridines are slightly more potent inhibitors of BuChE than AChE indicating that tissues with a significant BuChE content (such as heart and liver) may exhibit adverse effects from these drugs. Furthermore, although the potencies are similar, the structural requirements for inhibition of the two enzymes are quite different.

DEGENERATIVE DISEASE: ALZHEIMER'S—OTHER IV

424.1

INCREASED GLIAL REACTIVITY TO BRAIN INJURY IN AGING RATS. M.N. Gordon*, L.A. Holcomb, W.A. Schreier and D.G. Morgan. Dept. of Pharmacology and Therapeutics, Univ. South Florida College of Medicine, Tampa, FL 33612-4799.

Although clinical literature suggests that brain injury in the aged is associated with a poorer prognosis, little research has examined this phenomenon at a cellular or molecular level. We examined astrocyte and microglial reactivity after 6-hydroxydopamine (6-OHDA) lesions of the nigrostriatal system in male F344 rats aged 6, 15 or 24 mo. Rats were killed 2,4,7,10 or 14d after lesioning. Sections through the substantia nigra (SN) and neostriatum were immunocytochemically stained for tyrosine hydroxylase (TH) to quantify lesion severity, for the astrocyte specific marker glial fibrillary acidic protein (GFAP), and for the microglial specific markers complement C3b receptor (OX42) and MHC class II antigen (OX6). Unlesioned rats served as controls.

In control rats, the area immunostained for GFAP, OX42 and OX6 were all increased with aging. In lesioned rats, substantial loss of TH+ neurons in the SN was observed 2d after 6-OHDA injection and was maximal at 14d, producing virtually complete loss of TH immunoreactivity in the SN and neostriatum in rats of all ages. A lesion-induced elevation of neostriatal immunostaining for GFAP, OX42 and OX6 was observed at all ages, but the magnitude of this response over control levels was greatest in the oldest rats. These data confirm our earlier work concerning exaggerated GFAP reactivity to fornix transections in aged mouse hippocampus, and extend this finding to dopamine depleted rats, and to microglia as well. Exaggerated glial reactivity in the aged after brain injury may have deleterious consequences. These findings support the inflammation/complement theories of Alzheimer's pathogenesis. Technical assistance by David G. Berg, Xiaorong Ou and Chun Wang is gratefully acknowledged. Current affil. for WAS: Baxter Diagnostics, Inc., Clinical Chemistry Controls R&D, Miami, FL. Supported by AG07892 (astrocytes) and AFAR (microglia). DGM is an Established Investigator of the American Heart Assn.

424.3

MICROGLIAL DISTRIBUTION IN NORMAL CEREBRAL CORTEX CORRESPONDS TO REGIONAL LOCALIZATION OF ALZHEIMER'S DISEASE (AD) PATHOLOGY. L.G. Sheffield and N.E.J. Berman*. Dept. of Anatomy and Cell Biology, Univ. of Kansas Med. Ctr., Kansas City, KS 66160-7400.

Microglia function as macrophages during development, injury and pathological processes such as AD. This role may extend to direct involvement in the disease process as microglia have been found in association with neuritic plaques (NPs). Regional localization of neurofibrillary tangles (NFTs) and NPs is the hallmark of AD pathology. Those areas most vulnerable to NFTs are the entorhinal cortex, hippocampus and amygdala, while the motor, visual and auditory cortices are largely spared (Arnold et al., *Cerebral Cortex*, 1:103-116, 1991).

Our study focused on the distribution of microglia in the normal brain. Samples were taken from those cortical areas with the highest and lowest density of NFTs and NPs. Microglia were visualized using the lectin *Ricinus communis* agglutinin-I (RCA-I; Hutchins et al., *Developmental Brain Research*, 55:95-102, 1990). Our initial results reveal a higher density of microglia in cortical areas most susceptible to AD pathology and fewer microglia in areas least affected by AD. Interestingly, an area of low microglial density, i.e. motor cortex, had a high density of blood vessels, but an area of high microglial density, i.e. temporal lobe, had a low density of blood vessels. One explanation for the regional variability of AD pathology may be the larger microglial presence in susceptible areas. Supported by MH38399 and HD02528.

EXPRESSION OF GFAP AND S-100 β GENES IN LYMPHOCYTES OF DOWN SYNDROME (DS) PATIENTS. H. Riol*, G. Lévesque, M. Tardy, L. Demers and M.R.V. Murthy. Département de biochimie, Faculté de Médecine, Université Laval, Québec, Qué, G1K 7P4 Canada.

After 40 years of age, persons with DS develop neuropathological features of Alzheimer's disease (AD) which suggest that DS may constitute a precocious model for AD. We have previously shown that glial fibrillary acidic protein (GFAP) and S-100 β genes were expressed in human lymphocytes and that their mRNA levels were perturbed (respectively increased and decreased) in lymphocytes of AD patients with moderate to middle mental deterioration. In this study, we are interested to test if perturbations of these brain specific gene expressions occur also in DS lymphocytes, and to analyse the relationship between the level of their expression and the age of the patients. Therefore, we have investigated the GFAP and S-100 β mRNA levels in lymphocytes of 11 DS patients (25-47 years old), in comparison to normal controls.

Total RNA was extracted from lymphocytes and after a reverse transcription (RT) step, the mRNA sequences were amplified by polymerase chain reaction (PCR). We have developed a semi-quantitative method of RT-PCR to quantify their relative amounts, using endogenous aldolase C mRNA level as internal standard.

As expected, a surexpression of the S-100 β gene was found in lymphocytes of DS patients, reflecting trisomy of chromosome 21 containing this gene. However, the resulting amount of S-100 β -mRNA was three times the level in normal individuals ($p=0.0001$), suggesting that mechanisms other than gene dosage were also implicated. A similar level of S-100 β -mRNA was found whatever the age of the DS patients, indicating that no further change in the expression of this gene occurs from the age of 25 years to 47 years. In contrast, some increase in the GFAP-mRNA level was observed in lymphocytes of DS patients after the age of 36 years and may be associated with an early stage of AD in older DS patients, since such increase has been previously observed in lymphocytes of AD patients. However, this increase is presently under further verification with a larger group of DS patients to check if it is statistically significant.

EXPRESSION OF GLUT5 ON MICROGLIA IN NORMAL AND AD BRAIN. J. Payne*, L.A. Mattiace, E. Maher, J.A. Simpson, P. Davies. ¹Dept. of Pathology, Albert Einstein College of Medicine, Bronx, NY 10461; ²NIDDK, NIH, Bethesda, MD 20892.

GLUT5 is a member of a group of structurally related facilitative glucose transporter proteins that are involved in enhancing transportation of glucose and/or fructose across plasma membranes. Although some isoforms are present in non-CNS tissue, GLUT5 is one of three isoforms present in human brain. RaGLUT5, a commercially available (East Acres Biologicals) affinity purified polyclonal antibody raised to a 12 amino acid synthetic peptide specific for the C-terminal of the human GLUT5 sequence, has been used to determine the cellular localization of GLUT5 protein in tissue sections. Formalin-fixed brain tissue was obtained postmortem from both AD and normal individuals. Using the ABC (Vector) procedure, fifty micron consecutive free floating vibratome sections were stained with 1) RCA-1, a lectin that reacts with β -galactose residues that labels microglia in addition to blood vessels, 2) RaGLUT5, 3) GFAP, an antibody that immunolabels astrocytes, 4) Alz-50, an antibody that immunolabels AD-type pathology. In a peptide competition experiment, RaGLUT5 was pretreated with a saturating concentration of the GLUT-5 C-terminal peptide before incubation with tissue sections. Preliminary results suggest that RaGLUT5 immunolabels microglia in both the cortical grey and subcortical white matter in older adult normal and AD brain. Although the intensity of immunoreactivity and number of microglia is consistent in the older normal individuals, considerable variability exists in the AD cases. Morphologically, RaGLUT5 appears to consistently immunolabel the fine tertiary processes of microglia particularly evident in the cortical grey matter. No staining was seen in peptide competition or in the control without antibody. Our results suggest that GLUT5 may mediate glucose uptake by microglial cells in the brain and that GLUT5 is an excellent microglial marker in formalin-fixed human brain tissue.

MICROGLIAL-INDUCED CYTOTOXICITY OF HIPPOCAMPAL NEURONS BY REACTIVE OXYGEN INTERMEDIATES: SELECTIVE VULNERABILITY TO NITRIC OXIDE L. Torgersen*, C.E. Nolan, and R.B. Nelson, Department of Neuroscience, Pfizer Central Research, Groton, CT.

Neurodegenerative pathologies such as Alzheimer's disease (AD) are characterized by the sparing of superoxide dismutase-containing neurons, suggesting a role for reactive oxygen intermediates (ROIs) in neuronal loss. A likely source of ROIs in AD are activated brain macrophages (microglia), a prominent feature of dense-core β -amyloid plaques. Activation of cultured rat microglia with opsonized zymosan causes the release of high levels of both nitric oxide (NO, measured by formation of the NO breakdown product NO_2^-) and superoxide (measured by luminol-enhanced chemiluminescence). The relative contribution of individual ROIs in killing hippocampal neurons was examined by establishing a co-culture system of freshly-plated primary hippocampal neurons and microglia plated in 0.4 μm filter insert chambers. Activation of the microglia caused the death of neurons situated immediately under the insert chambers, but not of neurons outside the perimeter of the insert chambers (indicative of a short-lived toxin). This death could be completely blocked by the NO synthase inhibitors N-monomethyl-L-arginine and N-nitro-L-arginine; the relative potencies of these inhibitors indicated targeting of the inducible macrophage NO synthase rather than the constitutive neuronal NO synthase. Inhibitors of other ROIs, including superoxide dismutase (target species O_2^-), catalase (H_2O_2), mannitol (OH^\cdot), and sodium azide (HOCl) were ineffective at preventing neuronal death beneath the chamber inserts. While activated microglia also release large amounts of glutamate, freshly plated neurons are insensitive to this type of toxicity, and the NMDA receptor antagonist MK-801 was unable to protect against neuronal loss in this culture system. These results indicate that microglia are able to release levels of NO toxic to neurons, and that hippocampal neurons may have greater sensitivity to NO than to other reactive oxygen intermediates.

BRAIN CLUSTERIN (SGP-2): SECRETION BY CULTURED ASTROCYTES AND NEURONS T. Oda*, G.M. Pasinetti, T.H. Hogan, S.A. Johnson and C.E. Finch, Andrus Gerontology Center, Neurogerontology Division and Dept. of Biological Sciences, University of Southern California, Los Angeles, CA 90089-0191

Clusterin is a sulfated glycoprotein (SGP-2) that is found in brain and many other peripheral tissues. Several functions have been proposed for clusterin such as inhibiting complement mediated cell lysis, cell aggregation, lipid transport and apoptosis (P. C. May and C. E. Finch, TINS, 1992). Elevation of clusterin expression in the brain is associated with experimental lesioning in rodent, responses to injury and Alzheimer's disease.

We have found clusterin mRNA and secretion of protein from the primary cultures of rat astrocytes, human astrocytoma (HTB 14) and human neuroblastomas (HTB 10 and HTB 11). To further elucidate the role of clusterin in brain, we purified clusterin from the conditioned media of human astrocytoma. The molecular weight was about 70KDa under non-reducing conditions and about 41KDa under reducing conditions, respectively. Ongoing experiments examine the effect of glia-derived clusterin on complement mediated cytotoxicity and transformed neuronal cell lines and primary neuronal culture. Supported by grants to CEF from NIA AG-7909 and Sankyo Co.

THE MECHANISM OF LIPID PEROXIDATION MAY VARY DEPENDING UPON THE BRAIN REGION: POSSIBLE IMPORTANCE FOR NEURODEGENERATIVE DISEASES. A.C. Andorn, M. Franko and B.R. Bacon, Depts. of Psychiat. and Human Behavior, and Med. St. Louis Univ. Schl. of Med., and St. Louis VAMC, St. Louis, MO 63125.

We have previously reported that ascorbate stimulated lipid peroxidation (LP_{asc}) in postmortem human caudate and putamen (C/P) is apparently not mediated by hydroxyl radicals (Mol. Pharm. 33:155-162, 1987). We, and others, have previously reported that basal and stimulated LP is increased in postmortem prefrontal cortex (PFC) from Alzheimer's disease patients and in C/P of Parkinson's disease patients (Dexter, et al., J. Neurochem. 52:381-389, 1989; Subbarao, et al. J. Neurochem. 55:342-345, 1990; Hajimohammadreza and Brammer, Neurosci. Lett. 112:333-337, 1990). We now report that LP_{asc} may occur by a different mechanism in cortical areas as compared to C/P. In the C/P, hydroxyl-radical scavengers, such as mannitol, were without effect on LP_{asc} , while in PFC and temporal cortex (TC), 10 μM mannitol inhibits $28.0 \pm 15\%$ and $37.2 \pm 8.5\%$ of LP_{asc} (using 0.1 mM ascorbate) respectively. Similarly, in the C/P, indomethacin (10 μM) was without effect on LP_{asc} . But in PFC and TC, this indomethacin inhibited $47.7 \pm 22\%$ and $46.9 \pm 19.3\%$ of LP_{asc} respectively. These findings suggest that hydroxyl radicals and possibly the prostaglandin pathway play a more marked role in LP in cortical areas than in the basal ganglia.

ACTIVATED MICROGLIA CAUSE NEURONAL DEATH BY RELEASE OF GLUTAMATE AND NITRIC OXIDE C.E. Nolan, L. Torgersen, M. Prochniak, I.A. Shalaby, and R.B. Nelson*, Department of Neuroscience, Pfizer Central Research, Groton, CT.

Dense-core β -amyloid plaques, each associated with multiple activated microglia (brain macrophages), are a major hallmark of Alzheimer's disease (AD) and indicate a massive inflammatory component of AD. Because chronically activated macrophages in peripheral inflammatory diseases release a number of cytotoxins and cause extensive local tissue damage, we investigated whether activated microglia release substances directly toxic to neurons. Activation of cultured rat microglia with complement-opsonized zymosan caused basal release of glutamate (measured by HPLC) to increase from subtoxic (5 μM) to toxic levels (150 μM) in the culture media by 24 h. Exposure of >2-week-old primary hippocampal neurons (glutamate-sensitive) to activated microglial supernatants for 15 min caused extensive neuronal loss which could be blocked with the NMDA receptor antagonist MK-801. Activated microglia also released high levels of nitric oxide (NO, measured by formation of the NO breakdown product NO_2^-) versus undetectable release from non-activated microglia. NO-mediated neurotoxicity was detected in co-cultures of freshly-plated primary hippocampal neurons (glutamate-insensitive) and microglia plated in 0.4 μm filter insert chambers. Activation of the microglia caused the death of neurons situated immediately under the insert chambers, but not of neurons outside the perimeter of the insert chambers (indicative of a short-lived toxin). This death could be completely blocked by the macrophage NO synthase inhibitor N-monomethyl-L-arginine. These results indicate that: 1) microglia are able to release toxic levels of recognized neurotoxins; and 2) activated microglia associated with dense-core β -amyloid plaques may cause AD-associated neurodegeneration by local neurotoxin release.

INCREASE IN NADPH-d NEURONS WITHIN ALZHEIMER BASAL FOREBRAIN: COMMENTS ON FIXATION SENSITIVITY OF NADPH-D HISTOCHEMISTRY. W.C. Benzinger* and E.J. Mufson, Dept. of Neurol. Sci., Rush Presb. St. Luke Med. Ctr., Chicago, IL 60612.

NADPH-d, a cofactor in the formation of nitric oxide, colocalizes with nitric oxide synthase (NOS) containing CNS neurons. Excess nitric oxide synthesis by NADPH-d/NOS neurons may be neurotoxic within the CNS. Interestingly, these neurons are spared in the caudate and hippocampus, areas of severe degeneration in Huntington's and Alzheimer's (AD) disease, respectively. We determined whether NADPH-d histochemically stained neurons were similarly spared within the cholinergic basal forebrain, which undergoes extensive neuronal loss in AD compared to normal controls (NC). AD (n=8) and NC (n=8) subjects were matched for age, sex, brain weight, post-mortem interval and fixation length. Paraformaldehyde fixation periods greater than 36-48 hours greatly reduces the NADPH-d reaction product. Numbers of light, medium and darkly stained NADPH-d neurons were quantified using a computer assisted system. Quantitative analysis revealed a statistically significant increase in the number of medium and dark stained NADPH-d neurons within the anterolateral and posterior divisions of the nucleus basalis (NB) in AD as compared to NC ($F[2,42] = 4.95; p \leq .05$). Interestingly, the cholinergic neurons within these NB subfields are the most severely depleted in AD (Mufson et al., '89). Moreover, many NADPH-d containing fibers were in close apposition to cholinergic magnocellular neurons in AD and NC. Increased numbers of NADPH-d neurons within the basal forebrain may be a mechanism underlying the severe cholinergic cell death seen in AD.

DOES URATE PROTECT ASCORBATE FROM METAL-CATALYZED OXIDATION? M. Romanas, F.E. Samson, S.R. Nelson* and T.L. Pazdernik, Ralph L. Smith Res. Ctr., Univ. Kansas Med. Ctr., Kansas City, Kansas 66160.

Oxygen radicals are implicated in a variety of neuropathologies including ischemia-reperfusion, trauma, ALS, and Alzheimer's disease. Ascorbate (ASC) and urate play major roles in neutralizing these radicals. Ascorbate, on the other hand, can reduce transition metals enabling them to participate in oxygen radical generation. Urate may limit this metal-catalyzed oxidation of ascorbate by forming an inactive metal complex. This was studied by following ASC (100 μM) oxidation at 265 nm in Chelex-treated PO_4 buffer (50 mM, pH 7.3) with the addition of aliquots of preincubated solutions containing urate with Cu^{2+} , Fe^{3+} , or Fe^{3+} -EDTA. The rate of ASC oxidation with 12 μM Fe^{3+} was 5 milli-absorbance units/min (mABS U/min), but the rate with 12 μM Fe^{3+} -EDTA was ten-fold higher, 50 mABS U/min. Neither rate was affected by urate (6, 12, 24 μM). Cu^{2+} (1.3 μM) markedly activated ASC oxidation (165 mABS/min) which was inhibited 56, 67, and 84% with 6, 12, and 24 μM urate, respectively. These results indicate that urate, at levels in cerebrospinal fluid (ca. 20 μM), may preserve ascorbate from oxidation catalyzed by Cu^{2+} but not necessarily from that catalyzed by Fe^{3+} or Fe^{3+} -complexes. Supported in part by NIH 1-P30-AG10182.

Decreased Ratio of Transferrin to Iron in Alzheimer's and Parkinson's Disease Brains.

D. A. Loeffler¹, J. R. Connor², B. S. Snyder³, A. J. DeMaggio¹, P. L. Juneau¹, and P. A. LeWitt^{1*}, ¹Sinai Hospital, Detroit, MI 48235, ²M.S. Hershey Medical Center, Hershey, PA 17033, and ³Warner Lambert Co., Ann Arbor, MI 48106

Brain iron (Fe) metabolism is abnormal in both Alzheimer's disease (AD) and Parkinson's disease (PD), and may contribute to free radical generation in both disorders. The objective of this study was to investigate the relationship between Fe and the Fe transport protein transferrin (TF) in AD, PD, and aged normal brain. Our hypothesis is that there is a decrease in the TF/Fe ratio, suggesting a decrease in brain iron mobility, in some neurological diseases. TF/Fe was highest in frontal cortex, intermediate in caudate and putamen, and lowest in substantia nigra and globus pallidus. TF/Fe was decreased in all AD and PD brain regions, particularly caudate and putamen, where TF/Fe ratios were 47-55% of normal. These results support the hypothesis that iron mobility is decreased in specific brain regions and specific disease states, and imply a close association but potentially significant differences in iron homeostasis between AD and PD. FERRITIN ISOFORMS IN NORMAL AND DISEASED HUMAN BRAIN TISSUE. J.R. Connor¹, S.L. Menzies, B.S. Snyder, D.A. Loeffler and P.A. LeWitt. Dept. of Neurosci & Anatomy, PSU Sch. of Med., Hershey, PA and Sinai Hospital, Detroit, MI.

Ferritin is the major iron storage protein and as such plays a significant role in regulating the intracellular availability of iron. Because of the ability of iron to generate free radicals, alterations in the synthesis or function of ferritin could result in enhanced susceptibility of cells to oxidative damage. In this study, we use monoclonal antibodies (provided by P. Arosio) to investigate the cellular distribution of the ferritin isoforms, and to quantitate the ratios of the ferritin isoforms in selected regions of human brain tissue (tissue provided by E.D. Bird, McLean hospital). Immunohistochemical analysis revealed specific cellular distributions for the different isoforms. Microglia stain intensely for L-chain ferritin, whereas oligodendrocytes contain both H and L isoforms. Neurons (specifically pyramidal neurons) contain only H-chain ferritin. Astrocytes normally do not contain either ferritin isoform except in the basal ganglia where they stain robustly and specifically for L-chain. In Alzheimer's Disease, considerable L-chain cellular staining occurs around neuritic plaques, while H-chain is relatively uninvolved. Quantitatively, H-chain ferritin was higher than L-chain in each of the brain regions studied with H:L ratios ranging from ~1.1 (globus pallidus; GP) to 2.8 (substantia nigra; SN). The H:L ratio is altered from normal in the caudate and putamen in Parkinson's Disease, but not in frontal cortex, SN, or GP. In AD tissue, the H:L ratio is only altered in the frontal cortex. These results reveal cellular specificity in ferritin distribution and region specific, disease specific changes in H:L ratios.

424.13

AUTORADIOGRAPHIC EXAMINATION OF NADH:UBIQUINONE OXIDOREDUCTASE (COMPLEX I) IN HIPPOCAMPUS AND CEREBELLUM IN ALZHEIMER'S DISEASE D.S. Higgins¹, J.T. Greenamyre¹ University of Rochester, Rochester, NY 14642

Accumulating evidence implicates impaired energy metabolism in AD, with abnormalities of ferrocycytochrome c oxidase (complex IV) and the pyruvate dehydrogenase complex having been described. [³H]Dihydroroteneone (DHR) autoradiography identifies the NADH dehydrogenase subunit 1 of NADH:ubiquinone oxidoreductase (complex I) specifically and with high affinity. NADH enhances DHR binding and provides a measure of the interaction between the proximal NADH binding site and the distal rotenone inhibition site. This technique was employed to examine complex I of the electron transport chain in a series of Alzheimer's Disease (AD) and control postmortem samples of hippocampus and cerebellum. [³H]DHR binding was reduced in all regions of the AD hippocampus (48-61% of control) when examined in the absence of exogenous NADH. The granular and molecular layer of the cerebellum contained equivalent amounts of DHR binding in AD and control samples. NADH (500 μM) enhanced binding in all regions 2 - 3 fold. Under enhanced conditions, binding was normal in AD cerebellum and significant decreases were only apparent in CA1 and dentate gyrus (42 and 52% of control, respectively). No association between [³H]DHR binding and age or postmortem delay was identified. Abnormalities of complex I may significantly alter neuronal function as demonstrated in the mitochondrial encephalomyopathies. Whether the changes identified in AD are pathogenic or secondary in nature remains to be determined. (Supported by USPHS grants NS01487 and T32 AG107)

DEGENERATIVE DISEASE: ALZHEIMER'S—OTHER V

425.1

Genotypic/Phenotypic Analysis of Apolipoprotein E in Alzheimer's Disease. G.W. Rebeck¹, J.S. Reiter, and B.T. Hyman Dept. of Neurology, Mass. General Hospital, Boston, MA, 02114.

We have recently shown that variability in the number of senile plaques between Alzheimer's disease (AD) cases cannot be accounted for by duration or severity of dementia. We have now initiated a study to determine whether expression of specific isoforms of Apolipoprotein E (ApoE) can account for some of this phenotypic variation. A disproportionate number of patients with late-onset AD express the E4 isoform of ApoE (Strittmatter et al., PNAS (1993) 90:1977-1981), suggesting that ApoE may be a risk factor in the development of AD. Furthermore, we have confirmed that anti-ApoE immunostains both diffuse and compact senile plaques, as well as amyloid angiopathy and extraneuronal neurofibrillary tangles. We have determined the ApoE genotype of neuropathologically examined individuals with sporadic AD (n=17) and age-matched controls (n=14) by DNA amplification and restriction digestion with the HhaI enzyme. We found disequilibrium between the ApoE-E4 isoform and AD (62% of AD patients, 22% of controls). In addition, we examined whether AD patients expressing ApoE-E4 differed neuropathologically from patients expressing only ApoE-E2 or ApoE-E3. Those expressing ApoE-E4 did not have a higher number of senile plaques in temporal neocortex (100 vs. 159 plaques/mm²), or a greater amyloid burden (4.7% vs. 6.1%). We are continuing to genotype additional control and AD cases for these analyses. Supported by NIHAG05598 and NIHAG08487.

425.2

QUANTITATIVE ANALYSIS OF NEUROPATHOLOGIC CHANGES IN THE CEREBRAL CORTEX OF CENTENARIANS. C. Bouras^{1,2}, P. Giannakopoulos⁴, M. Surini¹, J.P. Michel⁴, J. Richard¹ and P.R. Hof^{2,3} ¹Dept of Psychiatry, Univ. of Geneva, CH-1225, Geneva-Switzerland, ²Fishberg Research Center for Neurobiology and ³Dept. of Geriatrics, Mt Sinai Sch. Med., New York, NY 10029, and ⁴Institutions Universitaires de Gériatrie, CH-1226, Geneva-Switzerland.

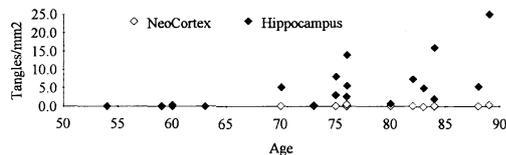

We performed analysis of 67 nonagenarians and centenarians brains (96-104 years old). The patients included 10 men (97.2 ± 1.5 years old) and 57 women (97.5 ± 1.8 years old). Clinical diagnosis was based on review of the medical records and neuropsychological testing. Twenty four patients presented with preserved intellectual abilities and 43 with dementia (15 with senile dementia of the Alzheimer type and 28 with mixed dementia). We assessed quantitatively the localization and distribution of neurofibrillary tangles (NFT) and amyloid deposits (AMLD) using antibodies to Tau and β-A4. In all cases, analysis was performed in the CA1 field of the hippocampus (CA1), the subiculum, in layers II and V of the entorhinal cortex (EC) and in layers II-III and V-VI of the inferior temporal (ITC) and superior frontal cortex (SFC). NFT were present in 100% of the cases in the CA1 and in layers II and V of the EC, 95.2% in subiculum, 95% in layers V and VI of the ITC but only in 44% of the cases in the SFC. AMLD were not always observed. For instance, AMLD were found in 78% of all cases in CA1, 71% in subiculum, 75% in the EC, 80.8% in the ITC and 80% in the SFC. Extensive NFT formation was restricted to the anterior part of the CA1 in demented subjects, whereas the SFC was relatively spared in severely demented cases as compared to the ITC. Significant differences in NFT counts between demented and non-demented cases were found only in the CA1 and in the SFC. The AMLD densities were significantly higher in the demented patients in all areas. These suggest that NFT formation involve different cortical structures in very old people compared to younger individuals. The NFT densities in the CA1 and in the SFC could be crucial for the neuropathological diagnosis of dementia in this particular group.

425.3

THE DISTRIBUTION AND DENSITY OF TANGLES AND PLAQUES IN NON-DEMENTED AGING. J.L. Price*, M.M. Rundle and J.C. Morris. Depts of Anatomy & Neurobiology and Neurology, Washington Univ. Sch. Med., St. Louis, MO 63110

Tangles and plaques were studied in 24 brains from non-demented subjects aged 54 to 89, with the Bielschowsky method and immunohistochemical stains for paired helical filaments or β -amyloid. The cognitive status of each subject was determined by pre-mortem clinical assessment, and/or by a retrospective post-mortem interview with a close relative, in all cases. The distribution and density of tangles and plaques was mapped from serial sections with a microscope digitizer system.

At least a few tangles were found in all cases, especially in the hippocampal formation. Few tangles were found in the neocortex. The density of tangles in the hippocampus increased progressively with age (Spearman rank correlation = 0.69, $p < 0.01$). In contrast, many of the cases had no detectable plaques. Where present, plaques were primarily or exclusively found in the neocortex, with few if any in the hippocampus. The density of plaques showed no relationship to age. This indicates that tangles develop with aging, especially in the hippocampal formation, independent of detectable amyloid deposition. Plaques develop in the neocortex without direct relation to age or to tangles, although amyloid may subsequently exacerbate tangle formation in the hippocampus and elsewhere. NIH AG03991

425.5

A COMPARATIVE ANALYSIS OF CORTICAL AND NUCLEUS BASALIS PATHOLOGY IN ALZHEIMER'S DISEASE USING SEVERAL METHODS INCLUDING A NOVEL NICKEL-ENHANCED PEROXIDASE STAIN. K.M. Callen, G.M. Halliday and J.M. Freeman*. University of Sydney, NSW, Australia 2006

We examined the brains of 8 prospectively studied patients with Alzheimer's disease (diagnosis confirmed postmortem (pm)) and 4 age-matched, non-demented controls in order to test a correlation between lesions in the nucleus basalis (NB) and pathology in its putative cortical terminal fields. Blocks containing the NB and specific gyri from 7 cortical regions were taken from formalin-fixed brains (pm delay <26 hrs). For the quantitation of plaque areal fraction and the number of neurofibrillary tangles (NFT), several staining methods were applied to serial (1/15) 50 μ m frozen sections of the blocks. These techniques included anti-GFAP, -calbindin, -ubiquitin, -BA4 and -Alz90 immunohistochemistry, the Garvey silver stain (Garvey, 1991 *J Histotech* 14, 39-42) and a novel nickel-enhanced peroxidase method (NEP). Briefly, for the NEP, free-floating sections were incubated with Avidin-Biotin Complex followed by the application of the chromogen, 3,3'-diaminobenzidine, in 0.16% nickel ammonium sulfate. NB neurons were counted in a complete series of cresyl violet-stained sections. Three-dimensional reconstructions of NB neurons and NFT were assembled to visualize the topography of lesions. Results: The NEP most clearly discerned NFT as no cell nuclei were stained. A considerably higher plaque areal fraction was obtained with the NEP compared to the Garvey silver stain and the BA4 and Alz90 immunostains, thus the NEP may be useful as a sensitive marker for an extensive range of AD pathology. Astrocytic and microglial changes were profound in the cortex and forebrain although not seen within the NB in every AD case. The NB of patients with AD contained numerous globose NFT but no plaques; however, NFT were rarely seen in control NB. Cell loss in the NB varied (30%-88%) and did not correlate with the number of NFT seen in either the cortex or the NB itself. Neither cell loss nor NFT in the NB correlated with cortical plaque density, nor did plaque areal fractions correlate with NFT counts in any cortical region. These results suggest that a) NFT and plaque formation may be independently regulated, b) NB pathology is not directly related to cortical plaque or NFT formation, and c) the presence of globose NFT in the NB is diagnostic for AD.

425.7

SPATIAL MEMORY LOSS WITHOUT MORPHOLOGICAL DAMAGE TO CA1 NEURONS. J.C. de la Torre*, T. Fortin, G. Park, B. Pappas. University of Ottawa, Faculty of Medicine and Carleton University, Ottawa, Canada K1H 8M5.

Evidence indicates that the hippocampal formation and specifically the CA1 pyramidal neurons, is involved in spatial memory input. Experiments in animals and humans show that selective damage to CA1 neurons results in spatial and recent memory deficits.

In the present study, aging male Sprague-Dawley rats 9 and 19 months old were subjected to chronic cerebrovascular insufficiency (CVI), which consisted of occluding both carotids and 1 subclavian artery (Group 3-VO) or both carotids (Group 2-VO) for 9 weeks.

After 9 weeks, all rats were tested in the Morris water maze test and compared to age-matched intact controls (Group C). Hippocampal and cortical cerebral blood flow was measured prior to sacrifice. Following perfusion-fixation, brains were prepared for histological evaluation of the hippocampus and cortex. Results show that both Group 3-VO and Group 2-VO showed significant memory impairment with respect to Group C. However, while Group 3-VO showed a mean damage to 36% of its CA1 neurons, Group 2-VO showed no neuronal damage in the hippocampus or cortex. CVI resulted in significant reduction of hippocampal and cortical blood flow but no micro-infarcted brain vessels were seen in any animal. These findings suggest that spatial memory impairment (which is the first important clinical sign in Alzheimer's disease) does not depend on the structural integrity of CA1 or other hippocampal neurons. It is reasonable to assume from this data that such memory deficits in aging rats can result from chronic CVI which could provoke neurochemical changes within the neuron or its synaptic contacts even before neuronal cell loss or neuropathological damage is detected. It is tempting to conjecture whether the evolution of Alzheimer's disease follows a similar course.

425.4

CORRELATES OF SUBCORTICAL NEURONAL LOSS IN ALZHEIMER AND PARKINSON DISEASES. C. Zarow*, J.A. Mortimer, S.A. Lyness, H. Chui. Department of Neurology, Univ. of Southern California, Los Angeles, CA 90242.

In AD and PD, selective neuronal loss occurs in several subcortical nuclei including the nucleus basalis of Meynert (NB), the locus ceruleus (LC) and the substantia nigra (SN). This histopathologic study was designed to assess: 1) the relationship between severity of subcortical neuronal loss and age at symptom onset and duration of illness, and 2) the relationship between neuronal loss in each of the three subcortical nuclei. The sample was comprised of 70 cases with AD (50% male), 20 PD (90% male) and 20 elderly controls (50% male). In both patient groups there was significant neuronal loss in all three nuclei. The mean number of nucleolated neurons (expressed as a percentage of controls) in AD was 50.75% (NB), 33.5% (LC) and 78.8% (SN); and in PD, 55.7% (NB), 16.4% (LC) and 15.0% (SN). In both patient groups, age at symptom onset was inversely correlated with duration (AD: $r = -0.42$, $p < 0.0004$; PD: $r = -0.79$, $p < 0.005$). In PD, the only significant correlation was between duration and numbers of neurons in SN ($r = -.66$, $p < 0.02$). In AD, stepwise-multiple regression showed a significant correlation between age at onset and numbers of neurons in the NB ($r = 0.34$; $p < 0.01$) and LC ($r = 0.39$, $p < 0.01$), but not in the SN ($r = 0.06$). In addition, numbers of neurons in NB and LC were correlated with each other. In AD, the degree of neuronal loss in the SN was highly variable: in 60% of cases counts were similar to controls; in 40% of cases loss was similar to PD. Lewy bodies were found in 1 of 20 AD cases with normal numbers of SN neurons, while these inclusions were found in 7 of 18 cases with significant SN loss (Fisher exact test: $p < 0.02$). These findings suggest two factors that may define subgroups of AD: 1) early symptom onset - which is associated with more severe neuronal loss in NB and LC, and 2) Lewy bodies - which are associated with more severe neuronal loss in SN. A QUALITATIVE AND QUANTITATIVE IMMUNOHISTOCHEMICAL STUDY OF THE MICROVASCULATURE IN AGING AND ALZHEIMER'S DISEASE. L. Buge¹*, C. Bouras², P.R. Hof³, M. Surini², J.H. Morrison³, H.M. Fillit³ and A. Delacourte¹. 1) INSERM U156, 59045 Lille, France; 2) Psychiatry, Univ. of Geneva, CH-1225, Switzerland; 3) The Mount Sinai Medical Center, New York NY 10029, U.S.A.

Pathological changes of the microvasculature in normal aging and Alzheimer's disease (AD) were investigated by immunohistochemistry using the monoclonal antibody 7E12 directed against vascular heparan sulfate proteoglycan protein core. Rare atrophic cortical microvessels were observed in control brains. In AD cases, microvascular pathology was more severe than in control cases. These vascular changes were primarily found in layers III and V of frontal and temporal cortex demonstrating that the alterations display both regional and laminar distribution. Some vascular pathologic changes, such as twisted and coiling vessels also displayed regional and laminar distributions in AD cases. Furthermore, in AD patients, extracellular 7E12-immunoreactive deposits, consistent with thioflavine S-positive senile plaques, were observed. Cortical atrophy and vascular density (VD) were quantified by image analysis and compared between control cases and AD patients. VD was assessed as a relative ratio of "vascular surface"/"cortical surface". Vascular surface was markedly decreased in AD (0.27 ± 0.06 mm²) compared to control cases (0.31 ± 0.06 mm²; $p = 0.008$). Cortical thickness was also severely decreased in AD patients (1.17 ± 0.20 mm) compared to control cases (1.83 ± 0.46 mm; $p = 0.0001$) demonstrating a 34.6% atrophy. Even with this significant cortical atrophy, significantly lower relative vascular density ($VD = 16.59 \pm 3.64\%$) was found in AD patients compared to control cases ($VD = 19.48 \pm 3.77\%$; $p < 0.01$).

Thus, these data suggest that vascular abnormalities are heterogeneous in aging and Alzheimer's disease. VD is likely to be related to the neurodegeneration process in selected regions and cortical layers in AD. (Supported by the France Alzheimer Association, the Florence J. Gould Foundation; the Brookdale Foundation and NIH grant AG05138).

DIFFERENTIAL IMPAIRMENT OF SPATIAL LEARNING IN TWO ANIMAL MODELS OF ALZHEIMER'S DISEASE. G.L. Dunbar*, L.S. Janis, and C.L. Weaver. Psychology Dept., Central Michigan University, Mt. Pleasant, MI.

Degeneration of basal forebrain cholinergic neurons has been linked to Alzheimer's disease (AD) and has provided the basis for animal models of AD using lesions of the nucleus basalis (NB) and the medial septum (MS). We compared the effects of these lesions on the ability of rats to use different strategies for solving a radial-arm maze task. In the first study, both rats given electrolytic MS lesions or sham surgery could solve the task, but only the sham rats could solve the task when forced to use a "nonstereotypic" strategy (i.e., when the rats were prevented from using a stereotypic response pattern, such as entering each adjacent arm in a clockwise fashion). In a second study, rats given either ibotenic acid lesions of the NB or sham surgery were able to solve the same task, even when forced to use a "nonstereotypic" response strategy. Our results indicate that damage to additional neuronal systems (e.g., GABAergic neurons, which also were destroyed by the electrolytic MS lesions) may be critical to produce severe memory deficits, or that the MS-hippocampal system is more-critical for spatial learning than the NB-cortical system. In either event, our work suggests that ibotenate NB lesions is an inadequate model of AD, because it doesn't mimic the profound memory loss observed in AD patients. Supported by NSF-ILI grant USE - 9051323.

COGNITIVE FUNCTION AND ALZHEIMER'S-LIKE PATHOLOGY IN THE AGED CANINE: I. SPATIAL LEARNING AND MEMORY.

E. Head^{1*}, G. Ivy¹, B.J. Cummings², C.W. Cotman² and N.W. Milgram¹.

¹Life Sciences Division, Scarborough Campus, U. Toronto, Scarborough, Ontario, Canada, M1C 1A4. ²IRU in Brain Aging, Dept of Psychobiology, U. California, Irvine, CA 92717.

A spatial non matching to sample paradigm was developed in order to study the effects of age on spatial working memory in the dog (E. Head *et al.*, Soc. Neurosci. Abst. 376.3, 1992). Animals were rewarded for responding to the side opposite to the one where a sample stimulus was presented. At delays of 10 seconds, this was a far easier task to learn for a dog than a visual recognition memory task. Acquisition at short delay was not a good predictor of an animals ability to respond at long delays. Old animals showed little deficit in learning, but were deficient in their capacity to perform above chance at long delays. Within the sample of aged animals, there was considerable variability in both acquisition and in performance over long delays. There was a subpopulation of aged dogs which were unable to achieve the acquisition criterion. On anatomical analysis, the animals in this subpopulation had abnormal accumulation of beta amyloid protein throughout the brain (see accompanying abstract, B.J. Cummings *et al.*) and an apparent loss of CA1 pyramidal neurons. These results suggest that spatial memory provides a measure of age-dependent cognitive deterioration while spatial learning may be a predictor of abnormal amyloid accumulation.

LONGITUDINAL STUDY ON CONSTRUCTIONAL DISABILITY IN ALZHEIMER'S DISEASE

M. Fujii^{*}, S. Murakami, R. Fukatsu, N. Nakano, K. Utsumi, N. Takahata

Dept. of Neuropsychiatry, Sch. of Medicine, Sapporo Medical Univ. 060, Japan

Constructional disabilities are one of the most prominent clinical feature in the patients with Alzheimer's disease. We have demonstrated characteristic eye movement associated with constructional apraxia, which is similar to lt. unilateral spatial neglect and Balint syndrome, using a vision analyzer. We presented these results indicated that there might be disconnection between visual cognition of objects and visuo-spatial language function in the last conference.

In this study, we have examined the behavior of the eye movements using a vision analyzer and constructional ability based on verbal instruction, when drawing geometrical figures for 3 years.

The results obtained indicated that gazing points of focus located mainly on copying figure in light visual field, and dislocated gazing point of focus became prominent as the disease progressed. Then, they showed constructional disabilities. In their constructional behavior, closing-in phenomenon was observed often and finally they overwrote copying figure on the original ones.

These findings indicate that the strategy on copying figures was disturbed first and abstract thinking (categorizing process) from visual presentation was involved later in the early stage in Alzheimer's disease.

SINGLE VOLUME 1H SPECTROSCOPY IN ALZHEIMER'S DISEASE

J.P. Kesslak¹, D. Atkinson², M. Brant-Zawadzki³ and C.W. Cotman¹.

¹Dept Neurol, IRU Brain Aging, Univ Calif, Irvine, CA, ²Siemens Med Systems, ³Dept Radiol, Hoag Hospital, Newport Beach, CA.

Alzheimer's disease (AD) is characterized by progressive neural degeneration that clinically produces a variety of behavioral deficits. Hydrogen magnetic resonance spectroscopy (MRS) provides a novel means to detect biochemical changes in AD brain pathology *in vivo*. This study examined the relative amounts of N-acetyl aspartate (NAA) as an index of neural density, and the metabolites creatine (Cr) and choline (Cho) as neural and non-neural components.

Thirty AD patients (69±8 years of age) diagnosed according to NINCDS-ADRDA guidelines were compared to 10 age matched controls (70±6 years of age). MRS was done within 4 weeks of clinical evaluations on a 1.5 Tesla Siemens Magnetom 63/84 SP system and head coil. Placement of a 2x2x2 cm³ volume of interest in the parietal and temporal cortices was done from coronal, sagittal and axial images. Peak area for NAA, Cho and Cr was integrated and ratios calculated.

Analysis of variance indicated significantly lower levels of NAA, Cr and Cho for the AD group in the parietal lobe. In the temporal lobe the levels of NAA and Cho were significantly lower in the AD group. The ratios of NAA/Cho, NAA/Cr and Cho/Cr did not indicate any significant differences between groups in either area. There did not appear to be any age related differences in this small sample of normal-aged controls, however, it should be noted that variability did increase with age. These results may indicate cell loss characteristic of AD pathogenesis.

COGNITIVE FUNCTION AND ALZHEIMER'S-LIKE PATHOLOGY IN THE AGED CANINE: II. NEUROPATHOLOGY.

B.J. Cummings^{1*}, P.E. Honsberger¹, A.J. Afagh¹, E. Head², G. Ivy², N.W. Milgram² and C.W. Cotman¹ IRU in Brain Aging¹, Dept. of Psychobiology, University of California, Irvine, CA 92717 and Life Sciences Division², University of Toronto, Scarborough, Ontario M1C 1A4

We have previously reported that the hippocampal region in aged beagles exhibits neuropathological changes similar to those found in Alzheimer's disease (Cummings *et al.* Neurobiol Aging). Due to the archival nature of this tissue, no behavioral data was available on these animals. We have now examined 17 aged canines (beagles and mixed-breeds) both behaviorally (see accompanying abstract, E. Head *et al.*) and with a variety of AD related neuropathological markers. After behavioral testing, animals were perfused with 4.0% paraformaldehyde on sacrifice. The hippocampus, entorhinal and frontal cortices, and cerebellum were examined with antibodies to β -amyloid, the amyloid precursor protein, and cytoskeletal markers. In addition, routine Bielschowsky's, thioflavine, and Congo Red staining were utilized. In agreement with previous reports, canine pathology consisted primarily of amyloid angiopathy and diffuse early stage plaques containing intact neurons. No neurofibrillary tangles were detected. When plaques were detected in the hippocampus, they were also present in entorhinal and frontal cortex; however, little pathology was observed in the cerebellum regardless of plaque density in the hippocampus. After the animals were ranked with regard to the extent of β -amyloid accumulation by an observer blind to the behavioral results, β -amyloid pathology and spatial task performance were compared. The four animals with the most severe β -amyloid accumulation were the poorest performers on a spatial task, while the top five performers had no β -amyloid accumulation. These data suggest that poor performers have an accompanying accumulation of β -amyloid.

425.12

ESTROGEN REPLACEMENT AND ALZHEIMER'S DISEASE

IN WOMEN. A. Paganini-Hill, J.G. Buckwalter, C. G. Logan, and V.W. Henderson^{*}. Departments of Preventive Medicine, Neurology, and Psychology, and Schools of Medicine and Gerontology, University of Southern California, Los Angeles, CA 90033-1084

In a retrospective analysis of women who volunteered for a research program on aging and dementia, we found that cases meeting criteria for "probable" Alzheimer's disease (AD) (n = 143) were significantly less likely than elderly nondemented subjects (n = 92) to be using estrogen replacement at the time of their enrollment (7% versus 18%, $P < 0.01$), but groups did not differ with regard to the total number of prescription medications. AD cases using estrogen did not differ significantly from cases not using estrogen in terms of age, education, or duration of dementia symptoms, but they performed significantly better on a brief cognitive screening instrument (the Mini-Mental State examination — $P < 0.005$).

Separate analyses from a large retirement community (Leisure World) surveyed in 1981 used a case-control study nested within a prospective cohort study. 127 of 2418 female cohort members who died between 1981-1992 had AD or related diagnoses mentioned on the death certificate. Four controls were matched to each case by birth and death dates. The risk of AD and related dementia was significantly less in estrogen users relative to non-users (RR = 0.61, 95% CI = 0.40-0.94), and the risk decreased with increasing dose of the longest used estrogen and with increasing duration of use.

Results of these two separate studies support hypotheses that estrogen replacement therapy decreases the risk of AD in women and may also improve cognitive performance of women with AD.

426.1

NIGRAL NEURON NUMBERS IN NORMALS MAY BE RELATED TO PREDISPOSITION TO DEVELOP PARKINSON'S DISEASE. U.B. Muthane*, Ramsay K.A., Jackson-Lewis V., Jiang H., Przedborski S. Dept. of Neurology, Columbia University, 650 West 168th St., Black Bldg. Rm 310, New York, NY 10032.

The reason why some individuals develop Parkinson's disease (PD) and some do not is unclear. Similarly, in the mouse 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) model of parkinsonism it is also unclear as to why mice belonging to C57/bl strain have a greater loss of nigral dopaminergic neurons compared to the CD-1 strain. To examine whether the strain-dependent sensitivity to MPTP is related to the difference in the number of tyrosine hydroxylase (TH) and calbindin (Cal) positive neurons in the substantia nigra, we quantified these neurons in C57/bl and CD-1 mice. In normal mice of the same age and sex, consecutive sections of the midbrain were stained by immunohistochemistry and the number of TH- and Cal-positive nigral neurons quantified. We observed that C57/bl mice had significantly lower number of TH- and Cal-positive neurons ($p < 0.005$) compared to CD-1 mice. We hypothesize that a greater postnatal loss of both TH- and Cal- positive nigral neurons occurs in the C57/bl compared to CD-1 mice. Because the more sensitive C57/bl mice have lesser TH positive nigral neurons to begin with and also lesser protective mechanisms like Calbindin it may be possible that humans predisposed to develop Parkinson's disease also may have fewer TH-positive nigral and lesser protective mechanisms compared to those who do not develop the disease.

DOPAMINE TRANSPORTER mRNA NEURONAL CONTENT IN THE HUMAN MIDBRAIN DOPAMINERGIC NUCLEI.

C. Casan., V. Blanchard., R. Raisman., S. Vyas., G. Uhl., F. Javoy-Agid* U289 INSERM, Hôpital de la Salpêtrière, 75013 PARIS, and Molecular Neurobiology, NIDA/ARC, PO BOX 5180 BALTIMORE.

Loss of midbrain dopaminergic (DA) neurons is a major neurochemical characteristic of Parkinson's disease. However, not all DAergic neurons are equally vulnerable, the most severe neuronal loss always occurs in the substantia nigra (SN) in comparison to the ventral tegmental area (VTA) or central gray substance (CGS), the latter area preserved in the disease. Thus, DA neurons are not equally vulnerable to the disease. In a search for the etiology of the disorder, the involvement of dopamine uptake process has been considered. The expression of plasma membrane DA transporter (DAT) was studied at cellular level in human midbrain post mortem by *in situ* hybridization using an antisense 35 S labelled riboprobe. Throughout the midbrain sections, positively hybridized cells identifiable as TH positive neurons were observed in the various DA areas. The cellular abundance order of this transcripts was: highest in the SN followed by VTA and then by CGS neurons. These data provide evidence of the phenotypic distinctions among DAergic cell groups and suggest that the expression of DAT gene is relatively high in the neurons which are most vulnerable to the disease. This characteristic might provide a greater susceptibility to the neurotoxic factors, or contribute to the severity or progression of neuronal death.

3 H-HEMICHOLINUM-3 AUTORADIOGRAPHY IN DEGENERATIVE PARKINSONISM. J. Pascual., R. Rodríguez-Puertas., M. Lafarga* and A. Pazos. Depts. of Physiol. and Pharmacol., Anat. and Cell. Biol. and Service of Neurology, Univ. Hospital "Marqués de Valdecilla" and Faculty of Medicine, Santander, Spain.

The high-affinity choline uptake carrier (HACU), a selective marker of presynaptic nerve terminals, was labeled by using 5 nM 3 H-hemicholinium-3 (3 H-HC) in tissue sections of 3 representative brain areas from 7 patients who had died from levodopa-responsive, degenerative parkinsonisms (DP) and from 10 matched controls.

In the striatum 3 H-HC binding sites were clearly increased in DP brains as compared to control brains, both over caudate (mean \pm SD controls vs DP cases= 224 \pm 88/333 \pm 85; % change= +49%; $p < 0.05$) and putamen (178 \pm 99/326 \pm 177; +83%; $p < 0.05$). No significant changes could be found in the frontal cortex of DP cases as compared to controls, both in layers I-III (32 \pm 7/34 \pm 11; +7%) and in layers IV-VI (28 \pm 9/35 \pm 31; +24%). On the other hand, in the hippocampus of DP brains as compared to control brains 3 H-HC binding sites tended to decrease along all the layers, though this reduction only reached statistical significance in the hilus of the dentate gyrus (105 \pm 55/51 \pm 17; -52%, $p < 0.05$).

Our data help to clarify the state of the presynaptic cholinergic compartment in levodopa-responsive parkinsonism, demonstrating first the striatal cholinergic hyperfunction compensating dopamine deficiency, and second a slight to moderate loss in the presynaptic cholinergic tone in parkinsonian hippocampal formation. These neurochemical changes very probably play an important role in the pathophysiology of some motor and mental symptoms observed in DP patients.

426.2

THE LEVELS OF TYROSINE HYDROXYLASE AND DOPA DECARBOXYLASE ARE REDUCED IN STRIATUM OF PATIENTS WITH DOMINANTLY INHERITED OLIVOPONTOCEREBELLAR ATROPHY (OPCA). X.H. Zhong*, J.W. Haycock. and S.J. Kish. Clarke Institute of Psychiatry, Toronto, Canada, and LSU Medical Center, New Orleans, Louisiana, U.S.A.

We have reported a 60%-80% striatal dopamine reduction, but without substantia nigra cell loss, in seven patients with OPCA, a hereditary cerebellar ataxia disorder (Neurology 42:1573, 1992). The selective deficit was suggestive of a "dying-back" phenomenon, in which nerve terminal loss was preceding retrograde degeneration of cell bodies.

We have now measured two additional dopaminergic markers in these patients. Tyrosine hydroxylase (TH) and DOPA decarboxylase (DDC) levels were quantitated by Western blot analysis. TH levels were 66% and 64% lower in the caudate and putamen (respectively) of patients with OPCA. DDC levels were reduced 31% (caudate) and 45% (putamen). The smaller decrement in DDC levels resulted, at least in part, from the appearance of an additional DDC-immunoreactive band of slightly different M, in 6 of the 7 OPCA cases but in none of the controls (n=15). Notably, multiple isoforms of DDC mRNA have been identified in humans, rat and *Drosophila*, but the mammalian DDC mRNAs that have been reported to date do not encode different proteins. Thus, the present findings of reduced TH and DDC levels in striata from OPCA patients provide further support for a "dying-back" phenomenon in the progression of this disorder. In addition, the appearance of multiple M, DDC bands in 6 of the 7 OPCA cases may be indicative of disease-induced changes in alternative splicing. (Supported by USPHS grants NS26034 and NS25134)

CALCIUM BINDING PROTEINS DIFFERENTIATE MIDBRAIN DOPAMINERGIC SYSTEMS IN HUMANS. D.A. McRitchie., G.M. Halliday and D.L. Tracey*. Neuropathology Unit, Department of Pathology, University of Sydney, 2006, *School of Anatomy, University of New South Wales, Kensington, 2033, Australia.

Previous studies have reported that substantia nigra neurons containing calbindin-D28K (Cal) are selectively spared in patients with Parkinson's disease (Yamada *et al.* Brain Res. 1990;526:303-307). The aim of this study is to determine the distribution of Cal and parvalbumin (Parv) in the human ventral midbrain using immunohistochemistry. Formalin-fixed midbrains from 11 cases (aged 37-88yrs) with no evidence of neurological or neuropathological abnormalities were used. The tissue was taken with consent at routine hospital autopsies (mean post mortem delay = 19hrs) and the study was approved by the Human Ethics Committee. 50 μ m sections were cut in the transverse or horizontal planes. Three parallel series of sections were stained with cresyl violet, mouse anti-Cal or mouse anti-Parv. The distribution of Cal- and Parv-immunoreactive (Cal+ or Parv+) neurons was quite exclusive. Cal+ neurons overlapped in their distribution with some pigmented and presumably dopaminergic midbrain neurons while Parv+ neurons were restricted to non-pigmented regions. Many Cal+ neurons were present in the A10 (paranigral and parabrachial pigmented nuclei) and A8 (retrobulbar fields) dopaminergic cell groups, but were virtually absent from the A9 dopaminergic cell group (substantia nigra pars compacta). Cal+ neurons were both pigmented and non-pigmented and were concentrated caudally. In contrast, Parv+ neurons were non-pigmented and dispersed throughout the rostral substantia nigra pars reticulata. In contrast to past reports, A9 dopaminergic neurons do not contain Cal in humans. In addition, Parv appears to be exclusively contained in reticulata neurons.

426.6

AUTORADIOGRAPHIC DISTRIBUTION OF [59 Fe]-FERROTRANSFERRIN BINDING SITES IN THE MESENCEPHALON AND THE STRIATUM OF CONTROL SUBJECTS AND PATIENTS WITH PARKINSON'S DISEASE. B.A. Faucheux*, E.C. Hirsch*, J. Villares*, F. Javoy-Agid*, J.J. Hauw*, Y. Agid*. *Lab. Physiopathol. Pathogénèse Maladies Syst. Nerveux, INSERM (U289) and *Lab. Neuropathol., Hôpital Salpêtrière; *Ctre Gérontol. Ass. Cl. Bernard; Paris, France.

Parkinson's disease (PD) is characterized by a progressive degeneration of dopaminergic (DA) neurons, which is severe in substantia nigra (SN) and moderate in other DA areas of the mesencephalon (ventral tegmental area, cell group A8, central grey substance). Iron levels are increased in the SN of patients with PD. This metal can promote the formation of a variety of cytotoxic reactive oxygen species and membrane lipid peroxidation. A dysregulation of its intracellular uptake by neurons and glial cells in the SN may thus be involved in neuronal death. Localization and number of receptors for transferrin (Tf), the likely most important pathway for iron to gain access to neurons, have been studied by quantitative autoradiography on autopsy mesencephalon and striatum tissue from 7 control subjects and 7 PD patients. In the mesencephalon, densities of [59 Fe]-Tf(Fe), binding sites were highest in central grey substance (about 10fmol/mg tissue equivalent), lowest in SN (about 1fmol/mg tissue equivalent), and intermediate in ventral tegmental area and peri- and retrobulbar fields. There were no statistically significant differences between PD and control brains. In the basal ganglia, levels were highest in caudate nucleus and putamen, and lowest in globus pallidus. These results show a heterogeneous distribution of Tf binding. Regional density of Tf binding among brainstem cell groups was highest in the areas which are the least affected by DA neurons losses in PD. The results suggest 1) that the presence of Tf receptors on surrounding glial cells or neurons may protect DA neurons from toxic effects of excess iron, and 2) that iron does not accumulate through a large increase of Tf receptors density in the SN. [Research supported in part by INSERM, ACB and FdF (grant No 91-5716)]

426.7

ALTERED NUMBER OF [125I] BH-SUBSTANCE P BINDING SITES IN PALLIDUM AND SUBSTANTIA NIGRA IN PARKINSON'S AND ALZHEIMER'S DISEASE. L. Rioux*, Q. Huang and J.N. Joyce. Depts. of Psychiatry and Pharmacology, Univ. of Pennsylvania Sch. Med., Philadelphia, PA, USA.

Previously, we observed a significant increase in the number of NK1 ([125I] Bolton-Hunter labeled substance P sites in the striatum of Parkinson's disease (PD) patients when compared to non-neurologic controls and to Alzheimer's (AD) patients (Rioux et al, 1993; J. Neurotraum.). This may reflect responses to altered release of substance P in striatal neurons in response to losses of dopaminergic input. The present study examined possible changes in the density of NK1 sites in striatal output structures. We quantified by receptor autoradiography the number of NK1 receptors, in substantia nigra (SN) and pallidum [internal (GPI) or external (GPe) segment] of patients suffering from AD and PD. Preliminary results show a trend toward an elevation of NK1 sites in the GPI (162%) and GPe (49%) of AD patients and of patients co-affected with AD and PD (Gpi, 75%; Gpe, 19%) when compared to non-neurologic controls. The results also show a trend toward a decrease of these sites in Gpi (32%), Gpe (54%) and SN (33%) in PD patients and in SN (17%) of patients co-affected with AD and PD. This study suggests that the expression of NK1 receptors in the basal ganglia is differently affected in PD and AD. As with studies exploring changes in DA systems in PD, AD and AD coexistent with PD it appears that alterations in NK-1 sites are more similar for AD and AD with PD as compared to PD. Thus, AD with PD is not simply two co-existing diseases.

APOMORPHINE INHIBITS DOPAMINE (DA) METABOLISM IN HUMANS. M. Levisier*, A. Naini*, C. Raftopoulos*, J. Hildebrand* and S. Przedborski^{2,3}. Depts of ¹Neurosurgery and ²Neurology, Univ. Libre de Bruxelles - Hôp Erasme, Brussels, Belgium and ³Dept of Neurology, Columbia Univ., New York, NY 10032.

Apomorphine is a potent DA post-synaptic receptor agonist increasingly used in Parkinson's disease (PD). In animals, apomorphine inhibits DA metabolism through a potent agonistic effect on pre-synaptic DA receptors. Because the pre-synaptic effect of DA agonists may be of interest in neuroprotective therapeutic strategies for PD, we examined the apomorphine plasma and CSF pharmacokinetics as well as its effects on the brain DA metabolism in humans.

Six patients (1 woman, 5 men, mean age 79.5 yr.) with presumed normal-pressure hydrocephalus, who underwent 48-hours intracranial pressure monitoring, were injected with 50 µg/kg apomorphine, s.c. Blood and ventricular CSF samples were collected from 0 to 120 min. after injection and were processed for HPLC.

Maximal plasma apomorphine concentration (24.92 ng/ml) was found 20 min. after injection (area under the curve: 1438.65 ng/ml/120 min.). Maximal ventricular CSF apomorphine concentration (1.07 ng/ml) was found 60 min. after injection (area under the curve: 101.37 ng/ml/120 min.). Apomorphine caused a progressive reduction in ventricular CSF concentrations of DA and its metabolites that started after 10 min., was maximal after 30 min. (free DA: 30%, conjugated DA: 28%, HVA: 21%, DOPAC: 31%) and was still present (5-10%) after 120 min.

Our study reports plasma and CSF pharmacokinetics of apomorphine in humans without evidence of PD. We also show, for the first time in humans, that a dose of apomorphine commonly used in PD, causes significant inhibition of DA metabolism that last for more than 120 min. Thus, in addition to its symptomatic effects, apomorphine may play a role in preventing or slowing down the progression of neurodegeneration in PD.

LOCALIZATION OF CATECHOLAMINE SYNTHETIC ENZYMES IN LARVAE OF CRASSOSTREA GIGAS. P.L. Levantine* and D.B. Bonar. University of Maryland, College Park, MD 20742.

Larvae of the Pacific oyster, *Crassostrea gigas*, were examined for catecholamine synthetic enzymes. Serial sections of staged larvae were probed with antibodies to dopamine beta-hydroxylase (DBH), phenylethanolamine N-methyltransferase (PNMT), and tyrosine hydroxylase (TH). Two classes of anti-DBH cells are evident. The primary anti-DBH cells contain tightly packed vesicles and surround the ciliated opening found at the "heel" of the foot. Secondary anti-DBH cells have more dispersed vesicles and are found around the edge of the ciliated opening, and in the mid- and distal foot. Anti-TH staining appeared to be co-localized with anti-DBH staining. In all 6 stages anti-PNMT stained a ring of vesicles around the velum. In later stage larvae anti-PNMT staining is also evident in the proximal portion of the byssus gland. No catecholamine-like immunoreactivity was localized in any ganglion cells, or in the neuropil or connectives. Norepinephrine levels, as measured by HPLC, increase at class 4, as do cross-sectional area of anti-DBH staining, settlement behavior, and metamorphosis.

426.8

EFFICACY OF D₁ AGONISTS IN HUMAN CAUDATE: RELATIONSHIP TO PARKINSONISM. J.H. Gilmore*, V.J. Watts¹, C.P. Lawler¹, E.P. Noll¹, D.E. Nichols² and R.B. Mailman¹. University of North Carolina¹, Chapel Hill, NC 27599 and Purdue University², W. Lafayette, IN 47907

The full efficacy D₁ agonist dihydroxidine (DHX) has profound antiparkinsonian activity in MPTP treated monkeys (Taylor et al., 1991). Although we had hypothesized that these effects were related to its full efficacy at stimulating the enzyme adenylate cyclase, another purported full efficacy D₁ agonist (SKF82958) has recently been shown to have only weak antiparkinsonian activity. One explanation for this discrepancy is that the biochemical efficacy studies were conducted in rodents; it is possible that the D₁ receptor affinity and efficacy of these two compounds are similar in rodent brain, but differ significantly in primate brain. To examine this possibility, we compared the D₁ receptor affinity and functional activity of DHX, SKF82958 and another purported full efficacy compound (A68930) in human brain. Results from *in vitro* binding studies with membranes from human caudate [n = 4; age = 36 ± 2 yr (SD); post mortem interval = 19 ± 8 hrs (SD)] indicated that these D₁ agonists competed for [³H]-SCH23390 labeled sites with a rank order of potency similar to that in rat striatum [IC₅₀ = 36.8 nM (DHX); 18.6 nM (SKF82958); 3.9 nM (A68930)]. We also examined the ability of these compounds to stimulate the enzyme adenylate cyclase in tissue homogenates of human caudate. DHX and A68930 were of full efficacy (relative to 100 µM dopamine), whereas the prototypical partial D₁ agonist SKF38393 induced less than 50% maximal stimulation. Interestingly, the purported full efficacy D₁ agonist SKF82958 exhibited efficacy lower than that of dopamine or DHX (albeit greater than that of SKF38393). The difference in biochemical efficacy between DHX and SKF82958 in human brain may underlie the dramatically different clinical responses elicited by these drugs in primate models of parkinsonism. MK-801 PREVENTS MPTP-INDUCED REDUCTION OF CATECHOLAMINES IN GOLDFISH BRAIN AREAS. A. Poli*, M. Virgili, R. Lucchi, O. Gandolfi, and O. Barnabei Dept. of Biology, University of Bologna, 40126-Bologna, Italy.

Previous study from this laboratory demonstrated that treatment with MPTP caused a marked disappearance of tyrosine hydroxylase immunoreactivity and degeneration of neurons in several areas of goldfish brain, with concomitant depletion of DA and NA levels. Except for a marked darkening of the skin, MPTP effects appeared not different from those observed in higher vertebrates. Since the involvement of excitatory amino acids in the mechanism of MPTP toxicity has been demonstrated in mammals, we have examined the effects of the neurotoxin on amino acids release in synaptosomes prepared from discrete goldfish brain areas and the effect of MK-801, a noncompetitive antagonist for the NMDA receptors, on MPTP catecholamines depletion. Although MPTP (10⁻⁵ ÷ 10⁻³ M) did not alter the basal amino acids release in synaptosome preparations from telencephalon and hypothalamus, i.p. injection of the toxin (10 mg/kg for 3 days) caused a strong loss of DA and NA in the aforementioned brain regions. Pretreatment of fish with MK-801 (1 mg/kg every 6 h for 48 h) significantly reduced DA (31% in telencephalon; 46% in hypothalamus) and NA (29% in telencephalon; 55% in hypothalamus) MPTP-induced depletion. These results indicate that NMDA receptors appear to be involved in mediating MPTP catecholamine depletion, at least in goldfish brain areas.

NEUROFILAMENTS MAINTAIN THE STRUCTURAL- AND FUNCTIONAL INTEGRITY OF DOPAMINERGIC NEURONS IN CULTURE. R. Hao, R.B. Norgren, Jr., J.F. Rodriguez-Sierra, M. Ebadi and R.F. Pfeiffer. Sec. of Neurol.; Dept. of Cell Biology and Anatomy; and Dept. of Pharmacol., Univ. Neb. Coll. Med., Omaha, Nebraska 68198-6260.

The major histological changes in brains of Parkinson's patients include the aggregation of neurofilaments and the formation of Lewy bodies in dopaminergic neurons of corpus striatum. In order to delineate the etiology of parkinson's disease, mesencephalic cells of 14 day embryonic rats were cultured in a serum-free medium, and the integrity of dopaminergic neurons was assessed by tyrosine hydroxylase immunocytochemistry and by the presence of high affinity [³H]dopamine uptake and release mechanisms. Cytochalasin B (5 µg/ml) but not colchicine inhibited the dopamine uptake mechanism in a time-dependent fashion without influencing the release of dopamine. Fluorescence immunochemical analysis of cells exposed to cytochalasin B but not colchicine, revealed shortened axons and dendrites and disappearance of the microspikes. The results of these studies suggest that normal organization of neurofilaments is necessary in order to maintain the morphological and functional integrity of dopaminergic neurons.

THE PRESENCE OF DOPAMINE-IMMUNOREACTIVE STRIATAL CELLS IN 6-HYDROXYDOPAMINE-LESIONED RATS TREATED WITH L-DIHYDROXYPHENYLALANINE. A. Mura, D. Jackson, M.S. Manley, S.J. Young, and P.M. Groves. Dept. of Psychiatry, Univ. of California at San Diego, La Jolla, CA, 92093.

The dopamine (DA) precursor, L-dihydroxyphenylalanine (L-DOPA), alleviates symptoms of Parkinson's disease despite major degeneration of nigrostriatal DA afferents. Though these afferents contain the vast majority of aromatic amino acid decarboxylase (AADC) which converts L-DOPA to DA, AADC has also been detected in a small number of striatal neurons. A greater number of such neurons is unmasked by destruction of nigrostriatal afferents. Disclosure of AADC in striatal neurons leaves open the possibility that exogenous L-DOPA may be converted to DA in these cells. We have examined striatal DA-like immunoreactivity in DA-depleted rats treated with exogenous L-DOPA. Male Sprague Dawley rats (150-200 g) received unilateral medial forebrain bundle injections of 6-hydroxydopamine (8 µg). Five days after surgery, some animals were given the peripheral decarboxylase inhibitor, benserazide hydrochloride (50 mg/kg, i.p.) followed two hours later by L-DOPA (100 mg/kg, i.p.). Rats exhibiting at least 20 contralateral rotations per min, indicative of large DA lesions (>90%), were perfused with a 5% glutaraldehyde fixative two hours after L-DOPA injections. Untreated lesioned rats were also perfused. Brains were removed, cryoprotected, then cut with a freezing microtome (40 µm). Tissue was processed for DA immunoreactivity with a rabbit anti-DA polyclonal followed by avidin-biotin peroxidase staining methods. Immunoreactivity in striatum ipsilateral to the lesion was notably less than that observed in the contralateral striatum. L-DOPA increased immunoreactivity in striatum ipsilateral to the lesion and we observed DA-like immunoreactivity in some dorsomedial striatal cells. These cells exhibited labeled processes and soma (area; 45-55 µm²). They were infrequently encountered in lesioned striatum in the absence of L-DOPA or in striatum contralateral to the lesion. Collectively, our results demonstrate the formation of DA in striatal cells, a process which may have consequences related to the therapeutic as well as possible neurotoxic effects of L-DOPA. A QUANTITATIVE ANALYSIS OF THE DISTRIBUTION OF TYROSINE HYDROXYLASE-POSITIVE CELLS COLOCALIZED WITH CALRETININ IN THE RAT SUBSTANTIA NIGRA. K.R. Isaacs and D.M. Jacobowitz Lab. Clinical Sciences, NIMH, Bethesda, MD 20892.

Calretinin (CR) and tyrosine hydroxylase (TH) were reported to be colocalized in the substantia nigra (SN) (Rogers, 1992) but a detailed mapping of the distribution of the cells and an estimate of the percent colocalization was needed establish baseline values. CR and TH were colocalized within the same section by immunofluorescence microscopy using antibodies to CR (rabbit polyclonal) and TH (monoclonal) and secondary antibodies conjugated with FITC or Texas Red. Sections were photographed to make black and white montages. CR was found in 55% of the TH cells. Colocalized cells were more frequent in the rostral sections (approx. 55% of total cells counted) and dropped to approx. 33% in caudal sections. Areas of colocalization were most frequent in the medial and lateral portions of the SN compacta. CR-only cells were rare (10%) in rostral sections while TH-only cells accounted for approximately half of the total counted cells. In more caudal sections, CR-only and TH-only cells each accounted for 33% of the total count. Because of the possible Ca²⁺ buffering capacity of calcium binding proteins, the presence of CR within dopamine containing cells may be relevant for neuroprotection in Parkinson's disease.

ADVERSE EFFECTS OF L-DOPA AND DOPAMINE RECEPTOR AGONISTS ON CULTURED RAT MESENCEPHALIC DOPAMINE NEURONS. P.J. Kontur*, K.L. Marek, D.E. Redmond, Jr. and R.H. Roth. Neural Transplant Program, Depts. of Pharmacology, Psychiatry and Neurology, Yale U. Sch. of Med., New Haven, CT 06510.

Continued administration of L-DOPA after treatment of Parkinson's disease by transplantation of fetal brain tissue may adversely affect developing dopamine (DA) neurons in the graft. Cell cultures prepared from the ventral mesencephalon of 13 to 13.5 day old rat embryos were used to study the potential toxicity of L-DOPA, the D1 receptor agonist dihydroxidine (DHX) and the D2 receptor agonist (±)-4-propyl-9-hydroxynaphoxazine (PHNO) on the survival and function of DA neurons. A single addition of 25, 50, or 100µM L-DOPA to the culture media resulted in general cellular degeneration, and concentration-dependent decreases in ³H-DA and ¹⁴C-GABA uptake and numbers of tyrosine hydroxylase (TH) immunoreactive cells. Daily administration of 1, 5 or 10µM L-DOPA resulted in concentration-dependent decreases in ³H-DA and ¹⁴C-GABA uptake and numbers of TH immunoreactive cells. A single addition of DHX resulted in concentration-dependent changes; severe cell loss and decreased ³H-DA uptake after 100µM DHX and increased uptake after 1µM DHX. PHNO did not affect ³H-DA or ¹⁴C-GABA uptake except after daily treatment with a 1ng/ml concentration. The demonstration of morphological and biochemical changes in cultured DA neurons after short-term administration of L-DOPA and DA receptor agonists suggests that continued administration of agents used for treatment of Parkinson's disease may affect the development of transplanted fetal DA neurons. Age-related changes in nigrostriatal dopamine System in Squirrel Monkeys. L. Irwin, L. E. DeLanney*, P. Chan, D. A. DiMonte, M. Sandy and J. W. Langston. California Parkinson's Foundation, San Jose, CA, 95128.

Changes in regional brain neurotransmitter systems are often considered as factors that underlie the cognitive and behavioral alterations associated with normal aging. Normal age-related decreases in brain neurotransmitter concentrations have also been implicated as possible contributory factors in neurodegenerative disorders known to affect the elderly. Nowhere has the hypothetical connection between age-related neurotransmitter loss and neurodegenerative disease been more evident than in the case of nigrostriatal (NS) dopamine (DA) and Parkinson's disease (PD).

Non-human primates provide a useful animal model to determine age-related changes in NS-DA across many years in animals closest to humans. We studied changes in DA, serotonin (5HT) and the metabolites DOPAC, HVA and HIAA in young (3 yr), middle aged (10 yr) and old (19 yr) squirrel monkeys (n=7/group) previously characterized for their motoric activity.

Significant age-related loss of DA occurred only in the substantia nigra (70%) and the putamen (30%). These changes in DA correlated with reduced motoric activity. No age-related changes in DA were observed in the caudate or globus pallidus nor were any changes in 5HT or HIAA observed in any of these areas. Although regional age-related changes in DOPAC and HVA were detected these did not correlate with the loss of DA, nor was there a consistent pattern of increased turnover in areas selectively subject to DA loss.

These results suggest that the aging squirrel monkey may serve as a useful model to investigate the effects of age related NS-DA loss and to determine the relationship between normal age related DA loss and PD.

IN VIVO ELECTROCHEMICAL STUDIES OF DOPAMINE OVERFLOW AND CLEARANCE IN NORMAL AND MPTP-LESIONED STRIATUM OF RHESUS MONKEYS. G.A. Gerhardt*, J. Hudson, W. A. Cass, B. J. Hoffer, Z. Zhang, A. Ovadia, L. Ketonen, and D.Gash, Univ. of Colo. Health Sci. Ctr., Denver, CO, and Univ. of Rochester, Rochester, NY.

Rapid chronoamperometric recordings using Nafion-coated carbon fiber electrodes (30-90 microns O.D.), combined with pressure ejection of drugs from micropipettes, were used to investigate striatal dopamine (DA) fibers in 3 normal and 5 MPTP-treated Rhesus monkeys. The MPTP was administered from 1 to 18 months prior to recording and all treated monkeys exhibited stable Parkinsonian features. For recording, monkeys (20-24 years old) were anesthetized with isoflurane and placed in a stereotaxic apparatus. MRI-guided sterile stereotaxic procedures were used for implantations of the electrochemical recording arrays. Pressure ejection of potassium from micropipettes, which were positioned approx. 300 microns from the electrochemical sensor, was used to evoke the overflow of DA in the putamen and caudate of both normal and MPTP-treated monkeys. In addition, DA clearance was evaluated in normal and MPTP-treated striatum. Potassium was seen to evoke robust overflow of DA into the extracellular space in the unlesioned putamen and caudate nucleus of the Rhesus monkey. In contrast, potassium did not produce any detectable changes (sensitivity 25-50 nanomolar) in extracellular levels of DA in the MPTP-lesioned striatum. In addition, DA clearance was markedly diminished in the lesioned caudate and putamen as compared to unlesioned striatum, supporting that MPTP produces a loss of high-affinity uptake of DA through its destruction of DA nerve endings. These data demonstrate that the residual dopaminergic fibers remaining after MPTP lesions are incapable of supporting the potassium-evoked overflow of DA, and suggest that the remaining DA fibers following MPTP lesions are incapable of properly releasing DA. Evidence of the Presence of a Potent Dopamine-Releasing Protein (DARP) in Rat and Human Serum. D.A. Llano and Y.D. Ramirez*
Department of Physiology, University of Illinois, Urbana, Illinois. 61801.
Work from our laboratory has revealed the presence of a potent dopamine (DA)-releasing protein (DARP) in rat and bovine adrenal extracts as well as in the media of primary mesencephalic cell culture from 17 day-old rat embryos. In this report, we demonstrate the presence of this factor in the serum of rats and humans. Serum glycoproteins were isolated by treatment with 50% ammonium sulfate and concanavalin A. Both human and rat extracts had potent DA-releasing activity when used in an *in vitro* superfusion assay in which fragments from the rat corpus striatum (CS) were superfused with extract diluted in Krebs-Ringer phosphate. The activity was attenuated by preincubation of the extract with pronase E (maximum increase in DA release = 19.70 ± 4.41 (n=8) vs. 5.75 ± 1.76 (n=9) pg DA/mg wet tissue/min. for the controls and pronase-treated samples, respectively) and with a DARP-specific monoclonal antibody (maximum increase in DA release = 23.09 ± 8.08 (n=8) vs. 8.73 ± 4.87 (n=8) pg DA/mg wet tissue/min. for the controls and antibody-treated samples, respectively). This DA-releasing activity was not seen in similarly prepared extracts from the spleen. Western blot analysis and immunoaffinity chromatography indicate that it has a molecular weight of about 60kD, which corresponds to the molecular weight of adrenal-derived DARP. In addition, preliminary data using serum extracts from two 15-day adrenalectomized (ADX) animals demonstrate elevated DA-releasing activity relative to that of two sham-ADX animals (maximum increase in DA release = 19.70 ± 4.41 (n=8 superfusions) vs. 49.79 ± 10.53 (n=7) pg DA/mg wet tissue/min. for the controls and 15-day ADX samples, respectively). Furthermore, dopaminergic neuronal activity (determined by analyzing the DOPAC:DA ratio using HPLC-EC) in the hypothalamus and the CS is enhanced in 15-day ADX animals. This ratio increased significantly in the hypothalamus (DOPAC/DA = $.860 \pm .131$ (n=8 rats) and $1.651 \pm .286$ (n=5) in the sham ADX and 15-day ADX animals, respectively) and the CS (DOPAC/DA = $.138 \pm .008$ (n=8) and $.183 \pm .023$ (n=5)). These data demonstrate the presence of a DARP-like substance in the sera of rats and humans and suggest that the removal of the adrenal glands leads to an increase in basal dopaminergic activity in the hypothalamus and CS.

DEGENERATIVE DISEASE: PARKINSON'S—HUMAN PERFORMANCE AND PRIMATE MODELS

FURTHER CHARACTERIZATION OF COGNITIVE AND MOTOR DEFICITS IN CHRONIC LOW DOSE MPTP-TREATED MONKEYS.
Z.-O. Sun, A. Pope, J. S. Schneider, and D. P. Roelgen. Dept. of Neurology, Hahnemann University, Philadelphia, PA. 19102.

We have previously reported that macaque monkeys exposed chronically to low doses of the neurotoxin MPTP develop cognitive and behavioral deficits similar to those reported in early Parkinson's disease (PD), in frontal lobe patients, and in people with attention deficit hyperactivity disorder (ADHD). We now further examine the chronic low dose MPTP syndrome in 8 monkeys by examining effects of this treatment on the following tasks: delayed matching-to-sample (DMS), object retrieval (OR) (with cognitive and motor components), persistence (during a difficult or impossible task), simple or difficult visual pattern discrimination (VPD), discrimination reversal (DR), and food retrieval tasks (with easy or difficult motor requirements). Monkeys received MPTP (0.05-0.20 mg/kg) on a variable schedule for approximately 3 to 6 months. All monkeys eventually had difficulty performing DMS, the cognitive component of OR, and DR. The first deficits to appear were deficits in persistence tasks and DMS. VPD remained intact throughout the study. Some motor slowing was eventually observed during OR and food retrieval tasks, but this did not appear to significantly impair the animal's ability to correctly perform the tasks. On cognitive tasks, errors of omission or commission were made. Dopamine D-2 agonists reduced the number of omission errors but not commission errors while adrenergic alpha-2 agonists had opposite effects. These results further demonstrate the "frontal" nature of cognitive deficits in monkeys with a primary neurochemical lesion affecting the striatum and further underscore the importance of these animals as models for early PD and ADHD. Supported by MH46531.

SPEECH AND VOICE CHARACTERISTICS OF EARLY PARKINSON'S DISEASE. L. Carol Gracco, K. L. Marek, and V. L. Gracco*. Haskins Laboratories and Yale University, New Haven, Ct 06511.

Movement of the speech articulators and vibration of the vocal folds are two important processes for human communication. To be effective, the actions of the lips, jaw, tongue, and larynx must be appropriately scaled and coordinated to produce the aerodynamic and acoustic patterns for speech. Damage to the basal ganglia often produces disruptions in speech and voice resulting in a variety of perceptual and movement symptoms such as hoarse voice, imprecise articulation, and slowed speaking rate. One objective of the present investigation was to examine the breakdown in speech and voice production to obtain insight into the role of the basal ganglia in human communication. Secondly, the speech and voice impairments were compared to limb characteristics, to determine the consistency in degree and severity across motor systems. It is conceivable that speech and voice difficulty in individuals with Parkinson's disease may be more readily apparent or occur earlier in the disease process than the more traditional limb signs. Twenty subjects with early Parkinson's disease (based on standardized neurological exam) were used. A number of instrumental measures were obtained allowing analysis of the movements of individual articulators and their coordination. In addition, videostroboscopic laryngeal imaging and detailed acoustic analysis of the voice signal were correlated with perceptual ratings of each subjects speech and voice capability. In these mildly involved subjects, some difficulties were noted in the scaling and coordinating of the speech articulators. Qualitatively, the degree and character of the speech movement deficits were not consistent with those observed in the limbs. Moreover, deficits in laryngeal vibration and subsequent acoustic analysis proved to be more sensitive than the standardized neurological exam and may contribute significantly to early evaluation and diagnosis. Supported by NIH grants DC00121, DC00594, DC00044, and the National Parkinson's Foundation.

428.2

PROGRAMMING OF A MOVEMENT SEQUENCE IN PARKINSON'S DISEASE. P. Weiss¹, G.E. Stelmach^{1*}, H. Hefter², H.-J. Freund² ¹Motor Control Lab., Arizona State Univ., Tempe, AZ 85287 -0404, ²Department of Neurology, Univ. of Duesseldorf, Germany.

A group of Parkinsonian (age: 59 ± 13 yrs.), elderly (age: 57 ± 9 yrs.) and young (age: 27 ± 3 yrs.) subjects performed sequential movements with a stylus on a digitizer board (100 Hz sampling frequency, 0.1 mm accuracy). After an imperative auditory stimulus, subjects had either to draw a 10 cm horizontal line from a starting point into a square (side length: 2 cm), or draw the 10 cm line and proceed to a second square (side length: 2 cm, Index of difficulty (ID): 2.3), or draw the 10 cm line and proceed to a second smaller square (side length: 0.7 cm, ID: 3.3). 50 trials in each condition were digitally recorded and the movement kinematics were analyzed; movements were compared by examining the peak velocity (PV), time to peak velocity (TPV) and deceleration time (DT) for the first and second movement components.

The Parkinsonian group showed a lengthening of movement time and a decrease in velocity under all three task conditions. In the Parkinsonian group, the longer DT and total time in the first movement component revealed that the patients had difficulties in stopping their actions and that they performed movements faster, when there was a second movement. The significant group by task interaction [$F(1,17) = 11.74, P = 0.003$] for the peak velocity in the second component of the movement (ID 2.3 versus ID 3.3) showed that Parkinson patients did not modulate movement speed. We interpreted these findings to indicate that patients with Parkinson's disease have problems in scaling the velocity of their movements under accuracy constraints.

428.4

OBJECTIVE ANALYSIS OF SIMPLE REACTION TIME IN PARKINSONIAN AND CONTROL SUBJECTS FOR FIXED AND RANDOM PREPARATORY INTERVALS. A.S. Mandir¹, J.F. Paulsen, C.W. Schultz and L.A. Flashman, The Johns Hopkins Univ Sch of Med, Dept of Neurology, Baltimore, MD 21205, UCSD, VA Med Ctr, Depts of Psychology and Neurology, San Diego, CA 92161 and Univ of Iowa, MHCRC, Iowa City, IA 52242.

Preparatory cues may enhance reaction time (RT) by allowing the advantage of premovement "set" phenomena. Simple RT is prolonged in Parkinson Disease (PD) in part from dysfunction of preparatory "set" processing. A paradigm was employed which objectively examined the effect of preparatory intervals on reaction time in PD and control subjects. A computer RT task presented "GO" signals at 1,2,4,7,5,15 and 25 second intervals from a ready state (S1-S2 preparatory interval). Trials were performed in blocks of fixed intervals (allowing for "set") and random intervals. Preliminary data were obtained for 9 PD and 12 control subjects. PD subjects demonstrated prolonged RT compared to controls at all preparatory intervals (Mann-Whitney; $p < .01$). All subjects demonstrated reduced RT at shorter preparatory intervals for fixed compared to random block trials (Mann-Whitney; $p < .01$). However, as the preparatory interval lengthened, 7 of 9 PD subjects compared to 1 of 12 control subjects failed to maintain reduced RT for fixed versus random blocks. Those PD subjects eventually demonstrated prolonged RT for fixed compared to random blocks at the longer preparatory intervals ("crossed over"). A propensity for "set" premovement programming dysfunction in PD may occur as the preparatory interval is increased and serve to hinder performance of simple RT tasks.

428.5

POSTURAL TREMOR OF MIDDLE FINGER IN PARKINSON PATIENTS AND AGE-MATCHED CONTROLS. Suzanne S. Palmer¹ and J. Thomas Hutton². Dept. of Physical Therapy, Texas Tech Univ. Health Sciences Center, Lubbock, TX 79430¹ and Neurology, St. Mary of the Plains Hospital, Lubbock, TX 79410².

If a central mechanism were the primary cause of enhanced finger tremor in Parkinson's disease, the peak frequency in spectral analysis of rectified electromyographic activity (EMG) of finger extensor muscle would be correlated with tremor frequency. Age-matched control subjects would not show correlated peak frequencies of EMG and movement acceleration because several other causal factors might also contribute to their tremor.

EMG was recorded from extensor digitorum, and acceleration from the proximal phalanx of the middle finger of 14 Parkinson patients (\bar{x} = 69.7 yrs) and 14 age-matched control subjects (\bar{x} = 63.8 yrs). They extended the middle finger of their nondominant hand off the table top for 10 min at 20-30° with their hand placed flat. Spectral analysis was done of a 5.44 min epoch of time after the first two min. A multifactor ANOVA test showed peak frequency of tremor was related to type of subject (normal or Parkinson) and peak frequency of EMG, but not to the power of either tremor or EMG. A linear regression analysis of data from Parkinson patients showed peak frequency of tremor was correlated with peak frequency of EMG (correl. coeff. = 0.983, $p < 0.001$). Controls showed a lack of correlation of peak frequency of tremor with peak frequency of EMG (correl. coeff. = 0.389, $p = 0.169$). These results provide evidence central mechanisms enhance activity in the motoneuron pool and muscle and contribute to Parkinson tremor.

CORRELATION BETWEEN DOPAMINE D₂ RECEPTOR INDUCED BEHAVIOR AND IN VIVO RECEPTOR OCCUPANCY IN A MONKEY MODEL OF PARKINSON'S DISEASE. R.J. Vermeulen^{1,3}, B. Drukarch¹, M.P. Witter², N.P.L.G. Verhoeff⁴, E.A. van Royen⁴, E.Ch. Wolters¹, C. Goosen³ and J.C. Stoof¹. Depts of Neurology¹ and Anatomy & Embryology² Free University, Dept. of Nuclear Medicine⁴, Academic Medical Center Amsterdam, Medical Biological Laboratory TNO³, Rijswijk, The Netherlands.

Dopamine D₂ receptors are a pivotal target in the pharmacotherapy of Parkinson's disease. Unfortunately, almost no data are available linking clinical effects of drug treatment with the extent of D₂ receptor occupancy in the brain. Therefore, we investigated the correlation between motor behavioral effects of the selective D₂ agonist LY 171555 and in vivo D₂ receptor occupancy in a monkey model of Parkinson's disease using Single Photon Emission Computerized Tomography (SPECT). Four male rhesus monkeys (*Macaca mulatta*) were unilaterally (i.e. by left intracarotid infusion) lesioned with MPTP. The MPTP-lesioned monkeys consistently showed signs of unilateral parkinsonism. Administration of LY 171555 (0.01 or 0.3 mg/kg i.m.) induced a significant increase of contralateral rotation (away from the lesion). In the SPECT studies intravenous infusion of ¹²³I-IBZM (3-iodo-6-methoxybenzamide) was used to label D₂ receptors. In the MPTP-lesioned monkeys the ¹²³I-IBZM binding in the left (lesioned) striatum was significantly higher as compared to that in the right (non-lesioned) striatum (approximately 13 % increase, $P < 0.05$). Upon administration of LY 171555 (0.01 or 0.3 mg/kg) a significant displacement of ¹²³I-IBZM at both sides (left and right) was detected only at the highest dose. We conclude that LY 171555 induces behavioral effects in unilaterally MPTP-lesioned monkeys at relatively low doses. However, using ¹²³I IBZM SPECT scanning, no direct correlation could be demonstrated between these behavioral effects and D₂ receptor occupancy in vivo.

428.9

GABA DELIVERY TO THE SUBTHALAMIC NUCLEUS ALLEVIATES MPTP INDUCED HEMIPARKINSONISM IN NON-HUMAN PRIMATES. A.P. Signore¹, M. Goddard¹, P.A. Tresco^{2*}, R. Burrill¹, P. Aebischer^{1,3}. ¹Division of Biology and Medicine, Brown University; ²Department of Bioengineering, University of Utah; ³Division of Surgical Research, CHUV, University of Lausanne Medical School, Switzerland.

Parkinson's disease is characterized by the degeneration of the dopaminergic nigral neurons projecting to the striatum, resulting in altered levels of neurotransmitters in several basal ganglia nuclei. Overactivity of the subthalamic nucleus (STN) occurs in Parkinson's disease as a result of a decreased γ -aminobutyric acid (GABA) innervation to this nucleus, secondary to a decreased dopaminergic innervation of the striatum. To attempt to achieve normalization of STN activity, polymer rods slowly releasing GABA were implanted near the STN in two unilaterally MPTP-lesioned primates. The first primate showed a significant improvement of parkinsonian symptoms, including scoring on an object retrieval task, whereas no significant improvement was observed in the second primate. Morphological evaluation revealed a correct placement of the rod only in the first primate. Extensive lesioning of the substantia nigra was seen in both primates as assessed by tyrosine hydroxylase immunohistochemistry. An additional primate was also implanted with a rod releasing the specific GABA_B receptor agonist, baclofen in the vicinity of the STN. This primate also shows a significant improvement in the object retrieval task. Delivery of GABA or its agonists to the STN through a controlled release process may be a viable strategy in the treatment of Parkinson's disease as this structure is significantly smaller than the dopamine depleted striatal target.

428.6

NALTREXONE DECREASES DOPAMINE D₂ BUT NOT D₁ RECEPTOR MEDIATED ROTATIONAL BEHAVIOUR IN UNILATERALLY MPTP-LESIONED MONKEYS. B. Drukarch¹, R.J. Vermeulen^{1,3}, A.N.M. Schoffeleers², E.Ch. Wolters¹, C. Goosen³, and J.C. Stoof¹. Depts of Neurology¹ and Pharmacology², Free University Amsterdam, ³ Medical Biological Laboratory TNO³, Rijswijk, The Netherlands.

Reportedly, in the unilateral 6-hydroxydopamine rodent model of Parkinson's disease L-Dopa induced rotational behaviour is attenuated by μ -opioid antagonists. However, no information is available whether this effect of μ -opioid receptor blockade on rotational behaviour also occurs upon selective D1 or D2 receptor stimulation. In order to investigate this question and to extend the findings also to other kinds of dopamine receptor induced behaviours, we used the unilateral MPTP monkey model of Parkinson's disease.

The lesion was made by an unilateral infusion of MPTP in the left internal carotid artery. All animals (n=4) showed a loss of handuse at the right side. The D1 agonist SKF 81297 (0.3 mg/kg, i.m.) and the D2 agonist LY 171555 (0.01 mg/kg, i.m.) induced a statistically significant stimulation of both rotational behaviour (away from the lesion) and right hand use. The μ -opioid antagonist naltrexone (0.5 mg/kg, i.m.) alone did not induce any effect on rotations or hand use. However, naltrexone caused a statistically significant (46%, $P < 0.05$) reduction of LY 171555 induced rotational behaviour whereas no effect was seen on LY 171555 induced handuse. Interestingly, no effect of naltrexone was observed on D1 agonist stimulated rotational behaviour and handuse.

These preliminary data indicate that, in models of Parkinson's disease, the effect of μ -opioid receptor blockade on dopamine receptor induced behaviours is limited to D2 receptor stimulated rotations.

428.8

ABNORMAL DYNAMIC MODULATION OF PUTAMEN NEURONAL ACTIVITY FOLLOWING MPTP. Erwin B. Montgomery, Jr.¹, The Univ of Arizona Col of Med, Department of Neurology, Tucson AZ

The dynamic modulation of neuronal activity associated with movement generation was compared in 26 putamen neurons recorded before MPTP injection and 25 neurons after. The monkey was parkinsonian in cage behavior and had prolonged reaction times in a wrist task after MPTP. Wave-forms representative of dynamic modulation were constructed from peri-event histograms of neuronal activity from 500 ms before to 500 ms after movement onset. Wave-forms were compared by calculating the Pearson correlation coefficients between all possible pairs. The table of Pearson correlations was represented in a three-dimensional space by principal component analysis. Wave-forms of neurons recorded after MPTP were distributed over a smaller region of the similarity space implying a reduction in the dynamic range of neuronal activity modulation. The reduced range may reflect a simpler or reduced repertoire of movement programs that would be most evident when complex movements are required. This may account for the greater impairment of complex vs. simple movements in humans with Parkinson's disease. New models of pathophysiology are needed to explain these changes in dynamic modulation.

ALLEVIATION OF BRADYKINESIA AND RIGIDITY BY HIGH FREQUENCY STIMULATION OF THE SUBTHALAMIC NUCLEUS IN MPTP-TREATED MONKEY. Ch. Gross, A. Benazzouz, T. Boraud, J. Féger¹ and B. Bioulac². Laboratoire de Neurophysiologie, CNRS URA 1200, Université de Bordeaux 2, 33076 Bordeaux Cedex, France. ¹Laboratoire de Pharmacologie, Université de Paris VI, France.

Parkinsonian bradykinesia and rigidity are the consequence of degeneration of dopaminergic neurons in the substantia nigra (SN). This leads to the abnormal hyperactivity in the basal ganglia output structures: internal part of globus pallidus (GPi) and pars reticulata of substantia nigra (SNr). The main driving force of this hyperactivity appears result from the afferent excitatory glutamatergic pathway of the subthalamic nucleus (STN). The lesion of this structure alleviates the parkinsonian motor signs but induces dyskinesia and hemiballismus in the monkey.

In the present work, we have studied the effect of high frequency stimulation (HFS) of the STN in two unilaterally MPTP-treated monkeys. Rigidity was measured using EMG recordings of biceps and triceps during passive repetitive flexion and extension movements of the forearm. Bradykinesia was quantified by mechanographic and EMG recordings associated to voluntary trained movements. The results demonstrate that HFS of the STN alleviated the hemiparkinsonian motor symptoms in both monkeys. Neither dyskinesia nor hemiballismus was observed during HFS of the STN.

This work confirms the involvement of subthalamic nucleus in the genesis of parkinsonian signs and suggests that this technique may have a therapeutic potentiality for treating parkinsonism.

428.11

STIMULATION OF SUBTHALAMIC NUCLEUS ACUTELY CHANGES CLINICAL STATUS IN PARKINSON'S DISEASE. A.L. Benabid¹, P. Pollak¹, C. Gross², D. Hoffmann¹, A. Benazzouz², D.M. Gao¹, A. Laurent¹, M. Gentil¹, J. Perret¹ and C. Feuerstein¹. 1: Dept of Neurosciences and INSERM U 318, Grenoble. 2: CNRS URA 1200, Bordeaux, France.

In animal models of Parkinson's disease (PD), it is postulated that the excessive output from the subthalamic nucleus (STN) plays a critical role. Selective lesions or high frequency electrical stimulation of STN can alleviate parkinsonian symptoms in MPTP-treated monkeys. We decided to carry out STN stimulation in patients suffering from severe akinetic forms of PD. After approval from ethical committees, we operated a 51 old PD patient, suffering since 8 years from a strongly disabling akineto-rigid form of PD, with on-off effect (Høhn & Yahr stage 5). Stereotaxic surgery was done under local anaesthesia on one side. The theoretical target was chosen according to stereotaxic atlases. Final position of the chronic electrodes was optimized using electrophysiological recording and stimulation altogether with clinical assessment and surface EMG. Increase in neuronal activity was recorded in the subthalamic area. In the same place, 130 Hz stimulation induced acute and reversible akinesia alleviated mainly on the contralateral limbs, comparable to that obtained with dopaminergic drugs. No dyskinesia, such as hemiballism, was induced by surgery. Studies of the effects of chronic stimulation were extensively performed before and after connection of electrodes to implantable programmable Medtronic Irel II stimulators. Mechanisms of stimulation which can induce similar effects than destruction are still unknown. Nevertheless, the interest of stimulation versus neural grafts must be discussed in patients with highly disabling forms of PD.

REVERSAL OF EXPERIMENTAL PARKINSONISM IN PRIMATES WITH GM1 GANGLIOSIDE: QUANTITATIVE AUTORADIOGRAPHIC AND IMMUNOHISTOCHEMICAL STUDIES. A. Pope* and J.S. Schneider. Dept. of Neurol., Hahnemann University, Phila. PA. 19102.

We have previously reported that chronic GM1 ganglioside treatment could significantly improve motor and cognitive functioning in monkeys made parkinsonism by MPTP as well as increase striatal dopamine levels and the density of striatal tyrosine hydroxylase (TH)-positive fibers (Science (1992), 256, 843). This study further examines effects of GM1 on the density of striatal dopamine uptake sites ([3H] mazindol binding) D2 ([3H] spiperone binding), and D1 ([3H] SCH23390) receptors as well as the number and distribution of TH-positive ventral mesencephalic neurons in MPTP-exposed monkeys. MPTP caused more extensive losses of [3H] mazindol binding in dorsal than ventral striatal regions. Animals that received GM1 treatment for 6 weeks subsequent to the induction of parkinsonism had significantly increased [3H] mazindol binding, compared to MPTP + saline-treated animals, in most dorsal and ventral striatal regions examined. D2 receptor density was not increased following MPTP exposure and was not influenced by GM1 treatment. Striatal D1 binding was increased in MPTP + saline animals but not in MPTP + GM1-treated animals. Examination of TH-positive ventral mesencephalic neurons revealed more and healthier appearing neurons in GM1-treated monkeys. These results suggest that GM1 ganglioside treatment, instituted within 48 to 60 hours of the last of several MPTP injections, and during a period of active degeneration of dopaminergic neurons, has the ability to stimulate the survival of neurons that perhaps would otherwise have died and promote the sprouting of dopaminergic terminals in the denervated striatum. These data add further support for the use of GM1 ganglioside as a potential therapeutic agent for Parkinson's disease. Supported by Fidia Research Laboratories and the F. M. Kirby Foundation.

A NEW ANIMAL MODEL OF DYSTONIA. Joel S. Perlmutter*, Lee W. Tempel, & Lennis Lich. Depts of Neurology and Radiology, Washington University School of Medicine, St. Louis, MO 63110.

An animal model of dystonia may permit evaluation of the underlying pathophysiology as well as assessment of new treatments. We found that intracarotid (i.c.) administration of MPTP in a baboon may produce a transient hemidystonic syndrome followed by hemiparkinsonism. Six male baboons were studied. Each was fasted overnight, anesthetized with ketamine and kept asleep with nitrous oxide and oxygen. A Hanafee angiographic catheter was advanced under fluoroscopic control from the femoral artery high into either the right or left common carotid artery. Placement of the catheter was confirmed with injection of contrast and a permanent record was made by radiograph. MPTP (about 4 mg/kg dissolved in normal saline, .1 mg/ml) was infused through the catheter no faster than 1 ml per minute. Blood pressure, pulse and temperature were monitored and remained constant throughout the procedure. After completion of MPTP infusion, the position of the catheter was re-confirmed by fluoroscopy. Animals recovered quickly from the sedation and usually appeared normal that day. By the next day, most animals displayed spontaneous ipsilateral turning. Later that day or within a few days, they developed varying severity of contralateral hemidystonia with the arm and leg held in an extended and externally rotated posture. Postural tremor was variably present at that time. This dystonic phase lasted from 1 week to 2 months and was followed by a more typical hemiparkinsonian phase with flexed posture and bradykinesia. Some animals also had postural or resting tremor. The parkinsonian phase remained constant in these animals for as long as 1 1/2 years. We propose that i.c. administration of MPTP can produce a clinical syndrome of hemidystonia that appears similar to the human condition. In particular, this appears directly analogous to dystonia in a lower extremity that may be the presenting, and frequently a transient, manifestation of Parkinson's disease in humans.

INCREASED POTENCY OF ORALLY ACTIVE SEMISYNTHETIC SPHINGOLIPIDS COMPARED TO GM1 GANGLIOSIDE: IN VIVO AND IN VITRO STUDIES. J. S. Schneider*, N. Stull, L. DiStefano and L. Jacovitti. Dept. of Neurol., Hahnemann University, Phila., PA. 19102.

Although GM1 ganglioside has been shown to exert reparative effects on the MPTP-damaged dopamine (DA) system in vivo and in vitro, its clinical testing has been limited due to its availability only as an injectable. We have investigated the reparative potential of 2 orally administered semisynthetic sphingolipids, LIGA 4 and LIGA 20, on the MPTP-damaged DA system in vivo. C57 black mice were administered MPTP-HCl once daily for 5 days (20 mg/kg) and given either LIGA 4 or LIGA 20 (50 mg/kg daily) or water by oral gavage for 2 weeks beginning 24 hrs. after the last MPTP injection. Other animals received GM1 ganglioside (30 mg/kg, i.p.) for 2 weeks. LIGA 4 and LIGA 20 increased striatal DA levels by 84-95% above lesion controls while GM1 increased DA levels by only 68%. In a dose response study, GM1 was found to have an optimal dose range of 15-30 mg/kg, with decreased efficacy at low and high doses. In vitro, LIGA 20 was shown to be effective at increasing tyrosine hydroxylase (TH) activity levels in E15 rat ventral mesencephalic neurons previously exposed to MPP+ at much lower concentrations than GM1 ganglioside. The ability of GM1 to promote recovery of DA neurons in vitro depends in large part on the extent to which the cultures have been damaged by the neurotoxin. LIGA 20 produced a moderate recovery of TH activity in severely MPP+-damaged cultures where GM1 had no or minimal effects. These results suggest that the semisynthetic sphingolipids LIGA 4 and LIGA 20 are more potent in exerting reparative effects on the damaged DA system than the parent natural GM1 ganglioside. This, combined with the ability of these compounds to maintain activity after oral administration, make them attractive potential therapeutic agents for Parkinson's disease. Supported by AG 10280 and Fidia Research Laboratories.

DEGENERATIVE DISEASE: PARKINSON'S—TRANSPLANTATION AND GLIA

429.1

EVALUATION OF A NEW STEPPING TEST TO MONITOR LIMB FUNCTION IN THE RAT PARKINSON MODEL: LESION, DRUG, AND TRANSPLANT EFFECTS. M. Olsson, G. Nikkiah¹, C. Bentlage and A. Björklund*. Department of Medical Cell Research, Biskopsgatan 5, S-223 62 Lund, Sweden and (1) Neurosurgical clinic, Nordstadt hospital, D-3000 Hannover 1, Germany.

To further evaluate functional effects of nigral transplants as well as dopaminergic drugs in the rat Parkinson's disease (PD) model, there is a need for quantitative tests of spontaneous, i.e. non-drug induced behaviors that are analogous to the deficits seen in PD patients. Schallert et al. (Soc. Neurosci. Abstr. 451:5, 1992) have recently introduced a test of stepping movements to study forelimb akinesia in rats with 6-hydroxydopamine (6-OHDA) lesions of the nigrostriatal pathway. In the present study we have used a modification of this test to monitor changes in forelimb stepping, ipsilateral and contralateral to a unilateral 6-OHDA lesion, after administration of dopamine receptor agonists, or amphetamine, and after transplantation of fetal nigral neurons to the denervated caudate-putamen. Two parameters were measured: (1) Time to initiate stepping with either forelimb when the other limb is immobilized by the experimenter and the hind part of the rat is raised (initiation time); (2) Number of adjusting steps when the rat is passively moved sideways by the experimenter over a distance of 1 m. Both initiation time and adjustment stepping are severely impaired in the forelimb contralateral, but not ipsilateral, to the 6-OHDA lesion. Preliminary results indicate that multiple intrastriatal nigral transplants can significantly improve stepping movements with the impaired limb, and that a similar improvement can be obtained by a low dose of apomorphine (0.0125 mg/kg) but not amphetamine (0.05 mg/kg).

429.2

TRANSPLANTATION OF PRIMARY FIBROBLASTS GENETICALLY MODIFIED TO EXPRESS TYROSINE HYDROXYLASE IN A PARTIAL 6-OHDA RAT LESION MODEL OF PARKINSON'S DISEASE (PD): EFFECTS OF SYSTEMIC TETRAHYDROBIPTERIN. R.J. Mandel*, D.G. Clevenger, C.K. Unruh, S.K. Spratt, M. Schinstine, K. Bankiewicz, and M.V. Sofroniew. Somatix Therapy Corp., 850 Marina Village Pkwy., Alameda, CA 94501.

Primary fibroblasts genetically modified to express tyrosine hydroxylase (TH) have been shown to release L-dopa *in vitro* and have a positive effect on apomorphine (apo)-induced rotation in unilateral 6-hydroxydopamine (6-OHDA) lesioned rats (Fisher et al., *Neuron* 6:371-380, 1991). This study was undertaken to determine whether systemic administration of the co-factor for TH, tetrahydrobiopterin (BH₄), could improve the function of TH⁺ fibroblast grafts in a rat model of PD (Uchida et al., *Dev. Neurosci.* 14:173-180, 1992). Ten rats received specific A-9 6-OHDA lesions. Four wks post-lesion, 5 rats received 5 x 10⁵ TH⁺ cells in 10 µl spread equally over 4 intrastriatal injection sites on the lesioned side, while the 5 control rats received identical transplants of primary fibroblasts expressing the *lac-Z* gene. One wk following transplantation, the rats were tested in cross-over designs for apo- (0.1 mg/kg, sc) and d-amphetamine- (2 mg/kg, ip) ± BH₄ (50 mg/kg, ip) induced rotational behavior. Transplantation of TH⁺ fibroblasts significantly reduced apo-induced rotational behavior (-25%) relative to rats which received *lac-Z* expressing fibroblasts (p = 0.05) regardless of BH₄ treatment but had no effect on amphetamine-induced rotations. BH₄ treatment significantly increased apo- and significantly decreased amphetamine-induced rotations regardless of graft treatment (p < 0.05).

These data indicate that exogenous BH₄ treatment modifies drug-induced behavior in the rat PD model while the blood brain barrier is disrupted. In contrast, BH₄ treatment did not augment the positive functional effects of TH⁺ grafts in this preliminary study.

429.3

PURIFIED BOVINE CHROMAFFIN CELL GRAFTS DO NOT REDUCE AMPHETAMINE-INDUCED ROTATION IN HEMIPARKINSONIAN RATS M. Bresjanac¹, Sagen¹, G. Seigel, Jeffrey H. Kordower² and D. M. Gash. Dept. of Neurobiol. and Anat., U. of Rochester Sch. of Med. Rochester, NY 14642; U. of Illinois, Chicago, IL 60612²; Rush Presbyterian/St. Lukes Hospital, Chicago, IL 60612²**

Recently, adrenal medullary grafts have been used in animal and clinical studies of treatment for parkinsonism. Survival of such grafts has not been satisfactory. Reported concomitant functional recovery has been variable. The present study aimed to (a) ensure optimal survival of adrenal chromaffin cells in the striata of partially hemiparkinsonian rats, and (b) determine if the presence of viable chromaffin cells leads to a reduction in amphetamine-induced rotation of the recipient animals.

Adult male Fisher 344 rats were rendered partially hemiparkinsonian by intranigral injection of 4 µg of 6-hydroxydopamine. Four weeks later, they were selected for the study if they rotated ipsilaterally to the lesion in response to amphetamine (5 mg/kg), while not responding to a low dose of apomorphine (0.025 mg/kg). The selected animals were rank-ordered into three treatment groups. The experimental group received dissociated, purified bovine chromaffin cells. One control group received dissociated non-chromaffin cells from the same glands. All intrastriatal implants contained 100,000 cells in 4 µl of Hank's buffered salt solution. The third group were non-implanted hemiparkinsonian rats. All animals received daily injections of cyclosporine A (10 mg/kg). In the fourth week postimplantation, they were again challenged with amphetamine. At 28 days, they were sacrificed and the brains were processed for histological evaluation.

Viable grafts were found by immunohistochemistry to tyrosine hydroxylase, chromogranin A and bovine fibronectin in 14 out of 16 animals. Nevertheless, there was no reduction in amphetamine-induced rotation in any of the groups during our observation period.

RESTORATION OF DOPAMINE OVERFLOW AND CLEARANCE FROM 6-OHDA LESIONED RAT STRIATUM REINNERVATED BY FETAL VENTRAL MESENCEPHALIC GRAFT. S.D. Wang*, J.C. Liu and Y. Wang. National Defense Medical Center, Taipei, Taiwan.

The purpose of this experiment is to investigate the electrochemical functions of the mesencephalic dopaminergic grafts in the rat striatum. Sprague Dawley rats were injected unilaterally with 6-hydroxydopamine (6OHDA) into the anterior forebrain bundle and screened by measuring apomorphine-induced rotation. These unilaterally lesioned rats were later transplanted with fetal ventral mesencephalon (VM). Only animals received VM transplantation showed significant decreases in rotation postgrafting. A high-speed chronoamperometric recording techniques using Nafion-coated carbon fiber electrode was used to evaluate dopamine turnover in the striatum of urethane-anesthetized rats. We found that 6OHDA lesions resulted in loss of KCl-induced DA overflow and clearance. These electrochemical functions were regenerated after VM graft. Furthermore, immunohistochemical studies using tyrosine hydroxylase confirmed graft survival and outgrowth from the graft into the lesioned striatum. In conclusion, these findings suggested that the behavioral improvements by grafts of fetal mesencephalic tissue correlated with the morphological nerve reinnervation and the restoration of DA turnover.

IN VIVO PROLIFERATION OF A7 GLIAL CELLS IS REDUCED AFTER GRAFTING INTO ADULT RAT STRIATUM. G.S. Okoye*, R.S. Nowakowski¹, W.J. Freed* and H.M. Geller. Neurosurgical Research Laboratory and Dept. of Pharmacology, #Dept. of Neuroscience and Cell Biology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854, and +NIMH Neurosciences Center at St. Elizabeths, Washington, DC 20032.

The SV40 large T-antigen immortalized A7 glial cell line is currently being evaluated for potential use as an *in vivo* implant to promote functional recovery in animal models of neurodegenerative diseases, especially Parkinson's disease. A major concern for the use of immortalized cells for somatic therapy for neurodegenerative diseases is their potential to give rise to intracerebral tumors. This study was designed to evaluate the degree of proliferation of A7 cells after grafting into adult rat striatum. Cultured A7 cells were dissociated, labeled with the fluorescent dye DiI and resuspended at 500 cells/µl. 5.5 µl of A7 suspension were injected into adult rat striatum. Twenty four hours prior to each time point (7 and 14 days, respectively), 4 animals received 6 equally spaced serial injections of 5-bromo-4-deoxyuridine (BrdU) at 50 µg/gm, i.p. Twelve hours following the last BrdU injection, animals were transcardially perfused and cryostat sectioned. The surviving A7 cells and the BrdU positive cell some of the sections were determined. The results demonstrated that while the total surviving A7 cells remain approximately constant, the relative percentage of proliferating (% BrdU positive) A7 cells, decreased from 36% at 7 days to 9.8% at 14 days after grafting. Thus, *in vivo* implantation may reduce the rate of proliferation of immortalized cells. Supported in parts by: NIMH Grant T32 MH 19547 and NIH PO1 NS 21469.

429.4

USE OF THE ANTI-APOPTOTIC GENE BCL-2 IN NEURAL TRANSPLANTATION. R. Anton*, D.J. Kane, J.S. Manaster, J.H. Kordower¹, S.B. Schueler¹, C.H. Markham, D.E. Bredesen. Dept. of Neurol., UCLA, L.A., CA 90024 & Univ. of Ill. Sch. Med. Dept. of Neuro. Sci., Rush Presbyterian Med. Cr.¹, Chicago, IL 60612.

Long-term survival of grafted neural cells is a major goal of neural transplantation, but typical survival rates of grafted fetal neurons are in the range of 1-10%. Whether the death of transplanted neural cells is apoptotic or necrotic is unknown. We recently reported that the expression of the proto-oncogene *bcl-2* inhibits both apoptotic and necrotic neural cell death (Zhong *et al.*, 1992, 1993; Kane *et al.*, submitted). Therefore, we questioned whether the expression of *bcl-2* in a subclone of conditionally immortalized nigral neural cells (Durand *et al.*, 1990) would enhance survival and efficacy of grafts of these cells. In a 6-OHDA induced rat model of Parkinson's disease, Hoechst 33258 prelabelled cells were stereotactically transplanted into the striatum ipsilateral to the lesioned nigrostriatal pathway. Six rats received *bcl-2* transfected cells, 5 received cells transfected with vector alone, and 6 were sham operated. Four weeks following transplantation, the rats with grafts containing *bcl-2* expressing cells showed a stable 30% decrease in apomorphine-induced rotational behavior. In contrast, no improvement occurred in the rats with transplanted cells containing vector alone or in rats with sham injections. Histological examination showed the presence of Hoechst 33258 labelled cells in the striatum of rats which received the cells expressing *bcl-2*. No tumor formation was observed in these rats. No immunofluorescence was detectable in the other two groups of rats at the transplantation site.

429.6

HOST COMPENSATORY RESPONSE TO NEURAL GRAFTING IN THE UNILATERAL 6-OHDA PARTIAL LESIONED RAT. K. Sakai*, S. Moran, and J.T. Hansen. Department of Neurobiology and Anatomy, University of Rochester School of Medicine and Dentistry, Rochester, NY 14642.

Evidence suggests that the host brain can respond to neural transplantation, even with poor graft survival, by mounting a sprouting response presumably from spared elements of an existing neuroanatomical pathway. To test the hypothesis that a host sprouting response is an important compensatory mechanism for restoring damaged or degenerated input to a brain region, we used a selective unilateral 6-OHDA lesioned rat model in which the dopamine (DA) neurons of the ventral tegmental area (VTA; A10) were spared but the DA neurons of the substantia nigra, pars compacta (A9) were lesioned. Tyrosine hydroxylase-like immunoreactivity (TH) and Lucifer yellow (LY) tract tracing were used to examine the host response following co-grafts of adrenal chromaffin cells and peripheral nerve into the partially denervated rat neostriatum. Two weeks following grafting, an increase in TH stained fibers was observed adjacent to the ventromedial aspect of the implant site. LY retrograde tracing confirmed that these fibers originated, in part, from spared A10 and medial A9 DA neurons. This apparent increase in TH staining in striatal fibers occurred regardless of grafted chromaffin cell survival. At least two mechanisms may account for this striatal neural plasticity: (1) an absolute increase of striatal TH axons and terminals in response to grafting, and/or (2) an upregulation of DA synthesis in spared fibers. Studies currently are underway to examine these two mechanisms and to determine the role that neurotrophic factors and cytokines play in this host response. This host response may have significant implications for ameliorating deficits in patients with neurodegenerative disorders. (Supported by NS 25778)

A7 GLIAL CELLS MIGRATE AFTER GRAFTING INTO ADULT RAT STRIATUM. H.M. Geller, G.S. Okoye, M. Marone, W.J. Freed¹, X.R. Zhou, Paul Manowitz². Neurosurgical Research Laboratory, and Department of Pharmacology and *Department of Psychiatry and Neurology, UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ 08854 and #NIMH Neurosciences Center at St. Elizabeths, Washington, DC 20032.

The A7 cell line represents an alternative cell source for transplantation to promote functional recovery in animal models of neurodegenerative diseases, especially Parkinson's disease. This study was designed to evaluate the ability of A7-AP cells grafted into the adult rat striatum to migrate away from the implant site. We have transfected A7 cells with the gene for human placenta alkaline phosphatase to permit cellular localization after implantation into the rat brain; these cells are called A7-AP. Cultured A7-AP cells were dissociated and resuspended at 500 cells/µl. 5.5 µl of A7-AP suspension were injected into the left striatum. After 1, 2, 4, 8 and 12 week(s) respectively, animals (4 at each time point) were transcardially perfused and cryostat sectioned; every fifth section was histochemically stained for alkaline phosphatase. The results indicated that, while most A7-AP cells remained within 40 µm of the graft site, other cells were found as far as 70 µm. Many of the migrated A7-AP cells were located in areas apparently free of damage caused by implantation procedure. Several of the A7-AP cells appear to integrate with rat host brain cells, suggesting possible cell-cell communication between the A7-AP and the host brain cells. Immunofluorescence histochemical staining revealed enhanced expression of certain extracellular matrix molecules (fibronectin and laminin) at the graft site. Supported in part by: NIMH Grant T32 MH 19547 and NIH PO1 NS 21469.

FGF-2-MEDIATED NEUROPROTECTION IN THE MPTP-MODEL OF PARKINSON'S DISEASE: FOCUS ON ASTROGLIAL CELLS. D. Otto and K. Unsicker*, Dept. Anatomy and Cell Biology, University of Heidelberg, D-69120 Heidelberg, Germany.

We have previously shown that FGF-2 causes marked protection of DAergic parameters in the MPTP-mouse model of Parkinson's disease (Otto and Unsicker, J. Neurosci. 10:1912 1990). Since FGF-2 has been shown to (i) exert its neurotrophic effect on cultured DAergic neurons via astroglial cells (Engelke and Bohn, J. Neurosci. 11:3070, 1991) and (ii) cause reactive gliosis after injection into the CNS, we have investigated the astroglial cell response to MPTP and FGF-2. MPTP (3x30mg/kg) induced a transient 20% increase in striatal GFAP at day 4. Morphologically, MPTP induced a marked increase in number, size, arborization, and stainability of GFAP-immunoreactive cells at d4, which persisted in milder forms until d18. Administration of 4µg of either FGF or cytochrome C, soaked into a piece of gelfoam, to the right striatum in MPTP- or saline-injected mice increased striatal GFAP-levels bilaterally about 2- to 2.5-fold at 14d, when FGF-2 showed marked protection of DAergic parameters. GFAP-positive cells were increased in numbers under any experimental situation. Subtle differences in their morphologies were only noted at greater distances away from the site of application. The lack of a marked FGF-mediated gliotic reaction may limit concerns regarding potential applicability of FGF-2 to the Parkinsonian striatum.

429.10

CRITICAL ROLE FOR ASTROCYTES IN EXPERIMENTAL PARKINSONISM. T.J. Langan*, R.J. Plunkett, N. Razack and K. Kelly. Depts. of Neurology and Neurosurgery, School of Med. and Biomed. Sci., S.U.N.Y., Buffalo, N.Y., 14222.

In rat parkinsonism (nigral injection of 6-OH-dopamine), surgical cavitation causes transient improvement, and gelfoam implants into the cavities contain factor(s) that promote dopaminergic re-sprouting. We investigated the composition of these implants. Trypsinization (0.25 g%) for 10 min. was followed by DNase (0.1 mg/ml), trituration, and plating in calf serum/DMEM (10%) on polylysine-coated coverslips (10⁴ cells/cm²). In 3-4 d, the cultures consisted of 100% vimentin positive (VIM+) cells and only rare GFAP(+) cells. By 7 d, they were dividing actively, and were 93 ± 14 % (GFAP+), 100% (VIM+) and 67 ± 6 % (RAN 2+). At confluence (14 d), <10% were (VIM+) or (GFAP+); most still were (RAN 2+). The 7 d cultures were synchronized by 48 h of serum depletion followed by readdition: After a 12 h lag, S phase nuclei increased from 16 ± 4 to 74 ± 12 %. The gliosis caused by cavitation included dramatic, parallel increases in GFAP and VIM staining which also peaked at 7 d.

Therefore, type 1 astroglia are the apparent source of trophic factors that improve parkinsonism in this animal model, and their *in vitro* differentiation resembles the gliosis occurring *in situ*. In addition, a system is provided for examining cell cycle regulation in these cells that potentially are critical in recovery.

SYMPOSIA

WEDNESDAY PM

430

SYMPOSIUM: THALAMOCORTICAL MECHANISMS UNDERLYING GENERALIZED ABSENCE SEIZURES. D.A. Prince (Chairperson), Stanford Univ., J. Huguenard, Stanford Univ., D. McCormick, Yale Univ., J. Noebels, Baylor College of Medicine, D.A. Hosford, Duke Univ.

Clinical and basic neurophysiologic data emphasize the importance of abnormal oscillatory burst activity within the thalamocortical circuit during generalized absence seizures. Recent advances in our understanding of the intrinsic membrane conductances of thalamic neurons that promote rhythmic activities, the modulation of these currents by the neurotransmitters of ascending brainstem, descending cortical and intrinsic thalamic circuits have allowed a more complete understanding of the normal regulation of thalamocortical excitability. This symposium will provide an overview of the neuroanatomic and neurophysiologic basis for normal and abnormal thalamocortical oscillations, their modulation by transmitter systems and pharmacologic agents, and the use of animal models of absence seizures to test the validity of predictions regarding basic mechanisms of dysfunction within the thalamocortical circuit. Furthermore examples will be provided of how pharmacological predictions based on this neurophysiological/neuroanatomical framework can be tested in animal models.

SYMPOSIUM. CORTICAL OSCILLATORY RESPONSES AND FEATURE BINDING.

J. Anthony Movshon, Howard Hughes Medical Institute and New York University (Chairperson); Christoph von der Malsburg, Ruhr-Universität Bochum and University of Southern California; Wolf Singer, Max-Planck-Institut für Hirnforschung; Ralph D. Freeman, University of California, Berkeley; David C. Van Essen, Washington University.

In recent years, several groups have reported that neurons in visual cortex can respond to visual stimuli with an oscillatory discharge whose frequency is in the range of 20-70 Hz; these oscillations can be synchronized over substantial distances in cortex. These findings have been linked to theoretical work on the possible role of synchronized oscillatory responses in the "binding" of perceptually-unified features across a scene. This area has not been without controversy, and a number of investigators have found that oscillatory responses in cortical neurons are rather rare, and have raised doubts about the relationship of these responses to perceptual phenomena.

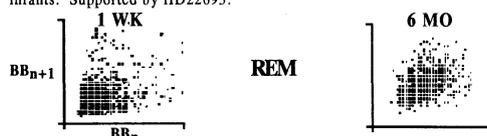

Freeman, Movshon, and Singer will present experimental evidence on the nature, prevalence, origins and perceptual significance of neuronal oscillations and synchrony; von der Malsburg and Van Essen will consider the implications and possible utility of these signals in the context of theories of visual binding and attention.

BIOLOGICAL RHYTHMS AND SLEEP III

434.1

DEVELOPMENT OF BREATH-TO-BREATH PATTERNING DURING SLEEP AND WAKING STATES IN NORMAL INFANTS. S.L. Raetz*, V.L. Schechtman & R.M. Harper. Brain Research Institute and Dept of Anatomy & Cell Biology, UCLA, Los Angeles, CA 90024-1763.

The number of breathing pauses, amount of periodic breathing, and mean respiratory rate vary substantially with maturation and behavioral state. We used nonlinear procedures to describe moment-to-moment respiratory patterning in developing infants. Twelve-hour, nighttime polygraphic recordings, consisting of electroencephalogram, electrooculogram, electromyogram, electrocardiogram, nasal air flow, abdominal movement and expired CO₂ were obtained from 6 normal infants on 2 occasions, at 1 wk and at 6 mo of life. Each 1-min epoch was defined as waking (AW), quiet sleep (QS), rapid-eye-movement (REM) sleep, or indeterminate state by two trained observers. For every recording, approximately 60 min of data from each behavioral state throughout the night were selected for analyses, and breath-to-breath (B-B) intervals were calculated from the expired CO₂ signal. Each B-B interval within a particular behavioral state was plotted as a function of the previous interval, resulting in a BB_{n+1} vs. BB_n (Poincaré) scatter plot. The most marked breath-to-breath changes occurred during both REM sleep and AW. At 1 wk of age, as respiratory rates increased, the extent of change from 1 breath to the next decreased, resulting in a V-shaped scatter. At 6 mo of age, interbreath variability was no longer a function of rate (no V-shape in scatter plot). Overall variation was comparable across the 2 ages; however, interbreath intervals increased with age. These data confirm our finding from a data set with a different population of younger infants that during AW, the V-shape is not apparent in older infants. These findings suggest that mechanisms underlying respiratory variability during REM sleep and AW are less effective at faster rates in young infants. Supported by HD22695.

THE TEMPORAL DISTRIBUTION OF SLOW-WAVE EEG ACTIVITY ACROSS THE NIGHT IN NORMAL INFANTS. V.L. Schechtman*, R.K. Harper and R.M. Harper. UCLA Brain Research Institute and the Dept. of Anatomy and Cell Biology, Los Angeles, CA 90024.

Adults show a decline in slow-wave (delta) EEG activity across the night. This decline is thought to reflect a sleep-dependent reduction in the need for slow wave sleep following a period of sleep deprivation. In the present study, we examine the ontogeny of this pattern of delta activity in normal infants from 1 week to 6 months of age.

Twelve-hour overnight recordings of EEG, eye movements, digastric EMG, EKG, and respiration were obtained from 25 normal infants at 1 week, and 1, 2, 3, 4, and 6 months of age. EEG was band-pass filtered leaving only activity ranging from 0.5 to 2.5 Hz, and the filtered EEG traces were full-wave rectified and integrated over 1-minute periods. The night was divided into four 3-hour segments, beginning at sleep onset, and the mean integrated 0.5-2.5 Hz EEG activity during all minutes of quiet sleep was determined for each segment of the night.

At 1 week and 1 month of age, infants showed no significant decay in delta activity across the night. In infants 2 to 4 mo of age, integrated delta declined significantly from the first to the second period of the night, and in 6-mo-old infants, integrated delta amplitude declined over three segments of the night. Thus, delta activity declines with sleep time in infants as young as 2 months of age. The duration of this decline increases (from 6 hours to 9 hours) as infants establish longer consolidated waking periods.

THE DYNAMICS OF PHASE RELATION BETWEEN DIFFERENT FREQUENCY BANDS DURING SLEEP. J. Rösche*, K. Mann. Department of Psychiatry, University of Mainz, Germany

The conventional scoring procedure (Rechtschaffen & Kales) enables a quantitative assessment of the sleep profile. The value of this method is limited in order to determine dynamical attributes of the sleep EEG.

Therefore we extended computerized EEG analysis by applying a special method of spectral analysis. In this approach the sleep process was characterized as a dynamic and continuous cycle. Different EEG rhythmicities in the delta (0.5-3.5 Hz), theta (3.5-7.5 Hz), alpha (7.5-15 Hz), beta (15-35 Hz) and gamma range (35-45 Hz) has been taken into account. Following digital filtering of sleep EEG data in these frequency bands the RMS values of successively digitized ($f_s=100\text{Hz}$, bipolar registration C_2/P_2 , 12 bit ADC) EEG epochs, each consisting of 2048 data points, have been performed. After artifact rejection, data reduction and smoothing the RMS values versus time represent the temporal course of EEG activity in certain frequency bands during the night. For assessment of relationship between these different EEG rhythms the cross correlation coefficient has been calculated.

Our results, based on the evaluation of 11 healthy male subjects (21-31 years, mean 24.8 years), revealed a highest RMS value in the delta range. In the fast frequency bands the RMS values decreased continuously. Considering the relationship between different frequency bands a reciprocal oscillation of the slower rhythmicities and the faster frequency components were observed ($r(\text{delta}, \text{beta}) = -0.57$).

Taken together it can be expected that this approach seems to be a suitable procedure to give deeper insight into the dynamics and the microstructure of the sleep process.

EVENING VS. MIDDAY BRIGHT LIGHT-INDUCED rCBF CHANGES IN HUMAN SUBJECTS USING PET: DEVELOPMENT OF A PROBE OF CIRCADIAN TIMING SYSTEM FUNCTION. D.J. Diehl, M.A. Mintum* and D.J. Kupfer. Dept. of Psychiatry and Radiology, University of Pittsburgh, Pittsburgh, PA 15213.

The circadian timing system (CTS) is most vulnerable to bright light-induced phase shifts during early or late night, while it is relatively nonresponsive to bright light during midday. Bright light initiates its CTS effects via the retinohypothalamic tract which projects directly to the suprachiasmatic nucleus (SCN). The objective of our study was to use the positron emission tomography (PET) activation method to map the regional cerebral blood flow (rCBF) changes induced by an evening, but not by a midday, bright light stimulus. Such evening-specific rCBF changes are likely to be mediated by the SCN via its efferent systems, reflecting a functional response of the CTS.

We conducted evening (9pm) and midday (12N) ^{15}O -water rCBF PET scanning sessions with five normal human subjects. Each scanning session consisted of six rCBF scans at three different light intensities (50, 2500, and 7000 lux). Significant changes in rCBF between the 7000 lux stimulus-state and the 50 lux control-state were identified using the statistical parametric mapping method developed by Friston et al ($p < .001$). The evening 7000-50 lux comparison demonstrated bright light-induced rCBF increases in the visual cortex and right orbitofrontal cortex, and rCBF decreases in the pineal gland, medial temporal lobe bilaterally, left superior and middle temporal gyri, and right putamen. In contrast, the midday 7000-50 lux comparison revealed only a rCBF increase in the left putamen.

Our results demonstrate an extensive circadian variation in rCBF response to bright light in normal human subjects. The evening-specific rCBF decrease in the pineal gland is almost certainly mediated by the SCN via the well described SCN-pineal gland multisynaptic pathway. The other evening-specific rCBF changes may also be mediated by the SCN via as yet uncharacterized efferent pathways. Thus, our PET activation paradigm may have utility as an in vivo probe of CTS function in normal and pathological conditions.

INFLUENCE OF THE SITE OF IMPLANTATION ON THE RESTORATION OF CIRCADIAN RHYTHMICITY BY DISSOCIATED CELL GRAFTS OF THE SUPRACHIASMATIC NUCLEUS.

M.N. Lehman*, K.A. Zimmer and W.N. Strother. Dept. Anat. & Cell Biol., Univ. Cincinnati Coll. Med., Cincinnati, OH 45267-0521.

Dissociated cell suspensions of the suprachiasmatic nucleus (SCN) implanted into the medial hypothalamus can restore free-running locomotor rhythms to SCN-lesioned hamsters (Silver et al., *Brain Res.* 1990). In order to examine the potential range of host targets for the recovery of circadian function after grafting, we implanted freshly dissociated fetal (E13) hamster anterior hypothalamic cells (100,000 cells/ $2 \mu\text{l}$ injection) bilaterally into either the medial hypothalamus ($n=4$), medial preoptic area ($n=3$), midbrain periaqueductal gray ($n=4$), or dorsal cortex ($n=2$) of arrhythmic SCN-lesioned adults. In order to unambiguously attribute restored rhythms to the presence of the grafted SCN, donor tissue was taken from heterozygous *tau* mutant hamsters whose free-running period is 22 hrs, while hosts were wild type animals with free-running periods of 24 hrs. Injections into the hypothalamus restored free-running locomotor rhythms in two of four recipients; recovery was correlated with the presence of SCN peptidergic cells and fibers in the middle and caudal hypothalamus and/or midline thalamus. In contrast, none of the other placements restored rhythmicity despite the presence in some instances of robust SCN peptidergic cells and fibers at the sites of implantation. Hosts with restored rhythms exhibited free-running periods (21.2, 20.9 hrs) shorter than that observed after whole tissue grafts from *tau* heterozygote donors (Ralph et al., *Science*, 247:975). The results suggest that proximity of donor SCN cells to a subset of normal efferent targets of the SCN, specifically those in the medial hypothalamus and/or midline thalamus, may be required for restoration of rhythmicity. COHERENT SPONTANEOUS 40-HZ OSCILLATIONS AND A LACK OF RESET BY SENSORY STIMULI DURING DREAM-STATES IN HUMANS. U. Ribary*, R.L.linás, M.Joliot, R.Jagow, and J.Volkman. Center for Neuromagnetism, Dept. of Physiology and Biophysics, New York University Medical Center, New York, N.Y., 10016, USA.

A 37-channel MEG system (BTi) was used, in order to determine the spatio-temporal dynamic properties of 40-Hz oscillatory activities in the human brain during different sleep stages.

Earlier MEG data recorded on humans, indicated synchronized spontaneous 40-Hz oscillations and a reset of activity by auditory stimuli. This reset was observed during averaging procedures and resulted in a relative increase in power of 40-Hz activity during auditory stimulation. In addition, by filtering the data in different frequency bands, we demonstrated a spatio-temporally organized pattern of activity at around 40-Hz. Recent magnetic recordings, obtained from five healthy adults, demonstrated large spontaneous 40-Hz coherent magnetic activity in the awake and in rapid-eye-movement (REM) sleep states but very reduced such activity during delta sleep. This 40-Hz magnetic oscillation had not been shown to be reset by sensory stimuli during REM or delta sleep, as observed in the awake state. The spontaneous 40-Hz activity in REM sleep was characterized, as that in the awake state, by a fronto-occipital phase shift over the head having a duration of approximately 12-13 msec. Because spontaneous 40-Hz oscillations were seen in wakefulness and in dreaming we propose it as a correlate of cognition, probably resultant from coherent 40-Hz resonance between thalamocortical specific and nonspecific loops. As such, consciousness may arise by the coactivation of at least these two systems, which would temporarily conjoin cerebral cortical sites specifically activated at or around 40-Hz frequency. In this manner the specific system would provide the content, and the nonspecific system the temporal binding of such content into a single cognitive experience evoked either by external stimuli or, intrinsically, during dreaming.

ACUTE PLASMA MELATONIN SUPPRESSION IN COLOR-BLIND MALES. F.L. Ruberg, J.R. Gaddy, J.P. Hanifin, M.D. Rollag and G.C. Brainard*. Dept. of Neurology, Jefferson Medical College, Philadelphia, PA 19107; Dept. of Anatomy, USUHS, Bethesda, MD 20815.

Most demonstrations of acute plasma melatonin suppression in humans have involved test subjects with normal trichromatic photopic visual systems. Previously, we observed a male with a red-green color vision deficiency who failed to manifest melatonin suppression after exposure to 10,000 lux of white light from 2:00AM to 3:00AM. This study sought to determine conclusively whether a retinal deficiency in the color perceptual system could effect light mediated melatonin suppression. Male recruits were screened for color vision defects using Ishihara's test for color-blindness (24 plate edition), the Farnsworth-Munsell D-15, and the Farnsworth-Munsell 100-Hue test. Color deficient volunteers ($n=5$) were identified, diagnosed (2 protanopes, 1 deuteranomaly, 1 deuteranomaly, and 1 unspecified dichromat) and differentiated from normally sighted controls ($n=5$). Subjects were exposed to 90 minutes of 200 lux polychromatic light via a uniform illumination system from 2:00AM to 3:30AM. Pupils were dilated to assure full retinal exposure. Blood samples taken by venipuncture before and after light exposure were assayed for melatonin content by radioimmunoassay. Preliminary analyses of the data clearly reveal melatonin suppression after light exposure in both experimental groups ($p < .05$), with no significant difference in the degree of suppression between the normal and color-blind volunteers. Specifically, melatonin suppression was noted in the 4 dichromat subjects—that is, in the 2 protanopes (lacking the "red" cone pigment), the deuteranope (lacking the "green" cone pigment), and the unspecified dichromat (with an unknown deficiency). These findings suggest that a normal trichromatic photopic system is not necessary for light mediated neuroendocrine regulation. (Supported by NASA#NAGW1196, LRI#91SP1, and USUHS#R07049).

TRANSPLANTATION OF GOLDEN HAMSTER SUPRACHIASMATIC NUCLEI INTO SCN LESIONED HOSTS: EFFECT OF DONOR AGE ON RHYTHM RESTORATION. CM Kaufman* and M Menaker. Dept. Biology, University of Virginia, Charlottesville, VA 22903.

Suprachiasmatic nucleus (SCN) transplants using hamsters previously have been conducted with embryonic day (E) 13 to E 15 donor SCN tissue (gestation is 16 days in duration). Rat tissue has been used over a 7 day age span ending at postnatal day (P) 1 (gestation lasting 22 days). We investigated the age range of donor hamster SCN tissue that yielded functional transplants in SCN-lesioned hosts (i.e., restored activity rhythms with the circadian period of the donor—in this case a 20 hr period). SCN from hamsters as young as E 11 and as old as P 12 became functional grafts. The success of transplanted tissue from older animals was surprising (e.g., P 10 SCN were successful in 3/5 transplants). Neither the time between transplantation and the appearance of a rhythm nor the robustness of the restored rhythm correlated with donor age. The presence or absence of at least one patch of VIP immunoreactive cells was a good indicator of transplantation success or failure, respectively, in 48/50 cases. The findings reported here suggest that the SCN may be capable of developing in a host animal and that the SCN exhibits what may be an extended duration of neural plasticity. The span of 18 days during which hamster SCN tissue can be harvested for transplantation should enable the expansion of applications for which SCN transplantation can be used.

SCN TRANSPLANTS ARE SUFFICIENT TO SUSTAIN CIRCADIAN

LOCOMOTOR RHYTHMS IN HAMSTERS. J. LeSauter¹, M.N. Lehman² and R. Silver¹. ¹Barnard College of Columbia U., New York, NY 10027, ²U. of Cincinnati, Coll. Med., Cincinnati, OH 45267.

Though the mammalian suprachiasmatic nuclei (SCN) are known to be the dominant pacemaker controlling circadian rhythmicity, several lines of evidence leave open the possibility that important oscillators lie outside of the SCN. Ablation of the SCN results in a loss of most but not all circadian rhythms. Furthermore, while circadian rhythms are restored by intraventricular perinatal SCN transplants, these grafts invariably contain extra-SCN hypothalamic tissue. Together, this evidence suggests the possibility that oscillators outside the SCN may be necessary or sufficient to sustain circadian rhythmicity.

In order to better define the hypothalamic region that controls circadian rhythms, we made 500µm vibratome sections of postnatal day 1 (PN1) brains (shown to be effective in restoring circadian rhythms in SCN-lesioned adult hamsters; Romero et al., *Dev. Brain Res.*, 1993), and made hypothalamic punches (500µm diameter) of the SCN, sub-PVN, and SON for implantation. Host animals were partially SCN-lesioned *tau* mutant hamsters with free-running circadian periods of 20 or 22 hours while donor animals were wild type with free-running periods of about 24 hours. Circadian locomotor rhythms with the period of the donor tissue were restored in 6/9 animals bearing SCN punches, indicating that the SCN are sufficient to sustain circadian rhythmicity. Neither sub-PVN nor SON punches restored rhythmicity. Staining for NP and VIP suggests that the latter grafts were not as robust as the SCN grafts, possibly because PVN and SON mature earlier, and harvesting at PN1 was too late for optimal survival of grafts from these regions. OPTICAL RECORDINGS WITH INFRARED DARK-FIELD MICROSCOPY IN HYPOTHALAMIC SLICES CONTAINING THE SUPRACHIASMATIC NUCLEI. L. Trachsel¹, H.U. Dodt and W. Zieglgänsberger. *Max Planck Institute of Psychiatry, Clinical Institute, 8000 Munich 40, FRG.*

A novel type of infrared video microscopy visualizes cellular activity of the CNS (Dodt et al.). We applied this technique in the suprachiasmatic nuclei (SCN), the putative circadian pacemaker in mammals. During the light phase, frontal hypothalamic slices (300-400 µm) were prepared from adult male Wistar rats kept in a 12 h light-dark cycle. Spatial resolution of the video microscopy was 1.4 µm/pixel, potentially allowing analyses on a cellular level. Time resolution of image processing was 2.5 frames/s, intensity resolution 8 bits/pixel. Electrical stimulation (2 s, 50 Hz, 8-13 V) in the optic chiasm resulted in a transient response of the ventral SCN cell population, as seen in the surge of image intensity. Image intensity peaked 3-5 s (control level = 100%) after stimulation onset. Slices were pharmacologically treated during 1 h at subjective midday. Post-stimulation 30-s recordings were done before, during and after treatment. The elicited response was reversibly depressed to 27.3% (n=12) by D-AP5 (50 µM) + CNQX (10 µM), by CNQX alone to 68.3% (n=19), by octanol (2 mM) to 20.3% (n=9), by Mg²⁺ (10 mM) + Ca²⁺ (0.5 mM) to 58.3% (n=18), and elevated to 151% (n=6) by mecamylamine (10 µM). The response was elevated by bicuculline (50 µM) at subjective midday to 204% (n=15) and at midnight to 156% (n=18). The results suggest that afferent input from the optic tract leads to cellular excitation in the ventral SCN, possibly mediated by excitatory amino acids. Its daytime GABA_A-ergic inhibition may be different from its nighttime level. The nicotinic acetylcholine system, as well as electrotonic transmission through gap junctions may be involved in the transient response in the SCN to tetanic stimulation of the optic chiasm. (Supported by the BMFT.)

ESTABLISHMENT AND CHARACTERIZATION OF AN IMMORTAL CELL LINE DERIVED FROM THE RAT SCN. D.J. Earnest¹, S. DiGiorgio¹, M.J. Gallagher¹, R.L. Gannon², and M.A. Rea². ¹Dept. of Neurobiology/Anatomy, Univ. of Rochester Sch. of Med., Rochester, NY 14642 & ²Circadian Neurobiol. Res. Group, Armstrong Lab., Brooks AFB, TX 78235.

Development of an experimental strategy enabling the study of individual cells or types of cells derived from the suprachiasmatic nucleus (SCN) could yield insight into the cellular organization of the circadian pacemaker mechanism in mammals. Consequently, the present study was conducted to determine whether mitotic, immortal cell lines could be established from progenitors of the SCN and whether the immortalized lines retained phenotypic properties of the parent cells.

Primary cultures derived from mitotic progenitors of the rat SCN were established and targeted for transfer of an immortalizing oncogene using a retroviral vector. After drug selection, expansion of infected colonies yielded continuous cell lines with dynamic growth rates in which cells doubled in number once every 24 hours. The growth potential of these cell lines has remained stable even after extensive passage for over 2 years. Although growth-stimulated, immortalized cells did not express properties associated with tumorigenicity. Morphological observations indicate that the cell lines exhibit both glial and neuronal phenotypes. The neuronal component of the cell lines was confirmed by the consistent expression of immunostaining in individual colonies for neuron-specific antigens and peptides that distinguish SCN neurons. Further increases in the expression of immortalized cells with peptidergic phenotypes of SCN-like neurons were observed in response to differentiating agents. Experiments are currently in progress to determine whether immortalized cells also retain the unique functional capacity of the SCN *in situ* to endogenously generate circadian rhythms. Supported by AFOSR 90-0182 (D.E.) and 2312W6 (M.R.).

ANOXIC LTP : SELECTIVE PERSISTENT POTENTIATION OF THE NMDA RECEPTOR-MEDIATED CURRENTS INDUCED BY ANOXIA IN CA1 HIPPOCAMPAL NEURONS. C. Hammond, V. Crépel and Y. Ben Ari[†]. INSERM U29, 123 Bd Port Royal 75014 Paris, France.

Global ischemia induces a delayed degeneration of CA1 pyramidal neurons. Since ischemia induces a transient (10-20 min) increase of glutamate release yet glutamate receptors antagonists have protective effects when administered several hours after the insult, we have tested the hypothesis that brief anoxic episodes induce long term changes in glutamate transmission. In presence of normal Mg²⁺ concentration, a brief (1.30-2min) anoxic-aglycemic (AA) episode (n=13) persistently (1h) potentiated the APV-sensitive (NMDA) component (+43±6%, p<0.0001) but not the CNQX-sensitive (non-NMDA) component (-1.2±3.5%) of the glutamatergic EPSP recorded at Vm=-65 mV. Furthermore, at Vm=-100mV, in contrast to the control glutamatergic EPSP which was exclusively mediated by NMDA receptors, after anoxia more than 50% (58±18%, n=9) was APV-sensitive and thus mediated by NMDA receptors. This novel form of LTP to which we refer as anoxic LTP was also observed in experiments in which the NMDA receptor-mediated EPSP was pharmacologically isolated (+50±7%, p<0.0001, n=12). Induction of anoxic LTP is NMDA-dependent since it is sensitive to NMDA receptor antagonists given before during and shortly after the AA episode (15-21 min, n=8). It is also voltage dependent since it was prevented by clamping the cell membrane to resting potential during anoxia (n=6). The maintenance of anoxic LTP has a postsynaptic locus since the current evoked by focal pressure application of NMDA (300 µM) was also persistently potentiated (+59 ± 7%, p<0.001, n=6). Therefore after anoxic episodes, large NMDA receptor-mediated currents will be generated even at -100 mV in presence of physiological Mg²⁺ concentration. Crépel V et al., *J. Physiol* (1993), 459, 201P and J. Neurophysiol (1993) in press

REDUCTION IN FOCAL ISCHEMIC INFARCTIONS BY CEREBELLAR STIMULATION IS NOT ATTRIBUTABLE TO CHANGES IN CEREBRAL BLOOD FLOW (rCBF) OR METABOLISM (rCGU). S. Yamamoto^{*}, E.V. Golanov, D.V. Wilson and D.J. Reis. Div. of Neurobiol., Dept. of Neurol. & Neurosci., Cornell Univ. Med. College, New York, NY 10021.

Stimulation of the fastigial nucleus (FN) decreases, by over 50%, the infarction produced by occlusion of the middle cerebral artery (MCAO) in rat (Reis et al. *JCBFM* 11:810, 1991). The zone of salvage corresponds to the hypermetabolic hypoperfused ischemic penumbra. We investigated if neuroprotection was attributable to increasing rCBF and/or decreasing rCGU in the penumbra. Rats were anesthetized, the MCA exposed (controls) and occluded (MCAO). The FN was stimulated for 1h without (FNstim) or with MCAO (FN+MCAO). rCBF and rCGU were measured autoradiographically simultaneously with ¹⁴C-IAP or ¹⁴C-2-DG in the ischemic core and penumbra and contralateral cortex. In summary (Table): (a) MCAO reduced rCBF and increased rCGU in penumbra ipsilaterally; (b) FNstim alone globally increased only rCBF; (c) FNstim + MCAO did not differ from MCAO alone. We conclude: the neuroprotection elicited from FN does not result from increased rCBF or decreased rCGU. The mechanism of salvage may relate to molecular events conceivably affecting channel or receptor functions across brain.

CGS-19755 PREFERENTIALLY DISTRIBUTES TO AREAS OF ISCHEMIC BRAIN IN A RABBIT MODEL OF FOCAL CEREBRAL ISCHEMIA. E. Yoon*, G.H. Sun, D.M. Kunis, A. Kotake, G.K. Steinberg. Department of Neurosurgery, Stanford University School of Medicine, Stanford, CA. 94305.

We have measured the regional brain uptake of CGS-19755 in a rabbit model of focal cerebral ischemia. Eighteen New Zealand white rabbits underwent occlusion of the left middle cerebral, internal carotid and anterior cerebral arteries for 2 hours. Ten minutes after occlusion, animals were given a bolus of 40 mg/kg (100 µCi) CGS-19755, and were sacrificed at 1 hour (n=5), 2 hours (n=8) or 4 hours (n=5) after occlusion. Animals sacrificed at 4 hours were unoccluded at the end of 2 hours of ischemia to allow reperfusion. Somatosensory evoked potentials were used to confirm ischemia. Technetium 99-m pyrophosphate was also administered i.v. to account for the brain vasculature contribution of ³H-CGS-19755. While blood levels of CGS-19755 declined between 1 and 4 hours (1 hour, 40.29 µg/ml; 2 hours, 18.07 µg/ml; 4 hours, 8.31 µg/ml), brain and CSF levels remained stable (brain 1 hour, 1.13 µg/g; 2 hours, 1.13 µg/g; 4 hours, 1.60 µg/g; CSF 1 hour, 2.65 µg/ml; 2 hours, 3.79 µg/ml; 4 hours, 2.83 µg/ml). Unexpectedly, in the 1 hour group, the concentration of CGS-19755 in left frontal cortex (2.46 µg/g) was significantly higher than in areas of non-ischemic brain, such as the left cerebellum (.80 µg/g, p < .01). Concentrations of CGS-19755 in ischemic left frontal cortex for the 2 hour group (3.16 µg/g), and 4 hour group (3.99 µg/g), also were higher than in non-ischemic regions (p < .01, p < .10, respectively). Local ischemic damage to the blood-brain barrier may explain the preferential uptake of CGS-19755, a drug whose distribution is primarily limited by its low permeability coefficient.

ENERGY METABOLISM AND EXCITOTOXICITY: GLUCOSE PREVENTS GLUTAMATE OVERFLOW IN ISCHEMIC BRAIN. R.A. Swanson*, J. Chen, and S.H. Graham. Dept. of Neurology, Univ. of California and V.A.M.C., San Francisco, CA 94121.

Acute excitotoxic neuronal injury probably cannot occur in brain as long as energy-dependent reuptake mechanisms are functional. Astrocytes in culture can maintain glutamate uptake during hypoxia if glucose is available. To determine whether this capacity is shared by astrocytes *in situ*, glutamate levels were measured in ischemic brain during exogenous glucose delivery.

Microdialysis probes were placed bilaterally in caudate nuclei of rats and perfused with artificial CSF containing either 30mM or 0mM glucose. Ischemia was induced by cardiac arrest. Dialysate collected from probes without glucose showed a prompt rise in glutamate to 17 times baseline values, while dialysate collected from probes perfused with 30mM glucose showed only a 4-fold increase in glutamate at up to 60 minutes of ischemia.

These results show that glycolytic metabolism alone can fuel efficient uptake of glutamate in brain. The findings have implications for several disorders, particularly incomplete ischemia, in which impairment of energy metabolism has been linked to excitotoxic neuronal injury.

IMMUNE RESPONSES IN PHOTOCHEMICALLY INDUCED CORTICAL ISCHEMIA IN THE RAT. S. Jander, M. Kraemer, Q.W. Witte and G. Stoll (SPON: European Neuroscience Association). Dep. of Neurology, Heinrich Heine Univ., Duesseldorf, Germany.

The mechanisms leading to secondary cell damage after ischemia are not well understood. In this study, focal cerebral ischemia in rats was induced by intravenous application of Rose bengal and subsequent illumination of the motor cortex (photothrombosis). To examine the contribution of the immune system in this model we stained paraffin and cryosections at various stages after ischemia with the following antibodies: a rat pan-T-cell marker, antibody (ab) ED 1 for macrophages, and ab OX-6 and OX-18 for MHC Class II and I antigens, respectively. 4 hours after ischemia no cells were stained, on day 1 T-cells predominated, up to 3 days increasing numbers of T-cells and macrophages appeared which persisted for 14 days. At day 30, only a few T-cells were left in the lesion, macrophages concentrated at the bottom of the lesion. Concomitantly, increased MHC class II expression was found which was not restricted to the lesion in contrast to MHC class I antigens. Our data indicate that the immune system strongly responds to photochemically induced ischemia and point toward a pathogenetic role of infiltrating cells for secondary cell damage.

SHOULD GLUCOSE BE ADDED TO THE DIALYSATE FLUID WHEN PERFORMING INTRACEREBRAL MICRODIALYSIS?

E. Ronne-Engström ^{*1}, H. Carlson¹, J. Yansheng³, U. Ungerstedt², L. Hillered¹. 1. Dpt of Neurosurgery University Hospital Uppsala, Sweden. 2. Dpt of Pharmacology Karolinska Institute, Dpt of Neurosurgery Karolinska Hospital Stockholm Sweden.

Introduction: Intracerebral microdialysis is a method to measure, *in vivo*, substances in the extracellular fluid (ECF), during e.g. ischemia and seizures. It has been argued that the method may drain substances e.g. glucose, which could influence the results.

Methods: In this study microdialysis was performed with two probes, placed bilaterally in rat parietal cortex. The probes were perfused with artificial CSF with (CSF +G) or without (CSF -G) 3 mM glucose respectively. After obtaining basal levels hypoxia was induced. The extracellular concentrations of aspartate (ASP), glutamate (GLU), lactate (LACT) and pyruvate (PYR) were measured. The results obtained with CSF+G and CSF -G were compared before, 10 and 40 minutes after induction of hypoxia.

Results: Twenty animals were investigated. Mean pO₂ during the hypoxic period was 3.66, and during this period electroencephalography showed decreased amplitudes. There were no significant differences between basal levels or changes induced by hypoxia in dialysate concentrations of ASP, GLU, LACT or PYR in samples obtained with CSF -G or CSF+G.

Conclusion: The results suggest that microdialysis does not drain glucose from the surrounding tissue to an extent that influence short term measurements of energy related metabolites and excitatory amino acids.

INCREASED CYTOKINE RELEASE AND EXPRESSION IN BLOOD VESSELS OF RATS WITH RISK-FACTORS FOR STROKE. A.-L. Sirén, T. Liu, Y. Liu, M. Spatz, R. McCarron, M. Grojec, G. Feuerstein, and J.M. Hallenbeck. Dept. of Neurology, USUHS, Bethesda, MD 20814; Dept. of Pharmacology, SmithKline Beecham, King of Prussia, PA 19406; and Stroke Branch, NINDS, Bethesda, MD 20892.

We have proposed that risk-factors for stroke promote a perivascular accumulation of monocyte/macrophages and an intensified cytokine-mediated interaction between monocyte/macrophages and endothelial cells which prepares local segments of blood vessels for subsequent thrombosis or hemorrhage. Therefore, the cytokine release and mRNA expression were studied in isolated carotid arteries and aortas of rats with and without the stroke-risk factors hypertension or advanced age. Spontaneously hypertensive rats (SHR), normotensive Wistar-Kyoto (WKY) as well as 2-year-old (2Y) and 16-week-old (16W) normotensive Sprague-Dawley (SD) rats were used. Incubation with lipopolysaccharide (LPS, 30-300 ng/ml) increased in a concentration-dependent manner the release of tumor necrosis factor alpha (TNF-α) and mRNA for interleukin-1β (IL-1β) in carotid arteries of SHR. IL-1β mRNA was also increased in the aortas of SHR. In WKY rats a significant increase in TNF-α release was found only after the highest LPS dose. The LPS-stimulated TNF-α release in carotid arteries of aged (2Y) SD rats (762±243 units/mg tissue) was significantly greater as compared to young (16W) controls (387±173 units/mg, n=12, p<0.05). The results indicate that hypertension and aging are associated with an increased cytokine production in the vascular cells which could increase the tendency for the endothelium to convert from an anticoagulant to a procoagulant surface.

LEUKOCYTES AND LEUKOTRIENE B₄ (LTB₄) RECEPTORS IN STROKE. F.C. Barone, L.M. Hillegeass, M.N. Tzimas, D.B. Schmidt, R.E. White, W.J. Price, G.Z. Feuerstein, R.K. Clark, D.E. Griswold and H.M. Sarau. Division of Pharmacology, SmithKline Beecham Pharmaceuticals, King of Prussia, PA 19406.

In previous studies, we validated the use of a myeloperoxidase activity assay (MPO) to quantitate increased polymorphonuclear leukocytes (PMN), and also identified increased LTB₄ receptor binding (LTB₄-RB) as another marker for inflammatory cell infiltration following MCAO. In the present study we determined the time-course for these effects following middle cerebral artery occlusion (MCAO) made permanently (PMCAO) or transiently (160 min; TMCAO) in spontaneously hypertensive rats. Ischemic and contralateral (control) cortical samples were removed from isotonic saline perfused animals and assayed for MPO (units/g wet weight) and ³H-LTB₄-RB (fmol/mg protein). Data were analyzed by ANOVA (*p<0.05 vs control cortex; N=4-7/timepoint). Results were as follows:

Time (Days)	0.08	0.25	0.5	1	5	15
PMCAO-MPO	.12±0.2	.17±0.2	.27±0.2*	.30±0.9*	4.7±1.4*	.12±0.3
PMCAO-LTB ₄ -RB	2.2±0.2	2.9±0.2	5.5±0.5*	4.6±1.0*	11.7±2.3*	11.5±1.4*
TMCAO-MPO	.12±0.3	.20±0.4*	.44±1.2*	.93±2.1*	3.2±1.1*	.11±0.7
TMCAO-LTB ₄ -RB	2.6±0.3	4.0±0.2*	7.3±0.8*	11.1±1.6*	10.7±1.1*	15.5±1.9*

No changes occurred due to sham surgery. These results correspond well to our immunohistochemical data that characterized leukocyte infiltration and active gliosis under these conditions and demonstrated that TMCAO produces a significantly larger early influx of PMN than PMCAO. LTB₄-RB correlates well with early MPO changes but remains elevated when MPO has returned to baseline and PMN are no longer present. This persistent increase in ischemic cortex RB appears to be on the LTB₄ receptors of activated macrophages and astrocytes that increase in response to tissue injury.

INTRAVENTRICULAR INSULIN & IGF-1 IN GLOBAL ISCHEMIA IN RATS. Chang Z, Zhu, Roland N, Auer* Department of Neuroscience, University of Calgary, Canada, T2N 4N1

A beneficial effect of insulin in reducing cerebral ischemic necrosis has been recently shown. A portion of the neuroprotective effect in some ischemia models may be due to a direct central mechanism of insulin action, possibly via a growth factor effect. To test this hypothesis of the neuroprotective mechanism of insulin action, we delivered either insulin, insulin-like growth factor (IGF-1), or phosphate-buffered saline (PBS) via continuous intraventricular infusion, and performed quantitative neuropathology one week after transient cerebral ischemia. In fed Wistar rats, cortical ($p < 0.05$) and striatal ($p = 0.01$) damage were significantly reduced by 23 IU/rat/day insulin ($n = 8$), and hippocampal necrosis was less severe at all coronal levels ($p < 0.05$). This intraventricular dose of insulin reduced the blood sugar significantly ($p < 0.01$), probably by leakage of insulin into the periphery. However, low dose insulin (7 IU/rat/day; $n = 10$), which did not reduce the blood sugar, also reduced selective necrosis in striatum ($p < 0.05$) and one level of the hippocampus ($p < 0.05$). IGF-1 (50 μ g/rat/day) also caused no alterations in blood glucose, but significantly ameliorated hippocampal damage in four of the six hippocampal levels in fed rats ($p < 0.05$; $n = 8$). We conclude that insulin has a dose-dependent direct neuroprotective effect on CNS tissue, and that this direct effect may be mediated partly by IGF receptors. The results also confirm the more powerful, previously described neuroprotective effect of insulin-induced hypoglycemia in transient ischemia.

EVALUATION OF PATHOLOGICAL STAGE AND TEMPORAL EVOLUTION OF ISCHEMIC BRAIN INJURY BY COMBINED MRI (DWI, T2WI AND T1WI) K. Matsumoto, E.H.Lo*, A.Pierce and Y.Pan. Center for Imaging and Pharmaceutical Research, Massachusetts General Hospital and Harvard Medical School, Charlestown, MA 02129.

MRI may provide the ability to noninvasively differentiate pathophysiological conditions related to the amount and biophysical state of water in brain tissue. We evaluated the temporal evolution of ischemic brain damage using diffusion weighted imaging (DWI), T2WI and T1WI from the acute (30-90 min) to chronic (6 day) stage following permanent middle cerebral artery occlusion (MCAO) in Sprague-Dawley rats (250-350g). Infarction area was confirmed by TTC and cresyl-violet staining. MCAO was induced under halothane anesthesia using Tamura's subtemporal approach. Immediately after surgery the rat was placed in a GE-2T-CSI with gradient coils. 30-90min after occlusion, signal intensity was increased in the occluded hemisphere on DWI but no apparent changes were seen on T2WI or T1WI. On the 2nd day after occlusion, increased signal intensity areas were seen on both DWI and T2WI. However, on the 6 day after occlusion, DWI intensity decreased dramatically in the occluded hemisphere and in some cases the lesion showed a well demarcated low signal area with a high intensity rim. High or mixed intensity areas were seen on T2WI and low signal areas appeared on T1WI. TTC and cresyl-violet staining showed infarction in the basal ganglia and cortex. The basal ganglia tended to demonstrate a cystic necrosis which corresponded to the circumscribed low signal lesion on DWI. DWI combined with T2WI may be valuable not only for detecting early ischemic changes but also for evaluation of the pathological stage or condition of infarction in the chronic phase that may be related to ischemic density.

MR IMAGING OF BLOOD OXYGENATION AND WATER DIFFUSION CHANGES IN HYPERACUTE BRAIN ISCHEMIA C Pierpaoli, A Richini, J Mattiello, R Miletich*, J Alger, G di Chiro *Neuroimaging Branch, NINDS, NIH, Bethesda MD 20892*

Fast echo planar magnetic resonance imaging (EPI-MRI) techniques, permit the investigation of evolving brain ischemia in-vivo with high temporal resolution. Pathophysiological events occurring during ischemia can be evaluated by measuring two parameters: the tissue water Apparent Diffusion Coefficient (ADC), which is sensitive to ischemic injury, and the Blood Oxygenation Level Dependent signal (BOLD), which depends upon tissue perfusion and oxygen consumption. We used an EPI sequence that monitors these parameters simultaneously to study a rat model of global ischemia. We investigated both incomplete ischemia (induced by inflating vascular occluders positioned around the innominate and left subclavian arteries) and complete ischemia (cardiac arrest following KCl i.v.). ADC and BOLD were calculated with a 43 s time resolution from EPI images acquired with a 2 tesla magnet.

Following cardiac arrest, BOLD decreases abruptly, reaching a plateau at 94% of the control value after only 90 s, consistent with rapid oxygen desaturation of the stagnant blood. The ADC decreases more slowly reaching a plateau at 60% of the control value in 8-10 minutes. During incomplete ischemia (12 minutes long) the ADC reduction is small (5-15%) and there is a complete return to normal values after reperfusion. The BOLD signal drop can be as large as in complete ischemia, although the change is delayed (4-6 minutes to reach the plateau), consistent with a less rapid oxygen desaturation due to residual perfusion. After reperfusion the BOLD signal overshoots above the preischemic values (postischemic hyperperfusion). EPI-MRI permits one to grade the degree of severity of the ischemic insult in vivo, with high temporal and spatial resolution.

MRI AND IMMUNOHISTOCHEMICAL STUDY OF ISCHEMIC EDEMA AND GLIAL REACTION IN RABBIT FOCAL CEREBRAL ISCHEMIA. Y. Pan*, E.H.Lo, K. Matsumoto and N.W. Kowall. Center for Imaging and Pharmaceutical Research, Massachusetts General Hospital and Harvard Medical School, Charlestown, MA 02129.

Although MRI is a sensitive means of detecting ischemic cerebral injury, the correlation between in vivo scans and the underlying pathophysiology is not well understood. A rabbit model of focal ischemia was used to compare in vivo MRI with immunohistochemical techniques for demonstration of neuronal damage, BBB disruption and astrocytic reaction. Four hrs transorbital occlusion of the left internal carotid, middle cerebral and anterior cerebral arteries were performed in 6 halothane anesthetized rabbits. After 6 hrs reperfusion, T2W, T1W, Gd-enhanced and dynamic MRI were performed in a 1.5 T magnet. T2W scans showed increased signal intensity in the cerebral cortex and basal ganglia of the ischemic hemisphere. T1W images showed decreased intensity in corresponding areas. Dynamic MRI demonstrated delayed hypoperfusion in the ischemic hemisphere compared to the contralateral side. Gd-enhanced scans showed signal enhancement in the center of the lesions in 4 rabbits and peripheral lesion enhancement in the other 2. In all 6 rabbits, pyknotic, shrunken neurons and IgG leakage were noted in areas similar to the T2W lesions. Astrocyte hypertrophy and increased GFAP staining were observed in the ischemic hemisphere, especially near the edge of lesions that showed peripheral Gd-enhancement. The difference between Gd leakage and IgG leakage may be due to the biphasic opening of BBB during reperfusion. IgG leakage may be caused by transient reactive hyperemia after unocclusion, whereas Gd leakage may be due to BBB damage during infarction. Support: Sterling-Winthrop Pharmaceuticals.

CYTOSKELETON TRANSPORT AND MEMBRANE TARGETING II

436.1

THE N-TERMINAL DOMAIN OF GAD 65 IS SUFFICIENT TO TARGET A SOLUBLE PROTEIN TO THE PERINUCLEAR REGION OF TRANSFECTED CELLS

Michele Solimena*, Ronald Dirks, Adrian Hayday and Pietro De Camilli. Howard Hughes Med Inst, Dept of Cell Biology, Yale Univ School of Medicine and Dept of Biology, Yale Univ, New Haven, USA.

Glutamic acid decarboxylase (GAD), the enzyme responsible for the synthesis of GABA in neurons and pancreatic β -cells, is represented by two isoforms of 67 kD (GAD 67) and 65 kD (GAD 65), respectively. GAD 65 is a dominant autoantigen in Stiff-Man syndrome and insulin-dependent diabetes mellitus. GAD 65 and GAD 67 are 65 % similar to each other and differ primarily at their N-terminal region. In neurons and β -cells a pool of GAD is concentrated at the cytoplasmic surface of synaptic vesicles and synaptic-like microvesicles, respectively, as well as in a perinuclear area corresponding to the Golgi complex. The mechanism responsible for the targeting of GAD to these organelles is not known, but is thought to involve palmitoylation of cysteine residues. The targeting of the two GAD isoforms was analyzed by immunofluorescence in CHO cells transfected with rat GAD 65 or GAD 67. GAD 67 was homogeneously diffuse in the cytoplasm. Conversely, both GAD 65 and a chimeric GAD 65-GAD 67 protein in which a. a. 1-88 of GAD 67 were replaced by a. a. 1-83 of GAD 65 were concentrated at the area of the Golgi complex. Addition of the N-terminal fragment of GAD 65 (a.a. 1-83) to the N-terminal of β -galactosidase (which otherwise would have a diffuse distribution), also resulted in a perinuclear distribution of β -galactosidase, demonstrating that the signal(s) required for the targeting of GAD 65 to membranes resides within the first 1-83 amino acids. Individual point mutations of each of the six cysteines contained within this region of GAD 65 are insufficient to determine a redistribution of GAD 65 similar to that observed for GAD 67. Further studies of the N-terminal domain of GAD 65 will establish the role of palmitoylation and of primary sequence motifs in the targeting of GAD 65.

HERPES SIMPLEX VIRUS (TYPE 1) INFECTIONS OF HUMAN RETINAL PIGMENT EPITHELIAL CELLS IN VITRO. K. S. Topp*, N. D. Saks, K. Bisla and J. H. LaVail. Dept. of Anatomy and Neuroscience Program, UCSF, San Francisco, CA 94143.

We have cultured human retinal pigment epithelial cells (RPE) derived from perinatal donors on permeable filters to study transport of Herpes simplex virus (HSV) in an intact polarized epithelial cell *in vitro*. After 2 months, the cells are tightly coupled by junctional complexes, as determined by electron microscopy, immunofluorescent staining of tight junctions and measurements of transepithelial resistance > 350 ohms cm^2 . Indirect immunofluorescence and confocal microscopy were used to visualize microtubule orientation. In subconfluent RPE cells, the microtubules were dispersed and often arranged parallel to the filter surface. In contrast, the microtubules in confluent, polarized RPE cells were arranged in bundles, oriented perpendicular to the filter surface. Furthermore, the microtubules were polarized with plus ends directed toward the basal surface of the cells. We infected RPE cells at the apical surface with HSV and assayed the uptake and transport of virus from the apical surface to the nucleus by quantitative immunoblot and immunocytochemical staining for the HSV immediate early gene product, ICP4. ICP4 antigen first appeared in RPE cell nuclei at 2 hrs after infection. Treatment of the cells with 33 μ m nocodazole, a microtubule-destabilizing drug, delayed the appearance of nuclear ICP4 staining by 1 hr. These data indicate that human RPE cells are infectable with HSV at the apical surface and that the centripetal transport is dependent on intact microtubules. The data are consistent with the hypothesis that the transport of HSV from the apical surface is mediated by a plus-end directed motor molecule, e.g. kinesin.

436.3

MICROTUBULE POLARITY IN THE PERIPHERAL PROCESSES OF TRIGEMINAL GANGLION CELLS: RELEVANCE FOR THE RETROGRADE TRANSPORT OF HERPES SIMPLEX VIRUS. J.H. LaVail*, K.S. Topp and L.B. Meade. Dept. of Anatomy and Neuroscience Program, UCSF, San Francisco, CA 94143.

The directional movement of many organelles in neurons is dependent on polarized microtubules and direction-specific motor molecules. Microtubules also mediate the retrograde transport of Herpes simplex virus (HSV) in sensory neurons. We have investigated the polarity of microtubules in the peripheral axons of trigeminal ganglion neurons. The long ciliary nerves of rabbits were prepared for a standard "hook assay" of microtubule polarity. The axons contained microtubules with the fast growing, plus ends located distal to the cell body and the slow growing, minus ends directed centrally. To determine the role of microtubules in the retrograde transport of HSV in these axons, we injected the retrobulbar space of mice with the microtubule-inhibiting drugs, colchicine, vinblastine or nocodazole, or with the microfilament-inhibitor, cytochalasin D, and 1 day later inoculated the cornea with HSV. We found that colchicine, vinblastine or nocodazole reduced by 52% to 87% the amount of virus recovered from the ganglion 3 days postinoculation, compared to vehicle-treated animals. In contrast, cytochalasin D or β -lumlcolchicine did not significantly reduce the amount of HSV recovered from the ganglion. We conclude that the retrograde axonal transport of HSV from axon endings in the cornea to the trigeminal ganglion cell bodies requires intact microtubules and occurs in a plus to minus direction on the microtubules. Our data are consistent with the hypothesis that the retrograde axonal transport of HSV is mediated by a minus end-directed motor molecule, e.g., cytoplasmic dynein.

GENETIC INTERACTIONS BETWEEN OSM-3, UNC-104, AND UNC-116, THREE LOCI ENCODING DIFFERENT MEMBERS OF THE KINESIN SUPER FAMILY IN CAENORHABDITIS ELEGANS. Shahid S. Siddiqui*, Lab. of Molecular Biol. Toyohashi Univ. of Technology, Tempaku, Toyohashi, 441, JAPAN.

We report here a genetic analysis of interactions in mutants of three genes that encode kinesin like proteins in the nematode *C. elegans*. Previous work has shown that *unc-104* encodes a large member of kinesin family (6.0 kb transcript), mediates axonal transport of synaptic vesicles and locomotory behavior (Otsuka et al., 1991; Hall and Hedgecock, 1991). Recently we have cloned the *osm-3* gene, which encodes another kinesin like protein (3.0 kb mRNA), and that is 44.5% homologous to the *unc-104* kinesin (M. A. Shakir et al. unpublished). Mutants in *osm-3* fail to avoid high concentrations of salts and sugars, and fail to take up fluorescein dyes in chemosensory neurons due to a short cilium structure (Culotti & Russell, 1978; Perkins et al., 1986). Finally, *unc-116* encodes another member of the kinesin superfamily (3.0 kb mRNA), mediates locomotion, and affects axonal outgrowth and guidance (Patel et al. 1991, J. Mancillas; S. Siddiqui, unpublished). We have constructed double mutants between different alleles of *osm-3* gene, and various alleles of *unc-104* gene, to study the epistatic relations between these loci. Similarly, we plan to construct various doubles with the *unc-116* alleles to learn how these three kinesins interact genetically in the structure and function of the *C. elegans* nervous system.

436.4

PROTEIN-RNA INTERACTIONS AT THE SYNAPSE. M.E. Chicurel*, C. DeFranco, D.M. Terrian, and H. Potter. Program in Neuroscience, Dept. Neurobiology, Harvard Medical School, Boston, MA 02115; @Dept. Anatomy and Cell Biology, East Carolina School of Medicine, Greenville, NC 27858-4354.

Using a preparation of synaptosomes from the MF-CA3 region of the hippocampus, we have identified a series of RNA molecules that are specifically localized to the synapse. Some appear to be localized in the dendritic spines, and some in the astrocytic processes. Other mRNAs are excluded from the synaptosome preparation. Our studies indicate that at least two of the synaptosomal RNAs, GAP-43 and RC3, form complexes with protein in synaptosomal extracts. We have delineated two protein binding sites on both the GAP-43 mRNA and RC3 mRNA. These binding sites lie within the 3' untranslated regions of the mRNAs. It appears that at least some synaptosomal proteins that bind to GAP-43 mRNA also bind to RC3 mRNA. In addition, a preparation of microtubule-associated proteins, like some synaptosomal proteins, interact with the 3' UTRs of GAP-43 and RC3 mRNAs. Specifically, we have identified one of the proteins that interact with both GAP-43 and RC3 mRNAs as the microtubule-associated protein, MAP1. Possible functions of these cytoskeletal interactions include transport and anchoring of RNAs to the region of the synapse and regulation of local translation.

436.6

SUBCELLULAR TARGETING OF TWO DEVELOPMENTALLY REGULATED ISOFORMS AND MUTATED VARIANTS OF THE MEMBRANE ASSOCIATED PROTEIN SNAP-25. L.C. Bark*, P.P. Mehia & M.C. Wilson. Dept. of Neuropharmacology, The Scripps Research Institute, La Jolla, CA 92037.

The nerve terminal protein SNAP-25 has been recently implicated as one of several neuron-specific receptors of a 20S protein complex that may help target vesicle fusion at the presynaptic plasma membrane (Söllner et al., 1993, *Nature* 362, 318-324). SNAP-25 is a 206 amino acid polypeptide that contains two domains which may play important roles for biological function and targeting. The amino terminus can form an amphipathic helix and at least one out of four clustered cysteine residues, present in a central domain in the protein, is substrate for posttranslational palmitoylation. There exist two alternatively spliced isoforms of SNAP-25, which show distinct and regulated expression during development (Bark & Wilson, *Neurosci. Abs.* 38.19, 1992). The differences are only 9 amino acids between the two forms but results in altered organization and sequence context of the cysteine quartet, suggesting that the substrate for palmitoylation is changed.

To evaluate the potential function of the alternative fatty acylation domains of SNAP-25, the two isoforms and mutated variants with the different cysteine residues changed have been expressed in CHO fibroblasts. Our studies have shown that the cysteine residues are crucial for localizing the protein to the periphery, apparently to the plasma membrane in CHO cells, suggesting palmitoylation as a requirement for targeting the protein to membrane compartments. To determine the importance of the 9 amino acid differences in targeting and localizing the alternative isoforms in neuron-like cells, tagged cDNA constructs were transfected into NGF differentiated PC12 cells. In induced PC12 cells, both isoforms of SNAP-25 are translocated into developing neurites, although with different efficiency and subcellular targeting preferences. These data show that the two forms exhibit distinct subcellular targeting and biochemical properties that might correlate with different membrane fusion events. Supported by Swedish NSRC B-PD9714-303 (I.C.B.) and NSF IBN9121121 and PHS MH 48989 (M.C.W.).

SEROTONIN: ANATOMY, REGULATION, AND CLINICAL STUDIES

SEROTONERGIC NERVE TERMINALS IN RAT CEREBRAL CORTEX AND HIPPOCAMPUS: NEUROVASCULAR RELATIONSHIPS. Z. Cohen* and E. Hamel. Montreal Neurological Institute, McGill University, Montréal, QC, Canada, H3A 2B4.

Physiological evidence suggest that serotonin (5-HT) is a potent intracerebral vasoconstrictor which can regulate cerebral blood flow (CBF). We studied the relationships between 5-HT nerve terminals and microvessels (MVs) in the rat cerebral cortex and hippocampus (Hi) by electron microscopic immunocytochemistry. Vibratome-cut, transverse sections of the fronto-parietal cortex and Hi were immunolabelled for tryptophan-5-hydroxylase (TPH), the synthesizing enzyme for 5-HT. All perivascular (located within a 3 μ m perimeter from vessel walls) TPH-immunostained terminals were systematically photographed and analysed in single thin sections. In the cortex, 2.8% of all perivascular terminals (n=250) appeared to be directly apposed to the basal lamina, 11.6% were separated from it by an astrocytic leaflet with an additional 12% located further away up to 0.25 μ m from the MVs. In the Hi, none of 108 perivascular TPH terminals was in direct contact with the MVs, 9.3% exhibited an intervening glial process and another 3.7% were within 0.25 μ m from MVs. Perivascular terminals in the Hi were more distant (1.31 \pm 0.08 μ m) from MVs than those in the cortex (0.98 \pm 0.05 μ m) but were of similar size (0.23 \pm 0.02 μ m², Hi, and 0.22 \pm 0.01 μ m², cortex). In both areas, perivascular TPH terminals never exhibited membrane specializations at the neurovascular or neuroglial interface. Analysis of cortical (n=1321) and Hi (n=1024) TPH terminals in similarly vascularized regions showed that 11% and 4%, respectively, were within 3 μ m from MV walls. The results show that 5-HT terminals are more closely associated with cortical MVs than with those of the Hi, a finding consistent with the reported changes in cortical, but not Hi CBF following raphe stimulation. Overall, the data suggest an important role for perivascular astroglia in the neurogenic control of brain microcirculation by serotonin. Supported by grant MA-9967 of the Medical Research Council of Canada.

ASCENDING PROJECTIONS FROM THE DORSAL (DR) AND MEDIAN RAPHE (MR) NUCLEI: POSSIBLE FUNCTIONAL IMPLICATIONS WITH RESPECT TO ETHANOL TOLERANCE. A.J. Lanca, W.J. Irving, P.H. Wu, H. Kalant and J.A. Saint-Cyr*. Dept. of Pharmacology, Univ. of Toronto, and Addiction Research Foundation, Toronto, Ont., Canada.

Vasopressin (AVP) can maintain ethanol tolerance, but only in the presence of intact ascending projections from the brainstem, including both the serotonergic (5HTergic) and catecholaminergic components. As part of a study of the neuroanatomical circuitry underlying these interactions, a combined retrograde tracing and immunocytochemistry (ICC) approach was used to demonstrate the origin and the neurochemical nature of the ascending raphe projections to the medial septum (MS) and the hypothalamic paraventricular nucleus (PVN). Adult male Sprague-Dawley rats (n=27) were stereotaxically injected with true blue (TB) in the MS, and with diamidino yellow (DY) in the left PVN. After a 3-8 day survival time the animals were sacrificed, and serial brain sections were processed for ICC with antibodies against 5-HT, tyrosine-hydroxylase (TH), and substance P (SP). Tracer studies revealed that both the MS and PVN receive ascending projections originating from both the DR and MR nuclei. ICC showed that most of these projections originate in 5HT-immunoreactive (IR) perikarya located in the DR and MR alike. However, a substantial part of these projections also originated in TH-IR (dopaminergic) neurons of the DR and MR. No SP-IR cell bodies were seen in the DR and MR nuclei. SP-IR fibers were seen in the periaqueductal gray (including the DR), and in the lateral part of the interpeduncular nucleus. These results suggest that the MS, as well as the PVN, are possible loci of functional interactions between the 5HTergic and AVPergic systems in the regulation of tolerance to alcohol. Supported by NIAAA grant #1 R01-AA08212-03.

TOPOGRAPHY OF DUAL PROJECTIONS FROM THE DORSAL RAPHE NUCLEUS (DRN) TO THE PREFRONTAL CORTEX AND NUCLEUS ACCUMBENS. A. Biswas, E. J. Van Bockstaele, V.M. Pickel and J. Chan*, Dept. of Neurol. & Neurosci., Cornell Univ. Med. Coll., New York, N.Y. 10021.

Diverse physiological actions have been reported for 5-hydroxytryptamine (5-HT) in the medial prefrontal cortex (MPFC) and the nucleus accumbens (Acb) suggesting that the 5-HT innervation of these forebrain areas may be derived from different neurons. We examined this possibility by mapping the distribution of 5-HT-immunoreactive (ir) and non-5-HT-ir neurons containing retrograde labeling following injections of different tracers into both these target regions. The analysis was focused in the DRN of the midbrain since 5-HT pathways to the MPFC and Acb primarily originate from this area. Microinjections of Fluoro Gold (FG) and a protein gold complex (CT-Au) were placed into the MPFC and Acb, respectively, of the same rat. Sections through the DRN were further processed for immunofluorescent localization of 5-HT using a rhodamine marker. Neurons retrogradely labeled from the Acb were greater in number than those projecting to the MPFC. In addition, Acb-projecting neurons extended into the lateral wings of the DRN, whereas MPFC-projecting neurons were more restricted to the midline. Both groups of labeled neurons, however, were more numerous in the caudal aspect of the DRN and were scattered amongst 5-HT immunoreactive perikarya. Of 783 ± 69 CT-Au cells, 15% also contained the FG label and 11% contained FG and 5-HT immunoreactivity. Of 613 ± 48 FG cells, 24% also contained the CT-Au label and 21% were also immunoreactive to 5-HT. The results suggest a more prominent input to the Acb from neurons in the caudal aspect of the DRN and further indicate that while most 5-HT-ir and non-5-HT-ir neurons project differentially to both forebrain regions, a few cells also show collateralization to the MPFC and Acb. Such collateralization to divergent targets may integrate cognitive and motor activities in response to pharmacological manipulations of ascending 5-HT pathways. Supp. by NS09100-01, MH40342, 00078.

IN VIVO MODULATION OF SEROTONIN RELEASE IN FRONTAL NEOCORTEX. F. Petty*, G.L. Kramer, M. Moeller, S. Jordan, VA Med. Ctr., Univ. Tex. Southwestern Med. Schl., 4500 S. Lancaster Rd., Dallas, TX 75216.

The hypothetical neurochemical map we have proposed to account for the development and maintenance of learned helplessness (LH) in the rat involves a central role for serotonin (5-HT) in prefrontal cortex (PFC). LH develops with increased 5-HT release leading to depletion of intracellular 5-HT. Microinjection of 5-HT into PFC reverses LH, and reversal by chronic antidepressant drug treatment is accompanied by restoration of intracellular 5-HT stores. Other data suggest glutamate, GABA, and norepinephrine to also influence LH. Therefore in vivo pharmacological interactions influencing PFC 5-HT release were studied with brain microdialysis. Drugs were administered both IP and through the microdialysis probe (IC). 5-HT measured was K⁺ stimulated, Ca⁺⁺ dependent, and decreased by tetrodotoxin. The 5-HT releasing agent fenfluramine, the uptake blockers, fluoxetine and fluvoxamine and the tricyclic antidepressants imipramine and desipramine increased 5-HT release both IP and IC, and the 5-HT precursors did so IP. Bupropion increased IC but decreased IP, suggesting systemic administration to differentially influence impulse flow at the raphe level. Propranolol, with both beta-adrenergic and 5-HT_{1A} antagonism, increased IC. GABA agonists muscimol and baclofen had no effect IP, but gamma-vinyl GABA increased 5-HT IP, while bicuculline increased IC. Alpha-2 agent yohimbine decreased but clonidine had no effect IC. Haloperidol increased IC, but apomorphine had no effect. Atropine also had no effect. Overall these results suggest a complex regulation of PFC 5-HT release, with 5-HT agents having expected results, D2 and GABA-A blockade releasing 5-HT, and GABA releasing 5-HT though a mechanism independent of GABA-A or GABA-B modulation. Of the agents tested IC, only yohimbine decreased 5-HT release.

EFFECTS OF ACUTE AND CHRONIC FLUOXETINE ON 5-HT OVERFLOW IN THE FRONTAL CORTEX AND RAPHE REGIONS. K.M. Wozniak*, A. Part and M.L. Linnoila, LCS/NIAAA and BPB/NIMH, Bethesda, MD 20892.

This study investigates further the effects of the antidepressant fluoxetine (Flu) on serotonin (5-HT) in two different brain areas of the rat, monitored simultaneously. Male Sprague-Dawley rats (300-350g) were anesthetized with chloral hydrate and stereotactically implanted with microdialysis probes into both the terminal region of the frontal cortex and the cell body region of the raphe nuclei. In one set of experiments, Flu was applied focally (100µM) to either of these areas or given systemically (15 mg/kg i.p.) to naive rats. Another group of rats were treated chronically with Flu (15 mg/kg/day for 14 days) and were similarly challenged about 24 hours after their last injection. Basal levels of 5-HT in the cortex and raphe regions of naive rats were similar (averaging about 9 fmoles/5µl), and both areas displayed equal sensitivities to focal Flu, with peak local increases in 5-HT of about 400%. Rats receiving chronic Flu pretreatment had markedly elevated 5-HT as compared to naive rats, only in the raphe region. Although both the cortex and raphe regions still displayed similar sensitivities to focal Flu, these were significantly reduced compared to naive rats, with maximum increases in local 5-HT of less than 200%. Systemic challenge with Flu significantly increased 5-HT (by about 300%) only in the raphe region of naive rats. In contrast, there was no significant effect of systemic Flu in either region of chronically pretreated rats. The results indicate that systemic fluoxetine has differential effects in the two brain areas. The increase of 5-HT in the raphe presumably activates somato-dendritic autoreceptors, which tends to inhibit firing of raphe neurones projecting to the cortex. The apparent subsensitivity of both regions to focal or systemic Flu following a chronic pretreatment regimen, suggests the development of an adaptational reduction in 5-HT transporter sensitivity, amongst other possible mechanisms. We are further investigating the exact nature of this effect.

CELLULAR ELECTROPHYSIOLOGY OF 5-HT_{1A}-MEDIATED RESPONSES IN CA1 AND CA3 HIPPOCAMPAL SUBFIELDS WITH AGING. M.I. ARENTSEN and J.M. LAKOSKI*, Dept. HBC&G, University Texas Medical Branch, Galveston, TX 77555-0498.

We have investigated age-related alterations of serotonergic responses in the hippocampus. Changes in neuronal sensitivity to selective 5-HT_{1A} compounds were assessed in both CA1 and CA3 hippocampal subfields using extracellular microiontophoretic recording techniques in chloral hydrate anesthetized female Fischer 344 rats (Young, ovariectomized [OVX] 2-6 mo; Middle-aged, OVX, 14-16 mo; and Old, 22-26 mo).

Average spontaneous firing rates in anterior CA1 and CA3 pyramidal cells peaked at Middle age and then significantly declined in Old age; CA3 cell firing rates were consistently less than CA1 across all ages. The 5-HT_{1A} agonist 8-OH-DPAT more potently inhibited cell firing in CA1 than CA3. An age-related increase in pyramidal cell response to DPAT was observed in both CA1 (Young, 39.0±5.5; Middle, 44.6±4.9; Old 54.8% inhibition at 60nA) and CA3 (Young, 23.3±13.6; Middle, 48.7; Old, 68.2 at 60nA). The results identify significant age-related changes in hippocampal physiology and serotonin function.

BRAIN SEROTONERGIC NEURONS DEMONSTRATE NORMAL AXONAL TRANSPORT FOLLOWING SHORT- AND LONG-TERM TREATMENT WITH DEXFENFLURAMINE. M. Kalia* and N. P. O'Malley, Dept. of Neurosurgery, Jefferson Medical College, Thomas Jefferson University, Philadelphia PA 19107

There is now convincing evidence that serotonergic perikarya in the raphe nuclei are unaffected by fenfluramine (Appel *et al.* '89, and Molliver and Molliver, '90). There is however an observed biochemical and immunocytochemical (IC) reduction in 5-HT in regions of the brain where 5-HT terminal fields are located. This latter finding (which is consistent with the pharmacological effect of fenfluramine and is rapidly reversible - Kalia, '91) is frequently interpreted to represent neuropathology of the 5-HT terminals. We examined the viability of 5-HT terminals following treatment with the more potent fenfluramine isomer, dexfenfluramine (DFF) by testing the ability of 5-HT terminals to take up the retrograde label (cholera toxin horseradish peroxidase-CTHRP) and transport it to the cell bodies of origin. DFF was administered orally (8 & 16 mg/kg/day) for 4 or 21 days. The animals survived 18 hrs to 3 weeks post-treatment following which selected areas of the parietal cortex (Mamounas and Molliver, '88) were injected with 2 nl of CTHRP under chloral hydrate anesthesia. Following a 3 day survival period, the animals were perfused and the brain stem was processed using single and double labeling techniques for HRP-histochemistry and 5-HT-IC (Rye *et al.* '85). A positive control was done with parachloramphetamine (6 mg/day for 2 days). Analysis of variance revealed no significant treatment effect. In the PCA treated animals the number of retrogradely labeled neurons in the dorsal raphe was markedly reduced 61% (Mamounas and Molliver '88 had found a 66% decrease with their retrograde label) as compared with controls. These results confirm earlier observations that had established the functional viability of serotonergic nerve terminals. This viability is not influenced by dose, duration of treatment and post-treatment survival. (Supported by Interneuron Pharmaceuticals Incorporated & IRIS).

NEUROENDOCRINE PROFILE OF A POTENTIAL ANXIOLYTIC DRUG, S-20499: COMPARISONS WITH BUSPIRONE.

L.D. Van de Kar*, A.D. Levy, Q. Li, & M. Gustafsson, Dept. Pharmacol., Loyola Univ. Chicago, 2160 S. First Av, Maywood, IL 60153.

The endocrine profile of a 5-HT_{1A/D} agonist and potential anxiolytic drug S-20499 was compared with that of a structurally related compound, buspirone. In male Sprague-Dawley rats, S-20499 (0.01 - 20 mg/kg, i.p.) dose-dependently elevated plasma ACTH and corticosterone concentrations, with maximal effects observed at 30 and 60 minutes respectively. Buspirone (0.05 - 10 mg/kg, i.p.) produced similar effects. In contrast, S-20499 reduced, while buspirone increased plasma prolactin concentration, while only buspirone reduced plasma renin activity. The minimal doses of S-20499 and buspirone that increased plasma ACTH and corticosterone concentration were 5 mg/kg, while a dose of 1 mg/kg of S-20499 reduced plasma prolactin concentration. Injection of 1 mg/kg (i.p.) of S-20499 also reduced blood pressure and heart rate within 10 min post-injection, suggesting reduced sympathetic output. Pretreatment with the 5-HT_{1A/β} antagonist (-)-pindolol (0.3 mg/kg i.p.) significantly attenuated the stimulatory effects of S-20499 on plasma ACTH and corticosterone concentrations. (-)-Pindolol alone also reduced plasma prolactin concentration, and this effect was not altered after injection of doses of S-20499. Taken together, the data suggest that S-20499 stimulates the hypothalamic-pituitary adrenal axis by activating 5-HT_{1A} receptors. Additionally, it reduces prolactin secretion, presumably by activating dopamine D₂ receptors in the pituitary. Supported in part by NIMH MH45812 and by IRIS (France).

HIGH SEROTONIN ACTIVITY OF NON-EMIGRATING MALE RHESUS MONKEYS. I.R. Kaplan*, M.B. Botchin, J.J. Mann, S.B. Manuck, J. Berard. Dept. of Comp. Med., Bowman Gray Sch. of Med., Winston-Salem, NC, 27157-1040.

Male rhesus monkeys typically leave their groups of birth to become social transients when they are between three and five years of age. Some males, however, do not emigrate, and instead retain membership in their birth group. In the current study we evaluated concentrations of 5-hydroxyindoleacetic acid (5-HIAA), 3-methoxy-4-hydroxyphenylglycol (MHPG), and homovanillic acid (HVA) in the cerebrospinal fluid (CSF) of 60 randomly selected adolescent and adult male rhesus monkeys captured on Cayo Santiago during annual trapping. There was a significant inverse correlation between age and CSF concentrations of both 5-HIAA ($p < 0.01$) and HVA ($p < 0.001$); thus, all further analyses used age as a covariate. Comparisons among animals less than five years of age indicated no significant differences between emigrating and non-emigrating monkeys in CSF monoaminergic metabolites. However, among the 39 animals five years of age or greater, the six monkeys remaining in their birth groups had significantly higher concentrations of CSF 5-HIAA than did animals that had emigrated ($p < 0.03$). No significant differences were observed in HVA or MHPG. These data indicate that the tendency of some males to remain in their birth groups instead of becoming socially transient may reflect, in part, elevated central serotonergic activity and associated behavioral characteristics (including reduced impulsivity and increased sociability).

437.10

IN VIVO IMAGING OF THE 5-HYDROXYTRYPTAMINE REUPTAKE SITE IN PRIMATE BRAIN USING SPECT AND $[^{123}I]$ 5-iodo-6-NITROQUIPAZINE. W.J. Jagust*, J.L. Eberling, J.A. Roberts, K.M. Brennan, S.M. Hanrahan, H.F. VanBroeklin, A. Bigeon, C.A. Mathis Center for Functional Imaging, Lawrence Berkeley Laboratory, Berkeley, CA 94720.

Previous experiments in rats using in vitro binding and ex vivo autoradiography have demonstrated that 5-iodo-6-nitro-2-piperazinylquinoline (5-I-6-NQP) is a potent and selective ligand for studying brain 5-HT reuptake sites. We performed in vivo imaging in non-human primates using single photon emission computed tomography (SPECT) and $[^{123}I]$ 5-I-6-NQP. 8 experiments were performed in 4 adult male macaca mulatta using a SPECT tomograph with 6 mm in-plane resolution. Animals were injected with 4 - 8 mCi of tracer i.v., and images were acquired for either 0 - 6 h in one set of experiments or from 5 - 9 h in another set of experiments. Each type of experiment was performed in quadruplicate; for each set 2 experiments were performed with paroxetine pretreatment (2 mg/kg i.v.).

These studies showed rapid brain uptake of the tracer, with slow egress from the brainstem, a region rich in 5-HT reuptake sites. Loss of the tracer from regions with a lower density of these sites, such as cerebellum, was relatively more rapid. Pretreatment with paroxetine increased the washout of tracer from the brainstem to rates similar to that seen in cerebellum. Brainstem to cerebellar ratios of tracer accumulation were >2 by 8 hours after injection, and in paroxetine pretreated animals remained close to 1. These results indicate that the radiotracer has characteristics suitable for use as a SPECT imaging agent of serotonin reuptake sites.

POTASSIUM CHANNEL STRUCTURE, FUNCTION, AND EXPRESSION II

438.1

CLONING OF A NOVEL HUMAN BRAIN ION CHANNEL HIGHLY SIMILAR TO K_{ATP} CHANNEL IN RAT KIDNEY Gabriel G. Haddad¹*, Trushna Desai², and Santosh N. Krishnan¹
¹Department of Pediatrics (Section of Respiratory Medicine), and ²Department of Genetics, Yale University School of Medicine, New Haven, Connecticut 06510.

Previous work from this laboratory has demonstrated the important role of ATP-regulated potassium channels in anoxia-induced depolarization and neuronal survival during anoxia. A number of questions regarding the structure and regulation of this channel, however, remain to be answered. For example, it is not clear what the relationship is between glibenclamide binding site and the channel. In order to further understand the function of this protein, we decided to clone it from the brain.

Starting from the sequence of an ATP-regulated potassium channel cloned from rat kidney (Nature 362: 31), we used the PCR to clone the brain isoform. We isolated a PCR product from human cerebral cortex mRNA that is highly similar to the rat ATP-regulated potassium channel. This product has an M0, M1, and H5 (pore-forming region) domains as described for the rat kidney channel. With this PCR product, we will screen for cDNA clones from a human fetal brain cDNA library in λ ZAP and genomic clones from a human genomic library in λ EMBL3. Using fluorescent in situ hybridization (FISH), we will determine the chromosomal location of this gene. Genomic organization and functional expression studies are also in progress.

PRIMARY STRUCTURE AND FUNCTIONAL EXPRESSION OF A POSSIBLE G-PROTEIN COUPLED INWARD RECTIFIER E. Reuveny*, Y. Kubo, P.A. Slesinger, Y.N. Jan and L.Y. Jan. Howard Hughes Medical Institute, Univ. of Calif. Med. School, San Francisco, CA 94143.

Two novel inward rectifier potassium channels have been recently cloned, IRK1 (Kubo et al., Nature, 362:127, 1993) and ROMK1 (Ho et al., Nature, 362:31, 1993). Both of these channels differ from voltage-gated potassium channels in that they have two putative membrane spanning regions, rather than six, and may comprise a new superfamily of potassium channels. Based on sequence homology, we have searched for other members of this superfamily, such as a G-protein coupled inward rectifier from heart. We designed degenerative primers to the core region (M1-M2) of the channel and amplified a fragment by PCR. Using this fragment as a probe, we have isolated a cDNA from rat heart library that has ~40% homology with IRK1 and ROMK1. The cRNA expressed in *Xenopus* oocytes produces a channel that is inwardly rectifying and is active in patches which are excised into a solution containing 100 μ M GTP γ S, 2-4 mM MgATP and 90 mM K⁺. The channel has a single-channel conductance of ~35 pS (in symmetrical 90 mM K⁺) which is similar to the heart G-protein activated channel. We are currently investigating whether this channel is indeed a G-protein coupled inward rectifier.

438.2

mSlo, A COMPLEX MOUSE GENE ENCODING HIGH CONDUCTANCE CALCIUM-ACTIVATED K^+ CHANNELS. D. McCobb¹*, A. Wei¹, S. Tsunoda¹, A. Butler¹, N. Fowler¹, M. Schreiber¹, J. Krause¹, M. Saito², C. Solaro³, C. Lippale³, and L. Salkoff^{1,2}. ¹Dept. of Anatomy and Neurobiology, ²Dept. of Genetics, ³Dept. of Anaesthesiology, Washington University School of Medicine, Box 8108, 660 S. Euclid Avenue, St. Louis, MO 63110.

cDNAs from mSlo, a gene encoding mouse brain and skeletal muscle calcium-activated K^+ channels, were isolated, sequenced, and expressed in the *Xenopus* oocyte expression system. mSlo channels had properties of high conductance "maxi" or "BK" channel types; single channel conductance was 272 pS with symmetrical potassium concentrations, and whole cell and single channel currents were blocked by charybdotoxin, iberiotoxin, and TEA. cDNAs encoding many alternative forms of mSlo channels were isolated. The large number of variant channel forms may reflect the need for regulatory diversity, as well as a diversity of biophysical properties. mSlo channel peptides are conserved with their *Drosophila* homologue, slo, over a large region encompassing ten hydrophobic domains. Conservation of the S1 through S6 region suggests that mSlo belongs to a vast gene family that includes voltage-gated K^+ channels. The mSlo protein, however, is more complex than that of the voltage-gated K^+ channels, having areas of highest conservation with *Drosophila* slo outside of those conserved with the voltage-gated channels. Perhaps over the course of evolution, the calcium gating mechanism and/or regulatory domains have been appended to the basic structure of a voltage gated K^+ channel.

438.4

EXPRESSION AND CLONING OF AN ATRIAL G-PROTEIN-ACTIVATED POTASSIUM (KGA) CHANNEL IN *XENOPUS* OOCYTES. Nathan Dascal*, Nancy F. Lim, Wolfgang Schreibmayer†, Weizhen Wang, Norman Davidson, Henry A. Lester. Division of Biology, California Institute of Technology, Pasadena, CA 91125. (Permanent addresses: * School of Medicine, Tel Aviv University, Ramat Aviv 69978, Israel; † Institut für Medizinische Physik und Biophysik, Universität Graz, A-8010 Graz, Austria).

Injection of rat atrial RNA into *Xenopus* oocytes resulted in the expression of a G protein-activated K^+ (KGA) channel. Current through the channel could be activated by acetylcholine (ACh) or, if RNA encoding a neuronal 5HT1A receptor was co-injected with atrial RNA, by serotonin (5HT). A 5HT-evoked current (I_{5HT}) was observed in oocytes injected with ventricle RNA fractions (of 2.5-5.5 kb size) and 5HT1A receptor RNA. I_{5HT} displayed strong inward rectification, showing very little conductance above the K^+ equilibrium potential; was highly selective for K^+ over Na^+ ; and was blocked by 5-300 μ M Ba²⁺. I_{5HT} was suppressed by intracellular injection of the non-hydrolysable analog of GDP, GDP- β -S, but not by treatment with pertussis toxin (PTX), suggesting coupling of the receptor to the KGA channel via a PTX-insensitive G protein possibly endogenously present in the oocyte. Co-expression of the α subunit of a PTX-sensitive G-protein, G_{i2}, rendered I_{5HT} sensitive to PTX inhibition. Native oocytes displayed a constitutively active inward rectifying K^+ current with a lower sensitivity to Ba²⁺ block; expression of a similar current was also directed by atrial or ventricle RNA of 1.5-3 kb size. A directional cDNA library from atrial poly(A) RNA was constructed in pBluescript II (Stratagene), and *Xenopus* oocytes were injected with RNA transcribed *in vitro* from cDNA pools, together with 5HT1A receptor RNA. Further progress in cloning of the KGA channel will be reported at the meeting. Supported by: Israel-US BSF, GM-29836, MH-49176, NRSA, Austrian Research Foundation.

FUNCTIONAL EXPRESSION OF DELTA OPIOID RECEPTOR K56 IN XENOPUS OOCYTES. C. Chavkin¹, D. Henry^{1*}, N. Dascal², N. Lim², W. Schreimbauer², B.L. Kieffer³, C. Gaveriaux-Ruff³, N. Davidson² and H. Lester². Dept. of Pharmacol¹, Univ of Wash, Seattle WA, Div of Biol², Caltech, Pasadena, CA, and Ecole Supérieure de Biotechnologie, Strasbourg, FR³.

When cRNA prepared from the delta opioid receptor cloned from NG108-15 cells was injected into *Xenopus* oocytes, delta opioid specific binding sites were expressed. Peak expression of 11 pmoles receptor per mg of oocyte membrane protein was obtained at 4 days after injection of 18 ng cRNA. Binding site density was defined using the delta selective antagonist [³H]-naltrindole, and uninjected oocytes do not express specific binding sites. Co-injection of the delta receptor cRNA with cRNA derived from a rat atrial library conferred the ability of delta opioid agonists to activate an inwardly-rectifying potassium conductance similar to that controlled by delta receptors in neurons in several brain regions. The potassium current induced by the delta agonist DPDPE was dependent on the co-injection of atrial cRNA, was blocked by the antagonists naloxone (1 μM) or naltrindole (1 μM), and was also blocked by 100 μM Ba²⁺. DPDPE activated the inward rectifier with an EC₅₀ of 1.3 nM which closely agrees with its measured binding affinity of 1.6 nM. Although delta receptor coupling to potassium channels in brain is known to be sensitive to pertussis toxin, pertussis toxin treatment of the oocytes (1 μg/ml, 24 hrs), did not affect the response to DPDPE. These results demonstrate that the cloned delta receptor expressed by oocytes is functional and that the oocyte expression system will be useful in the analysis of opioid receptor effector coupling. Supported by DA04123, GM 29836, MH 49176, Israel-US BSF.

INACTIVATION BALL PEPTIDE FROM THE SHAKER K⁺ CHANNEL BLOCKS OPEN CYCLIC NUCLEOTIDE-GATED (CNG) CHANNELS BY BINDING TO THEIR PORE DOMAINS R.H. Kramer¹, E. Goulding² and S.A. Siegelbaum¹ Ctr. for Neuro. and Behav., Columbia U., NY, NY 10032, and Dept. of Pharm., Univ. of Miami, Miami, FL 33101.

CNG channels are crucial for olfactory and photosensory transduction. While these channels are ligand-gated (cAMP and/or cGMP) and voltage-insensitive, their primary amino acid sequences resemble that of voltage-gated K⁺ channels. Here we show that a 20 amino acid peptide derived from the NH₂-terminus of the Shaker K⁺ channel ("ball" peptide) blocks olfactory (OLF) and photoreceptor (RET) CNG channels with a K_i of 22 and 175 μM, respectively. Application of ball peptide followed by cGMP reveals a transient CNG current, indicating that channels must be open before they can be blocked. If cGMP is washed away from the blocked channels, the channels re-open after the block is relieved, indicating that the peptide retards channel closing. We conclude that cGMP binding opens an internal gate that allows the peptide to block, and bound peptide prevents the gate from closing. Wild-type and mutant peptides with different affinities for K⁺ channels have similar relative potencies for CNG channels, suggesting that CNG and K⁺ channels have conserved peptide binding sites. However, block of CNG channels is 4-fold more voltage-sensitive than block of K⁺ channels, suggesting that the peptide inserts deeper into CNG channels. Mutational studies suggest that the peptide directly contacts the pore-lining H5 region of CNG channels. When the H5 of the RET channel is replaced with that of the OLF channel, block of the chimeric channel shows the high affinity (K_i=21 μM) characteristic of the OLF channel. Supported by HHMI and NIH grant NS30685.

MUTATIONS OF A CONSERVED CYSTEINE RESIDUE IN S6 OF Kv2.1 (DRK1) ALTER INACTIVATION AND DEACTIVATION KINETICS. H.-j. Zhang, R.D. Zühke and R.H. Joho^{*}. Department of Cell Biology and Neuroscience, The University of Texas Southwestern Medical Center, Dallas, TX 75235-9111.

Two cysteines in the putative transmembrane segments S2 and S6 are absolutely conserved among cloned and functionally expressed voltage-gated K⁺ channels. We have investigated functional changes in Kv2.1 (DRK1) resulting from site-directed mutagenesis of these two conserved cysteine residues. In S2 (C232), twelve out of thirteen amino acid substitutions maintained channel function in *Xenopus* oocytes after microinjection with cRNA transcripts. In contrast, only seven out of fifteen cysteine replacements in S6 (C393) resulted in functional channels, and the expressed S6 mutants showed alterations of channel properties. Substitutions by glycine, asparagine, and valine shifted the midpoint of activation by 10-20 mV in the depolarizing direction, and C-type inactivation was two to tenfold faster. In addition, asparagine and valine substitutions displayed extremely fast deactivation kinetics. Serine and threonine substitutions, however, slowed C-type inactivation and deactivation. Also, the serine substitution increased the Rb⁺/K⁺ conductance ratio twofold.

Although our results suggest that the conserved cysteines in S2 and S6 are not essential for channel expression in *Xenopus* oocytes, the cysteine residue in S6 appears to play an important role in channel function; it may participate in controlling the transition from the open to the closed state of the channel. (Supported by NS28407 to R.H.J.)

DETECTION OF A HETEROMULTIMERIC POTASSIUM CHANNEL IN RAT BRAIN: POTENTIAL MOLECULAR BASIS OF A PRESYNAPTIC A-CURRENT. Morgan Sheng, T.J. Baldwin, Y. Joyce Liao, Yuh Nung Jan, and Lily Yeh Jan^{*}. Howard Hughes Medical Institute and Dept. of Physiology, UCSF, San Francisco, CA 94143.

The heterogeneity of K⁺ channels arises in part from the large number of genes encoding different K⁺ channel subunits. In addition, heterologous expression studies suggest that assembly of distinct subunits into heteromultimeric channels may contribute further to K⁺ channel diversity. A question has been whether heteromeric K⁺ channels actually form in vivo, and if so, whether specific combinations of subunits could account for major K⁺ currents identified in neurons. Based on biochemical copurification, and co-immunoprecipitation with subunit specific antibodies, we show that Kv1.4 and Kv1.2, two K⁺ channel subunits of the Shaker subfamily, coassemble in rat brain. The Kv1.4/Kv1.2 heteromultimer combines features of both parents, resulting in a dendrotoxin-sensitive A-type K⁺ conductance. Based on immunocytochemical localization in axons and nerve terminals, we hypothesize that Kv1.4/Kv1.2 heteromultimers may form the molecular basis of a pre-synaptic A-type K⁺ channel involved in the regulation of neurotransmitter release.

438.8

NONE OF THE CYSTEINES IN THE SHAKER POTASSIUM CHANNEL IS ESSENTIAL FOR CHANNEL ACTIVITY OR FOR ZINC MODULATION. L.M. Boland^{*}, M.E. Jurman, G.Yellen, Neuroscience Research Center and Dept. Neurobiology, Mass. Gen. Hosp. and Harvard Med. Sch, Charlestown, MA 02129

All voltage-gated ion channels described to date have several endogenous cysteine residues, many of which are highly conserved. In other proteins, cysteines are essential for functions such as protein folding, enzyme activity, and coordination of metal ions. We investigated whether the cysteine residues in potassium (K) channels are essential for activation and inactivation gating or for modulation of activation gating by external zinc and cadmium.

Shaker H4 K channels were expressed in *Xenopus* oocytes or a mammalian cell line (HEK293) and macroscopic currents were studied by two-electrode voltage-clamp or excised membrane patch recordings. We used oligonucleotide-directed mutagenesis to replace the seven endogenous cysteine residues at positions 96, 245, 286, 301, 308, 462, and 505 with serine, alanine, or valine. Substitutions were made in a mutant (ShR, Δ6-46) lacking N-type ("fast") inactivation. Replacement of all cysteines did not alter several properties of the macroscopic currents. There was little or no effect on the activation kinetics or the voltage-dependence of activation gating. Both wild-type channels and those lacking cysteines showed a positive shift and slowing of activation gating upon perfusion with external zinc or cadmium (0.1 - 1 mM). Replacement of the cysteine at position 462 alone or 462 plus other cysteines led to progressive rundown of the current with successive pulses, suggesting a faster rate of entry and slower rate of recovery from the C-type ("slow") inactivated state.

These results indicate that the seven cysteine residues in the Shaker K channel subunit are not essential for channel activity or the modulation of activation gating by external divalents. Not surprisingly, replacement of cysteine 462 alters C-type inactivation, consistent with previous reports for nearby residues in the S6 region.

438.10

POTASSIUM CHANNELS SHOW DIFFERENTIAL EXPRESSION AND SUBCELLULAR LOCALIZATION WITHIN THE MOUSE RETINA. D.J. Klump, E.-J. Song, M. Sheng, L.Y. Jan, and L.H. Pinto^{*}. Dept. of BMBCB and Dept. of Neurobiol. and Physiol., Northwestern University, Evanston, IL 60208, and †HHMI, University of California, San Francisco, CA 94143.

Many voltage-gated potassium channels have now been cloned, and their physiological properties have been characterized in vitro. For some channels, gross distribution within the CNS is also known. However, the pattern of expression is not yet understood for a variety of channels within a well-defined tissue. The mouse retina provides an attractive system for studying potassium channels because of its well-characterized anatomy and connectivity, and because retinal neurons exhibit a wide range of physiological properties.

We have studied the expression of K channels within intact mouse retinas and within enzymatically isolated retinal neurons using RNA PCR, in situ hybridization and immunohistochemistry. Using RNA PCR, we found the retina expresses members of the Kv1.x, Kv2.x, Kv3.x and Kv4.x families. In situ hybridization revealed Kv1.2 message in the inner nuclear layer (INL) and in the ganglion cell layer. We detected Kv1.3 message in rods, the entire INL and the ganglion cell layer. Employing immunohistochemistry, we found Kv1.3 expression in rods, punctate labelling in the outer plexiform layer, and light staining of the inner plexiform layer. Staining for Kv1.4 revealed light staining of cell bodies within the INL and heavy, banded labelling within the innerplexiform layer. Kv4.2 protein expression was limited to a population of cell bodies within the ganglion cell layer which project processes that form two bands in the middle of the inner plexiform layer. Thus, within the mouse retina, potassium channels are differentially expressed, a given neuron may express multiple channels, and channels show subcellular distribution.

438.11

ANALYSIS OF THE SPATIAL DISTRIBUTION AND CO-EXPRESSION OF SHAW RELATED K⁺ CHANNELS IN THE RAT CENTRAL NERVOUS SYSTEM. M. Weiser*, E. Vega-Saenz de Miera, C. Kentros, H. Moreno, H. Baker, and B. Rudy. Dept. of Physiology and Biophysics, NYU Medical Center, NY 10016 and Burke Med. Res. Institute, White Plains, NY 10605

Transcripts of the Shaw related or ShIII gene subfamily are thought to encode subunits of tetrameric voltage gated K⁺ channels. Recent *in vitro* experiments have suggested that K⁺ channels with a large functional diversity may arise from heteromultimeric aggregation of subfamily specific subunits. In order to identify the potential for heteromultimer formation *in vivo*, the current experiments examined the spatial distribution and co-expression of the mRNAs for native ShIII channels. Northern blot analysis demonstrated that three of the four K⁺ channel genes (KV3.1, KV3.2 and KV3.3) are expressed primarily in the CNS. KV3.4 transcripts also were present in the CNS but were more abundant in skeletal muscle. *In situ* hybridization in the CNS revealed expression of ShIII mRNAs in discrete and cell type specific neuronal populations. Although each ShIII gene exhibits a unique hybridization pattern many neuronal populations expressing KV3.1 also contained KV3.3 mRNA. In addition, KV3.4 transcripts were present, although at lower levels, in several neuronal populations which also expressed KV3.1 and/or KV3.3 providing evidence for possible heteromultimer formation *in vivo*. To further establish the functional role of heteromultimer formation in this subfamily, specific ShIII cRNAs were co-injected into *Xenopus* oocytes. Small amounts of KV3.4 cRNA, which expressed small, fast inactivation currents when injected alone, produced fast inactivating currents that were several fold larger when co-injected with an excess of KV3.1 or KV3.3 cRNA. Together these data suggest the significance of the apparently limited, low level expression of KV3.4. Based upon these findings we propose the existence of a ShIII channel system whose functional repertoire results from variable subunit composition. Supported by NS30989 to B.R. and AG09686 to H.B.

A RE-EXAMINATION OF THE STRUCTURE OF THE PORE OF VOLTAGE-SENSITIVE CATION CHANNELS EXCLUDES THE ANTI-PARALLEL β -SHEET MODEL. John A. Schetz* and P. A. V. Anderson, Dept. of Neuroscience and the Whitney Laboratory of the Univ. of Florida, Gainesville, Florida 32610.

Functional differences between different members of the voltage-sensitive cation channel superfamily reside primarily in their pore regions where ion selectivity and many specific aspects of their pharmacology are manifested. The structure of the pore of VSCCs has, therefore, been the subject of considerable attention. Current models envisage the loop between the fifth (S5) and sixth (S6) trans-membrane spanning helices of each domain being formed of two short β sheets (SS1 and SS2) linked by a β -hairpin turn, and that the resulting anti-parallel β -sheet inserts part way into the membrane to form the lining of the pore. However, close examination of the residues designated as forming the turn regions of many channels reveals certain inconsistencies in the assignment of turns at those locations. To better evaluate this, we determined the turn probability (P_{bead}) for all tetrapeptide sequences within the putative pore region of 26 different isoforms from the VSCC superfamily, a total of 80 domains. Tetrapeptide sequences with significant P_{bead} were identified in the S5-S6 loops of all 80 domains. However, these turns were shifted sufficiently far towards the C-terminus of each S5-S6 loop, as to lengthen the SS1 regions and altogether eliminate the SS2 β -sheet. This suggests that the pore of the channel cannot be formed by an anti-parallel β -sheet, as currently envisaged, and that other models of the pore region must be considered. CATECHOLAMINE RECEPTORS: DOPAMINE II

439.1

DOPAMINE RECEPTOR-MEDIATED INOSITOL PHOSPHATE ACCUMULATION IN CHICK RETINAL CELL CULTURES. P.M. Iuvone* and J. Gan Dept. of Pharmacology, Emory Univ. Sch. of Medicine, Atlanta, GA.

This study examined the effects of dopamine receptor activation on phospholipase C in retinal cells, using accumulation of inositol phosphates as an index of phospholipase C activity. Monolayer cultures of neurons and photoreceptors were prepared from embryonic day 8 chick retinas, and were cultured for 6 days. The cells were prelabeled with [³H]adenine or [³H]myo-inositol for measurement of cyclic AMP formation or inositol phosphate accumulation, respectively. Accumulation of inositol phosphates was measured in the presence of 10 mM lithium to inhibit their metabolism to inositol. Dopamine stimulated inositol phosphate accumulation by retinal cells with an EC₅₀ of approximately 10 μ M. Apomorphine and SKF82958, a D1 receptor agonist, also stimulated inositol phosphate accumulation. The maximal accumulation of inositol phosphates in response to SKF82958 was greater than that elicited by dopamine. Stimulation of inositol phosphate accumulation by dopamine and SKF82958 was antagonized by SCH23390, a D1 dopamine receptor antagonist, or by haloperidol, a nonselective dopamine antagonist. Both dopamine and SKF82958 produced smaller responses than did carbachol, an acetylcholine receptor agonist, suggesting that a small number of putative dopamine receptors are coupled to phospholipase C or that the coupling efficiency is low. Stimulation of inositol phosphates by dopamine receptor agonists was not a consequence of stimulation of cyclic AMP formation, as the two responses showed different concentration-response relationships and forskolin, an activator of adenylate cyclase, had no effect on either basal or dopamine-stimulated inositol phosphate accumulation. Dopamine-stimulated inositol phosphate accumulation was only slightly reduced by pertussis toxin pretreatment or by reducing extracellular Ca²⁺. The data suggest that a population of D1-like dopamine receptors on retinal cells is coupled to phospholipase C.

DOPAMINE AND D₁ DOPAMINE RECEPTOR AGONISTS: DOPAMINE RECEPTOR SELECTIVITY AND RESPONSE TO GUANINE NUCLEOTIDES IN NONHUMAN PRIMATE BRAIN. B.K. Madras*. Harvard Medical School, New England Reg. Primate Res. Ctr., Southborough, MA, 01722.

D₁ dopamine receptor agonists has been proposed as therapeutic agents for Parkinsonism (Madras et al., 1992) and have been considered for the pharmacological management of cocaine abuse. The behavioral effects of D₁ receptor agonists differ, however, and these divergent effects may reflect differing efficacies of these drugs for stimulating adenylate cyclase or other systems. In order to characterize D₁ dopamine receptor agonists in primate brain, D₁ receptor affinity, D₁/D₂ receptor selectivity and response to guanine nucleotides was determined for a series of dopamine agonists in cynomolgus monkey caudate-putamen. Of the drugs tested, SKF 81297 was the most selective for the D₁ dopamine receptor (300-fold). The drugs responded differently to the nonhydrolyzable analog of GTP, GpNHpp (100 μ M). GpNHpp decreased the affinity of dopamine for the D₁ receptor by 12-fold and the affinities of SKF 81297, SKF 83189, SKF 82958, CY 208243 by 3-fold. SKF 38393 affinity was reduced 1.5-fold whereas the affinities of SKF 75670, SKF 77434, and SCH 39166 were unaffected by GpNHpp. Dopamine and D₂ dopamine receptor agonists differ in their responses to guanine nucleotides and these differences may contribute to differing behavioral effects. ADENYLYL CYCLASE ACTIVATION BY THE D1B DOPAMINE RECEPTOR MIMICKS PROPERTIES OF CONSTITUTIVELY ACTIVE MUTATED G PROTEIN-COUPLED RECEPTORS. M. Tiberi*, K. B. Janvie, S. Cotecchia and M. G. Caron. HHMI Labs, Dept. of Cell Biology, Duke Univ. Med. Ctr., Durham, NC 27710.

Dopamine D1A and D1B receptor subtypes belong to the superfamily of G-protein coupled receptors. These two D1 receptor subtypes are coupled to activation of adenylyl cyclase and exhibit a distinct anatomical localization. The primary structure of the two receptors is highly conserved within the transmembrane domains but differs within the third intracellular loops and the carboxy tails. To identify functional differences, binding and stimulation of adenylyl cyclase were assessed in 293 and COS-7 cells expressing either D1A or D1B receptor. In general, membranes expressing D1B receptors displayed higher affinities for agonists than those expressing D1A receptors, whereas antagonists had generally a lower affinity at the D1B than at the D1A receptor. Basal activity of adenylyl cyclase in 293 cells expressing various levels of D1B receptors was markedly higher than the basal activity measured in cells expressing D1A receptors. Thus, the fold and maximal stimulation of adenylyl cyclase resulting from activation of the D1B receptor was significantly less than that obtained following agonist activation of the D1A receptor. In cells expressing D1B receptors, the increased agonist affinity appeared to translate in an increased potency of agonists in stimulating adenylyl cyclase in comparison to the potencies determined at the D1A receptor. These properties are reminiscent of those of constitutively active G protein-coupled receptors obtained by site-directed mutations. Experiments with chimeric D1A/D1B receptors reveal that part of the constitutive activity and increased affinity for agonists might be explained by sequences of the third intracellular loop. The different anatomical distribution and biochemical properties of these D1 receptors strengthen the functional distinctions between the two subtypes.

IN VIVO KNOCKOUT OF BRAIN DOPAMINE D₂ RECEPTORS BY AN ANTISENSE OLIGODEOXYNUCLEOTIDE. Ian Creese* and M. Zhang. Center for Molecular and Behavioral Neuroscience, Rutgers, The State University of New Jersey, Newark, NJ 07102.

A 3 day intraventricular infusion of an antisense oligodeoxy-nucleotide corresponding to the NH₂-terminus of the dopamine D₂ receptor mRNA resulted in a 48% decrease in the number of rat striatal dopamine D₂ receptors, as measured by homogenate binding assays. D₂-receptor autoradiography also indicated a homogeneous knockout of about 50% throughout the striatum and over 70% in the nucleus accumbens. In contrast, the antisense treatment failed to affect the receptor densities of striatal D₁, M₁, or 5-HT₂ receptors, indicating that the knockout was specific for D₂ receptors. The specificity of the antisense treatment was further confirmed by the failure of a random oligodeoxynucleotide to induce changes in D₂ receptor number. Behavioral observations indicated that the antisense knockout of D₂ receptors reliably induced catalepsy, a behavior previously associated with decreased D₂ receptor activation. The catalepsy was maintained for at least 6 days after the offset of antisense oligo delivery. Spontaneous locomotor activity was also significantly inhibited by the antisense treatment. These results suggest that antisense treatment has the ability to affect CNS receptors with specificity and efficacy, and hence may have general value in determining the functional significance of CNS receptors.

FUNCTIONAL CHARACTERIZATION OF HUMAN D₂ AND D₃ DOPAMINE RECEPTORS. M. N. Potenza*[§], G. F. Graminski[¶], C. Schmauss[†], and M. R. Lerner[‡]. Depts. of Cell Biology[§], Internal Medicine[¶], & Pharmacology[†] & Howard Hughes Medical Institute #, Yale Univ. Sch. of Med., New Haven, CT 06510 & Dept. of Psychiatry[‡] & Brookdale Center for Molecular Biology[¶], Mount Sinai Sch. of Med., NY, NY 10029

Functional characteristics of human D₂ and D₃ receptors (DRs) were examined using a recently developed bioassay suited for the study of G_i-protein coupled receptors (G_iRs). The bioassay utilizes pigment granule aggregation within cultured *Xenopus laevis* melanophores for the evaluation of ligands as agonists or antagonists upon particular G_iRs. A microtiter plate reader is employed to quantitate pigment aggregation and, as cell sacrifice is not necessary for measurement, time course analyses as well as dose-responses can be readily generated. Melanophores were transiently transfected with cDNAs coding for the human D₂R (short form) or D₃R. Expression of either receptor conferred upon the cells the ability to aggregate their melanosomes in response to selective dopaminergic agonists. The same ligands also inhibited cAMP accumulation within the transfected melanophores, and the agonist-induced melanosome aggregation was shown to be sensitive to pertussis toxin. Although the magnitude of ligand-induced pigment aggregation was after greater in the D₂R-expressing melanophores than in the D₃R-expressing cells, EC₅₀ value determinations revealed that agonists activated the D₂R and D₃R at similar concentrations. IC₅₀ value measurements showed that antagonists revealed the same rank order potency upon the two dopamine receptors. However, each of the antagonists displaying an effect was more potent upon the D₂R. The results reveal functional similarities and differences between the D₂R and D₃R.

439.7

BINDING OF [125I](R)trans-7-HYDROXY-2-(N-n-PROPYL-N-3'-IODO-2-PROPENYL)AMINOTETRALIN ([125I](R)trans-7-OH-PIPAT) TO DOPAMINE D₃ RECEPTORS IN RAT OLFACTORY TUBERCLE. K. D. Burris*, J. M. Filiz, M. P. Kung, C. Foulon, S. Chumpradit, H. F. Kung and P. B. Molinoff. Depts. of Pharmacology and Radiology, Univ. of Penn., Sch. of Med., Philadelphia, PA 19104-6084

The lack of selective ligands for members of the D₂-like family of receptors has made it difficult to study D₂, D₃ and D₄ receptors in tissues expressing multiple subtypes. [125I](R)trans-7-OH-PIPAT binds with high affinity to D₃ receptors expressed in Sf9 cells. No specific binding is seen in Sf9 cells expressing a high density of D₂ receptors. However, [125I](R)trans-7-OH-PIPAT bound with high affinity to membranes from HEK-293 cells expressing transfected D₂ or D₃ receptors and to membranes from CHO cells expressing 5-HT_{1A} receptors. Binding of [125I](R)trans-7-OH-PIPAT to 5-HT_{1A} and D₂ receptors was decreased or eliminated in the presence of GTP or guanylyl-imidodiphosphate (Gpp(NH)p), however binding of [125I](R)trans-7-OH-PIPAT to D₃ receptors was not affected by Gpp(NH)p. Therefore, coupling of receptors to G-proteins appears to be a requirement for the binding of [125I](R)trans-7-OH-PIPAT to D₂ and 5-HT_{1A}, but not D₃, receptors. Saturation binding of [125I](R)trans-7-OH-PIPAT to membranes from rat olfactory tubercle resulted in markedly curvilinear Scatchard plots suggesting that the radioligand was binding to more than one class of receptors. In the presence of Gpp(NH)p, linear Scatchard plots with K_d values of 0.1-0.3 nM and densities of 100-200 fmol/mg of protein were obtained. Agonists and antagonists inhibited binding of [125I](R)trans-7-OH-PIPAT with K_i values which are in good agreement with values obtained using membranes from HEK-293 cells expressing D₃ receptors. These results suggest that, in the presence of Gpp(NH)p to eliminate binding to D₂ and 5-HT_{1A} receptors, [125I](R)trans-7-OH-PIPAT labels D₃ receptors in rat olfactory tubercle. THE EFFECT OF CHRONIC NICOTINE ON DOPAMINE RECEPTOR - EFFECTOR MECHANISMS IN THE NUCLEUS ACCUMBENS AND STRIATUM. I. L. Holt* and T. C. Westfall. Dept. of Pharm. Phys. Sci. St. Louis Univ. Med. Ctr. St. Louis, MO 63104.

Previous studies from this laboratory have demonstrated development of tolerance to the effects of nicotine on dopamine (DA) synthesis in the nucleus accumbens (NAc) without a similar development of tolerance in the striatum (Str) (Holt, I.L. and Westfall, T.C.; Soc. Nsci. Abstr. 517.5, 1989). Using a similar experimental paradigm for chronic treatment of nicotine, pellets implanted subcutaneously designed to administer 1 mg/kg/day for 14 days, we explored potential mechanisms for tolerance development. We examined the effects of chronic nicotine on dopamine D₁ and D₂ receptors in the NAc and Str and found no change in either the B_{max} or K_d of either D₁ or D₂ receptors in either area after chronic treatment. We further examined the effects of chronic nicotine on D₁- or D₂-mediated effects on cAMP efflux in both dopaminergic target areas and found that D₁ agonist SKF-38393-induced enhancement of cAMP efflux in the NAc was attenuated after chronic nicotine but was not affected in the striatum. We did not observe any effects of nicotine on D₂ agonist quinpirole-induced inhibition of cAMP. We additionally examined the effects of chronic NIC on autoreceptor activity in both tissues by treating animals with GBL to block nerve activity and DA release (and hence remove autoreceptor activation) in DAergic neurons and observed the ability of quinpirole to reactivate autoreceptors. This was measured by the ability of quinpirole to inhibit the enhanced DA synthesis stimulated by GBL-induced removal of autoreceptor activity. Although NIC was able to moderately decrease the ability of GBL to enhance DA synthesis, it did not affect autoreceptor induced inhibition of synthesis. These results suggest that chronic nicotine may effect a functional uncoupling of D₁ receptors to adenylate cyclase in the NAc, not Str, and that chronic nicotine does not appear to modify D₂ or autoreceptor function in either tissue.

THREE COMPARTMENT MODELING OF [123I]IBF BINDING TO DOPAMINE D₂ RECEPTORS IN HUMAN BRAIN. C. H. Van Dyck*, M. Laruelle, A. Abi-Dargham, S. S. Zoghbi, Y. Zea-Ponce, R. M. Baldwin, D. S. Charney, P. B. Hoffer, R. B. Innis. Yale Univ and West Haven VA Medical Center, West Haven, Connecticut, 06516

The iodinated benzamide analog, [123I]IBF (iodobenzofuran), a high affinity dopamine D₂ antagonist (K_D = 0.11 nM, Kung et al, J Nuc. Med., 30:88-92, 1989), was used as a SPECT radiotracer to measure D₂ receptor binding potential (BP = B_{max}/K_D) in healthy humans (n=4, age = 29 ± 5 years, ±SEM). Data were acquired with the brain dedicated, high resolution, CERASPECT camera for 160 min after bolus injection of the tracer (6.0 ± 0.1 mCi). Arterial plasma activity was measured and corrected for metabolites by HPLC. Plasma clearance of the parent compound was 682 ± 380 l/h. Striatal activity equilibrated at 40-80 min. Occipital and striatal time activity curves were fit to a two and three compartment model, respectively, to estimate transfer rate constants, K₁ to k₄. Occipital equilibrium distribution volume (DV) was calculated as K₁/k₂*f₁, where f₁ is the measured free fraction in the arterial blood. Striatal BP was calculated as K₁k₃/k₂*k₄*f₁ with K₁/k₂ ratio constrained to the value derived in the occipital region. Occipital DV was 63 ± 13 and striatal BP was 197 ± 49. The striatal BP to occipital DV ratio was 3.0 ± 0.2. Assuming an *in vivo* K_D of 0.11 nM, these values indicate a B_{max} of 22 ± 4 nM, which is in accordance with the literature. These studies demonstrated the feasibility of measuring D₂ receptor BP with SPECT using three compartment kinetic modeling. As this method corrects for between subjects differences in plasma clearance, it is more accurate than simple striatal to occipital ratio methods for measurement of receptor density.

IN VIVO AGONIST PROPERTIES OF 7-OH-DPAT, A DOPAMINE D₃-SELECTIVE RECEPTOR LIGAND. J.F. McElroy*, K.A. Amy, K.A. Ward, K.L. Zeller, J.F. Cawley and A.L. Mazzola. CNS Diseases Research, The Du Pont Merck Pharmaceutical Co., Experimental Station, P.O. Box 80400, Wilmington, DE 19880-0400

7-OH-DPAT (7-hydroxy-N,N-di-n-propyl-2-aminotetralin), recently identified as a high affinity and selective ligand at dopamine D₃ receptors (Levesque et al., *Proc. Natl. Acad. Sci.*, 89: 8155-8159, 1992), was evaluated in a battery of *in vivo* tests highly predictive of dopamine agonist or antagonist activity. In contrast to well established dopamine receptor antagonists such as haloperidol and eticlopride, 7-OH-DPAT was inactive in the rat conditioned avoidance and catalepsy tests and did not antagonize apomorphine-induced stereotypy or climbing behavior in mouse (all ED₅₀ values > 30 mg/kg, s.c.). However, similar to the dopamine agonist apomorphine, 7-OH-DPAT produced stereotypical sniffing in mouse and rat (ED₅₀'s < 3.0 mg/kg, s.c.), increased locomotor activity in rat (ED₅₀ < 10 mg/kg, s.c.), and caused 6-OHDA-lesioned animals to rotate in a contralateral direction (ED₅₀ < 1.0 mg/kg, s.c.). Taken together, these results indicate that 7-OH-DPAT is an agonist at dopamine receptors, *in vivo*. Antagonism studies using antagonists at dopamine D₁ (SCH23390), D₂/D₃ (haloperidol, eticlopride), and D₄ (clozapine) receptors are in progress.

5,7-DIHYDROXYTRYPTAMINE DESTRUCTION OF SEROTONIN FIBERS ELIMINATES THE ENHANCED ORAL ACTIVITY RESPONSE TO SKF 38393 IN NEONATAL 6-HYDROXYDOPAMINE-LESIONED RATS. R.M. Kostrzewa*, R. Brus*, K.W. Perry² and R.W. Fuller³. ¹Department of Pharmacology, East Tenn St Univ, Johnson City, TN 37614; ²Silesian Academy of Medicine, Zabrze, Poland and ³Lilly Research Labs, Indianapolis, IN.

Previous experiments show that neonatal 6-hydroxydopamine (6-OHDA) lesioned rats exhibit an enhanced oral activity response to the dopamine (DA) D₁ agonist SKF 38393 and that this response is mediated by serotonin 5-HT_{1c} receptors. Therefore, we tested whether the 5-HT neurotoxin, 5,7-dihydroxytryptamine (5,7-DHT), would eliminate SKF 38393 effects. At 3 days after birth rats were treated with desipramine (20 mg/kg IP) 1 hr before vehicle, 6-OHDA (134 µg, ICV) and/or 5,7-DHT (50 µg). At 2-4 months rats treated with 6-OHDA alone showed an enhanced response to SKF 38393 and the 5-HT_{1c} agonist m-chlorophenylpiperazine (m-CPP). However, there was no change in the dose response curve for these drugs in rats treated neonatally with vehicle or 5,7-DHT alone. In rats treated neonatally with both 6-OHDA and 5,7-DHT the m-CPP response was still present, while the SKF 38393 response was fully attenuated. Neonatal 6-OHDA and 5,7-DHT treatments reduced striatal DA and 5-HT contents by >98% and >90%, respectively. The findings demonstrate that the enhanced DA D₁ agonist-induced oral activity response of DA lesioned rats is dependent on 5-HT fibers. Supported by NS 29505 and the Fogarty Int'l Center.

TYPICAL AND ATYPICAL NEUROLEPTICS DIFFERENTIALLY AFFECT STRIATAL DOPAMINE RELEASE AND METABOLISM STUDIED BY MICRODIALYSIS IN FREELY MOVING RATS. K. S. Rayevsky, R. R. Gainetdinov, T. V. Grekhova, T. D. Sotnikova, and A. Kharlamov. Institute of Pharmacology, Russian Academy of Medical Sciences, Moscow 125315, Russia.

The dopamine (DA) D3 receptor is a novel D2-like receptor yet its pharmacological profile differs from that of D2. Both receptors are considered as the target for the antipsychotic effect of neuroleptics and it has been suggested that they both might be functioning as presynaptic autoreceptors responsible for the regulation of DA release and metabolism in DAergic neurons. In the present study we examined the effects of a number of typical and atypical neuroleptic drugs on the extracellular level of DA, homovanilic (HVA) and dihydroxyacetic (DOPAC) acids in the striatum of freely moving rats using a transcranial microdialysis probe and HPLC/ED technique. Classical neuroleptics such as haloperidol (0.2 mg/kg), thioriperazine (0.2 mg/kg) and spiperone (0.07 mg/kg, all injected i.p.) produced a gradual increase in the level of extracellular DA (up to 50%) and much greater elevation of the DOPAC (up to 75%) and HVA (up to 200%), while the atypical neuroleptic clozapine (20 mg/kg, i.p.), unlike haloperidol, produced a sharp increase in DA release (up to 100%) followed by delayed increase of the metabolite level. The D3 antagonist (+) AJ-76 (14 mg/kg, i.p.) resulted in a large increase of DA release with less pronounced elevation of HVA and DOPAC. In conclusion, classical and atypical neuroleptics might be clearly distinguished by their different effect upon extracellular levels of DA and related metabolites.

Supported by a grant from the Scottish Rite Foundation.

Irreversible monoaminergic receptor antagonism partially blocks the striatal neurotensin mRNA response to haloperidol in young but not senescent rats. D.J. Dobie, M.R. Adams, K.M. Mercham, E.R. Paskind, and D.M. Dorsa. Depts. of Psychiatry and Pharmacology, Univ. of WA, Seattle WA 98195 and GRECC, VAMC, Seattle WA 98108.

To assess further the impact of the age-related decline in dopaminergic function on the induction of neurotensin/neuromedin (NT/N) mRNA by haloperidol (H), we gave the irreversible monoaminergic receptor antagonist N-ethoxycarbonyl-2-ethoxy-1,2 hydroquinolone (EEDQ) to 3 month and 24 month old Fischer 344 rats. Rats received an acute (7 hour) challenge of either H (1 mg/kg i.p.), EEDQ (10 mg/kg i.p.), or vehicle. Separate groups of rats were pretreated with EEDQ either 3 days or 7 days prior to an acute challenge with H or saline. *In situ* hybridization was performed for NT/N mRNA in the dorsolateral striatum (DLS).

Acute administration of EEDQ or H each induced a significant NT/N mRNA response in the DLS in young and old animals compared to controls. The magnitude of this response was greater in the H-treated than in the EEDQ-treated animals in both age groups. In young rats, pretreatment with EEDQ resulted in a significant blunting (although not total elimination) of the NT/N mRNA response to H at both 3 and 7 days. In aged rats, the NT/N mRNA response to acute H was significantly diminished when compared to the response in acutely H-treated young rats. Pretreatment with EEDQ did not affect further the blunted response to acute H in aged rats. These data suggest that, while dopamine receptors may play an important role in regulating the NT/N mRNA response to H in the striatum, receptors insensitive to EEDQ inactivation may also be involved. (Supported by NIA, NARSAD, NIH, and Dept. of Veterans Affairs).

INVERTEBRATE LEARNING AND BEHAVIOR IV

A POSSIBLE ROLE FOR PKC IN THE EXPRESSION OF ENHANCED EXCITABILITY IN LATERAL TYPE A PHOTORECEPTORS OF CONDITIONED *HERMISSENDA*. R.J. Fryszak* & T. Crow. Department of Neurobiology & Anatomy, Univ. Texas Medical School, Houston, TX 77225

Identified type A photoreceptors of *Hermisenda* express differential effects of excitability following conditioning. Lateral type A photoreceptors of conditioned animals exhibit decreased spike frequency accommodation and an increase in excitability to both the conditioned stimulus (CS; light) and extrinsic current (Fryszak & Crow, 1993). In contrast, medial type A photoreceptors do not express enhanced excitability, although they do show an increase in the amplitude of spike-elicited IPSPs following conditioning. Protein kinase C (PKC) contributes to the induction of enhanced excitability in identified type B photoreceptors produced by one-trial conditioning. The broad spectrum kinase inhibitors H-7 and sphingosine, applied before conditioning, can block the induction of enhancement in type B photoreceptors. We report here preliminary evidence for the effects of various PKC inhibitors on the expression of excitability in identified lateral type A photoreceptors of conditioned animals. Bath application of H-7 (Seikagaku; final concentration 100 μ M) resulted in a decrease in the frequency of current-elicited action potentials in lateral type A photoreceptors of conditioned animals (\bar{x} =61.3%; n=3), as compared to pseudorandom controls (\bar{x} =40.2%; n=3). The intracellular application of PKC inhibitor 19-36 (Gibco BRL) into identified lateral type A photoreceptors of conditioned animals resulted in a decrease in the frequency of action potentials elicited by extrinsic current 30 minutes after cell penetration (\bar{x} =70.8%; n=5). Pseudorandom controls treated with PKC 19-36 did not show a decrease (n=3), nor did conditioned animals treated with the non-inhibitory PKC analog (n=2). These results indicate that the enhanced excitability expressed in the lateral type A photoreceptor following conditioning may be mediated in part by protein kinase C.

440.3

PERSISTENT ACTIVATION OF THE Ca^{2+} -ACTIVATED PKC IN *APLYSIA* REQUIRES PROTEIN SYNTHESIS. W. S. Sossin* and J. H. Schwartz. Center for Neurobiology and Behavior, Columbia University College of Phys. and Surg., New York, NY

Aplysia neurons contain only two isoforms of protein kinase C, the Ca^{2+} -activated Apl I and the Ca^{2+} -independent Apl II. The pattern of activation of the two isoforms suggests that they play distinct roles in inducing long-term synaptic plasticity. Both isoforms are activated 30 min after a 90-min application of 20 μ M 5-HT, a protocol that produces long-term presynaptic facilitation of sensory-to-motor synapses. But, only Apl I remains active 2 h after the treatment. This persistence of Apl I requires protein synthesis; it is prevented by anisomycin during the 5-HT application. Anisomycin alone has no effect on activity of Apl I nor does it block its short-term activation. In contrast, Apl II is not stimulated by a short-term 5-HT protocol, and is only transiently stimulated by the long-term protocol. It is difficult to determine whether the transient increase in Apl II is due to changes in gene expression as the inhibitor of protein synthesis alone activates Apl II also. The stimulation of Apl II by anisomycin suggests that Apl II is continually under regulation by proteins that turnover quickly.

Pharmacological agents that distinguish between physiological actions of 5-HT also have differential effects on short-term activation of Apl I. The activation of Apl I by applying 5-HT for 30-min is not blocked by 10 mM THFA, an inhibitor of adenylyl cyclase, but is blocked by 200 μ M cyproheptidine (CYP), a serotonin-receptor antagonist. This provides further evidence that the stimulation of PKC by 5-HT is independent of the cAMP pathway and that CYP antagonizes the 5-HT-receptor coupled to PKC activation.

G-PROTEIN MEDIATED UP- AND DOWN-MODULATION OF POTASSIUM CURRENTS AS A FUNCTION OF INTRACELLULAR CALCIUM CONCENTRATION. L.D. Matzel, R.F. Rogers, and A.C. Talk. Department of Psychology, Rutgers University, New Brunswick, NJ 08903

Numerous receptors are linked to second messenger systems that require the interaction of regulatory G proteins. For instance, stimulation of hair cells in the vestibular system of *Hermisenda* results in a K^+ efflux and resultant hyperpolarization of ipsilateral B photoreceptors which is dependent on a receptor stimulated, pertussis toxin-insensitive G protein. Here we report that in isolated B photoreceptors from *Hermisenda*, hydrolysis-resistant stimulation of G proteins by bath application of fluoride ions (AlF_4^- ; 5 mM NaF + 5 μ M Al) selectively increases (\approx 25%) a slow outward, TEA-sensitive K^+ current (I_k), while the magnitude and steady-state inactivation of a fast, voltage-dependent K^+ current (I_A) was unaffected. If the application of AlF_4^- was accompanied by a depolarizing train, both I_k and a Ca^{2+} -dependent K^+ current (I_{KCa}) were markedly reduced (\approx 50-60%). The direct enhancement of I_k by AlF_4^- was unaffected by intracellular injection of the Ca^{2+} chelator EGTA (25 mM), but the pairing-specific reduction of I_A was eliminated, indicating that depolarization modified the response to AlF_4^- by increasing intracellular Ca^{2+} concentrations. Preincubation (24 hr) of the nervous system in the G_i protein inhibitor pertussis toxin blocked the reduction of currents induced by AlF_4^- paired with depolarization. These results suggest that a G protein-mediated, Ca^{2+} -dependent regulation of a second messenger system may contribute to the modulation of membrane excitability when presynaptic activity is paired with postsynaptic depolarization. This process may serve a critical role in the induction of short-term storage of associative memory in *Hermisenda*.

440.4

TEMPORAL ASPECTS OF ACTIVATION OF THE Ca^{2+} /CaM-SENSITIVE ADENYLYL CYCLASE: POSSIBLE CONTRIBUTION TO DETECTION OF CS-US PAIRING DURING CONDITIONING. T.W. Abrams* and J. Galun. Inst. of Neurological Sciences, Univ. of Penn., Phila., PA 19104.

During classical conditioning in *Aplysia*, Ca^{2+} /CaM-sensitive cyclase serves as a molecular site of convergence within the siphon sensory neurons for Ca^{2+} and 5HT, the cellular representations of the conditioned and unconditioned stimuli (CS and US). Using a perfused membrane cyclase assay, we previously found that a prepulse of Ca^{2+} resulted in both a faster rate of cyclase activation and greater peak activation by a brief pulse of 5HT than did a backwards pulse of Ca^{2+} . This suggested that Ca^{2+} /CaM binding to the cyclase might enhance the rate of activation by receptor and G_s . This interaction appeared to be specific for G_s because there was no similar interaction between a Ca^{2+} pulse and a pulse of forskolin. To more directly test the hypothesis that Ca^{2+} modulation of G_s interactions with cyclase underlies the pairing requirements of conditioning, we have begun to study interactions between recombinant type I cyclase and preactivated $G_{s\alpha}$. Preliminary experiments in which a Ca^{2+} pulse was paired with a brief pulse of preactivated $G_{s\alpha}$ suggested that pairing results in more powerful cyclase stimulation than the sum of the separate stimulations. We further observed that the CaM-mediated stimulation of cyclase by Ca^{2+} has a relatively delayed and prolonged time course; this delay may contribute to the requirement that the CS (and Ca^{2+} influx) begin before the US (and 5HT binding). In contrast, the direct, inhibitory effect of Ca^{2+} occurs rapidly and is relatively brief.

MOLECULAR CHARACTERIZATION OF *DROSOPHILA* CALCIUM/CALMODULIN-DEPENDENT PROTEIN KINASE II: A REQUIRED ELEMENT IN BEHAVIORAL PLASTICITY L.C. Griffith* and B. GuptaRoy. Dept. of Biology and Center for Complex Systems, Brandeis University, Waltham, MA 02254

Inhibition of calcium/calmodulin-dependent protein kinase II (CaM kinase) activity in transgenic *Drosophila* carrying a gene for a specific peptide inhibitor produces defects in both associative and nonassociative plastic behaviors [Griffith, et al. (1993) *Neuron* 10:501-9]. To understand the molecular basis of this phenomenon, we have cloned and characterized several CaM kinase isoforms. Unlike mammals, which have several highly related genes for CaM kinases, *Drosophila* uses a single gene to produce many CaM kinase isoforms. These isoforms differ in primary amino acid sequence only at a point immediately distal to the regulatory domain of the kinase. CaM kinase isoforms are expressed throughout development in *Drosophila* and in the adult nervous system, gut and ovaries. The functional significance of isoform variability is being assessed in terms of catalytic properties and tissue distribution of the different forms. Expression of full length cDNAs in COS cells produces immunoreactive protein for every isoform tested. Each isoform also has calcium/calmodulin-dependent activity when assayed with a specific peptide substrate under saturating activator conditions. At subsaturating conditions, however, amino acid insertions at the variable region change the affinity of the enzyme for calmodulin and may have effects on autophosphorylation and regulation of enzyme activity.

ASSOCIATIVE LEARNING IN *C. ELEGANS*: CONTEXT CONDITIONING OF HABITUATION. C.H. Rankin*. Department of Psychology, University of British Columbia, Vancouver, B.C. V6T 1Z4

Many studies of associative learning have shown the importance of context in the retention of the learned association. Context is often composed of the environmental stimuli that were present when the original association was made. In this experiment the context in which worms were given habituation training was varied by the presence or absence of a chemical ion during training. The protocol involved habituating worms to tap in the presence or absence of the ion, and then, following a 1 hour recovery period, retesting them in either the presence or absence of the ion. Thus worms were rehabituated in either the same context as the original training, or a different context (counterbalanced: half of the worms received original training in the presence of the ion, half in the absence of the ion). Using this protocol and habituating at either a 10 s ISI or a 60 s ISI, worms appeared to retain habituation training to a greater extent if the context of rehabituation was the same as the context of the original habituation than if the context changed between original training and rehabituation. Worms rehabituated significantly more rapidly in the same context than in the different context (60 s ISI slopes: $t(38)=2.01$, $p<.05$). In addition, worms had significantly smaller response magnitudes on the first response of rehabituation in the same context than in a different context (60 s ISI response magnitude: $t(68)=2.01$, $p=.05$).

INTERACTIONS BETWEEN NEURONS IN THE ABDOMINAL GANGLION OF *APLYSIA*. Y.Tsau, J-Y.Wu, L.B.Cohen*, D.Schiminovich, H-P.Hopp, and C.X.Falk. Department of Physiology, Yale University School of Medicine, New Haven, CT 06510

It is important to record as many neurons as possible and know how these neurons interact in order to understand the mechanism by which a nervous system works. This is especially true when many neurons are thought to be involved in generating a behavior. We employed optical recording to simultaneously monitor the spike activity of about half of the neurons in the abdominal ganglion of *Aplysia*, and cross-correlation analysis to investigate the interactions between the neurons. We used two stimuli, current steps from an intracellular microelectrode in a cell body (probably L10) or a light touch to the siphon skin. The data were stored and analyzed on a Motorola VME bus computer and a Silicon Graphics workstation. One cross-correlation, the normalized cross-covariance function (NCCVF) was calculated to estimate the interactions between neurons. Approximately 100-200 out of $2 \cdot 10^3$ pairs had larger NCCVF values. Most of these had a wide peak half-width (about 1000 msec), implying that most of the synaptic interactions between these neurons are slow. Because there were many simultaneously active neurons it was difficult to determine the synaptic interactions responsible for these slow time-scale correlations. A few pairs (about 20) were found with a short time delay (<100ms) and narrow peak half-widths (<50ms), implying that only a few synaptic interactions are large and fast. It was easier to interpret this kind of cross-correlation in terms of synaptic interactions. The interaction pattern changed from animal to animal, implying that the same behavior might be executed by different neuronal circuitry. Supported by NIH grant NS08437.

STOMACH DISTENTION INHIBITS BOTH FEEDING BEHAVIOR AND THE SWALLOWING MOTOR PROGRAM IN THE NUDIBRANCH, *MELIBE LEONINA*. W.H. Watson III* and M.J. Iannucci, Zoology Dept., Univ. of New Hampshire, Durham, NH 03824 & Friday Harbor Labs, Friday Harbor, WA 98250

Melibe respond to prey by increasing their feeding activity from 0.2 hood closures/min to 1-3 closures/min. After feeding for several hours prey capture rate returns to resting levels. This decrease is closely associated with expansion of the stomach and it is likely that stomach distention inhibits feeding behavior.

We tested this hypothesis by: (1) injecting inert material into the stomachs of hungry animals to induce satiation and; (2) cutting the posterior nerves which lead from the stomach to the buccal ganglia and brain. Animals with artificially distended stomachs responded like fed animals, and those with posterior nerve lesions failed to become satiated after feeding for 24 hours. These data indicate that stomach distention activates receptors which feedback to the CNS and depress the neural circuits underlying feeding and possibly swallowing behavior.

This hypothesis was tested using several semi-intact preparations. First, during stomach distention, we recorded a large increase in the firing rate of several units in the posterior nerve. Second, we discovered that stomach inflation suppressed both spontaneous and stimulus-induced expression of the swallowing motor program by the buccal ganglia. Suppression was accompanied by: (1) inhibition of constriction motoneurons and; (2) excitation of dilation neurons and the large SCPb-containing neuron B1. Distention was mimicked, somewhat, by application of either SCPb or serotonin. The influence of stomach distention on the feeding motor program in the brain is presently being investigated and our long-term goal is to identify the site(s) where the feeding system is being modulated, and then determine the neural mechanisms that are responsible.

We would like to thank the staff of the Friday Harbor Laboratories for their help. This work was supported by a NIH grant (NS29555) to WHW.

INDEPENDENT MEMORIES IN *DROSOPHILA* AFTER PAVLOVIAN CONDITIONING. T. Tully^{1,2}, M. DelVecchio¹, S. Boynton² and T. Preat^{2,3}.

¹Center for Learning & Memory, Cold Spring Harbor Laboratory, Cold Spring Harbor NY 11724 U.S.A., ²Department of Biology, Brandeis University, Waltham MA 02254 U.S.A., ³Theodor-Boveri-Institut (Biozentrum), Lehrstuhl für Genetik, Am Hubland, D-8700 Würzburg FEDERAL REPUBLIC OF GERMANY

With extended training using a Pavlovian odor avoidance procedure, we have produced long-lasting memory retention in wild-type *Drosophila*. Massed training produces moderate 24-hr retention, which then decays to zero within four days; spaced training produces strong 24-hr retention, which still is 30% of initial learning levels 7 days later. When flies are fed the protein synthesis inhibitor cycloheximide, 24-hr retention after massed training is normal -- indicating that such memory is protein synthesis independent. Cycloheximide affects memory after spaced training, however, producing 24-hr retention scores similar to those after massed training (with or without drug). These results indicate that spaced training induces a protein synthesis-dependent form of LTM above and beyond the protein synthesis-independent form.

Interestingly, 24-hr retention after massed training is zero in *radish* flies, suggesting that the protein synthesis-independent form of memory is blocked by this single-gene mutation. Nevertheless, spaced training of *radish* flies produces memory lasting several days, suggesting that the protein synthesis-dependent form of memory is intact in these mutants.

Taken together, these behavior-genetic experiments reveal the existence of (at least) two phases of memory after extended Pavlovian conditioning. Massed training induces a shorter-lived form, the expression of which is not dependent on protein synthesis. Spaced training induces the protein synthesis independent memory along with a longer-lived, protein synthesis dependent form -- which most likely represents a bona fide long-term memory (LTM). Finally, since LTM can form in *radish* mutants in the absence of the protein synthesis-independent phase of memory, these two types of memory must be genetically distinct and must function independently.

NEURONAL ACTIVITY DURING THE *APLYSIA* GILL WITHDRAWAL REFLEX AND SPONTANEOUS GILL CONTRACTIONS SUGGESTS A DISTRIBUTED NEURONAL ORGANIZATION. Jian-young Wu*, Lawrence B. Cohen, and Chun Xiao Falk. Dept. of Physiol., Yale Univ. Sch. of Med., New Haven, CT 06510

In a distributed neuronal organization behaviors are generated by different configurations of a large integrated neuronal network rather than dedicated circuits. Neuronal activity in the *Aplysia* abdominal ganglion suggests a distributed neuronal organization. A large fraction of neurons in the abdominal ganglion was optically monitored during three forms of spontaneous or evoked behavioral events (respiratory pumping, the gill withdrawal reflex, and a small spontaneous gill contraction). About 300 of neurons were activated during all three of the behaviors. More than 90 per cent of the neurons activated during the gill withdrawal reflex were also being activated during both small and large spontaneous gill contractions. While the active neuronal populations and the total numbers of spikes during three behaviors were similar, the activity patterns were substantially different during the three events. When an evoked gill withdrawal was elicited a few seconds after a large spontaneous gill contraction, substantial changes in the evoked neuronal activities were observed. These results imply that a distributed neuronal network is reconfigured to generate these different forms of gill contractions. It was known that the gill withdrawal reflex and the respiratory pumping share many motor neurons and interneurons. Our data suggest that a much larger integrated circuit, containing a large fraction of the neurons in the ganglion, is shared by those forms of gill withdrawal behaviors. Supported by NIH grant NS08437.

RECORDING OF MEMBRANE POTENTIAL CHANGES FROM NEURONAL PROCESSES BY FLUORESCENCE MEASUREMENTS. S. Antic and D. Zecevic*, Univ. of Belgrade Sch. of Biology, Belgrade, Yugoslavia

We are investigating optical signals from neurons injected with voltage-sensitive dyes: our aim is to analyze signal integration in neuronal processes. Experiments were done on ventral cerebral giant cells of Helix pomatia that project large axons into the commissures and peripheral nerves. The anatomy of giant cells is particularly suitable for epi-fluorescence measurements. Multi-site optical recording was done using 124 or 464 element rectangular photodiode array supported by Motorola VME bus computer. Best results were obtained with positively charged styryl dyes. Using dye designated JPW1114 we found that signals from soma and distant processes can clearly be distinguished. Signal-to-noise ratio in recording did not require extensive averaging. The temporal resolution was sufficient to enable us to follow the spread of the signal along the axon and determine the site of spike initiation. To further improve signal-to-noise ratio we are currently investigating the effect of size of the neuron, and the effect of the amount of time allowed for the dye to spread into the processes on signal size. We are also testing newly synthesized close analogues of dye JPW1114 with different degrees of hydrophobicity. Supported by NIH grant NS28443.

HYPOTHALAMIC TRH STIMULATES NEUROPEPTIDE Y SYNTHESIS IN THE ANTERIOR PITUITARY GLAND. M. Michalkiewicz*, Department of Physiology, West Virginia Univ. Morgantown, WV 26506.

We have shown that neuropeptide Y (NPY) expression in the anterior pituitary gland (AP) is increased in hypothyroid rats and that this effect is mediated by some hypothalamic factor. In the present study we examined the hypothesis that stimulating effect of low thyroid hormone on NPY synthesis in the AP is mediated by the hypothalamic TRH. Male Sprague Dawley rats (7-9 per group) were anesthetized and one of the surgery was performed: 1) Sham thyroidectomy (STx); 2) Thyroidectomy (Tx) + radio-frequency lesion of the paraventricular nucleus (PVNx); 3) Tx + Sham PVNx; 4) Tx + PVNx + TRH (100 µg/day, continuous infusion using osmotic pumps); 5) Tx + PVNx + Placebo; 6) Tx + anterolateral hypothalamic deafferentation (ALHx); 7) Tx + ALHx + TRH; 8) Tx + ALHx + Placebo. 12 days after surgery animals were killed and tissue samples collected for measurement of the AP NPY, plasma TSH, T₃, and T₄ (by RIA). In addition, NPY was measured in blood, superior cervical ganglion, adrenal gland, and prefrontal cerebral cortex. Identity of radioimmunoassayable NPY extracted from the AP and other organs was confirmed by HPLC. Hypothyroidism was verified by low plasma T₃ and T₄ and high TSH. Only animals with complete hypothalamic lesions (confirmed histologically) were included for analysis. In the hypothyroid rats the AP contents of NPY were significantly increased. These changes were completely prevented by PVNx or by ALHx. Treatment with TRH significantly increased AP contents of NPY in the PVNx and ALHx rats. Effect of TRH was specific to the AP because no changes in NPY levels in other organs were observed. These data suggest that the hypothalamic TRH of the PVN origin stimulates the synthesis of NPY in the AP gland. Supp.: WVU BRS #2S07RR05433-31.

DIRECT ROLE OF *FURIN* IN MEDIATING ENDOPEPTOLYTIC CLEAVAGE OF PROSOMATOSTATIN (PSS) IN COS-7 CELLS. A. Galanopoulou and Y.C. Patel*, Fraser Labs, McGill University, Montreal.

We have previously reported that mammalian PSS significantly cleaves at monobasic Arg⁶⁴ and Lys¹³ sites to yield respectively SS-28 and PSS_[1-10] in COS-7 cells (JBC 268:6041, 1993). In addition, SS-14 is produced in low quantities via cleavage at a third Arg-Glu-Arg-Lys⁷⁸ site. We suggested that *furin*, the only known converting enzyme endogenously expressed in COS-7 cells, may be responsible for these cleavages. Here we have directly assessed the role of *furin* in PSS processing. COS-7 cells were infected either with wild type vaccinia virus (VV:wt) at different concentrations or VV:*furin* and subsequently transfected with the vector p601:rPSS expressing rat prePSS cDNA under a VV promoter. Cell extracts and media were analysed by HPLC and region-specific RIAs.

	VV:wt	VV: <i>Furin</i> (0.8 pfu/cell)	VV: <i>Furin</i> (2.4 pfu/cell)	VV: <i>Furin</i> (12 pfu/cell)
SS-14 (% SS-14 LI):	10	13	10	24
SS-28 (%):	27	38	38	51
unprocessed (%):	63	49	52	25

Furin induced dose-dependent conversion of PSS to SS-28. It also cleaved SS-14 weakly, but had no additional effect on PSS_[1-10] conversion, beyond that observed with control vaccinia infections. CONCLUSIONS: (1) *Furin* is capable of monobasic cleavage and qualifies as a SS-28 converting enzyme. (2) Another endoprotease, not *furin*, appears responsible for PSS_[1-10] conversion in the constitutive pathway. (3) The low affinity cleavage to SS-14 at the R-X-R-K site, and the inability to cleave at monoLys¹³ site compared to monoArg⁶⁴ site suggests preference for Arg versus Lys at P-1 site in *furin* mediated cleavage.

MICRODIALYSIS SAMPLING FROM THE PARAVENTRICULAR NUCLEUS OF THE HYPOTHALAMUS REVEALS INCREASED NEUROPEPTIDE Y IN RESPONSE TO DIABETES AND FOOD DEPRIVATION. P. D. Lambert, J. P. H. Wilding, S. G. Gilbey, M. A. Ghatei and S. R. Bloom. (SPON: Brain Research Association) Department of Endocrinology, Royal Postgraduate Medical School, Hammersmith Hospital, London, W12 0NN.

Microdialysis is widely used for monitoring changes in the release of various substances in areas of the brain. However, consistent recovery of some neuropeptides has been impossible due to their inherent physical properties. We have developed a microdialysis method to sample neuropeptide Y (NPY) and determined the effect of diabetes and food deprivation on NPY release. Microdialysis probes (CMA/12, 2mm) were stereotactically implanted into the paraventricular nucleus of the hypothalamus (PVN) of anaesthetized male Wistar rats and perfused (3µl min⁻¹) with phosphate buffer containing a polyclonal antibody to NPY (YN10, 1:2000). The experiment was carried out in satiated and fasted animals. After one hour, six 30 minute samples were collected and NPY measured using radioimmunoassay. We also dialysed from the PVN of freely-moving normoglycaemic and streptozotocin-diabetic rats. The concentration of NPY sampled from anaesthetized rats was <1fmol/50µl and increased to 2.4±0.3fmol/50µl (p<0.01) after a 48hr fast. In freely-moving rats, NPY release was significantly greater in streptozotocin-diabetic rats (15±2fmol/50µl, n=5) compared to controls (8±1fmol/50µl, n=5, p<0.01). In conclusion, NPY release is reduced by anaesthesia and diabetes leads to an increase in NPY release which may induce hyperphagia.

441.4

IN VIVO REGULATION OF PEPTIDE α-AMIDATING ACTIVITY IN THE HEART: EVIDENCE FOR TWO SEPARATE MECHANISMS. M. Altarac, D.B. Newman* and G.P. Mueller. Departments of Physiology and Anatomy, Uniformed Services University of the Health Sciences, Bethesda, MD 20814

Peptidylglycine hydroxylating monooxygenase (PHM) catalyzes the rate limiting step in the conversion of glycine-extended peptides to active α-amidated products. PHM is concentrated in cardiac atrium where its expression *in vitro* is induced by glucocorticoids. Recently we have determined that *in vivo* treatment with disulfiram (DIS) increases the V_{max} of PHM (assayed *in vitro*) without altering its biosynthesis. The present investigation sought to determine if these separate mechanisms interact in the control of PHM *in vivo*. Male rats were treated daily with the glucocorticoid, dexamethasone (DEX), DIS, or the 2 agents in combination for seven days; samples were collected and assayed for PHM activity under optimal conditions *in vitro*. Both DEX and DIS treatments increased soluble PHM activity in the atrium by approximately 2-fold; their combined effects were greater (3-fold) than either alone. This pattern of response was tissue specific; PHM activity in the anterior and neurointermediate pituitary was increased by DIS, but not affected by DEX, and activity in blood and brain (hypothalamus & cortex) was unaltered by the treatments. These findings indicate that the expression and activity of PHM in atrium may be regulated by two separate mechanisms *in vivo*; synthesis of new PHM protein (DEX) and modification of PHM protein to increase its V_{max} (DIS).

441.5

IN VIVO INHIBITION OF PEPTIDE α -AMIDATING ACTIVITY BY 4-PHENYL-3-BUTENOIC ACID (4P3B). G.P. Mueller*, and M. Altarac. Department of Physiology, Uniformed Services University of the Health Sciences, Bethesda, MD 20814, Peptidylglycine α -amidating monooxygenase (PAM) catalyzes the sequential hydroxylation and lyase steps in the bioactivation of α -amidated peptides. Peptidylglycine hydroxylating monooxygenase (PHM) is rate limiting, whereas the peptidylhydroxyglycine α -amidating lyase (PAL) step occurs more rapidly. 4P3B has been shown to inhibit PHM *in vitro* irreversibly. This study evaluated 4P3B as a tool for investigating α -amidation *in vivo*. 4P3B caused dose and time related reductions in PHM activity in serum, and extracts of atrium, anterior and neurointermediate pituitary and brain of rats. Levels of serum PHM activity were reduced to less than 5% of control values 3h after sc injection of 500 mg/kg 4P3B; levels were restored to normal by 24h. Similar, though less dramatic responses were observed for PHM activity present in tissue extracts. Interestingly, the activity of PAL was unaffected by 4P3B. The effects of 4P3B were not cumulative; animals receiving daily injections of 500 mg/kg for up to 10 days had nearly normal levels of serum and tissue PHM activity 24 h after the last treatment. Inhibition of extracted PHM by 4P3B was not reversed by dialysis or solvent extraction. Thus, inhibition of PHM by 4P3B *in vivo* may be overcome by either synthesis and secretion of new PHM protein or via a mechanism for PHM regeneration that is not evident *in vitro*.

441.7

UNIQUE SUBSTRATE SPECIFICITY OF 'PROHORMONE THIOL PROTEASE' RELATED TO PROENKEPHALIN PROCESSING.

A.V. Azaryan* and V.Y.H. Hook. Dept. of Biochemistry, Uniformed Services University of the Health Sciences, Bethesda, MD. 20814.

'Prohormone thiol protease' (PTP) that cleaves at dibasic and monobasic sites has been found to be the major enkephalin precursor processing enzyme in bovine adrenal medullary chromaffin granules. In this study, further characterization of PTP's cleavage site specificity has been assessed with a series of peptide-MCA substrates containing paired and single basic residues: Z-Arg-Arg-MCA, Boc-Gln-Arg-Arg-MCA, Boc-Gly-Arg-Arg-MCA, Z-Arg-Val-Arg-Arg-MCA, Boc-Gly-Lys-Arg-MCA, Boc-Glu-Lys-Lys-MCA, Z-Phe-Arg-MCA, Bz-Arg-MCA, Boc-Gln-Gly-Arg-MCA, Bz-Val-Leu-Lys-MCA, and Ac-Lys-MCA. After incubating these substrates with PTP, measurement of the generated AMC fluorescent leaving group with and without aminopeptidase M treatment provided information concerning PTP cleavage at the COOH- or NH₂-terminal side of basic residues. PTP demonstrated: (a) cleavage at dibasic- and monobasic sites; (b) preference for cleaving paired basic residues on the NH₂-terminal side of the pair and between the dibasic residues, compared to the COOH-terminal side; (c) cleavage at both the COOH- and NH₂-terminal sides of a single basic residue with high affinity for Gly-Arg bond. These results are consistent with PTP's cleavage pattern with proenkephalin-derived intermediates -- peptides E and F, and BAM-12P. PTP's unique cleavage specificity, compared to other prohormone convertases, provides further support for this protease as a novel prohormone processing enzyme.

SECOND MESSENGER EFFECTS ON CCK, PC1, AND PC2 mRNA IN THE HUMAN NEUROBLASTOMA CELL LINE SK-N-MCIXC. B. L. Mania-Farnell*, B. J. Merrill, R. Davy, N.G. Seidah, and T. P. Davis. Department of Pharmacology, College of Medicine, University of Arizona, Tucson, AZ 85724.

Regulation of cholecystokinin (CCK), pro-hormone convertase 1 (PC1) and pro-hormone convertase 2 (PC2) mRNA expression was studied in SK-N-MCIXC cells. These cells express the human CCK gene at high levels and perform posttranslational processing of CCK (Verbeek and Burbach, FEBS 268, 1990). SK-N-MCIXC cells also express mRNA for PC1 and PC2 (Konings et al., Neuropeptides, 1993), which are neuroendocrine precursor processing enzymes. To examine the effect of the cyclic AMP (cAMP) second messenger pathway on mRNA levels, SK-N-MCIXC cells were treated with the phosphodiesterase inhibitor isobutyl-methylxanthine (IBMX, 0.5mM). Phorbol-12-myristate-13 acetate (PMA, 0.5 μ M) was used to determine if the protein kinase C (PKC) pathway regulated mRNA levels. Messenger RNA levels were quantitated using Northern blot analysis in combination with cRNA hybridization probes, human CCK, human PC1 and rat PC2. After 12 hour treatments CCK mRNA levels were raised 1.8 -fold (IBMX), 2.5 fold (PMA) and 2.7 -fold (PMA) in combination with IBMX). Similar results were seen at 6 hours. PC1 mRNA levels were raised 1.3 -fold (IBMX), 1.5 -fold (PMA) and 1.7 -fold (PMA) in combination with IBMX) with 3 hour treatments. Similar results were seen at 6 hours. Six hour treatments with second messengers did not affect PC2 mRNA levels. Our results show that the cAMP and PKC pathways regulate CCK and PC1 mRNA levels in SK-N-MCIXC cells and raise the question that PC1 may play a role in processing CCK. Supported by N.I.H. Grant DK 36289 and MH42600 and MRC Grants MT11268 and PG2.

IN VITRO PROCESSING OF POMC BY PURIFIED RECOMBINANT PC1. T.C. Friedman, K.T. Kalogeras*, Y.P. Loh and N.P. Birch. LDN, NICHD and CNE, NIMH, NIH, Bethesda, MD 20892 and School of Biological Sciences, Univ. of Auckland, Private Bag 92019, New Zealand.

The prohormone convertases, PC1 (also called PC3) and PC2, are subtilisin-like serine proteases capable of processing neuropeptide precursors. In cotransfection experiments, other investigators have found that PC1 and PC2 can process pro-opiomelanocortin (POMC) to peptide products found in the pituitary. In this study, recombinant rat PC1 was stably expressed in a mouse L cell line and partially purified. Mouse POMC was cleaved by recombinant PC1 to generate N-POMC-ACTH intermediates, ACTH, 16 kDa N-POMC and β -LPH. Purified β -LPH was cleaved to a very small extent to β -endorphin, while purified bovine N-POMC¹⁻⁷⁷ was not processed to γ^3 -MSH. The pH optima for these cleavages were 6.0. Media from L-cells not transfected with PC1 did not process POMC. We conclude that purified recombinant PC1 is capable of processing POMC *in vitro* at paired basic residues to peptides similar to those found in the anterior pituitary. The specificity of PC1 is consistent with a role for this enzyme in the biosynthesis of biologically active peptides from POMC.

441.8

 α 1-ANTICHYMOTRYPSIN-LIKE PROTEASE INHIBITOR REGULATION OF A PROENKEPHALIN PROCESSING ENZYME.

V.Y.H. Hook*, A.V. Azaryan and T. Purviance. Dept. of Biochemistry, Uniformed Services University of the Health Sciences, Bethesda, MD.

Evidence is presented showing that α 1-antichymotrypsin (ACT)-like protein inhibits and is colocalized with the novel 'prohormone thiol protease' (PTP) involved in processing the enkephalin precursor. These results are the first demonstration that neuropeptide precursor processing may be regulated by an endogenous protease inhibitor. ACT immunoreactivity was colocalized with PTP within secretory vesicles of bovine adrenal medulla and posterior pituitary. The purified 60 kDa bovine pituitary ACT-like protein was a potent inhibitor of both PTP and chymotrypsin in the nanomolar range. Typical of serpin protease inhibitors, the bovine pituitary ACT-like protein formed SDS-stable complexes with chymotrypsin, and PTP formed SDS-stable complexes with human liver ACT. PTP cleavage of enkephalin-containing peptides at the NH₂-terminal side of paired basic residues (Lys-Arg, Arg-Arg, Lys-Lys) that flank the COOH-terminus of (Met)enkephalin (Tyr-Gly-Gly-Phe-Met), indicates methionine at the P₁ position of the cleavage site. These results showing PTP processing at a Met residue resemble the allowable P₁ specificity of ACT and are compatible with inhibition of PTP by ACT. The estimated molar ratio of PTP/ACT-like protein of 2-3 within secretory vesicles of adrenal medulla suggests that PTP *in vivo* may be partially inhibited; this is consistent with the presence *in vivo* of a high level of incompletely processed proenkephalin.

EFFECT OF DEVELOPMENT ON CARBOXYPEPTIDASE H AND LEVELS OF CHOLECYSTOKININ IN THE RAT HYPOTHALAMUS AND CORTEX. M. G. Oakes*, M. C. Beinfeld and T. P. Davis. Dept. of Pharmacology, University of Arizona College of Medicine, Tucson, AZ 85724.

Bioactive cholecystokinin (CCK-8) is produced by sequential cleavage of Pro-CCK by a series of peptidases. Specific enzyme assays were run to measure the activity of the processing enzyme, Carboxypeptidase H (EC 3.4.17.10, CPH) responsible for the cleavage of the glycine extended form of CCK-8 prior to amidation, and two metabolic enzymes: Neutral Endopeptidase (EC 3.4.24.11, NEP) and Metallo Endopeptidase (EC 3.4.24.15, MEP). In addition, four immunoreactive forms of CCK present at birth and post-natal ages 4, 7, 30, and 90 days were measured. In hypothalamus, Pro-CCK-like forms remain constant, whereas CCK-33-like forms predominate at birth and increase from day 7 to 3 fold higher at adult age. The glycine extended forms and CCK-8 show a significant increase at ages 30 (2-fold) and 90 days (10 fold). Total CPH activity increased two fold from birth to adult reflecting the increase of bioactive CCK-8. NEP activity increased two-fold from birth to day 7 and remained constant to adult, whereas MEP activity decreased from day 30 to 90. In cortex, CCK-33-like forms predominate at birth and Pro-CCK forms remain constant. Interestingly, CCK-33 decreased throughout the life of the rat suggesting a more rapid conversion of Pro-CCK forms to bioactive forms than that found in the hypothalamus. CCK-8 increased significantly over birth levels on days 7, 30 and 90 whereas glycine-extended forms showed no effect. The constant level of Pro-CCK-like peptides in the hypothalamus and cortex as compared to significant shifts in the levels of CCK-33 and CCK-8 suggests that Pro-CCK may not be fully regulated by transcription alone but could be affected by peptidases. Supported by N.I.H. Grant HD26013 and MH42600.

PEPTIDASES AT THE BLOOD BRAIN BARRIER: EFFECT ON PERMEABILITY. E.A. Brownson*, T.J. Abbruscato, T.P. Davis. Dept. Pharmacology, University of Arizona College of Medicine, Tucson, AZ.

The present study characterized the presence of specific membrane associated peptidases at the blood brain barrier (BBB). An *in vitro* model of the BBB using bovine microvessel endothelial cells (BMEC) was employed to measure the effect of aminopeptidase and enkephalinase activity on the permeability of two opiate compounds, [Met⁵]-Enkephalin and an enzymatically protected analogue of Met-Enk, DPDPE. The measured enzyme activity of BMEC grown to confluency was 1215, 447 and 224 pmol/mg protein/min for total aminopeptidase, aminopeptidase M (3.4.11.2) and enkephalinase (3.4.24.11), respectively. Permeability coefficients (PC) were calculated based on the diffusion of Met-Enk and DPDPE across the BMEC with and without peptidase inhibitors. We have found that in the presence of specific inhibitors of aminopeptidase (bestatin, puromycin) or enkephalinase (phosphoramidon, thiorphan) the PC of Met-Enk was increased three-fold (6×10^{-4} cm/min) compared to Met-Enk alone (2×10^{-4} cm/min). However there was no difference in the PC of DPDPE alone (10×10^{-4} cm/min) compared to DPDPE with inhibitors (9×10^{-4} cm/min). The data from this *in vitro* model of the BBB provide strong evidence for the presence of peptidases at the BBB that prevent blood to brain passage of peptides. Further, the potential for the delivery of drugs across the BBB can be enhanced by the development of enzymatically protected and biologically active peptide analogues. EVIDENCE FOR A TWO-STEP MECHANISM OF GnRH METABOLISM BY PROLYL ENDOPEPTIDASE AND METALLOENDOPEPTIDASE EC 3.4.24.15. R.A. Lew,¹ T. Tetaz,¹ M.J. Glucksmann,² K.E. Sheppard,¹ J.L. Roberts,² and A.J. Smith,¹ ¹Baker Med. Res. Inst., Prahran, Victoria, Australia 3181; ²Fishberg Res. Ctr. Neurobiol., Mount Sinai Sch. Med., NY, NY, USA 10029.

The soluble metalloendopeptidase EC 3.4.24.15 has been implicated in both the central and peripheral clearance of gonadotropin-releasing hormone (GnRH), and in crude preparations cleaves GnRH at the Tyr⁵-Gly⁶ bond. Although 24.15 activity is high in rat brain, to date the enzyme has only been sequenced and cloned from the testes (Pierotti et al., *Biochemistry* 29: 10323, 1990). In the present study, we determined the substrate specificity of both brain and recombinant testicular 24.15 for several GnRH-related peptides. When crude recombinant 24.15 (5 µg protein) was incubated with GnRH (25 µM) for 1 hr, only 10% of the peptide was degraded to GnRH₁₋₅ as determined by HPLC, compared with 83% of GnRH free acid and 97% of des-[Gly-NH₂]-GnRH, suggesting that C-terminal amidation hinders enzyme-substrate interaction. Interestingly, a very similar enzyme (EC 3.4.24.19) will not cleave GnRH unless the C-terminal Gly-NH₂ residue is removed by a prolyl endopeptidase (Camargo et al., *J. Biol. Chem.* 257:9265, 1982). To test the hypothesis that crude brain extracts contain an activity which cleaves between the Pro⁹ and Gly¹⁰-NH₂ residues, thus generating a much more favorable substrate for 24.15, we examined the effects of a specific inhibitor of 24.15, CPP-AAY-PAB, and an inhibitor of prolyl endopeptidase, bacitracin, on degradation of GnRH by soluble extracts of sheep hypothalamus. In the absence of inhibitors, most GnRH was degraded to GnRH₁₋₅, with some production of GnRH₁₋₉. Addition of CPP-AAY-PAB (5 µM) reduced GnRH₁₋₅ production, with a concomitant increase in GnRH₁₋₉; in contrast, bacitracin (0.1 mg/ml) reduced both GnRH₁₋₅ and GnRH₁₋₉ generation. These results suggest that the degradation of GnRH may occur via a two-step process involving first removal of Gly-NH₂ by prolyl endopeptidase, followed by cleavage by 24.15 at the Tyr⁵-Gly⁶ bond.

NEUROENDOCRINE REGULATION: GENE EXPRESSION AND CO-LOCALIZATION

442.1

COLOCALIZATION OF MULTIPLE NEUROPEPTIDES (ENKEPHALIN, NEUTROTENSIN AND DYNORPHIN) AND THEIR MESSAGES WITHIN TUBEROINFUNDIBULAR (TIDA) NEURONS OF LACTATING RATS. J. Merchenthaler*, D.E. Lennard and D.M. Bronstein. Functional Morphology Section, LMN (I.M. and D.E.L.) and Laboratory of Integrated Biology (D.M.B.), NIEHS/NIH, Research Triangle Park, NC 27709.

TIDA neurons in the dorsomedial subdivision of the arcuate nucleus (dmAN) project to the median eminence (ME) where dopamine (DA) is released into the hypophysial portal circulation. Prolactin secretion from the pituitary is under the tonic inhibitory control of DA produced by TIDA neurons. We report here that, in contrast to cycling female or male rats, TIDA neurons of lactating rats coexpress enkephalin, dynorphin and neurotensin. mRNA of enkephalin and dynorphin were demonstrated with *in situ* hybridization histochemistry using ³⁵S- or digoxigenin-labeled cRNA probes or ³⁵S-labeled deoxynucleotide probes. The peptides were detected with single- or double-labeling immunocytochemistry (ICC). When retrograde labeling from the ME with Fluoro-Gold was combined with double-labeling ICC, we found that every DA neuron (demonstrated by the presence of tyrosin hydroxylase) coexpressing these peptides was connected to the portal circulation. These findings indicate that the multihormonal TIDA neurons in the dmAN may possess a hypophysiotropic function. Since enkephalin, dynorphin and neurotensin exhibit prolactin-releasing activity, these results suggest that in lactating rats a cocktail of these peptides released by TIDA neurons may be responsible for the elevated prolactin and consequent milk secretion. The activity of TIDA neurons in synthesizing and releasing DA is inhibited by the suckling stimulus. Therefore, the action of the peptides cosynthesized with DA during lactation may be particularly important during the non-suckling periods of lactation.

ESTROGEN RECEPTOR IMMUNOSTAINING IN THE PREOPTIC AREA AND HYPOTHALAMUS OF FEMALE GUINEA PIGS AFTER ESTROGEN AND PRAZOSIN TREATMENT. K.F. Malik*, H.H. Feder, and J.I. Morrell. Inst. of Animal Behav., Rutgers University, Newark, NJ 07102.

Systemic administration of the alpha-1-adrenergic antagonist prazosin decreases binding of estrogen to hypothalamic lysates of estradiol benzoate (EB) treated females (Brain Res., 330:197-199). We investigated if prazosin treatment alters estrogen receptor (ER) protein content as reflected by changes in ER-immunoreactivity. We used the rat monoclonal antibody H222 directed against ER to detect ER-immunoreactive (ER-ir) cells in eight preoptic and hypothalamic neuronal groups in ovariectomized guinea pigs treated with 10 µg EB and prazosin (1.0 mg/kg, i.p.; N=8) or EB and vehicle (N=8). Neuronal groups studied included the medial preoptic area, the central nucleus of the hypothalamus, the ventrolateral nucleus of the hypothalamus, and the infundibular nucleus. Immunocytochemical parameters that provided optimum conditions for detection of even modest changes in ER-immunoreactivity were first established. Using these optimum conditions we detected no changes in 1) mean number of ER-ir profiles, 2) mean density of ER-ir staining, or distribution of ER-ir staining density readings 6 h after prazosin treatment in any of the eight brain regions investigated. These data suggest that mechanisms other than alterations in ER protein should be considered when interpreting effects of prazosin on retention of estradiol by hypothalamic lysates. 442.2

COLOCALIZATION OF ANDROGEN RECEPTOR AND THYROTROPIN RELEASING HORMONE PROHORMONE IN RAT BRAIN. H. Xu, E.M. Wilson, R.A. King*, and M. Sar. Dept. of Cell Biol. & Anat., Labs for Reprod. Biol., Univ. of N.C., Chapel Hill, NC 27599.

Evidence from our laboratory and others has indicated a direct action of androgen on thyrotropes in rat pituitary while androgen action on TRH neurons is not known. This study was conducted to determine whether thyrotropin releasing hormone prohormone (pro-TRH) neurons contain androgen receptors (AR). Adult male rats treated with testosterone propionate sc also received colchicine. Twenty hr later the rats were perfused with Zamboni's fixative. Brains were frozen and 10µm serial sections were processed for dual immunostaining. Sections were immunostained with antipeptide antibody AR32 using DAB and with anti pro-TRH antibody using 4-chloro-1-naphthol. AR was localized in nuclei of neurons in several nuclear groups of the brain where immunoreactive TRH or pro-TRH cells exist. These include the preoptic region, bed nucleus of the stria terminalis, periventricular nucleus, parvocellular portion of the paraventricular nucleus, dorsomedial nucleus and basolateral hypothalamus. Nuclear localization of AR was observed in a subpopulation of immunoreactive pro-TRH cells in preoptic nucleus, bed nucleus of the stria terminalis, periventricular hypothalamic nucleus and basolateral hypothalamus. The results suggest that androgen may have direct effects on certain TRH neurons. (Supported by NIH Grant NS17479).

INDUCTION OF CFOS EXPRESSION IN BRAINSTEM AREAS IN RESPONSE TO NMA AND KAINATE: DIFFERENTIAL PATTERNS OF ACTIVATION IN CYCLING AND LACTATING RATS. R. Abbud*, G.E. Hoffman and M.S. Smith. Department of Neurobiology, University of Pittsburgh, Pittsburgh, PA 15261.

During lactation, there is an inhibition of cortical and hippocampal activation in response to NMA, but not to kainate. The lack of response to NMA is revealed as the absence of both behavioral excitation and the induction of cFos expression. This lack of responsiveness to NMA could be due to suckling-induced inhibition of pathways that provide excitatory afferent input to the cortex and hippocampus. To examine this idea, we used the expression of cFos to identify brainstem areas activated in response to either NMA (40 mg/kg iv, 4 injections, one every 10 min) or kainate (2.5 mg/kg iv, 4 injections, one every 10 min) injected into cycling (diestrus-1) or lactating (day 10 suckling 8 pups) rats. NMA or kainate administration to cycling animals induced cFos expression in many areas of the brainstem, including the locus coeruleus (LC), the dorsal raphe (DR), the nucleus tractus solitarius (NTS), the parabrachial nucleus (PBN) and the A1 noradrenergic cell bodies. During lactation, NMA induced cFos expression in similar areas of the brainstem as during the cycle, except in the LC and DR, where there was little evidence for cFos expression. In contrast, in response to kainate, there were no differences in the patterns of cFos expression between cycling and lactating animals. In summary, these data reveal significant differences between cycling and lactating animals with respect to the brainstem areas activated in response to NMA, but not to kainate. The lack of NMA-induced activation of the LC and DR, areas which send major afferent projections to the cortex and hippocampus, may contribute to the lack of cortical activation during lactation.

EXPRESSION OF CYTOCHROME P-450 SIDE-CHAIN CLEAVAGE ENZYME AND 3- β HYDROXYSTEROID DEHYDROGENASE IN THE RAT CENTRAL NERVOUS SYSTEM. J.L. Sanne and K.E. Krueger.* Fidia-Georgetown Institute for the Neurosciences, Georgetown University School of Medicine, Washington, D.C. 20007

Recent developments regarding the possibility of steroid synthesis in the brain prompted the present studies to study the expression of two enzymes involved in the initial steps of steroid synthesis. The mitochondrial cytochrome P-450 side-chain cleavage enzyme (P-450_{sc}) which converts cholesterol to pregnenolone, and 3- β -hydroxysteroid dehydrogenase (3- β -HSD) which catalyzes the oxidation of pregnenolone to progesterone were examined. Using polymerase chain reaction the presence of the mRNAs for P-450_{sc} and 3- β -HSD are found in the adult rat brain, although their levels are considerably lower than those found in rat adrenals and testes. Proper control experiments verified that the amplified products derived from total RNA of rat brain were not due to genomic DNA or other contaminants having these sequences. Cerebral cortex, cerebellum, and spinal cord all contain comparable levels of mRNA for both enzymes. Furthermore, the two known isozymes of 3- β -HSD were identified as determined using discriminative restriction enzymes and sequencing analysis of the amplified brain products. Primary glial and cerebellar granule neuronal cultures prepared from neonatal rat brains were used to examine cell type expression. Both cultures were found to express P-450_{sc} at comparable levels, however, glial cultures express much higher levels of mDRC which is known to participate in mitochondrial steroidogenic activity. In contrast, 3- β -HSD was clearly identified in granule neuronal cultures but only barely detectable in glial cell cultures. These findings support the proposal that the central nervous system may have the capacity to synthesize steroids and suggest that in addition to glial cells certain neuronal cells may play an important part in their expression.

GONADOTROPIN-RELEASING HORMONE NEURONS (GTI-7) EXPRESS IGF-I AND IGF-II RECEPTORS. BR Olson*, DC Scott, LK Nieman. Developmental Endocrinology Branch, NICHD, NIH, Bethesda, MD, 20892.

Insulin growth factor I (IGF-I) and insulin regulate metabolism and modulate the expression of differentiated cellular functions in some systems. Changes in insulin and IGF-I systemically parallel changes in hypothalamic gonadotropin releasing hormone (GnRH) and pituitary gonadotropin release. It is not known whether systemic or central IGF's and insulin play any role in the activity of the reproductive axis and in particular the GnRH neuron. Studies on explant cultures of rat hypothalamic fragments have suggested that IGF-I stimulates GnRH release. We used a well-characterized, immortalized, GnRH-secreting mouse cell line (GTI-7) to investigate whether these neurons express IGF-I, IGF-II and insulin receptors and to study the effects of the IGF's and insulin on GnRH secretion. All experiments were done on confluent static cultures in serum-free media. Competitive binding studies with ¹²⁵I-IGF-I, ¹²⁵I-IGF-II detected specific IGF-I (Kd = 3.22 x 10⁻⁹) and IGF-II (Kd = 1.95 x 10⁻⁹) receptors. The specific binding for ¹²⁵I-insulin was too low to allow characterization of an insulin receptor on intact cells. GnRH peptide secretion was measured by RIA in media harvested at 2 and 8 hours after incubation with IGF-I or IGF-II at dose of 1-100 ng/ml, and after 2 hours with insulin at doses 1-1000 ng/ml. Insulin did not affect GnRH secretion. GnRH secretion was decreased from basal values by IGF-I and IGF-II at the physiologic dose of 1 ng/ml, though at different time points. We found no dose response effect at the doses tested, thus the physiologic significance of these findings awaits studies using lower doses of these growth factors. Nonetheless, the presence of these receptors on the GTI-7 cell line suggests a possible role for these growth factors in the regulation of the GnRH neuron, and represents a new system in which to investigate further the functions and mechanisms of action of these growth factors in vitro.

442.9

IDENTIFICATION AND CHARACTERIZATION OF GROWTH HORMONE RELEASING FACTOR (GRF) BINDING SITES IN THE HYPOTHALAMUS OF THE RAT. K.J. McDonnell, J.W. Bordeaux, J.I. Koenig*, K.J. Kellar, and M.D. Lumpkin. Depts. of Physiology and Pharmacology, Georgetown Univ. Med. Sch., Wash., D.C. 20007.

We previously reported that administration of small doses of GRF into the third ventricle results in attenuation of growth hormone (GH) secretion from the pituitary. An ultrashort-loop feedback model was proposed to explain this finding. In this model, GRF released by the hypothalamus may modulate hypothalamic GRF receptors (Endo Soc #1372, p.394, 1992) resulting in an autoinhibition of GRF release and subsequent decrease in GH secretion. The present study sought to identify these GRF binding sites in the hypothalamus of the rat. Tissue homogenates were prepared from freshly harvested hypothalamic fragments dissected to a depth of 2 mm with the following landmarks: anteriorly, the optic chiasm; posteriorly, the mammillary bodies; and laterally, the hypothalamic sulci. We observed binding of human (3-[¹²⁵I]iodotyrosyl) GRF 1-44 amide to hypothalamic homogenates. Binding was displaceable by both 1 μ M human GRF and 1 μ M GRF antagonist [N-acetyl-Tyr, D-Arg-GRF (1-29)]. No displaceable binding of ligand could be obtained in any previously frozen tissues. At a concentration of 100 pM, 0.84 fmol/mg hypothalamus was specifically labeled by ¹²⁵I-hGRF, and specific binding represented 28-40% of total binding. Specific binding was also present in anterior pituitary homogenate (2.64 fmol/mg pituitary) but absent in the homogenate of brain cortex. These data represent the first demonstration of GRF binding sites in neural tissue and provide support for the proposal that hypothalamic GRF receptors mediate GRF ultrashort-loop feedback inhibition. (Supported by NIH RO1 NS 23036 to MDL)

FUNCTIONAL POSTNATAL RAT HYPOTHALAMIC NEURONS IN CULTURE. S.Hellbach, A.H.S.Hassan & O.F.X.Almeida*. Max Planck Institute of Psychiatry, Kraepelinstrasse 2, W-8000 Munich 40, Germany.

A new method for culturing selected neuron types from postnatal (up to 4 week-old) rat hypothalamus is described, with initial data on the morphological and functional characteristics of the cultures. Slices of the arcuate (ARC) or paraventricular (PVN) nuclei are dispersed with papain and plated on PDL-coated cover-glasses in a custom-designed serum- and steroid-free medium. Immunostaining (ICC) for neurofilament proteins revealed only a minor content of glial cells. *In situ* hybridisation and ICC demonstrated that cells from the PVN and ARC synthesize and store corticotropin-releasing hormone (CRH) and β -endorphin, respectively, as would be expected from *in vivo* observations. Acute treatments with either veratridine (1 μ M) or tumor necrosis factor- α (10⁻⁵M; a known secretagogue of CRH) stimulated the release of CRH-like immunoreactive material, whereas colchicine (10⁻⁶M) significantly inhibited CRH release. Chronic exposure of cultures to either 17 β -estradiol (5 pM) or progesterone (10⁻⁷M), markedly reduced basal CRH release; this trend was reversed following withdrawal of both steroids. Contrary to expectations based on *in vivo* results, chronic dexamethasone treatment (10⁻⁶M) caused increased release of CRH; subsequent withdrawal of the glucocorticoid resulted in a tendency towards basal levels of CRH release. The fact that neurons *in vitro* lack their normal afferents may account for these last findings. Our cultures appear to offer a promising tool for the study of long-term adaptational processes in differentiated neurons. Preliminary studies involving co-culture of neurons originating from different hypothalamic nuclei, suggest that we may better our understanding of neuronal interactions by first, teasing the system apart, before putting it back together again. Supported by DFG (SFB 220/C8)

442.8

DEVELOPMENTAL EXPRESSION OF THE ENDOTHELIN-1 (ET-1) AND OXYTOCIN (OT) GENES IN THE HYPOTHALAMUS AND PLACENTA OF THE PREGNANT RAT. M.J. Horwitz, N.B. Kim, J.A. Amico. Dept. of Medicine, Univ. of Pittsburgh and VA Medical Center, Pittsburgh, PA 15261.

ET-1, an endothelial-derived peptide with potent vasoconstrictive properties, has been found in the rat placenta and hypothalamus, suggesting a role for this peptide in reproductive-related events. Within the hypothalamus, ET-1 IR and mRNA occur in the same distribution as OT within the supraoptic (SON) and paraventricular (PVN) nuclei. Synthesis of OT also occurs within the placenta. The co-existence of OT and ET in these organs suggests that these hormones may work in concert during gestation. We investigated the developmental pattern of ET and OT gene expression within the placenta and hypothalamus of the gravid rat. Blot hybridizations of placental and hypothalamic mRNA with a ³²P labeled cDNA probe specific for ET-1 revealed a single ET-1 transcript, = 2.3 kb. Placental ET-1 mRNA increased 3.5 fold from day 14 to 18 and 7 fold from day 14 to 21 gestation (p = 0.01, Kruskal Wallis test). ET-1 mRNA also increased significantly in the SON (p = 0.01, ANOVA) from early (day 4) to late (day 21) gestation. Blots were reprobed with ³²P-labeled cDNA probe specific for Exon C of the OT gene. Placental OT mRNA abundance did not change significantly during gestation but showed a downward trend. In contrast, OT gene expression increased significantly in the SON from early (day 4) to late (day 21) gestation (p = 0.01, ANOVA). OT transcript size within the SON remained stable throughout gestation. Placental and hypothalamic ET-1 transcripts display stage-specific increases during gestation. OT gene expression, on the other hand, displays both tissue-specific and stage-specific regulation. ET-1 may exert paracrine effects upon the placenta or uterus and may be a neuroendocrine regulator of pregnancy-related events in the rat, where it may act in concert with OT.

442.10

EFFECT OF HYPOPHYSECTOMY ON PITUITARY ADENYLATE CYCLASE ACTIVATING POLYPEPTIDE (PACAP) GENE EXPRESSION IN RAT. Y. Shuto, J.T. Weber*, H. Onda, and A. Arimura. US-Japan Biomed. Res. Labs, Tulane U. Hebert Ctr, Belle Chasse, La, 70037; Dept. of Anatomy, Tulane U. Sch. of Med., New Orleans, LA, 70112; and Discovery Res. Div. Takeda Chem. Ind., Tsukuba, Japan.

Pituitary adenylyl cyclase activating polypeptide (PACAP) may be a novel hypothalamic hypophysiotropic hormone. It stimulates adenylyl cyclase of cultured rat pituitary cells, and its specific receptors are present in the pituitary cells. Our previous immunohistochemical study indicated that the PACAP-like immunostaining in the paraventricular nucleus and supraoptic nucleus, and in the median eminence considerably increased after hypophysectomy suggesting a negative feedback regulation between hypothalamic PACAP synthesis and the pituitary function. In the present study, we determined whether the transcriptional rate of PACAP gene in the rat hypothalamus would change after hypophysectomy. The probe used was PACAP cDNA plasmid PRB38P1 which contained the entire coding region of rat prepro-PACAP and used to remove selectively the labeled PACAP mRNA from the pool of entire transcripts. On the contrary to our expectation, the transcriptional rate of PACAP gene decreased one and two weeks after hypophysectomy as compared with the control animals. The discrepancy between the immunohistochemical findings and the present observation could be explained by that the transcriptional rate of PACAP gene secondarily decreased as an autocrine feedback mechanism following accumulation of PACAP in the PACAP-synthesizing neurons in the hypothalamus which might be resulted from the prevention of the release of the peptide after stalk section associated with hypophysectomy. However, a possible feedback between the level of pituitary hormone(s) in the blood and the synthesis of PACAP in the hypothalamic neurons cannot be excluded. (Supported in part by NIH grant DK09094 and a research aid from Takeda Chemical Ind.)

COOPERATIVE GLUTAMATE- AND GABA-EVOKED CALCIUM SIGNALING IN GnRH NEURONS. D.J. Spiegel*, L.Z. Krstanovic, S.S. Stojilkovic and K.J. Catt. ERRL, NICHD, NIH, Bethesda, MD 20892.

Glutamate and GABA receptors in GnRH neurons have been proposed to regulate Ca²⁺-dependent GnRH secretion. To determine which GABA receptor subtypes are expressed in GnRH neurons, and how glutamate and GABA act together, we measured [Ca²⁺]_i responses to glutamate and to GABAergic agonists and antagonists, alone and in combinations, in the GT1-7 cell line of GnRH-secreting hypothalamic neurons. GT1-7 cells were cultured on poly-L-lysine coated glass coverslips (5 x 10⁵ cells/cm²) for 2-3 days, during which they formed monolayer networks, and were then loaded with the acetoxymethyl ester of fura-2 for [Ca²⁺]_i measurements. Glutamate and GABA each induced a moderate, concentration-dependent increase in [Ca²⁺]_i, with EC₅₀'s of 10 μM and 2 mM, respectively, which was markedly attenuated in Ca²⁺-free solution and by 5 μM nifedipine. The action of GABA was mimicked by the GABA_A agonist, muscimol (EC₅₀ = 4 μM), but not by the GABA_B agonist, baclofen (100 μM). The GABA_A antagonists (all 10 μM), bicuculline, (+)-hydrazine and tert-butyl-bicyclo[2,2,2]phosphorothionate (TBPS) decreased basal [Ca²⁺]_i. Bicuculline (100 μM) decreased basal [Ca_A]_i and the response to GABA (1 mM), but also decreased the response to glutamate (100 μM). The response to a combination of 100 μM glutamate and 1 mM GABA (or 100 μM muscimol) was nearly equal to the sum of the individual responses to these two agonists, but was smaller than the sum when glutamate and GABA were applied sequentially. In contrast, the response to 100 μM glutamate was unaffected by simultaneous or prior addition of 100 μM baclofen. The results indicate that GnRH neurons express both glutamate and GABA_A receptors. Activation of GABA_A receptors is followed by Ca²⁺ influx through L-type voltage-sensitive Ca²⁺ channels, which is enhanced by simultaneous activation of glutamate receptors. (D.J.S. is a National Research Council-ADAMHA/NIH Associate. L.Z.K. is supported by a grant from Sigma-Tau, Rome, Italy.)

DEMONSTRATION OF MEMBRANE-ASSOCIATED TUBULIN IN THE RAT ANTERIOR PITUITARY PLASMA MEMBRANES. R. Ravindra*, R. G. Nagele, and S. A. Patel. Departments of Cell and Molecular Biology, UMDNJ-School of Osteopathic Medicine, Stratford, NJ 08084.

We have recently observed that colchicine and taxol, drugs that interact with tubulin, inhibited GnRH and TRH-stimulated G protein GTPase activity in plasma membranes from the rat anterior pituitary lobe, suggesting the presence of tubulin in association with these membranes (J. Reprod. Fert. 97:27-33, 1993). In the present study, we have further tested for the presence of membrane-associated tubulin. Plasma membranes were prepared from anterior pituitary lobes of adult male Sprague-Dawley rats using discontinuous sucrose gradient centrifugation. Ouabain-sensitive Na⁺-K⁺-ATPase activity, a plasma membrane marker, in the pituitary homogenates and plasma membranes was 2.68 ± 0.14 and 20.84 ± 3.9 μmol/min/mg protein, respectively (n = 3). For detection of tubulin using immunofluorescence, membranes (1-2 mg/ml) were fixed briefly in 2% paraformaldehyde, exposed to monoclonal anti-β tubulin antibodies (1:500 dilution) or non immune IgG, and treated with FITC-labeled anti-mouse IgG. Specimens were mounted in glycine-glycerol buffer (pH 8.6) and visualized with Nikon Optiphot microscope equipped with epifluorescence optics, a SIT-66 video camera, and a DAGE digital image processor. Tubulin-specific fluorescence was very prominent in the membranes incubated with tubulin antibody and was negligible in membranes incubated with non immune IgG or FITC-labeled anti-mouse IgG alone. These results suggest that tubulin is a component of plasma membranes of the rat anterior pituitary and are consistent with the notion of tubulin involvement in signal transduction.

PHOSPHOROTHIOATE ANTISENSE OLIGONUCLEOTIDES TO PROTEIN KINASE C (PKC) α INHIBIT HUMAN GLIOMA GROWTH *IN VITRO*. N.P. Dooley*, G.H. Baltuch, J.-G. Villemure, and V.W. Yong. Neuroimmunology Unit, MNI, McGill University, Montreal, CANADA, H3A 2B4.

The PKC family of serine/threonine kinases consists of both Ca²⁺-dependent (α, β₁, β₂, and γ) and -independent isoforms (δ, ε, ζ, and η). The various isoforms of PKC have been shown to play a central role in both the differentiation and proliferation of transformed cells. We have previously demonstrated using reverse transcriptase-polymerase chain reaction (RT-PCR) that of the Ca²⁺-dependent PKCs, glioma cell lines (A172, U251, and U563) express only the α isoform. To determine whether PKC α was essential in glioma growth, phosphorothioate antisense oligonucleotides (20-mers) specific for the translation initiation site of PKC α were applied to cell cultures (10 μM) every 36 hours over a 4 day period. The effect of the antisense treatment was monitored using ³H-thymidine incorporation and I¹²⁵ Western blotting. In serum-free media the proliferation rate of the glioma lines treated with antisense oligonucleotides was decreased by more than 40% over sense controls. A lactate dehydrogenase assay (Sigma) confirmed that this effect was not a result of cytotoxicity. These preliminary findings are consistent with the postulate that protein kinase C α is critical in glioma proliferation.

COLLAGENASES EXPRESSED IN HUMAN MALIGNANT GLIAL TUMORS AND MICROVASCULAR ENDOTHELIUM; IMPLICATIONS FOR NEOVASCULARIZATION. P.C. Costello*, and R.F. Del Maestro. Brain Research Laboratory, University of Western Ontario, London, Ontario, N6A 4G5

During solid tumor angiogenesis, endothelial cells must bridge the basement membrane. Either the tumor is degrading the basement membrane to acquire a new blood supply using proteases and/or the endothelium are responding to angiogenic stimuli and breaking down the surrounding matrix themselves. Using Northern hybridization analysis, only collagenase IV (gelatinase A) mRNA was detected in human malignant glial tissues in significantly higher levels than in non-tumor brain tissue. To determine the role of the endothelium from human brain capillaries, expression of collagenase IV mRNA was determined using *in situ* hybridization on cell cultures. mRNA levels were highest in sub-confluent cultures. The collagenase IV and general protease activity levels secreted by endothelial cultures were assessed and consistently found to be 20 to 30 % higher in sub-confluent cultures than confluent cultures. Primary cell conditioning generated an overall decrease in the endothelium's general protease activity and in collagenase IV activity. Malignant glial tumor conditioning caused an increase in collagenase IV and general protease activity, but only in sub-confluent endothelium. Immunohistochemistry revealed gelatinase A antigenicity in glial tumor cells and microvessels of sections from human surgical specimens. Detection of type IV collagenase (gelatinase A) mRNA, protein, as well as activity in human brain tumors and blood-brain barrier endothelium strongly implicates a role played in the neovascularization cascade of malignant glial tumors.

GENE THERAPY FOR EXPERIMENTAL GLIOMAS USING VIRUS VECTORS. E. Antonio-Chiocca, M.X. Wei, E. Boviatsis, M. Chase, P. Pechan, T. Tamiya, N. Kowall, D. Kennedy, P. Filipek and X. O. Breakefield*. Neuroscience Center, Massachusetts General Hospital, Charlestown, MA 02129

Virus vectors provide an efficient means of delivering foreign genes into tumor cells for therapeutic purposes. We have focused our work on gliomas as they are resistant to current modes of therapy and should be selectively vulnerable in the adult brain by virtue of being essentially the only dividing cell population there. Both recombinant herpes simplex type 1 (HSV1) and Moloney murine leukemia-based retrovirus vectors have been used for selective killing of glioma cells in adult rat brains. Changes in tumor size over time have been evaluated by computerized volumetric analysis of gadolinium-enhanced magnetic resonance images. HSV1 vectors, bearing the lacZ marker gene and deleted in genes for thymidine kinase or ribonucleotide reductase, are able to replicate in and kill 9L tumor cells, gradually spreading throughout the tumor with only localized necrotic effects on surrounding normal tissue. Herpes vectors can infect tumor cells that have migrated some distance from the tumor mass. Additional features are being introduced into these "backbone" vectors to increase their selective toxicity for tumor cells. Grafting of a packaging cell line which releases a replication-defective retrovirus vector bearing the HSV1 thymidine kinase (TK) gene into 9L glioma tumors, combined with ganciclovir therapy, has also been tested with and without co-infection with wild type retrovirus. Variable regression of tumors has been observed in this latter model. Combinatorial retrovirus therapy using other conditionally toxic genes, such as IL4 (see abstract by Wei et al), is currently being evaluated to increase the extent of tumor regression. These studies represent a new mode of therapy for brain tumors which is highly versatile and can be combined with traditional therapies.

GENETIC TREATMENT OF INTRACEREBRAL RODENT BRAIN TUMORS WITH AN INTERLEUKIN-4 RETROVIRUS VECTOR. M. X. Wei, R. K. Hurford Jr., R. I. Tepper, X. O. Breakefield, E. A. Chiocca. Neurosci. Ctr. and Cancer Ctr., Mass. Gen. Hosp., Charlestown, MA 02129, Harvard Med. Sch., Boston, MA 02115.

There are no effective therapies resulting in long-term survival for patients suffering from glioblastoma multiforme, the most common adult primary central nervous system neoplasm. One reason for the lack of tumor regression may be a poor host response against the tumor due to its poor antigenicity and to the blood-brain barrier. Retrovirus vectors can be used to deliver genes to tumor cells, rendering them sensitive to drugs or to other oncolytic mechanisms. Interleukin-4 has been previously shown by one of us (R.I.T.) to provoke an eosinophilic response against subcutaneous sarcomas and to prolong the life of nude mice harboring human U87 intracranial gliomas. Rat C6 glioma cells were infected in culture with a retrovirus vector bearing an interleukin-4 (IL4) gene (or as a control, a lacZ gene) to demonstrate efficient gene transfer. We then tested the ability of IL4 retrovirus-producer cells (CREIL4) or, as a control, lacZ retrovirus-producer cells (CRElacZ) to inhibit the subcutaneous growth of rat C6 glioma cells in nude mice (the ratio of tumor cells to retrovirus producer cells was 1:10). The CREIL4-treated C6 gliomas exhibited only a 3.9-fold increase in tumor volume over a 21 day period, while the CRE-, CRElacZ-, and untreated-C6 gliomas exhibited 69.2-, 53.3-, and 86-fold tumor volume increases respectively. As an additional control, plain CRE cells were not tumorigenic in these mice. To further test the ability of IL4 retroviruses to prolong survival of rodents harboring brain tumors, we inoculated 10,000 rat C6 glioma cells into the frontal lobes of nude mice. Three days later we stereotactically delivered either CREIL4 or CRElacZ cells (1.5 x 10⁵) into the tumor. The average survival for the CRElacZ-treated mice (n=9) was 24.66 days, while that for the CREIL4-treated mice (n=9) was 33.22 days.

ALTERATIONS OF CHROMOSOMES 9q, 11p, AND 17p IN MEDULLOBLASTOMA. S. Albrecht, A. von Deimling, T. Pietsch, S. Brandner, P. Kleihues, O.D. Wiestler*. Depts. of Neuropathology, University of Bonn, D-5300 Bonn, Germany, and University of Zürich, CH-8091 Zürich, Switzerland.

Little is known about genetic alterations involved in the pathogenesis of cerebellar medulloblastoma (MB). There is evidence for MB loci on 11p & 17p. An additional candidate locus is the locus for Gorlin syndrome (GS), an autosomal dominant syndrome consisting of multiple basal cell carcinomas, epithelial jaw cysts, & skeletal anomalies. Since GS can be associated with MB, we examined sporadic cases of MB for loss of heterozygosity (LOH) on chromosome 9 where a putative GS locus has been localized to band q31. Nineteen paired blood & tumor DNA samples from 16 patients (11 primary tumors, 2 primary with recurrent tumors, 1 primary tumor and cell line, 2 cell lines) were studied by PCR analysis of microsatellites with > 70% heterozygosity at D9S55 (9p12), D9S15 (9q13-q21.1), D9S109 (9q31), D9S127 (9q13-q31), D9S12 (9q22.3), D9S58 (9q22.3-q31), GSN (9q33), ASS (9q34.1), D9S67 (9q34.1-q34.3), TH (11p15.5), D17S5 (17p13.3), TP53 (17p13.1) & by RFLP analysis at WT-1 (11p13). Only 2 of 19 tumors had LOH on 9q. One was non-informative at D9S15 & GSN but had LOH at D9S109, D9S127, D9S12, D9S58, ASS, & D9S67. The other was non-informative at D9S15, D9S58, & D9S67 but had LOH at D9S12, D9S109, D9S127, GSN, & ASS. This is compatible with loss of most or all of one copy of 9q. Both cases were informative for D9S55 without LOH. No case had LOH on 11p. Four cases had LOH at both D17S5 & TP53 & another case was non-informative at D17S5 but had LOH at TP53. None of the cases with LOH on 9q had LOH on 17p & vice-versa. These data indicate that LOH on 9q occurs rarely in sporadic MB. This does not rule out a role for the GS locus in sporadic MB but makes it less likely.

SHORT-TERM EFFECTS OF PROTON MICROBEAM IRRADIATION ON FELINE LGN. D.C. Lau, C.S. Reder, S.J. Ashwal, and M.A. Kirby*. Depts. of Pediatrics and Anatomy, and the Division of Perinatal Biology, Loma Linda University School of Medicine, Loma Linda, CA 92350.

Little is known of the short-term effects of proton irradiation on neural tissue. We used a 1.0mm microbeam on the cat lateral geniculate nucleus (LGN) to quantify the short-term effects of radiation damage. The LGN is a large structure with well defined afferent, efferent, and receptive field properties.

Electrophysiological and histological techniques were used to examine the effects of the microbeam at 20, 50, and 75 gray, administered as a single bolus. Recordings of light evoked responses in the LGN were obtained using microelectrodes in nine animals within 12 weeks of irradiation. Receptive fields were mapped onto a tangent screen using standard receptive field techniques. Histological measures included afferent termination, myelination, and soma/nuclear area.

Physiological and histological abnormalities were found in the 75 and 50 gray, but not the 20 gray animals. In contrast to controls, areas unresponsive to visual stimuli were found in the irradiated LGN that were surrounded by normally responsive regions. A disruption in the progression of the size of the visual fields in the irradiated LGN was found. Histological analyses correlated with the physiological data by the absence of afferent termination to regions of the LGN, and having significantly larger soma areas ($p < .05$) on the irradiated vs. the control LGN. No necrosis was observed. All effects were isolated to the irradiated LGN.

These results suggest that the proton beam is capable of disruption of function in the absence of acute cellular necrosis. Moreover, this disruption was confined to a single target structure with no observable disruption to surrounding regions.

IN VIVO HIGH-RESOLUTION OPTICAL IMAGING OF NEURONAL TUMOR TISSUE IN RATS AND HUMANS. D.W. Hochman*, M.S. Berger, A.M. Spence, and M.M. Haglund. Department of Neurological Surgery, University of Washington, Seattle, WA 98195.

Currently, intraoperative methods for identifying and grading brain tumors depend primarily on 1) ultrasound and 2) histological criteria. Both techniques suffer drawbacks - ultrasound cannot be used to reliably identify tumor margins once the resections has begun, and the acquisition of the intraoperative biopsy suffers from sampling error.

We have developed a new optical imaging technique that can be used to provide a high-resolution intraoperative map of tumor vs. non-tumor tissue in rat and human brain. Furthermore, our technique can provide online information regarding the tumor grade and presence of residual tumor in resection margins.

A CCD camera is attached to the operating microscope. Either the cranium or exposed brain is illuminated with light (>690 nm). Images are digitized every 1-4 sec and combined to produce percentage difference maps by subtracting images acquired prior to indocyanine green (ICG) injection with images acquired at various times following ICG injection.

The % optical changes imaged in the rat glioma model at various times after ICG injection were as follows:

Time	EXPOSED BRAIN			INTACT SKULL	
	Tumor	Tumor Surround	Normal	Tumor	Normal
2 sec	40.5±9.6	16.4±6.8	9.7±4.7	13.9±3.9	8.2±2.3
60 sec	27.9±5.7	8.3±2.0	4.4±2.1	5.8±1.6	3.1±0

In eight patients undergoing surgical resection for primary gliomas, graded optical changes were observed - the largest in high-grade gliomas, followed by low-grade and then normal brain. Optical changes in high-grade gliomas persisted for more than 10 min. after ICG injection, while normal brain returned to baseline within 1 min.

Optical imaging has the potential to provide real-time intraoperative information with near cellular resolution (50 μ m - 1.5 mm/pixel) of margin biopsy sites.

MECHANOSENSITIVE CHANNELS IN ADULT HUMAN DRG NEURONS T.K. Baumann^{1,2}, K.J. Burchiel¹ and M.E. Martenson¹, Division of Neurosurgery¹ and Department of Pharmacology², Oregon Health Sciences University, Portland, OR 97201

In recent years, many different cell types have been shown to possess mechanosensitive (MS) ion channels. Surprisingly, with the exception of one abstract,¹ there appear to have been no studies of MS channels in mammalian primary afferent somatosensory neurons. Such channels are likely to play a role not only in the normal functioning of such neurons, e.g., mechanotransduction or volume regulation, but also in pathological states following nerve injury when the mechanosensitivity of primary afferent neurons is known to be markedly increased. We have used patch clamp recording techniques to search for MS channels in the somata of neurons cultured from dorsal root ganglia excised from patients treated surgically for chronic pain. In a large proportion of cell-attached recordings (using electrodes filled with 160 mM KCl, 10 mM HEPES and 8.13 mM EGTA), the application of tension to the patch caused bursts of large amplitude unitary currents (-20 pA, electrode held at 0 mV). Increased tension (negative pressure between 0 and -3 kPa) resulted in an increased probability of channel openings.

CLUSTERING SKIN AFFERENTS OF IDENTICAL MODALITY IN HUMAN NERVES HAVE OVERLAPPING RECEPTIVE FIELDS. R.Ekedahl, R.G.Hallin*, G.Wu, Dept of Clinical Neurophysiology, Huddinge University Hospital, 141 86 Huddinge, Sweden.

The human palm and finger tips are densely innervated. Thus, even restricted skin stimuli might occasionally excite a few cutaneous afferents of the same modality. Since, in contrast to previous reports (1,2), we recently demonstrated how peripheral myelinated fibres are orderly organized by both modality and somatotopy (3,4) the above phenomenon might be more common than previously realized.

To elucidate the issue we used concentric needle electrodes which image both functional and structural aspects of human nerves (3,4). The studied median nerve units sometimes had separate receptive fields. However, neighbouring myelinated fibres regularly had the same modality and innervated adjacent or even overlapping receptive fields. A combination of natural and/or electrical stimuli applied simultaneously to the area where these fibres ended facilitated the otherwise difficult unit identification. At certain stimulus intensities and repetition frequencies latency changes or blockings were elicited in the myelinated afferents. Reminiscent but more marked refractory phenomena were previously demonstrated and used to characterize cutaneous C units in man.

Thus, subtle recording and stimulation techniques facilitate the identification of neighbouring myelinated afferents in human nerves with overlapping receptive fields in the skin.

CORTICOTROPIN RELEASING FACTOR (CRF) AND INTERLEUKIN-1 β (IL-1 β) PRODUCE ANTINOCICEPTION IN INFLAMMATION MEDIATED BY PERIPHERAL OPIOID RECEPTORS. M. Schäfer, L. Carter, S.R. Goldberg and C. Stein*.

NIDA Addiction Research Center and Dept. of Anesthesiology, Johns Hopkins Hospital, Baltimore, MD 21224

In vitro studies have shown that opioid peptides can be released from immune cells by different agents. In our animal model of subcutaneous inflammation we demonstrated such peptides within inflammatory cells and opioid receptors on sensory nerves in situ. The present experiments examined whether CRF or IL-1 β induce endogenous opioid release in inflamed tissue and result in antinociception.

Male Wistar rats received an injection of Freund's complete adjuvant into one hindpaw and developed unilateral localized inflammation. After four days, when injected into the inflamed paw, CRF and IL-1 β produced potent antinociception. This effect was dose dependently antagonized by the specific antagonists alpha-helical-CRF and IL-1-receptor antagonist, respectively, as well as by naloxone and other opioid antagonists. To demonstrate the involvement of immune cells we abolished this effect by immunosuppression using intraperitoneal cyclosporine A.

Our results suggest that CRF and IL-1 β , by activation of their receptors on immune cells, cause a release of opioids which subsequently occupy their receptors on sensory nerves resulting in inhibition of pain.

SPINOTHALAMIC NEURONS CONTAIN N-ACETYL-ASPARTYL-GLUTAMATE (NAAG) IMMUNOREACTIVITY IN THE RAT.

K.E. Miller*, D.L. O'Donoghue, C.R.D. Poff, Dept. Anatomical Sciences, Oklahoma Center for NeuroSciences, Univ. Oklahoma Health Sciences Center, Oklahoma City, OK 73190.

NAAG is a dipeptide found in abundance in the mammalian CNS. It has been suggested that NAAG has a role as an excitatory neurotransmitter or as a source for excitatory amino acid neurotransmitters. The distribution of NAAG immunoreactive neurons in the spinal cord is similar to the organization of spinothalamic (STT) neurons. The purpose of this study was to examine STT neurons for NAAG immunoreactivity (IR). The thalamic VPL nucleus was injected with colloidal gold labelled, apo-HRP (Au-HRP). After 48-72 hrs, animals were perfused transcardially with ethylcarbodiimide. Cryoprotected spinal cord segments (C1, C7, T9, L4, L6) were sectioned on a cryostat. Sections were processed for silver intensification of Au-HRP and NAAG immunohistochemistry. Most silver labelled STT neurons also contained NAAG-IR. Silver labelled STT neurons containing NAAG-IR were found in the marginal zone, nucleus proprius, lateral cervical and spinal nuclei, and central gray region (lamina X) from cervical to lumbosacral segments. We conclude from these results that NAAG may be used as a neurotransmitter by STT neurons.

LOCALIZATION OF α_2 -ADRENERGIC RECEPTOR SUBTYPES IN NOCICEPTIVE PATHWAYS IN RAT CNS. E.L. Gustafson*, M.M. Durkin, J. Bard, C. Forray, Y. She, A. Illy, R.L. Weinschenk, and T.A. Branchek.

Synaptic Pharmaceutical Corp., Paramus, NJ 07652.

The involvement of adrenergic receptors in nociceptive processes takes place at multiple sites in the CNS. We have used receptor autoradiography and *in situ* hybridization histochemistry to define the distribution of the α_{2A} and α_{2C} receptors and their mRNAs in rat CNS. Radioligand binding studies were carried out using [³H]MK-912. The distribution of the α_{2A} and α_{2B} + α_{2C} adrenoceptors were defined by their sensitivity to oxymetazoline and prazosin, respectively. Nonspecific binding was determined using the radiolabelled ligand in the presence of phentolamine. α_{2B} mRNA localization was performed using ³⁵S-labelled antisense and sense oligonucleotide probes (45mers) to the rat RG-20 (α_{2A}) and RG-10 (α_{2C}) adrenoceptor mRNAs. In rat, radioligand binding studies indicate that oxymetazoline-sensitive α_{2A} receptors are the most prominent α_2 subtype in nociception-related structures, including the periaqueductal gray, locus coeruleus, nucleus of the solitary tract, lateral reticular nucleus, and dorsal horn of the spinal cord. *In situ* hybridization studies suggest that α_{2A} mRNA predominates in the locus coeruleus, nucleus of the solitary tract, and lateral reticular nucleus, while α_{2C} is the most prevalent subtype mRNA in the spinal cord dorsal horn, in sensory afferent neurons of the dorsal root ganglia, and in some midline thalamic nuclei. The localization of α_{2A} and α_{2C} adrenoceptor subtypes, and their respective mRNAs, in nociceptive pathways indicates that multiple α_2 adrenoceptor subtypes are involved in the regulation of pain. The development of subtype-specific α_2 -adrenergic drugs may help to alleviate some of the deleterious side-effects associated with traditional analgesics and anesthetics.

444.4

A β MECHANO-ALLODYNIA AND COLD HYPERALGESIA FOLLOWING LARGE DOSES OF INTRADERMAL CAPSAICIN. R.H. Gracely, S.A. Barcellos, S.J. Saltzman, M.G. Byas-Smith, M.B. Max and G.J. Bennett*.

Neurobiology and Anesthesiology Branch, NIDR, NIH Bethesda MD 20892.

Intradermal injection of 1000 μ g capsaicin into the volar forearm in 8 subjects evoked an immediate intense spontaneous pain sensation that rapidly decreased to "weak" or less at 45 min in all but one subject. An area of mechano-allodynia developed rapidly, peaked at 11.4 min, and persisted to the end of all sessions (75-312 min).

In these experiments and in those using lesser doses (500 μ g n=5, 250 μ g n=4, 100 μ g n=3), a 1-s train of constant current electrical stimuli (1-msec cathodal pulses at 100 Hz) was painful at the threshold for detection in each of the 12 cases evaluated, indicating that the mechano-allodynia was mediated by large diameter A β low-threshold mechano-receptive (A β -LTM) afferents. A β allodynia was supported further by reaction times to painful detection-level stimuli in one subject, and the concurrent abolition of allodynia and touch sensation during tourniquet cuff blocks (n=4). Local anesthesia of the injection site in 2 subjects (25 and 82 min post capsaicin injection) did not abolish allodynia. Stimuli (0-23°C) perceived as cold before the injection evoked a distinct pain sensation following 11/19 injections.

The presence of A β -LTM allodynia without spontaneous pain, and during local anesthesia of the injection site, suggest that the central processes mediating allodynia can persist in the absence of ongoing nociceptive input. Intradermal capsaicin may provide a model of the initiation of neuropathic pain syndromes.

444.6

SPINAL CORD LAMINA I TERMINATIONS IN BRAINSTEM

CATECHOLAMINE CELL GROUPS. K.N. Westlund* and A.D. (Bud) Craig.

Marine Biomedical Institute, UTMB, Galveston, TX 77555-0843, and Div. of Neurobiol. and Neurosurg., Barrow Neurol. Inst., Phoenix, AZ 85013.

Ascending lamina I projections were identified with *Phaseolus vulgaris* leucoagglutinin (PHAL) and the relationship of the lamina I termination in the brainstem to catecholamine (CA) cell groups examined with immunofluorescent double-labeling techniques.

The lamina I terminations were labeled with Texas Red and the CA cells were labeled with FITC using a primary antibody to tyrosine hydroxylase. The double DAB process (for black terminals and brown somata) was also employed. In both cats and monkeys ascending lamina I fibers course through the contralateral A1, C1, A5, and A7 cell groups that form a column through the ventrolateral medulla extending into the pons. Lamina I terminations were observed in each of these groups on both the ipsilateral and contralateral sides, and also in A2 and A6 dorsally. Many of the terminations were located very near and not in apparent contact with CA processes, but others were found that were in close apposition to CA cells and their dendrites. Such putative synaptic contacts were most common in A1 and A7.

These anatomical findings provide a sound basis for thermoreceptive and nociceptive inputs to the brainstem CA system, a major system that coordinates somatic and visceral motor activity and influences sensory processing. These inputs may modulate nociceptive information by direct or multisynaptic descending pathways. These projections may include the substrates for spino-bulbo-spinal somatosympathetic reflex activity and the relay of specific thermoregulatory afferent information to the hypothalamus. (Supported by NIH grant NS25616; NS11255; and NS01445, RCDA to KNW).

NOCICEPTIVE- AND THERMORECEPTIVE-SPECIFIC NEURONS IN A DISCRETE REGION OF THE MONKEY LATERAL THALAMUS. M.C. Bushnell and A.D. (Bud) Craig*.

Univ. Montreal, Quebec, Canada and Barrow

Neurological Inst., Phoenix AZ.

In 1911 Head and Holmes hypothesized a specific substrate for pain and temperature sensation in the ventral caudal part of lateral thalamus. This hypothesis is supported by the recent identification of a dense, topographic lamina I spinothalamic and trigeminothalamic projection to the posterior part of the ventral medial thalamic nucleus (VMpo). We now demonstrate that this region contains a concentration of nociceptive and thermoreceptive cells.

In 7 barbiturate-anesthetized cynomolgus monkeys, tungsten microelectrodes were used to record from 87 single somatosensory units located histologically in the cytoarchitectonic region of VMpo. Receptive fields (RFs) found on the face, head, hand, and arm were usually small (1-3 cm², 48%), but were sometimes large (whole head and/or forelimb, 15%) or bilateral (11%). Cells with trigeminal RFs were located anterior to cells with cervical RFs. Of the 87 units, 71 were nociceptive, 8 were cold-specific, 3 were low-threshold, and 5 were inhibited by noxious or cold stimuli. Neurons responding to noxious stimuli were NS (90%) or WDR (10%) cells; a few neurons responded to cold as well as to noxious heat and pinch. Quantitatively tested NS and WDR cells produced graded responses to noxious heat (46-58°C) or pinch (300-1200 g on 3 mm²). Notably, small clusters of nociceptive cells with overlapping RFs were recorded in the middle of this region and large clusters of "cold" cells with RFs on the tongue were found at the rostradorsal limit of this region.

We conclude that VMpo processes specific temperature and pain information. The recent proposal that lamina I conveys the "feelings" of the body (Gemeingefühl) is congruent with the conjoint processing of temperature and pain in VMpo and with VMpo's location relative to VMB and VP. This also implies that VMpo may process not only pain and temperature but also other body sensations such as itch and tickle. (Supported by NIH grant NS 25616)

THALAMIC OSCILLATIONS GENERATED BY THE INTERACTIONS BETWEEN THALAMIC VENTROBASAL AND RETICULAR NUCLEI IN VITRO. R.A. Warren* and E.G. Jones, Dept. of Anatomy and Neurobiology, Univ. of California, Irvine, CA 92717.

Thalamic neurons display oscillatory activity during periods of drowsiness and slow wave sleep. The oscillations are associated with the synchronization of the cortical EEG during these behavioral states. The cortical feedback acting upon the reticular nucleus of the thalamus (RTN) is thought to play an important role in the generation and maintenance of thalamic oscillations. We found that the excitatory projections from thalamic relay neurons to RTN neurons can also induce oscillations.

Whole cell recording from ventrobasal (VB) and RTN neurons was obtained in a mouse thalamocortical slice preparation (Agmon and Connors, *Neuroscience* 41:365, 1991) from animals aged 12 to 21 days. A single electrical shock to the internal capsule routinely induced recurrent IPSPs at a frequency of 1-4Hz for 2 to 8 seconds in VB neurons. These IPSPs often generated typical bursting of VB neurons and were blocked by the application of bicuculline. The same stimulus evoked oscillatory bursting in RTN neurons that was sustained by a rhythmic sequence of EPSPs at a frequency similar to the IPSPs observed in VB neurons. The addition of bicuculline to the perfusing medium abolished the rhythmic EPSPs but spared the initial short latency EPSPs in RTN neurons, suggesting that the recurrent EPSPs in RTN were evoked by input from bursting VB relay neurons.

We conclude that the synaptic connectivity between RTN and VB is sufficient to generate thalamic oscillations and that the excitatory projections from thalamic relay neurons to the RTN may be important in the generation of thalamic oscillations in behaving animals.

POSITRON EMISSION TOMOGRAPHY (PET) STUDIES OF PAIN AND ALLODYNIA IN NORMALS AND PATIENTS WITH CHRONIC NEUROPATHIC PAIN. M. J. Iadarola^a, K. F. Berman^a, M. Byas-Smith, R. H. Gracely, M. Max, T. Zeffiro^b, G. J. Bennett. ^aNeurobiology & Anesthesiology Branch, NIDR; ^bClinical Brain Disorders Branch, NIMH; ^cMedical Neurology Branch, NINDS; NIH, Bethesda MD, 20892.

The PET oxygen-15 water bolus method was used to image regional brain activity during a) capsaicin-induced pain and allodynia in normals and b) 3 patients with spontaneous pain in one limb. Sixty sec tissue count data were acquired for normal subjects (7M,4F) during 6 experimental conditions: 1) rest, 2) brushing, 3) intradermal injection of capsaicin (250ug, volar forearm) to produce pain, 4) and 5) during the waning period of capsaicin, and 6) allodynia produced by brushing adjacent to the capsaicin injection. Fifteen slices with resolution of 6-6.5 mm were acquired for each scan and analyzed with statistical parametric mapping. Capsaicin activated contralateral somatosensory cortex, thalamus, anterior cingulate cortex, cerebellar vermis and insular cortex and putamen bilaterally. A distinctly different regional profile of activation was seen during allodynia which was characterized by prominent activation of orbito-frontal cortex but comparatively little in anterior cingulate cortex or cerebellar vermis. PET scans of the 3 patients revealed that chronic spontaneous neuropathic pain is associated with a decrease in thalamic activity contralateral to the affected limb. The decrease is similar to that reported for cancer patients with chronic lateralized pain (Di Piero et al, *Pain*, 46:9, 1991). The capsaicin/allodynia data suggest that pain driven by C-fiber activation involves a different regional network compared to allodynia produced by light brushing. The initial observations with the patients suggest that functional alterations in thalamic processing may be an important component of chronic pain.

444.13

SOMATOSENSORY CORTICAL NEURONS IN MONONEUROPATHY MODEL. M. Backonja*, G. Miletich, University of Wisconsin, Madison, WI 53792.

Cortical neurons are thought to have only minimal involvement in processing sensory information related to pain. Somatosensory cortical neurons probably participate in encoding sensory-discriminative properties of painful stimuli. It is proposed that cortical neurons undergo plasticity changes, as well as do neurons at lower levels of neuraxes, in the case of neuropathic pain.

Somatosensory cortical electrophysiological recordings with 1M NaCl filled glass electrodes were made in anesthetized ventilated male rats during chronic phase of mononeuropathy 2-3 weeks after surgery for loose ligation of sciatic nerve (Bennett and Xie, 1988). Control animals had sham surgery. A battery of mechanical and thermal stimuli were used for characterization of receptive fields.

Forty neurons were recorded in the study group and thirty six in the control group. In each group a largest subpopulation of neurons had characteristics of wide dynamic range responses. Neurons of rats with painful mononeuropathy had larger receptive fields and more neurons in this group had prolonged afterdischarges.

Data from this study demonstrates that cortical neurons respond to painful stimulation and that the response is altered (increased receptive fields and prolonged afterdischarges) in the case of mononeuropathy.

444.10

DIFFERENCES IN CORTICAL AND SUBCORTICAL RESPONSES TO NOXIOUS HEAT AND COLD STIMULI IN HUMANS.

K.L. Casey^{*1,2}, S. Minoshima³, R.A. Koeppe³, T.J. Morrow^{1,2}, and K.A. Frey^{1,3} Depts of Neurology¹, and Physiology², and Div. of Nuclear Medicine, Dept of Internal Medicine³, Univ. of Michigan, and Neurology Research Lab., VAMC, Ann Arbor, MI 48105

We investigated regional increases in cerebral blood flow (CBF) responding to three types of noxious thermal stimuli using positron emission tomography (PET). In each subject, stimulation and baseline studies were performed using the following stimuli: 1) phasic noxious heat stimuli (50°C, 5 sec pulse) and phasic warm baseline stimuli (40°C) delivered using a contact thermode (n=9), 2) tonic noxious cold stimuli (6°C, 60 sec) and cold but not noxious baseline stimuli (24°C) delivered using ice and cold water (n=9), 3) phasic noxious cold stimuli (1°C, 10 sec pulse) and phasic cold but not noxious baseline stimuli (15°C) delivered using ice and cold water (n=7). Each stimulus was delivered to subjects' left forearm 1) and hand 2), 3) during 60 sec PET data acquisition following an intravenous bolus injection of 66 mCi [O-15] water. Stereotactic subtraction and summation analyses were performed to localize increased CBF areas due to noxious stimuli in comparison with baseline stimuli for each group. Different patterns of increased forebrain CBF involving several cortical and subcortical structures were produced by each type of noxious stimulation. Contralateral thalamic activation was seen only with phasic stimuli, but the contralateral anterior cingulate gyrus was most active during tonic cold pain. These results suggest that a reciprocal relationship between thalamic and cortical pain processing.

444.12

IMAGING PAIN IN HUMANS WITH HIGH RESOLUTION FUNCTIONAL MAGNETIC RESONANCE IMAGING (MRI) AT 4 TESLA (4T). H. Wen, S. Wolff, R. Balaban, R. Turner, D. Kenshalo^b, K.F. Berman^a and M.J. Iadarola^b. Laboratory of Cardiac Energetics, NHLBI, ^aClinical Brain Disorders Branch, NIMH; and ^bNeurobiology & Anesthesiology Branch, NIDR; National Institutes of Health, Bethesda MD, 20892.

This study focuses on mapping changes in neural activity induced by pain in primary somatosensory cortex. Increases in brain activity produce increases in blood flow which can be assessed with recently developed MRI methods sensitive to hemodynamic parameters. These parameters include blood oxygenation level and flow and are manifested as magnitude and phase changes in the MR signal. A 4T MRI system, volume head coil and spoiled gradient recalled echo sequence, were used to image brain activity evoked by placing a finger on a metal plate maintained at 49-50°C in multiple alternations with a room temperature stimulus. Image acquisition was 8.5 or 12 sec and voxel size of transaxial or coronal slices was 1 x 2 x 8 mm. Activation produced by thermal stimuli was also compared to that obtained by moving the digit. Noxious stimuli produced magnitude increases and phase changes that were (a) spatially contiguous (b) observed in postcentral gyrus and vessels in postcentral sulcus, (c) coincident with periods of stimulation, (d) up to 20% above the basal condition and (e) contralateral to the stimulus. Dorsoroventrally, the active region was highly localized: in one subject only one of 3 sequential 8 mm thick transaxial slices contained the pain signal. Motor activity was mainly localized in precentral gyrus and vessels of precentral and central sulcus and this profile is readily distinguishable from that evoked by thermal pain. The high anatomical resolution of the functional scans reveals the focal nature of the hemodynamic changes. This resolution, coupled with the capacity for multiple stimulus presentations, yields a new approach to investigating neural processing of pain in conscious man.

STRUCTURE OF THE ISOLATED BRAIN PREPARATION. **JE Moreira, PM Reuss, EC Ribeiro, TS Reese and RR Llinás***. NINDS, Bethesda MD, 20892 and Physiol. & Biophys. NYU, NY, NY 10016.

A new technique for perfusion of isolated brains has proven useful for a variety of physiological studies (Llinás et al., *J Physiol.*, 4114:16P, 1989). We examined the structural features of isolated brains from 30 day-old mice and compared the results with those obtained by freeze-substitution. The ultrastructure of surface samples of isolated brains rapidly excised, quick frozen, and freeze substituted served as a benchmark for a variety of fixation experiments designed to determine whether deeper cortical regions of perfused brains were structurally intact. Three perfusion fixative solutions were compared: 1) buffered 2% glutaraldehyde+2% paraformaldehyde; 2) buffered 3% glut. containing 22 mM H₂O₂ and 4% PVP; 3) 3% glut.+1% paraform. in an 3% dextran 70 "artificial blood" (de Curtis et al., *Hippocampus*, 1:4 341, 1991) modified by adding 10 mM H₂O₂. Results closest to those from freeze substitution were obtained by method 2 and, especially, method 3. Areas CA1 to 4 and dentate gyrus in the hippocampus as well as cerebellar folia showed neuropil arrangements with precise rounded shapes and straight plasma membranes, well defined cytosolic density, and synapses and vesicles resembling freeze substituted samples. Method 1, in contrast, produced sinuous membrane profiles which often appeared empty. Microtubule structure also showed marked improvement with H₂O₂-containing fixatives. The morphology of synaptic structures in the isolated brain throughout the two hours of perfusion remained equivalent to the control brain perfused *in situ*. These results provide an excellent method for structural work on the isolated brain preparation and explain the persistence of many electrophysiological functions in this preparation. ACETYLCHOLINESTERASE SITE DENSITY AT FROG NEUROMUSCULAR JUNCTIONS. **L. Anglister*, J. R. Stiles¹ and M. M. Salpeter¹**. Dept. Anatomy, Hebrew Univ. Med. Sch., Jerusalem 91010, Israel. ¹Section of Neurobiology & Behavior, Cornell Univ., Ithaca, NY 14853.

Muscle acetylcholinesterase (AChE) is concentrated at neuromuscular junctions, where it exists largely in association with the synaptic basal lamina. Positioned between the presynaptic terminal and the postsynaptic acetylcholine receptors (AChRs), it terminates synaptic transmission by hydrolyzing acetylcholine. Knowledge of the junctional AChE and AChR concentrations is crucial for understanding the function of this synapse. Although AChR concentration has been measured in endplates of several species and shows little variability, AChE concentration has been determined only in mouse endplates. The aim of this study was to measure the concentration and catalytic activity of AChE at the neuromuscular junction of frog, and to investigate the physiological importance of our findings using computer modeling. Frog *cutaneous peboris* muscles were first incubated with diisopropylfluorophosphate (DFP) to inactivate covalently all serine-hydrolases, including AChE. Subsequently, true AChE sites were reactivated by pyridine-2-aldoxime methiodide (2-PAM) and labelled by ³H-DFP. Quantitative EM-autoradiography showed approximately 600 AChE-sites/μm² of postsynaptic surface, a value which is about 4-fold lower than the AChE site density for mouse endplates. Biochemical studies supported the frog AChE site density value. After correction for extra-junctional activity, solubilized extracellular frog muscle AChE hydrolyzed 12.7±1.3 pmol ACh/sec/muscle (mean ± s.e.m., n=27). The catalytic turnover number per active site (Kcat) was 6500-10000 mol/sec, more than 3-fold greater than that for rat or chicken AChE, but significantly less than that for eel enzyme. The total junctional activity divided by Kcat and by the total junctional surface area yielded an AChE density similar to the value measured by autoradiography. Further analysis indicates that the major extracellular molecular form of AChE at the neuromuscular junction was a small globular form (4-6S), although substantial amounts of asymmetric collagen-tailed forms were also present. The physiological implications of the AChE concentration and catalytic turnover number were examined by Monte Carlo simulations of miniature endplate currents. Surprisingly, such modeling showed that normal neuromuscular transmission is possible over a wide range of values for AChE site density and Kcat. MEMBRANE TRAFFICKING AT THE NERVE TERMINAL: THE SYNAPSE-SPECIFIC PHOSPHOPROTEIN F1-20 IS IDENTICAL TO THE CLATHRIN ASSEMBLY PROTEIN AP-3. **E.M. Later*, S. Zhou, N. Tannery and W. Ye**. Dept. of Biological Sciences, University of Pittsburgh, Pittsburgh, PA 15260.

F1-20 was cloned and characterized because of its synapse-specificity. AP-3 was purified and studied biochemically because of its function as a clathrin assembly protein. Monoclonal antibodies against F1-20 and AP-3 both specifically recognize a single protein from mouse brain with an apparent molecular weight of 190 kD on SDS-PAGE. These monoclonal antibodies also specifically recognize bacterially expressed F1-20, and purified bovine AP-3. The anti-F1-20 and the anti-AP-3 Mabs specifically recognize the same spot on a 2-D gel run on a bovine brain clathrin coated vesicle extract. Purified preparations of bovine AP-3 and bacterially expressed F1-20 give identical patterns of protease digestion with bromelain and subtilisin. Bacterially expressed F1-20, like AP-3, specifically binds clathrin.

By having connected the synapse-specific phosphoprotein F1-20 with the clathrin assembly protein AP-3, we are now able to integrate our knowledge of these two molecules into a single model for the role of F1-20/AP-3 in synaptic function. During synaptic vesicle exocytosis, the synaptic vesicle membrane fuses with the pre-synaptic plasma membrane. The synaptic vesicle membrane proteins are clustered in a multimeric complex within the presynaptic plasma membrane. The soluble form of F1-20/AP-3 is able to recognize a feature of this complex and bind to it. The N-terminal domain of F1-20/AP-3 then initiates the assembly of clathrin coated pits, which drive the re-internalization of the synaptic vesicle membrane proteins in CCVs. It is possible that phosphorylation and/or alternative splicing of F1-20/AP-3 serve to regulate this process. Our model further predicts that the developmental expression of the F1-20/AP-3 protein is required for the maturation of the synaptic vesicle recycling mechanism, and as such represents an important event in synapse development. Future work is aimed at testing the predictions of this model.

CABLE ANALYSIS OF FOUR INSECT MUSCLES SUGGESTS THAT PROPERTIES OF THE INDIVIDUAL SYNAPTIC UNITS UNDERLY DIFFERENCES IN NEUROMUSCULAR TRANSMISSION. **M.B. Rheuben* and S.M. Baer**. Dept. of Anatomy, Michigan State Univ., East Lansing, MI 48824 and Dept. of Mathematics, Arizona State Univ., Tempe, AZ 85287.

The amplitudes of the excitatory junction potentials (EJPs) of four flight muscles of *Manduca* are consistently different when examined under subthreshold conditions produced by low Ca⁺⁺ saline. The fibers, however, of each muscle differ in diameter and perimeter, and their neuromuscular junctions have characteristic lengths and shapes. To see if the EJP amplitudes could simply be determined by differences in the total number and distribution of synapses relative to the dimensions of the particular fiber type, we examined the morphometric data using a new cable model derived from continuum cable theory (Baer and Rinzel, 1990, *J. Neurophysiol.*, 65: 874). This model allows us to simulate the amplitude and timecourse of EJPs generated by multiterminal innervation from a single motor axon. In simulations where properties of individual synaptic units were held constant, the number and distribution of synapses relative to the muscle fiber sizes predicts subthreshold EJPs of quite similar amplitudes, suggesting a close matching of number and length of junctions to muscle fiber dimensions. The actual differences in function must then rely on physiological differences in membrane properties of the muscle fibers or on pre- and postsynaptic characteristics of the synaptic units. Ultrastructural differences in the active zones and postsynaptic specializations support this latter hypothesis. Supported by NIH Grant NS17132 (to MBR) and NSF DMS-9107538 (to SMB).

A novel epitope of entactin is found at the neuromuscular junction. **A.Y. Chiu* and J. Ko**, Division of Neurosciences, Beckman Research Institute of the City of Hope, Duarte, CA 91010

The extracellular matrix (ECM) at the neuromuscular junction (NMJ) is biochemically and functionally specialized, and bears molecules that can regulate both the development and activity of this peripheral synapse. We have previously purified one synaptic component of the muscle ECM - a unique laminin isoform named s-laminin - from a schwannoma cell line (Chiu et al., *J. Neurochem.* 59:10). To develop new probes for the ECM, monoclonal antibodies were generated against other components produced by this cell line. One of these antibodies, 9H6, binds very selectively at the synaptic cleft of NMJs in adult rats, but not at extrasynaptic sites on the muscle surface. On Western blots, 9H6 recognizes a 150 kD band that co-localizes with the laminin-binding, ECM glycoprotein, entactin, under both reducing and non-reducing conditions. N-terminal sequence analysis also indicates that the 9H6 antigen is an entactin-related molecule. However, polyclonal antibodies to entactin stain both synaptic and extrasynaptic sites on rat muscles. Thus, 9H6 appears to recognize an entactin epitope that has a very restricted distribution. Recent studies have shown that novel isoforms of laminin, acetylcholinesterase, agrin and collagen IV are selectively sequestered at the NMJ. Our results suggest that the entactin present at the synaptic cleft also differs from entactin present outside the synapse. The synaptic form of entactin may contribute to the unique functions of the ECM at the neuromuscular synapse.

VAT-1, AN ABUNDANT COMPONENT OF TORPEDO SYNAPTIC VESICLE MEMBRANE IS A CALCIUM BINDING PROTEIN. **M. Linnal* and O. Levius**. Dept. of Biological Chemistry, Institute for Life Sciences, The Hebrew University of Jerusalem, 91904, Israel.

VAT-1, is an abundant 41 kDa membrane protein expressed in the cholinergic synaptic vesicles of *Torpedo*. To elucidate its biological function we produced *Torpedo* VAT-1 in bacterial expression systems, purified it and examined its Ca²⁺-binding properties in solution and in solid phase interactions. An overlay assay using ⁴⁵Ca²⁺ as a tracer, demonstrated the ability of a recombinant VAT-1 to bind calcium. High yields of recombinant VAT-1 was obtained from the glutathione S-transferase (GST) expression system. A direct Ca²⁺-binding study was performed with purified VAT-1 by a quick spin column technique. A quantitative analysis revealed a 1:1 molar stoichiometry for binding of Ca²⁺ to VAT-1, with a dissociation constant of 130 μM. A GST-linked truncated protein consisting of 13 kDa from VAT-1 carboxy-terminal domain was found to retain the capacity to bind Ca²⁺. Our findings demonstrate that VAT-1 is a low affinity Ca²⁺-binding protein and attribute a Ca²⁺-sensory function to this vesicular protein within the nerve terminal. IMAGING OF CALCIUM VARIATIONS IN LIVING DENDRITIC SPINES OF CULTURED HIPPOCAMPAL NEURONS. M. Segal* Dept. Neurobiology, The Weizmann Institute, Rehovot 76100 Israel.

Dissociated rat hippocampal neurons were grown in tissue culture plates for 1-6 weeks. Cells were loaded with the calcium indicator Fura-2 using microelectrodes, and were visualized with 100x oil objective in an inverted microscope, equipped with a cooled CCD camera. Segments of dendrites containing spines were selected for analysis. $[Ca]_i$ variations in spines ($[Ca]_s$) and dendrites ($[Ca]_D$) resulting from exposure to NMDA, synaptic stimulation and drugs which regulate $[Ca]_i$ were measured. A brief exposure to NMDA caused a rapid rise of $[Ca]_s$ and a parallel, but smaller (by up to 40%) rise of $[Ca]_D$. The recovery of $[Ca]_i$ to pre-NMDA occurred in the spine and the parent dendrite simultaneously, and was delayed in sodium-free medium. Synaptic potentials were activated using latrotoxin. In these cases $[Ca]_s$ was more elevated than the adjacent $[Ca]_D$. Conversely, release of Ca^{2+} from mitochondria, using proton uncouplers, elevated $[Ca]_D$ more than $[Ca]_s$. It is suggested that regulation of $[Ca]_s$ and $[Ca]_D$ are independent, but closely coupled.

A NEW METHOD TO QUANTIFY SYNAPTIC VESICLE EXOCYTOSIS: UPTAKE OF ANTIBODIES TO THE LUMENAL DOMAIN OF SYNAPTOTAGMIN I. K. Kraszewski^{1,2}, O. Mundigl^{1,2}, C. Verderio⁴, R. Jahn^{1,3}, P. De Camilli^{1,2} and M. Matteoli⁴. ¹Howard Hughes Med Inst, ²Dept Cell Biol. and ³Pharm. Yale Univ. Med School, New Haven, USA and ⁴CNR Center of Cytochem, Univ. of Milan, Italy

The elucidation of molecular mechanisms of neurotransmitter release is crucially dependent on the availability of assays to quantify synaptic vesicle (SV) exocytosis. Until now SV exocytosis has been primarily studied by recording postsynaptic currents or by detecting neurotransmitter release into extracellular media. It will be very useful to have available an assay which measures SV exocytosis independently of neurotransmitter release. We have recently reported the possibility to monitor SV exocytosis by detecting luminal epitopes of synaptotagmin which are exposed at the surface of a neuron as a result of SV fusion with the plasmamembrane. We have used this approach to study exo-endocytosis of SV in isolated processes of hippocampal neurons developing in primary culture (Matteoli et al. JCB.117:849-861). We report here that this method can be used to quantitate SV exocytosis. Hippocampal neuronal cultures were incubated at 37°C with rabbit antibodies (Abs) directed against the luminal domain of synaptotagmin I (Syn_{lum} Ab) for 5 - 20 min in media with different ionic concentrations or including neurotoxins known to affect SV exocytosis. At the end of the incubation cells were fixed, permeabilized, stained with CY3-conjugated secondary Abs and counterstained for the cytoplasmic domain of synaptotagmin I with FITC-conjugated Abs. Images were collected by a chilled CCD camera and Metamorph image-processing-system. Levels of SV exocytosis were inferred from the ratio between CY3 (Syn_{lum} Ab uptake) and FITC (total synaptotagmin I pool) label. Incubation with high K⁺ (55 mM) of cultures rich in synaptic contacts evoked significant increase in this ratio over control levels. The increase was dependent on extracellular Ca²⁺. An even higher stimulation was produced by α -latrotoxin (5 nM). Tetanus toxin (50 nM) caused a massive decrease in Syn_{lum} Ab uptake. A Ca²⁺ and depolarization dependent increase in SV exocytosis was already observed in isolated axons before the onset of synaptogenesis.

CALCIUM CURRENT MAGNITUDE CORRELATES WITH PRESYNAPTIC FUNCTION IN CHICK COCHLEAR HAIR CELLS. P.A. Fuchs* and K.A. Fagan. Dept. Physiol. and Neurosci. Prog., U. Colo. Sch. Med., Denver, CO, 80262.

It has been suggested that voltage-gated calcium channels are found only at sites of transmitter release in frog saccular hair cells (Roberts et al., *J. Neurosci.* 10:3664-3684, 1990). If a similar rule applies in the chick's cochlea then calcium currents should be larger in tall (inner) hair cells that make many afferent contacts, and smaller in short (outer) hair cells that make few afferent synapses (Fischer, *Hear. Res.* 61:167-178, 1992).

We have used whole-cell, tight-seal recording to measure voltage-gated inward current carried by barium (20 mM) in hair cells isolated 1 mm from the apical pole of the chick's cochlea. We observed rapidly-activating, non-inactivating barium currents positive to -50 mV and peaking near -10 mV in 26 tall, intermediate and short hair cells. While the kinetics and voltage-dependence of the barium currents were similar in all cells, the peak currents were usually larger in taller hair cells than in shorter hair cells. The 11 tallest isolated cells had average peak barium currents of 209 pA (\pm 79 S.D.). Based on morphological studies performed in this laboratory (B.W. Murrow Ph.D. thesis, U. Colo.), these originated from within the neural (innermost) 30% of the cochlear cross section. The 6 shortest cells originated from the abneural (outermost) 30% of the cochlear width and had smaller peak currents, 51 pA (\pm 24 S.D.). Nine intermediate cells had an average peak current of 71 pA (\pm 26 S.D.).

Preliminary electron microscopic studies showed that the frequency of appearance of release sites declines several-fold from the tallest cells to the shortest cells at this cochlear location. The co-variance of barium (calcium) current magnitude with number of release sites supports the hypothesis that voltage-gated calcium channels in hair cells are found only at these presynaptic membrane specializations. Supported by NIDCD DC00276.

The kinetics of synaptic vesicle recycling measured at single presynaptic boutons. T. A. Ryan, H. Reuter^S, B. Wendland, F. E. Schweizer, R. W. Tsien, S. J. Smith*. Department of Molecular and Cellular Physiology, Stanford University, Stanford CA, 94305. ^SDepartment of Pharmacology, University of Bern, CH-3010 Bern, Switzerland.

We used the fluorescent membrane probe FM 1-43 to label recycling synaptic vesicles within the presynaptic boutons of dissociated hippocampal neurons in culture. By applying quantitative timelapse fluorescence imaging as well as rapid superfusion techniques we directly measured exocytosis, the kinetics of endocytosis as well as the recycling time of synaptic vesicles within single CNS synaptic boutons at room temperature (~ 24°C). These measurements indicate that endocytosis persists much longer than exocytosis with a $t_{1/2}$ ~ 60 sec and that once internalized, vesicles are available for exocytosis in ~ 30 sec. Furthermore we have shown that endocytosis is not dependent on membrane potential and unlike exocytosis, that it is independent of extracellular Ca²⁺.

CARDIOVASCULAR REGULATION: BRAINSTEM INTEGRATION

446.1

STEREOSELECTIVE ACTION OF S-NITROSO-L-CYSTEINE (L-SNC) IN NUCLEUS TRACTUS SOLITARI (NTS) OF RATS. H. Ohta*, W.T. Talman, J.N. Bates and S.J. Lewis, Departments of Neurology, Pharmacology and Anesthesiology, University of Iowa and VAMC, Iowa City, IA 52242

Possible roles for nitric oxide (NO) in neurotransmission in the central nervous system have received much attention. Free NO may diffuse through membranes to activate soluble guanylate cyclase and then increase cyclic GMP in the intracellular space. However, some have suggested that NO may react with thiols and may exist as S-nitrosothiols before activating soluble guanylate cyclase in target cells. The present study was designed to investigate involvement of an S-nitrosothiol in signal transduction. Male Sprague Dawley rats anesthetized with chloralose were instrumented for recording arterial pressure and heart rate and injecting agents into NTS. Injection of L-SNC (50 - 1250 pmol) into NTS produced dose-related depressor and bradycardiac responses. Maximum depressor (-38 \pm 4 mmHg) and bradycardiac (-66 \pm 9 bpm) responses were obtained at 250 pmol. Responses produced by similar doses of other NO moieties, D-SNC and sodium nitroprusside, injected into NTS were one third of those produced by L-SNC. Both L- and D-SNC when injected intravenously produced equivalent depressor responses. Furthermore, both isomers released the same amount of NO in a brain homogenate. Responses to L-SNC (150 pmol) injected into NTS were blocked by prior administration of methylene blue (500 pmol) but not by oxyhemoglobin (5 pmol). Injection of L-cystine, a metabolic product of L-SNC, did not produce significant effects. These results indicate that actions of exogenous nitrosothiols are not due to release of NO extracellularly. Rather, L-nitrosothiols may be efficient NO transporters in the extracellular space and may act at a specific recognition site on the membrane to release NO into the intracellular space. Support: VA Merit Review and Clin. Investigator (WTT), and NIH HL32205 and HL14388.

446.2

NMDA RECEPTORS IN THE NUCLEUS TRACTUS SOLITARI (NTS) ARE INVOLVED IN THE BRADYCARDIC RESPONSE TO CAROTID CHEMORECEPTORS (CC) STIMULATION. B.H. Machado*, E. Colombari, D.A. Chianca Jr., L.G.H. Bonagamba and A.S. Haibara. Dept. Physiol., School of Medicine of Ribeirão Preto, USP, 14049, Ribeirão Preto, SP, Brazil.

Stimulation of CC with potassium cyanide (KCN, 80 μ g/kg, i.v.) in conscious rats produces pressor and bradycardiac responses, which are not observed in rats with ligation of carotid body artery. Activation of CC was performed by KCN and the chemoreflex neurotransmission into the NTS was studied using AP-5, a selective NMDA receptor antagonist. KCN was injected before and after bilateral microinjection of AP-5 (2 nMoles/100 nl) into the NTS of conscious rats. The results (n=6) show that the pressor response to CC stimulation (+55 \pm 3 vs +51 \pm 3 mmHg) was not changed, while the bradycardia (-193 \pm 15 vs -83 \pm 22 bpm) was significantly reduced from 5 to 30 min after AP-5 microinjection. These data suggest that bradycardiac response to chemoreceptor activation is mediated by NMDA receptors while the pressor response seems to be mediated by non-NMDA receptors.
